Methods: We included data from 5549 active PD patients who were introduced to the patient portal prior to Sep 30, 2017 and had <=10 hospitalizations days in Sep 2017. Patients who documented data for ≥20 treatments during Sep 2017 were considered "the engaged group" (n=1199). The remaining 4350 patients who did not document any treatment data on the portal were considered "the non-engaged group." Patients who documented data on >0 and <20 treatments were not included in this analysis. Patients were followed 6 months starting Sep 30, 2017 up until the earliest of discharge from the clinic (including death), switch from PD to hemodialysis (HD) or end of follow-up. We compared the percent of patients who switched modality from PD to HD using Chi-square test without accounting for the length of follow-up. We compared the hospital admission rate during follow-up period using Poisson regression model adjusted for prior hospitalizations.

Results: We observed that patients in "the engaged group" had a 20% lower risk of hospitalization compared to the "non-engaged group" (Relative Risk=0.8, p<0.001). We found no significant difference in modality changes from PD to HD between groups (11% engaged patients vs 13% non-engaged patients, p=0.11).

Conclusions: Consistent documentation of treatment data in the patient portal was associated with lower hospital admission rates among PD patients suggesting that better patient engagement as well as more real-time clinician involvement may impact patients' hospitalization rates. However, observations may be confounded by indication of portal use, which could represent a more adherent group of patients. Further analysis is needed to confirm these findings.

FR-PO687

Role of Peritoneal Phosphorus Transport in Peritoneal Dialysis Regimen for the Management of Hyperphosphatemia

Elena Guillen,[1] Marc Xipell Font,[1] Enrique Montagud,[1] Raquel Ojeda lopez,[2] Lida M. Rodas Marin,[1] Francisco Maduell,[1] Manel Vera.[1] Peritoneal Dialysis Department, Hospital Clínic *[1]Hospital Clinic, Barcelona, Spain; [2]University hospital, Córdoba, Spain.*

Background: The ratio D/P-Creatinine (DP-Cr) obtained by the peritoneal equilibrium test (PET) is the most widely used parameter to characterize the type of peritoneal membrane transport, and it is used to determine the dialysis regimen for ultrafiltration (UF). It has been suggested that net UF influences the final clearance of solutes, so guiding ultrafiltration by D/P-Phosphorus (DP-P) instead of DP-Cr could have some added value in the management of hyperphosphatemia. The objective of this study is to define if there is a correlation between DP-P and DP-Cr, and if these are related to the clearance of phosphorus (P) and creatinine (Cr).

Methods: Retrospective analysis of PET performed in our center in 2016-2017. DP-Cr and DP-P were calculated, and in patients with 24h effluent sample the day of the PET, it was also analyzed weekly Kt/V-urea, and peritoneal Cr and P clearance (CrCl and PCl). Statistical analysis was done using t-Student test for independent data and Pearson correlation coefficient, establishing a significance level of $p<0.05$.

Results: 68 PET were analyzed in 54 patients, mean age 60.4 years (SD 17), predominantly men (69% vs 31%). The mean plasma P, DP-Cr and DP-P were respectively 4.5 mg/dL (SD 1.2), 0.74 (SD 0.12) and 0.71 (SD 0.17). The correlation coefficient DP-P/DP-Cr showed a significant relationship ($r=0.84$, $p<0.001$), which was maintained when analyzing patients according to phosphorus levels: DP-P/DP-Cr with P<5 mg/dL ($r=0.81$); and P≥5 mg/dL ($r=0.93$) ($p<0.001$). Patients in DP-P ≥50th percentile had P levels of 4.2 (± 1.05), and those in <50th percentile had levels of 4.88 (± 1.38) ($p <0.031$). Moreover, in patients with 24h effluent analyzed the day of the PET (n=35), the average PCl and CrCl was 4.1 and 2.85 ml/min, with statistical significant correlation ($r=0.92$, $p<0.001$). However, in these patients no relationship was found between DP-Cr and CrCl ($r=0.068$, $p=0.7$), nor between DP-P and PCl ($r=0.052$, $p=0.7$).

Conclusions: The DP-P/DP-Cr high correlation suggests that both parameters could be useful to classify the type of peritoneal transport. However, although patients with higher DP-P had better control of hyperphosphatemia, thus suggesting a direct positive relationship between DP-P and PCl, our data showed no correlation between them.

FR-PO688

Tissue Sodium Stores in Peritoneal Dialysis Patients

Supisara Tintara,[1] Aseel Alsouqi,[2] Serpil muge Deger,[5] Aihua Bian,[3] Thomas G. Stewart,[2] Jens Titze,[4] Talat Alp Ikizler.[2] *[1]Vanderbilt University School of Medicine, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Vanderbilt University, Nashville, TN; [4]Duke - National University of Singapore, Singapore, Singapore; [5]Vanderbilt University Faculty of Medicine Department of Nephrology, Nashville, TN.*

Background: A remarkable amount of sodium (Na^+) is stored in the tissue without commensurate water retention, particularly in the skin and muscle. Using ^{23}Na-magnetic resonance imaging (MRI), elevated tissue Na^+ content was found in hemodialysis patients. Peritoneal dialysis (PD) patients generally have higher residual kidney function than HD patients, yet the effectiveness of PD in tissue Na^+ removal has not been evaluated.

Methods: We examined tissue Na^+ levels in 10 PD patients. PD patients were matched with healthy controls by age, race, gender and body mass index (BMI). All study subjects underwent ^{23}Na-MRI to quantify Na^+ levels in lower leg muscle and skin.

Results: We studied 10 PD patients and 41 controls. PD patients had significantly higher skin and muscle Na^+ levels compared to controls (figure 1). In PD subjects, skin Na^+ level was inversely correlated to ultrafiltration volume, a marker of Na^+ removal adequacy (figure 2).

Conclusions: Our data suggest that PD patients have elevated tissue Na^+ stores. The mechanisms by which this abnormality develops and its consequences should be further examined.

Funding: Commercial Support - Baxter Healthcare Corporation

Characteristics of the study population

	Patients on PD (n=10)	Controls (n=41)	P value^
Age (years)	55 [48.8, 61.5]	51 [45, 59]	0.55
Male	3 (30)	23 (56.1)	0.14
African American	4 (40)	23 (56.1)	0.25
Caucasian	5 (50)	18 (43.9)	
BMI (kg/m^2)	23.6 [21.9, 17.9]	27.6 [25.4, 31.4]	0.07
Creatinine (mg/dL)	10.3 [7.2, 13.3]	0.9 [0.8, 1.1]	<.001
Urine output (mL/day)	100 [50, 520]		

Continuous variables are presented as median [interquartile range], categorical variables are presented as n (%).

Comparison of Low and Standard Dose Adrenocorticotropic Hormone (ACTH) Stimulation Test in the Diagnosis of Adrenal Insufficiency in Peritoneal Dialysis Patients

Yun Jung Oh,[1] Su mi Lee,[2] Jiwon Ryu,[1] Chungsik Lee.[1] *[1]Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea; [2]Internal medicine, Dong-A University hospital, BUSAN, Republic of Korea.*

Background: Adrenocorticotropic hormone (ACTH) stimulation test is the current standard for diagnosing adrenal insufficiency (AI). The low dose (1 μg) ACTH stimulation test (LDT) has been introduced to detect incomplete impairment of adrenal function with partial corticotropin deficiency, which might be masked by the conventional supraphysiological dose (250 μg) of ACTH employed in the standard dose ACTH stimulation test (SDT). Indeed, several studies have shown an increased sensitivity of LDT over SDT in chronic ill patients with secondary AI. This study aims to investigate the diagnostic value of low and standard dose ACTH stimulation tests for identifying AI in patients on peritoneal dialysis (PD).

Methods: A total of 60 prevalent PD patients were enrolled and underwent LDT and SDT using doses of 1 μg and 250 μg synthetic ACTH, respectively. The two tests were performed in random sequence with minimum one week interval and a cut-off level of peak serum cortisol for AI was <18 μg/dL in both tests. Surveys of AI-associated symptoms and laboratory test were performed.

Results: Overall, 22 (36.7%) patients in the LDT and 8 (13.3%) patients in the SDT showed an insufficient increase of cortisol to ACTH stimulation and were categorized as having AI. In the LDT, no remarkable difference in presence of symptoms associated with AI was observed between the AI patients and non-AI patients. Laboratory findings were not different between the two groups, either. However, the patients who were diagnosed with AI by the SDT complained fatigue (62.5% vs. 15.4%, P=0.009) and constipation (50.0% vs. 13.5%, P=0.031) more frequently compared with the patients without AI. The adequacy of dialysis (Kt/V) was significantly lower in patients diagnosed with AI by the SDT than non-AI patients (1.64±0.21 vs. 1.99±0.37, P=0.019).

Conclusions: Adrenal response to ACTH was diminished in low dose compared with standard dose and the use of LDT diagnosed more adrenal abnormalities than SDT in PD patients. However, the clinical significance of identifying AI patients using the LDT was not observed in those patients.

FR-PO690

Hyperosmolality in Peritoneal Dialysis Increases Plasma Arginine Vasopressin Levels

Hiromichi Ueno,[1] Tetsu Miyamoto,[3] Kenya Sanada,[2] Yoko Fujimoto,[1] Kenichiro Bando,[4] Yoichi Ueta,[1] Yutaka Otsuji,[1] Masahito Tamura.[5] *[1]University of Occupational and Environmental Health, Kitakyushu, Japan; [2]University of Occupational and Environmental Health, Japan, Kitakyushu-shi, Japan; [3]Second Department of Internal Medicine, Kitakyushu, Fukuoka, Japan; [4]University of occupational and environmental health, Kitakyushu, Japan; [5]University of Occupational & Environmental Health, Kitakyushu, Japan.*

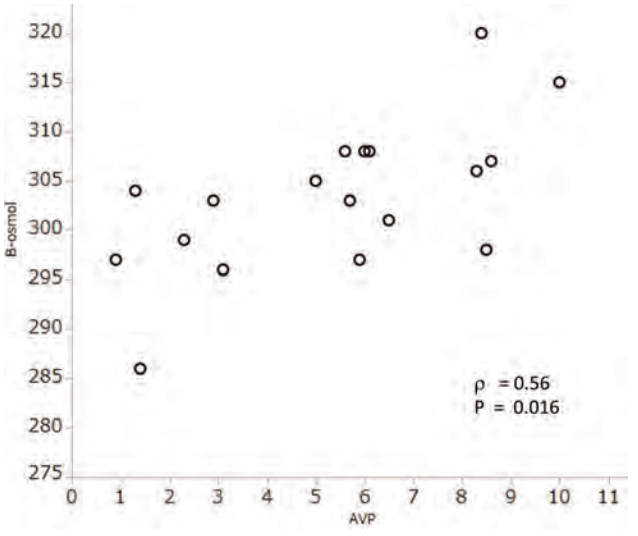
Background: Fluid retention is common in peritoneal dialysis (PD) patients. Arginine vasopressin (AVP), an antidiuretic hormone, promotes fluid retention and stimulates thirst. Consequently, AVP is important for fluid management in PD patients. Although several studies have reported an increase in plasma AVP levels in hemodialysis patients, the dynamics of plasma AVP levels in PD patients has not yet been clarified.

Methods: We measured plasma AVP levels and osmolalities in 20 PD patients aged 48-79 years-old over 2-145 months of PD duration. Blood volumes were evaluated by bioelectrical impedance analysis.

Results: Plasma AVP levels (5.5 ±0.6 pg/mL) and osmolality (303.4 ±1.6 mOsm/kgH_2O) increased significantly in PD patients. In addition, a positive correlation was observed

between plasma AVP levels and osmolality, and a small increase in plasma glucose levels (138.5 ±11.0 mg/dl) was observed in PD patients.

Conclusions: Several studies have shown that PD solution increases plasma glucose levels. Therefore, we considered that PD-induced hyperglycemia may cause an increase plasma osmolality and AVP levels. To the best of our knowledge, this is the first report to demonstrate an increase in plasma AVP level in PD patients. These findings provide novel insights into the fluid management of PD patients.



FR-PO691

Use of Raman Spectroscopy Analysis to Evaluate the Molecular Composition of Spent Peritoneal Dialysate and Urine over Time

James L. Pirkle,[1] John L. Robertson.[2] *[1]Wake Forest School of Medicine, Winston Salem, NC; [2]Virginia Tech, Blacksburg, VA.*

Background: Common indices to assess peritoneal dialysis (PD) adequacy – Kt/V urea and creatinine clearance – may not reflect clearance of other small and middle-molecular weight molecules that may be more important in the pathogenesis of uremia and patient outcomes. These indices may not reflect changes in residual renal function, peritoneal membrane integrity, local/systemic inflammation, patient metabolism, or mineral/electrolyte balance. Identification of other potentially important molecules in both spent dialysate (SD) and urine (UR) may provide better measures of treatment adequacy. However, analysis of these potentially-important molecules, with current technology (chromatography, mass spectroscopy), is time-consuming, expensive, and unlikely to be widely available in clinical settings.

Methods: We used novel methods, based on Raman spectroscopy and computational analysis, to study the molecular composition of SD and UR collected periodically from 15 PD patients over a two-year period of observation. Raman spectra were generated by irradiation of SD and UR samples at 785 nm, corrected for incident (background) radiation and then computationally normalized. The spectra of SD and UR samples from PD patients were compared to analytical standards, to unused dialysate fluid (SD samples) and urine (UR) collected from consented, healthy volunteers. Quantification of prominent spectral peaks (urea, creatinine, glucose, for example) was achieved by comparison with analytical standard calibration curves.

Results: As expected, spectra of SD and UR differed significantly. Of note, SD spectra among 15 patients also differed significantly from one another, as did UR spectra. For individual patients, both SD and UR spectra varied over time, reflecting changes in types of molecules being dialyzed and/or excreted in urine. Variations in either SD or UR spectra were not well-correlated to Kt/V urea or creatinine clearance. Prominent spectral peaks representing collagen and nucleic acids in some SD specimens may signal changes in peritoneal membrane integrity; this requires further analysis.

Conclusions: Changes in the molecular composition of peritoneal dialysate and urine over time can be identified using computational Raman spectroscopy. This method may yield a viable tool for assessing the clinical effectiveness of the peritoneal dialysis therapy.

FR-PO692

Time-Course Changes in the Levels of Biomarkers in Peritoneal Dialysis Effluent Among Patients Using New Neutral Fluids

Risa Terashima, Yudo Tanno, Nanae Matsuo, Yukio Maruyama, Ichiro Ohkido, Keitaro Yokoyama, Takashi Yokoo. *The Jikei University School of Medicine, Tokyo, Japan.*

Background: Recently, new neutral peritoneal dialysis fluid (PDF) contained bicarbonate 25mEq/L and lactate 10mEq/L (Bic/Lac PDF), instead of lactate 40mEq/L contained neutral fluid (Lac PDF), was available in Japan. The levels of biomarkers in PD effluents are used as the indexes of peritoneal deterioration associated with PD. However, there are few reports evaluating time-course changes in biomarker levels according to dwell time using Bic/Lac PDF.

Methods: Six stable PD patients were included (72±6 y/o, male 83%, PD duration 52.8±32.8 months). We compared the levels of CA125, IL-6, FDP, VEGF, and TNF-α in PD effluents between Bic/Lac PDF and Lac PDF after a dwell time of 2, 4, 6, and 8 hours.

Results: The levels of CA125 and IL-6 after the dwell time of 2, 4, 6, and 8 hours were as follows; CA125: Bic/Lac PDF, 13.2±6.5, 21.3±10.9, 26.8±14.2, and 33.6±19.1 U/mL; Lac PDF, 10.5±3.6, 16.6±5.6, 21.5±8.0, and 27.4±10.5 U/mL, and IL-6: Bic/Lac PDF, 10.1±7.8, 16.9±9.0, 23.4±10.3 and 33.2±11.9 pg/mL; Lac PDF, 12.1±6.9, 21.1±11.6, 29.4±16.2, and 43.2±23.6 pg/mL, respectively. The levels of FDP also showed increasing trends over time. The levels of VEGF and TNF-α in some samples were below the detection limits up to a dwell time of 6 hours.

Conclusions: The levels of biomarkers in PD effluents are greatly affected by PDF dwell time. Time-course changes in the levels of biomarkers are similar between two PDF.

T Regulatory Cells in Peritoneal Dialysis: Effect of the First Dialysis Session

Carlotta Caprara,[1] Rahul Sharma,[2] Anna chiara Frigo,[3] Diego Pomare' Montin,[1] Valentina Corradi,[4,1] Massimo de Cal,[4,1] Claudio Ronco.[4,1] *[1]IRRIV, Vicenza----, Italy; [2]University of Virginia, Charlottesville, VA; [3]University of Padova, Padova, Italy; [4]San Bortolo Hospital, Vicenza, Italy.*

Background: T Regulatory (Treg) cells are a subpopulation of T cells that modulate the immune system, maintain tolerance to self-antigens, prevent autoimmune disease and regulate key immune responses across a variety of disease settings. In the literature, contrasting results have been reported about the influence of dialysis on Treg cells, in chronic kidney disease stage G5 patients that show activated but impaired immune system. Moreover the influence of dialysis on T cells needs further investigation. The aim of this study is to evaluate the influence of the first peritoneal dialysis (PD) treatment on Treg cells subset.

Methods: A total of 13 patients that have to start PD were enrolled. Treg were studied by flow cytometry with: CD3(PerCP); CD4(FITC); CD25(PECy7); CD127(PE) and FOXP3(APC) antibodies. Time point: T0 (before the first dialysis treatment); T1 (after 1 month). We performed Wilcoxon for dependent samples to compare the mean delta percentage difference between T0 and T1(100*(T1-T0)/T0).

Results: Treg cells (either considered as CD25+FoxP3+ or as Foxp3+) analyzed as percentage of lymphocytes showed a statistically significant increase during time (median=35.92; p=0.0425 for CD25+FOXP3+ and median=30.85; p=0.0479 for FOXP3+); Splitting Foxp3+ cells into CD25Hi, CD25Int and CD25Lo, showed an increment during time of Foxp3+CD25hi population (median=53.85; p=0.0215) while the other two populations remained unchanged (median=23.81 and median=15.38 respectively; p>0.05), as well as T lymphocytes (median=-6.58; p>0.05).

Conclusions: The study analyzed for the first time T cells variation before and after the first PD treatment. PD treatment improves T cells status by increasing Treg percentage, and Treg expressing CD25 after one month of treatment, while it does not influence other cells populations.

FR-PO694

miRNAs and Hyalinizing Vasculopathy in Peritoneal Dialysis Patients

Rafael Selgas,[1,2] Raúl R. Rodrigues díez,[2] Ricardo Ramos-Ruiz,[5] Gloria Del peso,[6] Maria A. Bajo,[1] Marta Ruiz-Ortega,[2] Manuel Lopez-Cabrera,[4] Carlos Llorens.[3] Peritoneal Studies Group in Madrid *[1]Hospital University La Paz, Madrid, Spain; [2]Universidad Autonoma, Madrid, Spain; [3]Biotechvana, Paterna, Spain; [4]Consejo Superior de Investigaciones Cientificasn, Madrid, Spain; [5]parque científico de madrid, MADRID, Spain; [6]Hospital Universitario La Paz, Madrid, Spain.*

Background: Peritoneal membrane is conditioned by lesions appearing at long-term for dialysis purposes. Among these lesions, Hialynazing Vasculopathy has received less attention than others, and mechanisms causing this damage are incompletely studied although it is regularly found at advanced peritoneal stages. miRNAs are important regulators of cell biology. A miRNA transcriptomic study is an appropriate approach to independently (non-hypothesis driven) explore molecular mechanisms involved in this pathology.

Methods: We studied 7 patients affected by peritoneal vasculopathy and 4 patients without it. Total RNA was extracted from FFPE peritoneal tissue, small RNA libraries were prepared and sequenced.

Results: 20 miRNAs differentially expressed between groups were found (Table, up/down in vasculopathy). Remarkably, 9 of them belong to a cluster of miRNA loci separated by less than 10 kb in chromosome 14 (marked in Table). We also detected messenger RNAs which were differentially expressed, and positive correlations between miRNAs and these messenger RNAs were found

Conclusions: GO enrichment performed based on coding genes shown as differentially expressed, revealed differential enrichment in proteins with hydrolase activity and proteins with RNA and protein binding functions. Differential enrichment was also observed in proteins involved in translation processes with sub-localizations mainly exosomal vesicles and extracellular space besides of cytosol sub-localisations probably related with translational processes. Enrichment analysis of metabolic pathways reveals enrichment in enzymes involved in three pathways; Aminoacyl-tRNA biosynthesis, N-Glycan biosynthesis and Galactose metabolism. The impact of these new findings in terms of gene function will be discussed.

Funding: Government Support - Non-U.S.

Predictors of Icodextrin Induced Hyponatremia

Ankur Gupta,[2] Susan D. Lavoie,[1] Swapnil Hiremath,[3] Pierre-Antoine Brown,[4] Brendan Mccormick.[1] Kidney Research Centre, University of Ottawa *[1]Ottawa Hospital, Ottawa, ON, Canada; [2]TOH, OTTAWA, AB, Canada; [3]University of Ottawa, Ottawa, ON, Canada; [4]The Ottawa Hospital, Ottawa, ON, Canada.*

Background: Icodextrin (ICO) is a polyglucose peritoneal dialysis (PD) solution used in the long dwell. It is known to produce a mild dilutional hyponatremia due to its absorption and metabolism to maltose. In our program, many patients are treated with a single ICO dwell overnight as part of an incremental PD approach. We hypothesized that these patients are more likely to develop ICO induced hyponatremia due to decreased peritoneal clearance of maltose.

Methods: We performed a cross sectional analysis of our prevalent PD patients treated with ICO to determine the predictors of a significant (≥ 5 mmol/L) drop in serum sodium (Na) after ICO initiation. From our electronic database, demographic and biochemical information was abstracted. Serum Na values immediately before and a minimum of two weeks post ICO initation were compared.

Results: 107 of 193 prevalent patients had at least once ICO exposure and 98 patients had pre/post Na values and were included. Predictors of a significant drop in Na are shown in the table. When age and modality were entered into a regression model, the adjusted OR for hyponatremia with single ICO exchange was 1.88 (CI 1.16 to 3.13, P=0.01) compared with a single ICO and full CAPD or CCPD.

Conclusions: We conclude that use of a single overnight ICO exchange is associated with a significantly higher risk of hyponatremia than when ICO is used as part of a full CAPD or CCPD regime. This suggests that peritoneal clearance of maltose is important in attenuating the apparent drop in serum sodium with ICO. Further prospective studies are needed to validate this concept.

Body Mass Index Trends in Patients Undergoing Peritoneal Dialysis for Decades and Their Effect on Patient Survival: Analysis of Data from an ESRD Registry (1985–2014) in Korea

Seon Deok Hwang,[1] Jin ho Lee,[2] Woo Yeong Park,[3] Jeong Ho Kim,[4] Jong Hyun Jhee,[1] Seoung Woo Lee.[5] *[1]Inha University College of Medicine, Incheon, Republic of Korea; [2]Bong Seng Memorial Hospital, Busan, Republic of Korea; [3]Dongsan Medical Center, Daegu, Republic of Korea; [4]Daejeon St. Mary's Hospital, Daejeon, Republic of Korea; [5]Inha University Hospital, Inchon City, Republic of Korea.*

Background: Significant increases in the prevalence of obesity have been observed among patients with end-stage renal disease (ESRD). However, the changes in body mass index (BMI) status in prevalent Korean patients undergoing peritoneal dialysis (PD) over the recent decades and their impact on patient survival remains unknown.

Methods: Among 80,674 patients from the ESRD registry of the Korean Society of Nephrology. Prospective cases for Our analysis were outpatients ≥ 18-years-old who underwent maintenance peritoneal dialysis between 1985 and 2015. Among the possible (10,495) cases identified, cases with sufficient data was not measured were excluded. After screening, our analysis was based on the data of 6,095cases. BMI divided the entire patient population into quartiles. As a result, BMI was divided into <21.19 in group 1, 21.19 to 23.18 in group 2, 23.18 to 25.71 in group 3, and >25.70 in group 4. Among the 6,095 cases included in our analysis, 2,229 (36.7%) all-cause deaths was recorded over the follow-up period, Kaplan-Meier survival curves confirmed increase in all-cause mortality among BMI. We additionally analyzed these patients by dividing them into diabetic and non-DM patients.

Results: The log rank of the Kaplan-Meier survival curves according to the BMI Group was 19.53 and the P-value was 0.001. Cox proportional hazards model, Even after adjustment for potential confounders, the all-cause mortality HR was 1.29 (95% CI, 1.10–1.551; $P = 0.001$) in quartile 3 and 1.36 (95% CI, 1.14–1.59; $P< 0.001$) in quartile 4 respectively. However, There was no statistical significance between quartile 1 and quartile 2(HR, 1.17; 95% CI, 0.99–1.37; $P = 0.055$). In diabetic patients which were adjusted for several parameters that was important to mortality, meaningful values were seen in group 4 and mortality was 1.45 times higher in patients with BMI 25.7 or higher in diabetic patients 1.45 (95% CI 1.20-1.76 p-value<0.001).

Conclusions: In the Korean PD patients BMI elevation is significantly correlated with increased mortality of CAPD patients. In particular, the high BMI of DM CAPD patients increases mortality

FR-PO697

A Single Center Validation Study of a Korean Version of the SARC-F for Patients on Peritoneal Dialysis

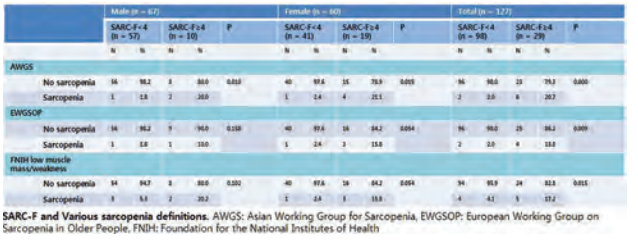
Joonhyuk Seo, Seok hui Kang, Kyu-hyang Cho, Jong-Won Park, Jun-Young Do. *Devision of Nephrology, Department of Internal Medicine, Yeungnam University Medical Center, Daegu, Republic of Korea.*

Background: The SARC-F is a simple screening tool for sarcopenia, consisting of 5 questions covering strength, assistance in walking, rising from a chair, climbing stairs, and falls. Given most of those on peritoneal dialysis (PD) have low muscle mass and poor physical function, it is worth examing an usefulness of SARC-F for them. This study aimed to **validate the Korean version of SARC-F** for patients **on PD**.

Methods: The Korean version of SARC-F, which was introduced from a previous study validating it in community-dwelling older adults, was tested in regular visiting 127 outpatients on PD (men 52.8%, women 47.2%). **Validity was analyzed by standard criteria based on the Foundation for the National Institutes of Health, Asian and European Working Group**. The subjects were divided into two groups according to SARC-F score (<4 and ≥4) and its correlation with multiple factors including age, KT/V, residual renal function, skeletal muscle mass, handgrip strength, etc. was inspected by sex.

Results: The prevalence of sarcopenia in men and women according to SARC-F was 14.9% and 31.6%, respectively. **For men**, SARC-F showed low sensitivity and low positive predictive value (PPV) [33.3%-66.7%, 10.0%-20.0%, respectively], but **high specificity and high negative predictive value (NPV) [85.9%-87.5%, 94.7%-98.2%, respectively]**. Similary, **for women**, SARC-F showed low sensitivity, low PPV and **high NPV** [50.0%-80.0%, 5.3%-21.1%, **97.6%**, respectively], although specificity was relatively lower than men [69.0%-72.7%]. The SARC-F<4 group had less muscle mass and poorer hand grip strength.

Conclusions: As the **specificity and NPV of Korean version of SARC-F were high**, it is useful, particularly for men on PD, to **rule out** sarcopenia in a simple way. Regarding the lower specificity for women, it is suggestive that applying a **different cut-off value according to sex** is necessary. The **sensitivity was too low to screen** the sarcopenic patient on PD, and hence, further attention for screening sarcopenia would be required.



SARC-F and Various sarcopenia definitions. AWGS: Asian Working Group for Sarcopenia, EWGSOP: European Working Group on Sarcopenia in Older People, FNIH: Foundation for the National Institutes of Health

SARC-F Validated Against Different Sarcopenia Definition

FR-PO698

Comparison of the Risk of Fracture in Peritoneal Dialysis Patients with Sarcopenia Using the FRAX

Heeryong Lee, Jeongmyung Ahn, Dong Ryeol Lee. *Nephrology, Maryknoll Medical center, Busan, Republic of Korea.*

Background: For chronic patients with chronic diseases such as peritoneal dialysis, the rate of sarcopenia is high. This sarcopenia increases the risk of dying by causing heart failure, fractures, infection, frailty, and resistance to insulin. This study was initiated because of the lack of evidence of a risk of fractures in patients with peritoneal dialysis.

Methods: : We studied 146 patients on peritoneal dialysis. For the diagnosis of sarcopenia, we measured muscle mass (measured using a bioimpedance analysis), muscle strength (measured using a handgrip strength), and physical performance (measured using a gait speed). Sarcopenia was diagnosed on the basis of the European Working Group on Sarcopenia in Older People (EWGSOP). The risk of fracture was measured using the fracture risk assessment tool (FRAX) after measuring the femoral neck bone mineral density. The FRAX is computerized algorithm that determines fracture probability in individuals by integrating important individual clinical risk factors for fracture and mortality.

Results: The mean age was 57.7 ± 11.8; There are 63 men and 83 women. There were 101 patients with continuous ambulatory peritoneal dialysis and 45 patients with automated peritoneal dialysis. A total of 45 patients were sarcopenia (30.8 %), of which 21 were men and 24 were women. There was no difference between the two groups of dialysis duration (1713.4 ± 1621.6 days vs 1804.3 ± 1917.4 days, p=0.761). Differences in values of the 10-year probability of fractures were seen depending on the presence of sarcopenia. The risk of 10-year of major osteoporotic fractures was low in a group that did not have sarcopenia (4.3 ± 3.0 % vs. 6.9 ± 5.9, p = 0.021). And the risk of 10-year of hip fractures was also lower in the group without sarcopenia (1.3 ± 2.0 vs 2.3 ± 1.5, p=0.022).

Conclusions: In peritoneal dialysis patients, the risk of fractures increases if they have sarcopenia. In peritoneal dialysis patients, it is desirable to reduce the risk of fractures by preventing sarcopenia.

FR-PO699

A Study Based on Bioelectrical Impedance Analysis on the Weight Gain in Peritoneal Dialysis: Fat or Muscle?

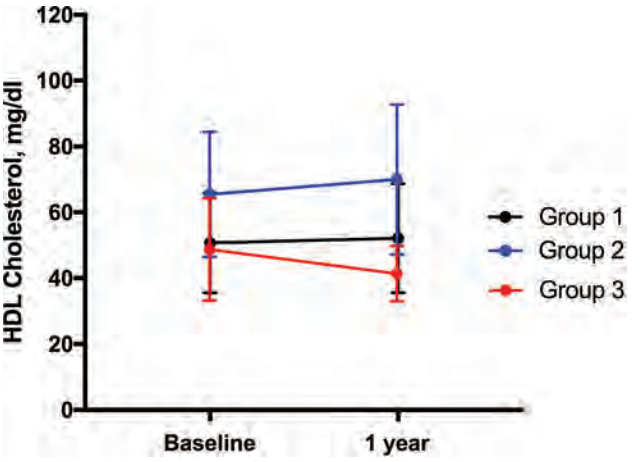
Guilherme P. Santa Catharina, Fernanda T. Ferreira, Erica A. Guimarães, Gabriel C. Barsotti, Lilian Cordeiro, Bruno C. Silva, Benedito J. Pereira, Hugo Abensur, Rosilene M. Elias. *University of São Paulo, São Paulo, Brazil.*

Background: Patient weight gain after the beginning of Peritoneal Dialysis (PD) is a well-known phenomenon, yet whether this is resultant from increased overhydration, fat or muscle mass is not well established. Bioelectrical Impedance Analysis (BIA) can assess both nutritional status and tissue hydration in these patients.

Methods: This is a cross-sectional study that included 44 incident patients on PD. A subset of 20 patients underwent BIA at baseline and 6 months after PD initiation for the following variables: fat mass (FM), muscle mass (MM), phase angle (PA), extracellular/total body water ratio (ECW/TBW). Weight, body mass index, fasting glucose, total and HDL cholesterol, albumin, creatinine and FM/MM behavior during study period were also evaluated.

Results: Patients aged 52±17 years (43% men, 30% diabetic). There was an increase in weight gain (p<0.001), with no significant increase in fasting glucose, total and HDL cholesterol. Serum albumin reduced from 3.7±0.5 to 3.5±0.6g/dl (p=0.024). Fat increased from 19±6 to 21±7kg (p=0.041), with no increase in MM (from 23±4 to 24±5kg p=0.142), PA (from 4.4±2.5 to 3.5±5.6° p=0.914), and ECW/TBW (from 0.40±0.01 to 0.40 ±0.02, p=0.667). There were 3 distinct behaviors: Group 1: increased FM/decreased MM (N=7); Group 2: decreased FM/increased MM (N=6); Group 3: increased FM and MM (N=6). Groups were similar by age, gender, albumin and presence of diabetes, albeit group 2 presented higher HDL cholesterol at 1 year (p=0.049), independent of statin prescription. [Figure 1]

Conclusions: PD is associated with weight gain, which is mostly due to a FM component. Intriguingly, some patients presented reduced FM and increased MM, and exhibited high levels of HDL cholesterol. Further studies are necessary to establish a link between weight gain, body composition and cardiovascular risk in PD patients.



FR-PO700

Elevated Serum Uric Acid Is Associated with Greater Skeletal Muscle Mass in Patients on Peritoneal Dialysis

Xi Xiao,[3] Xiao Yang,[1] Chunyan Yi,[3] Yuan Peng,[3] Haishan Wu,[3] Meiju Wu,[3] Xuan Huang,[3] Xueqing Yu.[2] *[1]The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [2]Department of Nephrology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [3]The First Affiliated Hospital, Sun Yat-sen University, Guang Zhou, China.*

Background: Serum uric acid (UA) has been identified as a good nutritional marker in hemodialysis patients, but was little investigated in patients on peritoneal dialysis (PD). The aim of this study was to investigate the relationship between uric acid and skeletal muscle mass (SMA) in PD patients.

Methods: This is a cross-sectional study. The patients who performed multi-frequency bioelectrical impedance (BIA) from January 1, 2013 to December 31, 2016, and with SUA values were enrolled. Collected data included demographic characteristics, clinical and laboratory measurements. Skeletal muscle mass was measured by BIA. The relationship between SUA and the skeletal muscle mass was tested by multiple linear regression models.

Results: A total of 734 prevalent PD patients (57.4%male) were enrolled, with a mean age of 48.3±14.2 years, a mean SMA of 27.0±5.5kg and a mean serum UA of 6.8±1.3mg/dl. Compared with participants in lowest quartile of UA, those participants in highest quartile showed a higher SMA(28.22±5.88 vs. 25.97±4.70, p =0.015). When examined as a continuous variable in multiple linear regression models, serum UA was positively associated with skeletal muscle mass in total patients [standardized coefficients (β) 0.453; 95% confidence interval(CI) 0.145 - 0.760, p = 0.004]. And gender-stratified analysis shows that the association exists both in male (β 0.433; 95% CI 0.010 - 0.856, p= 0.045) and female patients (β 0.486; 95% CI 0.032 to 0.940, p= 0.036). Furthermore, a significant association was found between the highest or the second highest quartiles of UA and skeletal muscle mass in fully adjusted models in PD patients(β 1.952; 95% CI 0.801 -3.102, p= 0.001; β 1.453; 95% CI 0.305-2.600, p= 0.013, respectively).

Conclusions: The elevated serum UA was associated with a greater skeletal muscle mass in PD patients, and uric acid could be a potential nutritional marker in PD patients.

Home-Based Aerobic and Resistance Exercise Training on Peritoneal Dialysis Patients: A Randomized Controlled Trial

Kiyotaka Uchiyama,[1] Shu Wakino,[1] Naoki Washida,[1,2] Kohkichi Morimoto,[1] Takahiro Kasai,[2] Hiroshi Itoh.[1] *[1]Division of Endocrinology, Metabolism and Nephrology, Keio University, School of Medicine, Tokyo, Japan; [2]Department of Nephrology, International University of Health and Welfare School of Medicine, Chiba, Japan.*

Background: Muscle wasting, common and progressive in uremic patients, is associated with a high probability for morbidity, lower health-related quality of life (HRQOL), and mortality. However, potential effect of aerobic and resistance training on peritoneal dialysis (PD) patients has not been fully elucidated. This randomized, controlled study investigated whether a home-based exercise program for PD patients would improve their physical function, PD-related parameters and HRQOL.

Methods: 47 PD participants (mean age, 64 years; mean PD vintage, 3.8 years; 35 men) were randomly assigned to home-based training (n = 24) or usual care (n = 23). Participants were included if they started PD more than 3 months prior to baseline assessment. Patients were excluded if they had unstable medical conditions. Home-based-exercise patients were instructed to perform aerobic exercise at 40–60% of the peak oxygen uptake (VO_{2peak}) thrice weekly, and resistance training at 70% one-repetition maximum twice weekly for 12 weeks. Exercise capacity was assessed by VO_{2peak} estimated from incremental shuttle walking test and handgrip and quadriceps strength. In addition to evaluation of PD-related parameters, HRQOL was assessed by the Kidney Disease Quality of Life-Short Form questionnaire.

Results: 44 participants completed the study (home-based training, n = 22; usual care, n = 22). Analyses of covariance, adjusted for baseline values, revealed significant differences between home-based training and usual care in VO_{2peak} (12.5 ± 3.6 to 13.1 ± 4.2 mL/kg·min versus 11.9 ± 2.8 to 11.2 ± 3.1 mL/kg·min; P = 0.02) and serum albumin (3.46 ± 0.49 to 3.51 ± 0.44 g/dl versus 3.55 ± 0.41 to 3.42 ± 0.47 g/dl; P = 0.03). Moreover, compared to usual care group, exercise group showed significant improvements in HRQOL scores of physical role functioning (P = 0.02) and role/social component summary (P < 0.01), as well as non-significant improvements in kidney disease component summary (P =0.06), bodily pain (P = 0.07), and vitality (P = 0.06). There were no reported adverse events as a result of the intervention.

Conclusions: A 12-week home-based aerobic and resistance exercise improved aerobic capacity, serum albumin and HRQOL in PD patients. The present study demonstrated for the first time, the efficacy of home-based training in PD patients.

FR-PO702

Roles of Matrix Metalloproteinase (MMP)-2 and MMP-9 in Arteriovenous Fistula (AVF) Development

Yan-Ting Shiu,[1] Ha D. Le,[1] Yuxia He,[1] CS Jason Tey,[1] Isabelle D. Falzon,[1] Yanhang Zhang,[5] Michael Allon,[2] Timmy C. Lee,[2] Scott A. Berceli,[3] Karl A. Nath,[6] Edgar A. Jaimes,[4] Alfred K. Cheung.[1] *[1]University of Utah, SALT LAKE CITY, UT; [2]University of Alabama at Birmingham, Birmingham, AL; [3]University of Florida, Gainesville, FL; [4]Memorial Sloan-Kettering Cancer Center, New York, NY; [5]Boston University, Boston, MA; [6]Mayo Clinic, Rochester, MN.*

Background: Collagen is one of the most abundant vascular extracellular matrix components, and collagenolytic MMP-2 and MMP-9 are key regulators of vascular remodeling. MMP-2 and MMP-9 are known to stimulate the proliferation of vascular endothelial cells (ECs) and smooth muscle cells (SMCs) and cause collagen disruption. These properties may respectively promote the formation of neointimal hyperplasia (NH) and alter the ability of the AVF wall to expand in patients with chronic kidney disease (CKD). Thus, we investigated the effect of CKD on MMP-2 and MMP-9 expression, and their roles in AVF development.

Methods: Human vascular ECs and SMCs were cultured in serum obtained from CKD patients or non-CKD control subjects and then quantified for MMPs by western blot. We used a modified low-dose adenine diet to induce CKD in Wistar rats. Baseline femoral venous MMPs were quantified and femoral AVFs were created in CKD rats and non-CKD rats. Baseline vascular compliance was measured and carotid-jugular AVFs were created in global MMP-2 or MMP-9 knockout (KO) mice on C57BL/6 background, with C57BL/6 mice serving as wild-type (WT) controls. AVFs from both animal models were harvested for histology.

Results: Compared to non-CKD serum, CKD serum enhanced MMP-2 (1.3-fold) and MMP-9 (20-fold) protein expression in cultured ECs. Similar trends were found for SMCs. When compared to non-CKD rats, CKD rats had higher baseline venous MMP-2 (3-fold) and MMP-9 (4-fold), and smaller AVF vein lumen area 4 weeks after creation. Baseline carotid arteries from the MMP-2 KO mice and MMP-9 KO mice had higher compliance when compared to WT mice. The percent open lumen area of the AVF veins at 1 week after creation was larger in the MMP-2 KO mice (39% ± 6%) and MMP-9 KO mice (47% ± 3%) vs. the WT mice (11% ± 2%).

Conclusions: Our animal studies showed that MMP-2 and MMP-9 were strong impediments to AVF development. Therapeutic approaches of inhibiting these molecules may enhance AVF maturation in CKD patients.

FR-PO703

Preexisting venous Medial Matrix Metalloproteinase (MMP)-2 and Arteriovenous Fistula (AVF) Maturation: Findings from the Hemodialysis Fistula Maturation (HFM) Consortium Study

Yan-Ting Shiu,[1] Ha D. Le,[1] Michael Allon,[2] Michelle L. Robbin,[2] Kelly L. Hudkins,[3] Charles E. Alpers,[3] Tom Greene,[1] Alfred K. Cheung.[1] *[1]University of Utah, SALT LAKE CITY, UT; [2]University of Alabama at Birmingham, Birmingham, AL; [3]University of WA, Seattle, WA.*

Background: AVF maturation requires adequate outward remodeling (luminal expansion) and limited inward remodeling (neointimal hyperplasia) to facilitate increases in AVF diameter and blood flow. MMP-2 and MMP-9 are critical for vascular remodeling in other settings. Inhibition of MMP-2 and MMP-9 reduces neointimal hyperplasia following vascular injury or graft implantation in animals with normal renal function. However, the clinical relevance of MMP-2 and MMP-9 in AVF diameter (a net result of luminal expansion and neointimal hyperplasia) and blood flow remains unclear.

Methods: We prepared histological slides of venous samples from 100 randomly selected patients at the time of AVF creation in the HFM Study. The protein expression levels of MMP-2 and MMP-9 were quantified by immunohistochemistry and ImageJ, and reported as a percentage of the total medial area. We then investigated the statistical associations of MMP-2 or MMP-9 levels with AVF diameter and blood flow assessed using duplex ultrasound at 6 weeks after AVF creation.

Results: Venous medial MMP-2 (Fig. 1) and MMP-9 expression varied widely among patients. We found a negative association of venous medial MMP-2 with the 6-week AVF diameter (Δ diameter = –0.23 mm; 95% CI, –0.44 to –0.02; p=0.029) and a trend for AVF blood flow (Δ flow = –39 ml/min; 95% CI, –106 to –29; p=0.26), per 10% increase in MMP-2. No association was found between MMP-9 and the 6-week AVF diameter or blood flow.

Conclusions: Preexisting venous medial MMP-2 expression was associated with impaired AVF maturation in this subset of HFM patients. More rigorous validation of this observation using a larger cohort is necessary.

Funding: NIDDK Support

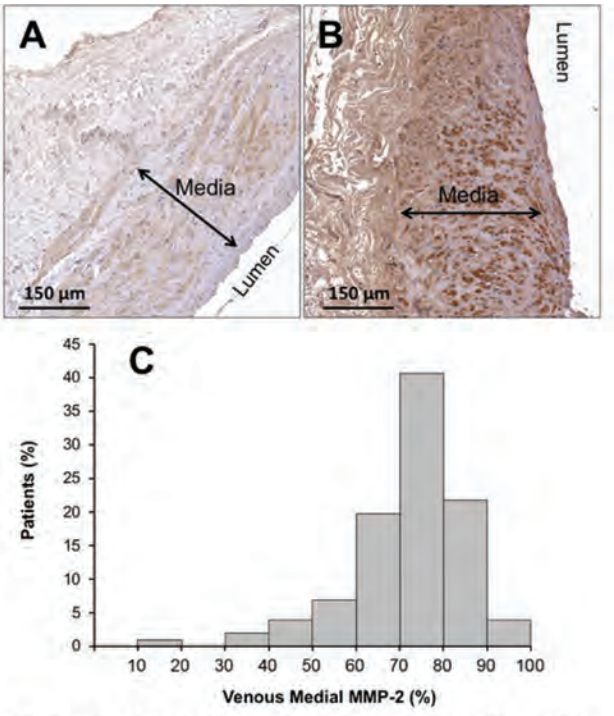

Fig. 1. Representative immunohistochemistry images of MMP-2 (rust color) show **(A)** a patient whose venous medial layer had low MMP-2 quantity (50% of area stained positive of MMP-2), and **(B)** a different patient whose venous medial layer had substantially more MMP-2 (93%). **(C)** Distribution of MMP-2 in 100 patients.

FR-PO704

Transcriptomics of Human Arteriovenous Fistula Failure Uncovers an Unexpected Source of Inflammation

Laisel Martinez,[2] Marwan Tabbara,[2] Juan C. Duque Ballesteros,[2] Guillermo Selman,[1] Angela Paez,[2] Loay H. Salman,[1] Roberto I. Vazquez-Padron.[2] *[1]Albany Medical College, Albany, NY; [2]University of Miami, Miller School of Medicine, Miami, FL.*

Background: Improving arteriovenous fistula (AVF) outcomes requires a better understanding of the biology underlying maturation or failure. Unfortunately, our current knowledge of the biological processes associated with maturation relies on assumptions and extrapolation from other vascular pathologies, which overlooks the uniqueness of AVF remodeling.

Methods: In this study, we used an unbiased "omics" approach based on high-throughput RNA sequencing of human pre-access veins and fistulas to uncover novel molecular targets associated with nonmaturation. We obtained native vein and juxta-anastomotic AVF tissues from patients undergoing two-stage upper arm AVF surgeries at a single center. Paired venous samples from both stages were used to study the vein to AVF transformation at the transcriptomics level.

Results: We discovered a unique molecular signature of pro-inflammatory genes (*CSF3R, FPR1, S100A8, S100A9,* and *VNN2*) that was upregulated in native veins that failed vs. matured (FDR<0.05), and whose expression co-localized to smooth muscle cells in the media. Furthermore, expression of *S100A8* and *S100A9* was significantly associated with postoperative intimal hyperplasia (IH) and the product of medial fibrosis x IH (R^2 0.10-0.15, P<0.05). We revealed the drastic vascular transformation that occurs during early remodeling at the molecular level, with >9,500 genes differentially expressed between native veins and AVFs in paired tissue samples.

Conclusions: In conclusion, this work demonstrates the importance of the subclinical inflammatory status of the pre-access vein in AVF nonmaturation, and identifies calprotectin (S100A8/A9) as a potential therapeutic target to prevent this complication. Our transcriptomics data underscores the complexity and uniqueness of vascular remodeling after fistula creation.

FR-PO705

Endothelial-to-Mesenchymal Transition in Neointimal Hyperplasia of a Mice Model of Arteriovenous Fistula

Chung-te Liu. *Division of Internal Medicine, Wanfang Hospital, Taipei Medical University, Taipei, Taiwan.*

Background: To date, arteriovenous fistula (AVF) is the preferred vascular access for hemodialysis. However, for the matured AVF, the 2-year patency without intervention was only 30-50%. In addition, frequent interventional procedures were required to maintain AVF patency, which causes immense suffer to patients. As such, medical treatment to prevent AVF stenosis is desired. Stenosis of AVF resulted from the process of neointimal hyperplasia, signifying thickening of subintima caused by proliferation of cells express α-smooth muscle actin (α-SMA) and vimentin. The pathogenic role of neointimal hyperplasia in AVF stenosis has been confirmed by multiple studies, however, understanding of its molecular mechanism is still suboptimal. Endothelial-to-mesenchymal transition (EndMT) is the process that endothelial cells transform to mesenchymal cells, which had been demonstrated in pathogenic fibrogenesis of cardiovascular diseases. This study tries to demonstrate EndMT in a mice AVF model.

Methods: Chronic kidney disease (CKD) in mice is induced by diet containing 0.2% adenine. After 10 days of adenine diet, CKD was confirmed by elevated serum creatinine and surgical creation of AVF was performed. Murine AVF model is created by aortocaval puncture to form AVF between abdominal aorta and inferior vena cava (IVC). The successful creation of AVF was confirmed by doppler ultrasound during surgery. Six weeks after AVF creation, the mice were sacrificed and AVF was resected. The specimens were stained for α-SMA and vascular endothelial-cadherin (VE-cadherin) to show the expression of both endothelial and mesenchymal features of the proliferated intima.

Results: After 10 days of adenine containing diet, serum creatinine increased significantly from 0.25 mg/dL to 0.73 mg/dL. Immediately after AF creation, doppler ultrasound showed increased blood flow and exaggerated pulsation wave form of the IVC proximal to AVF site. The IVC wall adjacent to AVF site showed proliferated intima, which stains positive for α-SMA. Co-staining the same area showed that the proliferated intima expressed both α-SMA and VE-cadherin, which indicated possible EndMT.

Conclusions: This pilot study provided preliminary evidence of the presence of EndMT in AVF mice model, which may underly the pathogenic stenosis of human AVF. However, more evidence is still required to confirm EndMT in AVF and its molecular pathway.

FR-PO706

The Role of PDE5A Inhibition in Arteriovenous Fistula Remodeling

Maheshika S. Somarathna, Tatyana Isayeva Waldrop, Jessica N. Redmann, Timmy C. Lee. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Impaired outward vascular remodeling along with neointimal hyperplasia (NH) are thought to be the major underlying causes of arteriovenous fistula (AVF) maturation failure. We hypothesize that a selective phosphodiesterase type 5A (PDE5A) inhibitor, sildenafil, administered before and after AVF creation can be used to improve vascular outward remodeling. The aims of this study are to evaluate in a rat AVF model, the effect of PDE5A inhibition on: 1) venous and arterial diameter 2) venous blood flow and 3) venous NH formation.

Methods: Sildenafil was administered to 12-16-week-old Sprague-Dawley rats two weeks prior to AVF (Femoral vein to artery) creation and continued until sacrifice at 7 days. Venous blood flow was measured using transonic perivascular flow probes and the diameters of the AVF venous and arterial segments were measured at a point proximal and a point distal to the anastomosis using the microscopic ocular micrometer (Fig. 1A), at the time of sacrifice. Morphometric analysis of the AVF vein was also carried out to assess the changes in NH development.

Results: When compared to control group, a significant increase in venous and arterial diameter was observed in the sildenafil treated group in proximal and distal regions, at 7days after AVF creation. Furthermore, increased venous blood flow was also observed in sildenafil treated AVFs. However, no significant difference in the NH development was observed between the two groups.

Conclusions: Sildenafil administered before and after AVF creation, improves venous blood flow and the outward expansion in AVF vessels without affecting the level of NH at 7 days. These observations suggest that, outward expansion of venous limb of the AVF can preserve the luminal caliber and allow proper maturation of AVF, in the presence of NH formation. Therefore, targeting mechanisms that enhance outward vascular remodeling could be a potential therapeutic approach for treating AVF maturation failure.

Funding: Veterans Affairs Support

FR-PO707

Neutrophil Activation Status Was Associated with the Degree of ºArteriovenous Fistula Stenosis in Chronic Hemodialysis Patients

Hye Min Choi,[1] Young Eun Kwon,[2] Dong-jin Oh.[2] *[1]Internal medicine, Myongji Hospital, Goyang-si, Republic of Korea; [2]Myongji Hospital, Koyang, Republic of Korea.*

Background: Although arteriovenous fistula (AVF) dysfunction is a major cause of morbidity in hemodialysis (HD) patients, detailed pathogenesis of AVF stenosis is still under investigation. Leukocytes have been shown to play an important role in the development AVF stenosis. However, prior reports have focused on monocyte lineage cells, and little is known about the possible role of neutrophils. We aimed to evaluate the association between AVF stenosis and neutrophil activation status by measuring circulating levels of neutrophil elastase (NES), lactoferrin, and angiogenin, which are markers of neutrophil activation and inhibition, respectively.

Methods: A total of 69 patients were included who received HD with native AVF for more than 3 months. Patients with recent history of infection, antibiotics, or AVF intervention were excluded. Degree of AVF stenosis was expressed by the percent of the greatest stenotic diameter to the widest adjacent vessel diameter by ultrasound

Results: The pre-dialysis circulating NES and lactoferrin levels were not significantly different between HD patients and control (healthy and CKD stage 3), although angiogenin level was significantly higher in HD population. The degree of AVF stenosis was positively correlated with NES (r=0.360, p=0.002) and lactoferrin (r=0.352, p=0.003) levels. Patients with AVF stenosis (stenosis > 50%) were older (65.9±9.7 vs 58.0±13.7, p=0.004), had longer duration of AVF use (52.9±45.8 vs 39.5±46.0 month, p=0.019), higher hsCRP (0.34±0.35 vs 0.15±0.17 mg/dl, p=0.029), and higher NES (421.0±254.2 vs 192.2±136.3 ng/ml, p<0.001) and lactoferrin (279.4±127.4 vs 144.0±68.9 ng/ml, p=0.001) levels compared with the other group. There was no significant difference in gender, presence of diabetes, angiogenin, and other biochemical measurements including albumin, calcium, phosphorus, iPTH, and cholesterols according to the degree of AVF stenosis. In multivariable analysis, however, only age and duration of AVF use were statistically significant factors for AVF stenosis.

Conclusions: Circulating levels of NES and lactoferrin, indirect markers of neurophil activation, were associated with the degree of AVF stenosis. Larger scales of long-term prospective studies are needed to show whether they could be used as independent predictors of at-risk AVF.

FR-PO708

The Role of Heme-Degrading and Heme-Binding Proteins in Decreasing Thrombosis

Meryl C. Nath,[1] Anthony J. Croatt,[1] Joseph P. Grande,[1] Allan W. Ackerman,[1] John D. Belcher,[2] Raymond F. Regan,[3] Gregory M. Vercellotti,[2] Karl A. Nath.[1] *[1]Mayo Clinic, Rochester, MN; [2]University of Minnesota, Minneaplis, MN; [3]Thomas Jefferson University, Philadelphia, PA.*

Background: Induction of the heme-degrading enzyme, heme oxygenase-1 (HO-1), protects against dysfunction and closure of an arteriovenous fistula (AVF) and other types of vascular injury. Thrombosis contributes to AVF dysfunction and closure, and to certain types of vascular and renal injury. The present study examined whether HO-1 induction or administration of its products reduces thrombosis in vivo.

Methods: We employed the murine clot model induced by infra-renal ligation (L) of the inferior vena cava (IVC). Clot size is assessed in this model by determining the clot

weight/clot length ratio. Our prior studies in this model demonstrated that HO-1 is induced, and that clot size is increased in HO-1$^{-/-}$ mice as compared with HO-1$^{+/+}$ mice.

Results: Clot size in the IVCL model was significantly reduced in mice treated with hemin (an inducer of HO-1) as compared with saline on day 1 (1.13±0.54 vs 2.92±0.21), day 2 (1.72±0.26 vs 3.58±0.36), and day 3 (1.70±0.47 vs 3.29±0.24) after IVCL. These beneficial effects of hemin were accompanied by reduced expression of proinflammatory and thrombogenic genes. We confirmed marked induction of HO-1 mRNA and protein and HO activity in the IVC in hemin-treated mice. HO-1 upregulation in the IVC by adeno-associated viral delivery also reduced clot size in the IVCL model. Biliverdin, a product of HO activity, reduced clot size on day 2 after IVCL, as did another product of HO activity, carbon monoxide, delivered as CORM-3. The constitutive HO isoform, HO-2, did not exhibit the anti-thrombotic efficacy of HO-1 as clot size was not increased in HO-2$^{-/-}$ mice as compared with HO-2$^{+/+}$ mice. Analysis of the clot model further demonstrated that the heme-binding protein, hemopexin (HPX) was induced in the IVC, and that clot size was increased in HPX$^{-/-}$ mice as compared with HPX$^{+/+}$ mice.

Conclusions: HO-1 and its products are markedly effective in inhibiting thrombosis, whereas such efficacy is not exhibited by HO-2. The beneficial effect of HO-1 in reducing AVF closure and vascular injury likely reflects, at least in part, its inhibitory effect on thrombogenesis. HPX is identified as a novel inhibitor of thrombogenesis in the IVCL model.

Role of Mevalonate Pathway on Vascular Access Failure in Maintenance Hemodialysis

Manabu Kanda, Satoru Sanada, Mitsuhiro Sato, Toshinobu Sato, Yoshio Taguma.
Japan Community Health Care Organization Sendai Hospital, Sendai, Japan.

Background: We have reported the effectiveness of statins against vascular access (VA) dysfunction. Despite statin administration, there was no difference in serum cholesterol levels between the statin users and the non-users, suggesting that the VA protective role of statin is different from the cholesterol lowering effect. In recent years, Yes-associated protein (YAP) and transcriptional co-activator with PDZ-binding motif (TAZ) were found as a new pathway associated with arteriosclerosis. The turbulence of intravascular blood flow triggers the YAP/TAZ pathway, which enhances gene expressions correlated with inflammation and fibrosis, resulting in arteriosclerosis. Mevalonate acid (MA) activates this pathway and statins are known to inhibit the MA production. Therefore, we hypothesized that VA protective effect of statin could be inhibition of YAP/TAZ pathway via MA reduction.

Methods: Patients on maintenance hemodialysis and people with stage 4 or 5 chronic kidney disease were enrolled in this study. The serum MA levels were measured using an enzyme cycling method. Gene expressions of connective tissue growth factor (CTGF) and cysteine-rich angiogenic inducer 61 (CYR61) in the peripheral blood mononuclear cells were evaluated using real-time PCR.

Results: Serum MA levels in patients with CKD and maintenance hemodialysis increased compared to healthy subjects (6.6±0.7, 8.8±0.6, and 4.6±0.8 μg/dL, respectively). Among hemodialysis patients, serum MA levels were higher in patients with VA dysfunction than without dysfunction (9.2±0.6 vs 6.6±0.7 μg/dL, p=0.07). Moreover, serum MA levels in patients who required VA angioplasty more than a year showed a higher value than those without repeated angioplasty (9.4±0.9 vs 8.7±0.7 μg/dL, p=0.60). These data suggest that serum MA levels associate with an increased risk of VA dysfunction. Serum MA levels were lower in statin users compared to non-users (7.4±1.1 vs 9.4±0.6 μg/dL, p=0.10), indicating that statin could decrease serum MA levels. Lastly, CTGF and CYR61 gene expressions were decreased in statin users compared to non-users (0.13±0.02 vs 0.17±0.01, 0.48±0.05 vs 0.67±0.11, respectively), implying that statin inhibits the YAP/TAZ pathway.

Conclusions: Statin treatment could be effective on VA dysfunction through lowering MA and YAP/TAZ suppression.

Zinc Deficiency Is a Risk for Vascular Access Failure in Hemodialysis Patients

Yukiko Hasuike,[1] Naoto Kakita,[2] Masayoshi Nanami,[1] Kosuke Mizusaki,[1] Wataru Fukao,[1] Aritoshi Kida,[1] Mana Yahiro,[1] Yasuyuki Nagasawa,[1] Takahiro Kuragano,[1] Masaharu Ishihara.[1] *[1]Internal Medicine, Division of Kidney and Dialysis, Nishinomiya, Japan; [2]Mitsubishi Kobe Hospital, Kobe, Japan.*

Background: Vascular access (VA) is essential for the hemodialysis (HD) patients. Percutaneous transluminal angioplasty (PTA) is an effective therapy against VA failure, however, re-failure of VA is often occurred even after PTA. Zinc plays a role in endothelial cell function, and Zinc deficiency can effect vascular dysfunction. To investigate the association of Zinc deficiency with VA failure, serum Zinc and the patency of VA following PTA were examined.

Methods: Blood samples were taken from 337 HD patients at PTA against VA failure. Serum Zinc, factors related to mineral-bone metabolism (Ca, iP, PTH-intact [iPTH], ALP), 8-hydroxy-2'-deoxyguanosine (8OHdG) as a maker of oxidative stress, inflammation (CRP, interleukin-6, tumor necrosis factor-α), and uremia (BMI, albumin, urea nitrogen, Hb) were measured. The end point of study was VA failure (re-vascularization or re-operation) during the observational period after PTA. Cox proportional hazards models for the end point was used.

Results: During follow-up period (median 367 days), re-vascularization was performed in 67 participants and re-operation in 69. The median of serum Zinc was 63 pg/ml (IQR 56 to 74), and 130 (38.6%) participants had Zn deficiency (<60 pg/ml). The participants with VA failure had lower Zn (p=0.03), higher iPTH, and a tendency to high 8OHdG compared with the participants without VA failure. There was no difference in the other factors. The Kaplan-Meier analysis showed that the participants with Zn deficiency was associated with higher incidence of VA failure (Figure 1). Cox regression analysis also revealed that Zn deficiency (adjusted hazard ratio 1.51, 95% CI 1.06 to 2.13, p=0.022) was a risk for VA failure.

Conclusions: Zinc deficiency was an independent risk for VA failure. Zinc might be associated with the maintenance of VA patency in HD patients.

Increased Monocyte-to-High-Density Lipoprotein Ratio Is Associated with Recurrent Vascular Access Stenosis

Yaeni Kim,[1] Hye Eun Yoon,[2] Seok Joon Shin.[3] *[1]Incheon St. Mary's Hosp, Catholic Univ of Korea, Incheon, SEoul, Republic of Korea; [2]The Catholic University of Korea, Incheon, INCHEON, Republic of Korea; [3]Incheon St. Mary's Hospital, The Catholic University of Korea, Incheon, Incheon, Republic of Korea.*

Background: Previous studies indicate that increased monocyte count and decreased high-density lipoprotein (HDL) cholesterol levels are associated with chronic kidney disease, and increased risk for cardiovascular diseases, indicating its possible role in pro-inflammatory and pro-oxidant states. We tried to investigate the clinical significance of circulating monocyte count-to-serum HDL cholesterol ratio (M/H ratio) in predicting recurrent vascular access stenosis after angioplasty in hemodialysis patients.

Methods: M/H ratio at access creation and prior to angioplasty was measured in a total of one-hundred and fifty hemodialysis patients in Incheon St. Mary's hospital from July, 2006 to September, 2017. The impact of M/H ratio in predicting recurrent access stenosis was evaluated retrospectively by using Kaplan-Meier, Cox regression, and ROC curve analyses.

Results: The patient group comprised of 67% male and 58% diabetes, aged 62±14 years old (n=150). Baseline M/H ratio at access creation was not different between those with vascular access stenosis (n=71) and those without stenosis (n=79) (10.74 vs. 12.42, p = 0.11). Among patients with vascular access stenosis, there also was no difference in baseline M/H ratios between those with recurrent stenosis (n=33) and those without recurrence (n=38) (9.98 vs. 11.4, p = 0.24). However, pre-angioplasty M/H ratio increased significantly when compared to that of baseline (10.75 vs. 17.95, p < 0.001). Delta M/H ratio, as defined by a difference between baseline and pre-angioplasty ratios was calculated and mean delta M/H ratio was 1.9. Increased delta M/H ratio (delta M/H ratio greater than or equal to 1.9) was associated with recurrent stenosis (HR 4.16, CI 1.43-12.12, p = 0.009). Moreover, increased delta M/H ratio was clinically significant in predicting recurrent vascular access stenosis (AUC 74%, p = 0.001).

Conclusions: Increased delta M/H ratio may play a role in pro-inflammatory and pro-oxidant environment and predispose vascular access for recurrent stenosis after angioplasty.

FR-PO712

Artery to Fistula Diameter Ratio as a Predictor of Early Re-Occlusion of Immature Arteriovenous Fistulas After Percutaneous Transluminal Angioplasty

Hong jin Bae,[3] Chang hun Song,[4] Youngrok Ham,[2] Dae Eun Choi,[1] Kang Wook Lee,[2] Jiwon M. Lee,[1] Ki Ryang Na.[2] *[1]Chungnam National University, Seoul, Republic of Korea; [2]Chungnam National University Hospital, Daejeon, Republic of Korea; [3]Chung Nam National University hospital, Daejeon, Republic of Korea; [4]Chungnam national university, Daejeon, Republic of Korea.*

Background: Percutaneous transluminal angioplasty (PTA) is widely performed for arteriovenous fistula (AVF) that fails to mature after initial formation. We observed that some immature AVFs re-occlude earlier than others. We sought to investigate the predictors for early post-intervention failure of immature fistulas after the primary PTA.

Methods: We retrospectively reviewed the records and angiographic images of patients who had immature fistulas and thereby received PTA between years 2013 to 2017 at our center. We investigated the short-term post-intervention outcomes of the patients within 90 days post PTA. Patients who had re-occlusion within the period were defined as early failure group and the rest as patent group. We investigated factors associated with early failure.

Results: There were 80 eligible patients with 22 brachiocephalic (BC) and 58 radiocephalic (RC) AVFs. The median age of the patients was 64 years [range, 38-87]. There were 51 (63%) males and 29 (36%) females. Among the 58 RC AVFs, 10 (17%) patients had early failure. Logistic regression analysis showed that larger artery to fistula (A/F) diameter ratio was the sole independent predictor of early failure after primary PTA (odd ratio 2.29 [1.023-5.147], P= 0.044).

Conclusions: Although further studies in a larger scale are required to confirm the clinical significance, larger A/F diameter ratio was a potential predictor of early re-occlusion in immature fistulas after primary PTA.

Funding: Government Support - Non-U.S.

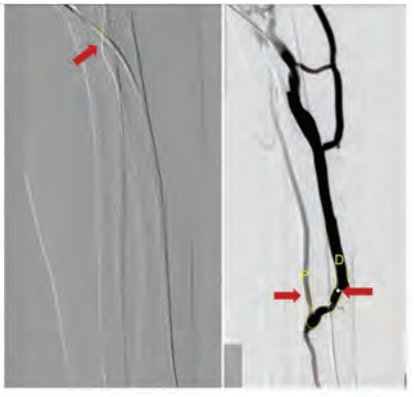

Figure 1. Measuring diameters of vessels using The Cardiovascular Angiography Analysis System. (A) The diameter of catheter (red arrow) was used for calibration reference. (B) A/F ratio was measured by ratio of diameter of radiocephalic artery (red arrow and yellow letter P) and AVF vessel (red arrow and yellow letter D).

FR-PO713

Comparison of the Outcomes of Upper Arm Arteriovenous Fistula and Forearm Arteriovenous Graft

Xueqin Bian, Yuan Luo, Hong Ye, Junwei Yang. *Second Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: Forearm arteriovenous graft (AVG) and upper arm arteriovenous fistula (AVF) are secondary choices when forearm AVF fails or the vascular quality is poor because of the increased hemodialysis duration or primary disease, such as diabetes. In this study, we compared the outcomes of upper arm AVF and forearm AVG in our dialysis center.

Methods: Patients underwent upper arm AVF or forearm AVG in our hospital from October 2014 to December 2017 were enrolled. The primary and secondary patency, complications were compared between the two groups. Kaplan-Meier survival curves and univariate Cox proportional hazard models were used.

Results: There were 116 (55.2%) patients underwent AVF and 94 (44.8%) patients underwent AVG, respectively. The characterizations of the patients, including age, gender, primary renal disease, comorbidities, hemodialysis duration and previous fistulation history were similar between the two groups. The primary patency of AVG *vs.* AVF were 83.5% *vs.* 93.1%, 75.8% *vs.* 91.4%, 60.3% *vs.* 75.3%, 42.1% *vs.* 56.6%, 31.6% *vs.* 57.1% at 3, 6, 12, 24, 36 month after the surgery, respectively; however, no significant differences were observed between the two groups (P=0.13). Compared with AVF, AVG has higher secondary patency (P=0.03), which were 94.7% *vs.* 93.1%, 95.6% *vs.* 91.4%, 85.7% *vs.* 80.4%, 73.6% *vs.* 66.0%, 68.4% *vs.* 57.1% at 3, 6, 12, 24, 36 month after the surgery, respectively. The incidences of complications were higher in AVG than AVF, including thrombosis (23.3% *vs.* 13.4%), stenosis (50.0% *vs.* 21.2%), infection (2.4% *vs.* 0.5%) and steal syndrome (2.4% *vs.* 1.7%). In all kinds of comorbidities, fistulation history was correlated with reduction of primary patency (HR: 0.42; 95% CI: 0.26 to 0.67) and secondary patency (HR: 0.44; 95% CI: 0.28 to 0.69) in AVF group but not in AVG group.

Conclusions: Forearm AVG has superiority in secondary patency than upper arm AVF. AVG has more complications than AVF. Upper arm AVF may be recommended to increase primary patency and reduce complications.

FR-PO714

Use of Smaller Vessels to Create an AVF Increases the Need for Interventions to Promote Its Maturation

Crystal A. Farrington,[1] Michelle L. Robbin,[1] Timmy C. Lee,[2] Michael Allon.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Univ of Alabama at Birmingham, Birmingham, AL.*

Background: Preoperative vascular mapping using ultrasound (US) is often used to aid in the creation of an arteriovenous fistula (AVF). Current vascular access guidelines recommend minimal arterial and venous diameters of 2.0 mm and 2.5 mm, respectively, to optimize *overall* (assisted and unassisted) AVF maturation. However, the relationship of preoperative US measurements with *unassisted* AVF maturation (successful use without a prior intervention) has not been evaluated.

Methods: We reviewed the clinical, demographic, and preoperative mapping ultrasound information of 189 hemodialysis patients from a large dialysis center who received new upper extremity AVFs from 2010-16. We then evaluated the association of preoperative US measurements of venous diameter, arterial diameter, and brachial blood flow with two AVF outcomes: unassisted AVF maturation and overall AVF maturation.

Results: The mean age of the study population was 53 years. 58% of the patients were male, 81% were black, 57% were diabetic, and 48% were obese. 74% of the AVFs were located in the upper arm. Progressive increases in preoperative arterial diameter, venous diameter and brachial artery blood flow were each associated with corresponding increases in unassisted AVF maturation. Incremental increases in preoperative arterial diameter and blood flow were likewise associated with progressive increases in overall AVF maturation. In contrast, there was no significant association between preoperative venous diameter and overall AVF maturation (**Table 1**). Finally, the proportion of AVFs requiring assisted maturation was 52, 32, 31, and 22% when the preoperative arterial diameter was < 3, 3-3.9, 4-4.9, and ≥ 5 mm, respectively.

Conclusions: Preoperative arterial diameter and blood flow are associated significantly with both unassisted and overall AVF maturation. Preoperative venous diameter is associated with unassisted, but not with overall, AVF maturation. Use of smaller vessels to create an AVF increases the need for interventions to promote its maturation.

Sirolimus Treated AV Fistulae: Maturation Profile and Impact of Processes of Care

Sriram Iyer,[1] Nelson P. Kopyt,[2] Nirav Gandhi,[3] Naveen K. Atray,[4] Thomas D. Wooldridge,[5] Joseph J. Lee,[6] Kendra S. Hendon,[7] William D. Paulson,[8] Osman S. Khawar,[9] Robert I. Lynn,[10] Prabir Roy-Chaudhury,[11] Maria V. DeVita.[12] on behalf of the ACCESS Trial investigators *[1]Vascular Therapies, Cresskill, NJ; [2]Lehigh Valley Hospital, Bethlehem, PA; [3]Southern California Kidney Consultants, Anaheim, CA; [4]Capitol Nephrology, Sacramento, CA; [5]Nephrology & Hypertension Associates, LTD, Tupelo, MS; [6]Nephrology Associates Medical Group, Riverside, CA; [7]Knoxville Kidney Center, Knoxville, TN; [8]Augusta University, Augusta, GA; [9]Balboa Nephrology Medical Group, Escondido, CA; [10]Albert Einstein College of Medicine, Bronx, New York, NY; [11]University of Arizona, Tucson, AZ; [12]Lenox Hill Hospital- Northwell Health System, New York, NY.*

Background: An arteriovenous fistula (AVF) is clinically mature if it can be reproducibly cannulated with 2 large-bore needles and has enough blood flow to support adequate hemodialysis. This analysis relates to AVF maturation data from patients (pts) who received intraoperative sirolimus delivered perivascularly at and around the AVF anastomosis from a collagen membrane (Drug product Vascular Therapies, Cresskill, NJ). The 7 center Hemodialysis Fistula Maturation (HFM) Study (n=602) recently reported impact of care processes on AVF maturation outcomes (Allon AJKD 2018)

Methods: Data for sirolimus treated AVF is from 30 Phase 2 + 22 open label pts. (from an ongoing US multicenter Phase 3 study NCT 02513303) undergoing surgery for a first, single stage upper extremity AVF. Mature AVF is defined as ability to use the AVF for 3 consecutive 2-needle dialysis sessions with a mean flow of ≥300 mL/min for pts on dialysis or vein diameter of 6 mm and blood flow of ≥500 mL/min on ultrasound for patients not on dialysis.

Results: 52 pts; 51 ESRD, 1 CKD, 67% Male, mean, age 56±17y, 42% diabetic; 65% forearm AVF. Table compares metrics of AVF that matured without (Gp1) and with (Gp 2)

supplementary procedures (SP) which included balloon PTA, vein elevation and exclusion of collateral vein(s)

Conclusions: 1. Excluding the 6 AVF that thrombosed early, all (100%) remaining 46 sirolimus treated AVF matured into a useful fistula (HFM: 77.6%) 2. 38/46 (83%) of sirolimus treated AVF matured after a median of 48 days (HFM: 125 days) 3. The median time of 121 days to maturation for the 8/46 (17%) AVF which required supplementary procedure(s) for maturation was roughly 2.5 times > than Gp 1. 4. For 83% of sirolimus treated AVF's (Gp1) the ONLY metric influencing use of the AVF for dialysis was the anatomical and functional readiness of the fistula for cannulation. 5. For the 17% AVF that required supplementary interventions (Gp2), optimizing processes of care should help in reducing time to first AVF use.

Funding: Commercial Support - Vascular Therapies, Inc. Cresskill, NJ

Risks and Benefits of Antiplatelet Agents and Anticoagulants on Preventing Vascular Access Dysfunction in Hemodialysis Patients

Hsin-Hsu Wu.[1,2] *[1]Nephrology Department, Chang-Gung Memorial Hospital, Taipei, Taiwan; [2]Chang Gung University, Taoyuan, Taiwan.*

Background: Dialysis adequacy is one major determinant of survival for patients with end-stage renal disease. Good vascular access is essential to achieve adequate dialysis. This study evaluated the impact of different drugs on the vascular access dysfunction rate of an arteriovenous fistula or arteriovenous graft and the rate of major bleeding in hemodialysis patients

Methods: Patients with end-stage renal disease registered in the Taiwan National Health Insurance program from January 1, 1997 to December 31, 2012. A total of 95,992 patients were enrolled in our study. Vascular access dysfunction, defined as the need of thrombectomy or percutaneous angioplasty. Major bleeding, defined as emergent department visits or hospitalization with a primary diagnosis of gastrointestinal bleeding or intracerebral hemorrhage. Adjusted odds ratio between person-quarters with or without antiplatelet or oral anticoagulant using were calculated using logistic regression and inverse probability treatment weighting.

Results: The odds ratio of vascular access dysfunction was 0.17 (0.10-0.28) for aspirin, 0.69 (0.67-0.71) for clopidogrel, 0.62 (0.55-0.71) for dipyridamole, 0.62 (0.50-0.77) for Aggrenox, and 0.86 (0.81-0.90) for warfarin. The highest odds ratio for intracerebral hemorrhage was 2.55 (1.36-4.79) in patients using Aggrenox. The odds ratio for gastrointestinal bleeding was 1.53 (1.28-1.83) for clopidogrel, 1.11 (0.09-13.4) for aspirin, 0.90 (0.38-2.17) for dipyridamole, 1.22 (0.29-5.16) for Aggrenox, and 1.27 (0.79-2.03) for warfarin.

Conclusions: Antiplatelet and anticoagulant agents might reduce vascular access dysfunction rate. The gastrointestinal bleeding rate was increased in clopidogrel using group. Aggrenox might increase the intracerebral hemorrhage rate and should be used with caution.

Effect of Aspirin Resistance and Mean Platelet Volume on Vascular Access Failure in Hemodialysis Patients

Jung-woo Noh,[3,1] Hayne C. Park,[1] Chaehoon Han.[2] *[1]Hallym University Kidney Research Institute, Seoul, Republic of Korea; [2]kangnam secred heart hospital, Seoul, Republic of Korea; [3]Dr. Chun & Cho Medical Clinic & Dialysis Center, Seoul, Republic of Korea.*

Background: Maintaining patency of vascular access in hemodialysis patients is important because it is a life-saving vessel. We investigated the effect of aspirin resistance and mean platelet volume (MPV) on vascular access(VA) failure in hemodialysis (HD) patients.

Methods: We enrolled 163 maintenance HD patients. Aspirin resistance was defined as aspirin resistance unit (ARU) >550. VA failure was defined as thrombosis or a decrease of greater than 50% of normal vessel diameter which was angiographically documented reduction with ≥ 50 % luminal diameter accompanied by abnormal clinical findings.

Results: 163 patients showed a mean age of 57.6 ±12.0 years and 79 were male (48.5 %). Mean dialysis duration was 50.1 ± 52.1 months. Aspirin resistance was observed in 17 out of 109 patients who measured the value. During a follow-up period of 34 months, 65 VA failures occurred out of all subjects while 41 events among the failures occurred in a patient group who measured aspirin resistance. There was no significant difference between the two groups according to aspirin resistance in the cumulative event rate of VA failures (57% vs. 38.2%, log-rank test, p=0.051). Mean MPV was 9.15 ± 0.05 fl. The 163 patients were grouped according to half-tile values of MPV (9.08 fl) at baseline and ones with higher MPV levels (n=82) had exhibited lower levels of platelet count (p=0.002), albumin (p=0.009). The Kaplan-Meier curve showed significant difference between two groups in cumulative events of VA failure (54.1% vs 35.3%, p=0.018). In multivariate analysis, MPV (HR 1.794; 95% CI1.066-3.020; p=0.028), platelet count (HR 1.003; 95% CI 1.001-1.006; p=0.01) and smoking (HR 1.894; 95% CI 1.019-3.519; p=0.043) were independent predictive factors of VA failure.

Conclusions: High MPV was associated with increased risk of VA failure. However, aspirin resistance showed a weak relationship with VA failure. MPV may be a potential marker for prediction of VA survival in HD patients.

FR-PO718

Intermittent Pneumatic Compression Devices Assists in Vascular Access Selection: A Hierarchical Regression Model Study

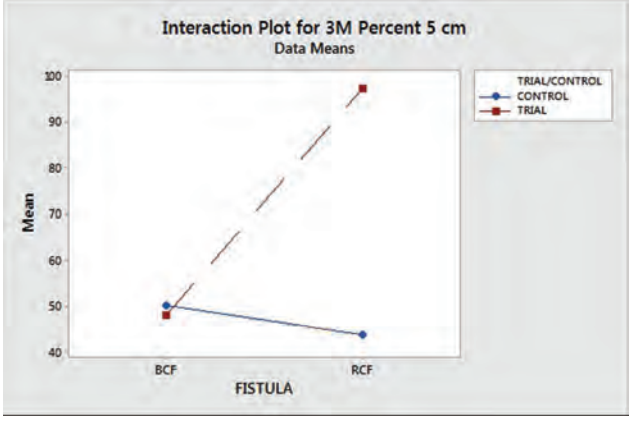
Tej M. Singh. Fist Assist Research Team *Vascular Surgery, El Camino Hospital, Los Altos Hills, CA.*

Background: Arteriovenous fistulas (AVF) are the preferred type of vascular access for hemodialysis patients. Among AVF, radiocephalic fistulas (RCF) are recommended. RCF placement has dropped in the USA to low rates. The aim of the present study is to determine if the use of a novel intermittent compression device can assist in vascular acces fistula selection.

Methods: After AVF creation, an intermittent pneumatic compression device enabling 60 mm Hg of cyclic compression was worn proximal to AVF intermittently for 6 hours daily for 3 months. Patients in the treatment group (n=41) wore the device. Twenty-four (n=24) had BCF, while seventeen (n=17) had RCF. Controls (n=12) used a sham device. Vein size was measured at baseline and at 3 months by duplex. Percentage increase was tested for significance. Hierarchical regression models were developed to model vein size dilation based on factors such as patient group, fistula type (BCF or RCF), the interaction between patient group and fistula type, and patient demographics.

Results: The interaction effect between patient group and fistula type was found to be significant. In a stepwise regression procedure, the first term enteresd in the model is the *interaction* between patient group and AVF type. At a proximal distance of 5 cm and 10 cm, the interaction term was highly significant ($p < .01$). Vein size increase is affected by patient group (treatment vs. control) as well as the type of fistula created for vascular access. The type of fistula created for vascular access, has an interaction effect with patient-group type (treatment vs. control) in affecting vein size dilation

Conclusions: The use of a novel, pneumatic compression device has significant impact on the recommended guidelines for vascular access selection. For patients who use the non-invasive device, a larger vein size dilation is achieved with a radiocephalic fistula. Novel, pneumatic devices may assist in RCF placement in the future.



Hierarchical regression modeling at 5 cm of fistula

Correspondence of Low Wall Shear Stress and Cephalic Arch Stenosis in Brachiocephalic Arteriovenous Fistula Access

Mary S. Hammes,[1] Kevin Cassel,[2] Brian Funaki,[1] Fredric L. Coe.[1] [1]*University of Chicago, Chicago, IL;* [2]*Illinois Institute of Technology, Chicago, IL.*

Background: An arteriovenous fistula (AVF) is the optimal access for hemodialysis. A brachiocephalic fistula (BCF) is often placed, but cephalic arch stenosis (CAS) commonly develops leading to failure. We hypothesized that a contribution to AVF failure is low wall shear stress (WSS) (less than 0.076 *Pa*), resulting in neointimal hyperplasia and venous stenosis. The aim of this study was to determine the correspondence of low WSS and the development of CAS in a large cohort followed longitudinally.

Methods: 39 subjects with ESRD and a primary BCF were followed from time of placement for three years or until the time of CAS. A venogram, Doppler, and blood viscosity were performed at time of AVF maturation (3 months), then annually up to three years or to time of CAS. Geometric measurements of venous diameter, radius of curvature, and arch angle were made. Computational modeling determined the location and percent low WSS in the arch. The relationship between WSS at three months and location of CAS was estimated by correlating computational modeling and quadrant location of CAS. Correspondence was examined using Chi-square.

Results: 32 subjects developed CAS by three years as shown by dots in the Figure. Of these, 25 subjects (red dots) displayed correspondence between low WSS at three months and CAS, whereas 7 subjects did not (blue dots) ($p=0.0015$). Most subjects with correspondence had low WSS areas evident in greater than 20% of the arch ($p=0.0006$). Venous diameter, radius of curvature and arch angle at three months did not predict CAS($p>0.05$).

Conclusions: The presence and magnitude of low WSS in the cephalic arch is a factor associated with the development of CAS. Determination and attenuation of low WSS at 3 months may help to prevent the development of CAS which is difficult to treat once it develops.

A Computational Fluid Dynamics (CFD) Approach to Optimize Arterio-Venous Fistula (AVF) Anastomotic Hemodynamics with Ôan External Support Device (VasQ™)

Dirk M. Hentschel. *Brigham and Women's Hospital, Boston, MA.*

Background: The complex AVF geometry induces hemodynamic changes in the juxta-anastomotic region (JAR). Multidirectional flow and oscillating wall shear stress (WSS) along the venous wall invoke undesirable inward vein remodeling through aggressive development of neointimal hyperplasia. A CFD model was utilized to study the effect of geometric parameters on hemodynamic profiles to inform optimal design of the VasQ™ device.

Methods: A fully developed 3D end-to-side AVF CFD model was evaluated through a range of artery and vein diameters (2.9-8mm) and flow volumes (40–1100 ml/min) assuming steady, laminar, Newtonian flow. 2D velocity streamline patterns were analyzed. Geometric parameters controllable by external scaffold were optimized for minimizing multidirectional flow along the venous wall (A1) and maximizing its distance from anastomosis (P1). Parameters included anastomotic angle (20°-60°), Proximal Vein (PV)/Distal Vein (DV) diameter ratio (conical shape) (1.2-2) and conical segment length(CSL) (15-25mm). Each parameter was analyzed by fixing all model values excluding the tested one.

Results: Improved flow patterns (small mean λ value; λ =A1/P1) were observed for anastomotic angle between 40°-50° (0.92±0.2) compared to angle between 20°-30° (2.3±1.7) and 60° (1.74±1.3). Optimal PV/DV (conical shape) was 1.5 (0.23±0.07) with higher λ values for PV/DV lower or higher than 1.5. λ values of 0.2±0.8, 0.27±0.05 and 0.35±0.06 for CSL of 25mm, 20mm and 15mm accordingly.

Conclusions: Improved unidirectional flow pattern directly correlated to uniform WSS in the JAR were observed for anastomotic angle between 40°-50°, conical vein shape with 1.5 PV/DV and CSL of 25mm in multiple configurations. These conclusions were the basis for designing VasQ™.

New Approach for Assessing Vascular Stiffness in Patients with Hemodialysis

Dong Ho Shin,[1] Do Hyoung Kim,[2] Jung-woo Noh,[3] Chaehoon Han.[4] *[1]College of Medicine, Hallym University, Seoul, Republic of Korea; [2]Hallym University Hangang Sacred Heart Hospital, Seoul, Republic of Korea; [3]Hallym University, Seoul, Republic of Korea; [4]kangnam secred heart hospital, Seoul, Republic of Korea.*

Background: It is known that increased vascular stiffness, as measured by pulse wave velocity (PWV), can predict cardiovascular events in hemodialysis (HD) patients. Additionally, the measurement of static intra-access pressure ratio (SIAPR), using transducer on HD machines, is preferred vascular access surveillance method. However, little is known about the clinical usefulness of SIAPR in predicting the degree of vascular stiffness.

Methods: A total of 209 patients on maintenance hemodialysis were evaluated between January 2014 and February 2018 at three hospitals. Brachial-ankle pulse wave velocity (baPWV) and SIAPR were measured in HD patients. After that, we performed echocardiography at study enrollment and investigated cardiovascular (CV) events after study enrollment, respectively.

Results: Patients with arteriovenous (AV) graft and AV fistula was 172 and 37, respectively. Among AV fistula group, SIAPR was significantly negative correlation with baPWV (ß = - 0.16, p =0.04). The area under the receiver operating (ROC) curve for SIAPR value to predict CV events was 0.09 (95% confidence interval [CI]; 0.86 - 0.95, $p < 0.001$). A SIAPR value of 0.09 was selected as the cut-off value for CV events. baPWV (222.7 ± 418.1 vs. 2010.2 ± 511.4 cm/s, $P = 0.04$) and the proportion of left ventricular diastolic dysfunction (86% vs. 25%, $p = 0.01$) was significantly higher in patients with a SIAPR value ≤ 0.09 than with a SIAPR value > 0.09. Kaplan-Meier analysis revealed that cumulative incidence of CV events was significant higher in patients with a SIAPR value ≤ 0.09 ($p.= 0.04$). Among AV graft group, there were significantly negative correlation between SIAPR and baPWV. When a SIAPR value of 0.15 was selected as the cut-off value for CV events, similar trends were observed.

Conclusions: SIAPR was significantly associated with baPWV and left ventricular diastolic dysfunction in HD patients. Additionally, lower value of SIAPR could predict cardiovascular events.

FR-PO722

Adjunctive Use of Color-Coded Digital Subtraction Angiography During Percutaneous Transluminal Intervention of Hemodialysis Vascular Access

Swee Ping Teh, Ru Yu Tan, Suh Chien Pang, Kian Guan Lee, Alicia H. Ong, Tze tec Chong, Apoorva Gogna, Chieh-suai Tan. *Singapore General Hospital, Singapore, Singapore.*

Background: Parametric color-coding of digital subtraction angiography (DSA) has been successfully used in interventional neuroimaging and diagnostic imaging for peripheral arterial disease. We aimed to examine the utility of color-coded DSA for quantitative hemodynamic analysis in percutaneous transluminal angioplasty (PTA) of hemodialysis access.

Methods: This is a prospective, single center study. DSA acquisitions were post-processed into color-coded images. Regions of interest (ROI) were selected for each image. Hemodynamic parameters including time-to-peak (TTP) contrast opacification, contrast transit time (TT) and contrast decay time were obtained. These parameters were compared pre-and post-PTA.

Results: DSA of 16 patients who underwent PTA were included. 9 interventions were performed on arteriovenous fistulas and 7 on arteriovenous grafts with median access age of 3.5 ± 3.1 years (interquartile range 1.8-6.7). All patients had improvement in percentage of stenosis post PTA with a mean difference of 39.71 ± 16.25% ($p<0.01$). TTP improved significantly following PTA, with mean reduction of 0.35 ± 0.65 seconds (s) ($p<0.01$) and 0.60 ± 0.83s ($p<0.01$) for pre- and post- stenosis ROIs respectively. Mean reduction in contrast transit was 0.23 ± 0.53s ($p=0.04$). Receiver operator characteristics analysis showed that 10% contrast decay time at 0.05s correlated with access flow of 800cc/min with sensitivity of 0.91 and specificity of 0.5 (area under the curve 0.89, 95% confidence interval 0.71 – 1.0).

Conclusions: Adjunctive usage of parametric color-coded DSA could provide hemodynamic information, which may be useful for decision-making during PTA of hemodialysis access.

FR-PO723

Timing of Vascular Access Creation in Hemodialysis Patients

Annemiek Borsje, Daan M. Van velzen, Willem A. Bax, Karina de Groot, Erik L. Penne. *Northwest Clinics Alkmaar, Alkmaar, Netherlands.*

Background: Late referral for vascular access creation in Chronic Kidney Disease (CKD) patients who opted for hemodialysis (HD) may lead to high central venous catheter (CVC) rates. In contrary, too early referral potentially leads to unnecessary vascular access interventions. The aim of the present study was to analyze timing of vascular access creation in patients starting HD.

Methods: We conducted a retrospective, observational study in stage 4 and 5 CKD patients from a single center in the Netherlands, referred for first vascular access creation between 2009 until 2011. Patients were divided in three groups: (too) early, optimal or (too) late vascular access creation. Early was defined as vascular access surgery ≥6 months prior to start HD. Optimal was defined as starting HD with an adequate vascular access and surgery was within 6 months prior to start. Late was defined as starting HD with a CVC. Patient characteristics as well as vascular access interventions were recorded.

Results: Forty-two patients were included (age 68±11y; 50% male; eGFR 11±3ml/min/1.73m^2). Mean time from vascular access surgery to initiation of HD was 338±470 days. Vascular access creation was early in 60% (n=25), optimal in 29% (n=12) and late in 12% (n=5). Forty-four percent of the patients in the early group (n=11; 26% of all included patients) never started HD after a mean follow-up of 8 ±0.7 years (7 patients died, 2 had stabilized kidney function, 1 underwent pre-emptive kidney transplantation, and 1 was lost to follow up). Overall, in 45% (n=19) of patients a surgical and/or endovascular intervention was performed before initiation of HD. Of the 11 patients that never started HD an intervention was performed in 36% (n=4). All patient in the early and optimal group had an adequate vascular access at start of HD. Higher age and high eGFR were associated with late vascular access creation.

Conclusions: In this study, the majority of patients started HD with an adequate vascular access. However, in a substantial proportion of patients interventions were needed prior to start HD, also in the subgroup of patients that never started HD during follow up. More studies are warranted to investigate the optimal timing of vascular access creation aiming at adequate vascular access at time of start HD on the one hand and avoiding too early referral resulting in unnecessary interventions on the other hand.

FR-PO724

Evolution of Vascular Access in the First Year of Dialysis in the Irish Health System: A National Cohort Study

Gasim Ahmed,[1,2] Leonard Browne,[2] Wael F. Hussein,[2,1] Liam Plant,[3] Austin G. Stack.[2,1] *[1]Nephrology, University Hospital Limerick, Liimerick, Ireland; [2]Graduate Entry Medical School, University of Limerick, Limerick, Ireland; [3]Cork University Hospital, Cork, Ireland.*

Background: Although the arteriovenous fistula (AVF) confers superior benefits over central venous catheters (CVC), utilisation rates remain low among prevalent haemodialysis (HD) patients. The goal of this study was to determine the type and frequency of vascular access provision in the first year of dialysis and identify factors associated with conversion to AVF.

Methods: Data was obtained from the *National Kidney Disease Clinical Patient Management System* which tracks all patients with end stage kidney disease (ESKD) in Ireland. All adult patients who began HD in 2015 and 2016 and treated for at least 90 days were included. Data was captured on demographics factors, primary cause of ESKD (P-CKD), comorbid conditions, and biochemical indicators at day 90 (D90). Univariable and multivariable Cox regression quantified the risk of conversion from CVC to AVF with follow-up to D360 expressed as hazard ratios (HR), censored at change in modality and death.

Results: The study cohort included 610 patients, mean age 61.7yr (±15.8), 65% men and 76.7% were using a CVC for dialysis at D90. At D90, the likelihood of CVC varied significantly across HD centres (from 63 % to 91%, P<0.001) and these differences persisted when adjusting for case-mix. From D90 to D360, rates of AVF increased modestly from 23% to 41%, P<0.001 with a corresponding fall in CVC rates from 77% to 59%, P<0.001. Factors associated with conversion from CVC to AVF included age [HR, 0.45, (0.21- 0.96) for age > 78 vs < 60 years (ref)]; P-CKD-hypertension [HR, 0.19 (0.05- 0.72) and P-CKD-unknown [HR 0.25, (0.10- 0.61) vs P-CKD-polycystic kidney disease (ref)], increasing BMI, [HR1.05 (1.02- 1.08)] per unit increase, and HD centre (Figure 1).

Conclusions: CVCs remain the major type of vascular access in Irish HD patients with only a modest rise in AVF provision observed during the first year. Substantial centre

variation exists at dialysis initiation and continues throughout the first year which is not fully explained by patient-level factors.

Funding: Government Support - Non-U.S.

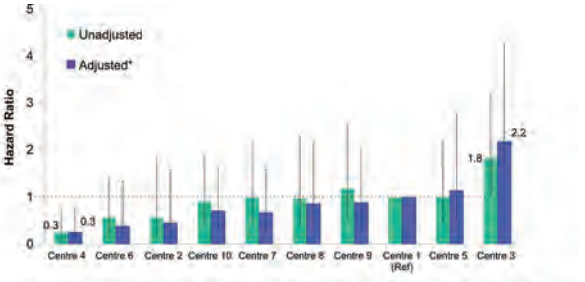

Figure 1. Hazard Ratio for Conversion from CVC at Day 90 to AVF at Day 360 by Primary Centre
*Model adjusted for age, gender, primary cause of ckd, comorbidities and primary HD centre

FR-PO725

Improving Rate of Access Placement for Inpatients with eGFR Less Than 20 mL/min/1.73 m2

Peter Burke,[1] Goni Katz Greenberg,[2] Yasmin G. Brahmbhatt.[1] *[1]Thomas Jefferson University Hospital, Philadelphia, PA; [2]Thomas Jefferson University and Hospital, Philadelphia, PA.*

Background: The most common form of renal replacement therapy in the US is hemodialysis (HD) which requires Arterio-Venous (AV) access placement. Challenges with obtaining timely permanent AV access include late referral to nephrology and vascular surgery, patient non-compliance, and lack of effective patient pathways. Baseline data at our institution for inpatients with eGFR < 20 ml/min, revealed there was a greater prevalence of patients without permanent AV access for HD initiation compared to national data. Using Quality Improvement (QI) methodology and interventions, we aimed to improve AV access creation in this population.

Methods: Over a three month period on five medicine teaching services, residents were given a protocol to order venous mapping, consult nephrology and vascular surgery for all patients with an eGFR<20 ml/min. The vascular team established care and scheduled outpatient appointments for permanent HD access. The nephrology fellows scheduled follow up appointments and conducted post-discharge physician phone calls. Baseline data was collected on patients with an eGFR< 20 ml/min who were discharged without initiation of HD including readmitted patients over a 3 month period.

Results: The study population had a greater rate of AVF/AVG present at 62% compared to the baseline data at 23% and did not significantly alter the length of stay (Table 1).

Conclusions: Hospitalizations are stressful and making decisions regarding long term care can be difficult. Follow-up physician phone calls allowed care teams to speak to patients when they were more receptive and motivated to make healthcare decisions. This improved patient compliance and follow-up rates, and resulted in timelier AV access rates without adversely affecting length of stay. Study limitations included the time-intensive nature of care coordination, lack of a transitions of care coordinator and the structure of patient capture. We conducted a successful QI intervention in a limited pilot project. Creating an effective patient pathway for inpatients with advanced CKD can increase rates of AV access placement without significantly increasing length of stay.

Vascular Access Rate and Length of Stay

Transitions of Care Category	Baseline Data N=22	Study Population N=27
AVF/AVG Present	23%	62%
Average Length of Stay	8.31 days	8.4 days

FR-PO726

Outcomes of Coordinated Late Vascular Access Creation

Robin Shah, Nabil J. Haddad, Khaled Boobes, Sharon Vancleef, Anil K. Agarwal. *Division of Nephrology, The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Guidelines recommend timely pre-dialysis access creation to reduce incident catheter utilization which is associated with higher risk of hospitalization, procedures, mortality and cost. The process to achieve this goal is ambiguous and access coordination could be valuable, especially if the creation is late. Our program utilizes a hemodialysis (HD) access coordinator working closely with nephrologists and surgeons. This study analyzes how this system affects the outcomes of late access creation in our patient population.

Methods: Prospectively collected data from an electronic access database and the medical records of patients undergoing HD access creation between 2011-2017 prior to HD initiation from a single hospital system were analyzed.

Results: A total of 130 patients between the age of 22 to 89 years at the time of access placement had 146 accesses created. Seventy-eight (60%) were male, 52 (40%) female, 52% Caucasian and 42% African American. At time of access creation, median age was 60.5 and 56.5 years and median eGFR was 13.5 and 15.5 ml/min per 1.73 m^2 in the AVF and AVG group, respectively. A total of 131 AVF and 15 AVG were created. Seventy six patients started HD with a median time after creation of 109 and 131 days for non-diabetics and diabetics, respectively. At this time, 54 (42%) patients remain pre-HD-18 (33%) with failed access and 6 (11%) have died with a functioning access. Access success rate in those who initiated dialysis was 63%. HD was initiated with a catheter in 36% (46% in females vs. 30% in males). The average time to an interventional procedure after creation was shorter in non-diabetics (153 days) vs diabetics (197 days) and shorter in AVF (184 days) vs AVG (219 days). Interestingly, non-diabetics and patients under the age of 70 had a higher rate of access failure.

Conclusions: Nationally, 60-80% of incident HD patients have a catheter with fewer than 15% access placed less than 3 months prior to HD initiation. In our program, access placement occurred 3.5-4.5 months prior to dialysis initiation, later than recommended 6 months and at a very low eGFR. Despite that, our incident catheter rate was about half the national average. Our data emphasizes the importance of access coordination in order to reduce the incident catheter use and unnecessary access creations.

FR-PO727

Patient Centered Care: The Effect of an Integrated Nephrology-Vascular Surgery-Ultrasound Clinic on Arteriovenous Fistula Use

Teresa Kuo,[1] Sumie Iwasaki,[2] Jessica B. Lapasia,[2] Liisa Lyon,[3] Aaron C. Baker,[4] Hong T. Hua,[4] Aida Shirazi,[3] Tracy Y. Jonelis.[2] *[1]Department of Medicine, Kaiser Permanente, San Francisco, CA; [2]Department of Nephrology, Kaiser Permanente, San Francisco, CA; [3]Division of Research, Kaiser Permanente, San Francisco, CA; [4]Department of Vascular Surgery, Kaiser Permanente, San Francisco, CA.*

Background: Arteriovenous fistula (AVF) is the preferred form of vascular access for hemodialysis due to their association with lower rates of complication and lower cost of maintenance. Multiple teams are involved throughout the course of AVF creation but they are often not seeing the patient simultaneously. We hypothesize that an integrated, multidisciplinary clinic including nephrologists, vascular surgeons, and an ultrasonographer will improve initiation of hemodialysis using AVF.

Methods: The study population included adults at least 18 years old who received an AVF between March 2013 and March 2016 at Kaiser Permanente San Francisco (KPSF), during which an integrated clinic was formed. This cohort was retrospectively compared to KPSF patients who received an AVF between March 2009 to March 2012. Subjects were excluded if they had a prior AVF placed in the previous 12-24 months, history of renal transplant, death before AVF use, or lost to follow up. The final analytic cohort included 233 patients. Chi-square tests and t-tests were used to compare the demographic (age, race, gender) and clinical characteristics (diabetes mellitus, HbA1c, estimated glomerular filtration rate, peripheral vascular disease, and tobacco smoking status) by integrated vs the non-integrated clinic. Chi-square tests and logistic regression were used to compare clinical outcomes of patients in integrated clinic compared to patients in the non-integrated clinic.

Results: There were 118 patients in the integrated clinic (mean age 70.4±13.7 years, 30.5% women) and 115 patients in the non-integrated clinic (mean age 66.2±13.1 years, 40.9% women). Enrollment in the integrated clinic significantly improved initiation of dialysis using an AVF (48.3% versus 33.9%; odds ratio, OR, 1.8; p=0.03). The integrated clinic also significantly decreased initiation of dialysis using a central venous catheter (CVC) (35.6% versus 51.3%; OR 0.5, p=0.02).

Conclusions: An integrated, multidisciplinary AVF surveillance clinic increases initiation of hemodialysis using AVFs and decreases initiation of hemodialysis using CVCs.

FR-PO728

Clinical Outcomes and Economic Impact of Starting Hemodialysis with a Catheter (CVC) vs a Permanent Access After Pre-ESRD Arteriovenous Fistula (AVF) Creation

Saad Mohammed Shariff,[1] Alian Albalas,[2] Michael Allon.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]UAB, Birmingham, AL.*

Background: Patients progressing to ESRD frequently have an AVF placed pre-ESRD, but may initiate HD with a CVC if the access is not yet suitable for use. Little is known about the clinical outcomes and economic impact of such patients initiating HD with a CVC vs a permanent access.

Methods: We identified 205 patients who received an AVF pre-ESRD between 2006 and 2012, and started hemodialysis within 2 years. Of these, 91 initiated HD with a CVC and 114 with a permanent access. We compared these two groups in terms of demographics, co-morbidities, the frequency of percutaneous access procedures, surgical access procedures, total access procedures, hospitalizations due to catheter related bacteremia (CRB), and annual cost of vascular access management from ESRD to the end of patient follow-up.

Results: The groups initiating HD with a CVC vs a permanent access were similar in terms of age, sex, race, diabetes, vascular disease, and heart failure. As compared to patients initiating HD with a permanent access, those initiating with a CVC had a 61% greater annual frequency of percutaneous access procedures, a 41% greater frequency of surgical access procedures, a 55% greater frequency of total access procedures, and a 5-fold higher frequency of CRB hospitalizations (Table 1). Patients initiating HD with a CVC incurred a median annual cost of access management that was $2,930 higher ($5,478 [2,011-12,497) vs $2,548 [924-6717], p<0.001).

Conclusions: Among patients with pre-ESRD AVF creation, those initiating HD with CVC had substantially more frequent percutaneous, surgical, and total access procedures, as well as CRB hospitalizations. The annual cost of access management was substantially higher in those initiating HD with a CVC vs a permanent access.

Frequency of post-ESRD access procedures and CRB hospitalizations in patients starting HD with permanent access vs a CVC after pre-ESRD AVF surgery.

	Permanent access	Catheter	p-value
N of patients	114	91	
Years of follow-up, median [IQR]	4.6 [2.1-6.7]	4.7 [2.2-7.5]	0.82
All percutaneous procedures per pt-yr	0.82 (0.75-0.90)	1.32 (1.22-1.43)	<.001
All surgical procedures, per pt-yr	0.34 (0.29-0.39)	0.48 (0.42-0.55)	0.001
All access procedures per pt-yr	1.16 (1.07-1.25)	1.80 (1.68-1.93)	<.001
CRB hospitalisation per 100 pt-yr	7.22 (1.14-3.87)	10.00 (7.29-13.37)	<.001

FR-PO729

Incremental Costs of Arteriovenous Fistula (AVF) Non-Use Among US Hemodialysis Patients

Mae Thamer,[1] Timmy C. Lee,[3] Monnie Wasse,[4] Marc H. Glickman,[5] Joyce Z. Qian,[6] Daniel Gottlieb,[7] Scott Toner,[7] Timothy A. Pflederer.[2] *[1]MTPPI, Bethesda, MD; [2]Illinois Kidney Disease and Hypertension Center, Peoria, IL; [3]Univ of Alabama at Birmingham, Birmingham, AL; [4]Rush University Medical Center, Chicago, IL; [5]Hancock Jaffe Labs, Virginia Beach, VA; [6]Johns Hopkins University, Potomac, MD; [7]Proteon Therapeutics, Waltham, MA.*

Background: Despite the importance of vascular access (VA) for adequate hemodialysis (HD), few studies have examined the real world costs related to AVF maturation and use. We used national Medicare claims data to examine per patient VA costs over a 3 year period based on AVF use for dialysis among a cohort of dialysis patients.

Methods: We conducted a retrospective observational study using USRDS data for all incident Medicare patients who initiated dialysis from 2010-2011 and initiated dialysis with a mature AVF (n=2,704) or initiated dialysis with a CVC and underwent AVF creation in the next 6 months (n=3,901). Using a multidisciplinary expert panel, we identified VA-related diagnostic, imaging, endovascular, surgical, infection, hospitalization and anesthesia codes to calculate total VA costs paid by Medicare. *Annualized per patient per year (PPPY) costs* were calculated from the AVF creation date with costs censored at death or change in renal replacement modality. VA costs were calculated from the AVF creation date and were compared based on whether the AVF was successfully used for dialysis, as defined by the presence of at least one monthly ESRD billing claim in which AVF was recorded as the VA in use.

Results: Regardless of timing of fistula insertion, AVFs that were not successfully used for dialysis resulted in incremental VA-related costs to Medicare of more than $20,000 PPPY in the first year after AVF creation, compared to AVFs that were successfully used. Incremental VA-related costs were also observed in the second and third year following AVF creation. In aggregate, annualized VA costs for three years after AVF creation are more than three times as high for patients whose fistula does not mature compared to those whose fistula matures.

Conclusions: Improvements in processes of care and technologies to enhance AVF maturation and use for dialysis as well as better patient selection should result in less morbidity with the potential for significant cost-savings.

Funding: Commercial Support - Proteon Therapeutics Inc

FR-PO730

Procedural Burden Following Arteriovenous Graft Placement Among Incident Hemodialysis Patients in the United States

Kenneth J. Woodside,[1] Kaitlyn Repeck,[2] Purna Mukhopadhyay,[2] Douglas E. Schaubel,[1] Vahakn Shahinian,[1] Rajiv Saran,[1] Ronald L. Pisoni.[2] *[1]University of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: We previously reported that half of patients required interventional procedures for successful maturation of arteriovenous fistula (AVF), with additional post-maturation burden of 0.40 and 0.52 procedures per person-year (ppy) for those with natural and assisted maturation, respectively (p<0.0001). Herein, we sought to determine the procedural burden during 'maturation' and maintenance phases of newly placed arteriovenous grafts (AVG).

Methods: Using data from the United States Renal Data System (USRDS), patients new to HD from 7/1/12 to 12/31/14 with initial billing codes for AVG placements (since HD start) from 7/1/12 to 12/31/15 were included. Successful maturation was defined as first documentation of AVG use in CROWNWeb monthly data. Patients were followed until 12/31/2016, or 1 year post-AVG placement.

Results: Among 258,731 incident HD patients, there were 23,629 first-time AVG placements. Of these, 59.9% were successfully utilized, 28.7% had no recorded use, and 11.3% were lost to follow-up (Table). Of successfully utilized AVG, 18.2% required interventions during the maturation phase, for 0.31 procedures per person (pp), while 43.3% of unsuccessful AVG underwent intervention, for 1.03 pp (p<0.0001). Following successful first use, those with assisted maturation underwent 2.05 ppy, while those without assistance demonstrated 1.59 ppy (p<0.0001).

Conclusions: Surprisingly, AVG utilization following placement was lower than anticipated. Interventions on AVG were common for both maturation and maintenance. While the maturation procedural burden for AVG compares favorably with AVF, the maintenance phase procedural burden is much higher, implying potential logistic and cost advantages of AVF over AVG.

The Repeatability of AVF Mean Blood Flow in Temperate and Sub Saharan Environments

David H. King,[1] Abdelgalil A. Ali,[1] Mo Al-Qaisi.[2] *[1]Broomfield Hospital, Chelmsford, United Kingdom; [2]Imperial College London, London, United Kingdom.*

Background: We have previously demonstrated a 70% difference between Dialysis AVF blood flow in the UK and Sudan, the Sudan mean being greater than the UK mean [(1)]. The study has recently been extended to 4 renal centres in Sudan.. A recent 7 centre study in the USA has published the mean AVF blood flow at 6 weeks maturation [(2)]. We have characterised UK and USA environments as temperate and the Sudan environment as sub Saharan.

Methods: AVF blood flow was measured with a Duplex device in all centres. Clinical indications were used in the USA study to eliminate failing or failed AVF from the study of mature fistulae.. The incidence of failing AVF in each cohort in the UK and Sudan was studied using a new device Bluedop ™ [(1)]

Results: The results are tabulated below. Additional data was recorded including patient Age, Gender and AVF location.

Conclusions: Conclusion: A number of explanations for the elevated Sub Saharan mean Blood Flow results have been explored. Mean annual temperature appears to be a possible cause, Published values for minimal seasonal ambient temperatures show Khartoum is approximately 14 degrees C warmer than London thoughout the year. USA ambient temperatures have not been studied. Deep Infra Red studies have been shown to speed AVF maturation. It should also be noted that although AVF failure rates were comparable in Sudan and the UK, that active intervention was not available in Sudan. Outcomes of Expanded Polytetrafluoroethylene Vascular Grafts as Dialysis Access in Chinese Population: A Retrospective Study

Yuan Luo, Xueqin Bian, Hong Ye, Junwei Yang. *The second affiliated hospital of nanjing medical university kidney centre in China, Nanjing, China.*

Background: With the increased prevalence of end stage renal disease and extended life expectancy of hemodialysis patients, more and more patients had limited quality and availability of superficial vessels for fistula. It is recommended to apply expanded polytetrafluoroethylene (ePTFE) vascular grafts if native fistula is not possible. The aim of our study is to analysis the outcomes of arteriovenous graft (AVG) in our dialysis center.

Methods: It was a retrospective study enrolled all the patients who underwent AVG from October 2014 to December 2017 in our dialysis center. The demographic characteristics, dialysis duration, laboratory tests, location and configuration of AVG, operation outcome,as well as the patency rate were analyzed.

Results: A total of 222 patients with the mean age of 60.5±13.9 were included in this study. 56% of the study population was female. The most common comorbidities were hypertension (84%) and diabetes (49%). All the grafts were successfully implanted. The follow-up period ranged from 3 to 40 months. The configurations of the grafts were 73% loop and 27% straight, and 57% of them were implanted in forearms. There was no operation-related mortality. However, 3 early failure were noted. The primary and secondary patency rates were 81% and 98%, 63% and 92%, 49% and 82%, 30% and 63%, at 6, 12, 24, 36 months after the surgery, respectively. The primary and secondary patency of grafts in forearm was markedly better than those in upper arm. Comorbidities and configurations were not correlated with patency. There were 160 postoperative complications developed in 96 patients during the study period, including thrombosis (74), proximal vein stenosis (72), infection (11), bleeding with hematoma (1), steal syndrome (1), and pseudoaneurysm (1).

Conclusions: AVGs implanted in forearm has superior primary and secondary patency than in upper arm. We recommended using ePTFE grafts as an alternative in patients with poor autogenous vascular conditions.

A Prospective Outcome Analysis of the Early Cannulation Graft ACUSEAL® versus the Standard Expanded Polytetrafluoroethylene (ePTFE) Graft in Hemodialysis (HD) Patients

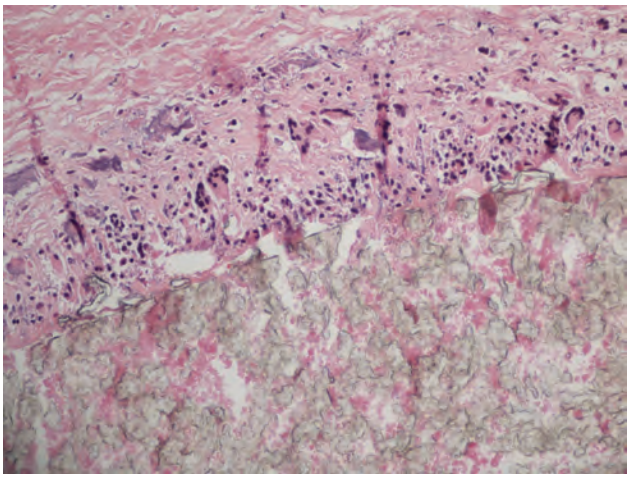
Ioannis E. Giannikouris,[1,2] Giovanni Giordano,[3] Periklis P. Kyriazis,[4] Dimitra Bacharaki,[5] Giuseppe Bacchini.[6] *[1]Medifil SA, Athens, Greece; [2]Thriasio General Hospital of Elefsina, Elefsina, Greece; [3]Vanvitelli L. Hospital, Tramonti, Italy; [4]Internal Medicine, Baystate Medical Center/University of Massachusetts, Springfield, MA; [5]University Hospital Attikon, Chaidari, Greece; [6]Alessandro Manzoni Hospital Lecco, Lecco, Italy.*

Background: Our objective was to prospectively compare survival, assisted primary (APR) and secondary (SEC) patency rates of the early cannulation ACUSEAL® and standard ePTFE arteriovenous grafts (AVG) for HD access.

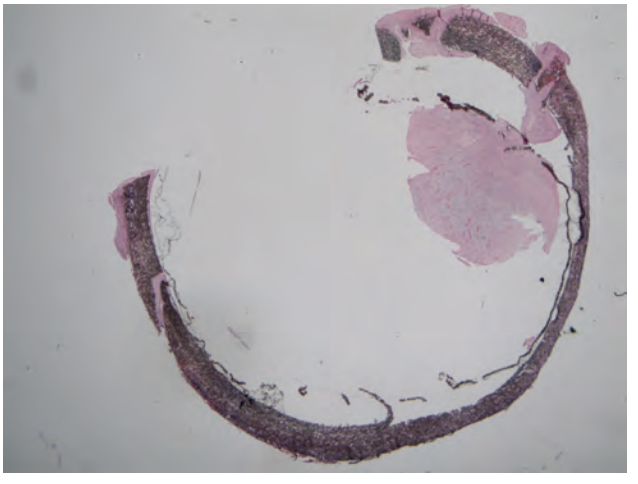
Methods: Incident patients requiring implantation of an AVG for HD initiation or therapy continuation were enrolled between December 2014 and December 2017. Outcome measures were APR, SEC survival, APR and SEC patency rates of these AVG.

Results: A total of 146 HD patients had AVG implanted, 63 were ACUSEAL® and 83ePTFE. For ACUSEAL® APR survival was 190 days and APR patency rate was 31%, 12%, 6% in 12, 24 and 36 months. For ePTFE grafts APR survival was 537 days(p=0.001) and APR patency rate 56%, 43% and 30%. Whereas, SEC survival was 596 days for ACUSEAL® and 1,365 days for ePTFE(p=0.04) while SEC patency was 72%, 49%, 34% and 80%, 70% και 57% in 12, 24 and 36 months, respectively. Wall destruction and lumen stenosis were common findings in removed ACUSEAL®AVG.

Conclusions: The advantage of early cannulation of ACUSEAL® AVG seems to be partly neutralized by the inferior clinical outcomes seen by this graft compared to those of ePTFE AVG. Prospective randomized trials are needed to confirm these preliminary results



Foreign-body giant and mononuclear cell Inflammatory infiltrate penetrating the inner and intermediate graft layers



Polypoid granulation tissue causing wall, layer separation and luminal stenosis

FR-PO734

The Effect of Citrate Dialysate on Clot Formation and Anemia in Hemodialysis Patients

Thananda Trakarnvanich. Hemodialysis Nurses team at Vajira Hospitl,Ruenrudee Clinic and Bangpai Hospital *Vajira Hospital, Bangkok, Thailand.*

Background: Citrate anticoagulation in renal replacement therapy is increasingly becoming a favorite choice to prevent extracorporeal circuit clotting. The use of citrate rendered the reduction of heparin in conventional hemodialysis. This is a study to test the effect of citrate on heparin avoidance and other parameters such an ESA dose, anemia, adequacy of dialysis, and inflammatory cytokines compared to acetate dialysate.

Methods: Sixty one chronic HD patients were switched from acetate to citrate dialysate and treated in 3 phases, with each phase lasting for four weeks. These phases comprised 50% and 25% heparin reduction and heparin free treatments. Visual clotting score, as graded by a visual analog scale, ESA doses and laboratory data including pre- and post-HD ionized calcium levels,IL-6 and hs-CRP were measured

Results: Except for two episodes of clotting, the dialyzers could be used thoroughly throughout the citrate phases. The mean visual clotting scores for all three study periods were comparable. Hemoglobin decreased slightly in phase 2 (9.68±1.88 VS 9.06±1.60 g/dL, p=0.001, pre and post protocol) despite constant ESA dose. There were no significant differences in electrolytes, adequacy of dialysis, and inflammatory cytokine levels, as measured by IL-6 and hs CRP between acetate and citrate dialysis. The post protocol level of iCa^{2+} paradoxically rose after HD in most sessions. We observed no adverse events during citrate dialysis.

Conclusions: During periods of citrate dialysis in chronic HD patients, heparin can be avoided while maintaining balanced electrolyte levels and adequacy of dialysis and hemoglobin. No significant adverse events, including hypocalcemia, were found.

FR-PO735

The Total IV Iron Burden and Insulin Sensitivity in ESRD

Monique E. Cho,[1,2] Jared Hansen,[2,1] Iran Lavasani,[1] Ranganath Muniyappa.[3]
[1]University of Utah, Salt Lake City, UT; [2]Veterans Health Administration, Salt Lake City, UT; [3]NIDDK, NIH, Bethesda, MD.

Background: Systemic iron overload has been strongly associated with increased incidence of diabetes in non-CKD patient populations. Despite the high prevalence iron overload in hemodialysis (HD) patients due to frequent IV iron infusion, there are no studies to evaluate the association between total accumulative IV iron dose and insulin sensitivity.

Methods: We performed an observational pilot study of prevalent hemodialysis patients at University of Utah (N=16). Patients with history of dementia, chronic hepatitis, steroid use, malignancy, thalassemia, hemochromatosis, sickle cell disease, hospitalization or IV antibiotic use within one month of screening were excluded. The total accumulative dose of IV iron for the entire duration of dialysis was calculated for each participant. All 16 participants underwent 3-hour oral glucose tolerance test to calculate whole-body insulin sensitivity (Matsuda Index, MI). The total accumulative IV iron dose was log transformed to enable parametric analysis with Pearson correlation coefficient to evaluate its association with MI.

Results: The study group was diverse (8 Hispanics, 4 Whites, 1 Asian, and 3 mixed), with 9 men and 7 women. Half of the group had diabetes. The mean±SD values for age, dialysis duration, systolic blood pressure, hemoglobin, and albumin were 52±14 years, 7.4±5.8 years, 142±28 mmHg, 10.6±1.9 g/dL, and 3.9±0.2 mg/dL, respectively. The median (IQR) transferrin saturation and ferritin were 28 (21, 39)% and 652 (300, 971) ng/mL. The median (IQR) total IV iron dose over the mean HD duration was 10,825 (6,986, 16675) mg (range of 2,400 to 29,748 mg). The insulin sensitivity as assessed by MI showed a *significant inverse relationship* with the total IV iron dose (r = -0.50, Figure 1).

Conclusions: This is the first study to evaluate the association between IV iron therapy and insulin sensitivity and to suggest a possible role of IV iron therapy in metabolic risk in HD patients. Larger studies are required to confirm the result and to further investigate the underlying mechanisms.

Comparison of Measured and Prescribed Dialysate Sodium in Three Brands of Dialysate Acid Concentrate

Ambreen Gul,[1] Dana Miskulin,[2] Serena Cumber,[3] S. Paine,[1] N. Trujillo,[1] Joseph J. Anaya,[4] Huan Jiang,[1] Philip Zager.[1] *[1]Dialysis Clinic, Inc., Albuqerque, NM; [2]Tufts Medical Center, Boston, MA; [3]Dialysis Clinic, Inc., Albuquerque, NM; [4]Dialysis Clinic, Inc., Albuquerque, NM.*

Background: There is ongoing controversy regarding the optimal dialysate sodium concentration (DNa). This issue is further complicated by differences between prescribed and measured DNa. These differences are higher in facilities utilizing Fresenius K2 dialysate delivery machines, dialysate concentrates mixed on site, and a centralized delivery system. These differences may reflect errors in the DNa acid dialysate concentrate, abnormal pressures in the distribution loop, or machine malfunction. The present study was conducted to assess the measured DNa in three brands of dialysate acid concentrate.

Methods: We measured DNa in two lots of Diasol, NaturaLyte and Rockwell acid concentrates, delivered from individual jugs by Fresenius T-machines. We used a single lot of pre-mixed bicarbonate concentrate. The prescribed DNa was 140 mEq/L. We sampled acid concentrates on a single day. We measured DNa on three consecutive days by both direct and indirect ion selective electrode method. We computed least square means of measured DNa concentrations from linear mixed models.

Results: The least square mean DNa concentrations are shown in the Table. There were no statistically significant differences between prescribed and measured DNa observed with different brands of dialysate acid concentrates, measurement method, lot and day of measurements (p=0.3 for each).

Conclusions: There were no significant differences between the prescribed and measured DNa in any of the three pre-mixed dialysate acid concentrates. The significant differences between prescribed and measured DNa previously reported may reflect errors in mixing dialysate concentrates on-site or pressure abnormalities in the delivery loop.

Funding: Clinical Revenue Support

	Least square means (95% CI) of measured DNa with prescribed DNa of 140mEq/L	
	Indirect ISE (n=18 samples each)	Direct ISE (n=18 samples each)
Diasol	139.7 (136.9, 142.4)	139.3 (136.6, 142.1)
NaturaLyte	141.7 (138.3, 143.8)	140.4 (137.7, 143.2)
Rockwell	140.5 (137.8, 143.2)	138.3 (135.6, 141.1)

FR-PO737

Effect of a Hemodialysis Treatment on Platelet Function Using PFA-100

Komal Patel,[1] Jordan L. Rosenstock,[1] Maria V. DeVita,[2] Warda Zaman.[3] *[1]Northwell Health Lenox Hill Hospital, Paramus, NJ; [2]Lenox Hill Hospital- Northwell Health System, New York, NY; [3]Northwell Lenox Hill Hospital, New York, NY.*

Background: Platelet dysfunction is well known to be present in patients with end-stage renal disease (ESRD). Various tests have been used to assess platelet function in patients with ESRD, but few studies involve the platelet function analyzer (PFA-100). PFA-100 is more accurate in assessing platelet function compared to prior methods such as skin bleeding time and platelet aggregation. The purpose of this study was to show the effect of a hemodialysis (HD) session on platelet function in a patient with ESRD on chronic HD.

Methods: The study enrolled 16 patients undergoing chronic HD three times a week from a single unit. Exclusion criteria were hemoglobin < 9 mg/dL, thrombocytopenia and the use of antiplatelet agents. Blood was drawn prior to and after HD after the long interdialytic period, and sent for PFA-100 analysis. Heparin was held during the treatment. PFA -100 measured both the collagen /epinephrine (COL/EPI) and collagen/ ADP (COL/ADP) closure times in seconds.

Results: Pre-HD, 11 (69%) started with an abnormal COL/EPI of which none normalized. Of the 5 patients that started with a normal COL/EPI, 1 developed an abnormal COL/EPI post-HD. Pre-HD, 11 (69%) started with an abnormal COL/ADP of which one normalized. Of the 5 patients that started with a normal COL/ADP, 4 patients developed an abnormal COL/ADP post-HD. Overall post-HD, there was an increase in COL/EPI closure time in 11 (69%), no change in 2 (12%), and decrease in 3 (19%) patients. There was an increase in COL/ADP in 12 (75%), no change in 1 (6%), and decrease in 3 (19%) of patients. Only one patient who originally had an abnormal PFA test, had normalization of the PFA- 100 after a HD treatment.

Conclusions: This study found that the majority of regularly dialyzed patients in our population had abnormal platelet function as measured by the PFA -100 analyzer after the long interdialytic interval. Only one patient had normalization a abnormal PFA-100 after a HD treatment. Most patients appeared to have worsening of platelet function as indicated by a longer closure time. This could be due to an interaction with the dialyzer membrane. Our findings don't support a common practice of performing a HD treatment prior to surgical procedures in order to help avoid bleeding complications. This study involved a small cohort of patients from a single HD unit, a larger multi-centered trial is warranted to confirm results.

FR-PO738

Hemodialysis (HD) Using Molecular Hydrogen-Enriched Dialysate Generates Greater Amount of Exhaled Hydrogen Than Conventional HD, Decreases Plasma Glucose, and Increases Serum LDL-C in One Session

Hirotsugu Iwatani, Yuta Asahina, Shintaro Koizumi, Masafumi Yamato.
Nephrology, Osaka National Hospital, Osaka, Japan.

Background: Novel hemodialysis using molecular hydrogen-enriched dialysate (Hydrogen HD) is reported to improve the prognosis of patients on chronic dialysis. To investigate whether or not this effect is derived from the hydrogen infused through dialysate, we aimed to investigate the difference of exhaled hydrogen concentration between novel Hydrogen HD and conventional HD. We also investigated the effect of Hydrogen HD on glucose and lipid metabolism.

Methods: We investigated the exhaled hydrogen concentration (ppm) of patients undergoing Hydrogen HD and conventional HD and compared the concentrations between the two groups. The subjects are eight adult HD inpatients in our hospital that gave written informed consent to go through Hydrogen HD and conventional HD. Exhaled hydrogen concentration were monitored at 0h, 0.5h, 1h, 2h after the start of HD, at the end of HD, and 0.5h after the end of HD (6 points). Exhaled hydrogen was calculated as AUC. Plasma glucose and lipid profile were also investigated before and after the each session of HD. Statistical analyses were performed by Wilcoxon signed rank test using JMP. The ethics committee in our hospital approved this study.

Results: The patients' characteristics were as follows; age 74 (63-79) y.o., sex F/M 3/5. Total exhaled hydrogen in Hydrogen HD was 502 (261-1541) ppm*hour and that in conventional HD was 45 (11-149) ppm*hour (p=0.0078). Serum LDL-C changes from 75 (39-102) to 78 (43-105) in Hydrogen HD significantly (p= 0.0156) and from 79 (45-105) to 78 (49-103) in conventional HD (n.s.). Plasma glucose changes from 142 (111-168) to 117

(99-144) in Hydrogen HD significantly (p=0.0078) and from 144 (111-184) to 129 (105-166) in conventional HD (n.s.).

Conclusions: Exhaled hydrogen in hemodialysis treatment using molecular hydrogen-enriched dialysate is significantly greater in amount than that in conventional HD. Overflowed molecular hydrogen from exhaled gas is the clue that the beneficial effect of this novel HD is based on the infused molecular hydrogen from dialysate. Hydrogen HD decreases plasma glucose and increases serum LDL-C in one session.

FR-PO739

Effect of Statins on Life Prognosis in Japanese Patients Undergoing Hemodialysis

Yuki Ota,[1] Mineaki Kitamura,[1] Kumiko Muta,[1] Hiroshi Yamashita,[1] Yoko Obata,[1] Takashi Harada,[2] Satoshi Funakoshi,[2] Tomoya Nishino.[1] *[1]Nagasaki University Hospital, Nagasaki, Japan; [2]Nagasaki Renal Center, Nagasaki, Japan.*

Background: Although large-scale studies have not proved the benefits of statin use in patients undergoing maintenance hemodialysis, recent studies suggest that statins could be useful to reduce the risk of cardiovascular events and all-cause mortality in specific groups of patients undergoing hemodialysis. The aforementioned large-scale studies included a small percentage of Asians, and few studies have investigated the effects of statins in Asians undergoing dialysis. We investigated the benefits of statins in patients undergoing maintenance hemodialysis at a large single center in Japan.

Methods: We obtained demographic, clinical, and hemodialysis data pertaining to all patients who underwent maintenance hemodialysis at the Nagasaki Renal Center between July 2011 and June 2012. Data were based on the patients' birth month. Patients were followed-up until September 2017.

Results: We studied 339 patients among which 51 (15.0%) were prescribed statins. The mean duration of observation was 3.7±2.0 years, 43% were women, and the mean hemodialysis vintage was 90±96 months. During the follow-up, 194 patients (57%) died. Among those who died, 43% (n=23) had been prescribed statins and 61% (n=171) had not been prescribed statins. After propensity score matching based on age, gender, dialysis vintage and time, diabetes mellitus, ischemic heart disease, dry weight, left ventricular ejection fraction, and serum albumin, an intergroup comparison between those who received statins and those who did not (44 patients in each group) showed significant differences in the survival rate based on the log-rank test, P=0.03. Although causes of death did not differ between groups, there were fewer causes of death from cardiovascular events, infections, and cancer in the group prescribed statins.

Conclusions: Our results suggest that statins may improve life prognosis in Japanese patients undergoing maintenance hemodialysis. Although potential residual confounders could not be excluded, statins may have an effect in reducing cardiovascular events, infections, and cancer. Further studies are required to prove this hypothesis.

FR-PO740

Erythropoietin-Stimulating Agent Dose Not Associated with Patient Transition to Nocturnal In-Center Hemodialysis

Adam S. Wilk,[1] Courtney E. Hoge,[1] Laura Plantinga,[2,1] Janice P. Lea.[2] *[1]Rollins School of Public Health, Emory University, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA.*

Background: Nocturnal dialysis (ND) can support longer sessions with better clearances of uremic toxins, compared to traditional in-center hemodialysis (HD). It has been suggested that patients with improved clearances may have improved responses to erythropoietin-stimulating agents (ESAs). We compared use of ESAs for ND patients before and after they initiated ND treatment.

Methods: We identified ND patients at a medium-sized dialysis organization to be those HD patients for whom ≥80% of dialysis sessions were ND sessions—starting at 6:30pm or later and lasting ≥5 hours—over the 3 months after their first ND session (≥20 sessions total) during 2010-16. Outpatient dialysis session and administered ESAs data were extracted for these patients within 12 months of ND transition (pre and post). Epogen units administered per month before December 2012 (when the organization switched to Aranesp) were converted to approximately equivalent Aranesp mcg/month dosages to support a single measure of ESA use per patient-month. Descriptive analyses of ESA use were performed for all months with ≥7 sessions (i.e., still in care). The effects of post-transition ND care status on ESA use were estimated using a generalized linear model (GLM) with a Gaussian distribution and random intercepts and slopes; standard errors were clustered at the patient level.

Results: We identified 64 ND patients (4.7% of 1,357 eligible patients in care), with 354 pre-transition patient-months (3,974 sessions) and 496 post-transition patient-months (5,841 sessions). Across descriptive analyses and GLM analyses accounting for patient-level clustering, we found no statistically significant differences in ESA use post-transition. We estimated ESA use levels of 158.3 mcg/month post-transition versus 147.1 pre-transition (p=0.24) in descriptive analyses, and our GLM point estimate associated with post-transition was +5.5 mcg/month (p=0.69).

Conclusions: After transitioning to ND, patients may not experience any change in their ESA use. Further studies are needed to more fully assess any changes in patients' anemia management, including iron use; these analyses should also account for potential differences in Kt/V, hemoglobin, and other lab results.

FR-PO741

Effects of Glucose-Containing Dialysate During Hemodialysis

Mijung Yoo,[1] Yang Wook Kim,[4] Bongsoo Park,[2] Sihyung Park,[2] Yoo jin Lee.[3] *[1]Inje University Haeundae Paik Hospital, ULSAN, Republic of Korea; [2]Inje University, Haeundae Paik Hospital, BUSAN, Republic of Korea; [3]Haeundae Paik Hospital, BUSAN, Republic of Korea; [4]Haeundae Paik Hospital, inje university, BUSAN, Republic of Korea.*

Background: When hemodialysis is performed using glucose-free dialysate, glucose is released into the dialyzer and hypoglycemia may occur. Repeated occurrence of hypoglycemia increases the risk of cognitive decline and reduces the quality of life of patients. In this study, we aimed to compare the incidence of hypoglycemia and biochemical changes in patients with hemodialysis using glucose-containing dialysate and glucose-free dialysate.

Methods: All patients were dialyzed with glucose-free dialysate and changed to glucose-containing dialysate. We measured the levels of albumin, BUN, creatinine, total cholesterol, triglyceride, C-reactive protein, calcium, phosphorus, SPKt/V and URR 3 months before and after dialysate change. Two hours after the start of dialysis, blood glucose level was measured. When the blood glucose level was less than 90 mg/dl, 100 ml of 50% dextrose fluid was administered and the number of times was recorded.

Results: A total of 53 patients participated in the study. When comparing before and after dialysis solution change, no statistically significant differences were found in albumin(g/dl)(3.53±0.36 vs 3.54±0.34; p-value 0.87), BUN(mg/dl)(60.02±19.07 vs 60.46±16.26; p-value 0.87), creatinine(mg/dl)(9.42±2.66 vs 9.36±2.68; p-value 0.95), total cholesterol(mg/dl)(148.83±33.39 vs 147.19±30.44; p-value 0.56), triglyceride(mg/dl)(113.57±75.55 vs 117.34±78.40; p-value 0.65), C-reactive protein(mg/dl)(0.38±0.63 vs 0.37±0.60; p-value0.61), calcium(mg/dl)(9.63±9.31 vs 8.35±0.58; p-value 0.61), phosphorus(mg/dl)(4.77±1.43 vs 5.03±1.31; p-value 0.18), SPKt/V(1.57±0.23 vs 1.59±0.24; p-value 0.40) and URR(71.74±10.36 vs 73.26±5.01; p-value 0.49). The mean number of dextrose fluid administration was statistically significant(0.16±0.27 vs 0.03±0.08; p-value 0.00).

Conclusions: Hyperglycemia is known to increase the production of free radials and to induce oxidative stress. However, in our study, with glucose-containing dialysate, the deterioration of inflammatory markers associated with oxidative stress was not observed, the incidence of hypoglycemia was reduced, and the dialysis efficiency remained similar. It is believed that the use of glucose-containing dialysate will be more beneficial to the patient.

FR-PO742

Accuracy of Dialysate Sodium from Dialysate Conductivity Compared to Measured Sodium: A Quality Assurance Study

Pierre-Antoine Brown,[3,2] Rayees Y. Sheikh,[1] Edward G. Clark,[3,2] Ayub Akbari,[3,2] Swapnil Hiremath.[3,2] *[1]The Ottawa Hospital, Ottawa, ON, Canada; [2]The Ottawa Hospital and Kidney Research Centre - Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada; [3]University of Ottawa, Ottawa, ON, Canada.*

Background: Dialysate sodium is traditionally set at a constant with the intention of providing isonatric dialysis. A dialysate sodium higher than plasma levels can result in transfer of sodium to the patient, while a lower sodium can lead to cramps and hypotension. Modulations of dialysate sodium are done by changing dialysate conductivity, since sodium is the primary driver of conductivity. Recent studies have suggested that the agreement between dialysate conductivity and measured dialysate sodium is imperfect. This quality assurance study was designed to examine the bias between machine reported conductivity and measured dialysate sodium and determine the factors associated with the bias, if present.

Methods: We conducted patient-free dialysis sessions using 3 different dialysis machines (Gambro Artis, Bellco Formula and Fresenius 4008) with varying sodium and potassium baths. Machine reported conductivity was recorded at time 0, 1hour, 2 hour, and 4 hours. Concurrently, dialysate samples were sent for measurement of sodium (indirect ion selective [ISE] method) and other electrolytes. A total of 46 sessions with different sets of dialysate sodium (135 mEq/L or 140 mEq/L) and K baths (2 mEq/L or 3mEq/L) were analyzed.

Results: At all 4 time points, the measured dialysate sodium was significantly higher than the set dialysate sodium. At T0, the difference was 6.11 ± 1.62 mEq/L (mean +/- SD) with similar results noted for all time points. The difference between measured and set dialysate sodium was higher for 3K (6.48 ± 1.85 mEq/L) bath than 2K bath (5.58 ± 1.07 mEq/L) (p=0.003), but not different whether set sodium was 135 or 140 (p = 0.80). There also was a difference between the 3 models of HD machines tested; model one: 6.23 ± 1.36 mEq/L; two: 4.80 ± 1.93 mEq/L; three: 7.10 ± 1.10mEq/L; p=0.0035.

Conclusions: Our analysis shows that, for 3 common dialysis machine models, there is a significant difference between the ordered dialysate sodium (I.e. conductivity) and the measured dialysate sodium. The bias persists throughout session time, and a range of common sodium and potassium baths. It is large enough to have clinical implications.

FR-PO743

Evaluation of Albumin Loss During Hemodialysis with Theranova® Medium Cut-Off (MCO) Dialyzer: Six Months Follow-Up

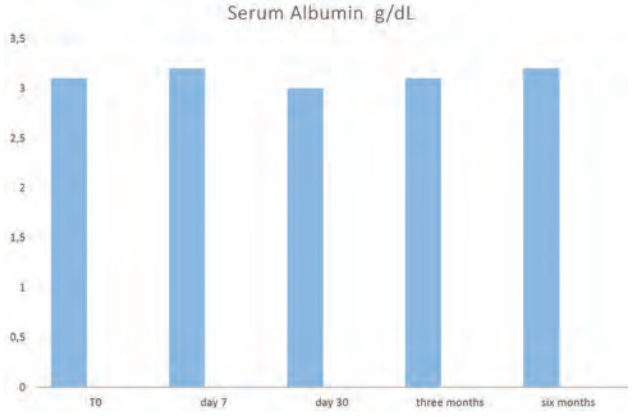
Nicola Marchionna,[1] Sara Samoni,[1] Mauro Neri,[2] Anna Lorenzin,[2] Alessandra Brendolan,[1] Monica Zanella,[1] Claudio Ronco.[1] *[1]S Bortolo Hosp, Vicenza, Italy; [2]IRRIV, Vicenza, Italy.*

Background: Theranova® medium cut-off (MCO) dialyzer is an innovative membrane designed to expand the spectrum of medium molecules removal, beyond standard high-flux dialysis, using conventional hemodialysis (HD) infrastructure. It represents a novel method to remove uremic toxins in an increased range of molecular weight (MW).

Methods: The purpose of this observational study was to evaluate the safety of treatment in terms of albumin removal, evaluating the albumin concentrations in plasma and dialysate. Six patients on chronic HD were observed for a period of six months. Each patient was treated with Theranova® 400 filter (PAES/PVP membrane, 1.7 m2 surface area, Baxter) in dialysis bicarbonate 4 h Qd 500 ml/min. Pre-treatment patient albuminemia and protein loss at the end of the treatment (dialysate sample) were assessed at the first treatment, one week, one month, three and six months after.

Results: Serum levels of predialitic albumin remained constant throughout the observation period (figure). Protein loss in each hemodialysis session was similar or lower than in HD bicarbonate treatments with high flux membranes, previously tested (3.7 ± 2.2 g).

Conclusions: In addition to a high efficiency in low and medium MW uremic toxins removal, in this study Theranova medium cut-off filters demonstrated not to cause an increased protein loss in comparison with a standard high flux dialyzer



FR-PO744

The Role of Neutrophil/Lymphocyte Ratio as a New Paradigm to Determine Hemodialysis Initiation

Tae won Lee,[1] Ha nee Jang,[2] Ji-Hye Kwak,[2] Eunjin Bae,[1] Hyun Seop Cho,[2] Hyun-Jung Kim,[4,3] Se-Ho Chang,[2,3] Dong Jun Park.[1,3] *[1]Department of Internal Medicine, Gyeongsang National University Changwon Hospital, Changwon-si, Gyeongsangnam-do, Republic of Korea; [2]Department of Internal Medicine, Gyeongsang National University Hospital, Jinju-si, Gyeongsangnam-do, Republic of Korea; [3]College of Medicine, Gyeongsang National University, Jinju-si, Gyeongsangnam-do, Republic of Korea; [4]School of Medicine, Gyeongsang National University, Jinju, Republic of Korea.*

Background: There are still much controversies about the timing of initiation of the dialysis in patients with chronic kidney disease (CKD) although absolute and relative indications have been well established. This study underwent to evaluate whether neutrophil/lymphocyte ratio (NLR) could be used as an important index of dialysis initiation by comparing the other clinical presentations and biochemical findings.

Methods: We retrospectively evaluated the medical records of patients to start chronic maintenance hemodialysis from January 2011 to December 2016 in our institutions. We compared laboratory findings of the last 3 months with those of just before timing of dialysis initiation. Patients with acute infection, using steroid or immunosuppressive agent use, and undergoing acute hemodialysis for acute kidney injury were excluded.

Results: Total 300 patients were included. The mean age was 61 years old. The mean estimated glomerular filtration rate (eGFR) by MDRD was 5.93 ± 2.78 (ml/min/1.73m^2) at the time of hemodialysis, whereas it was 7.86 ± 3.28 (ml/min/1.73m^2) 3 months before hemodialysis ($p<0.001$). The mean NLR significantly increased from 2.50 ± 1.02 to 4.32 ± 2.08 ($p<0.001$) in this duration. We found significant correlations between NLR and hemoglobin ($r=-0.523$, $p<0.001$), serum albumin level ($r=-0.685$, $p<0.001$), serum phosphorus level ($r=0.465$, $p<0.001$), total CO_2 level ($r=-0.361$, $p<0.012$), and CRP level ($r=0.458$, $p<0.001$). In addition, patients undergoing planed dialysis through prepared arm vascular access showed significantly lower NLR than those of emergency dialysis requiring Perm-cath or temporary catheter (3.58 ± 1.55 vs.4.75 ± 2.23, $p<0.001$) although eGFR was not different between two groups. Lower hemoglobin, total CO_2, albumin, sodium and calcium level was shown in patients undergoing emergency dialysis, compared with patients using planned arm vascular access ($p<0.001$, $p=0.002$, $p<0.001$, $p=0.006$, and $p=0.002$, respectively).

Conclusions: In conjunction with many other components, NLR might be used valuable marker in CKD patients when clinician consider the initiation of renal replacement therapy or prepare vascular access.

FR-PO745

Quantification of Lipoteichoic Acid, Biofilm Morphology, and Microbiology in Hemodialysis (HD) Patients with Catheters

Amy B. Pai, Lenar T. Yessayan, Michael Heung, Karen N. Davidge, Michael Dean, Gabrielle M. Costello. *University of Michigan, Ann Arbor, MI.*

Background: Lipoteichoic acid (LTA) is a Gram-positive bacteria cell wall component that is shed and induces inflammation through toll-like receptor 2. Currently, there are no non-invasive approaches to assess biofilm burden within a dialysis access. The purpose of this study was to characterize LTA concentrations in HD patients with central venous catheters (CVCs) compared to arterio-venous grafts (AVGs), and arterio-venous fistulas (AVFs) and to evaluate biofilm distribution and microbiology in pulled CVCs.

Methods: Eligible patients were adults with indwelling CVC, AVG or AVF being used for HD at the time of sample collection with no concurrent treatment for infection. Venous blood samples were collected prior to dialysis initiation, at 30 minutes, 2 hours and end of treatment (EOT). Catheter aspirate was also collected. LTA concentrations were measured by ELISA. In an ongoing sub-study, catheters that were pulled by clinical decision were evaluated by scanning electron microscopy (SEM) for biofilm surface area and the tip, mid-section and hub were cultured and bacterial species determined by MALDI-TOF.

Results: LTA profiles were measured in 17 CVC, 15 AVG and 16 AVF patients. Unexpectedly, LTA was detectable in serum from all access types at baseline and increased significantly over the dialysis session at each time point measured compared to baseline ($p<0.012$ for all comparisons). Catheter aspirate LTA concentration significantly correlated with serum concentrations at 2 hours and EOT (r^2 0.34 and 0.30, respectively $p=0.02$) The rate of change from baseline to EOT was highest in patients with CVCs but was not statistically significantly different from AVF and AVG. Among catheters pulled (n=4) large plaques of biofilm were observed on all sections examined by SEM. *Staphylococcus sp.* including *epidermidis, caprae, hominis, lugdenisis* were most abundant, however, *Candida albicans* was also cultured from some external hub and external/internal tip sections.

Conclusions: LTA was detectable in the serum of HD patients across access types and large increases during dialysis sessions were observed. Further study of the relationship of serum LTA to biofilm surface area and biomarkers of inflammation are warranted to understand the extent to which access type contributes to inflammation in HD patients.

FR-PO746

Calcium Mass Balance During Hemodialysis: A Comparison of Different Dialysate Calcium Concentrations Including Citrate-Acid Calcified Dialysate

Karlien J. ter Meulen,[1] Frank van der Sande,[1] Constantijn Konings,[3] Marijke J. Dekker,[1] Bernard J. Canaud,[2] Jeroen Kooman.[1] *[1]Maastricht University Medical Centre, Maastricht, Netherlands; [2]FMC Deutschland GmbH, Bad Homburg, Germany; [3]Catharina Hospital, Eindhoven, Netherlands.*

Background: Bone and mineral disorders are still cause of morbidity and mortality among chronic kidney diseases, even though adjustments made in therapy and techniques. The optimal dialysate calcium (dCa) and magnesium (dMg) is debated in hemodialysis as international guidelines differ. Citric-acid dialysate may affect Mg and Ca removal during dialysis. The aim of this study was to compare the mass balances in calcium (CaMB) and magnesium (MgMB) between bicarbonate/acetic-acid dialysate with dCa1.50 (dAcetCa1.50) and dCa1.25 (dAcetCa1.25), as well with citric-acid dialysate with dCa1.50 (dCitCa1.50) and dMg of 0.5 mmol/l.

Methods: Twenty patients were enrolled in this 4-week prospective multicenter randomized cross-over trial where they received a baseline week (dAcetCa1.50), followed by the randomized sequence of dAcetCa1.25 or dCitCa1.50 for one week and the alternate treatment was provided after a washout week with dAcetCa1.50. Spent dialysate was collected from the outlet of the dialysis machine in a fractionated way.

Results: Eighteen patients completed the study, one session was excluded due to unclear dialysate. CaMB was in general positive during dAcetCa1.50 and negative during dAcetCa1.50 and dCitCa1.50. MgMB was negative during all different treatments There was an inverse correlation for pre-dialytic serum ionized calcium (iCa) with CaMB in dAcetCa1.50 (r; p-value) (-0.687; 0.002) and in dCitCa1.50 (-0.725; 0.001). This was also found for total calcium in dAcetCa1.50 (-0.579; 0.012) and dCitCa1.50 (-0.708; 0.001), and corrected total calcium in dAcetCa1.50 (-0.687; 0.002) and dCitCa1.50 (-0.725; 0.001).

Conclusions: Our study shows that whereas dAcetCa1.50 leads to net gain of calcium by the body during dialysis, net loss occurs during dCitCa1.50, with levels comparable to dAcetCa1.25. Given the strong dependence of CaMB on pre-dialytic iCa, the introduction of dCa solution with 1.375 mmol/l may be relevant for individualizing CaMB during dialysis. Major losses of Mg occur during the use of conventional dialysis solutions.

Reduction in Mean Patient Body Weights and Blood Pressures Were Observed During a Fluid Management Quality Improvement (QI) Project Utilizing Relative Blood Volume Monitoring (RBV-M)

Paul Balter,[1,2] Yisha Li,[3] Claudy Mullon,[3] Robert J. Kossmann,[3] Linda Ficociello.[3] *[1]Nephrology Associates of Northern Illinois and Indiana (NANI), Oak Brook, IL; [2]Renal Research Institute, New York, NY; [3]Fresenius Medical Care Renal Therapies Group, Waltham, MA.*

Background: A one-year fluid management QI project utilizing RBV-M was conducted at 20 Renal Research Institute clinics. A retrospective database analysis of the QI project was conducted to assess changes in body weight and blood pressure in hemodialysis (HD) patients.

Methods: Patients included in this analysis received HD in the month before QI initiation (Pre-QI) and QI end. RBV-M was used to monitor relative blood volume during hemodialysis with Crit-Line® Monitors (CLM-III, CLM-IV, or CLiC). All available PreHD- and PostHD- body weights (wt) and PreHD- and PostHD- systolic blood pressure (SBP) and diastolic blood pressure (DBP) values were averaged monthly for each patient. A subgroup analysis of patients with Pre-QI hypertension was conducted for patients with PreHD-SBP ≥ 140 mmHg and/or PreHD-DBP ≥ 90 mmHg during Pre-QI. Paired t-tests were utilized to test for difference between Pre-QI and QI month 12 (M12).

Results: In total, 651 patients were included in the analysis and 473 had Pre-QI hypertension. Mean PreHD-wt decreased from 84.06 to 83.27 kg (-0.79 kg, p<0.0001) and PostHD-wt from 81.71 to 80.96 kg (-0.75 kg, p<0.0001) from Pre-QI to M12. Mean PreHD-SBP decreased from 152.04 to 149.92 mmHg (-2.12 mmHg, p=0.005) and mean PostHD-SBP decreased from 139.32 to 137.09 mmHg (-2.23 mmHg, p=0.003) from Pre-QI to M12. Mean PreHD-DBP decreased from 80.07 to 78.70 mmHg (-1.37 mmHg, p=0.002) and PostHD-DBP decreased from 73.69 to 72.41 mmHg (-1.28 mmHg, p=0.001) from Pre-QI to M12. On average, in the subgroup of patients with hypertension during Pre-QI, PreHD-SBP decreased from 161.54 to 156.55 mmHg (-4.99 mmHg, p<0.0001) and PostHD-SBP decreased from 145.56 to 141.56 mmHg (-4.00 mmHg, p<0.0001).

Conclusions: A QI project on fluid management utilizing RBV-M was associated with reductions in patient body weights and blood pressures. Most patients had Pre-QI hypertension (73%). These patients had an average decrease in PreHD-SBP of 4.99 mmHg and may be a population that could particularly benefit from a QI initiative on fluid management.

Impact of PEAK Methodology on Interdialytic Weight Gain: A Multi-center Experience

Atef Z. Altaher, Marta C. Bento, Janet Cowperthwaite. *DaVita-Saudi Arabia, Riyadh, Saudi Arabia*.

Background: Hemodialysis (HD) patients who experience larger interdialytic weight gains (IDWG) are at increased risk of cardiovascular and all-cause mortality. Diastolic dysfunction, associated with fluid overload is reported in a significant numbers of dialysis patients directly reducing survival. In addition reports suggest that IDWG > 4% increases the risk of death substantially. This risk prompted us to focus quality improvement activities on the IDWG of chronic patients on HD.

Methods: PEAK methodology based on six sigma and lean processes was introduced incrementally into each of the 15 DaVita KSA clinics included in this study. During the implementation period the teams were provided with education about PEAK and supported to hold daily reviews of the current status, then to discuss ideas and action plans to implement patient centered strategies to promote compliance. The percentage of patients showing ≥ 4% IDWG on each treatment day during the 9 month study period was counted. The data included all prevalent and incident patients with valid data reported in the electronic medical records system (n=1472). Average data were calculated for each treatment week and month. Results were compared at 3, 6 and 9 months using Chi² test.

Results: The percentage of patients not achieving IDWG in each of the clinics at the start of the study period ranged from 20.5%-66.1%. Improvement in IDWG was observed in 11 of 15 and 12 of 15 clinics after 3 and 6 months, respectively. After 9 months, the percentage of patients not achieving target IDWG ranged from 15.6%-63.7% and had decreased by 36% of the initial value for the whole population. At the end of the study the percentage of patients not achieving target had decreased in all 14 clinics.

Conclusions: By implementing the PEAK methodology and encouraging team focus on this defined outcome, all clinics that implemented the program achieved a decrease in average IDWG in their patient populations.

Funding: Commercial Support - DaVita

FR-PO749

The Swelling of the Median Nerve Is the Independent Risk Factor for Carpal Tunnel Syndrome in Patients with Short-Term Hemodialysis

June hyun Kim,[1] Soo Bong Lee,[1] Il Young Kim,[1] Dong Won Lee,[1] Sang Heon Song,[2] Harin Rhee,[2] Miyeun Han.[2] *[1]Pusan National University Yangsan Hospital, Yangsan, Republic of Korea; [2]Pusan National University Hospital, Busan, BUSAN, Republic of Korea*.

Background: A carpal tunnel syndrome (CTS) is a frequent complication of long-term hemodialysis. 20% to 50% of the patients dialyzed for 10 years or longer are reported to have CTS. However, risk factors for CTS in short-term hemodialysis have been less known. In this study, we investigated whether the swelling of median nerve could be a risk factor for CTS in patients with relatively short-term hemodialysis (mean duration of hemodialysis: 4.03 years).

Methods: The study included 43 patients (23 male & 20 female) on maintenance hemodialysis and 97 healthy controls. We diagnosed the CTS by nerve conduction study (NCS) and clinical symptom. The cross-sectional area (CSA) of median nerve was measured at the wrist (CSA–W) and forearm (CSA-F) by ultrasonography. The wrist to forearm ratio (WFR; CSA-W/CSA-F) was calculated for each arm. The degree of swelling of median nerve was assessed by the WFR.

Results: The mean duration of hemodialysis (n=43) was 4.02 ± 3.30 years. The WFRs in hemodialysis patients were higher than those in healthy controls (1.37 ± 0.45 vs. 1.21 ± 0.25, P = 0.021). We classified into patients with CTS (n=19) and without CTS (n=24). There were no significant differences in age, sex, duration of hemodialysis, the cause of renal failure, β2-microglobulin, and adequacy of dialysis (Kt/V) between patients with CTS and without CTS. The WFRs in patients with CTS were higher than those in patients without CTS (1.5 ± 0.5 vs. 1.2 ± 0.2, P = 0.001). We performed ROC analysis to investigate the best cut-off value of WFR for predicting the CTS in all study subjects (n=43). The AUC of the WFR was 0.825 (95% CI: 0.678-0.923). The best cut-off value of the WFR was > 1.25 with a sensitivity of 84.2% and specificity of 70.8%. In multivariate analysis, the patients with WFR > 1.25 were 6.3 times more likely to have the CTS compared with patients WFR (HR: 6.30, 95% CI: 1.45-27.5, P = 0.014)

Conclusions: This study demonstrated that the swelling of median nerve was the independent risk factor for the CTS in patients with relatively short-term hemodialysis.

FR-PO750

Development of a Microparticle-Based Bio-marker of Hemodialysis Induced Vascular Injury

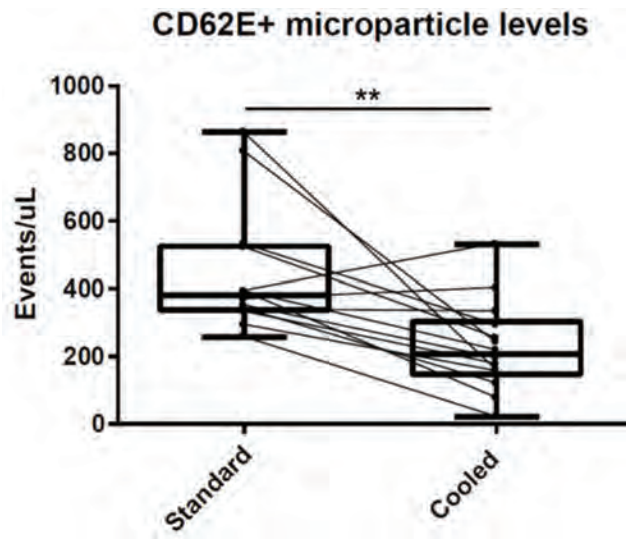
Janice Gomes,[1,2] Claire Grant,[2] Elena Qirjazi,[1,2] Christopher W. McIntyre.[1,2] *[1]University of Western Ontario, Toronto, ON, Canada; [2]Lawson Health Research Institute, London, ON, Canada*.

Background: Hemodialysis (HD) is a treatment option that is associated with complications such as microvascular dysfunction and damage to vulnerable vascular beds. This damage has been observed through gold standard imaging techniques such as Echo, CT, MRI, and PET, however there are no reliable blood based bio-markers available to identify this injury that might be suitable to use in general clinical practice. We therefore investigated the use of blood vessel and circulating blood cell derived microparticles as an indicator of vascular damage in a cohort of HD patients under standard treatment condition and a state of reduced circulatory stress (using dialysate cooling).

Methods: An assay was created to assess the level of endothelial, platelet, erythrocyte, and leukocyte derived microparticles. By utilizing Nanoscale Flow Cytometry (Apogee A50), we measured microparticle levels within plasma samples obtained from patients receiving standard hemodialysis treatment (36.5 degrees Celsius, n=31) and 16 of the same patients receiving cooled dialysate treatment (35 degrees Celsius). Microparticles were enumerated at pre, during, and post treatment.

Results: CD31+/CD62E+ microparticles (derived from activated endothelium) correlated with ultrafiltration rate (as the primary driver of HD-based circulatory stress) (R^2=0.1720, p<0.05). There was no relationship between erythrocyte, leukocyte, and platelet derived microparticles and ultrafiltration rate. Furthermore, we observed that 86% of patients experienced a reduction in CD62E+ (e-selectin) microparticle levels when administered cooled dialysate treatment in comparison to standard treatment (Figure, **p<0.01).

Conclusions: The use of microparticles as a bio-marker of HD induced ischemic injury shows promise and warrants further refinement and investigation to identify and risk assess patients receiving HD, as well as monitoring response to efforts to individualize and optimize HD treatment.



FR-PO751

Hospitalizations for Cryptococcal Meningitis in End-Stage Kidney Disease (ESKD) Patients Without HIV: National Estimates 2006-15

Ahmed A. Awan,[1] Samaya J. Anumudu,[2] Sankar D. Navaneethan,[2] Wolfgang C. Winkelmayer,[2] Carl P. Walther.[1] [1]*Baylor College of Medicine, Houston, TX;* [2]*Baylor College of Medicine, Houston, TX.*

Background: While cryptococcal meningitis (CM) has been reported in HIV-negative persons with ESKD, its epidemiology is poorly described

Methods: Using the National Inpatient Sample, a national all-payer database, we estimated CM hospitalizations among persons with ESKD from 2006-15. Using ICD9 codes, we identified patients with ESKD on dialysis (CKD-G5D), and transplanted (CKD-T), CM (in first 5 discharge diagnoses, to improve specificity), and HIV. We evaluated in-hospital mortality in CKD-G5D and CKD-T patients without HIV using logistic regression models, adjusted for demographics and *a priori* comorbidities (age, sex, diabetes, liver disease, heart failure, lung disease, rheumatic disease).

Results: We estimated 1855 hospitalizations of ESKD patients with non-HIV CM from 2006-15, with409 (95% CI:317-502) on dialysis, and 1446 (95% CI:1212-1680) with kidney transplant. The number of hospitalizations increased from 2006-2007 to 2008-2009, especially in the CKD-T population, and has remained steady since then (Figure). In-hospital mortality was higher for patients with CKD-G5D compared to CKD-T:21% (95% CI 12.3-29.9%) vs. 9% (95% CI 2.0-16.0%), respectively. Adjusted odds -ratio for death in CKD-T vs.CKD-G5D was 0.39 (95% CI [0.16-0.96]).

Conclusions: ESKD patients without HIV are at risk for cryptococcal meningitis, and nephrologists should be aware of this risk. Mortality among those on dialysis is significantly higher than among those with a kidney transplant, perhaps reflecting underlying severe comorbidities causing the immune suppression among affected dialysis patients.

FR-PO752

Hemodialysis Transportation Modality and Their Effects on Treatment Adherence

Candace D. Grant, James Drakakis, Naveed N. Masani, Nobuyuki (Bill) Miyawaki. *NYU Winthrop Hospital, Mineola, NY.*

Background: A common reason for nonadherence to hemodialysis (HD) treatments is difficulty with transportation. Health disparities occur in groups of people that experience suboptimal health care based on their social, economic, and/or environmental disadvantage. The modality used for transportation is dependent on a patient's socioeconomic status and can be related to health disparities. Identifying how transportation modality affects adherence to HD regiments can hopefully lead to improved strategies in HD transportation and improve clinical outcomes for all HD patients. We examined transportation modality and HD treatment adherence.

Methods: We reviewed the electronic charts of patients enrolled at our outpatient HD units. We identified 306 eligible patients that had documented transportation modality as well as health insurance information. HD compliance was calculated for the group between April 2014 to April 2018. The modes of transportation were designated as self/family (SF), ambulance/ambulette (AMB) and Taxi/AbleRide (TX). Health insurance was divided into three groups: Medicare (MCR), Medicaid (MCD) and private insurance/self-pay (PVT).

Results: The study population was 53% white, 57% male with a median age of 66 years. 59%, 18% and 23% of the patients had MCR, MCD, or PVT for insurance respectively. Patients with more than one mode of transportation (n=20) had an average compliance of 91.27% versus 90.95% with only one mode (n=286). Of the patients with only one mode of transportation, the average compliance was 91.78%, 90.39%, and 88.21% for travel by SF, AMB, and TX, respectively. HD compliance by primary insurance varied at 92.3%, 91.8% and 86.7%, for PVT, MCR and MCD, respectively ($P<0.01$). When comparing compliance of different transportation modes within the designated insurance groups, there was a significant difference between the modes of transportation at 90.3% and 85% for SF and combined AMB/TX respectively, ($p<0.05$).

Conclusions: Our findings suggest that health insurance and transportation modality both play a significant role in HD treatment compliance. Patients on MCD experience more health disparities that can interfere with HD regiment complaince. Further prospective studies are required to explore this relationship and why MCD insured patients would experience lower HD compliance when relying on commercial sources for transportation.

FR-PO753

Screening for Obstructive Sleep Apnea in Hemodialysis Patients Using the Crit-Line Monitor

Ohnmar Thwin, Xia Tao, Mirell Tapia, Priscila Preciado, Stephan Thijssen, Peter Kotanko. *Renal Research Institute, New York, NY.*

Background: Obstructive sleep apnea (OSA) is common among end-stage renal disease patients. The absence of airflow leads to a decrease in arterial and peripheral blood oxygen saturation (SO_2). A saw-tooth pattern of SO_2 is considered as a sign of OSA. The Crit-Line monitor (CLM) is being used in hemodialysis (HD) centers. Our goal was to investigate if CLM can be used to identify sleep-related breathing disorders

Methods: Prospective, observational study done in chronic HD patients. Subjects were studied twice and equipped with a WatchPAT device (FDA approved device for OSA) and videotaped and CLM data was recorded. The degree of similarity between SO_2 from WatchPAT and CLM was determined by cross-correlation analysis

Results: We studied 14 patients (age 55.4±10 yrs, 64% males, BMI 25.6±6.8 kg/m^2) with a total of 27 visits. We identified a saw-tooth pattern in the SO_2 signals in 9 sessions (Fig 1). The cross-correlation coefficient between CLM and WatchPAT for SO_2 was 0.93±0.11 for 9 visits. Prolonged desaturation (>3% points from baseline) episodes occurred in 5 visits, with 4 showing SO_2 saw-tooth patterns. Fig.2 shows the SO_2 signals from CLM and WatchPAT for one of these visits. Cross-correlation coefficient is 0.89±0.10 for these 5 visits, and 0.53±0.23 for visits without saw-tooth pattern

Conclusions: While there was a high degree of correlation between the SO_2 from the CLM and the WatchPAT device, the CLM captures a higher-resolution. CLM provides richer information and reveals SO_2 nuances (such as the signature SO_2 saw-tooth patterns) better than the WatchPAT device. It is ought to be possible to use the CLM for screening for sleep apnea as well as other blood oxygenation disorders. Further validation is required (e.g. comparison to polysomnography)

FR-PO754

Determination of Calf Normalized Resistivity at 50 kHz in the General Population

Fansan Zhu,[1] Samer R. Abbas,[1] Laura Rosales,[1] Nathan W. Levin,[1,2] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]Mount Sinai School of medicine, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: We have developed 5 kHz calf normalized resistivity (CNR_5) method to identify degrees of fluid status in dialysis patients. However, the 50 kHz BIA method have been used in clinical studies for many years. The aim of this study was to evaluate whether 50 kHz CNR (CNR_{50}) could be used to determine fluid status by comparing CNR_5 and CNR_{50} chosen randomly from a general population.

Methods: Subjects from a general population were studied once. Calf multi-frequency bioimpedance spectroscopy measurements (Hydra 4200) was performed in the supine position. Further measurements included body height, weight and calf circumference. Resistances at 5 kHz (R_5) and at 50 kHz (R_{50}) respectively were extracted from the raw data. Calf resistivities (Rho_5 and Rho_{50}) were calculated based on resistances and average cross-sectional areas over a calf length measurement of 10 cm. CNR_5 and CNR_{50} were obtained by normalizing calf resistivities with body mass index (BMI).

Results: Ninety-one subjects (sex: 49 f, age: 57±10 year, BMI: 27.9± 4.7 kg/m^2) were evaluated. Although calf R_{50} (R^2=0.89, p<0.0001), Rho_{50} (R^2=0.9, p<0.0001) and CNR_{50} (R^2=0.91, p<0.0001) highly correlated with CNR_5, Rho_5 and CNR_5 respectively, the values of R_{50} (36.6±6.0, Ohm), Rho_{50} (352.9±60.6, Ohm*cm) and CNR_{50} (13.0±2.5, 10^{-2} *Ohm*m^3/kg) were significantly lower than in R_5 (48.1±7.2, Ohm), Rho_5 (464.9±79, Ohm*cm) and CNR_5 (17.1±3, 10^{-2} *Ohm*m^3/kg) respectively (Fig.1 and Fig.2). Bland-Altman analysis showed that the differences between CNR_5 and CNR_{50} was 4.08±0.95 10^{-2} *Ohm*m^3/kg (Fig.3). The difference between CNR_5 and CNR_{50} was weakly (R^2=0.13) but significantly (p<0.001) associated with subject age (Fig.4).

Conclusions: Values of 50 kHz data R_{50}, Rho_{50} and CNR_{50} were lower than that of 5 kHz data with BIA respectively, presumably because a 50 kHz current passes into part of the intracellular space, while this does not occur measurably with 5 kHz current. This difference offers the practicability of using the CNR_{50} range in healthy subjects, as a criterion of normal fluid status.

Effects of Medium Cut-Off (Theranova) Dialyzer on Hemodialysis Patients: A Prospective, Cross-Over Study

Mario Cozzolino. *Department of Health Sciences, University of Milan, Milan, Italy.*

Background: Recent data suggest that expanded hemodialysis (HDx) enabled by middle cut-off membrane promotes greater clearance for large middle molecules implicated in inflammation and immune function modulation.

Methods: In prospective, open-label, controlled, crossover pilot study, 20 prevalent hemodialysis (HD) patients were studied for 6 months in two dialysis treatments as follows: one MCO (Theranova) dialyzer and one high-flux dialyzer.

Results: In table 1, we present the baseline characteristics of HD patients. Hemoglobin, ferritin, transferrin, calcium, phosphate, parathyroid hormone and 25(OH) vitamin D levels were similar with MCO and high-flux HD. In addition, we did not find any albumin loss in the two treatment groups. Also, dialysis adequacy was similar in MCO and high-flux HD treated patients. Interestingly, the cumulative number of episodes of infection, confirmed clinically and treated with antibiotics) was significantly lower in HDx (# 6), compared with high-flux HD patients (# 20) (Figure 1), while number of hospitalizations did not change.

Conclusions: In conclusion, our pilot study demonstrates that Theranova dialyzer has a good tolerance profile and, intriguingly, reduces the cumulative number of infections in HD patients.

Impact of Bemiparin, a Low Molecular Weight Heparin, in the Oxidative Stress of Patients in Chronic Hemodialysis

Elba O. Medina,[1] Rafael Valdez-Ortiz,[2] L. M. Perez-Navarro,[3] Josue W. Tapia Lopez.[4] *[1]Hospital General de Mexico "Dr. Eduardo Liceaga", Mexico City, Mexico; [2]Hospital General de Mexico, Mexico City, Mexico; [3]Hospital General de México Dr. Eduardo Liceaga, México, Mexico; [4]ISSSTE, Estado de Mexico, Mexico.*

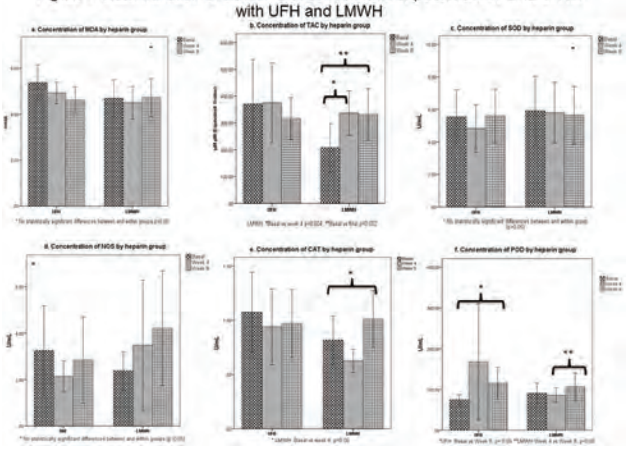
Background: Patients in hemodialysis (HD) has increased oxidative stress (OS), what it produces endothelial damage secondary to the generation of reactive oxygen species (ROS), and consequently progression of cardiovascular disease (CVD). It has been observed, that the use of low molecular weight heparin (LMWH) could decrease the OS in this patients. We evaluated the effect of bemiparine a LMWH on the OS of patients in chronic HD.

Methods: Randomized, open, single-blind controlled clinical trial in chronic HD patients: group with UFH (n=19) as standard anticoagulation during HD and group with LMWH (n= 19). The OS markers were measured basal, at 4 and at 8 weeks: malondialdehyde (MDA), total antioxidant capacity (TAC), Superoxide Dismutase (SOD), Nitric Oxide synthase (NOS), Catalase (CAT) and Peroxidase (POD). Student's t-test, one-way ANOVA were performed.

Results: The mean age of the study groups was 33.5± 4.4 years. The comparison between groups did not present statistically significant differences in markers of OS. While, the intragroup comparison group with LMWH, was statistically significant differences in the levels of TAC (basal vs intermediate and, basal vs final); CAT (Intermediate vs final) and POD (intermediate vs final); while, the group with UFH showed statistically significant differences ($p \leq 0.05$) in the levels of POD (basal vs final), see Figure 1. None of the groups presented events of thrombosis or hemorrhagic complications.

Conclusions: There was a prospective increase in the concentration of OS markers in the LMWH group, what it demonstrates that the continuous use of LMWH participates in the antioxidant defense against the generation of ROS and the OS of patients with CKD in HD. It is necessary to evaluate the long-term use of LMWH on oxidative stress markers and evaluate the possible benefit of it use in the reduction of cardiovascular mortality.

Figure 1. Determination of oxidative stress markers in patients with CKD in HD with UFH and LMWH



FR-PO757

Safety and Efficacy of Heparin During Dialysis in the Context of Systemic Anticoagulant and Antiplatelet Medications

Steven M. Brunelli,[1,2] Dena E. Cohen,[1,2] Gilbert Marlowe,[1,2] Daniel Liu,[2] Levi Njord,[2] David B. Van Wyck,[2] George R. Aronoff.[3] *[1]DaVita Clinical Research, Minneapolis, MN; [2]DaVita Institute for Patient Safety, Denver, CO; [3]DaVita Kidney Care, Denver, CO.*

Background: Heparin is widely used to prevent coagulation during hemodialysis (HD). Although systemic anticoagulants and antiplatelet agents are commonly prescribed in the HD population, the safety and efficacy of heparin in the presence versus absence of these medications is unclear.

Methods: This retrospective, longitudinal, time-updated cohort study considered adult patients receiving in-center HD (Aug 2015 – Jul 2017). Study data were derived from deidentified patient electronic health records. For each calendar month, patients were ascribed a 3-part exposure status (use of heparin, systemic anticoagulant, systemic antiplatelet agent). Outcomes included anemia measures, peri-treatment bleeding and clotting, and hospitalization for gastrointestinal (GI) bleeding. Within each systemic medication exposure category, associations of heparin use (vs. non-use) were examined using adjusted general linear, negative binomial, or Poisson models.

Results: Across all systemic medication exposures, heparin use (vs. non-use) was associated with significantly lower erythropoiesis stimulating agent (ESA) dose and higher hemoglobin values; slightly lower intravenous (IV) iron dose; and similar serum ferritin and transferrin saturation. Heparin use was also associated with lower rates of clotting during treatment. Heparin use was not associated with excess risk of hospitalization for GI bleeding, or with peri-treatment bleeding episodes. Associations with respect to ESA, IV iron, hemoglobin, and clotting were approximately 2-fold more potent in the absence of a systemic anticoagulant; the presence of a systemic antiplatelet agent did not impact these associations. Neither systemic medication type influenced associations between heparin use and peri-treatment or GI bleeding.

Conclusions: Heparin use was safe and effective regardless of systemic anticoagulant and antiplatelet agent status. Clinical judgment must be applied to assess bleeding risk in individual patients; however, the decision to withhold heparin should not solely be based upon the concurrent use of systemic anticoagulant or antiplatelet agents.

Decreasing the Incidence of Catheter-Related Blood Stream Infections in Hemodialysis Patients: A Quality Improvement Program

Wisam H. Al-Badr, Mahmoud M. Shaheen, Hany A. Salama, Mahmoud A. Ahmed, Hany Elshiekh, Ibrahim A. Jubran, Saad S. Alobaili, Abdulkareem Alsuwaida. *DaVita-Saudi Arabia, Riyadh, Saudi Arabia.*

Background: Hemodialysis patients dialyzing with a central venous catheter are at risk for developing catheter-related bloodstream infections (CRBSI), which are associated with substantial morbidity. In 2009, the US Centers for Disease Control and Prevention (CDC) sponsored a collaborative project to reduce CRBSIs in outpatient hemodialysis facilities. The aim of our study was to evaluate the impact of applying the CDC program on the occurrence of CRBSI in an outpatient hemodialysis population.

Methods: All cases of CRBSI that occurred among patients treated at 20 outpatient dialysis centers operated by DaVita-Saudi Arabia (Oct. 2015 to Dec. 2017) were recorded. The quality improvement project, which involved adopting the CDC Dialysis BSI Prevention Collaborative Interventions was initiated in April 2016. Interventions used included the CathAway protocol, ideal catheter lock, standardization of antibiotic therapy, training protocols, closed audits for catheter care, and maximal barrier precautions at the time of catheter insertion. The rate of CRBSI was calculated monthly as the incidence of CRBSI per 1000 catheter-days.

Results: During the studied period, the monthly CRBSI incidence decreased from 5.6 per 1000 catheter-days in the first quarter 2016 to a nadir of 1.8 during the last quarter 2017. There was also a substantial decrease in the mean monthly incidence of CRBSI from 5.1 ± 3.8 among 1477 patients in 2016 to 2.7 ± 0.86 among 2255 patients in 2017.

Conclusions: The most effective strategy for prevention of CRBSIs is reducing the use of catheters. However, given the reality that catheter use cannot be eliminated, adoption of CDC-recommended programs may reduce the rate of CRBSI.

FR-PO759

Characteristics of Hospital Acquired Central Line Associated Bloodstream Infection (CLABSI) in Hemodialysis (HD) Patients in a Single Tertiary Medical Center in Hawaii

Nattawat Klomjit,[1] Ekamol Tantisattamo.[2,3] [1]*John A. Burns School of Medicine. University of Hawaii, Honolulu, HI;* [2]*University of California, Irvine School of Medicine, Orange, CA;* [3]*Division of Nephrology, Department of Internal Medicine, William Beaumont Hospital, Oakland University William Beaumont School of Medicine, Multi-Organ Transplant Center, Royal Oak, MI.*

Background: Hospital acquired CLABSI is one of an important complication of dialysis catheter and is associated with high morbidity and mortality in HD patients. We studied baseline characteristics of HD patients who developed hospital acquired CLABSI as part of our institutional quality improvement project.

Methods: We identified index patients through the hospital database based on CDC definition of CLABSI. We studied the hospital acquired CLABSI patients who had HD catheter presented at the time of CLABSI diagnosis between 1/1/12 and 12/31/17. We studied baseline characteristics, hospital-related factors, and mortality rate associated with CLABSI.

Results: Of the 13 patients, 46% were male and median± SD age was 66±11.28 years old. Asian is the most prevalent (46%) followed by mixed race (31%). There were no Caucasian patients in the cohort. More than half had diabetes. Infection (46.2%) was the most common admitting diagnoses followed by cardiovascular diseases (30.1%). The majority of patients had ESRD (69.2%) followed by AKI on CKD (23.1%), and AKI (7.7%) and two-third of the patients infected tunneled HD catheter (TDC) and the remaining one-third had non-TDC. A quarter of patients (23%) was in ICU when CLABSI was diagnosed. Only 38% of blood cultures were drawn from peripheral sites and central line. Up to 31% had an early CLABSI occurred within 7 days after HD catheter placement. Gram positive cocci is the most common pathogens (54%), followed by gram negative bacilli (31%), anaerobe (8%), and fungus (7%) and 85% of cases were managed by infectious disease physicians. Median length of hospital and ICU stays were 21 and 17 days, respectively. In-hospital mortality rate was 15.4%.

Conclusions: Our patients are elderly with diabetes mellitus being the major co-morbidities. There are unexplained racial disparities of races given no Caucasian patients in our cohort. The majority of hospital acquired CLABSI occurred in ESRD patients and the prevalence of infected TDC was greater than that of non-TDC. A third of patients developed CLABSI within 7 days of HD catheter placement therefore strict measures should be employed during this phase to prevent early HD catheter infection.

FR-PO760

ESRD and a Risk of Tuberculosis: A Nationwide Population-Based Cohort Study

Soon Kil Kwon,[1] Hye-Young Kim,[1] Sun Moon Kim,[2] Hyunjeong Cho.[2] [1]*Nephrology, Chungbuk National University College of Medicine, Cheongju, Chungbuk, Republic of Korea;* [2]*Chungbuk National University Hospital, Cheongju, Republic of Korea.*

Background: The converging epidemics of tuberculosis (TB) and end-stage renal disease (ESRD) have generated a significant public health burden and difficulties in controlling TB, although the relationship between these conditions remains poorly understood. This nationwide propensity score-matched cohort study aimed to assess the rateof developing TB among patients receiving dialysis for ESRD.

Methods: The Korean national health insurance database was used to identify patients receiving dialysis for new-onset ESRD during 2004–2013, who were matched to an equivalent number of non-dialysis subjects. We also collected data from the KNHIS National Sample Cohort (NSC), which is stored in the same database. The KNHIS-NSC included approximated 1,000,000 individuals (2.2% of the total Korean population) and was created by sampling the records of the National Health Information database. The incidences of active TBin the dialysis and control cohorts during 2004–2013 were identified using International Classification of Disease, tenth revision (ICD-10) codes (A15–19, U88). The diagnosis of active TBwas then confirmed based on simultaneous prescriptions for ≥2 anti-tuberculosis drugs during a 30-day period. The incidences of TB in the ESRD and control cohorts were calculated for 2004–2013, and multivariable Cox proportional hazards modelwas used to evaluate the ESRD-related risk of developing TB.

Results: During 2004–2013, 59,584 patients received dialysis for newly diagnosed ESRD, which was associated with a significantly higher risk of TB than among the controls (incidence rate ratio: 4.80). The cumulative TB incidence was significantly higher in the dialysis cohort than in the control cohort (p<0.0001; log-rank test), and subgroup analyses revealed similar results for both hemodialysis and peritoneal dialysis (both p<0.0001; log-rank test). However, there was no significant difference in the risk of TB between the hemodialysis and peritoneal dialysis subgroups(p= 0.67; log-rank test). The ESRD cohort had an independently elevated risk of TB (hazard ratio: 4.39, 95% confidence interval: 3.60–5.37).

Conclusions: Similar to the findings of previous studies, we found that patients receiving dialysis for ESRD had an elevated risk of TB. These results highlighted the need of detailed and well-organized guidelines for TB screening among patients with ESRD.

FR-PO761

Effect of Vancomycin on Plasma Concentration of Uremic Solutes

Leland R. Soiefer,[2,4] Michelle Chang,[2,3] Farah Tamizuddin,[2] Daria Schatoff,[2] Lucas Cofer,[2] Albert Matalon,[2] Lama Nazzal,[2] Bjorn Meijers,[1] Robert Holzman,[2] Jerome Lowenstein.[2] [1]*University Hospitals Leuven, Leuven, Belgium;* [2]*New York University School of Medicine, New York, NY;* [3]*NYP Hosp-Columbia University Medical Center, New York, NY;* [4]*New York- Presbyterian Weill Cornell Medical Center, new York, NY.*

Background: Many uremic retention solutes are products of gut bacterial metabolism. Protein-binding renders these solutes poorly dialyzable. In a prior study we observed that a single dose of 250 mg of vancomycin, given by mouth, resulted in a significant (40%) decrease in the plasma concentration of indoxyl sulfate and p-cresyl sulfate over a period of one week. In this study we compared the changes in plasma concentration of a panel of protein-bound uremic retention solutes in response to the once-weekly oral administration of 250 mg of vancomycin or placebo over a period of 8 weeks.

Methods: Eight subjects with chronic, stable ESRD on thrice-weekly hemodialysis via AV fistula in the River Renal Dialysis Unit in Bellevue Hospital, were randomized to two groups, utilizing a single-blinded procedure. Baseline plasma samples were collected prior to the initial dose of vancomycin or placebo and at weeks one, two, three, four, and eight. Uremic retention solutes were measured by MS-HPLC.

Results: Six of the eight uremic retention solutes (Table 1) demonstrated a significant decline in concentration over the eight week period of once-weekly vancomycin administration. The magnitude of the decline makes it more likely that gut production was reduced rather than renal excretion increased. Solute concentrations remained unchanged over the same period of placebo administration.

Conclusions: The significant decline in the plasma concentrations of multiple uremic retention solutes provides evidence of the importance of the gut microbiome in the generation of these solutes. The reduction in concentrations of indoxyl sulfate, p-cresyl sulfate, and kynurenic acid, recognized as likely uremic toxins, suggests that altering the gut microbiome might provide a valuable therapeutic strategy in the management of ESRD.

Funding: Private Foundation Support

Linear Trends in Solute Concentrations Over 8 Weeks

Solute	Placebo	Vancomycin	Change	p-value
Hippuric acid	3.50	-26.60	-30.10	0.026
Phenyl Acetyl Glutamine	1.63	-21.78	-23.41	0.002

FR-PO762

The Amino Acid Losses Are Equal Between Pre and Post On-line HDF Under the Same Dialysis Dose (Kt/V)

Shunichiro Urabe,[1] Motoko Kato,[1] Emi Hiyama,[1] Asami Kurii,[1] Toru Hyodo,[2] Makoto Kitamura,[3] Miho Hida,[3] Yasuhisa Kurata,[3] Kenichi Kokubo.[4] [1]*Eijin Clinic, Hiratsuka, Japan;* [2]*Eijin Clinic and Cambodian Association of Nephrology, Hiratsuka, Japan;* [3]*Kurata Hospital, Hiratsuka, Kanagawa, Japan;* [4]*Kitasato University School of Allied Health Sciences, Sagamihara, Japan.*

Background: We analyzed the amino acid losses that occur on performing pre-dilution on-line HDF (Pre-HDF) and post-dilution on-line HDF (Post-HDF) because the amino acid kinetics of HDF has been unknown until now.

Methods: We compared the total amino acid, total non-essential/essential/branched-chain amino acid amount into the total waste fluid, and Kt/V (urea) between 9 patients undergoing Pre-HDF (7 males, 4 diabetic, mean age: 72.4±2.1 years) and the same patients receiving Post-HDF. The mean blood flow rate in the former and latter was 222.2±24.8 and 200.0±0.0 mL/min, respectively. The dialysate flow rate was 328.7±48.6 and 556.0±0.0 mL/min, respectively. The replacement fluid flow rate was 251.3±27.4 and 44.0±0.0 mL/min, respectively. The replacement fluid volume was 56.7±6.2 and 10.0±0.0 L, respectively.

Results: In the Pre-HDF group, the total and total non-essential amino acid losses (4814.3±1055.6 and 3058.4±632.0 mg, respectively) were not significantly different from in the Post-HDF group (5257.3±698.9 and 3421.9±446.8 mg, respectively) (p = 0.180 and 0.116, respectively). In the former, the total essential amino acid (1755.9±503.3 mg) was

not significantly different from in the latter (1835.3±351.0 mg) (P=0.401) and also in the former, the branched-chain amino acid (780.2±224.2 mg) was not significantly in the latter (816.4±210.1 mg) (P=0.139). In the Pre-HDF group, the urea and Cr reduction rates were 69.5±7.4 and 63.2±6.7%, respectively. In the Post-HDF group, the values were 70.9±4.4 and 64.8±3.9%, respectively. The values showed no significant differences between the Pre-HDF and Post-HDF group (Urea: P=0.354, Crea: P=0.309). The Kt/V (urea) values in the former and latter were 1.46±0.28 and 1.45±0.19, respectively; there was no significant difference (p=0.862).

Conclusions: Under the same dialysis dose of Kt/V for urea, the amino acid losses were same between Pre-HDF and Post-HDF, suggesting that the moderate volume Post-HDF (replacement fluid volume: around 10.0 L) is as favorable as the Pre-HDF as a blood purification method from the viewpoint of nutrition.

FR-PO763

Safety and Effectiveness of Sucroferric Oxyhydroxide in Dialysis Patients: 24-Month Interim Analysis of the VERIFIE Study

Markus Ketteler,[8] John Boletis,[9] Angel Luis M. De Francisco,[11] Marc G. Vervloet,[1] Philip A. Kalra,[2] Denis Fouque,[3] Piergiorgio Messa,[7] Manuela Stauss-Grabo,[13] Anja Derlet,[13] Viatcheslav Rakov,[4] Sebastian Walpen,[4] Linda Ficociello,[6] Jacques B. Rottembourg,[12] Christoph Wanner,[5] Jorge B. Cannata-Andia.[10] *[1]VU university medical centre, Overveen, Netherlands; [2]Salford Royal Hospital NHS Trust, Salford, United Kingdom; [3]University Claude Bernard, Pierre Benite, France; [4]Vifor Fresenius Medical Care Renal Pharma, Glattbrugg, Switzerland; [5]Nephrology, University Hospital, Wuerzburg, Germany; [6]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [7]Nephrology, Maggiore Hospital, Milan, Italy; [8]Klinikum Coburg GmbH, Coburg, Germany; [9]Laiko University Hospital, Athens, Greece; [10]Medicine, Hospital Universitario Central de Asturias, Oviedo, Spain; [11]Hospital Univ. Marques de Valdecilla, Santander, Spain; [12]Nephrology, Groupe Hospitalier Pitié-Salpêtrière, Paris, France; [13]Clinical Research, Fresenius Medical Care, Bad Homburg, Germany.*

Background: Sucroferric oxyhydroxide (SFOH) is an iron-based phosphate binder (PB) for the treatment of hyperphosphatemia in dialysis patients (pts).

Methods: VERIFIE is a non-interventional prospective, multicenter, European cohort study evaluating the real-world safety and effectiveness of SFOH. This interim analysis was performed 24 months after first-patient, first-visit.

Results: 1075 pts (mean age 61.5 yrs; 66.7% male) were included in the safety analysis set, with 1023 pts in the full analysis set to evaluate SFOH effectiveness. Prior PB use was reported for 58.9% of pts at study entry, while 40.1% received concomitant PBs during the study. The mean observation period was 186 days. In total, 378 (35.2%) pts reported ≥1 adverse drug reaction, the vast majority of which were gastrointestinal-related (**Panel A**). 263 (24.5%) pts withdrew from the study during the observation period. No statistically significant changes in serum ferritin, TSAT or hemoglobin were observed from baseline (BL) to Month 18. Mean daily dose of SFOH during observation period was 1144.3 mg (2.3 pills/day). Overall, serum phosphorus (sP) levels decreased significantly from 6.3 mg/dL at BL to 5.4 mg/dL at Months 6, 12 and 18 with SFOH therapy ($p \leq 0.0001$). The % of pts achieving sP control (≤5.5 mg/dL) from BL to Month 6 increased across all participating countries (**Panel B**).

Conclusions: The safety profile of SFOH was comparable to that observed in the Phase 3 study; no new safety signals were identified. SFOH effectively reduced and maintained sP levels, with a relatively low pill burden.

FR-PO764

Changes in Serum Magnesium During Hemodialysis in Three Facility Settings

Eduardo K. Lacson,[1,2] Gideon N. Aweh,[3] Dwayne J. Bergeaux,[6] Deana Fontenot,[2] Bhabendra Putatunda,[4] Nand K. Wadhwa.[5] *[1]Tufts University School of Medicine, Boston, MA; [2]Dialysis Clinic Inc., Nashville, TN; [3]Dialysis Clinic, Inc., Nashville, TN; [4]Nephrology Associates PC, Murfreesboro, TN; [5]Stony Brook Medicine, Stony Brook, NY, East Setauket, NY; [6]DCI, Crowley, LA.*

Background: A quality improvement project monitored serial serum magnesium (sMg) after a manufacturer changed dialysate magnesium (dMg) content. Three Medical Directors decided to order facility-wide post-dialysis sMg in addition to pre-dialysis sMg. Only 60-75% of sMg diffuse during hemodialysis (HD) due to sequestration by albumin a.k.a. the Gibbs-Donnan effect.

Methods: All maintenance HD patients in three outpatient units were included and sMg were tested with the monthly blood draws for December, 2017. Facility A utilized a dMg of 1.0 mEq/L which is most commonly used by DCI, a non-profit dialysis provider. Facility B also utilized dMg of 1.0 mEq/L but routinely gave oral magnesium supplements to target pre-dialysis sMg of ~2.0 mEq/L. Facility C utilized a dMg of 1.6 mEq/L with a citrate-based bath for over three years.

Results: The facilities (A-B-C) had varying levels of pre-dialysis sMg with A having levels consistent with other DCI facilities at ~1.8 mEq/L.; B had higher pre-dialysis sMg of ~2.0 mEq/L consistent with its target; and C also had elevated pre-dialysis sMg consistent with prior reports at dMg ~1.5 mEq/L. At dMg = 1.0 mEq/L A (representing usual care) had ~10% decline of sMg post-dialysis compared to ~17% decline in B, which started with higher pre-dialysis sMg. The sMg was unchanged in C with no net removal at dMg of 1.6 mEq/L. Results are summarized in the table.

Conclusions: Serum magnesium did not fully equilibrate with dialysate consistent with the Gibbs-Donnan effect. Net sMg removal increases with higher sMg levels at dMg of 1.0 mEq/L; At dMg of 1.6 mEq/L, sMg is maintained at ~2.1 to 2.2 mEq/L with no net dialytic magnesium removal. These findings illustrate what could be expected in a comparative effectiveness study comparing dMg at 1.0 vs. 1.5 mEq/L.

Pre- & Post-HD Magnesium Under 3 Different Settings

Facility	Dialysate Mg	Oral Mg Supplement	N	Pre-HD Mg	Post-HD Mg	% Change
A	1.0 mEq/L	No	52	1.79 ± 0.25	1.61 ± 0.10	-10%
B	1.0 mEq/L	Yes	131	2.07 ± 0.27	1.71 ± 0.12	-17%
C	1.6 mEq/L	No	42	2.15 ± 0.31	2.15 ± 0.19	0%

Mg = Magnesium; Note: Pre-HD & Post-HD serum magnesium shown as mean +/- standard deviation, in mEq/L.

FR-PO765

High Risk of Pyogenic Spondylitis in CKD Patients: Its Characteristics and Incidence

Rikako Oki, Hidekazu Moriya, Yasuhiro Mochida, Kunihiro Ishioka, Sumi Hidaka, Takayasu Ohtake, Shuzo Kobayashi. *Shonan Kamakura General Hospital, Kamakura, Japan.*

Background: Pyogenic spondylitis is a rare but life- threatening disease. Mortality has been reported to be approximately up to 11% with the incidence of 2.5 - 7.4/100,000 population per year, particularly more in elderly people or compromised hosts. CKD patients often have infectious complications. However, little information is available regarding the incidence of this disorder in CKD patients. In this study, we examined to clarify the incidence and characteristics of pyogenic spondylitis in CKD patients.

Methods: A retrospective observational study was conducted in our hospital. Fifty-seven patients (45 CKD patients without HD (eGFR < 60ml/min/1.73m^2) [ND] and 12 HD patients [HD]) were diagnosed to have pyogenic spondylitis between January 2012 and October 2016. We investigated age, disease background, affected site, causative microorganism, therapy, hospitalization period, mortality rate, causes of death in ND group and HD group.

Results: Median of age in all patients was 79 years old (IQR: 72-86): 54% were male, 30% had diabetes and 21% were HD patients. In-hospital mortality was 23%, and average hospitalization period was 55 days. Staphylococci species were the most frequent pathogen (49%). Comorbidities are diabetes (30%), ischemic heart disease (17.5%), peripheral vascular disease (11%), and cerebral vascular disease (10%). There was no significant difference in hospitalization period and mortality rate between ND and HD group. The rate of pyogenic spondylitis caused by Staphylococci tended to be higher in HD group(P=0.056). Fifty percent of pyogenic spondylitis developed due to infection of AV fistula (AVF), and the causative microorganism of all cases due to infection of AVF was Staphylococci.

Conclusions: Mortality of pyogenic spondylitis is high in CKD patients. Bacteremia caused by blood access infection is a risk factor of pyogenic spondylitis and more attention should be paid to infection of AVF.

FR-PO766

Long Term Effects of Expanded Hemodialysis (HDx) on Clinical and Laboratory Parameters in a Large Cohort of Dialysis Patients

Alfonso Bunch,[1] Lars-Goran Nilsson,[2] Jasmin Vesga,[1] Freddy Ardila,[1] Eduardo Zuniga,[1] Juan Alarcon,[1] Adriana M. Suarez,[1] Ricardo Sanchez,[3] Mauricio Sanabria.[4] *[1]RTS, Bogota, Colombia; [2]Baxter International Inc., Lund, Sweden; [3]Universidad Nacional de Colombia, Bogotá, Colombia; [4]RTS Baxter, Bogota, Colombia.*

Background: Expanded hemodialysis (HDx) enabled by medium cut off membrane provides clearance of large middle molecules which have been linked to inflammation, immune modulation and atherosclerosis. The long term effects of HDx on serum levels of small solutes and albumin has not been investigated in large cohort of patients.

Methods: Multicenter prospective study in prevalent hemodialysis patients, older than 18 years old; enrolled from September 1 to November 30 of 2017, and converted to HDx using Theranova 400 (3 sessions per week, 4 hours per session, same heparin dose). Albumin assay used was bromocresol blue with laboratory reference values between 3,5 gr/dl – 5,1 gr/dl Measurements were done at baseline, week 2, and month 1,2,3,4,5,6; descriptive statistics and ANOVA were used.

Results: We analyzed data on 524 patients, 61.6% (n=323) men, mean age 60.1 years (SD=15.3), dialysis vintage was 5.4 years (SD=5.01). We did not observe clinically significant differences in laboratory variables after 6 months of intervention with expanded hemodialysis; details are presented in Table 1. We found an initial small decrease in serum albumin level which stabilized and within the normal range per our laboratory references. See Table 1 Dialysis performans adequacy (Kt/V) was achieved. No clinically significant differences in laboratory values at 6 months with HDx was observed (Table 2).

Conclusions: The expended hemodialysis (HDx) shows a very good safety and performance profile during the first three months of use.

In-Vivo Dialysis Kinetics of 300 mL/min and 500 mL/min Dialysate Flows

Dimitri A. Augustin,[1] Leslie A. Spry,[2] Sarah S. Prichard,[3] Glenn M. Chertow,[1] Luis Alvarez.[4] *[1]Stanford University School of Medicine, Palo Alto, CA; [2]Unafilliated, Lincoln, NE; [3]Unafilliated, Montreal, QC, Canada; [4]Palo Alto Medical Foundation, Palo Alto, CA.*

Background: Conventional dialysate flow rates (Q_D) are typically 500-800ml/min with the intent to maximize urea removal during hemodialysis. We previously conducted kinetic modeling of 300 ml/min compared to 500 ml/min (Q_D) and concluded that lower Q_D would be expected to provide adequate hemodialysis. Little is known about the kinetics of dialysis with a 300 ml/min (Q_D) since the bulk of literature focuses on (Q_D) above 500ml/min. We present in-vivo kinetic testing of hemodialysis patients with 500ml/min and 300ml/min (Q_D) and evaluate the differences in kinetic curves.

Methods: The study group included 6 patients undergoing chronic hemodialysis via a fistula (n=4) or graft (n=2). Mean age was 58 years; mean weight was 85kg. We performed a prospective, open label, randomized, cross-over evaluation of in-vivo kinetics of serum urea, phosphorus, and other solutes at variable (Q_D). All patients participated in 2 complete dialysis sessions in each of 3 treatment conditions: 1. 500ml/min (Q_D), 2. 300ml/min (Q_D), and 3. 300ml/min (Q_D) with extended time.

Results: The mean urea kinetic curves with (Q_D) 300ml/min and 500ml/min mirrored each other in all 6 patients. The figure displays data for the 3 patients with 240 minutes prescriptions. The inverted curves include an initial steep decline and gradual trough at the end of hemodialysis treatment; the curves conclude with a slight rebound curve within an hour post treatment. Mean serum beta$_2$ microglobulin, bicarbonate, potassium, phosphate, and sodium all followed similar kinetic curves during Q_D 300ml/min and 500ml/min.

Conclusions: With a fixed dialyzer size and blood flow rate, solute kinetics of 300 ml/min (Q_D) are similar to those of a 500 ml/min (Q_D).

FR-PO768

Neutrophils to Lymphocytes Ratio Prior to Death in Hemodialysis Patients: Results from the Global MONDO Initiative

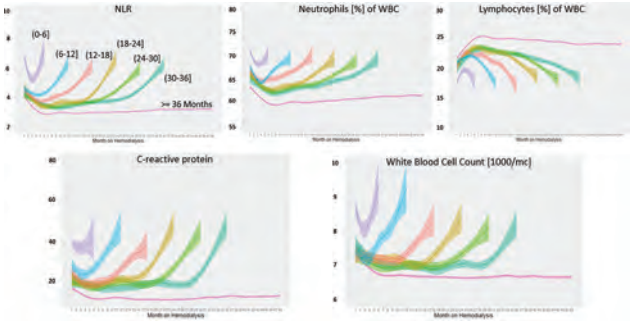
Xiaoling Ye,[1] Dalia E. Yousif,[1] Jochen G. Raimann,[1] Yuedong Wang,[6] Jeroen Kooman,[2] Frank van der Sande,[2] Stefano Stuard,[3] Bernard J. Canaud,[4] Adrian M. Guinsburg,[3] Len A. Usvyat,[5] Peter Kotanko.[1] The MONDO Initiative
[1]Renal Research Institute, New York, NY; [2]Maastricht University Medical Centre, Maastricht, Netherlands; [3]Fresenius Medical Care, Bad Homburg, Germany; [4]FMC Deutschland GmbH, Bad Homburg, Germany; [5]Fresenius Medical Care North America, Melrose, MA; [6]University of California - Santa Barbara, Santa Barbara, CA.

Background: Among patients(pts) with end stage renal disease (ESRD), chronic inflammation is highly prevalent and associated with adverse clinical outcomes including CVD and death. Understanding the dynamics of readily available inflammatory markers (NLR,CRP,WBC) across different survival time is an essential way to explore patient- and process-related factors that contribute to adverse outcomes.

Methods: MONDO Initiative is a global retrospective cohort study that contained data of 150k+ pts with in-center HD from 41 countries&6 continents. Adult pts who died within the first 36 months (mos) on HD were stratified into 6 groups, pts died from 0-6, 6-12,12-18,18-24,24-30 and 30-36 mos after HD initiation. Pts who survived 36+ mos were chosen as the control group. Monthly average of NLR, CRP, Neutrophils, Lymphocytes, WBC were obtained, cubic spline function were applied to access the trends and rate of changes for each of the parameters of interest. Additionly, subgroup analysis were performed to explore the sex and regional differences.

Results: 18,276 incident HD pts were included, 2,068 died within 6 mos,1,231 died 6 -12 mos,971 died 12 -18 mos,792 died 18-24 mos,721 died 24-30 mos, 648 died 30-36 mos, and 12,295 survived 36+ mos. For pts who with shorter survival time, NLR, Neutrophils, Lymphocytes, WBC&CRP were observed to be higher at HD initiation. Additionaly, all the inflammatory markers were declined after the HD initiation and reached nadir from 3-0 mo, vary by pts' survival time. All the markers with an accrelated trend mos before death. For pts who survived 36+ mos, NLR, CRP and WBC seem to be stable after they reached the nadir. No sex and regional differences were observed.

Conclusions: Understanding the dynamics of readily available inflammatory markers is an important way to explore patient- and process-related factors that contribute to outcomes. NLR variations over survival time may have a prognostic impact.



FR-PO769

Are Cytokines and Body Composition Surrogate Markers for Outcomes in Hemodialysis Patients?

Ana Rita M. Martins,[1,2] Inês C. Moreira,[1] Andre L. Weigert.[1,2] *[1]Davita, Óbidos, Portugal; [2]Pharmacology Department, Medical School; Lisbon University, Lisbon, Portugal.*

Background: Obesity has been linked to better outcomes in hemodialysis (HD) patients (pts). Persistent inflammation, an important contributor to wasting, is associated with increased levels of tumor necrosis factor-alpha (TNF-α), hepcidin (Hpc) and soluble CD-163 (sCD163). TNF-α is a pro-inflammatory adipokine, sCD163 is a marker of macrophage activation and Hpc is the main regulator of hepcidin-ferroportin axis, all relevant inflammatory mediators. Our aim was to identify potential targets to minimize inflammation in HD pts.

Methods: Prospective cohort study with 160 prevalent HD pts. Baseline demographic data, blood biochemistry, serum inflammatory markers, comorbidities, anthropometric parameters and multifrequency bioimpedance were evaluated.

Results: In our cohort, 91 pts were male, mean age was 67 years, 40% had diabetes (DM) and average time on HD was 92 months. During the follow up (39±16 months), 38 pts died of cardiovascular (CV) events. Charlson comorbidity score was 4.4±2.3 and body index mass was 26.3±4.6 kg/m^2. Pts were divided in two groups, according to their lean mass (LM): 51% had LM≥27%; no differences seen in age and time on HD between the two groups. Pts with LM≥27% had lower TNF-α (p=0.004), sCD163 (p=0.047), Hpc (p=0.038), hospital admissions (p=0.048) and had higher serum albumin (p=0.008). In a Kaplan Meier test, pts with higher LM had a better survival (139 vs 117 months; log rank 5.1; p=0.024). TNF-α was positively correlated with ferritin (p=0.005); sCD-163 was negatively correlated with serum albumin (p=0.02) and positively with CV events (p=0.025). Hpc was positively correlated with ferritin (p=0.018) and with cardiac failure (p=0,005) and negatively with triglycerides (p=.005). In a Cox hazards model, LM <27% was an independent predictor of mortality (HR=2.82; p=0.021; IC 95% 1.2-6.8), adjusted for age and DM.

Conclusions: We observed an association between a higher LM and better clinical outcomes and attenuation in inflammatory markers. Further studies of whether interventions that optimize body composition and interfere with the inflammatory profile of HD pts will improve survival are warranted.

FR-PO770

Immunogenicity and Safety of a Single Booster Dose of Heplisav-B in Patients Undergoing Hemodialysis

Randall N. Hyer, Robert Janssen. *Dynavax Technologies, Berkeley, CA.*

Background: Patients with end-stage renal disease (ESRD) undergoing hemodialysis have a greater risk of hepatitis B virus (HBV) exposure, a lower seroprotection response to primary HBV vaccination, and experience a more rapid decline in antibody to HBV surface antigen (anti-HBs) levels compared with healthy subjects. Anti-HBs levels should be assessed annually, and a booster provided if levels decline to <10 mIU/mL. Heplisav-B® is a TLR9-agonist-adjuvanted HBV vaccine with higher protection rates than commonly used alum-adjuvanted HBV vaccine (Engerix-B®), particularly in populations known to be hyporesponsive. This phase 3, randomized, open-label study assessed the immunogenicity of a single booster dose of Heplisav-B in patients with ESRD receiving hemodialysis who had previously received HBV vaccinations.

Methods: Adult patients with or without seroprotection from at least 1 HBV vaccine series (prior responders and prior nonresponders, respectively) and with anti-HBs levels <10 mIU/mL were randomized 1:1:1 to receive a booster vaccination of Heplisav-B, Engerix-B, or Fendrix (not available in the US). Seroprotection rates (SPRs) (proportion of patients with anti-HBs ≥10 mIU/mL) were assessed at week 4. Here we report the comparison between Heplisav-B and Engerix-B.

Results: A total of 76 prior nonresponders (Heplisav-B, n=38; Engerix-B, n=38) and 28 prior responders (Heplisav-B, n=16; Engerix-B, n=12) were enrolled. Among prior nonresponders, a single dose of Heplisav-B induced a higher SPR at week 4 compared with a double dose of Engerix-B (42.1% vs 18.9%); treatment difference was 23.2% (95% CI: 1.4, 43.1). Among prior responders, SPRs at week 4 were comparable (Heplisav-B: 80.0% vs Engerix-B: 90.9%; treatment difference: –10.9% [95% CI: –41.3, 23.5]). In a post hoc analysis based on criteria established in prior phase 3 trials, the SPR at week 4 with Heplisav-B group was significantly higher than with Engerix-B among prior nonresponders. Adverse events (AEs), serious AEs, and deaths were comparable between groups.

Conclusions: A single booster of Heplisav-B provides better protection against HBV than a double dose of Engerix-B with a comparable safety profile in patients undergoing hemodialysis who were nonresponders to prior HBV vaccination. **Acknowledgement:** Writing assistance, funded by Dynavax Technologies, provided by Caroline Walsh Cazares, PhD, of JB Ashtin.

Successful Hepatitis B Seroconversion Using Intradermal Engerix-B in Hemodialysis Patients Unresponsive to Two Courses of Standard Double-Dose Intramuscular Vaccine - Real World Experience

Daniel L. Landry,[2,1] Gregory L. Braden,[2,1] Spencer Hodgins,[2] Jeffrey Mulhern.[1]
[1]Kidney Care and Transplant Services of New England, Springfield, MA; [2]Baystate Medical Center, Springfield, MA.

Background: Double dose intramuscular (DDIM) hepatitis B vaccination of nonimmune incident hemodialysis patients remains standard of care. Given best case reported seroconversion rates of only 70 percent in this population following a standard DDIM regimen, a significant number of hemodialysis patients are deemed non-responders, remain at risk for infection and ultimately require cohorting away from isolation rooms when an actively infected patient is present. Multiple protocols have been recommended to convert these non-responders including administration of a single DDIM booster dose, repetition of an entire DDIM series or conversion to an intradermal delivery protocol. We report our experience with short-term intradermal hepatitis B vaccination in 28 patients who failed to respond to two courses of standard DDIM hepatitis B vaccination.

Methods: Non-responder patients were defined as those with an anti-HBsAg titer < 10 mIU/mL 30 days after receiving two DDIM series consisting of Engerix-B (GlaxoSmithKline) 40 mcg at months 0, 1, 2 and 6. All non-responders subsequently received 5-10 mcg intradermal Engerix-B every two weeks for a total of 8 doses. An anti-HBsAg titer > 10 mIU/mL at one year after completion of intradermal dosing was considered a successful response.

Results: Twenty-five of 28 (89%) patients unresponsive to two courses of DDIM Engerix-B responded to intradermal dosing with a mean anti-HBsAg titer of 258 mIU/mL at 1 year. Twenty of the 25 patients who seroconverted responded with a titer > 30 mIU/mL. No significant differences in age, race, gender, dialysis access type, comorbidities, nutritional parameters, bone mineral markers, dialysis adequacy, or dialysis vintage were noted between the two groups. There were no reports of adverse events associated with intradermal dosing.

Conclusions: Intradermal dosing of Engerix-B to hemodialysis patients unresponsive to two courses of DDIM vaccination is highly effective in achieving a sustained serologic response. The practice of administering a second DDIM vaccination series to non-responder hemodialysis patients should be abandoned and replaced with an intradermal Engerix-B dosing regimen.

FR-PO772

HCV in Hemodialysis Patients: Where Is the Difference?

Adrian M. Guinsburg,[1] Marcelo D. Ferder.[2] *[1]Fresenius Medical Care, Moron, Argentina; [2]Fresenius Medical Care Argentina S.A., Buenos Aires, Argentina.*

Background: Several authors have described worst outcomes in HCV patients (pts) due to cardiovascular (CV) diseases, cirrhosis and hepatocarcinoma. Though, outcomes in HD pts are controversial. The aim of this study was to identify HCV+ pts characteristics affecting long term survival in HD.

Methods: Pts from Fresenius Medical Care Argentina database were included and classified as HCV+ when HCV antibodies were detected by ELISA and then followed until death, transplant or lost to follow-up. Differences in baseline labs were compared and all-cause, CV and liver mortality were analyzed using uni and multivariate Cox models.

Results: 35,707 incident pts were included. Age 57.1±16.9 yrs, gender 57.7% male, DBT 16.5%, CVD 12%, neoplasia 1.1%. HCV+ prevalence 5.9% (2121). Mean follow-up time 3.45 ± 3.2 yrs CI [3.42 - 3.48]. HCV+ pts were younger (52.3 ± 15 vs 57.4± 17 yrs), had higher Hb (9.98 ± 2.1 vs 9.28 ± 1.9 mg%), higher ferritin (543 ± 646 vs 469 ± 521 ng/ml), higher Ca (8.94 ± 1.1 vs 8.59 ± 0.9 mg%), higher albumin (3.69 ± 0.5 vs 3.61 ± 0.6 g/dl), lower CRP (11.9 ± 21 vs 18.8 ± 36 mg/l), higher liver enzymes (AST 32.5 ± 28 vs 21.4 ± 24, ALT 34.6 ± 41 vs 22.2 ± 58, ALP 377.7 ± 438 vs 256 ± 236 IU/l) and lower total cholesterol (163.5 ± 44 vs 172.8 ± 51 mg%). Surprisingly, unadjusted Cox models showed advantage in HCV+ for all-cause mortality (n=35,707, events 15,839 RR 0.87 p < 0.0001, CI [0.82-0.93]) and CV mortality (n=35,707, events 2,545 RR 0.31 p < 0.0001, CI [0.24-0.39]) but no difference for liver mortality. After adjustment to case-mix, nutritional and inflammation markers, survival advantage disappears for all-cause (n=4,283, events 1,227 RR 1.17 pNS) and CV mortality (n=4,283, events 470 RR 1 pNS).

Conclusions: In our study HCV+ pts showed lower CRP and higher Hb levels, as well as lower all-cause and CV mortality. Lower CRP levels were previously reported associated with disturbance in production of CRP[1]. Higher Hb levels were published related to increased production of EPO in the liver[2]. Even paradoxical unadjusted effect of HCV+ was reported[3], it's not in accordance with several studies and may be related to ameliorated inflammatory response. In fact, adjusting to inflammatory markers vanished this effect. Prospective, controlled trials may be needed to identify HCV effect on HD patients [1]Braz J Med Biol Res. 2005;38:783-8 [2]Blood Purif 2011;32:69–74 73 [3]J Bras Nefrol 2010;32(4): 335-339

FR-PO773

Procalcitonin as a Predictor of Sepsis in Patients with ESRD

Raman Dhillon,[1] Shideh Doroudi,[2] Puja Patel.[1] *[1]St. Joseph's University Medical Center, Clifton, NJ; [2]Family Medicine, St. Joseph's University Medical center, Clifton, NJ.*

Background: Procalcitonin is a helpful biomarker in the diagnosis of sepsis in critically ill patients, especially in identifying occult bacterial infections. Procalcitonin levels rise 3-6 hours after onset of sepsis, and peak at 24-48 hours. It has been found that renal clearance of procalcitonin is low, and the use of procalictonin in kidney disease has not been widely studied.

Methods: A Retrospective chart review of patient admitted with diagnosis of Sepsis and End Stage Renal disease was reviewed for 57 months. All patients with end stage renal disease and sepsis with procalcitonin measured at admission or during hospitalization were included. We used two-way ANOVA table to explore the relationships between procalcitonin, lactic acid levels, hemodialysis, and cultures.

Results: Of 362 patients, 190 were male and 172 were female with ages ranging from 30-100 years. 158 of 362 patients were on hemodialysis. 210 of 362 had procalcitonin levels measured during hospitalization. Procalcitonin of these patients ranged from less than 0.05 to 235.94 ng/mL. 148 of 362 patients had lactic acid measured, with 62 having lactic acid ≥ 2 mmol/L. Of the 362 patients, 41 had positive cultures. By using our method of statistical analysis, we found that only age was statistically significant, with a P-value 0.0107, meaning that procalcitonin levels were increased with increasing age. We also found that lactic acid and culture growth when compared with procalcitonin levels, were not statistically significant, with P-values of 0.4095 & 0.9148, respectively.

Conclusions: Procalcitonin's role has not been well studied in patients with end stage renal disease on hemodialysis, although it has been found that it is the best predictor of infection in hemodialysis patients. Previous studies have found that higher cutoff levels of procalcitonin should be used to rule in or rule out infection, and it has been found that a procalcitonin of ≥0.5 ng/mL can be used to rule in infection in patients on hemodialysis. Our study looked at patients with end stage renal disease on hemodialysis and sepsis comparing procalcitonin, lactic acid and culture growth. We found that lactic acid and culture results were not statistically significant, meaning that those values may be negative despite positive procalcitonin levels. Therefore, clinical judgment should be used when a patient has sepsis.

FR-PO774

Analysis of Infection Rate According to Natural Killer Cell Activity in Hemodialysis Patients

Seok-hyung Kim,[1] Jung eun Lee,[2] Hyung Jong Kim,[3] Hoon Young Choi,[1] Hyunwook Kim,[1] Tae hoon Kim,[1] Mirae Lee,[1] Taeyeon Kim,[1] Hyeong cheon Park.[1] *[1]Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Yongin Severance Hospital, Yongin-si, Republic of Korea; [3]Bundang CHA Medical Center, CHA University, Seongnam, GYEONGGI-DO, Republic of Korea.*

Background: Natural killer (NK) cells are lymphocytes of innate immune system that play a key role in host defense against diverse range of pathogens. NK cell deficit has been suggested in patients undergoing hemodialysis (HD) with conflicting results regarding their activity and impaired antimicrobial activity in host defense. Aim of this study was to determine the susceptibility to bacterial infection according to NK cell cytotoxic activity in HD patients.

Methods: Clinically stable HD patients without active malignancy or immunosuppressive medications were enrolled (N=204). NK Vue™ assay (ATGen Co. Seoul, Korea), that uses serum of ex vivo stimulated whole blood to detect interferon (IFN)-γ secreted from NK cells, was used to assess NK cell activity. This NK cell activity was consecutively assessed at six-month intervals from 2015 to 2017. We further investigated the incidence of major infections requiring intravenous antibiotics or hospitalization according to NK cell activity during the study period.

Results: Mean patient age was 61.4 ± 13.8 years and 58.8% were male. During the study period, a total of 214 major infections occurred. Mean baseline NK cell activity was 586.2 ± 540.7 pg/mL. Decreases in NK cell activity were significantly correlated with incidence of major infections. Furthermore, mean changes in NK cell activity were significantly different between periods at which infections have occurred and those periods free of infections, -71.7 ± 875.7 pg/mL and 110.5 ± 846.0 pg/mL, respectively (P=0.016). In univariate logistic analysis, older age [odds ratio (OR): 1.018; 95% CI, 1.004-1.032, P=0.010], higher serum C-reactive protein (CRP) [OR: 1.052; 95% CI, 1.010-1.096, P=0.014] and decreased NK cell activity [OR: 0.975; 95% CI, 0.955-0.995, P=0.017] were associated with higher incidence of infection. After adjusting for age, sex and CRP, decreased NK cell activity was independently associated with higher incidence of infection. [OR: 0.976; 95% CI, 0.956-0.996, P=0.019] Increases in CRP was not significantly correlated with decreases in NK cell activity (R=-0.056, P=0.189).

Conclusions: Our results show higher incidence of infection during period of greater decrease in NK cell activity from baseline. NK cell activity could thus be a useful marker to predict risk of infection in HD patients.

FR-PO775

Short-Chain Fatty Acids Increase CD25HighCD127Low-Regulatory T-Cells in Patients with ESRD

Fabian Meyer,[2] Ulrik Stervbo,[2] Felix S. Seibert,[2] Frederic Bauer,[2] Benjamin Rohn,[1] Mikalai Nienen,[2] Timm H. Westhoff,[2] Nina Babel.[2] *[1]Marien Hospital Herne, Herne, Germany; [2]University Hospital Marien Hospital Herne, Herne, Germany.*

Background: Patients with End Stage Renal Disease (ESRD) suffer from an elevated systemic inflammation, which can lead to an increased morbidity and mortality. Previous data obtained from the EAE mouse model of MS, revealed the potential of disease amelioration by short-chain fatty acids. This clinical improvement was accompanied by increased frequency of regulatory T-cells (Treg). We hypothesized that the elevated systemic inflammation of patients with ESRD could be reduced though a dietary supplement with a short-chain fatty acid.

Methods: ESRD patients and healthy volunteers supplemented their diet with a daily dose of 2 x 500 mg propionic acid (PA) for 30 days. PBMCs were isolated at day 0, 15, and 30 of the PA supplement and 60 days later for a follow-up after PA supplementation. The baseline status and possible physiological oscillations in cell numbers were assessed through sampling at days -60, -45, and -30. We established a 12 color flow cytometry panel to quantify Tregs, and characterized them with respect to their developmental and gut homing phenotype through expression of CCR7/CD45RA and CCR9/β7 integrin, respectively. We also analyzed changes in functional activity of antigen-specific memory/effector T cells by stimulation with recall antigens. Here, we used stimulation with Tetanus/Diphteria vaccine and subsequent evaluation by 13 parameter flow cytometry.

Results: We observed a gradual and significant expansion in the frequencies of $CD25^{high}CD127^{low}$ Tregs in the ESRD patients and healthy volunteers already at day 15 of PA supplementation. At day 30, an increase of 20-35% as compared to Treg baseline counts was observed in both study groups. Treg numbers returned to baseline values after discontinuation of the PA supplement. Despite significant expansion of Tregs during PA diet, the responsiveness and functionality of effector T cells remained stable as demonstrated by the stable frequencies of antigen-specific T effector cells upon ex vivo stimulation.

Conclusions: Our data revealed that dietary supplements with short-chain fatty acids might have a beneficial effect on the elevated systemic inflammation of ESRD patients. The effect can be achieved through an expansion of circulating Tregs without affecting the antigen-specific memory response.

HBV Vaccination Non-Responders with ESRD Demonstrate Available Cellular Memory Immunity Against Hepatitis B Vaccine

Gounwa Awad, Mikalai Nienen, Ulrik Stervbo, Frederic Bauer, Felix S. Seibert, Timm H. Westhoff, Nina Babel. *University Hospital Marien Hospital Herne, Herne, Germany.*

Background: In the compromised immune system of patients with end-stage renal disease (ESRD) undergoing hemodialysis, the adequacy of host protection upon hepatitis B vaccination is crucial. Whereas seroconversion rates to hepatitis B (HBV) vaccine in this population is known to be lower than the general population, the cellular immune response to the vaccine in hemodialysis patients remain under study. Here, we functionally analyze and quantify HBV surface antigen (HBsAg)-specific T cells in patients with ESRD vaccinated against HBV with HBsAg vaccine. Cellular immunity against HBsAg and its correlation with humoral response were explored in 35 patients with ESRD undergoing hemodialysis and 13 healthy controls (HC).

Methods: Patients were divided according to their Hepatitis B vaccine titers into three groups: High responders (HR), Low-responders (LR), Non-responders (NR). Using multi-parameter flow cytometry HBsAg-specific T cells were quantified and functionally analyzed according to expression of activation markers CD40L and/or CD137 and cytokine release upon stimulation with HBsAg overlapping peptide pools. We also performed immunophenotyping of B cells, dendritic cells and regulatory T cells.

Results: HBsAg-specific CD4+T cells were detected not only in LR (88.8%) and HR (100%) but also in almost all NR; 78.6% of NR demonstrated HBsAg-specific memory T-cell response. Counts of HBsAg-specific CD4+CD40L+ T cells were significantly higher in HR compared to NR ($p<0.001$). No difference in cytokine release between the groups was. A correlation between vaccine-specific CD4+ T cell response and humoral response was identified ($r=0.7537$, $p=0.0021$). No significant difference was found in the number of myeloid and plasmacytoid dendritic cells between patients with ESRD of different titer groups. Interestingly, they were significantly higher in HR than in HC ($p<0.05$). A significantly larger Naïve B cell (IgD+CD27-) population was found in HR and HC compared to NR ($p<0.05$).

Conclusions: Our results show that HBV-specific memory T cells producing effector cytokines are detectable in humoral non-responders and might provide antiviral effects in case of HBV exposure in ESRD patients.

The Clinical Utility of Routine Screening of Multi-Drug Resistant Organisms in Hemodialysis Outpatients

Elizabeth S. Lee,[1] Adeera Levin,[2] Jacek Jastrzebski,[1] Mercedeh Kiaii,[1] John E. Antonsen.[3] *[1]University of British Columbia, Vancouver, BC, Canada; [2]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada; [3]Vancouver Island Health Authority, Victoria, BC, Canada.*

Background: Hemodialysis (HD) outpatients are routinely screened for Methicillin Resistant Staphylococcus Aureus (MRSA) and Vancomycin Resistant Enterococcus (VRE) despite limited information on effective MRSA/VRE control in outpatients. Yet, MRSA/VRE colonized patients are not subject to different care in the community. HD patients would be empirically treated for MRSA if clinically appropriate, regardless of their colonization status. Patients may have negative experiences from swab collection +/- cohort.

Methods: We aimed to assess the clinical utility of the current practices by evaluating a) the MRSA/VRE infection rates and b) the estimated costs of such practice for the local HD patients. We evaluated the 12-month-data on access related infection (bacteremia and exit site infection) in the two typical HD units, using a provincial renal database. We reviewed 1) the prevalence of MRSA/VRE access infections, 2) the relationship between colonization and infection in this cohort, and 3) the costs of routine screening and contact precaution practices for the provincial HD cohort.

Results: There were 52 access related infections (among 43/410 HD patients) (2016). 40/52 (77%) infections were not caused by MRSA or VRE (Figure 1). The prevalence rates for MRSA and VRE were 10-25% and 3-5% in both units. There was poor correlation between colonization and infection. The annual cost of provincial screening practice (2,200 prevalent and 600 incident HD patients) was estimated to be over 120,000 Canadian dollars.

Conclusions: We provide additional evidence demonstrating little clinical utility for routine MRSA/VRE screening in HD outpatients, which leads us to advocate for practice re-evaluation.

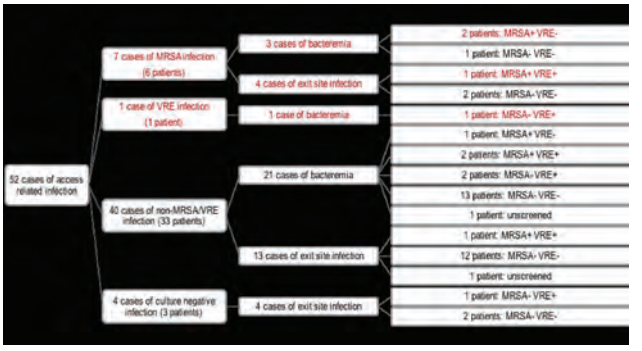

Figure 1. Number of MRSA/VRE infections among the 52 access related infections in the study HD units

Routine Screening for Staphylococcus aureus in Haemodialysis Patients – Is It Worthwhile?

Tayeba Roper,[1] James Scuffell,[2] Maggi Steele,[1] John Clark,[3] David Makanjuola.[3] *[1]Epsom & St Helier NHS Trust, Surrey, United Kingdom; [2]Epsom and St Helier University Hospitals NHS Trust, Surrey, United Kingdom; [3]St. Helier Hospital, Surrey, United Kingdom.*

Background: *Staphylococcus aureus* (*S. aureus*) is common in haemodialysis (HD) patients, with manifestations varying from asymptomatic colonisation to bacteraemia. This has led to the development of guidelines for routine screening for both methicillin-sensitive and methicillin-resistant *S. aureus* (MSSA and MRSA). We aimed to establish the effectiveness of screening and de-colonisation for *S. aureus* in a cohort of HD patients.

Methods: We screened all HD patients at a UK satellite unit between September 2009 and July 2010 for *S. aureus* carriage. Screening was at 0, 1, 2, 3, 6 and 9 months with nasal, groin and HD line site swabs, cultured on chromogenic agar. Isolates were characterised by antibiogram. Eradication with Chlorhexidine solution was given to all carriers. A further course of eradication therapy was given to those in whom repeat swabs were positive. Due to limited capacity, not all patients with MRSA were isolated in side rooms. Universal precautions were used in all cases. Clinical and demographic data were collected from patient records.

Results: 82 patients were included. 68% were male; median age was 68.5 years (range 57-78). 42% were carriers of *S. aureus*; 80% had MSSA, 20% had MRSA. 15/28 MSSA carriers underwent successful eradication; of these 8/15 re-acquired MSSA. 3/7 MRSA carriers underwent successful eradication, all three re-acquired the same strain of MRSA. MRSA antibiograms were identical in 2/7 patients. These patients dialysed on separate days, making transmission between them unlikely. All other MRSA strains had different antibiograms.

Conclusions: Our data show that *S. aureus* colonisation is common in HD patients. We found that, despite treatment, eradication is often short-lived or unsuccessful. We believe that *S. aureus* is often re-acquired from non-clinical areas such as hospital transportation, the home environment and perhaps close relatives/friends. We question the benefit of routinely screening for *S. aureus*, given the poor de-colonisation and high re-acquisition rates. The antibiotic resistance profile showed that there was no evidence of cross-transmission within the unit and in the absence of facilities to segregate colonised patients, we have shown that universal infection control measures are sufficient to prevent spread between patients.

FR-PO779

Vitamin D and Risk of Infection in Long-Term Dialysis Patients: A Systematic Review and Meta-Analysis

Guobin Su,[1,2] Zhuangzhu Liu,[2] Xindong Qin,[2] Hong Xu,[1] Xusheng Liu,[2] Zehuai Wen,[2] Bengt Lindholm,[1] Juan J. Carrero,[1] David W. Johnson,[3] Nele Brusselaers,[1] Cecilia S. Lundborg.[1] *[1]Karolinska Institutet, Stockholm, Sweden; [2]The Second Affiliated Hospital, Guangzhou University of Chinese Medicine, Guanghzou, China; [3]Princess Alexandra Hospital, Brisbane, QLD, Australia.*

Background: Infections are common and can be fatal in patients undergoing long-term dialysis. Current studies have shown conflicting evidence associating infection with vitamin D, which have not been systematically reviewed in this population

Methods: We searched PubMed, Web of Science, Cochrane Library, Embase databases and three Chinese databases, from inception through December 2017, for interventional (non-randomized or randomized controlled trials, RCTs), cohort and case-controlled studies on levels of serum 25-hydroxy vitamin D (25(OH)D); or use of vitamin D [supplemental nutritional vitamin D or vitamin D receptor activator (VDRA)] and infection (any infection, infection-required hospitalization or infection-related death, or composite), in long-term dialysis patients. We conducted a meta-analysis on the relative risk of infection and level of 25(OH)D or use of vitamin D.

Results: Of 2,440 reports identified, 17 studies met inclusion criteria, all with moderate quality, with 6 cohort studies evaluating 25(OH)D serum concentrations (N=5,714) and 11 (2 RCTs and 9 observational studies) evaluating the use of vitamin D (N=92,309). The risk of composite infection was 39% lower (relative risk [RR] 0.61, 95% CI 0.41-0.89) in those

with high/normal levels of 25(OH)D than in those with low levels. Compared to those who did not use vitamin D, the pooled adjusted risk for composite infection was 41% lower in those who used vitamin D (RR 0.59, 95% CI 0.43-0.81).

Conclusions: High/normal serum levels of 25(OH)-vitamin D and use of vitamin D, particularly VDRA, were each associated with a lower risk of composite infection in long-term dialysis patients.

Funding: Government Support - Non-U.S.

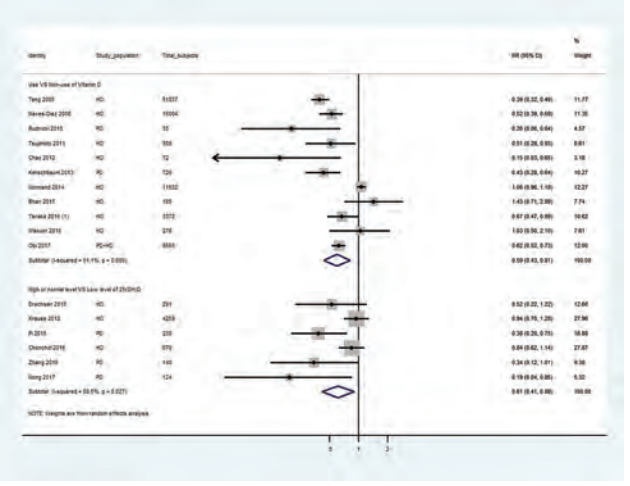

Figure: Forest plot depicting the meta-association between use and non-use of Vitamin D, and high/normal vs. low level of 25(OH)D, and risk for infection-related outcomes

FR-PO780

Vaccinations for Patients with ESRD: Crossroads Between Nephrology and Primary Care

Samuel Phen, Maryam Sattari, Shahab Bozorgmehri, Tezcan Ozrazgat-baslanti, Amir Kazory. *University of Florida, Gainesville, FL.*

Background: A subset of patients with end-stage renal disease (ESRD) who receive maintenance hemodialysis consider their nephrologist as their primary care provider (PCP). Preventive measures such as vaccinations markedly reduce mortality among these patients, yet their vaccination rates fall far below recommended. We aimed to (1) determine whether there is a difference in rates of compliance with recommended vaccinations between ESRD patients with PCPs (PCP group) and those without PCPs (No PCP group), and (2) identify differences in the characteristics between the PCP and No PCP groups.

Methods: We performed a cross-sectional survey of adult patients with ESRD in two outpatient dialysis centers affiliated with the University of Florida. A survey instrument was used to conduct one-to-one interviews. We used the Advisory Committee on Immunization Practices (ACIP) guidelines to determine eligibility for various vaccinations. We used X^2 or *t*-test to compare various characteristics.

Results: The mean age of the 132 study participants was 57.8 ±14.7 years. Sixty-six (50%) were male, 81 (61.3%) were African American, and 118 (89.4%) reported having a PCP. The PCP group had significantly higher rates of influenza vaccination (89.8% vs. 71.4%, p=0.046), pneumonia (75% vs. 42.9%, p=0.012), and tetanus (Tdap) (96.4 vs. 78.6%, p=0.006). The rates of vaccination for human papillomavirus (HPV), hepatitis B, and shingles were also higher among the PCP group but did not reach statistical significance. The PCP group was older than the no PCP group (mean age 58.9 vs. 47.9 years, p=0.008) with higher education level; none of the patients without PCP had higher education while 54.2% of those with PCP had undergraduate or graduate education; p<0.001). Men were more likely not to have a PCP (p=0.024), but no difference was observed among races.

Conclusions: This study suggests that among ESRD patients receiving hemodialysis, having a PCP is associated with higher rates of recommended vaccinations and that female gender, advanced age, and higher education level are associated with higher likelihood of having a PCP. These findings could have important implications for optimizing the preventive care of these patients. Future studies are needed to explore whether increasing the number of patients with a PCP will portend salutary impact on their care.

FR-PO781

Recent Trends in Emergency and Observation Room Admissions Among Medicare Dialysis Patients

Eric D. Weinhandl,[1,2] Debabrata Ray,[1] Kristine Kubisiak,[1] Allan J. Collins.[1,2] *[1]NxStage Medical, Inc., Victoria, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: Among dialysis patients, emergency room (ER) and observation room (OBS) admissions - excluding those resulting in transfer to inpatient care - may reflect several factors, including morbidity and insufficient availability of outpatient clinic appointments. We assessed trends in ER/OBS admissions among Medicare dialysis patients in 2014-2016.

Methods: We analyzed Medicare limited data sets. For each calendar week (Monday to Sunday) in 2014-2016, we identified all Medicare Parts A and B beneficiaries with ≥1 outpatient dialysis treatment. We excluded patients hospitalized on Sunday and not discharged before the end of the day. During the next week, we calculated the percentage of patients with ≥1 ER/OBS admission not resulting in transfer to inpatient care. We fit an ARIMA(1,0,0)x(0,1,0) model to the time series of admission percentages and used a likelihood ratio test to assess whether a secular trend remained after accounting for serial correlation and seasonality. We analyzed the aggregate population and strata defined by age, race, sex, concurrent Medicaid enrollment, US Census Division, and dialytic modality (hemodialysis, peritoneal dialysis).

Results: The average number of Medicare dialysis patients per week was more than 286,000. As displayed in the figure, the mean percentage of dialysis patients with ≥1 ER/OBS admission each week was 2.97% in 2014, 3.04% in 2015, and 3.12% in 2016 ($P < 0.001$, from test of secular trend). The percentage of dialysis patients with ≥1 ER/OBS admission each week increased significantly ($P < 0.05$) in every stratum. Strata with the highest mean percentages of dialysis patients with ≥1 ER/OBS admission each week in 2016 were ages 20-34 years (5.14%), ages 35-44 years (4.04%), and Medicaid enrollees (3.83%).

Conclusions: Utilization of emergency and observation room care is increasing among Medicare dialysis patients.

FR-PO782

Discrepant Associations of Hemodialysis Intensity and Survival in the Facility and at Home

Eric D. Weinhandl,[1,2] Kristine Kubisiak,[1] Debabrata Ray,[1] Allan J. Collins.[1,2] *[1]NxStage Medical, Inc., Victoria, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: Incremental hemodialysis (HD) has recently garnered interest. Mathew *et al* (*Kidney Int*, 2016) reported that in US incident patients on in-center HD, adjusted hazard ratios (AHRs) of death for 2 vs. 3 and ≥4 vs. 3 sessions/week were 0.88 (95% confidence interval, 0.72-1.08) and 1.56 (1.21-2.03), respectively. These data may reflect either the relative efficacy of twice-weekly HD as an initial prescription or residual confounding. We assessed whether these associations could be replicated among in-center hemodialysis (IHD) and home hemodialysis (HHD) patients.

Methods: We used data from the United States Renal Data System. We identified adult patients who initiated HD in 2011-2015, and we retained patients with an initial HD prescription of 2 to 7 sessions/week and 2-8 hours/session, according to form CMS-2728. We followed patients until death, but for a maximum of one year. Using Cox regression, we assessed associations of HD frequency, HD hours per week, and HD product (frequency^2 × hours/session) separately among IHD and HHD patients, with adjustment for demography, vascular access type, and disease severity, including estimated glomerular filtration rate.

Results: We identified 503,678 IHD patients and 2849 HHD patients. With IHD (vs. HHD), the percentage of patients prescribed 2 sessions/week was 1.1% (vs. 1.1%), the percentage of patients prescribed ≥4 sessions/week was 0.5% (vs. 59.7%), mean HD hours per week were 11.4 (vs. 14.0), and mean HD product was 34 (vs. 62) points. With IHD, the AHRs of death for 2 vs. 3, ≥4 vs. 3, and ≥4 vs. 2 sessions/week were 0.84 (0.80-0.89), 1.05 (0.96-1.14), and 1.24 (1.12-1.38), respectively; with HHD, the AHRs were 0.83 (0.39-1.76), 0.63 (0.52-0.75), and 0.76 (0.36-1.61), respectively. With IHD, the AHR of death for each additional HD hour per week was 1.012 (1.008-1.016); the corresponding AHR for HHD was 0.967 (0.943-0.993). Finally, with IHD, the AHR of death for each 10-point increment in HD product was 1.039 (1.028-1.051); the corresponding AHR for HHD was 0.946 (0.915-0.979).

Conclusions: Associations of HD frequency, HD hours per week, and HD product are almost entirely discrepant with IHD and HHD. In the facility, lower HD frequency and fewer HD hours are associated with better survival. In the home, higher frequency and greater HD hours are associated with better survival.

FR-PO783

Predictors of Hyperkalemia-Related Emergency Department Encounters Among Patients Receiving Hemodialysis Care

Paul E. Ronksley, James Wick, Meghan J. Elliott, Robert G. Weaver, Jennifer M. MacRae. *University of Calgary, Calgary, AB, Canada*.

Background: Almost 10% of emergency department (ED) visits among dialysis patients are for conditions that could potentially be managed in an outpatient setting such as hyperkalemia. We used population-based data to identify factors that place hemodialysis patients at increased risk of hyperkalemia-related ED events.

Methods: We identified all chronic hemodialysis patients age ≥18 years from March 2009–March 2015 within southern Alberta, Canada. We used a nested case-control design to identify differences between patients with and without hyperkalemia-related ED events (defined by ICD-10 related codes and/or serum K^+ ≥6mmol/L). Cases were matched to controls based on dialysis site type (satellite or in-centre) and time period. Clinical and dialysis-specific variables were measured 2-4 weeks prior to outcome dates. We assigned a random date within each control's period on hemodialysis to serve as a proxy for an outcome date. Potential predictors included demographic/clinical characteristics, prior health system use, and dialysis run sheet variables. Conditional logistic regression models were used to identify significant predictors of hyperkalemia-related ED events.

Results: Of 2012 patients on chronic hemodialysis, 129 had 180 hyperkalemia-related ED events (cases) within the study timeframe. Controls were matched to cases at a ratio of ~3-to-1 (508 controls). In bivariate analysis, cases were younger, had higher levels of comorbidity, higher acute care use in the prior 6 months, and received more intensive dialysis treatment (e.g. higher ultrafiltration (UF) volume, cumulative duration of dialysis) in the weeks prior to an ED event. Multivariate modeling identified the following predictors of hyperkalemia-related ED events: ED use in prior 6 months (OR: 2.70; 95% CI: 1.69-4.33), dialysate potassium concentration ≤3.0mmol/L (2.95; 1.28-6.77), average UF volume>2.5L per dialysis session (2.73; 1.59-4.71), >15 hours of cumulative dialysis time in the prior week (5.84; 2.32-14.70), dialysis access via fistula (1.79; 1.20-2.66).

Conclusions: We identified a number of predictors that place patients at greater risk of presenting to the ED with hyperkalemia. Identification of such patients may allow for targeted strategies for preventive care, thus avoiding unnecessary acute care use and cost while improving patient quality of life.

FR-PO784

Predicting Who Needs Urgent Dialysis Prior to Ambulance Transport to the Emergency Department

Karthik K. Tennankore,[1] Amanda J. Vinson,[1] John E. Bartolacci,[2] Judah Goldstein,[2] David Clark.[3] *[1]Dalhousie University/NS Health Authority, Halifax, NS, Canada; [2]Dalhousie University, Halifax, NS, Canada; [3]London Health Sciences Centre, London, ON, Canada*.

Background: Chronic hemodialysis patients who require ambulance transport to the emergency department (ambulance-ED) may subsequently need urgent dialysis. However, little is known about predictors of urgent dialysis based on patient factors identified prior to ED transport. The purpose of this study was to develop a risk prediction model for urgent dialysis after ambulance-ED based on patient characteristics identified at the time of paramedic assessment.

Methods: We analyzed a cohort of incident thrice-weekly hemodialysis patients between 2009-2013 (last follow-up of 2015) who experienced one or more ambulance-ED events. Chief complaint, vital sign parameters and time from last dialysis to ambulance dispatch was assessed for all patients at the time of paramedic assessment prior to ED transport. Urgent dialysis was defined as a need for dialysis within 24 hours of an ambulance-ED in a monitored setting or among patients with an initial ED potassium of >6.5 mmol/L. Associations with urgent dialysis were analyzed using logistic regression. A risk prediction model was created and internally validated.

Results: Among 197 patients, there were 624 ambulance-ED events and 87 episodes of urgent dialysis. Weakness as a presenting complaint (OR 4.62, 95% CI 1.23-17.29), >24 hours since last dialysis (OR 2.09, 95% CI 1.15-3.81), and triage vitals (heart rate <60 beats/minute (OR 3.06, 95% CI 1.09-8.61), systolic blood pressure >160 mmHg (OR 2.37, 95% CI 1.32-4.25), respiratory rate ≥20 breaths/minute (OR 2.00, 95% CI 1.06-3.75) and oxygen saturation <90% (OR 3.04, 95% CI 1.55 – 5.94)) were associated with an increased need for urgent dialysis after ambulance-ED. A risk prediction model incorporating these variables had very good discrimination (C-statistic: 0.81, 95% CI 0.76-0.86). The negative predictive value for not needing urgent dialysis was 93.6% using the optimal cut point (≥15% predicted probability). Of the patients who were predicted to need urgent dialysis but were transported to a dialysis incapable facility, 31% required a second transport for urgent dialysis.

Conclusions: We created a risk prediction model for urgent dialysis after ambulance-ED based on patient characteristics at the time of paramedic assessment. This model has the potential to guide dialysis patient transport to dialysis-capable facilities when needed.

FR-PO785

Cumulative Time in Hospital After Initiation of Dialysis: A Cohort Study

Karthik K. Tennankore,[1] David Clark,[2] Kara Matheson,[3] Amanda J. Vinson.[1] *[1]Dalhousie University/NS Health Authority, Halifax, NS, Canada; [2]London Health Sciences Centre, London, ON, Canada; [3]Nova Scotia Health Authority, Halifax, NS, Canada*.

Background: Chronic dialysis patients are at risk for frequent and prolonged hospitalizations. Less is known about predictors of cumulative time in hospital after initiation of dialysis, including each subsequent hospitalization. Having an awareness of the predictors of cumulative hospital time is important for informed decision making between patients and providers prior to initiation of dialysis.

Methods: We analyzed a cohort of incident, chronic dialysis patients from 2009-2014 (last follow-up of 2015) at a tertiary care center. Baseline characteristics including demographics, comorbidities, frailty status (assessed using the clinical frailty scale; CFS rated from 1: very fit to 7: severely frail) and laboratory parameters were captured in all patients at dialysis initiation. The primary outcome was cumulative time in hospital (proportion of time in hospital/total follow-up time and inclusive of the time in hospital after dialysis initiation for inpatient dialysis starts). Generalized linear models were used to fit a negative binomial distribution of cumulative time with total time of followup as the offset.

Results: A total of 647 patients were included in the study. Mean age was 62 ± 15 years, 90% were caucasian and the majority (63%) were male. Diabetes (48%), coronary artery disease (30%), congestive heart failure (22%), and cancer (11%) were prevalent at dialysis initiation; a smaller proportion (5%) had underlying liver disease. The median CFS score was 4 (IQR 2.5) corresponding to "vulnerable but not frail". Median days in hospital for the cohort was 13 (IQR 41) and cumulative hospital time was 3% of total follow-up time (48/1704 years). In an adjusted model, the percent change in the incident rate of cumulative days in hospital was 22% for each 1 point increase in frailty severity. Other factors associated with higher cumulative time included age (IRR 1.02, 95% CI 1.01-1.03 per year), liver disease (IRR 2.07, 95% CI 1.07-4.02), malignancy prior to dialysis initiation (IRR 1.78, 95% CI 1.09-2.90) and low albumin (IRR 0.93, 95% CI 0.91-0.96 per each g/L decrease in albumin).

Conclusions: Demographics, comorbidities, frailty status and laboratory parameters are associated with a higher cumulative time in hospital after dialysis initiation. This information may be used to better inform patients of their risk of hospitalization after starting chronic dialysis.

FR-PO786

B-Line Score Is Predictive of Repeat Acute Care Utilization in Hemodialysis Patients

Nathaniel C. Reisinger, Jordan Brown, Proma Mazumder, Erik Yarmey, Frances Shofer, Anthony J. Dean, Nova Panebianco. *University of Pennsylvania, Philadelphia, PA*.

Background: ESRD is burdensome both for patients and healthcare systems because of high acute care utilization. Hemodialysis (HD) patients present to an emergency department (ED) an average of 3 times per year and are hospitalized an average of twice per year with readmission rates of 30%. Readmissions are particularly taxing on hospitals as they are not reimbursed by Medicare. Cardiovascular disease, due in large part to visits for fluid overload (FO), drives these high rates of acute care utilization. The standard of care for assessment of FO remains physical exam despite its poor accuracy. 28-point B-line score (BLS) has emerged as a quantitative marker of FO, outperforming the physical exam. The goal of this study was to determine if BLS is predictive of hospital readmissions or ED revisits.

Methods: A convenience sample of patients with ESRD presenting to a large urban tertiary care ED was enrolled consecutively. Patients were excluded if they were not chronically on HD or were unable to consent. BLS was obtained after enrollment, prior to their first HD session at our center. The patients were followed for 30 days to determine the rate of readmissions and 60 days to determine the rate of ED revisits. Presence of FO was determined by the treating nephrologist or on chart review. Visits for FO were determined by discharge diagnosis.

Results: Of 101 patients enrolled, median age was 60, 51% were male, 84% identified as Black or African American. Comorbidities included 65% diabetic, 27% coronary artery disease, 33% airways disease, 40% systolic heart failure, 75% diastolic heart failure. Median dialysis vintage was 33 months. Access type was 54% arteriovenous fistula, 29% graft, and 17% catheter. ESRD vintage was 33 months. Residual renal function was minimal. 62% of patients had FO on arrival and 27% of visits were for FO. 45% of patients had an ED revisit within 60 days. Median BLS for patients with a 60-day ED revisit was significantly higher than those without (64 vs 29, p=0.001). Median BLS for patients with a 30-day readmission was also higher (57 vs 32, p=0.12).

Conclusions: BLS for patients with a 60-day ED revisit or 30-day readmission was higher than patients without revisits or readmissions. BLS is a useful metric in the ED for determining whether patients with ESRD on HD are likely to have repeat visits.

FR-PO787

Correspondence Between Causes of Recurrent Hospitalizations Among Hemodialysis Patients

Scott Sibbel, Adam G. Walker, Francesca Tentori, Steven M. Brunelli. *DaVita Clinical Research, Minneapolis, MN*.

Background: Despite targeted efforts, hospitalizations represent a major burden for end-stage kidney disease patients, with an average of 1.7 admissions per patient-year and

30.7% of patients being readmitted to the hospital. There is a need to identify factors that drive hospitalization risk in this population. We evaluated cause of initial admission and readmission among patients receiving in-center hemodialysis at a large dialysis organization (LDO) in the US.

Methods: Using Medicare claims we identified all patients with at least one index hospitalization ≥ 1 day during 2014. Readmissions were defined as hospitalizations that occurred within 30 days after index admission. Cause of hospitalizations were determined by primary ICD-9 diagnosis code and were classified using the clinical classification system (CCS). The relationship between causes of index hospitalization and readmission were determined through cross-tabulation of the percent difference between observed (O) and expected (E) readmissions accounting for background admission rate (O-E/E*100).

Results: During the study period the overall probability of readmission was 31.5%. Diseases of the circulatory system were the most common cause for both hospitalizations and readmissions. Overall, the probability of readmissions did not vary greatly by cause of index admission (28.8%-35.8%) and the leading cause of readmission was the same as that of the index hospitalization.

Conclusions: We found that the cause of readmission was closely related to the cause of prior hospitalization in a large sample of US dialysis patients. Despite potential misclassification of readmission cause, these results raise the possibility that the clinical issue was not fully addressed during the index admission. Further studies are needed to identify clinical practices that may help reduce readmission rates.

FR-PO788

Lower Rates of Hospital Admissions During a Fluid Management Quality Improvement (QI) Project Utilizing Relative Blood Volume Monitoring (RBV-M) - A Retrospective Database Analysis

Paul Balter,[1,2] Panduranga S. Rao,[3] Yisha Li,[4] Claudy Mullon,[4] Robert J. Kossmann,[4] Linda Ficociello.[4] *[1]Nephrology Associates of Northern Illinois and Indiana (NANI), Oak Brook, IL; [2]Renal Research Institute, New York, NY; [3]University of Michigan Health System, Ann Arbor, MI; [4]Fresenius Medical Care Renal Therapies Group, Waltham, MA.*

Background: Hemodialysis (HD) patients experience high rates of hospitalization and mortality, especially in the first 90 days of dialysis. A clinic-wide fluid management QI project was conducted at 9 dialysis facilities utilizing RBV-M. The aim of this retrospective analysis was to assess hospital admissions among incident HD patients during the QI project compared to incident HD patients not participating in the QI project.

Methods: Incident patients in their first 90 days of HD were analyzed. The analysis included 3 periods: before the QI start (Pre-QI); during the QI project (QI); and following the end of the QI project (Post-QI). RBV-M was conducted using Crit-Line® monitors. Hazard ratios were modeled using all hospital admissions during the first 90 days of dialysis. Poisson regression was used to compare hospital days across 3 periods.

Results: 1068 adult incident HD patients (Pre-QI: 501, QI: 376, Post QI: 191) who started HD between 2009 and 2017 were analyzed. There was a difference in hospital admission rates among the 3 periods (P=0.02). Compared to the QI period, the Pre-QI period had a 20% increased rate of hospitalization (HR= 1.2, 95%CI: [0.99,1.47]) and the Post-QI period had a 40% increased rate (HR= 1.4, 95%CI: [1.11,1.84]). Fewer hospital days were observed for the QI period (P=0.04) compared with the non-QI groups, with 5.84 (P=0.01) less hospital days per person-year (PPY) and 4.7 (P=0.12) less hospital days PPY compared with Pre-QI and Post-QI, respectively (Figure).

Conclusions: The use of RBV-M as part of a QI on fluid management was associated with a decreased rate of hospital admissions and fewer hospital days among incident HD patients during the first 90 days of dialysis.

FR-PO789

Early Readmissions Are More Common After Long Hospitalizations Among Hemodialysis Patients

Adam G. Walker, Scott Sibbel, Francesca Tentori, Steven M. Brunelli. *DaVita Clinical Research, Minneapolis, MN.*

Background: Approximately one-third of dialysis patients who are hospitalized will be readmitted post discharge. In this study, we characterized patterns of readmissions by length of index hospitalizations.

Methods: Patients included in this analysis were Medicare beneficiaries, receiving in-center hemodialysis at a large dialysis organization (LDO,) and had a qualifying index hospitalization lasting ≥ 1 day during the study period (2014). Hospitalizations were considered readmissions if they occurred ≤ 30 days post-discharge from the index admission. Causes of hospitalizations were determined by primary ICD-9 diagnosis code.

Results: The mean length of stay for index admissions was 7.1 ± 9.5 days (median 4 days). The longest index hospitalizations were those due to infectious and parasitic disease and the shortest were related to endocrine, nutritional, metabolic diseases and immunity disorders. The overall probability of readmission was 31.5%; 27.6% and 52.4% of all readmissions occurred within 6 ("early readmissions") and 12 days post-discharge, respectively. Patients with index hospitalization duration > 7 days had a higher probability of readmission overall (34.7% vs. 30.3 %) and of early readmission (30.0% vs. 26.1%) compared to those with shorter index hospitalizations.

Conclusions: These results suggest that patients with longer hospitalizations are more vulnerable to readmissions overall and to early readmissions, likely due to the severity of disease. This was particularly common among patients admitted for infections. These results raise the possibility that the clinical issue was not fully addressed during the index admission or shortly after discharge. There is a need to identify clinical practices that may help reduce readmission rates.

Recent Trends in Hospital Admissions Among Medicare Dialysis Patients

Debabrata Ray,[1] Kristine Kubisiak,[1] Allan J. Collins,[1,2] Eric D. Weinhandl.[1,2]
[1]NxStage Medical, Inc., Victoria, MN; [2]University of Minnesota, Minneapolis, MN.

Background: Hospital admissions not only reflect the morbidity of dialysis patients, but also account for more than one-third of Medicare Parts A and B expenditures among patients (USRDS Annual Data Report, 2017). We assessed trends in hospital admissions among Medicare dialysis patients in 2014-2016.

Methods: We analyzed Medicare limited data sets. For each calendar week (Monday to Sunday) in 2014-2016, we identified all Medicare Parts A and B beneficiaries with ≥1 outpatient dialysis treatment. We excluded patients hospitalized on Sunday and not discharged before the end of the day. We calculated the percentage of patients with ≥1 hospital admission during the next week. We fit an ARIMA(1,0,0)x(0,1,0) model to the time series of admission percentages and used a likelihood ratio test to assess whether a secular trend remained after accounting for serial correlation and seasonality. We analyzed the aggregate population and strata defined by age, race, sex, concurrent Medicaid enrollment, US Census Division, and dialytic modality (hemodialysis, peritoneal dialysis).

Results: The average number of Medicare dialysis patients per week was over 286,000. As displayed in the figure, the mean percentage of dialysis patients who were newly hospitalized each week was 3.09% in 2014, 3.07% in 2015, and 3.10% in 2016 ($P = 0.90$, from test of secular trend). This percentage increased significantly ($P < 0.05$) among ages 20-34 years (3.47%, 3.58%, and 3.70% in 2014, 2015, and 2016, respectively), ages 35-44 years (2.93%, 2.98%, and 3.09%), Medicaid enrollees (3.33%, 3.33%, and 3.39%), and West South Central residents (2.91%, 2.92%, 3.00%). In other strata, secular trends were not significant ($P > 0.05$).

Conclusions: Between 2014 and 2016, the risk of hospital admission among all Medicare dialysis patients was stable, although a secular trend of increasing risk was evident in young adult and dual-eligible patients.

Using Artificial Intelligence to Help Predict Imminent Hospitalizations in Patients with ESRD

Andrew Long,[2] Tommy C. Blanchard,[2] Joanna Willetts,[2] Hao Han,[2] Michael R. O'Connell,[2] Amanda K. Ward,[1] Lisa Reighter,[1] Scott Braverman,[1] Kendra N. Smith,[1] Annette L. Baker,[1] Gamaela D. Brown,[1] Greg S. Garza,[1] Cara Gallagher,[1] Jodi Conti,[1] Sheetal Chaudhuri,[2] Len A. Usvyat,[2] Terry L. Ketchersid,[2] Franklin W. Maddux.[2] *[1]Fresenius Health Partners, Austin, TX; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: Patients with end-stage renal disease are hospitalized two times per year on average; approximately 35% have a re-admission within 30 days of discharge (USRDS 2017). The cost of hospitalizations represents about one-third of the total Medicare spending for patients on dialysis. We developed a model to predict which patients treated at a large dialysis provider are at imminent risk of hospitalization to highlight patients who might benefit from additional interventions.

Methods: We built a machine learning model using over 1500 variables to predict the probability that a patient would be admitted within 7 days of the current outpatient dialysis treatment. Some of the variables in the model include treatment vital signs, administered medications, lab values, prior hospitalizations, demographics, comorbidities, lifestyle, and free-text clinical notes. Training data was extracted from patients treated at a large dialysis provider between January 2016 through May 2017. The results shown below are from unseen test data with 200,000 patients in June 2017.

Results: Approximately 2.7% of patients are hospitalized weekly. Results from the test data show the model has an area under the receiver operating curve (AUROC) of 0.78, sensitivity of 69%, and specificity of 72%. The confusion matrix for test data is shown in Table 1. Top variables for predicting hospitalization are related to prior hospitalizations, the content of free-text clinical notes, serum albumin, blood pressure, interdialytic weight gain, and hemoglobin.

Conclusions: This work demonstrates that data routinely collected during dialysis treatments can be used to predict imminent hospitalization. We are currently pilot-testing this model to determine if surfacing the results of these real time artificial intelligence-based machine learning algorithms to the local care team can help patients avoid hospitalizations and lead to improved patient outcomes.

Funding: Commercial Support - Fresenius Medical Care North America

Confusion matrix for test data (n = 200000)

		Actual admit in 7 days	
		Positive	Negative
Predicted admit in 7 days	Positive	1.8%	27.2%
	Negative	0.8%	70.2%

FR-PO792

Prior Hospitalization Burden and the Relatedness of 30-Day Readmissions in Patients Receiving Hemodialysis

Eugene Lin,[1] Jay Bhattacharya,[1] Glenn M. Chertow.[2] *[1]Stanford University, Palo Alto, CA; [2]Stanford University School of Medicine, Palo Alto, CA.*

Background: Thirty-day readmissions are common in patients receiving hemodialysis and costly to Medicare. Because patients on hemodialysis have a high background hospitalization rate, thirty-day readmissions might be less likely related to the index hospitalization or to the quality of post-discharge care than in patients with other conditions.

Methods: We evaluated whether prior hospitalization burden was associated with increased 30-day readmissions unrelated to the index hospitalization in adults with Medicare receiving hemodialysis in the United States from 1/1/2012-12/31/2013. We categorized a hospitalization, 30-day readmission pair as "related" if the principal diagnoses came from the same organ system. Using multinomial logistic regression, we estimated the likelihood that an index hospitalization was followed by a related or unrelated 30-day readmission.

Results: The adjusted probability of an unrelated 30-day readmission after any index hospitalization was 19.1% (95% CI: 18.9%, 19.3%) in patients with 0-1 hospitalizations in the prior year, 22.6% (95% CI: 22.4%, 22.8%) in patients with 2-4 hospitalizations, and 31.2% (95% CI: 30.8%, 31.5%) in patients with 5 or more hospitalizations. Cardiovascular index hospitalizations had the highest adjusted probability of a related 30-day readmission: 10.4% (95% CI: 10.2%, 10.7%), 13.6% (95% CI: 13.4%, 13.9%), and 20.8% (95% CI: 20.2%, 21.4%) respectively. Conversely, renal index hospitalizations had the lowest adjusted probability of a related 30-day readmission, 2.0% (95% CI: 1.8%, 2.3%), 3.9% (95% CI: 3.4%, 4.4%), and 5.1% (95% CI: 4.3%, 5.9%) respectively.

Conclusions: High prior hospitalization burden increases the likelihood that a patient receiving hemodialysis experiences a 30-day readmission unrelated to the index hospitalization. Healthcare payers such as Medicare should consider incorporating clinical relatedness into 30-day readmission quality measures.

FR-PO793

Hospital-Acquired Anemia in Hemodialysis Patients: Opportunities for Improvement

Marta Christov,[1,2] Anastasios Papanagnou,[2] Michael D. Klein.[2,1] *[1]New York Medical College, Valhalla, NY; [2]Westchester Medical Center, Bayside, NY.*

Background: Anemia is a significant comorbidity in end-stage renal disease (ESRD) patients. Hospital-acquired anemia (HAA) is well-described in non-ESRD patients, where

it correlates with increased morbidity and mortality. Little is known about the development of HAA in hospitalized ESRD patients and potential modifiable factors.

Methods: We used retrospective chart review to compare hemoglobin (Hgb) on admission, at its lowest (nadir) and on discharge in 52 adult patients with ESRD admitted over a three month period to our medical center. Inclusion criteria were age > 18 years and admission between December 1st 2016 and February 28th 2017, as well as a billing code of ESRD (N18.6). Exclusion criteria were: bleeding-related admission, multiple admissions over the observation period, admission longer than 30 days, peritoneal dialysis. We analyzed change in hemoglobin from admission to discharge or admission to nadir and factors that were associated with the changes. Total diagnostic blood volume refers to the total amount of blood drawn by phlebotomy during the stay.

Results: The mean Hgb on admission was 10.6 (+/-1.5) g/dL and the mean discharge Hgb was 9.6 (+/-1.7) g/dL. The mean lowest Hgb was 9.0 (+/- 1.6) g/dL. Total diagnostic blood volume for the admission was significantly correlated with Hgb change from admission to lowest (0.578, p<0.001); 23% of patients required blood transfusions. Age, sex, comorbidities, admission diagnosis and access type were not associated with the change in Hgb, while length of stay and total diagnostic blood volume were associated with a Hgb drop from admission to nadir. We propose a definition of HAA for the ESRD population to include a Hgb decrease from admission to discharge of 1.5 g/dL or greater or need for transfusion.

Conclusions: Hospitalized ESRD patients showed significant decrease in hemoglobin during inhospital stay that correlated most closely with length of stay and total diagnostic blood volume. Strategies to minimize phlebotomy volume in this vulnerable population need to be tested.

FR-PO794

Determinants of Dialysis Facility Hospital Readmissions

Ziad M. Ashkar. *Lafayette General Health, Lafayette, LA.*

Background: Hospital readmissions are common, costly, and potentially avoidable. In ESRD, factors including anemia, CHF, cardiovascular disease, malignany, vascular access and low albumin were associated with readmissions. No studies have looked into dialysis units specific determinants of dialysis facility readmission rate. The purpose of this study is to identify unique dialysis facility determinants of hospital readmissions.

Methods: Observational retrospective, cross-sectional design. Data are obtained from CMS Dialysis Facility Compare, release date April 2018. Dialysis facility readmission rate was used as outcome variable. (defined as a percentage of hospital discharges). Multilinear regression with cluster by network was then done, with number of dialysis stations, % of patients with hemoglobin<10g/dl, % with KT/V>=1.2, % with AV Fistula in use, % with catheters more than 90 days, % with Calcium > 10.2mg/dl, phosphorus < 3.5 mg/dl and >7mg/dl

Results: For each increase in number of dialysis stations, there is a 6.3 % increase in dialysis facility readmission rate (DFR). For each increase in % patients with Hb < 10g/dl, there is a 3.8 % increase in DFR. Each increase in % with KT/V>=1.2 is associated with 13.5 % decrease in DFR. There are no associations with the other variables.

Conclusions: Using data from dialysis facility compare, hemodialysis clinics with KT/V>=1.2 are associated with significant decrease in dialysis facility readmission rates. Increase in dialysis stations and increase in percent with hemoglobin < 10g/dl are associated with increase in readmission rates. Strategies targeting adequate clearance and anemia management will likely have significant impacts towards decreasing hospital readmissions in individual dialysis facilities. More studies are needed to understand drivers behind increase in station numbers and readmissions in dialysis.

FR-PO795

Post Hoc Ergo Propter Hoc: A Multilevel Strategy to Reduce 30-Day Readmissions in Patients on Dialysis

Frank J. O Brien,[1] Sadaf N. Sheikh,[2] Anitha Vijayan.[3] *[1]Washington University in St. Louis, St. Louis, MO; [2]Washington university St Louis MO, Valley Park, MO; [3]Washington University in St. Louis, St. Louis, MO.*

Background: Patients with end-stage renal disease (ESRD) requiring dialysis are twice as likely as the general population to be readmitted within 30 days of hospital discharge. Inpatient care costs account for approximately 40% of total Medicare expenditures for dialysis. As of 2017, outpatient dialysis facilities have been penalized by the Centers of Medicare and Medicaid (CMS) for excessive readmissions as the standardized readmission ratio (SRR) became part of the ESRD quality incentive program. Our study examines the effect of a multi-level strategy to reduce readmission rates.

Methods: Washington University owns and operates 2 out-patient ESRD facilities in the city of St. Louis, with a census of approximately 400 patients. Using 2014-2017 data as our benchmark, we examine the impact of a dedicated transitional care nurse (TCN) and communication improvements (between the inpatient nephrology service and dialysis facilities) on readmission rates. The role of the TCN is to reconcile patient's hospitalization with their outpatient care plan and bridge the gap from hospital to home. The TCN commenced work in the 3rd quarter of 2017.

Results: Admission and 30 day readmission data are outlined below in table 1. Admissions and readmissions have been decreasing over the past 3 years. 30 day readmissions reduced since introduction of readmission prevention strategy. An influenza outbreak was responsible for the increased number of admissions in the first quarter of 2018. The TCN was able to see approximately 50% of patients within 48 hours of discharge and the patient's nephrologist saw 90% of patients within one week of discharge.

Conclusions: This study highlights the ongoing difficulty dialysis units have with reducing readmission rates. We show that increased patient engagement with a TCN in the first 48 hours post discharge and improved structured communication between in patient nephrology services and dialysis facilities has led to reduced rates of readmissions.

In-Hospital Hemodialysis Services Provided by Tele-Nephrologists Using the NxStage System One S

Janice P. Lea,[1] Tahsin Masud,[1] James T. Someren,[1] Jason Cobb,[2] Jerome S. Tannenbaum.[3] *[1]Emory University, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA; [3]Sanderling Healthcare, LLC, Nashville, TN.*

Background: Telemedicine has recently permeated into the nephrology space allowing ESRD patients in rural hospitals without access to traditional hemodialysis (HD) to receive dialysis care without transfer to larger healthcare systems. We report 5 months of experience using non-traditional dialysis machines (Nxstage System One S) in providing hemodialysis to patients remotely monitored by tele-nephrologists in rural hospitals.

Methods: A retrospective, descriptive study of patients receiving tele-nephrology consultation and chronic dialysis services between January 2018 and May 2018 in rural community hospitals across the U.S. Consultations were requested by the on-site physicians and were performed by reviewing the patient's hospital EMR and performing a real-time history and physical exam with audio-video technology and Littman electronic stethoscope. Tele-nephrologists ordered HD using Nxstage System One S technology and Certified Clinical HD Technicians per standard nephrology practice. Hemodialysis treatment data was captured electronically and extracted into Excel for analysis

Results: A total of 6 rural hospitals across the U.S, provided 145 HD treatments to 51 ESRD patients (25 females, 26 males; average age 64.9 (22-88 years) during the first 5 months of 2018. HD prescription details with average blood flow (Qb), dialysate flow (Qd), dialysate volume, duration, flow fraction, and fluid removal (UF) rates are listed in Table 1. Average pre-systolic BP (SBP) was 134 and post- SBP -131 with low SBP- 109. For those with pre- SBP 100-130, and pre-SBP>130, 18% and 3% respectively had intradialytic drop to SBP<90. 7% of treatments utilized a 1 K bath, 44% - 2 K bath, and 48% - 3K bath. Average hours in between subsequent HD sessions was 47.

Conclusions: Hemodialysis services provided by NxStage System One S in ESRD patients in rural hospitals is effective and safe. This low dialysate volume platform is performed at similar frequencies and UF rates as traditional dialysis platforms (high dialysate volume) without high rates of hypotension.

Table 1 HD NxStage prescription

duration	Qb	Qd	volume dialysate	FF	UF volume	UF ml/hr	UFR	pre-wt
209 min.	365 ml/min	300 ml/min	61 L	82%	1581 ml	803	10.1 ml/hr/kg	85.4 kg

FR-PO797

Factors Affecting Sudden Death in Hemodialysis Patients: Ten-Years Outcome of the Q-Cohort Study

Hiroto Hiyamuta,[1] Shigeru Tanaka,[2] Masatomo Taniguchi,[3] Toshiaki Nakano,[1] Masanori Tokumoto,[4] Kazuhiko Tsuruya,[5] Takanari Kitazono.[6] *[1]Kyushu University, Fukuoka, Japan; [2]Fukuoka Dental College, Fukuoka, Japan; [3]Fukuoka Renal Clinic, Fukuoka, Japan; [4]Department of Internal Medicine, Fukuoka Dental College, Sawara-ku, Japan; [5]Nara Medical University, Kashihara, Japan; [6]Department of Medicine and Clinical Science, Fukuoka, Japan.*

Background: Sudden death is a serious problem in hemodialysis patients. However, the precise incidence rate of sudden death and its risk factors remain unclear.

Methods: A total of 3,506 Japanese HD patients aged ≥18 years were prospectively followed for 10 years. Sudden death was defined as sudden and unexpected natural death within 24 hours. Multivariate-adjusted hazard ratios (HR) with 95% confidence intervals (95% CI) of each risk factor of sudden death were calculated using a Cox proportional hazards model.

Results: During a follow-up period, 1,748 patients died from any causes and 227 of them (13%) were attributed to sudden death. In multivariable-adjusted Cox analysis, male sex (hazard ratio [HR] 1.65; 95% CI 1.19–2.30), age (HR 1.44; 95% CI 1.26–1.65 for every 10-years increase), presence of diabetes (HR 2.45; 95% CI 1.82–3.29), history of

cardiovascular events (HR 1.85; 95% CI 1.38–2.46), cardiothoracic ratio in chest X-ray (HR 1.21; 95% CI 1.07–1.39 for every 5-percentage-point increase), serum levels of phosphate (HR 1.15; 95% CI 1.03–1.30 for every 1-mg/dL increase), and C-reactive protein (HR 1.11; 95% CI 1.03–1.20 for every 1-mg/dL increase) were independent predictors for developing sudden death. In subgroup analysis, shorter dialysis session length (<5 hours) was associated with an increased risk of sudden death in male group (HR 1.51; 95% CI 1.03– 2.21; p for interaction 0.01) or elderly group (≥ 65 years) (HR 2.45; 95% CI 1.82–3.29), and lower serum calcium level was a significant predictor for sudden death in female group (HR 1.88; 95% CI 1.36–2.63 for every 1mg/dL decrease; p for interaction <0.001).

Conclusions: The present study demonstrated the lower occurrence rate of sudden death compared to previous reports, but elucidated its specific risk factors, related to atherosclerosis, vascular calcification, left ventricular hypertrophy, and chronic inflammation, in hemodialysis patients.

FR-PO798

Characteristics of Sudden Cardiac Death in Our Hemodialysis Unit

Carmen Mon, Milagros Ortiz, Olimpia Ortega, Aniana Oliet, Maria Sanchez, Rosa E. Camacho, David Arroyo, Jessica Urdaneta, Diego Navazo, Juan Carlos Herrero. *Hospital Severo Ochoa, Madrid, Spain.*

Background: In hemodialysis (HD) patients sudden cardiac death (SCD) accounts for one out of every four deaths. It is complicated to determine how unexpected death is on ESRD patients whose illness is chronic and have a high comorbidity. Our aim was to study mortality in our dialysis unit, focusing on SCD.

Methods: Retrospectively, we collected mortality data for ten years. Clinical, biochemical (analytical closer to the date of death) and causes of death were analyzed. SCD was defined as an unexpected circulatory arrest or an unwitnessed, unexpected death in patients known to be well within the past 24 h.

Results: 215 deaths were reviewed. First cause of death was cardiovascular disease (CVD) (54 p, 25%), the second SCD (42p, 19%). Risk factors for SCD at univariate study are showed in Table 1. In the logistic regression analysis, SCD was associated with: lack of AF (p0,05, HR0,27,CI 0,107-0,67), higher potassium levels (p0,02, HR1,64,CI 1.0,7- 2,4), higher albumin levels (p0,02,HR2,CI 1,1-3,8) and lower CRP levels (p:0,01 HR0,99,CI 0,98-0,99).

Conclusions: SCD was the second cause of death in our HD patients and was not associated to traditional risk factors. There was no relationship between SCD and previous diagnosis of CVD, malnutrition and inflammation nor structural heart disease (AF). High value of serum potassium was the only risk factor associated to SCD that we can modify.

Plasma Syndecan-1 in Hemodialysis Patients Associates with Survival and Reduced Volume Status

Josephine Koch,[1] Nienke Idzerda,[2] Wendy Dam,[3] Solmaz Assa,[2] Jacob van den Born,[4] Casper F. Franssen.[2] *[1]University of Groningen, Groningen, Netherlands; [2]University Medical Center Groningen, Groningen, Netherlands; [3]University medical center groningen, Groningen, Netherlands; [4]Univ. Med. Center Groningen, Groningen, Netherlands.*

Background: Syndecan-1, a transmembrane heparan sulfate proteoglycan, associates with renal and cardiovascular functioning. We earlier reported syndecan-1 to be involved in renal tubular regeneration. We now examined plasma values of syndecan-1 in a hemodialysis cohort and its association with volume, inflammatory and endothelial markers in addition to outcome parameters.

Methods: Eighty-four hemodialysis patients were evaluated for their plasma syndecan-1 levels by ELISA before, 60, 180 and 240 minutes after starting dialysis. Patients were divided into sex-stratified tertiles based on predialysis plasma syndecan-1 levels. We studied the association between plasma levels of syndecan-1 and volume, inflammation and endothelial markers and its association with cardiovascular events and all-cause mortality using Kaplan-Meier curves and cox regression analyses with adjustments for gender, age, diabetes and dialysis vintage.

Results: Predialysis syndecan-1 levels were two-fold higher in males compared to females (P=0.0003). Patients in the highest predialysis plasma syndecan-1 tertile had a significantly higher ultrafiltration rate (P=0.034) and lower plasma values of BNP (P=0.019), pro-ANP (P=0.024) and endothelin (P<0.0001) compared with the two lower predialysis syndecan-1 tertiles. No significant associations with inflammatory markers were found. Cox regression analysis showed that patients in the highest syndecan-1 tertile had significantly less cardiovascular events and better survival compared with the lowest syndecan-1 tertile (P=0.02 and P=0.005, respectively).

Conclusions: In hemodialysis patients, higher plasma syndecan-1 levels were associated with lower concentrations of BNP, pro-ANP and endothelin, and with better patient survival. This may suggest that control of volume status in hemodialysis patients allows an adaptive tissue regenerative response as reflected by higher plasma syndecan-1 levels.

FR-PO800

Gender Differences in Three-Year Clinical Outcomes in Japanese Dialysis Patients

Takatoshi Morinaga,[1] Atsushi Fukatsu,[2] Daijo Inaguma,[3] Hirofumi Tamai.[1] *[1]Nephrology, Anjo Kosei Hospital, Aichi prefecture Anjo city, Japan; [2]Fukatsu Medical Clinic, Anjo, Japan; [3]Nephrology, Fujita Health University School of Medicine, Toyoake, Japan.*

Background: A recent Dialysis Outcomes and Practice Patterns Study (DOPPS) has shown a male-to-female mortality ratio one-to-one, notwithstanding women's statistically longer life expectancy in the general population (Hecking et al., 2014). This finding contrasts with the recent report that Japanese women on dialysis treatment have more favorable longevity (Jap. Soc. Dial. Ther., 2009). Accordingly, we further investigated clinical procedures and outcomes in order to clarify the gender differences in Japanese patients on chronic dialysis treatment in order to establish an optimal dialysis modality.

Methods: Subjects were patients in 17 centers participating in the Aichi Cohort Study of Prognosis in Patients Newly Initiated into Dialysis (AICOPP) from October 2011 to September 2013. We excluded 129 from the study because their three-year outcome data was unavailable. Thus, 1,395 subjects were enrolled in the study. Three-year mortality was analyzed by multivariate logistic regression model adjusted by age, gender, body mass index (BMI), diabetes mellitus, C-reactive protein, serum albumin, use of statin, history of cardiovascular disease (CVD) and malignancy. Three-year mortality and CVD events were studied separately in women and men with or without CVD at baseline.

Results: Overall, 458 (32.4%) of 1,395 test subjects were women. Women had lower rates of diabetes mellitus (Women 49.8% vs Men 56.0: P=0.028) and history of CVD (38.2% vs 49.8: P<0.001). Age (mean ± SD, 68.2 year ± 12.7 vs 67.7 ± 12.8: P=0.51) and BMI (23.3 ± 5.3 vs 23.5 ± 3.9: P=0.30) were similar in both sexes. Female gender (adjusted odds ratio 0.66: 95% CI 0.47-0.91) was a positive and history of CVD (OR 1.85: 1.37-2.51) was a negative independent predictor of three-year mortality.

Conclusions: Women on chronic dialysis treatment had a lower mortality risk than men. However, women with CVD comorbidity had a higher mortality rate which cancelled out the survival advantage. These data suggest that the dialysis modality for women with a risk of CVD needs to be modified.

Three-year outcome in subgroups (N=1395)

	Women CVD+ N=175	Women CVD- N=283	Men CVD+ N=467	Men CVD- N=470	P value
Age, year: Mean (SD)	71.5 (11.3)	66.2 (13.2)	70.6 (11.6)	64.9 (13.3)	0.05
All-cause mortality: N (%)	50 (28.6)	26 (9.2)	140 (30.0)	83 (17.7)	<.001
CVD mortality: N (%)	31 (17.9)	11 (3.9)	75 (16.4)	35 (7.5)	<.001

FR-PO801

Estimating the Fraction of First-Year Hemodialysis Deaths Attributable to Potentially Modifiable Risk Factors: Results from the DOPPS

Bruce M. Robinson,[1] Hal Morgenstern,[2] Angelo Karaboyas,[1] Yun Li,[2] Brian Bieber,[1] Raymond M. Hakim,[5] Takeshi Hasegawa,[7] Michel Y. Jadoul,[6] Elke Schaeffner,[3] Raymond C. Vanholder,[4] Ronald L. Pisoni,[1] Friedrich K. Port.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Charite, Berlin, Germany; [4]University Hospital Gent, Gent, Belgium; [5]Vanderbilt University, Franklin, TN; [6]Cliniques Saint-Luc, University of Louvain Medical School, Brussels, Belgium; [7]Showa University, Yokohama, Japan.*

Background: Despite recent improvements in survival on chronic hemodialysis (HD), mortality soon after HD start remains high. We aimed to identify potentially modifiable risk factors with the greatest impact on early HD mortality.

Methods: The analysis included 15,891 incident HD patients (<60 days on HD) from 21 countries in phases 1-5 (1996-2015) of the Dialysis Outcomes and Practice Patterns Study (DOPPS). Using adjusted Cox regression, we estimated the fraction of deaths in the first year of HD attributable to potentially modifiable risk factors at study entry (the attributable fraction, AF) by comparing predicted survival based on risk factors observed vs. counterfactually set to reference levels.

Results: Of 12 risk factor chosen based on known mortality associations, the highest AFs were observed for catheter use (22%), serum albumin <3.5 g/dL (19%), and serum creatinine <6 mg/dL (12%). Risk factors with an AF of 5-9% were lack of pre-HD nephrology care, lack of residual urine volume, SBP out of range 130-160 mm Hg, phosphorus out of range 3.5-5.5 mg/dL, hemoglobin out of range 10-12 g/dL, and WBC count >10,000/μL. The AFs for ferritin >800 ng/mL, serum calcium out of range 8.4-9.5 mg/dL and PTH out of range 150-300 pg/mL were <3%. Overall, 65% (95% CI 59-71%) of deaths were attributable to these 12 risk factors. The AF for CRP was 21% in facilities where it is routinely measured.

Conclusions: A substantial proportion of first-year HD deaths could potentially be reduced by successfully modifying a few risk factors. Highest priority targets should include decreasing catheter use and avoiding or treating malnutrition/inflammation whenever possible.

Table. Attributable fractions for risk factors for 1-year mortality

Risk Factor	% pts	HR (95% CI)	AF (95% CI)
Catheter use	57%	1.52 (1.37-1.71)	22% (17-27%)
Albumin < 3.5 g/dL	51%	1.51 (1.35-1.68)	19% (14-24%)
Creatinine < 6 mg/dL	43%	1.32 (1.18-1.48)	12% (7-16%)
Lack of pre-ESRD care	26%	1.38 (1.24-1.56)	9% (6-12%)
No residual urine volume	32%	1.32 (1.18-1.50)	9% (5-12%)
SBP > 160 mm Hg	27%	0.87 (0.78-0.99)	8% (4-12%)
SBP < 130 mm Hg	23%	1.51 (1.35-1.70)	
Phosphorus > 5.5 mg/dL	39%	1.20 (1.06-1.36)	7% (2-11%)
Phosphorus < 3.5 mg/dL	13%	1.12 (0.96-1.31)	
Hemoglobin > 12 g/dL	9%	1.04 (0.87-1.27)	6% (1-11%)
Hemoglobin < 10 g/dL	50%	1.14 (1.02-1.29)	
WBC count > 10,000/µL	19%	1.30 (1.17-1.46)	5% (3-8%)
Ferritin > 800 ng/mL	8%	1.35 (1.14-1.63)	2% (1-4%)
Calcium > 9.5 mg/dL	13%	1.09 (0.92-1.27)	< 0%
Calcium < 8.4 mg/dL	38%	0.96 (0.86-1.08)	
PTH > 300 pg/mL	39%	0.88 (0.76-1.01)	< 0%
PTH < 150 pg/mL	33%	0.92 (0.77-1.04)	
All risk factors			65% (59-71%)

Cox model stratified by DOPPS phase and country, adjusted for all risk factors, plus age, gender, black race, BMI, and 12 comorbidities

FR-PO802

Poor Immune Response to Influenza Vaccine Is Associated with Increased Mortality in Hemodialysis Patients

Jaromir Eiselt,[1] Daniel Rajdl.[2] *[1]Internal Dept. 1, Charles University, Plzen, Czechia; [2]Dept. of Biochemistry, Plzen, Czechia.*

Background: Immune response reflects an individual's immune status. Hemodialysis (HD) and renal transplantation (TX) are associated with the state of immune dysfunction. The aim of our study was to assess natural levels of pneumococcal IgG (pne-IgG, patients unvaccinated against pneumococcus) and hemagglutination-inhibition antibodies (HIA, post influenza vaccine) in HD and TX patients. We tried to determine the factors influencing the immune status and the relationship of the immune response to mortality.

Methods: A total of 99 HD and 64 TX patients who have never received a pneumococcal vaccine were vaccinated against influenza in seasons 2015/16 and 2016/17. Their pne-IgG, pre- and post-vaccine HIA titre, iron status, C-reactive protein (CRP), albumin and 25-OH vitamin D were measured at baseline and after one year. Total follow-up was 30 months. To identify variables associated with mortality, univariate Cox regression analyses were performed with mortality as a dependent variable, and age, gender and the above mentioned markers as predictors. Markers with $p<0.1$ (post-vaccine rise in HIA, CRP, albumin, age) were subsequently included into a multivariate Cox regression model.

Results: Pneumococcal IgG levels and percentage of seroprotective HIA were comparable in HD and TX groups and between the two consecutive years (Table 1). Mortality was higher in the HD, in which 30 patients died, while only one death was recorded in TX. According to the multivariate Cox regression model (adjusted R^2 0.246, $p<0.0001$), the predictors of death were low postvaccination HIA titre ($p=0.019$), and high CRP ($p=0.003$).

Conclusions: The immune response to the influenza vaccine and the natural production of pne-IgG are comparable in HD and TX patients. Besides dependence on HD, significant independent predictors of mortality in HD population are low antibody response to influenza vaccine and high CRP.

Funding: Government Support - Non-U.S.

	HD 2015/16	HD 2016/17	TX 2015/16	TX 2016/17
Pneumococcal IgG (mg/L)	72 (43-125)	62 (35-108)	54 (34-88)	66 (32-104)
A H1N1 SPpost (%)	93	89	91	80
A H3N2 SPpost (%)	82	88	83	77
B SPpost (%)	91	68	87	75

Data are medians (interquartile ranges), unless stated otherwise; Mann-Whitney and $\chi 2$ test; A H1N1, A H3N2, B are influenza virus strains, SPpost is post-vaccine seroprotection rate; differences among groups were not statistically significant.

FR-PO803

Association of Fruit and Vegetable Intake with All-Cause Mortality in Hemodialysis Patients (DIET-HD): A Prospective Cohort Study

Valeria M. Saglimbene,[1,4] Germaine Wong,[1] Marinella Ruospo,[4] Suetonia Palmer,[5] Patrizia Natale,[4] Armando Teixeira-Pinto,[1] Juan J. Carrero,[6] Peter Stenvinkel,[7] David W. Johnson,[8] Marcello Tonelli,[9] Amparo Bernat,[2] Marietta Török,[2] Anna Bednarek,[2] Delia Timofte,[4] Elisabeth Fabricius,[4] Paul Stroumza,[2] Charlotta Wollheim,[12] Jorgen B. Hegbrant,[3] Jonathan C. Craig,[10] Giovanni F. Strippoli.[11,4] on behalf of DIET-HD investigators *[1]University of Sydney, Sydney, NSW, Australia; [2]Diaverum Renal Services, Valencia, Spain; [3]Diaverum Renal Services Group, Lund, Sweden; [4]Diaverum, Bari, Italy; [5]University of Otago, Christchurch, New Zealand; [6]Karolinska Institutet, Stockholm, Sweden; [7]Karolinska University Hospital Huddinge, Stockholm, Sweden; [8]Princess Alexandra Hospital, Brisbane, QLD, Australia; [9]University of Calgary, Calgary, AB, Canada; [10]University of Sydney/Children's Hospital, Sydney, NSW, Australia; [11]University of Bari, Bari, Italy; [12]Diaverum Healthcare Services, Malmoe, Sweden.*

Background: Higher fruit and vegetable intake is associated with lower vascular and all-cause mortality for the general population. However, whether fruit and vegetable consumption benefits patients treated with haemodialysis is uncertain. We evaluated the association of fruit and vegetable intake with mortality outcomes in adults on hemodialysis.

Methods: The DIET-HD study was a prospective cohort study involving 9757 adults treated with hemodialysis. Fruit and vegetable intake was measured using the GA²LEN food frequency questionnaire. Cox regression analyses adjusted for sociodemographic and clinical variables and clustered by country were conducted.

Results: During a median follow up of 2.7 years (18,666 person-years), there were 2087 deaths, of which 958 were vascular deaths. Overall, higher combined intake of fruit and vegetables was associated with lower risks of non-vascular and all-cause mortality. The risk for vascular mortality was lower with the highest tertile of intake although the 95% confidence interval included the possibility of a null effect. With reference to the lowest tertile of intake (0 to 5.5 servings per week), the adjusted hazards ratios (95% confidence interval) for the middle (5.6 to 10 servings per week) and highest (>10 servings per week) tertiles were 0.88 (0.76-1.02) and 0.77 (0.66-0.91) for non-vascular mortality; 0.90 (0.81-1.00) and 0.80 (0.71-0.91) for all-cause mortality ; and 0.95 (0.81-1.11) and 0.84 (0.70-1.00) for vascular mortality.

Conclusions: Higher consumption of fruit and vegetables is associated with lower risk of mortality in hemodialysis patients.

FR-PO804

Variability of Pre-Dialysis Serum Sodium, a Risk Factor of Survival in Hemodialysis Patients: Results from the Global MONDO Initiative

Xiaoling Ye,[1] Jeroen Kooman,[2] Frank van der Sande,[2] Bernard J. Canaud,[3] Stefano Stuard,[4] Michael Etter,[7] Xiaoqi Xu,[7] Adrian M. Guinsburg,[4] Len A. Usvyat,[5] Yuedong Wang,[8] Albert J. Power,[6] Peter Kotanko,[1] Jochen G. Raimann.[1] The MONDO Initiative *[1]Renal Research Institute, New York, NY; [2]Maastricht University Medical Centre, Maastricht, Netherlands; [3]FMC Deutschland GmbH, Bad Homburg, Germany; [4]Fresenius Medical Care, Bad Homburg, Germany; [5]Fresenius Medical Care North America, Melrose, MA; [6]Richard Bright Renal Unit, Bristol, United Kingdom; [7]Fresenius Medical Care Asia Pacific, Wanchai, China; [8]University of California - Santa Barbara, Santa Barbara, CA.*

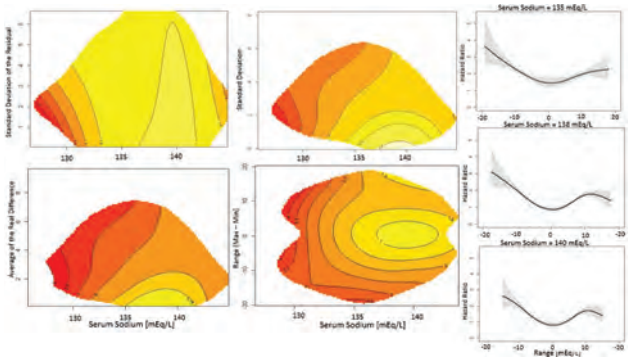
Background: Variability of laboratory parameters and serum sodium (SNa) observed to associated with adverse physical conditions in chronic hemodialysis (HD) patients (pts) [Nakazato Y et al]. SNa, the main determinant of plasma osmolality, play a key role in fluid shifts between the extra-& intracellular compartments. Variability SNa, denoted as the measured-to-measured variation, affects the stability of cell volume.

Methods: All adult incident pts with more than 5 SNas during the first year on HD were included, outcomes were recorded over a 2 yrs period. Average baseline SNa as well as variabilities were computed by standard deviation (SD) of the residual, SD, relative range (the difference between the largest and smallest), average real variability (ARV). Cox proportional models with bivariate spline functions were applied to study the joint effects of SD of residual, SD, ARV and relative range of SNa, respectively. Cox proportional models with multiple adjustments were also used to further evaluate the adverse effect of SNa variability.

Results: Out of 30,174 pts (EU:15,660, Asia:8,749,US:2,691,UK:2,282, South America:791) were included, 7,021 (23.3%) died. Hyponatremia (SNa<=135) was the most prominent predictor of increase mortality. For pts with SNa>135, we didn't observe an association between SD residual and mortality. Increased risk of death with higher SD and ARV appeared to be present at all levels of SNa. A more pronounced effect of relative range

was observed compared to SD and ARV. More significant effect was observed with the maximal SNa happened before the minimal SNa [Figure 1]. Cox proportional model with adjustments also yield the same results.

Conclusions: Given the positive association between mortality and hiher SNa range,S, ARV regardless of the SNa level, these measures constitute novel prognostic indicators in HD therapy.



FR-PO805

Incidence and Mortality of Cancers Among ESRD Patients Receiving Hemodialysis or Peritoneal Dialysis: A National Cohort Study in Korea

Young kyung Ko,[2] Sug kyun Shin,[3] Young-Il Jo.[1] *[1]Nephrology, Konkuk University Medical Center, Seoul, Republic of Korea; [2]Konkuk University Medical Center, SEOUL, Republic of Korea; [3]Ilsan Hospital NHIS, Goyang-si, GYEONGGI-DO, Republic of Korea.*

Background: Patients with end-stage renal disease (ESRD) have a higher-than-normal cancer risk. However, the incidence and mortality of cancers in ESRD patients receiving hemodialysis (HD) or peritoneal dialysis (PD) have been rarely studied for Korean populations.

Methods: We analysed data from the National Health Insurance Service (NHIS) of Korea to identify the incidence and mortality of cancers in ESRD patients receiving HD or PD. The study population was all ESRD patients starting maintenance dialysis between 2006 and 2014. They were followed from initiation of dialysis until death, discontinuation of dialysis, or the end of 2015. Cox proportional hazard regression models was used to identify the risk factors for cancer in ESRD patients.

Results: Of 17,140 ESRD patients, 4,258 (24.8%) had been newly diagnosed with cancer. The incidence of any cancer was higher for certain subgroups: older age, DM, hypertension, stroke, and coronary artery disease. In age-, gender-, and 1:2 propensity score-matched general population, 24.7% had been newly diagnosed with cancer. Rate of cancer in HD patients was 1.06 times higher than in the general population (95% CI 1.025-1.110, p=0.0014), while PD patients did not differ from general population (HR 0.897, 95% CI 0.765-1.051, p=0.1782). There were no significant differences in rates of cancer (HD vs. PD, 24.9% vs. 21.7%), the time from start dialysis to diagnosis of cancer (HD vs. PD, 4.49±3.00 vs. 3.68±2.92 years), and mean age at diagnosis of cancer (HD vs. PD, 64.44±12.14 vs. 60.23±13.20 years) between patients on HD and PD. Figure-1 showed the overall survival curves of cancers after newly diagnosed in ESRD patients and general populations.

Conclusions: These results suggested that the frequency of cancer is higher in ESRD patients on HD, not PD, than in the Korean general population.

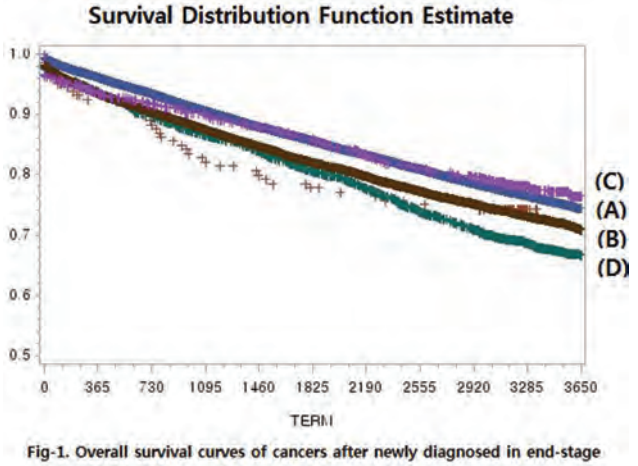


Fig-1. Overall survival curves of cancers after newly diagnosed in end-stage renal disease patients and general populations. (A) General population, (B) Hemodialysis, (C) Peritoneal dialysis, (D) Switched modality group

FR-PO806

Effects of the Specific Oriented Care in Hemodialysis Incident Patients (SOCHIP) Program on Key Performance Indicators and Early Mortality

Charles Chazot,[1] Stefano Stuard.[2] *[1]Fresenius Medical Care, Fresnes, France; [2]Fresenius Medical Care, Bad Homburg, Germany.*

Background: An increased risk of early mortality exists for patients (pts) starting chronic hemodialysis (HD) therapy. In the French NephroCare (NC) centers a Specific Oriented Care for HD Incident Patients (SOCHIP) program has been implemented.

Methods: The SOCHIP program started in October 2015. One nurse was in charge to recover monthly the Key Performance Indicators (KPIs) for all incident HD pts during the first 4 months. The prescriptions of pts out of target were reviewed monthly. We have retrospectively calculated monthly the % of pts in target before and after the implementation of the SOCHIP program.

Results: Respectively, 816 (SOCHIP-) and 666 (SOCHIP+) pts have been analyzed (age:68,4 and 68,7 yo; % females: 35 and 31,3; Charlson Index:5,1 and 5,2). At M4 the % of pts in target has been significantly increased for effective treatment time (≥720 minutes/week; 33 versus 43%, p=0,0007), the processed blood volume (240 liters/week; 20,0 versus (vs) 43,8%, p<0,0001), KT/V (≥1.4; 37,5 vs 56,4%, p<0,0001) the HyS (<13% (females) and <15% (males); 38,7 vs 65,9%, p<0,0001), the hemodynamic status (BCM® + predialysis systolic blood pressure <160 mmHg; 53,2 vs 65,7%, p<0,0001), albuminemia (≥35g/l; 51,6 vs 59,4, p=0,094). There was no significant changes of the % of patients in target for the vascular access (AV fistula; 54,0 vs 49,2%), hepatitis-B protection (Ac antiHbs+ or complete immunization record in E5; 96,7 vs 98,0%), Hemoglobine (≥10g/dl ou between 10 et 12g/dl if EPO; 52,8 vs 54,8%) and mid-week phosphatemia (<1,65 mmoles/l or >0,75 mmoles/l if Pi-binders prescription; 67,9 vs 69,4%). The crude mortality has significantly decreased from 30,1 to 22,4 for 100 patient/years p=0.0002).

Conclusions: These data show that the SOCHIP program has allowed to improve the % of pts in target for 6 out of 10 usual KPIs. The KPIs improvement parallels the improvement of the early mortality. Other parameters included in the SOCHIP program have not been evaluated (early access to cardiologist and diabetologist). Moreover, the significant increase of pts in target for albuminemia suggests that the early access to the dietitian has been improved by the SOCHIP program. We can conclude that a specific program for incident HD patient improves the % of pts in target of most of the KPIs and may improve the early mortality in this setting.

FR-PO807

Estimated Glomerular Filtration Rate (eGFR) at Initiation of Hemodialysis and Long Term Mortality

Hussain Aboud,[1] Shahab Bozorgmehri,[1] Tezcan Ozrazgat-baslanti,[1] I-Chia Liu,[1] Amir Kazory,[1] Ashutosh M. Shukla,[1,2] Azra Bihorac,[1] Mark S. Segal,[1,2] Rajesh Mohandas.[1,2] *[1]University of Florida, Gainesville, FL; [2]North Florida/South Georgia Veterans Health System, Gainesville, FL.*

Background: The results of the Initiating Dialysis Early and Late (IDEAL) study suggested that patients with stage V CKD, randomized to late initiation of Hemodialysis (HD) had similar mortality to those who started early. However, more than 3/4th of patients assigned to the late arm received dialysis earlier than planned. Moreover, IDEAL study population was very different from that of the United States and had close nephrology followup. We used a propensity score based analysis of the USRDS database to examine how the eGFR at the time of initiation of dialysis affects total and cardiovascular (CV) mortality in the US population in a real word setting.

Methods: Patients ≥18 years old who initiated in-center HD between 2006 and 2014 were included. 676,196 patients were categorized based on the tertiles of MDRD eGFR levels prior to initiation of HD, into late (eGFR <8.7), intermediate (eGFR 8.7 to <13.0) and ≥ and early start (eGFR >13.0 ml/min) groups. Associations between eGFR groups and 10-year all-cause and CV mortality were assessed using KM curves and multivariable Cox proportional hazards models with propensity-score weighted regression.

Results: Mean age was 64±15 years. Elderly, Caucasians, males and those with diabetes or heart failure were more likely to be initiated on HD early. Compared to the late start group, the intermediate and early start had a 42% and 93% increased risk of 10-year all-cause mortality, respectively (HR=1.42; 95%CI: 1.41-1.43 and HR=1.93; 95%CI: 1.91-1.94 respectively). This association was attenuated, but remained significant when adjusted for multiple covariates (adjusted HR=1.13; 95%CI:1.12-1.14 for intermediate and HR=1.37; 95%CI: 1.36-1.39, for early start respectively). The 10-year CV mortality was similarly increased with early dialysis (adjusted HR=1.13; 95%CI: 1.12-1.15 and HR=1.40; 95%CI: 1.38-1.42, for late and early start respectively). This association was robust and consistent across multiple sub-groups and sensitivity analyses.

Conclusions: Our results demonstrate that early initiation of dialysis is associated with increased toal and cardiovascular mortality. This increased mortality is not completely accounted for by co-morbidities in the early initiation group. The mechanistic basis of these observation requires further study.

FR-PO808

Planned Initiation of Hemodialysis Alleviates the Survival Disadvantage of Hemodialysis over Peritoneal Dialysis

Yi-Wen Chiu,[1,2] Ming-Yen Lin,[1,2] Shuang-Yi Yeh,[2] Shang-Jyh Hwang.[1,2] *[1]Kaohsiung Medical University, Kaohsiung, Taiwan; [2]Kaohsiung Medical University Hospital, Kaohsiung, Taiwan.*

Background: Since the discovery of initial survival disadvantage of hemodialysis (HD) over peritoneal dialysis (PD), selection bias has been questioned when making this comparison. To minimize the bias, patients with planned initiation of HD have previously been chosen for comparison, but the results were inconclusive. Here, with a different definition for planned initiation, we tested the hypothesis that the dialysis modality had no effect on the one-year mortality rate in incident dialysis patients.

Methods: A total of 45,825 incident dialysis patients with maintenance dialysis for more than 3 months in Taiwan between 2007 and 2011 were enrolled. Planned initiation of HD was defined as the initiation of HD through peripheral vascular access at an outpatient clinic (planned-HD), and the one-year mortality rate was compared between HD and PD groups in cohorts by planned initiation of HD and propensity score matching using Cox model.

Results: In all, 39,635(age 64±14y, F:48%, DM:60%), 9,184(age 65±13y, F:46%, DM:57%), and 6,190(age 55±15y, F:51%, DM:44%) incident dialysis patients were enrolled in HD, planned-HD, and PD groups, respectively. During the observation period, the death was reported for 4,453, 812, and 342 patients, respectively. HD group had a higher one-year mortality rate than PD group after either adjusting the baseline clinical characteristics (age, sex, socioeconomic status, urbanization, hypertension, diabetes, cardiac disorder, ischemia stroke, gout, peripheral vascular diseases, and Charlson score) [adjusted hazards ratio (95% confidence interval) 1.17 (1.04–1.30)] or propensity score matching [1.23 (1.07–1.42)]. However, this survival disadvantage disappeared when the planned-HD group was compared with the PD group after either adjusting the baseline clinical characteristics [0.96 (0.85–1.10)] or propensity score matching [0.99 (0.85–1.16)].

Conclusions: The initial survival disadvantage of HD over PD can be alleviated by planned initiation of HD in the dialysis population in Taiwan.

FR-PO809

Serum Globulin and All-Cause Mortality in Hemodialysis Patients

Joseph Kim,[1] Christina Park,[1] Jui-Ting Hsiung,[1] Neda Naderi,[2] Connie Rhee,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh,[1] Elani Streja.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, Orange, CA; [2]Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran; [3]University of Tennessee Health Science Center, Memphis, TN.*

Background: Nutritional status and inflammation are significant markers for mortality and morbidity, especially in hemodialysis patients. While there is much evidence to support the association between albumin levels and nutritional status and inflammation, less is known about the associations between globulin levels and mortality risk in hemodialysis patients.

Methods: We retrospectively examined a cohort of 104,164 incident hemodialysis patients treated by a large dialysis organization from 2007 to 2011 whose first patient quarter (dialysis start + 91 days) globulin measurements were obtained during treatment. Patients were grouped into 9 globulin categories. Using Cox models, we explored the association between serum globulin levels and all-cause mortality from the time of dialysis initiation with adjustments for case-mix variables and laboratory markers of malnutrition inflammation complex syndrome (MICS), including albumin.

Results: Mean patient age was 63±15 years; 44% were female, 31% were African American, and 58% were diabetic. Mean globulin level was 1.16±0.31 g/dL. Compared to the reference group of 3.0-<3.2 g/dL, patients with lower globulin (<2.8 g/dL) and higher globulin (≥3.8 g/dL) had higher mortality risk in the unadjusted model. After case-mix adjustment, compared to the referent, patients with lower globulin had lower mortality risk while higher globulin still had higher mortality risk. After adjustment for MICS covariates, the associations were attenuated; however, patients with globulin >3.8 g/dL still had a higher mortality risk compared to the referent [figure1].

Conclusions: Among incident hemodialysis patients, higher globulin level is associated with higher mortality risk, independent of other markers of malnutrition and inflammation, including albumin.

FR-PO810

Comparison of All-Cause Mortality Between Maintenance Dialysis and Cancer Patients

Kyla L. Naylor,[1,2] Joseph Kim,[3] Eric McArthur,[2] Amit X. Garg,[4] Greg A. Knoll.[5] *[1]University of Toronto, Toronto, ON, Canada; [2]Institute for Clinical Evaluative Sciences, London, ON, Canada; [3]Toronto General Hospital, University Health Network, Toronto, ON, Canada; [4]London Health Sciences Centre, London, ON, Canada; [5]Ottawa Hospital, Ottawa, ON, Canada.*

Background: Mortality risk is high in dialysis patients. Yet, the mortality risk in dialysis compared to other diseases like cancer is poorly understood. We conducted a population-based cohort study using healthcare databases from Ontario, Canada, to examine survival probabilities for all-cause mortality in maintenance dialysis patients compared to patients with common cancers (women: breast, colorectal, lung, or pancreas; men: prostate, colorectal, lung, or pancreas) from 1997 to 2015.

Methods: We used the Kaplan-Meier product limit estimator to determine the cumulative probability of survival for all-cause mortality. Additional analyses examined the risk of mortality adjusting for clinical characteristics and trends in survival probability using Cox proportional hazards regression.

Results: 33,500 maintenance dialysis patients and 532,452 cancer patients (median follow-up 4.4 years). In males, dialysis had worse 5-year survival (50.8%, 95% confidence interval [CI]: 50.1, 51.6%) compared to prostate (83.3%, 95% CI: 83.1, 83.5%) and colorectal cancer (56.1%, 95% CI: 55.7, 56.5%) but better survival than lung (14.0%, 95% CI: 13.7, 14.3%) and pancreas cancer (9.1%, 95% CI: 8.5, 9.7%). In females, dialysis had worse 5-year survival (49.8%, 95% CI: 48.9, 50.7%) compared to breast (82.1%, 95% CI: 81.9, 82.4%) and colorectal cancer (56.8%, 95% CI: 56.3, 57.2%) but better survival than lung (19.7%, 95% CI: 19.4, 20.1%) and pancreas cancer (9.4%, 95% CI: 8.9, 10.0%). After adjusting for clinical characteristics, similar results were found. Survival significantly improved across eras (1997-2001, 2002-2006, 2007-2011, 2012-2015) for all cancer types ($P<0.01$) but no significant change was observed in dialysis patients (females, $P=0.89$; males, $P=0.48$) (**Figure**).

Conclusions: Survival in dialysis patients was lower than patients with several types of common cancers. Unlike cancer patients, the prognosis of patients on dialysis has not improved over time. Results highlight the need to develop and test interventions to improve survival in maintenance dialysis patients.

A Simple Vitality Question, Its Correlates, and Clinical Outcomes in Patients Receiving Hemodialysis: The Japanese Dialysis Outcomes and Practice Pattern Study

Noriaki Kurita,[1] Tadao Akizawa.[2] *[1]Department of Innovative Research and Education for Clinicians and Trainees, Fukushima Medical University Hospital, Fukushima, Japan; [2]Showa University School of Medicine, Tokyo, Japan.*

Background: The lack of an assessment of vitality in daily practice may be partially due to inadequate understanding of lack of vitality and the lack of a concise method of assessing it. The aim of this study was to examine the predictability of a simple 1-item vitality question and its correlates.

Methods: This was a cohort study involving hemodialysis patients who participated in the Japan Dialysis Outcomes and Practice Pattern Study (phase 3 to 4 [2005–2011]). Predictor was one-item vitality measured via the 12-item Medical Outcomes Study Short Form survey version 2.0, using a 5-level Likert scale. Outcomes were all-cause mortality and a composite of multiple cardiovascular hospitalization and all-cause mortality. A pooled ordered logit model was fitted to examine correlates of 1-item vitality. Cox and mixed-effects Poisson regression models were fitted for mortality and composite outcomes, respectively.

Results: 3,667 patients were analyzed. Decrease in vitality category was associated with tachycardia (≥ 100 vs. 60 to < 70 beats/min) and benzodiazepine, hypnotics, or antidepressant use. In contrast, increase in vitality was associated with increase in single-pool Kt/V, serum albumin, and BMI. Compared with the lowest vitality category, the second highest and middle categories were negatively associated with all-cause mortality (Figure; adjusted hazard ratio [AHR] 0.66, 95% confidence interval [95% CI] 0.47–0.93 and AHR 0.75, 95% CI 0.59–0.96, respectively). A one-category increase in vitality was consistently associated with lower mortality (AHR 0.86, 95% CI 0.78–0.96). The associations between 1-item vitality and multiple cardiovascular hospitalization and mortality were similar to those between vitality and mortality.

Conclusions: 1-item vitality predicted all-cause mortality and a composite of multiple cardiovascular hospitalization and all-cause mortality, and correlates with some modifiable factors, including vital signs. Dialysis staff should consider asking this simple question in daily practice to improve patient quality of life and outcomes.

All covariates adjusted	0.85	0.79 - 0.93

FR-PO812

Epilepsy and All-Cause Mortality Among ESRD Patients in the US Renal Data System, 2013-2014

Salina Waddy,[1] Julia B. Ward,[2] Timothy Powers,[2] Paul Eggers,[3] Kevin C. Abbott,[1] Korwyn Williams,[4,5] Chyng-Wen Fwu,[2] Paul L. Kimmel.[1] *[1]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), National Institutes of Health, Bethesda, MD; [2]Social & Scientific Systems, Inc., Durham, NC; [3]Retired, Olney, MD; [4]Barrow Neurological Institute at Phoenix Children's Hospital, Phoenix, AZ; [5]Department of Child Health, College of Medicine, University of Arizona, Phoenix, AZ.*

Background: Despite the long-appreciated association of seizures with uremia, there are few national data regarding the prevalence and outcomes of ESRD patients with epilepsy compared to those without epilepsy.

Methods: We assessed claims-based diagnoses of epilepsy, baseline characteristics, anticonvulsant drug prescriptions and outcomes by comparing ESRD patients with and without epilepsy in the USRDS. Study population comprised of prevalent US ESRD patients with continuous Medicare Part A, B, and D coverage from Jan. 1, 2013 to Dec. 31, 2014. Epilepsy was defined as one claim with an International Classification of Disease-9th Revision-Clinical Modification (ICD-9-CM) code for *epilepsy* or two claims with ICD-9-CM codes for *seizures* at least 30 days apart from Jan. 1, 2013 to Dec. 31, 2014. The outcome was all-cause mortality from Jan. 1, 2015 to July 31, 2016. We used modified Poisson regression with a robust variance estimator to estimate risk ratios and 95% confidence intervals for the association between epilepsy status and mortality. Final models were adjusted for sociodemographics, ESRD treatment history, and comorbidities.

Results: Of 195,319 ESRD patients in the cohort, 15,233 patients (7.8%) were classified as having epilepsy. Of ESRD patients with a claims-based diagnosis of epilepsy, 80.4% filled an anticonvulsant or hydantoin prescription compared to 31.6% of patients without epilepsy. 19 anticonvulsant medications were prescribed. Levetiracetam and Phenytoin were the most commonly prescribed anticonvulsant drugs without another indication such as pain. 20.1% of patients died during the 19-month follow-up period: 27.9% of patients with epilepsy and 19.4% of patients without epilepsy (p <0.0001). After adjustment for confounders, the estimated mortality risk among those with epilepsy was 1.14 (95% CI: 1.11, 1.18) times that among those without epilepsy.

Conclusions: ESRD patients have a high prevalence of epilepsy and many are treated with anti-convulsant drugs such as Levetiracetam and Phenytoin. ESRD patients with epilepsy had an increased risk of death compared to those without epilepsy. Given the high epilepsy prevalence among the ESRD population, continued efforts are needed to identify appropriate treatment/medication selection and to prevent premature mortality among ESRD patients with epilepsy.

FR-PO813

All-Cause Mortality in Relation to Intradialytic Relative Blood Volume and Central-Venous Oxygen Saturation Among Hemodialysis Patients

Hanjie Zhang,[1] Priscila Preciado,[2] Lili Chan,[3] Stephan Thijssen,[1] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]Renal Research Institute, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Relative blood volume (RBV) and central venous oxygen saturation ($ScvO_2$) monitoring is increasingly adopted. We previously identified that at higher $ScvO_2$ levels, that RBV had only a small effect on mortality risk, whereas at lower $ScvO_2$ levels, RBV tends to drive mortality risk. In this study, we further explored the association between RBV and $ScvO_2$ values on all-cause mortality.

Methods: This is a retrospective multicenter cohort study of HD patients with central-venous catheter (CVC) as vascular access from 17 Renal Research Institute clinics from January 2012 to June 2017 where the Crit-Line® Monitor (CLM) is used. The CLM allows for monitoring of extracorporeal hematocrit (Hct) and $ScvO_2$. The patients were stratified into 2 groups depending on their RBV and $ScvO_2$ at 3 hours (mean values between minutes 170 and 190) into HD.

Results: We included 151 patients with a total of 3,937 HD treatments. The median follow-up time was 2.8 years. The patients were stratified into 2 groups, 52 patients with their RBV larger than 91.74% and $ScvO_2$ lower than 56.72% at 3 hours into HD were labeled right corner patients (based on the position from our last study [1]). The results indicate a significantly increased mortality in patients with lower $ScvO_2$ and higher RBV levels compared to others (Figure 1 KM plot). Multivariate Cox analysis with different levels of adjustments corroborated the higher hazards ratios for all-cause mortality in these patients.

Conclusions: We found that patients with lower $ScvO_2$ and higher RBV levels had higher mortality. These findings may be related to patients' volume status and cardiac function. **References** Hanjie Zhang et. al. Association of intradialytic relative blood volume and central-venous oxygen saturation with mortality among hemodialysis patients. ERA EDTA 2018 abstract.

FR-PO814

Association Between Reduction of Extracellular Volume by In-Center Short Daily Hemodialysis and Survival

Ana Beatriz L. Barra,[1] Ana P. Silva,[1] Eufronio D'almeida,[1] Marcos Sandro F. Vasconcelos,[1] Jorge P. Strogoff-de-Matos.[2] *[1]Fresenius Medical Care, Rio de Janeiro, Brazil; [2]Universidade Federal Fluminense, Niteroi, Brazil.*

Background: Overhydration (OH) is associated with a higher mortality risk in maintenance hemodialysis. A better management of OH through daily hemodialysis (DHD) could improve survival.

Methods: Retrospective analysis of patients on hemodialysis 3 sessions/week for >3 months who shifted to in-center short DHD (≥ 5 sessions / week) between 2012 and 2016 at 23 dialysis units in Brazil. Hydration status was evaluated before and 6 months after initiating DHD by bioimpedance spectroscopy. Pre-dialysis hydration state was considered adequate when OH ≤15% of extracellular volume. For survival analysis, data were censored 2 years after initiating DHD.

Results: A total of 208 patients were included in the analysis (56±16 years old, 64% males, 38% diabetics, 56% on dialysis 6 sessions/week, treatment time was 12.5±1.8 h/week. After 6 months on DHD, 177 patients were re-evaluated. OH was reduced from 13.9% (IQR 5.4 – 22.3%) to 8.9% (IQR 0.4 – 15.9%), P<0.0001, the rate of patients with OH>15% dropped from 47% to 29% (P= 0.0005) and pre-dialysis systolic blood pressure fell from 139±21 mmHg to 134±21 mmHg (P= 0.029). The 2-year survival rate was 76%, with no difference according to the OH status before DHD initiation (P= 0.92). However, survival was higher for patients reached OH ≤15% after the beginning of DHD than those with OH >15% (83% vs. 70%; P= 0.02). In a Cox regression model, after adjustment for

demographic, clinical and laboratory variables, OH ≤15% persisted associated with a lower mortality risk (hazard ratio 0.40 [95% confidence interval 0.18 – 0.90]).

Conclusions: Moving from standard hemodialysis to short DHD was associated with a better control of excessive extracellular volume and blood pressure. Patients who reached OH ≤15% after initiating DHD presented a lower risk of death.

FR-PO815

Weight loss Increases Risk of Cardiovascular Events and Mortality in Incident Dialysis Patients

Sawako Kato,[1] Bengt Lindholm,[2] Yukio Yuzawa,[3] Shoichi Maruyama.[1] *[1]Nagoya University Graduate School of Medicine, Aichi, Japan; [2]Karolinska Institutet, Stockholm, Sweden; [3]Fujita Health University School of Medicine, Toyoake, Japan.*

Background: Protein-energy wasting is a common and established risk of cardiovascular events and mortality in dialysis patients, while obesity is associated with a greater survival as well known "reverse epidemiology". Recent study suggested that short-term weight loss was more associated with worse outcome. Here we explored if weight loss just before initiation of dialysis could predict CVD events and mortality among incident dialysis patients.

Methods: In an ongoing prospective cohort study, 175 incident Japanese dialysis patients (113 males, age 59 ±11 years) were enrolled and followed for a median of 55.2 months (range 1-112 months). Laboratory biomarkers were determined at baseline. We defined [dry weight of the first month of start dialysis therapy] – [body weight at 6 months before start dialysis therapy] as the delta body weight (DBW), patients with over 5kg weight loss during this term as weight loss and patients with under 5kg weight loss or weight gain as stable weight, respectively.

Results: In Spearman rank test, DBW negatively correlated with body weight (rho=-0.15, P=0.042), abdominal circumference (rho=-0.21, P=0.007), serum CRP (rho=-0.17, P=0.032) and cardiothoracic ratio (rho=-0.20, P=0.013), while there was no correlation between DBW and body mass index (BMI). In Kaplan-Meier curves, the CVD death was associated with weight loss (Log rank 5.91, P = 0.015). And the duration from start of dialysis therapy to the first CVD events was significantly shorter in patients with weight loss (Log rank 10.74, P = 0.001). In Cox hazard model, after adjustments for age, gender, and BMI, the weight loss had a significantly increased relative risk of CVD deaths (2.89, 95% CI; 1.05-9.22, P = 0.0385).

Conclusions: In Japanese incident dialysis patients, short-term weight loss just before initiation dialysis therapy associated with increased risk of CVD deaths and events. These results may suggest that we should pay attention to lean losing weight rather than physical status.

FR-PO816

Association of White Blood Cell Count with Survival in Incident Hemodialysis Patients

Tiffany Zai,[1] Christina Park,[1] Jui-Ting Hsiung,[1] Melissa Soohoo,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh,[1] Elani Streja.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: Higher white blood cell counts (WBC) have been shown to be strongly and independently associated with all-cause mortality in maintenance hemodialysis (HD) and incident peritoneal dialysis patients; however, the association between WBC count and mortality in incident HD patients has been understudied.

Methods: We retrospectively examined a cohort of 109,767 incident HD patients receiving treatment within a large dialysis organization from 2007-2011, with available WBC measurements during the first 91-days of dialysis. Patients were grouped into 6 WBC categories. Using Cox models, we examined the association between WBC count and all-cause mortality with hierarchical adjustments for case-mix variables, albumin and additional laboratory markers of malnutrition and inflammation (MICS).

Results: Mean patient age of the cohort was 63±15 years; 44% of patients were female, 32% were African American, and 58% were diabetic. Mean WBC count was 7.82±2.68 $x10^3/mm^3$. Compared to the reference group of WBC 7.0-<8.0 $x10^3/mm^3$, we observed a J-shaped association between WBC and mortality. Patients with low WBC (<6.0 $x10^3/mm^3$) had a higher risk of mortality (hazard ratio (HR): 1.04 [95% CI: 1.00, 1.08]), and patients with greater WBC (>9.0 $x10^3/mm^3$) had the highest risks of mortality in case-mix adjusted models. After further adjustment for albumin and MICS covariates, associations were modestly attenuated; however, patients with WBC >9.0 $x10^3/mm^3$ still had a higher mortality risk compared to the referent [figure1].

Conclusions: Among incident HD patients, higher WBC count is associated with higher mortality risk, independent of other markers of malnutrition and inflammation, including albumin. These data suggest that WBC count may need closer monitoring in patients who are new to dialysis, but further studies are needed to examine this relationship.

FR-PO817

Intradialytic Relative Blood Volume Changes and All-Cause Mortality Among Hemodialysis Patients

Priscila Preciado,[1] Hanjie Zhang,[1] Stephan Thijssen,[1] Jeroen Kooman,[2] Frank van der Sande,[2] Peter Kotanko.[1] *[1]Renal Research Institute, New York, NY; [2]Maastricht University Medical Centre, Maastricht, Netherlands.*

Background: Adequate volume control is a major challenge in hemodialysis (HD) patients, as both fluid overload and depletion are associated with increased mortality. Ultrafiltration is the only means for fluid removal in anephric patients. Whenever the ultrafiltration rate (UFR) exceeds the plasma refilling rate, the blood volume declines and hypotension may ensue. Relative blood volume (RBV) monitoring during HD is used as a means to tailor UFR. Our goal was to explore the association between intradialytic RBV levels and all-cause mortality in maintenance HD patients

Methods: We conducted a retrospective analysis of data from HD patients dialyzed in 17 Renal Research Institute clinics between 1/2012 and 12/2016. A 6-months baseline period preceded a follow-up. Censoring events were change in treatment modality, transfer to another clinic, and study end. RBV was measured using the Critline monitor. RBV was assessed after 25%, 50%, 75% and 100% of the elapsed treatment time. The relationship between mortality and RBV at these four time points was analyzed using Cox proportional hazards models with spline terms

Results: We studied 842 patients with a total of 28,119 HD treatments (mean age 61.0±14.8 years, 50% whites, 62% males, 56% had diabetes mellitus, 22% had congestive heart failure). Median follow-up time was 30.8 months. The mortality rate was 11.5/100 patient years. We identified specific intradialytic RBV levels after 25%, 50%, 75% and 100% of the elapsed dialysis treatment time that were associated with a significantly lower all-cause mortality **[Fig 1].**

Conclusions: We showed in a large cohort of HD patients that specific RBV levels are associated with better outcomes. These findings corroborate the notion that RBV monitoring has the potential to improve outcomes. Prospective studies are warranted to explore if active attainment of these RBV levels translates into improved patient outcomes.

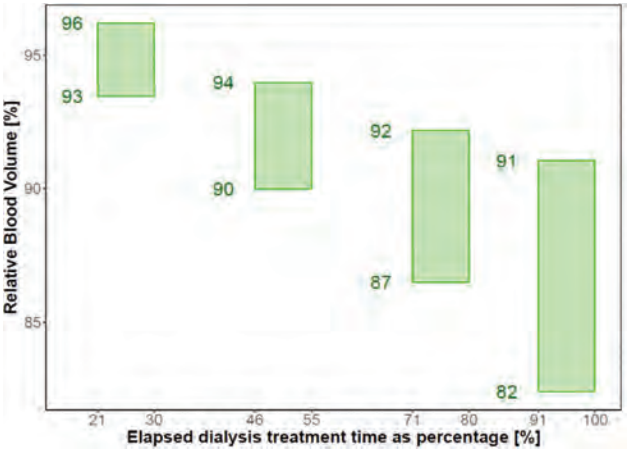

Fig 1. Intradialytic RBV ranges associated with hazard ratios significantly below 1.0 for all-cause mortality.

FR-PO818

Synergic Impact of BMI, Diabetes, and Age on Long-Term Mortality in Incident Japanese Hemodialysis Patients: A Cohort Study of the Large National Dialysis Registry

Tatsunori Toida,[1,2] Yuji Sato,[3] Satoshi Ogata,[4] Atshushi Wada,[4] Ikuto Masakane,[4] Shouichi Fujimoto.[1] *[1]Department of Hemovascular Medicine and Artificial Organs, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan; [2]Department of Internal Medicine, Nobeoka Hospital of Miyazaki Prefecture, Nobeoka city, Japan; [3]Dialysis Division, University of Miyazaki Hospital, Miyazaki, Japan; [4]Committee of Renal Data Registry, The Japanese Society for Dialysis Therapy, Tokyo, Japan.*

Background: In general Japanese with diabetes, leanness has been associated with an increased risk of all-cause mortality. However, it currently remains unclear whether BMI and age influence the prognosis of diabetic patients who start hemodialysis.

Methods: Study design: Cohort study. Participants: Data from the national dialysis registry in 2007, including 35,415 patients on incident hemodialysis and 6,061 patients aged ≥20 years with BMI data. Predictor: Patients were divided into 6 categories according to baseline BMI levels (Leanness: <18.5, Normal: 18.5-25, Obesity: ≥25) and the presence or absence of diabetes. Outcomes: All-cause mortality during a 5-year follow-up. Measurements: Hazard ratios were estimated using Cox's model for the relationships between diabetes, BMI categories, and all-cause mortality, and adjusted for potential confounders including sex, age, systolic BP values, a previous history of cardiovascular disease, and so on. Patients with normal BMI levels without diabetes were set as our reference category. We also examined the effects of age on these relationships.

Results: Among 3239 and 2822 patients with or without diabetes, 993 and 887 patients died of all-cause mortality, respectively. Cox's regression analysis showed that leanness, but not obesity, was independently associated with an increased risk of all-cause death in patients with and without diabetes. When patients were divided into two groups: younger and older than 60 years, the risk of all-cause death in the younger group was markedly increased among lean diabetic patients as well as among those with a normal BMI and diabetes, but not obesity. However, in the older group, the risk of death among diabetic patients with a normal BMI was not significantly different from that among those without diabetes. In diabetic patients of the older group, only leanness was associated with an increased risk of mortality.

Conclusions: Among incident Japanese hemodialysis patients, leanness, but not obesity, increases the risk of all-cause mortality. Particular attention must be paid to the markedly high mortality rate in lean diabetic patients regardless of age. Furthermore, diabetes may be associated with mortality in patients younger than 60 years with a normal BMI.

FR-PO819

A Higher Mortality Rate in Afebrile Bacteremia in Chronic Hemodialysis Patients

Keun-hoi Park, Wonhak Kim, Soon Bae Kim. *Seoul Asan Medical Center, Seoul, Republic of Korea.*

Background: Body temperature (BT) has received little attention as a prognostic factor in hemodialysis patients. Some previous studies reported that fever in initial bacteremia is associated with better survival. Therefore, we aimed to analyze the difference in hospital mortality between febrile and afebrile chronic hemodialysis (CHD) patients with bacteremia and investigated positive blood culture rate according to the C-reactive protein (CRP) level.

Methods: The blood culture data in CHD patients from 2006 to 2014 were collected and the bacteremic events were assigned to either "febrile group" or "afebrile group" based on the BT measured on the day of blood culture. Fever was defined as a tympanic temperature > 37.5 degrees Celsius or an axillary temperature > 37.0 degrees Celsius. Empirical antibiotics were administered immediately after blood culture. Laboratory values were considered only for the day of blood culture sampling. The primary outcome was in-hospital mortality rate, the length of ICU stay and the length of hospitalization.

Results: From a total of 1556 blood cultures, 190 bacteremias were identified excluding cases of immunosuppressive agents or anti-cancer drug use and cases of delayed blood culture. Both the febrile group (n=162) and afebrile group (n=28) showed no difference in baseline characteristics. With regard to primary outcome, in-hospital mortality rate was higher in the afebrile group (41.4% vs. 6.1%) and the interval from admission to blood culture was longer in the afebrile group (3 hours v. 1 hour). The major reason for blood culture in the afebrile group was a high CRP level. Assessing the positive blood culture rate according to the CRP level in all the 1556 cultures, we found that the rate was 5.7 % (34/600) in patients with CRP levels <5mg/dL, 15.1 % (44/292) in those with CRP levels between 5 and 10 mg/dL, and 23.8 % (158/664) in those with CRP levels >=10 mg/dL.

Conclusions: An afebrile state with bacteremia in CHD patients was associated with a higher in-hospital mortality rate. Therefore, a prompt blood culture and empirical antibiotics administration should be considered in CHD patients with high CRP levels irrespective of fever.

FR-PO820

Long-Term Blood Pressure Variability Better Predicts All-Cause Mortality in Hemodialysis Patients than Intradialytic Blood Pressure Variability

Ruoxi Liao,[1] Li P. Lin,[1] Jiameng Li,[3] Yuqin Xiong,[2] Yupei Li,[1] Baihai Su.[3] *[1]West China Hospital, Sichuan University, Chengdu, China; [2]West China Medical School, West China Hospital, Sichuan University, Chengdu, China; [3]West China Hospital of Sichuan University, Chengdu, China.*

Background: Blood pressure variability (BPV) is a potential prognostic predictor for all-cause mortality. Here we conducted a retrospective cohort study to compare the affecting factors and prognostic ability of long-term BPV with intradialytic BPV in hemodialysis(HD) patients.

Methods: We included 611 HD patients, collected their baseline characteristics including one-year blood pressure, and followed up for 40 months. Long-term BPV was assessed by pre-dialysis SBP residual metric, while intradialytic BPV was assessed by intradialytic absolute SBP residual.

Results: Long-term BPV showed a correlation with intradialytic BPV (Spearman r from 0.5997 to 0.6883). According to logistic regression, both long-term and intradialytic BPV were associated with age, vascular access type, dialysis time, dialysis vintage, pre-dialysis blood pressure and serum albumin(Alb), while only intradilytic BPV was affected by body mass index (Fig 1 A-D). High long-term BPV but not intradialytic BPV was associated with high all-cause mortality (p= 0.0047 and 0.3682, respectively)(Fig 1 E-F). According to receiver operating characteristic (ROC) curve with mortality as dependent variable, long-term SBP residual metric showed a stronger prognostic ability than intradialytic BPV (area under curve [AUC] 0.679 *vs.* 0.568, p=0.0381), which was more significant in patients with blood pressure≥140/90mmHg (AUC 0.713 *vs.* 0.556, p=0.0191)(Fig1 G-H). After complete adjustments, long-term BPV remained significantly associated with all-cause mortality (hazard ratio 1.628 per quartile; 95% confidence interval, 1.086 to 2.441).

Conclusions: Our results implied an advantage of long-term BPV in predicting all-cause mortality in HD patients, suggesting long-term BPV as an additional target of blood pressure management.

Funding: Government Support - Non-U.S.

FR-PO821

Predialysis Hyponatremia and Post-Dialysis Elevation in Serum Sodium Concentration During Hemodialysis as Significant Predictors of Mortality in Patients Undergoing Hemodialysis

Kiichiro Fujisaki,[1] Nobuhiko Joki,[2] Shigeru Tanaka,[3] Eiichiro Kanda,[4] Takayuki Hamano,[5] Ikuto Masakane,[6] Kazuhiko Tsuruya.[7] *[1]Kyushu University Hospital, Fukuoka, Japan; [2]TOHO University Ohashi Medical Center, Tokyo, Japan; [3]Fukuoka Dental College, Fukuoka, Japan; [4]Kawasaki Medical School, Kurashiki, Japan; [5]Osaka University Graduate School of Medicine, Suita, Japan; [6]Honcho-Yabuki Clinic, Yamagata, Japan; [7]Nara Medical University, Kashihara, Japan.*

Background: Previous studies have reported that hyponatremia is associated with increased mortality in hemodialysis (HD) patients. However, there have been few reports on studying the fluctuation of serum sodium (Na) concentration during HD (ΔNa: postdialysis Na – predialysis Na) in HD patients. We conducted this cohort study using a nation-wide registry of patients with end-stage renal disease in Japan to examine the association of predialysis hyponatremia and ΔNa during HD with mortality.

Methods: We identified 178,114 patients from a nation-wide database of HD patients receiving thrice-weekly HD in Japan. The study outcome was 2-year all-cause mortality and baseline Na levels were categorized into quintiles. We examined the association of serum Na concentration and ΔNa with the mortality using a Cox proportional hazards model.

Results: During a 2-year follow-up period, 25928 patients died from any cause. Each 1-mEq/L decrement in pre-dialysis Na concentration was associated with increased risk of all-cause death (Hazard ratio [HR], 1.05; 95% confidence interval [CI], 1.05-1.06). In contrast, higher ΔNa level was associated with higher all-cause mortality (HR for 1 mEq/L increment in ΔNa, 1.02; 95% CI, 1.01-1.02). The combined association of tertiles of predialysis Na concentration and ΔNa with all-cause mortality showed the highest mortality (HR 1.09, 95% CI 1.05–1.13) in subjects with the lowest Na concentration (Na ≤136 mEq/L) and the highest ΔNa level (ΔNa >4 mEq/L) compared with those (reference) with intermediate predialysis Na concentration (137–140 mEq/L) and the lowest ΔNa level (ΔNa ≤2 mEq/L).

Conclusions: Lower predialysis Na concentration and higher ΔNa are associated with an increased risk of death in HD patients.

FR-PO822

Blood Pressure Variability along Hemodialysis: Is It Related to Mortality?

Eduardo Baamonde,[1] Elena Oliva-Damaso,[1] Nicanor Vega-diaz,[1] Roberto Gallego Samper,[2] Nestor Oliva-Damaso,[3] Silvia Marrero- Robayna,[1] Jose C. Rodriguez-Perez.[1] *[1]Hospital General Universitario de Gran Canaria Dr Negrin, Las Palmas, Spain; [2]Hospital Universitario de Gran Canaria Dr Negrin, Las Palmas de Gran Canaria, Spain; [3]Hospital Costa del Sol, Marbella, Spain.*

Background: Recent studies, link Hemodialysis systolic blood pressure (BP) variability and mortality. However BP variability can be seen with different (BP) components, including systolic and diastolic as well as predialysis, intradialytic, and postdialysis BP. Aims: To analyze BP variability in different measurements along Hemodialisys (HD) session and verify which of them predict mortality in incident patients.

Methods: Retrospective analysis of 277 incidents patients on conventional HD. BP records were collected throughout the hemodialysis sessions from the beginning of treatment. BP variability was calculated using the coefficient of variation (CV). Demographic and clinical data were analyzed during a 24 month follow-period as well as mortality rate. Survival analisys (Cox proportional hazards) was carried out by stratifying patients in tertiles of BP variability.

Results: 277 incident HD patiens (186 M, 91 F). Age (yr): 65,1 ± 13,1. Sex (%men): 67,1. Diabetes (%): 45,8. Hypertension (%): 95. Systolic preHD BP (mmHg): 137,6 ± 14,5 CV: 11,5 ± 3,7, Diastolic preHD BP (mmHg): 73,3 ± 6,8. CV:12,1 ± 7,7. Systolic postHD BP(mmHg) : 137,2 ± 14,7. CV: 11,2 ± 3,05. Diastolic postHD BP: 73,5 ± 6,5. CV: 13,5 ± 14,5. We observed 51 deaths (18,4%) during the follow-up period. Higher Diastolic post hemodialisys blood pressure variability (DBPV) was associated with an increased risk of death, as shown in the table below (Fig1). Survival analysis (Kaplan-Meyer) shows significative differences between tertiles of DBPV (p<0.009) (Fig2).

Conclusions: In our study we observed and increased risk of mortality in patients with higher diastolic blood pressure variability, especially those with greater variability post hemodialysis.

Risk Factor	Parameter estimate	P-Value	Hazard Ratio (HR) (95% CI for HR)
Diabetes Mellitus	-0,128	0,880	0,872 (0,489-1,554)
Age	-0,011	0,289	0,990 (0,971-1,010)
Male Sex	0,104	0,734	1,037 (0,567-1,896)
DBPV post HDT1	Reference	Reference	Reference
DBPV postHD T2	0,413	0,313	1,511 (0,678-3,368)
DBPV post HD T3	0,996	0,009	2,708 (1,286-5,703)

The Impact of Sunlight Exposure on Mortality of ESRD Patients: A Bi-Directional Case-Crossover Study in the Korean Nation-Wide ESRD Cohort

Yong Chul Kim,[1] Soie Kwon,[2] Jung Nam An,[3] Dong Ki Kim,[4] Chun Soo Lim,[3] Jung Pyo Lee.[3] *[1]SNUH, Seoul, Republic of Korea; [2]Seoul national university, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, SEOUL, Republic of Korea; [4]Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Recent data suggest that reduced sunlight exposure is associated with increased mortality in the general population. To date, the association between sunlight exposure and mortality in dialysis patients has not been examined.

Methods: Among 134,478 dialysis patients in the Korean end-stage renal disease (ESRD) cohort from 2001 to 2014, 31,291 patients were enrolled from seven metropolitan cities, and data were analyzed using bi-directional case-crossover design. We examined the association between short-term sunlight exposure and mortality in ESRD patients. We adjusted for temperature, humidity, and daily concentrations of nitrogen dioxide (NO_2), sulfur dioxide (SO_2), ozone (O_3), carbon monoxide (CO), and particle matter (PM_{10}) as confounders.

Results: The characteristics of the study population included age (65.6 ± 12.26 (mean ± standard deviation [SD]) years), sex (male, 59.96%; female, 41.04%), comorbidity (diabetes, 53.58%; hypertension, 40.5%), and kidney dialysis type (hemodialysis, 73.02%; peritoneal dialysis, 26.98 %). The mean ± SD follow-up time was 4.68 ± 4.37 years. The daily sunlight exposure was significantly decreased in the case group compared with the control group (P=0.004). Sunlight exposure was associated with all-cause death overall (ORs [95%CI]: 0.99 [0.98-0.99], P=0.042) in a fully adjusted model. Patients with diabetes (ORs [95%CI]: 0.98 [0.97-0.99], P=0.016) or aged higher than 75 years (ORs [95%CI]; 0.97 [0.96 – 0.99], P=0.020) had higher risks of mortality than patients without diabetes or aged below 75 years, respectively.

Conclusions: These findings suggest that sunlight exposure is inversely correlated with all-cause mortality in dialysis patients, especially in high-risk patients with diabetes and older adults.

FR-PO824

Association Between Endothelin-1 Levels and Mortality Among Hemodialysis Patients

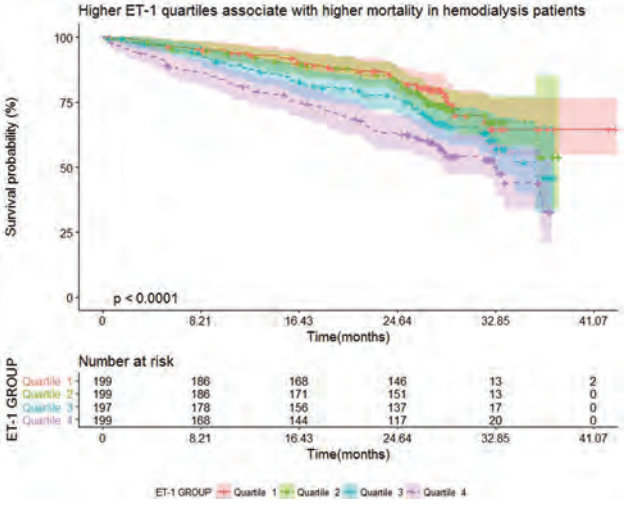
Ping Li,[1,2] Finnian R. McCausland,[1] Sushrut S. Waikar.[1] *[1]Harvard Medical School, Boston, MA; [2]Department of Nephrology, State Key Laboratory of Kidney Disease, 2011DAV00088, National Clinical Research Center for Kidney Disease, 2013BAI09B05, Chinese PLA General Hospital, Beijing, China.*

Background: Endothelin-1 (ET-1) is a potent endothelium-derived vasoconstrictor peptide implicated in the pathogenesis of hypertension, heart failure, and CKD. The association of endothelin with adverse outcomes in individuals with end stage renal disease on hemodialysis is unclear.

Methods: We measured pre-dialysis plasma levels of ET-1 in 794 individuals with ESRD on maintenance hemodialysis from the DaVita BioReg Biorepository, a prospective cohort study of prevalent hemodialysis patients. ET-1 was measured with a commercially available ELISA, with CV's of 7.3% from blind split replicate samples. Unadjusted and adjusted proportional hazards regression models were fit to exam the association of ET-1 with all- cause mortality.

Results: Mean age was 60, 41.4% were women, and median vintage was 37.2 months. Median (IQR) endothelin-1 concentration was 2.02 (1.56 – 2.71) pg/mL. ET-1 levels were positively correlated with pre-dialysis blood pressure (r=0.13, p<0.001), weight difference before and after dialysis (r=0.119, P<0.001) and longer dialysis vintage (r=0.084, P=0.019). In multivariable proportional hazards models adjusted for age, race, sex, BP, BMI, vintage, laboratory variables, and dialysis access, higher ET-1 levels were associated with a 37% higher risk of all-cause mortality (hazard ratio 1.37; 95% confidence interval, 1.23 to 1.53; $P < 0.001$) during median 27.8 months of follow-up time.

Conclusions: Higher pre-dialysis plasma ET-1 levels are associated with an increased risk of death. The mechanisms underlying this association and its potential therapeutic relevance merit further investigation.



FR-PO825

Beta-2 Microglobulin Levels and All-Cause Mortality: Results from the Dialysis Outcomes and Practice Patterns Study (DOPPS)

Jeffrey Perl,[1] Daniel G. Muenz,[2] Brian Bieber,[2] Aleix Cases,[3] Eiichiro Kanda,[4] Francesco Locatelli,[5] Hal Morgenstern,[6] Friedrich K. Port,[2] Bruce M. Robinson.[2] *[1]St. Michael's Hospital, Toronto, ON, Canada; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Nephrology Department, Hospital Clinic, Barcelona, Spain; [4]Kawasaki Medical School, Kurashiki, Japan; [5]Ospedale Alessandro Manzoni, Azienda Socio Sanitaria Territoriale, Lecco, Italy; [6]University of Michigan, Ann Arbor, MI.*

Background: Dialysis-related amyloidosis due to beta-2 microglobulin (β2M) accumulation among hemodialysis (HD) patients is now uncommon due to HD delivery improvements. The impact of β2M levels and other middle molecules on other adverse

events among HD patients remains unclear. We sought to identify patient factors that may affect β2M level and estimate the effect of β2M on mortality.

Methods: Facilities in DOPPS phases 4-6 were included in this study if ≥50% of patients had β2M levels reported in ≥50% of follow-up rounds. Cox regression was used to estimate the association (hazard ratio [HR]; 95% CI) between β2M, categorized in tertiles, and all-cause mortality, adjusting for demographic factors, comorbidities, HD treatment factors, and stratified by study phase and region (Japan vs. Europe).

Results: We identified 5366 patients from 77 HD facilities in Japan (n=3837), France, Italy, and Spain (n=1529). Median (IQR) values of β2M (mg/dL) were 2.58 (2.17-3.00) in Japan and 2.55 (1.98-3.21) in Europe. In cross-sectional, unadjusted analysis, patients in the upper β2M tertile had longer dialysis vintage, greater likelihood of urine volume <200mL/day, lower prevalence of diabetes, higher serum phosphorus, and higher C-reactive protein, relative to the lower β2M tertile. Little association was observed between β2M and HD treatment time. Compared with the lower β2M tertile, the adjusted HR for mortality was 1.20 (0.98-1.48, 95% CI) for the middle tertile and 1.44 (1.17-1.75, 95% CI) for the upper tertile (Figure).

Conclusions: β2M is positively associated with mortality, controlling for several potential confounders. Interventions targeting greater β2M clearance during HD therapy may be an effective therapeutic strategy to improve outcomes among these patients.

Polyvascular Disease and Cardiovascular Risk in Hemodialysis Patients: Ten-Year Outcomes of the Q-Cohort Study

Shigeru Tanaka,[1] Toshiaki Nakano,[2] Hiroto Hiyamuta,[2] Masatomo Taniguchi,[3] Masanori Tokumoto,[4] Hiroaki Ooboshi,[1] Kazuhiko Tsuruya,[5] Takanari Kitazono.[6] *[1]Fukuoka Dental College, Fukuoka, Japan; [2]Kyushu University, Fukuoka, Japan; [3]Fukuoka Renal Clinic, Fukuoka, Japan; [4]Department of Internal Medicine, Fukuoka Dental College, Sawara-ku, Japan; [5]Nara Medical University, Kashihara, Japan; [6]Department of Medicine and Clinical Science, Fukuoka, Japan.*

Background: Patients with polyvascular disease (PVD), which indicates co-existing arteriosclerotic disease on multiple vascular beds, have been identified to be a high-risk group of recurrent ischemic events in a community setting. However, the impact of PVD on the risk of cardiovascular events has not been evaluated previously in a hemodialysis population.

Methods: A total of 3,504 hemodialysis patients were prospectively followed for 10 years. PVD were defined as prior cardiovascular disease plus co-existing vascular diseases in one or more vascular beds. We examined the relationship between PVD and the occurrence of composite end point of ischemic events, including cardiovascular death, non-fatal coronary artery disease, stroke, and critical limb ischemia.

Results: The proportion of participants with PVD was 5.7% (n=200) at baseline. During follow-up period (median: 106.6 months, interquartile range: 50.1–121.8 months), 1,316 patients experienced at least 1 or more events of cardiovascular death (n=620), non-fatal coronary artery disease (n=456), stroke (n=524) or critical limb ischemia (n=257). In multivariable analysis, PVD was the most powerful predictor for ischemic events exceeding the contribution of presumed risk factors such as diabetes, aging and hypertension. Compared to the group without injured vascular beds, the risk of the events significantly elevated with the increase in the number of injured vascular beds (hazard ratio [HR] 1.71, 95% confidence interval [CI] 1.52–1.92 in the group of single vascular bed lesions, and HR 2.16, 95% CI 1.78–2.67 in the group of polyvascular bed lesions).

Conclusions: This study clearly demonstrates that PVD is the most powerful predictor for future incidences of ischemic events in hemodialysis patients.

FR-PO827

An Inverse Association of Proteinuria with Mortality in Incident Hemodialysis Patients

Manabu Hishida,[1] Tariq Shafi,[2] Lawrence J. Appel,[3] Daijo Inaguma,[4] Kunihiro Matsushita.[5] *[1]Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]Johns Hopkins Medical Institutions, Baltimore, MD; [4]Nephrology, Fujita Health University, Nagoya, Japan; [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Background: Proteinuria is a potent predictor of mortality. However, in patients with severely reduced kidney function, a few studies from the CKD Prognosis Consortium and Veterans Affairs showed a J-shaped association between proteinuria and mortality. To our knowledge, no studies have explored this association in incident dialysis patients.

Methods: We examined data from 1380 Japanese incident dialysis patients (mean age 67 years). Baseline data were collected just before or during the hospitalization at which dialysis was initiated. The associations of dipstick proteinuria (negative/trace, 1+, 2+ and ≥3+) with all-cause mortality and cardiovascular disease (CVD) mortality were quantified in Cox models after accounting for potential confounders such as age, cause of CKD, and history of CVD.

Results: Proteinuria ≥3+ was the most prevalent category (n=765 [55.4%]), followed by 2+ (430 [31.2%]), 1+ (137 [9.9%]), and negative/trace (48 [3.5%]). Patients with lower proteinuria were likely to be older and have a history of CVD, compared to the patients with higher proteinuria. During a mean follow-up of 3.3 years, there were 352 deaths (129 due to CVD). Patients with lower proteinuria had a higher risk of mortality, with unadjusted hazard ratios 3.86 (2.55-5.85) for negative/trace, 1.62 (1.16-2.26) for 1+, and 1.35 (1.07-1.71) for 2+ (Model 1 in Table). Although attenuated, this pattern remained significant after accounting for potential confounders (p for trend ≤0.001 and adjusted hazard ratio 2.60 [1.62-4.17] for negative/trace in Model 4 in Table). This association was consistent for CVD and no-CVD mortality, even when restricting to adults aged ≥70 years, or further adjusting for cardiac ejection fraction.

Conclusions: We documented a progressive inverse trend of proteinuria with mortality among incident dialysis patients, with a strikingly high risk of mortality in persons with negative/trace proteinuria. Our study highlights the prognostic value of predialysis data and suggests that absence of proteinuria as a potential indicator of the highest postdialysis mortality risk.

Funding: Private Foundation Support

Table. Hazard ratios (95% CI) of all-cause mortality according to dipstick proteinuria categories

	Proteinuria (dipstick)				
	negative/trace (n=48)	1+ (n=137)	2+ (n=430)	3+ (n=765)	P for trend (n=1380)
All-cause mortality (n = 352)	26 deaths	44 deaths	119 deaths	163 deaths	
model 1	3.86 (2.55-5.85) **	1.62 (1.16-2.26) **	1.35 (1.07-1.71) *	ref	<0.001

FR-PO828

Low Eosinophil Count and Decrease in Eosinophil Count During the First 6 Months After Hemodialysis (HD) Are Associated with High Mortality

Duk-Hee Kang,[1] Yong kyu Lee,[1] Carola-Ellen Kleine,[1] Connie Rhee,[1] Csaba P. Kovesdy,[2] Elani Streja,[1] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: Eosinophilia has been recognized to occur in HD patients, however its causes and clinical significance are still uncertain. Eosinophils are traditionally known as the moderator of allergic reactions, however they have now emerged as one of the most important immune-regulating cells, and an increase in eosinophil count is also reported to be a predictor of vascular disease in the general population. Associations of eosinophil count (EOS) and its changes with mortality in dialysis patients are still unknown.

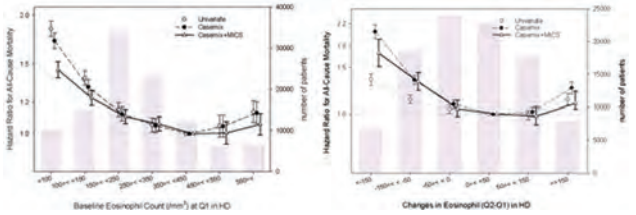
Methods: In a cohort of 107,056 incident HD patients treated by a large dialysis organization during 2007-2011, we examined the relationships of baseline EOS (Q1-average within 3 months of HD transition) and 6-month changes in EOS (Q2-Q1) with mortality using Cox proportional hazards models. Three adjustment models were used including case-mix variables and markers for malnutrition and inflammation.

Results: Baseline EOS and fraction during Q1 were 231 (interquartile range: 155-339) /mm^3 and 3.2% (2.2-4.6). Eosinophilia (>350/mm^3) was observed in 23.4% of patients. There was a gradual increase in mean EOS after the initiation of dialysis. The 6-month mean and percent changes in EOS were 5.1 (-53 to 199) /mm^3/quarter and 0.11 (-0.22 to 0.28) %/quarter, which did not parallel with the changes in WBC count. In fully adjusted models, mortality risk was highest in subjects with lower baseline EOS (<150/mm^3), and also slightly higher in patients with higher levels (>550/mm^3) resulting in a reverse J-shaped relationship. Compared to the group with stable EOS (change: -50 to <50/mm^3/quarter), both decrease or increase in EOS was associated with higher all-cause mortality risk. Case-

mix-adjusted HR [95% CI] 2.05 [1.93-2.18] in the decrease group and 1.25 [1.19-1.32] in the increase group, respectively. [Figure]

Conclusions: Low baseline EOS and a 6-month EOS decrease following dialysis initiation were associated with higher all cause mortality risk.

Funding: NIDDK Support



FR-PO829

Syncope and Collapse Is Associated with an Increased Risk of Cardiovascular Disease and Mortality in Patients Undergoing Dialysis

Tung-Min Yu. *Taichung Veterans General Hospital, Taichung ---, Taiwan.*

Background: Patients undergoing dialysis have a higher risk of cardiovascular disease and mortality than the general population. Syncope and collapse (SC) is often observed in patients before and after dialysis sessions. However, the epidemiology of SC is undetermined and the association between SC and cardiovascular outcomes in a dialysis population has not been discussed. This study explored the impact of SC on cardiovascular events and mortality.

Methods: This study retrospectively examined data of patients undergoing dialysis from population-based medical registries between 1998 and 2011. Patients undergoing dialysis who have SC (N = 3876) were selected as the study cohort and those without SC who were propensity score-matched at a 1:1 ratio were included as controls. Major adverse cardiovascular events (MACEs), included acute coronary syndrome (ACS), arrhythmia or cardiac arrest, stroke, and overall mortality, were evaluated and compared in both cohorts.

Results: In 2011, the incidence and prevalence rates of SC were 7.05% and 10.8%, respectively, in the dialysis population. The mean follow-up periods until the occurrence of ACS, arrhythmia or cardiac arrest, stroke, and overall mortality in the SC cohort were 3.51 ± 2.90, 3.43 ± 2.93, 3.74 ± 2.97, and 3.76 ± 2.98 years, respectively. Compared with the patients without SC, those with SC had higher incidence rates of ACS (30.1 vs. 24.7 events/1000 people/year), arrhythmia or cardiac arrest (6.75 vs. 3.51 events/1000 people/year), stroke (51.6 vs. 35.7 events/1000 people/year), and overall mortality (127.7 vs. 77.9 deaths/1000 people/year). The SC cohort also had higher risks of ACS, arrhythmia or cardiac arrest, stroke, and overall mortality (adjusted hazard ratios: 1.28 [95% confidence interval (CI) = 1.11–1.46], 2.05 [95% CI = 1.50–2.82], 1.48 [95% CI = 1.33–1.66], and 1.79 [95% CI = 1.67–1.92], respectively) than did the non-SC cohort.

Conclusions: SC was significantly associated with cardiovascular events and overall mortality in the patients on dialysis. SC may serve as a prodrome for cardiovascular comorbidities, thereby assisting clinicians in identifying high-risk patients.

FR-PO830

Elevated Levels of Soluble ST2 but Not Galectin-3 Are Associated with Increased Risk of Mortality in Patients with Hemodialysis

Ae jin Kim, Kayeong Chun, Han Ro, Jae Hyun Chang, Hyun Hee Lee, Wookyung Chung, Ji Yong Jung. *Division of Nephrology, Department of Internal Medicine, Gachon University Gil Medical Center, College of Medicine, Gachon University, Incheon, Republic of Korea.*

Background: Soluble ST2 (sST2) and galectin-3 has been proposed as novel biomarkers of cardiac fibrosis and heart failure, and may also predict cardiovascular event and mortality. However, there are limited data on the association between sST2 and galectin-3 and clinical outcomes in patients with end-stage renal disease. To determine this, we examined associations of sST2 and galectin-3 with all-cause mortality and cardiovascular events in patients with hemodialysis (HD)

Methods: This study included maintenance HD patients 18 years or older who consent to preserve their serum to the Bio Bank at our institution between March 2014 and March 2015. The primary outcome was all-cause mortality. The secondary outcome was composite of the cardiovascular event (CVE) and mortality. We used Cox proportional hazards regression analysis to evaluate associations between sST2 and galectin-3 levels and clinical outcomes. Patients were followed for CVE and mortality through March 2018.

Results: A total of 296 patients were analyzed in this study. Mean age was 57 ± 13 years, 52.9% were male. The mean serum level of sST2 was 24.81 ± 12.43 ng/ml and mean serum level of galectin-3 was 35.50 ± 9.91 ng/ml. Serum sST2 concentration was significantly associated with higher mortality (hazard ratio [HR], 1.043; 95% confidence interval [CI], 1.017 – 1.070; P = 0.001) and composite outcome including CVE and mortality (HR, 1.022; 95% CI, 1.003 – 1.040; P = 0.022) after adjustment for confounding factors. However, serum galectin-3 level was not independently associated with mortality nor composite outcome after adjustment.

Conclusions: Elevated levels of sST2 is independently associated with increased risk of adverse clinical outcomes in patients with HD.

FR-PO831

Racial and Sex Disparities in Mortality in Incident ESRD Patients

Silvi Shah, Anthony C. Leonard, Karthikeyan Meganathan, Annette Christianson, Charuhas V. Thakar. *University of Cincinnati, Cincinnati, OH.*

Background: End Stage Renal Disease (ESRD) is a global public health problem; and is characterized by high morbidity and mortality. Although mortality in patients is highest during the first year of dialysis, differences in mortality across five different races among men and women is not well studied.

Methods: We evaluated 944, 650 adult patients who initiated dialysis between 1/1/2005 and 12/31/2014 from the United States Renal Data System (USRDS). Using adjusted logistic multivariate regression models adjusted for major cofounders, we examined the effect of race and sex on all cause mortality after dialysis initiation.

Results: Mean age of the study population was 65±14 years. Of the study cohort, 56% were male. 53% were White, 28% were Black, 14% were Hispanic, 4% were Asian, and 1% were Native American. Of those who started dialysis, 77% initiated with a catheter. Overall, 30% did not receive pre-dialysis nephrology care. One-year mortality was 24% and 90-day mortality was 9%. In adjusted analyses, as compared to Whites, one-year mortality was lower among Blacks (odds ratio [OR], 0.73; 95% confidence interval [CI], 0.72-0.74]), Hispanics (OR, 0.64; CI, 0.63-0.65), Asians (OR, 0.55; CI, 0.53-0.56), and Native Americans (OR, 0.67; CI, 0.63-0.71). Females were less likely to die within one year after initiating dialysis than were males (OR, 0.98; CI, 0.97-0.99). Other significant predictors of mortality included absence of predialysis nephrology care, use of central venous catheter as dialysis access, older age, poor functional status, serum albumin < 3.5 mg/dl, and comorbidities (congestive heart failure, cancer, and chronic obstructive pulmonary disease).

Conclusions: Among incident dialysis patients; as compared to White patients, Black patients are 27% less likely, Hispanic patients 36% less likely, Asians patients 45% less likely, and Native Americans are 33% less likely to die within one year. Females have lower mortality than males. Biological factors associated with these disparities need to be explored further to understand the reasons behind the survival advantage among minorities and women.

FR-PO832

Impact of Transferrin Saturation on All-Cause Mortality in Patients on Maintenance Hemodialysis

Kosaku Nitta. *Tokyo Women's Medical University, Shinjuku-ku, Japan.*

Background: To evaluate iron status, transferrin saturation (TSAT) and serum ferritin levels are commonly used. TSAT provides an assessment of how much transferrin has bound iron, whereas serum ferritin is a marker used to reflect body iron storage. Our aim was to evaluate the prognostic importance of TSAT in Japanese patients on maintenance hemodialysis (MHD).

Methods: A total of 398 MHD patients were recruited and divided into 3 groups according to baseline TSAT of <20%, 20–40%, and >40%. The mean duration of the study was 52.2 ± 16.3 months. The primary endpoint was all-cause mortality, and the secondary endpoint was cardiovascular (CV) mortality.

Results: A total of 130 patients died during a mean follow-up duration of 52.2 ± 16.3 months. There were no differences in the proportion of patients on erythropoiesis-stimulating agents or iron supplements among the 3 groups. During a mean follow-up duration of 52.2 ±1 6.3 months, 130 patients died of CV causes (n = 63, (15.8%) and infection (n = 47, 11.8%). Compared with the reference group (TSAT 20–40%), patients with TSAT <20% had significantly higher all-cause mortality rates (6.44 vs. 9.55 events per 100 patient-year, p = 0.0452). Kaplan-Meier analysis also showed that all-cause mortality rates were significantly higher in patients with TSAT <20% compared to the other two groups (p =0.0353).

Conclusions: Low TSAT was a significant independent risk factor for all-cause mortality in a cohort of Japanese MHD patients. These findings suggested that the adverse clinical outcomes in patients with low TSAT can be partly attributed to iron-deficiency anemia.

FR-PO833

Modelling Survival in Dialysis Patients to Improve Their Access to Life Insurance for Loan

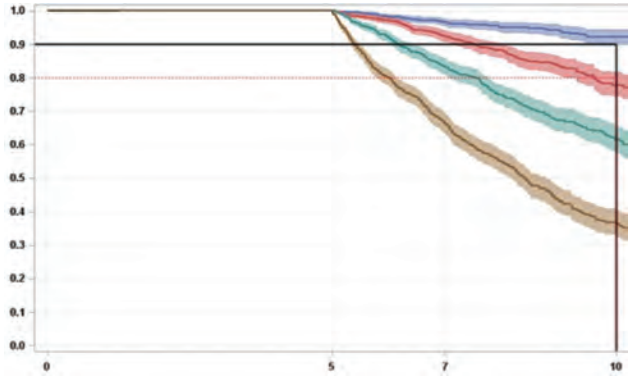
Christian Jacquelinet.[1,2] on behalf the REIN Registry [1]*Agence de la biomedecine, Saint-Denis La Plaine, France;* [2]*CESP-U1018, INSERM, Villejuif, France.*

Background: "AERAS convention" (Access to Loan for People with Increased Health Risk Agreement) aims in France to provide insurance companies with evidence-based data to improve their assessment of risk for patients with chronic diseases.Data from the French REIN registry were used to predict survival for ESRD patients who frequently face the highest difficulties to borrow money due to high (often precluding) life insurance premiums, especially for those under dialysis.

Methods: The study included a cohort of 27952 patients who started a replacement therapy between 2002-1-1 and 2016-12-31 at the age of 25 to 60 yo. We focus here on 10-years survival conditionally on being alive and not previously transplanted at 1, 3 or 5 years. A Cox model was used to build multivariate risk functions for each conditional time points, taking into account updated data from the closest annual follow-up. A 10-year survival threshold significantly greater than 90% with an unilateral alpha risk of 2.5% was considered as a proxy for considering a potential access to loan without major life insurance premiums.

Results: Age, albuminemia, diabetes, number of cardio-vascular comorbidities, respiratory insufficiency, dialysis modalities and placement on the waiting list were significant and independent predictors of 10-years survival, with varying HRs and ß coefficients with conditional time points (e.g. 1, 3 or 5 years from dialysis start). C-indexes were greater than 0.6 and discrimination was good, as illustrated by quartile-stratified 10-years survival conditionally on being alive and not previously transplanted at 5 years (Figure 1). More than a quarter of patients who were 25 to 65 yo at start of dialysis and respectively alive after 1, 3 and 5 years of dialysis are predicted with 10-year survival greater than 90%.

Conclusions: ESRD registries indeed provide useful personalized tools to improve access to loan for many patients with ESRD, thus contributing to their social and professional integration of these patients, and finally to their quality of life.



FR-PO834

Cause of Death in Patients on Renal Replacement Therapy Varies Across Australia, New Zealand, and Malaysia - Results from the Study of Heart and Renal Protection-Extended Review (SHARP-ER)

Ben Talbot,[1] Louisa Sukkar,[1,3] Brendan Smyth,[1,3] Min Jun,[1] Meg J. Jardine,[1] Alan Cass,[4] Robert J. Walker,[2] Christina A. Reith,[5] Hooi L. Seong,[6] Martin P. Gallagher.[1] *[1]The George Institute for Global Health, The University of New South Wales, Sydney, NSW, Australia; [2]University of Otago, Dunedin, New Zealand; [3]Sydney School of Public Health, The University of Sydney, Sydney, NSW, Australia; [4]Menzies School of Health Research, Darwin, NT, Australia; [5]CTSU, Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom; [6]Sultanah Aminah Hospital Johor Baru, Malaysia, Johor Bahru, Malaysia.*

Background: The mortality rate among dialysis patients is high with regional variability. The Study of Heart and Renal Protection-Extended Review (SHARP-ER) comprised extended 5-year follow up of eligible participants in Australia, New Zealand and Malaysia alive at the end of SHARP (a randomised double-blind trial of simvastatin and ezetimibe vs. placebo in chronic kidney disease). We compared survival and cause of death between countries in dialysis patients in the SHARP-ER cohort.

Methods: Eligible participants in Australia, New Zealand and Malaysia alive at the end of SHARP were identified and extended 5-year follow up data collected. Cause of death was determined using registry data (national death index in Australia and New Zealand and national death registry in Malaysia) for participants receiving chronic dialysis (haemodialysis or peritoneal dialysis) at the beginning of the extended review period. Multivariate survival analysis and multinomial logistic regression were conducted to assess for differences.

Results: The cohort comprised 1136 participants in total. Of these, 526 were receiving chronic dialysis and were included in the analysis. During the 5 year follow up 203 died (38.6%). Median age was lowest in Malaysia (56.2 years [50.4-63.8]), followed by New Zealand (60.4 years [55.5-67.3]) and Australia (66.1 years [55.3-75.8]). Treating country did not significantly affect survival following adjustment for age, gender and dialysis modality. Cardiovascular disease was the most common cause of death (New Zealand 52.4%, Australia 43.2%, Malaysia 32.6%). Infectious causes of death were significantly more common in Malaysia versus Australasia (Australia and New Zealand combined; RR 4.56, p=0.002, 95% CI 1.75-11.85) following adjustment. Crude rates of infectious death by country were: Malaysia 31.8%, New Zealand 9.5%, Australia 6.8%. Peritoneal dialysis was also associated with an increased risk of infectious death (RR 3.64, p=0.017, 95%CI 1.26-10.48) following adjustment.

Conclusions: In the SHARP-ER cohort, survival on dialysis was comparable between Australia, New Zealand and Malaysia but causes of death differed. This suggests a need for region specific interventions.

FR-PO835

Prevalence of Oral Mucosal Lesions in Hemodialysis Patients and Association with Mortality: A Prospective Cohort Study

Marinella Ruospo, Marietta Török, Marco A. Murgo, Anna Bednarek, Domingo Del castillo caba, Amparo Bernat, Paul Stroumza, Charlotta Wollheim, Jorgen B. Hegbrant. Oral-D investigators: M Ruospo, S Palmer, P Natale, V Saglimbene, G Graziano, G Wong, J Craig, M Petruzzi, M De Benedittis, E Celia, R Gelfman, M Leal, M. Torok, A Bednarek-Skublewska, J Dulawa, D del Castillo, A Bernat, P Stroumza, L Frantzen, J Hegbrant, C Wollheim, L Gargano, S Schon and GFM Strippoli *Diaverum Medical Scientific Office, Lund, Sweden*.

Background: Oral mucosal lesions are highly prevalent and frequently severe for adults treated with longterm hemodialysis. We aimed to evaluate the prevalence of mucosal lesions and association with mortality among hemodialysis patients.

Methods: The ORAL-D study was a multinational cohort study that involved a comprehensive, standardized oral and dental examination among 4726 patients with ESKD disease treated with haemodialysis in Europe and South America. We evaluated oral mucosal lesions assessed by trained dentists according to standard WHO guidelines. The association between mucosal lesions and all-cause and cardiovascular mortality was estimated using a Cox proportional hazard regression model. Analyses were adjusted for sociodemographic and clinical variables. The primary outcome was all-cause mortality.

Results: 70 participants (1.7%) had mucosal ulceration, 147 (3.5%) presented white stain, 169 (4%) red stain, 85 (2%) neoformation, and 331 (7.9%) had petechial lesions. Overall, 207 (4.9%) had geographical tongue and 450 (10.7%) had a fissured tongue. Oral candidiasis was observed in 192 (4.6%) participants and 21 had oral herpetic lesions. 401 participants (9.5%) had a cancer-related mucosal lesion and 213 participants (5%) an infection-related lesion. During a median 3.47 (1.55-5.78) months of follow-up, there were 2114 deaths including 1013 cardiovascular deaths. In unadjusted survival analyses, the proportion of patients who died was higher among those with red stain, fissured tongue, and petechial lesions. Similarly, the estimated proportion of patients who had a cardiovascular death was higher among those with red stain, fissured tongue, petechial lesions, neoformation and oral candidiasis. When adjusting for clinical and sociodemographic factors, only the presence of oral candidiasis was significantly associated with an increased risk of all cause (adj HR 1.37, 95% CI 1.00-1.86) and cardiovascular mortality (adj HR 1.64, 95% CI 1.09-2.46). This association was confirmed in competing risks analysis and using a shared frailty model to account for clustering by country.

Conclusions: There is generally limited evidence of an independent association between oral mucosal lesions and mortality outcomes among hemodialysis patients.

FR-PO836

Outcomes of Treatment of Myeloma in Patients Requiring Renal Replacement Therapy – A Single Centre Experience

Aruni Ratnayake, Mukunthan Srikantharajah, David Makanjuola, Simon C. Stern. *Epsom and St Helier University Hospitals NHS Trust, London, United Kingdom.*

Background: Renal impairment is a complication of multiple myeloma (MM). The incidence of renal impairment at diagnosis of MM is 20-50%; about 10% of these present with acute kidney injury requiring renal replacement therapy (RRT). Treatments including Bortezomib have improved prognosis with full or partial recovery of renal function; however they cause side effects e.g. peripheral neuropathy. We reviewed outcomes of MM treatments in patients requiring RRT over an 11 year period.

Methods: Patients diagnosed with MM requiring RRT between January 2007 - December 2017 were identified. Patient data was obtained from electronic records.

Results: 29 patients met the inclusion criteria. Median age 64 years (range 45-86); 59% were male; 72% were Caucasian. Median follow up time was 33 months (range 8-96 months). 65% (N=19) were treated with first line chemotherapy including Bortezomib; of these 84% showed complete (21%), or partial (63%) response to therapy. 1 year survival was 89% (N=19), 5 year survival 71% (N=14). Complications were thrombosis (11%), neuropathy (53%) and infection requiring hospital admission (42%). 37% recovered enough renal function to cease RRT. 35% (N=10) did not have Bortezomib as part of initial treatment. Of these 50% responded to therapy; all with partial response, none with complete response. 1 year survival was 90% (N=10), 5 year survival was 50% (N=10). Complications were thrombosis (20%) and infection requiring hospital admission (20%). No patient experienced neuropathy. Only 10% recovered sufficient renal function to stop RRT. Patients who gained dialysis independence had significant reduction of free light chains after 2 chemotherapy cycles (median 85%, range 61%-99%). Those who were still on RRT had more variation in change in free light chains ranging from -99% to +63%.

Conclusions: Our study coincides with the introduction of Bortezomib as first-line treatment in 2010. In our cohort, Bortezomib resulted in increased rates of response to first line therapy, greater likelihood of dialysis independence and improved overall survival. However, more side effects were associated with Bortezomib. As has been shown in patients with renal amyloid (Rezk et al, Kidney International 2017), reduction of free light chains post chemotherapy can be used as a predictor for dialysis independence and our results support this.

FR-PO837

End-of-Life Care Among Patients with ESRD Who Undergo a Lower Extremity Amputation

Catherine Butler,[1] Susan M. Hailpern,[4] Margaret Schwarze,[6] Ronit Katz,[1] Manjula Kurella Tamura,[3] Maria E. Montez-Rath,[5] Yoshio N. Hall,[7] William Kreuter,[1] Ann M. O'Hare.[2] *[1]University of Washington, Seattle, WA; [2]VA Puget Sound Health Care System, Seattle, WA; [3]Stanford University, Palo Alto, CA; [4]Medicine, University of Washington, Kidney Research Institute (retired), Seattle, WA; [5]Stanford University School of Medicine, Palo Alto, CA; [6]UW School of Medicine and Public Health, Madison, WI; [7]University of Washington-Kidney Research Institute, Seattle, WA.*

Background: Patients with ESRD have a high incidence of lower extremity amputation and limited post-operative long-term survival, but little is known about the relationship between amputation and patterns of their end-of-life care.

Methods: We used Medicare claims to compare patterns of amputation and health care utilization in the last year of life among 754,762 patients with ESRD registered in the USRDS and 958,412 Medicare beneficiaries without ESRD who died between 2002 and 2014.

Results: During the last year of life, 8.2% of Medicare beneficiaries with, and 0.9% of those without ESRD underwent at least one lower extremity amputation. After adjustment for differences in patient characteristics, patients with ESRD were more likely to have undergone at least one amputation (relative risk (RR) 2.30, 95% confidence interval (CI) 2.24-2.35) and multiple amputations (RR 3.65, 95% CI 3.36-3.97) within a year of death. During their last year of life, patients with ESRD who underwent amputation were more likely to be admitted to the hospital, ICU, and/or to a SNF and less likely to be enrolled in hospice than other patients (figure). During this time, they spent a median of 58 days admitted to a hospital (vs. 35 days for patients without ESRD who underwent amputation, 29 days for patients with ESRD who did not undergo amputation, and 13 days for patients without ESRD who did not undergo amputation), 12 days admitted to an ICU (vs. 8, 9, and 5), 54 days admitted to a SNF (vs. 56, 39, and 32), and 5 days enrolled in hospice (vs. 10, 6, and 17).

Conclusions: Almost one in ten patients with ESRD undergo an amputation in the last year of life. These patients spend prolonged periods of time in acute and subacute care settings towards the end of life, but receive relatively little hospice care. These findings argue for more work to understand the end-of-life experience of these patients and suggest opportunities to improve care.

FR-PO838

Regional Factors Associated with Hospice Use in the US Hemodialysis Population

Jessica Cruz Whitley,[1] Heejung Bang,[2] Andrew I. Chin.[3] *[1]UC Davis, Sacramento, CA; [2]UC-Davis, Davis, CA; [3]University of California Davis, Sacramento, CA.*

Background: Hospice use remains underutilized in the US ESRD population. We explored patient, hospice, and community factors at the county level for hospice use in a contemporary cohort of hemodialysis (HD) patients.

Methods: All deaths in patients on HD from 2014-2015 in the USRDS database were obtained. Hospice use was based on the death form hospice indicator or at least one Medicare hospice charge the year of death. Number of Medicare-certified hospices, their profit status, and regional characteristics at the County level were obtained from publically available databases and linked to the patient by County. Univariate comparisons and Multivariables Logistic Regression models were used.

Results: Of 140,729 deceased patients, 25% utilized hospice at the time of death. Those who utilized hospice were older at the time of death, predominantly White (74%), and non-Hispanic (89%). In logistic regression analyses, men were 11% less likely to utilize hospice than women, Hispanics were 12% less likely to use hospice than non-Hispanics, and Blacks were 33% less likely to utilize hospice than Whites. Those who utilized hospice were 3% more likely to have a Medicare certified hospice within their county. The number of hospices within county of residence and non-profit status were positively associated with hospice use. Residing in the Northeast region of the US and higher % of Medicare recipients eligible for Medicaid in the county were negatively associated with hospice use. Other socio-economic factors and intensity of care measures did not appear to be associated with hospice use.

Conclusions: Patient demographics associated with hospice use are consistent with published research. We also found that the region in the US, number of hospices in the county of residence and the composition of Medicare recipients in the county appear to also be associated with hospice use in a contemporary HD cohort.

Postoperative Outcomes in Chronic Dialysis Patients: A Meta-Analysis of 37 Studies and 75,428 Patients

Dharmenaan Palamuthusingam,[1,3] Arun Nadarajah,[1] David W. Johnson,[1,3] Jonathan C. Craig,[2] Elaine M. Pascoe,[3] Carmel M. Hawley,[1,3] Magid Fahim.[1,3] *[1]Princess Alexandra Hospital, Brisbane, QLD, Australia; [2]University of Sydney/ Children's Hospital, Sydney, NSW, Australia; [3]The University of Queensland, Brisbane, QLD, Australia.*

Background: Chronic dialysis patients frequently undergo major surgery, but their absolute and relative risk of postoperative complications is unclear. The aim of this study was to estimate the risks of fatal and non-fatal postoperative outcomes in chronic dialysis patients undergoing non-transplant surgery.

Methods: Two authors performed a systematic review of observational studies indexed in Embase and MEDLINE till July 2017 that reported postoperative outcomes in chronic dialysis and non-dialysis patients undergoing major, non-transplant surgery. Summary level data on study characteristics, type of surgical procedure, patient demographics and comorbidity were extracted. The primary outcome was death(30-day or in-hospital mortality); secondary outcomes were myocardial infarction and sepsis. Random effects meta-analysis was performed to derive summary risk estimates and meta-regression was performed to explore heterogeneity.

Results: 37 studies involving 75,428 chronic dialysis and 9,624,178 non-dialysis patients undergoing orthopedic, vascular, cardiothoracic, general and urological procedures were included. Summary, unadjusted risk estimates showed increased risks of postoperative mortality (7.2% vs. 0.2%, OR 5.61, 95%CI 4.5-7.0, $I^2$90%), myocardial infarction (1.1% vs. 0.3%, OR 3.3, 95% CI 2.3-4.7, $I^2$74%) and sepsis (6.3% vs. 0.6%, OR 3.6, 95% CI 2.4-5.3, $I^2$96%) in dialysis patients compared to non-dialysis patients irrespective of discipline. Adjustment for age and comorbidity attenuated the risks of postoperative death (OR 3.1, 95% CI 2.9-3.3 $I^2$90%), myocardial infarction (OR 1.8, 95% CI 1.3-2.3, $I^2$0%) and sepsis (OR 2.6, 95% CI 2.3-2.9, $I^2$70%). Weighted univariate metaregression showed a significant association between individual study reported mortality odds ratios and differences in age (slope 0.099, p<0.01), cardiac disease prevalence (slope 0.002, p<0.01) and diabetes prevalence (slope 0.49, p<0.01) between dialysis and non-dialysis patients.

Conclusions: Chronic dialysis patients have substantially increased risks of both fatal and non-fatal postoperative complications across all surgical disciplines. This heightened risk is attributable not only to their dialysis dependency, but also to their older age and higher comorbid illness burden.

FR-PO840

The Association Between Race/Ethnicity and Mortality Is Modified by BMI

Carola-Ellen Kleine,[1] Hamid Moradi,[1] Christina Park,[1] Jui-Ting Hsiung,[1] Connie Rhee,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh,[1] Elani Streja.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: African-Americans (AA) and Hispanics have better survival rates once on hemodialysis (HD). This phenomenon is known as "racial paradox". Besides, obese HD patients might have a survival benefit, too. Therefore, we aimed to examine if BMI is an effect modifier of the race/ethnicity-mortality association.

Methods: We retrospectively examined a cohort of 140,817 HD patients from a large dialysis organization in 2007 to 2011 who had known race/ethnicity and recorded BMI value. Patients were grouped according to their self-identified race/ethnicity. We explored the effect modification of BMI on the association between AA vs White, Hispanic vs. White, Asian vs. White and White vs non-White and all-cause mortality with adjustments for case-mix variables and laboratory markers of malnutrition and inflammation by using restricted cubic spline models, which splined the impact over continuous BMI.

Results: The cohort consisted of 29% AAs, 3% Asians, 14% Hispanics, 50% Whites and 3% others with a mean age of 64±15 years and mean BMI value of 28.2±7.3 kg/m^2. We found a survival benefit of both AA and Hispanic patients when compared to White patients.

This survival benefit was more observed in those with higher BMI and attenuated for low BMI patients. We observed a similar trend for Asians (reference Whites), however it did not reach statistical significance for higher BMI values. For Whites, the mortality association mirrored the findings in non-Whites. [figure1].

Conclusions: Among HD patients, BMI is an effect modifier of the race/ethnicity-mortality association.

Normothermic Ex-Vivo Kidney Perfusion Restores the Gene Expression Profile of Marginal Kidney Grafts Subjected to Warm Ischemia

Peter Urbanellis,[1,2] Caitriona M. McEvoy,[3] Ivan Linares,[4] Dagmar Kollmann,[5] Sujani Ganesh,[4] Istvan Mucsi,[2] Darius Bagli,[6] Ana Konvalinka,[7] Lisa Robinson,[8] Markus Selzner.[5] *[1]University of Toronto, Toronto, ON, Canada; [2]Multi-Organ Transplantation, University Health Network, Toronto, ON, Canada; [3]University Health Network, Toronto, Toronto, ON, Canada; [4]University Health Network, Toronto, ON, Canada; [5]Toronto General Hospital, Toronto, ON, Canada; [6]Hospital for sick children / univ of Toronto, Toronto, ON, Canada; [7]University Health Network, University of Toronto, Toronto, ON, Canada; [8]The Hospital for Sick Children, Toronto, ON, Canada.*

Background: Normothermic ex-vivo kidney perfusion (NEVKP) results in improved marginal renal graft function compared to static cold storage (SCS) post-transplantation. To determine the mechanisms responsible for the beneficial effects of NEVKP, we investigated gene expression profiles of donation-after-cardiac-death (DCD) grafts stored with NEVKP or SCS to that of unmanipulated naïve-kidneys.

Methods: Kidneys from Yorkshire pigs were removed following 30-min of warm ischemia modelling DCD. Grafts were stored in SCS or NEVKP for 8hr prior to heterotopic autotransplantation. On POD3, grafts were collected and microarray analysis was performed.

Results: During NEVKP storage, DCD-grafts demonstrated favorable perfusion characteristics including lactate clearance, decreasing intra-renal resistance, and urine production. NEVKP resulted in improved graft function compared to SCS post-transplant with decreased peak serum creatinine (POD1: 4.0+/-1.15mg/dL vs POD3: 12.0+/0.78mg/dL, n=5, p<0.01) and higher creatinine clearance (POD3: 39.6+/-11.8mL/min vs 2.6+/-0.9mL/min, n=5, p<0.01). Transcriptomic analysis demonstrated significant differences in the expression of 27 genes in NEVKP grafts compared to naïve-kidneys (Table 1, ≥±2-fold change, n=3, FDR q<0.20). In contrast, 668 genes were differentially expressed between grafts stored with SCS and naïve-kidneys (Table 2, ≥±2-fold change, n=3, FDR q<0.20).

Conclusions: NEVKP of DCD kidney grafts resulted in a gene expression profile more closely resembling naïve kidneys. Conversely, grafts stored with SCS demonstrated increased expression of genes related to inflammation, apoptosis, and repair.

Dextran-Based and Albumin-Based Perfusates in Normothermic Ex Vivo Kidney Perfusion

Yilun Wu,[1] Xiuhua (sue) Wang,[2] Darren Freed.[1,2] *[1]Department of Physiology, University of Alberta, Edmonton, AB, Canada; [2]Department of Surgery, University of Alberta, Edmonton, AB, Canada.*

Background: Kidney transplantation is the definitive treatment for end-stage renal disease. Transplantation is superior to the alternative, dialysis, in survival, quality of life, and cost-savings. However, the gap between kidney donation and demand for donor kidneys is growing, and improved utilization of renal grafts, especially extended criteria donors, is necessary. Normothermic *ex vivo* kidney perfusion (NEVKP) is a novel method for graft preservation; it maintains metabolism, allows assessment, and allows therapeutic interventions. Currently many NEVKP systems use perfusates composed of a combination of physiological saline, red blood cells, and supplemental source of oncotic pressure and nutrients. Our study examines the effect of dextran-40 based perfusate compared to albumin based perfusates in NEVKP.

Methods: We establish a NEVKP model using porcine kidneys extracted with 10 minutes of warm ischemia perfused using cardiopulmonary bypass equipment. Donor kidney is perfused at normothermia and 60mmHg arterial pressure. Perfusate is composed of donor whole blood and a modified plasmalyte solution containing either 8% dextran-40 or 8% bovine serum albumin. Glucose and insulin are infused.

Results: Dextran and albumin produced similar intra-renal resistance during 12 hours of perfusion. However, dextran based perfusate shows improved urine production rates and urine quality (lower pH, lower/undetectable glucose and calcium) and lower plasma and tissue inflammatory markers (plasma interleukin-6 2.45±0.88ng vs 5.24±0.52ng, plasma tumor necrosis factor-α undetectable in dextran perfusates vs 0.55±0.14ng, tissue expression of toll like receptor-4 77% higher in albumin perfusate group tissues). Neither perfusate groups significantly increase plasma kidney injury molecule-1 (KIM-1), however both perfusate groups show lower tissue KIM-1 compared to tissue from start of perfusion.

Conclusions: With improved perfusion characteristics and reduced inflammatory profile, we believe a dextran based perfusate is superior to albumin based perfusates in NEVKP and that our system provides a viable platform for *ex vivo* preservation of porcine kidneys and further study of different interventions during *ex vivo* kidney perfusion.

FR-PO843

Proteomics Analysis Reveals Novel Molecular Mechanisms Associated with Normothermic Ex-Vivo Perfusion

Caitriona M. McEvoy,[1] Shelby Reid,[6] Peter Urbanellis,[2] Moritz Kaths,[7] Lisa Robinson,[3] Markus Selzner,[4] Ana Konvalinka.[5] *[1]University Health Network, Toronto, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]The Hospital for Sick Children, Toronto, ON, Canada; [4]Toronto General Hospital, Toronto, ON, Canada; [5]University Health Network, University of Toronto, Toronto, ON, Canada; [6]Institute of Medical Science, University of Toronto, Toronto, ON, Canada; [7]University Hospital Essen, Essen, Germany.*

Background: Normothermic ex-vivo perfusion (NEVKP) is associated with significantly improved graft function following transplantation in comparison to static cold storage (SCS); however, the molecular mechanisms underpinning this improvement remain unclear. We hypothesized that NEVKP induces key alterations in the renal proteome compared to SCS, enabling us to characterize the molecular mechanisms that lead to superior graft function in this setting.

Methods: Porcine kidneys were removed following 30 minutes of warm ischemia, before being subjected to either SCS or NEVKP (n=5, each group) for 8 hours prior to autotransplantation. Kidney biopsies were collected at time zero, upon reperfusion, and at POD3. We conducted an unbiased proteomics analysis by LC-MS/MS on Q-Exactive-Plus mass spectrometer. Subsequent analyses were performed using MaxQuant, Perseus, pathDIP, mirDIP, NaVIGaTOR and Cytoscape.

Results: Renal function was significantly improved with NEVKP in comparison to SCS with decreased peak serum creatinine on POD1, and higher creatinine clearance on POD3. We detected 6354 proteins in total (FDR <0.01), with 71 proteins identified as significantly differentially expressed between experimental groups and time points (2-way ANOVA, p<0.05). Pathway enrichment analysis demonstrated that proteins increased in SCS compared to NEVKP kidneys mediated inflammation, antigen presentation, extracellular matrix production and fibrosis (e.g. THBS1, XRCC6, TMCO1, JUN, CD40). We identified microRNAs predicted to regulate these SCS-dominant proteins (e.g. miR-129, miR-206). In contrast, proteins increased in NEVKP compared to SCS were mostly metabolic, mediating energy production through TCA cycle (ACO2, COX4I1, ATP5J2, ETFB, MPC2, NDUFAF7). These proteins were predicted to be regulated by miR-203 and miR-199, and the transcription factor ZNF143.

Conclusions: NEVKP may thus repair grafts by diminishing inflammatory/fibrotic signals and altering metabolism via the TCA cycle. Conversely, proteins enriched in SCS kidneys are associated with fibrogenic and inflammatory pathways. Our findings may yield novel therapeutic targets to attenuate injury associated with warm ischemia.

FR-PO844

RNA-Seq Analysis of Human Renal Allograft Biopsies Reveals Key Mediators of Interstitial Fibrosis/Tubular Atrophy

Caitriona M. McEvoy,[1] Eoin P. Brennan,[4] Denise M. Sadlier,[4] Peter J. Conlon,[3] Ana Konvalinka,[5] Catherine Godson.[2] *[1]University Health Network, Toronto, Toronto, ON, Canada; [2]The Conway Institute of Biomolecular and Biomedical, Belfield, Dublin, Ireland; [3]Beaumont Hospital, Dublin 9, Co Dublin, Ireland; [4]University College Dublin, Dublin, Ireland; [5]University Health Network, University of Toronto, Toronto, ON, Canada.*

Background: Interstitial Fibrosis/Tubular Atrophy(IFTA) is the final common pathway of most progressive renal diseases and is a potent predictor of renal outcome in both native and transplanted kidneys. IF/TA is a major cause of late allograft loss; however, our understanding of the molecular mechanisms underpinning this complex process remains incomplete.

Methods: We performed RNA-Seq gene expression profiling on renal tissue from transplanted patients undergoing a clinically indicated biopsy (n=21). IF/TA was determined from the renal biopsy report, and by quantitative morphometric analysis. Bioinformatic analysis was performed by DESeq2 to obtain differentially expressed (DE) genes. Ingenuity Pathway Analysis and MatInspector were employed to identify the key pathyways & transcription factors related to the dysregulated genes. NetworkAnalyst was used to generate a gene-protein interaction network.

Results: We identified 671 DE genes (381 upregulated, 236 downregulated; FDR<0.1) between severe and mild/moderate IF/TA in our cohort. Pathway analysis revealed that B-Cell development, NRF2-mediated oxidative stress response & superoxide radical degredation comprise the top canonical pathways associated with the perturbed genes in our dataset. Pivotal upstream regulators are associated with lymphoid cell development (SPI1), proteasomal degradation (BACH1,LONP1) & regulation of antioxidant proteins (NFE2L2). In silico cell-type enrichment analysis reveals enhanced transcriptional signatures from CD19+ B-Cells, Dendritic cells & CD4+ T-cells in the expression profiles of patients with severe IF/TA. DE genes were validated using external datasets prior to generating a gene-protein interaction network. Zero & first order interactions were examined. Significant gene modules detected in the networks relate to oxidative stress and mitochondrial function, T & B-Cell signalling, ECM-Receptor interaction, scaffolding proteins & chemokine signalling pathways.

Conclusions: Our dataset reveals novel molecular signatures and transcriptional regulators central to IF/TA using systems biology tools. These data underscore a prominent role of inflammation and oxidative stress in the development of IF/TA and reveal novel potential mediators of this process.

FR-PO845

Proteomics of Microdissected Glomeruli and Tubulointerstitium Reveals Compartment-Specific Alterations in the Extracellular Matrix of Kidney Allografts with Antibody-Mediated Rejection

Sergi Clotet-Freixas,[1] Caitriona M. McEvoy,[1] Ihor Batruch,[3] Max Kotlyar,[1] Chiara Pastrello,[1] Julie Anh Dung Van,[2] Andrea Bozovic,[1] Vathany Kulasingam,[1] Andrzej Chruscinski,[1] Rohan John,[1] Ana Konvalinka.[1,2] *[1]University Health Network, Toronto, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]Mount Sinai Hospital, Toronto, ON, Canada.*

Background: Kidney transplantation is the optimal treatment for end-stage kidney disease, but most grafts fail prematurely. Antibody-mediated rejection (AMR) is responsible for >50% of graft loss. AMR is caused by antibodies against HLA and non-HLA antigens, which are directed against proteins in the two main compartments of the kidney: glomeruli and tubulointerstitium (TI). We hypothesized that renal AMR is associated with compartment-specific proteome alterations that may uncover the mechanisms of early antibody-mediated injury.

Methods: We performed laser capture-microdissection to isolate glomeruli and TI from paraffin-embedded kidney biopsies, and subjected samples to proteome analysis on Q-Exactive mass spectrometer. We compared 8 biopsies with pure AMR with 23 matched 'non-AMR' biopsies with cellular rejection (ACR) or acute tubular necrosis (ATN). Biopsies were for-cause and scored using Banff criteria-2017.

Results: Biopsies were performed early post-transplant; none of them had marked fibrosis. AMR biopsies were C4d+ and had no chronic lesions. We identified 2026 proteins in glomeruli and 2426 in TI. Podocyte-specific proteins were exclusively found in the glomeruli (NPHS1, PTPRO), and tubular proteins were found only in TI (CUBN, UMOD), indicating compartment-specific enrichment. 141 proteins were differentially expressed in AMR vs. non-AMR glomeruli (73 up- and 68 downregulated) and 123 in TI (15 up- and 108 downregulated). Proteins involved in HLA-mediated antigen presentation were increased in both AMR compartments. Interestingly, proteins significantly decreased in both compartments in AMR (e.g.LAMC1, COL1A1, NID1) belong to basement membranes and processes such as integrin signaling, collagen, extracellular matrix (ECM) and cytoskeleton. Levels of collagens, laminins, and other ECM proteins directly correlated (R>0.7; p<0.05), suggesting co-regulation in renal AMR.

Conclusions: Basement membranes are often remodeled in late chronic AMR and are the targets of non-HLA antibodies, suggesting that these proteomic changes may represent early, important alterations in AMR. Targeting early ECM remodeling in AMR may represent a new therapeutic opportunity.

FR-PO846

The Difference of IgA1 O-Glycosylation Between IgA Nephropathy Transplant Recipients and IgA Deposition Donors

Shigeaki Nakazawa,[1] Toyofumi Abe,[2] Ryoichi Imamura,[1] Taigo Kato,[3] Norio Nonomura.[4] *[1]Osaka University Graduate School of Medicine, Suita, Japan; [2]Urology, Oska University Graduate School of Medicine, Suita, Japan; [3]Osaka University, Suita, Japan; [4]Department of Urology, Osaka University Graduate School of Medicine, Osaka, Japan.*

Background: IgA nephropathy (IgAN) is most common primary glomerulonephritis, and recurrence of IgAN after renal transplantation is frequent. On the other hand, IgA deposition (IgAD) from donor kidney without any manifestation of renal disease is often observed. The reason why IgA depositionD does not progress to IgA nephropathyN is not clear. In this study, we firstly analyzed the frequency of IgAD in living renal transplant donors, and we secondarily evaluated the IgA1 *O*-glycan structure in IgAN recipients, IgAD donors, and non-IgAD healthy donors (healthy donors).

Methods: We investigated *O*-glycan structure of IgA1 hinge region in 25 IgAN recipients, 17 IgAD donors, and 26 normal healthy donors matrix-assisted laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF MS).

Results: In *O*-glycans analysis using MALDI-TOF-MS, GalNAc and Gal content in HR of IgAN recipients were significantly decreased than IgAD donors and healthy donors. However, in all patterns of *O*-glycans, there was no significant difference between IgAD donors and healthy donors.

Conclusions: This is first report to compare the *O*-glycans structure in IgAN recipients and IgAD donors using MALDI-TOF-MS. Our result indicated that the decreased number of GalNAc and Gal content in HR could play pathogenic role in IgAN.

FR-PO847

Kynurenine 3-Monooxygenase Is a Key Mediator in the IDO Signaling Pathway for Prevention of Rejection in Experimental Kidney Transplantation

Youli Wang,[2] Todd D. Merchen,[1] Randi Lassiter,[2] Xuexiu Fang,[2] Daniel T. Kleven,[2] Chak-Sum Ho,[3] N. Stanley Nahman.[1] *[1]Medical College of Georgia at Augusta University, Augusta, GA; [2]Augusta University, Evans, Colombia; [3]Gift of Life Michigan, Ann Arbor, MI.*

Background: Indoleamine 2,3-dioxygenase (IDO) degrades tryptophan to kynurenine (KY), and the IDO-transprotein prevents rejection (RJX) in rat kidney transpants (KTx). KY is the substrate for KYnurinase (KYase), KYamiotransferase II (KAT), and KY 3-monooxygenase (KMO), each of which may generate immunosuppressive KYs, including the product of KMO, 3HK. Thus, in pig KTx we showed loss of graft KMO expression in RJX. 3HK is toxic to Tcells and neurons, yet tubular cells with elevated KMO appear normal, suggesting lineage specificity to 3HK toxicity. In this work, we further gauged the effect of RJX on enzymes degrading KY and studied the in vitro effects of 3HK on cultured kidney and Tcells.

Methods: Yorkshire pigs underwent allogeneic (Allo) or auto renal transplants (Auto [control for ischemia]) as we described (Trans Immun, 42:40, 2017). Allos had SLA testing and received mismatched kidneys. All pigs had R UNx before closure (control tissue). 72 hr post-op all grafts were taken and probed for IDO and tandem enzymes (qPCR, immunohistochemistry (IHC), and HPLC for IDO activity). 3HK cytotoxicity and cell proliferation was assessed using human primary kidney cortical endothelial (Endo) and epithelial (Epi) cells, and human peripheral blood Pan-T cells (Tcells).

Results: Allografts showed acute RJX (Banff 1-3), a 6X increase in IDO mRNA and 19.5X increase in IDO activity vs Auto. When compared to R UNx, KMO, KYase and KAT all showed a near 50% reduction in Autos, a change attributed to ischemia. However in rejecting Allos vs Autos, there was an over 90% reduction in KMO mRNA with no additive effect on KYase or KAT. IHC of kidney showed dramatic reductions in KMO protein in Epi and Endo cells. 3HK inhibited proliferation of active Tcells and promoted Tcell injury and death. The same and higher concentrations of 3HK had no effect on cortical Epi and Endo cells.

Conclusions: The loss of KMO, KYase and KAT from ischemia may partially explain RJX in the face of elevated IDO levels. The dramatic decline in KMO in RJX vs the other enzymes may exacerbate the process. 3HK destroys Tcells without affecting Epi or Endo cells. These data suggest that KMO is a key player mediating RJX in the IDO pathway and that the loss of 3HK from reductions in KMO may favor Tcell proliferation and promote RJX.

Dimethyl Fumarate Ameliorates Tacrolimus-Induced Nephrotoxicity in Rats

Akihiro Shimomura, Shiri Li, Donald C. Dafoe, Hirohito Ichii. *University of California, Irvine, Orange, CA.*

Background: Tacrolimus (TAC) is an important maintenance immunosuppressive drug that is widely used for organ transplant. However, patients treated with TAC are at high risk of developing organ injuries such as kidney and pancreas, especially kidney is more susceptible to TAC. TAC causes renal dysfunction or failure not only on donor kidneys but also on native kidneys. The incidence is 52%, 40% and 59% in patients after kidney, liver and heart transplants, respectively. Despite the tremendous efforts to reduce TAC-induced kidney injury, satisfactory therapies have not been established because the exact pathogenesis has remained unclear. There are increasing evidences that oxidative stress is involved in both TAC-induced kidney and pancreas injuries. Dimethyl fumarate (DMF), which has recently been approved by FDA for the treatment of relapsing forms of multiple sclerosis (MS) and relapsing-remitting MS patient, is a modifier of the nuclear factor-2-keap1 pathway that induces antioxidative and antiapoptotic effects. In the present study, we investigated the effects of DMF on TAC-induced kidney and pancreas injuries.

Methods: Male Sprague-Dawley rats at 9 weeks of age were divided randomly into four groups; low-salt (LS) diet (group LS), LS+DMF (group DMF), LS+TAC (group TAC), or LS+TAC+DMF (group TAC+DMF). DMF at a dose of 50 mg/kg·BW or vehicle was gavaged once a day. TAC at a dose of 1.5 mg/kg·BW or vehicle was subcutaneously injected once a day.

Results: At 15 weeks of age, significantly elevated levels of serum creatinine and urea nitrogen were detected in group TAC. Group TAC+DMF showed significantly lower levels of them than group TAC. Both Masson's Trichrome staining and immunohistochemical collagen1 staining of rat kidney showed consistent results with renal function. On the other hand, intraperitoneal glucose tolerance test, HOMA-IR and HOMA-β showed significantly impaired glucose tolerance and β cell function in group TAC, which could not be improved by DMF.

Conclusions: DMF ameliorated kidney injury but not pancreas injury in the TAC-induced rat model. This provides a novel approach for preventing TAC-induced nephrotoxicity in patients after organ transplant. Our data also indicates that TAC-induced kidney and pancreas injuries may have different pathogenic mechanisms. We expect to further investigate the pathogenic mechanisms of TAC-induced organ injuries.

FR-PO849

The Potential Role of IL-33/ST2 Pathway in Renal Allograft Rejection

Mi-yeon Yu,[1] Jae Wook Lee,[6] Yong Chul Kim,[3] Sunhwa Lee,[3] Un Sil Jeon,[2] Hajeong Lee,[4] Dong Ki Kim,[3] Yon Su Kim,[4] Seung Hee Yang.[5] *[1]Seoul national university hospital, Seoul, Republic of Korea; [2]Sheikh Khalifa Specialty Hospital, Ras Al Khaimah, United Arab Emirates; [3]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [4]Seoul National University College of Medicine, Seoul, Republic of Korea; [5]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [6]National Cancer Center, Seoul, Republic of Korea.*

Background: Interleukin (IL)-33 is one of IL-1 family cytokine that has pleiotropic effects, such as inflammation promotion and immune response regulation. Recent studies showed that IL-33 and its receptor, growth stimulation gene-2 (ST2) are biomarkers in heart allograft rejection. However, there is no studies about their role in renal allograft rejection. Moreover, its response according to rejection type remain unclear. We that IL-33 and ST2 expression differently express according to rejection type in renal allograft rejection.

Methods: Serum and kidney biopsy tissue were obtained from healthy controls and kidney transplanted recipients with acute antibody mediated rejection (AAMR), acute cell mediated rejection (ACMR), and chronic antibody mediated rejection (CAMR). We compared the expression of IL-33 and ST2 between 4 groups. To test the suppressive effect of anti-ST2 monoclonal antibody (anti-ST2 Ab), mixed lymphocyte reaction and chemotaxis assays by Boyden chambers were performed. We also evaluated the change of expression of IL-33/ST2 in dose of the anti-ST2 Ab (0.5 and 1 μg/ml).

Results: In comparison with the ELISA, ST2 level was higher in rejection group than in control group. The level of IL-33 was too low to be analyzed. Immunohistochemical analysis demonstrated that IL-33 and ST2 elevate in kidney tissue with rejection, especially in acute rejection. However, the expressions of IL-33/ST2 were no difference between AAMR and ACMR. In response to anti-ST2 Ab, primary human renal proximal tubular epithelial cells, which was stimulated by recipients' serum, showed a decrease in fibronectin and IL-33/ST2. IL-8, pro-inflammatory cytokine, was also decreased after treatment with anti-ST2 Ab by each group. In vitro validation, anti-ST2 Ab caused decreases in proliferation of lymphocyte and the level of IL-8. These decreases were significantly at high concentrations. We found that anti-ST2 Ab was able to significantly decrease chemotaxis.

Conclusions: Expressions of IL-33 and ST2 are higher in acute rejection than chronic rejection. Pro-inflammatory cytokines associate with IL-33/ST2 pathway during rejection. Blocking of the IL-33/ST2 axis may contribute to protect the allograft rejection.

FR-PO850

Effect of Klotho on Autophagy Clearance in Tacrolimus-Induced Renal Injury

Sun Woo Lim,[1] Yoo-Jin Shin,[2] Kang Luo,[3] Yi Quan,[4] Eun jeong Ko,[5] Byung ha Chung,[6] Chul Woo Yang.[6] Seoul St. Mary's Hospital, The Catholic University of Korea *[1]The Catholic University of Korea, Seoul, Republic of Korea; [2]College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea; [3]The Catholic University of Korea, Seoul, Korea., Seoul, Republic of Korea; [4]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea; [5]Seoul St.Mary's Hospital, Seoul, Republic of Korea; [6]Seoul St. Mary's Hospital, Seoul, Republic of Korea.*

Background: Recently, we showed that tacrolimus-induced renal injury is closely associated with impairment of autophagy clearance, and Klotho deficiency aggravates tacrolimus-induced renal injury. In this study, we evaluated the effect of Klotho treatment on autophagy clearance in tacrolimus-induced renal injury.

Methods: We evaluated the effect of Klotho on tacrolimus-induced renal injury in an experimental mouse model and in vitro by treatment with tacrolimus and/or recombinant mouse Klotho.

Results: In vivo and in vitro studies showed that tacrolimus treatment impaired lysosomal acidification and decreased cathepsin B activity, expression of lysosome-associated membrane protein 2, and transcription factor EB (TFEB), a master regulator for lysosomal biogenesis. These results were improved by Klotho treatment. Moreover, addition of bafilomycin A1, an inhibitor of lysosomal function, abolished the protective effect of Klotho, indicating that the protective effect of Klotho was closely associated with lysosome function. Klotho induced nuclear translocation of TFEB through inhibition of phosphorylation of glycogen synthase kinase 3β (GSK3β) by confirming using CHIR99021, a GSK3β inhibitor.

Conclusions: Collectively, our data suggest that Klotho improves autophagy clearance via activation of lysosomal function in tacrolimus-induced nephrotoxicity.

FR-PO851

Self In Vivo Production of a Synthetic Biological Drug, Anti-IL-2Rα/IL-10 Fusion Protein Using Minicircles in Skin Allograft Model

Sun Woo Lim,[1] Yoo-Jin Shin,[6] Kang Luo,[3] Yi Quan,[4] Eun jeong Ko,[5] Byung ha Chung,[2] Chul Woo Yang.[2] Seoul St. Mary's Hospital, The Catholic University of Korea *[1]Transplant Research Center, The Catholic University of Korea, Seoul, Republic of Korea; [2]Seoul St. Mary's Hospital, Seoul, Republic of Korea; [3]The Catholic University of Korea, Seoul, Korea., Seoul, Republic of Korea; [4]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea; [5]Seoul St.Mary's Hospital, Seoul, Republic of Korea; [6]College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea*.

Background: Anti-IL-2Rα monoclonal antibodies are typically used to prevent acute rejection in patients after transplantation. Minicircle DNA, one of the most remarkable gene therapy technologies of late, has the advantage of being small in size, non-viral, and free of unwanted immune responses such as no bacterial backbone. The aim of this study was to investigate the therapeutic effects of anti-IL-2Rα and IL-10, anti-inflammatory cytokine, in vitro and in vivo using a minicircle vector system.

Methods: Minicircle DNA was prepared by inserting the sequences for Basiliximab (anti-IL-2Rα) and IL-10 into the parental plasmid and removing the bacterial backbone. After minicircle DNA administration, protein production for anti-IL-2Rα and IL-10 was determined in HEK293T cell line and mice, and the therapeutic effect was evaluated in skin allograft rejection model.

Results: Minicircle DNA was transfected into the HEK293T cells and observed up to 30 days and detected the protein production in the conditioned media. In mice, in vivo imaging was used to confirm that DNA expression persists for up to 30 days after single administration. The produced protein was maintained in the blood for up to 10 days. Anti-IL-2Rα/IL-10 fusion protein increased survival effect more than single protein expressing anti-IL-2Rα or IL-10 in the skin allograft rejection model.

Conclusions: Anti-IL-2Rα/IL-10 fusion protein, which is synthesized in the body using minicircle DNA, has demonstrated an effective therapeutic effect on acute rejection after transplantation. We also demonstrated the potential of the minicircle DNA as a powerful biological agent to induce immune tolerance of grafts by combining various therapeutic target designs.

FR-PO852

Accelerated Cellular Senescence Associated with CFHR3-1 Variants Influences Graft Survival in IgA Nephropathy Transplanted Patients

Francesco Pesce,[1] Chiara Divella,[1] E. D. Stea,[1] Matteo Accetturo,[2] Francesca Cianciotta,[3] M. Rossini,[4] Giulia Fontò,[1] G. Lucarelli,[1] Loreto Gesualdo,[1] Giuseppe Castellano.[5] *[1]University of Bari, Bari, Italy; [2]University of Bari - Dept. Emergency and Organ Transplants, Bari, Italy; [3]Università di Bari, Bitetto, Italy; [4]University of Bari, Department of Emergency and Organ Transplantation, Nephrology Unit, Bari, Italy; [5]UNIVERSITA STUDI BARI, BARI, Italy*.

Background: The deletion of complement factor H-related genes 1 and 3 (CFHR3-1Δ) has been associated with a decreased risk of IgA nephropathy (IgAN) and is in linkage disequilibrium (LD) with the SNP rs6677604 ("A" allele), which can be used as a proxy to detect it. We hypothesized that CFHR3-1Δ is also implicated in the processes that influence graft survival in recipients with IgAN and tested whether cellular senescence is involved in mediating the damage.

Methods: A total of 67 biopsy-proven IgAN patients who received a renal transplant at the Kidney Transplant Center of the Department of Emergency and Organ Transplantations (D.E.T.O), University of Bari between 1993 and 2017 where included in the study. The region in CFHR3-1 encompassing the SNP rs6677604 was amplified using PCR and sequenced by Sanger. Immunohistochemical expression of p16INK4A was performed on paraffin-embedded kidney transplant biopsies of 8 patients (4 with rs6677604-AA vs 4 with rs6677604-GA), and quantified using the Aperio Positive Pixel Count Algorithm. Masson's trichrome staining and quantification of positive area was performed. Clinical data at baseline and during the follow-up were recorded. An eGFR < 60mL/min/1.73m2 (MDRD equation) was considered as main outcome at a univariate and multivariate analyses.

Results: The rs6677604-A allele was found in 22 (32.8%) patients (genotype rs6677604-AG) whereas 45 (67.2%) carried the GG genotype. These two groups had no difference as for demographic features, donor and transplant-related variables (incidence of delayed graft function and acute rejection episodes). Patients with the rs6677604-GG had a worse outcome during a mean follow-up of 69 ± 62 months at univariate (P=5.81E-05) and multivariate analysis (HR 30.8; 95% IC 3.3-285.5; P=0.003). Graft biopsies in this group featured a significantly higher expression of the senescence marker p16INK4a (P=0.001) in tubular epithelial cells showing increased levels of fibrosis (P=0.005).

Conclusions: These findings suggest that CFHR3-1Δ and its proxy rs6677604 are associated with long term graft function in transplant recipients with IgAN nephropathy through mechanisms involving accelerated cellular senescence.

FR-PO853

Extracellular Vesicles (EVs) Induce Tubular Epithelial Cells (TEC) Inflammaging in Antibody-Mediated Rejection (AMR)

Chiara Divella,[1] Alessandra Stasi,[1] Rossana Franzin,[1] Fabio Sallustio,[1,2] Claudia Curci,[1] Guido Merlotti,[3] Marco Quaglia,[5] Loreto Gesualdo,[1] Vincenzo Cantaluppi,[4] Giuseppe Castellano.[1] *[1]University of Bari, BARI, Italy; [2]Department of Basic Medical Sciences, Neuroscience and Sense Organs, University of Bari, Bari, Italy; [3]University of Piemonte Orientale, Novara, Italy; [4]University of Piemonte Orientale (UPO), Novara, Italy; [5]Università del Piemonte Orientale, Torino, Italy*.

Background: Recent data suggest a strong correlation between chronic kidney disease development and activation of accelerated senescence processes known as "inflammaging" in tubular epithelial cells (TEC). However, the role of TEC inflammaging and its mediators in kidney transplantation remains incompletely understood.

Methods: Renal biopsies of 10 transplanted patients with Acute and Chronic AMR were collected. Serum samples (5% for 24h) and EVs isolated from the same patients ($5E^{+4}$EVs/cells target for 24h) were incubated with primary culture of TEC (3th passage); p21 and p53 gene levels were measured by qPCR to assess TEC senescence. IHC staining for markers of inflammaging ($p16^{INK4a}$ and Klotho) were performed on paraffin tissue of the same patients.

Results: Pre-implantation biopsies did not showed signs of TEC Inflammaging. TEC from patients with Chronic AMR expressed significant levels of $p16^{INK4a}$ indicating occurrence of senescence phenotype, compared with Acute AMR ($p<0.05$). *In vitro*, the exposure of TEC to serum of Acute and Chronic AMR patients induced senescence by up-regulating of p21 and p53 gene levels, compared to basal condition ($p<0.05$). Interestingly, EVs isolated from the AMR patients induced senescence *in vitro* promoting a significant increase in p21, p53 and cyp1b1 gene level, and a down-regulation of klotho gene ($p<0.05$).

Conclusions: Our data demonstrated that TEC inflammaging induced by EVs might represent a new pathogenetic mechanism involved in acute and chronic AMR and could be identified as a potential new therapeutic target to counteract accelerated aging in kidney transplantation.

FR-PO854

The (R)-Enantiomer of the 6-Chromanol Derivate SUL-121 Counteracts Renal Vasoconstriction by Antagonism of the A1-Adrenoceptor

Dalibor Nakladal,[1,3] Hendrik Buikema,[1] Atilio Reyes romero,[2] Guido Krenning,[4] Robert H. Henning,[1] Leo E. Deelman.[1] *[1]Department of Clinical Pharmacology, University of Groningen / University Medical Center Groningen, Groningen, Netherlands; [2]University of Groningen, Groningen, Netherlands; [3]Department of Pharmacology & Toxicology, Comenius University in Bratislava, Bratislava, Slovakia; [4]Pathology and Medical Biology, University Medical Center Groningen/ University of Groningen, Groningen, Netherlands*.

Background: In kidney transplantation, impaired graft perfusion associates with decreased graft survival. Disturbed adrenergic signal transduction during rewarming is an important factor limiting renal perfusion. Recently, we developed a class of 6-chromanol based SUL-compounds which maintain mitochondrial function and limit reactive oxygen species (ROS) during cooling and metabolic stress. Here, we investigate the effects of SUL-121 on vascular function of porcine kidneys.

Methods: Porcine kidneys were collected at a local slaughterhouse and immediately flushed with UW with heparin, placed on ice and transported to the laboratory. The effects of SUL-121 and its enantiomers *(R)*-SUL-150 and *(S)*-SUL-151 on renal perfusion pressure was assessed in an isolated kidney perfusion system. In addition, rings from isolated intrarenal arteries were used to measure constriction responses to various agonists after pre-incubation with SUL-compounds. Receptor binding and intracellular calcium transients were assessed in α_1 adrenoceptor transgenic CHO cells. Molecular docking simulation was performed in an α_1 adrenoceptor flexible homology model using Induced Fit software.

Results: Addition of SUL-121, SUL-150 but not SUL-151 caused a decrease (-11±1, -13±2 and -1±1 mmHg, respectively) in renal perfusion pressure. Pre-incubation with SUL-121 and SUL-150 competitively inhibited contraction responses to the α_1 adrenoceptor agonist phenylephrine (pA_2 5.37±0.03). SUL-151, other 6-chromanols and their metabolites were without effect. Contraction responses to histamine and U46619 were not influenced by SUL-150. Phenylephrine-induced calcium signalling was similarly inhibited by SUL-150 in transgenic CHO cells (pA_2 5.31±0.03). SUL-150 effectively displaced radiolabelled prazosin in a competitive binding assay. Simulation of molecular docking demonstrated shared binding characteristics of SUL-150 and prazosin.

Conclusions: SUL-150, the *(R)*-enantiomer of SUL-121, is an antagonist of the α_1 adrenoceptor with ligand-receptor interactions similar to prazosin. Considering the improvement of renal perfusion through adrenergic antagonism in addition to previously reported beneficial effect on mitochondrial function and ROS production, we propose SUL-150 as a novel and unique protectant in kidney transplantation.

FR-PO855

Effect of Deceased Donor Inflammatory Pathways on Chronic Renal Graft Dysfunction

Montserrat M. Diaz Encarnacion,[5] Elena Guillen-gomez,[1] Iara Dasilva Santos,[2] Irene Silva,[3] Lluis Guirado,[4] Nuria Serra.[6] *[1]Fundación Puigvert, Barcelona, Spain; [2]Fundacio Puigvert, BARCELONA, Spain; [3]FUNDACION PUIGVERT, BARCELONA, Spain; [4]Fundació Puigvert, Barcelona, Spain; [5]Fundación Pugvert, Barcelona, Spain; [6]Fundació puigvert, Barcelona, Spain.*

Background: In deceased donor (DD) renal transplantation an inflammatory activity is established prior to nephrectomy. It produces macrophage infiltration and has been associated with the onset of fibrosis. Adenosine exerts its anti-inflammatory activity mainly through the A2A receptor. Monocytes and macrophages release TNF-α which induces A2A activity and mediates renal interstitial fibrosis through an increase in TGF-β1 and macrophage M2 switching. The aim of this study is to determine the effect of DD inflammation on chronic renal graft dysfunction.

Methods: Samples of pre-implantation renal tissue, 17 from living donor (LD) and 40 from DD were analyzed by Real-time PCR with the TaqMan® OpenArray® and western-blot.

Results: Infiltration of macrophages in DD kidneys was significantly greater than in LD. The expression of TNF-α, TGF-β1 and A2A was also higher than in LD and correlated positively with each other. A2A receptor also correlated with: pro-fibrotic markers such as α-SMA, fibronectin, vimentin, and collagen; the enzyme adenylate cyclase and the M2 macrophage marker CD163, C/EBPβ and IL-10, which are most expressed in DD kidneys. Western-blot results show PKA and CREB activation and increased CD163 and A2A protein translation.

Conclusions: TNF-α-mediated inflammation in DD kidneys is associated with the increase/activation of anti-inflammatory factors such as TGF-β1 and adenosine receptor A2A. Our results indicate that the activation of this pathway induces PKA-mediated CREB phosphorylation, which in turn stimulates transcription of C/EBPβ and promotes the induction of factors that could lead to fibrosis in the renal graft via M2 macrophages.

FR-PO856

Tacrolimus Results in Increased CTGF Expression by Human Proximal Tubule Cells and Is Associated with Donor ABCB1 3435C>T Genotype

Noel Knops,[1] Yasaman Ramazani,[3] Elena N. Levtchenko,[1] Tri Q. Nguyen,[2] Dirk R. Kuypers.[1] *[1]University Hospitals Leuven, Leuven, Belgium; [2]UMC Utrecht, Utrecht, Netherlands; [3]KU Leuven, Leuven, Belgium.*

Background: Clinical studies have demonstrated the importance of genetic variation in *CYP3A5* and *ABCB1* for tacrolimus disposition and suggested a role in the development of renal fibrosis associated with long-term tacrolimus treatment. Our aim was to explore the implications of tacrolimus exposure in a model of human proximal tubule cells incorporating genetic variation in *CYP3A5* and *ABCB1* on the expression of profibrotic cytokine CTGF and correlate these findings with CTGF expression in kidney allograft biopsies.

Methods: We selected 8 clones of human conditional immortalized PTC (ciPTC) with 4 different combinations of *CYP3A5 (rs776746)* and *ABCB1 (rs1045642)* genotypes. Cells were incubated with vehicle, 50 ng/ml and 300 ng/ml tacrolimus (in vivo concentration range). Quantitative RT-PCR and western blot were performed to study CTGF expression. In addition, CTGF staining was performed on protocol biopsies with a known pharmacogenetic background derived from 21 allograft recipients over a period of 2 years.

Results: CTGF mRNA and protein expression increased with tacrolimus concentration (CTGF vs. β-actin vs. vehicle at 50ng/ml: + 34.1% (95% CI: 22.3 - 45.9) and at 300 ng/ml: +45.0% (95% CI: 35.2 - 54.8); p<0.001). Subgroup analysis demonstrated 46% higher protein expression in *CYP3A5 *3/*3* allele carriers vs. **1* allele carriers (p=0.047) and more than 2-fold higher CTGF expression in *ABCB1 3435 TTs*, while in the genetic *CC/CT* counterparts CTGF expression decreased (p=0.01). Immunohistochemical studies of protocol biopsies demonstrated a 37.1% increase in tubular cell CTGF staining between 3 to 24 months in kidneys from *3435 TT* genotype donors, while in *CC/CT* donor grafts the percentage of CTGF positive tubuli remained stable (p=0.015).

Conclusions: Tacrolimus exposure in human PTCs results in a concentration-dependent increase in CTGF expression. Tacrolimus exposure for 72 hours resulted in increased CTGF expression in PTC derived from *CYP3A5 *3/*3* allele carriers, and in particular with the *ABCB1 3435TT* genotype. Immunohistochemical studies on protocol biopsies confirm increasing CTGF expression over time in donor kidneys with the *ABCB1 3435TT* genotype.

A Biomarker of Collagen Type VI Formation Is Associated to Allograft Outcome in Kidney Transplant Recipients

Federica Genovese,[1] Nadja Sparding,[1] Daniel Guldager Kring Rasmussen,[1] Morten A. Karsdal,[1] Henrik Birn,[2] Bente Jespersen,[3] Rikke Norregaard.[4] *[1]Nordic Bioscience, Herlev, Denmark; [2]Department of Biomedicine and Department of Nephrology, Aarhus C, Denmark; [3]Aarhus Universityhospital, Aarhus N, Denmark; [4]Aarhus University, AARHUS N, Denmark.*

Background: A careful evaluation of kidney transplant recipients is important for a successful allograft outcome. Non-invasive biomarkers are needed to predict immediate and long-term kidney function after transplantation. Preliminary findings have identified PRO-C6, a non-invasive biomarker of collagen type VI formation related to burden of kidney fibrosis, as a good prognostic marker for kidney function loss and mortality in chronic kidney disease patients.

Methods: Here we evaluate the prognostic potential of PRO-C6 in kidney transplant recipient by measuring PRO-C6 in plasma of 219 patients before transplantation, and 1 day, 3 months and 12 months after transplantation, by means of an ELISA developed at Nordic Bioscience.

Results: Levels of the serum PRO-C6 decreased significantly from baseline (median, 95% CI: 50.7, 46.7-53.5) to day 1 (median, 95% CI: 34.8, 31.1-38.3) and further decreased at month 3 (median, 95% CI: 14.2, 12.7-14.5), but not significantly from month 3 to month 12 (median, 95% CI: 13.5, 12.7-14.5). PRO-C6 correlated with plasma creatinine before transplantation (rho =0.43, p<0.0001), 1 day after rho for PRO-C6 vs plasma creatinine was 0.67, p<0.0001, at 3 months after rho for PRO-C6 vs measured GFR was -0.58, p<0.0001, and at 12 months after rho for PRO-C6 vs measured GFR was -0.57, p<0.0001. PRO-C6 measured either before transplantation and at day 1 after transplantation could identify patients who required dialysis one week after transplantation (delayed graft function) (AUC: 0.679, p<0.0001; and AUC: 0.860, p<0.0001, respectively). PRO-C6 measured 1 day after transplantation identified patients who still required dialysis three months after transplantation (AUC: 0.789, p<0.0001). Plasma creatinine measured one day after transplantation did not have any prognostic ability to identify patients with no graft function after 3 months. PRO-C6 measured 1 day after transplantation was also associated to the time needed to reach a 50% reduction in plasma creatinine after transplantation (HR per doubling of PRO-C6: 0.659 (0.548-0.792), p<0.0001).

Conclusions: PRO-C6 measured in plasma was associated with delayed graft function and no function at 3 months after transplantation and it can potentially be used to identify the patients at risk of graft function loss.

Liposomal Delivery Improves the Efficacy of Prednisolone to Reduce Renal Inflammation in a Mouse Model of Acute Renal Allograft Rejection

Carla van Alem,[1] Schmidbauer Martina,[5] Song Rong,[4] Jan H. Braesen,[3] Anja Thorenz,[4] Rongjun Chen,[4] Jurjen Ruben,[1] Elizabeth M. Winter,[1] Maaike Schilperoort,[1] Sander Kooijman,[1] Reshma Lalai,[1] Josbert Metselaar,[6,7] Christian Klemann,[8,9] Martin Meier,[2] Cees van Kooten,[1] Faikah Gueler,[4] Joris I. Rotmans.[1] *[1]Internal medicine, Leiden University Medical Center, Leiden, Netherlands; [2]Institute for Animal Science, Hannover Medical School, Hannover, Germany; [3]Pathology, Hannover Medical School, Hannover, Germany; [4]Nephrology, Hannover Medical School, Hannover, Germany; [5]Radiology, Hannover Medical School, Hannover, Germany; [6]Enceladus Pharmaceuticals, Naarden, Netherlands; [7]Experimental Molecular Imaging, University Clinic, RWTH-Aachen University, Aachen, Germany; [8]Pediatric Surgery, Hannover Medical School, Hannover, Germany; [9]Pediatric Pneumology, Allergy and Neonatology, Hannover Medical School, Hannover, Germany.*

Background: Allograft rejection remains one of the main obstacles in kidney transplantation. Although treatment with high doses of corticosteroids is often efficacious, systemic exposure and activation of the glucocorticoid receptor (GR) results in substantial side effects. In this study we used a mouse model of acute renal allograft rejection to investigate whether liposomal encapsulation could facilitate local delivery of prednisolone to the allograft and enhance its therapeutic effect.

Methods: Male BalbC^{HanZtm} recipients received a kidney transplant from male C57BL/6J^{HanZtm} donors (n=10 per group). Recipients were injected daily with 5 mg/kg cyclosporine A and received either 10 mg/kg prednisolone (P), or liposomal prednisolone (LP) intravenously on day 0, 3, and 6, or no additional treatment (NA). Functional MRI was performed at day 6 (N=6) to study graft perfusion and organs were harvested at day 7 for FACS- and qPCR analysis.

Results: MRI analysis revealed better allograft perfusion upon LP treatment, as compared to NA treatment (428.3±114 vs 218.5±117 ml/min*100g, p<0.05) while P vs NA treatment showed no significant improvement. FACS analyses of allografts revealed a reduced number of CD45+ leukocytes in LP vs P or NA treatment (5,3 and 6,6 fold decrease, p<0.05), less CD3+ T cells in LP vs NA (3,7 fold decrease, p<0.05), and less F4/80+ macrophages in LP vs P and NA (4,3 and 4,2 fold decrease, p<0.05). Upon LP treatment, the expression of the GR responsive gene *Fkbp5* was upregulated in the allograft, as compared to P and NA treatment (3,7 and 4,4 fold change, p<0.05). This was also observed in the spleen, but not in the heart, a non-target organ.

Conclusions: Liposomal delivery results in a higher local bioavailability of prednisolone, increased perfusion and a reduced cellular infiltrate in the transplanted kidney, compared to conventional prednisolone. Future clinical studies should reveal if treatment with LP results in improved efficacy and reduced side effects in patients with renal allograft rejection.

Variability in Outcome in Patients with DSAs Is Modulated by the Expression of HLA Antigens on the Allograft Endothelium

Stephanie Beland, François Bouchard-Boivin, Olivier Desy, Sacha A. De Serres. *University Health Center (CHU) of Quebec, Laval University, Quebec, QC, Canada*.

Background: The development of *de novo* donor-specific antibodies (DSAs) is associated with antibody-mediated rejection and allograft failure. However, some patients with DSAs escape graft rejection. We hypothesized that DSA-mediated injury is modulated by 1) the variability in expression of HLA-II antigen subtypes (DR, DP and DQ) on a within-patient basis and 2) the variability in HLA antigen expression on a between-patient basis.

Methods: We measured *in vitro* HLA-I and II (DR, DP and DQ subtypes) antigen expression on 2 glomerular endothelial cell lines and on blood outgrowth endothelial cells (BOEC) from patient's collected PBMCs (n=12). Endothelial cells were treated following a time-course of IFN-g for 10 days to induce HLA-II expression. HLA antigen expression was assessed by flow cytometry over time. Unstimulated cells were used as controls.

Results: Across all individuals, the maximal percentage and the standard deviation of HLA-positive cells varied substantially (97±3 vs. 96±3 vs. 89±9 vs. 44±37% for HLA-I vs. –DR vs. –DP, vs –DQ respectively, $p<0.001$) as well as the time of incubation to reach maximal expression (5±2 vs. 4±1 vs. 6±2 vs. 9±1days, $p<0.001$). Maximal MFI also varied between HLA subtypes (98±49 vs. 12±8 vs. 10±6 vs. $4\pm3x10^3$, $p<0.001$) as well as the time to reach this maximum (4±1 vs. 6±2 vs. 8±2 vs. 10±1days, $p<0.001$). Repeated experiments on the same individuals showed little variation between experiments (mean SD 12±8 vs. 7±5 vs. 6±4 vs. 1±1, $p<0.07$), indicating that the variability was not due to inter-assay variation.

Conclusions: Among HLA-II subtypes, the DR antigen seems to be the most inducible, whereas DQ has a lower and more variable expression. The use of BOEC is breaking new in the analysis of HLA antigen expression *in vitro*. A better understanding of the expression of DSA ligand could be instrumental in our understanding of antibody-mediated rejection.

FR-PO860

MHC Class II Ligation on Glomerular Endothelial Cells Upregulates Adhesion Molecules and Chemoattractants

Sarah E. Panzer,[1] Nancy A. Wilson,[1] James F. Dylewski,[2] Arjang Djamali,[1] Judith Blaine.[3] *[1]University of Wisconsin Madison, Madison, WI; [2]University of Colorado Hospital, Aurora, CO; [3]University of Colorado Denver, Aurora, CO*.

Background: Microvascular injury and leukocyte margination across endothelial cells are key pathologic processes in kidney allograft rejection. The mechanisms of glomerular endothelial cell injury and leukocyte infiltration remain unclear. We hypothesize MHC class II ligation on glomerular endothelial cells will result in upregulation of adhesion molecules and chemoattractants.

Methods: A Bl/6 mouse glomerular endothelial cell (MGEC) line was stimulated with IFNγ to upregulate MHC class I and II; then incubated with anti-MHC class II antibodies or plasma from balb/c mice sensitized with Bl/6 splenocytes. Expression of adhesion molecules were assessed by flow cytometry. Gene expression was measured by RT2 profiler and Taqman RT PCR. Cytokine expression was analyzed in culture supernatants with LegendPlex.

Results: MGEC stimulated with IFNγ upregulated gene expression of TRAIL, RANTES, MCP-1, caspase1, beta2microglobulin, Vcam1, IL-6 and Icam1 (**A**). IFNγ stimulation of MGEC increased surface expression of MHC class I, MHC class II, VCAM1, and ICAM1; but not P-selectin **(B)**. Subsequent ligation with MHC class II antibody transiently increased surface expression of P-selectin at 6 hours; while sensitized plasma resulted in a greater increase in P-selectin, which persisted at 24 hours (**C**). MGEC secretion of chemoattractants (MCP-1 and RANTES) increased with IFNγ stimulation and was further enhanced with MHC II ligation (**D**). Adhesion molecules and MHC co-localize on the cell surface (**E**).

Conclusions: MHC II crosslinking on MGEC resulted in an upregulation of P-selectin as well as chemoattractants. MHC molecules and adhesion molecules are co-localized on the endothelial cell surface. Future studies will examine therapeutic targets, such as inhibitors of mTOR (inhibition of ICAM1 clustering) and Nox4 (TRAIL pathway).

Funding: Other NIH Support - This project was supported by the Clinical and Translational Science Award (CTSA) program, through the NIH National Center for Advancing Translational Sciences (NCATS), grant UL1TR000427, and the KL2 training Award (KL2TR000428)., Clinical Revenue Support

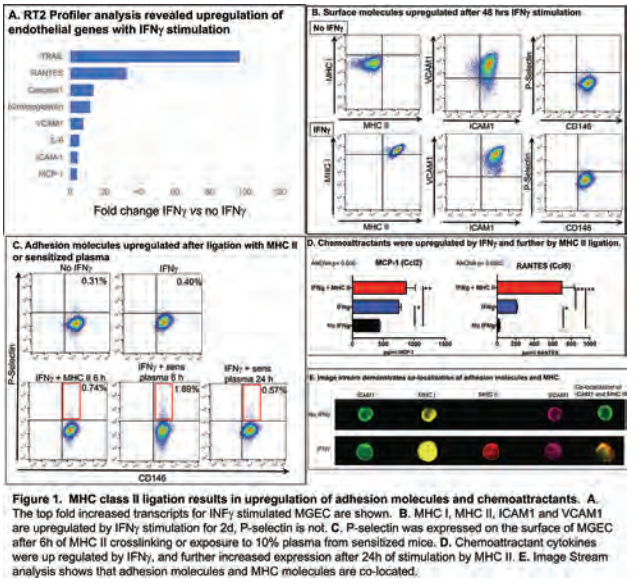

Figure 1. MHC class II ligation results in upregulation of adhesion molecules and chemoattractants. A. The top fold increased transcripts for INFγ stimulated MGEC are shown. **B.** MHC I, MHC II, ICAM1 and VCAM1 are upregulated by IFNγ stimulation for 2d, P-selectin is not. **C.** P-selectin was expressed on the surface of MGEC after 6h of MHC II crosslinking or exposure to 10% plasma from sensitized mice. **D.** Chemoattractant cytokines were up regulated by IFNγ, and further increased expression after 24h of stimulation by MHC II. **E.** Image Stream analysis shows that adhesion molecules and MHC molecules are co-located.

FR-PO861

B Cell Deficiency in a Rat Kidney Transplant Model Reduces Glomerular Basement Membrane Duplication in Early Transplant Glomerulopathy

Sarah E. Panzer, Yabing Huang, Weixiong Zhong, Arjang Djamali. *University of Wisconsin Madison, Madison, WI.*

Background: B cells play core roles in the humoral response and are able to contribute to cellular immunity, but the specific role of B cells in early transplant glomerulopathy (TG) remains unclear. We hypothesize B cell deficiency will attenuate the pathology of TG.

Methods: A rat kidney transplant model was used with 4 treatment groups: **Syngeneic** (Lewis to Lewis), **Allogeneic** (Fisher to Lewis), **Sensitized** (Fisher to Lewis 3 weeks following donor blood transfusion), or **Allogeneic B cell deficient ($B^{-/-}$)** recipients (Fisher to $B^{-/-}$ Lewis). All animals were harvested at 3 or 6 months. The following 5 parameters were measured by electron microscopy: duplication of glomerular basement membrane (GBM), total length of GBM, diameter of endothelial cell (EC), height of EC, and layers of peritubular capillary basement membrane (PTCBM). The ratio of GBM injury and mean data was determined among these groups.

Results: At 3 months after transplant, GBM duplication was reduced between $B^{-/-}$ recipients and sensitized recipients (10.2±0.8% versus 6.5±0.7%; p=0.01). The percent of GBM with duplication was reduced at 6 months after transplant in $B^{-/-}$ recipients compared to allogeneic and sensitized recipients ($B^{-/-}$:8.5±1.1%, allogeneic:17.2±0.8%, sensitized:32.6±3.3%; $p<0.001$) (Figure 1). The mean maximum diameter and the mean height of EC demonstrated no differences among allogeneic, sensitized, and $B^{-/-}$ recipients in both 3 and 6 months samples. PTCBM multilayering was also similar among allogeneic, sensitized, and $B^{-/-}$ recipients in both 3 and 6 months samples.

Conclusions: B cell deficiency in this model reduces the duplication of GBM in early TG. The GBM injury occurs before obvious EC injury and PTCBM multilayering. Future studies of B cell directed interventions are needed in TG.

Funding: Other NIH Support - This project was supported by the Clinical and Translational Science Award (CTSA) program, through the NIH National Center for Advancing Translational Sciences (NCATS), grant UL1TR000427, and the KL2 training Award (KL2TR000428).

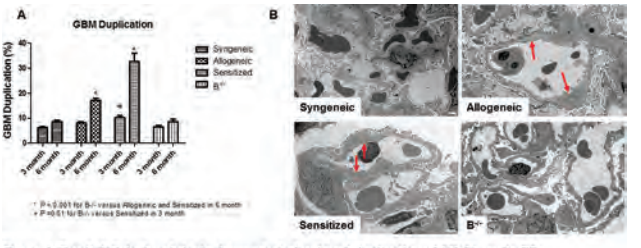

Figure 1. B cell deficient recipients demonstrated reduced duplication of GBM in early TG.
(A) Electron microscopy showed reduced duplication of GBM in $B^{-/-}$ recipients at 3 and 6 months.
(B) Representative photos of pathology at 6 months is shown. Areas of GBM duplication are highlighted with red arrows.

FR-PO862

An Optimized Protocol to Quantify Signaling in Human Transitional B Cells by Phospho Flow Cytometry

Nicholas Zwang,[1] Kim Cardenas,[2] Anita S. Chong,[3] Patricia W. Finn,[4] David L. Perkins.[5] *[1]Nephrology, The University of Illinois at Chciago, Chicago, IL; [2]BioLegend, Chicago, IL; [3]University of Chicago, Chicago, IL; [4]University of Illinois at Chicago, Chicago, IL; [5]University Illinois Chicago, Chicago, IL.*

Background: Phospho flow cytometry is a powerful technique to analyze signaling in rare cell populations. This technique, however, requires harsh conditions for cell fixation and permeabilization, which can denature surface antigens or antibody-conjugated fluorochromes. These are among several technical limitations which have been a barrier to quantify signaling in unique B cell subsets. One such immature subset, transitional B cells (TrBs), may play a role in suppressing solid organ transplant rejection, graft-versus-host disease, autoimmunity, and even the immune response to malignancy. Here we sought to optimize a protocol for quantification of signaling in human TrBs compared with mature B cell subsets.

Methods: TrBs were defined by surface marker expression as $CD19^{+}CD24^{hi}CD38^{hi}$. Key parameters optimized included antibody clone selection, sequence of surface epitope labeling in relation to paraformaldehyde-based fixation and methanol-based permeabilization, photomultiplier tube (PMT) voltages, and compensation. Special attention was paid to labeling of CD38 with regard to these parameters, and an optimized protocol enabled reliable identification of TrBs, naïve ($CD24^{+}CD38^{+}$), early memory ($CD24^{hi}CD38^{-}$), and late memory ($CD24^{-}CD38^{-}$) B cells.

Results: Phospho flow cytometry enabled simultaneous quantification of phosphorylation among at least three different signaling molecules within the same sample. Among normal donors, transitional B cells exhibited diminished mitogen activated protein kinase/extracellular signal-regulated kinase and Akt phospho signaling upon nonspecific stimulation with phorbol 12-myristate 13-acetateand ionomycin stimulation.

Conclusions: We optimized an effective protocol to quantify B cell subset signaling upon stimulation. Such a protocol may ultimately serve as the basis for assessing dysfunctional B cell signaling in disease, predict clinical outcomes, and monitor response to B cell-directed therapies.

FR-PO863

Utility of Immunoglobulin/T-Cell Receptor Gene Rearrangements As a Tool for Early Detection and Monitoring of Post-Transplant Lymphoproliferative Disorder in Renal Transplant Recipients

Wee Song Yeo,[1] Chang-Yien Chan,[1] Hui Kim Yap.[2] *[1]National University of Singapore, Singapore, Singapore; [2]National University Hospital, Singapore, Singapore.*

Introduction: Post-transplant lymphoproliferative disorder (PTLD) is a well-known complication post-transplant and contributes significantly to the morbidity and mortality seen in transplant recipients. A key limitation in the management of this dreaded disease involves its early detection and subsequent monitoring. A potential solution involves Ig/TCR gene rearrangement analysis. This molecular clonality analysis technique is based on the principle that, all cells of a malignancy have a common clonal origin and demonstrate clonally rearranged Ig or TCR genes. The diagnosis of malignant B- and T-cell proliferations is therefore supported by the finding of Ig/TCR gene clonality, whereas reactive lymphoproliferations show polyclonally rearranged Ig/TCR genes. We report our experience with two renal transplant recipients with PTLD whereby Ig/TCR gene rearrangements may play a role in the surveillance of this lymphoproliferative disorder.

Case Description: The 2 patients reported underwent cadaveric renal transplantation with subsequent development of PTLD. Both had reduction in immunosuppressants with rituximab therapy, following diagnosis of PTLD. One of the patients went on to CHOP chemotherapy and even lost her renal allograft secondary to PTLD involvement. Both patients were in clinical, hematological and radiological (PET scan) remission at the point of performance of Ig/TCR gene rearrangements. In these two pediatric renal transplant recipients with PTLD, it was noticed that there were Ig/TCR gene rearrangements detectable in their peripheral blood suggestive of clonal remnant of their PTLD.

Discussion: Lymph node/tissue biopsies remain the gold standard for the diagnosis of PTLD. Transplant recipients could not and should not be subjected to infinite repeated biopsies or expensive imaging studies (e.g. PET-CT scans) for the purpose of monitoring for the development of PTLD in view of inherent risks associated with biopsies and radiation risks, respectively. Our case report suggests the potential utility of Ig/TCR gene rearrangements as a non-invasive tool for early detection and monitoring of PTLD. Further large prospective trials are required to validate the above proposal.

FR-PO864

Multiplexed Immunofluorescence to Investigate the Immune Response to BK Virus in Kidney Transplant Recipients

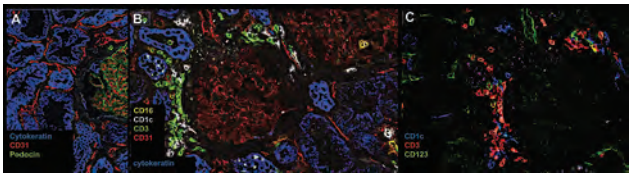
Cecile Fajardo,[1] Paul C. Grimm,[2] Neeraja Kambham.[3] *[1]Stanford University, Stanford, CA; [2]Stanford University Medical Center, Stanford, CA; [3]Stanford University, Stanford, CA.*

Background: BK virus nephropathy is a complication in renal transplant that leads to allograft dysfunction or failure. Acute inflammation, tubular atrophy, and interstitial fibrosis are seen in both BKVN and acute rejection making it challenging to differentiate. Previous studies have characterized the immune response on histology, but the identification and characterization of infiltrating cells was limited due to constraints of traditional immunohistochemistry. Multiplexed immunofluorescence allows a more comprehensive understanding of the spatial relationships of immune cell phenotypes and ongoing signals within the kidney microenvironment.

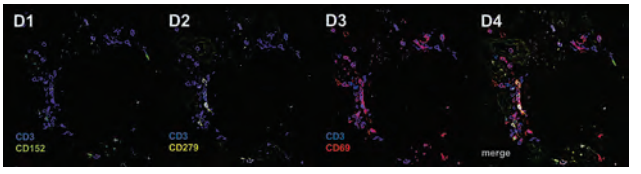
Methods: Using CO-detection by inDEXing (CODEX), the expression of 50 markers for identifying renal structural elements, immune cell subsets, and immune function were evaluated on a single tissue section of a pediatric kidney transplant recipient.

Results: See images and caption for results.

Conclusions: CODEX is a novel technique in characterizing the immune repertoire in BKVN and visualizing renal histology. Predominant immune infiltrate in BKVN consists of T cells, plasmacytoid and myeloid dendritic cells, and sparse NK cells, which have not been previously described. A majority of CD3 T cells in BKVN appear to be activated and a minority expressing markers of exhaustion and inhibition. Comparing the immune repertoire of BKVN and acute rejection is an important and clinically significant future direction.



A) Renal tubules with cytokeratin, endothelial cells and blood vessels using CD31, and glomerular podocytes using podocin. B) Co-localization of CD3 T cells (green), CD1c myeloid dendritic cells (white), CD16 NK cells (yellow). C) Infiltration of interdigitating plasmacytoid dendritic cells (green) and myeloid dendritic cells (blue) in a cluster of T cells (red).



D) Functional analysis of CD3 T cells (blue) show co-expression of markers of inhibition with CD152/CTLA4 (green), exhaustion with CD279/PD1 (yellow), activation with CD69 (red), D4 shows a merge of all markers.

FR-PO865

Inhibition of Cyclophilin A and Large T Antigen Interaction Reduces Polyomavirus BK Replication

Ya-chung Tian. Linkou Kidney Research Center *Chang-Gung Memorial Hospital, Taipei County, Taiwan.*

Background: Specific treatment for polyomavirus BK (BKV) infection in kidney transplant recipients remains unsolved. We previously demonstrated that cyclophilin A (CypA) was crucial for BKV replication. The aim of this study was to assess the impact of interaction of CypA and BKV large T antigen (TAg) on BKV replication.

Methods: HRPTEC or HK-2 were used in this study.

Results: The immunoprecipitation (IP) revealed an interaction between TAg and CypA. Similarly, the ELISA assays using purified TAg and CypA confirmed a binding between CypA and TAg. Atomic force microscope (AFM) revealed a binding between TAg and CypA. This binding was reduced if the TAg-coated probe was pretreated with anti-TAg blocking antibody. Immunocytochemistry (IHC) also verified nuclear colocolization of CypA and TAg expression. Both N-terminus (DN-CypA) and C-terminus (DC-CypA) failed to colocalize with nuclear TAg expression. The IP assay confirmed a failure of DN-CypA binding to TAg. Overexpression of DN-CypA in the CypA-knockdown cells reduced BKV replication, confirming that the N-terminus of CypA binding to TAg is crucial for viral replication. Overexpression of CypA but not DN-CypA enhanced TAg-induced promoter activity of BKV. Overexpression of CypA in the NFATc3-knockdown cells still enhanced viral replication, indicating a NFATc3-independent pathway. Addition of Debio-025 caused a reduction in BKV replication. IHC showed that Debio-025 caused a reduction of nuclear CypA expression. Immunoblotting assay confirmed a dramatic reduction of CypA in the nuclear fraction by addition of Debio-025. Mutant CypA proteins at six different functional residues in the enzyme pocket of CypA (possible functional sites of Debio 025) did not affect TAg and CypA interaction detected by the IP assay and the ELISA assay. In vivo, following BKV injection, BKV copies in the kidneys were reduced in the CypA-knockout mice or in the Debio-025-treated mice, when compared with those in the wild-type mice or non-treatment controls.

Conclusions: Nuclear translocation of CypA and interaction with nuclear TAg, both of which depends on N-terminus of CypA is essential for BKV replication. Blockade of the CypA-dependent NFAT-independent pathway by Debio-025 suppressed BKV replication. As no anti-BKV treatment is satisfactory so far, alisporivir that has no immunosuppressive effect can be potentially applied for anti-BKV treatment.

Efficacy and Safety According to Dose of Valganciclovir for Cytomegalovirus (CMV) Prophylaxis in Transplantation: Network Meta-Analysis Using Recent Data

Jin ho Lee,[1] Seon Deok Hwang,[3] Seoung Woo Lee,[4] Woo Yeong Park,[7] Jeong Ho Kim,[8] Hee yeoun Kim,[2] Seong min Kim,[5] Joon Seok Oh,[6] Dongyeol Lee,[1] Yong hun Sin,[9] Joong Kyung Kim.[1] *[1]Bong Seng Memorial Hospital, Busan, Republic of Korea; [2]Bongseng hospital, Busan, Republic of Korea; [3]Inha University College of Medicine, Incheon, Republic of Korea; [4]Inha University Hospital, Inchon City, Republic of Korea; [5]Dongrae Bongseng Hospital, Busan, Republic of Korea; [6]Bong Seng Hospital, Korea, Dong-gu, Busan, Republic of Korea; [7]Dongsan Medical Center, Daegu, Republic of Korea; [8]Daejeon St. Mary's Hospital, Daejeon, Republic of Korea; [9]Bong Seng Hospital, Busan, Republic of Korea.*

Background: Valgancivlovir is used to prevent post-transplant CMV infection among kidney transplantation patients. However, the dose of drug being used still remains controversial since the continuous use of such drug decrease kidney functions and induces leukopenia in some of the cases. Accordingly, the purpose is to measure the appropriate dose of the drug required for preventing CMV using network Meta analysis

Methods: We searched the Cochrane Central Register, OVID MEDLINE, EMBASE, and Pubmed until April 15, 2017. We reviewed the reference lists of relevant reviews, registered trials, and relevant conference proceedings. Definition of low dose valganciclovir group is 450mg and standard dose one is 900mg. Studies evaluating among valganciclovir 900 mg, 450 mg and controls were evaluated. We performed direct and indirect network meta-analysis using Bayesian models and generated rankings of the different dose of valgaciclovir agents by generation mixed treatment comparison (GeMTC).

Results: Twenty-four studies involving 3,730 participants were eligible. As a result of analyzing among three groups, following completion of the research, the analysis revealed that the glomerular filtration rate, graft loss, tacrolimus level, antibody mediated rejection, fungal, and *Candida* infection rates were not different among groups. Compared with control, there was no difference between low dose 0.79 [95% Crl, 0.50-1.40] and standard dose 1.0 [95% Crl, 0.61-1.60] groups when CMV incidence was compared. In the Rank probabilities table, the best order for lowering the CMV event was as high as dose of 450mg (71.1%). Incidence of leukopenia showed a significant difference, but there was no statistical significance in the low dose group 1.5 [95% Crl, 0.99-2.20] compared with the control group, but 4.3 times higher in the high dose group 4.3 [95% Crl, 2.69-7.10], which was 2.9 times higher in the low dose group and the high dose group 2.9 [95% Crl, 1.88 -4.67].

Conclusions: The use of valganciclovir did not show any difference in other side effects, but the use of low doses of leukopenia significantly reduced side effects. The incidence of CMV was not different among the three groups, but the tendency was also decreased at low dose.

FR-PO867

Cytomegalovirus Serostatus and Living Donor Kidney Transplant Outcomes in the Era of Routine CMV Prophylactic and Preemptive Therapy

Napat Leeaphorn,[1] Natanong Thamcharoen,[2] Neetika Garg,[3] Woojin James Chon,[1] Lee S. Cummings,[1] Martha Pavlakis.[2] *[1]Renal Transplant Program, University of Missouri-Kansas City School of Medicine/Saint Luke's Health System, Kansas City, MO; [2]Transplant Institute, Beth Israel Deaconess Medical Center, Boston, MA; [3]University of Wisconsin-Madison, Madison, WI.*

Background: The impact of CMV serostatus on living donor kidney transplant outcomes in an era when CMV prophylactic and preemptive strategies are used routinely has never been examined.

Methods: Using UNOS/OPTN data, adult patients with first living donor kidney transplant between 2010 and 2015 were stratified into 4 groups: D-/R-, D+/R-, D+/R+, and D-/R+. Death-censored graft survival, all-cause mortality and cumulative incidence of rejection at 1-year were examined using D-/R- as a reference group.

Results: A total of 28,730 recipients were included: 4,972 (17.3%) in D+/R-, 7,404 (25.8%) in D-/R-, 10,233 (35.6%) in D+/R+, and 6,121 (21.3%) in D-/R+ group. In the multivariable analysis, D+/R- was associated with an increased risk of graft failure (HR=1.18, P=0.049) when compared to D-/R-. There was also an increased risk of graft failure in D+/R+ when compared to D-/R- (HR=1.09, P=0.021). CMV serostatus did not have any statistically significant effects on all-cause mortality or acute rejection at 1 year.

Conclusions: In living donor kidney transplantation, CMV mismatch (D+/R-) is not an independent risk factor for patient mortality in the era of effective prophylactic and preemptive strategies. D+/R- and D+/R+ serostatus have a slightly negative impact on graft survival. These findings can be informative and used for patient counseling before undergoing living donor kidney transplantation.

CMV Serostatus	Graft failure		Mortality, all cause		Acute rejection at 1-year	
	HR (95% CI)	P-value	HR (95% CI)	P-value	OR (95% CI)	P-value
Main cohort

The Outcomes of Kidney Retransplantation After Graft Loss Due to BK Virus Nephropathy

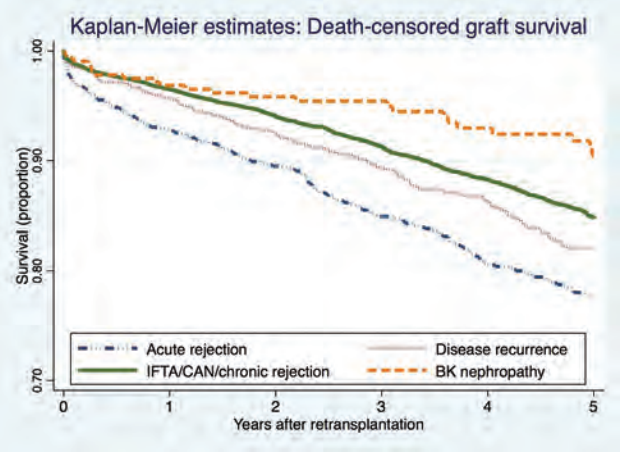
Napat Leeaphorn,[1] Woojin James Chon,[1] Lee S. Cummings,[1] Wisit Cheungpasitporn.[2] *[1]Renal Transplant Program, University of Missouri-Kansas City School of Medicine/Saint Luke's Health System, Kansas City, MO; [2]Division of Nephrology, Department of Medicine, University of Mississippi Medical Center, Jackson, MS.*

Background: Existing literature on outcomes of kidney retransplantation in patients with previous graft failure due to BK virus nephropathy (BKVN) is scarce.

Methods: Using UNOS/OPTN data, we analyzed adult patients who received their second kidney transplant between 2005 and 2015.

Results: 321 out of 15,724 patients lost their first graft to BKVN (BK-group) with a median follow-up time of 4.2 years. Of these 321 patients in BK-group, 54 patients underwent preemptive second kidney transplantation. Retransplant occurred at a median of 2.2 years after graft failure. Patients in BK-group were twice more likely to receive basiliximab when compared to patients who lost their first graft due to other causes. One-year acute rejection rate in BK-group was 15%. As of March 3, 2017, 264/321 grafts were still functioning with 6 grafts that failed due to BKVN. Kaplan- Meier death-censored graft survival rates at 1, 3, and 5-year after retransplantation in BK-group were 96.9%, 95.4%, and 90.5%, respectively, which were comparable to other causes of graft loss (and perhaps superior to patients who lost their first graft due to acute rejection) [Figure 1]. Patient survival in BK-group was similar to other causes of graft loss. The log-rank test was not performed due to unbalanced sample sizes across the groups.

Conclusions: Retransplantation after graft loss due to BKVN appears to be associated with good outcomes. However, the clinical interpretation of this study is limited by the lack of information on viral clearance and transplant nephrectomy prior to retransplantation.



FR-PO869

Impact of Antiviral Dose Adjustments on Risk for Breakthrough CMV Viremia After Kidney Transplantation

Suphamai Bunnapradist, Korntip Phonphok, Ittikorn Spanuchart, Tin N. Duong, Erik L. Lum, Elaine F. Reed, Joanna Schaenman. *David Geffen School of Medicine at UCLA, Los Angeles, CA.*

Background: CMV infection continues to cause significant morbidity in kidney transplant recipients in the modern era of transplantation. CMV seronegative patients with CMV seropositive donors are at highest risk for complications, including invasive disease and loss of allograft function. Inadequate drug dosing is associated with breakthrough viremia and drug resistance. We sought to evaluate whether drug dosing was associated with CMV viremia.

Methods: We reviewed CMV PCR testing results from 1297 adult kidney transplant recipients (excluding multiorgan transplants) between the years 2013-2017. We performed chart review to obtain antiviral prophylaxis regimens prior to viremia, and assessed sCr and calculated GFR at regimen start. Adequacy of dose adjustment for renal insufficiency was determined based on the package insert for valganciclovir to determine whether there was an association between antiviral dosing and breakthrough CMV viremia.

Results: We identified 14 seronegative kidney transplant recipients who developed CMV viremia during the first year after transplantation. 9 had received basiliximab (64%) and 5 (36%) antithymocyte globulin. 3 patients experienced biopsy-proven rejection (2 ACR and 1 AMR) prior to CMV viremia. The median time to viremia was 75 days (range 62-178). 5 patients (36%) were not taking valganciclovir at the time of viremia detection, while 9 patients (64%) were on valganciclovir. 8 of the 9 (89%) patients on valganciclovir were on dose-adjusted regimens at the time of viremia, correct according to the Valcyte package insert, at doses ranging from 450 mg once daily to 450 mg 3x/week.

Conclusions: Despite appropriate valganciclovir dose-adjustment, breakthrough CMV viremia occurred. This suggests that renal impairment is associated with CMV infection either because standard dose adjustments are inadequate, impaired drug absorption, or exacerbation of impaired CMV immune response. This suggests a role for therapeutic drug monitoring, and for the need for more effective antiviral prophylaxis medications. Future

studies will evaluate patterns of drug dosing associated with CMV viremia in seropositive transplant recipients. Immunologic analysis will be performed to identify patients lacking effective CMV-specific immune response in need of prolonged antiviral prophaylaxis.

FR-PO870

The Molecular Profile in Kidney Allograft Highlighting Subclinical Acute Rejection (SAR): Towards a Targeted Treatment

Sharon N. Cox,[1,2] Samantha Chiurlia,[2] Francesco P. Schena.[1,2] The Italian Transplantomics Group *[1]University of Bari, Bari, Italy; [2]Schena Foundation, Valenzano, Bari, Italy.*

Background: SAR diagnosed by protocol biopsy is an independent risk factor for chronic allograft injury. We organized a molecular study on 24 AB0 compatible cadaveric kidney transplant recipients with standard immunological risk who received protocol biopsy in the first post-transplant year. Aim of our study was to identify specific gene expression changes that characterize SAR and to highlight specific therapeutic interventions based on the molecular fingerprints.

Methods: Total RNA was extracted from archival FFPE renal tissue samples of 12 patients with SAR scored by 2 pathologists according to the updated Banff criteria and a control group of 12 patients with normal histological findings in protocol biopsies performed at 3- and 12-months post-transplant. All patients had a stable renal function (mean serum creat < 1.65 mg/dL). The cRNA fragments were hybridized on GeneChips Agilent. Genome-wide gene expression profiles were generated and bioinformatic analysis was done with Genespring. A false discovery rate (FDR) <0.02 and fold change > 2 were applied. Canonical pathways and biological functions were explored using Ingenuity pathway analysis (IPA) software. Real Time PCR was used for validation of the identified transcripts.

Results: We identified 1849 genes aberrantly modulated in SAR biopsies, 184 were down-regulated and 1257 up-regulated. Three-dimensional Principal Component Analysis showed a different spatial distribution between the SAR patients and control Patients. The most significant canonical pathways were *Natural killer cell signalling (p=0.00413)*, Wnt/β-catenin pathway (p=0.03) *Role of cytokines in mediating communication between immune cells* (p=0.04). The top selected networks highlighted several modulated genes involved in Acute Kidney Injury and candidate transcripts were validated by qRT-PCR.

Conclusions: Our data demonstrates a specific fingerprint associated with SAR characterized by various genes involved in molecular inflammatory processes and crosstalk between immune cells. These results suggest the possibility of early recognition and targeted treatment before chronic allograft disease.

FR-PO871

Urinary Exosomal MicroRNA as a Non-Invasive Biomarker for the Diagnosis of Acute Rejection in Kidney Transplant Recipients

Yu ho Lee,[1] Seo Jung-Woo,[1] Su Woong Jung,[1] Yang gyun Kim,[1] Ju young Moon,[1] Jin sug Kim,[1] Kyung-hwan Jeong,[1] Byung ha Chung,[2] Sangho Lee.[1] *[1]Department of Nephrology, Kyung Hee University, Seoul, Republic of Korea; [2]Seoul St. Mary's Hospital, Seoul, Republic of Korea.*

Background: Acute rejection (AR) is the main obstacle to the graft survival after kidney transplantation. Urinary exosome is a promising source of biomarker for various kidney diseases, but few studies determined the clinical relevance of urinary exosomal microRNA in kidney transplant recipients. The purpose of this study was to investigate the profiles of urinary exosomal microRNAs to discover novel biomarkers of AR in patients who underwent kidney transplantation.

Methods: urinary exosomal microRNAs from 108 kidney transplant recipients were extracted. The candidate microRNAs for the diagnosis of AR were selected based on Nanostring analysis of urinary exosomal microRNAs, meta-analysis and the review of literature. The levels of candidate microRNAs were further confirmed by quantitative real-time polymerase chain reaction. The diagnostic value of final candidate microRNAs was determined in independent validation group.

Results: Nanostring analysis found that the expressions of 14 microRNAs were significantly altered in patients with AR compared to those with stable graft function. Meta-analysis and the review of literature revealed 10 and 7 additional candidate microRNAs of AR, respectively. Quantitative real-time polymerase chain reaction confirmed that a total of 7 microRNAs maintained their differential expressions, and 4 microRNAs (hsa-miR-21-5p, hsa-miR-30a-3p, hsa-miR-4488, and hsa-miR-4532) were chosen as final candidate microRNAs of AR by forward stepwise logistic regression model. The combinations of the levels of these 4 microRNAs effectively discriminated patients with AR from other patients in validation group, with an AUC value of 0.790.

Conclusions: This study demonstrated that the profiles of urinary exosomal microRNAs are altered in kidney transplant recipients having AR, and these differences could be potential non-invasive biomarkers for the diagnosis of AR.

FR-PO872

Involvement of Genetic Variation and Related Gene Expression Changes on Acute Rejection in Renal Transplant Recipients

Hyeon Seok Hwang,[1] Yang gyun Kim,[1] Ju young Moon,[1] Tae won Lee,[1] Chan-Duck Kim,[2] Byung ha Chung,[3] Sangho Lee.[1] *[1]Division of Nephrology, Department of Internal Medicine, College of Medicine, Kyung Hee University, Seoul, Republic of Korea; [2]Kyungpook University Hospital, Daegu, Republic of Korea; [3]Seoul St. Mary's Hospital, Seoul, Republic of Korea.*

Background: Acute rejection (AR) is one of the major risk factors for renal allograft loss. The effect of genetic factors on the transplant outcomes has been clear. However, the correlation between genetic variation and acute rejection remains undetermined.

Methods: We collected blood samples from recipients with biopsy-proven AR (n = 81) and with stable graft function (n = 48). Gene expression data was pooled from RNA microarray and RNA sequencing. Integrative analysis combining genome-wide association studies (GWAS) and expression quantitative trait loci (eQTL) was used to identify single nucleotide polymorphisms (SNPs) for acute rejection.

Results: In eQTL analysis, we detected potential 35,465 SNPs, which correlated with RNA expression. We analyzed AR-related SNPs in GWAS with covariate adjustment, and detected 140 overlapped SNPs in integrative analyses of eQTL and GWAS. The corresponding genes of these SNPs were matched with genes whose expression level differs between patients with AR and stable graft, and three loci were finally mated. One locus encompasses *PFDN6*, which involves the activation and development of lymphocyte. Two other loci encompasses *ZSCAN10* and *HEBP2*, which involves the DNA binding transcription factor activity and microtubule dynamics, respectively.

Conclusions: Our integrated analysis of GWAS and eQTL helps to find relevant genes, which had both biological and clinical significance, and identify three novel acute rejection susceptibility loci in renal transplant recipients.

FR-PO873

Differential Expression of Plasma miRNA in Acute Transplant Rejection

Amaryllis H. Van Craenenbroeck,[2,1] Steven J. Van laere,[1] Els M. Gielis,[1] Annemieke Smet,[1] Amélie Dendooven,[2,1] Rachel Hellemans,[2] Marie M. Couttenye,[2] Benedicte De winter,[1] Emeline M. Van craenenbroeck,[2,1] Kristien J. Ledeganck,[1] Daniel Abramowicz.[2,1] *[1]University of Antwerp, Antwerp, Belgium; [2]University Hospital of Antwerp (UZA), Edegem, Belgium.*

Background: Transplant rejection remains a major clinical problem in nephrology. miRNAs, negative epigenetic regulators of gene expression at the posttranscriptional level, are involved in various conditions including kidney disease. We performed next-generation sequencing (NGS-)based miRNA profiling of plasma to discover a miRNA signature of acute graft rejection in kidney transplant recipients.

Methods: 6 stable (STA, 4 male, 46 ± 8 years) and 4 patients with biopsy-proven acute rejection (AR, 1 male, 44 ± 10 yrs) within the first 3 months after transplantation were studied. AR was defined as a rise in creatinine ≥ 0.3 mg/dl and a score ≥ Banff 2 on biopsy. STA patients had normal biopsies and stable creatinine levels. NGS was performed on isolated miRNA from EDTA plasma. Obtained read counts were normalized for library size, log2 transformed and subjected to differential miRNA expression analysis (*limma*-package BioConductor). Support Vector Machine (SVM) classification was applied to build and cross-validate (i.e. leave-one-out method) a predictive model for graft rejection.

Results: 68 miRNA (26 novel) were differentially expressed in AR vs STA ($p<0.05$) with 16 miRNA being downregulated and 52 miRNA upregulated (Fig1). The SVM classification model revealed a signature of 4 miRNAs (miR-16-2, miR-361, miR-629 and miR-199a) that could predict AR with 90% accuracy, and a positive and negative predictive value of 100% and 86%, respectively.

Conclusions: We found a novel and unique plasma signature of 4 miRNA in AR patients. Prior to clinical implementation, prospective validation in an independent cohort with sensitivity and specificity analysis is mandatory. In addition, study of the involved miRNA and their mRNA targets can offer more insights into underlying disease mechanisms.

Reduced Early Acute Rejection with Depleting Induction and Steroid Minimization Maintenance in Pediatric Kidney Transplant Recipients

Megan V. Yanik, Lucinda Weaver, Michael E. Seifert. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Prolonged steroid exposure in pediatric kidney transplant recipients (PKTRs) can result in adverse effects. Recent studies indicate steroid minimization (SM) is effective compared to steroid based (SB) regimens, but outcomes data in PKTRs are limited. Subclinical rejection is prevalent in PKTRs, and is associated with poor outcomes.

Methods: We hypothesized that SM with depleting induction would decrease risk of acute rejection (AR) during the first post-transplant year in PKTRs compared to a SB regimen with non-depleting induction. A single-center, retrospective cohort study was performed on PKTRs from 8/2011 to 8/2017. The primary exposure was the immunosuppression regimen. Biopsies were performed for surveillance at 3- and 6-months post-transplant, and as indicated for allograft dysfunction. The primary outcome was AR by 1 year, including borderline, cellular, and antibody mediated. Secondary outcomes included allograft function, calcineurin inhibitor nephrotoxicity (CNIT), viral infections, and neutropenia.

Results: The cohort included 63 PKTRs; 21 and 42 patients on the SM and SB regimens. The median age at transplant was 12.9 years. The cohort included 37% black and 71% deceased donor PKTRs. Overall, 32% of PKTRs had AR by 1 year post-transplant, with 80% of those detected on surveillance biopsy. By Kaplan-Meier analysis, PKTRs on SM had significantly less AR than those on the SB regimen (Figure 1, log rank p = 0.02). There was no significant difference in mean eGFR at 1 year in the SM vs SB groups. There were also no differences in the rate of CNIT, BK nephropathy, CMV viremia, or neutropenia. PKTRs in the SM group had a lower incidence of EBV viremia (33% vs 69%, p = 0.01).

Conclusions: The incidence of AR in the first year post-transplant was significantly reduced in PKTRs undergoing a SM regimen. Further study is needed to determine the effect of SM on long term outcomes in PKTRs.

Molecular Assessment of Pre-Implantation Transplant Kidney Biopsies

Enver Akalin,[1] Mariel Barbachan e Silva,[2] Maria Ajaimy,[1] Valeria Mas,[3] Pilib Ó Broin.[4] *[1]Montefiore Medical Center, Bronx, NY; [2]National University of Ireland, Galway, Galway, Ireland; [3]University of Virginia, Charlottesville, VA; [4]NUI Galway, Galway, Ireland.*

Background: Deceased-donor (DD) kidneys are at higher risk for ischemia/reperfusion injury leading to increased inflammatory mediators compared to living donors (LD). We investigated the association between intragraft molecular gene expression profiles and clinical outcomes including delayed graft function (DGF) and allograft function.

Methods: The study included 48 pre-implantation kidney biopsy samples (29 LD and 19 DD). Patients were grouped on the basis of cold ischemia time (CIT) < 16 or > 16 hrs and presence of poor clinical/histological markers (final donor serum creatinine > 1.9 mg/dl, donor age > 60 yo, glomerulosclerosis/interstitial fibrosis/vascular sclerosis > 10%). The gene expression profiles were assayed using Affymetrix HuGene 1.0 ST arrays.

Results: DD pre-implantation biopsies showed increased expression of injury and repair (IRIT), gamma interferon and rejection (GRIT), cytotoxic T cell (CAT) and constitutive macrophage (CMAT) associated pathogenesis based transcripts (PBTs) compared to LD biopsies. CIT did not affect intragraft gene expression profiles. Biopsies with poor clinical/histological markers had increased expression of NKAT and endothelial cell associated transcripts (ENDAT). DGF occurred in 47% of DD patients but intragraft gene expression profiles were similar to patients who did not develop DGF. Patients with lower eGFR (<50 ml/min) at 1 year had increased expression of CAT, NKAT, CMAT and B cell associated transcripts at their pre-implantation biopsies compared to patients with higher eGFR (> 50 ml/min).

Conclusions: Pre-implantation DD biopsies showed increased expression of transcripts associated with increased immune activity. This is exacerbated if the donor had any poor clinical/histological markers, but not with increased CIT. Molecular analysis of pre-implantation biopsies did not differentiate patients based on DGF status but did show association of specific PBTs with better allograft function at 1 year

Pathogenesis Based Transcripts	DD vs LD	CIT > 16 hours vs. < 16 hours	Poor clinical/histological markers vs. better clinical markers	DGF vs. No DGF	eGFR < 50 ml/min vs. eGFR > 50 ml/min

FR-PO876

CYP4F11 - A Potential Marker of Accommodation in ABO-Incompatible Renal Transplant Biopsies

Candice A. Roufosse,[1] H. Terence Cook,[3] Michelle Willicombe,[1] Tom Cairns,[2] Jack W. Galliford,[2] Frederic J. Toulza,[1] Kathy M. Dominy.[1] *[1]Imperial College London, London, United Kingdom; [2]IMPERIAL COLLEGE HEALTHCARE, LONDON, United Kingdom; [3]Imperial College of London, London, United Kingdom.*

Background: Recipients of an ABO incompatible transplant have circulating anti-AB antibodies, A and/or B antigens expressed on endothelium and usually C4d deposition on the endothelium, yet this seldom leads to antibody-mediated rejection. It has been hypothesised that this is related to upregulation of complement regulator and/or anti-apoptotic transcripts. We sought to identify differentially expressed genes between ABO-incompatible (ABOi) and ABO-compatible (ABOc) surveillance biopsies with normal histology.

Methods: RNA sequencing was performed to identify differentially expressed genes between 4 ABOi and 4 ABOc surveillance biopsies with normal histology. Differential expression was validated using RNA from formalin-fixed paraffin-embedded tissue from 14 ABOi and 80 ABOc renal transplant patients, using a Nanostring nCounter custom panel.

Results: RNA sequencing identified a number of differentially expressed genes. None of the complement regulator and/or anti-apoptotic genes were upregulated in ABOi samples. Eighteen genes considered the top hits in sequencing analysis were validated using a Nanostring nCounter custom panel. The only differentially expressed gene that was confirmed was CYP4F11, which was reduced in ABOi biopsies (p=0.001, Mann-Whitney test) (See figure 1).

Conclusions: Genes classically hypothesised to be up-regulated in ABOi transplants were not found to have differential expression. Expression of cytochrome p450 4F11 isoform (CYP4F11) is reduced in ABOi patients. Most of the substrates of cytochrome p450 4F isoforms are eicosanoids, which play important roles in the inflammatory response. Down-regulation of CYP4F11 in ABOi transplants may be be playing a role in accommodation to the anti-A or B antibodies and the presence of complement on the endothelial cell surface..

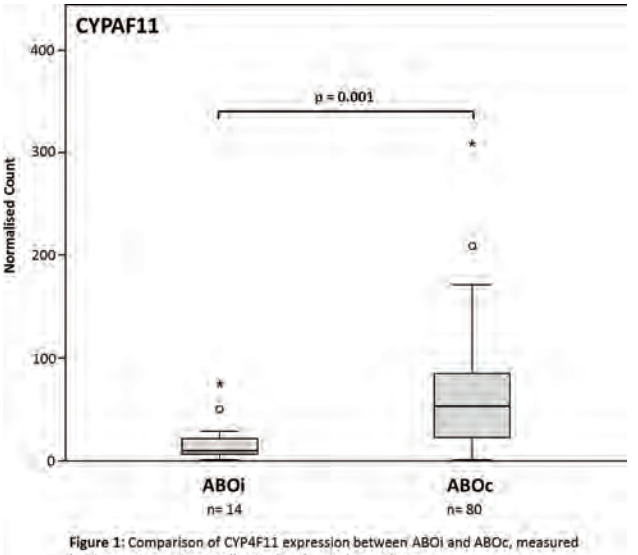

Figure 1: Comparison of CYP4F11 expression between ABOi and ABOc, measured by Nanostring and normalised using the nSolver software.

FR-PO877

C4d Positive Renal Transplant Biopsies with No Other Evidence of Rejection: A Transcript Expression Investigation Using NanoString nCounter Technology

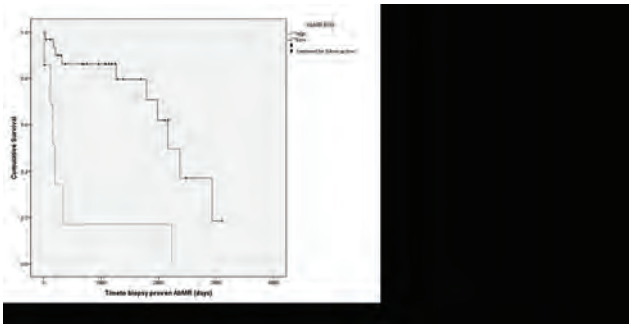
Candice A. Roufosse,[2] Michelle Willicombe,[3] Hannah K. Beckwith,[3] Tom Cairns,[1] Dawn Goodall,[1] Paul Brookes,[1] H. Terence Cook,[3] Kathy M. Dominy.[4] *[1]Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Centre for Inflammatory Diseases, Imperial College, London, United Kingdom; [3]Imperial College of London, London, United Kingdom; [4]Imperial College London, London, United Kingdom.*

Background: Immunohistochemical staining for C4d in peritubular capillaries has been part of antibody-mediated rejection (AbMR) definition in the Banff Classification for Allograft Pathology since 2003. However, with limited sensitivity and specificity, the clinical significance of C4d-positive biopsies without evidence of rejection (C4d+ WER) is unknown. We investigated the molecular significance of C4d positivity in such biopsies from both ABO-compatible and incompatible renal transplant patients.

Methods: RNA was extracted from formalin-fixed paraffin-embedded renal transplant biopsies (n=125) and gene expression analysis of 35 AbMR-associated transcripts carried out using the NanoString nCounter system.

Results: AbMR-associated transcripts were significantly increased in samples with AbMR or suspicious for AbMR. A subgroup of 17/35 transcripts that best distinguished AbMR from C4d-negative biopsies without evidence of rejection was used to study C4d+ WER samples. There was no differential expression between C4d negative and C4d positive biopsies WER from both ABO incompatible and compatible transplants. The geometric mean of 17 differentially expressed genes was used to assign the C4d+WER biopsies a high- or low-risk score for AbMR. Follow-up biopsies showed AbMR within 1 year of initial biopsy in 5/7 high-risk patients but only 2/46 low-risk patients. In multivariate logistic regression analysis, elevated transcript levels in a C4d+ WER biopsy were associated with increased odds for biopsy-proven AbMR on follow-up (p=0.032, odds ratio 16.318), whereas factors including DSA status and time from transplant to biopsy were not.

Conclusions: Gene expression analysis in C4d+WER samples has the potential to identify patients at risk of imminent AbMR.



FR-PO878

C3 Deposition on Biopsy Is an Independent Risk Factor for Allograft Failure in Transplant Glomerulopathy

Emily Joachim, Daniel C. Felix, Christi A. Albert, Brad C. Astor, Weixiong Zhong, Arjang Djamali, Sarah E. Panzer. *University of Wisconsin, Madison, WI.*

Background: Transplant glomerulopathy (TG) is a well-established cause of renal allograft loss, but the prognostic significance of complement activity in TG remains unclear. We hypothesized patients with evidence of complement-mediated allograft injury are at higher risk of graft failure.

Methods: Kidney transplant recipients who received a biopsy diagnosis of TG (cg score≥1a) between 2011-2014 and had immunofluorescence (IF) performed were eligible for the study. Primary outcome was allograft failure (re-transplant, return to dialysis or death).

Results: Of the 111 patients included in the study, 72 (65%) had allograft failure, with a median follow-up of 3 years. Patients with C3 deposition vs. no C3 deposition had a higher rate of allograft failure (78 vs. 55%, respectively). Adjusted multivariate analysis demonstrated an increased risk of graft failure in patients with C3 deposition vs. no C3 (HR 1.37, 95% CI 1.12-1.69, P=0.002); this was not observed for C4d and C1q (Fig 1). Chronicity score was also associated with allograft loss (HR 1.26, 95% CI 1.13-1.42, P=0.0001). C3 positive vs. negative patients did not differ with respect to cause of ESRD, induction or maintenance immunosuppression, donor type, PRA or presence of Class I or II donor-specific antibodies.

Conclusions: In this cohort of patients with TG, C3 deposition was independently associated with increased risk of allograft failure. Other complement products were not found to be significant in predicting allograft loss. Future studies are needed to validate these findings, but our results suggest that IF should routinely be performed on transplant biopsies, as C3 deposition may indicate TG patients who are at higher risk for allograft loss.

C4d Staining Following Thymoglobulin Treatment for Acute Cellular Rejection

Veronica A. Taylor,[1] Aesha Maniar,[3] David P. Witte,[1] Bradley P. Dixon,[2] David K. Hooper.[1] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Children's Hospital of Colorado, Aurora, CO; [3]University of Cincinnati College of Medicine, Cincinnati, OH.*

Background: Rejection is an important cause of allograft failure in kidney transplant recipients (KTRs). Treatment is guided by histologic and biochemical findings indicating cellular and/or humoral origin. C4d staining is one of the diagnostic criteria for antibody mediated rejection (ABMR). At our center we observed an increase in C4d staining on some biopsies following thymoglobulin treatment for acute T-cell mediated rejection (TCMR).

Methods: We performed retrospective review of all KTRs at our pediatric center from January 2013 to April 2018 who received thymoglobulin treatment for acute TCMR and who had a follow-up biopsy within 45 days of diagnosis. Patients who had C4d staining or other histologic evidence of ABMR on initial biopsy were excluded. We evaluated C4d staining on repeat biopsy and compared patients who did not have existing or de novo donor specific antibodies (DSAs) within 12 months of diagnosis to those who did.

Results: 14 KTRs received an average of 12.7mg/kg of thymoglobulin over 4-14 days. Mean time between TCMR diagnosis and follow-up biopsy was 14.9 days. 8 patients remained negative for DSAs during the defined peri-rejection period. Of the 6 patients found to have positive DSAs, 1 showed persistence of known chronic class II DSAs and 5 developed de novo DSAs (4 within 6 weeks of TCMR diagnosis and 1 at 7 months). Post-thymoglobulin C4d staining increased in all 6 DSA-positive patients but only 3/8 (37.5%) of DSA-negative patients (p=0.03). Histologic evidence of ABMR (capillaritis) on follow-up biopsy was seen in two patients with de novo DSAs.

Conclusions: Positive C4d staining can be seen following thymoglobulin treatment of rejection even in the absence of DSAs. C4d staining increased following thymoglobulin therapy in all patients with DSAs, sometimes before the DSA was detectable. These findings may indicate thymoglobulin enhancement of complement activation by DSAs, non-DSA ABMR, or independent in situ complement activation facilitated by the polyclonal xenoantibody preparation.

C4d staining following thymoglobulin treatment of TCMR

Causes of Living Donor Rejection: A Single Center Experience

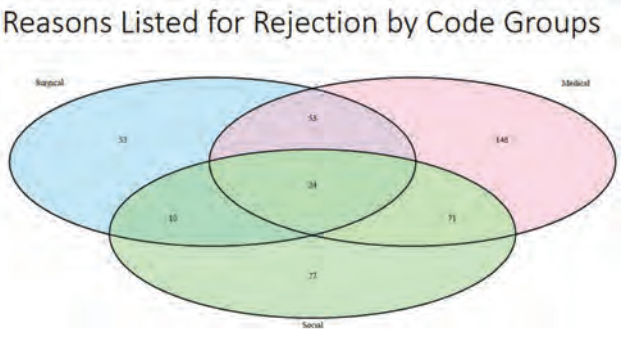
Erik L. Lum,[1] Jenny I. Shen,[2] Jennifer L. Beaumont,[6] Satoru Kawakita,[6] Amy D. Waterman,[3] Anjay Rastogi,[5] Hans A. Gritsch.[4] *[1]Nephrology, David Geffen School of Medicine, Los Angeles, CA; [2]LaBiomed at Harbor-UCLA, Torrance, CA; [3]Transplant Research and Education Center/ Terasaki Research Institute, Los Angeles, CA; [4]UCLA, Los Angeles, CA; [5]Division of Nephrology, Los Angeles, CA; [6]Terasaki Research Institute, Los Angeles, CA.*

Background: Living donor kidney transplantation (LDKT) is the preferred treatment for end stage kidney disease because it leads to better survival than either dialysis or deceased donor transplantation. Yet, the rate of LDKT has not grown despite high numbers of potential donors. Understanding the reasons that potential donors are rejected is key to developing effective interventions to increase LDKT.

Methods: In this single center retrospective observational study from UCLA Medical Center, both a transplant nephrologist and a transplant surgeon reviewed the medical records of all potential living donors presented to the living donor selection committee from 2009 to 2014 and coded the reasons they were rejected as donors. Reasons were categorized as medical, surgical, social, or "other".

Results: Out of 1370 patients, 55% (760) were accepted as potential donors, 16% (225) required further workup, and 29% (385) were denied as donors. 84% (323) of those rejected were rejected for multiple reasons (Figure). The top 3 most common reasons for rejection were medical: young age, family history of diabetes, and obesity. The top social reason was a prior history of psychiatric illness other than depression, and the top surgical reason for rejection was evidence of a renal lesion.

Conclusions: Most potential donors were denied for multiple reasons. Effective interventions to increase the rate of acceptance of potential donors will need to be multi-faceted since addressing just a single cause for rejection is unlikely to clear a potential donor for donation.



FR-PO881

Does Non-Adherence Predict the Futile Treatment of Severe Acute Kidney Transplant Rejection?

Ahmed Al-Sheyyab,[1] Laura Binari,[1] Meghan E. Kapp,[1] Stefanie Bala,[2] Nikita Wilson,[1] Beatrice P. Concepcion.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt.University Medical Center, Nashville, TN.*

Background: To treat or not to treat-- that is the question a clinician faces when a patient presents with renal failure in the setting of non-adherence and is found to have acute rejection. Potent rejection therapy, with its associated risks and cost, should arguably be withheld if treatment is to be futile. In this study we aimed to identify clinico-pathologic characteristics, with particular interest on non-adherence, that are associated with futile treatment. We defined futile treatment as graft loss occurring within 6 mos of acute rejection treatment.

Methods: The study included patients >=18y with biopsy-proven acute rejection and received maximal rejection therapy with a lymphocyte-depleting agent, with/without AMR treatment. Patient/transplant characteristics, adherence status and outcomes were collected via chart review. Descriptive statistics were utilized to compare groups. The outcome was all-cause graft loss within 6 mos of acute rejection treatment. Multivariable poisson regression with robust variance analysis was utilized to quantify the association of predictors with the outcome.

Results: 115 patients were included in the study, 46% of which were non-adherent. Non-adherent patients were younger (36 vs 46 y), more likely to be on steroid withdrawal (32 vs 16%), attained a lower nadir SCr (1.2 vs 1.8 mg/dL) and rejected later (65 vs 19 mos from transplant). There was no difference in eGFR at presentation or Banff grade on biopsy. Overall, 31% of patients lost their grafts within 6 mos of acute rejection, with a higher percentage in the non-adherent group (42% vs 23%, p=0.03). In adjusted analysis, non-adherent patients had an increased RR of graft loss within 6 mos of acute rejection (RR 1.9, p<0.01). Other predictors of futile treatment included eGFR <=10 at presentation and >5% interstitial fibrosis on biopsy. Age, race, Banff grade, presence of concomitant AMR and type of lymphocyte depleting agent used were not significantly associated with the outcome.

Conclusions: Patients who are non-adherent are at 2-fold higher risk for futile treatment of acute rejection despite lymphocyte depletion. Other risk factors include severe renal dysfunction on presentation and the presence of interstitial fibrosis. In such patients, withholding potent rejection therapy should be considered, and ESRD planning should be initiated.

FR-PO882

Treatment of Biopsy-Proven Borderline Rejection in Kidney Transplant Recipients

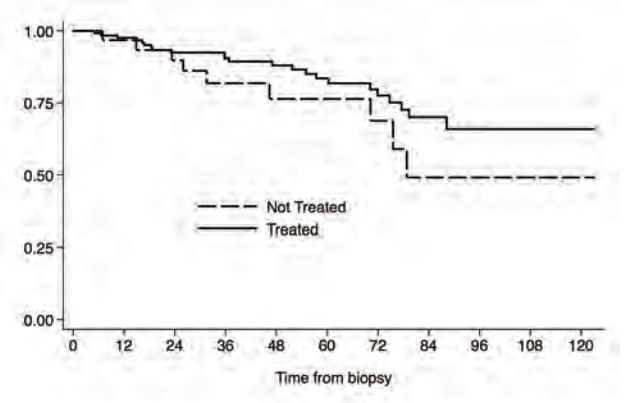
Leigh-Anne Dale,[1] Demetra Tsapepas,[3] Syed A. Husain,[1] Sumit Mohan.[2] Columbia University Renal Epidemiology [CURE] *[1]Columbia University Medical Center, New York, NY; [2]Columbia University, New York, NY; [3]NewYork-Presbyterian Hospital, Columbia University Medical Center, New York, NY.*

Background: Borderline cellular rejections are now the most common type of rejection found after kidney transplantation. Most centers either treat borderline rejection episodes with a pulse of high dose corticosteroids or do not provide any additional immunosuppression.

Methods: We identified 161 consecutive patients (50.6 ± 14.8 yrs, 62% male) who had a borderline rejection on allograft biopsy with no prior evidence of biopsy proven acute rejection between 2008 – 2015 at our center. While the majority of patients received our protocol of high dose corticosteroids, we identified 29 patients who did not receive any additional immunosuppression. We compared improvement in renal function over 4 weeks after the rejection episode for those who were treated versus those who were not.

Results: Recipients who were treated were significantly younger (55.7±12.7 vs 49.4±15.1 years p=0.03) than recipients who were not treated but were similar with respect to gender distribution, time from transplant to biopsy (347.7±486 vs 264.1±481.9 days, p=ns), and the creatinine at the time of biopsy (2.29±0.95 vs 2.57±1.48 mg/dL, p=ns). There was no difference in the decrease in serum creatinine at 4 weeks (0.31±0.55 not treated vs 0.59±1.28 mg/dL treated, p=ns) and 90 days (0.48±0.2 not treated vs 0.64±1.1 mg/dL not treated) following the biopsy between the two groups. While there were a higher number of graft failures among patients who were not treated (28.1% vs 18.2%, p=ns), this difference was not significant. [figure1]

Conclusions: The treatment of isolated borderline rejections with high dose pulse steroids did not improve short term outcomes in this single-center retrospective study. The higher rate of graft failure in the nontreated arm is however concerning and more studies are needed to understand the optimal management strategy for biopsy proven borderline rejections.



Time from biopsy to graft failure

FR-PO883

Adenovirus Allograft Nephropathy Mimicking Acute T Cell Rejection

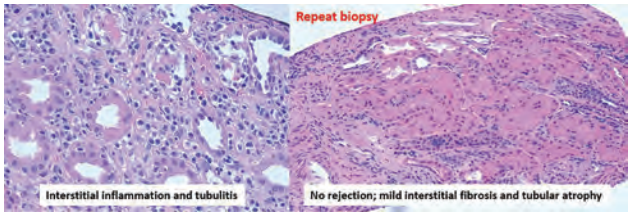
Kawther F. Alquadan, Xu Zeng, Abhilash Koratala. *University of Florida, Gainesville, FL.*

Introduction: Adenovirus is associated with significant morbidity and mortality in renal transplant recipients and may even lead to the loss of allograft. Adenovirus nephropathy can be confused with acute cellular rejection as illustrated in our case. As the management of these two entities is completely different, clinical correlation is crucial.

Case Description: A 33-year-old African American woman with a history of ESRD status post deceased donor kidney transplantation was admitted for acute kidney injury (AKI) with a Scr of 8mg/dL (baseline 1.3). Her pre-transplant CPRA was 29%, received Alemtuzumab for induction immunosuppression (IS) followed by mycophenolate mofetil, tacrolimus and prednisone for maintenance. Her post-transplant course was complicated by BK viremia that resolved with reduction in IS. This time, BK virus serology was negative and she was given methylprednisolone 1 gram/day for 3 days for suspected rejection. She later developed fever and hematuria and clinically deteriorated despite receiving broad-spectrum antibiotics. Blood cultures remained negative. Allograft biopsy demonstrated severe interstitial inflammation with T cells, mononuclear cells and plasma cells with severe tubulitis [Figure]. Immunohistochemistry staining was negative for adenovirus but serum adenovirus PCR was positive with 10 million copies/ml. Her respiratory status worsened and CT scan of the chest showed tree-in-bud nodular opacities. Adenovirus PCR was positive in BAL and in the urine suggestive of adenovirus

pulmonary and renal allograft involvement. Mycophenolate was held and she received treatment with intravenous immunoglobulin and cidofovir. Patient clinically improved and Scr was 1.5mg/dl at discharge. A repeat biopsy at follow-up visit was negative for rejection, showed mild interstitial fibrosis and tubular atrophy with no glomerulosclerosis [Figure].

Discussion: High index of suspicion for adenovirus infection is required in renal graft dysfunction, especially in the setting of hematuria. Histology can mimic acute rejection, which creates a diagnostic dilemma. Tissue adenovirus immunostains, though usually reliable, may not be always positive like in our case.



FR-PO884

The Role of Plasma Donor-Derived Cell-Free DNA in Minimal Invasive Graft Monitoring

Els M. Gielis,[1] Kristien J. Ledeganck,[1] Amélie Dendooven,[2] Pieter Meysman,[3] Charlie Beirnaert,[3] Kris Laukens,[3] Joachim De schrijver,[4] Steven Van Laecke,[5] Marie-Paule Emonds,[6] Benedicte De winter,[1] Jean-Louis Bosmans,[7,1] Jurgen Del favero,[4] Daniel Abramowicz.[7,1] *[1]Laboratory of Experimental Medicine and Pediatrics, University of Antwerp, Antwerp, Belgium; [2]Dept. of Pathology, University Hospital of Antwerp (UZA), Edegem, Belgium; [3]Biomedical informatics research center Antwerpen (Biomina), University of Antwerp, Antwerp, Belgium; [4]Agilent Technologies, Niel, Belgium; [5]Renal Division, Ghent University Hospital, Ghent, Belgium; [6]Histocompatibility and Immunogenetic Laboratory, Belgian Red Cross Flanders, Mechelen, Belgium; [7]Dept. of Nephrology and Hypertension, Antwerp University Hospital, Edegem, Belgium.*

Background: After transplantation, cell-free DNA derived from the donor organ (ddcfDNA) can be detected in the recipient's circulation. We aimed to investigate plasma ddcfDNA kinetics in renal transplant recipients thereby evaluating the role of this biomarker in graft monitoring.

Methods: From 107 renal transplant recipients, plasma samples were collected longitudinally from day 1 until 3 months after transplantation within a multicenter set-up. Cell-free DNA from the donor was quantified in plasma as a fraction of total cell-free DNA by next generation sequencing using a targeted, multiplex PCR based method for the analysis of single nucleotide polymorphisms.

Results: Slope normalization analysis was performed in 42 patients that met predefined criteria for stable graft recipients. After an exponential decrease in ddcfDNA, a mean stable baseline level of 0.455% + 0.427 (2 SD) was reached on average 9.85 (± 5.6 days) after transplantation. In the entire cohort, patients that were not stabilized by day 10 (n = 37) had higher individual baseline ddcfDNA values (p = 0.007) and higher ddcfDNA fractions on day 1 (p = 0.0002). Sixteen recipients exhibited abnormal non-exponential ddcfDNA kinetics in the early post-engraftment phase; and this was associated with the occurrence of an early adverse event including a urinary tract infection, a surgical adverse event or episode of hydronephrosis that required treatment, a BKV or CMV infection episode or prerenal acute kidney injury (p=0.0012). From day 10 onwards, increases of ddcfDNA% above the baseline value of 0.882% (mean+2 SD) were significantly associated with the occurrence of episodes of acute rejection (p = 0.017), acute tubular necrosis (p = 0.011) and pyelonephritis (p = 0.032).

Conclusions: Within 10 days after transplantation, plasma ddcfDNA fractions decrease to a stable baseline level. From day 10 onwards, increases of ddcfDNA% are associated with graft injury related to acute rejection, acute tubular necrosis or pyelonephritis.

FR-PO885

Donor-Derived Cell-Free DNA in Renal Transplant Recipients with Delayed Graft Function

Thin Thin Maw,[4] Jonathan Bromberg,[2] Jim Yee,[1] Matthew Gillespie,[1] Daniel C. Brennan.[3] *[1]CareDx, Pasadena, CA; [2]University of Maryland, Baltimore, MD; [3]Johns Hopkins, Baltimore, MD; [4]Keck School of Medicine USC, Los Angeles, CA.*

Background: Delayed graft function (DGF) is a major barrier to improved outcomes after kidney transplantation (KTx) with no definitive tool available to assess severity or chances for recovery. Donor-derived cell-free DNA (dd-cfDNA) was previously validated to discriminate active rejection in KTx pts but its characteristics have not been defined in those with/at risk for DGF. This report describes dd-cfDNA levels in a cohort of KTx pts with suspected DGF.

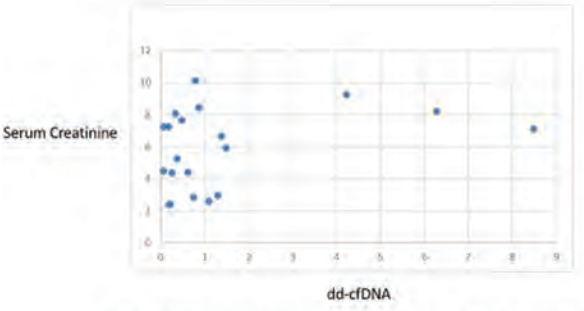
Methods: dd-cfDNA samples of KTX pts with suspected DGF at three centers were obtained between Days 1-16 post-tx as part of the Donor-derived Cell-free DNA in Blood for Diagnosing Acute Rejection in Kidney Transplant Recipients (DART) study. Similar clinical data were collected at each sample visit during this early post-tx period as was collected during later visits per DART protocol.

Results: dd-cfDNA samples were obtained from 17 KTx pts with suspected DGF. All received a deceased donor KTx (mean CIT 23 ±9 hours; mean KDPI 64 ±17). Mean dd-cfDNA level was 1.47% (SD 2.25%) in samples collected Days 1-16 post-tx and 0.60% (SD 0.99%) in samples collected at Months 1-24 post-tx. By comparison, the mean level in a reference cohort without DGF from DART was 0.34% (SD 0.58%) in samples collected 30 or more days post-tx. No obvious correlation was seen between Scr and dd-cfDNA in samples from Days 1-16 (Fig. 1) or in Months 1-24 (Fig. 2).

Conclusions: dd-cfDNA levels are higher early post-tx in suspected DGF samples vs. later time points and in those without DGF. Larger studies with long-term follow-up are needed comparing dd-cfDNA levels directly in pts with vs. without DGF after KTx. This may allow for more accurate assessment of dd-cfDNA patterns related to DGF severity/recovery.

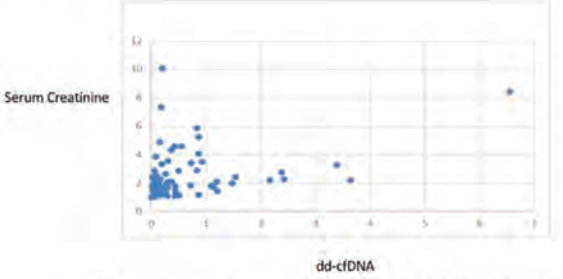
Funding: Commercial Support - CareDx

Figure 1



No obvious correlation between Scr and dd-cfDNA levels in all samples collected between Day 1 and Day 16 post-transplant

Figure 2



No obvious correlation between Scr and dd-cfDNA levels in all pooled samples collected between Visit 1-Visit 11 (Month 1-Month 24) post-transplant

FR-PO886

The Association Between Location of Eplet Mismatches, De Novo Donor Specific Antibodies, and Acute Rejection in Simultaneous Pancreas-Kidney Transplant Recipients Using Novel Machine Learning Methods

Ankit Sharma,[1,2] Craig Coorey,[1] Anne T. Taverniti,[1] Brian J. Nankivell,[3] Jeremy R. Chapman,[3] Jonathan C. Craig,[1] Wai H. Lim,[5] Jean Yang,[4] Germaine Wong.[1,2] *[1]Centre for Kidney Research, Westmead, NSW, Australia; [2]School of Public Health, University of Sydney, Sydney, NSW, Australia; [3]Westmead Hospital, WESTMEAD, NSW, Australia; [4]University of Sydney, Sydney, NSW, Australia; [5]Sir Charles Gairdner Hospital, Nedlands, WA, Australia.*

Background: To determine the association between HLA class and location of eplet mismatches with de novo donor specific antibodies (dnDSA) and acute rejection in simultaneous pancreas-kidney (SPK) transplant recipients.

Methods: The cohort consisted of SPK recipients (n=170) transplanted in New South Wales, Australia between 2005 and 2017. Using machine learning models (random forest), we determined the association between the number and location of class specific eplet mismatches, and adverse allograft outcomes (dnDSA formation and acute rejection (acute cellular (ACR) and (antibody-mediated (AMR)). One hundred times 5-fold cross validation was conducted using R.

Results: The cohort included 93 (55%) males, with mean age at transplant of 38.7 years (SD 7.0) and median follow up time of 5.0 years (IQR: 2.1, 7.1). The median total number of class I and II eplet mismatches were 17 (IQR: 13-22) and 34 (IQR: 22-47), respectively. The most important (highest Mean Decrease Accuracy) class I eplet mismatches for predicting dnDSA and any acute rejection corresponded to locations 102HV, 149TAH, 152RE, 163RW, 21H, 44RM, 44RMA and 82LR; and for class II mismatches at 76L. For the prediction of class I and II dnDSA, the median AUC and balanced error rate from the

location of class I eplet mismatches were 57.8% (SD: 3.5%) and 47.0% (SD: 1.6%); and for class II were 53.5% (SD: 2.6%) and 50.9% (SD: 2.5%), respectively. The median AUC and balanced error rate for predicting any acute rejection from class I eplet locations were 54.3% (SD: 2.7%) and 50.2% (SD: 2.7%); and for class II were 56.7% (SD: 3.3%) and 43.9% (SD: 2.7%), respectively.

Conclusions: In this cohort of SPK recipients, the location of class I mismatches best classify recipients with dnDSA and any acute rejection.

FR-PO887

Comparison of Banff Allograft Injury Scores of Patients with De Novo Donor-Specific Antibodies (DSAs) to Patients with Preformed DSAs

Maria Ajaimy, Adriana Colovai, Nicole A. Hayde, Enver Akalin. *Montefiore Medical Center, Bronx, NY.*

Background: We aimed to compare histological features of rejection in patients with preformed and de novo DSAs and its association with clinical outcomes

Methods: This is a prospective study including 681 non-HLA-identical patients who received a kidney tx between 1/2009 and 12/ 2014 at our center. Protocol testing for DSA via LABScreen single antigen beads was done before and at 1, 3, 12 months, and then annually after kidney tx or when clinically indicated. Tx kidney biopsies are performed as clinically indicated

Results: 114 (17%) patients had preformed DSA. During a median 3.8 (2.4-5.3) years of follow-up, de novo DSA developed in 92 patients (13%) at a median of 1.24(0.71-2.35) years after kidney tx. While there was no difference in patient survival, de novo DSA group had significantly lower graft survival (63.8% vs. 88.6%, P<0.001), higher antibody-mediated rejection (ABMR) (13.04% vs. 6.14%, p=0.001), transplant glomerulopathy (16.6% vs. 9% vs. 4.7%, P=0.004) and T cell mediated rejection (14.13%vs. 2.63%, p=0.001) compared to patients with preformed DSA. ABMR developed at a median 0.39 years (0.13-1.4) in pre-transplant DSA patients and at 1.25 years (0.25-3.31) in de novo DSA ones. When comparing the Banff allograft injury scores in 16 pre DSA and 34 de novo DSA biopsies, mean total acute Banff allograft injury score (g+ i+t+ptc+v, 6.29±3.57 vs. 4.19±3.39, p=0.046) was statistically significantly higher in the de novo DSA. The rest of acute and chronic allograft injury scores were not significantly different

Conclusions: Development of de novo DSA after kidney tx is associated with higher total acute allograft injury score, rejection episodes, and lower allograft survival compared to preformed DSA.

Banff Scores

	Pre Transplant DSA	De novo DSA	P
g(mean, SD)	0.52±0.77	0.51±0.76	0.87

FR-PO888

Long Term Follow Up for Antibody Mediated Rejection of Kidney Transplant Due to Angiotensin II Type 1 Receptor Antibodies

Sami Alasfar,[1] Nada Alachkar,[3] Edward S. Kraus,[4] Mary Carmelle Philogene.[2] *[1]Medicine, Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD; [3]Johns Hopkins University, Baltimore, MD; [4]Johns Hopkins University, Baltimore, MD.*

Background: A new appreciation for the contribution of non-HLA antibodies (Abs) in kidney transplantation (K-TXP) has arisen as a result of reports of antibody mediated rejection (ABMR) without HLA Abs. Abs directed against the angiotensin II type 1 receptor (AT1R-Ab) have received greater scrutiny because of the existence of a commercially available assay. Studies on the treatment and long term follow up of AT1R-Ab mediated ABMR are lacking

Methods: Among K-TXP patients with positive (≥17 Units/ml) or borderline (10-17 Units/ml) AT1R-Ab, we retrospectively identified those with biopsy proven ABMR by Banff 2017 and had negative or low level HLA Abs at the time of rejection

Results: 14 patients were identified. Patients' characteristics are shown in table 1. Median time of follow up from ABMR is 24 months. Median time from transplant to ABMR is10 months. With regards to treatment, 9 received plasmapheresis and intravenous immunoglobulins +/- high dose corticosteroids (HDCS), 1 received HDCS, and 1 received HDCS and thymoglobulin. Of treated patients, 6 responded. One lost allograft due to recurrence of ABMR. Of all patients, 10 had follow up biopsy. 5 had improvment in histological findings, and the other 5 developed transplant glomuerlopathy. Of the 3 who did not receive any treatment, 1 progressed to allograft loss, 1 had resolution on follow up biopsy, and 1 remained with elevated but stable serum Creatinine. Of the 11 who received treatment, 9 had evidence of reduction in AT1R-Ab titer. Of the three who did not receive treatment, 1 had improvement in AT1R-Ab titer

Conclusions: AT1R-Ab mediated ABMR is seen in HLA sensitized and non sensitized patients. Conventional ABMR treatment reduces AT1R-Ab titer in most patients but not all achieve clinical response. As with HLA antibodies, AT1R-Ab may lead to transplant glomerulopathy

Table 1

Mean age at current transplant (yr)	40.8 +/- 3.8
Number of males	11/14
Number with previous K-TXP	8/14
Deceased donor K-TXP	9/14
Mean number of mismatches in ABCDRDQ	4/10
Number with HLA sensitization at transplant	8/14
Number with HLA DSA at transplant	6/14
Number with positive or borderline AT1R-Ab at transplant	13/13, one unavailable
Induction immunosuppression with thymoglobulin	14/14
Maintenance immunosuppression at time of ABMR	14/14 tacrolimus, mycophenolate, and prednisone

FR-PO889

ABO Incompatible Kidney Transplantation Without Use of Anti-CD20 Antibody or Splenectomy: Experience from Northern India

Amit Sharma, Harinder J. Gill. *FORTIS HOSPITAL MOHALI, MOHALI, PUNJAB, India.*

Background: ABO-incompatible (ABOi) renal transplants help in crossing an important immunological barrier against kidney transplantation, thereby meeting the unmet demands of renal transplants. The study was conducted to assess ABOi transplant without the use of Anti CD20 antibody or splenectomy and compare their outcomes with ABO compatible (ABOc) transplants.

Methods: The study period was from January 2014 to February 2018. 290 patients were divided into two groups: ABOi (n=33) or ABOc (n=257) living renal donors. In ABOi cases, plasmapheresis and low dose intravenous immunoglobulin (100 mg/kg) was given till isoagglutinin titer were <1:8. All patients received induction immunosuppression: Thymoglobulin (1 mg/kg/day for 3 days) for all ABOi and ABOc with HLA mismatch > 3/6 and Basiliximab in ABOc with HLA mismatch < 3/6. In ABOi, titers were monitored post-operatively and plasmapheresis was done if they increased to >1:8 in first week and >1:16 in second and third week post transplant. Patient and allograft survival; 1, 3, 6, 12, 24, and 36-month renal function; infectious complications; and incidence of rejection were measured.

Results: 30.3% of the ABOi recipients and 22.17% of ABOc recipients were females. Median isoagglutinin titer at start was 1:32 (1:1 to 1:256). Mean number of plasmapheresis required were 3. In ABOi group, Mean±SD creatinine levels were 1.37±0.41 mg/dL at 1 month, 1.29±0.31 mg/dL at 12 months, and 1.36±0.39 mg/dL at 36 months. In ABOc group, Mean±SD creatinine levels were 1.26±0.41 mg/dL at 1 month, 1.26±0.44 mg/dL at 12 months, and 1.28±0.45 mg/dL at 36 months. In the ABOi group, there were 6 episodes of acute antibody mediated rejection (AMR) and 1 patient had acute cellular rejection (ACR), which were successfully treated (3 AMR and 4 ACR were observed in the ABOc group). Two patients succumbed to fungal sepsis in the ABOi group.

Conclusions: Successful ABOi renal transplantation is possible without the use of splenectomy or Anti-CD20 treatment but AMR episodes as well as fungal sepsis are significantly high.

Table 1: Patient characteristics of ABO incompatible (ABOi) and compatible (ABOc) transplant groups

		ABOi (n=33)	ABOc (n= 257)
Donor	Age (Mean ± SD) in years	47.12±12.15	48.96±13.78
	Females	51.51%	80.54%
Recipient	Age (Mean ± SD) in years	42.93±11.71	41.31±12.94
	Females	30.30%	22.17%
Serum Creatinine (Mean ± SD) in mg%	At discharge	1.39±0.59	1.31±0.51
	At 1 month	1.37±0.41	1.26±0.41
	At 3 months	1.27±0.33	1.26±0.46
	At 6 months	1.29±0.36	1.27±0.47
	At 12 months	1.29±0.31	1.26±0.44
	At 24 months	1.31±0.38	1.27±0.44
	At 36 months	1.36±0.39	1.28±0.45

CD19+ Cell Behavior in the 12 Months Following a Single Dose of Rituximab in Patients with Humoral Rejection: Clinical and Histological Outcomes

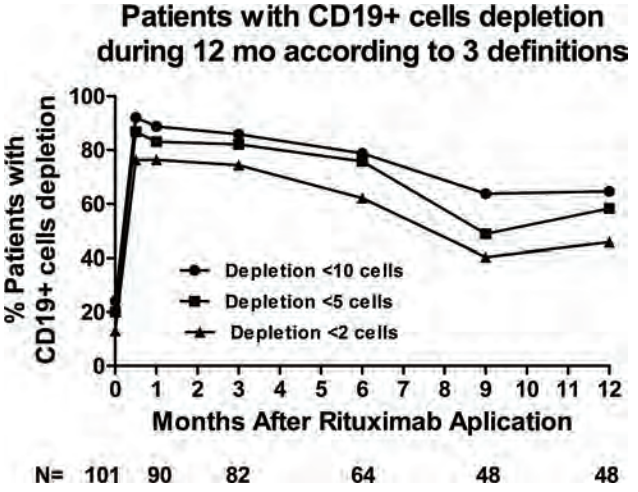
Itzel A. Martinez, José roberto Marino sanchez, Mariedel Trujeque, Jesus I. Santander, Flor M. Zamora-Mejia, Hilda Juárez-Contreras, Raquel A. Vazquez, Luis Llorente Peters, Guadalupe Lima gonzalez, Abraham Cohen-Bucay, Josefina Alberú, Lluvia A. Marino-Vazquez, Luis E. Morales-Buenrostro. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico.*

Background: Treatment of antibody mediated rejection (AMR) commonly includes rituximab (RTX). It has been suggested that a single dose of RTX is enough to deplete CD19+ cells. Aim: to analyze CD19+ cell behavior during the 12 months following a 500 mg dose of RTX and its correlation with clinical and histological outcomes.

Methods: Prospective cohort study of 122 kidney transplant recipients with biopsy proven AMR who received a single dose of RTX 500 mg as part of standard AMR treatment between 2012 and 2018. Peripheral CD19+ cells were measured at baseline, 15, 30, 90, 180, 270, and 360 days after RTX infusion, and correlated this data with clinical and histological outcomes.

Results: 122 patients were included. Mean age was 35±13 y, 56.6% female, median time to rejection was 6y post-transplant. Treatment included PE and IVIG in 75%, 21% also received Bortezomib. All patients received 500 mg of RTX and were followed for a median of 21mo (0.1-83). Median allograft survival after AMR was 5.5y. CD19+ cell depletion (<10 cells) at 1mo was associated with less IFTA at follow-up biopsy (p=0.01) and improvement of proteinuria at last follow-up (p=0.05). Early CD19+ cell repopulation was associated with higher graft loss and dead (p=0.03). Persistent CD19+ cell depletion (<10 cells) at 12mo was associated with better graft and patient survival (0.04).

Conclusions: A single dose of RTX achieved CD19+ cell depletion in more than 80% of patients, which lasted at least 6 mo. CD19+ cell depletion is associated with improvement of proteinuria and less IFTA; and the persistence of CD19+ cell depletion at 12mo improves graft and patient survival.



CD19+ cell depletion patterns.

FR-PO891

High Level of HLA-DP Expression in Kidney Donors Is Associated with a Reduced Graft Survival

Andreas Heinzel,[1] Roman Reindl-Schwaighofer,[1] Alexander Kainz,[1] Kira Jelencsics,[1] Karin Hu,[1] Petra Hruba,[2] Ondrej Viklicky,[2] Georg Bohmig,[1] Brendan Keating,[3] Rainer Oberbauer.[1] *[1]Department of Nephrology, Medical University of Vienna, Vienna, Vienna, Austria; [2]Institute for Clinical and Experimental Medicine, Department of Nephrology, Prague, Czechia; [3]University of Pennsylvania, Philadelphia, PA.*

Background: HLA-DP mismatch between kidney allograft donors and recipients has increasingly been recognized as risk factor for adverse long-term outcome following transplantation. Current matching algorithms do not account for HLA-DP mismatch. The single nucleotide variant rs9277534 in the 3′ UTR of DPB1 is associated with HLA-DPB1 expression levels.

Methods: We made use of the iGeneTrain consortium and genotyped 477 first kidney transplant recipients and respective deceased donors from two centers in Vienna and Prague. HLA eplet mismatch was calculated for the HLA-A, -B, -C, -DP, -DQ, and -DR loci. The median follow-up time of the cohort was 6.5 years. Kaplan-Meier analysis and a Cox PH model were used to assess the association of rs9277534 with death censored graft loss.

Results: The rs9277534 variant influencing HLA-DPB1 expression levels is associated with graft loss after kidney transplantation. Kaplan-Meier analysis (figure 1) showed that presence of one or two copies of a 'G' allele at rs9277534 in the donor was associated with an elevated risk for graft loss. This association remained significant in a multivariable Cox model after adjustment for donor age and full HLA eplet mismatch (HR of rs9277534: 2.05 CI: 1.15 – 3.67).

Conclusions: Presence of the high expression variant in kidney allograft donors is associated with a reduced graft survival.

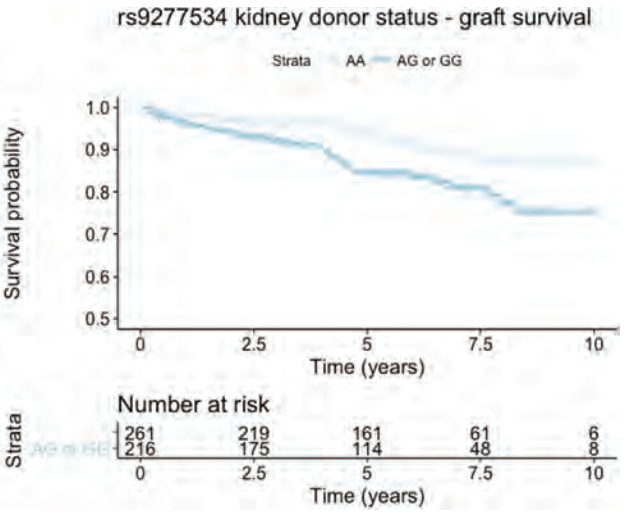


Figure 1: KM plot relating kidney allograft donor status of the rs9277534 variant influencing HLA-DPB1 expression with death censored graft loss after transplantation.

FR-PO892

Biopsy Guided Evaluation in Patients with Renal Impairment Awaiting Liver Transplantation - How Kidney Biopsies Save Organs

Bojana Simunov,[1] Mladen Knotek.[2] *[1]University Hospital Merkur, Zagreb, Croatia; [2]University of Zagreb Medical School, Clinical Hospital Merkur, Zagreb, Croatia.*

Background: After the introduction of MELD score in liver allocation, the number of simultaneous liver-kidney transplantations (SLKT) significantly increased therefore contributing to the shortage of allografts for patients waitlisted for kidney transplantation. We analyzed the data in our high-volume transplant center with a stable number of SLKT and reviewed our biopsy-guided kidney allocation policy in pts with renal dysfunction undergoing liver transplantation (LT).

Methods: We analyzed LT and SLKT performed in UH Merkur, Croatia from April 2007 to April 2018. As significant renal impairment at time of enlisting we defined serum creatinine higher or equal to 2 mg/dL, renal replacement therapy (RRT) or pathologic proteinuria higher than p/c 1 g/g.

Results: In total 1056 LT and 19 SLKT were identified. 129 pts fulfilled the criteria for renal impairment given above. There were 95 male pts (73,6%). 13 patients had ESRD receiving RRT prior to referral for LT and were automatically enlisted for SLKT. From those 13, in 2 pts SLKT was performed because of primary hyperoxaluria. In evaluation of other pts with renal dysfunction 22 renal biopsies were performed under US guidance after correction of coagulation parameters. There were no major complications of biopsies. Other 94 pts were diagnosed with acute kidney injury/hepatorenal syndrome (AKI/HRS). The most common pathohistological diagnosis was IgA nephropathy (63,6%), followed by ATN (18,2%) and diabetic nephropathy (9,1%). The cut-off for SLKT was more than 40% interstitial fibrosis and tubule atrophy (IFTA), or more than 30% of globally sclerosed glomeruli (GS) on biopsy. Based on biopsy results additional 6 pts were enlisted for SLKT. None of the patients with presumed AKI/HRS who received only LT and survived for more than one-month post-LT required RRT at one-month post-LT.

Conclusions: We believe that kidney biopsy is a useful and safe tool to avoid kidney graft wasting when evaluating enlistment for SLKT. We enlist a patient for SLKT if IFTA is higher than 40% or GS more than 30%. A separate indication for SLKT are metabolic diseases. In decompensated liver cirrhosis HRS develops and makes evaluation of kidney recovery potential speculative. In our experience, percutaneous kidney biopsy in pts with advanced liver disease was not linked to adverse events and is a safe procedure in experienced centers.

FR-PO893

Proteomic Analysis of Perfusate from Machine Cold Perfusion of Transplant Kidneys: Comparison Between Circulatory and Neurological Death

Andrea Angeletti,[2] Chiara Donadei,[1] Matteo Ravaioli,[1] Vanessa De pace,[2] Valeria Corradetti,[1] Giorgia Comai,[1] Gaetano La Manna.[1] *[1]University Hospital of Bologna, Bologna, Italy; [2]University Hospital of Bologna, Bologna, Italy.*

Background: Renal donation after circulatory death (DCD) is associated with increased of delayed graft function (DGF) events shortly after transplant and with a decrease in renal function at 1 year compared to donation after neurological death (DND). Machine cold perfusion has been suggested to reduce incidence of DGF and improved long and short-term function in marginal kidneys and those obtained from DCD donors. We compared several early biomarkers of renal injury in perfusate of kidneys from DCD and DND.

Methods: Perfusates from DCD and DND were collected (n=25) at the beginning (T0) and at the end (T1) of perfusion and analyzed by Luminex technology for neutrophil

gelatinase-associated lipocalin (NGAL), Cystatin C, Kidney Injury Molecule-1 (KIM-1), Monocyte chemoattractant protein-1 (MCP-1), and trefoil factor 3 (TFF3).

Results: Donor kidneys characteristics are resumed in **Table**. The highest levels of early biomarkers of renal tubular injury were seen for the DCD compared to DND kidneys for all markers except for MCP-1, the key chemokine that regulate migration and infiltration of monocytes/macrophages (**Figure**). No differences are reports for DGF of recipients.

Conclusions: Comparison of the perfusates from the different types of kidneys has allowed us to identify increased levels of biomarkers, representatives of increased acute tubular damage, that will be useful in future research into improving DCD kidneys outcome.

Funding: Clinical Revenue Support

Table

	DND n= 11	DCD n= 14	p-value
Donor Age (yrs±SEM)	59.9±1.4	61.9±2.3	n.s.
Donor Gender (M:F)	8:3	12:2	n.s.
Donor baseline serum creatinine (mg/dl±SEM)	0.7±0.07	0.9±0.13	n.s.
Machine cold perfusion (min±SEM)	184±29	215±29	n.s.
Machine cold perfusion flow (ml/min±SEM)	47.4±5.3	59.9±7.9	n.s.
Cold ischemic time (hours±SEM)	14.3±1.1	9.8±0.8	0.013

FR-PO894

Urinary RANTES, IL-4, and IL-6 as Potential Prognostic Markers of Early Renal Outcome in Living Donor Kidney Transplantation

Minjung Kim, Hyo jin Boo, Song in Baeg, Eun jeong Lee, Hye Ryoun Jang, Jung eun Lee, Dae Joong Kim, Ha Young Oh, Wooseong Huh, Yoon-Goo Kim. *Samsung medical center, Seoul, Republic of Korea*.

Background: Changes in intrarenal immunologic micromilieu has been shown to affect the renal outcome in kidney transplantation. Recent studies have shown that some cytokines and chemokines may have potential as non-invasive diagnostic markers that detect early injury after kidney transplantation. This prospective study aimed to investigate the diagnostic value of urinary cytokines and chemokines after living donor kidney transplantation as prognostic markers of early renal outcome.

Methods: Serum and urine samples were serially collected from kidney transplant patients at the following time points; during transplantation, 8 hours, 24 hours, 72 hours, 1 week, 3 months, and 1 year after transplantation. Cytokines and chemokines including regulated on activation, normal T cell expressed and secreted (RANTES), fractalkine, interleukin (IL)-10, IL-4, IL-6, monocyte chemoattractant protein (MCP)-1, tumor necrosis factor (TNF)-α, and vascular endothelial growth factor (VEGF) were measured in 64 patients. Patients were divided into either the good prognosis group (eGFR at post-transplant 3 months ≥ 60ml/min/1.73m^2 or eGFR change ≥ -5 between post-transplant 3 and 12 months) or the poor prognosis group (eGFR at post-transplant 3 months < 60ml/min/1.73m^2 or eGFR change < -5 between post-transplant 3 and 12 months). T-test and one-way or two-way ANOVA tests were used for statistical analysis.

Results: The median age of patients was 42.3 years and 70.3% were male. Urinary RANTES ($P < 0.001$) and urinary IL-4 ($P < 0.05$) at 24 hours after transplantation were higher in the good prognosis group. When patients were divided by eGFR change between 3 months and 1 year after transplantation, urinary IL-6 at 3 months after transplantation ($P < 0.05$) was higher in the good prognosis group. There were no differences in serum cytokines or chemokines between groups.

Conclusions: Our study showed the potential clinical value of urinary RANTES and IL-4 measured at 24 hours after transplantation as well as urinary IL-6 at 3 months after transplantation as non-invasive predictors of early renal outcome after living donor kidney transplantation.

FR-PO895

Plasma Fibroblast Growth Factor 21 Plasma Concentration in Patients After Kidney Transplantation

Marcin Adamczak, Magdalena Bartmanska, Andrzej Wiecek. *Department of Nephrology, Transplantation and Internal Medicine, Medical University of Silesia, Katowice, Poland, Katowice, Poland*.

Background: Fibroblast growth factor 21 (FGF21) is a protein hormone involved in the regulation of energy expenditure. The results of clinical studies suggest that plasma FGF21 concentration increases with the progression of chronic kidney disease. The aim of the present study was to analyze the effect of successful kidney transplantation on plasma FGF21 concentration and to study the factors related to plasma FGF21 concentration in patients long-term after kidney transplantation.

Methods: Forty patients with chronic kidney disease (CKD) 5 or 5D before kidney transplantation [27 women and 13 men aged 47.0 (39.3 - 54.0)], 180 patients long-term after kidney transplantation [70 women and 110 men aged 52 (47,4 – 54)] and 50 healthy subjects [28 women and 22 men aged 50.0 (47.6 - 58.0)] were enrolled into this study. In CKD patients, plasma FGF21 concentrations were measured four times (immediately before and 14 and 30 days, and 6 months after kidney transplantation). In patients long-term after kidney transplantation and in healthy subjects, this measurement was made once.

Results: In patients before kidney transplantation plasma FGF21 concentration were significantly higher than in healthy subjects [1013.0 pg/ml (744.4-1635.7 pg/ml) vs 256.0 pg/ml (219.0 – 332.0 pg/ml); $p < 0.001$]. At 14, 30 days and 6 months after kidney transplantation, a significant decrease of plasma FGF21 was observed [1013.0 pg / ml (744.4 - 1635.7 pg / ml); 322.5 pg/ml (199.0 - 546.8 pg/ml); 367.5 pg/ml (289.3 - 483.5 pg/ml); 363.5 pg/ml (293.5 - 508.2 pg/ml) ($p < 0.001$), respectively]. In patients long-term after kidney transplantation, a negative correlation was found between plasma FGF 21 concentration and estimated glomerular filtration (eGFR) ($R = -0.165$, $p < 0.05$) and a positive correlations between plasma FGF21 concentration and HOMA ($R = 0.185$, $p < 0.02$), BMI ($R = 0.148$, $p < 0.05$) and serum triglycerides concentration ($R = 0.362$, $p < 0.001$).

Conclusions: 1. In patients after kidney transplantation a decrease of plasma FGF 21 concentration was found. 2. Plasma FGF21 concentration in patients long-term after kidney transplantation is related to the degree of impairment renal function and metabolic status.

Oxalate Nephropathy Due to Enteric Hyperoxaluria in the Renal Allograft: A Case Series

Christine Firth, Margaret Ryan, Mira T. Keddis. *The Mayo Clinic Arizona, Scottsdale, AZ.*

Background: Secondary hyperoxaluria due to enteric causes is an underrecognized cause of renal allograft injury and loss. We present a single center case series of oxalate nephropathy in kidney transplant (KTx) patients due to enteric hyperoxaluria (EH).

Methods: Cases of oxalate nephropathy based on pathological description from 2008 to 2018 were ascertained. Cases of primary hyperoxaluria were excluded. Clinical risk factors for EH, serum and urine oxalate levels around the time of the biopsy, treatment, and allograft outcomes were analyzed.

Results: Fifteen cases of oxalate nephropathy were identified. Median follow-up was 3.0 years (range 0.4 to 8.6 years). Median time from transplant to allograft biopsy showing oxalate nephropathy was 104 days (range 14 days to 8.6 years). The most common pre-Tx risk factors for EH included short bowel syndrome (27%) and gastric bypass (13%). Post-Tx risk factors included chronic diarrhea (33%) and frequent antibiotic use (27%) with presumed altered gut flora. Median serum oxalate was 13.4 umol/L (range 2.7 to 37.5 [normal 0.4 to 3]) and median 24-hour urine oxalate was 97.7 mg/24 hours (range 40.5 to 121.2 [normal 9.7 to 40.5]). The predominant treatment was a low oxalate diet, increased oral fluids (93%), coupled by dietician counseling (87%) and calcium supplementation (93%). At last follow-up, 6 patients had GFR<45ml/min, 4 had GFR<30ml/min and 4 were on dialysis. [Table1]

Conclusions: Enteric causes of hyperoxaluria in KTx patients can be attributed to pre and post-transplant risk factors. Oxalate nephropathy due to EH in KTx patients is an important cause of allograft failure and warrants a standardized approach for early detection and treatment approach tailored for patients' unique risk factors.

Table 1: Summary of identified renal transplant oxalate nephropathy cases.

Case	Risk Factors	Management	HD at Time of Biopsy	GFR at Last Follow-up
1	Crohn's disease, short bowel syndrome	IVF, low oxalate diet, calcium, pyridoxine	No	27
2	Chronic diarrhea, diabetic gastroenteropathy, vitamin C, frequent antibiotic use for recurrent UTI	Hydration, low oxalate diet, calcium	No	24
3	High oxalate diet, frequent antibiotic use for recurrent UTI	Hydration, low oxalate diet, calcium, potassium citrate	Yes, DGF	36
4	Gastric bypass, diabetes, chronic diarrhea	Hydration, low oxalate diet, calcium	No	47
5	Short bowel syndrome	Hydration, low oxalate diet, calcium	No	17
6	Frequent antibiotic use, diabetes	None	Yes, DGF	32
7	Chronic diarrhea, diabetic enteropathy	Hydration, low oxalate diet, calcium, GI consult, cholestyramine	No	HD
8	Short bowel syndrome	Hydration, low oxalate diet, calcium, potassium citrate, GI consult	No	25
9	Cholestasis, diabetes	Hydration, low oxalate diet, calcium	Yes, DGF	38
10	Chronic diarrhea, diabetes	IVF, low oxalate diet, calcium, probiotic, GI consult	No	32
11	Chronic diarrhea, diabetes	Low oxalate diet, calcium	No	HD
12	Chronic pancreatitis, diabetes	Hydration, low oxalate diet, calcium, potassium citrate, pyridoxine, pancreatic enzymes	No	32
13	Bowel resections, gastric bypass, diabetes	Intensified HD, low oxalate diet, calcium	Yes, primary non-function	HD
14	Diabetes, frequent antibiotic use for recurrent UTI	Hydration, low oxalate diet, sodium citrate	No	HD
15	Gastric bypass, chronic diarrhea	Hydration, low oxalate diet, calcium, potassium citrate, probiotic, changed MM to azathioprine	No	35

Delayed graft function (DGF); Gastroenterology (GI); hemodialysis (HD); intravenous fluids (IVF); mycophenolate mofetil (MM); urinary tract infection (UTI)

FR-PO897

Glomerular Neovascularization in Renal Allograft: Clinical and Pathological Significance

Anri Sawada,[1,2] Masayoshi Okumi,[3] Kohei Unagami,[3] Shohei Fuchinoue,[3] Sekiko Taneda,[4] Hideki Ishida,[6] Motoshi Hattori,[3] Kazunari Tanabe,[3] Akira Shimizu,[2] Junki Koike,[5] Yoji Nagashima,[7] Kosaku Nitta.[3] *[1]Tokyo women's medical university, Tokyo----, Japan; [2]Nippion Medical School, Tokyo, Japan; [3]Tokyo Women's Medical University, Shinjuku-ku, Japan; [4]Tokyo womens' medical university, Tokyo, Japan; [5]St.Marianna University, Kawasaki, Japan; [6]Tokyo Women's Medical University, Tokyo, Japan; [7]TTokyo Women's Medical University, Tokyo, Japan.*

Background: An extra efferent arteriole is often observed in the glomerular vascular pole. This morphological change is referred to as polar vasculosis (PV). PV has been associated with glomerular hypertrophy and is considered as a sign for detecting early recurrent diabetic nephropathy after renal allograft. We have often noted PV even in cases without diabetic nephropathy after renal allograft; however, its significance remains uncertain. In the present study, we examined the clinical and pathological significance of PV in renal allograft.

Methods: This study included 9,004 renal biopsy specimens obtained from January 2007 to December 2017 at the Tokyo Women's Medical University.

Results: PV was identified in 186 biopsies obtained from 165 patients. We excluded 44 biopsies from 36 patients because of transmitted PV, which was detected in pre-transplantation biopsy. We identified 142 biopsies from 129 patients as the PV group. In addition, we identified 130 control renal allograft recipients who were matched according to their age and post-transplantation period. We obtained the clinical information of 48 and 116 patients in the PV and control groups, respectively. In the PV group, the mean age was 49.0 ± 14.0 years, and the mean post-transplantation period was 1850.1 ± 2235.7 days. In the pathological findings, a significant correlation was observed among glomerulomegaly, focal segmental glomerulosclerosis lesion, mm score, ah score, and aah score in Banff score ($P < 0.05$). The clinical findings revealed a significant correlation between the tacrolimus trough level at two weeks post-transplantation and the systolic blood pressure ($P < 0.05$).

Conclusions: This findings of this study indicated that polar vasculosis is associated with calcineurin inhibitor toxicity along with glomerular hypertrophy.

FR-PO898

Validation of a Cellular Assay for Detection of Over-Immunosuppression in Kidney Recipients: An Interim Report

François Bouchard-Boivin, Olivier Desy, Stephanie Beland, Sacha A. De Serres. *CHU de Québec - Laval University, Quebec, QC, Canada.*

Background: The transplantation community lacks a clinical tool to diagnose over-immunosuppression, resulting in major clinical side effects. Recently, our laboratory has unveiled an association between the cytokine secretion of intermediate CD14+CD16+ monocytes stimulated *in vitro* with Epstein-Barr Virus (EBV) peptides and the status of over-immunosuppression in a prospective, longitudinal cohort of kidney recipients. We are now validating the test in a large cross-sectional cohort.

Methods: We recruited 120 unsensitized kidney recipients, isolated their peripheral blood mononuclear cells at 2 timepoints (3mo interval) and stimulated the cells with EBV peptides overnight. Staining for viability, CD14 and CD16 and tumor necrosis factor (TNF-α) was performed to quantify cytokine secretion of intermediate monocytes by flow cytometry.

Results: We report interim results of the first 24 patients. Mean±SD age was 56±13 years and mean glomerular filtration rate was 46±15 mL/min/1.73m². Median time (25-75th percentiles) post-transplant was 2 (1 – 8) years. Patients were treated with prednisone, mycophenolate and tacrolimus. Eleven patients received induction therapy. There were 15 controls and 9 cases, including 7 opportunistic infections, 1 recurring bacterial infections and 1 *de novo* neoplasia, events which happened on mean of 1.4±2.0 months after blood was withdrawn for the assay. Mean TNF-α-positive cells on the first sample was 70±20% for the controls and 53±15% for the cases. All but one patient who scored below the previously established threshold (<73% TNF-α) were confirmed on the second sample. AUC of the ROC curve was 0.83±0.09 ($p<0.01$). Preliminary values of sensibility, specificity, positive and negative predictive values were 89% (8/9), 60% (9/15), 57% (8/14) and 90% (9/10) respectively.

Conclusions: These interim results seem to confirm that over-immunosuppressed patients have lower intermediate monocyte response to EBV peptides. Furthermore, they show high sensibility and negative predictive value, similar to the derivation cohort. This assay could allow ruling out over-immunosuppressive state in the clinical setting.

FR-PO899

Mammalian Target of Rapamycin (mTOR) Inhibitor Might Augment Klotho Levels of Kidney Transplant Recipients

Yukiko Hasuike,[1] Kosuke Mizusaki,[1] Tomoko Kimura,[1] Yasuyuki Nagasawa,[1] Takahiro Kuragano,[1] Yusuke Yamada,[2] Michio Nojima,[2] Shingo Yamamoto,[2] Masaharu Ishihara.[1] *[1]Div Kidney and Dialysis, Dep Internal Medicine, Hyogo College of Medicine, Nishinomiya City, Japan; [2]Dep. Urology, Hyogo College of Medicine, Nishinomiya, Japan.*

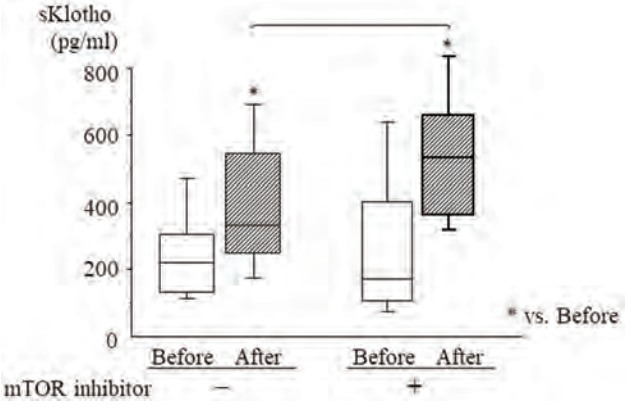
Background: α-Klotho, an anti-aging kidney-secreted hormone, exists in several forms including the membrane and a soluble form (sKlotho). sKlotho level of chronic kidney disease (CKD) patients is reduced. sKlotho administration attenuated renal fibrosis and dysfunction. It was reported that mTOR inhibitor reduce interstitial fibrosis and glomerular sclerosis of kidney transplantation (TPL) recipients, however, the mechanism is unclear. We investigated the influence of mTOR inhibitor on sKlotho of CKD patients before and after TPL.

Methods: This was a retrospective, observational study of kidney TPL recipients who were treated in Kidney Transplant Center of Hyogo College of Medicine (from 2001 July to 2016 October). Blood samples were collected before and 1-year after TPL and stored until assay. Serum sKlotho and fibroblast growth factor (FGF)-23 concentrations were measured using human ELISA, respectively. Several factors related to CKD (Ca, iP, intact parathyroid hormone, and $1,25(OH)_2$vitamin D) were examined.

Results: The CKD patients (n=36) were participated. Median age and vintage of participants was 37.0 (IQR, 27.5-50.5) y.o. and 4.6 (1.0-8.8) years. In this study, 75.0% (n=27) of kidney TPL were living donor, 8.3% (n=3) were received preemptive TPL, and 36.1% (n=13) were administrated mTOR inhibitor (everolimus). Comparing before and after TPL, sKlotho level was significantly increased ($p<0.001$) and FGF23 level was decreased ($p<0.001$). After TPL, sKlotho level of participants with mTOR inhibitor was significantly higher than that without mTOR inhibitor, 537 (367-659) pg/ml vs 332.4 (250-550) pg/ml ($p=0.026$, Figure 1). There was no significant difference of the other parameters between before and after TPL.

Conclusions: Administration of mTOR inhibitor might augment Klotho level of CKD patients after TPL.

Figure 1.



FR-PO900

Clinicopathologic Characteristics of Kidney Allografts with Donor-Derived Diabetic Nephropathy

Kuang-Yu Jen,[1] Hannah Lee,[2] Ling-Xin Chen,[1] Guofeng Gao,[1] Junichiro Sageshima.[1] *[1]University of California, Davis, Sacramento, CA; [2]UCSF, Cupertino, CA.*

Background: The general consensus is that donor kidneys with biopsy proven diabetic nephropathy (DN) should be discarded, although data regarding outcomes of these cases is lacking. In this study, the clincopathologic characteristics of allografts with moderate to advanced donor-derived DN was examined.

Methods: Retrospective analysis (between 06/2011 to 01/2017) of all kidney transplant recipients with biopsy proven class II or III DN within the first six months post-transplantation was performed. For each patient, all biopsies were reviewed to assess progression/regression in disease. Glomerular changes were classified based on Tervaert

pathologic classification. Associated clinical data were extracted from electronic medical records, including donor information.

Results: Fifteen recipients received donor kidneys with DN from 11 donors. All but one donor had confirmed history of long-standing diabetes, while 47% of recipients had history of diabetes. Nine grafts had class III, two had class IIb, and four had class IIa donor-derived DN. Mean clinical follow up time was 13.2 months (range 3-30 months). Four grafts (27%) failed within the first year, three of which were due to primary non-function and one showed slow graft function without need for dialysis but had subsequent rapid deterioration within 9 months. Two failed grafts had class IIb and two had class III DN, while none of the class IIa grafts failed. Two of the failed grafts had contralateral sister kidneys that demonstrated good renal function. Of the functional grafts, four (36%) experienced delayed graft function. Average creatinine at latest follow up for functional grafts was 1.4 mg/dL, and none experienced rejection episodes. No significant histologic progression/regression in DN class was observed, and no histologic findings on initial biopsy were significant for predicting graft failure.

Conclusions: Despite the high incidence of failed grafts, 73% of recipients in this cohort experienced successful transplantation using kidneys with moderate to advanced donor-derived DN. Although no histologic findings were statistically significant for predicting graft failure, the grafts that failed showed either class IIb or III DN and not class IIa DN, suggesting that kidenys with class IIa DN may be safe to use.

FR-PO901

Plasma Cell Infiltrate in Allograft Rejection in Kidney Transplant Recipients

Shuo-ming Ou,[1] Der-Cherng Tarng.[2] *[1]Division of Nephrology, Taipei Veteren General Hospital, Taipei, Taiwan; [2]Taipei Veteran's General Hospital, Taipei, Taiwan.*

Background: Allograft rejection has always been the chief obstacle to renal outcomes in kidney transplant recipients. We aimed to evaluate the different kidney allograft rejection phenotypes between acute cellular rejection with and without plasma cell infiltrate.

Methods: We conducted a hospital-based study including 1237 kidney transplant recipients between Jan 1, 2002 to Dec 31, 2017 in a tertiary medical center. Of them, we assessed patients who received renal biopsy and biopsy samples showed allograft rejection, which was defined by the renal function deterioration and histopathological lesions. The primary outcome of interest included kidney allograft loss and reinitiation of dialysis, graft histology, the severity of microvascular invasion and tubulitis.

Results: In our study, 1237 patients were included in the main analyses, of whom 293 (23.7%) had acute biopsy-proven rejection. We evaluated distinct patterns of kidney allograft rejection: T cell rejection and antibody mediated rejection with and without plasma infiltrates. Risk of failure to achieve graft function returning to to baseline after 6 month rescue therapy was highest in rejection with plasma cell infiltrate (hazard ratio [HR], 2.00; 95% confidence interval [CI], 1.142–3.307; $P = 0.0105$), followed by antibody rejection without plasma cell infiltrates (HR 1.25), compared with T cell mediated rejection without plasma cell infiltrate.

Conclusions: In our study, we found that allograft rejection with plasma cell infiltrates were associated with poor renal outcomes compared to those without plasma cell infiltrates. Therefore, nephrologists and renal pathologists need to be aware of this entity and arrange more aggressive management to salvage kidney allografts.

FR-PO902

Safety and Efficacy of Management of Refractory Cytomegalovirus Infection in Kidney Transplant Recipients Treated with Foscarnet and Conversion from Antimetabolite to mTOR Inhibitor

Renato D. Foresto,[1,2] Maria A. Hazin,[3] Alejandro Zapata,[3] Daniel wagner C. Santos.[4] *[1]Federal University of São Paulo, São Paulo, Brazil; [2]Tranplantation, Hospital do Rim, São Paulo, Brazil; [3]UNIFESP, São Paulo, Brazil; [4]Federal University of Sao Paulo, Sao Paulo, Brazil.*

Background: Cytomegalovirus (CMV) infection is a frequent complication after kidney transplantation and it is associated with graft dysfunction and increased mortality. Foscarnet may be an alternative to ganciclovir-resistant or CMV refractory infections. As additional therapies, there are limited published studies assessing the conversion from antimetabolite (mycophenolate or azathioprine) to mTOR inhibitor (mTORi) to avoid recurrence.

Methods: We retrospectively evaluated the adverse events and outcomes of the treatment of refractory CMV with foscarnet from January 1, 2010 to April 30, 2018 and we analyze the outcomes of the group of patients who were submitted to conversion from antimetabolite to mTORi.

Results: We evaluated 28 patients with refractory CMV treated with foscarnet; 89.3% received thymoglobulin as induction therapy and, as a maintenance therapy, 46.4% started with azathioprine and 53.6% with mycophenolate. The first episode of CMV occurred, on average, 40 days after transplantation. The average duration of therapy with ganciclovir was 98 days and 34.9 days with foscarnet. The UL97 mutation was present in all cases and the UL54 mutation was in 28.7%. After treatment with foscarnet, 17.8% had CMV recurrence. During treatment, 92.8% had antimetabolite discontinued, 64.3% were converted to mTORi. There were 19 recurring cases of CMV, 7 of them (36.8%) after conversion to mTORi against 12 cases (63.2%) in patients that not received mTORi. About the adverse effects to foscarnet, hypomagnesemia is the most common (82.1%), followed by hypophosphatemia (57.1%) and leucopenia (46.4%). There were 4 graft rejections and 3 deaths.

Conclusions: Prolonged use of ganciclovir with doses not adjusted for renal function as well as the immunological status of the transplanted patient are considered the main risk factors for resistance to ganciclovir therapy. Foscarnet seems to be an effective alternative in the control of viremia and treatment of CMV invasive disease. However, adverse events should be monitored cautiously, avoiding unfavorable outcomes for the graft. Preliminary data show that the conversion from antimetabolite to mTOR inhibitor is effective to avoid recurrence of CMV episodes.

FR-PO903

The Rate of Cytomegalovirus Infection and Disease in Renal Transplant Patients

Mark allen T. Bibera, Muna Alnimri, Diana Hao, Kathie Le, Elizabeth Zhu, Andrea Rieland, Denise M. Roach, Jennifer Brown. *UC Davis Medical Center, Sacramento, CA.*

Background: Cytomegalovirus (CMV) is a common opportunistic pathogen in renal transplant recipients (RTR) and is known to cause significant morbidity and mortality. To prevent CMV infection and disease, this single center academic institution utilizes both valganciclovir prophylaxis and continued monitoring through the outpatient transplant refill and mailing program (RAMP). The purpose of this study is to determine the incidence of CMV infection and disease in RTR who received valganciclovir and were enrolled in RAMP.

Methods: This is a retrospective, single center, cohort study of adult RTR between 2014-2016. Patients were eligible if enrolled in RAMP, >18 years old, and able to take oral valganciclovir. The primary endpoint was the incidence of CMV infection or disease in the first year post-transplant. The secondary endpoint was the dose of valganciclovir at various time intervals post-transplant for a subgroup of 100 patients (including all patients with infection and disease).

Results: A total of 418 RTR of CMV high risk (Donor+/Recipient-) and intermediate risk (D+/R+, D-/R+) were included. Most were male (59%) and of Hispanic (38%) or Caucasian (26%) descent. Their mean age was 51 years old (range 18 to 81). Of the 418 patients, CMV infection occurred in 15 (3.6%) and disease occurred in 2 (0.48%), with the majority of these cases occurring in the D+/R- group (11/17). For the subgroup of 100 patients evaluated for valganciclovir dosing, 50% of patients were dosed higher and 20% were dosed lower than recommended at hospital discharge. At weeks 4, 8, and 12 post-transplant 54-58% received lower and 12-20% received higher dosing than recommended.

Conclusions: The incidence of CMV infection and disease was lower than what is reported in the literature, with the highest prevalence in the D+/R- group. A combination of outpatient monitoring through RAMP and aggressive upfront dosing, followed by subsequent dose reductions in the outpatient setting likely contributed to the low rate of CMV infection and disease.

FR-PO904

Clinical Significance of Using the Banff 2017 Polyomavirus Nephropathy Classification in Kidney Transplantation: A Single Center Experience

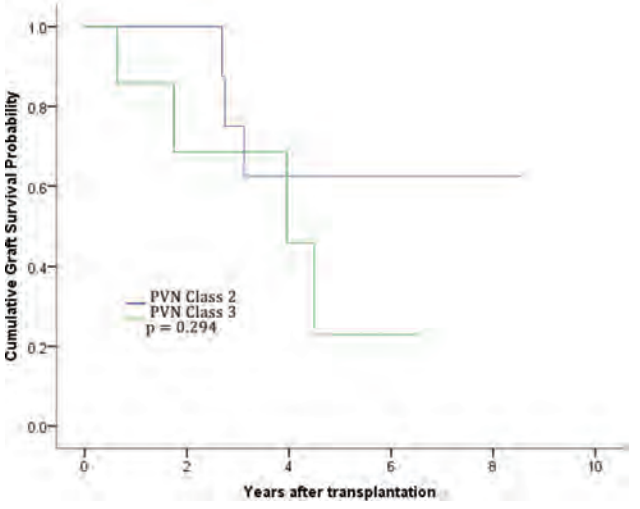
Amita Maibam,[1] Virgilius Cornea,[1] Ana L. Castellanos,[1] Amr E. Mohamed,[1] Waleed Hassan,[1] Xiaonan Mei,[1] Maria Yaseen,[1] Roberto Gedaly,[1] Thomas H. Waid.[2] *[1]University of Kentucky, Lexington, KY; [2]University of Kentucky Medical Center, Lexington, KY.*

Background: BK virus is a known cause of BK polyomavirus nephropathy (PVN) and renal allograft failure. The 2017 Banff PVN classification is based on intrarenal polyoma viral load and Banff interstitial fibrosis score. The aim of this study is to examine the clinical significance of using PVN classes and its correlation with allograft survival.

Methods: This is a single-center retrospective analysis of all patients with BK viremia (BKV) > 10,000 copies/ml from 2009 to 2017 who underwent for-cause renal allograft biopsy. Patients were histologically classified into Banff Class 1, 2 or 3. Kidney function was compared between groups. A Kaplan-Meier analysis was performed to compare renal allograft survival differences among the groups using log rank test.

Results: BKV was identified in 122 patients (88 male and 34 female). Renal allograft biopsy was performed in 61 patients (50%). Seventeen patients (27.9%) had only PVN, and another 17 patients (27.9%) had only acute cellular rejection (ACR), whereas concomitant PVN and ACR were found in 4 patients (6.6%). The remaining 23 patients (37.7%) had neither PVN nor ACR. There was no statistically significant difference in clinical, demographic and laboratory parameters between the PVN groups. Out of 17 patients with PVN, one patient had class 1 (5.8%), 9 had class 2 (52.9%) and 7 had class 3 (41.2%). The single patient with class 1 PVN was excluded from the analysis. There was a trend toward better graft survival in PVN class 2 compared to class 3 (figure 1), but it failed to reach statistical significance.

Conclusions: Allograft survival was not statistically different between PVN class 2 and 3 although a non-significant trend towards worse graft survival was seen in PVN class 3.



Survival Curves

FR-PO905

BKV Clearance Time Correlates with the Exhaustion State and T-Cell Receptor Repertoire Shape of BKV-Specific T-Cells in Renal Transplant Patients with Severe BKV Infection

Ulrik Stervbo,[1] Mikalai Nienen,[1] Petra Reinke,[2] Timm H. Westhoff,[1] Nina Babel.[1] *[1]University Hospital Marien Hospital Herne, Herne, Germany; [2]Charité, Campus Virchow Klinikum, Berlin, Germany.*

Background: Reactivation of the BK polyomavirus is known to lead to severe complications in kidney transplant patients. The current treatment strategy relies on decreasing the immunosuppression to allow the immune system to clear the virus. Recently we demonstrated a clear association between the resolution of BKV reactivation and reconstitution of BKV-specific CD4+ T-cells. However, the factors determining the duration of the clearance of the viral infection remain unknown.

Methods: Here we apply a combination of in-depth multiparametric flow cytometry and CDR3 beta chain receptor repertoire analysis of BKV specific T-cells to a cohort of 5 kidney transplant patients with BKV reactivation. In this manner we were able to track the TCR repertoires at single clone levels during the clinical course of BKV infection.

Results: The number of BKV-specific T-cells in peripheral blood did not affect the duration of BKV infection. In contrast, the diversity of the T-cell receptor repertoire as well as exhaustion status of BKV-specific T-cells correlated with the duration of viral clearance. This duration was further found to be independent of hyperexpanded, immunodominant BKV-specific T-cell clones and of the overall magnitude of cellular immunity. Rather, the diversity of BKV-specific TCR repertoire in peripheral blood: high diversity of the repertoire and lack of PD1 and TIM-3 exhaustion markers on BKV-specific T-cells is associated with short remission time.

Conclusions: Our data demonstrate that the quality (exhaustion status and shape of the repertoire) rather than quantity of BKV-specific T-cells determines the remission time after BKV reactivation.

BK Virus Seroprevalence in Donors and Kidney Transplant Recipients and Their Correlation with Development of BK Virus Infection in the Post-Transplant Period

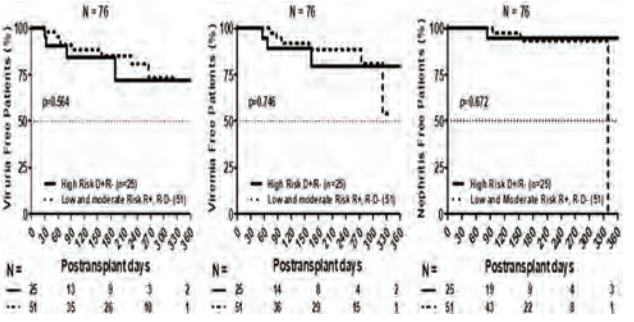
Andrea Portilla,[1] Idalia Parra,[6] Rodrigo Rosado canto,[1] José roberto Marino sanchez,[4] Cristinoc Cruz,[5] Abraham Cohen-Bucay,[2] Norma O. Uribe-uribe,[3] Josefina Alberú,[5] Luis E. Morales-Buenrostro.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de México, Mexico; [2]Boston University Medical Center, Boston, MA; [3]Instituto Nacional de Ciencias Medicas y Nutricion, "Salvador Zubiran", Mexico City, Mexico; [4]Instituto Nacional de ciencias médicas Salvador Zubirán, Ciudad de mexico, Mexico; [5]INCMNSZ, Mexico, Mexico; [6]Instituto Mexicano del Seguro Social, Guadalajara, Mexico.*

Background: BK virus (BKV) nephritis is a common cause of allograft dysfunction, which is related to the level of immunosuppression. Since no specific antiviral treatment is available, predictive markers that could help clinicians personalize the level of immunosuppression given to a specific patient are needed. Aims: to evaluate BKV seroprevalence in kidney donors and recipients as a predictive factor of BKV viruria, viremia and BKV nephritis in the post-transplant period.

Methods: BK-IgG ELISA qualitative test (MyBioSource Inc, San Diego, CA), was measured in 169 pts (81 donors and 88 recipients) before kidney transplantation. 76 recipients were followed post-transplant with BKV-PCR in blood and urine at 1, 3, 6, 9, and 12 months after transplantation. In addition, protocol biopsies at 3 and 12 months, and for-cause biopsies due to allograft dysfunction were performed.

Results: 58% of donors and 62.5% of recipients were seropositive prior to transplantation. Mean follow-up of transplant recipients was 198 days. They were divided into high risk (D+/R-, n=25) and moderate/low risk (D-/R+, D+/R+ and D-/R-, n=51). Viruria, viremia and BK nephritis developed in 16%, 12%, and 4% in the high risk, and 15.7%, 11.7%, 5.8% in the moderate/low risk group, respectively (p=0.9). Time to development of viruria, viremia, and BKV nephropathy was evaluated with the Kaplan-Meier in both groups and no statistically significance was observed [Figure 1].

Conclusions: BKV seroprevalence in Mexican population was 58.0% in donors and 62.5% in kidney transplant recipients. No correlation was observed between pretransplant serological status of donor and/or recipient and the post-transplant development of BKV viruria, viremia, and nephritis.



FR-PO907

Plasma Cell Neoplasms After Renal Allograft: A Single-Center Experience

Chitra Bhosekar, Tepsiri Chongkrairatanakul, Anita D'Souza, Bhavna Bhasin. *Medical College of Wisconsin, Menomonee Falls, WI.*

Background: Plasma cell disorders (PCD) are B-cell neoplasms that develop as a consequence of dysregulated B-cell clonal proliferation. The various types of PCD include monoclonal gammopathy of unknown significance (MGUS), multiple myeloma (MM) and monoclonal gammopathy of renal significance (MGRS). PCD and their complications can impact graft survival and other outcomes following kidney transplantation (KT). This underscores the need to investigate the natural history of PCD after KT.

Methods: Retrospective chart review was done at our institution in patients >18 years who had KT between 2008 and 2017 to identify those developing PCD after KT. Patients with a PCD before KT were excluded from the study.

Results: Of the 711 patients who received KT, 12 (1.68%) developed PCD. Three patients developed MM, 2 developed MGRS and 7 had MGUS in the post-transplant course. The study population was predominantly male (75%). Patients in the MM group were younger (mean age 54 years, range 47-67) than those in the MGUS (mean age 57, range 39-69) and MGRS groups (mean age 80 years, range 74-86) at the time of transplant. The mean time from transplant to PCD was 2.9, 3.2 and 4.6 years respectively in the MGRS, MGUS and MM groups. Mean follow up of survivors in the study was 5.9 years. Epstein Barr virus (EBV) positivity was noted in all 3 MM patients but in 50% of MGRS and 28% of MGUS groups. The mean creatinine at last follow up was higher (2 mg/dL) in MM subjects and was similar (1.7 mg/dL) in the MGRS and MGUS groups. Induction and maintenance immunosuppressive regimens used were similar in three groups. One MM patient died 3 years after diagnosis but all other patients were alive with a functioning graft at last follow up.

Conclusions: We found an incidence of new PCD after KT of 1.68% over a 10-year period after KT, which is similar to the incidence of post-transplant lymphoproliferative disorder (1.5%-2%). The risk of developing MM may be higher in patients who are transplanted at a younger age though the time from transplant to diagnosis may be longer than other types of PCD. EBV status at KT may influence development of MM post-transplant suggesting a role of immunosuppression. These findings merit further examination in a larger study.

FR-PO908

Mutational Signature of Urothelial Carcinoma After Kidney Transplantation as Revealed by Whole-Exome Sequencing (WES)

Lee-Moay Lim, Daw-yang Hwang, Hung-Tien Kuo. *Kaohsiung Medical University Hospital Division of Nephrology, Kaohsiung City, Taiwan.*

Background: Urothelial carcinoma (UC) has the characteristic of high degree molecular heterogeneity. In Taiwan, UC is the most common cancer after kidney transplantation(KT). Mutational profiles by WES could help in identifying not only UC-specific genes but also novel genes for disease specific therapeutic target and outcomes. We perform WES of UC developed after KT in an effort to discover the molecular genetics of UC.

Methods: Formalin-fixed paraffin-embedded archival samples of UC from 6 kidney transplant patients in our center were obtained. Patients with UC diagnosed before the transplant surgery were excluded. All patients were sporadic, without any family history of UC. For control group, we selected 5 hemodialysis patients with UC diagnosed after the commencement of dialysis treatment. DNA was extracted for WES analysis.

Results: Missense mutations were the most common type of somatic mutation (Figure 1a, 2). The A:T→T:A transition was the most significant nucleotide changes (Figure 1b).

Our WES data was matched with the Cosmic, Intogen, and TCGA database for onco-driver genes. We newly identified five genes, including *GNAQ, MLLT10, SEPT6, SLC34A2, NTRK3*, which comprised of 25% of mutations specifically in our patients (Figure 2).

Conclusions: The finding of A:T→T:A transition as the most significant nucleotide changes was different from TCGA cohort, as about 51% of their mutation resulted in TpC>T or G. Our results suggest that the genetic mutation in our cohort might be associated with aristolochic acid (AA) exposure, which is the one of the risk factor for renal failure and UC development. This preliminary data provides clues for understanding the mutational landscape of UC developed after KT.

Predictive Role of Histological and Immunological Parameters in ABMR in a Cohort of Renal Transplanted Patients

Anna Regalia,[1] Mariarosaria Campise,[1] Carlo M. Alfieri,[1] Donata Cresseri,[1] Gabriella Moroni,[1] Maria Teresa Gandolfo,[1] Valentina Binda,[1] Piergiorgio Messa.[1,2] *[1]Fondazione IRCCS Ca' Granda Ospedale Policlinico Milan, Milan, Italy; [2]Università degli Studi di Milano, Milan, Italy.*

Background: In clinical practice, the diagnosis of antibody-mediated rejection (ABMR) is based on three main components: specific histological lesions, presence of peritubular capillaries C4d and of circulating anti-HLA donor specific antibodies (cDSA). Our study aims to evaluate the concordance between histological and immunological diagnostic elements of ABMR and their predictive role on renal transplant (RTx) prognosis.

Methods: Among the 486 RTx patients transplanted from deceased donors in our Unit (2004-2015), 115 patients were submitted to renal biopsy (RBx) on clinical indications and evaluated for tissue C4d and cDSA (Luminex). Follow-up time was 3.7±2.7 yrs. According to histological lesions, RBx were categorized in: ABMR (hABMR), T-cell mediated rejection (hTCMR) or other lesions (hO). In addition, a categorization according to C4d positivity (C4d+/C4d-) and presence of cDSA at RBx (cDSA+/cDSA-) was made. In the relationship between histological and immunological elements, we considered 4 groups: cDSA-/C4d- (gr-A); cDSA-/C4d+ (gr-B); cDSA+/C4d- (gr-C); cDSA+/C4d+ (gr-D).

Results: Among the 115 RBx, 20%, 21% and 59% were respectively hABMR, hTCMR and hO. Compared to others, hABMR had higher PRA at RTx (p=0.03), higher Prot-U at RBx (p=0.01), more prevalence of C4d+ and cDSA+ (both p <0.0001) and shorter follow-up after RBx (p=0.03). In hABMR, 17.4% and 8.7% were in gr-A and gr-B, 30.4% and 43.5% in gr-C and gr-D (p<0.0001); in hTCMR, 95.8% and 0% were in gr-A and gr-B, 4.2% and 0% in gr-C and gr-D (p<0.0001); in hO, 80.9% and 2.9% were in gr-A and gr-B, 14.7% and 1.5% in gr-C and gr-D (p<0.0001); hABMR, C4d+ and DSA+ were singularly associated with graft loss, but among them h-ABMR was the only independent predictive factor for graft loss (HR 2.64 - p=0.01). Kaplan Meier analysis showed a worse graft outcome in hABMR compared to other histological diagnoses (p<0.001). h-ABMR had also higher graft loss discriminative power than C4d+ and cDSA+ (AUC 0.70, p<0.001). No discriminative informative advantages were found considering together h-ABMR and/or C4d+ and/or cDSA+.

Conclusions: Our data suggest that the histological evaluation of RTx is an unavoidable test for the diagnosis of graft dysfunction and represents the best prognostic parameter.

FR-PO910

Outcomes of Two Diarrhea-Causing Infections in Kidney Transplant Recipients

Stacey Rolak,[1] Sarah E. Di Bartolomeo,[1] Brad C. Astor,[3] Sandesh Parajuli.[2] *[1]University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]UW Health, Madison, WI; [3]University of Wisconsin, Madison, WI.*

Background: Diarrhea caused by infection from *Clostridium difficile* (*CD*) or Norovirus (NV) is a common complication in immunosuppressed kidney transplant recipients (KTRs). There is limited data comparing the outcomes of these infections in KTRs. Comparing the outcomes of these two prevalent infections may inform preventive and therapeutic strategies in patient management.

Methods: We examined KTRs transplanted at our center between 01/01/1994 to 12/31/2014 who suffered from *CD* or NV infection-related diarrhea. Those who suffered *CD* or NV infection were matched with controls randomly selected from surviving recipients without these infections to that point in time with a 5:1 ratio. Outcomes examined include number of *CD* or NV infections, interval from transplant to infection, and graft failure.

Results: Of 4941 kidney transplants performed during the study period, 294 developed primary *CD* and 64 developed NV. Mean interval from transplant to infection was 1401±1621 days for *CD* infection and 1355±1357 days for NV infection. Polycystic kidney disease, diabetes, and glomerulonephritis were more common in the *CD* group compared to NV (p<0.05). Median uncensored graft survival following infection was 456 days for *CD*, 541 days for NV, and 1276 days for controls. Cox proportional hazard regression demonstrated that those with *CD* had higher risk of graft failure than controls (HR 2.43, 95% CI 2.07 to 2.87, p<0.01). Graft failure in the *CD* group and NV group were higher than for the control group at different times (Table 1).

Conclusions: Both *CD* and NV infection are associated with deleterious effects on kidney graft survival. Prevention and early management of these infections may prolong graft survival.

Funding: Private Foundation Support

Table 1. Graft failure in CD, NV, and control study groups.

	Graft failure by 6 months of infection	*Graft failure by 12 months of infection*	*Graft failure by 36 months of infection*	*Graft failure by 5 years of infection*
CD	21%	30%	47%	60%
NV	5%	10%	30%	44%
Control	3%	6%	20%	32%

FR-PO911

Presence of Anti-HBs Confers Protection Against Hepatitis B Virus Infection in HBsAg-Negative and Anti-HBc-Positive Patients Undergoing Kidney Transplantation

Jae wan Jeon,[1] Kang Wook Lee,[1] Ki Ryang Na,[1] Youngrok Ham,[1] Dae Eun Choi,[2] Haeri Kim.[1] *[1]Chungnam National University Hospital, Daejeon, Republic of Korea; [2]Chungnam National University, Daejeon, Republic of Korea.*

Background: The American Gastroenterological Association (AGA) and European Association for the Study of the Liver (EASL) recommend that hepatitis B surface antigen (HBsAg)-negative and hepatitis B core antibody (anti-HBc)-positive patients who receive immunosuppression should be monitored for hepatitis B virus (HBV) infection regardless of hepatitis B surface antibody (anti-HBs) status. However, anti-HBs may provide protection against HBV infection. To investigate whether the presence of anti-HBs in addition to anti-HBc confers protection, we classified HBsAg-negative kidney transplantation (KT) patients into 4 groups according to anti-HBc and anti-HBs status, and compared the HBV infection rate between the anti-HBc(+)/anti-HBs(+) group and the other 3 groups.

Methods: In this single-center retrospective study, we classified 1,959 patients into 4 groups: anti-HBc(-)/anti-HBs(-) (n=356), anti-HBc(-)/antiHBs(+) (n=652), anti-HBc(+)/anti-HBs(-) (n=142), and anti-HBc(+)/anti-HBs(+) (n=809).

Results: HBV infection was noted in 31 patients (1.6%) after KT. There was a significant difference in HBV infection rate between anti-HBc(+)/anti-HBs(+) (1.2%) and anti-HBc(+)/anti-HBs(-) (5.6%) (p<0.001), but not between anti-HBc(+)/anti-HBs(+) and anti-HBc(-)/anti-HBs(-) (1.1%) or anti-HBc(-)/anti-HBs(+) (1.4%). There was a significant difference in HBV infection rate according to anti-HBs titer, but no difference according to the donor viral profile. Hepatic failure occurred in 1 anti-HBc(+)/anti-HBs(-) patient and 1 anti-HBc(+)/anti-HBs(+) patient, both of whom died. Hepatocellular carcinoma was noted in 4 anti-HBc(-) patients, but not in anti-HBc(+) patients.

Conclusions: The presence of anti-HBs confers protection against HBV infection. The EASL or AGA guidelines may be modified to indicate that monitoring should be performed for HBV infection after KT in HBsAg(-)/anti-HBc(+)/anti-HBs(-) patients, but not in HBsAg(-)/anti-HBc(+)/anti-HBs(+) patients.

FR-PO912

The Risk of Hepatitis B Virus Reactivation with Rituximab Desensitization in HBsAg-Positive Kidney Transplant Recipients

Yuri Seo,[1] Chung Hee Baek,[2] Su-Kil Park.[2] *[1]Asan medical center, Seoul, Republic of Korea; [2]Asan Medical Center, Songpa-gu, SEOUL, Republic of Korea.*

Background: Rituximab, as a powerful immunosuppressive agent, is used for ABO mismatched Kidney transplantation (KT) or flow cytometry positive patients. Because rituximab has elevated risk for hepatitis B virus (HBV) reactivation, antiviral prophylaxis is

recommended for positive hepatitis B surface antigen (HBsAg(+)) recipients. The purpose of this study was to evaluate whether treatment with an antiviral agent is enough for preventing HBV reactivation in HBsAg(+) patients who had KT with rituximab desensitization.

Methods: The 128 patients who underwent KT from 2009 to 2016 identified as HBsAg(+) before KT in a single center were retrospectively analyzed. They were divided into two groups according to whether rituximab was used or not (29 patients in Rituximab(+) group, 99 patients in Rituximab(-) group). HBV reactivation was diagnosed by an increase in HBV DNA more than 2 $\log_{10}$ international units/mL or a detectable HBV DNA level when previously undetectable HBV DNA. In addition, HBV reactivation was compared between 500 mg and 200 mg in rituximab(+) group.

Results: Reactivation of HBV DNA was detected in 4 among 29 (13.79%) HBsAg(+) patients in rituximab(+) group and 20 among 99 (20.20%) HBsAg(+) patients in rituximab(-) groups (P=0.592). The 4 patients with HBV reactivation in rituximab(+) group had already taken antiviral agents since KT (Table1). LFT elevation was detected in 2 of the 4 patients that HBV DNA was reactivated. The elevated LFT or reactivated HBV DNA was spontaneously resolved without change of antiviral agents. The Number of HBV DNA reactivation was not lowered according to changing rituximab dose from 500 mg (1/8, 12.50%) to 200 mg (3/21, 14.29%) in rituximab(+) group.

Conclusions: When HBsAg(+) patients received KT, the use of Rituximab may not increase HBV reactivation. It is suggested that the usage of antiviral agents is efficient prophylaxis for HBV reactivation of HBsAg(+) recipients who had KT with rituximab desensitization.

Table 1. Time of DNA reactivation after KT in the 4 patients with HBV reactivation in rituximab(+) group (by year)

	Antiviral agent	Time of DNA reactivation after KT				
		0-1 year	1-2 year	2-3 year	3-4 year	4-5 year
Patient 1	entecavir			v		
Patient 2	entecavir		v			
Patient 3	entecavir				v	
Patient 4	telbivudine				v

HIV-Infected Kidney Allograft Recipients Managed with Anti-Thymocyte Globulin Induction

Ayman Al Jurdi,[1] Esther C. Liu,[3] Meredith J. Aull,[4] Michelle L. Lubetzky,[2,1] David Serur,[5] Sandip Kapur,[4] Thangamani Muthukumar.[1] *[1]New York Presbyterian Hospital / Weill Cornell Medicine, New York, NY; [2]Division of Nephrology and Hypertension, New York, NY; [3]New York Presbyterian, New York, NY; [4]Weill Cornell Medical College, New York, NY; [5]The Rogosin Institute, New York, NY.*

Background: Reconsiderations of the risks involved in using immunosuppressive therapy in patients with HIV have resulted in a welcome foray into providing kidney allografts to HIV-infected patients. Anti-thymocyte globulin (ATG) induction reduces acute rejection but its use in HIV-infected kidney transplant recipients is limited. We assessed the long-term outcomes of HIV-infected kidney transplant recipients at our center managed with ATG induction.

Methods: Single center chart review of HIV-infected kidney allograft recipients between 2006 and 2016 who received induction immunosuppression with ATG. Maintenance immunosuppression included tacrolimus and mycophenolate with or without corticosteroids. Infection prophylaxis included clotrimazole, valganciclovir and co-trimoxazole. Primary outcome measures were patient and graft survival. Patients who did not meet their primary outcomes were censored at their last follow up.

Results: Twenty-nine HIV-infected patients (34% female, 66% black, 83% early corticosteroid withdrawal) underwent deceased (n=24) or living donor (n=5) kidney transplantation. Median (IQR) age was 54 years (50-59). CD4+ T-lymphocyte count was 455 (392-508). Graft and patient survival were 96.6% and 96.6% at 12 months respectively (Fig. 1). At 12 months post-transplantation, acute rejection-free survival was 96.4% and infection-free survival was 55.2%. Sustained HIV viral suppression was observed in 69% of patients. Ten patients (34%) developed 11 malignancies during their follow up.

Conclusions: Induction immunosuppression with anti-thymocyte globulin is associated with excellent clinical outcomes in HIV-infected kidney allograft recipients.

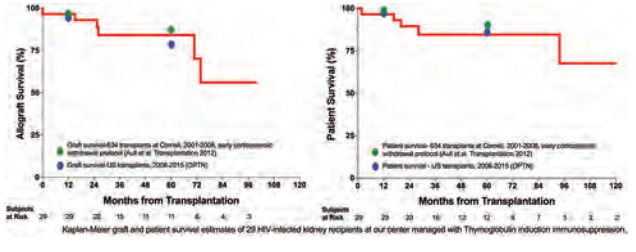

Figure 1. Kaplan-Meier graft (Left) and patient survival (Right) estimates of 29 HIV-infected kidney recipients at our center managed with Thymoglobulin induction immunosuppression.

FR-PO914

Clinical Experience of Prevalence and Prophylaxis for Latent Tuberculosis Infection in Living Donor Kidney Transplant Recipients

Tae Hyun Ban,[1] Byung ha Chung,[2] Bumsoon Choi,[4] Cheol Whee Park,[3] Yong-Soo Kim,[5] Chul Woo Yang.[2] *[1]Seoul St. Mary's hospital, Seoul, SEOUL, Republic of Korea; [2]Seoul St. Mary's Hospital, Seoul, Republic of Korea; [3]The Catholic University of Korea, Seoul, Republic of Korea; [4]Division of Nephrology, Department of Internal Medicine, Seoul, Republic of Korea; [5]The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.*

Background: Latent tuberculosis infection (LTBI) is a risk factor of active tuberculosis (TB) in kidney transplant recipients (KTRs). Transplant-associated TB poses a significant risk for both graft loss and patient death. Current guideline recommends LTBI prophylaxis in KTRs. The aim of this study was to assess the property of current LTBI prophylaxis.

Methods: We investigated 404 living donor KTRs between November 2013 and December 2017. We analyzed Data including QFT, TST, chest radiography, past TB history, post-transplant TB incidence, and current practice of LTBI prophylaxis. LTBI was diagnosed to one of following criteria: (1) positive result in tuberculin skin test (TST) or interferon-gamma release assays (IGRA) by QuantiFERON-TB Gold In-Tube test (QFT); (2) the old healed TB sequelae in chest radiography without TB treatment history; (3) previously insufficient TB treatment history; (4) contact history with active pulmonary TB patient within a year. Initial prophylactic agent for LTBI was isoniazid 300mg per day.

Results: The mean follow-up period of the patients 25.6 ± 14.2 months. QFT was positive in 37.6% (n=152), while TST was only positive in 13.1% (n=30). Additionally, only seven patients (1.7%) among patients with negative QFT were positive TST. On the other hand, there was no tuberculosis outbreak in living donor kidney transplant recipients during followed-up period. A total of 137 subjects were prescribed INH. Of them, 37 patients (27%) underwent adverse events, with the most common adverse event being hepatotoxicity, most occurring within three months.

Conclusions: Careful surveillance in KTRs needs at early period of INH prophylaxis. High incidence of adverse events of INH prophylaxis including hepatotoxicity suggests to need additional strategies to reduce that in LTBI prophylaxis.

FR-PO915

High Plasma Cadmium and Late Graft Failure in Renal Transplant Recipients

Joppe J. Vodegel,[1] Michele F. Eisenga,[1] Tim J. Knobbe,[1] Rosa G. Lammerts,[1] Martin H. De Borst,[3] Stefan P. Berger,[1] Ilja M. Nolte,[2] Daniel J. Touw,[3] Stephan J. Bakker.[1] *[1]Nephrology, University Medical Center Groningen, Groningen, Netherlands; [2]Epidemiology, University Medical Center Groningen, Groningen, Netherlands; [3]Clinical Pharmacy and Pharmacology, University Medical Center Groningen, Groningen, Netherlands.*

Background: Although short-term outcome after kidney transplantation has strongly improved, late graft failure remains a major distress for both patient and physician, and its etiology is poorly understood. This urges the identification of new treatable risk factors for late graft failure. In the general population, substantially increased plasma cadmium levels contribute to progressive renal function loss. Since renal transplant recipients (RTRs) only have one functioning kidney which is also exposed to noxious factors during transplantation, we assumed that RTRs are more susceptible to cadmium nephrotoxicity. Therefore, we hypothesized that higher plasma cadmium levels, even below the normal range, are associated with an increased risk of graft failure in RTRs.

Methods: The study was conducted in the TransplantLines Food and Nutrition Biobank cohort study. Plasma cadmium was measured using inductive coupled plasma mass spectrometry (ICP-MS). All RTRs (age>18 years) had a functioning graft for more than one year. Cox regression analyses were used to investigate prospective associations of cadmium with graft failure.

Results: We included 706 RTRs (age 53±13 years; 56.8% males at mean 5.4 (1.9-12.0) years after transplantation). Mean plasma cadmium levels were 0.70 ± 0.13 µg/L (normal range <5 µg/L) and eGFR was 45.0 ± 18.7 ml/min/1.73m^2 (normal range 90 – 120 ml/min/1.73m^2). During follow-up for 4.9 (3.3-5.5) years, 80 (11.3%) RTRs developed graft failure. In univariable analysis, increased plasma cadmium levels were associated with increased risk of graft failure (hazard ratio (HR) 2.49 [95%CI 1.73-3.58], P < 0.001). In multivariate analysis, after adjustment for age, sex, proteinuria, primary renal disease, time since transplantation, acute rejection, cold ischemia time, HLA mismatches, deceased donor status, BMI, systolic blood pressure, plasma glucose, diabetes, smoking, and alcohol use, the association of cadmium with graft failure remained (HR 2.23 [1.39-3.57], P = 0.001).

Conclusions: We conclude that cadmium levels are associated with an increased risk of graft failure in RTRs. Interventions aiming at reducing bodily cadmium concentrations, e.g. chelation therapy, seem warranted to improve long-term graft survival after renal transplantation.

FR-PO916

Evaluating the Functional Response of a Barrier-Free Glomerulus-on-a-Chip System to Injury: A Novel Tool for Renal Personalized Medicine

Julia Marcheque,[2] Paolo Cravedi,[4] Roger E. De Filippo,[3] Laura Perin,[3] Stefano Da Sacco.[1] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]Children's Hospital Los Angeles, Los Angeles, CA; [3]Childrens Hospital Los Angeles, Los Angeles, CA; [4]Mount Sinai, New York, NY.*

Background: With increasing rates of renal failure, there is an urgent need of implementing new strategies for understanding glomerular pathophysiology and for developing efficient patient-specific drug screening tools. To this regard, we recreated an in vitro 3D multicellular platform that allows fluid perfusion and proper interactions between podocytes and glomerular endothelial cells (hGEC). This glomerulus-on-a-chip system can be used to study the complex architecture and function of the glomerular filtration barrier (GFB).

Methods: Human amniotic fluid derived podocytes (hAKPC-P), human immortalized podocytes (iPod), primary human podocytes (pPod) and human fibroblasts (negative control) were seeded on microfluidic chips (Organoplates™) with hGEC. Immunofluorescence was performed for podocyte, endothelial and GBM markers. Barrier selective-permeability was investigated. Feasibility of the system for high throughput screening and disease modeling was evaluated by measuring permselectivity following Puromycin Aminonucleoside (PAN) injury or culture with serum from FSGS (focal segmental glomerular sclerosis) and membranous nephropathy (MN) patients.

Results: We have developed an innovative, barrier-free, glomerulus-on-a-chip system. hAKPC-P, iPOD and pPOD formed a slit diaphragm-like structure expressing nephrin and podocin. CD31-expressing hGEC formed capillary-like structures. De-novo deposition of GBM components such as collagen IValpha3,4,5 and laminin alpha5 was confirmed for hAKPC-P and pPOD but not iPOD. Albumin permselectivity was confirmed on chips with hAKPC-P, pPOD and less efficiently for iPOD while use of fibroblast lead to marked albumin leakage. Permselectivity was impaired following PAN administration as confirmed by our experiments. In the presence of MN serum (but not from healthy controls or FSGS) IgG-mediated injury to the barrier caused albumin leakage, suggesting an MN specific mediated damage.

Conclusions: We have successfully developed a glomerulus-on-a-chip system that closely mimics the GFB and provides a powerful tool for studying renal regenerative, disease mechanisms and toxicity effects. In conclusion, this system will increase our ability to individualize treatments and drug susceptibility, thus ultimately benefiting patients affected by renal failure.

FR-PO917

Dynamic Chromatin Accessibility at Poised Developmental Enhancers of Nephron Progenitors

Renfang Song, Melody C. Baddoo, Hongbing Liu, Zubaida R. Saifudeen, Samir S. El-Dahr. *Tulane University School of Medicine, New Orleans, LA.*

Background: Remodeling of chromatin accessibility at dynamic lineage-specific enhancers has emerged as a key mechanism in the control of cell fate in health and disease. Recent studies defining the gene regulatory network of nephron progenitor cells (NPC) have identified cis-acting modules bound to the master transcription factors (mTF) Six2, Osr1, and Wt1. However, it is unclear how these combinatorial factors gain access to chromatin to define enhancer function. In this study, we mapped the chromatin landscape of NPC to determine accessibility of developmental enhancers to mTFs during the NPC lifespan.

Methods: Self-renewing young (E13.5, E16.5), and differentiating old (P0 and P2) $Six2^{+}/GFP^{+}$ NPCs were subjected to genome-wide ATAC-seq to map open chromatin regions, i.e., accessible enhancers. Chromatin states (poised, active, repressed) of enhancers were determined by ChIP-seq of H3K4me1, H3K27ac, and H3K27me3, respectively. Enhancer access and chromatin states were integrated with genome-wide mTF binding (ChIP-seq) and gene expression (RNA-seq).

Results: We examined 80 poised NPC genes that bind the three mTFs and show >4-fold increase in mRNA expression during NPC lifespan. mTFs occupancy corresponded to K4me1-marked (poised) chromatin regions in young NPC and to K4me1/K27ac-marked active enhancers in old NPC. Surprisingly, activation of differentiation poised enhancers (and gene transcription) correlated with progressive reduction in the size of open chromatin regions and thus to accessible cis-acting elements. In comparison, NPC lacking the H3K27 methyltransferases, Ezh1 and Ezh2, displayed persistent open chromatin at poised enhancers.

Conclusions: Progressive restriction of access to dynamic developmental enhancers may act as a gateway to fine-tune the timing of differentiation gene expression and cessation of nephrogenesis. Targeted epigenome editing of developmental enhancers may be a useful strategy to manipulate NPC fate and lifespan.

Comprehensive Analysis of Chromatin Signature and Transcriptome Uncovers Functional lncRNAs Expressed in Nephron Progenitor Cells

Masaki Nishikawa,[1,2] Shunsuke Yuri,[3] Hiroshi Kimura,[4] Naomi Yanagawa,[1,2] Morgan Hamon,[1,2] Peter V. Hauser,[1,2] Lifu Zhao,[1,2] Oak D. Jo,[1,2] Norimoto Yanagawa.[1,2] Renal Regeneration Laboratory *[1]David Geffen School of Medicine, University of California, Los Angeles, CA; [2]Medical and Research Services, Greater Los Angeles Veterans Affairs Healthcare System at Sepulveda, North Hills, CA; [3]Nara Institute of Science & Technology, Nara, Japan; [4]Tokai University, Hiratsuka, Japan.*

Background: Emerging evidence from recent studies has unraveled the roles of long noncoding RNAs (lncRNAs) in the function of various tissues. However, little is known about the roles of lncRNAs in kidney development. In our present study, we aimed to identify functional lncRNAs in one of the three lineages of kidney progenitor cells, i.e., metanephric mesenchymal (MM) cells.

Methods: MM cells were purified by FACS from *Cited1*$^{nuc\text{-}TagRFP\text{-}T}$ mouse embryonic kidneys, and comprehensive analyses of the chromatin signature and transcriptome were conducted by RNA-seq and ChIP-seq.

Results: We found seventeen lncRNAs that were expressed specifically in MM cells with an active chromatin signature, while remaining silenced in a bivalent chromatin state in non-MM cells. Out of these MM specific lncRNAs, we identified a lncRNA, Gm29418, in a distal enhancer region of Six2, a key regulatory gene of MM cells. We further identified three transcript variants of Gm29418 by Rapid Amplification of cDNA Ends (RACE), and confirmed that the transcription-start-sites (TSSs) of these variants were consistent with the result of Cap Analysis Gene Expression (CAGE). In support of the enhancer-like function of Gm29418 on Six2 expression, we found that knock-down of Gm29418 by two independent anti-sense locked nucleic acid (LNA) phosphorothioate gapmers suppressed Six2 mRNA expression levels in MM cells. We also found that over-expression of Gm29418 led to an increase in Six2 mRNA expression levels in a mouse MM cell line.

Conclusions: In conclusion, we demonstrated in our present study that a comprehensive analysis of chromatin signature and transcriptome can be a powerful tool in screening lncRNAs in various tissues, which led us to identify a lncRNA, Gm29418, in renal progenitor cells that has an enhancer-like function on a key regulatory gene, Six2.

Netrin-1 Directs Neurovascular Patterning Required for Proper Kidney Development

Lori L. O'Brien,[1] Deanna M. Hardesty,[2] Shamus L. Cooper.[2] *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Proper kidney development requires the coordinated growth and differentiation of multiple cell types. Alterations to nephron number and function can have significant health consequences. While advances have been made in elucidating how nephron progenitors form, differentiate, and interact with the adjacent stroma and collecting duct system, almost nothing is known about how the neural and vascular systems influence these processes or even how they become established in the fetal kidney. This is a significant void in our understanding, given the critical importance of vascular perfusion and innervation for mature organ formation and function.

Methods: To this end, we have interrogated the function of netrin-1 in the developing kidney. Netrin-1 is an axon guidance cue which also regulates vessel pathfinding. Netrin-1 (*Ntn1*) is highly expressed by the stromal progenitors. We conditionally deleted *Ntn1* in these cells and examined the resulting phenotypes with light-sheet and confocal microscopy in addition to standard histological techniques.

Results: *Ntn1* loss results in abbarent neural and vascular networks. Normal patterning is disrupted, leading to localized networks which are in excess or deficient. Additionally, ectopic neurovascular tracts are found on the outside surface of the kidney which can infiltrate and severely disrupt local tissue morphology. Mutant kidneys are hypoplastic with an extension of nephron progenitor lifespan by ~2 days. Deletion of *Unc5c*, a known receptor for netrin-1 which is expressed by the nephron progenitors, does not result in any obvious developmental defects. Therefore, we predict the hypoplastic and progenitor phenotypes we observe are due to a disruption in signals that the nerves/vessels supply to nephron progenitors and the branching collecting duct system, rather than a direct action of netrin-1. Consistent with congenital renal defects having ongoing effects into adulthood, we find that mutant adult kidneys show focally dilated and vacuolated tubules indicative of tubular injury, as well as abnormal glomerular histology.

Conclusions: These studies have provided novel insights into the establishment of neurovascular networks in the developing kidney and the implications for adult function. Such findings will help inform efforts to engineer kidneys de novo, where establishing proper kidney filtration will be essential.

FR-PO920

Stromal Prorenin Receptor (PRR) Is Critical for Normal Kidney Development

Ihor V. Yosypiv,[1] Maria Luisa S. Sequeira Lopez,[2] Renfang Song.[3] *[1]Pediatrics, Tulane University, New Orleans, LA; [2]University of Virginia, Charlottesville, VA; [3]Tulane University, New Orleans, LA.*

Background: The transcription factor Foxd1, a specific marker of kidney stromal cells, is critical for normal kidney development. Global loss of the PRR, a receptor for renin and prorenin, is lethal in mice, indicating its essential role in embryonic development. Here, we investigated the role of the PRR in Foxd1+ stromal progenitors in mice.

Methods: *Foxd1-eGFP-Cre*$^{+}$ mice were crossed with *PRR*$^{flox/flox}$ mice. The resulting *Foxd1*$^{Cre+}$/*PRR*$^{flox/flox}$ mice represent deletion of the *PRR* in Foxd1+ stromal progenitors (*cKO*). Control mice consisted of *Foxd1*$^{Cre-}$/*PRR*$^{flox/flox}$ littermates (*Con*). Molecular marker analysis was performed by immunohistochemistry in kidneys on E17.5. Glomerular number was counted at P0 from 3 consecutive H&E-stained sections/kidney adjacent to the longitudinal midplane. Conscious systolic, diastolic and mean tail-cuff arterterial blood pressure (BP) was measured in heterozygous (*Foxd1*$^{PRR+/-}$) (*Het*, n=3) and *Con* (n=3) mice at 2 months of age using a Visitech BP2000 system (Visitech Systems, Apex, NC).

Results: *cKO* mice showed neonatal mortality. Although kidney weight did not differ in surviving *cKO* mice on P0, the number of glomeruli per kidney section was reduced in *cKO* compared with *Con* (39±3.7 vs. 68±2.3, p<0.001). Immunofluorescence showed reduced expression of stromal markers Foxd1 and Meis1, expansion of Six2+ nephron progenitors, reduced expression of Jag1, lack of WT1+ glomeruli in more differentiated nephrons, decrease in the expression of renin and of α-SMA in the developing interstitium in *cKO* kidneys. *cKO* mice had fewer and thinner intrarenal arteries and arterioles. Systolic, diastolic and mean BP did not differ in *Het* and *Con* mice (124±3.5 vs. 133±11, p=0.4; 69±3 vs. 68±5, p=0.9; 88±3 vs. 92±7, p=0.6).

Conclusions: We conclude that stromal PRR restricts excessive expansion of nephron progenitors, thereby promoting nephron differentiation. In addition, stromal PRR is crucial for the differentiation of renin-positive cells as well as smooth muscle and the proper formation of the renal arterial tree.

FR-PO921

DNMT1 in Six2 Progenitor Cells Is Essential for Transposable Element Silencing and Kidney Development

Jihwan Park,[1] Szu-Yuan Li,[2] Kiwung Chung,[1] Rojesh Shrestha,[1] Matthew Palmer,[1] Katalin Susztak.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]Taipei Veterans General Hospital, Taipei City, Taiwan.*

Background: In mammalians cytosine methylation (5mC) is erased in the embryo and reestablished during development and differentiation. De novo DNA methyltransferases such as Dnmt3a and 4b plays key role in establishing methylation, while Dnmt1, a hemimethylase copies methylation during cell division. Much attention has been placed on promoters and enhancer methylation as they play role in gene expression regulation.

Methods: We performed genome methylation analysis by reduced representation of bisulfate sequencing (RRBS) during kidney development. We examined the renal phenotype of mice with genetic deletion of Dnmts and Tets in the Six2+ population which can differentiate nephrons in mice.

Results: Differential methylation of enhancer regions was the most prominent when kidneys of newborn and adult mice were compared. Mice with conditional deletion of Dnmt3a, 3b, Tet1 and Tet2 showed no significant renal abnormalities. In contrast, Six2^{Cre}/Dnmt1$^{fl/fl}$ mice died within 24hrs of birth and had small kidneys. Surprisingly, the greatest methylation difference in Dnmt1 knock-out mice was observed on transposable elements (TE). RNA sequencing also detected the expression endogenous retroviruses indicating the release of silencing of TE. In addition, Dnmt1 KO kidneys expressed high levels of genes that exclusively expressed in early embryos. The re-expression of ERV was not tolerated by the cells and induced the expression of endogenous RNA sensing pathways and interferon response and ultimately resulting in cell death.

Conclusions: Our results showed that Dnmt1-mediated DNA methylation is essential for kidney development by preventing the demethylation of TEs and dedifferentiation of progenitor cells.

Modulation of Lef/Tcf Activity in Response to Differential β-Catenin Levels Underlies Nephron Progenitor Differentiation

Qiuyu Guo,[1] Albert D. Kim,[4] Trinh k (tracy) Tran,[4] Nils Lindstrom,[5] Aaron C. Brown,[2] Leif Oxburgh,[2] Andrew P. McMahon.[3] The McMahon Laboratory *[1]University of Southern California, Los Angeles, CA; [2]Maine Medical Center Research Institute, Scarborough, ME; [3]Keck School of Medicine of the University of Southern California, Los Angeles, CA; [4]University of Southern California, Los Angeles, CA; [5]The University of Southern California, Los Angeles, CA.*

Background: The Wnt9b ligand and β-catenin are required for both nephron progenitor cell (NPC) self-renewal and differentiation (Carrol et al., 2005; Park et al., 2007; Karner et al., 2011). Though high Wnt pathway activity stimulates NPC commitment, stabilized β-catenin binds to enhancers regulating both self-renewal and NPC differentiation targets, with opposing transcriptional outcomes (Park et al., 2012). How different levels of β-catenin result in distinct outcomes for NPCs remains to be determined.

Methods: To investigate the molecular mechanism behind Wnt/β-catenin-driven NPC self-renewal and differentiation, we modeled the two processes *in vitro* in NPEM culture medium (Brown et al., 2015) which enables NPC expansion when supplemented with low levels of CHIR99021 (CHIR), a β-catenin agonist, and NPC differentiation with elevated CHIR levels. Gene expression and epigenetic profiles were determined by bulk RNA-Seq and ATAC-Seq, followed up with immunohistochemistry on key targets-of-interest. To directly map genomic targets of Lef/Tcf factors and β-catenin, we performed ChIP-Seq on NPCs under expansion and differentiation conditions.

Results: RNA-Seq and immunohistochemistry data suggests differential expression levels of Lef/Tcf factors between NPC cultured in low and high levels of CHIR. In the high CHIR condition, the transcriptional repressor *Tcf7l1* is down-regulated, while the activators *Tcf7* and *Lef1* are up-regulated. ATAC-Seq analysis showed strong enrichment of Tcf/Lef footprint in open chromatin regions specific to high CHIR condition, suggesting a role of β-catenin in activating relevant enhancers. Direct ChIP-Seq for Lef/Tcf factors showed a rapid replacement of Tcf7l1/Tcf7l2 repressors by Tcf7/Lef1 activators at enhancers for differentiation target genes on stabilization of β-catenin.

Conclusions: We propose a model wherein Tcf7l1/Tcf7l2 repressors maintain NPC self-renewal state by silencing enhancers involved in differentiation and β-catenin stabilization triggers a switch promoting the engagement of Tcf7/Lef1 activators. This state is reinforced by a positive feedback loop where *Lef1* is a target of itself. Given the widespread role of Wnt signaling in stem/progenitor cell programs, these findings are likely to have broader significance beyond the mammalian kidney.

FR-PO923

SIX2+CITED1+ Human Nephron Progenitors: Novel Insights of Wilms Tumor Biology

Astgik Petrosyan,[2] Matthew E. Thornton,[1] Julia Marcheque,[2] Brendan Grubbs,[1] Stefano Da Sacco,[2] Laura Perin.[2] *[1]University of Southern California, Los Angeles, CA; [2]Children's Hospital Los Angeles, Los Angeles, CA.*

Background: Wilms tumor (WT) accounts for 95% of renal malignancies in children and is characterized by uncontrolled proliferation of nephron progenitors (NP) without generation of functional nephrons. Due to inability of isolating these human NP, little is known about WT formation and specifically the involvement of NP in tumor progression. Using our validated Smartflares technique we isolated NP expressing SIX2 and CITED1 (the master genes regulating nephrogenesis) from WT samples and from human fetal kidneys (hFK) and compared them in terms of gene expression by RNA-seq. We also performed in vivo and in vitro experiments to study regulation of self-renewal *vs* differentiation of NP.

Methods: WT (#3) and hFK (#3) samples were digested to single cell suspension, incubated with Smartflare-probe and SIX2+CITED1+ cells were immediately sorted and processed for RNA-seq. Using a nephrogenic specific media, we established conditions for long-term culture of NP cells and study in vitro mechanism of self-renewal *vs* differentiation of NP from both WT and hFK. We also transplanted NP in vivo to study tumorogenesis.

Results: We confirmed expression of SIX2+CITED1+ cells in WT samples within the blastema and ~ 9% of the total population was expressing these markers (while ~0.2% was present in hFK). WT-NP present a similar pattern of expression of developmental genes as hFK-NP but increased expression of EYA1, SALL4 and decreased expression of LEF1 and FOXD1 suggesting their self-renewal state. WT-NP showed, as expected, upregulation of pluripotency genes (OCT-4, NANOG) and modulation of cell cycle regulators indicating their shorter G1 phase (typical of pluripotent/cancer stem cells). WT-NP presented modulation of integrin signaling, which plays an important role in exit to differentiation during nephrogenesis. WT-NP and hFK-NP were cultured in vitro for more than 28d maintaining expression of SIX2 and CITED1. Modulation of integrin outside-in signaling reduced SIX2 and CITED1 long-term in vitro and reduced tumor growth in vivo.

Conclusions: This work represents the first characterization of SIX2+CITED1+ cells from WT and suggests the importance of matrix-cell interaction in development and tumor formation. These studies can help to increase our knowledge on human nephrogenesis and the development of new strategies aimed at halting tumor progression.

FR-PO924

TAZ Plays an Important Role in Maintenance of Podocyte Viability

Jianchun Chen,[1,2] Raymond C. Harris.[1,2] *[1]Nephrology/Medicine, Vanderbilt University Medical Center, Nashville, TN; [2]Nephrology, Department of Veterans Affairs, Nashville, TN.*

Background: TAZ (also known as WWTR1), a paralogue of YAP, is an important nuclear effector of the Hippo signaling pathway. TAZ shares 45% amino acid identity with YAP and they share some redundant roles in some organ development, but they also differ in some functions. TAZ is highly expressed in kidney, especially in renal proximal tubule cells. TAZ global knockout causes early mortality in a subset of homozygous mice, while bilateral kidney cysts and a pulmonary emphysema-like phenotype presented in the surviving adult mice. YAP is highly expressed in the nucleus of podocytes, and podocyte-specific deletion of YAP causes FSGS and progressive renal failure. The goal of these studies was to determine whether TAZ also plays a physiologic role in podocytes.

Methods: Mice with podocyte-TAZ deletion (TAZ^{podKO}) were generated by crossing TAZ$^{flox/flox}$ mice with podocin-Cre recombinase transgenic mice. Urinary albumin excretion and kidney histology and podocyte number per glomerulus were evaluated in TAZ^{podKO} and WT mice. Immunoblotting analysis of isolated glomerulus lysates of TAZ^{podKO} or TAZ^{podWT} mice were performed. In cultured mouse podocytes, cell morphology and cell lysates were evaluated after silencing TAZ with specific siRNAs.

Results: 41.7% of TAZ^{podKO} mice develop mild proteinuria at age of 3-4 weeks (n=36), with a urine albumin/creatinine ratio of 89.57 ± 12.67 vs 27.86 ± 1.55 (µg/mg, n=7). At 9 weeks of age, compared to TAZ^{podWT} mice, the glomeruli of TAZ^{podKO} mouse kidney had focal sclerosis and significant podocyte loss (WT1+ cells: 13.23 ± 0.699 vs. 17.85 ± 0.608 (n=13). There was increased YAP expression and nuclear localization in the TAZ^{podKO} mice compared with TAZ^{podWT} mice. Glomeruli of TAZ^{podKO} mice had increased cleaved-caspase 3 and decreased Bcl2 expression. In cultured podocytes, silencing TAZ by siRNA altered cell morphology and F-actin distribution, up-regulated of cleaved-caspase 3 and inhibited Bcl2 expression.

Conclusions: This study demonstrates that TAZ expression plays an important role in maintenance of podocytes, which cannot be compensated by its paralogue YAP.

FR-PO925

Clathrin-Dependent Nephrin Endocytosis Mediated by Y1139RSL Motif Is Essential for Glomerular Slit Diaphragm Formation

Eugenel B. Espiritu,[1] Matt G. Sampson,[4] Kunimasa Yan,[2] Neil A. Hukriede,[1] Agnieszka Swiatecka-Urban.[3] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Kyorin University School of Medicine, Mitaka, Japan; [3]Children's Hospital of Pittsburgh of UMPC, Pittsburgh, PA; [4]University of Michigan, Ann Arbor, MI.*

Background: Nephrin is critical to the glomerular slit diaphragm. The cytoplasmic tail of human nephrin contains a YxxØ-type motif Y^{1139}RSL & genetic variation of this motif in human cases supports its potential importance. A c.C3418T nucleotide change, resulting in p.R^{1140}C, has been implicated as causal for congenital nephrotic syndrome (CNS) in one of the first reported patients, & was found as a single allele in siblings with CNS.

Methods: We generated expression plasmids for human (hs) nephrin (hs-Nephrin-WT), hs-Nephrin-Y^{1139}F mimicking non-phosphorylated tyrosine, or hs-Nephrin-Y^{1139}A disrupting YxxØ endocytic motif. We transfected these into a human podocyte line, which were used for coimmuprecipitations (CoIP), clathrin-coated vesicle & endocytic assays. In zebrafish, we depleted endogenous nephrin by morpholino (dr-Nephrin-MO) injections & performed rescues with RNA derived from the aforementioned hs-Nephrin plasmids. We assayed for edema, a phenotype previously shown in nephrin morphants, & for glomerular organization imaged by single plane illumination microscopy & electron microscopy.

Results: In podocytes, Hs-Nephrin CoIP with clathrin & the adaptor complex AP-2; residue Y^{1139} was phosphorylated. The Y^{1139}F substitution increased clathrin-dependent nephrin endocytosis & reduced the steady-state abundance & stability of nephrin at the podocyte plasma membrane. By contrast, the Y^{1139}A substitution had the opposite effects. Zebrafish embryos depleted of nephrin exhibited pericardial & yolk edema, curvature of the body axis, & amorphous glomerular & podocyte foot process organization. Co-injecting the hs-Nephrin-Y^{1139}F transcript with dr-Nephrin-MO partially rescued the phenotype & improved defects in glomerular & foot process organization, similar or superior to hs-Nephrin-WT. By contrast, morphants injected with hs-Nephrin-Y^{1139}A failed to rescue, having phenotypes similar to dr-Nephrin-MO alone.

Conclusions: The Y^{1139}RSL motif is a structural element for clathrin-dependent nephrin endocytosis & functions as a phosphorylation-sensitive signal essential for the slit diaphragm formation. We propose that the Y^{1139}RSL-mediated endocytosis helps to maintain asymmetric distribution of nephrin in specialized membrane domains leading to podocyte differentiation & formation of the slit diaphragm.

FR-PO926

Role of the Circadian Clock in the Timing of Branching Morphogenesis and Kidney Development

Rosemary V. Sampogna,[1] Hanbin Dan,[2] Thomas L. Ruan.[3] *[1]Medicine, Columbia University, New York, NY; [2]Columbia University, New York, NY; [3]Columbia University Medical Center, New York, NY.*

Background: Kidney development is guided by a complex array of molecular signals that guide precise arrangement of ~1 million nephrons. Developmental errors such as renal hypodysplasia are a leading cause of pediatric kidney failure. Extremely rapid and stereotypic branching of the ureteric tree during early kidney development gives rise to a stochastic branching pattern but with a much slower, controlled and constant tip doubling rate during the second half of development (JASN 2015;26(10):2414). We also found that iron deficiency has a profound effect on nephron number and branching morphogenesis. Because core circadian clock transcription factors bind heme, we hypothesized that this timer plays a role in the timing of kidney development.

Methods: We studied the roles of circadian clock regulators Clock and Bmal1 during kidney development by quantitating branching parameters in global knockout and in conditional mutants. We also measured continuous circadian clock gene expression in developing kidneys using luminescence microscopy. Mice also were mated for a 1-hour time period at "lights on" and subsequently RNASeq was performed from embryonic days 18.0 to 20.0 (E18.0 to E20.0) at exact 4-hour intervals to measure gene expression patterns. Relevant genes were mapped to specific nephron structures and compared to adult kidneys.

Results: Luminescence studies confirmed the activity of an autonomous peripheral clock in the developing kidney. Oscillatory expression of core clock genes became measurable by E18.5. Quantification of branching parameters showed decreased nephron number in Bmal1-/- kidneys at E14.5 and at E19.5 (mean glomerular number [SD] 664±103 vs. 956±84, p> 0.05). Moreover, when pregnancies were timed strictly, RNASeq analysis identified 6,949 transcripts with significant rhythmicity between days E18.0 and E20.0 (p<0.05). Many genes were kidney-specific and known to regulate cell cycle and core developmental processes.

Conclusions: While known to regulate renal processes in the adult, we found that circadian regulators also provide a critical timing mechanism during kidney development by controlling gene expression. These regulators are required during a critical developmental window. Investigation of circadian-regulated pathways may uncover new targets that can be exploited to prevent disease or aid kidney development.

Genetic Regulation of Intermediate Mesoderm Specification

Elliot Perens,[1] Jasmine Hernandez,[2] Andrew Houk,[2] Kristina M. Garske,[3] Camilla Teng,[5] Gage Crump,[5] Deborah Yelon.[2] *[1]Pediatrics & Biological Sciences, University of California, San Diego, La Jolla, CA; [2]University of California, San Diego, La Jolla, CA; [3]University of California, Los Angeles, Los Angeles, CA; [5]University of Southern California, Los Angeles, CA.*

Background: The kidneys are derived from the intermediate mesoderm (IM), yet the pathways that determine the precise dimensions of the IM in the early embryo are poorly understood. We have found that the bHLH transcription factor Hand2 limits the size of the pronephron by refining IM dimensions. In *hand2* mutants, the IM is expanded, and the IM is diminished when *hand2* is overexpressed. The *hand2*-expressing portion of the posterior mesoderm lies laterally adjacent to the IM, and a set of venous precursors arises at the interface between these two territories. *hand2* promotes venous precursor development while suppressing IM formation in this region. Furthermore, Hand2 and the similarly localized zinc-finger transcription factor Osr1 have functionally antagonistic influences on both kidney and vein development.

Methods: Our studies of *hand2* and *osr1* provide valuable entry points for the identification of additional factors that regulate IM specification. How do *hand2* and *osr1* coordinate the development of the IM and venous progenitor populations? Do *hand2* and *osr1* impact the same genes as they execute these functions? To address these questions, we aim to identify additional genes in the *hand2* and *osr1* pathways.

Results: Preliminary analysis has revealed a potent role for bHLH transcription factor Twist1a in modulating IM and vessel precursor formation. Furthermore, to identify genes regulated by *hand2*, we have evaluated expression profiles from wild-type, *hand2* loss-of-function, and *hand2* gain-of-function embryos. Additionally, to increase the sensitivity of our investigation, we have compiled expression profiles from sorted *hand2*-expressing cells in wild-type and *hand2* loss-of-function embryos. We are currently analyzing our most intriguing candidate genes, including *twist1a*, through loss-of-function, gain-of-function, and genetic epistasis experiments to determine their roles in IM formation and their genetic interaction with *hand2* and *osr1*; updated findings will be presented.

Conclusions: Together, our studies will elucidate the roles of *hand2* and *osr1* in defining the boundaries of the IM by balancing formation of the kidney and vein lineages.

Transcription Factor 21 Is Required for Branching Morphogenesis and Regulates the GDNF-Axis in Kidney Development

Gal Finer,[2,4] Shintaro Ide,[1] Tomokazu Souma,[3] Tuncer Onay,[2] Jing Jin,[2] Minghao Ye,[2] Xiangmin Zhao,[2] Yoshiro Maezawa,[1] Susan E. Quaggin.[2] *[1]Chiba University Graduate School of Medicine, Chiba, Japan; [2]Northwestern University, Chicago, IL; [3]Duke University, Durham, NC; [4]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL.*

Background: The definitive mammalian kidney develops through reciprocal inductive signals between the metanephric mesenchyme (MM) and ureteric bud (UB). Transcription factor 21 (Tcf21) is highly expressed in cells of the MM including Six2+ condensing mesenchyme (CM) and Foxd1+ stromal mesenchyme (SM). *Tcf21* knockout (KO) mice die in the perinatal period with severe renal hypodysplasia. In humans, Tcf21 levels are reduced in renal tissue from stillborn infants with renal dysplasia. However, molecular mechanism(s) to explain these renal defects are not yet known.

Methods: We utilized systemic and conditional *Tcf21 k*nockout mouse models and employed immunohistochemistry, in-situ hybridization, RT qPCR and kidney explant studies.

Results: Tcf21 null kidneys show very abnormal UB branching and arrested mesenchymal-to-epithelial transition, reminiscent of human CAKUT. These changes are accompanied by decrease in *Gdnf* mRNA levels and protein and by low *Ret* and *Wnt11* mRNA levels starting at embryonic day (E)12.5. In contrast, global deletion of *Tcf21* does not attenuate the expression of members of the retioic acid and fibroblast growth factor signaling pathways, nor does it reduce expression of inducers of *Gdnf* (e.g. Osr1, Eya1, and Pax2). The stromal factor Bmp4, a potent inhibitor of Gdnf, is increased in kidneys from *Tcf21* KO mice, offering a potential mechanism. Under the hypothesis of pleiotropism, we dissociated Tcf21's effects in distinct cell lineages of the MM by studying the kidney phenotype of selective removal of *Tcf21* from the renal stroma (Tcf21$^{fl/fl}$;FoxD1-Cre strain) and from the CM (Tcf21$^{fl/fl}$;Six2-Cre strain). Absence of *Tcf21* from the stroma leads to low Gdnf and abnormal UB branching at E14.5 and results in paucity of collecting ducts and severe urinary concentrating defect at 4 wks of life. In contrast, deletion of *Tcf21* from the CM leads to abnormal glomerulogenesis and proteinuria but has no obvious effects on Gdnf expression or the development of the collecting ducts.

Conclusions: Taken together, our data illustrate distinct roles of Tcf21 in the stromal mesenchyme and cap mesenchyme in kidney development and support a model whereby Tcf21 regulates key molecular pathways required for branching morphogenesis. Direct genetic targets for Tcf21 in the kidney have not yet identified.

Developmental Loss of Intercalated Cells increases but Pharmacological Carbonic Anhydrase Suppression Decreases Pyelonephritis Susceptibility

Andrew L. Schwaderer,[1] Vijay Saxena,[1] John Ketz,[2] George J. Schwartz,[3] David S. Hains,[1] Robert L. Fairchild.[4] *[1]Indiana University, Zionsville, IN; [2]Nationwide Children's Hospital, Columbus, OH; [3]University of Rochester, Rochester, NY; [4]Lerner Research Institute, Cleveland Clinic Foundation, Cleveland, OH.*

Background: We had previously shown that carbonic anhydrase (CA) 2 knockout mice (*Car2*$^{-/-}$) have an intercalated cell deficiency and are susceptible to pyelonephritis. However it was not known whether this pyelonephritis risk is due to systemic absense CA, renal absence of CA, decreased CA activity or developmental depletement of intercalated cells. We hypothesized that the pyelonephritis susceptibility in *Car2*$^{-/-}$ *mice i*s secondary to intercalated cell deficiency

Methods: We compared pyelonephritis susceptiblity following transplantation of *Car2*$^{-/-}$ kidneys into wild type mice (isolated renal *Car2* absence), transplantation of wild type (WT) kidneys into *Car2*$^{-/-}$mice (nonrenal Car2 absence) and transpantation of control WT kidneys into WT mice. To determine whether pharmacological suppression of CA results in a similar pyelonephritis risk to developmental intercalated cell absence, we identified the dose of acetazolamide that suppressed renal carbonic anhydrase activity then compared pyelonephritis risk in treated versus untreated C57Bl/6J WT mice. Experimental pyelonephritis was induced by transurethral inoculation of uropathogenic E.coli (UPEC).

Results: Results are presented in Figure 1: Compared WT donor/WT recipient, the *Car2*$^{-/-}$donor/WT recipient, but not the WT donor/*Car2*$^{-/-}$recipient group had higher kidney (A) but not bladder (B) bacterial burdens at 24-hours post UPEC inoculation. Both 50 mg and 100 mg of acetazolamide given intraperitoneally suppressed CA (C) and increased urine pH (D). There was no difference between kidney (E-F) or bladder (G) bacterial burdens at 24 hours between acetazolamide treated and control mice. Mice treated with acetazolamide had lower kidney (H-I), but not bladder (K) bacterial burdens at 6-hours.

Conclusions: Developmental absence of intercalated cells is responsible for the pyelonephritis risk in *Car2*$^{-/-}$mice. Surprisingly acetazolamide appears to be protective against pyelonephritis, at least at an early time point.

Homeogene Emx1 Is a Required Downstream Component of the Mecom-Tbx2 Genetic Pathway That Regulates Pronephros Distal Segment Formation

Elvin e Morales, Rebecca A. Wingert. *University of Notre Dame, Notre Dame, IN.*

Background: Vertebrate kidneys contain nephron functional units where specialized cell types are organized into segments with discrete physiological roles. Many gaps remain in our understanding of how segment regions develop. To date, several studies have identified key signaling molecules and transcription factors that are essential for segment patterning in the pronephros, which has been speculated to offer a primitive blueprint for nephron segmentation in other kidney forms. *empty spiracles homeobox gene 1* (*emx1*) encodes a homeodomain transcription factor that is expressed in renal progenitors during early stages of pronephros development, and numbers among those genes that have been implicated to act downstream of retinoic acid (RA) signaling during segmentation.

Methods: Here, we used reverse genetics approaches to study the role of *emx1* during nephron formation. We discovered that *emx1* is required to regulate the balance of distal segment domains within the distal pronephros, and then performed a suite of genetic epistasis and expression studies to elucidate its relationship with other essential segment patterning components.

Results: *emx1* deficiency altered distal segment domains without changes in cell turnover or physical traits like cell size and morphology. In exploring further how Emx1 influences nephron pattern, we found that RA, which induces proximal and represses distal fates during early intermediate mesoderm development, negatively regulates *emx1* expression. Next, through a series of epistasis studies, we found that Emx1 acts downstream of a genetic cascade involving the essential distal segment genes Mecom and Tbx2. Finally, we determined that Emx1 restricts the expression boundary of *irx3b* to control distal segment territories.

Conclusions: Taken together, our work reveals how *emx1* is a necessary component of the pronephros genetic segmentation network, which has broad implications for understanding the regulatory cascades that orchestrate vertebrate nephron patterning.

Morphogenesis and Function of the Nephron-Collecting Duct Connection

Ping Zhang,[1,2] Ling Gu,[1] Jing Cong,[1,3] Jie Zhang,[1] Jesper S. Thomsen,[4] Arne A. Andreasen,[4] Hui Wang,[1] Si-Qi Deng,[1] Erik I. Christensen,[4] Xiao-Yue Zhai.[1] *[1]China Medical University, Shenyang, China; [2]Jin Zhou Medical University, Jinzhou, China; [3]Shenyang Medical College, Shenyang, China; [4]Aarhus University, Aarhus, Denmark.*

Background: A correct morphogenesis of the connection between nephrons and collecting ducts (CD) profoundly impacts the ability of the renal system to regulate the water-salt and acid-base balances in adults. However, the origin of the nephron-CD connection has yet to be established.

Methods: These observations were based on the morphology and computer-assisted tubular tracing on LM and EM serial sections.

Results: The present study showed that the nephron-CD connection was initiated by fusion of cells arising from the renal vesicle (RV) and the terminal tip of the ureteric bud (UB). One terminal tip often connected with two nephrons at different developing stages. A lumen in the nephron-CD connection was observed early at the S-shaped body stage, where the opening to the tip consisted mainly of distal tubule cells mixed with a few tip cells. With nephron development, the nephron-CD connection elongates with tip and RV cells, and the connection is then composed of cells expressing Na^+-Cl^- co-transporters, H^+-ATPase, and AQP2, with a similar distribution as in the adult kidney. AQP2 and H^+-ATPase, was constantly expressed at the UB trunk, increasingly expressed at the UB neck, while the expression was undetectable at the UB tip.

Conclusions: The study suggests that the nephron-CD connection is initiated by cell-cell fusion between RV and UB tip cells, then it elongates with participation of UB tip and neck cells, and finally it matures into the connecting tubule as the glomerulus develops.

Loss of Dicer Activity in the Peri-Wolffian Duct Stroma Leads to Increased Rates of Vesicoureteral Reflux

Melissa J. Anslow,[1] Sunder Sims-Lucas,[1] Carlton M. Bates,[1] Jacqueline Ho.[2] *[1]Children's Hospital of Pittsburgh, Pittsburgh, PA; [2]Children's Hosp of Pittsburgh of UPMC, Pittsburgh, PA.*

Background: Vesicoureteral reflux (VUR) is associated with urinary tract infections, hypertension, and reflux nephropathy, a leading cause of pediatric end-stage renal disease. Formation and location of the vesicoureteral junction is determined largely by the induction site of the ureteric bud from the Wolffian duct, which depends mostly on signals from the surrounding stroma. VUR appears heritable, but no single genetic mutation causes most known cases of VUR. miRNAs are small, noncoding RNAs, processed by Dicer, that regulate gene expression post-transcriptionally. We hypothesize that miRNAs are necessary for vesicoureteral junction development and prevention of VUR.

Methods: We generated a transgenic mouse model with loss of Dicer in the peri-Wolffian duct stroma (Tbx18cre; Dicer$^{Fl/Fl}$). We performed euthanized cystograms and 3D reconstructions of the ureters and bladder on mutants and controls (Tbx18Cre negative littermates). We performed whole mount Calbindin immunostaining at E11.5 to assess the ureteric bud induction site.

Results: Euthanized cystograms demonstrated significantly higher rates of VUR in the mutant mice compared to control [40% (6/15) of Dicer mutants as opposed to 3.8% (2/52) of controls ($p < 0.01$)]. 3D reconstructions showed lower ureteral insertions into the bladder and shorter intravesicular tunnel lengths on the side of VUR in mutants compared to control mice and non-refluxing mutant ureters ($p < 0.05$). Calbindin immunostaining reveals a cranially shifted ureteric bud induction site in E11.5 mutants compared to controls ($p < 0.05$).

Conclusions: These data suggest for the first time that miRNAs have a role in preventing VUR. This appears due to a requirement for miRNAs in peri-Wolffian duct stroma for normal ureteric bud induction and subsequent ureter insertion into the bladder. Future work will assess molecular mechanisms by which deletion of miRNAs in the peri-Wolffian duct stroma leads to VUR and elucidate which miRNAs in the peri-Wolffian duct stroma are critical for normal ureteric bud induction.

FR-PO933

Role of Fgfr2 in DNA Damage in Bladder Urothelium After Cyclophosphamide Injury

Sridhar T. Narla,[2] Caitlin M. Schaefer,[2] Daniel S. Bushnell,[2] Carlton M. Bates.[1,2] *[1]Children's Hospital of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA.*

Background: Stimulation of fibroblast growth factor 2 (Fgfr2) (IIb isoform) by keratinocyte growth factor (KGF), reduces injury in many epithelial cells. Deletion of Fgfr2IIIb prolongs cyclophosphamide (CPP)-induced bladder urothelial injury. Our purpose was to identify roles for Fgfr2 in bladder urothelial repair after CPP- injury.

Methods: We first subjected wildtype mice to a 150 mg/kg intraperitoneal (IP) dose of CPP to characterize the injury/ repair and to determine expression of Fgfr2 after injury. To determine roles of Fgfr2 in CPP-induced injury, we used a Tamoxifen inducible ShhCre line to knockout *Fgfr2* in all urothelial layers (*ShhcreFgfr2KO*), and subjected Cre-negative and

knockout mice to IP CPP. We performed general histological staining, *in situ* hybridization, and immunostaining.

Results: In controls, we observed major loss of urothelium, hemorrhage, and inflammation 1-day post CPP. We noted urothelial hyperplasia from 3-10 days post injury. *In situ* hybridization showed increased *Fgfr2* expression at 1 and 3 days post injury in control urothelium. We also observed evidence of DNA damage by γH2AX immunostaining in control urothelium at 3-7 days, which was reduced by 10 days. In the knockout studies, we observed significant decreases in weight at 1 and 3 days post-CPP in *ShhcreFgfr2KO* vs. Cre-negative mice. We noted similar urothelial loss, hemorrhage and inflammation 1-day post CPP in Cre-negative and mutant bladders. At 3 days post injury, *ShhcreFgfr2KO* bladders had ongoing marked hemorrhage and inflammation with reduced uroplakin staining vs. Cre-negative mice. While mutants and Cre-negative mice had expansion of Keratin 14 (Krt14)-positive presumptive progenitor cells across basal layers 3 days-post CPP, Cre negative mice had 6-7 urothelial cell layers while *ShhcreFgfr2KO* had only 3-4 cell layers. Also, mutants had many (mostly Krt14+) cells that were hypertrophic with enlarged nuclei (suggesting a cell cycle block). Furthermore, mutants had 2-fold increases in γH2AX+ nuclei vs. Cre negative mice.

Conclusions: Together, Fgfr2 appears dispensable for Krt14+ progenitor cell expansion after CPP-injury, but appears required for DNA repair and proliferation/cell cycle progression/differentiation of Krt14+ progenitors. Administration of KGF to wildtype bladders injured by CPP may enhance DNA repair.

Comprehensive Gene Expression Analysis for Pax2 Related Genes with Existing FANTOM Database

Yuta Yamamura, Kengo Furuichi, Akinori Hara, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Takashi Wada. *Kanazawa University, Kanazawa, Japan.*

Background: Pax2 is essential transcriptional factor for kidney development. Pax2 homo knockout mouse shows kidney agenesis and neonatal lethal. In human, PAX2 mutation is major causative genes for Renal coloboma syndrome (RCS), which is characterized by kidney hypoplasia or dysplasia and abnormality of the optic nerve. It is reported that Pax2 involved in ureteric bud branching via the regulation of Gdnf expression. Pax2 is known to involve both gene expression and suppression through epigenetic mechanism, apart from the role of transcriptional factor. In this study, using gene expression of mouse embryonic kidney from FANTOM database, comprehensive analysis for the genes which involved to Pax2 were evaluated. Furthermore, the role of PAX2 gene during human kidney development is not clear. Gene expression analysis in the kidney lineage cells differentiated from human induced pluripotent stem cells(iPSC)was performed.

Methods: To evaluate Pax2 related genes in mouse, we extracted gene expression data during kidney development (from embryonic day 14.5 to neonatal day 30). In the view of embryonic time course and organs, the correlation to Pax2 gene expression was evaluated. To evaluate PAX2 related gene in human, human iPSCwas differentiated into kidney lineage cells with reported methods (Taguchi, et al. Cell Stem Cells 2014). Some markers for kidney lineage cells were checked by immunocytochemistry and qPCR. Gene expressions of extracted candidate genes from mouse database were confirmed using the kidney lineage cells differentiated from human iPSC.

Results: About 180000 promoter expression data during mouse kidney development were extracted. The correlation to Pax2 promoter for time course and organswas evaluated. 3646 genes and 135 genes were extracted respectively. 18 genes, including some known essential genes for kidney development were overlapping. Human iPSC was differentiated to kidney lineage cells and checked PAX2 and other kidney lineage markers by immunocytochemistry and qPCR.A part of 18 genes were confirmed by qPCRin human differentiated kidney lineage cells.

Conclusions: Comprehensive analysis using FANTOM databaseis useful for identification of Pax2 related genes during kidney development.

FR-PO935

Effect of Hypoxia on Subpopulations of Cells During Kidney Development

Peter V. Hauser,[1,2] Morgan Hamon,[1,3] Lifu Zhao,[4] Masaki Nishikawa,[1,3] Naomi Yanagawa,[4] Norimoto Yanagawa.[1,3] *[1]Greater Los Angeles Veterans Administration, Los Angeles, CA; [2]Department of Integrative Biology and Physiology, University of California at Los Angeles, Los Angeles, CA; [3]Department of Medicine, University of California at Los Angeles, Los Angeles, CA; [4]Sepulveda Research Corporation, North Hills, CA.*

Background: During early developmental stages, embryonic kidneys are not fully vascularized and exposed to hypoxic condition (HC). HC is known to influence cell proliferation and survival, ureteric bud (UB) branching and vascularization of the developing kidney. We aimed in our present study to gain further insight into the effect of HC on different subpopulations of cells in embryonic kidneys at early developmental stages.

Methods: E11.5-13.5 embryonic kidneys were obtained from *Hoxb7*^{Venus}, *Foxd1*^{GFP}, *Six2*^{EGFP},*Cited1*^{RFP}mice and cultured under either HC or normal condition (NC) for up to 120h. Cell viability and gene expression pattern of Hoxb7^{+}, FoxD1^{+}, Six2^{+}and Cited1^{+}cells were analyzed by flow cytometry and q-RT-PCR, respectively. UB branching morphogenesis was analyzed under confocal microscopy to generate 3D images for measurements of organ volume, branching generations, branching length and diameter by using a gradient vector based software (TreeSurveyor).

Results: We found that HC reduced overall cell viability after 24, 48, 72, 96 and 120h. However, as compared to Foxd1^{+}stromal cells and Six2^{+}metanephric mesenchymal (MM) cells, Hoxb7^{+}UB cells and Cited1^{+}MM cells were less susceptible to HC and showed reduced cell death after 48, 72, and 96h. HC increased the number of branching generations in E12.5 and E13.5 kidneys after 24h and decreased at 48 and 72h, while E11.5 kidneys were not affected. HC further increased the length and diameter of UB branches in E13.5 kidneys at 24h but not at 48 and 72h. HC increased HIF1a mRNA levels in E12.5 kidneys at 48h and 72h, but normalized at 96h. HC also upregulated the mRNA levels of angiotensinogen at 24h, 48h and 72h, renin and angiotensin receptor 2 at 72h, while angiotensin receptor 1 was unchanged.

Conclusions: We conclude that HC imposes different effects on different subpopulations of cells in embryonic kidneys at different developmental stages. Studies are ongoing to further characterize the effects of HC on different subpopulations of cells during kidney development.

Transcription Factor HNF-1β Regulates Axonal Guidance Genes During Kidney Development

Annie Shao, Karam S. Aboudehen, Siu Chiu Chan, Peter Igarashi. *University of Minnesota, Minneapolis, MN.*

Background: Mutations of the transcription factor hepatocyte nuclear factor 1β (HNF-1β) represent the most common genetic cause of congenital anomalies of the kidney and urinary tract (CAKUT). HNF-1β plays essential roles in kidney development through the regulation of branching morphogenesis, nephrogenesis, and nephron patterning. However, the molecular mechanisms whereby mutations of HNF-1β cause CAKUT remain incompletely understood. Here, we used chromatin immunoprecipitation and deep sequencing (ChIP-seq) to identify novel transcriptional targets of HNF-1β in the developing mouse kidney.

Methods: Chromatin was extracted from wild-type E14.5 mouse metanephroi, immunoprecipitated with an anti-HNF-1β antibody, and sequenced using next-generation sequencing. HNF-1β binding sites were mapped to the mouse genome, and nearby genes were identified. The functions of HNF-1β target genes were determined using Ingenuity Pathway Analysis (IPA). The expression of HNF-1β target genes in wild-type and HNF-1β-deficient mIMCD3 cells was measured using RNA-seq.

Results: ChIP-seq identified 8,490 HNF-1β binding sites in chromatin from E14.5 mouse kidneys, including peaks at known HNF-1β developmental genes, such as Wnt9 and Pax8. 6,104 binding sites were novel and were not previously detected by ChIP-seq in mIMCD3 cells. IPA analysis of HNF-1β target genes revealed that axonal guidance was the highest scoring canonical pathway. HNF-1β binding sites were identified near 63 axonal guidance genes, including netrins (Ntn4), netrin receptor (Unc5c), semaphorins (Sema4a, Sema3g, Sema3d, Sema6a), and ephrins (Eph4b). RNA-seq analysis showed altered expression of core axonal guidance genes in HNF-1β-deficient cells compared to wild-type cells, suggesting that they were directly regulated by HNF-1β.

Conclusions: HNF-1β regulates the transcription of axonal guidance genes in the developing mouse kidney. In addition to their roles in axonal guidance, netrins, semaphorins, and ephrins are essential for branching morphogenesis in epithelial organs such as the lung. Dysregulation of axonal guidance genes may underlie branching defects in HNF-1β mutant kidneys.

ZEB2 in Renal Stromal Progenitors Regulates Nephrogenesis and Nephron Endowment in Mice

Sudhir Kumar, Weining Lu. *Boston University Medical Center, Boston, MA.*

Background: ZEB2 is a SMAD-interacting transcription factor that is mutated in Mowat-Wilson syndrome, a congenital disorder with renal anomalies. ZEB2 is highly expressed in developing kidney stromal progenitors and is a target gene for FOXD1, a transcription factor and an early marker for renal stromal progenitors. FOXD1 regulates nephrogenesis and nephron endowment during kidney development while *Foxd1* knockout mice have aberrant ZEB2 expression. However, the role of ZEB2 in nephrogenesis and nephron endowment is not known.

Methods: We analyzed the nephrogenesis and nephron endowment in *Zeb2* stroma-specific conditional knockout mice *Zeb2*$^{flox/flox}$;*Foxd1Cre*$^{+}$ (*Zeb2* cKO) and their wild-type littermate controls. Glomerular numbers were quantified by direct counting using kidney histology and nephrin immunostaining. Nephron progenitors were analyzed using SIX2, WT1 and PAX2 markers. Nephrogenesis was analyzed by immunostaining using nephron morphogenesis markers Jagged1, megalin, uromodulin, pan-cytokeratin and Dolichos Biflorus Agglutinin (DBA). Cell proliferation in developing kidney was analyzed by phospho-Histone H3.

Results: We found that *Zeb2* cKO had significantly less glomerular numbers at newborn and 3 weeks old compared to wild type littermate controls ($p<0.01$). Immunohistochemical analysis showed that newborn *Zeb2* cKO kidneys have fewer SIX2+ nephron progenitors compared to wild type littermate controls. This result was also confirmed by WT1 and PAX2 immunostaining. Jagged1, megalin, and uromodulin staining demonstrated abnormal nephron structure in *Zeb2* cKO kidneys. Pan-cytokeratin and DBA staining showed defective ureteric branching morphogenesis. Newborn *Zeb2* cKO mice also have reduced cell proliferation in the nephrogenic zone as compared to wild type littermate controls.

Conclusions: ZEB2 in renal stromal progenitors regulates SIX2+ nephron progenitor self-renewal and differentiation. Loss of *Zeb2* in renal stromal progenitors leads to abnormal nephrogenesis, low nephron endowment and congenital renal anomalies.

FR-PO938

Abcg2-Expressing Endothelial Cells Contribute to Kidney Postnatal Vascular Growth and Maintenance

Ellen Go,[1] Yang Lin,[2] Mervin C. Yoder,[2] David P. Basile.[2] *[1]Indiana University, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: Tissue blood vessels are lined by endothelial cells (EC) with heterogeneous states of proliferative potential. Several groups have recently identified resident vascular endothelial stem cells (VESC) and confirmed their critical role in vascular growth as they are highly proliferative, give rise to clonal endothelial colonies and are able to form vessels upon in vivo transplantation into sites of ischemia and hypoxia. Many other tissue resident stem cells express the ATP-binding cassette family drug transporter, *Abcg2*. We examined if *Abcg2*-expressing EC contribute to development of the kidney vasculature.

Methods: We crossed *Abcg2CreERT2* knock-in mice, which faithfully express Cre in *Abcg2*-expressing cells, with *ROSATdTomato* transgenic reporter mice to make Abcg2TT mice. TdTomato labels *Abcg2*-expressing cells and their progenies upon tamoxifen injection. We performed lineage tracing studies by injecting Abcg2TT mice at postnatal day 0 (neonate) or 42 (adult). Flow cytometry analysis of TdTomato+ EC was performed at days 1, 7, 21 and 56 post-tamoxifen in neonates, and days 1, 42 and 84 post-tamoxifen in adults. MACS-sorted EC from transgenic mice one day after tamoxifen injection were plated on OP-9 cultures and examined for the presence of endothelial colonies after 14 days.

Results: In neonates, 8.3±1.7% of total EC expressed TdTomato one day after tamoxifen injection. After 7 days, this population contributed to 36.0±11.1% of all kidney EC. In adult mice, 2.9±1.3% of total EC was labeled one day after a single tamoxifen injection. This population contributed to 15.4±2.9% of total kidney EC after 84 days. BrdU labeling studies are currently examining whether the turnover of kidney EC during these stages of development are derived from this population. The frequency of colony formation of TdTomato labeled EC is significantly higher than non-labeled EC.

Conclusions: Neonate and adult murine kidney blood vessels contain *Abcg2*-expressing EC that contribute to kidney vessel growth during development and maintenance of kidney vessel homeostasis in vivo. Thus, *Abcg2*-expressing EC may represent kidney VESC.

FR-PO939

The Role of Mir218 in the Function of the Renal Vasculature

Wenqing Yin,[1] Andrew M. Siedlecki.[2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Background: Vascular density is critical to normal kidney function. Reduced renal capillary number is associated with hypertension, chronic kidney disease, and kidney failure. Endothelial progenitor cells play a pivotal role in the construction of endocapillaries as well as their repair following ischemic injury. The function of endothelial progenitor-derived cells is dependent on cellular programs regulated by select microRNA. Mir218 directs retinal endothelial cell migration and motor neuron development. The role of mir218 in the function of the renal vasculature is widely unknown.

Methods: With CRISPR/Cas9 gene editing, we created an animal model, with germ-line miR-218-2 deletion (miR218-/-). These miR218-/- mice were subjected to bilateral renal ischemia-reperfusion injury (IRI) for 26 minutes, or sham surgery at 3 months of age and then evaluation the kidney function at 48 and 96 hours. Immunofluorescence staining of CD31 was assessed for the vascular density in this context.

Results: Following renal-specific ischemia/reperfusion injury, miR218-/- mice (n=6) were slow to recover renal function after 48 and 96 hours. There was a 20% of miR218-/- mice suffered fulminant renal failure and died within 96 hours. In miR218-/- mice, a lower vascular density in kidney with reduced renal capillary number were identified by CD31 staining.

Conclusions: With CRISPR/Cas9 gene editing approach to knock out miR-218-2 in the regulation of endothelial cell migration, we demonstrate for the first time the critical role of mir218 in the function of the renal vasculature.

Single Nucleus RNA-Seq from Fresh and Frozen Adult Mouse Kidney Offers Major Advantages over Single Cell RNA-Seq

Haojia Wu, Yuhei Kirita, Erinn L. Donnelly, Benjamin D. Humphreys. The Humphreys Lab *Renal Division Washington University School of Medicine, Saint Louis, MO.*

Background: Single-cell sequencing methods (scRNA-seq) have emerged as powerful tools for identification of cell types and states in kidney. However, generating a healthy single cell suspension is one of the biggest challenges to the field, limited by stress artifacts, RNA degradation and dissociation bias. We tested the hypothesis that single nucleus RNA-seq (snRNA-seq) is a superior approach.

Methods: We created 3,796 single cell transcriptomes from mouse kidney using the Dropseq platform, and single nucleus transcriptomes using the protocols from sNuc-Dropseq (2,951 nuclei), DroNc-seq (2,739 nuclei) and 10x Chromium (2,027 nuclei). We applied unbiased computational approaches to compare the gene expression and cell composition for each kidney cell type across different platforms. Finally, we aligned the cell types from snRNA-seq techniques to uncover the variations in gene expression within the shared subpopulations across techniques.

Results: 12 clusters were identified in the scRNA-seq dataset with most clusters from tubule and no cells at all from glomerulus. One cluster specifically expressed genes that were previously defined as artifactual dissociation-induced stress response genes induced by the cell dissociation protocol. By contrast, snRNA-seq from all platforms captured a diversity of kidney cell types including glomerular podocytes, mesangial cells and endothelial cells. The artifact cell cluster was not observed in the snRNA-seq datasets since the procedure is carried out on ice. Integrated analysis revealed that all snRNA-seq techniques can detect the same kidney cell types but DroNc-seq can capture more transcripts at the same sequencing depth over other snRNA-seq techniques. We also demonstrate that snRNA-seq is feasible on snap frozen tissue.

Conclusions: snRNA-seq provides substantial advantages over scRNA-seq in kidney, including the absence of dissociation-induced transcriptional artifacts, better representation of glomerular cell types (reduced dissociation bias) and the ability to perform snRNA-seq on archival, frozen samples.

Single-Nucleus Transcriptome Sequencing of Fetal Kidney Cells Identifies a Transient Pro-Angiogenic Signature in Developing Podocytes

Albert D. Kim,[2,1] Andrew P. McMahon,[2] Kun Zhang,[3] McMahon Laboratory *[1]University of Southern California, Los Angeles, CA; [2]Keck School of Medicine of the University of Southern California, Los Angeles, CA; [3]University of California at San Diego, San Diego, CA.*

Background: The renal corpuscle is composed of cell types including parietal epithelium, podocytes, mesangium, and endothelium. How this critical structure is generated from its constituent precursor cells during development is not well understood. Transcriptional profiling of the developing human kidney can provide novel insights into developmental processes.

Methods: Nephrogenic zone and renal corpuscles from 13 to 16 week human fetal kidneys were profiled by single nuclear Drop-seq and cell clusters were resolved using Pagoda2. To better understand nephron development, we performed trajectory analysis using Monocle. Specific predictions of genes identifying specific cell types and developmental transition were validated by in situ hybridization and immunohistochemistry. A specific hypothesis formulated on the transient production of secreted factors by podocytes co-regulating vascular and mesangial cell types was explored in vitro.

Results: SnDrop-seq identified 12 different nephrogenic clusters that were identified by known markers. Novel gene expression was discovered and validated in our analysis. Computational ordering of transcriptomes along a developmental trajectory revealed that a novel transient expression signature was present within precursors progressing to the podocyte lineage prior to expression of mature markers. Anatomical and *in vitro* characterization of these genes support an angiogenesis-promoting function within this transient population.

Conclusions: Previous studies have established that cell signaling including VEGF signaling is required for glomerular vascularization *in vivo*, however attempts to recapitulate this process *in vitro* have failed. Our findings provide insight into a critical spatiotemporal program that aids in the formation of the primary filtration unit in the kidney. Our findings provide new insight into human glomerular developmental programs and highlight novel targets-of-interest to explore in human kidney disease.

Single Cell RNA-Seq Identifies Molecular Fingerprints of Endothelial Cell Subpopulations in Kidney

Alex X. Zhou,[1,2] Liqun He,[3] Christer Betsholtz,[3,2] Pernille B. Laerkegaard Hansen.[4] *[1]IMED CVRM, AstraZeneca Gothenburg, Mölndal, Sweden; [2]ICMC, Karolinska Institute, Stockholm, Sweden; [3]Uppsala University, Uppsala, Sweden; [4]IMED CVRM, AstraZeneca Gothenburg, Mölndal, Sweden.*

Background: The kidney consists of functionally and anatomically discrete vascular plexus, and correspondingly distinct endothelial cell (EC) subpopulations. The precise targeting of renal vascular plexus in treatment requires a comprehensive understanding of the molecular characteristics of EC subpopulations. This study aims to distinguish renal EC subpopulations through dissection of their molecular fingerprints using single cell RNA-Seq (scRNA-Seq) analysis.

Methods: The BTBR mouse was perfused with magnetic Dynabeads that were subsequently trapped in glomeruli. The kidneys were enzymatically digested and glomeruli containing Dynabeads were removed. The cell suspension was further incubated with Pecam1 antibody and Pecam1$^+$ single cells were FACS sorted onto a 384-well plate. Single EC cDNA library was generated and RNA-Seq was performed on Illumina HiSeq 2500. Unsupervised clustering of EC subpopulations was performed with BackSPIN analysis.

Results: Pecam1 antibody selection of renal cell suspension produced a rather purified EC population, with ~80% successfully sequenced single cells being ECs. The ECs were clustered into 3 major subpopulations: the big vessel ECs (~30% of total ECs), peritubular capillary ECs (~36%), and glomerular ECs (~34%). These subpopulations displayed distinct molecular fingerprints. In particular, the glomerular and peritubular ECs showed differential gene expression patterns in vascular endothelial growth factor receptors, angiopoietin receptors, adrenomedullin system, caveolae-associated proteins, endocytic transport proteins, etc. The recent whole kidney scRNA-Seq analysis (Park et al, Science 2018) provided us an overall picture of the renal single cell population but limited resolution in ECs (Pecam1$^+$ ~1% of total cell population, peritubular ECs ~10% of EC population). In contrast, a dedicated EC scRNA-Seq may facilitate balancing various EC subpopulations in a single study and revealing in-depth definition of EC subpopulations in kidney.

Conclusions: The renal EC subpopulations display certain distinct gene expression patterns as revealed by scRNA-seq, which underscores the potential of selecting specific mechanisms for targeted vascular therapies in renal diseases.

Single Cell Transcriptional Profiling of Kidney Organoids Identifies a Novel Gene Activation Signal in Human Glomerular Disease

Jennifer L. Harder,[1] Rajasree Menon,[1] Edgar A. Otto,[1] Jian Zhou,[5] Sean Eddy,[1] Viji Nair,[1] Jeffrey B. Hodgin,[4] Roger C. Wiggins,[6] Olga Troyanskaya,[5] Benjamin S. Freedman,[3] Matthias Kretzler.[2] *[1]University of Michigan, Ann Arbor, MI; [2]U.Michigan, Ann Arbor, MI; [3]University of Washington, Seattle, WA; [4]The University of Michigan, Ann Arbor, MI; [5]Princeton University, Princeton, NJ; [6]University of Michigan Health System, Ann Arbor, MI.*

Background: Proposed mechanisms for podocyte (PC) compensation in kidney disease include dedifferentiation and non-PC transdifferentiation. Identifying genes expressed during PC development may reveal novel aspects of pathogenesis and progression of glomerular disease. Analysis of developing human kidneys is limited by availability and relative rarity of PCs in tissue. Kidney organoids generated from human stem cells offer a novel *ex vivo* system to explore gene expression during PC development.

Methods: We generated kidney organoids from human stem cells and performed single cell RNA sequencing. Over 10,000 transcriptomes were combined and clustered using an unsupervised algorithm. Single cell transcriptomes from organoids and developing human kidneys were combined to create developmental trajectories for multiple cell lineages originating from central progenitors. Genes expressed uniquely in cell clusters were identified and expression was quantified in bulk transcriptomic data from microdissected glomeruli isolated from humans with kidney disease (ERCB) and analyzed relative to eGFR and proteinuria.

Results: Cell clustering revealed two putative groups of PCs. Trajectory analysis confirmed both groups mapped to the same cell lineage expressing *NPHS2* but separated along the spectrum into early and mature. Early and mature clusters uniquely expressed 69 and 169 genes respectively. The cumulative expression score for the early (but not mature) PC gene set was significantly upregulated ($p<0.01$) in diseased glomerular tissue relative to living donors. Intriguingly, the early PC set contained genes previously unrecognized as being involved in kidney disease including *LYPD1* and *PRSS23*, each of which correlated with proteinuria and inversely correlated with eGFR.

Conclusions: Developing PCs in kidney organoids express a group of genes that are not expressed in later stage PCs. Expression of these genes in the human adult glomerulus is associated with the presence of kidney disease, suggesting reactivation of a developmental transcriptional program in cells in the glomerulus. This approach identifies the beneficial role of single cell transcriptional profiling of kidney organoids in identification of novel biomarkers of kidney disease.

High-Throughput Analysis of Single Cells in Immunofluorescent Kidney Sections

Christian Hugo,[1] Friederike Kessel,[2] Michael Gerlach,[3] Anne Steglich,[4] Todor Tschongov,[5] Florian Gembardt,[4] Leo Ruhnke,[7] Vladimir T. Todorov.[6] *[1]University of Dresden, Dresden, Germany, Dresden, Germany; [2]Unilkinikum Dresden, Dresden, Germany; [3]Division of Nephrology, Medical Clinic III, Universital Hospital Carl Gustav Carus Dresden, Dresden, Germany; [4]Universitätsklinikum Carl Gustav Carus, Dresden, Germany; [5]Uniklinikum Dresden, Dresden, Germany; [6]Dresden University of Technology, Dresden, Germany; [7]Div of Nephrology, Dept of Internal Medicine III, Univ Hospital CGC, Dresden, Germany, Dresden, Germany.*

Background: Immunofluorescence staining is a standard method for analyzing histological, physiological and pathophysiological markers in a variety of cell types and compartments of kidney tissue. However the final quantification of image data is still often performed by manual counting, a time consuming and potentially biased process.

Methods: With the open source software Fiji and R we are able to automatically analyze a variety of markers in complete kidney sections. Following the automatic acquisition of high-resolution sections our batch-processing is able to classify and detect up to 100.000 nuclei per kidney section by marker-controlled watershed with a systematic error rate below 5%. This approach largely eliminates personal bias, reduces analysis time and enables semiautomatic tissue compartmentation for stereometric analysis. By thresholding and segmentation of additional channels cells can be classified as marker-positive. Parallel documentation and a database creation with nuclear characteristics, spatial parameters and marker-positivity enable complete reproducibility and verification of the results in the original image.

Results: We used our approach to quantify renin-abundancy in a previously described triple-transgenic mouse with an inducible Gs alpha knockout (Lachman et al., 2017, JASN). This evaluation correlated to the counting of renin-producing cells by kidney FACS ($p<0.001$, Pearson). Furthermore we successfully quantified proliferation (PCNA) and apoptosis (TUNEL)-staining in a mouse model of serum induced kidney damage with our analysis algorithms. We could also asses the differential activation of TGF-beta signaling pathway in kidney compartments in an animal model of STZ-induced diabetic nephropathy by quantifying nuclear pSMAD.

Conclusions: Our novel quantification approach is easily implementable, versatile and generates high amounts of data. The systematic nature of methodic errors combined with high cell count in complete sections and the absence of personal bias results in advantages towards manual quantification. While the high number of nuclei assessed per sample is comparable to FACS, our approach requires less tissue, avoids artifacts related to organ disintegration and provides a spatial resolution of the data sets.

Spatial and Sex-Related Cell Diversity in the Adult Mouse Kidney Through scRNA-Seq Profiling

Andrew Ransick,[1] Albert D. Kim,[2] Andrew P. McMahon.[3] *[1]Broad-CIRM Center for Regenerative Med.& Stem Cell Research, Keck School of Med. of USC, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA; [3]Keck School of Medicine of the University of Southern California, Los Angeles, CA.*

Background: Applying single cell RNA Sequencing (scRNA-seq) methodology to adult mouse kidneys facilitates examination of the gene expression profiles of individual kidney cell-types in high resolution. Recent studies have shown the power of this approach for adult mouse whole kidney (Han et al., *Cell*; Park et al, *Science*). By incorporating zonal dissection of tissue samples and both sexes, we are generating a high resolution map of kidney cell types that integrates spatial organization and sex-related differences.

Methods: We profiled adult kidneys from two male and female wildtype C57B6/J strain mice. Prior to tissue dissociation, kidneys were dissected along the corticomedullary axis (CMA) to isolate pieces containing exclusively cortex, outer medulla or inner medulla/papilla. Tissue dissociation at 12 C utilized cold active proteases to reduce stress responses. scRNA-seq profiling used 10XGenomics Chromium platform. PCA and identification of variably expressed genes executed with Seurat v2.3 package in RStudio.

Results: We obtained 38,039 transcriptional profiles from four mice representing all expected cell types of the adult kidney, though podocytes were underrepresented. Initial analysis has focused on identifying lineage, zonal and sex differences. We observe expected zonal clustering for known cell types. Although within specific lineages distributed along the CMA, we find regional diversity in profiles and can identify cell types excluded from published scRNA-seq studies. A marked sex diversity was observed in specific cell populations, confirming and extending known sex-related differences in kidney gene expression. Our zonal analysis also facilitates mapping regional diversity amongst the associated cell populations (eg. vascular, mesenchyme, immune-related).

Conclusions: These data generate a solid foundation for building a high resolution map of cell diversity in the adult male and female mouse kidney. We will discuss our progress towards this goal and review new insights that have come from scRNA-seq analysis of specific kidney lineages.

Transcriptome Analyses of Altered Mouse Kidney Development Following Maternal Interleukin-6 Exposure During Gestation

Tarak Srivastava,[1] Daniel P. Heruth,[1] Robert E. Garola,[1] Mukut Sharma.[2] [1]*Childrens's Mercy Hospital, Kansas City, MO;* [2]*KCVA Medical Center, Kansas City, MO*.

Background: Children born to obese mothers have higher incidence of renal anomalies. Obesity is characterized by systemic inflammation. IL-6, an inflammatory cytokine, can cross the placental barrier, and is elevated in the amniotic fluid of obese women. Increasing evidence suggest that epigenetic mechanisms and microRNA (miRNA) interact in a bidirectional manner, a potential key mechanism for environmental effects on development. We hypothesized that renal development would be affected by elevated levels of maternal IL-6 brought about by epigenetic changes that alter both miRNA and RNA expression.

Methods: Pregnant C57BL/6 mice received either normal saline or IL-6 (10 pg/g BW) intraperitoneally on alternate days from E12.5. Fetal kidneys (E20.5) were removed from uterine horns by dissection and fixed in 10% formalin or used to isolate DNA and total RNA. LC-MS analysis of hydrolyzed DNA was performed to evaluate for methylation changes. TruSeq RNA Libraries (saline n=5, IL-6 n=5) were subjected to miRNA- and RNA-seq on an Illumina platform. Reads were mapped to the mouse reference genome and analyzed by miRDeep2.pl and Tuxedo Suite for miRNA-seq and RNA-seq, respectively.

Results: Maternal IL-6 administration resulted in decreased renal cortical parenchyma (358.4±74.3μm) compared with control (453.9±80.5μm, n=5, p=0.04). LC-MS analysis found a 10% increase in methylated cytosine in the IL-6 group suggesting epigenetic modifications in fetal kidney DNA. These modifications correlated ($q<0.05$) with 58 and 2087 differentially expressed (DE) miRNAs and RNAs, respectively. Stringent target prediction (score>90) identified 1350 mRNA regulated by the 58 miRNA of which 196 (9.4%) were present in the list of 2087 DE genes. Nephrotoxicity, as predicted by Ingenuity Pathway Analysis, associated with *Renal Necrosis/Cell Death* (p=1.5E-11, 104 genes) and *Renal Damage* (p=1.2E-8, 52 genes). We have identified the *STAT3* (p=3.2E-06, 20 genes), *NRF2-Mediated Oxidative Stress Response* (p=3.5E-06, 37 genes) and *Glucocorticoid Receptor Signaling* (1.9E-05, 53 genes) pathways for further analysis and confirmation.

Conclusions: Our model of maternal IL-6 administration has allowed us to better understand the role of environment mediated changes on epigenetics and global gene expression in kidney development.

Amphiregulin Mediated Cellular Reprogramming Modulates Inflammation and Tissue Remodeling Following Kidney Injury

Vikram Sabapathy,[1] Nardos T. Cheru,[2] Saleh Mohammad,[1] Rajkumar Venkatadri,[1] Rahul Sharma.[1] [1]*Center for Immunity, Inflammation and Regenerative Medicine (CIIR), University of Virginia, Charlottesville, VA;* [2]*Department of Chemistry, University of Virginia, Charlottesville, VA.*

Background: Acute Kidney injury (AKI) is a major cause of mortality and morbidity. There is a growing evidence of interaction between tissue-resident immune cells and epithelial progenitor cells that participate in the process of regeneration. Recent studies indicate that Amphiregulin (AREG), a member of epidermal growth factor (EGF) family, also secreted by immune cells and has been shown to modulate both host immunity and tolerance mechanism. We hypothesize that AREG, produced by Regulatory T Cells (Tregs) promotes tissue repair and regeneration. In this study, we investigated differential effects of AREG towards promoting tissue homeostasis and regeneration using both *in vivo* and *in vitro* models.

Methods: Murine ischemia-reperfusion injury (IRI) and Endotoxemic renal injury models were developed to investigate a therapeutic effect of AREG. The protective effect of cytokine treatment both before and after the injury was examined. The structure and function of the kidney were probed using flow cytometry, intravital microscopy, histology, immunohistochemistry, quantitative gene expression and biochemical analysis. Kidney organoids and tubular epithelial cell line were used to probe the efficacy of AREG under *in vitro* conditions.

Results: Our findings showed that treatment with AREG immediately after injury not only enhanced the expansion of Tregs but also accentuates the suppressive function of Tregs, thus preventing kidney damage and preserving renal function in murine models. On the other hand, impediment of EGFR signaling resulted in increased fibrosis and deterioration of kidney function. Experiments using kidney organoids showed that addition of exogenous AREG attenuated cell death in an *in vitro* model of injury. Interestingly, direct addition of AREG to proximal tubular epithelial cell culture resulted in the development of cellular plasticity. Furthermore, AREG knockout mouse model was used to elucidate the role of AREG mediated regeneration in AKI.

Conclusions: This study addresses the application of AREG in immunomodulation and renal regeneration as a therapeutic approach for renal injury and sheds light on the mechanisms enforced by immune cells in the switch of maladaptive repair to successful regeneration.

FR-PO948

c-Myc Is a Modulator of Pkd1 Gene and Polycystic Kidney Disease Progression

Camila Parrot, Almira Kurbegovic, Guanhan Yao, Marie Trudel. *Institut de Recherches Cliniques de Montreal, Montreal, QC, Canada*.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common disorders associated mainly with Pkd1/Pc1 mutations. Orthologous Pc1 dosage-reduced and -increased mouse models develop renal tubular cysts. A causal connection between c-Myc-targeted overexpression and PKD was determined from transgenic SBM mice that closely resemble ADPKD and orthologous mouse models. Using these mouse models, we investigated for a clear regulatory interplay and signaling crosstalk between c-Myc and Pkd1 or Pc1.

Methods: Kidney tissues of SBM and four Pc1-dosage models were analyzed for molecular expression at mRNA levels by qPCR, at protein levels by WB and for cellular expression by IHC. Pkd1 gene regulation was assessed *in vivo* using genome ChIP analysis. Direct causal connection was interrogated by *in vivo* genetic interactions.

Results: We showed that renal regulation in four Pc1 dosage-reduced and -increased mouse models converge toward stimulation of c-Myc expression along with β-catenin (~5-10-fold) in tubular epithelial cells as in ADPKD renal tissues. This systematic increase defined c-Myc as a key *Pkd1* node in cystogenesis and confered the high relevance of the SBM transgenic mice for further analysis. Enhanced c-Myc in SBM transgenic mice led conversely to striking upregulation of *Pkd1*/Pc1 expression (~10-fold) and β-catenin activation, uncovering reciprocal crosstalk between c-Myc and Pc1. In adult SBM kidneys, c-Myc ChIP analysis showed strongly enriched binding on *Pkd1* promoter associated with RNA pol II, consistent with *Pkd1* upregulation during cystogenesis. Similar c-Myc direct binding also at birth uncovered an equivalent role on *Pkd1* regulation during renal developmental program, suggesting a role in condensing metanephric mesenchymal stem cells as for c-Myc. These data revealed an inter-regulatory network of c-Myc and Pc1 in normal physiologic and PKD conditions and shed light on PKD1 upregulation in the face of human ADPKD mutation. Genetic ablation of *c-Myc* in Pc1-reduced and -increased mouse models significantly attenuates cyst growth, proliferation and PKD progression, providing evidence that c-Myc is a Pkd1 causal cystogenic factor.

Conclusions: Together our data determined a dual role for c-Myc, as a major contributor in a feed-forward regulatory *Pkd1*–c-Myc loop mechanism and in Pc1-induced cystogenesis that may also prevail in human ADPKD.

FR-PO949

A RhoA-YAP-c-Myc Signaling Axis Promotes the Development of Polycystic Kidney Disease

Jing Cai. *University of Texas Southwestern Medical Center, Dallas, TX*.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is an inherited disorder caused by mutations in *PKD1* or *PKD2* and affects 1 in 500-1000 humans. Limited treatment is currently available for ADPKD and there is great interest in identifying molecular targets and/or pathways for the development of mechanism-based therapeutics. In mammals, the Hippo signaling pathway comprises several tumor suppressors (NF2, Sav1, Mst1/2, Lats1/2, etc.) acting through a kinase cascade to affect the phosphorylation and cytoplasmic retention of the oncoproteins YAP/TAZ, transcriptional coactivators of the TEF/TEAD family transcription factors to transactivate growth-promoting genes. In this study, we investigated the function and regulation of the Hippo signaling pathway in ADPKD.

Methods: We performed gene set enrichment analysis of YAP/TAZ/TEAD target genes after global gene profiling on human *PKD1* polycystic kidney cysts compared to minimally cystic tissues using Affymetrix cDNA arrays, analyzed various genetically engineered mouse models with kidney cystogenesis, and searched for kinase inhibitors that promoted tubulogenesis in 3D-cultured *Pkd1* mutant mouse kidney inner medullary collecting duct (mIMCD3) cells through an unbiased kinase inhibitor screen.

Results: Our results showed that YAP/TAZ were activated in human ADPKD kidney cysts compared to minimally cystic tissues. While transgenic overexpression of YAP promoted proliferation and tubule dilation in mouse kidneys, loss of YAP/TAZ or their transcription target c-Myc suppressed cystogenesis in a mouse ADPKD model resulting from *Pkd1* deficiency. Through the comprehensive kinase inhibitor screen, we identified a signaling pathway involving the RhoGEF LARG, the small GTPase RhoA and the RhoA effector Rho-associated kinase (ROCK) as a critical signaling module between PKD1 and YAP. Further corroborating its physiological importance, inhibition of RhoA signaling suppressed cystogenesis in 3D culture of *Pkd1* mutant kidney cells as well as *Pkd1* mutant mouse kidneys in vivo.

Conclusions: Taken together, our findings shed light on the mechanisms underlying ADPKD pathogenesis and implicate the RhoA-YAP-c-Myc signaling axis as a critical mediator and potential drug target in ADPKD.

FR-PO950

Reconstitution of ADPKD Cyst Formation in 3D Culture Reveals a Role for YAP 1 in Cyst Lumen Size

Robert L. Bacallao,[1,2] Sherry G. Clendenon,[4] Clark D. Wells.[3] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Medicine, Richard Roudebush VAMC, Indianapolis, IN; [3]Indiana University School Medicine, Indianapolis, IN; [4]Indiana University, Bloomington, IN.*

Background: Proximal tubule cells grown in 3D culture, initiate cyst emergence with uniformly small lumens upon expression of CDH8. Prior studies indicate that cyst expansion in ADPKD results from increased proliferation from increased YAP1 signaling. We tested the hypothesis that YAP1 action is sufficient to cause enlarged cyst lumens in 3D culture and YAP1 interference by AMOTL1 decreases lumen size.

Methods: Immune-blots were carried out on lysates of confluent PKD Q4004X and HmPKT cells using antibodies for SAV1, MST1/2, MOB1, p-MOB1 (thr 35), LATS1, YAP/TAZ, p-YAP (ser 127) and p-YAP (ser 397). HK2 cells were transduced with lentivirus bearing constitutively active *YAP1-5SA* and grown in 3D culture. Cyst emergence was activated by cell transduction with adenovirus bearing *CDH8*. Separately, PKD Q4004X cells were transduced with lentivirus expressing *YAP1-5SA* or *AMOTL1 (S262E)* and grown in Matrigel for 14 days. Cysts were imaged and analyzed with Image J.

Results: Cyst epithelia had lower expression of SAV1, MST2, LATS1, YAP1 and TAZ and reduced ratio of p-YAP (ser 127) over YAP1. These cells also showed increased levels of p-MOB1 and p-YAP (Ser 397). HK-2 cells transduced with lentivirus expressing YAP1-5SA formed normal tubule arrays in 3D culture. However, when cyst emergence is activated by microinjected CDH8 expressing adenovirus, large lumen cysts are formed. In separate experiments, PKD Q4004X cells were grown in Matrigel for 14 days to allow for cyst formation. PKD Q4004X cells transduced with YAP1-5AS or AMOTL1 (S262E) were compared to control PKD Q4004X cells. After 14 days, samples were fixed, stained and imaged to determine cyst size using ImageJ. PKD Q4004X cells had an average maximum area of 177.89 ± 7.16 μm^2 . PKDQ 4004X cells transduced with AMOTL1 (S262E) had an average area of 122.77± 6.03 μm^2 ($p<0.01$). PKDQ4004X cells transduced with YAP1-5SA had an average area of 6619.66 ± 773.78 μm^2 ($p<0.01$).

Conclusions: 1) Cystogenesis can be reproduced by the combined activation of CDH8 and YAP1. 2) CDH8 expression initiates decreased cell-cell adhesion that is sufficient for cyst emergence. 3) YAP1 expression in the absence of CDH8 activation does not promote cyst formation. 3) Cyst size in ADPKD cells can be inhibited by AMOTL1 and increased by YAP1. 4) Overall, YAP1 activation following cyst emergence is necessary for increased lumen size in ADPKD.

Bile Acid Receptor Agonists and Metformin Slow Cyst Growth and Correct Perturbed Energy Metabolism in PKD1-Null Kidney Cells

Hui Li,[1] Polly Huang,[1] Aurash Naser-Tavakolian,[1] Daniel Rivera,[1] Moshe Levi,[2] Kenneth R. Hallows.[1] *[1]USC Keck School of Medicine, Los Angeles, CA; [2]Georgetown University, Washington, DC.*

Background: Autosomal dominant polycystic kidney disease (ADPKD), caused by mutations in polycystin-1 (PKD1) or polycystin-2 (PKD2), presents with progressive development of renal cysts and eventual end-stage kidney disease. PKD1-null cells have increased proliferation and decreased AMP-activated kinase (AMPK) activity, along with dysregulated cellular metabolism. Bile acid receptor agonists, INT-777 and INT-767, promote a shift from glycolytic to fatty acid oxidative metabolism and regulate several key signaling pathways, including inflammation, fibrosis and the AMPK and extracellular signal-regulated kinases (ERK) pathways. Here we sought to determine whether these agonists alone or in combination with the AMPK activator metformin, may be effective as novel therapeutics for ADPKD by correcting dysregulated metabolism and slowing cyst growth in PKD1-null cells in vitro.

Methods: Using PKD1-null kidney epithelial cells, we examined AMPK and ERK pathway markers and levels of key glycolytic enzymes by immunoblotting, which were correlated with effects of various treatments. 3-D cultures were used to assess cyst growth after treatment with INT-767 or INT-777 alone or in combination with metformin. Seahorse assays were performed to evaluate cellular metabolic phenotypes under different conditions.

Results: INT-767 treatment of PKD1-null cells activated the AMPK and inhibited the ERK pathways and expression of the key glycolytic enzyme PDK1. INT-767 also reduced glycolytic fluxes while significantly increasing mitochondrial oxidative respiration as compared with control cells. INT-777 treatment also increased fatty acid oxidation in PKD1-null cells. Both INT-767 and INT-777 inhibited cystogenesis of PKD1-null cells in 3D cultures. Moreover, combination INT-767 or INT-777 treatment with metformin, another potential therapeutic for ADPKD, achieved much better control of cyst growth than either drug alone.

Conclusions: The bile acid receptor agonists INT-767 or INT-777 in combination with the AMPK activator metformin appear to have a synergistic effect on slowing cyst growth and correcting perturbed energy metabolism in PKD-deficient ADPKD kidney epithelial cells. These beneficial effects may potentially occur via activation of the AMPK pathway and will be explored further using in vivo ADPKD mouse models.

FR-PO952

New Organoid Model for ADPKD Reveals Pkd2 Loss Disrupts Apical Junctional Complex and Master Scaffold Ezrin

Eryn E. Dixon, Owen M. Woodward. *University of Maryland School of Medicine, Baltimore, MD.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by progressive cystogenesis, resulting in end stage renal disease. This common monogenetic disorder is attributed to loss of function mutations in the genes, *PKD1* and *PKD2*, that encode for transmembrane proteins, polycystin 1 and 2. Hallmark components of cystogenesis, including increased proliferation, changes in apicobasolateral compartmentalization, and a secretory phenotype, suggest a defect in the organization of renal epithelial cells following *PKD1/2* loss.

Methods: Immunofluorescent morphometric analysis of nephrectomized kidney tissue from ADPKD patients recently revealed significant changes in the morphology of the apical compartment, demarcated by zonula occludens 1 (ZO-1), in small, emerging cysts, when compared to normal tubules. Additionally, transepithelial electrical resistance assays using inducible *Pkd2* Cre (*Pkd2 Pax8 rtTA TetOCre +mTmG*) primary cells suggest that inactivation of *Pkd2* results in a decrease in resistance, indicating disruption of junctional integrity.

Results: While many pathways have been implicated in the complex progression of cystogenesis, these results suggest disruption of the apical junctional complex (AJC), may be responsible for changes in the organization and compartmentalization of apical proteins and signaling. Using a new in vitro tubule model system designed to investigate the initiation of cyst formation directly following the loss of functional polycystin 2 (PC2), we have demonstrated that loss of PC2 results in a decrease in master scaffold of apical compartment organization, ezrin. Furthermore, an inducible *Pkd2* Cre mouse model demonstrates that ezrin loss can be recapitulated in vivo following inactivation of *Pkd2* with doxycycline. Human ADPKD cystic tissue exhibits a decrease in ezrin protein abundance relative to normal kidneys and aberrant localization in cyst walls.

Conclusions: Therefore, the initiation of cystogenesis in ADPKD may be dependent on PC2's regulation of the AJC and master scaffold, ezrin, highlighting a novel function of PC2 in renal epithelial cells.

FR-PO953

Mitochondrial Morphological Abnormality in Cyst Epithelial Cells of Autosomal Dominant Polycystic Kidney Disease Patients

Yu Ishimoto,[6] Masaomi Nangaku,[6] Saori Nishio,[1] Haruna Kawano,[9] Shigeo Horie,[5] Tomoko Kasahara,[7] Kenji Osafune,[8] Junichi Hoshino,[2] Yoshifumi Ubara,[2] Akira Shimizu,[4] Masanori Kugita,[3] Shizuko Nagao,[3] Kenjiro Honda,[6] Reiko Inagi.[6] *[1]Hokkaido University, Sapporo, Japan; [2]Toranomon Hospital, Tokyo, Japan; [3]Fujita Health University, Toyoake, Japan; [4]Nippion Medical School, Tokyo, Japan; [5]Juntendo University, Tokyo, Japan; [6]University of Tokyo School of Medicine, Tokyo, Japan; [7]Kyoto University, Kyoto, Japan; [8]Center for iPS Cell Research and Application, Kyoto University, Kyoto City, Kyoto, Japan; [9]Juntendo university, Tokyo, Japan.*

Background: Recent studies reported that polycystin-1 affects mitochondrial function directly or indirectly and facilitates pathogenesis of autosomal dominant polycystic kidney disease (ADPKD). However, it is not confirmed in the kidney of ADPKD patients.

Methods: We conducted multi-center study, collected the kidney tissues from 20 ADPKD patients (this study was approved by the research ethics committees of the Graduate School of Medicine and Faculty of Medicine, The University of Tokyo. No.11560-(2)). By transmission electron microscopy, mitochondrial morphology was assessed in the kidney from ADPKD patients or ADPKD model animals. Quantification of mitochondrial morphology was done using ImageJ software.

Results: In cyst epithelial cells with cuboidal shape, mitochondria are abundant. In contrast, in the cyst epithelial cells, which reduce their height, the number of mitochondria was decreased, and subsequently, mitochondria are almost gone in the cyst epithelial cells with flat shape. The mean volume of the cyst epithelial cells of ADPKD patients (mtADPKD) were about 1.2 times larger than in the tubules of normal human control (mtCON). Mitochondria of mtCON exhibited a wide variety of morphologies (elongated and fragmented), however that of mtADPKD showed almost uniform with round shape. In addition, mtADPKD showed indistinct cristae formation. These characteristics of abnormal mitochondrial shape are the same with that observed in the cyst epithelial cells of *$Pkd1^{flox/flox}$:Ksp-Cre* mice and *$Pax8^{rtTA}$;TetO-Cre;$Pkd2^{lox/flox}$* mice but different from that of *Cy/+* rat.

Conclusions: Our results indicate that mitochondria in the cyst epithelial cells of ADPKD patients swollen with indistinct cristae formation and this might be the characteristics of polycystin-1 or polycystin-2 dysfunction in the kidney of ADPKD patients. Mitochondrial dynamics serves a variety of different functions, including cell proliferation. Similar mitochondrial morphological change was observed in cancer cells and which might reflect pathological derangements characteristic of ADPKD has marked similarities to those of solid tumors.

CaSR Activation Corrects the Impaired Mitochondrial Energy Status in Human Cell Models of ADPKD

Annarita Di Mise,[1] Marianna Ranieri,[1] Mariangela Centrone,[1] Maria Venneri,[1] Grazia Tamma,[1] Daniela Valenti,[2] Giovanna Valenti.[1] *[1]University of Bari, Bari, Italy; [2]Institute of Biomembranes, Bioenergetics and Molecular Biotechonologies, Bari, Italy.*

Background: Clinical and fundamental research data suggest that reduced resting cytosolic calcium (Ca^{2+}) concentration and increased level of cAMP are two of the most proximal events in the pathogenesis of Autosomal Dominant Polycystic Kidney Disease (ADPKD). Reduced cellular free Ca^{2+} found in ADPKD, can on the other hand affect mitochondrial function and ATP production and, interestingly, a relationship between mitochondria and renal polycystic diseases have been suggested. CaSR is a G protein coupled receptor, which plays an essential role in regulating Ca^{2+} homeostasis whose activation is associated with an increase in intracellular Ca^{2+} and decrease in cAMP. We have recently reported (Di Mise et al, Sci Rep, 2018) that selective CaSR activation reduces intracellular cAMP and mTOR, and increases intracellular Ca^{2+}, reversing the principal ADPKD dysregulations. Here, the effect of CaSR activation on mitochondrial energy status is investigated.

Methods: Control human conditionally immortalized Proximal Tubular Epithelial cells with stably down-regulated PKD1 (ciPTEC-PC1KD) were used as experimental tools.

Results: The investigation of the bioenergetics status in ciPTEC-PC1KD revealed a multilevel inhibition of the mitochondrial ATP production by oxidative phosphorylation (OXPHOS) in ciPTEC-PC1KD compared with wt cells, specifically at complex I, complex II and complex IV levels. Interestingly, ciPTEC-PC1KD have significantly lower mitochondrial Ca^{2+} levels (88.05 2.6%), associated with a severe deficit in mitochondrial ATP production (38 ± 4%), with respect to wt cells, secondary to the OXPHOS impairment. Notably, selective CaSR activation with the calcimimetic NPS-R568 increases mitochondrial Ca^{2+} content close to the levels found in resting wt cells, and fully recovers the cell energy deficit associated to the PC1 silencing.

Conclusions: Together these data indicate that, besides reversing altered intracellular Ca^{2+}, cAMP and mTOR, selective CaSR activation in PKD1 deficient cells corrects mitochondrial energy status that, in ADPKD, is known to facilitate cyst formation. These findings identify CaSR as a potential therapeutic target.

Connective Tissue Growth Factor Is Regulated by TGF-β2 and ERK via Smad2/3 in Autosomal Dominant Polycystic Kidney Disease

Hyunho Kim,[1] Ji-Hye Kim,[1] Jinmo Sung,[1] Hyunsuk Kim,[4] Jeong ok So,[1] Jiseon Kim,[1] Hyunjin Ryu,[1] Hayne C. Park,[2] Yun Kyu Oh,[3] Curie Ahn.[1] *[1]Seoul National University Hospital, JongNo-Gu, SEOUL, Republic of Korea; [2]Kangnam Sacred Heart Hospital, SEOUL, Republic of Korea; [3]Department of Internal Medicine, Boramae Medical Center, Seoul, Republic of Korea; [4]Chuncheon Sacred Heart Hospital, Chuncheon, GangWon-Do, Republic of Korea.*

Background: In autosomal dominant polycystic kidney disease (ADPKD), the mechanism of pericystic fibrosis is not elucidated. Connective tissue growth factor (CTGF) plays an important role in the renal fibrosis. Also, It is known that ERK phosphorylates the linker region of Smad3 to enhance and activity of ERK is increased in ADPKD. Here, we study whether CTGF is regulated by TGF-β and ERK via Smad2/3 signal pathway in ADPKD.

Methods: To examine the expression of CTGF and phosphorylation of Smad2/3, we performed immunohistochemistry(IHC) and Western blot of ADPKD kidney tissues and isolated cyst cells. To investigate whether Smad2/3 signal pathway was involved in the upregulation of CTGF and the role of ERK in Smad2/3 pathway, we treated A83-01, which blocked phosphorylation of Smad2/3, and ERK inhibitor, PD98059, into cyst cells. Next, we performed ELISA and RT-PCR to examine which TGF-β induced Smad2/3 pathway in ADPKD.

Results: In kidney tissues and isolated cyst cells of ADPKD patients, we found that expression of CTGF and phosphorylation of Smad2/3 were increased. The expression of CTGF and nuclear localization of phospho-Smad3 were reduced on treatment of A83-01. Thus, Smad2/3 pathway induced the expression of CTGF. We found that TGF-β2 was secreted and mRNA of TGF-β2 was increased in cyst cells. On the treatment of TGF-β2, phosphorylation of Smad2/3 and expression of CTGF were increased. When we treated ERK inhibitor, PD98059, it was found that nuclear phospho-Smad2/3 was reduced in nuclear/cytosol fractionation and immunofluorescence. Next, we study whether PC1 repressed TGF-β2 via AKT. IMCD cells expressing PC1 showed that secretion and mRNA of TGF-β2 were reduced. After treatment AKT inhibitor, the secretion and mRNA of TGF-β2 were increased indicating PC1 downregulated TGF-β2 via AKT.

Conclusions: Taken together, our results suggested that CTGF was regulated by TGF-β2 and ERK via Smad2/3 signal pathway in pericystic fibrosis of ADPKD.

FR-PO956

Dysregulated 4E-BP1 Pathway in Polycystic Kidney Disease

Sara Holditch,[1] Daniel Atwood,[2,1] Carolyn N. Brown,[1] Charles L. Edelstein.[1] *[1]UC Denver Anschutz Medical Campus, Aurora, CO; [2]University of Colorado Anschutz, Aurora, CO.*

Background: Unchecked proliferation of cystic epithelial cells is a major contributor to cyst growth in PKD. The 4E-BP1 pathway is a crucial checkpoint in translation and cellular proliferation, regulated by multiple stimulatory factors like PKCα, ERK, and AKT. The aim of this study was to 1) determine whether the 4E-BP1 pathway is dysregulated in human $PKD1^{-/-}$ cells, 2) examine the effects of an AKT and mTOR insensitive 4E-BP1 (F113A) on protein translation, proliferation, and 3) assess the feasibility of *in vivo* gene therapy of F113A 4E-BP1 adeno-associated virus (AAV9) in neonatal and adult mice.

Methods: Immunoblot, proliferation, and luciferase assays were performed on human epithelial cells from normal renal cortical tubular epithelium ($PKD1^{+/+}$) and ADPKD cyst-lining epithelium ($PKD1^{-/-}$) transfected with pCAG-TdTomato or pCAG-F113A. AAV9 F113A, and AAV9-TdTomato vectors were prepared and administered from D3 and to D17, or D120 to D180.

Results: There was increased phospho (p4E-BP1) species and increased pPKCa(3.6±0.2 vs 0.6±0.0DU***), pERK(3.6±0.2 vs 0.5±0.2DU***), and pAKT(0.6±0.1 vs 0.2±0.1DU*), in $PKD1^{-/-}$ vs. $PKD1^{+/+}$ cells respectively. *In vitro*, F113A expression reduced p4E-BP1 S65 (1.4±0.2 vs 0.02±0.01DU***), reduced cyclin D1 (0.65±0.04 vs 0.51±0.10DU*) and increased autophagosome marker, LC3-II, (0.02±0.00 vs 0.31±0.13DU*) expression in $PKD1^{-/-}$ cells. Stimulation with insulin resulted in maintained p4E-BP1 suppression with F113A in $PKD1^{-/-}$ (2.1±0.3 vs 0.2±0.1DU***). F113A also reduced cap-dependent protein translation (by 37%**), and 72hr proliferation (250±4 vs 180±5 480/528nm O.D***). In neonatal and adult mice, administration of AAV9 resulted in detectable F113A RNA in the heart, kidney, and liver, and reduced p4E-BP1 S65 expression in the heart (2.0±1.3 vs 0.6±0.4DU*). *p<0.05, **p<0.01, *** p<0.001 vs to control.

Conclusions: In PKD, a setting of cystic tubular epithelial hyperproliferation, the 4E-BP1 pathway is dysregulated with increased phosphoregulation of 4E-BP1 by multiple overactive kinases such as; PKCa, ERK, AKT. *In vitro*, F113A expression in $PKD1^{-/-}$ cells, results in hypophosphorylated 4E-BP1 species, reduced cap dependent protein translation, reduced proliferation, and increased autophagosomes. F113A gene therapy to counter the dysregulated 4E-BP1 pathway in *in vivo* models of PKD is feasible to inhibit a pathway seemingly integral to the pathobiology of PKD.

Polycystin-1 Signaling Is Regulated by a Stachel-Like Sequence

Brenda S. Magenheimer, Robin L. Maser. *University of Kansas Medical Center, Kansas City, KS.*

Background: Polycystin-1 (PC1) is involved in modulation of G protein signaling, but the regulatory mechanism is unknown. Similar to the Adhesion class of GPCRs, PC1 undergoes auto-catalyzed cleavage at a GPS motif present within its conserved GAIN domain that generates noncovalently-associated extracellular N-terminal (NTF) and membrane-embedded C-terminal (CTF) fragments. Adhesion GPCR signaling can be regulated by residues in the extracellular stalk (the so-called 'Stachel sequence') of the CTF that are exposed upon removal of the NTF. We hypothesized that PC1-mediated signaling is regulated by a Stachel-like sequence within the N-terminus of its CTF.

Methods: Full-length (FL) or CTF forms of PC1 with wild type or mutant stalk sequences (i.e., deletion, ADPKD-associated missense, or alanine substitution) were transiently expressed in HEK293T cells. Activation of a co-transfected NFAT promoter-luciferase reporter and levels of total and surface-expressed protein were compared between mutant and wild type PC1.

Results: FL PC1 activated the NFAT reporter in a dose-dependent fashion, while the CTF demonstrated an inverse dose relationship possibly dependent on its % surface expression. Deletion of the entire stalk region from CTF eliminated NFAT reporter activation, which was not solely due to reduced total protein or surface expression levels. Alanine-scanning of the CTF stalk sequence resulted in a range of effects on NFAT activity, from abolishment to augmentation, which were not entirely consistent with changes in mutant CTF expression characteristics. ADPKD missense mutations in the CTF stalk abolished NFAT activation with varying effects on total or surface protein expression. The same ADPKD mutations when engineered into FL PC1 also inhibited NFAT reporter activation, but had differing effects on GPS cleavage and cell surface expression.

Conclusions: The CTF may be the 'native form' of PC1 responsible for signaling to the NFAT reporter, whose signaling ability is dependent on the presence of the extracellular stalk. Mutation analyses implicate specific residues within the stalk that are critical for NFAT activation, which are likely involved in intramolecular interactions with membrane-embedded portions of the CTF. These observations are consistent with an adhesion GPCR-like and a stalk/Stachel sequence-dependent mechanism for PC1-mediated signaling.

FR-PO958

Protection Effect of Klotho on Cyst Growth in Autosomal Dominant Polycystic Kidney Disease

Xiaoyan Li, Lei Bu, Jiayi Lyu, Xia Zhou, Ewud Agborbesong, Xiaogang Li. *University of Kansas Medical Center, Kansas City, KS.*

Background: ADPKD is the most common hereditary renal disorder. Klotho is a protein with a single transmembrane domain, which is mainly expressed in the kidney

and acts as a co-receptor for fibroblast growth factor 23 (FGF23). The membrane bound extracellular domain of Klotho (soluble α-Klotho) can be cleaved and released into the blood stream. The soluble a-Klotho levels in ADPKD patients was decreased. However, the mechanisms for the downregulation of Klothos and its roles in regulating cyst development remain unknown.

Methods: To evaluate a potential role of Klotho in cyst pathophysiology, we investigated the expression of Klotho in cystic kidneys from ADPKD patients and *Pkd1*$^{flox/flox}$ conditional knockout mice by using immunohistochemistry staining, western blot and qRT-PCR. A recombinant mouse Klotho was used to evaluate its effects on cyst growth *in vivo*.

Results: We found that the expression of Klotho in the kidneys from ADPKD patients and Pkd1 knockout mice was decreased in addition to the decrease of the soluble a-Klotho levels in the serum of ADPKD patients. We further found that the methylation on the promoter of *Klotho* was increased in the genome of ADPKD patients and *Pkd1* mutant mice, which provided a mechanism for the downregulation of Klothos in ADPKD by the upregulated DNA methyltransferases (DNMTs). Treatment with the recombinant mouse Klotho delayed cyst growth as seen by decreased cystic index, kidney weight (KW)/ body weight (BW) ratios, blood urea nitrogen (BUN) levels, cyst lining epithelial cell proliferation, and increased cyst lining epithelial cell apoptosis in *Pkd1* mutant mice (all $p < 0.01$). Klotho treatment decreased the activation and phosphorylation of Akt, ERK, Rb, S6, and STAT3, whereas it increased the expression of p21. Since Klotho overexpression mice is normal and the average lifespan is about 20-30% longer that the wild type mice, overexpression or treatment with Klotho should not only protect renal function but also has less side effect.

Conclusions: The expression of Klotho was not only deceased in the serum of ADPKD patients but also in the kidneys from ADPKD patient and *Pkd1* knockout mice, which was regulated by the DNMTs mediated methylation on the promoter of *Klotho*. Treatment with the recombinant Klotho may be a viable new therapy for ADPKD.

Homeostasis of Phosphate Kinase PIPKIγ and Phosphatase INPP5E Modulates the Ciliary Accumulation of Polycystin2 in ADPKD

Chuan Chen. *Mayo Clinic, Rochester, MN.*

Background: Primary cilia defects lead to a panel of genetic human disorders, collectively termed as ciliopathies. Polycystin2 as a transmembrane protein functions to interact with PKD1 and maintains normal orientationof tubular architecture. Mutations in either PKD1 or PKD2 causes autosomal dominant polycystic kidney disease (ADPKD), which is also considered to be among the ciliopathy diseases. The function of phosphoinositides in mediating acute response, and acting as constitutive signals to help define organelle identity, are also emphasized by various human diseases. Recently, several studies implicated the involvement of PI species in ciliopathies. Also, Homeostasis of Phosphoinositide PI(4)P and PI(4,5)P2 functions significantly in cilia, and mutations in the phosphatases INPP5E can significantly increase ciliary PI(4,5)P2. But the relationship between regulated homoeostasis of PIs and ciliopathy proteins still remain to explore in the future.

Methods: Cell culture and transfection of DNA constructs and siRNA Immunofluorescence microscopy Immunoprecipitation and pull-down assay

Results: Phosphatidylinositol phosphate kinase PIPKIγ and phosphatase INPP5E cordinate to regulate homeostasis of PI(4)P and PI(4,5)P2 in cilia. Recently, we discovered In INPP5E knock-out MEF cells, endogenous ciliary pool of polycystin2 is significantly increased, while PIPKIγ depletion can partially reduce the accumulation of polycystin2. Also, in GANAB cell which always exhibits the absent ciliary localization of polycystin2, after knocking down INPP5E, we also observed increased PC2 accumulation. To verify this observation, we treated GANAB cell with the INPP5E inhibitor and found similar ciliary accumulation of PC2 after 24h treatment. As mutations in INPP5E increased ciliary PI(4,5)P2, we hypothesized that the enriched PI(4,5)P2 promoted PC2 accumulation. By overexpressing PIPKIγ kinase domain or its activator protein HYLS1 in GANAB cells, the increased PC2 signal in cilia also convinced our hypothesis.

Conclusions: By activating PIPKIr or inhibiting INPP5E, we found enriched PI(4.5) P2 is associated with ciliary PC2 accumulation. As reduced level of PC2 can always lead to kidney disease ADPKD, increased dosage of ciliary PC2 by PI(4,5)P2 may provide some new targets to understand the relationship between PIs and kidney diseases and also new methods for studying ADPKD.

Polycystin 1 (PC1) and NPHP1 Interact with Ciliary LKB1 to Regulate Inflammation, Providing New Insights into the Pathophysiology of Ciliopathy Phenotypes

E. Wolfgang Kuehn,[4] Amandine Viau,[2] Frank Bienaime,[3] Kamile Lukas,[4] Abhijeet Todkar,[4] Toma A. Yakulov,[4] Alexis Hofherr,[4] Florian Grahammer,[1] Oliver Kretz,[1] Roland Nitschke,[7] Tobias B. Huber,[1] Fabiola Terzi,[6] Michael Kottgen,[4] Melanie Boerries,[8] Hauke Busch,[5] Gerd Walz.[4] *[1]University Hospital Hamburg-Eppendorf, Hamburg, Germany; [2]INSERM U1151 / INEM, Paris, France; [3]INSERM U845 - Universite Paris Descartes - APHP, Paris, France; [4]University Freiburg Medical Center, Freiburg, Germany; [5]University of Lübeck, Lübeck, Germany; [6]INSERM, Paris, France; [7]University Freiburg, Freiburg, Germany; [8]DKFZ/DKTK, Freiburg, Germany.*

Background: Peritubular inflammation and fibrosis are key aspects of the renal ciliopathies nephronophthisis (NPH) and autosomal dominant polycystic kidney disease (ADPKD). In addition, macrophages drive cyst growth in the latter. Yet, the mechanism, how mutations in *NPHP* or *PKD* genes cause inflammation, is unknown.

Methods: Biochemistry, expression screens, molecular biology, imaging, transgenic animal models, immune phenotyping.

Results: We find that loss of *Lkb1* in the kidney results in an NPH phenotype. LKB1 interacts with NPHP1 and PC1 to regulate CCL2 expression through an intra-ciliary mechanism. Loss of *Lkb1* or *Pkd1* in the kidney leads to increased numbers of CCR2 positive mononuclear phagocytes. Simultaneous targeting of *Ccl2* or the essential cilia protein *Kif3a* in *Pkd1* mutant mice prevents CCL2 expression, macrophage expansion and leads to an ameliorated phenotype.

Conclusions: Our findings describe a novel physiological role for PC1 and NPHP1 as gatekeepers of peritubular immune cell numbers and explain how disturbance of this function results in an essential pathological process driving these entities.

FR-PO961

Deletion of Ift-A Gene, Thm1, Differentially Affects Cystic Kidney Disease in Pkd1 and Jck Mouse Models

Wei Wang, Luciane M. Silva, Bailey A. Allard, Robin L. Maser, Pamela V. Tran. *University of Kansas Medical Center, Kansas City, KS.*

Background: Primary cilia are signaling organelles that are built and maintained by intraflagellar transport (IFT) complexes B and A. The role of primary cilia in renal cystic disease is poorly understood. Ciliary dysfunction causes renal cystic disease, yet ablation of cilia via Ift-B gene deletion and pharmacological shortening of cilia attenuated renal cystic disease in *Pkd1* conditional knock-out (cko) and *jck* mutant mice, respectively. Such results suggest that cilia-mediated signaling within a renal cystic disease background may be pro-cystogenic. In contrast to deletion of an Ift-B gene, which often results in cilia loss, deletion of an Ift-A gene causes shortened cilia with protein accumulation in bulbous distal tips and can have opposing effects on signaling. Thus we examined the effect of Ift-A deficiency on a renal cystic disease background.

Methods: Using the ROSA-Cre^{ERT} recombinase, *Thm1* was deleted together with *Pkd1* in mice at 5 weeks of age, and in *jck* mutant mice at perinatal and postnatal (4 weeks) ages.

Results: *Thm1* deletion attenuated *Pkd1* cko renal cystic disease, decreasing BUN, cell proliferation, and P-STAT3 and P-ERK levels in *Thm1;Pkd1* dko kidneys relative to *Pkd1* cko kidneys. In contrast, *Thm1* deletion caused a combinatorial effect in *jck* mice. While *jck* mice showed renal cysts of collecting duct and Loop of Henle tubular origins, perinatal deletion of *Thm1* in *jck* mutants caused additional cysts of proximal tubular origin, and increased BUN. Deletion of *Thm1* at 4 weeks of age in *jck* mutants did not affect proximal tubules, but did increase cell proliferation and BUN in *Thm1*; *jck* double mutant females. Renal P-STAT3 and P-ERK levels correlated with disease severity in all mutants. Additionally, primary cilia were elongated in *jck* mice, and *Thm1* deletion in *jck* mice caused elongated cilia with IFT81 accumulation at the distal tips.

Conclusions: Attenuated renal cystic disease in *Thm1;Pkd1* dko mice suggests that *Pkd1* renal cystogenesis requires Ift-A, while the combinatorial effect in *Thm1*;*jck* double mutant kidneys suggests independent cyst-promoting roles for *Thm1* and *jck*. The contrasting effects of *Thm1* deletion in *Pkd1* and *jck* mutants may reveal divergent mechanisms underlying *Pkd1* and *jck* renal cystogenesis.

FR-PO962

Targeting Axoneme Polyglutamylation as a Potential Therapeutic Approach for ADPKD Treatment

Kai He. *Mayo Clinic, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited renal disorders, causing uncontrolled growth of cysts in kidney eventually leading to kidney failure. Primary cilia, the non-motile sensory devices on most cell surfaces, have been suggested as the key organelles in the pathogenesis of ADPKD. Proper targeting/maintenance of Polycystin 1(PC1)/ Polycystin 2(PC2) heterodimer on cilia surface are critical for cilia as mechano-sensor. Dysfunctional polycystins would compromise cilia-dependent signaling in maintaining normal nephron structure and lead to cystogenesis. Recently, accumulating evidence suggest a link between the level of functional Polycystins and disease severity, indicative of a dosage model of cystogenesis in ADPKD. Theoretically, restoring the functional level of cilia polycystins is a promising therapeutic strategy to delay or even prevent the cystogenesis. However, perusing this strategy is impeded by the lack of understanding of how the ciliary targeting/maintenance of polycystins is controlled.

Methods: 1. Immunoprecipitation and GST pull-down. 2. MDCK cyst formation in 3D culture. 3. Immunofluorescence microscopy. 4. Live-cell imaging. 5. Western blotting. 6. Bio-ID.

Results: Axoneme polyglutamylation is specifically regulated by a Joubert syndrome protein ARL13B and tuned by the balance of glutamylases TTLL5/6 and deglutamylase CCP5. ARL13B interacts with RAB11 effector FIP5 to promote the ciliary import of glutamylases. Hypoglutamylation caused by a deficient FIP5-regulated trafficking impairs the proper anchoring of PC2 in cilia. Remarkably, depletion of CCP5 effectively promotes hyperglutamylation and restores the ciliary PC2 in *GANAB*$^{-/-}$ cells. By implementing axoneme polyglutamylation as readout, we initiated a preliminary imaging-based drug screen. We identified several hits which could induce axoneme hyperglutamylation and increase PC2 dosage and, importantly, suppress MDCK cyst formation in 3D culture, implicating the therapeutic potential of targeting axoneme polyglutamylation for ADPKD.

Conclusions: 1. ARL13B-FIP5-regulated ciliary import of glutamylases is essential for axoneme polyglutamylation. 2. Axoneme polyglutamylation anchors ciliary PC2. 3. Restoring ciliary polycystins by increasing axoneme polyglutamylation could be a potential therapeutic approach for ADPKD treatment.

Genomic Background of Adults with Suspected Ciliopathy on Renal Biopsy

Takuya Fujimaru,[1] Takayasu Mori,[1] Shintaro Mandai,[1] Motoko Chiga,[1] Hiroaki Kikuchi,[1] Fumiaki Ando,[1] Yutaro Mori,[1] Koichiro Susa,[1] Kiyoshi Isobe,[1] Soichiro Iimori,[1] Naohiro Nomura,[1] Shotaro Naito,[1] Tomokazu Okado,[1] Tatemitsu Rai,[1] Katsushi Nagatsuji,[2] Kiyotaka Nagahama,[3] Eikan Mishima,[4] Toshio Mochizuki,[5] Akinari Sekine,[6] Junichi Hoshino,[6] Yoshifumi Ubara,[6] Shinichi Uchida,[1] Eisei Sohara.[1] *[1]Tokyo Medical and Dental University, Tokyo, Japan; [2]Osaka City General Hospital, Osaka, Japan; [3]Kyorin University, Tokyo, Japan; [4]Tohoku University, Miyagi, Japan; [5]Tokyo Woman's Medical University, Tokyo, Japan; [6]Toranomon Hospital, Tokyo, Japan.*

Background: In adult patients, ciliopathy is often difficult to make a precise diagnosis based on clinical features, because they usually have no specific findings such as retinitis pigmentosa or liver dysfunction. Furthermore, it is impossible to make a definitive genetic diagnosis by renal biopsy. Therefore, genetic testing is crucial for precise diagnosis and clinical management of the patients and their families.

Methods: We investigated 17 adult patients who were suspected ciliopathy by renal biopsy. Their pathological findings were tubular dilatation or thickening and lamellation of tubular basement membranes. All patients had no extrarenal findings (retinitis pigmentosa and liver function disorder) and no family history of ciliopathy. Comprehensive genetic testing was performed using capture-based next-generation sequencing for 69 genes that cause nine types of hereditary cystic kidney diseases (autosomal dominant polycystic kidney disease, autosomal recessive polycystic kidney disease, nephronophthisis, Joubert syndrome, Meckel syndrome, Senior-Loken syndrome, Bardet-Biedl syndrome, autosomal dominant tubulointerstitial kidney disease, etc.).

Results: Median age at renal biopsy was 55 (17–84) years old and seven patients (41%) were male. Through our analysis, two patients had homozygous full gene deletions of *NPHP1*. Additionally, compound heterozygous mutations in *NPHP3*, *NPHP4* and *CEP164* were found in each one patient. The patients who had pathogenic mutations were significantly younger than those without mutations (median, 26 years old vs 68 years old, $P = 0.045$, Mann-Whitney U test), and no mutations in the known genes were detected in those aged ≥50 years ($n = 9$).

Conclusions: In the adult patients suspected of ciliopathy by renal biopsy, 29% were genetically diagnosed as nephronophthisis by our comprehensive genetic testing. Additionally, older patients tend not to have any pathogenic mutations in the known genes.

FR-PO964

Deletion of Cep164 in the Collecting Duct Causes Polycystic Kidney Disease-Like Phenotype

Rannar Airik,[4] Merlin Airik,[4] Markus Schueler,[3] Carlton M. Bates,[1] Friedhelm Hildebrandt.[2] *[1]Children's Hospital of Pittsburgh, Pittsburgh, PA; [2]Boston Children's Hospital, Boston, MA; [3]University of Erlangen, Erlangen, Germany; [4]University of Pittsburgh, Pittsburgh, PA.*

Background: Nephronophthisis is an inherited cause of polycystic kidney disease that represents the most common cause of end-stage renal failure in the first three decades of life. Although all known genes associated with the disease phenotype localize to the cilia, the underpinning pathomechanisms remain largely unknown. We recently reported that mutations in *centrosomal protein 164*(*CEP164*) gene, cause nephronophthisis with extrarenal manifestations in humans. In order to study the function of Cep164 in mouse we generated a Cep164 transgenic mouse model.

Methods: Targeted *Cep164* ES cells were obtained from KOMP and injected into blastocysts to generate the *Cep164*$^{-/-}$ mice. Collecting duct-specific deletion of *Cep164* was achieved by crossing *Hoxb7-Cre* mice with *Cep164*$^{loxP/loxP}$ mice. Immunofluorescence staining was used to study the expression of ciliary proteins both in celture and in the kidney. Gross morphological characterization and tissue histological analysis of mutant mice was performed on E9.5 embryos, P7, P14 and P21 animals.

Results: Whole body deletion of *Cep164* resulted in mid-gestational lethality in mice. Molecular analysis revealed that the mutant animals lacked primary cilia and had impaired hedgehog signaling. To circumvent embryonic lethality, Cep164 was deleted from the kidney collecting duct using Hoxb7-Cre mice. Deletion of *Cep164* abolished cilia in the collecting duct cells of *Hoxb7-Cre*;*Cep164*$^{loxP/loxP}$ mice. The mutant kidneys developed normally until P7, after which they underwent a rapid cyst formation in the collecting ducts, which led to widespread structural damage, kidney failure and mortality by P21. Morphological and molecular analysis demonstrated that the rapid cyst growth was caused by uncontrolled cell proliferation in the collecting duct epithelium. Treatment with cyclin-dependent kinase inhibitors mitigated the rapid cyst growth in *Hoxb7-Cre*;*Cep164*$^{loxP/loxP}$ mice.

Conclusions: Our data demonstrate that abrogation of Cep164 leads to severe developmental abnormalities in early mouse embryogensis due to defective ciliary signaling. Conditional ablation of Cep164 in the collecting duct results in massive cyst growth in postnatal kidneys, resembling the pathogenesis of autosomal polycystic kidney disease. Together, Cep164 mouse represents a novel genetic model of autosomal recessive polycystic kidney disease.

FR-PO965

Consequences of Centrosome Numerical Aberrations in Cystic Kidney Disease

Moe Mahjoub,[1] Tao Cheng,[1] Lai Kuan Dionne,[2] Kyuhwan Shim.[1] *[1]Washington University School of Medicine/Nephrology, ST LOUIS, MO; [2]Washington University St. Louis, St. Louis, MO.*

Background: The centrosome and primary cilium act together as a cellular "hub" to regulate several important developmental signaling pathways. Defects in centrosome biogenesis can result in numerical aberrations in centrosome-cilium number, resulting in cells that either lose these structures or assemble too many. Importantly, numerical aberrations in centrosomes have been reported in various types of cystic kidney disease including ADPKD, nephronophthisis, and cystic kidneys of ciliopathy patients. What remains unknown are the consequences of centrosome numerical aberrations during embryonic kidney development, adult kidney homeostasis, and after renal injury.

Methods: To ablate centrosomes we utilized mice harboring a conditional allele of Cep120 (Cep120^{fl}), which we previously showed is essential for centrosome formation. To increase centrosome number, we used a transgenic mouse with a conditional overexpression allele of the kinase Plk4 (Tg::mChPlk4), known as the master regulator of centrosome duplication. Cep120^{fl}or Tg::mChPlk4 mice were crossed with Six2-Cre or Hoxb7-Cre animals to cause ablation/amplification of centrosomes in the metanephric mesenchyme or ureteric bud epithelium, respectively. Finally, these mice were mated with Slc34a1-Cre^{ERT}or Ksp-Cre^{ERT}to induce overexpression/loss of centrosomes in fully developed kidneys.

Results: Increasing centrosome number perturbed mitotic spindle morphology, ciliary assembly, and signaling pathways essential for growth of renal progenitors. This resulted in defective branching morphogenesis, renal hypoplasia, and rapid cystogenesis after birth. Moreover, centrosome amplification sensitized kidneys in adult mice, causing cystogenesis following ischemic renal injury. In contrast, loss of centrosomes did not have an adverse effect on progenitor cell proliferation, nor caused renal hypoplasia. In fact, loss of centrosomes resulted in enlarged kidneys that became rapidly cystic. Remarkably, loss of centrosomes during kidney homeostasis did not affect overall kidney function, nor cause cyst formation.

Conclusions: Our results highlight the heterogeneity of response to centrosomal numerical aberrations in different renal cells types and developmental stages. These results indicate that the underlying signaling changes are likely to be different, and suggest that therapeutic strategies will have to be developed separately for each case.

FR-PO966

Structure-Function Analysis of Inversin in Proximal Ciliary Patterning and Ciliary Transport

Lillian Xu,[1] Giada G. Bianchi,[2] Peter G. Czarnecki,[3] Jagesh V. Shah.[4] *[1]Princeton University, Crozet, VA; [2]Dana Farber Cancer Institute, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA; [4]Harvard Medical School, Boston, MA.*

Background: The proximal end of the primary cilium contains the inversin compartment (IC), comprised of four interacting ciliopathy proteins, inversin (INVS), NEK8, ANKS6 and NPHP3. Mutations in these proteins give rise to a multiorgan malformation syndrome, with L-/R-asymmetry perturbations, congenital heart defects and polycystic kidney disease. The most upstream factor in the IC is inversin, which is necessary for IC localization of the other proteins. The goal of this study is (1) to identify the structural determinants of inversin, necessary and/or sufficient for IC reconstitution and (2) to analyze ciliary length and intraflagellar transport (IFT) phenotypes in presence or absence of IC proteins.

Methods: CRISPR/Cas9-mediated gene knockout Lentiviral and retroviral transduction Immunofluorescence microscopy Immunoprecipitation Western-blot Live fluorescence cell imaging Kymograph analysis

Results: Immunofluorescence for FLAG-antigen revealed proximal ciliary localization only of FLAG-tagged full-length inversin and C-terminal truncations (INVS[745-1065] and INVS[554-1065]), but not N-terminal truncations INVS[1-553] and INVS[1-744]. Furthermore, only full-length inversin, and none of the partial add-backs were capable to localize NEK8 and ANKS6 to the IC. These results suggest that the ciliary signal sequence of inversin lies in its C-terminal domain, but the full-length protein, including the N-terminal ANK-repeat domain is required to assemble the other proteins in the IC. Moreover, we analyzed ciliary length and IFT-B particle velocities in CRISPR/Cas9-knockouts and full-length add-backs of IC proteins. Loss of inversin led to a >30% decrease in ciliary length and of IFT-B particle velocity, while a lentiviral full-length INVS add-back completely rescued both knockout phenotypes. An identical phenotype was observed with NPHP3, while NEK8 knockout revealed ~30% ciliary length increase and acceleration in IFT-B transport velocity.

Conclusions: As ciliary lengthening control and IFT particle velocity are physiological readouts for ciliary function, our results indicate that inversin is necessary and sufficient for ciliary homeostasis. The similar behavior of inversin and NPHP3 knockout phenotypes suggests that inversin may function through NPHP3, while NEK8 may play an independent role as a kinase.

Stat3 Activation Is Elevated in Pre-Cystic Kidneys of Thm1 Conditional Knock-out Mice

Luciane M. Silva, Sumedha S. Gunewardena, Pamela V. Tran. *University of Kansas Medical Center, Kansas City, KS.*

Background: Primary cilia are sensory organelles that mediate signaling pathways. Dysfunction of cilia leads to renal cystic disease. Multiple cellular and signaling aberrations contribute to renal cystogenesis, while the initiating molecular mechanisms remain unknown. In mice, perinatal global deletion of the ciliary gene, *Thm1,* causes renal cysts beginning at postnatal day (P) 15.

Methods: To identify molecular events that initiate renal cystogenesis in *Thm1* conditional knockout (cko) mice, we performed RNA sequencing on kidney RNA lysates of pre-cystic P9 and cystic P42, *Thm1* cko mice and control littermates. We reasoned that genes with significantly altered expression at both P9 and P42 would represent early initiation events leading to cystogenesis.

Results: *Endothelin 1, Egr2, Fos, Jun, Stat3,* endothelial *Vcam1,* immune genes, *Complement C3* and *Adcy7,* were upregulated at P9 and further upregulated at P42. Western blot analysis showed increased P-STAT3 at P10, and upregulation of multiple components of STAT and EDN1-MAPK signaling pathways at P42. Immunohistochemistry revealed more intense nuclear localization of P-STAT3 in epithelial cells of non-dilated and dilated tubules at P20, and in cyst-lining epithelial cells and interstitial cells at P42. To study the connection between primary ciliary dysfunction and upregulated STAT3 signaling, we have generated *Thm1* knock-down human renal 293T clonal cell lines. These cell lines show shortened primary cilia with IFT81 accumulation in a bulb-like structure at the distal tip, indicative of a retrograde ciliary protein trafficking defect.

Conclusions: Our data reveal upregulated Stat3 activation in pre-cystic *Thm1* cko kidneys and suggest that simultaneous alteration of gene expression and signaling in renal epithelial, vascular and immune cells may potentiate renal cyst initiation. We are examining mechanisms by which *Thm1*-deficient cilia cause increased Stat3 activation and are inhibiting Stat3 pharmacologically in *Thm1* cko mice. This may reveal initiating mechanisms underlying *Thm1*-deficient renal cystogenesis.

FR-PO968

Collecting Duct-Specific Deletion of the Transcription Factor Grainyhead-Like 2 (Grhl2) Aggravates Cyst Growth in Polycystic Kidney Disease

Zeliha Y. Yurtdas,[1,5] Ergin Kilic,[4] Emanuel Wyler,[5] Peter Boor,[3] Kai M. Schmidt-Ott.[2,5] *[1]Berlin Institute for Urologic Research, Berlin, Germany; [2]Charite - Universitaetsmedizin Berlin, Berlin, Germany; [3]RWTH University Aachen, Aachen, Germany; [4]Institut für Pathologie am Klinikum Leverkusen, Leverkusen, Germany; [5]Max Delbrück Center for Molecular Medicine, Berlin, Germany.*

Background: Polycystic kidney disease (PKD) is a genetic disorder characterized by the development of cysts as a result of abnormalities in proliferation, apoptosis and dedifferentiation of the renal epithelium. The transcription factor Grhl2 is highly expressed in the collecting duct cells of the kidney and controls epithelial barrier function in the mouse kidney. The collecting duct is known to be an important source of cysts in PKD, but whether Grhl2 is involved in cyst formation and growth is not known.

Methods: To investigate the role of Grhl2 in PKD pathogenesis, we first examined GRHL2 protein expression in kidney samples from patients with autosomal dominant PKD (ADPKD). We then studied the effects of a collecting duct-specific Grhl2 deletion on a mouse model with slowly progressive PKD caused by overexpression of the human MYC proto-oncogene. We compared renal phenotypes of HoxB7-Cre; R26StopFLMYC; $Grhl2^{flox/flox}$ mice and HoxB7Cre; R26StopFLMYC mice using functional, histological assays and gene expression profiling.

Results: Analyses of patient samples with ADPKD (n=6) revealed that GRHL2 protein was downregulated by 65% in collecting duct-derived cyst-lining epithelia when compared with its expression in healthy collecting ducts (n=4). HoxB7Cre; R26StopFLMYC mice developed slowly progressive bilateral polycystic kidneys that mimicked human ADPKD. Collecting duct-specific deletion of Grhl2 in the kidneys of HoxB7Cre, R26StopFLMYC mice (HoxB7-Cre; R26StopFLMYC; $Grhl2^{flox/flox}$) markedly accelerated PKD progression, led to a more aggressive bilateral cystic kidney disease, and caused early lethality. Proliferation and apoptosis rates of cyst-lining epithelia were found to be significantly higher in HoxB7Cre; R26StopFLMYC; $Grhl2^{flox/flox}$ mice compared with HoxB7Cre; R26StopFLMYC mice. Furthermore, a genome-wide analysis of differentially regulated genes in HoxB7Cre; R26StopFLMYC; $Grhl2^{flox/flox}$ mice compared with HoxB7-Cre; R26StopFLMYC mice identified deregulation of genes involved in cell-cycle regulation and epithelial cell polarity.

Conclusions: Our data indicate a role for Grhl2 and its target gene program in the progression of collecting duct-derived cyst formation in PKD. Targeting Grhl2 activity may constitute a novel strategy to limit cyst progression.

Cyst Growth in the Anks6pR823W Model of ADPKD Is Reduced by the Anks3I454E Mutation

Euan Clark,[1] Christian Gosmann,[1] Hermann-Josef Groene,[2] Dominique Gauguier,[3] James Bowie,[4] Sigrid C. Hoffmann.[1] *[1]Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany; [2]German Cancer Research Center, University of Heidelberg, Heidelberg, Germany; [3]INSERM, Paris, France; [4]University of California, Los Angeles, Los Angeles, CA.*

Background: The $Anks6^{R823W}$ mutation in rats causes an ADPKD-like phenotype with massive renal cyst growth leading to kidney failure and death. Previously we demonstrated that this mutation prevents the Anks6-SAM domain from binding to the Anks3-SAM domain and disrupts the spatial expression of both proteins. Since Anks6-Anks3 binding prevents Anks3-Anks3 SAM domain interactions it is possible that increased formation of Anks3 homopolymers is part of the pathological process. Thus, we created a rat with an $Anks3^{I454E}$ mutation in the SAM domain where Anks3 can no longer bind to itself but can interact with Anks6.

Methods: The $Anks3^{I454E}$ mutation was generated using CRISPR-Cas9 in Sprague Dawley rats. Clinical parameters in 24-h urine and blood plasma were determined to evaluate renal function. Histological analysis and western blots were performed by standard techniques. These rats were crossed into the TGR-CMV-$Anks6^{pR823W}$ line and the kidneys of the offspring investigated at 2 and 4 weeks. Cysts were counted and scored using a 4 point scale.

Results: No histological abnormalities were observed in the kidneys of $Anks3^{I454E/I454E}$ rats up to 1 year of age. There was an increase in urine osmolarity and a decrease in the concentration of plasma parameters in these rats, probably due to increased water reabsorption in the kidney, supported by an increase in aquaporin 2 expression. In TGR-CMV-$Anks6^{pR823W}Anks3^{WT}$ rats, cyst growth started within the first 10 days after birth leading to massive kidney hypertrophy. In both the 2 and 4 week old TGR-CMV-$Anks6^{pR823W}$ carrying the $Anks3^{I454E}$ mutation there was a significant reduction in the kidney to body weight ratio and cyst score with the largest reduction in $Anks3^{I454E/I454E}$ rats versus TGR-CMV-$Anks6^{pR823W}Anks3^{WT}$ rats (2 weeks: kw/bw p=0.0003, cyst score p=0.0001; 4 weeks: kw/bw p=0.0086, cyst score p=0.0001).

Conclusions: 1) The disruption of Anks3-Anks3 binding via the SAM domain is not pathological in rats and causes increased water reuptake in the kidney. 2) The disruption of Anks3-Anks3 binding in the $Anks6^{pR823W}$ rat model of ADPKD significantly reduces the rate of cyst growth and this effect is increased in $Anks3^{I454E}$ homozygous versus heterozygous rats. *This study was supported by the grant of the NIH (5RO1DK100482) to JB and SH.*

FR-PO970

Biallelic ANKS6 Variants Causing Late Onset Ciliopathy with CKD in Adulthood

Markus Schueler,[3] Bernt Popp,[1] Karl Knaup,[2] Michael S. Wiesener.[3] *[1]Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Erlangen, Germany; [2]University of Erlangen-Nuremberg, Erlangen, Germany; [3]University Hospital Erlangen, Erlangen, Germany.*

Background: The progressive and irreversible conditions summarized under the term "Chronic kidney diseases" (CKD) are a heterogeneous group of disorders with significant health and economic effects. Affected individuals and their nephrologists are often unaware of underlying causes. Diagnostic tools used in clinical practice, such as kidney biopsy do not always yield to a definitive diagnosis. High-throughput sequencing methods have advanced our ability to identify the underlying molecular etiology in families with unknown origin of CKD.

Methods: Whole exome sequencing (WES) was performed in two sisters from a non-consanguineous family of German descent who presented with CKD onset in mid-adulthood (>30 years of age). DNA was extracted from whole blood, enriched, and sequenced on a HiSeq2500. In addition patient-derived fibroblasts from skin biopsies were cultured for performing functional studies via immunoblotting.

Results: WES detected two disease associated variants c.[934G>C;938A>C], p.[(A312P);(D313A)]) and c.1973-3C>G in the *ANKS6* gene in both affected siblings. Segregation testing by Sanger sequencing confirmed compound heterozygosity. The ciliary protein ANKS6 localizes to the proximal compartment of the cilium, where it regulates ciliary signaling. Mutations in *ANKS6* are known to cause Nephronophthisis-related ciliopathies in humans, including laterality defects and congenital hepatic fibrosis. Renal biopsy of both patients showed tubulointerstitial fibrosis and glomerulosclerosis. Careful clinical examination does not reveal any extra-renal findings in both affected individuals. Interestingly, immunoblotting studies from patient-derived fibroblasts show a nearly complete loss of the ANKS6 protein and suggest an effect on gene dosage for both the missense and the splicing variant.

Conclusions: In summary, we confirmed the diagnosis of an ANKS6-associated Nephronophthisis which is typically syndromic and juvenile-onset in two adults with CKD onset in mid-adulthood, highlighting the extreme heterogeneity of CKD. Offering genetic testing to families with renal disease of unknown origin can improve our knowledge of the clinical course in CKD entities, leads to a better understanding of pathophysiological mechanism and may help to develop novel therapeutic strategies, possibly also of relevance to the broader field of kidney diseases.

FR-PO971

The Exhaustive Screening Tool Is Superior to the Simplified Version to Identify Pediatric Patients with a Pathogenic HNF1β Genotype

Mallory L. Downie,[1] Rebekah Jobling,[1] Natasha Jawa,[1] Damien G. Noone,[1] Mathieu Lemaire.[2] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]Hospital for Sick Children, Toronto, ON, Canada.*

Background: Pathogenic genotypes involving hepatocyte nuclear factor-1 beta (HNF1β) are now recognized as the most frequent cause of monogenic congenital anomalies of the kidney and urinary tract (CAKUT), a leading cause of paediatric-onset chronic kidney disease (CKD). Identifying these patients is challenging due to the substantial phenotypic heterogeneity across age groups. We sought to characterize the paediatric phenotype of HNF1β disease and to assess the utility of established screening tools (exhaustive or simplified) for pediatric patients with renal cysts.

Methods: Between 2011 and 2018, 45 patients with renal cysts from our institution were tested for mutations in the gene HNF1β.

Results: Testing was positive in 17/39 (44%) unrelated kindreds (total, 21/45 patients) with median age at diagnosis of 6.1 years (range 0.1-17.3). A heterozygous deletion encompassing the entire HNF1β gene was detected in all but 2/17 kindreds that had either a gene duplication or a point mutation, respectively. Analysis of the three multiplex kindreds revealed significant intrafamilial phenotypic heterogeneity. The most common clinical features included hypomagnesemia (53%, 9/17), neurodevelopmental problems (43%, 9/21), hyperuricemia (50%, 4/8), hyperparathyroidism (33%, 3/9), and pancreatic hypoplasia (14%, 3/21). Clinical features commonly reported in adults were rare: no patients with hypokalemia or early-onset gout, and two patients with either maturity-onset diabetes of the young (MODY) or unexplained elevated liver enzymes. The exhaustive screening tool identified all affected patients but required testing 80% of the patients who tested negative (19/24). In contrast, the simplified screening tool called for genetic testing for only 4/45 patients, all of whom ultimately tested positive.

Conclusions: We observed that patients harboring a HNF1β mutation display variable phenotypic penetrance and expressivity. This heterogeneity was even noted among members of multiplex kindreds. A comparison of the simplified and exhaustive screening tools applied to pediatric patients with renal cysts reveals that the latter is more sensitive to identify patients with pathogenic HNF1β genotypes.

FR-PO972

ADTKD-HNF1B Has a Slow-Progressive Phenotype in Childhood—with the Exception of Very Early Onset Cases: Results of the German Multicenter HNF1B Childhood Registry

Stefanie Weber,[1] Christine Okorn,[2] Martin Kömhoff,[1] Peter F. Hoyer.[2] HNF1B Registry Study Group *[1]University Children's Hospital Marburg, Marburg, Germany; [2]University Hospital Essen, Essen, Germany.*

Background: *HNF1B* nephropathy is part of the autosomal dominant tubulointerstitial kidney disease spectrum (ADTKD) and affects pediatric patients with bilateral (cystic) dysplasia. The clinical variability, the absence of genotype-phenotype correlations, and limited long-term data render counseling of affected families difficult.

Methods: Longitudinal data of 62 children with ADTKD-*HNF1B* was obtained in a multicenter approach. Genetic family analysis was performed in 30/62 cases.

Results: 87% of ADTKD-*HNF1B* patients had bilateral dysplasia, 74% visible bilateral and 16% unilateral renal cysts at the end of observation. Cyst development was non-progressive in 72% with a mean GFR loss of -0.33 ml/min/1.73qm per year (±8.9). In patients with an increase in cyst number, the annual GFR reduction was -2.8 ml/min/1.73qm (±13.2), in the total cohort -1.0 ml/min/1.73qm (±10.3). A subset of ADTKD-*HNF1B* patients differs from this group and develops ESRD at very early ages < 2 years. Hyperuricaemia (37%) was a frequent finding at young age (median 1 year), whereas hypomagnesemia (24%), elevated liver enzymes (21%) and hyperglycaemia (8%) showed an increased incidence in the teenaged child. Genetic analysis revealed no genotype-phenotype correlations but a significant parent-of-origin effect with a preponderance of 78% of maternal inheritance in dominant cases.

Conclusions: In most children, ADTKD-*HNF1B* has a non-progressive course of cyst development and a slow-progressive course of kidney function. A subgroup of patients develops ESRD at very young age < 2years requiring special medical attention. Patients will be annually followed in the registry and new patients can be included at any time.

FR-PO973

Clinical Characteristics of HNF1B Related Disorders in Japanese Population

China Nagano,[1] Naoya Morisada,[3] Nana Sakakibara,[1] Tomohiko Yamamura,[1] Kandai Nozu,[1] Kazumoto Iijima,[1] Shogo Minamikawa.[2] *[1]Department of Pediatrics, Kobe University Graduate School of Medicine, Hyogo, Japan; [2]Kobe University Graduate School of Medicine, Kobe, Japan; [3]Department of Clinical Genetics, Hyogo Prefectural Kobe Children's Hospital, Hyogo, Japan.*

Background: Hepatocyte nuclear factor 1β (*HNF1B*) gene is located at chromosome 17q12 and is known as the causative gene for the renal cysts and diabetes syndrome (RCAD). It is also well known that various phenotypes of congenital anomalies of the kidney and urinary tract (CAKUT) or Bartter-like electrolyte abnormalities can be caused by *HNF1B* variants. In addition, 17q12 deletion syndrome shows multi-system disorders as well as RCAD.

Methods: We conducted gene screening for cases with RCAD, CAKUT and Bartter-like syndrome cases. As a result, 31 cases were detected heterozygous variants or whole gene deletions in *HNF1B* (heterozygous variant: 18 cases and deletion: 13 cases). All cases with deletion were diagnosed with 17q12 deletion syndrome confirmed by MLPA or array CGH. A retrospective review of clinical data was conducted for these cases.

Results: Most cases had morphological abnormalities in the renal urinary tract system. Diabetes developed in 11 cases (38%). Hyperuricemia and hypomagnesemia were associated with 5 cases (17%) and 12 cases (41%), respectively. Pancreatic malformations were detected in 6 cases (21%). Nine patients (31%) had liver abnormalities. When data were classified by mutation types, the eGFR (estimated glomerular filtration rate) levels were significantly lower in the patients who carried heterozygous variants compared with those in the patients who carried deletions (median: 37.9 ml/min/1.73 m^2 vs 55.9 ml/min/1.73 m^2, p=0.0264). Patients who carried deletions had higher frequencies of hypomagnesemia (p=0.0005) and neurological complications (p=0.0064) than those who carried variants.

Conclusions: We presented the clinical characteristics of *HNF1B* related disorders. To predict the renal prognosis or onset of extra renal complications, accurate genetic diagnosis at an early age is important. *HNF1B* related disorders show various clinical symptoms and should be noted for accurate diagnosis.

FR-PO974

Extracellular Vesicle Induction of Cortical Collecting Duct Cell Growth

John J. Bissler,[1] Sharon L. Barone,[2] Kamyar A. Zahedi,[2] Manoocher Soleimani.[2] *[1]Le Bonheur Children's Hospital and St. Jude Children's Research Hospital, Memphis, TN; [2]University of Cincinnati, Cincinnati, OH.*

Background: Tuberous sclerosis complex (TSC), a genetic tumor suppressor syndrome, is caused by inactivation of either *TSC1* or *TSC2* genes. Renal manifestations include early onset chronic kidney disease, angiomyolipomata and multiple patterns of renal cystic disease. The mechanism of cystogenesis has been assumed to be somehow linked to the *PKD1* gene that is adjacent to the *TSC2* gene, though the precise mechanism remains unclear.

Methods: We used transgenic animals with aquaporin-2 promoter driven Cre recombinase and renin-1c promoter regulated Cre recombinase to specifically inactivate the Tsc2 and Tsc1 genes in principal cells (*Aqp2CreTsc2*) and renal pericytes (*Ren1cCreTsc1*), respectively. We also used CRISPR/CAS9 technology to disrupt the *Tsc1* or *Tsc2* gene in a principal cell line and used ultracentrifugation to isolate extracellular vesicles. Conditioned media or isolated extracellular vesicles were used in cell culture studies with M1 intercalated cell line as a target. We measured the phosphorylation of S6 expression as a read out.

Results: Both animals develop renal cystic disease, by far more prominently in the renal cortex, and the cysts highly expressed pS6. Cystic epithelium was predominantly type A intercalated cells, and principal cells seemed to drop out with time in the *Aqp2CreTsc2* renal cysts. The cysts in both animals continued to express tuberin and hamartin, and we noted extracellular vesicles in some of the smaller cyst lumens of perfused animals. Using a tissue culture model we found that principal cell extracellular vesicles activated intercalated cell mTORC1 activity, and this was exaggerated if either the Tsc1 or Tsc2 gene was disrupted.

Conclusions: We demonstrate that mice with principal cell specific *Tsc2* inactivation and mice with renal pericyte *Tsc1* inactivation develop cortical cystic disease comprised of type A intercalated cells. The cystic epithelium appears to have an activated mTORC1 axis, though still express hamartin and tuberin. Cell culture experiments suggest a role for extracellular vesicles in this growth activation signal.

FR-PO975

Manifestations of Renal Disease in Adult Patients with Tuberous Sclerosis Complex–Reference Center Experience

Agnieszka Tarasewicz,[1] Alicja Debska-Slizien,[1] Beata Rutkowska,[2] Edyta Szurowska,[2] Anna B. Marcinkowska,[2] Marcin Matuszewski.[3] *[1]Department of Nephrology, Transplantology and Internal Medicine, Medical University of Gdansk, Gdansk, Poland; [2]Department of Radiology, Medical University of Gdansk, Gdansk, Poland; [3]Department of Urology, Medical University of Gdansk, Gdansk, Poland.*

Background: Renal involvement is a considerable cause of mortality and morbidity in tuberous sclerosis complex (TSC) patients and include angiomyolipomas (AMLs), cysts and malignant tumors. Surgical treatment of life-threatening bleeding from AMLs additionally impairs kidney function, while treatment with mammalian target of rapamycin inhibitor (mTORI) is effective in preventing bleeding complications and preserving renal function. However, data concerning proteinuria, albuminuria and hypertension in TSC patients, as possibly modifiable risk factors of chronic kidney failure (CKF) is limited.

Methods: The initial assessment was performed in 32 TSC patients admitted to reference academic TSC center from 03/2016 to 01/2018. Study group consisted of 15 men and 17 women in the mean age of 32±11.6 yrs. Prevalence of renal manifestations, CKF, hypertension, proteinuria (urinary protein-to-creatinine ratio;uPCR) and albuminuria (urinary albumin-to-creatinine ratio;uACR) were studied.

Results: TSC renal manifestations were: AMLs (29/32; 91%), cysts (17/32; 53%) and renal cell carcinoma (1/32; 3%). 25% patients were previously nephrectomised due to complications related to AMLs. eGFR<60 mL/min was found in 19% individuals. The incidence of proteinuria (uPCR>150mg/g), albuminuria (uACR>30mg/g) and hypertension were 41%, 44% and 34%, respectively. TSC patients after nephrectomy in comparison with non-nephrectomised patients had statistically significant decline of kidney function-higher

creatinine level (1.48±0.52mg/dL vs 0.97±0.63mg/dL) and lower eGFR (52.5±21.4mL/min vs 93.67±30.91mL/min) and also higher albuminuria (uACR 346.7±677.6mg/g vs 49.41±90.27mg/g);($p<0.05$). The differences in prevalence of hypertension (50% in patients after nephrectomy vs 29% in non-nephrectomised;$p=0.397$) and quantity of proteinuria (uPCR 579.3±1003.2mg/g vs 263.8±516.7mg/g;$p=0.25$) were insignificant.

Conclusions: The incidence of renal manifestations was consistent with previous reports. Adult TSC patients have relatively high prevalence of CKF as well as its potentially modifiable risk factors, hypertension, proteinuria, albuminuria. The previous nephrectomy seems to have a significant impact on kidney function, that supports the invaluable role of pre-emptive treatment of AMLs with mTORI to prevent need of surgery.

FR-PO976

Renal Involvement in Tuberous Sclerosis Complex

Agne Cerkauskaite,[1] Marius Miglinas,[1] Dovile Jonuskaite,[1] Ausvydas Patasius,[2] Augustina Jankauskiene,[1] Rimante Cerkauskiene.[1] *[1]Institute of Clinical Medicine, Faculty of Medicine, Vilnius University, Lithuania, Vilnius, Lithuania; [2]National Cancer Institute, Faculty of Medicine, Vilnius University, Lithuania, Vilnius, Lithuania*.

Background: Tuberous sclerosis complex (TSC) is a rare, genetic disorder caused by alterations in tumor suppresor proteins such as hamartin or tuberin leading to uncontrolled activity of the mTOR pathway and, consequently, to the development of the tumors, known as hemartomas. TSC manifestation is multisystemic including renal, cardiac, pulmonologic, neurological, cutaneous lesions and can differ depending on disease related genetic variants. Mutations of at least two different genes, the TSC1 gene or the TSC2 gene, are known to cause TSC. We analyzed clinically or genetically diagnosed TSC with different TSC gene mutations and disease manifestations, focusing on renal findings: renal cysts (RC), angiomyolipomas (AML) or renocellular carcinoma (RCC).

Methods: A retrospective data analysis of the clinical and radiographic (CT or MRI) records of the patients with TSC was made.

Results: 25 patients (14 children and 11 adults), 13 females and 12 males were included. Diagnosis was genetically confirmed in 56% patients, with TSC2 and TSC1 genes 64,3%, 35,7% respectively. All patients had more than one organ involvement. Renal lesions were seen in 72 % of patients with an average age at diagnosis 25,3 years (2 – 60 y). AML occurred in 72,2%, bilateral RC - in 44,44%, while no RCC was observed. Both cysts and AML were significantly more frequent and more numerous in *TSC2* comparing with *TSC1*. Bilateral renal cysts were presented in 50% of all AML cases. TSC2 gene mutation was not more common in patients with combination of AML and renal cysts than in those with AML as would be expected. Two patients with bilateral AML underwent nephrectomy before systemic disease was suspected. Disease progression correlated with the age ($p<0.05$). Everolimus was introduced in 4 patients, 1 of them had TSC, 2 patients had TSC2 mutations and 1 was not genetically confirmed. Response to the treatment was successful in 89% at 6 months period and did not differ between different mutation types ($p<0.01$).

Conclusions: Renal involvement is high and significantly associated with genotype, TSC2 mutation has more severe manifestation. Everolimus showed effectiveness in reducing angiomyolipoma in all types of mutations.

FR-PO977

Metformin Ameliorates Kidney Injury of Tsc1ptKO Mice Through AMPK/AKT Pathway

Yili Fang, Zhigang Zhang, Huijuan Wu. *Department of Pathology, School of Basic Medical Sciences, Fudan University, Shanghai, China.*

Background: As an intractable branch among chronic kidney diseases, tuberous sclerosis complex (TSC) in kidney usually expresses kidney enlargement, increasing cysts, interstitial fibrosis and serious damage on renal function. One of the critical mechanism underlies TSC is aberrant down-regulation of 5'AMP-activated protein kinase (AMPK) phosphorylation. Indicated by several researches, metformin showed excellent functions in reducing inflammation and inhibiting proliferation through AMPK phosphorylation, as well as decreasing the level of interstitial fibrosis. Therefore, we investigated whether metformin could induce the amelioration of kidney injury in TSC.

Methods: Firstly, we established the *Tsc1* knockout in proximal tubule ($Tsc1^{ptKO}$) mice model, which caused striking kidney growth. Then we performed metformin by intraperitoneal injection in $Tsc1^{ptKO}$ mice by 1 week of age for 1-3 weeks every day.

Results: We observed that metformin significantly reduced kidney growth in $Tsc1^{ptKO}$ mice by 4 weeks of age, with obvious shrunken kidneys size, decreased amount and size in cysts as well as obvious decline in proteinuria and serum creatinine level. Besides, immunochemistry showed metformin inhibited proliferation and induced apoptosis of proximal tubular epithelial cells in $Tsc1^{ptKO}$ mice, meanwhile reduced inflammation and interstitial fibrosis. The above alterations were induced by apparent AMPK phosphorylation under the influence of metformin, which was confirmed by immunoblotting and immunochemistry.

Conclusions: Altogether, these results proved the amelioration effect of metformin on the kidney injury of $Tsc1^{ptKO}$, which provides an innovative idea for clinical treatment on TSC and related kidney diseases.

FR-PO978

Proliferation of Intercalated Cells in Cystic Epithelium of Principal Cell-Specific Tsc1-KO Mice

Sharon L. Barone,[1,2] Kamyar A. Zahedi,[1,2] Marybeth Brooks,[1,2] Stefan Somlo,[3] Jie Xu,[1] John J. Bissler,[4] Manoocher Soleimani.[1,2] *[1]University of Cincinnati, Cincinnati, OH; [2]Research Services, Veterans Affairs Medical Center, Cincinnati, OH; [3]Yale University, New Haven, CT; [4]Le Bonheur Children's Hospital and St. Jude Children's Research Hospital, Memphis, TN*.

Background: Tuberous sclerosis complex (TSC) is a genetic disorder caused by inactivation of either TSC1 or TSC2 genes and affects multiple organs. In the kidney, TSC presents with development of angiomyolipomas and renal cysts, which lead to renal failure. Despite our knowledge regarding its genetics, little is known about the promotion of cyst growth and enlargement in TSC.

Methods: Mice with principal cell specific inactivation of Tsc1 (Tsc1 floxed mice crossed with Aqp-2-promoter driven cre mice) develop an increasing number of cortical cysts as they age.

Results: Single and double immunofluorescence labeling studies demonstrated that cyst epithelium is predominantly comprised of A-intercalated (IC) cells, as shown by strong expression of apical H^+-ATPase and pro-renin receptor (PRR). Cyst formation in Tsc1-KO mice is preceded by extensive areas of proliferation in the cortical collecting ducts (CCD), which are exclusively comprised of mitotically active (PCNA-positive) A-intercalated cells. This is distinct from a mouse model of ADPKD (Pkd1-KO mice), in which CCD-derived cystic epithelium contains numerous principal cells. Expression of Foxi1 transcription factor, a master regulator of intercalated cells and their acid base transport machinery, robustly increased in kidneys of young Tsc1-KO mice. Kidney cysts show mTORC1 activation in intercalated cells as determined by phosphorylation of p70-S6 kinase 1 (S6K1). Kidney cysts from humans with TSC display a similar preponderance of intercalated cells in their epithelium.

Conclusions: We propose that the robust proliferation and propagation of A-intercalated cells is crucial to kidney cystogenesis in Tsc1-KO mice. We further propose that unlike cysts in PKD, which respond to AVP antagonism by reduction in their fluid secretion and size, TSC1 cysts, which hardly contain any principal cells will be resistant to AVP antagonists. We suggest that the pathogenesis of kidney cyst formation and fluid secretion into the cyst in TSC is distinct from PKD, is associated with proliferation of intercalated cells and gradual disappearance of principal cells in cyst epithelium, is independent of AVP-receptor/ADH axis and is energized by H^+-ATPase and Pro-renin Receptor.

The C-Term of Human Fibrocystin Regulates STAT3-Dependent Transcription

Amrei Maxi Mandel,[1] Claudia Dafinger,[1,2] Thomas Benzing,[3,4] Thomas Weimbs,[5] Bernhard Schermer,[3,4] Max Liebau.[3,6] *[1]Cologne Excellence Cluster on Cellular Stress Responses in Ageing-Associated Diseases (CECAD), University of Cologne, Cologne, Germany; [2]Department of Pediatrics and Department II of Internal Medicine, University Hospital of Cologne, Cologne, Germany; [3]Cologne Excellence Cluster on Cellular Stress Responses in Ageing-Associated Diseases (CECAD) and Systems Biology of Ageing Cologne (Sybacol), University of Cologne, Cologne, Germany; [4]Department II of Internal Medicine and Center for Molecular Medicine (CMMC), University Hospital of Cologne, Cologne, Germany; [5]University of California Santa Barbara, Santa Barbara, CA; [6]Department of Pediatrics and Center for Molecular Medicine (CMMC), University Hospital of Cologne, Cologne, Germany*.

Background: Autosomal recessive polycystic kidney disease (ARPKD) is the rare but severe form of PKD characterized by early fibrocystic renal alterations and congenital hepatic fibrosis. The disease is mainly caused by mutations in *PKHD1*, encoding the 4,074aa transmembrane protein Fibrocystin (FC). The molecular mechanisms leading to ARPKD and Fibrocystin's cellular function are poorly understood. Experimental and clinical data suggest that there may be partial overlap with pathomechanisms of autosomal dominant PKD.

Methods: We evaluated effects of the C-term of human FC on STAT3-dependent transcription and the SRC-STAT3 axis by applying standard techniques such as immunoprecipitation, immunochemistry and luciferase reporter assays.

Results: We identify a link of human FC to the regulation of STAT3-dependent transcription with activation of factor STAT3 in cyst-lining epithelial cells of ARPKD patient kidneys. Strikingly, a C-terminal truncation of FC negatively regulates SRC- and JAK2-dependent STAT3 activity and can be found in a common protein complex with SRC and JAK2. C-terminal FC also modulates SRC-dependent STAT3-activation after SRC-activation by forskolin-induced increased intracellular levels of cAMP. Mutation analyses point to a role of C-term FC in the activation of SRC.

Conclusions: This data is in accordance with recent observations that showed a beneficial effect of both SRC and STAT3 inhibitors in orthologous and non-orthologous rodent models of PKD. We present insights into potential molecular mechanisms by providing evidence for a regulation of the SRC-STAT3-axis by human C-terminal FC.

Human Urine Derived Renal Epithelial Cells Provide Insights into Kidney Specific Alternate Splicing Variants in NPHP3

Holly R. Mabillard,[2] Elisa Molinari,[3] Friedhelm Hildebrandt,[4] Carsten Bergmann,[5] John A. Sayer.[1,2] *[1]Newcastle University, Newcastle, United Kingdom; [2]Renal Services, Newcastle Hospitals NHS Trust, Newcastle, United Kingdom; [3]University of Newcastle, Newcastle upon Tyne, United Kingdom; [4]Boston Children's Hospital, Boston, MA; [5]Center for Human Genetics, Bioscientia, Ingelheim, Germany*.

Background: The majority of multi-exon genes undergo alternative splicing to produce different mRNA transcripts and this may occur in a tissue-specific manner. Assessment of mRNA transcripts isolated from blood samples may sometimes be unhelpful in determining the pathogenicity of putative splice-site variants affecting kidney specific mRNA transcripts.

Methods: Here we present data demonstrating the power of using human urine derived renal epithelial cells (hUREC) as a source of kidney RNA. We report clinical and molecular genetic data from 3 affected cases from two families all with end stage renal disease by 15 years of age.

Results: In both families, heterozygous variants which are predicted to affect function in NPHP3 were found on one allele, in combination with a synonymous SNV (c.2154C>T; p.Phe718=, 18 base pairs from the exon-intron boundary within exon 15 of NPHP3. The only mRNA transcript amplified from wild type whole blood showed complete splicing out of exon 15. Urine samples obtained from control subjects and the father of family 2, who carried the synonymous SNV variant, were therefore used to culture hUREC and allowed us to obtain kidney specific mRNA. Control kidney mRNA showed normal splicing of exon 15 whilst the mRNA from the patient's father confirmed evidence of a heterozygous alternate splicing of exon 15 of NPHP3.

Conclusions: Analysis of RNA derived from hUREC allows for a comparison of kidney specific and whole blood RNA transcripts and for assessment of the pathogenicity of putative splice variants leading to end stage kidney disease.

CD206 Positive Renal Resident Macrophages Are Associated with Cyst Progression in a Juvenile-Induced Cilia Mutant Mouse Model

Zhang Li, Kurt Zimmerman, Michal Mrug, Bradley K. Yoder. *University of Alabama at Birmingham, Birmingham, AL*.

Background: Polycystic kidney disease (PKD) is one of the most common inherited genetic renal diseases. Abnormalities in the structure or function of primary cilia are one cause of kidney cyst growth in animal models of PKD and human patients, but the mechanism of how primary cilia regulate cystogenesis is largely undefined. Recent data suggests that macrophages are associated with cyst formation in PKD; however, the contribution of specific macrophage subsets in promoting renal cyst formation and how this is related to ciliary dysfunction and cyst progression is unknown.

Methods: To address the involvement of cilia and macrophage subtypes in cyst formation, our lab utilized an inducible cilia deletion mouse model by conditionally disrupting the *Ift88* gene. Macrophage populations were analyzed in both wild type and cilia mutant backgrounds as well as in human autosomal dominant PKD (ADPKD) patients with end-stage renal disease via immunofluorescence microscopy and flow cytometry at different time points following cilia loss.

Results: Our mouse data indicate that there is a predominant subset of renal resident macrophages expressing CD206 in juvenile WT mice and that the number of CD206+ macrophages decreases rapidly as the mice mature into adulthood. However, in conditional cilia deficient mice, induction of cilia loss in juvenile stages leads to persistently elevated numbers of CD206+ macrophages compared to control mice. Moreover, our data show that in the juvenile period the severity of cyst formation is associated with the time of cilia deletion. Early induction of cilia loss (e.g. P3), coincides with greater number of CD206+ macrophages and increased cyst severity compared to induction at later ages (e.g. P7). Preliminary analysis of kidneys from ADPKD patients shows increased numbers of CD206+ macrophages compared to normal human kidneys.

Conclusions: These data suggest that CD206+ macrophages are involved in renal cystogenesis in human patients and mouse models of renal cyst formation.

Clinical and Radiologic Features of Older-Age ARPKD Patients

André L. Moraes, Elieser H. Watanabe, Precil D. Neves, Andreia Watanabe, Luiz F. Onuchic. *University of Sao Paulo, S?o Paulo, Brazil*.

Background: Autosomal recessive polycystic kidney disease (ARPKD) presents classically in pediatric age, affecting primarily kidney and liver and constituting a frequent cause of ESKD in children. While its manifestations are well characterized and quantified in pediatric population, they are not so well established in adults.

Methods: To assess the disease burden in older patients (pts), we retrospectively analyzed the biometric, clinical, laboratorial and radiologic features in a case series of 12 ARPKD individuals with ≥16 years of age.

Results: This study included 7 male and 5 female pts, with median age of 22 years (19.0-34.5). Mean height and body mass index were 172.0±10.5 cm and 21.3±2.8 kg/m^2 in males and 160.2±6.4 cm and 20.9±3.9 kg/m^2 in females. Half of the pts were hypertensive, evenly distributed among the 6 cases in renal replacement therapy (RRT) and the 6 pts not in this therapy. RRT was initiated at 17.5±8.1 years, including 5 kidney transplants and 1 hemodialysis. Two pts (16.7%) developed nephrocalcinosis, 1 of them with associated nephrolithiasis. One pt underwent unilateral nephrectomy prior to kidney transplantation. Total kidney volume (TKV) was calculated in 8 pts for whom computed tomography or magnetic resonance imaging was available, showing a mean value of 575.6±540.4 mL. TKV did not correlate with RRT requirement (p=0.49). The 2 pts with shrunken kidneys were in RRT. Post-transplant native TKV (3-9 years of follow-up) displayed a trend of lower values compared to kidneys of nontransplanted pts [115.1 mL (50.5-337.8) *vs* 535.4 mL (396.2-1387.0); p=0.07]. Most of the 12 cases developed liver and/or portal hypertension-related manifestations, including hypersplenism (66.7%), esophageal varices (50%), Caroli syndrome (25%), and need of liver transplantation (8.3%). One pt died due to rupture of a basilar artery dolichoectasia, however no episodes of cholangitis were observed.

Conclusions: In addition to findings expected in older ARPKD pts, our analyses revealed relevant complementary information and brought interesting insights into ARPKD clinical reality. Our data suggest absence of growth deficit and lower frequencies of hypertension and cholangitis in older pts than reported for younger or broad-age pt populations. Moreover, kidney size tends to decrease after transplantation, reproducing findings obtained in autosomal dominant PKD.

A Cross-Sectional Characterization of Young Adult ARPKD Patients – Data from the ARegPKD Cohort Study

Kathrin Burgmaier,[1] Thomas Benzing,[2] Djalila Mekahli,[3] Bruno Ranchin,[6] Franz S. Schaefer,[4] Max Liebau.[5] *[1]University Hospital Cologne, Cologne, Germany; [2]University of Cologne, Köln, Germany; [3]KULeuven, Leuven, Belgium; [4]University of Heidelberg, Heidelberg, Germany; [5]University Hospital Of Cologne; Children's Hospital, Koeln, Germany; [6]Pediatrics, Lyon, France*.

Background: Autosomal recessive polycystic kidney disease (ARPKD) shows pronounced phenotypic variability. Although the classic phenotype is a severe disease of early childhood, a substantial number of ARPKD patients nowadays reaches adulthood and a minor proportion of patients is diagnosed with ARPKD in adulthood. Knowledge about clinical courses of adult patients suffering from ARPKD is scarce.

Methods: A cross-sectional analysis was performed on data sets of 45 adult patients with documented visits after their 18th birthday deriving from the international ARPKD cohort study ARegPKD.

Results: Median age at analysis was 21.4 (18.0-29.0) years, age at diagnosis 0.5 (-0.2-25.0) years. 53.3 % of patients are male. *PKHD1* was sequenced in 22/45 patients with a variant detection rate of 78%. One quarter of patients showed prenatal abnormalities. Most frequent symptoms at primary manifestation were extended abdomen with palpable tumor, arterial hypertension and urinary tract infection. One patient suffered from gastrointestinal bleeding at primary manifestation. 22 patients received 34 transplanted organs (median age at first transplantation 14.7 (2.4-42.8) years), with 7 patients receiving at least two transplantations. More than half of the young adults showed hepatomegaly, one third showed splenomegaly. Complications due to portal hypertension in form of varices were observed in one quarter of patients. 84.4% of patients received antihypertensive medication. At the timepoint of analysis renal function of native kidneys lies within CKD stages 1 to 3 in more than 50% of patients, 40.5% of patients received renal replacement therapy in their history.

Conclusions: Although ARPKD is classically a severe pediatric hepatorenal disorder, more and more patients reach adulthood. We describe a well-phenotyped cohort of young adult ARPKD patients setting a basis for the identification of clinical complications evolving in adulthood.

CRISPR-Mutant Organoids Identify Cystogenic Signal Pathways in the Early and Late Stages of Polycystic Kidney Disease

Tomoya Miyoshi,[1] Navin R. Gupta,[1,2] M. Todd Valerius,[1,2] Ryuji Morizane.[1,2] *[1]Brigham & Women's Hospital/Harvard Medical School, Boston, MA; [2]Harvard Stem Cell Institute, Cambridge, MA.*

Background: Human pluripotent stem cell (hPSC)-derived nephron organoids have significant potential for the development of targeted therapies for polycystic kidney disease (PKD). Previously, we generated heterozygous and homozygous *PKHD1* mutant hPSCs by CRISPR/Cas9 genome editing to establish autosomal recessive PKD (ARPKD) models in human cells. Following standardization to isogenic controls, here we identify cystogenic signal pathways of ARPKD for the potential development of novel therapeutics.

Methods: Following an identical differentiation protocol, nephron organoids were generated from heterozygous (*PKHD1*+/-, isogenic control) and homozygous (*PKHD1*-/-) mutants in 3D culture. Organoids were treated with and without forskolin, a cAMP inducer, and cyst formation was evaluated by bright field and fluorescent microscopy. Cell proliferation was assessed by Ki67 positivity in proximal (LTL+) and distal (CDH1+) tubule cells. RNA was isolated from organoids on differentiation day 35. RNA was amplified, fluorescently labeled, hybridized to a microarray (Toray, 3D-Gene® Human mRNA Oligo chip 25k), and signal pathway analysis was conducted using Metacore™.

Results: Gene expression analysis identified 1056 genes that differed by > 2-fold between heterozygous and homozygous mutants cultured without forskolin, the latter manifesting tubular dilatation (early cystic phase). Pathway analysis identified 50 signal pathways specific to the homozygous mutant in this early cystic phase ($p<0.01$), including the Rho kinase pathway known to induce loss of cellular polarity in PKD. Treatment with forskolin induced large cysts (late cystic phase) limited to homozygous mutants, which

display 1876 genes differing by > 2-fold compared to similarly treated isogenic controls. 96 signal pathways were identified as specific in the late cystic phase of the disease and included proliferative transcriptional phenotypes.

Conclusions: The CRISPR approach enabled generation of isogenic controls which differentiated into nephron organoids following an identical protocol. Global gene expression analyses identified 50 and 96 specific signal pathways in the early and late cystic phases of PKD, respectively, in comparison to an isogenic control. These signals may identify novel therapeutic targets for PKD at different stages of the disease.

Post-developmental Inactivation of Pkhd1 Results in Liver Cysts in Mice

Whitney E. Besse,[1] Charlotte E. Roosendaal,[1] Xin Tian,[1] Rachel Gallagher,[1] Stefan Somlo.[1,2] *[1]Dept. of Internal Medicine, Yale School of Medicine, New Haven, CT; [2]Dept. of Genetics, Yale School of Medicine, New Haven, CT.*

Background: Autosomal recessive polycystic kidney disease (ARPKD), caused by recessive mutations in the *PKHD1* gene, is a rare congenital disease characterized by diffusely cystic kidneys and hepatic fibrosis. We recently found genome-wide significant enrichment of adult heterozygous *PKHD1* carriers in our cohort of genetically unresolved autosomal dominant polycystic kidney and liver disease (ADPKD/ADPLD). ADPKD/ADPLD cysts originate when over time somatic second hit mutations in scattered cells result in the cellular recessive genotype. In order to explore the hypothesis that, like ADPLD cysts, cysts in *PKHD1* carriers could result from post-developmental biallelic loss, we used the Cre;Lox system to inactivate *Pkhd1* post-developmentally in mouse liver.

Methods: Using a $Pkhd1^{flox}$ allele, originally used to generate the $Pkhd1^{del3\text{-}4/del3\text{-}4}$ mouse model, we generated the following mice; $Pkhd1^{fl/fl}$;UBC-Cre (experimental, n=13) and $Pkhd1^{fl/+}$;UBC-Cre (littermate controls, n=12). All mice were induced with Tamoxifen at postnatal day 28 for 5 days and aged to 17 weeks. Liver and kidney histology was examined for cystic disease.

Results: Histological analysis performed on experimental (n=8) livers demonstrated polycystic livers with minimal pericystic inflammatory infiltrate, while "control" livers were normal. Anti-cytokeratin 19 (CK19) staining demonstrated the cysts were of biliary origin, consistent with both ARPKD and ADPKD mouse models, with significant increase in the CK19+ cell area percentage [6.1% (n=8) vs. 0.5% (n=8)] and cystic index [15.6% (n=8) vs. 3.0% (n=8)]. The mean liver weight to body weight ratio (LW/BW) for the $Pkhd1^{fl/fl}$;UBC-Cre animals was 5.8 ± 0.8% (n=13) versus 4.3± 0.6% (n=12) (P<0.0001). These data are comparable to $Pkhd1^{del4/del4}$, and within range of the ADPKD mouse model $Pkd1^{fl/fl}$;UBC-Cre with the same age and induction regime. Female mice had the most profound effect (LW/BW, 6.2± 0.4% vs. 3.8± 0.2%, n=5 females each). The $Pkhd1^{fl/fl}$;UBC-Cre kidneys appeared histologically normal.

Conclusions: Post-developmental inactivation of *Pkhd1* results in cystic liver disease indicative that *Pkhd1* after development is required for biliary epithelial homeostasis. This finding supports investigation of whether the human polycystic liver disease seen in *PKHD1* carriers may indeed fit the ADPKD/ADPLD mechanistic paradigm.

FR-PO986

Pkd1-Pkhd1 Interaction During Embryonic Development via a Mitochondria-Dependent Mechanism

Rebecca V. Walker,[1] Qin N. Yao,[1] Hangxue Xu,[1] Kristen F. Swaney,[2] Rong Li,[3] Patricia Outeda,[4] Terry J. Watnick,[5] Gregory G. Germino,[6] Feng Qian.[5] Qian *[1]umaryland, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD; [3]Johns Hopkins University SOM, Baltimore, MD; [4]University of Maryland, Baltimore, MD; [5]University of Maryland School of Medicine, Baltimore, MD; [6]Deputy Director, NIDDK/NIH, Bethesda, MD.*

Background: PKD occurs in autosomal dominant or recessive forms, caused by mutations mainly in *PKD1* (PC1) *or PKHD1* (FC) respectively. PC1 cleavage at the GPS motif is required for efficient ciliary trafficking and is frequently disrupted by *PKD1* mutations. Non-cleavable PC1 in $Pkd1^{V/V}$ knockin mice sufficiently maintains kidney structure during embryonic development, yet rapid cystogenesis in distal tubules (DTs), but not proximal tubules (PTs), ensues postnatally. The pancreas remains intact throughout the lifespan. *Pkhd1* mutants display negligible renal and pancreatic disease but show increased dilation in the renal DTs and pancreas in adult stages with heterozygous *Pkd1* deletion; yet early-onset cystogenesis was not detected.

Methods: We performed genetic studies using $Pkd1^{V}$ and *Pkhd1* mutant alleles to test for their interaction during development and the role of PC1 cleavage. To examine the role of *Pkhd1* in the interaction, we analyzed biochemical, morphological and subcellular characteristics of mutant kidneys by western blot, scanning electron and immunofluorescent microscopy.

Results: When combined with *Pkhd1* hypomorphic or null mutation, $Pkd1^{V/V}$ mice developed rapid renal cystic dilation, progressing from PTs to DTs, during embryonic development and die perinatally. Pancreas is also severely dilated with a single central lumen. Mitochondrial structural defects were observed in *Pkhd1* mutant kidneys. A FC C-terminal fragment translocated into mitochondria in cultured renal epithelial cells. Deleting this FC region caused PT cystic dilation and enhanced DT dilation in early postnatal $Pkd1^{V/V}$ mice.

Conclusions: *Pkhd1* inactivation triggers severe early-onset renal and pancreatic cystogenesis in the absence of PC1 cleavage. *Pkd1* and *Pkhd1* interact for regulating proper tubular structure of the two major organs during embryonic development. This interaction operates for uncleaved PC1 at a non-ciliary site and involves FC's C-terminus. *Pkhd1* mutation may confer a strong procystic state that significantly contributes to early-onset kidney and pancreas disease through its C-terminus by a mitochondria-dependent mechanism.

FR-PO987

Mice Lacking Pkhd1 Exons 3-67 Develop Biliary but Not Renal Abnormalities

Luis F. Menezes,[1] Fang Zhou,[1] Mahiro Kurashige,[1] Patricia Outeda,[2] Terry J. Watnick,[2] Gregory G. Germino.[1] *[1]NIDDK, National Institute of Health, Bethesda, MD; [2]University of Maryland School of Medicine, Baltimore, MD.*

Background: Autosomal recessive polycystic kidney disease (ARPKD; OMIM 263200) is caused by mutations in *PKHD1* and is characterized by cysts/dilations in kidney collecting ducts, liver biliary cysts and portal fibrosis. While orthologous mouse models of ARPKD reproduce the liver phenotype, the kidney disease is mild, of low penetrance and strain-dependent. It was suggested that *Pkhd1* alternative splicing could compensate for the lack of full-length *Pkhd1*. Here we tested if genomic deletion of most of the *Pkhd1* locus could exacerbate the renal pathology.

Methods: We had previously generated two *Pkhd1* mouse models: $Pkhd1^{flox3\text{-}4}$, with loxP sites flanking exons 3-4; and $Pkhd1^{flox67HA}$, with loxP sites flanking the last exon (67). We bred mice carrying $Pkhd1^{del3\text{-}4/del67}$ alleles to Ddx4-Cre mice, a transgenic line with cre activity in embryonic germ cells of males and females. Starting with 6 independent $Pkhd1^{del3\text{-}4/del67}$ vs. Ddx4-Cre crosses, we obtained 9 heterozygous $Pkhd1^{del3\text{-}67}$ mutants, and started 4 independent founder lines, which were bred separately to homozygosis, generating a total of 28 $Pkhd1^{del3\text{-}67/del3\text{-}67}$ (4 to 12 per founder) with overlapping phenotypes. Subsequent generations were allowed to interbreed across founder-lines. A total of 84 $Pkhd1^{del3\text{-}67/del3\text{-}67}$ were harvested between 30 and 440 days at approximately 10-day intervals, and two animals were allowed to age to 620 days. Animal body, liver and kidney weights were measured; kidneys and livers were visually inspected. In a subset of samples we measured eye weight and embedded kidney, liver and eyes for histological analysis.

Results: None of the animals had abnormal kidney size or macroscopic appearance, and histologic analysis confirmed absence of dilated tubules. In contrast, all analyzed animals had some degree of liver pathology, characterized by biliary cysts, duct proliferation and variable degrees of periportal fibrosis and cholangitis. Large coledochal and pancreatic cysts, and ascitis were occasionally observed. Additional phenotypes included ophthalmic pathology.

Conclusions: Compensation by alternative splice variants cannot explain the mild kidney phenotype in orthologous ARPKD mouse models. Further studies are required to determine if *Pkhd1* or other sequences in the deleted genomic region are responsible for the additional unexpected phenotypes.

FR-PO988

Adult Inactivation of Pkhd1 Results in Liver Cysts in an ARPKD Mouse Model

Luis F. Menezes, Fang Zhou, Gregory G. Germino. *NIDDK/NIH, Bethesda, MD.*

Background: Autosomal recessive polycystic kidney disease (ARPKD; OMIM 263200) is a severe disease of infancy and childhood caused by mutations in *PKHD1*. A common feature of both human disease and orthologous mouse models is biliary duct cysts with portal tract fibrosis, usually attributed to ductal plate malformation, a developmental disorder. According to this model, immature biliary ducts fail to remodel/involute during embryogenesis, leading to congenital fibrosis and biliary cysts. In this study we tested if adult loss of *Pkhd1* could result in biliary cysts and portal fibrosis in mature livers.

Methods: The $Pkhd1^{Tm1Ggg}$ ($Pkhd1^{flox3\text{–}4}$) mouse line was crossed to FLPeR mice expressing the FLP1 recombinase (stock 003946, Jackson Laboratories) to remove the neomycin cassette, since previous studies determined that uninduced mice developed liver lesions over time. The resulting $Pkhd1^{delneo.flox3\text{–}4}$ was bred to C57/BL6 tamoxifen-Cre (stock 004682, Jackson Laboratories). A set of 53 $Pkhd1^{delneo.flox3\text{–}4}$ mice with or without transgene cre expression (cre negative: 8 females and 8 males; cre positive: 15 females and 22 males) was induced at 40 days of age by one intraperitoneal injection of 0.2 mg/g tamoxifen and harvested between ages 100 and 328. An additional set of 29 mice was aged without being induced with tamoxifen (cre negative: 4 females and 7 males; cre positive: 9 females and 9 males). Animal body, liver and kidney weights were measured, and the kidney and livers were visually inspected. A subset of samples was embedded for histological analysis.

Results: Uninduced animals and induced cre negative mice had normal kidney and macroscopically normal liver morphology up to 300 days of age. Cre positive animals had enlarged livers with visible cysts starting on day 200 (n=7), progressively more affected with age. Expression of cre recombinase was a statistically significant determinant of liver cystic phenotype (p<0.001) in induced mice. No obvious kidney cysts were detected in any mice, and there was no statistical significance in kidney/body weight between induced animal with or without cre expression.

Conclusions: Adult inactivation of *Pkhd1* mimics germline inactivation in causing an ARPKD liver phenotype in a mouse model. This suggests that additional mechanisms, independent of ductal plate remodeling and involution, may play a role in the ARPKD polycystic liver.

FR-PO989

Fibrocystin-Deficient MDCKII Cells: Defective Control of Cell Adhesion and Polarity Blocks Epithelial Morphogenesis

Wolfgang H. Ziegler, Birga Soetje, Lisa P. Marten, Ljupcho Fenov, Dieter Haffner. *Hannover Medical School, Hannover, Germany*.

Background: Mutations of the *Pkhd1* genecause autosomal recessive polycystic kidney disease (ARPKD). *Pkhd1* encodes fibrocystin/polyductin (FPC), a very large, ciliary type I membraneproteinof mostly uncharacterized function, which is suggested to affect adhesion signaling of cells. Contributions of altered epithelial cell interaction to the disease process of ARPKD are not understood. Here, we propose a model wherein inadequate control of cell adhesion and centrosome positioning prevent formation (and homeostasis) of correctly polarized epithelia.

Methods: Based on *Pkhd1* silencing, we analyze FPC function in cells with renal collecting duct characteristics, Madin-Darby canine kidney cells (MDCKII). Cells are studied on micro-pattered chips in 3D cell culture conditions allowing analysis of polarity, lumen formation and ciliogenesis in epithelial spheroids. Quantitative automated image processing is applied to analyze z-stacks of 5-color fluorescence images. To determine critical differences in cell adhesion parameters, MDCK cells are studied also on chips in their 1-/2-cell stages. Activation of adhesion signaling is addressed based on phosphorylation of the FAK/Src axis.

Results: Using defined adhesion conditions, we quantified the impact of FPC deficiency on size / density of adhesion sites, cell shape characteristics and initiation of an apical surface. Effects on apicobasal polarity and lumen formation correlate significantly with positioning of centrosomes in 1-/2-cell stages, and activation of adhesion signaling. FPC-deficient cells reveal defects in the formation of correctly polarized epithelial spheroids, which are restored upon transient reduction of actomyosin contractility during the critical early phase of the morphogenesis assay.

Conclusions: Altered adhesion sensing and interaction of FPC-deficient epithelial cells lead to impaired epithelial morphogenesis and by implication homeostasis, which are suggested to lie at the heart of progressive epithelial defects in ARPKD. Closely controlled cell-based models with selective genetic alterations provide the means for a better molecular understanding and furthermore options to test pharmacological correction of epithelial defects.

FR-PO990

Nuclear Complexes Containing FPC-CTD/Mcm3/Mcm5/STAT1 Define a Myc-Regulatory Pathway in Mouse with Implications for Renal Cystogenesis

Santiago Cuevas,[1] Chaozhe Yang,[6] Naoe Harafuji,[2] Maryanne Odinakachukwu,[6] Gregory G. Germino,[5] Patricia Outeda,[4] Terry J. Watnick,[3] Lisa M. Guay-Woodford.[2] *[1]Center for Transitional Science, Children's National Health System, Washington, DC; [2]Children's National Health System, Washington, DC; [3]University of Maryland School of Medicine, Baltimore, MD; [4]University of Maryland, Baltimore, MD; [5]Deputy Director, NIDDK/NIH, Bethesda, MD; [6]Children's National Medical Center, Bowie, MD.*

Background: ARPKD (MIM 263200) typically results from mutations in *PKHD1*. The intracellular C-terminal domain (FPC-CTD), encoded by exon 67, undergoes regulated membrane-release (Kaimori, 2007). Using single particle EM, we have shown that affinity-captured, natively-formed FPC-CTD nuclear assemblies integrate into DNA networks in ring-shaped structures reminiscent of known DNA-binding proteins (Harafuji, 2016). The current study was designed to examine FPC-CTD binding partners and their nuclear function.

Methods: Stable cell lines expressing V5-tagged FPC-CTD were generated; cell lysates fractionated on glycerol gradients; and immunoprecipitation (IP) were performed. Proteins were identified by mass spectrometry (IP-MS) and interactions confirmed by co-IP. Kidneys from ARPKD patients as well as the *Pkhd1*^{cyli}, *Pkhd1*^{del67}, *Pkhd1*$^{del3\text{-}67}$, *Cys1*^{cpk} mouse models were examined by RT-PCR, immunohistochemistry, and IB. Chromatin immunoprecipitation (ChIP) and luciferase reporter assays were conducted using the *Myc* P1 promoter.

Results: IP-MS identified 34 proteins, including four members of the minichromosome maintenance protein complex (Mcm3, Mcm5, Mcm6, Mcm7). IP confirmed FPC-CTD-Mcm3, FPC-CTD-Mcm5, and Mcm5-STAT1 interactions. In FPC-CTD stable cell lines, *Myc* is upregulated. FPC-CTD binds to the P1 promoter (ChIP) and enhances *Myc* P1 promoter activity (luciferase assay). When compared to controls, we observed *Myc* overexpression in human ARPKD and *Cys1*^{cpk} cystic kidneys, but not in *Pkhd1*^{cyli}, *Pkhd1*^{del67}, or *Pkhd1*$^{del3\text{-}67}$ kidneys, none of which express cystic disease.

Conclusions: Trudel (2015) has proposed that *Myc* overexpression defines a causative pathway in renal cystic disease. In this study, we show that: 1) *in vitro*, FPC-CTD upregulates *Myc* expression; and 2) FPC-CTD nuclear complexes contain Mcm3/Mcm5. Mcm5 interacts with STAT1, which transcriptionally represses *Myc* expression (Ramana, 2000). Our data suggest a reciprocal mechanism in which FPC-CTD activates, while STAT1 represses *Myc* expression. This model may explain the lack of *Myc* upregulation in mouse kidneys with reduced or absent FPC-CTD. Given that the mouse and human FPC-CTD share only 41% identity, we speculate that there are species-specific differences in *Myc* translational regulation.

FR-PO991

Urinary Metabolic Profiling by NMR Spectrometry Associates with eGFR in a Cohort of Patients with ADPKD

Shosha E. Dekker,[1] Aswin Verhoeven,[2] Darius Soonawala,[1] Oleg Mayboroda,[2] Johan W. De Fijter.[1] *[1]Nephrology, Leiden University Medical Center, Leiden, Netherlands; [2]Center for Proteomics and Metabolomics, Leiden University Medical Center, Leiden, Netherlands.*

Background: With the advent of therapeutic options to slow the rate of disease progression in patients with autosomal dominant polycystic kidney disease (ADPKD), there is an unmet need for biomarkers to select those at high-risk of rapid progression in the early stages of their disease. This study explored changes in the urinary metabolome associated with different chronic kidney disease (CKD) stages or estimated glomerular filtration rate (eGFR) in ADPKD, which is a first step towards identifying markers for early risk stratification.

Methods: Quantitative metabolic profiling (^{1}H NMR-spectrometry) was performed on spot urine samples obtained from 338 ADPKD patients with various CKD-stages, 84 healthy controls and 42 chronic, non-ADPKD, renal disease patients. Uni- and multivariate analyses were used to detect differences between the groups and associations between metabolic profiles and eGFR (CKD-EPI equation). Findings were validated in an independent cohort of 163 ADPKD patients.

Results: Twenty-nine urinary metabolites were quantified from the spectra. Logistic regression reliably distinguished ADPKD patients from healthy controls (AIC(DF 30,392)=185.7, $p=6\times10^{-46}$, $pR^2=0.70$; cross-validated AUC of 0.947 for CKD stage 1 in ADPKD). In patients with ADPKD, six metabolites were significantly decreased and seven significantly increased as compared to healthy controls, while metabolic profiling did not discriminate ADPKD from other renal diseases with comparable eGFRs. Sixteen metabolites correlated with eGFR in ADPKD patients, with the metabolite with the highest negative correlation having a pearson correlation coefficient of -0.72 ($p=5\times10^{-55}$) and the highest positive correlation of $r=0.66$ ($p<2\times10^{-16}$). A multiple linear regression model for eGFR was constructed based on all metabolite levels ($F(30,308)=39.95$; $p=5\times10^{-87}$, $R^2=0.79$). A much simpler model, however, based on the ratio of the two metabolites with the highest correlation only also served as a good predictor for eGFR ($F(2,336)=536.2$; $p=1\times10^{-71}$, $R^2=0.615$). Using the later model, the results were validated in a separate cohort ($F(30,133)=6.293$; $p=6\times10^{-14}$, $R^2=0.578$).

Conclusions: Quantitative NMR profiling enabled identification of urinary metabolic markers that distinguished ADPKD patients from healthy controls and markers that were also significantly associated with eGFR.

FR-PO992

Kidney-Targeting Nanoparticles for Drug Delivery in Polycystic Kidney Disease

Eun ji Chung,[1] Jonathan Wang,[1] Hui Li,[1] Kenneth R. Hallows.[2] *[1]University of Southern California, Los Angeles, CA; [2]Keck School of Medicine of USC, Los Angeles, CA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by progressive kidney cyst growth and leads to ESRD. Currently, one drug, tolvaptan has been recently FDA-approved to decrease cyst expansion, although repurposed drugs such as metformin and rapamycin used for diabetes and immunosuppression, have also been proposed. Unfortunately, these drugs suffer from short half-life, poor bioavailability, and adverse side effects. To mitigate these limitations, we describe the development of kidney-targeting multimodal micelles (KMs) that accumulate in the kidneys and can deliver therapy for ADPKD via oral administration.

Methods: KKEEE$_3$K is synthesized on an automated peptide synthesizer, and conjugated to DSPE-PEG2000. Metformin, cy7, and peptide amphiphiles are purified by HPLC and mass spectrometry. Upon micelle construction, nanoparticles were characterized by dynamic light scattering, transmission electron microscopy (TEM), and zeta potential. To assess therapeutic efficacy in vitro, mouse cortical collecting duct cells were treated with metformin-KMs and AMPK activation measured by immunoblotting against phospho-AMPK and ENaC current. Towards oral delivery of nanoparticles, KMs were encapsulated into chitosan nanocapsules to enhance mucoadhesion and passage through the GI tract.

Results: KMs and non-targeting (NT) micelles were found to have an average diameter of 15.0 and 12 nm, and zeta potential -7.8 and -1.4 mV, respectively. To test therapeutic effciacy, mouse cortical collecting duct cells incubated with 300 uM metformin-KMs showed enhanced activation of phospho-AMPK and decreased ENaC current compared to metformin-NT micelles or free metformin. Chitosan nanocapsules were developed by ionic gelation using sodium tripolyphosphate. TEM images showed chitosan particles were between 20-150 nm in diameter, which is large enough to encapsulate KMs. Current work includes investigating additional factors affecting chitosan particle size, stability, and mucoadhesive strength, such as deacetylation, molecular weight, and tri-methylation of chitosan, and assessing metformin-KM release kinetics, adhesion to CaCo-2 cells, and in vivo therapeutic studies in ADPKD mouse models.

Conclusions: Our approach is the first nanomedicine effort for ADPKD and will provide many new insights as well as potentially establish a novel therapeutic for ADPKD.

Kidney-Specific Targeting Using PLGA Nanoparticles in Polycystic Kidney Disease Mice

Yasin Oduk,[1] Jifeng Huang,[2] Lan He,[2] Takamitsu Saigusa.[2] *[1]Biomedical Engineering, University of Alabama at Birmingham, Birmingham, AL; [2]Medicine/Nephrology, University of Alabama at Birmingham, Birmingham, AL.*

Background: Drugs that slow cystogenesis in murine models may not show similar results in clinical trials, possibly due to the smaller dose used in humans to avoid systemic side effects. One way to improve the efficiency of the drugs in the kidney, without increasing the drug dose/risk for adverse effects, is kidney-specific drug delivery. Polymeric nanoparticles (NP) can encapsulate drugs and they are small enough in size which can freely filter through the glomerulus and be reabsorbed in the tubules, without potentially being taken up by extra-renal organs. The purpose of this study is to determine the bio distribution of NP in polycystic kidney disease (PKD) mouse.

Methods: Fluorescent coumarin-6 encapsulated poly(lactic-co-glycolic acid) (PLGA) biodegradable polymer nanoparticles were prepared by a double emulsion method with an average size of 124 ± 26nm, confirmed by scanning electron microscopy (SEM). PLGA-NP was administered via tail vein injection at the concentration of 50mg/kg to adult Pkd1 mice with moderate kidney cyst formation and control mice with no kidney cyst. Mice were sacrificed at 1, 4, 24, 48 and 72 hours after injection. Kidney, liver, heart, lung, and spleen were harvested and fixed for immunofluorescence and transmission electron microscopy (EM).

Results: Kidneys from both PKD and control mice revealed strong green fluorescent staining in the proximal tubules and in the arterial endothelium at 1 to 4 hour after injection, retaining its fluorescence at 24 hours and fading at 72 hours. There was PLGA-NP uptake in kidney cystic structures for both proximal and distal tubular cysts. PLGA NPs were present in the liver, heart, lung, and spleen early after the NP injections (1 to 4 hours) but diminished over time. The overall intensity of NP's in the extrarenal organs were significantly lower compared to the kidney. EM of kidney harvested at 24 hours revealed an intact NP structure in the cytosolic compartment of the tubular epithelium.

Conclusions: PLGA-NP in PKD mice were predominantly reabsorbed in the kidney tubules and cystic epithelia compared to extra-renal organs including the liver. PLGA-NP may have a role in kidney-specific drug delivery in PKD.

A Bioinformatics Analysis of Gene Expression in Experimental Alport Syndrome Reveals an Fstl1 Signature in the Kidney

Nicholas Maksimowski,[1] Xuewen Song,[1] Eun Hui Bae,[2] York P. Pei,[3] James W. Scholey.[1] *[1]University of Toronto, Toronto, ON, Canada; [2]Chonnam National University Hospital, Gwangju, Republic of Korea; [3]University Health Network and University of Toronto, Toronto, ON, Canada.*

Background: Alport syndrome (AS) is a rare inherited form of chronic kidney disease characterized by progressive nephropathy and the development of end stage renal disease. It is caused by mutations in the Col4a3, Col4a4, and Col4a5 genes. The goal of my studies is to better understand the pathogenesis of AS in the kidney.

Methods: We performed studies using a well-characterized experimental murine model of AS. Global gene expression profiling of renal cortical mRNA samples was performed in male Col4a3-/- mice and Col4a3+/+ control mice at 4 and 7 weeks of age to identify early differentially expressed genes. We performed a cluster analysis and constructed a heat map on the microarray studies at 4 and 7 weeks of age. Studies using HK2 cells were conducted to analyze inflammation and apoptosis related to a protein of interest and its cognate receptor. Finally, using a transgenic mouse model with a reduction in our protein of interest we performed UUO at 7 weeks of age.

Results: The microarray analysis revealed that only 5 genes were differentially expressed in the kidneys of male Col4a3-/- mice at 4 weeks of age compared to Col4a3+/+. Amongst these genes was Follistatin-related protein 1 (FSTL1). We used search tool for the retrieval of interacting genes/proteins to predict protein-protein interactions (PPIs) thereby identifying a functional protein association network for FSTL1. The network included 39 proteins. Cluster analysis of the cognate genes from the FSTL1 protein network showed marked upregulation of gene expression at 7 weeks of age. FSTL1 increased NFκB mediated luciferase activity, caspase 3 activation and PARP cleavage in HK2 cells. These effects were due, at least in part to TLR4 receptor activation. The RT-qPCR analysis of mice that were subjected to UUO surgery showed an increase in FSTL1 expression as well as an increase in the expression of FSTL1's cognate receptors compared to sham controls.

Conclusions: Our microarray and bioinformatics analyses identified early upregulation of FSTL1 in the kidneys of Col4a3-/- mice. A FSTL1 gene signature, based on predicted PPIs, emerged in the kidneys by 7 weeks of age. FSTL1 elicited an inflammatory response and activated apoptosis in HK2 cells. These findings support the hypothesis that FSTL1 may be a novel determinant of kidney injury in mice with experimental AS.

Sparsentan, a Dual Angiotensin II Type 1 (AT1) and Endothelin Type A (ETA) Receptor Antagonist, Prevents Renal Disease in COL4A3 -/- Autosomal Alport Mice

Dominic E. Cosgrove,[1] Brianna M. Dufek,[1] Duane C. Delimont,[1] Daniel T. Meehan,[2] Gina C. Samuelson,[1] Kai Liu,[3] Celia P. Jenkinson,[3] Bob Armstrong,[3] Radko Komers.[3] *[1]Boys Town National Research Hospital, Omaha, NE; [2]Boys Town National Research Hospital, Omaha, NE; [3]Retrophin, Inc., Portland, OR.*

Background: Strain-mediated induction of endothelin (ET-1) in glomerular endothelial cells activates ET_A receptors on mesangial cells, initiating invasion of glomerular capillaries by mesangial filopodia. The filopodia deposit matrix in the glomerular basement membrane resulting in stimulation of NFκB activity in podocytes and expression of pro-inflammatory cytokines, culminating in glomerulosclerosis and interstitial fibrosis. Both ET_A receptor blockade and angiotensin-converting enzyme (ACE) inhibition have been shown to ameliorate these events in Alport mice. Therefore, we explored the ability of sparsentan to improve nephropathy in this model.

Methods: Alport mice were treated once daily with sparsentan (60 or 200 mg/kg given orally; n=3–4/group) or vehicle (n=4) from 3–7 weeks of age. Blood pressure (BP) and urinary protein/creatinine ratio (UP/C) were determined at the end of the study, together with determination of fibronectin and collagen 1 protein (COL1) immunohistochemistry (IHC) in kidney sections as an assessment of glomerulosclerosis and tubulointerstitial fibrosis.

Results: BP was not significantly different in Alport mice treated with sparsentan compared to vehicle at 7 weeks of age. Sparsentan led to significantly lower UP/C (60 mg: 5.6±3.0 mg/mg, n=4, $P<0.05$; 200 mg: 0.8±1.4 mg/mg, n=3, $P<0.01$) compared to vehicle-treated Alport mice (34.1±17.4 mg/mg, n=4). The percentage of sclerotic glomeruli, determined from fibronectin IHC was lower ($P<0.01$) in Alport mice that received sparsentan at 60 mg/kg (3.5±1.6%) or 200 mg/kg (1.4±1.3%) compared to vehicle-treated mice (39.0±19.5%). COL1 immunoreactivity was absent in sparsentan-treated Alport mice, similar to wild-type mice. In contrast, vehicle-treated Alport mice had a COL1 score of 2.5±0.6 (arbitrary units).

Conclusions: This preclinical study demonstrates that sparsentan, a dual ET_A and AT_1 receptor antagonist provides nephroprotection in Alport mice, in both glomerular and tubulointerstitial compartments. A further preclinical study is under way to explore the activity of sparsentan compared with ACE inhibition, the current standard of care in Alport renal disease.

Transcriptome-Based Discovery of Lysine Deacetylase Inhibition as a Novel Treatment Approach to Alport Syndrome

Vanessa R. Williams,[1] Ana Konvalinka,[2,1] Xuewen Song,[2] Rohan John,[2,1] York P. Pei,[2,1] James W. Scholey.[2,1] *[1]University of Toronto, Toronto, ON, Canada; [2]University Health Network, Toronto, ON, Canada.*

Background: Alport syndrome (AS) is a hereditary progressive disorder caused by mutations in type IV collagen genes. It is characterized by early proteinuria and activation of the renin-angiotensin system (RAS). Few effective treatment approaches to AS are currently available. Therefore, we applied a drug repurposing strategy to examine a novel therapy.

Methods: RNA expression profiling of kidney cortices from *Col4a3*$^{-/-}$ (KO) and wild-type (WT) mice on a 129/SvJ background was performed at 4 and 7 weeks of age. A disease progression signature composed of differentially expressed genes was used to query the Connectivity Map (CMAP). CMAP identified vorinostat, a lysine deacetylase inhibitor, as a potential therapy. KO mice were treated with vorinostat (50 mg/kg/day in DMSO by oral gavage) from 4 to 7 weeks of age. Mice were euthanized at 7 weeks of age for kidney function, structure, inflammation, and fibrosis analyses. Separate groups were followed for assessment of lifespan. Finally, angiotensin II-stimulated human proximal tubule epithelial (HK-2) cells were treated with vorinostat (5 μM) and used to assess mechanisms of drug action.

Results: Vorinostat increased the acetylation of lysine in the kidney. This was associated with a significant increase in survival (n = 19/group) and a trend toward decreased serum creatinine and proteinuria (n = 6-10/group). Vorinostat had no effect on glomerulosclerosis, but significantly reduced urinary excretion of NGAL, a marker of tubular injury. mRNA for cytokines and kidney injury markers including *Fn1*, *Havcr1*, and *Tnf* were reduced in the kidneys of treated mice (n = 6/group). Kidney tissue protein analysis showed lowered αSMA and proinflammatory cytokine expression. Pilot mechanistic studies revealed that vorinostat exerts its beneficial effects, at least in part by, dampening mitogen-activated protein kinase (MAPK) signaling and subsequent activator protein 1 (AP-1) transcription factor activation.

Conclusions: CMAP analysis identified vorinostat as a novel therapy for AS. Testing of the putative therapy showed that it exerts renoprotective effects and extends the lifespan of KO mice. Future studies will provide more insight into the molecular mechanisms of vorinostat through assessment of lysine acetylation, and MAPK and AP-1 signaling pathways in the progression of AS nephropathy.

Urine and Blood Biomarkers Correlate with Rate of eGFR Decline in Alport Syndrome

Michelle N. Rheault,[1] Oliver Gross,[2] Bertrand Knebelmann,[4] James F. Simon,[3] Jale Guner,[5] Mark Deeg,[5] Clifford E. Kashtan.[1] *[1]University of Minnesota, Minneapolis, MN; [2]University Medicine Goettingen, Goettingen, Germany; [3]Cleveland Clinic, Cleveland, OH; [4]Necker Hopsital, Paris, France; [5]Regulus Therapeutics, San Diego, CA.*

Background: Alport syndrome (AS) is a genetic condition leading to progressive glomerular disease and hearing loss in many affected individuals. This natural history study was performed to identify novel predictors of kidney function decline in patients with AS in order to populate future clinical trials with individuals at greatest risk of progressive kidney disease.

Methods: ATHENA (NCT02136862) was a non-interventional, global, multicenter study enrolling patients with CKD due to AS. Urine and plasma renal biomarkers and estimated GFR (eGFR) were assessed at baseline and every 12 weeks thereafter for up to 2 years. Pearson correlations of the GFR slope (provided at least 3 time points) with each baseline biomarker were derived. Statistical significance was based on FDR adjusted p-value <0.02.

Results: 165 individuals were enrolled (33.9% male, 64.8% X-linked, age mean 44.8 years, 83% white). Baseline mean eGFR was 63.9 (SD 21.6) ml/min/1.73m^2 and 24 urine protein was 1844mg (SD 2608). The median slope of eGFR was -2.35 ml/min/year. Higher serum albumin, protein, and CO2 correlated with a less negative slope of decline in eGFR. Higher urine albumin/cr ratio, urine protein/cr ratio, chloride, cholesterol, LDL cholesterol, and NGAL correlated with a more negative slope of decline in eGFR.

Conclusions: A number of urine and blood biomarkers correlate with short term rate of decline in eGFR in patients with AS. Multivariable models to predict slope of GFR decline using demographic and baseline biomarker data are in progress.

Funding: Commercial Support - Regulus Therapeutics

Glomerular Endothelial Cell Identity and Contribution to CKD in Alport Syndrome

Sargis Sedrakyan,[1,2] Hasmik Soloyan,[1] Valentina Villani,[1] Matthew E. Thornton,[2] Laura Perin.[3] GOFARR laboratory for organ regenerative research and cell therapeutics *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA; [3]Childrens Hospital Los Angeles, Los Angeles, CA.*

Background: Many studies suggest that glomerular endothelial cell (GEC) injury plays a key role in the development of chronic kidney disease, but whether they contribute to pathogenesis and progression of Alport syndrome (AS) is not clearly established. In AS, a hereditary CKD characterized by the mutations in the collagen IVα3α4α5 protein, the major constituent of the glomerular basement membrane (GBM), we found morphological and biological alterations in GEC very early during disease progression and before the onset of heavy proteinuria. Thus, we hypothesized that in our model of CKD, GEC damage plays a key role.

Methods: To investigate our hypothesis we generated GEC specific (Tek-Cre driven) *td*Tomato reporter AS mice, harvested their glomeruli by the sieving method and isolated GEC by FACS. GEC were characterized and studied by flow cytometry analysis, PCR and WB at different time points along disease progression. GEC transcriptome profiling was performed by NGS on Illumina HiSeq 4000 and further analyzed by alignment of reads to Genecode M16 mouse genome. Differential gene expression analysis was performed post RUV normalization by BIOBASE and Ingenuity Pathway Analysis tools.

Results: We identified two unique subsets of endothelial cells within the glomerulus of WT mice, and for the first time also in AS mice, which might present different functional roles during AS progression. We showed a significant increase in endothelial fenestration size, loss of glycocalyx integrity and alteration of VEGF signaling in GEC, early during progression and before the onset of proteinuria in AS mice. In addition, we identified differentially expressed genes involved in the angiogenic, stress response and metabolic regulatory pathways such as VEGF, PPAR, and FATp4.

Conclusions: In sum, our data indicate that GEC injury is an important early event that sets the stage for further progression and onset of proteinuria in Alport mice. Characterization of the transcriptional profile of GEC in AS mice could lead to the development of targeted new therapies for the treatment of CKD.

Factors Regulating the Severity in Male X-Linked Alport Syndrome: Study of 367 Cases

Tomohiko Yamamura,[1] Kandai Nozu,[1] China Nagano,[1] Tomoko Horinouchi,[1] Keita Nakanishi,[1] Shogo Minamikawa,[1] Hiroshi Kaito,[1] Yuko Shima,[2] Koichi Nakanishi,[3] Kazumoto Iijima.[1] *[1]Kobe University Graduate School of Medicine, Kobe, Japan; [2]Wakayama Medical University, Wakayama City, Japan; [3]Graduate School of Medicine, University of the Ryukyus, Nishihara-cho, Japan.*

Background: X-linked Alport syndrome (XLAS) is a hereditary disease caused by mutations of *COL4A5* gene. Affected males generally develop end-stage renal disease (ESRD) in early or middle adulthood. It has been reported some factors such as genotype or ACEI treatment affect renal prognosis. However, comprehensive analysis for the influence of factors regulating the severity using large-scale data has not been reported.

Methods: We conducted a retrospective study of 367 male patients in 231 families who were genetically diagnosed with XLAS at our institute. We collected clinical data from medical records and constructed renal survival curve. These curves were compared depending on the following differences in clinicopathological or genetic features; presence of hearing loss, findings of α5 staining positivity on glomerular basement membrane, treatment with ACEI/ARB and genotype. Regarding genotype, renal survival curve was constructed on not only each mutation type but also dividing all genotypes into two groups of truncating and non-truncating variants.

Results: The median age of our cohort was 12yrs. 149 cases reached ESRD and the median renal survival period was 33yrs. Ocular changes were detected in 6.1% and hearing loss was 34%. There was a significant difference in the median renal survival period between cases with (27yrs, n=94) and without hearing loss (55yrs, n=134) (P=0.0116), α5 staining positive (>60yrs, n=54) and negative (28yrs, n=75) (P=0.0052), treated by ACEI/ARB (43yrs, n=112) and not treated (28yrs, n=72) (P=0.0079). The median renal survival period of each mutation type was 18yrs (nonsense mutation, n=29), 21yrs (large rearrangement, n=14), 25yrs (splicing variant, n=57), 26yrs (small rearrangement, n=62) and 40yrs (missense mutation, n=196). In addition, there was a significant difference between cases with truncating (20yrs, n=102) and non-truncating variants (39yrs, n=241) (p<0.0001).

Conclusions: It was shown that the renal prognosis of male XLAS was regulated by various factors. In particular, treatment with ACEI/ARB dramatically improved renal prognosis. In addition, we also showed that the strong genotype-phenotype correlation was observed not only among mutation types but also, and for the first time, between cases with truncating and non-truncating variants.

FR-PO1000

Angiotensin-(1-7) Attenuates Renal Injury in Experimental Alport Syndrome

Hong sang Choi,[1] Chang Seong Kim,[1] Seong Kwon Ma,[1] Soo Wan Kim,[1] James W. Scholey,[2] Eun Hui Bae.[1] *[1]Chonnam National University Medical School, Gwangju, Republic of Korea; [2]University of Toronto, Toronto, ON, Canada.*

Background: Angiotensin-(1–7) [Ang-(1–7)] antagonize the actions of the renin-angiotensin-aldosterone system via the Mas receptor and thereby has a renoprotective effects. Previously, murine recombinant angiotensin-converting enzyme (ACE) 2 has been reported to have renoprotective effects in experimental Alport syndrome but the effect of direct administration of Ang-(1-7) has not been studied.

Methods: To examine the effects of Ang-(1-7) on Alport syndrome, Col4a3 knockout mice, a model of Alport syndrome were used. Mice were divided into three groups: saline-treated wild type mice group, saline-treated Col4a3 knockout mice group, and Ang-(1-7) treated Col4a3 knockout mice group. Ang-(1–7) was continuously infused (25 μg/[kg×h]) using osmotic mini-pumps.

Results: Col4a3 knockout mice revealed increased α-smooth muscle actin (SMA) and fibronectin expression which attenuated by Ang-(1-7) treatment. Messenger RNA (mRNA) expression of α-SMA, fibronectin and Collagen I were suppressed by Ang-(1-7) treatment. Ang-(1-7) treatment alleviated the transforming growth factor (TGF)-β/Smad signaling. Ang-(1-7) attenuated protein expression of ED-1 and heme oxygenase-1, indicating the attenuation of renal inflammation. mRNA expression of inflammatory cytokine, TNF-α, MCP-1 and adhesion molecule ICAM-1, VCAM-1 were also decreased by Ang-(1-7) treatment. The ratio of cleaved caspase 3 to caspase 3 was increased in Col4A3 knockout mice kidney which was decreased by ang-(1-7) treatment, indicating attenuation of apoptosis by ang-(1-7). Lastly, ang-(1-7) influenced the alter the ACE2-Ang-(1-7)-Mas receptor axis, as it downregulated angiotensin-1 receptor and upregulated ACE2 and Mas receptor.

Conclusions: Thus, treatment with ang-(1-7) alter the ACE2-Ang-(1-7)-Mas receptor axis in the kidneys of Col4a3 knockout mice and attenuates the progression of Alport syndrome nephropathy.

FR-PO1001

Quality of Life Changes as Measured with SF-36 in Patients with Alport Syndrome: Results from the ATHENA Natural History Study in Alport Syndrome Patients

James F. Simon,[1] Mark Deeg,[5] Jale Guner,[5] Oliver Gross,[3] Bertrand Knebelmann,[4] Clifford E. Kashtan,[2] Michelle N. Rheault.[2] *[1]Cleveland Clinic, Cleveland, OH; [2]University of Minnesota, Minneapolis, MN; [3]University Medicine Goettingen, Goettingen, Germany; [4]Necker Hopsital, Paris, France; [5]Regulus Therapeutics, San Diego, CA.*

Background: Alport Syndrome (AS) is a rare genetic disorder caused by mutations in genes coding for type IV collagen (COL4) α3, α4 and α5 proteins leading to hematuria, renal failure, hearing loss and eye involvement. CKD is associated with progressively worse quality of life (QOL) scores. The presence of a progressive genetic disease can also impact QOL. QOL in patients with AS has not previously been reported.

Methods: ATHENA (NCT02136862) was an international multi-center observational cohort study designed to characterize the progression of renal dysfunction in subjects with AS. Patients were followed for up to 24 months with serial evaluations. An SF-36 questionnaire was completed at baseline and every 24 weeks. The change in SF-36 score over time was modeled using mixed model repeated measures. The models incorporated baseline score, time in weeks, and subgroup indicators.

Results: 165 patients were enrolled. The study population is described elsewhere. For the entire cohort, the baseline score for physical component summary was 52.5; mental component summary was 49.7. Five domains decreased ($p<0.05$) during the study: general health, role limitations due to physical health, mental health, role limitations due to emotional problems and social functioning. The mental component summary was lower in females, those with X-linked mutations, and eGFR>60ml/min/1.73m^2. These three groups were more likely to have domain scores decrease with time. The only significant domain difference between subgroups was general health which was lower in females and those with eGFR>60 ml/min/1.73m^2.

Conclusions: In patients with AS, QOL scores using the SF-36 are low and decrease with time. Lower baseline eGFR is associated with lower QOL. Women, those with X-linked mutations and with eGFR>60 ml/min/1.73m^2 showed significantly greater decreases in QOL scores over time.

FR-PO1002

Identification of Novel Secretion-Defective Mutations of Type IV Collagen α5 Genes by Split NanoLuc-Based α345(IV) Trimer Formation Assay

Misato Kamura,[1,4] Tomohiko Yamamura,[2] Kohei Omachi,[3] Tsuyoshi Shuto,[1] Kandai Nozu,[2] Kazumoto Iijima,[2] Hirofumi Kai.[1,4] *[1]Kumamoto University Graduate School of Pharmaceutical Sciences, Kumamoto, Japan; [2]Kobe University Graduate School of Medicine, Kobe, Japan; [3]Washington University, St. Louis, MO; [4]Program for Leading Graduate Schools "HIGO Program", Kumamoto University, Kumamoto, Japan.*

Background: Alport syndrome (AS) is a hereditary glomerular disease caused by a mutation in type IV collagen α3, α4, or α5 (α3/α4/α5(IV)), components of the glomerular basement membrane (GBM). Several hundred different mutations have been found in AS patients and the phenotype differs depending on the mutation. Generally, immunostaining of renal *biopsy* specimens for type IV collagen is useful for predicting prognosis; however, its invasiveness and incompleteness on the prediction accuracy are clinically problematic. Here, by utilizing the cell-based system to assess α345(IV) trimer formation (Omachi K., *et al., Cell Chemical Biology* **2018**), we evaluate the capability of α345(IV) trimer formation of several α5 missense mutants that are clinically relevant but poorly understood.

Methods: Split nanoLuc-fusion α3/ α5 and α4 were transfected into HEK293T cells, and luminescence was assessed in the cell lysate for intracellular trimer and in culture media for secreted trimer. Scatterplot analysis of the intracellular/secreted RLU ratio from cells expressing the WT or several α5 missense mutants classifies the character of mutants.

Results: Trimer formation assay revealed that *G509R, G805R, G953V, G1000V, G1030S, G1140V, G1143S* α5 mutants have normal properties of intracellular trimerization (>98%) and extracellular secretion (>65%). Scatterplot analysis showed that most of the mutants (*G509R, G805R, G953V, G1143S*) with mild phenotype (no obvious proteinuria) showed the similar pattern as the WT, while some mutants (*G1000V, G1030S, G1140V*) exhibited secretion-dependent defect. Particularly, *G1140V* with severe phenotype (obvious proteinuria) showed significantly increased intracellular accumulation of trimer (>130%).

Conclusions: Trimer formation assay reveals that three α5 mutants (*G1000V, G1030S, G1140V*) had defect in secretion. Because patient with *G1140V* mutation had relatively severe clinical phenotype, our system may, at least in part, reflect genotype-phenotype correlation. Further phenotypic characterization would also be needed for *G1000V* and *G1030S* mutations. Moreover, because adjacent mutations *G1140V* and *G1143S* had severe and mild phenotypes, respectively, structure and molecular bases on differential phenotypes is now under investigation.

FR-PO1003

Human NOS1AP Recessive Mutations Impair Podocyte Filopodia Formation and Cell Migration and Cause Steroid-Resistant Nephrotic Syndrome Through CDC42 Dysregulation

Amar J. Majmundar,[1] Verena Klambt,[1] Ronen Schneider,[1] Thomas Kitzler,[1] Eugen Widmeier,[1] Daniela A. Braun,[1] Shirlee Shril,[1] Neveen Soliman,[2] Christoph Aufricht,[3] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]Cairo University, Cairo, Egypt; [3]Medical University of Vienna, Vienna, Austria.*

Background: Steroid resistant nephrotic syndrome (SRNS) is the second leading cause of chronic kidney disease in the first three decades of life. Mutations in >39 genes provide a monogenic cause in up to 29.5% of SRNS cases (*JASN* 26:1279, 2015) with defined pathomechanisms (*NDT* 31:1802, 2016) including dysregulation of the small GTPase CDC42 (Ashraf *Nat Commun* 2018, in press).

Methods: Whole exome sequencing (WES) was performed in ~500 SRNS subjects to discover a novel genetic cause. IF was performed on rat kidney sections. In a human podocyte cell line, we performed active-CDC42 ELISA, live cell imaging as well as shRNA-mediated downregulation and cDNA over-expression of *NOS1AP*.

Results: We identified homozygous recessive mutations in 2 unrelated children with SRNS in *NOS1AP* (c.428G>A; p.C143Y and c.345-3T>G; p.I116Afs*4). *NOS1AP* encodes an adaptor protein that interacts with nitric oxide synthase (NOS) and with NOS effectors through its phospho-tyrosine binding domain (PTB) (*Neuron* 28:183, 2000). The C143 residue within the PTB is conserved to *C. elegans* and in 85/101 human PTB sequences and registered strong *in silico* conservation scores. The c.345-3T>G coding change is predicted to reduce splicing, cause skipping of exon 5, and result in the truncation p.I116Afs*4. Both mutations are not observed, even heterozygously, in the gnomAD Genome Aggregation Database. NOS1AP is expressed selectively in podocytes, not endothelial or mesangial cells, of rat kidney glomeruli. Transfection of wild-type *NOS1AP* induced filopodia in 58% of immortalized human podocytes, while *NOS1AP* constructs containing SRNS subject mutations failed to generate filopodia. *NOS1AP* shRNA-mediated knockdown reduced podocyte migration. This was rescued by wild-type *NOS1AP* over-expression but not by *NOS1AP* mutants. Active CDC42 levels, which promote filopodia and migration (*Curr Opin Cell Biol* 36:103, 2015), were induced by wild-type *NOS1AP* but not by patients' mutants. Induction of filopodia by *NOS1AP* over-expression was inhibited by CDC42 chemical inhibitor CASIN.

Conclusions: We discovered recessive *NOS1AP* mutations as a novel monogenic cause of SRNS, leading to podocyte dysfunction through CDC42 dysregulation.

2,4-Dihydroxybenzoic Acid Improves Survival and Demonstrates a Renoprotective Effect in a Podocyte-Specific Coq8b-Knockout Mouse Model of Nephrotic Syndrome

Eugen Widmeier,[1,2] Makiko Nakayama,[1] Hannah Hugo,[1] Seyoung Yu,[5] Heon Yung Gee,[4] Friedhelm Hildebrandt.[3] *[1]Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Department of Nephrology, University of Freiburg Medical Center, Freiburg, Germany; [3]Boston Children's Hospital, Brookline, MA; [4]Yonsei University College of Medicine, Boston, Republic of Korea; [5]Yonsei University, Seoul, Republic of Korea.*

Background: Steroid resistant nephrotic syndrome (SRNS) inevitably progresses to end-stage renal disease (ESRD) within the first three decades of life, requiring dialysis or transplantation for survival. Human mutations in the *COQ8B* gene (known also as *ADCK4* - aarF domain containing kinase 4) cause SRNS (Ashraf *JCI* 123:5179, 2013). To study the function of *COQ8B* in podocytes we generated a podocyte specific *Coq8b*-knockout mouse model

Methods: *Nphs2.Cre* mice were crossed with *Coq8b$^{lox/lox}$* mice, to generate podocyte specific *Coq8b* knockout mice (*Coq8b$^{\Delta Podocyte}$*) on a C57BL/6 background. Treatment with 2,4-dihydroxybenzoic acid (2,4-diHB) at 25 mM in the drinking water was started at 3 months of age. Kidneys were harvested for histological and ultrastructural analysis at 9 months in the untreated cohort and at 13 month in the cohort under treatment. Blood and urine were collected monthly for metabolic studies

Results: *Coq8b$^{\Delta Podocyte}$* mice displayed onset of proteinuria at 4 months. Non-treated *Coq8b$^{\Delta Podocyte}$* mice displayed a significant reduction in survival (40% alive) being moribund at 12 months of age progressing to ESRD (n=15). In contrast, *Coq8b$^{\Delta Podocyte}$* mice treated with 2,4-diHB (n=12) showed significantly improved survival (100% alive), comparable to their untreated *Coq8b$^{\Delta Podocyte}$* and wild type littermates. Histological analysis of *Coq8b$^{\Delta Podocyte}$* kidneys at 9 months demonstrated severe global and focal segmental glomerular sclerosis (FSGS) with extensive interstitial fibrosis and tubular atrophy. Electron microscopy studies revealed severe foot process effacement and disturbed podocyte cell morphology. In contrast, treatment of *Coq8b$^{\Delta Podocyte}$* mice with 2,4-diHB significantly reduced the levels of proteinuria and prevented the development of FSGS as well as foot process effacement maintaining normal renal function in treated mice at 13 months (n=12)

Conclusions: Our data demonstrate that 2,4-diHB, metabolite that functions to bypass the hydroxylation step mediated by Coq7 of the CoQ_{10} biosynthesis pathway efficiently ameliorates proteinuria and prevents FSGS in *Coq8b$^{\Delta Podocyte}$* mice. Further, our study reveals a potential novel treatment option in 2,4-diHB for human SRNS caused by dysfunction in the CoQ_{10} biosynthesis pathway

GAS2L2 as a Candidate Gene for Nephrotic Syndrome

Eugen Widmeier,[1] Hannah Hugo,[2] Shirlee Shril,[3] Friedhelm Hildebrandt.[2] *[1]Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Boston Children's Hospital, Boston, MA; [3]Boston Childrens Hospital, Boston, MA.*

Background: Steroid resistant nephrotic syndrome (SRNS) inevitably progresses to end-stage renal disease (ESRD) within the first three decades of life requiring dialysis or transplantation for survival. To date discovery of more than 50 different monogenic causes of SRNS has helped to elucidate the pathogenesis of SRNS.

Methods: To identify novel mongenic causes of NS, we performed whole exome sequencing, homozygosity mapping, and targeted exon sequencing. To investigate molecular mechanisms of a newly identified monogenic cause of NS *in vitro*, we generated immortalized human podocyte cell lines with stable knockdown of the *GAS2L2* gene.

Results: By next-generation sequencing, we identified a homozygous recessive missense mutation in a region of high evolutionary conservation (*Drosophila melanogaster*) within the GAS2 domain of *GAS2L2* gene (c.817C>T, p.Arg273Cys) in a patient with early onset NS. *GAS2L2* is a known linker between actin filaments and microtubules. We show that GFP-*GAS2L2* localizes to the cytoskeleton filaments and that knockdown of *GAS2L2* results in severe defect of podocytes migration rate.

Conclusions: We discovered a recessive mutation of *GAS2L2* as a likely novel monogenic cause of early-onset SRNS. We propose that the disease phenotype is caused by defect of crosstalk between actin filaments and microtubules.

Recessive Mutations in the Kirrel Gene in Human Nephrotic Syndrome (NS)

Ashish K. Solanki,[1] Eugen Widmeier,[2] Ehtesham Arif,[1] Ankana Daga,[2] Martin Helmstädter,[4] Pankaj Srivastava,[1] Kenneth Kwon,[1] Shirlee Shril,[2] Carsten Bergmann,[3] Tobias B. Huber,[3] Friedhelm Hildebrandt,[2] Deepak Nihalani.[1] *[1]Medical University of South Carolina, Charleston, SC; [2]Boston Children's Hospital, Harvard Medical School, Boston, MA; [3]Nephrology, University Medical Center Freiburg, Breisacher Straße, Germany; [4]University of Freiburg, Freiburg, Germany.*

Background: Steroid-resistant nephrotic syndrome inevitably progresses to end-stage renal disease within the first three decades of life requiring dialysis or transplantation for survival. Podocyte proteins Neph1 and Nephrin form a critical structural framework of a functional glomerular filtration barrier. While many mutations in the Nephrin gene have been described, there are no reports of human mutations in the *Neph1/Kirrel* gene associated with the NS.

Methods: To identify novel monogenic causes of NS, we performed whole exome sequencing. To investigate the molecular mechanisms of a newly identified monogenic cause of NS *in vitro* we generated stable podocyte cell lines expressing human wild-type and mutant Neph1. IF studies were performed for localization defects for *Neph1* mutants. *Neph1* knockdown in podocytes using specific shRNA was performed to evaluate the effect of *Neph1* depletion on cell proliferation and migration.

Results: Using next-generation sequencing, we identified two homozygous recessive missense mutations in two unrelated families with NS, which were in a region of high evolutionary conservation (*Danio rerio*). Immunofluorescence studies revealed that unlike WT *Neph1*, both *Neph1* mutants failed to localize at the podocyte cell membrane (**Fig 1**). Additionally, we find an increased accumulation of these proteins in endosomes suggesting defective localization, which may contribute to the disease phenotype. Further, these mutant cell lines formed impaired tight junctions as evaluated by the permeability assay using labeled BSA.

Conclusions: This is the first report showing mutations in the *Kirrel* gene in FSGS patients.

Mutations of NEK3, PREX1, or TIAM1 Are Novel Causes of Nephrotic Syndrome

Shazia Ashraf,[1] Heon Yung Gee,[2] Youying Mao,[1] Tilman Jobst-Schwan,[1] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] *[1]Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]Dept of Pharmacology, Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Nephrotic syndrome (NS) is a heterogeneous group of disorders characterized by gross proteinuria with hypoalbuminemia and edema. The identification of >55 single-gene causes provided new insights into the pathogenesis of NS, linking Rho-like small GTPases to podocyte function.

Methods: We performed whole exome sequencing (WES) to identify novel monogenic causes of NS in >1,000 individuals with NS.

Results: We identified 4 different recessive mutations in 3 different genes *NEK3*, *PREX1* and *TIAM1* in 4 unrelated families with NS. Specifically, in a family of two siblings (F754) with steroid-sensitive NS, we identified a homozygous truncating mutation, N209Kfs*21 in *NEK3* (*NIMA Related Kinase 3*), which is known to be activated by prolactin stimulation, leading to phosphorylation of the GEF-VAV2 and thereby activation of the Rac1-GTPase. Accordingly, by coimmunoprecipitation, we demonstrated that NEK3 interacts with VAV1, VAV2 and EDH2 proteins. The mutated NEK3 protein showed stronger binding affinity with VAV1 but abrogated the interaction with EHD2. Coimmunofluorescence staining of NEK3 in developing rat kidney sections (P1) showed that NEK3 localizes to the cytoplasm of podocytes. Additionally, we discovered mutations in *PREX1* (family F1070, M1546T [Hom], conserved to *D. rerio*) and *TIAM1* (family F1287, R23C [het] and A163V [het], both conserved to *D. rerio*; family F1, p.R23C [Hom]). We thereby identified *PREX1* and *TIAM1* as two novel GEFs for Rac1 that are relevant for podocyte function.

Conclusions: We have identified mutations of *NEK3*, *PREX1* and *TIAM1* as novel causes of NS. Our findings confirm that Rho-like small GTPase signaling in podocytes can cause NS.

FR-PO1008

Mutations in 4 Diaphanous Related Formins as Novel Causes of Nephrotic Syndrome

Ronen Schneider,[1] Shazia Ashraf,[2] Verena Klambt,[7] Henry N. Higgs,[8] Sergio Padilla lopez,[6] Michael C. Kruer,[5] Daniela A. Braun,[9] Shirlee Shril,[4] Friedhelm Hildebrandt.[3] *[1]Nephrology, Boston Children's Hospital, Boston, MA; [2]Boston Childrens Hospital, Harvard Medical School, Boston, MA; [3]Boston Children's Hospital, Boston, MA; [4]Boston Childrens Hospital, Boston, MA; [5]Phoenix Children?s Hospital, Phoenix, AZ; [6]Phoenix Children's Hospital, Phoenix, AZ; [7]Nephrology, Boston Children's Hospital, Boston, MA; [8]Geisel School of Medicine at Dartmouth, Hanover, NH; [9]Boston Children's Hospital, HMS, Boston, MA.*

Background: Nephrotic Syndrome (NS) is the second most frequent cause of end-stage renal disease in the first 3 decades of life. Identification of >55 monogenic genes that cause NS if mutated (Vivante et al, *Nat Rev Nephrol*, 12:133, 2016), has rendered first insights into disease mechanisms of NS. Diaphanous Related Formins (DRF) regulate actin polymerization and bundling, and have a role in directing microtubules, filopodia and lamelipodia formation. Mutations in the DID domain of the Formin gene, *INF2*, have been shown to cause NS (Brown, Nat Gen, 42:72, 2010).

Methods: To identify novel monogenic causes of NS we performed whole exome sequencing (WES) in a worldwide cohort of ~600 individuals with NS.

Results: In 5 unrelated patients with early onset NS, we discovered recessive mutations in the following 4 DRF encoding genes: A homozygous mutation in *DIAPH1* (individual B1678, p.Gln1098Leu). Gln1098 is part of the DIAPH1 actin nucleating domain, FH2. A hemizygous mutation In *DIAPH2* (B2506, p.Arg1075Trp). Arg1075 is part of the basic region ('RRKR' sequence) of the DAD domain and is critical for auto-inhibition by binding to the DID domain. From the crystal structure of mDia1 we predict that the mutation would interrupt the DID-DAD interaction. In *DIAPH3* we found mutations in two individuals with NS (A1938 p.Thr431Ala, homozygous, and F983 p.Asn346Ser; p.Arg28His compound het.). Thr431 is located in a loop between alpha helix 1 and alpha helix 2 of the predicted dimerization domain. In the crystal structure, Asn346 is in the DID domain and within the DAD-binding site, thus the Asn346Ser substitution is predicted to alter DID-DAD binding. Furthermore, we found a mutation in *DAAM2* (individual B1068, Ala335Gln, homozygous). Ala335 is located in the DID domain of DAAM2. All mutations are deemed disease causing by SIFT, MutTaster and PolyPhen2 prediction programs. All variants are absent hemizygously or homozygously from the gnomAD database.

Conclusions: We here discovered mutations in the DRF encoding genesDIAPH1,2,3 and DAAM2 as 4 potential novel monogenic causes of NS. Crystal structure analysis predicts disruption of the interacting domains DIA- DAD and of the interaction of FH2 with actin as the underlying mechanisms.

FR-PO1009

Recessive Mutations of LAMA3 Cause Nephrotic Syndrome

Youying Mao, Shazia Ashraf, Nina Mann, Makiko Nakayama, Caroline M. Kolvenbach, Ronen Schneider, Amar J. Majmundar, Shirlee Shril, Friedhelm Hildebrandt. *Boston Childrens Hospital, Harvard Medical School, Boston, MA.*

Background: Integrin α3β1 represents the major podocyte integrin heterodimer. *Itga3* knock out mice have severe defects in podocyte growth and differentiation, and in glomerular basement membrane organization (Kreidberg Development 122:3537, 1996), and *ITGB4* mutation causes nephrotic syndrome (NS) in humans. In the glomerular basement membrane, integrin α3β1 is the main receptor for laminins, which are heterotrimers composed of laminin subunits α5 (*LAMA5*) or subunits α3 (*LAMA3*), β2 (*LAMB2*) and g1 (*LAMC1*). Monogenic mutations in two laminin genes have been identified to cause NS in humans, including *LAMA5* (Braun NDT, in press 2018) and *LAMB2* (Zenker Hum Mol Genet 13: 2625, 2004). In additional *LAMA3* knock out mice have abnormal glomerulogenesis (Abrass KI 70:1062, 2006).

Methods: To identify additional monogenic causes of NS, we performed whole exome sequencing in a cohort of 600 families with pediatric NS under a recessive model.

Results: In 3 families, in whom mutation in the 55 known monogenic genes of NS were excluded, we identified 3 different homozygous mutations in the gene *LAMA3* as likely causative for NS. In family B149 with congenital NS, we detected the mutation p.S1359A (homozygous, conserved to *X.tropicalis*). In A2069 2 siblings with steroid dependent NS, we detected the mutation p.T2527I (homozygous, conserved to *G.gallus*). In A2563 with steroid sensitive NS, we detected homozygous truncation mutation p.E1354*.

Conclusions: We here identified *LAMA3* as a new candidate gene for pediatric NS.

Funding: Other NIH Support - National Institutes of Health to F.H. (DK076683)

Rare Variants in PLCG2 in a Large Cohort of Multi-ethnic Children With Nephrotic Syndrome

Brandon M. Lane,[1,2] Jennifer D. Varner,[1,2] Megan Chryst-Stangl,[2] Guanghong Wu,[1,2] Gentzon Hall,[3,2] Robert F. Spurney,[3] Adebowale A. Adeyemo,[4] Rasheed A. Gbadegesin.[1,2] *[1]Pediatrics, Duke University School of Medicine, Durham, NC; [2]Duke Molecular Physiology Institute, Durham, NC; [3]Duke University Medical Center, Durham, NC; [4]National Institutes of Health, Bethesda, MD.*

Background: We have previously shown that variants in *PLCG2* are associated with the development of SSNS in a cohort of South Asian children. PLCγ2 is an essential signaling component of leukocyte driven adaptive immunity and inflammation. Therefore, we hypothesized that *PLCG2* variants are associated with pattern of response to corticosteroid therapy in NS and variability in prevalence of NS across ancestries/ethnicities.

Methods: We performed high throughput next generation targeted sequencing of *PLCG2* in a multi-ethnic cohort of 583 children with the nephrotic syndrome. Identified variants that are likely to have effects on gene function (missense, stop codon, frameshift, and obligatory splice site variants) were compared with presumed controls in the gnomAD database. Additionally, we analyzed specific *PLCG2* variants and their association with steroid therapy response (SSNS vs SRNS) and ancestry (European, African, Asian) in our cohort.

Results: We identified 10 distinct variants that are associated with NS in our multi ethnic cohort, most of which were associated with SSNS (majority with $p<0.001$). One of the variants (N174H) is novel, i.e. absent from all public databases. Seven of the variants are predicted to be pathogenic by *in silico* analysis and one occurs at an obligatory splice site (Q838). The variants associated with SSNS are grouped tightly in the EF-hand domain that is predicted to affect calcium binding and in the autoregulatory region, a region that is linked to increased PLCγ2 activity and inflammation. Variant burden was associated with disease in patients with European or Asian ancestry but not in those of African ancestry.

Conclusions: Rare variants in *PLCG2* are associated with NS and may predict the pattern of response to therapy. The clustering of variants in specific PLCγ2 regulatory domains suggests that these variants are important in the pathogenesis of NS and pattern of response to therapy. Furthermore, this data indicates that SSNS-associated variants in PLCG2 may alter calcium-dependent inflammation signaling.

ER Stress Induced by Dysregulated PI3K/AKT/mTOR Signaling Drives Increased Apoptosis in Podocytes Expressing the Human FSGS-Causing ANLN R431C Mutation

Brandon M. Lane,[2,1] Gentzon Hall,[3,1] Guanghong Wu,[2,1] Liming Wang,[3] Megan Chryst-Stangl,[1] Robert F. Spurney,[3] Rasheed A. Gbadegesin.[2,1] *[1]Duke Molecular Physiology Institute, Durham, NC; [2]Pediatrics, Duke University School of Medicine, Durham, NC; [3]Medicine, Duke University School of Medicine, Durham, NC.*

Background: We previously reported that mutations in *ANLN* cause familial forms of focal segmental glomerulosclerosis (FSGS). Anillin is a F-actin binding protein that modulates podocyte cell motility and interacts with the phosphoinositide 3-kinase (PI-3K) pathway through the slit diaphragm adaptor protein CD2A-associated Protein (CD2AP). However, it is unclear how $ANLN_{R431C}$ causes the FSGS phenotype. We hypothesized that the R431C mutation exerts its pathogenic effects by uncoupling ANLN from CD2AP and inducing aberrant PI3K/AKT signaling.

Methods: To understand the cellular effects of $ANLN_{R431C}$, we performed *in vitro* functional assays using human podocyte cell lines stably expressing $ANLN_{WT}$ or $ANLN_{R431C}$.

Results: We found that $ANLN_{R431C}$ increased cell migration ($p=0.001$), enhanced cellular proliferation ($p=0.001$), and apoptosis ($p=0.029$) relative to $ANLN_{WT}$ cells. Biochemical characterization of these dysregulated phenotypes revealed hyperactivation of the PI-3K/AKT/mTOR/Rac1 signaling axis and activation of mTOR-driven ER stress in $ANLN_{R431C}$ podocytes. Podocyte hypermotility, hyperproliferation, and ER stress-induced apoptosis were ameliorated by inhibition of mTOR, GSK-3b, Rac1, or calcineurin (Cn). Additionally, we found that endogenous ANLN and mTOR expression are regulated by the Cn/NFAT pathway suggesting that the benefits derived from calcineurin inhibition in FSGS may be due, in part, to the suppression of endogenous anillin and mTOR protein levels.

Conclusions: The $ANLN_{R431C}$ mutation causes multiple derangements in podocyte function through hyperactivation of PI-3K/AKT/mTOR/p70S6K/Rac1 signaling. These studies illustrate that rational therapeutic targets for familial FSGS can be identified through biochemical characterization of dysregulated podocyte phenotypes.

Splicing Assay with Hybrid Minigene: Assessing Pathogenicities in COL4A5 Intronic Mutations

Tomoko Horinouchi,[1,2] Kandai Nozu,[1] Tomohiko Yamamura,[1] Nana Sakakibara,[1] China Nagano,[1] Rini Rossanti,[1] Keita Nakanishi,[1] Junya Fujimura,[1] Shogo Minamikawa,[1] Takeshi Ninchoji,[1] Hiroshi Kaito,[1,2] Yuko Shima,[3] Koichi Nakanishi,[4] Kazumoto Iijima.[1] *[1]Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan, Kobe, Japan; [2]Department of Nephrology, Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan; [3]Department of Pediatrics, Wakayama Medical University, Wakayama, Japan, Wakayama, Japan; [4]Department of Pediatrics, Graduate School of Medicine, University of the Ryukyus, Nishihara-cho, Japan, Nishihara-cho, Japan.*

Background: X-linked Alport syndrome is a congenital renal disease caused by mutations in *COL4A5*. In recent years, splicing is focused on as the origin of pathogenicity and the target of treatment. But the effect and mechanism of aberrant splicing caused by intronic mutations of *COL4A5* are not fully established. To assess the splicing abnormalities arising from intronic mutations of *COL4A5*, we conducted this research.

Methods: We conducted functional splicing assay with hybrid minigene for 7 intronic mutations in *COL4A5* (1 was found in our case and 6 were in reported cases shown on the Human Gene Mutation Database). In addition, we conducted *in silico* analysis using HSF (http://www.umd.be/HSF3/HSF.shtml) and SVM-BP finder (http://regulatorygenomics.upf.edu/Software/SVM_BP/) to predict and assess the mechanisms for aberrant splicing.

Results: The minigene assay showed exon skipping by 4 variants, exon skipping+10bp insertion by 1 variant and no change by 1 variant. For 1 variant, it was difficult to assess the splicing pattern by some reason and our assay did not work. Among 3 of them, the patients' transcript analyses were conducted and the results were completely consistent with our *in vitro* assay results. *In silico* analysis revealed that in 3 variants, polypyrimidine tracts were weakened and in 2 variants, dramatic change in splicing regulation elements binding sites were observed.

Conclusions: Our splicing assay with hybrid minigene make it possible to assess whether the mutation cause aberrant splicing. In addition, *in silico* tools can assess the mechanisms for causing aberrant splicing. Our findings may help the discovery of treatment strategy.

FR-PO1013

Genomic Analysis of Focal Segmental Glomerulosclerosis in Thailand

Suramath Isaranuwatchai, Ankanee Chanakul, Chupong Ittiwut, Chalurmpon Srichomthong, Kanya Suphapeetiporn, Kearkiat Praditpornsilpa, Vorasuk Shotelersuk. *Chulalongkorn University, Bangkok, Thailand.*

Background: Focal segmental glomerulosclerosis (FSGS) has currently been found to be caused by mutations in at least 62 genes. Recently, next generation sequencing has provided a robust tool to identify its causative genes. Mutational spectra of various populations are usually different. We sought to identify causative variants in Thai patients with FSGS.

Methods: Patients aged one year or older with biopsy-proven FSGS without clinical and laboratory evidence of secondary causes were included in this study. DNA samples, pedigree and clinical information were obtained. Mutation analysis was performed by whole exome sequencing (WES) method. Patients were screened in 62 known genes formerly reported to cause FSGS. Exome data were interpreted using Variant Interpreter and the American College of Medical Genetics and Genomics (ACMG) criteria. Patients without causative mutations identified by WES will be analyzed by trio study to determine pathogenicity in variant of uncertain significance. New gene may also be discovered by trio study.

Results: WES identified the pathogenic variants in two out of 24 unrelated patients (8.3%) with biopsy-proven FSGS. A novel c.905del (p.G302Vfs*23) in exon 15 of the *COL4A4* gene resulting in frameshift was detected in one patient. Mutations in *COL4A4*, encoded collagen type 4 alpha 4, are responsible for autosomal dominant Alport's syndrome, revealing the fact that this patient was previously misdiagnosed as idiopathic FSGS. Another patient harbored a novel c.357+1G>A mutation in exon 3 in the *ZMPSTE24* gene, which encoded zinc metallopeptidase. *ZMPSTE24* mutations are found to be associated with mandibuloacral dysplasia, an autosomal recessive musculoskeletal disorder in which some patients developed FSGS. In addition to FSGS, our patient also had jaw malocclusion. Although we could identify only one mutant allele in *ZMPSTE24* in the patient, it remains possible that the other mutant allele could not be detected by WES.

Conclusions: Using WES, we successfully identified disease-causing variants in only 4.2% of patients with FSGS. To date, this is the first study in Thailand for genetic approach toward diagnosis of FSGS which could provide more accurate disease management and counseling. An appropriate testing algorithm is needed for developing future Thai guideline.

FR-PO1014

Genetic Alterations in Familial Focal Segmental Glomerulosclerosis

Yasar Caliskan,[1,2] Whitney E. Besse,[1] Ashima Gulati,[1] Erol Demir,[2] Mehmet S. Sever,[2] Shuta Ishibe,[1] Stefan Somlo.[1] *[1]Division of Nephrology, Yale School of Medicine, Yale University, New Haven, CT; [2]Division of Nephrology, Department of Internal Medicine, Istanbul School of Medicine, Istanbul University, Istanbul, Turkey.*

Background: The phenotypic variability observed in focal segmental glomerulosclerosis (FSGS) patients bearing mutations in the same gene suggests that modifier genes may impact renal presentation and outcomes. We investigated genetic alterations observed in inherited adult FSGS patients.

Methods: We analyzed 172 unrelated patients with biopsy proven idiopathic FSGS including familial (n=46) and non-familial (n=126) cases. Genetic sequencing, either whole exome sequencing (n=32) or a targeted gene panel (n=14), was performed on these 46 index patients with family history of kidney disease. Variants were included if: minor allele frequency <0.01 (recessive) or <0.001 (dominant); loss of function mutation or missense with CADD score ≥15; not seen as homozygotes in any control databases; amino acid residue conserved through evolution in multicellular organisms. Variant interpretation was done using the ACMG guideline.

Results: The median age of onset [29 (12-48) vs 35.5 (3-73) years] was significantly earlier in patients with familial FSGS compared to non-familial cases (p=0.004). The median follow up in months after diagnoses was similar between familial [38 (2-276)] and non-familial [42 (1-235)] cases (p=0.86). During follow-up, ESRD progression was higher in familial cases (21/46, 45.7%) compared with non-familial cases (22/126, 17.5%) (p<0.001). We identified a pathogenic genotype in 26 out of 46 familial cases. Thirteen individuals were explained by heterozygous (7/46, 15%) or homozygous/hemizygous/compound heterozygous (6/46, 13%) collagen IV gene (*COL4*) mutations. Thirteen individuals (13/46, 28%) were explained by mutations in the documented or recently proposed FSGS genes with or without a concurrent *COL4* mutation [*NPHS2* hom (n=2), *NPHS2* hom/*COL4A5* hem (n=1), *ADCK4* hom (n=2), *NUP107* hom (n=1), *SCARB2* hom (n=1), *TRPC6* het (n=1), *LMX1B* het (n=1), *ARHGAP24* het/*COL4A3* het (n=1), *ABCA6* hom/*COL4A4* het (n=1), *LAMA5* hom/*COL4A4* het (n=1), *PALLD* hom/*COL4A5* het (n=1)].

Conclusions: Collagen IV gene mutations explain a significant fraction of familial FSGS in our population. In a limited number of patients with parental consanguinity carrying pathogenic genotype in podocyte-related genes, *COL4* mutations were also found. Further analysis of the phenotype in patients with this co-inheritance could shed light on variations in phenotype in familial FSGS.

Loss of Podocyte-Specific SGPL1 Results in Albuminuria and Focal Segmental Glomerulosclerosis in Hypertensive Mice

Jeffrey B. Hodgin,[1] Piming Zhao,[2] Jinghui Luo,[4] Yingbao Yang,[4] Julie D. Saba.[3] *[1]The University of Michigan, Ann Arbor, MI; [2]Children's Hospital Oakland Research Institute, Oakland, CA; [3]Children's Hospital Oakland Research Institute, Oakland, CA; [4]University of Michigan, Ann Arbor, MI.*

Background: Steroid-resistant nephrotic syndrome (SRNS) often manifests as focal segmental glomerulosclerosis (FSGS), has no efficient treatment, and carries a high risk of relapse after transplant. Inactivating SGPL1 mutations cause a familial form of SRNS, but the cellular and molecular mechanisms are unknown. SGPL1 encodes sphingosine phosphate lyase (SPL), an enzyme responsible for the irreversible degradation of sphingosine-1-phosphate (S1P). S1P is a bioactive lipid that ligates to a family of G protein-coupled receptors (S1PRs) whose signaling regulates cell survival, migration and immune cell trafficking. Because whole body SGPL1 knockout mice die in the perinatal period, and most monogenic causes of SRNS result from recessive or dominant mutations in genes localized to the podocyte, we focused on podocyte-specific SGPL1.

Methods: We generated conditional knockout mice lacking SGPL1 expression in podocytes (SPL^{Podo_KO}). Hypertension was induced in wild-type (WT) and SPL^{Podo_KO} mice by nephrectomy, implanted osmotic minipumps releasing angiotensin II (AngII, 1.2 μg/kg/min), and 1% NaCl in the drinking water. Blood pressure was measured by tail-cuff, 24-hr-urine was collected, and kidneys harvested at 4 weeks for histology. SPL-deficient cultured human podocytes were generated by CRISPR/Cas9, assayed for S1P levels, and treated with AngII. Autophagy was assayed by Western blotting of LC3A-I and -II.

Results: SPL^{Podo_KO} mice had no spontaneous phenotype. Compared to WT mice (n=6), hypertensive SPL^{Podo_KO} mice (n=8) had elevated albumin-to-creatinine ratio (ACR g/g) (2.7+/-1.8 vs 0.5+/-.1 at 2 wks and 8.1+/-5.7 vs 1.93+/-3.7 at 4 wks; both P<0.05). In addition, the % glomerulosclerosis in hypertensive SPL^{Podo_KO} was more than double than WT mice (1.51+/-0.71% vs 0.70+/-0.21%; P<0.05). In vitro studies revealed undetectable SPL expression and activity and sphingolipid accumulation in SGPL1-KO vs WT human podocytes. In addition, SGPL1-KO human podocytes showed increased autophagy with AngII exposure, indicating increased sensitivity to injury.

Conclusions: We found that SPL^{Podo_KO} mice are profoundly sensitive to glomerular stress, indicating a prominent role for this signaling pathway in FSGS. Therapeutic targeting of S1P signaling, such as with the S1PR antagonist FTY720, which is already FDA approved for use, may be beneficial.

Modeling of FSGS in Podocin R138Q Knock-in iPSC-Derived Human Organoids

Amy D. Westerling-Bui, Christina N. Cheng, Alyssa Fanelli, Grinal M. Corriea, Hien G. Hoang, Thomas Soare, Thomas T. Tibbitts, Jean-Christophe P. Harmange, Peter H. Mundel. *Goldfinch Bio, Cambridge, MA*.

Background: The recent development of iPSC derived human kidney organoids has opened the possibility to study human kidney physiology and pathophysiology in a differentiated, three-dimensional human experimental system in vitro. Organoids are an attractive approach to study genetic causes of human kidney diseases, such as FSGS. However, due to the fact that organoids are thought to represent second trimester human kidneys and due to lack of vascularization and urine flow, whether they can be used as a model system of human kidney diseases remains uncertain.

Methods: To explore whether FSGS can be reproducibly modeled in human iPSC-derived organoids, we generated CRISPR/Cas9-engineered podocin R138Q knock-in iPSCs and developed a protocol for their successful differentiation into human kidney organoids. The human podocin R138Q mutation was chosen in this proof-of-concept study because this variant causes FSGS with early disease onset and rapid progression to end-stage renal disease in patients and homologous R140Q causes FSGS in knock-in mice.

Results: Here we present a thorough characterization of R138Q organoids at the structural, molecular, cellular and pathophysiological level. We also present data on the phenotypic changes resulting from the treatment of organoids with pharmacologic agents.

Conclusions: We conclude that using iPSC-derived organoid technology is a promising tool for modeling human kidney disease, as it empowers ongoing drug discovery for genetically defined FSGS.

A Novel Heterozygous Missense Mutation of Wilms' Tumor 1 May Cause FSGS Through Dysregulated Expression of ARHGAP24

Gentzon Hall,[1] Matt G. Sampson,[2] Brandon M. Lane,[3] Olivia G. Gregory,[4] Maria E. Kovalik,[3] Guanghong Wu,[5] Megan Chryst-Stangl,[6] Liming Wang,[1] Robert F. Spurney,[1] Rasheed A. Gbadegesin.[1] *[1]Duke University Medical Center, Durham, NC; [2]University of Michigan, Ann Arbor, MI; [3]Duke University, Durham, NC; [4]Duke University Medical Center, Durham, NC; [5]Duke university, Durham, NC; [6]Duke Molecular Physiology Institute, Durham, NC.*

Background: Mutations of the transcriptional regulator Wilms' Tumor 1 are most commonly associated with syndromic disease but some mutations have been shown to cause renal-limited disease. We previously reported a novel heterozygous missense mutation (Exon 9; p.R458Q) of Wilms' Tumor 1 that caused non-syndromic autosomal dominant FSGS in two Northern European kindreds. We now report a second novel WT1 mutation (Exon 8; p.R443G) as a cause of non-syndromic autosomal dominant FSGS in a 3-generation kindred from North-Central India.

Methods: Direct sequencing, lentivirus-mediated WT1 expression, immunoblot, immunofluorescence imaging, electrophoretic mobility shift assay (EMSA) and apoptosis assays.

Results: A novel heterozygous missense mutation of WT1 (Exon 8; p.R443G) was identified by direct sequencing of the proband and an affected cousin in a North-Central Indian kindred with non-syndromic FSGS. An autosomal dominant pattern of inheritance was suggested by male-to-male transmission across three generations of the family. Substitution of the highly conserved arginine residue at position 443 was considered damaging by *in-silico* prediction. The R443G mutation impaired DNA-binding by EMSA and distorted the secondary structure of the transcription factor DNA-binding domain by *in-silico* modeling. WT1 was previously identified as a potential regulator of *ARHGAP24*; a known FSGS gene that regulates podocyte cytoskeletal dynamics and survival through modulation of Rac1 activity. ARHGAP24 protein expression was significantly upregulated in $WT1_{R443G}$ podocytes (p=0.003; n=3) relative to $WT1_{WT}$ podocytes. Consistent with the increase in ARHGAP24 expression, $WT1_{R443G}$ podocytes exhibited decreased motility (p=0.01; n=3) and increased apoptosis (p=0.04; n=5) accompanied by a significant decrease in STAT3 phosphorylation at Ser727 (p=0.02; n=3); a Rac1-mediated prosurvival post-translational modification. These findings suggest that WT1 functions as an inhibitor of *ARHGAP24* expression and the R443G mutation impairs this inhibitory effect.

Conclusions: The novel $WT1_{R443G}$ mutation causes non-syndromic FSGS. The mutation induces an upregulation of *ARHGAP24* expression and increases podocyte apoptosis probably through decreased Rac1-mediated prosurvival signaling.

The LMX1βR246Q Mutation Induces Podocyte Injury Through Dysregulation of Cholesterol Transport Gene Expression

Gentzon Hall,[1] Gloria Michelle Ducasa,[2] Brandon M. Lane,[3] Maxwell S. Lagas,[4] Maria E. Kovalik,[3] Olivia G. Gregory,[5] Guanghong Wu,[1] Megan Chryst-Stangl,[1] Liming Wang,[1] Robert F. Spurney,[1] Alessia Fornoni,[6] Rasheed A. Gbadegesin.[1] *[1]Duke University Medical Center, Durham, NC; [2]University of Miami School of Medicine, Miami, FL; [3]Duke University, Durham, NC; [4]University of Arizona, Phoenix, AZ; [5]Duke University, Durham, NC; [6]University of Miami, Miami, FL.*

Background: We previously reported a heterozygous missense mutation of the LIM Homeobox Transcription Factor 1 Beta (LMX1β) as a cause of nail-platella-like renal disease (NPLRD) in two families with hereditary FSGS. Currently, there are no targeted therapies for $LMX1\beta_{R246Q}$-induced glomerulopathy. We hypothesized that $LMX1\beta_{R246Q}$ disrupts the expression of disease-relevant molecular targets within key signaling pathways that may be amenable to pharmacotherapy. To test this hypothesis, we performed an unbiased, whole-transcriptomic analysis in our established $LMX1\beta_{WT}$ and $LMX1\beta_{R246Q}$-overexpressing podocyte lines to uncover potential therapeutic targets.

Methods: We conducted RNA-seq, qPCR, immunoblot, cholesterol efflux assays and apoptosis assays in our established $LMX1\beta_{WT}$, $LMX1\beta_{R246Q}$- and VIVIT overexpressing podocytes to evaluate the effect of the $LMX1\beta_{R246Q}$ mutation on cholesterol transport gene expression, cholesterol efflux and viability.

Results: Using RNA-seq, we determined that $LMX1\beta_{R246Q}$-overexpressing podocytes express significantly reduced levels of ATP-binding Cassette Transporter Family A1 (*ABCA1*) and *ABCG1* relative to $LMX1\beta_{WT}$-overexpressing podocytes. These results were confirmed by qRCR. Protein expression of ABCA1 and ABCG1 was similarly reduced. Consistent with these findings, $LMX1\beta_{R246Q}$-overexpressing podocytes displayed significantly increased lipid droplet accumulation, decreased basal and Apo-AI-stimulated cholesterol efflux and increased apoptosis relative to $LMX1\beta_{WT}$-overexpressing podocytes. Evaluation of the putative promoter regions for ABCA1 and ABCG1 revealed no LMX1β binding sequences (i.e. FLAT-E or FLAT-F) but did reveal multiple candidate NFAT binding sequences. $LMX1\beta_{R246Q}$-overexpressing podocytes displayed decreased NFAT4 expression and ABCA transporter expression was decreased in VIVIT-overexpressing podocytes.

Conclusions: The $LMX1\beta_{R246Q}$ mutation may cause FSGS, in part, through the dysregulation of NFAT-dependent lipid trafficking gene expression. This study provides the first demonstration of a potential role for impaired lipid trafficking in the pathobiology of familial FSGS and suggests that lipid depleting therapies may have a role in the treatment of some forms of familial FSGS.

Interstrain Variation in Severity of Nephropathy and Immunoglobulin Levels in HIV-1 Transgenic Mice

Nicholas J. Steers,[1] Young-Ji Na,[1] Natalia D. Demaria,[1] Wan yee Lam,[1] Vivette D. D'Agati,[2] Ali G. Gharavi.[1] *[1]Columbia University, New York, NY; [2]Columbia University College of Physicians and Surgeons, New York, NY.*

Background: We studied the genetic and immunological determinants of nephropathy in HIV-1 transgenic (Tg) mice, a model that displays the clinical and molecular signatures of collapsing FSGS. On the FVB/NJ background over 80% of the Tg-FVB mice develop significant glomerulosclerosis; however F1 hybrids with other inbred strains of mice demonstrate variable penetrance from completely resistant to highly sensitive.

Methods: Tg-FVB mice were crossed with 12 different inbred strains of mice to generate F1 hybrids. At 8 weeks of age, we evaluated the severity of nephropathy by histology, analysis BUN, and serum IgA and IgG. Urine was analyzed for proteinuria, hematuria and NGAL.

Results: Three stains (A/J, C3H/HeJ, and DBA/1J) were highly sensitive to the Tg resulting in severe glomerulosclerosis, 4 strains (129S1/SvImJ, C57BL6/J, C57BL6/NJ, and CAST/EiJ) were resistant to the Tg resulting in limited to no glomerulosclerosis, and 5 strains (CBA/J, DBA/2J, NOD/ShiLtJ, NZO/HlLtJ and WSB/EiJ) had intermediate glomerulosclerosis. Preliminary analysis of the laboratory strains of mice indicated that the MHC haplotype b was associated with limited to no glomerulosclerosis. The glomerulosclerosis score correlated with the presence of casts, interstitial fibrosis and tubular atrophy, interstitial inflammation, proteinuria, elevated plasma BUN, and decreased plasma IgG concentrations. To determine if there were baseline differences between the 12 wildtype F1 hybrid mice, IgA, IgG and BUN plasma concentrations were determined. Significant differences were observed in the BUN (ANOVA p-value = 0.014), IgG (ANOVA p-value = 0.016), and highly significant differences were observed in plasma IgA (ANOVA p-value = 0.0022), between the groups of mice. No kidney pathologywas observed in the wildtype F1 hybrid mice.

Conclusions: Our data demonstrates differences in the immunoglobulin levels and BUN in the steady state of 12 different F1 wildtype strains of mice. The MHC b haplotype was associated with reduced penetrance of nephropathy. Future studies will include additional inbred stains of mice and GWAS analysis, to confirm findings and identify additional immunological and genetic influences.

FR-PO1020

Precise Modeling of NUP93 Highlights Downstream Pathways

Katherine R. Bull,[1] Moin Saleem,[2] Richard J. Cornall.[1] *[1]University of Oxford, Oxford, United Kingdom; [2]University of Bristol, Bristol, United Kingdom.*

Background: Variants in nuclear pore complex components, including *NUP93*, cause steroid resistant nephrotic syndrome (SRNS), but underlying mechanisms are not understood. *NUP93* null mutations are likely to be lethal. Genetic validation and investigation requires tools to link genetics to cellular function. Conventional methods in immortalized podocytes fail to model non-null variants under physiological promotors, and are limited by transfection resistance. To better mimic human disease we applied CRISPR/Cas9 to model a *NUP93* variant.

Methods: Lentivirus was used to generate human podocytes constitutively expressing Cas9 and introduce guide sequences. Motility was assessed by scratch assay. 150 bp PE polyA RNA-Seq (HiSeq4000) was analysed in R, fitting a quasi likelihood generalised linear model with edgeR.

Results: Lentiviral podocyte CRISPR is efficient, disrupting 43% of alleles, 98% after single cell selection. We modeled a homozygous mutation in exon 13 of *NUP93*, identified

in a child with SRNS. Edited podocytes had NUP93 protein but reduced motility. We performed RNA-Seq on NUP93, wildtype and two Wilms Tumor 1 (WT1) podocyte lines. WT1 requires cofactor translocation; the WT1 transcriptomes clustered, but were distant from NUP93, suggesting NUP93 is not essential for WT1 function. Comparing NUP93 to wildtype, 3011 genes were significantly differentially expressed. Gene ontology analysis highlighted cell cycle, proliferation and interferon signalling. Highly overexpressed genes included *ID2*, which regulates proliferation and is repressed by SMAD4. Since NUP93 facilitates SMAD4 nuclear transport, this suggests a pathway.

Conclusions: Lentiviral CRISPR efficiently induces mutation in immortalized podocytes, providing a new technique for genetic manipulation of this cell line. Using this approach we modeled human SRNS disease due to aberrant NUP93 and highlight potential downstream targets.

Ablation of PFN1 Expression Causes Proteinuric Disease

Christopher E. Pedigo,[1] Kazunori Inoue,[2] Xuefei Tian,[2] Elizabeth Cross,[2] Ying Wang,[1] Shuta Ishibe,[1] Wei Li.[1] *[1]Yale University, New Haven, CT; [2]Yale University, New Haven, CT.*

Background: Understanding the pathobiology of glomerular diseases is paramount as it accounts 80% of end stage kidney disease cases in the US. Recent reports have identified human mutations in INF2 to cause proteinuric disease leading to loss of F-actin stress fiber formation in podocytes. Our study focused on an INF2 interactor Profilin 1(PFN1), a protein involved in the elongation of F-actin fibers. Despite the discovery of reduced PFN1 expression in microdissected Diabetic Kidney Disease(DKD) patient glomeruli, the function of PFN1 in podocytes is unknown. To investigate the role of Pfn1 in podocytes we studied diabetic mice, generated podocyte specific Pfn1 knockout mice and used CRISPR-Cas9 to knockout PFN1 in cultured human podocytes.

Methods: Glomeruli from the DKD model, db/db, were isolated using dynabeads. Analysis for RNA and protein were performed. Podocyte specific *Pfn1* knockout mice were generated and phenotyped. Purified primary podocytes were isolated from *Pfn1*KO mice by breeding to the Terminator mouse. CRISPR-Cas9 mediated PFN1 knockout (*PFN1*KO) cultured human podocytes were generated and analyzed.

Results: Pfn1 expression is reduced in glomeruli from db/db mice compared to controls. To understand the role PFN1 in podocytes, podocyte specific *Pfn1* knockout(*Pfn1*KO) mice were generated. *Pfn*1KO mice demonstrated progressive albuminuria starting at 3 weeks($p<0.05$) and severe kidney failure ($p<0.05$) leading to morbidity and mortality by ($p<0.05$) by 9 weeks of age. Histological analysis revealed increased mesangial expansion (PAS staining, $p<0.05$) and progressive interstitial fibrosis/proteinaceous casts (Trichrome Staining, $p<0.05$) by 6 weeks of age. Ultrastructural analysis revealed podocyte foot process effacement and vacuole-like structures which was recapitulated by similar structures in *PFN1*KO cultured human podocytes. Primary mouse *Pfn1*KO podocytes and *PFN1*KO cultured human podocytes revealed a significant reduction in ability to spread and migrate ($p<0.05$).

Conclusions: Our data suggest that loss of podocyte *Pfn1* expression is sufficient to cause podocyte injury, identifying PFN1 as an essential regulator of podocyte function and maintenance. These data support further identification of PFN1 regulatory targets in podocytopathies.

FR-PO1022

Elucidating Transport Kinetics of Risk-Variant APOL1 Through the Secretory Pathway Helps to Understand Molecular Mechanism of Kidney Cell Toxicity

Zayd Daruwala,[1,3] Jayne Raper,[2] Joseph A. Giovinazzo,[4] Alejandro J. Friedman.[4] *[1]CUNY Hunter College, New York City, NY; [2]City University of New york, New York, NY; [3]The Graduate Center of the City of New York, New York City, NY; [4]Hunter College, New York, NY.*

Background: APOL1 is an innate immunity factor circulating on HDL particles, forming cation specific channels in African trypanosomes that lead to ionic imbalance and osmotic lysis. When endocytosed by the parasite, APOL1 undergoes a necessary acidification followed by neutralization upon recycling to the plasma membrane. G1 and G2 variants of APOL1 protect against human-infective trypanosomes but increase the risk of kidney disease. Within a human cell, APOL1 traffics along the secretory pathway, which is acidified at the golgi followed by neutralization at the plasma membrane. We show that the trafficking kinetics of G2 and non-risk G0 are similar as they travel along the secretory pathway. We also find that APOL1 is membrane-bound within the cell and is not secreted out.

Methods: Stably transfected FlpIn Trex HEK 293 cells were generated expressing the cDNA of APOL1 variants under a tet-inducible promoter. Soluble proteins were separated from membrane-bound proteins through subcellular fractionation. Cells were collected at different time points to analyze intracellular APOL1 localization. Organelles were separated using mechanical lysis and sucrose gradient ultracentrifugation. Protein co-localization with organelles was analyzed via Western blot. Toxicity was measured by quantifying LDH release. Culture media was immunoprecipitated to pull down APOL1.

Results: Subcellular fractionation showed APOL1 co-localizing in membrane-bound fractions. Sucrose gradient separation of organelles revealed that the majority of G0 and G2 APOL1 localized to the plasma membrane within 10 hours of induction of expression. Unlike G0, the G2 variant leads to cell swelling followed by cell lysis. No APOL1 secretion was detected in the media of cells expressing any of the variants.

Conclusions: We report that there is no secretion of G0 or G2 APOL1 into the media, indicating that the toxicity is related to intracellular localization of G2. There appears to be no distinction between G0 and G2 APOL1 in relation to their trafficking through the secretory pathway to the plasma membrane. However while both associate with the membrane fraction, G2 is toxic to cells but G0 is not, hinting to a hypothetical chaperone or regulatory mechanism that G2 evades, allowing for ion channel formation.

FR-PO1023

A Modifier Genetic Screen for APOL1 in Drosophila Nephrocytes Identified Potential Therapeutic Targets That Rescue the Renal Toxicity of APOL1

Zhe Han.[1,2] *[1]Genetic Medicine, Children's National Health System, Washington, DC; [2]Precision Medicine and Genomics, George Washington University, Washington, DC.*

Background: African Americans are at higher risk for developing chronic kidney diseases due to APOL1 risk alleles (RA), but the treatment is lacking. We generated a *Drosophila* model of APOL1 nephropathy by expressing APOL1-G1 in nephrocytes, which share striking similarities with podocytes. APOL1-G1 expression in nephrocytes led to loss of renal function and cell death, providing a platform to identify genes that modifies APOL1 renal toxicity.

Methods: We designed and performed a modifier genetic screen for APOL1 in *Drosophila*, by crossing thousands of transgenic RNAi lines to a master line that carries four transgenes: a nephrocyte-specific driver (Dot-Gal4), a nephrocyte function readout (MHC-ANF-RFP), a marker (Hand-GFP) and the UAS-APOL1-G1 over a balancer chromosome. We examined and compared the effects of silencing each individual gene in nephrocytes, with or without APOL1-G1. We also used a human kidney cell line to validate our findings.

Results: We identified ~20 genes (out of ~1000) that could modify the APOL1-G1 toxicity in nephrocytes. Silencing of these genes alone in nephrocytes did not generate a phenotype, but the toxicity was increased in a synergistic manner together with APOL1-G1, suggesting that these genes could antagonize APOL1-G1 toxicity when over-expressed. We therefore generated transgenic lines to over-express these genes in nephrocytes. We discovered that two of these genes, when over-expressed with APOL1-G1, could rescue the functional defects of nephrocytes caused by APOL1-G1 expression. We further tested these two genes in a human kidney cell line, and found that they encode proteins that co-localize and directly bind to APOL1. Furthermore, expression of these two genes in human kidney cells significantly rescued the cell death caused by APOL1-G1 expression.

Conclusions: Our findings suggest that the *Drosophila* genetic screen can be used to identify modifier genes for APOL1 renal toxicity. Our data suggest that an evolutionarily conserved genetic network mediates the renal toxicity of APOL1-RA. Using *Drosophila* genetic screen and cultured human kidney cells, we discovered two genes that antagonize the renal toxicity of APOL1-G1 in both fly nephrocytes and human kidney cells, as potential therapeutic targets for APOL1 nephropathy.

FR-PO1024

pH-Dependent Channel Formation by APOL1: Gateway to Toxicity?

Russell P. Thomson,[1] Joseph A. Giovinazzo,[1] Charles M. Schaub,[2] Alan Finkelstein,[3] Jayne Raper.[1] *[1]Department of Biological Sciences, Hunter College, City University of New York, New York, NY; [2]The Graduate Center of the City University of New York and Hunter College CUNY, New York, NY; [3]Department of Physiology and Biophysics, Albert Einstein College of Medicine, New York, NY.*

Background: African variants of apolipoprotein L-I (APOL1) are strongly associated with kidney disease among African Americans. APOL1 variants are cytotoxic when expressed in human cells, a property which is associated with the formation of pH-dependent cation fluxes across the plasma membrane. This cation flux is likely mediated by APOL1 itself as recombinant APOL1 forms pH-gated cation-selective channels in planar lipid bilayers that are similarly affected by pH. Here we show that APOL1 of baboons also forms a cation-selective conductance in planar lipid bilayers, but that this conductance is largely unaffected by pH. We identify two human APOL1-specific residues - tyrosine-351 and glutamate-355 - that combine to produce channel closure at acidic pH and opening at neutral pH.

Methods: We utilized human-baboon APOL1 chimeras and site-directed mutagenesis to identify residues involved in pH gating. Recombinant proteins were produced in *E. coli* and incorporated into planar lipid bilayers using established techniques.

Results: Similar to baboon APOL1, a human-baboon APOL1 chimera containing the C-terminal 46 residues of baboon APOL1 produced channels that remained open at acidic, as well as neutral pH. This effect could be entirely replicated with the single change of tyrosine-351 for its baboon-specific counterpart glycine, but was only partially recapitulated by the more conservative tyrosine-351 for phenylalanine substitution. A single substitution of human APOL1 glutamate-355 for the uncharged glutamine also abrogated pH gating.

Conclusions: We propose that under acidic conditions the bulky side-chain of Tyr-351 is positioned to effect channel closure. Upon pH neutralization Glu-355 becomes negatively charged, allowing for displacement of Tyr-351 and for channel opening to occur. Investigations are currently underway to determine if mutation of channel gating behavior affects the toxicity of APOL1 when expressed in human cells.

FR-PO1025

Changing the Channel: Mutational Analysis of APOL1 Reveals Structural Insights Impacting G1 and G2 Associated Kidney Disease

Charles M. Schaub,[1,2] Russell P. Thomson,[3] Joseph A. Giovinazzo,[3] Alan Finkelstein,[4] Jayne Raper.[5] *[1]Biochemistry, The Graduate Center of the City of New York, New York, NY; [2]Biology, Hunter College CUNY, New York, NY; [3]Hunter College, New York, NY; [4]Albert Einstein College of Medicine, New York, NY; [5]City University of New york, New York, NY.*

Background: The human innate immunity factor Apolipoprotein L-1 (APOL1), is a cation selective channel that protects against African Trypanosomes. The channel has two putative transmembrane domains, requires acidification for activation, and opens upon subsequent neutralization. Natural variants of APOL1, G1 and G2, have been recognized as risk factors for kidney disease. Investigating the structure of APOL1 would assist in identifying mechanisms of channel formation responsible for kidney cell toxicity caused by the G1 and G2 variants.

Methods: Recombinant APOL1 (rAPOL1) was purified from *E. coli* BL21-DE3-RIPL cells expressing the pNIC-28 vector. The effects of single and multiple amino acid substitutions were first tested for trypanolytic activity, followed by channel formation and ion selectivity in planar lipid bilayers. Blue Native PAGE of APOL1 expressing FlpIn TREX 293 cells along with SDS-PAGE of rAPOL1 was performed to visualize oligomers of the APOL1 channel. Protease protection assays of rAPOL1 channels in LUVs were used to ascertain orientation and channel transmembrane domains via silver stain and mass spectrometry.

Results: At acidic pH, rAPOL1 G0 is a non-ideal cation channel. Substituting amino acids in the second predicted transmembrane domain not only inhibited *in vitro* trypanolytic activity, but also altered channel conductance and cation selectivity. Changes in the leucine zipper motif at the C-terminus abolished rAPOL1 activity *in vitro* and in planar lipid bilayers. Mutations within the C-terminus, that retain trypanolytic activity, indicate that rAPOL1 is an oligomer as a functional channel. Furthermore, oligomers of APOL1 have been visualized by Blue Native PAGE from the TREX 293 cells upon release from the ER. Fragments of the digested rAPOL1 channel protected by LUVs designate orientation and transmembrane regions.

Conclusions: These findings reveal that APOL1 requires oligomerization to form a functional channel, which is driven by residues in the C-terminus. In addition, we identified specific amino acids in the second transmembrane domain that govern cation selectivity.

FR-PO1026

APOL1 (G0) Confers Protection from HIVAN by Facilitating Parietal Epithelial Cell (PEC) Transition to Podocytes (PD)

Vinod Kumar,[1] Nitpriya Paliwal,[2] Xiqian Lan,[2] Kamesh R. Ayasolla,[2] Seyedeh Shadafarin Marashi Shoshtari,[8] Sheetal Chowdhary,[7] Ashwani Malhotra,[3] Catherine Meyer-Schwesinger,[5] Karl Skorecki,[4] Pravin C. Singhal.[6] *[1]Fienstine Institute for Medical Research, NEW YORK, NY; [2]Feinstein Institute for Medical Research, Jersey city, NJ; [3]Feinstein Institute Medical Research and NSLIJ, MANHASSET, NY; [4]Rambam Health Care Campus, Haifa, Israel; [5]University of Hamburg, Hamburg, Germany; [6]North Shore LIJ Health System, Great Neck, NY; [7]Feinstein Institute of Medical Research, New Hyde Park, NY; [8]The Feinstein Institute for Medical Research, Manhasset, NY.*

Background: The majority of HIV infected Africans carrying APOL1 risk alleles develop HIVAN if not treated with antiviral therapy. On the contrary, HIV infected Africans as well as Caucasians carrying APOL1 wild-type (G0), rarely develop HIVAN. We hypothesize that APOL1G0 facilitates PDs renewal by PECs, thus allowing replenishment of HIV-induced podocyte loss, whereas, PECs expressing APOL1G1 or APOL1G2 are not able to complete the transition and accumulate into Bowman's space.

Methods: To aim transition (differentiation) to PDs, immortalized human PECs were incubated in special media for 14 days. PEC- transduced with either Vector or HIV (NL4-3) were assayed for APOL1 expression. To determine the role of APOL1, differentiated PECs were transduced with Vector, APOL1G0, APOL1G1, or APOL1G2 lentivirus. After 48 hours, cellular lysates were probed PEC (PAX2 and Claudin 1) and PD (CD2AP, WT1, α-actinin, and podocalyxin) markers. To determine the role of APOL1-miR193a axis, cellular lysates of above-mentioned transduced cells were assayed for miR193a expression and PEC/PD markers. To confirm the disruption of APOL1-miR193a axis, HEKs (human embryonic kidney cells with undetectable APOL1 expression) were transfected with Vector, APOL1G0, APOL1G1, or APOL1G2 plasmids followed by evaluation of miR193a expression and PEC/PD markers. Human renal biopsy specimens and renal cortical sections of 4-week and 8-week old HIV transgenic mice (Tg26) expressing APOL1G0, APOL1G1, and APOL1G2 were graded for the severity of renal lesions.

Results: HIV induced the expression of APOL1 in PECs. The induction of APOL1 in undifferentiated PECs and HEKs down-regulated miR193a expression but stimulated the expression of PD markers. APOL1G1 and APOL1G2 in differentiated PDs as well as in differentiated PECs down-regulated PD markers but upregulated the expression of miR193a. Renal biopsy specimens of HIVAN patients displayed accumulation of PECs in Bowman's space with the expression of occasional PD markers. Tg26: APOL1G0 mice displayed minimal accumulation of PECs in Bowman's space as well as minimal renal lesions vs. TG26: APOL1 G1/G2 mice.

Conclusions: APOL1G0 prevents the development of HIVAN through facilitating PECs transition to PDs.

Role of Epigenetics in Parietal Epithelial Cell Transition

Vinod Kumar,[1] Kamesh R. Ayasolla,[2] Xiqian Lan,[2] Nitpriya Paliwal,[2] Sheetal Chowdhary,[8] Seyedeh Shadafarin Marashi Shoshtari,[3] Ashwani Malhotra,[4] Catherine Meyer-Schwesinger,[5] Karl Skorecki,[6] Pravin C. Singhal.[7] *[1]Fienstine Institute for Medical Research, NEW YORK, NY; [2]Feinstein Institute for Medical Research, Manhasset, NY; [3]The Feinstein Institute for Medical Research, Manhasset, NY; [4]Feinstein Institute Medical Research and NSLIJ, MANHASSET, NY; [5]University of Hamburg, Hamburg, Germany; [6]Rambam Health Care Campus, Haifa, Israel; [7]North Shore LIJ Health System, Great Neck, NY; [8]Feinstein Institute of Medical Research, New Hyde Park, NY.*

Background: APOL1 is a minor component of circulating lipid-rich multiprotein complexes in certain primate species including humans. It is expressed in liver, pancreas, kidney, brain, macrophages, and endothelial cells. In kidneys, APOL1 protein is expressed in podocytes, tubular, and vascular smooth muscle cells. Parietal epithelial cells (PECs) do not express APOL1 under a normal physiologic state. We hypothesize that epigenetic factors have a potential to induce APOL1 expression in PECs for their participation in PDs renewal in adverse milieus

Methods: Immortalized human PECs (at 33°C) were transduced with either vector (V) or HIV (NL4-3) (n=4); PECs were incubated in media containing variable concentration of IFN-γ (0, 5, 10, and 20 nM) for 48 hours (n=4); PECs were treated with either buffer, azacytidine (5 μM, a demethylating agent), or SAHA (10μM, a histone deacetylation inhibitor) for 48 Hours (n=4). Protein blots were probed for APOL1, DNMT 1-3, HDAC 1-4, $H3K27me^3$, $H3K4me^3$, $H3K8/9^{ac}$, and reprobed for β-actin. cDNAs were amplified for *DNMT1-4*, *HDAC1-4*, and *APOL1* with specific primers. RNAs were assayed for miR193a. To confirm histone acetylation at miR193a gene promoter, ChiP assay was carried out. To confirm binding of miR193a to APOL1 gene promoter, RIP-ChIP assay was performed. To measure methylation of CpG islands at miR193a gene, Bisulphite sequencing was carried out in PECVs and PECHIVs.

Results: Both HIV and IFN-γ induced APOL1 expression in PECs. PECHIV and IFN-γ-treated PECs showed 2- to 2.5-fold decrease in miR193a expressions, respectively; as expected, inhibition of miR193a in PECs also resulted in the induction of APOL1expression. The treatment of PECs with either azacytidine or SAHA induced the expression of APOL1 as well as decreased (3-fold) miR193a levels. HIV and IFN-γ enhanced the expression of DNMT3b, HDAC4, $HK4me^3$, and $H3K27me^3$, but down-regulated the expression of $H3K8/9^{ac}$. ChIP assay revealed histone methylation at 27 lysine residues. RIP-ChIP assay

confirmed binding of miR193a on APOL1 gene promoter. Bisulphite-sequencing displayed enhanced methylation of CpG islands at miR193a gene in PECHIVs.

Conclusions: Epigenetic factors play a role in the induction of PECs expression of APOL1 through modulation of miR193a expression in adverse milieus.

FR-PO1028

Community-Based Evaluation of APOL1 Genetic Testing in African Americans: National Stakeholder Meeting and Return of Results Recommendations

Bessie A. Young,[1,2] Kerri L. Cavanaugh,[3] James G. Wilson,[4] Erika Blacksher,[5] Stephanie M. Fullerton,[5] Ebele Umeukeje,[3] Jonathan Himmelfarb,[2] Wylie Burke.[5] *[1]Hospital and Specialty Medicine and Seattle COIN, Veterans Affairs Puget Sound Health Care System, Seattle, WA; [2]Kidney Research Institute, Department of Medicine, Division of Nephrology, University of Washington, Seattle, WA; [3]Vanderbilt University Medical Center, Nashville, TN; [4]University of Mississippi Medical Center, Jackson, MS; [5]University of Washington, Seattle, WA.*

Background: African Americans (AA) are 2-4 times more likely to develop ESRD, compared to whites. Apolipoprotein L1 (*APOL1*) high-risk variants have been associated with greater risk of developing non-diabetic ESRD among African Americans (AAs), incident CKD, proteinuria, and transplant failure compared to those with wild type *APOL1*. Currently there is a lack of national guidelines for genetic testing for *APOL1* in transplantation and general clinical care.

Methods: We convened a national meeting of stakeholders (researchers, clinicians, patients, family members, community members, national advocacy and professional organizations, and NIH representatives) to develop guidance for policy-makers and clinicians regarding *APOL1* genetic testing in transplantation and general clinical care. We identified areas of consensus, disagreement, and needed research. Participants received educational information, *APOL1* research updates, results of stakeholder interviews and of community deliberative groups. Participants discussed *APOL1* relevant policy concerns regarding genetic testing.

Results: After 2 days of discussion, draft conclusions regarding *APOL1* were developed, including: 1) AA should be informed about *APOL1* risk; 2) *APOL1* testing should be integrated into renal transplant programs; 3) routine use of *APOL1* testing in general clinical care is not recommended, because it is not actionable; 4) research is crucial to ensure better understanding of *APOL1* risk; and 5) AA community involvement in the development of policies and educational materials about *APOL1* risk and testing is recommended to ensure testing policies address community preferences. Areas with lack of consensus included: 1) whether transplant programs should require *APOL1* testing of living donors; 2) whether transplant recipients should be told the *APOL1* status of transplanted kidneys; and 3) access to *APOL1* testing in general clinical care.

Conclusions: Draft conclusions from a national stakeholder meeting regarding *APOL1* risk indicate consensus regarding informing the AA community regarding *APOL1* genetic testing in transplantation, but lack of consensus regarding using *APOL1* testing to determine eligibility for transplant donation or in general clinical care, given current research knowledge.

Loss of Function of EMP2 Does Not Cause Glomerular Disease in Mice

Michael D. Donnan, Rizaldy P. Scott, Tuncer Onay, Ummiye venus Onay, Antoine Tarjus, Susan E. Quaggin. *Northwestern University, Feinberg School of Medicine, Chicago, IL.*

Background: Mutations in the human gene Epithelial Membrane Protein 2 (EMP2) have been linked to childhood-onset nephrotic syndrome (OMIM#615861) with expression reported within podocytes. In mice, the Emp2 gene is necessary for embryo implantation and placental angiogenesis. Its gene product, a tetraspan integral membrane protein, affects various cell behaviors including cell adhesion and migration. To further understand its role in glomerular disease, we studied Emp2 expression and generated cell-specific Emp2 knockout (KO) mice.

Methods: Emp2 mRNA was profiled in various tissues using qRT-PCR analysis. We created a conditional floxed Emp2 allele carrying a lacZ cassette that allows whole-mount β-galactosidase (β-gal) histochemical analysis of Emp2 expression. We created podocyte-specific knockout and null Emp2 mutant mice by breeding floxed Emp2 animals with Nphs1-Cre and EIIa-Cre driver strains, respectively. Emp2 mutant mice were assessed for proteinuria and renal histology.

Results: Based on qRT-PCR analysis, Emp2 expression was highest in lungs, but is expressed in multiple other organs including the kidney. β-gal staining reveals that Emp2 is present in the vasculature. In the kidney, β-gal staining is found in large caliber vessels but is surprisingly absent in glomeruli. By 3 months of age, mice lacking Emp2 within podocytes or globally do not exhibit proteinuria or renal abnormalities.

Conclusions: In contrast to previous reports, we did not observe significant Emp2 expression in podocytes or within the glomerulus. Emp2 deficiency in mice did not cause overt kidney disease. Our data demonstrate a vascular pattern of expression throughout multiple tissues. These findings suggest that Emp2 may have a key endothelial function, which would explain reports implicating Emp2 in placental vascular development and tumor angiogenesis. Our findings do not support a causative role for EMP2 mutations in patients with childhood-onset nephrotic syndrome.

Exome-Wide Association Study for C3 Glomerulopathies

Young-Ji Na,[2] Yifu Li,[2] Maddalena Marasa,[2] Priya Krithivasan,[2] Nicholas J. Steers,[2] Elena Sanchez,[2] Elena Goicoechea de jorge,[6] Manuel Praga,[3] Andrew S. Bomback,[2] Krzysztof Kiryluk,[2] Santiago Rodriguez de Cordoba,[4] Gerald B. Appel,[5] Ali G. Gharavi.[2] *[2]Columbia University, New York, NY; [3]Hospital 12 de Octubre, Pozuelo De Alarcon, Spain; [4]Consejo Superior de Investigaciones Cientificas, Madrid, Spain; [5]Columbia University College of Physicians and Surgeons, Scarsdale, NY; [6]Complutense University Madrid, Madrid, Spain.*

Background: C3 glomerulopathies (C3Gs) include a spectrum of rare diseases such as C3 glomerulonephritis (C3GN) and dense deposit disease (DDD), which share phenotypic similarities and underlying genetic commonalities. Mutations in components of the complement pathway have been implicated, but the genetic underpinnings are largely unknown. The aim of this study is to use whole-exome sequencing to improve understanding of the genetic architecture of C3G.

Methods: We performed a case-control exome-wide collapsing analysis using 282 case subjects with C3Gs [C3GN, DDD, and immune complex-mediated MPGN] and 9,825 control subjects with no known kidney diseases. To identify risk signals, we tested all protein-coding genes for an excess of ultra-rare genetic variation among the cases, compared with control samples. We tested multiple models, including loss-of-function variants and non-benign nonsynonymous variants. We also applied regional intolerance model based on missense tolerance ratio (MTR).

Results: In multiple model, patients with C3G had a higher frequency of loss-of-function variants and non-benign nonsynonymous variants in *Complement Factor H* ($P = 6.51 \times 10^{-07}$), *C3* ($P = 1.04 \times 10^{-04}$) in the dominant models and *C5* ($P = 0.0279$) and *CFB* ($P = 0.0279$) in the recessive models. Rare putatively pathogenic variants were detected mainly among C3GN cases. In addition, we identified many signals that did not reach exome-wide significance but represent interesting candidate genes for C3Gs.

Conclusions: We identified excess ultra-rare variation in several known C3G genes under both dominant and recessive models. These data suggest that exome sequencing can discover rare risk alleles for C3Gs enhancing the established gene-mapping paradigms.

FR-PO1031

Kank1 Knockout Fish Causes Proteinuria

Keiko Oda,[1] Kan Katayama,[1] Akiko Tanoue,[1,2] Eiji Ishikawa,[1] Masaaki Ito.[1] *[1]Mie University Graduate School of Medicine, Tsu, Japan; [2]Murase Hospital, Suzuka, Japan.*

Background: Kank family consists of Kank1-4 and contains KN motif, coiled-coil domains, and ankyrin-repeats. Kank1 protein is mostly located in the cytoplasm and is thought to play a role in organizing actin cytoskeleton. Recently, Kank1 is reported to be associated with nephrotic syndrome.

Methods: The expression pattern of Kank1 protein was examined in human frozen kidney sections. Since Kank1 is a conserved gene between human and zebrafish, kank1 knockout zebrafish has been used in this study. The mutant kank1 zebrafish line has a C to T point mutation in exon 3 of kank1 gene, which results in a premature stop codon from CAA (Q) to TAA. By utilizing kank1 knockout zebrafish embryos, we examined its phenotype and performed a functional assay by injecting fluorescent-conjugated dextrans.

Results: Kank1 protein was localized in the podocytes and the proximal tubules. Genotyping of zebrafish embryos from kank1 heterozygous parents was performed by polymerase chain reaction method. The phenotype of kank1 knockout embryos at 4 days per fertilization (dpf) was comparable with that of wild-type embryos. The morphology of pronephros in kank1 knockout embryos was also comparable with that in wild-type embryos under Periodic acid–Schiff stain. However, there was an uptake of both 500-kDa fluorescein isothiocyanate and 10-kDa rhodamine dextrans in the proximal tubules of kank1 knockout embryos at 3.5 dpf while there was only an uptake of 10-kDa rhodamine dextran in the those of wild-type embryos.

Conclusions: Knockout of kank1 in zebrafish might be related to the disturbed filtration barrier in the pronephros and support the human data in nephrotic syndrome.

FR-PO1032

TRPC6 Overexpression Mice Produced Proteinuria with Downregulated Podocyte Genes

Zi Jin Sun,[1] Yaochun Zhang,[1] Jun li Ng,[1] Ping Liao,[3] Tuck wah Soong,[4] Siong-Chuan Chong,[5] Yiong Huak Chan,[6] Hui Kim Yap,[2,7] Kar Hui Ng.[1,7] *[1]Paediatrics, National University of Singapore, Singapore, Singapore; [2]National University Hospital, Singapore, Singapore; [3]Research, National Neuroscience Institute, Singapore, Singapore; [4]Physiology, National University of Singapore, Singapore, Singapore; [5]Paediatrics, National University of Singapore, Singapore, Singapore; [6]Biostatistics Unit, National University of Singapore, Singapore, Singapore; [7]Khoo Teck Puat – National University Children's Medical Institute, National University Health System, Singapore, Singapore.*

Background: Mutations in transient receptor potential channel-6 (TRPC6) can cause autosomal dominant FSGS. We have previously identified novel p.R68W TRPC6 gain-of-function mutation. We aim to study the disease-causing mechanism of p.R68W mutation.

Methods: Wild type (OE^{wt}) and p.R68W (OE^{mut}) TRPC6 were overexpressed in FVB/N mice by pronuclear microinjection. The albumin:creatinine ratios were obtained. Podocyte gene expressions were measured by reverse-transcription PCR and western blot analysis. Podocyte ultrastructural changes were assesssed by transmission electron microscopy and transgene localization was performed by immunogold staining. Statistical analysis was performed using Mann-Whitney U test.

Results: Over one third of both groups of overexpression mice had albuminuria, and lower body weights compared with control mice from 6 month. Interestingly, OE^{wt} were significantly lighter compared with OE^{mut} since 6.5 month. Kidney electron microscopy slices demonstrated extensive podocyte foot process effacement in both OE mice. Immunogold staining revealed TRPC6 in OE^{wt} mice localized predominantly in the central cytoplasmic areas, whereas in OE^{mut}, TRPC6 occurred predominantly at the peripheral and central parts of the foot processes. Quantitative PCR data showed that nephrin and podocin expressions were decreased in OE mice compared to wild-type, and to a greater degree in the OE^{wt} compared to OE^{mut}.

Conclusions: Our work suggests p.R68W mutation may affect TRPC6 intracellular trafficking and its interactions with the slit diaphragm proteins in the podocytes.

FR-PO1033

Targeting MTAP-Deficient Cells in Advanced Renal Cell Carcinoma

Jihao Xu, David Yang, Robert Weiss, Ching-Hsien Chen. *UC Davis, Davis, CA.*

Background: The metabolic enzyme methylthioadenosine phosphorylase (MTAP) has been reported to function as a tumor suppressor and the lack of this gene was found in approximately 58% of kidney cancer (or renal cell carcinoma, RCC) cases. However, the mechanisms of how MTAP regulates RCC progression still remain unknown.

Methods: Tissue microarray and immunohistochemistry (IHC) were performed to analyze the correlation between MTAP expression and IGF-1R phosphorylation in RCC. A phospho-receptor tyrosine kinase array screen was utilized to assess RCC signaling pathway activity. Genetic manipulations were achieved by siRNA knockdown, CRISPR/Cas9 and ectopic expression approaches. In addition, we used an IGF-1R inhibitor, linsitinib, to suppress type 1 Insulin Growth Factor 1 Receptor (IGF-1R) signaling. *In vitro* and *in vivo* tumor suppressive activities of MTAP were confirmed by MTT, colony formation, migration assays and *in vivo* subcutaneous implantation. MTAP-regulated gene expression and signaling were determined by qRT-PCR and Western blots.

Results: We found a decrease of protein-methylation level concomitant with an increase in tyrosine phosphorylation in MTAP-knockout cells. We next performed a receptor tyrosine kinase array screen and identified IGF1R as the top-one candidate with upregulated tyrosine phosphorylation in response to MTAP loss. Western blots showed an elevation of IGF1R phosphorylation and its signaling after MTAP knockout. IHC staining on a tissue microarray has also confirmed an inversely association between IGF-1R phosphorylation and MTAP expression. We noticed a decrease of cell viability, migration, invasion and colony-forming capabilities in MTAP-knockout RCC cells after linsitinib treatment. Surprisingly, RCC cells were more sensitive to this inhibitor in response to MTAP loss, suggesting that MTAP-deficient become addicted to IGF1R activity.

Conclusions: IGF-1R signaling is a driver pathway conferring aggressive nature to MTAP-deleted renal cell carcinomas.

Stromal Signaling Promotes ccRCC Tumor Growth Through FOXD1 Overexpression

Kyle H. Bond, Ashwani K. Gupta, Leif Oxburgh. Oxburgh Lab *Maine Medical Center Research Institute, Scarborough, ME.*

Background: Clear cell renal cell carcinoma (ccRCC) is the 8th most common cancer in the U.S.. Although tyrosine kinase inhibitors (TKIs) have improved survival in patients, many patients are not responsive to TKI are in need of more options. The tumor microenvironment (TME) in ccRCC is not well understood and may be a potential target. The transcription factor FOXD1 has been shown to be upregulated in lung, breast, and kidney cancer. Functionally, FOXD1 regulates epithelial-stromal signaling in the developing kidney. We hypothesize that FOXD1 overexpression in ccRCC would promote tumor growth through stromal signaling.

Methods: The relevancy FOXD1 was first determined through RNA-seq and staining analyses. ccRCC tumor microarrays (TMAs) were stained for FOXD1, PECAM, aSMA, PDGFRb, and NG2. A Kaplain-Meier survival analysis for FOXD1 expression was performed using data from The Cancer Genome Atlas (TCGA). A potential FOXD1 binding site analyses using the TRANSFAC FOXD1 binding site matrix was performed. Binding site were compared to previously reported FOXD1-/- RNA-microarray data to determine direct binding targets. Results were confirmed by qPCR in renal proximal tubule cells (RPTECs) after transfection with a FOXD1 adenovirus. SLIT2 was found to be a functionally relevant target in kidney cancer and was assessed for its role in fibroblast signaling through scratch assays, 3D migration assays, and multiplex proximity ligation assays. Knockdown of FOXD1 in the 786-O cell line followed by qPCR, western blot, and migration analyses.

Results: 65% of TMA samples stained positively for FOXD1. FOXD1 expression within the cancer cells correlated with stromal PDGFRβ expression ($p<4.5x10-6$). FOXD1-high ccRCC patients had a worse survival outcome (FOXD1 low= 2830 days; FOXD1 high= 1913 days). FOXD1 binding site analysis, RNA-microarray, and qPCR found FGF1, SLIT2, and Decorin to be potential secreted signaling molecules repressed by FOXD1. Scratch assays on fibroblasts showed that SLIT2 reduced PDGFBB-induced cell migration ($p<0.27$). Additionally, 3D migration co-culture with 786-O cancer cells determined a repulsive effect of SLIT2 in 3D culture as well (5μm p=1.34x10-4; 50μm p=1.64x10-2).

Conclusions: FOXD1 is an important prognostic marker for aggressiveness in ccRCC. The importance of fibroblast recruitment by cancer cells in ccRCC is still not known.

Birt Hogg Dubé Syndrome (BHD) and Hereditary Leiomyomatosis and Renal Cell Carcinoma Syndrome (HRLCC): An Effective Multidisciplinary Approach to Hereditary Renal Cancer Predisposing Syndromes

Andrew J. Mallett,[1,2] Helen Mar fan,[3] Rachel Susman,[3] Janette L. Wakeling,[3] Simon T. Wood,[4] Mohammad Al-shinnag.[1,3] *[1]Kidney Health Service, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [2]Faculty of Medicine, The University of Queensland, Brisbane, QLD, Australia; [3]Genetic Health Queensland, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [4]Department of Urology, Princess Alexandra Hospital, Brisbane, QLD, Australia.*

Background: BHD and HLRCC are rare hereditary disorders caused by germline *FLCN*and *FH*mutations respectively. BHD is characterized by skin fibrofolliculomas, lung cysts, spontaneous pneumothorax and Renal Cell Carcinoma (RCC). HLRCCis characterized by skin piloleiomyomas, uterine leiomyomas and RCC. BHD and HLRCC are autosomal dominant disorders and have estimated cumulative risk of RCC 16% with life-long screening recommended. We aimed to assess adherence to surveillance guidelines in an Australian BHD and HLRCC cohort and to describe disease characteristics.

Methods: All patients with a diagnosis of BHD or HLRCC at RBWH 01/01/2014-31/12/2017 were included (HREC/17/QRBW/276). All patients were initially assessed and counselled by a Clinical Geneticist and then referred to an Adult Nephrologist. Baseline and incidental clinical variables were extracted and analysed.

Results: 40 patients were identified (18 BHD, 22 HLRCC) with a median age of 49.5years. The median and cumulative follow up were 1year and 76years respectively. Surveillance renal MRI occurred in 32/40 patients on annual basis. Of 8/40 without surveillance imaging 4 were yet to have imaging, 3 were lost follow up and 1 patient had logistic difficulties. RCC was diagnosed in 8/40 patients: 2/18 with BHD were diagnosed with RCC aged 73 and 77 both prior to commencement of surveillance. 6/22 patients with HLRCC were diagnosed with RCC (2/22 during surveillance) and 4/22 prior to commencement of surveillance (11-43 years). Amongst BHD patients, cutaneous fibrofolliculoma was noted in 8/18 patients, lung cysts in 3/18 patients, spontaneous pneumothorax in 3/18 patients, and past parotid oncocytoma in 2/18. Amongst those with HLRCC, cutaneous leiomyoma were noted in 15/22, cutaneous leiomyosarcoma in 1/22 and uterine fibroids in 10/16 female patients.

Conclusions: Evidence-based RCC screening in BHD and HLRCC cohort is feasible and able to identify incident renal lesions. Multidisciplinary patient management enables expedited genetic counselling, diagnosis, longitudinal screening and RCC management. The success of this clinical model warrants consideration of undertaking longitudinal screening of BHD and HLRCC patients by nephrologists.

FR-PO1036

Efficiency and Safety of mTOR Inhibitors for Tuberous Sclerosis Complex-Associated Renal Angiomyolipoma

Andreea Andronesi,[1,2] Bogdan Obrisca,[1] Bogdan M. Sorohan,[1] Danut Andronesi,[3] Cristina Cristache,[1] Gener Ismail.[1,2] *[1]Nephrology Department, Fundeni Clinical Institute, Bucharest, Romania; [2]Nephrology Department, University of Medicine and Pharmacy Carol Davila, Bucharest, Romania; [3]General Surgery and Liver Transplant Department, Fundeni Clinical Institute, Bucharest, Romania.*

Background: Kidney involvement is the most important cause of morbidity and mortality in adult patients with tuberous sclerosis complex (TSC). mTOR inhibitor Everolimus (EVE) is the only pathogenic treatment approved. Since TSC is a rare genetic disease, long-term experience with EVE is still limited.

Methods: TSC patients treated with EVE for renal angiomyolipoma (AML) at increased bleeding risk without immediate surgery indication were followed prospectively. Kidney CT or MRI (same modality throughout the study for each patient) was done at baseline and annually thereafter. Treatment response was evaluated as percentage of reduction of sum of volumes of all target AML identified at baseline. Adverse events (AE) were graded according to the CTCAE v3.0.

Results: Between January 2015-May 2018 17 patients (12F, 5M), mean age 34.8±7.5 years (17-61), started treatment with EVE. Baseline diameter of the biggest AML was 7.7±2.8 cm (3.8-12), 7 patients had a history of spontaneous AML bleeding with 4 of them suffering total one-sided nephrectomy. Baseline eGFR was 78.8±36.1 ml/min/1.73 m^2 CKD-EPI (9-126): 5 patients had stage 2 CKD, 1 patient stage 3, 2 patients stage 4 and 1 patient stage 5. Initial EVE dose was 10 mg/day, with dose adjustments according to target trough level (5-15 mcg/l) and tolerance. Total treatment period was 23.4±11.4 months (5-45). 69.2% of patients had a more than 30% response after 12 months and the proportion of patients with response ≥50% increased over time. No patient had new bleeding episodes, neither increase in AML volume or new AML (Table 1). All patients experienced AE, the most frequent one being dyslipidemia in 16 patients. The severity of AE was grade 1 or 2, with maximum incidence during the first 12 months, with no need for permanent treatment withdrawal.

Conclusions: Treatment of TSC-associated renal AML with EVE is efficient and well tolerated. mTOR pathway regulates many major cellular processes, so AE to EVE

are frequent. Since this is a life-time treatment, careful surveillance is essential to rapidly identify and treat these AE.

Patients treated (n)	AML response rate (%)			
	<15	15-29	30-49	≥50

FR-PO1037

Outcomes of Arterial Embolization in Treating Renal Angiomyolipomas: A Single Center Experience

Saad Mohammed Shariff, Alian Albalas, Ammar Almehmi, Ahmed K. Abdel Aal. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Selective arterial embolization (SAE) of renal angiomyolipoma (AML) is associated with parenchymal loss and contrast exposure. The aim of this study was to evaluate the baseline characteristics and the change in glomerular filtration rate (GFR) in patients with AML following SAE.

Methods: This study included all AML cases that were treated with SAE procedure at our center from 2004 to 2017. Data on demographics, tumor size, and other laboratory values were collected. Serum creatinine and calculated GFR were assessed immediately prior and 3 months after SAE procedure. GFR was calculated using CKD-EPI formula.

Results: Our cohort included 44 patients who underwent SAE. The indications for SAE included back pain, hematuria and retroperitoneal hemorrhage. Baseline characteristics were: age (mean ± SD) 47± 16.5 years; 77% females; 68% whites; and 36% were hypertensive. Acute kidney injury (AKI) was encountered in 4 patients (9%) following the SAE procedure. The (mean ± SD) serum creatinine increase from 0.97 ± 0.48 to 1.17 ± 0.88 mg/dl (p=0.008) after SAE procedure. The GFR dropped from 86.7 ± 25.8 to 79.7 ± 28.8 ml/min after procedure (p= 0.001). Post SAE GFR correlated with the tumor size (p= 0.047). Further, patients who developed AKI was found to have larger AML as compared to those with no AKI (16.8 vs 7 cm; p<0.0001).

Conclusions: Following the embolization of renal AML, there was a statistically significant decrease in GFR. Further, tumor size was associated with post procedure GFR and AKI incidence. Although the decrease in GFR could be in part attributed to the partial parenchymal loss and contrast exposure, its clinical significance is yet to be elucidated.

Baseline Characteristics and changes in GFR & Creatinine after AML Embolization

	Large (Tumor size >4cm) N=40	Small (Tumor Size >4cm) N=4	p-Value
Age Mean ± SD	47.1 ± 16.7	46.3 ± 17.1	0.84
Female	30 (75%)	4 (100%)	0.26

Trans-Ethnic Genome-Wide Association Study of Kidney Function Identifies Novel Loci Influencing the Risk for Kidney Stone

Nora Franceschini,[1] Thu H. Le,[2] Artur Akbarov,[3] Maciej Tomaszewski,[3] Andrew P. Morris.[4] COGENT-Kidney Consortium *[1]Epidemiology, University of North Carolina Chapel Hill, Chapel Hill, NC; [2]University of Virginia, Charlottesville, VA; [3]University of Manchester, Manchester, United Kingdom; [4]University of Liverpool, Liverpool, United Kingdom.*

Background: Genetic variants in the *UMOD* and *RGS14* genes are associated with kidney function and the risk of kidney stone. We hypothesized that additional kidney function loci influence the risk of kidney stone.

Methods: We performed trans-ethnic meta-analysis of genome-wide association studies of estimated glomerular filtration rate (eGFR) in 312,468 individuals of diverse ancestry, followed by fine-mapping of regions informed by functional and regulatory annotations. Variants driving eGFR association signals were queried in 452,264 UK Biobank participants of European descent for association with ICD clinical code of calculus of kidney or ureter. Associations were validated in an independent sample of 20,339 individuals of diverse ancestry (44% European ancestry) with self-reported diagnosis and history of kidney stones.

Results: We identified 93 loci attaining genome-wide significant evidence of association with eGFR ($p<5x10^{-8}$), of which 20 were novel. After adjusting for multiple testing, five eGFR loci were associated with an ICD-code diagnosis of kidney stone in the UK Biobank. These included the two loci previously associated with kidney stones (*UMOD*, rs77924615, $p=1.6 \times 10^{-16}$ and *RGS14*, $p=2.0 \times 10^{-8}$), a novel eGFR locus *CERS2* (rs267738, $p=1.6 \times 10^{-5}$), and two known eGFR loci: *CYP24A1* (rs17216707, $p=9.0x10^{-10}$), and *PRKAG2* ($p=2.4 x10^{-5}$). The association of the *CERS2* variant with kidney stone replicated in the independent multi-ethnic study ($p=0.008$).

Conclusions: Several genetic variants associated with eGFR also confer risk for kidney stone, supporting shared genetic factors for kidney function and stone formation.

Autosomal Dominant Tubulointerstitial Kidney Diseases: A Single Center Five-Year Cohort

Joana Gameiro,[1] Jose A. Lopes,[1] Sofia C. Jorge.[2] *[1]Service of Nephrology and Renal Transplantation, Centro Hospitalar Lisboa Norte, Lisbon, Portugal; [2]Portuguese Society of Nepghrology, Lisbon, Portugal.*

Background: In patients with chronic kidney disease of unknown cause, certain aspects of clinical history, urinalysis and renal ultrasound might point to hereditary chronic interstitial nephritis (CIN). Recent sequencing technologies, such as *Next-Generation Sequencing* (NGS), have been used to identify and characterize different genetic kidney diseases, difficult to diagnose up until recently. The authors present this single center cohort of patients with identified mutations in genes responsible for autosomal dominant tubulointerstitial kidney diseases (ADTKD) in the last 5 years.

Methods: Over the last five years, when patients with CKD of unknown cause presented with a phenotype suggestive of CIN, NGS study of the *UMOD*, *REN* and *HNF1B* genes was performed, if negative, variable number tandem repeat (VNTR) mutations of the *MUC1* gene were researched, if negative, multiplex ligation-dependent probe amplification (MLPA) was performed to find further mutations of the *HNF1B* gene.

Results: In the past five years, our department has identified ADTKD in 22 patients. Mutations identified included *UMOD* gene in 2 families (c.1463G>A (p.Gly488Asp); c.628G>A (p.Gly210Ser)) and 1 patient (c.859T>C (p.Cys287Arg)), *MUC1* gene in 4 families, *REN* gene in 1 patient with two variants one of them not described yet (c.29G>A e c.338C>T), and *HNF1*β gene in 2 patients.

Conclusions: A suggestive phenotype includes bland urinalysis, hyperuricemia without proportion to the CKD stage, anemia not proportional to the CKD stage, hypercalemia, acidemia, urinary concentration defects, normal to low blood pressure and medullary renal cysts. Although some clinical manifestations might suggest a specific gene, many clinical aspects of different gene mutations might have a similar phenotype. NGS technology is promising in improving the approach to patients with hereditary CKD, and has allowed us to diagnose several patients with CKD of unknown cause. The availability, celerity and cost-effectiveness of this approach make it advantageous over the sequential study of each gene with Sanger sequencing technique. The generalization of these technologies to identify genetic diseases requires consistent identification of phenotypes and integration of data obtained. Therefore, the creation of diagnostic panels is crucial to increase diagnostic accuracy.

BM-Transplant Mouse Model of MPO-ANCA-GPA

Marco A. Alba,[2] Peiqi Hu,[2] Hong Xiao,[2] Ronald J. Falk,[1] J. Charles Jennette.[2] *[1]UNC Kidney Center, Chapel Hill, NC; [2]UNC-Chapel Hill, Chapel Hill, NC.*

Background: Granulomatosis with polyangiitis is an ANCA-vasculitis characterized by necrotizing granulomatous inflammation and small vessel vasculitis. Pathogenic mechanisms involved in the development of GPA remain poorly understood. Therefore, we sought to develop a reliable murine GPA model.

Methods: MPO-knockout mice (n=8) previously immunized with mouse MPO were exposed to lethal irradiation, followed by transplantation of MPO-expressing bone marrow ($1.5x10^7$ BM cells); resulting in circulating anti-MPO antibodies and MPO^+ neutrophils. Lipopolysaccharide (LPS, 5μg) was administered by intratracheal instillation 3 weeks after BM transplant; mice were euthanized one week after.

Results: Engraftment of MPO-positive BM in combination of IT LPS resulted in the development of typical pulmonary and kidney ANCA-associated lesions in various phases of evolution, i.e., lung granulomatous lesions and vasculitis in addition to necrotizing crescentic glomerulonephritis (Figure 1).

Conclusions: A reproducible mouse model of MPO-ANCA-GPA is reported. Our results demonstrate that: 1) LPS functions as synergistic pro-inflammatory factor for facilitating anti-MPO induced pulmonary granulomatosis and 2) The effect of long-term exposure to anti-MPO-ANCA resulted in lung and kidney inflammatory lesions of different ages of evolution, closely mimicking human disease.

The Investigation on the Production of Anti-Neutrophil Cytoplasmic Antibodies in Chronic Bronchitis Rat

Guangqun Xing. Department of Nephrology *The Affiliated Hospital of Qingdao University, Qingdao, China.*

Background: The purpose of this study was to investigate the possibility of the production of Anti-Neutrophil Cytoplasmic Antibodies(ANCA) in the rat model of chronic bronchitis with a long-term and recurrent infection.

Methods: The chronic bronchitis model was designed by double stimulation with smoke and lipopolysaccharide(LPS). Rats were divided into four groups, including healthy control rats (group N), group with chronic bronchitis(group CB), group with healthy rats stimulated with PBS and Phorbol-12-mytistate-13-Beetate(PMA)(group N/PBS+PMA), group with chronic bronchitis stimulated with LPS and PMA(group CB/LPS+PMA). Immunological markers, which include Citrullinated Histone H3(CitH3), myeloperoxidase anti-neutrophil cytoplasmic antibodies(MPO-ANCA) and proteinase 3 anti-neutrophil cytoplasmic antibodies(PR3-ANCA) were measured by enzyme-linked immune sorbent assay(ELISA) at different timepoint after each stimulation. The pulmonary and kidney tissue samples were taken for histopathology. All of related parameters indicators were measured and compared by optimal statistical methods.

Results: (1) The rat models of chronic bronchitis were established and verified by histopathology. (2)With multiple and recurrent stimulation with LPS and/or PMA, the serum levels of CitH3 and MPO-ANCA were found increased gradually. (3)Compared to those in group N, group CB and group N/PBS+PMA, the serum levels of CitH3 in group CB/LPS+PMA were found increased significantly. (4)The serum levels of MPO-ANCA in group N/PBS+PMA and group CB/LPS+PMA were higher than those in group N and group CB. (5)The serum levels of CitH3 in rats were positively correlated with the serum levels of MPO-ANCA(r=0.490, p=0.024). (6)In group with CB/LPS+PMA, mild renal pathology changes could be observed with inflammatory cells infiltration, while no significant functional changes were detected.

Conclusions: With a rat model of chronic bronchitis, recurrent infections combined with multiple stimulation with PMA, MPO-ANCA could be produced.

FR-PO1042

Urinary CD163 Levels Reflect Crescentic Glomerulonephritis in ANCA-Associated Vasculitis

Joop Aendekerk,[1] Sjoerd Timmermans,[1] Peter Heeringa,[2] Pieter V. Paassen.[1] *[1]Maastricht University Medical Center, Maastricht, Netherlands; [2]University Medical Center Groningen, Groningen, Netherlands.*

Background: Early recognition of renal flares in ANCA-associated vasculitis (AAV) can be challenging, particularly among patients with persistent or recurrent urinary abnormalities. Kidney biopsies are therefore often needed to detect active vasculitis. Urinary soluble CD163 (usCD163) has been shown to reflect early renal disease. Animal studies demonstrated that increased usCD163 reflects early stage necrotizing and crescentic glomerulonephritis (GN). However, this needs confirmation in humans to establish its role as a marker of active renal AAV. Also, it is unknown whether tubulointerstitial and/or vascular damage can affect usCD163 levels. Therefore, we analyzed usCD163 in relation to histologic data on kidney biopsy.

Methods: Thirty-two patients with AAV underwent a kidney biopsy because of suspected renal vasculitis (de novo, n=13; renal flare, n=19); concurrently, urine samples were collected. None of the patients were receiving immunosuppressive treatment before biopsy. usCD163 was analyzed by ELISA and corrected for creatinine excretion. Kidney tissue samples were classified according to the ANCA GN classification and scored for tubulointerstitial and vascular damage.

Results: Increased usCD163 levels were found in 27 (90%) out of 30 patients with crescentic GN but not those with normal kidney tissue (n=2) or controls (n=6), underlining usCD163's specificity; median usCD136 levels did not differ between de novo and relapsing patients (302 versus 521 ng/mmol, P=0.1). In patients with crescentic GN, usCD163 correlated with the number of affected glomeruli (R^2=0.61, P<0.001), but no differences were found according to ANCA GN class. Neither tubulointerstitial nor vascular damage affected usCD163 levels. Patients classified as sclerotic class however, progressed more often to the composite endpoint of CKD5, ESRD, and death as compared to those classified as focal, crescentic, and mixed class (n/N= 6/11 and n/N=3/18; P<0.05). No association between usCD163 and the composite endpoint were found.

Conclusions: usCD163 is linked to crescentic GN in de novo patients with AAV, as well as during relapses. Both tubulointerstitial and vascular damage do not affect usCD163 levels, suggesting that usCD163 specifically reflects crescentic GN and should be used as a marker of active renal disease in AAV.

FR-PO1043

Familial Goodpasture's Disease Associated with a Deletion in COL4A3: A Potential Clue to Etiology

Harald Seeger,[1] Vadim Pedchenko,[2] Sergey Budko,[7] Ariana Gaspert,[3] Carsten Bergmann,[4,6] Johan Lorenzen,[1] Rudolf P. Wuthrich,[1] Billy G. Hudson,[2] Andreas D. Kistler.[5] *[1]Department of Nephrology, University Hospital Zurich, Zurich, Switzerland; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Institute of Surgical Pathology, University Hospital Zurich, Zurich, Switzerland; [4]Center for Human Genetics, Ingelheim, Germany; [5]Nephrology, Kantonsspital Frauenfeld, Frauenfeld, Switzerland; [6]Department of Medicine, University Hospital Freiburg, Freiburg, Germany; [7]Vanderbilt Univ Medical Center, Nashville, TN.*

Introduction: Goodpasture's (GP) or anti-glomerular basement membrane (GBM) disease is characterized by glomerulonephritis (GN) and/or alveolar hemorrhage. It is caused by antibodies that bind the non-collagenous domain (NC1) of the collagen IV α345 network in the GBM and alveolar basement membranes. Antibodies bind to α3 and α5 NC1 monomers but not native α345NC1 hexamers, indicating that a perturbation of the quaternary structure of the hexamer is required for eliciting an autoimmune response. We describe a case of familial GP disease associated with a structural alteration in the α345NC1 domain.

Case Description: The index patient was affected at the age of 45 years by alveolar hemorrhage and renal failure due to GN with linear IgG deposits in the GBM and circulating anti-GBM antibodies. Her son developed the same clinical phenotype at the age of 24 years. Genetic analysis revealed a heterozygous 18 base pair deletion in both subjects in the region of the *COL4A3* gene coding for the NC1 domain. The deletion contains the stop codon and leads to an elongated collagen α3NC1 domain, which substitutes 8 additional amino acid (AA) residues for the very last C-terminal AA.

Discussion: *COL4A3* mutations typically cause autosomal Alport's or thin basement membrane disease, yet there was no evidence for this in our patients. Anti-GBM antibodies behaved like in classical GP cases. They reacted with dissociated, but not native α345NC1hexamers, and bound to the wild type α3NC1 monomer at both EA and EB epitopes. Analysis of the 3D model of the α345 hexamer revealed that the mutant extension of 8 polar and hydrophobic residues is located proximal to the EA and EB epitopes. Potentially, the extension can fold into the crevice between both epitopes and lead to conformational changes that impact epitope presentation. The epitope structure may be altered to include residues of the extension or rendered accessible by the antibody. In conclusion, this is the first report of a *COL4A3* mutation associated with GP disease. The occurrence of this mutation in two family members, with autoantibodies against the α3NC1 autoantigen, indicates that it plays a key role in disease etiology. The association of this mutation with disease may be a clue to the etiology of both familial and sporadic cases of GP disease.

FR-PO1044

Significance of Glomerular Fibrinoid Necrosis in ANCA-Associated Vasculitis

Marco Delsante,[1] Francesca Costigliolo,[2] S.M. Bagnasco,[1] Avi Z. Rosenberg.[1] *[1]Renal Pathology, Johns Hopkins Hospital, Baltimore, MD; [2]Nephrology, University of Genoa, Genova, Italy.*

Background: ANCA-associated vasculitis (AAV) represent a group of severe diseases with frequent kidney involvement and poor renal prognosis. Risk factor for progression to ESRD include creatinine at presentation, presence of globally sclerosed glomeruli and arteriosclerosis. The 2010 histologic classification of AAV includes 4 classes (focal, crescentic, mixed and sclerotic), based on the rate of globally sclerosed glomeruli, cellular crescents and normal glomeruli. To our knowledge, the prognostic value of glomerular fibrinoid necrosis (FN) quantification in AAV has not been evaluated.

Methods: We retrospectively studied 45 consecutive renal biopsies with diagnosis of AAV (01/2010-5/2015). Conventional stains were used to assess the percentage of glomeruli showing FN, cellular crescents, global sclerosis and presence of vascular FN. For 31 patients, follow-up data were available for clinicopathological correlations

Results: Fibrinoid necrosis was observed frequently in our cohort (91%), involving an average of 22% (SD±20.5) of the glomeruli. When different histological classes were analyzed, percentage of FN was higher in crescentic (biopsies with >50% of the glomeruli showing cellular crescents) compared to other categories (**Figure 1**). The presence of >20% of the glomeruli showing FN was not correlated with a worse renal survival at any time of the follow up. No significant correlation was found between percentage of

glomerular FN and gender, ethnicity, age, ANCA levels (ELISA), eGFR at diagnosis and presence of vascular FN. The distribution of glomerular FN was the same in different vasculitis (granulomatosis with polyangiitis, microscopic polyangiitis and eosinophilic granulomatosis with polyangiitis).

Conclusions: FN is seen in the presence of active crescentic lesions and is less likely observed in biopsies with advanced chronicity. Higher percentage of FN is not associated with worse renal prognosis, suggesting an active inflammatory process, potentially reversible after adequate therapy.

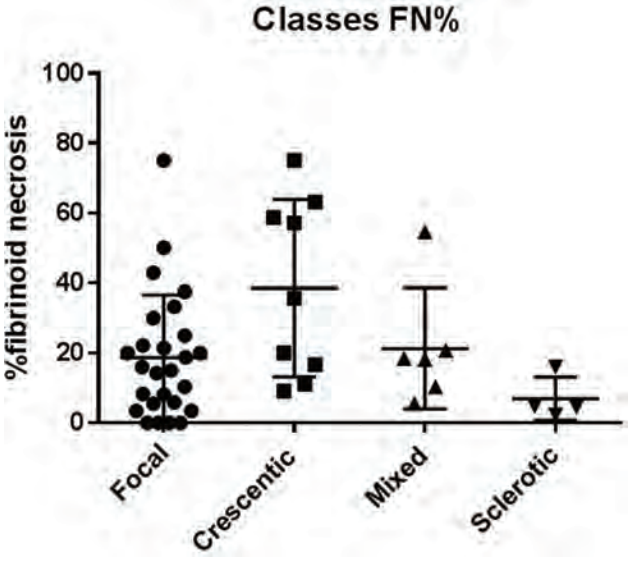

Figure 1. Distribution of percentage FN in different classes of AAV.

FR-PO1045

Transcriptional Dysregulation in Low Density Granulocytes from Patients with ANCA Vasculitis

Dominic J. Ciavatta,[1,2] Britta E. Jones,[1] William Bass,[1] Carolina A. Herrera,[1,3] Christian Agosto-Burgos,[1,3] Caroline J. Poulton,[1] Joshua Starmer,[2] Meghan E. Free,[1,3] J. Charles Jennette,[3,1] Ronald J. Falk.[1,4] *[1]UNC Kidney Center, University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Genetics, Univesity of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Pathology and Laboratory Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: ANCA vasculitis is characterized by elevated expression of autoantigen genes, *MPO* and *PRTN3*; however, the source and implications of the elevated expression are unresolved.

Methods: We isolated monocytes, neutrophils, and an enriched fraction of PBMC from 30 healthy controls (HC) and 75 patients. PBMC from 8 HC and 18 patients were sorted for CD15+ and CD15+/CD10+ cells. Low density granulocytes (LDG) were enriched from PBMC of 28 HC and 67 patients. Gene expression was measured by quantitative RT-PCR. LDG were immunophenotyped by flow cytometry for cell surface markers.

Results: Expression of *MPO* and *PRTN3* was significantly elevated in active patients compared to controls in neutrophils (2.6 and 3.6-fold) and in an enriched PBMC fraction (7 and 15.8-fold). Based on the greater fold-change expression in the PBMC fraction we sorted PBMC into CD15+ and CD15+/CD10+ cells. The nuclear morphology of the CD15+ cells is consistent with immature progenitor granulocytes, while the CD15+/CD10+ cells had segmented nuclei of mature neutrophils. We purified LDGs containing both CD15+ and CD15+/CD10+ cells. *MPO* and *PRTN3* expression in LDGs were elevated in active patients compared to controls (9.3 and 16.5-fold), and correlated with expression in total leukocytes (WBC). LDG heterogeneity was analyzed by flow cytometry and the percentages of cell populations were compared to autoantigen gene expression. The percent of LDGs in PBMC and the percent of CD15+ cells in the LDG population showed weak correlations with *MPO* and *PRTN3* expression (r^2<0.09) (Figure).

Conclusions: The frequency of LDGs or CD15+ cells explains less than 10% of the variation in *MPO* and *PRTN3* expression suggesting transcriptional dysregulation, not an increase in neutrophil progenitors, drives increased expression.

Immunoproteasome-Deficiency Attenuates Antibody-Mediated Podocyte Injury

Wiebke Sachs,[1] Marlies Sachs,[2] Catherine Meyer-Schwesinger.[3] AG Meyer-Schwesinger *[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]UKE, Hamburg, Germany; [3]University of Hamburg, Hamburg, Germany*.

Background: Membranous nephropathy (MN) is an autoimmune disease characterized by subepithelial immune complex deposition and podocyte injury. Persistent podocyte injury during MN is associated with the upregulation of the ubiquitin-proteasome system (UPS), wherein the immunoproteasome is responsible for enhanced protein degradation and for generating peptides for MHC class I presentation. Here we address the impact of immunoproteasome-deficiency on the development of antibody-mediated podocyte injury.

Methods: Anti-podocyte nephritis (APN), a model for MN, was induced in global-β5i and podocyte-specific β5i deficient mice as well as littermate controls. As clinical parameters urine albumin/creatinine and BUN were measured. Morphological analysis of the kidney was obtained *via* PAS staining. Proteasomal function and activity of isolated glomeruli were analyzed via Western Blot and proteasomal activity assays.

Results: The development of proteinuria during APN was attenuated in global- and podocyte-specific β5i deficient mice compared to wildtype littermates. Western blot analysis revealed the upregulation of the standard proteasome in β5i deficient mice during APN. This was also shown in the upregulation of the chymotrypsin-like activity (the major proteasomal activity) in the β5i deficient mice.

Conclusions: Immunoproteasome-deficiency protects against antibody-mediated podocyte injury in mice. This can be explained by the upregulation of the standard proteasome, which leads to a different quantity and quality of peptide generation.

FR-PO1047

The Effect of B Cell Targeted Therapies on Autoantibodies and Excessive Neutrophil Extracellular Trap Formation in Systemic Lupus Erythematosus Patients

Laura S. van Dam,[1] Zgjim Osmani,[1] Tineke Kraaij,[1] Sylvia Kamerling,[1] Jaap A. Bakker,[1] Hans Ulrich Scherer,[1] Ton J. Rabelink,[1] Reinhard E. Voll,[2] David Isenberg,[3] Cees van Kooten,[1] Yoe Kie Onno Teng.[1] *[1]LUMC, Leiden, Netherlands; [2]University Medical Center Freiburg, Freiburg, Germany; [3]University College London, London, United Kingdom.*

Background: Systemic lupus erythematosus (SLE) is a severe systemic autoimmune disease characterized by immune-complexes (ICx) which cause inflammation and damage. Effective targeting of autoantibody secreting cells could be key to reset autoimmunity. Functionally, SLE-specific ICx are important triggers of neutrophil extracellular trap (NET) formation. A consortium was formed to study B-cell targeted therapies, including RTX, Bortezomib (BTZ) or combination of RTX + Belimumab (BLM). The present study aimed to investigate the effects of these therapies on relevant autoantibody levels and excessive NET formation.

Methods: This study involved three cohorts of severe SLE patients that were eligible to experimental treatment with RTX (n=16), BTZ (n=12) or RTX+BLM (n=16). A cross-sectional cohort of 35 SLE patients served as a control cohort. A panel of SLE relevant autoantibodies against dsDNA, histones, nucleosomes and C1q were measured by ELISA. NET formation was quantified by a novel highly-sensitive assay using 3D confocal microscopy (Kraaij et al. 2016).

Results: Comparing three regimens, RTX+BLM resulted in the strongest significant reduction on anti-dsDNA, anti-Histone and anti-Nucleosomes antibodies compared to a smaller decrease by RTX and BTZ. Interestingly, RTX+BLM specifically decreased anti-C1q antibodies, which were not targeted by RTX or BTZ. ICx-mediated NET formation was only significantly decreased with a median of 75% [53 – 85%] after RTX+BLM

(p=0.0002). Successful seroconversion of autoantibodies associated with decreased NET formation (p=0.02). The latter phenomenon was further corroborated in an independent cohort of SLE patients, where excessive NET formation associated with the presence of three or more autoantibody specificities (p=0.02), and specifically with the presence of anti-C1q antibodies (p=0.03).

Conclusions: In this reverse, translational study of B-cell targeted therapies, we demonstrate that anti-C1q autoantibodies were derived from Blys-dependent proliferating plasmablasts because they were only susceptible to RTX+BLM therapy. Moreover, therapeutically narrowing of the autoantibody repertoire decreased immune-complex mediated NET formation.

FR-PO1048

Efficiency and Safety of Thalidomide Combined with Dexamethasone in Patients with Proliferative Glomerulonephritis with Monoclonal IgG Deposit

Zhen Cheng, Zhihong Liu, Zhou Wei, Juan Li. *National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.*

Background: To evaluate the efficacy and safety of thalidomide combined with dexamethasone (TD) in patients with proliferative glomerulonephritis with monoclonal IgG deposits(PGNMID).

Methods: We retrospectively analyzed the clinical data of 12 patients diagnosed with PGNMID from December 2015 to November 2017 in Jinling Hospital, who received TD regimen, and 32 PGNMID patients treated with non-TD regimen from 2011 to 2016.

Results: There are 4 males and 8 females with a median age of 48.5(27,63) yr taking the regimen of TD. With a mean follow-up of 7.5 mo, 6(50%) patients achieve renal response, including 2(16.7%) patients achieving complete response and 4(33.3%) patients achieving partial response, median time of response was 5.5 mo. 5(83.3%) patients got hematological response, in which 1(16.7%) patients obtain complete response, 2(33.3%) patients obtain very good partial response and 2(33.3%) patients obtain partial response. After treatment, serum albumin improved(P=0.002), serum creatinine kept stable(P=0.79), urine protein decreased(P=0.099), and no patient progressed to ESRD. One patient got histopathological recovery. During the secondary renal biopsy, the monoclonal IgG3 and κ light chain deposited in kidney disappeared completely, and glomerular nodular changes also improved. There was no statistical difference in clinical data between the two groups except for gender. With a mean follow-up of 19.2 mo in non-TD group, 5(15.6%) patients achieve renal response, including 3(9.4%) patients achieving complete responseand 2(6.3%) patients achieving partial response. The renal response rate was lower than those in TD group (P=0.045). 3 (33.3%) patients got hematological response. Serum creatinine in the last follow-up were worse than the baseline(P=0.046), albumin (P=0.005) and proteinuria (P=0.044) were improved, and 8(25%) patients progressed to ESRD with an average time of 25.2 mo. The common side effects of TD group were numbness (50%), edema (50%) and sleepiness (50%), but most of the patients were tolerable through symptomatic treatment and drug reduction.

Conclusions: The TD regimen is effective for PGNMID patients. Side effects are common but most of the patients can tolerate it.

FR-PO1049

Suboptimal Dosing of Initial Eculizumab Therapy in aHUS?

Caroline Duineveld,[1] Kioa L. Wijnsma,[2] Elena Volokhina,[3] Nicole Van De Kar,[2] Jack F. Wetzels.[1] *[1]Department of Nephrology, Radboudumc, Nijmegen, Netherlands; [2]Department of Pediatric Nephrology, Amalia Children's Hospital, Nijmegen, Netherlands; [3]Department of Laboratory Medicine, Radboudumc, Nijmegen, Netherlands.*

Background: Atypical hemolytic uremic syndrome (aHUS) is caused by dysregulation of the alternative complement pathway. With the introduction of the complement inhibitor eculizumab the prognosis of aHUS patients has significantly improved. Initiation of eculizumab immediately at disease onset is advised to prevent persistent kidney injury. For complete blockade of the terminal complement pathway eculizumab trough levels of 50-100 µg/ml are recommended. However, recent data suggested that the advised treatment protocol may be insufficient: low eculizumab levels in the induction phase were followed by eculizumab levels exceeding the recommended trough levels in the maintenance phase. (Volokhina, 2017).

Methods: We have extended previous observations and evaluated all adult aHUS patients who were treated with eculizumab in our center from 2013 to 2018.

Results: Eculizumab was used as induction therapy 23 times in 19 adult aHUS patients. Eculizumab trough levels after the first dose were measured in 12 patients. Five patients did not maintain eculizumab levels of >50 µg/ml after the first dose. This was paralleled by incomplete complement blockade. After the second infusion target levels were attained in all patients. No differences in gender, body-weight, CRP, creatinine-protein ratio and the presence of edema at presentation were found between the patients who did and did not reach target level. Eculizumab levels after the second dose increased far above target range and resulted in near complete blockade of the classical complement pathway (measured with Wieslab® Euro Diagnostica complement system screen) in all patients (reference value 69-129%, complete deficiency <1%) (Figure).

Conclusions: After the first dose of eculizumab trough levels were not reached in 41% of the patients. Subsequent eculizumab levels exceed the recommendation. Our results suggest that the current induction protocol is insufficient: the first dose should be increased or the interval shortened, later doses may be reduced.

Funding: Commercial Support - Health insurance association, The Netherlands, Government Support - Non-U.S.

FR-PO1050

The Study on the Mechanism of SOCS1/STAT1 Regulate Renal Inflammation in Mesangial Proliferative Glomerulonephritis Models

Jiuxu Bai, Xiangmei Chen. *Chinese PLA General Hospital, Beijing, China.*

Background: Glomerulonephritis (GN) is characterized by intraglomerular inflammation and is a major cause of end-stage renal disease. Inflammation plays a crucial role in the progress of mesangial proliferative glomerulonephritis (MsGN). The suppressor of cytokine signaling (SOCS) proteins which are inhibitors of cytokine signaling pathways unveiled an important mechanism for the negative regulation of the cytokine-induced JAK/STAT pathway. This study examined whether SOCS1 can regulate renal inflammation in MsGN models.

Methods: In Vivo: Rat (Thy 1.1 GN) and mouse (Habu GN) mesangial proliferative nephritis models were established. The expression of SOCS1, MHC class II, STAT1, inflammatory cells and cytokines were analyzed in MsGN modes. In Vitro: IFN-γ-stimulated mouse mesangial cells(MMCs)were transfected with SOCS1 plasmids. Meanwhile, we used STAT1 inhibitor fludarabine in IFN-γtreated MMCs. The expression of MHC class II, STAT1 and cytokines were analyzed.

Results: Thy1.1 GN recapitulates the main features of human mesangial proliferative glomerular diseases, was generated. In addition, mouse GN was induced with Habu snake venom (HV). The number of macrophages and CD4 T cells increased significantly in glomeruli of MsGN models. Expression of IFN-γ, TNF-α, IL-12A and IL-12B increased significantly in the course of Thy 1.1 and Habu nephritis. MHC class II is expressed in mesangial cells of MsGN models. SOCS1 protein also showed a significant decrease and P-STAT1 increased significantly at early stage in MsGN models. It suggested that SOCS1/STAT1 participate in MsGN model progression. STAT1 inhibitor decreases renal inflammation and ameliorates glomerular lesions in Habu GN. The overexpression of SOCS1 repress MHC class II and STAT1 phosphorylation which is induced by IFN-γ in mesangial cells. STAT-1 inhibitor could inhibit IFN-γ-induced CIITA promoter activity and MHC class II significantly.

Conclusions: This study emphasizes the pivotal role of the SOCS1/STAT1 axis in regulating inflammation in mesangial proliferative glomerulonephritis. In addition, it demonstrates that SOCS1 is a critical regulator of cellular sensitivity to IFN-γ-induced CIITA and MHC class II expression in mesangial cells. The negative feedback between the expression of SOCS1 and inflammation may play an important role in the mesangial proliferative glomerulonephritis.

FR-PO1051

Evolution of Autoantibody Function in C3 Glomerulopathy

Alexandria Leonhardt,[2] Dingwu Shao,[2] Yuzhou Zhang,[2] Richard J. Smith,[1,2] Carla M. Nester.[1,2] *[1]Medicine and Pediatrics, University of Iowa Hospitals and Clinics, Iowa City, IA; [2]Molecular Otolaryngology and Renal Research Laboratory, University of Iowa, IOWA CITY, IA.*

Background: Autoantibodies play an important role in the pathogenesis of C3 Glomerulopathy (C3G). Binding of either C3 nephritic factors (C3Nef) or Factor B autoantibodies (FBAA) to the alternate complement (AP) pathway's C3 convertase (C3C) stabilizes this critical enzyme, prolonging its half-life and preventing normal regulation of the AP. The stabilizing characteristic of these antibodies are well described. Little is known about their correlation with disease natural history. Further characterization of C3G disease related autoantibodies has the potential to influence patient management algorithms.

Methods: Our study cohort included 8 C3G patients (drawn from the University of Iowa's C3G Natural History Study) in whom at least 3 squential draws were available (4 FBAA and 4 C3Nef). Comprehensive biomarker studies and autoantibody kinetic studies (SPR) were performed across multiple times points of disease course. Comparisons were made between C3C t ½, comprehensive biomarker assays and measures of clinical activity.

Results: FBAA kinetics were independent of FBAA titer or complement biomarker, and tended to be static over time. In contrast, the C3C stabilizing kinetic of C3Nef were more variable over disease course - tending to trend downward. In one patient, the C3Nef stabilization of C3C dropped by factor of 4 (211 minutes to 49.5 minutes over a 6 yr period

- with 5min being normal). This change was associated with a normalization of a previously undetectable C3.

Conclusions: Point assessments of C3Nef are insufficient to fully characterize the function of this autoantibody. C3Nef kinetics evolve over disease course and are associated with changes in both biomarkers of complement dysregulation and clinical activity. This preliminary data prompts a number of interesting hypotheses, not the least of which is the concept that C3Nef functional testing may be a way to detect "windows" of relative disease quiescence in given patients.

FR-PO1052

Complement and Cytokine Characterization of C3GN

Nicholas J. Steers,[1] Debanjana Chatterjee,[1] Wan yee Lam,[1] Natalia D. Demaria,[1] Andrew S. Bomback,[1] Gerald B. Appel,[2] Ali G. Gharavi.[1] *[1]Columbia University, New York, NY; [2]Columbia University College of Physicians and Surgeons, Scarsdale, NY.*

Background: The complement pathway is an innate immune defense mechanism, when uncontrolled can cause damage to host tissues including the kidney upon uncontrolled activation of the alternative complement pathway (ACP). C3GN is characterized by deposits in the glomerulus made up entirely of complement C3 protein without the presence of immunoglobulins.

Methods: We determined the cytokine and complement profiles derived from the plasma of 40 C3GN cases, and 15 healthy controls (HC), utilizing the Luminex assay.

Results: Analysis of the plasma from 40 C3GN patients compared to HC revealed significant decreases in the complement pathway proteins C3 (424±336 vs 673±118 μg/ml), C4 (233±71 vs 392±115 μg/ml), C4b (10.9±4.3 vs 15.9±3.1 μg/ml), C5 (15.8±8.3 vs 24.3±6.4 μg/ml), CFH (247±60 vs 285±44 μg/ml), and Properdin (19.2±5.3 vs 25.2+5.6 μg/ml). In-depth analysis of the plasma derived from C3GN patients identified significantly low C3 levels (2*SD below Average HC) in 21 patients, in which 72% of these had significantly low levels of plasma C5. Key components of the ACP are CFH and properdin, and we only identified 10 patients with significantly low levels CFH (7 associated with low plasma C3), and 11 with significantly low levels properdin (8 associated with low plasma C3). Global cytokine analysis in C3GN plasma determined significant increases in proinflammatory cytokines TNFα detected in 100% of C3GN patients (17.9+8.9 pg/ml) and IL-1α detected in 82% of C3GN patients (80.3±80.1 pg/ml) compared to HC ((100%) 7.2+3.6 and (40%) 29.7+29.9 pg/ml, respectively). Cytokine analysis demonstrated bi-modal patterns with increased percentage of C3GN patients having elevated levels of pro-inflammatory cytokines, IL-6 and IL-12p40 was more prevalent in the plasma of C3GN patients (45% and 50% respectively), compared to HC (26% and 26% respectively)

Conclusions: The plasma of C3GN patients demonstrates activation of the ACP and elevated levels of proinflammatory cytokines that are associated with stimuli know to activate the ACP. Our data set is being expanded to include additional samples and will be correlated with the clinical status of patients. In-depth profiling of immunological markers and the specific relationships will able to design a panel specific to individual complement associated glomerular pathology.

FR-PO1053

C3 Glomerulopathy: Pattern of Injury and Response to Treatment

Luis A. Castillo. *Nephrology, Clínica de la Costa, Barranquilla, Colombia.*

Background: C3 glomerulopathy refers to those renal lesions characterized histologically by predominant C3 accumulation within the glomerulus with absent or scanty immunoglobulin deposition, and pathogenetically by aberrant regulation of the alternative pathway of complement. Objectives:To describe the evolution of renal involvement and the response to treatment with 1year follow- up.

Methods: Observational study case series type. The data were extracted from NefroRed©, a platform that contains the socio-demographic, anthropometric, clinical and laboratory data of 1340 patients with kidney biopsies from 2007-2015. It was selected for the study those patients that showed the pattern of glomerulonephathy and C3 deposits only or predominant. The primary endpoint for subjects enrolled was change in proteinuria and serum creatinine over treatment period. Patients will be subclassified into three groups, those who had been treated with mycophenolate mofetil (MMF), Cyclophosphamide (CP) and those who had anti-complement therapy with eculizumab (ECZ). Statistical analysis descriptive.

Results: 34 patients with C3 glomerulopathy were identified. Pathological lesion: 80% membranoproliferative glomerulonphritis, 6.7% GSFS, 6.7% mesangial proliferative, 6.7% membranous. Clinical preentation: 86.67% Nephrotic Syndrome, 26.67% nephrytic syndrome, 13% renal insuficiency, 53.33% Hypertension. 15 patients received active treatment with CP, 12 with MMF and 3 with eculizumab.

Conclusions: The scope of the study is limited largely because of the rarity of these disorders. There was not a response to ECZ. The treatment with MMF improved proteinuria but not renal function. The CP improved proteinuria and creatinine. Reports suggest that a in our population the cyclophosphamide is more effective. Formal trial of comprising a greater number of well-characterized patients is warranted.

Comparison of the CrSr and Proteinuria between MMF, ECZ and CP

SrCr	Baseline	12 months	p-value
MMF	1.52 CI 0.74	1.21 CI 0.38	NS
ECZ	3.01 CI 2.07	1.83 CI 0.47	NS
CP	1.53 CI 0.95	1.10 CI 0.42	<0.05
Prot	Baseline	12 months	p-value
MMF	1677.42 CI 1031.83	1212.42 CI 717.24	<0.05
ECZ	1266.33 CI 1735.97	1162.67 CI 1382.19	NS
CP	2624.00 CI 1882.23	2098.44 CI 1608.42	<0.05

MMF: Mofetil Mycophenolate; CP: Cyclophosphamide; ECZ: Eculizumab; SrCr: Serum Creatinine; NS: Not Significant.

FR-PO1054

Comparison Among Dominant C1q Positive Cases Including C1q Nephropathy Classified by Immunofluorescence

Erina Ono, Shuichiro Endo, Takeshi Matsubara, Hideki Yokoi, Eri Muso, Motoko Yanagita. *Department of Nephrology, Kyoto university Hospital, Kyoto, Japan.*

Background: Although the disease entity of C1q nephropathy was first described by Jennette and Hipp in 1985, the characteristics of the heterogeneous phenotypes and the pathogenic role of C1q for the disease progression has not been elucidated yet. We analyzed dominant C1q positive renal biopsy specimens to speculate the significance of C1q localization.

Methods: A total of 1763 consecutive patients performed renal biopsy at Kyoto University Hospital from 1982 through 2001 were investigated. We analyzed 34 cases (1.9%) with dominantly C1q-positive staining excluding lupus nephritis, IgA nephropathy, and membranous nephropathy. Next, we classified these patients into three groups; C1q mono-dominant (mC1q) group (n=3) with no immunoglobulin deposition and C1q co-dominant group (total n=31) with IgG (cC1q-IgG) (n=19) or IgM (cC1q-IgM) (n=12).

Results: Precise pathological analysis showed in mC1q group, minor glomerular abnormality in light microscopy (LM), with mesangium localization of C1q with C3d positivity in immunofluorescence microscopy (IF). Apparent electron dense deposit (EDD) and foot process effacement were observed in electron microscopy (EM). CC1q-IgG group revealed variety of glomerulonephritis pattern frequently showing capillary wall involved glomerular lesion such as double contour, subendothelial deposit and crescent formation with high frequency of global sclerosis. C1q localized in capillary wall and mesangium accompanying IgG, and IgM in all cases and additional IgA in 15 cases with strongly positive C3c and C3d in IF. CC1q-IgM group exhibited focal segmental sclerosis and double contour in LM. C1q was positive in mesangium colocalized with IgM and C3d in all but C3c in some in IF. EDD was negative in all 6 cases in EM. Laboratory data revealed cC1q-IgG group included relatively severe cases in creatinine level and hematuria compared with the other two groups.

Conclusions: The hypothesis of glomerular injury through activation of complement system might be applicable via immune complex formation in cC1q-IgG group, directly in mC1q group and not applicable in cC1q-IgM group. The analysis of dominant C1q-positve renal biopsy specimens include several diseases in these case series raises the possibility that current category of C1q nephropathy indicates some specific condition of existing diseases.

FR-PO1055

Fibrillary Glomerulonephritis: Clinical Features and Outcomes in an Ethnically Diverse Urban European Population

Sandhi W. Nyunt, Kassiani Skordilis, Peter Hewins, Miriam Berry. *University Hospitals Birmingham, Birmingham, United Kingdom.*

Background: Fibrillary glomerulonephritis (FGN) is a rare glomerular lesion characterised by the presence of 20nm fibrillary deposits on electron microscopy (EM). It is usually associated with poor renal outcomes. The largest case series to date describe North American populations.

Methods: We performed a retrospective case note review of patients with FGN, identified through the renal histology database at our tertiary referral hospital in the UK from 2001-17. EM has been performed routinely on all native biopsies since 2014.

Results: We identified 19 patients with FGN. 7 had a second histological lesion present including: IgA disease (2), vasculitis (4) nodular glomerulosclerosis (1). The median age at presentation was 58 (47-72) years, with a female preponderance (1.7:1 F:M). 83% were Caucasian. There were no strong associations with systemic disease. At presentation, median eGFR was 44 (20-68) ml/min and urine albumin:creatinine ratio 264 (80-351) mg/mmol. Hypertension (35%), proteinuria (88%), haematuria (71%) and hypercholesterolaemia (71%) were common while nephrotic syndrome was rare (11%). 38% patients received immunomodulatory therapy: corticosteroids (n=6), mycophenolate mofetil (n=2), azathioprine (n=1), cyclophosphamide (n=1). After median 44 (22-49) months follow-up, 47% patients were clinically stable, 6% had progressive CKD, 35% had progressed to end stage renal disease (ESRD) and 12% had died. Of those patients receiving immunomodulatory therapy, n=3 were stable, n=2 progressed to ESRD and n=1 had died. Renal insufficiency and significant proteinuria at diagnosis were risk factors for poor renal outcomes. Patients with FGN alone had significantly better renal outcomes than those with a second histological lesion; 75% of patients with vasculitic lesions progressed to ESRD.

Conclusions: Diagnosis of FGN has become more common with routine use of EM. FGN was more common in Caucasian patients, even in an ethnically diverse population. In contrast to previous studies, there were no strong associations with systemic disease. The efficacy of immunomodulatory therapy is difficult to evaluate in a small sample size. Significant proteinuria and renal insufficiency were poor prognostic indicators. Renal outcomes were better than in published case series; longer follow-up is required to determine the significance of this observation.

FR-PO1056

ABIN1 Contributes to Glomerulonephritis via Induction of IP-10 Expression and Activity

David W. Powell,[1] Mark B. Vieyra,[1] Shweta Tandon,[1] Erik Korte,[2] Michelle T. Barati,[1] Kenneth Gagnon,[1] Kenneth R. McLeish,[1] Dawn J. Caster.[1] Immune-Mediated Kidney Disease Laboratory *[1]Medicine/Nephrology and Hypertension, University of Louisville, Louisville, KY; [2]University of Louiville, Louisville, KY.*

Background: Our research to define genetic risks of glomerular inflammation identified variants in TNIP1 as risks for development of lupus nephritis. TINIP1 encodes ABIN1, a physiological inhibitor of NF-κB and MAPK-mediated inflammation. We reported that loss of ABIN1 function in podocytes (ABIN1[D485N]) exacerbates immune-mediated podocyte injury and enhances podocyte cytokine and chemokine production in vivo and in vitro, leading to enhanced neutrophil recruitment and activation. The NF-κB-mediated chemokine IFN-γ-inducible protein 10 (IP-10) had a > 20-fold increase in gene expression in podocytes with loss of ABIN1 activity. The current study tested the hypothesis that IP-10 contributes to ABIN1-mediated podocyte injury and glomerular inflammation.

Methods: In vitro exocytosis (flow cytometry for granule markers CD66b and CD35) and chemotaxis (transwell migration assay) of primary human neutrophils was measured following incubation with recombinant IP-10 w/wo a known activator FMLF. Urinary IP-10 levels were measured by ELISA 24 h following administration of nephrotoxic anti-GBM antibody in WT and ABIN1[D485N] mice. Proteinuria was measured 24 h following administration of anti-GBM in WT and ABIN1[D485N] mice w/wo pre-treatment with neutralizing IP-10 antibody.

Results: Recombinant IP-10 did not activate neutrophil chemotaxis alone, but significantly primed the response to FMLF. IP-10 activated neutrophil exocytosis alone and also primed the FMLF response. Urinary IP-10 levels were significantly higher in ABIN1[D485N] mice than WT mice 24 h-post anti-GBM administration. Anti-GBM-induced proteinuria was inhibited by pre-treatment with IP-10 antibody in WT and ABIN1[D485N] mice.

Conclusions: Our data suggest that genetic disruption of ABIN1 in podocytes results in enhance production of IP-10 during experimental glomerulonephritis and that IP-10 production regulates neutrophil activation and contributes to glomerular damage leading to proteinuria. Our data provide clinical relevance for the finding that IP-10 is a urinary biomarker for lupus nephritis (LN). The use of IP-10 neutralizing antibody for treatment of ulcerative colitis and rheumatoid arthritis, suggests a new therapeutic approach for patients with LN associated with variants for TNIP1 or other NF-κB or MAPK regulatory genes.

FR-PO1057

Elevated Levels of Urinary Extracellular Vesicle Fibroblast-Specific Protein 1 in Patients with Active Crescentic Glomerulonephritis

Yukie Morikawa,[1] Naoki Takahashi,[1] Kazuko Kamiyama,[1] Kazuhisa Nishimori,[1] Yudai Nishikawa,[1] Mamiko Kobayashi,[1] Sachiko Fukushima,[1] Seiji Yokoi,[1] Daisuke Mikami,[1] Hideki Kimura,[1] Kenji Kasuno,[1] Masanori Hara,[2] Masayuki Iwano.[1] *[1]University of Fukui, Yoshida-gun, Japan; [2]Niigata Wellness (Iwamuro Health Promotion Center), Niigata, Japan.*

Background: Extracellular vesicles (EVs), including exosomes, are present in a variety of bodily fluids, including urine. We previously reported that large numbers of fibroblast-specific protein 1 (FSP1)-expressing cells accumulate within damaged glomeruli and that urinary FSP1 could potentially serve as a biomarker of ongoing glomerular injury. However, the precise mechanism by which urinary FSP1 is secreted is unknown.

Methods: To address that issue, we collected urine samples from 37 patients with various types of glomerular disease (6 with ANCA-associated nephritis, 11 with IgA nephropathy, 11 with membranous nephropathy, 6 with minimal-change disease and 3 with lupus nephritis), purified the urinary EVs using total exosome isolation regent, and characterized the vesicles using Nanosight, western blotting and immunoelectron microscopy. We measured FSP1 levels in total urine and EVs fraction with sandwich ELISA. FSP1 level associated with crescentic formation were evaluated by receiver operating characteristic (ROC) curve analysis.

Results: Deemed to be mainly exosomes, based on their size distribution, the vesicles contained FSP1. Moreover, a portion of these FSP1-positive EVs were also positive for podocalyxin. ELISAs showed that FSP1 levels in urinary EVs correlated positively with rates of biopsy-proven cellular crescent formation ($r = 0.562$, $P < 0.001$) and total crescent formation ($r = 0.448$, $P = 0.005$) among total glomeruli. FSP1 levels in urinary EVs were significantly higher in patients with cellular crescents affecting 20% or more of their glomeruli than in those with fewer affected glomeruli ($P = 0.003$). FSP1 level in EVs for predicting cellular crescent formation affecting more 20% was 2.4 ng/mL, with an area under the ROC curve were 0.88 (95%CI, 0.693 to 1.070). FSP1 levels in urinary EVs also correlated positively with total urinary FSP1 levels ($r = 0.834$, $P < 0.001$) in patients with at least one cellular crescent.

Conclusions: These data suggest that a portion of urinary FSP1 is secreted as microvesicles originating from podocytes, and that FSP1 levels in urinary EVs reflect active and ongoing glomerular injury, such as cellular crescent formation.

FR-PO1058

Deficiency for the Chemokine Receptor CCR2 Protects from Glomerular Injury and Interstitial Fibrosis in Adriamycin-Induced Glomerulosclerosis

Anja Wilkening, Nuru Eltrich, Bruno Luckow, Volker Vielhauer. *Nephrologisches Zentrum, Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, Ludwig-Maximilians-University Munich, Munich, Germany.*

Background: Glomerulosclerosis and tubulointerstitial fibrosis are hallmarks of chronic kidney injury leading to end-stage renal disease. Inflammatory mechanisms contribute to glomerular and interstitial scaring including chemokine-mediated recruitment of leukocytes. In particular, accumulation of chemokine receptor CCR2 expressing macrophages promotes renal injury and fibrotic remodeling in diseases like glomerulonephritis and diabetic nephropathy. However, whether CCR2 plays a functional role in the initiation and progression of primary glomerulosclerosis induced by podocyte injury remains unclear.

Methods: To explore potential pro-inflammatory and pro-fibrotic functions of CCR2 in focal segmental glomerulosclerosis (FSGS) we analyzed adriamycin-induced nephropathy, a murine model of FSGS, in BALB/c wild-type and *Ccr2*-deficient mice.

Results: In adriamycin-induced FSGS progressive glomerular scaring and reduced glomerular nephrin expression was paralleled by induced glomerular expression of the CCR2 chemokine ligand CCL2. In comparison to wild-type, *Ccr2*-deficient mice with adriamycin nephropathy showed reduced albuminuria and preserved renal function. Whereas the extent of glomerular podocyte and endothelial cell injury was similar, glomerular sclerosis and glomerular macrophage infiltration were reduced in *Ccr2*-deficient mice. Moreover, *Ccr2* deficiency decreased tubular damage, interstitial leukocyte infiltration, renal inflammation and renal expression of extracellular matrix molecules. Consistently, tubulointerstitial fibrosis, accumulation of αSMA-positive myofibroblasts and renal fibroctyes were reduced in *Ccr2*-deficient kidneys.

Conclusions: Our data indicate that the chemokine receptor CCR2 contributes to glomerular scaring and interstitial fibrosis in FSGS by facilitating glomerular and tubulointerstitial infiltration of macrophages, renal inflammation, and renal accumulation of fibrocytes. Thus, CCR2 is an important mediator of glomerular injury and progression of FSGS. CCR2 targeting therapies may represent a novel approach for its treatment.

The Acute-Phase Protein α1-Acid Glycoprotein Ameliorates Proteinuria Through Maintaining Renal Endothelial Barrier Function and Modulating Macrophages Polarization in Proteinuric Kidney Disease

Rui Fujimura,[1,2] Kento Nishida,[1] Jing Bi,[1,2] Hiroshi Watanabe,[1] Toru Maruyama.[1] *[1]Department of Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kumamoto University, Kumamoto-shi, Japan; [2]Program for Leading Graduate Schools "HIGO (Health life science: Interdisciplinary and Glocal Oriented) Program", Kumamoto University, Kumamoto, Japan.*

Background: Proteinuria is the hallmark of progressive chronic kidney disease (CKD). It is highly desired to develop an effective strategy that prevents glomerular filtration barrier injury and renal inflammation which can cause proteinuria. The acute phase plasma protein, α_1-acid glycoprotein (AGP) is a component of glomerular endothelial barrier and contributes to maintaining an intact barrier. In addition, we have previously showed that AGP has anti-inflammatory action via up-regulating CD163 in macrophage. The purpose of this study is to evaluate the renoprotective effect of exogenously administered-AGP against adriamycin-induced nephropathy (AN), a model of chronic proteinuric renal disease.

Methods: AN-mice were created by the administration of 15mg/kg of adriamycin. AGP was administered to AN mice (*iv*) from day 1 to day 5. Mice were sacrificed on day 7 or 21. Renal function, structural injury and inflammation were evaluated. The renal glomerular distribution of exogenous administered AGP was examined by immunostaining using anti-AGP antibody. To investigate the effect of AGP on macrophage polarization, *in vitro*experiments were performed using PMA-differentiated THP-1 cells.

Results: AGP administration ameliorated AN-induced proteinuria, histological changes and macrophage infiltration in renal tissue. We also found the decreased distribution of endogenous AGP on the glomerulus in AN-mice, but this decrease was recovered by the administration of exogenous AGP. In kidney of AGP-treated mice, increased mRNA expression of CD163, M2 macrophage marker, and decreased mRNA expression of iNOS,

M1 macrophage marker, were observed. To confirm this finding in vitro, we investigated the effect of AGP on THP-1-derived macrophage polarization. The data showed that AGP treatment significantly increased CD163 mRNA expressions, while it decreased iNOS mRNA expression, suggesting that AGP could be able to modulate the macrophage phenotype to anti-inflammatory potential.

Conclusions: AGP ameliorates proteinuria through maintaining renal endothelial barrier function and modulating macrophages polarization.

FR-PO1060

Classic IL-6R Signaling in CD4+ T Cells Directs Nephritogenic Th17 Responses and Enhances Treg Function

Julia Hagenstein, Simon Melderis, Anna Nosko, Matthias Warkotsch, Johannes V. Richter, Malte A. Kluger, Oliver M. Steinmetz. Steinmetz Lab *University Hospital Hamburg Eppendorf, Hamburg, Germany*.

Background: Th17 cells are central pathogenic mediators of glomerulonephritis (GN), while regulatory T cells (Tregs) mediate protection. The pleiotropic cytokine IL-6 was shown to modulate the function of both cell populations, but many aspects in this process remain unclear. These include the mode of IL-6 signaling responsible (classic, alternative or cluster), whether IL-6 effects are mediated in a cell intrinsic fashion or indirectly and finally the functional importance of T cell subtype specific IL-6R signaling for GN.

Methods: Selective abrogation of classic IL-6 signalling on T cells was achieved by generating quadruple transgenic $CD4^{Cre}$xIL-$6Ra^{fl/fl}$ mice, harbouring flourochromes under control of the Foxp3 (FIR) and IL-10 promoters (Tiger). The NTN model of crescentic GN was studied in these mice and in $Rag1^{-/-}$ recipients after transfer of different $CD4^+$ T cell populations.

Results: $Rag1^{-/-}$ recipients of IL-6R deficient $CD4^+$ T cells showed significantly and selectively reduced splenic and renal Th17 responses. In line, renal neutrophil recruitment was substantially diminished. Surprisingly, however, the course of NTN was not ameliorated. As one possible explanation, we found reduced Treg infiltration into recipient kidneys of IL-6R deficient $CD4^+$ T cells. Additional studies in $CD4^{Cre}$xIL-$6R^{fl/fl}$xFIRxTiger mice revealed, that production of anti-inflammatory IL-10 by $Foxp3^+$ Tregs and $Foxp3^-$ Tr1 cells, was not affected by absence of IL-6R signaling. In a next step, we transferred Treg depleted $CD4^+$ T cells into $Rag1^{-/-}$ mice and again studied NTN. Also in this setting, Th17 responses were strikingly reduced by lack of IL-6R signaling in $CD4^+$ T cells. Importantly, however, in the absence of Tregs in both groups, NTN was significantly ameliorated in recipients of IL-6R deficient $CD4^+$ Teff.

Conclusions: Our data indicate, that classic IL-6R signaling on T cells, induces nephritogenic Th17 reponses and aggravates crescentic GN. Surprisingly, however, classic IL-6R signaling also enhances Treg function via currently undefined pathways. Given the impact on potential IL-6R directed therapies, the underlying molecular mechanisms clearly need to be defined by further studies.

Kidney-Targeted Autoimmunity Exposed in Human Immune System Mice

Jeffrey R. Ord, Amy G. Clark, Anastasiya Birukova, Lanette Fee, Yohannes G. Asfaw, Robert M. Tighe, Mary H. Foster. *Duke University Medical Center, Durham, NC.*

Background: Lupus and anti-GBM nephritis are paradigmatic systemic and organ-specific autoimmune diseases, respectively, in which kidney and other organ injury is induced by pathogenic autoantibodies. Gene-environment interactions are implicated in disease induction, yet mechanisms by which this occurs in man are poorly understood. We explored the utility of an in vivo human immune system model (HuHSC-NSG) to study autoimmune regulation by inhaled crystalline silica, an environmental exposure compellingly linked to multiple human autoimmune diseases with a prominent humoral component.

Methods: Conditioned immunodeficient NOD-scid-gamma (NSG) mice were intravenously injected with CD34+ human hematopoietic stem cells (HSC) from two different donors and monitored for reconstitution with a human immune system. Three months after engraftment, mice were exposed to crystalline silica (Si) or vehicle (V, saline) by oropharyngeal aspiration. Tissue was collected 1-3 months post-aspiration. Chimerism was determined by flow cytometry, and lung pathology and lymphocytic infiltrates were scored by investigators blinded to experimental conditions. Serum autoantibodies that bound DNA or the NC1 domain of the alpha3 chain of collagen IV were measured using enzyme linked immunosorbent assay. Data are reported as mean±SD.

Results: HuHSC-NSG mice (n=29) demonstrated mean spleen chimerism of 57.6±28.4%, with the human CD45+ subset composed of 70.7±18.6% B cells and 19.4±20.1% T cells. Si-exposed subjects developed significantly greater lung injury and inflammation than did their V-exposed counterparts, with composite lung pathology score 2.8±2.2 vs 0.7±1.7, Si vs V, $p<0.05$. Focal infiltrates of human CD45+ leukocytes were observed in Si-exposed lungs. All mice developed circulating human IgM and IgG, and a subset had detectable circulating human anti-DNA or anti-alpha3(IV)NC1 collagen autoantibodies.

Conclusions: NSG mice reconstituted with a human immune system develop Si-induced lung injury and circulating autoantibodies with specificities relevant to human antibody-mediated nephritis. This model should be useful in studying gene-environment interactions that promote pathogenic autoimmunity in humans, without putting volunteers or patients at risk.

Treatment of Glomerulonephritis Using Drugs Targeting Folate Receptor Expressing Activated Macrophages

Gabriela E. Garcia,[1] Yingjuan J. Lu,[4] Luan D. Truong,[2] Richard J. Johnson,[1] Christopher P. Leamon.[3] *[1]University of Colorado Denver, Greenwood Village, CO; [2]The Methodist Hospital, Houston, TX; [3]Endocyte Inc, West Lafayette, IN; [4]Endocyte, West Lafayette, IN.*

Background: Macrophages are linked with the irreversible scarring that leads to end-stage renal disease. Since activated macrophages highly express a functional folate receptor β (FRβ), targeting this population of macrophages with folate-linked drugs could increase selectivity in the treatment of inflammatory diseases.

Methods: Accordingly, we synthesized and investigated the biologic activity of a novel folic acid-aminopterin conjugate (FA-AMT) designed to intracellularly deliver AMT specifically via the FR. The anti-inflammatory activity of FA-AMT was evaluated in a model of severe, macrophage-mediated anti-glomerular basement membrane glomerulonephritis in WKY rats.

Results: Toxicity assessment demonstrated that FA-AMT is not toxic (its maximum tolerated dose was 40-fold higher compared to unmodified AMT). We found that treatment with FA-AMT significantly attenuated kidney injury and preserved normal renal function. Glomerular proliferation, necrotizing lesion, crescent formation, tubulointersititial injury (TIN), and the number of tubular casts, a good indicator of chronic TIN injury, were markedly reduced in the FA-AMT-treatment group compared with the control group. FA-AMT reduced glomerular macrophage infiltration (52%) and decreased M1 macrophage phenotype without affecting M2 macrophages. Notably, interstitial macrophage accumulation that predicts progression of kidney injury was decreased in rats treated with FA-AMT. The expression of CCL2 and the pro-fibrotic cytokine TGF-β were reduced in nephritic glomeruli with FA-AMT treatment. Importantly, in rats treated with FA-AMT there was a significant reduction in the deposition of type I, III, and IV, collagens. Staining with specific anti-FRβ antibody showed no expression of this receptor in normal kidneys, however, in nephritic kidneys FRβ was mainly expressed on macrophages present in the crescents and also on macrophages within the glomerular capillaries. Notably, in rats treated with FA-AMT, the expression of FRβ was decreased and correlated with less macrophage infiltration and reduced crescent formation.

Conclusions: These findings suggest that targeting kidney activated macrophages attenuates inflammation and prevents progression of kidney injury and that because this is a FR-restricted specific treatment systemic immunosuppression can be prevented.

KLF4 on Macrophages Attenuates TNF-α Mediated Kidney Inflammation and Fibrosis in Autoimmune Nephritis

Yi Wen,[1] Jamie Privratsky,[1] Xiaohan Lu,[1] Jiafa Ren,[1] Bi-Cheng Liu,[2] Steven D. Crowley.[1,3] *[1]Duke University Medical Center, Durham, NC; [2]Zhong Da Hospital, Southeast University Medical School, Nanjing, China; [3]Division of Nephrology, Department of Medicine, Duke University and Durham VA Medical Centers, Durham, NC.*

Background: The Kruppel-like factor (KLF) family of transcriptional regulators play complex roles in the pathogenesis of kidney disease. We recently found that activating type 1 angiotensin receptors in macrophages upregulates KLF4 and paradoxically limits renal fibrosis. As KLF4 attenuates NF-kB-dependent vascular injury, we directly investigated the role of macrophage KLF4 in renal inflammation and fibrosis using the murine nephrotoxic serum nephritis (NTS) model. As KLF4 suppressed TNF-α in intra-renal macrophages in our studies, we additionally probed the contribution of macrophage TNF-α to NTS progression.

Methods: Mice with floxed alleles for the genes encoding KLF4 or TNF-α were bred with LysM-Cre mice to yield KLF4 or TNF "MKO" mice with macrophage-specific deletion of KLF4 or TNF-α, respectively. NTS was induced in KLF4 MKO, TNF MKO, and wild-type (WT) littermate control mice by IV injections of sheep IgG followed 5 days later by sheep anti-mouse GBM serum.

Results: At day 14 NTS, KLF4 MKO mice compared to WTs had augmented glomerular matrix deposition (44.4 ± 3.3 vs 33.7 ± 2.5%; P = 0.04), urinary albumin/Cr ratios (7.7 ± 0.8 vs 5.3 ± 0.6 mg/mg; P = 0.05), and renal NGAL mRNA (1.3 ± 0.1 vs 1.0 ± 0.2 au; P = 0.03). KLF4 MKO kidneys also showed increased mRNA levels for collagen 1 (1.9 ± 0.2 vs 1.0 ± 0.3 au; P = 0.01), fibronectin (1.7 ± 0.2 vs 1.0 ± 0.2 au; P = 0.03), and the fibrosis mediators TGF-β (1.4 ± 0.1 vs 1.0 ± 0.2 au; P = 0.03) and PAI-1 (1.4 ± 0.1 vs 1.0 ± 0.2 au; P = 0.03). CD11b+ Ly6Chi inflammatory macrophages isolated directly from NTS kidneys of KLF4 MKO animals had 50% higher TNF-α expression than WTs (1.5 ± 0.1 vs 1.0 ± 0.1 au; P = 0.04). To explore whether macrophage KLF4 protects the kidney by suppressing TNF-α, we repeated our NTS studies in TNF MKO mice and WT controls. At day 14 of NTS, TNF MKOs compared to WTs had reduced glomerular matrix deposition (33.2 ± 0.6% vs 43.8 ± 1.6%; P < 0.01), urine albumin/Cr ratios (3.6 ± 0.4 vs 4.7 ± 0.3 mg/mg; P = 0.04), and mRNA levels for NGAL (0.5 ± 0.1 vs 1.0 ± 0.2 au; P = 0.02), collagen 1(0.5 ± 0.2 vs 1.0 ± 0.2 au; P = 0.04), aSMA (0.3 ± 0.1 vs 1.0 ± 0.2 au; P < 0.01), and PAI-1 (0.6 ± 0.1 vs 1.0 ± 0.1 au; P < 0.01).

Conclusions: KLF4 activation on macrophages mitigates renal injury and fibrosis during NTS by inhibiting production of macrophage-derived TNF-α.

FR-PO1064

Characterisation of a Novel P2X7 Deficient Rat and Differential Requirement for P2X7 for Release of IL-1β from Bone Marrow Derived Cells In Vitro

Maria Prendecki,[1] Ana Isabel Garcia Diaz,[1] Stephen P. McAdoo,[1] Jacques Behmoaras,[1] H. Terence Cook,[1] Robert J. Unwin,[2] Charles D. Pusey,[1] Frederick W. Tam,[1] Tim Aitman.[3] *[1]Imperial College London, London, United Kingdom; [2]University College London Medical School, London, United Kingdom; [3]University of Edinburgh, Edinburgh, United Kingdom.*

Background: P2X7 is an ionotropic receptor activated by extracellular ATP and expressed on immune cells including macrophages and dendritic cells. P2X7 may have an important role in kidney disease. However, the specific role of P2X7 in different cell types is controversial. We characterise a novel P2X7 knockout (KO) rat and define the role of P2X7 in IL-1β production in bone marrow derived macrophages (BMDM) and dendritic cells (BMDC).

Methods: A P2X7 KO rat was created using zinc finger nucleases. Cells and tissues were used for extraction of protein and mRNA for Western blot and PCR. P2X7 function was assessed using uptake of Yo-pro1 dye in response to ATP and by stimulating cells with LPS 1μg/ml followed by ATP 5mM, and measuring IL-1β production. When P2X7 antagonist or caspase-1 inhibitor was used this was added 30 mins prior to LPS.

Results: No P2X7 protein was detected in P2X7 KO rat cells or tissue. BMDM and BMDC from WKY WT but not P2X7 KO rats formed pores and took up Yo-pro1 following ATP stimulation. As expected, WKY WT BMDM produced significant IL-1β when stimulated with LPS plus ATP compared to LPS alone. In contrast, BMDM from P2X7 KO rats did not produce IL-1β (Figure 1A). However, both WKY WT and P2X7 KO BMDC were able to cleave IL-1β following stimulation with LPS alone, Use of a P2X7 antagonist (A438079) confirmed this was P2X7 independent (Figure 1B). IL-1β release was independent of K+ efflux from cells, but was inhibited by a caspase-1 inhibitor.

Conclusions: This is the first description of a novel P2X7 KO rat showing it is a true knockout. BMDC (but not BMDM) do not require a second signal via P2X7/ATP to produce active IL-1β. IL-1β is a powerful pro-inflammatory cytokine and is thought to play a role in human and experimental glomerulonephritis; understanding how different cell types use different pathways to produce IL-1β will improve our understanding of the pathogenesis of kidney diseases.

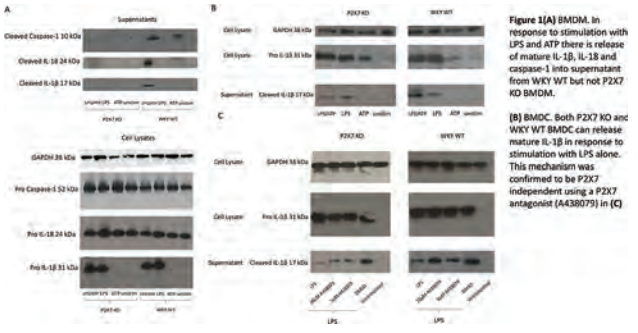

Figure 1(A) BMDM. In response to stimulation with LPS and ATP there is release of mature IL-1β, IL-18 and caspase-1 into supernatant from WKY WT but not P2X7 KO BMDM.

(B) BMDC. Both P2X7 KO and WKY WT BMDC can release mature IL-1β in response to stimulation with LPS alone. This mechanism was confirmed to be P2X7 independent using a P2X7 antagonist (A438079) in **(C)**

FR-PO1065

Neuraminidase Activity Mediates IL-6 Secretion from Activated Lupus Mesangial Cells Through TLR4 and MAPK p38

Tamara Nowling,[1] Kamala Sundararaj,[2] Jessalyn I. Rodgers.[2] *[1]Medicine, Medical University of South Carolina, Charleston, SC; [2]Medical University of South Carolina, Charleston, SC.*

Background: Glycosphingolipid (GSL) levels and the activity/levels of the enzyme neuraminidase (NEU), which mediates GSL catabolism, are elevated in the kidneys and/or urine of lupus mice and human patients with nephritis compared to their non-nephritic counterparts and healthy controls. We recently demonstrated that NEU activity mediates IL-6 secretion from mesangial cells (MCs) in response to activation by heat aggregated IgG (HA-IgG) and lupus serum. Our previous results demonstrated that NEU1 and NEU3 staining partially overlapped with IgG deposits in cell cultures of primary MCs stimulated with HA-IgG and in renal sections of kidneys from nephritic lupus mice. Both Fcγ receptors (FcγRs) and TLRs can mediate immune complex activation of cells, are expressed by MCs, and were shown to be involved in progression of lupus nephritis. In this study, we examined the role of FcγRs and toll like receptors (TLRs), and downstream signaling pathways in NEU-mediated secretion of IL-6 by activated lupus prone MCs.

Methods: Cell surface receptors and MAPK pathways were identified by treating MC cultures with antibodies and inhibitors, respectively, prior to activation with HA-IgG or lupus serum. Phosphorylation of p38 was analyzed by western immunoblot. Cellular localization of NEUs and TLR4 was performed by immunofluorescence. Screening of cytokines secreted by MCs was performed using a 20-plex Luminex cytokine array. Levels of individual cytokines were quantified by ELISA.

Results: Blocking TLR4 significantly inhibited, while blocking FcγRs had no effect on, NEU-mediated IL-6 secretion by activated MCs. Preliminary results show overlap between TLR4 and NEU1 at the plasma membrane of MCs. An inhibitor of the p38 MAPK pathway significantly blocked NEU mediated IL-6 secretion. Phosphorylation of p38 was increased following activation of MCs with HA-IgG or lupus serum and was blocked when NEU activity was inhibited or NEU1 expression was reduced. Although several cytokines were secreted in response to activation by both HA-IgG and lupus serum, only IL-6 and IP-10 (CXCL10) were blocked when NEU activity was inhibited.

Conclusions: Together our results suggest that NEU specifically mediates secretion of IL-6 and IP-10, two cytokines important during early development of lupus nephritis, from activated lupus prone MCs through a TLR4-p38 MAPK pathway.

Patient Derived Endothelial Cells as Tool to Study the Effects of Shiga Toxin on the Vascular Endothelium: The BO(ST)EC-Study

Wouter J. Feitz,[1] Nicole Van De Kar,[2] Christoph Licht.[1] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]UMC St. Radboud Nymegen, Nijmegen, Netherlands.*

Background: Hemolytic Uremic Syndrome (HUS) is a form of thrombotic microangiopathy (TMA), which is characterized by hemolytic anemia, thrombocytopenia and acute renal failure. HUS is caused by infections with Shiga toxin (Stx) producing Escherichia coli with subsequent damage of the vascular endothelium (STEC-HUS or eHUS). We have established an *in vitro*system to screen for endothelial susceptibility factors: using Blood Outgrowth Endothelial Cells (BOECs) we can study the function of the endothelium of individual eHUS patients. We hypothesize that endothelial characteristics determine the response to Stx and thus the manifestation of eHUS.

Methods: BOECs from a healthy donor were used (male, 50 years old). Experiments were done in threefold (N=3) or as indicated in the figure. Previous literature has shown that Stx preferentially binds to the endothelial Gb3 receptor. In our study, Vero cells (positive control) and BOECs were cultured. Immunofluorescence imaging of live cells was used to confirm presence or absence of the Gb3 receptor on the cell surface. Using confocal immunofluorescence microscopy, binding of Stx to the cell surface was determined. A lactate dehydrogenase (LDH) cytotoxicity assay was used to assess for cytotoxicity of Stx and to standardize Stx concentrations for future experiments aiming at a level of cell damage of 50%. With flow cytometry, using antibodies for Annexin V and PI, necrotic vs. apoptotic cell death in response to Stx incubation was quantified. Finally, the effect of Stx on endothelial cell motility was determined in a scratch wound assay.

Results: We found that: 1) the Gb3 receptor is present on the cell surface of BOECs; 2) there is an expected positive dose-response relationship, wherein a higher concentration of Stx resulted in increased cell damage. Pre-treatment with TNF-alpha 10 ng/ml for 24 hours and treatment with Stx type 2 10^{-5} ug/ml resulted in 50% cell death; 3) incubation of BOECs with Stx resulted in more apoptotic than necrotic cell death; and 4) endothelial wound healing was impaired when cells were incubated with Stx.

Conclusions: BOECs are a promising tool with high translational potential to study effects of Stx on the vascular endothelium.

Glomerular Endothelial Cells Lacking Neonatal Fc Receptor Have Decreased Major Histocompatibility Complex Type II Expression Due to Decreased Transcriptional Signaling

James F. Dylewski,[2,1] Evgenia Dobrinskikh,[2] Sizhao Lu,[2] Linda Lewis,[2] Judith Blaine.[3] *[1]Denver Health Medical Center, Denver, CO; [2]University of Colorado, Denver, Aurora, CO; [3]University of Colorado Denver, Aurora, CO.*

Background: Glomerulonephritis (GN) requires intrinsic renal cells that express Major Histocompatibility complex type II (MHCII) to propagate the disease. Glomerular endothelial cells (GEnC) can express MHCII but it is unclear if they can present antigen. Neonatal Fc receptor (FcRn) is a trafficking protein that is required for antigen processing and presentation and is also expressed in GEnC. It has been demonstrated that when FcRn is globally knocked out, GN is prevented. The exact mechanism by which knock out of FcRn offers protection from GN is incompletely understood. An understanding of how FcRn is involved in MHCII expression by GEnC could lead to novel therapeutic options.

Methods: We isolated and purified GEnC from wild type (WT) & FcRn knockout (KO) mice by isolating glomeruli. We then used von Willebrand factor (vWF) coated dynabeads to isolate the endothelial cells. The cells were characterized using IF for vWF and a podocyte specific marker (WT1). Once characterized & purified, we used a temperature sensitive SV40 virus to conditionally immortalize both the cell lines. The cells were grown under permissive conditions at 33°C and differentiated at 37°C. Quantitative PCR (qPCR) was used to demonstrate appropriate expression of endothelial cell markers and verify the expression of FcRn in WT and absence in KO. We then treated our GEnCs with INFγ and TNFα and used flow cytometry to evaluate for the expression of CD146 (an endothelial cell marker) and MHCII. We also used qPCR to evaluate mRNA expression of MHCII, MHCII chaperone protein (CD74 also known as invariant chain), and transcript regulator protein (CIITA) to evaluate for differences in level of expression of MHCII and its key transcriptional components.

Results: We demonstrated by flow cytometry that while IFNγ significantly upregulated expression of MHCII in both WT and KO, KO GEnC had significantly less expression of MHCII compared to WT. We also found significantly less MHCII, CD74, and CIITA mRNA in KO compared to WT GEnC.

Conclusions: These findings suggest that the absence of FcRn alters the signaling needed for MHCII transcription. This finding may provide new insight and offer potential new targets for therapies GN.

Concerted Role of Kruppel-Like Factor 4 and Endothelial Nitric Oxide Synthase in the Renal Endothelium

Chelsea C. Estrada,[2] Stephanie Cardona,[1] Sandeep K. Mallipattu,[1] Vivette D. D'Agati.[3] *[1]Stony Brook Medicine, Lynbrook, NY; [2]Stony Brook University Medical Center, Stony Brook, NY; [3]Columbia University College of Physicians and Surgeons, New York, NY.*

Background: Both the transcription factor, Kruppel-like Factor 4 (KLF4), and endothelial nitric oxide synthase (NOS3), play critical roles in the maintenance of a healthy endothelium. A cooperative relationship between the two genes is likely, as endothelial *KLF4* positively regulates *NOS3* expression. In the kidney, at baseline, endothelial deletion of either *Klf4* or *Nos3* does not result in overt changes. Upon stress however, endothelial *Klf4* knockout mice had exacerbated renal failure after ischemic reperfusion injury. Similarly, *Nos3* deletion resulted in increased glomerular injury and albuminuria in models of chronic kidney disease. Based on these data, we hypothesize that endothelial-specific double-knockout of *Klf4* and *Nos3* will disrupt maintenance of the renal endothelium in the healthy kidney.

Methods: Endothelial-specific *Klf4* knockdown mice ($Klf4^{\Delta EC}$) were generated (C57BL/6) by crossing $Klf4^{fl/fl}$ with *Cdh5-Cre* mice. $Klf4^{\Delta EC}$ and $Nos3^{-/-}$ mice were crossed to generate double knockout mice (DKO), and $Klf4^{fl/fl}$ mice used as control. Periodic acid-Schiff (PAS), electron microscopy (EM), immunofluorescence (IF), ELISA and RT-PCR were performed to investigate the effects of DKO on the renal endothelium. 12 week male mice we used in all studies.

Results: In the renal cortex, $Klf4^{\Delta EC}$ mice had decreased *Nos3* expression as compared with control, while $Nos^{-/-}$ mice exhibited increased *Klf4* expression. DKO mice had decreased expression of both *Klf4* and *Nos3*. DKO mice had increased albuminuria and serum creatinine as compared with $Klf4^{fl/fl}$, $Klf4^{\Delta EC}$, and $Nos^{-/-}$ mice. PAS of DKO mice revealed glomeruli with capillary congestion and endothelial cell (EC) swelling, and some glomeruli with widespread loss of ECs and tuft collapse, as well as increased glomerular volume, as compared to all other groups. On EM, DKO mice exhibited ECs with loss of fenestrae and focal areas of subendothelial widening, mesangiolysis and glomerular basement membrane duplication. IF revealed increased glomerular Isolectin B4 and complement membrane attack complex (C5b-9) in DKO mice as compared with all other groups, suggesting disruption of the endothelium and complement activation.

Conclusions: Our results suggest a synergistic interaction between endothelial *Klf4* and *Nos3* signaling in the maintenance of glomerular endothelial function and structure.

Anti-Angiogenic Factors Increase Thrombomodulin Expression in the Kidney in Pre-eclampsia: A Role for Endothelin?

Manon Bos,[1] Katrina M. Mirabito Colafella,[2] Marie-Louise Van der hoorn,[1] Rosanne J. Turner,[6] Jan A. Bruijn,[3] Kitty Bloemenkamp,[5] Alexander H. Danser,[4] Anton H. Van den meiracker,[7] Hans J. Baelde.[1] *[1]Leiden University Medical Center, Leiden, Netherlands; [2]Monash University, Clayton, NSW, Australia; [3]Leiden University Medical Center, Dept.Pathology, Leiden, Netherlands; [4]Erasmus Medical Center, Rotterdam, Netherlands; [5]Birth Centre Wilhelmina Children's Hospital,University Medical Cetre Utrecht, the Netehrlands, Leiden, Netherlands; [6]Leiden University Medical Centre, Leiden, Netherlands; [7]Erasmus MC, Rotterdam, Netherlands.*

Background: Pre-eclampsia (PE) is a pregnancy related syndrome characterized by angiogenic imbalance, which results in symptoms such as hypertension. Furthermore, the kidney is frequently affected in PE. Similar symptoms are observed during treatment of patients with angiogenesis inhibitors like Sunitinib. Thrombomodulin is an essential endothelial regulator of inflammation and coagulation. Serum levels of the breakdown product of thrombomodulin are increased in PE. Here, we investigated thrombomodulin expression in kidneys of women with PE and hypertensive rats exposed to Sunitinib.

Methods: Renal tissue was collected from 34 pregnant women (23 controls, 11 PE) and 14 hypertensive non-pregnant women. Furthermore, kidneys were collected from male WKY rats treated with vehicle, Sunitinib (14 mg/kg/day) alone or in combination with endothelin receptor type A (ET_A) antagonist Sitaxentan (30 or 100 mg/kg/day) or non-selective $ET_{A/B}$ antagonist Macitentan (30 mg/kg/day) for 8 days. Blood pressure in rats was measured by telemetry. Thrombomodulin expression was investigated with immunohistochemistry and qPCR.

Results: Glomerular thrombomodulin protein expression is increased in kidneys of women with PE compared to pregnant women and hypertensive non-pregnant women ($P<0.01$). Renal thrombomodulin expression originated from the glomerular vascular pole, and is not associated with other histopathologic lesions. Exposure to Sunitinib results in 1.5-times higher renal thrombomodulin mRNA expression in WKY rats ($P<0.05$), and Sitaxentan at both doses ($P<0.001$), but not macitentan, normalized this increase. Both antagonists fully prevent the Sunitinib-induced rise in blood pressure.

Conclusions: Renal thrombomodulin expression is increased both in PE and during Sunitinib mediated angiogenic inhibition. Thrombomodulin upregulation appears to be ET_A receptor-mediated, and ET_B receptors counterbalance this effect in a blood pressure-independent manner. Our data suggest that selective ET_A receptor blockade may have long-term renoprotective effects. This may also be true in patients treated with angiogenesis inhibitors.

FR-PO1070

Functional Consequences of Complement Activation on Vascular Endothelial Cells - Results of a Pilot RNA Seq Study

Erin N. Jacobs,[1,2] Magdalena Riedl Khursigara,[3] Carolina Ortiz,[4] Christoph Licht.[3] *[1]University of Toronto, Toronto, ON, Canada; [2]Cell Biology, SickKids Research Institute, Toronto, ON, Canada; [3]The Hospital for Sick Children, Toronto, ON, Canada; [4]Hospital for Sick Children, Toronto, ON, Canada.*

Background: Complement dysregulation on vascular endothelial cells (ECs) causes EC injury and leads to thrombotic microangiopathy (TMA), such as atypical hemolytic uremic syndrome (aHUS). As 50% of aHUS causing mutations are unknown, there is clinical need to find additional pathways and genes involved in the TMA phenotype. Here, we report the results of an unbiased RNA seq approach to investigate complement-induced responses of ECs on a molecular level.

Methods: Complement activation on ECs was induced via sensitization, activating the classical complement pathway, on blood outgrowth endothelial cells (BOECs) from healthy controls. RNA was isolated 1 hour after treatment. A stranded paired end RNA seq library was used, quality assessed with FASTQC software, and adapters trimmed using Trim Galore. Manual analysis of regulated genes was carried out with a cutoff of fold change > |1.5|. Gene function was determined based on literature analysis (pubmed; genecards). Functional assays included neutrophil adhesion in a microfluidic chamber (Bioflux), wound closure assay, measurement of transendothelial resistance with a voltohmmeter and IF staining for VE-Cadherin.

Results: RNA seq revealed three major findings, (i) upregulation of genes involved in leukocyte adhesion (e.g. ICAM, E-selectin); (ii) regulation of genes collectively resulting in loss of cytoskeletal re-arrangement (e.g. downregulation of RhoA activators and upregulation of ROCK 1 inhibitors); and (iii) downregulation of genes involved in cell adhesion (e.g. VE-Cadherin). Functional relevance of these findings was confirmed by complement-induced (i) EC neutrophil adhesion (Bioflux); (ii) defective EC migration (wound closure assay); and (iii) decreased transendothelial resistance and VE-Cadherin staining (voltohmmeter and IF). Importantly, all these effects were reversible when complement activation was blocked, using complement inactivated serum.

Conclusions: Complement activation on ECs results in an array of molecular responses functionally resulting in (i) neutrophil adhesion, (ii) defective cell migration, and (iii) loss of cell-cell adhesion. Detailed mechanism and their link to the clinical phenotype of TMA remains to be elucidated in future research.

Erythropoietin Prevents TH17 Induction and Sodium Chloride-Driven Kidney Inflammation by Inhibiting SGK1-Dependent IL-17 Production

Chiara Cantarelli,[3] Andrea Angeletti,[1] Chiara Donadei,[2] Clara Fischman,[1] Julian Horwitz,[1] Gaetano La Manna,[2] Peter S. Heeger,[1] Paolo Cravedi.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Nephrology, Dialysis and Kidney Transplantation, Bologna, Italy; [3]University Hospital, Parma, Parma, Italy.*

Background: High sodium chloride (NaCl) intake worsens kidney pathology by promoting T_H17 differentiation. Since erythropoietin (EPO) is predominantly produced in the kidney where NaCl concentrations are high, and because EPO has newly recognized immunoregulatory functions, we tested the hypothesis that kidney-derived EPO prevents T_H17 differentiation and thereby modulates T_H17-dependent kidney pathology.

Methods: To study the role of endogenous and recombinant EPO on T_H17 cells *in vivo*, we used murine models of kidney disease associated with T_H17 induction, including aristolochic acid (ArA) nephropathy (+/- high NaCl diet), MRL-*lpr* and pristane lupus nephritis models. *In vitro* studies supplemented by adoptive transfer of naïve or T_H17 cells into $rag1^{-/-}$ mice were used to determine the direct role of EPO on T_H17 induction (**Figure 1A**).

Results: Recombinant EPO and transgenic EPO overexpression limited pathology, while *in vivo* shRNA-induced EPO downregulation augmented ArA-induced T_H17 formation and the clinical expression of disease. Recombinant EPO administration also prevented development of glomerular disease in lupus models, clinical results that were associated with reduced frequencies of T_H17 cells. In $rag1^{-/-}$ adoptive transfer experiments, EPO directly inhibited *in vivo* T_H17 development (**Figure 1B-C**) and promoted trans-differentiation of T_H17 into regulatory T cells. Using murine and human T cells, we then showed that EPO ligation of its T cell-expressed receptor abrogated NaCl-induced upregulation of *Sgk1* gene expression and blocked p38 activity to prevent SGK1 phosphorylation, thereby limiting RORC induction and T_H17 differentiation.

Conclusions: EPO physiologically and therapeutically inhibits T_H17 cell differentiation and T_H17-associated autoimmune kidney pathology by antagonizing intracellular signaling pathways required for NaCl-driven T_H17 differentiation.

Funding: NIDDK Support

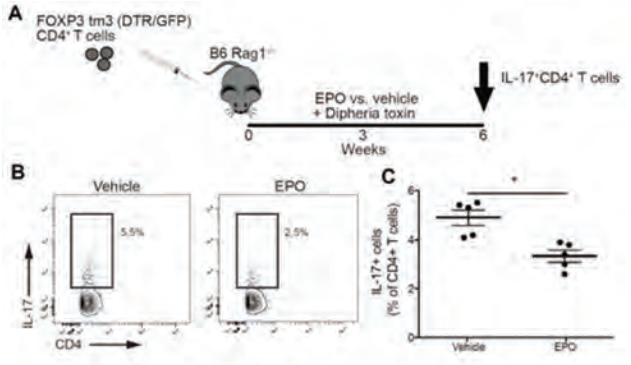

Figure 1. EPO inhibits T_H17 induction in vivo in a Treg-independent system. We transferred Foxp3-DTR naive CD4+ T cells into Rag1-/- mice and treated them with diphteria toxin +/- EPO (**A**). After 6 days, we measured IL17+CD4+ T cells (T_H17) (representative flow plots, **B** and data quantification, **C**). *P<0.05.

FR-PO1072

Role of the ICOS/ICOS-L Costimulatory Pathway and of Circulating Extracellular Vesicles as Potential Biomarkers and New Therapeutic Targets in Lupus Nephritis

Vincenzo Cantaluppi,[1] Martina Mazzariol,[2] Guido Merlotti,[3] Marco Quaglia.[4] *[1]University of Piemonte Orientale (UPO), Novara, Italy; [2]University of Piemonte Orientale, Novara, Novara, Italy; [3]University of Piemonte Orientale, Novara, Italy; [4]Università del Piemonte Orientale, Torino, Italy*.

Background: The costimulatory pathway ICOS/ICOS-L and extracellular vesicles (EV), microparticles known to have a role in cell-to-cell communication, both appear to be involved in tissue injury associated with SLE. The aim of this study was to evaluate the association between ICOS, ICOS-L or EV plasma levels and clinical expression of lupus nephritis (LN).

Methods: Main clinical and laboratory parameters were compared among 67 SLE patients (52 with LN and 15 with only rheumatological SLE) and 50 healthy controls. Plasma levels of ICOS/ICOS-L were assessed by ELISA and EV were evaluated by Nanotrack and FACS analysis.

Results: Serum levels of ICOS and ICOS-L were significantly increased in SLE as compared with healthy controls ($p<0.001$) and associated with disease duration ($p=0.036$ for ICOS and $p<0.001$ for ICOS-L), presence and severity of LN at diagnosis ($p=0.017$ and $p=0.001$), proteinuria ($p=0.014$ and $p<0.001$) and nephritic sediment ($p=0.005$ and $p=0.010$). ICOS levels also correlated with established scores such as SLICC ($p=0.027$) and SLEDAI-2K ($p=0.001$) at diagnosis. At univariate logistic regression analysis, disease onset at younger age ($p=0.007$), ICOS ($p=0.044$) and ICOS-L levels ($p=0.009$) were associated with LN; however, at multivariate analysis only disease onset at younger age ($p=0.018$) and ICOS-L ($p=0,047$) were indipendently associated with renal involvement. Plasma EV levels were higher in SLE patients with LN ($p<0.001$) without discrimination between prolipherative and non-prolipherative classes: however, EV levels correlated with proteinuria ($p=0.032$) and ICOS levels ($p=0.026$). Of interest, FACS analysis revealed the presence of both ICOS and ICOS-L on EV surface.

Conclusions: ICOS and ICOS-L plasma levels are increased in SLE and appear to identify a subset of SLE patients with long-lasting disease and severe LN at presentation. In addition, plasma EV levels were also higher in SLE patients with LN and correlated with ICOS: circulating EV carried ICOS and ICOS-L proteins. ICOS/ICOS-L pathway and circulating EV may be potential biomarkers and new therapeutic targets in LN.

FR-PO1073

Targeting TH17 Plasticity in Immune Mediated Inflammatory Diseases

Shiwa Soukou. *Universitätsklinikum Hamburg Eppendorf, Hamburg, Germany*.

Background: During T cell development, naive T cells can differentiate into effector T cells (e.g T_H1 and T_H17) or into regulatory T cells (e.g. $Foxp3^{Neg}T_R1$ and $Foxp3^{Pos}$ Treg cells). Originally every single CD4 T cell lineage was thought to be stable after differentiation and to represent a functional homogenous population of cells. Recent data suggest that CD4 T cells and T_H17 cells in particular, have higher plasticity in the brain and in the intestine, where T_H17 cells are able to convert into T_H1 cells and into T_R1 cells respectively.

Methods: To prove the conversion from TH17 cells towards TR1exTH17 and the role of TR1exTH17 cells in the kidneys of nephritic, we used Fate+ (Foxp3RFP IL-10eGFP IL-17AKata IL-17ACRE R26YFP mice) and IL17ACre IL10fl/fl mice. Mice were immunized with nephrotoxic sheep serum. Additionally we treated them with PBS or 15 µg of αCD3 monoclonal antibody (mAB) intraperitoneally (i.p.). Injections were done at day 8 and day 10 post immunization. The mice were analyzed 4 hours after the last injection. Multiparametric flow cytometric analysis was performed and clinical parameters were measured in urine and plasma. Moreover histological analysis was done using Periodic acid–Schiff (PAS) staining that detects polysaccharides and mucosubstances.

Results: We could show that spontaneous and induced conversion of TH17 cells into TR1exTH17 over the course of NTN induction take place. Furthermore induction of NTN in IL17ACre IL10fl/fl mice showed aggravated glomerulonephritis.

Conclusions: Our first aim was to demonstrate the existence of TR1exTH17 in the kidneys of nephritic mice. Moreover we showed that the regulatory fate of TH17 cells (IL-10 producing TH17 and TR1exTH17 cells) can play an important role. Furthermore preliminary data show that deletion of IL-10 production by TH17 and exTH17cells can result in aggravated outcome of GN. However whether kidney IL-10 producing Foxp3Neg CD4 T cells are a functional homogenous population of regulatory cells remains unknown and the molecular mechanism underlying the conversion of TH17 into TR1 cells remain to be discovered

Funding: Government Support - Non-U.S.

FR-PO1074

Elucidating the Role of Neutrophil Extracellular Traps in Atypical Hemolytic Uremic Syndrome

Samuel E. Suntharalingham,[1] Carolina Ortiz,[2] Christoph Licht.[3] *[1]University of Toronto, Toronto, ON, Canada; [2]Hospital for Sick Children, Toronto, ON, Canada; [3]The Hospital for Sick Children, Toronto, ON, Canada*.

Background: About 10% of patients manifest hemolytic uremic syndrome (HUS) without toxins or diarrhea. These cases are referred to as atypical HUS (aHUS) and occur due to a dysregulated complement system leading to unchecked complement activation on the vascular endothelium. Genetic mutations account for only 50-60% of aHUS cases only with a large variation in the age and severity of the disease phenotype. For the past decade, neutrophils have been shown to produce neutrophil extracellular traps (NETs), which are associated with proinflammatory and prothrombotic properties. We propose that NETs are involved in aHUS pathogenesis.

Methods: Resting neutrophils freshly isolated from healthy donors were used (male, ages 18-24 years old). Experiments were done at least threefold (N=3). We have previously shown that neutrophils contain complement components, which they deposit on NETs, and that NETs contribute to complement activation. In this study, we aim to determine if NETosis can be induced by complement activation. In order to activate complement, neutrophils were sensitized via a monoclonal anti-human CD59 (x30 min) followed by incubation with 50% human serum as source of complement (x4 h). Immunofluorescence (IF) imaging was used to quantify the kinetics of NETs formation.

Results: We found that: 1) the use of our complement sensitization protocol resulted in C3b deposition and C5b-9 complex formation on neutrophils; 2) NETosis could be induced in a complement-dependent manner; 3) both citrullinated Histone 3 (cit-H3) and myeloperoxidase (MPO) are both present in the NETs of complement-stimulated neutrophils.

Conclusions: Complement activation taking place on the surface of neutrophils induces NETosis, a new finding pointing towards a crucial role for neutrophils in the pathogenesis of complement-mediated TMA.

FR-PO1075

Rituximab Associated Hypogammaglobulinaemia in Autoimmune Disease: Long Term Outcomes

Joanna Tieu,[2] Rona M. Smith,[1] Seerapani Gopaluni,[3] David R. Jayne.[3] *[1]Cambridge University Hospitals, UK, Cambridge, United Kingdom; [2]University of Cambridge, University of Adelaide, Cambridge, United Kingdom; [3]University of Cambridge, Cambridge, United Kingdom*.

Background: Despite a low incidence of hypogammaglobulinemia (HG) in clinical trials using rituximab (RTX), HG occurs in follow-up of patients with autoimmune disease. Immunoglobulin replacement therapy (IRT) has been used to reduce infection rates but there is a paucity of data on its efficacy and impact on longer-term outcomes. We examined the characteristics of patients with RTX associated HG in autoimmune disease, and their long-term outcomes with and without IRT.

Methods: Patients attending a Vasculitis and Lupus clinic, who received RTX for autoimmune disease between 2004 and 2012, with an immunoglobulin G (IgG) <7 g/L on at least 2 occasions were included in this retrospective case note review. Patients were categorized into nadir IgG subgroups of <3 g/L, 3 to <5 g/L and 5 to <7 g/L. Categorical variables are summarised as proportions, and continuous variables as mean ± standard deviation or median [interquartile range (IQR)]. Differences between nadir IgG subgroups were assessed by Chi squared tests and trends across subgroups confirmed by Somer's D tests. Continuous variables were compared using analysis of variance (ANOVA), Kruskall-Wallis and Wilcoxon sign ranked tests as appropriate. Analyses were performed in SPSS.

Results: Of 142 patients, 101 (71.1%) had ANCA associated vasculitis, 18 (12.7%) systemic lupus erythematosus and 23 (16.2%) other diagnoses. Most received RTX for relapsing (69.3%) or refractory (25.0%) disease. Mean follow-up was 97.2 months. Progressive HG was observed. Median time to IgG <5 g/L was 22.5 months [IQR 3.0 to 61.5] and to IgG <3 g/L was 24.5 months [IQR 4.0 to 80.75]. Mycophenolate use prior to RTX ($p=0.05$) and prednisolone use following RTX ($p=0.04$) were associated with a lower nadir of IgG. IRT was commenced in 29 patients, the majority (65.5%) with IgG <3 g/L. It was well tolerated, with 2 discontinuing due to adverse effects. IRT was withdrawn without excess recurrent infections in 5 patients. IRT was associated with a reduction in annual infection rates ($p<0.001$). Severe infections (requiring intravenous antibiotics or hospital admission) were uncommon, with no change with the use of IRT.

Conclusions: RTX associated HG is progressively identified with longer term follow-up. Although annual infection rates were low, in patients with recurrent infection, IRT was associated with a reduction in infection burden.

FR-PO1076

Persistent B-Cell Depletion After Rituximab

Debbie Chen,[1] Zachary S. Wallace,[2] Jillian Rosenthal,[2] Alexander T. Sipilief,[2] Karen A. Laliberte,[2] John Niles,[2] Frank B. Cortazar.[2] *[1]MGH, Boston, MA; [2]Massachusetts General Hospital, Boston, MA.*

Background: Rituximab (RTX), an anti-CD20 monoclonal antibody, is an effective therapy for many glomerular diseases. Following RTX, B cell reconstitution occurs at a median of 8 months, and the vast majority of patients have B cell return by 18 months. We report 7 patients with autoimmune kidney disease who developed persistent B cell depletion following RTX.

Methods: We performed a retrospective analysis of patients with glomerular disease treated with rituximab between 2006-2017. Patients who had persistent B cell depletion, defined as undetectable CD20+ B cells determined by flow cytometry for > 2 years after their last rituximab dose, were included in the study. Patient characteristics, serological markers of disease, adverse events, and survival were examined.

Results: We identified 7 patients with persistent B cell depletion. Six patients were treated for ANCA vasculitis and one for lupus nephritis. Patients received a median of 13 RTX doses (range, 5 to 22). Following the final RTX, B cells in these patients have remained undetectable for a median of 5.2 years (range, 3.9 to 6.9). Four patients developed significant hypogammaglobulinemia (IgG < 400 mg/dL) and two received IVIG. RTX-induced late-onset neutropenia occurred in 3 patients. Five patients developed serious infections and one patient died in the setting of infection associated with recurrent late onset neutropenia. No patient had recurrence of their underlying autoimmune disease.

Conclusions: Persistent B cell depletion after rituximab is a rare but important complication of therapy that appears to be associated with late-onset neutropenia and serious infections. The mechanism of this phenomenon is unclear. Additional investigation into the risk factors and pathogenesis of this complication are needed.

Patient and Outcome Characteristics

Age	Gender	Disease	Years of B cell depletion	# rituximab doses	Significant hypogammaglobulinemia	IVIG given	LON episodes	Major infections
61	M	MPO ANCA	3.9	22	No	No	0	Recurrent sinusitis
67	M	MPO ANCA	4.2	13	No	Yes	22	Neutropenic sepsis
50	M	PR3 ANCA	6.2	21	Yes	No	0	None
43	F	SLE	6.9	7	Yes	Yes	3	Recurrent gastroenteritis, colitis
62	M	MPO ANCA	6.9	13	No	No	0	Recurrent pneumonia
34	F	MPO ANCA	5.2	5	Yes	No	4	Recurrent sinusitis
60	F	MPO ANCA	3.9	9	Yes	No	0	None

LON: late onset neutropenia

Major infections: infection leading to hospitalization or requiring intravenous antibiotics

FR-PO1077

The Oxidized Linoleic Acid Metabolite 12,13-Dihydroxy-9Z-Octadecanoid Acid (12,13-DiHOME) Mediates Recovery from Nephrotoxic Nephritis

Nino Kvirkvelia,[1] Malgorzata McMenamin,[1] Ahmed Ibrahim,[1,2] Mohamed Al-Shabrawey,[1] Michael P. Madaio.[1] *[1]Augusta University, Augusta, GA; [2]Mansoura University, Masoura, Egypt.*

Background: The number of anti-inflammatory lipid molecules is increasing and their role in nephritis is not well investigated. In particular, the enzymatic activity of soluble Epoxide Hydrolyze (sHE) and its products such as 9,10-DiHOME and 12,13-DiHOME were shown to be critical for resolution of inflammation. Biosynthesis of these products starts from linoleic acid by cytochrome P450 (CYP) oxidases, followed by hydrolysis catalyzed by soluble epoxide hydrolases. We hypothesized that synthesis, metabolism or signaling of oxidized linoleic acid metabolites may be affected at the site of inflammation and that 12,13-DiHOME has an important role in resolution of nephritis.

Methods: To investigate changes in lipid profiles in differentially treated mice, lipidomic analysis was carried out by LC/MC in Lipidomics Core Facility (Wayne State University, Detroit, MI). Panel of 144 lipid molecules were measured in plasma of mice at day 7 after induction of nephrotoxic nephritis (NTN), induced by injection of nephrotoxic serum (13,5µl/g bw). Kidney endothelial cells were treated with 12,13-DiHOME (250nM) and TNF-α (10ng/ml) was added after 1h. TNF-α induced upregulation of VCAM-1 was investigated by flow cytometry after 24 h.

Results: Lipidomic plasma profiles of polyunsaturated fatty acid metabolites in nephrotic mice showed marked decrease of two molecules: 9,10-DiHOME and 12,13-DiHOME. The role of 12,13-DiHOME was further evaluated in NTN: after induction of nephritis mice were treated with 12,13-DiHOME (20ng/g bw) or vehicle, starting on day 2, than every 48h, and mice were sacrificed on day 7. 12,13-DiHOME treatment completely normalized both BUN levels and histology (NTN mice: BUN = 117.72 ± 3.2, NTN 12,13-DiHOME injected mice BUN = 15.50 ± 0.43, $p<0.0002$). In glomerular endothelial cells, 12,13-DiHOME treatment reduced TNF-α induced upregulation of VCAM-1 by 49%.

Conclusions: The results of the study suggest that administration of 12,13-DiHOME during NTN protects kidneys from severe inflammation, in part, by limiting upregulation of adhesion molecules on kidney endothelial cells and therefore, may have therapeutic potential for the treatment of nephritis.

Urine Podocin to Nephrin mRNA Ratio Is Associated with Activity of Crescentic Necrotizing Glomerulonephritis

Akihiro Minakawa,[1] Akihiro Fukuda,[2] Masao Kikuchi,[1] Yuji Sato,[1] Shouichi Fujimoto.[1] *[1]University of Miyazaki, Miyazaki, Japan; [2]Oita University, Yufu, Japan.*

Background: Crescentic necrotizing glomerulonephritis (CNGN) rapidly leads to progressive glomerulonephritis syndrome, which then leads to irreversible renal failure without appropriate therapy. To estimate the severity of CNGN, renal biopsy is required. However, renal biopsy is sometimes not applied because of a severe general condition. If urine podocyte-specific mRNA predicts the severity of CNGN, it may be a useful tool.

Methods: A total of 28 patients with biopsy-proven CNGN (males: 16, mean age: 64.6±12.8 years) were enrolled during the past 7 years, with pathological data available for 27 patients. Kidney biopsy samples were used for immunostaining of podocytes and urine samples for podocyte mRNA with the patient's consent by document.

Results: A blood test showed an estimated glomerular filtration rate of 24.9±18.7 mL/min and C-reactive protein level of 3.33±3.68 mg/dL. Histological analysis showed 3 patients with crescent class, 3 with sclerotic class, 9 with focal class and 12 with mixed class according to EUVAS classification. Immunostaining showed a podocyte number of 297.2±133/glom and podocyte density of 75.8±32/10^6µm^3. A urinary mRNA study showed a urine podocin:nephrin mRNA ratio (PNR) of 1.46±0.80 and urine podocin mRNA:urine creatinine ratio (U-pod/CR) of 476.8±525.3. The podocyte number and density were lower, and the PNR and U-pod/CR were higher compared with those of healthy controls in our previous report (419±81/glom, 129±49/10^6µm^3, 0.36±0.29, 4.3±4.6, respectively). Using EUVAS criteria, the podocyte number in the sclerotic class and podocyte density in the crescent and sclerotic classes tended to be lower compared with the other classes. The PNR and U-pod/CR in these classes, except for the sclerotic class, tended to be increased, which suggested a "podocyte-depleted" stage of sclerotic class. Remarkably, the PNR was significantly correlated with the percentage of glomeruli with acute crescents per unsolidified glomeruli ($p<0.01$, $R^2=0.28$). Log10 of the U-pod/CR was also correlated with it, except for 6 severe crescentic cases ($p<0.01$, $R^2=0.40$).

Conclusions: Urine podocyte mRNA, especially the PNR, might be a useful tool for evaluating activity of CNGN.

FR-PO1079

miR-150 Inhibitor Ameliorates Three Immune-Involved Kidney Diseases by Reducing Inflammation and Fibrosis

Junjun Luan,[1] Huimeng Qi,[1] Jingqi Fu,[2] Congcong Jiao,[1] Weiwei Kong,[1] Chengjie Chen,[2] Xiangfei Cui,[1] Jingbo Pi,[2] Yanqiu Wang,[1] Detian Li,[1] Hua Zhou.[1] *[1]Department of Nephrology, The Affiliated Shengjing Hospital of China Medical University, Shenyang, China; [2]Program of Environmental Toxicology, School of Public Health, China Medical University, Shenyang, China.*

Background: Renal fibrosis from immune-involved kidney diseases remains refractory. We previously reported that miR-150 increased in the repeated renal biopsies from patients with lupus nephritis (LN) and found that miR-150 mimic promoted fibrosis in three human kidney resident cells in vitro. We aimed to clarify whether miR-150 inhibitor can ameliorate renal fibrosis in three kidney disease mouse models and to identify the corresponding mechanisms.

Methods: We first examined miR-150 in renal biopsies from patients with new onset LN or focal segmental glomerulosclerosis (FSGS). Then we observed the time course of renal miR-150 in mouse models including spontaneously developed *Fcgr2b*$^{-/-}$ LN, adriamycin-induced FSGS, and folic acid-induced tubulointerstitial fibrosis (TIF). Lastly, the efficacy and safety of locked nucleic acid (LNA)-anti-miR-150 (2mg/kg, twice a week) were studied when it was subcutaneously injected to LN mice for 8 weeks, to FSGS mice for 6 weeks, and to TIF mice for 4 weeks. The kidney injury (proteinuria, serological indices, and histology damage on PAS and Masson staining), renal levels of pro-inflammatory cytokines (IFN-γ, IL-6, and TNF-α), profibrotic genes (TGF-β, α-SMA, fibronectin, and collagen1), antifibrotic gene suppressor of cytokine signaling 1 (SOCS1), and the infiltration of lymphocytes and macrophages were investigated in mice with LNA-anti-miR-150 treatment comparisons to the scrambled LNA.

Results: miR-150 was increased in renal biopsies of LN and FSGS patients compared to normal kidneys. miR-150 showed higher expression in the kidneys of mice than in other studied organs. LNA-anti-miR-150 downregulated renal miR-150 levels and ameliorated kidney injury in LN, FSGS, and TIF mice without any organ toxicity. The above observed pro-inflammatory cytokines, profibrotic genes, and the infiltration of lymphocytes and macrophages increased while antifibrotic gene SOCS1 decreased in the kidneys of disease mice. LNA-anti-miR-150 decreased the inflammation, fibrosis, and inflammatory cells while increased SOCS1 compared to the scrambled LNA.

Conclusions: miR-150 inhibitor played important renal protective roles in three immune-involved kidney diseases with final renal fibrosis. This suggests that miR-150 inhibitor might be a promising therapeutic agent for renal fibrosis.

The Histopathological Spectrum of Monoclonal Gammopathies of Renal Significance: A Single Centre Experience

Andreas Kousios,[1] Tara K. Brah,[1] Ethan Troy-Barnes,[1] Neill D. Duncan,[1] Rawya Charif,[1] H. Terence Cook,[3] Candice A. Roufosse.[2] *[1]West London Renal and Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Renal Pathology, Imperial College Healthcare NHS Trust, London, United Kingdom; [3]Imperial College of London, London, United Kingdom.*

Background: Monoclonal Gammopathy of Renal Significance (MGRS) encompasses renal histopathological entities caused by Monoclonal Immunoglobulins (MIg) in patients who do not meet criteria of symptomatic lymphoma or myeloma (MM). We describe the spectrum of MGRS histopathological diagnoses in the context of the underlying haematological disease in our centre.

Methods: Native renal biopsies performed during 2006-2017 were reviewed. Those with evidence of MIg or light chain in glomeruli, tubules, vessels and/or interstitium were included. C3GN and TMA were excluded.

Results: Out of 4,374 kidney biopsies, MIg-associated lesions were identified in 163 cases (3.7%). After exclusion of symptomatic MM and lymphomas 68 biopsies (1.5%) were consistent with MGRS. Renal histological diagnoses included: AIg amyloidosis (n=28, 41%), Proliferative GN with MIg Deposits(PGNMID) (n=13, 19%), MIg Deposition Disease(MIDD) (n=12, 18%), Light Chain Tubulopathy (n=5, 7%), Type-1 Cryoglobulinaemic GN (n=6, 9%), Intracapillary Monoclonocal IgM without Cryoglobulin (n=2, 3%), Crystal Cryoglobulinaemia (n=1, 1.5%) and Fibrillary Light Chain restricted GN (n=1, 1.5%). Only 24 out of 42 patients in whom Serum Free Light Chain assay was performed had an abnormal ratio. Overall, haematological diagnosis was possible in bone marrow histology (BMAT) or lymph node biopsy in 53 patients. These included: MGRS with less than 10% plasma cells in BMAT (n=30, 56.6%), Smouldering Myeloma (n=17, 32%), lymphoplasmacytic lymphoma/Waldenstrom's macroglobulinaemia (n=2, 3.7%), chronic lymphocytic leukaemia (n=3, 5.6%) and marginal zone lymphoma (n=1, 1.8%). In 8/13 PGNMID and 3/12 MIDD cases a clonal B cell or plasma cell clone was undetectable in BMAT.

Conclusions: MGRS are increasingly recognised since the term introduction in 2012 and this type of renal histopathology is also frequent in Smouldering Myeloma. Renal histopathology must be interpreted in conjunction with the haematological diagnosis to guide treatment decisions. However, current diagnostic methods underperform and consensus diagnostic approaches incorporating renal and haematological histopathology are lacking.

FR-PO1081

Diagnosis and Outcomes of Monoclonal Gammopathy of Renal Significance: A Single Centre Study

Andreas Kousios,[2] Neill D. Duncan,[2] Candice A. Roufosse,[1] H. Terence Cook,[3] Rawya Charif.[2] *[1]Imperial College Healthcare NHS Trust, London, United Kingdom; [2]West London Renal and Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom; [3]Imperial College of London, London, United Kingdom.*

Background: Monoclonal Gammopathies of Renal Significance (MGRS) are caused by monoclonal immunoglobulins (MIg) produced by B cell or plasma cell clonal disorders, which do not meet criteria of symptomatic lymphoma or myeloma (MM). Treatment objective in MGRS is the preservation of kidney function.

Methods: Records of patients with native kidney biopsy during 2006 – 2017 were reviewed. Amyloidosis, C3GN and TMA were excluded.

Results: 41 biopsies out of 4.374 (1%) were consistent with MGRS. Mean age at diagnosis was 63±12 years. Renal histological diagnoses included: proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) (n=16, 39%), monoclonal immunoglobulin deposition disease (MIDD) (n=13, 32%), light chain tubulopathy (LCT) (n=5, 12%), type-1 cryoglobulinaemic glomerulonephritis (n=6, 15%), fibrillary glomerulopathy (FibGN) (n=1, 2%). 22/41 patients had abnormal protein electrophoresis and/or free light chain ratio. 32/41 had bone marrow biopsy and haematological diagnoses included: MGRS with <10% plasma cells (n=22, 69%), smouldering myeloma (n=5, 15%), Waldenstrom's Macroglobulinaemia (n=1, 3%), chronic lymphocytic leukaemia (n=3, 10%) and marginal zone lymphoma (n=1, 3%). 16 patients were treated with myeloma-based protocols (bortezomib ± autologous stem cell transplantation). In cases with very low or unidentifiable clone, treatment was heterogenous, including glomerulonephritis protocols (cyclophosphamide, steroids ±Rituximab) (n=16) or conservative management (n=9). During median follow-up of 26 months (4-123) in 38 patients, 26 had stable/improved renal function, 1 worsening renal function (>30% eGFR decrease) and 11 progressed to ESRD. 9 patients died (table 1).

Conclusions: Haematological assessment of MGRS must exclude symptomatic myeloma or lymphoma and identify the pathogenic clone to direct specific therapy. Case studies in our series indicate that early detection and treatment improves renal outcomes, however consensus diagnostic and treatment approaches are missing.

Table 1:

Characteristic		All	PGNMID	MIDD	LCT	Type 1 Cryo
Number of patients		38 **	15	12	4	6
Median follow-up(months)		26(4-121)	24(6-106)	40(4-121)	29(19-53)	20(14-48)
Treatment N(%)	None	8 (21%)	5	2	1	0

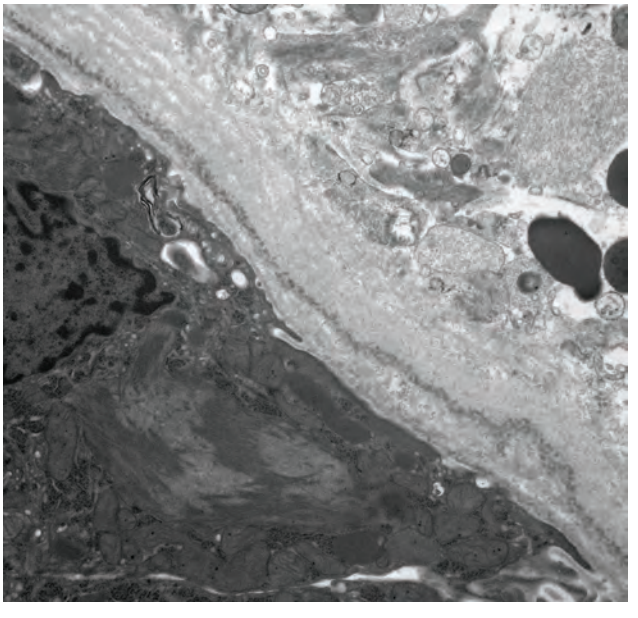
Multiple Deposition Phenotypes of Monoclonal Immunoglobulin Deposition Disease on Renal Biopsy: Significance of Treatment

Sreedhar R. Adapa,[2] Cynthia C. Nast,[1] Hemant Dhingra.[2] *[1]Cedars-Sinai Medical Center, Los Angeles, CA; [2]The Nephrology Group, Inc, Fresno, CA.*

Introduction: Plasma cell dyscrasias frequently involve the kidney causing renal dysfunction. Various morphologies occur in kidneys, infrequently with several manifestations in one biopsy. We present a case, which revealed multiple pathological features on same biopsy, which responded to treatment.

Case Description: A 61 year old female presented with fatigue and dyspnea for 3 months. She had new onset renal failure with creatinine 3.0 mg/dL and proteinuria. Serological work up revealed monoclonal gammopathy with elevated K:L ratio of 1394. Renal biopsy revealed several paraprotein manifestations including kappa light chain deposition disease, monoclonal fibrillary glomerulonephritis, cryocrystalglobulenemia and fibrillary/tubular cast nephropathy. There was also incidental LECT 2 amyloidosis, negative for kappa light chain and confirmed by mass spectrometry. Bone marrow biopsy revealed 10-20% kappa restricted plasma cells. She received 8 cycles of CyBorD (Cyclophosphamide, Bortizomib and Dexamethasone) chemotherapy. Renal function improved with the recent creatinine 1.1 mg/dL and decreased proteinuria. K:L ratio improved to 1.7. Repeat bone marrow biopsy showed no evidence of abnormal plasma cells by immunohistochemistry. The patient is currently being evaluated for an autologous stem cell transplant.

Discussion: The finding of several concurrent morphologic manifestations of light chain deposition in one biopsy suggests local microenvironment effects in addition to structural properties of the light chain. The renal recovery demonstrates responsiveness to chemotherapy irrespective of the form of light chain deposition noted on biopsy. In this setting, amyloid may not always be light chain related, and other amyloid types should be considered when light chain staining is discrepant.



FR-PO1083

A Clone-Directed Treatment Approach for the Monoclonal Gammopathies of Renal Significance

Alex Dinh,[1] Jordana B. Cohen,[2] Matthew Palmer,[3] Alfred Garfall,[4] Laura M. Dember,[2] Dan T. Vogl,[4] Brendan M. Weiss,[4] Jonathan J. Hogan.[2] *[1]Division of Internal Medicine, University of Pennsylvania School of Medicine, Philadelphia, PA; [2]Division of Nephrology, University of Pennsylvania School of Medicine, Philadelphia, PA; [3]Pathology, University of Pennsylvania, Philadelphia, PA; [4]Division of Hematology-Oncology, University of Pennsylvania School of Medicine, Philadelphia, PA.*

Background: Monoclonal gammopathy of renal significance (MGRS) is a non-malignant hematologic condition causing paraprotein-mediated kidney disease. We recently published our experience using a clone-directed approach to patients with PGNMID. Here, we present our experience using the same approach to 22 patients with non-PGNMID paraprotein-mediated nephropathies.

Methods: We retrospectively reviewed 22 patients with MGRS to describe their renal and hematologic presentations and outcomes. For patients with initial proteinuria <0.5 g, complete renal response (CR) was defined as proteinuria <0.01 g (24h urine) or g/g (Uprot/Cr ratio) and partial renal response (PR) as proteinuria reduction by 50%. For patients starting with nephrotic range proteinuria, CR and PR were defined as proteinuria <0.5 g and <3.5 g, respectively. For patients with initial proteinuria between 0.5 and 3.5 g, CR and PR were defined as proteinuria <0.49 g and 50% reduction of proteinuria, respectively. Renal response required stable/improved eGFR. Hematologic studies and responses are presented descriptively.

Results: Histologic diagnoses included LCDD (n= 9), immunotactoid glomerulopathy (n= 3), paraprotein-associated C3 GN (n= 2), monoclonal membranous nephropathy (n= 3), and 1 case each of monoclonal fibrillary GN, heavy chain deposition disease, light and heavy chain deposition disease, type 1 cryoglobulinemic GN, and light chain proximal tubulopathy. Median eGFR (interquartile range) was 30 mL/min (18 to 48 mL/min). Median baseline proteinuria (IQR) was 2.11 g (1.1 to 3.9 g). 4 patients presented on RRT. An underlying clone was detected in 18 patients (82%), of whom 13 had plasma cell clones and 5 had B cell clones. 17 (77%) patients had detectable paraprotein on serum or urine immunofixation. 4 patients were not treated due to stable renal disease. Of 18 patients who underwent treatment, 3 achieved renal CR and 6 achieved renal PR (50% overall response rate). No patient on HD came off RRT, and 1 patient progressed to ESRD during follow-up. Of patients who received clone-directed therapy and were not on RRT at diagnosis, the overall renal response rate was 64%. 71% of patients had an improvement in paraprotein levels.

Conclusions: Clone-directed therapy led to a high overall response rate in patients with MGRS.

FR-PO1084

Chemotherapy Response and 2 Years Follow-Up of Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits (PGNMID)

Ricardo Valjalo,[1] Camila Pena,[1] Gonzalo P. Mendez.[2] *[1]Hospital del Salvador, Santiago, Chile; [2]Pontificia Universidad Catolica de Chile., Vitacura, Chile.*

Background: The term monoclonal gammopathy of renal significance (MGRS) represents all monoclonal gammopathies that are associated with the development of a kidney disease but do not meet the definition of hematological malignancies. PGNMID is an uncommon MGRS–related glomerular disorder characterized by monoclonal Ig deposits resulting in an endocapillary proliferative or membranoproliferative histological pattern of injury. It usually manifests with proteinuria, microscopic hematuria and renal impairment. Treatment for PGNMID has included RAS blockage, rituximab, chemotherapy and immunosuppressive therapy with variable results. Nonetheless, reports with treatment outcomes are scarce, heterogeneous and retrospective, so the benefits of specific treatment remain unclear. Here we report for first time, the prospective results of 3 cases of PGNMID treated with a cyclophosphamide, thalidomide and dexamethasone (CTD regimen) based oral chemotherapy.

Methods: Prospective analysis. Three cases of PGNMID were identified during 2015 at Hospital del Salvador (Santiago, Chile). The biopsies were analyzed using standard techniques for light microscopy, IF, and EM. The presence of plasma cell dyscrasia and other conditions were evaluated. All patients received CTD regimen and RAS blockage.

Results: Two patients made their debut with impure nephrotic syndrome and rapidly progressive renal failure. Patient 2 had subnephrotic proteinuria and hematuria. In all cases M-protein could not be detected by serum or urine PEP/IF and only κ/λ relation was elevated. All patients had no bone marrow involvement, and autoimmunity study was negative. The IF revealed mesangial deposits restricted to IgG3-kappa in patients 1 and 3, and IgA kappa in patient 2. After CTD regimen, two patients achieved complete remission with no adverse effects and no relapses after 2 years of follow-up. The third patient had a serious pneumonia with severe AKI and dialysis requirement after 8 months of initiating chemotherapy. Thereafter had a serious *Clostridium difficile* infection, chemotherapy was stopped and the patient continued on dialysis.

Conclusions: The CTD chemotherapy regimen was successful in the treatment of PGNMID attaining long-term complete remission. CTD regimen seems to be an effective treatment, but we must put attention on chemotherapy related adverse effects

FR-PO1085

Comparison of Two Renal Staging Systems and Response Criteria of AL Amyloidosis

Maria E. Drosou, Eli Muchtar, Nelson Leung. *Mayo Clinic, Rochester, MN.*

Background: Light chain (AL) amyloidosis affects the kidney in 70% of the patients. Renal survival and response are critical for the treatment decision. We carried out this study to evaluate the two sets of baseline staging system and renal response and progression criteria (Palladini et al. and Kastritis et al.) recently proposed in our own population.

Methods: AL cases with renal involvement at Mayo Clinic between 01/2003 and 01/2015 were screened. Patients were excluded if: dialysis dependence at the time of diagnosis or <3 months of treatment initiation, incomplete data set and treatment initiation more than 1 month before AL diagnosis. Our cohort was evaluated at baseline and at 3, 6 and 12 months. The study's endpoint was renal survival, defined as the time from treatment initiation to dialysis initiation or of last follow up. We used competing risks statistical analysis and the C (Concordance) index to compare the two models.

Results: Out of 836 patients with AL and renal involvement, 495 were selected. The median age was 61(54-68) years and 62% were male. Median serum creatinine was 1.1(0.9-1.4) mg/dl, median eGFR was 66(47-82) ml/min/1.73 m^2 and median proteinuria was 5.1(2.5-8.2) g/d. Table 1 shows the distribution of our cohort in stages. For ESRD onset, hazard ratio (HR) for stage II vs I was 21[NL1] (p= 0.003) and for stage III vs II was 3.02(p<0.001) for the Palladini staging system (C= 0.74). HR for stage II vs I was 4.3 (p=0.161) and for stage III vs II was 4.76 (p< 0.001) for the Kastritis staging (C =0.73). At 3 months, neither criteria met statistically significant predictive value. The Palladini progression criteria were superior both at 6 months [HR: 9.68 (p<0.001, C =0.79) vs HR: 3.03 (p=0.002, C= 0.65)] and at 12months [HR: 7.24 (p<0.001, C =0.75) vs HR: 5.47(p<0.001, C=0.72)]. Both response criteria showed comparable results at 6 and 12 months after treatment initiation.

Conclusions: Both Palladini and Kastritis renal staging systems predict renal survival well. Renal progression and response assessed using serum creatinine and 24 hour urine protein appear to have little prognostic value earlier than 6 months.

Distribution of Patients by Different Staging Systems

	Palladini Stage System	Kastritis Staging System
Stage I	171 (34.5%)	89 (18%)
Stage II	257 (52%)	221 (45%)
Stage III	67 (13.5%)	185 (37%)

FR-PO1086

Renal Outcome and Prognosis Analysis of Light Chain Amyloidosis and Renal Involvement

Zixuan Zhu,[1] Xuemei Li,[1] Ming-Xi Li.[2] *[1]Peking Union Medical College Hospital, Beijing, China; [2]Peking Union Medical College Hospital (PUMCH), BEIJING, China.*

Background: Light-chain (AL) amyloidosis is the most common and serious type of systemic amyloidosis. Most studies only focused on the overall survival of AL amyloidosis. Renal involvement is one of the most common complications of the disease which can lead to end-stage renal disease (ESRD). Our study compared clinical features of the amyloidosis cohort in multiple aspects, and emphasized on renal outcomes. And we also aimed to validate two staging system for renal involvement in Asian populations firstly.

Methods: Patients with newly diagnosed AL amyloidosis and kidney involvement which was proved by renal biopsy in Beijing Union Medical College Hospital from January 1, 2002 to December 31, 2017 were included. Demographic characteristics and clinical features were summarized. Cases diagnosed after 2011 were followed up. A comparative analysis of the baseline condition and prognosis was made between primary and secondary amyloidosis, κ and λtype. Two renal staging system were proposed in 2014 and 2017, based on proteinuria (24hUP>5g/d) and eGFR (<50ml/min/1.73m²) or 24hUP/eGFR at diagnosis. Patients were divided into renal stage I-III and renal stage 1-3 respectively by two criteria. The baseline conditions and renal outcomes were analyzed and compared to evaluate the prognostic value of the two systems.

Results: A total of 76 cases were included. All cases had renal involvement. 44 cases were followed up. 49 cases (64.5%) showed nephrotic syndrome, and 28 cases (36.8%) showed renal insufficiency at the time of diagnosis. There was no significant difference in clinical features, organ involvement renal outcome and survival between κ and λ cases, primary AL amyloidosis and AL amyloidosis secondary to multiple myeloma(MM). The renal staging system based on 24hUP and eGFR were validated. There was a significant difference in renal outcome among renal stage I-III (p=0.003). Based on the 24hUP/eGFR system, there was no ESRD in both stage 1 and stage 2. A significant difference was seen between phase 3 and two other stages (p=0.008).

Conclusions: The clinical manifestations, renal outcome, and survival of AL amyloidosis are not affected by primary or secondary to MM, and different type of light chain. For the first time, the prognostic value of renal staging system based on 24hUP and eGFR was validated in Asian populations, which is of great significance in guiding clinical treatment.

FR-PO1087

Significant Reduction in Proteinuria After Treatment with Tafamidis

Asuncion Ferrer-Nadal,[1] Tomas Ripoll,[2] Mercedes Uson,[3] Antoni Figuerola,[4] Juan Buades.[5] TTRhA Spanish Group *[1]Nephrology, Hospital Son Llàtzer, Palma de Mallorca, Spain; [2]Cardiology, Hospital Son Llatzer, Palma de Mallorca, Spain; [3]Neurology, Hospital Son Llatzer, Palma de Mallorca, Spain; [4]Neurology, Hospital Son Llatzer, Palma de Mallorca, Spain; [5]Internal Medicine, Hospital Son Llatzer, Palma de Mallorca, Spain.*

Introduction: Hereditary Transthyretin Amyloidosis (hATTR) in Mallorca represents the fifth world focus. Tafamidis (Vyndaqel, Pfizer) has been used since 2011 with promising expectations. It promotes stabilization of the TTR tetramer and slow tissue deposition. Consequently, it contributes to change the course of disease, slowing the presentation of clinical manifestations. The Portuguese group presented few cases with small reduction in proteinuria last year. We present now an interesting case of a significant decrease in heavy proteinuria.

Case Description: We display the first case presented (to our knowledge) with great proteinuria reduction from nephrotic range to mild range. This is a well documented female case of late onset Val30Met. Amyloid deposits were confirmed by positive congo red stain in a skin biopsy. Patient came into the outpatient consultation due to cardiology manifestations. Patient was studied in depth, and then neurologic, intestinal and nephrologic impairment was also found. Nephrotic range proteinuria of 4,2 g in 24h with kidney dysfunction were present. We also found an unusual dissociation among glomerular filtration rate formulas (urine and blood results). Therefore, we performed a 51Cr-EDTA renal function, and also conducted a dynamic study with 99mTc-MAG3 scintigraphy. 6 months after taking tafamidis, proteinuria was reduced to 1,6 g in 24h.

Discussion: This finding may be very promising for the future to slow the natural course of proteinuric kidney TTR amyloidosis disease. It will permit to avoid or slow progression to end-stage renal disease and renal replacement therapy.

Masked Hypertensive Disorders Are Prevalent in Active Lupus Nephritis Patients

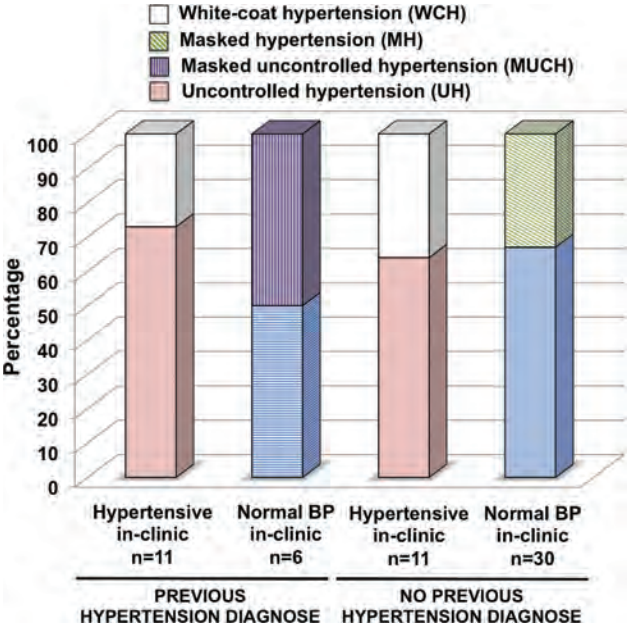
Mariedel Trujeque, Yesser J. López hernández, Jesus I. Santander, Luis E. Morales-Buenrostro, Juan M. Mejia-Vilet. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico.*

Background: SLE patients have an increased cardiovascular mortality. In CKD, 24h-ABPM studies demonstrate a high-prevalence of masked hypertensive disorders.

Methods: From March 2016 to April 2018, 58 active lupus nephritis patients were evaluated by 24h-BP monitoring the day of the renal biopsy procedure. Two validated oscillometric-based devices were used (Spacelabs 91207 and Welch Allyn 6100). A registry was considered appropriate if >20 daytime and >7 nighttime measurements were available. For analysis, patients were divided into those with or without previous hypertension.

Results: Out of 58 LN patients, 17 (29%) had a previous hypertension dx. These patients were older, had higher in-clinic BP and their renal biopsy showed higher interstitial fibrosis/tubular atrophy. In the 24h-BPM, patients with previous HT had higher overall, daytime and nocturnal BP. However, the nocturnal decrease of BP was diminished and not different between groups. Only 11 (19%) patients had normal dipping, in 30 (52%) it was decreased, and in 17 (29%) was absent. White-coat hypertension (WCH) was found in 3/11 (27%) in-clinic HT and masked uncontrolled hypertension in 3/6 (50%) of in-clinic controlled patients. In the non-previous HT group, WCH was found in 4/11 (36%) of in-office HT patients and masked hypertension in 12/30 (40%) of in-office controlled patients. The nighttime systolic and diastolic BP were more frequently abnormal compared to daytime measurements.

Conclusions: Masked hypertensive disorders are frequent in lupus nephritis patients. As BP thresholds are part of an appropriate management of proteinuric diseases, 24h blood pressure measurements should be considered in clinical practice. These studies were made as inpatients and should be corroborated with ambulatory measurements.



FR-PO1089

Urinary Soluble CD163 as a Biomarker for Lupus Nephritis

Junya Suwa,[1] Hidekazu Ikeuchi,[1] Hiroshi Kajiyama,[3] Hiroko Hamatani,[1] Masao Nakasatomi,[1] Yoriaki Kaneko,[1] Toru Sakairi,[1] Yoshihisa Nojima,[2] Keiju Hiromura,[1] Toshihide Mimura.[3] *[1]Gunma University Graduate School of Medicine, Maebashi, Japan; [2]Japan Red Cross Maebashi Hospital, Maebashi, Japan; [3]Saitama Medical University, Saitama, Japan.*

Background: Recently, it has been reported that urinary soluble CD163 (UsCD163) reflects glomerular inflammation of ANCA-associated nephritis and lupus nephritis (LN). We examined the significance of UsCD163 as a biomarker for histological activity and treatment response of LN.

Methods: We investigated the levels of UsCD163 before and after treatment in 52 LN patients (49 females, median age 37 years old) who were diagnosed as ISN/RPS Class III, IV or V and treated for LN since 2010 to 2015 in Gunma University and Saitama Medical University hospitals by ELISA. We also examined whether UsCD163 could be a predictor of remission of LN.

Results: RESULTS: Levels of UsCD163/creatine (Cr) were higher in Cass IV and Class V compared to Class III: III, 2.55 (1.40-5.55); IV, 8.84 (3.05-19.1); V, 8.10 (7.14-10.3) ng/mgCr;, median, (IQR). Significant correlations were observed between levels of UsCD163/Cr and urinary protein/Cr or systemic lupus erythematosus disease activity index (SLEDAI) score, but not eGFR (r=0.421, p=0.0026; r=0.465, p<0.001; r=-0.212, p=0.143). Associations between UsCD163/Cr and histological parameters were shown in Table 1. Significant positive correlations were found between levels of UsCD163/Cr and activity index, leukocyte infiltration or cellular crescents. UsCD163/Cr levels rapidly decreased after treatments. Receiver operating characteristic analysis showed UsCD 163/Cr >17.3 ng/mgCr before treatment was predictor of the presence of cellular crescent (sensitivity 85%, specificity 44%). UsCD163/Cr <3.0 ng/mgCr before treatment was a predictive marker for early proteinuria remission defined as urine protein/Cr <0.3 g/gCr at 3 months after treatment (sensitivity 42%, specificity 92%, positive predictive value 92%, negative predictive value 69%).

Conclusions: UsCD163 could be a potential biomarker for histological activity and treatment response of LN.

A Composite Urinary Biomarkers to Predict Pathological Tubulointerstitial Lesions in Lupus Nephritis

Ying Tan,[1] Ying Ding,[2] Minghui Zhao.[3] *[1]Peking University first hospital, Beijing, China; [2]Pekin university international hospital, Beijing, China; [3]Reanl division, Peking University First Hospital, Beijing, China.*

Background: This study aims to evaluate the clinical value of urinary biomarkers including kidney injury molecule-1 (KIM-1), neutrophil gelatinase–associated lipocalin (NGAL) and monocyte chemoattractant protein 1 (MCP-1) in lupus nephritis.

Methods: A total of 109 biopsy-proven lupus nephritis patients were included, and 50 healthy individuals were collected as the normal controls. The urinary KIM-1, NGAL and MCP-1 levels were measured by ELISA, and the correlations of clinical and histological features with them were further assessed. Receiver operating characteristic curves were performed and cox regression model was applied to identify prognostic factors associated with renal outcomes.

Results: Active lupus nephritis patients exhibited elevated urinary levels of KIM-1, NGAL and MCP-1 in comparison with lupus nephritis patients in remission (P<0.001) and healthy controls (P<0.001). The urinary KIM-1 level was correlated with pathological tubular atrophy (r=0.208, P<0.05) and increased significantly in the presence of interstitial inflammatory lesions (P=0.031). The urinary KIM-1, NGAL and MCP-1 levels were higher in patients with active tubulo-interstitial lesions than those with only chronic lesions (P=0.015, P=0.230 and P=0.086, respectively). A combination of KIM-1, NGAL and MCP-1 was a good indicator for diagnosing active tubulo-interstitial lesions (AUC: 0.796). The combination of KIM-1 and NGAL was identified as an independent risk factor for renal outcomes (HR 7.572, P<0.05).

Conclusions: The urinary KIM-1, NGAL, MCP-1 levels were associated with kidney injury indices in lupus nephritis. The combination of the three biomarkers increased its power in predicting tubulo-interstitial lesions and renal outcomes.

Urine Epidermal Growth Factor Is a Biomarker of Tubulointerstitial Damage in Lupus Nephritis (LN)

John P. Shapiro,[1] Juan M. Mejia-Vilet,[2] Huijuan Song,[1] Daniel J. Birmingham,[1] Samir V. Parikh,[1] Brad H. Rovin.[1] for the CKD Biomarker Consortium *[1]Ohio State University Wexner Medical Center, Columbus, OH; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico.*

Background: An agnostic proteomic survey of urine from patients with LN showed significantly decreased levels of pro-epidermal growth factor (EGF) in patients who had developed chronic kidney disease (CKD). Urine (u)EGF has previously been shown to predict progressive CKD in several glomerular diseases. Therefore, we examined the association of uEGF with kidney biopsy findings and kidney function in patients with LN.

Methods: EGF was measured by specific ELISA in urine collected at the time of kidney biopsy in 23 Mexican and 29 Midwestern (45% African American, 45% Caucasian) LN patients, and was characterized by immunoblotting. uEGF was also measured in serial urine samples from patients with 1-5 years of longitudinal follow-up.

Results: Results: uEGF in 29 Midwestern LN patients at kidney biopsy was 11.7±10.1 ng/mg Cr compared to 26.5±13.7 ng/mg Cr in 8 lupus patients with no history of LN (p<0.05). Immunoblotting demonstrated uEGF was mainly high molecular weight (pro-EGF forms). uEGF correlated inversely with serum creatinine (SCr), biopsy chronicity index (CI), tubular atrophy and interstitial fibrosis (Table). There was no correlation with proteinuria, biopsy activity index (AI) or the histologic components of the AI (Table). Patients (n=7) with stable CKD showed low but steady levels of uEGF over 1-4 years of follow-up. Patients with progressive CKD (n=6) showed a decline in uEGF over 1-5 years. uEGF fell in patients with acute kidney injury (AKI, n=7), rebounded in 4 (57%) patients when AKI resolved but remained below baseline in 3 (43%) patients, who either did not recover AKI or recovered but later developed CKD.

Conclusions: uEGF is a biomarker of chronic tubulointerstitial damage in LN. Low and falling uEGF suggests progressive CKD. uEGF also decreases in AKI and may signal future CKD if levels do not improve.

Polyomavirus BK, BKV MicroRNA, and Urinary Neutrophil Gelatinase-Associated Lipocalin Can Be Used as Potential Biomarkers of Lupus Nephritis

Yi-Jung Li. Linkou Kidney Research Center *Nephrology, Kidney Research Center, Department of Nephrology, Linkou Chang-Gung Memorial Hospital, Taiwan, Tauyuan, Taiwan.*

Background: Lupus nephritis (LN) frequently progresses to end-stage renal disease. Finding a biomarker for LN and a predictor for the development of chronic kidney disease (CKD) is important for patients with systemic lupus erythematosus (SLE).

Methods: Ninety patients with SLE were divided into biopsy-proven LN (n = 54) and no kidney involvement (non-LN) (n = 36) groups and followed up for 54 months.

Results: Of 36 patients with LN, 3 (5.6%) had class II disease, 3 (5.6%) had class III, 35 (64.8%) had class IV, 10 (18.5%) had class V, and 3 (5.6 %) had class VI (advanced sclerosis). Compared to the non-LN group, patients in the LN group had higher autoimmunity evidenced by a higher proportion of low C3 and C4 levels, positive anti-double-stranded DNA antibody levels, and lower estimated glomerular filtration rates (eGFR). Urinary neutrophil gelatinase-associated lipocalin (uNGAL) levels were significantly higher in the LN group (LN vs non-LN, 670 vs 33 ng/mL, respectively). The patients with LN had a higher urinary polyomavirus BK (BKV) load (3.6 vs 3.0 log copies/mL) and a lower urinary BKV miRNA (miR-B1) 5p level (0.29 vs 0.55 log copies/mL, p = 0.025), while there was no significant difference in the level of miR-B1-3p. Urinary miR-B1-5p level but not urinary BKV load was negatively correlated with uNGAL level (r = -0.22, p = 0.004). At the cutoff value of 80 ng/mL, the receiver operating characteristic curve analysis showed that uNGAL level as a predictor of the presence of LN had a high sensitivity (98%) and specificity (100%) (area under the curve [AUC], 0.997; p < 0.001). During the 54-month follow-up period, 14 (7%) patients with LN and none of the non-LN patients developed CKD. Multivariate Cox regression analysis revealed that baseline uNGAL level was the only predictive factor for CKD development, while baseline serum creatinine level and eGFR were not.

Conclusions: An elevated urinary BKV viral load with a decreased level of miR-B1 implies the presence of LN. In addition, an increased uNGAL level is a good biomarker not only in predicting the presence of LN but also for prediction of CKD development in patients with SLE.

FR-PO1093

Glomerular Phospholipase A2 Receptor Antigen in Lupus Membranous Nephritis

Mayumi Nakata,[1] Tomo Suzuki,[1] Shiika Watanabe,[1] Daisuke Ichikawa,[1] Junki Koike,[2] Yugo Shibagaki.[1] *[1]St. Marianna University Hospital, Kawasaki, Japan; [2]Kawasaki Municipal Tama Hospital, Kawasaki, Japan.*

Background: Phospholipase A2 receptor (PLA2R) is the major pathogenetic antigen in idiopathic membranous nephropathy (iMN). Anti-PLA2R antibody is detected in approximately 70% with iMN and glomerular PLA2R expression by immunofluorescence and serum PLA2R antibody are often observed. Its prevalence and characteristics in lupus membranous nephritis remains to be undetermined.

Methods: We conducted a cross-sectional study at two-centers in Japan, including patients whose renal biopsies show ISN/RPS Class V lupus nephritis, between May 25, 2012 to March 31, 2018. We performed immunofluorescence analysis of frozen section for PLA2R expression using anti-PLA2R antibody. We evaluated the clinical and pathological features between positive-PLA2R group (PLA2R-P) and negative group (PLA2R-N) and checked the serum anti-PLA2R antibody only in PLA2R-P.

Results: We analyzed the glomerular expression of PLA2R Ag in 23 patients, as many as 5 patients had positive glomerular PLA2R antigen expression. As shown in the Table, we compared the characteristics between PLA2R-P and PLA2R-N. The age and the duration from the diagnosis of SLE to biopsy were higher in PLA2R-P, but not significantly. Although the difference in the levels of proteinuria was not significant, the level of serum total protein was significantly lower in PLA2R-P. The levels of C3 and C4, and the intensity of glomerular IgG1 deposition were significantly higher in PLA2R-P. On the other hand, serum anti-PLA2R antibody level are all normal in the PLA2R-P.

Conclusions: Significant proportion of class V lupus nephritis showed positive PLA2R in kidney specimen in spite of absence of circulating anti-PLA2R antibody. Cases with positive PLA2R had significantly lower serum total protein and higher complement levels. Higher complement and proteinuria level may indicate poor activity of lupus nephritis and more phenotypical similarity to iMN.

		Lupus class V (N = 23)		
		PLA2R-P	PLA2R-N	P value

APOL1 Risk Variants in Brazilians with Lupus Nephritis

Gisele Vajgel,[2,1] Suelen C. Lima,[1] Pamela J. Hicks,[6] Denise M. Costa,[2,3] Camila B. Oliveira,[2,3] Lucila Maria Valente,[2] Gianna Mastroianni-kirsztajn,[4] Barry I. Freedman,[6] Paula S. Sandrin-Garcia.[1] *[1]Biomol Lab, LIKA/UFPE, Recife, Brazil; [2]Hospital Das Clinicas, Recife, Brazil; [3]IMIP, Recife, Brazil; [4]Nephrology, UNIFESP, Sao Paulo, Brazil; [6]Wake Forest Baptist Health, Winston Salem, NC.*

Background: APOL1 2 risk variants have been associated to collapsing glomerulopathy and end stage renal disease (ESRD) in lupus nephritis (LN) patients. The prevalence of APOL1 G1 and G2 variants in Brazilians is unknown. The present study aimed to analyze the frequency of APOL1 risk variants in a cohort of LN patients in 3 GN clinics in Brazil.

Methods: APOL1 G1 and G2 variants were genotyped in 173 patients who fulfilled SLEDAI criteria for lupus and LN class III, IV or V, randomly chosen in three outpatient clinics. DNA extraction from whole blood was performed using the PureGene system. Two single- nucleotide polymorphisms (SNPs) in the APOL1 G1 nephropathy risk variant (rs73885319; rs60910145) and an indel for the G2 risk variant (rs71785313) were genotyped using Taqman assays on the ViiA 7 platfom (Applied Biosystems for Life Tech). Clinical and lab data were analyzed using R studio.

Results: Patients data are summarized in table1. G1/G1 genotype was found in 3 non-white women (1.7%). They were 21, 29 and 51 years and had LN for 12, 120 and 47 months, respectively. All of them had LN class IV and received treatment with CF, MMF and steroids. Their outcomes in the last follow-up were ESRD in the youngest and CKD stage 4 in the others.

Conclusions: APOL1 risk variants are rare in Brazilians LN patients, however all patients who expressed 2 risk variants had worse outcomes (ESRD or CKD stage 4).

Table 1: Clinical characteristics and outcomes of 173 patients.

Mean age (SD), years	34.5(±11)
Female sex	90%
Non-White	77%
Mean BMI (SD)	25(±5)
Positive ANA	97%
Mean SLICC (SD)	6.8(±2)
Median LN age(25th-75th), mo	48(18-89)
LN Class III(+/-V)	26%
LN Class IV(+/-V)	54.3%
LN Class V	19.7%
Induction treatment: CF	69.5%
Maintenance treatment: MMF	86%
Partial or Complete response (last F/U)	66%
CKD, eGFR<60mL/min (last F/U)	22%
ESRD (last F/U)	8%

CF: Cyclophosphamide; MMF: Micophenolate Mophetil; F/U: follow-up.

What Is the Value of a Repeat Kidney Biopsy in Children and Young Adults with Lupus Nephritis?

Suhas M. Radhakrishna, Johanna Chang, Robert Sheets, Peter D. Yorgin. *UC San Diego/Rady Children's Hospital, San Diego, CA.*

Background: Adult lupus nephritis (LN) studies have shown a lack of correlation between follow-up kidney biopsy results and clinical parameters. This study investigated whether kidney biopsy findings in children and young adults with LN performed after induction and maintenance therapy would better determine the response to medical therapy than clinical parameters.

Methods: 64 subjects, 11-18 yrs of age, met 1997 revised ACR classification criteria for systemic lupus erythematosus (SLE) with biopsy proven LN at Rady Children's Hospital in San Diego between 1/1/2005 - 1/1/15. 12 subjects had a repeat biopsy 1 yr after diagnosis and 14 additional subjects had a repeat biopsy within 5 yrs of diagnosis. ACR criteria for complete remission (CR), partial remission (PR) and no remission (NR) were assessed at the time of repeat biopsy. Correlation between clinical remission status and biopsy findings was investigated. The study had IRB approval (#161748X, 6/30/17).

Results: At the time of repeat biopsy, 6 of 26 subjects achieved CR, 3 subjects achieved PR and 17 subjects had NR. Changes in IgG deposition, activity, and chronicity were statistically significant between the CR and NR groups. However, within CR and NR groups there were unexpected results: Among the 6 subjects achieving CR, 4 had the same or worse WHO class, 1 had higher activity and 3 had higher chronicity scores at the time of repeat biopsy. Among the 17 NR subjects, 5 had better or stable WHO classification. Furthermore, repeat kidney biopsies led to significant changes in therapy in both CR and NR groups.

Conclusions: In general, there was poor concordance between ACR remission criteria and repeat biopsy findings in children who achieved CR and NR, with notable exceptions. The discrepancy between clinical findings and kidney biopsy results in such cases should be further investigated. The large number of NR patients likely reflects bias toward repeat biopsy in clinical non-responders.

Lupus Nephritis IV-S versus IV-G: Different Characteristics and Renal Outcomes

Camila B. Oliveira, Gisele Vajgel, Denise M. Costa, Maria Alina G. Cavalcante, Lucila Maria Valente. *Hospital das Clinicas - UFPE, Recife(PE) BRAZIL, Brazil.*

Background: The ISN/RPS classification of lupus nephritis (LN) divided class IV into segmental and global (IV-S and IV-G), based on evidence suggesting different characteristics and renal outcomes. However, others subsequent studies failed to detect these differences. The aim of this study was to compare characteristics and renal outcomes of classes IV-S and IV-G.

Methods: Retrospective cohort of adult patients with lupus and biopsy proven class IV according to ISN/RPS classification. Clinicopathological characteristics and long-term follow-up were analyzed. Primary end point was ESRD.

Results: Clinicopathological data and renal outcomes of 89 patients with LN class IV are shown in Table 1. There was no difference in tubular atrophy and interstitial fibrosis between classes. Compared to patients with class IV-S, patients with class IV-G had a risk 2.8 times greater of doubling sCr (95%CI 1.4-6.7; p=0.001) and 3.9 times greater of ESRD (95%CI 1.4-5.6; p=0.006).

Conclusions: Patients with class IV-G had more severe clinicopathological presentation and worse renal outcomes compared to patients with class IV-S.

Activation of the Alternative Complement Pathway Predicts Renal Outcome in Patients with Lupus Nephritis

Hyunwoo Kim, Jinseok Kim. *Jeju National University Hospital, Jeju City, Republic of Korea*.

Background: The aim of this study was to clarify the glomerular activation of complement pathways in patients with lupus nephritis, and to elucidate the association between these complement activation types and clinical outcomes.

Methods: We enrolled 100 patients with biopsy-proven lupus nephritis from 2003 to 2016 from the lupus cohort at the Busan Paik Hospital and the Jeju National University Hospital in Korea. The patients were divided into two groups based on the patterns of glomerular complements deposits: The presence of C4 and C1q deposits with C3 deposits in the glomerulus was considered to be the evidence for the activation of the classical pathway (group I, n=83) and glomerular C3 deposition without C4 and C1q deposits was considered as a marker for the activation of the alternative pathway (group II, n=17). The study endpoint was progression of kidney dysfunction defined as the decline rate of estimated glomerular filtration rate (GFR) of more than 1 ml/min/1.73 m^2 per year.

Results: The mean age of the patients was 32.9 ± 10.7 years. Ten patients were male, 34 patients were hypertensive, 24 patients had a GFR < 60 ml/min/1.73 m^2, and 38 patients had nephrotic range of proteinuria at the time of kidney biopsy. Compared to the group I patients, those in group II were older (31.1 ± 10.1 vs. 41.5 ± 9.5 years, p <0.001), more hypertensive (29% vs. 59%, p=0.020), and more male dominant (6% vs. 29%, p=0.003). Considering histopathologic features, group I patients had higher glomerular deposition of IgG and IgA than those in group II. Endocapillary hypercellularity and fibrinoid necrosis were also more frequently found in group I patients compared with those in group II. The median follow-up time was 4.3 years (interquartile range: 2.6–7.6 years). The rate of decline in estimated GFR was greater in group II patients than in group I patients (-5.7 ml/min/1.73 m^2 per year vs. 1.4 ml/min/1.73 m^2 per year; p=0.034).

Conclusions: This study showed that the patients with the alternative complement activation had poor renal outcome compared to the patients with the classical complement pathway, suggesting that the alternative complement activation may play a pathogenic role in the progression of lupus nephritis.

FR-PO1098

The Clinical Indicators to Predict Active Lesion in Kidney Biopsy Specimen in Patients with Lupus Nephritis

Daisuke Ichikawa,[1] Eri Okada,[3] Tomo Suzuki,[1] Shiika Watanabe,[1] Junki Koike,[4] Yugo Shibagaki.[2] *[1]St Marianna University of Medical School, Yokohama City, Japan; [2]St Marianna University Hospital, Kawasaki, Japan; [3]St. Marianna University School of Medicine, Kawasaki, Japan; [4]the Kawasaki Municipal Tama Hospital, Kawasaki Citiy Tama Ward, Japan*.

Background: The histological activity of International Society of Nephrology/Renal Pathology Society (ISN/RPS) class IIIa or IVa lupus nephritis affect physician's decision making in treatment. Because renal biopsy has inevitable risk for bleeding, it is preferable that we can make decision only with clinical parameters. However, few studies have addressed this important issue so far.

Methods: We reviewed the renal biopsy specimen of 120 patients with SLE retrospectively. We analyzed whether and which laboratory findings are correlated with histological activity.

Results: The histologically active lesion of lupus nephritis was found in 73.3% of all the patients, in 50% of the patients with the group of no hematuria, and in 70.8% of the patients with intermittent hematuria. Hematuria significantly correlated with histological activity with a sensitivity of 86.4% and a specificity of 37.5%, and significant proteinuria [≧0.5 g/gram creatinine (gCr)] significantly correlated with histological activity with a sensitivity of 84.1% and a specificity of 34.4%. If combining hematuria and proteinuria, the sensitivity for histological active lesion increased to 96.6%. Low serum C3 (< 65 mg/dl) significantly correlated with renal disease activity with a sensitivity of 79.1%, and high serum anti-DNA antibody (≧10 IU/ml) significantly correlated with histological activity with a sensitivity of 91.4%. Existence of at least one of these clinical indicators (hematuria, proteinuria, high anti-DNA antibody and low C3) showed 100% sensitivity for histological activity. Those with high specificity were persistent hematuria (specificity 71.5%), anti-DNA antibody≧40 IU / ml (specificity 73.1%), and existence of all 4 of the clinical indicators (specificity 81.3%).

Conclusions: Isolated or intermittent hematuria did not predict histological activity so well. In order to avoid overlooking active lupus nephritis without kidney biopsy, we should count not only hematuria but also significant proteinuria, low C3 and high anti-DNA antibody. If the renal biopsy is not possible, but we still suspect activity such as in cases with progressive decline in kidney function, persistent hematuria, anti-DNA antibody≧40 IU/ml and presence of all 4 of clinical indicators strongly suggest disease activity and may help us make decision for active treatment.

FR-PO1099

Lupus Nephritis (LN) Patients with Crescentic Proliferative Lesions Show Lower IgG Glomerular Staining

André L. Moraes,[1] Marcela T. Aguirre,[3] Lectícia Jorge,[2] Cristiane B. Dias,[4] Viktoria Woronik.[1] Nephrology Division *[1]Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil; [2]University of São Paulo, São Paulo, Brazil; [3]Hospital das Clinicas FM USP Sao Paulo, CUENCA, Ecuador; [4]University of Sao Paulo, Brazil, São Paulo, Brazil*.

Background: Literature is scarce in describing outcomes and histological associations of LN patients with crescents. The immunofluorescence findings may suggest the pathophysiology of lesions and therefore have implications in the clinical behavior of LN. Our objective was to evaluate renal outcome and histological associations of patients with proliferative LN with and without crescents.

Methods: In this single-center, retrospective cohort study, 138 eligible LN patients were evaluated. The clinical features at baseline and at the end of follow-up were evaluated. eGFR was calculated using CKD-EPI equation. Kidney biopsies were classified according to the ISN/RPS Classification and immunofluorescence patterns. We performed comparative analyses between groups with different proportions and without crescentic lesions in kidney biopsy. Univariate analysis utilized Chi Squared test (n,%) for count and one-way analysis of variance, followed by Student- Newman Keuls tests for continuous variables.

Results: As shown in the image below.

Conclusions: Patients with crescentic (≥50% crescents) form showed at baseline, lower CKD-EPI (p<0.05), higher activity index (p<0.05) and lower intensity of IgG staining (p<0.05) than patients with no crescents on biopsy. The groups presented no difference in clinical outcomes, however, at the end of follow-up, the crescentic group presented a trend towards a higher proportion of individuals with CKD-EPI under 60ml/min/1.73m2.

Evaluation of the Full-House Immunofluorescence Pattern (FH) in Patients Without Systemic Lupus Erythematosus (SLE): A Single Centre Observation Study

Pinelopi Kouki,[1] Aikaterini A. Damianaki,[1] Aglaia Chalkia,[1] Panagiota E. Giannou,[1] Harikleia Gakiopoulou,[2] Dimitrios Vassilopoulos,[3] Dimitrios I. Petras.[1] *[1]Nephrology Department, Hippokration Hospital of Arhens, Athens, Greece; [2]University of Athens, Athens, Greece; [3]National and Kapodistrian University of Athens School of Medicine, ATHENS, Greece.*

Background: Strong interest is shown recently for FH pattern in patients without SLE nephritis. The purpose of the study is to identify patients with the above-mentioned entity and to evaluate clinical-laboratory findings and outcomes.

Methods: It consists of 8 patients with a FH pattern, defined as concomitant deposition of immunoglobulins (IgA, IgM, IgG) and two complement factors (C3, C1), non-diagnosed SLE who have undergone kidney biopsy over 4 years. Existing biopsies were reassessed by a nephropathologist and categorized according to the international histological classification of SLE. Anthropometry, eGFR, proteinuria, clinical course and histological findings were recorded.

Results: Two groups, idiopathic FH-non-lupus-nephropathy (iFHN) (n = 4) were identified based on the absence of histological findings defining specific glomerulonephritis(GN) (e.g. absence of PLA2R-antigen expression etc.) and secondary FH-non-lupus-nephropathy (sFHN) (n = 4) (e.g., expression of PLA2R-antigen, IgA +++, etc.). Patients with iFHN exhibit higher proteinuria (mean 9.45g / 24h), low eGFR (mean 28.8 ml / min / 1.73m2), significant consumption of C1q, C3, significant glomerulosclerosis and interstitial inflammation. The most common light microscopy pattern was membranoproliferative GN and response to personalized treatment was unsatisfactory. Patients with sFHN exhibit lower proteinuria (mean 7.32 g / 24 h), high eGFR (mean 81.1 ml / min / 1.73 m 2), mild deposition of C1q, C3, mild glomerulosclerosis and interstitial inflammation. The prominent light microscopy pattern was membranous nephropathy and response to treatment was satisfactory.

Conclusions: IFHN may reflect a clinicopathological entity with aggravating features and an unfavorable prognosis. Further studies are needed in order to corroborate that conclusion and to establish better approach to the treatment.

FR-PO1101

Chronic Changes in Lupus Nephritis Biopsies – When to Treat? Could Complement C3c Be an Indicator for Missed Activity?

Hannah R. Wilson, Tabitha Turner-Stokes, Iara Dasilva Santos, Megan Griffith, Jeremy B. Levy, Tom Cairns, H. Terence Cook, Liz Lightstone. *Imperial College London, Hammersmith Hospital, London, United Kingdom.*

Background: Management of biopsies showing chronic disease only is a common clinical conundrum in lupus nephritis (LN), especially when the biopsy is performed due to clinical features indicating activity. We have recently demonstrated that complement C3c staining is an indicator of current activity of the complement pathway in LN. We analysed characteristics that prompted treatment of patients with biopsies showing LN class III/IV(C) only from our LN cohort & reviewed whether positive C3c staining is a surrogate for disease activity.

Methods: Demographic, clinical, histopathological & outcome data were reviewed for renal biopsies showing III/IV(C) LN between 1/1/1996 & 1/1/2016. Treated patients were compared with untreated patients. C3c positive & C3c negative biopsies were then compared.

Results: 129 biopsies were performed over the 20 years which showed III/IV(C) disease only. 53% of these patients had escalation of their treatment post biopsy. 31 of the patients with a "chronic" biopsy had a subsequent biopsy available for review.

Conclusions: Deciding to treat patients with only chronic changes on biopsy was significantly associated with indication for biopsy, positive C3c staining, presence of subendothelial deposits & eGFR at the time of biopsy. However, our analysis thus far does not show a benefit of treating these patients as uPCR is actually higher in treated patients at 1 year although improved from baseline & eGFR, better at baseline in the treated group, actually falls. The repeat biopsies may suggest that not treating those with C3 positivity may lead to progressive scarring.

Baseline Variables	Treated	Untreated	p value
Indication for biopsy:

Comparison of Treatment Eras in a Large Cohort of Lupus Nephritis: Maintenance of Long Term Outcomes with Significantly Lower Burden of Immunosuppression and Corticosteroid Use

Hannah R. Wilson,[2] Tabitha Turner-Stokes,[2] Iara Dasilva Santos,[1,2] Megan Griffith,[2] Jeremy B. Levy,[2] Tom Cairns,[2] H. Terence Cook,[2] Liz Lightstone.[2] *[1]Fundacio Puigvert, BARCELONA, Spain; [2]Imperial College London, Hammersmith Hospital, London, United Kingdom.*

Background: Lupus Nephritis (LN) is a common & severe manifestation of systemic lupus erythematosus (SLE) requiring long courses of immunosuppression. Our lupus centre was established when 2 renal units merged in late 2005 & new protocols were developed focused on reducing the use of corticosteroids & increasing the use CD20+ B cell depletion therapy. We reviewed our large multi-ethnic cohort to assess the impact of these changes.

Methods: Demographic, clinical, histopathological & outcome data were reviewed for all patients with renal biopsies showing LN from 1/1/1996 to 1/1/2016. Patients treated 1996-2005 & 2006 onwards were compared. Data analysed per patient or per biopsy as appropriate.

Results: 819 biopsies (151 pre 2006, 668 post 2006) were performed on 476 patients over the 20 years. 172 patients were diagnosed with LN pre 2006 & 302 post. Whilst there was no significant difference in patient gender or ethnicity between the eras, age at diagnosis was significantly different with a mean of 32 pre 2006 & 37 post 2006 ($p<0.001$). The baseline eGFR, urine protein creatinine ratio & dsDNA titres were not significantly different between the eras.

Conclusions: Treatment regimens have altered significantly post 2006 with a much greater use of anti CD20 therapy & a significant reduction in (high dose) CyP & prednisolone exposure for patients. Despite the significant reduction in the burden of immunosuppression, rates of response to treatment, flare & 10 year survival with preserved renal function have been maintained.

Baseline variables	1996-2005	Post 2006	p value
• Antiphospholipid positive	37%	22%	0.002
• Antinuclear antibody positive	89%	91%	ns
• Anti-Sm antibody positive	14%	38%	<0.001
• dsDNA positive	78%	77%	ns
• Complement low	85%	81%	ns
• Proportion of biopsies class III or IV +/- V	68%	62%	ns
• Proportion of biopsies pure class V	21%	27%	ns
Treatment			<0.001
• Anti CD20 therapy (+ MMF/Aza/Tac +/- Pred)	8%	68%	
• Cyclophosphamide ((Cy)Pge/orally NIH protocol)	37%	11%	
• Anti CD20 therapy + CyP (Euenlupus doses)	2%	11%	
• Oral (MMF/Aza/Tac +/- Pred)	53%	11%	
• Hydroxychloroquine use	51%	77%	<0.001
• Oral prednisolone use	86%	51%	<0.001
Outcomes			
• Complete response to treatment	41%	48%	ns
• Flare	32%	39%	ns
• Extra-renal features SLE	64%	76%	0.015
• 10 year survival with eGFR >60ml/min/1.73m²	76%	69%	ns

FR-PO1103

Characteristics Associated with Repeat Native Renal Biopsy in Lupus Nephritis

Harpreet K. Singh,[1] Susan L. Hogan,[3] Caroline J. Poulton,[4] Yichun Hu,[5] Patrick H. Nachman.[2] *[1]University of North Carolina, Chapel Hill, NC; [2]University of Minnesota, Minneapolis, MN; [3]University of North Carolina, Chapel Hill, Chapel Hill, NC; [4]UNC Kidney Center, Chapel Hill, NC; [5]UNC Kidney Center & Dividdions of Nephrology & Hypertension, Chapel Hill, NC.*

Background: There is great interest in using repeat kidney biopsies to determine the response to treatment and outcomes of patients with lupus nephritis (LN). Although some patients with lupus nephritis undergo a repeat kidney biopsy, the factors that lead to the decision to repeat a biopsy and how the repeat biopsy alters treatment are not well understood. We evaluated the timing and explored factors associated with repeat kidney biopsy.

Methods: We identified 42 patients ≥ 18 years old with biopsy proven LN who underwent a repeat native renal biopsy from 2010 to 2018. A retrospective review was performed focusing on the clinical and histopathologic characteristics associated with a repeat biopsy. Both the reference and repeat biopsies were evaluated via the ISN/RPS classification.

Results: Of the patients included, 37 (88%) were women, 30 (71%) were black. The median age at reference biopsy was 28.74 years (IQR: 22.41, 37.77) and 34.33 years (26.70, 43.58) at repeat biopsy. The median interval time to repeat biopsy 2.96 (2.21, 7.83). The interval time between biopsies increased over the selected time period. The serum creatinine increased between reference and repeat biopsies (median 1.12 (0.1, 1.70) vs. median 1.38 (0.90, 2.54)). The results of the clinical and histological factors are addressed in the figure below.

Conclusions: Several factors were associated with the decision to repeat a native kidney biopsy in patients with lupus nephritis including time from reference biopsy, elevated serum creatinine, active urine sediment, hypoalbuminemia, and anti dsDNA positivity. The decision to repeat a biopsy was associated with a change in immunosuppression for the majority of our cohort. Looking ahead, we hope to use these clinical and histopathologic factors to establish and clarify how a repeat biopsy can lead to changes in management in our patients with lupus nephritis.

	Repeat biopsy
Albumin (g/dL)	N=36, median 2.9 (IQR 2.4, 3.3)
UPCR (g/g)	N=41, median 2.5 (1.5,6.5)
Low C3	20/38 (52)
Low C4	19/38 (50)
Positive Anti dsDNA	22/33 (67)
Active urine sediment	24/35 (69)

A Nationwide Analysis of Outcomes of Adult Lupus Nephritis in Japan

Keiju Hiromura,[1] Hidekazu Ikeuchi,[1] Hitoshi Sugiyama,[2] Hiroshi Sato,[3] Hitoshi Yokoyama,[4] Yoshihisa Nojima.[5] JSN Lupus Nephritis Study Group *[1]Gunma University Graduate School of Medicine, Maebashi, Japan; [2]Okayama University Graduate School Medicine, Okayama, Japan; [3]Tohoku University Graduate School of Pharmaceutical Sciences, Sendai, Japan; [4]Kanazawa Medical University, Ishikawa, Japan; [5]Japan Red Cross Maebashi Hospital, Maebashi, Japan.*

Background: Although the prognosis of lupus nephritis (LN) has been improved, some patients reached end-stage renal disease (ESRD). We aimed to examine recent prognosis of LN in Japan using nation-wide registry.

Methods: This study is a retrospective cohort study. Adult patients (18 years old or older) who were registered as LN in Japan Renal Biopsy Registry (J-RBR) between 2007 and 2012 were examined. Primary endpoint was defined as doubling serum creatinine (S-Cr) or ESRD requiring renal replacement therapy. Data were expressed as median (IQR).

Results: 498 patients (88 male), age 39 (30-52) years-old, from 27 institutions were evaluated. New-onset of LN, 348 patients; relapse, 106 patients; refractory, 35 patients; others, 9 patients. Clinical data at the renal biopsy were as follows: eGFR 78.3 (56.3-100.8) ml/min/1.73m^2, urinary protein 2.04 (0.87-4.30) g/gCr. 40.0% of patients had nephrotic syndrome and 12.2% of patients showed rapidly progressive glomerulonephritis clinically. The frequency of each ISN/RPS Class was as follows: I, 1.6%; II, 5.8%; III, 26.9%; IV, 46.6%; V, 18.5%; VI, 0.6%. During the observation period of 63 (49-82) months, 36 patients (7.2%) reached primary endpoints, 75 patients (15.1%) reached 1.5 times increase in S-Cr or ESRD, and 27 patients (5.4%) died. Renal survival (not doubling S-Cr or ESRD) curve in each Class was calculated by Kaplan-Meier analysis and shown in Figure 1. The 5-year renal survival and 5-year patient survival was 94.0% and 94.8% in total patients, and 92.1% and 93.1% even in Class IV, respectively. Among patients with new-onset LN (n=348), the 5-year renal survival and 5-year patient survival was 94.8% and 94.2% in total patients, and 93.1% and 92.4% in Class IV, respectively.

Conclusions: Recent prognosis of LN are relatively good at least 5 years after renal biopsy in real-world clinical practice in Japan.

Funding: Government Support - Non-U.S.

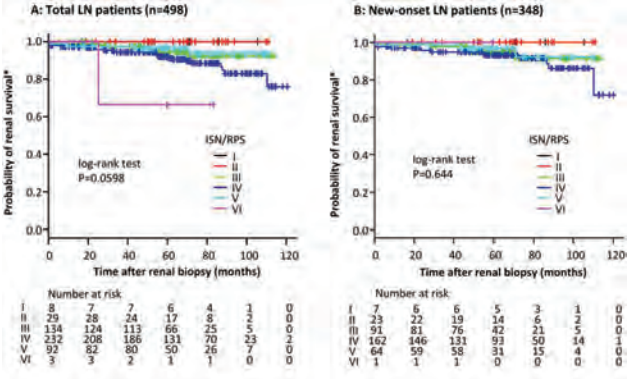

Figure 1. Kaplan-Meier Curve for renal survival by ISN/RPS classification.

* Renal survival was defined as not reaching doubling S-Cr or ESRD requiring renal replacement therapy.

FR-PO1105

A Proposal for Outcome Prediction in Lupus Nephritis Based on Bayesian Statistics

Juan M. Mejia-Vilet, Luis Tamez Pedroza, Sonia Rodriguez, Ricardo Correa-Rotter, Luis E. Morales-Buenrostro. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico.*

Background: A focus in lupus nephritis (LN) is to define the best criteria for response to therapy based on hard renal outcomes. The definition of resistant disease remains heterogeneous.

Methods: The aim of the study was to determine the prognostic value of clinical parameters to predict renal survival and progression to ESRD. Clinical predictors were evaluated at 6/12 months after treatment as absolute values, absolute or percentage changes and predictor's value normalization. The best cutoff was defined as the value where positive likelihood ratios (+LR) were persistently >3.0 for renal survival (response) or ESRD development (resistance).

Results: Of 248 patients with proteinuria >2.0g/g and complete induction treatment, we included 133 patients with >5 years follow-up. 36 (27.1%) progressed to ESRD. The best predictors for response were creatinine or eGFR at 6/12 months (AUC 0.798/0.856), proteinuria at 6/12 months (0.735/0.832) and hemoglobin at 6/12 months (AUC 0.689/ AUC 0.786). Predictors for resistance after 6 months of treatment included creatinine or eGFR (AUC 0.815), proteinuria percentage change (0.735), and albumin percentage change (AUC 0.599). Hematuria and serological parameters (dsDNA-antibodies, C3, C4) were not appropriate prognostic predictors. After censoring at different times of follow-up, it was observed that the longer the follow-up, the cutoff for each parameter had a lower valule. The best prognosis for renal survival was given by 12-month proteinuria <0.75g/g (+LR=3.08),

eGFR>82ml/min (+LR=3.00) and hemoglobin>12g/dl (+LR=3.04). The best predictors for resistance were 6-month eGFR<61ml/min (+LR=3.13), proteinuria decrease <10% (+LR=3.29) and increase of serum albumin <0.3g/dl (+LR=3.39).

Conclusions: Likelihood ratios may be used to define the best values for response and resistance to therapy in LN. Proteinuria, renal function and hemoglobin at 12-months predict renal survival while proteinuria, eGFR and change in serum albumin may define resistant disease.

	Baseline	6-month	12-month
Resistance	NA	>4.4g/g	>0.75g/g
Response	NA	<1.2g/g	<0.75g/g

	Baseline	6-month	12-month
Resistance	<32ml/min	<61ml/min	<82ml/min
Response	>64ml/min	>74ml/min	>82ml/min

FR-PO1106

The Risk of ESRD in Systemic Lupus Erythematosus: A Nationwide Population-Based Study in Korea

Hong sang Choi, Chang Seong Kim, Eun Hui Bae, Seong Kwon Ma, Soo Wan Kim. *Chonnam National University Medical School, Gwangju, Republic of Korea.*

Background: SLE is known to be one of the leading cause of end-stage renal disease (ESRD). The aim of this study was to estimate the incidence rate of ESRD and the risk factors for progression to ESRD in SLE patients compared to general population.

Methods: 21,253 SLE patients (mean age, 41.91±13.22 years; female, 90.4%) were extracted from the Korean National Health Insurance Service database between 2008 and 2014. Age-and sex-matched controls (n=106,265) were randomly sampled in a 5:1 ratio from non-SLE individuals. Both cohorts were followed up for incident ESRD until 2015.

Results: During the total 8 years of follow-up, 145 (0.14%) cases of ESRD was newly developed in SLE patients and 533 (2.51%) cases in matched controls (incidence: 4.075 and 0.219 per 1000 person-year, respectively). SLE patients were at higher risk for ESRD development compared to matched controls (odd ratio (OR), 10.134; 95% confidence interval (CI) 8.368-12.343) after multivariate adjustment. In subgroup analysis, the risk for ESRD was higher in male with SLE (OR, 7.952; 95% CI 5.26-12.272), in female with SLE (OR, 10.82; 95% CI 8.719-13.526), in 20-39 year-old patients with SLE (OR, 22.57; 95% CI 14.588-36.449), in 40-64 year-old patients with SLE (OR, 22.57; 95% CI 14.588-36.449), in elder than 65 year-old patients with SLE (OR, 5.122; 95% CI 3.431-7.649) than matched control, respectively.

Conclusions: SLE was associated with an increasing incidence of ESRD

FR-PO1107

Outcomes of Pure Membranous Lupus Nephritis in an Urban Predominantly African-American Patient Population

Jeffy Kenny Thomas,[1] Muhannad Alqudsi,[1] Furheen Baig,[1] Courtney E. Hoge,[1] Sung S. Lim,[1] Jason Cobb.[2] Emory Nephrology *[1]Emory University, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA.*

Background: Treatment options for pure membranous (class V) lupus nephritis (LN) include prednisone, cyclophosphamide (CYC), calcineurin inhibitors (CNI), and mycophenolate mofetil (MMF). There is a paucity of data on the use of MMF; a pooled analysis from studies for the treatment of proliferative LN have compared MMF to CYC for the treatment of pure membranous LN. We are comparing the outcomes of pure membranous LN patients treated with MMF in comparison to other therapies in our urban predominantly African-American patient population.

Methods: Kidney biopsy log from 2010 – 2017, and a retrospective chart review was completed. We excluded any patients with proliferative disease (active or chronic). We analyzed data (t-test comparison) comparing LN class V patients treated with MMF in comparison to other therapies.

Results: There was 101 patients with pure membranous LN and 54 patients with sufficient follow-up data were included. Induction regimens: MMF (n=29) and (n=25) other therapies (6=CYC, 3=CNI, 12=prednisone alone, 3=azathioprine, 1=ARB alone). Racial demographics: 51=black race (94%), 1=Hispanic, 1=white, 1=native Hawaiian. 52 female patients. Average follow-up 3.5 years. MMF treated group: initial serum creatinine (Scr) - 0.85 mg/dL, initial serum albumin (Salb) 2.67 g/dL, and initial urine protein/creatinine ratio (UPC) of 4.14 mg/g. Other therapies group: initial Scr – 1.58 g/dL, initial Salb 2.53 g/dL, and initial UPC of 4.32 mg/g. MMF treated: final Scr – 0.89 mg/dL, final Salb 3.30 g/dL, and final UPC 1.39 mg/g. Other therapies: final Scr – 1.53 mg/dL, final Salb 3.55 g/dL, and final UPC of 0.70 mg/g. There was no difference in percent with abnormal C3, C4, or dsDNA. At baseline Scr was 1.58 mg/dL (other group) vs. 0.85 mg/dL (MMF group) p <.05, and at final Scr 1.53 mg/dL (other group) vs. 0.89 mg/dL (MMF) p =.08.

Conclusions: In our predominantly African-American patient population MMF is effective as other therapies for Class V LN. There was a significant difference in initial Scr between the MMF and other therapies group, and the difference remained throughout. There was a greater than 50% reduction in UPC in both groups. The study displayed a good prognosis in both groups at the end of treatment.

FR-PO1108

Progressive Improvement of Renal Survival over the Last Five Decades in 499 Italian Patients with Lupus Nephritis

Gabriella Moroni,[1] Francesca Raffiotta,[1] Augusto Vaglio,[4] Piergiorgio Messa,[1,2] Renato A. Sinico.[3] *[1]IRCCS Fondazione Ca Granda Ospedale Policlinico Milano, Milan, Italy; [2]Università degli Studi di Milano, Milan, Italy; [3]AO San Carlo Borromeo, Milano, Italy; [4]Parma University Hospital, Parma, Italy.*

Background: To examine the changes in lupus nephritis (LN) prognosis during the course of the last fifty years and to search for the prognostic factors associated with patient and renal outcomes.

Methods: Four hundred and ninety-nine patients (pts) (85.6% women) were included in the study; they were followed for a median period of 10.6 years (IQR 4-18). They were diagnosed from 1970 to 2016 and were subdivided into three periods (P) based on the year of LN diagnosis: P1 1970-1985: 106 pts; P2 1986-2001: 158 pts; P3 2002-2016: 235 pts.

Results: As Induction therapy, in each period, more than 2/3 of pts received methylprednisolone pulses, and more than 50% received cyclophosphamide. Azathioprine was given to 16% of pts in P1, 12% in P2, and 4% in P3, mycophenolate mofetil (MMF) in 3% of pts in P2 and in 34% in P3. For maintenance therapy, azathioprine and MMF were used respectively in P1 in 28% and in 1% of patients, in P2 in 39% and in 15%, and in P3 in 30 and in 54%. The CKD free survival at 10 and at 20 years was 75% and 66% in P1, 85.5% and 80.2% in P2 and 91.5% in P3 (p=0.0069). The ESRD free survival at 10 and at 20 years were respectively 87% and 80% in P1, 94% and 90% in P2 and 99% in P3 (p=0.0019). Patient survival at 10 and at 20 years were respectively: in P1 94% and 87%, in P2 98% and 94% and in P3 95%. At multivariate analysis, carried out in the entire cohort, among the characteristics at presentation, Log serum creatinine (RR 2.39 for any increase in Log serum creatinine), high activity (RR 1.06 for any unit increase in activity index) and chronicity index (RR 1.13 for any unit increase in chronicity index), arterial hypertension (RR4.16) and the absence of maintenance immunosuppressive therapy (RR 2.08) predicted CKD. The same features predicted ESRD with the addition of male gender (RR 3.34). Male gender (RR 2.88), older age (1.07 for any increase in one year of age) and Log serum creatinine (RR1.8) were independent predictors of death.

Conclusions: The progressive improvement in renal survival in our cohort is the result of a comprehensive approach, which includes a prompt diagnosis of renal involvement, treatment based on renal biopsy, and increased clinical experience in the management of LN complications.

FR-PO1109

The Short and Long Term Effect of Methylprednisolone Pulse Therapy for Lupus Nephritis Treated with Multi-target Therapy

Lan Lan, Xiabing Lang. *Zhejiang University, Hangzhou, China.*

Background: Muti-target therapy was applied to the severe lupus nephritis, especially the patients with severe proteinuria. Methylprednisolon pulse therapy was used in the initial phase of induction therapy in some patients. We conducted this study to assess the short and long term effect of methylprednisolon pulse therapy on the lupus nephritis patients treated with muti-target therapy.

Methods: It's a retrospective study from 2007-2016, 43 patients diagnosed as lupus nephritis received muti-target therapy in our center, including prednisone combined with MMF and tacrolimus. 19 patients received methylprednisolon pulse therapy in the initial phase of induction therapy, 24 patients only received prednisone combined with MMF and tacrolimus. The dose of methylprednisolon pulse therapy was intravenous injection 500mg*3 days, following prednisone dose was 0.8-1.0mg/kg. The dose of MMF was 1.0-1.5g/d, the initial dose of tacrolimus was 0.05 mg/kg/d, the target trough levels was 3 to 8 ng/mL for 24 weeks, and then reduced to 3 to 6 ng/mL. In the patients combined with acute renal injury (AKI), we accessed the short term outcome by the decrease of serum creatinine in 1 and 3 month. Long term outcome variables included mean remission rate, average remission time.

Results: There was a significant difference in the decrease of creatinine between the two groups in 1 month (P=0.04). However, there was no significant difference in 3 month. In the 12 months follow up, 16 of 19 patients in the methylprednisolon pulse therapy group (84.2%) experienced remission (either complete or partial), and 12 of 19 patients (63.1%) experienced complete remission. In the group only receive muti-target therapy, 20 of 24 (83.3%) patients experienced remission, and 13 of 24 patients (54.2%) experienced complete remission. There were no significant difference in remission rate and remission time between the two groups (p=0.93 p=0.87). We also did not found significant difference in the serum creatinine and UP/Cr in 3, 6, 12month.

Conclusions: Methylprednisolon pulse therapy seemed had no significant effect on the long-term prognosis of lupus nephritis treated with muti-target therapy, but maybe it had better effect on the recovery of AKI patients.

FR-PO1110

Mycophenolate Mofetil in Lupus Nephritis: Long Term Efficacy and Safety Outcomes

Hannah K. Beckwith,[1,2] Beatriz R. Cubillo,[1] Camilla Pillay,[1] Megan Griffith,[1] Jeremy B. Levy,[1] Tom Cairns,[1] Liz Lightstone.[1,2] *[1]Imperial College Lupus Centre, London, United Kingdom; [2]Imperial College London, Hammersmith Hospital, London, United Kingdom.*

Background: There is a lack of long-term (LT) efficacy and safety data for Mycophenolate mofetil (MMF) in the treatment of lupus nephritis (LN) [1]. We have used MMF since 1999 and undertook a retrospective case-note review of all patients whose treatment included MMF and at least 10 years follow-up (FU).

Methods: 96 patients with biopsy-proven LN who started MMF ≥10 years ago were identified for the study.

Results: 75 (78%) were female; 20 (21%) Black and 8 (8%) Asian. At diagnostic renal biopsy, median age was 35 years (IQR 26-45), serum creatinine (SCr) 90umol/l (IQR 73-140) and UPCR 318 mg/mmol (IQR 153-569). The median length of FU was 11.6 years (IQR 10.7-13.6). Median cumulative MMF exposure was 8.4 years (IQR 5.5-11.5). 17/96 (18%) reached ESRD (median 67 months, range 3-188) and 5/96 (5%) died during FU (median 124 months, IQR 86-129). The rates at 7 years FU (12/96 and 1/96) were not statistically different to those reported in the LT FU of the MAINTAIN trial (p= 0.55, p=0.08) [2]. Median duration of MMF was 5.4 years (IQR 2.0-7.2) in the patients who died. At our unit, treatment regimens changed during the time period reviewed, moving to induction with MMF +/- Rituximab, mostly without oral steroids. We found no difference in adverse events between the Cyclophosphamide and MMF regimens, and patients did equally well on either regimen (Table 1). Importantly, no significant difference in adverse events was seen with MMF exposure ≥10 years vs <10 years (p=0.91) (IQR 11.2-13.6 vs 3.8-7.6).

Conclusions: This is the largest study to report LT outcomes in patients receiving MMF and the first to report data over ten years. LT treatment with MMF appears to be safe and our data supports the use of non-CyP based regimens. The increase in number of patients with ESRD or who died after 7 years FU emphasises the importance of LT follow up data in these cohorts. **References** [1] Bertsias GK *et al. Ann Rheum Dis* 2012;**71:**1771-1782 [2] Tamirou F *et al. Ann Rheum Dis* 2016;**75**:526–531

Table 1: Cyclophosphamide (CyP) vs MMF induction regimens

	CyP induction (n=40)	MMF induction (n=56)	P Value *=sig

Mycophenolate Mofetil in the Treatment of Chinese Patients with Active Lupus Nephritis: A Systematic Review and Meta-Analysis

Minlin Zhou,[1] Hongxin Zhao,[2] Yuxian Zhu,[2] Xin Wang,[2] Haitao Zhang.[1] *[1]National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China; [2]Shanghai Roche Pharmaceuticals Ltd., Shanghai, China.*

Background: Mycophenolate mofetil (MMF) has been recommended as induction and maintenance therapy for lupus nephritis (LN). MMF has shown superiority over cyclophosphamide (CYC) in LN patients of Hispanic or mixed race. So far, there has been no comprehensive review of the efficacy and safety of MMF in the treatment of LN that focused on Chinese patients. Thus, the present study aims to investigate the efficacy and safety of MMF in the treatment of Chinese patients with LN.

Methods: The following databases were searched: PubMed and EMBASE (from January 1979–January 2018); and the Cochrane Collaboration, China National Knowledge Infrastructure, Wanfang, and SinoMed (in January 2018). The search strategies comprised: (mycophenolate mofetil AND (cyclophosphamide OR azathioprine)) AND (lupus nephritis OR lupus glomerulonephritis OR proliferative glomerulonephritis OR membranous glomerulonephritis OR systemic lupus erythematosus) in English and in Chinese. Two reviewers independently assessed each identified clinical trial. Meta-analysis was conducted by using RevMan5.3 software.

Results: A total of 12 eligible randomized controlled trials (RCTs; 5 English and 7 Chinese articles; total 557 patients) were included. Nine RCTs reported complete remission (CR). The complete remission rate was significantly higher in the MMF group (48.9%) than in the CYC group (37.4%) (relative risk [RR] 1.28; 95% confidence interval [CI]: 1.05, 1.55; p=0.01). There was no significant difference in the total remission rate between the two groups of induction therapy (TR [CR + partial remission]; RR 1.11; 95% CI: 0.97, 1.26; p=0.12). MMF versus CYC during induction therapy was associated with significantly lower risks of infection (RR 0.58; 95% CI: 0.41, 0.84; p=0.004), leukopenia (RR 0.26; 95% CI: 0.11, 0.66; p=0.004), alopecia (RR 0.12; 95% CI: 0.03, 0.43; p=0.001), and amenorrhea (RR 0.15; 95% CI: 0.04, 0.56; p=0.004). No significant difference in relapse rate was evident between the MMF and AZA groups (RR 1.15; 95% CI: 0.59, 2.26; p=0.68).

Conclusions: MMF for induction treatment of lupus nephritis in China is superior to CYC in complete remission and is safer.

Insights from Machine Learning Analysis of Collated Lupus Nephritis Trials

Liliana M. Gomez Mendez,[2,1] Jian Dai,[1] Jason Kutarnia,[3] Scott Howser,[7] Jay Schuren,[7] Dana Mcclintock,[5] Matthew Cascino,[6] Marco Prunotto.[4] *[1]Genentech, South San Francisco, CA; [2]University of California San Francisco, San Francisco, United States Minor Outlying Islands; [3]Mitre, Bedford, MA; [4]F. Hoffmann-La Roche Ltd., Basel, Switzerland; [5]Genentech, Inc, South San Francisco, CA; [6]Genentech, Inc., South San Francisco, CA; [7]DataRobot, Boston, MA.*

Background: Machine learning (ML) analyses are being increasingly used in diverse fields of medical research to identify parameters associated with disease progression and/or outcome. We tested this method for identifying variables associated with complete renal response (CRR) in lupus nephritis (LN).

Methods: Data collated from two clinical trials, LUNAR (NCT00282347)[1] and BELONG (NCT00626197)[2], compared the addition of rituximab[1] or ocrelizumab[2] vs. placebo in addition to background therapy for the treatment of LN. We deployed supervised ML method of symbolic regression using Eureqa® software to analyze variables for CRR in these studies. For patients with baseline creatinine >1, CRR was defined as urine protein/creatinine ratio (UPCR) <0.5 and creatinine <1 at 1 year. CRR for patients with baseline creatinine <1 was UPCR <0.5 and creatinine <125% of baseline at 1 year. Logistic regression was used to validate the association between identified variables and CRR found via ML analyses.

Results: We found that unbiased ML analysis identified variables known to be associated with CRR, such as baseline UPCR and eGFR. Furthermore, ML analysis identified other variables to be associated with CRR, including systolic blood pressure (BP) at baseline and Week 16, and positive anti-RNP antibody at baseline. Logistic regression determined that every 10 mmHg increment in systolic BP had an odds ratio (OR) of 0.84 (95% CI: 0.73, 0.96) for CRR at 1 year. At Week 16, every 10 mmHg increment in systolic BP had an OR of 0.82 (95% CI: 0.7, 0.95) for CRR at 1 year. Logistic regression showed an OR of 2.1 (95% CI: 1.3, 3.5) for CRR at 1 year with anti-RNP antibody positivity at baseline (n=182), adjusting for treatment received, baseline proteinuria, and eGFR.

Conclusions: In conclusion, ML algorithms can be successfully used in identifying variables associated with clinical response, especially in a complex and heterogeneous disease such as LN. These analyses highlighted systolic BP at baseline and Week 16, as well as baseline anti-RNP antibody positivity, to be associated with CRR. The association between anti-RNP antibody at baseline and CRR at 1 year warrants further investigation. 1. Rovin et al., *Arthritis Rheum* 2012; **64**, 1215-26. 2. FR-PO1113

Clinical Outcomes and Response to Anti-Thrombotic Treatment Among Patients with Concomitant Lupus Nephritis and Thrombotic Microangiopathy: A Multicentre Cohort Study

Savino Sciascia,[2] Roberta Fenoglio,[1] Dario Roccatello.[3] *[1]Hospital Hub San Giovanni, Turin, Italy; [2]Nephrology and Dialysis Unit and Center of Research of Immunopathology and Rare Diseases (CMID), Giovanni Bosco Hospital and University of Turin, Italy, Center of Research of Immunopathology and Rare Diseases (CMID), Division of Clinical Immunology, Giovanni Bosco Hospital and University of Turin, Ita, Turin, Italy; [3]Ospedale San GIovanni Bosco, Torino, Italy.*

Background: The renal vascular involvement is an important prognostic marker of lupus nephritis (LN). The thrombotic microangiopathy (TMA) presents with severe clinical manifestations and have a high mortality. However, the management of patients (pts) with TMA and LN needs further investigation. AIM: We sought to assess renal outcomes to anti-thrombotic treatments in addition to conventional immunosuppression (IS) in pts with biopsy proven LN and TMA

Methods: 97 pts with biopsy-proven LN and TMA were retrospectively analysed. A complete response (CR) was defined as proteinuria <0.5 g/24h and normal or near-normal (within 10% of normal GFR if previously abnormal) GFR. Partial Response (PR) was defined as a ≥50% reduction in proteinuria to subnephrotic levels and normal or near-normal GFR. Renal outcomes were assessed at 1 year post biopsy.

Results: The mean age of the pts was 38.9±15.2 years. The clinical presentations were nephrotic syndrome, nephritic syndrome, and asymptomatic urinary abnormalities. 9 pts were classified Class III (including 2 as ClassIII + V), 82 as Class IV (10 as Class IV-segmental(IV-S) and 72 as Class IV-global (IV-G), including 4 as Class IV-G +V) and 6 as Class V. 42 (43%) pts presented with acute and 55 (57%) with features of chronic TMA. All pts had received treatment with standard IS and steroids. At 12 months, CR was observed in

37 pts (38.1%), PR in 22 (22.6%) and no response in 38 (39.1%). 61 patients (62.9%) were antiphospholipid positive (aPL) and 37 (38.1%) received anticoagulation with vitamin-K antagonist (VKA) and/or heparins. Presence of aPLs (OR, 2.4; p=0.03), anti-DNA positivity (OR, 12.8; p=0.002), and chronic features of TMA (OR, 3.0; p=0.04) were all found to be associated with no response. In aPL positive pts, variables that were significantly associated with CR+PR were features of acute TMA rather than chronic (OR, 8.62; 95% CI 1.4–97.1; p=0.03) and the use of VKA/heparins (OR, 2.1; 95% CI 1.02–16.2; P=0.046).

Conclusions: In pts with concomitant LN and TMA, the presence of aPL and chronic features of TMA were associated with poorer renal outcomes. In pts with aPL, the use of anticoagulation appeared protective and warrants further investigation as a therapeutic tool, especially in the setting of acute TMA.

FR-PO1114

Herpes Zoster and Disseminated Zoster in Lupus Nephritis: Incidence Rates in Real-World Claims Data

Katherine Belendiuk,[1] Yingjie Ding,[2] Devika Chawla,[1] Matthew Cascino.[1]
[1]Genentech, South San Francisco, CA; [2]Genesis Research, Hoboken, NJ.

Background: Herpes zoster is a highly morbid condition. Overall rates of herpes zoster in immunocompetent individuals in a claims database were 0.45 per 100 PY, with risk increasing with age [1]. Rates of herpes zoster and disseminated herpes zoster among patients with lupus nephritis (LN) have not previously been described. This study characterized rates of herpes zoster and disseminated zoster infections in patients with LN using population-based claims data.

Methods: We conducted a retrospective cohort study using the Truven Healthcare MarketScan® Commercial Claims and Encounters and Medicare Supplemental and Coordination of Benefits database between 2000 and 2014. Patients with LN were identified using modifications to a validated claims data algorithm [2]. Herpes zoster cases were identified using ICD9 codes 053.xx. All patients received medical care in the U.S. and had 6 months of continuous medical and drug coverage ± first LN diagnosis (i.e. index). End of study was the first of end of enrollment or end of database.

Results: 11,068 patients with LN were identified and followed for a mean of 6.8 years (Table). Among patients with LN there were 955 incident cases of herpes zoster events reported, of which 157 (16%) were considered disseminated. Incidence rates of herpes zoster and disseminated zoster were 2.6 (95% CI 2.4 to 2.7) and 0.4 (95% CI 0.3 to 0.5) per 100 PY, respectively.

Conclusions: Patients with LN appear to be at increased risk for herpes zoster relative to the general population. A substantial minority of LN patients with herpes zoster develop dissemination. Further characterization of the relative contributions of age, immunosuppressive therapies, and disease factors is warranted. 1. Johnson BH et al. BMC Infectious Diseases, 2015;15:502. 2. Clinical Implications on Simple Attachment and Endothelial Damage in the Glomeruli of Adult Nephrotic Focal Segmental Glomerulosclerosis (FSGS): A Retrospective Cohort Study

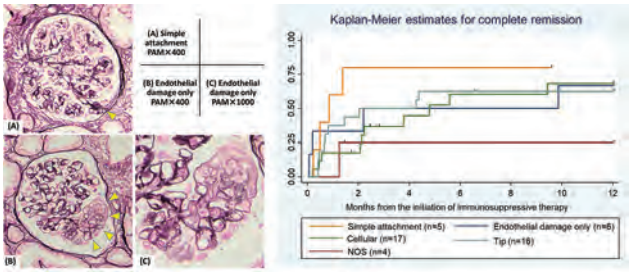
Takaya Ozeki,[1] Michio Nagata,[2] Takayuki Katsuno,[1,3] Sawako Kato,[1] Yoshinari Yasuda,[1] Naotake Tsuboi,[1,4] Shoichi Maruyama.[1] *[1]Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Kidney and Vascular Pathology, University of Tsukuba, Tsukuba, Japan; [3]Department of Nephrology and Rheumatology, Aichi Medical University, Nagakute, Japan; [4]Department of Nephrology, Fujita Medical University, Toyoake, Japan.*

Background: Although Columbia classification are widely used, clinical importance of specific pathological findings in FSGS is unclear. We focused on simple attachment and findings of endothelial damage in the glomeruli on light microscopy and evaluated the association between these findings and therapeutic reactivity of adult nephrotic FSGS.

Methods: Forty-eight out of 183 biopsy-proven FSGS during 2005-2015 were included: ≥20 years old, nephrotic syndrome, received immunosuppressive therapy and whose pathological slides or paraffin blocks were available. Pathological review was done by 3 nephrologists and 1 renal pathologist. Among 11 patients who did not fit the definition of any variants in Columbia classification, cases who only have small synechia to Bowman capsule were categorized to "simple attachment" and who only have findings indicating endothelial damage i.e., mesangiolysis and/or double contour of GBM without matrix accumulation were categorized into "endothelial damage only". Response to immunosuppressive treatment of these patients were compared with that of typical FSGS variants.

Results: There were 16 TIP (33.3%), 17 CEL (35.4%) and 4 NOS (8.3%). None showed collapsing or perihilar variant. There were 5 "simple attachment" cases and 6 "endothelial damage only" cases. No difference was observed in the details of immunosuppressive treatment among the subgroups. Kaplan-Meier method revealed that "simple attachment" cases showed the best therapeutic response and NOS showed the worst response. And "endothelial damage only" cases showed similar response to CEL or TIP.

Conclusions: Synechia or findings of endothelial damage are commonly observed in FSGS on light microscopy, although they do not play key roles in diagnosis and classification of FSGS. In adult nephrotic FSGS, simple attachment indicated good therapeutic response. On the other hand, even if patients only have the findings of endothelial damage, it might be clinically equivalent to other variants of FSGS.



FR-PO1116

Renal Disease in Pregnancy - Doing Biopsy Matters to Lives

Asif A. Ansari,[1] Anand C. Reddy,[1] Narothama Reddy Aeddula,[2] Rajnarsing Chennamaneni,[3] Uzair Waheed,[4] Srikala Meda,[3] Leela sharath Pillarisetty,[5] Rami Batarseh.[6] *[1]Permian Basin Kidney Center, Midland, TX; [2]Deaconess Health System, Evansville, IL; [3]Medical Center Hospital, Odessa, TX; [4]Texas A&M, College Station, TX; [5]MCHS, Midland, TX; [6]Texas Tech University health and science center - Permian Basin, Odessa, TX.*

Background: Renal disease is extemely rare in pregnancy but presents a therapeutic dilemma when diagnosed. It is a poor prognostic marker for fetal and maternal health. There is limited data and recommendations to guide therapy in this subset of population are lacking. We report our experience with 19 pregnant patients undergoing renal biopsies over a period of 5 years.

Methods: All pregnant patients undergoing renal biopsy at our facility were included in this retrospective analysis. Electronic medical records of nephrology, obstetrician services and histo-pathological reports were accessed. Patient confidentiality was preserved. Data was collected from january 1, 2013 to april 30, 2018.

Results: Nephrotic syndrome was the most common indication for a renal biopsy during pregnancy accounting for 16/19 patients (84%). Lupus nephritis was diagnosed in 4/18 patients necessitating an immunosuppressive regimen. The median gestation was 32 weeks (range 20–40) with loss of two fetuses. Non diabetic patients with nephrotic syndrome were at a higher risk for pre ecclampsia than diabetic patients with nephrotic syndrome ($p<0.05$). Three patients progressed to end stage renal failure needing dialysis, there were no maternal deaths during the follow up period. Table 1 shows characteristic features of this group.

Conclusions: Our series of selected pregnant patients undergoing renal biopsy demonstrates the variety of pathology in this group. Ante partum renal biopsy is safe in early pregnancy but should be considered only if there is a high likelihood to alter conventional therapy, and aid progression of pregnancy to fetal viability. Close monitoring and early intervention is key to improving feto-maternal outcomes particularly in non diabetic patients with nephrotic syndrome.

	Age	Gravida	Gestational age (weeks)	Indication for renal biopsy	Histological diagnosis	Pregnancy outcome
1	20	1	22	Nephrotic syndrome	Focal segmental glomerulo sclerosis	Pre ecclampsia
2	36	2	14	Nephrotic syndrome with positive lupus serology	Lupus nephritic Class V	Pre ecclampsia
3	25	4	16	Nephrotic syndrome with no history of DM	Diabetic glomerulosclerosis	Uneventful
4	27	3	23	Nephrotic syndrome with no history of DM	Diabetic glomerulosclerosis	Uneventful
5	27	1	12	Nephrotic syndrome	Focal segmental glomerulo sclerosis	Pre ecclampsia
6	26	1	12	Nephrotic syndrome with positive lupus serology	Lupus nephritic Class IV and V	Pre ecclampsia
7	19	1	23	Nephrotic syndrome	Minimal change disease	Pre ecclampsia
8	29	1	12	Nephrotic syndrome	Diabetic glomerulosclerosis	Uneventful
9	30	3	20	Nephrotic syndrome	Ig A nephropathy	Pre ecclampsia
10	23	4	22	Nephrotic syndrome with hematuria	Lupus nephritic Class IV	Pre ecclampsia
11	31	3	24	Positive lupus serology	Pre ecclampsia changes	Pre ecclampsia
12	22	3	24	Nephrotic syndrome	Membranous glomerulonephropathy	Pre ecclampsia
13	29	3	20	Nephrotic syndrome with positive lupus serology	Lupus nephritic Class V	Pre ecclampsia
14	30	5	14	Proteinuria and elevated creatinine	Ig M nephropathy	Uneventful
15	28	3	22	Nephrotic syndrome with elevated creatinine	Focal segmental glomerulo sclerosis	Pre ecclampsia
16	25	3	14	Nephrotic syndrome	Minimal change disease	Uneventful
17	26	2	18	Nephrotic syndrome with history of gestational DM	Diabetic glomerulosclerosis	Uneventful
18	32	3	24	Nephrotic syndome with elevated creatinine	Diabetic glomerulosclerosis	Pre ecclampsia with fetal demise
19	24	1	20	Hematuria, elevated creatinine	Thrombotic microangiopathy	Pre ecclampsia with fetal death

FR-PO1117

Histopathological Findings in Mixed Connective Tissue Disease with Renal Involvement

Silvia Ramirez,[1] Luis E. Morales-Buenrostro,[1] Ricardo Correa-Rotter,[2] Eduardo Martin,[1] Norma O. Uribe-uribe,[3] Laura Cardenas,[1] Montserrat Reyes,[1] Tatiana S. Rodriguez.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; [2]Institutor Nacional de la Nutricion, Mexico City, Mexico; [3]Instituto Nacional de Ciencias Medicas y Nutricion, "Salvador Zubiran", Mexico City, Mexico.*

Background: Renal involvement in mixed connective tissue disease (MCTD) is uncommon and present in up to 20% of patients, most commonly, an immune-complex nephropathy. The aim of the study was to identify the prevalence of renal involvement and describe renal histophatological findings in MCTD.

Methods: Single center retrospective cohort of MCTD (2003-2017) according to the Alarcón-Segovia criteria, assessed to identify cases with renal involvement. Histological findings of biopsied patients are described.

Results: 131 MCTD patients were identified, of which 14 (10.7%) had renal involvement, 7 underwent a renal biopsy, 6/7 were women; mean age at onset of renal involvement 47.1 ± 7.5 years. Most frequent extra-renal clinical manifestations were: Raynaud's phenomenon and arthritis, both in 7 (100%), puffy hands in 6 (85.7%), sclerodactily in 5 (71.4%), myositis in 5 (71.4%), and interstitial lung disease in 3 (42.8%). Median time elapsed from MCTD diagnosis to renal involvement was 82 (2-208) months. Four (57.1%) presented with sub-nephrotic proteinuria, 3 (42.8%) with nephrotic range proteinuria and 3 (42.8%) with CKD-EPI eGFR <60ml/min/1.73m^2. Histological diagnoses: pauci-immune focal necrotizing and crescentic glomerulonephritis (GN) (2 pts; one developed positive ANCA antibodies), lupus nephritis (LN) class III + V ISN/RPS 2003 (1), LN class IV ISN/RPS 2003 with thrombotic microangiopathy (1), non-LN membranous GN (2) and minimal mesangioproliferative GN (1). Six (85.7%) achieved either total or partial remission at a median follow up of 61 (1-363) months with combination of steroids and other immunosuppressant. No patient required renal replacement treatment.

Conclusions: In our cohort of MCTD, prevalence of renal involvement was low. Renal biopsy demonstrated a diversity of histological patterns: glomerulonephritis, vasculopathy, and overlap with ANCA associated vasculitis; these options should be considered in the differential diagnoses of MCTD patients with renal involvement.

FR-PO1118

Clinical Outcomes of Renal Biopsy-Proven Thrombotic Microangiopathy

Eunjeong Kang,[1] Dong Ki Kim,[1] Kook-Hwan Oh,[1] Kwon Wook Joo,[1] Yon Su Kim,[2] Ho Jun Chin,[3] Hajeong Lee.[2] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Seoul National University Bundang Hospital, Seong nam, Republic of Korea.*

Background: The kidney is the most commonly affected organ by thrombotic microangiopathy (TMA)-associated pathologic changes, however, there is lack of studies regarding the clinical outcomes of renal-biopsy proven TMA.

Methods: The patients diagnosed as TMA from 2005 to 2018 in 2 tertiary hospitals were enrolled. Of these 186 patients, children and those who not diagnosed with renal biopsy were excluded. These patients divided into 3 groups according to causes of TMA; typical hemolytic uremic syndrome (HUS), atypical HUS, and secondary TMA. Only 1 patient who classified typical HUS was excluded in the statistical analysis. Renal outcome was defined in 2 ways; renal function deterioration to end-stage renal disease (ESRD) who were depended on dialysis or kidney transplantation (KTPL) and the last measured estimated glomerular filtration rate (eGFR) <45mL/min/1.73m^2. Age, sex, eGFR rate at diagnosis, systolic blood pressure (SBP), hemoglobin, platelet, albumin, diabetes, hypertension, and classification of TMA were included as covariates in the multivariable analysis.

Results: Among 67 patients, patients who diagnosed with TMA after KTPL were 15(22.3%). Mean age was 54.0±15.5 years and 44(62.0%) were male. During 48.6 months of follow-up, 12 (17.9%) patients died, and 18(26.9%) patients (11 [26.8%] of secondary TMA vs. 7 [26.9%] in aHUS) had maintenance dialysis or KTPL. The patients who had last eGFR <45mL/min/1.73m^2 was 35(49.3%). There was no significant difference in all-cause mortality (log-rank *P*=0.293) and ESRD (log rank *P*=0.378) between atypical HUS and secondary TMA. SBP (hazard ratio [HR] 1.030, 95% confidential interval [CI] 1.006-1.055, *P*=0.015) and eGFR at diagnosis (HR 0.966, 95% CI 0.939-0.993, *P*=0.014) were associated with ESRD progression in univariate analysis, however, these associations did not observed in multivariable analysis. eGFR at diagnosis was the only risk factor for the final measured eGFR <45mL/min/1.73m^2 in multivariate logistic regression (OR 0.952, 95% CI 0.920-0.985, *P*=0.004). Only age was associated with all-cause mortality (HR 1.079, 95% CI 1.010-1.152, *P*=0.024) in multivariable analysis.

Conclusions: SBP and eGFR at diagnosis were significantly associated with ESRD progression in renal biopsy-proven TMA. There was no significant difference in all-cause mortality and ESRD progression between atypical HUS and secondary TMA.

FR-PO1119

A Combined Unenhanced Computed Tomography and Biopsy-Based Method for Estimating the Total Nephron Number in Humans

Takaya Sasaki, Nobuo Tsuboi, Yusuke Okabayashi, Kotaro Haruhara, Go Kanzaki, Kentaro Koike, Akimitsu Kobayashi, Izumi Yamamoto, Takashi Yokoo. *Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Methods for estimating the individual total nephron number in the clinical setting may be useful for predicting the progression of renal diseases. Rcently, simple methods have been proposed for estimating the total nephron number by the combined use of enhanced computed tomography (CT) and a renal biopsy in living kidney donors. However, renal disease patients are often not suitable candidates for intravenous contrast media administration. Thus, these methods are limited in daily clinical use for such patients, with further improvements in the methodology required. This study aimed to establish a method of estimating the total nephron number by the combined use of unenhanced CT and biopsy-based stereology.

Methods: We made a model for estimating the renal cortex volume measured by enhanced CT imaging as a true renal cortex volume. Using pre-donation contrast CT angiograms, transplantation donor kidneys were three-dimensionally reconstructed, and the total renal cortical volume was measured. The cortical volume estimates in unenhanced CT were determined by multiplying the semi-automatically measured parenchymal volume and the cortex coefficient. The total nephron number was determined by the combined use of the CT-based cortical volume and the glomerular density per volume in an implantation biopsy. The relative errors were calculated to assess the agreement between the methods.

Results: The values for the parenchymal volume and those for the cortical volume measured in enhanced CT showed a tight correlation (r = 0.949). The cortical to parenchymal volume ratio (0.715) was unaffected by any clinical factors, including age, body size and hypertension, and was defined as the cortex coefficient. The cortical volume and total nephron number estimated by unenhanced CT were consistent with those estimated by enhanced CT, with minimal relative errors (**Table**).

Conclusions: These results support the feasibility of estimating the total number of nephrons by the combined use of unenhanced CT and biopsy-based stereology, with a possible application for renal disease patients.

	Enhanced CT	Unenhanced CT	Relative error
Parenchymal volume per kidney	125 ± 27 cm^3	128 ± 29 cm^3	-0.7 ± 4.5 %
Cortical volume per kidney	92 ± 21 cm^3	92 ± 21 cm^3	0.0 ± 10.3 %
Total nephron number per kidney	653,000 ± 225,000	651,000 ± 215,000	0.1 ± 9.2 %

FR-PO1120

The Total Nephron Number and Responses to Corticosteroid Therapy in Patients with Minimal Change Nephrotic Syndrome

Takaya Sasaki, Nobuo Tsuboi, Yusuke Okabayashi, Kotaro Haruhara, Go Kanzaki, Kentaro Koike, Takashi Yokoo. *The Jikei University School of Medicine, Minato-ku, Japan.*

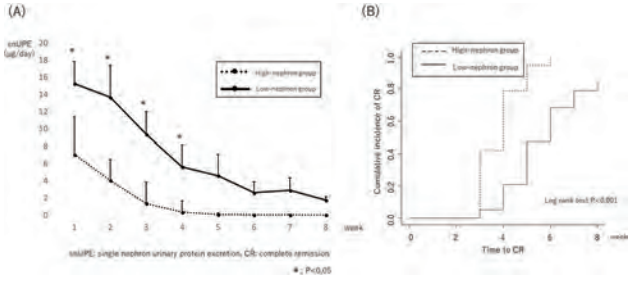
Background: The etiologies of minimal change nephrotic syndrome (MCNS) remain largely unknown; however, indirect evidence suggests that the weight at birth, which is related to the total nephron number, may affect the response to corticosteroid therapy. This study investigated the involvement of the total nephron number in the clinical course of MCNS.

Methods: Patients who exhibited acute-onset nephrotic syndrome, with a histological diagnosis of MCNS, were retrospectively analyzed. The total nephron number was estimated using a simplified method based on the combined use of unenhanced computed tomography and the non-sclerotic glomerular density of renal biopsy specimens. The single nephron glomerular filtration rate (snGFR) and single nephron urinary protein excretion

(snUPE) values were calculated by dividing the eGFR or UPE by the total nephron number. The glomerular volume (GV) was estimated by the measured mean glomerular area.

Results: A total of 38 MCNS patients were analyzed. The estimated total nephron number ranged from 140,000 to 1,800,000 per kidney among the patients and was inversely correlated with GV (r=-0.433, p=0.007). At the time of the diagnosis, the snGFR and snUPE values of the low-nephron group were significantly higher than those of the high-nephron group (139 vs 58 nl/min/1.73m^2 and 15.3 vs 7.1 µg/day, respectively). There was no significant difference in the total amount of UPE (7.4 vs 8.7 g/day) or the selectivity index (0.05 vs 0.05) of the groups. The reduction in snUPE (**Figure A**) and the time to complete remission (**Figure B**) during corticosteroid therapy were significantly slower in the low-nephron group, with no difference in the dose of corticosteroids. The total nephron number was found to be associated with the UPE at four weeks after the initiation of corticosteroid therapy, independent of age and the renal function.

Conclusions: Individual differences in the total nephron number in MCNS patients may influence the responses to corticosteroid therapy, possibly through the alteration of the single nephron dynamics.



FR-PO1121

The Impact of Birth Weight in Children with Biopsy Confirmed Nephrotic Syndrome

Candace D. Henderson,[1] Yichun Hu,[2] Susan L. Hogan,[2] Caroline J. Poulton,[1] Keia Sanderson,[3] Carmen E. Mendoza,[4] Kristin B. Kennedy,[1] Keisha L. Gibson.[3]
[1]UNC Kidney Center, Chapel Hill, NC; [2]University of North Carolina, Chapel Hill, Chapel Hill, NC; [3]University of North Carolina Kidney Center, Chapel Hill, NC; [4]University of North Carolina, Chapel Hill, NC.

Background: Nephrotic syndrome is a growing cause of chronic kidney disease (CKD) in children and can lead to end-stage kidney disease (ESKD). This study evaluates the impact of low birth weight (LBW) in children with nephrotic syndrome. Additional risk factors such as gestational age and kidney size were also assessed.

Methods: This retrospective cohort study reviewed the medical records of 75 children included in the UNC Glomerular Disease Collaborative Network ages 0-18 years with biopsy proven minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS), and membranous nephropathy (MN) for both modifiable and non-modifiable risk factors to determine potential associations between birth history and disease and its impact on disease progression to ESKD.

Results: Thirteen (17%) were born with LBW. FSGS was more frequent in LBW children (92%) compared to normal birth weight (NBW) (55%), while NBW children were more likely to develop MCD (37%) compared to LBW children (8%). LBW children had higher body mass index (BMI) compared to NBW children. The proportion of LBW and NBW children progressing to ESKD was similar (23% vs 27% respectively).

Conclusions: Our findings suggest that LBW is associated with disease type, specifically FSGS, and higher weight. Although numbers are small, progression to eGFR≤30 appeared similar by birth weight. A larger sample size and longer follow-up is needed to further investigate the potential impact of low nephron number from LBW, especially in the setting of these glomerular diseases, and the relationship with overweight/obesity status.

FR-PO1122

Variability in Treatment of Childhood Nephrotic Syndrome in Africa

Chris Esezobor,[1] Damien G. Noone,[2] Rasheed A. Gbadegesin,[3] Rulan S. Parekh.[4] H3 Africa Kidney Disease Research Network *[1]Department of Paediatrics, College of Medicine University of Lagos, Lagos, Nigeria; [2]The Hospital for Sick Children, Toronto, ON, Canada; [3]Duke University Medical Center, Durham, NC; [4]The Hospital For Sick Children, Toronto, ON, Canada.*

Background: Idiopathic nephrotic syndrome (NS) is the most common glomerular disease in African children. Clinical practice is guided based on limited resources for diagnosis and management of NS in most of the African continent. We aimed to determine variability in treatment of NS in Africa to develop a consensus guideline for the treatment of NS in middle and low-income countries.

Methods: Using the KDIGO guidelines as the basis for the management of NS, we developed a survey to assess current practices in 6 Sub-Saharan African countries. Approximately 50 adult and pediatric nephrologists from West, East and South Africa, in the H3 Africa Kidney Disease Research Network, were invited to complete the survey. Responses on treatment choices, duration of therapy, management of relapses and management of steroid resistant NS (SRNS) were collected.

Results: 30 nephrologists (20 pediatric, 4 adult and 6 both) from 19 hospital centers located in Nigeria, Ghana, Cameroon, Uganda, Tanzania and South Africa, completed the survey. Variability in treatment choices and practice were observed when compared with international guidelines. The definition of child varies by country, ranging from ages 12-18 (median 17), thus adult nephrologists also manage idiopathic NS. The initial treatment of steroid sensitive NS, and the definition and management of relapses varied widely across the respondents (Figure). Remission was defined by negative urinary protein ranging from 3-7 days (median 3). Only about 50% prescribed calcineurin inhibitors for children with SRNS.

Conclusions: Management of NS varied widely across and within countries in Africa, thus the importance of a consensus guideline tailored to an African context. Adult nephrologists often manage adolescents and youth, thus need to be aware of the pediatric management. Standardizing practice across the continent will provide an opportunity to understand the burden and long-term outcomes of NS.

Variability in treatment of NS

FR-PO1123

Effects of LDL-Apheresis in Adult Refractory Nephrotic Syndrome and Its Reproducibility

Hideki Takizawa,[1] Yoshinosuke Shimamura,[1] Yayoi Ogawa.[2] *[1]Teine Keijinkai Hospital, Sapporo, Japan; [2]Hokkaido Renal Pathology Center, Sapporo, Japan.*

Background: In 2018, Humanitarian device exemption allowed to utilize LDL-apheresis (LDL-A) for the treatment in adult patients with nephrotic-range focal segmental glomerulosclerosis (FSGS), but the efficacy is still uncertain. We performed case series of LDL-A in patients with refractory nephrotic syndrome, including FSGS, in a tertiary care center in Japan.

Methods: The efficacy of LDL-A was evaluated in 15 cases of refractory nephrotic syndrome (FSGS, n=4; minimal change disease (MCD), n=7; membranous nephropathy (MN), n=4) enrolled from April 2008 to April 2018. Demographic and clinical parameters were compared before and after performing LDL-A. Additionally, the efficacy of the second trial of LDL-A was evaluated in relapsed cases after the first trial of LDL-A.

Results: In 15 patients, all patients, except one, received immunosuppressive agents (prednisolone, 14; cyclosporine, 6; cyclophosphamide, 2), and there was no statistically significant reduction in proteinuria before initiating LDL-A (p=0.051; t-test). However, there were statistically significant reduction in proteinuria after performing the first trial of LDL-A in all groups (FSGS, 9.1 ± 1.9 g/day to 2.6 ± 1.0; MCD, 5.4 ± 1.4 to 0.4 ± 0.1; MN, 6.4 ± 0.5 to 2.3 ± 0.5; p <0.005; MANOVA). Multivariate analysis revealed the rate of remission was higher in MCD compared to other groups (R^2=0.49, p<0.005). In relapsed cases after the first trial of LDL-A (n=7), the second trial of LDL-A was effective to reduce proteinuria, and there was no statistically difference in between the first trial and the second trial of LDL-A (First trial, 5.6 ± 1.1 to 0.7 ± 0.3; Second trial, 7.2 ± 1.5 to 0.8 ± 0.5, p=0.382; MANOVA).

Conclusions: This study suggested that LDL-A was effective for reducing proteinuria in patients with refractory nephrotic syndrome, and its effectiveness was reproducible. This may contributed to planning treatment strategies in these patients.

FR-PO1124

Lower Doses of Prednisolone Are Sufficient for Initial Treatment in Adult-Onset Minimal Change Nephrotic Syndrome

Maiko Kimura,[1] Takayuki Fujii,[2] Tanaka Hiroaki,[2] Noriko Terasaki,[2] Kaiji Saito,[2] Satoshi Suzuki.[2] Seirei Sakura Citizen Hospital *[1]Graduate School of Medicine and School of Medicine, Chiba University, Chiba, Japan; [2]Seirei Sakura Citizen Hospital, Sakura city, Japan.*

Background: KDIGO Guideline suggests that prednisolone (PSL) should be given at a single daily dose of 1 mg/kg, as initial treatment in adult-onset minimal change nephrotic syndrome (MCNS). However, there is no convincing evidence to support the guideline's suggestion. It remains unclear how much the initial dose of PSL for MCNS should be given. On the other hand, from the viewpoint of side effects, the lower dose of PSL is fairly advantageous.

Methods: This retrospective cohort trial was performed in a single center between 1987 and 2017. Inclusion criteria were adult-onset MCNS diagnosed by kidney biopsy. These participants were classified into Low PSL group (L group, < 0.6 mg/kg), Moderate PSL group (M group, ≧ 0.6 mg/kg and < 0.8 mg/kg) and High PSL group (H group, ≧ 0.8mg/kg). The primary outcomes of interest were time to first remission and first relapse of proteinuria. They were analyzed with ANOVA, log-rank test, and multivariate Cox proportional hazards models.

Results: A total of 58 patients were enrolled in this clinical trial. All of these patients at any dose of prednisolone achieved remission within a median of 16 (8-45) days in L group, 14 (6-166) days in M group, and 20 (8-37) days in H group. Long-rank test showed that there were no significant differences in the primary outcomes among three groups. Multivariate Cox proportional hazards revealed that although age (per 10 yr) and serum creatinine (per log 1mg/dl) were prognosis factors for the time to the first remission, PSL dose was not a significant factor (HR, 1.07; 95%CI, 0.43 to 2.79 (L group vs H group), 0.99 ; 95%CI, 0.41 to 2.44 (M group vs H group)). Additionally, multivariate Cox regression analysis for the incidence of relapse did not significantly indicate any prognostic factor.

Conclusions: Low or moderate doses of PSL are sufficient for initial treatment in adult-onset MCNS regarding the time to remission and incidence of relapse.

FR-PO1125

Adult Outcome of Childhood-Onset Steroid-Dependent Idiopathic Nephrotic Syndrome in the Rituximab Era

Emmanuelle M. Plaisier,[1] Claire Dossier,[2] Karine Dahan,[1] Pierre M. Ronco,[1] Veronique Baudouin,[4] Tim Ulinski,[3] Georges Deschênes.[2] *[1]Nephrology and Dialysis, APHP Tenon, Paris, France; [2]Pediatric nephrology, APHP Robert Debré, Paris, France; [3]Pediatric Nephrology, APHP - Trousseau and UPMC, Paris, France; [4]APHP-Robert Debré Hospital, Paris, France.*

Background: Idiopathic nephrotic syndrome (INS) represents the most frequent glomerular disease in childhood, with up to 60% of patients experiencing frequent relapses and steroid dependency requiring long-lasting steroid therapy and immunosuppressive (IS) drugs. Outcome and optimal therapy at adulthood, as well as long-term complications of childhood IS exposure is poorly documented.

Methods: We retrospectively analyzed a monocentric cohort of 43 patients with childhood-onset steroid-dependent INS. Relapses in adulthood were treated with steroids or a combinaison of steroids and rituximab (RTX), with the exclusion of all other IS.

Results: Median age at the INS diagnosis and at the last follow-up was 4 years (1-17) and 24 (19-40) years, respectively, with a median duration of follow-up at adulthood of 7 (1-21) years. At pediatric age, 42 (98%) patients received at least one nonsteroidal IS drug, including calcineurin inhibitors in 29 (67%), mycophenolate mofetil in 26 (60%), RTX in 17 (39%), an alkylating agent in 15 (35%), and levamisole in 13 (30%). At entry in the adult care, 16 (37%) of the patients still received an IS drug other than RTX. Relapse occurred in 32 (74%) of patients at adult age with 5 patients presenting at least 2 episodes. In 9 patients, relapse occurred more than 3 years after steroids and IS discontinuation. Relapses were treated with steroids alone in two patients, while the other 29 received a combination of steroids and RTX, followed, for 20/29 patients, by a reinfusion of RTX either at B-cell recovery or at fixed intervals (6 to 12 months), up to 24 months. At last follow-up, 36 (84%) patients were in complete remission, with a treatment-free duration of more than 24 months in 12 (28%), of 12 to 24 months in 8 (19%) and of less than 12 months in 16 (37%). All but one patients were free of steroids and IS drugs. No patient experienced infection or cytopenia and one patient developed neoplasia most likely unrelated to IS.

Conclusions: Childhood-onset steroid-dependent INS remains a concern at adulthood with a high rate of relapse occurring after a variable delay. RTX is a safe and efficient steroid-sparing agent allowing maintenance of remission and discontinuation other IS. No late-onset severe complication related to childhood therapies was recorded.

Identifying Functional Subclasses of Nephrotic Syndrome by Consensus Non-Negative Matrix Factorization Clustering of Glomerular Transcriptome

Habib Hamidi,[1] Sean Eddy,[1] Matthias Kretzler,[1] John R. Sedor,[3] Lawrence B. Holzman,[2] John F. O'Toole,[3] Laura H. Mariani.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of Pennsylvania, Philadelphia, PA; [3]Cleveland Clinic, Cleveland, OH.*

Background: Defining nephrotic syndrome in mechanistic terms is a prerequisite to develop targeted therapies. Consensus non-negative matrix factorization (NMF) is a clustering approach used with tumor specimen transcriptomics to identify functionally relevant subtypes.

Methods: NMF clustering was applied to glomerular mRNA expression from nephrotic syndrome patient biopsies (NEPTUNE cohort). Individual gene expression levels from the glomerular compartment were normalized to mean expression to maximize individual patient differences over shared disease & tissue expression. Cox proportional hazards models were fit for complete proteinuria remission (CR, UPCR <0.3 mg/mg) and ESRD/40% eGFR decline. Significance analysis of microarray identified cluster specific differentially expressed genes that were used in pathway enrichment analysis to determine functional relevance.

Results: NMF separated 138 patients into 4 clusters which did not differ by diagnosis (MCD, FSGS, MN and IgAN, p 0.25), age (p 0.72), sex (p 0.25) or UPCR (p 0.28). Cluster 1 had lower mean eGFR (63 mL/min vs 81, 77 and 85; p 0.04) and greater black race (54% vs 10%, 24%, 19%, p <0.01). In unadjusted models, cluster 1 had least CR (HR 0.51, 95%CI 0.3–1.0, p-value 0.06) and greatest loss of eGFR (HR 5.4 95%CI 2.5–12.0, p-value <0.01). The eGFR association persisted after adjustment for baseline eGFR and race. Pathway enrichment of cluster-specific genes demonstrated unique processes: cluster 1-targetable signaling pathways (e.g. integrin, EGF-R, TLR), cluster 2-pentose phosphate metabolism, cluster 3-metabolic pathways (e.g.Vit D, pyruvate, galactose), cluster 4-cadherin signaling.

Conclusions: NMF clustering of glomerular kidney tissue mRNA expression levels revealed 4 clusters which were distinct from conventional classification. Pathway enrichment of gene signatures for each cluster revealed distinct molecular processes which may help to inform future treatment strategies.

APOL1 Risk Alleles Are Critical for the Development of Collapsing Glomerulopathy in Brazilian Children

Andreia Watanabe,[3] Precil D. Neves,[3] Elieser H. Watanabe,[3] Antonio M. Lerario,[2] Fabiola L. Padovan,[3] Amanda M. Narcizo,[3] Friedhelm Hildebrandt,[1] Matt G. Sampson,[2] Luiz F. Onuchic.[3] *[1]Boston Children's Hospital, Boston, MA; [2]University of Michigan, Ann Arbor, MI; [3]University of Sao Paulo, Sao Paulo, Brazil*.

Background: Collapsing glomerulopathy (CG) is associated with worse renal outcome than any FSGS histologic variant, while *APOL1* risk alleles are associated with FSGS and increased susceptibility to CG. In pediatric population, such alleles are related to later FSGS presentation, worse eGFR and faster progression to ESKD.

Methods: A retrospective analysis of 41 children with steroid-resistant nephrotic syndrome (SRNS) or congenital NS (CNS) with onset at 2 months-16 years was performed. All had biopsies analyzed by renal pathologists. Mutational analysis in 42 genes related to glomerular diseases was performed using a capture-based, customized panel followed by NGS using an Illumina MiSeq V2.

Results: CG was diagnosed in 10/41 patients, all negative for HIV, hepatitis B and C and CMV. Of these 10, 5 were Caucasian (C) and 5 mixed race (MR); all self-reported. Five CG children were treated with prednisone plus FK506/CyA/MMF and 2 with methylprednisolone boluses (renal failure at presentation). Two with CNS were given no immunosuppression. 8/10 CG patients reached ESKD within 0.0-3.8 years after initial manifestation. The other 2 have eGFR of 88 and 60 mL/min/1.73m^2, after 4 and 5 years of follow-up, respectively. A high-risk (HR) *APOL1* genotype was detected in 5/10 CG patients, 2 C and 3 MR. 2/5 were extreme preterm; the other 3 had birth weight <3 kg. Of the remaining 5 with CG, 2/5 had 1 *APOL1* risk allele (1 C and 1 MR), 1 was homozygous for a novel likely pathogenic variant in *PLCE1* (p.L1233P), and 1 was heterozygous for a rare, frameshift variant in *LAMB2*. Of the 31 without CG, 4 had a single *APOL1* risk allele and 27 none. Overall, Brazilian children with CG had significantly higher odds of harboring a HR *APOL1* genotype (OR=∞, CI:6.6,∞: p=0.0003).

Conclusions: For Brazilian children with SRNS/CNS, as compared to other histologic diagnoses, those with CG have greatly increased odds of having a HR *APOL1* genotype. Furthermore, the burden of *APOL1*-associated SRNS/CNS spanned self-described races. Finally, all with CG and HR *APOL1* genotype had an abnormal birth history. The discovered racial, histologic, and birth history correlates of a HR *APOL1* genotype have important implications for future *APOL1* genotyping efforts in research and clinical settings in Brazil.

Predictors of Remission in Collapsing Glomerulopathy

Mateus J. Luvizotto, Gerard F. Sales, Precil D. Neves, Luis Yu, Cristiane B. Dias, Viktoria Woronik, Lectícia Jorge. *University of Sao Paulo, Brazil, São Paulo, Brazil*.

Background: Collapsing Glomerulopathy (CG) has usually been associated with poor renal outcomes. The goal of this study was to identify predictors of remission in the CG.

Methods: A retrospective analysis was performed on all CG diagnosed by kidney biopsy between 1996 and 2016. Clinical and laboratory data were collected at baseline and at the end of follow up. Remission has been defined as 50% reduction in baseline proteinuria and <3.5 g/day. Outcome was defined as ESRD or doubling of baseline creatinine.

Results: Logistic regression analysis showed that remission was significantly associated with a better renal outcome (OR 0.08, 95%CI 0.02-0.3, p<0.001), even after adjustments for baseline CKD-EPI and proteinuria. Clinical features of the groups with and without remission are summarized in Figure 1. A second logistic regression analysis showed that female and interstitial fibrosis are the only independent predictors associated with remission in CG (OR 0.28, 95%CI 0.09-0.84, p 0.02 and OR 10.9,95%CI 1.2-98 p 0.034)

Conclusions: Predicting remission with baseline features is difficult, but female and patients without interstitial fibrosis are more likely to achieve remission. Moreover, patients with CG who showed remission had a better outcome and this should be (a goal of therapy) attempted.

n	Remission (n=34)	No Remisson (n=33)
Age (Y)	34.6±15.4	30.2±15.2
Male (n,%)*	14 (41%)	22 (66%)
CKD-EPI baseline	53.4±35.8	52.9±34.4
Proteinuria g/day	6.7±6.1	9.1±6.1
No Interstitial Fibrosis (n, %)*	8 (24%)	1 (3%)
Immunosuppression (n,%)	26 (76%)	24 (73%)
CKD-EPI at the end*	64.3±39.9	19.6±29.2
Proteinuria end (g/day)*	1.3±1.6	6.9±4.7
Follow up (months)*	82.6±75.6	30.9±46.7
Outcome*	9(27%)	28(85%)

Collapsing Glomerulopathy in Hepatitis C Virus Positive Patients: A Retrospective Autopsy Study of 95 Cases

Yasir Lal, Hania Kassem, Aijan T. Ukudeyeva, Derald D. Charles, Samantha V. Etienne, Wayne G. Fischer, Marjan Afrouzian. *UTMB, Galveston, TX*.

Background: Patients (pts) with hepatitis C virus (HCV) infection may present with a variety of glomerular diseases, however Collapsing glomerulopathy (CG) is an uncommon presentation. In most pts, this lesion is associated with human immunodeficiency virus (HIV) infection while in a small number of cases, CG is considered to be idiopathic. The aim of this study was to determine the prevalence of CG in HCV-positive, HIV-negative (HCV+ HIV-) pts, using autopsy material to explore the significance of this association through clinical, pathological and laboratory correlation.

Methods: We performed a retrospective autopsy study, examining the renal parenchyma of 95 HCV+ pts. Pts with positive or unknown HIV status or those who had exposure to interferon (IFN) therapy were excluded. Thereafter, the presence of CG (test group) or absence of CG (control group) was recorded using hematoxylin and eosin, periodic acid-Schiff and Jones stains. Clinical and laboratory correlation included evaluation of demographics, terminal serum creatinine, HCV serology, viral load (VL), dipstick proteinuria, serum albumin (Alb), and cause of death. A t-test (pooled variances) was used for comparison of continuous variables such as age, BMI, HCV VL and Alb. Comparison of categorical variables such as gender, race, and HCV genotype was based on contingency analysis.

Results: Forty cases were excluded based on HIV status and IFN exposure. CG was identified in 19/55 pts (34.5 %). There was no significant difference in age, race, BMI, Alb, creatinine, proteinuria or cause of death among the two groups. HCV VL was higher in the test group but the difference was not statistically significant.

Conclusions: To our knowledge, this is the largest autopsy study describing the occurrence of CG in HCV+ HIV- pts. Our results demonstrate an association and prevalence of CG in HCV infection that have not been previously established. Therefore, CG should be considered in HCV+ HIV- pts who present with renal failure and proteinuria. Further studies are needed to elucidate prevalence and pathogenesis of CG in these pts.

Quantitative Mass Spectrometry Aided Urine Biomarker Analysis in Nephrotic Syndrome

Timothy Cummins,[1,2] Daniel W. Wilkey,[1,2] Michelle T. Barati,[1,2] Dawn J. Caster,[1,2] Frederick W. Benz,[3] Michael Merchant,[1,2] Jon B. Klein.[1,2] *[1]University of Louisville Kidney Disease Program, Louisville, KY; [2]University of Louisville Medicine, Louisville, KY; [3]Pharmacology, University of Louisville, Louisville, KY.*

Background: Accurate and precise diagnosis of chronic renal diseases can be aided using biomarkers. Methodological advancements in mass spectrometry and bioinformatics have improved the ability to identify and quantitate protein biomarkers induced in disease. Proteins and peptides that are present in patient urine are indicative of changes in homeostasis of the kidney and other organs. Identification and quantitation of these components of the urine proteome will be useful in determining effective new biomarkers of kidney disease. Loss of kidney function corresponds with increased leakage of protein and peptide components into the urine. Profiling and quantitation of urinary markers of renal disease progression is important towards a better understanding and characterization of distinct glomerular diseases.

Methods: In this work we present a mass spectrometry workflow utilizing multiplex tandem mass tag (TMT) quantitation of whole urine proteins from patients with nephrotic syndrome and in remission.

Results: Combined 2D-LC-MS/MS-TMT analysis yielded ~800 protein identifications, ~480 were quantitated. Over 200 proteins were upregulated in disease and 50 were downregulated.

Conclusions: Our current study includes urine TMT analysis from 3 patients with nephrotic syndrome and post-treatment follow-up upon remission. The sample set, though small, is ideal for looking at effects of normalization on intra and inter-patient protein quantitation as we were also able to see a difference in the effects of race and sex in one sample that clearly clusters differently from the other two patients. Clinical data, specifically urinary creatinine, was used to normalize TMT values. Employing these methods on larger patient cohorts will help in uncovering novel biomarkers of nephrotic syndrom.

FR-PO1131

Clinical and Histological Risk Factors Predicting Progression to ESRD in Patients with Secondary FSGS

Aditya S. Pawar, Andrew D. Rule, Kriselle maris Lao, Mariam P. Alexander, Lisa E. Vaughan, Fernando C. Fervenza, Ladan Zand. *Mayo Clinic, Rochester, MN.*

Background: Secondary FSGS is a proteinuric renal disease that develops as a result of increased hemodynamic stress on the glomeruli. The aim of study was to identify clinical characteristics and histological factors in patients with secondary FSGS that predicted progression to ESRD.

Methods: Adult patients (>18 y) with a native kidney biopsy and diagnosis of FSGS between 1993-2015 were identified. Those with additional glomerular lesions (e.g. diabetes or vasculitis) or missing clinical or biopsy data were excluded. Comprehensive chart review was performed on the remaining FSGS patients to identify candidate clinical and histological predictors (n=149). Cox proportional hazards regression models were used to identify predictors for incident ESRD (eGFR <15 or need for transplantation or dialysis).

Results: Out of 149 patients, 60 had primary FSGS (S. albumin <3.5 g/dL & urinary protein (UP) ≥ 3.5g/24h), 89 had secondary FSGS (S. albumin ≥3.5 g/dL & any degree of proteinuria). In patients with secondary FSGS mean (SD) age was 52 (17) years, 41% female, & 73% white. Median [IQR] BMI was 30 [26-34] kg/m^2, S. creatinine was 1.7 [1.3-2.4] mg/dL, $eGFR_{creatinine}$ was 40 [28-57] ml/min, 24h UP was 2.6[1.3-4.4] g, and median follow-up was 34 [12-60] months. ESRD occurred in 33% of these patients. Clinical predictors of ESRD were older age, lower eGFR, use of immunosuppression, and absence of renin-angiotensin blockade (Table 1). The only renal biopsy histological predictor of ESRD was severe arteriosclerosis, though IFTA was borderline significant. The degree of global sclerosis, foot process effacement and glomerulomegaly was not predictive. Severe arteriosclerosis was predictive after adjusting for age (p=0.04).

Conclusions: Arteriosclerosis appears to be an important and under-recognized predictor of progression to ESRD in patients with secondary FSGS independent of age.

Univariate analysis

Variable	Hazard Ratio(CI) (P value)
Female	0.5 (0.08-1.77) (0.36)
Age @ Biopsy / 10 years	1.66 (1.22-2.37) (0.002)
eGFR per 10 ml/min	0.96 (0.53-0.94) (0.03)
Urine Protein per g/day	1.08(0.93-1.23) (0.21)
Global glomerulosclerosis per %	1.00(0.98-1.02) (0.38)
IFTA >50%	2.4 (0.97 – 6.8) (0.07)
Arteriosclerosis > 50%	7.26 (1.87-24.43) (0.004)
Use of immunosuppression	1.38(0.39-3.88) (0.04)
Use of ACE-I/ARB	0.3 (0.12-0.72) (0.008)

FR-PO1132

Clinicopathological Discrimination of Primary and Genetic Focal Segmental Glomerulosclerosis in Children

Kiyonobu Ishizuka,[1] Yutaka Harita,[2] Takaya Iida,[1] Takeshi Nagasawa,[1] Hideki Ban,[1] Yoko Shirai,[1] Tomoo Yabuuchi,[1] Naoto Kaneko,[1] Kenichiro Miura,[1] Taeko Hashimoto,[3] Motoshi Hattori.[1] *[1]Tokyo Women's Medical University, Shinjuku-ku, Japan; [2]Dept. of Pediatrics, Tokyo University, Tokyo, Japan; [3]Yamagata University, Yamagata-city, Japan.*

Background: (Background) FSGS is classified as primary FSGS caused by unidentified humoral factor(s) and secondary FSGS including genetic abnormalities, and the cause of the disease of each patient has crucial implication on treatment strategies and renal transplant success. Sethi S, et al. described that >80% foot process effacement covering glomerular surface area is suggestive of primary form in adult FSGS by comparing nephrotic patients with non-nephrotic ones (Nephrol Dial Transplant, 2015). However, it is known that nephrotic syndrome can be observed not only in primary form but genetic one in children. Therefore, we conducted a clinicopathological study comparing clinically proven primary FSGS with genetic FSGS.

Methods: Pediatric FSGS patients (10 primary and 8 genetic) who progressed to ESRD and underwent renal transplantation were included in this study. All the primary FSGS patients had posttransplant recurrence, and all the patients with genetic FSGS carried pathogenic mutations and did not have posttransplant recurrence. We retrospectively analyzed their clinical course and histology of the native kidneys before transplantation. The degree of foot process effacement (FE) of podocytes was calculated as the ratio of the FE area on capillary loops to glomerular surface area.

Results: There were no differences between primary and genetic FSGS on age at onset (5.5 ± 3.0 years, 4.6 ± 3.0 years) and the period from onset to ESRD (5.5 ± 4 years, 4.5 ± 3.5 years). The period from onset to kidney biopsy was significantly shorter in genetic than primary FSGS (0.7 ± 1.4 years vs 3.4 ± 3.4 years) (p = 0.02). The rate of nephrosis at onset, and of edema observed during the course, and of the initial responsiveness to steroid treatment were all significantly higher in primary FSGS (p <0.01). Serum total protein (TP) at the time of kidney biopsy was significantly lower in primary FSGS (3.7 ± 0.6 g / dl vs 5.3 ± 1.1 g / dl) (p <0.01) with TP above 3.9 g/dl predicting genetic (sensitivity 100%; specificity 75%; AUC 0.927). The percentage of FE at 80% completely discriminated primary from genetic cases (98 ± 6% vs 61 ± 12%).

Conclusions: Discrimination between primary and genetic FSGS could be possible by integrating the pathological findings with clinical information.

FR-PO1133

Idiopathic FSGS: Outcome in Adult Patients with Initial Steroid-Resistance

Ilse M. Rood, Aernoud Bavinck, Marieke van Rijn, Jeroen Deegens, Jack F. Wetzels. *Radboud University Medical Center, Nijmegen, Netherlands.*

Background: Idiopathic focal segmental glomerulosclerosis (iFSGS) is a common cause of nephrotic syndrome (NS) in adults. Guidelines advise initial therapy with corticosteroids (CS). The clinical outcome of patients with initial steroid-resistance is ill-defined.

Methods: Retrospective cohort study of adult patients with biopsy-proven FSGS, nephrotic syndrome, and steroid-resistance (no complete remission (CR) after 8 weeks of treatment with high dose CS). We evaluated late response (CR or partial remission (PR); use of second line immunosuppressive treatment; predictors for kidney function deterioration; and long-term outcome.

Results: We included 51 patients (31 males), mean age 46 years, referred to our academic clinic between 1995 and 2014. Only 6 patients were in PR at 8 weeks. High dose CS monotherapy was continued for a median of 17 weeks (IQR 11-21), with a total duration of 56 weeks (IQR 28-83). The cumulative incidence of CR and PR were 0 and 16 patients at 16 weeks and 1 and 23 patients at 24 weeks of treatment. In total, 9 patients (18%) attained a CR and 16 patients (31%) attained a PR during initial (continued) treatment with CS. Seven patients in PR were subsequently treated with other immunosuppressive therapy (IS), resulting in CR in three. 22 patients received additional immunosuppressive therapy because of persistent nephrotic range proteinuria, seven attained a CR and 10 attained a PR. Additionally, one patient attained a spontaneous CR 2.5 years after IS therapy was discontinued. At end of FU 12 patients were in CR, 22 in PR, 17 had a (persistent or relapsed) NS. 6 patients had developed ESRD. In 29 patients eGFR was below p5 of age-matched controls.19 patients had kidney function deterioration ≥ 3ml/min/1.73m^2 per year. Older age, FSGS-tip, and CR were associated with stable kidney function. Remarkably, PR was not a predictor for a stable kidney function. The definition of PR as recently proposed by Troost et al. (a 40% reduction in proteinuria (<1.5 g/g)) was also not associated with a stable kidney function.

Conclusions: Long-term outcome in patients with steroid resistance is not uniformly dismal. Still, kidney function deterioration ≥ 3ml/min/1.73m^2 per year occurs in 37%. Better biomarkers are needed to predict long term outcome in patients with iFSGS.

FR-PO1134

Kidney Outcome with Primary Focal Segmental Glomerulosclerosis (FSGS) by Using a Predictive Model

Shahrzad Ossareh,[1] Mansoureh Yahyaei,[1] Mojgan Asgari,[3] Hanri Afghahi.[2] *[1]Medicine, Iran University of Medical Sciences, Hasheminejad Kidney Center, Tehran, Tehran, Islamic Republic of Iran; [2]Nephrology, Skaraborg Hospital, Skövde, Sweden; [3]Pathology, Iran University of Medical Sciences- Hasheminejad Kidney center, Tehran, Islamic Republic of Iran.*

Background: To develop a model of prediction of chronic kidney disease (CKD)/ end-stage kidney disease (ESKD) (dialysis or kidney transplantation) in patients with primary FSGS by baseline clinical, laboratory and pathological findings as predictors.

Methods: 201 patients with primary FSGS (59% male, mean age: 38±15 years, baseline serum creatinine (bSCr): 1.89±1.64 mg/dl, eGFR 65±38 ml/min/1.73 m² (MDRD) and mean proteinuria: 4.6±3.6 g/24 hours were followed. Time-dependent Cox model and C statistics for discrimination were used to develop a predictive model. The patients were classified into 3 risk groups of low (bSCr<1.5 mg/dl and interstitial fibrosis/ tubular atrophy (IF/TA) and segmental glomerulosclerosis (SGS)< 25%, medium (bSCr: 1.5- 2 mg/dl, and IF/TA and SGS: 25-50%) and high (bSCr>2 mg/dl and IF/TA and SGS> 50%). Kaplan–Meier and the log-rank tests were used to estimate kidney survival in each group. Interaction between independent variables was estimated.

Results: During the mean follow-up of 55±27 months, 46 patients (23%) developed CKD and 36 (18%) ESKD. Ninety patients (44%) did not respond to treatment and among them, 76 patients (84%) developed CKD/ESKD. In multivariate model 1 mg/dl higher bSCr (HR: 1.63, 95% CI: 1.12-2.37), 1% increase in SGS (HR: 1.04, 95% CI: 1.01-1.08) and 1% increase in IF/TA (HR: 1.06, 95% CI: 1.03-1.09)in kidney biopsy, were associated with increased risk. In adjusted model, higher baseline proteinuria and collapsing variant (NOS variant as reference) were not significantly associated with risk of CKD/ESKD (P=0.671 and P=0.136, respectively). The median kidney survival was 8.1 years (95% CI, 7.7-8.6 years) in low risk and 3.1 years (95%, 2.2- 4.1 years) in high-risk patients. In prediction model the accuracy of the applied score for prediction of CKD with discrimination by C statistics was C= 0.84 (95% CI: 0.78-0.91) for 5 years.

Conclusions: In patients with primary FSGS, higher bSCr, SGS and IF/TA scores were the strongest predictors for CKD/ESKD. In adjusted model higher proteinuria at baseline was not associated with increased risk of CKD/ESKD. Interestingly collapsing variant did not increase the risk of CKD/ESKD after adjustment for IF/TA score. These findings indicated the importance of baseline GFR and the degree of chronicity at biopsy rather than histologic variants as predictors of kidney outcome.

FR-PO1135

Utility of Columbia Classification in Focal Segmental Glomerulosclerosis: Renal Prognosis and Treatment-Response Among the Pathological Variants

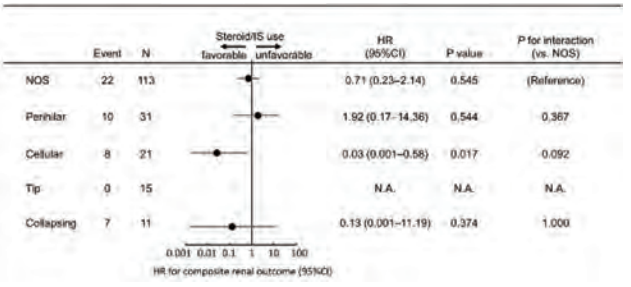
Akihiro Tsuchimoto,[1] Yuta Matsukuma,[1] Kenji Ueki,[1] Kaneyasu Nakagawa,[1] Shigeru Tanaka,[2] Kosuke Masutani,[3] Koji Mitsuiki,[4] Ritsuko Katafuchi,[5] Kazuhiko Tsuruya,[6] Toshiaki Nakano,[1] Takanari Kitazono.[1] *[1]Kyushu University, Fukuoka, Japan; [2]Fukuoka Dental College, Fukuoka, Japan; [3]Fukuoka University, Fukuoka, Japan; [4]Fukuoka Red Cross Hospital, Fukuoka, Japan; [5]National Fukuoka-Higashi Medical Center, Koga, Fukuoka, Japan; [6]Nara Medical University, Kashihara, Japan.*

Background: The utility of the Columbia classification (Col-class) for focal segmental glomerulosclerosis (FSGS) has not yet been fully proven.

Methods: We extracted 201 FSGS patients from 10 nephrology centers in Japan and investigated the differences of a composite renal endpoint, defined as doubling of serum creatinine and/or development of end-stage renal disease, in pathological variants. Sensitivity analysis was used to prove the utility of the Col-class to predict renal outcomes. Additionally, the renal protective effects of steroids and/or immunosuppression (steroid/IS) were investigated in patients stratified according to Col-class.

Results: The patients were classified into the variants as follows: not otherwise specified (NOS) (n=120, 60%), perihilar (n=31, 15%), cellular (n=24, 12%), tip (n=15, 7%), and collapsing variant (n=11, 5%). No tip variant patients reached the renal endpoint. The renal outcome in the collapsing variant was significantly poorer than those in the NOS (hazard ratio [HR] 3.65, *P*=0.010), while the outcome in perihilar and cellular variant were similar to those in NOS. In the sensitivity analysis, the area under the receiver operating characteristics curve for the renal endpoint was increased by adding Col-class to a model including common risk factors (*P*=0.041). Steroid/IS use was associated with good renal outcome in the cellular variant (HR 0.03, *P*=0.017).

Conclusions: The Col-class is useful to predict renal prognosis in Japanese patients with FSGS. In addition to good prognosis in the tip and poor in the collapsing variant, renal protective effect of steroid/IS in the cellular variant was newly revealed.



Effect of steroid/immunosuppressant use on composite renal survival in each pathological variant of focal segmental glomerulosclerosis.

FR-PO1136

Systolic Blood Pressure Z-Score Accurately Predicts Development of Posterior Reversible Encephalopathy Syndrome in Children

Emily K. Gall, Andrew M. South. *Wake Forest School of Medicine, Winston-Salem, NC.*

Background: While posterior reversible encephalopathy syndrome (PRES) is often reversible, it increases morbidity and mortality in children and adults. High blood pressure (BP) is a major risk factor for PRES and is thought to alter cerebral vascular autoregulation leading to vasogenic edema. However, little is known about what severity of high BP predicts PRES, especially in children, as most patients with high BP do not develop PRES. The purpose of this study is to determine a clinically meaningful BP threshold above which the risk of developing PRES is increased.

Methods: We recorded the maximum systolic BP and diastolic BP and BP z-scores in the 14 days preceding development of PRES in a case-control study of 35 children with PRES compared to 14 controls matched on similar risk factors (underlying disease, renal function, and medications) and who had clinical concern for PRES but had normal brain magnetic resonance imaging. We used logistic regression models to determine the effect of maximum BP on the risk of developing PRES, reported as odds ratios with 95% CI. We then constructed receiver operator characteristic (ROC) curves for different maximum-BP cut points to determine their prognostic ability to predict PRES and calculated sensitivity, specificity, and positive and negative predictive values.

Results: Cases had a higher rate of baseline hypertension (97.1% vs 64.3%, *p*=0.005) but were otherwise well matched. 14-day maximum SBP z-score was strongly associated with PRES (OR 4.0, 95% CI 1.6 to 9.6). ROC analysis revealed that 14-day maximum SBP z-score ≥3.0 accurately predicted PRES (AUC 0.95, 95% CI 0.88 to 1.0) with 91.2% sensitivity (95% CI 81.4 to 100%) and 84.6% specificity (65.2 to 100%), indicating a positive predictive value of 93.9% (84.3 to 100%) and a negative predictive value of 78.6% (56.9 to 100%).

Conclusions: Our study demonstrated that a maximum SBP z-score of 3.0 or higher in the preceding 14 days accurately predicted PRES development in pediatric cases as compared to controls with similar risk factors. This indicates that the SBP 99th percentile for age, sex, and height (equivalent to a z-score of 3.0) may be a clinically relevant threshold indicating that aggressive BP reduction is warranted in children at high risk for PRES in order to prevent target organ damage in the brain.

FR-PO1137

Standardizing and Optimizing Blood Pressure Measurement Across 16 Pediatric Transplant Centers: The Improving Renal Outcomes Collaborative

Michael E. Seifert,[1] Rouba Garro,[2] Roshan P. George,[2] Gina-Marie Barletta,[13] Craig W. Belsha,[6] Abanti Chaudhuri,[16] Jens W. Goebel,[7] David B. Kershaw,[5] Debora Matossian,[15] Jason Misurac,[4] Corina Nailescu,[8] Christina R. Nguyen,[17] Meghan Pearl,[9] Ari Pollack,[14] Cozumel S. Pruette,[10] Pamela Singer,[11] Bradley A. Warady,[12] Devesh S. Dahale,[3] David K. Hooper.[3] Improving Renal Outcomes Collaborative *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Emory Children's Center, Atlanta, GA; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]University of Iowa, Iowa City, IA; [5]University of Michigan, Ann Arbor, MI; [6]Saint Louis University, Saint Louis, MO; [7]Children's Hospital Colorado, Aurora, CO; [8]James Whitcomb Riley Hospital For Children, Indianapolis, IN; [9]Mattel Children's Hospital at UCLA, Los Angeles, CA; [10]Johns Hopkins University, Baltimore, MD; [11]Cohen Children's Medical Center, New Hyde Park, NY; [12]Children's Mercy Kansas City, Kansas City, MO; [13]Pediatric Kidney Disease & Hypertension Centers, Phoenix, AZ; [14]Seattle Children's Hospital, Seattle, WA; [15]Lurie Children's Hospital, Chicago, IL; [16]Stanford University, Stanford, CA; [17]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA.*

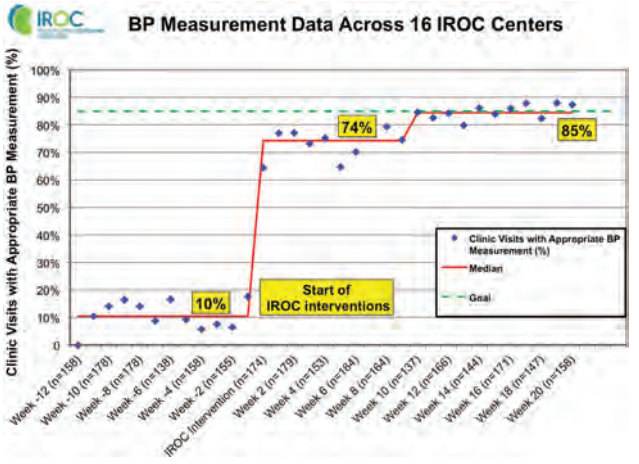
Background: Hypertension is prevalent in 60-90% of pediatric renal transplant recipients. Uncontrolled hypertension contributes to cardiovascular (CV) death and graft loss. Non-standardized blood measure (BP) measurement limits the ability to control hypertension in this population. Here, we report efforts from the Improving Renal

Outcomes Collaborative (IROC) to standardize appropriate BP measurement across 16 pediatric kidney transplant centers.

Methods: In total, 16 centers participated in structured quality improvement (QI) activities as facilitated by the IROC QI fundamentals course. We prospectively collected clinic BP data from August 2016 to May 2018 and calculated the proportion of visits with appropriate BP measurement according to 5 criteria from published guidelines. For each center, data were analyzed over 2 time periods: a 12-week baseline pre-intervention period and a 20-week post-intervention period. We used run charts to quantify improvements in BP measurement.

Results: We analyzed BP measurement data from 5,242 transplant clinic visits. Prior to IROC interventions, BP was measured appropriately at 10% of visits. Less than 15% of centers were measuring arm circumference, allowing 5 minutes of rest, or averaging 2 manual readings if the initial BP was elevated. Within 10 weeks post-intervention, BP was measured appropriately at 85% of visits. This improvement was sustained for at least 10 weeks (Figure).

Conclusions: Using the infrastructure of the IROC learning health system, we standardized BP measurement across 16 pediatric transplant centers, allowing for more accurate assessment of BP and further interventions to reduce CV risk in pediatric kidney transplant recipients.



FR-PO1138

Effect of Elevated Systolic Blood Pressure and Pulse Pressure on the Progression of CKD in Children

Rupesh Raina,[1,2] Vinod Krishnappa,[3] Shyam sunder R. Polaconda,[4] Gaurav Kapur,[5] Kirsten Kusumi,[6] Maroun Mhanna.[7] *[1]Cleveland Clinic Akron General, Broadview Heights, OH; [2]Pediatric Neprhology, Akron Children's Hospital, Akron, OH; [3]Akron Nephrology Associates/Cleveland Clinic Akron General, Akron, OH; [4]Akron Nephrology Associates, Akron, OH; [5]Children's Hospital of Michigan, Detroit, MI; [6]Akron Children's Hospital, Akron, OH; [7]Metrohealth Medical Center, Cleveland, OH.*

Background: Increased systolic blood pressure (SBP) and pulse pressure (PP) are associated with the progression of chronic kidney disease (CKD) and there is a good correlation between increased left ventricular mass index (LVMI) and decline in glomerular filtration rate (GFR). However, the exact nature of the relationship between PP, SBP, and LVMI has not been established in children with CKD, which this study aims to investigate.

Methods: This is a retrospective study of pediatric patients with CKD utilizing Chronic Kidney Disease in Children (CKiD) database from the National Institute of Diabetes and Digestive Kidney Disease (NIDDK) registry. Only children with iohexol-based GFR (iGFR) < 60 ml/min/1.73 m^2(n=620) were included for analysis. Analysis of relationships between SBP vs iGFR, diastolic blood pressure (DBP) vs iGFR, PP vs iGFR and LVMI vs iGFR were done using a two-tailed significance test and Pearson's correlation coefficient. Statistical analysis was done using SPSS software.

Results: The clinical characteristics at baseline were age 9.8 ± 4.4 years (mean ± SD), iGFR 37.9 ± 12.1 ml/min/1.73 m^2, SBP 107.9 ± 13.5 mm Hg, DBP 66.3 ± 11.4 mm Hg, PP 41.7 ± 10.8 mm Hg, and LVMI 30.9 ± 9.3. Increasing SBP and PP strongly correlated with decreasing iGFR (r=-0.16, p<0.001 and r=-0.08, p<0.003) (Figures 1 & 2). Increasing DBP also correlated well with decreasing iGFR (r=-0.11, p<0.01). This inverse relationship was also maintained between LVMI and iGFR (r=-0.09, p<0.05). No significant association found between PP and LVMI (r = 0.037; p = 0.334).

Conclusions: A strong inverse relationship exists between iGFR and LVMI, SBP, DBP, PP. These findings suggest that effective blood pressure control is of paramount importance in CKD children to decrease the rate of decline in renal function.

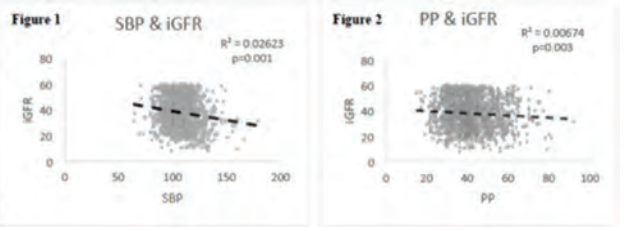


Figure 1 & 2. Relationship between iohexol-based GFR (iGFR)with systolic blood pressure and pulse pressure in children with chronic kidney disease

FR-PO1139

Hypertension in Children with Acute Lymphoblastic Leukemia in the Modern Era

Reeti Kumar,[1] Suzanne Reed,[1] John D. Mahan.[2] *[1]Nationwide Children's Hospital, Columbus, OH; [2]Nationwide Children's Hospital, Columbus, OH.*

Background: In recent decades, the prognosis of acute lymphoblastic leukemia (ALL) has improved with innovations in chemotherapy, bone marrow transplantation (BMT), & better supportive therapy. Given these better outcomes, understanding & managing complications associated with ALL have become more important. Hypertension (HTN) is a known complication of ALL & has been attributed to multiple factors, including renal leukemic infiltration, AKI, & high dose steroids. There is a paucity of data on the incidence of HTN in children diagnosed with ALL in the recent decades. Prior studies have shown wide variation in incidence of HTN ranging from 6.3-52.9% in children with ALL. The aim of this study is to define the incidence of acute & chronic HTN in pediatric patients diagnosed with ALL in more recent years.

Methods: This study is a retrospective chart review of pediatric patients diagnosed with ALL at Nationwide Children's Hospital between 1/1/2008 & 12/31/2016. BP data was collected from diagnosis to 9 yrs post-diagnosis or until a following end point: lost to follow-up, received BMT, or deceased. BP values obtained in the lower extremity or while the patient was agitated were excluded. Acute HTN was defined as systolic blood pressure (SBP) %/or diastolic blood pressure (DBP) ≥ 95th %tile for age/height at diagnosis & 1 month post diagnosis. Chronic HTN was defined as 2 consecutive SBP %/or DBP readings ≥ 95th %tile for age/height 6 months or more after ALL diagnosis.

Results: 222 patients were reviewed. The incidence of acute HTN was 35% & chronic HTN 34%. 52% of pts who had acute HTN developed chronic HTN, whereas 24% of pts who were normotensive in 1st month of diagnosis developed chronic HTN. There was an overall trend in increased HTN indices (subject's BP/subject-specific 95th %tile) from diagnosis to 1 month post diagnosis. Median HTN indices for SBP increased from 0.98 to 1.04 & for DBP increased from 0.91 to 1.00. A large percentage of hypertensive patients did not receive anti-HTN therapy - 55% with acute HTN & 76% with chronic HTN were untreated.

Conclusions: Among children with ALL, there is a high incidence of HTN at time of diagnosis & in long-term follow-up. There is an overall trend for higher blood pressures after initiation of induction chemotherapy. In children with ALL, HTN often goes undiagnosed & untreated & yet is likely to convey long term sequelae.

FR-PO1140

Left Ventricular Mass Index (LVMI) Improves with Resolution of Hypertension in Incident Pediatric Hemodialysis Patients

Shweta S. Shah,[1,2] Alisa A. Acosta,[1,2] Sarah J. Swartz,[1,2] Jessica Geer,[1] Marisa D. Juarez,[1] Poyyapakkam Srivaths.[1,2] *[1]Texas Children's Hospital, Houston, TX; [2]Baylor College of Medicine, Houston, TX.*

Background: Left ventricular hypertrophy (LVH), determined by increased left ventricular mass indexed for allometric height^ 2.7 (LVMI), is highly prevalent in children receiving chronic dialysis (CD). Natural history of LVH in pediatric (ped) CD patients (pts) is not well known; one study showed no change in LVMI after 6 months of starting CD. We have shown LVMI improves with control of HTN in CD patients. For this study, the aim was to investigate the relationship of fluid overload (FO) and HTN with LVMI in incident HD patients.

Methods: Retrospective chart review from a single center to identify pts starting HD from 2012-2017. Pts with echocardiogram (ECHO) within 3 months of starting HD and repeat ECHO in 6-12 months while continuing HD were included. Pts were excluded if follow up ECHO was not available or pts initiated CD at another center and initial ECHO not available. Charts reviewed for demographics, relevant labs, hypertension (HTN) defined by treatment with antihypertensive meds; FO as identified by % above dry wt; LVMI was converted to percentiles based on published normative values for age and gender.

Results: 43 pts (22 male), mean age 13.1 (range 3-17.41 years); 38/43 pts who had HTN at HD initiation also had increased LVMI (96.6 ± 8.09%tile vs. 81.25 ± 12.5%tile). Mean LVMI from initiation decreased significantly on follow up ECHO (initiation 94.7 ± 9.94 %tile vs. 81.13 ± 24.8%tile, p= 0.0006), independent of age or gender. Those who had resolution of HTN had improved LVMI, while those with continued HTN did not improve LVMI (Table). Pts in our study had only minimal FO over the 6-12 month period: (3.6 ± 1.2 %, range 1.25% -6.54%). FO was not associated with LVMI change (mixed effects model p=0.2). Hgb, phosphorus, calcium or PTH were also not associated with LVMI change.

Conclusions: Ped HD pts with HTN at initiation had elevated LVMI. LVMI improved significantly within 6-12 months of HD initiation. Hypertension resolution was associated

with improvement of LVMI. In our population of pts with tight fluid control, FO was not associated with change in LVMI.

43 patients total	HTN resolved*(26)	HTN persisted** (17)
LVMI%tile at start	95 ± 9.4	96±10.7
LVMI%tile after 6-12 months	79 ± 26.6	90 ± 17.2

*p=0.003, ** NS; paired t test

FR-PO1141

Left-Ventricular Hypertrophy and Diastolic Dysfunction in Korean Children with CKD: Data from the KNOW-Ped CKD Study

Yeonhee Lee,[1] Heeyeon Cho,[1] Hyun Jin Choi,[2] Hee Gyung Kang,[2] IL-Soo Ha,[2] Hae Il Cheong,[2] Kyoung Hee Han,[3] Seong heon Kim,[4] Min Hyun Cho,[5] Jae Il Shin,[6] Hyesun Hyun,[7] Joo Hoon Lee,[8] Young seo Park.[8] *[1]Pediatrics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [2]Pediatrics, Seoul National University Children's Hospital, Seoul, Republic of Korea; [3]Pediatrics, Jeju National University School of Medicine, Jeju, Republic of Korea; [4]Pediatrics, Pusan National University Children's Hospital, Yangsan, Republic of Korea; [5]Pediatrics, Kyungpook National University Hospital, Daegu, Republic of Korea; [6]Pediatrics, Yonsei University College of Medicine, Seoul, Republic of Korea; [7]Pediatrics, St. Vincent's Hospital, The Catholic University College of Medicine, Suwon, Republic of Korea; [8]Pediatrics, Asan Medical Center, Seoul, Republic of Korea*.

Background: Left-ventricular (LV) hypertrophy (LVH) and LV diastolic dysfunction are early marker of cardiovascular disease in pediatric chronic kidney disease (CKD), and the early detection of LVH is important to prevent morbidity and mortality in children with CKD. However, there is no consensus on the ideal method of defining LVH in pediatric CKD patients. The aim of this study was to evaluate the LVH measurement methods and the association the presence of LVH and LV diastolic dysfunction in Korean children with CKD.

Methods: We used the baseline data of the KoreaN cohort study for Outcome in patients With Pediatric Chronic Kidney Disease (KNOW-Ped CKD), a nationwide, 10-year, prospective, observational cohort study of pediatric CKD. A total 310 patients were included in the final analysis.

Results: The mean age of the patients was 10.3±5.2 years, and male to female ratio was 2.2:1. The mean value of LV mass index (LVMI) was 38.3g/m$^{2.7}$. The mean ejection fraction and fractional shortening was 66.8 and 36.6%, respectively. According to an LVH diagnosis by LVMI ≥ 38.6 g/m$^{2.7}$, 128 patients (41.3 %) were diagnosed with LVH. Using the z-score > 1.64 reference values, 19 patients (6.1 %) were diagnosed with LVH. According to the ratio of early/late diastolic myocardial velocity (E/A ratio < 0.9 or > 2.0), 101 patients (32.5 %) had diastolic dysfunction. Sixteen patients (6.4 %) were diagnosed as having diastolic dysfunction by mitral peak velocity of early filling to early diastolic mitral annular velocity (E/E' ratio > 15). Kappa coefficient showed a significant value of 0.076 between LVH by LVMI >38.6g/m$^{2.7}$ and diastolic dysfunction by E/E' ratio > 15. LVMI calculation for predicting E / E '> 15 by Youden's index method is 32.1g/m$^{2.7}$

Conclusions: The study suggests that the definition of LVH by LVMI ≥ 38.6 g/m$^{2.7}$ could be more associated with diastolic dysfunction according to E/E' > 15. Further investigation to find a better method of defining LVH to predict cardiac dysfunction in the children with CKD is necessary.

FR-PO1142

Secular Trends in Prevalence of Hypertension and Elevated Blood Pressure Among Korean Children and Adolescents: The Korea National Health and Nutrition Examination Survey 2007-2015

Yeonhee Lee,[1] Hyesun Hyun,[2] Heeyeon Cho.[1] *[1]Pediatrics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [2]Pediatrics, St. Vincent's Hospital, The Catholic University College of Medicine, Suwon, Republic of Korea*.

Background: Hypertension is an important health problem and the prevalence of hypertension in children and adolescents has been gradually increasing. We aimed to analysis the recent trends in blood pressure (BP) levels and the prevalence of hypertension among Korean children and adolescents. We also analyzed the potential contributing factors.

Methods: This study examines data obtained from the Korea National Health and Nutrition Examination Survey (KNHANES) 2007-2015 which were combined into 3 time periods (2007-2009, 2010-2012, and 2013-2015). The KNHANES is a nationally representative surveillance system, which has been conducted cross-sectionally since 1998 by the Korea Centers for Disease Control and Prevention and the Ministry of Health and Welfare. In the present study, a total of 7,889 Korean children and adolescents aged 10-18 years were included.

Results: The distributions of sex and age were not significantly different across 3 periods (2007-2009, 2010-2012, and 2013-2015). There were no significant changes in proportion of obesity and overweight from 2007-2009 to 2013-2015, while body mass index z-score significantly increased in total population from 2007-2009 to 2013-2015. Additionally, weight circumference and abdominal obesity were significantly increased from 2007-2009 to 2013-2015. For dietary factors, daily intake of calories, total fat, carbohydrate, protein and fiber increased, while daily intake of sodium decreased significantly. Mean systolic BP levels significantly increased from 2007-2009 to 2013-2015 in total population, while diastolic BP values did not increase in total population. In 2013-2015, the prevalence of elevated BP and hypertension were 8.8% and 9.0%, respectively. Compared to those in 2007-2009, the prevalence of elevated BP in 2013-2015 increased in total population, especially, boys, and obese subgroup. The prevalence of hypertension in obese group in 2013-2015 was 27.7%, which was significantly increased from 2007-2009 to 2013-2015. Regression analysis revealed the association between central obesity and diastolic BP. Girls were less likely to have hypertension than boys.

Conclusions: Mean systolic BP and the prevalence of elevated BP increased from 2007-2009 to 2013-2015. The possible influencing factor is obesity, and further analysis is necessary.

FR-PO1143

Association of Body Mass Index with CKD and Hypertension 4 Years After Pediatric Cardiac Surgery

Michael Zappitelli,[1] Chirag R. Parikh,[2] Jason H. Greenberg,[3] Paul L. Kimmel,[4] James S. Kaufman,[5] Prasad Devarajan.[6] ASSESS-AKI investigators *[1]Toronto Hospital for Sick Children, University of Toronto, Toronto, ON, Canada; [2]Yale University and VAMC, New Haven, CT; [3]Yale University, New Haven, CT; [4]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [5]VA New York Harbor Healthcare System, New York, NY; [6]Cincinnati Children's Hospital, Cincinnati, OH*.

Background: We previously found that children undergoing cardiac surgery (CS) are at high risk of developing chronic kidney disease (CKD) and hypertension (HTN); however, CKD was not associated with post-operative (postop) acute kidney injury. Hypothesis: Body mass index (BMI) and peri-operative factors are associated with long-term CKD and HTN development after pediatric CS (PedCS).

Methods: Prospective cohort study (Montreal, Canada; Cincinnati, USA). Subjects: <18 years(y) old having CS, recruited pre-operatively (preop) followed postop and serially for 4y. At 4y, clinical data, height/weight, blood pressure (BP), blood and urine were collected. **4y outcomes**: *CKD* (eGFR<90ml/min/1.73m^2) *or* albumin-to-creatinine ratio≥3 mg/mmol; *HTN*: BP≥95th percentile. Age at surgery <1y, RACHS-1 (surgical complexity score)≥3, preop eGFR, and 4y BMI z-score and overweight (OW, BMI≥85th percentile), were compared between outcome groups. 4y BMI association with CKD (adjusted for perioperative factors) was evaluated using multiple logistic regression (LR).

Results: 96/124 children had 4y data available: 24% had CKD; 13% had HTN; 22% were OW. Age<1y at surgery, RACHS-1≥3, smoking and OW were more common in CKD *vs.* no CKD patients(Table). No study variables were significantly associated with 4y HTN(Table). In multiple LR including age, RACHS-1 and preop eGFR, age<1y at surgery and each 10-unit decrease in preop eGFR were associated with a 5.9 (95% CI 1.8-18.6)-fold and 1.2 (95% CI 1.0-1.4)-fold adjusted risk for 4y CKD, respectively. When adjusted for age, RACHS-1 and preop eGFR, each 1 unit BMI z-score increase (at 4y) was associated with 1.5 (95% CI 1.0-2.2)-fold adjusted risk for 4y CKD. Sample size did not allow for LR analysis on HTN risk.

Conclusions: Young age at surgery and OW at follow-up are associated with CKD 4y after PedCS. Research is needed to understand the relation between young age and other risk factors for CKD development after PedCS. Post-PedCS interventions should aim to reduce long-term cardiovascular risk.

Funding: NIDDK Support

Table. Comparison of peri-operative characteristics and BMI between CKD *vs.* non-CKD and HTN *vs.* non-HTN groups

	No CKD n=67	CKD n=29	No HTN n=80	HTN n=12
Age at surgery<1	51%	79%*	58%	42%
RACHS-1 ≥3	49%	52%	44%	58%
Pre-operative eGFR (ml/min/1.73m^2)	125±40	115±39	127±40	110±34
Smoking reported	0	17%*	2.5%	8.3%
BMI z-score	0±1.2	0.8±2.0	0.1±1.2	-0.1±1.1
BMI ≥85th percentile (OW)	17%	38%*	23%	17%

* = p<0.05 for difference between outcome groups.

Diacylglycerol Kinase Epsilon (DGKE) Deficiency in Endothelial Cell Results in Marked Abnormalities in Phosphoinositides

Vincent So,[2] Christopher H. Choy,[3] Joanne Grimmer,[4] Roberto Botelho,[3] Alexis Traynor-Kaplan,[5] Mathieu Lemaire.[1] *[1]Nephrology/Cell Biology, Hospital for Sick Children, Toronto, ON, Canada; [2]University of Toronto, Hospital for Sick Children, Markham, ON, Canada; [3]Ryerson University, Toronto, ON, Canada; [4]Children's Hospital of Western Ontario, London, ON, Canada; [5]University of Washington, North Bend, WA*.

Background: Loss-of-function mutations in DGKE cause a rare form of atypical hemolytic-uremic syndrome (aHUS) that does not implicate complement hyperactivation. Patients are typically diagnosed before age 1, have disease relapses until age 5 and develop end-stage kidney disease before adulthood. There is currently no treatment, but renal transplantation is safe. Diacylglycerol (DAG) is produced when phosphatidylinositol

4,5-bisphosphate (PIP_2) is cleaved by phospholipase C. DGKE is a lipid kinase that phosphorylates DAG to phosphatidic acid (PA). When produced, PA is shuttled to the endoplasmic reticulum where it is used to reconstitute the pool of PIP_2 (as part of the PI cycle). The consequences of DGKE deficiency in human endothelial cells are unknown. A better understanding of DGKE disease pathophysiology is critical to developing new therapies for these patients. Our objective is to quantify the impact of DGKE deficiency in endothelia on membrane lipids that play key roles in DGKE biology, including diacylglycerol, phosphatidic acid and phosphoinositides.

Methods: We used orthogonal methods to compare the lipid levels in wild-type and DGKE-deficient endothelial cells derived from human vein endothelial cells (HUVEC) with a CRISPR/Cas9-engineered deletion in the DGKE gene. These methods included mass spectrometry lipidomics, cellular labelling with ^{3}H-inositol followed by high-performance liquid chromatography (HPLC), and live-tracking of transfected fluorescent-labelled PIP_2 biosensor. The novel mass spectrometry lipidomics approach that we developed was also applied to an endothelial cell line derived from a patient with novel pathogenic DGKE mutations (c.A494G; p.D165G) and glomeruli extracted from the kidneys of a new Dgke-null mouse model (generated with CRISPR/Cas9).

Results: Mass spectrometry lipidomics revealed significant PIP_2 reduction in DGKE-null HUVEC. These results were corroborated using the same protocol applied to a patient-derived endothelial cell line and glomeruli from Dgke-null mice. ^{3}H-inositol labelling and fluorescent lipid biosensor experiments confirmed a significant reduction in PIP_2 in DGKE-deficient HUVEC.

Conclusions: Low endothelial PIP_2 levels is likely to play a central role in the triggering the pro-thrombotic phenotype observed in patients with DGKE aHUS.

Child and Parental Perspectives on Communication and Decision-Making in Pediatric CKD: A Focus Group Study

Talia M. Gutman,[2,1] Camilla S. Hanson,[2,1] Sarah Bernays,[2] Jonathan C. Craig,[1,3] Allison Tong.[2,1] SONG-Kids Investigators and SONG-Kids Steering Group *[1]Centre for Kidney Research, The Children's Hospital at Westmead, Bondi Junction, NSW, Australia; [2]School of Public Health, The University of Sydney, Sydney, NSW, Australia; [3]College of Medicine and Public Health, Flinders University, Adelaide, SA, Australia.*

Background: Effective communication and shared decision-making improves quality of care and patient outcomes, but can be particularly challenging in pediatric chronic disease as children depend on their parents and clinicians to manage complex healthcare and developmental needs. This study aims to describe the perspectives of children with chronic kidney disease (CKD) and their parents with regard to communication and decision-making.

Methods: Children with CKD (n=34) and parents (n=62) from six centers across six cities in Australia, Canada and the United States participated in 16 focus groups. Transcripts were analyzed thematically.

Results: We identified four themes: (1) disempowered by knowledge imbalance (unprepared and ill-informed, suspicion of censorship, inadequacy as technicians); (2) recognizing own expertise (intuition and instinct unique to parental bond, emerging wisdom and confidence, identifying opportunities for control and inclusion, empowering participation in children); (3) striving to assert own priorities (negotiating broader life impacts, choosing to defer decisional burden, overprotected and overruled, struggling to voice own preferences); and (4) managing child's involvement (respecting child's expertise, attributing 'risky' behaviors to rebellion, protecting children from illness burden).

Conclusions: Parents value partnership with clinicians and consider long-term and quality of life implications of their child's illness. Children with CKD want more involvement in treatment decision-making but are limited by vulnerability, fear, and uncertainty. There is a need to support the child to better enable them to become partners in decision-making and prepare them for adulthood. Collaborative and informed decision-making that addresses the priorities and concerns of both children and parents is needed.

FR-PO1146

Timing of Dialysis Education and Patients' and Families' Preferences in Children with CKD

Julien Hogan,[1] Runze Li,[1] Michael Arenson,[1] Rachel E. Patzer,[2] Larry A. Greenbaum.[1] *[1]Emory University, Atlanta, GA; [2]Emory Transplant Center, Atlanta, GA.*

Background: There is no strong evidence favoring PD or HD in children; it is recommended that patients actively participate in the choice of dialysis modality. The first step for including patients in the decision-making process is to provide them with information on dialysis modalities. However, there is currently limited data on the timing of RRT education in children with CKD and on families' and patients' preferences.

Methods: The CKiD study is a prospective cohort study that enrolled patients 1–16 yrs with an eGFR of 30–90 mL/minute/1.73 m^2. Clinical data and laboratory data are collected annually. Patients and families are asked at baseline and annually about the information received on dialysis modalities and their preferred dialysis modality. Logistic regression was used to study factors associated with education status.

Results: 240/370 patients reported not having received any information on RRT prior to inclusion in the cohort. Patients informed at baseline were more likely to have advanced CKD; there was a trend toward a lower probability of information in African American patients or if no family history of CKD. There was no association between CKD duration and the probability of information on RRT. Among the 94 patients who discussed dialysis with their provider during follow-up, 69 (73%) had no preference between PD and HD. Among them, 22 had repeated assessment of their preference; 5 decided on HD, 3 on PD. CKD progression was the only factor associated with change in modality preference. 118 patients discussed transplantation with their provider during follow-up; 23 discussed only deceased donor transplantation, 3 only living donor, 22 both options and 70 reported not being informed of donor sources.

Conclusions: Patient and family self-reported prevalence of education on RRT is low. Starting education on RRT at earlier CKD stages and focusing on populations reporting a low level of information such as African American patients and patients with no familial history of kidney disease may improve education rates. Moreover, the extremely low rate of selecting a dialysis modality is very concerning and could lead to less thoughtful decision-making when patients approach ESRD. Further studies are needed to develop educational interventions and assess their ability to help the patients and families choose their dialysis modality.

FR-PO1147

Sex and Glomerular Filtration Rate Trajectories: Insights from the CKiD Cohort Study

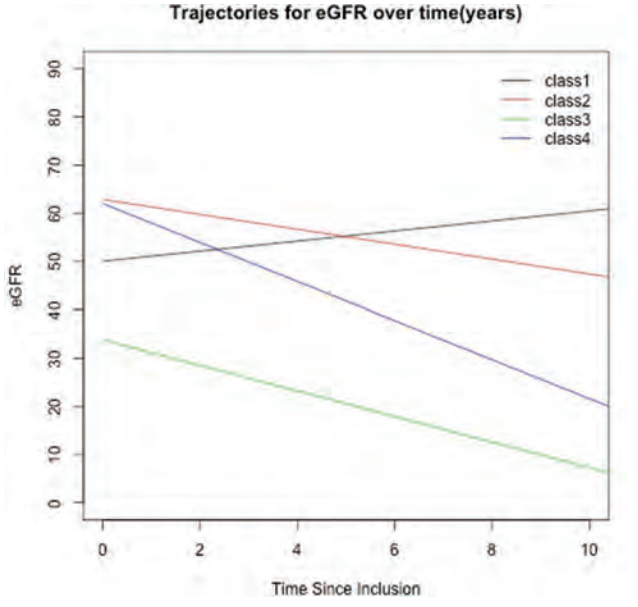
Julien Hogan,[1] Geeta Karadkhele,[1] Stéphanie Bonneric,[2] Rachel E. Patzer,[1] Larry A. Greenbaum.[1] *[1]Emory University, Atlanta, GA; [2]Hôpital Robert Debré, Paris, France.*

Background: The effect of gender on CKD progression has not been specifically studied in children. Moreover, differences in CKD progression have been hypothesized to partially explain gender disparities in access to transplantation. This study aims to identify distinct trajectories of GFR decline and to investigate the effect of gender on GFR decline.

Methods: The CKiD study is a prospective cohort study that enrolled patients 1–16 yrs with an eGFR of 30–90 mL/minute/1.73 m^2. Clinical and laboratory data, including GFR, are collected annually. Latent class mixed model was used to identify GFR trajectories. Multinomial logistic regression was used to study patient characteristics associated with each trajectory.

Results: 888 patients were included. Among nonglomerular patients (613), we observed 4 GFR trajectories: 35 with median baseline GFR/no decline; 327 with high baseline GFR/slow decline; 231 with low baseline GFR/slow decline and 20 with high baseline GFR/rapid decline (Figure 1, class 1 to 4 respectively). Known risk factors of progression differed between trajectories. The proportion of girls was higher in the group with stable GFR (57%) than in other groups (32-35%). Patients with stable GFR had lower prevalence of acidosis, anemia and proteinuria. Female gender remained associated with the absence of progression (OR 2.7 [1.3-5.5]) after adjusting for other risk factors. This effect remained after stratification on pubertal status. Among glomerular patients (275), progression was mostly related to the underlying glomerulopathy.

Conclusions: The slower progression in girls is driven by a subgroup with nonglomerular diseases and stable GFR. The effect of gender seems independent of pubertal status, arguing against a direct effect of sex hormone to explain gender disparity in CKD progression.



FR-PO1148

Impact of Chronic Illness in Children on Families: Kidney Disease (KD) versus Diabetes Mellitus (DM)

Howard Trachtman,[1] Laura Malaga-Dieguez,[1] Suzanne M. Vento,[2] Laura Jane Pehrson,[1] Sandra L. Rodgin,[1] Hayley Y. Adkisson,[1] Lara Brodzinsky,[1] Rebecca Lois,[1] Jeniece Ilkowitz,[1] Mary P. Gallagher.[1] *[1]NYU Langone Health, New York, NY; [2]NYU Langone Health, New York, NY.*

Background: Chronic illness in children has adverse effects on family members besides the patient and can impact the integrity and function of the family unit. Most previous studies have examined a single disease entity. However, there has been limited assessment comparing the effect of different illnesses on family function.

Methods: Established patients treated in the pediatric ambulatory Nephrology or DM clinics were included in the study. Their parents were asked to complete the 2-page Pediatric Quality-of-Life Family Impact Module (PedsQL-FIM), version 2.0, a validated survey instrument. Clinical and laboratory data were retrieved from the electronic health record. Data were summarized as mean±SD. Disease group and child age were entered as predictors in linear regression analyses with FIM total and subscale scores as outcome variables. Comparisons between groups were assessed using paired t-tests.

Results: 96 patients (43 F: 53 M) were evaluated in the Nephrology Clinic and 55 (30 F: 25 M) in the DM Clinic. The mean age of the patients was 13.0±3.9 and 10.4± 6.3 yr, respectively. Within the KD sample, older age was significantly associated with lower scores on all FIM subscale scores. Gender was not a significant predicator for FIM scores in either disease group. Controlling for age, chronic illness group was a significant predictor of the FIM total and subscale scores. Parents of D patients endorsed significantly lower total FIM scores compared to the KD patients (D 58±16; KD 79±17 p <0.001) as well as on subscales of physical, emotional, social, and cognitive functioning, communication, worry, daily activities, family relationships, and reports of health-related quality of life (P<0.01).

Conclusions: Our findings confirm that chronic illness in childhood adversely affects a wide range of aspects of family function. The impact is greater in older children with KD and varies depending on the disease context. Families with children who have DM manifested greater disturbances than those with children who have isolated KD. Further study is warranted to assess the effects of the underlying renal disease and intensity of medical care and whether there are specific features can be used to identify vulnerable families.

Serum Soluble Urokinase-Type Plasminogen Activator Receptor (suPAR) Levels During Pregnancy

Howard Trachtman,[1] Suzanne M. Vento,[1] Joseph F. Gilbert,[1] Tony T. Koshy,[1] Yelena Afanasyeva,[1] David C. Wei,[3] Jochen Reiser,[2] Leonardo Trasande.[1] *[1]NYU Langone Health, New York, NY; [2]Rush University Medical Center, Chicago, IL; [3]Rush University, Chicago, IL.*

Background: suPAR is an inflammatory mediator that has been linked to the pathogenesis of FSGS and progression of chronic kidney disease in children and adults. Overexpression of suPAR leads to reduced nephron development in preclinical models. This study was designed to measure suPAR in pregnant women to determine the range of fetal exposure to this molecule and its potential influence on antenatal human kidney growth.

Methods: Pregnant women enrolled in the Children's Health and Environment Study (CHES) provided serum samples obtaining during 1-3 trimesters. Clinical information was obtained from the electronic health record. suPAR levels were determined by ELISA (Virogates, Copenhagen, Denmark). Data are presented as mean±SD. Results were analyzed by Pearson correlation and ANOVA.

Results: 515 mothers were studied, age 31±6 yr, and racial distribution 44% Caucasian, 7% African American, 9 % Asian, and 41% other/unspecified. 46% of the women were Hispanic. 29% had completed a high school education or less and 28% had an annual income <$50,000. There were 464 livebirths, 50.4% girls. The serum suPAR levels (mean, SD, minimum, maximum) are summarized in the Table. The suPAR levels in the subgroup of women who provided more than one sample during pregnancy were closely correlated (r=0.79-0.94, P<0.0001)). The decline in serum suPAR levels from trimester 1 to 3 was highly significant (P<0.001).

Conclusions: Maternal suPAR levels are detectable throughout pregnancy but decline from trimester 1 to 3. The levels are highly correlated and steady during the course of pregnancy in an individual woman. There is more than a 10-fold range in suPAR concentration which may contribute to the biological variation in nephron number at birth. Follow-up assessment in the infants will be performed in the prospective Environmental Influences on Child Health Outcomes (ECHO) cohort study.

Funding: NIDDK Support

Serum suPAR :Levels During Pregnancy

Establishing an Organisational Entity to Support Development of Therapeutics in Children with CKD: A KHI Initiative

Michelle N. Rheault,[1] H. William Schnaper,[8] Pam Duquette,[7] Debbie S. Gipson,[2] Teresa Lewis,[9] Alicia Neu,[10] Franz S. Schaefer,[3] Melissa West,[4] Johan Vande walle,[5] Stuart Goldstein,[6] Katrin Uhlig.[11] *[1]University of Minnesota, Minneapolis, MN; [2]University of Michigan Mott Children's Hospital, Ann Arbor, MI; [3]University of Heidelberg, Heidelberg, Germany; [4]American Society of Nephrology, Washington, DC; [5]UZGent, Gent, Belgium; [6]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [7]Nephcure Kidney International, Baltimore, MD; [8]Feinberg School of Medicine, Chicago, IL; [9]The University of Oklahoma Health Sciences, Oklahoma City, OK; [10]Johns Hopkins University School of Medicine, Baltimore, MD; [11]Keryx Biopharmaceuticals, Brookline, MA.*

Background: A Kidney Health Initiative (KHI) workgroup on 'Overcoming Barriers to Drug Development in Children with CKD' identified the need for more concerted and rational planning and conduct of clinical trials in children with CKD to address EMA and FDA regulatory requirement.

Methods: An Implementation Committee was charged to establish an organizational entity that will help optimize planning of therapeutic trials in children with CKD. Its charter addresses aims, guiding principles, composition of a standing Leadership Committee, committee operations, and funding.

Results: The aims of the new entity are to a) Enable feasibility assessment of available patient populations through data sharing and access to CKD pediatric registries b) Facilitate assessment of the capacity of various pediatric kidney clinical trial organizations c) Assist with identification of expertise that can provide consultation on study planning. To manage potential conflicts of interest, this entity needs to adhere to guiding principles regarding transparency, information sharing, international participation and collaboration, and financial independence, while respecting the rights and intellectual property of principal investigators, sponsors, and trial networks, and ensuring the confidentiality of proprietary information and protected patient information. The Leadership Committee will be comprised of representatives from pediatric collaborative trial networks, patient/family support groups and subject matter experts without industry sponsors. Operationally, industry sponsors will be able to submit queries and requests that will be reviewed, triaged, and addressed by the Leadership Committee. The Implementation Committee will draft a finance model, sustainability plan, and identify a permanent administrative home with a commitment to transparency, equity, and economy. In the interim, KHI will continue to support this entity.

Conclusions: This new entity will seek collaboration with other stakeholders to better support therapeutic development in children with CKD.

FR-PO1151

Risk Factors for Progression of CKD in Children: Results from the Korean Cohort Study for Outcome in Patients with Pediatric CKD (KNOW-Ped CKD)

Yo Han Ahn,[1] Hyun Jin Choi,[2] Kyoung Hee Han,[3] Seong heon Kim,[4] Heeyeon Cho,[5] Min Hyun Cho,[6] Jae Il Shin,[7] Joo Hoon Lee,[8] Hee Gyung Kang,[2] Young seo Park,[8] Hae Il Cheong,[2] IL-Soo Ha.[2] *[1]Department of Pediatrics, Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]Department of Pediatrics, Seoul National University Children's Hospital, Seoul, Republic of Korea; [3]Department of Pediatrics, Jeju National University School of Medicine, Jeju, Republic of Korea; [4]Department of Pediatrics, Pusan National University Children's Hospital, Yangsan, Republic of Korea; [5]Department of Pediatrics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [6]Department of Pediatrics, Kyungpook National University, School of Medicine, Daegu, Republic of Korea; [7]Department of Pediatrics, Yonsei University College of Medicine, Severance Children's Hospital, Seoul, Republic of Korea; [8]Department of Pediatrics, Asan Medical Center Children's Hospital, University of Ulsan College of Medicine, Seoul, Republic of Korea*.

Background: The prevalence of chronic kidney disease (CKD) has increased over the last decades. Several large studies of Western countries have reported risk factors of CKD progression in pediatric patients, while comprehensive studies on pediatric CKD are rare in Asian countries. We aimed to evaluate risk factors for the progression of CKD of Korea using KNOW-Ped CKD data.

Methods: In KNOW-PedCKD, 437 children with stage 1 to 5 of CKD were enrolled and 432 patients were followed more than 6 months between July 2011 and May 2017. The progression of CKD was defined as a composite renal event of renal replacement therapy or a ≥50% decline in estimated glomerular filtration rate. The baseline clinical and laboratory variables were analyzed.

Results: The progression of CKD occurred in 136 (31.4%) patients after median follow ups of 1.9 (IQR 0.7-3.2) years. In Kaplan-Meier analysis, the median renal survival of all analyzed CKD patients was estimated as 5.2 years. In multivariate analysis, after adjustment with Cox regression model, 6 variables remained as independent risk factors of CKD progression: male sex, CKD stage 4 and 5, hypertension, urine protein/creatinine ratio ≥0.5 mg/mg, serum albumin <3.8 mg/dL, and anemia. Among them, proteinuria, hypoalbuminemia, hypertension and anemia could be modifiable and treatable, in accordance to previous findings in the Western studies.

Conclusions: In KNOW-pedCKD cohort, risk factors for CKD progression in Korean pediatric patients were found, including modifiable factors. Applying these findings to the clinic might improve the outcome of pediatric CKD.

Funding: Government Support - Non-U.S.

Observational Descriptive Analysis from the Korean Pediatric CKD Registry

Yo Han Ahn,[1] Hyun Jin Choi,[2] KyungMi Jang,[3] Eun mi Yang,[4] Kyoung Hee Han,[5] Seong heon Kim,[6] Jin-Soon Suh,[7] Heeyeon Cho,[8] Min Hyun Cho,[9] Jae Il Shin,[10] Joo Hoon Lee,[11] Hee Gyung Kang,[2] Meekyung Namgoong,[12] Young seo Park,[11] Hae Il Cheong,[2] IL-Soo Ha.[2] *[1]Department of Pediatrics, Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]Department of Pediatrics, Seoul National University Children's Hospital, Seoul, Republic of Korea; [3]Department of Pediatrics, Yeungnam University School of Medicine and Yeungnam University hospital, Daegu, Republic of Korea; [4]Department of Pediatrics, Chonnam National University Medical School, Gwangju, Republic of Korea; [5]Department of Pediatrics, Jeju National University School of Medicine, Jeju, Republic of Korea; [6]Department of Pediatrics, Pusan National University Children's Hospital, Yangsan, Republic of Korea; [7]Department of Pediatrics, Bucheon St.Mary's Hospital, Catholic University, Bucheon, Republic of Korea; [8]Department of Pediatrics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [9]Department of Pediatrics, Kyungpook National University, School of Medicine, Daegu, Republic of Korea; [10]Department of Pediatrics, Yonsei University College of Medicine, Severance Children's Hospital, Seoul, Republic of Korea; [11]Department of Pediatrics, Asan Medical Center Children's Hospital, University of Ulsan College of Medicine, Seoul, Republic of Korea; [12]Department of Pediatrics, Wonju Severance Christian Hospital, Wonju, Republic of Korea*.

Background: The prevalence of chronic kidney disease (CKD) has increased over the last decades. Nevertheless, there still are limited data on epidemiology of childhood CKD in Korea. To improve the understanding and management of Korean pediatric patients with CKD, we established the Korean Pediatric CKD Registry in 2004. We aimed to assess the incidence and prevalence of end stage renal disease (ESRD), etiology, renal replacement therapy (RRT) modalities in children with CKD.

Methods: From January 2004 to December 2016, 713 patients <20 years of age with CKD have been registered in the Korean Pediatric CKD Registry. Demographic and clinical data were collected from 16 centers. Updating of the data was done at least once a year. We analyzed patients who started RRT before the age of 20 years.

Results: Among 713 enrolled patients, 442 patents developed end stage renal disease at mean age of 9.8±5.4 years. The age distribution was as follows: <5 years 21.0%, 5-9 years 27.1%, 10-14 years 33.0%, and 18.8% were >15 years. The main causes of ESRD were glomerulopathy (40.7%) and congenital anomalies of kidney and urinary tract (CAKUT, 24.8%). Glomerulopathy predominated in females, while CAKUT was the majority among males. The annual incidence of ESRD had increased from 1.75 per million age-related populations (pmarp) in 2004 to 2.58 pmarp in 2016. The point prevalence of ESRD was 2.38 pmarp in 2004, and 4.67 pmarp in 2016. The first modality of RRT was peritoneal dialysis in 240 (54.3%), hemodialysis in 118 (26.7%), and preemptive kidney transplantation in 84 (19.0%) patients. Pre-emptive kidney transplantation was more common in older age group (5.1% in age of 0 to <5 years and 28.9% in age of 15 to <20 years).

Conclusions: This study provided the epidemiologic profile of Korean pediatric patients with ESRD. The number of pediatric patients with ESRD had steadily increased. Peritoneal dialysis was the preferred method of RRT for children in Korea.

FR-PO1153

Longitudinal Measures of Serum Bicarbonate and Kidney Disease Progression: Results from the CKiD Cohort

Denver D. Brown,[1] Kimberly J. Reidy,[2] Jennifer Roem,[3] Derek Ng,[3] Juhi Kumar,[4] Matthew K. Abramowitz,[9] Susan L. Furth,[5] George J. Schwartz,[6] Bradley A. Warady,[7] Frederick J. Kaskel,[8] Michal L. Melamed.[9] *[1]The Childrens Hospital at Montefiore, Bronx, NY; [2]Children's Hospital at Montefiore/ Albert Einstein College of Medicine, Bronxville, NY; [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [4]Weill Cornell Medical College, New York, NY; [5]The Children's Hospital of Philadelphia, Philadelphia, PA; [6]University of Rochester, Rochester, NY; [7]Children's Mercy Kansas City, Kansas City, MO; [8]Children's Hospital at Montefiore, Bronx, NY; [9]Albert Einstein College of Medicine, Bronx, NY*.

Background: Acidosis is a frequent complication of pediatric CKD; however, the longitudinal changes of serum bicarbonate over time in glomerular and non-glomerular kidney disease has not been examined.

Methods: This study consisted of 787 children with at least two serum bicarbonate measurements in the CKiD cohort. To describe baseline bicarbonate levels and changes over time, linear mixed models with random intercepts were fit with bicarbonate in the log scale. The relationship between bicarbonate and eGFR was described using a repeated measures linear regression with generalized estimating equations. All analyses were stratified by underlying non-glomerular and glomerular diagnoses.

Results: 558 children with non-glomerular CKD contributed 3325 visits, and 229 with a glomerular diagnosis contributed 1050 visits. The prevalence of acidosis (serum bicarbonate <22 mmol/L) at baseline was 38% and 28% for those with a non-glomerular and glomerular diagnosis, respectively (p= 0.01). The prevalence of alkali therapy at baseline was 30% and 8%, respectively. For those with non-glomerular disease, the mean baseline bicarbonate level was 23.1 mmol/L (95%CI: 22.9, 23.3) and the mean change per year was +0.1% (95%CI: -0.1%, +0.3%). Among those with glomerular disease, the mean baseline bicarbonate level was 24.0 mmol/L (95%CI: 23.6, 24.4) and the mean change per year was -0.4% (95%CI: -0.7%, -0.003%), indicating a significant reduction over time. Per 20% decrease in eGFR, those with non-glomerular CKD had a decrease of -2.39% (-2.79% to -1.99%) while children with glomerular disease had a -3.23% decrease (-3.72% to -2.74%) in their bicarbonate levels (p=0.01 for the comparison). Baseline acidosis was associated with a faster decline in eGFR (-6.0% [-12.8% to -1.0%] vs. -2.9% [-6.8% to -0.4%], p<0.001) in non-glomerular CKD but not in glomerular CKD (-4.8% [-14.9% to 0.3%] vs. -6.0% [-14.0% to -1.4%]).

Conclusions: In non-glomerular CKD, bicarbonate levels start lower but do not decrease as rapidly as in children with glomerular CKD. However, low baseline bicarbonate levels are associated with a faster decline in eGFR only in those children with non-glomerular CKD. Future data will assess whether these relationships may be attenuated by effective alkali therapy.

FR-PO1154

Primary Care Prescriptions of Nephrotoxic Medications to Children with CKD

Claire Lefebvre,[1] Kristian B. Filion,[4] Pauline Reynier,[3] Robert Platt,[1] Michael Zappitelli.[2] *[1]McGill University, Montreal, QC, Canada; [2]Toronto Hospital for Sick Children, University of Toronto, Toronto, ON, Canada; [3]Lady davis institute, Montreal, QC, Canada; [4]McGill University, Montreal, QC, Canada*.

Background: Nephrotoxic medication (NTM) prescription practices for children with chronic kidney disease (CKD) are unknown. Our objective was to determine if primary care prescriptions of NTMs differ for children with and without CKD.

Methods: We conducted a retrospective, population-based, matched cohort study of patients aged <18 years registered at a general practice participating in the UK Clinical Practice Research Datalink (CPRD) from 1997 to 2017, with linkage to Hospital Episode Statistics data. Patients with incident CKD were matched 4:1 to non-CKD patients on CKD diagnosis date, sex, age, CPRD practice, and number of pre-cohort entry physician visits.

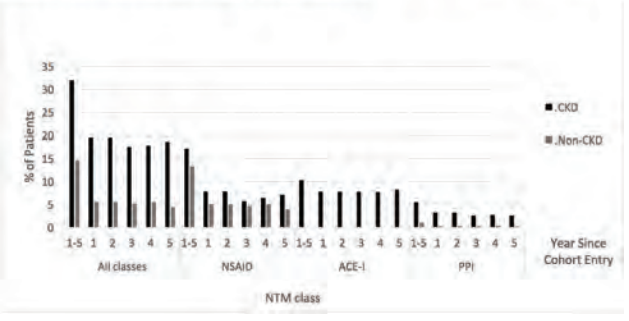
Prevalence of prescription of NTM was compared between CKD and non-CKD patients, with adjusted prescription rates calculated using multivariable binomial regression.

Results: From our base cohort of 1,535,816 patients, we identified 1018 with incident CKD and 4072 non-CKD matches; mean age: 9.8 years [range: 1.1-17.9]; 52% male; mean follow-up time 3.2 vs. 3.3 years in CKD *vs.* non-CKD patients. CKD patients had higher prevalences of diabetes, hypertension, heart failure/surgery, and past hospitalizations (p<0.01 for all). A total of 32% CKD patients and 14.6% non-CKD patients were prescribed ≥1 NTM during follow-up (p<0.01). Excluding ACE-inhibitors and salicylates, 25.8% and 14.5% were prescribed ≥1 NTM, respectively. From cohort entry to end of follow-up, the proportion of CKD patients receiving ≥1 NTM remained similar (17.6%-19.5%/year). Adjusted NTM prescription rates in CKD *vs.* non-CKD patients were 37.0 (95% CI 19.4-70.6) *vs.* 3.7 (95% CI 2.1-6.6) prescriptions/100 person-years, respectively (rate ratio [RR]: 9.9 (95% CI 7.3-13.4). Excluding ACE inhibitors and salicylates, the adjusted RR was 4.1 (95% CI 2.1-6.6).

Conclusions: NTMs are prescribed at elevated rates to children with CKD. There may be a need for awareness/education interventions aimed at primary care practitioners on potential harm from NTMs on pediatric CKD progression.

Funding: Government Support - Non-U.S.

Figure 1: Proportion of Patients who Received ≥1 Nephrotoxic Medications (NTM) During Entire 5-Year Follow-up and by Each Year of Follow-Up



FR-PO1155

Long-Term Safety of Cinacalcet in Pediatric CKD Subjects on Dialysis

Bradley A. Warady,[2] Sunfa Cheng,[1] Fei Wang,[1] William W. Stark,[1] Karel Vondrak.[3] *[1]Amgen INC, Newbury Park, CA; [2]Children's Mercy Kansas City, Kansas City, MO; [3]University Hospital Prague-Motol, Prague 5, Czechia.*

Background: The calcimimetic cinacalcet is indicated for treatment (tx) of secondary hyperparathyroidism in adults with CKD on dialysis. Its use was evaluated in pediatric CKD subjects (subj) on dialysis in 2 parent trials: NCT01439867 (single arm; age 28d-<6y) and NCT02138838 (open-label; cinacalcet vs standard of care [SOC]; age 6-<18y). This phase 3, single-arm, open-label extension evaluated cinacalcet use in subj who completed the parent trials or were still on study at early parent trial termination.

Methods: This 32-week (W) (28 tx+4 follow-up) study assessed the safety of cinacalcet based on incidence of tx-emergent adverse events (TEAE) of interest (primary endpoint [EP]). Secondary EP included ≥30% mean iPTH reduction during W11+15 and 23+28, % mean iPTH change during W23+28 (each assessed only in SOC subj in NCT02138838), and ≥30% mean iPTH reduction and change in serum Ca and P during W23+28 (all subj). Cinacalcet subj in the parent study continued the same dose; SOC subj had iPTH ≥300pg/mL and Ca ≥8.8mg/dL, and received initial doses of 0.2mg/kg/d. Cinacalcet was titrated (up to 2.5mg/kg/d; ≤60mg/d [age <6y] or ≤180mg/d [age ≥6y]) to PTH ≥150-<300pg/mL and to maintain corrected Ca ≥8.4mg/dL or ionized Ca ≥1.05mmol/L for subj 6-<18y, and ≥9.0mg/dL or ionized Ca ≥1.13mmol/L for subj <2y.

Results: Of 28 enrolled subj, 5 discontinued tx due to renal transplant (n=2), parathyroidectomy, death unrelated to tx, and subj request (n=1 each). Mean (SD) age and cinacalcet exposure were 12.6 (3.9) y and 170 (52) d. 10 (40%) (W11-15) and 4 (18%) (W23-28) subj had ≥20% of doses withheld. 20 (71.4%) subj had ≥1 TEAE, most commonly hypocalcemia and pyrexia (n=3 each). Incidence of TEAE of interest were: hypocalcemia (n=5,17.9%), nervous system disorders excluding seizures (n=4,14.3%), hypersensitivity (n=2,7.1%), drug-related hepatic disorders, and fracture (n=1,3.6% each); none deemed serious. The proportion achieving ≥30% iPTH decrease is below. Median (Q1,Q3) iPTH change (prior SOC only) at W23+28 was 11.4% (-20.6, 27.3). Overall W23+28 median (Q1,Q3) serum Ca and P (mg/dL) change was -0.25 (-0.66, 0.10) and 0.06 (-0.94, 0.69).

Conclusions: There were no new/unexpected safety concerns in these pediatric CKD subj on dialysis.

Funding: Commercial Support - This study was funded by Amgen, Inc.

Response to Erythropoietin in Pediatric Patients with CKD: Insights from an In Vitro Bioassay

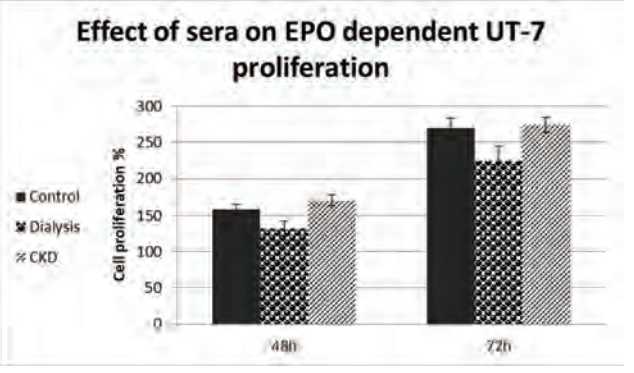
Rachel Gavish,[1] Salmas Watad,[1] Nathalie Bencalifa,[2] Ori J. Goldberg,[1] Orly Haskin,[3] Miriam Davidovits,[3] Gili Koren,[3] Yafa Falush,[3] Drorit Neumann,[2] Irit Krause.[1] *[1]Pediatrics C, Schneider Children's Medical Center of Israel, Petah Tikva, Israel; [2]Cell and Developmental Biology, Tel-Aviv University, Tel - Aviv, Israel; [3]Institute of Pediatric Nephrology, Schneider Children's Medical Center of Israel, Petah Tikva, Israel.*

Background: Decreased production of erythropoietin (EPO) is a major cause of anemia associated with chronic kidney disease (CKD). Treatment with recombinant human EPO (rHuEPO) improves patients' quality of life and survival, yet, there is a marked variability in response to rHuEPO. At present, there is no available laboratory test which can evaluate responsiveness to EPO treatment. The aim of the present study was to exploit an in vitro bioassay for estimating the inhibitory effect of uremic environment on EPO-dependent erythroid cell proliferation

Methods: EPO-dependent human erythroleukemia cells (UT-7) were incubated with exogenous EPO (2u/ml) and sera obtained from 60 pediatric patients (age 1-23 years). Three groups were studied: 1) 12 children on dialysis (4 peritoneal, 8 hemodialysis), 2) 28 patients with CKD1-5 (not on dialysis) and 3) 20 healthy children.

Results: Sera from dialysis patients inhibited UT-7 cell growth in comparison to the CKD group and healthy controls at 48 hours (p=0.003 and p=0.04, respectively) and at 72h (p=0.02 and p=0.07, respectively). In 18 patients treated with rHuEPO, a significant inverse correlation was found between the EPO resistance index and cell proliferation at 48 (p=0.007, r=-0.63) and 72 hours (p=0.03, r=-0.52).

Conclusions: Our findings support the presence of erythropoiesis inhibitory substances in uremic sera. EPO/EPO-R dependent mechanisms may play a role in inhibiting erythropoiesis. The in vitro bioassay described herein may serve as an indicator of rHuEPO responsiveness and enable further investigation of underlying mechanisms of EPO resistance



FR-PO1157

Ultrafiltration Rates Observed in a Large Pediatric Hemodialysis Cohort Routinely Exceed Weight Based Adult Limit: Call for Action

Verena Gotta,[1,2] Olivera Marsenic Couloures,[3] Marc Pfister.[4] *[1]Pediatric Pharmacology and Pharmacometrics, University of Basel Children's Hospital, Basel, Switzerland; [2]Hosptital Pharmacy, University Hospital Basel, Basel, Switzerland; [3]Pediatric Nephrology, Yale University School of Medicine, New Haven, CT; [4]Pediatric Pharmacology and Pharmacometrics, University of Basel Children's Hospital, Basel, Switzerland, Hilterfingen, Switzerland.*

Background: Ultrafiltration rates (UFR) in adult hemodialysis (HD) patients of >10 and especially >13 ml/kg/hr were found to be associated with greater risk of cardiovascular (CV) morbidity and mortality, leading to limiting UFR in adults to 13 ml/kg/hr. CV disease is the main cause of death in children on HD. Children have higher need for UF than adults to allow adequate nutrition and growth, but there is no data of UFR routinely provided to children. This is the first study to report UFR from a large pediatric HD cohort.

Methods: We retrospectively analyzed data from 17844 HD sessions in 1592 children and adolescents 1-18 years and weight (wt) 8.3-163 kg, receiving standard outpatient HD in DaVita centers between 2004 and 2016. There were total of 2535 patient-years with median 16 (interquartile range (IQR): 5-42) HD sessions per patient. Median UFR [ml/kg/hr; (preWt-postWt)/postWt/hr)] was calculated for each patient and year of age. HD was provided 3x/week for a duration of 1.75-5 (median 3.25, IQR: 3.0-3.6) hrs. UFR of >10 and >13 were analyzed in relation to age, weight and HD duration (Chi-squared/Fisher-exact test).

Results: UFR was significantly different between patients of different age and wt, and among patients receiving different HD duration (Table). UFR >10 and >13 ranged between 35-57% and 17-46% respectively based on age (P<0.05) while it was 14-62% and 1-43% respectively based on wt (P<0.001). Patients with highest UFR were 6-11 years old and weighed 25-50 kg. UFR >13 mL/kg/min remained similar (30-34%) for HD durations 93-210 min, but decreased to 27% and 18% for longer sessions of 211-240 and >240 min, respectively.

Conclusions: Pediatric UFR frequently exceed upper limit recommended for adults if HD lasts <4 hrs especially in children weighing 25-50 kg. Additional studies are needed to define pediatric-specific upper UFR limits that could decrease CV mortality. If lower UFR is found to be beneficial in children, a global change in chronic pediatric HD prescription will be required allowing longer and/or more frequent HD treatments.

Acquired Cystic Kidney Disease in Children and Young Adults Undergoing Dialysis

Myung hyun Cho,[1] Ji hyun Kim,[1] Hee Gyung Kang,[2] Hae Il Cheong,[2] IL-Soo Ha.[2]
[1]Seoul National university Children's hospital, Seoul, Republic of Korea; [2]Seoul National University Children's Hospital, Seoul, Republic of Korea.

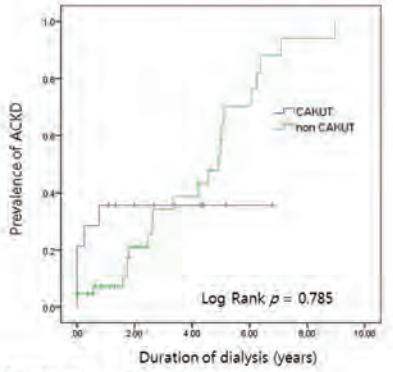
Background: Acquired cystic kidney disease (ACKD) describes bilateral cystic degeneration of the kidneys in patients who do not have cystic diseases. It is known as a common complication of end-stage renal disease (ESRD) in adults, however pediatric studies were scarce. We aimed to determine the prevalence, time of occurrence, and complications of ACKD in children and young adults undergoing dialysis.

Methods: We retrospectively reviewed the medical records of ESRD patients who were followed at Seoul National University Children's Hospital between January 2015 and April 2018. We enrolled a patient if he/she had taken kidney imaging of ultrasonography or computer tomography after initiating maintenance dialysis. Patients with hereditary cystic disease were excluded.

Results: A total of 64 patients (male : female = 40 : 24) were enrolled. Maintenance renal replacement therapy was required at their mean age of 9.3 ± 6.0 years old. Causes of ESRD were non-cystic congenital anomalies of the kidney and the urinary tract (CAKUT) in 14 (21.9%), non CAKUT (glomerulonephritis in 34, nephrotoxin induced nephropathy in 4, hyperoxaluria in 2, and so on) in 44 (68.8%), and unknown in 6 (9.4%). Forty seven (73.4%) patients were on peritoneal dialysis, 12 (18.8%) on hemodialysis, and 5 (7.8%) on both. ACKD was found in 32 (50.0%). ACKD was detected 3.0 ± 2.5 years after the start of dialysis. In non CAKUT, the prevalence of ACKD increased with duration of dialysis, however it was not significant in non-cystic CAKUT (Fig. 1). Four (non CAKUT in 3 and unknown etiology in 1) had serious complications of ACKD; two had renal cell carcinomas, and 2 experienced massive hemorrhage. Complications occurred 3.9 to 12.2 years after the start of dialysis.

Conclusions: ACKD complicates ESRD of children and young adults as well. Since ACKD may accompany serious complications such as malignancy and hemorrhage, routine surveillance is necessary in high risk patients on maintenance dialysis.

Kaplan-Meier curve comparing the prevalence of ACKD by ESRD etiolgy



FR-PO1159

Distribution of the Pediatric Refugee Population with Renal Replacement Therapy in Germany

Johanna Lemke,[2] Raphael Schild,[2] Lars Pape,[1] Jun Oh.[2] and Members of the German Society for Pediatric Nephrology (GPN) *[1]Hannover Medical School, Hannover, Germany; [2]Universtiy Childrens Hospital Hamburg Eppendorf, Hamburg, Germany.*

Background: In 2016, about 2 million people immigrated to the EU. With 1 million people Germany reported the largest number of immigrants, of which an estimated 300,000 were children. Data on prevalence and management of refugee patients with end-stage renal disease are rare. Numbers focusing on the pediatric cohort are not available. Our goal was to obtain information on the size and distribution of the pediatric refugee population with renal replacement therapy (RRT). In addition, we wanted to gain insights into the problems and challenges in the care of these patients.

Methods: We interviewed all pediatric dialysis centers in Germany about the number of pediatric refugee patients on RRT at the time of the survey. We also asked the number of patients from the most common countries of origin (Syria, Afghanistan and Iraq). Subjective problems and challenges in the care of this cohort should be listed.

Results: 86% of the centers indicated that they provide care to refugee children on RRT. A total of 69 refugee children were treated with RRT in the centers surveyed. 52/69 (75%) received dialysis therapy, 43 of which were on HD and 9 on PD. 17/69 children (25%) underwent RTx. 34/69 (46%) came from either Syria, Afghanistan or Iraq. In 2017 a total of 232 children were on dialysis in Germany, which makes the group of dialyzed refugee children account for approximately 22% of the total German pediatric dialysis population. With regard to the challenges in the care of these patients, difficulties in communication, non-compliance, administrative as well as psychosocial problems were most frequently mentioned. In summary, most centers indicated that the care of this group of patients presents their institution with great financial and logistical challenges.

Conclusions: Our survey shows that the majority of pediatric dialysis centers care for refugee children. The refugee population represents a large proportion of the total pediatric dialysis population in Germany. The challenges in treating these patients are complex and consume many personnel and logistical resources. To ensure holistic care for these children close cooperation between medical staff, dieticians, social workers, interpreters and psychologists is required. Interdisciplinary training should be established in the treating centers. The additional burden should be registered and compensated for by public authorities.

FR-PO1160

Serum Albumin and Hospitalization Among Pediatric Patients Who Started Dialysis Therapy

Yusuke Okuda,[1] Yoshitsugu Obi,[1] Elani Streja,[1] Marciana Laster,[2] Connie Rhee,[1] Craig B. Langman,[3] Stephanie M. Jernigan,[5] Isidro B. Salusky,[2] Francesca Tentori,[4] Martin J. Schreiber,[4] Steven M. Brunelli,[4] Kamyar Kalantar-Zadeh.[1]
[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, Orange, CA; [2]University of California Los Angeles, Los Angeles, CA; [3]Feinberg School of Medicine, Northwestern University, Chicago, IL; [4]DaVita Clinical Research, Denver, CO; [5]Emory University School of Medicine, Atlanta, GA.

Background: Hypoalbuminemia is a strong predictor of hospitalization in adult dialysis patients. However, there are scarce data on the association between serum albumin levels and hospitalization among pediatric patients new to dialysis therapy.

Methods: In a cohort of children (1–17 years) who received dialysis therapy at a large US dialysis organization during 2007–2011 and who had available data on serum albumin within 1 year following initiation of dialysis, we examined the association of serum albumin levels with hospitalization frequency and total hospitalization days using negative binomial regression models. Hospitalizations for transplantation were excluded.

Results: Among eligible patients, median (IQR) age was 14 (10–16) years and mean±SD baseline serum albumin level was 3.7±0.8 g/dL. There appeared to be a U-shaped association between serum albumin and hospitalization frequency; hospitalization rates (95% CI) were 2.7 (2.2–3.2), 1.9 (1.5–2.4), 1.6 (1.3–1.9), 2.7 (1.7–3.6) per patient-year among patients with serum albumin levels <3.5, 3.5 to <4.0, 4.0 to <4.5 and ≥4.5 g/dL, respectively. The case mix-adjusted incidence rate ratios (IRRs) (95% CI) were 1.63 (1.24–2.13), 1.32 (1.10–1.58), and 1.25 (1.06–1.49) at serum albumin level of 3.0, 3.5, and 4.5 g/dL, respectively (ref: 4.0 g/dL). Consistent trends were observed in hospitalization days [Figure].

Conclusions: Both high and low serum albumin levels were associated with hospitalization in children with ESRD on dialysis. Hospitalization for high serum albumin may be due to favorable or unfavorable status, such as access placement or dehydration, respectively.

FR-PO1161

Analysis of Survival of Low Weight Children (<15 kg) Undergoing Chronic Hemodialysis: Mortality and Risk Factors

Cristina Henriques,[1] Simone Vieira,[1] Shirlei Komi,[1] Maria fernanda C. Carvalho,[1] Paulo C. Koch nogueira.[2] *[1]Hospital Samaritano, Sao Paulo, Brazil; [2]UNIFESP, Sao Paulo, Brazil.*

Background: With the technological advances in hemodialysis, it is currently possible to offer this type of therapy to young and low weight children. Our objective is to analyze the survival of children undergoing hemodialysis and risk factors impacting mortality

Methods: Retrospective analysis of patients undergoing chronic hemodialysis between January 2015 and January 2018 was performed. The sample included 65 patients (14F and 51M) with median age at start of hemodialysis of 1.3 years (13 days - 9.6 years) and median follow-up of 536 days (54 days - 5.2 years). The most frequent etiology was CAKUT (63%) followed by Renal Dysplasia (8%). At study baseline, median weight was 8.1Kg (2.3kg-13.7kg), median Z-score for weight/age -3.94 and median Z-score for height/age -3.16. Enteral feeding was required in 32 patients via gastrostomy. In this sample, 30 patients had anuria and 43 patients had undergone peritoneal dialysis prior to hemodialysis. 61 patients were on daily hemodialysis (8 patients had 7 sessions/week) with 90-180 minute sessions according to individual needs. Vasoactive drugs to maintain adequate blood pressure for the procedure were required in 26 patients.

Results: Of the 65 patients, 30 (46%) were transplanted, 27 (42%) remained on HD and 8 (12%) died. The cumulative survival rate was 96% for 1-year, 86% for 2-year, 80% for 3-year and 70% for 5-year survival. Considering transplant as a concurrent event, the following factors had the greatest impact: a) Cardiopathy – presence associated with a 23 times greater probability of death (95%CI= 5 - 103; p<0.001) b) Anuria – presence associated with an 8 times greater probability of death (95%CI = 1 - 67; p=0.050) c) Z-score for height/age - every 1 SD increase in Z-score reduced chance of death by 46% (95%CI = 16% - 66%; p=0.006) d) Z-score for weight/age - every 1 SD increase in Z-score reduced chance of death by 56% (95%CI = 33% - 71%; p<0.001)

Conclusions: Hemodialysis is a viable therapy in low weight children awaiting kidney transplant. Survival rates found were similar to those reported in the literature. The presence of cardiopathy risk factor had the greatest impact on probability of death in the sample. The patients with highest survival rates were those with better nutritional status and residual renal function.

FR-PO1162

End-of-Life Care in Young Dialysis Patients

Robert N. Foley,[1] Donal J. Sexton,[2] Scott Reule.[3] *[1]University of Minnesota, Minneapolis, MN; [2]The Irish Longitudinal Study on Ageing (TILDA), Trinity College Dublin., Dublin, Ireland; [3]VA, Minneapolis, MN.*

Background: Although end-stage kidney disease in the young is often a progressive disorder with high mortality, end-of-life care in this population has not been well characterized. In particular, it is unknown whether end-of-life care has changed over time and whether racial and ethnic disparities are present.

Methods: We used United States Renal Data System files to examine these issues among patients dying on maintenance dialysis in the US at age 0-20 years, between 2000 and 2014 (N=1647).

Results: While the proportions that discontinued dialysis were similar in 2000-2006 and 2007-2014 (14.8% Vs. 17.9, *P*-Value 0.09), the proportions receiving hospice care (3.6% Vs. 12.8%, *P*-Value <0.001) and dying outside of hospital (25.1% Vs. 33.8%, *P*-Value <0.001) both rose. Dialysis discontinuation (20.6% in white Vs. 10.4% in African American, *P*-Value <0.001), hospice care (11.1% in white Vs. 3.9% in African American, *P*-Value <0.001) and non-hospital death (35.6% in white Vs. 23.7% in African American, *P*-Value <0.001) were less likely in decadents from minority populations than in those of non-Hispanic white race-ethnicity. Findings regarding temporal trends and racial disparities were similar when adjustment was made for age, sex, and race/ethnicity.

Conclusions: While end of life care has changed substantially over time, discontinuation of dialysis, hospice care and death outside of hospital remain exceptional in young patients dying on maintenance dialysis. In addition, substantial racial and ethnic disparities are present.

FR-PO1163

A Nephrology Transition Clinic in the Adult Care Setting: A Pilot Program

Laura Nishi,[1] Cybele Ghossein.[2] *[1]Nephrology/HTN, Northwestern Medicine, Chicago, IL; [2]Northwestern University- Feinberg School of Medicine, Chicago, IL.*

Background: Young adults (YA) with chronic illnesses transitioning care from pediatric to adult medical facilities face many obstacles. Pediatric care providers are mindful of barriers to a smooth transition and the importance of a formal transition process, while adult care providers are often unaware, leading to an inconsistent transition process in the adult care setting. Three years ago, Northwestern Medicine (NM) Nephrology implemented a pilot transition of care program for YA with renal disease transitioning from Lurie Children's Hospital to NM. We report here on our experiences.

Methods: Pediatric nephrology providers identified patients who they deemed ready to transition to adult providers. Prior to transition clinic, the adult multidisciplinary team, consisting of the nephrologist, physician assistant (PA), and social worker, reviewed patients with the pediatric team. The first appointment occurred at Lurie Children's Hospital, which is located across the street from NM. Subsequent visits were then held at NM. At the initial visit, the patient was seen by the PA, nephrologist and if deemed appropriate, the social worker. The transition team reviewed each patient bimonthly to determine if proper follow up including testing and appointments had occurred, and if not, the patient was contacted to arrange for these.

Results: A total of 69 patients were seen in a three year period. Of these, 6 patients have been lost to follow up. 5 patients were no longer able to be followed due to insurance changes. 2 patients were deemed not to require further nephrology follow up. 42 patients have followed up as instructed at NM. There are 9 patients who have pending follow ups. 4 patients started peritoneal dialysis and are thus are no longer cared for in the transition clinic. Finally, 1 patient started hemodialysis right away, was subsequently transplanted, and is now seen back in the transition clinic.

Conclusions: Based on our three year pilot experience, transition of care from pediatric to adult nephrology providers can be successfully facilitated with engagement of an adult nephrology team, close communication with a pediatric team, and a formal transition clinic protocol. In the future, we plan to continue this as a formal program in nephrology as well as extending it to other medical specialties within the NM system.

FR-PO1164

Evaluating Renal Outcomes in Adolescents Born Extremely Premature of the ELGAN (Extremely Low Gestational Age Newborn) Cohort

Keia Sanderson,[1] Emily H. Chang,[2] William A. Primack,[3] Michael O'Shea.[3] *[1]University of North Carolina Kidney Center, Chapel Hill, NC; [2]UNC Kidney Center, Chapel Hill, NC; [3]University of North Carolina, Chapel Hill, NC.*

Background: Premature birth is associated with decreased nephron number and an increased lifetime risk for chronic kidney disease (CKD). Yet there is lack of recommendation for renal follow up of children born prematurely. The aim of the study is to characterize the prevalence of macroalbuminuria, elevated blood pressure, and/or abnormal renal mass (predictors of CKD) in adolescents with a history of extremely premature birth.

Methods: We obtained 2 manual blood pressures, a random urinalysis, and sonographic measurements of kidney length and volume on 17 consecutively enrolled 15-year old children born at <28 weeks gestation of the UNC Extremely Low Gestational Age Newborns (ELGAN) cohort.

Results: Of the 17 currently enrolled participants, 65% were male, 53% were Caucasian (33%identified as Hispanic) and 47% were African-American. Their mean age was 15 years. Median blood pressure was 115/69 mmHg with 35% of the cohort demonstrating elevated mean blood pressures. Median urine albumin/creatinine ratio was 7.75µg/mg with 24% of the cohort demonstrating significant random macroalbuminuria (>30µg/mg). Sonographic measurements are listed in Table 1. Twenty-nine percent of participants demonstrated abnormal renal mass (18% right renal hypoplasia, 6% right renal hypertrophy, 6% left renal hypoplasia, 6% left renal hypertrophy). No gross renal anatomical abnormalities were seen via ultrasound.

Conclusions: Nearly half (47%) of adolescents in this extremely low gestational age cohort were found to have abnormal renal mass, macroalbuminuria, or elevated blood pressures. Enrollment is ongoing. This data suggests that renal follow up of children with a history of extremely premature birth should be considered.

Funding: Other NIH Support - KL2TR001109, National Institutes of Health, John Buse, MD, PhD (PI), North Carolina Translational & Clinical Sciences Institute, Scholar Project: Renal outcomes in children with a history of extreme prematurity. Role of first author: Post-Doctoral KL2 Scholar

Table 1: Sonographic Renal Measurements of Adolescents of the ELGAN cohort

	ELGAN Cohort	Normative Data
Mean Right Kidney Length(cm)	9.09 (+/-0.85)	9.2(+/-0.7)
Mean Right Body Surface Area related Kidney Volume (ml/m2)	61.82(+/-17.3)	45-85
Mean Left Kidney Length(cm)	9.47(+/-1.1)	9.9(+/-0.6)
Mean Left Body Surface Area related Kidney Volume (ml/m2)	67.77(+/-17.6)	45-85
Mean Total Kidney Volume (cm3)	219 (+/-78.5)	256.43(+/-14.58)

FR-PO1165

Incidence and Long-Term Outcomes of Neonatal Renal Vein Thrombosis in Ontario: A Population-Based Cohort Study

Allison C. Ouellette,[1] Liz Darling,[1] Glenda Babe,[2] Richard Perez,[3] Anthony K. Chan,[1] Rahul Chanchlani.[1] *[1]McMaster University, Hamilton, ON, Canada; [2]Institute for Clinical and Evaluative Sciences, Hamilton, ON, Canada; [3]ICES, Hamilton, Cabo Verde.*

Background: There is limited data at a population level on the burden and long-term outcomes of neonatal renal vein thrombosis (nRVT). We conducted a cohort study to determine the incidence and long-term outcomes including hypertension (HTN), chronic kidney disease (CKD), end-stage renal disease (ESRD) and mortality associated with nRVT during a period of 24 years.

Methods: Health administrative databases, housed at the Institute for Clinical Evaluative Sciences, were used to identify all neonates ≤28 days of age born in Ontario, Canada from 1992-2016 and compared all neonates with nRVT vs. the total neonatal population without nRVT. The primary outcome was the composite risk of long-term outcomes including CKD, ESRD (chronic dialysis or kidney transplant) and all-cause mortality. The secondary outcome was the long-term risk of HTN. Incidence rates (IR) were calculated and Cox proportional hazard models were fitted for all outcomes.

Results: The annual IR of nRVT in Ontario from 1992-2016 was 2.6 per 100,000 live births (total 85 cases from 3,001,637 live births). The median follow-up was 11 years in both cohorts. There was a male preponderance (64%) of nRVT. A greater proportion of nRVT vs. comparator cohort was premature (45% vs. 8%, Standardized Difference 0.92). After adjusting for confounders, patients with nRVT were at a 17-fold increased risk of CKD

or death (Hazard Ratio (HR) 16.9, 95% CI 12.3-23.2, p<.0001) and an 18-fold increased risk of HTN (HR 17.7, 95% CI 12.6-25.0, p<.0001) vs. the comparator cohort. None of the nRVT cohort developed ESRD.

Conclusions: Patients with nRVT remain at higher risk than the general neonatal population of long-tern morbidity and mortality, indicating the need for long-term follow-up.

Table 1: Incident rates and hazard ratios of adverse outcomes among patients with nRVT in Ontario from 1992-2016

Outcomes		Proportion of live births with outcome		Risk of adverse outcomes			
		nRVT Cohort n=85	Comparator Cohort n=3,001,552	Unadjusted HR	95% CI†	Adjusted HR*	95% CI†
Primary Outcome	CKD or Death	43%	0.7%	67.6	49.4 - 92.5	16.9	12.3 - 23.2
Secondary Outcome	HTN	39%	2%	30.0	21.3 - 42.2	17.7	12.6 - 25.0

† All outcomes were significant with p<0.0001

*Adjusted for sex, congenital heart disease, respiratory distress syndrome, sepsis, maternal preeclampsia or eclampsia, and maternal diabetes.

CKD, chronic kidney disease; HTN, hypertension; HR, hazard ratio; CI, confidence interval.

FR-PO1166

Common Clinical Markers Predict ESRD in Children with Obstructive Uropathy

Daryl J. Mcleod, Christina B. Ching, Yuri V. Sebastião, Kirk M. McHugh, Brian Becknell. *Nationwide Children's Hospital, Columbus, OH.*

Background: Obstructive uropathy (OU) is the leading cause of pediatric chronic kidney disease (CKD) and end stage renal disease (ESRD). Children who escape the newborn period with mild to moderate CKD continue to be at increased risk for progression, especially as they undergo pubertal changes. The predictive ability of clinical markers throughout childhood is poorly defined in OU.

Methods: Patients with OU were identified in the Chronic Kidney Disease in Children Study (CKiD), a prospective observational cohort of children with mild to moderate CKD. The primary outcome of interest was ESRD (Cases). OU patients who did not progress to ESRD during follow-up (Controls) were age matched to Cases. Glomerular Filtration Rate (GFR), urine (protein/Cr and microalbumin/Cr), and serum (CO_2, phosphate, albumin, and hemoglobin), were evaluated as predictor variables both at baseline and over time.

Results: Median age at baseline and outcome was 10 vs.16 years(y) respectively. Cases (n=27) and Controls (n=41) had significant differences in baseline GFR (36.9 vs. 53.5 ml/min/1.73m^2), urine protein/Cr (0.40 vs. 0.22) and microalbumin/Cr (0.58 vs. 0.03), and serum $C0_2$ (20 vs. 22 mmol/L) and hemoglobin (12.4 vs. 13.2 g/dL) respectively. GFR declined 3.07 ml/min/1.73m^2/y faster in Cases (p<.0001) (Figure). Urine protein/Cr and microalbumin/Cr declined 0.16/y and 0.11/y faster in Cases respectively (p≤0.001 for both). Serum phosphate increased 0.11 mg/dL/y and albumin and hemoglobin decreased 0.04 g/dL/y and 0.14 g/dL/y faster for Cases respectively (p<0.05 for all).

Conclusions: Baseline and longitudinal evaluation of clinical measures predicts ESRD in children with mild to moderate CKD from OU. Optimal cutoff values require further evaluation so that children identified at high risk can undergo closer surveillance that may allow changes in management to slow or halt progression.

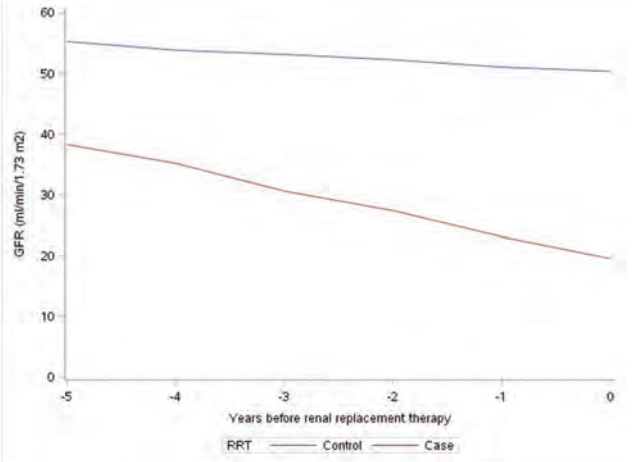

Figure. Estimated change in GFR over time in the CKiD OU cohort

FR-PO1167

Antibiotic Prophylaxis for Prevention of Urinary Tract Infections in the First Year of Life in Children with Vesicoureteral Reflux Diagnosed Following Antenatal Hydronephrosis: A Systematic Review

Jennifer Leigh,[1] Stephanie Sanger,[1] Jo-Anne Petropoulos,[1] Luis H. Braga,[2] Rahul Chanchlani.[1] *[1]McMaster University, Hamilton, ON, Canada; [2]Hamilton Health Science, Hamilton, ON, Canada.*

Background: Children with antenatal hydronephrosis (ANH) and vesicoureteral reflux (VUR) are presumed to be at higher risk of urinary tract infection (UTI) after birth. As such, continuous antibiotic prophylaxis (CAP) has been empirically recommended for newborns who have ANH and VUR to reduce the rate of UTI during the first year of life, however, there is limited data to support this practice. The objective of this systematic review was to determine whether CAP prevents UTI within the 1st year of life in children with VUR diagnosed in the workup of ANH.

Methods: A systematic search of all relevant studies was conducted using 4 electronic (Medline, Embase, CINAHL, and CENTRAL) databases using appropriate key words without language restriction by an expert librarian. A time limit of January 1985 to May 2017 was applied. Eligible studies included children with VUR diagnosed in the workup of ANH with or without antibiotic prophylaxis, and reported development of UTI. Two independent reviewers performed title and abstract screening and full-text review. Primary outcome was to compare rate of UTI among those on CAP to those not on CAP.

Results: Of 6903 citations screened, 17 were selected, giving a total population of 845 (69.1 % male, median age 6 days (IQR= 29) who met the inclusion criteria. Most studies were retrospective, and of low quality evidence. Overall, 14.7% of patients developed at least one breakthrough UTI despite being on CAP. A common theme throughout studies was that higher grade VUR (IV-V) was associated with higher incidence of breakthrough UTI. Only two studies included in our review compared UTI rates in children on CAP (combined UTI risk 13.2%) compared to those not on CAP (UTI risk 42.7%), and thus meta-analysis could not be performed.

Conclusions: Despite the use of CAP, 14.7% of children with VUR diagnosed in the setting of ANH continue to develop UTI. However, there is limited published literature comparing UTI rates in this patient population to those not on CAP, thereby making any meaningful inference impossible. The effect of CAP on UTI rates in patients with ANH and postnatal VUR thus remains unclear and requires further investigation.

FR-PO1168

Congenital Nephrogenic Diabetes Insipidus: A Review of 50 Pediatric Patients from MWPNC Centers

Cynthia J. D'Alessandri-Silva,[1] Melinda Carpenter,[2] Rose M. Ayoob,[12] Aftab S. Chishti,[3] John P. Barcia,[4] Alexandru R. Constantinescu,[5] Julie Goodwin,[6] Shireen Hashmat,[13] Larry A. Greenbaum,[7] Sherene Mason,[1] Jason Misurac,[8] Melissa A. Muff-Luett,[9] Shweta S. Shah,[10] Patricia L. Weng,[11] John D. Mahan.[12] *[1]Connecticut Children's Medical Center, Hartford, CT; [2]Connecticut Children's Medical Center, Hartford, CT; [3]University of Kentucky, Lexington, KY; [4]UVA Pediatric Nephrology, Charlottesville, VA; [5]Joe DiMaggio Children's Hospital, Hollywood, FL; [6]Yale University School of Medicine, New Haven, CT; [7]Emory University, Atlanta, GA; [8]University of Iowa, Iowa City, IA; [9]University of Nebraska Medical Center/ Children's Hospital of Omaha, Omaha, NE; [10]Texas Children's Hospital, Houston, TX; [11]UCLA, Los Angeles, CA; [12]Nationwide Children's Hospital, Columbus, OH; [13]University of Chicago, Chicago, IL.*

Background: Congenital Nephrogenic Diabetes Insipidus (NDI) is a rare genetic disorder that causes massive polyuria. To better understand NDI in children, we present, to our knowledge, the largest retrospective case series to date. Our objective for this study was to describe clinical presentation, genetic etiology, treatment and outcomes in patients < 21 years with NDI.

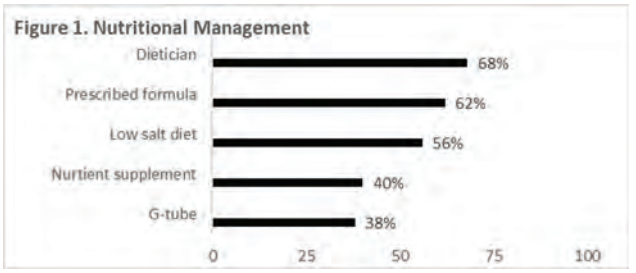
Methods: Midwest Pediatric Nephrology Consortium centers (MWPNC) conducted a retrospective chart review.

Results: We report 50 subjects from 12 centers. Median age at diagnosis was 125 days (interquartile range (IQR), 37, 296) with 86% male. 66% were white, 14% black, 8% Asian and 12% other race. 18% had a water deprivation test and 50% had a DDAVP loading test (median age at DDAVP 155 days (IQR, 101, 392)). At diagnosis, 74% had an elevated serum osmolality (> 300 MOsm/L). 54% had genetic testing with mutations in *AVPR2* (65%), *AQP2* (14%), and unavailable (21%). 28% had a diagnosis of CKD; 55% Stage 1, 36% Stage 2 and 9% Stage 5. Median age at time of CKD diagnosis was 4.1 years (IQR, 3.1, 9.4). 18% had abnormal renal ultrasound findings; the majority were hydronephrosis and pelvicaliectasis. Table 1 lists pharmacologic interventions. Other medications included chlorothiazide (2%), chlorthiadone (4%), other NSAIDS (8%) and spironolactone (6%). Figure 1 lists nutritional management. At last follow-up, 52% reported to have enuresis.

Conclusions: Our results suggest a multi-centered approach to this rare disease yields robust information that can inform future novel treatment studies and creation of a clinical consensus for management of children with NDI.

Pharmacologic Interventions

Intervention	Used % (n=50)	Start age in days Median (IQR)	Length of treatment in days Median (IQR)
Hydrochlorothiazide	96	136 (57, 334)	446 (233, 1823)
Amiloride	64	369 (64, 949)	175 (13, 1721)
Indomethacin	44	580 (89, 863)	162 (9, 1685)



FR-PO1169

Albuminuria Sparing Effects of Hydroxyurea in Children with Sickle Cell Anemia

Rima S. Zahr,[1] Jane S. Hankins,[2] Winfred C. Wang,[2] Guolian Kang,[2] Chen Li,[2] Jeremie H. Estepp,[2] Jeffrey Lebensburger.[3] *[1]University of Tennessee, Memphis, TN; [2]St. Jude Children's Research Hospital, Memphis, TN; [3]UAB, Mountain Brook, AL.*

Background: Renal complications in sickle cell anemia (SCA) begin early in childhood as hyposthenuria, glomerular hyperfiltration and albuminuria. Hydroxyurea (HU) use in SCA improves anemia, induces fetal hemoglobin and reduces sickle cell complications. We evaluated the long term effects of initiating hydroxyurea in patients with albuminuria and without albuminuria. We tested the hypothesis that initiation of HU in SCD children and young adults with albuminuria would improve urine measurements.

Methods: Participants were children < 18 yrs of age with SCA who were enrolled in two prospective cohorts and had longitudinal assessment of urine albumin to creatinine ratios (ACR) available. ACR values were captured at baseline, during the first 12 months of HU therapy and every year thereafter. The main outcome of the analysis, the development of albuminuria, was evaluated by two methodologies: a comparison of proportion between baseline and on hydroxyurea therapy and a time-to-development of albuminuria during hydroxyurea therapy.

Results: Albuminuria was present at baseline in 49% of our cohort. At one year of HU treatment, 38% with albuminuria normalized. Participants older than 10 at HU initiation had a 1.35x increase in the hazard ratio for developing ACR compared to younger than 10 years. We found that an ACR level of ≥ 100 mg/g to be a significant cut-point for recurrence.

Conclusions: The impact of HU on normalizing albuminuria may be dependent on baseline age at initiation of treatment and level of albuminuria. Our study provides the novel finding that hydroxyurea, initiated in younger age with lower levels of albuminuria can strongly benefit from the addition of HU therapy and titration to the maximal tolerated dose. Clinicians should not defer initiating HU for renoprotection until patients are older and experiencing moderate to severe albuminuria.

Morbidity of Childhood Nephrotic Syndrome: The Childhood Nephrotic Syndrome Observational Study, a Midwest Pediatric Nephrology Consortium Study

Chia- Shi Wang,[2] Oleh M. Akchurin,[3] Larry A. Greenbaum,[4] John D. Mahan,[5] William E. Smoyer,[5] Michelle N. Rheault.[1] CNOS investigators *[1]University of Minnesota, Minneapolis, MN; [2]Emory University, Atlanta, GA; [3]Weill Cornell College of Medicine, New York, NY; [4]Emory University, Atlanta, GA; [5]Nationwide Children's Hospital, Columbus, OH.*

Background: Childhood nephrotic syndrome (NS) is one of the most common pediatric chronic kidney diseases. Systematic studies of the complexity of treatment and disease complications are rare.

Methods: The Childhood Nephrotic Syndrome Study (CNOS) is an international, prospective, observational study of children 1-18 yrs with idiopathic NS enrolled within 2 mos of NS diagnosis. Demographic and clinical data are collected at presentation, 3 mos, and yearly. We describe healthcare utilization, treatment, treatment response, and disease complications among CNOS participants followed for at least 1 yr. Changes in corticosteroid (CST) treatment response from initial episode were noted.

Results: As of April 1, 2018, 127 had completed 12 mos follow-up. All patients were hospitalized at least once, with a total of 265 hospitalizations (2.1 hospitalizations/patient-year). The most common primary reason for hospitalization (82/265, 31% hospitalizations) was edema. Hospitalizations were complicated by blood clots in 3 patients (2.4%) and infections in 13 (10.2%). The majority of patients (77.2%) responded to the initial course of CST; however, an additional 5/98 (5.1%) were CST-resistant at 1 yr (i.e., late steroid-resistance). Frequently relapsing or CST-dependent NS was seen in 38/127 (29.9%). Second-line therapies were used in 69/127 (54.3%, Table). One patient (0.8%) reached end-stage renal disease.

Conclusions: Healthcare utilization and disease morbidity are high in childhood NS. Treatment is complex, with a large proportion of patients exposed to immunosuppressive agents in addition to CST, even among those initially responsive to CST. Further research and quality improvement efforts are needed to decrease hospitalizations and morbidity in children with NS.

Funding: Private Foundation Support

Risk Stratification for Disease Recurrence in Children with Steroid Resistant Nephrotic Syndrome (SRNS) Following Kidney Transplantation (Midwest Pediatric Nephrology Consortium [MWPNC] Study)

Rasheed A. Gbadegesin,[1] Jonathan H. Pelletier,[9] Karan Kumar,[10] Rachel M. Engen,[15] Adam R. Bensimhon,[11] Jennifer D. Varner,[2] Michelle N. Rheault,[3] Tarak Srivastava,[4] Cynthia J. D'Alessandri-Silva,[16] T. Keefe Davis,[1] Scott E. Wenderfer,[12] Keisha L. Gibson,[5] David T. Selewski,[1] John P. Barcia,[6] Patricia L. Weng,[7] Christoph Licht,[13] John W. Foreman,[14] Delbert R. Wigfall,[1] Annabelle N. Chua,[10] Eileen W. Tsai,[7] Christoph Hornik,[10] Shashi K. Nagaraj,[1] Larry A. Greenbaum.[8] *[1]Duke University Medical Center, Durham, NC; [2]Duke University School of Medicine, Durham, NC; [3]University of Minnesota, Minneapolis, MN; [4]Childrens's Mercy Hospital, Kansas City, MO; [5]University of North Carolina Kidney Center, Chapel Hill, NC; [6]UVA Pediatric Nephrology, Charlottesville, VA; [7]UCLA, Los Angeles, CA; [8]Emory University, Atlanta, GA; [9]Duke University Hospital, Durham, NC; [10]Duke University, Durham, NC; [11]Duke, Chapel Hill, NC; [12]Baylor College of Medicine, Houston, TX; [13]The Hospital for Sick Children, Toronto, ON, Canada; [14]Duke University Health System, Durham, NC; [15]Seattle Children's Hospital, Seattle, WA; [16]Connecticut Children's Medical Center, Hartford, CT.*

Background: Steroid resistant nephrotic syndrome (SRNS) due to FSGS and MCD is a leading cause of end stage kidney disease (ESKD) in children. Recurrence of primary disease following transplantation is a major cause of allograft loss. The clinical determinants of disease recurrence are not completely known. Our objective was to determine risk factors for recurrence of FSGS/MCD following kidney transplantation.

Methods: Multicenter study of pediatric patients with kidney transplants performed for ESKD due to SRNS between 1/2006-12/2015. Patients with primary-SRNS (PSRNS) were defined as those initially resistant to corticosteroid therapy at diagnosis, and patients with late-SRNS (LSRNS) as those initially responsive to steroids who subsequently developed steroid resistance. We performed logistic regression to determine risk factors associated with nephrotic syndrome (NS) recurrence.

Results: We included 158 eligible participants in our analysis; 64 (41%) had recurrence of NS in their renal allograft. Disease recurrence occurred in 78% of patients with LSRNS

compared to 39% of those with PSRNS. Patients with MCD on initial native kidney biopsy had a 76% recurrence rate compared with a 40% recurrence rate in those with FSGS. The recurrence rate in patients with monogenic SRNS was 0%. Multivariable analysis showed that MCD histology (OR; 95% CI: 5.6; 1.3-23.7) compared to FSGS predicted disease recurrence.

Conclusions: Pediatric patients with MCD and LSRNS are at higher risk of disease recurrence following kidney transplantation. Based on our findings, it is possible to use genetic findings, native kidney biopsy findings and pattern of therapy response prior to kidney transplant to stratify patients with SRNS undergoing renal transplant into a low-risk group (monogenic NS), a medium-risk group (FSGS on native kidney biopsy and PSRNS), and a high-risk group (MCD on native kidney biopsy and/or LSRNS).

Renal Recovery and Prognostic Factors in Children Following Liver Transplantation: A Single Center Experience

Rainer Büscher,[1] Nicholas Gantenberg,[1] Tobias Storbeck,[2] Anja K. Büscher,[1] Henrike Stopfkuchen,[1] Peter F. Hoyer.[1] *[1]Paediatric Nephrology, University Hospital Essen, Essen, Germany; [2]Paediatric Gastroenterology and Liver Transplantation, University Hospital Essen, Essen, Germany.*

Background: Progression to chronic renal disease (CKD) is highly prevalent in adults following liver transplantation (LT) with a profound impact on patient survival, assuming that the prevalence of renal dysfunction is also considerably high in children. We report our experiences in a large paediatric transplant center and try to identify risk factors leading to a decline of renal function.

Methods: We retrospectively analyzed all 161 LT patients at our hospital from 2010 to 2017 (84 female). Medical records were reviewed for demographic, laboratory and clinical data. Patients were stratified into groups < 5 kg, 5-10 kg and > 10 kg. Change of renal function (slopes) was defined as loss/increase of GFR using the Schwartz formula and progress to renal failure within the first 4 weeks after LT was stratified according to the pRIFLE criteria. Mean observation time was 31 months (6 to 93 months).

Results: Out of 161 patients, 134 were younger than 6 years at time of LT (74%). Average survival time in 5 years was 86%. CKD preexisted in 16 children (10%), nine undergoing dialysis before LT (5.5%). 7/145 proceeded to ESRD over 5 years (4.8%). Other patients developed pRIFLE I (21%), II (23%), III (11%) within the first 4 weeks after LT. Average GFR within 4 weeks after LT was lower in group <5kg (66 ml/min/1.73m^2) compared to 81 (5-10 kg) and 114 (>10kg) ml/min/1.73m^2. All GFR-slopes remained stable and were not significantly different from each other (<5kg: 0.01 vs. >5-10kg: 0,01 vs. >10kg: -0,35 ml/min/1,73m^2/28 days). Within the entire observation time, all GFR-slopes showed a significant increase (<5kg: 14 vs. 5-10kg: 4 vs. >10kg: 3 ml/min/1.73m^2/year). Regarding potential risk factors, 16 patients (10%) exceeded ABPM mean blood pressure values higher the 95th percentile, and 8 patients (5%) higher the 75th percentile. All other patients remained lower the 50th percentile. Albuminuria was rare (4%) and did not occur significantly more often in any subgroup. No independent risk factors for a decline of GFR to ESRD could be detected in all patients.

Conclusions: In contrast to adults, progress to ESRD in children following LT was rare (<5%) and most patients developed a normal GFR. Independent risk factors could not be defined. However, renal function, hypertension and proteinuria should be monitored regularly.

FR-PO1173

Trends in Living Donation by Race/Ethnicity in Pediatric ESRD

Sandra Amaral,[1] Charles E. McCulloch,[2] Celina Brunson,[1] Erica Winnicki,[2] Garrett R. Roll,[2] Brian K. Lee,[2] Elaine Ku.[2] *[1]The Children's Hospital of Philadelphia, Philadelphia, PA; [2]University of California San Francisco, San Francisco, CA.*

Background: Living donation is the best treatment option for children with ESRD, yet living donation rates have declined. With increased knowledge about living donor (LD) risk, racial/ethnic disparities in LD rates for children may have increased.

Methods: We performed a retrospective cohort study of children <18 yrs with incident ESRD 1995-2015 in the US Renal Data System. Using Cox models, we examined associations between race/ethnicity, LD transplant rates and changes over time, adjusting for recipient and donor factors. We also examined donor-recipient relationships by race/ethnicity.

Results: Among 14,926 children, 46.8% received LD transplants. Overall, LD rates declined by 3%/yr since 1995, however the LD rates for Asian children remained stable. Notably, differences in LD rates by race/ethnicity persisted (Fig. 1). Compared with non-Hispanic whites (NHW), Hispanic children were 50% less likely (HR 0.50 (0.45-0.55)), Asians 57% less likely (HR 0.43(0.35-0.52)) and Blacks 70% less likely (HR 0.30 (0.27-0.34)) to receive LD transplant within 2 yrs. of ESRD onset. While 96% of NHW recipients had white donors, only 59% of Asian recipients had Asian donors (p<0.001). Asian recipients were more likely to have non-related donors and Black recipients were less likely to have parents as donors (p< 0.001, Table 1).

Conclusions: Stark racial/ethnic disparities in pediatric access to LD transplant persist. Differences in donor-recipient relationships as contributors to these disparities should be further explored.

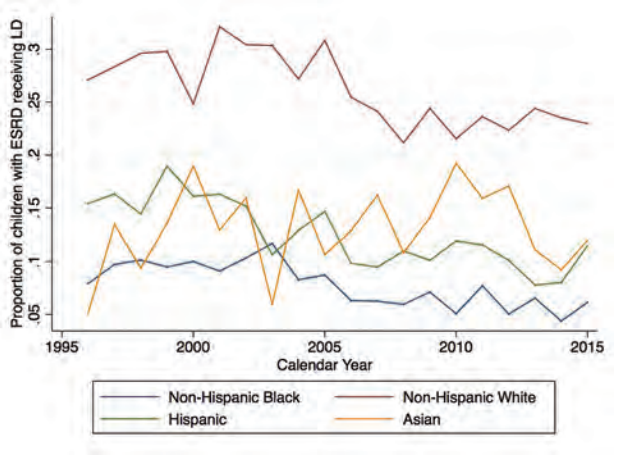

Fig.1. Time trends in LD transplant by race/ethnicity, 1995-2015.

Table 1: Characteristics of donor-recipient pairs

%	NHW recipient N=4710 (67.4%)	Black recipient N=876 (12.5%)	Hispanic recipient N=1197 (17.1%)	Asian recipient N=205 (2.9%)	P-value for difference

FR-PO1174

Risk Factors for Early Readmission Post Pediatric Kidney Transplantation

Shanthi S. Balani,[1] Stephanie T. Nguyen,[2] Jessica L. Brennan,[3] Paul R. Brakeman.[1] *[1]UCSF, San Francisco, CA; [2]Pediatric Nephrology, University of California, Davis, Sacramento, CA; [3]UCSF Medical Center, San Francisco, CA.*

Background: Early hospital readmissions are associated with morbidity, mortality and significant health care costs. To date, no published studies have evaluated risk factors for early readmission following pediatric kidney transplantation.

Methods: Retrospective chart review was performed for all pediatric kidney transplant recipients from 2012 – 2017 at the University of California, San Francisco. Early hospital readmissions were defined as any unplanned admission within 30 days of being discharged from the hospital following a kidney transplant; admissions for elective procedures were excluded. Baseline characteristics evaluated included age, insurance, race, education, prior dialysis, donor type, cold ischemia time, prior transplantation, peritoneal placement of transplant, immunosuppressive regimen, length of hospital stay, weekend/holiday discharge, discharge medications, tacrolimus level, hemoglobin, albumin, and creatinine at discharge. Analysis was done using Student t-test and Pearson chi square test.

Results: There were 90 pediatric kidney transplant recipients. The rate of early readmission was 25%. Causes for readmission were: elevated creatinine (26%), vomiting/diarrhea with dehydration (26%) and hypertension associated complications (9%). Pre-transplant dialysis significantly predicted readmission (Hemodialysis 43.7%, peritoneal dialysis 21.4% and pre-emptive transplants 10.3%, p<0.05). Racial distribution among readmissions was also found to be statistically significant (Blacks 62%, Whites 21%, Hispanic 23%, Asian 0%, other 42%, p=0.05). Other non-significant predictors for readmission included: public versus private insurance (30% vs 16%, p=0.8) and number of anti-hypertensives at time of discharge (36% on 2 or more medications vs 18% on none, p=0.3). No difference was seen in readmission rates based on age, education, donor type or immunosuppressive regimen.

Conclusions: The rate of early readmissions for our pediatric population was less than for adult patients (25% vs 30-36%). The most common causes for readmission were elevated creatinine and vomiting/diarrhea. Prior dialysis and race significantly predicted readmission. Targeted interventions for patients identified as being at risk based on these results may help reduce the rate of readmissions for pediatric patients after kidney transplantation.

FR-PO1175

Change in Kidney Function for Three Years in Pediatric Kidney Transplant Recipients

Junya Hashimoto,[1,2] Yuko Hamasaki,[1,2] Yusuke Takahashi,[1,2] Masaki Muramatsu,[2] Takeshi Kawamura,[2] Ken Sakai,[2] Seiichiro Shishido.[1,2] *[1]Pediatric Nephrology, Toho University Faculty of Medicine, Ota-ku, Japan; [2]Nephrology, Toho University Faculty of Medicine, Ohta-ku, Japan.*

Background: Few data show the changes in graft function after kidney transplantation (KTx) in children. We retrospectively investigated the change in kidney function for three years in pediatric kidney transplant recipients based on estimated glomerular filtration rate (eGFR).

Methods: We enrolled the recipients aged 2–15 years who underwent living-donor KTx at our institution between 2009 and 2017. We excluded the recipients with primary non-function (n=2), low muscle bulk due to being bedridden (n=2). In 56 recipients, changes in eGFR were evaluated for three years after KTx. eGFR was calculated by the creatinine-based equation for Japanese children and adolescents aged 2–18 years.

Results: During follow-up, patient and graft survival rates were 100%. Twenty-five recipients (44.6%) experienced acute rejection with treatment. The mean age of recipients and donors were 8.1±4.0, and 41.1±7.8 years old. Congenital anomalies of the kidney and urinary tract (n=34) was the most common disease for end stage kidney disease. The mean eGFR (ml/min./1.73m^2) at 1, 4, 12, 24, and 36 months (M) after KTx were 85.1±18.6, 73.4±16.6, 67.0±15.7, 65.3±15.0, 66.4±18.9, respectively. eGFR at 1 and 12 M post-transplant showed significant difference ($p<0.0001$, paired t-test). eGFR became stable at 12 M post-transplant and thereafter. In 17 recipients (30.4%), eGFR at 36 M was below 60. On multivariable logistic regression analyses, eGFR <60 at 1 M after KTx was the impact factor related to eGFR <60 at 36 M.

Conclusions: Approximately 70% of the recipients showed kidney function equivalent to over CKD stage 3 at three years after KTx, though eGFR declined within the first year post-transplant. To preserve long-term kidney graft function, the recipients with low eGFR at one month post-transplant need careful management.

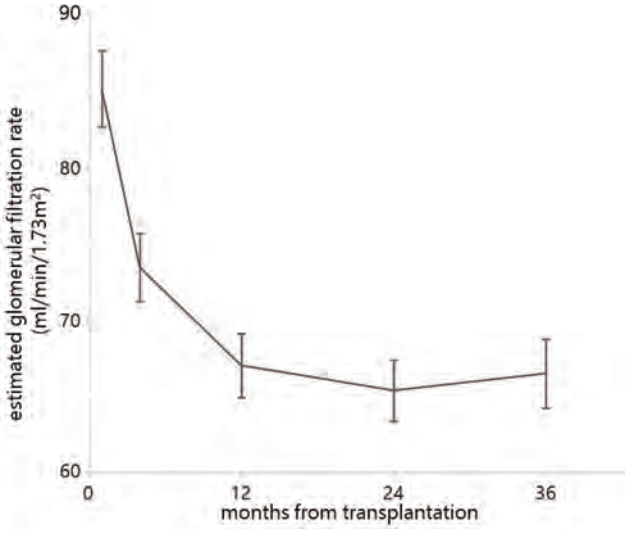

Fig. Change of the mean eGFR of 56 pediatric recipients after living-donor KTx.

FR-PO1176

Co-Produced Videos to Improve Knowledge Among Patients and Caregivers with a Kidney Transplant

Devesh S. Dahale,[1] Margret Kamel,[2] Ansara Piebenga,[3] David K. Hooper,[1] Pamela D. Winterberg.[2,4] Improving Renal Outcomes Collaborative (IROC) *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Pediatrics, Emory University School of Medicine, Atlanta, GA; [3]Improving Renal Outcomes Collaborative, Cincinnati, OH; [4]Children's Healthcare of Atlanta, Atlanta, GA.*

Background: The Improving Renal Outcomes Collaborative (IROC) is a networked learning health system of 23 pediatric centers committed to improving the health, longevity, and quality of life of children with kidney disease. IROC's Community Engagement Workgroup (CEW) was established to engage patients and caregivers in co-production to achieve health care goals. In line with IROC's first aim to improve blood pressure (BP) control in children with kidney transplants, the CEW implemented a project to raise awareness of BP management amongst its members using video content.

Methods: CEW members created a list of questions regarding the relevance of BP control to health, accurate BP measurement, and treatment of high BP. They then co-produced 10 short videos of pediatric nephrologists teaching these topics on camera. Videos were distributed to patients and caregivers and multiple-choice questions were used to assess knowledge of topic areas before and after viewing the content. Open-ended questions prompted viewers to describe future behaviors influenced by watching each video. Paired responses were analyzed to determine knowledge of topic areas most improved by the video content. Thematic analysis of free-text responses was used to identify future behaviors.

Results: A total of 23 participants (3 patients, 14 caregivers, 4 healthcare professionals and 2 caregiver/healthcare), viewed a median of 5 (IQR 3-9) videos. Videos had on average 11.4 ± 1.1 viewers who submitted paired pre- and post-video responses. Participants demonstrated the largest improvements in knowledge about the prevalence of high BP after kidney transplant (correct response 7% pre- vs 92% post-video), ideal BP levels (45% vs 100%), and the nutrient focus of the DASH diet (25% vs 100%). Future behaviors stimulated by the content viewing included BP self-monitoring, implementation of lifestyle modification, and desire to have more in-depth conversation with healthcare providers about BP management.

Conclusions: Co-produced videos improved BP knowledge among participants who also appear motivated to engage in self-care and conversations with healthcare providers about lifestyle modifications for BP control. We intend to use the feedback from this pilot to create a patient education program at IROC centers using the Knowledge-Attitude-Behavior (KAB) model.

FR-PO1177

Ethnography: A Novel Approach to Improving Care for Pediatric Kidney Transplant Recipients

O. N. Ray Bignall,[1] Veronica A. Taylor,[1] Ahna L. Pai,[1] Jens W. Goebel,[2] Justin Masterson,[3] Cassie L. Kirby,[1] David K. Hooper.[1] Improving Renal Outcomes Collaborative *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Children's Hospital Colorado, Aurora, CO; [3]SEEK Company, Cincinnati, OH.*

Background: Current models of care for pediatric kidney transplant recipients (pKTRs) may be ill-suited to meet their needs, leading to suboptimal utilization, barriers to adherence, and psychosocial stressors that adversely affect both patients and families. Optimizing care delivery for these complex patients requires insight into their social and emotional needs, perceptions of care, and future goals. Aiming to inform design of an improved system of care, we assessed convergent and divergent perceptions of pKTRs and their families.

Methods: We conducted a qualitative analysis of semi-structured interviews and ethnographies with pKTRs (n=12; ages 11-22) and caregivers (n=15) identified in the Improving Renal Outcomes Collaborative (IROC). Participants were selected and stratified according to medical and psychosocial complexity, and level of engagement with their transplant team. Audio recorded interviews were transcribed and assessed for themes using a grounded theory approach.

Results: *Considerations around Kidney Care* was the major theme that emerged from both pKTRs and caregivers, particularly experience on dialysis and learning about kidney disease care. Other cross-cutting themes included maintaining a sense of normalcy; inability to recognize signs of kidney disease prior to transplant; and reluctance to meet other pKTRs. Major themes more common among caregivers were *Family Dynamics* (e.g. caregiver stress/strain and consideration of family members as organ donors; $p<0.001$) and *Life Stressors* (e.g. moving or traveling for a child's transplant care; $p<0.001$). More common among patients were *Education/Social Development* (e.g. impact of disease on school and extracurricular activities; $p<0.001$), and *Transition of Care* (e.g. transition to an adult provider; $p<0.001$). Co-produced with patients and families, ethnographies were used to generate thematic personas to aid in the development of IROC, our learning health system designed to improve health and quality of life for pKTRs.

Conclusions: Understanding patient and family motivations and needs are fundamental to designing new, more effective systems of care. Such systems should address both common motifs as well as those specific to patients and caregivers in order to foster engagement and shared decision making between patients and the medical team.

FR-PO1178

Proteinuria in Children and Adolescents Following Renal Transplantation: Results from the Cooperative European Pediatric Renal Transplant Initiative (CERTAIN)

Anja K. Büscher,[1] Daniel Bernard,[1] Henrike Stopfkuchen,[1] Rainer Büscher,[1] Peter F. Hoyer,[1] Tomas Seeman,[3] Kai Krupka,[2] Burkhard Toenshoff.[2] Members of the CERTAIN registry study group *[1]Pediatric Nephrology, University Children's Hospital, Essen, Germany; [2]University Children's Hospital, Heidelberg, Germany; [3]University Children's Hospital Motol, Prague, Czechia.*

Background: Proteinuria is a major risk factor for the progression of chronic kidney disease and - in patients after renal transplantation (RTx) - associated with higher mortality and an increased risk of graft failure. Pediatric studies are rare, often limited due to small patient numbers and present heterogenous results regarding prevalence and outcome.

Methods: Data of 195 children (mean age at RTx 10.6±5.2 years, 60% male) from the CERTAIN registry was analyzed 3 months, 1 and 3 ys post RTx. Prevalence, quantity and quality of proteinuria was correlated with GFR and potential influencing factors were evaluated (underlying disease, BMI, dialysis, HLA-mismatch, cold ischemia time, immunosuppression (IS), BKV infection).

Results: 77% of patients developed proteinuria >200mg/g creatinine (crea) within 3 months post RTx, 9% of these > 1000mg/g crea; Proteinuria was of glomerular origin in 71% and decreased by 40% within 3 ys. Increasing proteinuria was negatively correlated with GFR especially in the long-term follow-up ($p=0.004$, 3ys post RTx). Patients with glomerulopathies had significantly higher proteinuria ($p<0.001$) after 3ys post RTx. BMI SDS was positively correlated with proteinuria ($p<0.03$) at time of RTx, but this effect did not persist over time. Cold ischemia time was correlated with the extent of proteinuria ($p=0.01$) as well as the number of HLA mismatches. Patients with BKV infection developed proteinuria in 52% (with higher urinary protein excretion compared to BKV negative patients ($p<0.001$). The mode of dialysis and the type of IS did not influence proteinuria

significantly, but we detected slightly higher levels of urinary protein in patients with a history of peritoneal dialysis and in mTOR inhibitor-based IS, respectively. Proteinuria did not correlate with hypertension, duration of dialysis, CMV/EBV or urinary tract infections.

Conclusions: The majority of pediatric patients developed proteinuria following RTx, Although proteinuria was of only mild to moderate extent in most patients and decreased over time, it was significantly correlated with a reduction of GFR. Proteinuria was associated with several risk factors with the highest impact for a prolonged cold ischemia time, high number of HLA mismatches and BKV infection.

FR-PO1179

Differential Cytokine Profiles for Non-Human Leukocyte Antigen (Non-HLA) and HLA Antibodies in Pediatric Kidney Transplantation

Meghan Pearl,[1] Jonathan Grotts,[1] Maura Rossetti,[1] Qiuheng J. Zhang,[1] Patricia L. Weng,[1] David Elashoff,[1] Elaine F. Reed,[1] Eileen W. Tsai.[2] *[1]UCLA, Los Angeles, CA; [2]Duke University, Durham, NC.*

Background: The inflammatory profiles associated with human leukocyte antigen (HLA) and non-HLA antibodies to G-protein coupled receptors in kidney transplant recipients (KTRs) are unknown. We have recently shown that angiotensin II type 1 receptor antibody (AT1R-Ab) and Endothelin-1 Type A receptor antibody (ETAR-Ab) are prevalent and associated with poor outcomes in pediatric KTRs. We aimed to compare inflammatory profiles of AT1R-Ab, ETAR-Ab, and HLA donor specific antibodies (DSA) in pediatric KTRs.

Methods: 233 blood samples from 65 pediatric KTRs were analyzed. ETAR-Ab (ELISA), AT_1R-Ab (ELISA), HLA DSA (Luminex), and TNF-α, IL-1β, IL-8, IFN-γ, IL-17, IL-6 (Luminex) were measured in blood samples taken at 6 months (m), 12m, and 24m post-transplant and during episodes of rejection. Based on a receiver operating curve analysis, > 10 and >17 units/ml was considered positive for ETAR-Ab and AT_1R-Ab and ≥1000 MFI was considered positive for HLA DSA.

Results: HLA DSA, AT1R-Ab, and ETAR-Ab were positive in 25 (11%), 92 (40%), and 50 (22%) of samples respectively. 96% of samples positive for ETAR-Ab also had AT1R-Ab. All three antibodies were associated with elevations in IL-8 while AT1R-Ab was associated with elevations in all 6 cytokines (Table 1).

Conclusions: AT1R-Ab is associated with a distinct inflammatory profile compared to HLA DSA or ETAR-Ab in the first 2 years post-transplant. Further studies are needed to understand the distinct mechanisms of HLA vs. non-HLA antibody mediated allograft injury.

Funding: Private Foundation Support

Cytokine	**HLA DSA** OR (95% CI)	p-value	**AT1R-Ab** OR (95% CI)	p-value	**ETAR-Ab** OR (95% CI)	p-value
TNF-α	1.6 (0.66 - 3.85)	0.297	2.29 (1.27 - 4.13)	0.006	1.66 (0.81 - 3.42)	0.166

Weight Changes on Dialysis and During Transplant Associate with Mortality Risk in Children

Matthew Roberts,[1] Mark Mitsnefes,[2] Charles E. McCulloch,[1] Larry A. Greenbaum,[3] Barbara A. Grimes,[4] Elaine Ku.[1] *[1]University of California San Francisco, San Francisco, CA; [2]Cincinnati Children's Hospital, Cincinnati, OH; [3]Emory University, Atlanta, GA; [4]UCSF, San Francisco, CA.*

Background: Few studies have explored how weight change during ESRD may associate with survival in children. Our objective was to examine the association between weight changes during RRT and risk of death in a prevalent cohort of children with ESRD. Secondarily, we sought to determine whether the association between weight changes and mortality would differ based on ESRD treatment modality (dialysis vs. transplant).

Methods: We performed a retrospective cohort study using data from the Pediatric Growth and Development Special Study, a longitudinal study within the United States Renal Data System that followed children with ESRD over a 3-year period. The primary predictor was annualized BMI z-score changes divided into quintiles. Cutoff values for these BMI z-score changes were -0.50, -0.13, 0.09, and 0.57, and the middle quintile served as the reference category. Outcome was all-cause mortality. We used Cox models (adjusted for age, sex, race, cause of ESRD and median neighborhood income) to examine the association between the predictor and outcome and to test for an interaction with treatment modality.

Results: We included 1,182 children followed for a median duration of 19 years, of whom 35% died during follow-up. Mean age was 15 years, 40% were female, and 21% had CAKUT as the cause of their ESRD. We found a U-shaped association between weight change and mortality (Figure 1): both large declines in BMI z-score (>-0.50 per year) and large gains in BMI z-score (>0.57 per year) were associated with an increased risk of death. No interaction was noted between annualized BMI z-score change and treatment modality (p=0.15). Results were similar when follow-up was limited to 5 and 10 years after the last weight and height measurements were obtained.

Conclusions: Weight gain and weight loss after dialysis initiation or during transplant are strong predictors of long-term survival for children with ESRD. Maintenance of a stable weight may be associated with better survival in children receiving RRT, regardless of RRT modality.

Executive and Intellectual Functions of Young Hungarian Kidney Transplant Recipients

Marta M. Varga,[1] Miklos Gyori,[1] Anett Nagy,[2] Aniko Varga,[3] Gyorgy S. Reusz,[4] Attila J. Szabo.[4,5] *[1]Institute for the Psychology of Special Needs, Faculty of Special Education, ELTE University, Budapest, Hungary, Budapest, Hungary; [2]Institute of Special Needs Education for People with Atypical Behaviour and Cognition, Faculty of Special Education, ELTE University, Budapest, Hungary, Budapest, Hungary; [3]ELTE University, Budapest, Hungary, Budapest, Hungary; [4]1st. Department of Pediatrics, Semmelweis University, Budapest, Hungary, Budapest, Hungary; [5]MTA-SE Pediatrics and Nephrology Research Group, Budapest, Hungary, Budapest, Hungary.*

Background: CKD is frequently associated with impaired executive functions, intellectual problems and atypical development in children and adolescent. Results of the last decade indicate that neuropsychological outcomes with kidney transplant (Tx) recipients are more favorable than was detected in earlier reports. However, data on factors associated with neurocognitive dysfunctions in Tx recipients are limited.

Methods: We conducted a cross-sectional analysis comparing digital measuring of executive functions (using Wisconsin Card Sorting Test /WCST/, Corsi Test /Corsi/, Stroop Effect Test /STROOP/) of 26 kidney transplant recipients by matching them in pairs on gender, age, maternal education and IQ with healthy controls. Socio-demographic characteristics, laboratory data and comorbidities have been collected.

Results: The average age was 17±2 years, 73% was male, the average estimated GFR was 60±14 ml/min. Kidney transplant adolescent had a below average overall IQ (WISC-IV/WAIS-IV IQ=85±17). The first preliminary data on executive functions suggest no significant differences between the achievement of transplant and IQ matched healthy pairs in visuo-spacial short term memory (Corsi) (F=2.37, p=0.41), cognitive flexibility (WCST) (F=0.31, p=0.95) and selective attention and inhibition (STROOP) (F=2.97, p=0.32). All IQ domain of Tx recipients had significant negative correlation with transplant vintage (Full IQ scores: R=-0.52, p<0.01). The intellectual function had also inverse correlation with cumulative lifetime length of hospitalization (R=-0.47, p=0.01). Hospitalization time and maternal education had strong negative correlation (R=-0.57, p<0.01) while IQ and maternal education had no relation in our sample of Tx group (R=0.31, p=0.13). Cognitive flexibility (perseverative (R=-0.42 p=0.03) and conceptual level responses (R=-0.59 p=0.001) indicated a strong inverse correlation with lifetime cumulative dialysis vintage in Tx recipients.

Conclusions: Young kidney transplant recipients have impairments of intellectual function that are associated with transplant vintage and lifetime hospitalization. IQ matched transplant and healthy groups had no differences in executive functions. Higher dialysis vintage of Tx adolescents indicated lower cognitive flexibility.

Outcomes of Belatacept Regimen with the Use of Precision Medicine in Kidney Transplantation

Jun Shoji,[1] Qizhi Tang,[2] Flavio Vincenti.[3] *[1]Transplant Nephrology, University of California San Francisco, San Francisco, CA; [2]University of California San Francisco School of Medicine, San Francisco, CA; [3]University of California San Francisco, San Francisco, CA.*

Background: Belatacept is a costimulation blocker that has been increasingly used as maintenance immunosuppression to improve long term outcomes in kidney transplant recipients. Since acute rejection in patients on belatacept have been noted to be more frequent and histologically more severe, identifying the select population of patients with Precision Medicine who will benefit from belatacept is important. We investigated pretransplant recipient immune profiles to determine which lymphocyte populations would be the best predictor in identifying patients who will be at lowest risk for costimulation blockade-resistant rejection.

Methods: We prospectively enrolled 64 kidney transplant recipients (44 deceased; 20 living donors) at our center to receive denovo belatacept from August 2012 to March 2017. PMBCs were collected prior to transplantation and at the time of cause and protocol biopsies. All patients received thymoglobulin for induction with belatacept 10mg/kg administered on POD 1, 4, 14, 28, 56, and 84. Monthly maintenance dose of 5mg/kg was given starting week 16. Patients were initially on MMF but were converted to everolimus after 1 month. Prednisone was maintained on 56 patients and withdrawn on 8 patients. Protocol biopsies were performed at 6 months.

Results: On cause biopsies, 3 patients were noted to have ACR 1a (at 4 weeks, 6 weeks, 4 months), 1 with ACR 1b (at 2 months), 3 with ACR 2b (at 2 months, 3 months, 9 months), 1 with AMR (at 4 months), and 1 with simultaneous ACR 1a and AMR (at 7 months). In addition, 16 patients were found to have borderline rejection on protocol biopsies. 28 patients did not have any inflammation on biopsies. 56 patients remained on belatacept and 8 patients were converted to tacrolimus (1 patient was switched to tacrolimus due to poor intravenous access and not due to rejection). 6 of the 9 rejections occurred in those who were on MMF and not on mTORi. 2 of 9 patients who were noted to have rejection were patients on steroid withdraw.

Conclusions: CD28-CD8 T cells are associated with belatacept-resistant rejection since these are memory cells unaffected by CD28 blockade. Pretransplant immunotyping and functional assessment of circulating lymphocytes may provide a useful tool for selection of patients suitable for belatacept therapy.

At 12 months (median):

	Total (N=64)	Acute rejection (N=9)
Serum creatinine (mg/dL)	1.13	1.2
eGFR (mL/min)	65	46
Urine protein/creatinine (g/g)	0.195	0.29

SA-PO002

One Year Kidney Transplant Outcomes Using Belatacept and Sirolimus Maintenance Immunosuppression

Carol A. Traynor,[2] Allan D. Kirk.[1] *[1]Duke University School of Medicine, Durham, NC; [2]Division of Nephrology, Duke University, Durham, NC.*

Background: Calcineurin inhibitors (CNIs) are the cornerstone of immunosuppression fafter kidney transplantation, but are associated with adverse events when used long term. Belatacept, a CTLA4-Ig fusion protein, is a costimulation blocker that prevents T-lymphocyte activation. It provides effective immunosuppression post kidney transplant and allows CNI free immunosuppression. Typical regimens include belatacept with mycophenolate mofetil and steroids, and have been associated with higher acute rejection rates than CNI based regimens. We describe our experience using a belatacept and sirolimus based maintenance immunosuppression regimen.

Methods: This is a retrospective analysis of patients treated with belatacept maintenance therapy at a single center. Patients were eligible for belatacept if: age<70, BMI<35, EBV IgG positive, no donor specific antibody. They received alemtuzumab induction (30 mg, intravenously), infusion of belatacept (10mg/Kg Day 0,4 and end of week 2,4,8, and 12; then 5 mg/kg every month, and oral sirolimus 2mg daily, dose adjusted for 24-hour trough 8-10ng/ml.

Results: Baseline demographics are outlined in table 1. There was 100% patient and graft survival at one year. There was no delayed graft function. Acute rejection occurred in 13.6%. Median GFR at one year was 55ml/minute. Median protein/creatinine ratio was 262 mg/g Creatinine. There were 25 infections in 13 patients. There were 9 viral infections. CMV and BK virus occurred at a rate of 13.6% and 13.6%, respectively. There were 10 bacterial infections-the majority (80%) were urinary tract infections. There were 6 fungal infections-all were mucocutaneous infections. There were no cases of post transplant lymphoproliferative disease.

Conclusions: A combination of costimulation blockade with belatacept, alemtuzumab induction and daily sirolimus enables use of a CNI and steroid free maintenance immunosuppression regimen in select patients. There were excellent one-year graft outcomes, and it was well tolerated with an acceptable side effect profile. Longer follow up is needed.

SA-PO003

The Epidemiologic Burden of Tacrolimus Variability Among US Kidney Transplant Recipients

Pratik B. Shah,[1] Jennifer L. Ennis,[2] Patrick Cunningham,[1] Michelle A. Josephson,[1] Rita L. McGill.[1] *[1]University of Chicago, Chicago, IL; [2]Litholink Corporation, Chicago, IL.*

Background: Within-patient tacrolimus level variability has been shown to be a risk factor for *de novo* donor specific antibody (DSA) formation and increased death censored graft failure (DCGF) among kidney transplant recipients in single-center reports. We evaluated the correlation between subtherapeutic tacrolimus levels and tacrolimus variability in a large national data set.

Methods: We evaluated all tacrolimus levels drawn at any LabCorp® facility in the United States, between November 2011 and September 2017, with a diagnosis code for kidney transplant. Levels drawn within the six months after the earliest value were excluded, to exclude patients with new allografts. Patients were included if there were at least three tacrolimus levels thereafter. Tacrolimus variability was calculated as the coefficient of variability of the tacrolimus levels as: 100 x (standard deviation/mean) and compared to a risk threshold of 30% (Rodrigo et al., 2016). The percentage of subtherapeutic (< 4.0 ng/dL) tacrolimus levels (%subT) was calculated for each subject. The associations of tacrolimus variability with %subT were assessed with correlation analysis and linear regression.

Results: There were 410,257 tacrolimus levels among 27,375 patients, of whom 43.1% were women. Mean age was 52.5±14.4 years. Median follow-up was 26.5 (IQR=12.8-46.1) months. The median number of tacrolimus levels per patient was 11 (IQR=6-20). Median tacrolimus variability was 30.6%, with 51.6% of patients exceeding 30% variability. Median %subT was 11.1% (IQR=0-30.8%), and 34.3% of patients had no subtherapeutic levels. The correlation coefficient between tacrolimus variability and %subT was 0.253 (P<0.001). In linear regression, tacrolimus variability increased 1.86% for each 10% increase in %subT (P<0.001), but R-squared for this model was only 0.06.

Conclusions: More than half of established kidney transplant patients from a large national sample exhibited a level of tacrolimus variability that has been previously associated with 2 to 3- fold increased hazards of DSA and DCGF. Tacrolimus variability has an association with subtherapeutic levels, but likely reflects a complicated constellation of clinical factors and scenarios that merit further study.

SA-PO004

Calcineurin Inhibitors, Macrolides, and the Risk of Adverse Drug Events in Kidney Transplant Recipients

Rachel H. Jeong,[1] Robert R. Quinn,[2] Krista L. Lentine,[3] Anita Lloyd,[1] Pietro Ravani,[2] Brenda Hemmelgarn,[2] Branko Braam,[1] Amit X. Garg,[4] Kevin C. Wen,[1] Anita Wong,[5] Sita Gourishankar,[1] Ngan Lam.[1] *[1]University of Alberta, Edmonton, AB, Canada; [2]University of Calgary, Calgary, AB, Canada; [3]Saint Louis University, St. Louis, MO; [4]London Health Sciences Centre, London, ON, Canada; [5]Alberta Health Services, Edmonton, AB, Canada.*

Background: Calcineurin inhibitors (CNI; cyclosporine, tacrolimus) are critical for kidney transplant immunosuppression, but have multiple potential drug interactions, such as with macrolide antibiotics. Clarithromycin and erythromycin inhibit CNI metabolism and increase the risk of CNI nephrotoxicity, while azithromycin does not.

Methods: We conducted a retrospective cohort study using linked healthcare databases in Alberta, Canada to study kidney transplant recipients from 2008-2015. We identified CNI-macrolide co-prescriptions and compared outcomes in those who received clarithromycin/erythromycin vs. azithromycin. The primary outcome was a composite of all-cause hospitalization, acute kidney injury (creatinine increase ≥0.3 mg/dL or 1.5-times baseline), or death within 30 days of the macrolide prescription.

Results: Of the 293 recipients who were co-prescribed a CNI and a macrolide, 38% (n=112) were prescribed clarithromycin/erythromycin while 62% (n=181) were prescribed azithromycin. Over half of the clarithromycin/erythromycin prescriptions were from general practitioners. There was no significant difference in the primary outcome between the two groups (17% vs. 11%, p=0.11); however, the risk of all-cause hospitalization was 3-times higher in the clarithromycin/erythromycin group than in the azithromycin group (10% vs. 3%; odds ratio [OR] 3.18, 95% CI 1.14 to 8.84, p=0.02). The odds of having an outpatient serum creatinine measurement within 30-days of the macrolide prescription were 41% less likely for clarithromycin/erythromycin users compared to azithromycin users (56% vs. 69%; OR 0.59, 95% CI 0.36 to 0.96, p=0.03). Although there was no difference in acute kidney injury between the two groups, there was a significantly greater decrease in eGFR in the clarithromycin/erythromycin group compared to the azithromycin group (-5.4 vs. -1.9 mL/min/1.73 m^2, p<0.05).

Conclusions: In conclusion, clarithromycin and erythromycin were frequently co-prescribed in kidney transplant recipients on CNIs despite known drug interactions. Clarithromycin/erythromycin users were at higher risk of hospitalization compared to azithromycin users. Safer prescribing practices in kidney transplant recipients are warranted.

SA-PO005

Trough Tacrolimus Levels in Kidney Transplant Recipients and Non-Melanoma Skin Cancer Risk over Follow Up

Donal J. Sexton,[1] Susan L. Murray,[1] Peter J. Conlon.[2] *[1]Nephrology and Kidney Transplantation, Beaumont Hospital and The Royal College of Surgeons in Ireland, Dublin, Ireland; [2]Beaumont Hospital, Dublin 9, Co Dublin, Ireland.*

Background: Whether Tacrolimus exposure is independently associated with non melanoma skin cancer (NMSC) incidence has not been fully characterised.

Methods: Retrospective analysis of the Irish National Kidney Transplant database linked with laboratory data from clinical practice. Generalised estimating equations with random effects were used to investigate repeated measures of trough Tacrolimus levels tested in clinical practice in recipients (as a time-varying covariate) and NMSC development. Exposure to Tacrolimus was also calcuated using the trapezoid rule to calcuate area under the curve (AUC), and time-averaged trough values. SAS v9.4 was used for data analysis.

Results: N=1540 kidney transplant recpieints were included, 95% of whom were deceased donor transplants and 41% female. 38% of donors were female. NMSC development (N=188), was independently associated with serum trough Tacrolimus levels over follow up (see table 1). However this association was not significant after adjusting for era of transplantation. This was true both of serum tacrolimus as a time-varying parameter and AUC Tacrolimus. Factors such as mean, median, min, max, and variability in Tacrolimus were not associated with NMSC overall. Limiations include possible confounding by overall imunnosupressive burden, survivor bias as well as the fact that follow up length and frequency of testing varied for each participant.

Conclusions: From repeated measures analysis of clinical practice laboratory data, while Tacrolimus exposure as measured by trough values and AUC associate with NMSC development over follow up, this association is attenuated after accounting for transplant vintage.

Results of generalized estimating equation analysis with trough Tacrolimus levels as a time-varying covariate

Parameter	Estimate	Standard error	P value
Intercept	4.05	0.58	<.001

SA-PO006

Outcomes in Simultaneous Pancreas Kidney Transplant in the US Stratified by Induction and Use of Corticosteroids

Daniel Keys, Samy M. Riad, Robert N. Foley. *University of Minnesota, Minneapolis, MN.*

Background: Simultaneous Pancreas Kidney (SPK) transplantation is an excellent option for patients with significant renal impairment and diabetes. Outcomes for SPK have improved over the past decade. However, the ideal immunosuppression and induction remains unclear. We sought to analyze outcomes of graft loss and death as stratified by induction and use of low dose corticosteroid.

Methods: Between 2000-2016, 14676 SPK transplants were analyzed in the Scientific Registry of Transplant Recipients (SRTR) database. Groups were made by no induction, IL-2 antagonism, anti-thymocyte globulin (ATG), and alemtuzumab induction with (CCS) and without steroids (CSW). We adjusted for multiple variables including donor age, recipient age, PRA, length of time on dialysis, sex, race, history of heart disease, and HLA mismatches. We analyzed HR for death, kidney and pancreas allograft loss. Adjustment factors included: era; donor and recipient age, sex, race, weight and number of HLA mismatches; recipient time on dialysis, comorbidity, and panel reactive antibodies.

Results: Mean follow up for the cohort was 7.4 years. Regarding induction and steroid strategies, the likelihood of kidney allograft loss was lowest with CCS/ATG (13.2%, adjusted hazards ratio [AHR] 0.63 [0.53-0.76], P-Value <0.01, Table 1); pancreas allograft loss was least likely with CSW/ATG (15.9%, AHR 0.61 [0.51-0.73], P-Value <0.01, Table 2); death likelihood was lowest with CCS/ATG (12.7%, 0.8 [0.66-0.96], P-Value 0.02, Table 3).

Conclusions: In 14676 SPK transplants from the US, different induction and maintenance steroid strategies were associated with substantial variationin allograft survival and death. Kidney and pancreas allograft survival were longer with corticosteroids and overall survival was longer with CCS/ATG.

SA-PO007

Utility of Induction Agents in Simultaneous Liver-Kidney Transplantation

Nashila AbdulRahim, Suman Krishna Kotla, Lee E. Anderson, Hao Liu, Bekir Tanriover, Venkatesh Kumar Ariyamuthu. *Internal Medicine/Nephrology, UT Southwestern Medical Center, Dallas, TX.*

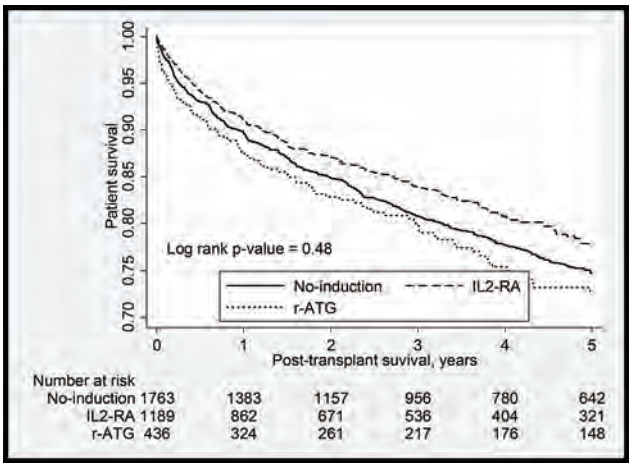
Background: The number of simultaneous liver-kidney transplants (SLKT) and utilization of induction therapy in SLKT is on the rise. There is little published evidence of utility of induction agents when contemporary maintenance immunosuppression regimen with tacrolimus, mycophenolic acid, and prednisone (TAC/MPA/PRED) is used.

Methods: We queried the OPTN registry for adult SLKT recipients in the US between 2002-2016. We divided the cohort into three groups based on induction agent: rabbit anti-thymocyte globulin (r-ATG, N=436), interleukin 2 receptor antagonists (IL2-RA, N=1,189) and no-induction (N=1,763) being the reference group. All patients were maintained on TAC/MPA/PRED at the time of discharge. The primary outcomes were post-transplant all-cause mortality and acute rejection rates at 6 months. Survival rates were analyzed using Kaplan-Meier (KM) method and compared between groups using the log rank test. We estimated hazard and odd ratios for our primary outcomes using a propensity score analysis (inverse probability weighting -IPW) adjusted Cox proportional hazard and logistic regression models.

Results: Compared with no-induction, the multivariable IPW adjusted Cox proportional hazard analyses showed an increased mortality with r-ATG (HR=1.31, 95% CI 1.04-1.65, p-value=0.02). At six-months post-transplant, acute rejection rates (both liver and kidney) were less than 10% and were not statistically significant between three induction categories

based on multivariable IPW adjusted logistic regression analysis. Mortality secondary to infection was statistically higher in r-ATG group.

Conclusions: In SLKT recipients maintained on TAC/MPA/PRED, induction categories were associated with similar rejection rates at six-months. Compared to no induction, r-ATG appears to increase mortality risk, probably secondary to infections. Benefit of IL2-RA induction in SLKT remains controversial.



SA-PO008

Steroid Maintenance and Outcomes in Kidney Transplant Recipients with Native Kidney Glomerulonephritis: An Analysis of OPTN/UNOS Database

Swati Arora, Kalathil K. Sureshkumar, Bhavna Chopra. *Division of Nephrology, Allegheny General Hospital, Pittsburgh, PA.*

Background: Kidney transplant recipients with history of native kidney glomerulonephritis (GN) are at increased risk of graft loss from recurrent GN. It is unclear if steroid maintenance could help in preventing recurrent disease and improve outcomes in these patients.

Methods: Using the United Network for Organ Sharing database, we identified adult kidney-only transplant recipients from 2001-2015, who had GN as cause of ESRD, who received induction therapy and were discharged on calcineurin inhibitor/mycophenolic acid with steroid maintenance (SM), n=14,610 or steroid withdrawal(SW), n=6, 406. Using a multivariate Cox-model adjusting for donor, transplant and recipient related factors, overall and death censored graft failure rates and patient death rates were compared between the SM and SW groups in patients with GN.

Results: There was significant difference between SM and SW groups in overall graft failure and patient death with a Hazard ratio (95% CI) of 1.10 (1.03-1.19) p-value of 0.009 and 1.21 (1.09-1.34) p-<0.001, respectively. However, there was no significant difference between the groups for death censored graft failure, hazard ratio 1.04 (0.95-1.14).

Conclusions: Despite a presumed potential benefit of steroid maintenance in reducing the risk for recurrent post-transplant GN, our study found increased risk for death with functioning graft associated with steroid use in KTRs with history of native kidney GN who received peri-operative induction followed by CNI/MMF maintenance. This could be a consequence of enhanced cumulative immunosuppression since these patients were likely exposed to prior immunosuppressive therapy for native kidney GN. Limitations are retrospective study design and possibility of residual confounding.

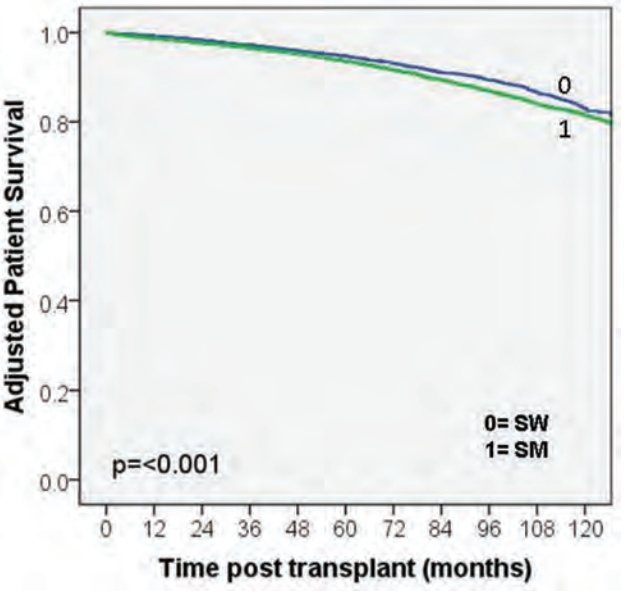


Figure: Patient Survival comparing Steroid Maintenance(SM) vs Steroid Withdrawl(SW) in Transplant Recipients with Glomerulonephritis

Corticosteroid Avoidance Among Low Immunologic Risk Adult Renal Transplant Recipients of a Living Donor: A Meta-Analysis

Amor Patrice Socorro E. Estabillo,[1] Luis V. Limchiu,[1] Anthony Russell Villanueva,[1] Marichel P. Coronel.[2] *[1]National Kidney and Transplant Institute, East Avenue, Quezon City, QUEZON CITY, Philippines; [2]Adult Nephrology, National Kidney and Transplant Institute, Quezon CIty, Philippines.*

Background: Chronic kidney disease is a devastating condition causing global public health burden with high economic cost to health care systems. Renal Transplantation is the standard of care among other forms of renal replacement therapy. Corticosteroids have a critical role, yet its long-term use is associated with a multitude of adverse effects leading to a greater deal of morbidity and mortality post-transplantation. Most researches include heterogenous group of populations: adult and pediatric, low and high immunologic risk recipient of a living or deceased donor. Studies including deceased organ donor population may not be applicable in our local setting since deceased organ donation in some countries are low, mainly due to scarcity of potential donor. Outcome studies on rejection rates may be varied by the immunological-risk status of the donor-recipient pair. Despite the increasing research, corticosteroid sparing following renal transplantation remains a controversial issue, hence the first meta-analysis to focus on a corticosteroid avoidace among low immunologic risk adult renal transplant recipients of a living donor.

Methods: Systematic literature review of the electronic database Cochrane Library, MEDLINE Ovid SP and Clinical Trials.gov were searched for randomized-controlled trials from September-November 2017. Statistical analyses used was random-effects model.

Results: Included 5 studies met the eligibility criteria (N=788). There is no increased risk in the steroid avoidance group having biopsy proven acute rejection at 12 months (RR:0.72[0.51,1.01]) I^2 10% p=0.05). A significant reduction towards the risk of New Onset of Diabetes Mellitus After Transplantation (RR:0.41[0.25,0.67]; I^2=0% p=0.0003). Likewise, hypertension (RR:0.35[0.12,1.02] I^2=82%p=.05) and Infection (RR:0.69[0.46,1.04]; I^2=71%p=0.07) was reduced post-transplantation.

Conclusions: Steroid avoidance is non-inferior to maintenance group in terms of biopsy proven acute rejection at 12-months. Metabolic complications and risk of infection were reduced post-transplantation as well.

SA-PO010

Clinical Outcomes and Factors Related with Mycophenolate Mofetil Withdrawal in Kidney Transplant Recipients

Woo Yeong Park,[1,2] Hayeon Park,[1] Jin hyuk Paek,[1,2] Kyubok Jin,[1,2] Seungyeup Han.[1,2] *[1]Department of Internal Medicine, Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Keimyung University Kidney Institute, Daegu, Republic of Korea.*

Background: Although the most effective initial maintenance immunosuppressants in kidney transplantation (KT) have been known as a combination of calcineurin inhibitor (CNI), steroid, and mycophenolate mofetil (MMF), immunosuppressive regimen has been changed due to several reasons within 1-year after KT. The most common changing pattern was MMF withdrawal, but the clinical course of the kidney transplant recipients (KTRs) after MMF withdrawal was not known clearly. The purpose of this study is to investigate the causes of MMF withdrawal, and the clinical outcomes and factors related with MMF withdrawal in KTRs.

Methods: We retrospectively analyzed the medical records of 626 KTRs performed KT at Dongsan Medical Center between 2000 and 2016. We evaluated the incidence of acute rejection, allograft and patient survival rates, and factors related with MMF withdrawal.

Results: Mean age of KTRs was 44.1 ± 11.6 years. Median time between KT and MMF withdrawal was 6.4 (range, 3.2 – 32.1) months. The most common cause of MMF withdrawal was infection (70.7%), followed by hematologic abnormalities (9.1%), and gastrointestinal trouble (7.7%). The proportion of cytomegalovirus infection was the highest (60.5%) among all infections, followed by BK virus infection (18.4%). The proportion of female KTRs and the incidence of BPAR were significantly higher in the MMF withdrawal arm compared with the non-MMF withdrawal arm (57.7% vs. 34.4%, P < 0.001; 27.4% vs. 8.9%, P < 0.001). Death-censored graft survival and patient survival rates were significantly lower in the MMF withdrawal arm compared with the non-MMF withdrawal arm (P < 0.001; P < 0.001). In multivariate analysis, MMF withdrawal was an independent risk factor for graft failure after adjustment for recipient age, gender, infection, and deceased donor KT (HR 6.058, 95% C.I., 3.172-11.569, P < 0.001).

Conclusions: The incidence of acute rejection, graft failure, and patient mortality rates in KT were high after MMF withdrawal. Therefore, MMF withdrawal should be considered carefully and resumed as soon as possible.

SA-PO011

A Promising Novel Approach with Everolimus-Based Quadruple Maintenance Therapy in Kidney Transplant Recipients with Difficult-to-Treat Rejections

Pierre Larsson,[1] Bodil Englund,[1] Jana Ekberg,[1] Marie Felldin,[1] Verena Broecker,[3] Lars Mjörnstedt,[1] Seema Baid-Agrawal.[2] *[1]Transplant Institute, Sahlgrenska University Hospital, Gothenburg, Sweden; [2]Department of Nephrology and Transplant Institute, Sahlgrenska University Hospital, University of Gothenburg, Gothenburrg, Sweden; [3]Department of Pathology, Sahlgrenska University Hospital, Gothenburg, Sweden.*

Background: Chronic rejections and treatment-resistant acute rejections are difficult to treat and lead to progressive loss of graft function in kidney transplant recipients (KTR). Here we review our experience with a novel approach to treat such rejections by adding everolimus, an inhibitor of mammalian target of rapamycin (mTOR) as a "rescue therapy" to the conventional triple maintenance therapy (prednisolone + mycophenolate mofetil + calcineurin inhibitor).

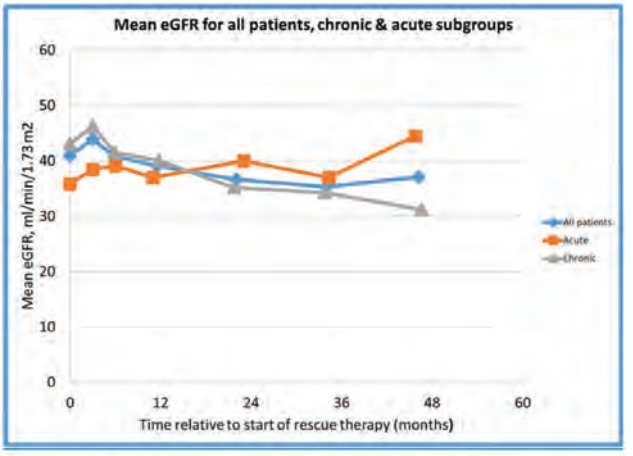
Methods: We analysed in detail electronic medical charts of 34 KTR who received everolimus-based quadruple therapy for biopsy-proven chronic rejections or treatment-resistant acute rejections between 2011-2017. A response to treatment was defined as an improvement/stabilization in the graft function (eGFR slope/year ≥1 ml/min/1.73m2/year).

Results: The results are summarized in the table below. Stabilization in graft function (eGFR) was seen at 48 months after treatment (table + figure), more so in acute as compared to chronic rejection subgroup. Treatment was stopped in 10 patients due to adverse events.

Conclusions: Everolimus-based maintenance quadruple therapy appears to be apromising novel approach for chronic rejections and treatment-resistant acute rejections, both of which are difficult to treat. Further randomized controlled studies are needed to confirm our findings.

Patients receiving quadruple therapy (N=34)

10 with acute rejection (2 acute cellular, 2 mixed cellular and antibody-mediated) 24 with chronic rejection (7 chronic cellular, 6 chronic antibody-mediated, 11 mixed)	
Age in years (mean ± SD)	44.5 ± 18.5
Gender (% males)	53%
Time from transplant to quadruple therapy in months (mean ± SD)	28.4 ± 31
Duration of treatment (mean ± SD)	29.7 ± 18.9
Response to treatment	14/34 (41%)
eGFR in ml/min/1.73m2, at baseline vs 48 months in all patients, acute and chronic subgroups, respectively (mean ± SD)	37.1 ± 19.2 vs 40.9 ± 16.8, 35.9 ± 8.8 vs 44.5 ± 23.1, 47.0 ± 19.0 vs 31.2 ± 15.3 (P=NS for all)
Patient and graft survival at 6 years after start of treatment (Kaplan-Meier)	77% and 51%, respectively. Not significantly different between the acute and chronic subgroups



Patients still on treatment at each point on the curve, n.							
Month:	0	3	6	12	24	36	48
A) All patients	34	33	32	31	27	18	9
B) Acute	10	10	10	10	8	7	4
C) Chronic	24	23	22	21	19	11	5

SA-PO012

Immunosuppression in the Failing Allograft: To Wean or Not to Wean?

Michelle L. Lubetzky,[1] Rex Friedlander,[3] Darshana Dadhania.[2] *[1]Division of Nephrology and Hypertension, New York, NY; [2]Weill Cornell Medical College, New York, NY; [3]The Rogosin Institute, New York, NY.*

Background: Sensitization is frequent after failed allograft yet there are no clear management strategies for tapering of immunosuppression.

Methods: We performed cross-sectional chart review of patients who were re-listed for repeat kidney transplant after either failed/failing allograft and subdivided them based upon their most recent calculated panel reactive antibody (cPRA) into two groups, LOW PRA, cPRA of <10% (n=18) or HIGH PRA, cPRA 100% (n=20).

Results: Table 1 describes the baseline characteristics. More patients in the 100% cPRA group had >1 prior transplant (35% versus 5.5%, p=0.05), but there was no difference in other sensitizing events or acute rejection episodes between the groups. All patients in the HIGH cPRA had failed allografts, while 8 patients in the LOW PRA group were pre-emptive and had functioning grafts (p<0.001). In the HIGH CPRA group, 30% had 0 CPRA at time of graft failure and the CPRA significantly increased in this cohort at follow up (Figure1; p<0.001), most of which (75%) were taken off immunosuppression during that time.

Conclusions: Graft failure leading to subsequent tapering of immunosuppression may be a risk factor for increase in CPRA while awaiting re-transplant. There is a need for a more standardized approach to weaning immunosuppression to avoid sensitization.

Table 1

Characteristic	Low cPRA n=18	High cPRA n=20	P value
Age (years)	58.61±11.94	53.35±14.42	0.23
Sex (Female)	6/18 (33.3%)	7/20 (35%)	1.00
Type of Transplant (%Living donor)	8/18 (44.4%)	9/20 (45%)	1.00
Race	9/18 (50%)	3/20 (15%)	0.0354
Sensitization events			
Pregnancy	5/6 (83.3%)	3/8 (37.5%)	0.14
>1 prior transplant	1/18 (5.5%)	7/20 (35%)	0.05
Transfusion	15/18 (83.3%)	18/20 (90%)	0.65
Acute Rejection	5/18 (27.8%)	10/20 (50)%	0.53
AMR	6/7 (85.7%)	9/10(90%)	1.0
Viral Complications	5/18 (27.8%)	3/20 (15%)	0.44
Mean Time to Failure (Days)	2101.0±1383	1796.2±1479.7	0.59
Graft Failure	10/18 (55.5%)	20/20 (100%)	<0.001
cPRA at graft failure (mean±SD)	8.1±16.1	50.26±41.85	0.01
cPRA at last measurement (mean±SD)	1.33±3.04	100±0	<0.001
Mean time from graft failure cPRA to most recent	790±472.2	1474±1192	
Immunosupression at PRA sample			
Prednisone	8/18 (44.4%)	5/19 (26.3%)	0.31
Tacrolimus	12/18 (66.6%)	1/19 (5.3%)	<0.001

SA-PO013

Trends in Transplant Nephrectomy After Kidney Allograft Failure in the United States

Medha Airy, Jingbo Niu, Wolfgang C. Winkelmayer. *Baylor College of Medicine, Houston, TX.*

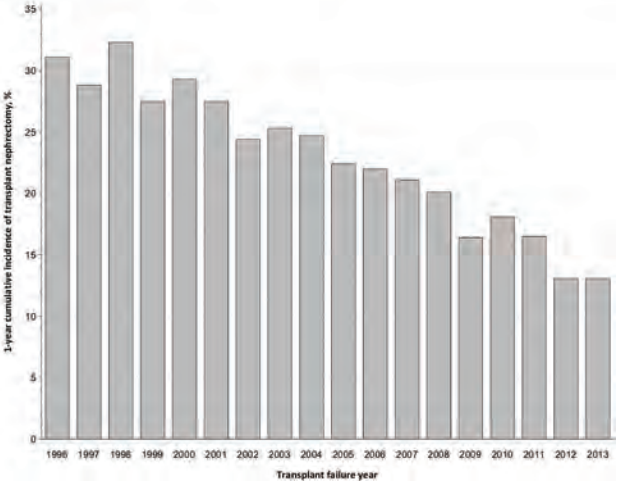
Background: Patients with end-stage kidney disease whose transplants have failed experience worse outcomes compared to those on dialysis not previously transplanted. Following allograft failure, transplant nephrectomy is commonly considered in patients with symptomatic rejection, infections, malignancy, or resistant anemia. Over the years, early allograft nephrectomies have declined due to improved short-term transplant outcomes, but information on the trends regarding nephrectomy among patients with later allograft failure is lacking. This study examined the trends over two decades in transplant nephrectomy following kidney allograft failure.

Methods: We used the US Renal Data System to identify all patients whose first kidney allograft failed >90 days after transplant and who had Medicare fee-for-service at the time. Patients were followed for any allograft nephrectomy within 1-year post-allograft failure. We used Cox proportional hazards models with year of allograft failure as the exposure of interest while adjusting for sociodemographic and health-related patient characteristics. Follow-up was censored at 1 year, loss of Medicare fee-for-service, re-transplantation, or death

Results: We included 29,496 patients whose first kidney transplant failed between 1996 and 2013. Multivariable-adjusted Cox models indicated non-significant hazard ratios (HR) for transplant nephrectomy between 1996 (referent) and 2006; thereafter, the rates of transplant nephrectomy declined considerably with HR of 0.85 (0.73, 1.00) for 2007 and 0.58 (0.49-0.69) for 2013

Conclusions: While adjusted rates of transplant nephrectomy were essentially static between 1996 and 2006, they have decreased considerably thereafter. The reasons for this trend are unclear but may reflect greater recognition of transplant nephrectomy-associated allosensitization.

Figure 1: Trends in 1-year Cumulative Incidence of Transplant Nephrectomy after Failure of a First Kidney Transplant



SA-PO014

Successful Kidney Transplantation in Adults with Antibody Deficiencies

Melanie Schoutteten, Maarten H. Christiaans. *Maastricht University Medical Centre, Eersel, Netherlands.*

Introduction: Antibody deficiencies (common variable immunodeficiency (CVID) and hypogammaglobulinemia (HGG)) associate with a high prevalence of infections, autoimmunity, granulomas and malignancies. Immune suppression in transplantation may amplify this risk. Therefore, in many centers these patients are not considered as suitable candidates for renal transplantation. In literature, only 2 cases of kidney transplantation in CVID patients are reported, both with bad short-term outcome. Because our center has a long track record in kidney transplantation with reduced immune suppression we decided to develop a set of preconditioning criteria and pioneered a transplantation program. We present 1 patient with CVID and 1 with HGG, both transplanted with good clinical and renal outcome.

Case Description: A 43-year old female known with ESRD due to reflux nephropathy and CVID, received a 43-year old DBD-renal transplant. Immunosuppression consisted of tacrolimus and low dose steroids. IVIG was continued. Protocol biopsy at month 3 was normal and steroids were withdrawn. Posttransplant, she had a few recurrent urinary and respiratory infections for which prophylactic azithromycin was given. 3 years posttransplantation patient is still in good clinical condition without malignancies and with a persistent good renal function (eGFR 40ml/min). A 61-year old male with ESRD due to polycystic kidney disease, known with HGG, was transplanted with a 64-year old DCD donor kidney with IGF. Immunosuppression consisted of tacrolimus, low dose steroids for 10 days and mycophenolate mofetil for 3 months. IVIG was continued. He had no acute rejection nor infection besides twice an asymptomatic cystitis. Until now, 2 years after transplantation, he has a persistent renal function of 28.3ml/min.

Discussion: Uniqueness of the cases We present 2 pioneer cases of successful renal transplantation in patients with antibody deficiency. Take away lesson Our data provide a framework for a pre-transplant risk reduction strategy combined with a specific immune suppressive regimen under an umbrella of IVIG supplementation allowing safe kidney transplantation of immune deficient patients.

SA-PO015

Induction Therapy in Elderly Kidney Transplant Recipients with Low Immunological Risk

Christophe Masset,[1,7] Julie Boucquemont,[2] Fanny Buron,[3] Valerie Garrigue,[4] Elisabeth Cassuto,[5] Marc Ladrière,[6] Yohann Foucher,[2] Jacques Dantal.[1,7] *[1]Nantes University Hospital, Nantes, France., Nantes, France; [2]Université de Nantes; UMR INSERM 1246 - SPHERE, Nantes, France; [3]Hospices Civils de Lyon, Lyon, France; [4]University Hospital Montpellier, Montpellier, France; [5]chu Nice, NICE Cedex 3, France; [6]CHRU NANCY, Vandoeuvre les Nancy, France; [7]Institut de Transplantation Urologie Néphrologie, Nantes, France.*

Background: Thymoglobulin (ATG) and Basiliximab (BSX) lead to similar rejection rates in low immunological risk patients. ATG could be benefit on Delayed Graft Function (DGF) and allow corticosteroid avoidance, supporting its use in elderly recipients. In contrast, it seems to be associated with infectious and malignancy risk, supporting the use of BSX, especially in recipients with low immunological risk. The benefit-risk balance remains unclear. We thus compared post-transplantation outcomes in elderly recipients with low immunological risk according to their induction therapy.

Methods: We conducted a French multicentric study on non-immunized ≥ 65 years patients receiving a first kidney transplant between 2010 and 2017 and an induction therapy by ATG or BSX. The principal outcome was patient and graft survival. We also studied the cumulative probabilities of infection, first acute rejection episode, malignancy; de novo DSA and eGFR at 1-year post transplantation; and occurrence of DGF. Cox, logistic or linear models were used depending on the studied outcome. To consider possible confounding variables, we weighted the models on the propensity scores.

Results: 204 (53.3%) patients were included in the BSX group, 179 (46.7%) in the ATG group. Average age was respectively 71.0 and 70.5 years. Patient and graft survival at 3 years post-transplantation were 74% (95%CI from 65% to 84%) in the ATG group, and 68% (95%CI from 60% to 78%) in the BSX group. The corresponding HR (Hazard Ratio) equalled 0.96 between the BSX group compared to the ATG group (95%CI from 0.58 to 1.60). The probability of infection at 1-year post-transplantation were 52% (95%CI from 59% to 44%) in the BSX group versus 51% (95%CI from 59% to 42%) in the ATG group, without significant difference. There was no difference in all the others evaluated outcomes as indicated in **Figure 1**.

Conclusions: In elderly recipients, induction therapy by ATG does not seem to lead to poorer outcomes compared to BSX.

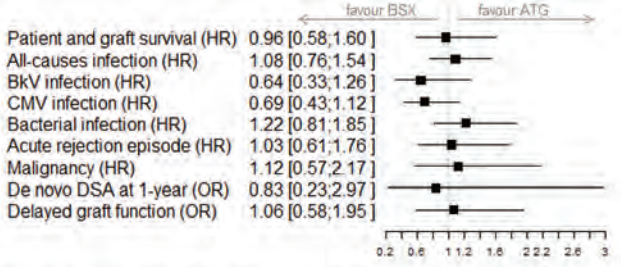


Figure 1: Summary of the relative risks of using Basiliximab instead of Thymoglobulin for the studied outcomes (BSX: Basiliximab; ATG: Thymoglobulin; OR: Odds-Ratio; HR: Hazard-Ratio).

SA-PO016

Is More Intensive Induction Immunosuppression Therapy for Highly Sensitized Kidney Transplant Recipients Better?

Inna Mohamadou,[1] Marie Matignon,[4] Stephanie Malard,[2] David Buob,[3] Philippe Grimbert,[4] Anissa Moktefi,[5] Eric Rondeau,[1] Yosu Luque.[1] *[1]Urgences Néphrologiques et Transplantation rénale. Hôpital Tenon. Assistance Publique Hopitaux de Paris, Paris, France; [2]Saint Louis Hospital APHP, Paris, France; [3]Tenon Hospital, Paris, France; [4]Nephrology and transplantation department, Mondor Hospital, Creteil, France; [5]AP- HP, Hopital Henri Mondor, Creteil, France.*

Background: Induction immunosuppression for highly sensitized kidney recipients varies, in particular the use of plasma exchanges (PE) and rituximab following transplantation to prevent antibody-mediated rejection (ABMR) and increase graft survival. We compared two induction strategies for patients undergoing kidney transplantation with a high level (MFI>3000) of pre-formed donor-specific antibody (DSA).

Methods: Our retrospective study included 45 kidney transplant recipients in two French centers, transplanted between 2012 and 2017. All patients had at least one pre-formed DSA (MFI > 3000) within 6 months before transplantation. All patients received anti-thymocyte globulin, a calcineurin inhibitor, mycophenolate mofetil and steroids on the day of transplantation. 22 of these 45 patients also received 5 PE and one rituximab dose (group A), whereas the remaining 23 patients did not (group B). Patients were followed for 1 to 6 years after transplantation.

Results: Comparing group A to group B, recipients' age (48±14 vs. 47±12 years), donors' age (54±16 vs. 57±12 years), cold ischemia time (16±6 vs. 19±7 hours) and MFI of the immunodominant DSA (8735±4192 vs. 10106± 6015) were similar (p=ns for all). There was no overall difference in the rate of biopsy-proven acute rejection at 1 year post-transplantation (n=9, 41% in group A vs. n=7, 30% in group B). ABMR occurred in n=6 vs. n=7 patients, and T-cell mediated rejection was observed in n=3 vs. n=0 patients, respectively in groups A and B. There was no difference in graft survival rate at 1 year post-transplant (91% in group A vs. 83% in group B, p=ns). Finally, the incidence of infectious, anaphylactic, thrombotic or hemorrhagic events was similar between the two groups.

Conclusions: Our study suggests that an intensive induction immunosuppressive therapy using PE and rituximab during early post-transplantation period does not decrease ABMR incidence or improve 1-year graft survival in highly sensitized recipients. An effect of PE on anti-thymocyte globulin pharmacokinetics could not be excluded.

SA-PO017

Risk Factors for Delayed Graft Function in Deceased Donor Kidney Transplantation: Is Intra-Operative Thymoglobulin Preventive?

Neda Naderi,[1,2] Mohammad reza Khatami,[1] Mahboob Lessan-Pezeshki,[1] Simin Dashti-Khavidaki,[1] Azam Alamdari,[1] Armin Safdarpour,[1] Hamid Moradi.[2] *[1]Nephrology Research Center, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran; [2]Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, CA.*

Background: Delayed graft function (DGF) is associated with significant adverse outcomes in deceased donor kidney transplantation including lower graft survival. However, risk factors and potential preventive strategies like intraoperative thymoglobulin (ATG) have not yet been fully evaluated.

Methods: We retrospectively examined medical records of 182 first time cadaveric kidney transplant recipients from two major kidney transplant centers from 2014-2016. Risk factors for DGF in recipients were evaluated using multivariate logistic regression analysis.

Results: The mean age was 43±13 years and the majority of participants were male (64%). The rate of intra-operative blood transfusion was 16%. The overall rate of DGF was 24.2%. Mean serum creatinine at discharge and length of hospital stay were significantly higher in patients with DGF compared with those without DGF (2.5 vs. 1.4 mg/dl and 25 vs. 14 days, respectively). Intra-operative ATG was significantly associated with a lower rate of DGF (adjusted odds ratio [AOR], 0.33, 95% CI, 0.11-0.95). Intra-operative transfusion (AOR, 3.7, 95% CI, 1.4-9.9) and diabetes mellitus (AOR, 3.7, 95% CI, 1.5-8.9) were significantly associated with higher risk of DGF. There was no statistically significant association between DGF and recipients' age, sex, body mass index or duration of pre-transplant dialysis.

Conclusions: This study showed that intra-operative blood transfusion and diabetes mellitus were independent risk factors for the development of DGF. Meanwhile, administration of intra-operative ATG was associated with a reduced odds ratio of DGF. Future studies are needed to evaluate the potential role of ATG in DGF-related renal outcomes.

SA-PO018

Role of Liver Transplantation in the Treatment of Fibrinogen Aa-Chain Amyloidosis

Arie Stangou,[2] Steven R. Zeldenrust,[1] Nelson Leung,[1] Jennifer H. Pinney,[7] Maria E. Drosou,[1] Thomas R. Schwab,[4] Oren Fix,[5] Russell H. Wiesner,[3] Merrill D. Benson.[6] *[1]Mayo Clinic, Rochester, MN; [2]Queen Elizabeth Hospital, Birmingham, United Kingdom; [3]Mayo clinic, Rochester, MN; [4]Mayo Clinic Rochester, Rochester, MN; [5]Swedish Medical Center, Seattle, WA; [6]Indiana University School of Medicine, Indianapolis, IN; [7]Department of Renal Medicine, University Hospital Birmingham, Worcestershire, United Kingdom.*

Background: Variants of fibrinogen Aα-chain (AFib) cause the commonest type of hereditary amyloid nephropathy in Europe and probably the US. Fibrinogen production is exclusively hepatic and kidney transplants often fail within 1-5 years with recurrent amyloidosis. The addition of liver transplantation (LT) offers curative potential. We present the long-term experience of the first 15 AFib patients who received liver grafts in our Institutions in the UK and US, and discuss the merits and scope for optimal utilisation of this valuable resource.

Methods: Ten British and 5 US patients with AFib E526V and amyloid nephropathy were listed for transplantation between 1995-2017. Dominant features were proteinuria (66%) median 7.37 (2.5-9.8) g/D and kidney impairment, median GFR 25 (0-104) ml/min. Extra-renal amyloid manifestations included cardiac (40%) and gastrointestinal (66.6%) autonomic neuropathy and clinically significant splenic amyloidosis (27%). Thirteen patients, median age 59 (49-63), 9 male, received liver-kidney transplant (LKT); two females aged 54 and 58, kidney disease stage 1 and 3 respectively, received isolated liver grafts (LT).

Results: At median posttransplant fol-up 133 months (12-277), there is no amyloid progression and cumulative patient survival in the entire cohort is 80%. LKT patient survival is 76.9%, kidney/ liver graft 92.3%, posttransplant GFR 46 (41-78) ml/min. Three adverse outcomes due to biliary or vascular complications occurred early postoperatively in the subgroup of 9 patients who received LKT after long-term haemodialysis (survival only 66.7%). In contrast, in those receiving pre-emptive LKT or LT alone patient survival was 100%. Both recipients of isolated LT maintain normal liver and stable renal function with diminishing proteinuria at 12 and 95 months.

Conclusions: The therapeutic potential of liver transplantation in fibrinogen amyloidosis is truly curative. Best transplant benefit from the addition of liver to kidney grafts was achieved in low risk pre-dialysis patients. Timely intervention in the pre-dialysis

setting utilising liver transplantation alone is rational, feasible and effective. We support consideration of this approach to halt disease progression and prevent haemodialysis.

SA-PO019

Impact of CYP3A5 Polymorphism on Clinical Outcome After Renal Transplantation

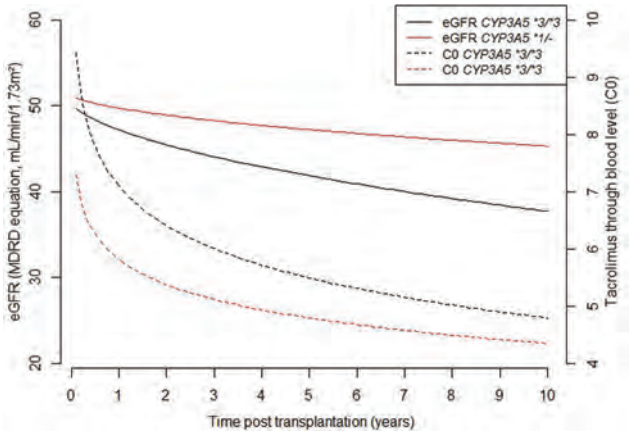
Remi Lenain,[2,1] Aghiles Hamroun,[2,1] Mehdi Maanaoui,[2,1] Cynthia Van der hauwaert,[6] Franck Broly,[5] Myriam Labalette,[7] Nicolas Pottier,[4] Christelle Cauffiez,[3,1] Francois Glowacki.[2,1] *[1]Lille University Hospital Center, Lille, France; [2]CHRU Lille, Lille, France; [3]EA4483, Lille, France; [4]University of lille, Lille, France; [5]Centre de Biologie Pathologie Génétique, Lille, France; [6]EA 4483 Faculté de Médecine de Lille, Lille, France; [7]CHRU Lille, Lille, France*.

Background: Tacrolimus exhibits pharmacokinetics variability partly explained by CYP3A5 activity. In contrast to *3/*3 genotype, those carrying at least one *CYP3A5*1* allele exhibit higher enzyme activity leading to lower Tac through blood level despite higher daily dose. In this study, we aimed to evaluate the impact of CYP3A5 polymorphism on renal graft outcome

Methods: This monocentric cohort includes 1252 renal transplant recipients with a mean follow up (FU) of 4 years (up to 12.1y). Genotyping of the 6986A>G allelic variant corresponding to *CYP3A5*3* was systematically performed. After 3-months post-transplant, Tac through blood level target range was 5-7ng/ml. However in order to avoid Tac-induced nephrotoxicity, Tac daily dose was limited to a maximum of 0.1 mg/kg/day irrespective of CYP3A5 genotype

Results: Our sample includes 224 *CYP3A5*1/-* patients (13.9%) including 35 *1/*1 genotype recipients. During the FU, we observed 221 graft losses or deaths (17.65%). At baseline, there was no significant difference in characteristics between *3/*3 and *1/- groups. Despite higher daily dose, *1/- recipients exhibit systematically significant lower Tac through blood level during the FU (p<0.01). Multivariate analysis doesn't show any significant influence of *1/- genotype (HR=0.73, CI95% 0.48–1.09, p=0.12) on patient-graft survival. However, GFR decline was significantly lower for the *1/- group (p=0.004). At five years, eGFR was significantly better for *1/- recipients (47 vs 42 mL/min/1.73m2, p<0.001). *CYP3A5* genotype doesn't impact the risk of rejection (HR for *1/- group=0.96, CI95% 0.66-1.42, p=0.87)

Conclusions: In this long-term study, *CYP3A5*1/-* recipients exhibited lower Tac through blood level with no impact on the rejection rate. Renal survival was independent of CYP3A5 genotype. However, the kidney graft function was significantly better in this subgroup showing a lower Tac-induced nephrotoxicity



SA-PO020

HLA Desensitization Using Rituximab/Immunoadsorption Before Kidney Transplantation

Lionel Rostaing.[1,2] *[1]Pôle DIGIDUNE, La Tronche, France; [2]Faculté de médecine, université Joseph Fourié, GRENOBLE, France*.

Background: Many kidney-transplant (KT) candidates are sensitized against HLA-antigens, making it difficult to find a suitable HLA-compatible donor. Pretransplant HLA-desensitization strategies have shown improved patient survival after transplantation. This single-centre study included 14 KT candidates (of which seven had a potential living-donor) that underwent kidney transplantation after desensitization comprising two rituximab injections (375 mg/m2) with concomitant immunosuppression [tacrolimus + mycophenolic acid + steroids, and semi-specific immunoadsorption (IA) (GlobaffinÒ columns)].

Methods: IA sessions were performed until anti-HLA alloantibodies become ≤3,000 mean fluorescent intensity (MFI). At transplantation, all patients were induced with ATG. On average, recipients of a living-kidney had 12 (12-15) pretransplant IA sessions; at transplant their donor-specific alloantibodies (DSA) had MFI of ≤3,000 except for 2 with no rebound at posttransplant. Recipients of deceased donors had 15 (8-83) pretransplant IA sessions; all of them had a DSA at transplantation; however, MFI was ≤4,000 in all cases but one (anti-DPA1 at 7,000). After transplantation, there was no prophylactic IA therapy in both groups.

Results: No living-kidney recipients and one deceased-donor recipient had antibody-mediated rejections (ABMR), which was successfully treated with eculizumab. Follow-up kidney biopsies (at a median of 12 months posttransplantation) were normal except for two cases in which there were signs of subclinical ABMR. There was no significant infectious complications.

Conclusions: Semi-specific immunoadsorption was very effective at achieving HLA desensitization.

SA-PO021

De Novo Complement-Activating Donor Specific Antibodies Are Highly Responsive to Therapy

Vaka K. Sigurjonsdottir, Paul C. Grimm. *Stanford University Medical Center, Stanford, CA.*

Background: After recognizing that graft failure was more common in our patients with positive *de Novo* DSAs (*dn*DSAs) by C1q we started using the C1q assay as a guide to therapy of rejection. The aim of this study was to investigate response to treatment as well as characteristics and allograft function of pediatric renal transplant patients with positive *dn*DSA by C1q.

Methods: Retrospective cohort of 35 pediatric renal transplant patients, age 1-20 years, who formed C1q *dn*DSAs identified by screening or investigation of allograft dysfunction with at least 6 month follow up. C1q *dn*DSAs were identified by single-antigen flow bead assay. Outcomes were evolution of C1q *dn*DSAs and graft function in patients with C1q. GFR was estimated using Schwartz method. The same pathologists reviewed all biopsies.

Results: Followup was 36 months (11-96) (Median (range).) Figure 1 shows evolution of C1q. Therapy consisted of Solumedrol (n=19), Thymoglobulin (n=15), IVIG (n=23), Rituximab (n=20) and 1 received Bortezomib / plasmapheresis. Steroid free immunosuppression was converted to steroid based in 9 patients. Maintenance immunosuppression was adjusted/increased when appropriate, adherence anticipatory guidance was provided as needed. During the follow up period, 5 patients, had allograft failure. Figure 2 shows Kaplan–Meier curves for renal survival.

Conclusions: Interventions directed against complement-binding DSA at our center, reduced or eliminated the C1q biomarker significantly. Persistence of C1q antibodies was associated with worse allograft outcome

Patient characteristics		
DSA evolution	C1q eliminated N=28	C1q persisted N=7
Identified risk of rejection (n)		
BK/EBV/CMV (decreased immunosuppression)	6	0
Non-adherence	3	6
Lymphocytopenia (off MMF)	1	0
PTLD (decreased immunosuppression)	0	1

No rejection	2	0
Borderline rejection.	6	1
Banff IA	0	2
Banff IB	6	1
Banff IIA	2	1
Banff IIB	2	0
CD4+	11	2
No biopsy	10	2

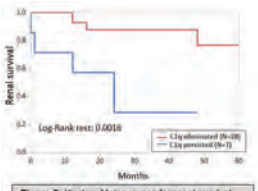

Figure 2: Kaplan–Meier curves for renal survival, defined as decline of at least 50% of GFR or ESKD

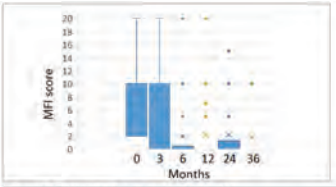

Figure 1: De Novo DSA titer trend by C1q I and II.
Time 0 represents when dnDSA were detected. DSA is plotted using relative intensity score (RIS.) Ranges from 0 points = No DSA; 2 points = <5000MFI (weak intensity); 5 points = 5000-10,000 MFI (moderate intensity); 10 points = >10,000MFI (strong intensity).

SA-PO022

Predictors of Graft Survival at Diagnosis of Antibody-Mediated Renal Allograft Rejection

Michael Duerr,[1] Friederike Bachmann,[1] Nils Lachmann,[1] Jens Klotsche,[2] Fabian Halleck,[1] Kaiyin Wu,[3] Lutz Liefeldt,[1] Klemens Budde,[1] Johannes Waiser.[1] AG Duerr & Waiser *[1]Charité Universitaetsmedizin Berlin, Berlin, Germany; [2]German Rheumatism Research Center Berlin, a Leibniz Institute, Berlin, Germany; [3]Institut für Pathologie, Charite Campus Mitte, Berlin, Berlin, Germany*.

Background: Treatment of antibody-mediated rejection (ABMR) after renal transplantation is unsatisfactory. In order to improve treatment efficacy, it is necessary to identify parameters, which independently predict graft survival at diagnosis.

Methods: We investigated 54 consecutive renal allograft recipients with a diagnosis of ABMR between 2005 and 2015. Patients were treated with five different consecutive treatment groups of 10-12 patients. Patient characteristics, renal function and HLA antibody status at diagnosis, baseline renal biopsy results and immunosuppressive treatment were thoroughly recorded. The identification of diverse risk factors of graft loss at 24 months after diagnosis was investigated uni- and multivariate by a Cox proportional hazard model.

Results: Concerning the underlying patient characteristics including baseline parameters at diagnosis, we found no major differences between treatment groups. Multivariable analysis showed that transplant glomerulopathy, microvascular inflammation, and eGFR were predictive for graft loss at 24 months after diagnosis (table 1). In our analysis proteinuria (per 500mg/day) was statistically not a risk factor in the univariate analysis (HR 1.12; 95% CI 0.99-1.27; p=0.072). Notably, a significant (>10%) decrease of DSAmax (HR 0.62; 95% CI 0.25-1.52; p=0.294) following treatment was not associated with an improved graft survival compared to patients with no significant DSA decrease. Treatment with cyclophosphamide (6x15mg/m^2) plus high-dose intravenous immunoglobulins (IVIG) (1.5g/kg) was superior compared to treatment with rituximab (1x500mg) (HR 0.10; 95% CI 0.02-0.54; p=0.008) or bortezomib (4x1.3mg/m^2) plus low-dose IVIG (30g) (HR 0.16; 95% CI 0.02-0.99; p=0.049).

Conclusions: Histopathological signs of acute and chronic ABMR as well as renal function at diagnosis are independent risk factors for graft survival. Treatment with cyclophosphamide plus high-dose IVIG seems to be advantageous. Prospective studies including patients with defined risk factors are needed in order to further improve treatment efficacy.

Funding: Clinical Revenue Support, Government Support - Non-U.S.

Table 1- Risk factors for graft loss at 24 months after transplantation – multivariate analysis

	HR	95% CI	p value	c-statistics
Glomerular double contours (cg) (grade 0-3)	1.57	1.01 ; 2.58	0.045	0.61
Interval between transplantation and diagnosis (per year)	1.11	0.99 ; 1.24	0.065	0.60
eGFR (CKD-EPI, per mL/min) at diagnosis	0.94	0.89 ; 0.98	0.018	0.65
Microvascular inflammation (mvi) (g+ptc, per grade, 0-6)	1.37	1.01 ; 1.88	0.048	0.53

c-statistics = Harrel's C (range 0.5 to 1), measure for the predictive power of a risk factor of graft loss at 24 months

Outcomes Following Living Donor Kidney Transplantation in Patients with Donor-Specific HLA Antibodies After Desensitization with Immunoadsorption

Florian Kälble,[2,1] Luiza Pego silva,[2,1] Claudius Speer,[2,1] Christian Nusshag,[2,1] Matthias Schaier,[2,1] Martin G. Zeier,[2,1] Arianeb Mehrabi,[2] Caner Süsal,[2] Christian Morath.[2,1] *[1]Nierenzentrum Heidelberg, Heidelberg, Germany; [2]University Hospital Heidelberg, Heidelberg, Germany*.

Background: Due to the current organ shortage, living donor kidney transplantation is increasingly performed over human leukocyte antigen (HLA) or ABO antibody barriers. Uncertainty still exists concerning the risk for antibody-mediated rejection episodes, possibly limiting long-term graft survival. The present study aimed to evaluate the outcomes of kidney transplantations performed after desensitization in patients with donor-specific HLA antibodies compared to standard risk recipients.

Methods: Thirty-eight sensitized patients were included in the study. Sixteen patients had a positive CDC and/or ELISA crossmatch result with their prospective living donor and 32 patients had Luminex-detected donor-specific HLA antibodies (DSA). Patients were successfully desensitized by immunoadsorption treatment (median of 8 treatments) and anti-CD20 antibody rituximab (N=36) combined with antithymocyte globulin (N=20) or anti-IL2 receptor antibody therapy (N=18). Twelve patients were additionally treated by plasmapheresis. All patients received a kidney transplant from a living donor. Postoperative apheresis was performed in 28 patients. The outcomes of the 38 patients were retrospectively compared to outcomes of 76 standard risk recipients (2:1 matching).

Results: During a median of 8 pretransplant immunoadsorption treatments, IgG was reduced by 98% and IgM by 78% in sensitized patients. After transplantation, sensitized patients showed comparable death-censored graft survival and patient survival compared to standard risk recipients. Infectious complications, surgical complications and rejection rates (18% in both groups) were not significantly different between groups. Median 1-year serum creatinine was with 1.31 mg/dL in sensitized recipients not significantly different to the 1.38 mg/dL in standard risk recipients. One-year urinary protein excretion was also not significantly different with a low 10.8 and 10.5 g/mol creatinine, respectively.

Conclusions: Our desensitization protocol for sensitized living donor kidney transplant recipients results in good graft outcomes with comparable side effects and rejections rates to standard risk recipients.

SA-PO024

Outcomes in Sensitized Kidney Transplant Recipients Treated with Rituximab

Perola Lamba,[1] Isha Lamba,[2] Rex Friedlander,[3] Michelle L. Lubetzky,[4] John R. Lee,[4] Jun B. Lee,[3] Choli Hartono,[3] David Serur,[3] Thangamani Muthukumar,[4] Vijay K. Sharma,[3] Darshana Dadhania.[4] Weill Cornell Medicine *[1]Department of Medicine, New York Presbyterian/Weill Cornell Medicine, New York, NY; [2]Weill Cornell Medicine-Qatar, Doha, Qatar; [3]The Rogosin Institute, New York, NY; [4]Division of Nephrology and Hypertension, Weill Cornell Medicine, New York, NY*.

Background: Donor specific antibodies (DSAs) are associated with increased risk of rejection & graft loss following kidney transplantation (KT). Patients with DSA & positive flow cytometry crossmatch (XM) were treated with rituximab at transplant while those with negative XM and DSA were not. We evaluated clinical outcomes of patients with DSA at time of transplant stratified by rituximab therapy.

Methods: Retrospective review of sensitized KT recipients with DSA were studied excluding ABO-incompatible transplants. Graft survival was compared using log-rank test & multivariable analysis was performed using logistic regression.

Results: Individuals treated with rituximab were more likely to receive steroid maintenance & had higher DSA MFI-Sum (Table 1). One-year acute rejection rates were not different between those treated with & without rituximab. The survival of rituximab treated group was significantly lower (Fig. 1, P=0.02). In a logistic regression model, none of the variables were independent predictors of graft survival, rituximab therapy (P=0.24), steroid therapy (P=0.83), MFI-Sum category (P=0.44).

Conclusions: Among sensitized patients, those treated with rituximab had higher levels of DSA and had decreased overall graft survival. Treatment with rituximab was not independently associated with increased risk of graft loss. Additional studies are need to truly evaluate the risks & benefits of rituximab therapy in the highly sensitized patient population.

Table 1: Baseline Characteristics and Outcomes in Sensitized Patients with and without Anti-CD20 Therapy

	Rituximab (N=27)	No Rituximab (N=83)	p-value
Age (years, mean ± sd)	58 ± 11	55 ± 15	0.41

SA-PO025

The Risk of Renal Re-Transplantation

Anke Schwarz, Theodor Framke, Hermann G. Haller. *Hannover Medical School, Hannover, Germany*.

Background: Renal transplant programs comprise around 15% of re-transplantations. We aimed to know if renal re-transplantation (Tx2) has a higher risk than first transplantation (Tx1), and if so, to analyze the reasons for it.

Methods: This is a retrospective monocenter study by comparing graft and patient survival of all 162 Tx2 patients transplanted 2000 to 2009 (study group) with 162 Tx1 patients matched for age (± 10 years), gender, date of transplantation (± 18 months), and the kind of kidney donation (control group). We looked for differences in clinical parameters with a possible influence on graft and patient survival (observation time 8 to 17 years).

Results: Graft and patient survival of TX2 was inferior to that of TX1 patients (p=0.0011 resp p=0.0477, test for paired data). Group TX2 had a longer dialysis treatment than TX1 (113.0±52.5 vs 65.6±33.9 months; p<0.0001); more often HLA mismatches (MM) (2.54±1.75 vs 2.08±1.65, p=0.0129) and preformed panel reactive HLA-antibodies (PRA) >30% (15.4% vs 1.9%, p=0.0001); and more often induction therapy by thymoglobulin instead of IL-2R antibody (59.9% vs 1.9%, p<0.0001). The number of patients with rejection (39.57% vs 36.4%) and of rejections per patient (0.58±0.92 vs 0.56±0.87) were not different; however, graft failure by acute and chronic rejection was more frequent in the Tx2 group (32.22% vs 21.21%, p=0.0137). The number of patients with severe infections threatening life and/or graft function was not different (41.36% vs 39.5%); however, death by severe infection was more frequent in group Tx2 (0.0411). Testing several variables by Kaplan-Meier curves, Tx2 show an inferior graft survival than Tx1 patients with a higher number of HLA-MM (logrank p=0.0137), with humoral rejection (logrank p=0.0037), and have a higher mortality with several concomitant diseases, (logrank p<0.0001), especially cardiovascular disease (logrank p<0.0001), and severe infection (logrank p=0.0001).

Conclusions: Tx2 patients have several reasons for an inferior graft and patient survival compared to Tx1 patients: a) Immunologic reasons (more often HLA MM and high PRA, more often graft failure by rejection); b) higher mortality by concomitant diseases, especially cardiovascular disease and infection; c) less capacity to adapt to immunologic and infectious problems and failure to cope with them.

SA-PO026

Kidney Transplantation Outcomes in Patients with Idiopathic Membranous Nephropathy as Primary Disease

Sophia Lionaki,[1] Sophia Akritidou,[1] Alexandra Mavroudi,[1] Georgios Liapis,[1] Aliki Iniotaki,[2] Georgios Zavos,[3] John Boletis.[1,4] *[1]Nephrology, Laiko Hospital, Athens, Greece; [2]Histocompatibility, Gennimatas Hospital, Athens, Greece; [3]Transplantation Unit, Laiko, Athens, Greece; [4]Medicine, National & Kapodistrian University of Athens, Athens, Greece*.

Background: Kidney transplantation (KTx) is the treatment of choice for patients with glomerular diseases. However, in some occasions relapse of the primary disease in the graft may impact graft survival. We aimed to explore the outcome of KTx in patients who ended in ESRD due to idiopathic membranous nephropathy (IMN), the frequency of disease relapse in the graft along with the response to the current treatment options.

Methods: We retrospectively studied all patients with IMN as primary disease, transplanted in our hospital between 1990-2016. All patients had biopsy proven IMN in their native kidneys. Demographics and characteristics related to the donors and the recipients at KTx were recorded, including, dialysis time, immunosuppressive schemes, histocompatibility data, acute rejection episodes, patient and graft survival, and eGFR at the end of the follow up time. Relapses of IMN were recorded in conjunction with the given treatment and the related response. All patients with IMN relapse were initially treated with an ACE inhibitor (fosinopril) and depending on the response or not, received either the Ponticelli protocol, as 2ndline therapy, or more recently rituximab.

Results: We identified 18 patients with ESRD due to IMN who received a graft between 1990-2016 in our hospital. The mean age at the time of KTx was 47±11.5 years and 13(72.2%) of them were males. The mean time in dialysis was 63.2(±51.5) months, the graft was from deceased donors in 13 cases (72.2%), with a mean donor age of 46(±15.46) years. During a follow up time of 84.97(±57.6) months after KTx, 7 patients (38.8%) experienced at least one episode of IMN relapse. Time to relapse was 45.6(±42.7) months from KTx and 24-hour proteinuria was 4.12(±2.88) gr. Two patients experienced acute rejection, one of them during the relapse of IMN. At the end of the follow up time, patients' survival was 100%, graft survival was 88.9%, with a mean serum creatinine of 1.8(±0.23) mg/dl, eGFR of 60.84 (±27.3) ml/min/1.73m^2 and mean 24-hour proteinuria of 0.75(±0.58) gr.

Conclusions: Relapse of IMN in the graft is not rare, but in most occasions is responsive to therapy, either with inhibition of the renin angiotensin system, either with enhancement of immunosuppressive treatment, and generally it does not affect long term graft survival.

SA-PO027

Outcomes of Kidney Transplant Recipients with Pre-Transplant, Recurrence, and Post-Transplant Malignant Melanoma

Sarah E. Di Bartolomeo, Stacey Rolak, Brad C. Astor, Sandesh Parajuli. *University of Wisconsin School of Medicine and Public Health, Madison, WI*.

Background: Kidney transplant recipients (KTRs) have an increased risk of malignancy, especially skin cancer. Patients with pre-transplant melanoma usually wait a longer period before transplantation than their counterparts with non-melanoma skin cancers as there is limited data on risk of recurrence and outcomes of pre, recurrent and post-transplant melanoma.

Methods: We analyzed the outcomes of KTRs transplanted at our center between 01/01/1994 and 12/31/2014 who reported pre-transplant melanoma, recurrence of melanoma after transplant and post-transplant melanoma.

Results: Of 4941 KTRs within the abovementioned time-period, thirty-four had a history of melanoma prior to renal transplant, of which 6 (18%) had recurrence of melanoma post-transplant. Mean wait time from melanoma diagnosis to transplant was 389 ± 311 days for non-recurrent patients and 422 ± 411 days (p=0.32). The mean interval to recurrence of melanoma was 6.2 ± 3.7 years after transplant. Five of the 6 patients with recurrence had end stage renal disease due to diabetes. All KTRs with or without recurrence were Caucasian. The cumulative incidence of biopsy-confirmed rejection was 50% (n=3) in those with recurrence, compared to 4% (n=1) in those without recurrence (p=<0.001). The mean interval from transplant to rejection was 2.9 ± 1.6 and 1.4 years respectively. The cumulative incidence of death censored graft loss was 17% (n=1) among recurrent melanoma patients with an interval from transplant to graft loss of 6.0 years while the incidence among only pre-transplant melanoma was 14% (n=4) with an interval of 5.0 ± 3.1 years. Similarly, there were a total of forty-five Caucasian KTRs with post-transplant melanoma. The mean interval from transplant to melanoma was 4.4 ± 3.1 years. The incidence of death censored graft loss was 11% (n=5) at last follow-up.

Conclusions: Recurrence of melanoma is common among KTRs with pre-transplant melanoma, especially among KTRs with diabetes. Incidence of biopsy proven rejection and graft failure among recurrent melanoma is high. Proper risk stratification and early diagnosis may improve patient and graft survival.

SA-PO028

History of Posttraumatic Stress Disorder, and Mortality After Kidney Transplantation

Miklos Z. Molnar,[1,3] Ashmita Siwakoti,[1] Praveen Kumar Potukuchi,[1] Abduzhappar Gaipov,[1] Manish Talwar,[1,3] Vasanthi Balaraman,[1,3] Arijit Chakravarty,[1,3] Elani Streja,[2] James D. Eason,[1,3] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]University of California Irvine, School of Medicine, Orange, CA; [3]University of TN/Methodist Transplant Institute, Memphis, TN*.

Background: History of posttraumatic stress disorder (PTSD), if uncontrolled, represents a relative contraindication for kidney transplantation. However, no previous large study assessed the association between pre-transplant history of PTSD and post-transplantation outcomes.

Methods: We examined 4,479 US veterans who underwent kidney transplantation. The diagnosis of history of PTSD was based on a validated algorithm. Associations between pre-transplantation PTSD and all-cause mortality was examined in unadjusted and multivariable adjusted Cox proportional regression models.

Results: From among 4,479 veterans, 282 (6.3%) had a history of PTSD. The mean±SD age of the cohort at baseline was 61±11 years, 91% were male, 66% and 28% of patients were white and African-American, respectively and 31% received living transplantation. Compared to patients without history of PTSD, patients with a history of PTSD had similar risk of all-cause death [Hazard Ratio (HR) (95% Confidence Interval (CI)): 1.12 (0.82-1.51)] in our unadjusted model as shown in Figure 1. After adjustment for socio-demographic, comorbidity, medication, dialysis and transplant related variables there was no association between history of PTSD and all-cause mortality [HR (95%CI): 1.17 (0.83-1.65)].

Conclusions: After careful selection, pre-transplantation PTSD does not appear to be associated with higher mortality in kidney transplant recipients.

Funding: NIDDK Support

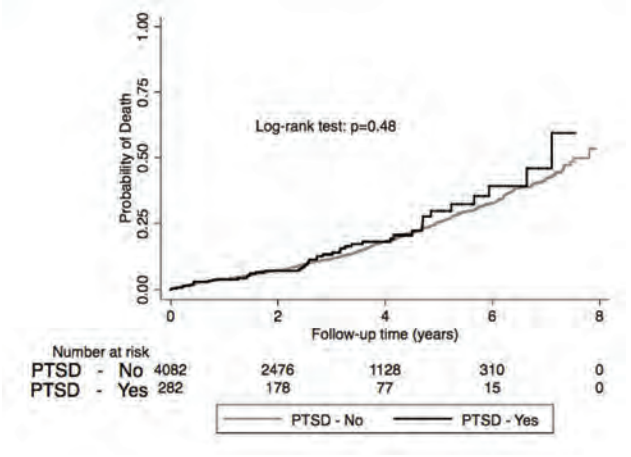

Figure 1: Probability of Death in Recipients with and without PTSD

Establishing a Core Outcome Measure for Life Participation: A Standardized Outcomes in Nephrology – Kidney Transplantation (SONG-Tx) Consensus Workshop Report

Angela Ju,[1,2] Michelle A. Josephson,[3] Kevin J. Fowler,[4] Jonathan C. Craig,[5] Martin Howell,[6] Allison Tong.[7] *[1]The University of Sydneyd, Sydney, NSW, Australia; [2]Center for Kidney Research, Westmead, NSW, Australia; [3]University of Chicago, Chicago, IL; [4]Kidney Health Initiative, Elmhurst, IL; [5]University of Sydney/Children's Hospital, Sydney, NSW, Australia; [6]University of Sydney, School of Public Health, Sydney, NSW, Australia; [7]The University of Sydney, Seven Hills, NSW, Australia.*

Background: Kidney transplantation confers substantial survival and quality of life benefits for many patients with end-stage kidney disease compared with dialysis but complications and side effects of immunosuppression can impair participation in daily life activities. Life participation is a critically important patient-reported outcome for kidney transplant recipients but it is inconsistently and infrequently measured in trials. We convened a consensus workshop on establishing a core outcome measure for life participation for use in all trials in kidney transplantation.

Methods: Twenty-five (43%) kidney transplant recipients/caregivers and 33 (57%) health professionals from eight countries participated in six facilitated breakout group discussions. Transcripts were analyzed thematically

Results: Four themes were identified. *Returning to normality* conveyed the patients' goals to fulfil their given roles (i.e. in their family, work, and community) and re-establish a normal lifestyle. *Recognizing the diverse meaning and activities of 'life'* explicitly acknowledged life participation as a subjective concept that could refer to different activities (e.g. employment, recreation, family duties) for each individual patient. *Capturing vulnerability and fluctuations post-transplant* (e.g. due to complications and side-effects) distinguished between experiences in the first year post-transplant and the long-term impact of transplantation. *Having a scientifically rigorous, feasible and meaningful measure* was expected to enable consistent and frequent assessment of life participation in trials in kidney transplantation.

Conclusions: A feasible and validated core outcome measure for life participation is needed so this high-priority patient-reported outcome can be consistently and meaningfully assessed in trials in kidney transplantation to inform decision-making and care of patients.

SA-PO030

Fatigue Predicts Graft and Patient Survival After Kidney Transplant

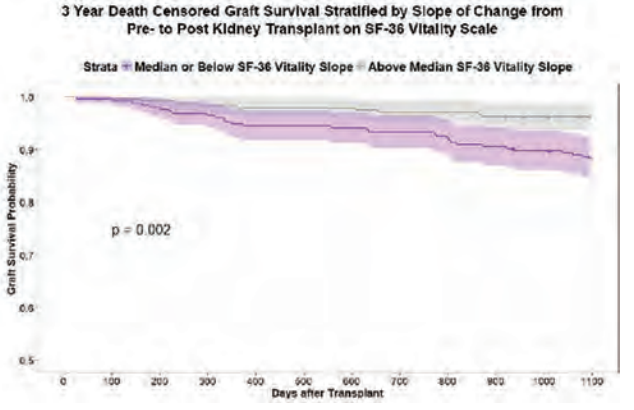
John D. Peipert, Juan C. Caicedo, Kelsey L. Ensor, David Cella, John J. Friedewald, Michael Abecassis, Daniela Ladner, Zeeshan Butt. Northwestern University Transplant Outcomes Research Collaborative-NUTORC *Northwestern University, Chicago, IL.*

Background: Fatigue is a prevalent post- kidney transplant (KT) symptom, and it is associated with reduced overall health-related quality of life and decreased kidney function. Yet, its association with graft and patient survival is unclear.

Methods: Using the SF-36 Vitality (Vit) scale and a single question from the Functional Assessment of Cancer Therapy – Kidney Symptom Index, "I have a lack of energy" (GP1), we examined change in fatigue from pre- and post-KT (3 months and 1 year) among **528** KT patients between 10/29/2007 and 08/18/2016 at a large academic transplant center. The Vit scale ranges from 0-100, and GP1 ranges from 0-4. On both measures, higher scores indicate less fatigue. We examined whether pre-KT fatigue and slope of change in fatigue from pre- to post-KT were associated with 1- and 3-year death censored graft survival (DCGS) and patient survival.

Results: Respectively, mean Vit and GP5 scores increased from pre-KT to 3 mo and 1 year post-KT: Vit - 45.4, 63.5, 67.3 (p<0.001); GP1 – 1.8, 2.7, 2.9 (p<0.001). There was a significant association with change in creatinine from pre- to post-KT with fatigue measured by both the Vit and GP1 (p<0.001 for each). Patients with median or below Vit scores pre-KT had significantly lower 1 year DCGS rates (93.2% vs. 96.9%, p=0.045) and patient survival rates (96.2% vs. 99.6%, p=0.006). Patients with median or below slope in Vit score change from pre- to post-KT had lower 3 year DCGS rates (88.5% vs. 96.2%, p=0.002) (Figure). Similar to these results, patients with median or below slope in GP1 score change from pre- to post-KT had lower 3 year DCGS rates (88.8% vs. 94.6%, p=0.04).

Conclusions: Fatigue is associated with reduced kidney function, graft failure, and mortality after KT. Patients with high risk for graft loss and mortality also suffer from higher fatigue after KT than those with well working kidneys. Future research should explore how monitoring fatigue might improve post-KT follow-up.



SA-PO031

Long-Term Outcome of Kidney Transplant Recipients Admitted to the Intensive Care Unit

Amgad E. El Agroudy.[1,2] *[1]Medicine, College of Medicine and Medical Sciences, Arabian Gulf University, Manama, Bahrain; [2]Nephrology and Transplantation Unit, Salmaniya Medical Complex, Manama, Bahrain.*

Background: The goal of this study was to evaluate the course and outcome of kidney transplant (KT) recipients admitted to ICU.

Methods: We reviewed the data of all adult renal transplant recipients who are admitted to the ICU at our center, between 1997 and 2017 that included the demographic features, causes of end-stage renal disease (ESRD), causes of admission, time between transplantation and admission and ICU courses and outcome. Among 379 KT followed up in our center, 60 patients were admitted to ICU and were categorized to early (during first 3 months; n=28); intermediate (3–12 months; n=7); and late (12 months and afterwards, n=25).

Results: The rate of ICU admission was 15.9% and the mean age was 48.3 ± 12.6 years. The main cause of admissions was surgical complication (71%) in early group and infection (57% and 80%) in later groups, respectively. Mortality on discharge was significantly higher in late admission (52%) (p=0.0001) and the leading cause of death in all groups was sepsis (89%). Twenty patients required ventilator that was an independent risk factor for mortality (P < 0.05). There was statistically significant decrease in the overall 5-year and 10-year patient survival (P = 0.031) in KT patients admitted to the ICU.

Conclusions: Our study shows that the main reason for ICU admissions was infections especially in late admission. Mortality rate were relatively high and was linked to need for ventilators. Admission to the ICU is usually associated with decrease in the graft and patient survival.

SA-PO032

Anemia at One Year After Kidney Transplantation Is a Risk Factor of Graft and Patient Survival

Amgad E. El Agroudy.[1,2] *[1]Medicine, College of Medicine and Medical Sciences, Arabian Gulf University, Manama, Bahrain; [2]Nephrology and Transplantation Unit, Salmaniya Medical Complex, Manama, Bahrain.*

Background: Post-transplant anemia is multifactorial and highly prevalent. The purpose of this study was to assess whether the presence of anemia at 12 months year is an independent risk factor of mortality and graft survival.

Methods: All patients followed-up at a single center who survived at least 1 year after transplantation and with serum creatinine ≤140 μmol/l (n = 297) were included. Demographic and clinical data were collected at baseline and at 1 year. Patients were divided into two groups (anemic and nonanemic) based on the presence of anemia (hemoglobin; 13 g/dl in men and 12 g/dl in women) at 12 months.

Results: Baseline characteristics such as age, gender, type of donor, etiology of end-stage kidney disease, pre-emptive transplant, duration of pre-transplant dialysis, type of primary immunosuppression and mismatches were similar in both groups. There was statistically higher use of induction therapy (p=0.021), rate of acute rejection after the first year (p=0.020), CMV infection (p=0.015) and chronic allograft damage (p=0.004) in anemic group compared to nonanemic group. Creatinine clearance at last follow-up was significantly lower in anemic (59.3 ± 10.8 ml/min) and nonanemic groups (45.3 ± 12.5 ml/mim)

(P = 0.039). A Kaplan–Meier survival analysis at 10-year post-transplant showed significantly poorer death-censored graft survival in the anemic group, P = 0.04 and patient survival (p=0.03). There was more statistically rate of death with function graft in anemic group (p=0.043).

Conclusions: In this study, anemia at 1 year was independently associated with death-censored graft and patient survival. Anemic patients have higher rate of acute rejection, and chronic allograft damage.

SA-PO033

The Combination of Area Under Curve of Estimated Glomerular Filtration Rate for 2 Years and Annual Rate Change of Estimated Glomerular Filtration Rate Predicts Long-Term Outcome in Kidney Transplants

Eun jeong Lee, Song in Baeg, Hyo jin Boo, Minjung Kim, Hye Ryoun Jang, Jung eun Lee, Dae Joong Kim, Yoon-Goo Kim, Ha Young Oh, Wooseong Huh. *Samsung Medical Center, Seoul, Republic of Korea*.

Background: Improvement of short-term outcomes in kidney transplant (KT) has required clinical trials to evaluate long-term hard outcomes for validation of new therapies. However, because of time and cost, it is very difficult to conduct a clinical trial using hard outcomes in KT. To solve the problem, the use of surrogate marker should be considered. We examined the possibility of the combination of area under curve of estimated glomerular filtration rate for 2 years ($AUCeGFR_{2yrs}$) and % change in estimated glomerular filtration rate (eGFR) between years 1 and 2 after KT as a surrogate marker for long-term graft failure.

Methods: We studied 1423 kidney transplants performed from 1996 to 2013 at Samsung Medical Center, Seoul, Korea, including 202 graft losses (time to graft failure, median 8.4 years [5.4 - 12.4]) and 54 deaths (time to death, median 9.1 years [5.7 - 13.2]). Combination of $AUCeGFR_{2yrs}$ (>1300 ml/min·month vs ≤ 1300 ml/min·month) and % change in eGFR (> 2% vs ≤ 2%) was assessed to determine risk of graft failure using Cox proportional hazard analysis.

Results: The combination was significantly associated with graft failure ($p < 0.0001$). Patients with $AUCeGFR_{2yrs}$ ≤ 1300 ml/min·month and % change in eGFR ≤ 2% formed 16.7% of all patients and showed higher graft failure risk (hazard ratio [HR], 3.36; 95% confidence interval [95% CI], 2.52 to 4.48). The Harrell C-index of the combination was 0.65 (95% CI, 0.60 to 0.69), and was internally validated via 5-fold cross-validation (average Harrell C-index, 0.64; 95% CI, 0.60 to 0.68). We also evaluated a known surrogate marker, ≥ 30% decline in eGFR between years 1 and 3 after KT. The incidence of ≥ 30% decline in eGFR was 6.9% of patients. HR of graft failure was 7.18 (95% CI, 5.22 to 9.89) and Harrell C-index was 0.65 (95% CI, 0.63 to 0.66).

Conclusions: We conclude the proposed combination might be useful as a surrogate outcome in KT trials in that it requires shorter surveillance period (2 years) than the known surrogate marker (3 years) while having comparable predictability. External validations should be conducted.

SA-PO034

Impact of Donor Age on Outcome of Kidney Transplantation from Deceased Donor with Histologic AKI

Myung-Gyu Kim, Junyong Lee, Jihyun Yang, Sewon Oh, Sang-Kyung Jo. *Korea University Anam Hospital, Korea University College of Medicine, Seoul, Republic of Korea*.

Background: The shortage of donors has expanded donor criteria and kidneys from elderly donors with AKI have been used for transplant recently, but safety and prognosis are not well known. Here, we examined the effect of donor age on outcomes of kidney transplant (KT) from donor with histologic AKI.

Methods: We analyzed retrospectively the medical records of 59 deceased-donor KT with acute tubular necrosis (ATN) on pre-implantation donor kidney biopsy between March 2012 and October 2017. Histologic quantifications of ATN and inflammation, glomerular sclerosis (GS), interstitial fibrosis, tubular atrophy, and arterial sclerosis were performed.

Results: Twenty and thirty nine recipients were received kidney from old (>60, 68.9±5.0) and young donors (≤60, 45.9±9.6) with ATN, respectively. In the old donors, a significant increase in donor Cr was observed only in 44%, diabetic patients were higher, women were dominant, and the percent of GS(%) was significantly higher than in young donors. After KT, six months eGFR was significantly lower in recipients who received kidney from old donors than form young donors. Donor creatinine level and AKI severity according to AKIN criteria did not significantly affect the recipient outcome in both groups during 6mo post-transplant. However, only in KT from old donors, the presence of ATN and GS(%) were found to be significant factors exacerbating renal outcome at 6mo, but not in KT from young donor. In particular, in multivariate analysis, the sum of ATN scoring and GS percent was the strongest independent factor for predicting elderly recipient renal function, suggesting that aged kidney is an important factor in modifying the outcomes of AKI.

Conclusions: Taken together, the assessment of AKI based on creatinine is not useful for predicting prognosis, but in KT from old donors, acute tissue injury as well as GS could predict renal outcome. Therefore, a donor allocation protocol with evaluating histologic acute and chronic lesions through pre-implantation donor kidney biopsy need to be developed when KT from old donors.

SA-PO035

Incidence, Outcomes, and Predictors of Pregnancy in Kidney Transplant Recipients

Silvi Shah, Annette Christianson, Karthikeyan Meganathan, Anthony C. Leonard, Charuhas V. Thakar. *University of Cincinnati, Cincinnati, OH.*

Background: Although kidney transplant improves reproductive function in women with end stage renal disease (ESRD), pregnancy in kidney transplant recipients remains challenging due to risk of adverse outcomes. Temporal trends in pregnancy rate, fetal outcomes and its predictors in women with kidney transplants are not well studied.

Methods: We evaluated women aged 15-49 years who received a kidney transplant between 1/1/2005 and 12/31/2011 from the United States Renal Data System and who had Medicare as the primary payer for the entire 3 years after the date of transplantation or until graft failure or death. Temporal trends in pregnancy rates and fetal outcomes were studied. Case mix adjusted multivariate Poisson regression analysis was used to determine predictors of pregnancy.

Results: Overall, 308 pregnancies were identified in 9939 women. Mean maternal age was 30±7 year. Pregnancy rate was 11.4 per 1000 person-year (95% CI, 10.1-12.7). Pregnancy rates were roughly constant in the years 2005-2011. Of the known pregnancy outcomes, rate of live-birth was 42.6%, and stillbirth was 3.7%. Another 14.4% were reported as either live birth or stillbirth. Rate of spontaneous abortion was 32.4%, therapeutic abortion was 6.5% and ectopic pregnancy was 1.4%. Compared to women aged 25–29 years at time of conception, the pregnancy rate was lower in women aged 30–34 years (Incidence risk ratio [IRR], 0.56; CI, 0.41-0.77), 35-39 years (IRR, 0.16; CI 0.10-0.25), 40-44 years (IRR, 0.08; CI, 0.04-0.13), and 45-49 years (IRR, 0.06; CI, 0.03-0.10). Hispanic women had higher rates of pregnancy as compared to White women (IRR, 1.6; CI, 1.2-2.1). In transplant recipients, as compared to women with ESRD due to diabetes, pregnancy rate was higher in women with ESRD due to hypertension (IRR, 1.3; CI, 1.0-1.7), glomerulonephritis (IRR, 2.4; CI, 1.1-5.3), and cystic/hereditary diseases (IRR, 3.3; CI, 1.4-7.8). Women had higher rate of pregnancy in the second (IRR, 1.7; CI, 1.3-2.3) and third post transplant year (IRR, 1.7; CI, 1.3-2.3) as compared to first post transplant year.

Conclusions: Pregnancy in kidney transplant recipients is not uncommon and rates were relatively constant in in the last decade. Younger and Hispanic patients; and those with conception after the first post transplant had the highest rates of becoming pregnant.

SA-PO036

Pregnancy Outcomes in Women with Kidney Transplant: Meta-Analysis and Systematic Review

Silvi Shah,[1] Renganathan Lalgudi venkatesan,[1] Ayank Gupta,[3] Emily B. Kean,[1] Maitrik K. Sanghavi,[1] Tiffany J. Grant,[1] Anu Gupta.[2] *[1]University of Cincinnati, Cincinnati, OH; [2]Buffalo Medical Group, Buffalo, NY; [3]The University of Cincinnati, Cincinnati, OH.*

Background: Reproductive function in women with end stage renal disease generally improves after kidney transplant. However, pregnancy remains challenging due to the risk of adverse clinical outcomes. This systematic review aimed to determine the pregnancy outcomes in patients with kidney transplant, including live birth rate, nature and rates of maternal and fetal adverse events, and risk of graft failure.

Methods: We searched PubMed/MEDLINE, Elsevier EMBASE, Scopus, BIOSIS Previews, ISI Science Citation Index Expanded, and the Cochrane Central Register of Controlled Trials from their date of inception through August 2017 according to PRISMA guidelines for studies reporting incidence and outcomes of pregnancy in women with kidney transplant.

Results: Of 1343 unique studies, 87 met inclusion criteria, representing 6712 pregnancies in 4174 kidney transplant recipients. Mean maternal age was 29±2 years. The live-birth rate was 72.9% (95% CI 70.0-75.6). Other pregnancy outcomes included induced abortions (12.4%; 95% CI, 10.4-14.7), miscarriages (15.4%; 95% CI, 13.8-17.2), stillbirths (5.1%; 95% CI, 4.0-6.5), and ectopic pregnancies (2.4%; 95% CI, 1.5-3.7). Maternal complications that were determined included preeclampsia (21.5%; 95% CI, 18.5-24.9), gestational diabetes (5.7%, 95% CI 3.7-8.9), pregnancy induced hypertension (24.1%; 95% CI, 18.1-31.5), and cesarean section (62.6%, 95% CI 57.6-67.3). Fetal complications of preterm delivery was 43.1% (95% CI 38.7-47.6). Mean gestational age was 34.9 weeks, and mean birth weight was 2470 grams. With regards to graft outcomes, rate of acute rejection during pregnancy was 9.4% (95% CI, 6.4%-13.7%). Adverse pregnancy outcomes of cesarean section and neonatal deaths were highest, and live birth rate were less favorable in the 2-3 year interval as compared to 1-2 year and > 3 year interval following kidney transplant. Rates of spontaneous abortion were highest in women with mean maternal age < 25 years and > 35 years as compared to women aged 25-35 years.

Conclusions: Majority of pregnancies following kidney transplant are successful and do not have an adverse impact on fetal survival. However the risks of maternal and fetal complications are high in women with kidney transplant and should be considered in patient counseling and clinical decision making.

SA-PO037

Timing of Native Nephrectomy and Kidney Transplant Outcomes in Children

Sarah J. Kizilbash,[1] Priyamvadha Balaji,[1] Resha Tejpaul,[2] Jane M. Lewis,[1] Priya Verghese.[3] *[1]University of Minnesota, Minneapolis, MN; [2]Univ of MN Dept of Urology, Minneapolis, MN; [3]University of Minnesota Masonic Children's Hospital, Minneapolis, MN.*

Background: Native nephrectomies are indicated for various reasons in pediatric kidney transplant (pKtx) candidates. Nephrectomies may be performed prior to (2-stage) or at the time of transplant (1-stage). The optimal timing of nephrectomies remains controversial and there are no data comparing the outcomes associated with two approaches.

Methods: We retrospectively examined 32 consecutive pKtx recipients who underwent native nephrectomies at the University of Minnesota between 01/01/2011 and 12/31/2016. We investigated the effect of the timing of nephrectomy on patient and graft survival using Kaplan-Meir and log-rank test. We compared categorical variables using Fisher exact and continuous variables using Wilcoxon rank sum tests.

Results: Our cohort included 21 patients with 1-stage and 11 patients with 2-stage nephrectomies. Clinical characteristics are presented in table 1. Although statistically insignificant, patients with 2-stage tended to be older. Indications for nephrectomy included vesicoureteral reflux/urinary infections (40.6%), nephrotic syndrome (31.3%) and cystic kidney diseases (15.6%). There were no differences in the indications for nephrectomy between 1-stage versus (vs.) 2-stage patients. There was no difference in the rate of peri-operative complications between two groups. For 2-stage, median length of hospital stay (LOS) after nephrectomy was 7.5 days (range: 6-10), and median time to transplant was 4.3 months (range: 3-73) for living and 15 months (range: 3 -180) for deceased donor recipients. Posttransplant LOS was significantly shorter for 2-stage patients (median days: 12 vs. 8, p 0.03). There were no differences in 1-year patient (100% vs. 100%, p 1.0) or graft survival (95% vs. 90.9%, p 0.68) between 1-stage vs. 2-stage patients.

Conclusions: There were no differences in 1-year patient and graft survival between pKtx recipients with 1-stage vs. 2-stage native nephrectomies. Posttransplant LOS was shorter for patients undergoing 2-stage nephrectomies; however, they required two hospitalizations.

Variables	1-stage procedure N= 21	2-stage procedure N = 11	p value
Age at transplant in years Median (range)	2 (1-17)	7 (1-16)	0.09
Male % (n)	52.4 (11)	54.6 (6)	0.9
Caucasian % (n) African American % (n) Other % (n)	76.2 (16) 4.8 (1) 19.1 (4)	63.6 (7) 9.1 (1) 27.3 (3)	0.74
Donor source % (n) Deceased	57.1 (12)	45.5 (5)	0.71
Pre-nephrectomy Dialysis % (n)	71.4 (15)	54.6 (6)	0.44

SA-PO038

Solid Organ Transplantation and Mortality Following Diffuse Large B Cell Lymphoma

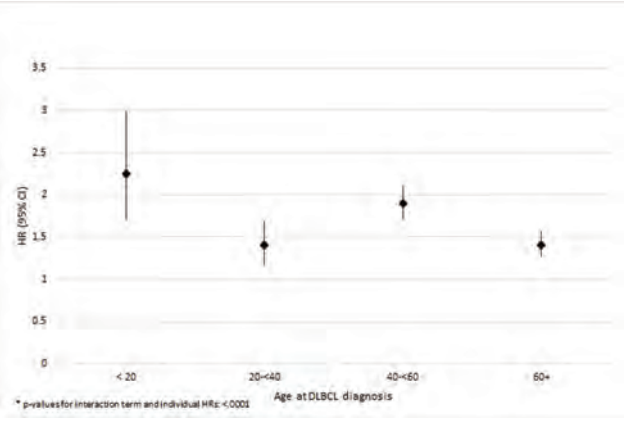
Sarah J. Kizilbash,[1] Michaela R. Richardson,[1] Jon J. Snyder,[3] Bertram L. Kasiske,[2] Eric A. Engels,[4] Ajay K. Israni.[2] *[1]University of Minnesota, Minneapolis, MN; [2]Hennepin County Medical Center, Minneapolis, MN; [3]Minneapolis Medical Research Foundation, Minneapolis, MN; [4]National Cancer Institute, Bethesda, MD.*

Background: Diffuse large B cell lymphoma (DLBCL) is a common malignancy in all age groups after solid organ transplant. The effects of prior transplant on mortality following DLBCL and the effect modification by age at diagnosis have not been described.

Methods: We used 11 state cancer registries to identify all DLBCL cases in those states and ascertained history of organ transplant through a linkage to the Scientific Registry of Transplant Recipients. We used a Cox proportional hazard model to examine the effect of transplant on mortality after adjusting for age at DLBCL diagnosis, sex, race, year of diagnosis, site of DLBCL, stage of cancer at diagnosis and treatment. We also investigated an interaction between age at diagnosis and transplant status.

Results: Our cohort included 1,338 DLBCL cases with prior organ transplant and 132,713 without. Compared with non-transplant patients, transplant recipients had lower mean age at diagnosis (48.5 vs. 62.4 years, p <0.0001), male preponderance (67.5 vs. 53.3%, p <0.0001), higher incidence of extranodal disease (49.7 vs. 37.5%, p <0.0001), and higher prevalence of distant stage at diagnosis (47.5 vs. 43%, p <0.0001). After multivariate adjustment, overall (adjusted hazard ratio (aHR): 1.83, 95% CI: 1.71-1.96) and cancer-specific mortality (aHR: 1.21, 95% CI: 1.1-1.33) were higher in transplant recipients than in non-transplant patients. The effect of transplant on mortality following DLBCL was highest in patients aged younger than 20 years at diagnosis (Figure).

Conclusions: Prior organ transplant is associated with an increased risk of overall and cancer-specific mortality following DLBCL. The effect of transplant on mortality is highest in DLBCL patients aged younger than 20 years at diagnosis.



Overall mortality of patients with DLBCL with prior organ transplant compared to those without

SA-PO039

Adult Educational and Vocational Outcomes of Pediatric Solid Organ Transplant Recipients in Canada

Mina Matsuda-Abedini,[1,2] Jeffrey Schiff,[3] Jennifer Harrison,[3] Bethany J. Foster.[4] *[1]The Hospital for Sick Children, Toronto, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]Toronto General Hospital, Toronto, ON, Canada; [4]McGill University Health Center, Montreal, QC, Canada.*

Background: There are a paucity of data on educational attainment and vocational outcomes in young adults who received solid organ transplants in childhood.

Methods: Young adults (18-25 years) who had received a solid organ transplant at <18y old completed questionnaires in outpatient transplant clinics at seven centres across Canada. The transplant cohort was compared with the age-matched general Canadian population over the same time period (2016-2017) using Statistics Canada survey data (over 3.5 million people 18-25 years).

Results: There were 161 transplant recipient participants with a mean age of 22 ±2.3 years; 55% were male. The median age at diagnosis of organ failure was 9.5 years [IQR 2, 15]. There were 112 (70%) who had received a kidney, 37 (23%) a liver, and 12 (7%) a heart. Compared with the age-matched general population, transplant recipients were less likely to have a university degree (9.3% vs. 14.9%; risk difference -5.5% [95%CI -10.0% to -1.1%]; P=0.048) or to be employed (68.4% vs. 83.0%; risk difference -14.6% [95%CI –22.0% to -7.2%]; P<0.0001). Among those employed, a higher percentage of transplant recipients (81.6%) earned less than the Low Income Cut-Offs (LICO) compared to the general population (64.6%); risk difference 17.1%[95%CI 8.9% to 25.2%]; p<0.001). LICO is defined as an income threshold below which a family will likely devote a larger share of its income on the necessities of food, shelter, and clothing than the average family.

Conclusions: Young adult survivors of pediatric solid organ transplantation in Canada have lower educational achievement and are less likely to be employed than the age-matched general population. Similar findings were recently reported in Europe. In order to improve the educational and vocational outcomes, greater advocacy and support are needed for pediatric recipients of solid organ transplant as they transition to adulthood.

MR Urogram Without Contrast in Transplant Obstructive Uropathy

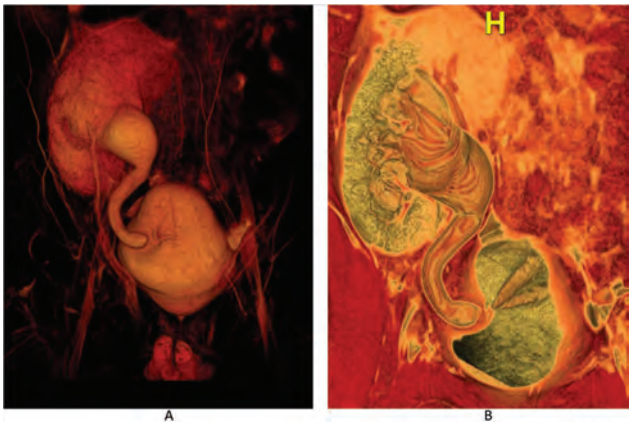
Juan C. Infante,[1,2] Jayanthi Chandar,[2,4] Gaetano Ciancio,[1,2] Marissa J. Defreitas,[2,4] Alireza Alam,[3,4] Chryso P. Katsoufis,[2,4] Mohammed Farhan Ali,[2] Carolyn L. Abitbol.[2,4] *[1]University of Miami, Miami, FL; [2]University of Miami/Jackson Health Systems, Miami, FL; [3]Jackson Memorial Hospital, Miami, FL; [4]University of Miami/ Pediatric Nephrology, Miami, FL.*

Introduction: After kidney transplantation, hydronephrosis is a common problem that may result from obstruction or reflux. A voiding cystourethrogram entails urethral catheterization, radiation exposure, and patient discomfort. Alternatively, an MR urogram (MRU) can be performed without any potentially toxic intravenous (IV) contrast agent. We present a case that shows the feasibility MRU with an IV saline bolus and furosemide only.

Case Description: A 17 year-old boy with a kidney transplant presented with rising creatinine and recurrent hydronephrosis 9 months after the transplant. The immediate post-transplant course was notable for hydronephrosis and stricture in the ureterovesical junction (UVJ) treated with balloon ureteroplasty one month after surgery. The hydronephrosis improved after balloon ureteroplasty, but over the next 5 months there was a gradual decline in kidney function and the patient experienced recurrent episodes of acute kidney injury (AKI). Renal ultrasound showed recurrence of the hydronephrosis; the differential included recurrence of the UVJ stricture versus reflux. An MRU without contrast revealed "moderate hydroureteronephrosis with tight narrowing at the UVJ." Intraoperatively, stone fragments were discovered along the wall of the distal ureter causing obstruction of the UVJ, but no stricture was present. The ureteral re-implantation was revised to allow passage of possible

future stones. There were no further episodes of AKI or hydronephrosis up to 4 months after the revision.

Discussion: MRU using IV saline and furosemide can yield high-quality 3D images that identify targets for intervention in the setting of renal dysfunction while also avoiding nephrogenic systemic fibrosis.



3D MR urogram without contrast showing (A) moderate hydroureteronephrosis and tight narrowing near the UVJ. (B) Hollow view shows the narrowing near the UVJ followed by the urine jets in the bladder, consistent with partial obstruction.

SA-PO041

Outcomes of Dialysis and Transplantation in Cystinosis from NAPRTCS Database

Ewa Elenberg. *Texas Children's Hospital, Baylor College of Medicine, Houston, TX.*

Background: Cystinosis (Cys) is a rare genetic disease. There are no sufficient published data on outcomes of dialysis and kidney transplantation in Cys patients (pts). North American Pediatric Renal Trials and Collaborative Studies (NAPRTCS) was established in 1987 with the goal to study transplant pts. The database was expanded in 1992 to include dialysis pts. As of 2015, the NAPRTCS has data on over 7039 dialysis and 18225 transplant pts.

Methods: Retrospective analysis of NAPRTCS database of registered dialysis and renal transplant cystinosis pts. Data on Cys pts are compared to other registry pts with non-recurrent, i.e. non-immunologic causes (NIC) of potential graft loss. Specific aims were to investigate potential differences among studied dialysis and transplant pts.

Results: Dialysis data from 95 Cys pts were compared to 1472 NIC dialysis pts. There was statistical significance in blood pressure (BP), height and weight Z-Score, growth deficit, the use of rGH, calcium and PTH levels. Dialysis survival was better in Cys pts (p-value 0.046). There is no statistical difference in gender, dialysis modality, anemia, erythropoietin use, albumin, phosphorus level and time to transplant while on dialysis. Transplant data from 231 transplant Cys pts were compared to 2844 transplant NIC pts. Data was collected in 6 months (mo) interval from baseline at 30 days post transplant (p/Tx) to 60 mo p/Tx. Baseline height Z-Score was low in both groups: with mean Z-Score in NIC -2 and in Cys – 3.39 (p-value<0.005). Though improved height Z-Score at 60 mo p/TX to mean -1.84 in NIC, vs.-2.92 in Cys, the difference remains statistically significant. Weight Z-Score between 2 groups remains statistically significant with baseline mean at -1.22 for NCI vs. -2.59 for Cys. Although weight Z-score is gradually improving over time in both groups, at 60mo p/Tx mean Z-Score for NIC is -0.33 vs Cys -1.68 (p-value <0.005). There was no statistical difference in gender, creatinine levels, systolic and diastolic blood pressure Z-Scores, graft survival, donor source (LRD vs. DD), preemptive transplant, time to first rejection, number of transplants.

Conclusions: Height and weight Z-Scores in Cys dialysis and transplant pts were poorer when compared NIC pts. Cys pts have improved dialysis survival. Cys transplant pts did not differ from NIC pts in BP Z-Scores, donor source, preemptive transplant, graft survival, time to first rejection.

Mortality and Morbidity in Kidney Transplant Recipients with a Failing Graft

Ngan Lam,[1] Robert R. Quinn,[2] Devon J. Boyne,[2] Peter Austin,[3] Patricia Campbell,[1] Brenda Hemmelgarn,[2] Greg A. Knoll,[4] Serdar Yilmaz,[2] Pietro Ravani.[2] *[1]University of Alberta, Edmonton, AB, Canada; [2]University of Calgary, Calgary, AB, Canada; [3]Institute for Clinical Evaluative Sciences, Toronto, AB, Canada; [4]Ottawa Hospital, Ottawa, ON, Canada.*

Background: There is little information on mortality and morbidity in kidney transplant recipients with a failing graft. Due to their history of renal disease and exposure to immunosuppression, recipients may be at higher risk of adverse outcomes compared to non-transplant controls with similar degree of chronic kidney disease.

Methods: We performed a retrospective study of kidney transplant recipients with a failing graft in Alberta, Canada (2002-2013), defined as ≥2 eGFR measurements between 15-30 mL/min/1.73 m^2 that were 90-365 days apart. We propensity-score matched (1:1) recipients with a failing graft to non-transplant patients on several demographic characteristics, clinical, and laboratory data. We used Cox regression to compare the hazard for death between the two groups and negative binomial regression to compare hospital admission rates.

Results: We identified 521 kidney transplant recipients with a failing graft and matched 487 (93%) of them to a non-transplant control. The median age of the cohort was 56 years (IQR 45-65) and 41% were women. Compared to matched non-transplant controls, kidney transplant recipients with a failing graft had a higher rate of death (hazard ratio 1.25, 95% CI 1.01-1.55; p=0.039) and hospitalization (rate ratio 1.72, 95% CI 1.44-2.06; p<0.001). Kidney transplant recipients also had significantly higher rates of hospitalization for cardiovascular events and infections, but not cancer.

Conclusions: A failing kidney transplant adds further mortality and morbidity burden to chronic kidney disease. This information may assist the discussion of prognosis in kidney transplant recipients with a failing graft and the design of strategies to minimize risks.

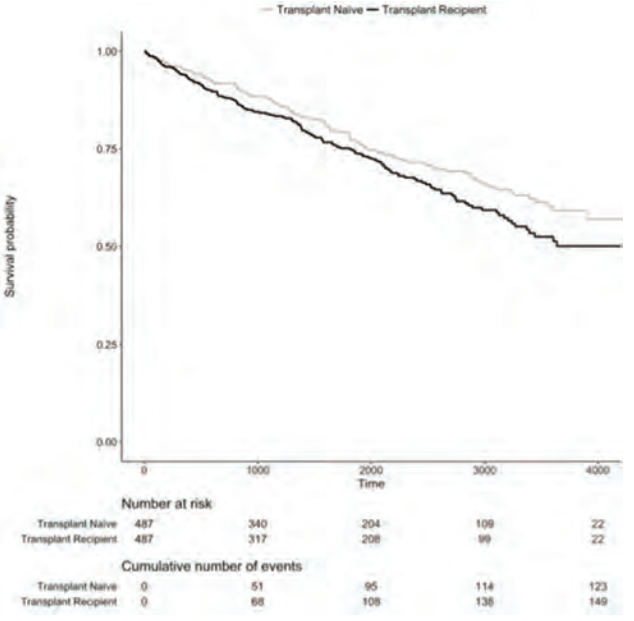

Figure. Kaplan-Meier estimated survival probabilities stratified by transplant status

SA-PO043

Benzodiazepines and Opioid Co-Prescriptions: Outcome Implications in Kidney Transplant Recipients

Ngan Lam,[2] Mark Schnitzler,[11] David A. Axelrod,[3] Vikas R. Dharnidharka,[6] Dorry L. Segev,[4] Abhijit S. Naik,[10] Huiling Xiao,[5] Gregory P. Hess,[7] Bertram L. Kasiske,[8] Tarek Alhamad,[9] Krista L. Lentine.[1] *[1]Saint Louis University, St. Louis, MO; [2]University of Alberta, Edmonton, AB, Canada; [3]Lahey Hospital and Clinic, Burlington, MA; [4]Johns Hopkins University, Baltimore, MD; [5]St. Louis University, St. Louis, MO; [6]Washington University School of Medicine, St Louis, MO; [7]LDI University of Pennsylvania/Symphony Health, Conshohocken, PA; [8]Hennepin County Medical Center, Minneapolis, MN; [9]Washington University in St. Louis, St. Louis, MO; [10]University of Michigan, St. Louis, MI; [11]Saint Louis Univ, St Louis, MO.*

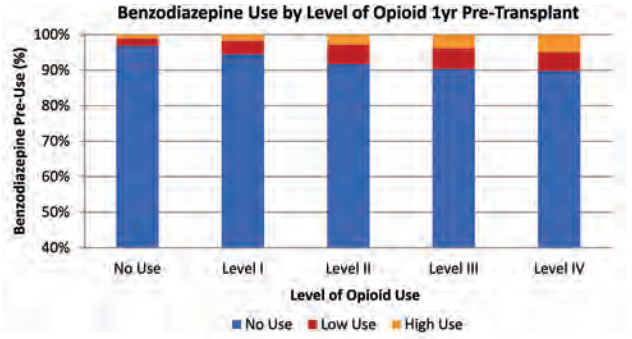
Background: Recent studies identify coprescription of benzodiazepines and opioids as a risk factor for adverse outcomes in the general population. We previously described associations of opioid use before kidney transplantation (KTx) with mortality after KTx, but the implications of benzodiazepine use in the KTx population have not been described.

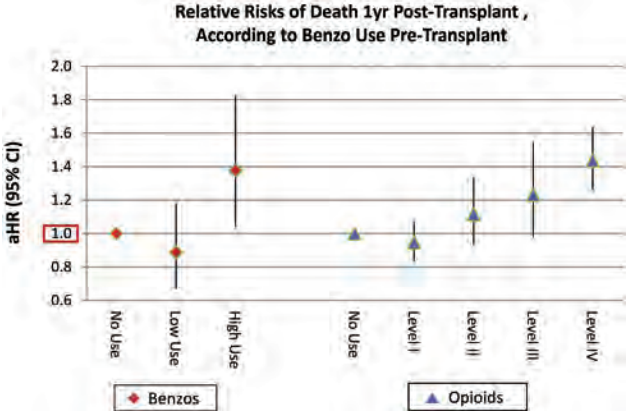
Methods: We examined a novel linkages of SRTR registry data with records from a pharmaceutical claims warehouse (2008-2015) to characterize benzodiazepine and opioid use in the year before KTx and associations (adjusted hazard ratio, $_{95\%\ LCL}$aHR$_{95\%\ UCL}$) with death over 1yr post-KTx.

Results: Among 75,430 KTx recipients with available medication data in the year prior to KTx, 7.3% & 43.1% filled a prescription for a benzodiazepine or opioid in the pre-KTx year. Use of both medications was more common among recipients who were white, unemployed, and received prior KTx. Benzodiazepine use rose with higher opioid use, from 3.2% among opioid non-uses to 10.2% among those with highest level opioid use (**Fig 1**). Compared to non-users, high-level pre-KTx benzodiazepine use was associated with a 51% (aHR $_{1.14}1.51_{1.99}$) increased risk of death in the year after transplant. Opioid use bore a strong graded relationship with post-KTx survival, and prognostic impact high pre-KTx benzodiazepines was preserved after adjustment for opioids, although an interaction was not present (aHR $_{1.04}1.37_{1.83}$) (**Fig 2**).

Conclusions: Benzodiazepines use is correlated with opioid fills before KTx, and these agents have additive associations with post-KTx mortality. Future research is needed

to examine mechanisms of these associations and impact of reducing coprescription on improving outcomes after KTx.





SA-PO044

Transplantation for Veterans Receiving Dialysis in VA and Non-VA Settings

Virginia Wang,[1,2] Cynthia Coffman,[1,2] Karen M. Stechuchak,[1] Paul Hebert,[3] Ann M. O'Hare,[3] David Edelman,[1,2] Matthew L. Maciejewski.[1,2] *[1]Durham VA HCS, Durham, NC; [2]Duke Univ, Durham, NC; [3]VA Puget Sound HCS, Seattle, WA.*

Background: Veterans with end-stage renal disease can receive dialysis under a range of different settings and payment structures including Medicare community dialysis, VA, and VA-purchased community-based dialysis (VA-PC). An earlier study reported similar rates of renal transplant among VA and Medicare users but little is known about rates of transplantation among Veterans receiving dialysis in different settings. This study compares receipt of renal transplantation among Veterans across dialysis settings.

Methods: We merged VA and Medicare data to construct a national cohort of VA-enrolled Veterans who initiated chronic dialysis in 2008-2011. Cohort members were classified based on dialysis setting during the 2-year period immediately following dialysis initiation: VA, VA-PC in community, Medicare-financed dialysis in community, or more than one of these arrangements ("Dual settings"). We used a Cox proportional hazards model (censoring at death) to examine associations between 2-year dialysis setting and transplantation, adjusting for patient characteristics.

Results: Of the 27,301 cohort members, 67% received dialysis under Medicare only, 11% received dialysis through VA-PC only, 4% were treated in VA only, and 18% were treated in Dual settings. Roughly 2.5% of Veterans received a kidney transplant within 2 years, in an average 375 days after dialysis start (median=366, IQR=358). In adjusted analyses, Veterans receiving dialysis in VA, VA-PC, and Dual settings had similar transplantation rates that were lower than those under Medicare (HR=0.45, 95% CI= 0.29, 0.72; HR=0.49, 95% CI=0.35, 0.68; and HR=0.57, 95% CI=0.43, 0.76, respectively). Estimated 2-year transplant rates are shown in Fig 1.

Conclusions: Rates of renal transplant are lower among Veterans who receive any VA-financed dialysis than for those receiving Medicare-financed dialysis. More work is needed to identify barriers to kidney transplant among Veterans whose dialysis is financed by the VA.

Funding: Veterans Affairs Support

Is It Time to Switch? Comparing Transplant Outcomes Among Dialysis Modalities: Analysis from the United States Renal Data System (USRDS)

Brittany L. Schreiber, Omar A. Aleter, Vishy Chaudhary, Wayne G. Fischer, Yasir Lal, Hania Kassem. *University of Texas Medical Branch, Galveston, TX.*

Background: The effect of pre-transplant dialysis modality (DM) on transplant (Tx) outcomes has been a topic of study for many years. However, studies have largely compared patients (pts) on a single modality, either hemodialysis (HD) or peritoneal dialysis (PD). Though still controversial, pts on PD have been shown to have a higher likelihood of Tx, shorter time to Tx, and higher recipient survival rates than pts on HD. It is unknown whether pts who switch from HD to PD benefit similarly. This question has become particularly important given the incentive provided by the prospective payment system dialysis bundle for transitioning pts to PD. The aim of our study was to compare the effect of DM, including pts who switch from HD to PD, on the likelihood of Tx, time to Tx and recipient survival.

Methods: Our study is a retrospective analysis of data obtained from the USRDS from May 2012 to December 2015. Pts were divided into 3 groups: HD only (n=637778), PD only (n=43733) and pts who switched from HD to PD (n=23816); pts who switched from PD to HD were excluded. Groups were then compared to determine the likelihood of Tx among each group. Groups were further divided into pts who had received a single kidney Tx to determine the effect of DM on time to Tx and recipient survival rate. Statistical analysis included Contingency Analysis for likelihood of Tx, Oneway ANOVA for time to Tx, Kaplan-Meier survival curves, and Cox Proportional Hazards for the effects of predictor variables on pts survival.

Results: Pts in the HD to PD group had a higher likelihood of Tx (5% absolute, $p<0.01$), shorter time to Tx (1.54 years, $p<0.01$), and higher recipient survival compared to the HD only group ($p<0.01$). Besides higher age upon dialysis initiation, the only baseline characteristic negatively affecting survival in the HD to PD group was the presence of diabetes. This group also had similar advantages over the PD only group except for likelihood of Tx.

Conclusions: Our study showed that pts who switched from HD to PD had a higher likelihood of Tx, shorter time to Tx and improved recipient survival compared to other DM. Given the potential benefit gained by pts on PD, switching to PD regardless of initial modality may lead to improved Tx outcomes.

SA-PO046

Cost of Follow-Up Care within the First Year of Kidney Transplantation at the National Kidney and Transplant Institute

Irina M. Rey-Roxas,[1] Benita S. Padilla,[1] Concesa Casasola,[1] Carlo irwin A. Panelo.[2] *[1]National Kidney and Transplant Institute, Quezon City, Philippines; [2]University of the Philippines Manila, Manila, Philippines.*

Background: The high cost of kidney transplantation (KT) and follow-up care contribute to the low rate of transplantation among Filipino End Stage Renal Disease (ESRD) patients. The cost of transplant procedures is better understood and provided basis for a transplant benefit package in the National Health Insurance Program. However, no studies on the cost of follow-up care, particularly on which subgroups of patients incur higher costs have been done in the Philippines. **Objectives.** This study aims to estimate the direct medical cost of follow-up care within the first year of kidney transplantation.

Methods: We analyzed records of 129 adult Filipino patients who underwent primary kidney transplant from June 2014 to May 2016 at the National Kidney and Transplant Institute (NKTI). A subgroup analysis based on immunologic risks as well as comorbidities using the Charlson comorbidity index (CCI) was also done. Direct costs of medical care were estimated by computing for the average cost of medical care consisting of professional fees, medicines and supplies, and diagnostics for both outpatient consults and hospital admissions.

Results: The estimated average direct cost of medical care within the first year of transplantation was PHP 655,616 (USD 13,312 based on USD1=PhP50) per patient. Those with high CCI incurred 46% higher average direct cost than those with low CCI (USD 17,899 vs USD 11259). Diabetics incurred 56% higher costs compared to non-diabetics (USD 20,237 vs USD 11,399). The difference in average cost between those with high immunologic risk and low immunologic risk was negligible. The cost of care showed a downward trend in the first year post KT, regardless of immunologic risk or CCI score. For

outpatient care, medications (85%) was the main cost driver while for admitted cases it was diagnostic work-up (37%).

Conclusions: The high cost of outpatient medications, especially for immunosuppressive drugs and insulin therapy, indicate the need for financing of follow-up care after kidney transplantation. A prospective study with a span of more than a year is needed to better understand the cost of follow up care after transplantation.

SA-PO047

Economic Impacts of Alternative Kidney Transplant Immunosuppression: A National Cohort Study

Krista L. Lentine,[1] David A. Axelrod,[2] Vikas R. Dharnidharka,[3] Huiling Xiao,[4] Daniel C. Brennan,[5] Dorry L. Segev,[6] Rosemary Ouseph,[7] Henry B. Randall,[13] Abhijit S. Naik,[12] Ngan Lam,[8] Tarek Alhamad,[9] Bertram L. Kasiske,[10] Gregory P. Hess,[11] Mark Schnitzler.[14] *[1]Saint Louis University, St. Louis, MO; [2]Lahey Hospital and Clinic, Burlington, MA; [3]Washington University School of Medicine, St Louis, MO; [4]St. Louis University, St. Louis, MO; [5]Johns Hopkins, Baltimore, MD; [6]Johns Hopkins University, Baltimore, MD; [7]St Louis University, St Louis, MO; [8]University of Alberta, Edmonton, AB, Canada; [9]Washington University in St. Louis, St. Louis, MO; [10]Hennepin County Medical Center, Minneapolis, MN; [11]LDI University of Pennsylvania/Symphony Health, Conshohocken, PA; [12]Unviersity of Michign, Ann Arbor, MI; [13]SSM Health/ SLUH, St. Louis, MO; [14]Saint Louis Univ, St Louis, MO.*

Background: Economic outcomes are increasingly considered along with clinical efficacy to guide choice of alternative therapies. We examined the cost impact of kidney transplant (KTx) induction and maintenance suppression (ISx) in a large national US cohort.

Methods: Cost data for the transplant hospitalization were drawn from linkage of the SRTR registry with financial records from the University HealthSystem Consortium of US academic hospitals (2002 –2013, N= 62,002 KTx). Cost of post-transplant care were estimated from Medicare Part A %B payments (N= 62,698). Marginal costs of induction (all periods) and maintenance (Yr 1, Yr 2, Yr 3) ISx were estimated from multivariate regression, including adjustment for baseline recipient, donor, and transplant factors.

Results: Compared to IL2rAb, Thymoglobulin (TMG, $10,066) and other induction ($21,627) was associated with increased costs of the transplant hospitalization, while Campath was initially cost saving ($4,208. Subsequently, patients induced with TMG had significantly lower costs in Yr1 ($2,108) and Yr 2 ($1,834) post-KTx. Compared to triple maintenance ISx, steroid-free recipients incurred lower costs in Yr 1 ($4,011), while all other maintenance regimens were associated with higher costs in Yr 1. Patients who received mTORi-based and CsA-based ISx continued to incur higher costs in Yrs 2 and 3 post-KTx. (**Figure**)

Conclusions: Induction and maintenance ISx are associated with differential costs of care during the transplant hospitalization and post-transplant periods, which may be mediated by different complication rates. Initial higher costs of TMG induction appear to be followed by later cost savings

SA-PO048

RISE to Transition: A Structured Transition Protocol for Renal Transplant Recipient Children

Rupesh Raina,[1,2] Vinod Krishnappa.[3] *[1]Cleveland Clinic Akron General, Broadview Heights, OH; [2]Akron Children's Hospital, Akron, OH; [3]Akron Nephrology Associates/Cleveland Clinic Akron General, Akron, OH.*

Background: The transition from pediatric to adult medical services is an important time in the life of an adolescent or young adult with a renal transplant. Failure to properly transition can lead to medical non-adherence and subsequent loss of graft and/or return to dialysis.

Methods: To establish a locally-adapted, patient-focused, kidney transplant transition program, we implemented the RISE protocol. This was defined by four competency areas: Rise, Insight, Self-Reliance, and Establish; identified through literature review and experience. Seventeen patients (6 female and 11 males, mean age 14.5 yrs), who received a renal transplant in the preceding 2-9 years (mean 5.6 years, median 7), went through transition protocols. The transition process spanned two years to overlap medical care between pediatric nephrologists and key adult physicians and related services. The final transition was completed at 21 years of age.

Results: Adolescents and parents did not differ significantly in their general views and stated that they would appreciate the support provided by a transition program. However, the parents appreciated the support during transfer significantly more than did the adolescents. Eighty five percent of patients and family felt generally well informed of the RISE transition. However, 70% preferred to receive more information about their disease and overall health during their transfer period. When asked for the key person during the transfer, 62% of respondents mentioned the pediatrician, 6% said "others," and 30% stated that it was the nurses. The relevant issues during transfer were cited as medication (35%), education and employment (27%), disease knowledge (13%), and environment in the adult service (25%).

Conclusions: RISE protocol and its four competency areas are the key to an effective transition to the adult services. Self-reliance and the establishment of healthy choices aim to improve patient autonomy and emotional burden, and to minimize disruptions in their daily lives. Recognition and insight aim to educate the patient in all aspects of their disease. Education about medical, social, vocational/educational, and interpersonal effects of their disease and treatment will help to improve adherence as well as alter patient perspectives of their disease.

SA-PO049

Kidney Cancer After Renal Transplant: 14 Year Review

Dennis Hu,[1] Suresh K. Rijhwani,[2] Harlan C. Rust,[2] Usama T. Hussein,[2] Sandeep Magoon,[2] Thomas R. McCune.[2] *[1]Eastern Virginia Medical School, Norfolk, VA; [2]Nephrology Associates of Tidewater, Norfolk, VA.*

Background: Renal transplant patients are 7 times more likely than the general population to have renal cell carcinoma (RCC). Possible explanations include immunosuppression leading to increased oncogenic viral infections and acquired cystic kidney disease from hemodialysis. Due to the rapid growth and metastasis of RCC, renal ultrasounds (US) have been used as a screening tool; however, there is no uniform guideline on US frequency after renal transplantation.

Methods: Retrospective chart review of 962 renal transplant recipients at Sentara Norfolk General Hospital from 7/1/04-9/30/17 was performed. All patients received similar immunosuppression regimens and serial US by protocol at year 1,3,5,7,9,11 and 13 after transplant. Data involving gender, race, age at transplant, underlying cause of ESRD, and US results were collected. Tumor characteristics including timing of development, mass location, pathology, staging, and outcome were assessed.

Results: 27 RCC cases were diagnosed in 19 patients. RCC incidence was 2.8%. Multifocal RCC was seen in 4 patients (3 at the same interval, 1 four years after previous nephrectomy) and all had bilateral nephrectomies. RCC was significantly higher in males than females (89% males, 11% females, $p<0.05$). Median time of RCC diagnosis was 3.55 years. Tumor staging was 78% T1aNxMx, 18% T1bNxMx, 4% T3aNxMx. All patients had nephrectomies.

Conclusions: Renal US at 2 year intervals after transplant captured all RCC cases. 5 patients were diagnosed in between the standard interval due to symptoms (e.g. hematuria). Men are at increased risk of RCC. Polycystic kidney disease is not associated with developing RCC. All RCC involved native kidneys and were cured with nephrectomy. Biannual US should be continued indefinitely after transplant and on any remaining kidneys after nephrectomy due to multi-centric occurrence.

US post-transplant (years)	RCC cases/total RCC	Age of transplant (years)	RCC cases/total RCC	Etiology of ESRD	RCC cases/total RCC	Tumor characteristics	RCC cases/total RCC
0-1	3.7%	30-40	15%	Hypertension	44%	Clear cell	33%
1-3	22%	40-50	22%	Diabetes mellitus type 2	37%	Papillary	41%
3-5	48%	50-60	30%	Polycystic kidney disease	4%	Oncocytoma	7%
5-7	19%	60-70	33%	Unspecified glomerulonephritis	11%	Chromophobe	4%
7-9	0%			Calcineurin inhibitor nephrotoxicity of previous transplant	4%	Tubulocystic	4%
9-11	3.7%					Unclassified	11%
>11	3.7%						

SA-PO050

Exposure to a Functioning Kidney Transplant and Cancer Risks

Eric H. Au,[1,2] Jeremy R. Chapman,[3] Armando Teixeira-Pinto,[1,2] Jonathan C. Craig,[1,2] Germaine Wong.[1,2] *[1]School of Public Health, Faculty of Medicine and Health, The University of Sydney, Sydney, NSW, Australia; [2]Centre for Kidney Research, Children's Hospital at Westmead, Sydney, NSW, Australia; [3]Centre for Transplant and Renal Research, Westmead Hospital, Sydney, NSW, Australia.*

Background: Kidney transplant recipients experience higher cancer incidence and mortality compared to the general population. It is uncertain whether this increased risk varies with graft function. This study aims to compare the cancer incidence and mortality rates in transplant recipients during periods of graft function and graft failure with the age- and gender-matched general population.

Methods: All Australian patients who commenced renal replacement therapy between 1982 and 2014 were included from the Australia and New Zealand Dialysis and Transplant Registry. Cancer incidence and mortality for dialysis patients and transplant recipients during periods of graft function and graft failure were compared with the Australian general population using standardized incidence (SIR) and mortality (SMR) ratios.

Results: A total of 47,127 dialysis patients without transplants, 15,413 with 1st transplants, 3873 after 1st graft failure, 1596 and 545 with 2nd transplants and 2nd graft failure were identified and followed for 297,626 patient-years. The standardized incidence and mortality rates (per 100,000 patient-years) were 727 and 336 in dialysis patients; 1322 and 675 in recipients with 1st transplants; 1017 and 367 after 1st graft failure; 1531 and 870 for 2nd transplants and 1434 and 880 after 2nd graft failure. Cancer SIRs (95% CI) and SMRs (95% CI) were 1.2 (1.1-1.2) and 1.3 (1.2-1.4) for dialysis patients; 2.1 (2.0-2.2) and 2.6 (2.4-2.8) for recipients with 1st transplant; 1.6 (1.4-1.9) and 1.4 (1.0-1.9) after 1st graft failure; 2.4 (2.1-2.9) and 3.4 (2.6-4.2) for 2nd transplants; 2.3 (1.5-3.4) and 3.4 (1.8-5.9) after 2nd graft failure.

Conclusions: An increased cancer incidence and mortality risk is observed during periods with a functioning kidney transplant. Among patients with failed allografts, cancer incidence and mortality remained higher than the general population, but the increased risk appears lower than recipients with functioning grafts.

SA-PO051

Post-Transplant Survival Among Patients with Pretransplant Treatment for Prostate Cancer

Nagaraju Sarabu,[1] Nicholas K. Schiltz.[2] *[1]University Hospitals Cleveland Medical Center, Cleveland, OH; [2]Case Western Reserve University, Cleveland, OH.*

Background: Optimal pre-kidney transplant treatment and waiting time for transplant among patients with prostate cancer is unclear.

Methods: We studied male patients, 40 years or older, with ESRD who had Medicare claims for prostate cancer and two main types of treatment (radiation and prostatectomy) utilizing USRDS (United States Renal Data System). We stratified patients into three categories based on waiting time to transplant from the time the prostate cancer was treated (0-2, 2-5, >5 years). We used Kaplan-Meier method to compare post-transplant survival among the strata. We used Cox proportional hazards model to assess relative risks of death between the groups.

Results: There were a total of 920 patients who had kidney transplants with prior history of treatment for prostate cancer. Figure 1a shows KM curves, stratified by waiting time (p-values = <0.01). Compared to 0-2 years of waiting time, 2-5 years had 13% higher likelihood of death (HR: 1.13, 95% CI:0.88-1.44) and >5 years had 73% higher likelihood of death (HR: 1.73, 95% CI:1.30-2.3). Prostatectomy was associated with a better post-transplant survival than radiation (Figure 1b).

Conclusions: Prostatectomy and kidney transplant without significant delay may be optimal choices for patients with prostate cancer and eligible for kidney transplant.

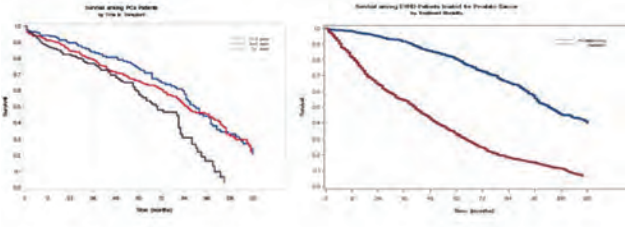

Figure 1a Figure 1b

Kaplan Meier survival curves for patients, stratified by waiting time (1a) and type of treatment (1b)

SA-PO052

Long-Term Outcomes of Sequential Hematopoietic Stem Cell Transplantation and Kidney Transplantation

Carla L. Moreira,[1] M Hasib Sidiqi,[2] Fernando G. Cosio,[3] Nelson Leung.[3] *[1]Nephrology Department, Centro Hospitalar do Porto, Porto, Portugal; [2]Division of Hematology, Mayo Clinic, Rochester, MN; [3]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Hematopoietic stem cell transplantation (HSCT) patients are known to be at risk for both acute and chronic kidney disease. Experience on sequential HSCT and kidney transplant (KT) is limited.

Methods: We conducted a retrospective cohort study of adult patients who underwent both HSCT and KT at Mayo Clinic, Rochester, between 1988 and 2018.

Results: In our cohort of 54 patients, male represented 57% (n=31) and the median age was 64.2 (56.8, 70.1) years-old. Thirty-six patients (66.7%) received HSCT first followed by KT, while 18 (33.3%) received KT prior to HSCT. In both groups, immunoglobulin related amyloidosis represented 50% of hematologic diagnosis. Living kidney donor was equally distributed in both groups, representing 83% (n=45) of the donors, with 60% (n=27) from a relative. T-cell depleting induction was significantly more frequent in

the KT first group (94% vs 19%, p<0.001). Primary kidney disease recurrence was not significantly different in HSCT first vs KT first (19% vs 39%, p=0.19), and both groups displayed excellent kidney allograft survival at 1y (94% vs 89%) and 5y (94% vs 89%), p=0.51. KT first did not affect allograft outcome (HR 1.7, 95% CI 0.4-7.9, p=0.51) nor did maintenance immunosuppression (HR 2.8, 95% CI 0.6-11.9, p=0.16). Acute cell mediated rejection (ACMR) seemed to worsen KT prognosis (HR 10.7, 95% CI 1.6-71.7, p=0.01). However, in multivariate analysis, ACMR revealed only a trend towards significant worse allograft prognosis (HR 22.8, 95% CI 1.0-520.8, p=0.05). Overall patient survival was better in patients submitted to HSCT first, both at 5y (97% vs 76%) and 10y (90% vs 63%), p=0.0001. EBV seronegative status at KT (HR 2.9, 95% CI 1.1-7.8, p=0.039), KT first (HR 6.0, 95% CI 2.2-16.5, p=0.0001), use of T-cell depleting agent (HR 3.2, 95% CI 1.2-8.7, p=0.02), severe infection (HR 19.6, 95% CI 2.6-148.1, p=0.004) and renal allograft failure (HR 3.2, 95% CI 1.2-8.8, p=0.02) were significantly associated with poor patient outcome. In multivariate analysis, only history of severe infection was significantly associated with poor survival (HR 14.0, 95% CI 1.6-125.8, p=0.02).

Conclusions: Our study supports KT safety in patients with history of HSCT, with better allograft function and overall patient survival observed when HSCT is performed first.

SA-PO053

Post Transplantation Anemia: Causes, Severity and Their Association with Graft and Patient Survival

Amir Schechter, Ruth Rahamimov, Anat Gafter-Gvili, Benaya Rozen-zvi. *Rabin Medical Center, Petah Tikva, Israel*.

Background: Post transplantation anemia (PTA) is common among kidney transplant patients. PTA is associated with increased graft loss and in most studies with increased mortality. We aimed to evaluate association of PTA its severity and specific causes with late outcomes.

Methods: Patients who underwent kidney transplantation in Rabin Medical Center (RMC). Data were collected from the kidney transplant registry during the years 2002-2016. Anemia was defined in accordance with World Health Organization (WHO) criteria, severe anemia was defined as hemoglobin lower than 11 g/dL. We evaluated all separate anemia events during the follow-up period, for each event a full laboratory workup was collected. Specific causes for each anemia episode were documented (acute rejection, acute kidney injury [AKI], infection and nutritional deficiencies). Primary outcome was a composite of patient and graft survival. We used univariate and multivariate time varying Cox models to evaluate association between severity and specific causes of anemia to the outcomes.

Results: Our cohort included 1139 patients, out of which 412 (36.2%) had PTA during the follow-up period. Distribution of causes of anemia were acute rejection and/or AKI (11.9%), infections (16.7%), hematological disorders, bleeding or hemolysis (9%) and nutritional deficiencies (29.1%). No obvious reason was found in 137 patients (33.3%). On multivariable analyses, the anemia group was significantly associated with a composite of graft loss and mortality, (HR 2.063, 95% CI 1.542-2.761, p<0.001), and with each outcome separately. Severe anemia was significantly associated with graft loss and mortality combined (HR 4.362, 95% CI 3.035-6.270, p<0.001) and separately. A weaker association was found between mild anemia and graft loss, but not with mortality. Causes of anemia: AKI & acute rejection (HR 5.570, 95% CI 3.784-8.198, p<0.001), infectious (HR 2.483, 95% CI 1.536-4.016, p<0.001) and nutritional deficiencies (HR 1.882, 95% CI 1.203-2.942, p=0.006) were all associated with graft loss or mortality.

Conclusions: PTA is associated with graft loss and mortality. Anemia severity and etiology affects this association. An anemia workup is recommended for PTA.

SA-PO054

Predicting CKD in Lung Transplant Recipients

Salman Ahmed,[1] Leonardo V. Riella,[2] Gary C. Curhan.[3] *[1]Brigham and Women's Hospital, Boston, MA; [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [3]Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA.*

Background: There is a high incidence of chronic kidney disease (CKD) following lung transplantation. We examined baseline risk factors for CKD in a cohort of patients who had undergone lung transplantation.

Methods: Retrospective cohort study of 333 patients who underwent lung transplantation between January 2005 and September 2016. The follow-up period ended April 2018. Of 333 patients, we excluded: 22 underwent transplantation elsewhere; 26 had prior CKD; 8 had fewer than two outpatient serum creatinine values available; 10 died within 6 months; 2 were excluded for missing BMI data; and 17 lacked data on pre-transplant pulmonary arterial systolic pressure. The primary outcome was CKD III at up to 2 years following lung transplantation, defined by two eGFR values < 60 ml/min/1.73 m^2 at least three months apart on outpatient labs.

Results: Of the 248 eligible patients, 185 developed CKD III or worse. In a multivariate logistic regression model, age (OR 1.06, per year, 95% CI 1.02-1.11) and female sex (OR 4.42, 95% CI 1.92-10.18) were associated with a higher risk of CKD III. The following pre-transplant variables were not significantly associated with increased risk of CKD: body mass index (BMI), pulmonary arterial systolic pressure (PASP), diabetes, hypertension, or etiology of lung disease. Higher pre-transplant eGFR showed a trend towards a lower risk. New onset hypertension post-transplant was not associated with CKD III.

Conclusions: Older and female patients are at higher risk for developing CKD III after lung transplantation. Future research should evaluate risk factors for additional renal outcomes, including acute kidney injury, dialysis and renal transplantation.

Funding: NIDDK Support

Multivariate adjusted odds ratios for CKD III in lung transplant patients

Effect	Odds Ratio	95% CI	
Age, y	1.06	1.02	1.11
Female	4.42	1.92	10.18
BMI, kg/m2	1.02	0.94	1.12
Estimated GFR (eGFR), per 10 ml/min/1.73m2	0.84	0.64	1.00
Pulmonary Artery Systolic Pressure, mmHg	1.02	1.00	1.04
Cystic Fibrosis vs other	2.00	0.55	7.24
Chronic Obstructive Pulmonary Disease vs other	2.94	0.61	14.22
Idiopatic Pulmonary Fibrosis vs other	2.19	0.83	5.78

SA-PO055

Outcomes of CRRT in Patients with End Stage Liver Disease (ESLD)

Margaret Spolnik, Maryn Gardner, Marwan Ghabril, Eric S. Orman, Sharon M. Moe, Melissa D. Anderson. *Indiana University School of Medicine, Indianapolis, IN*.

Background: Patients with ESLD have high mortality when dialysis is required. In 2015, a hepato-renal service was started in order to improve outcomes of patients with combined kidney-liver failure. We compared outcomes of all ESLD patients that underwent CRRT (venous-venous hemofiltration) before and after the implementation of the novel inpatient rounding service.

Methods: Patients undergoing CRRT with a concomitant diagnosis of ESLD (based on ICD-9/10 codes) were identified in the pre year (all of 2013 n = 46) and the post hepatorenal service year (all of 2016, n = 39). Charts were then manually reviewed to confirm diagnoses, and compare the cohorts by t-test/Mann/Whitney for continuous variables, and chi-square/Fisher's exact for categorical variables.

Results: There were no differences in the two cohorts (2013 and 2016) for age, gender, BMI, cause of ESLD, ascites, etoh intake, smoking and baseline co-morbidities on admission. More patients had a history of CKD in 2013 than in 2016 (p<0.002). CRRT was started after 4 and 7 days from admission (median, 2013 and 2016 respectively). At the time of initiation of CRRT, there was no difference between the two cohorts in laboratory data (albumin, sodium, INR, creatinine, bilirubin), or MELD score. The outcomes of patients in both cohorts are shown in Table 1.

Conclusions: Patients with ESLD requiring CRRT have very high mortality within 90 days unless transplanted, higher than predicted by MELD scores. The implemtation of a hepato-renal inpatient rouding service staffed by both Nephrology and Hepatology facilitated collaborative and consistent decisions about goals of care in these critically ill patients, increasing the proportion of patients transplanted.

Outcomes of ESLD patients receiving CRRT

	Admit MELD Score (mean/SD)	Transplanted p = 0.04	Alive at 30 days from admission	Alive at 90 days from admission (p = 0.35)	Discharged home/LTAC at 90 days (p = 1.0)
2013	33 ± 7.0	0 out of 46	6 out of 46	4 (8%)	3
2016	31 ± 7.2	5 out of 39 (three livers, one liver-kidney, one multi-visceral)	7 out of 39 (3 on dialysis, 4 transplant) Multi visceral tx died	7 (18%)	6

SA-PO056

Systematic Review of Risk Indices Used in Pancreas Transplantation

Jonathan E. Ling,[2] Timothy E. Coughlan,[3] Kevan Polkinghorne,[2] John Kanellis.[1] *[1]Monash Medical Centre, Clayton, VIC, Australia; [2]Monash Medical Centre and Monash University, Melbourne, VIC, Australia; [3]Monash Health, Hawthorn, NSW, Australia*.

Background: Risk indices (RI) using donor and recipient characteristics assist in organ allocation and acceptance decisions by predicting post-transplant outcomes such as graft and patient survival. While RI have been derived for use in pancreas transplantation (PTx), they are not widely utilised. We intend to review the ability of available RI to predict PTx outcomes.

Methods: Medline Plus, Embase via OVID and the Cochrane Library were searched for studies describing derivation or use of RI in PTx up to 1st November 2017. Primary outcomes of interest were pancreas graft and patient survival, with secondary outcomes of organ acceptance. Data extraction was performed using the Checklist for Critical Appraisal and data extraction for Systematic Reviews of Prediction Modelling Studies (CHARMS) and risk of bias assessment was done via the Quality in Prognostic Studies (QUIPS) tool.

Results: 2418 abstracts were screened with 32 studies entering full-text analysis. Of these 32 studies, 8 were abstracts with no full-text retrievable despite contacting authors. 10/32 studies derived 23 models predicting outcomes of interest. 2/23 models were RI that were externally validated in 24/32 studies. 21/23 models were derived without external validation. RI were the pancreas donor risk index (PDRI) and the pancreas pre-procurement score (P-PASS). Apart from their covariates, common covariates in other models included recipient age and body mass index (BMI), dialysis duration pre-transplant, history of diabetes, transplant type, and immunosuppression regimen. Risk of bias was generally low in the studies with model derivation. Conversely, abstracts tended to have high risk of bias. Deficiencies in reporting included handling of missing data, covariates and follow-up duration. Discrimination and calibration was only described in 10 and 2 studies respectively.

Heterogeneity was present in model derivation method, outcome definitions and study results. PDRI was significantly associated with pancreas graft survival in 9 studies and P-PASS was significantly associated with pancreas donor acceptance in 3 studies.

Conclusions: RI in PTx have not been widely validated apart from P-PASS and PDRI. Within a validated cohort, PDRI (as a categorical variable) and P-PASS have value in predicting pancreas graft survival and in predicting donor pancreas acceptance respectively.

SA-PO057

One-Year Outcome Experience of Deceased Donor Kidney Transplantation Post-KAS Implementation

Priyamvada Singh,[1] Bhavnish Bucktowarsing,[1] Jon R. Von Visger,[1] Uday S. Nori,[1] Hemant K. Parekh,[2] Todd E. Pesavento,[1] Alejandro Diez.[1] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Ohio State University Wexner Medical Center, Columbus, OH.*

Background: The new kidney allocation system (KAS) implemented on December 4, 2014, has a goal to improve access to transplant for under represented groups, such as the highly sensitized patients (calculated panel reactive antibodies, cPRA ≥90%).

Methods: We performed a single-center retrospective review of transplants performed on highly sensitized recipients and compared outcomes, in relation to the implementation of KAS.

Results: 164 DDKT were performed in 22 months prior to KAS implementation whereas 187 were performed 22 months post-KAS implementation. Out of 351 transplants during this period, 33 had a PRA of ≥ 90% (11 pre-KAS, 22 Post) and 14 had a PRA of 100% (2 Pre, 12 Post) consistent with the bolus effects seen in the previous reports. We also compared the one-year outcomes of patients with '0' cPRA with ≥ 90% CPRA. Out of 148 patients selected between periods of December 2014 to October 2016, 126 had cPRA of 0% and 22 had a cPRA of ≥ 90. All patients had at least one-year post-transplant follow up. We didn't find any significant differences in primary outcomes of graft survival, all-cause mortality, delayed graft function and return to dialysis (table 1). Cold ischemia time was significantly higher post KAS possibly owing to a greater regional sharing (table 2). Although biopsy-proven rejection was more prevalent in highly sensitized patients compared to non-sensitized it was not statistically significant. Unlike previously published reports, we didn't find any difference in outcomes among the two groups based on waitlist time and time on dialysis. Additionally, duration of hospital stay, readmissions and serum creatinine was similar in both groups.

Conclusions: Results are reassuring as we found no differences in outcomes between both groups but it still warrants long-term follow up.

Table 1 – Odds ratio of outcomes of zero cPRA when compared to high cPRA

	Odds ratio	Confidence interval	P-value
Delayed graft function	3.26	0.72-14	0.18
All-cause mortality	0.47	0.089-2.5	0.71
Graft survival	3.1	0.52-17.7	0.51
Any type Rejection	0.425	0.13-1.3	0.25
Dialysis at 1 year	0.867	0.09-7.8	0.89

Table 2 – Medians of baseline characteristics of zero CPRA compared to high cPRA

	Median 0 cPRA	Median 90-100% cPRA	Mann-Whitney U stats	P-value
Cold ischemia time (hours)	12.42	17.54	734	0.0004
Dialysis days before transplant	1556	1736	1191	0.29
Waitlist time (days)	1599	1736	1160	0.22
Hospital days during transplant admission	6	7	1284	0.57
Creatinine	1.62	1.43	1213	0.35
Number of readmissions	1	2	1267	0.51

SA-PO058

The Impact of New Kidney Allocation System on Health Care Utilization

Randeep Kashyap, M Katherine Dokus, Sheel Clerk, Jeremy G. Taylor, Mark S. Orloff, Todd Jusko, Scott Mcintosh. *University of Rochester Medical Center, Rochester, NY.*

Background: The kidney allocation system (KAS) in the United States was dramatically changed in December 2014 with the goal of increasing access, decreasing inequities and improving longevity matching. Studies have shown that duration of pre-transplant dialysis, cold ischemia times and delayed graft function rates significantly increased as a result. We hypothesize that these downstream effects of KAS would impact health care resource utilization- namely readmission rates and length of hospital stay.

Methods: The Organ Procurement and Transplantation Network's Standard Transplant Analysis and Research (STAR) file containing only adult deceased-donor kidney only transplants from 6/3/14- 6/5/2015 was analyzed. The cohort of recipients transplanted in the 6 months prior to KAS was compared to a cohort of those transplanted during the first 6 months after the allocation change.

Results: A total of 11,964 kidney-only transplants with six months of post-transplant follow-up data were included in the analysis. Demographics were comparable between the two groups. Median length of hospital stay post-transplant was not different between groups (median 5 days, IQR 4-8 for both). Hospital readmissions within 6 months of transplant discharge, however, were significantly higher post-KAS (37.4% vs. 40.1%, p=0.004). Reasons for readmission were not included as part of the dataset, but due to increased rates of delayed graft function and its consequences in the post-KAS cohort 23.7% pre vs. 29.9% (p<0.001), it is hypothesized that known related complications such as hyperkalemia, acid-base disturbances and fluid imbalance may have contributed to readmissions.

Conclusions: Although the new kidney allocation system seems to be achieving many of the goals it set out to accomplish, it appears that more health care resources are being utilized post-transplant as measured by readmission and delayed graft function rates. Insurers and hospital administrators should be aware of the potential constraints and make accommodations in contract language and reimbursement rates as a result of the observations from this study. A formal cost-effectiveness analysis should be the subject of future investigations.

SA-PO059

Use of Virtual Crossmatch Exclusively to Allocate Deceased Donor Kidney Transplant

Essa Abuhelaiqa,[1] Shaefiq B. Thappy,[1] Mohamad M. Alkadi,[1] Jehan Mahmoud,[2] Mona Jarman,[2] Awais Nauman,[1] Muhammad Asim,[1] Omar Fituri,[1] Hassan A. Al-Malki.[1] *[1]Nephrology, Hamad Medical Corporation, Doha, Qatar; [2]Hamad Medical Corporation, DOHA, Qatar.*

Background: Virtual crossmatch (VXM) using Luminex single antigen bead has significantly improved prediction of a negative crossmatch due to its high sensitivity. An actual pretransplant lymphocyte crossmatch such as complement dependent cytotoxicity crossmatch (CDCXM) or flow cytometry crossmatch (FCXM) is typically required; however, it may delay deceased donor renal transplantation (DDRT) and possibly affect allograft outcomes. We evaluated the safety of only using VXM pretransplant without waiting for actual crossmatch to allocate DDRT.

Methods: In our center, we have initiated a protocol to allocate kidneys from brain-dead deceased donors based on VXM since 2015. 46 DDRT were performed at our center between 2010 to 2017. 21 (45%) recipients only underwent pretransplant VXM, and all were found to have a negative FCXM retrospectively. We evaluated the effect of this protocol on cold ischemia time (CIT), delayed graft function (DGF), acute rejection (AR) within first year post transplant, and graft survival.

Results: There was a significant reduction of CIT by more than 6 hours (P=0.001) when FCXM was not done prospectively prior to transplant. 3 out of 25 (12%) patients with prospective FCXM had DGF, while no DGF was observed in retrospective FCXM (P=0.2). AR within first year occurred in 4% of prospective vs. 5% retrospective FCXM. 1-year and 3-year graft survival rates were 96% vs. 100% and 92% vs. 88%, in prospective vs. retrospective FCXM, respectively.

Conclusions: Use of pretransplant VXM exclusively for final DDRT allocation decision reduces duration of CIT and may reduce incidence of DGF without increasing risk of AR or affecting graft survival

SA-PO060

Disproportionate Allocation of High Quality Kidneys to Highly Sensitized Recipients in the New Kidney Allocation System Despite a Limited "Bolus Effect"

Syed shahyan Bakhtiyar, Abbas Rana, Natasha N. Dave, Michael Kueht, John A. Goss, Bhamidipati V. Murthy. *Baylor College of Medicine, Houston, TX.*

Background: The 2014 Kidney Allocation System (KAS) aims to minimize death with functioning grafts, and increase transplantation rates among highly sensitized patients (PRA≥98%). We examined if preferential allocation to high PRA patients results in disproportionate allocation of high quality kidneys (Kidney Donor Performance Index < 0.2) to these patients, and if a "bolus effect" dissipates the allocation over time.

Methods: Using the UNOS data, kidney transplantations from the start of the new system 12/4/2014-12/31/17 (study group) were compared with those for two preceding years - 12/4/2012-12/3/2014 (control group) for pre- and post-transplant characteristics, and overall graft and patient survival.

Results: Excluding living donors (n=28,785) and multi-organ transplants (n=8,896), there were 37,933 recipients in study group, and 21,412 in control group. One year patient and graft survival in the study versus the control group were 96.8% vs 96.9% (p<0.0001) and 94.4% vs 94.2% (p<0.0001) respectively. In the study group, 4,564(12%) high PRA patients were transplanted, compared to 704(3.3%) in the control group. 1,384/8,180 (16.9%) of high quality kidneys in the study group were received by high PRA patients, compared to 181/4,542 (4%) in the control; four-monthly analysis of the study group shows that high PRA recipients of these kidneys decreased from 116/532 (21.8%) in December 2014–March 2015 to 122/936 (13.03%) in September–December 2017. Among these high PRA recipients of high quality kidneys, there was no difference in one year patient (98% vs 96.1%, p=0.8) and graft survival (96.6% vs 92.2%, p=0.5) between the study and control group respectively.

Conclusions: Despite a decreased trend in high quality kidney allocation to high PRA patients in the new system over time, it is still significantly higher than in the old system. Thus, any bolus effect is only partial. While there is no difference in patient and graft survival in this cohort, follow-up may be too short to show a difference. As such, a national policy may be needed to optimize this allocation in the new KAS.

SA-PO061

Association Between Kidney Donor Risk of ESRD (KDRE) and Donor Selection/Deferral

Divya Seth,[1] Jennifer R. Milan,[1] Se ri Bae,[1] Kirsten L. Johansen,[2] Brian K. Lee,[4] Deborah B. Adey,[3] Elaine Ku.[1] *[1]UCSF, Berkeley, CA; [2]University of California, San Franicsco, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA; [4]University of California San Francisco, San Francisco, CA.*

Background: The Kidney Donor Risk of ESRD equation (KDRE) provides transplant centers a tool to assess the patient-specific risk of developing ESRD in living kidney donors based on age, sex, race, body mass index (BMI), and relationship to the recipient (http://www.transplantmodels.com/donesrd/). The goal of this study was to determine whether medical decisions surrounding donor eligibility align with the empirical KDRE predicted risk. We hypothesized that higher KDRE scores would be associated with a higher likelihood of donor deferral due to medical unsuitability.

Methods: The KDRE was determined by chart review of donor evaluations performed at a single center from 2009 - 2017 for a convenience sample of potential donors. The association between the 5-year predicted risk of ESRD and odds of deferral/acceptance was examined using unadjusted logistic models. Due to a lack of association between the KDRE score and donor deferral, we adjusted for factors within and outside of the KDRE (systolic BP, smoking) to determine which factors were most strongly associated with deferral from donation.

Results: 313 donors had sufficient data to calculate the KDRE score. Mean age was 31±10 years and median BMI was 33. Evaluated donors were 49% White, 31% Hispanic, 6% Black; 44% male, and 52% of donors were related to the recipient. 34% of evaluated donors were deferred. There was no association between the KDRE predicted ESRD risk and donor deferral (Table), even after accounting for factors not in the KDRE score (systolic BP and smoking). When we adjusted for factors already in the KDRE score, older age was the only factor that was strongly associated with odds of deferral (OR 2.14 per 10-year increase in age [95% CI 1.48-3.10]).

Conclusions: We did not find the KDRE predicted ESRD risk to be associated with donor deferral or acceptance. Of the factors considered, older age was the strongest factor that was associated with donor deferral.

Funding: NIDDK Support

Table 1. Models comparing different predictors of the likelihood of deferral from donation.

Model Predictors All OR for KDRE are per 1 point increase in risk	Odds Ratio (95% CI)
KDRE estimated risk (per 1 point increase)	1.08 (0.88-1.31)
KDRE estimated risk + SBP (per 1 mm Hg increase)	1.09 (0.86-1.38) 1.01 (0.99-1.03)
KDRE estimated risk + current smoker (vs. never)	1.09 (0.86-1.38) 1.07 (0.25-1.04)
KDRE estimated risk + SBP + smoking	1.07 (0.81-1.39) NS
KDRE estimated risk + Age (per 1 year increase)	1.01 (0.82-1.24) 1.04 (1.02-1.07)
KDRE estimated risk + age, race, sex, donor relationship to recipient, and BMI	0.80 (0.50-1.29) NS*

NS = not statistically significantly associated; p>0.05
*No factors were associated with outcome except age as reported in abstract

SA-PO062

State-Wide Coordination of the Follow-Up of Living Kidney Donors Only Marginally Improves the Follow-Up Rate

Matthew D. Jose,[1,2] Ellie Cash,[2] Gabrielle E. Brailsford,[2] Geoff Kirkland.[1] *[1]Renal Unit, Royal Hobart Hospital, Hobart, TAS, Australia; [2]School of Medicine, University of Tasmania, Hobart, TAS, Australia.*

Background: Post-donation follow-up care is recommended by KDIGO for Living kidney donors (LKD). There is little long-term data on living kidney donors in Australia due to incomplete follow-up. In 2012 we centralised the follow-up of all LKD within the state. Our aim was to audit the effectiveness of this intervention and the effect on the rate of LKD follow-up.

Methods: In 2012 we reported follow-up of LKD at 1 year of 70%, but less than 10% at 5 years. Statewide follow-up was changed to be coordinated out of a single follow-up centre, with tests and appointments organized by standard mail and follow-up phone calls. We reviewed the effectiveness of this intervention.

Results: We identified 183 LKD, of which 126 (63% female, mean age 62 years, mean time since donation 9 years) were recorded in the both the statewide database and the Living Kidney Donor Registry (LKDR) at ANZDATA. Changing to a single, statewide follow-up centre achieved 50-70% of follow-up every year from 2014-17. This ranged from 75% at one year post-donation, 61% at 5 and 48% > 5 years post-donation as recorded locally in 2017. Reporting to the LKDR was lower at 25%, 33% & 22% respectively. From the ANZDATA follow up, 63 patients had a recorded systolic blood pressure measurement at their last follow up. 31% of these patients had hypertension requiring anti-hypertensive medication with 1.3 the average number of agents required.

Conclusions: The results show that clinical follow up decreases as time post donation increases. Statewide coordination of donor follow-up improved baseline results but there is still further improvement to be made. There is discrepancy between local data collection and submission to the Living Kidney Donor Registry at ANZDATA. Improved coordination and data submission would allow for more accurate follow up data of LKD.

SA-PO063

Differences in Transplant Rates Across Race/Ethnicities Post-KAS Implementation

Andric C. Perez-Ortiz,[1,2] Nahel Elias.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]School of Public Health, Yale University, New Haven, CT.*

Background: The Kidney Allocation System (KAS) aimed to decrease racial allocation disparity, indirectly improving transplant rates (TR) for non-Whites. 3 years after implementation, we lack evidence of this specific efficacy. We here assess whether the waitlisting and transplant rates across races/ethnicities have improved after KAS implementation.

Methods: To assess any systematic difference in US TR (1989-2017) and the effect pre-(1989-2014) and post-KAS (2015-2017), we calculated the slope per year basis. We then, using linear regression, estimated the effect of race/ethnicity on kidney waitlist addition and TR across periods, also addressing donor type for TR. To eliminate improved deceased donation effect, we compared kidney and liver TR. A difference indicates a positive impact of KAS. Finally, we similarly evaluated the rate of change for kidney waitlist additions. We used data from OPTN database and for linear models R.

Results: We show three distinct periods wherein the kidney TR varied. Between 1989–2006 and 2015–2017, there was a significant positive slope, higher in the later. However, between 2006–2014 there was no change in TR. Furthermore, compared to deceased liver TR after KAS implementation (2015-2017), kidney TR increased up to 76% (p=0.02). Before 2015, there were no differences between the two groups (p>0.2). Moreover, kidney TR has steadily risen for non-Whites compared to Whites (p=0.03). KAS implementation increased the rate for non-Whites 13-fold compared to Whites (p=0.04). Lastly, this improvement was not mirrored in the waitlist additions, and KAS did not change the slope.

Conclusions: We have preliminary evidence that KAS allocation has improved TR especially benefiting non-Whites (Blacks, Hispanics, Asians). Waitlist addition did not equally change, arguing for the need to alter referral and listing practice.

Figure. Number of kidney transplants performed between 1998 – 2017 and TR as a function of three time periods.

SA-PO064

Should Kidneys at High Risk for Discard Be Allocated to Preemptive Deceased Donor Kidney Transplant Candidates?

Justin Gill,[1] Matthew J. Kadatz,[1] John S. Gill,[3] Jagbir Gill.[2] *[1]University of British Columbia, Vancouver, BC, Canada; [2]St. Paul's Hospital, West Vancouver, BC, Canada; [3](St. Paul's Hospital/University of British Columbia), Vancouver, BC, Canada.*

Background: Over 19% of recovered kidneys are discarded annually in the US. Identifying patients with favourable outcomes after transplantation with kidneys at high

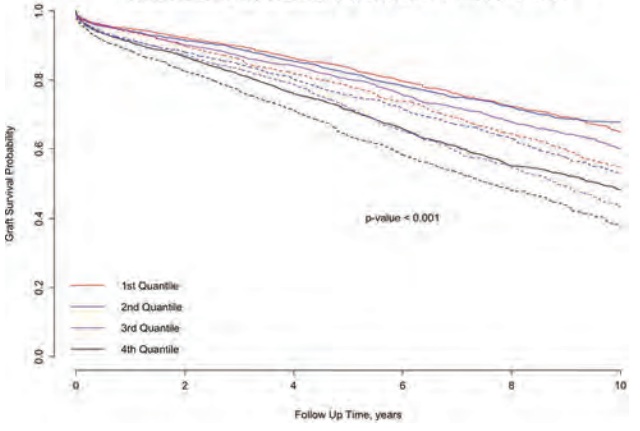
risk of discard may inform strategies to increase organ utilization. Preemptive deceased donor kidney transplant recipients have superior post-transplant outcomes compared to recipients on dialysis, partly due to the presence of native kidney function. We hypothesize that allocation of kidneys at high risk of discard to selected preemptive candidates could offer acceptable outcomes.

Methods: We ranked and grouped into quartiles all deceased donors in SRTR between 2000-15 based on their probability of kidney discard using a validated score that predicts discard based on donor characteristics. We conducted a paired kidney analysis, where 1 kidney was transplanted in a preemptive recipient and the mate kidney from the same donor was transplanted into a nonpreemptive recipient, to compare the risk of DGF and all cause graft loss (ACGL) in non-preemptive and preemptive recipients, stratified by donors' risk of kidney discard using Cox and logistic regression models.

Results: The figure shows unadjusted graft survival in preemptive and non-preemptive recipients, stratified by donors' probability of kidney discard. The risk of discard was associated with inferior graft survival, as recipients of kidneys at the greatest risk of discard (Q4) demonstrated the worst graft survival. However, outcomes among preemptive recipients were significantly better. After adjusting for recipient and transplant factors, preemptive recipients who received kidneys at the greatest risk of discard (Q4) had a significantly lower risk of DGF (OR; 95%CI 0.22; 0.18-0.26) and of ACGL (HR; 95%CI 0.81; 0.72-0.90).

Conclusions: Allocation of kidneys at high risk of discard to selected preemptive candidates (eg. patients with prolonged wait-times) may increase organ utilization while optimizing outcomes.

Figure: Kaplan-Meier curves of all cause graft loss in mate kidney cohort stratified by quartiles of predicted donor risk of discard.



SA-PO065

APOL1 Genotyping in Potential Kidney Donors of African Descent

Vasishta S. Tatapudi, Bonnie E. Lonze, Nicole M. Ali, Bruce Gelb, Robert A. Montgomery. *NYU Langone Health, New York, NY.*

Background: Inheritance of two *APOL1* risk variants accounts for the excess risk of non-diabetic ESRD in African Americans when compared to Caucasian, Hispanic and Asian Americans. African American living donors have a higher risk of ESRD than matched non-black donors. *APOL1* genotyping in potential kidney donors of African descent may identify individuals at risk for progressive CKD following donation.

Methods: We report the retrospective analysis of *APOL1* genotyping in a cohort of African American potential kidney donors. In July 2016, we initiated targeted genotyping of all African American kidney donor candidates. African American candidates with two *APOL1* risk variants were excluded from kidney donation.

Results: A total of 28 African American kidney donor candidates were evaluated between July 2016 and April 2018. 2 (7%) were found to have two *APOL1* risk variants (high risk genotype). Low risk genotype was identified in 10 (36%) candidates who had one risk variant and 16 (57%) candidates who had none. To date, 15 candidates have completed their donor work-up. Of these, 7 (47%) have already undergone donor nephrectomy, and 4 (27%) were cleared for surgery and are awaiting operation. 4 (27%) of the candidates did not meet our center specific criteria for donation. 2 out these 4 candidates who were excluded from donation were ruled out expressly for having been found to have two *APOL1* risk variants.

Conclusions: *APOL1* genotyping led to the exclusion of two donors who might have previously been allowed to donate, possibly mitigating their risk of CKD/ESRD and suboptimal graft outcomes in recipients.

Baseline characteristics of potential kidney donors

	APOL1 High risk genotype Mean ± SD	APOL1 Low risk Genotype Mean ± SD	p-value
Age (years)	40.5 ± 6.3	36 ± 10.2	0.52
Gender – Male: n (%)	13 (50%)	0 (0%)	not calculated
BMI (kg/m2)	32.4 ± 2.5	27.2 ± 4.2	0.23
Creatinine (mg/dL)	0.8 ± 0.002	0.9 ± 0.026	0.09
Systolic BP mm Hg	118 ± 11.3	115 ± 7.9	0.78
Diastolic BP mm Hg	75 ± 7.1	70.9 ± 9.3	0.76
MDRD eGFR (ml/min/1.733m2)	101.5 ± 10.6	106.9 ± 19.8	0.76

SA-PO066

Community Deliberations on APOL1 Testing in African Americans

Ebele Umeukeje,[1,2] Wylie Burke,[3] Kerri L. Cavanaugh,[1,2] Stephanie M. Fullerton,[3] James G. Wilson,[4] Bessie A. Young,[3,5] Erika Blacksher.[3] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt Center for Kidney Disease, Nashville, TN; [3]University of Washington, Seattle, WA; [4]University of Mississippi Medical Center, Jackson, MS; [5]VA Puget Sound Health Care System, Seattle, WA.*

Background: African Americans (AA) are 2-4 times more likely to develop ESRD, compared to whites. Apolipoprotein L1 (*APOL1*) variants have been associated with greater risk of developing non-diabetic ESRD among African Americans (AAs), and greater risk of developing incident CKD, proteinuria, and transplant failure. Mechanisms of risk and penetrance, and effective preventive measures for kidney disease remain unclear. We engaged AAs to discuss potential pros and cons of *APOL1* risk testing in routine patient and kidney transplant care.

Methods: As part of a larger assessment of stakeholder views, we conducted community deliberations with self-identified AAs in Seattle WA (n=14), Nashville TN (n=14), and Jackson MS (n=11). Information on *APOL1* genetic risk was provided prior to, and during each meeting. Plenary and small group discussions were held followed by 2 rounds of polling on *APOL1* testing options. Deliberations occurred over 2 days for 10 hours per site. Participants at each site reviewed results and provided feedback.

Results: Participants were diverse in gender, age, education, and kidney disease experience. With regard to routine patient care, responses varied on who should be tested: all AAs(64%); AAs with CKD risk factors(21%); AAs with signs of CKD(10%); no AAs(5%). Increased knowledge, improved self-care, and aid to clinical management and research were reasons to support testing. Lack of clinical utility and increased psychological burdens, potential discrimination and cost, were reasons to oppose testing. Participants agreed unanimously that deceased donor kidneys be tested. Views on *APOL1* testing in other kidney transplant scenarios varied: offer testing to potential living donors(95%); require testing in potential living donors(73%), and prevent living donors with *APOL1* risk from donating(10%). Participants felt that *APOL1* testing was 'actionable' in the transplant setting, but expressed concern that it might reduce kidney supply.

Conclusions: Well-informed AAs have valuable input on best practices in *APOL1* testing in routine patient and kidney transplant care. There was consensus that deceased donor kidneys should be tested for *APOL1* risk; however, views on *APOL1* risk testing in other scenarios were divergent. Continued stakeholder deliberation is imperative as the science evolves to inform best practices.

SA-PO067

Prevalence of G1 and G2 APOL1 Gene Variants in Afrodescendant Patients from the Unit of Kidney Transplant in a High Complexity Medical Center in Cali, Colombia

Carlos D. Rebolledo. *Fundacion Valle del Lili, Cali, Valle, Colombia.*

Background: In recent years, the presence of APOL1 genetic variants has been recognized as a risk factor of chronic kidney disease in afrodescendant patients, especially variants related to the risk alleles G1 and G2 (1)(2). Patients with two allelic variants are at higher risk, and tend to require dialysis up to 9 years earlier than patients with no risk alleles (2). In addition, receptors of kidney transplant from donors with APOL1 variants seem to have a worse posttransplant prognosis and higher risk of graft dysfunction (3)(4) (5). The aim of this study is to determine the prevalence of these allelic variants among the afrodescendant patients from the kidney transplant unit at Fundacion Valle del Lili (FVL).

Methods: Observational, cross-sectional study including afrodescendant patients with chronic kidney disease from the kidney transplant unit at FVL, who were on the waitlist or were already recipients of kidney transplant. The study period was defined from January to November 2017

Results: A total of 103 patients were included, 56% (n=57) were female. The mean age was 48 years old (SD 13 years), the mean time of dialysis before kidney transplant was 4 years, 89% had clinical history of arterial hypertension. APOL1 gene variants were found in 62% (n=64) of patients, of them 32.8% (n=21) were G1 heterozygotes, 39% (n=25) were G1 homozygotes, 4.6% (n=3) were G2 homozygotes, and 23.4% (n=15) were mixed G1/G2. There were none G2 heterozygotes.

Conclusions: This study describes that in the afrodescendant population with chronic kidney disease at FVL the frequency of APOL1 variants is high, nevertheless these results cannot be extrapolated to the general population, and larger population studies are required to accurately assess the frequency of APOL1 variants in our country. This study represents

a cornerstone for new lines of research on this field in our institution, a national referral center for kidney transplants.

SA-PO068

Racial Disparities in Long-Term Outcomes in Kidney Transplantation from Elderly Donors in United States

Silvi Shah, Masaaki Yamada, Rohit P. Jain. *University of Cincinnati, Cincinnati, OH.*

Background: Kidney transplantation offers survival benefit and improved quality of life in end stage renal disease (ESRD) patients. Because the waiting list continues to grow, there has been an increase in the utilization of kidneys from older donors. We examined the racial disparities in graft and patient outcomes of patients after transplantation with old kidneys.

Methods: We identified 19,820 kidney transplant recipients based on donor age ≥ 60 year between January 2000 and December 2016 from the United Network for Organ Sharing (UNOS) Standard Transplant Analysis and Research data. Using case-mix adjusted logistic regression models; we examined the effects of race on 3-year death censored graft loss (DCGL) and 3-year recipient survival in kidney transplant recipients (KTR) of elderly donors.

Results: Elderly donors accounted for 7.9% of all donors. Of the 19,820 recipients of old kidneys, 57.9% were Whites, 22.8% were Blacks, 6.4% were Asians, 11.1% were Hispanics and 1.9% were others. 45.6% were males. Mean donor age was 64±3 years and mean recipient age was 59±11 years. Overall, 3-year DCGL was 12% and 3-year recipient survival was 86.2%. In adjusted analyses, Blacks were more likely than Whites (odds ratio [OR], 1.21; 95% confidence interval [CI], 1.08-1.36, p<0.001) to experience DCGL at 3 years. Additionally, both Hispanics (OR, 0.77; CI, 0.66-0.91, p=0.002) and Asians (OR, 0.72; CI, 0.58-0.90, p=0.003) were less likely than Whites to experience DCGL at 3 years. In adjusted analyses, Blacks (OR, 0.83; CI, 0.74-0.92, p<0.001), Hispanics (OR, 0.71; CI, 0.61-0.82, p<0.001) and Asians (OR, 0.75; CI, 0.62-0.90, p<0.001) were less likely than Whites to die at 3 years after receiving a kidney from an elderly donor.

Conclusions: Among KTR of elderly donors, Blacks are at 21% higher risk of graft failure than Whites at 3 years but survive longer after transplantation. As compared to Whites, both Hispanics and Asians are less likely to experience DCGR at 3 years and are less likely to die within 3 years of getting a kidney transplant from older donor. Further studies are needed to assess additional factors contributing to disparities in graft and recipient survival in KTR of old kidneys.

SA-PO069

Genetic Ancestry as a Predictor of Kidney Transplant Outcomes

Y. Dana Neugut, Lili Liu, Junying Zhang, David Fasel, Karla Mehl, Jaclyn L. Wold, Fatih Ozay, Olivia Balderes, Sumit Mohan, Jai Radhakrishnan, Lloyd E. Ratner, David J. Cohen, Ali G. Gharavi, Krzysztof Kiryluk. *Columbia University Medical Center, New York, NY.*

Background: African-American (AA) kidney recipients have higher rates of allograft rejection and failure. However, it is unknown to what extent the inferior outcomes in self-reported AA's are due to genetic effects or confounding by socioeconomic status (SES). In this study, we test the effects of recipient African admixture, a quantitative measure of genetic ancestry derived from genome-wide SNP data, in multivariable models adjusted for SES factors.

Methods: Our study used a multiethnic retrospective single center cohort of 1,083 kidney allograft recipients, including 206 self-reported AA's. Subjects were genotyped with high resolution SNP arrays (MEGA chip, Illumina); African admixture proportions were derived using ADMIXTURE software. All subjects were geo-coded and U.S. census tract variables were used as proxies of SES. Multivariable Cox models were constructed to predict time to biopsy-proven rejection and time to death-censored allograft failure, and race-related variables of interest were tested in each model.

Results: The cohort median follow-up time was 78.3 months, and included 432 patients with rejection (median 5.9 months) and 193 with failure (median 72.3 months). We confirmed significant impact of recipient's self-reported AA race (HR 1.47 (95% CI: 1.18-1.83)) and African admixture proportion (HR 1.64 (95% CI: 1.22-2.19)) on acute rejection. Both race-related metrics also had similar effects in the adjusted models of allograft failure (self-report: HR 1.42 (95% CI: 1.02-1.97); admixture: HR 1.48 (95% CI: 0.96-2.29)). Recipient *APOL1* risk genotype status, associated with African ancestry and several kidney diseases, did not explain these associations. U.S. census-derived median income and education level did not confound the association between race and either rejection or failure.

Conclusions: Our study is the first to test a genetic measure of recipient African ancestry for inclusion in clinical models of kidney transplant outcomes. Based on our results, self-reported AA race and a genetically-derived continuous measure of African ancestry performed similarly in predicting the risk of allograft rejection and failure, and both predictors were independent after multivariable adjustment for U.S. census-based metrics of SES.

The Multiple Faces of a Hepatitis C Donor

Cagla Keceli,[2] Nashila AbdulRahim,[1] Burhaneddin Sandikci,[2] Yuan Zhong,[2] Ricardo M. La Hoz,[1] Bekir Tanriover,[1] Venkatesh Kumar Ariyamuthu.[1] *[1]UT Southwestern Medical Center, Dallas, TX; [2]The University of Chicago Booth School of Business, Chicago, IL.*

Background: Public Health Service (PHS) increased risk donors are on the rise in the US and provide an underutilized pool of organs. With the advent of a myriad of Hepatitis C treatment options, use of these organs has become an attractive option for select recipients. An updated list of characteristics of all PHS increased risk donors is presented here.

Methods: UNOS database was queried for all deceased donor kidneys retrieved between 4/1/2015 and 9/30/17. The study population was divided into four categories based on their hepatitis C antibody (Ab) and nucleic acid testing (NAT): Ab-/NAT-, Ab-/NAT+, Ab+/NAT-; Ab+/NAT+. Characteristics of age, gender, race, donation after cardiac death (DCD), PHS increased risk, BMI, diabetes, macrovesicular fat, and KDPI are investigated across the four donor categories.

Results: Mean age of Ab-/NAT- donors is slightly higher than Ab-/NAT+, Ab+/NAT+, and Ab+/NAT- donors; Ab-/NAT-, Ab+/NAT-, and Ab+/NAT+ donors are predominantly male. Region 2 has the highest number of donors with NAT and/or Ab + carrier status. Ab+/NAT- donors have the highest, mean KDPI of 54.1. Less than 10% of all deceased donors are diabetics. While 21% of Ab-NAT- donors were characterized as PHS increased risk, nearly 15% of NAT and/or Ab + carrier donors did not meet PHS criteria by definition.

Conclusions: Our data sheds light into characteristics of all deceased donors over a 2.5 year period. It questions the accuracy of screening criteria for PHS increased risk donors. Delineation of these features allows for identification of an underutilized organ pool for an appropriate kidney transplant recipient group.

Donor Characteristics

	Ab-/NAT-	Ab-/NAT+	Ab+/NAT-	Ab+/NAT+	p-value
N	28740	33	372	739	
Age (mean years +/- standard deviation)	37.9 ± 15.8	27.4 ± 8.4	35.2 ± 10.1	32.6 ± 8.2	< 0.001

SA-PO071

Ten-Year Analysis of Transplant Recipients of High KDPI Kidneys

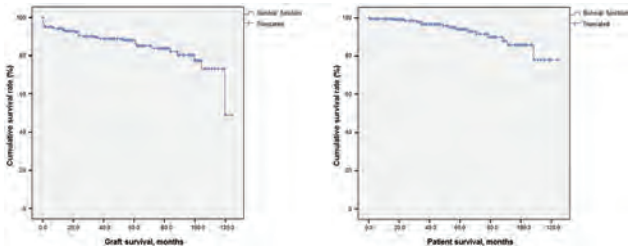
Giorgia Comai,[1] Maria Cappuccilli,[1] Andrea Angeletti,[1] Valeria Corradetti,[1] Vania Cuna,[1] Olga Baraldi,[1] Diletta Conte,[1] Chiara Donadei,[1] Matteo Ravaioli,[2] Gaetano La Manna.[1] *[1]Department of Experimental Diagnostic and Specialty Medicine, University of Bologna, Bologna, Italy; [2]Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy.*

Background: The growing shortage of transplantable kidneys have pointed a great attention on the use of expanded criteria donors (ECDs). About 15% of deceased donor kidneys come from marginal donors, but there is some evidence to indicate that ECD recipients have poorer prognosis, higher incidence of DGF (31% vs 23%) and elevated risk of graft loss, up to 70%. However, the use of ECDs is an effort to increase the pool of organs available for transplant, reduce waiting times on transplant list and ensure optimal allocation of marginal kidneys in the elderly. Kidney Donor Profile Index (KDPI) is a score, ranging from 0% to 100%, based on the quality of all kidneys recovered in the previous year, and estimates the potential function of a donated kidney. A donor KDPI>85% is assumed to be equivalent to an ECD kidney. UNOS data show that only 11% of kidneys from donors with KDPI>85% are used for transplant, and their 5-year survival approximates only 50%.

Methods: This is a retrospective analysis of KDPI in 246 adult kidney transplants (192 single, 54 double) from ECD donors between 2007 and 2016. The mean recipient age was 60.2 years, donor age 67.4 years, KDPI 90.5%, cold ischemia time 14 h, total Karpinski score 3.9, glomerulosclerosis 0.4, interstitial fibrosis 0.9. tubular atrophy 0.6, IFTA 1.5, vascular score 1.1.

Results: Ten-year graft and patient survival were 76% and 80%, respectively (Fig. 1). The incidence of DGF was 44.7%, that of acute rejection 14.6%. GFR at discharge, at 1 year, at 5 years, and at 10 years were 41.5±21.8, 44.9±18.4, 49.5±20, and 53.4±27 mL/min, respectively. Considering total Karpinski score or single histological lesions, no correlation was found with graft and patient survival, DGF and rejection rates. KDPI, donor age and recipient age were predictive of 1-year eGFR decline.

Conclusions: The high survival rates and the satisfying functional performance suggest a good medium-long term prognosis for renal transplant recipients of high KDPI kidneys considered as marginal according to the ECD classification.



SA-PO072

Usefulness of the Assessment of CT-Based Donor Kidney Function Compared with Radionuclide Scintigraphy

Sun-myoung Kang,[1] Soomin Jeung,[1] Yuri Seo,[2] Chung Hee Baek,[1] Su-Kil Park,[1] Hyosang Kim.[3] *[1]Asan Medical Center, Seoul, Republic of Korea; [2]Asan medical center, Seoul, Republic of Korea; [3]Asan Medical Center, University of Ulsan College of Medicine, SEOUL, Republic of Korea*.

Background: Pretransplant graft volume and function has been demonstrated to be an important factor in subsequent allograft outcomes. Most transplant centers underwent renal split function test to assess functional asymmetry with technetium dimercaptosuccinic acid (^{99m}Tc-DMSA) renography and/or computed tomography (CT). We evaluated which of the two methods better reflected posttransplant renal function.

Methods: We analyzed 159 living donors who underwent pretransplant kidney evaluation with both ^{99m}Tc-DMSA renography and CT, and their matching recipients. We measured glomerular filtration rate (GFR) in donor with ^{51}Chromium (Cr) plasma clearance and in recipients using the chronic kidney disease epidemiology collaboration formula (CKD-EPI) equation at 1, 6, and 12 months after transplantation. Kidney volumes were calculated using semi-automatic, three-dimensional (3D) CT volumetry methods. Absolute transplanted graft GFR was calculated by donor GFR (ml/min) x the proportion of donated kidney to total kidney (transplanted kidney volume/total kidney volume in CT, and transplanted kidney isotope uptake/total uptake in renography).

Results: The mean absolute transplanted graft GFR were 53.3±10.6 ml/min by renography and 53.5±10.7 ml/min by CT (p=0.872). Posttransplant graft functions were 84.5±18.6, 72.3±14.1, and 74.9±16.7 ml/min/1.73m^2, at 1, 6, and 12 months after transplantation, respectively. Pearson correlation coefficients between absolute transplanted graft GFR and posttransplant GFR were 0.289, 0.362, and 0.256 in renography (all p<0.001), and 0.318, 0.378, and 0.269 (all p<0.001) in CT at 1, 6, and 12 months, respectively. Multiple linear regression analysis adjusted by age and gender demonstrated that a 1 ml/min increase in absolute transplanted graft GFR calculated by 3D CT volume was associated with 0.56±0.13 ml/min/1.73m^2 increase in posttransplant GFR, and one year increase in recipient age was associated with a 0.46±0.12 ml/min/1.73m^2 reduction of GFR.

Conclusions: 3D CT volumetry method is more useful to predict renal graft outcome than isotope renography before transplantation.

SA-PO073

Patients with a Failed Transplant Derive a Greater Survival Benefit from Transplantation Than Primary Transplant Recipients

Stephanie Clark,[1] Ahad Abdalla,[1] Jagbir Gill,[2] John S. Gill.[3] *[1]Providence Health Care, Vancouver, BC, Canada; [2]St. Paul's Hospital, West Vancouver, BC, Canada; [3](St. Paul's Hospital/University of British Columbia), Vancouver, BC, Canada*.

Background: The organ shortage demands evidence to support the use of deceased donor kidneys in higher risk groups. Repeat transplant recipients have a higher risk of allograft failure than first transplant recipients.

Methods: Using data from the United States Renal Data System between 2000-2016 we determined the relative risk of death in adult patients wait-listed for a first (n=334,162) or repeat (n= 26,815) deceased donor kidney transplant using multivariate non-proportional hazards analyses in which transplantation was treated as a time dependent co-variate. The models adjusted for differences in patient age, sex, race, cause of ESRD, comorbid conditions and year of wait-listing.

Results: The figure shows the relative risk of death in patients who received a first or repeat transplant at different time points after transplantation compared to similar patients (i.e. either first or repeat wait-list candidates) who remained on dialysis. Early after transplantation, first transplant recipients had a higher risk of death compared to first transplant candidates who remained on dialysis; this risk declined with time after transplantation. In contrast repeat transplant recipients had an immediate decreased risk of death compared to failed transplant recipients who remained on dialysis and this risk continued to decrease over time. Accordingly the time to equal risk of death compared to continued treatment with dialysis was 105 days in first transplant recipients versus 0 days in repeat transplant recipients; and the time to equal survival compared to treatment with dialysis was greater in first transplant recipients than in repeat transplant recipients.

Conclusions: Transplantation is associated with a *greater* survival benefit in repeat transplant candidates. Further studies are needed to determine whether current wait-listing practices of patients with a failed transplant are overly restrictive.

Applying Computer Vision to Evaluate Percent Global Glomerulosclerosis in Donor Kidney Biopsies

Satoru Kudose, Matthew S. Hunt, Jon N. Marsh, S. joshua J. Swamidass, Joseph Gaut. *Washington University School of Medicine, St. Louis, MO*.

Background: Determining percent global glomerulosclerosis (GS) in donor kidney frozen wedge biopsies is used to determine organ viability. However, pathologic examination is labor-intensive and error prone. Previously, we developed a convolutional neural network (CNN) to quantify percent GS in scanned kidney biopsy whole slide images (WSI). The aim of this study is to compare CNN with pathologist evaluation of percent GS in scanned WSI.

Methods: Twenty consecutive donor kidney frozen wedge biopsies taken from April to August 2016 were scanned at 20x using an Aperio Scanscope CS scanner as part of routine clinical workflow. Four pathologists and one trainee manually enumerated globally sclerosed and non-sclerosed glomeruli using Aperio ImageScope, blinded to clinical data, in a setting mimicking routine clinical practice. The CNN evaluated the same WSI. Pathologist agreement was assessed using intraclass correlation coefficient (ICC).

Results: ICCs for pathologist evaluation of percent GS showed excellent agreement (0.8). Variability increased among cases with >10% GS. Percent GS determined by the CNN was within the pathologist range in 15/20 (75%) cases (Figure 1). CNN determined mean absolute difference of percent GS from pathologist median was 2% (range 0 – 6.1%).

Conclusions: The CNN quantifies percent GS in frozen section donor kidney wedge biopsies with performance comparable to pathologists and has potential to be incorporated in clinical practice.

SA-PO075

Estimation of the Total Nephron Number in Japanese Living Kidney Donors Using Combined CT Angiography and Biopsy Approach

Takaya Sasaki, Nobuo Tsuboi, Yusuke Okabayashi, Go Kanzaki, Kotaro Haruhara, Kentaro Koike, Akimitsu Kobayashi, Izumi Yamamoto, Makoto Ogura, Takashi Yokoo. *Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Increasing evidence suggests that individuals with low nephron number have an increased lifetime risk of renal insufficiency, thereby emphasizing the importance of evaluating total nephron number in each individual. In recent years, new methods have been described for estimating human total nephron number using a combination of image analysis and renal biopsy, though the reproducibility and accuracy of these methods remain uncertain. This study estimated total nephron number in healthy Japanese subjects using such a method.

Methods: Implantation biopsies from forty-four living kidney donors were analyzed. Using pre-donation contrast CT angiograms, transplantation donor kidneys were three-dimensionally reconstructed, and total renal cortical volume was estimated. Total nephron number was estimated based on glomerular density in biopsy specimens and total renal cortical volume. The obtained results were analyzed in relation to clinical variables and compared with those of a previously reported Japanese autopsy study.

Results: The estimated total nephron number in this cohort was 650,000±220,000 (mean±SD) per kidney. Total nephron number ranged from 280,000 to 1,220,000 per kidney (4.4-fold) and correlated directly with eGFR (r=0.328, p=0.030) and inversely with age (r=-0.355, p=0.018). The estimated total nephron number obtained in the present study was 25% less than that reported in American living kidney donors using the same procedure, and similar to that obtained in a previous Japanese autopsy study using the dissector/fractionator method (**Table**).

Conclusions: These results confirm the feasibility of a combined CT angiography and biopsy-based method to estimate total nephron number in humans.

Comparison of estimated total nephron number by different methods

Study population	Methods	Sample size	Age (year) (mean±SD or mean)	Estimated nephron number per kidney (mean±SD or mean)	Reference
Caucasian autopsy series (normotensive)	Dissector/fractionator	55	41	901,011 ± 298,334	Am J Kidney Dis 2008
Japanese autopsy series (normotensive)	Dissector/fractionator	9	64.1 ± 6.3	640,399 ± 160,016	JCI insight 2017
American kidney donors (92.7% Caucasian)	CT angiogram and biopsy	1638	43.2 ± 11.7	873696	J Am Soc Nephrol 2017
Japanese kidney donors	CT angiogram and biopsy	44	56.7 ± 9.5	650,000 ± 220,000	This study

SA-PO076

Outcomes of Declined Kidneys Subsequently Transplanted Elsewhere: A National Registry Analysis

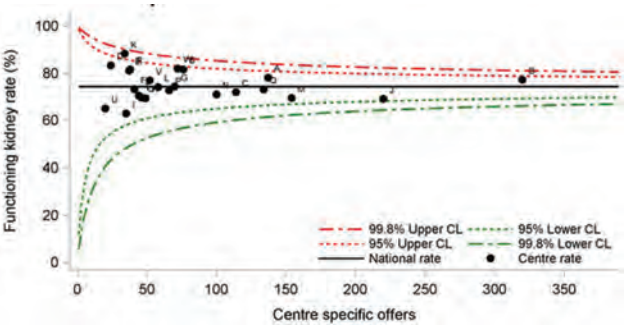
Maria Ibrahim,[1] Jennifer D. Mehew,[1] Chris Callaghan.[2] *[1]NHS Blood and Transplant, Bristol, United Kingdom; [2]Guy's Hospital, London, United Kingdom.*

Background: A recent trend in donor demographics has led to transplantation of organs from donors with increasing age and comorbidities in the UK. In view of this changing climate, individual assessment of kidneys offers is increasingly important.

Methods: Data from the UK Transplant Registry held by National Health Service Blood and Transplant (NHSBT) were analysed. Offers made to adult patients through the National Kidney Allocation Scheme (NKAS) from donation after brain-death (DBD) donors between 1 January 2010 and 31 December 2014 were included. A cohort of 5,973 offers was identified, excluding offers made via the UK fast track scheme and those leading to dual or en bloc transplants. Only kidneys declined for donor-specific reasons were examined.

Results: There was a large variation in offer decline rates between centres across the UK, ranging from 17% to 54%. 'Donor unsuitable - past medical history' was the most common reason for decline. Comparisons were made for kidneys that were declined, subsequently transplanted elsewhere, and remained 'functioning ' (as defined as patients with an eGFR > 20 at 12months) and stratified by centre (Figure 1). There was some disparity between centres however no significant outliers were identified. Centre specific outcomes of patients on the waiting list for whom kidney offers were declined, where the kidney was subsequently transplanted (n=976) in another patient and remained functioning, were also analysed. In this cohort, up to 9% of patients were removed from the transplant waiting list due to clinical deterioration and mortality was up to 15% for each centre.

Conclusions: There is variation in donor-specific decline rates across centres in the UK which could reflect a disparity in 'risk-appetite' amongst clinicians. Approximately 75% of declined DBD kidney offers that are transplanted elsewhere have >20 at 12 months. Mortality and morbidity of patients who remain on the waiting list is high. Better means of assessing donor risk are needed due to a high decline rate of these organs.



SA-PO077

Appropriateness and Outcomes of Premature Pre-emptive Renal Transplants (PPRT), i.e. Renal Transplants at GFR>/= 19mL/min

Snehal Shrivastava,[1] Naoru Koizumi,[3] Deepak K. Malhotra,[2] Jorge Ortiz.[1] *[1]University Of Toledo Medical Center, Toledo, OH; [2]The University of Toledo, Toledo, OH; [3]George Mason University, Arlington, VA.*

Background: A pre-emptive kidney transplant is the best renal replacement therapy for ESRD patients. There are no guidelines for the GFR at which pre-emptive transplantation should occur. Pre-emptive renal transplants at GFR >15 ml/min represent about nine percent of total recipient population per year. The goal of this study is to evaluate the outcomes of PPRTs. Another objective of this study is to outline the donor, recipient, and transplant characteristics of pre-emptive renal transplants.

Methods: Retrospective analysis of the UNOS database was performed on19,207 preemptive renal transplants, including deceased donors (n=12,951) and living donors (n=6,256), between years 2010-2016. Patient survival or death-censored graft survival were compared across predetermined eGFR groups at the time of transplantation, using Kaplan-Meier curves. Relevant donor, transplant & recipient characteristics were compared using t-/Wilcoxon-Mann-Whitney & Chi-sq/Fishers exact tests. Logistic regression was used to identify factors associated with pre-emptive renal transplants. Cox regression analysis was used to identify risk factors for adverse outcomes.

Results: In PPRT with all types of donors, the rate of graft survival is lower at higher GFRs (>/=19). History of diabetes in the recipient (OR=1.176, p=0.000), high number of previous transplants (OR=1.332, p=0.000) & older age (OR=1.004, p=0.012) increase the odds of receiving pre-emptive renal transplants. High BMI (OR=0.988, p=0.000) and high levels of HLA mismatch (OR=0.965, p=0.001) are less likely to receive a preemptive transplant. Increased risk of graft failure is seen in recipients with an increased number of previous transplants (HR=1.155, p=0.029), higher KDRI (HR=1.567, p=0.009) and diabetes (HR=1.218, p=0.021).

Conclusions: PPRT is associated with worse graft outcomes across all donor and recipient characteristics studied. Installation of guidelines for GFR at which pre-emptive renal transplants should occur is warranted through further research. This is especially important as PPRTs, (transplants occurring at GFR >/=19) may represent wastage of existing renal function in recipients, earlier exposure to surgical risks for live donors and recipients, and potential early requirement of next renal transplant.

SA-PO078

Clinical Significance of Kidney Donor Profile Index on the Post-Transplant Clinical Outcomes Between Elderly and Young Kidney Transplant Recipients: A Multicenter Cohort Study

Woo Yeong Park,[1,2] Jong hoon Lee,[3] Jeong Ho Kim,[4] Kyubok Jin,[1,2] Seungyeup Han,[1,2] Bumsoon Choi,[3] Chul Woo Yang,[3] Byung ha Chung.[3] *[1]Department of Internal Medicine, Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Keimyung University Kidney Institute, Daegu, Republic of Korea; [3]Seoul St. Mary's Hospital, Seoul, Republic of Korea; [4]Daejeon St. Mary's Hospital, Daejeon, Republic of Korea.*

Background: We investigated the clinical significance of Kidney Donor Profile Index (KDPI) system for the prediction of the clinical outcomes of elderly- or young kidney transplant recipients (KTRs) in deceased donor kidney transplantation (DDKT).

Methods: Six hundred fifty-seven KTRs receiving kidneys from 526 deceased donors (DDs) were included from four transplant centers. We divided high KDPI and low KDPI by 65%, the median value of KDPI score, and divided elderly KTRs and young KTRs at 55 years old. We investigated the incidence of delayed graft function (DGF), biopsy-proven acute rejection (BPAR), allograft and patient survival rates between elderly and young KTRs donated from DDs with high KDPI- or low KDPI score.

Results: We analyzed 224 (34.1%) elderly KTRs and 433 (65.9%) young KTRs. There were no significant differences in the incidence of DGF and BPAR between elderly KTRs and young KTRs donated from DDs with high KDPI- or low KDPI score. In elderly KTRs, there was no significant difference of death-censored graft survival and patient survival rates between high KDPI-KT and low KDPI-KT groups. However, in young KTRs, high KDPI-KT group was significantly lower in death-censored graft survival rate compared with low KDPI-KT group (P=0.006), and there was no significant difference of patient survival rate between the two groups. In multivariate analysis, high KDPI score was an independent risk factor for allograft failure in young KTRs after adjustment for recipient

and donor age, gender, acute rejection, and induction immunosuppresant (HR 2.376, 95% C.I., 1.251-4.511, P = 0.008), but not in the elderly KTRs. Among 4 groups, high KDPI-young KT group showed the highest risk for allograft failure compared with other three groups and a significant interaction between high KDPI donors and young KTRs on the allograft outcome (P=0.002).

Conclusions: High KDPI in DDs showed significant adverse impact on the allograft survival in young KTRs, but it was not prognostic factor in elderly KTRs.

SA-PO079

Follow-Up Care of Living Kidney Donors

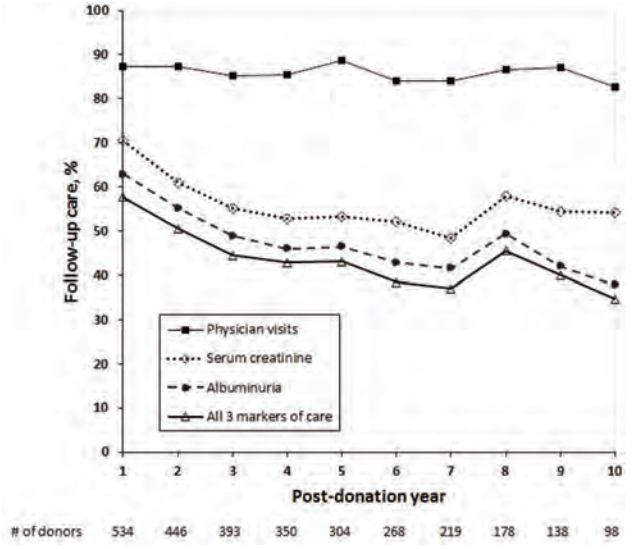
Ngan Lam,[1] Krista L. Lentine,[2] Brenda Hemmelgarn,[3] Scott Klarenbach,[1] Robert R. Quinn,[3] Anita Lloyd,[1] Sita Gourishankar,[1] Amit X. Garg.[4] *[1]University of Alberta, Edmonton, AB, Canada; [2]Saint Louis University, St. Louis, MO; [3]University of Calgary, Calgary, AB, Canada; [4]London Health Sciences Centre, London, ON, Canada.*

Background: Previous guidelines recommend that living kidney donors receive lifelong annual follow-up care to assess renal health. Whether these best practice recommendations are currently being followed is unclear.

Methods: We conducted a retrospective study using linked databases in Alberta, Canada to follow living kidney donors from 2002 to 2014. We determined the proportion of donors who had an annual outpatient physician visit and laboratory measurements for serum creatinine and albuminuria.

Results: There were 534 living kidney donors with a median follow-up of 7 years (maximum 13 years). The median age at the time of donation was 41 years and 62% were female. Overall, 25% of donors had all three markers of care (physician visit, serum creatinine, albuminuria measurement) in each year of follow-up. Adherence to physician visits was higher than serum creatinine or albuminuria measurements (67% vs. 31% vs. 28% of donors, respectively). Donors with guideline-concordant care were more likely to be older, reside closer to the transplant center, and receive their nephrectomy in more recent years.

Conclusions: These findings suggest significant evidence-practice gaps, in that the majority of donors saw a physician, but the minority had measurements of kidney function or albuminuria. Future interventions should target improving follow-up care for all donors.



Proportion of donors who have evidence of follow-up care during each post-donation year.

SA-PO080

Trends in the Timing of Preemptive Kidney Transplantation in Children

Erica Winnicki, Kirsten L. Johansen, Charles E. McCulloch, Jason T. Lee, Elaine Ku. *UC San Francisco, San Francisco, CA.*

Background: There has been a recent trend toward starting dialysis at higher levels of kidney function in children. Whether there has been a similar trend for preemptive kidney transplantation (PKT) in children is unknown.

Methods: We identified 3,278 children (age 1-17 years) in the US Renal Data System who underwent PKT between 1995 and 2015 and had data available to estimate glomerular filtration rate (eGFR) using the bedside Schwartz equation. We evaluated the trend in eGFR at time of PKT over time and differences in recipient characteristics between those who received PKT early (eGFR >10 ml/min/1.73m^2) vs. late (eGFR ≤10 ml/min/1.73m^2).

Results: Mean eGFR at the time of PKT increased significantly over time (Figure), from 9.1 ml/min/1.73m^2 in 1995 to 13.5 ml/min/1.73m^2 in 2015 (p<0.001). The trend toward earlier transplantation was similar among recipients of living and deceased donor organs (p for interaction=0.67). The proportion of children undergoing PKT early increased from 31% in 1995 to 71% in 2015. Overall, 57% of children underwent PKT early (mean eGFR 15.5 ml/min/1.73 m^2). Compared to children who underwent PKT late (mean eGFR 7.5 ml/min/1.73 m^2), those who were transplanted early were older, more often of white race, and less likely to have a living donor (Table).

Conclusions: PKT is occurring at higher levels of eGFR over time in children. Further studies should examine possible reasons for this trend and whether timing of PKT is associated with allograft survival or mortality.

Funding: NIDDK Support

	Early PKT (N=1,880)	Late PKT (N=1,398)	P-value
eGFR (ml/min/1.73m^2), mean (SD)	15.5 (6.1)	7.5 (1.8)	<0.001
Age (years), median (IQR)	12 (8,15)	11 (6,15)	<0.001

Mapping Compensatory Renal Hypertrophy and Hyperfiltration in Living Kidney Donors Using Multiparametric Magnetic Resonance Imaging

Anna S. Li,[1,2] Josephine H. Naish,[1] Matthew J. Gough,[1] Patrick Hamilton,[1,2] Paul E. Brenchley,[1,2] Rachel Lennon,[1,2] Alastair J. Hutchison.[1,2] *[1]University of Manchester, Manchester, United Kingdom; [2]Manchester University NHS Foundation Trust, Manchester, United Kingdom.*

Background: Despite sustained glomerular hypertrophy and hyperfiltration, the vast majority of living donors do not develop hyperfiltration injury with fibrosis and progressive GFR decline. Our study uses serial multiparametric MRI to assess volume and blood flow of the remaining kidney in the first month post-donor nephrectomy. Relationships between changes in kidney volume, renal blood flow (RBF) and single kidney GFR (SKGFR) may reflect functional reserve of the remaining kidney and provide insight into the early stages of nephron loss in the development of CKD.

Methods: 6 living kidney donors underwent 3 sessions of MRI and creatinine-based eGFR measurements prior to, 4 days after, and 4 weeks after nephrectomy. The non-contrast multiparametric MR protocol includes: whole kidney volumetric assessment by manual delineation using a multi-slice T1-weighted (inversion-recovery) turbo-spin echo; assessment of RBF using a FAIR arterial spin labelling (FAIR-ASL) technique; and quantitative T1-mapping using a MOLLI technique.

Results: Median age of the donors was 57 (35 to 67); baseline kidney volume was 141±21mL, increasing to 183±38mL at day 4 and 179±32mL at week 4. SKGFR was 46±5mL/min at baseline, increasing to 61±12mL/min at day 4 and 60±9mL/min at week 4. RBF per unit weight did not change significantly at either day 4 (5.7±0.8 mL/g/min) or week 4 (6.4±0.4mL/g/min) from baseline (5.8±1.6mL/g/min). T1 value of the renal cortex saw a small increase at day 4 (1.64s) compared to baseline (1.53s), which is maintained at week 4 (1.62s).

Conclusions: The results show that compensatory hypertrophy and hyperfiltration started rapidly following renal tissue loss, became established within a few days, and sustained over the next 3-4 weeks. Given adult glomerular number does not increase in compensatory hypertrophy, our preliminary findings indicate that average single glomerular volume and GFR rose post-donation. As RBF per unit weight did not change post-nephrectomy in our cohort, with glomerular hypertrophy, this suggests that overall single glomerular blood flow would also increase. Further study into this growth of normal tissue is required to identify imaging biomarkers for nephron reserve and capacity for compensation before the onset of hyperfiltration injury.

Clinical Significance of the Kidney Donor Profile Index in Deceased Donors for Prediction of Post-Transplant Clinical Outcomes: A Multicenter Cohort Study

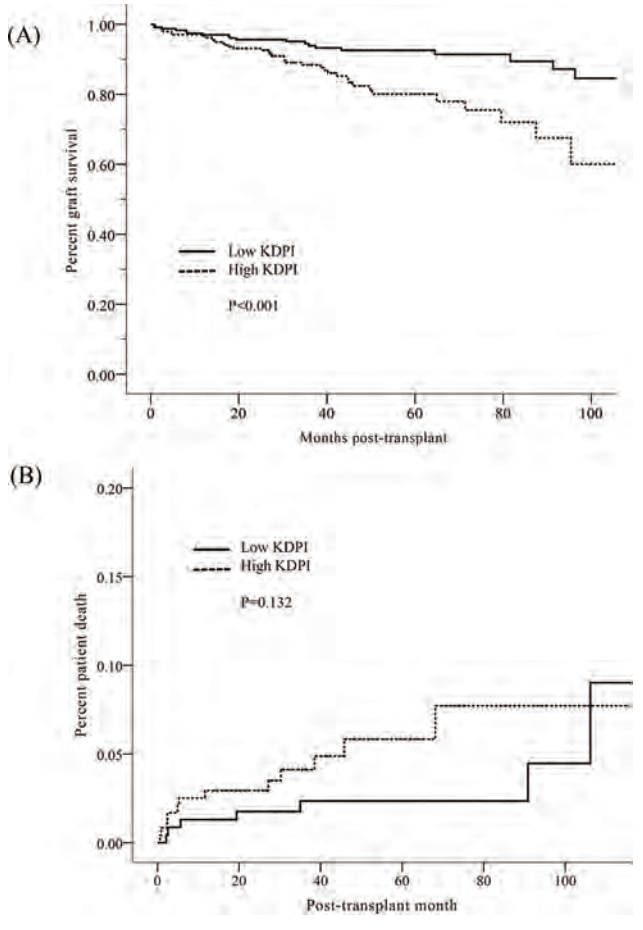
Jong hoon Lee,[1] Woo Yeong Park,[2] Bumsoon Choi,[3] Cheol Whee Park,[4] Chul Woo Yang,[5] Yong-Soo Kim,[7] Kyubok Jin,[6] Seungyeup Han,[6] Byung ha Chung.[8] *[1]Seoul St. Mary's hospital, Seoul, Republic of Korea; [2]Dongsan Medical Center, Daegu, Republic of Korea; [3]Division of Nephrology, Department of Internal Medicine, Seoul, Republic of Korea; [4]The Catholic University of Korea, Seoul, Republic of Korea; [5]Seoul St. Mary's Hospital, Seoul, Republic of Korea; [6]Keimyung University School of Medicine, Daegu, BUSAN, Republic of Korea; [7]The Catholic University of Korea College of Medicine, Seoul, Republic of Korea; [8]Seoul St. Mary's Hospital, Seoul, Republic of Korea*.

Background: We investigated whether the Kidney Donor Profile Index (KDPI) system is useful in predicting clinical outcomes in deceased donor kidney transplantation (DDKT).

Methods: Four hundred sixty-nine kidney transplant recipients (KTRs) receiving kidneys from 359 deceased donors were included in this study, which involved three transplant centers. KTRs were divided into high and low KDPI KTR groups based on the median KDPI score of 67%. We compared clinical outcomes between the high KDPI and low KDPI groups.

Results: There were no significant differences in the incidence of delayed graft function and acute rejection between high and low KDPI KTR groups. In comparison with histologic findings in allograft tissues obtained within three months from KT, the proportion of glomerulosclerosis was significantly higher in the high KDPI KTR group than in the low KDPI KTR group. With Kaplan-Meier analysis, the graft survival rate was significantly lower in the high KDPI KTR group than in the low KDPI KTR group (Log rank, P=0.017), and multivariate analysis also demonstrated that a high KDPI score was a significant risk factor for death censored allograft failure (HR 2.62, 95% CI, 1.29–5.33, P=0.008).

Conclusions: The KDPI scoring system is useful in predicting allograft outcomes in a Korean DDKT cohort.



Analysis of long-term outcome. (A) Comparison of death-censored graft survival rates between high and low KDPI KTR groups (P<0.001, Log-rank test) (B) Comparison of patient survival rates between high and low KDPI KTR groups (P=0.132, Log-rank test)

Interdisciplinary Care Improves Transplant Evaluation Rates Prior to ESRD Among High-Risk Patients with Advanced CKD

Tanya S. Johns,[1] Michelle M. Estrella,[2] L. Ebony Boulware,[3] Michal L. Melamed.[4] *[1]Montefiore Medical Center, Bronx, NY; [2]University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA; [3]Duke University School of Medicine, Durham, NC; [4]Albert Einstein College of Medicine, Bronx, NY.*

Background: Despite the established benefits of kidney transplantation for patients with advanced CKD, data suggest that referral to transplant nephrology is often delayed, even among patients with established nephrology care. Healthcare delivery interventions to foster transplant evaluation prior to developing ESRD are greatly needed. Interdisciplinary care (IDC), which includes nurse practitioner care coordination, is a promising intervention that may increase transplantation evaluation among patients with CKD.

Methods: We compared incident ESRD patients who received nurse practitioner care coordination as part of our IDC clinic (n= 100) to a contemporaneous cohort of incident ESRD (n= 1872) patients who received usual nephrology care alone at Montefiore Medical Center from 10/1/2013 - 10/31/2017. Montefiore Medical Center is a large tertiary institution that serves a predominately urban and poor African American and Hispanic population. All patients studied had established care with a general nephrologist and were eligible for IDC but receipt of IDC was limited by resource availability.

Results: Of the 1,972 patients included in our study, the mean age was 58 (SD 14.8), 43% were female, and 69% self-identified as African American or Hispanic. The baseline characteristics were similar between the two groups. Patients who received IDC were more likely to be evaluated by transplant nephrology prior to developing ESRD, 44% versus 24% ($p < 0.001$). The odds of transplant evaluation prior to developing ESRD was 3 times higher (OR 3.0 [CI 1.9- 4.6) for patients who received IDC versus usual care alone after adjusting for age, race, ethnicity, sex, and baseline comorbidities including diabetes, hypertension and cardiovascular disease. African Americans or Hispanics were less likely and younger patients were more likely to be evaluated by transplant nephrology prior to ESRD.

Conclusions: Interdisciplinary care (also known as multidisciplinary care) is associated with greater likelihood of transplant evaluation prior to ESRD compared to usual nephrology care alone in a racially and ethnically diverse population of lower SES. Larger multicenter studies are needed to determine the impact of IDC on transplant evaluation rates among patients with advanced CKD.

SA-PO084

Use and Outcomes of Kidneys from Donors with Angiomyolipoma: A Systematic Review

Desiree Garcia Anton, Franco H. Cabeza Rivera, Wisit Cheungpasitporn. *University of Mississippi Medical Center, Ridgeland, MS.*

Background: Renal angiomyolipoma (AML) is the most frequent mesenchymal tumor of the kidney. Although there is a rare possibility of malignant transformation of AML, this risk has not been studied in immunosuppressed patients. The safety of donors with AML and their kidney transplant recipients has not been well established.

Methods: A literature search was conducted utilizing MEDLINE, EMBASE and Cochrane Database from inception through May 15th, 2018. We included studies that reported outcomes of kidney donors with AML or recipients of donor with AML. The protocol for this meta-analysis is registered with PROSPERO (International Prospective Register of Systematic Reviews; no. CRD42018095157).

Results: 15 studies with a total of 17 donors with AML were identified. None of the donors had a diagnosis of tuberous sclerosis (TSC), pulmonary lymphangioleiomyomatosis (LAM), or epithelioid variant of AML. Donor age ranged from 35 to 77 years, and recipient age ranged from 27 to 62 years. 92% of the donors were female. Only 8% were deceased donor renal transplant. The majority of donors underwent ex-vivo resection (65%) prior to transplantation, followed by no resection (18%), and the remaining had in-vivo resection. Tumor size varied from 0.4 cm to 7 cm, and the majority (87%) were localized in the right kidney. Follow up time ranged from 1 to 107 months. Donor creatinine pre-nephrectomy ranged 0.89-1.1 mg/dL and post-nephrectomy creatinine 1.0 to 1.17 mg/dL. In those who did not have resection of the AML, tumor size remained stable. None of the donors with AML had end-stage renal disease or died at last follow-up. None of the recipients had malignant transformation of AML.

Conclusions: These findings are reassuring for the safety of donors with AML (without TSC or LAM) as well as their recipients without evidence of malignant transformation of AML. As such, this can also positively impact the donor pool by increasing the number of available kidneys.

SA-PO085

Racial Disparities in Access to Kidney Transplant: Medically (In) Appropriate?

Elaine Ku,[1] Brian K. Lee,[1] Charles E. McCulloch,[1] Garrett R. Roll,[1] Deborah B. Adey,[3] Kirsten L. Johansen.[2] *[1]University of California San Francisco, San Francisco, CA; [2]University of California, San Franicsco, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA.*

Background: Racial and ethnic disparities are known to be present in kidney transplant access. Our objective was to understand whether differences in recipient medical eligibility contribute to these known disparities.

Methods: We included 1,573,786 adults who started dialysis between 1995-2015 according to the US Renal Data System. The exposure was race/ethnicity (non-Hispanic white [NHW], non-Hispanic black [NHB], or Hispanic). Outcomes were differences in medical eligibility for and time to kidney transplant after dialysis initiation. We used multivariable Cox models to examine the association between predictor and outcome. We then repeated our Cox models, excluding individuals who may be medically ineligible for transplant (e.g. age>70, malignancy, heart disease, and body mass index>35 kg/m^2).

Results: During 4.1 years of mean follow-up, 129,820 patients received a transplant. NHBs and Hispanics had a lower prevalence of potential medical barriers [Figure 1] to transplant at time of dialysis initiation than NHWs. Overall, access to transplant was 56% lower in NHBs and 43% lower in Hispanics compared to NHWs [Figure 2A]. When we repeated our Cox models after excluding patients who may be medically ineligible for transplantation (70% of the population), these disparities widened in the remaining "very healthy" subcohort [Figure 2B].

Conclusions: NHBs and Hispanics had fewer medical contraindications but lower access to transplantation than NHWs. Differences in medical eligibility do not appear to explain racial/ethnic disparities in access to transplant, and in fact, may mask the magnitude of the inequities that are present. These findings are concerning, as the healthiest candidates appear to have the lowest access to transplant.

SA-PO086

Effects of Age and Body Mass Index on Enlargement of the Remaining Kidney in Living Kidney Transplant Donors

Makoto Tsujita. *Nagoya Daini Red Cross Hospital, Nagoya, Japan.*

Background: In living kidney transplant donors, recent studies have reported some problems related to long term safety of living kidney donations. After nephrectomy, compensatory hypertrophy of the remaining kidney occurs to recover kidney function. To know how large it would be is very informative. However, factors that affect compensatory hypertrophy remain unknown.

Methods: Kidney volumes were measured using computed tomography volumetry before donation and one year after kidney donation in continuous 83 living kidney transplant donors from 2014 to 2015 at Nagoya Daini Red Cross Hospital, Japan. Ratio of kidney volume before donation and one year after donation was measured. Factors such as age, body mass index (BMI), estimated glomerular filtration rate (eGFR), blood pressure (BP) and so on which could affect the ratio were evaluated. Selection of kidney transplant donors was done according to the guideline set by the Japanese Society of Transplantation.

Results: Thirty-seven donors among all kidney donors evaluated in the study were men. Mean age before donation was 57.0 ± 10.7 years. eGFR before donation was associated with kidney volume (r=0.24 p=0.04). Age had a negative correlation with the ratio (r=0.40, p<0.001), but BMI and eGFR had a positive correlation respectively (r=0.21 p=0.05, r=0.24 p=0.04, respectively). However, the difference in eGFR before donation and one year after donation was not associate with the ratio. Multivariate analysis showed that age and BMI had strong association with the ratio.

Conclusions: Age and BMI were associated with compensatory renal hypertrophy. These factors would be taken more into consideration in the selection of living kidney transplant donors.

SA-PO087

Renal Transplantation: Does Race Play a Role?

Sarah T. Suliman, Jeremy Carlson, Carmen Smotherman, Shiva Gautam, Ljubomir M. Ilic. *University of Florida College of Medicine Jacksonville, Jacksonville, FL.*

Background: Multiple studies have revealed discrepancy in healthcare access and outcomes in certain racial populations. We present a retrospective cohort study of end stage renal disease (ESRD) patients from our institution scrutinizing whether or not race is a factor in the referral process for renal transplantation.

Methods: The study population included all of the adult 200 ESRD patients who are currently receiving hemodialysis at the outpatient dialysis unit at the University of Florida (UF) Health in Jacksonville from January 2016 to February 2018. We divided race into 3 categories: Blacks, Whites, and Others, which consisted mostly of Hispanic patients together with other races/ethnicities. Outcomes were categorized as the patients who refused referral, who were not referred for transplant, and who were referred for transplant. We also collected established factors in the transplant evaluation process such as age, Hemoglobin A1c ≥ 7, Body mass index ≥ 40, left ventricular ejection fraction ≤ 40, presence of coronary or peripheral arterial disease (PAD/CAD), albumin level < 3.5, and cancer, cirrhosis and smoking history. All data were collected using chart review and analyzed using univariate analyses and multinomial logistic regression. Associations between the race and outcome categories are presented as adjusted Odds Ratios (OR) with 95% confidence interval (CI) using the not-referred group as the reference category. The study was approved by the UF IRB committee.

Results: In the univariate analysis, age, PAD/CAD, and albumin level were found to be potential confounders and were included in the final model. Blacks (OR=16.0, 95%CI 3.3-77.2, p=0.018) and Whites (OR=22.5, 95%CI 3.4-149.8, p=0.013) were more likely to be referred for transplant than not compared to Others. The odds of transplant refusal versus a non-referral in Blacks and Whites were not different from Others (p=0.270, and p=0.171, respectively).

Conclusions: In our nephrology practice, Blacks and Whites were more frequently referred for renal transplant than other ethnicities/races. There was no difference between the races in transplant refusal, which might point to satisfactory education and communication across the race groups. At this point we speculate the lack of funding and immigration status might play a role in the observed differences. Future studies are needed to address these possibilities.

SA-PO088

Does Financial Assistance for Travel and Subsistence Costs Alleviate Racial/Ethnic Disparities in Living Kidney Donation? An Analysis of NLDAC and SRTR Data

Amit K. Mathur,[1] Jiawei Xing,[2] Patricia H. Warren,[5] Kimberly A. Gifford,[4] Barry A. Hong,[6] Akinlolu O. Ojo,[3] Robert Merion.[2] National Living Donor Assistance Center *[1]Mayo Clinic, Phoenix, AZ; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]University of Arizona Health Sciences, Tucson, AZ; [4]American Society of Transplant Surgeons (ASTS), Arlington, VA; [5]American Society of Transplant Surgeons, Arlington, VA; [6]Washington University School of Medicine, St Louis, MO.*

Background: The National Living Donor Assistance Center (NLDAC) enables living donor kidney transplants (LKDT) through means-tested financial assistance of living kidney donors (LKD). Since LKDT occurs at lower rates in minority populations, we aimed to determine whether NLDAC utilization is associated with minority donor and recipient characteristics.

Methods: We retrospectively matched LKD data from NLDAC to Scientific Registry of Transplant Recipients (SRTR) data (2012-2015). We compared sociodemographic factors between NLDAC-using and non-NLDAC-using donors. Generalized linear mixed models with center-level random effects were used to estimate the impact of demographics on donor NLDAC use.

Results: There were 16,822 LKDT from 2012-2015. Matching to SRTR was successful for 86% of 1,419 NLDAC LKDT. Compared to non-NLDAC LKD, NLDAC LKD had a higher proportion of females (67% vs 62%), black race (15% vs 11%), Latino ethnicity (20% vs 14%), and were less educated (less than bachelors vs bachelors or more, 48% vs 45%).. NLDAC LKDT recipients were more often black (17% vs 13%), Latino (20% vs 14%), and less educated (all p<0.05). On multivariable analysis, NLDAC utilization was associated with LKD characteristics included LKD black race (OR 1.46, p=0.008), Latino ethnicity (OR 1.32, p=0.029), and female sex (OR 1.23, p=0.001); and LKDT recipient characteristics of black race (OR 1.38, p=0.017), Latino ethnicity (OR 1.29, p=0.047), and lower education (OR 1.17, p=0.012).

Conclusions: Living donor and recipient racial and ethnic minority status, as well as recipient educational status, were associated with higher NLDAC utilization among LKDT in the US. These data suggest that financial assistance programs for living donors alleviate disparities in access to LKDT.

SA-PO089

Impact of Machine Perfusion on Delayed Graft Function and Graft Survival from High-Risk Donors

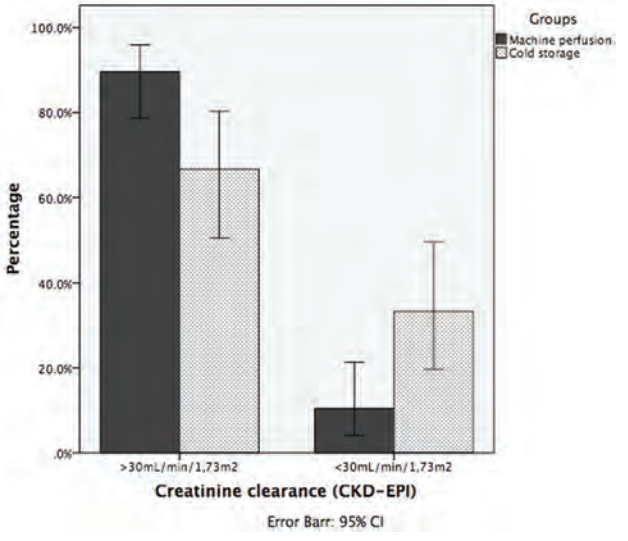
Larissa G. Andrade, Frederico C. Cavalcanti, Lucila Maria Valente. *Universidade Federal de Pernambuco, Recife, Brazil*.

Background: After kidney transplantation(KT), graft may not function immediately and patient needs to undergo dialysis, characterizing delayed graft function (DGF). DGF increases length of hospital stay (LHS), costs and reduces graft survival (GS). DGF incidence is higher in expanded criteria donor (ECD), prolonged cold ischemia time (CIT) and donors with renal dysfunction. Machine perfusion (MP) is a method of preservation that can reduce DGF incidence. We analyzed DGF incidence, its duration, CIT, LHS, 1-year graft and patient survival and renal function estimated by the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) at 1, 3, 6, 9 and 12 months in KT with CS compared to MP after CS.

Methods: Retrospective cohort, in a single center. We included KT from DCE or standard deceased donors if CIT ≥ 24 hours, cardiorespiratory arrest before donation or creatinine ≥1.8mg/dL prior to retrieval from January 2015 to December 2016, 1-year follow up.

Results: Sample was 92 patients, 52 in MP group. Differences between groups were: age of recipient higher in MP group and donor creatinine prior to retrieval 0.7mg/dL higher in CS group. DGF incidence was 86.5% in MP group and 95% in CS group, p=0.29. There were no differences in DGF duration or LHS. CIT was 8.19 hours higher in the MP group, p<0.01. GS was 90.4% in the MP group and 87.5% in CS group. Patient survival was 94.2% in MP group and 95% in CS group. There were no differences in CKD-EPI at 1, 3, 6, 9 and 12 months. After 1-year KT, 89.6% of MP group and 66.7% of CS group had CKD-EPI higher than 30mL/min/1.73m2, p=0.01. In multivariate analysis, risk factors for worse 1-year graft function were: donor age (OR 1.11 CI95% 1.01-1.22; p=0,03) and CS preservation (OR 6.52 CI 95% 1.46-29.08; p=0.01).

Conclusions: The higher CIT in MP group did not increase incidence of DGF. 1-year graft function were better in MP preservation.



SA-PO090

Selecting and Educating Hepatitis C Virus (HCV) Un-infected Kidney Transplant (KT) Waiting List Recipients for a Clinical Trial to Receive an HCV-Infected KT

Meghan E. Sise,[1] Donald F. Chute,[1] Jenna L. Gustafson,[1] Sakuni Silva,[1] David Wojciechowski,[1] Nahel Elias,[1] Raymond T. Chung,[2] Winfred W. Williams.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]MGH, Boston, MA.*

Background: Using HCV-infected (HCV+) donors for KT into HCV-uninfected (HCV-) recipients is a novel strategy to increase access to KT and decrease high rates of organ discard. Patient (pt) selection and education is key to ensure ability to comply with protocol requirements and fully understand risks/benefits.

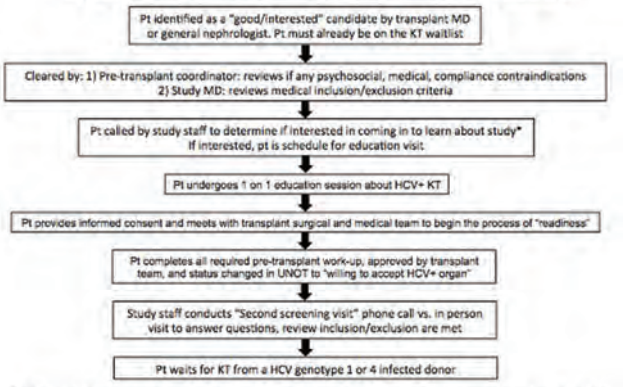
Methods: NCT02945150 is an investigator-initiated clinical trial to transplant 11 HCV- KT pts with a HCV+ KT. Pre-emptive use of elbasvir/grazoprevir to cure HCV in the recipient. We describe the criteria used to select pts, education process, characteristics of the consented pts, and study outcomes of HCV+ KT.

Results: We present enrollment criteria and rationale, which focus on ensuring that high quality HCV+ kidneys are accepted for transplantation and recipients have been selected to maximize safety and benefit. The process of enrolling pts is shown in **Figure 1**. Pt education focuses on 5 themes: 1) HCV in general 2) Effect of HCV on kidney availability 3) Genotypes of HCV and treatment 4) Logistics of study visits 5) Side effects of elbasvir/grazoprevir. The full "education session" is provided. 23 pts have provided consent, mean age 57 (SD 8), 61% Male, 78% White, 13% Black, 9% Hispanic. Two were excluded due to psychosocial or medical comorbidities. Twelve are undergoing medical clearance for KT. Nine were approved and their UNOS status changed to "willing to accept HCV+ organ." Five underwent KT and four are waiting. All donors had genotype 1A infection. None had resistance-associated variants. (Numbers, transplant, and viral outcomes to be updated at time of presentation).

Conclusions: It is important to have a multidisciplinary team to identify the appropriate pts for HCV+ to HCV- KT and a thorough process of education, consent, and evaluation so that pts understand the risks of the protocol and the KT itself.

Funding: Commercial Support - Merck

Figure 1. Identification, Education, Readiness for HCV+ KT



* All pts have already signed consent to be contacted for research purposes. Abbreviations: PT = patient, KT = kidney transplant, HCV = hepatitis C virus

SA-PO091

Access to the Kidney Transplant Waitlist for Patients with HIV and ESRD

Ashton A. Shaffer,[1] Hao Ying,[1] Nadia M. Chu,[1] Alvin G. Thomas,[2] Christine E. Haugen,[1] Dorry L. Segev,[1] Mara McAdams-DeMarco.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]UNC Chapel HIll, Chapel Hill, NC.*

Background: Patients with HIV and end-stage renal disease (ESRD) experience higher mortality on dialysis than those without HIV. These HIV+ dialysis patients may face barriers to kidney transplantation (KT) that result from delayed referrals or factors identified at the time of evaluation.

Methods: We used a prospective, longitudinal multi-center cohort to study 98 HIV+ and 3,105 HIV- patients with ESRD who were evaluated for KT between 2008 and 2017. We compared patient characteristics and estimated the likelihood of listing by HIV-status using adjusted Cox regression. The presence of comorbidities was defined as a Charlson comorbidity index (CCI) score ≥1; cognitive impairment was defined as a mini-mental state exam score ≤80.

Results: Patients with HIV were more often young (median 54 vs. 56 years old), African American (91 vs. 43%), men (72 vs. 59%), with cognitive impairment (15 vs. 6%), and longer time on dialysis prior to KT evaluation (median 2.4 vs. 1.3 years) than those without HIV. Within 1 year of KT evaluation, 52 HIV+ and 2,010 HIV- patients were listed for KT; median time from evaluation to listing was 133 days for HIV- patients and 315 days for HIV+ patients (Figure 1). Adjusting for age, gender, African American race, comorbidities, and cognitive impairment, patients with HIV were less likely to be listed (aHR: 0.70, 95%CI: 0.52-0.93; p<0.05). However, additionally adjusting for time on dialysis attenuated this difference (aHR: 0.90, 95%CI: 0.67-1.20; p=0.5).

Conclusions: HIV+ patients have a lower likelihood of KT listing that is not explained by differences in patients' characteristics other than time on dialysis prior to evaluation. Decreasing time from dialysis initiation to referral for evaluation may improve access to KT for HIV+ patients with ESRD.

Kidney Transplant Evaluation with Blood Oxygen Level Dependent (BOLD) and Diffusion-Weighted MRI: A Pilot Study

Meyeon Park,[1] Ying Gao,[3] Zoltan G. Laszik,[2] Zhen J. Wang.[4] *[1]UCSF, San Francisco, CA; [2]University of California San Francisco, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA; [4]UCSF Medical Center, San Francisco, CA.*

Background: Methods to identify etiologies of kidney allograft dysfunction in kidney transplant recipients (KTR) are generally limited to biopsy (bx). Blood oxygen level-dependent (BOLD) MRI can provide surrogate markers of tissue oxygen bioavailability. Diffusion-weighted (DW) intravoxel incoherent motion (IVIM) method can assess capillary perfusion and molecular diffusion, which may indicate tissue fibrosis. We explored these MRI methods as a non-invasive strategy to evaluate KTR undergoing bx.

Methods: We enrolled 14 KTR who underwent bx (12 protocol, 2 cause) at our center. Participants underwent research MRI scanning using BOLD and IVIM-DW protocols. Allograft bx were scored using Banff criteria by a single trained renal pathologist per clinical protocol. Individual Banff criteria were categorized as ordinal variables and corresponding MRI values were compared by the Kruskal-Wallis test. The mean difference estimate of the standardized MRI values between dichotomized abnormal and normal categories of Banff scores was calculated. Receiver operating characteristics (ROC) analysis was performed.

Results: Mean age was 50 (+/- 16); 9 (64%) were women. More severe grades of total inflammation (ti) were associated with lower BOLD R2* values (12.6 v. 13.8 v. 15, p=0.05); this may reflect lower oxygen consumption. Higher Banff scores for t, ptc, and i were associated with reduced capillary perfusion measured by IVIM-DW MRI (Fig). Area under curve (std error) for cortical interstitial fibrosis 0.8 (0.15) by BOLD and 0.95 (0.07) by DW.

Conclusions: BOLD and IVIM-DW MRI measures correlate with tissue pathology. IVIM-DW MRI may have more precision than BOLD to distinguish certain pathologic features on allograft bx. Functional MRI measures may be a useful screening tool to minimize kidney allograft bx.

Ferumoxytol-Enhanced MR Angiography (FeMRA) vs CT Angiography (CTA) for the Assessment of Potential Kidney Transplant Recipients

Sokratis Stoumpos,[1,2] Pauline Hall barrientos,[5] Aleksandra Radjenovic,[3] Giles Roditi,[6] David Kingsmore,[4] Patrick B. Mark.[2,1] *[1]Renal & Transplant Unit, Queen Elizabeth University Hospital, Glasgow, United Kingdom; [2]Cardiovascular Research Centre, University of Glasgow, Glasgow, United Kingdom; [3]University of Glasgow, Glasgow, United Kingdom; [4]NHS, Glascow, United Kingdom; [5]NHS, Glasgow, United Kingdom; [6]NHS GG & C, Glasgow, United Kingdom.*

Background: Conventional vascular imaging techniques are problematic in chronic kidney disease (CKD) patients due to associated risks, invasiveness and imprecision. CT angiography (CTA) is routinely used to assess the vasculature of CKD patients before transplant listing. Ferumoxytol, licensed for iron-deficiency anaemia, was originally developed as an MRI contrast agent and reduces T1 properties of tissue on MRI.

Methods: Prospective comparative study of ferumoxytol-enhanced MRA (FeMRA) vs CTA for aortoiliac imaging in kidney transplant (KT) candidates. MRA using ferumoxytol 3mg/kg as intravenous contrast agent was performed in addition to CTA. We also used a specific MRI sequence called StarVIBE to detect vascular calcifications in similar way to CT using contrast-free techniques. Two independent readers assessed the FeMRA/StarVIBE and a third reader the CTA (gold standard). Interclass correlation coefficient (ICC) was performed to assess interobserver agreement. Comparisons of lumen diameter, calcification, and signal intensity at predefined vascular sections were performed. For continuous variables, mean differences (and CI) were estimated and Bland-Altman plots of interobserver variability were created. Steady-state images were analyzed using the Horos image viewer (vs3, LGPL-3.0).

Results: 28 patients (mean age 68 [SD 15] yr; 58% men; 42% diabetics) undergoing CTA for pre-operative KT candidacy assessment were enrolled. There was excellent intraobserver agreement in assessment of the arterial diameter, vein diameter and calcification (ICC 0.91 [95% CI 079-0.96], 0.89 [0.79-0.94] and 0.95 [0.89-0.98], respectively). There were no significant differences in assessment of the arterial diameter and calcification between FeMRA/StarVIBE and CTA (arterial diameter 1.34 [0.42] vs 1.30 [0.44]cm; p=0.63, area of calcification 0.43 [0.35] vs 0.39 [0.29]mm^2; p=0.53, respectively). However, signal intensity and qualitative lumen depiction in the venous vasculature was superior with FeMRA (p<0.001).

Conclusions: FeMRA combined with StarVIBE is comparable to CTA for assessment of lumen diameter, calcification and signal intensity in the abdominopelvic arterial vasculature of CKD patients due for KT listing with the significant advantage of improved venous depiction with no nephrotoxicity.

Contrasting Relationships Between Deprivation, Kidney Transplantation, and Live Donation

Keith Gillis,[1] Julie Glen,[2] Jennifer S. Lees,[1] Maximilian R. Ralston,[2] Colin C. Geddes,[2] Karen S. Stevenson,[2] Jamie P. Traynor,[2] Patrick B. Mark.[1] Glasgow Renal Research Group *[1]University of Glasgow, Glasgow, United Kingdom; [2]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom.*

Background: Socioeconomic deprivation (SED) is associated with reduced access to pre-emptive and live kidney donation for end stage kidney disease (ESKD). We investigated the association between SED and access to, and progression through, potential live donor (PLD) assessment.

Methods: Retrospective analyses of routinely collected healthcare data were performed. A postcode of residence-based tool, the Scottish Index of Multiple Deprivation (SIMD), was used as a marker of SED; the cohort was grouped numerically into those with greater deprivation (SIMD≤3) and those without. A survival analysis was performed to test for interaction between SIMD and time to either drop-out or live donor nephrectomy.

Results: Of 7765 patients attending clinic, 1298 reached ESKD; 113 received a pre-emptive transplant. Patients receiving pre-emptive transplant had higher SIMD (5±7 vs 4±5; p=0.003); SIMD, cardiovascular disease, referral age and proteinuria were independently associated with pre-emptive transplant on logistic regression. 1208 PLDs were evaluated between 2009 and 2018 with an age of 45.8±21.4 years, follow-up 3.4±8.5 months and SIMD of 4±5. The PLDs from deprived areas were assessed at younger age (42.9±21.6 vs 48.4±21.1 years; p<0.001). SED was not asssociated with likelihood of successful donation (8 vs 11%; p=0.13) but was associated with more frequent referral for psychological assessment (13 vs 9%; p=0.03); there was no difference in discussion of the National Kidney Sharing Scheme (7 vs 9%; p=0.22). The cumulative incidence of successful donation was no different between groups (log rank p=0.27). In an analysis of the recipients of the PLDs, there was no association between SED and renal replacement therapy status (pre-emptive recipients 55 vs 62%; p=0.21), nor recipient eGFR (13.0±8.4 vs 13.1±7.6 ml/min/1.73m^2, p=0.56) at time of PLD approach. In an evaluation by postal code sector, there was no association between lower SIMD and the number of PLDs per 100,000 population (r = -0.024, p=0.75).

Conclusions: Although SED is associated with reduced incidence of live and pre-emptive transplantation, in recipients in whom PLDs are assessed, deprivation does not affect outcome of the evaluation process. Resources should be focused on encouraging an approach of PLDs for all suitable patients nearing ESKD.

SA-PO095

Multiparametric MRI Characteristics of the Renal Allograft in the Early Post-Transplant Period

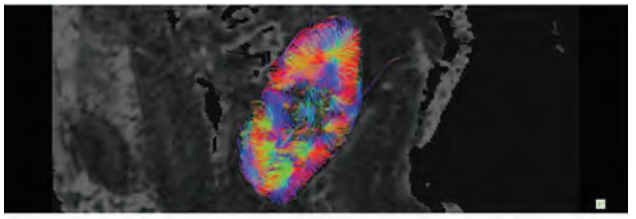
Keith Gillis,[1] Sarah Allwood-Spiers,[2] Alastair J. Rankin,[1] Giles Roditi,[2] Aleksandra Radjenovic,[1] Rajan Patel,[1] Patrick B. Mark.[1] Glasgow Renal Research Group *[1]University of Glasgow, Glasgow, United Kingdom; [2]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom.*

Background: Renal allograft function is currently measured using estimated glomerular filtration rate (eGFR) and proteinuria, however these do not provide comprehensive information regarding prognosis or presence of important pathological features such as fibrosis. Use of multi-parametric magnetic resonance imaging (MRI) may yield novel biomarkers for prediction of outcome and response to therapy in renal transplantation.

Methods: Patients undergoing renal transplantation underwent multi-parametric MRI at 6 weeks post operatively. Routine clinical and biochemical measures were made. MRI protocol entailed arterial spin labelling (ASL) perfusion, T1 relaxation time and R2*. Apparent diffusion coefficient (ADC) and fractional anisotropy (FA) were measured, and tractography maps produced, by diffusion weighted imaging.

Results: 20 patients were recruited with median age 55.5±12.8 years, eGFR of 51.8±27.4 ml/min/1.73m^2, and trough tacrolimus of 8.7±2.5 ng/mL. Cortical ASL was 283.0±116.2 ml/min/100g, ADC 1.69±0.11 x10^{-3} mm^2/s, FA 0.22±0.04, T1 was 1715±114 ms. ADC had a significant correlation with eGFR (r=0.48, p=0.03), and a negative association with cold ischaemia time (r=-0.55, p=0.01) and recipient age (r=-0.45, p=0.04). There was also a negative correlation between recipient age and cortical ASL (r=-0.60, p=0.04), Differences in transplant function were visible on diffusion tensor imaging (figure 1).

Conclusions: Diffusion weighted imaging may provide a novel method of evaluating renal transplant structure and function. Further research is required to determine if this provides increased prognostic information additional to existing biochemical measures.



Tractography map of kidney allograft derived from diffusion tensor imaging

SA-PO096

Social Determinants of Quality of Life in Patients Evaluated for Kidney Transplant

Hannah Wesselman,[2] Shu Wang,[2] Chung-Chou H. Chang,[2] John R. Pleis,[5] Kellee Kendall,[2] Emilee J. Croswell,[2] Mary amanda Dew,[2] Mark L. Unruh,[3] Ron Shapiro,[4] Larissa Myaskovsky.[1] *[1]University of New Mexico, Albuquerque, NM; [2]University of Pittsburgh, Pittsburgh, PA; [3]University of New Mexico, Los Ranchos, NM; [4]Recanati/Miller Transplantation Institute, New York, NY; [5]VA Pittsburgh, Pittsburgh, PA.*

Background: Non-Hispanic African Americans (AA) have a higher incidence of ESRD but lower rates of kidney transplant (KT), and poorer quality of life (QOL) compared to non-Hispanic whites (WH). Disparities persist after adjusting for medical factors (e.g., comorbidity, dialysis). We assessed whether race disparities in QOL would persist in patients evaluated for KT after adjusting for medical and social determinants, including demographic (e.g., age, income), cultural (e.g., perceived discrimination, medical mistrust), psychosocial (e.g., social support, emotional distress), and knowledge (e.g., knowledge, learning activities) factors.

Methods: We conducted a longitudinal cohort study with 1035 (AA=260; WH=775) patients undergoing KT evaluation at the UPMC Starzl Transplant Institute. Patients completed an interview after initiating KT evaluation to assess social determinants; and another interview after being accepted, rejected, or withdrawing from evaluation, to assess kidney-specific (symptoms/problems, sleep, lifestyle effects, burden, cognitive function, work, sexual function) and general QOL (mental and physical composite scores) using the Kidney Disease QOL scale. We built multivariable regression models to test the hypothesized relationships.

Results: Our sample was 38% female, mean age=57, 73% had family income < $50,000, 52% married, 35% public insurance, 27% private, and 38% public/private. Race differences in kidney-specific QOL outcomes were no longer significant when social determinants were included in the model. Instead, psychosocial (e.g., mastery, social support, emotional distress), transplant knowledge (e.g., concerns, learning activities, knowledge), and demographic (e.g., age, sex, income, insurance) factors were significant predictors. For general QOL outcomes, race continued to be a significant predictor even after we identified several significant psychosocial, transplant knowledge, and demographic predictors (all predictors significant at $p<.05$).

Conclusions: A combination of social determinants predicted QOL outcomes for KT patients, which mediated race differences, especially for kidney-specific QOL. Transplant centers may help ensure better QOL in their patients as they await KT by promoting psychosocial support, and ensuring candidates' understanding of KT.

SA-PO097

The Impact of Systematic Review of Status 7 Patients on the Kidney Transplant Waitlist

Ashish Kataria,[2,1] Rocco C. Venuto,[2,1] Jon R. Von Visger,[2,1] Shirley S. Chang,[2,1] Bryan Lamphron,[2] Vaqar H. Shah,[1] Aijaz A. Gundroo.[2,1] *[1]Medicine/Nephrology, University at Buffalo, Buffalo, NY; [2]Erie County Medical Center, Buffalo, NY.*

Background: Patients (pts) listed status 7 on the kidney transplant (Tx) waitlist are more likely to die rather than be transplanted. They need to overcome one or more barriers in order to move to status 1. These barriers could either be medical or psycho-social (PS) but are significant enough to exclude them from recieving organ offers. We speculated that by systematically re-evaluating status 7 pts, we might overcome the barriers and expedite their Tx.

Methods: Biweekly status 7 re-evaluation meetings were started in April 2016 and continued through April 2018. The attendees were a transplant physician champion and members of all components of the transplant team. These were held in parallel to the recipient selection meetings. For each status 7 patient, the attendees performed an intense scrutiny of the individual barriers against activation and developed a specific action plan. A descriptive analysis of the status 7 pts at the start and end of study was performed and patient demographic and listing outcomes were studied.

Results: A total of 266 status 7 pts were evaluated(Table1). 18.4% of them overcame remaining barriers preventing activation and majority (85.7%) in this group recieved a Tx after being inactive on the waitlist for average 805 days. 39% of inactive patients were deemed ineligible and were removed from the waitlist. These pts were older than those who recieved a Tx (mean age 60.6 versus 52.7 years) and were inactive for average 1593 days. 17.6% status 7 pts died while only 73 (27.4%) pts still remain inactive on the waitlist. Common barriers against activation were CP and PS issues in all categories.

Conclusions: Re-evaluation of status 7 pts has the potential to expedite their transplantation or removal of those pts from the waitlist who are unlikely to get activated for a kidney Tx. We have incorporated this process on a continuing basis.

Current waitlist status	Status 7	Activated and/or transplanted	Died	Removed from the waitlist
Number of patients(%)	73(27.4%)	49(18.4%) activated; 42 of these transplanted	47(17.6%)	104(39%)
Mean age (years)	51.3	53.4	59.3	60
Common barriers against activation(%)	CP(52) PS(30)	CP(41) PS(33) Onc(17)	CP(54) PS(21) Onc(15) I(13)	CP(46) PS(26) Onc(10)
Average inactive duration (days)	1685	805	1198	1593

Aged Kidney Grafts: Another Potential Long-Term Risk in Living Kidney Transplantation

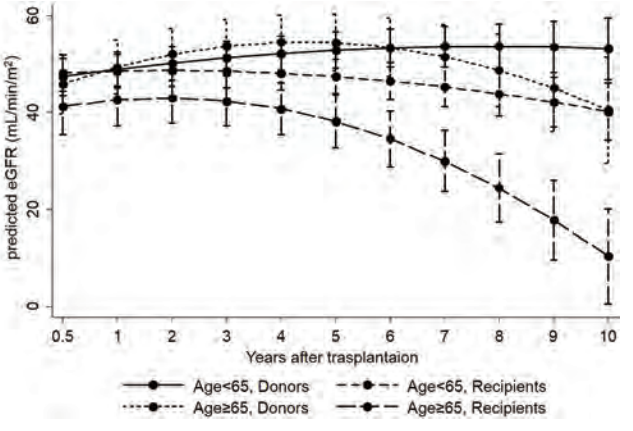
Sayoko Yonemoto,[1] Takayuki Hamano,[2] Naohiko Fujii,[1] Yoshitaka Isaka.[2] *[1]Hyogo Prefectural Nishinomiya Hospital, Nishinomiya-city, Japan; [2]Osaka University Graduate School of Medicine, Suita, Japan.*

Background: As marital kidney transplantaion increases, the living kidney donor's age, or the age of the kidney graft at transplantaion, becomes older in Japan; however, its effect on graft survival has not been well-studied. We evaluated the long-term kidney function of both donors and recipients in transplantaion with aged or non-aged kidney grafts.

Methods: In this prospective observational study, we enrolled 130 consecutive living kidney donors and recipients (65 pairs) in a single transplant unit in Japan from November 1, 2008 to May 31, 2013. We divided them into two groups by donor's age (D-Age<65 and D-Age≥65), and longitudinally followed estimated glomerular filtration rate (eGFR) every year until May 31, 2018. The temporal changes in eGFR of donors and recipients were analyzed by mixed effects models with random intercepts and random slopes, allowing a quadratic term for time-interaction and a 2-by-2 factorial interaction (D-Age and donor-recipient).

Results: The median donors' and recipients' ages were 60 and 46 years old, respectively. We had 19 donors (29.2%) who were over 65 years old. We had 39 females (60%) in donors and 25 females (38.5%) in recipients. There was no significant difference in eGFR before donation between D-Age<65 and D-Age≥65 group. In the D-Age≥65 group, eGFR declines started in donors and recipients four years and two years after transplantation, respectively, while in the D-Age<65 group eGFR was sustained in donors and slightly decline in recipients (p for interaction<0.01). No significant difference in trajectory of eGFR was observed between recipients and their donors in D-Age≥65 group (p=0.50).

Conclusions: In this study, eGFRs in both donors and recipients were declined after living kidney transplantation with aged grafts. We should be careful when we use aging kidney in transplantaion.



SA-PO099

Postdonation Renal Function Predicts New Onset Antihypertensive Medication Use After Living Kidney Donation

Krista L. Lentine,[1] Abhijit S. Naik,[9] Ngan Lam,[2] Amit X. Garg,[3] Dorry L. Segev,[4] David A. Axelrod,[10] Huiling Xiao,[5] Macey L. Henderson,[11] Allan Massie,[12] Chi-yuan Hsu,[8] Bertram L. Kasiske,[6] Gregory P. Hess,[7] Mark Schnitzler.[13] *[1]Saint Louis University, St. Louis, MO; [2]University of Alberta, Edmonton, AB, Canada; [3]London Health Sciences Centre, London, ON, Canada; [4]Johns Hopkins University, Baltimore, MD; [5]St. Louis University, St. Louis, MO; [6]Hennepin County Medical Center, Minneapolis, MN; [7]LDI University of Pennsylvania/ Symphony Health, Conshohocken, PA; [8]University of California San Francisco, San Francisco, CA; [9]University Michigan, Ann Arbor, MI; [10]Lahey Hospital and Clinic, Burlington, MA; [11]Johns Hopkins, Baltimore, MD; [12]Johns Hopkins School of Medicine, Baltimore, MD; [13]Saint Louis Univ, St Louis, MO.*

Background: Limited data are available on the outcome implications of renal function after living kidney donation.

Methods: We constructed a novel database linking SRTR registry identifiers, serum creatinine (SCr) values from an electronic medical records warehouse, and pharmacy fill records for 3,593 living kidney donors (1989–2016) without predonation hypertension per the registry. Estimated glomerular filtration rate (eGFR, ml/min/1.73 m2) was computed from SCr by the CKD-EPI equation. Pharmacy enrollment was assessed within ±90 days of each postdonation SCr, followed by identification of antihypertensive medication (AHM) fills in those with pharmacy records eligibility. A mixed effects model was constructed to assess associations of postdonation eGFR (adjusted odds ratio, $_{95\%LCL}$ aOR $_{95\%\ UCL}$) and other baseline factors with AHM treatment requirements after donation.

Results: The linked database captured an average of 3 post-donation SCr values per donor (range: 1 to 38). Lower postdonation eGFR bore a graded association with increased AHM use (eGFR 30–44: aOR $_{0.95}1.47_{2.26}$; <30: aOR $_{1.08}$ $5.90_{2.52}$). Other significant (P<0.05) correlates of postdonation AHM fills included black race (aOR 2.22), BMI >30 kg/m^2 (aOR 2.09), first-degree donor-recipient relationship (aOR 1.79), "pre-hypertension" at donation (SBP 120-139: aOR 1.94; DBP 80-89: aOR 1.99), and longer time since donation. Predonation eGFR was not significantly associated with AHM use in the multi-level model. [**Fig**.]

Conclusions: Lower eGFR levels after living kidney donation are associated with need for AHM treatment. Further work should define relationships of postdonation renal function with renal and cardiovascular morbidity.

SA-PO100

Which US-Listed Candidates Travel Abroad for Kidney Transplant?

Alvin G. Thomas,[1,2] Brittany Koons,[4] Ashton A. Shaffer,[2] Fawaz Al Ammary,[2] Krista L. Lentine,[3] Mara McAdams-DeMarco,[2] Tamara M. Kear,[4] Dorry L. Segev,[2] Helene Moriarty,[4] Macey L. Henderson.[2] *[1]UNC Chapel HIll, Chapel Hill, NC; [2]Johns Hopkins University, Baltimore, MD; [3]Saint Louis University, St. Louis, MO; [4]Villanova University, Villanova, PA.*

Background: Kidney transplant (KT) candidates listed in the United States (US) wait several years to receive a transplant. Some candidates opt to withdraw from the US waitlist and receive a KT abroad.

Methods: Using the SRTR 2010-2016, we compared 364 adult KT candidates who received KT abroad to 76,133 candidates removed for deceased donor KT. We assessed factors associated with receiving KT abroad using adjusted logistic regression accounting for possible race/citizenship interactions.

Results: KT candidates who received a KT abroad were more often male (p<0.001), younger (p<0.01), college educated (p<0.001), and had private insurance (p<0.001). These candidates spent less time on dialysis (1.6 vs. 3.8 years, p<0.001), and were often first-time KT candidates (p<0.001). The likelihood of KT abroad differed by race and citizenship (interaction p<0.001). White US citizens/residents (C/R) were the reference group. White non-US citizens/non-US residents (NC/NR) had the highest odds of KT abroad (aOR: $_{63.27}113.59_{203.92}$, p<0.001). Hispanic C/R residents had a 2.6-fold (aOR: $_{1.75}2.60_{3.84}$, p<0.001) higher odds and Hispanic NC/NR had a 13.9 fold (aOR: $_{6.04}13.87_{31.87}$, p<0.001) higher odds of KT abroad. Asian C/R had a 15.7-fold (aOR: $_{11.69}15.67_{20.99}$, p<0.001) higher odds and Asian NC/NR had a 34.2-fold (aOR: $_{14.11}34.16_{82.70}$, p<0.001) higher odds of KT abroad. The countries most frequently traveled to were the Philippines (n=93) and India (n=52) (Figure 1).

Conclusions: Although travel for transplant remains a rare practice for US-listed candidates, those with the means to travel, lower access to transplant, and possible connections outside the US might opt to travel abroad for transplant. Since follow-up care will primarily take place in the US, the nephrology community needs better data on these candidates and their post-transplant outcomes.

Funding: NIDDK Support, Other NIH Support - T32 HL007055 (Thomas), K01AG043501 (McAdams-DeMarco), R01AG055781 (McAdams-DeMarco), K24 DK101828 (Segev), K01 DK114388 (Henderson), Private Foundation Support

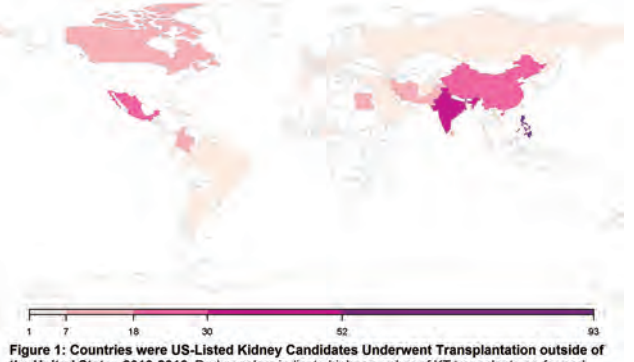

Figure 1: Countries were US-Listed Kidney Candidates Underwent Transplantation outside of the United States 2010-2016. Darker colors indicate higher number of KT transplants performed. The countries with the high number of kidney transplants of US listed candidates were the Philippines (n=93), India (n=52), China (n=30), Mexico (n=30), Iran (n=18), Pakistan (n=17), Canada (n=12), and Egypt (n=12).

SA-PO101

Nephron Dose Does Not Predict Renal Function After Live Donor Renal Transplantation

Steven Goorachan,[1] Rachel J. Youngs,[2] Richard J. Baker.[2] *[1]St. James Hospital, Leeds, United Kingdom; [2]SJUH, Leeds, United Kingdom.*

Background: In our live donor transplant programme we consider isotopic determinations of donor glomerular filtration rate (GFR) as an indicator of the donor kidney quality. We also measure isotopic split renal function and thus by multiplying the two together we can calculate the potential "nephron dose" of the transplant. This has been used anecdotally as a guide to the quality of the graft and to inform the likely outcome in terms of function. This consideration has recently become more pertinent with the expansion of the national live donor sharing scheme since multiple potential donors may be considered for any particular recipient.

Methods: We recorded 147 patients from August 2008 to August 2017 excluding: those without follow up data; paediatric patients; and those with early graft loss (< year). Data set included estimated and measured GFR, split function of kidneys, Recipient body surface area (BSA), and recipient eGFR (MDRD equation) at 3, 6 and 12 months post transplant. We determined Nephron Dose using the formula: Measured isotopic GFR x percentage function of donated kidney = Nephron dose. We also measured the recipient's eGFR post transplant at t=3, 6 and 12 months, and corrected these measurements to recipients BSA. We measured the strength of the association using correlation coefficients.

Results: We report that the was no clear correlation with nephron dose to renal function at 3, 6 or 12 months whether eGFR was corrected for recipient body surface area or not, (table).

Conclusions: Nephron dose was not found to be strongly correlated with recipient transplant function at 3, 6 or 12 months following live donor renal transplants. This may

represent inaccuracy of either isotopic studies in donors to determine renal function or the MDRD formula to estimate true GFR post renal transplant. However we propose that postoperative transplant function is determined by a complex interplay between several factors, many of which are either recipient derived or external (e.g. viral infections and drug toxicity). The weak correlation demonstrated does not support overzealous interpretation of donor functional data even when derived from isotopic studies.

Correlation Coefficients for Nephron Dose and eGFR

	3 Months	6 Months	12 Months
eGFR	0.355	0.320	0.342
eGFR Adjusted for BSA	0.359	0.321	0.340

SA-PO102

Characterization and Establishment of Non-Human Primate Models of Diabetic CKD

Rosario M. Perez, Flordeliza P. De Villa, Dawei Wang, Joseph A. Gabriel, Luping Zhu, Yong Yang, Lichuan Yang, Tony Wang, Zhiming Ding, Bob Zhang. *Kunming Biomed International, Kunming City, China.*

Background: The lack of translatable diabetic nephropathy animal models has greatly dampened the development of novel CKD therapies. This study aims to characterize a large cohort of high-fat diet (HFD)-induced type 2 diabetic nephropathy (T2DN) NHPs with substantial translational value to CKD drug development.

Methods: Animals with FBG ≥150 mg/dL and HbA1c ≥6% were screened from >1,500 male cynomolgus monkeys on HFD for ≥1.5 years. The following parameters were monitored: 24-h albumin-creatinine ratio (ACR); BP measurements; and, GFR by FITC-inulin. Animals were classified based on GFR severity grades and renal histology was scored based on the *International Pathologic Classification of Glomerular Changes in Diabetic Kidney Disease*.

Results: A 25% prevalence of T2DN-CKD was observed. Similar to human DN, albuminuria was confirmed as the earliest marker of glomerular disease. Serum creatinine was normal except in animals with kidney failure. DN-CKD monkeys had significantly elevated ACR levels compared to age-matched lean and obese monkeys, and to insulin-treated T2D monkeys. Systolic, diastolic and mean arterial pressure levels were significantly higher in DN-CKD. Over 75% had overt albuminuria with moderate to severe GFR reduction (GFR Stages 3-4) while 2% had kidney failure (GFR Stage 5). GFR reduction occurred even without substantive shifts from normo- or micro- to macroalbuminuria. No marked correlation between GFR and ACR was observed. These findings suggested that, as seen in human patients, macroalbuminuria did not represent an obligatory phase for renal function reduction in T2DN-CKD. Albuminuria with GFR Stages 3-4 were associated with mesangial expansion and thickening and/or fibrosis of the basement membranes (Class 1 to 2a/b). Kimmelstiel–Wilson lesions (Class 3) were seen with kidney failure.

Conclusions: A large cohort of DN-CKD monkeys was characterized using quantitative clinical laboratory and histopathologic indicators of DKD development and progression. The cynomolgus monkey CKD model resembles the disease characteristics in man and can be regarded as one of the most clinically relevant models for the efficacy evaluation of new therapeutic modalities for DN-CKD.

SA-PO103

A Novel Surgery-Induced Rat Model of Diabetic Nephropathy Displaying Progressive Albuminuria, Glomerular Hypertrophy, and Glomerulosclerosis

Mette V. Østergaard,[2] Thea T. Johansen,[2] Thomas Secher,[2] Frederikke E. Sembach,[2] Kristoffer Rigbolt,[2] Torben Skarsfeldt,[1] Niels Vrang,[2] Keld Fosgerau,[2] Lisbeth N. Fink.[2] *[1]Serodus, Oslo, Norway; [2]Gubra ApS, Hørsholm, Denmark.*

Background: Diabetic nephropathy (DN) is a long-term complication of diabetes characterized by albuminuria and loss of kidney function. No new therapies targeting DN have been introduced for decades, partly due to the lack of preclinical animal models recapitulating key features of human DN. Here, we characterized a novel preclinical model of DN in pancreatectomized (Px) uni-nephrectomized (UNx) rats.

Methods: Px-UNx (n=11) and sham (n=12) operations were performed at 8 wks of age in male SPD rats. Blood glucose was >18 mmol/L in Px-UNx rats from 2 wks post-surgery. Urinary renal injury markers were measured 2, 6 and 9 wks after surgery and glomerular filtration rate (GFR) 9 wks after surgery. At termination 11 wks post-surgery, kidneys were processed for histology, stereology and next generation sequencing (NGS).

Results: Urinary albumin and NGAL excretion was increased from 2 wks post-surgery in Px-UNx vs Sham and highest after 9 wks for both albumin (13473±7619 vs 370±170 µg/mg creatinine, p<0.001) and NGAL (13.28±1.76 vs 2.68±0.43 µg/mg creatinine, p<0.001). Urinary podocalyxin excretion was increased from 6 wks and peaked 9 wks post-surgery in Px-UNx (195.2±41.9 vs 11.8±2.0 ng/mg creatinine, p<0.001). GFR was higher in Px-UNx vs Sham (8.2±0.3 vs 6.6±0.3 mL/min/kg, p<0.01). At termination, plasma urea was increased in Px-UNx (9.4±0.7 vs 5.5±0.2 mmol/L, p<0.001). Right kidney weight and volume was nearly doubled in Px-UNx vs Sham (both p<0.001), as were renal cortex (69.1% increase, p<0.001) and glomerulus volumes (57.7% increase, p<0.001). Kidney fibrosis (398±24 vs 210±9.8 mg collagen III, p<0.001) and glomerulosclerosis (11.1±0.8 vs 6.3±0.3 mm^3 collagen IV, p<0.001) was increased in Px-UNx vs Sham rats. Px-UNx increased gene expression of tubular injury markers (KIM-1, NGAL), collagens and fibronectin in renal cortex and reduced nephrin expression.

Conclusions: The Px-UNx model of DN develops extensive renal hypertrophy, hyperfiltration and fibrosis concomitant with early excretion of both glomerular and tubular injury markers. In rats, Px in combination with UNx represents a novel time-saving and robust alternative to STZ-induced diabetes and genetic models for preclinical drug development targeting DN.

SA-PO104

Dysregulation of the Ubiquitin Ligase Component Kelch-Like 3 Causes Na-Cl Cotransporter Activation and Salt Retention in Type 2 Diabetes Mellitus

Kenichi Ishizawa,[1,2] Qin Wang,[1] Jinping Li,[1] Yoshikazu Nemoto,[1] Chikayuki Morimoto,[1] Toshiro Fujita,[3] Shunya Uchida,[1] Shigeru Shibata.[1] *[1]Teikyo University School of Medicine, Tokyo, Japan; [2]Shinsen Ikebukuro Clinic, Tokyo, Japan; [3]The University of Tokyo, Tokyo, Japan.*

Background: Salt-sensitive hypertension is frequently associated with type 2 DM. However, the pathogenesis remains unclear. Kelch-like 3 (KLHL3) is a component of an E3 ubiquitin ligase complex that targets With-No-Lysine kinases for degradation, thereby regulating downstream Na-Cl cotransporter (NCC). Mutations and inactivation of KLHL3 increase NCC activity, resulting in hypertension and hyperkalemia. Previously, we have reported that angiotensin II (Shibata et al. PNAS 2014) and K^+ depletion (Ishizawa et al. BBRC 2016) inactivate KLHL3 by protein kinase C (PKC)-mediated phosphorylation at S433 in the Kelch-domain. In this study, we examined the possible involvement of KLHL3 in the diabetic kidney, using a model of type 2 diabetes.

Methods: KLHL3 phosphorylated at S433 ($KLHL3^{S433\text{-}P}$), total KLHL3, and NCC levels were evaluated in the kidney of db/db mice by Western blotting. In some experiments, db/db mice received a PKC inhibitor bisindolylmaleimide I (BIMI), SGLT2 inhibitor ipragliflozin, and a thiazolidinedione pioglitazone.

Results: $KLHL3^{S433\text{-}P}$, NCC and active PKC levels were all increased in the kidney of db/db mice. Administration of BIM to db/db mice significantly reduced $KLHL3^{S433\text{-}P}$ and NCC levels ($P < 0.05$). Consistently, urinary Na^+ levels were increased in db/db mice receiving BIM (76 ± 8.7 µEq/6h in db/db mice receiving BIM vs. 48 ± 4.5 µEq/6h in db/db mice receiving vehicle; $P < 0.05$). To evaluate the effects of SGLT2 inhibition on this pathway, db/db mice received ipragliflozin or pioglitazone (as a control). Of note, KLHL3 phosphorylation and NCC induction were reduced by ipragliflozin but not by pioglitazone, although blood glucose levels were similarly reduced by the two hypoglycemic agents. PKC activity was reduced by ipragliflozin but not by pioglitazone, explaining the distinct effects of the two hypoglycemic agents on KLHL3 and NCC.

Conclusions: These data demonstrate the involvement of KLHL3 in the increased salt reabsorption in obese diabetes mellitus, and provide insights into the mechanisms for the protective effect of SGLT2 inhibitors.

A Mouse Model of Moderate Diabetic Nephropathy on a Metabolic Syndrome Background

Arianne van Koppen,[1,2] Christa De Ruiter,[1] Joline Attema,[1] Geurt Stokman,[1] Reinout Stoop.[1] *[1]Metabolic Health Research, TNO, Leiden, Netherlands; [2]Pathology, UMC Utrecht, Utrecht, Netherlands.*

Background: Mouse models of diabetic nephropathy (DN) which not only recapitulate the early phases of the disease but also progress to a more advanced phase are urgently needed. We aim to develop a translational DN mouse model on metabolic syndrome background by incorporating the three main features of DN viz hyperglycemia, hyperlipidemia and hypertension.

Methods: Male KKAy mice were uninefrectomized and received high fat (45%) diet alone (HFD) or with prohypertensive (HFD+hyp) for 14 wk. At regular intervals, systolic blood pressure (SBP), 24h diuresis and plasma was collected. At sacrifice, GFR (inulin clearance) was determined, and renal injury was scored using histology. Age-matched chow-fed animals were controls.

Results: Mice fed with HFD developed hyperglycemia and hyperlipidemia. The prohypertensive group developed hypertension. GFR was significantly reduced in the HFD+hyp group compared to controls (2.5µl/min/g BW vs 4.6µl/min/g BW). Renal injury score showed glomerular hypertrophy, mesangium expansion, glomerulosclerosis, hyalinosis, micro-aneurisms and tubulo-interstitial fibrosis.

Conclusions: Combining three key features of DN in one mouse model induces moderate DN with a decline in GFR and morphological features resembling the human situation. We are currently forming a consortium to identify the temporal dynamics of key processes involved in disease development and progression.

Glomerular Injury and Progressive Cardiac Dysfunction in the Obese ZSF1 Rat, a New Model of Diabetic Nephropathy and Heart Failure with Preserved Ejection Fraction

Elyse Di marco,[1] Erik Michaëlsson,[1] Charlotte Ericson,[1] Margareta Behrendt,[2] Maria Stromstedt,[1] Magnus Soderberg,[1] Johannes Wikstrom,[1] Anna Granqvist.[1] *[1]AstraZeneca, MOLNDAl, Sweden; [2]CVRM IMED Biotech, Gothenburg, Sweden.*

Background: Efforts to develop effective therapies against interlinked cardiac and renal diseases are hampered by the lack of preclinical models. We have investigated whether the hypertensive, diabetic, obese ZSF1 rat represents a valid experimental disease model for diabetic nephropathy (DN) and heart failure with preserved ejection fraction (HFpEF).

Methods: The renal (glomerular filtration rate- GFR, albuminuria, histology) and the cardiac (functional non-invasive imaging/invasive haemodynamics, histology) phenotypes were investigated in obese and lean male ZSF1 rats. Uninephrectomy (UNX) was performed in obese rats at 12-weeks of age followed by administration of high-salt diet (HSD) and treatment with ACE inhibitor Lisinopril for 10 weeks.

Results: Obese UNX ZSF1 rats displayed progressive albuminuria, reduced GFR and glomerular injury evidenced by increased desmin and reduced WT1 immunostaining, reduced podocyte-specific gene expression (podocin, nephrin, WT1) compared to lean ZSF1 rats. The renal histological phenotype was severely aggravated by HSD, consistent with marked increases in urinary biomarkers KIM-1, NGAL and Cystatin C. UNX rats fed HSD showed an increase in NTproBNP, a marker of cardiac stress, in line with progressive cardiac hypertrophy and impaired ventricular relaxation. Lisinopril treatment of UNX+HSD-rats had no effect on the renal phenotype or cardiac relaxation, but markedly improved systolic function.

Conclusions: The obese ZSF1 rat with UNX is a suitable model of renal dysfunction with progressive glomerular injury and the addition of HSD elicits a HFpEF phenotype. This model now allows us to investigate potential therapies targeting these interlinked diseases.

Loss of Podocyte Glucocorticoid Receptor Worsens Fibrosis in a Mouse Model of Diabetes

Swayam P. Srivastava, Julie Goodwin. *Pediatrics, Yale University School of Medicine, New Haven, CT.*

Background: Glomerular fibrosis, which is a key component of diabetic nephropathy, is characterized by deposition of extracellular matrix, alteration of the glomerular structure and dysfunction of the glomerular filtration barrier. The role of the podocyte glucocorticoid receptor (pGR) in the pathogenesis of diabetic nephropathy has not been explored yet. Based on previous studies which showed that pGR was critical in the response to renal injury, we hypothesized that loss of pGR would result in worsened fibrosis.

Methods: Streptozotocin (STZ) 200 mg/kg was used to induce diabetes in 10-week old pGR KO mice (($GR^{fl/fl}$; podocin Cre+) and control litter mates ($GR^{fl/fl}$; podocin Cre-). After STZ injection, mice were maintained for 4 months prior to sacrifice. Body weight, kidney weight, blood glucose and urine microalbumin/creatinine ratio were assessed in normal and diabetic mice of both genotypes. Glomerular fibrosis and segmental glomerulosclerosis were analyzed by staining kidney sections in diabetic mice of both genotypes. Western blot and immunofluorescent staining were also used to examine key pro-fibrotic targets. One way ANOVA with Tukey's post-test was used to determine statistical significance.

Results: Non-diabetic control and pGR KO mice did not have any differences in body weight, kidney weight, blood glucose, urinary microalbumin excretion, or kidney histology. Diabetic control and pGR KO mice showed similar body weight, and blood glucose levels, but kidney weight was significantly higher in diabetic pGR KO mice (15.8 vs. 14.7 mg/g body weight, n= 5/group, p=0.04). Glomerular collagen deposition, glomerular surface area and mesangial expansion were all significantly increased in pGR KO mice. We did not observe any significant differences in the level of interstitial fibrosis. Western blotting and immunofluorescent staining of kidney sections revealed induction of mesenchymal activation which was associated with glomerular deposition of fibronectin and collagen I in diabetic pGR KO mice.

Conclusions: From these results we conclude that: 1. loss of pGR worsens the severity of fibrosis in our mouse model of diabetes 2. pGR is tonically suppressing mesenchymal activation pathways 3. modulation of pGR may represent a novel therapeutic pathway for diabetic nephropathy

SA-PO108

Regulation of Renal Gluconeogenesis in Acidotic Proximal Tubule-(PT) Targeted Dual Insulin/Insulin-Like-Growth Factor (IGF) Receptor Knockout Mice

Maurice B. Fluitt,[1] Abdullah Aljaylani,[1] Swasti Tiwari,[2] Carolyn M. Ecelbarger.[1] *[1]Georgetown University, Washington, DC; [2]Sanjay Gandhi PGI, Lucknow, India.*

Background: Acidosis is associated with an increase in renal gluconeogenesis due to upregulation of ammoniagenesis, which liberates α-ketoglutarate, a substrate for gluconeogenesis. Insulin and IGF1 have been postulated to upregulate transport of glutamine into PT (precursor of ammoniagenesis), but may also be associated with decreased gluconeogenic capacity by phosphorylating forkhead box protein 01 (FOX01). Thus, net regulation of renal gluconeogenesis by insulin in the context of acidosis is uncertain.

Methods: We bred PT-select dual Insr/Igf1r knockout mice with Cre-recombinase driven by the γ-glutamyltransferase promoter. Male and female KO and WT littermates were made acidotic by consuming 280 mM NH4Cl in the drinking water for 7 days.

Results: Male KO mice demonstrated a 23% increase in fasting glucose (18-hr) with acid loading, while this increase was 2% in the WT males. In contrast, female WT mice had a mean 8% decrease and KO a 5% increase, indicating less sensitivity of females. Acid-treated male KO mice had lower blood pH and bicarbonate as compared to same sex WT (significant interaction). Female mice did not show this genotype dichotomy. Ex vivo capacity to synthesize glucose (with unlimited substrate) was measured in proximal tubule suspensions harvested from acid- and control- treated WT and KO mice. PT harvested from control KO males produced 56% more glucose then WT males. In agreement, the ratio of phosphorylated (Serine 256) FOX01 to total FOX01 was 37% lower in PT from the KO versus WT male mice. Acid loading increased glucose producing capacity of PT only in the WT males, while reducing the pFOX01/FOX01 ratio in all groups. In agreement, in males, acidosis significantly increased renal protein abundances of two rate-limiting enzymes in gluconeogenesis, i.e., fructose bisphosphatase-1 (FBP1) and phosphoenolpyruvate carboxykinase (PEPCK). The increase in FBP1 was 2-fold higher in the KO mice; however, KO mice also had significantly lower cortical expression of glucose-6-phosphatase (terminal gluconeogenic enzyme).

Conclusions: Chronic acidosis increases the capacity of the PT to produce glucose. Insulin and/or IGF1 appear to be involved in homeostatic regulation of this production via FOX01.

Anti-Proteinuric Actions of Angiotensin II Receptor Blockade in a Mouse Model of Diabetic Nephropathy

Kengo Azushima,[2,1] Susan B. Gurley,[3] Thomas M. Coffman.[2,4] *[1]Department of Medical Science and Cardiorenal Medicine, Yokohama City University Graduate School of Mediceine, Yokohama, Japan; [2]Cardivascular and Metabolic Disorders Program, Duke-NUS Medical School, Singapore, Singapore; [3]Oregon Health and Science University, Portland, OR; [4]Division of Nephrology, Department of Medicine, Duke University, and Durham VA Health Care System, Durham, NC.*

Background: The progress in the research field of Diabetic nephropathy (DN) has been disturbed by the lack of reliable animal models. We have developed a mouse model exhibiting cardinal characteristics of human DN including high-grade albuminuria, glomerulosclerosis and genetic susceptibility to kidney damage. Because responsiveness to blockade of the renin-angiotensin system (RAS) is a key feature of human DN, we examined the impact of an angiotensin II receptor blocker (ARB) in our mouse model.

Methods: We generated mice with heterozygous for the *Ins2*^{C96Y} (*Akita*) allele combined with a single-copy renin transgene (*ReninTg)*, with renin expression under control of the albumin promoter. *Akita-ReninTg* mice on a 129/SvEv inbred background, which tends to exhibit exaggerated susceptibility to kidney disease, were generated through back-crossing. In the *Acute* protocol, losartan (10mg/kg/day) was given to 16-week old 129 *Akita-ReninTg* for 10 days, whereas in the *Chronic* protocol, losartan was administered daily from 12-24 weeks of age. Urine samples were collected over a 24-hour period using metabolic cages and albumin levels were measured with immunoassay.

Results: By 24 weeks of age, 129 *Akita-ReninTg* mice develop substantial albuminuria with severe renal pathological changes including mesangial expansion, nodular glomerulosclerosis and renal interstitial inflammatory cells accumulation. In 16-week old 129 *Akita-ReninTg* mice, *Acute* ARB administration caused an abrupt and significant reduction of albuminuria from 1049±325 to 308±156 μg/day (p=0.004). In the *Chronic* protocol, baseline levels of albumin excretion were similar between treated and untreated groups (767±154 vs 905±169 μg/day). ARB treatment prevented the progressive increase of albuminuria compared to untreated controls at 18 (721±136 vs 142±27 μg/day; p=0.001) and 24 (1480±562 vs 193±42 μg/day; p=0.045) weeks of age.

Conclusions: 129 *Akita-ReninTg* mice replicate key features of human DN, including responsiveness to RAS blockade. As in humans, the anti-proteinuric actions of ARB can be seen early after initiating treatment, likely representing acute reversal of abnormal glomerular hemodynamics and/or permeability. Chronic ARB administration causes a significant reduction in albuminuria that is sustained during the entire treatment period, likely due to protection against Ang II-dependent kidney injury.

Protein O-GlcNAcylation Regulates Renal Lipolysis During Fasting and Diabetes

Sho Sugahara,[1] Shinji Kume,[1] Kosuke Yamahara,[1] Mako Yamahara,[1] Naoko Takeda,[1] Norihisa Osawa,[1] Masami Kanasaki,[1] Motoko Yanagita,[2] Shin-ichi Araki,[1] Hiroshi Maegawa.[1] *[1]Shiga University of Medical Science, Otsu, Japan; [2]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: Energy metabolism in kidney proximal tubular cells (PTCs) is unique because their ATP production largely depends on lipolysis rather than glycolysis, regardless of feeding or fasting. Furthermore, disrupted renal lipolysis is involved in the pathogenesis of tubular damage in various kidney diseases including diabetic kidney disease. Thus, elucidating detailed mechanisms of renal fatty acid metabolism should contribute to a novel therapy for kidney diseases. O-GlcNAcylation is a post-translational modification and acts an intracellular nutrient sensor. This study was designed to examine the role of O-GlcNAcylation in renal fatty acid metabolism under fasting and diabetes.

Methods: O-GlcNAc transferase (Ogt) is the sole enzyme for O-GlcNAcylation. We generated inducible PTC-specific Ogt-knockout mice (PTC-Ogt$^{y/-}$mice) by crossbreeding female Ogt$^{f/f}$mice with male tamoxifen-inducible PTC-specific Cre transgenic mice (NDRG1-CreER^{T2}mice), and analyzed their renal phenotype under fasting and high fat diet (HFD)-induced obese diabetes.

Results: PTC-Ogt$^{y/-}$mice showed no significant renal phenotype under *ad-libitum* feeding condition, but showed significant increases in urinary excretions of albumin, glucose and various ions after 48 hours fasting. Cellular apoptosis, significant intracellular lipid droplet accumulation, mitochondrial fragmentation and decreased ATP contents in renal cortex were observed in PTCs of fasted PTC-Ogt$^{y/-}$mice. Furthermore, PTC-Ogt$^{y/-}$mice developed severe tubular cell damage under HFD-induced obesity diabetic condition. Proteomic analysis revealed that PTC-Ogt$^{y/-}$mice showed significant change in lipid metabolism pathway and dramatic decrease in protein expression level of a neutral lipid esterase, Carboxilesterase-1 (CES-1), which was associated with decreased activity in Farnesoid X receptor (FXR).

Conclusions: Protein O-GlcNAcylation is essential for maintaining renal lipolysis under fasting and obesity diabetic condition through regulating FXR-CES1 axis.

SA-PO111

Elevation of NMN in the TG Mice Overexpressing Nampt in the Proximal Tubules Suppresses Albuminuria and Diabetic Tubulopathy by Maintaining Megalin Expression

Kazuhiro Hasegawa, Shu Wakino, Hiroshi Itoh. *Keio University, Tokyo, Japan.*

Background: Nicotinamide phosphoribosyltransferase (Nampt) synthesizes **nicotinamide mononculeotide (NMN)**, which is the precursor of **nicotinamide adenosine diphosphate (NAD)**. Nampt is expressed more abundantly in proximal tubules (PTs) than in other tissues. NMN injections have been shown to suppress acute kidney injury; however, the effects of renal NMN or Nampt in diabetic nephropathy remain unclear. We created kidney-specific Nampt-overexpressing transgenic (TG) mice using the promoter **sodium-phosphate cotransporter IIa (Npt2)** driven specifically in PTs for investigating them.

Methods: Wild-type littermate (WT) or TG 8-week old male mice were subjected to intraperitoneal injections of 50 mg/kg/day streptozotocin (STZ) or saline (Sal) for 5 days (WT+Sal, WT+STZ, TG+Sal, TG+STZ).

Results: After 16 weeks, **Nampt, NMN**, and **NAD** levels in WT+STZ were decreased, but were rescued in TG+STZ. Tubular Basement membrane (**TBM) thickening**, **type IV collagen deposition**, and **PT apoptosis** were significantly higher in WT+STZ, and were attenuated in TG+STZ. Our DNA microarray analyses showed the profibrotic and proapoptotic gene, **tissue inhibitor of metalloproteinases 1 (TIMP-1)**, was highly increased in WT+STZ, but suppressed in TG+STZ. Glomerular changes such as glomerular basement membrane (GBM) thickening and podocyte foot-process effacement occurred in both WT+STZ and TG+STZ. However, the albuinuria present in WT+STZ was significantly suppressed in TG+STZ. Thus, we hypothesized that TG elevates albumin reabsorption despite not affecting podocytes. Consistent with this, **albumin endocytosis** and **megalin** expression were reduced in WT+STZ, but retained in TG+STZ, whereas cubilin was not altered. In promoter assays, the decrease in Nampt/NMN/NAD repressed **Sirt6** activity, which acetylated and activated **RelA** binding to TIMP-1 promoter regions. The transfection of TIMP-1 vector in cultured PTs causes excessive collagen IV production and **Erk** phosphorylation, which reportedly reduces megalin expression and elevates PT apoptosis. These changes were totally blocked in TG mice.

Conclusions: Nampt TG/NMN/NAD potentiates Sirt6 activity, deacetylating RelA and silencing TIMP-1 transcription. This protects against TBM thickening, type IV collagen deposition, and Erk activation. Thus, Nampt appears to maintain megalin and albumin reabsorption.

SA-PO112

Dapagliflozin Reduces Glomerular Hyperfiltration and Improves Urine Parameters in db/db Mice on High Protein Diet: A 4-week Model of Diabetic Nephropathy

Francois Briand,[1] Sisse A. Nørgaard,[2] Noémie Burr,[1] Clément Costard,[1] Emmanuel Brousseau,[3] Nourdine Faresse,[1] Fredrik Wolfhagen Sand,[2] Thierry Sulpice.[1] *[1]Physiogenex SAS, Labege, France; [2]Novo Nordisk A/S, Maaloev, Denmark; [3]Physiogenex, Labege, France.*

Background: Preclinical animal models of glomerular hyperfiltration and diabetic nephropathy (DN) are needed for rapidly evaluating novel drugs targeting these complications. In this goal, obese and diabetic db/db mice are routinely used, but require several weeks to only show mild-albuminuria and early kidney disorders seen in human DN. Since high protein diet (HPD) are known to accelerate DN in human and animal models, we therefore developed a 4-week HPD fed db/db mouse model, in which the sodium glucose cotransporter 2 inhibitor dapagliflozin (DAPA) was evaluated.

Methods: 12-week old db/db male mice were placed on a HPD (60%kcal from protein) and treated with vehicle or DAPA 10mg/kg orally once daily for 4 weeks. Non-diabetic db/+ males on HPD treated with vehicle were included as negative control. Oral glucose tolerance test (OGTT), biochemical assays and glomerular filtration rate (GFR), assessed with FITC-sinistrin i.v. injection and transdermal monitors, were performed.

Results: Compared to db/+, db/db mice on HPD were strongly hyperglycemic, showed increased urine glucose excretion (UGE), higher albuminuria (+127%), and evident hyperfiltration, with a 40% higher GFR vs. db/+ ($p<0.05$ for all parameters). Compared to db/db treated with vehicle, DAPA blunted hyperglycemia in fasting state and during the OGTT (73% reduction in glucose area under the curve) and strongly increased fasting plasma ketone levels by 300% (all $p<0.001$). As expected, DAPA increased UGE by 116% ($p<0.01$ vs. vehicle) and reduced albumin/creatinine ratio by 40%, although not significantly. Compared with vehicle, DAPA reduced proteinuria and creatinine clearance by 36% ($p<0.001$) and 45% ($p<0.05$). Additionally, DAPA significantly reduced hyperfiltration with a 12% and 21% reduction in GFR at 2 and 4 weeks of treatment, respectively.

Conclusions: The present data indicate that DAPA shows significant benefits on kidney dysfunction in the 4-week HPD fed db/db mouse model. This fast model should be useful to rapidly evaluate drugs targeting diabetic nephropathy and glomerular hyperfiltration.

Unilateral Nephrectomy and Salt Loading Differentially Alter Glomerular Filtration Rate in the Hypertensive, Obese, Type 2 Diabetic SDT Fatty Rat Model of Diabetic Nephropathy

Francois Briand,[1] Fuminari Yamaguchi,[5] Yuko Katayama,[4] Tomohisa Suzuki,[3] Masami Shinohara.[2] *[1]Physiogenex SAS, Labege, France; [2]CLEA Japan, Inc., Meguro, Japan; [3]Scohia Pharma, Inc., Fujisawa, Japan; [4]SCOHIA PHARMA, Inc., Fujisawa, Japan; [5]SCOHIA PHARMA Inc., Fujisawa, Japan.*

Background: Evaluation of drugs targeting diabetic nephropathy (DN) requires diabetic animal models developing renal complications and alteration of glomerular filtration rate (GFR) in a short period of time. These models should exhibit hyperfiltration followed by a >50% GFR decline. The hypertensive, obese, Spontaneously Diabetic Torii (SDT) fatty rat develops kidney lesions and may serve as a relevant model for DN. To promote alteration of GFR, we here evaluated the effects of unilateral nephrectomy (Unx) and salt loading in SDT fatty rats.

Methods: 10-week old, male SDT fatty rats were included into 4 treatment groups (n=7/group): 1) normal water without Unx, 2) 0.3% salt water with Unx, 3) 0.6% salt water without Unx or 4) 0.8% salt water without Unx. Biochemical parameters and GFR were then followed for 13 weeks.

Results: Compared to SDT fatty rats under normal water without Unx, salt supplementation and Unx slightly attenuated the diabetic phenotype, with lower hyperglycemia (~400mg/dL vs. ~600mg/dL). However, it also resulted in a progressive induction of dyslipidemia, leading to a strong hypertriglyceridemia (~2000mg/dL vs. ~500mg/dL in rats under normal water without Unx) and hypercholesterolemia (~450mg/dL vs. ~150mg/dL) at 13 weeks. Under normal water without Unx, SDT fatty rats showed a gradual increase in hyperfiltration over 13 weeks with GFR raising from 13 +/- 2 to 22 +/- 5 mL/min/kg. This gradual increase was abolished by 0.6% salt without Unx, with stable GFR values over 13 weeks. However, 0.8% salt without Unx induced a progressive decline in GFR (36% lower at 13 weeks vs. baseline). In sharp contrast, 0.3% salt with Unx resulted in a rapid GFR decline from 2 weeks to 13 weeks (63% lower than baseline).

Conclusions: In the SDT fatty rat, Unx and salt loading have limited effect on diabetic state while they favor induction of dyslipidemia and differentially alter GFR. Depending on the experimental setting, this rat model should be helpful to evaluate the effects of drugs on hyperfiltration and GFR decline for the treatment of DN.

SA-PO114

Effect of Dual Inhibition of Dipeptidyl Peptidase IV (DPP4) and Sodium/Glucose Cotransporter (SGLT2) on Tacrolimus-Induced Diabetic Rats

Do-hyun Na. *The Catholic University of Korea, Seoul, Korea, Seoul, Republic of Korea.*

Background: Sodium/glucose co-transporter-2 inhibitor (SGLT2i) and depeptidyl peptidase IV inhibitor (DPP4i) are promising antidiabetic drug but their combined use in tacrolimus (TAC)-induced diabetes mellitus (DM) is still undetermined. We evaluated the effect of dual inhibition of dipeptidyl deptidase IV (DPP4) and sodium/glucose cotransporter (SGLT2) on TAC-induced diabetes mellitus (DM) and renal injury in an experimental rat model. DM.

Methods: DM was induced by injection of injection of TAC (1.5mg/kg, subcutaneously) for 3 weeks, then DPP4i gemigliptin (20mg/kg/day, oral gavage) and/or SGLT2i empagliflozin (10mg/kg/day, oral gavage) were given for 4 more weeks. The effect of gemigliptin and/or empagliflozin was evaluated by assessing intraperitoneal glucose tolerance test (IPGTT) and by measuring markers of oxidative stress, apoptosis. Also, Morphologic change of kidney was observed.

Results: IPGTT showed that dual inhibition of DPP4 and SGLT2 showed synergistic effect on glucose lowering compared to DPP4i alone or SGLT2i alone group. In Kidney, combination treatment group of gemigliptin and empagliflozin alleviated TAC-induced renal dysfunction and decreased albumin excretion and histopathogic injury compared with TAC group or gemigliptin or empagliflozin alone group. Increased oxidative stress and apoptotic cell death by TAC was remarkably decreased with gemigliptin or empagliflozin treatment in serum and renal tissues, and this improvement was significantly prominent in combination group compared to gemigliptin or empagliflozin alone group. TAC induced a two-fold increase in SGLT-2 expression, while combination of gemigliptin and empagliflozin decreased SGLT-2 expression and further increased urinary glucose excretion compared to the TAC group.

Conclusions: In conclusion, dual inhibition of DPP4 and SGLT2 is effective in controlling TAC-induced hyperglycemia and has protective effect on TAC-induced renal injury, this finding provides basis clinical use of dual inhibition of DPP4 and SGLT2 in renal transplant patients with TAC-induced DM.

SA-PO115

NADPH-Oxidase NOX5 Aggravates Renal Injury in Akita Mouse Model of Diabetic Nephropathy

Jay C. Jha,[1] Mark E. Cooper,[1] Chris R. Kennedy,[2] Rhian Touyz,[3] Karin Jandeleit-Dahm.[1] *[1]Monash University, Melbourne, VIC, Australia; [2]Kidney Research Centre, Ottawa, ON, Canada; [3]Glasgow University, Glasgow, United Kingdom.*

Background: Renal reactive oxygen species (ROS) play an important role in mediating kidney injury in diabetes. Increasing evidence suggests that the pro-oxidant enzyme, Nox5 plays a significant role in human diabetic nephropathy (DN). Nox5 is present in humans and rabbits but not in mice or rats. Thus, there is a paucity of information about Nox5 in conventional animal models of DN. We examined the role of Nox5 in the insulin deficient diabetic Akita mice model using human inducible transgenic mice that express Nox5 selectively in endothelial cells (VEcad+Nox5+) or in mesangial cells (SM22+Nox5+). We also examined the endogenous expression of Nox5 in a high fat fed rabbit model of kidney disease.

Methods: At week 10 mice were culled and kidneys were removed for the assessment of structural damage as well as gene and protein expression of markers of inflammation, fibrosis and oxidative stress. Protein expression of Nox5 and its localization in glomerular cells (endothelial and mesangial cells) were examined in transgenic mice by immunostaining. We also examined expression of pro-fibrotic gene in high fat fed rabbits by next generation sequencing (NGS) and RT-PCR and renal injury by histochemistry

Results: Expression of Nox5 was confirmed in glomerular endothelial and mesangial cells of transgenic mice. Diabetes induced increase in glomerulosclerosis, gene and protein expression of fibronectin and MCP-1 as well as nitrotyrosine were further increase in both diabetic Nox5 transgenic mice. Moreover, increased expression of Nox5 in high fat fed rabbits versus normal diet fed rabbits was associated with increased expression of fibronectin, CTGF, collagen IV and VCAM-1 as well as increased mesangial expansion in the kidney.

Conclusions: These findings in both transgenic mice model (endothelial and mesangial cells) suggest that Nox5 plays a significant role in mediating renal injury in diabetes.

SA-PO116

Suramin Inhibits Activation of Inflammasome and Protects Against Progression of Diabetic Kidney Disease in KK-Ay Mice

Kaori Oda,[1] Satoshi Miyamoto,[2] Ryo Kodera,[2,3] Jun Wada,[1] Kenichi Shikata.[2] *[1]Graduate School of Medicine Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, Japan; [2]Center for Innovative Clinical Medicine, Okayama University Hospital, Okayama, Japan; [3]Osafune Clinic, Setouchi, Japan.*

Background: Inflammasome is a protein complex that leads to production of IL-1β and IL-18 through activation of caspase-1, and danger-associated molecular patterns (DAMPs) trigger inflammasome activation via P2 receptors (P2Rs). We have shown that both serum and urinary IL-18 levels are elevated in patients with diabetic kidney disease (DKD). Mass spectrometry imaging has revealed that ATP, one of the major DAMPs, is increased in the glomeruli of diabetic mice. The aim of this study was to determine if suramin, a non-selective P2Rs antagonist, protects against DKD in KK-Ay mice.

Methods: Four weeks-aged male C57BL/6 (B) mice and diabetic KK-Ay (K) mice (KK-A^y/TaJcl strain) were randomly assigned to four groups: B+vehicle (BV), B+suramin, K+vehicle (KV) and K+suramin (KS), n=6-12/group. Vehicle or suramin (1 mg/kgBW) were injected intraperitoneally once every two weeks over an 8-week period. Glomerular size and mesangial matrix area were assessed by morphometric analysis. Expression of inflammasome-related genes and proteins were quantified by quantitative PCR and western blot. The localization of P2Rs were examined by double staining.

Results: Urinary albumin/creatinine ratio was elevated in KV (280.0 ± 29.3 mg/gCr, p<0.001) vs. BV (1.7 ± 0.3 mg/gCr), and significantly reduced in KS (160.6 ± 27.3 mg/gCr, p<0.01), whereas there were no significant differences in body weight or HbA1c between both diabetic groups. Glomerular size and glomerular mesangial matrix area were significantly increased in KV and reduced to 78% (p<0.001) and 66% (p<0.001) of KV levels by suramin treatment, respectively. Importantly, mRNA expression of P2X4R and P2X7R in both renal cortex and isolated glomeruli were significantly suppressed in KS compared with KV (p<0.05). P2X4R and P2X7R were mainly distributed in mesangial cells in the glomerulus of KK-Ay mice. Protein expression of NLRP3, a key component of inflammasome, was increased in KV vs. BV, and significantly suppressed in KS (p<0.05). The increase in IL-18 mRNA expression in KV was significantly suppressed in KS (p<0.01), and a similar trend was observed in IL-18 protein level in renal cortex.

Conclusions: We found that suramin can improve features of DKD with type 2 diabetes and may be renoprotective via suppression of inflammasome activation. Suramin may be beneficial for the treatment of DKD.

Marked Improvement of Renal Lesions by Treatment with Mimetic Peptide of SOCS1 in the Diabetic Model BTBR ob/ob

Lucas Opazo-Ríos,[1] Yenniffer Sanchez,[1] Raúl R. Rodrigues díez,[2] Daniel Carpio,[1] Carolina Lavoz,[1] Paola Krall,[1] Jesus Egido,[2] Carmen Gomez-Guerrero,[2] Maria A. Droguett,[1] Sergio A. Mezzano.[1] Unidad de Nefrología, Facultad de Medicina, UACH. *[1]Unidad de Nefrología, Universidad Austral de Chile, Valdivia, Chile; [2]Renal and Vascular Research Lab, IIS-Fundación Jiménez Díaz-Autónoma University of Madrid, CIBERDEM, Madrid, Spain.*

Background: Type 2 Diabetes (T2D) is a global public health problem, with Diabetic Nephropathy (DN) being the main cause of chronic renal disease worldwide. Although current treatments delay the evolution of the disease, it is necessary to establish new therapeutic strategies in early stages of DN, in order to promote renoprotection. The JAK/STAT signaling pathway participates in the diabetic renal disease, through the induction of genes involved in inflammation and oxidative stress. Among the different mechanisms for JAK/STAT control, the family of SOCS proteins has been proposed as new molecular targets for the treatment of DN. Our aim was to evaluate the effect of SOCS1 mimetic peptide (MiS1) on the development of early renal damage associated with T2D.

Methods: Four groups of BTBR ob/ob mice (6 weeks old) were treated 3 days/week for 7 weeks with active peptide (2 and 4 μg), mutant peptide (4 μg) or vehicle. At the end of the study, animals were sacrificed to obtain blood, urine and kidney tissue samples for further analysis.

Results: The treatment of diabetic mice with active MiS1 significantly reduced the ACR ratio and renal weight, improves the glomerular and tubulointerstitial damage and increased podocyte numbers. Treated mice exhibited a decrease in the renal inflammatory infiltrate (F4/80 and CD3), lower gene expression of proinflammatory cytokines (Tnfα and Il-12) and chemokines (Ccl2 and Ccl5) and reduced phosphorylation of STAT1 and STAT3. No changes were observed in glycemia and body weight. Concomitantly, peptide administration diminished the renal levels of superoxide anion and 8-hydroxy-2'-deoxyguanosine (marker of DNA oxidative damage) and altered the expression of the Nrf2/-heme oxygenase-1 pathway and redox balance enzymes (Nox4, Sod1 and Catalase). Finally, we observed a reduction of lipid peroxidation (4-hydroxy-2-hexenal) and gene expression of scavenger receptors (SR-B/CD36 and SR-A/CD204).

Conclusions: In conclusion, the MiS1 peptide improves the renal damage and is efective in modulating the inflammatory milieu and oxidative stress in an early renal damage in the BTBR ob/ob model. *Fondecyt Project N° 1160465. Overexpression of Sirtuin 3 in Obesity-Induced CKD Mice Model

Florian Juszczak,[2,1] Inès Jadot,[1] Julie Storder,[3] Olivia Botton,[1] Anne-Emilie Decleves,[2] Thierry Arnould,[1] Nathalie Caron.[1] *[1]University of Namur, Namur, Belgium; [2]Laboratory of Molecular Biology, University of Mons, Belgium, NIMY (MONS), Belgium; [3]University of Namur, Namur Research Institute for Life Sciences, Namur, Belgium.*

Background: Obesity and metabolic syndrome are independent risk factors for chronic kidney disease (CKD). Obesity-induced CKD is characterized by a progressive decline of the renal function and the development of tubulointerstitial fibrosis. Recently, studies showing ectopic lipid depositions in proximal tubular cells have emerged along with mitochondria dysfunction, suggesting a lipotoxicity in these cells. However, molecular mechanisms underlying these processes are still unclear. Our study will focus on the involvement of sirtuin 3 (SIRT3), a NAD^+-dependent deacetylase, in the ectopic lipid accumulation in kidney cells leading to CKD. SIRT3, mainly expressed in mitochondria, is known to play a critical role in metabolic responses and mitochondria functions.

Methods: Male C57BL/6 WT and SIRT3 transgenic mice were assigned either to a low fat diet (LFD) or a high fat diet (HFD) for 20 weeks. At the end of the protocol, urine, blood and kidney samples were collected. Kidney function was investigated and morphological analyses were performed.

Results: Wild-Type HFD mice presented renal hypertrophy and impaired renal function as attested by an increased albuminuria and proteinuria. Evidence of proximal tubule injury was observed in these mice with the presence of enlarged lipid vacuoles. In addition, these alterations were associated with the reduction of AMPK activity and the decrease in the relative mRNA and protein expression of SIRT3. Interestingly, renal hypertrophy and impaired renal function were significantly improved in SIRT3 transgenic mice fed a HFD. This was also associated with a reduced number and size of ectopic lipid vacuoles in proximal tubular cells.

Conclusions: These findings reveal that SIRT3 plays a critical role in ectopic lipid accumulation in proximal tubular cells and impairment of renal function. Systemic overexpression of SIRT3 normalizes the renal alterations observed in HFD WT mice and may thus be a potential strategy to improve altered lipid metabolism in HFD-induced CKD.

VHL Deletion in Renal Proximal Tubules of Mice Ameliorates Hallmarks of Diabetic Nephropathy

Martina Böttner,[1] Eileen Dahlke,[3] Franziska Theilig.[2] *[1]University of Kiel, Kiel, Germany; [2]Christian-Albrechts University zu Kiel, Kiel, Germany; [3]CAU Kiel, Kiel, Germany.*

Background: Diabetic nephropathy is the leading cause of end-stage renal disease and frequently affects patients with type 2 diabetes mellitus. Glomerular hyperfiltration and phenotypic changes in proximal tubule epithelial cells (PTECs) are the initial signs of diabetic nephropathy. Systemic activation of hypoxia-inducible factors (HIFs) was shown to prevent diabetes-induced alterations in kidney oxygen metabolism.

Methods: To analyze in detail whether renal tubular HIF activation is sufficient to prevent functional and morphological alteration of diabetic nephropathy, $SGLT2^{Cre}/VHL^{flox}$ mice were generated and diabetes mellitus was induced by streptozotocin application.

Results: FITC-inulin clearance analysis revealed a strong increase in diabetic VHL^{flox} control mice which was abrogated in diabetic $SGLT2^{Cre}/VHL^{flox}$ mice showing similar values as the non-diabetic control mice. Blood glucose concentration and urinary volume excretion were significantly increased in diabetic mice without significant differences between genotypes. However, osmotically-induced hyponatremia was only observed in diabetic VHL^{flox} mice whereas diabetic $SGLT2^{Cre}/VHL^{flox}$ had values similar to non-diabetic controls. Urinary electrolyte, glucose and phosphate excretion was increased in diabetic mice and more pronounced in diabetic $SGLT2^{Cre}/VHL^{flox}$ compared to diabetic VHL^{flox} mice.

Conclusions: In summary, our study reveals that induction of proximal tubular HIF are able to prevent diabetes induced glomerular hyperfiltration. Additionally, osmotically-induced hyponatremia was also prevented upon HIF activation most probably through reduced proximal tubular glucose reabsorption and thereby leading to its increased urinary excretion.

The Iron-Klotho-VDR Axis Is a Major Determinant of Proximal Convoluted Tubule Injury in Haptoglobin 2-2 Genotype Diabetic Nephropathy Patients and mice

Farid M. Nakhoul,[1,2] Evgeny Farber,[5] Nakhoul Nakhoul,[6] Inbal Dahan.[3,4] *[1]Nephrology %Hypertension, Baruch padeh Poriya Medical center, Tiberias, Israel; [2]Azrieli faculty of Medicine Bar Ilan University, Ramat gan, Israel; [3]Baruch Padeh Poriya Med Ctr, Tiberias, Israel; [4]Diabetes & Metabolism lab, Baruch padeh Poriya Medical center, Tiberias, Israel; [5]Nephrology & Hypertension, Baruch Padeh Poriya Medical Center, Tiberias, Israel; [6]Diabetic and metabolism Lab, Baruch Padeh Poriya Medical center, Lower Galille, Israel.*

Background: The haptoglobin (Hp) genotype (1-1, 2-2) is a major determinant of DN progression in DM patients. Hp 2-2 DM patients & mice have increased iron deposits in the PCT, leading to renal injury. The mechanism of the PCT injury in DN remains elusive. In the kidney, 1,25(OH)2D3 suppresses the inflammatory response to renal tubular injury and requires normal renal expression of the α-klotho protein. Increased renal iron deposits in the PCT of Hp 2-2 DN may affects α-klotho-Vitamin D receptor axis and exacerbates PCT injury

Methods: Seven-week-old male mice were made diabetic by IP injection of 50 mg/kg of STZ per day for 5 consecutive days. Mice were sacrificed after a DM duration of 2 months. DM **mice with Hp 2-2 and Hp1-1, DM and non-DM CKD patients were included. Kidney biopsies from mice and patients were subject to immunohistochemistry (IHC) and PAS staining. Mice kidney lysates were subjected to western blot analysis.**

Results: A marked accumulation of iron deposits in the renal PCT of Hp 2-2 DM mice compared to Hp 1-1 DM or with Hp 2-2 non-DM mice. The expression of renal α-klotho was reduced significantly in the PCT of DN mice and patients with the Hp 2-2 genotype in mice and humans compared to DM Hp 1-1 genotype in mice and CKD humans Western blot analysis of the mice renal lysates show that VDR renal expression was decreased significantly in the PCT of DN Hp 2-2 sections compared to DM Hp 1-1 genotype. The renal expression of 1-α-hydroxylase was increased significantly in DN mice with Hp 2-2 genotype compared with DM Hp 1-1 genotype

Conclusions: The Iron-Klotho-VDR axis is a key player in themechanism of iron-mediated PCT injury in DN mice and patients with Hp 2-2 genotype Increased iron deposits in the PCT of Hp 2-2 genotype can lead to reduced renal expression of α-klotho and VDR protein level and PCT injury. Targeting the iron-klotho-Vit. D axis in DM Hp 2-2 patients may explore new ideas on pathog. and TX of early DN

Overexpression of Hedgehog Interacting Protein in Renal Proximal Tubule Promotes Renal Tubulointerstitial Fibrosis in a Type I Diabetes Model

Shiao-Ying Chang,[1] Min-Chun Liao,[1] Xin-Ping Zhao,[1] Chao-Sheng Lo,[1] Isabelle Chenier,[1] Julie R. Ingelfinger,[2] John S. Chan,[1] Shao-Ling Zhang.[1] *[1]CRCHUM, Universite de Montreal, Montreal, QC, Canada; [2]The New England Journal of Medicine, Boston, MA.*

Background: We previously reported (*Sci. Report 2018*) that renal hedgehog interacting protein (*Hhip*) gene expression is highly elevated in the kidneys of diabetic animal models and promotes the development of diabetic nephropathy. Since the molecular mechanism(s) of action in renal proximal tubular cells (RPTCs) is incompletely known, we examined the action of Hhip and its underlying mechanisms under diabetic conditions in RPTCs.

Methods: At 11 weeks of age male wild type (WT, C57BL6) and Hhip-transgenic (Tg) mice that specifically overexpressed Hhip in their RPTCs had diabetes induced with streptozotocin (STZ) (i.p., 50 mg/kg/day) for five consecutive days. Mice were euthanized 4 weeks after the STZ injection. Physiological parameters, kidney function (urinary albumin/creatinine ratio (ACR) and glomerular filtration rate (GFR)), renal morphology and molecular analysis of genes expression in renal proximal tubules were carried out. For *in vitro* studies, a rat *immortalized RPTCs cell line (IRPTCs) was used.*

Results: Non-diabetic Hhip-Tg mice were phenotypically indistinguishable from WT animals but had higher mRNA levels of fibrotic genes (*TGFβ1, α-SMA*) in their RPTCs. As compared to diabetic WT animals, diabetic Hhip-Tg mice exhibited pronounced tubulointerstitial fibrosis -- 'tubulopathy' features-- and increased renal heparanase (HPSE) [HPSE is a key player in renal fibrosis by mediating TGFβ1- related epithelial-mesenchymal transition (EMT) in tubular epithelial cells]. *In vitro*, recombinant Hhip (rHhip) dose-dependently stimulated HPSE expression and increased rat *TGFβ1* promoter activity (pGL4.20/TGFβ1 (N-1016/+143)) in IRPTCs. Transient transfection of Hhip cDNA enhanced the expression of HPSE vs. control plasmid in IRPTCs. Finally, Hhip siRNA attenuated high glucose-stimulation of HPSE expression and/or TGFβ1- EMT signaling and ameliorated tubular fibrosis and apoptosis.

Conclusions: Overexpression of Hhip in RPTCs, which aggravates diabetes-related renal tubulointerstitial fibrosis, is mediated, at least in part, via elevated HPSE-TGFβ1-EMT signaling.

Angiotensin-Neprilysin Inhibition Protects Glomerular Function and Structure and Lowers TRPC6 in Diabetic Hypertensive Rats

Estrellita Uijl,[1] Daan C. 't Hart,[2] Lodi C. Roksnoer,[3] Marian Clahsen - van Groningen,[1] Robert Zietse,[4] Johan Van der vlag,[5] Tom Nijenhuis,[2] Jaap A. Joles,[6] Ewout J. Hoorn,[4] Alexander H. Danser.[4] *[1]Erasmus MC, Rotterdam, Netherlands; [2]Radboud university medical center, Nijmegen, Netherlands; [3]Maasstad ziekenhuis, Rotterdam, Netherlands; [4]Erasmus Medical Center, Rotterdam, Netherlands; [5]Radboud University Nijmegen Medical Centre; Dept of Nephrology, Nijmegen, Netherlands; [6]University Medical Center Utrecht, Utrecht, Netherlands.*

Background: Dual blockade with Angiotensin Receptor/Neprilysin Inhibition (ARNI) reduces glomerulosclerosis better than single AR blockade (ARB) in diabetic, hypertensive rats, but the renoprotective mechanisms remain unknown. Here, we hypothesized that this is mediated by superior blood pressure regulation, improved renal hemodynamics, protection of podocyte integrity and/or suppression of renal inflammation.

Methods: To address this, TGR(mREN2)27 rats (a model of angiotensin II-dependent hypertension) were made diabetic for 12 weeks and treated with vehicle (n=10), valsartan (n=7) or sacubitril/valsartan (ARNI; n=8) for the final 3 weeks. Mean arterial pressure (MAP) was measured via radiotelemetry.

Results: Sacubitril/valsartan lowered MAP by 50±4 mmHg and valsartan by 43±4 mmHg (P=0.3). Sacubitril/valsartan resulted in better glycemic control and lower heart weight compared to vehicle and higher urinary atrial natriuretic peptide vs. valsartan (P<0.05 for all). Histologically, sacubitril/valsartan resulted in markedly lower glomerulosclerosis scores than both valsartan and vehicle (P<0.05). Despite higher effective renal plasma flow and glomerular filtration rates, sacubitril/valsartan did not improve filtration fraction. Analysis of the renal cortex for protein abundance of the transient receptor potential cation channel C6 (TRPC6) showed ~50% reduction after sacubitril/valsartan (P=0.06 vs. vehicle). Kidney immune cell infiltration did not differ between groups.

Conclusions: In conclusion, ARNI offers drug-class specific renoprotection in a pre-clinical model of diabetes and hypertension. Renoprotection is unrelated to renal hemodynamics or inflammation but may be related to the protective effects of natriuretic peptides and/or improved glycaemia on podocyte integrity, possibly via attenuation of Ca^{2+} influx through TRPC6 channels.

SA-PO123

Angiopoietin-Like Protein 2 Promotes the Progression of Diabetic Kidney Disease

Toshihisa Ishii, Fumihiko Furuya, Kenichiro Kitamura. Third Department of Internal Medicine, University of Yamanashi, JAPAN *University of Yamanashi, 1110 Shimokato, Chuo,Yamanashi, Japan.*

Background: Angiopoietin-like protein 2 (ANGPTL2) is a circulating, pro-inflammatory protein. To examine the role of ANGPTL2 in the pathogenesis of diabetic kidney disease (DKD), we studied the epigenetic regulation of *angptl2* expression in diabetes patients.

Methods: We determined the relationship between serum ANGPTL2 levels and the progression of DKD in cross-sectional (220 patients) and cohort (145 patients, 7-year follow-up) studies. In addition, we investigated the effect of DNA methylation on *angptl2* expression and also studied the direct effect of ANGPTL2 on the podocyte function.The main outcome is the progression of DKD.

Results: Multivariate logistic regression analyses revealed that the baseline level of serum ANGPTL2 was an independent risk factor for the progression of DKD during follow-up periods. We found that DNA methylation levels of ANGPTL2 promoter in circulating monocytes were correlated with the serum ANGPTL2 levels in diabetes patients. Furthermore, *in vitro*, ANGPTL2 directly increased albumin permeability of the cultured podocyte through the translocation of zona occludens-1 from the membrane to the cytosol via the activation of focal adhesion kinase.

Conclusions: ANGPTL2 could be a strong mediator of DKD and serves as a good predictive biomarker for its progression.

SA-PO124

A1AR Alleviates Tubulo-Interstitial Fibrosis by Inhibiting Peritubular Capillary Loss in Diabetic Nephropathy

Dongli Tian, Xiaoxiao Shi, Xiaoyan Peng, Ying Ma, Peng Xia, Yubing Wen, Limeng Chen. *Department of Nephrology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China.*

Background: We previously observed A1 adenosine receptor (A1AR) had a protective role in the progression of diabetic nephropathy. But the mechanism was not clear. The disintegration of interstitial pericytes may cause peritubular capillary(PTC) loss and interstitial fibrosis. In this study, we used A1AR deficient diabetic mice to prove whether A1AR plays a role in the pericyte detachment mediated PTC loss and in the progress of renal interstitial fibrosis.

Methods: Eight week-old male C57BL/6J $A1AR^{-/-}$ and WT mice were given two consecutive days' intraperitoneal injection streptozotocin to establish type 1 diabetic nephropathy mice. At 4w and 16w for modeling, mice were sacrificed to collect blood, urine and kidney samples for intensive detection.

Results: We successfully established streptozotocin induced type 1 diabetic nephropathy model in WT and A1AR deficient mice. At 4 weeks, albuminuria and mild renal pathological leisure were observed in WT diabetic mice, with up-regulation of A1AR protein expression *(1.3times, P=0.042)*. At 16weeks, more serious albuminuria and renal pathological leisure were observed in WT diabetic mice than at 4weeks, along with pericyte detachment induced platelet-derived growth factor receptor (PDGFR) activation(*1.3times, P=0.023*) and peritubular capillary injury(CD34 staining). While in $A1AR^{-/-}$ diabetic mice, severer renal tubular interstitial fibrosis and increased pre-clollagen I expression(*1.8times, P<0.001*) were observed than in WT diabetic mice, along with activation of inflammation, including increased inflammasome nod -like receptor protein 3 (NLRP3, 2.0 times, P=0.006), and it's downstream proinflammatory cytokine IL-1β. Meanwhile more increased protein expression of PDGFR (*1.4times, P=0.008*) and PTC lost (*1.3times, P=0.016*) were detected by immunohistochemistry and western-blot.

Conclusions: A1AR plays a protective role in the PDGFR-mediated peritubular capillary loss to alleviate renal tubular interstitial fibrosis in type 1 diabetic nephropathy.

SA-PO125

High Protein Diet and Potassium Depletion Exacerbate Ammonia Synthesis and Renal Hypertrophy in Rats with Type I Diabetes

Hassane Amlal, Sihame Amlal, Perwez Alam. *University of Cincinnati, Cincinnati, OH.*

Background: We have previously reported that the early onset of hyperglycemia stimulates ammoniagenesis, which contributes to the development of early renal hypertrophy in both type 1 (T1) and type 2 diabetes mellitus (DM) (ASN abstarct, 2017). In these studies, we examined whether other ammoniagenic conditions such as K^+ depletion and high protein (HP) diet worsen renal hypertrophy in rat with T1 DM.

Methods: Male rats were housed in metabolic cages with free access to paired control diet and water and subjected to vehicle or streptozotocin (STZ)-induced DM. After 1 week, diabetic rats were divided into 3 groups: one group was switched to a K^+-free (KD) diet (DM+KD), another group was switched to a HP diet (DM+HP) and the 3rd group remained on normal diet for another week (DM). Vehicle-treated rats were fed control diet (control), K^+-free or HP diets for 1 week. On the last day, 24 hour urine was collected and assayed for NH_4^+ excretion. The animals were sacrificed, kidneys were removed, weighed and cortex was isolated. The protein abundance of ammoniagenic enzymes (glutaminase or GA and glutamate dehydrogenase or GDH) and glutamine transporter SN1 in the cortex was examined by immunoblotting.

Results: The results showed that NH_4^+ excretion and kidney mass (kidney weight/BW) were significantly increased in DM, KD and HP diet vs. control with a further increase in DM+KD and DM+HP diet vs. DM alone. Immunoblotting studies showed a significant increase in the protein abundance of GA, GDH and SN1 in KD and in HP diet, respectively, vs. control. Interestingly, the protein abundance of GA, GDH and SN1 was unchanged in DM vs. control. The results further showed a significant upregulation of GA (4-fold), GDH (2.5-fold) and SN1 (8-fold) in DM+KD vs. DM alone. In DM+HP group, GA (138%) and GDH (158%) were upregulated, but SN1 remained unchanged vs. DM alone.

Conclusions: 1- In all three conditions (DM, KD and HP diet), the stimulation of ammoniagenesis correlates with the development of renal hypertrophy. 2- Diabetic animals exhibited a further increase (additive effect) in ammonia production and renal mass when subjected to potassium depletion or high protein diet, indicating that these conditions activate different and synergistic signaling mechanism(s). 3- KD and HP diet are risk factors for rapid progression of kidney disease in diabetes mellitus.

The β2-Adrenergic Receptor Agonist Formoterol Improves Renal Function and Decreases Fibrotic and Mitochondrial Fusion/Fission Proteins in a Mouse Model of Diabetic Nephropathy

Kristan H. Cleveland, Robert B. Cameron, Frank C. Brosius, Rick G. Schnellmann. *University of Arizona, Tucson, AZ.*

Background: Diabetic nephropathy (DN) is a significant cause of chronic kidney disease and accounts for 50% of all end-stage renal disease. Current therapies for DN, such as glycemic and blood pressure control and renin-angiotensin system blockade, only slow the progression of DN. Therefore, we examined the effect of formoterol, a β_2-adrenergic receptor agonist previously shown to induce mitochondrial biogenesis and promote recovery from acute kidney injury, on renal function and fibrotic and mitochondrial proteins in db/db mice, a validated mouse model of DN.

Methods: Female diabetic db/db and non-diabetic db/m (control) mice 9 weeks of age were treated with formoterol (0.3 mg/kg, i.p.) or saline daily for three weeks. Mice were placed in metabolic cages weekly for 18 hr and urine collected. Body weight and serum glucose were measured weekly and renal function was measured by serum creatinine levels. Kidneys were harvested after three weeks and changes in expression of mitochondrial and fibrotic proteins were measured using immunoblot analysis.

Results: At 12 weeks of age, formoterol decreased serum glucose and creatinine in diabetic mice compared to vehicle treated mice without altering body weight. Mitochondrial fission protein phospho-Drp1, and fibrotic proteins TGF-β1, phospho-SMAD3 and α-SMA were increased in diabetic mouse kidneys and were restored to control levels with formoterol treatment. Additionally, mitochondrial fusion proteins Mfn1 and Mfn2 were decreased in diabetic mouse kidneys and increased to control levels with formoterol treatment. Complete DN phenotyping is ongoing.

Conclusions: Formoterol treatment in a DN model resulted in improved serum creatinine, decreased kidney profibrotic protein levels and restored mitochondrial fusion/fission protein levels in a DN model. These results suggest that formoterol could be a potential therapy for DN.

SA-PO127

RIP1 and RIP3 Inhibition Ameliorate Albuminuria and Renal Tubular Injury in Diabetic Nephropathy

Xi Tang,[1] Lingzhi Li,[1] Liang Ma,[1] Ping Fu.[2] *[1]West China Hospital, Sichuan University, Chengdu, China; [2]West China Hospital of Sichuan University, Chengdu, China.*

Background: Hyperglycemia is a key factor in the development of diabetic nephropathy, which is characterized by renal tubular inflammation, apoptosis and interstitial fibrosis. Receptor interaction protein 1 (RIP1) and 3 (RIP3) plays important role in necroptosis, apoptosis, autophage and inflammation. The present study was aimed to confirm the hypothesis that RIP3 mediated high glucose-mediated renal tubular cells and that inhibition of RIP3 confer protection against this injury in type 2 diabetes.

Methods: 10-week diabetic db/db mice were administrated with selective RIP1 inhibitor, necrostatin-1 (1.65 mg/kg.d, ip), or RIP3 inhibitor, GSK2399872A (1.9mmol/kg.d, ip), or an equal volume of PBS, or ramipril (3 mg/kg.d, po) for a total of 8 weeks. Non-diabetic db/m mice were used as control.

Results: In db/db mice, renal tubular RIP1 and RIP3 expression was significantly stonger than db/m mice. Treatment of necrostatin-1 or GSK2399872A ameliorate albuminuria, reducing the expression of TGF-β, collagen I, fibronectin, α-SMA, and caspase 3 in diabetic kidney. The albuminuria lowering effects of GSK2399872A (820.08±98.52 mg/g) is better than that of necrostatin-1 (1058.7704±102.35 mg/g) and ramipril (1800.66±15.68 mg/g).

Conclusions: Our findings suggest a pathogenic role of overexpressed RIP1 and RIP3 in diabetic nephropathy. Inhibition of Rip1 and Rip3 ameliorates albuminuria, renal tubular apoptosis and fibrosis in type 2 diabetes.

SA-PO128

Empagliflozin Ameliorates Diabetic Nephropathy in BTBR ob/ob Mice

Kelly L. Hudkins,[2] Xianwu Li,[2] Charles E. Alpers.[2,1] Alpers Lab *[1]University of Washington Medical Center, Seattle, WA; [2]University of Washington, Seattle, WA.*

Background: The SGLT2 inhibitor empagliflozin has demonstrated success in regulating elevated blood sugars in diabetic patients via enhanced glucose excretion in the urine, and has been successful in ameliorating complications of type II diabetes including cardiovascular disease and nephropathy. We sought to test whether treatment with empagliflozin (EMPA) with and without concurrent losartan (LOS) treatment would ameliorate pathology, proteinuria and restore podocyte number in the BTBR *ob/ob* model of diabetic nephropathy. The latter may be a relevant mechanism that contributes to the observed benefits seen in type II diabetic patients treated with this drug.

Methods: At 18 weeks of age BTBR *ob/ob* and BTBR WT female mice (n=12 each group), proven to be diabetic by elevated blood glucose levels, were fed chow formulated with 300 mg/kg EMPA with and without concurrent LOS treatment (EMPA/LOS), normal chow or were given leptin (LEP) vis osmotic minipump. They were treated for 6 weeks. At the end of the experiment, at 24 weeks of age, the mice were placed into a metabolic chamber for 6 hours to obtain a timed urine and a fasting blood glucose level was recorded. The mice were then euthanized, blood collected via cardiac puncture and organs harvested for study.

Results: Treatment with LEP, EMPA and EMPA/LOS all resulted in a significant reduction of blood glucose. Only treatment with LEP resulted in weight loss. EMPA and EMPA/LOS treatment did not affect proteinuria in individual BTBR *ob/ob* mice while LEP replacement resulted in a significant drop in proteinuria in individual BTBR *ob/ob* mice. Group averages of albumin creatinine ratios (ACR) and albumin excretion extrapolated to 24 hour urines did drop significantly in all treatment groups. Additionally, all treatment arms resulted in a significant reduction of mesangial matrix accumulation and prevented glomerular hypertrophy. Analysis of podocyte number is pending.

Conclusions: From these studies, we conclude that EMPA and EMPA/LOS is nearly as effective as LEP replacement in ameliorating some of the pathology and clinical manifestations of diabetic nephropathy in the leptin deficient BTBR *ob/ob* mouse. Further analysis will be done to determine whether podocyte number is restored by these treatments, which may be a contributing factor to the improvement seen in human diabetic patients being treated with SGLT2 inhibitors.

Low Doses of GDT-01 Improve Diabetic Nephropathy and Preserve GFR in ZSF1 Rats over 7 Months by Improving In Vivo Sialylation

Sumant S. Chugh,[1] Joubert B. Kharlyngdoh,[1] Maria Del Nogal Avila,[1] Ranjan Das,[1] Hector Donoro blazquez,[1] Eduardo Molina-Jijon,[1] Lionel C. Clement,[1] Camille E. Mace,[1] Carmen Avila-Casado.[2] Glomerular Disease Therapeutics Laboratory *[1]Rush University Medical Center, Chicago, IL; [2]University Health Network, University of Toronto, Toronto, ON, Canada.*

Background: Studies on rat diabetic nephropathy using the previously published sialic acid precursor ManNAc (Clement LC et al Nature Medicine Jan 2011) worsen hyperglycaemia in ZDF rats, which is harmful in the long term. We conducted a 7 month study to improve in vivo sialylation in the glomerulus using the compound GDT-01 with the goal of studying its effect on CKD and hyperglycaemia in rat diabetic nephropathy.

Methods: We treated 5 month old male ZSF1 rats (n = 6 rats / group) with taps water or GDT-01 in tap water over a period of 7 months, and measured proteinuria, BUN, creatinine, blood glucose, other blood parameters, and assessed renal histological changes on the termination of the study.

Results: A declining dose regimen for GDT-01 was used, and the actual dose delivered (mg / Kg; mean ± SE) over 3 separate periods was as follows: Period A, Days 0 to 95, 136.8 ± 11.8; Period B, Days 96 to 122, 21.5 ± 5; Period 3, Days 123 to 222, 3.7 ± 0.2. Proteinuria was consistently lower in the treated group in Period C (10/14 readings, P<0.05), occasionally in Period B (1/4 readings) and rarely lower in Period A (2/14 readings). Blood glucose levels were similar between the GDT-01 and water groups. BUN and creatinine were consistently lower in the treatment group in Period C (BUN, 7/14, P < 0.05 to 0.01; creatinine, 5/14, P<0.05), and only occasionally in Periods A and B. Detailed renal histology and sialylation analysis are ongoing.

Conclusions: Low oral doses of the sialylation inducing compound GDT-01 improve GFR and proteinuria over prolonged periods of time without worsening hyperglycaemia in ZSF1 diabetic rats.

H+-ATPase Blockade Reduced Renal Gluconeogenesis and Mitochondria Metabolism and Lowered Plasma Glucose in a Type 2 Diabetic Rat Model

Mayu Uchida, Akihiro Tojo, Yoshiki Murayama, Masahito Furuichi, Hiroshi Satonaka, Toshihiko Ishimitsu. *Department of Cardiology & Nephrology, Dokkyo Medical University, Mibu, Japan.*

Background: Vacuolar H^+-adenosine triphosphatase (ATPase) plays important roles in urinary acid excretion, vesicular acidification to activate enzymes, endocytosis, and the membrane recycling of transporters in the kidney. We have recently reported blockade of H^+-ATPase reduced plasma glucose in type 1 diabetic rat by reducing renal gluconeogenesis. Using proteome analysis of the kidney of type 2 diabetic rats, we investigated effect of bafilomycin B1, a specific blocker of H^+-ATPase, on renal glucose metabolism.

Methods: Male Spontaneously Diabetic Torii (SDT) rats were treated with Bafilomycin B1(BFM)100nmol/kg BW for 7 days. After 24-hour starvation in the metabolic cage, the kidneys were analyzed using iTRAQ protein expression and relative quantification analysis.

Results: Renal expression and activity of H^+-ATPase were increased with elevated urinary ammonium excretion. In the diabetic kidney, the enzymes in gluconeogenesis, TCA cycle, mitochondria respiratory chain, and ammoniagenesis were relatively increased compared with those in the kidney of control rat. The BFM reduced urinary ammonium excretion and decreased the plasma glucose level in diabetic rats (298±38 vs. 171±27 mg/dL, p<0.02, n=6). The protein expression of enzymes in mitochondria respiratory chain, TCA cycle, and gluconeogenesis were decreased by BFM treatment.

Conclusions: H^+-ATPase inhibitor, bafilomycin, lowered plasma glucose after 24-hour starvation by suppression of renal gluconeogenesis and mitochondria metabolism. H^+-ATPase could be a new therapeutic target for diabetes mellitus.

Renal Phospholipid Accumulation in High-Fat Diet Fed Streptozotocin Induced Diabetic Mice Depends on Ketohexokinase

Tomohito Doke,[1] Takuji Ishimoto,[1] Takahiro Hayasaki,[1] Richard J. Johnson,[2] Shoichi Maruyama.[1] *[1]Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]University of Colorado Denver, Aurora, CO.*

Background: Excessive fat intake contributes to the development of obesity and metabolic syndrome, which is associated with renal dysfunction in CKD patients including diabetic kidney disease (DKD). It has been reported that renal lipid metabolism may play a direct role in DKD progression. However, the detailed mechanisms of lipid metabolism in renal tubular cells of DKD remain unclear. Recently, we have reported that western diet induced steatohepatitis was dependent on ketohexokinase, a primary enzyme of fructose. Fructose is produced endogenously in DKD through the activation of polyol pathway. In this study, we investigated that the effects of fructose metabolism on lipid accumulation in DKD.

Methods: In male, C57BL6/J background wild type (WT) mice and ketohexokinase-knockout (KHK-KO) mice, which lack both KHK isoforms; KHK-A and C, diabetes was induced by streptozotocin (50mg/kg 5 consecutive days, intraperitoneal injection). They were fed 45% high fat diet (HFD) for 24 weeks, and then analyzed for renal lipid and fructose metabolism, and renal injury.

Results: Biochemical analysis demonstrated lipid parameters and blood glucose was not different between HFD fed diabetic WT and KHK-KO mice. We found remarkable vacuolization in renal proximal tubule in diabetic WT fed HFD. However, this vacuolization was prevented in diabetic KHK-KO fed HFD. This vacuolization was considered as phospholipid droplets by results of oil red o staining, toluidine blue staining and electron microscope images. The lipidomics showed renal phosphatidylglycerol (PG) was significantly increased in diabetic WT fed HFD compared to diabetic KHK-KO fed HFD. These increased renal PG was significantly correlated with phospholipid droplets, however renal triglyceride was not correlated significantly. The renal gene expressions of fatty oxidation (ACOX1, CPT1a) and cholesterol efflux (ABCA1, ABCG1, ApoE) were significantly decreased in diabetic WT fed HFD compared to diabetic KHK-KO fed HFD. These decreased gene expressions were significantly correlated with the number of phospholipid droplets.

Conclusions: These findings suggested that the inhibition of fructose metabolism in high fat fed diabetic mice ameliorated the renal phospholipid accumulation by improving the impaired fat oxidation and cholesterol efflux in kidney.

The Role of PCSK9 on the Glomerular Lipid Accumulation and Renal Injury in the Diabetic Kidney Disease

Jimin Park,[1] Boyoung Nam,[1] Sukyung Kang,[1] Arum Choi,[1] Meiyan Wu,[2] Seung Hyeok Han,[1] Tae-Hyun Yoo.[1] *[1]Yonsei University College of Medicine, Seoul, Republic of Korea; [2]The First Hospital of Jilin University, Changchun, China.*

Background: Glomerular lipid accumulation is one of the pathologic characteristics of diabetic kidney disease (DKD). Recent evidences suggested that proprotein convertase subtilisin kexin type 9 (PCSK9) has a particular effect on the cellular lipid homeostasis. We aimed to evaluate the role of PCSK9 on the lipid accumulation in glomeruli and podocyte under the diabetic conditions.

Methods: C57BL/6 and PCSK9 knockout (KO) mice were maintained with high fat diet for 12 weeks with low dose streptozocin intraperitoneal injection. Urinary albumin-to-creatinine ratio (ACR), total cholesterol and triglyceride in kidney tissues were measured. BODIPY 493/503 staining was performed for evaluating lipid accumulation in the kidney. Foot process effacement in glomeruli was evaluated by standard transmission electron microscopy. In vitro study, mouse podocytes were stimulated with TNF-α and palmitic acid, and PCSK9 was up- or down-regulated by overexpressing lenti virus or siRNA. Apoptosis, mitochondrial morphology and energy metabolic key enzymes were evaluated both in vivo and vitro.

Results: Blood glucose and serum cholesterol were significantly increased, and urinary ACR and foot process effacement were increased in diabetic mice and these changes were exaggerated in the PCSK9 KO mouse with diabetes. Cholesterol and triglyceride levels in the kidney tissues were higher in PCSK KO mice with diabetes than those in control and diabetic mice. Mitochondrial morphology and the expression of energy metabolic enzymes were disturbed in the kidneys of diabetic PCSK KO mice. In vitro, the intracellular lipid contents was increased and apoptosis combined with mitochondrial swelling and crista disruption were also increased in podotyes with TNF-α and palmitic acid stimuli. All of these changes were ameliorated through mPCSK9 overexpression and aggravated by PCSK9 siRNA treatment.

Conclusions: These findings suggest that PCSK9 down-regulation in the podocytes is involved in lipid accumulation and consequent mitochondrial dysfunction and apoptosis in the DKD.

Whole-Kidney 3D Imaging for Assessment of Glomerular Number and Size in a Mouse Model of Diabetic Nephropathy

Jacob Hecksher-Sørensen, Urmas Roostalu, Katrine Fabricius, Niels Vrang, Jacob Jelsing, Thomas Secher, Lisbeth N. Fink. *Gubra, Hørsholm, Denmark.*

Background: Diabetic nephropathy (DN) is a major long-term complication of diabetes characterized by kidney hypertrophy and hyperfunction. To facilitate a rapid and unbiased evaluation of drug efficacy on glomerular size and number in preclinical studies, we investigated the use of light sheet microscopy as a new high-end 3D methodology to study whole-kidney glomerular changes in a mouse model of DN.

Methods: Unilateral nephrectomy (UNx) was performed in diabetic *db/db* mice to accelerate the development of nephropathy. UNx was performed in 18 weeks-old male *db/db* mice and terminated 6 weeks later. Mice were stratified and randomly assigned into UNx (n=8) or sham (n=8) based on baseline blood glucose levels. To determine the effect of UNx on whole-kidney glomerular morphology, mice were injected with lectin-594 prior to termination. Intact kidneys were scanned using light sheet microscopy (LSM). Using 3D image analysis, the total number of glomeruli were quantified and segmented according to individual size.

Results: Progression of diabetes remained similar in *db/db* control and *db/db* UNx mice. In contrast, terminal kidney weight was increased in *db/db* UNx mice, indicative of renal insufficiency leading to kidney hypertrophy. In agreement with stereology-based quantitative analyses on tissue sections, 3D-LSM confirmed an increase in kidney glomerular size in *db/db* UNx mice compared to *db/db* sham controls, while glomerular numbers were similar in both groups (≈14.000 glomeruli/kidney). Lectin-594 labelled kidneys were subsequently processed for Wilms' tumor-1 (Wt1), collagen IV and podocin expression using conventional immunohistochemistry. All antigens were readily detected, confirming that whole-kidney imaging was compatible for subsequent conventional immunohistochemistry.

Conclusions: In conclusion, LSM was successfully applied to evaluate renal and glomerular hypertrophy at the whole-organ level in a *db/db* UNx mice model of DN. Whole-kidney 3D imaging offers a novel approach for evaluating changes in key glomerular markers of DN, while maintaining the ability to perform conventional immunohistochemistry on the same tissue. The detailed analysis of all glomeruli enables for high-resolution evaluation of glomerular effects of novel treatment modalities in DN.

Morphological Changes in the Kidney, Liver, and Pancreas of Type 2 Diabetic Rats Treated with H+-ATPase Inhibitor

Yoshiki Murayama, Akihiro Tojo, Mayu Uchida, Makoto Abe, Akiko Kaiga, Jun Hirao, Masahito Furuichi, Akihiko Nagase, Sho Onoda, Takehiro Ohira, Hiroshi Satonaka, Toshihiko Ishimitsu. *Department of Cardiology & Nephrology, Dokkyo Medical University, Tochigi, Japan.*

Background: We reported that H^+-ATPase specific inhibitor, bafilomycin (BFM), lowered fasting plasma glucose via suppression of renal gluconeogenesis in type 1 diabetic rat. To elucidate the plasma glucose lowering effect of BFM, we investigated morphological changes in the kidney, liver, and pancreas in the type 2 diabetic rats.

Methods: Male Spontaneously Diabetic Torii (SDT) rats were treated with BFM B1 100 nmol/kg for 7 days., After collecting urine, insulin glucose test was performed and then, the organs were fixed and observed with light microscope and electron microscope.

Results: H^+-ATPase was expressed in the proximal tubule, collecting duct, hepatocytes, and pancreatic islet cells. The endocytosis vesicles on the luminal side of the proximal tubules were increased in diabetics. BFM treatment decreased apical endocytotic vesicles, whereas vesicles were accumulated in the basal area of proximal tubule. Enlarged mitochondria in diabetic rats became smaller by BFM treatment. The liver of diabetic rat showed fatty changes, which was suppressed by BFM treatment. The islets of pancreas and insulin vesicles were decreased in diabetic rat. BFM treatment restored islet atrophy and increased insulin vesicles. Insulin sensitivity evaluated by KITT values was significantly decreased in diabetic rat compared with that in control (1.4±0.8 in diabetes vs. 8.8±1.1 in control, $p<0.001$), which was ameliorated by BFM treatment (3.4±0.1, $P<0.05$). BFM significantly reduced fasting blood glucose in diabetes.

Conclusions: In type 2 diabetes, H^+-ATPase inhibitor bafilomycin suppressed proximal tubular endocytic vesicles and mitochondrial enlargement, reduced hepatic fat accumulation, and restored pancreatic insulin vesicles in diabetic rat. Thus, bafilomycin lowered fasting plasma glucose and ameliorated insulin sensitivity.

Urinary Serum Amyloid A and Clinical Outcomes in Advanced Diabetic Kidney Disease

Brad Dieter,[1] Sterling McPherson,[2] Maryam Afkarian,[3] Rick L. Meek,[7] Ian H. de Boer,[4] Rajnish Mehrotra,[5] Katherine R. Tuttle.[6] *[1]Providence Health Care, Spokane, WA; [2]Washington State University College of Medicine, Spokane, WA; [3]University of California, Davis, Sacramento, CA; [4]Division of Nephrology and Kidney Research Institute, University of Washington, Seattle, WA; [5]University of Washington, Seattle, WA; [6]University of Washington School of Medicine, Spokane, WA; [7]Providence Sacred Heart Medical Center, Spokane, WA.*

Background: Serum amyloid A (SAA) is elevated in the kidneys from humans and mice with diabetic kidney disease (DKD). SAA promotes a broad inflammatory response and overexpression of SAA exacerbates albuminuria and glomerulosclerosis in diabetic mice. The study aim was to determine the relationship of urinary SAA to clinical outcomes in patients with advanced DKD.

Methods: Urinary SAA was measured (enzyme-linked immunosorbent assay) in a cohort with type 2 diabetes and advanced DKD defined by urine protein-to-creatinine ratio >500 mg/g. Associations of urinary SAA with ESRD and death were tested using Cox-proportional hazard models. The models were adjusted for DKD risk factors: age, sex, race, hemoglobin A1c, and systolic blood pressure.

Results: Baseline characteristics included: age 57±8 (mean±SD) years, women (65/115; 57%), Mexican-American (82/115; 71%), hemoglobin A1c 8.6±2.3%, systolic blood pressure 153±28 mm Hg, urine albumin-to-creatinine ratio 1874, 756-3950 mg/g (median, interquartile range), estimated glomerular filtration rate (eGFR; CKD-EPI-creatinine) 56±22 mL/min/1.73m^2, diabetes duration 15±6 years, body mass index 32±9 kg/m^2, renin angiotensin system inhibitor use (92/115; 80%). Participants with SAA-positive urine (58/115; 50%) had lower eGFR (SAA-positive 51±19 mL/min/1.73m^2 versus SAA-negative 60±24 mL/min/1.73m^2, p=0.025), and higher albuminuria (SAA-positive 3094 [1180–4677] versus SAA-negative 1089 [55 –1955], p=0.030). SAA positivity in urine was associated with ESRD (hazards ratio [HR] 2.50, 95% confidence interval [CI] 1.23–5.08, p=0.011), but not death (HR 0.92, 95% CI 0.44–1.94, p=0.83) over a median of 3.5 years. After DKD risk factor adjustment, risk of ESRD imparted by SAA positivity in urine remained similar (HR 2.42, 95% CI 1.15 – 5.12, p=0.020).

Conclusions: In patients with advanced DKD, those with SAA-positive urine had lower eGFR and higher albuminuria compared to those with SAA-negative urine. Urinary SAA forecasted ESRD after adjustment for DKD risk factors. These relationships point to SAA as a candidate mechanism for DKD progression in diabetic patients with advanced DKD.

Urine Metabolites Report on Dysregulated Kidney Metabolism in Diabetes and Hypertension

Julia J. Scialla,[1] James R. Bain,[1,2] Michael Muehlbauer,[1,2] Olga Ilkayeva,[2] Jean-Paul Kovalik,[3] Christopher B. Newgard,[1,2] Thomas M. Coffman,[1,3] Susan B. Gurley.[4] *[1]Duke University Medical Center, Durham, NC; [2]Duke Molecular Physiology Institute, Durham, NC; [3]Duke-NUS Medical School, Singapore, Singapore; [4]Oregon Health and Science University, Durham, NC.*

Background: Interrogating the molecular pathophysiology of kidney disease is challenged by limited clinical biopsy specimens. We evaluated concordance of kidney and urine metabolites in mouse models of diabetes mellitus (DM) and hypertension (HTN) to explore urine metabolomics as a tool to investigate kidney diseases in patients.

Methods: We profiled kidney and urine metabolites in the Akita model of type 1 DM (Akita$^{+/-}$), the Akita Renin transgene model of DKD (Akita$^{+/-}$Rtg$^{+/-}$), the Rtg$^{+/-}$ model of HTN, and wild type mice (WT; n=14 each). 24h urines were collected by metabolic cage and organs harvested at 12 wks. Kidneys were frozen and homogenized in acetonitrile:formic acid and urines concentrations were standardized. Nontargeted GC/MS was performed and annotated with spectral libraries. Unidentifiable metabolites or those missing >50% were removed, with other values imputed. Comparisons utilized principal components (PC),

partial least squares discriminant analysis (PLS-DA), and sparse generalized canonical correlation.

Results: Using PLS-DA, higher levels of multiple metabolites discriminated DM ($Akita^{+/-}$ and $Akita^{+/-}Rtg^{+/-}$) from non-DM ($Rtg^{+/-}$ or WT) including: branched chain amino acids, simple sugars, and ketones (β-hydroxybutyrate; BHB) in kidneys; and lactate, pyruvate, and ketones (BHB and acetoacetate) and related compounds (2-hydroxybutyrate) in urine. After data reduction by PC, similar kidney and urine PCs were correlated within phenotypes. In DM, kidney PC1 contained valine, pyruvate and simple sugars. This correlated with urine PC1 (r=0.65) characterized by branched fatty acids, keto acids and acyl glycines. Within non-DM, urine PC1 composed primarily of tricarboxylic acid (TCA) cycle-related organic anions (OAs) correlated directly with a similar TCA-cycle related PC in kidney lysates (r=0.71) with levels higher in $Rtg^{+/-}$.

Conclusions: Similar kidney and urine metabolite PCs correlate in models with and without DM. The predominance of sugars and ketones in profiles from uncontrolled DM models may obscure discovery relevant to treated DM in patients. Studies in non-DM highlight urine TCA cycle-related OAs as potential biomarkers of kidney metabolism. Whether TCA cycle-related OAs may be useful in human studies involving treated DM requires confirmation.

Effects of the SGLT-2 Inhibitor Dapagliflozin on Volume Status in Patients with Type 2 Diabetes and Elevated Albuminuria

Claire Dekkers,[1] Ron T. Gansevoort,[1] Bart J. Kramers,[2] Hiddo J. Lambers Heerspink.[1] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]Harvard, Groningen, Netherlands.*

Background: SGLT-2 inhibitors reduce the risk for heart failure events in patients with type 2 diabetes at high cardiovascular risk. These beneficial effects are thought to be attributed to diuretic effects. The aim of this study was to assess whether these diuretic effects can be attributed to osmotic or natriuretic diuresis in patients with type 2 diabetes and elevated albuminuria.

Methods: A post-hoc analysis was performed of a randomized placebo controlled cross-over trial that assessed the effects of dapagliflozin (DAPA) 10 mg/day therapy in 31 patients with type 2 diabetes and elevated albuminuria (median UAE 521 mg/24h). Blood samples and 24-hour urine were collected at start and end of each 6-weeks treatment period. Markers of volume status including sodium, urea, copeptin, renin, NT-proBNP and osmolality were measured. Free water clearance (FWC) was calculated as urine flow minus osmolar clearance.

Results: Compared to placebo, DAPA therapy increased fractional lithium excretion (reflecting reduced sodium reabsorption), urinary glucose excretion, urine osmolality, copeptin and renin, and it decreased FWC (table). DAPA therapy did not change plasma osmolality, sodium, and NT-proBNP.

Conclusions: The observed increases in fractional lithium excretion, glucose excretion and urine osmolality, and the combined increase in copeptin and renin during DAPA therapy suggests that both osmotic and natriuretic diuresis are involved. These findings are based on 6-weeks changes in fluid markers, when patients already have reached a new steady state. Further research is needed to characterize acute volume and diuretic effects of DAPA.

Volume biomarkers	DAPA Mean (95% CI)	PLACEBO Mean (95% CI)	Effect of DAPA vs PLACEBO Mean (95% CI)	P-value
Urea (mmol/l)	1.2 (0.6 to 1.8)	0.1 (-0.5 to 0.7)	1.1 (0.3 to 1.9)	<.01
Sodium (mmol/l)	0.3 (-0.4 to 1.1)	-0.1 (-0.8 to 0.7)	0.4 (-0.4 to 1.2)	0.35
Plasma osmolality (mosmol/kg)	-0.2 (-2.0 to 1.5)	-1.0 (-2.7 to 0.7)	0.8 (-1.1 to 2.7)	0.40
Copeptin (pmol/l)	3.4 (2.1 to 4.8)	-0.3 (-1.7 to 1.0)	3.8 (2.1 to 5.5)	<.01
Renin (%)	71.6 (33.0 to 121.4)	14.2 (-10.7 to 45.9)	50.3 (7.0 to 111.2)	0.02
NT-proBNP (%)	-3.6 (-19.6 to 15.5)	-10.6 (-24.9 to 6.4)	7.8 (-16.2 to 38.7)	0.55
Urine osmolality (mOsmol/kg)	34.3 (-8.5 to 77.2)	-27.5 (-67.5 to 12.4)	61.8 (12.2 to 111.5)	0.02
Fractional lithium excretion (%)	24.3 (10.1 to 40.3)	2.7 (-8.6 to 15.5)	21.0 (4.9 to 39.6)	0.01
Urinary glucose excretion (mmol/24h)	217.5 (176.0 to 259.0)	7.9 (-30.7 to 46.5)	209.5 (148.7 to 270.4)	<.01
FWC (ml/24h)	-503.7 (-794.3 to -216.2)	88.4 (-229.8 to 306.6)	-542.1 (-880.2 to -204.1)	<.01

SA-PO138

Effects of Dapagliflozin on Albuminuria, Renal Function, and Renin-Angiotensin-Aldosterone Hormones in Type 2 Diabetes

Mie K. Eickhoff,[2] Marie Frimodt-Moller,[2] Niklas R. Jørgensen,[3,4] Peter Rossing,[2] Frederik Persson.[1] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [3]Department of Clinical Biochemistry, Rigshospitalet, Glostrup, Denmark; [4]OPEN, Odense Patient data Explorative Network, Odense University Hospital, Odense, Denmark.*

Background: Sodium glucose cotransporter 2 inhibitors (SGLT2i) have shown a cardio- and renoprotective effect. The mechanism for this effect and the interaction with the renin-angiotensin-aldosterone system (RAAS) is only partially understood. Therefore, we aim to evaluate the effect of dapagliflozin treatment on albuminuria, measured GFR, 24h blood pressure (BP) and hormone levels of the RAAS when added to standard care including RAAS blocking treatment in patients with type 2 diabetes (T2D).

Methods: Double-masked randomized placebo-controlled crossover trial of 12 weeks treatment with dapagliflozin 10 mg or matching placebo. All patients were treated with RAAS blocking treatment. Included patients (n=40) had T2D and albuminuria at baseline. At the end of the treatment periods 3 consecutive morning spot urines were collected as well as 24h BP measurement and ^{51}Cr-EDTA clearance performed. Values at the end of treatment periods (placebo vs. dapagliflozin) were compared using mixed model analysis.

Results: Baseline age was 65 (SD±8), 90% were male, HbA_{1c} was 73 mmol/mol (SD±15), 24h BP 148/82 mmHg (SD±12.5/7.7), geometric mean urinary albumin creatinine ratio (UACR) 147 (IQR 75-289) mg/g and mean eGFR 85 ml/min/1.72 m^2 (SD±19.7). After 12 weeks treatment UACR was reduced 36% (95% CI 16-56%) during treatment with dapagliflozin vs. placebo (p<0.01), GFR decreased 10.9 (5-16) ml/min/1.72 m^2 (p<0.01), HbA1c was reduced 7.4 (5-10) mmol/mol (p<0.01) and 24h BP 4.8/2.7 mmHg (p=0.023/0.031). Plasma renin concentration increased 37% (9-66%, p = 0.012), plasma renin activity increased 41% (7—74%, p = 0.019), angiotensin II increased 37% (1-73%, p = 0.046) whereas plasma aldosterone was unchanged.

Conclusions: When added to standard RAAS blocking treatment dapagliflozin 10 mg vs. placebo once daily was associated with a significant reduction in albuminuria, 24h BP and GFR in patients with T2D and albuminuria. A concomitant increase in RAAS hormones was observed, possibly caused by increased diuresis as an effect of natriuresis.

SA-PO139

Effect of Dapagliflozin on Cardiac Function and Biomarkers in Patients with Type 2 Diabetes and Albuminuria – A Randomized Study

Mie K. Eickhoff,[1] Flemming J. Olsen,[3] Marie Frimodt-Moller,[1] Lars J. Díaz,[1] Jens Faber,[2] Magnus T. Jensen,[3] Peter Rossing,[1] Frederik Persson.[1] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Herlev University Hospital, Herlev, Denmark; [3]Department of Cardiology, Herlev-Gentofte Hospital, Copenhagen, Denmark.*

Background: Sodium glucose cotransporter 2 inhibitors (SGLT2i) have shown cardio- and reno-protective properties. The aim here is to evaluate the effect of dapagliflozin (dapa) treatment on myocardial function assessed with advanced echocardiography (TTE), and cardiac biomarkers when added to standard care in patients with type 2 diabetes (T2D).

Methods: This is a sub-study of a double-masked randomized placebo-controlled crossover trial of 12 weeks treatment with dapa 10 mg once daily or placebo. All patients (n=40) were on RAS blocking treatment, had T2D and albuminuria at baseline. At the end of the treatment period TTE was performed, ^{51}Cr-EDTA, albuminuria and 24h blood pressure were measured, as well as cardiac markers in plasma; NTproBNP, troponin I, MRproANP, MRproADM, TNF-α, IL-6 and copeptin. Global longitudinal strain (GLS) was the primary systolic echocardiographic endpoint. To assess diastolic function a combined diastolic endpoint was used including mean early diastolic myocardial velocity (e'), ratio between early transmitral inflow velocity (E) and e' (E/e'), atrial volume and pulmonary pressure (TRmaxPG).

Results: Baseline geometric mean urinary albumin creatinine ratio (UACR) was 147 (IQR 75-289) mg/g, mean eGFR 85 (SD±19.7) ml/min/1.72 m^2. Baseline HbA_{1c} was 73 (SD±15) mmol/mol, 24h blood pressure 148/82 (SD±12.5/7.7) mmHg, diabetes duration 16.5 (SD±4,8) years, age 65 (SD±8) years and 90% were male. After 12 weeks treatment with dapa vs. placebo, HbA_{1c} was reduced by 7.4 (5-10) mmol/mol (p<0.01) and 24h blood pressure decreased 4.8/2.7 mmHg (p=0.023/0.031). Left ventricular ejection fraction after placebo was 55.5 (SD±6.7) % and 53.7 (SD±6.7) % after active treatment – a non-significant change. GLS did not change whereas diastolic function improved significantly with 19.8% (3.3-36.3%, p = 0.021). Plasma concentration of NTproBNP, troponin I, MRproANP, MRproADM, TNF-α and IL-6 did not change. Plasma concentration of copeptin increased with 32.3% (p<0.0001).

Conclusions: Treatment of dapa 10 mg vs. placebo in patients with albuminuria was associated with an improvement in diastolic function but not in GLS in people with T2D and albuminuria. Also an increase in copeptin was observed possibly reflecting increased diuresis due to natriuresis.

Dapagliflozin Added to Verinurad plus Febuxostat Reduces Serum Uric Acid Without Increasing Urinary Uric Acid Excretion in Subjects with Hyperuricemia

Austin G. Stack,[1] Fredrik Erlandsson,[2] David S. Han,[3] Jan Oscarsson,[2] Ronald Goldwater,[4] Nalina Dronamraju,[5] Susanne Johansson,[2] Eva K. Johnsson.[2] *[1]Graduate Entry Medical School, University of Limerick, Limerick, Ireland; [2]AstraZeneca, Mölndal, Sweden; [3]PAREXEL International, California, CA; [4]PAREXEL International, Baltimore, MD; [5]AstraZeneca, Mölndal, Sweden.*

Background: Hyperuricemia is associated with gout, kidney stones and CV events. An intensive urate lowering strategy combines a xanthine oxidase inhibitor (febuxostat [FEB]) and a URAT-1 inhibitor (verinurad [VER]) to maximize serum uric acid (sUA) reduction. Dapagliflozin (DAPA, SGLT2 inhibitor) reduces sUA by an unknown mechanism(s). Excessive UA excretion may damage renal tubules due to crystallization at high levels, so any DAPA-mediated effect on urinary UA (uUA) should be explored. We examined effects of DAPA on sUA and uUA excretion on top of VER+FEB in hyperuricemia.

Methods: A randomized, placebo-controlled, 2-way crossover study was conducted in adults with asymptomatic hyperuricemia over 7-d periods after washout. Groups (1:1) received oral VER 9mg+FEB 80mg+DAPA 10mg (Gp1), or VER+FEB+placebo (Gp2). Urine was collected hourly and for 24h on D–1 (baseline [BL]) and D7 of each period. Primary endpoint was difference from D7 to D–1 in peak uUA excretion between groups (ΔGp1–ΔGp2). Secondary measures were change in serum levels and 24-h urinary excretion of UA, Cr, and Na. AEs were monitored. Data are shown as mean (SD) and LSM (95% CI).

Results: Enrolled subjects (n=24) were male, mean age 43y. At BL (D–2), median BMI and eGFR were 29 kg/m^2 and 85 mL/min/1.73m^2 with mean (SD) sUA 445.3 (60.8) µmol/L. BL levels of sCr and sNa were (Gp1/Gp2) 93.8/95.8 µmol/L and 138/139 mmol/L, respectively. Peak uUA was available for 13 subjects and 24h urine for all. After DAPA, subjects showed no increase in peak UA excretion on D7 (mg/h); Grp1 –5.33 (–15.04, 4.37), Gp2 –7.20 (–16.91, 2.51); mean difference 1.87 (–7.63, 11.36). No difference was seen in total 24h UA excretion. After DAPA, subjects showed significantly reduced sUA levels; mean difference (Gp1 vs Gp2) on D7 was –76.35 (–104.02, –48.68) µmol/L (p<0.01). No between-group differences were seen in sCr or sNa. 8 subjects had 9 AE (Gp1 n=5; Gp2, n=4), all mild, no inter-group differences. DAPA did not affect VER or FEB PK.

Conclusions: Addition of DAPA to an intensive UA lowering strategy with VER+FEB provides additional sUA lowering without increase in urinary UA excretion, or changes in sCr; suggesting a DAPA+VER+FEB combination will not adversely affect kidney function (NCT03316131).

Can Improvements in Cardiac and Vascular Hemodynamic Markers Explain the Kidney Benefit with Empagliflozin in the EMPA-REG OUTCOME® Trial?

Bernhard K. Krämer,[1] Johannes F. Mann,[2] Stefan Hantel,[3] Odd Erik Johansen,[4] Maximilian von Eynatten,[3] Christoph Wanner,[5] Sibylle J. Hauske.[1,3] *[1]University Medical Center Mannheim, University of Heidelberg, Mannheim, Germany; [2]KfH Nierenzentrum, München, Germany; [3]Boehringer Ingelheim International GmbH, Ingelheim, Germany; [4]Boehringer Ingelheim Norway, Asker, Norway; [5]Würzburg University Clinic, Würzburg, Germany.*

Background: In the EMPA-REG OUTCOME trial (NCT01131676) empagliflozin (EMPA) added to standard of care significantly reduced clinically relevant kidney outcomes by 39% in patients with type 2 diabetes (T2D) and established cardiovascular disease (CVD). As EMPA can reduce arterial stiffness and improve vascular compliance, these effects could be potential mediators of the kidney protective effects observed. We assessed whether the effect of EMPA on indices of arterial stiffness and vascular compliance could be related to kidney outcomes.

Methods: Patients were randomized (1:1:1) to EMPA 10 mg, EMPA 25 mg, or placebo (PBO); this post-hoc analysis compared the pooled EMPA group vs PBO. We calculated change from baseline to week 12 in indices of arterial stiffness (pulse pressure), vascular resistance (mean arterial pressure), and cardiac workload (double product). Subgroups for these indices (depicted as changes above or below the median) were used to assess potential effects on incident or worsening nephropathy (composite of progression to macroalbuminuria, doubling of serum creatinine, initiation of renal replacement therapy, or renal death) and all outcome events occurring after week 12 were included in this analysis.

Results: A total of 7020 patients were randomized and treated with ≥1 study drug dose. As previously reported, EMPA significantly reduced cardiac and vascular hemodynamic markers vs PBO at week 12. However, the reduction in risk of incident or worsening nephropathy with EMPA was consistent between the three subgroups for indices, regardless of magnitude of their respective changes (Figure).

Conclusions: In patients with T2D and established CVD, empagliflozin produced a consistent benefit on kidney outcomes between subgroups for indices of arterial stiffness, vascular resistance, and cardiac workload.

Reduction in Weight and Adiposity Indices and Kidney Outcomes with Empagliflozin in Patients with Type 2 Diabetes (T2D): Results from the EMPA-REG OUTCOME® Trial

Talat Alp Ikizler,[1] Peter Stenvinkel,[2] Ian J. Neeland,[3] Stefan Hantel,[4] Odd Erik Johansen,[5] Maximilian von Eynatten,[6] Christoph Wanner,[7] Audrey Koitka-Weber.[6,8] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Karolinska University Hospital Huddinge, Stockholm, Sweden; [3]UT Southwestern Medical Center, Dallas, TX; [4]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach an der Riss, Germany; [5]Boehringer-Ingelheim, Asker, Norway; [6]Boehringer Ingelheim, Ingelheim, Germany; [7]University Hospital, Wuerzburg, Germany; [8]Würzburg University Clinic, Würzburg, Germany.*

Background: Empagliflozin (EMPA), a sodium-glucose co-transporter-2 inhibitor, significantly reduced the risk of prespecified kidney outcomes by 39% when added to standard of care in patients with T2D and established cardiovascular disease (CVD) in the EMPA-REG OUTCOME® trial. As obesity increases the risk for chronic kidney disease (CKD) and its progression to end-stage kidney disease, we explored the potential interaction between changes in weight/adiposity and the kidney-protective effects of EMPA.

Methods: In EMPA-REG OUTCOME®, 7020 patients were randomized (1:1:1) to daily EMPA 10 or 25 mg or placebo (PBO). Background glucose-lowering therapy was unchanged for the first 12 weeks. We analyzed kidney outcomes in subgroups based on change in weight and adiposity markers from baseline to week 12. Differences in risk for pooled EMPA vs PBO were assessed using a Cox proportional hazards model adjusting for clinical covariates.

Results: Median observation time was 3.1 years. At baseline, the EMPA and PBO groups had similar mean weight (86.6 vs 86.2 kg, respectively), body mass index (30.7 vs 30.6 kg/m^2), waist circumference (105.0 vs 104.7 cm), and estimated total body fat (33.4% vs 33.5%). Changes in these parameters from baseline to week 12 did not significantly affect the reduced risk of incident or worsening nephropathy observed after week 12 with EMPA vs PBO (Figure; treatment by subgroup interaction p-value >0.05 for all).

Conclusions: The beneficial effect of EMPA on kidney outcomes was consistent irrespective of changes in weight or body fat in T2D patients with established CVD. The EMPA-KIDNEY trial will provide further insight into the effects of EMPA on adiposity and kidney outcomes in CKD patients with or without diabetes.

Effects of Canagliflozin on Serum Potassium in the CANVAS Program

Matthew R. Weir,[1] Dainius Balis,[2] Dick de Zeeuw,[3] Vlado Perkovic.[4] *[1]University of Maryland School of Medicine, Baltimore, MD; [2]Janssen Research & Development, LLC, Raritan, NJ; [3]University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [4]The George Institute for Global Health, Sydney, NSW, Australia.*

Background: Canagliflozin (CANA) is a sodium glucose co-transporter 2 (SGLT2) inhibitor used for the treatment of type 2 diabetes mellitus (T2DM). The US label Warnings and Precautions section notes a risk of hyperkalemia with CANA in patients with moderate renal impairment who are taking medications that interfere with potassium excretion. Serum potassium levels were assessed in patients at high cardiovascular (CV) risk in the CANagliflozin cardioVascular Assessment Study (CANVAS) Program, comprised of the CANVAS and CANVAS-R trials.

Methods: The CANVAS Program randomized 10,142 participants with T2DM and high CV risk to CANA or placebo (PBO); 80% were on renin-angiotensin aldosterone system (RAAS) inhibitors at baseline. Serum potassium measurements were performed in a central laboratory; values meeting predefined limit of change criteria (PDLC) were prespecified and assessed using results obtained up to 2 days after the last dose of study drug.

Results: In the CANVAS Program, the risk of decreased serum potassium (PDLC <3.4 mEq/L and >15% decrease from baseline) was similar between the CANA and PBO arms (**Table**; hazard ratio [HR] 0.96 [95% confidence interval (CI) 0.72, 1.28]). The HR (95% CI) for increased serum potassium (PDLC >5.4 mEq/L and >15% increase from baseline) was 1.03 (0.89, 1.20) and for serum potassium ≥6.5 mEq/L was 0.84 (0.50, 1.41). Generally similar results were seen in subgroups by baseline eGFR (<45, 45-<60, & ≥60 mL/min/1.73 m^2; **Table**).

Conclusions: In the CANVAS Program, no significant differences in the risk of hypo- or hyperkalemia were observed with CANA versus PBO overall or in participants with renal impairment.

Funding: Commercial Support - Janssen Research & Development, LLC

Table. Patients with Serum Potassium Values Outside Predefined Limits in the CANVAS Program

PDLC	Baseline eGFR	Events	CANA Rate per 1000 PY	PBO Rate per 1000 PY	HR (95% CI)
Potassium <3.4 mEq/L (LLN) and >15% decrease from baseline	Total	197	6.39	7.15	0.96 (0.72, 1.28)
	≥60 mL/min/1.73 m^2	153	5.89	6.98	0.93 (0.67, 1.28)
	45 to <60 mL/min/1.73 m^2	28	7.02	7.29	0.95 (0.45, 2.04)
	<45 mL/min/1.73 m^2	16	14.59	9.77	1.50 (0.50, 4.55)
Potassium >5.4 mEq/L (ULN) and >15% increase from baseline	Total	723	26.36	24.80	1.03 (0.89, 1.20)
	≥60 mL/min/1.73 m^2	549	24.10	23.09	1.00 (0.84, 1.20)
	45 to <60 mL/min/1.73 m^2	122	35.38	28.92	1.21 (0.84, 1.75)
	<45 mL/min/1.73 m^2	52	45.07	42.26	0.87 (0.48, 1.56)
Potassium ≥6.5 mEq/L	Total	62	2.06	2.13	0.84 (0.50, 1.41)
	≥60 mL/min/1.73 m^2	39	1.49	1.76	0.73 (0.38, 1.38)
	45 to <60 mL/min/1.73 m^2	11	3.05	2.41	1.14 (0.33, 3.93)
	<45 mL/min/1.73 m^2	12	10.62	7.87	0.94 (0.27, 3.30)

Comparison Between Clinical Trial and Real-World Use of Sodium-Glucose Co-Transporter-2 Inhibitors According to CKD Status

Jung-Im Shin,[1] Josef Coresh,[1] Elizabeth Selvin,[1] Lesley Inker,[3] Alex R. Chang,[2] Morgan Grams.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Geisinger Medical Center, Danville, PA; [3]Tufts Medical Center, Boston, MA.*

Background: Clinical trials typically enroll highly selective patient populations and often include few participants with chronic kidney disease (CKD). Our objective was to compare participants characteristics and outcomes in trials of sodium-glucose co-transporter-2 inhibitors (SGLT-2i) with SGLT-2i users in real-world settings according to CKD status.

Methods: We compared characteristics, mortality, and HbA1c change at 12 weeks among SGLT-2i users in the EMPA-REG OUTCOME trial (Empagliflozin Cardiovascular Outcome Event Trial in Type 2 Diabetes Mellitus Patients) with patients in the Geisinger Health System from June 2013 to January 2017 according to CKD status. CKD was defined as estimated glomerular filtration rate (eGFR) <60 mL/min/1.73 m^2 according to Modification of Diet in Renal Disease equation or macroalbuminuria.

Results: From 2013 to 2016, prescription of SGLT-2i increased in each category of eGFR (G1-2 [0.3% to 5.3%] and G3-5 [0.2% to 2%], all *P*<0.001). Compared to trial participants, real-world users of SGLT-2i were younger, more obese, with a much lower prevalence of coronary artery disease (Table). Real-world users had lower mortality than their counterparts in the trial, and these differences were present in patients with and without CKD. The magnitude of HbA1c reduction from baseline to 12 weeks was similar between trial participants and real-world users.

Conclusions: Despite the difference in baseline characteristics between trial and real-world users, SGLT-2i appeared to have similar glucose-lowering effect in individuals with diabetes regardless of CKD status. Further research is warranted to investigate the effects of SGLT-2i on cardiovascular and kidney outcomes in patients with CKD.

Intensive Insulin Therapy Reduces Urinary Angiotensinogen in Type 1 Diabetes: A Possible Mechanism of Renoprotection via Renin Angiotensin System (RAS) Downregulation

Sheeba H. Ba aqeel,[1] Alejandro Sanchez,[1] Minghao Ye,[1] Jan Wysocki,[1] Mark E. Molitch,[3] Daniel Batlle.[2] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Optimal glycemic control is well known to protect people with diabetes from developing kidney disease but the mechanism is unknown. Kidney angiotensinogen (AOG) gene expression has been shown to be regulated by glucose that stimulates AOG mRNA and also by insulin that inhibits glucose induced stimulation of AOG transcription in proximal tubule cells via an insulin responsive element that binds two transcription factors, hnRNP F & hnRNP K. We examined if in patients with type1 diabetes and microalbuminuria, urinary angiotensinogen (uAOG) is reduced by intensive insulin therapy. For this, we evaluated uAOG in biosamples from the Diabetes Control and Complications Trial (DCCT) participants with type1 diabetes and microalbuminuria allocated to either intensive or standard insulin therapy

Methods: Urine samples from DCCT participants provided by the NIDDK repository consisted of participants who had been allocated to intensive (n=58) or standard insulin (n=41) and had microalbuminuria at study entry. uAOG was measured after a median of 5years of therapy (range 3-6) in both groups. Patients were not taking any medications such as RAS blockers that could have influenced uAOG results. Mann-Whitney test was used to measure the differences in levels of uAOG between the two groups

Results: At the study entry, there were no significant differences in age, gender, disease duration, blood pressure, GFR, albumin excretion rate and HbA1C between the two groups. At the study visit there were again no significant differences in age, gender, disease duration, blood pressure or GFR. Albumin excretion rate was also not significantly different. HbA1c was higher in the group on standard when compared to intensive therapy (median 8.9, range 5.7-9.2 vs 7.0, 6.8-12% P<0.001). uAOG was significantly decreased in participants on intensive compared to standard therapy (median 3.98, range 0.4-96 vs 7.4, range 1.3-295ng/mg, P=0.005)

Conclusions: In type1 diabetes with microalbuminuria, intensive insulin decreases uAOG when compared to standard insulin. This suggests that optimization of glycemic control with intensive insulin, by suppressing uAOG downregulates kidney RAS overactivity and unravels an important mechanism for the well-known renoprotective effect of insulin in humans.

SA-PO146

Primary Efficacy Analyses from a Phase 2 Trial of the Safety and Efficacy of Bardoxolone Methyl in Patients with Type 1 Diabetes

Arnold L. Silva,[1] Ahmed M. Awad,[5] Geoffrey A. Block,[2] Melanie Chin,[3] Colin J. Meyer,[3] Kevin Schroeder,[6] Pablo E. Pergola.[4] *[1]Boise Kidney & Hypertension Institute, Meridian, ID; [2]Colorado Kidney Care, Denver, CO; [3]Reata Pharmaceuticals, Irving, TX; [4]Renal Associates, PA, San Antonio, TX; [5]Clinical Research Consultants, LLC, Kansas City, MO; [6]Ohio Kidney Consultants, Columbus, OH.*

Background: Bardoxolone methyl (BARD) has been shown to significantly increase eGFR in patients with CKD and type 2 diabetes or Alport syndrome suggesting that the anti-inflammatory and anti-fibrotic effects of BARD may target the common pathways contributing to GFR loss in multiple forms of CKD. As a result, a Phase 2 trial (PHOENIX, NCT03366337) was initiated to test the hypothesis that BARD will improve kidney function in patients with CKD due to type 1 diabetes mellitus (T1DM) as well as other forms of CKD.

Methods: The Phase 2 open-label, multicenter study enrolled a cohort of patients T1DM confirmed by fasting C-peptide levels. Eligible patients were 18 to 65 years of age with eGFR values between 30 to 90 mL/min/1.73 m^2 and urine albumin to creatinine ratio (UACR) ≤ 2500 mg/g. Patients received BARD at an initial dose of 5 mg, dose-escalated to 20 mg (for patients with baseline UACR ≤ 300 mg/g) or to 30 mg (for patients with baseline UACR > 300 mg/g) and were treated for 12 weeks. The primary efficacy endpoint was the change from baseline eGFR after 12 weeks of treatment. Interim results for the cohort enrolling patients with T1DM are described herein.

Results: At data cutoff on May 15th, 2018, 3/19 (16%) of the enrolled patients with T1DM had completed the study. From a mean (± SE) baseline eGFR of 68.2 ± 3.8 mL/min/1.73 m^2, BARD treatment resulted in a significant increase from baseline in eGFR of 7.9 ± 2.9 mL/min/1.73 m^2 (p=0.008) at Week 12. No patients have discontinued from the study and no serious AEs considered related to BARD have been reported in this ongoing trial.

Conclusions: BARD was generally well tolerated and significantly increased eGFR in patients with T1DM. In patients with other forms of CKD, short term eGFR increases with BARD are predictive of durable eGFR improvements and additional studies are needed to study the longer-term effects of BARD on eGFR in T1DM.

Disease Characteristics and Outcomes in Patients with CKD and Type 2 Diabetes: A Matched Cohort Study of Spironolactone Users and Non-Users

Michael Blankenburg,[1] Csaba P. Kovesdy,[2] Anne-Kathrin Fett,[3] Emile Schokker,[4] Alain Gay.[5] *[1]Bayer Pharma AG, Berlin, Germany; [2]University of Tennessee Health Science Center, Memphis, TN; [3]QuintilesIMS, Frankfurt, Germany; [4]IQVIA, Frankfurt, Germany; [5]Bayer, BERLIN, Germany.*

Background: This study aimed to assess disease characteristics and outcomes in cohorts of spironolactone users and non-users with chronic kidney disease (CKD) and type

2 diabetes (T2D) who were matched on demographic and clinical characteristics, including CKD stage.

Methods: Patients with CKD and T2D were identified in the US claims database PharMetrics Plus using ICD-9 and ICD-10 codes. Outcomes of interest including CKD progression, clinical events, healthcare use and costs were described in the matched cohorts using summary statistics; mortality analyses were conducted in a sub-cohort with linkable data in Experian. The impact of persistent or non-persistent spironolactone use (≥6 vs. <6 months treatment duration) was also evaluated.

Results: The matched cohorts (n=5,465 each) both had a median age of 62 years and 61% of patients were male. Despite matching, spironolactone users had more comorbidities at baseline than non-users (Charlson comorbidity index score 4+, 89% vs. 78%). During one-year of follow-up, progression to a more severe CKD stage occurred in 30% of spironolactone users and 18% of non-users. Annual median healthcare costs per person were $33,013 for spironolactone users and $22,598 for non-users; 62% and 50% of patients had at least one inpatient visit, respectively. The mortality rate per person-year was 4% for spironolactone users and 7% for non-users; however, the mortality rate assessment was conducted in a younger sub-cohort with lower rates of heart failure (n=1,431 each). Persistent spironolactone users had fewer clinical events, lower healthcare use and costs and a reduced likelihood of CKD progression than non-persistent users.

Conclusions: In this study, spironolactone users were more severely ill, had worse clinical outcomes and higher healthcare use and costs than non-users. These findings highlight the unmet medical need in this patient population and the need for better treatment options.

Low Dose Anti-Thromboxane Reduces Urinary Albumin in Patients with Diabetic Kidney Disease

Eva Steiness,[1] Nikolai Brun,[1] Torben Skarsfeldt,[1] Karl M. Derwahl.[2] *[1]Serodus, Oslo, Norway; [2]Ikfe Berlin, Berlin, Germany.*

Background: Thromboxane facilitates coagulation but is also a pro-inflammatory endogenous agent. SER150 is an oral, small molecule with a novel dual mode of action that inhibits thromboxane synthase and simultaneously blocks the thromboxane receptor. SER150 inhibited thrombocytes agglutination both in healthy and diabetic patients. Studies in healthy volunteers and in patients with Type 2 diabetes doses from 0,375 to 2,5 mg/kg body weight, SER150 dose-dependently increased bleeding time from insignificant values and up to 294 seconds after the highest dose investigated. However, a dose of 0,16 mg/kg insignificantly attenuated bleeding time compared to placebo and insignificantly reduced agglutination of ex-vivo stimulated (U16466) thrombocytes for few minutes.

Methods: A double-blind, placebo-controlled, clinical study included 49 diabetic patients with HbA1c of 7,08 mmol/mol, blood pressure of 132/75 mmHg and urine albumin > 30 mg/g creatinine (ACR). The patients were treated with SER150 at doses of either 15 mg BID or 30 mg BID (0,16mg/kg or 0,32mg/kg BID) for 4 weeks.

Results: SER150 treatment caused ACR gradually to decrease during the 4 weeks and was statistically significant reduced from baseline ($p<0,02$ and $p<0.04$ respectively). 25% of patients with micro-albuminuria at baseline (ACR >30 £300) became normo-albuminuric during the 4 weeks on SER150 treatment. All patients with macro-albuminuria (ACR >300) experienced a decrease in urinary albumin and 45% shifted from macro-albuminuria to micro-albuminuria.

Conclusions: These findings suggest two different sites of action with different dose-efficacy relation of the anti-thromboxane agent SER150. One at the thrombocytes and one at different, still unknown, site of action in the kidney at sites essential for the damage of renal filtration barrier in patients with diabetic kidney disease. The aim of the next clinical study is to confirm SER150 induced decrease in ACR in patients with diabetes and macro-albuminuria (ACR >500). Furthermore, to demonstrate that decrease in ACR is maintained over time (6 month) with a dose of 15 mg BID. The primary endpoint will be a composite of ACR and a group of relevant renal surrogate markers.

SA-PO149

Randomized Placebo-Controlled Trials of Tangshen Formula in Diabetic Kidney Disease

Meihua Yan, Ping Li. *China-Japan Friendship Hospital, Beijing, China.*

Background: Patients with diabetic mellitus are at high risk of progressing into diabetic kidney disease (DKD), which is associated with high morbidity and mortality. Current drug therapies for DKD are not entirely satisfactory. Tangshen Formula (TSF) is a Chinese herbal medicine remedy for DKD based on empirical evidence gleaned from Chinese medicine practitioners.The multinational, randomized, double-blind, placebo controlled trials of TSF Treatment on DKD (TTD)-1 and TTD-2 evaluated the effects of TSF on DKD when added to standard therapy.

Methods: In TTD-1 trial, we randomly assigned 180 DKD patients with mild to moderate disease (urinary albumin excretion rate (UAER) >20 μg/min, and/or 24-hour urinary protein (24h UP) between 0.5 and 2.0 g/d, and estimated glomerular filtration rate(eGFR) between 60 ml/min and 130 ml/min) to receive either placebo or TSF. In TTD-2 trial, 146 DKD patients with moderate to severe disease (24h UP between 0.5 and 3.5 g/d, and serum creatinine < 265 μmol/L (3 mg/dl)) to receive either placebo or TSF. Each trial continued intervention for 24 weeks. Primary outcome was urinary protein level, measured by UAER for participants with microalbuminuria, 24h UP for participants with macroalbuminuria. Secondary outcomes included renal function, serum lipids, quality of life, symptoms, and adverse events.

Results: For participants with macroalbuminuria, TSF displayed a statistically significant decrease in 24h UP in TTD-1(TSF –0.21 compared with placebo 0.36g, with a mean difference of –0.57g; 95% CI, –1.05 to –0.09, P=0.024), while no statistically significant difference was found in TTD-2(TSF 0.74 compared with placebo 0.21 g, with a mean difference of 0.55g; 95% CI, -0.03 to 1.13, P=0.111). The eGFR was improved in both trials (TTD-1: TSF 1.96 compared with placebo –7.05 ml/min/1.73m^2, with a mean difference of 9.01 ml/min/1.73m^2, 95% CI, –0.10 to 18.13, P=0.031) (TTD2: TSF 4.22 compared with placebo -4.8 ml/min/1.73m^2, with a mean difference of 7.8 ml/min/1.73m^2, 95% CI, 2.10 to 12.68, P=0.016). Other secondary outcomes showed no statistically significant difference between groups or in the incidence of adverse events in both trials.

Conclusions: TSF appears to provide additional benefits in improving eGFR in DKD patients, based on conventional treatments. Trial Registration TTD-1:Chinese Clinical Trial Registry ChiCTR-TRC-10000843 TTD-2: ChiCTR-TRC-13003566

SA-PO150

Tie2 Activation via VE-PTP Inhibition for Treatment of Diabetic Kidney Disease

Kevin G. Peters, Mitchell Brigell, Steve Pakola. *Aerpio Pharmaceuticals, Cincinnati, OH.*

Background: Considering the current epidemic of diabetes, new treatments for diabetic vascular complications, including diabetic kidney disease (DKD) are urgently needed. VE-PTP is a vascular endothelial receptor tyrosine phosphatase that negatively regulates Tie2 activation, a critical axis for maintaining endothelial function and vascular stability. Importantly, VE-PTP is upregulated by hyperglycemia and hypoxia, conditions associated with decreased Tie2 activation and progression of diabetic complications. Thus, targeting VE-PTP inhibition to restore Tie2 activation is a promising approach to treat diabetic vascular complications, including DKD. Here we report results from a post-hoc analysis demonstrating improvement in UACR in patients with diabetic eye disease treated for three months with AKB-9778, a potent and selective small molecule VE-PTP inhibitor.

Methods: The TIME-2 study was a Phase 2a, double-masked, parallel-group trial in which 144 patients with diabetic retinopathy complicated by diabetic macular edema were randomized to one of three treatment groups: AKB-9778 (15 mg) subcutaneous (SC) BID monotherapy plus sham intravitreal injection; AKB-9778 SC BID plus monthly Lucentis (0.3mg) intravitreal injection; and placebo SC BID plus monthly Lucentis intravitreal injection monotherapy. Although the study was designed to assess the effect of AKB-9778 on diabetic eye disease, UACR was measured at baseline and at end of the 3-month treatment period. Patients with increased UACR at baseline (UACR ≥30 mg/g) were included in the analysis.

Results: About 50% of patients in the study had UACR ≥30 mg/g at baseline, approximately equally distributed among the three treatment groups. There was an ~ 20% reduction in geometric mean UACR from baseline in both AKB-9778 active treatment arms, while there was an increase in UACR in the placebo arm (Figure 1).

Conclusions: These findings represent the first clinical evidence of potential beneficial effects of a VE-PTP inhibitor in patients with DKD and underscore the therapeutic potential of Tie2 activation in DKD and other diabetic vascular complications.

Effects of Senolytic Agents on Blood- and Urine-Borne Extracellular Vesicles from Senescent Cells in Diabetic Kidney Disease: A Pilot Study

LaTonya J. Hickson,[1] James L. Kirkland,[2] Kumar Sanjay,[3] Tamara Tchkonia,[2] Stephen C. Textor,[2] Lilach O. Lerman,[4] Muthuvel Jayachandran.[2] *[1]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Mayo Clinic, Rochester, MN; [3]Mayo Clinic, Rochester, MN, Rochester, MN; [4]Mayo Clinic College of Medicine, Rochester, MN.*

Background: Cellular senescence, from DNA damages leading to cell cycle arrest and increased expression of p16, contributes to the pathogenesis of diabetic kidney disease (DKD). Affected blood and kidney cells generate pro-inflammatory cytokines causing kidney injury. Extracellular vesicles (EV) shed by cells represent novel biomarkers of disease and disease activity. We tested the hypothesis that clearance of senescent cell abundance via senolytic agents would decrease markers of senescence, inflammation and kidney injury which could be identified through EV examination.

Methods: DKD subjects were randomized to senolytic drugs (**n=5**; a single 3-days oral regimen) vs "no treatment" (**n=2**). EVs were characterized and quantified in platelet-free plasma and cell-free urine sampled at Days 0, 14, and 120 by standardized digital flow cytometer methods using fluorophore conjugated preselected markers specific antibodies: senescence (p16), inflammation (CD45), kidney injury (KIM-1, NGAL). A non-EV (soluble) plasma biomarker of DKD progression, tumor necrosis factor receptor-1 (TNFR-1), was also measured.

Results: Of 7 male subjects, mean age was 71±6 years and eGFR 29±10 mL/min/1.73m^2. Over 120 days, treated subjects had decreased levels of inflammatory and senescent cell-derived EVs in plasma while untreated subjects showed progressive increases (**Figure**). Plasma TNFR1 biomarker levels did not differ. Similarly, senescent cell-derived urinary EVs and kidney injury marker (KIM-1 and NGAL) positive urine EVs tended to fall over time in treated while EVs rose in untreated subjects.

Conclusions: These early pilot study findings suggest that senolytic agents may attenuate progression of senescent cell abundance, inflammation, and kidney injury in patients with DKD.

Patient Motivation Scoring and Outcomes in the Diabetes CKD Clinic

LaTonya J. Hickson,[1] Bjoerg Thorsteinsdottir,[2] Kristin C. Mara,[3] Sudhi Upadhyaya,[4] Minji Lee,[4] Ladan Zand,[1] Felicity T. Enders,[3,4] Vincent J. Canzanello.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Primary Care Internal Medicine, Mayo Clinic, Rochester, MN; [3]Health Sciences Research, Mayo Clinic, Rochester, MN; [4]Center for the Science of Health Care Delivery, Mayo Clinic, Rochester, MN.*

Background: Given the global CKD burden, innovative methods to improve patient's perception of autonomy and self-care are needed. We examined the association of variables in a patient motivation "Kidney and Heart Health" (KHH) Scoring system on CKD progression.

Methods: Diabetic-CKD (DM-CKD) patients were treated in a single-center, specialized clinic combining consultation from 1) hypertension-trained nurses and 2) physician/advanced practitioners. At each visit, patients were assigned points for meeting **lifestyle** (tobacco use, weight loss, alcohol use, exercise, and healthy diet) **and objective** (blood pressure, hemoglobin, LDL cholesterol, bone mineral metabolism, proteinuria, hemoglobin A1c, aspirin use) **goals**. CKD progression composite endpoint was defined as eGFR<10, dialysis, kidney transplant, or 40% reduction baseline eGFR. Time dependent cox hazards regression models examined the association between each KHH goal and CKD progression.

Results: From 2010-2016, 422 DM-CKD (eGFR 10-60mL/min/1.73m^2 inclusion) patients were treated; 61% male, 91% white, mean Charlson index 8.7±3.5, mean eGFR 31.8 ±12.1. Mean KHH score was 8.8±3.5 (out of 12). KHH categories with <75% patients reaching goal were: LDL (68%), weight (68%), bone metabolism (63%), exercise (51%), hemoglobin A1c (47%), and proteinuria (43%). Over 2.6 years (median), 177 met CKD progression composite endpoint (86 dialysis, 26 transplant, 53 eGFR <10, and 127 had 40% reduction eGFR). 82 died. Univariate hazard ratios for each category are shown, **Figure**. Multivariable models revealed older age, achieving BP, LDL, hemoglobin, bone metabolism, and exercise goals significantly associated with lower risk of CKD progression while weight and lower eGFR associated with higher risk compared to those not meeting lifestyle or objective goals.

Conclusions: Patient motivation scores used in a specialty CKD clinic relate to observed DM-CKD progression outcomes.

Effect of Oral Sodium Bicarbonate on Urine TGF-β1 in Non-Acidotic Diabetic Kidney Disease (DKD)

Kalani L. Raphael,[1,2] Tom Greene,[2] Guo Wei,[2] Alfred K. Cheung,[1,2] Srinivasan Beddhu.[1,2] *[1]VA Salt Lake City Health Care System, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT.*

Background: Oral $NaHCO_3$ may preserve GFR in CKD patients with normal serum (s) HCO_3^- by attenuating physiological responses that enhance H^+ excretion to maintain normal s-HCO_3^-, but cause kidney fibrosis. Along these lines, urine (u) NH_4^+ is directly associated with uTGF-β1 in CKD. $NaHCO_3$ reduces uNH_4^+ and, in hypertensive CKD, uTGF-β1. Whether $NaHCO_3$ reduces uTGF-β1 in DKD is unknown.

Methods: We conducted a single-center, randomized, double-blinded, placebo-controlled study in 74 US veterans with stage 2-4 DKD, ACR ≥30 mg/g, and s-HCO_3^- 22-28 meq/L. Participants received $NaHCO_3$ (0.5 meq/kg-LBW/d, n=35) or placebo (n=39) for 6 months. The primary analysis applied a mixed effect model to compare mean Δ from baseline in uTGF-β1/Cr over 3- and 6-months after controlling for baseline uTGF-β1/Cr.

Results: Mean baseline values were age 71 years, eGFR 51 ml/min/1.73m^2, SBP 127 mm Hg, ACR (median) 121 mg/g, s-HCO_3^- 24 meq/L, u-pH 5.5, uNH_4^+ 1.4 meq/hr, and u-titratable acids (uTA) 1.3 meq/hr. Baseline characteristics were similar between groups. $NaHCO_3$ had expected effects on u-pH, u-TA, and s-HCO_3^- but did not lower uNH_4^+ (Table) or uTGF-β1/Cr (Figure). $NaHCO_3$ had no effect on ACR, however eGFR was higher with $NaHCO_3$ (5.7 ml/min/1.73m^2, 95% CI 1.2-10.2). There were no significant differences in BP, weight, or s-K^+ between groups during follow-up.

Conclusions: Oral $NaHCO_3$ did not reduce uTGF-β1 or uNH_4^+ in persons with non-acidotic DKD. The effect of $NaHCO_3$ on kidney NH_3 production may be attenuated in DKD, perhaps because kidney gluconeogenesis also produces NH_3. $NaHCO_3$ increased eGFR, however long-term effects of $NaHCO_3$ on eGFR in DKD should be determined.

Funding: Veterans Affairs Support

Mean values of acid-base indices over 3- and 6-months by treatment group.

Acid-base variable	Placebo	$NaHCO_3$	p
s-HCO_3^- (meq/L)	24.3 (1.8)	25.4 (2.6)	0.07
u-pH	5.5 (0.4)	6.2 (0.5)	<.01
u-TA (meq/hr)	1.3 (0.7)	0.9 (0.6)	0.02
u-NH_4^+ (meq/hr)	1.3 (0.7)	1.2 (0.7)	0.47

Design of Pentoxifylline in Diabetic Kidney Disease (VA PTXRx)

David J. Leehey,[1,2] Ian Craig,[3] Domenic Reda,[4] Kim Carlson,[4] Todd A. Conner,[5] Rajiv Agarwal,[6] James S. Kaufman,[7] Robert Anderson,[8] Grant D. Huang,[9] Nicholas Emanuele.[1] *[1]Hines VA Hospital, Hines, IL; [2]Loyola University Medical Center, Maywood, IL; [3]Perry Point Cooperative Studies Program Coordinating Center, Perryville, MD; [4]Hines VA Cooperative Studies Program Coordinating Center, Hines, IL; [5]VA CSP CRPCC, Albuquerque, NM; [6]Roudebush VA Hospital, Indianapolis, IN; [7]VA New York Harbor Healthcare System, New York, NY; [8]Omaha VA Hospital, Omaha, NE; [9]Director, Cooperative Studies Program (CSP), Washington, DC.*

Background: Diabetic kidney disease (DKD) is the most frequent cause of chronic kidney disease (CKD) and end-stage renal disease (ESRD) in the U.S. Despite control of blood pressure and blockade of the renin-angiotensin-aldosterone system (RAAS), many patients continue to progress to ESRD, requiring costly dialysis or transplantation and resulting in high mortality. The non-specific phosphodiesterase inhibitor pentoxifylline (PTX) was approved by the FDA in 1984 for the treatment of peripheral vascular disease. Recent experimental and clinical data suggest that PTX, when added to usual care, leads to a reduction in albuminuria and inflammation and may decrease progression of DKD. However, a large scale multicenter randomized clinical trial is needed to determine whether this agent can reduce hard endpoints such as ESRD and death in patients with DKD.

Methods: VA PTXRx is a randomized, controlled multicenter Veterans Affairs (VA) Cooperative Study to test the hypothesis that PTX, when added to usual care, leads to a reduction in the incidence of ESRD and death in type 2 diabetic patients with DKD when compared to usual care plus placebo. Secondary endpoints will be: (1) quality of life (2) time until doubling of serum creatinine, (3) hospitalization for congestive heart failure (CHF), (4) a three-point MACE (cardiovascular death, non-fatal myocardial infarction, non-fatal stroke), (5) peripheral vascular disease (PVD), (6) percentage of participants with ≥ 50% reduction in urinary albumin-to-creatinine ratio (UACR) from baseline, (7) Rate of change in estimated glomerular filtration rate (eGFR) per year during the study period. Drug safety will also be analyzed as a secondary outcome. The key statistical assumption is that the primary endpoint will occur in 26.6% of the placebo group at six years with a risk reduction of 19% for PTX compared with the placebo group. The study aims to randomize 2510 participants to either PTX or placebo. The expected event rates were estimated using retrospective data from a cohort of veterans meeting study inclusion criteria obtained from a nationwide VA database.

Results: N/A

Conclusions: If PTX is found to reduce the incidence of ESRD and/or death with an acceptable safety profile, this will reduce the personal and financial burden of renal replacement therapy for patients with DKD.

Pharmacokinetic-Pharmacodynamic Relationships for the Effect of Selonsertib on eGFR in a Phase 2 Study in Subjects with Diabetic Kidney Disease

Brian J. Kirby, Cara H. Nelson, Andrew Billin, Fang Chen, Uptal D. Patel, Anita Mathias. *Gilead Sciences, Inc., Foster City, CA*.

Background: Selonsertib (SEL) is a first-in-class, small molecule apoptosis signal-regulating kinase 1 (ASK1) inhibitor in clinical development for the treatment of diabetic kidney disease (DKD) and nonalcoholic steatohepatitis. In a Phase 2 dose ranging study in subjects with Stage 3a to 4 DKD, SEL was safe and well tolerated, showed a dose-dependent acute reduction in eGFR (baseline to WK4, as a result of inhibition of renal creatinine secretion), and at the 18 mg dose resulted in 75% reduction in the slope of chronic eGFR decline (WK4 to WK48) compared to placebo. This analysis characterizes the pharmacokinetic-pharmacodynamic (PK/PD) relationships observed in this study.

Methods: Subjects were administered 2, 6, or 18 mg SEL, or placebo once daily for 48 WKs. Serum creatinine based eGFR was assessed at baseline and throughout treatment. Samples were collected for plasma exposure of SEL (AUC_{tau} by population PK) and phosphorylation status of p38 (%P-p38: downstream marker of ASK1 inhibition) in blood. PK/PD relationships for SEL exposure, %P-p38 and eGFR were characterized.

Results: 260 subjects with measureable SEL AUC_{tau},%P-p38, and eGFR estimates were included in this analysis. SEL PK/PD relationships (figure) depict the acute and chronic changes in eGFR versus SEL exposure or dose (A) and %P-p38 (B), respectively. Mean exposure from SEL 18 mg provided near maximal %P-p38 inhibition (74% of E_{max}), and resided on the flat portion of the exposure-response curve for effect on chronic eGFR slope.

Conclusions: These PK/PD analyses provide further understanding of the relationships between SEL, ASK1 pathway inhibition, acute change and chronic slope of eGFR, supporting further clinical evaluation of the safety and efficacy of SEL 18 mg in subjects with DKD.

Toxic Renal Effects from Intravitreal Bevacizumab for Proliferative Diabetic Retinopathy in the Patients with Chronic Diabetic Kidney Disease

Anita Kamarzarian,[1] Adrian Au,[3] Madeline Yung,[4] Kirollos E. Zaki,[5] Cameron Pole,[4] Golriz Jafari,[2] Phuong-Chi T. Pham.[2] *[1]UCLA -Olive View Medical Center, La Canada, CA; [2]UCLA-Olive View Medical Center, Los Angeles, CA; [3]University of California, Los Angeles, Los Angeles, CA; [4]UCLA, Los Angeles, CA; [5]Olive View - UCLA Medical Center, Sylmar, CA.*

Background: Intravitreal injection of Bevacizumab, a monoclonal antibody directed against the vascular endothelial growth factor (VEGF), has revolutionized the management of proliferative diabetic retinopathy and diabetic macular edema. Here we evaluate the effects of intravitreal bevacizumab on renal parameters.

Methods: This study is a consecutive case-control retrospective study performed from January 01, 2016 to January 01, 2017 at the Olive View-UCLA Medical Center. An initial screening of all 2763 encounters in the outpatient adult renal clinic during the study period was performed to identify patients with proliferative Diabetic retinopathy (**PDR)** recieving bevacizumab intravitreal injections and were age matched controls with dilated fundoscopic exams demonstrating sin diabetic retinopathy (**sDR**), non-proliferative diabetic retinopathy (**NPDR**), or **PDR** without bevacizumab. T0 is defined as the first injection of bevacizumab. The average follow-up prior to T0 was empirically determined to be 13.15 months. Data collected from EMR and statistical tests were performed on Microsoft Excel.

Results: Patients treated with bevacizumab had significantly higher incidence of dialysis with 50% requiring dialysis as compared to 7.1% in NPDR and PDR groups. After injection the eGFR decline over 12 months in the bevacizumab group was twice as rapid as PDR without bevacizumab (p=0.02) and four times as rapid as NPDR (p = 2.67E-0.5). There was an increase in the amount of anti-hypertensive medications used to manage HTN from 1.9 ± 1.2 to 3.2 ± 1.3 (p=0.01)

Conclusions: Diabetic patients with diabetic CKD receiving intraocular anti-VEGF therapy have more rapid rate of progression of their CKD, have higher incidence of dialysis initiation and require more antihypertensive medications. We also noted both progression and higher level of proteinuria but could not capture this effect statistically based on our study scale.

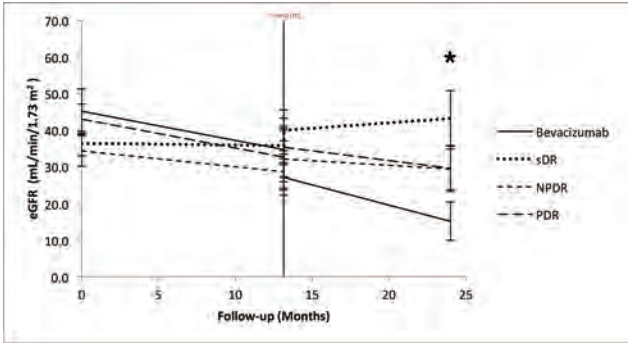

Figure 1. Rate comparison for e-GFR change between groups

SA-PO157

Effect of Bariatric Surgery on Renal Function in Morbidly Obese Patients

Anil Bhalla, Ashwani Gupta, Aakash Shingada, Anurag Gupta, Vinant Bhargava, Lovy Gaur, Anant Joshi, Devinder S. Rana. *Nephrology, Sir Ganga Ram Hospital, New Delhi, India.*

Background: Morbid obesity is associated with glomerular hyperfiltration, which favours the occurrence of proteinuria. We studied the effect of bariatric surgery on renal function in morbidly obese patients at 6 months post surgery.

Methods: This was a prospective observational study of 75 patients who underwent laparoscopic sleeve gastrectomy for weight reduction. Baseline pre-surgery BMI was calculated and serum creatinine, HbA1C level, 24 hour urinary protein excretion and creatinine clearance(CrCl) was estimated. Investigations were repeated 6 months post surgery to assess change in the renal parameters.

Results: Mean age was 38.8 years (60% females, 40% males). 51.5% patients were hypertensive & 17.6% had diabetes mellitus. Mean weight before bariatric surgery was

119.93kg with a reduction of 25.60kg (21.34%) at 6 months post surgery (p<0.0001). Mean BMI before surgery was 45.13 kg/m2 with a reduction of 9.79 kg/m2 (21.69%) at 6 months post surgery(p<0.001). Mean serum creatinine before surgery was 0.82 mg/dl with a reduction of 0.08 mg/dl (9.75%) 6 month post surgery (p<0.001). Mean pre-op HbA1c was 6.3% with a reduction of 0.74% (11.7%) at 6 months post surgery (p<0.001). Mean CrCl before surgery was 140.69 ml/min with a reduction of 22.89 ml/min (16.2%) 6 month post surgery (p<0.0001). Mean proteinuria before surgery was 224.82 mg/d with a reduction of 57.98 mg/dl (25.77%) 6 month post surgery (p<0.0001). Mean albuminuria before bariatric surgery was 62.53 mg/day with a reduction of 17.35 mg/day (27.74%) 6 months post surgery (p<0.0001). Sub-group analysis showed that pre-operative CrCl was higher in diabetics (144.50 ml/min vs 139.88 ml/min), but the reduction in creatinine clearance was similar between the two groups (p-0.092). Mean baseline proteinuria was higher in diabetics (331.25 mg/day vs 202.02 mg/day) and reduction in proteinuria at 6 month post op was more in diabetics (128.92 mg/day (38.91%) vs 42.79 mg/day (21.18%), p-0.001).

Conclusions: This study shows that obesity related glomerular hyperfiltration improves significantly after bariatric surgery with significant decline in proteinuria. The improvement in hyperfiltration may prevent the development of overt obesity related glomerulopathy.

SA-PO158

Acute Hyperoxia and Slow Deep Breathing Improve Baroreflex Sensitivity in Long-Duration Type 1 Diabetes Irrespective of Macroalbuminuria

Jens christian Laursen,[1] Christian S. Hansen,[2] Marco Bordino,[3] Emilie Hein Zobel,[2] Signe Abitz Winther,[1] Per-Henrik Groop,[3] Marie Frimodt-Moller,[1] Peter Rossing.[1] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Steno Diabetes Center, Gentofte, Denmark; [3]University of Helsinki and Helsinki University Hospital, Helsinki, Finland.*

Background: In previous studies, hyperoxia and slow deep breathing (SDB) acutely improved measures of autonomic dysfunction in young patients with type 1 diabetes (T1D) and in patients with type 2 diabetes (T2D). Such effects have not been addressed in patients with T1D and concomitant macroalbuminuria and/or existing autonomic dysfunction. The aim of this study is to examine the effect of acute oxygen inhalation and SDB on measures of autonomic dysfunction and whether these could be modified by albuminuria or existing autonomic dysfunction.

Methods: Fifty-four patients with T1D (57% male) were enrolled in a cross-sectional study where 29 patients had normoalbuminuria and 25 had presence of/or historical macroalbuminuria. Mean age (SD) and diabetes duration were 59.8 years (9.5) and 37.5 years (14.4) respectively. Patients were exposed to acute oxygen inhalation and SDB, while obtaining measures of autonomic function and blood oxygen saturation. Autonomic function was assessed by baroreflex sensitivity (BRS) and the standard deviation of the normal-normal intervals (SDNN).

Results: Acute oxygen inhalation was associated with an increase of 21.3% (95%CI 9.8;34) and 8.3% (95%CI 0.1;17) in BRS (ms/mmHg) and SDNN (ms) respectively. SDB was associated with an increase of 31.6% (95%CI 13.2;5) and 32.8% (95%CI 18.2;49.1) in BRS (ms/mmHg) and SDNN (ms) respectively. Combined oxygen inhalation and SDB was associated with an increase of 29.8% (9.8;53.4) and 44.2% (95%CI 27.1;63.5 in BRS (ms/mmHg) and SDNN (ms) respectively. Patients with existing autonomic dysfunction had an improved effect of combined interventions on BRS. Albuminuria or existing autonomic dysfunction did not modify any other associations.

Conclusions: Hyperoxia and SDB improve BRS and SDNN in T1D even in the presence of macroalbuminuria and existing autonomic dysfunction. This suggests that hypoxia might be involved in the pathogenic mechanisms of autonomic dysfunction in T1D. Further studies exploring the pathological pathways causing tissue hypoxia may improve the understanding of diabetic neuropathy.

SA-PO159

Both High Levels of Hb1Ac and HbA1c Variability Are Associated with Increased Risk of All-Cause Mortality in Patients with Diabetes and Maintenance Dialysis

Hanri Afghahi,[1] Salmir Nasic,[2] Helena Rydell,[5] Bogdan S. Matei,[4] Johan Svensson.[3] *[1]Nephrology, Skaraborgs hospital, Skövde, Sweden; [2]Skaraborg hospital, Skövde, Sweden; [3]Skaraborg Central Hospital, Skövde, Sweden; [4]Skaraborgs Hospital, Skövde, Sweden; [5]Karolinska University Hospital, Stockholm, Sweden.*

Background: Little is known of the association between variability of glycemic control and the risk of all-cause mortality in patients with diabetes and maintenance dialysis. **Aim:** We assessed the relationship between long-term glycemic control, as estimated using mean values and variability of blood HbA1c, and the risk of all-cause mortality in diabetic patients on chronic dialysis.

Methods: We included 3930 patients (age 65±14 years, 63% men) with diabetes (type 1 or 2) and regular dialysis treatment [hemodialysis (HD), n = 2487 (63%); peritoneal dialysis (PD), n = 796 (20%); and both HD and PD, n = 647 (17%)]. Data were available from the Swedish Renal Register (SNR); the follow-up period was 2008 - 2017 (mean follow-up: 2.3± 2.2 years). HbA1c was defined as the mean of the reported values. HbA1c variability was determined by the coefficient of variation (CV), calculated as the ratio between the standard deviation (SD) and the mean HbA1c, HbA1c(SD)/HbA1c(mean). Hazard ratios (HRs) and 95% confidence intervals (CIs) were calculated using time-dependent Cox models, which included adjustments for demographics, laboratory findings and comorbidity.

Results: During follow-up, 2027 (52%) deaths occurred. We used HbA1c 31-42 mmol/mol (5- 6%) as reference group. The multivariate Cox analyses showed increased mortality risk for HbA1c 62-72 mmol/mol (7.8-8.7%; HR 1.40, 95% CI 1.17 - 1.65) and HbA1c 73-82 mmol/mol (8.8-9.7%; HR 1.70, 95% CI 1.34 - 2.13) (both P<0.001). In a subanalysis of 2061 patients, we estimated the association between HbA1c variability and the risk of death. HbA1c CV< 0.5 was used as reference group. In the multivariate Cox analyses, HbA1c CVs of 2.84-4.60 and > 4.6 were associated with increased risk of mortality (HR 1.98, 95% CI 1.54- 2.47 and HR 1.99, 95% CI 1.54- 2.57, respectively) (both P<0.001).

Conclusions: We did not find a J-shaped relation between HbA1c level and risk of mortality in dialysis patients with diabetes. Instead, low mean HbA1c was associated with improved survival, and HbA1c variability was strongly associated with increased risk of all-cause mortality. These findings suggest that glycemic control as well as the stability of glycaemia level are important in patients with diabetes and maintenance dialysis treatment.

SA-PO160

Glycated Hemoglobin and Serum Fructosamine as Indicators of Glycemic Status in Patients with Type 2 Diabetes and CKD

Lubaina Presswala, Yael T. Harris, Susana Hong, Kenar D. Jhaveri, Vipulbhai Sakhiya, Meng Zhang, Steven Fishbane. CGM Study *Department of Medicine, Zucker School of Medicine at Hofstra / Northwell, Great Neck, NY.*

Background: Among patients with type 2 diabetes mellitus (T2DM) and nondialysis chronic kidney disease (n-CKD) it is unclear whether measures of chronic glycemia, HbA1C and serum fructosamine (SF), are accurate. Previous studies have been of very small sample size or failed to use continuous glucose monitoring (CGM), relying instead on a few random glucose levels. The purpose of this study was to determine the accuracy of HbA1C and SF in T2DM and n-CKD by relating to CGM data.

Methods: We studied 60 patients with T2Dm and n-CKD defined as eGFR 0-45 ml/min. Patients wore the CGM (Abbott FreeStyle Libre Pro) for 14 days, with glucose recorded every 15 minutes (maximum of 1,344 glucose measurements). Blood tests were drawn in the fasting state after the 14 day CGM. HbA1C and SF were compared by linear regression to patients' average glucose concentration (AGC) calculated as all of a patient's CGM glucose results divided by the total number of measurements.

Results: 60 patients wore the CGM for a mean of 12.7±2.9 days. Mean age was 72.4±10.4 years, 75% of patients were men, 15% were black, and mean eGFR 25.6±10.5. The mean glucose concentration was 152.2±56.6 mg/dL, mean HbA1C 7.1±1.5% and SF 301.9±57.7 μmol/L. HbA1C was significantly correlated with AGC, r=0.83, p<0.0001. The relationship was characterized by the formula, AGC=31.8 x HbA1C - 73.3. A sensitivity analysis among the 39 patients with eGFR < 30 ml/min. HbA1C remained significantly correlated with AGC, r=0.80, p=0.01 in these patients. There was no significant correlation between serum fructosamine and AGC, r=0.54, p=0.8.

Conclusions: HbA1C, but not serum fructosamine, was an excellent measure of chronic glycemic control among patients with type 2 diabetes and CKD. Further studies with larger sample sizes would be helpful to confirm these findings.

BP and Hemoglobin A1c Threshold Associated with Higher Prevalence of CKD in Elderly People with Diabetes

Jee eun Park,[2] Eun jeong Lee,[1] Wooseong Huh,[3] Dae Joong Kim,[3] Jung eun Lee.[3] *[1]Samsung Medical Center, Seoul, Seoul, Republic of Korea; [2]Kangwon National University Hospital, Chuncheon, Republic of Korea; [3]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Chronic kidney disease (CKD) is a major health problem in elderly with diabetes. The study examined the clinical parameters associated with CKD in elderly diabetes, stratified by age groups.

Methods: Total 3068 patients with diabetes ≥ 65 years old (YO) were identified. CKD was defined as albuminuria or eGFR < 60mL/min/1.73m². CKD prevalence was analyzed according to age (65-69, 70-74, ≥75 YO), HbA1c (<6.5%, intermediate, ≥7.5%) and blood pressure (BP) (<130/80, intermediate, ≥140/90mmHg).

Results: CKD prevalence increased with age (65-69 YO group: 40%, 70-74 YO group: 51%, ≥75 YO group: 67%, P < 0.001). CKD prevalence increased with HbA1c in

65-69, 70-74 YO group, but not in ≥75 YO group (P<0.001, P<0.001 and P=0.081 for trend, respectively). With higher BP levels, CKD prevalence also increased in 65-69, 70-74 YO group, but not in ≥75 YO group (P=0.002, P<0.001 and P=0.281 for trend, respectively). Multivariate analysis showed that age, sex, body mass index, HbA1c ≥7.5%, BP ≥140/90mmHg, diabetes duration were associated with CKD. However, when stratified by age, higher HbA1c and BP were not associated with risk of CKD in subjects ≥75 YO (Table 1).

Conclusions: Overall, the thresholds associated with increased prevalence of CKD were 7.5% for HbA1c level and 140/90 mmHg for BP in elderly diabetes. However, the association of CKD with BP and HbA1c levels were not evident in subjects ≥75 YO.

Anemia Modifies the Associations Between Hemoglobin A1c and Outcomes in CKD

Molly Jung,[1] Elizabeth Selvin,[10] Casey Rebholz,[2] Clare Lee,[13] Jing Chen,[3] Jiang He,[4] Chi-yuan Hsu,[5] James P. Lash,[6] Madhumita J. Mohanty,[14] Sankar D. Navaneethan,[7] Sylvia E. Rosas,[11] Elias Spanakis,[12] Matthew R. Weir,[8] Tariq Shafi.[9] *[1]Johns Hopkins University, Baltimore, CA; [2]Johns Hopkins University, Baltimore, MD; [3]Tulane School of Medicine, New Orleans, LA; [4]Tulane School of Public Health and Tropical Medicine, New Orleans, LA; [5]University of California San Francisco, San Francisco, CA; [6]University of Illinois at Chicago, Chicago, IL; [7]Baylor College of Medicine, Sugar Land, TX; [8]University of Maryland School of Medicine, Baltimore, MD; [9]Johns Hopkins University, Baltimore, MD; [10]Johns Hopkins University, Baltimore, MD; [11]Joslin Diabetes Center, Boston, MA; [12]University of Maryland, Baltimore, MD; [13]Johns Hopkins University, Baltimore, MD; [14]Wayne State University, Detroit, MI.*

Background: CKD and diabetes commonly co-occur. However, glycemic control and glycemic targets in these patients remain undefined.

Methods: In 1,833 participants of the Chronic Renal Insufficiency Cohort with diabetes, we assessed the association between baseline hemoglobin A1c (A1c) and death, first cardiovascular disease (CVD) event, and CKD progression using multivariable-adjusted Cox models. We also investigated: a) effect modification by anemia, eGFR, or albuminuria; and b) linearity of the association using spline models.

Results: At baseline, mean age was 59 years, mean eGFR was 41 mL/min/1.73 m2, mean A1c was 7.6%, and mean hemoglobin was 12 g/dL. During a median 6 years of follow-up, higher A1c was associated with worse outcomes (Figure 1); risk per 1% higher A1c was 10% for death, 10% for CVD events, and 5% for CKD progression. Anemia (hemoglobin<11 g/dL) was associated with non-linear associations for all three outcomes (Figure 2). A1c was associated with CKD progression in patients with eGFR≥30 ml/min/1.73m2 but not below that level. There was no effect modification by albuminuria.

Conclusions: In patients with CKD and diabetes, poor glycemic control contributes to a higher risk of death and CVD events. Individualized A1c targets and/or alternative markers of glycemia may be useful in diabetic CKD patients with anemia.

Poor Glycemic Control Increases Mortality in Elderly Dialysis Patients with Diabetes - A Nationwide Prospective Cohort in Korea

Jung Nam An,[1] Yong Chul Kim,[2] Yun Kyu Oh,[4] Yong-Lim Kim,[3] Chun Soo Lim,[1] Jung Pyo Lee.[1] *[1]Seoul National University Boramae Medical Center, Seoul, SEOUL, Republic of Korea; [2]SNUH, Seoul, Republic of Korea; [3]Kyungpook National University Hospital, Daegu, Republic of Korea; [4]Department of Internal Medicine, Boramae Medical Center, Seoul, Republic of Korea.*

Background: Glycemic control, defined as glycated hemoglobin (HbA1c), was known to be an important factor for mortality in diabetic end-stage renal disease (ESRD) patients. However, the clinical impacts of glycemic control had not been fully elucidated in the elderly diabetic ESRD patients. We investigated whether glycemic control had clinical impact on all-cause mortality of elderly dialysis patients with diabetes.

Methods: A total of 755 diabetic patients (≥ 65 years) who had a value of HbA1c at the time of cohort enrollment were extracted from a nationwide prospective ESRD cohort in Korea between August 2008 and February 2015. The patients were divided into three groups according to the degree of glycemic control (< 6.5%, 6.5-7.9%, and ≥ 8.0%).

Results: The patients in the highest group of HbA1c (≥ 8.0%) were 132 (17.5%), which were younger, had higher vintages of dialysis, and higher percentage of peritoneal dialysis than the other two groups. Mortality rate was 57.2% during the median follow-up of 56.3 months. Patients with poor glycemic control (≥ 8.0%) had a higher risk of mortality compared with those in the HbA1c < 6.5% (hazard ratio [HR] 1.37; 95% confidence interval [CI] 1.06-1.77; P = 0.016). In subgroup analysis by dialysis modality, HbA1c ≥ 8.0% was a risk factor for mortality in the patients on peritoneal dialysis (HR 1.66; 95% CI 1.02-2.70; P = 0.041). Multivariate analysis adjusting for age, sex, comorbidity, dialysis vintage, and dialysis modality verified a significant association between poor glycemic control (≥

8.0%) and mortality rate in the elderly diabetic ESRD patients (HR 1.53; 95% CI 1.17-2.00; P = 0.002).

Conclusions: Poor glycemic control was significantly associated with mortality in the elderly dialysis patients, which suggests that lowering HbA1c to at least less than 8.0% might decrease mortality rate.

Nutritional Status Is the Strongest Factor for Hemodialysis (HD)-Mediated Improvements in Insulin Resistance in Patients with Type 2 Diabetes

Satoshi Funakoshi,[1] Jyunichiro Hashiguchi,[2] Kenji Sawase,[1] Tayo Kawazu,[1] Yuko Maruyama,[3] Takashi Harada,[3] Yoko Obata,[4] Tomoya Nishino.[5] *[1]Nagasaki Kidney Center, Nagasaki, Japan; [2]Nagasaki Kidney Center, Nagasaki, Japan; [3]Nagasaki Kidney Center, Nagasaki, Japan; [4]Nagasaki University Hospital, Nagasaki, Japan; [5]Nagasaki University School of Medicine, Nagasaki, Japan.*

Background: Changes in C-peptide index (CPI) and HOMA-R before and after hemodialysis (HD) were compared to explore factors associated with insulin resistance in diabetic patients receiving HD.

Methods: Fasting blood samples were drawn from type 2 diabetic patients receiving maintenance HD but not insulin therapy at our clinic before HD on the first day of the week they went on HD (pre-HD) as well as on the next day (post-HD). Then CPI and HOMA-R were calculated from serum glucose, C-peptide and Immunoreactive Insulin (IRI) values to examine correlations between changes in CPI, HOMA-R, serum parameters and patient characteristics.

Results: The mean post-HD CPI and HOMA-R were significantly lower than the mean pre-HD values (CPI; 6.7 ± 2.7 vs. 8.1 ± 3.3 ng/mL, HOMA-R; 0.7 ± 0.3 vs. 1.1 ± 0.3 μU/mL, respectively) in the 19 type 2 diabetic patients (men/women, 12/7) included in the study. The rate of decrease in CPI and HOMA-R was strongly positively correlated with geriatric nutritional risk index (GNRI) (R^2 = 0.6423) in these patients, while it was not correlated with their glycoalbumin (GA) or fasting glucose values.

Conclusions: Despite reports that HD leads to resolution of uremia and excessive fluid overload resulting in improvements in insulin resistance, to date, very few reports compared insulin resistance before and after HD. This study showed that the rate of decrease in CPI was not increased in patients with favorable glycemic control but significantly increased in those with favorable nutritional status, suggesting that the patient's overall status may have a role to play in HD-mediated improvements in insulin resistance in the short term.

Free Vitamin D Is Independently Associated with Mean Arterial Blood Pressure in Diabetic Patients with Impaired Kidney Function

Daniela S. Bachert,[6] Mira Pavkovic,[3] Peter Sandner,[3] Shufei Zeng,[1] Carl-Friedrich Hocher,[5,3] Oleg Tsuprykov,[2,7] Saban Elitok,[4] Berthold Hocher.[2] Charité University Berlin *[1]Charité University Berlin, Berlin, Germany; [2]University of Potsdam, Potsdam, Germany; [3]Bayer AG, Pharmaceuticals, Wuppertal, Germany; [4]Department of Nepherology and Endocrinology/Diabetology, Klinikum Ernst von Bergmann, Potsdam, Germany; [5]Charles University, Prague, Prague, Czechia; [6]Dialysiscenter Potsdam /Institute for Nutritional Science, University of Potsdam, Potsdam, Germany, Potsdam, Germany; [7]IFLB, Institute for Laboratory Medicine Berlin, Berlin, Germany.*

Background: Blood pressure control is key for the prevention of complications of diabetes such as CKD progression. Vitamin D is thought to play a role in blood pressure regulation in diabetic patients. Total 25-hydroxyvitamin D are currently routinely used in clinical practice to assess vitamin D status. In the circulation, vitamin D – like other steroid hormones – is bound to a special carrier – vitamin D-binding protein (DBP). Only very tiny amounts of the total vitamin D are free and potentially biologically active, because only free vitamin D interact with the vitamin D receptor. The aim of the study was to compare the association of free and total vitamin D with blood pressure in diabetic patients with impaired kidney function.

Methods: Free and total vitamin D concentration were measured in 225 diabetic patients with impaired kidney function. Mean arterial blood pressure (MAP) was calculated based on 3 independent ambulatory blood pressure measurements and was 93.1 +/- 11.0 mmHg. Patients received cholecalciferol if needed. The cholecalciferol dose was adjusted after total vitamin D measurements every 3 months to meet vitamin D serum targets as defined by the German Society of Nutritional Medicine. Multiple linear regression analysis considering age, sex, BMI, eGFR, family history of hypertension, treatment with antihypertensive drugs and diuretics as confounding factors.

Results: This study revealed that free vitamin D was independently associated with MAP (p=0.026, CI: -1.285 – -0.049) whereas total vitamin D was not associated with MAP (p=0.308; CI: - 0.285 – 0.091).

Conclusions: Free – but not total - vitamin D serum concentrations in patients with diabetes and impaired kidney function are interdependently invers correlated with blood pressure, a key disease progression factor. This study suggests that free vitamin D measurements might be a better clinical tool – as compared to measurements of total vitamin D - to adjust vitamin D therapy in diabetic patients with impaired kidney function. However, reference values and treatment targets for free vitamin D in diabetic patients with impaired kidney disease have to be established.

SA-PO166

Trends of Non-Traumatic Lower Extremity Amputation in People with ESRD, by Diabetes Status, United States, 2000-2015

Jessica L. Harding, Meda E. Pavkov, Nilka Rios Burrows, Edward Gregg. *Centers for Disease Control and Prevention, Atlanta, GA.*

Background: Non-traumatic lower extremity amputation (NLEA) is a complication of end-stage renal disease (ESRD) and diabetes mellitus (DM). Contemporary trend data on NLEA among people with ESRD are lacking.

Methods: We estimated incident NLEA hospitalizations during 2000-2015 in adults with ESRD from the U.S. Renal Data System. Rates of first NLEA were estimated for any NLEA, minor NLEA (below ankle) and major NLEA (through or above ankle) using ICD-9 procedure codes from January 2000 to September 2015 and ICD-10 from October to December 2015. Hospitalization rates were stratified by primary cause of ESRD (DM or no-DM). Time trends were assessed using Joinpoint regression and annual percent changes (APC) reported.

Results: Among ESRD-DM, age-standardised rates for any NLEA declined 32% (from 36.4 to 24.9 per 1,000 persons) from 2000-2010 (APC= -3.87, p<0.05), and then did not change from 2010-2015 (APC=0.21, p=0.8) (Figure). Major NLEA rates declined 49% throughout the period (APC=-4.98, p<0.05), and minor NLEA rates declined 22% from 2000-2009 (APC=-2.63, p<0.05) and then did not change from 2009-2015 (APC=1.42, p=0.08). Among ESRD-noDM, rates for any NLEA declined 25% (from 5.3 to 4.0 per 1,000 persons) from 2000-2008 (APC=-3.66, p<0.05), and then did not change from 2008-2015 (APC=0.52, p=0.4). Major NLEA rates declined 39% from 2000-2011 (APC=-4.95, p<0.05) and then did not change from 2000-2015 (APC=1.02, p=0.6), and minor NLEA rates did not change from 2000-2008 (APC=-1.31, p=0.08) and then increased 19% from 2008-2015 (APC=2.47, p<0.05).

Conclusions: Despite an initial period of decline, the later stagnation in rates of any NLEA in adults with ESRD seem to be driven by a lack of further declines in minor NLEAs. Increased attention to preventive foot care in the ESRD population might be considered, particularly for those with ESRD-DM where NLEA rates remain almost six times higher than ESRD-noDM.

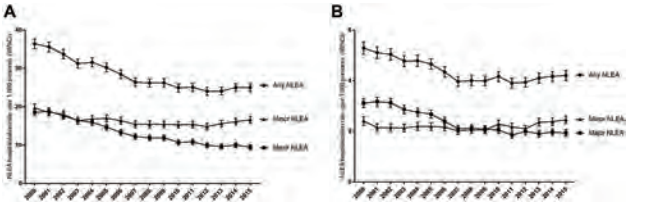

Figure Age-standardized hospitalization rates for non-traumatic lower extremity amputations (NLEA) among people with ESRD with diabetes (DM) (A) and without diabetes (noDM) (B), United States, 2000-2015

SA-PO167

A European Hemodialysis Multicenter Implementation of a Standardized Diabetic Foot Examination Protocol

Werner Kleophas,[1] Maciej B. Drozdz,[2] Szymon Brzosko,[3,4] Joao M. Frazao,[5] Fatima F. Silva,[6] Abdulkareem Alsuwaida,[7,8] Mahesh Krishnan,[9] Stefan H. Jacobson.[10] *[1]DaVita Germany, Dusseldorf, Germany; [2]DaVita Poland, Krakow, Poland; [3]DaVita Poland, Bialystok, Poland; [4]Department of Nephrology, Medical University of Bialystok, Bialystok, Poland; [5]Nephrology and Infectiology Research and Development Group, INEB, and School of Medicine, Porto University, Portugal, Porto, Portugal; [6]DaVita Portugal, Alfragide, Portugal; [7]King Saud University, Riyadh, Saudi Arabia; [8]DaVita Saudi Arabia, Riyadh, Saudi Arabia; [9]DaVita, Inc, Denver, CO; [10]Danderyd Hospital, Stockholm, Sweden.*

Background: Diabetics on hemodialysis (HD) have an increased risk for foot ulcers (FU), infections, and limb amputation. Pain and other symptoms are often reduced due to

neuropathy resulting in late diagnosis. We assessed the frequency of foot complications following implementation of a standardized foot examination in a cohort of prevalent diabetic HD patients in 26 DaVita centers in Germany, Poland and Portugal. We analyzed differences and associations with demographic data, practices and laboratory data.

Methods: A standardized foot examination was performed in 1025 diabetic HD patients in Germany (n=674), Poland (n=179) and Portugal (n=172). The examination includes: previous FU, amputation etc; inspection of feet (skin, nails); examination of pedal pulses (a dorsalis pedis and tibialis posterior) and foot sensory level. Foot complications were classified according to Wagner (grade 0-5); PAD was classified by clinical pulse measurement (normal=0, weak=1, missing=2).

Results: Mean (SD) patient age was 70.4 (14) years (NS between countries). 8.7% had a prior amputation; this was less common in Germany ($p<0.001$). A normal pulse in left and right a dorsalis pedis was present in 45% and 44% of patients, respectively, pulses were absent in 33% and 34% ($p<0.001$ between countries). For left and right a tibialis posterior, normal pulse was present in 37% and 37% of patients, respectively, pulses were absent in in 43% and 42% ($p<0.001$ between countries). Wagner classification score was 0 or 1 in 95.5% of patients and 4-5 in 1.8% (NS between countries). In a subgroup of 351 patients from Poland and Portugal there were no significant correlations between Wagner score and age, sex, BMI, Kt/V, vascular access, Charlson comorbidity index, Hb, albumin, phosphorus, and PTH. Patients with skin edema were older ($p<0.05$), had higher Charlson comorbidity index ($p<0.05$), lower Hb ($p<0.05$), lower albumin ($p=0.01$) and higher phosphorus ($p=0.004$).

Conclusions: Implementation of a standardized foot examination protocol in a large cohort of European diabetic patients on HD revealed a high prevalence of clinically significant complications that warrant close attention. This simple clinical tool is suitable to identify patients at high risk and could be the basis of a program to improve health outcomes.

SA-PO168

Prevalence of Increased Rate of Reduced Estimated Glomerular Filtration despite Advances in Diabetes Mellitus Treatment

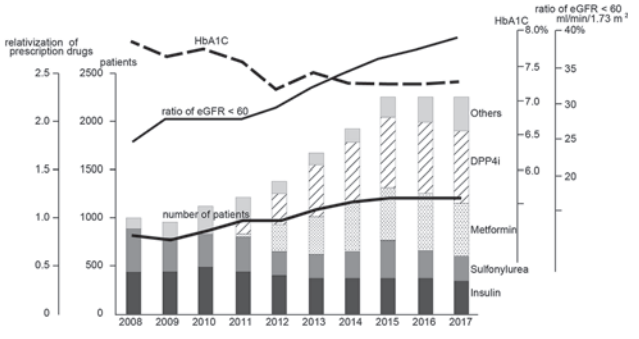
Makoto Araki. *Suwa Central Hospital, Chino, Japan.*

Background: Unlike in other countries, diabetes treatment in Japan follows a unique approach, such as the rare use of metformin before 2010 and the frequent use of dipeptidyl peptidase-4 inhibitor (DPP4i) after 2009. We investigated the pharmacological effects of antidiabetic drugs on glycemic control and renal function in Japan.

Methods: We conducted a retrospective, serial, cross-sectional analysis of individuals aged ≥18 years who used more than one antidiabetic drug at a single center in Japan between 2008 and 2017. The exclusion criteria were individuals who had continuously sustained an estimated glomerular filtration rate (eGFR) of <10 ml/min/1.73 m^2 (including those who received chronic dialysis). All data were extracted from patient's medical records.

Results: Between 2008 and 2017, the number of patients with diabetes mellitus has increased from 805 to 1190, and the average age of diabetic patients has increased from 65.6 to 68.8 years. Meanwhile, the number of prescription drugs has increased by 2.3 times. The use of antidiabetic drugs has remarkably increased the DPP4I and metformin levels (0% to 34% and 24%, respectively), whereas the insulin (46% to 15%) and sulfonylurea (42% to 11%) levels have decreased. The hemoglobin A1c levels have improved (7.8% to 7.3%); however, eGFR has decreased (from 73 to 65 ml/min/1.73 m^2), and the ratio of eGFR <60 ml/min/1.73 m^2 group has increased (from 25% to 39%). This tendency remained unchanged even when analyzed for background-matched cases between 2008 and 2017.

Conclusions: Pharmacological advances in the treatment of diabetes mellitus can improve glycemic control but not renal function.



SA-PO169

Declining CKD Prevalence Among Patients with Diabetes in the United States

Jennifer L. Bragg-Gresham, Xiaosong Zhang, William H. Herman, Rajiv Saran. *University of Michigan, Ann Arbor, MI.*

Background: Diabetes mellitus (DM) is a major risk factor for the development of chronic kidney disease (CKD) and is the assigned primary cause for almost half of all new end stage renal disease cases in the US. Diabetics with high blood pressure, poor glucose control, inherited tendency, and poor diet are at an increased risk of developing CKD. In this work, we sought to examine the prevalence of CKD among diabetics over time in the US.

Methods: Data from 5,278 patients with DM (diagnosed, taking medication, or HbA1c > 7%) from the National Health and Nutrition Examination Survey (NHANES, 2001-2016) was examined to estimate prevalence of CKD in 4-year cohorts, using population survey weights. CKD was defined either as an estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73m^2 or urine albumin-to-creatinine ratio (UACR) > 30 mg/g. Weighted logistic regression was used to assess significance of this decline.

Results: The prevalence of CKD among patients with DM declined steadily from 2001 to 2016. In contrast, the prevalence of CKD among patients with hypertension (HTN; diagnosed, receiving antihypertensive medication, or blood pressure >140/90) did not show a similar trend. The decline in CKD prevalence for DM is primarily driven by a lower prevalence of albuminuria (UACR > 30 mg/g) rather than low eGFR, which appeared stable over these years. This trend was significant with an OR=0.90 (95% CI: 0.85-0.96) per each 4-year more recent time period and increased in magnitude when adjusted for patient demographics (OR=0.88, 95% CI: 0.82-0.94).

Conclusions: The prevalence of CKD, in particular albuminuria, among patients with DM has decreased steadily in the US over the past 16 years, while its prevalence among patients with HTN has been stable. Future work will investigate potential reasons for this steady decline, such as greater awareness of diabetes and its complications, improvements in blood pressure control, glycemic control, adherence to healthier diet, weight control, and physical exercise.

SA-PO170

Younger Age, Afro-Caribbean Ethnicity, and Residual Albuminuria Predict Renal Function Decline in Patients with Diabetic Kidney Disease on Renin Angiotensin System Blockade

Nikolaos Fountoulakis,[2] Luigi Gnudi,[3] Janaka J. Karalliedde.[1] *[1]King's College London, Kent, United Kingdom; [2]King's College London, London, United Kingdom; [3]King's College London, London, United Kingdom.*

Background: There is heterogeneity in the progression of renal function decline in diabetic kidney disease (DKD). The clinical markers and patient features that predict loss of renal function in DKD despite renin angiotensin system (RAS) treament remain unclear.

Methods: In a single centre study we studied 266 (n=50 Type 1 and n=216 Type 2) patients with DKD on RAS blockade. All patients had baseline estimated glomerular filtration rate (eGFR) by Modification of Diet in Renal Disease Study equation >45 ml/min. Patients were followed up for a median 10 years with standardised clinical care measures. Primary endpoint was progression of DKD defined as eGFR fall >5ml/min/year or end stage renal disease (ESRD-dialysis or transplantation). In a cause specific Cox proportional hazards model predictors of ESRD were also evaluated with death from any cause as competing event.

Results: In the T1DM cohort patients with progression (n=13) as compared to those without (n=37), In multivariate analyses [odds ratio (OR) and 95% confidence intervals (CI)] duration of diabetes OR 0.74 (0.56 - 0.99), baseline eGFR 1.09 (1.01 to 1.17) and ACR 9.5 (1.35- 66.7) were independent predictors of progression, $p<0.05$ for all. Similarly for T2DM cohort (n=216, 62% male, 40% Afro-Caribbean), 20% (n=50) had progression. Baseline eGFR, OR (95%CI), 1.04 (1.02 to 1.06) and ACR 1.4 (1.05-1.9) were independent predictors of progression, $p<0.05$ for all. In T2DM 44 patients developed ESRD, these patients as compared to those without ESRD (n=172) were younger (57.3 ± 10.5 vs. 62 ± 10.4 years), more likely to be Afro-Caribbean (87% vs. 34%) with higher ACR [30.0 (12.7 - 30.0) vs. 9.1 (2.0 - 30.0) mg/mmol], $p<0.05$ for all. In cause specific competing risk analyses, hazard ratio (95% CI), age 0.94 (0.91 - 0.98), Afro-Caribbean ethnicity 2.30 (1.07 - 4.90), and ACR 1.53 (1.08 - 2.16) were independent predictors of ESRD, $p<0.05$ for all.

Conclusions: In DKD residual albuminuria despite RAS blockade increased risk of significant renal function decline. In T2DM younger age, residual albuminuria and Afro-Caribbean ethnicity increase risk of ESRD. Treatments that reduce residual albuminuria despite RAS may help reduce progression of DKD.

SA-PO171

Comparison of Risk Prediction Using the CKD-EPI Equations or the MDRD Study Equation for Estimated Glomerular Filtration Rate in Chinese Patients with Diabetic Nephropathy

Yiting Wang. *Division of Nephrology, West China Hospital of Sichuan University, Division of Nephrology, West China Hospital of Sichuan University, Chengdu, China.*

Background: To evaluate risk implications of estimated glomerular filtration calculated by CKD-EPI equations ($eGFR_{CKD\text{-}EPI\text{-}CysC}$, $eGFR_{CKD\text{-}EPI\text{-}Cr\text{-}CysC}$) compared to eGFR by $eGFR_{CKD\text{-}EPI\text{-}Cr}$ and $eGFR_{MDRD}$ in Chinese patients with diabetic nephropathy (DN).

Methods: A retrospective study was conducted 363 patients with renal-biopsy DN, 227 patients of them were followed up at least one year. The stages of chronic kidney disease (CKD) were classified by different equations. The eGFR concordance between each two equations was assessed by Bland–Altman plots. The correlation between eGFR and pathological findings was using Spearman analysis. The end point was defined by receiving renal replacement therapy (RRT). Log Rank and Cox regression were employed to evaluate risk implications of $eGFR_{CKD\text{-}EPI}$ and $eGFR_{MDRD}$.

Results: Overall, the proportion of CKD 3-5 stages (eGFR, 60mL/min/1.73 m^2) was 57.2%, 56.1%, 72.1%, and 64.1% by the $eGFR_{MDRD}$, $eGFR_{CKD\text{-}EPI\text{-}Cr}$, $eGFR_{CKD\text{-}EPI\text{-}CysC}$ and $eGFR_{CKD\text{-}EPI\text{-}Cr\text{-}CysC}$ respectively. The concordance between $eGFR_{CKD\text{-}EPI\text{-}CysC}$ and $eGFR_{CKD\text{-}EPI\text{-}Cr\text{-}CysC}$ (mean bias: 1.20), and between $eGFR_{MDRD}$ and $eGFR_{CKD\text{-}EPI\text{-}Cr}$ (mean bias: 4.21) were superior to others. However, the bias of $eGFR_{MDRD}$ and $eGFR_{CKD\text{-}EPI\text{-}Cr}$ enlarged when eGFR was great than 60mL/min/1.73 m^2. Compared to $eGFR_{CKD\text{-}EPI\text{-}Cr}$, 40% and 18% of patients were reclassified from CKD 1-2 stages to CKD 3-5 by CKD-EPI-CysC and CKD-EPI-Cr-CysC, respectively, and reached the end point quicker than not reclassified patients (P<0.01); 67.6% and 55.3% of patients with $eGFR_{CKD\text{-}EPI\text{-}Cr}$ 45-60 were reclassified to CKD 3b-5 stages by CKD-EPI-CysC and CKD-EPI-Cr-CysC, respectively, however, no significant difference of renal survival time was observed compared to not reclassified patients. The results were similar when compared to $eGFR_{MDRD}$. The hazard ratio was 0.960 (95% CI 0.949-0.971), 0.961 (95% CI 0.950-0.971), 0.940 (95% CI 0.925-0.955) and 0.947 (95% CI 0.934-0.960) for $eGFR_{MDRD}$, $eGFR_{CKD\text{-}EPI\text{-}Cr}$, $eGFR_{CKD\text{-}EPI\text{-}CysC}$ and $eGFR_{CKD\text{-}EPI\text{-}Cr\text{-}CysC}$ respectively, when eGFR was regarded as continuous variables.

Conclusions: $eGFR_{CKD\text{-}EPI\text{-}CysC}$ and $eGFR_{CKD\text{-}EPI\text{-}Cr\text{-}CysC}$ classified more patients to CKD 3-5 stages and more accurately categorized the risk of RRT than did $eGFR_{CKD\text{-}EPI\text{-}Cr}$ in Chinese DN patients.

SA-PO172

Socioeconomic, Demographic, and Clinical Associations of CKD in Diabetes in a Population-Based Australian Cohort: Results from the EXTEND45 Study

Louisa Sukkar,[1,2] Amy Kang,[1] Min Jun,[3] Celine Foote,[1] Roberto Pecoits-Filho,[4] Brendon L. Neuen,[1] Kris Rogers,[1] Alan Cass,[7] Carol A. Pollock,[5] Germaine Wong,[5] John Knight,[1] David Peiris,[1] Martin P. Gallagher,[1] Meg J. Jardine.[6] EXTEND45 Steering Committee *[1]The George Institute for Global Health, Sydney, NSW, Australia; [2]School of Public Health, The University of Sydney, Sydney, NSW, Australia; [3]The George Institute for Global Health, UNSW Sydney, Newtown, NSW, Australia; [4]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [5]The University of Sydney, St. Leonards, NSW, Australia; [6]The George Institute for Global Health, UNSW, Newtown, NSW, Australia; [7]Menzies School of Health Research, Darwin, NT, Australia.*

Background: Type 2 diabetes is the leading cause of Chronic Kidney Disease (CKD) in the developed world. Identifying people with diabetes at increased risk of developing CKD is the first step to developing preventative strategies to reduce this burden. We aimed to estimate the incidence rate and associations of CKD in people with diabetes.

Methods: Based on data from the EXTEND45 study (the 45 and Up Study linked to [1] hospital and community pathology datasets by the Centre for Health Record Linkage [CHeReL] and [2] the Medicare Benefits Schedule [MBS] and Pharmaceutical Benefits Scheme [PBS] datasets provided by the Department of Human Services), we identified a population-based Australian cohort (2006-2014) of 24,400 people aged ≥45 years with diabetes. We used Poisson regression to estimate CKD (eGFR<60 ml/min/1.73m^2) incidence and prevalence. Multivariable Cox regression was used to examine associations between baseline sociodemographic factors, comorbidities and incident CKD

Results: Of 24,400 participants with diabetes, 2,789 (11.4%) had prevalent CKD and 1,771 (7.2%) developed incident CKD over a mean follow-up of 4.3 years. CKD incidence rate was 4.93 (95% confidence interval [CI]: 4.70-5.16) per 100 person-years. Compared to those who had no CKD, those with CKD were older (mean age: 64.7, 75.2, 70.2 years, for no CKD, prevalent CKD, incident CKD respectively), had a lower proportion of current smokers (7.9%, 3.1% 4.7% respectively) and a lower proportion with an annual household income of >$70,000 (17.1%, 6.2%, 10.5%). Incident CKD was predicted by age (hazard ratio [HR]: 1.07 [1.07-1.08] per year increase), geography (Outer regional vs major city: 1.41 [1.17-1.69]), BMI (obese vs normal: 1.43 [1.23-1.68]), presence of hypertension (1.48 [1.27-1.73]), coronary heart disease (1.24 [1.11-1.40]) and depression (1.26 [1.09-1.45]).

Conclusions: In a contemporary cohort of Australians with diabetes, the incidence of CKD is high and independently predicted by age as well as geography, obesity, a baseline history of cardiovascular disease and depression. These associations provide potential targets for early intervention in these at risk groups.

Funding: Commercial Support - The EXTEND45 Study is funded through peer-reviewed (NSW Cardiovascular Research Network Collaborative Project Grant), and unrestricted industry (from MSD, Amgen and Eli Lilly) research grants.

Large Cross-Sectional Study Revealed the Conditions, Pathogenesis, and Progression of Diabetic Kidney Disease and Early Decliner in Japan

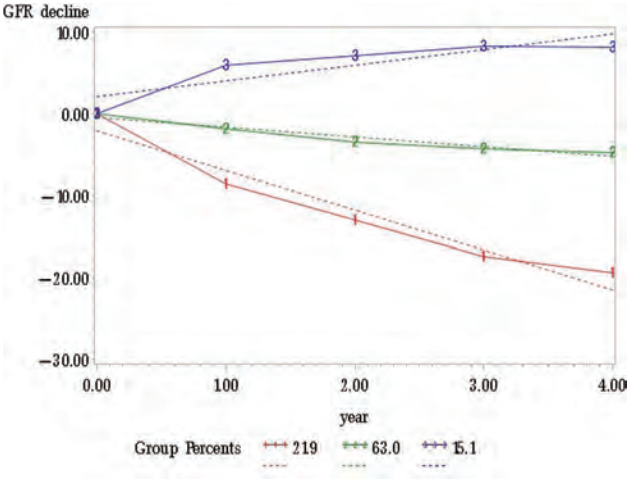
Yui Yoshida, Yosuke Hirakawa, Tetsuhiro Tanaka, Masaomi Nangaku. Division of Nephrology and Endocrinology, the University of Tokyo *the University of Tokyo, Tokyo, Japan.*

Background: Estimated glomerular filtration rate (eGFR) decline precedes albuminuria in a certain portion of diabetic patients. Thus, albuminuria and/or low eGFR in diabetic patients were defined as 'Diabetic Kidney Disease (DKD)'. In addition, the existence of 'early decliner' attracts a lot of attention, whose eGFR declines rapidly from early stage in DKD patients. To understand the prevalence of DKD and the risk factor of early decliner, we integrated several cohorts and cross-sectional data.

Methods: We continue adding up the 14,000 patients data with 9 hospitals, who were diagnosed as diabetes mellitus and did not receive dialysis. Prevalence was calculated based on cross-sectional data in the baseline of each cohort. We defined DKD as albuminuria ≥ 30 mg/gCr and/or eGFR < 60 ml/min/1.73m^2. We did 2 types of analysis to look for the risk factors of early decliner, firstly by defined eGFR declined by more than 5 ml/min/1.73m^2/year with normal eGFR in the baseline and secondly by trajectory analysis to compare with the provisional standard.

Results: The proportion of DKD was 52% in total with available data. 8.3% patients were categorized as early decliner with the definition of eGFR decline by more than 5 ml/min/1.73m^2/year. By trajectory analysis, 21% patients were classified as early decliner whose eGFR decline rate was 4.84 ml/min/1.73m^2/year (Image). Two kinds of analyses revealed that the common risk factors with early decliner group were high level of albuminuria and eGFR in the baseline.

Conclusions: The proportion of DKD were over 50% in all diabetic patients in Japan. The mean eGFR decline rate of early decliner by trajectory analysis was 4.84 ml/min/1.73m^2/year, similar to provisional standard. The common risk factors of early decliner were high level of albuminuria and eGFR in the baseline status by two types of analyses.



Classification of eGFR trajectories.

Inflammation and Kidney Injury in Diabetic African American Men

Elimelda M. Ongeri,[1] Lei Cao,[1] Olugbemiga E. Jegede,[2] Scott H. Harrison,[1] Robert H. Newman.[1] *[1]Biology, North Carolina A&T State University, Greensboro, NC; [2]Cone Health, Greensboro, NC.*

Background: African Americans (AA) are disproportionately burdened by diabetes and diabetic kidney disease (DKD). However, little is known about the cellular and molecular mechanisms underlying the onset and progression of DKD in this population. AA men are especially underrepresented in biomedical research. We recently reported undiagnosed kidney injury in a significant proportion of diabetic AA men served by a community clinic in Greensboro, NC. The goal of the current study was to determine the association between specific inflammation markers and kidney injury in diabetic AA men.

Methods: We recruited three groups of AA men aged 18-65 years: 1) diabetics without diagnosed kidney disease (n=87); 2) diabetics with diagnosed DKD (n=20); and 3) age-matched non-diabetic controls (n=81). Assays for urinary albumin and creatinine as well as plasma kidney injury molecule 1 (KIM-1) and urinary neutrophil gelatinase associated lipocalin (NGAL) were used for biochemical assessment of kidney function. Enzyme-linked immunosorbent assays were used to measure the plasma and urinary levels of seven inflammatory markers: adiponectin, C-reactive protein (CRP), tumor necrosis factor-α (TNF-α), TNF receptor 1 (TNFR1), TNF receptor 2 (TNFR2), interleukin-6 (IL-6), and intercellular cell adhesion molecule-1 (ICAM-1). A heat map was generated for the "inflammation profile" for each individual in the study.

Results: Plasma levels of TNF-α, TNFR1 and TNFR2 increased with severity of DKD and were significantly higher in diabetic patients with macroalbuminuria compared to non-diabetic controls and diabetics with normoalbuminuria or microalbuminuria. Likewise, urinary levels of ICAM-1 were higher in diabetic patients with macroalbuminuria compared

to the other groups. Indeed urinary ICAM-1, plasma TNF-α, and plasma adiponectin had moderate positive correlations with UACR while the levels of TNFR1 and TNFR2 in the plasma were strongly correlated with kidney injury. In contrast, though plasma CRP was elevated in diabetics relative to non-diabetic controls, its levels did not correlate with kidney injury. The number of individuals with elevated levels of multiple inflammation markers increased with the severity of kidney injury.

Conclusions: These data suggest that inflammation, particularly that mediated by the TNF-α/NF-κB signaling axis, may play a role in the pathogenesis of DKD in AA men.

SA-PO175

Sex Disparity to Kidney Transplant Varies by Cause of ESRD

Patrick Ahearn, Kirsten L. Johansen, Charles E. McCulloch, Barbara A. Grimes, Elaine Ku. *UCSF, San Francisco, CA.*

Background: Women are significantly less likely to undergo transplantation than men. The possibility that transplant access differs by underlying cause of ESRD among men and women has not been thoroughly evaluated.

Methods: Using data from the US Renal Data System (USRDS), we performed a retrospective cohort study of adults who required their first renal replacement therapy between January 1, 1995 and June 30, 2016. In two approaches, considering either all patients with ESRD or only those with a waitlist date, we examined the association between sex and likelihood of transplant by cause of ESRD (including diabetes mellitus type 2 (DM2), hypertension, cystic/obstructive disease, and diabetes mellitus type 1) using adjusted Cox models.

Results: There were 266,616 kidney transplants among 2,228,769 adults with ESRD. In fully adjusted analyses, the likelihood of transplant for women was 0.82 (95% CI 0.82-0.83) times that of men in the full cohort and 0.91 (95% CI 0.90-0.92) times that of men considering only those registered on the waitlist. In both analyses, cause of ESRD modified the association between sex and access to transplantation ($p<0.001$), such that likelihood of transplant was markedly lower in women (vs. men) with ESRD due to DM2. In contrast, the sex disparity in transplant access was less profound in women with other causes of ESRD (figure).

Conclusions: Sex disparity in kidney transplant access varies substantially by cause of ESRD. Regardless of whether analyses included all patients with ESRD or only those registered on the waitlist, women (vs. men) with DM2 had the lowest access to kidney transplant compared to women (vs. men) with other attributed causes of kidney disease. This disparity is concerning, given that DM2 is the leading cause of ESRD in the US, and these patterns were observed even among those waitlisted for transplant.

Establishing a Hazard Predictive Model of Renal Outcomes for Diabetic Nephropathy

Qiqi Feng,[1] Tan-qi Lou.[2] *[1]The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.*

Background: The present study aims to find out the independent risk factors associated with loss of renal functions in diabetic nephropathy (DN) and to further establish a hazard predictive model to evaluate prognosis of DN patients.

Methods: We enrolled patients with biopsy-proven DN in our hospital between January 2004 to June 2014. They were followed up until reaching the renal end-points including renal replacement therapy and doubling of serum creatinine before 31 December 2014. Univariate and multivariate Cox regression models were used to determine the independent variables associated with prognosis. A hazard predictive model was established based on the prognostic index (PI) determined by the regression coefficients in the multivariate Cox model.

Results: The mean follow-up duration was 25.9 months. Of the 57 people enrolled in this study, 25 reached the renal outcomes. The clinical and pathological parameters associated with renal outcomes in the univariate Cox regression models were introduced into the multivariate Cox models which showed that estimated glomerular filtration rate (eGFR), blood urea nitrogen (BUN), hemoglobin and scoring of interstitial fibrosis and tubular atrophy (IFTA) were independent risk factors for reaching renal end-points. The independent risk factors were included in the PI calculations to establish the hazard predictive model of renal outcomes. Participants were randomly divided into the training set ($n = 38$) and the validation set ($n = 19$). Patients with PI≤0.807 were assigned to the low-risk group while patients with PI>0.807 were assigned to the high-risk group based on the cut-off point of the ROC curve (AUC 0.901, 95%CI 0.800-1.000, $P = 0.000$) with the renal endpoints as the state variable and PIs as the test variable in the training set. The survival analysis showed that there was significant difference in the renal survival curves between the low-risk group and the high-risk group in both sets. The AUCs of ROCs in both sets were greater than the AUCs of ROCs of any single risk factors.

Conclusions: The hazard predictive model combining clinical and pathologic independent variables were able to predict prognosis of DN with more accuracy so as to help clinicians act early to patients with high risk of developing ESRD.

SA-PO177

The Relationship of Pathologic Classification and Prognosis in Diabetic Nephropathy

Qiqi Feng,[1] Meijun Si,[2] Yuanqing Li.[1] *[1]The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]The third affiliated hospital, Sun Yat-sen University, Guangzhou, China.*

Background: The present study is aimed to explore the relationship between clinical manifestations and pathological changes in diabetic nephropathy (DN) and to assess the predictive power of the pathologic classification for DN established by the Renal Pathology Society in 2010.

Methods: Patients with type 1 or type 2 diabetes and biopsy-proven DN in the Third Affiliated Hospital of Sun Yat-sen University between January 2004 to June 2014 were enrolled in the present study and were followed up until 31 December 2014. The outcome was defined as renal end-points including renal replacement therapy and doubling of serum creatinine as well as all-cause mortality. The laboratory and histologic data were analyzed and outcomes were assessed using survival analysis.

Results: The Fifty-seven people enrolled in this study were categorized into Class IIa ($n = 9$), Class IIb ($n = 9$), Class III ($n = 25$) and Class IV ($n = 14$) while no participants belonged to Class I. The changes of Class IIa were slight and those of Class IV were severe both in the clinical data (diabetic duration, blood pressure, eGFR, urine protein excretion rate, albumin and hemoglobin) and the pathological data (percentage of global glomerulosclerosis, percentage and scoring of interstitial fibrosis and tubular atrophy, scoring of interstitial inflammation and incidence of large vessel lesions). There were no significant differences between Class IIb and III in the above variables except for the scoring of arteriosclerosis. The mean follow-up duration was 25.9 months. Twenty-five patients reached the renal outcomes and six people reached all-cause mortality. The survival analysis showed that there were significant differences among the renal survival curves of different glomerular classes and of different interstitial and vascular scorings, but not in the survival curves related to all-cause mortality.

Conclusions: The glomerular classes were not completely associated with renal prognosis in that the clinical manifestations and renal outcomes were benign in Class IIa, moderate but similar in Class IIb and III and severe in Class IV. The glomerular classification and interstitial and vascular scorings were associated to renal prognosis but not to mortality.

SA-PO178

Similarity and Difference of Clinicopathological Features Between Diabetic Nephropathy and Hypertensive Nephrosclerosis: A Nationwide Kidney Biopsy Study in Japan

Kengo Furuichi,[1] Miho Shimizu,[2] Tadashi Toyama,[3] Yasunori Iwata,[1] Norihiko Sakai,[1] Takashi Wada.[1] *[1]Kanazawa University, Kanazawa, Japan; [2]Division of Nephrology, Kanazawa University Hospital, Kanazawa, Japan; [3]Kanazawa University Hospital, Kanazawa, Japan.*

Background: Diabetic kidney disease is the major cause of end-stage kidney disease in developed countries. Moreover, hypertensive nephrosclerosis is increasing cause of end-stage kidney disease in Japan. In this study, we evaluated clinicopathological features between diabetic nephropathy and hypertensive nephrosclerosis using nationwide biopsy samples in Japan.

Methods: The clinical data of 600 biopsy-confirmed diabetic nephropathy patients and 184 biopsy-confirmed hypertensive nephrosclerosispatients were collected retrospectively from 13 centres throughout Japan under the support from the Japan Agency for Medical Research and Development. Pathological features and decreasing rate ofestimated GFR (eGFR) were evaluated between the two biopsy cohorts under the CKD heat map classification.

Results: The median observation period was 70.4 (IQR; 20.9-101.0) months in diabetic nephropathy and 73.2 (IQR; 31.2-116.4) months in hypertensive nephrosclerosis. In the CKD heat map categories, Green and Yellow (G&Y), Orange and Red category contained 103, 149, and 348 cases in diabetic nephropathy and 36, 57, and 91 cases in

hypertensive nephrosclerosis, respectively. In clinical factors, body mass index, systolic and diastolic blood pressure were higher in patients with hypertensive nephrosclerosis than diabetic nephropathy in G&Y category. Declining speed of eGFR was no difference between two cohorts (diabetic nephropathy, hypertensive nephrosclerosis; 1.7, 2.4 mL/min/1.73 m^2/year, respectively). However, there was no difference in pathological findings between two groups in the category. In contrast to G&Y category, declining speed of eGFR was higher in patients with diabetic nephropathy than hypertensive nephrosclerosis in Red category (diabetic nephropathy, hypertensive nephrosclerosis; 5.8, 1.3 mL/min/1.73 m^2/year, respectively). In accordance with the clinical findings, pathological findings of interstitial fibrosis and cell infiltration and arteriolar hyalinosis were progressed in diabetic nephropathy in Red category.

Conclusions: Although, it is so difficult to clearly distinguish pure kidney lesions caused by diabetes and hypertension, it would be important that these overlapped pathological findings be confirmed on kidney biopsy in diabetic cases with hypertension.

The Safety and Feasibility of Obtaining Research Kidney Tissue from Patients with Diabetes: Transformative Research in Diabetic Nephropathy (TRIDENT Study)

Amy K. Mottl,[2] Katalin Susztak,[1] Jonathan J. Hogan,[3] Pietro A. Canetta,[14] Kirk N. Campbell,[4] Matthias Kretzler,[5] Tamara Isakova,[6] Christos Argyropoulos,[7] Richard A. Lafayette,[8] Shweta Bansal,[9] Harold M. Szerlip,[10] Salem Almaani,[11] Randy L. Luciano,[12] Raymond R. Townsend,[13] Kishor B. Devaraja-Narashimha,[15] Nick Cammack,[16] Shira Blady,[1] Matthew Palmer,[1] Paolo Guarnieri.[17] TRIDENT Consortium *[1]University of Pennsylvania, Philadelphia, PA; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Hospital of the University of Pennsylvania, Haddonfield, NJ; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]U.Michigan, Ann Arbor, MI; [6]Feinberg School of Medicine, Northwestern University, Chicago, IL; [7]University of New Mexico, Albuquerque, NM; [8]Stanford University, Stanford, CA; [9]University of Texas Health Science Center at San Antonio, San Antonio, TX; [10]Baylor University Medical Center, Dallas, TX; [11]The Ohio State University, Columbus, OH; [12]Yale University School of Medicine, New Haven, CT; [13]University of Pennsylvania School of Medicine, Villanova, PA; [14]Medicine, Columbia, New York, NY; [15]Regeneron Pharmaceuticals, Tarrytown, NY; [16]GSK, Stevenage, United Kingdom; [17]Boehringer Ingelheim, Ridgefield, CT.*

Background: There is a paucity of novel or specific therapeutics for diabetic kidney disease (DKD) due, in part, to its pathogenetic heterogeneity and lack of human kidney tissue for direct interrogation. TRIDENT (NCT02986984) is a multicenter consortium aimed at generating a longitudinal observational cohort study of 300 adults with diabetes and kidney tissue available for multi omics characterization of DKD. As part of the study initiation, we determined the safety and feasibility of obtaining research kidney tissue from patients undergoing clinical biopsy.

Methods: Individuals with diabetes, scheduled for clinical kidney biopsy, provided written consent to allow for an extra core of kidney tissue for research purposes. Inclusion criteria included confirmation of diabetic glomerulosclerosis, including superimposed non-DKD. A clinically significant complication was defined as a perinephric hematoma >5cm, drop in hemoglobin >2g/dl, need for transfusion or procedure to halt bleeding or anesthesia related complications leading to prolonged hospital stay.

Results: Recruitment began in JAN 2017. To date, 69 individuals (>70% of those approached) have provided written consent, 56 biopsies performed, 49 research cores obtained; 6 patients excluded due to a lack of diabetic glomerulosclerosis on biopsy. 40 participants met inclusion criteria with 18 instances of superimposed nondiabetic pathology: 12 diagnoses of GN, 2 of AIN, 2 of acute tubular injury, 1 CTIN, and 1 pyelonephritis. The mean age was 54 years (±13) and 15 (38%) were female and 13 (33%) African American. Of the 49 biopsies in which an extra core was obtained, there were 2 clinically significant complications; 1 was a hematoma >5cm and the other was respiratory distress from anesthesia-related aspiration.

Conclusions: These preliminary results indicate that it is safe and feasible to obtain research kidney tissue from patients with diabetes undergoing clinical kidney biopsy. The TRIDENT Study is positioned to generate the molecular profiles necessary to unravel the heterogenous pathways involved in DKD.

SA-PO180

Hyperkalemia in CKD: Can Virtual Patient Simulation Improve Management?

Amy Larkin,[1] Susan Gitzinger,[2] Donald Blatherwick,[2] Martin Warters,[2] Gwen S. Littman.[3] *[1]Medscape Education, Nicholasville, KY; [2]Medscape, Medford, NJ; [3]WedMD, Durham, NC.*

Background: We sought to determine if an online, virtual patient simulation (VPS)-based continuing medical education (CME) intervention could improve performance of nephrologists and primary care physicians (PCPs) in the evidence-based management of chronic kidney disease (CKD)-associated hyperkalemia.

Methods: The intervention comprised two patients presenting in a VPS platform that allows learners to order lab tests, make diagnoses, and prescribe treatments mirroring the scope and depth of actual practice. Eevidence-based clinical guidance (CG) was provided following each decision, followed by the opportunity to modify their clinical decisions. Each user's baseline (pre-CG) decisions were compared to their post-CG decisions using a 2-tailed paired t-test to determine *P* values. The CME launched online February 13, 2018, and data were collected through May 7, 2018.

Results: Case 1 (n=51 Nephrologists; n=367 PCPs): Diagnose hyperkalemia: 16% improvement among nephrologists (51% pre-CG vs 67% post-CG; P=.051), 51% improvement among PCPs (50% pre-CG vs 71% post-CG; P<.001) Continue/modify spironolactone therapy: 12% improvement among nephrologists (14% pre-CG vs 26% post-CG; P=.085), 15% improvement among PCPs (11% pre-CG vs 26% post-CG; P<.001) Order follow-up potassium test: 12% improvement among nephrologists (59% pre-CG vs 71% post-CG; P=.105), 17% improvement among PCPs (50% pre-CG vs 67% post-CG; P<.001) Prescribe a potassium binder: 22% improvement among nephrologists (16% pre-CG vs 18% post-CG; P=.395), 0% improvement among PCPs (4% pre-CG vs 4% post-CG; P=.5) Case 2 (n=34 Nephrologists; n=307 PCPs): Diagnose CKD Stage 3b: 41% improvement among nephrologists (9% pre-CG vs 50% post-CG; P<.001), 26% improvement among PCPs (17% pre-CG vs 43% post-CG; P<.001) Appropriately initiate hyperkalemia therapy: 47% improvement among nephrologists (18% pre-CG vs 67% post-CG; P<.001), 48% improvement among PCPs (7% pre-CG vs 54% post-CG; P<.001) Appropriately discontinue spironolactone: 29% improvement among nephrologists (9% pre-CG vs 38% post-CG; P=.001), 24% improvement among PCPs (30% pre-CG vs 54% post-CG; P<.001)

Conclusions: VPS that immerses and engages physicians in an authentic and practical learning experience improved evidence-based clinical decisions of both nephrologists and PCPs related to hyperkalemia management.

SA-PO181

The Electrolyte Club: A Flipped Hyponatremia Curriculum for Internal Medicine Residents to Promote Integration of Sodium and Water Physiology into Clinical Care

Helbert Rondon Berrios. *University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Decreased interest in nephrology has been linked to perceptions that nephrology encompasses complicated and poorly taught subjects. The flipped classroom has emerged as an innovative teaching approach by encouraging higher-order thinking and active participation. We examined the effectiveness and acceptability of a flipped hyponatremia curriculum for Internal Medicine Residents with the goals of improving hyponatremia knowledge and confidence in applying basic sodium and water physiology into clinical care.

Methods: Residents rotating in the renal service at UPMC Presbyterian hospital from June 2017 to May 2018 were eligible to participate. Residents were excluded if they declined to participate or were unable to either attend all sessions or undergo assessment. Residents rotated in 4-wk blocks. Residents in a given block were assigned to either a standard curriculum (SC) or a flipped curriculum (FC). Each curriculum was applied 6 times during the year. Residents in FC were required to watch 2-3 video lectures before each session. For this purpose, 10 video lectures on hyponatremia were developed using Camtasia software. FC in-class activities consisted of four 45-min sessions with a facilitator that included a clicker quiz, time for questions, and case discussions. SC consisted of two 1-h chalk talks. Residents completed a pretest, a posttest, and a 5-point Likert scale survey at the end of each curriculum. Paired sample t-test was used to compare pretest and posttest scores within each curriculum and two-sample t-test was used to compare knowledge improvement (posttest-pretest) between the two curricula.

Results: Twenty-nine residents were included in the study. There was a significant knowledge improvement after both curricula. There was no difference in knowledge improvement between FC and SC (33±15.6% vs. 31.7±14.9% respectively, P=0.79). Residents in FC rated 4.5±0.6 their confidence in applying basic sodium and water physiology into patient care, 3.9±1.1 their preference for the flipped classroom model over the traditional lecture, and 4.4±0.6 their overall satisfaction with FC.

Conclusions: FC improved residents' hyponatremia knowledge but was not superior to SC. FC improved resident confidence in applying basic sodium and water physiology into patient care. FC had a great acceptability among residents.

SA-PO182

Self-Guided Video-Based Modules to Teach Hyponatremia to Trainees: A Pilot Study

Lowell J. Lo, Thuy M. Nguyen. *Medicine, UCSF, San Francisco, CA.*

Background: Hyponatremia is the most commonly encountered electrolyte disturbance in the hospital with an estimated prevalence up to 42%. Despite its prevalence, medical students and residents do not feel comfortable managing this condition. Hyponatremia encompasses many complex concepts in renal physiology making it a difficult topic to learn and teach. We conducted a pilot study to evaluate the impact of an online video module on learners' ability to diagnosis and manage hyponatremia.

Methods: UCSF nephrologists created a module consisting of short online videos reviewing the pathophysiology of hyponatremia coupled with self-directed high-yield cases. This module is available on the UCSF collaborative learning environment website. We asked medical students and residents rotating through the nephrology elective to complete the module over the course of an assigned two-week block. We used ten board-style multiple-choice questions as a surrogate marker of comprehension. Learners were instructed to complete the same questions before and after completion of the module. Participants also completed a short Likert-scale survey to evaluate their experience with the module.

Results: Over nine months, six medical students and one resident completed the module. Paired sample T-test was conducted to compare mean scores pre and post module.

There was a statistically significant difference between scores before (mean = 4.38, SD 1.30) and after the module (mean = 5.25, SD 1.58, t(7) = -2.81, p = 0.026). Learners reported spending between 2-8 hours on the material. Of the seven learners who completed the survey, all felt more comfortable diagnosing and proposing a treatment plan for hyponatremia after completion of the module.

Conclusions: The results suggest learners' comprehension and comfort with hyponatremia concepts and treatment plans improves after completing our online module. Survey feedback regarding the mixed video and case format was positive. Our module is an effective method to teach hyponatremia and can serve as a guide for future online educational curricula on complex renal topics.

SA-PO183

On-line vs Face-to-Face Education to Improve Dietitians' Clinical Competence in Early CKD

Roxana Marquez-Herrera, Laura Cortes-Sanabria, Hector Martinez Ramirez, Alfonso M. Cueto-Manzano. *Unidad de Investigación en Enfermedades Renales, Guadalajara, Mexico.*

Background: Adequate clinical competence (CC) of dietitians for prevention and management of early chronic kidney disease (CKD) would have an important impact to reduce the burden of ESRD. Unfortunately, this is not frequently observed, particularly in primary health-care. Online education offers advantages for continuing education; however, its effect on CC remains unclear. Aim: To compare the impact of an online *vs* face-to-face education program on dietitians' CC regarding nutritional care of early CKD

Methods: Eighty-one dietitians were included; renal dietitians or those who were currently taking any CKD training were excluded. Dietitians were included in an *online* group (N 56) or *face-to-face* group (N 25). Educative interventions were developed by a multidisciplinary team (clinical and education experts), based on constructivism paradigm and focused on nutritional aspects of prevention and management of early CKD. Education content and duration (8 weeks) of both interventions were similar; online education was asynchronic, face-to-face was performed 1 session (4h)/week. To evaluate CC, a validated questionnaire (0-120 points) measuring dietitians' capability to identify risk factors, integrate diagnosis, correctly use of nutritional therapeutic resources and identify iatrogenic behaviors, was applied at the beginning and the end of study

Results: Age, gender, work experience (yrs), and previous attendance to online courses were similar between groups. Baseline CC score was low in both groups: face-to-face 47 (41-56) *vs* online 48 (39-58), p=0.60, but increased in both of them at the end of study: face-to-face 74% (29-97, p<0.0001) and online 63% (26-91,p<0.0001); no difference in intergroup comparison was observed (p=0.57). In general, 58% of dietitians increased from low to high CC (p<0.0001). Terminal efficiency was >90% in both groups, and >90% of participants rated the interventions as good or very good

Conclusions: Online and face-to-face educative interventions were successfully developed. CC of dietitians increased similarly after both educative interventions. Online education could be useful and effective to train dietitians in prevention and management of early CKD, overcoming limitations of time, distance and costs of face-to-face education

SA-PO184

WhatsApp in Nephrology Training

Kenar D. Jhaveri, Alia Hasan, Steven Fishbane. *Nephrology, Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Background: We are living in an era of technology where smart phones and hence social media have entered into many aspects of our life. Novel educational means are necessary to transfer knowledge in the current era of digital learners. WhatsApp is one such application that is used by several individuals to communicate internationally. The role of this app is unknown in medical education and specifically in nephrology education.

Methods: To explore the potential of WhatsApp as an instructional strategy for nephrology fellows via asynchronous question/answer methodology. To evaluate the WhatsApp fellows educational venture, focus groups are planned with experienced qualitative researchers.

Results: All fellows in our training program-8, participated for a 6 month pilot period. 5 faculty were assigned to run the app. The faculty would ask 1-2 questions per week that were board style multiple style questions and responses were received from all 8 fellows for 90% of the questions, with explanations provided. The faculty would then provide the correct answer along with the detailed discussion and references. Dialogues and discussions would be sparked as a result of questions. There was 100% satisfaction of fellows participating in the project. The questions ranged from various topics from ESRD, acid base, AKI, glomerular diseases and transplantation. Two focus groups are being planned to better evaluate the use of the app as a pedagogical tool integrated into fellowship training. First focus group will involve the fellows and a second one will involve the faculty. Results are pending for the focus group component of the project.

Conclusions: WhatsApp is an effective social media tool to motivate, augment and perhaps improve the learning of nephrology fellows in training. Similar strategies should be evaluated in resident and medical student education of nephrology.

SA-PO185

Handheld Ultrasound Devices May Lead to a Transformation of Physical Diagnosis Practices in Much the Same Way as Laënnec's 1816 Invention of the Stethoscope

Laith Al-Rabadi,[1] Patrick Ockerse,[2] Jennifer Cotton,[2] Megan Fix,[2] James Fair,[2] Qussay Marashly,[1] Ragheed Aldulaimi,[1] Josephine Abraham,[1] Boyd Richards,[3] Isaac E. Hall.[1] *[1]Internal Medicine Department-Renal Division, University of Utah Hospital, Salt Lake, UT; [2]Emergency Department, University of Utah Hospital, Salt Lake, UT; [3]Division of Pediatric Administration, University Of Utah, Salt Lake, UT.*

Background: Ultrasonography is a fundamental tool for assessing kidney dysfunction and volume status in multiple settings. As new handheld devices connected to small US probes have become available, it is now more practical for students to accurately and rapidly perform kidney and volume assessments themselves at the bedside. The lack of formal kidney US training during medical school and frequent clinical difficulties in determining volume status in settings of acute kidney injury (AKI) lead to trainee incompetence with regard to kidney imaging and AKI evaluation and management. Thus, our aim was to determine whether handheld US technology helps trainees learn significant and practical nephrology content.

Methods: *For this IRB-approved project, we measured the usefulness of handheld US among medical students.* We taught basic skills for focused US examination in hospitalized settings of AKI to exclude hydronephrosis, determine kidney size and echogenicity, and assess volume status by visualizing the inferior vena cava. These interactive, educational sessions were incorporated into the University of Utah "*Transition to Internship*" clerkship for 4th-year medical students. Introductory and interactive modules described basic US physics and additional concepts to acquire and interpret kidney sonograms. Teaching sessions were then followed by an 8-hour hands-on workshop. After participating, students were given surveys consisting of questions with five-point Likert scales.

Results: Out of the 64 students that filled out survey responses, 98% indicated that the curriculum enhanced their medical education, made them feel competent to perform handheld US, and that the handheld US technique was helpful for volume assessment. All responding students indicated that handheld US improved their understanding of 3D renal anatomy. Ninety-six percent of students wanted more US incorporated into the medical curriculum.

Conclusions: Handheld US was very well-received as a valuable teaching tool among 4th-year medical students. Students were able to demonstrate proper US technique and focused interpretation with regard to kidney and volume status assessment, and nearly all indicated that the experience enhanced their education.

SA-PO186

Hemodialysis Central Venous Catheter Placement by Nephrology Fellows

Denisse Arellano-Mendez, Javier Soto-Vargas, Julio A. Gutierrez-Prieto, Godhy E. Hernandez Gonzalez, Omar I. Delgado-Ayon, Carlos Daniel Jiménez Mejía, Leonardo Pazarin-Villaseñor, Ma Anabel Salazar Lopez, Mario A. García Cárdenas, Renato Parra Michel. *Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Especialidad en Nefrologia, Hospital General Regional No 46 del IMSS, Guadalajara, Mexico.*

Background: There is no evidence about the number of central venous catheter (CVC) procedures required for a nephrology fellow to acquire competency, besides, these procedures are now being perform by other specialties, moving those away from the basic training of a nephrology program. Nevertheless, in low and middle-income countries, the nephrologist has a key role in CVC placement. Our main objective is to present the experience in CVC placement in a nephrology fellowship program.

Methods: During March 2017 to February 2018, six first-year nephrology fellows performed 362 procedures. We collected information about number of catheter placed by every fellow, technique (anatomic landmarks or ultrasound guidance [USG]), if it was urgent, vascular region, number, and type of complications. Then we analyzed factors related to occurrence of complications in a multivariate model adjusted for vascular region, urgency of the procedure, use of USG and the time since the beginning of the study year.

Results: The median number of procedures was 60 (range 31-90) per fellow. The overall success rate was 95.3%, with 98 (27.1%) minor and no major complications. The more prevalent complications were bleeding (40, 11%), hematoma formation (15, 4.1%), >3 punctures (25, 6.9%), and arterial punctures (17, 4.7%). In the logistic regression model, the use of USG had a trend toward to a significant association for complications (OR 0.62, CI 95% 0.38-1.00, P =0.05), while in a Cox regression the use of USG reached significance with a 48% risk reduction for complications (HR 0.52 CI 95% 0.33-0.80, P <0.01). USG use increased after 90 days of training; therefore, we analyzed the association of USG to complications considering time as a covariate. Before 90 days the presence of complications was independent to USG usage (HR 0.81 CI 95% 0.47-1.41, P=0.47), and after 90 days there were a higher risk reduction (HR 0.23 CI 95% 0.11-0.5, P <0.01).

Conclusions: The CVC placement by nephrology fellows is safe and successful; it should be part of nephrologist formation and include training on USG to reduce the risk for complications.

SA-PO187

Dialysis Catheter Placement Experience of US Adult Nephrology Fellows: A National Survey

Hitesh H. Shah, Fatima Sheikh, Kenar D. Jhaveri. *Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Background: Nephrology fellows in the United States (US) are required to acquire skills and demonstrate competency in the placement of temporary/non-tunneled hemodialysis catheter (NT-HDC) during fellowship. To gain a greater insight in the dialysis catheter placement experience of US adult nephrology fellows, we carried out a national survey of nephrology fellows.

Methods: An anonymous on-line survey was created and sent to US adult nephrology fellows via fellowship program coordinators in May 2018.

Results: So far, 113 fellows have responded to our survey. 48% were graduating in 2018. Most NT-HDCs were placed in the hospital. While 26% had not placed any femoral NT-HDC during fellowship, 28% had placed >10. 36% had placed >10 internal jugular NT-HDC during fellowship, while 28% had placed none. 34% received simulation based training, 12% received bedside training, 23% received both simulation and bedside training, while 31% did not receive any formal training in NT-HDC placement. 53% had most of their NT-HDC placements supervised by a nephrology attending. However, 49% had no nephrology attending placing NT-HDC in their institutions. 43% needed to place at least 5 NT-HDCs before independently performing this procedure during fellowship, while 16% required ≥10. While 70% reported having received adequate training in NT-HDC placement during their fellowship, only 32% planned to place NT-HDC after graduation. While 67% felt that fellowship programs should be required to train fellows in NT-HDC placement, majority (57%) felt that nephrologist should not place NT-HDC in clinical practice. Reasons cited for those who had inadequate or no training in NT-HDC included: lack of formal training (23%), lack of opportunities to place NT-HDC (23%), lack of nephrology faculty interest (20%) and lack of faculty expertise (16%). 16% had placed at least 1 tunneled HD catheter and only 1 fellow had placed 1 PD catheter during fellowship.

Conclusions: While majority of fellows report adequate training in NT-HDC placement, a significant percentage of fellow had not placed a femoral or internal jugular NT-HDC during fellowship. Majority received simulation based training, however a significant percentage did not receive any formal training in NT-HDC placement during fellowship. Fellowship programs should take measures to ensure that all fellows receive adequate training in NT-HDC placement.

SA-PO188

Journal Publications of U.S. Adult Nephrology Fellowship Training Program Directors

Hitesh H. Shah,[1] Vipulbhai Sakhiya.[2] *[1]Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; [2]Northwell Health, Great Neck, NY.*

Background: Publication in peer-reviewed journals can be considered as one measure of scholarly activity among academicians. Peer-reviewed journal publications (PR-JPs) of current US adult nephrology fellowship training program directors (N-TPDs) are not known.

Methods: A PubMed search for PR-JPs was conducted for a period of 3 years (2015-2018) for N-TPDs serving in academic year 2017-18. Data was abstracted in May 2018. Publications were categorized as follows: basic science research (BSR), prospective clinical study (PCS), retrospective clinical study (RCS), clinical outcomes research (COR), randomized clinical trial (RCT), meta-analysis (MA), educational research (ER), quality improvement study (QIS), case report/series (CR/S), review article (RA), editorial (E) and letter to editor (LT-E). Data was analyzed for 150 N-TPDs.

Results: 35 (23%) N-TPDs had no PR-JP in the last 3 academic years. While 33% had ≤3 publications, 31% had 4-9 publications and 12% had ≥10 publications. We identified 656 PR-JPs by N-TPDs over the past 3years, out of which 125 (19%) publications had an N-TPD as the primary author (PA), 176 (27%) had an N-TPD as a corresponding author (CA) and 96 (15%) had an N-TPD as both the primary and CA. 37% were clinical research (PCS, RCS, COR, RCT, MA) related publications. The remaining publications were as follows: RA-22%, CR/S-16%, BSR-7%, ER-6%, E-6%, LT-E-3%, and QIS-2%. While 35% of N-TPDs had at least one PR-JP as a PA over the past 3 years, 41% had at least one publication as CA and 31% had at least one as primary and CA. In the last 3 years, 83 (55%) N-TPDs had authored at least one clinical research related publication, 25 (17%) had an ER related publication, while 18 (12%) had a BSR publication. When analyzed by gender, 51 female N-TPDs had total of 247 PR-JPs with a mean of 4.8 ±5.09 in past 3 years as compared to 99 male N-TPDs who had total of 409 PR-JPs with a mean of 4.1 ±5.05. There was no statistically significant difference between both groups ($p = 0.42$).

Conclusions: Nearly one in 4 N-TPDs had no PR-JP over the last 3 years. Nearly one-third N-TPDs were primary and CA on at least one PR-JP over the last 3 years. While half of the PR-JPs were either clinical research, BSR or ER related publications, the remaining were CR/S, RA, E, LT-E, or QIS. The top 2 categories with the most publications were RA and CR/S. Female N-TPDs had more PR-JPs than male N-TPDs.

SA-PO189

Enhancing Interest and Learning in Nephrology Among US Medical Students

Hitesh H. Shah, Nupur N. Uppal, Kenar D. Jhaveri. *Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Background: Interest in nephrology careers remains low among United States (US) medical graduates. The type of nephrology elective that US medical students experience may play an important role in creating and enhancing interest in nephrology career.

Methods: A redesigned 4-week nephrology elective was created at our institution for US medical students. Our redesigned elective included both 2-week inpatient (IP) and 2-week outpatient (OP) nephrology experiences. The OP rotation included 10 half-days of various nephrology clinic experiences, 2 half-days of immediate post-transplant clinic, 1 half-day of kidney donor evaluation clinic, 2 half-days of PD clinic and 3 half-days of outpatient HD rounding. Our redesigned elective also included educational conferences. To evaluate the elective experience, all medical students were asked to complete an on-line survey following the completion of their rotation.

Results: From July 2012 to February 2018, twenty-five 4th year medical students (from 15 different US medical schools) completed our redesigned elective. All students responded to our survey. All reported adequate OP nephrology experience during their elective. 80% of the students had worked with 1 or 2 faculty members during the IP setting. In comparison, 88% were exposed to at least 4 different faculty members during the OP experiences. 92% had interacted with at least 4 different fellows during the elective. All reported that the elective experience enhanced their exposure and knowledge in nephrology. They also thought that this elective structure provided them with a better insight into what nephrologists do in practice. 88% of the students reported that this elective experience created an interest in nephrology career. Majority (64%) of the students responded that they would consider nephrology as one of their 3 top career choices as a result of this elective experience.

Conclusions: Measures to enhance interest and learning in nephrology among medical students are needed. We believe that the restructured elective provides the medical student with a much needed and realistic exposure to nephrology careers. Based on our experience, we recommend all nephrology training programs to consider this elective structure for medical students.

Development and Preliminary Validation of a Formative Peritoneal Dialysis Objective Structured Clinical Examination

Brian C. Y'Barbo,[1] Christina M. Yuan,[1] Sam W. Gao,[4] Christopher J. LeBrun,[2] Robert Nee,[1] David K. Oliver,[1] Mark C. Saddler,[3] Maura A. Watson,[1] Lisa K. Prince.[1] Nephrology Education Research & Development Consortium *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Nephrology Associates PC, Columbus, MS; [3]Durango Nephrology Associates, Durango, CO; [4]Naval Medical Center Portsmouth, Virginia Beach, VA.*

Background: Only about 10% of incident end-stage renal disease patients beginning renal replacement therapy select peritoneal dialysis (PD) in the US. One reason may be limited PD experience during Nephrology fellowship training. Training programs often use simulation to boost experience in the absence of clinical opportunities. Structured test questions can provide this simulation, help to assess fellow knowledge in this area, and aid in determining program level practice patterns.

Methods: We devised a formative objective structured clinical examination (OSCE) focusing on the management of a PD patient with peritonitis and ultrafiltration dysfunction. After blueprint development and identification of key objectives (based on the International Society for Peritoneal Dialysis Peritonitis practice guideline), the case and the scoring rubric were constructed based on a real-life example. After review by 2 subject experts, it was evaluated by a 9-member test committee consisting of 8 board-certified nephrologists (4 academic, 4 clinical) and one experienced PD nurse. The final case consisted of 10 free response questions (total 22 points) and required written orders for PD exchanges and antibiotic management.

Results: The final OSCE was sent to two groups (test and validation committees) to determine the passing threshold. The test committee set the passing threshold using Ebel's method. The passing score was set at 16 of 22. Median relevance was essential or important for all questions with a content validity index of 91%. The validation committee (16 board-certified practicing nephrologist a median of 5 years (IQR 9) post-graduation) took the test. Mean score was 19 (SD 2). 94% of the validators passed the test and scored 85% on evidence based questions. Median time to take the test was 33 minutes (IQR 19).

Conclusions: Preliminary validation is now complete, and the next phase will involve testing of nephrology fellows who have just completed their first year of fellowship training. *Disclaimer: The views expressed are those of the authors and do not reflect the official policy of the Department of the Army/Navy/Air Force, the Department of Defense, National Institutes of Health, or the United States Government.*

SA-PO191

Safety of Kidney Biopsy Performed by Nephrology Trainees vs Interventional Radiology

Manasi Bapat,[1] Timothy C. Martin,[6] Siddhartha Kattamanchi,[2] Joji E. Tokita,[3] Shuchita Sharma,[1] Girish N. Nadkarni,[4] Steven G. Coca,[5] Swati Mehta,[6] Lili Chan.[1] *[1]Icahn School of Medicine, Mount Sinai Hospital, NY, New York, NY; [2]Mount Sinai Medical Center, New Rochelle, NY; [3]Mount Sinai School of Medicine, New York, NY; [4]Ichan School of Medicine, New York, NY; [5]Icahn School of Medicine at Mount Sinai, New York, NY; [6]Albany Medical Center, Rensselaer, NY.*

Background: Kidney biopsy is the gold standard in the diagnosis and management of kidney diseases, yet most nephrology fellows are not getting adequate training in kidney biopsies. Our aim was to review kidney biopsies performed by nephrology trainees under the supervision of nephrologist with outcomes compared to interventional radiology (IR).

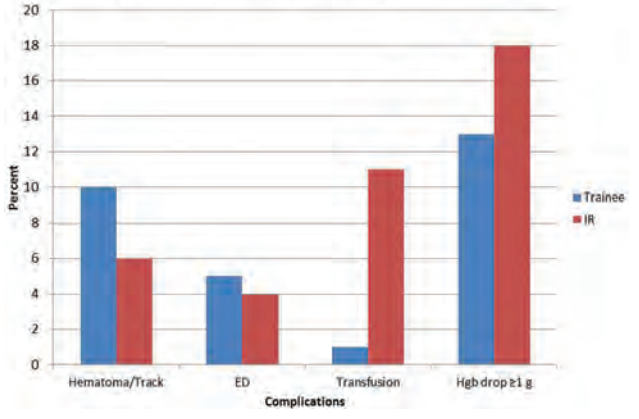
Methods: This is a retrospective cohort study of 251 patients who underwent a native kidney biopsy at Mount Sinai Hospital (MSH) and Albany Medical Center (AMC) from 2016 - 2017. Biopsies done at MSH were performed by nephrology fellows under nephrology supervision while those done at AMC were done by IR.

Results: There were 251 patients who underwent kidney biopsy; mean age was 51 ± 16 years, 52% were male, and 60% were done by nephrology fellows. The most frequent indication for biopsy was non-nephrotic range proteinuria, 83 (33.2%). ddAVP was given in15 of biopsies performed by nephrology trainees and 1 of biopsies performed by IR; there was no difference in BUN between the MSH or AMC cohorts (40±24 mg/dL vs 37±27 mg/dL respectively, P=0.24). Diagnostic yield (≥11 glomeruli) did not differ by operator, trainee 89% vs. IR 94%, p=0.14. There was no difference in hematoma or track formation by proceduralist (IR 6% vs. trainee 10%, p=0.1) or for ED visits for outpatient biopsies (IR 4% vs trainee 4%). Transfusions were higher in those performed by IR (11% vs. 1%, P<0.001). Mean change in hemoglobin while not statistically different was clinically meaningful (trainee 0.2±0.7 g/dL vs. IR 1.6±10.7, P=0.1) After adjustment for patient and biopsy characteristics, prebiopsy hemoglobin but not proceduralist type was a significantly associated with higher odds of 1gm drop in hemoglobin, (adjusted odds ratio 1.4, 95% CI 1.1 – 1.7).

Conclusions: Nephrology trainees can safely perform kidney biopsies with similar diagnostic yield and complication rates.

Funding: NIDDK Support

Figure 1: Complication rates of kidney biopsy by proceduralist



SA-PO192

Viability and Fidelity of Low-Cost Gelatin Percutaneous Renal Biopsy Phantom in Simulation Training

Elena Qirjazi,[1] Ian Y. Chan,[2] Juliya Hemmett,[1] Faisal Rehman,[1] Roya Etemad-Rezai.[2,3] *[1]Nephrology, Western University, London, ON, Canada; [2]Radiology, Western University, London, ON, Canada; [3]London Health Scinces Center, Western University, London, ON, Canada.*

Background: Percutaneous renal biopsies are crucial for the accurate diagnosis and prognosis of many renal diseases. Most trainees learn this procedure directly on patients, despite its risks. Commercially available phantoms are available for simulation training, but they are expensive and have a limited number of needling attempts. We developed and evaluated an inexpensive kidney biopsy phantom created using ingredients available in most grocery stores.

Methods: The renal biopsy phantom was constructed by inserting a weighted porcine kidney into a gelatinous solution consisting of a mixture of unflavored gelatin, sugar-free psyllium hydrophilic mucilloid fiber (Metamucil), and boiling water. The phantom was refrigerated to allow the gelatin to solidify before use. We evaluated this phantom during three separate 1-hour workshops attended by a combination of nephrologists, nephrology fellows, and radiology and internal medicine residents. Each workshop consisted of a 10-minute didactic demonstration on how to perform ultrasound-guided renal biopsies. The participants then had the opportunity to perform simulated ultrasound-guided biopsies on 1) the gelatin-phantom, and 2) a commercially available phantom (cost ~ $4000 USD). Participants evaluated the workshop and the phantoms using anonymous surveys. Data were analyzed using descriptive statistics and two sample t-tests.

Results: A reproducible gelatin phantom was engineered with a material cost under $20 USD. 39 individuals participated in the 3 workshops and completed the surveys. Most participants agreed that kidney biopsy simulations are helpful in training residents, and found the workshop effective. The gelatin and commercial phantoms were rated similarly over a number of characteristics, including size, consistency and sonographic changes with multiple needling. Overall, the gelatin phantom was considered superior by 80% of participants. Participants commented: "Great session!", and "Gelatin phantom is a brilliant simulation tool. It is cheap and you can make new models as needed for tracks".

Conclusions: We were able to construct an inexpensive and easily reproducible gelatin-based renal biopsy phantom. Our phantom was non-inferior to a more expensive commercial counterpart.

SA-PO193

Identifying and Integrating Patient and Caregiver Perspectives in Clinical Practice Guidelines for Percutaneous Renal Biopsy

Talia M. Gutman,[2,1] Pamela A. Lopez-Vargas,[1] Karine E. Manera,[2,1] Jonathan C. Craig,[1,4] Laura J. James,[2,1] Allison Tong,[2,1] Paul J. Champion de Crespigny.[3] KHA-CARI Renal Biopsy Guideline Writing Group and KHA-CARI Office Team *[1]Centre for Kidney Research, The Children's Hospital at Westmead, Sydney, NSW, Australia; [2]School of Public Health, The University of Sydney, Sydney, NSW, Australia; [3]Nephrology, The Royal Melbourne Hospital, Parkville, VIC, Australia; [4]College of Medicine and Public Health, Flinders University, Adelaide, SA, Australia.*

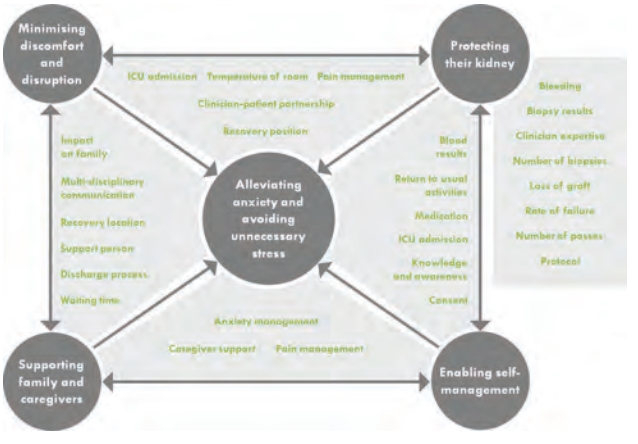
Background: Percutaneous renal biopsy is often essential for providing reliable diagnostic and prognostic information for people with suspected kidney disease, however the procedure can lead to complications and concerns among patients. This study aims to identify and integrate patient priorities and perspectives into the Kidney Health Australia – Caring for Australasians with Renal Impairment clinical practice guidelines for renal biopsy, to ensure patient-relevance.

Methods: We convened a workshop, consisting of three simultaneous focus groups and a plenary session, with ten patients who had undergone a renal biopsy and seven caregivers. Topics and outcomes prioritized by patients and their caregivers were compared to those identified by the guideline working group, which was comprised of seven nephrologists. Transcripts and flipcharts were analyzed thematically to identify the reasons for participants' choices.

Results: In total, 34 topics/outcomes were identified, 14 of which were common to the list of 28 previously identified by the guideline working group. Most of the new topics identified by patients/caregivers were related to communication and education, psychosocial support, and self-management. We identified five themes underpinning the reasons for topic and outcome selection: alleviating anxiety and unnecessary distress, minimizing discomfort and disruption, supporting family and caregivers, enabling self-management, and protecting their kidney. A new topic on patient care and education was added to the guideline as a result.

Conclusions: Patient and caregiver involvement in developing guidelines on renal biopsy ensured that their concerns and needs for education, psychosocial support, and self-management were explicitly addressed; enabling a patient-centred approach to renal biopsies.

Funding: Government Support - Non-U.S.



SA-PO194

Breaking Bad News: A 2 Year, Multi-Center Simulation Exercise Assessing Renal Replacement Therapy and Kidney Biopsy Communication Skills

Lisa K. Prince,[1] Brian C. Y'Barbo,[1] Jeffrey A. Mikita,[1] Anna M. Howle,[1] Scott D. Cohen,[7] Oliver Lenz,[2] Laura J. Maursetter,[3] Sharon E. Maynard,[4] Stephen M. Sozio,[5] Amy N. Sussman,[6] Christina M. Yuan.[1] Nephrology Education Research & Development Consortium *[1]Walter Reed National Military Medical Center, Silver Spring, MD; [2]University of Miami, Miami, FL; [3]University of Wisconsin School of Medicine & Public Health, Madison, WI; [4]Lehigh Valley Health Network, Emmaus, PA; [5]Johns Hopkins University School of Medicine, Baltimore, MD; [6]University of Arizona, Tucson, AZ; [7]The George Washington University School of Medicine and Health Sciences, Washington, DC.*

Background: There are few quantitative, simulation-based assessments for nephrology-specific interpersonal communication skills (ICS) and professionalism (PROF) milestones. We developed a "Breaking Bad News" simulation to assess fellow counseling competence in 3 scenarios: a surrogate decision maker for acute renal replacement therapy (RRT), a patient with end stage kidney disease for RRT, and a patient with glomerulonephritis for kidney biopsy.

Methods: After reviewing a clinical summary, fellows counsel each of the 3 simulated patients (SPs) who have received a summary of their character's medical and social situation. Faculty were instructed on the scenarios, use of the Mini-CEx, and the information provided to fellows and SPs. Fellow performance was assessed using 2 previously validated tools: the Mini-Clinical Examination Exercise (Mini-CEx) and the Essential Elements of Communication-Global Rating Scale 2005 (EEC-GRS). Both have a 1-5 rating scale with scores of 3 or greater being satisfactory. SPs rate fellow ICS and PROF using the EEC-GRS, and nephrology faculty, observing from outside of the room, use the Mini-CEx to evaluate medical knowledge and ICS. Fellows receive 5 minutes on-the-spot performance feedback at the end of each 15 minute scenario from both SP and faculty.

Results: 56 fellows completed the OSCE. The 2017 administration included 26 fellows (5 training programs), and the ongoing 2018 administration included 30 fellows (6 of a total 8 programs). EEC-GRS scores were not significantly different between first and second year fellows (p=0.27). No significant difference was found between training years when comparing any EEC-GRS score <3 or any Mini-CEx score <3. Only 13% of fellows scored <3 on any item in the chronic dialysis counseling Mini-CEx, while 45% and 43% respectively scored <3 on at least one item on the acute RRT counseling and kidney biopsy scenarios.

Conclusions: Overall, fellows communicate well and professionally with high ratings on EEC-GRS. Fellows counsel patients well on chronic RRT but had deficiencies in counseling on risks of acute RRT and kidney biopsy. The results allow program directors to adjust curriculum and provide quantitative assessment of ACGME milestones progress.

Funding: Other U.S. Government Support

SA-PO195

Differing Expectations of Transitions of Care Within a Nephrology Practice: Should We Transition to Train More?

Sayee Sundar Alagusundaramoorthy,[1] Samantha J. Strennen,[3] Laura J. Maursetter,[2] Gauri Bhutani.[1] *[1]University of Wisconsin, Madison, WI; [2]University of Wisconsin School of Medicine & Public Health, Madison, WI; [3]University of Wisconsin-Madison, Madison, WI.*

Background: Ineffective transitions of care (TOC) communication is a major contributing factor to medical errors.

Methods: As part of an endeavor to standardize TOC practice in our division, we conducted a two-step survey-based study of TOC perceptions among faculty and fellows over the last one year. Data was collected anonymously via two different electronic surveys. The first (Survey1) focused on providers' perceptions of the TOC practice in the division. The second (Survey2) asked for a self-assessment about providers' own TOC procedure. Fisher's exact test was used for statistical analysis of the survey results.

Results: Attendings were significantly less satisfied with the current division TOC practice as compared to fellows (table). Both attendings and fellows appeared equally satisfied with their own TOC methods. APP response fell between physician and fellow responses for most questions. Most faculty (71%) and fellow (66.7%) responses indicated they would prefer changes in current TOC practice.

Conclusions: Our results reveal a gap between TOC expectations and self-reflection amongst faculty and fellows in one division. This may reflect a lack of formal training to align expectations in TOC practice. The general acceptance of the division TOC environment by fellows likely stems from the fact that the majority of TOC documentation is done by this group. Overall, most providers were interested in changes to improve TOC practices. We plan on step-wise changes including instituting a standardized division TOC policy, EMR support, formal training in TOC, and continuing assessment of TOC practice and environment in the division.

	Physician (%)	Advanced Practice Provider (APP; %)	Fellow (%)	P-value
Survey1 respondents	75% (12/16)	75% (6/8)	83.3% (5/6)	
Always satisfied with weekend call sign-out received ?	0% (0/9)	NA	100% (5/5)	<.001
Mostly satisfied with weekend call sign-out received ?	55.6% (5/9)	NA	NA	NA
Felt patient safety compromised due to lack of appropriate TOC ?	41.75% (5/12)	33.3% (2/6)	0% (0/5)	0.298
I have adequate time to provide sign-out ?	83.3 % [10/12]	100% (5/5)	80% (4/5)	1.000

SA-PO196

Leveraging the Internet to Showcase Abstracts and ePosters: Online Engagement at a National Meeting

Vijay Lapsia, Joseph A. Vassalotti. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Scientific posters are traditionally printed and presented on site to interactively share research findings. However, this format is limiting, particularly with digital media and archival that allows for review of posters by attendees virtually after the meeting is over. It is unknown if hosting abstracts and posters online can improve access and enhance engagement.

Methods: Authors of accepted abstracts for National Kidney Foundation's 2018 Spring Clinical Meetings were invited to upload posters in an online gallery displaying abstracts, posters and supplementary media. As a part of the submission, authors completed a brief survey. Web analytics software tools were embedded to measure audience engagement and usage during and after the meeting. Categorical data from the survey and audience data from web analytics were analyzed for frequency & descriptive statistics and usage trends.

Results: A total of 458 abstracts with 254 supplementary media files were submitted for consideration, 365 of which were accepted for publication and currently displayed at https://nkf2018scm.site online. Almost all authors gave permission to publish the poster online (96.7%) and a little over half (58.6%) uploaded posters to the online gallery. The survey response rate was 35.2%. Top features that users recommended included the ability to connect with other authors (73.2%), comment and save gallery items (68%), ability to view the gallery as well as media files including video and images on smartphones (64.6%) and integration with social media to share submissions (52.7%). Audience analytics revealed 2,114 users from 59 countries accessed the gallery within 30 days of the meeting, 1,190 of which came online during the 4 day meeting. Users were predmoninatly from the USA (78.04%), more than half (55.95%) used a mobile device, with 78.5% on iOS devices and 30.2% using the chrome browser. Peak gallery usage coincided with the first two days of the meeting with late morning and early evening being the busiest hours. Notable referral sources included stocktwits.com a social media platform for investors (98 referrals), medical news sites and pharma company intranets.

Conclusions: Hosting abstracts, posters and supplementary media in an online gallery can extend and enhance engagement during and after the meeting. Access to the gallery on mobile devices may be key to improving usage.

SA-PO197

Use of a Standardized Curriculum to Increase Resident Interest in Nephrology

Srikar Kumar. *University of North Carolina, Chapel Hill, NC.*

Background: Interest in nephrology fellowship continues to be low among current internal medicine residents. While there are many reasons for this decline, several studies have suggested that residents develop negative perceptions of the field during their training. Given that most residents only spend a little time during their training working with the nephrology service, it is possible that they have minimal exposure to areas such as transplant, nephropathology, critical care nephrology, and interventional nephrology. This quality improvement project aims to increase resident interest in nephrology by implementing a curriculum for residents rotating on the nephrology consult service, increasing exposure to different aspects of the field, and facilitating mentorship. At our institution, residents have an opportunity to rotate through with the nephrology inpatient consult service during elective time. Currently, there are no guidelines for the residents while on the nephrology elective; they generally see 1-2 consults per day with guidance from a fellow or attending. Without any recommended guidelines, many residents finish their elective with no exposure to the breadth of the field.

Methods: A preliminary ten question survey was sent to the internal medicine residents. This survey was simple, with yes or no questions, determining what residents had exposure to during their elective. The final question assessed their interest in nephrology. Based on these findings, a curriculum was given to residents at the beginning of their rotation. Every six months, the survey will be resent and the curriculum revised based on the findings.

Results: A majority of residents received basic didactic lectures for topics such as acute kidney injury and fluids/electrolytes. But, most did not have exposure to dialysis catheter placement or renal biopsies, had no bedside teaching regarding how dialysis or CRRT machines work, and did not review renal pathology with the in-house renal pathologists. These are among the regular activities performed at our institution.

Conclusions: Without any guidelines, the survey confirmed that many residents were missing out on unique opportunities in nephrology. While the project is ongoing with changes to come, the preliminary findings suggest that a standardized curriculum with focus on mentorship can potentially improve resident experiences in our field.

SA-PO198

Keeping It Renal: Grassroots Effort to Increase Local Interest in Nephrology

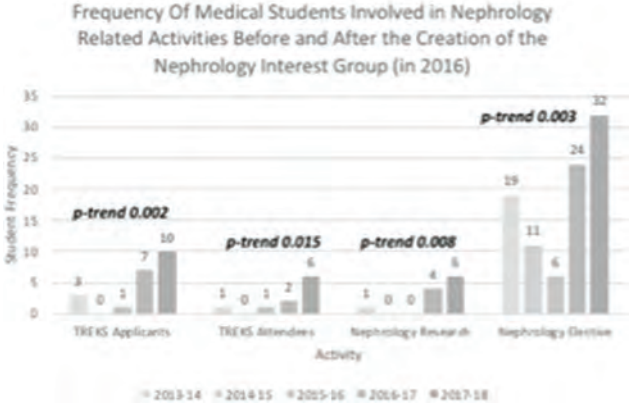
Sana Waheed,[1] Stephen M. Sozio,[2] Tripti Singh,[1] Laura J. Maursetter.[3] *[1]University Of Wisconsin School Of Medicine and Public Health, Madison, WI; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]University of Wisconsin School of Medicine & Public Health, Madison, WI.*

Background: National efforts have been made to increase medical student interest in nephrology through ASN sponsored programs like TREKS and STARS. Our goal was to create a local effort at University of Wisconsin (UW) to publicize nephrology as a career option for medical students to improve recruitment to nephrology.

Methods: As a result of curricular tranformation at UW in 2016, renal pathophysiology was taught during the first months of medical school with students learning about complex renal diseases early in their career with a more hands-on, case-based approach. This early exposure provided the opportunity to create a forum where students with an interest in nephrology could come together with nephrology faculty and explore the options of the field. As a result, the students created the nephrology interest group (N-IG). We describe the early experience of this, and analyze trends in involvement in nephrology-related activities.

Results: The N-IG hosts three events during the year: 1. Discussing different career trajectories in nephrology by faculty in various roles, 2. "Night with Nephrology", which was a jeopardy style game with a combination of trivia and nephrology questions and 3. Discussing interesting cases in nephrology with faculty to apply pathophysiology to patient care. By highlighting the cognitively stimulating and diverse nature of nephrology, we were able to increase the number of students spending dedicated time in nephrology related activities, most of them showing a statistically signifcant trend by year (Figure 1)

Conclusions: At our institution, a student led nephrology interest group was effective in increasing recruitment to nephrology related experiences. Similar interest groups can be created at other institutions by early nephrology involvement in the medical school curriculum, harnessing the energy of enthusiastic students, and utilizing support of nephrology faculty. Long-term follow up will determine if this involvement is fruitful for recruitment into the field.



SA-PO199

Targeted Primary Prevention Pilot for High School Students Living in High-Risk Areas for ESRD

Julie A. Wright Nunes,[1] Panduranga S. Rao,[1] Ben Ransier,[2] Jean DuRussel-Weston,[2] Brad Newman,[2] Kim Eagle.[1] *[1]University of Michigan Health System, Ann Arbor, MI; [2]University of Michigan, Project Healthy Schools, Ann Arbor, MI.*

Background: Development of chronic kidney disease (CKD) risk factors depends heavily on behaviors learned early in life. There is a paucity of research examining ways to improve youth health behavior and education to prevent later development of CKD.

Methods: A Health and Wellness community-based program partnered with clinicians and educators at one academic medical center to develop a kidney education module. This module was delivered by two kidney doctors to 11th grade students at an urban high school in Detroit, Michigan. The 1.5 hour kidney education module included didactic and hands-on exercises that were literacy-sensitive and introduced students to kidney anatomy, physiology, and function as well as risk factors for CKD and health behaviors needed to prevent it. Pilot aims were to; 1. Examine feasibility of delivering the kidney education module to high-school science classes, and 2. Determine student perceptions about the usefulness of the kidney education module.

Results: Thirty-seven students and one science teacher received the kidney education module in March 2016. Thirty-six students filled out voluntary surveys consisting of six questions asking about their perceptions of the kidney education module. All students (n=36, 100%) were of African American race and in the 11th grade. One-hundred percent (n=36) said the kidney education was personally helpful and that they learned "a good amount / a lot". Forty-four percent (16 students) reported knowing someone afflicted by kidney disease. The majority said the kidney education module would be helpful for future students (n=34, 94%), and that they would share what they learned with family (n=24, 67%) and friends (n=22, 61%). The program was repeated in Spring of 2017, and is now incorporated into the standard curriculum -- taught annually by the high school science teacher.

Conclusions: This pilot offers a promising model for educating and empowering youth to learn about chronic kidney disease and its prevention. Feasibility was supported in rapid uptake and adoption at the school. Student perceptions were overwhelmingly positive. There may be secondary gains when students share what they learned with family / friends. Next steps include adapting the program for other schools and examining its impact on behaviors, knowledge and clinical indices over time.

SA-PO200

Improving Health Behavior and Supporting Kidney Health Literacy in Kids to Prevent Kidney Disease

Julie A. Wright Nunes,[2] Kim Eagle,[2] Ben Ransier,[1] Jean DuRussel-Weston,[1] Brad Newman,[1] Panduranga S. Rao.[2] *[1]University of Michigan, Project Healthy Schools, Ann Arbor, MI; [2]University of Michigan Health System, Ann Arbor, MI.*

Background: The majority of chronic kidney disease (CKD) is preventable and largely depends on health knowledge and behaviors acquired early in life. There is a paucity of research examining ways to improve youth health behavior and education to prevent CKD.

Methods: The objective of this study was to pilot test a literacy-sensitive kidney education module to support healthy behavior and reduce long-term modifiable risk factors for kidney disease in youth located in two middle schools; one within the city of Detroit, Michigan. The other, in a suburb outside of Detroit. The kidney education module included 3 kidney health lesson plans delivered to 6th and 7th-grade students by their science teachers during science class. Content was didactic and hands-on, and included education on kidney structure, function and behaviors needed to reduce risk for CKD. We assessed feasibility of and fidelity to the kidney education module by direct observation, and elicited student and teacher perspectives about the program using standardized surveys.

Results: One-hundred and ninety-one (n=191) students received the kidney education module; 53% were located in the Detroit-based middle school and 47% in the outlying suburb. Collective demographics were: 28% African American, 50% female, 33% Hispanic or Latino, 12% Asian, and < 10% other / combined races. Science teachers (n=3) exhibited high fidelity with 100% completion of all 3 lesson plans at both middle schools. Eighty-five percent of students said they learned "a good amount / a lot"; 76% thought the kidney education would be helpful for other students; 51% shared what they learned with family or friends; and 65% said they were interested in receiving more science lessons about other body systems. Teachers and students reported an increase in knowledge about the kidneys and kidney disease. Next steps will include assessment of long-term knowledge gains and intent for behavior change in students over time.

Conclusions: Our kidney education module was feasible to implement seamlessly into two diverse middle school science curriculums. Both teachers and students reported immediate knowledge gains. Students rated the program very favorably. Future work will examine associations between the kidney education module and additional psychosocial, behavioral and clinical indices in students over time.

Raising Awareness on AKI: A Latin American Experience

Raul Lombardi,[1] Alejandro Ferreiro,[8] Guillermo J. Rosa diez,[2] Alvaro Margolis,[3] Luis Yu,[4] Mauricio Younes-Ibrahim,[9] Emmanuel A. Burdmann,[7] Fátima Oeyen,[5] Walter Douthat.[6] *[1]Servicio Medico Integral, Montevideo, Uruguay; [2]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [3]EviMed, Montevideo, Uruguay; [4]University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [5]AFEd Learning, Montevideo, Uruguay; [6]Hospital Privado-Universitario de Cordoba, Cordoba, Argentina; [7]University of Sao Paulo Medical School, Sao Paulo, Brazil; [8]School of Medicine, MONTEVIDEO, Uruguay; [9]Internal Medicine, University of Rio de Janeiro, Rio de Janeiro, Brazil.*

Background: Raising awareness on acute kidney injury (AKI) is an essential strategy for minimizing the burden of this lethal syndrome, and so the AKI Commission of the Latin American Society of Nephrology and Hypertension carried out an educational program based on network learning.

Methods: Two online courses with similar methodology were done, one for nephrologists and the other for primary care physicians (PCP). The courses were developed as a distance education, asynchronous online modality with multiple educational strategies: readings, videos, e-rounds and clinical simulation. Knowledge gain was explored through a 10-question test before and after completing the course.

Results: Course for Nephrologist: 779 participants from 21 countries; 52% male; 46% under 35 yrs. Mean qualification increased from 5.87 to 8.01 (36% gain of knowledge). Course for PCP: 2011 participants, 81% of whom physicians. Time from graduation <5 years in 52%. In both courses, clinical simulation was considered the best part and lack of time the main limitation for learning. Because 48% of attendees of the nephrologists' course stated their will to participate in AKI activities, a Latin American AKI Network site (RedIRA) composed by a brief review, a clinical forum, a self-assessment and a

bibliography on AKI was launched on a monthly basis on November 2016. To date there are 335 users from 18 countries.

Conclusions: Distance education techniques were effective for learning about AKI, and are a potential tool for the development of a sustainable structure for communication, exchange and integration of physicians involved in the care of patients with AKI.

Funding: Private Foundation Support

Comparative table of course's feaures

	Nephrologists	Primary care physicians

Will the Nephrologist See You Now? Results from the ASN/ERA-EDTA/ISN Global Nephrology Workforce Survey

Kurtis Pivert,[1] Stephen M. Sozio,[2] Fergus J. Caskey,[3] Adeera Levin.[4] *[1]Workforce and Career Advancement, American Society of Nephrology, Washington, DC; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]University of Bristol, Bristol, United Kingdom; [4]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada.*

Background: In low- and middle-income countries, concerns exist about nephrology workforce adequacy to meet population needs; and in high-income regions, concerns exist about declining interest in nephrology among trainees. ASN, ERA-EDTA, and ISN initiated a joint project to determine how kidney care delivery trends may affect future workforce demands by quantifying variation in nephrology scope of practice at the country- and region-specific level.

Methods: A survey was designed to capture national kidney health delivery measures, including nephrology training/certification and scope of practice; number of nephrologists/country; and range of kidney care provided by nephrologists, other physicians, and extenders. Given the global audience, the tool was translated and adapted to several formats before being distributed to leaders of national nephrology or medical societies in 167 countries.

Results: Sixty-eight countries (41%) have responded. There was little variation between regions in the scope of nephrology practice, with nephrologists the primary physicians for most key kidney health services/therapeutic areas (Fig 1 left). Yet ~50% noted nephrologists were not the primary physician for CKD stages 1–3 and hypertension. Nephrologists commonly prescribe biopsies (98%) yet are less likely to perform them (71%) (Fig 1 right). Stratified by region, Europe demonstrated the most intra- and interregional variability in scope of practice (e.g., 42% of European respondents reported nephrologists were primarily responsible for CRRT vs. 64% globally). A majority (60%) required nephrologists to be present in the dialysis facility, and many nephrologists rounded each dialysis session (hospitals, 50%; other facilities, 41%).

Conclusions: The *Global Nephrology Workforce Survey* found less interregional, but substantial intraregional, variation in the scope of kidney health services provided by nephrologists. A complete analysis of kidney health delivery trends will be translated to help assess nephrology workforce demands and inform regional efforts to ensure patients receive consistent, high-quality care.

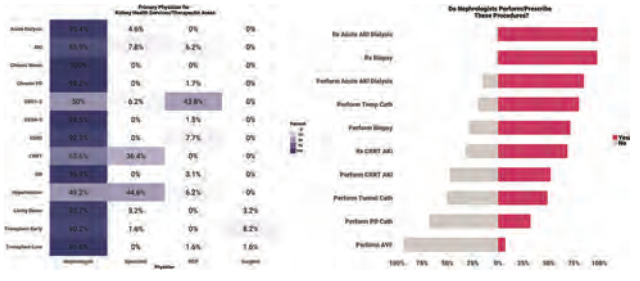

Fig 1

SA-PO203

The 2018 NKF Survey of Nephrology Advanced Practitioners

Kim Zuber,[1] Kevin F. Erickson,[2] Jane S. Davis.[3] *[1]American Academy of Nephrology PAs, Oceanside, CA; [2]Baylor College of Medicine, Bellaire, TX; [3]University of Alabama at Birmingham, Birmingham, AL.*

Background: For the last 10 years, NKF has administered a biannual online survey open to all nephrology APs asking about demographics, scope of practice, working experience and benefits. We describe the survey process and key findings from the most recent survey administered in early 2018.

Methods: A *Survey Monkey* link was sent to all nephrology APs (PAs, NPs, CNS) belonging to NKF's Council of APs. Respondents were encouraged to share the survey link with any nephrology AP, NKF member or not. The survey was open from 1/18-4/18 with monthly reminders & a push for responses at Spring Clinical Meetings. Response rate was 64%.

Results: Survey responses included 47 states and DC, with the most results from TX, OH, NC, GA and IL (18,16,14,13,13 respectively). The 2018 survey indicated an increase in minority representation among APs & a shift towards a younger workforce. HD management has been, and continues to be, a major activity of nephrology APs with 86% involved. Among APs reporting HD management, 82% conducted MCP visits. The average number of HD patients/wk is 50-100, a decrease from previous surveys. The average number of HD units/wk is 2-3 & 1-2 hours/wk driving. Office/Clinic duties were reported by 71% of the respondents with CKD clinic & emergent appointments (hospital discharge/ESRD/AKI work-ins) common. Teaching (patients, APs, RNs, staff) was reported by 54% of respondents, while 23% of respondents saw PD patients; mainly in PD clinic. 47% of respondents see patients in the hospital, with the majority seeing consults and inpatient rounds. More APs report taking call (HD/PD, hospital and office) although the majority report no after-hours call. Average salaries increased to $106,000/yr with PAs earning more than NPs. This was the 10th year in a row of salary increases, although the rate of increase has decreased. Most common benefits include CME, malpractice, retirement and health insurance.

Conclusions: The NKF survey includes a detailed overview of the nephrology AP workforce in the United States. While the nephrology AP job description has changed slightly over time, with more time spent on call, outpatient dialysis remains an important area of AP involvement and APs continue to work in hospitals, office/clinic and are involved in education. It will be important to continue monitoring the evolution of the role of APs in nephrology, as they continue to complement the needs of the nephrologist and increase income to the practice.

Funding: Private Foundation Support

SA-PO204

A Biopsy of the Nephrology Workforce in a Low-Middle Income Country: The Guatemalan Example

Pablo Garcia,[1] Ever O. Cipriano,[2] Vicente Sanchez Polo.[2] *[1]Saint Peter's University Hospital, New Brunswick, NJ; [2]Nephrology, Instituto Guatemalteco de Seguridad Social, Guatemala, Guatemala.*

Background: Chronic kidney disease (CKD) is an increasing global health concern, with increasing prevalence in low to middle income countries. The availability of nephrologists is integral to providing care to a large population of CKD patients. In this study, we describe and characterize the nephrology workforce in Guatemala.

Methods: Using the National Registry of Nephrologists, we divided practices by private settings, academic settings, or those in both settings. We reported the number of nephrologists per million inhabitants using data from the Guatemalan Institute of Statistics. We also determined the area of practice (urban or rural), and characterized practitioners based on the country of training. Lastly, we determined the number of fellowship positions available in Guatemala.

Results: We note a total of 72 nephrologists in Guatemala, of which 64 were adult nephrologists and 8 were pediatric nephrologists. This represents 4.9 nephrologists per million inhabitants. 68% of nephrologists practice in Guatemala City (urban area), while 32% practice in rural areas. Overall, 64% work in private settings, 6.25% in academics, and 30% in both settings. 74% trained in Guatemala, while 26% trained abroad. The workforce is 73% male. There are two adult and one pediatric nephrology fellowship training programs in Guatemala and all are located in Guatemala City (urban area). Currently, there are a total of 14 fellows in training of which 13 are adult nephrology fellows and 1 is pediatric nephrology fellow.

Conclusions: In Guatemala, there are only 4.9 nephrologists per million people. The majority of nephrologists are male and were trained in Guatemala. Most nephrologists work in private settings, and only one-third practice in a rural area. There are three nephrology programs in Guatemala. We still have room for improvement. Based on these results, we should focus in increasing educational opportunities, create incentives to increase the number of nephrologist practicing in rural areas, open more opportunities for female physicians, increase the number of nephrology fellowship training programs in rural areas and create incentives for physicians interested in academic medicine to increase the number of nephrologist practicing in academic settings.

SA-PO205

Teaching Communications Skills in Nephrology Utilizing Sociodrama

Maulin Shah,[1] Robert Lorch,[1] Walter F. Baile,[2] Biruh Workeneh,[2] Rajeev Raghavan.[1] *[1]Baylor College of Medicine, Houston, TX; [2]MD Anderson Cancer Center, Houston, TX.*

Background: Although conversations between patients and nephrologists regarding chronic kidney disease (CKD) prognosis are associated with improved patient care and decreased surrogate burden, they reportedly occur infrequently. Most Nephrology training programs lack dedicated communication skills training (CST), and graduating fellows feel unprepared for these difficult conversations. Simulated conversations using standardized patients are effective in CST but are costly, and it is difficult to find and train committed actors. Alternatively, incorporating sociodrama techniques have been successful in Oncology CST. Sociodrama involves group members enacting social situations guided by a facilitator using techniques (primarily role-play, role reversal, and doubling--revealing unspoken thoughts and feelings) to enhance learning.

Methods: We developed a one-day, sociodramatic, facilitator-led nephrology CST workshop. Workshops began with warm-up exercises to reduce anxiety and promote participation. Learners are then guided in enacting the clinical scenarios they find most challenging. Key communication skills are taught during these role-plays. Topics included giving bad news, discussing prognosis, eliciting goals of care, and addressing family concerns. Strategies included were giving information and assessing understanding as well as responding to emotion with empathic statements (e.g. 'tell me more", and 'I wish' statements). Participants were asked to complete surveys anonymously after the workshop.

Results: 24 surveys (18 trainees and 6 faculty) were collected in 2017 and 2018. Although 42% of participants were apprehensive of sociodramatic enactments, only 17% had some difficulty. 100% of responses indicated that sociodrama enhanced learning and 92% indicated plans to incorporate learned skills into practice with 75% interested in further CST. Participants also indicated the day-long session to be lengthy.

Conclusions: Teaching communication skills in nephrology utilizing sociodrama is feasible, effective, and economical. Most participants found the workshop effective and intended to incorporate learned skills into practice. Follow-up surveys are needed to determine whether participants have used learned skills. Incorporating CST in an abridged format intermittently in the context of fellowship training may further increase the impact of this training.

SA-PO206

Using Social Media to Augment Traditional Medical Education Delivery During Inpatient Rotations

Sayna Norouzi,[4] Matthew A. Sparks,[1] Swapnil Hiremath,[6] Pablo Garcia,[2] Joel M. Topf,[5] Silvi Shah.[3] *[1]Duke University and Durham VA Medical Centers, Durham, NC; [2]Saint Peter's University Hospital, New Brunswick, NJ; [3]University of Cincinnati, Cincinnati, OH; [4]Saint Louis University, Saint Louis, MO; [5]St. Clair, Detroit, MI; [6]University of Ottawa, Ottawa, ON, Canada.*

Background: Social media in medicine has the potential to encourage lifelong learning. Medical students and residents frequently use social media for a variety of purposes. We devised a pilot project to assess to utility of using social media to deliver medical education to trainees during inpatient rotations.

Methods: Two online tools (Twitter question polls and YouTube videos) created by an internal medicine resident were utilized to deliver educational content during a month-long inpatient rotation, including nephrology ward rotation. Medical students and internal medicine residents were notified about these teaching tools via website and by direct email. Twitter was used to post a one question poll for 5 days on important topics in nephrology relevant to inpatient nephrology. Trainees answered questions online and received a 5-10 minutes lecture about the topic on the following day. Short animation videos (2-3 minutes) were made on clinical trials about contrast induced acute kidney injury by the internal medicine resident, and posted on YouTube (https://youtu.be/DoOQ5-xFcvc). An anonymous electronic survey was conducted regarding trainees' educational experience after two months.

Results: From the total of 73 responses, 81% completed the survey: 26% interns, 55% residents and 19% medical students. 37% were women. Over a month, two videos received 290 combined views. Overall, 90% reported watching the online videos less than 3 times, 7% 3-5 times and the remaining more than 5 times. On their educational experience; 73% rated it as "very educational", 23%"somewhat educational" and only 4% as "minimal educational value". In addition, 63% of respondents believed the videos were extremely helpful to remember the clinical trial results and 97% of respondents said they would watch any upcoming videos, and would be keen to participate again in the online questions on Twitter.

Conclusions: Social media tools such as Twitter and YouTube can augment traditional content delivery to enhance the learners experience. These tools can be effectively deployed on inpatient rotations. Implementing innovative tools such as social media, can improve the educational experience for trainees.

SA-PO207

Landmark Nephrology: A Multi-faceted Interactive Tool Showcasing the Classic Trials in Nephrology

Nikhil Agrawal,[1] Diana Mina,[2] Neil Roy,[4] Danwen Yang,[3] Stewart H. Lecker.[1] *[1]Beth Israel Deaconess Medical Center, Brookline, MA; [2]UCSF Division of Nephrology, San Francisco, CA; [3]Bidmc, Boston, MA; [4]BIDMC, Boston, MA.*

Background: Nephrology has a long history of truly landmark clinical studies that have helped guide our clinical practice and make it evidence-based. To recognize the genesis of our current guidelines, it is critical to be familiar with the clinical studies that inform our current practice. Highlighting these studies also demonstrate the advances this field has made and motivates developing nephrologists to participate in clinical research. We took on the challenge of showcasing these landmark studies in nephrology in a way that is interactive, fun and useful.

Methods: We formed a committee of nephrology fellows and faculty from multiple major academic centers across US. A list of topics in clinical nephrology was developed and landmark clinical studies within each topic were selected, based on the relevance of these studies to current nephrology practice. Using these topic areas and leveraging concepts in adult learning, we created narrated short videos, visual abstracts, question banks, quizzes and games.

Results: We have developed a portal **landmarknephrology.com** which has free and easily accessible content on landmark clinical trials. Eight content areas are currently represented, ranging from peritoneal dialysis adequacy to steroids in IgA nephropathy. Another 12 topics are in production. The distribution of this content is via the website, and social media including YouTube and Twitter. The website also provides options for nephrology educators to easily identify the landmark studies and download material to create stimulating classroom lectures.

Conclusions: Landmark Nephrology provides a portal for trainees and practicing nephrologists to learn about evidence based practice in nephrology and challenge their knowledge about clinical trials in the field. It is a passionate effort to find new, exciting ways to showcase nephrology's track record of producing truly landmark clinical studies and motivate the next generation of renal clinicians and scientists.

SA-PO208

Renal-Limited TMA (Thrombotic Microangiopathy) in Patients with HSCT (Hematopoietic Stem Cell Transplant): An Endothelial Variant of Graft vs Host Disease (GVHD)

Alia Hasan,[2] Rimda Wanchoo,[4] James M. Pullman,[5] Kenar D. Jhaveri,[3] Nupur N. Uppal.[1] *[1]Hofstra Northwell School of Medicine, Great Neck, NY; [2]Northwell Health, Briarwood, NY; [3]Northwell Health Sys, Great Neck, NY; [4]Zucker School of Medicine at Hofstra Northwell, GREAT NECK, NY; [5]Montefiore Medical Center, Bronx, NY.*

Introduction: Thrombotic microangiopathy (TMA) and graft versus host disease (GVHD) are well-recognized complications of hematopoietic stem cell transplantation (HSCT). TMA in HSCT (TA-TMA) is characterized by endothelial injury triggered by chemo-radiotherapy, infections or immunosuppressive drugs. Recent data suggests that GVHD itself may be a trigger of TA-TMA. We report 2 cases where GVHD in HSCT was associated with renal-limited TMA.

Case Description: A 58-year-old female with history of HSCT one year ago, was admitted with sub-acute acute kidney injury (AKI), worsening hypertension (HTN), nephrotic range proteinuria and anemia. Patient was on cyclosporine treatment for gastrointestinal GVHD at the time of admission. During the hospitalization, cyclosporine was discontinued. However, kidney function continued to worsen and she eventually required dialysis. A kidney biopsy confirmed acute on chronic TMA with minimal fibrosis. She received 2 doses of rituximab which led to the resolution of her AKI over 6 weeks. The patient eventually died due to sepsis. Our other patient, a 58-year-old-female with a second HSCT on tacrolimus therapy for skin GVHD, developed AKI 1 year after transplant along with worsening HTN, new onset proteinuria, and anemia. Her SCr worsened from 1.1mg/dl to 3.8mg/dl despite discontinuation of tacrolimus. A kidney biopsy revealed chronic TMA, with tubular reticular inclusion bodies (TRIs) without any viral etiology demonstrable by serology or immunohistochemistry.

Discussion: A relationship between GVHD and TA-TMA has been previously described but was confounded by calcineurin inhibitor use, infections, heterogeneous study populations, and retrospective study designs. Our findings suggest a possible link between GVHD and TA-TMA since both our patients presented with active GVHD in another organ concomitant with renal HSCT-TMA. Our first patient's gastrointestinal GVHD and TA-TMA improved following anti-B cell therapy (rituximab). Our second patient showed evidence of a high interferon state (TRIs) in the kidney which is also seen in GVHD. Our findings suggest that TA-TMA represents a form of "renal GVHD" or "endothelial GVHD". However, more research is needed to understand the exact mechanism of development of GVHD associated TA-TMA.

SA-PO209

Influenza Triggered Thrombotic Microangiopathy

Eric Pitts,[3] Amanda Tchakarov,[1] Jaya Kala.[2,4] *[1]Department of Pathology, University of Texas Medical School at Houston, Houston, TX; [2]Division of Renal disease and Hypertension, UT Health Science Center, Houston, Houston, TX; [3]Division of Renal disease and Hypertension, UT Health Science Center, Houston, Houston, TX; [4]Section of Nephrology, UT- MD Anderson Cancer Center, Houston, TX.*

Introduction: Thrombotic microangiopathy(TMA) is a clinical entity characterized by intravascular microangiopathic hemolytic anemia, thrombocytopenia and acute kidney

injury. Influenza virus triggered TMA(iTMA) has been rarely reported. Paucity in literature of this clinical entity prompted this report of iTMA. With this report we would like to highlight the importance of understanding other potential causes of TMA in a patient on proteasome inhibitor, also known to cause TMA.

Case Description: A 69 year old lady with diabetes mellitus, hypertension, chronic kidney disease and multiple myeloma on chemotherapy, presented with fever, weakness, shortness of breath and cough for past one day. She received her 14th cycle of carfilzomib and dexamethasone, two days prior to presentation. Her blood pressure was 188/98 mm Hg. Laboratory testing showed creatinine at baseline of 2.2 mg/dl but revealed positive Influenza A. She was admitted for hypertensive urgency and sepsis due to influenza. She was started on Osteltamivir and cancer chemotherapy was held. On day 4 of admission, nephrology was consulted for elevated creatinine of 3.18 mg/dl. Despite volume resuscitation her creatinine continued to rise to 6.88 mg/dl. Further evaluation showed that her hemoglobin drop to 7.7gm/dl, platelets 34,000/uL, lactate dehydrogenase elevated at 849U/l, undetectable haptoglobin. This in addition to hypertensive urgency prompted the diagnosis of TMA. ADAMSTS 13 activity was normal. Hemodialysis was started for worsening renal function and oliguria. Renal biopsy suggested presence of TMA. She received a course of ostelamivir and needed dialysis for a week. After the therapy she stayed off dialysis and returned to baseline creatinine in 2 weeks. Our patient was on carfilzomib for the last 11 months, known to cause TMA, however she developed it only after the influenza infection. She couldn't restart carfilzomib due to financial issues.

Discussion: Influenza associated TMA is a rare entity. It has been reported to occur around 4 days after the onset of infection, like in our patient. The outcome of iTMA is generally favorable with supportive care.. Our patient was on carfilzomib for 11months and the only apparent trigger for the TMA was influenza. Identification of the etiology and differentiation between drug induced complement dysregulation and influenza associated HUS without identifiable complement abnormalities are crucial for treatment.

SA-PO210

Renal Thrombotic Microangiopathy with Multiple Myeloma: Resolution with Chemotherapy

Lindsey Ehren,[2] Dae Hyun Lee,[2] Kayla Shirley,[2] Abu-Sayeef Mirza,[2] Onyekachi C. Obi,[3] Claude Bassil,[3] Rachid Baz,[4] Donald E. Wheeler.[1] *[1]Pathology and Cell Biology, University of South Florida, Tampa, FL; [2]Internal Medicine, University of South Florida, Tampa, FL; [3]Nephrology and Hypertension, University of South Florida, Tampa, FL, FL; [4]H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL.*

Introduction: Thrombotic microangiopathy (TMA) is a clinical entity described by systemic microvascular occlusion, causing hemolytic anemia and thrombocytopenia resulting in end-organ ischemia. Numerous mechanisms may cause the condition including direct immunoglobulin deposition or chemotherapy. TMA is a pathological diagnosis characterized by fibrin thrombi within arterial vessels including the capillaries. Recent literature shows up to 13.7% of patients with thrombotic microangiopathy have monoclonal immunoglobulin. We present a case in which renal TMA-associated acute kidney injury responded to multiple myeloma treatment.

Case Description: A 43-year-old male with history of recent Bell's palsy and peripheral neuropathy presented with abdominal distension, dyspnea and unintended weight loss. Initial evaluation was significant for anemia (Hgb 8.9g/dL), normal platelet count (265,000/mm^3), normal LDH (139 U/L) and acute kidney injury (Creatinine 2.2mg/dL). CT of abdomen and pelvis demonstrated large-volume ascites and nonspecific sclerotic density in left iliac bone. Subsequent workup included a bone marrow biopsy significant for 30% plasma cells with 90% cellularity, and serum protein electrophoresis of positive IgA lambda monoclonal gammopathy (IgA 928mg/dL, M spike 0.5g/dL). Diagnosis of plasma cell myeloma was made. Renal biopsy was consistent with chronic thrombotic microangiopathy without immunoglobulin deposits by IFM or EM. The patient was treated with cyclophosphamide and prednisone (50mg). Renal function improved within the first three weeks of treatment to 1.3mg/dL.

Discussion: Very few cases have reported renal TMA with multiple myeloma to date. Distinct from the typical light-chain associated renal tubular injury of multiple myeloma, AKI due to TMA is also described. Our patient is one of few reported cases in which myeloma treatment resulted in improvement in renal TMA-induced renal insufficiency. Further investigation is needed to establish management guidelines for renal failure in this setting.

SA-PO211

A Case of Diffuse and Nodular Glomerulosclerosis in Waldenstrom's Macroglobulinemia

Lindsey Ehren,[2] Dae Hyun Lee,[2] Nicoleta Radoianu,[3] Abhishek M. Kumar,[1] Claude Bassil,[3] Liying Fu.[4] *[1]University of South Florida College of Medicine, New Port Richey, FL; [2]Internal Medicine, University of South Florida, Tampa, FL; [3]Nephrology and Hypertension, University of South Florida, Tampa, FL; [4]Tampa General Hospital, Tampa, FL.*

Introduction: Diffuse and nodular glomerulosclerosis (DNGS) is commonly associated with diabetic nephropathy and occasionally with tobacco users. However, it has also been associated with amyloidosis, cryoglobulinemia, and light-chain deposition disease. To the best of our knowledge, there is no published data on DNGS without light chain deposition in Waldenstrom's Macroglobulinemia (WM). We present a case of DNGS in a non-diabetic, non-smoker with WM.

Case Description: A 72-year-old male with past medical history of Waldenstrom's Macroglobulinemia develops worsening renal function after CP-R (cyclophosphamide/prednisone plus rituximab) treatment with partial remission. He does not have diabetes, hypertension or other comorbidities; he is a non-smoker. He uses minimal NSAIDs and denies recent or prior intravenous contrast use. Two months after completion of CP-R regimen, creatinine started rising from baseline 1.0mg/dL to 2.2mg/dL over two years. Serum IgM decreased from 3414 to 2360 after treatment. Blood glucose, liver function panel, and albumin levels were normal. Renal ultrasound showed normal echogenicity without hydronephrosis. Kidney biopsy showed moderate diffuse and nodular glomerulosclerosis with focal cortical atrophy, hypoperfusion and focal global and segmental glomerulosclerosis and moderate vascular sclerosis. Biopsy showed stronger background staining for kappa light chains compared to lambda light chains, without Randall-type electron dense deposits. There was no evidence of monoclonal immunoglobulin deposition, amyloidosis, light chain tubulopathy or light chain cast nephropathy.

Discussion: Waldenstrom's Macroglobulinemia is a hematologic malignancy characterized by clonal proliferation of B-lymphocytes producing IgM monoclonal gammopathy secretion. It could involve the kidney through large intracapillary IgM deposition, cryoglobulin or amyloidosis related injury. Per literature review, there are no documented cases of DNGS in a patient with WM without history of diabetes or tobacco use. Further research is required to evaluate the prevalence and mechanism behind the association of DNGS and WM.

SA-PO212

Anti-C5 Antibody for Thrombotic Microangiopathy in Scleroderma Renal Crisis

Shana M. Machado,[2] Jaya Kala.[1] *[1]Division of Renal disease and Hypertension, UT Health Science Center, Houston, Houston, TX; [2]Division of Renal disease and Hypertension, UT Health Science Center, Houston, Houston, TX.*

Introduction: Scleroderma renal crisis(SRC), presenting as malignant hypertension, acute kidney injury(AKI), thrombocytopenia and microangiopathic hemolytic anemia, is a major complication of systemic sclerosis. Seen more common in patients treated with glucocorticoids. Prognosis remains severe despite treatment with angiotensin converting enzyme inhibitor(ACEI). Studies suggest that complement activation trigger thrombotic microangiopathy(TMA) in SRC. We report a case of SRC with TMA treated with anti-C5 antibody

Case Description: 51 yr-old female with hypertension, hypothyroidism, dyspnea due to interstitial lung disease(ILD), without kidney disease, presented with worsening vision and severe headache. She was on myfortic and prednisone for the past 8 months for ILD. Her computed tomography scan revealed frontal cortical subarachnoid hemorrhage and bilateral posterior parietal subcortical hypo densities. For her high blood pressures she was started on Cardene drip. Hemodialysis was started for uremic symptoms with creatinine of 4.06 mg/dl and blood urea nitrogen 92 mg/dl. Laboratory evaluation with platelets 161,000/cmm, LDH 800U/L, hemoglobin10.5g/dl and haptoglobin undetectable, few schistiocytes, normal ADAMTS13activity, AKI and hypertensive emergency indicated possibility of TMA, likely atypical hemolytic uremic syndrome. Rheumatological evaluation of ILD revealed nucleolar pattern ANA and high PMSL antibody indicating NSIP with PM-Scl overlap without skin involvement. There was high suspicion of SRC, possibly precipitated with the use of glucocorticoids. Despite captopril she did not show any signs of renal recovery. Renal biopsy done revealed presence of acute TMA with arterial, arteriolar and glomerular C5b-9 staining. These findings were suggestive of the presence of complement dyregulation and therefore decision to start anti-C5 antibody(ecluzimab) was made. The patient's platelets count recovered with 3 doses of ecluzimab. The patient is currently on the maintenance dose of ecluzimab. She has improved renal functions, requiring dialysis once a week. Her genetic testing is awaited

Discussion: Scleroderma renal crisis have high incidence of end stage renal disease despite use of ACEI. Since, complement activation has been described in autoimmune disorders including SRC, we considered the use of anti-C5 antibody in the treatment of TMA in our patient to achieve decreased dialysis dependence.

SA-PO213

Eculizumab Responsive Atypical Hemolytic Uremic Syndrome Triggered by a Multisystem Lupus Flare

Bushra Syed,[2,1] Hernan Rincon-Choles,[2,1] Juan C. Calle.[2,1] *[1]Nephrology, Cleveland clinic Foundation, Cleveland, OH; [2]Cleveland Clinic, Cleveland, OH.*

Introduction: Uninhibited alternative complement pathway activation leads to complement mediated hemolytic uremic syndrome. Infections, pregnancy, drugs or ongoing lupus activity can trigger this cascade. Concurrent occurrence of aHUS with lupus is rare. We present a case of aHUS with hematological and renal responsiveness to eculizumab

Case Description: A 25-year-old Caucasian female with HTN, IgA deficiency and class III A + V lupus nephritis on maintenance prednisone, mycophenolate and hydroxychloroquine, presented with abdominal pain and encephalopathy. Workup showed Hb of 7.9g/dl, thrombocytopenia, schistocytes, low haptoglobin and elevated LDH. TTP and autoimmune hemolysis were ruled out. Hypocomplementemia and positive dsDNA and ANA were noted. Soluble membrane attack complex level was elevated and membrane cofactor protein was low. Factors H, I, B were within normal limits. Factor H autoantibody, antiphospholipid antibody panel and scleroderma antibodies were negative. Creatinine peaked at 5 mg/dl (baseline1.2mg/dl)and she had nephrotic range proteinuria -6g. Hemorrhagic pancreatitis and cerebritis seen on imaging. Infectious etiologies were ruled out. Renal biopsy showed Class III and V Lupus with moderate activity, thrombotic microangiopathy and diffuse ATN. Despite initiation of pulse dose steroids, cyclophosphamide she developed multisystem organ failure requiring mechanical ventilation, renal replacement therapy and multiple transfusions. Plasma exchange was deferred due to IgA deficiency. Subsequently initiated on eculizumab with improvement

in hematological parameters after 2 doses. Renal recovery with discontniuation of dialysis occurred after 4 doses. She remains in remission on prednisone, MMF, hydroxychloroquine and eculizumab at 9 month follow up with a Cr of 0.7 and proteinuria of 0.5g.

Discussion: Active Lupus serves as a driver for aHUS. Thrombotic microangiopathy is an independent risk factor for poor outcome in lupus nephritis with mortality rates of over 30% despite the use of multimodal treatment strategies. Terminal complement inhibitors can effectively induce hematological and renal response and there should be a low clinical threshold to initiate eculizumab in the setting of refractory disease. Data regarding the optimal dosing schedule, monitoring and treatment end points is lacking and needs additional studies.

SA-PO214

Eculizumab Treatment in Recurrent Dense Deposit Disease

Duy T. Vu,[1] Joe Ghata.[2] *[1]University of Oklahoma Heath sciences center, Yukon, OK; [2]OUHSC, Oklahoma City, OK.*

Introduction: Dense deposit disease (DDD) is a rare complement-mediated glomerular disease typically affecting children and young adults. About 50% of affected patients develop end stage renal disease by 10 years. Treatment decisions are primarily based on case reports, expert opinion, etc. Terminal complement proteins are thought to be involved in the pathogenesis of DDD. Eculizumab, an anti-C5 antibody, prevents the formation of the terminal complement complex, however the efficacy with this drug has been mixed.

Case Description: We present a 23 years old female with DDD diagnosed at age 10. She underwent cadaveric renal transplant at age 19. A year later, she developed biopsy proven recurrent DDD in her renal allograft. She also had elevation in the C5-9 complex (328 ng/mL), creatinine (1.65 mg/dL), and protein/creatinine ratio (6.1 grams). She was started on Eculizumab 900 mg weekly injection for 4 weeks and then 1200 mg every two weeks for 16 months. Biochemical markers normalized after 1 dose without adverse events. She was in clinical remission from DDD for 18 months when her creatinine (baseline 1-1.2 mg/dL) rose and peaked at 2.59 mg/dL with nephrotic range proteinuria (pro/cr ratio was 12 grams). Biopsy of her renal allograft again revealed recurrent DDD. She had elevated plasma Ba fragment and soluble C5b-9 and low C3, C4, and C5 which are consistent with abnormal activation of the alternative pathway. The alternative pathway functional assay was low and is consistent with the consumption of the above complements. The complement Bb level was borderline elevated. The C3Nef, C4Nef, C5Nef, and Nef activity assay were all negative. Complement factor I, factor H, and properdin levels were normal. In summary, these results support the recurrence of DDD. Subsequently, the patient was given Eculizumab 1200 mg every two weeks with rapid improvement in peripheral edema, creatinine, and proteinuria.

Discussion: Our patient suffered from DDD, a rare and incurable kidney disease, but demonstrated quick and effective response to eculizumab. Eculizumab induced remission in our patient. The natural history of this disease has a high recurrence rate which was evident in our patient. However, it is promising that she demonstrated clinical response despite relapse. This case suggests eculizumab may be effective in treating recurrent DDD and preserving the renal allograft.

SA-PO215

Eculizumab for the Treatment of Recurrent C3 Glomerulonephritis Caused by a C3 Gain of Function Mutation

Joon S. Kim,[1] Ryan Mullane,[2] Scott G. Westphal,[3] Eric D. Langewisch,[2] Clifford D. Miles.[2] *[1]University of Nebraska Medical Center, Omaha, NE; [2]University of Nebraska Medical Center, Omaha, NE; [3]University of Nebraska Medical Center-Nebraska Medicine, Omaha, NE.*

Introduction: C3 glomerulonephritis (C3GN) is a glomerular disease caused by excessive activation of the alternative complement pathway and often leads to end-stage renal disease. Following kidney transplantation, the recurrence risk is high and may cause premature allograft failure. Eculizumab prevents the membrane attack complex (MAC) formation and provides terminal complement inhibition. Here we present a case of early recurrent post-transplant C3GN in a patient with a C3 gene mutation that was successfully treated with eculizumab.

Case Description: A 38 year old female with a history of chronic kidney disease received a living unrelated kidney transplant. Prior to her transplant, she was diagnosed with C3GN which was refractory to corticosteroids, mycophenolate, and rituximab. Evaluation revealed a C3 gain of function mutation. Complement inhibitory factors were normal and she did not have a C3 nephritic factor. An elevated level of soluble MAC (sMAC) was noted prior to transplantation. She had immediate graft function following her transplant and she was maintained on tacrolimus, mycophenolate, and prednisone following basiliximab induction. Her creatinine reached a nadir of 1.1 mg/dl, but she developed early acute allograft dysfunction and proteinuria within the first few weeks of transplant and biopsy revealed early recurrence of C3GN. She was treated with high dose corticosteroids and plasmapheresis, but continued progression of renal dysfunction with rising sMAC levels, proteinuria, and activity of C3GN on a repeat biopsy. After initiation of eculizumab, her sMAC levels normalized, proteinuria resolved, and the allograft function improved. She is now >1 year out from transplantation with stable allograft function and no evidence of complications related to the eculizumab.

Discussion: Eculizumab appears to have a role in select patients with recurrent C3GN. Since not all patients with C3GN improve with eculizumab, more research is needed to define patients expected to benefit from this therapy. Patients with recurrent C3GN due to a gain of function mutation in the C3 gene should be considered for early eculizumab therapy to preserve allograft function and decrease excessive complement activity.

SA-PO216

C3 Glomerulonephritis, a Rare Etiology of the Pulmonary Renal Syndrome

Shane A. Bobart, Sanjeev Sethi, Fernando C. Fervenza. *Mayo Clinic, Rochester, MN.*

Introduction: C3 Glomerulopathy (C3GN) is a rare disease due to complement factor deposition in the glomerulus as a result of dysregulation of the alternative complement pathway. We present a rare case of C3GN presenting with diffuse alveolar hemorrhage (DAH) as a pulmonary-renal syndrome.

Case Description: A 20 year old female presented to the emergency department with flank pain and hematuria. Approximately 8 weeks prior, she had polyarthralgia, purpuric rash over the abdomen, buttocks and lower extremities with associated edema. She was treated for post-streptoccocal infection in the setting of high ASO titer (1490 IU/mL). On examination, she demonstrated persistent petechial rash and new right sided CVA tenderness. Blood pressure was 126/70 mmHg. On investigation, she was anemic with hemoglobin 8.1, had an acute kidney injury with creatinine 1.6 mg/dL and urinalysis showed 3.5 grams predicted 24 hour proteinuria, dysmorphic hematuria, >100 RBCs per high power field. Serology tests were notable for negative ANA, PR3-ANCA, MPO-ANCA, anti-GBM, Cryoglobulin, Hepatitis, HIV serology and paraproteinemia studies. Kidney biopsy showed focal endocapillary proliferative, crescentic, and necrotizing glomerulonephritis with bright glomerular C3 staining. On electron microscopy there was mesangial, intramembranous and sub-endothelial deposits with absence of sub-epithelial humps. She was initiated on pulse dose steroids and subsequently developed spontaneous hemoptysis requiring emergent intubation. Bronchoscopy confirmed DAH with cytopathology showing 0% hemosiderin-laden macrophages. Further work up revealed low complement (C3 40, C4 6 mg/dL) with decreased function of the alternate complement pathway at 55% (75-170% normal range). A diagnosis of C3GN with associated pulmonary hemorrhage was made. She required plasmapheresis and transitioned to prednisone and mycophenolate mofetil. As an outpatient, genetic testing showed 3 copies of C3GN risk alleles, but with negative mutations for complement factor H and factor I, negative factor H autoantibody or C3 nephritic factor. Renal function deteriorated despite aggressive immunosuppression and eculizumab therapy and she required hemodialysis.

Discussion: C3GN should also be considered part of the differential diagnosis in the setting of ANCA negative pulmonary renal syndrome.

SA-PO217

C3 Glomerulonephritis in Children

Ji hyun Kim, Hee Gyung Kang, IL-Soo Ha, Hae Il Cheong. *Seoul National University Children's Hospital, Seoul, Republic of Korea.*

Introduction: C3 glomerulonephritis (C3GN) is marked by subendothelial and/or mesangial electron dense deposits, which displays isolated glomerular C3 deposition without concomitant staining for Ig. Since clinical manifestations and long-term outcome of C3GN have not been clarified yet, especially those in children, we reviewed our cases of pediatric C3GN. Among more than two thousand biopsy cases performed in our center since Jan 2004 (for 15 years), ten cases (M:F 5:5) were compatible to C3GN. Their medical records were retrospectively reviewed.

Case Description: Pediatric C3GN patients at our center presented at their median age of 9.2 years with asymptomatic urinary abnormality (n=6), acute glomerulonephritis (n=3) or nephrotic syndrome (n=1). Hematuria was noted in nine (6 microscopic and 3 gross hematuria). Initial renal function was normal range in all. Initial serum C3 levels were low in all the cases but one. Pathologic diagnoses were C3GN for three, but those who were presented before 2015 had been initially diagnosed as PIGN (n=3) or MPGN (n=4); One patient with pathologic diagnosis of PIGN had follow-up biopsy in 20.2 months and finally diagnosed C3GN. All the patients were managed with ACE inhibitor or ARB, and eight were treated with additional steroid and other immunosuppressants of CNI or MMF. One patient with poor compliance progressed to ESRD in 5 years, despite therapeutic trial of eculizumab. The other 9 patients had normal renal function at last visit; Last serum C3 levels were normal in 4 and persistently low in the rest.

Discussion: Pediatric cases of C3GN showed diverse presentation, and some of the were initially mis-diagnosed as PIGN. Interestingly their outcome was fair, although our number of subjects was too small to draw any conclusion. For better understanding of this entity, further study on regulatory system of ACP is required, as well as other markers which can predict clinical course of C3GN.

Patient characteristics

SA-PO218

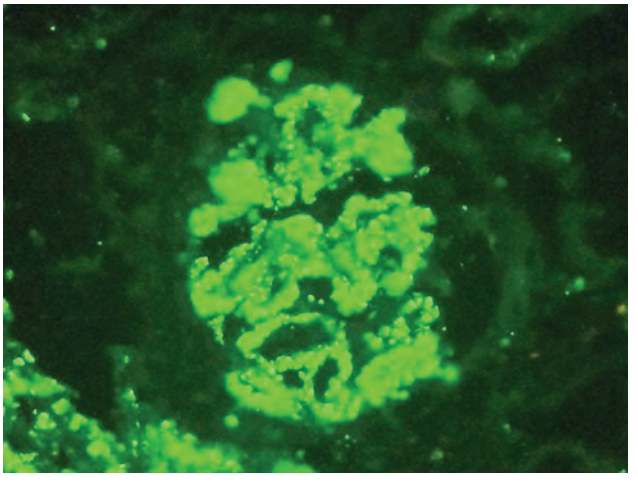
LCAT Deficiency with C3 Glomerulopathy: Case Report

Gerard F. Sales,[1] Jordan D. Vasconcellos,[3] Gabriela C. Segura,[1] Tomas D. Ferreira,[4] Lectícia Jorge,[2] Viktoria Woronik.[2] *[1]Hospital das Clínicas University of São Paulo (USP), SÃO PAULO, Brazil; [2]University of São Paulo, São Paulo, Brazil; [3]Faculdade de Medicida da Universidade de Sao Paulo, São Paulo, Brazil; [4]Universidade de São Paulo, São Paulo, Brazil.*

Introduction: Lecithin cholesterol acyltransferase (LCAT) deficiency is an autosomal recessive disorder of lipoprotein metabolism that produces deposit of unesterified cholesterol in the cornea, kidneys, and erythrocytes. Kidney biopsy typically shows vacuolation of glomerular capillary walls, foam cells and spiculation as well as duplication of the glomerular basal membrane (GBM). The immunofluorescense (IF) studies are typically negative although C3 non specific depositions are described. Here we present a case of LCAT deficiency that showed some C3 glomerulopathy aspects.

Case Description: We report a case of a 19-year-old woman with a brother diagnosed with LCAT deficiency who presented with low limb edema, foamy urine and corneal fish-eye-like alterations. Laboratory tests showed extremely low HDL levels (3 mg/dl), normal renal function (CKD-EPI 137 ml/min/1,73m2), subnefrotic proteinuria (1,8 gr/24 hours), anemia (hemoglobin 10,0g/dl) and normal complement (C3 108 mg/dL; C4 27,4 mg/dL). Kidney biopsy evidenced podocyte and mesangium vacuolation, double-contour basal membrane and subendothelial as well as intramembranous hyaline deposits. On IF we found only C3 granular depositions with medium intensity (2+) on the glomerular capillary wall and tubular basal membrane with diffuse distribution.

Discussion: In literature, we found two cases reported of LCAT deficiency associated with dense deposit disease (DDD). Our patient had mixed lesions of LCAT deficiency and medium (2+) intensity C3 deposition pointing more to a C3 glomerulopathy than to a non specific deposition. Electronic microscopy in process should define the diagnosis. It has been affirmed that structural changes in renal GBM could occur due to alterations in galactosyl fraction provoked by extraneous material deposition. Therefore, we can speculate that deposition of abnormal non esterified cholesterol in LCAT deficiency could be related to activation of complement cascade.



SA-PO219

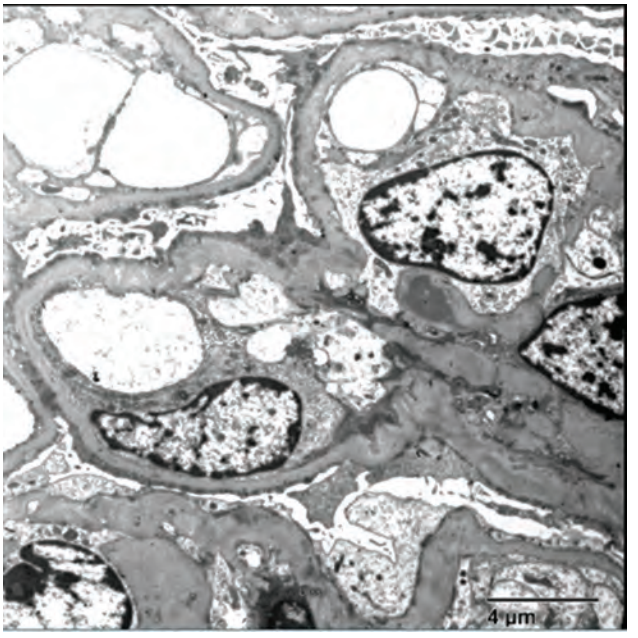
What Lies in-Between: A Case of C3 Glomerulopathy with Non-Hemolytic Renal Microangiopathy and a Unique C3 Variant

Ali D. Jandal, Weixiong Zhong, Sana Waheed, Gauri Bhutani. *University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Introduction: A difference in location of alternate pathway dysregulation is thought to be the cause of the distinct clinical disorders of C3 glomerulopathy (C3G) and atypical hemolytic uremic syndrome (aHUS).

Case Description: A 36 year-old female with history of prior alcohol abuse presented with abdomen pain, nausea, and vomiting for one day prior to admission. Serum creatinine (S.Cr) was 2.6 mg/dL (unclear baseline) and serum lipase was 445 U/L. Urinalysis showed hematuria and urine protein-creatinine ratio (UPC) was 6.35 g/g. Her pancreatitis was managed conservatively. Pain improved but S.Cr reached 7.5 mg/dL by hospital day (HD) #5 - a kidney biopsy was performed and pulse dose steroids were initiated. [Fig1] A membranoproliferative glomerulonephritis with focal crescents and positive C3 was found. Severe diffuse endothelial swelling and small amounts of electron dense deposits were seen on electron microscopy. No hemolysis was detected but plasmapheresis (PP) was started due to worsening S.Cr. Renal function improved; patient was discharged on steroids and cyclophosphamide as eculizumab was not approved by insurance. Complement genetic testing revealed a unique variant in 1 allele of C3 gene and a heterozygous deletion of CFHR3-CFHR1. Now, two months later, patient is readmitted with recurrence of her renal syndrome and pancreatitis.

Discussion: Endothelial damage, recurrent pancreatitis and response to PP are features of aHUS. These, together with a C3 positive crescentic glomerulonephritis, sparse deposits and a unique C3 genetic variant strongly suggest the possibility of a syndrome with overlap between C3G and aHUS.



SA-PO220

Postpartum Associated Atypical Hemolytic Uremic Syndrome

Hristo Shivarov,[1] Maria V. DeVita.[2] *[1]Lenox Hill Hospital - Northwell Health System, Secaucus, NJ; [2]Lenox Hill Hospital- Northwell Health System, New York, NY.*

Introduction: Pregnancy associated atypical hemolytic uremic syndrome is a rare, life threatening, progressive systemic disease of uncontrolled activity of the alternate complement pathway resulting in systemic thrombotic microangiopathy during pregnancy or postpartum period. The diagnosis of this condition is challenging and can mimic various diseases found during pregnancy and the postpartum.

Case Description: 35 year old woman without significant past medical history who presented to our hospital for elective delivery at 37th weeks gestation. During the induction period the labor arrested, the patient became hypertensive to 170/100 mmHg with subsequent fetal bradycardia necessitating a C-section. Immediately postpartum uterine atony with severe hemorrhage was observed. The patient was intubated and was placed on pressor support. Severe anemia was registered with hemoglobin drop to 6.8 from 12.0 g/dl. The hemoglobin level was 6.9 g/dl after transfusion 4 units of PRBC. There were no overt signs of bleeding. Additional studies showed: LDH 1324 u/l, haptolgobin <10 mg/dl, and platelets – 62 from 212 K/uL; schistocytes were noticed on peripheral smear. Deterioration of the renal function was observed over the next 48 hours with anuria, creatinine peaked to 7.02 mg/dl. Hemodialysis was initiated for oliguria, hyperkalemia and fluid overload. Subsequent studies showed decreased level of C3 at 73 mg/dl with normal C4. Differential diagnosis included TTP, severe pre-eclampsia, aHUS, malignant hypertension and ischemic ATN. Plasma exchange was started with iv prednisone 100 mg/daily, ADAMTS13 was 42% excluding TTP. Eculizumab 900 mg/weekly was started 5 days POD. Gradually the hemoglobin level and platelets stabilized. The patient was extubated and the hemolysis resolved. HD treatment was discontinued on POD 19 after significant improvement of the renal function and good control of blood pressure. During the hospital stay she received total of three doses of eculizumab. The patient was discharged with continuation with eculizumab biweekly

Discussion: Diagnosis of pregnancy associated aHUS must be considered early in postpartum period in patient with hemolysis, rapid deterioration of renal function despite the possibility of superimposed acute tubular injury, abnormal complement function and normal ADAMTS13 activity. Early initiation of treatment with plasma exchange and eculizumab has proven its efficacy in postpartum aHUS.

SA-PO221

A Rare Case of Clostridium Difficile Causing Atypical Hemolytic Uremic Syndrome

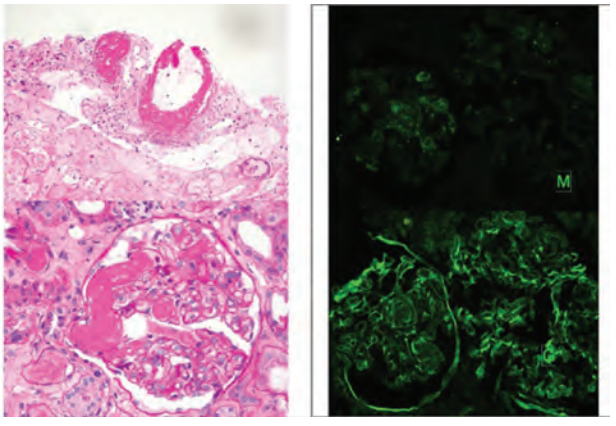
Jessamyn Carter, Narottam Regmi. *University of Oklahoma School of Community Medicine, Tulsa, OK.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is a rare form of thrombotic microangiopathy mediated by excess activation or dysregulation of the alternate complement pathway. The incidence is 2 per 1 million people in the United States. We present a case of aHUS caused by *C. difficile* with persistent renal failure.

Case Description: 52-year-old morbidly obese man with hypertension, sleep apnea, and recurrent deep vein thrombosis admitted for worsening fatigue and bloody diarrhea since treatment with clindamycin then trimethoprim-sulfamethoxazole 2 weeks prior. He had acute renal failure with creatinine 4.9 and oliguria, hemolytic anemia, thrombocytopenia, leukocytosis, and active urine sediment with RBCs, WBCs and protein. CT abdomen and

renal ultrasound were unremarkable. Left renal biopsy showed severe acute glomerular microangiopathic injury. He began intermittent hemodialysis (HD) and plasma exchange. ADAMTS13, total complement, C3/C4, ANA and ANCA and tests for *E.coli* 0157:H7, Shiga toxin, HIV, and hepatitis were normal. aHUS genotype panel was equivocal. Stool was positive for *C. difficile*. After plasma exchange and steroids, he remained oliguric on HD. Eculizumab was started for aHUS. Despite treatment, he remains HD dependent awaiting transplant.

Discussion: 90% of HUS is secondary, usually to *E.coli* 0157:H7 or Shiga toxin (typical diarrhea+ HUS), *S. pneumoniae* infection, pregnancy, or drugs. There is no known causation by clindamycin or trimethoprim-sulfamethoxazole. Normal complement and equivocal aHUS genotype results do not rule out aHUS. A few case reports suggest *C. difficile* infection may cause HUS, though prior cases had full renal recovery. Our patient's clinical, lab, and histopathologic findings support diagnosis of aHUS from *C. difficile* infection. Though rare, *C. difficile* must be considered as a cause of aHUS. Our patient presents further difficulty as renal function remains poor despite antibiotic therapy and eculizumab.



Biopsy with cortical necrosis, severe acute glomerular microangiopathy

SA-PO222

Myeloma Kidney with C3 Deposition

Asif Khan, Elie El-Charabaty, Suzanne E. El Sayegh. *Staten Island University Hospital, Brooklyn, NY.*

Introduction: Renal complications of multiple myeloma (MM) include monoclonal immunoglobulin deposition disease and myeloma cast nephropathy. Up to 50% of MM patients present with renal impairment at diagnosis, 20% may present with acute kidney injury (AKI) and 10% require dialysis. In C3 glomerulopathy, which is one of the complement-mediated types of Membranoproliferative Glomerulonephritis (MPGN), defects in complement regulatory proteins promotes the excessive activation of the alternative pathway.

Case Description: A 59-year-old man with a two-year history of hypertension presented with generalized weakness for the past 3 months. Physical examination reveals a well-appearing male with a bp 137/77 mmHg, pulse 103 bpm, with fairly normal physical findings. On admission: Hb 9.1 g/dl; RBC 1.45 mil/mm^3; WBC 3.2 th/mm^3; plt 94 th/mm^3; BUN 94 mg/dl; Cr 10.47 mg/dL (baseline Cr 1.5 mg/dL); BUN/Cr 8.77; FeNa 8.7%; Na 130 mEq/L; K 6.2 mEq/L; HCO3 14 mEq/L; Urine analysis showed 2+ protein with bland urine sediment and microscopic hematuria. 24-hour urine protein was 2g/day. Renal ultrasound showed 0.6 cm right renal cyst. The patient was admitted to ICU for hyperkalemia with AKI and was consequently hemodialyzed. Serologies were notable for low levels of C3 (46 mg/dL) with normal C4 were observed. Immunofixation by Electrophoresis of both serum and urine showed free Lambda band present. Serum plasma electrophoresis showed two M-spikes: Lambda light chains and IgG Lambda. Free kappa/lambda ratio <0.01. Urine electrophoresis showed three monoclonal bands. Serum levels of IgG 2500 mg/dl. A renal biopsy was performed and cast nephropathy was identified with mesangial staining for C3. Bone marrow biopsy showed CD 56 positive Plasma Cell Myeloma. MM was diagnosed with IgG lambda cast nephropathy and ESRD on dialysis with pancytopenia. He was treated with Velcade, Cytoxan, and dexamethasone. SPEP status post chemotherapy showed two M-spikes with improvement of renal function and normal C3 levels. At 4 months post-biopsy, the patient remained dependent on hemodialysis therapy and required multiple blood transfusions.

Discussion: We hypothesize in monoclonal gammopathy induced C3 glomerulopathy, paraprotein itself is acting as a trigger that activates and dysregulates the AC pathway systemically. Thus, it is highly feasible to tailor the treatment to reduce the amount of paraproteins in C3 glomerulopathy associated with Myeloma kidney.

Myeloma-Like Cast Nephropathy in a Patient with Pancreatic Mixed Acinar-Neuroendocrine Cancer

Haiyan Zhang,[1] Omar Mamlouk,[2] Manoj Bhattarai,[6] Amit Lahoti,[4] Biruh Workeneh,[5] William F. Glass.[3] *[1]Pathology, The University of Texas Health Science Center, Houston, TX; [2]Nephrology, University of Texas Health Science Center at Houston, Houston, TX; [3]Pathology, University of Texas – Houston Medical School, Houston, TX; [4]M D Anderson Cancer Center, Houston, TX; [5]MD Anderson Cancer Center, Houston, TX; [6]Nephrology, The University of Texas Health at San Antonio, San Antonio, TX.*

Introduction: Myeloma cast nephropathy is a very serious diagnosis, which triggers immediate work-up for multiple myeloma and aggressive chemotherapy. However, there are rare renal conditions with morphological features similar to myeloma cast nephropathy but without evidence of plasma cell dyscrasia or monoclonal gammopathy. "Myeloma"-like casts result from precipitation of abnormal proteins along with Tamm Horsfall glycoprotein in distal tubules and collecting ducts leading to an inflammatory response with giant cells and acute kidney injury. Myeloma-like casts have been reported occasionally in patients with pancreatic adenocarcinoma, thyroid cancer, HIV, antibiotic and cisplatin use. We present here a case of myeloma-like cast nephropathy in a patient with pancreatic mixed acinar-neuroendocrine cancer (MANEC).

Case Description: The patient was a 60-year old male undergoing chemotherapy for biopsy-confirmed pancreatic MANEC with metastasis to liver. He presented with acute kidney injury (AKI) and mild proteinuria without hematuria or pyuria. Ultrasound showed normal renal size and echogenicity with no signs of obstruction. The kidney biopsy was obtained due to AKI with no clear etiology. The biopsy showed diffuse acute tubular epithelial injury with focal tubular obstruction by casts that varied in size. Some casts appear crumbled or moth-eaten. Focal casts were also associated with an inflammatory reaction that included neutrophils and/or syncytial multinucleated giant cells. No monoconal paraprotein detected in the biopsy, serum or urine. HIV screening test was negative and patient had no history of cisplatin use.

Discussion: Pancreatic MANEC is very rare. Myeloma-like cast nephropathy associated with pancreatic neoplasia is even rarer and has been seen only with adenocarcinomas. Thus, in this case, the myeloma-like cast are more likely associated with the exocrine component (acinar carcinoma), which produces excessive proteins obstructing the distal tubules, and cause tubular epithelial injury and inflammation with multinucleated giant cells. To our knowledge, this is the first report of myeloma-like cast nephropathy associated with neuroendocrine neoplasms. Because of the significant clinical associations and treatment differences, it is critical not to misdiagnosis this entity as myeloma cast nephropathy.

SA-PO224

A Case of Monoclonal Gammopathy Presenting with an Unexpectedly High Level of Serum Creatinine Due to Positive Interference in an Enzymatic Assay

Ryoko Mizuhara, Naoto Hamano, Masahiro Koizumi. Tokai University School of Medicine Division of Nephrology, Endocrinology, and Metabolism *Tokai University School of Medicine, Isehara, Japan.*

Introduction: In Japan, serum creatinine level is routinely measured by enzymatic method and a variety of enzyme assay kits are available. Monoclonal gammopathy can interfere with enzymatic assay for creatinine.

Case Description: A 78-year-old man was referred to the department of thoracic surgery in our hospital for the evaluation of lung tumor. At the initial visit to our hospital, the level of serum creatinine increased sharply from 1.03 mg/dl to 4.68 mg/dl during 5 days before the referral. He was generally well, and did not complain of anorexia, fever or oliguria. (No causative drug or infection was detected.) Other laboratory tests revealed a BUN level of 21 mg/dL, almost normal urinalysis (with microscopic hematuria), and an IgM level of 1366 mg/dL. We performed kidney biopsy, but could not identify the cause of AKI. In the meantime, we diagnosed lymphoplasmacytic lymphoma based on bone marrow biopsy. Despite high creatinine level measured in our hospital, that measured in the other hospital soon after the biopsy was nearly normal. To elucidate the cause of the discrepancy in the measured values, we analyzed the measurement methods. We observed the formation of white precipitation after addition of the reagent of the creatinine assay kit using in our hospital to the serum of this patient. This turbidity was not found when measuring by Jaffe method or by enzymatic method after protein removal from his sera, leading to the diagnosis of pseudohypercreatininemia secondary to paraproteinemia. GFR estimated from serum cystatin C was 33.3 ml/min/1.73m^2, consistent with that from "true" serum creatinine.

Discussion: Pseudohypercreatininemia should be considered in the search for the cause of isolated creatinine elevation in patients with paraproteinemia. In such patients, we should measure serum creatinine by multiple methods to evaluate renal function accurately. Comprehensive evaluation of creatinine measured by multiple methods and cystatin C may provide accurate renal function of patients with monoclonal gammopathy.

SA-PO225

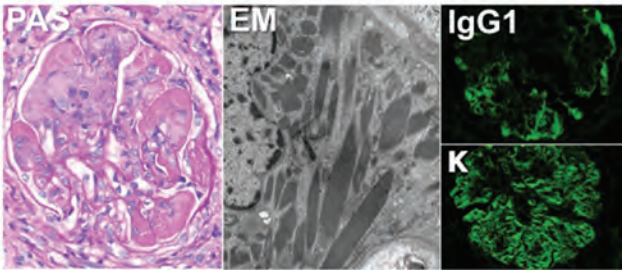
Where's the Clone? Successful Treatment of Monoclonal Gammopathy of Renal Significance with Type 1 Cryoglobulinemia with Plasma-Cell Directed Therapy

Ana C. Onuchic-Whitford,[1] Veronica E. Klepeis,[2] Andrew S. Allegretti.[2] *[1]Brigham and Women's Hospital / Massachusetts General Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA.*

Introduction: Type 1 cryoglobulins are monoclonal immunoglobulins produced by clonal expansion of B cells. They are often associated with an overt hematologic malignancy, but sometimes occur without identification of a monoclonal cell population. We describe a case of type 1 cryoglobulinemia with a rare crystalline morphology on renal pathology and without an evident monoclonal population, that had excellent response to plasmapheresis and plasma-cell directed therapy.

Case Description: A healthy 61 year old woman initially presented with one year of intermittent knuckle swelling in cold weather and bilateral calf pain. She later developed generalized weakness and was admitted with hypertensive emergency, AKI [serum creatinine (SCr) 2.0 mg/dL], edema, livedo reticularis, and blurry vision. Workup was notable for dysmorphic red cells on urine sediment, 2 grams of proteinuria, low complements, normal serum calcium, serum Kappa/Lambda ratio 5.73, IgG kappa M spike, and 2% type I cryoprecipitate. Renal biopsy showed crescentic and necrotizing cryoglobulinemic glomerulonephritis with crystalline morphology of monoclonal IgG1 kappa (see Figure). Bone marrow biopsy showed no clonal cell population. The patient was treated with pulse steroids, plasmapheresis, and maintained on cyclophosphamide, bortezomib and dexamethasone, resulting in rapid improvement of symptoms and SCr to 0.96 mg/dL after 7 weeks.

Discussion: This case illustrates a classical presentation of monoclonal gammopathy of renal significance, where renal damage ensues from cryoglobulin deposition, likely produced by a monoclonal population not detectable by standard testing. Treatment of this hidden population by clonal cell-directed therapy resulted in excellent renal and symptomatic recovery. Additionally, pathology images reveal the assembly of monoclonal immunoglobulins into crystals, a rare variant of cryoglobulinemia.



SA-PO226

The Clone Wars: Evolving Treatment of Proliferative Glomerulonephritis with Monoclonal Immunoglobulin G Deposits

Sandhya Manohar, Nelson Leung. *Mayo Clinic, Rochester, MN.*

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin G deposits (PGNMID) is a recently described entity and as we become more aware of this in our patients, its treatment poses the next challenge. Here we present a patient we cared for and the dynamic changes in his response to therapy that helped us guide his treatment regimen.

Case Description: A 63 year old male was found to have 8 g/d proteinuria and chronic kidney disease at the time of a cardiac evaluation 14 years ago. Kidney biopsy was reported elsewhere as membranous nephropathy and was treated initially with cyclophosphamide (C) and prednisone(P) with improvement in his proteinuria down to 3 g/d. Rituximab (R) was added with improvement in proteinuria to 1 g/d but was not continued due to coverage issues, and was eventually maintained on cyclosporine. He came to us for a second opinion and the diagnosis of PGNMID was made with no evidence of systemic disease. His kidneys eventually failed and he underwent a deceased donor kidney transplant. After 4 years he developed proteinuria of 800mg/d. Kidney allograft biopsy showed recurrence of PGNMID with same IgG kappa. Serology and bone marrow was negative but flow cytometry showed rare polyclonal plasma cells. He was treated with Rituximab initially with improvement in proteinuria down to 267mg/d but slowly increased to 1.1g/d after 3 months despite negative CD20. RCP was given with a more sustained response and his treatment was changed to be directed at CD38 cells with Rituximab and bortezomib (V) for a likely LPL clone with continued improvement in proteinuria.

Discussion: PGNMID in native kidney can be indolent but post-transplant it is usually aggressive and hence need prompt clone-directed therapy. The clones capable of producing PGNMID are plasma cell, lymphoplasmacytic (LPL) clone, and CLL clone. Our patient had no confirmed clone. Initial response to Rituximab suggests that it was a CD20 clone but he progressed and the regimen of RCP was given to knock out cells affecting both CD20 and CD38. His initial response to rituximab and quick recurrence is suggestive that he may have an LPL clone with CD38 cells that are more difficult to eradicate and considering his prior cytoxan exposure was switched to a bortezomib based regimen. The choice of therapy can be difficult, requiring a deeper understanding of PGNMID disease process.

SA-PO227

Plasmablastic Lymphoma Associated with IgD Lambda Light Chain Monoclonal Gammopathy and Severe AKI

Matthew Abramson,[1,2] Ilya Glezerman.[3] *[1]New York Presbyterian, New York, NY; [2]Nephrology, Memorial Sloan Kettering Cancer Center, New York, NY; [3]Memorial Sloan Kettering Cancer Center, New York, NY.*

Introduction: Light chain cast nephropathy is the most common pattern of acute kidney injury in patients with multiple myeloma, seen in up to 47.5% of cases. Free light chains (FLC) are freely filtered and undergo endocytosis by proximal tubular cells via apical receptors. When these receptors become saturated, the resultant load of urinary free FLC co-aggregate with uromodulin causing precipitation and obstruction of the distal tubules, and inducing an inflammatory response. Most cases result from a single plasma clone of multiple myeloma. 2% of myeloma cases are of the IgD variant; only 5 cases have been reported to cause light chain cast nephropathy, and none as a result of lymphoma. This report describes the first case of presumed IgD lambda light chain cast nephropathy due to plasmablastic lymphoma.

Case Description: 74 year-old man status-post nephrectomy at age 2, history of diffuse large B cell lymphoma status post R-CHOP in 2016 attaining complete remission, recent biopsy of new perisplenic lymph node revealing plasmablastic lymphoma, who presented with anorexia and decreased urine output. Nephrology was consulted for acute kidney injury (AKI) with creatinine of 9.7mg/dL (baseline of 1.2mg/dL). He was found to have an IgD monoclonal gammopathy (1.4 g/dL), increasing serum lambda light chains (from 91mg/dL 3 weeks prior to 624mg/dL), and a kappa:lambda ratio of <0.01. 24-hour urine protein was 2.39g with M-spike of 1.65g and urinary immune-fixation positive for IgD lambda light chains. There was no obstruction on renal ultrasound. Bone marrow biopsy showed 0.2% lambda restricted clone, but no plasmacytosis. Although kidney biopsy was not obtained, the presumed diagnosis was IgD lambda light chain cast nephropathy. He was given intravenous hydration followed by cyclophosphamide, bortezomib, and dexamethasone. Serum creatinine improved rapidly to 3.1 mg/dL, serum lambda FLC improved to 40 mg/dL over the following week and patient was discharged home.

Discussion: Our patient developed severe AKI in the setting of IgD lambda FLC gammopathy likely leading to the development of cast nephropathy. Multiple myeloma literature reports up to 80% chance of renal recovery in patients with 60% reduction of serum FLC by 21 days. This patient had a similar remarkable response to standard myeloma therapy although his underlying pathology was plasmablastic lymphoma.

SA-PO228

Proliferative Glomerulonephritis with Monoclonal Immunoglobulin M Deposits

Sneha Shrestha,[1] Surya V. Seshan,[2] James M. Chevalier.[1] *[1]Nyph/Weil Cornell Medical Center, New York, NY; [2]Weill Cornell Medical Center, New York, NY.*

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin G deposits (PGNMID) was first described as a distinct entity in 2004. Only few case reports of PGNMID with IgM or IgA dominant deposition have been described. Here we report our case with clinical and histopathological features of PGNMID with Ig M dominant deposit.

Case Description: A 37 year old gentleman with diabetes mellitus-type 2, hypertension and obesity, presented with leg swelling and foamy urine for two weeks. Clinical exam was significant for BP 155/97mmHg and 2+ pedal edema. Labs revealed elevated serum creatinine(1.28mg/dl, baseline 0.9mg/dl, peak over the course of follow up 6.26mg/dl) and albumin of 2.5gm/dl. Urinalysis showed specific gravity of 1.015, pH of 6.4, 4+ protein and 2+ blood, 11-30 RBCs per hpf. Urine microalbumin to creatinine ratio was 5680 and urine protein creatinine ratio was 8gm per gm. Hemoglobin A1c was 6.8. There was no M spike. Serum free light chains were mildly elevated with normal ratio. Bone marrow biopsy did not show monoclonal plasmacytosis. Cryoglobulin levels were repeatedly normal. Kidney biopsy showed moderately advanced diabetic nephropathy and nodular diabetic glomerulosclerosis, class III superimposed by IgM kappa proliferative glomerulonephritis. There was significant endocapillary and mesangial cellularity on light microscopy. Immunofluoroscence revealed granular 3+ IgM,3+ kappa light chain, 1-2+ C3 and 1-2+ C1q along the glomerular capillary walls and focally in the mesangium; and nonspecific 1+IgG, 1+ lambda and kappa light chains along the glomerular capillary walls, mesangial areas and tubular basement membrane. Electron microscopy showed scattered finely granular subendothelial electron dense deposits. He was treated with statin, diuretics and ARB was added when creatinine stabilized. He was given pulse dose of iv steroids, plasmapheresis (to remove IgM) and iv rituximab. Since he did not respond, he was further treated with cyclophosphamide and mycophenolate mofetil with regression of proteinuria and creatinine improvement.

Discussion: PGNMID is characterized by immunofluorescence findings of monoclonal IgG deposits and electron-dense deposits (EDDs) localized to glomeruli. Our case with histopathological features of PGNMID but with Ig M deposits adds to handful of similar case reports. We propose expansion of Nasr et al's classification to include IgM and IgA dominant variant.

SA-PO229

Proliferative Glomerulonephritis with Monoclonal IgG Deposits

Divya Shankaranarayanan,[1] Choli Hartono,[1] Jun B. Lee,[1] Steven Salvatore.[2] *[1]Department of Nephrology, Weill Cornell Medicine, New York City, NY; [2]Department of Pathology, Weill Cornell Medical College, New York, NY.*

Introduction: Proliferative glomerulonephritis with monoclonal IgG deposits (PGNMID) is a form of monoclonal gammopathy of renal significance (MGRS). We

present a case of rapidly progressive glomerulonephritis in a patient with smoldering multiple myeloma (SMM) who responded to steroid pulse in addition to bortezomib and cyclophosphamide.

Case Description: This was a 74-year-old female with SMM who presented with serum creatinine of 3.06mg/dl from 0.9mg/dL one week prior, normal C3/C4, negative cryoglobulin, κ/ λ ratio of 82.6/11.3 (7.29), serum albumin of 2.4g/dl, and no monoclonal spike on serum or urine protein electrophoresis. However, free κ light chains were present on urine immunofixation. The urinalysis revealed 5RBC/HPF and 24-hour urine protein was 3.93g. Bone marrow biopsy done at an outside facility showed κ light chain myeloma with 10-15% marrow involvement. Kidney biopsy (Figure 1.) showed a membranoproliferative pattern of glomerulonephritis with monoclonal IgG-kappa deposits by immunofluorescence and there were 8 glomeruli (of 31) with cellular crescents. No other monoclonal paraprotein related diseases were present. Electron microscopy showed occasional electron dense deposits in the subendothelial space and fine focal mesangial electron dense deposits. The patient was treated with methylprednisolone 500mg daily followed by a prednisone taper and bortezomib twice weekly 1.3mg/m^{2}alternating with cyclophosphamide along with dexamethasone. The serum creatinine had peaked at 6.8mg/dl and improved with treatment to 1.8mg/dl by day 25 of initial presentation

Discussion: First described in 2004, PGNMID is a renal-limited glomerular disease, characterized by paucity of circulating paraproteins with presence of monoclonal IgG (usually IgG3-kappa) deposits in the glomeruli. The optimal treatment for this disease is not known. This case is unique due to rapid renal progression and prompt response to treatment. Considering PGNMID as a differential diagnosis of AKI in a patient with SMM and RPGN "picture" is important since early treatment may alter the renal prognosis in such patients.

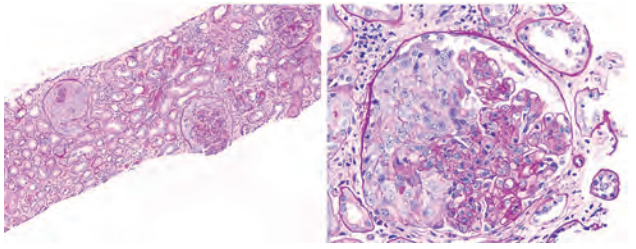


Figure-1

SA-PO230

Proliferative Glomerulonephritis with Monoclonal IgG Deposits Leading to the Diagnosis of B Cell Lymphoma

Wael A. Hanna,[1] Vivette D. D'Agati,[2] James P. Reichart.[3] *[1]Lehigh Valley Hospital, Breinigsville, PA; [2]Columbia University College of Physicians and Surgeons, New York, NY; [3]Valley Kidney Specialists, Macungie, PA.*

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is a rare glomerular disease within the MGRS spectrum, first described in 2004. Membranoproliferative GN is the most common histologic pattern.

Case Description: A 70-year-old female with a history of mild hypertension (HTN) was referred for renal insufficiency and uncontrolled HTN. On examination, BP was 180/84 with otherwise normal cardiopulmonary exam and no edema. Lab data showed elevated S Cr of 1.9 mg/dL. Urinalysis displayed proteinuria and microhematuria with dysmorphic RBCs. The urine protein:Cr ratio was 1.9 g/g with serum albumin of 3.8 g/dL. CBC showed Hb of 11.6 g/dL with normal WBC count and differential. Serology for hepatitis, cryoglobulin, C3, C4, ANCA and anti-GBM antibody were negative. Serum immunofixation revealed IgM- kappa and IgM-lambda M-spikes with FLC kappa/lambda ratio of 2.2. Renal biopsy showed diffuse endocapillary proliferative GN with membranoproliferative features. Immunofluorescence revealed mesangial and glomerular capillary wall staining for IgG, C3, C1q and kappa light chain, with restricted positivity for IgG subtype 3. EM displayed granular mesangial and subendothelial electron dense deposits. The findings were diagnostic of PGNMID with monoclonal IgG3-kappa deposits. Bone marrow biopsy showed (1%) kappa-restricted B cell lymphoma. She received four weekly doses of rituximab infusion after which she achieved clinical renal remission. Ten weeks after initiating rituximab, S Cr and UPCR had fallen to 1.3 mg/dL and 0.2 g/g respectively.

Discussion: PGNMID presents typically with nephrotic range proteinuria, renal insufficiency, hematuria and HTN and 20% of patients progress to ESRD. Only 20-30% of patients have a detectable M-protein in the serum or urine. The MIg detected in the serum may not be identical to the MIg in the kidney deposits, as shown in this case. Our case illustrates that an onconephrologic approach to detect and target the underlying B-cell clone can lead to clinical remission of PGNMID.

SA-PO231

Outcome of Patients with Multiple Myeloma Who Undergo Autologous Stem Cell Transplantation Followed by Renal Transplantation: A Case Series Report

Maria Ibrahim,[1,2] Sapna Shah,[2] Reuben Benjamin,[4] Michael Delaney,[1] Steve Schey.[3] *[1]National Health Service, Watford, United Kingdom; [2]Renal, Kings College Hospital NHS Foundation Trust, London, United Kingdom; [3]King?s College London, London, United Kingdom; [4]King's College Hospital, London, London, United Kingdom.*

Introduction: Autologous stem cell transplantation (ASCT) and novel therapies have improved the prognosis of patients with multiple myeloma (MM). For those who undergo ASCT whilst on dialysis, a similar survival compared with the overall MM population has been reported. For patients achieving remission following ASCT, kidney transplantation is an attractive option, offering an improved quality of life and significant economic advantage.

Case Description: This case series investigates the outcome of 5 subjects who underwent an ASCT for MM with subsequent kidney transplantation. Subjects were identified from our regional hospitals between 2006 and 2012. 2 females and 3 males were identified. All patients were Caucasian with a median age of 54years (range 37- 64). 4 patients presented with end stage renal disease (ESRD) and 1 progressed to ESRD shortly after diagnosis. Induction chemotherapy regimens with novel agents including thalidomide and bortezomib were utilised. Following attainment of very good partial remission (VGPR) or complete remission (CR), high dose melphalan ASCTs were performed after a median of 11 months (range 8-22months). Kidney transplantation (living donor, n=3, deceased donor, n=2) with tacrolimus based immunosuppression regimens were completed at a median of 27 months after ASCT (range 16-43months). Patients 1 and 3 experienced relapse of myeloma at 40 months and 13 months after kidney transplantation. Patient 1 received bortezomib based treatment to achieve CR, but later relapsed again. He developed sepsis related AKI and commenced dialysis. He died 1 month later. Patient 3 was treated with thalidomide and achieved VGPR. He developed a second relapse 5 months later and died with a functioning allograft (eGFR 21). Patients 2, 4 and 5 remained alive at the end of the follow up period (median time 67months) with eGFRs of 62, 11 and 50 respectively. Median kidney graft survival time was 66 months (range 47–95months).

Discussion: 5 patients with MM undergoing ASCT followed by renal transplantation achieved dialysis independence for a median of 66 months. Our study adds to the literature supporting kidney transplantation as the preferred treatment for ESRD following successful ASCT for MM and is useful when counselling patients reagrding renal and haematological outcomes.

SA-PO232

IgA Heavy Chain Monoclonal Immunoglobulin Deposition Disease in a Kidney Transplant Recipient

Rana El Sabbagh, Meghan E. Kapp, Kelly A. Birdwell, Beatrice P. Concepcion. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: IgA heavy chain deposition disease should be differentiated from disease with polytypic IgA deposits given distinct clinical, histological and pathophysiologic features. Here, we present a case of IgA heavy chain monoclonal immunoglobulin deposition disease in a transplant recipient with a reported primary disease of IgA nephropathy.

Case Description: A 49-year-old man with a reported history of IgA nephropathy who failed medical therapy including cyclophosphamide, prednisone and mycophenolate resulting in ESRD. He received a renal allograft 3 years prior which was reportedly lost due to recurrent disease. He underwent a second living unrelated transplant with alemtuzumab/steroid induction and tacrolimus/mycophenolate/steroid maintenance immunosuppression. Two years posttransplant, he developed worsening kidney function with a SCr of 2 mg/dL (baseline 1.6 mg/dL) and new proteinuria of 3.7g/g. Kidney biopsy was performed and light microscopy revealed mild to moderate mesangial expansion with apparent eosinophilic deposits and segmental double contours of the glomerular basement membrane (GBM). Immunofluorescence, showed 3+ pseudolinear staining along GBM and tubular basement membranes (TBM), smudgy mesangial staining and vascular staining for IgA without corresponding light chain staining. By electron microscopy, punctate amorphous deposits were present along the inner aspect of GBM and outer aspect of TBM and around vascular smooth muscle cells with mesangial deposits showing focal short fibrillary substructure. He was referred to hematology and a bone marrow biopsy which showed a plasma cell neoplasm. He was started on bortezomib and dexamethasone but after 1 cycle developed severe AKI requiring HD. He did not recover function and was ultimately declared ESRD.

Discussion: IgA heavy chain monoclonal immunoglobulin deposition disease is a distinct clinico-pathologic entity which if left unrecognized or untreated can cause kidney allograft loss. This disease warrants a careful hematologic work-up to evaluate for a plasma cell dyscrasia and progression towards symptomatic IgA multiple myeloma. Although unsuccessful in this case, anti-myeloma agents appear to favorably influence renal prognosis. A hematological response may ultimately permit successful kidney transplantation with improved graft viability and decreased risk of recurrence.

SA-PO233

A Rare Case of Crystalglobulin-Induced Nephropathy

Jon W. Mares,[2] Jason R. Pettus,[1] Elizabeth J. Brant.[1] [1]*Dartmouth-Hitchcock Medical Center, Lebanon, NH;* [2]*Dartmouth Hitchcock Nephrology Fellowship, Hanover, NH.*

Introduction: The term monoclonal gammopathy of renal significance (MGRS) describes paraprotein-dependent kidney diseases that do not meet criteria for overt multiple myeloma, including cast nephropathy, Ig deposition disease and amyloidosis. Crystalglobulin-induced nephropathy (CGN), a rare paraprotein-related disease, is most commonly associated with multiple myeloma. We herein report an extremely rare case of CGN associated with MGRS.

Case Description: A 75 year-old man with metastatic prostate cancer and normal renal function presented with anuric AKI requiring dialysis. Serum protein electrophoresis showed 0.3 g/dl IgG kappa monoclonal protein. Serum free κ/λ ratio was 2.3 (ref. 0.5-2.43). ANCA, anti-GBM, hepatitis serologies, rheumatoid factor, C3, C4, and cryoglobulins were normal. Hydronephrosis was not seen on renal ultrasound. Renal biopsy revealed overt coagulative necrosis (infarction) of 40% of sampled cortical tissue on light microscopy. Abundant PAS-positive crystalline thrombi were present in interlobular arteries, glomerular arterioles and capillaries, and focally extending into proximal tubules. (Fig. 1) Congo red staining was negative. Immunofluorescence showed dim IgG kappa staining in crystalline thrombi. By electron microscopy, crystalline thrombi displayed polygonal and angulated forms with distinctive fine parallel linear organization. Findings confirmed crystalglobulin-induced nephropathy. Bone marrow biopsy was then performed, revealing metastatic prostate cancer without demonstrable multiple myeloma. His hospital course was complicated by GI bleed and thromboembolic cerebral infarcts. He died 6 weeks after initial presentation upon discontinuing dialysis.

Discussion: CGN is a rare entity usually associated with multiple myeloma, whereas our patient had MGRS. Given a potentially devastating outcome, CGN should be considered in patients presenting with AKI and monoclonal gammopathy.

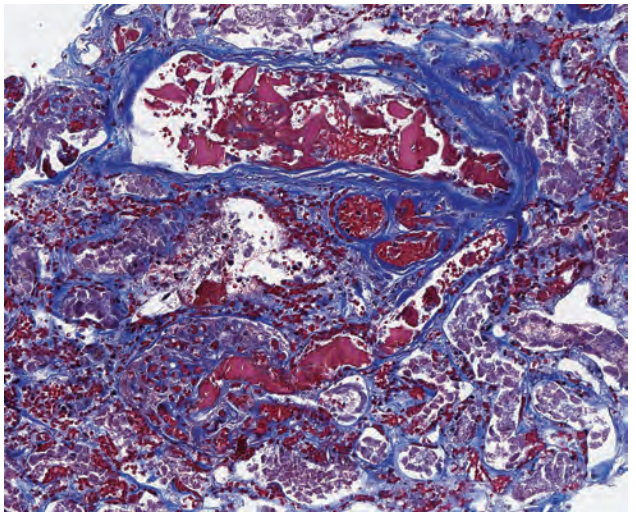

Fig. 1

SA-PO234

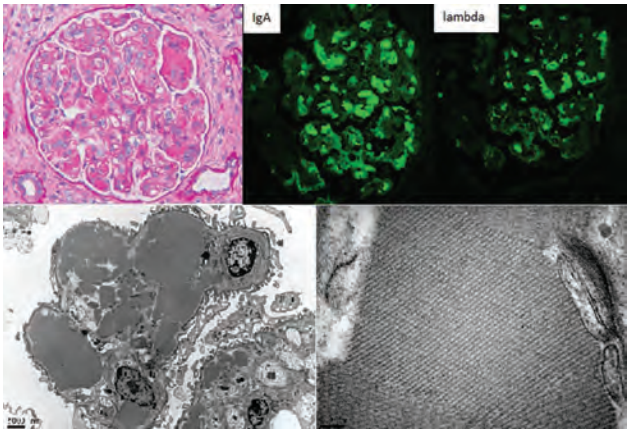
Crystalglobulinemia: A Rare and Complex Clinical Entity

Zi R. Zhang, Sara Ruddock-Walker, Pravir V. Baxi, Casey N. Gashti, Roger A. Rodby. *Rush University Medical Center, Chicago, IL.*

Introduction: Crystalglobulinemia (CryG) is a rare Monoclonal Gammopathy of Renal Significance (MGRS) that results in a crystalline appearing precipitation of paraproteins in the glomeruli. These paraproteins are unique in that they are not cryoprecipitable, but form immune aggregates that appear crystalline on Electron Microscopy (EM). Clinical manifestations include purpura, arthropathy and AKI. We present a case of crystalglobulin-induced AKI in a pt with a monoclonal IgA lambda paraproteinemia. Early recognition and treatment led to resolution of her AKI.

Case Description: A 44-y/o F p/w arthralgias, HTN and edema. Labs: Cr of 1.4 mg/dL and Alb 3.7 g/dL. UA: +RBCs with a urine alb/Cr ratio of 6.3 g/g. Workup: ANA, ANCA, C3, C4, and hepatitis all neg or nml. Monoclonal IgA lambda was seen on serum and urine immunofixation. Serum k/l ratio was 0.76. A renal biopsy demonstrated on Light Microscopy: Lobular glomeruli with the majority showing intracapillary eosinophilic thrombi that stained 3+ for IgA and lambda (kappa-). EM: the thrombi were composed of crystalline structures with an organized substructure of parallel linear arrays (Fig 1). No evidence of cast nephropathy. Serum cryoglobulins were repeatedly negative. She developed AKI (Cr of 4.2) and was started on plasmapheresis (TPE) and steroids. A bone marrow biopsy showed a plasma cell neoplasm in 7% of cells with lambda predominance by flow cytometry. Therapy with bortezomib and cyclophosphamide was administered. A bone survey showed no lytic lesions. Three weeks following initiation of therapy, her Cr improved to 1.0.

Discussion: CryG is rare and illustrates the complexity of the MGRS spectrum. Diagnosis requires histologic evidence of characteristic crystalglobulin deposition within the vasculature in the absence of circulating cryoglobulins. This case emphasizes the importance of specific histologic diagnosis to guide treatment for pts with MGRS. In this case, TPE and steroids served as a bridge until directed chemotherapy was started.



Renal Biopsy

SA-PO235

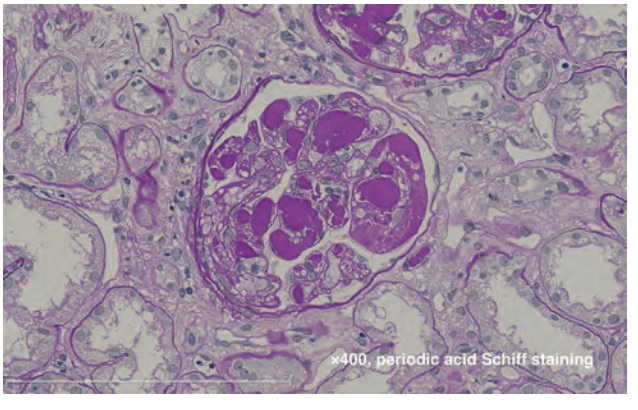
A Case of Waldenström Macroglobulinemia Recovering from Dialysis-Requiring AKI by Steroid Monotherapy

Naokata Kutsuzawa, Yosuke Nakagawa, Naoto Hamano, Masahiro Koizumi, Takehiko Wada, Masafumi Fukagawa. *Tokai University School of Medicine, Isehara, Japan.*

Introduction: Lymphoplasmacytic lymphoma (LPL) is an uncommon mature B cell lymphoma, whereas Waldenström macroglobulinemia (WM) is a subset of LPL involving the bone marrow with an IgM monoclonal gammopathy in blood. WM mainly presents with symptoms associated with anemia and hyperviscosity syndrome. WM-associated nephropathy is rare and its prognosis is unknown. Here, we report a case of LPL/WM recovering from dialysis-requiring acute kidney injury by steroid monotherapy.

Case Description: A 76-year-old Japanese woman who had been previously healthy admitted to the hospital with complaint of abdominal pain. She became anuric soon after admission, followed by progressive dyspnea due to pulmonary edema. She was referred to our hospital and hemodialysis was started for volume control. She presented with no neurological symptoms but funduscopy showed dilated and tortuous retinal veins with hemorrhagic exudates, which suggested hyperviscosity syndrome. She had severe anemia with rouleaux formation, high level of serum IgM (3776 mg/dl) and monoclonal IgM with lambda light chain on serum immunoelectrophoresis. Bone marrow biopsy demonstrated infiltration by small lymphocytes that exhibit plasma cell differentiation and she was given a diagnosis of LPL/WM. Renal biopsy demonstrated acute tubular necrosis with cast nephropathy and neoplastic lymphocytic infiltration in the interstitium. There were IgM deposits in the glomerular basement membrane and widespread thrombi in the capillaries. She underwent the treatment with high-dose dexamethasone, which steadily made her renal insufficiency ameliorated. Finally, hemodialysis therapy was discontinued at the 31st hospital day.

Discussion: Prognosis of WM-associated nephropathy depends on the type of renal pathology. This case suggested that acute kidney injury mainly caused by neoplastic lymphocytic infiltration might be reversible by chemotherapy.



SA-PO236

IgA Nephropathy Associated with Cystic Fibrosis: Role of Recurrent Infections as Etiology

Priyanka Wani,[1] Burl R. Don,[2] Andrew I. Chin.[3] *[1]University of California Davis Medical Center, Sacramento, CA; [2]University of California Medical Center, Sacramento, CA; [3]University of California Davis, Sacramento, CA.*

Introduction: Cystic fibrosis (CF), is the most common autosomal recessive condition in the caucasian population, and is due to mutations in cystic fibrosis transmembrane regulator (CFTR) gene that codes for a regulated chloride channel. CF is multisystem disorder primarily affecting the lungs, digestive system, sweat glands and reproductive tract; renal involvement is relatively uncommon in CF despite the high expression of CFTR in the kidney. Reported glomerular diseases associated with CF include AA amyloidosis, membranoproliferative and post-infectious glomerulonephritis. We present a 28 year old Caucasian male with CF who presented with worsening renal function, and nephrotic range proteinuria diagnosed with IgA Nephropathy

Case Description: A 28 year old Caucasian male with CF for over 10 years presented progressive worsening proteinuria from 700 mg/day two years ago to more recently 8 grams/day. His prior renal history included recurrent episodes of respiratory infections and acute kidney injury and the progressive loss of renal function. Evaluation of proteinuria noted negative ANA, ANCA, anti-dsDNA, but a low serum C3. Serum creatinine levels ranged from 2-3 mg/dL. Urine microscopy revealed many dysmorphic RBC's. A renal biopsy was performed and light microscopy revealed mild to moderate mesangial widening with mesangial hypercellularity but no endocapillary hypercellularity. IF staining was positive for IgA and C3. The tubulointerstitium demonstrated widespread interstitial fibrosis and tubular atrophy. Congo red stain was negative for amyloid. The MEST indices were noted as M1, E0, S0, and T2. The patient was treated conservatively with losartan and without immunosuppression. Renal function remained stable and proteinuria decreased from 8 grams to 5 grams/day over a four month period.

Discussion: Frequent mucosal infections and inflammation, as seen in CF, may be associated with a chronic production of IgA. This patient had an extensive 10 year history of recurrent mucosal infections which were poorly treated. This may have led to aberrant IgA production due to abnormal glycoforms leading to mesangial immune complex deposition and complement activation (low C3) as observed in our case. Therefore recurrent infections associated with CF may have an important role in the pathogenesis of IgA nephropathy.

SA-PO237

IgA Dominant Membranoproliferative Glomerulonephritis

Lance Bechtold,[1] Jennifer Aranas,[2] Mhd kussay Alsamkari,[3] Erika R. Bracamonte,[2] Sireesha Koppula.[2] *[1]Banner University Med Center Tucson, Tucson, AZ; [2]University of Arizona, Tucson, AZ; [3]Banner, Tempe, AZ.*

Introduction: IgA Nephropathy is widely accepted as the most common cause of glomerulonephritis worldwide. Far less common and somewhat controversial is IgA Dominant Membranoproliferative Glomerulonephritis. Most mentions of this unique pathology are described in case studies with suggested etiologies including: cirrhosis, burn victims, and children.

Case Description: We present a case of a 74 year old woman who presented with acute encephalopathy after one month of cough and URI like symptoms. She had recently returned from a family gathering where she was exposed to several sick contacts. The patient had prior history of CKD-3b, hypertension, and carcinoid tumor, for which she was on active treatment with octreotide for several years. Initial labs were significant for acute kidney injury with serum creatinine of 2.67mg/dL and urine protein to creatinine ratio of 18,134mg/g. She was initially treated with IV fluids and antibiotics with no improvement to her renal function. She underwent renal biopsy which demonstrated the characteristic features of MPGN on light and electron microscopy along with a notable predominance of IgA on immunofluorescence microscopy. She eventually required hemodialysis and pulse dose IV steroids followed by tapering course of oral steroids. Given the paucity of reported cases, along with the lack of proven treatment strategies and the issue of her active carcinoid tumor, our treatment options were limited to steroids. She was referred for re-evaluation and was cleared of carcinoid. She then began a trial of oral cyclophosphamide (CPA). After two weeks of treatment, she developed issues of recurrent *E.coli* UTI and later development of community acquired pneumonia, forcing us to stop CPA. She continued on hemodialysis for a total of three months before renal recovery allowed her to stop dialysis. At last follow up, the patient had returned to her baseline serum creatinine of 1.2 mg/dL and had improvement of her proteinuria with urine protein/creatinine ratio of 5121mg/g. She continued to have intermittent episodes of frank hematuria. The patient had not undergone repeat biopsy. She was pending infectious clearance to resume her course of CPA.

Discussion: Given the lack of proven treatment modalities, we felt that this case presented an opportunity to share a reasonable and effective treatment option for future patients.

SA-PO238

Membranoproliferative Glomerulonephritis Due to Monoclonal Gammopathy of Renal Significance: The Value of Pronase-Digestion

Win Win Moe,[2] Dominick Santoriello,[1] James Drakakis,[2] Naveed N. Masani.[2] *[1]Columbia University Medical Center, New York, NY; [2]NYU Winthrop Hospital, Mineola, NY.*

Introduction: Membranoproliferative glomerulonephritis (MPGN), a characteristic light microscopic (LM) finding seen on renal biopsy, is further classified based on immunofluorescence (IF) findings. Immune-complex deposition is one cause of MPGN and may be secondary to monoclonal immunoglobulin deposits. IF on pronase digested tissue can aid in revealing masked monoclonal deposits. A wide spectrum of hematologic diseases are associated with kidney deposition of monoclonal immunoglobulin deposits; however in many patients, there is no identifiable hematologic condition and the term monoclonal gammopathy of renal significance (MGRS) has been applied.

Case Description: A 65-year-old male presents with hypertension, weight gain with bilateral lower extremity edema, and subacute kidney injury with creatinine of 1.81 mg/dl (baseline: 0.9 mg/dl). Urinalysis demonstrated 3+ protein, 2+ blood, with protein creatinine ratio of 10.3 g/g and a serum albumin of 2.8 g/dL. Serum immunofixation was positive for IgG-kappa; remainder of paraprotein workup and glomerular serologies, including complement levels, were either normal or negative. Renal biopsy findings on light microscopy were consistent with an MPGN pattern of injury, subacute, with nodular mesangial sclerosing features; initial IF demonstrated trace to 1+ granular to semi-linear glomerular capillary wall staining for C3 only; repeat IF performed on pronase-digested tissue revealed trace to 1+ granular to semi-linear glomerular capillary wall staining for IgG with trace C3 and trace kappa, and no significant staining for lambda. Electron microscopy did not reveal any evidence of dense deposit disease. These findings support the diagnosis of MPGN with IgG-kappa monoclonal deposits. Subsequently patient underwent bone marrow biopsy and full body PET scan, neither of which demonstrated any evidence of B-cell clonal expansion/population. Given these findings, the patient's MPGN appears to be secondary to MGRS. Therapy was initiated with oral corticosteroids and Rituxamab.

Discussion: An MPGN pattern of injury represents a diagnostic and therapeutic challenge. Findings on IF are critical to help determine the underlying cause. This case demonstrates MGRS as underlying etiology of MPGN, and the value of IF analysis via pronase-digestion to aid in "unmasking" hidden monoclonal deposits.

SA-PO239

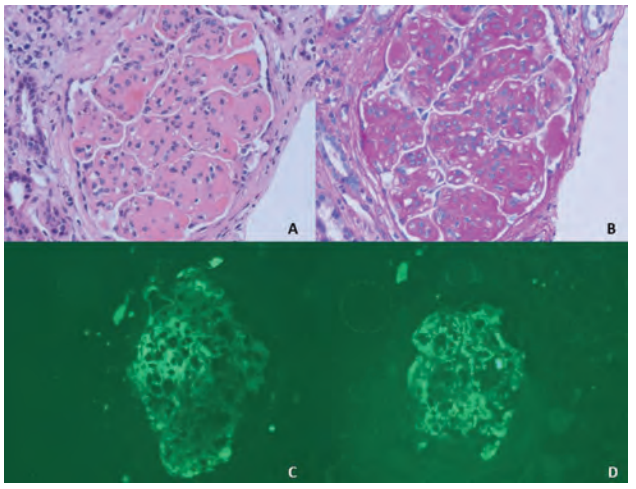
Idiopathic Membranoproliferative Glomerulonephritis: A Grey Zone

Justin Lee Loy, Freddy R. Malpartida, Xu Zeng, Abhilash Koratala. *University of Florida Gainesville, Gainesville, FL.*

Introduction: 'Idiopathic' membranoproliferative glomerulonephritis (MPGN) is rare compared to secondary forms and usually a progressive disease. Studies evaluating the role of steroids were primarily done in children and the data is sparse in adults. Mycophenolate mofetil is effective and can be used as a steroid-sparing agent in the treatment of idiopathic-MPGN.

Case Description: A 22-year-old White man a recent diagnosis of hypertension was referred to Nephrology department for elevated serum creatinine and proteinuria. He was asymptomatic at presentation except for swelling in the legs for few months. Laboratory data was significant for a creatinine of 2mg/dL, serum albumin 2.5g/dL, low serum complements and urine protein-creatinine ratio ~17g/g (Ref: <150 mg/g). Renal biopsy demonstrated MPGN [Figure] with moderate interstitial fibrosis. Secondary causes of MPGN including hepatitis C, lupus, and monoclonal gammopathies were excluded by appropriate tests. He was started on prednisone 80mg/day and proteinuria reduced to ~3.7g/g in 8 weeks. However, he did not tolerate steroid taper and proteinuria worsened. He was then started on Mycophenolate mofetil (MMF) 1000mg twice-a-day with reduction in proteinuria to 1.8g/g in ~6 weeks and serum albumin improved to 3.3g/dL. We plan to continue MMF monotherapy for 2-3 years similar to lupus nephritis treatment.

Discussion: Idiopathic MPGN is very uncommon in developed countries and the evidence base underlying the treatment recommendations is weak. MMF is a potent immunosuppressive agent which is being increasingly used in primary glomerulonephritides, along with lupus nephritis. Current data from small studies including our case supports the use of this agent in idiopathic MPGN.



SA-PO240

MPGN and Sarcoidosis: A Rare Presentation

Alamgir Mirza,[2] Sandeep Magoon.[1] [1]*eastern virginia medical school, Norfolk, VA;* [2]*eastern virginia medical school, Norfolk, VA.*

Introduction: Sarcoidosis is a chronic multi-system disease characterized by non-caseating granulomas. It can affect kidneys, but glomerular involvement is rare. There are few case reports of sarcoidosis with membranoproliferative glomerulonephritis (MPGN) where the causality was not proven clearly. Last case described in literature was in 1986. To best of our knowledge, our case is the first in which MPGN is causally related to Sarcoidosis, presented with rapidly progressive glomerulonephritis and severe AKI and first one to be reported since the new classification for MPGN has been proposed.

Case Description: A 32 years old African American male with past medical history of bilateral knee arthritis presented to the hospital with bilateral ankle edema and rash in lower extremities. He was in acute kidney injury (AKI) with creatinine of 3.5 mg/dL. Creatinine 2 years ago was 1.3 mg/dL. Urinalysis showed proteinuria, hematuria, no red blood cell cast. Proteinuia was 6.2 gm/day. Hepatitis B and C, and HIV tests were negative. Cryoglobulin and paraprotein studies were negative. ANA was positive at 1:40, other autoimmune serologies and complements were negative. Angiotensin converting enzyme was elevated at 92 U/L. Renal ultrasound was unremarkable. CT chest showed bilateral hilar lymphadenopathy. Renal biopsy showed MPGN of uncertain etiology. Immunofluorescence (IF) was positive for IgG, IgA, IgM, C3, C1q deposits. Creatinine improved from a peak of 7.4 mg/dL to 3.4 mg/dL with pulse steroids and was discharged on prednisone. A week later he presented back with worsening renal function and was started on dialysis. Lymph node biopsy revealed non caseating granulomas and no infection. Bone marrow biopsy was negative. Cellcept was added to his regimen. His interdylactic rise of creatinine is decreasing. Renal recovery is anticipated.

Discussion: Patient's presentation with arthritis and rash raised suspicion of sarcoidosis related vasculitis supported by a "full house" on IF in renal biopsy and non caseating granulomas on lymph node biopsy. Work up for lymphoma, paraproteinemia, infection and other autoimmune diseases were negative. In Summary, MPGN with Sarcoidosis is very rare. However when no other etiology is identified, Sarcoidosis should be considered in the differential. There is no consensus on treatment. Steroid is treatment of choice. Aggressive therapy, namely Rituximab, cellcept, plasmapheresis should be considered in severe AKI.

SA-PO241

Type 1 Cryoglobulinemia with Skin, Nerve, Pulmonary, and Renal Involvement Preceding a Diagnosis of Multiple Myeloma

Akshita Narra,[1] Nicole K. Andeen,[1,2] Rupali S. Avasare.[1] [1]*Division of Nephrology, Oregon Health and Science University, Portland, OR;* [2]*Renal Pathology, Oregon Health Science University, Portland, OR.*

Introduction: Type 1 cryoglobulinemia is a rare cause of glomerulonephritis(GN). Here we present a case of a patient with type 1 cryoglobulinemic vasculitis with multiorgan involvement who met criteria for multiple myeloma 1.5 years after initial presentation.

Case Description: A 56-year-old Caucasian male presented with progressively worsening bilateral lower extremity pain and numbness followed by a lacey purple rash and small volume hemoptysis. Serologic workup was negative for ANA, anti-cardiolipin-ab, ANCA, anti-GBM ab, hepatitis B/C, RF, CCP, and cryoglobulin. He had low C3(73mg/dL), normal C4, elevated M protein(0.3gm/dL), elevated serum kappa(175mg/dL) and normal lambda light chains. Bone marrow (BM) biopsy showed 5% monoclonal plasma cells. BM and fat pad biopsies were negative for amyloid. Bronchoscopy was unrevealing. Skin biopsy was inconclusive, but was notable for leucocytoclastic vasculitis vs thrombotic process. He was initiated on high dose prednisone and rituximab therapy. His symptoms waxed and waned and ultimately he developed hematuria, nephrotic-range proteinuria, and acute kidney injury (creatinine 2.3mg/dL) a year later. Kidney biopsy revealed segmental endocapillary hypercellularity, sub endothelial and mesangial eosinophilic immune deposits with 20% crescents. IF was positive for IgG(3+), kappa light chain(2-3+), and C3(1+). EM showed organized immune deposits with straight to slightly curved rods 10-17 nm in diameter very characteristic of cryoglobulinemic GN. A repeat BM biopsy showed expansion of the monoclonal plasma clone to 20%.He was initiated on plasmapheresis, steroids, cyclophosphamide, and carfilzomib with improvement in his symptoms and renal function. Repeat serum cryoglobulin and cryofibrinogen remained undetectable.

Discussion: This case highlights the challenges with diagnosing cryoglobulinemia based on serologic tests alone, and the differential diagnosis and treatment of cryoglobulinemia due to multiple myeloma. We emphasize therapy should be directed toward the causative plasma cell clone, which in this case was rituximab resistant. We present good outcomes after an induction therapy with steroids and plasmapheresis for a rapidly progressive GN due to cryoglobulinemia. Finally, we present a regimen of steroids, cyclophosphamide and carfilzomib in place of bortezomib for patients with significant nerve involvement.

SA-PO242

Persistent HCV-Related Cryoglobulinemic Glomerulonephritis Following Sustained Virologic Remission and Rituximab Monotherapy

Tyler Woodell, Divine Ribakare, Rupali S. Avasare, Nicole K. Andeen. *Oregon Health & Science University, Portland, OR.*

Introduction: Hepatitis C virus (HCV)-related cryoglobulinemia is treated with direct-acting antiviral therapy and immunosuppression if severe end-organ damage is present. We present a patient with persistent HCV-related cryoglobulinemic glomerulonephritis (GN) years after sustained virologic remission (SVR) refractory to rituximab monotherapy. With the help of our oncology colleagues we are targeting therapy to a low grade lymphoproliferative disorder producing cryoglobulins.

Case Description: A 62 year-old Caucasian man presented with palpable purpura on his lower extremities, nephrotic syndrome, and acute kidney injury in 2010. Serologic workup was notable for HCV (peak viral load 1.3 million iU/mL), depressed C4 level, markedly elevated rheumatoid factor (>650 iU/mL, nl 0 – 14) and type II cryoglobulinemia (monoclonal IgM kappa and polyclonal IgG); SPEP, UPEP, and serum free light chains were unremarkable. Kidney biopsy showed membranoproliferative GN with IgM kappa deposits, suggestive of cryoglobulinemic GN. A bone marrow biopsy did not show a clonal cell population. He achieved SVR at three months following treatment with simeprevir and sofosbuvir, but his nephrotic range proteinuria and purpura persisted. In 2015, the patient was treated with two courses of rituximab, however he continued to have nephrotic range proteinuria and cryoglobulinemia. A kidney biopsy was repeated and showed membranoproliferative GN with hyaline thrombi as well as subendothelial and mesangial deposits without a clear substructure, and a low-grade CD-20+ B cell lymphoma. He is currently being treated with rituximab and bendamustine for low grade B cell lymphoma. At last follow-up proteinuria improved from 8.1 to 4.2 grams/day; eGFR declined from 30 to 18ml/min/1.73m2.

Discussion: HCV-related cryoglobulinemic GN following SVR is increasingly recognized. This case of cryoglobulinemia highlights the intersection between HCV (typically types II-III) and lymphoproliferative disorders (typically type I), and draws attention to the need for appropriately targeted therapies. Given the growing use of direct-acting antiviral agents for HCV, novel therapeutic strategies are needed to effectively treat refractory cases of HCV-related cryoglobulinemic GN.

SA-PO243

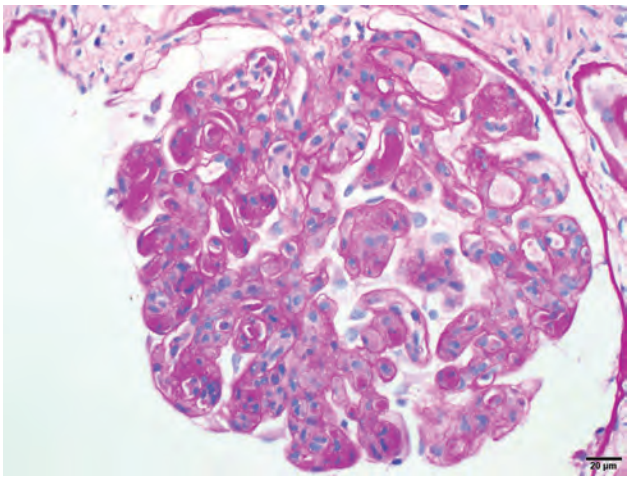
Cry, Cry Again: A Case of Idiopathic Cryoglobulinemia

Nupur Kikani,[1] Sehrish Ali,[2] Rajeev Raghavan.[1] [1]*Baylor College of Medicine, Houston, TX;* [2]*BCM Nephrology, Sugar Land, TX.*

Introduction: Cryoglobulinemia is characterized by the presence of cryoglobulins in the serum, and it is commonly associated with persistent viral infections, autoimmune diseases, and lymphoproliferative disorders. Although there are standardized treatments for viral or malignancy associated cryoglobulinemia, a protocol for idiopathic non-viral cryoglobulinemia has yet to be described. Literature supports using a combination of high dose glucocorticoid therapy and plasmapheresis. In true idiopathic cryoglobulinemia, Rituximab has improved outcomes in published cases. Here, we present a patient with newly diagnosed idiopathic cryoglobulinemia in whom Rituximab was added to high dose steroids resulting in improvement of renal function

Case Description: A 66-year old male with a history of leukocytoclastic vasculitis diagnosed by biopsy of a right leg rash 7 years prior, presented with 2.5 weeks of new onset lower extremity edema and scrotal swelling. He had new onset hypertension, acute kidney injury, hyperkalemia, and non-anion gap metabolic acidosis. A 24-hour urine collection was consistent with nephrotic range proteinuria. A laboratory work-up showed an undetectable C4, low-normal C3, positive rheumatoid factor, and positive ANA with titer >640. Kidney biopsy revealed immune deposits consistent with cryoglobulinemia and immunofluorescence was negative for other pathology (Figure 1). The remaining viral and autoimmune laboratory work up was negative, including both Hepatitis panel and HCV RNA. The patient received three days of pulse dose steroids followed by a single dose of rituximab at 375 mg/m2. His creatinine, proteinuria, and overall clinical picture improved and has persisted.

Discussion: Guidelines to treat idiopathic non-viral cryoglobulinemia do not exist. Rituximab may be an effective and intuitive adjunct treatment, per literature review and in our patient.



SA-PO244

Novel Approach to Treatment of Mixed Cryoglobulinemia with Kidney Involvement: Case Report

Marianne Camargo,[1] Tara I. Chang,[2] Robert T. Isom,[3] David J. Iberri,[4] Michelle M. O'Shaughnessy.[5] *[1]Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Stanford University School of Medicine, Palo Alto, CA; [3]Stanford University School of Medicine, Palo Alto, CA; [4]Stanford Cancer Center, Stanford, CA; [5]Stanford University, Palo Alto, CA.*

Introduction: Mixed cryoglobulinemia (CG) is rarely associated with hepatitis B virus (HBV) infection. Monoclonal CG can result from an underlying lymphoproliferative disorder. We report a case of mixed CG with treated HBV and a low-grade lymphoproliferative disorder. Adverse reactions to standard therapies motivated a novel proteasome-inhibitor based approach

Case Description: A 67-year-old woman with a 5-year history of mixed CG and membranoproliferative glomerulonephritis experienced cerebrovascular and gastrointestinal ischemia with deteriorating kidney function, persistent hematuria, and proteinuria, while receiving maintenance tacrolimus and prednisone. Prior therapies included mycophenolate (persistent disease activity), rituximab (serum sickness), cyclophosphamide (leukopenia), and azathioprine (persistent disease activity). Labs included: +RhF, +HBV sAg with negative sAb (treated with entecavir with undetectable viral load), negative HCV, +IgM monoclonal gammopathy, and hypogammaglobulinemia. Before further immunosuppressive therapy, she received subcutaneous immunoglobulin for hypogammaglobulinemia. She developed palpable purpura, increasing creatinine (2.1 to 4.3 mg/dL), and increasing cryocrit, consistent with an immunoglobulin-triggered CG vasculitis flare. Given underlying monoclonal gammopathy, we initiated bortezomib and dexamethasone. Her creatinine initially declined to 2.8 mg/dL; however, she then developed severe diarrhea (attributed to bortezomib toxicity). Repeat kidney biopsy revealed 5 of 19 glomeruli with global sclerosis, 6 of 19 with cellular crescents, and large IgM Kappa positive subendothelial cryoglobulin deposits. She received 5 days of plasma exchange and intravenous corticosteroids followed by carfilzomib as an alternate proteasome inhibitor: response pending at time of abstract submission.

Discussion: Unlike prior cases of HBV-associated CG, our patient had persistent disease activity despite viremia clearance. Cryoglobulinemic vasculitis flares following intravenous or subcutaneous immunoglobulin have not been widely reported. A proteasome inhibitor-based approach might represent a novel treatment option when standard therapies fail.

SA-PO245

Gall Bladder Arteritis in a 35-Year-Old Lady with Mixed Cryoglobulinemia Syndrome

Maria I. Kiliaris,[2] Husham R. Abuleis,[1] Packiam Shenbagaraman.[1] *[1]Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [2]Milton Keynes University Hospital NHS Foundation Trust, Milton Keynes, United Kingdom.*

Introduction: Mixed Cryoglobulinemia Syndrome is a systemic disease caused by the deposition of circulating immune complexes (cryoglobulins) in small and medium –sized arteries. Type II cryoglobulinemia is most often due to Chronic Hepatitis C infection and it is also seen in autoimmune disorders such as SLE and Sjogren's syndrome. Whilst skin and renal involvement are common clinical features, gall bladder involvement is very rare and we report a case of cholecystitis due to cryoglobulinemic vasculitis.

Case Description: A 35-year-old lady with Sjogren's syndrome presented in August 2016 with systemic symptoms, acute kidney injury(AKI), hypertension, significant hemoproteinuria, low C3 and C4 and positive cryoglobulins (type II). ANCA and anti GBM antibodies were negative. PET CT scan and a bone marrow trephine were done to exclude lymphoma. She underwent a kidney biopsy which confirmed cryoglobulinaemic glomerulonephritis and was managed with plasmapheresis, Rituximab and Methylprednisolone followed by oral prednisolone. Her systemic symptoms, kidney function and proteinuria improved. In December 2016 her condition relapsed with systemic symptoms, skin rash, worsening renal function and positive cryoglobulins (cryocrit 8%). She responded to another course of plasmapheresis, Rituximab and prednisolone. In May 2017 she was admitted under Gastroenterology for right upper quadrant pain, raised CRP and deranged liver function tests. She was diagnosed with acute cholecystitis. At this time she developed another cryoglobulinemic relapse with oliguric AKI. She was managed again with plasmapheresis, Rituximab and prednisolone. She also needed hemodialysis briefly. She had an interval cholecystectomy. The gall bladder histology was reported to show florid arteritis in the medium sized arteries related to cryoglobulinemia (images will be provided in the poster). Her kidney biopsy was repeated and it also showed arteritis with severe chronic damage. Cyclophosphamide was added to the treatment regimen to prevent further relapses and because of the extra-renal disease.

Discussion: To our knowledge this is the first case report of cryoglobulinemic vasculitis that manifested in the gall bladder and mimicked acute cholecystitis during a relapse. The diagnosis can be missed or delayed and therefore careful examination and correlation with the clinical picture is essential.

SA-PO246

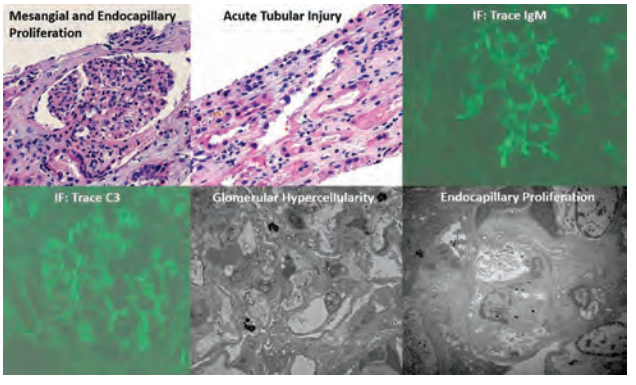
Fungal Endocarditis and ANCA-Vasculitis: More Than a Mere Coincidence?

Hussain Aboud, William L. Clapp, Abhilash Koratala. *University of Florida, Gainesville, FL.*

Introduction: Glomerulonephritis (GN) due to infective (bacterial) endocarditis is well documented, with the most common lesions being necrotizing and crescentic GN, followed by endocapillary proliferative GN. Prominent C3 staining and subepithelial immune deposits on EM are commonly associated with infection-related GN than Pauci-immune picture of ANCA vasculitis. Herein, we present a case of Pauci-immune proliferative GN in a patient with fungal endocarditis.

Case Description: A 52-year-old White man with a history of intravenous drug abuse, chronic hepatitis C and diabetes mellitus initially presented to our institution with fever and bilateral lower extremity rash/palpable purpura. Biopsy of the rash demonstrated small and medium vessel vasculitis. He was also found to have native aortic valve endocarditis with ~1.5 cm vegetation and *Candida parapsilosis* fungemia which failed treatment with Micafungin and therefore switched to amphotericin B and flucytosine. Later, he developed worsening renal function with sub-nephrotic proteinuria and work up revealed dysmorphic RBCs in the urine, hypocomplementemia, positive C-ANCA, PR3 and cryoglobulins. In the presence of multiple confounding factors and varied differentials (e.g. hepatitis C-MPGN, post-infectious GN, ANCA vasculitis), a renal biopsy was obtained which showed proliferative Pauci-immune glomerulonephritis with ATN [Figure]. His renal function worsened requiring dialysis. Immunosuppressive therapy was not attempted because of active fungemia.

Discussion: Interestingly, ANCA antibody is found in up to 28% of the tested patients with infective endocarditis. However, Post-infectious Pauci-immune GN in association with *Candida parapsilosis* has never been reported in the literature to the best of our knowledge. It is likely that the fungal capsular polysaccharide activates complement cascade and triggers inflammation. Whether ANCA-antibody was a coexistent distinct entity or induced by fungal infection or underlying hepatitis C in our patient remains elusive.



SA-PO247

Relapsing Hepatitis B (HBV)-Associated Vasculitis with Features of Polyarteritis Nodosa (PAN) and cANCA-Associated Vasculitis

Usman A. Khan,[2] Sardar H. Ijaz,[1] Aemen S. Khakwani,[2] Joe Ghata.[2] *[1]internal medicine, University of Oklahoma Health Sciences Center, Oklahoma city, OK; [2]OUHSC, Oklahoma City, OK.*

Introduction: HBV-associated vasculitis typically manifests as the medium vessel vasculitis, PAN. HBV-associated PAN (HBV-PAN) is ANCA(-), without glomerulonephritis (GN) or pulmonary involvement; relapse does not occur after successful HBV seroconversion. We describe a unique case of HBV-associated vasculitis with features of a small and medium sized overlap vasculitis and atypical long term course.

Case Description: The patient is a 60-year-old male with hypertension and HBV who initially presented with abdominal pain and scrotal swelling. Abdominal angiogram revealed beaded morphology and aneurysms involving mesenteric, hepatic, and

intraparenchymal renal arteries. Hepatitis B core antibody, cANCA, PR3, and rheumatoid factor were (+). He received pulse steroids and Cytoxan for treatment of PAN and Entecavir for HBV, resulting in resolution of symptoms. Serum Cr rose from 0.8 mg/dL to 2.0 mg/dL during the first 2 months of treatment, and then remained stable. Multiple urinalysis (UA) measurements were negative. Two years later, the patient developed abdominal pain, orchitis, hemoptysis, and acute kidney injury (serum Cr of 11 mg/dL). HBV viral load was negative. UA showed 3+ blood and 3+ protein. Renal biopsy displayed pauci-immune crescentic GN with active crescents involving ~ 50% of the glomeruli (Figure A, Jones stain). Two arteries had evidence of past arteritis with elastic lamina disruption (Figure B, EVG stain); acute necrotizing arteritis was not present. The patient recovered renal function (most recent serum Cr=3.2 mg/dL) after therapy with pulse steroids, plasma exchange, Rituxan, and Cytoxan.

Discussion: Our patient with HBV-associated vasculitis initially presented with manifestations of medium vessel involvement, but with an unusual feature of cANCA/PR3 seropositivity. Relapse occurred 2 years later with PAN symptoms (orchitis, severe abdominal pain) and evidence of ANCA-associated small vessel vasculitis (GN, hemoptysis). While the initial trigger may have been HBV, the vasculitis later became self-perpetuating as it recurred during a time when there was no HBV viremia. Patients with HBV-PAN who are ANCA+, should be closely followed because they could be at higher risk of vasculitis relapse.

SA-PO248

ANCA Negative Pauci-Immune Crescentic Glomerulonephritis Associated with Cervical Carcinoma

Ujjala Kumar,[1] Kioumars Bolourian kashi,[1] Cynthia Miracle,[1] Dinna Cruz,[2] Aleksandra Novikov,[1] Bethany E. Karl.[1] *[1]UCSD, San Diego, CA; [2]University of California San Diego, San Diego, CA.*

Introduction: Glomerulonephritis (GN) associated with solid tumors is a rare but well-known entity. Various forms of paraneoplastic GN have been described in the literature, most common being membranous and minimal change disease. Here we present a case of cervical cancer and rapidly progressive crescentic GN involving near 100% of the glomeruli sampled.

Case Description: A 58-year-old woman admitted for rising creatinine found on routine labs prior to initiation of chemotherapy. Medical history was significant for recently diagnosed poorly differentiated cervical carcinoma, AJCC stage IIB., for which she had been actively receiving radiation therapy. She denied prior kidney disease, use of non-steroidals nor recent antibiotics. On presentation, Cr was 2.4 mg/dL from baseline of 0.9 mg/dL a month prior to presentation. Urinalysis revealed active sediments. 24-hour urine quantified proteinuria in nephrotic range (8 gms/24-hr). Extensive GN work-up was negative. Serum protein electrophoresis and urine immunofixation showed no monoclonal gammopathy. A renal ultrasound showed normal size kidneys. A kidney biopsy divulged severe, active necrotizing and crescentic glomerulonephritis involving nearly 100% of 22 sampled glomeruli. There were cellular crescents and amyloidosis, type AA, with extensive glomerular and focal vascular involvement. Acute tubular injury and extensive tubulointerstitial inflammation were also noted. Patient's renal function continued to deteriorate in parallel to progression of her malignancy and was eventually started on hemodialysis five months after her initial diagnosis of GN. Unfortunately, patient was never deemed a candidate for chemotherapy due to poor performance status. She continued to decline and transitioned to comfort care passing less than 7 months from her initial renal diagnosis.

Discussion: We present a unique case of rapidly progressive crescentic GN associated with cervical cancer. There have been cases of membranous glomerulonephritis associated with cervical cancer but crescentic GN has not been reported in the literature to the best of our knowledge. As in other cases of paraneoplastic GN, treatment targeted towards the cancer results in resolution of the GN in most cases but our patient was not a chemotherapy candidate and her disease ultimately progressed to end stage renal disease.

SA-PO249

Necrotizing ANCA Positive Glomerulonephritis Associated in Culture Negative Endocarditis

Lumen A. Mendez Castaner,[1] Antonio A. Armstrong,[1] Aza Abdalla,[2] Lorena Cuebas-Rosado,[4] David B. Thomas,[3] Zain Mithani.[5] Jackson Memorial Hospital *[1]Jackson Memorial Hospital, Miami, FL; [2]Jackson health Miami, Coral Springs, FL; [3]University of Miami, Miller School of Medicine, Miami, FL; [4]Miami VA Hospital, Miami, FL; [5]University of Miami, Miami, FL.*

Introduction: Renal involvement is a common extra cardiac manifestation of infective endocarditis (IE) affecting up to 50% of all patient. Kidney manifestations in IE are variable, including direct consequence of infection such septic emboli, immune complex glomerulonephritis and more interestingly ANCA associated glomerulonephritis have been described. Making challenging the differentiation between infectious endocarditis related glomerulonephritis and small vessel vasculitis. Even more a subgroup of patient with culture negative infectious endocarditis has been associated with glomerular disease and seropositive ANCA titers caused by *Bartonella species*, been the most common cause of culture negative endocarditi. Diagnosis relies on clinical suspicion and serologic titers diagnostic tools.

Case Description: Case of a 73 year old with no past medical history who presented with progressive shortness of breath for 3 weeks associated with fever and chills. Complaining of bloodey sputum for the past 3 days. Physical Exam showed bilateral ronchies and crackles. Pitting edema +2. Labs serum cr 5.90mg/dL, eGFR 9mL/min/1.73m^2. WBC 7.7, Hgb 6.5g/dl. UA RBC > 182, WBC 27, Upr > 100mg/dL. UPCR 4.4, C3 73, C4 14.8, ANCA PR3 positive. CT chest showing bilateral calcified granulomas. Echocardiogram showed 1.5 x 1.4cm calcified irregular mass noted in the tricuspid valve. Received broad spectrum antibiotics. Blood cultures negative. Renal biopsy showed crescetic focal necrotizing glomerulonephritis, with moderate fibrosis. Immunofluorescence(IF) showed mensagial IgG(1+), IgA(1+), IgM(2+), C3(2+),C1q(2+), kappa(2+) and lambda(2+). Ultrastructurally showed mesangial matrix immune complex type dense deposits. Bartonella henselae titers IgG 1:1024. Treated antimicrobial and pulse steroid followed by tapered.

Discussion: This case highlights the unique complexity in differentiating between primary small vessel vasculitis vs infectious endocarditis related glomerulonephritis, where initial serology can be misinterpreted. Ultimately with the clinical and renal biopsy findings along with bartonella titers lead to the diagnosis of culture negative endocarditis related glomerulonephritis

Eosinophilic Granulomatosis with Polyangiitis - Renal Biopsy Can Aid in Guiding Therapy

Mayanka Kamboj, Gajapathiraju Chamarthi, Rupam Ruchi. *University of florida, Gainesville, FL.*

Introduction: Eosinophilic granulomatosis with polyangiitis (EGPA), a rare systemic vasculitis; can cause end organ damage with eosinophilic infiltration of the extravascular tissue and necrotizing vasculitis. Patients with renal involvement usually develop rapidly progressive glomerulonephritis (GN).

Case Description: 61-year-old female with 1.5-year history of asthma, recurrent sinusitis with nasal polyposis presented with fever. Lab work showed leukocytosis (WBC 23,400/mm^3 with 29% eosinophils), serum creatinine (SCr) 0.7 mg/dL, microscopic hematuria, proteinuria and positive antineutrophil cytoplasmic antibody (ANCA) 1:320 with myeloperoxidase specificity. Therapy with glucocorticoids was initiated. She developed acute kidney injury, initially atrribited to volume depletion; when SCr worsened to 1.9 mg/dL and improved to 1.3 mg/dL with IV fluids. Renal biopsy showed segmental necrotizing pauci-immune GN with crescent formation. Treatment with cyclophosphamide (CYC) (10mg/kg) was initiated. On 3 week follow up, SCr worsened to 2.7 mg/dL when CYC was escalated to 15mg/kg/dose for the next 3 doses. Her SCr improved and stabilized at 2 mg/dL over the next 2 months.

Discussion: Renal function as measured by SCr can be relatively preserved in crescentic ANCA vasculitis. Biopsy showing renal involvement affected the decision to initiate therapy with CYC in this patient. The rapidity of decline in renal function despite treatment foretells that the patient could have had a worse renal outcome with delay in appropriate immunosuppressive (IS) therapy. Our case emphasizes the importance of doing a renal biopsy in patients with systemic features of EGPA and active urine sediment even with normal relatively preserved SCr, not only for definitive diagnosis but also guide clinicians to pursue aggressive early IS therapy and improve renal prognosis.

PSGN – When Kidneys Take a Hit

Muhammad Deen,[2] Omomengbe Oni,[1] Rahmat Na'Allah.[1] *[1]University of Illinois College of Medicine at Peoria, Peoria, IL; [2]University of Illinois College of Mediicine at Peoria, Peoria, IL.*

Introduction: Complication of Streptococcal pharyngitis leading to post-streptococcal glomerulonephritis.

Case Description: 12 year old boy presented with hematuria, oliguria, arthralgia, periorbital and peripheral edema in the setting of acute kidney injury. 10 days prior to admission, patient was diagnosed with recurrent strep throat infection which was treated with Amoxicillin-Clavulanic acid. Examination findings were positive for diffuse maculopapular rash and presence of cola colored urine. On admission, lab work was significant for Cr 1.10 (baseline Cr 0.50), elevated ASO titer 983, DNase B Ab 1390 and UA

positive for blood and protein. What was surprising, that the patient had normal complement (C3 and C4) levels at presentation. Appropriate fluid resuscitation was initiated, resulting in an improvement in urine output and renal function, but a fall in C3 and total complement levels was noted. Given this atypical presentation, along with possible concerns for other forms of vasculitis especially Henoch Schonlein Purpura, a short burst of steroid treatment was initiated. Patient showed significant clinical improvement with complete resolution of hematuria, oliguria, proteinuria, edema and rash. Follow up with PCP and nephrology in 6 weeks revealed a normal complement level and given this scenario, a diagnosis of post-streptococcal glomerulonephritis (PSGN) was made.

Discussion: The hallmark of GN is inflammation within the glomeruli that typically manifests as hematuria and proteinuria. Renal function may be reduced, depending on the severity of the acute condition or the presence of chronic glomerular injury. Post-streptococcal glomerulonephritis is the leading cause of acute nephritic syndrome. Most cases are sporadic, although the disease has been known to occur in epidemic form. The overall incidence of PSGN in the United States has significantly decreased with good long term prognosis. More than 95% of patients recover spontaneously and return to baseline renal function within three to four weeks with no long term sequelae. Acute PSGN usually is diagnosed on clinical and serologic grounds without the need for biopsy, especially in children with a typical history.

A Challenging Diagnosis and a Missed Treatment Opportunity: A Case of Bartonella Endocarditis Complicated with Rapidly Progressive Glomerulonephritis

Mohamed Mortagy,[1] Lauren Lamie.[2] *[1]Western Michigan University School of Medicine, Kalamazoo, MI; [2]WMU Homer Stryker MD School of Medicine, Kalamazoo, MI.*

Introduction: Bartonella is the most common cause of culture negative endocarditis in the USA which is complicated by kidney failure in 45% of patients. Diagnosing Bartonella endocarditis is very challenging but crucial. Treating bartonella associated glomerulonephritis (GN) with immunosuppressants is fatal.
