Elodie Speyer,[1] Lucile Montalescot,[3] Karine Legrand,[2] Carole Ayav,[4] Christian Combe,[5] Benedicte Stengel,[1] Aurelie Untas.[3] *[1]CESP Inserm U1018, VILLEJUIF Cedex, France; [2]CHRU Nancy, Vandœuvre les Nancy, France; [3]Paris Descartes University, Boulogne Billancourt, France; [4]University Hospital of Nancy, Vandoeuvre les Nancy, France; [5]CHU de Bordeaux, Bordeaux, France.*

Background: Social support is associated with higher well-being in chronic kidney disease (CKD), but has only been explored in ESRD patients. We describe family profiles and their associations with self-reported quality of life and depression in patients with moderate or advanced CKD.

Methods: Four questionnaires were administrated to 3,033 adult patients with CKD stage 3-5 under nephrology care: the 12-item Family Relationships Index (FRI) to assess family relationships through 3 subscales [***family cohesion*** (degree of support within the family), ***family expressiveness*** (extent to which family members express feelings) and ***family conflict*** (amount of conflict among family members), the KDQoL scale to measure CKD effects, burden, and symptoms, the SF-12 to assess mental and physical composite scores (MCS, PCS), and the CES-D scale for depression symptoms. Comparisons between profiles were adjusted for age, sex, and living status.

Results: Based on 2,004 patients (median age 68, 68% men, 20% living alone, 56% stage 3 CKD) with complete data for the FRI, cluster analysis yielded 3 family profiles (Upper Figure). Patients with profile 3 (the highest family cohesion and expressiveness, and the lowest conflict) had the best patient-reported outcomes. In comparison, patients with profile 1 (the lowest family cohesion and expressiveness, and intermediate conflict) had significantly lower KDQoL and SF-12 scores (p<.001) (Lower Figure), and a higher prevalence of self-reported depression symptoms, 9% vs 6% (p<.001). Patients with profile 2 (high family cohesion, intermediate expressiveness, and highest conflict) did not differ significantly from those with profile 3.

Conclusions: Family environment plays a crucial role in patients' adaptation to CKD. Accounting for it could allow health professionals to better assist their patients.

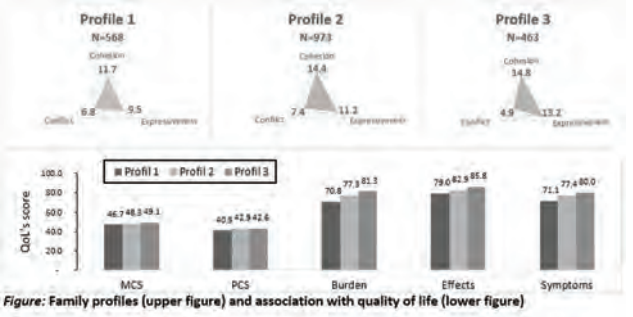

***Figure:* Family profiles (upper figure) and association with quality of life (lower figure)**

Score range: 4-16 (FRI: Cohesion; Conflict; Expressiveness); 0-100 (KDQoL: Burden, Effects, and Symptoms; SF12: MCS and PCS). Quality of life scores were adjusted for age, sex, and living status.

TH-PO1085

Association of Social Support with CKD Among African-Americans

Rasheeda K. Hall,[1] Clementina A. Davenport,[1] Mario Sims,[3] Cathleen Colon-emeric,[1] Tiffany R. Washington,[4] Jennifer St. Clair Russell,[1] Jane F. Pendergast,[1] Nrupen A. Bhavsar,[1] Julia J. Scialla,[1] Crystal C. Tyson,[1] Nancy Min,[3] Bessie A. Young,[2] L. Ebony Boulware,[1] Clarissa J. Diamantidis.[1] *[1]Duke University School of Medicine, Durham, NC; [2]Uniiversity of Washington, Seattle, WA; [3]University of Mississippi Medical Center, Jackson, MS; [4]University of Georgia, Athens, GA.*

Background: Low social support (LSS) negatively affects health behaviors. Because disease self-management and lifestyle modifications improve outcomes in chronic kidney disease (CKD), we sought to examine the independent association of LSS with CKD prevalence or rapid renal functional decline (RRFD) in African Americans at risk of CKD incidence or progression in the Jackson Heart Study (JHS).

Methods: The JHS is a prospective cohort of African Americans within the Jackson, MS metropolitan area. At baseline (2000-2004), social support was assessed using the Interpersonal Support Evaluation List (ISL); a 16-item survey with four subscales: appraisal, belonging, self-esteem, and tangible support. ISL scores < 32 indicate LSS. CKD was defined as an estimated glomerular filtration rate (eGFR) < 60ml/min/1.73m2 or a urine albumin/creatinine ratio (ACR) ≥30mg/g in those with an eGFR ≥ 60ml/min/1.73m2. We conducted multivariable logistic regression to evaluate the association between LSS and CKD prevalence in the general JHS cohort, as well as the association of LSS and RRFD (defined as a > 30% decrease in eGFR over a 10 year period) among JHS participants with diabetes, hypertension, or CKD at baseline. Models were adjusted for baseline sociodemographics, comorbidities and ACR.

Results: Of 5301 JHS participants, 4015 (76%) completed the ISL. 843 (21%) had LSS. Participants with LSS (vs. high) were more likely to have lower income (47% vs. 28%), be current or former tobacco users (39% vs. 30%), have diabetes (25% vs. 21%), and CKD (14% vs. 12%) (all p<0.05). After multivariable adjustment, LSS was not independently associated with prevalent CKD or with RRFD. However, a low self-esteem subscale score was associated with increased odds of prevalent CKD [OR 1.06 (95% CI 1.01-1.12)].

Conclusions: Overall, LSS was not independently associated with CKD outcomes among African Americans in the JHS, but low-self-esteem was associated with CKD. Self-esteem may have a role in CKD management and warrants further study.

TH-PO1086

Tele-Nephrology to Provide Efficient and Patient-Centered Ambulatory Care

Charuhas V. Thakar,[1,2] Nicole Piero,[3] Cristy A. Goodall,[4] Anthony C. Leonard.[1] *[1]University of Cincinnati, Cincinnati, OH; [2]Renal Section, Cincinnati VAMC, Cincinnati, OH; [3]VA Medical Center, Milford, OH; [4]Cincinnati VA Medical Center, Cincinnati, OH.*

Background: Subspecialty referrals in ambulatory care in the U.S. have doubled in the last decade. According to an AAMC-commissioned study in 2017, there will be a projected a shortage of up 61,800 nonprimary care specialists by 2030. We evaluated whether the incorporation of tele-nephrology within ambulatory care could improve efficiency and patient-centeredness.

Methods: In a large Veteran's Affairs health system, we assessed outpatient utilization of tele-nephrology via e-Consults (e-C), defined as either electronic, telephonic or video communication with the referring provider and/or the patient. We implemented a pilot to pro-actively triage eligible renal consults in patients 75 or older (Grp I) to be initially addressed via e-Consults compared to those < 75 (Grp II). e-C assessments and ability to completely address the consult without need for in-person (IP) visit were compared by Chi-square or Fishers tests.

Results: In FY 2016-17, of the 1,803 consults, inital e-C assessments were peroformed on 172 (9.5%), leaving 1,631 IP visits. Since the pilot, between 1/1/18 and 5/29/18, 249 renal consults were received of which, 9% (22/249) patients were Grp I. 86% (19/22) in Grp I underwent initial e-C assessments compared to 14% (33/227) in Grp II ($p < 0.001$). Of the initial e-C assessments 26% (5/19) in the Grp I were completed by avoiding IP visit; whereas 42% (14/33) in Grp II were completed without IP visit ($p = 0.37$). Pilot Grp I was 100% male (mean age of 81.3; mean serum creatinine 1.84 mg/dl); 78% were diabetic and 78% hypertensive. They resided between 2 and 42 miles from the clinic, and 20% were receiving home-based primary/hospital care. The mean time to complete an e-C assessment was 1.43 days from date of referral, as compared to > 30 day wait for IP visit. Along with comprehensive medical review, 93% received renal-specific diagnostic assessments (lab tests, radiology tests, medication review management). Overall, initial e-C (52/249) created 21% efficiency; and created 8% capacity (19/249) by avoiding the need for IP visits, with same resources.

Conclusions: e-Consults reduced time to initial renal assessment, allowed prompt diagnostic testing, medication management, and avoided travel burden for patients and relatives. Tele-nephrology models of ambulatory care delivery can improve efficiency, enhance patient-safety, and reduce real and opportunity costs.

CKDApps: A Systematic Evaluation of Patient-Facing Smartphone Apps for CKD by Patients and Nephrologists

Karandeep Singh,[1] Clarissa J. Diamantidis,[2] Shreyas Ramani,[1] Nrupen A. Bhavsar,[2] Peter Mara,[1] Julia Herzog Warner,[1] Tianshi Wang,[1] Julie A. Wright Nunes.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Duke University School of Medicine, Durham, NC.*

Background: Many aspects of chronic kidney disease (CKD) management rely heavily on patient self-care, including medication and dietary adherence, self-monitoring of blood pressure, and daily physical activity. There is growing evidence that incorporating technology, specifically smartphone-based applications (apps), can help support self-care in CKD and chronic disease more generally.

Methods: We identified apps targeting CKD patients by conducting a search of the Apple App Store (iOS) and Google Play Store (Android) using the following 4 phrases: "kidney disease," "renal," "dialysis," and "kidney transplant." We considered the first 50 apps for each search term on each app store. We modified a previously described framework for assessment of mobile health apps to account for kidney disease-specific content areas and evaluated apps on their clinical focus, types of patient engagement, quality, usability, safety, and cost. Engagement and quality were assessed by both a patient and a nephrologist, usability was assessed by patients, and safety was assessed by nephrologists.

Results: Our search strategy identified 174 unique apps on Android and 165 unique apps on iOS. After excluding apps that were not related to kidney disease, not patient-facing, or were last updated prior to 2014, 12 Android-only apps, 11 iOS-only apps, and 5 dual-platform apps remained. Patient and nephrologist ratings showed a positive correlation that was not statistically significant ($p = 0.063$, see Figure). Consumer ratings on the app stores did not correlate with patient ratings ($p = 0.177$).

Conclusions: Only a small subset of CKD apps are highly rated by both patients and nephrologists. Patients' impressions of app quality are not directly linked to consumer app ratings or nephrologist impressions. Efforts to develop and disseminate apps for CKD self-care should involve direct patient input.

Relationship between (A) nephrologist and patient ratings and (B) consumer and patient ratings.

TH-PO1088

Attitude, Motivation, and Barriers to Exercise in Patients with CKD: A Focus Group Study

Jessica B. Kendrick,[1] Emily Andrews.[2] *[1]University of Colorado School of Medicine, Aurora, CO; [2]University of Colorado Denver, Aurora, CO.*

Background: Physical activity is remarkably low in patients with chronic kidney disease (CKD). Data suggests that exercise is beneficial for patients with CKD. The adjusted risk of death and end stage renal disease is lower in CKD patients who are physically active compared to those who are inactive. Despite the benefits of exercise in patients with CKD, the majority of patients remain sedentary. The purpose of this formative evaluation was to identify CKD patient attitudes, beliefs and barriers to exercise.

Methods: Adult individuals from the Denver Metro area with CKD stage 3 and 4 who were not currently physically active were recruited for 10 focus groups (3 in English speaking males, 3 in English speaking females, 2 in Spanish speaking males and 2 in Spanish speaking females) from May 2016 to December 2016. Focus groups were transcribed verbatim and transcripts were coded and thematically analyzed.

Results: A total of 41 individuals participated in the study. 51.2% were female and 44% were Hispanic. The majority of the participants held a CKD diagnosis for 1-7 years. Participants recognized the benefits of physical activity on both physical and mental health but physical activity was not viewed to have a significant impact on CKD. Social support was a strong motivational factor to physical activity. Social support was preferred from friends, family, or peers with similar health conditions. Spanish speaking participants saw family as a barrier if the family member was not directly participating in physical activity. Additional barriers to physical activity included poor health, fatigue, a fear of worsening their disease and lack of guidance from their nephrologist. Spanish speaking participants in particular expressed frustration with their nephrologist's lack of advice regarding exercise.

Conclusions: Barriers and motivators to physical activity were similar amongst male and female participants with CKD. Lack of advice from nephrologists regarding exercise was a significant barrier. Physical activity interventions in patients with CKD should include not only increased patient self-efficacy and social support but also counseling and prescribing of exercise by nephrologists.

TH-PO1089

Quality of Life of Patients with CKD: A Cross Sectional Analysis from the ICKD Cohort

Ashok K. Yadav,[1] Vivek Kumar,[2] Sishir D. Gang,[3] Sreejith Parameswaran,[4] Narayan Prasad,[5] Santosh Varughese,[8] Krishan Lal L. Gupta,[6] Vivekanand Jha.[7] ICKD study Investigators *[1]Nephrology, PGIMER, Chandigarh, India; [2]Postgraduate Institute of Medical Education and Research, Chandigarh, India; [3]Muljibhai Patel Urological Hospital, Nadiad, India; [4]JIPMER, Ponidcherry, India; [5]SGPGIMS CAMPUS, Lucknow, India; [6]Postgraduate Institute of Medical Education & Research, Chandigarh, India; [7]George Institute for Global Health, New Delhi, India; [8]Nephrology, CMC, Vellore, India.*

Background: Improving symptoms and function in daily life are important patient centered outcomes in chronic diseases. Health-related quality of life (QOL) is an important key indicator of how a condition affects the patient's life, and QOL has been expressed as the subjective assessment of the impact of disease and its treatment across the physical, psychological and social domains of functioning. We report QOL in patients with early stages of CKD who have been enrolled in the ICKD study.

Methods: All subjects, who had been enrolled in the on-going, multi-centric ICKD cohort study and had KDQOL-36™ survey data recorded at baseline, were eligible for the present study. We assessed QoL by KDQOL-36™. Raw scores are converted to subscale scores using the Microsoft Excel tool (KDQOL-36™ Scoring Program, v 2.0). These subscales are Mental Component Summary (MCS), Physical Component Summary (PCS), Symptoms, Effect and Burden. Each subscale category is scored between 0-100, with higher scores indicating better quality of life. demographic and socioeconomica as well as clinical parameter were studied for association with QOL. Low QOL was defined as subscale score that was 1 SD less than the mean for the respective subscale.

Results: The mean scores for KDQOL-36™ subscales were 48.81±9.93, 44.17±9.49, 65.29±31.40, 81.31±24.70 and 86.68±21.43 for PCS, MCS, burden, effects and symptoms,

respectively. Urban residence, non-vegetarian dietary pattern, education below high school, occupational exposure and lower income were associated with lower scores across all KDQOL-36 subscales (p<0.05). Professional workers had high score across all KDQOL-36 subscales compared to farmers, housewife and unemployed subjects (p<0.01). Increasing quartile of annual income ws associated with higher scores in all subscales (p<0.01). Urban residence, occupational exposure and housewife status were associated with low QOL across all KDQOL-36™ subscales (p<0.05). Education below high school, lower eGFR, low annual income and BMI <18 kg/m^2 were associated with low QOL in all subscale scores (p<0.01) except in symptoms subscale.

Conclusions: We identified the association between a number of clinical and socio-economic variables related and one or more KDQOL-36™ subscales.

A Worrisome Explosion: Time Series Analysis of Kidney Cancer Incidence in the United States

Achintya Ray,[1] Bhabendra Putatunda.[2] *[1]Tennessee State University, Nashville, TN; [2]Nephrology Associates PC, Murfreesboro, TN.*

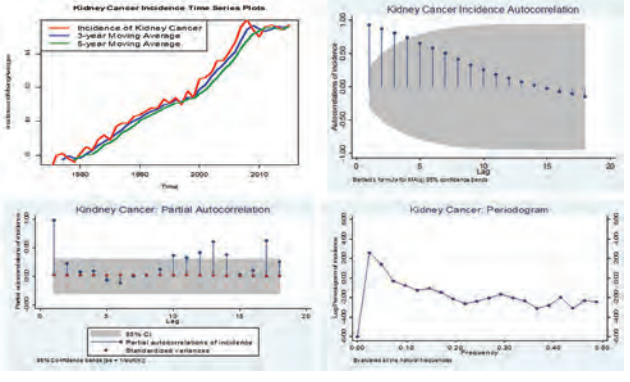
Background: With over 500,000 adults in the US suffering from kidney & renal pelvis cancer and 65,000 new cases are estimated to be diagnosed in 2018 (representing 3.8% of all new cancer cases), kidney cancer poses a major public health challenge and remains a significant source of healthcare cost and mortality. Between 1975-2015, national incidence of kidney cancer more than doubled from 7.1 to 15.7 per 100,000 population.

Methods: Annual time series data covering 1975-2015 is collected from NCI's SEER. Level and smoothed (moving average, 3-year and 5-year) time series plots are obtained (details in Figure 1). Autocorrelation and partial autocorrelation functions obtained from the time series data point to a long memory in the data generating process and help us in understanding the magnitude of rising in renal cancer incidence during the last half-century. Augmented Dickey-Fuller (ADF) tests are performed to check the stationarity in the time series data.

Results: ADF tests using the standard estimation equation rejected stationarity of the incidence data for lag lengths 1, 3, and 5 points to the presence of strong non-stationarity in longitudinal incidence in kidney cancer. The results pointing to non-stationarity hold even after controlling for trend, and random walk with or without drift.

Conclusions: Analysis of 41 years of kidney cancer incidence data strongly establishes that kidney cancer incidences have been increasing statistically significantly over time. The incidence has more than doubled in the last half-century. Current evidence does not support any immediate possibility of a reversal in that increasing trend. Results point to a strong need for urgent interventions and robust public health awareness campaigns aimed at slowing or perhaps reversing the explosive trend in kidney cancer incidence.

Figure 1: Time Series Properties of the Kidney Cancer Incidence Data (SEER 1975 – 2015)



TH-PO1091

Referral to Nephrology Care and Mortality Risk in People with Stage 4 CKD: A Population-Based Study

Ping Liu,[1] Robert R. Quinn,[1] Mohammad E. Karim,[3] Aminu K. Bello,[2] Paul E. Ronksley,[1] Robert G. Weaver,[1] Helen Tam-Tham,[1] Brenda Hemmelgarn,[1] Braden J. Manns,[5] Marcello Tonelli,[1] Giovanni F. Strippoli,[4] Pietro Ravani.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]University of Alberta, Edmonton, AB, Canada; [3]University of British Columbia, Vancouver, BC, Canada; [4]University of Bari, Bari, Italy; [5]Foothills Medical Center, Calgary, AB, Canada.*

Background: Guidelines recommend referral for specialist kidney care when estimated glomerular filtration rate (eGFR) is <30 ml/min/1.73m^2 (stages 4-5 CKD). These recommendations are largely based on studies in people treated with dialysis showing 40% lower mortality with predialysis care of at least 4 months vs. shorter or no predialysis care. The effects of nephrology referral for the broader population of CKD patients are unknown. We examined the association between referral to nephrology care and mortality risk in people with stage 4 CKD.

Methods: Using population-based administrative and laboratory data, we identified all adults, residing in Alberta, with at least two consecutive outpatient measurements of eGFR ≥15 to <30 ml/min/1.73m^2 spanning more than 90 days between 2002 and 2014. Patients were followed from date of the first eGFR after the 90-day qualifying period (study entry) until the earliest of death, out-migration from the province, or March 31, 2015. We used outpatient nephrology visit for at least once as a proxy for referral to nephrology care. We estimated hazard ratios (HRs) and confidence intervals (CIs) for all-cause mortality with nephrology referral (vs. no referral) and whether this effect varied by age, adjusting for baseline demographics and key laboratory and clinical characteristics, and using methods that address immortal time bias and time-varying confounding potentially affected by previous exposure status.

Results: Of the 15,315 study participants, 78% were ≥75 years old; 35% were referred to a nephrologist (median time-to-referral 8 months); and 67% died (median time-to-death 2.6 years). People who were referred were younger and had less comorbidity. Compared to non-referral, referral at any time during follow-up was independently associated with 12% lower mortality (HR 0.88; 95% CI, 0.83-0.93). The association was stronger in people aged <70 years (HR 0.80; 95% CI, 0.68-0.95) and absent in people aged ≥90 years (HR 1.05; 95% CI, 0.88-1.24).

Conclusions: Among people with stage 4 CKD meeting the criterion for nephrology referral, most of them are very old and the survival benefit of nephrology referral may be smaller than expected and become smaller with older age.

Funding: Government Support - Non-U.S.

TH-PO1092

Decline in Glomerular Filtration Rate Before and After Multidisciplinary Care Referral in Moderate to Advanced CKD

Makoto Hirakawa. *Iizuka Hospital, Iizuka, Japan.*

Background: The multidisciplinary care (MDC) model has been used in our hospital for years. We investigated whether the outpatient chronic kidney disease (CKD) treatment by the MDC contributed to the inhibition of the progression of renal failure.

Methods: This study provides a retrospective review of the individual rates of estimated glomerular filtration rate (eGFR) decline (ml/min/1.73m^2/year) for the 6 months before and after referral in 40 referrals with stages 3–5 CKD to one renal unit between March 2010 and June 2012. The MDC team consisted of a nephrologist, nurses, dieticians, and other professionals.

Results: The Age and eGFR at the time of referral was 66 ± 12 and 14.7 ± 6.6 ml/min/1.73m^2 (mean ± SD), and the mean observation period was 395 days (172 to 862 days). The decrease in the eGFR before and after the referral was significantly improved from -8.0 ± 8.0 ml/min/1.73m^2/year to -1.3 ± 5.9 ml/min/1.73m^2/year (P<0.01). Blood pressure also reduced significantly (139/80 to 133/73mmHg, P<0.05).

Conclusions: The outpatient renal failure treatment by using multidisciplinary care might contribute to the suppression of renal failure.

TH-PO1093

Comparing Glomerular Filtration Rate Measured by Radionuclide Imaging with Creatinine Based Equations

Camilo A. Gonzalez,[2,1] Alejandro Durán,[3] María T. Vargas,[3] Paola Garcia,[2,3] Patricia Rodriguez,[2,3] Kateir Contreras.[2,3] *[1]Nefrology, Clinica Universitaria Colombia, Bogotá, Colombia; [2]Nefrology, Hospital Universitario San Ignacio, Bogota, Colombia; [3]Pontificia Universidad Javeriana, Bogota, Colombia.*

Background: Glomerular filtration rate (GFR) is the best index of kidney function. Creatinine based equations (CBE) are recomended by guidelines. In Colombia sometimes we use radionuclide imaging(RI) with ^{99m}Tc-DTPA to measure GFR thinking that it could be better. The aim of this study is to estimate correlation and concordance between this method and eGFR with CBE.

Methods: We included patients who had standarized creatinine and GFR meassured with ^{99m}Tc-DTPA RI in the same week from 4 institutions in Bogota, Colombia between November 2008 and October 2017. We excluded patients with expected source of error in CBE and RI. CBE used were CKD-EPI, MDRD4 and Cockcroft Gault adjusted to body surface (CGa). We estimated the correlation with Spearman coefficient and concordance with kappa coefficient for CKD diagnosis (<60ml/min/1.73m^2) and CKD grades. We considered p<0.05 as statistically significant.

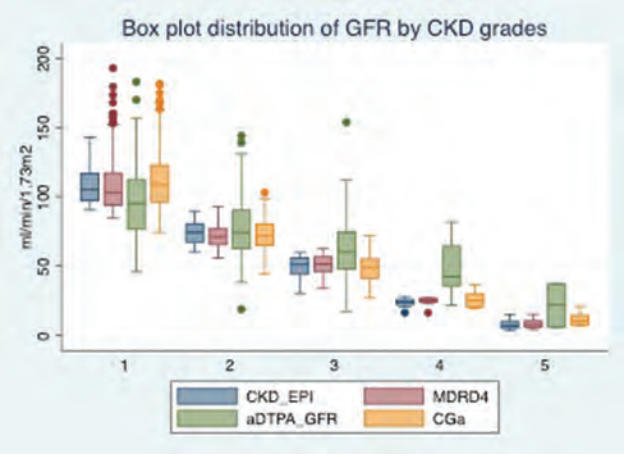
Results: We included 421 patients. Mean age 54 years (± 17.1), 46.8% female, mean eGFR 75.9 (± 26.6), 76.3 (± 28.8), 77.1 (± 31.6) and 77.9 (±28.4) ml/min/1.73m^2 with CKD-EPI, MDRD4, CGa and RI respectively; 29.4% had eGFR less than 60. There were no differences of mean. In the graph, we show the distribution by grades of CKD. The correlation was good between equations, but acceptable when comparing CBE with 99mTc-DTPA RI. Weighted kappa concordance between CBEs was good but for ^{99m}Tc-DTPA RI compared to all CBE was fair.(Table)

Conclusions: GFR with ^{99m}Tc-DTPA RI had a low correlation and fair concordance compared with CBE. There are no reasons to consider RI as a better tool. And also, is an expensive test with limited availability.

Spearman coeficiente and weighted Kappa coefficient by CKD grades 1 to 5.

	CKD-EPI	MDRD4	99mTc-DTPA
MDRD4	ρ=0.98 κ=0.92		
CGa	ρ=0.94 κ=0.82	ρ=0.91 κ=0.75	ρ=0.50 κ=0.36
99mTc-DTPA	ρ=0.57 κ=0.40	ρ=0.55 κ=0.39	

All p<0.00001



TH-PO1094

Improved Time to eGFR Decline Outcomes in Glomerular Disease

Sarah Mansfield,[1] Jarcy Zee,[1] Laura H. Mariani,[2,1] Brenda W. Gillespie.[2] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.*

Background: The standard method of using two estimated glomerular filtration rate (eGFR) measures to calculate time to a percentage decline in eGFR may result in inaccurate event times due to eGFR variability and restriction of events to study visit times. We propose fitting a regression line to all observed eGFR measures to improve accuracy and power of time to percentage decline in eGFR outcomes.

Methods: Using data from the Nephrotic Syndrome Study Network (NEPTUNE) of patients with minimal change disease, focal segmental glomerulosclerosis, or membranous nephropathy, we compared time to 40% decline in eGFR using both event time calculation methods. We also used computer simulations to assess power and accuracy of event times under both methods. Parameters for the simulations, such as eGFR variability, percent missing eGFR observations, and correlation between successive eGFR measurements, imitated NEPTUNE data.

Results: 380 NEPTUNE patients with a mean of 6.5 eGFR measurements over a mean of 33 months of follow-up were included in the analysis. Among these patients, 91 had a 40% decline in eGFR using the two-point method, while 68 had a 40% decline in eGFR using our proposed linear regression method. For patients who had an event under both methods (n=64), the two-point method estimated earlier event times compared to the linear regression method (Figure 1). Under simulated data conditions, the standard two-point method was less accurate in estimating event times than our proposed regression method, particularly with high eGFR variability or more missingness. The two-point method was also less powerful in detecting time-to-event differences between groups.

Conclusions: Using our proposed regression method to estimate time to a percentage decline in eGFR increases accuracy and power. Reducing noise in outcome estimation with our proposed method increases the ability to discover treatment or biomarker effects.

Validation of the Kidney Risk Failure Equations (KFRE) in Patients with CKD in Singapore

Ian tatt Liew,[1] Wanting Weng,[1] Yee Ang,[2] Chun wei Yap,[2] Peng Shen,[1] Xi yan Ooi,[1] Regina Lim,[1] Adrian Liew.[1] *[1]Tan Tock Seng Hospital, Singapore, Singapore; [2]National Healthcare Group, Singapore, Singapore.*

Background: Accurate identification of patients with CKD at risk of progressing to require renal replacement therapy (RRT) would allow optimal care. Tangri et al developed models to predict progression in patients with CKD stages 3-5 (eGFR 10-59ml/min/1.73m^2) to kidney failure using data from Canadian cohorts. The aim of our study is to validate the 4-variable and 8-variable KFREs in the multiethnic population in Singapore.

Methods: Demographics, clinical and laboratory data of patients with CKD stages 3-5 referred from primary care physicians to TTSH Renal Department between 1 January 2009 to 31 December 2012 were collected. Kidney failure was defined as the initiation of chronic dialysis or kidney transplant. The 2 year and 5 year kidney failure risks were predicted using the 4-variable(age, sex, albuminuria and eGFR) and 8-variable(4-variable and calcium, phosphate, bicarbonate and albumin) models. This was compared with actual kidney failure rate at 2 and 5 years of follow up. Patients who died before kidney failure were excluded. Model performance was evaluated using the area under the receiver operating characteristic curve (ROC-AUC) and by comparing the observed and predicted risks of kidney failure.

Results: The KFRE models were validated using 2,238 and 1,845 patients for the 2 and 5 year kidney failure risks respectively. 158 (7.1%) and 355 (15.9%) patients developed kidney failure at 2 years and 5 years respectively. ROC-AUC for the 4-variable KFRE at 2 and 5 years are 0.921 (95% confidence interval [CI] 0.899-0.943) and 0.866 (CI 0.844-0.887) while those for the 8-variable KFRE are 0.925 (CI 0.905-0.945) and 0.862 (CI 0.840-0.883) respectively. The mean differences between the observed and predicted kidney failure risk was lower for the 4 variable equation compared to the 8 variable equation at 2 and 5 years.

Conclusions: Discrimination of the 4-variable and 8-variable KFRE were similar and were able to predict the progression to kidney failure in our patients. To further improve the accuracy of the KFRE, we would need to recalibrate the 8-variable equation for our local multiethnic population

Mean difference between observed and predicted risks

	2 years risk	5 years risk
4-variables KFRE	-1.5%	-2.9%
8-variables KFRE	-4.1%	-8.6%

TH-PO1096

Lower Diastolic Blood Pressure Increases the Risk of Mortality and Progression to ESRD – Multicenter Large Cohort Study

Do Hyoung Kim,[1] Yong Chul Kim,[3] Jung Nam An,[2] Dong Ki Kim,[3] Yon Su Kim,[4] Chun Soo Lim,[2] Dong Ho Shin,[5] Jung Pyo Lee.[2] *[1]Hallym University Hangang Sacred Heart Hospital, Seoul, Republic of Korea; [2]Seoul National University Boramae Medical Center, Seoul, SEOUL, Republic of Korea; [3]Seoul National University Hospital, Seoul, Republic of Korea; [4]Seoul National University College of Medicine, Seoul, Republic of Korea; [5]College of Medicine, Hallym University, Seoul, Republic of Korea.*

Background: Higher systolic blood pressure (BP) is known to be associated with an increased risk of cardiovascular events and mortality in chronic kidney disease (CKD) patients. However, the clinical impacts of diastolic BP and the ideal diastolic BP target in Asian elderly CKD patients have not been well studied.

Methods: A multicenter CKD cohort from 2001 to 2016 was used. We examined the associations of systolic and diastolic BP with all-cause mortality and progression to end-stage renal disease (ESRD) using multivariate Cox proportional hazards regression models.

Results: A total of 13,700 patients with complete data for multivariable analysis were enrolled. Systolic BP showed a U-shaped association with mortality and a linear association with progression to ESRD. Systolic BP greater than 140 mmHg or diastolic BP less than 50 mmHg was significantly associated with higher mortality, regardless of the presence of diabetes or hypertension. In subgroup analysis of age, the patients with diastolic BP < 60 mmHg and aged < 50 years, or diastolic BP < 50 mmHg and aged < 70 years had a higher risk of mortality compared to those with diastolic BP 70-79 mmHg after adjusted systolic BP (age < 50, hazard ratios [HRs], 4.46; 95% confidence interval [95% CI], 2.38 to 8.35; age 50-59, HRs, 2.92; 95% CI, 1.33 to 6.38; age 60-69, HRs 2.84; 95% CI, 1.49 to 5.43). However, there was no association in those aged ≥ 70 years. The risk for progression to ESRD was also increased with diastolic BP < 60 mmHg (HRs 1.20; 95% CI, 1.01 to 1.43). The risk for mortality and progression to ESRD was also increased with diastolic BP < 60 mmHg in patients with diabetes (HRs 2.65; 95% CI, 1.67 to 4.22; HRs 1.43 95% CI 1.01-1.89).

Conclusions: In the CKD patients, lower diastolic BP was significantly associated with mortality and progression to ESRD; however, the effects were reduced in elderly patients (≥ 70 years).

TH-PO1097

Prevalence and Clinical Outcome of Apparent Treatment Resistant Hypertension in CKD in Korea: Korean Cohort Study for Outcome in Patients with CKD (KNOW-CKD)

Young jin Kim,[1] Hong sang Choi,[1] Chang Seong Kim,[1] Eun Hui Bae,[1] Seong Kwon Ma,[1] Kook-Hwan Oh,[2] Curie Ahn,[2] Soo Wan Kim.[1] *[1]Department of Internal Medicine, Chonnam National University Medical School, Gwangju, Republic of Korea; [2]Department of Internal Medicine, Seoul National University, Seoul, Republic of Korea.*

Background: It is not well defined the prevalence and clinical outcome of apparent treatment resistant hypertension(ATRH) in Korean CKD patients. The present study was aimed to investigate the prevalence of ATRH, and its effects on the renal and cardiovascular outcomes and all-cause mortality.

Methods: We collected data of 1878 patients with hypertension in the Korean Cohort Study For Outcome in Patients with Chronic Kidney Disease(KNOW-CKD) to understand ATRH. The definition of ATRH is; 1) systolic blood pressure(BP)≥140mmHg or diastolic BP≥90mmHg with 3 classes of antihypertensive agents, 2) any BP with 4 antihypertensives, at baseline.

Results: 374(19.9%) patients revealed ATRH. Presence of ATRH was associated with baseline renal function, sex, diabetes, severity of proteinuria, BMI, and prior history of myocardial infarction. Patients with ATRH showed higher risk of adverse renal outcome than non-ATRH patients. The adjusted renal event hazard ratio(HR) was 1.362[95% CI 1.079-1.719], p=0.0093. Cardiovascular outcome and all-cause mortality were not statistically different (0.884[0.528-1.481], 1.731[0.898-3.338]). The risk of renal events increases with lower baseline renal function. Patients with eGFR<30 ml/min/1.73m2 and eGFR 30~60 showed higher HR than patients with eGFR≥ 60(24.547[12.082-49.875], 4.278[2.072-8.833]). In subgroup analysis, patients used loop diuretics at baseline had higher HR (1.361[1.076-1.720]). Patients who didn't achieved BP goal(140/90mmHg) with 4 antihypertensives showed higher risk of renal event risk(2.189[1.469-3.269]).

Conclusions: Our study shows that ATRH is associated with high risk of adverse renal outcome in patient with chronic kidney disease. Especially patients with ATRH and CKD stage III~V need more careful approach and management to prevent worsening of renal function.

The Interactions Between Proteinuria, Activity of Fibroblast Growth Factor 23, and Serum Phosphate on Renal Progression in Patients with CKD: A Result from the KNOW-CKD Study

Hyoungnae Kim,[1] Ki Heon Nam,[2] Seung Hyeok Han,[2] Tae-Hyun Yoo.[2] *[1]Soonchunhyang University Hospital, Seoul, Republic of Korea; [2]Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Both of proteinuria and hyperphosphatemia are well known risk factors of CKD progression. Recent experimental study reported that proteinuria increases serum phosphate by decreasing biologic activity of fibroblast growth factor 23 (FGF-23). We examined this relationship in a large chronic kidney disease (CKD) cohort and evaluated combined effect of proteinuria, FGF-23 activity, and serum phosphate on CKD progression.

Methods: This prospective longitudinal study was conducted with 1909 patients from CKD stage 1 to 5. The activity of FGF-23, measured by fractional excretion of phosphate (FEP)/FGF-23 ratio, was compared according to the degree of proteinuria. Primary outcome was CKD progression defined as ≥50% decline of estimated glomerular filtration rate (eGFR), doubling of serum creatinine, start of dialysis, or kidney transplantation.

Results: The patients with more proteinuria had significantly higher serum phosphate levels from CKD stage 2 to 5 than those with less proteinuria. In addition, there was a negative relationship between 24 hour urine protein (24h UP) and FEP/FGF-23 ratio (γ, -0.07; P = 0.005). In addition, after matching variables associated with serum phosphate, patients with more proteinuria had higher serum phosphate (P < 0.001) and FGF-23 (P = 0.012), and lower FEP/FGF-23 ratio (P = 0.007) compared to those with less proteinuria. In the matched cohort, low FEP/FGF-23 ratio was a risk factor of CKD progression (hazard ratio, 0.86 per 1 log increase; 95% confidence interval, 0.79-0.94; P = 0.001), and there was significant interaction between 24h UP and FEP/FGF-23 ratio (P = 0.027). Furthermore, 24h UP and serum phosphate also had a significant interaction on CKD progression (P < 0.001).

Conclusions: Proteinuria is associated with decreased biologic activity of FGF-23 and serum phosphate. Furthermore, diminished activity of FGF23 is an independent risk factor for renal progression in proteinuric CKD patients.

Association Between Serum Lipid Profiles and Progression of CKD: KNOW-CKD Study

Ki Heon Nam, Yooju Nam, Seon yeong Lee, Joohwan Kim, Tae-Hyun Yoo, Dae-Suk Han, Seung Hyeok Han. *Yonsei University College of Medicine, Seodaemun-gu, SEOUL, Republic of Korea.*

Background: Dyslipidemia has been linked to an increased risk of cardiovascular morbidity and mortality in patients with chronic kidney disease (CKD). However, the role of individual lipid parameter in the development of in the progression of CKD is not well established.

Methods: Among 2,238 patients with non-dialysis CKD enrolled in the KoreaN cohort study for Outcome in patients With Chronic Kidney Disease (KNOW-CKD), 1,939 patients who measured total cholesterol (TC), low density lipoprotein cholesterol (LDL-C), high density lipoprotein cholesterol (HDL-C), and triglycerides (TG) were included in the analysis. Study endpoint was a composite of a ≥ 50% decline in estimated glomerular filtration rate or the onset of end-stage renal disease.

Results: The mean age was 53.8 ± 12.2 years and 1,192 (61.5%) patients were males. The mean serum concentrations of TC, LDL-C, HDL-C, and TG were and 174.1 ± 38.9, 96.9 ± 31.3, 49.3 ± 15.5, and 156.6 ± 96.9 mg/dl, respectively. During a median follow-up of 3.0 years, 421 patients (21.7%) reached the composite end point. In the fully adjusted multivariable Cox models, HDL-C was significantly associated with increased risk of CKD progression (HR, 1.11 per 10 mg/dl increase; 95% CI, 1.01-1.22; P = 0.03), while TC (HR, 0.99 per 10 mg/dl increase; 95% CI, 0.95-1.03; P = 0.53), LDL-C (HR, 1.01 per 10 mg/dl increase; 95% CI, 0.97-1.06; P = 0.68), and TG (HR, 0.99 per 10 mg/dl increase; 95% CI, 0.98-1.01; P = 0.35) were not. However, areas under the curve of these 4 lipids were similar and none of the parameters did not improve the net reclassification improvement and the integrated discrimination improvement for the progression of CKD.

Conclusions: HDL-C only was significantly associated with CKD progression. However, all lipid parameters had limited roles in improving risk stratification for adverse renal outcome.

TH-PO1100

Serum Bilirubin Is a Significant Prognostic Marker for Renal Progression and Mortality in Patients with CKD

Young Lee Jung,[1] Eunjeong Kang,[2] Jung Nam An,[3] Chun Soo Lim,[3] Yun Kyu Oh,[4] Jung Pyo Lee.[3] *[1]Seoul National unioversity Hospital, Bucheon, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, SEOUL, Republic of Korea; [4]Department of Internal Medicine, Boramae Medical Center, Seoul, Republic of Korea.*

Background: Mildly elevated bilirubin could protect kidney damage by reducing oxidative stress. However, it is still unclear that serum bilirubin level can predict clinical outcomes in the patients with CKD. The aim of our study is to investigate the association of serum bilirubin and clinical outcomes in CKD patients.

Methods: A total of 5479 patients who visited nephrology clinic at Seoul National University Boramae Medical Center between 2006 and 2016 were enrolled. Patients were divided 4 groups according to different baseline serum total bilirubin levels. Primary outcome was ESRD and secondary outcome was all-cause mortality. We conducted Cox analysis to evaluate the association between all-cause mortality and ESRD progression. Age, sex, eGFR, hypertension, and diabetes were included as covariates.

Results: Mean serum bilirubin level was 0.7±0.5 mg/dL. A total of 1029patients were a group with the lowest serum bilirubin level (0.5 mg/dL<Bb) and 1723patients had bilirubin level between 0.5mg/dL and 0.7mg/dL.1658patients had bilirubin level between 0.7 g/dL and 1.0mg/dL, 1069 patients with more than 1.0 mg/dL bilirubin. Low bilirubin groups were older and had more hypertension and diabetes. Also, eGFR of low bilirubin groups was lower than that of high bilirubin group. During the follow-up period of 79.4±10.3 months, 412 patients developed ESRD and 691 patients were dead. In the multivariate cox analysis, the higher serum bilirubin level groups had significantly lower risk of ESRD progression, while the group with the lowest mortality rate was not the group

with highest bilirubin level but the group with mildly elevated bilirubin(0.7≤Bb<1.0mg/dL) representing reverse J shaped curve.

Conclusions: The lower serum total bilirubin level was significantly related with ESRD progression and mortality. Total serum bilirubin can be used as early biomarker for predicting ESRD development and survival in CKD patients.

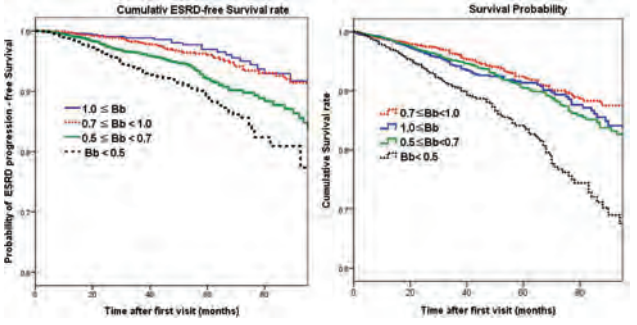

Figure 1. Survival curves showing ESRD risk and mortality according to bilirubin levels.

TH-PO1101

The Relationship Between Body Mass Index (BMI) and Outcomes in Health and CKD

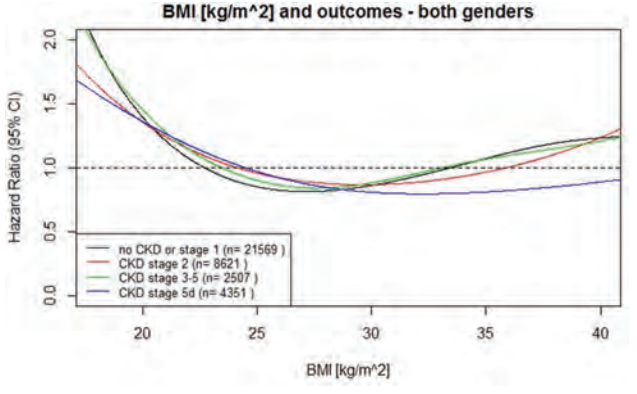
Jochen G. Raimann,[1] Peter Kotanko,[1] Levi D. Waldron.[2] [1]*Renal Research Institute, New York, NY;* [2]*Waldron Lab, CUNY Graduate School of Public Health and Health Policy, New York, NY.*

Background: In the general population the relationship between BMI and mortality is U-shaped, while in the hemodialysis (CKD 5D) population lower risk at higher BMI was observed. Pathophysiologic explanations exist, but disease may also act as a statistical collider creating a "selection bias by death". We studied the relationship across CKD stages and in various subpopulations.

Methods: We studied healthy subjects, CKD patients at various stages (NHANES 1999 to 2010), and CKD5D patients dialyzing in Renal Research Institute (RRI) clinics. We constructed Cox proportional hazard models and depicted hazard ratios over a wide BMI range using spline functions and evaluated differences between subsets stratified by age (</>= 55 years), gender, race, and ethnicity. We also constructed polynomial models to test for an interaction between CKD stage and BMI in the Cox models. Akaike Information Criterion (AIC) was computed to determine the most accurate model.

Results: We studied 21569 healthy subjects, 8621 CKD stage 2 patients, 2507 CKD stage 3-5 patients, and 4351 CKD5D patients. We found consistently an inverse association between BMI and mortality in CKD5D patients and variations in the other subsets. While the interaction between CKD stage and BMI were significant in all constructed models, the final model with the lowest AIC value include only an interaction between CKD5D and BMI.

Conclusions: Our data show a consistent U-shaped relationship between BMI and all-cause mortality in the general population, but an "obesity paradox" in CKD5D. While the biological reasons are elusive, the consistency of the observation across all analyses suggests a pathophysiological relationship in concert with CKD acting as a statistical collider.



Spline function of hazard ratio of all-cause mortality over a 3-year follow-up period as a function of body mass index (BMI).

Race, Gender, and the Participation Gap: Evaluation of Clinical Trials in Kidney Disease

Krishna A. Agarwal,[1] Nayan Agarwal,[2] Pranav S. Garimella,[3] Tushar Chopra,[4] Michelle M. Wong,[5] Rakesh Malhotra.[3] [1]*UMass Medical School-Baystate, Springfield, MA;* [2]*University College of Medical Sciences and GTB Hospital, Delhi, New Delhi, India;* [3]*University of California, San Diego, CA;* [4]*University of Virginia, Charlottesville, VA;* [5]*University of British Columbia, Vancouver, BC, Canada.*

Background: Disparities in kidney disease by race, ethnicity, and sex are well documented. However, the representation of these groups in randomized controlled trials (RCTs) is largely unknown. Here, we aim to determine differences in gender and race participation in kidney disease RCTs.

Methods: The ClinicalTrials.gov electronic database was searched from January 1, 1970 to January 1, 2018, with the following keywords: "kidney disease," "chronic kidney disease" (CKD), "acute kidney injury" (AKI), "hemodialysis" (HD), "peritoneal dialysis", "glomerulonephritis" (GN), "kidney stones", "kidney transplant", or "polycystic kidney disease" (ADPKD). RCTs that were registered as completed and which reported results were eligible for inclusion. We limited our search to studies which were conducted in United States and published in the English language. Two reviewers independently extracted race and gender data onto standardized extraction forms.

Results: The initial search provided 2436 citations with 339 studies (CKD 109; HD 75; AKI 44; GN 40; Transplant 33; ADPKD 19; Misc. 19) potentially eligible for inclusion. Of the 339 trials (n=102,361, mean age 56±12 years), sex was reported for 98% (n=100,452) of trial participants. Women accounted for 43% of participants overall, with similar percentages in non-dialysis CKD RCTs and dialysis RCTs. Race was reported for 60% (n= 61, 697), of which 78.5% were Caucasians, 15.6 % African American (AA), 3.7% Hispanics, 1.5% Asians, 0.6% American Indians and 0.1% were Native Hawaiian. In HD RCTs, Caucasian (44.9%) and AA (42.0%) were equally represented, and Hispanics accounted for 9.6% of trial participants. Low recruitment of AA (3.2% and 11.6%, respectively) and Hispanics (5.8% and 0.7%, respectively) was observed in both transplant and AKI RCTs.

Conclusions: Our findings suggest that racial minorities, especially AA and Hispanics, and women are less likely to be enrolled in clinical trials. Future studies should focus on addressing the barriers to recruitment of women and minorities in RCTs, in order to achieve representative RCT populations.

TH-PO1103

Sex and Racial Differences in Pre-Dialysis Hospitalization in Incident ESRD Patients

Silvi Shah, Karthikeyan Meganathan, Annette Christianson, Anthony C. Leonard, Charuhas V. Thakar. *University of Cincinnati, Cincinnati, OH.*

Background: Pre-dialysis hospitalization is an independent predictor of mortality, and significant contributor to health care costs in patients with end stage renal disease. Sex and racial differences in the pre-dialysis hospitalizations has not been studied for incident dialysis patients.

Methods: We evaluated 165,452 adult patients who initiated dialysis between 1/1/2010 and 12/31/2014 from the United States Renal Data System with linked claims for Medicare Part A and Part B or Medicare Primary Other as the primary payer for the entire two years prior to dialysis initiation. Using case-mix adjusted logistic regression models, we examined the impact of race and sex on the two year pre-dialysis hospitalization as the primary outcome identified using ICD-9 codes.

Results: Mean age was 73 ± 11 years. In the study sample, 54.3% were men. 65% were Whites, 21.6% were Blacks, 8.9% were Hispanics, 3.5% were Asians, and 0.9% were Native Americans. Overall, 77% of patients had at least one pre-dialysis hospitalization. Among the causes of pre-dialysis hospitalization, 28.6% of patients experienced cardiovascular hospitalization, 12.4% had infection hospitalization, 11.5% had both cardiovascular and infection hospitalization and 24.5% had neither cardiovascular nor infection hospitalization. Overall, one-year all-cause mortality was 30.7%. Women had higher odds of pre-dialysis hospitalization as compared to men (odds ratio [OR], 1.17; 95% confidence interval [CI], 1.14-1.20]). In adjusted analyses, as compared to Whites patients, odds of pre-dialysis hospitalization was lower among Asians (OR, 0.55; 95% CI, 0.52-0.59]), and Hispanics (OR, 0.80; CI, 0.77-0.84); and was not statistically significant for Black patients or Native Americans.

Conclusions: Among dialysis patients, women have 17% higher odds of pre-dialysis hospitalization as compared to men. As compared to White patients, Asians have 45% lower odds and Hispanics have 20% lower odds of pre-dialysis hospitalizations. Process of care and biological factors need to be explored further to understand the reasons behind these disparities associated with pre-dialysis hospitalization.

TH-PO1104

Pregnancy Outcome Predictors Among Japanese Patients with CKD

Satoshi Kumakura,[1] Takashi Nakamichi,[1] Tasuku Nagasawa,[1] Tae Yamamoto,[1] Masatoshi Saito,[2] Mariko Miyazaki,[1] Hiroshi Sato,[1] Sadayoshi Ito.[1] [1]*Department of Nephrology, Endocrinology and Vascular Medicine, Tohoku University Hospital, Sendai, Japan;* [2]*Department of Obstetrics and Gynecology, Tohoku University Hospital, Sendai, Japan.*

Background: Studies on pregnant patients with chronic kidney disease (CKD) have been performed worldwide; however, data on the size of the study population, race, as

well as information on CKD are limited. On account of limited data rendering the studies non-generalizable, some of the guidelines remain controversial, thereby restricting their application in clinical practice. We conducted a retrospective cohort study to address this problem by clarifying the association between CKD status and pregnancy outcomes.

Methods: Patients with CKD who gave birth or miscarried at our institution between January 1, 2010, and December 31, 2017 were selected as the study population. Clinical data were collected from medical records. We analyzed the correlations between CKD status (age, body mass index, estimated glomerular filtration rate [eGFR], urinary protein-creatinine ratio [UP], mean blood pressure [MBP], and antihypertensive drug use [HTND]) at the time of referral and severe adverse events (SAE). We also focused on the incidence of small-for-gestational-age (SGA) infants and birth weight (BW).

Results: The study included 113 pregnancies among 88 patients. Median age was 32 years (interquartile range [IQR]: 29-36). Median eGFR was 101.8 ml/min/1.73 m^2 (IQR: 80.9-120.3). Median UP was 0.17 g/gCr (IQR: 0.04-1.1). Of the 88 patients, most were Japanese, 28 had IgA nephropathy, 15 had nephrotic syndrome. SAE in 34 cases included severe pregnancy-induced hypertension, preterm delivery, emergency cesarean section, neonatal intensive care unit admission, low BW, and fetal death. Multivariate logistic regression analysis showed that SAE was correlated with age (odds ratio [OR]=1.14, p=0.025), eGFR (OR=0.98, p=0.013), MBP (OR=1.05, p=0.033), and HTND (OR=4.00, p=0.025). BW was correlated with age (t=-2.20, p=0.03), UP (t=-2.05, p=0.043), and HTND (t=-2.36, p=0.021) according to multivariate linear regression analysis (R-squared =0.20). However, UP alone was a predictor for SGA (OR=1.42, p=0.021) according to multivariate logistic regression analysis.

Conclusions: As in previous reports, eGFR was found to be a predictor of SAE. However, we found that it was UP rather than kidney function that might affect child growth. Therefore, the mechanism of SAE development and the effect on child growth might be different among CKD pregnancies.

TH-PO1105

Anti-Mullerian Hormone in Women with CKD

Kate Wiles,[1,2] Emma Wayman,[6] Catherine Nelson-piercy,[5] Liz Lightstone,[3] Lucy C. Chappell,[1] Kate Bramham.[4] *[1]King's College London, London, United Kingdom; [2]Guy's and St. Thomas' NHS Foundation Trust, London, United Kingdom; [3]Imperial College London, Hammersmith Hospital, London, United Kingdom; [4]King's College Hospital, London, United Kingdom; [5]Guy's & St Thomas' Foundation Trust, London, United Kingdom; [6]Guys and St Thomas' trust, London, United Kingdom.*

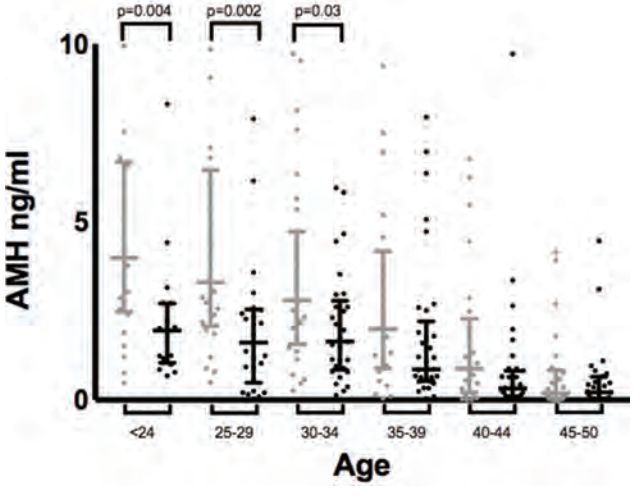
Background: Although CKD is recognised to impact female fertility, underlying pathophysiological mechanisms are poorly understood. Serum concentrations of anti-Mullerian hormone (AMH) are used in women without CKD as a marker of ovarian reserve, which is a key component of female fertility. There are limited data on the utility of serum AMH quantification in women with CKD.

Methods: Serum AMH was quantified by Roche Elecsys AMH assay in 163 women with CKD (30 CKD stage 1, 37 Stage 2, 26 Stage 3a, 31 Stage 3b, 21 Stage 4, 18 Stage 5) seeking pregnancy advice. Values were compared to assay-specific percentiles.

Results: In women with CKD there was no correlation between eGFR and age-corrected AMH centile (r=-0.001, p=0.98). There was a strong correlation between AMH and age (r=-0.5, p<0.0001). Women with CKD had a lower age-corrected AMH concentration compared to women without CKD across all CKD stages (p=<0.0001 to 0.007). The effect of CKD on AMH was greatest for women <35 years (p=0.002-0.03).

Conclusions: Women with CKD have lower levels of serum AMH compared to women without CKD, across all stages of CKD. This suggests that women with CKD have reduced ovarian reserve. The clinical significance of a lower serum AMH, especially in women with CKD <35 years, warrants further investigation. There is no evidence that renal clearance modifies serum AMH concentration.

Funding: Government Support - Non-U.S.



Age-specific serum AMH concentrations (median ± IQR) in women with CKD (black) compared to controls (grey)

TH-PO1106

The Impact of Gender on Inpatient Mortality of Hypertensive Patients with CKD3 to ESRD in the US

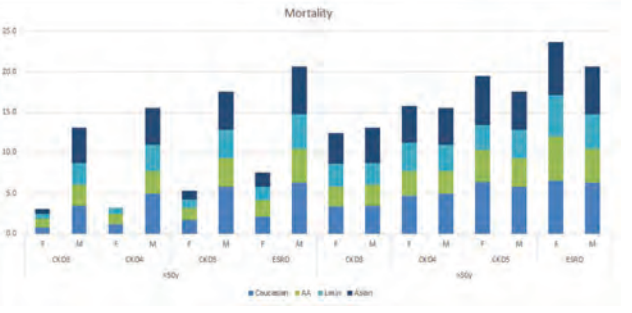
Mark A. Nader,[1,2] Rodrigo Aguilar Campos,[2] Oussama Hassan,[3] Carmen E. Cervantes,[7] Ricardo Correa,[4] Prabin Sharma,[9] Rehan Shafique,[1] Hieu Q. Vo,[5] Omar Hamze,[1] Ping Li,[6] Judit Gordon.[8] *[1]Kidney Care Consultants, Memphis, TN; [2]Georgetown University Hospital, Washington, DC; [3]Royal London Hospital, Austin, TX; [4]University of Arizona, Phoenix, AZ; [5]Nephrology and Hypertension, university of Tennessee, Memphis, TN; [6]George Washington University, Washington, DC; [7]Aventura Hospital and Medical Center, Aventura, FL; [8]Medstar Georgeotown University Hospital, Washington, DC; [9]Yale University Bridgeport Hospital, Bridgeport, CT.*

Background: HTN and CKD are 2 of the most important risk factors for CVD in the US population.The impact of gender or race in this equation remains unclear. Studies comparing the inpatient mortality between males and females with HTN and CKD are sparse. Our aim was to determine if gender in the US population and menopausal age, affect the inpatient survival rate of hypertensive patients across CKD stages.

Methods: Data was extracted from the 2005-2012 Nationwide Inpatient Sample (NIS). Using propensity score matching, hypertensive female with CKD (stage3-5 + ESRD) patients were matched with hypertensive males at a 1:1 ratio. We compared inpatient mortality per CKD stage, menopausal age and race. Analyses were performed using SAS9.3.

Results: Among 2,121,750 hospitalized hypertensive patients, 51.5% were males and 48.5% females. There was 32.1% females with CKD3, 14.7% with CKD4, 3.4% CKD5 and 54% with ESRD. Similarly, 32.7% of males have CKD3, 13.2% CKD4, 3.2% CKD5 and 50.9% with ESRD. In-hospital crude mortality was significantly higher for males compared to females at CKD stages 3 (3.1 vs 3.3% p<0.0001), CKD4 (4.1 vs 4.4%p=0.0004) and ESRD (5.1 vs 5.2%p=0.0039) but was non-significant in CKD5 not on dialysis (4.7 vs 4.8%p=0.45). Factoring menopausal age for each race group, we find women<50y old to have significantly less mortality than men, across all CKD stages and races. Women> 50y have similar mortality rate to men with CKD 3,4 or 5; while women>50y with ESRD have a significantly higher mortality than ESRD men of similar race group (fig1).

Conclusions: Inpatient mortality risk of women compared to men through stages of CKD 3 to ESRD, appears to be reduced in pre-menopausal women, comparable after menopause and increased when on dialysis, irrespective of the race group. Further studies are needed to elucidate the possible links of menopause and the effect of gender with mortality in patients with hypertension and CKD and to assess if this holds true in outpatient settings.



TH-PO1107

Impact of Thyroid Hormones on Kidney Function in Patients with a Renal Transplant – A Retrospective Data Analysis

Benjamin Schairer, Georg Punzengruber, Wolfgang Winnicki, Harald Herkner, Gurkan Sengoelge. *Medical University of Vienna, Vienna, Austria.*

Background: High levels of thyroid-stimulating-hormone (TSH) correlate with reduced estimated glomerular filtration rate (eGFR) and an increased risk of developing chronic kidney disease (CKD), even in euthyroid patients. Thyroid-hormone-replacement-therapy has been shown to delay progression of end-stage renal disease in sub-clinically hypothyroid patients with CKD. However, the presence of such a link after kidney transplantation (NTX) has not been previously investigated. This study tested whether TSH levels are associated with eGFR in patients with a renal transplant.

Methods: 398 patients who received an NTX between 2003 and 2016 in Vienna, Austria, were included in this retrospective study. Thyroid and kidney function parameters were collected at 12 and 24 months post NTX. Linear regression models estimated the association between thyroid- and renal function. Functional variables at both time-points or their differences over time were used to avoid within-individual correlations in a longitudinal setting. Multivariable linear regression models were employed to adjust main effect estimates due to potential confounding factors: BUN/creatinine ratio, tacrolimus plasma levels, CRP, BMI, gender, age.

Results: A linear regression analysis comparing the changes in eGFR and TSH between months 12 and 24 post NTX showed a significant inverse correlation (p=0,0183). For every 1-unit increase in the change of TSH over 12 months eGFR decreased by 1,39 ml/min in the same time frame. The strongest confounder in this comparison was BUN/creatinine ratio. TSH had no impact on eGFR when values 12 and 24 months post NTX were compared: p=0,6296 or p=0,8578, respectively.

Conclusions: Normothyroid renal graft recipients with increasing TSH values between the months 12 and 24 post NTX had less stable, even decreasing eGFR levels. The single thyroid and kidney function values at selected time-points did not show a correlation. Prospective randomized placebo-controlled studies are underway to clarify whether treatment with thyroid hormones reaching low-normal TSH levels could enhance eGFR of patients with a kidney graft.

TH-PO1108

Creating Axes of Kidney Tubule Health: A Factor Analysis of Biomarkers in SPRINT

Alexandra K. Lee,[1] Ronit Katz,[2] Vasantha Jotwani,[1] Pranav S. Garimella,[3] Joachim H. Ix,[3] Michael Shlipak.[4] *[1]Kidney Health Research Collaborative, UCSF & VA, San Francisco, CA; [2]University of Washington, Seattle, WA; [3]UCSD, San Diego, CA; [4]San Francisco VA Medical Center, San Francisco, CA.*

Background: Several biomarkers of kidney tubule function and injury associate with cardiovascular disease (CVD) and mortality risks, but associations are weakened by their physiological overlap and inter-correlation. Factor analysis is an agnostic method to condense information by analyzing covariance of measurements. We hypothesized that factor scores would represent underlying physiology and be associated with outcomes independently of eGFR and albuminuria.

Methods: Among 2,376 SPRINT participants with eGFR <60, we measured urine levels of kidney tubule injury (IL-18, NGAL, KIM-1, MCP-1, YKL-40) and function (α-1 microglobulin, β-2 microglobulin, uromodulin), and serum levels of PTH and FGF23. Factor analysis utilized principal-component factor estimation and promax rotation. We used Cox models to evaluate associations of factor scores with composite CVD, heart failure (HF), and all-cause death.

Results: Mean age was 73±9, 40% female, and mean eGFR 46±11. Factor scores reflected biology: there were two injury factors, Factor 1 comprised by IL-18, NGAL, and YKL-40; Factor 2 by MCP-1 and KIM-1; one factor of proximal tubule reabsorption, Factor 3, α-1 and β-2; and one factor of renal reserve: Factor 4, uromodulin, PTH, and FGF23. After adjusting for eGFR, albuminuria, and CVD risk factors, Factors 1, 3, and 4 were associated with CVD risk (**Table**), and Factor 1 was associated with HF. Factors 1 and 4 were associated with higher mortality risk. In participants without prior CVD or HF, Factor 3 was more strongly associated with CVD (HR 1.28, 95%CI 1.08-1.52) and HF (1.36, 1.02-1.81) (p-for-interaction=0.03, 0.04).

Conclusions: Combining biomarkers into factors may be an efficient method to create biologically plausible axes of kidney tubule health that have important associations with CVD risk, independently of glomerular markers.

Plasma TNF Receptor Concentrations After Hospitalization with AKI and Long-Term CKD and Mortality

Steven G. Coca,[1] Dennis G. Moledina,[2] Mark M. Wurfel,[3] Edward D. Siew,[4] Amit X. Garg,[5] Chi-yuan Hsu,[6] James S. Kaufman,[7] Paul L. Kimmel,[8] Chirag R. Parikh.[9] ASSESS-AKI *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Yale School of Medicine, New Haven, CT; [3]University of Washington, Seattle, WA; [4]Vanderbilt University School of Medicine, Nashville, TN; [5]London Health Sciences Centre, London, ON, Canada; [6]University of California San Francisco, San Francisco, CA; [7]VA New York Harbor Healthcare System, New York, NY; [8]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [9]Yale University and VAMC, New Haven, CT.*

Background: Plasma tumor necrosis factor receptor (TNFR)1 and TNFR2 provide prognostic information in ambulatory patients with diabetic kidney disease, but their utility in patients after an episode of AKI is unknown.

Methods: Hospitalized adults with and without AKI were enrolled in a parallel, matched cohort from 4 centers between 2009-2015 and had plasma TNFR1 and TNFR2 measured at the outpatient baseline visit within 3 months post-discharge. We tested for associations between biomarkers, expressed continuously and by quartiles, with time until the composite kidney outcome (CKD incidence, CKD progression, or ESRD) and death via a multivariable Weibull regression model that accounted for (1) the 1:1 matching of adults and (2) competing risk. We adjusted for demographics, comorbidities, AKI status during hospitalization, and concurrent eGFR, UACR, and CRP at the baseline visit.

Results: Among 1377 participants, median concentrations of TNFR1 and TNFR2 decreased from 3976 [IQR 2791-5936] and 8485 [IQR 5865-12774] pg/mL during hospitalization, to 2829 [IQR 2064-4162] and 6661 [IQR 4758-9692] pg/mL at the post-discharge baseline visit, respectively. The composite CKD outcome occurred in 257 (19%) and death before CKD occurred in 212 (15%) over a median follow-up of 4.2 years, and these events occurred more frequently in those with higher concentrations of each biomarker. After adjustment for a comprehensive panel of covariates, plasma TNFR1 and TNFR2 were independently associated with both the CKD outcome and death (**Figure**).

Conclusions: In hospitalized patients that survived at least 3 months, plasma TNFR1 and TNFR2 provide additional risk-stratification for kidney outcomes and death, even after accounting for concurrent measures of kidney function, albuminuria, and systemic inflammation.

Elevated Soluble ST2 Levels but Not Galectin-3 Is Associated with Renal Progression and Adverse Clinical Outcomes in Non-Dialysis Patients with CKD

Ae jin Kim, Kayeong Chun, Han Ro, Jae Hyun Chang, Hyun Hee Lee, Wookyung Chung, Ji Yong Jung. *Division of Nephrology, Department of Internal Medicine, Gachon University Gil Medical Center, College of Medicine, Gachon University, Incheon, Republic of Korea.*

Background: Soluble ST2 (sST2) and Galectin-3, novel biomarkers of heart failure and cardiovascular stress, predict cardiovascular event and mortality. However, the relationships with renal function and adverse outcomes are less certain. The purpose of this study was to determine whether sST2 and Galectin-3 associated with chronic kidney disease (CKD) progression and adverse clinical outcomes.

Methods: We measured baseline sST2 and Galectin-3 concentrations in CKD patient cohort at our institution included between October 2013 and December 2014. The primary outcome was CKD progression (≥50% reduction in estimated GFR [eGFR] from the baseline or reach to the end-stage renal disease [ESRD]). The secondary outcome was the composite of CKD progression, cardiovascular event, or death. We used Cox proportional hazards model to evaluate associations between sST2 and Galectin-3 level with renal and composite outcomes.

Results: A total of 312 patients were enrolled in this study. At baseline, sST2 was directly associated with serum creatinine (r = 0.492, P < 0.001) and urine protein-to-creatinine ratio (UPCR) (r = 0.309, P < 0.001). Galectin-3 was also directly associated with serum creatinine (r = 0.164, P = 0.004) and UPCR (r = 0.136, P = 0.027). Cox regression analysis showed that baseline sST2 level was independently predicted the CKD progression (hazard ratio [HR] per SD increase in log-transformed sST2 concentration, 16.383; 95% confidence interval [CI], 3.362 – 79.836; P = 0.001) and composite outcome (HR, 5.430; 95% CI, 1.459 – 20.213; P = 0.012) after adjustment for confounding factors. However, baseline Galectin-3 level was associated with CKD progression and composite outcome only in crude analysis, lost its statistical significance after adjustment for confounding variables.

Conclusions: In conclusion, elevated levels of sST2 are significantly associated with renal progression and adverse clinical outcomes in non-dialysis patients with CKD.

TH-PO1111

Serum Metabolomic Biomarkers Associated with Neurocognitive Dysfunction in Youth with CKD

Celina Brunson,[1] Lu Huang,[2] Justine Shults,[1,2] Susan L. Furth,[1,2] Michelle Denburg,[1,2] Erum A. Hartung.[1,2] *[1]Children's Hospital of Philadelphia, Philadelphia, PA; [2]Perelman School of Medicine University of Pennsylvania, Philadellphia, PA.*

Background: CKD is linked to worse neurocognitive (NC) outcomes, possibly related to effects of uremic toxins on the brain. Aims of this study are (1) to compare serum metabolomic profiles of children and young adults with CKD to healthy controls and (2) to evaluate the association between serum metabolite levels and NC outcomes in individuals with CKD.

Methods: Serum untargeted metabolomic profiling (Metabolon, Inc.) was performed in individuals aged 8-25 years with CKD Stage 2-4 (n=65) and matched healthy controls (n=69). Metabolite levels in CKD vs. control groups were compared by multivariable linear regression, with metabolite level as the outcome variable and CKD vs. control as the explanatory variable, adjusted for age, gender, obesity and race. Using the subset of metabolites that differed in CKD vs. controls after Bonferroni correction (threshold p=5.7x10e-7), the relationship of metabolite level and NC outcome within the CKD group was analyzed by multivariable linear regression, with NC composite score as the outcome variable and metabolite level as the explanatory variable, adjusted for estimated glomerular filtration rate (eGFR), glomerular vs. non-glomerular disease, maternal education, income, age, gender, obesity and race. The NC composite score was calculated using the mean

of z-scores within 4 domains: intelligence, attention regulation, working memory and executive function.

Results: 233 of the 876 metabolites identified differed significantly between CKD and control groups after Bonferroni correction, including metabolites previously found to be associated with CKD and NC dysfunction such as those within the kynurenine/tryptophan and glutamate pathways. Within the CKD group, 6 of the 233 metabolites examined were associated with NC composite score (raw p values <0.05), but the association was not significant after Bonferroni correction.

Conclusions: Youth with CKD have significantly different metabolomic profiles than healthy controls. We did not find an association between metabolite levels and composite NC outcome in the CKD group. However, use of a composite NC score may mask differences in individual NC domains, and adjusting for eGFR may mask associations with renally-cleared metabolites. Future analyses will include examining the relationships of metabolite levels with individual NC domains.

Robotic Technology Quantifies Cognitive Deficits in Multiple Domains for ESRD Patients

Jessica Vanderlinden, Stephen H. Scott, Rachel M. Holden, J. gordon G. Boyd. *Queen's University, Kingston, ON, Canada.*

Background: Cognitive impairment is highly reported among chronic kidney disease (CKD) patients, particularly in stage 5 CKD. Lack of validated assessments for quantifying cognition in CKD patients can lead to difficulty in determining the prevalence and degree of this impairment. Robotic technology, such as the KINARM, may be able to detect cognitive deficits associated with CKD, particularly because the KINARM has been shown to identify subtle neurocognitive deficits in ischemic stroke patients. Importantly, these subtle deficits may correlate better with quality of life assessments than routine clinical testing. Objective: To quantify the neurocognitive deficits of patients with stage 5 CKD.

Methods: Recruitment was performed at a CKD clinic in a tertiary medical centre. Eligible patients were stage 5 CKD patients with no history of neurodegenerative disease or stroke. Consented patients performed a neuropsychological battery that included: the Repeatable Battery for the Assessment of Neuropsychological Status (RBANS), and a robotic assessment (KINARM, BKIN Technologies, Kingston ON). The RBANS measures 5 cognitive domains along with giving an overall composite score, whereas the KINARM Standard Tests quantifies sensorimotor and neurocognitive control of the upper limb.

Results: From July 2015-April 2018, 30 patients were recruited. On the RBANS, only 3/30 patients scored outside the normative range (defined as >1.96 SD, representing the 95% performance of healthy controls) on the composite total score which measures global impairment. There was variability of impairment across domains, ranging from 0/30 on language to 8/30 on the visuospatial domain. In contrast, compared to age and gender matched controls, approximately one-third of patients were impaired on six of the nine tasks performed. These tasks correspond to deficits in: attention (10/30), sensorimotor (9/30), visuospatial (13/30), visuomotor (11/30), overriding of automatic response (10/13), and executive function (11/30).

Conclusions: Robotic technology can detect cognitive impairments in a higher proportion of patients with stage 5 CKD compared to a traditional neuropsychological assessment tool. The clinical relevance of these cognitive impairments needs further investigation.

Inflammatory Biomarkers Improve Prediction of Sertraline Treatment Response in CKD

L Parker Gregg,[1,2] Thomas Carmody,[1] Dustin Le,[1] Madhukar Trivedi,[1] Susan Hedayati.[1] *[1]University of Texas Southwestern, Dallas, TX; [2]VA North Texas Healthcare System, Dallas, TX.*

Background: Inflammation may mediate depression, and CKD is associated with elevated inflammatory markers and depression prevalence. We studied whether baseline inflammation predicts treatment response to sertraline in individuals with CKD and depression.

Methods: In 193 participants with stage 3-5 CKD and depression randomized to sertraline or placebo in the double-blind Chronic Kidney Disease Antidepressant Sertraline Trial (CAST), we measured baseline albumin, pre-albumin, interleukin-6 (IL-6), and high sensitivity C-reactive protein (hsCRP). Outcomes were a ≥3-point decrease (*improvement*) and ≥50% decrease (*response*) in depressive symptoms, assessed by the Clinician-Rated 16-Item Quick Inventory of Depression Symptomatology (QIDS). Logistic regression measured associations of inflammatory markers with outcomes after covariate adjustment. Inflammatory marker x treatment interaction $P<.1$ was considered significant. The areas under the curve (AUC) for nested models predicting response were compared using non-parametric tests.

Results: Mean age was 58±13 years, 58% were Black, 42% White, and 18% Hispanic. HsCRP correlated with baseline QIDS score (r=.19, $P<.05$). In the sertraline group, hsCRP was higher in those who did vs. did not achieve improvement, median (IQR): 5.0 (1.7-8.6) mg/L vs. 1.4 (0.6-3.7), $P=.005$, and response, 5.0 (2.0-14.6) vs. 2.7 (0.8-6.0), $P=.03$. A 1 log-unit increase of hsCRP independently predicted a differential degree of improvement and response to sertraline vs. placebo (**Table**). Baseline QIDS, eGFR, age, diabetes, site, and hsCRP (highest tertile) predicted sertraline response, AUC (95% CI) .71 (.58, .85). Addition of albumin and pre-albumin (lowest tertile) and IL-6 (highest tertile) improved the AUC to .82 (.72, .92), $P=.02$ (**Figure**).

Conclusions: Higher baseline hsCRP was independently associated with depressive symptom improvement and response to sertraline. Inflammatory biomarkers may identify CKD patients more likely to benefit from sertraline.

Funding: NIDDK Support, Other NIH Support - National Center for Advancing Translational Sciences, Veterans Affairs Support, Private Foundation Support

Outcome	All participants aOR (95% CI) N=193	Sertraline aOR (95% CI) N=97	Placebo aOR (95% CI) N=96	hsCRP x treatment group interaction P value
Improvement	1.32 (1.00, 1.74)	1.67 (1.11, 2.52)	0.92 (0.63, 1.34)	0.03

TH-PO1114

Expression of MMPS and TIMPS Is Differentially Regulated in Cataract Tissue of Patients with CKD and Diabetes Mellitus (DM) or Both

Calum W. Chong,[1] Minas T. Coroneo,[2] Ian C. Francis,[3] Zoltan H. Endre,[1,2] Jonathan H. Erlich.[2,1] *[1]Prince of Wales Hospital, Bellevue Hill, NSW, Australia; [2]UNSW, Randwick, NSW, Australia; [3]Prince of Wales hospital, Randwick, NSW, Australia.*

Background: Cataract is a common preventable cause of blindness particularly amongst diabetics and recent reports suggest an increased incidence in patients with CKD. Matrix metalloproteinases MMPS and their regulators, including tissue inhibitors of MMPS (TIMPS) are variably expressed in lens tissue and may play a role in the genesis of cataract formation. This may result from direct modulation of extracellular matrix or be secondary to cell cycle events or other pathways

Methods: We prospectively evaluated 270 patients (age range, 46-93 years; mean, 71 years) who had phacoemulsification cataract surgery with intraocular lens implantation. Cataracts were graded at time of surgery, noting the presence of renal impairment (eGFR<60ml/min), type 2 diabetes mellitus and use of hypolipidemic drugs. For analysis, subjects were categorized according to presence of absence of diabetes mellitus and the presence or absence of CKD. mRNA was extracted from 123 patients, and real time PCR performed for MMPs 1,2,3,9,14 and 15 and TIMPS 1,2,3 and 4. All samples were corrected for the housekeeper gene 18S

Results: Age and CKD but not DM were associated with higher grade cataracts. MMPs 1,3,14 and TIMPS 1,2, and 3 were readily quantifiable by RT PCR. Only low levels of MMP 2 and 9 were observed and could only be quantified as present or absent. MMP15 and TIMP 4 were not detected. Non-diabetic patients with CKD EGFR < 60 ml/ml had relatively increased expression of MMP1,3,14 and TIMPs 1,2, and 3. There were no detectable differences in MMP 2 and 9. The presence of DM eliminated many differences, with higher levels of MMP 14 and TIMPs 2 and 3 in patients without CKD compared to those with CKD and DM. Hypolipidemic agents modified MMP and TIMP expression in patients with eGFR> 60 ml/min but not CKD. In non-diabetic patients, the product of TIMP 1 or 2 and MMP-3 alone were highly predictive of renal impairment with ROCs of 0.88 and 0.89 respectively. In patients with DM and CKD only TIMP-2 x MMP3 was predictive of CKD with an AUC of 0.74

Conclusions: CKD, diabetes and hypolipidemic agents differentially regulate the expression of MMPS and TIMPs in cataracts. These regulators may be important in the pathogenesis and relevant to potential therapeutic interventions for slowing cataract formation

TH-PO1115

Type III Collagen Turnover Is Associated with Disease Progression and Mortality in CKD Patients from the Renal Impairment in Secondary Care Cohort

Daniel Guldager Kring Rasmussen,[1] Anthony Fenton,[2] Federica Genovese,[1] Morten A. Karsdal,[1] Charles Ferro,[2] Mark D. Jesky,[2] Paul Cockwell.[3] *[1]Nordic Bioscience, Herlev, Denmark; [2]University Hospital Birmingham NHS Trust, Birmingham, United Kingdom; [3]Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom.*

Background: Renal fibrosis is a major underlying pathological feature in patients with chronic kidney disease (CKD) and strongly predicts progression to end-stage renal disease. We hypothesized that non-invasive assessment of the development and remodeling of fibrosis may have utility for linking dynamic in situ pathology with clinical outcomes. We

focused on type III collagen (COL III), one of the most abundant collagens in renal fibrosis, utilizing PRO-C3 to assess COL III formation and C3M for COL III degradation.

Methods: We measured serum (S)-PRO-C3 and S-C3M and urine (U)-PRO-C3 and U-C3M in 499 patients from the Renal Impairment In Secondary Care (RIISC) study. RIISC is a prospective, observational cohort of patients with moderate to advanced CKD. One-year disease progression was defined as a decline in eGFR >30% or commencing renal replacement therapy within 12 months. Results were adjusted for potential confounders including age, gender, pulse pressure, eGFR, and urinary albumin:creatinine ratio. Median follow-up was 46 months (range 0–72).

Results: U-PRO-C3 and S-PRO-C3 levels increased significantly with increasing CKD stage ($p<0.0001$), but were very weakly correlated (rho=0.1, p=0.03). Conversely, U-C3M levels decreased with increasing CKD stage ($p<0.0001$); there was no change in S-C3M levels with increasing CKD stage. The odds ratio (OR) for one-year disease progression for a doubling in U-C3M was 0.29 (95% CI 0.17-0.51, $p<0.0001$) and 0.47 (95% CI 0.23-0.96, p=0.04) in the adjusted model. Interestingly, the levels of U-C3M divided by S-C3M gave rise to a hazard ratio for development of end-stage renal disease of 0.79 (95% CI 0.63-0.99, p=0.04) in the adjusted model. S-PRO-C3 levels at baseline was able to predict mortality with hazard ratios per-doubling of S-PRO-C3 of 2.03 (95% CI 1.31-3.16, p=0.002) in the adjusted model.

Conclusions: In conclusion, we have found a dysregulated balance between COL III formation and degradation in patients with CKD, and show that this is associated with an increased risk of adverse outcomes. These findings need urgent replication in an independent cohort; if confirmed they have implications for pathotyping and therapeutic targeting in patients with CKD.

TH-PO1116

Neutrophil/Lymphocyte Ratio in Prediction of Disease Progression in Patients with Stage 1-4 CKD in China: Results from the Chinese Cohort Study of CKD (C-STRIDE)

Qiongjing Yuan,[1] Jinwei Wang,[2] Hui Xu.[3] the C-STRIDE study group *[1]Xiangya Hospital, Central South University, Changsha, China; [2]Renal Division, Department of Medicine, Peking University First Hospital; Peking University Institute of Nephrology, Beijing, China; [3]Nephrology Department, Xiangya Hospital, Central South University, Changsha, Hunan, China, ChangSha, China.*

Background: Chronic kidney disease (CKD) leads to end-stage renal failure and cardiovascular events. An attribute to these progressions is abnormalities in inflammation, which can be evaluated using the neutrophil/lymphocyte (N/L) ratio. We aimed to investigate the association of N/L ratio with the progression of ESKD, CVD and all-cause mortality in Chinese patients with stages 1-4 CKD.

Methods: A total of 1341 stages 1-4 CKD (18–74 years of age) patients with complete N/L and other relevant clinical variables were included in the current analysis.. Patients were divided according to the median of baseline N/L ratio (≥2.26 or <2.26). ESKD was defined at time to start hemodialysis, peritonal dialysis or renal transplantation. CVD risk was determined with onset of new CVD events. All-cause mortality was recorded at time of decease. The follow-up was censored at June 30, 2017. Cox regression analysis was used in estimating the association between N/L and the outcomes.

Results: Baseline N/L ratio was related to anemia rate, total serum cholesterol, eGFR, blood pressure, uric acid, CKD-MBD rate, cardiovascular disease, ACR and metabolic acidosis. The study duration was 4.35 year(IQR 2.86-5.26). Patients with N/L ratio ≥2.26 were at risk of developing ESKD (HR 1.687(95% CI:1.288,2.209))and all-cause mortality (HR 3.220(95% CI:1.174,8.834))compared to patients with N/L ratio <2.26 ($P<0.05$); We did not observe a significant association between abnormal N/L and CVD risk in the multivariable adjusted model.

Conclusions: Our results suggest that N/L ratio other than hs-CRP is associated with the risk of ESKD and all-cause mortality in Chinese patients with stage1-4 CKD. N/L ratio is an easily accessible and useful marker for monitoring CKD patients in clinical practice.

Endothelial Cell Injury Marker CD146 Evaluates Disease Severity and Predicts Renal Outcomes of Early Diabetic Nephropathy

Ying Fan,[1] Yang Fei,[1] Yiyun Wang,[1] Jiejun Wen,[1] John C. He,[2] Niansong Wang.[1] *[1]Shanghai 6th People's Hospital affiliated to Shanghai Jiaotong University, Shanghai, China; [2]Mount Sinai School of Medicine, New York, NY.*

Background: Glomerular endothelial cell injury plays a crucial role in the development of diabetic nephropathy (DN). CD146, an endothelial marker, was shown to increase in chronic kidney disease (CKD), but its role in DN remains unknown.In the current study, we examined the circulating levels of sCD146 in plasma and renal expression of CD146 in kidney biopsies of DN patients at different CKD stages. We evaluated whether CD146 could be used to assess the severity of disease and predict renal outcomes in DN at early stages.

Methods: 159 non-dialysis type 2-DN patients from 2008 to 2015 were enrolled to measure the plasma concentration of soluble CD146 (sCD146). 94 diabetes mellitus (DM) patients without DN and 100 healthy subjects were used as controls. The patients with CKD stage 1-3 were referred as early stages. Another independent cohort of 48 patients with biopsy-proved DN was used for the immunohistochemistry study of CD146. Renal outcomes were defined as doubling of serum creatinine, progression to end-stage renal disease or death.

Results: The plasma levels of sCD146 was upregulated in patients with DN compared to those without DN. Elevated plasma sCD146 was inversely associated with renal function and proved to be a more optimal marker than urine albumin creatinine ratio (UACR) to evaluate disease severity in these DN patients. Staining of kidney sections showed that CD146 was co-localized with endothelial marker CD31 and its expression increased in DN when compared with minimal change disease (MCD) and normal controls. The positive area of CD146 staining in kidney was correlated with the severity of pathological changes in these DN patients. Survival analysis suggested that both plasma levels of sCD146 and the biopsy expression of CD146 were correlated with the renal outcomes.

Conclusions: Plasma CD146 levels and its renal expression are associated with kidney injury and renal function and could be potentially developed as a marker to predict renal outcomes in patients with early stages of DN.

TH-PO1118

Expression of CPT1α in Human Kidney Biopsy Samples Predicts the Deterioration of Renal Function and Progression of Tubulointerstitial Fibrosis

Yi Fang,[2] Qi Yuan,[1] Junwei Yang.[2] *[1]Nanjing Medical University, Jiangsu Nanjing, China; [2]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: Fatty acids are the preferred energy source for proximal tubule cells, defective fatty acid oxidation (FAO) leads to intracellular lipid accumulation, which plays an important role in the pathogenesis of kidney fibrosis. CPT1α is the rate limiting enzyme for FAO. In this study, we investigated whether expression of CPT1α in human biopsy samples predicts the progression of renal disease.

Methods: This was a retrospective cohort study enrolled 30 patients in our hospital from May 2015 to December 2015. The clinical data were collected and renal biopsy samples were immunhistochemically stained with CPT1α. Lipid droplets accumulation was detected by Oil Red O staining. Interstitial fibrosis was evaluated by Masson's trichrome staining. The association of CPT1α with lipid droplets accumulation, degree of renal fibrosis and decline rate of eGFR was investigated.

Results: In kidney biopsy samples, lipid droplets accumulation suggested damage in fatty acid metabolism. Expression of CPT1α was decreased in fibrosis area. Moreover, CPT1α level was negatively correlated to area of lipid droplet deposition and the area of fibrosis (fig. 1). Furthermore, expression of CPT1α is negatively correlated with the decline of eGFR per year.

Conclusions: These results suggest that expression of CPT1α in human kidney biopsy samples may predict the decline of renal function and progression of renal interstitial fibrosis. CPT1α may service as a novel biomarker for prognosis of renal disease.

Urinary Mitochondrial DNA Level as a Biomarker of Tissue Injury in Non-Diabetic CKD

Zhongping Wei, Cheuk-Chun Szeto. *The Chinese University of Hong Kong, Sha Tin, China.*

Background: Chronic kidney disease (CKD) is a global public health issue and an important economic burden to the health care system. However, the underlying mechanism of progressive renal function loss in CKD, it still remains incompletely understood. Emerging evidence shows that mitochondrial dysfunction plays an important role in the pathogenesis and progression of chronic kidney disease (CKD). We study the relation between urinary mitochondrial DNA (mtDNA) levels and renal dysfunction in non-diabetic CKD.

Methods: We recruited 102 non-diabetic CKD patients, 43 of them had kidney biopsy that showed non-specific nephrosclerosis. Urinary mtDNA level was measured by digital

polymerase chain reaction, and compared to baseline clinical, biochemical, histological parameters as well as renal function decline in the subsequent 48.3 ± 31.8 months.

Results: Urinary mtDNA was easily detectable. The median urinary mtDNA level was 1519.4 (501.61 – 3131.23) million copy/mmol creatinine. There were modest but statistically significant positive correlations between urinary mtDNA level and baseline estimated glomerular filtration rate (GFR) ($r = 0.427$, $p < 0.001$) and proteinuria ($r = 0.376$, $p < 0.001$). For patients with kidney biopsy, urinary mtDNA level also inversely correlated with the severity of glomerulosclerosis ($r = -0.537$, $p < 0.001$), tubulointerstitial fibrosis ($r = -0.309$, $p = 0.029$). Urinary mtDNA level predicts renal event-free survival by univariate analysis (unadjusted hazard ratio [HR] 0.685, $p = 0.033$), but the predictive value of urinary mtDNA level fell short of statistical significance ((adjusted hazard ratio [HR] 0.808, 95%CI 0.331 – 1.968, $p = 0.638$) after adjusting for confounding factors.

Conclusions: Urinary mtDNA levels correlate with baseline renal function, proteinuria, and the severity of histological damage in non-diabetic CKD. Our result suggests that urinary mtDNA level may be a surrogate marker of the degree of permanent renal parenchymal damage in non-diabetic CKD.

Reassessment of Native and Transplant Renal Biopsy Complications and Risk Factors as Performed by Nephrologists from a Large Australian Renal Unit

Jamie X. Cheong, Paul J. Champion de Crespigny. *The Royal Melbourne Hospital, Parkville, VIC, Australia*.

Background: Renal biopsies are the gold standard for diagnosis for many renal conditions. Approximately 250 renal biopsies per million population are performed in Australia per annum, 75 per million in the USA. In Australia biopsies are performed percutaneously under ultrasound guidance with spring loaded needles predominantly by nephrologists. Worldwide minor complications (5-30%) and major complications (1-7%) have been reported. Risk factors include hypertension, acute kidney injury, aspirin use, gender, BMI. There remains limited high quality data on biopsy complications and risk factors. We conducted a single centre audit of percutaneous renal biopsies with the aim to clarify complication rates and identify risk factors.

Methods: We retrospectively reviewed 997 native and transplant renal biopsies performed by nephrologists or trainees at our large tertiary renal and transplant centre between October 2015 to April 2018. Risk factors were recorded on a regulated form and review of the medical records. Major bleeding was defined as transfusion, embolisation or surgical management. Minor complications included macroscopic haematuria, urinary retention, non-diagnostic sample and pain.

Results: We report a total of 58 (5.8%) complications with 12 (1.1%) major complications and 46 (4.7%) minor complications. No nephrectomies or deaths were recorded. Macroscopic haematuria and pain were the most common. We found a significant increase in complications with systolic blood pressure >160 mmHg but no difference with diastolic blood pressure >90 mmHg. Of the 197 patients on aspirin, 17 (29.3%) had complications compared to those not on aspirin (5.1%, p=0.06). Urea ≥ 20 mmol/L had increased complications compared to Urea < 20 mmol/L(7.9% vs 5.3%, p=0.232). Males were more likely to have complications than females (10.2% v 3.2%, p<0.001). There were no increase in complications from BMI or gauge. 38(3.4%) patients recorded an incidental decrease in haemoglobin of > 10g/L but only 2 of these had documented complications.

Conclusions: Complication rates following percutaneous renal biopsies have markedly improved. Ongoing collection of prospective data and increase size of study is required. Detailed data will help provide further insight into the risks of renal biopsies and potential modifiable risk factors.

TH-PO1121

Pre-Renal Biopsy (PRB) Ultrasound (US) Assessment: Does It Count?

Haridian Sosa Barrios,[1] Paola M. Villabón ochoa,[2] Victor Burguera,[1] Laura V. Blanco,[1] Melissa Cintra Cabrera,[1] Milagros Fernandez lucas,[1] Maite Rivera.[1] [1]*Hospital Universitario Ramón y Cajal, Madrid, Spain;* [2]*Hospital Universitario de Guadalajara, Madrid, Spain*.

Background: PRB is an important technique providing relevant information to guide diagnosis and treatment in renal disease. As an invasive procedure it has complications, mainly bleeding related. At present, routine US assessment post PRB is recommended to diagnose haemorrhagic and/or vascular complications. In our centre a PRB drill (SimPRB) is done routinely by the same nephrologists who will perform the procedure to evaluate its feasibility and rule out any anomalies that could prevent the patient from being biopsied.

Methods: We retrospectively analyzed all SimPRB done by Interventional Nephrology in our centre from January 2014 until December 2017. Our aim was to assess SimPRB findings and their influence on PRB technique. During SimPRB we evaluate each patient's position and apnea tolerance, kidney US anatomy, previous renal abnormalities (like hydronephrosis and congenital deffects) and renal depth. This enables our team to avoid renal lesions and select needle size, puncture area and trajectory. Also, it allows interventional nephrologists to assess risks and benefits of PRB technique.

Results: Of 277 SimPRB done in the study period, 163 were male, 88 kidney transplants (KT) and 151 native kidneys (NK, 91% left sided). In 37 cases (13,3%) SimPRB found abnormalities and modified the technique: 7 patients were considered unsuitable for PRB and 30 had a relevant anomaly that modified the PRB procedure. SimPRB findings that contraindicated PRB were: hydronephrosis (n=2), bladder cancer (n=1), patient refusal (n=1), patient unable to tolerate apnea (n=1) and thinned parenchymal thickness (n=2 NK). In 30 cases SimPRB modified PRB technique changing the selected puncture area: cysts in usual puncture area (n=11), severe scoliosis (n=2), prone position intolerance (n=3), inaccesible KT pole (n=1) and right NK biopsy (n=13).

Conclusions: The SimPRB offers a first PRB approach for both patient and interventional nephrologist, reducing the number of failed procedures, anxiety and uncertainty about the technique. Also, SimPRB minimises complications and unnecessary hospital stays, thus improving patient safety and care. We suggest SimPRB should be included as a routine part of pre PRB protocols.

TH-PO1122

Transient Hypotension After Renal Biopsy Did Not Predict Major Bleeding Complication

Yoichi Takeuchi, Tasuku Nagasawa, Mariko Miyazaki, Sadayoshi Ito. *Tohoku University Hospital, Sendai, Japan*.

Background: The vasovagal reflex during the renal biopsy is likely to be considered less serious. We revealed that the reflex was one of the uncomfortable complications that impair QOL of the patients (Yoichi T et al. Clin Exp Nephrol., 2018). Here, we aimed to examine the association between the transient hypotensive events and the amount of retroperitoneal bleeding, accurately quantified by computed-tomographic (CT) images of all patients after the renal biopsy. And, we conducted a risk assessment of the major complication.

Methods: This is a single-center retrospective observational study. A total of 454 Japanese patients underwent ultrasound-guided renal biopsy at our hospital from 2013 through 2017. Demographic factors, eGFR, hemoglobin concentration, platelet counts, and renal volume were included as covariates. Renal and bleeding volumes were 3D-reconstructed from CT images. Major complications (blood transfusion, angiographic intervention and bladder obstruction) were defined as primary outcome and peritoneal bleeding volume as secondary outcome. Logistic regression analysis was used to control the possible confounders related to bleeding complications.

Results: Accurately measured by using the CT images, the retroperitoneal bleeding of total 454 patients had median amount of 40.3 mL (IQR: 19.6 - 88.2). Transient hypotensive events occurred in 26 patients (5.7%), with major bleeding complications occurring in 18 patients (3.9%). Significant difference was found in the retroperitoneal bleeding between the groups with and without transient hypotensive event (median 237.6 mL [IQR: 2.34 - 638.4] vs. median 38.9 mL [IQR: 1.00 - 974.0], $P = 0.0011$). A transient hypotensive event was associated with retroperitoneal bleeding of 100 mL or more by using logistic regression model (adjusted odds ratio 4.9 [95%CI: 2.12 - 11.30], $P < 0.001$). The hypotensive events, however, did not associated with major bleeding complications, and the risk factors for the complications were observed in lower eGFR and lower hemoglobin concentration before the biopsy, consistent with previous reports.

Conclusions: The vasovagal reflex after renal biopsy predicted substantial amount of retroperitoneal bleeding, but it had no association with the major bleeding complications. Major complication would develop owing to the other potential etiologies besides the absolute amount of bleeding.

TH-PO1123

Optimising Renal Perfusion Measurement with Arterial Spin Labelling

Keith Gillis,[1] Alastair J. Rankin,[1] Sarah Allwood-Spiers,[2] Aleksandra Radjenovic,[1] Giles Roditi,[2] Rajan Patel,[1] Patrick B. Mark.[1] Glasgow Renal Research Group [1]*University of Glasgow, Glasgow, United Kingdom;* [2]*NHS Greater Glasgow and Clyde, Glasgow, United Kingdom*.

Background: Arterial spin labelling is a magnetic resonance imaging technique, allowing measurement of renal perfusion without a contrast agent. The optimal manner of image analysis is not known, and we sought to determine which ASL measurement correlates with measured glomerular filtration rate (GFR).

Methods: Healthy volunteers underwent measurement of glomerular filtration rate (GFR) by technetium-99m dimercaptosuccinic acid (DMSA) renography; CKD-EPI eGFR was calculated from serum creatinine. Renal anatomy was evaluated on HASTE imaging whilst ASL was performed using flow sensitive alternating inversion recovery (FAIR) labelling and true fast imaging with steady state precession (True-FISP) acquisition. Perfusion was measured in regions of interest in cortex and whole kidney. The perfusion of each kidney was calculated as a factor of renal volume and whole kidney perfusion, whilst total kidney perfusion was the sum of right and left kidney perfusion.

Results: 12 healthy volunteers were recruited with an age of 50.8±13.7 years, and eGFR of 100.9±13.3 ml/min/1.73m^2, DMSA GFR was 97.3±23.4 ml/min/1.73m^2, mean cortical perfusion was 259.3±56 ml/min/100g, mean whole kidney perfusion was 215.6±35.4 ml/min/100g, and total kidney perfusion was 766.5±186.5 ml/min. In an analysis of 24 kidneys, there was significant correlation between single kidney GFR and kidney perfusion ($r=0.6$, $p=0.0018$) but not cortical ($r=-0.041$, $p=0.85$) or whole kidney perfusion ($r=0.091$, $p=0.67$). In an analysis of each individual, there was significant correlation of total GFR with total kidney perfusion ($r=0.71$, $p=0.01$).

Conclusions: Assessment of renal physiology using ASL MRI may be best expressed by measurement of total renal perfusion.

TH-PO1124

Functional MRI Defined-Renal Cortex Hypoxia Is a Proteinuria-Independent Predictor for Progression of CKD

Kei Sugiyama,[1] Tsutomu Inoue,[1] Eito Kozawa,[4] Masahiro Ishikawa,[2] Hiroaki Amano,[1] Akira Shimada,[3] Naoki Kobayashi,[2] Junji Tanaka,[4] Hirokazu Okada.[1] *[1]Nephrology, Saitama Medical University, Iruma-gun, Saitama, Japan; [2]School of Clinical Engineering, Saitama Medical University, Hidaka-shi, Japan; [3]Endocrinology and Diabetes, Saitama Medical University, Saitama, Japan; [4]Radiology, Saitama Medical University, Iruma-gun, Japan.*

Background: Progression of chronic kidney disease (CKD) is characterized by tubulointerstitial fibrosis and glomerulosclerosis. Chronic hypoxia followed by inflammation may be key to this process. Until now, however, there has been no means of evaluating this noninvasively. Here, we employed blood oxygen level-dependent (BOLD) and diffusion-weighted (DW) magnetic resonance imaging (MRI) to assess renal tissue oxygenation and fibrosis, respectively, and evaluated their correlation with clinical parameters in a single-center, longitudinal, retrospective observational study over five years.

Methods: We examined the prognostic significance of the T2* values of BOLD MRI and apparent diffusion coefficient (ADC) values on DW MRI at the cortex and medulla as well as diabetes mellitus, mean blood pressure, estimated glomerular filtration rate, serum urate levels, and proteinuria. Rate of decline in eGFR was calculated by linear regression analysis using changes in estimated glomerular filtration rate (eGFR) during the observation period. MRI was performed with a 1.5 T Imager (Sonata®; Siemens, Erlangen, Germany) and a six-channel body coil. Both T2* and ADC maps were generated using software in the MRI scanner.

Results: A total of 91 patients were enrolled. Participants, male = 51 (56.0%), were aged 55.8 ± 15.6 years. Thirty-eight (41.8%) had diabetes mellitus, and the eGFR was 49.2 ± 28.9 mL/min/1.73 m^2 at the time of enrollment. ADC values, but not T2* values, of renal cortex were well correlated with eGFR at the start point. Neither the ADC nor T2* values of the renal medulla showed significant correlation with clinical parameters due to large variations. The rate decline in eGFR per year (ΔGFR) during the observation period was -1.92 ± 3.00 mL/min/1.73 m^2. Multiple linear regression analysis revealed that ΔGFR was significantly correlated with eGFR at the start point, the amount of proteinuria, and the T2* values (t=2.980, p=0.004), but not with the ADC values.

Conclusions: Hypoxia as determined by low T2* values using functional MRI is a clinically valuable parameter that affords a proteinuria-independent predictor of CKD progression.

Magnetic Resonance Measurements of Intra-Renal Oxygenation and Fibrosis and Change in Kidney Function: COMBINE Trial

Tamara Isakova,[1] Cynthia A. Kendrick,[2] Brett Larive,[2] Jennifer J. Gassman,[2] Kalani L. Raphael,[3] Dominic S. Raj,[5] Linda F. Fried,[6] Kevin C. Abbott,[8] Stuart M. Sprague,[13] Myles Wolf,[7] Geoffrey A. Block,[10] Alfred K. Cheung,[4] Joachim H. Ix,[11] John P. Middleton,[7] Susan R. Mendley,[9] Pottumarthi V. Prasad.[12] CKD Optimal Management with Binders and NicotinamidE (COMBINE) Investigators *[1]Feinberg School of Medicine, Northwestern University, Chicago, IL; [2]Cleveland Clinic, Cleveland, OH; [3]VA Salt Lake City Health Care System, Salt Lake City, UT; [4]University of Utah, Salt Lake City, UT; [5]GWU Medical Faculty Associates, Washington, DC; [6]VA Pittsburgh Healthcare System, Pittsburgh, PA; [7]Duke University, Durham, NC; [8]The National Institutes of Health, NIDDK, Bethesda, MD; [9]NIDDK/NIH, Bethesda, MD; [10]Colorado Kidney Care, Denver, CO; [11]UCSD, San Diego, CA; [12]NorthShore University HealthSystems, Evanston, IL; [13]NorthShore University HealthSystem University of Chicago Pritzker School of Medicine, Chicago, IL.*

Background: Prior studies report differences between health and CKD in intrarenal oxygenation and fibrosis, as measured by MRI. Data on longitudinal relationships of MRI biomarkers with change in eGFR are limited.

Methods: We obtained baseline and follow up renal MRI in 87 of 205 participants of the COMBINE trial, which was a randomized, double-blinded, 12-month, 4-group parallel study of nicotinamide and lanthanum carbonate vs. placebo in individuals with CKD stages 3-4. Relaxation rate R2* was the BOLD MRI index; higher values of R2* may represent decreased oxygenation. Apparent diffusion coefficient (ADC) was the diffusion MRI index; lower values of ADC may be due to greater fibrosis. We evaluated longitudinal data from all 87 participants to test the hypotheses that higher R2* values and lower ADC values are associated with decline in eGFR.

Results: The mean baseline eGFR was 32.6±7.58 and the mean subject-specific eGFR slope was -2.1±4.15 ml/min/1.73 m^2/year. We observed minimal changes in R2* and ADC values over 12 months. Baseline R2* and ADC did not correlate with eGFR slope (R2* cortex: r=0.03; p=0.76; ADC cortex: r=0.17, p=0.12). However, change in ADC from baseline to end of study correlated with eGFR slope (r=0.22; p=0.04). Participants with diabetes and rapid eGFR decline (>3 ml/min/1.73 m^2/year) had the lowest baseline and follow up ADC values and individuals without diabetes and without rapid eGFR decline had the highest values (Table).

Conclusions: R2* and ADC remained stable during 12 months. While R2* did not correlate with change in eGFR, change in ADC correlated with faster decline in eGFR, and individuals with diabetes and rapid loss of eGFR had the lowest baseline and follow up ADC. Larger studies with longer duration are needed to further test BOLD and diffusion MRI measurements as possible imaging biomarkers of kidney function.

TH-PO1126

Use of Multi-Parametric Functional MRI to Identify Progressive CKD

Luping Li,[1,2] Wei Li,[1,2] Bradley K. Hack,[1] Orly F. Kohn,[2] Stuart M. Sprague,[1,2] Pottumarthi V. Prasad.[1,2] *[1]NorthShore University HealthSystem, Evanston, IL; [2]Pritzker School of Medicine, University of Chicago, Chicago, IL.*

Background: Only a quarter of those with stage 3 CKD will progress to end stage kidney disease over 10 years [PMID: 22545920]. Hence, there is a need for novel markers to identify individuals at risk of progressive CKD. The chronic hypoxia hypothesis suggests that progressive CKD involves loss of peritubular capillaries leading to hypoxia which results in development of fibrosis [PMID: 25401039]. MRI can evaluate perfusion, oxygenation and fibrosis using arterial spin labeling, blood oxygenation level dependent (BOLD) and diffusion MRI respectively. We evaluated a cohort of diabetic patients with CKD stage 3 using these three techniques to determine whether we can identify patients at risk of progressive CKD.

Methods: 41 patients (median eGFR = 49 (40 to 62) mL/min/1.73m2) participated in this IRB approved study. MRI data were acquired using 3T scanner. Following baseline MRI, each individual received 20 mg furosemide *iv*, and BOLD MRI scans repeated. R2* was used as BOLD MRI parameter, higher values of which indicate lower tissue oxygenation. Lower values of apparent diffusion coefficient (ADC) suggest higher levels of fibrosis. Annual loss of renal function (eGFR_slope) was estimated using eGFR measurements obtained from electronic medical records over a period of 2-7 years. MRI data and their associations with baseline eGFR, eGFR_slope were analyzed using Spearman correlation and linear regression analyses using SPSS.

Results: R2* was not associated with eGFR or eGFR_slope. Medullary response to furosemide (ΔR2*_Medulla) (ρ = 0.401, p= 0.014) and cortical perfusion (ρ= 0.441, p = 0.009) showed positive association with annual loss of eGFR. Cortical ADC was associated with cortical perfusion; but not with eGFR or eGFR_slope. The association for ΔR2*_Medulla (but not the cortical perfusion) *vs.* eGFR_slope remained significant even after adjusting for baseline eGFR, age, BMI, gender, systolic blood pressure and blood

glucose. In those individuals (n=9) with > 3 ml/min annual loss of eGFR, ΔR2*_Medulla (1.90 ± 2.53 *vs.* 5.39 ± 3.65 s^{-1}; p = 0.007) and cortical perfusion (88.99 ± 30.31 *vs.* 117.11 ± 34.76 ml/min/100gm; p = 0.045) were lower compared to the rest.

Conclusions: Quantitative functional MRI measurements may be useful in identifying individuals with moderate but progressive CKD. Larger prospective studies should be performed to confirm these associations.

TH-PO1127

Diffusion Weighted Imaging for Quantification of Cyst Volume in ADPKD

Anna Caroli,[1] Paolo Brambilla,[3] Sandro Sironi,[5,3] Giuseppe Remuzzi,[4] Andrea Remuzzi.[2,1] *[1]Mario Negri Institute, Bergamo, Italy; [2]Engineering Department, University of Bergamo, Dalmine, Italy; [3]ASST Papa Giovanni XXIII, Bergamo, Italy; [4]IRCCS - Istituto di Ricerche Farmacologiche Mario Negri, Bergamo, Italy; [5]University Milano-Bicocca, Milano, Italy.*

Background: In autosomal dominant polycystic kidney disease (ADPKD), kidney enlargement is mainly due to cyst growth and associates with renal function decline. Whilst total kidney volume is quite easy to be quantified, total cyst volume (TCV) is difficult and time consuming. In the last decades a number of different magnetic resonance imaging (MRI) modalities have been proposed to investigate renal structure, microstructure, and function. This study proposes a novel method to automatically quantify TCV in ADPKD patients using diffusion weighted MRI (DWI).

Methods: T2-weighted MRI and DWI (Figure 1A) were performed in 15 patients with ADPKD enrolled in the EuroCYST Initiative in Bergamo Hospital (Italy). TCV was quantified on each T2-weighted MRI using an accurate semi-automated method assumed as reference [Caroli et al. Lancet 2013]. Each DWI was processed using a bi-exponential model. The histogram of the pure diffusion component (D) was thresholded using the Otsu method, to separate cyst from non-cystic renal parenchyma, and TCV was automatically computed based on this threshold. DWI-computed TCVs were finally compared with the reference values.

Results: Fluid-filled kidney cysts were denoted by higher D values than non-cystic volume (Figure 1B). DWI-computed TCV highly and significantly correlated with TCV quantified on T2-weighted MRI (rho = 0.99, p <0.001)(Figure 1C), despite the former consistently underestimating TCV (DWI-computed TCV = 1144±1068 mL; reference T2-weighted TCV = 1356±1256 mL).

Conclusions: Current findings suggest that our method can be used to automatically quantify TCV on DWI to accurately estimate the extension of renal structural changes in ADPKD. The proposed method may be useful to monitor disease progression as well as to evaluate the effect of pharmacological intervention. **Acknowledgements.** This study was funded in part by ERA – EDTA (EuroCYST Initiative).

Implications of ADPKD Diagnosis at Young Age: A Post Hoc Analysis of the TEMPO 3:4 Trial

Peter Janssens,[2] Stephanie L. De Rechter,[5] Bert Bammens,[5] Franziska Grundmann,[6] Francois Jouret,[9] Max Liebau,[8] Roman-Ulrich Mueller,[7] Ronald D. Perrone,[4] Franz S. Schaefer,[3] Christina Pao,[1] Djalila Mekahli.[2] *[1]Otsuka Pharmaceutical Development and Commercialization, Princeton, NJ; [2]KULeuven, Leuven, Belgium; [3]University of Heidelberg, Heidelberg, Germany; [4]Tufts Medical Center, Boston, MA; [5]University Hospitals Leuven, Leuven, Belgium; [6]University of Cologne, Cologne, Germany; [7]Dept. 2 of Internal Medicine, University of Cologne, Koeln, Germany; [8]University Hospital Of Cologne; Children's Hospital, Koeln, Germany; [9]University of Liege Hospital (ULg CHU), Liege, Belgium.*

Background: In ADPKD, there is currently limited information whether early diagnosis and management improve outcomes. We studied the implications of early diagnosis on outcome.

Methods: A post hoc analysis of TEMPO 3:4, a prospective, double-blind RCT in adults with ADPKD, with eCr ≥60 mL/min and TKV ≥750 mL. Comparison between patients diagnosed at age ≤18 years (childhood diagnosis [CD]) and >18 years (adult diagnosis [AD]).

Results: Patients were classified as CD in 20%, AD in 76% (Table 1), and unknown age at diagnosis in 4% (not shown) of the cases. At time of TEMPO 3:4 inclusion, CD were younger and had better eGFR than AD (Table 1). There were no significant differences in TKV, hypertension or RAASi use. Rates of TKV growth and eGFR changes by age at diagnosis are shown in Table 2.

Conclusions: The characterization of CD patients in TEMPO 3:4 shows that these participants were more severely affected based on a larger age-adapted TKV. Despite this fact, yearly TKV increase and loss of eGFR in the placebo arm of the study showed a tendency (NS) to be milder in the CD cohort. These data suggest the need for further evaluation of early intervention in the treatment of ADPKD.

Funding: Commercial Support - Otsuka Pharmaceutical Development and Commercialization Inc.

Integrase Strand Transfer Inhibitor and Progression to CKD in an Outpatient Cohort of HIV-Infected Patients

Nora Franceschini. UNC Center for AIDS Research *University of North Carolina Chapel Hill, Chapel Hill, NC.*

Background: Recently introduced integrase strand transfer inhibitor (INSTI)-based regimens are highly effective in suppressing HIV viral load and have increased long-term survival of people living with HIV. The kidney outcomes among patients on INSTI regimens have not been compared.

Methods: The study included Center of AIDS Research (CFAR) HIV Clinical Cohort participants initiating an INSTI-based regimen (raltegravir [RAL], dolutegravir [DTG] and cobicistat-boosted elvitegravir [EVG/c]). Changes in eGFR over time were modelled using linear regression with restricted cubic splines. Multivariable Cox proportional hazards models were used to assess time to the first occurrence of low eGFR (<60 mL/min/1.73m²) in the full sample and in a sample restricted to tenofovir (TDF) users. Multivariable models were controlled for baseline age, sex, race, injection drug use as a mode of transmission, CD4 cell count, history of AIDS-defining illness, cardiovascular disease, hypertension and its pharmacological treatment, and diagnosis of diabetes and its pharmacological treatment. Patients were censored at death, lost to follow-up or October 1st, 2016.

Results: The anchor-agents for the 920 patient-regimens consisted of RAL (n= 156, 17%), DTG (n= 360, 39%) and EVG/c (n=404, 44%). eGFR remained relatively stable over time on all three INSTI-based agent treatment, following some minimal variation over the first few months on the regimen. Compared to EVG/c, RAL was not associated with a faster progression to low eGFR (overall sample, hazard ratio [HR]: 1.08; 95% Confidence Interval [C.I.]: 0.65, 1.77 and TDF-restricted sample, HR: 0.98; 95% C.I. 0.55, 1.72). Compared to EVG/c, DTG was associated with a faster progression to low eGFR in the TDF-restricted sample (HR 1.75; 95% C.I. 1.00, 3.06), but not in the full sample (HR 1.33; 95% C.I. 0.79, 2.25).

Conclusions: The changes in eGFR over time observed for DAG regimen may be due to tubular creatinine secretion inhibition rather than kidney injury, although progression to low eGFR might be accelerated with DTG use among TDF users.

Effect of Treatment of Chronic Hepatitis C Virus (HCV) Infection with Glecaprevir/Pibrentasvir (G/P) on Renal Biomarkers in Patients with CKD Stage 3b, 4, or 5

Meghan E. Sise,[1] Raymond T. Chung,[4] Marwan O. Kaskas,[5] Neddie Zadeikis,[2] Manal Abunimeh,[2] Zhenyi Xue,[2] Federico Mensa,[2] Marcello Persico.[3] *[1]Department of Medicine, Division of Nephrology, Massachusetts General Hospital, Boston, MA; [2]AbbVie Inc., North Chicago, IL; [3]Internal Medicine and Hepatology Unit, University of Salerno, Fisciano, Italy; [4]Department of Medicine, Division of Gastroenterology, Massachusetts General Hospital, Boston, MA; [5]Northwest Louisiana Nephrology, Shreveport, LA.*

Background: Chronic HCV infection is associated with CKD development and progression to end-stage renal disease (ESRD). HCV elimination may reduce risk of CKD progression. G/P, an all-oral pangenotypic HCV direct-acting antiviral (DAA) regimen, has minimal renal excretion. G/P is approved for patients (pts) with compensated liver disease and any degree of renal impairment, including ESRD, with high cure rates. Here we explore the impact of G/P on renal biomarkers in pts with CKD stage 3b, 4, or 5.

Methods: EXPEDITION-5 was a Phase 3b trial evaluating efficacy and safety of G/P for 8, 12, or 16 weeks (wks) in pts with CKD stage 3b, 4, or 5. Pre- and posttreatment

C-reactive protein, tumor necrosis factor-α, urine protein/creatinine ratio (PCR), urine albumin/creatinine ratio, and urine neutrophil gelatinase-associated lipocalin concentrations will be evaluated.

Results: 101 pts enrolled. Baseline characteristics are shown (**table**). 83% of pts received 8 wks of G/P. Sustained virologic response at posttreatment wk 12 (SVR12) was 97% with no virologic failures. There were no DAA-related serious adverse events (AEs) or clinically relevant lab abnormalities. 2 predialysis pts discontinued due to AEs. In predialysis pts (N=24), eGFR (mean±SD, mL/min/1.73 m^2) did not change from screening (27.1±9.2) to posttreatment wk (PTW) 4 (27.4±11.6); mean PCR was 2.7 g/g at baseline and 2.6 g/g at PTW4/12; 41% of pts had ≥30% improvement in PCR after G/P.

Conclusions: G/P for 8–16 wks was not associated with eGFR deterioration in predialysis pts. Preliminary data suggest G/P may improve PCR in a substantial number of pts. Other renal biomarker analyses will be presented.

Effect of Ledipasvir and Sofosbuvir (LDV/SOF) on Kidney Function and Urinary Biomarkers in Patients (Pts) with Proteinuric CKD

Meghan E. Sise,[1] Donald F. Chute,[1] Jenna L. Gustafson,[1] Sushrut S. Waikar,[2] Raymond T. Chung.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: HCV infection is associated with CKD incidence and progression. HCV may lead to immune-complex mediated glomerulonephritis, however HCV also promotes atherosclerosis, insulin resistance and chronic inflammation. We sought to determine whether HCV treatment improves kidney function, as assessed by biomarkers of kidney disease.

Methods: NCT02503735 was an investigator-initiated pilot trial that used SOF/LDV to treat pts with HCV genotype 1 or 4 and proteinuria (>300mg proteinuria/g Cr). Baseline proteinuria, cystatin-c, and creatinine were compared to on treatment values and post-therapy values. Insulin resistance (IR) was calculated by HOMA-IR. Urine biomarkers were measured by Luminex. The primary outcome was change in natural log proteinuria-to-creatinine (UPC) ratio from baseline to 12-weeks post SOF/LDV compared by paired t-test.

Results: 10 pts began 12-weeks of LDV/SOF mean age 64 (SD 10), 70% male, 60% White, 30% Black, 10% Native American. 4/10 had cirrhosis. 8/10 were cured of HCV, 2 relapsed. Baseline eGFR was 63.2 mL/min/1.73m2 (SD 26.2), baseline proteinuria was 1.05g/g (SD 0.95). Baseline to post-treatment values are in **Table 1**. Non-diabetic pts cured of HCV (pts 1-4) all had improvement in proteinuria: 1.8g/g, (SD 1.6) to 0.69g/g (SD 0.7g/g) (p=0.01). Diabetic pts and pts with HCV relapse had worsening proteinuria 0.77g/g, (SD 0.3) to 2.2g/g (SD 1.4) (p=0.05). Complement and cryoglobulins normalized in the majority, IR decreased slightly.

Conclusions: Non-diabetic pts with HCV-associated CKD had substantial improvement in proteinuria when HCV was eradicated with SOF/LDV.

Ankle Brachial Index Is Associated with Cardiovascular and Renal Events in Patients with CKD: Result from the KNOW-CKD Study

Chang Seong Kim,[1] Hong sang Choi,[1] Eun Hui Bae,[1] Kook-Hwan Oh,[2] Curie Ahn,[2] Soo Wan Kim.[3] *[1]Chonnam National University Hospital, Gwangju, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea; [3]Chonnam National University Medical School, Gwangju, Republic of Korea.*

Background: Vascular calcification of the media is an independent and strong predictor of cardiovascular risk in patients with chronic kidney disease (CKD). Ankle brachial index (ABI) is a useful tool for diagnosis of medial calcification as well as peripheral artery disease. However, few studies are reported its relation to the renal progression and risk of cardiovascular events in patients with CKD. We examined this relationship in a large CKD cohort.

Methods: In this prospective longitudinal study, we enrolled 2115 patients from the KoreaN cohort study for Outcome in patients with CKD (KNOW-CKD). The patients were categorized into low ABI (≤ 0.9), borderline ABI (0.9–1.1), normal ABI (1.1–1.3), or high ABI (≥ 1.3). The relationship between ABI and cardiovascular events (myocardial infarction, stroke, cerebral hemorrhage, or congestive heart failure), renal progression (as ≥ 50% decline of estimated glomerular filtration rate (eGFR), doubling of serum creatinine, or start of dialysis) was analyzed using Cox regression.

Results: Renal progression and cardiovascular events were occurred 330 (15.6%) and 86 (4.3%) in patients, respectively, during the median follow-up of 26.9 months. Compared to patients with high ABI, patients with low ABI had a lower prevalence of renal progression (low ABI: 17.5% vs. high ABI: 24.7%), whereas had a higher risk of cardiovascular events (low ABI: 17.3% vs. high ABI: 7.2%). In Cox regression model, patients with low ABI were at higher risk of cardiovascular events even after adjustments (hazard ratio [HR], 4.41; 95% confidence interval [CI], 1.63–11.9; P = 0.003), but high ABI had no significant risk of cardiovascular events (HR, 1.18; 95% CI, 0.46–3.07; P = 0.731) than those with normal ABI. However, there was no significant association between patients with low or high ABI and a risk of renal progression after adjustment.

Conclusions: Low ABI (≤ 0.9) is related to higher risk of cardiovascular events in patients with CKD. Measuring ABI might serve as a useful tool for predicting cardiovascular events in Korean CKD patients.

TH-PO1133

Association Between Serum Lipid Profiles and Cardiovascular Outcomes in CKD Patients: KNOW-CKD Study

Arum Choi, Yooju Nam, Seon yeong Lee, Joohwan Kim, Ki Heon Nam, Tae-Hyun Yoo, Dae-Suk Han, Seung Hyeok Han. *Yonsei University College of Medicine, Seodaemun-gu, SEOUL, Republic of Korea.*

Background: Dyslipidemia has been linked to an increased risk of cardiovascular morbidity and mortality in patients with chronic kidney disease (CKD). However, the role of individual lipid parameters in the development of cardiovascular events in the CKD population is not well established. Here, we analyzed the relative contribution of 4 lipid profiles such as total cholesterol (TC), low density lipoprotein cholesterol (LDL-C), high density lipoprotein cholesterol (HDL-C), and triglycerides (TG) to the risk of cardiovascular morbidity and mortality in patients with non-dialysis CKD.

Methods: Among 2,238 patients with non-dialysis CKD enrolled in the KoreaN cohort study for Outcome in patients With Chronic Kidney Disease (KNOW-CKD), 1,728 patients who measured TC, LDL-C, HDL-C, and TG and were not previously diagnosed with cardiovascular disorders were included in the analysis. Study endpoint was a composite of major cardiovascular events or death.

Results: The mean age was 52.9 ± 12.1 years and 1,023 (59.2%) patients were males. The mean serum concentrations of TC, LDL-C, HDL-C, and TG were and 175.5 ± 38.5, 98.0 ± 31.2, 49.8 ± 15.6, and 156.9 ± 96.6 mg/dl, respectively. Among 1,728 patients, 860 (49.7%) patients were treated with lipid-lowering drugs. During the median follow-up duration of 3.0 years, 105 patients (6.1%) reached the composite end point. In the fully adjusted multivariable Cox models, HDL-C (HR, 1.05 per 10 mg/dl increase; 95% CI, 0.92-1.12; P = 0.50), TC (HR, 1.03 per 10 mg/dl increase; 95% CI, 0.98-1.09; P = 0.23), LDL-C (HR, 1.03 per 10 mg/dl increase; 95% CI, 0.97-1.10; P = 0.36), and TG (HR, 1.00 per 10 mg/dl increase; 95% CI, 0.98-1.02; P = 0.75) were not associated with increased risk of cardiovascular events or death. Furthermore, areas under the curve of these 4 lipids were similar and none of these parameters improved net reclassification improvement and integrated discrimination improvement for the prediction of cardiovascular morbidity and mortality.

Conclusions: This study showed that four lipid profile parameters did not predict the future adverse outcomes nor improved cardiovascular risk stratification in patients with CKD.

TH-PO1134

Kidney Function Decline Affects Endothelial Dependent Flow Mediated Dilation Independently of HDL, LDL, and HsCRP

Victoria Whitfield,[2] Elvis A. Akwo,[2] Edward D. Siew,[3] Talat Alp Ikizler,[2] Adriana Hung.[1] *[1]Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Vanderbilt University School of Medicine, Nashville, TN.*

Background: Patients with CKD have a significant cardiovascular morbidity & mortality. Endothelial function is the earliest manifestation in the continuum of atherosclerosis. We investigated the relationship between glomerular filtration rate (GFR) and endothelium-dependent vascular function in a nondiabetic population.

Methods: Participants were 89 CKD patients and 22 with normal GFR who underwent brachial artery flow-mediated dilation (FMD_{BA}) by high resolution ultrasound. Clinical evaluation, renal function tests, lipid profile and high sensitivity C-reactive protein (hsCRP) assays were performed on all study participants. Multivariable linear regression models with robust standard errors were used to investigate the dose-response relationship between FMD% and estimated GFR (eGFR) – modeled as a restricted cubic spline with 4 knots. Covariates were age, sex, race, body mass index (BMI), systolic blood pressure (SBP), hsCRP, HDL and LDL cholesterol. Skewed variables were log transformed.

Results: Over 71% of participants were male, 21% were African-American. The mean (SD) age was 63.2 (13.7) years. Median (25^{th}, 75^{th}) FMD% was lower among CKD patients

compared to controls [4.2 (2.9, 6.3) vs. 8.5 (4.8, 10.4); p = 0.0004] (**figure 1**). After full adjustment for baseline covariates, CKD patients had a significant 3.2% (95% CI: 0.7, 5.7, p = 0.01) lower FMD%. Percent FMD had a significant inverse correlation with age (r = -0.36, p = 0.001). In a minimal model adjusted for age, sex, race and BMI, eGFR had a significant (p = 0.0006) positive nonlinear relationship with FMD% with a trough on the dose-response curve occurring at an eGFR ~ 60mL/min/1.73m^2 (**figure 1**). The association remained significant (p = 0.0005) after further adjustment for SBP, log hsCRP, log HDL and log LDL.

Conclusions: Endothelium-dependent vascular function diminishes across the kidney function continuum, independently of traditional CVD risk factors. Further investigation into the underlying mechanisms involved maybe warranted.

Insulin Sensitivity, Systemic Inflammation and GFR as Key Determinants of Arterial Stiffness

Elvis A. Akwo,[1] Aseel Alsouqi,[1] Victoria Whitfield,[1] Lori Wanko,[1] Talat Alp Ikizler,[1,2] Adriana Hung.[2,1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Veterans Affairs CSR&D, Nashville, TN.*

Background: Patients with chronic kidney disease (CKD) are at increased risk of cardiovascular disease (CVD). The underlying mechanisms of the burden of CVD in CKD remains poorly understood. We investigated the relationship of GFR, aortic arterial stiffness and the mediating effects of systemic inflammation and insulin sensitivity.

Methods: We studied 136 patients: 50 CKD and 86 normal GFR. Aortic pulse wave velocity (aPWV) was measured via transcutaneous tonometry. Insulin sensitivity index (ISI) was measured by hyperinsulinemic euglycemic clamp; high sensitivity C-reactive protein (hsCRP) and eGFR were measured at baseline. Sequential multivariable linear regression with robust standard errors was used to study determinants of aPWV and perform mediation analyses.

Results: Median age was 54 years; 51% were female and 38% African-American. Patients with CKD had significantly higher aPWV [10.7±2.2 vs. 7.7±1.4, p < 0.0001] compared to controls. Log aPWV was inversely correlated with eGFR (r = - 0.65, p < 0.0001) and log ISI (r = -0.38, p < 0.0001); and was positively correlated with age (r = 0.73, p < 0.0001), BMI (r = 0.17, p = 0.02) and log hsCRP (r = 0.23, p <0.0001). In the model adjusted for: age, sex, race, BMI and smoking, a 10 ml/min decrease in eGFR was associated with a 2.1% increase (95% CI: 0.8, 3.3, p = 0.001) in aPWV. Further adjustment for log ISI and log hsCRP attenuated the eGFR effect (percent increase in PWV = 1.4%, 95% CI: - 0.2, 3.0, p = 0.1). GFR had a significant (p = 0.01) inverse nonlinear association with CPP that became insignificant when adjusting for hsCRP and/or ISI [Figure 1].

Conclusions: Declining GFR is associated with increased aPWV and CPP. These adverse vascular outcomes in CKD are partly mediated by systemic inflammation and insulin resistance. Targetting both IS an/or inflammation could reduce CVD risk in CKD patients.

Association of Serum Uromodulin with Mortality and Cardiovascular Disease in the Elderly – The Cardiovascular Health Study

Dominik Steubl,[1] Petra Buzkova,[8] Pranav S. Garimella,[2] Joachim H. Ix,[2] Prasad Devarajan,[3] Michael R. Bennett,[6] Paulo H. Chaves,[7] Michael Shlipak,[4] Mark J. Sarnak.[5] *[1]Tufts Medical Center, Tufts University, Boston, MA; [2]UCSD, San Diego, CA; [3]Cincinnati Children's Hospital, Cincinnati, OH; [4]San Francisco VA Medical Center, San Francisco, CA; [5]Tufts Medical Center, Boston, MA; [6]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [7]Florida International University, Miami, FL; [8]UW, Seattle, WA.*

Background: Uromodulin is released by renal tubular cells into the serum (sUMOD) and urine. Lower urine UMOD has been linked to mortality and cardiovascular disease but much less is known about sUMOD. We evaluated the association of sUMOD with those outcomes in community-dwelling older adults.

Methods: We measured sUMOD in a random subcohort of 933 participants enrolled in the Cardiovascular Health Study. The association of sUMOD with all-cause mortality, incident heart failure (HF) and incident CVD (myocardial infarction, stroke and mortality due to coronary disease or stroke) were evaluated using multivariable Cox regression, adjusting for study participants' demographics, estimated glomerular filtration rate (eGFR), albuminuria and CVD risk factors. Generalized additive models with splines were used to address the functional form of sUMOD with outcomes. Due to non-linear associations of sUMOD with all outcomes, 2.5% of the values on either end of the sUMOD distribution were excluded from the analyses, limiting the range of sUMOD to 34.3 - 267.1 ng/ml.

Results: The mean age was 78±5 years, 40% were male, and 15% were non-white. Mean sUMOD level was 127±64 ng/ml, eGFR was 63 ml/min/1.73 m^2 and 42% had CKD defined as eGFR<60 ml/min/1.73 m^2. Patients in the lower sUMOD ranges had lower eGFR and higher albuminuria. During a median follow-up of 9.9 years, 805 patients died, 283 developed HF and 274 CVD. In multivariable analysis higher sUMOD was independently associated with lower mortality and CVD, and a trend for HF (Table).

Conclusions: Low sUMOD is independently associated with mortality and CVD in the elderly.

PSG is supported by National Institutes of Health training grant 5 T32 DK007777-13.

Table: Associations of serum uromodulin with mortality and cardiovascular outcomes

Outcome	Univariate HR (95%-CI)	Multivariate HR (95%-CI)[a]
Mortality	0.73 (0.67-0.80)	0.89 (0.80-0.99)
Heart failure	0.68 (0.59-0.80)	0.84 (0.70-1.01)
Cardiovascular disease	0.68 (0.58-0.79)	0.80 (0.67-0.96)

Cox regression analysis for a serum uromodulin (sUMOD) range of 34.3-267.1 ng/ml (SD=63.6). Hazard ratio (HR) for each 1-SD higher sUMOD.
[a] adjusted for age, sex, race, clinic site, body-mass index, level of education, estimated glomerular filtration rate, albumin-creatinine ratio, diabetes, smoking status, systolic blood pressure, serum cholesterol, (log) serum C-reactive protein, lipid-lowering medication, antihypertensive medication, prevalent heart failure and cardiovascular disease (CVD, for the mortality outcome), prevalent CVD (for the heart failure outcome) and prevalent heart failure (for the CVD outcome)

TH-PO1137

Kidney and Cardiac Parameters – Which Are More Important in Predicting Circulatory Congestion and Mortality Risk in CKD? Insights from a 5-Year Prospective Analysis

Angela Yee Moon Wang,[1] Henry H. Wu,[1] Qizhe Cai,[3] Hoi Kei S. Wong,[2] Xiuzhang Lu.[3] *[1]Queen Mary Hospital, University of Hong Kong, Hong Kong, China; [2]University of Hong Kong, Hong Kong, China; [3]Beijing Chao-Yang Hospital, Beijing, China.*

Background: Chronic kidney disease (CKD) patients are frequently complicated with circulatory congestion (CC). However, factors predicting the risk of CC are poorly understood.

Methods: 300 CKD stage 3-5 subjects (Mean age, 60±10yrs, 56.3% men) were randomly recruited from a University Teaching Hospital. All underwent 2D-echocardiography & tissue Doppler imaging (TDI) to assess cardiac structure & function, bloods & first void urine collection for eGFR & urine protein to creatinine ratio (UPCR), & blood pressure measurement.

Results: eGFR (mean±SD): 33 ± 17ml/min per 1.73m^2. Urine UPCR: 139 ± 202mg/mmol creatinine. All subjects were followed prospectively for a median of 68 (IQR, 30, 70) mths, 25% were complicated with CC or died from other causes. In the multivariable Cox regression analysis considering clinical, hemodynamic, biochemical, echo & TDI

parameters, eGFR (P=0.002) & UPCR (P=0.006) exhibited independent significance in predicting the risk of CC & mortality. Additional adjustment for cardiovascular medications including renin-angiotensin system blockers, beta-blockers, & diuretics did not change the significance of eGFR & UPCR in predicting CC & mortality. In a receiver-operator-characteristics curve analysis, UPCR showed the largest area under the curve (AUC) (0.78, 95% confidence intervals [CI], 0.72 - 0.84) in predicting the composite endpoint of CC & mortality, followed by eGFR (0.75, 95% CI, 0.69 - 0.81) & the ratio of early mitral inflow velocity to peak mitral annulus velocity (E/Em ratio, a marker of left ventricular [LV] filling pressure) (0.74, 95% CI, 0.67 – 0.80). The AUC of LV mass index & ejection fraction was 0.72 (95% CI, 0.65 - 0.79) & 0.50 (95% CI, 0.42 – 0.58), respectively.

Conclusions: Both proteinuria & eGFR exhibited independent significance & were more powerful than cardiac structural & functional parameters in predicting CC & mortality risk in CKD. Among the cardiac parameters, diastolic dysfunction outweighed systolic dysfunction in predicting CC & mortality risk. Further intervention study is needed to evaluate whether retarding proteinuria & CKD progression may effectively lower the incidence of CC and improve clinical outcomes of CKD patients.

Effect of Fructooligosaccharide on Endothelium Function in CKD Patients: A Randomized Controlled Trial

Rachel G. Armani, Christiane I. Ramos, Lilian Cuppari, Maria Eugenia F. Canziani. *Division of Nephrology - Federal University of São Paulo, Sao Paulo, Brazil.*

Background: Microbiota-derived uremic toxins have been associated with increased cardiovascular risk in chronic kidney disease (CKD). This has encouraged the investigation of alternative paths to modulate gut environment with ensuing reduction of toxin production, inflammation and endothelial dysfunction. This trial aimed to evaluate the effect of the prebiotic fructooligosaccharide (FOS) on endothelial dysfunction in CKD non-dialysis patients.

Methods: The 3-month double-blind randomized controlled trial included 46 non-diabetic CKD patients [52% men; 57.6±14.4 years; eGFR: 21.3±7.3 mL/min/1.73m]. Intervention and placebo consisted in 12g/day of FOS or maltodextrin, respectively. P-cresyl sulfate (PCS), indoxyl sulfate (IS), Interleukin 6 (IL6) were evaluated. Endothelial dysfunction was assessed through stroma derived factor 1 alfa (SDF1α), serum nitric oxide (NO) and flow-mediated dilatation (FMD).

Results: Aside for the intervention group being older (53.4±16.0 vs 61.9±11.4,p=0.04) the groups were homogeneous. During the study, renal function, electrolytes, remained stable in both groups. A downward trend in PCS serum levels (52.86±30.68 vs 43.06±32.43mg/L,p=0.07) was observed in the treated group. Regarding inflammation, IL6 decreased in this group (3.14±2.22 vs 2.65±1.37 pg/mL, p=0.04). There was no difference in NO, SDF1α levels and FMD (Figure 1). In an exploratory analysis, including only patients with less damaged endothelium at baseline (FMD≥2.2% median), we observed that treated group had significant greater values of FMD after 3 months (p=0.04).

Conclusions: There was no effect of FOS on endothelial function in the studied population. Nonetheless, in patients with less damaged endothelium at baseline, we could observe an improvement of endothelial dilatation in the treated group, which could suggest a potential impact of FOS in the recovery of endothelial function.

Funding: Government Support - Non-U.S.

Representation of Kidney Disease in Peripheral Artery Disease Therapy: A Systematic Review of Randomized Controlled Trials

Yumeng Wen,[2] O. Alison Potok,[1] Rakesh Malhotra,[1] Lili Chan,[2] Ioannis Konstantinidis,[2] Girish N. Nadkarni,[2] Steven G. Coca,[2] Pranav S. Garimella.[1] [1]*University of California San Diego Medical Center, San Diego, CA;* [2]*Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Kidney disease (KD) patients have a higher risk of peripheral artery disease (PAD) with worse outcomes than the general population. We assessed the inclusion of KD patients in randomized controlled trials (RCT) of PAD therapy.

Methods: We searched PubMed for RCTs of PAD therapy that reported clinical outcomes, randomized ≥ 50 subjects and were published in English from 01/2000 to 04/2018. Two independent reviewers selected studies and extracted data, including trial characteristics, criteria for KD patients' exclusion, proportion of KD patients and number of subgroup analyses by non-renal or renal parameters.

Results: We included 228 trials randomizing 122924 subjects. KD patients were excluded in 98 (42.6%) trials with 29 (29.6%) of these not reporting kidney specific exclusion criteria. The remainder excluded KD patients based on varied cutoffs for creatinine, glomerular filtration rate and need for dialysis. Trials assessing ACC/AHA class I or II recommendations were less likely to exclude KD patients (38.4 % vs 51.2%, p=0.04). Characteristics associated with a higher likelihood of KD patient exclusion were multicenter studies (47.4% vs. 33.8% in single center studies, p=0.04), industry funding (53.5% vs. 35.0% in academic grant or government-funding, p=0.02) and smaller patient samples (43.2% of studies with <100 subjects, vs 10.0% of studies with ≥1000 subjects, p=0.04). Only 9.6% (22/228) of the trials reported kidney function and 1.3% (3/228) reported subgroup analyses based on it. Exclusion of KD patients by diagnostic category and therapeutic class is depicted in the Figure.

Conclusions: Numerous PAD trials exclude KD patients, a majority uses non-specific renal criteria. Including KD patients in PAD trials is needed to improve the quality of evidence for interventions in this vulnerable population.

CKD and Incident Hearing Loss

Shruti Gupta,[3] Karen J. Cruickshanks,[1] Gary C. Curhan,[2] Sharon Curhan.[4] [1]*University of Wisconsin School of Medicine and Public Health, Madison, WI;* [2]*Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA;* [3]*Brigham and Women's Hospital, Boston, MA;* [4]*Brigham and Women's Hospital/Harvard Medical School, Boston, MA.*

Background: There is a strikingly high prevalence of sensorineural hearing loss among patients with chronic kidney disease (CKD), with estimates ranging from 36 to 77%. However, the etiology of hearing loss in CKD is not well-understood. In the only prior longitudinal study, estimated glomerular filtration rate ($eGFR_{CysC}$) <60 mL/min/1.73 m^2 was significantly associated with a 50% higher 20-year cumulative incidence of hearing impairment. We assessed whether lower baseline eGFR calculated using serum creatinine (SCr) was associated with incident hearing loss, and whether rapid decline in eGFR over time was associated with an evenhigher risk.

Methods: SCr was measured in 1843 individuals without hearing loss at the start of the Epidemiology of Hearing Loss Study in 1993. Follow-up SCr assessments were conducted at 5 (n=1500) and 10 (n=1086) years. The $eGFR_{Cr}$ was estimated using the CKD-EPI equation. Hearing tests were conducted at baseline, and at 5, 10, and 15 year follow-up visits. The risk of hearing loss was assessed as a function of baseline $eGFR_{Cr}$, as well as a function of a 20% decline in $eGFR_{Cr}$ between baseline and 5 years, and between 5 and 10 years. Incident hearing loss was defined as pure-tone average >25 dB for thresholds at 0.5, 1, 2, and 4 kHz. Cox proportional hazards regression was used to adjust for sex, cholesterol, smoking, waist circumference, schooling, NSAIDs, loop diuretics, hypertension, and diabetes.

Results: During 15,676 person-years of follow up, there were 802 cases of incident hearing loss (Table 1). There was no significant association between lower baseline $eGFR_{Cr}$ and incident hearing loss. There was also no association after stratifying by sex or age. Decline in $eGFR_{Cr}$ was not associated with incident hearing loss.

Conclusions: There were no significant associations between baseline $eGFR_{Cr}$ or decline in $eGFR_{Cr}$ and risk of incident hearing loss.

Factors Influencing Approval Rates of Peripherally Inserted Central Catheters (PICCs) in Patients with Kidney Disease

Irene Chernova,[1,2] Corey J. Cavanaugh,[1,2] Ravi Kodali,[1,2] Ngozi Okoba,[1,2] Sarthak Virmani,[1,2] Justin M. Belcher.[2,1] Yale Nephrology Fellows *[1]Yale New Haven Hospital, New Haven, CT; [2]Yale University, New Haven, CT.*

Background: Current guidelines recommend against placement of peripherally inserted central catheters (PICCs) in stage 3-5 CKD without nephrology consultation in an attempt to preserve veins for future arteriovenous fistula access creation for hemodialysis. In many instances, nephrology input is also required for PICC placement for patients with acute kidney injury (AKI). With no official guidelines delimiting patients appropriate for PICCs, the consult burden on renal fellows can be significant. Here we attempted to determine medical and demographic factors influencing our practice patterns for approving PICC placement to develop objective guidelines identifying patients who unanimously are or are not appropriate for PICCs to potentially reduce the burden of consults.

Methods: We identified over 100 patients in whom a PICC consult was placed to nephrology over 10 months at 3 separate hospitals. We evaluated the PICC approval rate accounting for age, gender, serum creatinine at time of consult and baseline, CKD stage, AKI stage, diabetes, hypertension and end-stage comorbidities (cirrhosis, heart failure, malignancy, dementia, hospice). PICC placement decision for the initial 51 patients was adjudicated by the first year class of clinical fellows and 1 attending nephrologist in a blinded manner.

Results: Of the 51 adjudicated patients, 24/51 (47%) had universal agreement between both the original consulting fellow and the adjudicating fellows and attending. Presence of end-stage diagnosis, hospice status and advanced age were the major factors predictive of universal agreement for PICC placement while stage 4-5 CKD in younger patients correlated highly with nephrology recommending against PICC placement.

Conclusions: These preliminary data suggest that certain patient characteristics (such as an end-stage diagnosis) correlate highly with PICC approval including in patients with CKD stage 3-5 who may otherwise be excluded from PICC placement based on strict guidelines. Further analysis is currently underway to facilitate the development of an objective criteria list which can be used to standardize decision-making regarding PICC placement amongst nephrology practitioners and provide guidance to practitioners as to when a nephrology consult is indicated.

Optimal Treatment for Prevention of Recurrent Thrombosis After Idiopathic Renal Infarction

Maurice I. Khayat,[2] Stephen W. Olson,[1] Robert Nee.[2] *[1]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]Walter Reed National Military Medical Center, Vienna, VA.*

Background: Idiopathic renal infarction (iRI) is rare but associated with significant morbidity. Recurrent episodes of systemic thrombosis have been reported after diagnosis. Anticoagulation and antiplatelet therapy have been previously described, but no prior studies have established an optimal treatment regimen following iRI.

Methods: We performed a retrospective cohort study of 104 iRI cases (2003-2018) confirmed by review of the military electronic medical record (EMR). iRI was defined by the absence of cardioembolic, hypercoagulable or vasculopathy risk factors. The cases were divided into groups receiving (n=48) and not receiving (n = 56) anticoagulation therapy. The non-anticoagulation group was further divided into antiplatelet (n=37) and no therapy (n=19) subgroups. All cases were reviewed for evidence of the primary outcomes of recurrent arterial thrombosis, de novo venous thrombosis, and bleeding events over the maximum duration of follow up available in the EMR.

Results: Median follow up was 53 months (IQR 27-99) following iRI. There was no significant difference in the incidence of recurrent arterial thrombosis between the anticoagulation group and the non-anticoagulation group [4% (2/48) vs. 0% (0/56), p =0.21] or between the anticoagulation group and the antiplatelet subgroup [4% (2/48) vs. 0% (0/37), p =0.50]. There was also no significant difference in the incidence of de novo venous thrombosis (different cases than arterial thrombosis) between the anticoagulation group and the non-anticoagulation group [4% (2/48) vs. 0% (0/56), p =0.21] or between the anticoagulation group and the antiplatelet subgroup [4% (2/48) vs. 0% (0/37), p =0.50]. More iRI patients in the anticoagulation group had a bleeding event than both the non-anticoagulation [13% (6/48) vs. 0% (0/56), p=0.008] and antiplatelet [13% (6/48) vs. 0% (0/37), p=0.03] subgroups.

Conclusions: Anticoagulation after iRI is not associated with a reduction in either recurrent arterial thrombosis or de novo venous thrombosis, but is associated with an increased risk of bleeding. This study suggests that antiplatelet agents may be the best treatment option following iRI, but further evaluation is warranted in a randomized study.

Acute Pancreatitis (AP) in CKD5 and Kidney Transplant (Tx) Recipients: Results of a US Nationwide Analysis

Paul T. Kroner,[3] Massimo Raimondo,[3] Karl Mareth,[1] Ali Alsaad,[1] Nabeel Aslam,[2] Hani Wadei.[2] *[1]Department of Medicine, Mayo Clinic, Jacksonville, FL; [2]Department of Medicine, Division of Nephrology, Mayo Clinic, Jacksonville, FL; [3]Department of Medicine, Division of Gastroenterology, Mayo Clinic, Jacksonville, FL.*

Background: The prevalence of AP in CKD5 has not been clearly defined. **The aim of this study** was to compare the prevalence, etiology and outcomes of AP in CKD5 and kidney tx recipients with those without CKD using a large national database

Methods: Using the Nationwide Inpatient Sample (NIS) database, 433,805 patients hospitalized in 2014 with ICD-9 admission code for AP were identified. All patients were >18 yrs old and had no history of pancreas tx. Patients with AP and CKD5 not on dialysis (n=690), CKD5 on dialysis (n=11,415) and kidney tx recipients (n=1,320) were identified and were propensity-matched in a 1:1 fashion and regressed against gender, age, ethnicity and Charlson Comorbidity Index to patients with AP and no CKD (n=13,425). A multivariate logistic regression was constructed to adjust for other variables such as patients' median income, hospital region, hospital size and teaching status

Results: Results are presented in **Table 1**. Adjusted prevalence of AP was comparable between the non-CKD, CKD5, and kidney tx populations. Crude and adjusted mortality was higher in CKD5 and kidney tx patients. CKD5 patients were more likely to develop shock and require ICU than the non-CKD group. Alcoholic and gall stone AP were more common in non-CKD group while hypercalcemia AP was more common in the CKD5 group

Conclusions: 1)The adjusted prevalence of AP is comparable between non-CKD patients, CKD5 and kidney tx recipients. 2)Adjusted mortality is more than double in CKD5 and kidney tx recipients comapred to non-CKD patients. 3)Dialysis-dependent CKD5 patients hospitalized with AP had highest rate of shock and ICU stay compared to non-CKD patients. 4)Hypercalcemia is the main cause of AP in the CKD5 population irrespective of dialysis need

Prevalence, mortality and etiology of AP in patients without CKD, with CKD5 and in kidney tx recipients

	No CKD (n=13,425)	CKD5 no dialysis (n=690)	CKD5 with dialysis (n=11,415)	Kidney Tx (n=1,320)

Surprise Question and Time-to-Hospitalization in Advanced CKD

Nicolas Baddour,[1] Cassianne Robinson-Cohen,[2] Loren Lipworth,[2] Aihua Bian,[2] Thomas G. Stewart,[2] Khaled Abdel-Kader.[2] *[1]Vanderbilt University School of Medicine, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: Hospitalization is a common and high-risk event for patients with CKD. The surprise question (SQ) is a provider-based subjective health measure (i.e., "Would you be surprised if this patient died in the next 12 months?") that associates with mortality in advanced CKD; however, the association with hospitalization has not been examined.

Methods: We enrolled 488 ambulatory patients with stage 4 or 5 CKD who were ≥ 60 years of age and followed in nephrology clinic. Providers were asked the SQ using a binary and 5-point Likert scale following each office visit. Hospitalizations were determined by linkage to a statewide health database. Death was determined through linkage with national or local public health records as well as obituary searches. Other covariates were abstracted by chart review using structured forms. We determined hazard ratios for time to first hospitalization using cox proportional hazards regression. In addition to the SQ Likert scale, our multivariable model included age, gender, race, marital status, insurance status, diabetes, hypertension, cardiovascular disease, heart failure, malignancy, liver disease, chronic lung disease, number of hospitalizations in the prior year, number of medications, BMI, eGFR, serum albumin, and hemoglobin.

Results: 293 (60%) patients were hospitalized. Median time to first hospitalization was 591 days in patients with SQ binary 'surprised' answer versus 277 days in 'not surprised' counterparts. 16 (3.3%) patients died before a hospitalization. The Likert SQ response was significantly associated (p = 0.01) with time to hospitalization with hazard ratios (95 % CI) of 1.67 (0.88 – 3.17), 2.25 (1.46 – 3.5), 1.60 (1.08 – 2.37), and 1.51 (1.01 – 2.26) for 1 (not at all surprised), 2, 3, and 4, respectively (versus reference: 5 very surprised).

Conclusions: Provider response to the SQ is associated with time-to-hospitalization in older adults with Stage 4 and 5 CKD. Future studies should examine whether the SQ is useful in identifying patients with high healthcare utilization.

Determinants of Renal Function After Nephrectomy for Renal Cell Cancer in Ethnic Minorities

Albert M. Osei,[1,2] Ankit M. Mangla,[1] Edwin Okyne,[1] Chimezie U. Mbachi,[1] Peter D. Hart.[1,2] *[1]John H. Stroger Jr. Hospital of Cook County, Chicago, IL; [2]Rush University Medical Center, Chicago, IL.*

Background: Renal cell cancer, unless metastasized at the time of diagnosis, is treated by partial or radical nephrectomy. Nephrologists are often consulted to predict renal function outcome especially for those with CKD. There is paucity of data on this subject for ethnic minorities.

Methods: Electronic medical records of all patients who underwent partial or radical nephrectomies from 2007 to 2017 in a large inner-city public teaching hospital were reviewed. Inclusion criteria included pathologic confirmation of renal cell cancer. Patients who had repeat nephrectomy of the contralateral kidney were excluded. Demographics, co-morbidity, preoperative and up to two years of postoperative laboratory data were reviewed. CKD was defined as eGFR < 60ml/min/1.73m^{2}and acute kidney injury was staged by AKIN criteria (KDIGO, Kidney Int. (suppl) 2012)

Results: 422 patients met the criteria for the analysis. Percentage of African Americans, Hispanics and Caucasians was 36, 31, 29 respectively. Males: Females-62% vs 38% with no ethnic differences. African Americans were older-mean age of Hispanics, Caucasians and African Americans was 51, 53, 56 respectively (P<0.001). Diabetes was present in 24% with no ethnic difference. Hypertension was present in 49% with disproportionate 51% of these being African Americans. 11% had baseline CKD with majority (63%) being African Americans. Partial nephrectomy was performed in 40% compared to radical nephrectomy in 60% with no group differences. Postoperative AKI developed in 54% of patients and was significantly higher with radical nephrectomy than partial nephrectomy (68% vs 39% P< 0.001). At 3 months, postoperative CKD increased to 34%, remained about this level at 2 years and African Americans, Caucasians, Hispanics constituted 52, 24, 16 percent (P=0.001) respectively. Associations with postoperative CKD were African American ethnicity, preexisting CKD, radical nephrectomy, diabetes mellitus, and postoperative AKI (P<0.001 for all)

Conclusions: African Americans compared to other ethnic groups have disproportionately increased risk of chronic kidney disease following nephrectomy and this is partly explained by the higher baseline CKD.

TH-PO1146

Hypoglycemia Is Common in Patients with Type 2 Diabetes and CKD

Susana Hong, Steven Fishbane, Kenar D. Jhaveri, Vipulbhai Sakhiya, Meng Zhang, Yael T. Harris. CGM Study *Department of Medicine, Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Background: It is unclear what the incidence of hypoglycemia is among patients with type 2 diabetes mellitus (T2DM) and non-dialysis chronic kidney disease (n-CKD). The magnitude of the problem remains largely unknown, as previous studies have generally relied on random laboratory blood testing to define hypoglycemia in this population. The purpose of our study was to use continuous glucose monitoring (CGM) to determine the frequency and severity of hypoglycemia in stable outpatients with T2DM and n-CKD.

Methods: We studied 60 patients with T2DM and n-CKD defined as eGFR 0-45 ml/min. Patients wore the CGM (Abbott FreeStyle Libre Pro) for 14 days, with glucose recorded every 15 minutes, with a maximum of 1,344 glucose measurements. Blood tests were performed in the fasting state at the end of the 14 day CGM. Hypoglycemia was defined as plasma glucose below 70 mg/dL.

Results: All 60 patients had analyzable data, having worn the CGM for a mean of 12.7±2.9 days. Mean age was 72.4±10.4 years, 75% of patients were men, 15% were black, and mean eGFR 25.6±10.5. The mean glucose concentration was 152.2±56.6 mg/dL. 47/60 (78.3%) patients had at least one hypoglycemic episode. The mean number of episodes was 7.8±9.6, with a range of 0-53 episodes. The mean number of minutes of hypoglycemia was 1574±2350. This represents a mean of 7.8±11.0% of total measurement time being hypoglycemic (figure), compared to studies in T2DM without CKD where the number is closer to 1.5%.

Conclusions: Hypoglycemia is very common among patients with T2DM and CKD. Extra glucose monitoring is advisable to avoid adverse events.

T Cell-Derived Cytokines in Urine as Biomarkers for Clinical Diagnosis of Acute Interstitial Nephritis

Dennis G. Moledina,[1] Randy L. Luciano,[1] Francis P. Wilson,[1] Wassim Obeid,[1] Michael B. Kuperman,[2] Gilbert W. Moeckel,[1] Michael Kashgarian,[1] Jordan S. Pober,[1] Mark A. Perazella,[1] Lloyd G. Cantley,[1] Chirag R. Parikh.[1] *[1]Yale School of Medicine, New Haven, CT; [2]Arkana Laboratories, Little Rock, AR.*

Background: The current clinical diagnosis of acute interstitial nephritis (AIN) is challenging as it relies on combining a high-index of clinical suspicion with subsequent biopsy confirmation. We hypothesized that AIN is a T cell-mediated process and tested urine for cytokines associated with T cell immunity as biomarkers for clinical diagnosis of AIN

Methods: We enrolled consecutive participants who underwent a kidney biopsy for evaluation of acute kidney disease at 2 academic hospitals from 2015 to 2017. We measured 6 cytokines associated with T cell-mediated inflammation (TNFα, IFNγ, IL2, IL4, IL5, and IL13) in urine samples collected before the biopsy. We established AIN diagnosis through adjudication of histological images by 3 independent renal pathologists. We considered univariable and multivariable associations of clinical variables and biomarkers with AIN to develop a clinical diagnostic model

Results: Of the 154 participants, 35 (23%) had AIN and 119 had other diagnoses including acute tubular injury (n=37), diabetic kidney disease (n=15), arterionephrosclerosis (n=18), glomerular disease (n=40), and others (n=9). Patients with AIN had higher levels of TNFα and IL2 (Figure). The AUC for AIN diagnosis based on clinicians' pre-biopsy diagnosis was 0.59 (0.50-0.69). The AUC of a model containing urinary markers of inflammation (pyuria) and glomerular injury (hematuria and proteinuria) was 0.72 (0.62-0.81), which increased on addition of TNFα and IL2 to 0.82 (0.73-0.90; P<0.001) and 0.76 (0.67-0.85; P=0.009), respectively

Conclusions: Urine cytokines associated with T cell immunity were higher in patients with AIN as compared with those who had other diagnoses. These biomarkers significantly improved discrimination for AIN compared to clinicians' prebiopsy suspicion of AIN

FR-PO002

The Association of Plasma Inflammatory Mediators with CKD and Mortality After AKI: The ASSESS-AKI Study

Dennis G. Moledina,[1] Chirag R. Parikh,[1] Edward D. Siew,[3] Mark M. Wurfel,[4] James S. Kaufman,[5] Paul L. Kimmel,[6] Alan S. Go,[7] Thida C. Tan,[7] Vernon M. Chinchilli,[9] Steven G. Coca,[8] Kathleen D. Liu.[2] ASSESS-AKI *[1]Yale School of Medicine, New Haven, CT; [2]University of California at San Francisco School of Medicine, San Francisco, CA; [3]Vanderbilt University School of Medicine, Nashville, TN; [4]University of Washington, Seattle, WA; [5]VA New York Harbor Healthcare System, New York, NY; [6]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [7]Kaiser Permanente Northern California, Oakland, CA; [8]Icahn School of Medicine at Mount Sinai, New York, NY; [9]Penn State College of Medicine, Hershey, PA.*

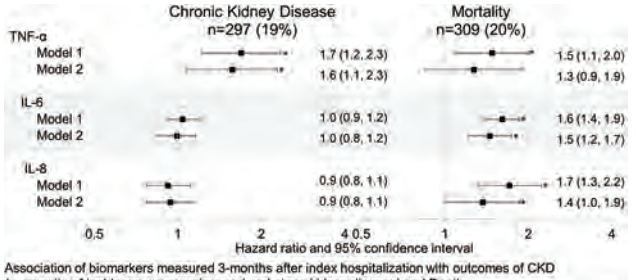
Background: Inflammation contributes to development and progression of chronic kidney disease (CKD) after acute kidney injury (AKI) in preclinical studies. We evaluated the association of plasma inflammatory mediators with clinical outcomes in the longitudinal cohort of the ASSESS-AKI study

Methods: The ASSESS-AKI study is a multicenter, prospective cohort of participants hospitalized with AKI and matched non-AKI controls (n=769 pairs). We collected plasma samples collected during the index hospitalization and 3-months after discharge. We measured 10 inflammatory mediators [interferon (IFN)γ, tumor necrosis factor(TNF)α, interleukin (IL)1β, IL2, IL4, IL6, IL8, IL10, IL12p70, and IL13] using a MesoScale multiplex assay. We tested the independent association of these mediators with (a) chronic kidney disease (CKD) composite outcome, which included CKD incidence, progression, and end-stage kidney disease, and (b) death using a multivariable trivariate Weibull regression model

Results: The CKD composite outcome occurred in 297 (19%) participants and 309 (20%) died after 4.8 (3.4, 5.9) years of follow-up. Participants with AKI were more likely to experience CKD outcome than non-AKI participants [207 (27%) vs. 90 (12%)]. In a multivariable analysis controlling for eGFR, albuminuria, smoking, body mass index, and AKI status, TNF-α levels at both hospitalization and 3-months after discharge were associated with higher risk of CKD (**Figure**), whereas none of the other biomarkers were associated with CKD. At 3 months after hospital discharge, IL6 and IL8 levels were associated with an increased risk of death, which remained significant after controlling for C-reactive protein.

Conclusions: Among the plasma inflammatory biomarkers, TNFα levels measured during hospitalization and 3-months after discharge were independently associated with CKD, whereas IL6 and IL8 at 3-months after discharge were associated with increased mortality.

Funding: NIDDK Support



Association of biomarkers measured 3-months after index hospitalization with outcomes of CKD (composite of incidence, progression, and end-stage kidney disease) and Death.
Hazard ratio per doubling in biomarker level. Model 1 controls for AKI during index hospitalization, CKD diagnosis prior to enrollment, eGFR, site, BMI, smoking status, COPD, age, sex, race, albuminuria. **Model 2** additionally controls for C-reactive protein. Asterisks indicate P<0.05

FR-PO003

Kidney Biopsy-Related Complications in Hospitalized Patients with Acute Kidney Disease

Dennis G. Moledina,[1] Randy L. Luciano,[1] Lidiya Kukova,[1] Lili Chan,[2] Aparna Saha,[2] Girish N. Nadkarni,[2] Francis P. Wilson,[1] Mark A. Perazella,[1] Chirag R. Parikh.[1] *[1]Yale School of Medicine, New Haven, CT; [2]Ichan School of Medicine, New York, NY.*

Background: We used data from the Yale biopsy cohort and Nationwide Inpatient Sample (NIS) to evaluate rates and risk factors of biopsy-related complications including adjudicated procedure-related bleeding requiring blood transfusions or angiographic interventions and death

Methods: We used data from the Yale biopsy cohort and Nationwide Inpatient Sample (NIS) to evaluate rates and risk factors of biopsy-related complications. We looked at complications including adjudicated procedure-related bleeding requiring blood transfusions or angiographic interventions and death

Results: Between 2015-2017, 159 hospitalized patients underwent a kidney biopsy at Yale for AKD evaluation. Median age of participants was 59 (47-68) years, 68 (43%) were women, 80 (51%) had stage 1 AKI, and 42 (27%) had stage 2 or higher AKI. Of these, 12 [9 (5-15)%] required a blood transfusion for biopsy-related bleeding and 3 [2 (1-5)%] required an intervention. Of the 4 [3 (1-6)%] deaths during hospitalization, none were related to the biopsy. We identified lower hemoglobin and platelet levels, female sex, trainee as proceduralist, and larger needle gauge as risk factors of post-biopsy transfusion (Table). Higher blood urea nitrogen was associated with higher rates of transfusion in patients who did not receive desmopressin [n=32 (20%)], but not in those who received desmopressin (interaction P=0.008). Among the 53,315 hospitalizations with kidney biopsies between 2012-2014 in the NIS, 925 (2%) required an intervention, similarly to the Yale cohort (P=0.88).

Conclusions: Hospitalized patients experience higher risk of post-biopsy complications and several risk factors such as lower hemoglobin and platelet count, female sex, and larger needle gauge are associated with this risk.

Funding: NIDDK Support, Private Foundation Support

Risk factors for post-biopsy bleeding requiring blood transfusion

Risk factor	Biopsy-related Transfusion (N=12)	No Biopsy-related Transfusion (N=147)	P-value*
Platelet count	112 (86, 189)	209 (150, 285)	0.003
Hemoglobin level	8.5 (7.4, 8.7)	9.4 (8.1, 10.4)	0.007
Female	9 (75%)	59 (40%)	0.02
BUN (No desmopressin)^	61 (59, 91)	38 (30, 52)	0.02
BUN (Desmopressin given)	70 (54, 120)	56 (37, 78)	0.16
Trainee	11 (92%)	88 (62%)	0.04
Needle gauge 16 (vs. 18)	10 (83%)	78 (53%)	0.04

FR-PO004

Assessment of Utility of Urine Sediment Microscopy in Hepatorenal AKI

Maria Soledad Rivera,[1,2] Ayman M. Alghamdi,[1] Juan Carlos Q. Velez.[1,2] *[1]Ochsner Clinic Foundation, New Orleans, LA; [2]Ochsner Clinical School, The University of Queensland, New Orleans, LA.*

Background: Microscopic examination of the urinary sediment (MicrExUrSed) is a useful diagnostic tool in acute kidney injury (AKI). However, its performance has not been examined in AKI in patients with end-stage liver disease (ESLD). Hepatorenal syndrome type 1 (HRS-1), a type of AKI in ESLD, is difficult to diagnose despite the existence of the International Club of Ascites (ICA) criteria. We hypothesized that MicrExUrSed improves accuracy of diagnosis of acute tubular injury (ATI) in ESLD patients with AKI.

Methods: MicrExUrSed was performed in patients with AKI stage ≥ 2 with or without ESLD over a 6-month period. HRS-1 was defined by the ICA criteria. Urine Na <20 mEq/L, urine volume <500 ml, mean arterial pressure <75 mmHg and serum Na <135 mEq/L were supportive criteria. Definite HRS-1 was defined as: ICA + supportive criteria were met. Possible HRS was defined as: only ICA criteria were met. No HRS was defined as: ≥1 ICA criteria was not met. Urinary cast scores (based on Chawla *et al* and Perazella *et al*) were assigned to each specimen. Chawla scores (CS) 3-4 and Perazella scores (PS) 2-3 were deemed consistent with ATI and not HRS-1.

Results: Distribution of casts (>25% lpf with ≥1 cast) differed between the ESLD (n=35) and non-ESLD (n=44) groups. Hyaline casts (HC), renal tubular epithelial cell casts (RTECC) and waxy casts (WC) were identified more often in ESLD compared to non-ESLD [57 vs 29% (p<0.05); 26 vs 5% (p<0.01) and 20 vs 5% (p<0.05) for HC, RTECC and WC], but not granular casts [43 vs 61%]. In the ESLD group, total bilirubin was significantly higher for those with RTECC [35.9 vs. 6.4 mg/dL (p<0.0001)] suggesting pathogenesis of bile cast tubulopathy. A diagnosis of Definite HRS-1 was assigned to 6 (17%), Possible HRS-1 to 14 (40%) and No HRS-1 to 15 (43%) patients. Addition of MicrExUrSed changed the diagnosis in 11 (31%) patients: Definite HRS-1 was changed to No HRS-1 in 2 and Possible HRS-1 was changed to No HRS-1 in 9, changing the final No HRS-1 count to 26 (74%) and HRS-1 to 9 (26%). Nonetheless, vasoconstrictor therapy to treat HRS-1 was given to 23 (66%) patients.

Conclusions: MicrExUrSed can aid in the diagnosis of AKI in ESLD by identifying those with evidence of ATI, i.e., not consistent with HRS-1, with potential implications on the use of vasoconstrictor therapy and/or dialysis decisions.

FR-PO005

Impact of Porto-Pulmonary Hypertension in the Course of Hepatorenal AKI

Maria Soledad Rivera,[1,2] Alaa E. Mohammed,[1] Juan Carlos Q. Velez.[1,2] *[1]Ochsner Clinic Foundation, New Orleans, LA; [2]Ochsner Clinic School, University of Queensland, New Orleans, LA.*

Background: Porto-pulmonary hypertension is prevalent in cirrhotic patients. However, its impact on the clinical course of hepatorenal acute kidney injury (AKI) has not been previously investigated. We hypothesized that echocardiographic evidence of pulmonary hypertension affects the interplay between change in mean arterial pressure (MAP) and course of hepatorenal AKI during vasoconstrictor therapy as well as the overall renal outcome.

Methods: We conducted a prospective observational study of hospitalized patients with AKI stage ≥ 2 (AKIN) and cirrhosis over a 4-month period. Daily MAP and serum creatinine (sCr) values were collected, as well as pulmonary arterial pressure (PAP) estimated by echocardiography at the time of AKI. Patients were divided into PAP tertiles: 1st ≤30, 2nd 31-40, 3rd >40 mmHg. Daily change in MAP (ΔMAP) and daily change in sCr (ΔsCr) from baseline were computed. Renal outcome chosen was need for renal replacement therapy (RRT).

Results: Among 52 patients, 19 (37%) were female, mean age was 56 (range 25-75). Baseline values were median MAP 76 (IQR 71–84) mmHg, median sCr 2.3 (IQR 1.7–3.7) mg/dL, median serum albumin 2.3 (IQR 1.8–3) g/dL and median total bilirubin 4.1 (IQR 1.8–27.2) mg/dL. A significant inverse correlation was found between ΔMAP and ΔsCr on the following day (r = -0.20, p=0.0003) throughout the course of AKI. PAP was obtained in 36 patients. The correlation between ΔMAP and ΔsCr within each PAP tertile were:

≤30: r = 0.08 (p=0.37), 31-40: r = -0.36 (p=0.002) and >40: r = -0.40 (p=0.0006). Thus, as PAP increases, a negative correlation between ΔMAP and ΔsCr on the following day strengthens. Furthermore, there was a trend for an increased need for RRT within those in the highest tertile of PAP (need for RRT: 28.6%, 33%, and 70%, for the 1st, 2nd, and 3rd tertiles, respectively (p=0.0511, chi-square for trend).

Conclusions: Cirrhotic patients with more severe pulmonary hypertension exhibit a significantly stronger negative correlation between ΔMAP and ΔsCr, suggesting that those with higher PAP may display increased sensitivity to improved kidney function upon optimization of MAP with vasoconstrictors. Moreover, higher PAP is associated with greater need for RRT, adding complexity to the pathogenesis of hepatorenal AKI.

FR-PO006

Angiopoietin-2 Predicts Mortality and Kidney Outcomes in Decompensated Cirrhosis

Andrew S. Allegretti,[1] Xavier F. Parada,[1] Guillermo Ortiz,[6] Joshua Long,[1] Scott Krinsky,[1] Sophia Zhao,[1] Bryan C. Fuchs,[1] Dongsheng Zhang,[3] S. Ananth Karumanchi,[2] Sahir Kalim,[4] Sagar U. Nigwekar,[1] Ravi I. Thadhani,[5] Samir M. Parikh,[3] Raymond T. Chung.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Cedars-Sinai Medical Center, Los Angeles, MA; [3]Beth Israel Deaconess Medical Center, Boston, MA; [4]Massachusetts General Hospital/ Harvard Medical School, Cambridge, MA; [5]Cedars-Sinai, Los Angeles, CA; [6]Medicine, St. Elizabeth's Hospital, Boston, MA.*

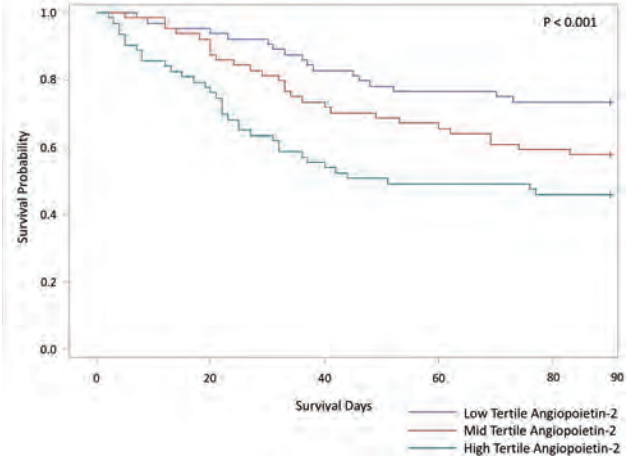
Background: AKI in decompensated cirrhosis has limited therapeutic options and novel mechanistic targets are urgently needed. Angiopoietin-2 is a context-specific antagonist of Tie2, a receptor that signals vascular quiescence. Considering the prominence of vascular destabilization in decompensated cirrhosis, we evaluated Angiopoietin-2 to predict clinical outcomes.

Methods: Serum Angiopoietin-2 was measured in a prospective cohort of hospitalized patients with decompensated cirrhosis and AKI. Clinical outcomes were examined over a 90-day period and analyzed according to Angiopoietin-2 levels. Primary outcome was 90-day mortality.

Results: We analyzed 191 patients (median Angiopoietin-2 level 18.2 [IQR 11.8, 26.5] ng/mL). Median MELD score was 23 [17, 30] and 90-day mortality was 41%. Increased Angiopoietin-2 was associated with increased mortality (died 21.9 [13.9, 30.3] ng/mL vs. alive 15.2 [9.8, 23.0] ng/mL; p <0.001), higher AKIN stage (stage I 13.4 [9.8, 20.1] ng/mL vs. stage II 20.0 [14.1, 26.2] ng/mL vs. stage III 21.9 [13.0, 29.5] ng/ml; p = 0.002) and need for renal replacement therapy (16.5 [11.3, 23.6] ng/mL vs. 25.1 [13.3, 30.3] ng/mL; p = 0.005). The association between Angiopoietin-2 and mortality was significant in unadjusted and adjusted Cox regression models (p ≤ 0.001 for all), and improved discrimination for mortality when added to MELD score (integrated discrimination increment 0.067; p = 0.001).

Conclusions: Angiopoietin-2 was associated with mortality and other clinically relevant outcomes in a cohort of decompensated cirrhotic patients with AKI. Further experimental study of Angiopoietin/Tie2 signaling is warranted to explore its potential mechanistic and therapeutic role in this population.

Funding: NIDDK Support, Private Foundation Support



90-day survival by Angiopoietin-2 tertile. Low (<13.5 ng/mL), Mid (13.5-23 ng/mL), High (> 23 ng/mL)

FR-PO007

Post-Discharge Long-Term Outcomes of the Dialysis-Requiring AKI During the Perioperative Period of Liver Transplantation

Soojin Lee,[1] Sehoon Park,[1] Yaerim Kim,[1] Chun Soo Lim,[2] Kwon Wook Joo,[1] Dong Ki Kim.[1] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University Boramae Medical Center, Seoul, Republic of Korea.*

Background: Patients undergoing liver transplantation (LT) are prone to acute kidney injury (AKI), which is known to decrease patient survival, and considerable portion of AKI patients require renal replacement therapy (RRT) during the perioperative period of LT. Nevertheless, long-term outcomes among the patients requiring RRT are not thoroughly evaluated yet.

Methods: The nationwide, population-based cohort study was conducted. Adult patients received LT in tertiary hospitals of Korea between 2006 and 2015 were considered. Patients who underwent RRT or received LT prior to the index admission were excluded. The RRT group consisted of the patients received RRT during the perioperative period of LT and the control group included the patients who did not underwent RRT.

Results: Of 8,421 patients underwent LT, 5,911 received RRT. Among the patients received RRT, 802 underwent continuous renal replacement therapy (CRRT). All-cause mortality [adjusted hazard ratio (HR) 1.52 (1.26-1.83), P<0.001] and progression to end-stage renal disease (ESRD) [adjusted HR 2.93 (2.34-3.66), P<0.001] were increased in RRT patients (Table 1). However, the risk of MACE [adjusted HR 1.17 (0.80-1.70), P=0.430] were similar between the two groups. Among the patients who received RRT, all-cause mortality [adjusted HR 2.92 (1.48-5.76), P=0.002] was worse in CRRT group, compared to intermittent renal replacement therapy (IRRT) group. ESRD progression [adjusted HR 0.36 (0.24-0.52), P<0.001] was improved with CRRT application and the risk of MACE [adjusted HR 1.11 (0.42-2.94), P=0.832] was comparable between the two groups.

Conclusions: Requirement of RRT during the perioperative period of LT had worse long-term mortality and ESRD progression compared to the patients who did not receive RRT. The risk of MACE in patients underwent RRT was comparable to the control groups.

Funding: Commercial Support - Baxter (LSO-18-70260)

Table 1. Prognosis of patients underwent RRT

	Model 1		Model 2	
	HR (95% CI)	p-value	adjusted HR (95% CI)	p-value
Mortality	1.14 (0.95-1.36)	0.162	1.52 (1.26-1.83)	<.001
MACE	1.03 (0.71-1.49)	0.876	1.17 (0.80-1.70)	0.430
Progression to ESRD	3.22 (2.60-3.99)	<.001	2.93 (2.34-3.66)	<.001

HR = hazard ratio, CI = confidential interval.

Model 1 was an unadjusted simple model.

Model 2 was adjusted for age, sex, comorbidities, and the etiology of liver disease.

FR-PO008

Cisplatin-Induced Kidney Injury Is Transient and Associated with Short-Term Elevation of Urine Interleukin-18 in Patients with Testicular Cancer

Kelly McMahon,[1] Alan C. Cameron,[2] Jeff D. White,[3] Paul Welsh,[2] Michael Zappitelli,[4] Rhian Touyz,[2] Patrick B. Mark,[2] Ninian N. Lang.[2] *[1]McGill University, Montreal, QC, Canada; [2]University of Glasgow, Glasgow, United Kingdom; [3]Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom; [4]Toronto Hospital for Sick Children, University of Toronto, Toronto, ON, Canada.*

Background: Cisplatin causes acute kidney injury (AKI) but changes in urinary AKI biomarkers are not well defined in clinical practice. We investigated short- and medium-term AKI using novel biomarkers over 9 months in patients with testicular cancer treated with cisplatin.

Methods: Prospective observational study of men with testicular cancer in 3 groups following orchiectomy: 1) surveillance; 2) adjuvant cisplatin (1-2 cycles); 3) metastatic disease with high dose cisplatin (3-4 cycles). Blood/urine was collected at 6 visits: baseline, 24h, 6 weeks, 3, 6 and 9 months for renal injury markers.

Results: 27 men (median age 34y [IQR 31-40y]) were recruited: surveillance (N=10); adjuvant cisplatin (N=7); metastatic cisplatin (N=10). Urine tubular injury markers (interleukin-18 [IL-18], neutrophil gelatinase-associated lipocalin [NGAL], vascular endothelial growth factor [VEGF], kidney injury molecule-1 [KIM-1]), urine albumin/creatinine ratio (ACR) and serum cystatin C (CysC) were elevated at 24h and 6 weeks (KIM-1) post cisplatin in adjuvant and metastatic groups (all: P<0.05 *vs.* baseline). These normalized by 6 weeks (IL-18, NGAL, VEGF, ACR, CysC) and 3 months (KIM-1). eGFR was within normal range throughout. Urine IL-18 rose in both cisplatin groups at 24h (median [IQR]: adjuvant 24h 22.8 [16.4-34.7] *vs.* baseline 6.8 [5.7-15.9]; metastatic 24h 23.7 [20.1-36.1] *vs.* baseline 9.2 [7.2-11.9] pg/mg, P<0.05) and returned to baseline by 6 weeks.

Conclusions: Cisplatin nephrotoxicity is reversible over 3 months and is evident with use of novel biomarkers. Elevation of IL-18 supports a major inflammatory renal insult. This provides evidence to support investigation of anti-inflammatory drugs to prevent cisplatin toxicity.

FR-PO009

Role of Plasma Cystatin C and Urine NGAL in Prediction of AKI and Mortality in Patients with Acutely Decompensated Cirrhosis: A Prospective Cohort Study

Sang-Kyung Jo, Jihyun Yang, Junyong Lee, Sewon Oh, Myung-Gyu Kim. *Korea University Anam Hospital, Seongbuk-Gu, SEOUL, Republic of Korea.*

Background: Acute kidney injury (AKI) is the most frequent and devastating complication in cirrhotic patients. Emerging evidence suggests that novel biomarkers could predict AKI earlier than conventional markers and better predict prognosis in these patients.

Methods: To determine the incidence and prognosis of AKI in acutely decompensated cirrhotic patients and also test whether plasma cystatin C, urine neutrophil gelatinase-associated lipocalin (NGAL) or tissue inhibitor of metalloproteinase-2 (TIMP-2), insulin-like growth factor 7 (IGFBP7) could predict the development of AKI and prognosis.

Results: Of 111 patients, 45 (40.5%) developed AKI during hospitalization. Although 53.3% of AKI episodes were transient, stage 1 AKI, overall mortality was significantly higher compared to those without AKI (25% vs. 46.5%, p=0.02). Although initial BUN and serum creatinine were not different, plasma cystatin C and urine NGAL at the time of admission were significantly increased in patients who developed AKI and also death. Plasma cystatin C and urine NGAL were independently associated with the development of AKI after adjusting for clinical variables including age, co-morbidity, and Child-Pugh score. [plasma cystatin C, odds ratio (OR) 2.09; 95% confidence interval (CI), 1.01-4.35), urine NGAL, OR 1.04, CI 1.01-1.05]. Although these biomarkers failed to predict mortality independent of clinical variables, urine NGAL significantly improved the accuracy of MELD in predicting mortality.

Conclusions: The incidence of AKI is high and even minor increase in serum creatinine is associated with high mortality in decompensated cirrhosis. Novel biomarkers including plasma cystatin C or urine NGAL might be useful in the earlier diagnosis of AKI and also in predicting mortality in acutely decompensated cirrhotic patients.

FR-PO010

Utility of Serum Cystatin C (SCysC) to Assess AKI and Day 90 (D90) Major Kidney Adverse Events (MAKE90) Following Cardiac Surgery (CS) in Subjects Treated with QPI-1002

Lukas J. Lehner,[1] U. Schwertschlag,[6] Matthias Thielmann,[2] Andre Lamy,[3] David Corteville,[4] D. P. Cafaro,[6] A. Patel,[6] Madhav Swaminathan,[5] D. J. Odenheimer,[6] P. Chan,[6] Gabor Szabo,[7] Yuval Mathews,[8] D. Rothenstein,[8] Elizabeth C. Squiers.[6] The Quark AKI Study Team *[1]Charité Universitätsmedizin Berlin, Berlin, Germany; [2]West-German Heart and Vascular Center Essen, University Duisburg-Essen, Essen, Germany; [3]McMaster University, Hamilton, ON, Canada; [4]McLaren Northern Michigan, Petoskey, MI; [5]Duke University Medical Center, Durham, NC; [6]Quark Pharmaceuticals, Inc., Fremont, CA; [7]University of Heidelberg, Heidelberg, Germany; [8]Quark Pharmaceuticals, Nes Ziona, Israel.*

Background: QPI-1002 (QPI), a siRNA targeting p53, is being developed for acute kidney injury (AKI) following CS. KIDGO guidelines recommend assessment of renal function based on SCysC in settings where serum creatinine (SCr) may be unreliable (e.g. decreasing muscle mass).

Methods: Initial results from a global Phase 2 double-blind study with QPI for AKI (N=341: QPI=165, Placebo (PL)=176) (NCT#02610283) (presented at ASN 2017: SA-OR124). SCr and SCysC levels were both measured.

Results: QPI significantly reduced (↓) AKI (35.4 % QPI vs 50.6% PL; p=0.0047), ↓AKI severity across all grades (p=0.002), and ↓ AKI duration (p=0.0016) assessed by SCysC similarly to SCr (ASN 2017). In a higher risk subpopulation [proteinuria, low baseline eGFR, and/or insulin dependent diabetes, (N=241)], QPI ↓MAKE (Death, RRT or a ↓in eGFR by 25%) at D90 using eGFRCys (37% QPI vs 51% PL; RRR=29%; p=0.024), but not using eGFRCr. To determine the cause of the divergence of SCr and SCys eGFRs at D90, subjects were grouped by the discordance of SCr and SCys after the method of Grubb using the differences of eGFRs between baseline and D90. Groups were as per Figure 1. The Concordant population (N=114) also had a treatment effect in favor of QPI using eGFRCr for MAKE90 (RRR23%). The largest discordant group, Discordant 1 (N=55), compared to Concordant population, had longer ICU stays (6 vs 4.4 days), more MACE events (10.9 vs. 6.2 %) and had muscle mass loss expressed as ↓sarcopenia index (Kashani et al 2018) with a 28% decrease.

Conclusions: SCr and SCys post CS (D1-D5) were concordant and QPI-1002 significantly reduced the incidence, severity and duration of AKI by either analyte. QPI significantly ↓MAKE 90 in a subpopulation of higher risk subjects when evaluated by SCys. Consistent with other reports, SCr appeared to overestimate eGFR at D90 as compared to SCys in a subset of subjects at risk for decreased SCr production.

FR-PO011

Improving the Kinetic GFR by Taking Volume Changes into Account

Sheldon Chen. *MD Anderson, Houston, TX.*

Background: The kinetic glomerular filtration rate (GFR) equation was developed to estimate the kidney function even as the serum creatinine is changing. One shortcoming of the equation is that it assumes a constant volume of distribution for the creatinine. The volume in hospitalized patients can fluctuate quickly and drastically. For example, in hypotension and multiorgan failure, aggressive volume resuscitation would dilute the creatinine concentration, slowing down a rise in creatinine and making the acute kidney injury (AKI) appear milder.

Methods: To undo the confounding effects of volume change, we improved the kinetic GFR model by introducing variables to describe the ongoing influence of volume change. In the upgraded model, we solved its differential equation to yield a formula that predicts how the serum creatinine would evolve, as determined by the creatinine generation rate, creatinine clearance rate (~GFR), and now a volume change rate. Clinically, the starting and ending creatinines are measured by the lab, so the equation is rearranged to solve for the kinetic GFR.

Results: The new kinetic GFR equation was tested in multiple patients, some of whom had extreme changes in volume. In all cases, incorporating volume information resulted in the calculated GFR being correctly adjusted, concordant with: 1) Volume Gain → A) AKI looks less severe; GFR is actually lower, or B) renal recovery looks very robust; GFR is actually not as high, and 2) Volume Loss → A) AKI looks quite severe; GFR is actually not as impaired, or B) renal recovery looks unimpressive; GFR is actually higher than believed. Case: a 66-year-old woman has ischemic lactic acidosis and hypotension (87/53 mm Hg). She was given normal saline at 300 mL/h. NS plus the many intravenous drips (pressors and antimicrobials) added up to a net volume gain of 5 liters in 12 hours. With oliguria, her serum creatinine rose from 0.84 to 1.25 mg/dL over a 16-hour period, encompassing the above 12 hours. The old equation would calculate a kinetic GFR of 48.3 mL/min. The new

equation would calculate a kinetic GFR of 38.6 mL/min. The difference of 9.7 mL/min was due to massive volume gain, which masked the true severity of her AKI.

Conclusions: Body volume changes can significantly affect creatinine kinetics. The new volume-adjusted equation improves the precision of kinetic GFR estimation, which could aid in diagnosis and medication dosing.

FR-PO012

Evaluation of Finger-Stick Point of Care Creatinine Assay for Early Diagnosis of AKI in the Community

Joshua Storrar, James Ritchie, Denise Darby, Khalid Alshawy, Smeeta Sinha, Dimitrios J. Poulikakos. Renal Medicine Department *Salford Royal NHS Foundation Trust, Salford, United Kingdom.*

Background: Acute kidney injury (AKI) is a major health problem which occurs in the context of infection in more than 50% of cases. Recent guidance for sepsis mandates the delivery of a sepsis bundle within one hour of presentation in patients with suspected infection and AKI. However, the majority of these cases arise in the community. Primary care physicians need to make a decision for hospital referral at the first assessment. The aim of this study was to evaluate finger-stick capillary point of care (POC) creatinine (Cr) testing for real time diagnosis of AKI and evaluate its role in the clinical decision making process during the assessment of sepsis in nursing home residents.

Methods: The precision of the POC Cr assay was measured as coefficient of variation (CV) ie the ratio of the standard deviation to the mean over 5 repeated measurements. Correlation, reliability and agreement were estimated by using Pearson's correlation, Intraclass Correlation Coefficient calculation and the Bland-Altman method respectively. POC Cr from finger-stick capillary samples, along with concurrent serum Cr samples measured by Siemens Advia 2400 Jaffe in our laboratory, were collected from nursing home residents and A&E patients.

Results: Mean CV from 9 samples with 5 repeated measurements was 0.044±0.018 (min=0.018, max=0.081). There were 70 paired samples from 66 patients aged 78±17. POC Cr was 116±64umol/L and Serum Cr 84±41umol/L. Pearson correlation was 0.804 (p=0.000), Figure 1A. Average Intraclass Correlation Coefficient was 0.843 (confidence interval 0.748-0.903, p=0.000). Bland-Altman plot is presented in Figure 1B. Mean difference between POC Cr and Serum Cr was 32±39, 4 values were outside the limits of agreement defined as mean difference ±1.96 SD (95% confidence interval) and 3 of 4 were above 200.

Conclusions: Finger-stick POC Cr has good agreement with laboratory method and may be used to assist clinical decision making. It can reliably detect severe AKI stages 2 and 3. POC Cr tends to overestimate serum Cr and has decreased agreement in Cr values above 200 umol/L.

Leucine Rich α-2 Glycoprotein Is a Novel Urinary and Serum Biomarker for AKI

Tomohiro Eguchi, Yoshio Terada, Yoshinori Taniguchi, Hirofumi Nishikawa. *Kochi University, Nankoku city, Japan.*

Background: Leucine-rich α-2 glycoprotein (LRG) is one of serum glycosylated proteins with 347 amino acids, and reported that serum LRG is a novel disease activity biomarker for rheumatoid arthritis and inflammatory bowel disease. However, little is known about the role of LRG in acute kidney injury (AKI) pathogenesis. We examined renal LRG expression and urinary LRG level using mice AKI model and clinical samples.

Methods: We evaluated LRG mRNA and protein expression in kidney in the bilateral renal ischemia-reperfusion injury (IRI) mice AKI model. We also examined immunohistological examination of LRG localization by confocal microscopy, and measured serum and urinary LRG levels. We evaluate the mechanism of LRG regulation using cultured renal tubular cells (NRK-52E cells). In clinical study, we measured urinary LRG in contrast media-induced AKI patients using ELISA, and immunohistological examination of LRG in AKI and minimal change renal biopsy samples.

Results: In mice with IRI-induced AKI, renal mRNA and protein expression of LRG were induced from 6 h and 12 h and peaked at 24 h and 48 h after IRI, respectively. In control mice kidney, only a very few expression of LRG was observed. Immunohistological examination showed that LRG expression was observed mainly on renal tubular cells in AKI mice. The LRG positive tubular cells are mainly co-stained with AQP1 using confocal microscopy. We also find that serum and urinary LRG levels were up-regulated in IRI-induced AKI from 12h. In NRK-52E cells, TNF-alpha and LPS stimulated LRG expression. Notably, in contrast media-induced AKI patients, urinary LRG levels were increased from 6 h. LRG staining were enhanced in AKI renal-biopsy samples mainly at proximal tubules. In contrast, only a few LRG staining was observed in minimal change renal biopsy samples.

Conclusions: Our results demonstrate that LRG is up-regulated in renal tissues in both mice and human AKI, and that urine and serum LRG are increased in early phase of AKI. Inflammatory cytokines such as TNF-alpha stimulates expression of LRG in renal tubular cells. Thus, urine and serum LRG could serve as a potential early biomarker in AKI.

FR-PO014

Performance of Urinary Osteopontin for the Prediction of AKI Prognosis and Clinical Outcomes in Critically Ill Adults

Lynn Redahan,[2] Stephen Duff,[2] Sebastian Vencken,[1] Peter P. Doran,[1] Patrick T. Murray.[2] The Dublin Acute bioMArker Group Evaluation (DAMAGE) Study Group *[1]University College Dublin, Dublin, Ireland; [2]UCD School of Medicine and Medical Science, Dublin 7, Ireland.*

Background: Osteopontin (OPN) is a secreted phosphoprotein whose expression is upregulated in several experimental models of acute kidney injury (AKI). Due to the localisation of its expression, it has been suggested to be a marker of injury to the ascending limb of the loop of Henle. OPN expression is increased in regenerating proximal tubular cells following injury and it may play a role in renal repair and regeneration. The full extent of the role of OPN in human AKI is incompletely understood. We hypothesised that OPN levels may predict adverse outcomes, such as AKI progression and mortality, in critically ill patients.

Methods: The Dublin Acute Biomarker Group Evaluation (DAMAGE) Study is a prospective multicenter observational study investigating the utility of several urinary biomarkers for the diagnostic and prognostic assessment of AKI in critically ill adults. We conducted a subgroup analysis of this cohort to evaluate whether urinary OPN levels could predict which patients would develop progressive AKI and other adverse clinical outcomes.

Results: The final analysis included a total of 33 patients with a mean age of 59.3 years (S.D. 17.5). Urinary OPN levels normalised to urinary creatinine on Day 1 and on the day of AKI diagnosis did not differ significantly between survivors to day 30 and non-survivors. There was no statistically significant difference in urinary OPN levels between those who met the criteria for progression (a composite of progression to a higher KDIGO AKI stage, renal replacement therapy or death) and those who did not. There was a significant difference in the distributions of urinary OPN levels in patients who survived to the time of ICU discharge and those who did not (p=0.043).

Conclusions: In conclusion, although the sample size for this subset analysis is small, the lack of major difference in estimated risks between groups (odds ratios: ~0.99-1.01 per 100 mg/g OPN/creatinine), even when adjusted for study centre, appears to show that OPN levels measured on Day 1 or on the day of AKI diagnosis is unlikely to be a predictor of AKI progression or survival.

FR-PO015

Biomarkers of Kidney Injury and Repair and Risk for Future Kidney Events: The ASSESS-AKI Study

Jeremy Puthumana,[3] Kathleen D. Liu,[2] Edward D. Siew,[4] William B. Reeves,[5] Jonathan Himmelfarb,[6] Steven G. Coca,[7] Alan S. Go,[8] Chi-yuan Hsu,[9] Talat Alp Ikizler,[13] Mark M. Wurfel,[15] Amit X. Garg,[10] James S. Kaufman,[14] Paul L. Kimmel,[11] Vernon M. Chinchilli,[12] Chirag R. Parikh.[1] ASSESS-AKI Study Investigators *[1]Yale University and VAMC, New Haven, CT; [2]University of California at San Francisco School of Medicine, San Francisco, CA; [3]Yale School of Medicine, New Haven, CT; [4]Vanderbilt University School of Medicine, Nashville, TN; [5]University of Texas Health Science Center San Antonio, San Antonio, TX; [6]Kidney Research Institute, Seattle, WA; [7]Icahn School of Medicine at Mount Sinai, New York, NY; [8]Kaiser Permanente Northern California, Oakland, CA; [9]University of California San Francisco, San Francisco, CA; [10]London Health Sciences Centre, London, ON, Canada; [11]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [12]Penn State College of Medicine, Hershey, PA; [13]Vanderbilt University Medical Center, Nashville, TN; [14]VA New York Harbor Healthcare System, New York, NY; [15]University of Washington, Seattle, WA.*

Background: Acute kidney injury (AKI) is a complex disorder associated with increased risk of CKD and mortality. While kidney function may improve after an episode of AKI, subclinical kidney damage may remain that connotes propensity for GFR decline over time. We sought to examine the utility of biomarkers associated with renal injury and repair during and after AKI.

Methods: In a prospective longitudinal parallel cohort study, we enrolled 769 adults hospitalized with AKI and 769 hospitalized adults without AKI from 4 centers in North America. Interleukin-18 (IL-18), neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule-1 (KIM-1), monocyte chemoattractant protein-1 (MCP-1), uromodulin (UMOD), and YKL-40 were measured in urine samples collected during index hospitalization and outpatient follow-up at 3 months. We followed patients for a median of 4.2 years and assessed the association of the biomarkers with a composite renal outcome (CKD incidence, CKD progression, or ESRD) and death.

Results: Urinary biomarkers at the time of index hospitalization were not significantly associated with the composite renal outcome or death. As shown in **Figure,** urinary IL-18, NGAL, KIM-1, MCP-1, and YKL-40 at 3 months were independently associated with risk of renal events in adjusted analyses. In addition, higher urinary NGAL and YKL-40 levels at 3 months were independently associated with increased risk of mortality.

Conclusions: Urine biomarkers were detectable at 3 months, suggesting ongoing inflammation, repair, and fibrosis even after clinical AKI has resolved. Biomarker levels at 3 months identify patients at risk for renal events and death.

FR-PO016

Early increase in Renal Injury Urinary Biomarkers Associated with AKI Development in Major Elective Non-Vascular Abdominal Surgeries

Lia J. Marçal,[2] Graziela R. de Souza,[2] Veronica Torres,[2] Flávia B. Azevedo,[2] Dirce M. Zanetta,[1] Luis Yu,[2] Leila Antonangelo,[2] Emmanuel A. Burdmann.[2] *[1]University of São Paulo, S Paulo, Brazil; [2]University of Sao Paulo Medical School, Sao Paulo, Brazil.*

Background: There are few data on the incidence of acute kidney injury (AKI) diagnosed by KDIGO criteria and the role of renal injury urinary biomarkers (uBMs) for predicting AKI in patients (pts) submitted to major elective non-vascular abdominal surgeries (MENVAS).

Methods: A total of 225 pts were evaluated, peri-operatively and from the ICU admission up to 7 days. Serum Creatinine (SCr) was assessed before surgery and once a day up to 7d or until ICU discharge. Hourly Urinary Ouput (ml/kg/h) was measured daily. AKI was diagnosed using either SCr or/and urinary output (UO) according to KDIGO definitions. Urine sample was collected 1 day before surgery (baseline), 30 min, 12 and 24h after ICU admission. Five uBMs were assessed: monocyte chemotactic protein 1 (MCP-1), interleukin 18 (IL-18), kidney injury molecule-1 (KIM-1), microalbuminuria (μalb) and neutrophil gelatinase-associated lipocalin (NGAL) by Luminex x-MAP method. Data are presented as median (first and third quartiles) or frequency. Statistical significance was p<0.05.

Results: Overall, age was 55±15y, 58,2% were female, hospital LoS was 17,7±16.9d, ICU LoS was 3.2±3.2d and mortality was 6,7%. A total of 126 pts (56%) developed AKI - majority KDIGO I (77,8%). Those developing AKI KDIGO II and III had significantly higher BMs values compared to pts AKI KDIGO I or non-AKI in all studied times, but the SCr didn't rise at the same period (IMAGE 1). UO has the best performance: 77,6% pts (KDIGO I) and 89,3% (KDIGO II and III) in 6h; NGAL showed a good performance 24h after ICU admission.

Conclusions: We found a strikingly high incidence of MENVAS-associated AKI diagnosed by KDIGO criteria in patients admitted ICU. Those who developed more severe AKI showed significantly higher uBMs in all times studied, including the preoperative period. uBM increase earlier and before SCr.

Diagnostic Utility of Serial Microscopic Examination of the Urinary Sediment in AKI

Ayman M. Alghamdi,[1] Maria Soledad Rivera,[2] Juan Carlos Q. Velez.[1,2] *[1]Ochsner Clinic Foundation, New Orleans, LA; [2]Ochsner Clinical School, The University of Queensland, New Orleans, LA.*

Background: Urine microscopy is a clinical tool of diagnostic and prognostic value in acute kidney injury (AKI). However, the natural history and timing of cast formation remains underexplored. A single inspection of a urine specimen during the course of AKI is a mere snapshot that depends on the day of inspection. We hypothesized that longitudinal inspection of the urinary sediment provides additional diagnostic information otherwise not identified in a single inspection.

Methods: Microscopic examination of the urinary sediment (MicrExUrSed) +/- Sternheimer-Malbin stain was undertaken in all patients with AKI stage ≥ 2 who were seen on consultation in an inpatient nephrology service during a 6-month period. MicrExUrSed were done on the day of consult (day 1), 48 hours later (day 3) and 96 hours later (day 5). Urinary cast scores (based on Chawla *et al* and Perazella *et al*) were assigned to each specimen. Chawla scores (CS) 3-4 and Perazella scores (PS) 2-3 were categorized as consistent with acute tubular injury (ATI), whereas CS 1-2 and PS 0-1 were categorized as non-diagnostic for ATI (non-ATI). Worsening AKI was defined as a rise in serum creatinine (sCr) ≥ 0.3 mg/dL at either day 3 or 5.

Results: At least 2 serial specimens were collected in 60 patients (mean age 58, 32% women, mean sCr at day 1 3.8 mg/dL). Overall, CS and PS category changed over time in 16 (27%) patients, and the change was observed at day 3 in almost all cases (15 of 16). On day 1, a CS and PS consistent with non-ATI was assigned to 31 (52%) patients. Among those 31 patients, CS and PS changed from non-ATI category to ATI in 9 (24%) at day 3. Those 9 patients accounted for 32% of the total 38 with ATI score. Patients with worsening AKI were more likely to change their score from non-ATI to ATI compared to those with stable or improved AKI [relative risk 3.3 (CI: 1.0 – 10.9) for CS (p = 0.047); 8.3 (CI: 1.1 – 63.1) for PS (p = 0.041)].

Conclusions: Serial MicrExUrSed reveals diagnostic findings of ATI otherwise not identified in a single examination, particularly in specimens of patients with worsening AKI. A repeat MicrExUrSed within 48 hours may be warranted in cases of worsening AKI with unclear etiology.

FR-PO018

Serum Procalcitonin as a Predictor for the Development of AKI in Critically Ill Patients

Kayeong Chun, Ae jin Kim, Han Ro, Jae Hyun Chang, Hyun Hee Lee, Wookyung Chung, Ji Yong Jung. *Division of Nephrology, Department of Internal Medicine, Gachon University Gil Medical Center, College of Medicine, Gachon University, Incheon, Republic of Korea.*

Background: Procalcitonin (PCT) has been recognized as one of useful markers for the diagnosis of systemic inflammatory response syndrome. In addition, it has been reported that PCT is affected by renal function. However, there are few studies regarding the relationships between PCT and the development of acute kidney injury (AKI). Hence, we investigated whether serum PCT levels at the time of admission can predict the development of AKI and clinical outcomes.

Methods: We retrospectively analyzed data of 790 patients in whom PCT were measured on admission to the intensive care unit. We attempted to investigate that the serum PCT level at the time of admission could be as a predictor for development of AKI according to the groups classified in to the septic and the non-septic patients and risk factor for all-cause mortality.

Results: The serum PCT levels were significantly higher in patients with AKI than in those without AKI (P < 0.001). After adjustment of confounding factors, PCT still remained an independent risk factor for AKI (odds ratio [OR], 2.096; 95% confidence intervals [CI], 1.378–3.190; P = 0.001). The OR (95% CI) for AKI development among those with and without sepsis were 2.620 (1.230–5.582, P = 0.013) and 1.928 (1.119–3.321, P = 0.018), respectively.

Conclusions: Serum PCT level could be used as a marker to predict the possibility of AKI in critically ill patients admitted to the ICU.

FR-PO019

Endogenous Ouabain (EO) as Predictor of AKI and Post-Operative Outcomes

Marco Simonini,[1] Elena G. Bignami,[2] Paola Casanova,[1] Roberta Meroni,[1] Chiara Lanzani,[1] Elisabetta Messaggio,[1] Simona Delli carpini,[1] Lorena Citterio,[1] Paolo Manunta.[1] *[1]San Raffaele Scientific Institute, Milan, Italy; [2]University of Parma, Italy, Parma, Italy.*

Background: AKI is a frequent complication of cardiac surgery. A large number of novel postoperative biomarkers have been proposed to assess the risk of AKI. However, there are neither preoperative biomarkers nor robust validated risk models that predict AKI. EO is an adrenal stress hormone with hemodynamic and renal effects. Our group have already reported that higher pre-operative EO levels are associated with a worse renal outcome after cardiac surgery. Our aim is to confirm levels of EO as predictive biomarker of AKI in a larger population.

Methods: EO preoperative level was measured in 1097 patients admitted for elective cardiac surgery. For the analysis, patients were grouped according to EO preoperative levels: 1st group EO<133 pmol/L; 2nd EO 133-210 pmol/L; 3rd EO>210 pmol/L. According to the 3 groups, it was evaluated 1) incidence of AKI, 2) requirement of RRT and 3) total in-hospital mortality (IHM).

Results: In this extended population, we confirmed our previous observations for the great impact of preoperative EO level in the development of post-operative AKI. Patients with the highest EO values (>210 pmol/L) had highest postoperative AKI incidence (28.9% vs. 24.3% vs. 15.6%, p<0.0001, fig 1) and required more RRT (p=0.006) postoperatively. Moreover, we observed a relationship between EO and total In Hospital Morality (IHM occurred in 3.2% of patients presenting the highest levels of EO; p=0.028). All results were corrected for main clinical variable associated to post-operative AKI (as age, sex, EF, basal eGFR, surgery type, history of hypertension/diabetes; re-intervention).

Conclusions: These results confirmed preoperative EO level as predictive for the outcomes in patients undergoing cardiovascular surgery: subjects with the highest level of

preoperative plasma EO experienced the worst outcomes (increased incidence of AKI, use of RRT and IHM).

Optimization of a Novel 5-Plex Panel for AKI

Candace M. Adamo,[1] Eibhlin M. McCole,[2] Ciaran Richardson,[2] Timothy H. Carlson,[1] Grainne Donnellan,[2] Amar Sethi.[1] *[1]Pacific Biomarkers, Seattle, WA; [2]Randox Teoranta, Dungloe, Ireland.*

Background: Since creatinine is a lagging index of AKI progression, studies are now underway to qualify a new set of biomarkers for detecting drug-induced kidney injury (DIKI). Here, following optimization, we present performance data for a novel multiplex composed of urine AKI biomarkers.

Methods: The AKI multiplex panel quantifies KIM-1, cystatin C, clusterin, OPN and NGAL levels in urine. Multiplex results were compared to those from ELISA using urine from one cohort (n=60) treated with a preservative prior to freezing, and urine from a second cohort (n=122) left untreated. Cross reactivity for each analyte with non-panel related proteins was tested. Interfering substances were tittered to determine non-interfering concentrations (within ± 10%). Potential interferents assessed included human albumin (HA), hemoglobin, bilirubin, pH, glucose, sodium chloride and creatinine.

Results: Comparison of preserved urine biomarkers obtained using the two analytical methods provided correlations (r^2) of 0.816, 0.970, 0.842, 0.718, and 0.741 for KIM-1, NGAL, cystatin C, clusterin and OPN, respectively. Slopes were 0.32, 0.87, 1.33, 0.53, and 1.06, respectively. The methods were poorly correlated for unpreserved urine with r^2 ranging from 0.203 to 0.705. Cross reactivity was <1% for all tested non-panel, related proteins. Interfering concentration for HA was <0.5 mg/mL for clusterin and was insignificant for remaining biomarkers. Hemoglobin interference was <62.5 µg/mL for clusterin and insignificant for all other biomarkers. Bilirubin, glucose, sodium chloride and creatinine interferences were insignificant for all biomarkers.

Conclusions: All five biomarkers tested with the novel panel and predicate ELISA methods correlated well when preserved urine was used. Recovery of some urinary AKI biomarkers is susceptible to variability, which can be controlled with preservative. No clinical significant interference was observed for several substances known to be present in urine and cross-reactivity for non-panel proteins was not significant. Previously reported performance of this multiplex combined with the present data demonstrate good multiplex selectivity, and document an *in vitro* diagnostic that fills the need for a robust and cost-effective approach to diagnosis and monitoring of DIKI.

FR-PO021

Histopathological Features of Acute Tubular Necrosis in Native Kidney Correlate with Clinical Outcomes

Joy C. Chen,[1] Aishwarya Ravindran,[2] Sanjeev Sethi,[2] Kianoush Kashani.[3,4] *[1]Internal Medicine, Mayo Clinic, Rochester, MN; [2]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; [3]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [4]Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, MN.*

Background: Acute kidney injury (AKI) is a life-threatening complication of critical illnesses and is associated with increased morbidity and mortality. Acute tubular necrosis (ATN) is a frequent cause of AKI; however, few studies have examined the histopathological features of ATN as prognostic factors of kidney function recovery in native kidneys. Our aim is to describe histopathological features of ATN systematically and correlate with clinical outcomes.

Methods: Analyses included adult patients who underwent kidney biopsy for AKI unrelated to kidney transplantation at Mayo Clinic Rochester from January 1st, 2000 through December 31st, 2015 and ATN was the primary histological diagnosis (n = 46). Biopsies were reviewed by a kidney pathology consultant (SS) semi-quantitatively. Features of ATN included vacuolization, the presence of tubular debris, tubular distension, tubular cell flattening, and the extent of interstitial fibrosis and tubular atrophy (IFTA). To evaluate the factors associated with kidney recovery, patients were divided into two groups: recovery (n = 28, serum creatinine (SCr) level at 30 days decreased by 0.3 mg/dL and renal replacement therapy (RRT) liberated) vs. no recovery (n = 18).

Results: The median age at time of biopsy was 67 [IQR 58, 75] years old; of which 50% were males, 91% Caucasian, with Charlson comorbidity index of 5 [IQR 4, 7], and SCr 3.9 mg/dL [IQR 2.2, 5.2] at the time of biopsy. 35 (76%) patients were inpatient, 9 (20%) required intensive care unit (ICU) admission, and 10 (22%) required RRT at time of biopsy. Twenty eight (61%) patients recovered kidney function within 30 days of biopsy. The presence of 3+ debris on biopsy was associated with a higher chance of recovery (Figure 1).

Conclusions: Among patients with AKI with biopsy-confirmed ATN, 61% recovered kidney function within 30 days of biopsy and recovery was associated with increased presence of tubular debris.

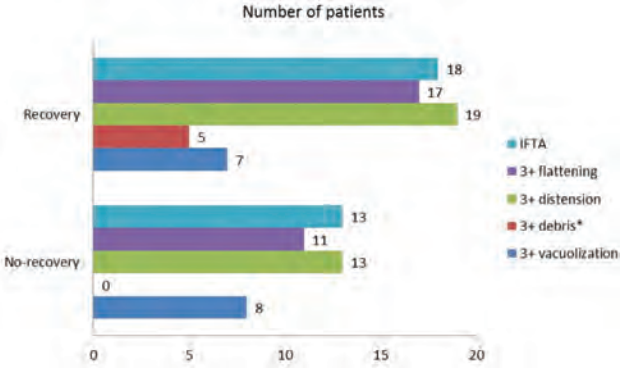

Figure 1 Histopathologic features of ATN in patients with and without recovery. *P-value <0.05.

FR-PO022

A Furosemide Excretion Stress Test (FEST) Predicts AKI Progression and Mortality After Sepsis

Jonathan Street,[1] Tiffany R. Bellomo,[1] Erik H. Koritzinsky,[1] Hiroshi Kojima,[1] Lakhmir S. Chawla,[2] Peter S. Yuen,[1] Robert A. Star.[1] *[1]NIDDK/NIH, Bethesda, MD; [2]University of California, San Diego, San Diego, CA.*

Background: The furosemide stress test (FST) has been shown to be a sensitive and specific predictor of progression to AKIN stage III in the ICU. FST measures the volume of urine produced after a furosemide bolus. Furosemide is actively excreted by the proximal tubules into the lumen where it inhibits NKCC2 in the thick ascending limb. We hypothesize that furosemide excretion (FEST) will be a more direct measure of tubule health than diuresis (FST). We developed a protocol for FST and FEST in mice and tested this hypothesis in a murine model of septic-AKI and in a human cohort.

Methods: Sepsis was induced in male and female CD-1 mice by cecal ligation and puncture (CLP). The FST/FEST started at 42 hours post-CLP. 1 mg/kg furosemide s.c. was given and urine collected for 12 hours. The mice were monitored until 7 days post-CLP. Furosemide concentration was determined by a new reverse phase HPLC assay in the mouse urine samples and urine samples from 49 patients in the PASSKI cohort.

Results: In the mouse model a moderate severity of sepsis was used and similar mortality was seen in the males and females. In the male group, from 79 mice 32 survived to 42 hours and underwent FST/FEST with 19 mice surviving to 7 days compared to 60/23/14 in the females. Urine production during the 12 hour collection varied from 0.08 to 2.62 ml. Urine production post-challenge and the fraction of furosemide recovered predicted mortality [AUC ROC values of 0.92 for FST in males, 0.95 for FST in females, 0.87 for FEST for males, and 1.00 for FEST in females]. Both FST and FEST predicted time of death in males (R^2 = 0.30 and 0.75), males and females combined (R^2 = 0.26 and 0.74) but not females alone. FST and FEST correlated with kidney NKCC2 mRNA levels (R^2 = 0.35 and 0.46), and weakly with BUN, ALT and CK. In the human cohort, FST and FEST were comparable in predicting progression to KDIGO stage III (AUC ROC values of 0.864 for FST and 0.848 for FEST).

Conclusions: In both the mouse model and human cohort the furosemide stress test and furosemide excretion stress test perform similarly with FST slightly superior in predicting mortality or progression. The furosemide excretion stress test predicted time to death in the mouse model.

FR-PO023

Loop Diuretic Challenge to Predict the Need for Renal Replacement Therapy Among Patients with Stage III AKI

Ankit Sakhuja, Erin F. Barreto, Robert C. Albright, Kianoush Kashani. *Mayo Clinic, Rochester, MN.*

Background: A poor response to a high dose loop diuretic challenge (LDC) predicts the progression of stage I and II acute kidney injury (AKI). Performance of this diagnostic test in stage III AKI is unknown. The objective of this study was to determine if poor response to LDC among patients with stage III AKI predicted the need for renal replacement therapy within 24-hours ($dialysis_{24h}$).

Methods: We included adults (≥18 years) admitted or transferred to medical or general surgical ICUs at Mayo Clinic, Rochester, MN between Jan 1, 2004, to Dec 31, 2016. Patients with stage III AKI were identified by an electronic surveillance tool using AKIN criteria. We then identified patients who received LDC, defined as at least 1mg/kg intravenous bolus dose of furosemide or equivalent intravenous bolus dose of bumetanide after the diagnosis of stage III AKI. We excluded patients with the end-stage renal disease, organ transplantation or who died within 24 hours of LDC. We modeled post-LDC urine output as a restricted cubic spline and compared the area under the curve (AUC) for urine output (mL) at 2h (UOP_{2h}) and 6h (UOP_{6h}) after LDC to predict $dialysis_{24h}$.

Results: We included 687 patients with stage III AKI who received LDC. The patients who received $dialysis_{24h}$ were younger (63.9 ± 14.5 years vs. 67.6 ± 15.6 years, p= 0.008), had lower Charlson comorbidity indices (4.9±2.4 vs. 5.8±2.7, p< 0.001) and higher SOFA scores on the day of LDC (10.4±3.9 vs. 8.2±3.4, p< 0.001). Both median total 2 hours (UOP_{2h}) and 6 hours (UOP_{6h}) urine output after LDC were lower in patients who needed $dialysis_{24h}$ (UOP_{2h} 48ml vs. 138ml, p<.001; UOP_{6h} 210ml vs. 616ml, p< 0.001) but UOP_{6h} was better in predicting $dialysis_{24h}$ (Area under the curve 0.71 vs. 0.67, p= 0.02). The sensitivity and specificity of a UOP_{6h} cutoff of ≤600ml to predict $dialysis_{24h}$ was 80.9% & 50.5% and for a cutoff of ≤300cc was 64.2% & 68.2%.

Conclusions: Among patients with AKI stage III the UOP_{6h} after loop diuretic challenge had a modest discriminant capacity to identify dialysis initiation within the next 24 hours. Though its predictive power seems better in earlier stages of AKI, LDC may be a useful adjunct to assess dialysis needs in patients with advanced AKI.

The Effect of Serum Neutrophil Gelatinase-Associated Lipocalin on Discontinuation of Continuous Renal Replacement Therapy in Critically Ill Patients with AKI

Ling Zhang. *West China Hospital of Sichuan University, Chengdu, China.*

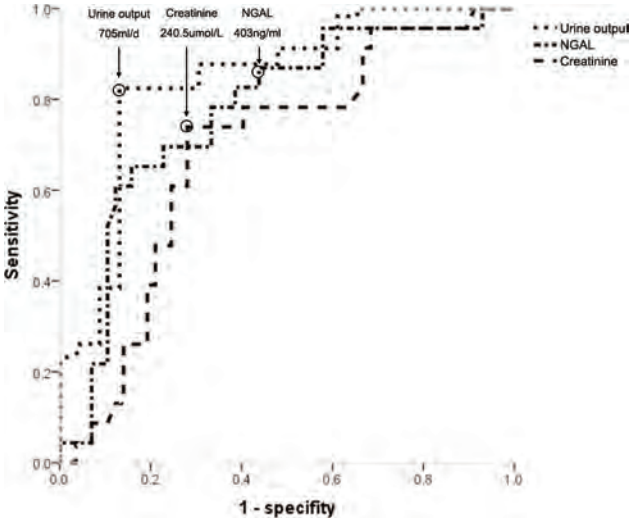
Background: To determine the optimal time for discontinuing continuous renal replacement therapy (CRRT) for critically ill patients with acute kidney injury (AKI) by evaluating serum Neutrophil gelatinase-associated lipocalin (NGAL).

Methods: Patients treated with CRRT at least 24 hours for AKI in ICUs were divided into "success" and "failure" groups according to their renal replacement therapy requirement within 7 days after the initial discontinuation of CRRT.

Results: 80 AKI patients were divided into the success (n = 57) and failure groups (n = 23). The patients in failure group was associated with higher mortality compared with successful group (39% vs.14%, p = 0.017). There were significant differences in serum NGAL, creatinine level and urine output at discontinuation between two groups. In patients without sepsis (n = 55), serum NGAL and urine output were found as significant predictors of successful cessation. The area under receiver operating characteristic (AUROC) to predict successful discontinuation of CRRT was 0.85 for NGAL and 0.82 for urine output. NGAL of 403 ng/ml had highest sensitivity (71%) and specificity (85%), as well as urine output of 695 ml/d with highest sensitivity (86%) and specificity (72%). However, in septic patients (n = 25), urine output, but not serum NGAL (OR, 0.990, p =0.43), was a significant variable (OR, 1.005, p =0.044), and the AUROC was 0.861 (p = 0.003), with a cutoff of 793.5 ml (sensitivity 75%, specificity 100%).

Conclusions: Serum NGAL was a significant factor to predict successful CRRT discontinuation in non-septic patients. However, urine output, rather than serum NGAL, was a significant predictor in septic AKI patients.

Funding: Clinical Revenue Support



AUROC and cutoff of NGAL, creatinine and urine output for successful CRRT discontinuation in all included patients

Different Roles of Functional and Structural Markers Measured at Discontinuation of Renal Replacement Therapy for AKI

Teruhiko Yoshida,[1,2] Ryo Matsuura,[1] Yoshihisa Miyamoto,[1] Yohei Komaru,[1] Takuya Isegawa,[1] Yoshifumi Hamasaki,[3] Eisei Noiri,[3] Masaomi Nangaku,[4] Kent Doi.[3] *[1]The University of Tokyo Hospital, Tokyo, Japan; [2]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [3]University of Tokyo, Tokyo, Japan; [4]the University of Tokyo School of Medicine, Tokyo, Japan.*

Background: Severe acute kidney injury (AKI) which requires renal replacement therapy (RRT) has been reported to show unacceptably high mortality of 50% or more. Successful discontinuation of RRT is supposed to be associated with better outcomes. Although functional and structural markers have been evaluated in AKI, little is known about their roles in predicting outcomes when measured at the time of RRT discontinuation.

Methods: We performed a prospective single-center cohort study. Patients received continuous RRT (CRRT) for AKI between August 2016 and March 2018 in the intensive care unit of The University of Tokyo Hospital (Tokyo, JAPAN) were analyzed. Clinical parameters and urine samples were obtained at CRRT discontinuation. Successful CRRT discontinuation was defined as neither resuming CRRT for 48 hours nor receiving intermittent hemodialysis during 7 days from the CRRT termination. Major adverse kidney events (MAKEs) was defined as death or dialysis requirement or more than 25% reduction of eGFR from the baseline at day 90.

Results: 73 patients who received CRRT for AKI were analyzed. 59 discontinued patients and 14 un-discontinued patients were identified. Among kinetic eGFR, urine volume, urinary NGAL and urinary L-FABP, urine volume had the highest AUC [95%CI] 0.91 [0.80-0.96] with the cut-off value of 740 ml/day. For predicting MAKEs at day 90, urinary NGAL had the highest AUC 0.76 [0.62-0.86], whereas kinetic GFR and urine volume failed to show statistical significance (kinetic eGFR AUC 0.49 [0.35-0.63], urine volume AUC 0.59 [0.44-0.73]).

Conclusions: Our prospective study revealed functional marker of urine volume could predict successful weaning of RRT, on the other hand, structural maker of urinary NGAL could predict long-term renal outcomes. This indicates different roles of functional and structural makers in predicting the outcomes of severe AKI requiring RRT.

Urinary Biomarkers and Renal Recovery at 4 Months After Community Acquired AKI: A Prospective Study in a Tertiary Care Hospital

Krishan Lal L. Gupta,[1] Vinod Nagesh,[1] Vivek Kumar,[1] Ravindra L. Mehta.[2] *[1]Postgraduate Institute of Medical Education & Research, Chandigarh, India; [2]University of California San Diego Medical Center, La Jolla, CA.*

Background: Acute kidney injury (AKI) in developing countries is most commonly community acquired. Despite advances in the epidemiology of AKI, prognostication remains a significant challenge. We studied the ability of urinary biomarkers to predict renal recovery at four months after community-acquired AKI

Methods: We studied 78 patients with community-acquired AKI (AKIN stage 1 to 3) at the Department of Nephrology, PGIMER, Chandigarh. Serum and urine samples were collected at admission, discharge and, at 1 and four months after discharge. Renal recovery was defined as eGFR (CKD EPI)>60 ml/min/1.73m2 and urine protein to creatinine ratio <500 mg/g at four months after discharge. We investigated whether urinary biomarker (uL-FABP, uNGAL, uKIM-1) at hospital discharge could predict failure to recover renal function at four months after discharge

Results: 75(96%) patients had AKIN stage 3 AKI and other 3 patients had AKIN stage 2 AKI. 21(27%) patients had failed to recover renal function at four months of discharge. Median urinary NGAL and urinary KIM-1 were significantly lower in patients with renal recovery (n=57) compared to those with persistent renal dysfunction (n=21). However, the differences in the median urinary L-FABP was not statistically different between the two groups (p-value = 0.55). Urinary NGAL and uKIM-1, individually predicted failure to recover renal function at four months after community-acquired AKI with AUCs of 0.71 (95% CI, 0.26 to 0.55) and 0.68 (95% CI, 0.52 to 0.84), respectively.

Conclusions: This is the first prospective study to evaluate urinary biomarkers as an outcome-specific biomarker in patients with community-acquired AKI cohort. The results of this study indicate that urine NGAL and uKIM-1 are an independent predictor of failure to recover renal function after community-acquired AKI

FR-PO027

Kinetic eGFR Can Predict AKI Recovery Earlier, Especially in Patients with CKD

Keita Uehara, Takahito Uema, Tadashi Miyara. *Department of Internal Medicine, Naha City Hospital, Naha, Okinawa, Japan.*

Background: The kinetic estimated glomerular filtration rate eGFR (KeGFR) obtained via consecutive serum creatinine (sCr) values is reportedly useful for predicting renal recovery after acute kidney injury (AKI). However, no studies have determined which patients can benefit using the KeGFR model. We predicted recovery from AKI with consecutive KeGFR and sCr values, comparing the usefulness of KeGFR.

Methods: This retrospective cohort study included patients admitted to our intensive care unit (ICU) from April 2014 to March 2016 and diagnosed with AKI after ICU admission. We defined renal recovery day as the first day when increasing consecutive sCr values turn to decrease or decreasing consecutive KeGFR values turn to increase,

comparing each recovery length from AKI. We examined patient characteristics when the KeGFR model was superior in predicting recovery from AKI.

Results: During the study period, 972 patients were admitted to our ICU and 74 were finally studied. On admission, median age was 75.5 (IQR: 64.0-83.0) years, median baseline sCr was 0.81 (IQR: 0.63-1.04) mg/dL, and median baseline eGFR was 65.0 (IQR: 51.1-77.6) mL/min/1.73 m^2. AKI recovery length was statistically shorter in KeGFR model than sCr model (median [IQR], 1.0 [1.0-2.0] vs 1.0 [1.0-2.0], p<0.01). In 17 (23.0%) patients, using the KeGFR model predicted AKI recovery earlier than when using the sCr model. Among those whose AKI recovery was predicted better than when using the sCr model, the baseline sCr was likely higher (median [IQR], 0.80 [0.61-0.93] vs 0.97 [0.79-1.42], p<0.01), baseline eGFR was likely to be lower (median [IQR], 68.0 [54.2-80.9] vs 51.6 [35.8-64.1], p=0.01), and the proportion of patients with CKD was higher (n [%], 18 [31.6] vs 13 [76.5], p<0.01). Other factors such as age, sex, mean blood pressure, sequential organ failure assessment score, infusion volume, and body weight were not associated with predicting early AKI recovery using the KeGFR model.

Conclusions: KeGFR can predict recovery from AKI earlier, especially in patients with a higher baseline sCr, lower baseline eGFR, and CKD. Using the KeGFR model, we can confirm the efficacy of our AKI therapy early, which would enable prompt and accurate management of patients with CKD.

FR-PO028

Post-AKI eGFR and ACR and Future Risk of Kidney Disease Progression

Chi-yuan Hsu,[1] Vernon M. Chinchilli,[5] James S. Kaufman,[7] Paul L. Kimmel,[3] Steven G. Coca,[2] Mark M. Wurfel,[6] Edward D. Siew.[4] *[1]University of California San Francisco, San Francisco, CA; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [4]Vanderbilt University School of Medicine, Nashville, TN; [5]Penn State College of Medicine, Hershey, PA; [6]University of Washington, Seattle, WA; [7]VA New York Harbor Healthcare System, New York, NY.*

Background: Some have advocated routine post-dischage nephrology follow-up for hospitalized patients who experienced AKI. We hypothesize that post-hospitalization eGFR and proteinuria levels risk stratify patients bettter than presence or severity of AKI.

Methods: We studied 1603 adult ASSESS-AKI study participants (PMID: 20799966). ASSESS-AKI prospectively enrolled hospitalized patients with and without AKI in a parallel, matched cohort. All participants had an outpatient baseline research study visit 3 months post-discharge when eGFR, ACR and comorbitidies were ascertained. Cox models were used to examine predictors of kidney disease progression, defined as time to halving of eGFR or ESRD.

Results: Median age of the study population was 66 (IQR 56-74) yrs; eGFR 69 (51-90) ml/min/1.73m2, ACR 14 (7-56) mg/g. 38% were female, 13% black, 3% Hispanic, and 41% had diabetes mellitus (DM). 772 participants had AKI and 831 did not. Most cases of AKI were mild to moderate in severity (72% stage 1, 15% stage 2). 139 participants had kidney disease progression after a median follow-up of 4.8 yrs. Severity of AKI was associated with kidney disease progression in simple and multivariable Cox models (Table). However, taking into account AKI severity did not materially improve risk stratification beyond a Cox model which contained basic demographics, DM status, SBP, BMI, eGFR and ACR (C-statistic 0.83 vs. 0.82). A Cox model with post-AKI ACR alone had a C-statistic of 0.81. (Similar results were seen when AKI was captured as presence or absence rather than staged by severity.)

Conclusions: Post-hospitalization levels of eGFR and ACR should guide triaging for implementation or intensification of reno-protective measures more so than presence or severity of AKI during hospitaliation. Patients who have preserved eGFR and low ACR after hospitalization have good renal prognosis and may not need referral to nephrology, regardless of whether AKI occured or not.

Recovery and Survival at Three Months Following Dialysis-Dependent AKI

Isabela V. Bertoni,[1] Doreen Zhu,[1] Michael P. Turner,[2] Richard Haynes.[2] *[1]Oxford Kidney Unit, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [2]University of Oxford, Oxford, United Kingdom.*

Background: Recovery from dialysis-dependent AKI is desirable because long-term dialysis is associated with significant morbidity and mortality. We examined how previous CKD stage, aetiology of AKI and co-morbidities influenced survival and dialysis dependence at three months after initial presentation.

Methods: 245 consecutive cases of AKI requiring RRT were identified from a tertiary referral centre in the UK, treated between 2008 and 2018. Baseline demographic and comorbidity data were extracted and logistic regression was used to assess the association of these characteristics with the primary outcome of renal recovery and survival at three months, in uni- and multi-variate models.

Results: Median age was 66 years (IQR 56.5-75). The most common diagnosis was ATN (60%) followed by vasculitis (9%) and myeloma (8%). At three months after presentation, 187 (76%) individuals were dialysis independent and 30 (12%) had died. Unadjusted and adjusted odds ratios (OR) are shown in table one. (Odds >1 means factor was associated with worse outcome).

Conclusions: This single centre study demonstrated that prior CKD stage and a history of cancer and higher were of the strongest predictors of renal recovery and survival at three months. This could assist clinical decision making and information given to patients.

Table 1: Unadjusted and adjusted odds ratios (OR) for association of patient characteristics with dialysis dependence and/or mortality at three months post presentation

AKI Followed by Complete Recovery Is Associated with Higher Risk of Upper Gastrointestinal Bleed

Asad Shafiq,[2] Zhiying You,[3] Benjamin Griffin,[2] John R. Holmen,[4] Titte Srinivas,[5] Michel Chonchol,[2] Sarah Faubel,[6] Anna J. Jovanovich.[1,2] *[1]Denver VA, Denver, CO; [2]University of Colorado, Aurora, CO; [3]UC Denver, Aurora, CO; [4]Intermountain Healthcare, Murray, UT; [5]Intermountain Medical Center, Murray, UT; [6]University of Colorado Denver, Denver, CO.*

Background: Recovery from dialysis dependent AKI is associated with future risk of upper gastrointestinal bleed (UGIB). To date, no studies have explored the association between complete recovery from non-dialysis dependent AKI and future risk of UGIB. We aim to determine the long-term risk of UGIB after a hospital admission complicated by non-dialysis dependent AKI followed by complete recovery of kidney function in a propensity score-matched cohort of cases and controls.

Methods: We identified 1140 AKI cases (AKI Network definition) with complete kidney function recovery at the time of discharge (serum creatinine <1.10 times the pre-admit baseline value) during hospital admission between January 1, 1999 and December 31, 2009 from an integrated health care delivery system. We matched 1140 controls (no AKI during index admit) based on a propensity score including: age, sex, race, prior inpatient visits, all components of the Charlson Comorbidity index, baseline creatinine, and admission season. The primary outcome was time to UGIB, defined by ICD-9 codes. Cox proportional hazards models were adjusted for prior UGIB, liver disease, and peptic ulcer disease (PUD) and censored for death.

Results: Baseline characteristics among the cases and controls were similar: age 62±17 years, 46% female, 92% white, baseline creatinine 0.9 ± 0.2 mg/dL. During a median post-discharge follow-up of 13 months, 646 (57%) cases and 470 (41%) controls had an UGIB. The risk of UGIB was 1.6 times higher among patients with AKI followed by complete recovery compared to controls (Hazard Ratio 1.65 [95% CI, 1.46 – 1.86]; p <0.0001). After adjusting the model for prior UGIB, liver disease, and PUD, the risk of UGIB was still higher among the patients with AKI followed by complete recovery compared to control group (Hazard Ratio 1.50 [95% CI, 1.32 – 1.69]; p <0.0001).

Conclusions: In this cohort, non-dialysis dependent AKI during a hospital admission, despite complete recovery of kidney function, was associated with future UGIB compared to patients without AKI. Future studies are needed to further investigate this relationship.

FR-PO031

AKI Followed by Complete Recovery Is Associated with Greater Risk of Subsequent Venous Thromboembolism

Benjamin Griffin,[2] Neil R. Shah,[2] Zhiying You,[3] John R. Holmen,[4] Titte Srinivas,[5] Michel Chonchol,[2] Sarah Faubel,[6] Anna J. Jovanovich.[1,2] *[1]Denver VA, Denver, CO; [2]University of Colorado, Aurora, CO; [3]UC Denver, Aurora, CO; [4]Intermountain Healthcare, Murray, UT; [5]Intermountain Medical Center, Murray, UT; [6]University of Colorado Denver, Denver, CO.*

Background: Acute kidney injury (AKI) is associated with long-term morbidity including chronic kidney disease and heart disease. Recent data suggest that AKI is associated with increased long-term event rates such as sepsis, cancer, and venous thromboembolism (VTE). A prior study included patients with dialysis-requiring AKI with recovery but the degree of kidney function recovery was unclear. We aim to determine the

risk of VTE following a hospital admission complicated by AKI with complete recovery in a propensity score-matched cohort of cases and controls.

Methods: We identified 1139 AKI cases (AKI Network definition) with complete kidney function recovery by the time of discharge, defined as serum creatinine <1.10 times the pre-admit baseline value, during a hospitalization between January 1, 1999 and December 31, 2009 from an integrated health care delivery system. We matched 1139 controls (no AKI during index admit) based on a propensity score including age, sex, race, number of prior inpatient visits, baseline creatinine, season of admission, and all co-morbidities in the Charlson Comorbidity index. The primary outcome was time to VTE. Cox proportional hazards models were adjusted for history of prior VTE and cancer and censored for death.

Results: Baseline characteristics among the cases and controls were similar: age 62 ± 17 years, 46% female, 92% white, serum creatinine 0.9 ± 0.2 mg/dL. During a median [IQR] post-discharge follow-up of 65 [9-89] months, 246 cases (22%) and 73 controls (6%) developed new VTE. In the unadjusted Cox model AKI with complete recovery was with a nearly four-fold increase in hazard ratio for subsequent VTE (HR 3.99 [95% CI, 3.06 – 5.18]; p <0.0001). This association did not change after adjusting for prior VTE and cancer diagnosis (HR 3.82 [95% CI, 2.94 – 4.97]; p <0.0001).

Conclusions: AKI with complete recovery is associated with increased risk of VTE. These data further support the idea that AKI is associated with long-term events dysfunction independent of decreased kidney function. Future research is needed to determine the mechanism of long-term changes following AKI.

FR-PO032

The Risk of Major Adverse Kidney Events After AKI: A Systematic Review and Meta-Analysis

Emily J. See,[1] Kushani C. Jayasinghe,[2] David W. Johnson,[1] Kevan Polkinghorne,[3] Nigel D. Toussaint.[4] *[1]Princess Alexandra Hospital, Greenslopes, QLD, Australia; [2]Monash Health, Clayton, NSW, Australia; [3]Monash Medical Centre and Monash University, Melbourne, VIC, Australia; [4]The Royal Melbourne Hospital, Parkville, VIC, Australia.*

Background: Acute kidney injury (AKI) is a common consequence of acute illness and is associated with high morbidity and mortality. Robust estimates of the long-term outcomes of AKI, using consensus definitions of exposure, are needed to inform clinical practice and guide optimal allocation of healthcare resources.

Methods: A systematic search was performed through EMBASE, MEDLINE, and grey literature sources to identify cohort studies reporting an association between AKI and chronic kidney disease (CKD), end-stage kidney disease (ESKD) or death. All studies published between 2004 and 2018 involving hospitalised adults were eligible if they defined AKI according to consensus definitions (RIFLE, AKIN, or KDIGO), included a non-AKI control group, and followed patients for at least 1 year. Risk of bias was assessed using the Newcastle-Ottawa Scale. Random effects meta-analysis was used to combine adjusted hazard ratios between studies. Subgroup, sensitivity and meta-regression analyses were performed to investigate potential sources of heterogeneity.

Results: The systematic search retrieved 6369 citations, of which 81 studies comprising more than 2 million participants were eligible for inclusion. One-third of studies were in cardiovascular surgery patients and one-third were performed in Europe. Reporting of methods was incomplete in many studies. The most common sources of bias were poor representativeness of patient cohorts, and insufficient duration and completeness of follow up. Funnel plot asymmetry reflected a lack of small studies with negative effects. AKI was associated with a significantly increased risk of death across all subgroups: angiography (HR 3.07, 95%CI 2.12-4.46), cardiovascular surgery (HR 1.75, 95%CI 1.55-1.98), intensive care (HR 1.47, 95%CI 1.32-1.65), and hospital (HR 1.41, 95%CI 1.26-1.56). The risk of death increased from stage 1 (HR 1.35, 95%CI 1.27-1.44) to stage 3 (HR 2.76, 95%CI 2.28-3.35). AKI was associated with increased risks of CKD (HR 2.86, 95%CI 2.09-3.91) and ESKD (HR 4.81, 95%CI 3.04-7.62). Heterogeneity between studies was high.

Conclusions: AKI was associated with inferior long-term survival and an increased risk of adverse renal outcomes. The risk of a poort outcome increased with greater AKI severity. Patients undergoing angiography and cardiovascular surgery were at greatest risk.

FR-PO033

Contrast-Induced AKI and Adverse Clinical Outcomes Risk in Acute Coronary Syndrome Patients Undergoing Percutaneous Coronary Intervention: A Meta-Analysis

Yi Yang,[1] Shuwang Ge,[2] Gang Xu.[3] *[1]Tongji hospital affiliated to Tongji medical college, Huazhong University of Science and Technology, Wuhan, Hubei, China, Wuhan, China; [2]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China; [3]Tongji hospital affiliated to Tongji medical college, Huazhong University of Science and Technology, Wuhan, China.*

Background: Recent studies have shown associations between contrast-induced acute kidney injury (CI-AKI), in patients undergoing percutaneous coronary intervention (PCI) for acute coronary syndrome (ACS), and increased risk of adverse clinical outcomes in ACS patients undergoing PCI; however, the estimates are inconsistent and vary widely.

Methods: EMBASE, PubMed, Web of Science™ and Cochrane Library databases were systematically searched from inception to December 16, 2016 for cohort studies assessing the association between CI-AKI and any adverse clinical outcomes in ACS patients treated with PCI. We calculated the pooled risk ratios (RRs) with 95% confidence intervals (CI) of these outcomes. Heterogeneity was explored by subgroup analyses.

Results: We identified 1857 articles in electronic search, of which 23 (n=33080) were included. Our meta-analysis revealed that CI-AKI significantly increased the risk of all-cause mortality (18 studies; n= 28367; RR=3.16, 95% CI 2.52–3.97; I^2 =56.9%), short-term all-cause mortality (9 studies; n=13895; RR=5.55, 95% CI 3.53–8.73; I^2 =60.1%), major adverse cardiac event(7 studies; n=19841; RR=1.49, 95% CI: 1.34–1.65; I^2=0), major adverse cardiovascular and cerebrovascular event (3 studies; n=2768; RR=1.86, 95% CI: 1.42–2.43; I^2=0) and stent restenosis (3 studies; n=130678; RR=1.50, 95% CI: 1.24–2.81; I^2=0), respectively, in ACS patients undergoing PCI. Subgroup analyses showed the study design, sample size and prevalence of CI-AKI might have effect on pooled RR.

Conclusions: CI-AKI may be a prognostic marker of adverse outcomes in ACS patients undergoing PCI. More attention should be paid to diagnosis and management of CI-AKI.

FR-PO034

Post-Trans-Catheter Aortic Valve Implantation AKI Stage 3 Requiring Renal Replacement Therapy and Mortality in Patients with Severe Aortic Stenosis and High Surgical Risk

Juan C. Duque Ballesteros, Manuel Rivera-Maza, Gabriel Contreras. *University of Miami, Miami, FL.*

Background: Trans-catheter aortic valve implantation (TAVI) is an established treatment for severe symptomatic aortic stenosis (AS) in high surgical risk patients. However, post TAVI complications affect outcomes. Acute kidney injury (AKI) stage 3 requiring renal replacement therapy (RRT) after TAVI has been associated with high hospital mortality. Efforts to understand the factors that contribute to increase morbidity and mortality in patient undergoing TAVI are needed in order to decrease their morbidity and mortality.

Methods: The data of patients who underwent TAVI between 2012 and 2014 from the nationwide inpatient sample database was analyzed in this investigation. ICD-9-CM codes were used to identify hospital admissions for TAVI (procedure codes: 35.05 and 35.06) and new AKI stage 3 requiring RRT post-TAVI (diagnostic codes 584.5 to 584.9 plus procedure code 39.95). The primary outcome was AKI stage 3 requiring RRT post-TAVI. Stata/IC 14.2 was used to identify predictors of the primary outcome using multivariable regression analysis.

Results: An estimated total of 41,050 patients underwent TAVI during the pre-specified study period. Patient mean age was 81.1 years, 47.7 were women and 81% were white. 685 (1.7%) patients developed AKI stage 3 requiring RRT after TAVI. Hospital mortality was 30.7% in this subgroup. Multivariable regression analysis identified trans-apical approach (OR [95%CI], 1.67 [1.13-2.46]), preexisting chronic kidney disease (CKD) (OR [95%CI], 1.84[1.30-2.61]), non-elective TAVI (OR [95%CI], 2.24[1.58-3.18]), heart failure (OR [95% CI], 2.48 [1.58-3.90]], and procedural or post-procedural mechanical circulatory support (MCS) use (OR [95%CI], 3.39[1.77-6.50]) as predictors for AKI stage 3 requiring RRT.

Conclusions: Patients complicating with AKI stage 3 requiring RRT after TAVI have a high hospital mortality. Preexisting CKD, trans-apical approach, non-elective TAVI, development of heart failure and the need for MCS were significantly associated with AKI stage 3 after TAVI.

FR-PO035

AKI After Non-Cardiac Surgery as an Independent Predictor of Infection and Malignancy During Long-Term Follow-Up

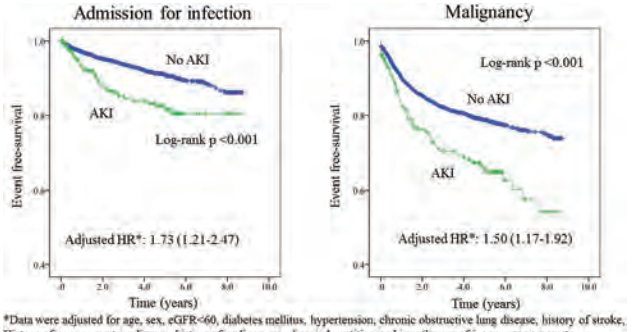
Miho Tagawa,[1] Masatoshi Nishimoto,[1] Maiko Kokubu,[4] Takayuki Hamano,[5] Masaru Matsui,[2] Ken-ichi Samejima,[3] Masahiro Eriguchi,[1] Yasuhiro Akai,[1] Kazuhiko Tsuruya.[1] *[1]Nara Medical University, Kashihara, Japan; [2]Nara Prefecture General Medical Center, Nara, Japan; [3]First Department of Internal Medicine, Nara Medical University, KASHIHARA, Japan; [4]nara medical university, NARA, Japan; [5]Osaka University Graduate School of Medicine, Suita, Japan.*

Background: Previous studies showed that acute kidney injury (AKI) was an independent predictor of all-cause mortality and cardiovascular events. However the associations between AKI and non-cardiac outcomes have not been studied.

Methods: This is a retrospective observational study. Inclusion criteria were adults who underwent non-cardiac surgery under general anesthesia from 2007 to 2011. Exclusion criteria were urologic and obstetric surgeries, subjects missing creatinine values perioperatively, or subjects on dialysis preoperatively. Exposure of interest was AKI within 7 days of surgery by KDIGO criteria. Outcome variables were admission for infection and diagnosis with malignancy (including recurrence). When the outcome was malignancy, subjects who underwent palliative resection of malignancy were excluded. Statistical analyses were performed using Kaplan-Meier curve and Cox regression analyses.

Results: Among 3,939 subjects, there were 289 events of AKI (7.3%). During median follow-up of 4.0 years, there were 291 admissions for infection and 668 were diagnosed with malignancy. Event-free survival among subjects with AKI was significantly lower. After adjustments for potential confounders, AKI was significantly associated with admission for infection and the diagnosis of malignancy (HR 1.73 [1.21-2.47] and 1.50 [1.17-1.92], respectively). Subgroup analyses stratified by age, sex, or history of malignancy yielded similar results. Among subjects with AKI, 11.4 % did not recover renal function during index admission for the surgery. Analyses excluding subjects without recovery of renal function did not change the results.

Conclusions: AKI was an independent predictor of infection and malignancy during long-term follow up after non-cardiac surgery, irrespective of recovery of renal function. There is a possibility that AKI predisposes patients to long-term immunosuppressed state.



*Data were adjusted for age, sex, eGFR<60, diabetes mellitus, hypertension, chronic obstructive lung disease, history of stroke, History of coronary artery disease, history of malignancy, chronic hepatitis, smoking, the use of immunosuppressants, corticosteroid, or chemotherapeutic agents

FR-PO036

Renal Dysfunction and In-Hospital Mortality Among Critically Ill Patients with Stroke

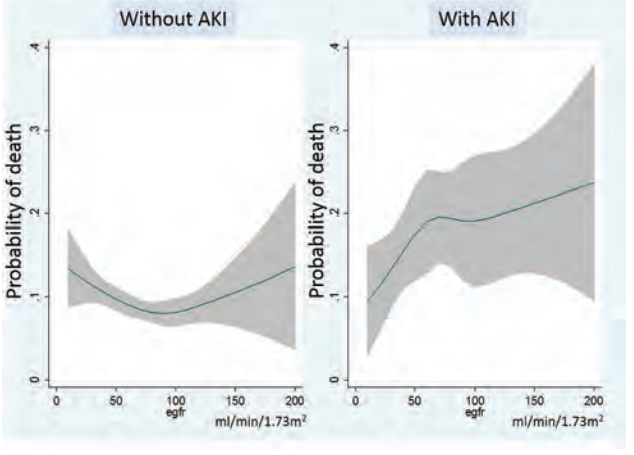
Katsuhito Ihara,[1] John Danziger,[2,3] Murray Mittleman.[1,2] [1]*Harvard T.H. Chan School of Public Health, Boston, MA;* [2]*Harvard Medical School, Boston, MA;* [3]*Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: The interplay between baseline renal function and acute kidney injury (AKI) on in-hospital mortality among critically ill patients hospitalized for stroke is largely unknown.

Methods: We used the multicenter eICU Collaborative Research Database to identify 4,736 adult non-dialysis patients admitted to ICU with acute stroke between 2013 and 2015. Baseline renal function was defined as estimated glomerular filtration rate (eGFR) calculated by the MDRD equation based on the first serum creatinine within 24 hours of ICU admission. AKI was defined based on the Kidney Disease: Improving Global Outcomes guidelines. We used a multivariable logistic regression with a restricted cubic spline of eGFR and an interaction with AKI to estimate the probability of in-hospital mortality according to baseline eGFR among patients who did and did not develop AKI.

Results: The mean age of the patients was 68.6 ± 14.8 years, 48.6% were male, and 80.8% were Caucasian. The mean eGFR on admission was 72.5 ± 30.7 ml/min/1.73m^2 with 18.0% (n = 852) presenting with an eGFR between 90 and 120 ml/min/1.73m^2 and 40.6% (n = 1,922) between 60 and 90 ml/min/1.73m^2. Patients with lower eGFR were older, more likely to have diabetes, require intubation, and have lower Glasgow coma scales. There were 460 deaths (9.8%) during hospitalization. After adjusting for confounding, both reduced (eGFR <45, odds ratio (OR), 1.83; 95% confidence interval (CI), 1.20-2.79) and highly elevated eGFR (≥120, OR, 1.37; 95% CI, 0.69-2.74) were associated with increased mortality when comparing to eGFR between 75 and 90 ml/min/1.73m^2. The figure shows that AKI was associated with higher in-hospital mortality and the relationship between eGFR at baseline and mortality was significantly different among those with and without AKI.

Conclusions: Both eGFR on admission and AKI are strong predictors of in-hospital mortality and the impact of eGFR is stronger among patients who develop AKI.



FR-PO037

AKI in Patients with Acute Exacerbation of Chronic Obstructive Pulmonary Disease Necessitating Hospitalization

Dawei Chen, Xin Wan. *Nanjing First Hospital, Nanjing, China.*

Background: Acute kidney injury (AKI) on patients with acute exacerbations of chronic obstructive pulmonary disease (AECOPD) remained unknown, and little is known about the differences between community-acquired AKI (CA-AKI) and hospital-acquired AKI (HA-AKI) in patients with AECOPD. Thus, we compared prevalence, risk factors, and outcomes for these patients with CA-AKI and HA-AKI.

Methods: Between January 2014 and January 2017, data from adult inpatients with AECOPD were analyzed retrospectively. In all, 1768 patients were included.

Results: Prevalence of CA-AKI was 15.8% and that of HA-AKI was 5.5%, giving an overall AKI prevalence of 21.3%. Comparing with patients without AKI, patients with AKI were more likely to require mechanical ventilation (38.7% *versus* 19.1%; $P < 0.001$), non-invasive mechanical ventilation (20.4% *versus* 16.0%; $P = 0.044$), invasive mechanical ventilation (18.3% *versus* 3.1%; $P < 0.001$), and intensive care unit (ICU) admission (33.7% *versus* 12.9%; $P < 0.001$). Patients with AKI had a longer duration of ICU stay (9 days *versus* 8 days; $P = 0.033$), a longer hospitalization (13 days *versus* 10 days; $P < 0.001$), and a higher inpatient mortality (18.0% *versus* 2.7%; $P < 0.001$). Patients with CA-AKI had a higher prevalence of chronic kidney disease (CKD) and lower prevalence of chronic cor pulmonale than patients with HA-AKI. Risk factors for developing HA-AKI and CA-AKI were similar: being elderly, requirement for mechanical ventilation and a history of coronary artery disease and CKD. Patients with HA-AKI were more likely to have stage-3 AKI and worse short-outcomes. In comparison with CA-AKI, patients with HA-AKI were more likely to require non-invasive mechanical ventilation (31.3% *versus* 16.8%; $P = 0.003$), and had a longer duration of mechanical ventilation (11 days *versus* 8 days; $P = 0.020$), longer hospitalization (14 days *versus* 12 days; $P = 0.038$), and higher inpatient mortality (32.0% *versus* 13.2%; $P < 0.001$). Those with HA-AKI had worse (multivariate-adjusted) inpatient survival than patients with CA-AKI (hazard ratio, 1.7 [95% CI, 1.03–2.81; $P = 0.038$] for the HA-AKI).

Conclusions: AKI was common in patients with AECOPD requiring hospitalization, and had a worse prognosis. CA-AKI was more common than HA-AKI but otherwise demonstrated similar demographics and risk factors. Nevertheless, patients with HA-AKI had worse short-term outcomes.

FR-PO038

In-Hospital Mortality of AKI in Those with and Without HIV at a Tertiary Hospital in South Africa: A 2-Year Retrospective Cohort Study

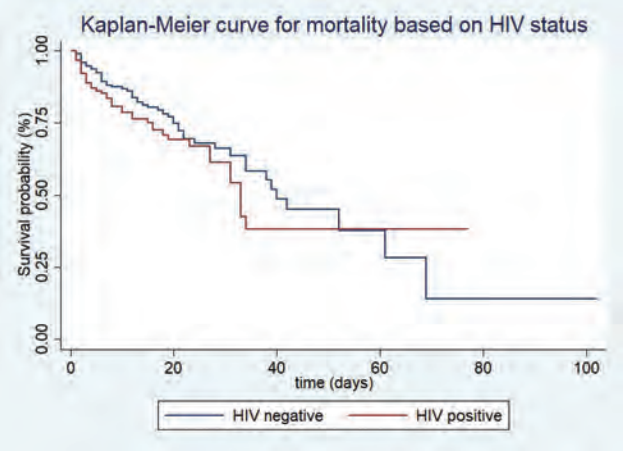
Nikash N. Ramsunder,[3] Mogamat-Yazied Chothia.[1,2] [1]*Medicine, Tygerberg Academic Hospital, Cape Town, South Africa;* [2]*Nephrology, Stellenbosch University, Cape Town, South Africa;* [3]*University of Stellenbosch, Durban, South Africa.*

Background: Acute kidney injury (AKI) in HIV patients in Sub-Saharan Africa is a common cause for hospitalisation and is associated with high morbidity and mortality. There is a paucity of comparative epidemiological data regarding the outcome of AKI in those with and without HIV from the African continent. The primary outcome was to determine the overall in-hospital mortality of AKI.

Methods: This was a single centre study of all consecutive adult patients with AKI referred to the renal unit at Tygerberg Hospital for the period from 1 January 2015 to 31 December 2016. AKI was defined as a recent normal serum creatinine (< 3 months) and/or normal kidney sizes on ultrasound examination (> 100 mm length). Those with proteinuria > 3.0 g/day were excluded. Kaplan Meier curves and logistic regression were used to assess survival and identify factors predicting mortality.

Results: We identified a total of 291 patients with AKI of which 116 (39.9%) were HIV positive. Overall, 91 (31%) patients died of which 40 (34.5%) were HIV positive and 51 (29.1%) were HIV negative (P = 0.34). At hospital admission, more HIV positive patients had tuberculosis (81.5% vs. 18.5%, P < 0.01) and had higher admission serum creatinine (551.1 umol/L vs. 190 umol/L, P < 0.01). Of those that died, the HIV positive patients were younger (41 years vs. 52 years, P < 0.01), were predominantly Black (87.5% vs. 23.5%, P < 0.01) and were predominantly admitted to medical wards (92.5% vs. 41.2%, P < 0.01). There was no difference in mortality regardless of renal replacement therapy (P = 0.50). Logistic regression identified Mixed race (OR 2.47, P = 0.02), HIV (OR 2.69, P < 0.01) and surgical ward admission (OR 2.05, P = 0.03) as strong predictors for death.

Conclusions: Overall in-hospital mortality of AKI was high. HIV was associated with a greater risk of death that may be the result of late presentation of both the AKI as well as the HIV.



FR-PO039

Incidence and Outcomes of Acute-on-CKD - The French CKD-REIN Cohort Study

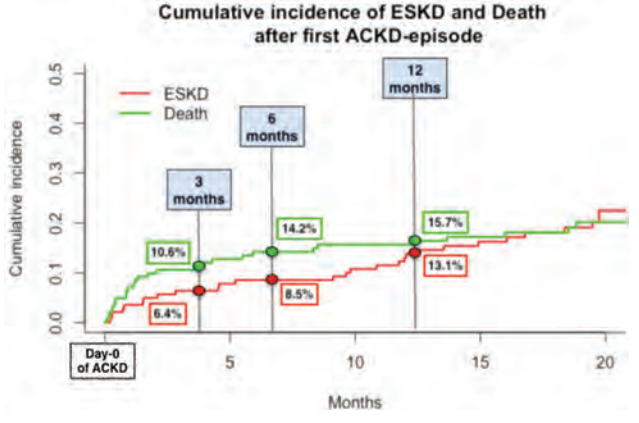
Aghiles Hamroun,[1] Luc Frimat,[2] Maurice Laville,[3] Marie Metzger,[1] Celine Lange,[4] Christian Combe,[5] Denis Fouque,[3] Jarcy Zee,[6] Ziad Massy,[7] Benedicte Stengel.[1] *[1]CESP U1018, INSERM, Villejuif, France; [2]Nancy University Hospital, Vandoeuvre les Nancy, France; [3]Université de Lyon, Pierre-Bénite, France; [4]Biomedicine Agency, La Plaine Saint-Denis, France; [5]CHU de Bordeaux, Bordeaux, France; [6]Arbor Research Collaborative for Health, Ann Arbor, MI; [7]Ambroise Pare University Hospital and Inserm U1018 Eq5, Boulogne Billancourt/ Paris cedex, France.*

Background: Incidence and outcomes of *de novo* acute kidney injury (AKI) are well documented, but less is known about acute-on-chronic kidney disease (ACKD).

Methods: We estimated ACKD incidence rate over 1-year follow-up in 2375 patients with any type of CKD stages 3-4, but without past AKI at baseline. AKI events were defined and classified according to KDIGO 2012, and validated by an expert committee. Cause-specific Cox regression models identified factors associated with full renal recovery, defined by <10% increase in post AKI serum creatinine as compared with baseline creatinine, during the year post-AKI. We estimated cumulative incidences for the competing risks of end-stage kidney disease (ESKD) and death after ACKD. The hazard ratios [HR, 95% confidence intervals] of these outcomes associated with ACKD during the first year of follow-up were estimated by cause-specific Cox regression models, adjusted for sex, age, eGFR, and albuminuria.

Results: Overall, 142 patients (mean age 70 years, 69% men, mean eGFR 29mL/min/1.73m^2, 50% with severely increased albuminuria -A3 range-) experienced a first AKI-event (25% outpatient) at a rate of 6 per 100 person-years: 73% were staged 1, 12% staged 2, and 13% staged 3. One hundred patients (70%) achieved full renal recovery, within a mean time of 4 months after AKI. Pre-renal AKI (HR=2.54 [1.42;4.54]), dehydration (HR=1.76 [1.00;3.17]) and drug-related AKI (HR= 2.04 [1.11;3,75]) were significantly associated with full renal recovery. The cumulative incidences of ESKD and death after ACKD reached 13.1% and 15.7% at 12 months, respectively (Figure). ACKD was significantly associated with increased ESKD risk (adjusted HR=2.13 [1.32; 3.46]) and mortality (adjusted HR=2.07 [1.11; 3.83]).

Conclusions: ACKD is common and, despite a high rate of full renal recovery, it is associated with very high risks of both ESKD and death.



Post-ACKD outcomes.

Renal Outcomes of Laparoscopic versus Open Surgery in Patients with Rectal Cancer: A Propensity Score Analysis

Jin hyuk Paek,[1] Ji Young Ryu,[2] Hyung Eun Son,[2] Ho Jun Chin,[2] Sejoong Kim.[2] *[1]Internal Medicine, Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea.*

Background: The laparoscopic approach in abdominal surgery is widely used and has many advantages over open surgery (OS). However, the renal outcomes of laparoscopic surgery (LS) are still not proven in rectal cancer. Thus, we compared the renal outcomes between LS and OS in patients with rectal cancer.

Methods: We conducted a retrospective cohort study of 1633 patients who underwent rectal cancer surgery between 2003 and 2017. Postoperative acute kidney injury (AKI) was determined according to the serum creatinine criteria of the Kidney Disease: Improving Global Outcomes classification. AKI stage 2 or 3 were classified as severe AKI and AKI recovery was defined as return of serum creatinine to < 1.2 times the baseline level.

Results: Among 1633 patients, 1072 patients (65.6%) underwent LS. The incidence of postoperative AKI in LS was significantly lower than in OS (9.3 vs. 17.3%, $p < 0.001$, respectively). After matching propensity scores (1:1), 395 patients were included in each group. LS group still demonstrated a significantly lower incidence of postoperative AKI than OS group (9.9 vs. 15.9%, $p = 0.011$, respectively). The operation time ($p < 0.001$), estimated blood loss ($p < 0.001$), incidence of transfusion ($p < 0.001$) in LS group were significantly lower than in OS group. However, there were no differences in incidence of severe AKI ($p = 1.000$), AKI recovery ($p = 0.962$) and in-hospital mortality ($p = 0.249$) between two groups. Cox proportional hazard models revealed that LS group had lower incidence of postoperative AKI than OS group (HR, 0.599; 95% CI, 0.402-0.893; $p = 0.012$). In subgroup analysis, LS had much lower incidence of postoperative AKI than OS in patients with American Society of Anesthesiologists (ASA) score ≤ 2 (HR, 0.516; 95% CI, 0.314-0.850; $p = 0.009$) and in patients who did not receive neoadjuvant chemotherapy (HR, 0.519; 95% CI, 0.295-0.912; $p = 0.023$).

Conclusions: This study showed that LS may reduce postoperative AKI in patients with rectal cancer and that its beneficial effect may be associated with operation time or intraoperative bleeding events and be dominant in patients with low ASA score and no neoadjuvant chemotherapy.

FR-PO041

Postoperative Blood Transfusion Predicts AKI in Patients with Rectal Cancer

Ji Young Ryu,[1] Jin hyuk Paek,[2] Sejoong Kim,[1,3] Ho Jun Chin,[1,3] Ki Young Na.[1,3] *[1]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]Keimyung University School of Medicine, Daegu, Republic of Korea; [3]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Preoperative anemia and perioperative transfusion are associated with postoperative acute kidney injury in cardiovascular surgery, but little is known about their relationship in patients with rectal cancer surgery. Thus, we investigated whether postoperative blood transfusion may predict postoperative acute kidney injury in patients with rectal cancer.

Methods: We collected 1328 patients who underwent rectal cancer surgery from a single-center prospective cohort between 2003 and 2017. Postoperative acute kidney injury (AKI) was determined according to the serum creatinine criteria of the Kidney Disease: Improving Global Outcomes classification.

Results: Among 1328 patients, 134 patients (10.1%) received blood transfusions and 1194 patients (89.9%) did not receive. American Society of Anesthesiologists (ASA) score ($p < 0.001$), preoperative hemoglobin ($p < 0.001$), albumin, operation time ($p < 0.001$), amount of intraoperative bleeding ($p < 0.001$) showed differences in the two groups. Overall AKI incidence was 12.6% and severe AKI incidence was 1.2%. The incidence of postoperative AKI in the transfused group was significantly higher than in no blood transfusions group (10.2% vs 2.3%, $p < 0.001$, respectively) and similar result was observed in severe AKI (1.1% vs 0.4%, p=0.007, respectively). Cox proportional hazard models revealed that the AKI incidence was different according to preoperative hemoglobin concentration (HR, 0.894; 95% 0.827-0.968; p=0.05) and transfusions (HR, 2.692; 95% 1.822-3.976; $p < 0.001$). But, there was no difference in perioperative changes in hemoglobin. Two of category of preoperative hemoglobin concentrations (>12 and 10.1-12.0) were associated with a risk of postoperative AKI, whether patients was received transfusions or not (OR, 3.676; 95% 1.703-7.933; p=0.01 and OR, 2.589; 95% 1.209-5.545; p=0.014, respectively).

Conclusions: This study showed that postoperative blood transfusions may increase postoperative AKI in patients with rectal cancer. It is also possible that close monitoring of blood transfusions after surgery may improve AKI outcomes in patients with rectal cancer.

FR-PO042

Association of Dietary Intakes with the Incidence of AKI During Chemoirradiation Using High-Dose Cisplatin in Patients with Head and Neck Cancer

Akihiko Kato,[1] Soichiro Nagata,[2] Tomoyuki Fujikura,[2] Naro Ohashi,[2] Hideo Yasuda.[2] *[1]Blood Purification Unit, Hamamatsu University Hospital, Hamamatsu, Japan; [2]Internal Medicine 1, Division of Nephrology, Hamamatsu University School of Medicine, Hamamatsu, Japan.*

Background: Cisplatin (CDDP)-based chemotherapy and radiotherapy can impact on nutrition intake because of reduction of eating ability. However, it remains to be fully clarified whether changes of nutritional status is associated with the development of CDDP-induced acute kidney injury (AKI). So, we aimed this study to clarify the nutritional impact on incident AKI in head and neck cancer patients with chemoradiotherapy.

Methods: We assessed nutritional parameters and dietary intakes just before and during the chemoradiotherapy including 66-70 Gy with CDDP 80 mg/m^2 on Days 1, 22 and 43 in 84 head and neck cancer patients (age: 61±10 years old, male/female=72/12). Nutritional intervention was conducted to reach the recommended intake of energy (30 kcal/kg/day) and protein (1.0-1.2 g/kg/day), considering with enteral, parenteral nutrition and oral intake. Adjustments were made during treatment, aiming to maintain stable or improving nutritional indicators.

Results: Thirty-three episodes of AKI developed in 30 patients (35.7%) during the 3 courses of CDDP administration (stage 1, N=28; stage 2; N=2, stage 3; n=3). Serum creatinine increased at the end of chemo-radiotherapy to a greater extent in AKI (0.79±0.19 to 1.16±0.38 mg/dL) than in non-AKI patients (0.73±0.18 to 0.87±0.51 mg/dL). No difference was found in basal energy (1,345±538 vs. 1,356±537 kcal/day) and protein intakes (53±21 vs. 53±22 g/day) between AKI and non-AKI patients. CDDP-based chemoradiotherapy decreased body weight (BW) by -5.6±6.4% during the therapy. A significantly greater decrease of BW was observed in AKI than in non-AKI patients (-7.5±5.9 vs. -4.6±6.4%, p<0.05). There was also a significantly lower intake of energy (909±392 vs. 1,166±421 kcal/day, p<0.05) and protein (37±0.7 vs. 46±17 g/day, p<0.05). A stepwise regression analysis revealed that energy and protein intakes and % decrease of BW at the end of treatment were significantly associated with the incident AKI (p<0.05).

Conclusions: The findings suggest that poor dietary intake during the platinum-based chemoradiation was associated with acute kidney toxicity. A more aggressive dietary support may be required to mitigate the onset of CDDP-induced AKI in patients with head and neck cancer.

FR-PO043

Effects of Obesity on Mortality in Critically Ill Patients with AKI

Sophia L. Ambruso,[1] Benjamin Griffin,[2] Zhiying You,[3] Jessica B. Kendrick,[4] Paul M. Palevsky,[5] Anna J. Jovanovich,[6] Sarah Faubel.[1] *[1]University of Colorado Denver, Denver, CO; [2]University of Colorado, Aurora, CO; [3]UC Denver, Aurora, CO; [4]University of Colorado School of Medicine, Aurora, CO; [5]University of Pittsburgh/VA Pittsburgh Healthcare System, Pittsburgh, PA; [6]Denver VA / University of Colorado, Denver, CO.*

Background: The prevalence of obesity is rising in the critically ill population, but little data exists on outcomes in critically ill obese patients with acute kidney injury (AKI) requiring renal replacement therapy (RRT). In this study, we assessed the impact of obesity on rates of mortality in patients with AKI initiated on RRT.

Methods: We conducted a secondary analysis of the Acute Renal Failure Trial Network (ATN) database, which compared less-intensive to more-intensive RRT dosing strategies in critically ill patients. Weights >128.5 kg, exceeding the max dose capabilities of the Prisma machine at the time, were excluded. Modalities used were CVVHDF and HD, often with cross-over during the admission. In the overweight patients who received CVVHDF, 88% received a dose reduction. The overweight group was defined as 'actual weight 30% greater than ideal body weight'. We categorized patients into an overweight group and a standard weight group (all other patients). A subgroup analysis looked separately at those who received CVVHDF at some point during the admission (CVVHDF group) and those who received no CVVHDF (HD only group). Our primary outcome was 60-day mortality. We used logistic regression to adjust for demographics, SOFA score and Charlson score.

Results: In the combined CVVHDF and HD cohort, the 60-day mortality rate was 45% (n=235, mean BMI 35.1) in the overweight group and 55% (n=633, mean BMI 25.7) in the standard weight group. Compared to the standard weight group, the overweight group had a 45% improved odds of survival, which persisted after illness severity adjustments (OR 0.55 [95% CI, 0.32-0.90]; p=0.016). Among patients receiving HD only, the overweight group had improved odds of survival (OR 0.42 [95% CI 0.21-0.84]; p=0.015). In contrast, there was no survival benefit in the overweight patients receiving CVVHDF (OR 0.83 [95% CI 0.52-1.21]; p=0.3).

Conclusions: Overweight patients with AKI had improved survival compared to the standard weight group. However, the survival benefit was only observed in overweight patients who received HD only, not CVVHDF. This benefit seems to parallel the protective effect of obesity seen in outpatient HD populations. Loss of benefit in the CVVHDF group is likely multifactorial. More outcomes studies in overweight and obese patients with AKI in the ICU are needed.

FR-PO044

Cannabis Use and Its Association with Incidence of AKI in Advanced CKD Patients Transitioning to ESRD

Praveen Kumar Potukuchi,[1] Keiichi Sumida,[2] Miklos Z. Molnar,[1] Abduzhappar Gaipov,[1] Frank Park,[1] Cameron M. Kaplan,[1] Hamid Moradi,[4] Fridtjof Thomas,[1] Justin Gatwood,[1] Elani Streja,[3] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [3]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [4]University of California Irvine, School of Medicine, Orange, CA.*

Background: Cannabinoid receptors are expressed in the kidneys and their stimulation may have both harmful and beneficial effects. Synthetic cannabinoid use is associated with acute kidney injury (AKI) in case reports, but the effects of cannabis use on the incidence of AKI in patients with advanced CKD is unknown.

Methods: We examined 2,416 US veterans who transitioned to dialysis during 2007-2014 and had undergone urine toxicology tests up to one year prior to dialysis, and had serial serum creatinine levels measured within 7 days after the test. We compared patients whose toxicology tests were positive for cannabis alone (primary exposure group, PEG, N=76) with those whose tests were negative (negative control group, NCG, N=1,138). AKI was defined according to KDIGO creatinine–based criteria. We examined the association of cannabis use with AKI using logistic regression adjusted for sociodemographics, comorbidities, medications, and vital signs.

Results: The mean (SD) age of the cohort was 60.6 (9.3) years; 97% were male, 46.7 % were African American and 76.4% were diabetic. AKI occurred in 58.6% of the cohort. Cannabis use was not associated with the odds of AKI in crude or in multivariable adjusted models (multivariable adjusted odds ratios (and 95%CI) in PEG vs. NCG: 0.75 (0.45-1.24); Figure 1).

Conclusions: Cannabis use in advanced CKD patients is not associated with the incidence of AKI.

FR-PO045

Role of Sweat and Core Body Temperature in AKI During Marathon

Sherry Mansour,[1] Yaqi Jia,[1] Wassim Obeid,[2] Thomas Martin,[4] Rachel W. Pata,[4] Karen M. Myrick,[4] Lanxin Jiang,[6] Heather Thiessen Philbrook,[5] Lidiya Kukova,[5] Chirag R. Parikh.[3] *[1]Yale University, New Haven, CT; [2]Yale, New Haven, CT; [3]Yale University and VAMC, New Haven, CT; [4]Quinnipiac University, Hamden, CT; [5]Yale University, New Haven, CT; [6]Yale University, New Haven, CT.*

Background: The strenuous physical activity of marathons is associated with AKI in runners. Given the increasing participation in marathons, it is important to understand the etiology behind runners' AKI to allow for future preventative measures. We hypothesized that sodium loss from sweat along with a rise in core body temperature during the race will be associated with AKI *via* thermoregulatory vasodilation and shunting of blood away from kidneys to muscles and skin. To test this hypothesis we conducted a prospective study of 22 runners participating in the 2017 Hartford Marathon.

Methods: Vital signs, blood and urine samples were collected 24 hours pre-marathon, and immediately post-marathon. We measured conventional and novel biomarkers. We also measured continuous core body temperature using Zephyr® technology and sweat volume and sodium using PharmChek® patches during the race. We performed linear regression analyses to determine the association between sweat sodium and core body temperature with kidney injury.

Results: Runners ranged from 22 to 63 years of age, had 2 to 25 years of running experience and 52% were males. Runners lost an estimated median range of 2.34 (0.50 to 7.21) grams of sodium, 2.47 (0.36 to 6.81) liters of volume *via* sweat and had temperatures of 101.12 (96.44 to 105.8)°F during race. The change in weight ranged from 1.81 (0.18 to 5.08) kg. 56% developed AKI based on creatinine definition and 83% had a positive urine microscopy for acute tubular injury. Runners with AKI and higher sweat sodium had higher increases in several injury, inflammatory and repair biomarkers (Figure). Sweat sodium and temperature were not associated with change in creatinine or urine microscopy during the race.

Conclusions: Runners have substantial rise in core body temperature and extensive weight loss mainly via sweat sodium and volume losses. The mechanisms associated with thermoregulatory vasodilation and associated reduced blood flow to the kidney may provide insights into the pathophysiology of runners' AKI.

Phenotypes of Volume Status in AKI Patients and Their Association with Intradialytic Hypotension

Rogerio Passos,[1,2] Etienne Macedo,[3] Mauricio Teixeira,[4] Fernanda O. Coelho,[1] Érica B. Melo,[5] Juliana R. Caldas,[6] Michel P. Ribeiro,[7] Joao G. Ramos,[1] Paulo benigno P. Batista.[8] SAPIENS MI *[1]Hospital Sao Rafael, Salvadir, Brazil; [2]Hospita Portugues, Salvador, Brazil; [3]University of California San Diego, San Diego, CA; [4]USP, Salvador Bahia, Brazil; [5]Hospital Português da Bahia, Salvador, Brazil; [6]HSR, Salvador, Brazil; [7]Hospital SÃo Rafael, Salvador, Brazil; [8]Hospital São Rafael, Salvador, Brazil.*

Background: Intradialytic hypotension (IDH) is a common complication during intermittent dialysis (IHD) in hospitalized patients. It is associated delay in organ failure and renal recovery, and a common reason for modality change and continuous renal replacement therapy (CRRT) initiation.. Knowledge of patient volume status could help tailor the ultrafiltration rate and prevent episodes of IDH This study aim to evaluate the association of volume status based on sonographic profiles before IHD and occurrence and severity of IDH. Intradialytic hypotension (IDH) is a common complication during intermittent dialysis (IHD) in hospitalized patients. It is associated delay in organ failure and renal recovery, and a common reason for modality change and continuous renal replacement therapy (CRRT) initiation.. Knowledge of patient volume status could help tailor the ultrafiltration rate and prevent episodes of IDH This study aim to evaluate the association of volume status based on sonographic profiles before IHD and occurrence and severity of IDH.

Methods: We conducted a prospective observational study including all consecutive AKI patients requiring IHD in the intensive care unit. Bedside sonography to evaluate inferior Vena Cava Colapsability (cIVC) measurement and B lines were assessed by two different trained attending physicians. Volume status profile was classified into 4 groups: (1) B Lines (+) cIVC (-); (2) B lines (+), cIVC (+); (3) B lines (-) cIVC (-); (4) B lines (-) / iICV (+)

Results: Of 248 patients 42% were classified as G1; 22% G2, 20% of group (3) and 16% of group (4). (55%) had at least one episode of hypotension during therapy, with different frequency among the groups ($p < 0.001$). Hypotension was more frequent in group (4) (85%), $p < 0.001$ versus others, and less frequent in group (1) (22%, $p < 0.001$ versus others). In the multivariate adjusted analysis, the risk of IDH remained different among the groups ($p< 0.001$) and group (4) exhibited the highest hazard ratio (HR = 6.58. 95% CI 3.22- 8.24).

Conclusions: Bedside sonography assessing B lines determination and cIVC can be used to define volume status profile in critically ill patients and risk of hypotension during IHD. Further studies are needed to design adequate targeted treatments

FR-PO047

Hyperchloremia Is Associated with AKI in Pediatric Patients with Septic Shock

Erin K. Stenson,[1] Natalie Z. Cvijanovich,[2] Neal J. Thomas,[3] Michael T. Bigham,[4] Julie C. Fitzgerald,[5] Michael W. Quasney,[6] Mark W. Hall,[8] Rainer Gedeit,[9] Robert J. Freishtat,[10] Jeffrey E. Nowak,[11] Riad Lutfi,[12] Shira J. Gertz,[13] Jocelyn R. Grunwell,[14] Hector R. Wong,[15] Parag N. Jain.[7] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]UCSF Benioff Childrens Hospital, Oakland, CA; [3]Penn State, Hershey, PA; [4]Akron Children's Hospital, Akron, OH; [5]Children's Hospital of Philadelphia, Philadelphia, PA; [6]University of Michigan, Ann Arbor, MI; [7]Texas Children's Hospital, Houston, TX; [8]Nationwide Children's Hospital, Columbus, OH; [9]Medical College of Wisconsin, Milwaukee, WI; [10]Children's National Health System, Washington, DC; [11]Children's Respiratory and Critical Care Services, P.A., Minneapolis, MN; [12]Riley Hospital for Children, Indianapolis, IN; [13]Saint Barnabas Medical Center, Livingston, NJ; [14]Emory University/Children?s Healthcare of Atlanta, Atlanta, GA; [15]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Hyperchloremia is associated with increased mortality in pediatric septic shock patients, and associated with increased rate of acute kidney injury (AKI) in adults. It is unknown whether hyperchloremia is associated with AKI in pediatric patients.

Methods: We tested the hypothesis that hyperchloremia is associated with increased rates of severe AKI in pediatric patients with septic shock. We performed a retrospective analysis of a pediatric septic shock database that included 619 children with septic shock from 29 PICUs in the U.S. We considered the minimum, maximum, and mean chloride values as separate hyperchloremia variables within the first 7 days of PICU admission. We considered hyperchloremia as a dichotomized variable defined *a priori* as a serum concentration ≥110mmol/L. We used multivariable logistic regression to determine the association between these hyperchloremia variables and outcomes, after adjusting for illness severity and age. Our primary outcome variable was day 3 AKI, defined as KDIGO stage 2 or 3.

Results: There were 125 subjects with AKI and 494 subjects with no AKI. Subjects with AKI were younger (1.7 years; IQR 0.7-5.4 v. 3.5 years; IQR 1.3-7.1; $p <0.001$) and had higher PRISM-III scores (15; IQR 9-24 v. 11; IQR 7-16; $p <0.001$). There were 42 subjects with a minimum chloride ≥110mmol/L, 117 subjects with a mean chloride ≥110mmol/L, and 359 subjects with a maximum chloride ≥110mmol/L. A minimum chloride ≥110mmol/L was associated with increased odds of AKI (odds ratio, 2.4; 95% CI, 1.2-4.9; $p = 0.014$). A mean chloride ≥110mmol/L was associated with increased odds of AKI (odds ratio, 1.8; 95% CI, 1.1-2.9; $p = 0.014$).

Conclusions: Hyperchloremia is independently associated with severe AKI in pediatric patients with septic shock. Further evaluation of the optimal fluid to be used in resuscitation of these patients is warranted.

Chloride Abnormalities Are Independently Associated with Mortality in Critically Ill Children

Matthew Barhight,[4] John T. Brinton,[5] Danielle Soranno,[4] Sarah Faubel,[2] Benjamin Griffin,[3] Jens W. Goebel,[4] Peter Mourani,[6] Katja M. Gist.[1] *[1]University of Colorado, Children's Hospital Colorado, Aurora, CO; [2]University of Colorado Denver, Denver, CO; [3]University of Colorado, Aurora, CO; [4]Children's Hospital Colorado, Aurora, CO; [5]University of Colorado Denver School of Medicine, Aurora, CO; [6]University of Colorado School of Medicine, Aurora, CO.*

Background: Chloride disturbances in critically ill adults are associated with mortality. The impact of chloride disturbances on outcomes in critically ill children is unknown. The purpose of this study was to determine if there is an association between mortality and 1) admission chloride levels and 2) changes in the chloride level following initial resuscitation in critically ill children.

Methods: We retrospectively studied all PICU patients (01/2014 – 12/2015) at Children's Hospital Colorado, excluding those 1) aged < 90 days or > 25 years, 2) without admission laboratory tests, 3) end stage renal disease, 4) a disorder of chloride transport and 5) admitted for diabetic ketoacidosis. Patients were stratified based on admission chloride levels (hypochloremia, <100 mEq/L; normochloremia, 100-109 mEq/L and hyperchloremia ≥110 mEq/L). Additionally, they were dichotomized based on the change in chloride (ΔCl) in the first 24 hours (< 5 mEq/L, ≥ 5 mEq/L). Multivariate logistic regression and analysis of covariance were performed to determine the impact of chloride derangements on mortality and length of stay respectively.

Results: 2022 patients were included; overall mortality was 4% (n = 77) and day 2 AKI occurred in 18% (n = 318). Hypochloremia, hyperchloremia, and ΔCl ≥ 5 mEq/L occurred in 7%, 21%, and 12% respectively. Hypochloremia and ΔCl ≥ 5 mEq/L were independently associated with a 4.57 (95% CI: 1.65 - 12.66) and a 3.17 (95% CI: 1.61 - 6.26) greater odds of mortality respectively, after adjusting for confounders. In ANACOVA models, hypochloremia and hyperchloremia were associated with an estimated increase in the expected length of hospital stay of 1.2 days (95% CI: 1.0 - 1.5; p=0.03), and 1.2 days (95% CI: 1.0 - 1.4 p=0.02) respectively. ΔCl ≥ 5 mEq/L was associated with an estimated increase in the expected time on mechanical ventilation of 1.3 days (95% CI: 1.0 - 1.4; $p = 0.02$).

Conclusions: Hypochloremia and ΔCl ≥ 5 mEq/L in the first 24 hours of admission are common and independent risk factors for mortality in critically ill children after adjusting for confounders. Further studies are needed to address the mechanism by which chloride disturbances increase mortality in critically ill children.

FR-PO049

Subclinical AKI Is Associated with Adverse Outcomes in Critically Ill Neonates and Children

Yanhong Li. *children hospital of Soochow University, Suzhou, China.*

Background: Acute kidney injury (AKI) is associated with adverse outcomes. Research in AKI has focused on identifying early biomarkers capable of detecting kidney injury before the rise in serum creatinine. However, whether AKI could be diagnosed in the absence of the classic signs of clinical AKI, and whether the condition of subclinical AKI, identified by using structural or functional biomarkers in the absence of oliguria or increased serum creatinine levels, is clinical significant, remained to be elucidated in critically ill children. The aims of the study were to investigate the association of urinary cystatin C (uCysC) level and mortality, and determine whether uCysC-positive subclinical AKI was associated with adverse outcomes in critically ill neonates and children.

Methods: In this prospective cohort study, uCysC levels were serially measured during the first week after intensive care unit (ICU) admission in a heterogeneous group of patients (n=510) presenting to a tertiary neonatal (n=239) and pediatric (n=271) ICU. The term of "uCysC(–)" or "uCysC(+)", indicating the absence or presence of tubular injury, was defined by the optimal cut-off value of the peak uCysC to predict ICU mortality.

Results: The initial and peak uCysC levels had odds ratios of 1.19 and 1.26 (per 10,000 ng/mg uCr increase), and achieved the area under-the-receiver-operating-characteristic curve of 0.76 and 0.81, respectively, for predicting ICU mortality. At the optimal cut-off value of 1,260 ng/mg uCr, the peak uCysC displayed sensitivity of 79.2% and specificity of 72.3% for predicting mortality. Among all patients, 130 (25.5%) developed uCysC(+)/AKI(–) status during the first week after admission. The adjusted odds ratio for patients with uCysC(+)/AKI(–) status being associated with an increased risk of mortality was 9.34 ($P<0.001$), compared to those with uCysC(–)/AKI(–). Patients with uCysC(+)/AKI(–) spent 2.8 times as long in ICU compared to those with uCysC(–)/AKI(–).

Conclusions: Both initial and peak uCysC levels are independently predictive of mortality in critically ill neonates and children. Subclinical AKI may occur without

detectable loss of kidney function, and uCysC-positive subclinical AKI was associated with worse clinical outcomes in this population.

FR-PO050

The Relationship Between Statin Use and 1-Year Mortality After Severe AKI

Chia-Lin Wu,[1,2] Chih-cheng Hsu,[3] Der-Cherng Tarng.[4] *[1]Division of Nephrology, Department of Medicine, Changhua Christian Hospital, Changhua, Taiwan; [2]Institute of Clinical Medicine, National Yang-Ming University, Taipei, Taiwan; [3]Institute of Population Health Sciences, National Health Research Institutes, Miaoli County, Taiwan; [4]Taipei Veteran's General Hospital, Taipei, Taiwan.*

Background: The potential survival benefits of statin use in patients with dialysis-requiring acute kidney injury (AKI) are still not known. We examined the association between statin use and 1-year mortality in patients with dialysis-requiring AKI.

Methods: This nationwide population-based retrospective cohort study included 6091 hospitalized patients with dialysis-requiring AKI (1271 statin users and 4820 statin non-users) retrieved from the National Health Insurance Research Database of Taiwan between January 1, 2000, and December 31, 2012. All patients were followed up until December 31, 2013. Primary outcome was 1-year mortality after dialysis-requiring AKI. All primary analyses were performed using the intention-to-treat approach.

Results: During the 1-year follow-up period, 492 of 1271 (38.7%) statin users and 2365 of 4820 (49.1%) statin non-users died after dialysis-requiring AKI. Statin use was independently associated with lower risks of 1-year all-cause mortality (hazard ratio [HR], 0.81; 95% confidence interval [CI], 0.73-0.91; p<0.001) and in-hospital all-cause mortality (HR, 0.82; 95% CI, 0.72-0.94; p=0.004). The survival benefit of statin treatment was dose-dependent and consistent across subgroups based on sensitivity analyses.

Conclusions: Statin use was independently associated with reduced risks of 1-year and in-hospital mortality in patients with dialysis-requiring AKI. However, further clinical trials are warranted to confirm our results.

Incidence and risk of 1-year mortality in patients with dialysis-requiring AKI

Cohorts	Events (n/N)	Incident rate	Crude HR (95% CI)	P value	Adjusted HR (95% CI)	P value
Statin non-users	2365/4820	68.7 (65.9–71.5)	1 (Reference)		1 (Reference)	
Statin users	492/1271	46.6 (42.4–50.7)	0.71 (0.65–0.79)	<.001	0.81 (0.73–0.91)	<.001
Stratified by cDDD						
cDDD <39	266/651	50.3 (44.3–56.4)	0.77 (0.67–0.87)	<.001	0.87 (0.76–0.99)	0.04
cDDD >=39	226/620	42.8 (37.2–48.3)	0.66 (0.58–0.76)	<.001	0.75 (0.65–0.87)	<.001

The Association of Fenofibrate with Kidney Tubular Injury in a Subgroup of Participants in the ACCORD Trial

Neha Debnath,[1] Kinsuk Chauhan,[1] Girish N. Nadkarni,[1] Amit X. Garg,[2] Chirag R. Parikh,[3] Steven G. Coca.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]London Health Sciences Centre, London, ON, Canada; [3]Yale University and VAMC, New Haven, CT.*

Background: In ACCORD, 48% of those randomized to fenofibrate demonstrated a ≥20% increase in the concentration of serum creatinine within 4 months, a finding consistent with other trials. The effect of fibrates on markers of kidney tubular injury is unknown.

Methods: We obtained stored urine samples from a subgroup of 571 ACCORD participants randomized to either placebo (n= 329) or fenofibrate (n=242) where all patients also received statins. Our outcome was 2-year changes in the concentration of two urine biomarkers of injury: kidney injury molecule-1 (KIM-1), interleukin-18 (IL-18), and 2 urine biomarkers of repair: YKL-40 and monocyte chemoattractant protein (MCP-1), along with the changes in eGFR and urine albumin to creatinine ratios (UACR) measured from random samples. We adjusted for clinical variables and randomization arm and compared the changes in the markers via analysis of covariance (ANCOVA).

Results: Baseline clinical characteristics and measures of eGFR (88 ml/min/1.73m^2), UACR (12 mcg/mg), and all 4 biomarkers were similar in the 2 groups. At 24 months, eGFR was 14.2 ml/min/1.73m^2 lower with fenofibrate vs. placebo and serum creatinine was 0.18 mg/dl higher. In contrast, UACR and all 4 urine biomarkers of kidney injury or repair were similar or decreased from baseline in fenofibrate vs. placebo (**Figure**). In a stratified analysis, even participants with the highest quintile 24-month decrements in eGFR with fenofibrate (-30.4 to -73.5 ml/min/1.73 m^2) still had lower or unchanged UACR and urine biomarkers.

Conclusions: These findings indicate the increase in the concentration serum creatinine with fibrates is not due to intrinsic damage to kidney tubule cells.

24-month change in eGFR, Serum Creatinine, UACR and Urinary Kidney Injury and Repair Biomarkers in ACCORD Participants Randomized to Fibrates vs. Placebo

FR-PO052

The LncRNA Profile in Control and Ischemically Injured Kidneys of Old Mice

Tamás Kaucsár, Peter Hamar. *Semmelweis University, Budapest, Hungary.*

Background: The expression profile of lncRNA is hardly known in the control and injured kidneys of old mice. We investigated the influence of aging on the lncRNA profile after renal ischemia-reperfusion (IR) injury in mice.

Methods: The left renal pedicle of adult (9.4±0.3 months, n=7) and old (28.5±1.2 months, n=8) C57BL/6N mice was clamped for 20 min. The right kidney was left intact. Plasma urea and urine NGAL (uNGAL) were measured prior to and 7 days after reperfusion. On day 7 tubular injury was evaluated by histology (PAS, HE) and KIM1 mRNA (qPCR) expression. The extent of fibrosis (FN1) and senescence (p21) was analyzed with qPCR. Long non-coding RNA profile (90 lnc) was examined with qPCR array.

Results: Older mice had higher baseline uNGAL (old: 285.7±93.8 ng/mg Crea vs. adult: 78.0±9.1 ng/mg Crea, p<0.05) and milder kidney injury (p<0.05). KIM1 (8.3x; p<0.001), FN1 (2x; p=0.05) and p21 (3.8x; p<0.05) mRNA levels were higher in their non-ischemic kidneys relative to the adult group. There was no significant difference in baseline plasma urea levels between the two groups (old: 75.9±10.2 mg/dl vs. adult: 57.6±5.3 mg/dl). Following IR tubular injury increased in both groups (p<0.05) with KIM1 (adult: 202x, old: 19.5x, p<0.0001) and FN1 (adult: 8.5x, old: 3x, p< 0.001) mRNA compared to the contralateral control kidneys. uNGAL level was higher after IR compared to the baseline (old: 3817±1975 ng/mg Crea, p<0.0001; adult: 2833±1201 ng/mg Crea, p<0.001). p21 mRNA increased only in the ischemic kidneys (4.5x, p<0.01), compared to the contralateral control. The plasma urea concentration increased only in the old group following 7 days of reperfusion (140.7±25.6 mg/dl, p<0.01). From the 81 measureable lncRNAs 8 increased and 1 decreased only by IR. Old age only influenced 1 lncRNA expression. Further 12 lncRNA expression was influenced by both IR and old age.

Conclusions: Our results demonstrated significant tubular damage and decreased renal function in the kidneys of old mice, in accordance with the literature. We have also found that several lncRNAs were differentially expressed in old and adult mice in both the control and ischemic kidneys. New National Excellence Program (Human Resources Department)

miR-146a Targeted to Splenic Macrophages Prevents Sepsis-Induced Multiple Organ Injury Including AKI

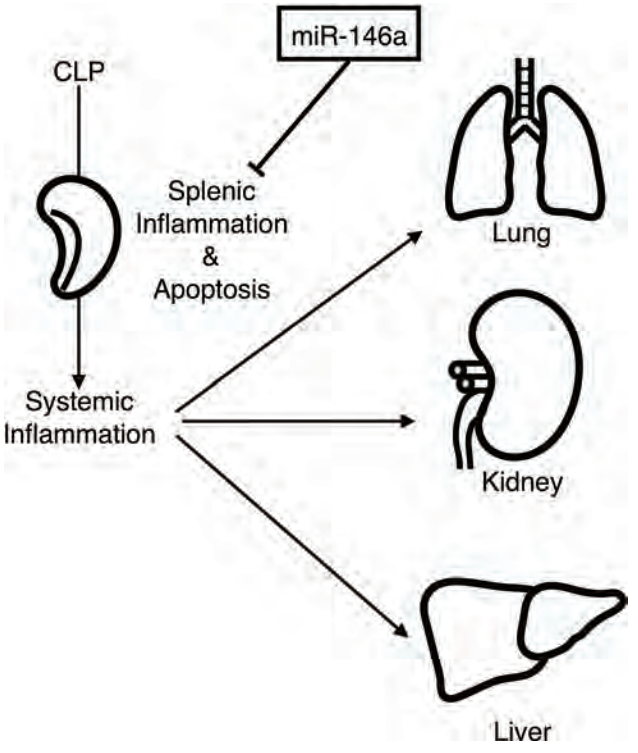
Yoshio Funahashi, Noritoshi Kato, Naotake Tsuboi, Shoichi Maruyama. Department of Nephrology *Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: To date, additional pathophysiology and new drug concept need to be provided in patients with multiple organ injury due to sepsis. microRNAs (miRNAs) have garnered attention as potent oligonucleotide therapeutics. The aim of the present study is to investigate the pathophysiological role of exogenous miR-146a in sepsis-induced acute kidney injury (AKI).

Methods: *In vitro* study, RAW264.7 cells were transfected with miR-16, miR-126, miR-146a, miR-200b, or a negative control, then treated with 1 mg/ml lipopolysaccharide (LPS) for 6 hours. *In vivo* study, young C57BL/6 mice were intravenously injected a mixture of miR-146a-expressing plasmid and polyethyleneimine (PEI). 7 days after transfection, sepsis was induced via cecal ligation and puncture (CLP).

Results: Among tested miRNA, miR-146a showed the best suppressive efficacy, whereby transcriptional activity of NF-κB was decreased by targeting IRAK-1 and TRAF6 in RAW264.7 cells. Treatment with the miR-146a-expressing plasmid/PEI complex significantly decreased the level of serum inflammatory cytokines, attenuated organ injury including kidney injury, and led to increased survival in CLP-induced polymicrobial sepsis. miR-146a-expressing plasmid was abundantly distributed in splenic macrophages, but not in kidney cells. The miR-146a-treated CLP mice also showed a significant decrease in NF-κB activation and apoptosis in splenocytes. Splenectomy diminished the anti-inflammatory effects of miR-146a.

Conclusions: The induction of miR-146a in splenic macrophages prevents excessive inflammation and sepsis-induced multiple organ injury, including AKI. This study provides a pathophysiological breakthrough in the relationship between splenic macrophages and sepsis-induced AKI.



FR-PO054

MicroRNA-219c Dependent Mincle Is Critical for Maintaining Proinflammatory Phenotype of Macrophage in Renal Inflammation

Linli Lv,[1] Zuolin Li,[3] Ye Feng,[2] Xin Zhong.[4] *[1]Southeast University, Institute of Nephrology, Nanjing, China; [2]Zhongda hospital, Southeast university, Nanjing, China; [3]Zhong Da Hospital, Southeast University, Nanjing, China; [4]Institute of Nephrology, Zhongda Hospital, Southeast University School of Medicine, Nanjing, China;, Nanjing, China.*

Background: Macrophages are a key inflammatory cell that plays a critical role in renal inflammation and fibrosis. Our previous study demonstrated that the pattern recognition receptor, Mincle is essential for maintaining inflammatory phenotypes of M1 macrophages in acute renal inflammation. However, the mechanism through which Mincle expression was regulated and its relation with different macrophage phenotypes remains largely unknown.

Methods: Unilateral urethral obstruction model of renal injury was established at day 1, 3, 7 to observe the dynamic change of Mincle expression and its relation with macrophage phenotype. For *in vitro* study, LPS and IL4 was used to induce M1, M2 polarization to explore Mincle expression in the process of phenotype switching. The regulatory effects of microRNA-219c in Mincle expression and kidney inflammation were also determined.

Results: During progression of renal inflammation in UUO model, Mincle^{+} macrophage significantly increased at day 1 while it decreased rapidly with theincreasing M2 macrophage infiltration. During macrophage phenotype switch, Mincle mRNA and protein was enhanced in LPS-primed M1 macrophage, while its expression decreased in M2 macrophage. Interestingly, Mincle overexpression induced proinflammatory phenotype polarization and also reversed the phenotype switching to M2 macrophage from either M0 or M1 macrophages. Bioinformatic analysis showed that Mincle was a potential target of microRNA-219c. Interestingly, microRNA-219c was reduced in injured kidney of UUO model when Minlce was upregulated at day1. Mincle protein was reduced in RAW264.7 with microRNA-219c mimic treatment. And the luciferase reporter gene assay confirmed that microRNA-219c was a novel regulator of Mincle expression. To explore the effect of microRNA-219c in renal inflammation, microRNA-219c was overexpressed in mice via lentivirus injection. Impressively, Mincle and inflammatory cytokines CCL2, IL6 mRNA was remarkably reduced in UUO kidney compared to empty vector group.

Conclusions: MicroRNA-219c was a novel regulator of Mincle which is critical for maintaining proinflammatory macrophage phenotype and contribute to renal inflammation. Targeting microRNA-219c-Mincle may represent as a novel therapy for macrophage-dependent kidney injury.

Funding: Government Support - Non-U.S.

MicroRNA-132 Mediates Tubular Cell Sensitivity and Increases Kidney Injury in Mice

Cory V. Gerlach,[1,2] Jia-Ren Lin,[1] Robert A. Everley,[1] Joseph V. Bonventre,[2,1] Vishal S. Vaidya.[2,1] *[1]Harvard Program in Therapeutic Science, Harvard Medical School, Boston, MA; [2]Renal Division, Brigham and Women's Hospital, Boston, MA.*

Background: MicroRNAs regulate multiple signaling pathways that can affect disease progression. We previously reported that miR-132 was upregulated in kidney tubular epithelial cells following injury with nephrotoxic chemicals and was positively correlated with kidney injury in mice and humans.

Methods: MiR-132 knockout (KO) mice and wild-type (WT) littermate controls were subjected to folic acid (FA) nephropathy (250 mg/kg, ip). Kidney structure and function was assessed by widely established methods. Cyclic immunofluorescence was conducted to evaluate 21 proteins representing inflammation, proliferation and DNA damage on the same fixed kidney tissue. For mechanistic investigations, tandem mass tag proteomics was conducted and targeted pathways were probed using Human Proximal Tubular Epithelial Cells (HPTECs) transfected with miR-132 mimics or inhibitors.

Results: In miR-132 KO mice, FA injections resulted in 37% less tubular injury and 64% lower levels of blood urea nitrogen after 2 days compared to WT mice ($p<0.05$). At day 2, tubular cell proliferation, DNA damage and inflammation were also decreased in miR-132 KO mice relative to WT. Interestingly, miR-132 KO and WT mice had similar kidney damage at day 1, demonstrating that miR-132 KO mice recovered more quickly despite less tubular cell proliferation. On the other hand, proteomics revealed that miR-132 overexpression in HPTECs upregulated proteins involved in promoting cell cycle progression. Out of the 9 proteins predicted to be miR-132 targets, RASA1 (inhibitor of Ras) and SOD2 (detoxifier of mitochondrial reactive oxygen species) were confirmed. In HPTECs, overexpression of miR-132 increased cell count by 69% while miR-132 inhibition decreased cell count by 33% ($p<0.05$). Testing the functional importance of these data in an injury setting, when HPTECs overexpressing miR-132 were treated with cisplatin there was ~2.5-fold increase in cell death ($p<0.05$).

Conclusions: Upregulation of miR-132 following kidney injury increases the sensitivity of the kidney to further damage. Therefore, inhibition of miR-132 may offer a therapeutic benefit for acute kidney injury and limit the extent of kidney damage.

Effect of NLRP3 on Rhabdomyolysis-Induced AKI Model

Suk jong Song,[1] Sangho Lee,[1] Ju young Moon,[3] Yang gyun Kim,[1] Kyung-hwan Jeong,[4] Dong-Jin Kim,[2] Su-Mi Kim,[2] Seo Jung-Woo,[2] Su Woong Jung,[1] Yu ho Lee.[5] *[1]Division of Nephrology Department of internal medicine Kyung Hee University College of Medicine, Seoul, Republic of Korea; [2]Kyung Hee University, Seoul, Republic of Korea; [3]Kyung Hee University, College of Medicine, Seoul, Republic of Korea; [4]Kyung Hee University, School of Medicine, Seoul, Republic of Korea; [5]Kyung Hee University Hospital at Gangdong, Seoul, Korea, Seoul, Republic of Korea.*

Background: Recent studies suggested NOD-like receptor, pyrin domain containing-3 (NLRP3) inflammasome contribute renal injury in rhabdomyolysis. However, a role of the inflammasome-independent tubular epithelial NLRP3 in rhabdomyolysis-induced acute kidney injury (RAKI) has not clarified yet. We investigated the role of both inflammasome-independent tubular NLRP3 and inflammasome-dependent NLRP3 in RAKI and evaluated the possibility of NLRP3 as the treatment target of RAKI.

Methods: HK-2 cells and THP-1 cells were treated with myoglobin to mimic the rhabdomyolysis environment in vitro. A glycerol-induced rhabdomyolysis animal model was used to generate RAKI model in NLRP3 knock-out (KO) and wild-type (WT) mice.

Results: Apoptosis increased by myoglobin-induced injury in HK-2 cells; however, the number of apoptotic cells significantly decreased in siNLRP3 treated HK-2 cells. The increase of inflammatory cytokines, IL-1β and IL-18, by myoglobin-induced injury in THP-1 cells attenuated by siNLRP3 treatment. The RAKI NLRP3 KO mice showed a marked decrease in serum creatine levels, renal KIM-1, and histologic renal injury scores than in RAKI WT mice. Apoptotic markers such as PARP and cleaved caspase-3 in the kidney decreased in NLRP3 KO mice compared with WT. Also, inflammatory cytokines such as IL-6, TNF-α, and IL-1β decreased in RAKI NLRP3 KO.

Conclusions: In conclusion, the deficiency of NLRP3 protected kidneys from RAKI by both inflammasome-independent and -dependent ways. The depletion of NLRP3 directly reduced the renal tubular cell apoptosis and blocked the NLRP3 inflammasome activation of the macrophage after RAKI. Our results suggest that NLRP3 could play the essential role in RAKI and be a candidate as a treatment target.

A New Mouse Model for Septic AKI with Vasopressor Support

Brianna C. Halasa,[1] Jonathan Street,[1] Peter S. Yuen,[2] Robert A. Star.[2] *[1]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [2]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD.*

Background: Sepsis, a common cause of acute kidney injury (AKI), is a dysregulated host response to infection that leads to multiple organ dysfunction. Currently, there is no specific therapy for sepsis/AKI. Patients with sepsis-induced AKI are treated with supportive care including fluids and vasopressors to manage hypotension. While blood pressure maintenance in sepsis patients is routine, blood pressure measurement and management is notoriously absent in small animal models. We established a mouse model of septic-AKI with conscious hemodynamic monitoring and vasopressor treatment. We hypothesize that stabilizing blood pressure with norepinephrine (NE) will partially mitigate the severity of sepsis-AKI, perhaps changing the responsiveness to specific treatments.

Methods: In CD-1 mice (n=22), we inserted a telemetry device into the left carotid artery to monitor blood pressure, and catheterized the right jugular vein for IV drug delivery. After recovery, sepsis-AKI was induced by cecal ligation and puncture (CLP). NE was administered IV via an osmotic minipump. Hemodynamics were recorded by telemetry from 24 hr before to 24 hr post-CLP. Glomerular filtration rate (GFR) was measured by loss of transcutaneous fluorescence of IV injected FITC-sinistrin.

Results: Surgical anesthesia caused transient 1 hr hypotension and bradycardia. Despite variability, septic NE-treated mice fell into 2 groups. In the first group (n=8), the effect of NE was short. The blood pressure increased for ~4 hr then dropped to septic-shock levels (<65mmHg). In the second group (n=12), NE effect lasted longer. The blood pressure rose to normal (90-110 mmHg) and remained constant for ~20 hr. In 2 outliers, the blood pressure fluctuated over 24 hr. The heart rate was consistent in all groups; returning to normal (650-750 bpm), then decreasing 3-5 hr later. We measured GFR in mice that survived to 24 hr; 2 mice from the second group had a normal GFR of 742 and 871 uL/min/100gBW.

Conclusions: We successfully delivered intravenous NE and monitored hemodynamics in septic mice. We found substantial mouse to mouse variability in blood pressure, making it crucial to monitor individual NE responses. NE had the expected hemodynamic response in blood pressure stability in over half of the mice.

A Novel Contrast-Induced AKI Mouse Model Based on Low-Osmolar Contrast Medium

Jianxiao Shen, Zhaohui Ni. *Renji Hospital, Shanghai, China.*

Background: The contrast-induced acute kidney injury (CI-AKI) has been becoming the third common cause of hospital-acquired acute kidney injury. An ideal animal model is essential for understanding the pathophysiology of CI-AKI. This study provides a novel, efficient and reproducible CI-AKI model which was developed in mouse by administrating a low-osmolar contrast medium (LOCM).

Methods: First, we applied the frequently-used pretreatments (uninephrectomy and water deprivation), which combined with HOCM on rats could induce CI-AKI, on mice with LOCM. Secondly,we attempted to find a novel preatment suitable for mouse and LOCM by combining two classic pretreatments(uninephrectomy, water deprivation and furosemide administration). Finally, we evaluate the kidney damage of the novel model.

Results: This mouse model possessed a significant reduction in renal function, severe renal tissue damage, and increased renal tubular cells apoptosis, indicating that LOCM is a feasible inducer for CI-AKI mice model.

Conclusions: We found that uninephrectomy(UPHT) combined with 24h water deprivation and furosemide administration 20 min before LOCM (iohexol, 10 ml/kg) application is a feasible pretreatment to establish a novel CI-AKI mouse model.

Neonatal AKI in a Juvenile Rabbit Model Results in Reduced Nephron Number Assessed by MRI

Jennifer R. Charlton,[1] Edwin Baldelomar,[2] Sejin Nam,[2] Kevin M. Bennett.[3] *[1]University of Virginia, Charlottesville, VA; [2]University of Hawaii at Manoa, Honolulu, HI; [3]University of Hawai'i, Honolulu, HI.*

Background: Acute kidney injury (AKI) affects 30% of preterm neonates. Preterm neonates develop AKI during nephrogenesis conferring a risk for chronic kidney disease. Current monitoring practices cannot detect microstructural changes in the kidney. Our objective was to assess if the renal microstructure, number (N_{glom}) and volume (V_{glom}) of the glomeruli, is affected by AKI during nephrogenesis using cationic ferritin enhanced MRI (CFE-MRI).

Methods: New Zealand rabbits were used as nephrogenesis occurs for 3 postnatal weeks. The AKI group received indomethacin and gentamicin at week #1 for four days. At six weeks, the AKI and control groups (5/grp) were injected with cationic ferritin, euthanized and kidneys were imaged (7T ClinScan GRE pulse sequence:TR:80/TE:20, thickness 0.17, FOV 29, 448*448 matrix, FA 25°). N_{glom} and V_{glom} were determined by threshold guiding with a watershed transformation.

Results: Body and kidney weights were significantly lower in the AKI group. The kidney/body weight and renal function measured by serum creatinine was not different between the groups. N_{glom} and V_{glom} were lower in the AKI group (N_{glom}: 86387 vs 178093, p=0.01; V_{glom}: 319044 vs. 425029 μm^3, p=0.01), Fig 1. AKI kidneys had a layer of glomeruli which were not labeled and undetectable by MRI. On histological assessment, the glomeruli in the undetectable region were shrunken, immature and lacked tubules (Fig 2).

Conclusions: Neonatal AKI from gentamicin and indomethacin causes permanent glomerular reduction without glomerular hypertrophy. Tools such as CFE-MRI that allow us to visualize and quantify renal microstructure to detect early CKD and evaluate the nephrotoxic potential of medications during nephrogenesis.

Experimental Aristolochic Acid Nephropathy: A Model to Study AKI-to-CKD Transition

Inès Jadot,[1] Florian Juszczak,[2,1] Olivia Botton,[1] Joelle L. Nortier,[3] Anne-Emilie Decleves,[2] Nathalie Caron.[1] *[1]University of Namur, Namur, Belgium; [2]Laboratory of Molecular Biology, University of Mons, Belgium, NIMY (MONS), Belgium; [3]Hospital Erasme, Brussels, Belgium.*

Background: Even though impaired kidney function is classified into two distinct categories, the acute (AKI) and the chronic (CKD) kidney disease, recent epidemiologic and mechanistic studies demonstrated that AKI and CKD are interconnected. Indeed, AKI is a risk factor for the development of CKD. In this regard, molecular and cellular mechanisms underlying the AKI-to-CKD transition are unclear, mainly due to a lack of appropriate experimental models. In the present study, we aim to highlight the benefit of using the experimental aristolochic acid (AA) nephropathy (AAN) model to further delineate the progression of CKD from an AKI episode.

Methods: C57BL/6J male mice were randomly subjected to daily ip injection of vehicle or AAI solution (3,5mg/kg) for 4 days. Mice were then euthanized at different time-

points to determine key biological markers of the AKI-to-CKD transition using urine and plasma assays, histological and molecular analyses.

Results: AA-treated mice developed a biphasic evolution of renal dysfunction and morphological alterations. First, an AKI phase (day 5) was demonstrated as attested by a significant increase in plasma creatinine along with PTEC necrosis as well as proteinuria. Later, during the progression of AKI to CKD, increased in oxidative stress and inflammatory cell infiltration (macrophages and lymphocytes) were characterized. Finally, chronic phase (day 20) was characterized by an extensive tubular atrophy and a massive tubulo-interstitial fibrosis as attested by Red Sirius staining and increased in pro-fibrotic gene expression.

Conclusions: AKI-to-CKD transition has clinical importance since patients surviving an episode of AKI present a significant risk of progression to CKD. However, the mechanisms by which AKI might initiate the CKD onset have not been fully defined. A better understanding of these mechanisms could lead to identify key biomarkers as well as new therapeutic strategies to prevent and treat AKI or impede progression to CKD. In this regard, animal models of AAN could represent a useful tool to provide important insights into the underlying mechanisms of AKI-to-CKD transition.

FR-PO061

Low Nephron Endowment-Induced Compensatory Nephron Hypertrophy Causes ER Stress Making the Nephrons More Susceptible to Injury

Hongxia Zhang,[2,1] Jinxian Xu,[2] Caihong Dai,[2] Shijun Lv,[1] Jian-Kang Chen.[2] *[1]Department of Clinic Medicine, Weifang Mecial College, Weifang, China; [2]Medical College of Georgia, Augusta University, Augusta, GA.*

Background: Functioning nephrons respond to nephron deficits by increases in size and mass but not in number. Such a growth response is called compensatory nephron hypertrophy (CNH), which can occur in many situations. However, the pathogenic role of CNH in determining the susceptibility and severity of AKI and the underlying molecular mechanisms remain poorly understood.

Methods: We generated an *mVPS34* gene-floxed mouse and crossed it with a HoxB7. Cre mouse. Utilizing a long-term selective breeding strategy for a low HoxB7.Cre activity, we established a stable sub-strain of renal collecting system-specific mVPS34 knockout (*KO*) mice with a genotype of $mVPS34^{flox/flox}$;$HoxB7.Cre^{(+)}$. These *KO* mice were challenged with bilateral renal ischemia/reperfusion (I/R) insults at 8 weeks of age. Gender-matched littermates with a genotype of $mVPS34^{flox/flox}$;$HoxB7.Cre^{(-)}$ were used as controls (*Ctrl*).

Results: The *KO* mice appear healthy, with normal levels of BUN, serum creatinine, and blood pressure (measured by telemetry). Using the newly developed accurate glomerular counting method, we found that *KO* mice have a 60% congenital nephron deficit, compared to *Ctrl* littermates: 11066 ± 776.5 (*N*=8 mice) vs. 27915 ± 1293 (*N*=11 mice) nephrons/mouse, with both left and right kidneys containing similarly lower nephron numbers. The mean renal glomerular and tubular areas of *KO* mice were significantly larger, with a 38% increase in single nephron GFR, confirming congenital nephron deficit-induced CNH. A 15-minute ischemia followed by 24 hours of reperfusion caused markedly more severe ischemia-reperfusion injury (IRI) and significant increases in both serum creatinine (Scr) and BUN in *KO* mice while *Ctrl* mice exhibited minimal structural damage but had no increase in either Scr or BUN. A 30-minute I/R also caused IRI in both *KO* mice and *Ctrl* mice, with significantly more severe morphological and functional damage in KO mice than in Ctrl mice. Mechanistic studies revealed markedly higher levels of Bip and C/EBP homologous protein (CHOP) in the *KO* mice, indicating the elevation of ER stress.

Conclusions: The congenital CNH caused by mVPS34 deletion in collecting duct is more susceptible and severe to ischemic nephron injury, which is likely mediated by elevated ER stress.

Repetitive Ischemic Injuries to the Kidneys Result in Lymph Node Fibrosis and Impaired Healing

Omar H. Maarouf,[1] Mayuko Uehara,[2] Vivek Kasinath,[2] Zhabiz Solhjou,[7] Naima M. Banouni,[2] Baharak Bahmani,[4] Liwei Jiang,[2] Osman A. Yilmam,[2] Indira Guleria,[6] Scott B. Lovitch,[4] Jane L. Grogan,[8] Peter Sage,[4] Jonathan Bromberg,[5] Martina M. McGrath,[3] Reza Abdi.[2] *[1]Thomas Jefferson University Hospital, Philadelphia, PA; [2]Medicine/Renal, Brigham and Women's Hospital, Boston, MA; [3]Harvard University, West Roxbury, MA; [4]Brigham and Women's Hospital, Boston, MA; [5]University of Maryland, Baltimore, MD; [6]Children's Hospital Boston, Boston, MA; [7]University of Central Florida, Kissimmee, FL; [8]Genentech, South San Francisco, CA.*

Background: The contribution of the kidney-draining lymph node (KLN) to the pathogenesis of ischemia-reperfusion injury (IRI) of the kidney and its subsequent recovery has not been explored in depth. In addition, the mechanism by which repetitive IRI contributes to renal fibrosis remains poorly understood.

Methods: Transgenic mice were used. Ischemia Reperfusion Injury (IRI) surgeries on mice were performed using clamps. Aseptic techniques were used to culture cells. Protein and mRNA were extracted according to generally accepted techniques. Light and electron microscopy were used in addition to immunofluorescence staining.

Results: Herein, we have found that IRI of the kidney is associated with expansion of high endothelial venules (HEVs) and activation of fibroblastic reticular cells (FRC) in the KLN, as demonstrated by significant expansion in the extracellular matrix. The lymphotoxin α signaling pathway mediates activation of FRCs. Chronic blockade of the LTα –LTβr axis with lymphotoxin β receptor immunoglobulin (LTβr-Ig) resulted in marked alteration of the KLN as well as augmentation of renal fibrosis. In the acute setting, depletion of FRCs reduced T cell activation in the KLN and ameliorated renal injury 2 days post-IRI. Repetitive renal IRI was associated with senescence of FRCs, fibrosis of the KLN, and renal scarring. FRC administration promoted repair of the kidney and KLN

Conclusions: Our study is novel in emphasizing the critical role of FRCs in KLN in both the initiation and repair phases of injury following IRI of the kidney. We also highlight the potential of FRCs as a cellular therapy to control inflammation and promote renal repair following IRI important in the progression of renal fibrosis.

Interferon Regulatory Factor 4 in Macrophages Promotes Renal Fibrosis Following Severe AKI

Zhilian Li,[1,2] Jessica M. Overstreet,[1] Sungjin Chung,[1,3] Yinqiu Wang,[1] Ming-Zhi Zhang,[1] Raymond C. Harris.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China; [3]The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.*

Background: Acute kidney injury (AKI) is characterized by abrupt and reversible kidney dysfunction, and incomplete recovery from AKI leads to chronic kidney injury. Macrophage proliferation and polarization to an M2 phenotype plays a key role in recovery from AKI. However, M2 macrophages can produce profibrotic factors such as TGF-β and FIZZ1/RELMα, and their persistence may contribute to interstitial fibrosis when recovery from AKI is incomplete. Interferon regulatory factor 4 (IRF4) plays an important role in macrophage M2 polarization. The present study examined the potential role of macrophage IRF4 in recovery from AKI.

Methods: Wild type (WT, $IRF4^{f/f}$) or macrophage $IRF4^{-/-}$ (LysM-Cre; $IRF4^{f/f}$) mice (male, 3 months old, C57BL/6) were uninephrectomized, immediately followed by unilateral I/R with renal pedicle clamping for 32 min. Mice were sacrificed after 4 weeks.

Results: The effectiveness of macrophage IRF4 deletion was confirmed by qPCR in isolated renal macrophages. In cultured bone marrow monocytes, IRF4 deletion led to significant increases in LPS/IFN-γ-induced proinflammatory cytokines/chemokines. Macrophage $IRF4^{-/-}$ mice had delayed functional recovery during the first five days of recovery and more histologic injury at 5 days post I/R. At four weeks post-severe AKI, kidneys of $IRF4^{-/-}$ mice had marked decreases in M2 markers, IL-4Rα, CD206, FIZZ1/RELMα, CD209, and B7-H4 as well as decreases in proinflammatory cytokines/chemokines, IL-1α, IL-1β, IL-6, IL-23, CCL3, iNOS, TNF-α, and IFN-γ. Surprisingly, macrophage $IRF4^{-/-}$ mice had less severe kidney injury, as indicated by fewer protein casts and dilated tubules and less tubular atrophy. Sirius red and Masson's Trichrome staining showed less renal interstitial fibrosis and decreased mRNA and protein levels of profibrotic and fibrotic components, TGF-β1, TGF-β2, CTGF, α-SMA, fibronectin, collagens I, III, IV as well as decreased immune cell infiltration in macrophage $IRF4^{-/-}$ mice.

Conclusions: Macrophage IRF4 facilitates functional and structural recovery of kidneys from AKI, possibly due to inhibiting proinflammatory cytokines/chemokines. When recovery from AKI is incomplete, IRF4-mediated pro-fibrotic, M2 polarization of macrophages/dendritic cells may contribute to development of fibrosis.

FR-PO064

Hydrodynamic Isotonic Fluid Delivery Following Renal I/R Reduces Inflammation Associated with the AKI-to-CKD Transition

Purvi Mehrotra,[1] Jason A. Collett,[2] Riley P. O'Shaughnessy,[2] David P. Basile.[2] *[1]Indiana School of Medicine, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: AKI represents a significant risk factor for CKD. T cells, most notably, Th17 cells, play an important role in the transition from AKI to CKD. We've previously shown that retrograde hydrodynamic delivery of isotonic fluid (HIFD) improved renal function in established AKI between 24-48 hours following ischemia and reperfusion injury. This improvement was associated with decreased inflammation and vascular congestion. However, it is unknown whether HIFD manifests sustained effects on renal function, inflammation and secondary development of CKD.

Methods: S.D. rats underwent left unilateral I/R: 35 min with right Unx to induce AKI. 24 hours later, renal function was evaluated (serum creatinine; SCre) and rats received either HIFD into the renal vein or 0.5ml of saline into the vena cava (VC) as control. The animals were then allowed to recover for 20 weeks while regularly monitoring renal function. Inflammatory cells were evaluated in kidney 20 weeks post-surgery.

Results: Rats were stratified into either moderate (SCre <3.0 mg/dl) and severe (SCre >3.0 mg/dl) injury groups based upon serum creatinine at 24 hours post I/R. In the severe injury group, sCre tended to be reduced between 24 to 48hrs by HIFD treatment relative to VC-treated rats (HIFD: -0.34 vs. VC: +0.03 mg/dl); HIFD had no effect on SCre between 24-48 hours in the mild injury group. At 20 weeks post I/R, the number of renal mononuclear cells were significantly reduced by HIFD treatment in both moderate (41%) and severe (54%) injury as compared to VC-treated rats. In addition, there was a significant reduction in Th17 cells (CD4+IL17+) following HIFD in both the moderate (HIFD: 889.7 vs. VC: 2480 cells/gram kidney; $p<0.05$) and severe groups (HIFD: 1351 vs. VC: 3838 cells/gram kidney; $p<0.05$). HIFD-treated rats also demonstrated significant reductions in CD4+IFNγ+ T cells (HIFD: 477.4 vs. VC: 1529 cell/gram kidney; $p<0.05$) compared with VC-treated rats in the severe group.

Conclusions: Renal vein HIFD treatment following established AKI reduces inflammation associated CKD progression. HIFD treatment improved chronic renal

inflammation despite the lack of improvement in renal function in moderately injured animals. Therefore, HIFD represent a novel therapeutic strategy for prevention of CKD following AKI.

FR-PO065

Significance of Pax2 Reactivation After Kidney Injury

Keisuke Sako, Shohei Makiishi, Yuta Yamamura, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Kengo Furuichi, Takashi Wada. *Kanazawa University, Kanazawa, Japan.*

Background: *Pax2* is a transcription factor necessary for kidney development. It has been reported that homozygous mutation of *Pax2* is embryonic lethal. On the other hand, *Pax2* expression in the mature kidney is almost diminished. However, it has been reported that *Pax2* is reactivated in the proximal epithelial tubular cells at the recovery phase of the injury. It has also been reported that *Pax2* is involved in stimulation of cell proliferation. In this study, we examined the effect of reactivating *Pax2* on kidney injury.

Methods: To determine the function of *Pax2* reactivation in mouse proximal tubules of kidneys, we generated kidneyproximal tubule-specific *Pax2* conditional knockout (K/O) mice. We generated a transgenic mouse that expresses Cre recombinase under the control of the promoter of the kidney androgen-regulated protein (KAP) gene (*Pax2* flox/flox; KAP-Cre^{+}male mouse). Kidney ischemia was induced in male mice of 6-week-old C57BL/6J (B6) male mice and conditional K/O mice. The left renal artery and vein of these mice were clamped for 60 min to induce ischemia -reperfusion (I/R) injury. Kidney tissues were removed for examination 2, 4, 7 or 14 days after I/R. We evaluated cell proliferation (immunohistochemical staining of Ki-67 and BrdU), inflammation (immunohistochemical staining of F4/80 and CD3) and fibrosis (sirius red staining and hydroxyproline assay). We also conducted similar experiments on *Pax2* hetero K/O mice and *Pax2* siRNA induction mice.

Results: In B6 male mice, the number of *Pax2* positive cells and mRNA expressions increased after I/R. Immunohistochemical analysis of CD3 and F4/80 showed at increasing number of the in inflammatory cell infiltration in conditional K/O mice ($p<0.05$). In analysis of interstitial fibrosis, the area ratio of sirius red staining and the hydroxyproline assay were higher in conditional K/O mice at day 14 after I/R ($p<0.05$). The number of Ki-67 positive cells was decreased in conditional knockout mice at day 2 after I/R ($p<0.01$). Almost of all the Ki 67-positive cells were co-positive with BrdU. In addition, the area ratio of sirius red staining was also higher in *Pax2* hetero K/O mice and *Pax2* siRNA induction mice at 14 days after I/R ($p<0.05$).

Conclusions: Reactivation of Pax2 after ischemia reperfusion injury may be involved in cell proliferation and interstitial fibrosis suppression in the injured kidney.

FR-PO066

Loss of Proximal Tubular Krüppel-Like Factor 15 Exacerbates Renal Injury

Ahmed A. Attallah,[1] Xiangchen Gu,[3] Yiqing Guo,[1] Sian Piret,[1] Monica P. Revelo Penafiel,[4] John C. He,[5] Sandeep K. Mallipattu.[2] *[1]Stony Brook University, Stony Brook, NY; [2]Stony Brook Medicine, Stony Brook, NY; [3]Yueyang hospital of integrated Traditional Chinese and Western Medicine, Shanghai University of Traditional Chinese Medicine, Shanghai, China; [4]University of Utah, Murray, UT; [5]Mount Sinai School of Medicine, New York, NY.*

Background: Although several causes contribute to the development of kidney fibrosis and eventual CKD, repeated bouts of acute tubular injury secondary to DNA damaging tubular toxins remains a major cause. Krüppel-Like Factor 15 (KLF15), a zinc-finger transcription factor that is expressed in renal stromal and proximal tubule (PT) cells was recently shown as a potential mediator of kidney fibrosis. KLF15 expression is reduced in early and late stages of human kidney fibrosis as compared to healthy control subjects. We sought to determine the mechanism by which tubular KLF15 serves a key mediator of DNA-damage induced PT injury leading to AKI and CKD.

Methods: PT-specific *Klf15* knockout mice (*Klf15*$^{\Delta Pepck}$) were generated by crossing *Klf15*$^{fl/fl}$ mice with *Pepck-Cre* mice. We utilized low-dose Aristolochic Acid I (AAI) to model DNA-damage induced PT injury, 3 mg/kg every three days for 2 weeks (active phase), followed by 2 weeks for remodeling (chronic phase), with DMSO as control. RNA-Seq was performed in active and remodeling phase samples.

Results: *Klf15*$^{\Delta Pepck}$ mice demonstrated worse renal function (elevated serum urea nitrogen and creatinine), increased PT injury (AQP1 & lotus lectin redistribution and reduced expression) and changes in fibrotic markers compared to AAI-treated *Klf15*$^{fl/fl}$ mice in the acute and chronic phase. RNA-seq analysis showed that integrin signaling and focal adhesion pathways were upregulated in AAI-treated *Klf15*$^{fl/fl}$ mice. In the active phase a subset of 36 genes in metabolic & oxidative stress pathways were downregulated in *Klf15*$^{\Delta Pepck}$ but not in *Klf15*$^{fl/fl}$ and have KLF15 predicted binding sites (BS). In the chronic phase versus DMSO a subset of 13 genes including additional members of Focal adhesion, Regulation of actin cytoskeleton, integrin signaling and Inflammation pathways were upregulated in *Klf15*$^{\Delta Pepck}$ but not in *Klf15*$^{fl/fl}$ and have KLF15 BS. In the active to chronic transition a subset of 55 genes including additional members of Cell adhesion, Cell differentiation and Integrin signaling pathways were upregulated in *Klf15*$^{\Delta Pepck}$ but not in the *Klf15*$^{fl/fl}$ and have KLF15 BS.

Conclusions: These data suggest that the loss of tubular KLF15 exacerbates AAI-induced AKI and CKD, which is mediated by metabolic, focal adhesion and integrin signaling pathways.

FR-PO067

Identifying the Target of Pro-Regenerative Compound, PTBA, to Improve Post-AKI Repair

Hwa I. Han, Amanda Crunk, Neil A. Hukriede. *University of Pittsburgh, Pittsburgh, PA.*

Background: Despite the high prevalence of AKI, no approved therapeutic directly repairs renal tubular epithelial cells (RTEC). We discovered a small molecule, phenylthio butanoic acid (PTBA), which improves post-AKI survival, RTEC dedifferentiation & proliferation, & attenuates fibrosis in various models of AKI. *In vitro* studies suggest histone deacetylase 8 (HDAC8) as a PTBA target. We utilize *hdac8* mutant zebrafish to investigate loss-of-function in a nephrotoxin model of AKI. HDAC8 deacetylates structural maintenance of chromosomes 3 (SMC3), a subunit of cohesin involved in sister chromatid cohesion & subsequent segregation. Without HDAC8, there is a perturbance of SMC3 acetylation resulting in G1/S delay. G1/S arrest has been reported as a protective mechanism to allow RTEC proliferation, while G2/M arrest produces pro-fibrotic factors. We hypothesize HDAC8 inhibition dysregulates the SMC3 acetylation cycle, thereby promoting G1/S delay rather than G2/M arrest in RTECs, acting as a protective mechanism.

Methods: We utilized *hdac8* null mutant fish to investigate changes in the repair response. To analyze injury response at a cellular level, we utilized immunohistochemistry to characterize cell cycle phases: EdU (S), PCNA (S), & Phospho-Histone H3 (pH3) (G2/M). We compared Smc3^{Ac} changes, a potential downstream target of Hdac8, in wild types & *hdac8*$^{-/-}$ by western blot & profiled the acetylome in wildtype, mutant, & compound treated zebrafish larvae.

Results: Upon gentamicin induced AKI, *hdac8*$^{-/-}$ fish exhibited increased survival as compared to genetically wildtype larvae. In assessing cell cycle changes, we identified an increased number of PCNA+ & EdU+ RTECs in *hdac8*$^{-/-}$. However, *hdac8*$^{-/-}$ showed a lower number of pH3+ RTECs, a marker of G2/M. Upon investigating SMC3^{Ac} levels, we observed increased SMC3^{Ac} in *hdac8*$^{-/-}$ larvae.

Conclusions: HDAC8 inhibition & SMC3 acetylation is a potential mechanism for increasing post-AKI repair. Genetic ablation of *hdac8* shows enhanced post-AKI survival. Cell cycle analysis suggests absence of Hdac8 activity increases PCNA & EdU, S-phase markers, while lowering G2/M arrest. This increase in S phase & decrease in G2/M may be attributed to the lack of interaction between Hdac8 & Smc3. Overall, we identified a target for HDAC8 & SMC3 as a potential molecular pathway for RTECs to prefer G1/S delay, rather than G2/M as a protective mechanism during AKI.

Senescence Associated Secretory Phenotype: Role of Plasminogen Activator Inhibitor-2 (PAI-2) in Acute and Chronic Kidney Disease

Payel Sen, Alexandra Helmke, Sibylle Von Vietinghoff, Song Rong, Jan H. Braesen, Hermann G. Haller, Anette Melk, Roland Schmitt. *Hannover Medical School, Hannover, Germany.*

Background: One of the important mechanisms that play a role in age-related kidney disease is cellular senescence and the senescence associated secretory phenotype (SASP), which activates fibroblasts and causes immune cell infiltration. We identified plasminogen activator inhibitor-2 (PAI-2) as an upregulated secreted protein in senescent primary tubular epithelial cells (PTEC). PAI-2 is best known for its expression by macrophages, which are integral in post-injury kidney repair. Therefore, we intended to study the role of PAI-2 in the renal tubular SASP and immune surveillance in AKI and CKD.

Methods: Microarray was used for SASP analysis in PTEC. PAI-2 mRNA expression was tested in PTECs after treatment with Phorbol and γ-irradiation. HEK cells transduced with PAI-2 were co-cultured with fibroblasts. PTEC and bone marrow derived macrophages (BMDM) were extracted from wild type (WT) and PAI-2 knock out (KO) mice. To assess differences in post-injury repair, PAI-2 WT and KO mice were subjected to ischemia/reperfusion (I/R) and unilateral ureteral obstruction (UUO).

Results: PTEC derived from PAI-2 KO mice showed higher proliferation and lower expression of senescence marker p16INK4a after Phorbol treatment. In co-culture assays secreted PAI-2 activated fibroblasts. BMDMs extracted from WT mice had a stronger inflammatory phenotype after activation with LPS and IFNγ. While in acute phase post I/R PAI-2 KO kidneys had a reduced damage load, PAI-2 KO was associated with enhanced chronic damage during the later phase of I/R. In UUO, the KO kidney had more damage in acute as well as chronic phase. WT kidneys compared to KO showed steady decline in classically as well as alternatively activated macrophages in the later time points in both forms of injury.

Conclusions: PAI-2 is produced and secreted by tubular cells upon stress and during senescence. In the peritubular milieu, PAI-2 plays a heterogeneous role by promoting senescence and activating fibroblasts. It also strongly affects macrophage polarization and infiltration. While PAI-2 might have damaging effects during early renal injury our results indicate that PAI-2 is needed for long-term adaptation. In summary, PAI-2 is a novel renal SASP component which has an important impact on kidney adaptive repair.

FR-PO069

Tubular Epithelial Proliferation Accelerates Tubular Atrophy After Kidney Injury Through Its Contractile Capacity

Noriyuki Yamashita, Tetsuro Kusaba, Keiichi Tamagaki. Department of Nephrology, Graduate School of Medical Science, Kyoto Prefectural University of Medicine *Kyoto Prefectural University of Medicine, Kyoto, Japan.*

Background: Tubular atrophy is a common pathological finding in kidney fibrosis and is characterized by flattened tubular epithelia surrounded by thickened tubular basement membrane (TBM). After injury, neighboring epithelia exert strong mechanical forces on the area surrounding the damaged site in order to close the wound. We hypothesize that the regeneration of tubular epithelia during repair itself drives the TBM to shrink, resulting in tubular atrophy.

Methods: In order to mimic the mechanical effects of tubular epithelia during repair on the TBM *in vitro*, tubular epithelial cells (NRK52E) were cultured on a thin floating collagen gel, and its changes by various stimuli were assessed. In *in vivo* experiments, we performed a clonal analysis of solely labeled tubular epithelia using bigenic mice with the proximal tubule-specific tamoxifen-inducible Cre gene (SLC34a1GCE) and tdTomato reporter gene. We then investigated the role of focal adhesion kinase (FAK), a key molecule in the mechanosensing of focal adhesion and the modulation of actin polymerization, during kidney injury and repair.

Results: An *in vitro* analysis showed that the active proliferation of NRK52E caused the floating gel to shrink and become thick, similar to the TBM of atrophic tubules. The TGFβ treatment accelerated gel contraction, whereas the inhibition of actin polymerization by a FAK or ROCK inhibitor suppressed it. An *in vivo* clonal analysis after severe ischemia reperfusion injury (IRI), together with upregulation of TGFβ, showed that tubules containing a larger clone number were more likely to be atrophic and lose terminally differentiated tubular markers. In contrast, tubules containing a large clone number were not atrophic in mild IRI kidneys, and differentiated tubule markers were preserved. Based on the active phosphorylation of FAK in the tubular epithelia and interstitial fibroblasts in IRI kidneys, an *in vivo* clonal analysis showed that the administration of a low dose of the FAK inhibitor ameliorated the atrophy of tubules with a larger clone size and interstitial fibrosis.

Conclusions: The present *in vitro* and*in vivo* results indicate that tubular atrophy after severe kidney injury is associated with the active proliferation of tubular epithelia through its contractile capacity induced by upregulation of TGFβ and subsequent actin polymerization.

FR-PO070

Nephrectomy Induced Renal Repair After AKI Prevents Progression to CKD by an Early Immunosuppressive Action

Lies Moonen,[1] Bart Cuypers,[3] Pieter Meysman,[1] Kris Laukens,[2] Patrick C. D'Haese,[4] Benjamin A. Vervaet.[4] Laboratory of Pathophysiology, University of Antwerp *[1]University of Antwerp, Wilrijk, Belgium; [2]Universiteit Antwerpen, Antwerpen, Belgium; [3]University Of Antwerp, Antwerp, Belgium; [4]University Antwerp, Edegem, Belgium.*

Background: Enhanced renal repair is defined as the remarkable repair of an acutely injured kidney upon removal of the healthy contralateral kidney. If the latter kidney is left in place, repair is only marginal and the injured kidney turns fibrotic. It is yet unclear to which extent and by which molecular mechanism a nephrectomy is able to alter the fate of injured kidney cells.

Methods: Acute kidney injury was induced by left ischemia/reperfusion (I/R) after which either right nephrectomy (Nx) or mock-Nx was performed 3 days later. Wild type C57BL/6J mice underwent 21 min of ischemia at 36°C. Control mice underwent mock-I/R and mock-Nx surgery. Mice were euthanized at either 7 days or 6 weeks after I/R. Kidneys were weighed and qPCR analysis of the profibrotic genes Col1, Col4, TGFbeta and CCN2 was performed. Masson/H&E stain was used to microscopically evaluate histopathology and the extent of collagen deposition. RNA-sequencing was used to compare differential gene expression.

Results: In the I/R without Nx group the median left kidney-to-body weight ratio (mg/g) at week 6 was 2.8 (range 2.1-3.1), whereas that of its right healthy kidney was 6.7 (range 6.4-7.0), indicating severe atrophy in the injured left kidney. In the Nx group, left kidney-to-body ratio was 6.9 (range 6.0-7.3) and that of its right kidney at the time of Nx 6.5 (range 5.9-7.5). When no Nx was performed, Col1, Col4, TGFbeta and CCN2 were upregulated 18-, 5-, 7- and 3-fold compared to controls at week 6, respectively. In case of Nx, this decreased to 5-, 2-, 2-, and 0-fold upregulation. On a histological level, Nx strongly attenuated cortical atrophy and tubulo-interstitial fibrosis. Preliminary whole transcriptome RNA-seq analysis at day 7 showed differential expression of 534 genes (257 up, 277 down) of which immune response and MAPK pathways were most significantly downregulated upon Nx.

Conclusions: In conclusion, Nx performed 3 days after I/R has an early immunosuppressive action and attenuates renal atrophy and fibrosis in C57BL/6J mice. This murine model is a useful alternate tool to further study the mechanism of physiology-driven enhanced renal recovery.

Pannexin1 Regulates Intracellular ATP in a Cisplatin Model of AKI

Jakub Jankowski,[1] Junlan Yao,[1] Shuqiu Zheng,[1] Amandeep Bajwa,[1] Diane L. Rosin,[1] Brant Isakson,[2] Kodi S. Ravichandran,[3] Mark D. Okusa.[1] *[1]University of Virginia, Charlottesville, VA; [2]University of Virginia School of Medicine, Charlottesville, VA; [3]University of Virginia, Carter Immunology Center, Charlottesville, VA.*

Background: Pannexin1 (Panx1) is a membrane channel that can release ATP upon injury, thereby exacerbating inflammation. We reported that *Panx1* deficiency protects kidneys from ischemia-reperfusion injury (IRI). We found significant differences in kidney ATP between *Panx1* KO and control kidneys after injury and hypothesized that retention of ATP is a universal protective mechanism in AKI, including the cisplatin model.

Methods: Global *Panx1* KO and WT mice (n=4) were subjected to 26min bilateral kidney ischemia and 24h of reperfusion. Global (n=8) and proximal tubule (PT, n=4) *Panx1* KO mice and appropriate controls (n=6 and 4, respectively) were given cisplatin (20 mg/kg, ip). Injury was assessed 72 h later by plasma creatinine (PCr), blood urea nitrogen (BUN) and weight loss. Whole kidney ATP was obtained by chloroform extraction of kidney homogenates. CRISPR/Cas9 was used to generate stable *Panx1* KO in murine proximal tubule cells (TKPTS). Cells were treated with 20 μM cisplatin overnight or 20 μM antimycin A for 1 hour to induce injury. Intracellular ATP concentration was measured using luminescent assay.

Results: At baseline, global *Panx1* KO had less ATP (normalized to tissue weight) in whole kidney homogenates than WT mice (n=8 and 9; 0.59 vs. 1.00; $p<0.05$). Following IRI kidney ATP was higher (2.9 vs. 1.0; $p<0.05$) and PCr was lower (0.48 vs. 1.45 mg/dL; $p<0.01$) in *Panx1* KO than in WT mice. After cisplatin, BUN was higher in *Panx1* KO than WT mice (81.74 vs. 58.46 mg/dL; $p=0.07$) but there was no difference in kidney ATP (0.89 vs. 0.92; $p=0.879$). Similarly, after cisplatin, BUN (113.8 vs. 61.49 mg/dL; $p<0.05$) and body weight loss (21.76 vs. 17.37%; $p<0.05$) was higher in PT-specific *Panx1* KO than WT mice. Kidney ATP was not greater in PT-*Panx1* KO than WT mice (1.31 vs. 1.00; $p=0.34$) after cisplatin treatment. Cultured *Panx1* KO cells retained more ATP than controls after cisplatin (54 vs. 36%, $p<0.0001$) or antimycin A (66 vs. 49%, $p<0.001$) treatment.

Conclusions: These results show that Panx1 influences ATP balance in cisplatin injury setting. PT-specific *Panx1* deletion is sufficient to exacerbate injury, contrary to *in vitro* observations that *Panx1* knockout tubules retain more ATP after antimycin A or cisplatin stimulation. The complex role of intracellular ATP homeostasis in AKI will require additional investigation.

Paricalcitol Ameliorates Cisplatin-Induced AKI by Inhibiting Cell Pyroptosis

Hao Zhang,[1] Siqing Jiang,[2] Bin Yi,[1] Zhaoxin Hu.[3] *[1]The Third Xiangya Hospital of Central South University, Changsha, China; [2]The third Xiangya Hospital, Central South University, CHANGSHA, China; [3]Central South University, CHANGSHA, China.*

Background: Cisplatin is a classic and effective chemotherapeutic agent, but its kidney toxicity has restricted its application. Vitamin D receptor (VDR), as an important nuclear receptor, is involved in the pathogenesis of acute and chronic kidney diseases. The VDR agonist paricalcitol exerts a protective effect on a variety of acute kidney injury. In this study, we investigated the protective effect and mechanism of paricalcitol in cisplatin-induced acute injury.

Methods: Eight week old male VDR KO mice and WT mice were randomly divided into 6 groups (n=6): (A) WT+Control, (B) WT+Cisplatin, (C) WT+Cisplatin+Paricalcitol, (D) KO, (E) KO+Cisplatin, (F) KO+Cisplatin+Paricalcitol. Pretreatment of paricalcitol (0.2mg/kg, intraperitoneally injected) was performed for five consecutive days. On the sixth day, cisplatin (20 mg/kg) was intraperitoneally injected to induce acute kidney injury (AKI). Samples were collected 72 hours after cisplatin injection. Real-time PCR and Western blot were used to detect the expressions of renal apoplexy-associated proteins such as NLRP-3, caspase-1 and IL-1β. Renal pathological specimens were subject to HE staining to assess the degree of renal tubular injury.

Results: 1. 72 hours after cisplatin injection, mice in groups B, C, E and F became depressed and ate less. The levels of Cr, BUN and CysC were significantly higher in groups B, C, E and F ($p<0.05$), as compared with those in groups A and D, while mice in group E showed the most serious renal damage ($p<0.05$). 2. The mRNA and protein levels of NLRP-3, caspase-1 and IL-1β in groups B, C, E and F were significantly higher than those in group A and D ($p<0.05$). The increase of the three mRNAs/proteins in group E was most significant ($p<0.05$), and the expression of the three proteins in group C was lower than that in group B. 3. HE staining indicated that the renal tubular injury index in group C was significantly lower than that in group B ($p<0.05$). The renal tubular injury index was highest in group E ($p<0.05$).

Conclusions: VDR plays an important role in cisplatin-induced AKI. The VDR agonist paricalcitol possibly reduce cisplatin-induced AKI by inhibiting cell pyroptosis.

Retinoic Acid Alleviates Cisplatin Induced Kidney Injury Through Activation of Autophagy

Junxia Wu,[1,2] Xin Wan.[3] [1]*Department of Nephrology, Nanjing First Hospital, Nanjing Medical University, Nanjing, Nanjing, China;* [2]*Charles and Jane Pak Center for Mineral Metabolism and Clinical Research, University of Texas Southwestern Medical Center, Dallas, TX;* [3]*Nanjing First Hospital, Nanjing, China*.

Background: Retinoic acid (RA) reduces injury, inflammation, and fibrosis in models of acute renal injury, including toxin and ischemia reperfusion AKI, but little is known about its effect on cisplatin induced kidney injury.

Methods: We examine the effects of RA on cisplatin induced kidney injury in vivo and introduce a murine model of cisplatin induced kidney injury by retro-orbital injection of cisplatin both in WT and autophagy-related gene 5–knockout mice. Renal function test, LDH test, HE staining, PCR, immunoblots and immunofluorescence were used in the study. And in vitro, NRK cells were treated with and without cisplatin and were transfected with GFP-LC3 plasmid. Data are representatives of at least three experiments and expressed as means ± SD. Statistical analysis was conducted using the GraphPad Prism software. Statistical differences in multiple groups were determined by multiple comparisons with ANOVA followed by homogeneity test for variance. $P<0.05$ was considered as significantly different.

Results: Cisplatin group mice exhibited typical features of clinical cisplatin induced kidney injury including renal histology changes, higher level of NGAL and plasm creatinine. In WT mice, RA alleviated cisplatin induced dilation and necrosis of renal tubular epithelial cells and improved renal function and upregulated autophagy. Knockout mice showed more severe kidney injury as was indicated by worsening renal function, more tissue damage. And the protective effect of retinoic acid was not significant in knock out mice as autophagy was blocked. In vitro, RA protected proximal tubular epithelial cells from cisplatin induced injury, inhibited apoptosis and promote the proliferation of epithelial cells after cisplatin induced injury and upregulated autophagy which were confirmed by higher level of LC3 -II / LC3 -I ratio, lower level of P62 by immunoblots and more autophagy punctae after transfection of GFP-LC3 plasmid.

Conclusions: RA alleviates cisplatin-induced kidney injury via upregulating autophagy.

FR-PO074

Cisplatin-Induced AKI: Preconditioning Protects by mRNA-Independent Proteome Alterations

Martin Späth,[1] Malte P. Bartram,[1] Nicolàs Palacio-Escat,[2] Karla J. Hoyer,[1] Bernhard Schermer,[1] Thomas Benzing,[1] Volker R. Burst,[1] Julio Saez-Rodriguez,[2] Pitter F. Huesgen,[3] Roman-Ulrich Mueller,[1] Markus M. Rinschen.[1] [1]*Department 2 of Internal Medicine, Renal Division; University of Cologne, Cologne, Germany;* [2]*RWTH Aachen, Aachen, Germany;* [3]*Forschungszentrum Juelich, Juelich, Germany*.

Background: Acute kidney injury is one of the most common kidney diseases, resulting in significantly increased morbidity and mortality. Unfortunately, strategies for prevention or causal treatment are lacking in routine clinical practice. During the last years it has been shown in animal models, that a number of preconditioning protocols have a protective effect.

Methods: We characterized two of these strategies - calorie restriction and hypoxic preconditioning - in a mouse model of cisplatin-induced acute kidney injury. To investigate the underlying mechanisms, we used multi-layered omic data (transcriptome, proteome, and N-degradome for measuring proteolytic activity) and functional parameters of preconditioned and non-preconditioned cisplatin-treated animals. These parameters were generated from identical animals and integrated bioinformatically.

Results: Both protocols significantly reduced cisplatin-induced acute kidney injury. Bioinformatic analysis revealed mRNA-independent proteomic changes affecting the extracellular compartment, mitochondrial function and tubular transporters. Interestingly, our analyzes showed a strong dissociation of protein and mRNA expression after cisplatin treatment. In the animal cohort, the degree of mRNA-protein dissociation showed a strong correlation ($R> 0.95$) with the degree of damage. N-degradome analysis revealed that most post-transcriptional changes were determined by Arg-specific proteolytic processing. This involved a characteristic cisplatin-induced complement activation, which was prevented by preconditioning. In addition, amyloid and acute phase proteins accumulated within the cortical parenchyma. Extensive analyzes of damage-associated molecular patterns (DAMPs) suggest that the transcription-independent deposition of serum amyloid P could play a key role in the contribution of the microenvironment to renal damage.

Conclusions: This study provides new insights into the pathogenesis of cisplatin-induced acute kidney injury and the molecular mechanisms that underly organ protection through preconditioning through multi-omic phenotype correlations.

Celastrol Ameliorates Cisplatin Nephrotoxicity by Inhibiting NF-κB and Improving Mitochondrial Function

Xiaowen Yu, Yue Zhang, Guixia Ding, Aihua Zhang, Zhanjun Jia, Songming Huang. *Children's Hospital of Nanjing Medical University, Nanjing, China*.

Background: Celastrol (CE) is an active ingredient of Chinese medicine Tripterygium wilfordii which is clinically used to treat immune diseases. Currently, celastrol is documented as a potent agent for treating cancer and inflammatory disorders. The present study was to investigate the effects of celastrol on cisplatin (Cis) nephrotoxicity and the underlying mechanisms.

Methods: In vivo, C57BL/6 mice were treated with cisplatin (20 mg/kg) with or without celastrol administration (1 mg/kg/day). After 3 days treatment, mice were sacrificed and the kidney and blood samples were collected for analysis. In vitro, renal tubular epithelial cells (RTECs) were treated with cisplatin (5 μg/ml) with or without celastrol treatment (50 nM).

Results: Pretreatment with celastrol markedly ameliorated cisplatin-induced kidney injury as shown by the improved renal function (BUN: Cis group 75.2±10.7 vs. Cis+CE group 31.1±10.9mmol/L, $p<0.001$; serum creatinine: Cis group 1.2±0.3 vs. Cis+CE group 0.37±0.18 mg/dl, $p<0.001$; and cystatin C: Cis group 16.0±1.68 vs. Cis+CE group 11.3±1.89 ng/ml, $p<0.001$), kidney morphology (PAS), and oxidative stress (MDA) in line with a robust blockade of renal tubular injury markers of KIM-1 (-86.97%) and NGAL (-82.09%). Meanwhile, renal apoptosis and inflammation were also strikingly attenuated in celastrol-treated mice. In vitro, celastrol inhibited cisplatin-induced cell apoptosis (-34.31%), suppressed NF-κB activation (-54.53%), and improved mitochondrial function shown by the restored mtDNA copy number (+29%), mitochondrial membrane potential (+61.09%), and OXPHOS activity (+1.67 folds) in cisplatin-treated renal tubular cells.

Conclusions: Our study suggested that celastrol could suppress NF-κB and improve mitochondrial function to protect against cisplatin nephrotoxicity. Celastrol serves as a promising drug for the treatment of AKI.

FR-PO076

Lactate Improves Survival in Mice with Sepsis Through HCA2 Activation

Ayumi Takakura,[2] Kambiz Zandi-Nejad.[1] [1]*BIDMC/HVMA-Harvard Medical School, Boston, MA;* [2]*Brigham and Women's Hospital, Boston, MA*.

Background: Sepsis is characterized by systemic inflammation due to infection and is the most common cause of acute kidney injury (AKI) in critically ill patients. During sepsis, activation of pro-inflammatory pathways results in dysfunction of mitochondria and cells, leading to multi-organ failure.

Methods: Wild-type and *Hca2*$^{-/-}$ mice were undergone cecal ligation and puncture (CLP) to induce sepsis. For survival study, we monitored the mice for 2 weeks after CLP. For treatment study, we administered either normal saline or lactated Ringer's solution once a day for total of 3 injections. The isolated peritoneal fluid or cells were subjected to ELISA assay and real time RT-PCR analyses.

Results: Here we show that: 1) in peritoneal immune cells from mice undergone cecal ligation and puncture (CLP), hydroxycarboxylic acid receptor 2 (HCA2) expression increased in parallel with pro-inflammatory cytokines; 2) survival rates for *Hca2*$^{-/-}$mice after CLP were lower than for wild-type mice (~40% vs. ~80%) 2 weeks after CLP-induced sepsis, suggestive of a protective role for HCA2 in sepsis; 3) early mortality of *Hca2*$^{-/-}$mice were associated with higher pro-inflammatory cytokine production in *Hca2*$^{-/-}$peritoneal fluid compared to wild-type; 4) administration of lactated Ringer's (LR) has beneficial effects on mortality in wild-type mice (but not *Hca2*$^{-/-}$mice) during sepsis; 5) unlike normal kidneys, kidneys in the setting of sepsis expressed *Hca2*; 6) LR administration attenuated sepsis-associated AKI, partly restored expression of the key regulator of mitochondrial biogenesis, peroxisome proliferator-activated receptor gamma coactivator-1-a(PGC1a), and reduced pro-inflammatory cytokine production. Our data suggest that lactate-induced activation of HCA2 regulates a negative feedback loop during sepsis to decrease the inflammatory response.

Conclusions: The data further suggest that fluid resuscitation with LR solution may benefit patients with sepsis, particularly those with sepsis-associated AKI treated with potentially lactate-depleting renal replacement therapies (RRT).

Preconditioning Mice with a Pharmacologic Activator of AMPK Ameliorates Ischemic AKI by Activating Akt

Wilfred Lieberthal,[1,2] Mersema Abate,[3,1] Jerrold S. Levine.[5,4] [1]*Nephrology, Stony Brook University Medical Center, Stony Brook, NY;* [2]*Medicine, Northport VA, Northport, NY;* [3]*Stony Brook University Hospital, Stony Brook, NY;* [4]*Department of Medicine, Jesse Brown Veterans Affairs Hospital, Chicago, IL;* [5]*Department of Microbiology and Immunology, University of Illinois, Chicago, IL*.

Background: We have reported that preconditioning renal tubular cells (RTCs) with A-769662 (a novel small molecule activator of AMPK), reduces the death of renal tubular cells (RTCs) induced by metabolic stress *in vitro* and ameliorates the severity of ischemic AKI in mice. (Liebertal, W. et al: American J Phyiol Renal Physiol 311:F731-739, 2016). Our objective in this study was to determine whether Akt plays a role in mediating these effects of A-769662.

Methods: We knocked down expression of the beta-domain of AMPK by > 85% using shRNA ("KD" RTCs). In control RTCs a "scrambled" shRNA was used. Ischemic AKI was induced by subjecting the kidneys to ischemia-reperfusion injury (IRI).

Results: Preconditioning control cells with A-769662 increased the phosphorylation (activity) of AMPK, and reduced the death of these cells induced by exposing them to metabolic stress. However, in KD cells A-769662 had no measurable effects on the activation of AMPK or on their survival after stress. These data show that the activation of AMPK by A-769662 is profoundly impaired in KD RTCs. A-769662 activated Akt in control but not in KD RTCs. These findings demonstrate that the activation of Akt by A-7609662 is AMPK-dependent, and not the result a nonspecific "off target" kinase. It also shows that AMPK acts upstream of Akt. We show, that inhibiting Akt with a specific Akt inhibitor in control cells during the preconditioning period, reduced the pro-survival effect of A-769662 by ~50%. These findings suggest that Akt contributes to the pro-survival effects of A-7698662 *in vitro*. We next evaluated the role of AMPK and Akt in modulating the severity of ischemic AKI *in vivo*. We show that preconditioning mice with A-769662 activated AMPK and Akt in the renal cortex, and that inhibiting Akt, while having no effect on the activation of AMPK, reduced the activation of Akt. Finally, we provide novel evidence, that A-769662 ameliorates the severity of ischemic AKI, and that Akt contributes to this effect.

Conclusions:) A-769662 activates AMPK and Akt in control RTCs and in the kidneys of mice; ii) the activation of Akt by A-760662 is mediated by AMPK; iii) The activation of Akt contributes to the pro-survival effects of A-769662 *in vitro*, and to the beneficial of A-769662 in ischemic AKI *in vivo*; iv) the mechanisms responsible for the activation of Akt by AMPK remain to be elucidated

Metabolic Alterations Following Renal Ischemia Reperfusion in Rats

Christina Bracken,[1] Jeff H. Stanwix,[1] Katelyn Pulito,[1] Mahati Krishna,[2] Effie Tozzo.[1] *[1]Mitobridge, an Astellas company, Cambridge, MA; [2]Syngene International Pvt. Ltd., Bangalore, India.*

Background: Acute kidney injury (AKI) is a major health issue, associated with high morbidity, mortality, fibrosis and CKD. Ischemia reperfusion injury (IRI) during surgical procedures such as coronary artery bypass grafting or transplantation can cause AKI. In this study, we sought to characterize the timecourse of molecular and cellular pathophysiological consequences of IRI in the rat.

Methods: Sprague-Dawley rats underwent 45-minute bilateral ischemia followed by reperfusion for 1, 4, 8, 12, 24, 48, 72 hours (hr) or 14 days. We characterized renal injury by measuring plasma and urine biomarkers at all timepoints. We also evaluated tubular injury/repair and subsequent development of renal fibrosis. To delineate IR-induced metabolic changes, we examined gene expression of metabolic pathways including pyruvate handling, fatty acid oxidation, oxidative stress, and mitochondrial homeostasis. We also evaluated NAD^+ utilization and biosynthesis using mass spectrometry and ELISA based methods.

Results: IR-AKI resulted in varying kinetics of plasma and urinary biomarkers. Plasma creatinine and NGAL were elevated 4hr post AKI, and peaked at 24hr, whereas BUN increase was slightly delayed. Urinary NGAL and KIM-1 had similar time-dependent profiles peaking at 24-48hr, whereas urinary FABP-1 excretion peaked at 4hr, then rapidly declined. Tubular and vascular injury were evident 4hr post AKI with proliferation occurring from 24 - 72hr. Gene expression analysis revealed downregulation of proximal tubular cell-specific genes, which suggests loss or de-differentiation. By day 14 post injury, there was clear biochemical and histological evidence for fibrosis despite normal GFR. Renal IRI negatively affected the expression of genes regulating oxidative stress, mitochondrial function, pyruvate handling and fatty acid metabolism through the reperfusion phase. Furthermore, data revealed reduced gene expression of NAD^+ biosynthetic enzymes concomitant with a drop of NAD^+, increased NAD^+ utilization and breakdown products.

Conclusions: Together, our data reveal dysregulation of metabolic processes that contribute to the pathophysiology of IR-induced AKI and may allow for investigation of previously unexplored therapeutic avenues.

FR-PO079

GSK3β-Mediated Keap1-Independent Regulation of Nrf2 Antioxidant Response: A Molecular Rheostat of AKI-to-CKD Transition

Minglei Lu,[1,2] Lance D. Dworkin,[2] Zhangsuo Liu,[1] Rujun Gong.[2] *[1]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [2]University of Toledo Medical Center, Toledo, OH.*

Background: How acute kidney injury(AKI) is transformed to chronic kidney disease(CKD) remains elusive. Evidence suggests that glycogen synthase kinase(GSK)3β, a pivotal mediator of Keap1-independent regulation of Nrf2 defense, contributes to kidney injury. Whether GSK3β-mediated Nrf2 regulation is involved in AKI to CKD transition is unknown and was explored here.

Methods: Mice with renal tubule-specific GSK3β knockout and control mice were injured with folic acid. Nrf2 response and CKD transition were evaluated. In cultured renal tubular cells expressing GSK3β mutants, hydrogen peroxide-elicited chronic injuries and Nrf2 response were examined.

Results: Following folic acid injury, mice developed AKI with ensuing CKD transition, characterized by variable degrees of tubular cell atrophy, growth arrest and interstitial fibrosis. This lingering injury of renal tubules was parallelized by sustained oxidative stress that coincided with an impaired Nrf2 antioxidant defense, marked by mitigated Nrf2 nuclear accumulation and blunted induction of its target antioxidant enzymes. The initiation of Nrf2 signaling, however, seems unaffected since cytoplasmic Nrf2 in injured tubules was persistently elevated. Moreover, renal expression of Keap1, a key repressor of Nrf2, was barely associated with the magnitude of CKD transition. In contrast, GSK3β was persistently overexpressed and hyperactive in renal tubules during CKD transition. Likewise, in patients who developed CKD following AKI related to diverse etiologies, GSK3β overexpression was evident in renal tubules and concomitant with impaired Nrf2 response and oxidative damages. Mechanistically, Nrf2 defense agaisnt oxidative stress was sabotaged in renal tubular cells expressing a constitutively active mutant of GSK3β in a Keap1-independent mode, in parallel with an exacerbated cell cycle arrest, dedifferentiation, apoptosis and extracellular matrix overproduction. Conversely, ectopic expression of dominant negative GSK3β reinforced Nrf2 response and diminished cytopathic changes. *In vivo* in folic acid-injured mice, targeting GSK3β in renal tubules *via* gene knockout or by microdose lithium reinstated Nrf2 response and hindered CKD transition.

Conclusions: GSK3β-regulated of Nrf2 may serve as a pragmatic therapeutic target for modifying the long-term sequelae of AKI.

Efficacy of Low Intensity Pulsed Ultrasound on an AKI Mouse Model via the Prevention of Endoplasmic Reticulum Stress and Apoptosis

Shing-Hwa Liu,[1] Kuan-yu Hung,[3] Chih-Kang Chiang.[1,2] *[1]Graduate Institute of Toxicology, National Taiwan University, Medical College, Taipei, Taiwan; [2]Department of Integrated Diagnostics & Therapeutics, National Taiwan University Hospital, Taipei, Taiwan; [3]Department of Internal Medicine, National Taiwan University Hospital, TAIPEI, Taiwan.*

Background: Acute kidney injury (AKI) is associated with high mortality rates and often predisposes patient to development of chronic kidney disease. Renal ischemia/reperfusion injury (IRI) is a major cause of AKI. The mechanisms of IRI have been found to be included endoplasmic reticulum (ER) stress, inflammatory responses, hypoxia, and generation of reactive oxygen species. Low intensity pulsed ultrasound (LIPUS), which is a kind of therapeutic ultrasound, has been shown to exert therapeutic effects on bone healing and accelerate the healing process. The effect and mechanism of LIPUS on AKI still remain unclear. Here, we investigated the therapeutic effect and possible mechanism of LIPUS on IRI.

Methods: We use a mouse model of unilateral IRI with nephrectomy of the contralateral kidney in the presence or absence of LIPUS treatment (3 MHz, intensity 0.1 W/cm^2, 20 mins, 50% duty factor) 5 day before and 1 day after surgery.

Results: The results showed that renal function markers (e.g. BUN, creatinine), ER stress-related molecules (e.g. GRP78, eIF2-α, CHOP) and apoptotic markers (e.g. Bax, caspase-3) were significantly increased in the kidneys of mice with IRI for 24 h, which could be significantly reversed by LIPUS treatment. The histopathological examination showed that the lesser renal tubular injury and inflammation were observed in IRI+LIPUS mice than in IRI alone mice.

Conclusions: Taken together, LIPUS treatment showed the benefits for renal protection in IRI mice. These findings suggest that LIPUS therapy may be used to serve as an auxiliary tool for management of AKI.

FR-PO081

UCP2-Dependent Improvement of Mitochondrial Dynamics Preserves AKI

Yang Zhou,[1] Nan Qin,[2] Xiaoming Mao,[2] Junwei Yang.[1] *[1]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China; [2]Nanjing Medical University, Nanjing, China.*

Background: Acute kidney injury (AKI) is a public health concern with high morbidity and mortality rate in hospitalized patients and the survivors have increased risk of progression to chronic kidney disease. Mitochondrial damage is the critical driver of AKI-associated dysfunction and loss of tubular epithelial cells; however, the pathways that mediate these events are poorly defined.

Methods: AKI was induced by ischemia/reperfusion injury. We generated proximal tubular cells specific uncoupling protein 2 (UCP2) knockout mice to investigate the role of UCP2 on AKI. Primary tubular epithelial cells were cultured under normoxia or hypoxia conditions. Mitochondrial dynamics were evaluated by electron microscopy, western blot analysis and immunofluorescent staining.

Results: Here, in murine ischemia/reperfusion-induced (I/R-induced) AKI model, we determined that mitochondrial damage is associated with the level of renal UCP2. In hypoxia-damaged proximal tubular cells, a disruption of mitochondrial dynamics demonstrated by mitochondrial fragmentation and disturbance between fusion and fission was clearly indicated. *Ucp2*-deficient mice suffered I/R injury experienced more severe AKI and mitochondrial fragmentation than wild-type (WT) mice. Moreover, Genetic or pharmacologic treatment increased UCP2 expression, improved renal function, reduced tubular injury and limited mitochondrial fission. In cultured proximal tubular epithelial cells, hypoxia-induced mitochondrial fission was exacerbated in Ucp2$^{-/-}$ cells, while increase of UCP2 improved hypoxia-induced disturbance between mitochondrial fusion and fission. Furthermore, modulation of UCP2 suggested its role in preserving mitochondrial integrity by preventing loss of membrane potential and reducing subsequent mitophagy.

Conclusions: Together, our results indicate that UCP2 is protective against AKI and suggest that enhancing UCP2 to improve mitochondrial dynamics has potential as a strategy for improving outcomes of renal injury.

AATF/Che-1 Controls Ribosomal Biogenesis Through Direct Binding of Ribosomal RNA and R-Protein Encoding mRNAs

Rainer Kaiser,[1] Michael Ignarski,[1] Constantin Rill,[1] Eric Van nostrand,[3] Markus M. Rinschen,[1] Bernhard Schermer,[1] Thomas Benzing,[1] Katja Hoepker,[2] Francesca Fabretti,[1] Roman-Ulrich Mueller.[1] *[1]Dept. 2 of Internal Medicine, University of Cologne, Koeln, Germany; [2]University of Cologne, Köln, Germany; [3]UCSD, La Jolla, CA.*

Background: AATF/Che-1 (Apoptosis Antagonizing Transcription Factor) is an RNA Pol II binding transcription factor that has been shown to play crucial roles in multiple essential cellular pathways - e.g. DNA damage response and mTOR signaling. It further has been linked to acute kidney injury. However, the exact molecular function of this protein is not known.

Methods: We have identified AATF as a putative RNA binding protein (RBP) in murine kidney cells. Here, we use Enhanced Crosslinking and Immunoprecipitation (eCLIP) as well as RNA editing followed by sequencing (TRIBE) techniques to identify both coding and non-coding RNAs bound by AATF. Binding of RNA as well as validation of specific targets was done by PNK assays and RIP-qPCR. Using TALEN-mediated genome engineering, we have created a set of transgenic cell lines that express GFP-tagged WT AATF or AATF mutant proteins. In addition, we perform MS/MS studies to uncover proteins interacting with AATF.

Results: Here we validate AATF as an RNA binding protein and identify hundreds of RNA targets bound by AATF. Analysis of transcripts bound by AATF were enriched for ribosomal and other non-coding RNA biotypes. More specifically, the 45S rRNA precursor was one of the most enriched transcripts bound to AATF. Moreover, both structural constituents of the RNP and components of the ribosome biogenesis machinery were strongly overrepresented among the mRNA transcripts. Both the 45S pre-ribosomal precursor and its product, 18S rRNA, were depleted upon knockdown of AATF. However, AATF did not only interact with RNA molecules associated with ribosomal function and integrity, but also with a large number of protein components of the rRNP and other RNA binding proteins.

Conclusions: Our study validates AATF as an RNA binding protein and reveals yet another link between rRNA metabolism, nucleolar integrity and other essential pathways such as the DNA damage response. An impact on ribosome abundance and functionality mediated by RNA binding could be an important feature of the role of AATF in carcinogenesis and may open new ways to address its role as a potential therapeutic target. To this end, a better understanding of its molecular function is of great importance.

The mRNA Interactome of Ciliated Renal Cells and Its Modulation by Hypoxia

Rainer Kaiser,[1] Constantin Rill,[1] Michael Ignarski,[1] Ilian Atanassov,[2] Bernhard Schermer,[1] Thomas Benzing,[1] Francesca Fabretti,[1] Roman-Ulrich Mueller.[1] *[1]Dept. 2 of Internal Medicine, University of Cologne, Koeln, Germany; [2]Max Planck Institute for Biology of Aging, Cologne, Germany.*

Background: RNA-binding proteins (RBPs) are fundamental regulators of cellular biology and affect every step in processing RNA-biology. The scale of their impact has been shown by recent studies that have linked RBPs to a number of human pathologies, ranging from neurological disorders and ischemia reperfusion injury to tumor growth. Despite this central role in cell biology, the global effect of RBPs in the kidney has not been assessed until now. Here, we identify the first set of RBPs in ciliated renal epithelial cells under both hypoxic and normoxic growth conditions.

Methods: Using Oligo(dT) beads to precipitate mRNA-protein complexes on ciliated mIMCD-3 cells, we aimed to identify the kidney-specific mRNA interactome using mass spectrometry. Cells were either exposed to hypoxia or grown under normoxic conditions. In parallel, the proteome of whole cell lysates was identified to assess the abundance of total protein in comparison to RBPs detected using the same conditions. Using TALEN-generated transgenic human cell lines, specific candidates were validated as RNA binding protein with the Polynukleotide (PNK) assay, showing RNA bound directly to the proteins of interest. Localization of the RBPs was analyzed using immunofluorescence.

Results: Our data revealed over 350 significant mRNA interactors and more than 300 candidate RBPs, 84 of which have not been described as RBPs in common data bases. We define these proteins as the renal epithelial cell mRNA interactome. The PNK assay validated all chosen candidates as RBPs and indeed showed direct binding to RNA. Since the whole cell proteome did not show these RBPs to be differentially expressed upon exposure to hypoxia, we hypothesize that the increased detection of RBP candidates in the hypoxic samples is indeed due to differential binding to their target transcripts.

Conclusions: Our data identify the first set of RBPs specific to ciliated renal epithelial cells and show that hypoxia can modulate RNA-binding, adding another regulatory layer to the diverse biology of the kidney. Using established human transgenic cell lines, we are now aiming for functional studies of individual candidates in order to address their impact on hypoxia signaling and their impact of preconditioning-mediated increase of viability both in vitro and in vivo.

AICAR, an AMPK Activator, Protects Against Cisplatin-Induced AKI Through JAK/STAT/SOCS Pathway

Tsogbadrakh B. Bodokhsuren, Jinho Lee, Sohyun Yun, Curie Ahn, Kook-Hwan Oh. Division of Nephrology, Department of Internal Medicine, Seoul National University *Division of Nephrology, Department of Internal Medicine, Seoul National University, Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Cisplatin causes acute kidney injury (AKI) through proximal tubular injury. We investigated protective effect of the adenosine monophosphate protein kinase (AMPK) activator 5-aminoimidazole-4-carboxamide ribonucleotide (AICAR) against cisplatin induced AKI. We investigated whether AMP-kinase activator AICAR ameliorates cisplatin induced AKI and through JAK/STAT/SOCS pathway.

Methods: Male Sprague-Dawley rats were randomly divided into four groups: control, AICAR, cisplatin and cisplatin + AICAR groups. On day 1, SD rats were injected with single dose of cisplatin (7 mg/kg, i.p.). From day 1 to 5, AICAR was administered to rats at 100mg/kg i.p. daily. Blood urea nitrogen (BUN) and the serum creatinine were measured. The kidneys were harvested on the day 5. Renal damage was analyzed in sections stained with Hemotoxylin and Eosin (H&E). Renal tissues were also examined for immunohistochemistry and western blot for p-AMPK, KIM1, cleaved caspase 3 and JAK/STAT/SOCS. For *in vitro* studies, NRK-52E normal rat kidney cells were treated with cisplatin and/or AICAR. By western blot, we also confirmed the expressions of p-AMPK and JAK/STAT/SOCS pathway in NRK-52E cells.

Results: A single injection of cisplatin caused marked increase of the serum creatinine and BUN levels on day 5. Peak BUN and serum creatinine levels were decreased by treatment with AICAR. As compared to the cisplatin group, acute tubular necrosis (ATN) score was improved in rats treated with cisplatin + AICAR. AICAR was protective against cisplatin induced acute tubular injury by up-regulating p-AMPK expression and down-regulating KIM-1 and cleaved caspase 3. JAK2/STAT1/SOCS1 pathway was down-regulated by AICAR treatment in our *in vivo* and *in vitro* study. AICAR was protective against cisplatin induced acute tubular injury by up-regulating p-AMPK expression in NRK-52E cells. Protein expression levels of JAK2/STAT1 were markedly ameliorated in NRK-52E cells by AICAR.

Conclusions: Thus, the present study demonstrates the protective effect of AICAR in cisplatin-induced ATN and shows a new renoprotective mechanism through JAK2/STAT1/SOCS1 pathway and apoptosis inhibition. This study suggests that activation of AMPK activator, AICAR might ameliorate the cisplatin induced AKI.

NAD+ Augmentation Improves Cell Survival Against Cisplatin via Enhanced Mitophagy

Matthew R. Lynch, Mei T. Tran, Samir M. Parikh. *Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Cisplatin nephrotoxicity is a common cause of acute kidney injury. Activation of autophagy in the renal tubule may be protective against cisplatin. We previously reported that nicotinamide adenine dinucleotide (NAD+) precursor treatment ameliorated cisplatin nephrotoxicity in mice. Given the role of NAD+ in mitochondrial function and homeostasis, we investigated if the protection afforded by NAD+ augmentation against cisplatin involved the induction of mitochondrial autophagy, i.e., mitophagy. Mitophagy has been traditionally difficult to quantify, requiring co-staining of cells with mitochondrial and lysosomal dyes which can be cytotoxic, non-specific, or both. Recently, a pH-sensitive non-toxic biosensor protein, mtKeima, has been developed to track the fraction of mitochondria that undergo autophagy and breakdown in the acidic lysosome.

Methods: We developed a stable renal tubular cell line expressing mtKeima, which we treated with cisplatin (10 mM) or vehicle. Another set of cells were pre-treated with the NAD+ precursor nicotinamide mononucleotide (NMN, 1 mM) 30m prior to cisplatin or vehicle. General autophagy was assessed by Western Blot for LC3 and p62. Cells were imaged 24h after treatment on a confocal microscope with two sequential excitations 440 nm and 559 nm and a 570 to 695 nm emission range. A mitophagy index was calculated by determining the ratio between the area of the red (acidic) and green (basic) emission.

Results: LC3 and p62 revealed no differences in response to cisplatin or NMN. However, cisplatin markedly inhibited mitophagy ($p<0.05$, 2-fold change). Conversely, NMN enhanced basal mitophagy ($p<0.001$, 4-fold change). Pre-treatment of cisplatin-exposed cells with NMN abrogated the decline in mitophagy induced by cisplatin ($p<0.001$, 6-fold change). Finally, application of the lysosome inhibitor, chloroquine, enhanced cisplatin toxicity.

Conclusions: Whereas traditional measurements of autophagy were uninformative, use of mtKeima illuminated a specific reduction in mitophagy triggered by cisplatin. This effect was abrogated with the addition of NMN. Our results indicate that preservation of mitophagy with its safe mitochondrial disposal, rather than generalized autophagy, may be critical for renal tubular cells to resist cisplatin. Further, NAD+ supplementation may represent a therapeutic option for the treatment of cisplatin nephrotoxicity.

Nrf2 Attenuates Tubular Epithelia Cell Transdifferentiation in Response to Hypoxia Through Regulating CTGF Secretion

Weiwei Kong,[1] Jingqi Fu,[1] Junjun Luan,[1] Congcong Jiao,[1] Huimeng Qi,[2] Yanqiu Wang,[1] Detian Li,[1] Jingbo Pi,[2] Hua Zhou.[1] *[1]The Affiliated Shengjing Hospital of China Medical School, Shenyang/China, China; [2]China Medical University, Shenyang, China.*

Background: Nuclear factor erythroid 2-related factor 2 (Nrf2) is a well-known regulator of oxidant and xenobiotic metabolism. We previously reported that Nrf2 ameliorates renal tubular transdifferentiation in mice on day 5 after unilateral ureteral obstruction (UUO); however, the mechanism of attentuation remains unclear. We aimed to clarify whether Nrf2 regulates the connective tissue growth factor (CTGF)/WNT pathway, which is a key pathway in tubular epithelia cell transdifferentiation.

Methods: Normal rat kidney-52E (NRK52E) tubular cells were divided into four groups: scramble control, Nrf2-knockdown (Nrf2-KD) control, scramble hypoxia (5%), and Nrf2-KD hypoxia groups. Expression levels of CTGF and WNT signaling pathway (p-Lrp6 and β-catenine) were detected by western blotting. Then, we used siRNAs to silence CTGF and Nrf2 simultaneously and to measure WNT signaling and vimentin, a transdifferentiation marker. We also investigated the expression of c-fos, a known transcription regulator of CTGF, and the expression of a group microRNAs as post transcription factors of CTGF. In addition, we evaluated the expression of CTGF in the kidneys of *Nrf2*$^{+/+}$ and *Nrf2*$^{-/-}$ mice 5 days after UUO by immunostaining and western blotting.

Results: We found that Nrf2 deletion significantly increased CTGF expression in response to 5% of hypoxia in NRK52E cell line. In hypoxia treated NRK52E cells, deletion of Nrf2 promoted expression of p-Lrp6 and β-catenine as well as vimentin. The overexpression of p-Lrp6, β-catenine and vimentin due to only silencing Nrf2 was decreased by double silencing Nrf2 and CTGF. Nrf2 knockdown increased expression of c-fos and p-c-fos in NRK52E cells. However, Nrf2 knockdown showed no regulation of post-transcription factors such as miR-26a, miR-26b, miR-30a and miR-133. Similarly, expression of CTGF and activity of WNT signaling were increased in *Nrf2*$^{-/-}$ mice compared to those in *Nrf2*$^{+/+}$ mice on the 5th day after UUO operation.

Conclusions: Nrf2 attenuated tubular epithelial cellular transdifferntiation may be mediated by downregulating WNT signaling pathway through inhibiting CTGF secretion in tubular epithelial cells. This suggests that Nrf2 activator might be a potential agent to slow down the progression from acute renal tubular damage to chronic tubulointerstitial fibrosis.

Nrf2 Interactions with the HIF System May Determine Long Term Outcomes After AKI

Corry D. Bondi, Brittney M. Rush, Roderick J. Tan. *University of Pittsburgh, Pittsburgh, PA.*

Background: Acute kidney injury (AKI) affects up to 1 in 5 hospitalized patients and is associated with an increased risk of developing chronic kidney disease. AKI is commonly caused by ischemia and proximal tubular epithelia are particularly vulnerable to injury. HIF-1α (Hypoxia-inducible factor-1α) and Nrf2 (Nuclear factor erythroid 2-related factor 2) are transcription factors with protective effects against AKI. Studies suggest an association between HIF system activation and Nrf2 activity but this has not been extensively studied in the kidney.

Methods: C57BL/6 mice were subjected to kidney ischemia-reperfusion to induce AKI. Ischemia times were titrated to induce mild to severe injury and kidneys were harvested at various acute and chronic timepoints post-reperfusion. To simulate mild and severe injury conditions *in vitro*, proximal tubular HK-2 cells were exposed to either nutrient replete or nutrient deficient conditions, respectively, in the presence of HIF activation with cobalt chloride ($CoCl_2$). Immunoblotting, qPCR, RNA interference, serum creatinine, and histologic methods were used.

Results: Kidneys obtained 24 h after mild injury had elevated protective Nrf2 activity, as evidenced by expression of the Nrf2 target gene *Nqo1*, and this was associated with minimal histologic injury at late timepoints. Kidneys exposed to severe injury failed to upregulate *Nqo1*, and this was associated with the development of chronic injury and fibrosis. Similarly, HK-2 cells exposed to mild stress conditions using nutrient replete media with $CoCl_2$ led to *Nqo1* upregulation, but cells exposed to nutrient deficient conditions with $CoCl_2$ did not show *Nqo1* induction. HIF-1α appeared to exert a negative effect on Nrf2 since HIF-1α knockdown enhanced *Nqo1* expression. HIF-1α activation also suppressed Nrf2 nuclear localization in nutrient deficient conditions.

Conclusions: Our data suggest there is a threshold of severity at which AKI leads to the development of progressive CKD, and disparate outcomes may be partly determined by Nrf2 activity. Also, we demonstrate differential regulation of Nrf2 by HIF activation in mild and severe injury conditions. Overall, our results show that there is an association between Nrf2 and the HIF system that may determine the long-term outcome of the kidney.

FR-PO088

Nrf2 Deficiency Aggravates Folic Acid-Induced AKI Through Upregulation of Renal Ferroptosis in Mice

Shiwen Zhang,[1] Junjun Luan,[1] Jingqi Fu,[2] Weiwei Kong,[1] Yanqiu Wang,[1] Detian Li,[1] Jingbo Pi,[2] Hua Zhou.[1] *[1]Department of Nephrology, The Affiliated Shengjing Hospital of China Medical University, Shenyang, China; [2]Program of Environmental Toxicology, School of Public Health, China Medical University, Shenyang, China.*

Background: The role of nuclear factor erythroid 2-related factor 2 (Nrf2) in folic acid (FA)-induced acute kidney injury (AKI) remains unstudied so far. Ferroptosis is demonstrated to be involved in FA-induced AKI. We aim to verify whether Nrf2 deletion aggravated FA-induced AKI in mice and to investigate the corresponding mechanism.

Methods: Male Nrf2$^{+/+}$ and Nrf2$^{-/-}$mice were injected FA (100 mg/kg) intravenously to induce AKI. NaHCO3 was used as the vehicle. AKI was evaluated by serum creatinine (Scr), blood urea nitrogen (BUN), and tubular damage on PAS staining 48h after FA injection. Meanwhile, we examined four types of tubular cell death including tubular necrosis, apoptosis (TUNEL staining), pyroptosis (*Caspase1*, *Pycard*, and *Txnip-1/2*), and ferroptosis (*Gpx4* and *Acsl4*). We also examined the renal expression of Nrf2-associated genes such as pro-inflammatory cytokines (*Il6* and *Tnfα*) and antioxidative factors (*Nqo1*, *Gclc*, and *Gclm*) in Nrf2$^{-/-}$mice compared to that in Nrf2$^{+/+}$ mice. In addition, we explored the influence of Nrf2 deletion on the activity of methylenetetrahydrofolate dehydrogenase (MTHFD), which is an enzyme involved in FA systemic metabolism.

Results: AKI occurred in both Nrf2$^{+/+}$ and Nrf2$^{-/-}$ mice. AKI features such as Scr, BUN, tubular damage degree on PAS staining, and tubular necrosis scores were more severe in Nrf2$^{-/-}$ mice than in Nrf2$^{+/+}$ mice. The number of TUNEL positive nuclei in kidneys of Nrf2$^{-/-}$ mice was higher than that in Nrf2$^{+/+}$ mice. However, the above four pyroptosis biomarkers showed no difference in the kidneys of both Nrf2$^{+/+}$ and Nrf2$^{-/-}$ mice. Interestingly, renal anti-ferroptosis gene *Gpx4* expression was downregulated while pro-ferroptosis gene *Acsl4* was upregulated. In addition, renal pro-inflammatory *Il6* and *Tnfα* genes were increased and antioxidative *Nqo1*, *Gclc*, and *Gclm* genes were decreased in Nrf2$^{-/-}$ mice compared to in Nrf2$^{+/+}$ mice. Further, we found FA increased the activity of MTHFA; however, no difference of this enzyme was seen in Nrf2$^{-/-}$ mice compared to Nrf2$^{+/+}$ mice.

Conclusions: Nrf2 deficiency aggravates FA-induced AKI in mice. Acute tubular protective roles of Nrf2 may be mediated by a combination of mechanisms such as anti-inflammation, antioxidative response, anti-apoptosis, and anti-ferroptosis.

FR-PO089

The Protective Role of Nrf2 Against Aristolochic Acid (AA)-Induced Renal Tubular Epithelial Cell Injury

Xuan Huang, Juan Wu, Haishan Wu, Xinhui Liu, Xueqing Yu, Xiao Yang. *Department of Nephrology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.*

Background: Aristolochic acid nephropathy(AAN) is a rapidly progressive tubulointerstitial disease induced by aristolochic acid(AA) and there are currently no effective treatments for it. Nrf2, as a major regulator of antioxidant response, has been proven by numerous studies to be protective in acute kidney injury and chronic kidney disease progression. However, its role in AA-induced kidney injury has not been elucidated yet. We previously demonstrated that Bardoxolone methyl(BARD) ameliorates AA-induced acute kidney injury through Nrf2 pathway. In this study, we further assessed the role of Nrf2 in AA-induced renal tubular epithelial cell injury.

Methods: NRK-52E cells were incubated with different concentrations of AA for 0-24 hours to evaluate cell viability, Nrf2 signaling pathway protein levels, ROS production, and cell apoptosis/necrosis. The role of Nrf2 in AA-induced ROS production and cell apoptosis/necrosis was determined through Nrf2 knockdown by its specific siRNA or Nrf2 overexpression by Nrf2 plasmid, respectively. Cell viability was evaluated by MTT. Cells were labeled with DCFH-DA for detection of ROS by flow cytometry. The cells also doubly labeled with Annexin V and propidium iodide(PI) for measurement of cell apoptosis/necrosis by flow cytometry. Expression of Nrf2 and its downstream protein HO-1 and NQO1 was analyzed by western blotting.

Results: AA increased intracellular ROS production and cell apoptosis/necrosis in a time-dependent manner. Meanwhile, the cell viability and the expression of Nrf2 signaling pathway proteins (Nrf2, HO-1, NQO1) were significantly decreased. Downregulation of Nrf2 by its specific siRNA further increased ROS levels(25.2±12.5 vs 8.5±2.5, P<0.05) and cell apoptosis/necrosis(50.21±5.65% vs 35.81±0.97%, P<0.05), and reduced the expression of Nrf2 signaling pathway proteins(P<0.05). Conversely, overexpression of Nrf2 significantly decreased AA-induced ROS production and cell apoptosis/necrosis(24.12±1.61% vs 32.61±0.81%, P<0.01). The expression of Nrf2 and its downstream protein HO-1 were significantly upregulated compared with non-Nrf2 transfected group(P<0.05).

Conclusions: Impaired Nrf2 signaling pathway is one of the mechanisms of AA-induced renal tubular epithelial cell injury, and activation of Nrf2 can ameliorate the cell injury by its antioxidant effect.

The Effect and Mechanism of Leptin in Ischemia Reperfusion Induced AKI

Siyao Li, Jing Xi, Yi He, Junxiang Chen. *Second Xiangya Hospital Central South University, Changsha, China.*

Background: Ischemia-reperfusion (IR)-induced acute kidney injury (AKI) is one of the most common causes of AKI, but the underlying pathogenesis is poorly understood. And there are little reports about the role of leptin in IR-induced AKI.

Methods: Bilateral renal ischemia (30 min)/reperfusion (48hrs) injury (IRI) model was performed using ob/+ mice (wild type) and ob/ob mice (Leptin deficient). Blood samples were collected for renal function evaluation and the kidneys were removed for histological examination and protein detection.

Results: Compared with the sham groups, both of the I/R groups showed significantly higher levels of serum urea nitrogen and creatinine, which were even much higher in the ob/ob/I/R group than those in the ob/+/I/R group. No obvious tubular damage and TUNEL positive cells were observed in the sham groups, but severe tubular lysis, loss of brush border, sloughed debris in tubular lumen space and TUNEL-positive cells were observed in the I/R groups and were much more obvious in the ob/ob/I/R group than those in the ob/+/I/R group. Significantly increased Caspase3, Caspase9 and LC3 II protein expression and decreased p-mTOR protein expression were detected in both of the I/R groups comparing with the sham groups, these changes were more significantly in the ob/ob/I/R group than in the ob/+/I/R group. P-AMPK,P-PTEN,P-AKT,P-ERK protein were significantly down-regulated and PTEN protein was significantly up-regulated in both of the I/R groups compared with the sham groups, these changes were were much more remarkable in the ob/ob/I/R group than in the ob/+/I/R group.

Conclusions: After IRI, Mice showed impaired renal function, damaged kidney tubules and increased apoptosis and autophagy, which were significantly more obvious in the ob/ob/I/R group than in the ob/+/I/R group. The ob/ob/I/R group showed remarkably increased PTEN protein and decreased P-AMPK,P-PTEN,P-AKT,P-ERK protein than the ob/+/I/R group. All the above results suggests that leptin may participates in the pathogenesis of I/R-induced AKI by regulating autophagy via a complicated network composed of mTOR dependent pathways, as well as by regulating apoptosis.

FR-PO091

A Single Dose of Lithium Attenuates Rhabdomyolysis-Associated AKI

Maria H. Shimizu, Ana Carolina de Braganca, Daniele Canale, Rildo A. Volpini, Antonio C. Seguro. *Faculty of Medicine - University of Sao Paulo, São Paulo, Brazil*.

Background: Acute kidney injury (AKI) is the most severe complication of rhabdomyolysis. Evidence suggests that glycogen synthase kinase 3β (GSK3β) inhibition protects against AKI. Treatment with a single dose of lithium, a selective inhibitor of GSK3β, accelerated recovery of renal function in models of cisplatin and ischemia/reperfusion- induced AKI. The aim of this study was to evaluate the efficacy of a single dose of lithium in the treatment of rhabdomyolysis-induced AKI in rats.

Methods: Male Wistar rats aged 3 months were allocated to four groups: 1- Control: received saline 0.9% intraperitoneal (IP); 2- Lithium: rats treated with a single IP injection of lithium chloride 80 mg/Kg body weight (BW) ; 3- Glycerol (50%, 5 ml/kg intramuscular,IM); 4- Glycerol plus Lithium: glycerol 50%, 5 ml/kg IM + lithium chloride 80 mg/kg IP injected 2 hours after glycerol administration. After 24 h the animals were anesthetized to measure inulin clearance (GFR, ml/min/100g BW). At the end of the clearance experiments the rats were euthanized, blood and kidney were collected to evaluate plasma levels of creatine phosphokinase (CPK), expression of GSK3β in renal tissue and kidney histological damage score.

Results: As described in the table below, glycerol-injected rats showed markedly reduction of GFR, increase of CPK levels, exaggerated increase of GSK3β renal expression and higher kidney injury score. A single dose of lithium administration ameliorated all these alterations.

Conclusions: Lithium treatment attenuated renal dysfunction in a model of rhabdomyolysis-associated AKI by improving inulin clearance and reducing kidney injury score. These therapeutic effects were due to an inhibition of renal GSK3β and were associated with a decrease in muscle injury. This may represent a new therapeutic approach for rhabdomyolysis-induced AKI. (FAPESP 2015/11933-3; 2015/05513-1)

Stress Granule Plays a Protective Role in Renal Proximal Tubular Cells

Shixuan Wang,[1,2] Zheng Dong.[1,2] *[1]Medical College of Georgia, Augusta, GA; [2]Charlie Norwood VA Medical Center, Augusta, GA.*

Background: Stress granule (SG) is one type of cytoplasmic structures formed in eukaryotic cells upon certain types of stress. Further study disclosed that SG mainly contains RNA-binding proteins (RBPs) and mRNAs. SGs are widely regarded as one mechanism for cells to survive a harsh insult. However, little is known about SG biogenesis in renal tubular cells.

Methods: To explore how tubular cells form SGs to a series of interventions, we applied different kinds of stressors to cultured mouse (BUMPT) and rat (RPTC) proximal tubular cells as well as a short period of ischemia/reperfusion to mouse kidneys.

Results: It was found that glycolytic inhibitors such as 2DG (2-deoxy-D-glucose) and 3PO (3-(3-pyridinyl)-1-(4-pyridinyl)-2-propen-1-one) can induce SG formation within 30 minutes in cultured BUMPT and RPTC cells. Similarly, SGs are induced by inhibitors for the respiratory chain of mitochondria such as sodium azide and CCCP (carbonyl cyanide m-chlorophenyl hydrazone). Interestingly, cisplatin, a common chemotherapy drug for many types of cancers, hardly induces SG formation. Ischemia/reperfusion to mouse kidneys can induce SG formation in renal proximal tubular cells. To further test the role of SGs in renal tubular cells, we stably knocked down G3BP1, a SG core protein, in BUMPT and RPTC cells by shRNA viral transduction. As expected, knockdown of G3BP1 partially disrupts the assembly of SGs. After azide or cisplatin treatment, more dead cells were found morphologically in knockdown cells in comparison to controls, accompanied by increment in cleaved caspase-3 expression. Re-introduction of exogenous G3BP1 into knockdown cells can rescue the cell death phenotype.

Conclusions: All taken together, SGs can form in cultured renal proximal tubular cells at certain conditions and kidneys after ischemia/reperfusion. Intervention on SG biogenesis may provide an approach to lessen the severity of a series of renal diseases.

Upregulation of Hypothalamic Arginine Vasopressin by Bilateral Nephrectomy in Transgenic Rats Expressing Arginine Vasopressin-Enhanced Green Fluorescent Protein

Kenya Sanada, Hiromichi Ueno, Tetsu Miyamoto, Kenichiro Bando, Yoko Fujimoto, Yoichi Ueta, Yutaka Otsuji, Masahito Tamura. *University of Occupational and Environmental Health, Japan, Kitakyushu-shi, Japan.*

Background: Acute loss of kidney function is a critical internal stressor. The paraventricular nucleus (PVN) of the hypothalamus is an integrative site of the neuroendocrine and autonomic nervous systems that deals with a variety of aversive stressors. Hypothalamic arginine vasopressin (AVP) and corticotropin-releasing hormone (CRH) in the parvocellular division of the paraventricular nucleus (pPVN) play important roles in the regulation of stress responses. However, hypothalamic AVP dynamics after acute kidney injury remain unclear.

Methods: We generated transgenic rats that express the AVP-enhanced green fluorescent protein (eGFP) fusion gene. Since eGFP fluorescent intensity is a quantitative indicator of AVP synthesis in the transgenic rats, we evaluated AVP-eGFP fluorescence in the hypothalamus after the rats had undergone bilateral nephrectomy. We then examined AVP gene expression by in situ hybridization histochemistry. Finally, we quantified Fos-Like immunoreactivity (IR) cells, which are used as a marker of neural activity, in several brain regions which modulate biological responses to severe stressors by controlling AVP synthesis.

Results: After bilateral nephrectomy, eGFP fluorescent intensities were significantly increased in the pPVN, but not in the magnocellular PVN. The mRNA levels of *eGFP*, *AVP*, and *CRH* in the pPVN were significantly increased after bilateral nephrectomy. Bilateral nephrectomy also caused a marked increase in Fos-IR in the locus coeruleus, nucleus of the solitary tract, area postrema, and rostral ventrolateral medulla, which are responsible for modulating sympathetic nervous system activity.

Conclusions: Bilateral nephrectomy caused upregulation of AVP synthesis and neuronal activity. Further studies are needed to identify the neural and/or humoral factors that activate the central AVP system after bilateral nephrectomy.

FR-PO094

Recognition of Apoptotic Cells by Viable Proximal Tubular Epithelial Cells (PTEC) Induces Death Receptor (DR)-Dependent Death of PTEC, but in a Ligand-Independent Manner

Michael E. Dietrich,[2] Jerrold S. Levine,[2,1] Joyce Rauch,[3] Lanfei Feng.[2] *[1]Jesse Brown VAMC, Chicago, IL; [2]University of Illinois at Chicago College of Medicine, Chicago, IL; [3]Research Institute of the McGill University Health Centre, Montreal, QC, Canada*.

Background: We have shown that mouse kidney PTEC have distinct non-competing receptors for apoptotic and necrotic targets. Receptor-mediated recognition of apoptotic, but not necrotic, targets induces apoptotic death of PTEC responders.

Methods: Responder cells were BU.MPT cells, a conditionally immortalized PTEC line. Target cells, induced to undergo apoptosis or necrosis, were homologous (BU.MPT) or heterologous (DO11.10 lymphocytes) cells.

Results: Apoptotic target-induced death of PTEC responders is profound (~100% by 48-72 h). Target-induced apoptotic death appears to involve death receptors (DRs), as

supported by the following data. First, death is associated with signaling events typical of DR-mediated apoptosis in type II epithelial cells, including cleavage of caspase-8, cleavage of the pro-apoptotic Bcl-2 family member BID to tBID, and activation of caspase-3. Second, PTEC constitutively express the DRs DR5, Fas, and TNFRI, as assessed by flow cytometry, and DR expression is significantly decreased following exposure to apoptotic targets, consistent with receptor activation and internalization. A fourth DR, DR3, is not expressed constitutively by PTEC, but is induced following exposure to apoptotic targets. Third, decreased DR expression correlates with activation of caspase-3 and induction of apoptosis. Surprisingly, DR activation appears to occur in a ligand-independent manner. No DR ligand (DR-L) expression (TRAIL, FasL, or TNF) is seen in responder PTEC by flow cytometry (surface or intracellular) or by ELISA (secreted into media). Moreover, target-induced apoptosis of PTEC responders was not prevented by inhibitors of DR-L, nor was it induced by addition of soluble DR-L.

Conclusions: Exposure of viable PTEC to apoptotic (but not necrotic) targets induces PTEC apoptosis via DR-dependent mechanisms. Surprisingly, target-induced apoptosis occurs in a ligand-independent manner, with recognition of apoptotic (but not necrotic) targets leading to DR-L-independent egagement of DRs. We hypothesize that PTEC injury *in vivo* is characterized by two distinct waves of cell death. In the 1st, PTEC death is the direct result of ischemic or other injury. In the 2nd, PTEC death is independent of injury, and the result of DR activation by recognition of adjacent dead or dying cells.

FR-PO095

Dynamin Regulates Membrane Tension in Renal Epithelial Cells by Establishing Architecture of Actin Cortex

Changkyu Gu,[1] Henning Hagmann,[2] Agnieszka Collins,[1] Kamalika Mukherjee,[1] Monica H. Stevens,[1] Paul T. Brinkkoetter,[2] Sanja Sever.[1] *[1]Massachusetts General Hospital/Harvard Medical School, Charlestown, MA; [2]University Hospital Cologne, Cologne, Germany.*

Background: The GTPase dynamin is essential for podocyte structure and function as it plays a role in regulating endocytosis and the actin cytoskeleton. Previously, we showed that dynamin can directly bind to actin and regulate actin polymerization. Importantly, our studies demonstrated that pharmacological targeting of dynamin with a small molecule, Bis-T-23 that promotes formation of dynamin oligomerization (Dyn^{OLIGO}), ameliorated kidney injury in animal models of human kidney disease by recovering functional actin structures in injured podocytes. Recently, dynamin is also reported to orchestrate the global actomyosin cytoskeleton that underlies renal epithelial cell polarity independent from its role in endocytosis. Here, we expand the role of Dyn^{OLIGO} to include regulation of membrane tension, and thus endocytosis in renal epithelial cells by establishing architecture of actin cortex.

Methods: Polarized renal epithelial cells (Inner Medular Collecting Duct) were used for this study. Atomic force microscopy was utilized to determine membrane tension. Actin polymerization assays were performed with cell lysates from IMCD cells. The structure of actin filaments was evaluated by electron microscopy of negatively stained specimens. Endocytosis was examined in IMCD cells stably expressing eGFP-clathrin light chain by Total Internal Reflection Fluorescence Microscopy, followed by computer-based image analysis.

Results: Using a combination of distinct dynamin mutants and Bis-T-23 we show that Dyn^{OLIGO} defines the length of actin filaments in conjunction with gelsolin. In addition, we show that dynamin crosslinks actin filaments into distinct structures in conjunction with its oligomerization state and the length of the actin filaments. Importantly, our data demonstrate that Dyn^{OLIGO} regulates membrane tension most likely by defining and crosslinking cortical actin. Furthermore, dynamin's effect on cell surface tension indirectly influences the speed of clathrin coated pit maturation in polarized renal epithelial cells.

Conclusions: Our study defines a novel role for Dyn^{OLIGO} cycle as a direct regulator of membrane tension and indirect regulator of endocytosis by orchestrating actin cortex architecture in polarized renal epithelial cells.

Mucin 1 Prevents Accelerated Shedding of Kidney Injury Molecule-1 Following Ischemic Renal Injury

Mohammad M. Al-bataineh,[1] Carol L. Kinlough,[3] Zaichuan Mi,[1] Edwin K. Jackson,[1] Rebecca P. Hughey.[2] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Dept Medicine-Renal Electrolyte Division, Pittsburgh, PA; [3]Department of Medicine University of Pittsburgh, Pittsburgh, PA.*

Background: Kidney injury molecule-1 (KIM-1) is a type I transmembrane glycoprotein that is rapidly induced after kidney injury in the proximal tubule (PT). The ectodomain of KIM-1 is cleaved and thereby constitutively shed into the urine providing a sensitive biomarker for kidney injury. It was reported recently that a transcription factor STAT3 is phosphorylated by extracellular signal-regulated kinases 1 and 2 (ERK1/2) and/or checkpoint kinase 1 (ChK1) following kidney injury and thereby upregulates KIM-1. KIM-1 also has anti-inflammatory role as it mediates phagocytosis of apoptotic and necrotic cells (efferocytosis) following kidney injury. However, the accelerated shedding of KIM-1 regulated by p38 MAPK blocks efferocytosis as the excess soluble KIM-1 acts as a decoy to cell-associated KIM-1. Mucin 1 (Muc1) is a transmembrane glycoprotein found primarily in the distal nephron that is also induced in the PT following kidney injury. We previously published data showing that Muc1 plays a protective role during ischemia-reperfusion injury (IRI) by stabilizing both HIF-1a and b-catenin.

Methods: More recently, using our hanging-weight protocol of 20 min ischemia and 48 h recovery, we observed a significant two-fold higher level of urinary KIM-1 as well as more severe kidney injury in Muc1 KO mice when compared to wild-type (WT) littermates. There was no significant difference in the levels of neutrophil gelatinase-associated lipocalin (the distal tubule injury biomarker NGAL) between Muc1 KO and WT littermates. Based on these findings, we tested the hypothesis that Muc1 plays a protective role during IRI by modulating the pathways known to regulate PT KIM-1 activity.

Results: Immunoblots of kidney tissue revealed that levels of both ERK1/2 and ChK1 were significantly higher in Muc1 KO mice when compared to WT littermates. Furthermore, the cytoplasmic and nuclear levels of active STAT3 were significantly higher and thus KIM-1 levels in Muc1 KO mice when compared to WT littermates. Moreover, levels of phosphorylated p38 MAPK are significantly higher in Muc1 KO mice when compared to WT littermates which enhances KIM-1 shedding, and consequently more severe kidney injury.

Conclusions: These results support the likelihood that Muc1 regulates KIM-1 function by regulating both its expression and shedding following kidney injury.

Gene Deletion of the Na-Glucose Cotransporter SGLT2 Does Not Affect Kidney Injury or Recovery in a Murine Model of Severe AKI

Josselin Nespoux, Rohit Patel, Winnie Huang, Brent Freeman, Volker Vallon. *Department of Medicine, University of California, San Diego & VA San Diego Healthcare System, San Diego, CA.*

Background: In normoglycemia, the renal Na-glucose cotransporter SGLT2 reabsorbs ~97% of filtered glucose in the early proximal tubule, while SGLT1 reabsorbs the remaining glucose in the downstream S3 segment. Pretreatment with an SGLT2 inhibitor appeared protective at 24 hrs after ischemia-reperfusion (IR)-induced acute kidney injury (AKI) in mice (PLoS ONE 11(7):e0160478, 2016). Here we determined whether gene knockout of SGLT2 (KO) affects kidney injury or recovery following IR.

Methods: Male KO and wild-type (WT) mice (C57BL/6J) underwent sham surgery (Sham) or IR (25 min of bilateral renal artery clamping) under ketamine/xylazine anesthesia, while body temperature was maintained at 36-37°C (n=7-15/group). Urine and blood were collected at several time points. GFR was measured 14 days after IR by plasma elimination kinetics of FITC-sinistrin in conscious mice. Kidneys were harvested 23 days after IR for renal gene expression analysis by RT-qPCR.

Results: On day 1 after IR, plasma creatinine (by LC-MS-MS) increased to similar levels in KO-IR and WT-IR (1.96±0.19 vs 1.87±0.25 mg/dL, NS) vs Sham groups (0.14±0.01 vs 0.11±0.01 mg/dL, NS); fractional urinary glucose excretion (based on creatinine) increased from 27 to 62% in KO-IR and from 0.1 to 20% in WT-IR. IR reduced urine osmolality and increased plasma osmolality to a similar extent in KO-IR and WT-IR; this was associated with a similar increase in urinary KIM-1 to creatinine ratio, a marker of proximal tubule injury. On day 14, GFR was similarly reduced in KO-IR and WT-IR (2.4±0.2 vs 2.8±0.3 µL/min/g BW, NS) vs Sham groups (12.0±0.8 vs 11.9±0.9 µL/min/g BW, NS). On day 23, plasma creatinine (0.28±0.03 vs 0.32±0.03 mg/dL, NS) and plasma osmolality were partially restored in KO-IR and WT-IR, and urine osmolality and renal mRNA expression of Na-2Cl-K cotransporter NKCC2 were reduced at similar levels vs. Sham groups. Moreover, renal mRNA expression of markers of injury, fibrosis, inflammation and oxidative stress (KIM-1, type 1 collagen, TGFB1, MCP-1, NOX2) was significantly and similarly increased in KO-IR and WT-IR versus Sham groups.

Conclusions: Absence of SGLT2 did not affect the initial injury and impairment of kidney function or the subsequent partial kidney function recovery in a mouse model of IR-induced severe AKI.

Urinary Symmetric Dimethylarginine Reflects Mild Renal Damage After Cisplatin Treatment in Rats

Yuji Hotta,[1] Aya Naiki-Ito,[2] Ayae Kitagawa,[1] Natsumi Tomita,[1] Masahiro Kondo,[3] Tomoya Kataoka,[4] Yasuhiro Maeda,[1] Satoru Takahashi,[2] Kazunori Kimura.[1,4] *[1]Hospital Pharmacy, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; [2]Experimental Pathology and Tumor Biology, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan; [3]Pharmacy, Nagoya City University Hospital, Nagoya, Japan; [4]Clinical Pharmaceutics, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan.*

Background: Serum symmetric dimethylarginine (SDMA) correlates with renal function, but the usefulness of measuring urinary SDMA levels is unclear. Here, we studied if urinary SDMA levels reflected mild nephropathy after cisplatin (CDDP) treatment that failed to increase serum creatinine (SCr) in rats.

Methods: [*Single CDDP treatment*] Eight-week-old male Wistar-ST rats were divided into control and CDDP groups, treated with saline and CDDP 1 mg/kg intraperitoneally, respectively. SCr, blood urea nitrogen (BUN), and urinary and serum SDMA levels were measured before and 5 days after treatment. SDMA was measured by ultra performance liquid chromatography-tandem mass spectrometry. Damage to proximal tubules (PTs) was evaluated by H&E staining. mRNA expression levels of organic anion transporter1 (Oat1) which transports SDMA were measured by real-time PCR. [*Multiple CDDP treatment*] We formed groups that were treated with saline and CDDP 1 mg/kg every 7 days (day 0, 7, 14, and 21) to study the effects of multiple CDDP treatment cycles. SCr, BUN and serum

and urinary SDMA levels were measured at day 0 and day 5 in each cycle. Damage of PTs were studied 28 days after treatment. Statistical analysis was performed by Welch's *t*-test.

Results: [*Single CDDP treatment*] SCr and BUN unchanged 5 days after treatment between control and CDDP groups. However, necrosis of PTs was partly observed in the CDDP group. Urinary SDMA levels in the CDDP group significantly increased on day 5 ($P<0.01$); serum SDMA levels did not change. mRNA expression levels of Oat1 unchanged between control and CDDP group. [*Multiple CDDP treatment*] SCr and BUN did not change even after 3 CDDP treatment cycles compared with control group. In CDDP group, heteromorphic regenerating endothelium was observed. Urinary SDMA in CDDP group was significantly increased compared with control group from day 5 until the endpoint ($P<0.01$).

Conclusions: Urinary SDMA levels reflect the mild damage of PTs after CDDP treatment, which SCr and BUN could not reflect. Thus, urinary SDMA may be a better biomarker than SCr and BUN.

FR-PO099

Involvement of Acid-Sensing Ion Channels in Ischemia/Reperfusion Induced Kidney Injury

Nana Song. *Zhongshan Hospital, Fudan University, Shanghai, China*.

Background: Acidic microenvironment is commonly observed in ischemic tissue. In the kidney, extracellular pH dropped from 7.4 to 6.5 within 10 min initiation of ischemia. Acid-sensing ion channels (ASICs) represent a family of H^+-activated Na^+ channels. Among six ASICs subunits, ASIC1a and ASIC3 are high proton sensitive, which can be activated by pH drops from 7.4 to 7.0 or lower. However, ASIC1a is the only one that is permeable to Ca^{2+} besides Na^+. Thus, activation of ASIC1a can mediate the intracellular Ca^{2+} accumulation and play crucial roles in apoptosis of neuron. The aim of the present study was to test the hypothesis that extracellular acidosis caused by ischemia increases renal epithelia cell apoptosis through ASIC1a-mediated calcium entry.

Methods: Immunofluorescence double staining and confocal analysis were applied to observe the co-localization of ASICs with AQP1 (proximal tubule marker), THP (thick ascending limbs and distal tubule marker) and Synaptopodin (podocyte marker). ASIC1a inhibitor PcTx-1 and ASIC3 inhibitor APETx-2 was injected previously to IR operation. After that, the pathological and functional injury of the kidney was assessed by PAS staining and serum creatinine, and the apoptosis of kidney epithelia cells was measured by TUNEL staining and immunohistochemical reaction of caspase3. To demonstrate the underlying mechanism of ASICs induced renal IRI, HK-2 cells was pretreated with PcTx-1 before hypoxia, the intracellular concentration of Ca^{2+}, mitochondrial transmembrane and apoptosis was measured by Fluo-4/AM, JC-1 and AnnexinV/PI and analyzed by flow cytometry.

Results: ASIC1a was found to be co-localized with AQP1 and Synaptopodin. ASIC3 was detected majorly in podocyte and mesenchyma. IRI up-regulated the expression of ASIC1a, however, had little effect on ASIC3, both in vivo and in vitro. Additionally, blocking ASIC1a by administration of PcTx-1 protects kidney from ischemia/reperfusion injury. Inhibition of ASIC3 by APETx2 had no significant effect on renal ischemia/reperfusion injury. Moreover, Blocking ASIC1a attenuated ischemia/reperfusion induced Ca^{2+} overflow, loss of mitochondrial transmembrane potential and apoptosis in HK-2 cells.

Conclusions: The results revealed that ASIC1a localized in the kidney proximal tubular and contributed to ischemia/reperfusion induced kidney injury. Consequently, targeting the ASIC1a may prove to be a novel strategy for AKI patients.

Mechanisms of Sex-Dependent Development of Acute Renal Failure - Insights from Preconditioning Experiments

Karla J. Hoyer, Martin Späth, Torsten Kubacki, Marc Johnsen, Thomas Benzing, Bernhard Schermer, Volker R. Burst, Roman-Ulrich Mueller. *University of Cologne, Koeln, Germany*.

Background: Experimental work on acute kidney failure in mice shows a clear sex distribution - the severity of renal failure in females is significantly lower than in males, however, the mechanisms are not clear. Interestingly, preconditioning (caloric restriction, hypoxia) prevents acute kidney injury (AKI) reliably. The aim of the work is to evaluate sex-specific mechanisms of the protective effect of caloric preconditioning.

Methods: 14 week old male and female C57Bl6 wild-type mice underwent no preconditioning serving as a control group or four weeks of a calorie-restricted diet as a method of preconditioning prior to ischemia-reperfusion-injury (IRI). Afterwards, we compared control animals with animals after CR and males and females by phenotyping (histology, urea).

Results: IRI led to a pronounced kidney damage in males compared to a significantly lower damage in females. CR can completely prevent kidney failure in males. There is no significant improvement in the female mice compared to the untreated females. For further investigations, we performed a transcriptome analysis after preconditioning and were able to demonstrate the downregulation of a cytochrome P450 enzyme, Cyp4a12a, which is predominantly expressed in male mice. Cyp4a12a is necessary for the enzymatic production of 20-HETE, a derivative of arachidonic acid, which has an influence on renal regulation of blood pressure and volume retention. After the treatment of preconditioned animals with 20-HETE, the protective effect of caloric restriction can be abrogated. This suggests a possible relationship between the effect of preconditioning, sex, and a reduction of the concentration of 20-HETE.

Conclusions: The fact that female animals show a significant reduction of damage compared to males emphasizes the importance of the sex-specific analysis of the development of acute renal failure. In addition, we can report on the effect of caloric restriction and sex depending on the concentration of 20-HETE for the first time.

FR-PO101

Selective Vasopressin V1a Receptor Antagonism Improves Renal Oxygenation and Perfusion in AKI

Hana Cernecka, Karoline Droebner, Thomas Mondritzki, Marie-Pierre L. Collin, Frank Eitner, Peter Kolkhof. *Bayer AG, Wuppertal, Germany*.

Background: Vasopressin (AVP) is a neurohormone with a well understood role in urinary volume control via activation of V2 receptors expressed in the collecting duct. The function of renal V1a receptors, which are broadly expressed on vascular smooth muscle cells throughout the medullary vasa recta, in mesangial as well as in macula densa cells, is less well understood. Since reduced blood supply and tissue hypoxia are frequent findings in kidney diseases, we aimed to investigate the potential benefit of selective V1a antagonism (using relcovaptan, SR 49059) in rat models of acute kidney injury (AKI).

Methods: The effects of relcovaptan on renal blood flow (RBF) and tissue oxygenation were investigated in isolated perfused rat kidneys as well as in anesthetized rats (n=7 per group) via Laser Doppler Flowmetry in settings of increased AVP levels induced by either infusion of AVP or renal ischemia/reperfusion injury (I/RI).

Results: Relcovaptan (0.3–300 nM; $p<0.001$) significantly improved the AVP-mediated (50 nM) reduction of perfusate flow in concentration-dependent manner while having no effect on urine excretion. *In vivo*, infusion of AVP (50 ng/kg/min i.v.) significantly increased mean arterial pressure (137±3; mean±SEM) which was normalized by relcovaptan in a dose-dependent manner (108±3; $p<0.01$). Infusion of AVP reduced both renal perfusion and tissue oxygenation (pO_2; 7.5±4). Relcovaptan dose-dependently restored renal perfusion and significantly increased pO_2 (30.7±6.4; $p<0.01$). Systemic hemodynamic parameters remained stable under I/RI conditions and concomitant infusion of relcovaptan. Fifteen minutes of ischemia resulted in decreased levels of both RBF and pO_2 after reperfusion in comparison with basal levels. In contrast, selective V1 a receptor antagonism significantly improved pO_2.

Conclusions: Selective V1a inhibition exerts beneficial effects on renal oxygenation under different pathological settings and might be a promising therapeutic approach to improve kidney hypoxia and subsequently kidney function in conditions of increased AVP levels, such as AKI and CKD.

Partitioning Defective Par1a Deletion Attenuates Renal Fibrosis in Mice

Estefany Maria,[2] Abhijeet Pal,[4] Zhongfang Du,[3] Kimberly J. Reidy.[1] [1]*Pediatrics/ Nephrology, Children's Hospital at Montefiore/ Albert Einstein College of Medicine, Bronx, NY;* [2]*Albert Einstein College of Medicine, Bronx, NY;* [3]*Albert Einstein College of Medicine, Children's Hospital at Montefiore, Bronx, NY;* [4]*The Children's Hospital at OU Medical Center, Oklahoma City, OK*.

Background: Chronic kidney disease (CKD) affects 1 in 7 U.S. adults; CKD leads to both increased morbidity and mortality. CKD progression correlates with tubulointerstitial fibrosis. As shown in mouse models, fibrosis is driven by Notch and Wnt activation. Notch and Wnt are important renal developmental pathways. In prior work from our laboratory focused on the developing kidney, Notch signaling pathway expression was decreased in Par1a/b mutant mice (*Par1a+/-:Par1b-/-*). Par1a and 1b are serine threonine kinases: they regulate protein trafficking, cell-cell adhesion, cell-matrix adhesion and the actin cytoskeleton. Par1a and 1b are paralogues and compensate for one another: while *Par1a+/-:Par1b-/-* mice die after birth, individual Par1a or 1b knockout mice have no renal developmental phenotype. We hypothesized: Loss of Par1a or 1b would attenuate Notch signaling and renal fibrosis.

Methods: To examine the expression of Par1a/b and Notch signaling components in renal injury, immunoflorescence (IF) staining was performed; Par1a and 1b paralogue specific antibodies were used. For acute kidney injury, mice were injected with 20 mg/kg cisplatin injection i.p. For chronic kidney injury, folic acid nephropathy and unilateral ureteral obstruction were used. To test the role of Par1a in renal fibrosis, folic acid injection (250 mg/kg dissolved in 300 mM NaHCO3) was performed in *Par1a-/-* and *Par1a+/+* mice. Vehicle injected mice served as controls. To detect renal fibrosis, Picrosirius red staining of collagen was performed. Quantification of 20x images was performed using Image J.

Results: Par1b expression increased in acute kidney injury, while Par1a expression increased predominantly in chronic kidney injury models. Consistent with other studies, Notch signaling component expression also increased following kidney injury. Folic acid injected *Par1a-/-* mice had decreased renal fibrosis: as quantified by sirius red staining, percent area of fibrosis was 12 +/- 6.8 % in folic acid treated *Par1a+/+* vs 3 +/- 2.2% in *Par1a-/-* kidneys. (p-value <0.01)

Conclusions: Par1a and Notch signaling pathway member expression are increased in renal fibrosis mouse models. In mice, Par1a deletion was protective against fibrosis. Par1a is a potential modifier of Notch activation during renal fibrosis.

A Downstream Molecule of 1,25-Dihydroxyvitamin D3, Alpha-1-Acid Glycoprotein, Protects Against Mouse Model of Renal Fibrosis

Jing Bi,[1,2] Hiroshi Watanabe,[3] Rui Fujimura,[4] Kento Nishida,[5] Ryota Nakamura,[3] Shun Oshiro,[6] Tadashi Imafuku,[6] Masako Miyahisa,[6] Toru Maruyama.[3] *[1]Dept of Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kumamoto University, Kumamoto, Japan; [2]Program for Leading Graduate Schools "HIGO (Health life science: Interdisciplinary and Glocal Oriented) Program", Kumamoto University, Kumamoto, Japan; [3]School of Pharmacy, Kumamoto University, Kumamoto, Japan; [4]Kumamoto university, Kumamoto-shi, Japan; [5]Department of Biopharmaceutics, School of Pharmacy, Kumamoto University, Kumamoto-shi, Japan; [6]Kumamoto University, Kumamoto, Japan.*

Background: Renal fibrosis, the central feature of the progression of chronic kidney disease, is associated with unremitting renal inflammation. 1,25-dihydroxyvitamin D3 (1,25(OH)2D3), the active form of vitamin D, has been reported for its anti-renal fibrotic effect in model of unilateral ureteral obstruction (UUO), but its molecular mechanism is still unknown.

Methods: ICR mice (male, 4-week-old) were randomized and anaesthetized before the abdomen was opened, then the left ureter was ligated with 4-0 silk and the abdomen was closed with sutures. 1,25(OH)2D3 was administered *i.p.* daily from day 0 to day 6 of the UUO treatment. Alpha-1-acid glycoprotein (AGP) was administered *i.v.* daily from day 1 to day 6 of the UUO treatment. Mice were sacrificed on day 7 after surgery. Phorbol 12-myristate 13-acetate (PMA)-treated THP-1 cells or HepG2 cells were treated with 1,25(OH)2D3 or AGP and incubated for 48 hr. LPS were incubated for 48 hr. Real-time PCR, immunofluorescence and Picrosirius Red staining were performed.

Results: Renal fibrosis and inflammation observed in the kidney of the UUO mice were attenuated by the treatment of 1,25(OH)2D3. Interestingly, the plasma protein level of AGP, a downstream molecule of 1,25(OH)2D3, was increased following the administration of 1,25(OH)2D3 to healthy mice. Additionally, the increase of *ORM1*, an AGP gene, was observed in 1,25(OH)2D3-treated HepG2 cells and THP-1-derived macrophages. To investigate the involvement of AGP, exogenous AGP was administered to the UUO mice, resulting in attenuated renal fibrosis and inflammation. Regarding the mechanism, we found the mRNA expression of CD163, a monocyte/macrophage marker with anti-inflammatory potential, was increased in THP-1-derived macrophages under 1,25(OH)2D3 or AGP stimulus, respectively. Moreover, AGP prevented lipopolysaccharide-induced macrophage activation.

Conclusions: We found for the first time that AGP could be a key molecule in the protective effect of vitamin D against renal fibrosis. AGP may function as an important immune regulator, replacing vitamin D to offer therapeutic strategy for renal inflammation and fibrosis.

FR-PO104

Reduction of Excess Renal Iron Acquisition Diminishes Tubular Injury in Experimental Focal Segmental Glomerulosclerosis

Rachel Van swelm,[2] Sanne Beurskens,[1] Henry Dijkman,[1] Jack F. Wetzels,[1] Erwin Wiegerinck,[1] Rian Roelofs,[1] Johan Van der vlag,[1] Bart Smeets,[1] Dorine W. Swinkels.[1] *[1]Radboud University Medical Center, Nijmegen, Netherlands; [2]Radboud University Medical Centre, Nijmegen, Netherlands.*

Background: Renal iron accumulation as a result of proteinuria is suggested to play a role in progression of chronic kidney disease (CKD). Here, we studied the molecular mechanisms of renal iron loading in experimental focal segmental glomerulosclerosis (FSGS; Thy-1.1 mouse model) and investigated if reduction in renal iron loading decreased tubular injury.

Methods: Thy-1.1 mice were injected with a monoclonal anti-Thy-1.1 antibody (mAb) or saline as control and sacrificed immediately after injection (D1), day 8 (D8) or day 22 (D22).

Results: Injection of mAb resulted in immediate and persistent albuminuria ($p<0.01$). Renal injury in mAb-injected mice was confirmed by standard histology, increased urinary kidney injury markers KIM1 ($p<0.05$) and NGAL ($p<0.01$) and elevated renal mRNA expression of *IL-6* ($p<0.001$) and *HO-1* ($p<0.01$). Increased distal tubular iron accumulation was observed with increasing renal injury in mAb-treated mice. QPCR analysis indicated distal iron accumulation via the NGALR and not transferrin receptor-1 (TfR1). *In vivo* silencing of renal NGALR resulted in significantly reduced *HO-1* and *L-ferritin* mRNA levels at D8 (both $p<0.05$), indicating reduced iron accumulation and injury. Systemic iron depletion by iron-deficient diet reduced renal iron accumulation and urinary KIM1 and NGAL on D8 (both $p<0.05$), but not D22. Interestingly, the iron-deficient diet did not reduce renal *IL-6* mRNA, whereas an iron-rich diet diminished *IL-6* (D22, $p<0.001$) and urinary KIM1 ($p<0.05$) and NGAL ($p<0.001$) on D8 and D22, despite concurrent increased iron deposition and oxidative stress as indicated by HO-1 immunostaining and mRNA expression ($p<0.001$). Alternatively, we aimed to prevent excess renal iron deposition by reducing glomerular protein filtration (captopril; CA) or iron chelation (deferoxamine; DFO) for 7 days after mAb injection. Both CA and DFO reduced renal iron accumulation, and urinary KIM1 and NGAL ($p<0.05$) on D8, which did not last until D22, suggesting requirement for continuous treatment.

Conclusions: In conclusion, our results indicate that prevention of excess renal iron accumulation could be useful to halt progression of tubular injury in CKD. However, disturbances in systemic iron balance are not feasible, warranting a targeted renal approach.

TRPM7 Is a Potential Therapeutic Target in Progressive Renal Disease

Sayuri Suzuki.[1,2] *[1]Queen's Center for Biomedical Research, The Queen's Medical Center, Honolulu, HI; [2]University of Hawaii Cancer Center, John A. Burns School of Medicine, University of Hawaii, Honolulu, HI.*

Background: Unilateral Ureteral Obstruction (UUO) is a representative model of nephritis with progressive tubulointerstitial injury and renal fibrosis occurring by inflammation that is suitable for investigating the cellular and molecular events that occur during progressive renal fibrosis associated with cell proliferation and apoptosis. Blocking tubular epithelial cell proliferation is crucial to preventing the renal tubule dilation and the progression of kidney damage. TRPM7 belongs to the Transient Receptor Potential Melastatin family of ion channels. Our work shows that TRPM7 is a Ca^{2+}- and Mg^{2+}-conducting ion channel fused with a functional kinase. TRPM7 plays a key role in a variety of diseases, including malaria invasion, neuronal death in ischemia, cancer and cardiac fibrillation. TRPM7 is aberrantly over-expressed in lung, liver and heart fibrosis. It is also overexpressed after renal ischemia-reperfusion, an event that induces kidney injury and fibrosis. However, the role of TRPM7 is unclear in kidney fibrosis.

Methods: We created UUO mouse model, compared the expression level of TRPM7 in UUO kidneys and control kidneys at Day7 using qRT-PCR, western blotting assay and immunohistochemistry. Our lab's drug screening efforts have identified waixenicin A that is the currently only specific and potent TRPM7 inhibitor. Using NRK49F and NRK52E cells, we investigated the inhibitory efficacy of waixenicin A on MTT cell growth assay.

Results: The expression levels of TRPM7 mRNA and protein in UUO kidneys were higher than control kidneys, TRPM7 particularly increased on tubular epithelial cells. The TRPM7 positive cell number increased twice on both of renal tubular epithelial cells and tubulointerstitial cells in UUO kidneys compared to control kidneys. Waixenicin A inhibited the cell growth of renal epithelial cells and fibroblasts *in vitro*.

Conclusions: TRPM7 up-regulated in progressing inflammatory renal damage, waixenicin A could be capable of inhibiting kidney cell proliferation and fibrosis in renal disease.

Apolipoprotein L1 Is Associated with Larger HDL Particles in CKD

Andrew N. Hoofnagle,[1] Michael L. Andrews,[2] Zsuzsanna Kuklenyik,[2] Ian H. de Boer,[1] Bryan R. Kestenbaum.[1] *[1]University of Washington, Seattle, WA; [2]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: Apolipoprotein L1 (**ApoL1**) is a potential mediator of inflammatory kidney injury and disease progression. Two polymorphisms in the APOL1 gene (G1 and G2) increase the risk of chronic kidney disease (**CKD**) in Blacks. The mechanism of injury may involve ApoL1 expressed within the kidney (e.g., in podocytes) and/or ApoL1 secreted by the liver (i.e., in plasma). We have previously demonstrated that ApoL1 is depleted from the HDL2/3 fraction of plasma in patients with lower eGFR. In this study, we aimed to quantify the distribution of ApoL1 within plasma to help clarify the biochemistry of ApoL1.

Methods: We determined ApoL1 phenotype and plasma concentrations using targeted mass spectrometry (**MS**) among 424 participants from the Seattle Kidney Study, a racially diverse, well-characterized cohort of patients with CKD. For 20 participants, we used asymmetric flow field-flow fractionation (**AF4**) to fractionate plasma into 40 fractions, which were each analyzed using MS to determine relative concentrations of ApoL1.

Results: Plasma concentration of ApoL1 was associated with age, race, and ApoL1 phenotype (**Table 1**). In addition, both plasma concentration of ApoL1 and the ratio of the amount of ApoL1 in HDL to total plasma ApoL1 were directly correlated with eGFR. However, only the ratio of ApoL1 in HDL to total ApoL1 was significantly associated with eGFR, after controlling for age, race, and phenotype, which suggested that ApoL1 is located in a different fraction of plasma in CKD. We then used AF4 and MS to determine that ApoL1 is associated with larger particles (similar to HDL1 particles containing ApoE) in participants with lower eGFR, after controlling for race and genotype ($p<0.01$).

Conclusions: These results demonstrate that plasma ApoL1 is biochemically different in patients with reduced eGFR, which may be related to the role ApoL1 plays in the progression of CKD.

Funding: NIDDK Support, Other NIH Support - NHLBI

	Total ApoL1 in plasma		Ratio of ApoL1 in HDL to total plasma ApoL1	
Independent variable	**% Change**	**p-value**	**% Change**	**p-value**

Inhibiting ApoL1 Translocation to Mitochondrial Matrix Can Protect Against Risk Variant Mediated Cytotoxicity

Shrijal Shah,[1] Herbert F. Lannon,[1] Leny Dias,[1] Martin R. Pollak,[2] David J. Friedman.[2] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA.*

Background: African Americans with two copies of ApoL1 risk variants (G1 and G2) are at high risk of developing chronic kidney disease. The subcellular localization of ApoL1 based on imaging studies has been a subject of conflicting reports.

Methods: HEK293 stable cells that express G0, G1, G2 in the presence of tetracycline were made using the T-Rex system. Cells were transfected with siRNA for specific outer mitochondrial membrane (OMM) and inner mitochondrial membrane (IMM) translocase machinery components and then ApoL1 expression was induced with tetracycline. After ApoL1 induction, mitochondrial and cytosolic fractions were prepared by differential centrifugation and presence of ApoL1 in each fraction was determined by immunoblotting. We also measured oxygen consumption rate using a Seahorse assay and measured cytotoxicity after knocking down specific OMM and IMM components.

Results: Using a biochemical approach to study ApoL1 localization, we found a large fraction of G0 as well as G1 and G2 in the mitochondria. Protease digestions of isolated mitochondria demonstrated that ApoL1 protein had been translocated into the mitochondrial matrix. siRNA knock-down of OMM protein TOMM20, which is involved in recognizing matrix-targeting presequences on nuclear-encoded proteins, reduces ApoL1 levels in mitochondria. TOMM20 knockout also rescues G1 and G2 mediated mitochondrial dysfunction as measured by oxygen consumption rate and reduces cell death. Knock-down of TIMM23/TIMM17 complex components, which are essential for translocating matrix-targeted proteins, rescues G1- and G2-mediated cytotoxicity whereas knock-down of TIMM22, which is essential for protein insertion into the IMM, has no effect.

Conclusions: G1 and G2 need to translocate to mitochondrial matrix to induce toxicity. Since both G0 and risk variants are translocated to the mitochondrial matrix, elucidating different behavior of these variants after mitochondrial translocation will be important for understanding why only the risk variants cause kidney injury.

FR-PO108

Combined Effects of GSTM1 Deficiency and Podocyte-Specific APOL1 G0 and G2 Transgene on Blood Pressure and Albuminuria in a Mouse Model of CKD

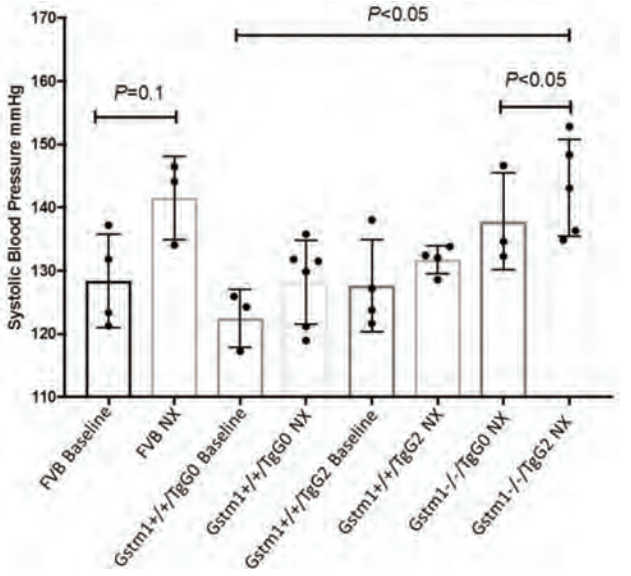
Shirin Pourafshar, Sylvia Cechova, Behnam Keshavarz, Rosa Chan, Thu H. Le. *University of Virginia, Charlottesville, VA.*

Background: We reported that *GSTM1* null allele (*GSTM1(0)*) is associated with accelerated kidney disease progression in the African Americans Study of Kidney Disease (AASK) participants, and those carrying both *GSTM1(0)* and *APOL1* risk variants had the worst composite outcomes. This suggests a potential interaction between these 2 genes in CKD. Transgenic mice expressing the human *APOL1* high risk variants in podocytes did not show kidney disease at baseline; however, females developed preeclampsia during pregnancy. The objective of this study was to investigate whether GSTM1 interacts with APOL1 to influence hypertension (HT) and kidney disease development in a mouse model of CKD.

Methods: We generated *Gstm1* deficient mice on the FVB background. We crossed the FVB *Gstm1-/-* mice with FVB podocyte specific *APOL1* G0 or G2 Transgenic mice (TgG0 and TgG2), respectively. The offspring were subjected to subtotal nephrectomy (Nx). Wild-type FVB were used as controls. After a 10-day training period, baseline systolic blood pressure (SBP) and SBP 6-8 weeks after Nx were measured using tail-cuff method. Urinary albumin and creatinine were measured using commercially available ELISA kits. Data are reported as means ± SD.

Results: There were no significant differences in albumin/creatinine ratios among groups. However, *Gstm1-/-/APOL1TgG2* mice had significantly higher SBP compared to other groups and also higher than *Gstm1-/-/APOL1TgG0* ($P < 0.05$) (see graph).

Conclusions: In experimental CKD, mice carrying podocyte specific *APOL1* G2 Tg and deficient of GSTM1 enzyme have worst HT, independent of albuminuria. These results suggest a potential interaction between these two genes in the development of HT in CKD.



Gstm1-/-/APOL1TgG2 mice had significantly higher SBP compared to other groups.

Glomerular Endothelial Cell Senescence Drives Aged-Related Glomerulosclerosis via PAI1

Camille Cohen,[1] Océane Le goff,[1] Frederic Soysouvanh,[4] Lucile Amrouche,[1] Alexandre Karras,[2] Dominique Nochy,[2] Fabien Milliat,[3] Fabiola Terzi.[1] *[1]INSERM U1151 mechanisms and therapeutic strategies of chronic kidney disease, Hopital Necker, Paris, France; [2]Hopital Europeen Georges Pompidou - Assistance Publique Hopitaux de Paris, Paris, France; [3]IRSN, Fontenay-aux Roses, France; [4]Institute for Radioprotection and Nuclear Safety, Fontenay-aux-Roses, France.*

Background: Chronic kidney disease (CKD) is a major public health problem with a prevalence that dramatically increases with age. One of the most frequent histological lesions observed in elderly is glomerulosclerosis. However, its pathophysiology is still unclear. A recent study indicated that cellular senescence may be implicated since targeted apoptosis of senescent cells in aging murine models delays glomerulosclerosis. However, how cellular senescence triggers the development of glomerulosclerosis is unknown. Elucidating this issue was the aim of our study.

Methods: In this aim, we used several murine models including wild type and transgenic mice experiencing physiological and accelerated aging.

Results: As expected, 24 months-old mice developed sclerotic glomeruli as compared to 4 months-old mice. Beta-galactosidase and 53BP1 staining revealed increased glomerular cell senescence with age. Interestingly, colocalization experiments demonstrated that senescence interested almost exclusively endothelial cells. Consistently, we observed that endothelial glomerular cells were blocked in G1. This phenotype was associated with an increased expression of several components of the senescence associated secretory phenotype (SASP). Among these, plasminogen activator inhibitor 1 (PAI1), a senescence inducer and mediator, was particularly interesting, since its expression increased in endothelial cells. These results were confirmed in an experimental mouse model of accelerated aging (sublethal irradiation at 8 weeks and sacrifice 12 months later) as well as in patients treated with genotoxic. Interestingly, specific deletion of PAI1 in endothelial cells prevented cell senescence and the development of glomerulosclerosis during physiological aging in transgenic *VECad-CreXPAI1$^{flox/flox}$* mutant mice. Podocytes loss was also decreased in transgenic mice, suggesting a cross-talk between endothelial cells and podocytes.

Conclusions: In conclusion, our study uncovers the critical role played by endothelial senescence in the development of glomerulosclerosis and podocyte rarefaction in aging and identified PAI1 as a novel promising therapeutic target for preventing age-related CKD progression.

FR-PO110

The Roles of Uremic Toxin Early Elimination on AKI to CKD Transition

Jia-Huang Chen, Chih-Kang Chiang. *National Taiwan University, College of medicine, Taipei, Taiwan.*

Background: The post-AKI fibrosis is emerging as a major driver of progressive CKD. However, the cause of abnormal renal recovery after AKI is multifactorial and still poorly understood. Indoxyl sulfate (IS) is a protein-bound uremic toxin produced by bacterial metabolism of the amino acid tryptophan, which excreted through organic anion transporter on renal tubular epithelial cells into urinary and generally accumulates in patients with CKD. Although the adverse effects of IS on CKD progression have been well documented, its impacts on post-AKI fibrosis are still unknown. Accordingly, we investigated whether

AKI induces an increased level of serum IS and its role in AKI to CKD transition. Also, the therapeutic potency of early elimination of uremic toxins by absorbent Kremezin (AST-120) was tested.

Methods: In animal study, the two-step unilateral ischemia reperfusion injury with contralateral nephrectomy (hereafter abbreviated as UIRI) was used as a post-AKI fibrosis model. Briefly, C57BL/6 mice were subjected to 30 minutes unilateral ischemia reperfusion injury and contralateral nephrectomy were conducted at day10, and then sacrificed at day 15. All mice are randomly divided into: (1) Sham, (2) UIRI, (3) UIRI + indole, (4) UIRI + indole+ AST-120, and (5) UIRI + AST-120. For in vitro investigation, HK-2 cells were treated with 1mM IS for 48 h, followed by 12 hours of hypoxia and 24 hours of reperfusion (H/R) to explore the underlying mechanism.

Results: In our animal studies, we observed an increased serum IS levels without simutaneous accumulation of small uremic toxin molecules following 10 days of UIRI. Furthermore, AST-120 administration actually reduced deterioration of renal function caused by UIRI combined with high protein intake. We also revealed the possible mechanisms underlying the IS-enhanced proximal tubule damage after AKI. IS exposure potentiated H/R-induced G2/M cell cycle arrest, which also aggravated ER stress-mediated epithelial mesenchymal transition (EMT) as demonstrated by 4-PBA-treated rescue experiments.

Conclusions: Our results support the pathological role of uremic toxins in post-ischemic AKI fibrosis, and low protein diets would be recommended to prevent advanced kidney disease progression. Furthermore, elimination of IS by AST-120 is likely to prove useful for the prevention/treatment of post-AKI renal impairment.

Kidney Genome Atlas: A Whole-Genome Landscape of More Than 2,000 Kidney Disease Patients

Wei Zhang,[1] Thomas Soare,[1] Adam Tebbe,[1] Liron Walsh,[1] Matthias Kretzler,[2] Girish N. Nadkarni,[3] Rasheed A. Gbadegesin,[4] Jamie L. Wenke,[5] Peter H. Mundel,[1] Thomas T. Tibbitts.[1] *[1]Goldfinch Bio, Cambridge, MA; [2]U.Michigan, Ann Arbor, MI; [3]Ichan School of Medicine, New York, NY; [4]Duke University Medical Center, Durham, NC; [5]Nashville Biosciences, Nashville, TN.*

Background: Chronic kidney disease (CKD) is a heterogeneous disease affecting more than 30 million people in the US, which is about 10% of the US population. Despite the urgent need for targeted therapeutics, the understanding of the mechanistic basis of CKD including the genetic variants that potentially drive it has lagged other diseases (e.g. cancer) for decades.

Methods: Here we report the generation and initial analysis of the Kidney Genome Atlas (KGA), the world's largest whole-genome landscape of individuals with molecularly defined kidney diseases. Focusing initially on focal segmental glomerulosclerosis (FSGS), related disorders, and diabetic kidney disease (DKD), KGA contains whole genome sequences (>30X coverage) from more than 2,000 patients and 2,500 matched healthy controls. Each genome is linked to longitudinal clinical records and for a subset of 500 patients, the atlas also includes matched transcriptomic data from microdissected glomerular and tubulointerstitial samples.

Results: The KGA has enabled the discovery of genetic variants associated with kidney disease and the integration of genomic and transcriptomic data to identify kidney disease-specific expression quantitative trait loci (eQTLs). The atlas also provides the foundation for establishing the relationships between genetic variants, histologic diagnoses, and quantitative clinical phenotypes of kidney function and disease progression. Computational integration of these datasets will enable the prioritization of candidate variants with putative disease modulating effect. Investigating and validating biological pathways derived from these analyses can also be used to stratify patients into subtypes most likely to respond to specific targeted therapies.

Conclusions: The KGA is a valuable resource fueling our understanding of the molecular mechanisms of kidney diseases at the whole genome scale.

FR-PO112

Sodium and Phosphate Dietary Additives Exacerbate Progression of CKD and Lead to Early Mortality

Claire Gerber,[1] Samantha Neuburg,[1] Corey Dussold,[1] Lixin Qi,[1] Guillaume Courbon,[1] Maralee Capella,[1] Connor Francis,[1] Xueyan Wang,[1] Myles Wolf,[2] Aline Martin,[1] Valentin David.[1] *[1]Northwestern University - Feinberg School of Medicine, Chicago, IL; [2]Duke University, Durham, NC.*

Background: Fibroblast growth factor 23 (FGF23) increases in response to high phosphate diets and states of impaired phosphate excretion, such as chronic kidney disease (CKD). Excess FGF23 hasemerged as a novel and powerful risk factor for cardiovascular disease (CVD) and death in patients with CKD and in the general population. Multiple studies have shown that excess FGF23 is often due to high consumption of processed foods, enriched in phosphate and sodium additives, that stimulate FGF23 production and increase risks of death. We hypothesized that consumption of excess phosphate stimulates FGF23 production, and that presence of CKD and simultaneous consumption of excess sodium exacerbates FGF23 negative outcomes.

Methods: To investigate the effects of dietary intake of phosphate and sodium on cardiovascular and CKD disease progression, 5 week old wild-type (WT) and Col4a3^{KO} (CKD) mice were fed a control (Ctr), high sodium (HN), high phosphate (HP), or a high sodium-high phosphate (HPN) diet for 18 weeks. We assessed survival, renal function and serum FGF23 in 23 week old mice.

Results: Phosphate and/or sodium did not impact renal function or overall survival in WT mice. In contrast, HP, HN and HPN diets further impaired renal function in CKD animals compared to CKD-CTR mice. HP and HN diets decreased survival in CKD mice, CKD-HN and CKD-HP mice showing an average survival of 26 and 22 weeks, repectively, compared to CKD-CTR mice that live in average 34 weeks ($p<0.05$). Interestingly, phosphate and sodium in HPN diet did not show additive effects on the overall survival of CKD mice (27 weeks). Consumption of phosphate in HP and HPN diets increased ($p<0.05$) FGF23 in WT mice, by 20 fold in WT-HP and by 3 fold in WT-HPN compared to WT-CTR mice, whereas HN did not affect FGF23 levels in WT mice. CKD-CTR mice showed increased FGF23 (3 fold) compared to WT-CTR mice. HP, HN and HPN diets all increased FGF23 in CKD groups, with the highest increase found in CKD-HP mice (20-fold) while CKD-HN and CKD-HPN animals showed only 3 and 5 fold increase respectively, in FGF23 ($p<0.05$ vs CKD-CTR).

Conclusions: Overall, our data suggest that consumption of high phosphate rather than high sodium raises FGF23 in CKD, exacerbates decline in kidney function, and leads to early mortality.

Translational Profiling and RNA-Seq of Proximal Tubule Reveals Gender-Specific Transcriptional Patterns, Tubulointerstitial Signaling, and lncRNA Regulation During Kidney Fibrosis

Chun-Fu Lai,[1,2] Haojia Wu,[1] Monica Chang Panesso,[1] Benjamin D. Humphreys.[1] *[1]Division of Nephrology, Department of Medicine, Washington University in St. Louis School of Medicine, St. Louis, MO; [2]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan.*

Background: Proximal tubule epithelial cells (PTEC) are central mediators of interstitial fibrosis in CKD. We applied Translating Ribosome Affinity Purification (TRAP) followed by RNA-seq to precisely measure the gene expression landscape of PTEC during renal fibrosis.

Methods: Bigenic Slc34a1^{GFPCreERT2}; R26$^{eGFP-L10a}$ mice received tamoxifen to activate expression of eGFP-L10a in PTEC with subsequent unilateral ureteral obstruction (UUO) surgery. Kidneys were harvested at day 5 or 10. Each group included three female and four male mice. PTEC-specific polysomal mRNA was isolated by affinity purification, and each sample sequenced to a depth of 30 million reads. Extensive informatic analysis identified critical genes and pathways, which were validated by *in situ* hybridization.

Results: Unexpectedly, we identified a group of genes with sexually dimorphic expression patterns including neuronal regeneration related protein (Nrep), interleukin 34 and nuclear factor interleukin-3-regulated protein (Nfil3). For both sexes, serpin family A member 10 (Serpina10), vascular cell adhesion molecule 1 (Vcam1), SRY-box 9 (Sox9), and nerve growth factor (Ngf) top the list of PTEC-specific highly upregulated genes after UUO. Functional annotations transcriptional changes in PTEC implicate the interleukin-1β and tumor necrosis factor signaling pathways in mediating tubule-interstitial crosstalk. Contrary to published reports, PTEC strongly upregulated Indian hedgehog (Ihh), not Sonic hedgehog (Shh), during renal fibrosis. All results were validated by quantitative PCR and *in situ* hybridization. Finally, two long intergenic noncoding RNAs (Snhg18 and predicted gene 20513) and microRNA 6358 were strongly upregulated in injured PTEC, suggesting novel regulatory roles in fibrosis. None of these genes have been described in kidney previously.

Conclusions: This is the first comprehensive RNA-seq-based transcriptional profile of PT cells during fibrosis. We reveal unexpected gene expression differences in male vs. female PT, validate novel pathways mediating tubule-interstitial crosstalk and identify novel lncRNA upregulation not previously associated with kidney.

FR-PO114

BION-1301: A Novel Fully Blocking APRIL Antibody for the Treatment of IgA Nephropathy

John Dulos, Paul Vink, Hans Van eenennaam, Andrea Van elsas. *Aduro Biotech Europe, Oss, Netherlands.*

Background: A PRoliferation Inducing Ligand (APRIL, TNFSF13) is a ligand for the receptors B cell maturation antigen (BCMA) and Transmembrane activator and CAML interactor (TACI). APRIL serum levels were found to be enhanced in patients diagnosed with IgA Nephropathy (IgAN) and treatment with an anti-mouse APRIL antibody reduced serum IgA and proteinuria increase in an IgAN mouse model (Kim Y.G. et al. PLOS one Sep 8, 2015). Altogether suggesting that the APRIL-axis is important in IgAN pathology and strongly supporting the development of our anti-APRIL antibody, BION-1301 to treat IgA nephropathy (IgAN).

Methods: BION-1301 affinity, binding to APRIL and blocking capacity to BCMA and TACI was characterized using Biolayer Interferometry and ELISA. A sinlge-dose non-human primate (NHP) PK and tolerability study was performed administering intravenous (i.v.) BION-1301 at 0.3, 3 and 30 mg/kg. Preclinical safety was assessed in a 4-week repeat-dose NHP study using weekly i.v. doses of 10, 30 and 100 mg/kg. In human primary B-cell cultures the effect of (anti-)APRIL on IgA production, BCMA and TACI expression was assessed.

Results: We developed a novel humanized high-affinity anti-APRIL antibody BION-1301 (KD 0.4 ± 0.15 nM, EC50 0.29 ± 0.05 nM). Its epitope was mapped to the BCMA and TACI binding site conferring fully blocking capacity to BION-1301. Blocking potency

(IC50) was 1.61± 0.78 nM (BCMA) and 1.29 ± 0.89 nM (TACI) respectively. The mouse anti-human parental antibody hAPRIL.01A inhibited APRIL-dependent B-cell proliferation and IgA production in vitro and in vivo (Guadagnoli et al. Blood Jun 23;117, 2011). In B-cell cultures, hAPRIL.01A reduced IgM, IgA and IgG-secreting cells after CpG pulse and APRIL stimulation. Following administration of a single-dose of BION-1301 to NHP, PK parameters typical for human IgG4 antibodies were observed, and confirmed a lack of tolerability issues. In a 4-week repeat dose NHP study BION-1301 demonstrated a favorable safety profile (No Observed Adverse Event Level was 100 mg/kg). Chronic exposure to BION-1301 led to a significantly reduced IgA level vs baseline of -50±14, -52±14, -59±7 % at 10, 30 and 100 mg/kg respectively.

Conclusions: Here, we report the in vivo and in vitro mechanism of action of a novel humanized APRIL neutralizing antibody modulating IgA, support the development of BION-1301 for the treatment of IgAN.

FR-PO115

Follistatin as a Novel Therapeutic Agent in CKD

Neel Mehta,[1] Dan Zhang,[2] Richard Van krieken,[1] Juehua He,[1] Bo Gao,[2] Joan C. Krepinsky.[1,2] *[1]McMaster University, Hamilton, ON, Canada; [2]St. Joseph's Hospital, Hamilton, ON, Canada.*

Background: Chronic kidney disease (CKD), characterized by progressively worsening glomerular and interstitial fibrosis accompanied by declining kidney function, is a major cause of morbidity and mortality. Follistatin (FST) is a glycoprotein which neutralizes members of the TGFβ superfamily, most prominently the activins. It does not directly inhibit TGFβ1. Recent studies have shown an increase in activin A in serum of mice with CKD. Here we assess the therapeutic efficacy of FST in a mouse model of CKD with reduced renal mass and proteinuria.

Methods: Male CD1 mice underwent either a 5/6 nephrectomy or sham surgery, after which 5μg human recombinant FST (PB01, Paranta Biosciences Ltd) or vehicle was given intraperitoneally every other day for 9 weeks. At endpoint, blood pressure, renal function, albuminuria and renal pathology were assessed.

Results: Activin A was significantly upregulated in the serum and kidneys of mice with CKD. Activation of Smad3, a downstream mediator of activin A signaling, was increased in CKD kidneys. This was inhibited by FST. Mice with CKD had elevated blood pressure, a significantly diminished glomerular filtration rate (GFR) and severe albuminuria. Pathologically, mice with CKD had prominent glomerulosclerosis and tubulointerstitial fibrosis, assessed using trichrome and picrosirius red staining. Immunoblotting showed increases in the profibrotic cytokine CTGF and the matrix proteins fibronectin, collagen Iα1 and collagen 4α1. Clinically, FST improved blood pressure, GFR and albuminuria, and pathologically both glomerulosclerosis and tubulointerstitial fibrosis were significantly attenuated.

Conclusions: Our data support a prominent pathologic role for the TGFβ family member activin A in CKD. We show that administration of the activin neutralizing protein FST is effective in preserving kidney structure and function and in attenuating the progression of CKD. These data highlight the promising role of FST as a novel renoprotective agent in CKD.

miR299a-5p Is a Pathogenic Driver of Renal Fibrosis in CKD

Neel Mehta,[1] Dan Zhang,[2] Juehua He,[1] Bo Gao,[2] Joan C. Krepinsky.[1,2] *[1]McMaster University, Hamilton, ON, Canada; [2]St. Joseph's Hospital, Hamilton, ON, Canada.*

Background: Chronic kidney disease (CKD) is a major cause of morbidity and mortality. It is characterized by glomerular and interstitial fibrosis. Glomerular mesangial cells (MCs) are a major contributor to glomerular fibrosis. Previously, we identified that caveolin-1 (cav-1) is required for basal and TGFβ1-induced MC synthesis of matrix proteins. The protective phenotype of cav-1 knockout (KO) MCs against fibrosis is associated with increased expression of a TGFβ family member neutralizing protein, follistatin (FST). To better understand the mechanism of FST upregulation and identify novel therapeutic targets, we performed a quantitative screen in cav-1 wild-type (WT) and KO MCs to identify differentially regulated miRNAs that bind to and regulate the 3'UTR of FST.

Methods: *In vitro* studies were carried out in primary MCs isolated from cav-1 WT and KO mice using standard molecular biology techniques. For *in vivo* studies, a 9-week 5/6 nephrectomy (5/6 Nx) mouse model of CKD was used.

Results: Expression and activity of miR299a-5p was significantly decreased in KO MCs which express high levels of FST. We confirmed that miR299a-5p regulates the 3'UTR of FST. In KO cells, FST downregulation increased TGFβ1-induced matrix synthesis. We thus examined whether miR299a-5p regulated this process. In WT MCs, TGFβ1 increased miR299-5p expression and downregulated FST, while exogenous FST reduced TGFβ1-induced matrix synthesis. Importantly, downregulation of miR299a-5p increased FST expression and decreased TGFβ1-induced matrix synthesis. Conversely, in KO cells, overexpression of miR299a-5p decreased FST expression and enhanced TGFβ1-induced matrix synthesis. These data demonstrate that miR299a-5p suppression of FST expression augments ECM production in response to TGFβ1, a key contributor to the pathogenesis of CKD. In the 5/6 Nx mouse model of CKD, we further identified significantly elevated expression of both TGFβ1 and miR299a-5p.

Conclusions: miR299a-5p expression is increased in the kidneys of mice with CKD. miR299a-5p augments TGFβ1-induced ECM production in glomerular MCs through downregulation of the antifibrotic protein FST. These data suggest that miR299a-5p plays a pathogenic role in the development and progression of renal fibrosis. Its inhibition thus represents a potential novel therapeutic target for the treatment of CKD.

FR-PO117

Cyclophilin D Deficiency Is Not Protective in Aristolochic Acid Nephropathy

Khai Gene Leong,[1,2] Elyce Ozols,[1,2] John Kanellis,[1,2] David J. Nikolic-Paterson,[1,2] Frank Y. Ma.[1,2] *[1]Department of Nephrology, Monash Health, Clayton, VIC, Australia; [2]Centre for Inflammatory Diseases, Monash University, Clayton, VIC, Australia.*

Background: Cyclophilins are a family of enzymes which regulate protein folding. Of these enzymes, cyclophilin D (CypD) facilitates mitochondrial-dependant cell death during pathological conditions. CypD-/- mice are protected from acute kidney injury (AKI) following renal ischaemia/reperfusion injury, and exhibit less renal fibrosis in the unilateral ureteric obstruction model. However, the contribution of CypD in the transition of AKI to chronic kidney disease (CKD) is not known. The aim of this study was to determine the role of CypD in promoting the transition of AKI to CKD using the aristolochic acid-induced nephropathy (AAN) model.

Methods: Groups (n=10) of wild type (WT) and CypD-/- mice on the C57BL/6J background were given intraperitoneal injections of 2mg/kg aristolochic acid every 2nd day for 28 days. Mice were killed on day 28. Controls were untreated.

Results: AAN caused >2.5-fold rise in serum creatinine (sCr) in WT mice (34.3±9.9mmol/L vs 13.5±2.3mmol/L in controls; P<0.0001), with evidence of tubular damage (KIM-1 & α-Klotho mRNA levels; P<0.0001), increase in tubular cell death (cleaved caspase-3+ cells; P<0.0001), and significant renal fibrosis (collagen IV immunostaining, and collagen I & α-SMA mRNA levels; all P<0.0001 vs controls). CypD-/- mice were not protected from AA-induced renal dysfunction (sCr 37.0±14.3 mmol/L; P=N.S.), and showed no reduction in tubular damage, cell death or renal fibrosis. Further analysis showed that AAN in WT mice caused loss of peritubular CD31+ capillaries (P<0.0001), and infiltration of macrophages (CD68 & CD206 mRNA levels; P<0.0001) and T-cells (CD3 & IL-2 mRNA levels; P<0.0001). CypD-/- mice were not protected from peritubular capillary loss or macrophage infiltration in AAN. However, CypD-/- mice showed reduced T-cell infiltration and activation (CD3 & IL-2 mRNA levels; P<0.0001), including Th1 cells (T-bet mRNA levels; P<0.05).

Conclusions: CypD does not contribute to the transition of AKI to CKD in experimental AAN.

FR-PO118

Polymyxin and Neomycin (P+N) Attenuates Inflammation and Fibrosis in Unilateral Ureteral Obstructed (UUO) Kidney by Altering Macrophage Phenotype

Siddhartha S. Ghosh,[1] Austin J. Gonzalez,[2] Richard Krieg,[3] Todd W. Gehr,[2] Shobha Ghosh.[3] *[1]VCU Medical Ctr, Richmond, VA; [2]Virginia Commonwealth University, Fredericksburg, VA; [3]VCU, Richmond, VA.*

Background: Gut bacteria have been shown to modulate inflammation in both acute and chronic kidney injury. P+N are non-absorbable antibiotics that are used to sterilize the gut. UUO mice develop acute inflammation in one kidney after surgery which progresses to fibrosis within 7 days. We wanted to investigate if gut sterilization by P+N can affect inflammation and fibrosis in UUO mice.

Methods: UUO surgery was done by the method adapted from Vanderbilt O'Brien Center. One group of mice was treated with P+N 7 days before UUO. One group was untreated (UT). Control mice did not receive surgery or treatment (C). Mice were sacrificed 3 days (n=5/group) and 10 days (n=5/group) after UUO. Macrophage (Mo) and macrophage phenotype M1 and M2 were determined by flow cytometry. Inflammation markers MCP1, IL1β, and fibrosis marker α-smooth muscle actin (SMA) were assessed by immunoblot. Lipopolysaccharide (LPS) was measured by LAL assay.

Results: 3 Days post UUO: P+N treatment did decrease Mo influx in kidney but not Mo phenotype (Table). Only MCP1 increased in UT kidney compared to C, and P+N significantly lowered it (p<0.05). 10 Days post UUO: Although Mo in the kidneys of both groups was significantly higher, UT had more M1 and less M2 compared to P+N (Table). High levels of MCP1, IL-1β and SMA were lowered by P+N. Average plasma LPS in 5 normal mice (C) was 0.8 EU/ml. LPS of UT mice was 3.7±0.32 EU/ml, 3 days after UUO and remained high (3.1±0.3 EU/ml) even after 10 days of UUO. In contrast, LPS levels of P+N group (1.1±.3 EU/ml) after 10 days was not different from group C.

Conclusions: LPS is known to modulate inflammation and Mo phenotype. M1 and M2 phenotypes are known to modulate fibrosis and inflammation respectively. Increased inflammation and fibrosis in UT (10 days) can be attributed to increased M1 and decreased M2. A decrease in inflammatory markers and fibrosis in P+N corresponds to the increased M2 and decreased M1 in this group. P+N can only act at the intestinal level and reduction of systemic LPS by this treatment implies that the gut might be a source of kidney inflammation.

Table

Breast Regression Protein-39 (BRP-39) Promotes Fibrosis Following AKI by Inducing Matrix Expression by PDGFRβ+ Myofibroblasts

Amirtha Chinnadurai,[1] Leyuan Xu,[2] Lloyd G. Cantley.[1] *[1]Yale University School of Medicine, New Haven, CT; [2]Yale University, New Haven, CT.*

Background: Maladaptive repair after unilateral ischemia-reperfusion injury (U-IRI) leads to sustained low-level mRNA expression of chitinase-3-like1(*Chi3l1*, protein name BRP-39). We have recently shown that persistent expression of BRP-39 promotes interstitial fibrosis following maladaptive kidney repair. At the whole kidney level, PDGFRβ+ myofibroblast accumulation was not significantly different in the injured wild-type (WT) and Brp-39 knockout. However, there was a significant decrease in the expression of collagen 1α1(*Col1a1*), collagen 3α1(*Col3a1*) and fibronectin(*Fn1*) by myofibroblasts in the injured kidney of BRP-39 knockout compared to the WT kidney. Here,we investigated the role of BRP-39 in PDGFRβ+ myofibroblast matrix gene expression during the acute kidney injury(AKI) to chronic kidney disease transition.

Methods: Male WT mice (9–11 weeks) subjected to U-IRI for 30 minutes. The injured kidney was removed on day 14 after U-IRI, and primary renal myofibroblasts were isolated via magnetic activated cell sorting using PE-tagged PDGFRβ antibody. Purity of the PDGFRβ+ myofibroblasts assessed by qPCR for PDGFRβ mRNA. Primary myofibroblasts were grown for 4 days in culture (~70% confluence), then stimulated with recombinant BRP-39 (0.5 μg/ml) or vehicle control for 24-hour followed by qPCR for *Col1a1*, *Col3a1* and *Fn1*.

Results: Primary PDGFRβ+ myofibroblasts were enriched 5.7fold compared to the initial population(n=7,p=0.04) and were also enriched for expression of the postulated BRP-39 profibrotic receptor, *Crth2* (n=7, p=0.004). The expression level of *Pdgfrb* and *Crth2* in these cells were 9.1 and 3.7fold higher than in immortalized fibroblast cell lines (NRK49 and NIH3T3). Stimulation of PDGFRβ+ myofibroblasts with BRP39 resulted in 3.4fold in *Fn*1 expression(p=0.038,n=6) with no significant effect on *Col1a1* or *Col3a1*. Preliminary findings (n=2, pooled from 8 kidneys) show with the addition of TGFβ1 (20 ng/ml) and PDGFβ (10 ng/ml) with BRP39 resulted in a further increase in fibronectin expression (dct = 8.489±5.22 vs 3.34±4.62)

Conclusions: We show that freshly isolated myofibroblasts express high levels of the profibrotic receptor,*crth2* and directly respond to BRP39 by increasing fibronectin expression. These *in-vitro* findings suggest that BRP39 and/or the *crth2* receptor may serve as therapeutic targets to limit fibrosis after AKI

AMPK Activation Improves Tissue Oxygenation in CKD

Zhi Zhao Liu,[2] Prabhleen Singh.[1] *[1]UC San Diego & VA San Diego Healthcare System, San Diego, CA; [2]University of California, San Diego, San Diego, CA.*

Background: Progressive intra-renal hypoxia is implicated in the pathogenesis of CKD. However, effective therapies to target intra-renal hypoxia are very limited. We have previously reported early alterations in renal oxygenation and oxygen demand-supply mismatch leading to hypoxia in subtotal nephrectomy (STN), a well-established experimental model of CKD. AMP-activated protein kinase (AMPK) is an important cellular metabolic sensor and regulator, which is dimished in CKD. In this study, we evaluated the quantitative changes in renal tissue oxygenation and the impact of AMPK activation by metformin (MET) on hypoxic and metabolic stress adaptation in STN.

Methods: Male Wistar rats were randomly divided into four groups/two time points: sham, sham+MET (250 mg/kg/day oral gavage), STN, STN+MET, and 1-week or 4-week treatment. Rats were anesthetized and placed on a temperature-controlled table. Left jugular vein, left femoral artery, and urinary bladder were cannulated. Intrarenal oxygen tension (pO2) was measured in the renal cortex and medulla by a Clark-type microelectrode (Unisense) after 60-min equilibration period.

Results: At 1-week post-STN, renal cortical pO2 declined in STN (33±10 vs. 52±7 mmHg in shams, $p<0.0001$). MET treatment improved the STN-induced decreased cortical pO2 (47±6 mmHg) ($p<0.0001$). At 4-week time point, renal cortical pO2 continued to be lower in STN (40±11 vs. 52±6 mmHg in shams, $p=0.0008$). MET prevented the STN-induced decrease in cortical pO2 (49±7 mmHg) ($p=0.0031$). However, in the renal medulla, the STN-induced decreased pO2 was not rescued by MET at both time points.

Conclusions: Our findings demonstrate that tissue oxygen tension is reduced in the STN kidneys in early and late stages. This was prevented by AMPK activation with metformin treatment in the renal cortex. Impact of AMPK activation on tubular transport and metabolism in STN is being investigated.

PGE2 EP1 Receptor Deletion Worsens Hypertensive Kidney Disease in TTRhRen Mice, Promoting Glomerular Podocyte and Endothelial Cell Injury

Rania Nasrallah,[2,1] Susan J. Robertson,[3] Jamie Ghossein,[1] Fengxia Xiao,[4] Dylan Burger,[2] Richard L. Hébert.[2,1] *[1]University of Ottawa, Ottawa, ON, Canada; [2]Kidney Research Centre, Ottawa, ON, Canada; [3]The Ottawa Hospital, Ottawa, ON, Canada; [4]Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

Background: Prostaglandin E2 (PGE2) regulates glomerular hemodynamics, renin secretion, and tubular transport. PGE2 EP1 receptors promote renal injury in diabetes, and EP1 deletion improves hyperfiltration, albuminuria, and fibrosis in several diabetic models. The role of PGE2/EP1 in hypertension remains controversial. The purpose of this study was to examine the contribution of PGE2/EP1 to long-standing hypertensive kidney disease.

Methods: Male FVB EP1-/- mice were bred with hypertensive TTRhRen mice (Htn) to evaluate kidney function and injury at 24 wks of age in 4 groups: wild-type (WT), EP1-/-, Htn, HtnEP1-/-. Blood pressure was measured by tail vein, and glomerular filtration rate (GFR) was estimated by FITC-inulin clearance. Urine was collected over 24 hrs in metabolic cages, and urine albumin was measured by ELISA. Total RNA was isolated from renal cortex for quantitative PCR analysis. Ultrastructural injury was assessed by electron microscopy. Urine microparticles were characterized by flow cytometry.

Results: Systolic blood pressure was elevated in Htn mice (150 mmHg) compared to WT mice (110 mmHg), but unchanged by EP1 deletion. However, EP1 deletion resulted in significantly increased albuminuria (>10-fold WT and >3-fold Htn) and reduced FITC-inulin clearance (50% of WT) in HtnEP1-/- mice, independent of blood pressure changes. Cyclooxygenase (COX)-2 mRNA was increased in all mice lacking EP1. Ultrastructural injury to podocytes and glomerular endothelium was prominent in HtnEP1-/- mice compared to Htn and WT mice: including widened subendothelial space, subendothelial lucent zones and focal lifting of endothelium from the glomerular basement membrane with focal subendothelial cell debris. This injury was associated with increased podoplanin-positive urine microparticles indicative of podocyte damage.

Conclusions: EP1 deletion increases albuminuria and reduces GFR in Htn mice, due to significant injury to podocytes and glomerular endothelium. Taken together, the data suggests that EP1 receptors play a protective role in hypertensive kidney disease. Highlighting the importance of carefully examining disease context (eg. diabetes vs hypertension) when characterizing underlying disease processes.

Superiority of ACF-TEI, a Novel Uremic Toxin Adsorbent, to Classical Oral Adsorbent in In Vitro and In Vivo Adsorption Profiles

Takashi Shirakura, Hiroshi Shimoyama, Yasumi Nishiwaki, Kumiko Hase, Yoshimasa Takahashi, Johji Nomura, Tsunefumi Kobayashi. *Pharmacology Research Department, TEIJIN Pharma Limited, Hino, Japan.*

Background: Uremic toxins (UTs) such as indoxyl sulfate (IS) accumulate in the blood of patients with impaired renal function. Since several observation studies have demonstrated a link between serum UT levels and clinical outcomes, UTs have much attention as key factors in the progression of chronic kidney diseases (CKDs) and cardiovascular diseases. Spherical activated carbon (AST-120) adsorbs UTs and those precursors such as indole in the intestinal tract and excretes them out of the body with feces, leading to reduce serum UT levels. Therefore AST-120 is effective in improving symptoms of uremia and delaying the introduction to dialysis in CKD patients. However, the oral adsorbents comprising AST-

120 have insufficient adsorption performance and need to be taken at high daily doses. To improve their compliance and efficacy, we focused on activated carbon fiber (ACF) and have identified a novel and potent oral UT adsorbent, ACF-TEI. In this study, we analyzed *in vitro* adsorption profiles of ACF-TEI and compared *in vivo* efficacy of ACF-TEI and AST-120 on serum IS levels. We also evaluated the effects of ACF-TEI on renal fibrosis in rat model of kidney injury.

Methods: As for the *in vitro* adsorption profiles, we examined the adsorption of precursors including indole and p-cresol, and digestive enzymes. In *in vivo* studies, we compared the effects of ACF-TEI and AST-120 on serum IS concentrations in rat model of CKD and dog model treated with tryptophan, a precursor of indole. To evaluate the effects on renal fibrosis, cisplatin-induced nephrotoxicity (CDDP) model were used.

Results: Compared with AST-120, ACF-TEI showed more potent capacity and speed in adsorbing the UT precursors. ACF-TEI had a low capacity to adsorb digestive enzymes and the capacity was comparable to that of AST-120. In rats and dogs, ACF-TEI reduced serum IS levels more potent than AST-120. ACF-TEI decreased serum and renal IS levels, urinary excretion of KIM-1, and a-SMA expression in CDDP model.

Conclusions: The adsorption capacity and efficiency of ACF-TEI were superior to AST-120. In addition, ACF-TEI reduced the serum IS levels more potent than AST-120 in *in vivo* models. Thus, ACF-TEI is expected to show more beneficial effects than AST-120 in clinical.

FR-PO123

Megalin Deletion Prevents Long-Term Loss of Glomerular Filtration Rate After Rhabdomyolysis

Katsuyuki Matsushita,[2] James A. McCormick,[2] Kiyoshi Mori,[4] Motoko Yanagita,[3] Michael Hutchens.[2,1] *[1]Portland VA Medical Center, Portland, OR; [2]Oregon Health & Science University, Portland, OR; [3]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [4]School of Pharmaceut Sci, University of Shizuoka, Shizuoka, Japan.*

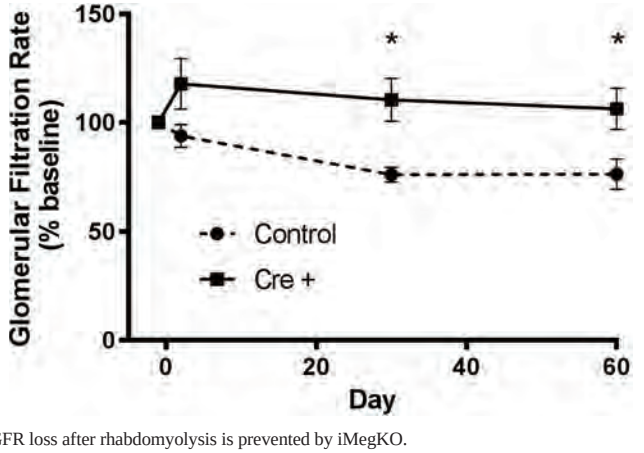
Background: Rhabdomyolysis, caused by injury, physical training, or medication, causes acute kidney injury and can lead to chronic kidney disease. Treatment is limited to supportive care and urinary alkalization, which is controversial. No specific therapy exists, but myoglobin-induced tubular epithelial apoptosis is a mechanism. Myoglobin undergoes tubular endocytosis via megalin, therefore we hypothesized that proximal tubule-specific megalin deletion would ameliorate chronic loss of glomerular filtration rate (GFR) caused by rhabdomyolysis.

Methods: Proximal tubule-specific inducible megalin deletion mice (iMegKO, LRP2 fl/fl NDRG1-CreERT2) were generated by breeding megalin floxed mice (a gift of Professor T. Willnow, Max Delbruck Institut) with NDRG1-CreERT2 (a gift of M. Yanagita, Kyoto University). Tamoxifen (150 mg/kg body weight) was injected intraperitoneally to 7 iMegKO and 7 cre- littermate control mice (all 8-12 week-old males) for 5 days, 2 weeks before rhabdomyolysis was induced by 50% glycerol injection (6.5 ml/kg). Before glycerol and 2, 30, and 60 days after injection, glomerular filtration rate (GFR) was measured by FITC-sinistrin transcutaneous clearance. After injection, all GFR measurements were expressed as %baseline. Statistical analysis was by repeated measures 2-way ANOVA.

Results: Tamoxifen only induced deletion of megalin in cre+ mice. Megalin deletion reduced GFR (745±42mL/min/100g body weight in iMegKO vs 872±35 μL/min/100g body weight in control, P<0.05). iMegKO mice did not demonstrate reduced GFR on day 2, maintaining baseline GFR to 60 days (102% baseline, ns), whereas in controls, glycerol injection induced significant, sustained decline in GFR at 30 and 60 days (76±7% baseline, p=0.005 compared with baseline, p=0.02 compared with KO).

Conclusions: Proximal tubule-specific deletion of megalin ameliorates chronic renal functional loss caused by experimental rhabdomyolysis.

Funding: Veterans Affairs Support



GFR loss after rhabdomyolysis is prevented by iMegKO.

Estimating the Health Economic Outcomes of Serum 25-Hydroxyvitamin D and Intact Parathyroid Hormone Levels in Stage 3-4 CKD: The Impact of Treatment Timing

Matthew Gitlin,[1] Kamyar Kalantar-Zadeh,[2] Christopher S. Hollenbeak,[3] Sophie Snyder,[1] Akhtar Ashfaq.[4] *[1]BluePath Solutions, Los Angeles, CA; [2]University of California Irvine, School of Medicine, Orange, CA; [3]Penn State College of Medicine, Hershey, PA; [4]OPKO Health, Inc., Miami, FL.*

Background: Serum 25-hydroxyvitamin D (25D) and intact parathyroid hormone (iPTH) levels in patients with Chronic Kidney Disease (CKD)are associated with meaningful clinical outcomes, including cardiovascular (CV) events, fractures, CKD progression, and death. This study estimated differences in outcomes (CV events, fractures, and CKD progression) and costs due to changes in 25D and iPTH levels associated with vitamin D (vit D) therapy among patients with CKD not on dialysis.

Methods: A cost-consequence model taking a Medicare payer perspective was developed to estimate the economic and clinical consequences of increasing 25D and lowering iPTH in stage 3-4 CKD patients. The base case Markov model assumed a 1000-patient cohort with 1-year cycles and a 5-year time horizon. Correction of 25D and iPTH level and associated clinical events were based on published meta-analyses. Costs of clinical events were based on data from national public databases.

Results: Across a 1,000-person cohort, increasing 25D and lowering iPTH may avert about 202 CV events, 6 fractures and 230 patient-years in the CKD stage 5/dialysis state. The estimated offsets total about $25 million (Figure 1). The analysis is sensitive to the cost inputs and the effectiveness of correcting 25D and iPTH. Under scenario analysis, when excluding the stage 5/dialysis, the total savings over a 1,000-person cohort is about $4.7 million, mainly attributable to averted CV events.

Conclusions: Vit D therapy in stage 3-4 CKD appears to be cost-saving by offsetting CV events, fractures, and CKD progression, although it may also be associated with such adverse events (AE) as hypercalcemia, hyperphosphatemia, and increased FGF23; further research is warranted to assess whether vit D treatment with extended-release calcifediol results in improved outcomes without these AEs.

Multiple, Systemic Effects of PHD Inhibitors Signify an Anti-Fibrotic and Anti-Inflammatory Impact on Cardiovascular Complications in the Remnant Kidney

Lisa Uchida,[1] Tetsuhiro Tanaka,[1] Hisako Saito,[1] Mai Sugahara,[1] Kenji Fukui,[1,2] Takeshi Wakashima,[1,2] Masaomi Nangaku.[1] *[1]Division of Nephrology and Endocrinology, The University of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]JT CPRI, Osaka, Japan.*

Background: Hypoxia plays a crucial role in the progression of chronic kidney disease(CKD) which is associated with fibrosis, inflammation and oxidative injury. Previous studies suggest that prolyl hydroxylase inhibitors(PHD inhibitors), stabilizers of hypoxia-inducible factors (HIFs), could be applied in acute organ injuries like renal ischemia-reperfusion and myocardial infarction. However, the effect of PHD inhibitor on CKD and its cardiovascular consequences remains unknown.

Methods: Male Sprague-Dawley rats underwent 5/6 nephrectomy (remnant kidney: RK). Rats were divided into three groups: (1)sham operation rats (2)RK rats with normal diet (3) RK rats with 0.005% enarodustat(PHD inhibitor) diet since 1 week before 5/6 nephrectomy. L-NNA(20 mg/L), NO synthase inhibitor, was supplemented in drinking water to accelerate the CKD model. At 6 weeks after 5/6 nephrectomy, kidney and heart were harvested after the echocardiography.

Results: Systolic blood pressure was lower in RK-Enarodustat group than in the RK group, but the difference did not reach statistical significance. Blood urea nitrogen and serum creatine levels at 2, 4, 6 weeks were reduced in the RK-Enarodustat group, whereas there was no difference in urinary protein excretion between the two groups. The number of ED-1-positive cells was significantly less in the RK-Enarodustat group (43.7±7.7 per ×200 field) than in the RK group (100.8±14.2, P<0.01). And, the number of infiltrated CD206 macrophages, the M2 macrophages, was also less in the RK-Enarodustat group. Immunohistochemical analysis revealed a significant decrease in nitrotyrosine accumulation in tubules in the RK-Enarodustat group(7.6±1.3 vs 11.5±0.9, p=0.036). In heart, the number of ED-1, CD206-positive infiltrating macrophages and picrosirius red staining showed significant reductions in the RK-Enarodustat group. Anterior and posterior wall thicknesses, markers for cardiac hypertrophy, were markedly less in the RK-Enarodustat group than in the RK group, whereas there was no difference in fractional shortening, ejection fraction and E/A.

Conclusions: These data show that PHD inhibitors significantly improve inflammation, oxidative stress and fibrosis in remnant kidney and may also mediate beneficial effects in cardiovascular complications.

FR-PO126

Targeted Ablation of Distal Cerebrospinal Fluid-Contacting Nucleus Alleviated Renal Fibrosis in CKD

Minzi Qiu, Jiawen Li, Lishan Tan, Aiqing Li. *Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: The distal cerebrospinal fluid-contacting nucleus (dCSF-CNs) is thought to be a linkage between the cerebrospinal fluid and brain. The potential function of dCSF-CNs in development of CKD is poorly understood. We hypothesized that dCSF-CNs might exert a signaling transmission effect on the cascade reaction of renin-angiotensin system (RAS) in the progression of kidney injury, and that ablation of the dCSF-CNs might alleviate the local RAS and renal fibrosis in five-sixths nephrectomied (5/6Nx) rat model.

Methods: Rats were subjected to intracerebroventricular (icv) administration of artificial cerebrospinal fluid (aCSF) followed by five-sixths nephrectomied or sham operation, or icv administration of Cholera toxin subunit B conjugated with saporin (CB-SAP) for dCSF-CNs lesion before five-sixths nephrectomied. The effect of CB-SAP treatment on ablation of dCSF-CNs was confirmed via double immunofluorescence staining. The expression levels of RAS components, NOX_2 and c-fos in SFO, PVN and hippocampus, as well as the numbers of Tyrosine Hydroxilase and c-fos positive cells in RVLM were detected. The expression levels of RAS components (AGT, ACE, AT1R, ACE2, Mas receptor), NADPH oxidase (NOX_2, catalase), inflammatory cytokines (MCP-1, IL-6), fibrotic readouts (fibronectin, collagen I) in kidney were compared.

Results: Compared with 5/6Nx rats, the number of CB-labelled neurons in dCSF-CNs decreased in CB-SAP treated rats. Treatment with CB-SAP down-regulated the expression levels of RAS components (AGT, Ang II, AT1R), NADPH oxidase (NOX_2, catalase), inflammatory cytokines (MCP-1, IL-6), fibrotic readouts (fibronectin, collagen I) in rats, and up-regulated the protein levels of ACE2 and Mas receptor, compared with CKD rats. Increased numbers of Tyrosine Hydroxilase and c-fos positive cells were observed in the RVLM of 5/6Nx rats, but that were decrease under the influence of ablation of dCSF-CNs.

Conclusions: Targeted ablation of the dCSF-CNs might alleviate renal inflammation and fibrosis in the development of chronic kidney injury through inhibiting activation of inhibit the cerebral and renal RAS/ NADPH oxidase.

A Novel, Selective TRPC6 Antagonist Reduces Renal Interstitial Fibrosis in the Mouse Unilateral Ureteral Obstruction Model

Steven S. Pullen,[1] Damian C. Matera,[1] Donato Del camino,[2] Nan Zheng,[3] Julia Doerner,[3] Hong Bian,[4] Hongxing Chen,[4] Nathaniel T. Blair,[3] Jayhong A. Chong,[3] David P. Hessler,[3] Matthew R. Netherton,[5] Diane Wong,[1] Steven M. Weldon,[1] Jay J. Kuo,[1] Achim Sauer,[6] Christopher R. Sarko,[7] Magdalene M. Moran.[3] *[1]Boehringer Ingelheim Pharmaceuticals, Ridgefield, CT; [2]Rheostat Therapeutics Inc., Brookline, MA; [3]Hydra Biosciences, Belmont, MA; [4]Boehringer Ingelheim, Ridgefield, CT; [5]Foghorn Therapeutics, Cambridge, MA; [6]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany; [7]Novartis Institutes for Biomedical Research, San Ramon, CA.*

Background: A role for dysregulation of the non-selective cation channel TRPC6 in the development of FSGS is well-established based on the identification of multiple gain-of-function mutations in humans which cause disease by cytoskeletal alterations in podocytes, leading to impairment of the glomerular filtration barrier. Despite the strong evidence linking elevated TRPC6 activity to CKD, no inhibitors have advanced to clinical testing due to challenges associated with achieving selectivity against related ion channels and identifying compounds with a suitable pharmacokinetic profile for oral dosing.

Methods: A novel TRPC6 antagonist, BI 749327, was characterized with in vitro electrophysiology measurements using HEK293 cell transfectants and in vivo in the mouse unilateral ureteral obstruction (UUO) model of renal fibrosis.

Results: BI 749327 has a manual patch-clamp IC_{50} value of 13 nM against TRPC6 and 85- and 42-fold selectivity against TRPC3 and TRPC7, respectively. Oral gavage dosing with BI 749327 produced plasma exposures predicted to provide potent 24 hour inhibition. Treatment of mice undergoing UUO surgery with BI 749327 inhibited the development of fibrosis as measured by hydroxyproline incorporation. TRPC6 dependent inhibition was confirmed as mice lacking TRPC6 had a similar reduction in fibrosis in the UUO model when compared with BI 749327 treated wild-type mice and by the demonstration that the compound had no further effect on fibrosis development in this model when administered to TRPC6 deficient mice.

Conclusions: The opportunity for treatment with a TRPC6 antagonist to inhibit renal fibrosis in addition to restoring podocyte calcium homeostasis further highlights the therapeutic potential of this mechanism for the treatment of CKD. These results are the first demonstration of in vivo benefit in a disease model with TRPC6 pharmacological inhibition, and BI 749327 provides a tool for further evaluating TRPC6 inhibition for the treatment of CKD.

Cerebral Microvasculature Impairments Induced Dementia in CKD

Jen Xu,[1] Hugo Y. Lin,[2] Li-lun Ho,[5] Kenneth Lim,[4] Thomas F. Hiemstra,[6] Joseph V. Bonventre,[3] Tzongshi Lu.[3] *[1]Harvard College, Cambridge, MA; [2]University of California, Irvine, Irvine, CA; [3]Brigham and Women's Hospital, Boston, MA; [4]Massachusetts General Hospital, Boston, MA; [5]Massachusetts Institute of Technology, Cambridge, MA; [6]University of Cambridge, Cambridge, United Kingdom.*

Background: Structural and functional impairments of brain microvasculature result in white matter hypo-perfusion and ischemia are major causes of Cerebral small vessel disease (CSVD). Recently, chronic kidney disease (CKD) has been identified as a significant risk factor for stroke and dementia as well as CSVD. Interestingly, both kidney and cerebral microvasculature share similar anatomical and physiologic characteristics particular in their endothelium. The goal of this study was to elucidate the molecular mechanisms of CKD induced cerebral microvasculature dysfunction and consequences neurological diseases.

Methods: CKD mice model was generated by 5/6 nephrectomy on C57BL/6 mice. Transcriptomic profiling of calcification medium (CM) and hyperglycemia medium (GM) treated primary human brain microvascular endothelial cells (HBMECs), *in vitro*, and human arteries collected from CKD (n=20), CAD (n=15) and healthy donors (n=20) were subjected to RNA sequencing, *ex vivo*. In addition, incidence and risk of dementia in CKD from a population-based study using the Taiwan National Health Insurance database with 1,000,000 subjects from 2000 to 2009.

Results: Our results showed that CKD mice had decreased myelinated nerve fibers in the corpus callosum and cerebral cortex and loosening myelinated fibers in the corpus callosum. Collagen IV accumulation in brain microvasculature and serum phosphate levels were significant increased in CKD mice compared to control mice. Tight junction (TJ) proteins occludin, claudin-5, and ZO-1 were down-regulated in both CM/GM-treated primary HBMECs. In human arteries, both claudin-5 and ZO-1 genes were down-regulated in CKD group together with anti-apoptotic gene Bcl2. Furthermore, cell viability decreased and caspase-3 mediated apoptosis increased as well as Collagen IV expression in CM treated HBMECs. The subsequent risks of dementia were 2.208-fold (Diabetes + CKD); 1.638-fold (CKD); 1.527 fold (Diabetes) higher in comparison with healthy cohort.

Conclusions: Our data show for the first time that TJ dysfunction in cerebral microvascular dysfunction occurs in CKD may play a role in dementia. It provides a potential mechanism for the development of CSVD in CKD patients. Our results may benefit CKD patients to reduce the following CSVD and dementia through controlling blood phosphate levels and maintain TJ's function.

Evaluation of Allostatic Load as a Mediator of Sleep and Kidney Outcomes in Blacks

Joseph Lunyera,[1] Clementina A. Davenport,[2] Chandra L. Jackson,[3] Dayna A. Johnson,[4] Nrupen A. Bhavsar,[1] Mario Sims,[5] Julia J. Scialla,[6] John W. Stanifer,[6] Jane F. Pendergast,[6] Ciaran J. McMullan,[8] Ana C. Ricardo,[7] L. Ebony Boulware,[1] Clarissa J. Diamantidis.[1] *[1]Duke University School of Medicine, Durham, NC; [2]Duke University Medical Center, Durham, NC; [3]National Institute of Environmental Health Sciences, Research Triangle Park, NC; [4]Harvard Medical School, Boston, MA; [5]University of Mississippi Medical Center, Jackson, MS; [6]Duke University, Durham, NC; [7]University of Illinois at Chicago, Chicago, IL; [8]Merck, Rahway, NJ.*

Background: Poor sleep associates with adverse chronic kidney disease (CKD) outcomes yet the biological mechanisms underlying this relation remain unclear. One proposed mechanism is *via* allostatic load (AL) – a cumulative biologic measure of stress. Using data from the Jackson Heart Study (JHS), we examined the potential mediating effect of AL on the relation between sleep patterns and kidney outcomes

Methods: We examined the association of self-reported sleep duration: very short, short, recommended, and long (≤5, 6, 7-8, or ≥9 hours per 24 hours, respectively) and self-reported sleep quality: high (excellent/very good) vs. good vs. low (poor/fair) with prevalent baseline CKD (Exam 1), estimated glomerular filtration rate (eGFR) decline, and incident CKD at follow-up (Exam 3). CKD was defined as eGFR <60ml/min/1.73m^2 or urine albumin-to-creatinine ratio ≥30mg/g. Models were adjusted for demographics, comorbidities and kidney function. We further evaluated AL (quantified at baseline using 11 biomarkers from neuroendocrine, metabolic, autonomic, and immune domains) as a mediator of these relations.

Results: Among 5177 JHS participants, 40% slept the recommended 7-8 hours; 25%, 29% and 6% reported very short, short and long sleep duration, respectively. Participants with very short sleep duration (vs. 7-8 hours) had greater odds of prevalent CKD (odds ratio [OR] 1.31, 95% confidence interval [CI] 1.03-1.66) after adjustment. Very short, short or long sleep duration (vs. 7-8 hours) were not associated with any other kidney outcomes over a median follow-up of 8 years. Low sleep quality (vs. high) associated with greater odds of prevalent CKD (OR 1.26, 95% CI 1.00-1.60) and 0.18 mL/min/1.73m^2 (95% CI 0.00 to 0.36) faster eGFR decline per year over follow-up. AL did not mediate the associations of sleep duration or sleep quality with kidney outcomes.

Conclusions: Very short sleep duration and low sleep quality were associated with adverse kidney outcomes in this all black cohort, but AL did not appear to mediate these associations. Future work should investigate the role of other biologic mediators in the relation between sleep and CKD outcomes in blacks.

Chemokine Ligand 14 Could Be a Possible Biomarker of CKD Progression

Sunhwa Lee,[1] Yong Chul Kim,[1] Mi-yeon Yu,[1] Hajeong Lee,[2] Seung Seok Han,[2] Jung Pyo Lee,[3] Ran-hui Cha,[8] Dong Ki Kim,[1] Un Sil Jeon,[4] Kyu hong Kim,[7] Jae Wook Lee,[5] Yon Su Kim,[2] Seung Hee Yang.[6] *[1]Seoul National University Hospital, Jongno-gu, SEOUL, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [4]Sheikh Khalifa Specialty Hospital, Ras Al Khaimah, United Arab Emirates; [5]National Cancer Center, Seoul, Republic of Korea; [6]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [7]Seoul National University Hosptial, Gyeonggi, Republic of Korea; [8]National Medical Center, Seoul, Republic of Korea.*

Background: Chemokine ligand 14 (CCL14), a ligand for CCR1, has been known as a M2 polarizing marker and chemotactic cytokine, which is expressed by fibroblast, monocyte, etc. Although it was first isolated from the hemofiltrate of chronic renal failure patients, its expression pattern in chronic kidney disease have never been investigated.

Methods: To elucidate concentration change of CCL14 in chronic kidney disease, we performed urine proteomic analysis using three patients' random urine per each CKD1 and 5. For validating tissue expression of CCL14, kidney biopsy tissues of three normal, nine CKD 3, and eight CKD 5 patients were evaluated by immunohistochemistry. Among CKD 3 group, patients with GFR decrease more than 5 ml/min/1.73 m^2 within a year were considered to have rapid progression. We also evaluated kidney tissue expression of CCL14 in acute tubular necrosis that is a well-known etiology of chronic kidney disease if it recurs frequently. For in vitro study, primary cultured human tubular epithelial cells (hTECs) and glomerular endothelial cells (GECs) were treated with rTGFβ for inducing fibrosis, and CCL14 expression level was measured using western blotting.

Results: In urine proteomics analysis, we discovered CCL14 showed a 122-fold increase in CKD 5 patients' urine comparing to CKD 1 ($p<0.001$). In other hands, in human kidney biopsy tissue, CKD 3 patients with rapid progression showed higher expression level of CCL14 (17.33±4.13) compared to non-progressive CKD 3 (10.12±3.60) ($p=0.032$), control (12.48±2.49) ($p=0.019$), and CKD 5 (9.63±5.52) ($p=0.049$). CRP was adversely lower in progressive CKD 3 patients compared to others ($p=0.017$), and interstitial inflammation or fibrosis pattern was not different ($p=0.861$). In kidney tissue of patients with acute tubular necrosis, CCL14 expression level was 1.6-fold higher than those of normal cases ($p=0.015$). In in vitro assay, CCL14 expression was increased 2 folded by treating rTGFβ in GEC cells.

Conclusions: CCL14 expression tends to increase in patients with progressive CKD or acute tubular necrosis. Moreover, its expression is increased by a rTGFβ-enriched fibrotic environment. Our results suggest CCL14 could be a possible biomarker of CKD progression that pre-existing inflammatory marker or pathologic variables could not predict.

FR-PO131

Pathogenesis of Chronic Renal Injury Following Acute Nephrotoxicity by Gentamicin

Amanda H. Albino, Fernanda F. Zambom, Karin C. Oliveira, Orestes Foresto-Neto, Simone C. Arias, Antonio C. Seguro, Denise M. Malheiros, Niels O. Camara, Clarice K. Fujihara, Roberto Zatz. *University of Sao Paulo, Sao Paulo, Brazil.*

Background: Subjects recovering from acute kidney injury (AKI) may develop renal fibrosis and chronic kidney disease (CKD) by unclear mechanisms that may involve innate immunity (InIm). In rats exposed to nephrotoxic agents, AKI is followed by mild fibrosis. Whether this process proceeds to CKD later on has not been examined. Here we investigated 1) whether renal injury resulting from treatment with Gentamicin (G) progresses to CKD in the long run by; 2) the role of InIm in this process.

Methods: Male Munich-Wistar rats received daily sc injections of G, 80 mg/kg, during 9 days. Control rats (C) received vehicle only. Rats were studied at 1, 30 and 180 days after G, to assess:Creatinine Clearance (Cl_{Cr}, mL/min), Albuminuria (ALB, mg/24h), Glomerular ischemia (%GI), Cortical Collagen 1 (%Coll) and Fibronectin (%FN), Macrophages (Mø) and AngII+ cells (/mm^2), as well as renal KIM1 and IL1β (pg/mg), αSMA, TLR4, NFkB (nuclear p65) and IL6 (xC)

Results: At Day 10, GI, tubular injury, ALB and low Cl_{Cr} were associated with marked inflammation and InIm activation. Partial reversal of these changes was seen at Day 30, along with incipient fibrosis. At Day180, worsened ALB was seen along with prominent GI and renal fibrosis, although inflammation was attenuated.

Conclusions: G leads to AKI, strong inflammation and InIm activation. In the long run, glomerular injury develops along with renal fibrosis. Since InIm activation and inflammation abate with time, the mechanisms of these late effects might involve other mechanisms, such as direct participation of tubular cells. FAPESP/CNPq

Apabetalone Downregulates Factors and Pathways Associated with Vascular Calcification

Dean Gilham,[1] Sylwia Wasiak,[1] Laura Tsujikawa,[1] Christopher D. Sarsons,[1] Christopher Halliday,[1] Stephanie Stotz,[1] Kenneth E. Lebioda,[1] Ravi Jahagirdar,[1] Michael Sweeney,[2] Jan O. Johansson,[2] Norman C. Wong,[1] Richard A. Robson,[3] Kamyar Kalantar-Zadeh,[4] Ewelina Kulikowski.[1] *[1]Resverlogix Corp., Calgary, AB, Canada; [2]Resverlogix Inc., San Francisco, CA; [3]CHristchurch Clinical Studies Trust, Christchurch, New Zealand; [4]University of California Irvine, School of Medicine, Orange, CA.*

Background: Apabetalone, an oral small molecule BET inhibitor, reduced the incidence of major adverse cardiac events (MACE) in patients with CVD and improved eGFR in a subgroup with CKD in phase 2 trials. Because vascular calcification (VC) is associated with MACE, effects of apabetalone on processes associated with VC were examined.

Methods: Plasma proteomics was conducted in CVD patients receiving apabetalone in the 3 month (ASSERT) and 6 month (SUSTAIN & ASSURE) phase 2 trials, as well as patients with stage 4/5 CKD that received a single 100mg dose. Coronary artery VSMCs were used to examine effects of apabetalone on transdifferentiation & calcium deposition.

Results: Apabetalone significantly reduced circulating levels of VC markers in CVD patients in phase 2 trials, including alkaline phosphatase, osteopontin and osteoprotegerin. Plasma proteomics of CKD patients (n=8) indicated activation of molecular pathways driving VC including IL-6 signaling, BMP-2 signaling & RANK signaling in osteoclasts. Downregulation of these pathways by apabetalone was predicted in the CKD cohort 12hrs post-dose. In VSMCs cultured in osteogenic conditions, apabetalone opposed induction of transdifferentiation markers & inhibited calcium deposition. BRD4 is a transcriptional regulator & target of apabetalone. ChIP-seq showed transdifferentiation of VSMCs to a calcifying phenotype promoted re-distribution of BRD4 on chromatin, resulting in fewer BRD4-rich enhancers (118 in osteogenic, 288 in basal). 38 genes were uniquely associated with BRD4-rich enhancers in osteogenic vs basal conditions; several of the genes have been linked to calcification. Apabetalone reduced BRD4 on many of these enhancers, which correlated with decreased gene expression. Bioinformatics indicated BRD4 may cooperate with specific transcription factors to promote calcification.

Conclusions: Involvement of BRD4 in VSMC transdifferentiation & calcification is a novel discovery. Further assessment of apabetalone as a therapeutic for VC is warranted. The impact of apabetalone on biomarkers, renal function & CVD outcomes in patients with impaired kidney function is being evaluated in a subgroup of the phase 3 BETonMACE trial.

The Role of Periostin in Aging Process

Young Wook Choi,[1] Jung Nam An,[1] Eun Nim Kim,[3] Jinhyuk Kim,[8] Seung Hee Yang,[4] Yun Kyu Oh,[5] Chun Soo Lim,[2] Yon Su Kim,[6] Bumsoon Choi,[7] Jung Pyo Lee.[2] *[1]Seoul National University, Boramae Medical Center, Seoul, Republic of Korea; [2]Seoul National University Boramae Medical Center, Seoul, SEOUL, Republic of Korea; [3]The Catholic University of Korea, Seocho-gu, Seoul, Republic of Korea; [4]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [5]Department of Internal Medicine, Boramae Medical Center, Seoul, Republic of Korea; [6]Seoul National University College of Medicine, Seoul, Republic of Korea; [7]Division of Nephrology, Department of Internal Medicine, Seoul, Republic of Korea; [8]SMG-SNU Boramae Medical Center, Seoul, Republic of Korea.*

Background: Periostin, a matricellular protein, has been reported in diverse processes and pathologies in tissue remodeling through the promotion of adhesion, cell survival, cellular dedifferentiation, and fibrogenesis. However, its role in aging process is unknown.

Methods: We analyzed tissues from 2-months and 24-months old wild-type and Postn null (Postn-/-) mice and performed high throughput RNA-Sequencing of kidney tissue in aged mice. The genes showing altered expression were confirmed by qRT-PCR analysis.

Results: At 24-months old Postn null mice had preserved kidney tissue and less markers of senescence than wild-type mice. The gross appearance and the kidneys of aged WT mice were bigger and heavier than young WT mice. Serum creatinine levels were also higher in the aged WT mice compared to those in the young WT mice. However,

all these changes were diminished in the aged Postn null mice; serum creatinine levels were considerably lower in aged Postn null mice than in aged WT mice. Apparent tubular atrophic changes, interstitial fibrosis, and collagen fiber deposition which were prominent in the aged WT mice than in the young WT mice, were remarkably alleviated in aged Postn null mice. Furthermore, the expressions of periostin were also attenuated in aged Postn null mice compared to in aged WT mice. Also, we found that many of the changes in gene expression that occur during the aging process by periostin.

Conclusions: The data obtained in this study should expand our knowledge on the periostin mediated aging and provide molecular mechanism. Periostin inhibition could have protective effects in aging process.

FR-PO134

Diverse Associations Between Oxidative Stress and Thromboxane A2 in Hypertensive Glomerular Injury

Yukihito Nakano, Yoshihisa Nakatani, Masahiro Takami, Shuji Arima. *Kindai University Faculty of Medicine, Osaka-Sayama, Japan.*

Background: In addition to lowering blood pressure, therapeutic strategies to ameliorate hypertensive renal injury need to be established. In this study, we studied the possible contribution of thromboxane A_2 (TXA_2) which contributes to impaired renal hemodynamics under pathological conditions and potently stimulates reactive oxygen species generation, to the development of regional heterogeneity in hypertensive glomerular injury. We examined the impact of the inhibition of TXA_2 synthesis in relation to its antioxidant effects on regional glomerular injury.

Methods: Experiments were performed using male stroke-prone spontaneously hypertensive rats (SHRSP) and Wistar–Kyoto rats (WKY) at 5, 10 and 15-week age, respectively. We investigated systolic blood pressure (SBP), the degree of glomerular injury (glomerular sclerosis index: GSI), urinary albumin excretion (UAE), serum creatinine concentration (Cr), urinary 8-OHdG excretion, thromboxane synthase (TXAS) and heme oxygenase-1 (HO-1) gene expression. We also evaluated difference in GSI and each gene expression between superficial and juxtamedullary glomeruli. Then we investigated the effect of tempol (an intracellular antioxidant) and ozagrel (TXAS inhibitor).

Results: Juxtamedullary glomeruli showed higher GSI after 10 weeks of age in both rats. TXAS and HO-1 mRNA expression was enhanced in both superficial and juxtamedullary glomeruli in SHRSP compared with that in age-matched WKY. Notably in juxtamedullary glomeruli, TXAS expression was progressively enhanced as rats grow. Neither tempol nor ozagrel had any effect on SBP or Cr in SHRSP. Ozagrel but not tempol improved GSI in both superficial and juxtamedullary glomeruli. Tempol significantly increased TXAS expression in superficial but not juxtamedullary glomeruli, whereas ozagrel suppressed it.

Conclusions: Under the established severe hypertension, the glomerular injury as well as TXAS expression was augmented. Since these changes were attenuated by ozagrel but not tempol, the TXA_2–TPR pathway and oxidative stress participate and interact together to promote hypertensive glomerular injury. Moreover, our results indicated that TXA_2 inhibition may be a better therapeutic target than ROS inhibition to inhibit the aggravation of hypertensive glomerular injury at an advanced stage.

FR-PO135

Upregulation of a Urea Transporter in Uremic Heart Promotes Cardiac Fibrosis and Increases Vimentin

Akihiro Kuma,[2] Janet D. Klein,[1] Jeff M. Sands,[3] Xiaonan H. Wang.[1] *[1]Emory University, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA; [3]Emory University Renal Division, Atlanta, GA.*

Background: Cardiac abnormalities are linked to increased morbidity and mortality in chronic kidney disease (CKD) patients. CKD induces hypertension and retention of water, urea, and salt within the body. These are strongly related with the cardiovascular disease known as uremic cardiomyopathy. Uremic cardiomyopathy consists of left ventricular hypertrophy and interstitial fibrosis. Urea transporters (UT) are mainly involved with the urine concentrating mechanism in the kidney medulla. There is an isoform of UT-A in heart, but its role is not well known. We investigated the role of UT in mouse heart with a focus on the uremic heart.

Methods: To create a CKD model, C57BL6 mice underwent a 5/6 nephrectomy (5/6Nx), and were given 0.45-1% NaCl water to drink. Mice were sacrificed at 8 weeks after surgery. Heart tissue and blood were harvested. Mouse blood pressure measurements were determined by the tail cuff method. Cell culture studies were performed using mIMCD3 cells that were stably transfected with UT-A1. Immunohistochemistry was performed on paraffin sections. Protein expression levels were detected by western blot.

Results: BUN was 28.9 mg/dL (sham) and 56.6 mg/dL (5/6Nx) ($P < 0.05$) proving success of the CKD model. In mouse heart, cardiac fibrosis of CKD mice was confirmed by Masson's Trichrome staining of paraffin-sections. The protein abundance of UT-A was increased 1.4-fold and the pro-fibrosis marker vimentin was increased 1.7-fold in CKD mice vs. sham mice. Using immunohistology, we found that vimentin was also increased in CKD heart. In vitro, the amount of vimentin protein was increased 3.7-fold in UT-A1 overexpressing cells compared with empty vector control mIMCD3 cells. Both systolic blood pressure (129 mmHg (5/6Nx) vs 116 mmHg (sham)) and heart to body weight ratio; (7.18 mg/g (5/6Nx) vs 4.73 mg/g (sham)) were increased ($P < 0.05$) in CKD mice 8 weeks after surgery.

Conclusions: The upregulation of UT-A in uremic heart was associated with an increased vimentin protein level, which could be related with increased cardiac fibrosis in chronic kidney disease.

FR-PO136

CKD Mediates Cardiac Dysfunction by Recruiting Monocyte Derived Inflammatory Macrophages

Kevin Woollard, Ana Isabel Garcia Diaz, James A. Tomlinson, Charles D. Pusey. *Imperial College London, London, United Kingdom.*

Background: The relationship between chronic kidney disease (CKD) and accelerated cardiac disease is complex and not fully explained by traditional cardiovascular risk factors. Macrophages have critical roles in both kidney and cardiovascular disease, however a mechanistic link is not well described.

Methods: Using the folate induced nephropathy and 5/6 nephrectomy mouse models of CKD, we show that monocyte derived macrophages infiltrate heart tissue in large numbers but not other organs.

Results: We show using monocyte/macrophage transgenic reporters, with flow cytometry, imaging and qPCR, that the cardiac macrophage pool switches phenotype to a pro-inflammatory state during CKD. This cellular infiltrate was associated with an increase in cardiac remodeling through changes in extracellular matrix gene expression, cardiomyocyte enlargement and decrease in cardiac function, as shown by reduced ejection fraction. This phenotype was rescued by global knockout of C-C chemokine receptor type 2 ($CCR2^{-/-}$), associated with monocytopenia, during folate nephropathy. Measurement of specific chemokine expression in heart and plasma identified a unique chemokine axis, involving overexpression of CXCL10 that was also present in the plasma of CKD patients.

Conclusions: This work uncovers a novel pathway via CXCL10 that mediates cardiac inflammatory monocyte derived macrophage infiltration in the context of CKD, thus identifying new biological targets for improved diagnosis, prognosis and treatment of cardiomyopathy risk in CKD patients.

FR-PO137

Role of Primary Cilia in Kidney Fibrosis

Su-Mi Kim, Seo Jung-Woo, Dong-Jin Kim, Suk jong Song, Su Woong Jung, Yu ho Lee, Yang gyun Kim, Kyung-hwan Jeong, Ju young Moon, Sangho Lee. *Division of Nephrology Department of internal medicine Kyung Hee University College of Medicine, Seoul, Republic of Korea.*

Background: The primary cilium is an organelle, present at the cell surface and plays a role as an antenna. The primary cilium mediates cell proliferation, differentiation, death, and planar cell polarity. Recently, it has reported that transforming growth factor (TGF)-β receptors are localized and concentrated within the primary cilium in human mesenchymal stem cells. Also, the primary cilium regulates the transdifferentiation into myofibroblast of human adipose progenitor cells. We investigated a role of the primary cilium in renal fibroblast-myofibroblast transdifferentiation through regulating TGF-β1 receptors and the modulating cilia would attenuate interstitial fibrosis in unilateral ureteral obstruction (UUO) model.

Methods: NRK-49F cells were differentiated into myofibroblasts with TGF-β1. Using immunocytochemistry staining and western blot, the primary cilium and the fibroblast-myofibroblast transdifferentiation in NRK-49F cells were studied. UUO was performed to evaluate the interstitial fibrosis.

Results: The primary cilium is crucial for the maintenance of the myofibroblasts phenotype and for TGF-β1-induced Smad phosphorylation. Knock-down of cilia proteins such as SMO, Arl13b, and IFT88 decreased the expression of α-SMA and Smad signaling. TGF-β receptors localized to the primary cilium in NRK-49F cells, especially when the cells are cytokinesis cycle. Colchicine, an inhibitor of microtubule polymerization, and HPI-4, ciliogenesis inhibitor, attenuates cilia growth and TGFβ1-induced fibrosis. In addition, colchicine treatment attenuates interstitial fibrosis in UUO mice kidney.

Conclusions: We provide the evidence that the primary cilium is indispensable for the transdifferentiation from fibroblast into myofibroblast by modulating TGF-β1 receptors. The cilia targeted therapy could be a promising option for attenuating renal fibrosis.

FR-PO138

The Dual Blockade Losartan/Erlotinib Attenuates Inflammation and Fibrosis Formation in Vitamin D Deficiency Rats Submitted to 5/6 Nephrectomy

Janaina G. Goncalves, Ana Carolina de Braganca, Daniele Canale, Maria H. Shimizu, Antonio C. Seguro, Rildo A. Volpini. *Faculty of Medicine - University of Sao Paulo, Sao Paulo, Brazil.*

Background: 5/6 nephrectomy (N) is a classical experimental model of chronic kidney disease (CKD). Some studies have been linking vitamin D deficiency (VDD) to inflammatory process and renal fibrosis formation (RFF). Besides the beneficial effects of AII type I receptor antagonists, many efforts have been made to investigate alternative pathways related to RFF and inflammation. We evaluated the effects of the dual blockade including losartan (L) and erlotinib (E), an inhibitor of the epidermal growth factor receptor (EGFr) activity on CKD in rats under VDD.

Methods: Male Wistar rats received a vitamin D free (D) diet for 90 days. On day 30, rats were submitted to N surgery. Four groups were studied: D+N; D+N+L (50 mg/Kg/day in drinking water for 53 days); D+N+E (6 mg/Kg/day intraperitoneally for 53 days); D+N+L+E (dual treatment). We measured serum levels of 25(OH)D and aldosterone by ELISA; inulin clearance (Cin); mean arterial pressure (MAP); proteinuria; immunoblotted for TGF-β1, TGF-α and p-EGFr; performed IHC for CD206 and CD68; and evaluated interstitium enlargement by fraction interstitial area (FIA).

Results: All animals had untedectable levels of 25(OH)D. L+E treatment improved renal function and decreased MAP and proteinuria. L+E treatment reduced the expression of TGF-β1, TGF-α and p-EGFr, attenuating the expansion of FIA. Also, L+E mitigated the inflammatory profile of macrophages.

Conclusions: The dual blockade L+E ameliorated the course of CKD by retarding RFF and modulating the inflammatory phenotype of macrophages. (FAPESP 2015/05513-1; 2015/11933-3)

Proteinuric Renal Injury Modulates Intestinal Lymphangiogenesis and Functionality of Plasma and Lymphatic HDL

Tadashi Otsuka, Haichun Yang, Babak Banan, Valentina Kon. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Evidence suggests that in addition to plasma, critical changes in lipoprotein metabolism occur in the lymphatic circulation. Proteinuric renal injury changes lipoprotein levels and homoeostasis. Liver is a major regulator of lipoprotein metabolism, however, intestines also play a role, including synthesis of apolipoprotein AI (apoAI), the major protein in HDL. We examined how proteinuric renal injury affects intestinal handling of apoAI and functionality of HDL.

Methods: We studied Sprague-Dawley rats injected with puromycin aminonucleoside (PAN) or saline (C). Lymph was collected in conscious animals by indwelling mesenteric lymph duct cannulation. Lymphatic vessels were identified by immunohistochemistry (IHC) and RT-qPCR of podoplanin (PD). Functionality of HDL was assessed by cytokine response (TNFa, IL-6, Il-12 and iNOS/Arg1 ratio) in macrophages exposed to apoB-depleted HDL fractions isolated from plasma and lymph by RT-qPCR. HDL-cholesterol (HDL-C)/apoA1 ratio served as a HDL-particle size marker.

Results: PAN significantly increased urinary albumin creatinine ratio vs C. Intestines of PAN had significant increase in PD$^+$lymphangiogenesis and enlargement of lacteals accompanied by higher mesenteric lymph flow (6.3±1.7 vs 0.8±0.4ml/h). VEGFA was significantly elevated in PAN lymph and plasma (2.8-fold and 2.2-fold, respectively). Plasma HDL of PAN caused significantly greater macrophage inflammatory response [TNFa, IL-6, Il-12 (3.5-fold, 5.1-fold, 6.4-fold, respectively)] vs C. By contrast, HDL from mesenteric lymph of PAN was not pro-inflammatory and rather significantly decreased iNOS/Arg1 vs controls (0.5-fold). Although PAN did not change intestinal expression of apoA1 mRNA and IHC showed lower ileal apoAI than C, hepatic apoAI mRNA expression was significantly higher (3.9-fold). However, total output of apoAI in mesenteric lymph (apoAI quantity over time) was significantly higher in PAN (59.4±24.7 vs 11.2±6.5μg/h). Although HDLC/apoA1 ratio in lymph was similar, this ratio doubled in plasma of PAN (129.2±45.2 vs 60.0±21.1).

Conclusions: PAN renal injury increases intestinal lymphangiogenesis, mesenteric flow, composition and functionality of lymphatic HDL which is distinct from functionality of plasma HDL.

FR-PO140

Measurement Characteristics of Proximal Tubular Secretory Solutes

Yan Chen,[1,2] Andrew N. Hoofnagle,[1,2] Leila R. Zelnick,[2] Ke Wang,[1,2] Jessica O. Becker,[1] Bryan R. Kestenbaum.[1,2] *[1]University of Washington, Seattle, WA; [2]Kidney Research Institute, Seattle, WA.*

Background: Reliable measurements of proximal tubular solute clearance, a vital kidney function, have been elusive. We developed targeted liquid chromatographic-tandem mass spectrometric methods to quantify 16 endogenously produced secretory solutes in serum and urine. We tested diurnal variation of each solute, determined their kidney clearances, and assessed associations with the estimated glomerular filtration rate (GFR) in studies of healthy subjects and those with chronic kidney disease (CKD).

Methods: Among healthy controls, we measured plasma concentrations of each solute at 7 time points throughout the day. We calculated 24-hour urinary clearances from timed urine collections using the weighted 24-hour mean plasma value of each solute. We determined the diurnal within-subject coefficient of variation (CV) of plasma concentration for each solute. We investigated associations of derived clearances with estimated GFR in 239 participants from the Seattle Kidney Study, a cohort study of CKD.

Results: Three of the 16 solutes had implausible kidney clearance values and 4 exhibited high diurnal variation (Table). Nine solutes demonstrated reasonable diurnal stability and plausible clearance values. The clearances of these solutes correlated with GFR among CKD patients.

Conclusions: We identified 9 solutes that show promise for estimating proximal tubular secretory clearance - cinnamoylglycine, indoxyl sulfate, p-cresol sulfate, isovalerylglycine, kynurenic acid, pantothenic acid, pyridoxic acid, tiglylglycine, and xanthosine.

Funding: NIDDK Support

Deubiquitinase Inhibitor PR-619 Reduces Smad4 Expression and Suppresses Renal Fibrosis in Mice with Unilateral Ureteral Obstruction

Kotaro Soji,[1,2] Shigehiro Doi,[1] Ayumu Nakashima,[1] Takao Masaki.[1] *[1]Hiroshima University Hospital, Hiroshima, Japan; [2]Hiroshima Red Cross Hospital & Atomic-bomb Survivors Hospital, Hiroshima, Japan.*

Background: Deubiquitinating enzymes (DUBs) remove ubiquitin from their substrates and, together with ubiquitin ligases, play an important role in the regulation of protein expression. Although transforming growth factor (TGF)-β1-Smad signaling is a central pathway of renal fibrosis, the role of DUBs in the expression of TGF-β receptors and Smads during the development of renal fibrosis remains unknown.

Methods: In this study, we investigated whether PR-619, a pan-DUB inhibitor, suppresses fibrosis in mice with unilateral ureteral obstruction (UUO) and TGF-β1-stimulated normal rat kidney (NRK)-49F cells, a rat renal fibroblast cell line. Either the vehicle (dimethyl sulfoxide) or PR-619 (100 μg) was intraperitoneally administered to mice after UUO induction once a day for 7 days.

Results: Administration of PR-619 attenuated renal fibrosis with downregulation of mesenchymal markers, extracellular matrix proteins, matrix metalloproteinases, apoptosis, macrophage infiltration, and the TGF-β1 mRNA level in UUO mice. Although type I TGF-β receptor (TGF-βRI), Smad2, Smad3, and Smad4 protein expression levels were markedly increased in mice with UUO, administration of PR-619 suppressed only Smad4 expression but not TGF-βRI, Smad2, or Smad3 expression. PR-619 also had an inhibitory effect on TGF-β1-induced α-smooth muscle actin expression and reduced Smad4 levels in NRK-49F cells.

Conclusions: Our results indicate that PR-619 ameliorates renal fibrosis, which is accompanied by the reduction of Smad4 expression.

Regulating Hyaluronan Deposition Attenuates Tubulointerstitial Fibrosis in Ureteral Obstruction

Xinyi Wang,[1,2] Swathi Balaji,[3] Emily Steen,[3] Hui Li,[3] Alexander Blum,[3] Paul Austin,[4] Paul L. Bollyky,[5] Thomas N. Wight,[6] Jizhong Cheng,[3] Sundeep G. Keswani.[3] Laboratory for Regenerative Tissue Repair *[1]Surgery, Baylor College of Medicine, Houston, TX; [2]Pediatric Surgery, Texas Children's Hopsital, Houston, TX; [3]Baylor College of Medicine, Houston, TX; [4]Texas Children's Hospital, Houston, TX; [5]Stanford University, Stanford, CA; [6]Benaroya Research Institute, Seattle, WA.*

Background: Renal fibrosis is an end-stage outcome of chronic kidney disease(CKD) without foreseeable cure. However, we recently found that interleukin-10 (IL-10) can abrogate dermal fibrosis by regulating hyaluronan(HA), an abundant glycosaminoglycan in the extracellular matrix (ECM). Here, we hypothesize that promoting the expression of the high molecular weight(MW) HA form attenuates renal fibrosis by regulating ECM remodeling and reducing inflammation.

Methods: *in vivo*: we used the UUO model in the presence or absence of IL-10 to assess the HA role. UUO/sham kidneys were collected at d3,7,14&21 for RNA, ELISA, and/or IHC analyses. HA synthases(HAS1-3) and hyaluronidases(HYAL1-2) enzyme levels were determined by qPCR and immunoblotting (IB), while HA MW was confirmed by gel electrophoresis. To test loss of function effects, we fed mice with 4-methylumbelliferone(4-MU,5%), a HA synthesis inhibitor, and evaluated the outcomes.*in vitro*: renal fibroblasts(FB) were isolated from C57BL/6J mice to measure total HA by pericellular matrix assays. α-

SMA, HAS1, 2 and p-STAT3 expression were also assessed by IB at 48h. Mean ±SD; p-values by ANOVA.

Results: *in vivo*: HAS1 & HAS2 expression was upregulated in normal and 4MU-fed UUO mice compared to control mice from d3 onwards. ELISA showed that total HA levels steadily increased from d3-14 for UUO mice, and up to d21 for IL-10-treated UUO mice. In normal diet mice, lenti-IL-10 resulted in decreased kidney fibrosis and preserved tubular integrity in comparison to controls. IL-10-treated 4-MU diet mice did not attenuated fibrosis. HA gel electrophoresis showed that unlike control/sham kidneys, d3&7 UUO kidneys had a previously unreported $1.5x10^6$D HA form. *in vitro*: A 1.88-fold increase in HA-rich matrix formation was shown with 24h of IL-10 stimulation, and the effect was abrogated by HYAL. Significant increased HAS2, α-SMA, & p-STAT3 in the IL-10-treated FBs after 48h. $p<0.05$

Conclusions: Our study provides the first evidence that injured mouse kidney expresses increased levels of an ultra-high MW HA variant not found in normal kidneys. This suggests that HA is critical for kidney function, homeostasis, and architectural integrity. Understanding the mechanisms behind HA-mediated in renal fibrosis could lead the design and application of innovative therapeutics.

A Critical Role of Histone Methyltransferase EZH2 in Mediating Renal Epithelial-Mesenchymal Transition and Renal Fibrogenesis

Xiaoxu Zhou,[2] Chongxiang Xiong,[2] Shougang Zhuang.[1] [1]*Department of Medicine, Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI;* [2]*Rhode Island Hospital, Brown University, Providence, RI.*

Background: EZH2 (Enhancer of Zeste Homolog 2) is a methyltransferase that induces histone H3 lysine 27 trimethylation (H3K27me3) and functions as an oncogenic factor in many cancer types. Its role in renal epithelial-mesenchymal transition (EMT) remains unknown.

Methods: In this study, we examined the effect of EZH2 inhibition on EMT and renal fibrosis in the kidney following unilateral ureteral obstruction (UUO).

Results: We found that EZH2 and H3K27me3 were highly expressed in the kidney of mice with and cultured mouse kidney proximal tubular cells (TKPT) undergoing EMT. Inhibition of EZH2 with 3-deazaneplanocin A (3-DZNeP) attenuated renal fibrosis, which was associated with preserving E-cadherin expression and inhibiting vimentin upregulation in the obstructed kidney. Treatment with 3-DZNeP or transfection of EZH2 siRNA also inhibited TGF-β1-induced EMT of TKPT. Injury to the kidney or cultured TKPT resulted in upregulation of Snail1 and Twist, two transcription factors, and downregulation of PTEN, a protein tyrosine phosphatase associated with inhibition of PI3K-AKT signaling; EZH2 inhibition or silencing reversed all those responses. 3-DZNeP was also effective in suppressing epithelial arrest at G2/M phase and dephosphorylating AKT and β-catenin in in vivo and in vitro.

Conclusions: These data indicate that EZH2 activation contributes to renal EMT and fibrosis through activation of multiple signaling pathways and suggest that EZH2 would be a novel therapy for treatment of renal fibrosis.

Single Nephron Dynamics in Patients with Obesity-Related Glomerulopathy

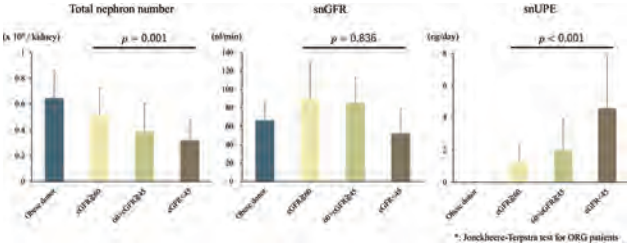
Yusuke Okabayashi,[1,2] Nobuo Tsuboi,[1] Takaya Sasaki,[1] Kotaro Haruhara,[1] Go Kanzaki,[1] Kentaro Koike,[1] Akira Shimizu,[2] Takashi Yokoo.[1] [1]*The Jikei University School of Medicine, Tokyo, Japan;* [2]*Nippon Medical School, Tokyo, Japan.*

Background: The etiologies and mechanisms underlying the progression of obesity-related glomerulopathy (ORG) remain largely unknown, and the urinary protein excretion (UPE) level is the only predictive factor for renal outcome. ORG is characterized by renal histopathological findings of low glomerular density with glomerulomegaly, related to glomerular hyperfiltration. In this study, we estimated total nephron number and related factors in patients with ORG at different stages of the disease.

Methods: The total nephron number was calculated using a simplified method based on combined use of unenhanced computed tomography and non-sclerotic glomerular density in renal biopsy. Single-nephron glomerular filtration rate (snGFR) and single-nephron UPE (snUPE) were calculated by dividing eGFR or UPE by total nephron number, respectively. The glomerular volume (GV) was estimated from the measured mean glomerular area. Obese kidney transplantation donors were included in the study as a control group.

Results: Among the 30 Japanese ORG patients included in the study, total nephron number ranged from 153000 to 1061000 per kidney and was inversely correlated with GV (r = –0.366, p = 0.047). The snGFR was correlated with GV (r = 0.631, p < 0.001), and snUPE was correlated with the degree of glomerulosclerosis (r = 0.633, p < 0.001). None of these parameters associated with total nephron number showed a correlation with body mass index (BMI). Patients with advanced renal impairment were characterized by diminished snGFR and markedly elevated snUPE level (**Figure**). Among the ORG patients with preserved renal function (eGFR ≧ 45 mL/min/1.73 m^2, n = 22), total nephron number was identified as a factor associated with UPE at diagnosis, independent of eGFR and BMI.

Conclusions: There is a close relationship between difference in total nephron number and severity of ORG, in relation to changes in the single nephron dynamics. Compensatory failure of glomerular hyperfiltration may be a characteristic of advanced ORG.



FR-PO145

Analysis of the Peritubular Capillaries and Lymphatics in a Model of Renal Injury and Repair

Marie-Louise Monaghan, Carolynn Cairns, Gary Borthwick, Laura Denby, Jeremy Hughes, Bryan Conway. *University of Edinburgh, Edinburgh, United Kingdom.*

Background: Chronic kidney disease has a diverse range of aetiologies, but all are associated with alterations in the renal interstitial microvasculature. We hypothesised that renal injury promotes loss of peritubular capillaries leading to tubular cell hypoxia, but conversely lymphatic vessel density may increase as a compensatory response to reduce inflammation and facilitate repair.

Methods: C57Bl/6 mice underwent unilateral ureteric obstruction (UUO) or sham surgery. After 7 days of UUO, 8 mice were culled while in the remaining mice the ureter was re-implanted into the bladder to relieve obstruction (R-UUO) for 1, 2 and 4 weeks (n=6-8). Kidneys were harvested and analysed by flow cytometry, immunostaining, RNAseq, qPCR and electron microscopy.

Results: Flow cytometry demonstrated a 16-fold increase in the proportion of dead $DAPI^+/CD31^+$ endothelial cells (ECs) in UUO kidney v sham (p=<0.001). CD31 quantification by IHC revealed a doubling in areas of capillary rarefaction in UUO v sham (p=<0.001), with the degree of rarefaction falling by 31% following R-UUO (p=<0.001). Electron microscopy analysis demonstrated a reduction in peritubular capillary fenestrations and an increase in EC vacuolation, which partially reversed following R-UUO. While the density of $Lyve\text{-}1^+$ lymphatic vessels remained similar in UUO kidney v sham, there was a doubling of lymphatic vessels after 4 weeks of relief of obstruction ($p<0.05$). RNAseq and qPCR analysis of renal cortex revealed a reduction in Vegfa in UUO v sham, which partially reversed following R-UUO. Conversely there was a significant up-regulation of Vegfc and Vegfd, most notably following R-UUO. Gene expression of Vegfr3 increased in UUO compared with sham ($p<0.01$), and this persisted through to week 4 after R-UUO. Dual immunofluorescence for VEGFR3 and LYVE-1 determined that the increase in VEGFR3 staining occurred largely in $CD31^+/Lyve1^-$ vessels, most likely peritubular capillaries. This was confirmed by flow cytometry with the proportion of $CD31^+/podoplanin^-$ cells that co-expressed VEGFR3 increasing from 7% in sham to 36% in UUO kidney.

Conclusions: Our data suggest that peritubular capillary rarefaction occurs following renal injury and only partially improves following cessation of injury. Therapies that prevent capillary rarefaction may reduce secondary renal injury and augment repair.

The Role of Complement C1r and C1s Serine Proteases in Kidney Fibrosis

Sandhya Xavier,[1] Ranjit K. Sahu,[2] Didier Portilla.[3] [1]*University of Virginia/ Department of Medicine, Charlottesville, VA;* [2]*University of Virginia, Charlottesville, VA;* [3]*University of Virginia Health System, Charlottesville, VA.*

Background: We previously reported increased expression of C1q in kidney cells as a pathophysiologic mechanism leading to kidney fibrosis. The classical pathway of complement activation is initiated by the assembly of the C1 complex which consists of C1q and serine proteases C1r and C1s. We hypothesize that activation of classical pathway in kidney cells contributes to tubulointerstitial fibrosis, and tested this idea in mice with global deletion of C1r.

Methods: We performed real time-PCR, immunohistochemistry, in situ hybridization, western blotting and microarray based gene expression analysis in wild type (WT) and in C1r-/- mice subjected to unilateral ureteral obstruction (UUO) or folic acid injury (FA). We overexpressed human C1r in human tubular epithelial cells

Results: Administration of FA or UUO injury in WT mice led to upregulation of C1r and C1s mRNA and protein in whole kidney tissue. In situ hybridization and immunohistochemistry localized increased expression of these proteases to distal tubular epithelial cells. C1r deletion reduced fibrosis in both animal models. While kidney inflammation and complement activation measured by increased expression of C3 fragments were significantly reduced in the FA model, C3 formation and inflammation were not affected in the UUO mice, despite the reduction in fibrosis. While C1r-/- mice had reduced C1s expression, stable transfection of human C1r in renal epithelial cells led to increased expression of both C1r and C1s. Gene expression arrays corroborated downregulation of probe sets representing C1r and C1s in kidney tissue of C1r-/- mice, as well as downregulation of genes associated with connective tissue and collagen. C1r-/- mice treated with FA had reduced expression of genes associated with increased inflammation.

Conclusions: In conclusion our studies support the role of classical complement pathway activation during fibrosis via increased expression of C1r in distal tubular epithelial cells and identify C1r as a novel potential therapeutic target for the treatment of progressive kidney disease.

Loss of C5aR1 in Foxd1+ Stromal Cells Reduces Kidney Fibrosis

Ranjit K. Sahu,[2] Sandhya Xavier,[1] Didier Portilla.[3] *[1]University of Virginia/ Department of Medicine, Charlottesville, VA; [2]University of Virginia, Charlottesville, VA; [3]University of Virginia Health System, Charlottesville, VA.*

Background: Recent studies have identified a population of perivascular mesenchymal cells in the kidney that express the transcription factor Foxd1. These cells are called resident fibroblasts or pericytes. Fate-mapping studies have identified these pericytes and resident fibroblasts as the major precursor population of interstitial myofibroblasts in animal models of kidney disease. We previously reported increased synthesis of complement components including anaphylatoxin receptor C5aR1 in PDGFβR-positive pericytes isolated from murine models of fibrosis. Reduced expression of C5aR1 using global deletion of C5aR1 ameliorates renal fibrosis. We hypothesize that deletion of C5aR1 in Foxd1-expressing cells can lead to reduced myofibroblast production, reduced inflammation, and reduced kidney fibrosis.

Methods: C5aR1GFP$^{fl/fl}$ mice were generated by inserting LoxP sites flanking exon 2 as previously reported. C5aR1GFP$^{fl/fl}$ mice were crossed with mice expressing Cre-recombinase under control of the Foxd1 promoter to generate Foxd1-Cre-C5aR1GFP$^{fl/fl}$ mice. Eight week old Foxd1-Cre-C5aR1GFP$^{fl/fl}$ mice and C5aR1GFP$^{fl/fl}$ (control mice) received intraperitoneal injections of either vehicle (sodium bicarbonate) or folic acid+sodium bicarbonate (FA). Two weeks later kidney tissue was harvested for analysis. Primary mouse pericytes were isolated from the kidneys of Foxd1CreC5aR1GFP$^{fl/fl}$ and C5aR1GFP$^{fl/fl}$ following FA-injury as previously reported

Results: Immunohistochemical analysis, flow cytometry, quantitative RT-PCR and western blots demonstrated reduced inflammation and reduced fibrosis in whole kidney tissue from Foxd1CreC5aR1GFP$^{fl/fl}$ mice treated with FA when compared to control mice. Cytokine production measured by Luminex assays in cell supernatants from cultured PDGFβR^{+} cells isolated from kidneys of FA-treated mice demonstrated that the absence of C5aR1 receptor in cultured pericytes reduces inflammatory cytokine production including IL6, TNFalpha, and MIP2.

Conclusions: The loss of C5aR1 in Foxd1 stromal cells reduces kidney fibrosis and reduces inflammatory response of kidney pericytes. These results support the role of increased expression of pericyte C5aR1 in the pathogenesis of kidney fibrosis.

FR-PO148

Study of the Expression of Renal PCSK9 in the Rrm2b Mouse Model of Nephrotic Syndrome

Eduardo Molina-Jijon,[1] Stephanie Gambut,[1] Camille E. Mace,[1] Carmen Avila-Casado,[2] Lionel C. Clement.[1] Glomerular Disease Therapeutics Laboratory *[1]Rush University Medical Center, Chicago, IL; [2]University Health Network, University of Toronto, Toronto, ON, Canada.*

Background: 85% of American chronic disease patient presenting nephrotic syndrome (NS) have high levels of low density lipoprotein cholesterol (LDL-c), compared to only 31.5% in the American general population. A factor from the kidney might be responsible for the increased susceptibility for high levels of LDL-c in NS patients. Proprotein convertase subtilisin/kexin type 9 (PCSK9) was shown to play an important role in the regulation of LDL-c levels in the liver. PCSK9 is expressed in the kidney at a lower level of expression compared to the liver, but its role in this organ is not clear. We decided to study the expression and the role of PCSK9 in NS in the Rrm2b mouse, a model collapsing glomerulopathy.

Methods: Male Rrm2b Control (+/+) and knock-out (-/-) mice (6 mice/group) were studied every week between the age 5 and 12 weeks. Albuminuria, PCSK9 and cholesterol serum levels were assessed. PCSK9 gene and protein expression in liver, kidney, intestine and serum were studied by RealTime PCR, Western blot, and confocal microscopy.

Results: Rrm2b$^{+/+}$ mice do not develop albuminuria, hypercholesterolemia, or high levels of serum PCSK9. Compared to controls, Rrm2b$^{-/-}$ develop albuminuria from the age of 7 weeks (from 425±239 μg/18h at 7 weeks to 3895±381 at 10 weeks (P<0.001)). Serum PCSK9 levels significantly increase from the age of 8 weeks (from 19.75±5.21 ng/ml at 8 weeks (P<0.05) to 55.54±13.07 at 10 weeks (P<0.01)). Serum total cholesterol levels significantly increase from the age of 8 weeks (from 124.16±10.27 mg/dl at 8 weeks (P<0.05) to 567.58±72.96 at 10 weeks (P<0.001)). PCSK9 gene expression is relatively unchanged as animal age. PCSK9 protein expression was shown by Western blot to increase in the renal cortex from the age of 9 weeks, and decrease in the liver from the age of 7 weeks. By confocal microscopy, PCSK9 was shown to co-localize with Aquaporin-2, indicating expression in the collecting duct where its expression is increased from the age of 7 weeks.

Conclusions: As Rrm2b$^{-/-}$ mice age and develop NS, PCSK9 protein levels increase in the kidney and serum, and decrease in the liver. Collecting duct expressed PCSK9 may play an important role in the initiation of hypercholesterolemia in NS in the Rrm2b mouse model, as a link between the kidney and the liver.

FR-PO149

Nephron Loss Reduces Excretion of Urinary Extracellular Vesicles

Charles J. Blijdorp,[1] Thomas Hartjes,[1] Bart J. Kramers,[2] Martin E. Van royen,[1] Ron T. Gansevoort,[3] Robert Zietse,[1] Ewout J. Hoorn.[1] *[1]Erasmus Medical Center, Rotterdam, Netherlands; [2]Harvard, Groningen, Netherlands; [3]University Medical Center Groningen, Groningen, Netherlands.*

Background: Urinary extracellular vesicles (uEVs) are emerging as non-invasive biomarkers for various kidney diseases. We previously showed that the uEV-marker CD9 decreases with disease progression in autosomal dominant polycystic kidney disease (ADPKD; Salih *et al.*, J Am Soc Nephrol 2016). Therefore, here, we hypothesize that nephron loss decreases uEV excretion.

Methods: We quantified uEVs in two different settings of nephron loss, including donor nephrectomy and ADPKD with progressive decline of estimated glomerular filtration rate (eGFR). We obtained spot and 24-hour urine samples from 20 kidney donors the day prior and 3 months after nephrectomy, and from 27 ADPKD patients at baseline and after a median follow-up time of 3 years. uEVs were quantified using 3 techniques, including EVQuant (a novel technique which counts individual fluorescently labeled EVs after immobilization in a matrix), nanoparticle tracking analysis (NTA), and a time-resolved fluorescence immunoassay (TRFIA) capturing CD9+ uEVs.

Results: Baseline kidney function correlated with uEV excretion in both healthy donors (EVQuant vs. eGFR: R^2 0.41, P = 0.01) and ADPKD patients (CD9-TRFIA vs. mGFR: R^2 0.23, P = 0.02). Donor nephrectomy reduced eGFR by 32 ml/min/1.73m^2 or 38% after 3 months. uEV excretion decreased by 18% as analyzed by EVQuant (95%CI: 6-31%), 21% by NTA (95%CI: 7-34%) and 22% by TRFIA (95%CI: 3-42%). In the ADPKD cohort the average loss in eGFR was 4.1 ml/min/1.73m^2/year (95%CI 2.9-5.2), or 18% after 3 years (95%CI 13-23%). In this period, the number of uEVs reduced by 22% (95%CI: 9-36%, as analyzed by TRFIA).

Conclusions: Nephron loss reduces uEV excretion both after donor nephrectomy and in progressive ADPKD. Therefore, it is important to adjust for uEV excretion when performing cross-sectional or longitudinal analyses of uEVs in patients with reduced kidney function.

FR-PO150

Deconvolving Bulk Disease Expression Datasets Using Markers Identified from Single-Cell Sequencing Data Defines CKD Associated Cell Types

Rachel S. Sealfon,[1] Rajasree Menon,[2] Evren U. Azeloglu,[3] Edgar A. Otto,[2] Paul J. Hoover,[6] Olga Troyanskaya,[4,1] Matthias Kretzler.[5] *[1]Center for Computational Biology, Flatiron Institute, New York, NY; [2]University of Michigan, Ann Arbor, MI; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Princeton University, Princeton, NJ; [5]U.Michigan, Ann Arbor, MI; [6]Broad Institute, Cambridge, MA.*

Background: Elucidating changes in cell type composition across diseases can provide insight into pathology-related alterations in kidney tissue. Single-cell data from tumor nephrectomy tissue allows the identification of cell type markers in the adult human kidney. By integrating this information with bulk expression data from 223 biopsies from the European Renal cDNA Bank cohort (ERCB), we identify cell type proportion alterations across 9 diverse glomerular diseases.

Methods: We first identify cell type specific genes in an unbiased, data-driven manner from eight adult kidney single cell 10X Genomics expression datasets from tumor nephrectomy tissue. We extract markers from the single-cell expression data using the Seurat R package (Butler et al., 2018). We then expand these cell type specific marker sets by identifying additional cell type specific marker genes using computational nanodissection (Ju et al., 2013) and perform pathway enrichment analysis. Using our expanded set of marker genes, we deconvolve microdissected glomerular bulk expression data from the ERCB cohort using CellCODE (Chikina et al., 2015) to identify differences in cell type composition across patients with diverse kidney diseases.

Results: Both the cell type specific marker genes identified from single-cell data and the additional cell type marker genes identified by nanodissection show relevant functional enrichments. Consistent with prior knowledge, we find that podocyte markers are lost in diseased patients compared to living donors, monocyte markers are elevated in immune-mediated diseases such as lupus nephritis relative to other kidney diseases, and mesangial/ vascular smooth muscle cell markers are elevated in diabetic nephropathy. Multiple cell type markers are correlated with GFR, with podocyte markers positively correlated and parietal epithelial cell markers negatively correlated

Conclusions: Integrating single-cell and bulk expression data provides insight into cell composition changes across diverse kidney diseases. Our approach illustrates the power of leveraging and integrating multimodal data types to understand the molecular underpinnings of disease processes.

Funding: NIDDK Support

FR-PO151

MicroRNA-34a Induces Renal Aging by Regulating SIRT1/p53/p21 Pathway and Promoting the Expression of Senescence-Associated Secretory Phenotype (SASP)

Fanfan Gao,[1] Hongli Jiang.[2] Dialysis Department of Nephrology Hospital, First Affiliated Hospital of Medicine School, Xi'an Jiaotong University, Xi'an 710061, Shaanxi, China *[1]Dialysis Department of Nephrology Hospital, First Affiliated Hospital of Medicine School, Xi'an Jiaotong University, Xi'an, China; [2]First Affiliated Hospital of Medicine School, Xi?an Jiaotong University, Xi'an, China.*

Background: An increasing number of investigations suggest that small non-coding microRNAs play an important role in the regulation of genes involved in various kidney disease. MicroRNA-34a (miR-34a) has been recently implicated in cardiac, endothelial, endothelial progenitor cell, vascular smooth muscle cell senescence, however, its contribution to the aging process of kidney has not been explored so far. The aim of the present study was to analyze miRNA expression profiles and the rule of miR-34a in mice kidney during the aging process.

Methods: The kidneys of male C57BL/6 mice at different ages (3 months, 12 months and 24 months, n=5 per group) were used. Total RNA was extracted using Trizol reagent following the manufacturer's procedure. The total RNA quantity and purity were analysis of Bioanalyzer 2100 with RIN number >7.0. Approximately 1 ug of total RNA were used to prepare small RNA library according to protocol of TruSeq Small RNA Sample Prep Kits. And then we performed the single-end sequencing (36bp or 50bp) on an Illumina Hiseq 2500 at the LC-BIO following the vendor's recommended protocol. In addition, the results were assessed by real-time PCR and western blotting in kidneys of mice.

Results: Several up- and downregulated miRNAs were identified in the mice kidneys at 3 different ages. We observed the upregulation of miR-26a, miR-214, miR-34a, miR-34c, miR-29c, miR-199a, miR-21a, miR-27a, miR-195a and miR-23a, whereas miR-335, miR-200b, miR-378a, miR-151, miR-486a, miR-615, miR-378 were downregulated in the aging mice kidneys. We found that miR-34a was highly expressed in kidneys isolated from old mice. Moreover, its well-known target, the longevity-associated protein SIRT1, was significantly downregulated during aging in both kidney tissue and HK-2 cells. miR-34a overexpression in HK-2 cells caused cell cycle arrest along with enhanced p21 and p53 protein levels and reduced SIRT1 protein expression. Furthermore, miR-34a ectopic expression induced the expression of SASP, including TNF-α, IL-1α, IL-6, plasminogen activator inhibitor-1 and monocyte chemoattractant protein-1.

Conclusions: In conclusion, our findings suggest that aging-associated increase of miR-34a expression plays an important role in renal aging by inhibition of SIRT1 and activation of p53/p21 pathway as well as the induction of SASP.

Weekly Subcutaneous Mutated Human Angiopoietin – Like 4 (8520) Improves CKD in Diabetic Rats via an Anti-Endothelial Apoptosis Mechanism

Sumant S. Chugh,[1] Maria Del Nogal Avila,[1] Ranjan Das,[1] Joubert B. Kharlyngdoh,[1] Hector Donoro blazquez,[1] Eduardo Molina-Jijon,[1] Lionel C. Clement,[1] Camille E. Mace,[1] Carmen Avila-Casado.[2] Glomerular Disease Therapeutics Laboratory *[1]Rush University Medical Center, Chicago, IL; [2]University Health Network, University of Toronto, Toronto, ON, Canada.*

Background: We previously showed that single intravenous dosing of recombinant mutated human Angptl4 (8520) reduces proteinuria for over 2 weeks in diabetic rats (Clement L, Mace C, et al Nature Medicine Jan 2014). We now tested whether subcutaneous doses in diabetic rats would reduce CKD.

Methods: We treated male ZSF1 rats (n = 5 rats / group) with 8520 or rat albumin once a week subcutaneously in declining doses, starting with 500 μg per dose on Week 0 (W0) to 125 μg on Week 9, to 100 μg on Week 15 and 50 μg on Week 16, after which the treatment was stopped and rats sacrificed on W20. Food and water intake, proteinuria, blood glucose, plasma human Angptl4 levels and serum parameters were measured periodically.

Results: Pharmacokinetic assessment of plasma human Angptl4 (8520) levels showed elevated levels between W1 and W15 at dose ranges between 500 μg and 100 μg subcutaneously per week. Plasma levels were statistically similar at doses between 500 μg and 125 μg. Plasma creatinine was significantly lower in the treatment group ($P < 0.01$ to $P < 0.001$) between doses 500 and 125 μg, and BUN between 500 and 100 μg ($P < 0.05$). 18-hour proteinuria was mostly similar between treatment and control groups, and as were the plasma glucose and triglyceride levels. Histological improvement revealed very significant improvement morphometric parameters in the treatment compared to control group. TUNEL staining for apoptosis revealed very significant reduction in interstitial capillary endothelial apoptosis in the treatment Vs. the control group ($P < 0.001$).

Conclusions: Weekly subcutaneous doses of mutated human Angptl4 in ZSF1 rats improves GFR at doses between 500 and 125 μg. Despite sub-therapeutic doses and stopping treatment towards the end, morphology was significantly improved, suggesting a memory effect. The absence of effects on proteinuria and the highly significant difference in interstitial capillary endothelial apoptosis suggests that the beneficial effects of subcutaneous dosing are mediated by preserving interstitial capillaries and presumably promoting repair in the treatment group.

miRNA Profiling of Kidney Disease Indicates a Conserved Role for miRNA99 Family

Archana Raman,[1] Verónica Miguel,[2] Chengxiang Qiu,[1] Jihwan Park,[1] Shizheng Huang,[1] Katalin Susztak.[1] Susztaklab *[1]University of Pennsylvania, Philadelphia, PA; [2]CBMSO, Madrid, Spain.*

Background: MicroRNAs (miRNAs) are short non-coding RNA molecules that play a crucial role in cellular homeostasis by regulating gene expression. Lately, miRNAs have become important therapeutic targets. To determine consistently altered miRNAs that could causally affect chronic kidney disease (CKD) development, we sought to define miRNA profiles in kidneys of five different CKD models and validated these results in patient samples.

Methods: miRNA fraction was isolated from the kidneys of wildtype mice or mice with CKD induced by 1) unilateral ureteral obstruction (UUO), 2) folic acid (FA) administration, 3) transgenic expression of Notch intracellular domain in tubule cells, 4) transgenic expression of PGC1α in podocytes and 5) transgenic expression of APOL1 risk allele in podocytes. Small RNA sequencing was followed by miRNA alignment and abundance quantification. qPCR analysis and *in situ* hybridization were used to validate candidate miRNAs differentially expressed in CKD. We used microRNA mimics and inhibitors to understand the role of miRNA in cultured renal tubule cells.

Results: We detected differences in levels of 457 miRNAs among all analyzed models of kidney disease. miR-99 family consisting of 99a, 99b and 100, were significantly downregulated in all five models. *In situ* hybridization for miR-99 family on wildtype, UUO, and FA kidney sections showed that these miRNAs were expressed widely in normal tubules but absent or significantly downregulated in injured/dedifferentiated tubules. Importantly, human renal biopsy sections also showed significant downregulation in the expression of the miR-99 family in CKD patients, compared to healthy volunteers. Furthermore, transfection of HKC8, a human proximal tubule cell line, with miR-99a and 100 mimics improved epithelial characteristics and reduced proliferation. We identified IGF1 and mTOR as likely targets of miR-99 family in kidney tubule samples.

Conclusions: We found that miR-99a, 99b and 100 are significantly downregulated across all examined CKD models and human subjects, implying a causal role in disease. Upregulation of miR-99 family *in vitro* significantly decreased expression of mTOR, IGF-1, cell proliferation and improved epithelial characteristics, suggesting a crucial regulatory function. In summary, miR-99 family could be potential therapeutic targets for CKD.

FR-PO154

The Effect of Autophagic Flow in the Phenotype Transformation of Macrophage M1/M2

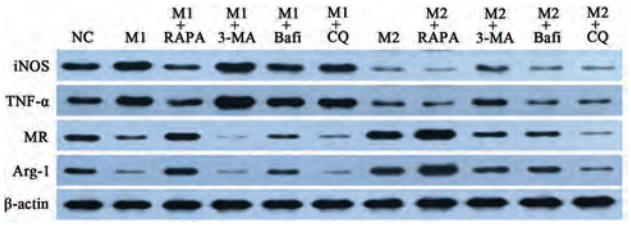
Yuqiu Liu,[1] Yuteng Jiang,[1] Yu Zhao,[1] Xiaodong Zhu,[1] Beibei Wu,[1] Xiaoliang Zhang.[2] *[1]Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, China; [2]Zhong Da Hospital, Southeast University, School of Medicine, Nanjing, China.*

Background: Macrophage infiltration is an important histopathological feature of kidney disease, and its activation state in the microenvironment is the main factor determines disease prognosis. Autophagy is a process in which lysosomes degrade their own damaged and excess proteins. It's highly dynamic, also known as autophagic flow. In this study, macrophages were cultured in vitro to fully observe the levels of autophagic flow and the effects on the M1/M2 phenotype transformation.

Methods: The macrophages RAW264.7 were stimulated with IFN-γ+LPS and IL-4 for 24h to induce M1 and M2 activation. Use of autophagosome-generating activator (RAPA), autophagosome production inhibitor (3-MA), autolysosome fusion inhibitor (BAFA) and autolysosome degradation inhibitor (CQ) to intervene M1/M2 for 24h. The expression levels of M1 markers, M2 markers and autophagy markers were detected by western blot and immunofluorescence. Then using an electron microscope to observe autophagic flow.

Results: 1. The expression of M1 markers (iNOS, TNF-α) increased with IFN-γ+LPS. Instead, IL-4 stimulated activation of M2 that the levels of MR and Arg-1 increased. 2. Autophagy-related proteins LC3 and Beclin-1 had higher level in M2 cells with the level of autophagy specific degradation protein p62 decreased, suggesting the autophagy level of M2 cells was higher than that of M1 cells. 3. The autophagosome formation, fusion of autophagosomes with lysosomes, autolysosome formation, and substrate degradation were observed by EM. 4. For M1 cells, RAPA increased the expression of LC3, Beclin-1 and p62, while those decreased with 3-MA. After BAFA intervention, the expression of LC3 and Beclin-1 decreased, when p62 was significantly increased. But the expression of LC3-II, Beclin-1 and p62 showed a tendency to increase after CQ intervention. 5. Activation of autophagy induced the transformation of M2 cells, while inhibition of autophagy induced M1 activation.

Conclusions: Autophagic flow can regulate the mutual transformation of macrophage M1/M2 phenotype. But changes in a single marker can't confirm the level of autophagy in the cell, the dynamic changes in autophagy flow need to be evaluated.



FR-PO155

Molecular Magnetic Resonance Imaging of Allysine to Quantify Renal Fibrogenesis

Bryan C. Fuchs, Yinching I. Chen, Diego Dos santos ferreira, Gunisha Arora, Ricard Masia, Ivy Rosales, Robert B. Colvin, Peter Caravan. *Massachusetts General Hospital, Boston, MA.*

Background: Chronic kidney disease (CKD), most commonly caused as result of type-2 diabetes or ischemic/hypertensive nephropathy, currently affects 12% of all adults in the US. The fibrotic deposition and remodeling of extracellular matrix proteins to form cross-linked collagen fibers is a characteristic feature of CKD and eventually results in end stage renal disease. Critical to fiber formation is the enzymatic production of allysine on collagen, which facilitates fibril cross-linking through condensation reactions with neighboring allysine and lysine residues. We have developed a novel Gd-based MRI probe, GdOA, designed to target allysine for noninvasive imaging of active fibrogenesis in kidney disease.

Methods: The ability of GdOA to detect fibrogenesis was evaluated in two animal models of CKD - nephrotoxic serum nephritis (NTN) and Col4a3-/- Alport mice. For the NTN model, 129/SvEv mice were dosed at day 0 with 250 μg Sheep IgG and then with 125 μL sheep anti-rat GBM serum on day 5. Control animals received PBS injections. Animals were imaged 7 days post GBM serum injection. For the Alport model, wild type and Col4a3-/- mice were imaged at 6-10 weeks of age to assess mild and advanced stages of disease. Following MRI, kidneys were collected and assessed for hydroxyproline (HYP) content and tissue histology.

Results: The NTN model resulted in diffuse tubular injury, glomerulosclerosis, and mild fibrosis. GdOA resulted in a 6.9 fold increase in ΔR1 (probe relaxivity) in the cortex of the NTN group compared to control mice ($p = 0.048$). Hydroxyproline content in tissue was 1.88 fold higher for NTN animals compared to control animals ($p = 0.0004$) and ΔR1 showed positive correlation with increasing HYP concentrations ($r = 0.625$). In the Col4a3-/- mice, Gd-OA was able to detect early stages of disease and also correlated with increasing HYP concentrations.

Conclusions: The requirement of allysine for the crosslinking of ECM proteins makes it a valuable biomarker of fibrogenesis. GdOA is an oxyamine derivative of GdDOTA designed for targeted binding to allysine, with minimal off-target accumulation and rapid renal excretion. GdOA MRI demonstrated a strong correlation with the extent of disease in two animal models of CKD and therefore might provide a novel means to quantify early stages of renal fibrosis in patients.

Nicorandil Plays a Protective Role Against Renal Fibrosis in Unilateral Ureteral Ligation Models via Reducing TGF-β1/Collagen Expression and Improving Energy Metabolism

Yingying Chen, Lan Chen, Yisheng Ling, Tianjun Guan. *Department of Nephrology, Zhongshan Hospital, Xiamen University, Xiamen, China.*

Background: As one of most important metabolic sensors, ATP-sensitive potassium channels (KATP) could regulate cellular activity to meet energetic demands. It has also been demonstrated that KATP plays a protective role on several ischemia-associated diseases. However, there are few studies to clarify whether KATP opener could directly improve renal function or renal fibrosis in unilateral ureteral ligation (UUO) models. This experimental study was designed to clarify the effect and mechanism of nicorandil (a KATP opener) on renal dysfunction, extracellular matrix expression and ATP generation in mice renal fibrosis model caused by unilateral ureteral ligation.

Methods: Mice UUO models were developed and observed at 7th and 14th day after operation. There were three groups in our study: sham-operation (n=12), UUO (n=12), UUO+nicorandil (n=12). In nicorandil treatment group, nicorandil was injected intraperitoneally daily (20mg/kg/d) for 12 days from the third day of UUO operation. Renal function and ATP synthesis (using an ATP assay kit, FLAA, Sigma, USA) were detected at 7th and 14th day after operation. Masson trichrome staining was performed to analyze collagen generation. TGF-β1 and Smad3 were detected by Western blot.

Results: Compared with sham-operation group, UUO groups had a significantly higher serum level of creatinine (7th day: 55.9±4.8 vs. 35.7±3.2μmol/L, $P<0.01$; 14th day: 82.0±7.8 vs. 35.2±6.2μmol/L, $P<0.01$). Nicorandil treatment not only reduced serum creatinine level (7th day: 45.7±3.6 vs. 55.9±4.8μmol/L, $P<0.05$; 14th day 64.3±5.5 vs. 82.0±7.8μmol/L, $P<0.01$), but also reduced collagen volume fraction (7th day: 10.5±2.8% vs. 17.6±3.8%, $P<0.01$; 14th day: 16.4±3.8% vs. 34.2±5.2%, $P<0.01$). We also found that TGF-β1 and Smad3 expression were significantly reduced in nicorandil treatment group. Furthermore, renal ATP synthase was also improved significantly (sham operation group: 8.55±2.74 nmol/L; UUO group: 2.92±1.96 nmol/L; UUO+nicorandil group: 4.88±1.48 nmol/L, $P<0.05$).

Conclusions: KATP opener nicorandil protected against UUO-induced renal fibrosis, which were associated with TGF-β1/collagen expression and energy metabolism recovery.

Vitamin D Receptor (VDR) Expression Determines Initiation and Progression of Renal Lesions in HIV-Transgenic Mice with Variable Angiotensinogen (Agt) Copies

Himanshu Vashistha,[2] Vinod Kumar,[4] Xiqian Lan,[3] Ashwani Malhotra,[5] Pravin C. Singhal.[1] *[1]North Shore LIJ Health System, Great Neck, NY; [2]Ochsner Health System, New Orleans, LA; [3]Feinstein Institute for Medical Research, Manhasset, NY; [4]Fienstine Institute for Medical Research, NEW YORK, NY; [5]Feinstein Institute Medical Research and NSLIJ, MANHASSET, NY.*

Background: Agt transgenic mice have been shown to carry higher serum and cellular levels of Angiotensin II levels and associated downstream effects. Since Ang II has been shown to play a role in the progression of HIVAN, we hypothesized that mice with enhanced expression of Agt would display a rapid progression of renal lesions in a mouse model of HIVAN. We evaluated the effect of different copies of Agt in the initiation and progression of HIVAN in genetically engineered HIVAN mice (Tg26) expressing variable copies of Agt.

Methods: Control and Tg26 mice with 2 (Tg26/Agt-2) and 4 (Tg26/Agt-4) copies of Agt were evaluated for severity of renal lesions, arteriosclerosis and hypertension at 8 weeks and 16 weeks. Renal cortical sections were stained with Sirus red and PAS. RNA was extracted from renal tissues and probed for AT1, AT2, VDR, and molecules involved in profibtotic and epithelial-mesenchymal transition (EMT) pathways. Renal lesions were graded for their severity.

Results: Tg26/Agt-4/8wks showed lower blood pressure ($P<0.01$) vs. Tg26/Agt-2/8 wks, while Tg26/Agt-4/16wks displayed higher blood pressure vs. Tg26/Agt-2/16wks. Tg26/Agt-4/8wks displayed attenuated expression of PAI-1 vs. Tg26/Agt-2/8wks; however, Tg26/Agt-4/16wks showed 3-fold greater PAI-1 expression than to Tg26/Agt-2/16wks. Tg26/Agt-2/8wks displayed attenuated expression of VDR and enhanced production of Ang II vs. Tg26/Agt-4/8wks; however, this pattern reversed at 16 wks. Tg26/Agt-4/8wks displayed attenuated expression of AT1 and AT2 and down-regulation of Tert, TGF-β, Snail, and vimentin when compared to Tg26/Agt-2/8wks. Nonetheless, all these markers were comparable between these groups at 16 wk of age. Tg26/Agt-2/8wks developed renal lesions which were more advanced than Tg26/Agt-4/8wks. Conversely, Tg26/Agt-4/16wks displayed more advanced renal lesions vs. Tg26/Agt-2/16wks

Conclusions: Tg26/Agt-4 displayed slower progression of HIVAN initially at 8 weeks associated with enhanced renal tissue VDR expression and attenuated expression of AT1, TGB-β, PAI-1, Tert and EMT markers. However, Tg26/Agt-4 at 16 wks displayed accelerated growth due to attenuated VDR expression leading to high blood pressure, upregulation of EMT and profibrotic molecules.

Sodium-Glucose Cotransporter 2 Inhibition Does Not Ameliorate Renal Progression in Adriamycin-Induced Nephropathy

Jin Joo Cha,[1] Jeong-Taek Lim,[1] Ji ae Yoo,[1] Jungyeon Ghee,[1] Hye sook Min,[2] Dae R. Cha,[1] Young Sun Kang.[1] *[1]Korea University, Ansan, Republic of Korea; [2]Wonkwang University Gunpo Hospital, Gunpo-si, Republic of Korea.*

Background: Sodium-glucose cotransporter 2(SGLT2) inhibitors target SGLT2 in renal proximal tubules and promotes glycosuria in type 2 diabetic mellitus, resulting in lowering blood glucose. Clinical studies have shown that SGLT2 inhibitors attenuate the progression of diabetic nephropathy, which results were not merely associated with improved glucose control. To understand the related mechanisms, we investigated the effects of SGLT2 inhibitior dapagliflozin (DAPA) in a mouse model of adriamycin (ADX)-induced nephropathy.

Methods: ADX induced nephropathy model resulted in severe proteinuria and progressive glomerulosclerosis. Seven week old Balb/c mice were divided in five groups;1) control with vehicle, 2) control with DAPA 3mg, 3) ADX(11.5mg/kg) with vehicle, 4) ADX(11.5mg/kg) with DAPA 1mg, 5) ADX(11.5mg/kg) with DAPA 3mg. With ADX injection, DAPA was administered via gavage for 2 weeks. Molecular analyses using RT-PCR, western blot and immunohistochemistry were performed.

Results: DAPA administration was associated with decreased systolic blood pressure (SBP) in control group, but not among ADX injected groups. DAPA administration did not alleviate proteinuria, glomerular sclerosis and interstitial fibrosis in the ADX-induced nephropathy. Also, there were no differences in the expressions of TGF-β, Smad2 and collagen IV in the renal cortex of ADX with DAPA groups compared to ADX control group. Expression of macrophage marker ED1 was significantly increased in the kidney of ADX control group. DAPA administration in ADX groups decreased macrophage infiltration in the renal medulla, whereas no significant difference was observed in the renal cortex. SGLT2 expressions in the kidney were decreased in DAPA groups as expected. Strangely, the expressions of SGLT2 increased in the medulla of ADX with DAPA groups.

Conclusions: SGLT2 inhibition with dapagliflozin had no effect on reduction in proteinuria and inflammatory changes in renal cortex of ADX-induced nephropathy. Our study suggest that SGLT2 inhibition may modulate inflammation in the renal medulla, which effect may have been masked by massive insult of cortex. More experimental studies on renal injury model is needed to clarify the underlying mechanisms.

Comprehensive Transcriptomic Mapping of Baseline and Pathological Human Kidneys at Single-Cell Resolution

Ayshwarya Subramanian,[1] Katherine A. Vernon,[3] Michal Slyper,[1] Julia Waldman,[1] Keith H. Keller,[3] Yiming Zhou,[3] Danielle Dionne,[1] Lan T. Nguyen,[1] Astrid Weins,[3] Orit Rosen,[1] Aviv Regev,[1] Anna Greka.[2] HCAKidney *[1]Broad Institute, Cambridge, MA; [2]Harvard Medical School, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA.*

Background: The heterogeneity of cell types and states in human tissues pose challenges for precision medicine and targeted therapeutics as not all patients present the same disease phenotype or treatment response. Most of our current understanding of cell-types comes from comprehensive histological observations of surface proteins and other molecules, gathered over the decades. However, recent advances in single cell and spatial genomics, such as single-cell RNA-Seq, now allow us to classify large numbers of individual cells by their profiles. In this study, as part of the Human Cell Atlas initiative, we aim to catalog cell-types in human kidney specimens obtained from healthy donors and patients with kidney diseases.

Methods: Discarded tissue from tumor nephrectomies was subjected to single-cell dissociation or single-nucleus isolation, the latter applicable to frozen tissue as well. Droplet-based single-cell or single nucleus RNA-Seq libraries were prepared, PCR amplified and sequenced. Single-cell profiles were clustered, and clusters were annotated post hoc based on known marker genes.

Results: We identified over 10 known cell-types, from around 2,000 cells from discarded healthy tissue. Recovered cell-types included both renal parenchymal and immune cells. Heterogeneity was observed in collecting duct and proximal tubular cells. Data-driven markers were inferred for the cell-types.

Conclusions: We have established working single-cell dissociation protocols optimized specifically for human kidney specimens with paired reproducible analyses and insights. Proportions of cell-types will be reported with more confidence as we gather more samples, and in comparison with specific disease phenotypes.

The Impact of Carbon Monoxide Poisoning on Long-Term Risk of CKD: A Nationwide, Population-Based Study in Taiwan

Kuangyu Wei, Chen-Yi Liao, Chia-chao Wu. *Tri-service general hospital, National defense medical center, Taipei, Taiwan.*

Background: Risk of chronic kidney disease (CKD) in patients with carbon monoxide poisoning (COP) and the hyperbaric oxygen (HBO) therapeutic effect had not been investigated.

Methods: Patients that survived after COP during index hospitalizations from 2000 to 2013 were identified in nationwide administrative registries. In a cohort study of 989,753 patients, we enrolled 8,616 COP patients and matched 34,464 comparison cohort as the non-COP group by propensity scores. Using this adjusted data, a possible association between COP and the risk of developing CKD was estimated using a Cox proportional hazard regression model. We further compared cumulative risk of CKD among COP patients stratified by HBOT with Kaplan-Meier analysis and the log-rank test.

Results: After a mean follow-up period of 4.28 years, the incident CKD rate was 261 per 10000 person-years. The COP group had higher risk (adjusted hazard ratio: 6.150; P < 0.001) than the non- COP group when measured over 4 years after CKD diagnosis. After stratification, the risk of CKD remarkably increased independent of status regarding sex, age, season and comorbidities (hypertension, diabetes mellitus, congestive heart failure, stroke, chronic obstructive pulmonary disease, liver cirrhosis, coronary artery disease, arrhythmia or hyperlipidemia) in the COP cohort. Age-specific COP to non-COP hazard was the greatest in the youngest group (18-29 years) (adjusted HR=34.18, 95% CI = 29.47–39.653). Additionally, HBOT did not result in statistically significant reduction in the risk of CKD in the COP cohorts (P=0.188, long-rank test).

Conclusions: The patients that survived after COP had a higher incidence of developing CKD. The results suggest that clinicians should enhance postdischarge follow-up of kidney function among COP patients

FR-PO161

The Presence of Simple Renal Cyst Is Associated with Increased Risk of Albuminuria in Young Adults

Hyo jin Boo,[1] Song in Baeg,[2] Minjung Kim,[1] Eun jeong Lee,[2] Wooseong Huh,[3] Dae Joong Kim,[4] Yoon-Goo Kim,[2] Ha Young Oh,[4] Jung eun Lee.[5] *[1]Samsung medical center, Seoul, Republic of Korea; [2]Samsung Medical Center, Seoul, Republic of Korea; [3]Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [4]Samsung medical center Sungkyunkwan University School of medicine, Seoul, Republic of Korea; [5]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: It is well-known that the prevalence of simple renal cyst increases with age. However, simple cysts are occasionally found in adults younger than 40 years of age. This cross-sectional study evaluated the clinical significance of simple renal cysts in young adults, focusing on the associations with hypertension and albuminuria.

Methods: Adults younger than 40 years who received comprehensive medical checkup from January 2005 to December 2013 were included. Simple renal cysts were identified by ultrasonography.

Results: Among 5832 young adults, renal cysts were found in 276 subjects (4.7%). Subjects diagnosed with polycystic kidney disease (n=5) or medullary sponge kidney (n=1) were excluded from the analyses. A single cyst and multiple cysts were found in 234 (4.0%) and 42 (0.7%) subjects, respectively. The locations of single cyst were cortex in 187, medulla in 26, and parapelvic region in 21. In univariate logistic regression analyses, age, male sex, body mass index, waist circumference, systolic blood pressure (SBP), hypertension, current smoking, high-density lipoprotein cholesterol, and uric acid levels were associated with a higher prevalence of simple cysts. Multivariate analyses of cysts showed that age (OR, 1.07; CI, 1.02-1.12), SBP (OR, 1.01; CI, 1.00-1.02), and hypertension (OR, 1.85; CI, 1.24-2.76) had independent associations with the presence of simple cysts. The subjects with cysts had a higher prevalence of albuminuria (defined as a urine albumin to creatinine ratio > 30μg/mg) than those without cysts (11.2% vs. 4.5%, P <0.001). Multivariate analyses of albuminuria revealed that the presence of simple renal cysts was associated with a 2.32-fold increase in the risk of albuminuria (95% CI, P <0.001). The location of the cysts was not related to the prevalence of albuminuria.

Conclusions: Age, SBP, and hypertension history were independently associated with simple renal cyst in adults younger than 40. The presence of the renal cyst was an independent risk factor of albuminuria.

FR-PO162

Renal Prognosis Evaluation with Contrast-Enhanced Ultrasound

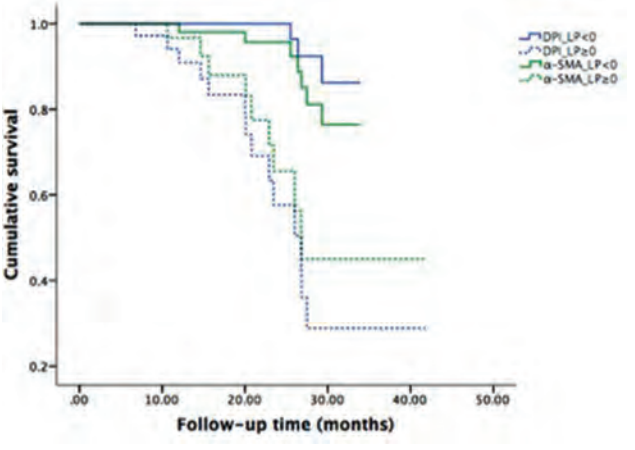
Yao Xu,[1] Shan Mou.[2] *[1]Ren Ji Hospital, school of Medicine, Shanghai Jiao Tong University Shanghai, PR China, Shanghai, China; [2]Renji Hospital, Shanghai, China.*

Background: The purpose of this initial study was to confirm the ability of contrast-enhanced ultrasound (CEUS) to detect and predict renal function changes in chronic kidney disease (CKD) patients. The prognostic efficacy of CEUS parameters was compared with that of the renal pathology.

Methods: Patients with biopsy-proved CKD and received CEUS were enrolled in this study. CEUS was performed after an intravenous bolus injection of 1.5 ml SonoVue (BR1; Bracco Milan, Italy). Time-intensity curves (TICs) and quantitative indexes were created using QLAB quantification software. All biopsies were analyzed with α-SMA immunohistochemistry. The Cox proportional hazards model retrospectively investigated risk factors on kidney survival.

Results: A total of 140 patients were followed for a median period of 22.0 months. In total, 18 (13%) patients exhibited CKD progression. Lower derived peak intensity (DPI) and higher resistance index (RI) was noted in CKD progression group. Multivariate Cox regression analysis revealed that the DPI associated with progression of kidney disease. Based on which, linear predictor score (LP) was made. Kaplan-Meier curve showed that DPI had the similar ability as fibrosis to estimate the risk of kidney progression for each CKD patient. Patients with a LP-DPI≥0 were less likely to recover from CKD progression. The area under the receiver operating characteristic (ROC) curves for the model of DPI was 0.82 (95%CI, 0.60-0.96, P<0.001) with a sensitivity of 82% and a specificity of 78%.

Conclusions: This study demonstrated that the DPI might be the most valuable CEUS parameter for the evaluation of renal function deterioration risk. The DPI could serve as an independent predictor of the long-term prognosis of CKD patients.



Kaplan-Meier plots showing renal survival stratified by linear predictor score (LP) from the multivariate Cox proportional hazards model included DPI and α-SMA.

FR-PO163

Doppler Indexes of the Renal Cortex Are Independently Related to Renal Perfusion in Hypertensive CKD Patients

Arkadiusz Lubas, Stanislaw Niemczyk. *Military Institute of Medicine, Warsaw, Poland.*

Background: In many studies, Resistive Index measured in segmental or interlobular intrarenal arteries has been used interchangeably as an equivalent of renal perfusion. Due to the diverging region of measurement, achieved indexes are significantly different. However, they were not compared to the renal perfusion estimated in the independent

method. The study aimed to investigate relations between different renal Doppler indexes (segmental renal Resistive Index (sRI), cortical renal Resistive Index (cRI), cortical renal Pulsatility Index (cPI)) and Renal Perfusion (RP) measured in contrast-enhanced computed tomography.

Methods: In fifteen patients (6F, 9M; age 61.5 ±19.3) with unilateral renal artery stenosis, ultrasound examination (GE Logic P6) with the estimation of sRI (a mean of 3 measurements using a Pulsed Wave Doppler); cRRI and cRPI (3-5 seconds movie of Color Doppler with PixelFlux software [Chameleon Software, Germany]) was performed. Then contrast-enhanced multidetector computed tomography (GE Discovery 750 HD) of renal and intrarenal arteries was completed, and a Renal Blood Flow in a whole cortex (cRBF, [mL/s/100g]) was measured. The data from 15 kidneys without a stenotic artery were considered for statistics. Based on creatinine, estimated glomerular filtration rate (eGFR) was calculated using MDRD formula.

Results: Values of intranenal indexes were estimated: sRI = 0.710 ±0.107; cRI = 0.751 ±0.185; cPI = 1.515 ±0.614, whereas mean RP = 206.8 ±64.9 ml/s/100g and eGFR = 54.8 ±29.6 ml/min/1.73m^2. All intrarenal Doppler indexes correlated significantly with age, eGFR, and with each other. In addition, cRI and cPI correlated with RP ($r = -0.547$, $p < 0.05$ and $r = -0.655$, $p < 0.05$, respectively). The multivariable regression analysis adjusted to age and eGFR showed independent connection between cRI and RP ($b = -0.55$; $R^2 = 0.30$, $p < 0.035$). In the same regression model, cPI independently related to RP ($b = -0.65$; $R^2 = 0.43$, $p < 0.008$). However, relation to RP was not significant for sRI ($p < 0.112$).

Conclusions: Doppler indexes measured in renal cortex area are independently related to the renal perfusion. Renal Resistive Index in segmental arteries should not be considered as a marker of renal cortical blood flow

FR-PO164

Oral Bisphosphonate Use and Renal Function Decline in Patients with CKD

Fergus J. Caskey,[1] Danielle E. Robinson,[2] Victoria Y. Strauss,[2] M sanni Ali,[3] Cyrus Cooper,[4] Yoav Ben-shlomo,[5] Bo Abrahamsen,[6] Antonella Delmestri,[2] Andrew Judge,[2,7] Muhammad K. Javaid,[2] Daniel Prieto-Alhambra.[2] *[1]UK Renal Registry, Southmead Hospital, Bristol, United Kingdom; [2]NDORMs, University of Oxford, Oxford, United Kingdom; [3]London School of hygiene and tropical medicine, London, United Kingdom; [4]MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton, United Kingdom; [5]School of Social and Community Medicine, University of Bristol, Bristol, United Kingdom; [6]University of Southern Denmark, Odense, Denmark; [7]Translational Health Sciences,University of Bristol, Bristol, United Kingdom.*

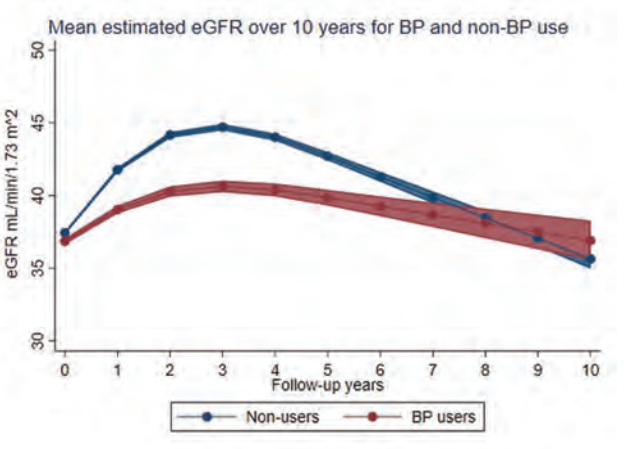
Background: Oral bisphosphonates (BP) are contraindicated in patients with moderate-severe chronic kidney disease (CKD) due to concerns regarding their effects on renal function. The aim of this study was to assess the effect of BP use on CKD stage worsening and annual changes in estimated glomerular filtration rate (eGFR) over time.

Methods: Patients aged 40+ with an eGFR<45 in UK primary care (CPRD) linked to hospital records. Followed for up to 10 years. BP users censored 210 days after the last BP prescription. Unexposed patients could become exposed; 10-year follow up re-started. Users were matched to up to 5 non-users using propensity scores (PS), stratified by the number of years of follow-up. Cox regression was used to estimate the hazard ratio (HR) of stage worsening. The rates of annual eGFR changes were estimated by the slopes of a mixed effect model with cubic splines and an interaction between BP use and time.

Results: 31275 patients (6309 BP users) were included in the PS matched analyses. 3,978 (13%) patients moved to a later stage. The HR for BP users was 1.69 (95% confidence interval (CI): 1.58, 1.80). Annual eGFR changes were different for BP users and non-users (Figure). In the first three years, the mean eGFR increased at the rate of 2.58 (2.50, 2.66) and 0.91 (0.65, 1.17) mL/min/1.73 m^2 per year for non-users and users, respectively. They were followed by slow decline slopes of -0.80 (-0.89, -0.70) and -0.24 (-0.55, 0.08) per year. No significant difference in mean eGFR after 8 years.

Conclusions: BP use has a 70% higher likelihood of worsening in CKD stages. Further research is needed to understand the longitudinal changes in eGFR trajectories.

Funding: Government Support - Non-U.S.



FR-PO165

Proton Pump Inhibitor Use and Progression to Major Adverse Renal Events: A Competing Risk Analysis

Christopher H. Grant,[2] Keith Gillis,[1,2] Jennifer S. Lees,[1,2] Jamie P. Traynor,[2] Patrick B. Mark,[1,2] Kathryn K. Stevens.[2] *[1]University of Glasgow, Glasgow, United Kingdom; [2]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom.*

Background: Proton pump inhibitors (PPIs) are commonly prescribed in primary and secondary care. PPIs are associated with acute tubulointerstitial nephritis, but their association with chronic kidney disease (CKD) is uncertain. We aimed to determine if PPI use is associated with adverse renal outcomes or survival in patients with CKD.

Methods: We conducted a retrospective observational cohort study comprising patients with CKD attending a secondary referral renal clinic between 01/01/2006 and 31/12/2016. Baseline exposure variables at start of PPI (PPI group) or study inception (control group) were derived for relevant clinical, socio-demographic and biochemical data. The primary outcome was a composite measure of doubling baseline creatinine or end stage renal disease (ESRD) denoted *Major Adverse Renal Events* (MARE). We defined tubular dysfunction as potassium or magnesium below laboratory normal range. A competing risks survival analysis evaluated the association between PPI exposure and MARE, with the competing risk of death.

Results: There were 7765 patients referred to a secondary care renal clinic during the study period: 6734 were included in the analysis of which 2928 were prescribed a PPI. The PPI group had more men (51.3 vs 48.7%, p=0.04) with higher GFR (35.6 vs 32.0, p<0.001), but similar burden of cardiovascular disease (69.2 vs. 67.4, p=0.13) and diabetes (61.8 vs 63.9%, p=0.09), and the same age (68.5 vs 68.0 years, p= 0.02). There was more tubular dysfunction in the PPI group (59.2 vs. 54.2%, p<0.001). In a competing risks survival analysis, there was no difference between progression to death (p=n/s), but greater progression to MARE in the PPI group (log rank p<0.001). After adjustment for the competing risk of death, the factors associated with progression to MARE were tubular dysfunction (SHR 2.33, 95% CI 20.80-2.60, P<0.001), diabetes (SHR 1.39, 95% CI 1.26-1.54, P<0.001) and hypereosinophilia (SHR 1.71, 95% CI 1.53-1.92, P<0.001). PPI use was not associated with increased risk of progression to MARE on multivariable adjustment.

Conclusions: PPI use may not be associated with progression to MARE in patients with renal impairment. Tubular dysfunction, hypereosinophilia and diabetes were associated with MARE regardless of PPI use. Further prospective analysis is required to validate these findings

FR-PO166

Discontinuation of Proton Pump Inhibitors in Patients with CKD

Amanda Mertz,[1] Danielle N. Cooney,[1] Mahboob Rahman,[2,1] Chirstopher S. Lacey,[1] Christopher J. Burant,[1] Niraj Desai.[2,1] *[1]Northeast Ohio VA Healthcare System, Cleveland, OH; [2]Case Western Reserve University, Cleveland, OH.*

Background: Proton pump inhibitors (PPIs) are commonly used medications in the US and are historically well tolerated. Recent studies have linked PPI use to development of chronic kidney disease (CKD) and end-stage renal disease (ESRD). We investigated whether discontinuation of PPIs in patients with CKD results in slower kidney disease progression compared to patients who continued PPIs.

Methods: This is a retrospective chart review of patients with established CKD taking a PPI from January 1, 2014 to December 31, 2014. Patient's eligible for inclusion were those with established CKD, defined as 2 eGFR measurements of < 60 ml/min/1.73m^2 at least 90 days apart, who were on a PPI from January 1, 2014 to December 31, 2014, with a medication possession ratio (MPR) of ≥70%. Patients were excluded if they were on dialysis at baseline and did not have baseline and final eGFR measurements. We compared baseline eGFR to a final eGFR after at least 6 months of discontinuation or continuation of a PPI.

Results: 100 patients in the PPI discontinuation group and 97 patients in the PPI continuation group met study inclusion criteria. Baseline renal function in the PPI

continuation group was eGFR of 47.9 ml/min/1.73 m^2 and 50.7 ml/min/1.73 m^2 in the PPI discontinuation group. Final eGFR in the PPI continuation group was significantly higher at 51.1 ml/min/1.73m^2 (p=0.01). Final eGFR in the PPI discontinuation group was 51.8 ml/min/1.73m^2 (p=0.3). The average time between baseline and final eGFRs was 270 days in the PPI continuation group and 301 days in the PPI discontinuation group. There was no statistically significant difference in the change in eGFRs between groups (95% CI -5.48-2.03; p=0.37).

Conclusions: Discontinuing a PPI after one year of continuous use in patients with CKD did not impact change in renal function after one year.

FR-PO167

Determining the Association of Allopurinol Prescription on Progression of Renal Dysfunction and Progression to Renal Replacement Therapy in Patients with CKD

Andrew J. Mallett,[1,2] Andrew S. Jeyaruban,[1,2] Anne Cameron (Salisbury),[2] Jianzhen Zhang,[2] Helen G. Healy,[1,2] Wendy E. Hoy.[2] on behalf of the CKD.QLD consortium *[1]Kidney Health Service, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [2]CKD.QLD and the NHMRC CKD.CRE, The University of Queensland, Brisbane, QLD, Australia.*

Background: Reports in the literature link hyperuricaemia with incident chronic kidney disease CKD. However, the relationship between allopurinol prescription and progression of renal dysfunction is not well understood. We aimed to determine the association of allopurinol prescription and changes in kidney function amongst patients with CKD.

Methods: A retrospective cohort study of 1,123 patients of a tertiary teaching hospital registered in the CKD.QLD registry between January 2011 and August 2017 (minimum of 2 years follow-up). Subject demographics (age), health data (BMI, comorbidities, laboratory test results) and allopurinol prescription were extracted from integrated medical records. Delta eGFR (CKD-EPI)was calculated as the difference between latest eGFR and initial eGFR. Subjects were stratified into two groups based on prescription of allopurinol.

Results: Subjects prescribed allopurinol were older (70.7 vs 65.8; p<0.01), had higher BMI (32.3kg/m^2 vs 30.5kg/m^2; p<0.01), worse renal function (35.2mL/min/1.73m^2 vs 43.6mL/min/1.73m^2; p<0.01), higher urate level (0.47mmol/L vs 0.42mmol/L; p<0.01) as well as higher proportion of diabetes (54% vs 46%; p=0.04), dyslipidaemia (54% vs 41%; p<0.01), hypertension (84% vs 72%, p<0.01) and gout (54% vs 11%; p<0.01). The proportion of subjects treated with allopurinol increased with CKD stage; stage 1:1.5%, stage 2:7.1%, stage 3: 21.7%, stage 4: 21.4% stage 5:17.3%. Prescription of allopurinol did not have a significant association with delta eGFR in patients with hyperuricaemia (1.8mL/min/1.73m^2/yearvs 1.6mL/min/1.73 m^2/year; p=0.2) or gout (2.2mL/min/1.73m^2/year vs 1.8mL/min/1.73m^2/year; p=0.5). Nor was allopurinol prescription in the subgroup with serum urate level < 0.36mmol/L associated with a significant change in delta eGFR (3.5mL/min/1.73m^2/year vs 1.6mL/min/1.73m^2/year;p=0.17). Multivariate analysis adjusting for age and comorbidities found no significant association of allopurinol prescription with either delta eGFR or progression to kidney replacement therapy (p>0.05).

Conclusions: Allopurinol prescription was more prevalent in advanced CKD. However, it did not appear to be independently associated with deterioration of kidney function.

FR-PO168

Association Between Plasma Myostatin Levels and Loop Diuretic Use in Non-Dialysis-Dependent CKD Patients

Seiko Ishikawa,[1,2] Shotaro Naito,[2] Soichiro Iimori,[2] Kiyoshi Isobe,[2] Naohiro Nomura,[2] Eisei Sohara,[2] Tomokazu Okado,[2] Tatemitsu Rai,[2] Shinichi Uchida.[2] *[1]Tokyo Kyosai Hospital, Tokyo, Japan; [2]Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: Myostatin (MSTN) is mainly synthesized in skeletal muscles and acts as a negative regulator of skeletal muscle mass. It is up-regulated in patients with chronic kidney disease (CKD) and considered to be associated with the development of sarcopenia. Recently, we have reported that loop diuretics, commonly used in patients with advanced CKD, suppress skeletal muscle differentiation (Mandai S. Sci Rep. 2017). So far, the association between serum MSTN (sMSTN) levels and loop diuretic use is unknown.

Methods: We conducted a cross-sectional study comprised of 362 non-dialysis-dependent CKD patients over 20 years of age. The primary outcome was sMSTN levels. Multiple linear regression analyses were conducted to assess the associations between sMSTN levels (logarithmically transformed) and baseline characteristics including skeletal mass index (SMI). Interaction between loop diuretic use and SMI to sMSTN levels was estimated after stratifying patients by loop diuretic use. We calculated SMI as follows: Total body skeletal muscle mass measured by DEXA was divided by height squared.

Results: Median age was 71 years, 64.4% were male, mean SMI was 6.49 kg/m^2, mean eGFRcysC was 39.0 ml/min/1.73m^2, median sMSTN level was 1130 pg/ml, and 14.6% were treated with loop diuretics. Multivariate analysis showed that sMSTN levels were positively correlated with SMI (β=0.128, *P*<0.001), and negatively with eGFRcysC and loop diuretic use (β=-0.004, *P*=0.005 and β=-0.231, *P*<0.001, respectively). When stratified by loop diuretic use, adjusted coefficient β of SMI for sMSTN was higher in patients treated with loop diuretics than in patients not treated with loop diuretics (β=0.237, *P*=0.001 and β=0.118 *P*<0.001), respectively).

Conclusions: Loop diuretic use was independently associated with lower sMSTN levels. This result indicates that loop diuretics serve as negative regulator of skeletal muscle mass and therefore sMSTN levels may be attenuated by negative feedback. However, the increase of sMSTN level associated with SMI among the patients treated with loop diuretics was larger than those without loop diuretics. Other potential factors which elevate sMSTN levels in patients treated with loop diuretics are suggested to affect the relationship between sMSTN levels and SMI.

FR-PO169

Circulating ADAM17 Activity as a Marker of CKD Progression

Vanesa Palau,[1] Maria Jose Soler,[1,2] David Benito,[1] Jose M. Valdivielso,[3] Angels Betriu,[3] Elvira Fernandez,[3] Julio Pascual,[1,2] Marta Riera.[1] *[1]Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain; [2]Parc de Salut Mar. Fundació IMIM, Barcelona, Spain; [3]IRB LLEIDA, LLEIDA, Spain.*

Background: Several substrates for ADAM17 have been identified, including TNF-α, EGFR ligands, L-selectin, VCAM-1 and angiotensin converting enzyme(ACE)2. We have studied circulating ADAM17 in chronic kidney disease(CKD) patients from the NEFRONA cohort study.

Methods: 2032 patients without history of CV disease from an observational and multicenter study (NEFRONA project) divided into two groups: non-dialysis CKD stage 3-5 patients and control patients were studied. Baseline circulating ADAM17 activity was analyzed using a fluorimetric assay in plasma samples. Increased serum creatinine and dialysis requirement after 24months of follow-up depending on basal circulating ADAM17 activity were studied. Logistic regression analyses were used to identify predictors of increasing serum creatinine and risk of dialysis requirement.

Results: Circulating ADAM17 activity was significantly increased in CKD3-5 patients as compared to CONT(p<0.05). Baseline circulating ADAM17 activity was higher in patients with a 30% increase in serum creatinine levels after 2 years(p<0.05). Circulating ADAM17 activity was also higher in patients that needed dialysis in comparison with patients that maintained kidney function(p<0.05). After multivariate logistic regression analysis we found an interaction between sex and sADAM17 activity for increasing 30% serum creatinine, dialysis requirement and composite renal outcome(p<0.05). Therefore, we decided to perform the analysis stratifying by sex. Increased ADAM17 activity was independently associated with CKD progression regarding 30% increase in serum creatinine, dialysis requirement and composite renal end point but only in males. In females, ADAM17 activity was not associated with CKD progression.

Conclusions: Circulating ADAM17 activity was increased in CKD patients. Circulating ADAM17 activity was increased in patients that doubled serum creatinine and/or patients that need dialysis therapy being an independent predictor of worsening renal function in males.

Association of Serum Uromodulin with ESRD and Kidney Function Decline in the Elderly – The Cardiovascular Health Study

Dominik Steubl,[1] Petra Buzkova,[8] Pranav S. Garimella,[2] Joachim H. Ix,[2] Prasad Devarajan,[3] Michael R. Bennett,[4] Paulo H. Chaves,[7] Michael Shlipak,[5] Mark J. Sarnak.[6] *[1]Tufts Medical Center, Tufts University, Boston, MA; [2]UCSD, San Diego, CA; [3]Cincinnati Children's Hospital, Cincinnati, OH; [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [5]San Francisco VA Medical Center, San Francisco, CA; [6]Tufts Medical Center, Boston, MA; [7]Florida International University, Miami, FL; [8]UW, Seattle, WA.*

Background: Uromodulin is released by tubular epithelial cells into the serum (sUMOD) and low levels are associated with tubular atrophy and interstitial fibrosis (IF/TA). However, little is known about the association of sUMOD with long-term kidney outcomes in the elderly, a population with a high prevalence of IF/TA.

Methods: We assessed the association of sUMOD with end-stage-renal-disease (ESRD) in a random subcohort (n=933) plus all additional cases of ESRD in the Cardiovascular Health Study using a modified Cox regression analysis. We also evaluated the association of sUMOD with kidney function decline (≥30% decline of estimated glomerular filtration rate (eGFR) at 10 years of follow up) using logistic regression. Sampling for the latter was from the random subcohort as well as all additional cases. Models were adjusted for demographics, eGFR, albuminuria and other risk factors.

Results: Mean age of the random subcohort was 78 years, 40% were male, and 15% were non-white. Mean±SD sUMOD level was 127±64 ng/ml and eGFR was 63±19 ml/min/1.73 m^2. 53 participants experienced ESRD during a median follow-up 9.9 years. Higher sUMOD was associated with lower hazard for ESRD in univariate analysis (Figure). In multivariable analysis each 1 SD higher sUMOD was associated with a 63% lower risk of ESRD (HR 0.37 (95%-CI 0.14-0.95)). 179 participants experienced kidney function decline. In demographic adjusted analyses, higher sUMOD was associated with lower

odds of kidney function decline (OR 0.75 (0.60-0.95)); after multivariable adjustment, the association was attenuated and no longer significant (OR 0.88 (0.68-1.14)).

Conclusions: Low levels of sUMOD may identify persons at increased risk for ESRD.

Additional support was provided by R01AG023629 from the NIA. PD was supported by National Institutes of Health grant P50 DK096418. PSG is supported by National Institutes of Health training grant 5 T32 DK007777-13.

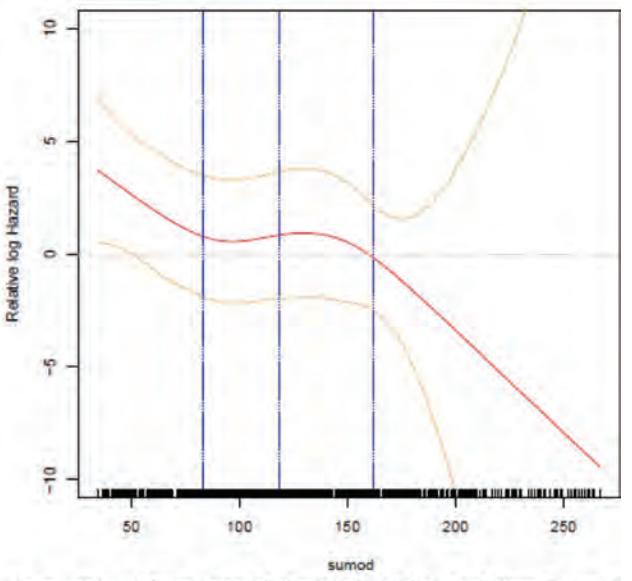

Figure: Association of serum uromodulin (sumod) with End-Stage Renal Disease. The model was fitted using restricted cubic splines with sumod as the exposure variable. The red solid line indicates the individual logarithmic hazard ratio, the yellow dotted lines the individual 95%-confidence interval. The vertical dotted purple lines separate the quartiles according to sumod levels. The lowest and highest 2.5% of the observations were excluded to minimize the influence of extreme values and outliers.

FR-PO171

Monocyte as a Marker of Renal Damage in Patients with Glomerular Hyperfiltration and Early CKD

Sewon Oh,[1] Junyong Lee,[2] Jihyun Yang,[2] Myung-Gyu Kim,[1] Sang-Kyung Jo.[1] *[1]Korea University Anam Hospital, Korea University College of Medicine, Seoul, Republic of Korea; [2]Korea universtiy Anam hospital, Seoul, Republic of Korea.*

Background: Experimental studies have shown that monocyte/macrophages play an important role in progression of chronic kidney disease (CKD). Recent epidemiologic study also suggests a significant association between higher monocyte count and risk of incident CKD in humans. Glomerular hyperfiltration (GH) is known as an early marker of progressive CKD in diverse clinical conditions. However, not all patients with GH progressed to CKD and monocyte may be associated with renal injuries caused by GH. The purpose of this study is to examine whether higher monocyte count is associated with GH and progressive kidney disease.

Methods: A longitudinal observational cohort study was performed using data from regular health checkup examinations in tertiary hospital during 2004-2017. We analyzed 56,258 adults at initial examination and selected 16,695 adults who had initial estimated glomerular filtration rate (eGFR) ≥ 60 ml/min/1.73m^2 with at least two tests of eGFR in follow-up analysis. Monocyte count was categorized into sex-specific quartiles. GH was defined as the upper 2.5 percentile of eGFR in the total population.

Results: The monocyte count showed a U-shaped association with eGFR. The monocyte count was significantly higher in participants with eGFR ≥ 120, 60-74, 45-59, 30-44, and <30 ml/min/1.73m^2 compared with those with eGFR 90-104 ml/min/1.73m^2 at initial examination (N=56,258, P≤0.025). The highest quartile of monocyte count was independently associated with GH in multivariate analysis compared with the lowest quartile (OR, 1.278; 95% CI, 1.070-1.525). In participants without GH, the highest quartile of monocyte count was associated with the higher risk of ≥ 25% eGFR decline (RR, 1.859; 95% CI, 1.254-2.755) and the development of proteinuria (RR, 1.377; 95% CI, 1.135-1.671) compared with lowest quartile. In participants with GH, the highest quartile was also associated with increased risk for the development of proteinuria (RR, 5.833; 95% CI, 1.196-28.453), but was not associated with ≥ 25% eGFR decline.

Conclusions: Higher monocyte count is associated with progressive CKD. In addition, monocyte count could be a marker to identify patients at risk for progression of kidney disease in GH.

FR-PO172

The Plasma Growth Differentiation Factor-15 Levels as Useful Biomarker for Renal Impairment in the Elderly: Korean Frailty and Aging Cohort Study

Hyung-seok Ihm, Jin sug Kim, Su Woong Jung, Chun-Gyoo Ihm, Kyung-hwan Jeong, Tae won Lee, Ji yung Lee, Hyeon Seok Hwang. *Kyung Hee University, School of Medicine, Seoul, Republic of Korea.*

Background: Growth differentiation factor-15 (GDF-15) expression has been reported to increase in response to tissue damage, and has recently emerged as a useful biomarker for various diseases. Although accumulating evidence supports the prognostic value of GDF-15 in renal impairment, few studies have analyzed it in the elderly. Thus, we conducted a cross-sectional study to investigate the association between plasma GDF-15 level and renal function in the elderly.

Methods: The present study was based on the baseline data of the Korean Frailty and Aging Cohort Study (KFACS), a nationwide cohort study that began in 2016. Of the 1,559 participants assessed in the first year, 443 with available plasma GDF-15 data were enrolled in this study. We investigated the association of plasma GDF-15 level with clinical and biochemical parameters. The study population was divided into two groups according to renal function (chronic kidney disease [CKD] and non-CKD groups) to analyze diagnostic predictive value for CKD.

Results: In a simple regression analysis, the level of plasma GDF-15 was negatively correlated with the estimated glomerular filtration rate (eGFR; $r = -0.383$, $p < 0.001$). In multiple linear regression analysis, GDF-15 level was still significantly correlated with eGFR, even after adjusting for other parameters ($r = -0.259$, $p < 0.001$). Plasma GDF-15 level was significantly higher in the elderly with CKD than in those with non-CKD (2364.025 ± 1052.23 ng/L and 1451.23 ± 835.79 ng/L, respectively, $p < 0.001$). The optimal cut-off value for CKD-predicting GDF-15 level was 1699.4 pg/mL (76.5% sensitivity and 76.0% specificity), as determined by receiver operating characteristic curve. The area under the curve was 0.793 ± 0.033 (95% CI 0.729-0.857, $p < 0.001$).

Conclusions: Our results suggest that plasma GDF-15 level can be a useful biomarker for renal impairment in the elderly. Further large and prospective studies of extended duration are needed.

FR-PO173

Wide Pulse Pressure as a Risk Factor for Kidney Dysfunction

Tadashi Toyama,[2] Shinji Kitajima,[2] Akinori Hara,[2] Kiyoki Kitagawa,[1] Yasunori Iwata,[2] Norihiko Sakai,[2] Miho Shimizu,[2] Kengo Furuichi,[2] Takashi Wada.[2] *[1]Kanazawa Medical Center, Kanazawa, Japan; [2]Division of Nephrology, Kanazawa University Hospital, Kanazawa, Japan.*

Background: The risk of kidney dysfunction due to hypertension has been drawing attention especially for people who have the characteristics of advanced arteriosclerosis. However, the relationships from the aspect of systemic arteriosclerosis were not well known. Pulse pressure (PP) is a routinely measured vital sign and is thought to reflect the arteriosclerosis of elastic arteries. The aim of this study is to clarify the relationships between pulse pressure for development of kidney dysfunction. Risks related to systolic blood pressure (SBP) according to wide pulse pressure was also studied.

Methods: People aged 40 years or older who had a medical checkup in Kanazawa city were included in the analysis. Kidney dysfunction was defined as a decline of eGFR by 30% from baseline. PP was classified as normal (40–60 mmHg) and wide (>60 mmHg). Cox proportional hazard model was used to estimate the risks for kidney dysfunction associated with wide PP and SBP.

Results: A total of 36,134 people was included in the analysis. The mean age was 69 years. Incidence rates of kidney dysfunction for people with normal and wide PP were 8.1 and 15.2 (per 1000 person-years), respectively. After multivariable adjustments, hazard ratio for the kidney dysfunction associated with wide pulse pressure compared with normal pulse pressure was 1.40 (95% CI 1.25 – 1.57). In the stratified analysis by baseline PP, hazard ratios related to higher SBP (+10 mmHg) in normal and wide PP group were 1.14 (95%CI 1.07 – 1.22) and 1.12 (95%CI 1.06–1.19), respectively. Among the people with wide PP, people with baseline SBP ≥160 mmHg showed significant risk (HR 1.52 [95%CI 1.03–2.24]) compared with the people with SBP 120 – <130 mmHg (reference), whereas SBP 130 – 160 mmHg was not related to significant risks.

Conclusions: Wide PP was associated with higher risks for kidney dysfunction. More studies are needed regarding the risks related to mild hypertension accompanied by wide PP.

FR-PO174

Trends in Angiotensin Converting Enzyme Inhibitor and Angiotensin II Receptor Blocker Use Among Those with CKD in the United States

Daniel P. Murphy, Robert N. Foley. *University of Minnesota, Minneapolis, MN.*

Background: Angiotensin converting enzyme inhibitors or angiotensin II receptor blockers (ACE/ARB) are first-line anti-hypertensives in chronic kidney disease (CKD). Even though evidence-based treatment of hypertension has changed considerably, and hypertension is common in CKD, nationally-representative, contemporary information regarding ACE/ARB use in CKD is lacking.

Methods: We examined ACE/ARB trends and racial/ethnic and other demographic disparities among adult National Health and Nutrition Examination Survey participants from years 1999 to 2014 with creatinine-based estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73m^2 or albumin-creatinine ratio (ACR) ≥ 30 mg/g.

Results: 33.9% of participants with CKD used ACE/ARB. Although ACE/ARB use in CKD rose across the four eras studied ($P < 0.001$), estimates changed little in the last 3 eras:

1999-2002, 24.1%; 2003-2006, 33.0%; 2007-2010, 38.0%; and 2011-2014, 38.7%. ACE/ARB use was greater in those of non-Hispanic white (35.3%) and black (37.0%) and lower in those of Hispanic (25.4%) and other (28.7%) race/ethnicity. In models that adjusted for age, sex and race/ethnicity, ACE-ARBs were associated ($P < 0.05$) with: era (adjusted odds ratios (AOR) 1.52 [95% CI: 1.21-1.92] for 2003-2006, 1.94 [95% CI: 1.56-2.41] for 2007-2010, and 2.07 [95% CI: 1.64-2.62] for 2011-2014, vs. 1999-2002) and non-Hispanic black race/ethnicity (AOR 1.41 [95% CI: 1.18-1.68], vs. non-Hispanic white). Other multivariate associations included older age, male sex, BMI ≥ 30 kg/m^2, diabetes mellitus, hypertension, cardiac failure, and myocardial infarction.

Conclusions: ACE/ARB use is the exception in community-based CKD. Although use increased early in the current millennium, subsequent estimates remained static. When age and sex are considered, disparities against participants from racial/ethnic minority subgroups were not apparent.

FR-PO175

Kidney Function Outcomes Following RAAS Inhibition in Patients with Heart Failure

Wendy I. McCallum,[1] Hocine Tighiouart,[1] Elaine Ku,[2] Deeb N. Salem,[1] Mark J. Sarnak.[1] *[1]Tufts Medical Center, Boston, MA; [2]University of California San Francisco Medical Center, San Francisco, CA.*

Background: Blockade of the renin-angiotensin-aldosterone system (RAAS) is beneficial for cardiovascular outcomes in patients with heart failure with reduced ejection fraction (HFrEF), but is also associated with decline in estimated glomerular filtration rate (eGFR). Long-term kidney outcomes after RAAS inhibition remain unclear in HFrEF.

Methods: We performed a retrospective analysis of the Studies Of Left Ventricular Dysfunction (SOLVD) trials, in which participants with HFrEF were randomized to enalapril vs placebo in the Treatment Trial (n=2423) if symptomatic, and in the Prevention Trial (n=4094) if asymptomatic. Joint models were used to estimate rate of decline in eGFR. Multivariable Cox models were used to evaluate the association of enalapril vs placebo for the following 3 outcomes at any timepoint: 1) ≥0.3 mg/dl increase in serum creatinine, 2) ≥30% decline in eGFR, and 2) incident CKD Stage 4 or 5 as defined by new eGFR ≤30 ml/min/1.73m^2.

Results: A total of 6,517 participants randomized to enalapril (n=3254) or placebo (n=3263) were included in this analysis. Mean baseline eGFR was higher in Prevention vs Treatment (76.2±18.6 vs 69.5±19.8 ml/min/1.73m^2, p<0.01). Over a median follow-up of 24 months, mean eGFR declined at similar rates, -1.6 (95% CI -1.8,-1.4) for Prevention vs -1.7 ml/min/1.73m^2/year (95% CI -2.0, -1.5) for Treatment (p=0.51) (Figure). Only 1.4% in Prevention Trial and 4.5% in Treatment Trial reached CKD stage 4 or 5. In adjusted analyses, randomization to enalapril was associated with a higher hazard of increase in creatinine by ≥0.3 mg/dl (HR of 1.32, 95% CI 1.18, 1.47), decline in eGFR by ≥30% (HR 1.33, 95% CI 1.18, 1.50) and CKD Stage 4 or 5 (HR 1.43, 95% CI 1.05, 1.95).

Conclusions: GFR decline on average was slow in both trials and only a small percentage of patients with HFrEF reached incident CKD Stage 4 or 5 over a median of 2 years. Randomization to enalapril carried a higher risk of reaching all kidney function endpoints but it remains to be determined whether these differences are of clinical importance.

FR-PO176

Long-Term Incense Use and the Risk of ESRD

Tingting Geng,[1] Tazeen H. Jafar,[2] Jian-Min Yuan,[3] Woon-puay Koh.[2] *[1]National University of Singapore, Singapore, Singapore; [2]Duke-NUS Graduate Medical School, Singapore, Singapore; [3]University of Pittsburgh, Pittsburgh, PA.*

Background: Animal study suggests exposure to incense burning has deleterious effects on kidney function and architecture. However, the association between domestic incense burning and risk of end-stage renal disease (ESRD) has not been reported previously.

Methods: We investigated this association in the Singapore Chinese Health Study, a prospective population-based cohort of 63,257 Chinese men and women of 45-74 years of age in Singapore at recruitment during 1993-1998. Information on the practice of incense burning at home, diet, lifestyle and medical history was collected at baseline interviews. ESRD cases were identified through linkage analysis with the nationwide Singapore Renal Registry through 2015. We used Cox proportional hazards regression analysis to estimate hazard ratio (HR) and 95% confidence interval (CI) of ESRD associated with domestic incense burning.

Results: Among cohort participants, 76.9% were current incense users. After an average 17.5 years of follow-up, 1,217 (1.92%) ESRD cases were documented. Compared to never users, the multivariable-adjusted HR for ESRD was 1.05 (95% CI, 0.80 to 1.38) for former users and 1.26 (95% CI, 1.02 to1.57) for current users of incense. The ESRD risk was restricted only to current daily users with a history of more than 20 years; HR was 1.25 (95% CI, 1.07 to 1.46), compared with non-current users. Conversely, those who did not use incense daily or those who had used daily for ≤ 20 years had no increased risk.

Conclusions: Our findings demonstrate that long-term daily exposure to domestic incense burning could be associated with a higher risk of ESRD in Singapore Chinese.

FR-PO177

The Association Between Lead and Cadmium Co-Exposure and the Renal Dysfunction

Xiao Chen, Jing Chen. *Department of Nephrology, Zhongshan Hospital Fudan University, Shanghai, China.*

Background: Cadmium (Cd) and lead (Pb) exposure both can induce kidney damage. However, the effects of combined exposure to Cd and Pb on renal function at environmental levels have not been fully clarified. In this study we investigate the renal function in a Chinese population co-exposed to Cd and Pb.

Methods: A total of 331 subjects (215 women and 116 men), living in either a control or a polluted area, were included in this study. Cd and Pb in blood and urine (BCd, BPb, UCd, and UPb), and kidney effect markers including urinary N-acetyl-β-D-glucosaminidase (UNAG) and estimated glomerular filtration rate (eGFR), were determined, and the association between exposure markers and renal effects biomarkers were analyzed.

Results: The exposure levels in the polluted area were significantly higher than in the control area (all $p < 0.01$). The eGFR of subjects in the polluted area was decreased compared with that in the control area ($p < 0.01$). The subjects with high BCd/BPb (BCd ≥ 2 μg/L, BPb ≥ 100 μg/L) or high UCd/UPb (UCd ≥ 3 μg/g creatinine, UPb ≥ 10 μg/g creatinine) showed higher UNAG and UALB levels compared with other subgroups ($p < 0.01$). The probability of having elevated UNAG in subjects with high BCd/BPb was greater than those for with low BCd/BPb [odds ratio (OR) = 2.6, 95% CI: 1.4-4.7], low BCd/high BPb (OR =3.1, 95% CI: 1.4-6.6), and high BCd/low BPb (OR = 1.7, 95% CI: 0.9-3.2). The OR of subjects with low UCd and high UPb, high UCd and low UPb, and high UCd/UPb were 2.9 (95% CI: 1.4-5.7), 3.3 (95% CI: 1.5-7.2), and 7.7 (95% CI: 4.0-14.7), respectively, compared with those with low UCd/UPb. The risk of decrease in eGFR was also higher in subjects with high UCd/UPb than for those with low UCd/UPb (OR =7.2, 95% CI: 0.8-62.2).

Conclusions: Our data demonstrate that Cd and Pb exposure, alone or in combination, are associated with renal impairment. In addition, co-exposure to Pb and Cd propagates the renal tubular dysfunction compared with Cd or Pb exposure alone.

FR-PO178

Association of Hyperuricemia to Mesoamerican Nephropathy

Ramon Garcia-Trabanino,[1,2] Joel E. Romero alejo,[5,2] Maria V. Rodriguez,[3] Emmanuel Jarquin,[4] Juan J. Vindell.[3] *[1]Centro de Hemodialisis, San Salvador, El Salvador; [2]Emergency Social Fund for Health, Tierra Blanca, El Salvador; [3]Universidad de El Salvador, San Salvador, El Salvador; [4]AGDYSA, San Salvador, El Salvador; [5]Instituto Salvadoreño del Seguro Social, Jiquilisco, El Salvador.*

Background: Mesoamerican nephropathy (MeN) is considered a new entity among chronic kidney diseases (CKD), but still of uncertain etiology (CKDu). Some risk factors and characteristics identified through previous cross-sectional studies are: agriculture work -mainly sugar cane work-, hot environment, hyperuricemia and dysuria. The aim of our study was to reassess the role of hyperuricemia in adult subjects with altered kidney function (AKF) and without diabetes mellitus (DM) and hypertension (HTN), traditional risk factors of CKD.

Methods: The studied sample came from 10 communities in a known hotspot of MeN in El Salvador (Bajo Lempa region). We used a cross sectional design where incoming participants were grouped depending on different exposures: Group 1: previous diagnose of DM and/or HTN, and agriculture work; group 2: DM/HTN without agriculture; group 3: agriculture without DM/HTN, and group 4: non-DM/HTN without agriculture. They were included independent of previous diagnosis of CKD or hyperuricemia. Our primary outcomes were: AKF, defined by elevated serum creatinine (SCr) or eGFR <60 mL/min/1.72m2 (MDRD equation), and hyperuricemia, defined by elevated serum uric acid (male: >7 mg/dL, female: >6 mg/dL) or daily intake of allopurinol prescribed by a physician.

Results: 681 subjects were included: 58.4% female, mean age 42 years (SD ± 17.291) with the following distribution: group 1: 14 subjects, group 2: 20 subjects, group 3: 282 subjects, and group 4: 365 subjects. Frequency of AKF for each corresponding group: 78.5%, 45%, 23.40%, and 18.63%, p=0.000. The frequency of hyperuricemia in subjects without AKF was 15.68%, and with AKF 43.27%, p=0.000. Comparing all subjects with AKF and hyperuricemia we found that working in agriculture presented higher frequency (62.2%, p=0.006). Comparing those in groups 2 and 3 with AKF for hyperuricemia we found a frequency of 44.44% and 54.44%, respectively. With a multivariate analysis, DM, HTA, dysuria, and hyperuricemia were statistically associated to AKF (p<0.0001) but not agriculture work (p=0.094) or ever working in sugar cane culture (p=0.252).

Conclusions: More research with stronger design is needed to study this factor as it might seem that uric acid has a role in AKF in this region, mostly in those without traditional risk factors (CKDu).

FR-PO179

The Impact of Hyperuricemia on Kidney Failure and Mortality in a Multi-center CKD Cohort: An Instrumental Variable Analysis

Yong Chul Kim,[1] Jung Nam An,[2] Dong Ki Kim,[3] Chun Soo Lim,[2] Yon Su Kim,[4] Jung Pyo Lee.[2] *[1]SNUH, Seoul, Republic of Korea; [2]Seoul National University Boramae Medical Center, Seoul, SEOUL, Republic of Korea; [3]Seoul National University Hospital, Seoul, Republic of Korea; [4]Seoul National University College of Medicine, Seoul, Republic of Korea*.

Background: Hyperuricemia is an independent risk factor for mortality, cardiovascular disease, and renal disease in general population. However, the relationship between hyperuricemia with kidney failure and death in chronic kidney disease (CKD) remains controversial.

Methods: The study investigated the association between uric acid with all-cause mortality, end stage renal disease (ESRD) in 42,253 CKD patients in a multi-center cohort from 2001 to 2016. We used the regional prevalence of hyperuricemia (uric acid ≥ 6.8 mg/dL) as an instrument to test our hypothesis that hyperuricemia is associated with ESRD and mortality.

Results: In all subjects, the mean uric acid level was 5.4 ± 1.8 mg/dL. During a median year follow-up, there were 3,556 (8.42%) of renal failure and 5,094 (12.06%) of death in this cohort. Using an instrumental variable analysis after adjusting confounders such as age, diabetes, hypertension and estimated GFR (eGFR), we found evidence suggesting a causal relationship between hyperuricemia and increased risk of all-cause mortality (HR 3.131, 95% CI 2.043-4.797, P < 0.001). This tendency was consistent regardless of gender (male: HR 2.270, 95% CI 1.338-3.851, P = 0.002, female: HR 2.656, 95% CI 1.459-4.834, P = 0.001). On the contrary, higher uric acid concentrations were independently associated with reduced risk for kidney failure in the entire participants (HR 0.539, 95% CI 0.318-0.915, P = 0.022), especially in patients with reduced renal functions (eGFR below 30, HR 0.189, 95% CI 0.098-0.366, P < 0.001).

Conclusions: Instrumental variable analysis supports that uric acid concentration is an independent risk factor for all-cause mortality, while hyperuricemia might have protective effect for ESRD, especially in reduced renal function.

FR-PO180

Physical Activity Is Associated with the Incident CKD in Subjects with Normal Renal Function: Community Based Prospective Cohort Study

Jimin Park, Yooju Nam, Seon yeong Lee, Joohwan Kim, Ki Heon Nam, Seung Hyeok Han, Tae-Hyun Yoo. *Yonsei University College of Medicine, Seoul, Republic of Korea*.

Background: Physical exercise has a beneficial effect on the prevention of cardiovascular disease and diabetes via improvement in the cardio-metabolic disturbances and is associated with better survival in patients with various chronic diseases as well as general population. However, the effects of physical activity on renal outcomes remains unclear. We aimed to investigate the association between daily physical activity and the development of chronic kidney disease (CKD) in relatively healthy population with normal renal function.

Methods: Data were retrieved from the Korean Genome and Epidemiology Study, a prospective community-based cohort study. Daily physical activity was estimated by semi quantitative daily activity questionnaire. The eGFR calculated by the CKD-EPI equation from a total of 8,261 subjects were followed up biennially from 2001 to 2014. The primary endpoint was incident CKD, defined as a composite of eGFR <60 mL×min^{-1}×1.73 m^{-2} and/or the development of proteinuria during the follow up period.

Results: The mean age of study subjects was 52.0 years and 3,953 (47.9%) participants were male. At baseline, the mean eGFR was 94.16 ± 14.16 mL×min^{-1}×1.73 m^{-2}. And the average daily physical activity was 1443.3 ± 896.5 MET*h. During a mean follow-up duration of 119.2 (79.1 – 159.3) months, CKD newly developed in 1,518 (18.4%) subjects. The incidence of proteinuria and eGFR decline lower than 60 mL×min^{-1}×1.73 m^{-2} were 288 (3.5%) and 1,319 (15.9%) subjects, respectively. When divided into quartiles according to daily physical activity, Kaplan-Meier analysis revealed that the risk of CKD development in the highest quartile (Q4) was significantly lower than that of the lowest quartile (Q1) (P <0.001). This association was remained significant even after adjustments were made for confounding factors by multivariable Cox proportional hazards model. (HR [95% CI] = 0.75 [0.65–0.87], P < 0.01).

Conclusions: High physical activity is independently associated with decreased risk of incident CKD in healthy population with normal renal function.

FR-PO181

Effect of Exercise Intensity on Autoregulation of GFR in Patients with CKD Stage 2

Kazuko Koutoku,[1] Tetsuhiko Yasuno,[2] Syotaro Kawakami,[6] Kanta Fujimi,[3] Takuro Matsuda,[3] Shihoko Nakashima,[1] Yoshinari Uehara,[4] Takao Saito,[5] Yasuki Higaki.[4] *[1]Fukuoka Univercity, Nanakuma, Johnan-ku, Fukuoka, Japan; [2]Fukuoka university, Fukuoka, Japan; [3]Fukuoka University Hospital, Fukuoka, Japan; [4]Fukuoka University, Fukuoka, Japan; [5]Sanko Clinic, Fukuoka, Japan; [6]Fukuoka University Chikusa Hospital, Fukuoka, Japan*.

Background: Several studies have showed that aerobic exercise improves cardiovascular function in patients with CKD. On the other hand, glomerular filtration rate (GFR) significantly decreased during severe exercise in healthy young men (Kawakami S, et al. 2018). The purpose of this study was to determine the association of GFR with intensity of exercise in patients with CKD stage 2.

Methods: Renal blood flow (RBF) was assessed by Duplex ultrasound. GFR was estimated by serum cystatin-C (eGFRcys). FF was calculated with eGFRcys/RBF (1-hemtocrit). Eight males with CKD stage 2 (eGFRcys: 60-89/min/1.73m^2) participated in the study, consisting of three separate trials using a cycle ergometer. The first is a maximal graded exercise test. The second is a multi-stage exercise test to determine their lactate threshold (LT). The third is a multi-stage exercise test (4 minutes/stage) at intensities of 60%, 80%, 100%, 120%, and 140% of LT.

Results: eGFRcys significantly decreased and FF significantly increased (eGFRcys: 73±14min/1.73m^2, FF: 0.44±0.17) after strenuous exercise (p< 0.01). eGFRcys did not decrease until 100% of LT was attained, and showed slight reduction at 120% of LT and 140% of LT (eGFRcys: 76±10min/1.73m^2 and 72±9min/1.73m^2) relative to its resting value. FF was significantly higher at 100% of LT (FF: 0.46±0.16), compared to its resting value (p< 0.01). Heart rate (HR) and the norepinephrine level (NE) also increased with the intensities of LT (HR: p< 0.01, NE: p< 0.05). (Fig. 1)

Conclusions: Our results demonstrate that GFR does not change during exercise until the LT is attained, although FF increases. These findings suggest that patients with CKD stage 2 might be able to maintain their GFR during exercise up to 100% of LT.

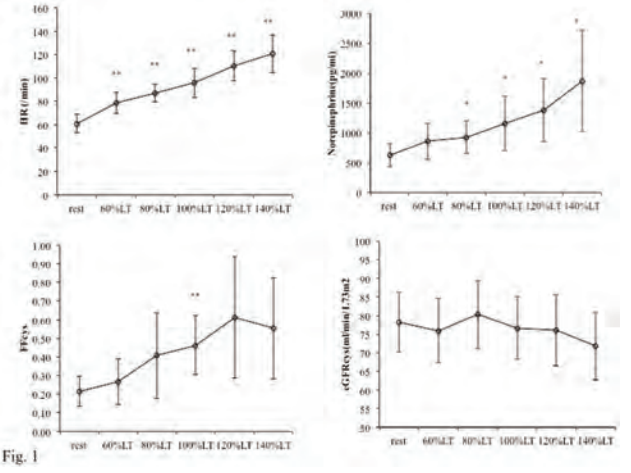

Fig. 1

FR-PO182

Concomitant Acute Pyelonephritis and Obstruction Duration Affects Renal Outcome in Obstructive Uropathy by Urolithiasis

Seongyup Yeo, Jin Ho Hwang. *Department of Internal Medicine, Chung-Ang University Hospital, Seoul, Republic of Korea*.

Background: Urolithiasis related obstructive uropathy is one of increasing causes of CKD, which commonly encountered in clinical field. Obstruction release from urolithiasis can be easily delayed with a lack of suggested golden time to prevent renal function deterioration. Here, we investigated the clinical significance and renal outcomes of urolithiasis related obstructive uropathy.

Methods: This is a study of 1646 from 2315 patients in urolithiasis related obstructive uropathy cohort which is recruited between Jan. 2005 and Dec. 2015. Clinical outcomes were evaluated with respect to obstruction duration, acute kidney injury (AKI), and acute pyelonephritis (APN) accompanied by obstructive uropathy.

Results: Median duration of obstruction (elapsed time to release obstruction) was 6 days and APN was accompanied in 14.3% of patients. Patients with HT, DM, and CKD had significantly higher rates of APN accompanied by obstructive uropathy. In the patients whose obstruction was relieved within 2 days from the symptom onset, 8.7% showed spontaneous release of obstruction. There was a significant increase in the number of APN (P=0.008) and AKI (P=0.002) patients who underwent early treatment of obstruction within 6 days from the symptom onset. People with Grade 1 or 2 hydronephrosis tended to release obstruction earlier, and those with Grade 3 or 4 had a higher rate of obstruction release after 7 days. In the patients with concomitant APN, mean age was older (59.4 vs 51.9 years-old, P<0.001), AKI occurred more frequently (73.7% vs 32.9%, P<0.001), estimated GFR (eGFR) at the last follow-up visit was lower (80.9 vs. 86.9 ml/min/1.73m2, P=0.024), and the use of NSAIDs were lower (49.3% vs. 74.9%, P<0.001). The AKI grades by KDIGO showed worse renal outcome in advanced stage (P=0.001). When we adjusted gender, age, HT, DM, use of NSAIDs, APN, AKI grades, and obstruction release over 2 days for a multivariate analysis, APN (HR 2.2, CI 1.01-4.65; P=0.047) and the obstruction release after 2 days (HR 3.55, CI 1.34-9.38; P=0.011) were independently associated with eGFR decrease of >30%.

Conclusions: In urolithiasis related obstructive uropathy patients, concomitant APN was strongly associated with renal function deterioration after obstruction release. The elapsed time to release obstruction also affected to renal function.

FR-PO183

IgG4-Related Kidney Disease (IgG4-RKD) a Large Single-Institution Study

Alessia Buglioni, Mariam P. Alexander, Loren P. Herrera hernandez, Mary E. Fidler, Samih H. Nasr, Sanjeev Sethi, Samar M. Said, Joseph P. Grande, Marie C. Hogan, Lynn D. Cornell. *Mayo Clinic, Rochester, MN*.

Background: IgG4-related disease (IgG4-RD) is an immune-mediated condition that can involve any organ, often by mass-forming inflammatory lesions. The kidney is usually affected in a pattern of tubulointerstitial nephritis (TIN); membranous glomerulonephritis (MGN) is another recognized pattern.

Methods: A retrospective biopsy (bx) - and nephrectomy-based study from a single institution with clinicopathological correlation was performed in cases of IgG4-RKD diagnosed between 1/2001 and 5/2018.

Results: 101 patients (80 M, 21 F) were identified with IgG4-RKD on bx (n= 96) or nephrectomy (n= 5), with a histologic pattern of TIN (94%) and/or MGN (15%). Race/ethnicity included white non-Hispanic (65%), African-American (11%), Asian (11%), Hispanic (11%), and American Indian (3%). The mean age was 62 years (range 20-84). Mean creatinine (SCr) at bx was 3.4 mg/dl (median 2.6 mg/dl, range 0.9-11.0 mg/dl). The primary indication for bx or nephrectomy was acute or chronic renal failure (68%), proteinuria (9%), or abnormal imaging (23%). Overall, 39% had renal masses. Extra-renal involvement was present in 85%. Serum IgG and/or IgG4 was increased in 88%. 29% had positive antinuclear antibody. Serum complement (C3 and/or C4) was decreased in 63%. Plasma cell-rich TIN was present in all cases of TIN and 93% showed an increase in IgG4+ plasma cells (focal >10 cells/40x field). Interstitial fibrosis was severe in 65% of cases, moderate in 15%, mild in 20%. 15% had MGN; of those with MGN, 71% also had a component of TIN. None showed granulomatous inflammation. 70% showed tubular basement membrane immune complex deposits by IF or EM. Follow-up was available in 49 patients (49%), with a mean length of 17 months. 98% were treated with immunosuppression (prednisone in 64%, rituximab in 6%, both 10% and other in 19%). 80% of patients with elevated SCr responded to therapy.

Conclusions: In our study, the most common manifestation of IgG4-RKD is TIN with functional impairment rather than mass lesions. MGN is not uncommon. Clinical features of IgG4-KRD included a higher prevalence of hypocomplementemia. Notably, 15% of patients have renal-limited disease. Immunosuppressive therapy improves renal function in the majority of patients.

FR-PO184

The Impact of Kidney Disease Etiology on the Association Between eGFR and Albuminuria with ESRD and All-Cause Mortality in the GCKD Cohort

Johannes B. Scheppach,[1] Josef Coresh,[2] Markus P. Schneider,[3] Anna Kottgen,[4] Morgan Grams,[1] Kai-Uwe Eckardt.[5] GCKD Study Investigators *[1]Johns Hopkins University, Baltimore, MD; [2]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [3]University of Erlangen-Nuremberg, Erlangen, Germany; [4]Medical Center - University of Freiburg, Freiburg, Germany; [5]University Medicine-Charite, Berlin, Germany*.

Background: Chronic kidney disease (CKD) is classified according to cause of kidney disease, estimated glomerular filtration rate (eGFR) and albuminuria, but risk prediction mainly relies on eGFR and albuminuria. We investigated the impact of kidney disease etiology on the association of kidney disease measures with adverse outcomes.

Methods: We studied 5,214 patients with CKD in the German Chronic Kidney Disease (GCKD) study, where the treating nephrologists assessed the cause of kidney disease. We grouped causes according to the KDIGO guideline with sensitivity analyses for alternative classifications. We analyzed the relative hazard of end-stage renal disease (ESRD) and all-cause mortality as a function of eGFR and urinary albumin-creatinine-ratio (UACR) using age, sex, German origin, systolic blood pressure, smoking, diabetes, BMI and history of cardiovascular disease as covariates. We tested for interaction between eGFR and UACR with cause of kidney disease in a Cox proportional hazards model.

Results: We observed 237 ESRD events and 418 deaths over 4.5 years of follow-up. Risk of ESRD and mortality increased with lower eGFR and higher UACR in each of the CKD causes where sample size was adequate. In the ESRD model, interaction of CKD cause was only present for eGFR with cystic or congenital diseases (p=0.004, see Table), although power to detect modest interactions is limited. For all-cause mortality, no significant interaction was observed between CKD cause and eGFR or UACR.

Conclusions: KDIGO staging of ESRD and mortality risk by eGFR and albuminuria is valid across different causes of CKD, although the eGFR relationship to ESRD risk is stronger in cystic or congenital kidney disease.

Funding: Private Foundation Support, Government Support - Non-U.S.

Cause of kidney disease	Prevalence in cohort, N=5,214	Incidence proportion of ESRD (events/N)	HR (95% CI) per 15 ml/min decrease in eGFR	p-value of interaction	HR (95% CI) per log10 increase in UACR	p-value of interaction
Glomerular diseases	36.5%	6.5% (124/1,902)	2.38 (1.89–2.94)	0.18	2.30 (1.78–3.09)	0.70
Tubulointerstitial diseases	7.4%	1.8% (7/386)	11.36 (2.33–55.55)	0.17	1.93 (0.68–5.47)	0.61
Vascular diseases	26.7%	2.8% (39/1,393)	6.41 (3.57–11.62)	0.15	1.84 (1.20–2.82)	0.26
Cystic and congenital diseases	4.3%	8.9% (20/224)	16.13 (6.67–38.46)	0.004	2.07 (0.97–4.43)	0.62
Other diseases	5.5%	2.8% (8/287)	8.40 (2.70–26.32)	0.18	2.74 (1.09–6.87)	0.91
Unknown disease	19.6%	3.8% (39/1,022)	3.56 (2.04–6.17)	reference	2.58 (1.76–3.92)	reference

Prevalence of CKD causes, incidence and HRs for ESRD associated with lower eGFR or higher UACR and p-values of the interaction between cause and eGFR/UACR, adjusted for age, sex, German origin, systolic blood pressure, smoking, diabetes, BMI, CVD history

FR-PO185

A Whole Blood Adsorber Particle for Future Applications in the Treatment of CKD Patients

Marieke Sternkopf,[2] Heidi Noels,[4] Vera Jankowski,[3] Joachim Jankowski.[1] *[1]RWTH Aachen, Aachen, Germany; [2]University Hospital Aachen, Aachen, Germany; [3]University hospital RWTH Aachen, Aachen, Germany; [4]RWTH University Aachen, Aachen, Germany*.

Background: Hydrophobic uremic toxins accumulate in patients with chronic kidney disease, contributing to a highly increased cardiovascular risk. The clearance of these uremic toxins by current hemodialysis techniques is limited due to their high binding affinity to plasma proteins, which prevents their removal through the pores of dialysis membranes. Adsorber techniques may be an appropriate alternative and/or additional technique to increase hydrophobic uremic toxin removal.

Methods: We developed an extracorporeal adsorber particle for efficient adsorption of these uremic toxins. The whole blood adsorber particle consists of a porous, activated charcoal core with a hydrophilic surface coating of cross-linked polyvinylpyrrolidone. The adsorption capacity of the particles was quantified by analytical chromatography after incubation or perfusion of the particles with an aqueous serum albumin solution or blood, each containing mixtures of hydrophobic uremic toxins.

Results: The particle hemocompatibility was assessed by quantifying the production of thrombin-antithrombin III complex (TAT) and complement component 5a (C5a) as well as leukocyte and thrombocyte counts in blood. A time-dependent increase in hydrophobic uremic toxin adsorption was depicted and all tested toxins showed a high binding affinity to the adsorber particles. Further, the particle showed a good hemocompatibility without significant effects on C5a, TAT or thrombocyte concentration, although leukocyte counts were slightly reduced

Conclusions: In conclusion, the whole blood adsorber particle is hemocompatible and shows a high adsorption capacity towards hydrophobic uremic toxins. Thus, it is an interesting candidate for further *in vivo* studies with the aim to increase the efficiency of conventional dialysis techniques and reduce mortality in CKD patients.

FR-PO186

Effect of Periodontal Therapy on CKD: Findings of the Kidney and Periodontal Disease (KAPD) Pilot Randomized Controlled Trial

Vanessa Grubbs,[1,2] Eric Vittinghoff,[3] Faviola M. Garcia,[3] Neil R. Powe.[4] *[1]San Francisco General Hospital Renal Center, San Francisco, CA; [2]UCSF, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA; [4]Priscilla Chan and Mark Zuckerberg San Francisco Gen Hosp & UCSF, San Francisco, CA.*

Background: CKD and periodontal disease (PD) disproportionately affect poor and minority populations. Observational studies suggest PD may be a modifiable CKD risk factor. The KAPD study (NCT01802216) was a pilot RCT to assess the feasibility of recruiting and retaining patients from a diverse, public hospital setting and to determine the variability of kidney and inflammatory biomarkers in response to PD treatment.

Methods: We randomly enrolled 51 adult patients with moderate/severe PD and CKD to immediate PD treatment (whole mouth deep cleaning + local minocycline to deep pockets, n=34) or delayed treatment with rescue (deep cleaning for worsening tooth sites, n=17) every 4 months for a 12-month protocol, with biomarkers assessed at baseline, 4-month, and 12-month study visits.

Results: Of enrolled patients, 82% were non-white; 47% had seen a dentist within the last 2 years; and 80% completed all 4 visits of the 12-month protocol (28 intervention, 13 rescue). 6 delayed treatment patients (35%) required rescue treatment. For intervention group, biomarkers of vascular injury (ADMA), and inflammation (IL-6) improved; tubular injury (urine NGAL) worsened; and UACR improved while serum NGAL worsened (markers of glomerular injury). Changes among UACR and serum NGAL in the rescue group were opposite, but similar otherwise.

Conclusions: KAPD demonstrated enrolling and retaining patients from a diverse, public hospital setting in a 12-month trial is feasible. There was variability in kidney and inflammatory biomarkers in response to PD treatment. Rescue treatment may have obscured decisive treatment effect. A larger trial is needed to determine the extent to which PD treatment may slow CKD progression.

Quantitative Analysis: Patient Experiences and Preferences About Being Informed of a CKD Diagnosis

Julie A. Wright Nunes,[2] Emily P. Chen,[1] Sam Harrison,[1] Eve Kerr,[2] Angela Fagerlin.[3] *[1]University of Michigan Center for Bioethics and Social Sciences in Medicine, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]University of Utah, Salt Lake City, UT.*

Background: Patients with chronic kidney disease (CKD) are often unaware of their diagnosis. Doctors may be hesitant to inform patients of a CKD diagnosis and may use heterogeneous terms when doing so. We examined patients' experiences and preferences about being informed of a CKD diagnosis.

Methods: 202 adults with CKD Stages 1-5 completed a cross-sectional survey between April 2015-May 2016. Survey questions focused on: patient experiences being informed about a CKD diagnosis, preferences about verbiage patients use to describe their CKD diagnosis ("Which of the following words or phrases do you use to talk about your kidney problem?"), and when patients thought they should have been told about their diagnosis ("If you had the choice, when would you have wanted to know that you had kidney disease?").

Results: Mean (SD) age was 59 (16) years. 48% were male, 78% Caucasian, 17% African American, 73% had CKD Stage 3-5, 51% had an annual income > $50K, and 95% had ≥ H.S. education. Most patients were first told they had CKD by a kidney doctor (n=87, 47%) in an outpatient setting (n=138, 72%). Others learned of their diagnosis from primary care doctors (33%), ER doctors (7%), and "others," e.g. inpatient providers (9%). Other settings included the hospital (15%), ER (7%), and at home via phone call (6%). Thirty percent of patients reported DM and/or hypertension as the cause of their CKD, and 49% did not recall being told or did not know the cause. Most patients preferred multiple terms to refer to their diagnosis; the majority used "kidney disease" (82%) and "chronic kidney disease" (65%), followed by "decreased kidney function" and "elevated creatinine" (both 61%). Least used terms were "kidney injury" (12%) and "renal insufficiency" (18%). Ninety-six percent felt patients should be informed of their CKD diagnosis upon identification by their doctor. Only 4% felt it was acceptable for the doctor to determine if informing the patient mattered or to not inform patients at all.

Conclusions: Most patients were not told about their CKD diagnosis until they saw a kidney doctor in an outpatient setting. Nearly half did not know the cause of their CKD. Preferred verbiage is largely congruent with current guidelines. In contrast to doctors' perspectives, patients feel they should be informed of their CKD diagnosis as soon as it is identified by a doctor.

Development and Validation of an Electronic (e) Phenotype for CKD

Jenna M. Norton,[1] Claudine T. Jurkovitz,[2] Krzysztof Kiryluk,[3] Meyeon Park,[4] Kensaku Kawamoto,[5] Ning Shang,[3] Kaltun H. Ali,[1] Andrew S. Narva,[1] Paul E. Drawz.[6] *[1]National Kidney Disease Education Program, National Institute of Diabetes and Digestive and Kidney Diseases, BETHESDA, MD; [2]Christiana Care Health System, Newark, DE; [3]Columbia University, New York, NY; [4]UCSF, San Francisco, CA; [5]University of Utah, Sandy, UT; [6]University of Minnesota, Minneapolis, MN.*

Background: Identifying CKD patients is an essential step for surveillance, research recruitment and quality improvement (QI). Using diagnostic codes to identify CKD patients is challenged by widespread under-diagnosis of CKD. An electronic CKD phenotype based on data widely available in the electronic health record could facilitate identification of patients likely to have CKD.

Methods: A working group of patients, nephrologists, primary care providers and informaticists developed the ePhenotype. Five clinical sites implemented the ePhenotype. Each site collected study population demographics (age, race, sex), labs (eGFR, UACR, UPCR, UA) and dialysis/transplant status. The ePhenotype determined CKD status (eGFR <60 ml/min/1.73m^2, UACR ≥30 mg/g), CKD stage and chronicity (prior lab value indicative of CKD 90+ days prior). Four sites conducted a blinded, manual validation on a random subsample of the population across CKD status. Diagnostic accuracy (proportion of patients with correctly identified CKD stage) and sensitivity/specificity of the ePhenotype for identifying CKD, dialysis and transplant were calculated for each site and overall.

Results: The validation population included 1,680,334 patients across 4 sites with average age 49.8±18.5. Of these, 58.7% were female, 10.4% were black, 59.3% had at least 1 eGFR and 40.6% had any proteinuria measurement. The proportion of patients with any proteinuria measurement varied across sites (20.2% to 52.1%) and increased as eGFR decreased. The ePhenotype was successfully implemented at all sites. Diagnostic accuracy for identifying CKD stage was 98%. Sensitivity and specificity, respectively, across the validation sites were 99.3% and 98.5% for CKD, 94.5% and 90.7% for dialysis and 97.3% and 91.1% for transplant (Table 1).

Conclusions: The ePhenotype was successfully implemented at multiple sites with a high degree of accuracy and has the potential to facilitate identification of patients with CKD for surveillance, research and QI.

A Machine Learning Approach to Identifying Patients at Risk of Developing Incident CKD

Tia Y. Yu,[1] Lauren A. Wiener,[1] Xiaoyan Wang,[1] Ollie Fielding,[1] Jung Hoon Son,[1] Praveen Kumar Potukuchi,[2] Csaba P. Kovesdy.[2] *[1]pulseData, New York, NY; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: Chronic Kidney Disease (CKD) is an under-identified condition and current methodology for identifying patients at risk of developing incident CKD is limited. Identifying patients who are high risk for CKD can improve awareness while delaying onset and progression of CKD. Machine learning algorithms can be used to stratify risk of those likely to develop incident CKD. Previous work has defined CKD using ICD codes or a limited number of eGFR readings.

Methods: Data from 1,780,262 patients with no baseline CKD in the Veterans Affairs healthcare system was analyzed. We used a random forest classifier to 1) predict incident CKD (eGFR >90 progressing to eGFR <60) and 2) predict the development of advanced CKD (eGFR >60 progressing to eGFR <45) utilizing information on patient demographics, comorbidities, laboratory values, and medication use. We excluded eGFR values during an AKI episode using an algorithm and selected sustained eGFR periods using slope-based analyses. One, two, and five-year prediction models were generated.

Results: The performance of the prediction models are summarized in Table 1. As models predict on outcomes across longer time ranges the lab values become less important while the comorbidities rise in importance. At the top risk quartile, our one year incident CKD model has an AUC of 0.839, a sensitivity of 0.754, and a specificity of 0.751, and our one year development of advanced CKD model has an AUC of 0.871, a sensitivity of 0.825, and a specificity of 0.751.

Conclusions: We demonstrate the ability to leverage advanced machine learning models to predict CKD incidence using longitudinal data commonly available in EHR systems. Future studies should validate our model in a clinical setting.

Funding: Veterans Affairs Support, Commercial Support - pulseData

Table 1

	Metric	One Year	Two Year	Five Year
eGFR of > 90 predicting decline to eGFR of < 60 (incident CKD stage 3a and above)	AUC	0.839	0.808	0.791
	Outcome	0.282%	0.572%	2.034%
	Sensitivity (top quartile)	0.754	0.723	0.651
	Specificity (top quartile)	0.751	0.753	0.758
eGFR of > 60 predicting decline to eGFR of < 45 (incident CKD stage 3b and above)	AUC	0.871	0.853	0.830
	Outcome	0.191%	0.474%	2.018%
	Sensitivity (top quartile)	0.825	0.784	0.739
	Specificity (top quartile)	0.751	0.753	0.760

FR-PO190

Rural Disparities in Estimated Glomerular Filtration Rate Changes in Patients with and at-Risk of CKD

Sterling McPherson,[1,5] Jenna Williamson,[6] Kenn B. Daratha,[7] Brad Dieter,[4] Radica Z. Alicic,[5] Obidiugwu Duru,[8] Susanne B. Nicholas,[3] Keith C. Norris,[9] Katherine R. Tuttle.[2] CURE CKD *[1]Washington State University College of Medicine, Spokane, WA; [2]University of Washington School of Medicine, Spokane, WA; [3]UCLA Medical Center, Westchester, CA; [4]Providence Sacred Heart, Spokane, WA; [5]Providence Medical Research Center, Spokane, WA; [6]University of Washington, Spokane, WA; [7]Washington State University, Colbert, WA; [8]David Geffen School of Medicine, Los Angeles, CA; [9]UCLA, Marina Del Rey, CA.*

Background: Little is known about chronic kidney disease CKD progression among rural versus urban dwelling patients. The study aim was to determine associations of residential location with estimated glomerular filtration rate (eGFR) over time in patients with and at-risk for CKD.

Methods: Providence and UCLA healthcare systems collaboratively formed a CKD and at-risk CKD registry from electronic health records (n=3,118,853). Participants were identified by diagnosis of CKD, at-risk for CKD (diabetes, pre-diabetes, or hypertension) by ICD-9/10 codes and condition-specific criteria from 2006-2016. The primary outcome was eGFR (CKD-EPI-creatinine) including ≥3 values over ≥90 days, and the main covariate of interest was rural versus urban dwelling defined by Rural-Urban Commuting Area codes. Other pre-specified covariates in the random effects regression model included: age, gender, race; and time-varying covariates: HbA1c, systolic blood pressure, and angiotensin converting enzyme inhibitor/angiotensin receptor blocker (ACE/ARB) usage.

Results: Baseline characteristics: 59±17 years of age, 56% female, 10% rural dwelling, 86% White, 6% Black or African American, and 7% Asian. Baseline eGFR was 60.6±22.5 mL/min/1.73m^2 in the CKD cohort and 90.0±18.3 mL/min/1.73m^{2}in the at-risk cohort. For both the CKD and at-risk cohort, patients dwelling in a rural versus an urban location experienced a nearly 4 mL/min/1.73m^{2}greater annual decline in eGFR (B = -3.81, 95% CI: -4.21 - -3.42, p<0.001) over a median of 5 years, controlling for other covariates. eGFR decline significantly varied across race and was inversely associated with age, time, and ACE/ARB usage. eGFR decline was positively associated with female sex and systolic blood pressure. HbA1c was not associated with eGFR change.

Conclusions: In patients with CKD and at-risk for CKD, rurality independently associated with faster loss of kidney function compared to urban dwelling. Facilitators and overcoming barriers to better care are needed for these patients in rural locations.

Monitoring Quality of Care for CKD in the United States

Shingo Fukuma,[1] Yun Han,[2] Diane Steffick,[2] Jennifer L. Bragg-Gresham,[2] Kevin He,[3] Tatsuyoshi Ikenoue,[4] Yukari Yamada,[1] Edward C. Norton,[2] John Z. Ayanian,[5] Rajiv Saran.[5] *[1]Kyoto University, Kyoto, Japan; [2]University of Michigan, Ann Arbor, MI; [3]Kidney Epidemiology and Cost Center, University of Michgian, Ann Arbor, MI; [4]Kyoto University Graduate School of Medicine and Public Health, Kyoto, Japan; [5]University of Michigan, Ann Arbor, MI.*

Background: Monitoring quality of CKD care and understanding geographic variation in care quality are important for improving patient outcomes; however this topic has received limited attention. We examined quality of care measures for CKD and geographic variation in elderly Medicare beneficiaries in the United States.

Methods: We analyzed the 5% sample of the Medicare fee-for-service population linked with Part D medication claims data from 2007 to 2015. We selected elderly (≧65 years) patients with diagnosed CKD (by ICD-9 codes) and examined their care in repeated annual crossections. We assessed 4 key CKD quality indicators including urine albumin testing, renin-angiotensin (RAS) inhibitors use, not receiving (i.e., <14 days per month prescription) of non steroidal anti-inflammatory drugs (NSAIDs), and receiving nutritional consultation. Variation in these practices by age, sex, race, comorbidities (diabetes, hypertension and history of cardiovascular disease) and county of residence, were examined. A multivariate logistic model identified factors associated with urine albumin testing and RAS inhibitor use.

Results: Of the total 2,162,085 elderly CKD patients, 43.1% were 80 years or older, 44.8% had diabetes, and 86.4% had hypertension. We observed steady increase in urine testing (from 21.5% in 2007 to 29.5% in 2015) and RAS inhibitor use (31.8% in 2007 to 40.6% in 2015) (each p for trend <0.01). During the same follow-up years, nutritional guidance was received in under 2%, but NSAIDs avoidance was observed in over 95%. County-level variation (Figure) in urine testing and RAS inhibitor use ranged widely from 0 to >50%, and increased over time. Age <80 years, diabetes, and hypertension, were associated with higher odds of urine testing and RAS inhibitor use.

Conclusions: Significant practice gaps and variations exist across the US for selected quality indicators of CKD care in older adults. More research into this area is vital as quality of care monitoring has potential to inform policy and practice improvements for this patient population..

Urinary Biomarkers of Tubular Dysfunction and Risk of CKD Progression Among SPRINT Participants

Vasantha Jotwani,[1] Ronit Katz,[2] Pranav S. Garimella,[11] Rakesh Malhotra,[11] Alfred K. Cheung,[3] Michel Chonchol,[4] Paul E. Drawz,[5] Barry I. Freedman,[6] William E. Haley,[7] Anthony A. Killeen,[5] Henry A. Punzi,[8] Mark J. Sarnak,[9] Mark S. Segal,[10] Joachim H. Ix,[11] Michael Shlipak.[12] *[1]University of California, San Francisco, San Francisco, CA; [2]University of Washington, Seattle, WA; [3]University of Utah, Salt Lake City, UT; [4]University of Colorado, Aurora, CO; [5]University of Minnesota, Minneapolis, MN; [6]Wake Forest School of Medicine, Winston-Salem, NC; [7]Mayo Clinic, Jacksonville, FL; [8]Punzi Medical Center, Carrollton, TX; [9]Tufts Medical Center, Boston, MA; [10]University of Florida, Gainesville, FL; [11]UCSD, San Diego, CA; [12]San Francisco VA Medical Center, San Francisco, CA.*

Background: Tubular atrophy on biopsy is a strong predictor of kidney disease progression, but tubular health is poorly quantified by traditional measures including estimated glomerular filtration rate (eGFR) and albuminuria. We hypothesized that urinary biomarkers of tubule dysfunction would be associated with faster kidney function decline in persons with chronic kidney disease (CKD).

Methods: We measured baseline urine concentrations of α1-microglobulin (α1m), β2-microglobulin (β2m), and uromodulin among 2,428 participants of the Systolic Blood Pressure Intervention Trial who had an estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m^2. We used linear mixed models to evaluate biomarker associations with annualized relative change in eGFR.

Results: At baseline, the mean age was 72±9 years and eGFR was 48±11 ml/min/1.73m^2. Over a median follow-up of 3.8 years, higher concentrations of urine α1m and β2m and lower concentrations of urine uromodulin were independently associated with faster annualized eGFR decline (**Table**). There were no statistically significant interactions by intervention arm (p>0.3 for all biomarkers).

Conclusions: Among hypertensive, nondiabetic patients with CKD, urinary biomarkers of tubular dysfunction were independently associated with subsequent declines in kidney function.

Funding: NIDDK Support, Veterans Affairs Support

Associations of urinary biomarkers with annualized relative change in eGFR among SPRINT participants with CKD at baseline (N = 2,428)

Biomarker	Demographic-adjusted β (95% CI)	Multivariable- adjusted β (95% CI)
α1-microglobulin	-0.57 (-0.69, -0.44)	-0.57 (-0.70, -0.45)
β2-microglobulin	-0.21 (-0.27, -0.15)	-0.20 (-0.26, -0.15)
Uromodulin	0.48 (0.33, 0.62)	0.48 (0.33, 0.62)

β coefficient represents % eGFR change in ml/min/1.73m2/year per doubling of the biomarker. Demographic-adjusted model includes age, sex, race, intervention arm and urine creatinine. Multivariable-adjusted model additionally includes baseline eGFR, urine albumin, smoking status, history of cardiovascular disease, number of antihypertensive medications, systolic blood pressure, diastolic blood pressure, body mass index, high-density lipoprotein, and total cholesterol.

FR-PO193

Kidney Tubular Damage and Risk of Cardiovascular Disease and Mortality Among SPRINT Participants with CKD

Vasantha Jotwani,[1,4] Alexandra K. Lee,[1] Ronit Katz,[2] Pranav S. Garimella,[3] Rakesh Malhotra,[3] Michelle M. Estrella,[1,4] Joachim H. Ix,[3] Michael Shlipak.[1,4] *[1]Kidney Health Research Collaborative & SFVAMC, San Francisco, CA; [2]University of Washington, Seattle, WA; [3]UCSD, San Diego, CA; [4]UCSF, San Francisco, CA.*

Background: Novel urine biomarkers have enabled earlier detection of kidney tubular damage, but their prognostic value for adverse cardiovascular outcomes is uncertain. We hypothesized that urinary biomarkers of tubular injury would be associated with higher risks for cardiovascular events and mortality in persons with chronic kidney disease (CKD).

Methods: We measured urine concentrations of interleukin-18 (IL-18), kidney injury molecule-1 (KIM-1), neutrophil gelatinase-associated lipocalin (NGAL), monocyte chemoattractant protein-1 (MCP-1), and chitinase-3-like protein-1 (YKL-40) among 2,377 participants of the Systolic Blood Pressure Intervention Trial who had an eGFR<60 ml/min/1.73 m^2. We used Cox proportional hazards models to evaluate biomarker associations with CVD events and all-cause mortality.

Results: At baseline, the mean age was 72±9 years and eGFR was 48±11 ml/min/1.73m^2. Over a median of 3.8 years, 305 CVD events (3.6% per year) and 233 all-cause deaths (2.6% per year) occurred. After multivariable adjustment, including baseline eGFR and albuminuria, higher urine IL-18 and YKL-40 concentrations were independently associated with higher mortality risk (**Table**). The biomarkers did not have statistically significant associations with CVD events. Associations were similar when stratified by randomization arm.

Conclusions: Among hypertensive, nondiabetic patients with CKD, urine IL-18 and YKL-40 were independently associated with higher mortality risk but not with CVD events. The remaining markers were not associated with CVD or mortality risk.

Funding: NIDDK Support

Associations of urine biomarkers with CVD events and mortality among SPRINT participants with CKD at baseline (N = 2,377)

Biomarker	CVD events Hazard Ratio (95% CI)	All-cause mortality Hazard Ratio (95% CI)
IL-18	1.06 (0.96, 1.18)	1.14 (1.01, 1.29)
KIM-1	0.93 (0.86, 1.02)	0.96 (0.86, 1.06)
NGAL	1.03 (0.96, 1.11)	1.03 (0.95, 1.12)
MCP-1	1.04 (0.94, 1.15)	1.03 (0.91, 1.17)
YKL-40	1.04 (0.99, 1.10)	1.08 (1.02, 1.14)

Hazard ratios per doubling in biomarker. Models adjust for age, sex, race, intervention arm, baseline eGFR, urine albumin, urine creatinine, smoking status, history of CVD or heart failure, number of antihypertensive medications, statin use, systolic and diastolic blood pressures, body mass index, and lipid profiles.

FR-PO194

Serum Metabolites Associated with Kidney Function Decline

Morgan Grams,[1] Casey Rebholz,[2] Adrienne Tin,[1] Jingsha Chen,[1] Vasan S. Ramachandran,[9] Amanda H. Anderson,[3] Andrew S. Levey,[4] Lesley Inker,[4] Mark J. Sarnak,[4] Harold I. Feldman,[3] Paul L. Kimmel,[5] Sushrut S. Waikar,[6] Eugene P. Rhee,[7] Josef Coresh.[8] for the CKD Biomarkers Consortium *[1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]University of Pennsylvania, Philadelphia, PA; [4]Tufts Medical Center, Boston, MA; [5]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [6]Harvard Medical School, Boston, MA; [7]Massachusetts General Hospital, Newton, MA; [8]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [9]Boston University School of Medicine, Framingham, MA.*

Background: Small molecules that associate with subsequent GFR decline in patients with CKD may help uncover novel pathophysiological mechanisms of disease or treatment targets.

Methods: Among 960 participants in the African American Study of Kidney Disease and Hypertension (baseline mGFR 47 +/- 15 ml/min/1.73 m^2), we evaluated the associations of 961 named and unnamed serum metabolites identified through untargeted metabolomic profiling with decline in measured GFR over time using linear mixed models and a median of 11 measures of mGFR over 4.1 years. We selected metabolites associated with mGFR decline ($p<0.05$) and subsequently assessed their associations with ESRD over a median of 8.9 years using Cox models (Bonferroni-corrected $p<0.05$). Analyses were adjusted for study arm, age, sex, smoking, heart disease, body-mass index, systolic blood pressure, log-transformed proteinuria, and, in the Cox model, baseline measured GFR.

Results: There were 112 metabolites associated with change in mGFR over time in AASK ($p<0.05$). Fourteen were also associated with ESRD after correcting for multiple comparisons ($p<0.0004$). All 14 metabolites were negatively associated with baseline mGFR. The top three metabolites associated with ESRD were 1-methylhistidine, erythronate, and O-sulfo-L-tyrosine. Six of the 14 were in the phosphatidylethanolamine pathway.

Conclusions: Several metabolites, including six in the phosphatidylethanolamine pathway, may relate to ESRD risk. Further studies are needed to determine if these associations are causal.

The Burden of Adverse Drug Events in Patients with Moderate or Advanced CKD: The CKD-REIN Study

Solene M. Laville,[1] Marie Metzger,[1] Benedicte Stengel,[1] Christian Jacquelinet,[2] Maurice Laville,[3] Luc Frimat,[4] Denis Fouque,[5] Christian Combe,[6] Valérie Gras,[7] Ronald L. Pisoni,[8] Ziad Massy,[9] Sophie Liabeuf.[7] *[1]CESP U1018, INSERM, Villejuif, France; [2]Agence de la biomedecine, Saint-Denis La Plaine, France; [3]Université de Lyon, Pierre-Bénite, France; [4]Nancy University Hospital, Vandoeuvre les Nancy, France; [5]University Claude Bernard, Pierre Benite, France; [6]CHU de Bordeaux, Bordeaux, France; [7]CHU Amiens, Amiens, France; [8]Arbor Research Collaborative for Health, Ann Arbor, MI; [9]Ambroise Pare University Hospital and Inserm U1018 Eq5, Boulogne Billancourt/ Paris cedex, France.*

Background: Little is known about the burden of adverse drug events (ADEs) in chronic kidney disease (CKD). We assess the incidence rate of ADEs and describe the suspected prescribed drugs associated with the main reported ADEs in the CKD-REIN cohort.

Methods: The CKD-REIN study includes 3033 outpatients (65% men) with CKD (estimated glomerular filtration rate (eGFR) <60mL/min/1.73m^2). ADEs were identified from medical records, hospital discharge reports, or patient interviews. All reported ADEs were reviewed by pharmacist experts who coded the type of events and the associated suspected drugs. Incidence rates were estimated by Poisson regression, overall and by patient characteristics.

Results: At baseline, patients' median age was 69(IQR, 60-76), median eGFR was 32(IQR, 23-41)mL/min/1.73m^2 and the median number of medications was 8 per day. During a median follow-up of 2.3 years, 777 ADEs were reported in 545 patients, 27% of whom had at least two. The overall incidence rate of ADEs was 10.7[95%CI, 9.9-11.4] per 100 person years, with significantly higher rates in women than men, and in patients with diabetes, lower eGFR, cardiovascular history and with a higher number of medications at baseline; it did not differ significantly according to age. Renin-angiotensin system inhibitors (RASi) (15%), antithrombotic agents (13%) and diuretics (9%) were the drug classes most frequently associated with ADEs. As expected, main ADEs were increased serum creatinine and hypotension with RASi and diuretics, hemorrhage with antithrombotic agents, and cough with RASi. Of note, 71% of ADEs led to discontinuing treatment and 16% to modifying treatment dose. Among the 777 evaluated ADEs, 161 (21%) were reported among inpatients, either as a cause of hospitalization or an incident event, 2.2[95%CI, 1.9-2.6] per 100 person years, four of which were linked with death. The drugs most frequently involved in ADEs associated with hospitalization or death, were vitamin K antagonists (n=39) and heparin (n=7).

Conclusions: The burden of ADEs is high in patients with CKD and led to discontinuing drugs prescribed to slow CKD progression and reduce cardiovascular complications. The impact of ADEs and resulting prescription changes on CKD outcomes need to be evaluated.

Urine Markers of Kidney Tubule Cell Injury and Kidney Function Decline: Results from SPRINT Trial

Rakesh Malhotra,[1] Ronit Katz,[2] Vasantha Jotwani,[3] Michael Shlipak,[4] Joachim H. Ix.[1] *[1]UCSD, San Diego, CA; [2]University of Washington, Seattle, WA; [3]UCSF, San Francisco, CA; [4]San Francisco VA Medical Center, San Francisco, CA.*

Background: Tubulo-interstitial fibrosis and atrophy are important risk markers for chronic kidney disease (CKD) progression on kidney biopsy, but are not evaluated in clinical testing. We examined the association between urinary kidney tubule injury biomarkers with subsequent loss of kidney function in persons with non-diabetic CKD who participated in The Systolic Blood Pressure Intervention Trial (SPRINT).

Methods: Among 2428 SPRINT participants with CKD (eGFR <60 ml/min/1.73m^2) at baseline, we measured urine concentrations of markers of *injury* (interleukin-18 [uIL-18], kidney injury molecule-1[uKIM-1], and neutrophil gelatinase-associated lipocalin [uNGAL]), *inflammation* (monocyte chemoattractant protein-1 [uMCP-1]) and *repair* (human cartilage glycoprotein-40 [uYKL-40]). We used linear mixed models to evaluate the associations of each biomarker with annualized change in eGFR; and used proportional hazards regression to evaluate the renal composite outcome of 50% eGFR decline, transplant or end-stage renal disease.

Results: At baseline, the mean age was 73±9 years and mean eGFR was 46±11 ml/min/1.73m^2; 60% were men and 66% were white. During 3.8 years mean follow-up, there were 87 composite renal events. In adjusted continuous models, higher uIL-18, uNGAL and uYKL-40 concentrations were associated with faster eGFR decline (Table). Associations with the renal composite endpoint appeared non-linear, with heightened risk in the highest quartile. The high quartiles of uKIM-1 (hazard ratio 2.84 [95% CI 1.31 to 6.17), uYKL-40 (1.95 [1.08 to 3.51]) and uMCP-1 (2.43 [1.13 to 5.23]) were each associated with risk of the renal composite outcome relative to the lowest quartiles. Associations were similar in the two randomization arms.

Conclusions: Urine markers of tubule cell injury provide information about risk of subsequent loss of kidney function independent of eGFR and albuminuria. Future studies are required to determine if dynamic changes in urine tubule injury markers provide information on subsequent risk of CKD progression.

Funding: NIDDK Support

Table: Association of Urine Markers of Tubule Injury with Annualized Relative Change in eGFR and 50% Kidney Function Decline, ESRD, or Transplant

Biomarkers (per doubling)	Annualized relative change in eGFR	50% kidney function decline, ESRD or transplant
	β (95% CI)	Hazard Ratio (95% CI)
Urine IL-18, pg/mL	**-0.14 (-0.25, -0.04)***	1.06 (0.89, 1.26)
Urine KIM-1, pg/mL	-0.08 (-0.16, 0.01)	1.07 (0.85, 1.35)

Markers of Kidney Tubule Function and Risk of Cardiovascular Disease Events and Mortality in the SPRINT Trial

Pranav S. Garimella,[1] Alexandra K. Lee,[2] Walter T. Ambrosius,[3] Udayan Y. Bhatt,[4] Alfred K. Cheung,[5] Michel Chonchol,[6] Timothy Craven,[3] Amret T. Hawfield,[3] Vasantha Jotwani,[2] Anthony A. Killeen,[7] Henry A. Punzi,[8] Mark J. Sarnak,[9] Michael Shlipak,[10] Joachim H. Ix.[11] *[1]University of California San Diego, San Diego, CO; [2]Kidney Health Research Collaborative, UCSF & VA, San Francisco, CA; [3]Wake Forest School of Medicine, Winston-Salem, NC; [4]The Ohio State University, Dublin, OH; [5]University of Utah, Salt Lake City, UT; [6]University of Colorado, Aurora, CO; [7]University of Minnesota, Minneapolis, MN; [8]Punzi Medical Center, Carrollton, TX; [9]Tufts Medical Center, Boston, MA; [10]San Francisco VA Medical Center, San Francisco, CA; [11]UCSD, San Diego, CA.*

Background: Biomarkers of tubule injury, inflammation and fibrosis have emerged as prognosticators of kidney and cardiovascular disease (CVD) outcomes. However, markers of tubular *function* have not been adequately evaluated as risk factors for CVD.

Methods: Using a sample of 2,377 persons with CKD at the baseline SPRINT visit, we evaluated the association of three urinary markers of tubular function; alpha-1 microglobulin (α1m), beta-2 microglobulin (β2m) and uromodulin with CVD events, heart failure and all-cause mortality using Cox regression over 3.7 years of follow up. Markers were log-transformed given skewed distributions.

Results: Mean age was 73 years, 40% were woman, 26% black, and mean glomerular filtration rate (GFR) was 46±11 ml/min/1.73m². In multivariable analyses, each two-fold higher α1m was associated with a 33%, 31%, 61% and 85% greater risk of composite CVD, mortality, CVD death and acute coronary syndromes (ACS), respectively [table]. There was no association of β2m with any of the outcomes. Each two-fold higher uromodulin was associated with a 22%, 30% and 31% lower adjusted risk of composite CVD, HF and CVD death, respectively. These associations were not modified by baseline CVD or intervention arm.

Conclusions: Among non-diabetic persons with CKD, biomarkers of tubular function are associated with incident CVD and mortality independent of GFR and albuminuria.

Urinary PTH1R: Novel Predictor of Mineral Metabolism Disorder and Renal Outcome of CKD

Dandan Qiu,[1] Yu Pan,[4] Jingsong Shi,[1] Minlin Zhou,[2] Feng Xu,[5] Zhihong Liu,[3] Song Jiang.[2] *[1]National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China; [2]National Clinical Research Center of Kidney Diseases Jinling Hospital, Nanjing, China; [3]National Clinical Research Center of Kidney Diseases, Nanjing, China; [4]National Clinical Research Center of Kidney Diseases, Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China; [5]Research Institute of Nephrology, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China.*

Background: There is short of early predictor of mineral metabolism disorder and renal outcome in patients with chronic kidney disease (CKD). This study aimed to explore the association of urinary parathyroid hormone 1 receptor (PTH1R) with mineral metabolism markers, and the predictive value for renal outcome in CKD.

Methods: 29 healthy controls and 140 diabetic nephropathy (DN) patientswere enrolled as discovery cohort and 200 general CKD patients were enrolled as an independent validation cohort. All patients were followed up for at least 1 year and measured the intact PTH (iPTH), fibroblast growth factor 23 (FGF23) in baseline serum and PTH1R in baseline urine. Urinary PTH1R was normalized to urine creatinine and log transformed [uPTH1R/Cr($\log_{10}$)].The composite renal endpoint was defined as end-stage renal disease (ESRD) or 30% reduction of baseline eGFR during follow-up.

Results: In discovery cohort, DN patients had a significantly higher mean uPTH1R/Cr($\log_{10}$) level compared with healthy control (2.53±0.61 pg/mg versus 1.89±1.14 pg/mg, P<0.01). uPTH1R/Cr($\log_{10}$) was significantly increased in DN patients with eGFR of 60~75 ml/min/1.73m², which was earlier than serum FGF23 and iPTH. Baseline uPTH1R/Cr($\log_{10}$) was associated with serum calcium (r=-0.224, P<0.01), serum FGF23 (r=0.232, P<0.05), and eGFR slope (r=0.318, P<0.001). 59 patients in discovery cohort entered into composite renal endpoint during follow-up. Cox regression analysis showed that higher uPTH1R/Cr($\log_{10}$) had a significantly higher risk for renal outcome [HR=2.190; 95%CI(1.048,4.575), P<0.05]. Validation cohort confirmed that uPTH1R/Cr($\log_{10}$) was an independent risk factor for renal outcome [HR=1.573; 95%CI(1.094,2.263), P<0.05] in general CKD patients. Addition of uPTH1R/Cr($\log_{10}$) to eGFR and proteinuria could significantly improve the prediction value for renal outcome (likelihood ratio test, P<0.001).

Conclusions: Urinary PTH1R was an independent risk factor for renal outcome in CKD patients, and was a novel biomarker of disordered mineral metabolism.

The Association of Blood Urea Nitrogen to Creatinine Ratio with Renal and Cardiovascular Outcomes in CKD: The CRIC Study

Georges Saab,[1] Edward J. Horwitz,[1] Wei Yang,[2] Jing Chen,[3] Jiang He,[4] Ana C. Ricardo,[5] James H. Sondheimer,[9] Nidhi Sukul,[10] Xiaoming Zhang,[8] Mahboob Rahman,[6] Sankar D. Navaneethan.[7] *[1]MetroHealth Medical Center, Cleveland, OH; [2]University of Pennsylvania, Philadelphia, PA; [3]Tulane School of Medicine, New Orleans, LA; [4]Tulane School of Public Health and Tropical Medicine, New Orleans, LA; [5]University of Illinois at Chicago, Chicago, IL; [6]Case Western Reserve University, Cleveland, OH; [7]Baylor College of Medicine, Sugar Land, TX; [8]University of Pennsylvania School of Medicine, Philadelphia, PA; [9]Wayne State University School of Medicine, Detroit, MI; [10]University of Michigan, Ann Arbor, MI.*

Background: Above a traditional cutoff point of 20, a blood urea nitrogen to creatinine ratio (BUN/Cr) has been suggested to be a marker of neurohormonal activation (NHA) which could contribute to progressive chronic kidney disease (CKD), cardiovascular disease (CVD) and higher mortality. We therefore examined the association of baseline BUN/Cr with these outcomes among persons with CKD.

Methods: [2] We examined 3908 adult participants in the Chronic Renal Insufficiency Cohort (CRIC) Study. Cox regression was used to examine BUN/Cr as a categorical predictor (< 20, 20-<25, 35-<30, and >=30) and a continuous predictor using splines. Outcomes included time to end-stage renal disease (ESRD), congestive heart failure (CHF), atherosclerotic events (stroke, myocardial infarction, and peripheral artery disease), atrial fibrillation, and all-cause mortality. Cox models were adjusted demographics, clinical and laboratory characteristics.

Results: Among the 3908 participants included in the analysis, mean age and eGFR was 57.7 (11.0) years and 44.9 (16.9) ml/min/1.73m2 respectively. Participants were 41.6% white and 45.2% female. Higher BUN/Cr was associated with increased risk of CHF, atherosclerotic events, atrial fibrillation, and overall mortality, but not with ESRD when examined as a continuous (Figure 1) or categorical predictor (Table 1)

Conclusions: Higher BUN/Cr is associated with an increased CVD risk and mortality but not ESRD among persons with CKD.

Funding: NIDDK Support

Table 1 Hazard Ratios (95% CI) for ESRD and CVD Outcomes

BUN/Cr	ESRD	CHF	Non-CHF CVD	Afib	Mortality
< 20	ref	ref	ref	ref	ref
20-<25	.85 (.69-1.03)	1.32 (1.05-1.69)	1.36 (1.06-1.75)	1.12 (.84-1.48)	1.12 (.89-1.40)
25-<30	.98 (.75-1.29)	1.50 (1.10-2.05)	1.45 (1.00-2.09)	1.18 (.79-1.76)	1.39 (1.02-1.90)
>30	.98 (.66-1.47)	2.25 (1.52-3.33)	1.35 (.77-2.37)	2.71 (1.75-4.21)	1.93 (1.31-2.84)
P value	.40	< .001	< 0.05	< 0.001	.004

Model was adjusted for age, race, gender, diabetes, hypertension, prior CVD, smoking status, history of hepatitis B/C, history of any cancer, systolic blood pressure, BMI, fat free mass, diuretic use, ACEARB use, corticosteroid use, eGFR, hemoglobin, 24 hour urine creatinine, 24 hour urine urea nitrogen, 24 hour urine protein, FGF-23, albumin

FR-PO200

Urine Citrate Excretion Non-Invasively Verifies Reduced Acid Retention in Response to Dietary Acid Reduction in CKD 2 Patients Without Metabolic Acidosis

Nimrit Goraya,[1,2] Jan Simoni,[3] Lauren N. Sager,[4] Nicolaos E. Madias,[5] Donald E. Wesson.[6,2] *[1]Internal Medicine, Baylor Scott and White Health, Temple, TX; [2]Medicine, Texas A&M HSC, Temple, TX; [3]Surgery, Texas Tech University Health Sciences Center, Lubbock, TX; [4]Biostatistics, Baylor Scott & White, Temple, TX; [5]Medicine, Tufts University School of Medicine, Boston, MA; [6]Baylor Scott and White Health and Wellness Center, Dallas, TX.*

Background: Some CKD stage 2 (eGFR=60-89 ml/min/1.73 m2, CKD 2) patients without metabolic acidosis (defined as plasma total CO_2 <22 mM) nevertheless have acid (H^+) retention and decreasing H^+ retention with dietary H^+ reduction slows eGFR decline. Current methods to verify a decrease in H^+ retention and thereby establish clinical effectiveness of dietary H^+ reduction require cumbersome and invasive methods with limited clinical utility. We explored the utility of urine citrate excretion to non-invasively verify decreased H^+ retention in response to dietary H^+ reduction in CKD 2 patients without metabolic acidosis.

Methods: We measured H^+ retention and 8-hour urine citrate excretion ($U_{citrate}V$) in macroalbuminuric, non-diabetic CKD 2 (n=40) and CKD stage 1 (eGFR >90 ml/min/1.73 m2, CKD 1, n=26) patients with hypertension-associated nephropathy but without metabolic acidosis (mean plasma total CO_2 25.9±0.8 and 26.4±0.6 mM, respectively). H^+ retention was measured before and after dietary H^+ reduction with 30 days of base-producing fruits and vegetables (F+V) by comparing observed to expected increase in plasma [HCO_3] in response to retained HCO_3 (dose minus $U_{HCO3}V$) 6 hours after oral $NaHCO_3$ bolus (0.5 mmol/kg bw), assuming 50% body weight HCO_3 apparent space of distribution.

Results: H^+ retention was higher in CKD 2 than CKD 1 (28.1±9.4 vs. 5.2±12.0 mmol, respectively, p<0.01) but $U_{citrate}V$ was lower in CKD 2 than CKD 1 (187±40 vs. 335±125 mg, respectively, p<0.01). F+V did not decrease H^+ retention in CKD 1 (p=0.88) but did so in CKD 2 (to 18.4±17.4 mmol, p<0.01 vs. baseline) and increased $U_{citrate}V$ (to 245±70 mg, p<0.01 vs. baseline) in CKD 2. Overall Pearson Correlation for $U_{citrate}V$ with H^+ retention after F+V was -0.71 (p<0.001). A mixed effects regression model showed $U_{citrate}V$ to be strongly predictive of H^+ retention (p<0.001) so that for every 1 mg increase in $U_{citrate}V$, H^+ retention decreased 0.096 mmol.

Conclusions: $U_{citrate}V$ non-invasively verifies decreased H^+ retention in response to 30 days of F+V in CKD 2 patients without metabolic acidosis. It should be further explored as a method to establish clinical effectiveness of dietary H^+ reduction in CKD patients with comparatively well-preserved eGFR and no metabolic acidosis, but who are at risk for nephropathy progression.

FR-PO201

Urine Citrate Excretion Non-Invasively Identifies Changes in Acid Retention over Time in CKD 2 Patients Without Metabolic Acidosis

Nimrit Goraya,[1,2] Jan Simoni,[6] Lauren N. Sager,[3] Nicolaos E. Madias,[4] Donald E. Wesson.[5,2] *[1]Internal Medicine, Baylor Scott and White Health, Temple, TX; [2]Texas A&M HSC College of Medicine, Temple, TX; [3]Biostatistics, Baylor Scott & White, Temple, TX; [4]Medicine, Tufts University School of Medicine, Boston, MA; [5]Baylor Scott and White Health and Wellness Center, Dallas, TX; [6]Surgery, Texas Tech University Health Sciences Center, Lubbock, TX.*

Background: Some CKD stage 2 (eGFR=60-89 ml/min/1.73 m^2, CKD 2) patients without metabolic acidosis (conventionally defined as plasma total CO_2 <22 mM) nevertheless have acid (H^+) retention that appears to exacerbate nephropathy progression, increases as eGFR decreases over time (Goraya et al, AJP, 2018), and this increase in H^+ retention might be ameliorated with chronic oral $NaHCO_3$. Current methods to measure H^+ retention are cumbersome and invasive so we explored the utility of urine citrate excretion to non-invasively identify changes in H^+ retention over time.

Methods: We measured H^+ retention and 8-hour urine citrate excretion ($U_{citrate}V$) in macroalbuminuric, non-diabetic CKD 2 patients with hypertension-associated nephropathy without metabolic acidosis (plasma total CO_2 >24 mM) given 0.5 meq/kg bw/day $NaHCO_3$ (HCO_3, n=40), 0.5 meq/kg bw/day NaCl (NaCl, n=40), or usual care (UC, n=40) and assessed them yearly for 10 years. H^+ retention was measured at baseline and 10 years by comparing observed to expected increase in plasma total CO_2 in response to retained HCO_3 (dose minus $U_{HCO3}V$) 2 hours after oral $NaHCO_3$ bolus (0.5 mmol/kg bw), assuming 50% body weight HCO_3 apparent space of distribution.

Results: Baseline H^+ retention and $U_{citrate}V$ were not different among groups. The 10-year vs. respective baseline value in HCO_3 was not different for H^+ retention (15.7±12.6 vs. 18.1±14.9 mmol, p=0.90) or $U_{citrate}V$ (204±43 vs. 195±49 mg, respectively, p=0.30). By contrast, the 10-year vs. respective baseline value in NaCl was higher for H^+ retention (27.5±15.2 vs. 19.2±16.7 mmol, respectively, p<0.01) and lower for $U_{citrate}V$ (158±47 vs. 193±52 mg, respectively, p<0.01). Similar to NaCl, 10-year vs. respective baseline value in UC was higher for H^+ retention (22.1±11.2 vs. 17.4±9.9 mmol, respectively, p<0.01) and lower for $U_{citrate}V$ (164±42 vs. 187±40 mg, respectively, p<0.01). A generalized linear model for repeated measures, adjusted for time, showed that $U_{citrate}V$ was a predictor of H^+ retention overall (p<0.01) and within each of the 3 groups (p<0.05).

Conclusions: $U_{citrate}V$ non-invasively identifies changes in H^+ retention over time in CKD 2 patients without metabolic acidosis. It should be further explored to follow clinical effectiveness of dietary H^+ reduction in CKD patients without metabolic acidosis.

FR-PO202

Urine Chloride levels Are Associated with CKD Progression in CKD Patients

Boyoung Nam, Joohwan Kim, Yooju Nam, Ki Heon Nam, Tae-Hyun Yoo, Seung Hyeok Han. *Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Tubuloglomerular feedback is the physiologic mechanism responsible for autoregulation of GFR and renal blood flow. This response is mainly driven by chloride level in the distal tubules, thus prevents glomerular hypertension. Here, we studied the relationship between urinary chloride level and CKD progression.

Methods: Data were retrieved from the KoreaN Cohort Study for Outcome in Patients With Chronic Kidney Disease cohort. Among 2,238 participants, a total of 2,019 patients were eligible for the analysis after excluding patients with missing data. Patients were categorized into 3 groups according to baseline tertiles of random urinary chloride excretion : < 76, 76-115, and ≥ 116 mEq/L. The study endpoint was a composite of >50% decrease in eGFR, or ESRD.

Results: The mean age was 53.7 ± 12.1 years, and 1234 (61.2%) patients were male. During a median follow-up of 2.8 years, 436 (21.6%) participants reached the renal endpoint. CKD progression occurred in 236 (34.8%), 159(24.1%), and 41(6.0%) patients in the lowest, middle, and highest tertile groups (P < 0.001), respectively. Compared to the lowest tertile, the middle (HR, 0.811; 95% CI, 0.660-0.997; P=0.047) and highest (HR, 0.619; 95% CI, 0.434-0.882; P=0.008) tertiles were significantly associated with decreased risk of adverse renal outcome in multivariable models after adjustment of confounding factors. This association was consistently observed in adjusted multivariable model where

urinary chloride was entered as a continuous variable (HR per 10 mEq/L increase, 0.961; 95% CI, 0.931-0.993; P=0.016) There was a significant interaction between urinary chloride level and eGFR (P=0.009) and the significant association between urinary chloride level and CKD progression was evident particularly in patients with eGFR < 60ml/min/1.73m^2; HR in the highest tertile was 0.444 compared to the lowest tertile (95% CI, 0.287-0.686; P < 0.001).

Conclusions: This hypothesis generating study showed that higher urinary chloride level is associated with the progression of CKD.

FR-PO203

Serum Chloride Associates with CKD Progression

Minesh Khatri,[1] Josh P. Zitovsky,[2] Melissa J. Fazzari,[2] Candace D. Grant.[2] *[1]Medicine, NYU Winthrop, Mineola, NY; [2]NYU Winthrop Hospital, Mineola, NY.*

Background: Chloride is the predominant extracellular anion in the body, serving important functions including maintenance of electroneutrality, modulation of renin secretion, and regulation of renal sodium transport. Limited data suggest it may predict mortality in heart failure, chronic kidney disease (CKD), and pulmonary arterial hypertension. Recent randomized trials in hospitalized patients have also shown that administration of crystalloid intravenous fluids with lower chloride concentration may have better renal outcomes than fluids with higher chloride concentration. However, chloride has not been studied longitudinally for CKD progression.

Methods: 536 subjects with predominantly stage 3 and 4 CKD were recruited into a prospective cohort study from a nephrology clinic at a single academic medical center. Renal function was re-assessed longitudinally. Logistic and Cox regression models were created for outcomes of upper quartile of annualized estimated glomerular filtration rate (eGFR) decline and > 30% decline in eGFR, respectively. Baseline chloride was modeled continuously as an independent variable, and models were adjusted for potential confounders including co-morbidities, proteinuria, and relevant serum labs and medications.

Results: Median follow-up time was 1.7 years. At baseline, median age was 73, 62% were male, 52% diabetic, 91% hypertensive, and median eGFR was 36 mL/min. Median serum chloride at baseline was 105 mEq/L (interquartile range 102-107 mEq/L). In fully adjusted models, higher serum chloride significantly associated with greater likelihood of upper quartile of annualized eGFR decline (OR 1.09 per 1 mEq/L increase in serum chloride, p = 0.031), and greater hazard of > 30% eGFR decline (HR 1.06 per 1 mEq/L increase in serum chloride, p = 0.036).

Conclusions: In this cohort of CKD patients, higher serum chloride levels associated with increased risk of eGFR decline. Chloride may be a useful, readily available biomarker to aid in predicting CKD progression. Further studies are needed to determine if there is causality, and if so to elucidate pathophysiology and delineate possible treatment strategies.

Association of Serum Bicarbonate Levels with Kidney Function Decline in Patients with Polycystic Kidney Disease

Roshini Yapa,[2] Zhiying You,[3] Berenice Y. Gitomer,[4] Michel Chonchol,[2] Jessica B. Kendrick.[1] *[1]University of Colorado School of Medicine, Aurora, CO; [2]University of Colorado, Denver, CO; [3]UC Denver, Aurora, CO; [4]Div. Renal Diseases and Hypertension, Aurora, CO.*

Background: Lower serum bicarbonate levels are associated with kidney disease progression in patients with chronic kidney disease. Whether serum bicarbonate levels are associated with kidney disease progression in patients with polycystic kidney disease (PKD) is unknown. We tested the hypothesis that lower bicarbonate levels are associated with kidney function decline in patients with PKD.

Methods: We included 774 patients from the HALT-PKD Study A (N=395) and B (N=379) with baseline serum bicarbonate levels and at least three measurements of estimated glomerular filtration rate (eGFR). Bicarbonate was examined as a continuous variable and in categories (≤ 24, 25-28 and >28 mEq/L, with 25-28 mEq/L as the reference group). The outcome was yearly change in slope of eGFR. Linear regression models were used to examine the association between serum bicarbonate and change in eGFR.

Results: The mean (SD) age was 43 ± 10 years. The mean (SD) serum bicarbonate and eGFR at baseline was 26.7 ± 2.4 mEq/L and 70 ± 26 ml/min/1.73m2, respectively. Participants with serum bicarbonate ≤ 24 mEq/L had lower eGFR, higher body mass index (BMI) and systolic blood pressure (SBP) than those with bicarbonate levels >24 mEq/L. In the fully adjusted model, each 1 mEq/L increase in serum bicarbonate level was associated with a 0.1 ml/min/1.73m^2 increase in annual slope of eGFR (β 0.1 ml/min/1.73m^2, 95% CI 0.002 to 0.15, p=0.04). A serum bicarbonate level ≤ 24 mEq/L was associated with a yearly decline in eGFR slope in unadjusted analysis and in partially adjusted analysis, but only trended towards significance in the fully adjusted model (p=0.09).

Conclusions: Lower serum bicarbonate levels are associated with an increased risk of decline in eGFR in patients with PKD.

Association Between Changes in Pre-Transition Sodium with Post-Transition Mortality and Hospitalization Among Patients Transitioning to Dialysis

Maria V. Marroquin,[1] Ekamol Tantisattamo,[1] Jui-Ting Hsiung,[1] Christina Park,[1] Carola-Ellen Kleine,[1] Melissa Soohoo,[1] Connie Rhee,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh,[1] Elani Streja.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: Disturbances in the serum sodium metabolism are common in advanced chronic kidney disease (CKD) and end-stage renal disease (ESRD). Additionally, CKD patients transitioning to dialysis-dependent ESRD have a particularly high mortality risk within the first month of transition. Thus, we examined the relationship between pre-ESRD change in sodium and post-ESRD outcomes.

Methods: We retrospectively examined a cohort of 22,644 veterans transitioning to ESRD between 2007-2015. Patients were grouped into three categories according to their change in sodium. Changes in sodium from 6 to 3 months prior to ESRD transition were calculated by using a mixed-effects model. We explored the association between change in sodium levels, with post-ESRD transition overall all-cause mortality using Cox proportional hazard models, and hospitalization incident rate ratio (HIRR) with Poisson regression. Associations were examined across multiple levels of adjustments including case-mix variables, markers of malnutrition and inflammation, glucose and medications.

Results: Mean age of the total cohort was 67±11 years and median change in sodium level was 0.4 (-1.1,2.0) mEq/L. Both, increasing and decreasing sodium levels were associated with a higher all-cause mortality risk in the fully adjusted model (HR 1.10, 95%CI 1.05-1.15) [figure 1A]. A similar pattern was observed for HIRR across hierarchical adjustments; however the association was attenuated for increasing sodium levels in the fully adjusted model (HR 1.06 95%CI 1.01-1.10) [figure 1B].

Conclusions: Changes in pre-ESRD serum sodium are associated with post-transition death risk and HIRR. Monitoring pre-transition sodium levels may help identify patients at risk for adverse outcomes after ESRD transition.

FR-PO206

Effect of Dietary Salt Intake on Renal Outcomes in Advanced CKD Patients

Minjung Kang, Eunjeong Kang, Hyunjin Ryu, Curie Ahn, Kook-Hwan Oh. *Seoul National University Hospital, Seoul, Republic of Korea.*

Background: The present study analyzed the effect of dietary salt intake on renal outcome for Asian CKD patients. The study is conducted on large number of CKD patients at stages G3a, G3b and G4, with long term follow-up. This study suggests the optimal amount of salt intake for advanced CKD patients.

Methods: Our data were extracted from The KoreaN cohort study for Outcome in patients With CKD (KNOW-CKD). A total of 1,409 CKD patients at stages G3a, G3b and G4, who were enrolled in the KNOW-CKD from 2011 to 2016 were included in the analysis. After excluding 413 patients with incomplete data to define 24-hour urine sodium excretion, 996 non-dialysis CKD patients were finally analyzed. Dietary salt intake, assessed by 24-hour urine sodium excretion, was divided into quartile groups. Second quartile (Q2, 6.72 ~9.14 g salt/day) was regarded as the reference group. Estimated glomerular filtration rate (eGFR) was assessed by CKD-EPI (Cr) equation based on isotope dilution mass spectrometry (IDMS)-traceable creatinine measured at a central laboratory. eGFR slope was analyzed by mixed model from the subjects who repeatedly measured the serum creatinine level more than 4 times at 6- to 12-month interval. Composite renal event is defined either as eGFR halving or as initiation of renal replacement therapy (RRT). Each component of composite renal event was also analyzed.

Results: During the mean 45.6 months of follow-up, 225 subjects developed the composite renal event. After adjustment for confounders including baseline eGFR, multiple Cox regression showed that the risk of composite renal outcomes is significantly higher in the highest quartile group (Q4, salt intake > 11.89 g/day, HR 1.86, p<0.024). Multiple linear regression showed that eGFR slope was not independently associated with daily salt intake (b=-0.02, P=0.23).

Conclusions: High salt intake, assessed by 24 hour urine sodium excretion, is associated with increased risk of CKD progression in advanced CKD.

FR-PO207

Effect of Aldosterone-Renin Level on Glomerular Filtration Rate Slope in Patients with Primary Aldosteronism: A Retrospective, Multi-Center Cohort Study

Hiroki Kobayashi,[2,1] Masanori Abe,[2] Masayoshi Soma,[5] Katsutoshi Takahashi,[3] Mitsuhide Naruse.[4] JPAS group *[1]Section on Genetics and Epidemiology, Joslin diabetes center, Harvard medical school, Boston, MA; [2]Division of Nephrology, Hypertension, and Endocrinology, Nihon University School of Medicine, Tokyo, Japan; [3]Showa General Hospital, Kodaira, Japan; [4]NHO Kyoto Medical Center, Kyoto, Japan; [5]Division of General Medicine, Nihon University School of Medicine, Tokyo, Japan.*

Background: Primary aldosteronism (PA) is recognized as renin-independent aldosterone overproduction, leading to glomerular hyperfiltration. Recent studies demonstrated higher morbidity of renal damage in PA patients compared with essential hypertension. In this study, we aimed to investigate the association of renin-aldosterone levels with adrenalectomy-induced estimated glomerular filtration rate (eGFR) decrease. Furthermore, we also sought to investigate whether renin-aldosterone level affect eGFR slope in PA patients who did or didn't undergo adrenalectomy.

Methods: This is a multicenter retrospective cohort from the Japan Primary Aldosteronism Study. In a total of 2,814 patients with PA, we identified three groups, A) 487 patients who underwent adrenalectomy, B) 284 patients who did not undergo adrenalectomy with follow-up data, and C) 106 patients who underwent adrenalectomy with follow-up data. In group A, we evaluated the predictors of adrenalectomy-induced eGFR decrease for aldosterone producing adenoma by linear regression model. In groups B and C, we analyzed associations between renin-aldosterone levels and annual eGFR decline (mL/min/1.73 m^2/year) by partial spearman correlation analysis, and the association was also assessed using ordinal logistic regression models adjusted for clinical cofounders.

Results: In group A, suppressed plasma renin activity (PRA) was an independent predictor for adrenalectomy-induced eGFR decrease. In group B, suppressed PRA was significantly correlated with higher annual eGFR decline ($r = -0.13$, $P = 0.036$). Furthermore, quartiled PRA was also associated with annual eGFR decline in ordinal logiostic regression model (adjusted cumulative odds ratio = -0.087, P = 0.019), although these associations could not be identified in group C.

Conclusions: Our study demonstrated that excess aldosterone levels with renin suppression affects eGFR slope, and glomerular hyperfiltration is one of the explanation of this association. Furthermore, suppressed PRA which indicate the inadequate mineralocorticoid receptor blockade might be a marker for steeper eGFR slope in patients with PA.

High Renin-Aldosterone Ratio and Lateralization Index Are Associated with Adverse Renal Outcomes in Primary Aldosteronism Patients Who Underwent Adrenalectomy

Sukyung Kang, Yooju Nam, Seon yeong Lee, Joohwan Kim, Ki Heon Nam, Seung Hyeok Han, Tae-Hyun Yoo. *Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Previous studies reported that renal impairment develop in PA patients after adrenalectomy. However, aldosterone-induced glomerular hyperfiltration can lead to masked preoperative renal dysfunction in PA patients. We aimed to elucidate risk factors for renal impairment after adrenalectomy in these subjects.

Methods: In this retrospective study, total 109 PA patients and 193 pheochromocytoma patients as control, who underwent adrenalectomy between January 2006 and November 2017 at Yonsei University Severance Hospital, were enrolled. Acute kidney injury (AKI) after adrenalectomy was defined as increase in serum creatinine >0.3 mg/dL or decrease in eGFR >30% from preoperative baseline values. Postoperative chronic kidney disease (CKD) was defined as eGFR <60mL/min/1.73m^2 for more than 3 months post-adrenalectomy. In all PA patients, adrenal vein sampling was performed to evaluate aldosterone and cortisol levels in each adrenal glands.

Results: Study patients, mean age was 49.6 years and 140(46.4%) were male. Among 109 PA patients, the incidence of AKI and CKD were 28 (25.7 %) and 34 (31.2 %). Meanwhile, among 193 pheochromocytoma patients, the incidence of AKI and CKD were 21(10.9%) and 6(3.1%). Multivariable regression analysis showed high relation of PA patients resulting in CKD compared to pheochromocytoma (Odds ratio 64.8). Univariable regression analysis identified coexisting diabetes mellitus (DM), duration of hypertension, high adrenal venous sampling (AVS) aldosterone-cortisol ratio and lateralization index as risk factors for development of postoperative CKD in PA patients. The AVS aldosterone-cortisol ratio in non-CKD and CKD patients were 84.93 and 113.86. Also lateralization index in non-CKD and CKD patients were 10.33 and 19.80.

Conclusions: Present study demonstrated incidence of CKD was more frequent in PA patients compared to pheochromocytoma patients post-adrenalectomy. Also, high AVS aldosterone-cortisol ratio and lateralization index are independent risk factors for adverse renal outcomes in PA patients post-adrenalectomy.

FR-PO209

Urinary Angiotensinogen Predicts Progressive CKD After an Episode of AKI

Wei Cao. *Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: One of the major obstacles to prevent AKI-CKD transition is the lack of effective methods to follow and predict the ongoing kidney injury in AKI survivors.

Methods: In this study, we test the utility of urinary angiotensinogen (UAGT) for dynamically evaluating renal structural changes and predicting AKI-CKD progression by using both mild and severe bilateral renal ischemia/reperfusion injury mice. Furthermore, we evaluated the value of UAGT in predicting AKI-CKD progression in patients with acute tubular necrosis.

Results: UAGT returns to pre-ischemic levels 14 days after mild AKI followed by kidney architecture restoration, whereas sustained increase in UAGT accompanies by ongoing renal fibrosis after severe AKI. UAGT at day 14-42 correlates with renal fibrosis 84 days after AKI. For predicting fibrosis at day 84, the area under receiver operating characteristics curve of UAGT at day 14 is 0.81. Persistent elevation in UAGT correlates with sustained activation of intrarenal renin-angiotensin system (RAS). Abrogating RAS activation markedly reduced fibrosis, consistent with a role of kidney RAS activation in AKI-CKD progression. Moreover, RAS intervention early in the course of AKI-CKD transition is more beneficial than late intervention in reducing renal fibrosis. Similar changes in the UAGT were observed in patients with AKI-CKD transition.

Conclusions: Our study suggests the potential use of UAGT in motoring renal structural recovery over time and the beneficial effect of early RAS intervention in reducing fibrosis after renal function recovery from AKI.

Estradiol and Renal and Cardiovascular Outcomes in Women with CKD: The Chronic Renal Insufficiency Cohort (CRIC) Study

Ana C. Ricardo,[1] Catherine Kim,[5] Jesse Y. Hsu,[2] Eunice Carmona,[1] Amanda H. Anderson,[2] Jing Chen,[3] Mirela A. Dobre,[4] John W. Kusek,[6] Marie Krousel-wood,[7] Nikhil A. Parikh,[1] Susan P. Steigerwalt,[5] Xue Wang,[2] Harold I. Feldman,[2] James P. Lash.[1] *[1]University of Illinois at Chicago, Chicago, IL; [2]University of Pennsylvania, Philadelphia, PA; [3]Tulane School of Medicine, New Orleans, LA; [4]Case Western Reserve University, Cleveland, OH; [5]University of Michigan, Ann Arbor, MI; [6]NIDDK, Bethesda, MD; [7]Ochsner Clinic Foundation, New Orleans, LA.*

Background: The incidence of end-stage renal disease (ESRD) and cardiovascular disease is lower in women than men. This observation may be explained by the protective effect that endogenous estrogens may have on vascular function. We evaluated the association of estradiol levels with renal and cardiovascular outcomes in women with chronic kidney disease (CKD).

Methods: Prospective, longitudinal study of 1125 women with measured plasma 17b-estradiol by electrochemiluminescent immunoassay at the second annual CRIC visit. We used multivariable mixed-effects and Cox models to examine the association of estradiol with estimated glomerular filtration rate (eGFR) slope, incident ESRD (dialysis or transplantation), atherosclerotic events (myocardial infarction/revascularization, stroke or peripheral arterial disease) and all-cause mortality.

Results: Overall mean (SD) age was 59.6 (10.9) years, and median (IQR) estradiol level 15.8 (8.5-30.2) pg/mL. Compared with women in the highest estradiol quartile (Q4), women in the lowest quartile (Q1) were more likely to be older (63.0 vs. 50.0 years), non-Hispanic white (56.8 vs. 37.4%), and post-menopausal (96.5 vs. 44.2%); and less likely to have diabetes (36.8 vs. 45.9%) and obesity (39.6 vs. 54.1%). Mean eGFR in ml/min/1.73m^2 was higher in Q1 (46.9) compared with Q4 (45.9). Median urine protein-creatinine ratio was similar in the two quartiles (0.09 vs. 0.10). Over a median follow-up of 6.9 years, 189 women developed ESRD, 121 had an atherosclerotic event, and 165 died. In mixed effects models adjusted for relevant demographic and clinical characteristics, the difference in eGFR slope between Q1 and Q4 was 0.34 ml/min/1.73m^2/year (p=0.5). We found no significant association between estradiol (Q1 vs. Q4) and ESRD (HR 0.61, 95% CI 0.35-1.09), atherosclerotic events (HR 0.59, 95% CI 0.29-1.19) or death (HR 0.75, 95% CI 0.4-1.41). The results were unchanged in analyses stratified by menopausal status.

Conclusions: In this cohort of women with CKD, estradiol levels were not associated with renal outcomes, cardiovascular events or death.

Funding: NIDDK Support

FR-PO211

Association of Thyroid Function with Prevalence and Development of CKD

Akiko Toda, Hiroshi Tsuji, Shigeko Hara. *Toranomon Hospital, Tokyo, Japan.*

Background: Previous cross-sectional studies indicated an association between hypothyroidism and kidney dysfunction, but few studies have investigated aboutthyroid dysfunction and chronic kidney disease (CKD), especially whether thyroid dysfunction is a risk factor for CKD development.

Methods: Using the data of annual health check-ups, we evaluated a relationship of thyroid dysfunction with CKD prevalence and development by a multivariate logistic regression analysis. In cross-sectional and longitudinal studies, 16,390 subjects and 7,609 subjects were analyzed, respectively. We categorized the subjects into four groups based on their serum thyroid-stimulating hormone (TSH) concentrations;below-normal (TSH

<0.54 mU/L), lower-normal (0.54–2.40 mU/L), higher-normal (2.40–4.26 mU/L) and above-normal (>4.26 mU/L). As covariate factors, age, gender, obesity, hypertension, dyslipidemia, hyperuricemia, diabetes mellitus, proteinuria, and hematuria were adjusted in cross-sectional study. In longitudinal study, the baseline eGFR was added to the covariate factors of the cross-sectional study.

Results: The cross-sectional study revealed a positive correlation between the TSH concentration and CKD prevalence. Compared with the lower-normal TSH group, the odds ratios (ORs) and 95% confidence intervals (CI) of CKD prevalence were 0.609 (0.452–0.821, p= 0.001) for the below-normal group, 1.492 (1.332–1.672, p<0.001) for the higher-normal group, and 1.900 (1.568–2.302, p<0.001) for the above-normal group. The longitudinal study revealed that the risk of CKD development within three years was significantly higher in the above-normal TSH group compared with the lower-normal TSH group: OR 1.578, 95% CI 1.016–2.451, p= 0.042. However, no significances of CKD development risk in the below-normal TSH group and the higher-normal TSH group were observed.

Conclusions: Our data indicated that a higher TSH concentration has a positive correlation with CKD prevalence, and that a high TSH concentration is a risk factors for CKD development. These results suggest thatthyroid function screening might be informative in patients whose eGFR declines without a clear cause, and thyroid hormone replacement therapy for hypothyroidism patients could have an effect on preventing CKD development.

FR-PO212

Thyroid Hormones and CKD in the German CKD (GCKD) Study

Ulla T. Schultheiss,[2,5] Inga Poguntke,[2,5] Peggy Sekula,[2,5] Kai-Uwe Eckardt,[3] Seema Baid-Agrawal,[4] Elke Schaeffner,[1] Anna Kottgen.[2,5] *[1]Institute of Public Health - Charite, Berlin, Germany; [2]Medical Center - University of Freiburg, Freiburg, Germany; [3]University Medicine-Charite, Berlin, Germany; [4]Sahlgrenska University Hospital, University of Gothenburg, Gothenburg, Sweden; [5]Institute of Genetic Epidemiology, Freiburg, Germany.*

Background: Clinical and translational research support a connection between kidney and thyroid function, e.g. hypothyroidism and low triiodothyronine (FT3) levels in combination with normal thyroid stimulating hormone (TSH) levels (= Euthyroid Sick Syndrome: ESS) and CKD. The relationship between these conditions and CKD progression is understudied. We evaluated the longitudinal association of TSH, free thyroxine (FT4), FT3, and thyroid diseases with a composite endpoint of renal events.

Methods: Thyroid markers were measured at baseline using standard laboratory methods. GFR was estimated using the CKD-EPI formula. Over four years of follow-up, 449 renal events occurred among 4,391 GCKD participants. Renal events included ESRD (dialysis, transplantation), acute kidney injury, or renal death abstracted from hospital records by trained personnel. Cox proportional hazard models of time to the composite outcome adjusted for age, sex, study site, smoking, BMI, history of cardiovascular disease, diabetes mellitus, and proteinuria were evaluated for continuous thyroid markers as well as for thyroid diseases (hypothyroidism: TSH>3.29, FT4≥9.8-18.8 or TSH>3.29, FT4<9.8; ESS: TSH≥0.49-3.29, FT3<3.3).

Results: Mean age was 60 years, with 59.4% males. Medians were TSH: 1.2 mIU/L, FT4: 14.3 pmol/L and FT3: 4.2 pmol/L; hypothyroidism and ESS were present in 5.0% and 5.4%. Thyroid hormone substitution was 21.0%. No association was observed for TSH and FT4, FT3 was significantly associated (HR 0.8, 95%CI 0.7-0.9). Compared to euthyroid patients, hypothyroid patients had a 1.6-fold higher risk and patients suffering from ESS had a 2.0-fold higher risk of reaching the composite endpoint (Table 1). Excluding patients on thyroid medication: the associations with FT3 and ESS remained (FT3: HR 0.7, 95%CI 0.7-0.9; ESS: HR 1.9, 95%CI 1.3-2.7), the association with hypothyroidism disappeared.

Conclusions: Lower FT3 levels, hypothyroidism and ESS were associated with a higher risk of a composite renal endpoint in a population with CKD stage 3 and at risk for thyroid dysfunction.

Funding: Government Support - Non-U.S.

Association results between the composite renal endpoints and thyroid function

	Hazard Ratio	95% Confidence Interval	p-value
FT3	0.8	0.7-0.9	<.001
Hypothyroidism	1.6	1.1-2.2	0.008
ESS	2.0	1.5-2.6	<.001

FR-PO213

A Dose Dependent Relationship Between Hypothyroidism and CKD within a Real-World Clinical Environment

Cheng-Wei Huang,[1] Bonnie H. Li,[2] Connie Rhee,[3] John J. Sim.[4] *[1]Department of Internal Medicine, Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA; [2]Department of Research and Evaluation, Kaiser Permanente Southern California, Pasadena, CA; [3]University of California Irvine Medical Center, Orange, CA; [4]Division of Nephrology and Hypertension, Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA.*

Background: Whether hypothyroidism (HT) engenders chronic kidney disease (CKD) is unknown. We sought to determine whether HT and different thyroid states are associated with CKD among a large diverse population.

Methods: A cross sectional study was performed among individuals with concurrent thyroid stimulating hormone (TSH) and creatinine measurements within Kaiser Permanente Southern California health system (1/1990-12/2017). Rates of CKD across different thyroid states were compared. Multivariable logistic regression analysis adjusted for age, sex, race, and comorbidities was performed to estimate odds ratios (ORs) for CKD by thyroid state. HT was defined as TSH>4mcIU/mL and/or receipt of thyroid hormone replacement. HT was further categorized into 1) hypothyroid state (HS): TSH>4mcIU/mL regardless of thyroid hormone replacement, and 2) attenuated-hypothyroid state (AS): TSH<4mcIU/mL and on thyroid hormone replacement. Euthyroid (ET) was defined as TSH<4mcIU/mL and on no thyroid hormone replacement. The primary outcome was CKD defined as eGFR<45mL/min/1.73m^2.

Results: A total of 378,101 individuals were identified. Among 114,872 (30.4%) meeting criteria for HT, 31,242 (27.2%) were HS and 83,630 (72.8%) were AS. Compared to ET individuals, multivariable OR (95% confidence interval) for CKD (eGFR<45mL/min/1.73m^2) were 1.59 (1.52-1.66) and 1.12 (1.08-1.16) for HS and AS respectively when compared to ET (Table 1).

Conclusions: Within a real-world clinical environment, there is a greater likelihood of CKD associated with HT. A stronger association was seen among those with HS compared to those with AS. Our findings suggest that there may be a dose dependent relationship between thyroid function and CKD. Whether treatment of hypothyroidism among CKD patients may improve and alter the course of CKD is an area warranting future investigation.

Table 1. Odds ratios of CKD (eGFR<45mL/min/1.73m^2) across each thyroid state

Thyroid State	Crude OR (95% CI)	Adjusted OR (95% CI) [1]	Adjusted OR (95% CI) [2]
Hypothyroidism	1.51 (1.47-1.55)	1.25 (1.22-1.29)	1.25 (1.21-1.29)
Hypothyroid state	2.02 (1.94-2.11)	1.56 (1.49-1.63)	1.59 (1.52-1.66)
Attenuated hypothyroid state	1.33 (1.28-1.37)	1.13 (1.10-1.17)	1.12 (1.08-1.16)

Prevalence of CKD, Xanthine Oxidase Inhibitor Treatment, and Serum Uric Acid Control in US Adults with Gout: NHANES 2007–2014

Jean J. Lim, An-Chen Fu, David S. Reasner, Douglas C. Taylor. *Ironwood Pharmaceuticals, Inc., Cambridge, MA.*

Background: Gout is the most common form of inflammatory arthritis, mainly caused by elevated serum uric acid (sUA). The American College of Rheumatology recommends lowering sUA to <6 mg/dL for gout patients, most commonly achieved by lifestyle changes and xanthine oxidase inhibitor (XOI) treatment. Elevated sUA is also associated with the prevalence of chronic kidney disease (CKD). This study aims to estimate the prevalence of CKD among US adults (age ≥20 years) with gout, stratified by XOI treatment status and sUA control (<6 mg/dL).

Methods: This cross-sectional study was conducted using the National Health and Nutrition Examination Survey (NHANES) 2007–2014 including patients who had ever been told by a doctor that they had gout. CKD was categorized based on 2012 Kidney Disease: Improving Global Outcomes using estimated glomerular filtration rate (eGFR; CKD-EPI equation) and urine albumin-creatinine ratio. Descriptive analyses were performed accounting for the survey's complex sampling design.

Results: Of 20,880 participants (representing an estimated 207 M US non-institutionalized adults), 899 (representing 7.8 M) had gout. Among the gout population, 4.9 M (63%) had uncontrolled sUA, 2.8 M (36%) had moderate or higher risk of CKD, and 2.2 M (28%) were taking an XOI. Of the gout population who were not taking an XOI, the majority were uncontrolled regardless of CKD risk (Table).

Conclusions: Among gout patients, more than one third have moderate or higher risk of CKD, and less than one third are currently treated with XOI and of those, 43% have uncontrolled sUA. Therefore, gout patients may benefit from sUA-lowering treatment options that are consistent with their renal function.

Funding: Commercial Support - Ironwood Pharmaceuticals, Inc.

Table. Prevalence of CKD by eGFR, albuminuria, and sUA control among US adults with gout, XOI-treated and untreated

eGFR	Subtotal n (%)	Gout patients currently taking XOI						Subtotal n (%)	Gout patients not currently taking XOI					
		A1 (%)		A2 (%)		A3 (%)			A1 (%)		A2 (%)		A3 (%)

Urate-Lowering Therapy for Asymptomatic Hyperuricemia in Patients with CKD: Controversial Role of Renal Outcome

Dong Ho Shin,[1] Do Hyoung Kim,[2] Chaehoon Han,[4] Jung-woo Noh.[3] *[1]College of Medicine, Hallym University, Seoul, Republic of Korea; [2]Hallym University Hangang Sacred Heart Hospital, Seoul, Republic of Korea; [3]Hallym University, Seoul, Republic of Korea; [4]kangnam secred heart hospital, Seoul, Republic of Korea.*

Background: Because serum uric acid increases as the glomerular filtration rate (GFR) falls, hyperuricemia has also been associated with chronic kidney disease (CKD). Although there are plausible evidences that hyperuricemia represents a risk factor for the progression of CKD, causal role of uric acid is still controversy in CKD patients with asymptomatic hyperuricemia.

Methods: We performed a retrospective single center study, enrolling 935 asymptomatic hyperuricemia patients with stage 3 - 4 CKD, between 2006 and 2018. By using propensity score matching, we matched 290 patients with and without urate-lowering therapy pairs from 935 patients. CKD progression was defined as a >30% reduction in GFR over 2 years. The changes in GFR over time compared between patients with and without urate-lowering therapy using a linear mixed model.

Results: In matched patients, the mean age was 63.2 ± 12.7 years, and 561 patients 60% was diabetic nephropathy. Mean estimated glomerular filtration rate (eGFR) was 44 ± 11 ml/min/1.73 m^2. Serum uric acid level was significantly higher in treatment group 8 ± 2 vs 12 ± 3 mg/dL). During the mean follow-up of 120 ± 48 months, the proportion of CKD progression was not different between treatment group and no treatment group (41.5% vs. 39.5%, p = 0.34). In addition, the overall rate of decline in GFR was also comparable between two group (p = 0.45).

Conclusions: Uric acid-lowering therapy may be controversy in delaying the progression of CKD. Therefore, further randomized controlled trials should be performed to confirm the effect of urate-lowering therapy on the progression of CKD.

FR-PO216

Stage of CKD Does Not Affect the Velocity of Tophus Reduction in Patients with Chronic Refractory Gout Treated with Pegloticase

Brian F. Mandell,[1] Michael Pillinger,[2] N. L. Edwards,[3] Richard J. Johnson,[4] Anthony Yeo,[5] Peter E. Lipsky.[6] *[1]Cleveland Clinic, Cleveland, OH; [2]NYU School of Medicine, New York, NY; [3]University of Florida College of Medicine, Gainesville, FL; [4]University of Colorado Denver, Aurora, CO; [5]Horizon Pharma, Lake Forest, IL; [6]AMPEL BioSolutions, Charlottesville, VA.*

Background: Impaired renal function is a recognized comorbidity of gout and gouty tophi may be more frequent in those with renal dysfunction. It is not known however, whether the velocity of resolution of tophi in response to urate lowering therapy is affected by renal insufficiency.

Methods: This analysis used results from two 6-month randomized controlled trials of pegloticase in patients with chronic refractory gout to address this issue. The velocity of tophus resolution was determined in 18 patients with chronic gout refractory to oral urate lowering therapy who responded to pegloticase administered at a dose of 8 mg every 2 weeks (q2w) with sustained serum urate reductions (<6 mg/dL) over 6 months. eGFR was determined at baseline and after 3 and 6 months of treatment. Tophi were photographed at baseline, 3, 4.5, and 6 months and measured using Computer-Assisted Photographic Evaluation technology. At baseline, the mean area of photographed tophi was 585.8 mm^2.

Results: Complete resolution of all tophi photographed was achieved by 34.8% of the patients. Using linear regression analysis, the velocity of tophus resolution for all the patients was calculated to be 60.1 mm^2 per month. There was no significant relationship between baseline eGFR and velocity of tophus resolution (p=0.5). In addition, there were no significant differences in the velocity of tophus resolution for patients with Stage 1 chronic kidney disease (CKD) vs Stage 2 CKD (P=0.7), Stage 3 CKD (P=0.9), or Stage 4 CKD (P=0.7).

Conclusions: The results from this analysis thus indicate that renal impairment does not compromise the ability of pegloticase to resolve tophi rapidly in patients who respond with sustained reductions in serum urate.

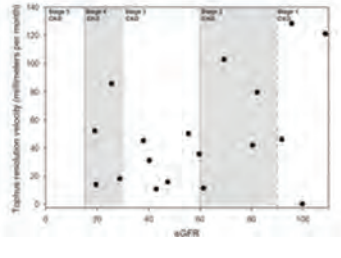
Relationship between baseline eGFR and velocity of tophus reduction in patients with chronic refractory gout who were biochemical responders to pegloticase (8 mg, q2w)



FR-PO217

Association of Renal Dysfunction and Development of Tophi in Subjects with Chronic Refractory Gout

Richard J. Johnson,[1] N. L. Edwards,[2] Michael Pillinger,[3] Anthony Yeo,[4] Peter E. Lipsky.[5] *[1]University of Colorado Denver, Aurora, CO; [2]University of Florida College of Medicine, Gainesville, FL; [3]NYU School of Medicine, New York, NY; [4]Horizon Pharma, Lake Forest, IL; [5]AMPEL BioSolutions, Charlottesville, VA.*

Background: Many, but not all patients with chronic gout develop tophi, and the factors that govern tophus formation are not fully understood. Several studies have suggested impairment of renal function increases the risk for development of tophi, but others have not.

Methods: This analysis addressed the relationship between estimated glomerular filtration rate (eGFR) and the presence of tophi in patients with chronic refractory gout, as well as effects of tophus resolution on eGFR using results from two randomized controlled trials of pegloticase in chronic gout patients.

Results: Overall, 73% of the 212 subjects in these trials had clinically apparent tophi at baseline and 27% did not. Subjects with tophi were significantly older than those without tophi (56.7 vs 51.9 years, P=0.034) and had a significantly longer disease duration (16.3 vs 11.7 years, P=0.0072). Subjects with tophi also had a significantly lower eGFR than those without tophi (59.8 vs 67.9 mL/min/1.73 m^2, P=0.0495). Subjects with advanced renal disease were also more likely to have tophi. Persistent serum urate lowering and resolution of tophi in subjects treated with pegloticase had no significant effect on eGFR despite a significant decrease in the urinary uric acid:creatinine ratio.

Conclusions: These results indicate that chronic refractory gout patients may present with or without clinically apparent tophi and that there is a significant association between the presence of renal dysfunction measured by eGFR and the frequency with which chronic refractory gout patients manifested tophi. However, persistent serum urate lowering and tophus resolution had no significant effect on eGFR over the period of observation in this group of subjects.

Evaluation of the Effects of Allopurinol on Metabolic Acidosis in Patients with CKD

Maryam Miri. *Kidney transplantation complications research center, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran.*

Background: Chronic kidney disease(CKD) is a disabling disease with multiple complications. Increased serum level of uric acid due to glomerular filtration rate (GFR) impairment is an importance and the lack of a similar study In Iran, this study was designed to evaluate the effect of allopurinol on metabolic acidosis in patients with renal failure.

Methods: In this randomised controlled trial (RCT) study, 50 patientswithCKDstage II-IV, who referred to Ghayem Hospital, were selected and randomly divided into two equal groups of 25 subjects. In addition to standard treatments, the intervention group received 100 mg allopurinol tablet for 3 months and the control group received placebo. Demographic data were obtained from each subject. Serum uric acid level, creatinine, pH blood and bicarbonate levels were obtained at the initiation of treatment and at the end of the third month.

Results: The mean age of subjects was 54.04±12.62 years. The most common cause of CKD was Diabetes Mellitus (36.0%). Allopurinol administration resulted in a significant increase bicarbonate and PH(p<0.001 each) compared to control group. A significant reduction in uric acid (p<0.05) and increase in GFR (p<0.05) was observed in both groups.

Conclusions: Allopurinol may ameliorate metabolic acidosis, glomerular filtration and uric acid in patients with CKD

FR-PO219

Post-Discharge Readmission Outcomes Following Hyperkalemia-Related Hospitalization

J. Michael Woolley,[4] Keith Betts,[1] Fan Mu,[2] Yao Wang,[3] Sneha S. Kelkar,[1] Eric Wu.[2] *[1]Analysis Group, Inc., Los Angeles, CA; [2]Analysis Group, New York, NY; [3]Analysis Group, New York, NY; [4]AstraZeneca, Wilmington, DE.*

Background: The objective of this study was to compare post-discharge outcomes, including hospital readmission rates, lengths of stay (LOS) per readmission, and total inpatient days, between hospitalizations in patients with and without hyperkalemia (HK).

Methods: Adults with available potassium lab results and at least one hospitalization were identified from a large US claims database (1/1/2010-12/31/2014). Hospitalizations with an HK diagnosis (ICD-9 276.7) were defined as case hospitalizations (cases), and hospitalizations from patients without HK (no HK diagnosis, no potassium lab tests above 5.0 mEq/L, and no sodium polystyrene sulfonate use) were defined as control hospitalizations (controls). Cases and controls were required to have continuous enrollment from 6 months prior to admission to 12 months after discharge from the hospitalization. Controls were matched 1:1 to cases on age, chronic kidney disease (CKD) stage, dialysis treatment, heart failure (HF), renin-angiotensin-aldosterone system inhibitor (RAASi) use, major diagnostic categories, and selected diagnosis-related groups. Readmission rates, LOS per readmission, and total inpatient days during the 1-year post-discharge period were assessed using Wilcoxon signed-rank and McNemar tests. Analysis was repeated in patients with CKD and/or HF.

Results: A total of 5,377 hospitalizations with HK (cases) were matched to hospitalizations without HK (controls). Compared with controls, cases had higher rates of readmission (30-day: 12.5% vs. 8.4%; 60-day: 18.3% vs. 12.7%; 90-day: 24.3% vs. 16.8%). Cases also had longer LOS per readmission (8.1 vs. 7.1 days) and more total inpatient days (10.5 vs. 5.8 days) during the 1-year post-discharge period (all p<0.001). In patients with CKD and/or HF, cases had higher rates of readmission (30-day: 13.8% vs. 9.4%, 60-day: 19.8% vs. 14.3%, 90-day: 26.5% vs. 19.2%), longer LOS per readmission (8.4 vs. 7.4 days), and more total inpatient days (12.4 vs. 7.2 days) during the 1-year post-discharge period compared with controls (all p<0.001).

Conclusions: Post-discharge, hyperkalemia-related hospitalizations were associated with higher readmission rates, longer lengths of stay per readmission, and higher total inpatient days.

What Characterizes the Patients Who Develop Repeated or Persistent Hyperkalemia? A Population-Based Laboratory Study of Potassium Trajectories in Patients with CKD

Reimar W. Thomsen,[1] Sia Kromann Nicolaisen,[1] Eirini Palaka,[2] Pål Hasvold,[3] Lars Pedersen,[1] Kasper Adelborg,[1] Henrik T. Sorensen.[1] *[1]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus N, Denmark; [2]Global Health Economics, AstraZeneca, Cambridge, United Kingdom; [3]Medical Department, AstraZeneca Nordic, Etterstad, Oslo, Norway.*

Background: Hyperkalemia (HK) (defined as blood potassium (K^+) >5.0 mmol/L) is common among patients with chronic kidney disease (CKD) and associated with adverse outcomes. Little is known about the characteristics of patients with repeated and persistent HK.

Methods: Observational laboratory study of all patients with CKD in Northern Denmark, 2000-2012. For all CKD patients with an incident HK event, we examined K^+ trajectories over 6 months. We described patient characteristics associated with persistent HK (2 or more elevated K^+ tests >5.0 mmol/L with ≤1 normal K^+ test in between) and repeated HK (2 or more elevated K^+ tests separated by ≥2 normal K^+ tests).

Results: In 157,283 patients with CKD (median age 73 years, 59% females, median number of annual K+ tests =4), 28% (n=43,845) had a subsequent HK event detected. Within 6 months after the first HK, 29% had died, 45% had no additional high K+ value, while 26% (n=11,390) fell into persistent or repeated HK pattern. FIGURE shows K+ trajectories for patients with persistent (A:2 high K+ tests, n=3,936; B:3 high tests, n= 1,236; C:≥4 high tests, n=974) or repeated HK (D, n=5,244). Important baseline predictors for persistent or repeated HK include low eGFR (prevalence ratio (PR)=2.40 (95% CI 1.91-3.01) for eGFR <15), severity of first HK event (PR=3.98 (95% CI 3.05-5.18) for K+ 6.0-6.5 mmol/L), and use of ACE-inhibitors (PR=1.32 (95% CI 1.23-1.41)) or spironolactone (PR=1.59 (95% CI 1.43-1.78)).

Conclusions: Repeated HK and persistently elevated K+ levels are common in CKD patients. The use of readily identifiable clinical predictors can help identify patients at highest risk, who can benefit most from effective K+ management.

Funding: Commercial Support - AstraZeneca

FR-PO221

Assessing the Impact of Hyperkalemia on Patient-Reported Quality of Life: A Global Analysis of the KDQOL-36 in a Real-World CKD Patient Population

Susan Grandy,[1] James Jackson,[2] Lei Qin,[1] Rebecca Moon,[2] Megan Scott,[2] Eirini Palaka.[3] *[1]Astrazeneca, Gaithersburg, MD; [2]Adelphi Real World, Macclesfield, United Kingdom; [3]AstraZeneca, Cambridge, United Kingdom.*

Background: Hyperkalemia (HK), defined as abnormally high serum potassium (K^+>5mmol/L), is common in patients with chronic kidney disease (CKD) because of the effects of kidney disease on K^+ homeostasis. Management of HK includes strict adherence to a low K^+ diet which can be unhealthy and an added burden to patients. Evidence describing the impact of HK on patient reported outcomes is limited. The objective of this analysis was to assess the impact of HK on the Quality of Life (QoL) of non-dialysis (ND) CKD patients using the Kidney Disease Quality of Life Instrument (KDQOL), a validated CKD-specific questionnaire.

Methods: Data from the 2015 and 2018 Adelphi CKD Disease Specific Programmes were pooled to create a cross-sectional dataset of unique patients, including global data from physicians and their ND CKD patients across EU-5, China and USA. Patients completed the KDQOL, a disease specific self-report measure targeted at the particular concerns of individuals with kidney disease. CKD ND patients with HK (K^+ >5.0 mmol/L) and without HK (i.e. those with normal K^+ levels 3.5-5.0 mmol/L) were stratified to study the association between HK and QoL. Multivariate analysis was used to identify the association between HK and QoL, adjusting for age, sex, eGFR levels, and presence of heart failure and diabetes.

Results: Results of the KDQOL analysis showed that ND patients with HK (n=216) had significantly lower mean QoL scores compared to those without HK (n=933) for 3 of the 5 KDQOL domains: burden of kidney disease (54.9 vs. 60.8; p=0.011), effects of kidney disease (69.6 vs. 76.1; p=<0.001) and physical health (39.1 vs. 41.6; p=0.001). Additionally, patients with HK had numerically lower scores for the remaining 2 KDQOL domains compared to patients without HK, namely symptoms/problems (80.1 vs. 82.1; p=0.134) and mental health (45.3 vs. 46.8; p=0.073).

Conclusions: This study highlights the negative impact of HK on the quality of life of CKD ND patients globally. HK contributes to the overall CKD disease burden, leading to further decrements in quality of life compared to patients without HK. Effective management of hyperkalemia may improve quality of life in this patient population.

FR-PO222

Quality of Life in CKD Patients with Hyperkalemia in the US: Results from the KDQOL-36

Susan Grandy,[1] James Jackson,[2] Lei Qin,[1] Rebecca Moon,[2] Megan Scott,[2] Eirini Palaka.[3] *[1]Astrazeneca, Gaithersburg, MD; [2]Adelphi Real World, Macclesfield, United Kingdom; [3]AstraZeneca, Cambridge, United Kingdom.*

Background: Hyperkalemia (HK), defined as abnormally high serum potassium (K^+ >5mmol/L), is common among patients with Chronic Kidney Disease (CKD) and is associated with increased risk of mortality and hospitalization. Over 6% of CKD patients in the US have HK, four times the corresponding rates in the general US population. The Kidney Disease Quality of Life Instrument (KDQOL) is a 36-item survey specifically targeting concerns of individuals with CKD, to identify the disease burden on quality of life (QoL). Limited real-world data exist on the impact of HK on the QoL of CKD patients in the US. While low K^+ diet is key for HK management, the established poor dietary habits of the US population together with the lack of universal health coverage and limited social support increase the importance of better understanding the impact of HK on the QoL of US CKD patients.

Methods: Real-world data of unique CKD non-dialysis (ND) patients from the 2015 and 2018 US Adelphi CKD Disease Specific Programmes were pooled and analyzed. Patients completed the KDQOL questionnaire, while physicians reported information on patient demographics, disease characteristics and comorbidities. Patients with and without HK (normal K^+ 3.5-5.0 mmol/L) were compared. The association between HK and QoL was measured using multivariate analysis adjusting for age, sex, eGFR level, and presence of heart failure and diabetes.

Results: Based on the results from US CKD ND patients with HK (n=64) and without HK (n=312), HK patients had significantly lower QoL scores across four of the five KDQOL domains, compared to those without HK: burden of kidney disease (54.4 vs. 66.0; p=0.023), effects of kidney disease (69.7 vs. 80.2; p=0.010), physical health (38.7 vs. 42.2; p=0.020) and mental health (44.8 vs. 48.9; p=0.018). US patients with HK also had a lower score on the fifth symptoms/problems domain compared to those without HK, without this difference being statistically significant (83.2 vs. 85.2; p=0.455).

Conclusions: CKD ND patients with HK in the US experienced a greater negative impact on their QoL compared to patients without HK, as they experienced higher disease burden, and a greater physical and mental impact. Effective management of K^+ levels has the potential to maintain or improve QoL in this patient population.

Secondary Hyperparathyroidism Is Associated with Erythropoietin Deficiency and Endogenous Erythropoietin Resistance in Patients with CKD

Il Young Kim,[1] June hyun Kim,[1] Dong Won Lee,[1] Soo Bong Lee,[1] Miyeun Han,[2] Harin Rhee,[2] Sang Heon Song.[2] *[1]Pusan National University Yangsan Hospital, Yangsan, Republic of Korea; [2]Pusan National University Hospital, Busan, Republic of Korea.*

Background: Erythropoietin (EPO) deficiency and resistance to endogenous EPO is an important pathophysiological feature in anemia of chronic kidney disease (CKD). Secondary hyperparathyroidism is known to contribute to anemia of CKD. We aimed to investigate the associations between parathyroid hormone (PTH) and anemia, EPO deficiency, and endogenous EPO resistance in patients with CKD.

Methods: This study included 409 patients with CKD [glomerular filtration rate (GFR) < 60 ml/min/1.73m^2] who were not on dialysis therapy. Patients on exogenous EPO therapy and patients with iron deficiencies were excluded. Endogenous EPO resistance was assessed by calculating the ratio of endogenous EPO to hemoglobin (Hb) (endogenous EPO/Hb ratio). The associations of Hb level, endogenous EPO level, and the endogenous EPO/Hb ratio with clinical and laboratory variables were investigated by univariate and multivariate analyses.

Results: In univariate analysis, intact PTH level was correlated negatively with the Hb level (r = -0.403, P < 0.001) and endogenous EPO level (r = -0.108, P = 0.029). The intact PTH level was correlated positively with the endogenous EPO/Hb ratio (r = 0.139, P = 0.005). Multiple regression analysis revealed that the intact PTH level remained significantly associated with the Hb level (β = -0.136, P = 0.006), endogenous EPO level (β = -0.148, P = 0.016), and the endogenous EPO/Hb ratio (β = 0.131, P = 0.021), even after adjusting for other confounding factors, including the levels of the inflammatory marker C-reactive protein.

Conclusions: Secondary hyperparathyroidism exhibited significant associations with anemia, EPO deficiency, and endogenous EPO resistance in CKD patients. These associations were independent of inflammation status.

FR-PO224

Fibroblast Growth Factor 23 and Adiposity in Patients with CKD Stages 3 and 4

Elvis A. Akwo,[1] Cassianne Robinson-Cohen,[1] Victoria Whitfield,[1] Edward D. Siew,[1,3] Talat Alp Ikizler,[1,3] Adriana Hung.[2,1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Veterans Affairs CSR&D, Nashville, TN; [3]Veterans Affairs, Nashville, TN.*

Background: Adiposity has been associated with higher Fibroblast Growth Factor 23 (FGF23) levels in patients with normal kidney function. If this relationship is observed in patients with moderate chronic kidney disease (CKD) is unknown. We investigated the relationship between adiposity and FGF23 in a cohort of patients with stages 3-4 CKD.

Methods: This was a cross-sectional investigation of 71 CKD patients who underwent body composition and anthropometric assessments. Dual energy x-ray absorptiometry (DEXA) scans were used to measure total fat mass and body mass index (BMI) was computed using baseline weight and height measurements. Biomarkers included estimated glomerular filtration rate (eGFR), serum leptin, FGF23, high sensitivity C-reactive protein (hsCRP) and serum lipids. Ordinary least squares regression with the sandwich estimator of variance was used to investigate the relationship between FGF23 and measures of adiposity (BMI, total fat mass) and the pro-atherogenic adipocytokine leptin. Log-transformation was performed for variables with considerable skewness.

Results: Mean (SD) age was 66 (12) years, 26% of participants were female, 23% were African-American. Median eGFR was 46.9 ml/min/1.73m2 (IQR 41.9, 52.8), median BMI was 31(IQR: 27, 35). Log FGF23 had a significant positive correlation with BMI (r = 0.27, p = 0.02), total fat mass (r = 0.30, p = 0.01) and serum leptin (r = 0.43, p < 0.0001). After full adjustment for age, sex, race, eGFR, log hsCRP, log HDL and log triglycerides, a 50% increase in FGF-23 was associated with 1 unit [95% I: 0.1, 1.9; p = 0.03] increase in BMI, 2.5 kgs [95% CI: 0.2, 4.8; p = 0.03] increase in total fat mass and a 6.7 ng/mL [95% CI: 1.0, 12.4; p = 0.02] increase in serum leptin.

Conclusions: We report in patients with stage 3 & 4 CKD a cross-sectional association between higher FGF23 and higher adiposity (BMI, total fat mass and the pro-atherogenic adipocytokine, leptin). The causes and the implications of these associations need to be further investigated. Particularly in bone and vascular health.

Elevated Serum Osteoprotegerin Associates with Microbiota-Derived Phenylacetylglutamine and Vascular Calcification in CKD

Lu Dai,[1] Abdul Rashid T. Qureshi,[1] Bengt Lindholm,[1] Olof Heimburger,[5] Peter F. Barany,[1] Magnus Soderberg,[2] Pieter Evenepoel,[3] Peter Stenvinkel.[4] *[1]Division of Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden; [2]Pathology, Drug Safety and Metabolism, IMED Biotech unit, AstraZeneca, Molndal, Sweden; [3]Department of Immunology and Microbiology, Laboratory of Nephrology, University Hospitals Leuven, Leuven, Belgium; [4]Division of Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden; [5]Division of Renal Medicine and Baxter Novum, Karolinska Institutet, Stockholm, Sweden.*

Background: Increasing evidence indicate that a complex interplay between reduced renal function, altered bone metabolism and increased levels of metabolites produced by the gut microbiota drives vascular calcification (VC) which causes considerable morbidity and mortality in patients with chronic kidney disease (CKD). Here we investigated if osteoprotegerin (OPG), an osteocyte-derived inhibitor of bone formation, is associated with phenylacetylglutamine (PAG), a gut microbial metabolite, and VC in CKD stage 5 patients.

Methods: In 112 living donor kidney transplant (LD-Rtx) recipients (63% males; median age 47 years), associations between severity of VC (score 0 to 3; evaluated by histological examination of epigastric artery specimens collected at LD-Rtx), and serum OPG and PAG were investigated. Patients with VC grade 0 (n=17) and 1 (n=51) were combined into Group 1, representing no or minimal VC (n=68), and those having moderate (score 2; n= 29) or extensive (score 3; n= 15) VC were combined into Group 2 (n=44).

Results: Group 2 patients had significantly higher OPG levels than Group 1 patients with no or minimal VC. In Spearman's rank correlations, OPG was positively associated with age, bone specific alkaline phosphatase, PAG, high-sensitive C-reactive protein and percentage calcification. Multivariate regression analyses showed that after adjustments for age, sex, diabetes and smoking habits, 1-SD higher level of PAG (β=0.35 P<0.001) was independently associated with 1-SD higher OPG level (adjusted r^2=0.44). OPG was significantly associated with VC score after adjustments for age, sex, diabetes, smoking habits and PAG (OR [95% CI]: 2.05 [1.08, 3.89]; p=0.03).

Conclusions: While gut microbiome assessed by PAG is closely related with bone metabolism as assessed by OPG in CKD patients, serum OPG is a strong predictor of biopsy-verified VC, independent of gut microbiota status as assessed by PAG.

FR-PO226

Serum Procalcitonin Level May Predict Secondary Hyperparathyroidism Resistance Among CKD Patients

Mahmoud H. Imam, Mohammed Shawki. *Internal Medicine Department, Faculty of medicine,Benha University, Benha, Egypt.*

Background: Secondary hyperparathyroidism (SHPT) is common among CKD patients stage 3-5D. Frequently, patients reveal resistance to the conventional medications including vitamin D and oral cinacalcet. Inflammation was postulated as a potential cause of such resistance. The aim of this study is to assess if serum procalcitonin (PCT) level may be useful to predict SHPT resistance among CKD patients.

Methods: In this prospective study, 516 CKD patients attending nephrology clinic at a tertiary hospital were recruited. Inclusion criteria included: (1) eGFR < 60 ml/min for more than 3 months or patients were on regular hemodialysis. (2) serum intact parathormone (iPTH) level ≥ 300 pg/ml. Exclusion criteria included: (1) patients who had a kidney transplant, (2) patients had an evident infection at the time of the initial visit, and (3) patient was already receiving either vitamin D supplementation or oral cinacalcet. PCT and C reactive protein (CRP) levels were measured for each patient during the initial visit. iPTH was measured monthly. Resistance was defined as less than 30% reduction in initial iPTH level despite three months of maximally tolerated cinacalcet and vitamin D therapy. Multiple regression analysis and ROC curve tests were performed to assess the causality between PCT level and SHPT resistance.

Results: 482 patients completed the study. The mean age of patients was 61.4 ± 11.2 years. Female patients were 49%. Mean eGFR was 38 ± 17 ml/min/1.73 m^2. Mean baseline iPTH was 845 ± 314 pg/mL. Serum PCT level was significantly higher among patients with resistance to SHPT therapy (mean PCT was 0.90 ± 0.28 vs 0.42±0.16 ng/mL; 95% CI: -0.5316, -0.4284; p .001). The area under the ROC curve for PCT, CRP, and age were 0.89, 0.71 and 0.65 respectively.

Conclusions: Serum procalcitonin level may be useful to predict resistance to therapy for secondary hyperparathyroidism among chronic kidney disease patients.

FR-PO227

The Oxidized Form of Serum Albumin, Non-Mercaptalbumin Is Significantly Associated with Renal Function and Anemia in CKD Patients

Shinya Nakatani,[1] Eiji Ishimura,[2] Keiko Yasukawa,[4] Norikazu Toi,[1] Hideki Uedono,[1] Akihiro Tsuda,[3] Shinsuke Yamada,[1] Katsuhito Mori,[1] Hitoshi Ikeda,[4] Yutaka Yatomi,[4] Masaaki Inaba.[1] *[1]Osaka City University Graduate School of Medicine, Osaka, Japan; [2]Meijibashi Hospital, Matsubara-shi, Japan; [3]Department of Nephrology, Endocrinology, Metabolism, and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan; [4]The University of Tokyo Hospital, Tokyo, Japan.*

Background: Human mercaptalbumin (HMA; reduced form of serum albumin) and non-mercaptalbumin (HNA; oxdized form of serum albumin) have been known to be an indicator for evaluating oxidative stress in the systemic circulation, including patients with end stage renal disease.

Methods: We investigated factors associated with fraction of HNA (f(HNA)) in 112 pre-dialysis CKD patients (age 63.6±14.0 years; 59 males and 53 females), using a newly established, anion-exchange column packed with a hydrophilic polyvinyl alcohol gel, along with high performance liquid chromatography.

Results: The means f(HNA) in CKD patients was 30.0 ±6.13%, whose value was higher than that reported in healthy subjects f(HNA) 25.1±3.0%. Age, estimated glomerular filtration rate (eGFR), blood urea nitrogen, hemoglobin, sodium-chloride, phosphate, intact parathyroid hormone (PTH), and fibroblast growth factor (FGF)-23 levels correlated significantly with plasma f(HNA) (ρ=0.302, $p<0.001$;ρ=-0.436, $p<0.001$; ρ=0.457, $p<0.001$;ρ=-0.382, $p<0.001$;ρ=-0.324, $p<0.001$;ρ=0.265, p=0.001; ρ= 0.367, p=0.001;ρ= 0.419, $p<0.001$;respectively). In multiple regression analyses, age (β=0.200, p=0.014), eGFR (β=-0.238, p=0.009), hemoglobin (β=- 0.346, p<0.001), and ferritin (β=0.200, p=0.019), were associated significantly and independently with f(HNA) (R^2=0.356, p<0.001). In addition, concerning factors related to CKD-mineral and bone disorder(CKD-MBD), intact-PTH (β=0.218, p=0.049) and 1,25-dihydroxyvitamin D ($1,25(OH)_2D$) levels (β=-0.178,p<0.001) were significantly and independently associated with serum f(HNA) (R^2=0.339, p<0.001), although fibroblast growth factor-23 were not.

Conclusions: We demonstrated that impaired renal function and renal anemia were strongly associated with oxidization of serum albumin. We also demonstrated that, intact PTH and $1,25(OH)_2D$ are significant factors associated with the redox states of serum albumin. Our findings suggest the importance of management of hemoglobin and ferritin levels, and appropriate control of CKD-MBD factors in regard to better redox state of albumin in CKD patients.

Bortezomib in the Treatment of Kidney Light Chain Amyloidosis

Nan Chen. *Ruijin Hospital, Shanghai, China.*

Background: Light-chain amyloidosis is a clonal plasma cell disorder. It can cause kidney injury including proteinuria and abnormal renal function. This study is in order to evaluate the efficacy of Bortezomib in the treatment of Kidney Light Chain Amyloidosis

Methods: This is a retrospective study. All participants were recruited from Department of Nephropathy, Shanghai Ruijin Hospital between February 2013 to February 2018. The diagnosis of Kidney light chain amyloidosis(KAL) was based on kidney biopsy. All the patients were given BD therapy per month (Bortezomib 1.3mg/m2 BSA on day 1,4,8,11, Dex on day 1-4 and 8-11). The primary outcome was kidney complete response(CR) defined as at least 50% reduction in 24-hour urinary protein(24hUP) compared to baseline, plus the decrease of estimated GFR(calculated by EPI-Creatinine equation) was less than 25% compared to baseline. Partial response(PR) was defined as 24hUP reduction within 20%~50%. Non response was defined as 24hUP reduction less than 20% or the decrease of eGFR more than or equal to 25%.

Results: Thirty patients were diagnosed as KAL in this study. Of all the patients, 18 (60%) were male and mean age was 56 (35-69) years old. Totally, 24 (80%) patients were λ type KAL, 6 (20%) patients were κ type KAL. Nineteen patients (63.3%) were CKD stage 1, 8 patients (26.7%) were CKD stage 2 and 3 patients (10%) were CKD stage 3~5. The mean frequency of BD therapy was 3.8 (1-12) times and the mean follow-up period was 8.21 (3-28) months after advanced remission or treatment. Finally, 12 of 30 patients (40%) reached CR,4 reached PR (13%). After BD therapy, the 24hUP was significantly decreased compared to baseline (3.6 vs 5.2 g/24h, P<0.05), serum albumin was increased (23.9 vs 28.13g/L, P<0.005)and there was no decrease of eGFR(83.9 vs 87.9, p=0.228).(Figure 1)

Conclusions: Bortezomib was effective in the treatment of patients with KAL and the renal remission rate of our study was 53%.

	Before treatment	After treatment	P value
mean 24hUP	5214.0	3585.9	0.012
(mg/24h)	(12156-517)	(9018-253)	
mean serum albumin	23.9	28.1	0.005
(g/L)	(36-10)	(49-12)	
mean serum creatinine	90.5	93.2	0.252
(μmol/L)	(412-45)	(598-44)	
EPI-GFR	83.9	87.9	0.228
(ml/min·1.73m²)	(124.0-13.0)	(134.9-8.4)	

Bortezomib in the Treatment of Kidney Light Chain Amyloidosis

FR-PO229

Treatment of Multiple Myeloma Related Kidney Disease by Bortezomib

Nan Chen. *Ruijin Hospital, Shanghai, China.*

Background: Only few evaluate the efficacy and safety of bortezomib in the treatment of multiple myeloma(MM) related kidney disease.

Methods: It is a retrospective cohort study. All the eligible patients were enrolled from Department of Nephropathy, Shanghai Ruijin Hospital between Sep 2009 and Aug 2017. Patients diagnosed MM with renal insufficiency were enrolled while patients with relapsed MM were excluded. All the subjects were given a bortezomib based treatment, including PD(bortezomib, dexamethasone)/PAD(bortezomib, adriamycin, dexamethasone)/ PCD(bortezomib, cyclophosphamide, dexamethasone). The primary outcome was clinical remission. Definition of hematological remission and renal response were according to the criterion made by IMWG(International Myeloma Working Group).

Results: Totally, 53 patients with MM related kidney diseases were recruited in this study. Of the 53 cases, 34M & 19F, mean age 59(35-86)y/o, median urinary protein 4.2g/24h, serum albumin 30g/L, EPI-eGFR 19ml/min, 10 cases received dialysis therapy. The MM type included 11 IgA,5 IgD,16 IgG,21 Light chain. Of 28 cases with renal biopsy, 6(21%)amyloidosis, 14(50%) cast nephropathy, 6(21%) tubulointerstitial lesions, 2(8%) light chain deposition disease(LCDD). The medium follow-up time was 7(3-47)months. Of 32 cases that taken at least 4 cycles of bortezomib treatment, hematological remission showed that 14(44%) achieved CR,9(28%)achieved PR,7(22%)were stable, 2(6%) were relapsed;23/32 baseline eGFR<60ml/min, renal response showed that 5(22%) achieved CR,1(4%)achieved PR,12(52%)achieved MR,5(22%)were stable. Of 10 cases that dialysis dependent, 5 got rid of dialysis. After treatment, patients showed improvement in clinical features.(Fig 1&2)

Conclusions: Bortezomib can significantly reduce urinary protein, increase EPI-eGFR and improve prognosis of MM related kidney disease, which means making patients benefit.

Table1 Efficiency after 4 cycles of treatment(n=32)

Clinical features	Baseline	Posttreatment	P value
Serum Albumin(g/L)	32(19-42)	38(24-45)	0.004
Urinary protein(mg/24h)	3184(107-15035)	265(85-5005)	0.000
EPI-eGFR(ml/min·1.73m²)	25.3(4-127)	47.5(8-110)	0.000
Hemoglobin(g/L)	88(55-130)	117(90-151)	0.000

Table2 Efficiency after 1-3 cycles of treatment(n=21)

Clinical features	Baseline	Posttreatment	P value
Serum Albumin(g/L)	29(14-41)	36(18-43)	0.013
Urinary protein(mg/24h)	5197(1360-14346)	1533(125-10712)	0.203
EPI-eGFR(ml/min·1.73m²)	15(5-100)	15(7-93)	0.826
Hemoglobin(g/L)	84（51-140）	94（54-141）	0.433

Direct Oral Anticoagulants vs Warfarin Across CKD Stages: Mortality Outcomes in US Veterans

Alissa Dratch,[3,1] Drake A. Edgett,[3,1] Elani Streja,[3,1] Ekamol Tantisattamo,[1] Kamyar Kalantar-Zadeh,[3,1] Csaba P. Kovesdy,[2] Wei Ling Lau.[1] *[1]University of California, Irvine School of Medicine, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN; [3]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA.*

Background: For over 50 years warfarin was the only oral anticoagulant available and was shown to prevent stroke and improve survival in the general population. However, evidence to support use of anticoagulation in patients with advanced CKD has been controversial. Direct Oral Anticoagulants (DOACs) became available in the past decade but outcomes data in CKD is limited. In this project we examined mortality outcomes associated with DOACs vs. warfarin therapy in the Veterans Affairs (VA) database.

Methods: In a national cohort of US veterans, we identified patients who were initiated on warfarin or DOAC treatment between 1/1/2012-12/31/2013. Cox models were used to calculate mortality hazard ratios across stages of kidney disease (or no kidney disease) with multivariable adjustment for age, gender, race and baseline comorbidities (diabetes, hypertension, heart failure, myocardial infarction, prior stroke, antiplatelet medications).

Results: The cohort included 27,787 patients of which 73% were non-CKD, 15% were CKD stage 3a, 5% were CKD stage 3b, and 1% were CKD stage 4. There were no CKD stage 5 patients on DOACs. Patients had a mean±SD age of 69±10 years and included 19% diabetics, 15% African-Americans and 2% Hispanics. Patients on warfarin were more likely to be older, African-American, and have pre-existing comorbidities. Compared to warfarin, patients initiated on DOAC medication had a lower risk of death in non-CKD and CKD stage 3a groups; however associations were attenuated and trended toward a reverse association in later stage CKD [Figure].

Conclusions: In a national cohort of US veterans DOACs were associated with a lower mortality risk in non-CKD and early stage CKD. Further studies with larger patient numbers are warranted to evaluate outcomes of DOACs vs. warfarin therapy in later stage CKD.

FR-PO231

The Bleeding Risk of Adding Pentoxifylline to Aspirin in Patients with CKD

Chia-Chun Wu,[1,2] Tzongshi Lu,[3] Jui-Yi Chen.[1] *[1]Chi Mei Medical Center, Tainan, Taiwan; [2]Pharmacy, Chia Nan University of Pharmacy and Science, Tainan, Taiwan; [3]Brigham and Women's Hospital, Harvard Medical School, Natick, MA.*

Background: Pentoxifylline (PTX) is found renoprotective in chronic kidney disease (CKD) by the effects of antiinflammation, antifibrosis and improvement on hemorheology. CKD is a risk factor of cardiovascular disease, therefore many patients with CKD are under antiplatelet treatment to prevent it. CKD is also known associated with a greater risk of bleeding. Herein, we want to know if adding on PTX in CKD patients who already under aspirin therapy will increase the risk of bleeding.

Methods: The National Health Insurance Research Database in Taiwan was used to identify patients who had diagnosis of CKD and under aspirin treatment longer than 3 months after CKD diagnosed. The exclusion criteria were having major bleeding events within one year prior the CKD diagnosed, liver cirrhosis, thrombocytopenia and history of hospitalization within three months before study index date. Patients who received PTX after aspirin were selected as study group (PTX group), the remaining patients who without PTX treatment and matched on age, gender and years of CKD diagnosis were selected as control group. The study outcome was any event of intracranial hemorrage (ICH) or gastrointestinal(GI) bleeding after using PTX. A conditional logistic regression model was used to estimate the risk of bleeding in PTX treated patients.

Results: A total 607 patients in PTX group and 1214 in control group were analyzed. The mean age of both groups was 65.7+/-12.4 yeas old. PTX group had higher percentage of diabetes mellitus (DM)(44.48% vs 35.91%, p<0.001) and stroke history (18.29% vs 14.33%, p=0.029). The percentage of ICH and GI bleeding events was 1.48% and 14.83% in the PTX group; 1.89% and 11.86% in the control group, without significant difference. The risk of having a bleeding event was not significant different between PTX group and control group after adjusting the comorbidities of DM, hypertension, hyperlipidemia, stroke history and end stage renal disease. (Adjusted Odds Ratio(AOR) of ICH: 0.78, 95% Confidence Interval(CI): 0.38-1.62; AOR of GI bleeding: 1.4, 95%CI :0.98-1.72).

Conclusions: Add-on PTX in CKD patients who under aspirin treatment would not increase the risk of ICH and GI bleeding.

FR-PO232

Is the Use of Opioids and Benzodiazepines Among Patients with CKD Stages 3-5 Associated with Postoperative Outcome?

Thorir E. Long,[1,2] Dadi Helgason,[1,2] Martin I. Sigurdsson,[3] Gisli H. Sigurdsson,[1,2] Runolfur Palsson,[1,2] Olafur S. Indridason.[1] *[1]Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland; [2]University of Iceland, Reykjavik, Iceland; [3]Duke University Medical Center, Durham, NC.*

Background: Preoperative use of opioids and benzodiazepines (BZDs) has been associated with adverse outcomes following surgery. The aim of this study was to examine the use of opioids and BZDs among individuals with chronic kidney disease (CKD) in association with postoperative outcomes.

Methods: This was a retrospective study of adult patients who underwent non-cardiac surgery at the University Hospital in Reykjavik in 2006-2015. Clinical data was obtained from electronic medical records. CKD stages 3-5 was defined according the the KDIGO classification system. Patients were considered to be using opioids or BZDs if they had filled a prescription within six months prior to surgery and a daily defined dose (DDD) was determined for all patients. Survival of CKD patients using opioids and BZD was compared to propensity score-matched (PSM, 1:1) control group of CKD patients not using these medications.

Results: A total of 42,600 patients underwent non-cardiac surgery during the 10-year study period, of whom 6973 (16.4%) had preoperative CKD 3-5, with 3877 (9.1%), 1845 (4.3%), 578 (1.4%) and 673 (1.6%) having stages 3A, 3B, 4 and 5, respectively. Preoperatively there were 8008 (19%), 3327 (8%), 2888 (7%) individuals taking opioids, BZDs and both opioids and BZDs, respectively. CKD patients were more often treated with BZDs (10.5% vs. 7.3%) and both opioids and BZDs (8.6% vs. 6.4%) than patients without CKD (p<0.001). CKD patients received a median (interquartile range, IQR) of 47 (20-112) DDD of opioids and BZDs over the 6 month period, compared with 33 (13-93) DDD in those without CKD (p<0.001). Preoperative use of opioids or BDZs among CKD patients was not associated with worse 30-day (97% vs. 96%, p=0.1) or one-year survival (86% vs. 86%, p=0.66) compared to the PSM control group. In an analysis limited to individuals with CKD stage 3B or higher, who were prescribed >90 DDD in the six months preoperatively, 30-day (96% vs. 97%) and one-year survival (84% vs. 84%) was similar to controls.

Conclusions: In this surgical cohort we found that patients with CKD were more commonly prescribed opioids, BZDs or both, but quantity of prescribed medications was modest. With this prescription pattern, adverse effect on postoperative survival was not observed.

Marijuana Use and Kidney Outcomes in the ASSESS-AKI Cohort

Joshua L. Rein,[1] Lindsay Texter,[2] Mark M. Wurfel,[3] Edward D. Siew,[4] Amit X. Garg,[5] Thida C. Tan,[6] Paul L. Kimmel,[7] James S. Kaufman,[8] Vernon M. Chinchilli,[2] Steven G. Coca.[1] on behalf of the Assessment Serial Evaluation, and Subsequent Sequelae of Acute Kidney Injury (ASSESS-AKI) Study Investigators *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Pennsylvania State College of Medicine, Hershey, PA; [3]University of Washington, Seattle, WA; [4]Vanderbilt University School of Medicine, Nashville, TN; [5]London Health Sciences Centre, London, ON, Canada; [6]Kaiser Permanente Northern California, Oakland, CA; [7]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [8]VA New York Harbor Healthcare System, New York, NY.*

Background: Legal recreational and medicinal use of marijuana (MJ) is increasing worldwide. Animal kidney injury models show that activation of the cannabinoid receptor CB1 can exacerbate kidney disease while activation of CB2 may be protective. Whether these effects apply to whole plant MJ remains to be determined.

Methods: We conducted a post-hoc analysis of MJ usage as a risk factor for kidney function decline and albuminuria in the ASSESS-AKI parallel matched cohort study that enrolled hospitalized adults with and without AKI from 4 US centers between 2009-2015, with a median of 4.1 years of follow-up. MJ usage was defined as responding yes to "have you used MJ since your last study visit?" at least once on any study visit questionnaire. Nonusers were defined as always responding no to this question. Kidney function decline was defined according to the parent study protocol. Association between MJ usage and the categorical and continuous outcomes were determined using multivariable Cox regression and linear mixed models, respectively.

Results: MJ users represented 113 of 1599 (7%) participants, were younger (mean age 54 vs. 65 years), mostly white (78%), men (78%), and were more likely to be heavy tobacco users (≥20 cigarettes/day; 26% vs. 8%). Baseline eGFR was higher in users vs. non-users (87 +/- 30 mL/min/1.73 m^2vs. 69 +/- 26 mL/min/1.73 m^2), while baseline UACR was similar (120 +/- 80 in users vs. 99 +/- 72 in nonusers). In those with baseline eGFR ≥60 mL/min/1.73 m^2, MJ use was not associated with incident CKD (adjusted HR 0.93; 95% CI, 0.5-1.8) or differences in eGFR slope over time (mean difference -0.12 mL/min/1.73 m^2/year, *P*=0.7). In contrast, in those with baseline eGFR <60 mL/min/1.73 m^2, MJ users had more rapid eGFR decline vs. nonusers (-3.2 vs -1.4 mL/min/1.73 m^2/year,*P*=0.002) and had a strong trend towards higher risk for CKD progression (adjusted HR 2.7; 95% CI, 0.83 to 8.5). MJ usage was not associated with the rate of change in UACR over time in those with (*P*=0.4) and without CKD (*P*=0.2).

Conclusions: MJ usage was associated with more rapid eGFR decline in those with baseline CKD, but not in those without CKD, nor was it associated with changes in albuminuria over time in those with or without CKD. Reasons for the effect modification by CKD status regarding MJ and kidney function should be explored.

FR-PO234

Cannabis Use and Its Association with eGFR Decline in Advanced CKD Patients Transitioning to ESRD

Praveen Kumar Potukuchi,[1] Keiichi Sumida,[2] Miklos Z. Molnar,[1] Abduzhappar Gaipov,[1] Frank Park,[1] Cameron M. Kaplan,[1] Hamid Moradi,[4] Fridtjof Thomas,[1] Justin Gatwood,[1] Elani Streja,[3] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [3]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [4]University of California Irvine, School of Medicine, Orange, CA.*

Background: The renal safety of cannabis use in patients with advanced CKD is unknown.

Methods: We examined 6,788 US veterans who transitioned to dialysis during 2007-2014 and had undergone urine toxicology tests within a year before the dialysis initiation. We compared patients whose toxicology tests were positive for cannabis alone (primary exposure group, PEG, N=195) with those whose tests were negative (negative control group, NCG, N=3,266). We estimated slopes of eGFR and the effect of inter-individual cannabis use on intraindividual slopes in multilevel mixed-effects models with random intercepts and slopes adjusted for sociodemographics, comorbidities, medications, and vital signs.

Results: The mean (SD) age of the cohort was 60.5 (9.6) years; 97% were male, 46 % were African American and 72% were diabetic. The median (IQR) eGFR slope was -10.9 (-17.2, -6.1) ml/min/1.73m^2/year. Cannabis use was associated with significantly steeper eGFR slopes in the unadjusted model (Figure 1, estimated slope in the PEG compared to NCG group (95% CI) -3.55 (-6.58, -0.51) ml/min/1.73m^2/year, P=0.02) However, after multivariable adjustments cannabis use was not associated with steeper slopes.

Conclusions: Cannabis use is not associated with more rapid loss of kidney function in patients with advanced CKD.

FR-PO235

Efficacy and Safety of Endothelin Receptor Antagonist on Renal Outcomes

Muh Geot Wong,[1,2] Edmund Chung,[2] Sunil V. Badve,[3] Meg J. Jardine,[1] Brendon L. Neuen,[1] Min Jun,[1] Hiddo J. Lambers Heerspink,[4] Dick de Zeeuw,[4] John McMurray,[5] Vlado Perkovic.[1,2] *[1]Renal and Metabolic Division, The George Institute for Global Health, Newtown, NSW, Australia; [2]Renal Medicine, Royal North Shore Hospital, St Leonards, NSW, Australia; [3]Department of Renal Medicine, St George Hospital, Kogarah, NSW, Australia; [4]University Medical Center Groningen, Groningen, Netherlands; [5]University of Glasgow, Glasgow, United Kingdom.*

Background: Preclinical studies suggest that blockade of the endothelin receptor reduces proteinuria and may confer renal protection. The aim of this systematic review and meta-analysis was to summarize evidence from randomized controlled trials (RCT) concerning the benefits and risks of ERA on renal outcomes.

Methods: MEDLINE, Embase and Cochrane Central Register of Controlled Trials were searched for RCTs evaluating ERAs in adults that reported renal outcomes. The primary outcome was kidney failure (end-stage kidney disease, renal failure, or doubling of creatinine, or as reported by the authors). The secondary outcomes were change in kidney function (estimated glomerular filtration rate or creatinine clearance), albuminuria and systolic blood pressure from baseline to last measurement, all-cause mortality, cardiovascular mortality and adverse events. Treatment effects were summarized using random-effects meta-analysis.

Results: Six RCTs (3963 participants, median sample size 333, median follow-up 15 weeks) met eligibility criteria. There was substantial heterogeneity in baseline kidney function and study population. Compared to placebo, ERA significantly reduced the risk of kidney failure (2 trials, risk ratio [RR] 0.75, 95%CI 0.56, 0.93). Compared to placebo, ERA significantly reduced albuminuria (3 trials, SMD -1.19, 95%CI -1.86, -0.53), and systolic blood pressure (weighted mean difference [WMD] -5.86, 95%CI -10.62, -1.09 mm Hg). ERA treatment was associated with a short term decrease in kidney function (5 trials, standardized mean difference [SMD] -0.11, 95%CI -0.22, 0.00). ERA had uncertain effect on all-cause mortality (4 trials, RR 1.62, 95%CI 0.62, 4.29), and pulmonary edema (2 trials, RR 2.07, 95%CI 0.65, 6.59); but increased the risk of systemic edema (6 trials, RR 1.90, 95%CI 1.29, 2.79).

Conclusions: Short-term trials suggest that ERA treatment may reduce the risk of kidney failure and reduce albuminuria. Adequately powered RCTs with long-term follow-up are required to evaluate whether ERA treatment improves renal outcomes.

FR-PO236

Effect of a Carbonaceous Adsorbent on the Progression of CKD

Hiroko Yamagishi, Hitoshi Suzuki, Yusuke Suzuki. *Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: AST-120 (Kureha Chemical, Tokyo, Japan) is an oral spherical carbonaceous adsorbent, which was approved for use in delaying the initiation of dialysis and ameliorating the symptoms of uremia in patients with progressive chronic kidney disease (CKD). It adsorbs the precursor of indoxyl sulfate in the intestines and prevents indoxyl sulfate production. Indoxyl sulfate, initially identified as a major uremic toxin that causes uremic symptoms, contributes to CKD progression. Although international multicenter prospective trials of AST-120 did not slow progression of CKD in patients with moderate to severe CKD, present study evaluated the efficacy of AST-120 in preventing the progression of CKD and its indication in our Japanese cohort.

Methods: Antihypertensive therapy using renin-angiotensin-aldosterone inhibitor (RAS-i) and a low-protein diet is conventionally used to treat patients with CKD. We retrospectively recruited 218 patients with CKD treated with AST-120 from 2014 to 2015. Changes of serum levels of blood urea nitrogen (BUN) and eGFR were analyzed for 4 years, from 1 year before medication. Moreover, we elucidated the recommended timing of initiation of AST-120 administration.

Results: The mean eGFR and BUN at the baseline were 24.1 ml/min/1.73m^2 and 35.9 mg/dL, respectively. Decline of eGFR before AST-120 treatment was -4.9 ml/min/1.73m^2/year. After 1-year and 3-year medication with AST-120, the decline of eGFR was significantly improved to -0.7 and -0.9 ml/min/1.73m^2/year, respectively. Increase slope of BUN also improved +4.7 to +1.9 mg/dl/year after 3-year administration with AST-120. We next divided patients into 3 groups depending on baseline eGFR, *i.e.*, >50 eGFR ≥*40, >40 eGFR* ≥30 and eGFR<30 ml/min/1.73m^2 groups. The effect of AST-120 to prevent progression of CKD was the highest in >50 eGFR ≥40 group in which decline of eGFR was -9.9 to -1.2 ml/min/1.73m^2/year during intervention period.

Conclusions: Present study suggests that treatment with AST-120 may delay progression of CKD. Especially, AST-120 administration is recommended to initiate relatively maintained renal function (>50 eGFR ≥40). Those findings provided insight into management of CKD patients.

FR-PO237

Improvement in Kidney Function upon Discontinuation of Fenofibrate in Outpatient Nephrology Consultations for CKD

Rafael A. Justiniano Magraner,[3] Manuel E. Gonzalez,[3] Juan Carlos Q. Velez.[1,2] *[1]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA; [2]Ochsner Clinical School, The University of Queensland, New Orleans, LA; [3]Ochsner Clinic Foundation, Metairie, LA.*

Background: It has been noted in observational and interventional trials that individuals exposed to fenofibrate can exhibit a rise in serum creatinine (sCr) concentration. However, it is not known to what extent this phenomenon impacts kidney function in patients who are referred to a nephrology clinic for consultation for chronic kidney disease (CKD).

Methods: We prospectively collected data in patients referred to a nephrology clinic for new evaluation of a recent rise in sCr or CKD who underwent discontinuation of fenofibrate to assess the effect of that intervention on kidney function, i.e., sCr and estimated glomerular filtration rate (eGFR). Fenofibrate was discontinued when no other cause for a recent rise in sCr or CKD was identified at the time of consultation.

Results: A total of 16 patients (69% women, 75% white, 56% type 2 diabetes, 31% peripheral arterial disease, 19% NASH) were captured over 1.5 years, median baseline sCr 1.9 (1.1 – 2.4) mg/dL and eGFR 34 (22 – 57) ml/min; proteinuria was absent in 13 (81%) patients. At 3 months (n = 16), median sCr decreased to 1.4 (0.9 – 2.2) mg/dL ($p < 0.01$) and median eGFR increased to 45 (27 – 71) ml/min ($p < 0.05$). At 6 months (n = 14), median sCr decreased to 1.5 (0.9 – 2.2) mg/dL ($p < 0.05$) and median eGFR increased to 42 (26 – 71) ml/min ($p = 0.08$). A ≥ 30% rise in eGFR was observed in 50% of patients at 3 months and it persisted in 46% and 50% of patients at 6 and 12 months, respectively. Median relative change in eGFR was +29% (+7 to +83), +24% (-13 to +68) and +29% (0 to +78) at months 3, 6 and 12, respectively. Triglyceride level increased by > 2-fold in 4 patients during follow up, whereas it remained within the same range in the remaining 12 patients (only 3 required gemfibrozil).

Conclusions: Discontinuation of fenofibrate in patients referred for CKD evaluation can result in sustained improvement in kidney function. There is a need to raise awareness among primary practitioners about this phenomenon that prompts consultations to nephrology. Furthermore, these proof-of-concept pilot data may serve as rationale for a prospective controlled study

FR-PO238

Ketosteril Effects on Advanced CKD: Implications from Taiwan Population-Based Study

Fan Pei-Chun. *Chang Gung Memorial Hospital, Linkou Medical Center, Taoyuan, Taiwan, Taoyuan, Taiwan.*

Background: Chronic kidney disease (CKD) is a risk factor for mortality and morbidity. Many clinical studies to investigate whether lowering protein intake with ketoacid analogue (LPD-KA) supplement can attenuate the progression of CKD which were unable to have a definite conclusion. This study aims to evaluate the benefit of LPD-KA in patients with advanced CKD.

Methods: The study analyzed encrypted datasets from Taiwan's National Health Insurance Research Database. The exposure group was the LPD-KA which fulfilled the medication possession rate > 90% during the first 90 days of follow up and the comparison group was non-users. Outcomes included mortality, dialysis, cardiovascular event, sepsis and blood transfusion at 2-year follow up. Diabetes mellitus (DM) was a stratum variable of interest.

Results: The data of 2654 patients in the LPD-KA group and 5308 propensity score matched patients in the LPD-KA naive group between January 1, 2001 and December 31, 2013 were analyzed. Patients on LPD-KA had lower mortality (8.1% vs. 11.5%; hazard ratio [HR] 0.69, 95% confidence interval [CI] 0.59-0.81) and lower composite cardiovascular events (10.1% vs. 12.5%; HR 0.78, 95% CI 0.68-0.90). When stratifying analyses by DM, LPA-KA had beneficial effects on composite cardiovascular events and dialysis in patients without DM, but not in patients with DM (P for interaction < 0.05). The LPD-KA prolonged the dialysis for a median of 1.8 months (P < 0.001) in the non-DM group, but not in the DM group (0.2 month, P = 0.515).

Conclusions: LPD-KA might be a effective therapy for patient of CKD especially in patients without DM. Cardiovascular and infective event is less in LPD-KA group. Further investigation with earlier treatment to improve the outcome is warranted.

FR-PO239

Effects of Brazilian Green Propolis Extract on Proteinuria in CKD Patients: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial

Marcelo D. Silveira,[1] Flavio Teles de Farias Filho,[3] Andresa Berretta,[2] Camila E. Rodrigues,[1] Talita R. Sanches,[1] Antonio C. Seguro,[1] Lucia Andrade.[1] *[1]University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [2]Apis Flora Indl. Coml. Ltda., Ribeirao Preto, Brazil; [3]Federal University of Alagoas, Maceio, Brazil.*

Background: Chronic kidney disease (CKD) is a public health problem of global proportions, and proteinuria is associated with disease progression. Brazilian green propolis (GP) is a natural resin that bees collect from plant sap, presenting anti-inflammatory, immunomodulatory and anti-oxidant properties. We tried to determine whether GP extract can reduce proteinuria and alter the estimated glomerular filtration rate (eGFR).

Methods: This was a randomized, double-blind, placebo-controlled study including 32 patients with diabetic or non-diabetic CKD; between 18 and 90 years of age; with an eGFR of 25-70 ml/min/1.73m^2; and with proteinuria (>300mg/day) or micro- or macro-albuminuria (urine albumin-to-creatinine ratio >30mg/g uCr or >300mg/g uCr, respectively). The patients were randomly assigned to receive GP (n=18) or placebo (n=14) at a dose of 500 mg/day and were followed for 12 months.

Results: Proteinuria (mg/24h) was significantly lower in the GP group than in the placebo group—695 (95% CI: 483-999) vs. 1403 (95% CI: 1031-1909)—(p=0.004). This finding was independent of variations in eGFR and systemic hemodynamics, which did not show differences between the groups during the follow-up. There was also a significant reduction of the urinary monocyte chemoattractant protein-1 (pg/mg uCr) was also significantly lower in the GP group than in the placebo group—58 (95% CI: 36-95) vs. 98 (95% CI: 62-155)—(p=0.038). At the dose used, GP was found to be safe and well tolerated.

Conclusions: Our findings broaden the perspectives for the use of GP as a natural adjuvant in reducing proteinuria in CKD. (ClinicalTrials.gov identifier: NCT02766036; Supported by FAPESP)

FR-PO240

Molidustat, a Daily Oral Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitor, and Vascular Endothelial Growth Factor in Patients with CKD

Tadao Akizawa,[1] Iain C. Macdougall,[2] Jeffrey S. Berns,[3] Nobuyuki Takakura,[4] Thomas Bernhardt,[7] Megumi Taguchi,[5] Eriko Ogura,[5] Kazuma Iekushi.[6] *[1]Showa University School of Medicine, Tokyo, Japan; [2]King's College Hospital, London, United Kingdom; [3]University of Pennsylvania School of Medicine, Philadelphia, PA; [4]Osaka University, Suita-shi, Japan; [5]Bayer Yakuhin, Ltd., Osaka, Japan; [6]Bayer Yakuhin, Ltd, Osaka, Japan; [7]Bayer AG, Berlin, Germany.*

Background: Hypoxia-inducible factor (HIF) transcriptionally upregulates a large number of genes including erythropoietin (EPO) and vascular endothelial growth factor (VEGF). EPO gene upregulation is helpful in treating anemia, whereas VEGF upregulation could potentially exacerbate conditions such as diabetic retinopathy or malignancy. We studied whether molidustat is linked to changes in VEGF concentrations and related adverse events (AEs) in patients with chronic kidney disease (CKD).

Methods: Three Phase 2b studies (A: 16 weeks, placebo-controlled, fixed-dose; B: 16 weeks, darbepoetin-controlled, variable-dose; and C: up to 36 months, darbepoetin-controlled, extension) were conducted in anemic subjects with CKD who were not on dialysis. Plasma VEGF concentrations were compared between baseline and last visit. We also assessed adverse events (AEs) of diabetic retinopathy (DR), macular degeneration (MD) and malignancy as these may potentially be influenced by VEGF. Subjects with proliferative diabetic retinopathy and previous or concurrent cancer at baseline were excluded from the studies.

Results: The results of VEGF concentrations are shown in Table 1. DR and MD as AEs were reported in none of 101 subjects in (A), in 1 of 92 subjects (1.0%) in (B), and in 2 of 103 subjects (1.9%) in (C) in molidustat group. None were reported in comparator groups in the three studies. Malignancy as AEs were reported in 1 of 101 subjects (1.0%) in (A), in 1 of 92 subjects (1.0%) in (B), and in 3 of 103 subjects (2.9%) in (C) in molidustat group. In 2 of 41 subject (4.9%) AE was reported in darbepoetin group (C).

Conclusions: No notable differences in changes of VEGF from baseline to last visit between molidustat and comparator groups were observed. Comparable numbers of subjects with an AE of DR, MD and malignancy in molidustat and comparator groups were identified. Due to the small number of treated patients the findings will need to be confirmed in larger Phase3 studies.

Primary Efficacy Analyses from a Phase 2 Trial of the Safety and Efficacy of Bardoxolone Methyl in Patients with Autosomal Dominant Polycystic Kidney Disease

Pablo E. Pergola,[1] Gerald B. Appel,[8] Ahmed M. Awad,[9] Judith A. Betts,[11] Geoffrey A. Block,[2] Melanie Chin,[7] Lesley Inker,[3] Colin J. Meyer,[7] Anjay Rastogi,[4] Dana Rizk,[5] Kevin Schroeder,[10] Arnold L. Silva.[6] *[1]Renal Associates, PA, San Antonio, TX; [2]Colorado Kidney Care, Denver, CO; [3]Tufts Medical Center, Boston, MA; [4]Division of Nephrology, University of California at Los Angeles Medical Center, Los Angeles, CA; [5]University of Alabama, Birmingham, AL; [6]Boise Kidney & Hypertension Institute, Meridian, ID; [7]Reata Pharmaceuticals, Irving, TX; [8]Columbia University College of Physicians and Surgeons, Scarsdale, NY; [9]Clinical Research Consultants, LLC, Kansas City, MO; [10]Ohio Kidney Consultants, Columbus, OH; [11]Austin Kidney Associates, Austin, TX.*

Background: Bardoxolone methyl (BARD) has been shown to significantly increase eGFR in patients with CKD and type 2 diabetes or Alport syndrome suggesting that the anti-inflammatory and anti-fibrotic effects of BARD may target common pathways contributing to GFR loss in multiple forms of CKD. Inflammation seems to correlate with disease initiation and progression in polycystic kidney disease (PKD). As a result, a Phase 2 trial (PHOENIX, NCT03366337) was initiated to determine if BARD will improve kidney function in patients with autosomal dominant PKD (ADPKD).

Methods: The open-label, multicenter study enrolled 31 patients with ADPKD with genetic confirmation of PKD1 mutation. Eligible patients (18 to 65 years of age) had eGFR values between 30 to 90 mL/min/1.73 m^2 and urine albumin to creatinine ratio (UACR) ≤ 2500 mg/g. Patients received BARD at an initial dose of 5 mg, dose-escalated up to 20 mg (for patients with baseline UACR ≤ 300 mg/g) or up to 30 mg (for patients with baseline UACR > 300 mg/g) and were treated for 12 weeks. The primary efficacy endpoint was the change from baseline eGFR after 12 weeks of treatment. Interim results are described herein.

Results: At data cutoff on May 15th, 2018, all 31 of the patients had completed Week 4 and 8/31 (26%) had completed the study. From a mean (±SE) baseline eGFR of 47.7 ± 2.4 mL/min/1.73 m^2, BARD treatment resulted in a significant increase in eGFR of 6.6 ± 0.9 mL/min/1.73 m^2 (n=31; p<0.0001) at Week 4 and 12.0 ± 1.4 mL/min/1.73 m^2 (n=8; p<0.0001) at Week 12. The improvements were consistent, all 8 (100%) of the patients had increases in eGFR at Week 12. UACR was not significantly different from baseline. No patients have discontinued from the study and no serious AEs considered related to BARD have been reported in this ongoing trial.

Conclusions: BARD was generally well tolerated and significantly increased eGFR in patients with ADPKD. In patients with other forms of CKD, short term eGFR increases with BARD are predictive of durable eGFR improvements and additional studies are needed to study the longer-term effects of BARD on eGFR in ADPKD.

One-Year Data Report from "CARDINAL": A Phase 2/3 Study of Bardoxolone Methyl in Patients with Alport Syndrome

Geoffrey A. Block,[1] Pablo E. Pergola,[2] Bernard V. Fischbach,[9] Lesley Inker,[3] Peter A. McCullough,[4] Melanie Chin,[5] Colin J. Meyer,[5] Michelle N. Rheault,[6] Clifford E. Kashtan,[6] David G. Warnock,[8] Oliver Gross.[7] *[1]Colorado Kidney Care, Denver, CO; [2]Renal Associates, PA, San Antonio, TX; [3]Tufts Medical Center, Boston, MA; [4]Baylor University Medical Center, Dallas, TX; [5]Reata Pharmaceuticals, Irving, TX; [6]University of Minnesota, Minneapolis, MN; [7]University Medicine Goettingen, Goettingen, Germany; [8]Medicine, University of Alabama Birmingham, Birmingham, AL; [9]Dallas Nephrology Associates, Fort Worth, TX.*

Background: A Phase 2/3 trial (CARDINAL, NCT03019185) was initiated to determine if bardoxolone methyl (BARD) will improve eGFR in patients with Alport syndrome (AS). Primary efficacy analyses from the Phase 2 portion of the trial previously showed that BARD increased eGFR by 13.4 mL/min/1.73 m^2 (n=30, p<0.0001) after 12 weeks of treatment. Interim results for patients who have completed 48 weeks of treatment are described herein.

Methods: The Phase 2 open-label portion of the trial enrolled patients on stable RAAS blockade, ages 12 to 60 years, with confirmed diagnosis of AS, eGFR values from 30 to 90 mL/min/1.73 m^2, and urinary albumin to creatinine ratio (UACR) ≤ 3500 mg/g. Patients received once-daily doses of BARD at 5 mg and dose-escalated to 20 mg or 30 mg (for patients with baseline UACR > 300 mg/g), as tolerated. Following the Week 48 visit, patients stopped receiving BARD during a 4-week withdrawal period before completing the Week 52 visit.

Results: As of May 15, 2018, 13/30 (43%) of the enrolled patients had received 48 weeks of treatment, and 8 patients had Week 52 data. Treatment with BARD produced mean increases in eGFR of 14.0 mL/min/1.73 m^2 at Week 48 (n=13; 95% CI: 9.5 to 18.5; p<0.0001). Moreover, after one year of treatment with BARD and withdrawal of drug, eGFR remained above baseline with mean increases in eGFR of 5.6 mL/min/1.73 m^2 at Week 52 (n=8; 95% CI: 0.3 to 10.9, p=0.04). Geometric mean UACR also increased, but log UACR/eGFR ratios were unchanged from baseline. The most commonly reported AE was muscle spasms, which were generally mild to moderate in severity, with no evidence of muscle toxicity. No drug-related serious AEs or discontinuations had been reported in the ongoing Phase 2 portion of the trial at the time of data cutoff.

Conclusions: In patients with AS, BARD was generally well tolerated and produced improvements in kidney function that were sustained for up to one year and remained significantly above baseline following treatment withdrawal. The Phase 3 double-blind, randomized, placebo-controlled portion of the trial that will enroll up to 150 patients is underway.

FR-PO243

A Randomized Trial of Ferric Citrate in Advanced CKD: Safety

Geoffrey A. Block,[1] Martha Persky,[5] Rupal Mehta,[2] Tamara Isakova,[2] Myles Wolf,[3] Glenn M. Chertow.[4] *[1]Colorado Kidney Care, Denver, CO; [2]Feinberg School of Medicine, Northwestern University, Chicago, IL; [3]Duke University, Durham, NC; [4]Stanford University School of Medicine, Palo Alto, CA; [5]Denver Nephrology Research Division, Denver, CO.*

Background: We hypothesized that provision of fixed dose ferric citrate (FC), independent of serum phosphate (P) or degree of anemia, would improve multiple biochemical manifestations of advanced chronic kidney disease and reduce associated complications.

Methods: Patients with eGFR ≤ 20 ml/min (50% eGFR ≤ 15 ml/min), P ≥3.0 mg/dL, hemoglobin (Hb) >8.0 g and who were not anticipated to start dialysis within 8 weeks were randomized 2:1 to received fixed dose FC, (two per meal) or standard of care treatment (SOC). 199 patients (133 FC, 66 SOC) attended at least 1 follow-up visit. Patients were seen monthly for 9 months, or, for individuals who started hemo- or peritoneal dialysis, for 3 months thereafter.

Results: Baseline characteristics were similar with the exception of diabetes, which was more common in the SOC arm. Mean baseline eGFR was 14 ml/min. Table 1 shows the proportion of patients with any AE and serious AEs by treatment arm. "Gastrointestinal" (GI) was the only SOC in which related AE's occurred in ≥ 5% of FC patients: discolored feces (28%), constipation (12%) and diarrhea (9%). No related serious adverse events occurred. Annualized admission rates were lower with FC than with SOC (median (10%, 90% range), 0 (0,1.9) versus 0 (0,5.2), Wilcoxon Rank Sum p=0.001). After adjusting for age, race, sex, baseline eGFR and diabetes, treatment with FC significantly reduced hospital admissions (p=0.002) and hospital days (p=0.0006).

Conclusions: In this randomized, unblinded trial in patients with advanced CKD, treatment with fixed-dose FC resulted in an increase in GI AEs and a reduction in annualized hospital admission rates and hospital days. Larger, placebo-controlled trials of FC in this patient population are warranted to determine the reproducibility of these findings.

Effects of Renal Denervation in Patients with Versus Without CKD: Results from the Global SYMPLICITY Registry with Follow-Up Data of 3 Years

Roland E. Schmieder,[1] Felix Mahfoud,[2] Giuseppe Mancia,[5] Krzysztof Narkiewicz,[9] Luis M. Ruilope,[6] Markus P. Schlaich,[3] Bryan Williams,[4] Michael Böhm,[7] Christian Ott.[8,10] *[1]University Hospital Erlangen, Erlangen, Germany; [2]University of the Saarland, Homburg, Germany; [3]The University of Western Australia, CRAWLEY, WA, Australia; [4]University College London, London, United Kingdom; [5]University of Milan-Bicocca, Milan, Italy; [6]National Instituto of Health, Spain, Madrid, Spain; [7]Kardiology, Saarland University Medical Center, Homburg, Germany; [8]Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany; [9]Medical University of Gdansk, Gdansk, Poland; [10]Department of Nephrology and Hypertension, Paracelsus Medical University, Nuremberg, Germany.*

Background: Activity of the sympathetic nervous system (SNS) is increased in hypertensive patients with chronic kidney disease (CKD). We tested the hypothesis that hypertensive patients with CKD enrolled in the Global Symplicity Registry (GSR) show different patterns in blood pressure (BP) outcomes in the short- and long-term follow-up.

Methods: The GSR (NCT 01534299) is a prospective, open-label, international, multicentre observational study for assessment of safety and effectiveness of renal denervation (RDN) among real-world patients treated with the Symplicity™ RDN system (Medtronic, Santa Rosa, CA, USA). Inclusion criteria are age ≥18 years and eligibility for RDN. 24-h ambulatory BP was assessed at pre-specified time-points (6, 12, 24 and 36 months). For the current analyses, enrolled patients (N=1600) were stratified based on baseline estimated glomerular filtration rate in <60 vs. ≥60ml/min/1.73m^2 into with (N=383) and without (N=1217) CKD groups.

Results: Patients with CKD were significantly older (p<0.0001) and were treated with more antihypertensive medications (p<0.0001) compared to patients without CKD. 24-h ambulatory diastolic (but not systolic) BP was lower in patients with compared to without CKD (152.9±19/81.3±13 vs. 153.2±18/87.2±14 mmHg, p=0.6380/<0.0001), resulting in an increased pulse pressure. In patients with and without CKD, 24-h ambulatory BP was reduced after RDN compared to baseline values at all time-points (all p<0.01). There was no difference in 24-h ambulatory systolic BP reduction after RDN in favor of patients with compared to without CKD, even after adjustment (Table).

Conclusions: Hypertensive patients with CKD did not show a greater short-term or long-term decrease in 24-hour ambulatory BP.

Meta-Analysis on the Effects of Intensive (INT) Blood Pressure (BP) Control on Incident CKD and ESRD

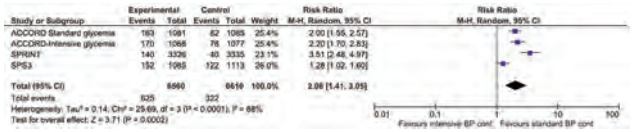
Srinivasan Beddhu,[1] Robert E. Boucher,[1] Adhish Agarwal,[1] Terrence S. Bjordahl,[1] Debra L. Simmons,[1] Linda F. Fried,[2] Sankar D. Navaneethan.[3] *[1]University of Utah School of Medicine, Salt Lake City, UT; [2]VA Pittsburgh Healthcare System, Pittsburgh, PA; [3]Baylor College of Medicine, Sugar Land, TX.*

Background: We examined the hypothesis that the effects of INT BP control on kidney outcomes could differ by the level of baseline kidney function.

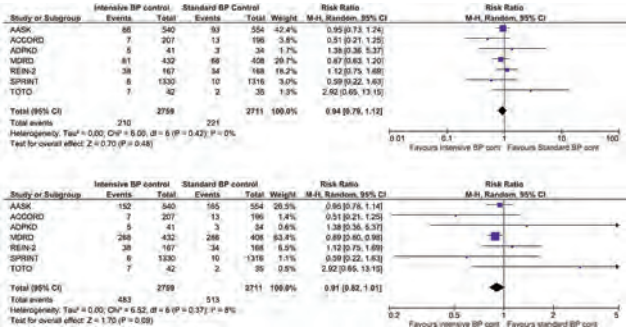
Methods: We performed a literature search and included studies that met one of the following criteria: 1. included participants without CKD at baseline and data for incident CKD were available and 2. included participants with stage 3/ 4CKD and data for ESRD available. We excluded BP studies that randomized by medications but not a BP goal, lifestyle intervention studies, with follow-up < 1 year or did not report the above outcomes. The estimates were pooled using a random effects model.

Results: Of the 3470 potentially relevant studies, 30 studies were extracted and 8 studies were included for analysis. There were 625 incident CKD events in 6560 non-CKD participants in 3 studies (Fig 1). Compared to the standard BP goal, intensive BP lowering had higher risk of incident CKD (RR 2.08, 95% CI 1.41 to 3.05). There were 210 ESRD events in 2759 CKD participants during the trial phase in 7 studies (Fig 2, panel A) with a RR of 0.94 (95% CI 0.79-1.12) for intensive vs. standard BP control. Two (MDRD and AASK) studies reported legacy folllow-up ; including these there were 483 ESRD events with a RR of 0.91, 95% CI 0.82-1.01 (Fig 2, panel B).

Conclusions: While INT BP lowering has higher risk of incident CKD in non-CKD, it might potentially reduce the risk of ESRD in CKD. Further RCTs of INT BP lowering in CKD participants are warranted to establish the risk-benefit ratio.



Effects of intensive BP control on incident CKD in non-CKD participants



Effects of intensive BP control on ESRD in participants with CKD in main trial phase (panel A) and entire legacy follow-up (panel B)

FR-PO246

Effects of Alkali Therapy on Renal Outcomes: A Systematic Review and Meta-Analysis

Sebastian O. Hultin, Christopher J. Hood, Nigel D. Toussaint, David W. Johnson, Sunil V. Badve. *Australasian Kidney Trials Network, Sydney, NSW, Australia.*

Background: Preclinical studies suggest that treatment of metabolic acidosis may slow the progression of chronic kidney disease (CKD). The aim of this systematic review is to summarize evidence from randomized controlled trials (RCTs) concerning the benefits and risks of alkali therapy on renal outcomes.

Methods: Medline, Embase and Cochrane Central Register of Controlled Trials were searched for RCTs with at least 3 months of follow-up in patients with CKD defined as eGFR <60mL/min/1.73m2 or the presence of albuminuria that reported renal outcomes. Treatment effects were summarized using random-effects meta-analysis.

Results: Eight trials involving 679 participants (median sample size 80, median follow-up 12 months) evaluating sodium bicarbonate treatment were eligible for inclusion. Of these, 3 trials were a placebo-controlled studies. Overall, risk of bias was unclear or high risk. Compared to no study medication or placebo, treatment with sodium bicarbonate resulted in slower decline in kidney function (7 trials, standardized mean difference [SMD] for change from baseline in glomerular filtration rate or creatinine clearance 0.29 [95%CI 0.11, 0.48]. Sodium bicarbonate abrogated increases in serum creatinine from baseline (4 trials, weighted mean difference [WMD] -0.07 [95%CI -0.12, -0.03] mg/dL) and reduced the risk of end-stage kidney disease (4 trials, risk ratio [RR] 0.44 [95%CI 0.22, 0.88]). Sodium bicarbonate had uncertain effects on proteinuria (3 trials, SMD -0.27 [95%CI -0.59, 0.05]) and systolic blood pressure (6 trials, WMD 0.27 [95%CI -3.01, 3.56] mm Hg). Data for effects of sodium bicarbonate on death and adverse events were scant.

Conclusions: Alkali therapy with sodium bicarbonate may slow the progression of CKD. Adequately powered RCTs are required to evaluate the benefits and risks of alkali therapy in CKD.

FR-PO247

Are Treatment Effects on eGFR Decline Greater in Patients with Faster Underling Disease Progression? A Report from an NKF FDA Workshop

Tom Greene. CKD-Epidemiology Collaboration *University of Utah, Salt Lake City, UT.*

Background: Analyses at the individual and trial level support the validity of eGFR slope as a surrogate endpoint in chronic kidney disease (CKD) RCTs. The gain in statistical power for eGFR slope vs. the clinical endpoint of doubling serum creatinine or kidney failure is limited if treatments reduce the rate of eGFR decline proportionally to the rate of CKD progression (attenuating slopes of fast more than slow progressors), rather than uniformly (attenuating slopes independent of progression rate) [Greene et al, this meeting]. By definition, proportional effects, but not uniform effects, attenuate the standard deviation (SD) as well as mean of eGFR slopes. We describe the effects of treatments on the slope SD in past RCTs to inform selection of endpoints in future RCTs.

Methods: We used mixed effects analyses to estimate treatment effects on the mean and SD of eGFR slopes after 3 months follow-up (chronic slopes) for 47 CKD RCTS (59074 patients), and used meta-regression to relate the ratio of the chronic slope SDs to the ratio of mean chronic slopes between treatment and control groups while accounting for random error in each RCT.

Results: The figure shows that treatments that reduce the mean chronic slope also often reduce the SD, indicating that effective treatments tend to slow progression more in faster than in slower progressors. The slope of the meta-regression line is 0.45 ± 0.13, about half way between 0 (corresponding to uniform effects) and 1 (corresponding to proportional effects), suggesting treatment effects are usually intermediate between uniform and proportional.

Conclusions: Effective treatments usually reduce CKD progression by effects that are intermediate between uniform and proportional. For intermediate effects, our simulation studies demonstrate that slope-based endpoints can substantially reduce required sample sizes and follow-up times when there is no acute effect and baseline eGFR is high [Greene et al, this session].

Optimizing Patient Enrollment in Clinical Trials Based on Albuminuria Inclusion Criteria

Simke W. Waijer,[1] Skander Mulder,[1] Michele Provenzano,[3] Vlado Perkovic,[2] Hiddo J. Lambers Heerspink.[1,2] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]The George Institute for Global Health, Newtown, NSW, Australia; [3]Second University of Naples, Naples, Italy*.

Background: Clinical trials in CKD enroll patients with elevated urinary albumin:creatinine ratio (UACR) levels to enrich the population for high renal risk patients. Screen failure rates are often high due to high intra-individual variability in UACR. We tested whether a screening approach with more flexible UACR thresholds would decrease screen failure rate without adversely impacting on overall study duration.

Methods: We performed a post-hoc analysis on data from the ALTITUDE trial. We selected patients randomized to placebo treatment with a baseline UACR >300 mg/g and eGFR between 30 and 60 ml/min/1.73m^2 at the first visit (pre-screening). We then used stepwise lower UACR cut-offs at the next qualifying visit (e.g. 300 (base scenario), 210, 150, 30 mg/g) as inclusion criteria. For each scenario we calculated the number of eligible patients and number of renal endpoints (ESRD/ doubling serum creatinine/ renal death). Based on these data we performed simulations for a future trial. We calculated the duration of enrollment and total duration of the clinical trial to accrue 961 endpoints, which provided 90% power to detect a 20% risk reduction assuming a renal event rate of 5.6% (base scenario).

Results: 848 patients (median UACR 1239 mg/g; median eGFR 44 ml/min/1.73m^2) were eligible for the base scenario. Lowering the UACR qualification threshold increased the number of eligible patients (thus decreasing screen failures) and resulted in only a modest decrease in average renal event rate. In simulations, lowering the UACR cut-off accelerated enrollment and did not increase overall trial duration to reach 961 events.

Conclusions: Relaxing UACR based inclusion criteria in a population with documented UACR levels in the protocol required range decreases screen failure rates without prolonging trial duration. This approach may increase recruitment feasibility and site investigators' motivation.

Table 1

	Observed data in ALTITUDE			Simulations for future trial	
UACR criteria qualifying visit (mg/g)	Eligible patients (N)	Renal events (N)	Renal event rate (% per year)	Duration enrollment (months)	Clinical trial duration (years)
300	848	117	5.6 (4.6-6.7)	24.0	4.2
210	923	122	5.3 (4.4-6.4)	21.9	4.3
150	958	126	5.3 (4.4-6.3)	20.9	4.2
30	988	129	5.3 (4.4-6.3)	20.0	4.2
0	995	129	5.2 (4.4-6.2)	19.8	4.2

FR-PO249

Using E-Consults in Nephrology to Improve Renal Care: A 5-Year Experience in the Miami VAMC

Antonio A. Armstrong,[2] Lumen A. Mendez Castaner,[2] Emilian A. Cristea,[3] Lorena Cuebas-Rosado,[4] Daniel J. Soberon,[4] Vasuki N. Venkat,[4] Marco A. LadinoAvellaneda.[1] *[1]Miami VA Medical Center/University of Miami/ Jackson Memorial Hospital, Plantation, FL; [2]Jackson Memorial Hospital, Orlando, FL; [3]University of Miami, Lauderhill, FL; [4]Miami VA Hospital, Miami, FL*.

Background: Electronic consultations (E-consults) are defined as asynchronous, consultative, provider-to-provider communications within a shared electronic health record or web-based platform. The primary objective of an E-consult is to expedite and improve patient care by increasing access to specialty knowledge and expertise without the need for a face-to-face visit. E-consults provide a virtual clinical discussion by the specialist after the information is reviewed and returned with suggestions and recommendations. Our review study evaluates our 5-year experience using this consultative method.

Methods: This is a retrospective study that evaluated 745 E-Consults for the Nephrology section at the Miami VAMC during a 5-year period (2013-2018). Data was obtained and included the following: gender, age, reason for the consult, time to answer the consult and improvement of the patient's condition after the consult. A simple survey was given to the referring health care provider to evaluate the quality of the E-consult and their satisfaction.

Results: The nephrology section answered the consult in an average of 40 hours. 95% were male patients (N=708), median age was 62.3 years old. The reasons for consulting: Chronic Kidney Disease 54% (N=401), proteinuria workup and co-management 16% (N=118), uncontrolled hypertension 12% (N=90), recommendations and clearance to use medications in patients with CKD grades III, IV and V 7% (N=52), electrolyte and metabolic disorder management 6% (N=43), contrast-induced nephropathy prevention 5% (N=41). 82% (N=611) of the E-consults resolved the referral, 18% (N=134) of the E-consults needed the patient to have a face-to-face encounter. In a scale from 1-5, where 5 is the highest and 1 lowest, health care providers satisfaction was 4.5, quality of the E-consult was 4.7, consult answer their concerns was 4.4. All health care providers (N=22) stated that they will continue to use E-consults.

Conclusions: E-consults improve the care of patients with renal conditions. They decrease waiting times and facilitate the access and evaluation of patients that need evaluation of a nephrologist. Referring health care providers were satisfied with the outcome of the E-consult and will continue to use in the renal care of their patients.

FR-PO250

The Effect of Integrated Care on the Rate of GFR Decline: A Community Hospital Approach

Teerawat Thanachayanont,[1] Kriang Tungsanga.[2] *[1]Nephrology, Bhumirajanagarindra Kidney Institute, Bangkok, Thailand; [2]King Chulalong Memorial lHospital, Bangkok, Thailand*.

Background: Due to limited amount of nephrologists in Thailand, most of CKD patients are taking care by primary care physicians especially in the rural area. To improve the quality of CKD care in the community hospital level, we had designed the integrated care model which composed of 2 main components including hospital-based multidisciplinary team (MDT) and community care network (CCN) at village level. In our previous study, integrated care model was effective in slowing progression of CKD. It is challenging if this model could be implemented in routine practice.

Methods: We are conducting a quasi experimental study. Patients aged 18-70 years old with stage 3 or 4 CKD were enrolled from 5 district hospitals. All patients were managed by integrated care teams. Hospital-based MDT provided group education, individual counselling in addition to standard CKD care. CCN team performed individual counseling and monitoring on proper lifestyle modification, protein and salt intake assessment. All patients will have hospital visit every 3 months and will receive home visit by CCN twice a year.

Results: 914 stage 3 and 4 CKD patients were enrolled. Mean age was 62±6.13 years. 37.2%,43.7%,19.1% of the cohort were in CKD stage 3A, 3B and 4, respectively. Diabetic kidney disease was the leading cause of CKD. Mean eGFR at baseline were 40.38±10.26 ml/ min/1.73 m^2. Baseline SBP and DBP were 128±17.07 and 73±10.56 mmHg, respectively. 79.9% of the study cohort had negative proteinuria by urine dipstick. The rate of eGFR change at 1 year of follow-up was – 0.838±10.06 ml/min/year. Patients with baseline BP less than 140/90 mmHg had a slower rate of eGFR decline when compared with patients with baseline BP 140/90 mmHg or more [-0.554±10.53vs-1.62±8.50 ml/min/year;*P*=0.04]. Patients with baseline proteinuria 1+ or more had greater rate of eGFR decline than those with negative proteinuria [-2.35±11.26vs-0.401±9.77 ml/min/year;*P*=0.001].

Conclusions: Our study revealed that this integrated care model has a beneficial effect on slowing the rate of eGFR decline in CKD stage 3-4 patients. Baseline BP and degree of proteinuria are 2 main factors that were significantly associated with greater rate of eGFR decline. Our study shows that the integrated care model could be successfully implemented at the community hospital level. It seems promising this integrated care could be implemented in another developing countries.

FR-PO251

Cost Analysis of a Virtual Monitoring System to Reduce Suboptimal Initiation of Dialysis

Drew Hager,[1] Thomas W. Ferguson,[1] Navdeep Tangri,[1] Paul Komenda,[2] Stewart Nadurak,[1] Claudio Rigatto.[3] *[1]Seven Oaks General Hospital, Winnipeg, MB, Canada; [2]University of Manitoba, Winnipeg, MB, Canada; [3]Chronic Disease Innovation Centre, Winnipeg, MB, Canada*.

Background: Patients with kidney failure require renal replacement therapy in the form of dialysis or kidney transplant to survive. Optimal initiation of dialysis includes outpatient, elective implementation of a patient's chosen modality once clinical indications for dialysis are met. Despite interdisciplinary nephrology care teams, suboptimal initiation requiring hospitalization occurs in approximately 30% of patients and is estimated to cost Canadians $33 million per year. Virtual monitoring in high-risk chronic kidney disease (CKD) patients may decrease the rate of suboptimal initiations and therefore decrease hospitalization expenses. The objective of this study is to evaluate the cost savings of a virtual monitoring program in high-risk CKD patients.

Methods: We constructed a decision analytic Markov model from the perspective of the Canadian health payer. A virtual monitoring strategy was compared with the status quo. Costs of a suboptimal initiation, CKD multidisciplinary clinic care, and for receiving dialysis were taken from a review of the literature. Probability of kidney failure was calculated based on the Kidney Failure Risk Equation (Tangri et al, JAMA, 2011), and risks of mortality on dialysis and with late stage CKD were taken from national dialysis registries. Effectiveness of the intervention was assumed to be similar to other virtual monitoring interventions in chronic disease patients and evaluated in sensitivity analyses (baseline relative risk reduction (RRR) of a suboptimal dialysis start 0.39).

Results: Compared with the status quo the virtual monitoring system was associated with a cost savings of $762.29 per patient enrolled in the intervention. With threshold analysis we found that the RRR of a suboptimal dialysis start afforded by the intervention would have to be reduced to 0.255 to reach cost neutrality. In univariate sensitivity analyses

the most influential variables included the probability of kidney failure per month, the relative risk reduction afforded by the intervention, the hospitalization cost of a suboptimal dialysis initiation, and the proportion of kidney failure starts that are assumed to be suboptimal.

Conclusions: Allocation of funds toward implementation of a virtual monitoring system with the potential to decrease rates of suboptimal dialysis initiation can produce significant cost savings.

FR-PO252

The End of the CKD Journey - Who Starts Renal Replacement Therapy and Who Dies Without It Among CKD Patients in Public Renal Speciality Practices in Queensland, Australia

Wendy E. Hoy,[2,1] Jianzhen Zhang,[2,1] Zaimin Wang,[1] Anne Cameron (Salisbury),[2,1] Helen G. Healy,[2,1] Andrew J. Mallett,[2,1] Sree Krishna Venuthurupalli.[3] NHMRC CKD.CRE and CKD.QLD Collaborative *[1]The University of Queensland, Brisbane, QLD, Australia; [2]NHMRC CKD.CRE & CKD.QLD, Brisbane, QLD, Australia; [3]Toowoomba Hospital, Toowoomba, QLD, Australia.*

Background: Persons with CKD who start renal replacement therapy (RRT) in Australia are well characterised, but the characteristics and outcomes of those who do not start RRT are less well understood. We examined the fate of patients with CKD in selected public renal specialty clinics in Queensland (in the CKD.QLD registry) and compare those who started renal replacement therapy (RRT) with those who died without RRT.

Methods: 6,371 patients in CKD.QLD (54% males, mostly CKD stages 3b, 4 and 5), were followed from date of informed consent until the start of RRT, death, or a censor date of June 30, 2016. Outcomes and causes of death were ascertained from Queensland Health records. Median follow-up (IQR) was 2.8 (3) years, with a total of 15,714 person years.

Results: By the censor date, 605 (9.5%) patients had started RRT, at a median (IQR) age of 63 (20) years and 837 (13.1%) had died without RRT, at median (IQR) age 78 years (14). RRT incidence rates per 100 person years for males and females respectively were 3.8 vs 2.7, p=0.001, and death rates were 5.8 vs 4.8, p=0.001. Among deaths without RRT, 377 (45.5%) mentioned terminal ESKF or chronic renal failure, an additional 193 (23.3%) mentioned CKD, and 57 (6.9%) mentioned AKI, with no gender differences.

Conclusions: Most of these patients with relatively advanced CKD experienced a "renal death" (started RRT or died with ESKF). Rates were higher for males. More died without RRT than started RRT. They were relatively distinct populations: average ESKF-free survival was 15 years longer for patients who did not start RRT (78 vs 63 years). About half the deaths without RRT were ESKF deaths, while another 30% mentioned a renal diagnosis. Ascertainment renal failure and CKD in death certificates was very good.

Developing a System to Track and Reinstate Kidney Patients Lost to Follow-Up

Lowell J. Lo. UCSF Nephrology & Hypertension Faculty Practice Clinic Team *Medicine, UCSF, San Francisco, CA.*

Background: In the care of chronic diseases, reducing the patients lost to follow-up (LTFU) is an important way to improve outcomes. At our tertiary academic center, we identified that approximately **24%** of patients seen over six months had been instructed to follow-up in the clinic but did not within the recommended time frame. We designed a method to trigger an alert for these patients and contact them to schedule appointments.

Methods: Leveraging alerts from our electronic medical record (EMR), we generated an LTFU report that identifies patients who did not return to the clinic as requested by the providers. The alerts were dependent on physician participation in an EMR follow-up trigger. Clinical staff called these patients and classified them into three groups: scheduled (appointment made successfully), no need to return (patients transitioned to dialysis, transferred to another nephrologist, or died), or call back (unable to reach or refused appointment). We also recorded individual conditions that could contribute to LTFU.

Results: Physician participation in the EMR trigger system was 76.5%. Over nine months, using our EMR alert and calling system, we reduced the percentage of LTFU patients from 24% to 3.8%. Of the 418 LTFU patients, we successfully scheduled 225 (54%) patients, identified 34 (8.1%) no need to return patients, and continued to reach out monthly to 157 (38%) patients. Among patients LTFU, a majority did not provide a reliable method to be contacted.

Conclusions: Retention in care is associated with improved outcomes. Our study identified a method by which patients LTFU were identified. Majority of the patients were able to have appointments successfully scheduled. Vulnerable patients may benefit from early identification of risk of LTFU. A limitation of our study is that we lack outcome data on patients who were LTFU and the development and implementation of the system is time-intensive.

FR-PO254

Longitudinal Kidney Care Program and Its Impact on Decreasing Hospitalizations and Increasing Home Dialysis as the First Choice for Dialysis

Saravanan Balamuthusamy,[1] Aruna Govindaraju,[2] Manonmani Ellappan,[3] Ranjit K. Dhelaria,[5] Alagarsamy l Reddi,[4] Roshni Veerappan ganesan,[6] Balamurugan P. Sankarapandian.[5] *[1]Research, PPG healthcare, Fort Worth, TX; [2]PPG Health, Fort Worth, TX; [3]PPG Health/ TRI, Fortworth, TX; [4]Texas Research Institute and PPG Healthcare PA, Fort Worth, TX; [5]PPG Healthcare, Fort Worth, TX; [6]Texas Research Institute, Fort Worth, TX.*

Background: The economic and morbidity burden of kidney disease has substantially increased in the past decade. With innovations on the pipeline for novel dialysis modalities, there is a lack of system-based practice applications in patients with kidney disease to decrease hospitalizations. We have initiated a systematic approach in educating patients with renal failure based on risk of progression to end stage kidney disease and assessed its efficacy in decreasing hospitalizations.

Methods: Retrospective analysis of patients in our nephrology practice who were hospitalized between January 2017 to January 2018. Also the rates of early home dialysis initiation were analyzed. ESRD patients were not included in the analysis for hospitalizations. The reason for hospitalizations were based on the admission diagnosis.

Results: The database included 4367 patients at low risk of progression and 1954 patients at a higher risk of progression based on the NKF heat map. The aggregate episode rate for hospitalization per 100 patients was calculated. The rate of hospitalizations was computed for three years. The first year serves as a control as the LKCP was not initiated at that time. The 2 years after that is when the program was actively implemented. The results are shown in Figures 1 and 2.

Conclusions: There is a significant reduction in hospitalizations and early initiation of home dialysis with a well-structured kidney care program that includes a multidisciplinary approach. These methods need to be validated in a much larger cohort for mortality risk and cost savings calculated with real time data from payors.

FR-PO255

Improving Patient and System Outcomes Through Integrated Care for CKD

Monica C. Beaulieu,[1,2] Mark Canney,[3,2] Dilshani Induruwage,[2] Adeera Levin.[1,2] BC Kidney Care Committee *[1]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada; [2]BC Provincial Renal Agency, Vancouver, BC, Canada; [3]University of British Columbia, North Vancouver, BC, Canada.*

Background: In British Columbia Canada, patients with Chronic Kidney Disease not on dialysis (CKD-ND) are cared for by interprofessional kidney care clinics (KCC's) using an integrated chronic disease model of care within a system which includes decision support

and clinical pathways, a single information system, feedback and audit systems, process and outcomes measures, provincial education of health care providers, policy makers, and patients, and dedicated patient focused funding. The BC-KCC's are integrated into a larger province wide renal network, with accountability for patient and system outcomes.

Methods: We describe the impact of a series of initiatives in KCC's to standardize education and support decision making and access for home- based therapies (HBT), conservative care (CC) and pre-emptive transplantation (Tx) over time. Initiatives were introduced sequentially, using change management and adult education principles, with materials developed by a diverse group of health care professionals and supported administratively with provincial dissemination.

Results: In March 2018, the cohort has 10,979 pts; mean age 71, median GFR 33 ml/min/1.73m2 at registration; 54% are male, 50% DM and 43% have CVD. 1285 new pts and 1017 pts exited KCC. Table 1 describes the 6 monthly prevalence of key outcomes over time. Documented treatment decisions for those with GFR <20 have increased slightly, as has formal symptom assessments, and numbers of pts choosing and starting on HBT and following conservative care pathways.

Conclusions: An integrated approach based on fundamentals of chronic care models has led to improved patient outcomes systemwide in BC.

Table 1. Kidney Care Clinic Key Outcomes Over Time

FR-PO256

Emerging Treatment Options for Anemia Associated with CKD: Success of Online Medical Education at Improving Knowledge and Confidence of Nephrologists

Amy Larkin,[1] David R. Anderson,[3] Karen Badal.[2] *[1]Medscape Education, Nicholasville, KY; [2]WebMD, New York, NY; [3]Medscape LLC, New York, NY.*

Background: As emerging therapies hold promise to improve treatment of anemia in patients with CKD, clinicians are in need of updates on development of new drugs that may ultimately influence their practices. We sought to assess baseline knowledge related to emerging treatments for CKD-related anemia and determine if online continuing medical education (CME) activities could improve the clinical knowledge and confidence of nephrologist in the area of Hypoxia-Inducible Factor Prolyl Hyproxylase Inhibitors (HIF-PHIs).

Methods: The effect of two online, CME-certified, roundtable video discussion activities were analyzed to determine efficacy of online education. Three multiple-choice knowledge/competence questions and 1 self-efficacy confidence question were presented both before and immediately after each activity. A repeated pairs pre-/post-assessment study design was used and McNemar's chi-squared test (5% significance level, $P < .05$) assessed educational effect for each activity. The activities launched November 18, 2016 and December 21, 2016, and data were collected through December 20, 2016 and February 1, 2017, respectively.

Results: In total, 264 nephrologists answered all pre-/post-assessment questions and were included in the study. Overall improvements were seen after participation in both CME activities: 10% more nephrologists ($P = .035$) correctly identified safety and efficacy data for an emerging HIF-PHIs 38% more nephrologists ($P < .001$) accurately characterized recently released data from a Medicare population of CKD patients On the 2 activities, 43% (n=126) and 38% (n=138) reported increased confidence in understanding of new therapies in development for the treatment of iron deficiency anemia in patients with CKD Continued educational gaps: About a third of nephrologists did not recognize new data presented at a major medical conference related to emerging HIF-PHIs

Conclusions: This study demonstrates the success of online, video-based roundtable discussion on improving knowledge and confidence of nephrologists related to emerging treatments for anemia associated with CKD. Continued knowledge gaps were identified for future educational targets.

FR-PO257

A Streamlined Electronic Decision Support for the Management of Patients with CKD

Abraham W. Aron,[1] Stewart H. Lecker,[2] Martin R. Pollak,[2] Ali Poyan-Mehr.[2] *[1]Department of Internal Medicine, Beth Israel Deaconess Medical Center, Boston, MA; [2]Division of Nephrology, Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Caring for patients with CKD requires the management of multiple medical conditions and is highly complex, data-driven and difficult to consolidate. Increased time spent on electronic health records (EHRs) is frequently perceived as an impediment to patient-centered care and has been shown to increase physician burnout. We have created a streamlined, electronic dashboard and decision support tool to consolidate CKD management, enhance efficiency and improve the clinician's work experience.

Methods: A total of 6 core content areas, 14 decision support notifications and over 90 data elements were systematically arranged into a single dashboard within our institution's EHR. This was further enriched by links to professional literature and patient handouts. To assess the impact of this decision support tool, we conducted a survey amongst providers at our single tertiary care center.

Results: We received over 300 responses. 12% were Nephrology attendings/fellows, 24% were primary care physicians and 64% were medical residents. Amongst responders, 60% used the tool in their clinical practice. It is used primarily in the outpatient setting (69%), and most frequently for the assessment of CKD etiology/stage (48%), management of mineral and bone disorders (29%) and anemia management (22%). The streamlined CKD dashboard and decision support tool was considered by 56% of respondents as helpful in preventing physician burnout.

Conclusions: While EHRs are frequently cited as a major source of physician burnout, an enhanced user interface can lead to an improved work experience. The widespread voluntary adoption of our CKD dashboard and electronic decision support suggests opportunities for EHRs to impact CKD management, enhance efficiency, and improve the clinician's work experience. Our data further suggests benefits of augmenting decision support and automated guidance while caring for patients with CKD.

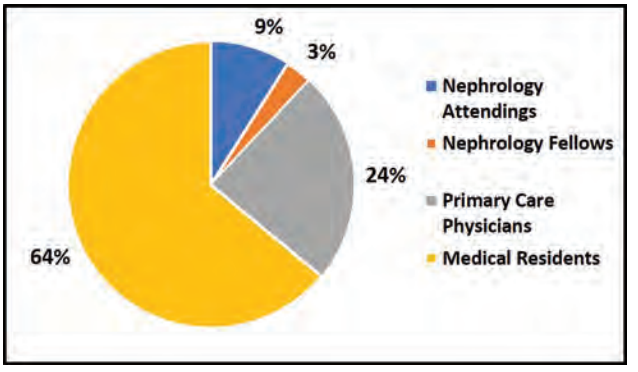

Figure 1. User deomgraphics of the decision support tool.

FR-PO258

Implementation of a CKD Panel Management Tool for Resident Physicians

Frederick M. Howard, James J. Connolly, William Ackley, Kaoru Harada, Steffne J. Kunnirickal, Naseema B. Merchant, Mark A. Perazella. *Yale School of Medicine, Cheshire, CT.*

Background: Chronic kidney disease (CKD) affects approximately 1 in 7 adults and over one million Veterans served by the Veterans Health Administration (VHA). These patients are at increased risk for numerous adverse sequelae, including anemia, metabolic acidosis (MA), proteinuria, mineral bone disease (MBD), and hypertension. Clinical practice guidelines have been published by the Kidney Disease: Improving Global Outcomes work group to assist clinicians in managing the sequelae of CKD, but guideline compliance was low in a test cohort of patients cared for by residents working at a VHA Medical Center.

Methods: We designed a panel management tool to provide an automated summary of guideline-based interventions relevant to each patient seen in clinic. Residents received up to 16 recommendations per patient – eight focusing on work-up of anemia, five on MBD, and one each on uncontrolled hypertension, evaluation for albuminuria, and correction of MA. Guideline compliance, both overall and for specific domains of care, was compared pre- and post-intervention using a two-sided t-test.

Results: We identified 365 encounters with patients with at least stage III CKD (eGFR < 60 ml/min/1.73 m^2) during the six months prior to intervention, and 272 encounters in the first four months of our intervention. Guideline compliance increased from $53.5 \pm 1.3\%$ pre-intervention to $61.0 \pm 2.5\%$ post-intervention ($p < 0.01$). In a subgroup analysis, there were significant improvements in MBD testing ($40.0 \pm 2.4\%$ vs $53.0 \pm 2.9\%$) and albuminuria screening ($25.6 \pm 2.0\%$ vs $42.1 \pm 3.3\%$).

Conclusions: Implementation of a panel management tool achieved significant improvement in overall guideline compliance, with particular efficacy in the domains of MBD and albuminuria screening. The short time course of the intervention may have limited our ability to assess for improvement in blood pressure control and MA. This effective tool could be universally applied to improve the management of CKD by VHA providers.

FR-PO259

eGFR in the Emergency Department as a Predictor of In-Hospital Mortality in Pneumonia

Chung-te Liu.[1,2] Division of Nephrology, Department of Internal Medicine, Wan Fang Hospital, Taipei Medical University *[1]Division of Nephrology, Department of Internal Medicine, Wanfang Hospital, Taipei Medical University, Taipei, Taiwan; [2]Graduate Institute of Clinical Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan.*

Background: Pneumonia is a global leading cause of mortality. Severity-assessment scores in pneumonia are crucial for guiding the treatment. Community-based studies have demonstrated the association between pre-existing low estimated glomerular filtration rate (eGFR) and outcomes in pneumonia. However, whether a single eGFR measurement in the emergency department can predict in-hospital mortality in pneumonia remains to be investigated.

Methods: This hospital-based, retrospective cohort study was conducted at Wan Fang Hospital and included 1554 patients hospitalized with pneumonia between January 2013 and December 2015. Patients under 20 years of age were excluded. The main predictor was eGFR in the emergency department calculated according to the equation suggested by Chronic Kidney Disease Epidemiology Collaboration. The outcomes included in-hospital mortality, intensive care unit (ICU) admission, need for ventilator, durations of hospital and ICU stay, and ventilator use. Receiver operating characteristic (ROC) curve and Youden criteria for determining the optimal cut-off value of eGFR to predict in-hospital mortality were used and confirmed using a multivariate logistic regression model.

Results: Of 1554 patients, 263 (16.9%) had chronic kidney disease (CKD) and demonstrated higher C-reactive protein (CRP) levels and SMART-COP score and more events of multilobar pneumonia, acute kidney injury, ICU admission, and in-hospital mortality. Patients with higher pneumonia severity scores tended to have lower eGFR. eGFR of 55.89 mL/min/1.73m^2 was the optimal cut-off value for predicting in-hospital mortality. Multivariate logistic regression analysis adjusted for sex, co-morbidities, CRP, liver function tests, and SMART-COP score demonstrated that eGFR <55.89 mL/min/1.73m^2 had odds ratio of 3.2 (95% confidence interval: 2.3–4.4) for in-hospital mortality.

Conclusions: Low eGFR in the emergency department is associated with higher pneumonia severity. eGFR <55.89 mL/min/1.73m^2 is an independent predictor of in-hospital mortality in patients hospitalized with pneumonia.

FR-PO260

The Effect of Peer Mentoring on Active Engagement Among Patients with Advanced CKD

Said Al Zein, Mo'Tasem Alkhasoneh, Tara Liaghat, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Background: Peer mentoring is an effective strategy in patient education and has been proposed as an effective model for active patient engagement. This study compares the effect of peer mentoring (face-to-face and online) with usual care on active engagement among patients with chronic kidney disease (CKD).

Methods: Patients with stage 4 or stage 5 CKD were randomly assigned either to face-to-face (FTF) peer mentoring, online peer mentoring, or usual care (control). For the FTF group, the frequency of contact by a mentor was weekly by phone and monthly FTF visit. For the online mentorship, the frequency of contact by mentor was weekly by the online platform, and more frequently as initiated by the mentee. The mentorships were maintained for at least 6 months. Usual care participants received a printed copy of an information handbook and were encouraged to discuss questions with their care team. We used the 13-item validated Patient Activation Measure® (PAM) at baseline and at 12 months to assess change in level of engagement. Univariate and multivariate analyses were used to compare the change in PAM scores from baseline to 12 months.

Results: A total of 130 patients completed the 12 month assessment. Baseline PAM score and demographic characteristics (mean age, educational attainment, gender and race distribution) were similar among the 3 groups. There was a significant improvement in the mean PAM score for the online peer mentoring group (69.7±15.6 vs. 76.44 ± 13.96; p=0.02). There was a slight (non-significant) improvement in PAM among the FTF group and no change in PAM among the control group. Improvements in PAM stage (by at least one level) were seen among 33% of the FTF, 48.7% of the online and 22.7% of the control group. PAM was decreased by at least one stage among 36% of the FTF, 12.8% of online and 31.8% of control group.

Conclusions: Compared with face-to-face mentoring and information only education, online peer mentoring is associated with improved scores in Patient Activation Measure and PAM stage among patients with advanced CKD. **Funding: PCORI**

The Effect of Peer Mentoring on Caregiver Burden Among Caregivers of Patients with CKD

Mo'Tasem Alkhasoneh, Said Al Zein, Tara Liaghat, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Background: Caregivers play a fundamental role in the treatment and management of patients with chronic kidney disease (CKD). Caregiver burden may result from providing care to patients with CKD and is often overlooked by clinicians. Peer mentoring is an effective educational strategy which may result in improvement in caregiver burden. This study compares the effect of peer mentoring (face-to-face and online) with usual care on caregiver burden among caregivers of patients with CKD.

Methods: A 16-hour structured program trained CKD patients and their caregivers to become peer mentors to newly diagnosed patients with CKD and their caregivers. Caregivers of patients with stage 4 or stage 5 CKD were randomly assigned either to face-to-face (FTF) peer mentoring, online peer mentoring, or usual care (control). For the FTF group, the frequency of contact by a mentor was weekly by phone and monthly FTF visit. For the online mentorship, the frequency of contact by mentor was weekly by the online platform, and more frequently as initiated by the mentee. The mentorships were maintained for at least 6 months. Usual care participants received a printed copy of an information handbook about care of the patient with CKD. We used the Zarit Burden Interview (ZBI) to measure caregiver burden at baseline and at 12 months. The ZBI is a self-administered questionnaire of 22 items, which measures the impact of caregiving in psychological, physical and social domains. The items are ranked on a five-point Likert scale and the total score is calculated; higher scores indicating heavier burden. Univariate and multivariate analyses were used to compare the change in ZBI scores from baseline to 12 months.

Results: A total of 61 caregivers completed the 12 month assessment. Baseline ZBI score and demographic characteristics (mean age, highest grade of education, gender and race distribution) were similar among the 3 groups. There was a significant decrease in the mean ZBI score for the online mentoring group (23.9±10.7 vs. 12.8 ± 12.3; p=0.03). There was a slight (non-significant) improvement in ZBI among the FTF group and among the control group.

Conclusions: Compared with face-to-face mentoring and information only education, online peer mentoring is associated with improved scores in caregiver burden among caregivers of patients with advanced CKD. **Funding: PCORI**

FR-PO262

Optimizing the Utility of Patient Experience Surveys to Advance the Quality of Renal Care

Helen Chiu,[1,2] Gloria T. Freeborn,[1] Ognjenka Djurdjev,[1] Sushila Saunders,[1] Adeera Levin.[3] *[1]BC Renal Agency, Vancouver, BC, BC, Canada; [2]Providence Health Care Research Institute, Vancouver, BC, Canada; [3]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada.*

Background: Patient experience is an essential indicator for advancing person-centred care. Although many patient experience measures are validated in chronic disease populations, how they can be utilized in guiding improvement in renal care is understudied. Thus, we verified how results of a validated patient experience survey can be used to guide improvement in the continuum of renal care.

Methods: A validated 20-item instrument, Patient Assessment of Chronic Illness Care (PACIC), was mailed out to >13,000 eligible patients receiving non-dialysis and dialysis care in British Columbia, Canada. The responses were descriptively analyzed by subscale (five dimensions in PACIC) and modality of care. Priority matrix analysis was also performed to identify specific areas of improvement.

Results: Nearly 4,000 patients responded (30% response rate). More than 75% of respondents rated the overall quality of kidney services as "excellent" or "very good." Based on the survey responses, the area of highest satisfaction was the overall organization and delivery of care, and areas of improvement included "goal setting" and "follow-up." Priority matrices by modality identify unique improvement opportunities (Fig 1) not otherwise apparent from conventional analysis by highlighting aspects of care highly associated with overall perception of the renal services quality.

Conclusions: Measuring patient experience across a diverse renal population yields important insights. When analyzed with respect to the overall perception of quality of kidney services, the utility of PACIC results is enhanced in that it can guide strategic action planning specific to each modality of renal care, with a greater potential for positively impacting those living with kidney disease.

Impact of a Phone App on the Referral to Nephrology

Nestor Oliva-Damaso,[1] Elena Oliva-Damaso,[2] Francisca Lopez,[1] Maria M. Castilla,[1] Jose C. Rodriguez-Perez,[3] Juan Payan Lopez.[1] *[1]Hospital Costa del Sol, Marbella, Spain; [2]Hospital General Universitario de Gran Canaria Dr Negrin, Las Palmas, Spain; [3]University Hospital, Las Palmas Gran Canaria, Spain.*

Background: Several factors might influence nephrology referral decisions by clinicians, including lack of training about guidelines regarding timing or indications. In the 21st century tools as phone apps can make knowledge more accessible.

Methods: Prospective quasi-experimental study. We studied referral to nephrology in the Hospital Costa del Sol of 2015. In 2016 we perform formative lectures to the principal departments that refer patients to nephrology of phone "Nefroconsultor" that recommends referrals attending to KDIGO criteria. We studied referral of 2017 after intervention.

Results: 628 patients with a mean age of 68 years-old, 63% were male, a mean creatinine at time of referral of 1,5mg/dL and a glomerular filtration rate of 46 ml/min/1,73m^2 (CKD-EPI). Comparing before and after intervention, previous implantation of phone app 333 patients were referred while after 295 patients were referred, a 10,1% less (p=0,001). There were no differences in age (p=0,13); gender (p=0,197); serum creatinine (p=0,59) and glomerular filtration rate CKD-EPI (p=0,41). In 2015, 132 patients of 333 met stablished KDIGO criteria of referral (39,8%) while in 2017 200 patients of 295 (60,2%) and considered well referred (p=0,001). The increase of intervention success was of a 28,8% (binomial effect size display with Cohen'd effect size of 0,751). Previous the app 208 patients of 333 (63,2%) were referred with data of albuminuria while after 258 of 295 patients (89% p=0,001). The increase of intervention success was of a 25,7% (Cohen'd effect size of 0,744). Referral including urine sediment improved from a 69,3% to 87,2% (p=0,001) with an increase of intervention success of 12,2% (Cohen'd 0,28). Multivariate regression analysis using referral meeting KDIGO criteria as dependent variable and adjusting by age, sex and department of provenance, 2017 was associated with a correct referral with a odds ratio of 3,57 (IC 95%: 2,52-5,05) compared to 2015 (p=0,001). Proteinuria as the reason of referral to nephrology also increased from a 24% to a 34,8% (p=0,004).

Conclusions: The use of a tool as phone app (Nefroconsultor) improves the referral to nephrologist a 28,8% attending to referral stablished criteria. The app also increases the study of albuminuria and urine sediment at the moment of referral, increasing proteinuria as reason of referral. UNDER REVIEW CJASN.

Evaluation of the Efficacy of CKD Support Decision-Making Application: How It Changes Home Blood Pressure and Kidney Functions

Shiho Kosaka,[1] Junichi Hoshino,[2] Yoshifumi Ubara,[2] Masami Hamada,[3] Masayuki Yamanouchi,[2] Akinari Sekine,[2] Keiichi Sumida.[4] *[1]Graduate school of Health Sciences, Tokyo Medical and Dental University, Tokyo, Japan; [2]Toranomon Hospital, Tokyo, Japan; [3]Nagoya university, Nagoya, Japan; [4]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan.*

Background: Disease management in patients with chronic kidney disease (CKD) is complicated. Appropriate information provision and daily self-monitoring of parameters such as blood pressure are required. Therefore, this study aimed to evaluate how a chronic kidney disease support decision-making application (CKD-SDM) app in patients with CKD affects the blood pressure, kidney functions, and disease-management knowledge at home.

Methods: This study was a randomized, controlled trial involving 54 patients with stage 3, 4, or 5 non-dialysis CKD. The intervention group was provided with a tablet equipped with the CKD-SDM app. An automated sphygmomanometer for home blood pressure monitoring (HBPM) was used in both groups for 8 weeks. The primary outcome measure is change in HBPM data from baseline to 8 weeks. Secondary outcomes are changes in renal functions and self-management knowledge level on CKD.

Results: The mean (SD) age, eGFR, and HBPM (morning and evening) of participants were 70.7±11.0 years, 37.0±14.4 ml/min per 1.73 m^2, and 133.7±11.5/78.3±8.9 and 130.5±13.4/76.0±8.9 mmHg, respectively. No significant differences between groups were observed at baseline. After 8 weeks, HBPM reduction in both groups were -5.8/-1.5 vs. -3.1/-0.7 mmHg in the morning and -6.1/-3.3 vs. -4.0/-1.5 mmHg in the evening, with no significant differences between the two groups. In the female intervention group, the morning systolic blood pressure (SBP) difference significantly decreased, -7.7 vs. -2.6 mmHg ($p<0.05$). All kidney functions were not significantly different. Similarly, the self-management knowledge level on CKD was not significantly improved in the intervention group.

Conclusions: Eight weeks of intervention with CKD-SDM app did not reduce the overall HBPM, despite the improved SBP observed in the female intervention group. In the future, we have to plan larger and long-term studies to evaluate HBPM reduction and kidney functions in patients with CKD. Trial Registration: This study is registered in the UMIN Clinical Trial Registry (000025792).

Patient Language and Guideline-Concordant Care Among Individuals with CKD in Primary Care

Sarah Rosenwohl-Mack,[1] Anna Rubinsky,[2] Leah Karliner,[1] Lenny Lopez,[1] Carmen A. Peralta.[2] *[1]University of California, San Francisco, San Francisco, CA; [2]University of California San Francisco/SFVAMC, San Francisco, CA.*

Background: Patients with a language barrier are at risk for poor communication and inadequate management of chronic conditions. We assessed the quality of Chronic Kidney Disease (CKD) management in primary care for non-English speakers compared to English speakers.

Methods: Using EHR data (2014-2015), we evaluated the association of non-English language preference with guideline-concordant care among adults with CKD in a primary care clinic in San Francisco where interpreters are available. Outcomes included: testing for albuminuria (all) and A1c (patients with diabetes); prescription of ACEi/ARB and statins; BP at goal < 140/90 and A1c<7 (patients with diabetes). We used multivariate modified Poisson regression to estimate relative risks of each outcome.

Results: Among 1,726 patients, mean age was 66 ±10, 26% were Asian, 14% Black and 7% Hispanic. 88% had Medicare and 10% Medicaid. Compared to English speakers, non-English speakers had higher prevalence of comorbidities (cerebrovascular disease, 16% vs. 12%; diabetes, 57% vs. 41%; and hypertension, 89% vs. 81%) and more frequent primary care visits, but similar eGFR (49 vs. 48 ml/min/1.73m^2). In unadjusted comparisons, non-English speakers were more likely to be tested for albuminuria and have a prescription for statins, but there were no differences in ACEi/ARB prescription, BP or A1c control. After adjustment, differences were mostly attenuated.

Conclusions: Overall, most guideline measures were sub-optimally met. However, there was consistent care across language preference: in a single clinic with access to professional interpreters, non-English language preference was not associated with differences in guideline-concordant processes of care for CKD.

Funding: NIDDK Support

Rates of Guideline-Concordant Care by Language Preference

Process of Care	English Speaker (%)	Non-English Preference (%)	Adjusted* RR (95% CI)
Testing for albuminuria	41	53	1.03 (0.90,1.17)
A1c testing in diabetics	98	98	0.99 (0.96,1.02)
Statin prescription	66	77	1.01 (0.94,1.09)
ACE/ARB prescription	72	73	0.90 (0.82,0.99)
BP control	75	74	1.05 (0.96,1.14)
A1c <7 in diabetics	77	59	0.97 (0.75,1.25)

*Fully adjusted (age, sex, race, insurance type, number of PC visits in the study period, CKD stage, count of comorbid conditions if applicable)

Evaluation of CKD Symptom Management Algorithms and Patient Information Sheets in Two Kidney Care Clinics

Puneet Vashisht,[4] Judith G. Marin,[1] Nadia Y. Zalunardo,[2] Monica C. Beaulieu,[3] Hilary Wu.[5] *[1]Providence Health, North Vancouver, BC, Canada; [2]Gordon & Leslie Diamond Health Care Ctr., Vancouver, BC, Canada; [3]University of British Columbia, North Vancouver, BC, Canada; [4]Lower Mainland Pharmacy Services, Vancouver, BC, Canada; [5]Vancouver General Hospital, Vancouver, BC, Canada.*

Background: As renal function declines, symptoms related to chronic kidney disease (CKD) become more prevalent and impact quality of life. To address symptom management systematically in patients with eGFR ≤ 15 mL/min not on dialysis, the British Columbia Provincial Renal Agency (BCPRA) developed 8 symptom management algorithms and patient information sheets. The objectives of this project are to assess patients' symptom burden before and after implementation of these tools and to assess patient and staff satisfaction.

Methods: We conducted a prospective quantitative and qualitative study at 2 Kidney Care Clinics (KCCs). Five patients who were followed with the symptom management algorithms for nausea, low appetite, pruritis, and fatigue/insomnia were interviewed to assess satisfaction with care received via the algorithms and patient information sheets. Symptom burden was assessed pre and post algorithm use using a validated symptom assessment tool (Edmonton Symptoms Assessment Score (ESAS)). Next, focus groups with renal nurses (RNs) and renal dieticians (RDs) were conducted to assess provider satisfaction with the tools.

Results: Following assessment of 5 patients, ESAS score improved for 4 patients after a mean (SD) follow up of 80 (13) days. Patients reported that recommendations provided were somewhat helpful for symptom and quality of life improvement and that the patient information sheets were helpful and easy to use. Of the 13 RNs and RDs in the focus groups, 12/13 were satisfied or very satisfied with the algorithms and 13/13 were satisfied or very satisfied with the patient information sheets. Major themes identified by patients and providers included their satisfaction with the ability to improve standardized care, patient education, patient-centered care, accountability, and follow-up.

Conclusions: Following implementation of BCPRA symptom management algorithms, we were able to show a reduction in symptoms for patients with a GFR ≤ 15 mL/min not on dialysis using validated symptom management tools. Patients and providers found the information sheets/algorithms helpful and easy to use.

FR-PO267

The Prevalence of Uremic Symptoms and Their Association with Adverse Outcomes in CKD

Tariq Shafi,[1] Eugene P. Rhee,[2] James P. Lash,[3] Chi-yuan Hsu,[4] Dominic S. Raj,[5] Jonathan J. Taliercio,[6] Bernard G. Jaar,[7] Jing Chen,[8] John W. Kusek,[10] Jeffrey C. Fink,[11] James H. Sondheimer,[12] Harold I. Feldman,[9] Eliseo Guallar.[13] CRIC Study *[1]Johns Hopkins University, Baltimore, MD; [2]Massachusetts General Hospital, Newton, MA; [3]University of Illinois at Chicago, Chicago, IL; [4]University of California San Francisco, San Francisco, CA; [5]George Washington University, Washington, DC; [6]Cleveland Clinic, Cleveland, OH; [7]Johns Hopkins University, Baltimore, MD; [8]Tulane School of Medicine, New Orleans, LA; [9]University of Pennsylvania, Philadelphia, PA; [10]NIDDK, Bethesda, MD; [11]University of Maryland, Baltimore, MD; [12]Wayne State University School of Medicine, Detroit, MI; [13]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Background: Fatigue, anorexia, and pruritus are important patient-reported symptoms of CKD. Their prevalence and association with adverse outcomes in patients with non-dialysis dependent CKD have not been well established or characterized.

Methods: Among 3,639 participants of the ongoing Chronic Renal Insufficiency Cohort Study (CRIC), we assessed fatigue, anorexia, and pruritus using the KDQOL-36, administered at baseline and then annually. We calculated a uremic symptom score (U-Score) by averaging the 3 symptom scores for each person. We determined the time-varying association of each symptom and the U-Score with the risk of CKD progression (50% reduction in eGFR or ESRD), death and first cardiovascular disease (CVD) events, using Cox models adjusted for demographic, clinical, and laboratory variables, including eGFR and albuminuria.

Results: At baseline, mean age was 58 yrs and eGFR was 45 ml/min/1.73m^2. The prevalence of fatigue was 52%, anorexia, 21%, and pruritus, 42%; each were associated with lower eGFR (p<0.001). During a median follow-up of 6.1 yrs, a higher U-Score (more symptoms) was significantly and positively associated with all outcomes (Table). Each individual symptom was associated with the risk of CKD progression; anorexia and fatigue were associated with death; none of the individual symptoms was associated with first CVD event.

Conclusions: A uremic symptom score, derived from three commonly reported symptoms, is associated with adverse outcomes in patients with non-dialysis dependent CKD. Our findings highlight the importance of patient-reported symptoms and underscore the need for unraveling their pathogenesis.

Funding: NIDDK Support

Perceived Significance of Engagement in CKD Research Priority Setting Among Stakeholders: A Qualitative Study

Meghan J. Elliott,[1] Zahra S. Goodarzi,[1] Joanna Sale,[4] Linda A. Wilhelm,[3] Brenda Hemmelgarn,[1] Sharon Straus.[2] *[1]University of Calgary, Calgary, AB, Canada; [2]Li Ka Shing Knowledge Institute, Toronto, ON, Canada; [3]Canadian Arthritis Patient Alliance, Midland, Kings County, NB, Canada; [4]St. Michael's Hospital, Toronto, ON, Canada.*

Background: Patients and other stakeholders are increasingly engaging as partners in research, although how they perceive such experiences, particularly over the long term, is not well understood. We sought to characterize how participants from a chronic kidney disease (CKD) research priority-setting project conducted two years previously perceived the significance of their involvement.

Methods: This was a qualitative study involving participants across Canada from a prior CKD research priority-setting project. We purposively sampled across stakeholder roles (i.e. patients with non-dialysis CKD, caregivers, healthcare professionals, and policymakers) and engagement types (i.e. involvement on the project's steering committee and/or final prioritization stage). We conducted individual, in-depth Interviews, which we analyzed using an inductive, thematic analysis approach.

Results: We conducted 23 interviews across all stakeholder roles and engagement types, and characterized three themes. Participants identified research engagement as an opportunity to facilitate integration of distinct CKD stakeholder communities (i.e. patients/caregivers and healthcare professionals/researchers). All participants appreciated the experiences that stakeholders, and particularly patients, brought to research, which furthered their understanding of the CKD lived experience and the value of patient-oriented research. Stakeholders suggested that their involvement in the project helped re-focus their commitment CKD research and care, which encompassed a subsequent interest in research engagement and patient-centered care approaches.

Conclusions: When reflecting on their of experience engaging in CKD research prioritization, stakeholders viewed the significance of their involvement in relation to the integration of different CKD communities, an appreciation of the CKD experience, and a re-focusing of their commitment to research and CKD care. Findings highlight considerations for future health research that engages stakeholders, and in particular those living with CKD or other chronic illnesses, as research partners.

Accurate Estimation of Arterial pH from Venous pCO2 and Venous CO2: An Easy Solution to an Old Problem

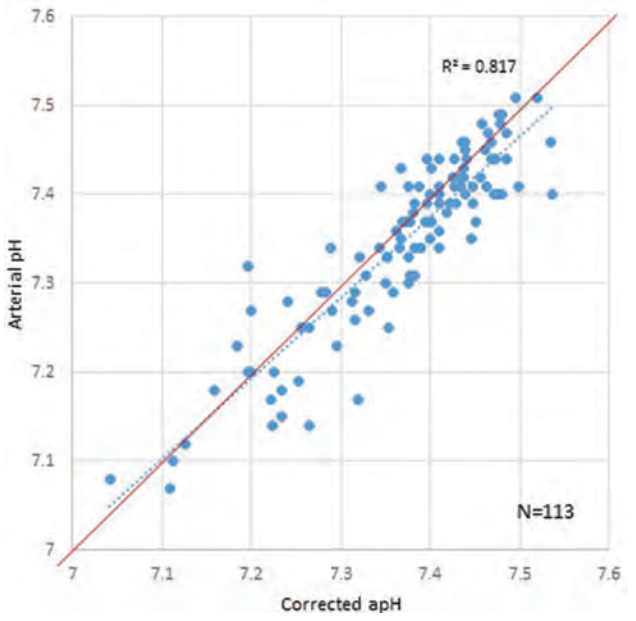
Sheeba H. Ba aqeel, Daniel Batlle. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Plasma CO2 from venous blood (vTCO2 or vCO2) is often used as a surrogate for arterial bicarbonate (aHCO3). Arterial PCO2 (aPCO2) can be estimated from the venous PCO2 (vPCO2) using regression equations derived from correlative studies. If the pH is recalculated using vPCO2, the HCO3 (numerator in the Henderson Hasselbalch equation) is also impacted thereby limiting the accuracy of the corrected pH. We reasoned that with proper validations of vCO2 as a surrogate for aHCO3 and vPCO2 corrected to reflect aPCO2, the arterial pH (apH) can be readily estimated from venous blood and the venous pH will not be needed. Here we tested this concept.

Methods: We analyzed a de-identified database of venous and arterial blood gases performed in the clinical lab of Northwestern Medicine, Chicago, USA. ABG, VBG and electrolyte panel were examined in 113 samples obtained simultaneously. Additionally, concurrent data for arterial and venous PCO2 obtained from 3911 samples and collected from various hospital departments was used for a regression equation to calculate aPCO2 from vPCO2. Pearson correlations and Bland-Altman analysis were done to examine the limits of agreement.

Results: vCO2 was in close agreement with the aHCO3 (R^2=0.93 P<0.001; 95% limits of agreement were 2.89 to -2.89 mmol/L, mean bias= -0.2 ±1.59). aPCO2 was estimated from vPCO2 to yield corrected PCO2 (cPCO2) using a regression equation, cPCO2=2.3+0.82*vPCO2. The apH was then calculated using this cPCO2 and vCO2 as follows: apH = 6.1 + log vCO2 / 0.03 x cPCO2. The corrected apH showed a close correlation and agreement with measured apH (R^2=0.81 P<0.001 (fig1) and 95% limits of agreement 0.46 to -0.39, mean bias 0.04±4.4)

Conclusions: 1)CO2 values in venous blood are in close agreement with aHCO3 calculated from the ABG. Accordingly, vCO2 can substitute for aHCO3 to recalculate the pH 2)The corrected vPCO2 and the measured vCO2 allow for an accurate calculation of apH which is close to measured apH. Moreover, this avoids altogether the measurement of venous pH which is not a good reflection of apH.



FR-PO270

Anion Gap (AG) Improves the Prediction of Ionized Hypocalcemia (HC) in Critical Care

Ernie Yap,[3] Andrea Roche-Recinos,[1] Philip Goldwasser.[2] *[1]Danbury Hospital, Danbury, CT; [2]VA New York Harbor, Brooklyn, NY; [3]SUNY Downstate, Brooklyn, NY.*

Background: The physiologically active form of total serum calcium (sCa) is ionized (iCa). It is reported in arterial (ABG) and venous (VBG) gas panels. The rest of sCa is bound, mainly to albumin (ALB), or chelated by small anions. Low ALB and high chelating anion levels are common in critical care patients (pts). A popular adjustment of sCa for ALB alone (BMJ 1977) yields a corrected value (cCa) that doesn't detect abnormal iCa well in such pts, perhaps because it ignores the chelating anions. AG reflects the levels of both such anions and ALB, and has been shown to correlate with iCa (Nordin 1989). We tested whether the diagnosis of HC in critical care could be improved by accounting for both AG and ALB.

Methods: In 769 critical care pts, simultaneous values of sCa (units: mg/dL), ALB (g/dL), and AG (mEq/L) were paired retrospectively with closely-timed (<20 min. apart) values of iCa (mM) derived from 309 ABGs (mean pH=7.390) or 460 VBGs (mean pH=7.363). We defined HC as iCa <1.10 in ABGs and, to adjust for the mean pH difference, as <1.11 in VBGs. The prevalence of HC was 28% (86/309) in ABGs and 21% (95/460) in VBGs. A model to predict HC in the ABG cohort was generated by multiple logistic regression with sCa, ALB, and AG as candidate predictors. Next, this model was validated in the VBG cohort. Areas under the ROC curve (AUC) of the model and of cCa were compared. Data are summarized as means [95%CI].

Results: sCa ($p<10^{-10}$), ALB (p<.004), and AG ($p<10^{-5}$) were each significant independent predictors of HC in the ABG cohort, with odds ratios of 0.064 [.029-.142], 2.87 [1.40-5.87], and 1.19 [1.11-1.28], respectively. The overall odds were $6{,}853{,}807\times0.064^{sCa}\times 2.87^{ALB}\times1.19^{AG}$. This model had a better AUC than cCa in both the ABG cohort (0.89 [.84-.93] vs 0.82 [.77-.88]; p<.005) and the VBG cohort (0.89 [.86-.93] vs 0.82 [.77-.87]; p=.0002). The predicted HC rate and the observed rate showed good agreement in the VBG cohort, divided into 4 prediction subgroups, each 25% wide (Table).

Conclusions: Adjusting sCa for both AG and ALB improves the diagnosis of HC. The absolute probability estimates of the logistic model are intuitive and may help clinicians decide when to obtain an ABG.

Etiology of the Elevated ΔAG/ΔHCO3 Ratio in Lactic Acidosis: Time for Another Delta?

Richard M. Treger,[1,2] Tristan Grogan,[3] Scott Rudkin.[4] *[1]Nephrology, Veterans Affairs, Los Angeles, CA; [2]Nephrology, UCLA, Los Angeles, CA; [3]UCLA, Los Angeles, CA; [4]UCI, Orange, CA.*

Background: The ratio of delta anion gap and delta bicarbonate ($\Delta AG/\Delta HCO_3$) is used to detect co-exisiting acid-base disorders in patients with high AG metabolic acidosis. The $\Delta AG/\Delta HCO_3$ ratio in lactic acidosis (LA) is 1.6-1.8, most commonly postulated to result from lactate anions remaining in the extracellular space while protons are buffered intracellularly. Others have proposed that hypochloremia, resulting from extrusion of cellular cations and resultant expansion of the extracellular compartment during the buffering process in LA, accounts for the increment in AG. This study examined the etiology of the elevated $\Delta AG/\Delta HCO_3$ seen in LA.

Methods: Data were obtained prospectively from adult trauma patients at a level 1 trauma center. Venous samples were drawn prior to administration of intravenous fluids. The associations between ΔLactate and ΔAG, arterial pH and $\Delta AG/\Delta HCO_3$, and serum chloride and $\Delta AG/\Delta HCO_3$ were examined using Pearson's correlations and linear regression models.

Results: 108 patients were included. 63 patients had normal serum lactate levels (≤ 2.1 mM) with a mean AG of 7.1 and a mean lactate level of 1.5 mM, the values used to calculate subsequent ΔAG and ΔLactate values. $\Delta AG/\Delta HCO_3$ was calculated for 45 patients who had elevated serum lactate levels (>2.1 mM). The mean $\Delta AG/\Delta HCO_3$ was 1.86. The mean $\Delta Lactate/\Delta HCO_3$ ranged between 0.95-1.21 and the ΔLactate only explained 24.6% of the observed variance in the ΔAG (Figure). There was no statistically significant association between arterial pH or serum chloride and the $\Delta AG/\Delta HCO_3$ ratio (p = 0.52 and 0.33, respectively).

Conclusions: The high ΔAG that results in an increased $\Delta AG/\Delta HCO_3$ ratio does not appear to be primarily a result of increased extracellular lactate, pH-dependent contribution of anions or cations to the AG, or hypochloremia. Therefore, the high $\Delta AG/\Delta HCO_3$ seen in lactic acidosis is likely a result of unmeasured organic anions, possibly including Krebs cycle intermediates. Further work to identify them needs to be carried out.

Genotype, Not Lactic Acidosis, Predicts Disease Progression in a Cohort of MELAS Patients

Krishna rekha Moturi,[4] Jifu Jin,[2] Jiangtao Li,[3] Ralitza H. Gavrilova,[1] Qi Qian.[5] *[1]Genetics, Mayo Clinic, Rochester, MN; [2]Nephrology, Zhongshan Hospital, Shanghai Medical College, Fudan University, Shanghai, China; [3]Nephrology, Tongji Hospital, Tongji University School of Medicine, Shanghai, China; [4]John H. Stroger Jr. Hospital of Cook County, Chicago, IL; [5]Nephrology and Hypertension, Mayo Clinic School of Medicine, Rochester, MN.*

Background: The clinical features of MELAS (mitochondrial myopathy, encephalopathy, lactic acidosis and stroke-like episodes) are heterogeneous. The role of lactic acidosis and MELAS genotypes in disease severity and progression has not been clarified. This study investigated MELAS phenotype in relation to the presence/severity of lactic acidosis and to the MELAS genotypes (classic [m.3243A>G] and other non-classic mutations).

Methods: MELAS patients in the North American Mitochondrial Disease Consortium (NAMDC) database, hospitalized in the Mayo Clinic for MELAS-related symptoms (up to Jan. 2018), were enrolled. Demographics, disease course, laboratory results, neuroimaging and muscle biopsies were obtained.

Results: Twenty-four (24) participants (15 female) were studied. Total follow-up was 170 person-years (median follow-up, 7.2 [IQR 1.3-11.6] years). The median age of disease onset was 6.5 (IQR 1.0-35.2) years. Headache, confusion, and ↓cognition were the most common initial presentations. 16.7% of the subjects died during the follow-up. Lactic acidosis, defined by serum lactate >2.2 mmol/L, was present in 83.3% of the patients with an average serum level 3.3±1.0 mmol/L. No significant association was found between the presence and severity of lactate levels and MELAS disease presentation and progression. 33.3% and 66.7% of the subjects harbored m.3243A>G and non-classic mutations, respectively. Patients with m.3243A>G mutation had a higher % occurrence of diabetes, hearing loss, cognitive dysfunction, migraine, seizures and stroke-like episodes and a lower % occurrence of skeletal myopathy than the patients with non-classic mutations, 50 *vs* 6.3; 100 *vs* 25; 87.5 *vs* 31.3; 75 *vs* 31.3; 100 *vs* 56.3; 75 *vs* 12.5; 12.5 *vs* 68.8, respectively (all P<0.05). Despite more aggressive treatment with antiepileptic, L-arginine and CoQ/Q10, cardiac functional and cognitive deterioration were more rapid and severe in patients with m.3243A>G mutation (all P<0.05). More diagnostic tests (CSF lactate, muscle biopsy and MRS) were performed for patients with non-classic mutations (P<0.05).

Conclusions: In this cohort of MELAS patients, the m.3243A>G mutation, not the presence or severity of lactic acidosis, was associated with a more severe MELAS phenotype.

FR-PO273

Effects of Treatment of Metabolic Acidosis in CKD: A Systematic Review and Meta-Analysis

Sankar D. Navaneethan,[1] Jerry M. Buysse,[3] Jun Shao,[2] Dawn Parsell,[4] David A. Bushinsky.[5] *[1]Baylor College of Medicine, Sugar Land, TX; [2]Tricida, Inc., South San Francisco, CA; [3]Tricida, Inc, South San Francisco, CA; [4]Parsell and Otto Consulting, Inc., Cedar Park, TX; [5]University of Rochester Medical Center, Rochester, NY.*

Background: Metabolic acidosis is an important risk factor for disease progression in chronic kidney disease (CKD) that also has significant adverse effects on muscle and bone. We conducted a systematic review and meta-analysis to evaluate the benefits and risks of treatment of metabolic acidosis with oral alkali supplements or reduction of acid load with dietary intervention.

Methods: We searched MEDLINE, Embase, and Cochrane Central Register of Controlled Trials for clinical trials (with a control group) of oral alkali supplementation or low acid-producing dietary intervention in stage 3-5 CKD patients for a minimum of 4 weeks. Data were pooled in a meta-analysis with results expressed as weighted mean difference (intervention versus control; WMD) for continuous outcomes and relative risk (RR) for categorical outcomes with 95% confidence intervals (CI) using a random effects model.

Results: Fourteen clinical trials were included (n=1810 participants). Both oral alkali supplementation and dietary intervention increased serum bicarbonate levels (Table). Treatment resulted in a slower decline in eGFR and a reduction in urinary albumin excretion, along with a reduction in the risk of progression to ESRD (4 trials; n=434; RR 0.32, 95% CI 0.18, 0.56). Important exclusions noted in the oral alkali studies were CKD patients with sodium-sensitive comorbidities (edema, heart failure, uncontrolled hypertension). Oral alkali supplementation was associated with significantly increased urinary sodium excretion, and trends of elevated diastolic blood pressure and increased antihypertensive therapy, although these trends were not statistically significant. Dietary intervention was associated with a significant reduction in systolic blood pressure. Included studies were of moderate quality.

Conclusions: In patients with CKD and metabolic acidosis, an increase in serum bicarbonate concentration induced either by oral alkali supplementation or reduction in dietary acid intake slows the rate of kidney function decline and reduces urinary albumin excretion.

Serum Chloride and All-Cause Mortality in CKD

Sankar D. Navaneethan,[1] Wolfgang C. Winkelmayer,[1] Susana Arrigain,[2] Joseph V. Nally.[2] *[1]Baylor College of Medicine, Sugar Land, TX; [2]Cleveland Clinic, Cleveland, OH.*

Background: We studied the associations of serum chloride with all-cause mortality in non-dialysis dependent CKD.

Methods: We included 62,643 patients with eGFR 15-59 ml/min/1.73 m^2 (twice 90 days apart) and had serum chloride measured using the same assay in a single health care system in this analysis. Cox proportional hazards model (including time-dependent) were used to study the associations between hypochloremia (<98 mmol/l, n=5246) and hyperchloremia (>110 mmol/l, n=702) with all-cause mortality while adjusting for demographics, comorbid conditions including heart failure, use of diuretics and kidney function.

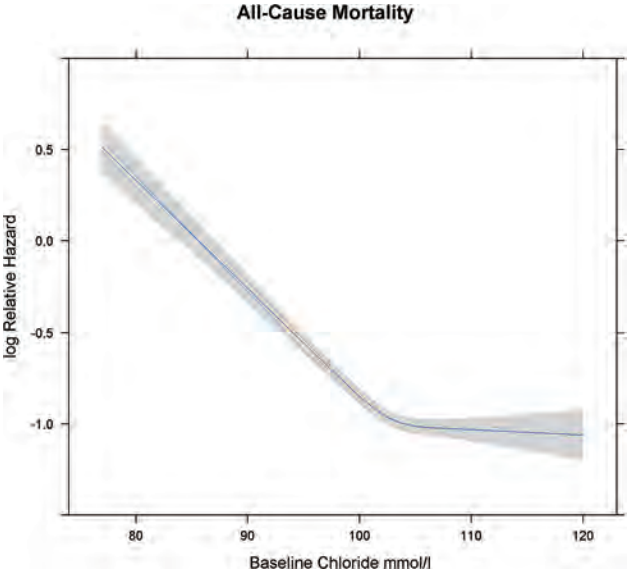
Results: During a median follow-up of 3.8 years, 18,181 patients died. In the Cox proportional hazards model using baseline serum chloride levels, hypochloremia (but not hyperchloremia) was associated with higher risk of death. Analysis of chloride as continuous measure yielded similar results. Restricting the analysis to those with normal serum sodium (n=59,964) yielded similar results. In the model with time dependent repeated measures of serum chloride, both hypochloremia (HR 2.54, 95% CI 1.44, 2.65) and hyperchloremia (HR 1.39, 95% 1.24, 1.55) were associated with higher risk of death. Presence or absence of CHF didn't modify the observed associations.

Conclusions: Among non-dialysis dependent CKD population, hypochloremia is associated with higher risk of death. Further studies examining the potential mechanisms for the observed associations are warranted.

Table 1. Associations of serum chloride with all-cause mortality in CKD

	HR (95% CI)*	HR (95% CI)**	HR (95% CI)* Among those with normal baseline sodium only
Low chloride vs. normal	1.64 (1.56, 1.72)	1.51 (1.42, 1.60)	1.65 (1.56, 1.75)
High chloride vs. normal	1.01 (0.89, 1.13)	0.99 (0.87, 1.12)	0.94 (0.83, 1.08)

*Adjusted for age, sex, race, ckd stage, BMI group, albumin, bicarbonate, diabetes, hypertension, malignancy, heart failure and diuretics
**Adjusted for above plus sodium level



FR-PO275

Chloride Increase Following Continuous Renal Replacement Therapy (CRRT) Initiation Is Associated with Mortality

Benjamin Griffin,[1] Nigel Arruda,[1] Isaac Teitelbaum,[2] Anna J. Jovanovich,[3] Muhammad Aftab,[4] Matthew Barhight,[5] Katja M. Gist,[6] Sarah Faubel.[7] *[1]University of Colorado, Aurora, CO; [2]University of Colorado Health Science Center, Aurora, CO; [3]Denver VA / University of Colorado, Denver, CO; [4]University of Colorado, Anschutz Medical Center, Aurora, CO; [5]Childrens Hospital Colorado, Aurora, CO; [6]University of Colorado, Children's Hospital Colorado, Aurora, CO; [7]University of Colorado Denver, Denver, CO.*

Background: Hyperchloremia is common in critically ill patients, and recent studies are increasingly linking elevated serum chloride with mortality. CRRT can rapidly shift chloride levels, and it is unclear what impact these changes have on patient outcomes. In this study we examined the association between changes in chloride following CRRT initiation and mortality.

Methods: We conducted a retrospective analysis of adult patients initiated on CRRT at the University of Colorado Hospital between July 2015 and September 2016. The main exclusion criterion was death within 24 hours of CRRT initiation. Chloride levels were measured upon admission to the ICU, prior to CRRT initiation, and every 8 hours thereafter until CRRT was discontinued. Changes in chloride were calculated from admission value to CRRT initiation. Changes after CRRT initiation were calculated from the first value following CRRT initiation to the highest value while on treatment. The primary outcome was in-hospital mortality. Logistic regression was used to adjust for SOFA score, body mass index, and gender.

Results: A total of 127 cases were included in the analysis. Average chloride on admission was 102 ± 6.7 mEq/L and 106 ± 8.3 mEq/L at CRRT initiation. After adjusting for all covariables, chloride on admission, though not at CRRT initiation, predicted mortality: for every 1 mEq/L increase in admission chloride there was an 8% increased risk of mortality. Mean changes in chloride from admission to CRRT initiation and from CRRT initiation to end of therapy were 3.6 ± 7.4 mEq/L and 2.8 ± 3.5 mEq/L respectively. Change in chloride from admission to CRRT initiation was not significantly associated with in-hospital mortality. Notably, change in chloride of 1 mEq/L following CRRT initiation was associated with a 15% increased risk of mortality.

Conclusions: Hyperchloremia upon ICU admission is associated with increased mortality. Increases in chloride levels following CRRT initiation are also associated with mortality, even after adjusting for illness severity. The role of chloride in critical illness, particularly in those requiring CRRT, warrants further investigation.

FR-PO276

Phosphorous and Magnesium Nadirs Following Continuous Renal Replacement Therapy (CRRT) Initiation Are Associated with Mortality

Benjamin Griffin,[1] Nigel Arruda,[1] Sophia L. Ambruso,[1] Joao P. Teixeira,[1] Anna J. Jovanovich,[2] Sarah Faubel.[3] *[1]University of Colorado, Aurora, CO; [2]Denver VA / University of Colorado, Denver, CO; [3]University of Colorado Denver, Denver, CO.*

Background: Severe acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT) is common in the intensive care unit, complicating 5% of all admissions. As CRRT therapy fluids typically contain no phosphorus and low magnesium concentrations, CRRT is known to rapidly deplete these electrolytes, and their repletion during CRRT is often required. Studies examining the impact of these electrolyte losses on patient mortality have been inconclusive. The purpose of this study was to examine the impact of phosphorous and magnesium levels on mortality in the setting of CRRT.

Methods: We conducted a retrospective analysis of adult patients initiated on CRRT at the University of Colorado Hospital between July 2015 and September 2016. Patients were excluded if they died within 24 hours of CRRT initiation. Phosphorous and magnesium levels were collected at CRRT initiation and every 8 hours thereafter. The primary outcome was in-hospital mortality. Logistic regression was used to adjust for SOFA score, body mass index, and gender.

Results: A total of 155 cases were included in the analysis. Mean phosphorous and magnesium levels at the time of CRRT initiation were 5.4 ± 2.7 mg/dL and 2.28 ± 0.58 mg/dL, respectively. Neither baseline levels nor changes from baseline were associated with mortality. However, higher nadir levels of both phosphorous and magnesium were independently associated with mortality, even after adjusting for confounders.

Conclusions: While baseline phosphorous and magnesium values were not associated with mortality, nadir levels were. We expected lower nadir levels to be associated with mortality, but observed the opposite. Lower nadir levels may have been indicative of higher dose or higher quality of CRRT. The frequency and quantity of electrolyte repletion were not evaluated in this study. Further investigation into the role of phosphorous and magnesium in AKI requiring CRRT is warranted.

Comparison of Indicators of Fluid Overload in Hemodialysis Patients

Erik Yarmey, Proma Mazumder, Jordan Brown, Frances Shofer, Anthony J. Dean, Nova Panebianco, Nathaniel C. Reisinger. *University of Pennsylvania, Philadelphia, PA.*

Background: Fluid overload (FO) contibutes to mortality in hemodialysis (HD) patients and is often undiagnosed. FO is determined by physical exam including systolic and diastolic blood pressure (SBP, DBP), lung crackles (rales), lower extremity edema (LEE), and jugular venous distention (JVD). Other signs of FO include serum n-terminal pro-BNP (BNP) and findings on chest x-ray (CXR) or thoracic computed tomography (CT). Point-of-care ultrasound is a as powerful tool for determination of FO via measurements of the inferior vena cava (IVC) and quantitative 28-point lung ultrasonography for B-line score (BLS). We present a cohort study of HD patients comparing indicators of FO.

Methods: Patients with ESRD on HD were enrolled from a large urban emergency department at a referral center. Patients were excluded if they were unable to consent. Indicators of FO were obtained prior to first HD including BLS (0-280). IVC size and collapse was graded by 2 independent observers on a 4-point scale. 10 indicators of FO (BLS, IVC, CXR, CT, BNP, rales, LEE, JVD, SBP, DBP) were compared against presence or absence of FO as determined by the treating nephrologist or on chart review.

Results: Of 101 patients enrolled, median age was 60, 51% were male, 84% identified as Black or African American. Comorbidities included 65% diabetic, 27% coronary artery disease, 33% airways disease, 40% had systolic heart failure, 75% diastolic heart failure. Median dialysis vintage was 33 months. Access type was 54% arteriovenous fistula, 29% graft, and 17% catheter. ESRD vintage was 33 months. Residual renal function was minimal. 62% of patients had FO on arrival and 27% of visits were for FO. BLS was available for 101 patients with median score of 34. Area under the receiver-operator characteristic curve (AUC) was 0.95 for BLS [95% CI 0.92-0.99] with optimal cutoff of 30. AUC was 0.60 for edema [0.53-0.68], 0.60 for rales [0.54-0.66], 0.53 for JVD [0.50-0.56], 0.53 for SBP [0.41-0.65], 0.49 for DBP [0.38-0.61]. IVC was obtained on 37 patients AUC 0.78 [0.61-0.95]. BNP was obtained on 39 patients AUC 0.80 [0.63-0.98]. CXR was obtained on 76 patients AUC 0.71 [0.61-0.80]. CT was available on 20 patients AUC 0.91 [0.81-1.00].

Conclusions: Quantitative BLS outperforms conventional physical exam, serologic, and other imaging indicators in determination of FO in HD patients.

FR-PO278

Fluid Overload Is Associated with Major Adverse Kidney Events in Critically Ill Patients with AKI Requiring CRRT

Connor W. Woodward,[1] Ye Li,[2] Joshua Lambert,[2] Marice Ruiz-Conejo,[3,1] Andrew Kelly,[2] Brittany D. Bissell,[1] Victor M. Ortiz-Soriano,[1] Lenar T. Yessayan,[4] Peter Morris,[1] Javier A. Neyra.[1] *[1]University of Kentucky, Lexington, KY; [2]University of Kentucky, Lexington, KY; [3]Palmetto General Hospital, Pembroke Pines, FL; [4]University of Michigan, Ann Arbor, MI.*

Background: Fluid overload (FO) has been associated with adverse outcome. The purpose of this study was to examine the association between FO and major adverse kidney events (MAKE) in critically ill patients with AKI requiring CRRT.

Methods: This was a single-center, retrospective, cohort study of ICU patients that suffered from AKI requiring CRRT. Patients with ESRD, kidney transplant or baseline eGFR <15 were excluded. FO was defined as cumulative fluid balance (from hospital admission to CRRT initiation) expressed as a percent of admission body weight. MAKE was determined up to 90 days following hospital discharge and consisted of the composite of mortality, RRT dependence and failure to recover at least 50% of baseline eGFR if not on RRT. A secondary outcome of ventilator-free days was also examined. Multivariable logistic regression and linear regression models were conducted.

Results: A total of 481 patients were included in the study. The median (IQR) FO was 9.9% (2.8 – 20.2%). FO ≥10% (clinical cut-off reportedly associated with adverse outcome) was found in 238 (49.5%) of patients on the day of CRRT initiation. MAKE was more frequent in patients with FO ≥10% vs <10% (79.4% vs 71.6%, p=0.047). After adjustment for demographics, comorbidity, acuity of illness, time from ICU admission to CRRT initiation, and baseline eGFR, FO ≥10% was independently associated with MAKE (OR, 1.60, 95% CI, 1.02 – 2.52). Furthermore, for each one-day increment from ICU admission to CRRT initiation, there was a 3% increase in the adjusted odds of MAKE (p=0.02). FO ≥10% was also associated with less ventilator-free days in adjusted models (p<0.01).

Conclusions: FO ≥10% on the day of CRRT initiation was independently associated with major adverse kidney events and less ventilator-free days in critically ill patients that suffered from AKI requiring CRRT. FO should be a clinical parameter routinely included in the evaluation of CRRT need in critically ill patients.

Fluid Overload Predicts Mortality in Critically Ill Patients Undergoing Continuous Renal Replacement Therapy

Nigel Arruda,[1] Benjamin Griffin,[1] Matthew Barhight,[2] Katja M. Gist,[3] Anna J. Jovanovich,[4] Muhammad Aftab,[6] Sarah Faubel.[5] *[1]University of Colorado, Aurora, CO; [2]Childrens Hospital Colorado, Aurora, CO; [3]University of Colorado, Children's Hospital Colorado, Aurora, CO; [4]Denver VA / University of Colorado, Denver, CO; [5]University of Colorado Denver, Denver, CO; [6]University of Colorado, Anschutz Medical Center, Aurora, CO.*

Background: Acute kidney injury (AKI) requiring renal replacement therapy (RRT) is common in the intensive care unit (ICU) and has a mortality rate of >50%. Fluid overload (FO) >10% of body weight has been shown to be deleterious in ICU patients, but studies specifically evaluating patients with severe AKI requiring continuous renal replacement therapy (CRRT) remain limited. Furthermore, the effects of volume removal following CRRT initiation are not well described. The purpose of this study was to examine the impact of (1) FO at CRRT initiation and (2) fluid removal on in-hospital mortality.

Methods: We conducted a retrospective analysis of adult ICU patients who underwent CRRT for a minimum of 24 hours at University of Colorado Hospital from September 2015 to July 2016. Patients were characterized by fluid balance at initiation of CRRT and total volume removed by CRRT during their hospitalization. The primary outcome was in-hospital mortality. Logistic regression was used to adjust for Sequential Organ Failure Assessment (SOFA) score, gender, and body mass index.

Results: A total of 87 patients were included in the final analysis, of which 41 (47.1%) patients had FO >10% of body weight at the time of CRRT initiation. Negative fluid balance on CRRT was achieved in 64 (73.5%) patients. The adjusted odds ratio for mortality in those with >10% FO was 2.69 (Table 1). There was no association between mortality and negative fluid balance on CRRT.

Conclusions: Our study adds to prior studies showing that fluid overload is independently associated with increased mortality in ICU patients requiring CRRT. However, we found no significant association between fluid balance during CRRT and mortality. The effect of fluid balance on mortality in ICU patients requiring RRT, both before and after RRT initiation, merits further investigation.

Funding: Other NIH Support - T32 DK 007135

Liver Stiffness Reflecting Renal Congestion Predicts Renal Outcome in Patients with Congestive Heart Failure

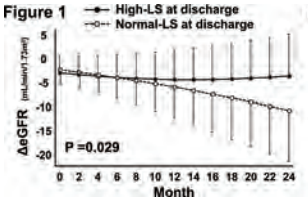
Tatsufumi Oka,[1] Takayuki Hamano,[2] Satoshi Yamaguchi,[1] Yohei Doi,[1] Yusuke Sakaguchi,[2] Isao Matsui,[1] Yoshitaka Isaka.[1] *[1]Nephrology, Osaka University Graduate School of Medicine, Suita, Japan; [2]Inter-Organ Communication Research in Kidney Disease, Osaka University Graduate School of Medicine, Suita, Japan.*

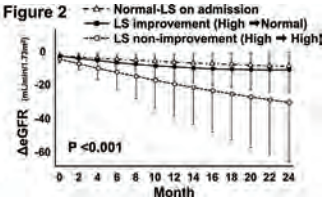
Background: Renal congestion is one of the underlying mechanisms for acute kidney injury in congestive heart failure (CHF). Reportedly, ultrasonographic liver stiffness (LS), originally developed for assessment of liver cirrhosis, reflects right atrial pressure (RAP) with great accuracy in CHF without liver cirrhosis. However, its association with renal congestion and its clinical relevance remain uncertain.

Methods: In this prospective cohort study (*JACC Cardiovasc Imaging* 2018), we enrolled inhospital patients with acute heart failure in an educational hospital. LS was evaluated in all participants. Using longitudinal inhospital data, we investigated the association between time-dependent LS and kidney length. High-LS was defined as ≥9 kPa (75 percentile, corresponding to RAP of ≥8.9 mmHg). Exposures were LS levels at discharge and changes in its levels during hospitalization. An outcome was eGFR change over time after discharge. We employed a multivariable mixed effects model with time-dependent eGFR as a dependent variable. In sensitivity analyses, we used coarsened exact matching to balance the baseline clinical characteristics.

Results: Among the 251 patients, median eGFR, BNP, LS at discharge, and follow-up were 54.7 mL/min/1.73m^2, 188.7 pg/mL, 6.3 kPa, and 12.0 months, respectively. During hospitalization, in patients with eGFR>30 mL/min/1.73m^2, LS decrease was observed in parallel with decrease in kidney length (P=0.01), suggesting a rationale to use LS as a proxy of renal congestion. After adjustment for 16 factors including BNP, ejection fraction, and blood pressure, patients with high-LS at discharge had lower eGFR over time than the rest of the patients (P=0.03) (Figure 1). In patients with LS improvement from high- to normal-LS during hospitalization, eGFR trajectory was higher than that in patients without improvement (P<0.01) and comparable to that in patients with normal-LS on admission (P=0.81) (Figure 2).

Conclusions: LS reflecting renal congestion predicts worse renal outcome in CHF. Renal function should be followed up carefully in patients with a high LS value at discharge.





FR-PO281

Simplified, Simulated Sodium Kinetic Modeling for Correction of Hyponatremia by Continuous Venovenous Hemofiltration

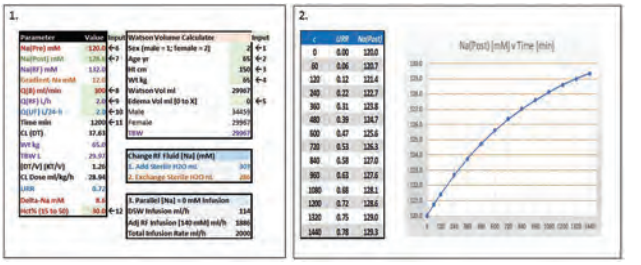
Junior Uduman, Naushaba Mohiuddin, Gerard Zasuwa, Jerry Yee, Stanley Frinak. *Division of Nephrology and Hypertension, Henry Ford Hospital, Detroit, MI.*

Background: Management of hyponatremic, oliguric patients is challenging using conventional dialytic therapy. Osmotherapy, targeted plasma sodium concentration [Na] elevation, delivered by continuous renal replacement therapy (CRRT), must be safely achieved without overcorrection of [Na], i.e., >6 to 8 mmol/L in 24 hours. Predictive modeling of controlled osmotherapy requires an appreciation of CRRT and ongoing Na kinetics. Utilizing an approach based on near-equivalence of Na dialysance and urea reduction ratio (URR), we developed a model that calculates [Na] elevations precisely using predilution continuous venovenous hemofiltration (CVVH), and contrasts the conventional strategy of using replacement fluid [Na] as the post-treatment goal [Na].

Methods: The model defines the post-treatment [Na] (Na_{Post}) at time (t), thereby defining ΔNa, the difference between pre-therapy [Na] (Na_{Pre}) and Na_{Post}. A [Na] gradient (,Na = Na_{RF} – Na_{Pre}) is defined by URR, derived from Na dialysance (D). Because D approximates K_{Urea}, URR is derived from Watson volume, treatment time, and D, determined by Q_B (hematocrit-adjusted blood flow rate), Q_{RF} (RF rate), and Q_{UF} (ultrafiltration rate). URR represents the time-varying decrease of ,Na, i.e., Na_{post} = [(1 – URR) × Na_{Pre} + (URR × Na_{RF})] and Na_{RF} = Na_{Pre} + (ΔNa/URR).

Results: The model calculates, tabulates, and plots time-varying Na_{Post}. Panel 1 of figure displays model input and output parameters for a hypothetical scenario of an anuric hyponatremic patient with tabulated data and graph in panel 2. Model extensions permit simultaneous initial targeting of Na_{Post}, URR, or effluent dose. Integrated calculations determine RF dilutions or infusion rates of parallel hypotonic solutions when RF solutions cannot be adjusted.

Conclusions: We conclude that safely controlled osmotherapy of oligoanuric, hyponatremic patients by predilution CVVH is feasible, and can determine time-varying Na_{Post}. Validation of the model in various clinical scenarios of hyponatremia is required to support utility.



FR-PO282

Continues Renal Replacement Therapy: A Simple Approach for Treating Hyponatremia

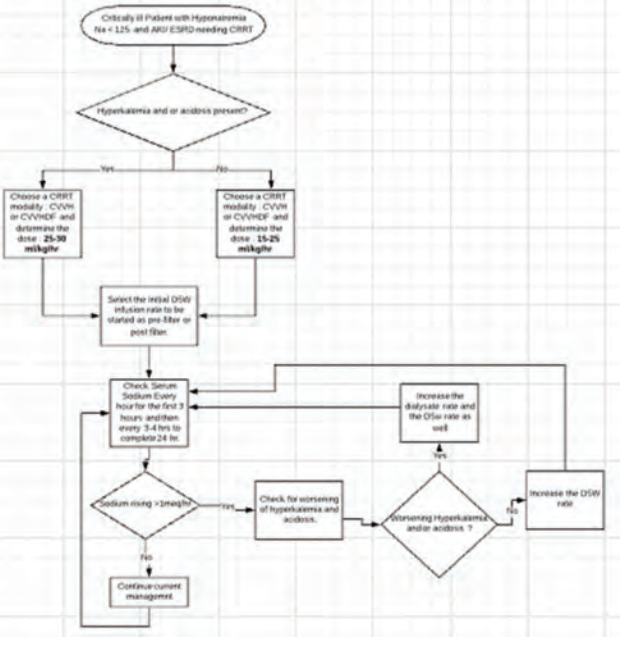
Pooja D. Amarapurkar,[1] Jiny Olickal,[2] Daniel J. Watford,[1] Daniel J. Soberon,[3] Vasuki N. Venkat,[3] Marco A. LadinoAvellaneda.[4] *[1]Jackson Memorial Hospital/ University of Miami, Miami, FL; [2]Jackson Memorial Hospital, Miami Beach, FL; [3]Nephrology, Miami VA medical Center, Miami, FL; [4]Miami VA Medical Center/University of Miami/ Jackson Memorial Hospital, Plantation, FL.*

Background: Severe hyponatremia (serum sodium(Na) <125) is frequently seen in critically ill patients. Often, this is unresponsive to fluid restriction, diuretics or 3% saline. The combination of hyponatremia and acute kidney injury (AKI) needing continuous renal replacement therapy (CRRT) makes management of hyponatremia challenging. Indication for CRRT include acidosis, volume overload & electrolyte abnormalities. Dialysate/replacement fluid solutions used during CRRT have a standard Na concentration of 140 meq/L. When dosed at 25-30 ml/kg/hr there is a risk of rapid correction of Na level & osmotic demyelination syndrome. There is limited data for CRRT in correcting hyponatremia. Few complex formulas help to calculate the appropriate CRRT dose for Na correction, providing adequate clearance. We report our experience of managing 33 cases with severe hyponatremia using CRRT.

Methods: Out of 33 patients with severe hyponatremia, 28 had AKI stage III needing CRRT & 5 had ESRD. 30 patients required vasopressor support. CRRT was initiated in all for correction of Na at 15-25 ml/kg/hr. Pre-pump infusion of D5W was added to dilute the replacement fluid. All the patients had the serum Na level checked every hour for the first 3 hours and then every 3-4 hours once a Na 125 mmol/l was reached.

Results: A steady 6-8 mmol/day rise in serum Na level was obtained along with the correction of other abnormalities & no complications.

Conclusions: This case series highlights the applicability of a simplified practical approach without using complex formulas to safely manage severe hyponatremia using CRRT despite a standard Na concentration in the dialysate/replacement solution. Close serum Na monitoring is imperative to adjust the delivered CRRT and D5W infusion doses.



FR-PO283

Sodium Fluctuations and Mortality in a General Hospitalized Population

Gianmarco Lombardi, Pietro Manuel Ferraro, Luca Calvaruso, Silvia D'Alonzo, Alessandro Naticchia, Giovanni Gambaro. *Fondazione Policlinico Universitario A. Gemelli, Rome, Italy*.

Background: Aim of our study was to describe the association between natremia (Na) fluctuation and hospital mortality in a general population admitted to a tertiary medical center.

Methods: We performed a retrospective observational study on the patient population admitted to the Policlinico A. Gemelli Hospital between January 2010 and December 2014 with inclusion of adult patients with at least two Na values available on the biochemistry database and with a normonatremic condition at hospital admission. Patients were categorized according to all Na values recorded during hospital stay in the following groups: hyponatremia, normonatremia, hypernatremia, mixed dysnatremia. The difference between the highest or lowest Na value reached during hospital stay and the Na value read at hospital admission was used to identify the maximum Na fluctuation. Cox proportional hazards models was used to estimate adjusted HRs for hospital mortality with the group of dysnatremia and with quartiles of Na fluctuation. Covariates assessed were age, sex, highest and lowest Na level, Charlson-Deyo index score, cardiovascular diseases, cerebrovascular diseases, dementia, congestive heart failure, kidney disease, eGFR.

Results: 57,156 admissions matched inclusion criteria. Incident dysnatremia was independently associated with in-hospital mortality (incident hyponatremia HR 2.55, 95% CI 2.14, 3.04, p<0.001; incident hypernatremia: HR 5.71, 95% CI 4.69, 6.95, p<0.001; mix-dysnatremia: HR 4.44, 95% CI 3.23, 6.10, p<0.001). We found a higher risk of in-hospital death by linear increase of quartile of Na fluctuation (p trend <0.001) irrespective of severity of dysnatremia (HR of 1.60, CI 95% 1.17, 2.20, p=0.004, in the 4th percentile Na fluctuation compared with the first one; Figure).

Conclusions: Fluctuation of natremia during hospital stay is a prognostic marker for hospital death independently by dysnatremia severity.

Association between quartile of sodium fluctuation (expressed as percentage) and in-hospital mortality

	1st quartile (<1.40%)	2nd quartile (1.40% - 2.13%)	3rd quartile (2.14% - 3.52%)	4th quartile (>3.52%)	p-value trend
N	14,598	14,272	14,505	13,781	
In-hospital death (N, %)	61 (0.4)	63 (0.4)	132 (0.9)	478 (3.5)	
HR crude (CI 95%)	1.00 (Reference)	0.83 (0.59, 1.18)	1.34 (0.99, 1.81)	3.22 (2.47, 4.19) P<0.001	P<0.001
HR adjusted for Na*	1.00 (Reference)	0.75 (0.51, 1.04)	1.10 (0.80, 1.50)	1.86 (1.36, 2.53) P<0.001	P<0.001
HR adjusted (CI 95%)^	1.00 (Reference)	0.67 (0.47, 0.96)	1.01 (0.74, 1.38)	1.60 (1.17, 2.20) P=0.004	P<0.001

*Adjusted for the lowest and the highest serum Na level reached during hospital stay.
^Adjusted for baseline covariates (age, sex, Charlson-Deyo Score, diabetes, cardiovascular diseases, congestive heart failure, neoplasms, eGFR, kidney disease, cerebrovascular disease, dementia, the lowest serum Na level reached in-hospital and the highest serum Na level reached during hospital stay).

FR-PO284

Maintaining Sodium Homeostasis During Liver Transplant - A Novel Approach

Courtney Jones, Charuhas V. Thakar, Taranpreet Kaur. *University of Cincinnati, Cincinnati, OH*.

Introduction: Following two cases of osmotic demyelination syndrome (ODS) in patients with near-normal serum sodium (Na) levels (134 mEq/L) at the start of orthotopic liver transplantation (OLT) at our institution, we sought a systems approach for minimizing ODS. Many patients presenting for OLT with hyponatremia have concomitant renal dysfunction necessitating intraoperative continuous renal replacement therapy (CRRT). Intraoperative CRRT using standard dialysate with a Na concentration of 140mEq/L could pose a risk due to rapid Na rise. A multi-disciplinary approach was taken with anesthesiology, nephrology, transplant surgery, and pharmacy to create a pathway for low Na dialysate with a Na concentration of 130mEq/L for OLT patients with hyponatremia that also need intraoperative RRT. Commercially available low Na dialysate does not contain calcium (Ca), which requires frequent replacement at baseline during an OLT. Pharmacy presented the data along with a failure modes and effects analysis (FMEA) to the hospital's drug policy committee and gained approval for compounding calcium into our commercially available low Na dialysate.

Case Description: Following implementation of our system change, a patient presented for OLT with a MELD-Na of 30, hepatorenal syndrome, acidosis, hyperkalemia, and hyponatremia (Na 124). This patient was admitted to the ICU preoperatively and initiated on CRRT with low Na dialysate compounded with Ca while waiting for the liver to arrive. Intraoperative fluid administration, transfusion, electrolytes, and acid-base status were managed in standard fashion plus the addition of low Na dialysate. At the end of the OLT, the Na had only risen to 126 over 14 hours. The low Na dialysate continued three additional days postoperatively in the ICU to allow the Na to gradually normalize. Four days after presentation, the Na was 135 and the patient was transitioned to standard dialysate and never developed ODS. He is currently off dialysis with an eGFR of 33.

Discussion: ODS occurs in approximately one percent of OLT patients with associated high morbidity and mortality. The rate of Na rise is strongly correlated with the development of neurologic changes and standard dialysate can contribute to that. A multi-disciplinary system based approach achieved patient safety and allowed a platform for broader implementation to hyponatremic patients without renal dysfunction.

FR-PO285

Hyponatremia Associated with Development of Sepsis

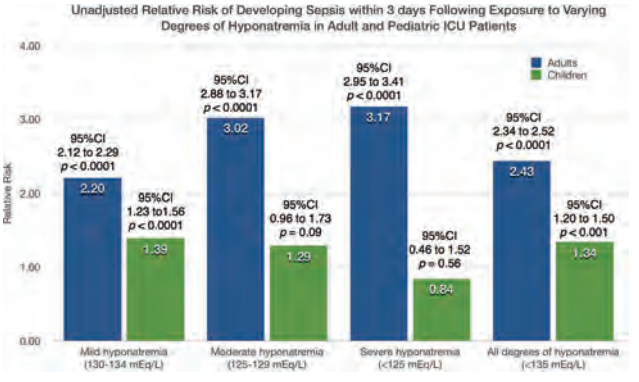
Win Kulvichit,[1,4] Cassandra L. Formeck,[1,2] Priyanka Priyanka,[1] Emily L. Joyce,[1,2] Shashank Badavanahalli Rajashekar,[1] Michael L. Moritz,[2] Juan Carlos Ayus,[3] John A. Kellum.[1] *[1]Center for Critical Care Nephrology, CRISMA, Department of Critical Care, University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Department of Nephrology, Children's Hospital of Pittsburgh, Pittsburgh, PA; [3]Renal Consultants of Houston, Houston, TX; [4]Division of Nephrology, Department of Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand*.

Background: Hyponatremia is a common electrolyte imbalance in critically ill patients and is associated with increased mortality and morbidity. Experimental evidence suggest that hyponatremia may compromise immune cell function. Thus, we sought to determine whether an association between hyponatremia and sepsis was present in critically ill adults and children.

Methods: Data was obtained from databases of 46,329 adult and 12,806 pediatric patients from the ICUs of UPMC hospitals. We included patients with a Na value measured within 6 hours of ICU admission and excluded patients with sepsis on admission. We analyzed the association between hyponatremia by severity (serum Na <135 mEq/L, mild; 130-134 mEq/L, moderate; 125-129 mEq/L, severe <125 mEq/L) and the development of sepsis over 7 days following the occurrence of hyponatremia.

Results: A total number of 39,403 adults and 3,977 children were included in the analysis. 40% of adult patients and 14% of pediatric patients had hyponatremia with rates of sepsis of 24% and 33% respectively. Critically ill patients with hyponatremia were at increased risk of developing sepsis (RR 2.43 for adult, RR 1.34 for pediatric patients). Risk for developing sepsis increased with the severity of hyponatremia in adults.

Conclusions: Critically ill patients with hyponatremia are at increased risk for developing sepsis. Further analysis is required to understand the nature of this relationship and to better control for confounding.



Unadjusted Relative Risk of Developing Sepsis within 3 days Following Exposure to Varying Degrees of Hyponatremia in Adult and Pediatric ICU Patients

FR-PO286

Communication of Hyponatremia and Outcomes

Kirsten Salline,[2] Jeffrey I. Silberzweig,[1,2] Vesh Srivatana,[1,2] Clara Oromendia,[3] Stephanie Tsai.[3] *[1]The Rogosin Institute, New York, NY; [2]Weill Cornell Medical College, New York, NY; [3]Weill Cornell Medicine, New York, NY*.

Background: Prior literature documents the prognostic importance of hyponatremia but it is commonly treated as a peripheral issue during hospital admissions. We seek to quantify the degree to which hyponatremia is reported to outpatient providers and to evaluate factors associated with communication and associations between communication and important clinical outcomes.

Methods: With IRB approval, we conducted a retrospective cohort study of patients admitted to the Weill Cornell Campus of the New York-Presbyterian Hospital in January 2014 with corrected serum sodium <130 mEq/L who survived the index hospitalization. Discharge summaries were reviewed for mention of hyponatremia; charts were reviewed for pertinent clinical data. Patients who did and did not have hyponatremia mentioned in the discharge summary were compared using chi-square (or Fisher's Exact) and Kruskal-Wallis tests for categorical and continuous variables, respectively. Statistical significance was determined be at the 0.05 alpha level.

Results: Hyponatremia was mentioned in 34% of 127 discharge summaries; patients with communicated hyponatremia were older (mean 72 vs 63 years; p=0.003) and had lower nadir (125 vs 128 mEq/L; p<0.001) and discharge sodium (132 vs 135 mEq/L, p=0.002). Communication was associated with diagnosis of hyponatremia within 24 hours of admission (p=0.006) and admission to general medicine (47% communicated) versus other hospital service (27%) (p=0.02). The cause of hyponatremia was more often SIADH (p<0.001) or hypovolemia (p=0.005) in the communication group. Communication of hyponatremia was not associated with improved one-year mortality, readmission or

readmission with hyponatremia. Patients with communicated hyponatremia were less likely to follow up with outpatient providers in our system (60% vs. 81%, p=0.03); of those who followed up in our system, hyponatremia was mentioned in an outpatient provider's note only twice.

Conclusions: Our results suggest that hyponatremia is infrequently communicated to outpatient providers. Higher rates of communication were associated with severity and timing of hyponatremia and hospital service. The lower rate of follow up in patients with communicated hyponatremia and outpatient providers' response may explain the lack of difference in clinically important outcomes. Alternatively, communication may be less for patients planning to follow up internally.

FR-PO287

Hyponatremia and Mortality Among Very Elderly Residents in a Geriatric Health Service Facility

Tamayo Naka,[2] Kentaro Kohagura,[1] Masako Kochi,[3] Yusuke Ohya.[3] *[1]Dialysis Unit, University of the Ryukyus Hospital, Nishihara-cho, Japan; [2]Nishizaki Hospital, Itoman city, Japan; [3]University of the Ryukyus, Nishihara-cho, Japan.*

Background: Hyponatremia is common among elderly patients. This study aimed to examine the prognostic value of hyponatremia among elderly residents in a geriatric facility.

Methods: We retrospectively examined the association between serum sodium levels and mortality among 118 residents (82% female, mean age 85.5 years) in a single geriatric health service facility. We defined hyponatremia as Na <135 mEq/L. On the basis of single measurements of serum sodium at periodic examinations, the patients were divided into hyponatremia and non-hyponatremia groups. Multivariable Cox proportional hazards models were used to evaluate the effect of hyponatremia on mortality from May 2005 to April 2007.

Results: Thirty-three patients (28%) had hyponatremia. Over a 1-year follow-up period, the cumulative survival rate was significantly lower in patients with hyponatremia than in those without hyponatremia. In a multivariate analysis, including traditional risk factors for death, hyponatremia was associated with an increased mortality risk (adjusted hazard ratio, 2.73; 95% confidence interval, 1.01–5.16; $p = 0.047$).

Conclusions: Hyponatremia is common and is a predictor of mortality in the near future among very elderly residents of a geriatric facility.

FR-PO288

Clinical Significance of Serum Sodium in Insomnia Patients

Eunjin Bae,[1] Tae won Lee,[2] Ha nee Jang,[1] Hyun Seop Cho,[2] Se-Ho Chang,[1] Dong Jun Park.[3] *[1]Gyeongsang national university hospital, Jinju, Republic of Korea; [2]Gyeongsang National University Hospital, Changwon-si, Gyeongsangnam-do, Republic of Korea; [3]Gyeongsang National University Changwon Hospital, Changwon, Republic of Korea.*

Background: Hyponatremia is thought to be associated with attention deficits, cognitive decline, gait disturbances, and fracture even if it is asymptomatic. However, there is no study of hyponatremia and its clinical effects in patients with insomnia. We investigated the prevalence of hyponatremia and the clinical relevance of serum sodium concentration in patients with insomnia.

Methods: We retrospectively enrolled patients with a diagnosis of insomnia from January, 2011 to December 2012. Among these, we excluded patients who were being treated with cancer or not cured, or had renal replacement treatment. Hyponatremia was defined as a serum sodium concentration of less than 135 mmol/L. We divided into 3 groups according to serum sodium: tertile 1 (<138 mmol/L), tertile 2 (138.0-140.9 mmol/L), and tertile 3 (≥141.0 mmol/L). Multivariable logistic regression was used to evaluate the association between serum sodium level and all-cause mortality, acute kidney injury (AKI).

Results: A total of 443 patients with insomnia were included, of which 14.9% (n=67) had hyponatremia. Patients with lower serum sodium concentration tended to have lower hemoglobin, calcium, phosphorus and albumin level and older age. During median follow up 48.5 months, 19.8% (n=33), 8.4% (n=12), 2.3% (n=3) patients died in tertile 1, 2, and 3. Twenty one percent (n=35), 11.9% (n=17), 11.3% (n=15) patients experience AKI in tertile 1, 2, and 3. Tertile 1 was significantly associated with all-cause mortality (reference tertile 2 group, Hazard ratio 1.96; 95% confidence interval 0.66 – 5.80; P=0.006) even after adjusted co-variates. However, there was no significant relationship between tertile 1 and AKI.

Conclusions: In patients with insomnia, lower serum sodium is significantly associated with all-cause mortality and thus we should have continuous interest in hyponatremia, and we need to identify the cause of hyponatremia and correct the correctable factors.

FR-PO289

No Added Salt…The Epidemiology of Severe Hyponatraemia in a Tertiary Referral Hospital

Susan Mcgrath,[1,3] Brona Moloney,[1,3] Dean S. Moore,[1,3] Yvonne M. O'Meara,[1,4] Aisling O'Riordan,[1] Peadar McGing,[2] Denise M. Sadlier.[1,4] *[1]Nephrology, Mater Misericordiae University Hospital, Dublin, Ireland; [2]Clinical Chemistry, Mater Misericordiae University Hospital, Dublin, Ireland; [3]RCPI, Dublin 8, Ireland; [4]University College Dublin, Dublin, Ireland.*

Background: Severe hyponatremia is defined as a serum sodium concentration less than or equal to 120mmol/L and can be associated with mild symptoms (e.g. decreased concentration) to more severe life-threatening symptoms (e.g. seizures and coma). Patients with severe symptomatic hyponatraemia should be managed with hypertonic saline to correct their serum sodium and reduce the morbidity and mortality associated with this condition. In this retrospective study, the aetiology, management and outcomes of severe hyponatraemia were examined over a 5-year period

Methods: All patients admitted to a tertiary referral hospital with serum sodium ≤120mmol/L were identified through the biochemistry laboratory database from January 2013 – December 2017 inclusive. Patient data was extracted from hospital records and included age, gender, presenting complaint, co-morbidities, medications, clinical exam findings, treatment received, laboratory results, length of stay, nephrology consult and in-hospital mortality.

Results: A total of 592 patients met the inclusion criteria, 46.7% (n=277) were male, 24.8% (n=147) were aged >80years. The commonest causes were hypovolaemia (30%, n=178), hypervolaemia (15%, n=89), Syndrome of Inappropriate ADH secretion (13.7%, n=81) and medication induced (15%, n=89), of which thiazides were the most common. The most common symptoms were falls (17.2%, n = 102), confusion (11.6%, n=69) and GI upset (9.7%, n=58). 7.2% (n=43) presented with seizures. Hypertonic saline was indicated in 26.2% (n=155) of cases, but of these only 19.4%(n=30) have it documented as part of their treatment, 5% of total cases. Of the patients who presented with seizure, only 16.3% (n=7) received hypertonic saline. Average length of stay for these patients was 25days. Mortality for an admission complicated by severe hyponatremia was 14% (n=84), with a one year mortality of 27.4% (n=162).

Conclusions: Severe hyponatraemia is associated with significant symptoms, length of stay and 1-year mortality. Hypertonic saline is indicated in the treatment of severe symptomatic hyponatraemia and is proven to be a safe therapy, but only a minority of patients received this important treatment. Further education is required in order to improve the management and outcomes in this patient group.

FR-PO290

Optimal Cut-Off Level of Urine Sodium in Differentiating Hypovolemic Hyponatremia and SIADH

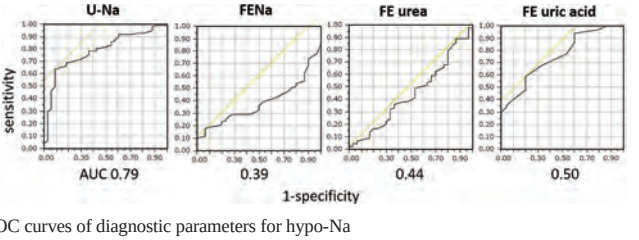
Raku Son,[1] Masahiko Nagahama,[1] Yasuhiro Komatsu,[2] Masaaki Nakayama.[1] *[1]St. Luke's international hospital, Tokyo, Japan; [2]Gunma University, Graduate School of Medicine, Maebashi, Gunma, Japan.*

Background: The European clinical guideline recommends using 30 mEq/L as the cut-off level of urine sodium (U-Na) to differentiate hypovolemic hyponatremia (hypo-Na) from others. However, due to the complexity of hyponatremia, we frequently encounter the patients whose U-Na are not completely suppressed and wonder the accuracy of this cut-off level. This study is to examine the diagnostic performance of U-Na and other parameters, and clarify optimal cut-off level of U-Na in patients with hyponatremia.

Methods: In this single-center, retrospective cohort study, we collected data of hospitalized patients with profound hypotonic hyponatremia evaluated by nephrology consultants, defined by serum Na (S-Na) ≦ 120 mEq/L and serum osmolality (Osm) ≦ 280 mOsm/kg H_2O from April 2011 to September 2017. The final diagnosis of hyponatremia was categorized into either hypo-Na or SIADH based on nephrologist evaluation through the hospital course. Patients with urine Osm ≦ 100 mOsm/kg H_2O or diagnosis of polydipsia, adrenal insufficiency and hypervolemia were excluded. The diagnostic accuracy of U-Na, fractional excretion of sodium (FENa), FE urea, and FE uric acid for hypo-Na were evaluated by receiver-operating characteristic (ROC) curves and the areas under the ROC curves (AUC).

Results: Of 130 patients (age 75.7 ± 13.1, 51% of males, minimal S-Na 115 ± 4.1 mEq/L), 97 patients (75%) were diagnosed as hypo-Na. In the ROC curves, U-Na showed the best diagnostic utility in differentiating hypo-Na and SIADH with AUC of 0.79 compared to FENa, FE urea and FE uric acid (AUC of 0.39, 0.44 and 0.50, respectively) (Figure). The optimal cut-off level of U-Na was 56 mEq/L with sensitivity of 64% and specificity of 90%, which was not significantly changed when assessed in patients with diuretics use (n=40) or not (n=90) with cut-off levels of 64 mEq/L and 56 mEq/L, respectively.

Conclusions: U-Na performed the best in differentiating hypo-Na and SIADH in hyponatremic patients with a cut-off level of 56 mEq/L, higher than that recommended in the current guidelines. The diagnostic accuracy was not influenced by diuretics use.



ROC curves of diagnostic parameters for hypo-Na

Safety and Efficacy of Tolvaptan in Lung Cancer with Hyponatremia Due to the Syndrome of Inappropriate Antidiuretics Hormone

Hyun Seop Cho,[1] Ji-Hye Kwak,[1] Ha nee Jang,[1] Tae won Lee,[2] Dong Jun Park,[2] Se-Ho Chang.[1] *[1]Internal medicine, Gyeongsang national university hospital, Jinju, Gyeongsangnam-do, Republic of Korea; [2]Internal Medicine, Gyeongsang National University Changwon Hospital, Changwon, Gyeonsangnam-do, Republic of Korea.*

Background: Hyponatremia is the most common electrolyte disorder in lung cancer patients and has been associated with poor prognosis. We investigated the safety and

efficacy of tolvaptan in lung cancer with the syndrome of inappropriate antidiuretics hormone(SIADH).

Methods: We reviewed medical record database for all lung cancer patients with SIADH treated with tolvaptan. All patients received 7.5mg/day as an initial dose. Overcorrection of serum sodium was defined as an increased of serum sodium exceeding 12 mmol/L over 24 hours or 8 mmol/L over 8 hours.

Results: 41 patients (32 male patients, aged 67.61 ± 10.1 years) with lung cancer treated with tolvaptan were enrolled. Serum sodium increased significantly from baseline during the first 24 hours (122.68 ± 4.54 vs 132.05 ± 4.27 mmol/L, p=0.03), and then plateaued until day 14(134.27 ± 6.11 mmol/L). There was no difference in baseline sodium level according to a type of lung cancer(121.97 ± 3.47 vs 123.68 ± 5.26 mmol/L, p=0.223). In small cell lung cancer, the change was significantly higher (11.09 ± 2.83 mmol/L) than in non-small cell lung cancer (7.36 ± 6.07 mmol/L, P= 0.029). But, there was no difference in the rate of correction between severe hyponatremia(<125 mmol/L) and moderate hyponatremia (p=0.48). Also, there was no difference in the rate of correction according to BMI (p=0.057). No serious adverse events were reported, but in 36.6 % of patient hyponatremia was overcorrected and in 14.6% of patients a slight increase in liver function test was observed.

Conclusions: In patients with lung cancer patient with SIADH, initial dose 7.5 mg tolvaptan was well-tolerated, relatively safe and effective.

FR-PO292

Non-Osmotic Sodium Storage Capacity in Patients with Glycosaminoglycan Alterations

Stijn Besseling,[1] Eliane Wenstedt,[1] Rik H. Olde Engberink,[2] Nienke M. Rorije,[1] Liffert Vogt.[1] *[1]Amsterdam Cardiovascular Sciences, Amsterdam Medical Center, University of Amsterdam, Amsterdam, Netherlands; [2]Academic Medical Center, Amsterdam, Netherlands.*

Background: In the 2-compartment model the kidneys are believed to be solely responsible for matching Na^+ intake and excretion. Recent observations that Na^+ can accumulate in the body without concurrent water retention, via binding to negatively charged glycosaminoglycans (GAG), challenge this model. Type 1 diabetic (DM1) patients are characterized by acquired GAG loss while hereditary multiple exostosis (HME) patients have defective heparan sulfate GAG polymerization due to mutations in either EXT1 or EXT2 genes. We questioned whether non-osmotic sodium storage is impaired in DM1 and HME patients as compared to healthy controls (HC).

Methods: Eight DM1, 7 HME patients and 11 HC were included, all non-smoking males with normal kidney function, BMI and blood pressure. Non-osmotic storage capacity was estimated after acute infusion of 0.54±0.1L hypertonic saline (2.4±0.2%) by measuring plasma $[Na^+]$ and urinary Na^+ and K^+ excretion at various time points during 4-hr follow-up. We compared the observed changes in plasma $[Na^+]$ with the expected changes that were estimated by Adrogue-Madias (AM) and Nguyen-Kurtz formulas, which are based on the 2-compartment model.

Results: Maximum increase (mean (SE)) of plasma $[Na^+]$ was reached 5 minutes after infusion in all 3 groups (DM1, 5.4±0.6; HME, 4.1±0.5, HC 3.5±0.4 mmol/L). The plasma $[Na^+]$ rise 5 minutes after infusion in DM1 was significantly higher than in HC (p=.01), without differences between HC and HME patient (p=.42). The formulas poorly predicted plasma $[Na^+]$ 5 minutes after infusion, with observed changes in plasma $[Na^+]$ exceeding expected changes. When using AM, DM1 showed the biggest discrepancy between observed and expected change in plasma $[Na^+]$ (DM1, -1.98±0.6, p=.01; HME, -0.87±0.5, p=.12; HC -0.31±0.4 mmol/L, p=.46). In all groups, the observed Na^+ and K^+ excretion were significantly lower compared to the expected excretion, but no differences between groups were observed. Blood pressure was not affected by infusion.

Conclusions: DM1 patients have reduced ability for non-osmotic sodium storage, possibly due to a reduced amount of GAGs. HME patients do not show a reduced ability for non-osmotic sodium storage, perhaps by compensatory synthesis GAGs other than heparan sulfate.

FR-PO293

Expression of Sodium Renal Transporters in Urinary Exosomes from Patients with Edema Associated with Cirrhosis, Heart Failure, or Nephrotic Syndrome

Ivonne Hurtado,[1] Silvana Bazua-Valenti,[2,1] Lorena L. Rojas,[1] Fabiola Gallardo,[1] Diego L. Carrillo Perez,[1] Braulio A. Marfil-Garza,[1] Pablo E. Galindo,[4] Tomas Alexis Becerra-Gamba,[3] Magdalena Madero,[3] Gerardo Gamba.[1,2] *[1]INCMNSZ, MEXICO, Mexico; [2]IIB, UNAM, Mexico City, Mexico; [3]INCICH, Mexico City, Mexico; [4]Instituto Nacional de ciencias medicas y nutrición salvador Zubiran, CUERNAVACA, Mexico.*

Background: The formation of edema requires sodium retention along the nephron. The molecular pathways in humans leading to salt retention in edematous states remain elusive. The use of urinary exosomes (UE) is a non-invasive powerful tool to study the pathophysiology of renal diseases. Here we analyzed the expression of a variety of renal sodium transporters in UE from patients with and without edema diagnosed with chronic failure of the liver or heart, as well as from patients with nephrotic syndrome.

Methods: We conducted a prospective and observational study. We obtained clinical and biochemical data, as well as urinary samples from adult patients with liver cirrhosis (LC), heart failure (HF) or nephrotic syndrome (NS) (N=9 with, N=9 no-edema for each group) and 5 healthy volunteers as controls. UE from 8 ml of urine were obtained by ultracentrifugation for western blot analysis of SGLT2, NHE3, NKCC2, NCC and ENaC. The amount of UE used per patient was adjusted to urinary creatinine.

Results: Clinical and biochemical data from edema and non-edema patients were similar, except for mild hyponatremia and lower MAP in LC and HF patients with edema, respectively. Analysis of UE of patients with LC showed a significant increase in NHE3 and SGLT2 only in the edema group, while there was decreased NCC expression in the non-edema group. Conversely, NS and HF patients showed increased proximal tubule transporters even in the non-edema group. These patients were also characterized by increased ENaC expression. NKCC2 was only increased in HF patients with or without edema. Interestingly, NCC did not increase in any of the groups.

Conclusions: Our observations suggest that in edematous patients, regardless of the underlying syndrome, the proximal tubule transporters are upregulated and may be the most important cause of sodium retention. Interestingly, NKCC2 was increased in HF patients, but not in LC or NS patients. Down regulation of NCC in some groups suggests that the distal nephron is trying to compensate proximal reabsorption. These results suggest that diuretic therapy in patients with edema could be revisited to explore the use of proximal tubule inhibitors.

FR-PO294

Kidney Functional MRI: A Potential Noninvasive Assessment of Early Change and NCC Function in Chinese Gitelman Syndrome Patients

Xiaoyan Peng, Gu-Mu-Yang Zhang, Dongli Tian, Hao Sun, Limeng Chen. *Peking Union Medical College Hospital, Beijing, China.*

Background: Gitelman syndrome (GS) is an inherited salt-losing tubulopathy with Na^+-Cl^-cotransporter (NCC) dysfunction. Diffusion kurtosis imaging (DKI) and inteavoxel incoherent motion imaging(IVIM) MRI are functional MRI(fMRI) which could disclose more precise tissue structure and water diffusion. Recently, we observed fMRI associated well with the pathologic changes in IgA nephropathy. In this study we first applied the novel technique in the kidney of GS patients.

Methods: Twenty patients with genetically confirmed GS and 24 age and gener matched healthy volunteers were enrolled. DKI and IVIM were performed at a clinical 3T MR scanner. The DKI parameters (K=mean kurtosis, D=mean diffusivity, ADC=apparent diffusion coefficient) and IVIM parameter(f_p=microvascular perfusion fraction, D_p=pseudodiffusion, D=diffusion coefficients) were generated by a post-processing software. The association between parameters and clinical data were investigated. The in vivo NCC function of patients were evaluated by thiazide test using $_{\Delta}$FECl(the increment of fractional excretion of Cl^-).

Results: The mean age of GS patients was 28.4±10.2y and 45.8% were male with a mean onset age of 22.2±11.7y. At admission, the mean serum $K^+$and Mg^{2+} was 3.22±0.55 mmol/L and 0.68±0.16 mmol/L. GS patients showed decreased reaction to thiazide test. Compared to controls, lower DKI-ADC (1.45±0.19 vs 1.55±0.12,*P*=0.048), which indicating greater diffusion restriction, was observed in the renal medulla of GS. Lower IVIM-DP (117.8±46.0 vs. 151.3±56.3,*P*=0.039) indicating less microvascular perfusion, was observed in the renal cortex of GS. Among GS patients, in DKI the cortex ADC was associated well with plasma upright renin activity and blood pressure. The D value and K value correlated well with serum Cl^-(D: r=-0.670, *P*=0.001; K: r=-0.470, *P*=0.037) and HCO_3^-(D: r=0.709, *P*<0.001; K: r=0.469,*P*=0.037). In the kidney medulla, only K value associated well with serum Cl^- (r=-0.514,*P*=0.020). In IVIM, both the cortex D (r=0.702,*P*=0.035) and medulla D_p(r=-0.683, P=0.048) correlated well with $_{\Delta}$FECl.

Conclusions: DKI and IVIM MRI potentially provides a novel method for examining microvascular perfusion and diffusion in the kidney of GS patients and can serve as a noninvasive assessment of early change and NCC function in Chinese Gitelman syndrome patients.

FR-PO295

Hyponatremia and Renal Dysfunction in Acute Heart Failure

Masaaki Yamada, Karthikeyan Meganathan, Silvi Shah, Hassane Amlal, Charuhas V. Thakar. *University of Cincinnati, Cincinnati, OH.*

Background: Acute heart failure (HF) is a common cause of hospitalization and risk factor for hyponatremia (hypoNa) as well as renal dysfunction. Although renal function influences both HF and sodium (Na) regulation, this interrelationship is not studied in acute care settings. Moreover, effect of Na correction in HF during acute care is not known.

Methods: We examined all adults, >18 years of age, requiring 24 or more hours of hospitalization for HF from a national multicenter sample derived from Cerner Health Facts between 1/2010 and 6/2016. Admission Na levels in mEq/L were classified as severe hypoNa (<130), moderate hypoNa (130-134), mild hypoNa (135-139), normal (140-144), or hypernatremia (≥145). By logistic regression adjusted for major confounders, with normal as a reference group, risk of all cause hospital mortality/hospice (primary outcome) or 30-day readmission was modeled for other Na groups. We further assessed effect of correction of Na at discharge relative to admission on the primary outcome as well.

Results: Sample included 109,906 HF patients with median age of 74 years (Q1, Q3, 63, 84); 49% female; 19% Black; median serum Cr 1.2 mg/dL (Q1, Q3, 0.9, 1.7). Na classes were 5% (<130), 13% (130-134), 41% (135-139), 36% (140-144), and 5% (≥145). Overall hospital mortality was 5%; crude mortality rate showed a "U"-shaped relationship by Na classes (p <0.001). Compared to the normal class, adjusted odds ratio (aOR); 95% confidence interval (CI) were 2.3 (2.1-2.6) in Na <130; 1.7 (1.6-1.9) in Na 130-134; 1.2 (1.1-1.3) in Na 135-139; and 1.8 (1.6-2.0) in Na ≥145. Renal dysfunction defined as Cr ≥1.3 mg/dL on admission was associated with increased mortality independent of Na (aOR 1.6; 95% CI, 1.5-1.7) compared to others. Among the 5,130 severe hypoNa patients,

compared to those who corrected from <130 to 130-139, the risk of mortality in patients who remained <130; corrected to normal (140-144); or over corrected (≥145) was aOR 2.1 (95% CI, 1.7-2.6), 2.5 (95% CI, 1.7-3.5), and 10.5 (95% CI, 6.0-18.5) respectively. Overall, 30-day readmission rate was 15%; compared to normal group (14%) it was higher in severe hypoNa (18%, p <0.001) and aOR 1.4 (95% CI, 1.3-1.5).

Conclusions: Management of hypoNa, in concert with level of renal function, is necessary to improve key HF outcomes. However, correcting severe hypoNa to normal or above normal may be harmful in acute HF.

Acetazolamide Therapy in Patients with Heart Failure: A Meta-Analysis

Janewit Wongboonsin,[1] Charat Thongprayoon,[2] Wisit Cheungpasitporn.[3] *[1]Medicine, Univeristy of Minnesota, Minneapolis, MN; [2]Bassett Medical Center, Cooperstown, NY; [3]Nephrology, University of Mississippi, Jackson, MS.*

Background: Fluid overload and central sleep apnea are highly prevalent in patients with heart failure (HF). Acetazolamide, although used as one of the first diuretics for heart failure, has not been readily added on as a therapy for diuretic resistance. In addition, its use in sleep apnea disorder has shown promising results, at least in the setting of high altitude conditions. We performed this meta-analysis to assess effects of acetazolamide therapy on 1) fluid and/or electrolytes, and 2)apnea indexes in heart failure patients.

Methods: A literature search was conducted using MEDLINE, EMBASE and Cochrane Database from inception through June 2017 to identify studies evaluating the use of acetazolamide in HF patients. Study results were pooled and analyzed using a random effects model. The protocol for this meta-analysis is registered with PROSPERO (International Prospective Register of Systematic Reviews; no. CRD42017065401).

Results: 9 studies (3 randomized controlled trials and 6 cohort studies) with a total of 229 HF patients were enrolled. After acetazolamide treatment, there were significant decreases in pH (mean difference [MD] of -0.04 [95% CI, -0.06 to -0.02]), pCO2 (MD of -2.06 mmHg [95% CI, -3.60 to -0.53 mmHg]) and serum bicarbonate levels (MD of -6.42 mmol/L [95% CI, -10.05 to -2.79 mmol/L]). Compared with placebo, acetazolamide significantly increased natriuresis (standardized mean difference [SMD] of 0.67 [95% CI, 0.08 to 1.27]), and decreased the apnea-hypopnea index (AHI) (SMD of -1.06, [95% CI, -1.75 to -0.36]) and central apnea index (CAI) (SMD of -1.10, [95% CI, -1.80 to -0.40]), respectively. We found no publication bias as assessed by the funnel plots and Egger's regression asymmetry test with p= 0.20, 0.75 and 0.59 for analysis of the changes of pH, pCO2, and serum bicarbonate levels with the use of acetazolamide in HF patients, respectively.

Conclusions: Our study demonstrates significant reduction in pH, increase in natriuresis, and improvements in apnea indexesamong HF patients with acetazolamide.

FR-PO297

Carbonic anhydrase Inhibitors (CAI) Use in Patients with Respiratory Failure and Metabolic Alkalosis: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

Bassem Y. Tanios,[1] Maryam O. Omran,[2,3] Carlos Noujeim,[4,5] Tamara Lotfi,[6,3] Samir G. Mallat,[1] Pierre K. Boukhalil,[4] Elie A. Akl,[7,6] Houssam S. Itani.[8] *[1]Division of Nephrology and Hypertension, American University of Beirut Medical Center, Beirut, Lebanon; [2]Nursing Department, American University of Beirut Medical Center, Beirut, Lebanon; [3]Faculty of Health Sciences, American University of Beirut, Beirut, Lebanon; [4]Division of Pulmonary and Critical Care, American Universtiy of Beirut Medical Center, Beirut, Lebanon; [5]Division of Pulmonary and Critical Care, Keserwan Medical Center, Ghazir, Lebanon; [6]Department of Clinical Research Institute, American University of Beirut, Beirut, Lebanon; [7]Internal Medicine, American University of Beirut Medical Center, Beirut, Lebanon; [8]Division Nephrology and Hypertension, Makassed General Hospital, Beirut, Lebanon.*

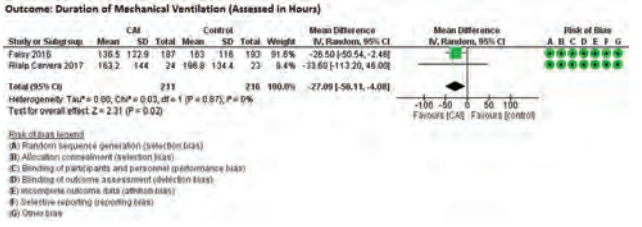
Background: Metabolic alkalosis is common in patients with respiratory failure and may delay weaning in mechanically ventilated patients. The objective of this systematic review is to assess the benefits and harms of CAI therapy in patients with respiratory failure and metabolic alkalosis

Methods: We conducted a comprehensive literature search for relevant randomized clinical trials(RCTs) assessing at least one of the following outcomes:mortality, duration of hospital stay, duration of mechanical ventilation(MV), blood gas parameters, and adverse events. Teams of two review authors independently and in duplicate selected eligible trials then abstracted data, and assessed risk of bias of the included trials. The primary meta-analysis used a random-effects model

Results: We identified 6 eligible RCTs with a total of 564 participants. The synthesized data did not exclude neither a reduction or an increase in mortality or in duration of hospital stay with the use of CAI(Table). There was a decrease in the duration of MV of 27(95% CI -50; -4) hours with CAI use(Figure). CAI therapy resulted in an increase in PaO2, and a decrease in PaCO2, serum bicarbonate and pH. There was an increased risk of adverse events in the CAI group(Table). Quality of evidence was judged to be low for most outcomes

Conclusions: In patients with respiratory failure and metabolic alkalosis, results of our systematic review suggest that CAI therapy has a favorable effect on blood gas parameters. In mechanically ventilated patients, the evidence suggests that CAI therapy may decrease duration of MV. Therefore, this clinically important outcome should be confirmed by future larger RCTs

Outcome	Number of studies	Number of Participants	Statistical Method	Effect Estimate
Mortality	2	427	Risk Ratio (M-H, Random, 95% CI)	0.94 [0.57, 1.56]
Duration of Hospital Stay (Days)	2	117	Mean Difference (IV, Random, 95% CI)	0.42 [-4.82, 5.66]
PaCO2 (mmHg)	5	185	Mean Difference (IV, Random, 95% CI)	-4.98 [-9.66, -0.30]
PaO2 (mmHg)	3	118	Mean Difference (IV, Random, 95% CI)	11.37 [4.18, 18.56]
Serum Bicarbonate (meq/L)	2	67	Mean Difference (IV, Random, 95% CI)	-5.03 [-6.52, -3.54]
pH	4	165	Mean Difference (IV, Random, 95% CI)	-0.04 [-0.07, -0.01]
Adverse Events	5	508	Risk Ratio (M-H, Random, 95% CI)	1.71 [0.98, 2.99]



FR-PO298

24-Hour Urine Magnesium Excretion in a Multi-Ethnic Asian Population of CKD and Healthy Participants

Umer F. Khan,[1] Titus W. Lau,[3] Boon Wee Teo.[2] *[1]National University Hospital Singapore, Singapore, Singapore; [2]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [3]National University Health System, Singapore, Singapore.*

Background: Magnesium (Mg) is implicated in bone metabolism, vascular tone, cardiovascular risk, and immunity. Its homeostasis is affected by diet, gut absorption, and kidney filtration, reabsorption, and excretion. Previous studies demonstrated an increase in serum Mg and urine fractional excretion of Mg (FEMg) in chronic kidney disease (CKD). The 24-hour urinary Mg (24UMg; mmol) excretion in a multi-ethnic Asian population of CKD and healthy participants without kidney disease is unknown. We aim to characterize serum Mg, 24UMg, and FEMg in a multi-ethnic Asian population.

Methods: Out of 335 (51% male) consenting participants, 232 (69%) were patients with CKD, and 103 (31%) were healthy individuals without kidney disease, diabetes, or hypertension. Following a 24-hr urine collection, participants underwent glomerular filtration rate (GFR; mL/min/1.73m^2) measurement using Tc^{99m}DTPA, and provided a spot urine and blood. No patients were on Mg supplementation. Data were analyzed on SPSS V23 using standard statistical tests, where appropriate.

Results: Of the 232 patients with CKD, 72 (31.0%) had GFR >60, 99 (42.7%) had GFR 30-60, and 61 (26.3%) had GFR <30; 51.3% were diabetic, and 82.8% were hypertensive. Mean 24UMg values were lower in patients with CKD (2.50±1.25) than healthy participants (2.93±1.45) [p=0.006]. Patients with GFR <30 had lower mean 24UMg values (2.00±1.10) compared to groups 30-60, and >60 (2.64±1.20, 2.75±1.34, respectively) [p=0.001]. Group with GFR <30 had a higher mean serum Mg (p=0.005) and an increased FEMg (p<0.001). 24UMg is associated with GFR (24UMg=2.032+0.009×GFR, p=0.002], which persists after excluding patients on diuretics. 24UMg and GFR is positively correlated in CKD patients with hypertension but not in non-hypertensives and diabetic patients.

Conclusions: Healthy participants have higher 24UMG excretion than CKD patients. With reduced GFR, serum Mg is higher, and 24UMg is lower, and is associated with an increased FEMg in Asian CKD patients.

FR-PO299

Tacrolimus Trough Levels and Risk of Hypomagnesemia in Renal Transplant Recipients

Antonio Gomes Neto, Joëlle C. Schutten, Michele F. Eisenga, Jan-Stephan Sanders, Stefan P. Berger, Martin H. De Borst, Gerjan Navis, Stephan J. Bakker. *University Medical Center Groningen, Groningen, Netherlands.*

Background: Magnesium (Mg) is the 2nd most abundant intracellular cation essential to neurochemical transmissions and many enzyme activities. Hypomagnesemia (hypoMg) is a risk factor for cardiovascular and mineral bone disease and in renal transplant recipients (RTR), Tacrolimus (Tac) use is associated with higher risk of hypoMg. However, it is unknown whether Tac trough levels further contributes to the risk of hypoMg. We aimed to investigate the association between Tac use and hypoMg in a large cohort of RTR.

Methods: For this study, we used data from the Transplantlines Biobank and Cohort Study comprising RTR with a functioning graft ≥1 year post-transplantation. Plasma Mg and Tac trough levels were measured using routine laboratory procedures. HypoMg was defined as a Mg level <1.7 mg/dL. Linear and logistic regression were used to assess the association of Tac use with plasma Mg and hypoMg, respectively. In additional analyses, we analyzed whether Tac trough levels were associated with plasma Mg and hypoMg in Tac users.

Results: We included 614 RTR (mean age 56±13 years; 59.2% male) at a median of 4.7 [1.0 - 11.7] years posttransplantation. Mean eGFR was 50±17 ml/min/1.73m^2 and mean

plasma Mg was 1.8±0.2 mg/dL. Of the total population, 170 (28%) RTR had a hypoMg and 378 RTR used Tac with a mean trough level of 5.8±1.8 ug/L. In linear regression analysis, Tac use was associated with lower plasma Mg (β -0.17 [95%CI -0.21;-0.12], $p < 0.001$), independent of age, sex, time after transplantation and eGFR. Similarly, in logistic regression analysis Tac use was independently associated with higher risk of hypomagnesemia (OR 4.5 [95%CI 2.6;7.8], $p < 0.001$). Within Tac users, Tac trough levels were strongly associated with lower plasma Mg (β -0.04 [95%CI -0.05 ; -0.03], $p < 0.001$) and higher risk of hypoMg (OR 1.4 [95%CI 1.2 ; 1.6], $p < 0.001$), independent of potential confounders.

Conclusions: HypoMg occurs in approximately 28% of RTR. Tac use is associated with a > 4 times greater risk of hypoMg. Importantly, we identified a dose-response effect between higher Tac trough levels and lower plasma Mg in Tac users. These results suggest that reducing Tac trough levels may be an effective treatment strategy for hypoMg in RTR treated with Tac.

FR-PO300

Association Between Use of Proton Pump Inhibitors and Hypomagnesemia: A Meta-Analysis

Paweena Susantitaphong,[1] Thawin Srinutta,[1] Api Chewcharat,[1] Kullaya Takkavatakarn,[2] Kearkiat Praditpornsilpa,[1] Bertrand L. Jaber,[3] Somchai Eiam-Ong.[1] *[1]Chulalongkorn University, Bangkok, Thailand; [2]Division of Nephrology, King Chulalongkorn Memorial hospital, Bangkok, Thailand; [3]St. Elizabeth's Medical Center, Boston, MA.*

Background: Hypomagnesemia is associated with an increased risk of cardiac arrhythmia and mortality. The use of proton pump inhibitors (PPIs) has been inconsistently associated with development of hypomagnesemia. To shed more light on this controversy, we performed a meta-analysis to examine the association between use of PPIs and hypomagnesemia.

Methods: The literature search was conducted in MEDLINE, Scopus, and Cochrane Central Register of Controlled Trials (through December 2017) to identify observational studies that examined the association between use of PPIs and development of hypomagnesemia. Random-effects model meta-analysis was used to compute the pooled odds ratio (OR) with 95% confidence interval (CI).

Results: Thirteen cohort studies were identified, totaling 125,280 patients. 38.7% (95% CI 29.5-48.7%) of patients were PPI users. The baseline prevalence of diabetes mellitus and diuretic use was not significantly different between PPI users and non-users. By meta-analysis, use of PPIs was associated with a higher odds for development of hypomagnesemia (pooled odds ratio 1.83; 95% CI 1.26, 2.67; P = 0.002; I^2 = 97%).

Conclusions: The use of PPIs is significantly associated with development of hypomagnesemia. As a result, serum magnesium levels should be monitored in patients receiving long-term PPIs.

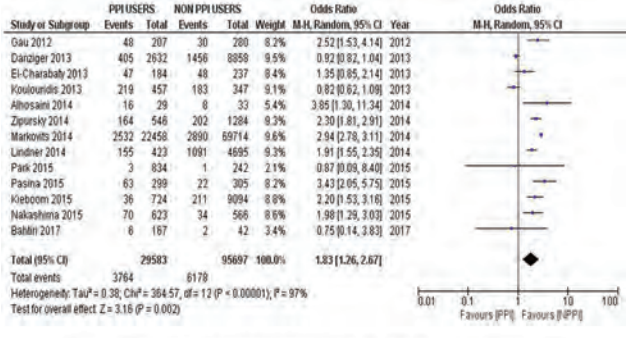


Figure 1. Forest plot of pooled unadjusted odd ratio. PPI, Proton pump inhibitor

FR-PO301

Efficacy and Safety of Patiromer in Participants with Diabetes: A Pooled Analysis

Patrick Rossignol,[1] Coleman Gross,[2] Martha Mayo,[2] Suzette Warren,[2] Jinwei Yuan,[2] Jeffrey J. Budden,[2] George L. Bakris.[3] *[1]Clinical Investigation Center-INSERM-CHU of Nancy, VANDOEUVRE LES NANCY, France; [2]Relypsa Inc., a Vifor Pharma Group Company, Redwood City, CA; [3]The University of Chicago Medicine, Chicago, IL.*

Background: The purpose of this post-hoc pooled analysis was to assess the efficacy and safety of patiromer (PAT) for treatment of hyperkalemia in participants with and without diabetes mellitus (DM^+ and DM^-).

Methods: We analyzed pooled data through Week 4 (Wk4) from 3 trials of PAT. Study participants who took ≥1 PAT dose and had ≥1 post-baseline (BL) serum potassium (sK) measurement were included. Participants were stratified according to DM^+ and DM^-, and assessed for: sK change from BL at Wk4, sK over time, and % with any sK measurement in target range (3.8–5.0 mEq/L).

Results: 653 participants were included; 82% DM^+ (mean BL HbA1c and DM duration: 7.4% and 14 years, respectively). Mean BL sK and eGFR were 5.4 mEq/L and 40.3 mL/min/1.73m² in DM^+, and 5.5 mEq/L and 34.8 mL/min/1.73m² in DM^-. At Wk4, overall mean (SE) sK change from BL was -0.72 (0.02) in DM^+ and -0.88 (0.06) in DM^- (**Figure**). In participants with BL sK ≥5.5 mEq/L, mean (SE) sK changes at Wk4 were -1.01 (0.05) in DM^+ and -1.21 (0.10) in DM^-, and -0.52 (0.03) and -0.51 (0.08), respectively, in DM^+ and DM^- participants who had BL sK <5.5 mEq/L. Regardless of BL sK status, >95% of all DM^+ and DM^- participants achieved any sK measurement in the target range through Wk4. The presence or absence of heart failure or eGFR <45 mL/min/1.73m² did not impact these results. At least 1 adverse event (AE) was reported in 31% of DM^+ and 38% of DM^- participants, most commonly (≥2%) constipation, diarrhea, hypomagnesemia (hypoMg), and nausea. AEs of hypoMg were reported in 2% of both DM^+ and DM^- participants. Lab values of Mg <1.4 mg/dL occurred in 5% and 1% of DM^+ and DM^- participants, respectively. Use of proton pump inhibitors and/or loop diuretics was common (43%) in those who experienced low serum Mg.

Conclusions: In this post-hoc analysis of pooled data, PAT was equally effective and well-tolerated in DM^+ and DM^- participants.

FR-PO302

The Association of Sodium Polystyrene Sulfate (Kayexelate™) Use and Adverse Gastrointestinal Events

Ariana Noel,[2] William Petrcich,[3] Sarah E. Bota,[3] Ziv Harel,[4] Manish M. Sood.[1,3] *[1]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]University of Ottawa, Ottawa, ON, Canada; [3]Institute for Clinical Evaluative Sciences, Ottawa, ON, Canada; [4]University of Toronto, Toronto, ON, Canada.*

Background: Sodium Polystyrene Sulfate (SPS, Kayexelate™) is a commonly prescribed medication for the treatment of hyperkalemia. Case reports implicate the possibility of intestinal injury with SPS with or without sorbitol. In this regard, we set out to assess the risk of GI adverse events (intestinal ischemia, ulceration and perforation, abdominal surgery) with SPS use.

Methods: Population-based, retrospective cohort study of 1,853,866 eligible adults of advanced age (> 66 years) between 1995 and 2015 in Ontario, Canada. A high dimensional propensity score was used to match adults with a SPS prescription to no SPS prescription. The primary outcome was a composite of adverse gastrointestinal outcomes (intestinal ischemia, ulceration/perforation, abdominal survey) within 1-year of initial SPS prescription. Secondary outcomes included each component of the composite primary outcome. Cox proportional hazards were used to examine the association of SPS and a composite of GI adverse events. Additional sensitivity analyses limited to patients with laboratory values (eGFR, serum potassium) and a unrelated dummy outcome (cataracts) were performed. Pre-specificed subgroups of interest were examined using interaction terms.

Results: From 1, 853, 866 eligible adults, 20,020 were prescribed SPS (mean age 78.5 SD 7.7 years, 46% female) and matched. The risk of any adverse GI event was higher with SPS use compared to non-use (n=370 events, HR 1.26 95%CI 1.03-1.55). Among the individual types of GI adverse injury, gastrointestinal ulceration and perforation (HR 1.56 95%CI 1.08-2.25) events were higher with SPS whereas intestinal ischemia and abdominal surgery were similar. Among SPS-users with laboratory values (n= 7557, mean eGFR 44.8 SD 20.3 ml/min/1.73m², mean serum potassium 5.6 SD 0.7 mEq/L), the risk of any adverse GI event was similarly elevated (HR 1.44 95%CI 1.09-1.90). The findings were consistent after additional adjustment for living in a rural residence or a long-term care home and there was no association with SPS use and the dummy outcome (cataracts). The results were consistent across all prespecified subgroups.

Conclusions: The use of SPS is associated with a higher risk of adverse gastrointestinal events. Our findings suggest caution with the use of SPS and alternative treatments for potassium lowering be considered.

FR-PO303

Acid-Base and Electrolyte Disturbances in Severe Hyperemesis Gravidarum

Maria Soledad Rivera,[1,2] Luis Estremadoyro,[4] Juan Carlos Q. Velez.[1,3] *[1]Ochsner Clinical School, New Orleans, LA; [2]School of Medicine, University of Queensland, Brisbane, QLD, Australia; [3]Department of Nephrology, Ochsner Clinic Foundation, New Orleans, LA; [4]Universidad Peruana Cayetano Heredia, Lima, Peru.*

Background: Hyperemesis gravidarum (HG) is a complication of pregnancy characterized by incessant vomiting and reduced oral intake. However, the effect of severe HG on acid-base and electrolyte balance has not been previously examined.

Methods: A cross-sectional study was conducted to assess for acid-base and electrolyte abnormalities in pregnant women with symptoms of HG that were severe enough to lead to a visit to an emergency room.

Results: A total of 22 women [9 (41%) primigravida] were included over a 6-month enrollment period in a large city hospital. Median age was 25 (17 – 38) and median gestational age was 10 (5 -16) weeks. Median duration of HG prior to arrival was 24 (3 – 63) days. Vomiting episodes per day were 6 (3 – 12) and ketonuria was found in 16 of 22 women (73%). Dehydration was clinically evident in 18 of 22 (82%) and the mean change in body weight was –12%. The mean arterial pH was 7.41 (7.30 - 7.50), mean bicarbonate was 19 mEq/L (14 – 28) and mean pCO_2 was 29 mmHg (19 - 39). Physiological respiratory alkalosis was found in 17 of 22 (77%), metabolic alkalosis from vomiting was present in 10 of 22 (45%) and high anion-gap metabolic acidosis from starvation ketosis in 12 of 22 (55%) patients. Among them, 8 of 22 (36%) presented with a triple acid-base disorder, i.e. simultaneous respiratory alkalosis, metabolic alkalosis and metabolic acidosis. Only 2 (9%) patients exhibited no acid-base disorder. The presence of high anion gap metabolic acidosis was associated with a greater degree of weight loss ($p < 0.05$) and a lower age ($p < 0.05$). In addition, 9 of 22 (41%) patients were hypokalemic [mean K 3.5 mEq/L (2.4 – 4.2)], 7 of 22 (32%) were hyponatremic, and only 1 patient was hypernatremic [mean Na 139 mEq/L (128 – 148)].

Conclusions: Triple acid-base disorder of respiratory alkalosis, metabolic acidosis and metabolic alkalosis is the most common diagnosis in severe HG. Lower age and a greater degree of reduction in body weight are associated with high anion gap metabolic acidosis. Hypokalemia and dysnatremia can also occur. Acid-base/electrolyte assessment in HG is warranted.

FR-PO304

Electrolyte-Related Events Among US Veterans with Hyperkalemia

Csaba P. Kovesdy,[1] Elvira Gosmanova,[2] Steven D. Woods,[3] Jeanene Fogli,[3] Christopher G. Rowan,[4] Jared Hansen,[5] Brian C. Sauer.[5] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]Stratton VA Medical Center and Albany Medical College, Albany, NY; [3]Relypsa, Inc., a Vifor Pharma Group Company, Redwood City, CA; [4]COHRDATA, LLC, Santa Monica, CA; [5]Salt Lake City VA Medical Center (IDEAS), Salt Lake City, UT.*

Background: Patiromer is a novel sodium-free potassium-binding polymer for treating hyperkalemia. The real-world impact of patiromer and sodium polystyrene sulfonate (SPS) on clinical outcomes is unclear.

Methods: Using the VA Informatics and Computing Environment (VINCI) database, we assessed the percentage of patients with electrolyte-related hospitalizations and emergency department (ED) visits 1, 3, and 6 months before and after the first patiromer and SPS dispensing (index date). Follow-up exposure was classified as of the index date and followed for 6 months (ITT) or censored at discontinuing/switching (continuous exposure, CE).

Results: 193 and 8492 patients initiated patiromer and SPS, respectively. All patients had a pre-index serum potassium ≥5.1 mEq/L and heart failure, diabetes, or renal disease. The percentage of patients with electrolyte-related ED visits and hospitalizations in the ITT population are shown in **Figure**. Although patient numbers were small in the CE population, decreases in electrolyte-related outcomes at months 1, 3, and 6 post-index were observed for ED visits (-2.9%, -9.6%, and -23.1%, respectively, for patiromer, and -4.1%, -4.1%, and -5.7%, respectively, for SPS) and hospitalizations (-1.2%, -3.8%, and -7.7%, respectively, for patiromer, and -0.5%, -0.9%, and -0.4%, respectively, for SPS).

Conclusions: The greatest reduction in electrolyte-related events was observed post-patiromer initiation. Given the limited number of patiromer users in this database, these findings merit additional study.

Funding: Commercial Support - Relypsa, Inc., a Vifor Pharma Group Company

FR-PO305

Mortality Associated with Hyperkalemia in Medicare Patients

J. Michael Woolley,[3] Keith Betts,[1] Fan Mu,[2] Yao Wang,[2] Akanksha Dua,[2] Eric Wu.[2] *[1]Analysis Group, Inc., Los Angeles, CA; [2]Analysis Group, Los Angeles, CA; [3]AstraZeneca, Wilmington, DE.*

Background: The objective of this study was to compare all-cause mortality between patients with and without hyperkalemia in the U.S. Medicare population.

Methods: Adult patients with and without hyperkalemia (cases vs. controls), were selected from a 5% random sample from the Medicare population (1/1/2010-12/31/2014). Hyperkalemia was defined as having at least one diagnosis of hyperkalemia (ICD-9-CM 276.7). The index date was a randomly selected claim date with a hyperkalemia diagnosis for cases and a randomly selected claim date for controls. Continuous enrollment for at least 6 months before the index date (baseline period) was required and patients were followed from the index date to death or the end of data availability (study period). Controls were exactly matched one-to-one to cases on age group, chronic kidney disease (CKD) stage, dialysis, and heart failure (HF). Mortality outcomes were analyzed at 36 months. Time to death was estimated with Kaplan-Meier analysis and compared using the log-rank test. Hazard ratios (HRs) were estimated using univariate and multivariate Cox proportional hazards (PH) models.

Results: A total of 157,441 cases were matched to 157,441 controls. Compared with controls in the overall population, cases had higher 3-year mortality rates (47.5% vs. 33.7%) and lower median time to death (40.3 months vs. median not reached). Among the 79,327 matched pairs of patients with CKD and/or HF, the 3-year mortality was higher (59.6% vs. 48.7%) and the median time to death was lower (22.7 vs. 38.4 months) (p for log-rank test<0.001) in cases compared with controls. In univariate Cox PH models, the risk of mortality was significantly higher for cases compared with controls overall (HR: 1.67, 95% CI: 1.65, 1.69) and among patients with CKD and/or HF (HR: 1.44; 95% CI: 1.42, 1.46) (all p<0.001). After adjusting for age, gender, region, diabetes, hypertension, and Charlson Comorbidity Index, the risk remained higher for cases compared with controls in the overall population (HR: 1.49, 95% CI: 1.48, 1.51) and among patients with CKD and/or HF (HR: 1.37, 95% CI: 1.35, 1.39) (all p<0.001).

Conclusions: In this study of Medicare patients, hyperkalemia was associated with increased mortality.

Association of Potassium Level and Mortality in Massive Health Record Databases

Christos Argyropoulos,[1] Cristian G. Bologa,[1] V. Shane Pankratz,[2] Mark L. Unruh,[1] Maria-Eleni Roumelioti,[1] Vallabh O. Shah,[3] Saeed K. Shaffi.[1] *[1]University of New Mexico, Albuquerque, NM; [2]UNM Health Sciences Center, Albuquerque, NM; [3]University of New Mexico Health Science Center, Albuquerque, NM.*

Background: Dyskalemias have been associated with mortality in studies of small to moderate samples. However the association of potassium (K) with mortality across the spectrum of renal function (est. glom. filtration rate, eGFR) remains poorly defined. Our aim was to characterize this relation in the **Cerner** Healthfacts database which abstracts data from 1/3 of US healthcare facilities over a period of 10 years.

Methods: Serum K levels, demographics, eGFR (CKD-Epi) and comorbidity (Charlson) collected within 24 hours of all adult patient encounters in Healthfacts were analyzed after excluding patients on dialysis. The most recent K level was associated with each death recorded in Healthfacts. Relative mortality risks (RR) were calculated by Poisson Generalized Estimating Equations, that accounted for the repeated measures of K levels in the same individual. Cubic splines were used to model the relation of K with death in fully adjusted models.

Results: We analyzed 20,697,035 K measurements in 15,376,693 individuals. Patients with CKD were more likely to be older, non-white and have higher K levels (Table). The RR of death with K level was U-shaped; the lowest RR was observed for K: 3.5-4.5 meq/l (Fig A). Hyperkalemia (K>5.5 meq/l) was associated with higher RR in those with low eGFRs (Fig B, p<0.001 for the interaction between eGFR and K).

Conclusions: The RR for hyperkalemia was higher relative to hypokalemia.The interaction between eGFR and K level reflects the variable causes of high K in patients with CKD & the inability of the kidneys to rapidly excrete the K load. Further studies are needed to understand this complex relationship.

Course and Outcomes of Hyperkalemia in Hospitalized Patients

Etienne Macedo,[2] Linda Awdishu,[1] Euyhyun Lee,[2] Ravindra L. Mehta.[2] *[1]UCSD Skaggs School of Pharmacy and Pharmaceutical Sciences, La Jolla, CA; [2]University of California San Diego Medical Center, La Jolla, CA.*

Background: Hyperkalemia (High K) is a common complication among hospitalized patients contributing to increased hospital stay and costs. In this study, we determined the incidence and severity of hyperkalemia and characterize its recognition, treatment, and complications in different hospital settings and patient populations.

Methods: Data regarding patient location, comorbidities, medications in use before/after High K detection and outcomes were extracted from the EMR of all adult patients with at least 2 consecutive K>5mEq/L during a hospital stay at an academic medical center. Need for ICU admission, dialysis, number of drugs to treat HighK, land ength of ICU/hospital stay were assessed during hospitalization. Mortality was recorded for the duration of the observation period.

Results: From January 1, 2013, to November 30, 2015, 133,807 hospitalized patients had at least one potassium assessment. Of these patients, 13,748 (10.3%) had at least one K≥ 5mEq/L, and 2,150 (1.6%) had two consecutive values, within 7 days, ≥ 5 mEq/L. Almost half of the highK episodes were present at hospital admission, and the majority of these cases were from the emergency room (ER) 497 (23%), ward 1318 (62.9%), and ICU 280 (13.4%). Of 1,815 patients with hyperkalemia diagnosis in the ward or ER, 225 (12%) were transferred to the ICU within 24 hours of hyperkalemia diagnosis. 126 (6%) patients that were dialyzed during hospital admission: 78 (61%) were ESRD, 22 (3.4%) AKI, and 104 (6.9%) AKI on CKD. The median length of hospital stay was 9 days and was higher in AKI patients 11 (4-22) vs. 9 (4-17) days in no AKI. Overall, the in-hospital mortality rate in patients with hyperkalemia diagnosis was 12%. Patients with AKI had a higher mortality rate (AKI; 122 (17%) vs. 159 (10%) no AKI). Within the study period interval, 29% of patients with a hyperkalemia episode died. Patients with no previous renal dysfunction showed a greater in-hospital mortality rate 179 (15%) than those with CKD stage 3-5 and ESRD, 67(11.3%) and 25 (6.8%), respectively.

Conclusions: HighK in hospitalized patients is associated with a high mortality rate and increases significantly over the period of observation. Presence of CKD and ESRD is not associated with worse outcomes, whereas development of AKI is associated with increased length of stay and mortality.

FR-PO308

Predicting Complicated Hyperkalemia in Hospitalized Patients

Etienne Macedo,[2] Linda Awdishu,[1] Euyhyun Lee,[2] Ravindra L. Mehta.[2] *[1]UCSD Skaggs School of Pharmacy and Pharmaceutical Sciences, La Jolla, CA; [2]University of California San Diego Medical Center, La Jolla, CA.*

Background: Hyperkalemia (HighK) is common in hospitalized patients and can be life-threatening. Patient-related factors and process of care, including drugs, are known to be associated with the development of hyperkalemia. In order to prevent hyperkalemia complications, it is fundamental to identify the cause and provide early treatment. In this study, we evaluated risk factors for complicated hyperkalemia (CK) during hospitalization.

Methods: Data regarding patient location, comorbidities, medications in use before and after HighK detection and outcomes were extracted from the EMR of all adult patients at an academic medical center with at least 2 consecutive K > 5mEq/L during a hospital stay. CK was defined as: (1) maximum K level ≥ 6.5 mEq/L, (2) need for ICU admission within 24h of HighK diagnosis, (3) need for dialysis, if not ESRD, (4) death with K ≥ 5 mEq/L, (5) more than 3 drugs for hyperkalemia treatment initiated after hyperkalemia diagnosis, and (6) more than 8 days for potassium normalization. We divided the cohort into derivation (n= 1,165), and validation (n=985) cohorts, to build and evaluate the performance of the model. The Least absolute shrinkage and selection operator (LASSO) with 10-fold cross-validation was used to build the model.

Results: From January 1, 2013, to November 30, 2015, 133,807 hospitalized patients had at least one K assessment. Of these patients, 13,748 (10.3%) had one K value higher than 5 mEq/L, and 2,150 (1.6%) had two consecutive values, within 7 days, more than 5 mEq/L. CK occurred in 822(38%) of patients; 488(42%) derivation and 334(34%) in the validation cohort. The majority of the patients, 1,193 (55%) had eGFR > 60ml/min, and 1310 (61%) fulfilled criteria for AKI during the admission, 192 (9%) were ESRD. Mortality in CK was significantly higher, 200(24.3%) vs. 71(5.3%) HighK group (p<0.001). Presence of hypotension, cardiopulmonary diagnosis, fluid overload, infection and ICU location were independently associated with CK. ESRD, myopathy and HIV diagnosis were protective factors. The model AUC was 0.70 in the derivation and 0.64 in the validation dataset.

Conclusions: HighK is common in hospitalized patients and associated with high mortality. A model based on clinical information and process of care may help identify patients with HighK who are at highest risk for complications and require surveillance.

FR-PO309

Timing Is Everything: Decreasing Mortality in Severe Hyperkalemia

Sayee Sundar Alagusundaramoorthy,[1] Andrew Gregory,[3] Laura J. Maursetter,[2] Tripti Singh.[1] *[1]University of Wisconsin, Madison, WI; [2]University of Wisconsin School of Medicine & Public Health, Madison, WI; [3]University of Wisconsin Madison School of Medicine and Public Heatlh, Eleva, WI.*

Background: Hyperkalemia is a modifiable risk factor for sudden cardiac death; a leading cause of mortality in hemodialysis patients. There is lack of data in literature guiding the treatment of hyperkalemia in hospitalized end stage renal disease (ESRD) patients. The goal of this study was to determine if time to dialysis after severe hyperkalemia will influence mortality in hospitalized ESRD patients.

Methods: We conducted a retrospective study of all adult ESRD patients admitted to the hospital who had hemodialysis for severe hyperkalemia between January 2011- June 2017. Chart review was conducted to determine patient and treatment characteristics. Logistic regression analysis was performed to determine the factors that influenced mortality.

Results: 346 ESRD patients on hemodialysis admitted at our center had severe hyperkalemia during the study period. Mean serum potassium was 7mEq/L. In-hospital mortality in ESRD patients with severe hyperkalemia was 6.9%. Median time to dialysis after serum potassium result was 2.13 hours (25, 75 IQR 0.98, 4.9 hours). Time to dialysis after serum potassium result was associated with a significantly increased risk of mortality in this population (HR 1.007, 95% CI 1.002-1.012, p <0.0045) (Table 1). Logistic regression analyses also determined age, length of stay, serum creatinine and serum albumin level as significant predictors of in-hospital mortality (Table 1). Sex, race, history of diabetes and hypertension, serum potassium level and serum CO2 level did not influence in-hospital mortality in this cohort.

Conclusions: We conclude that early dialysis after serum potassium result in hospitalized ESRD patients with severe hyperkalemia is associated with decreased in hospital mortality.

Table 1: Risk factors for mortality in hospitalized ESRD patients with severe hyperkalemia

Risk Factor	Odds Ratio (95%CI)	p- value
Age, per 1 year	1.07 (1.04-1.11)	0.0001
Length of stay, per 1 day	1.04 (1.02-1.06)	0.0002
Serum Albumin, per 1 g/dL	0.24 (0.07-0.76)	0.02
Serum Creatinine, per 1 mg/dL	0.72 (0.58-0.88)	0.0018
Time from potassium result to dialysis, per 1 hour	1.007 (1.002-1.012)	0.0045

Changes in Nephrologists' Understanding and Management of Hyperkalemia from 2015 to 2018

Amy Larkin,[1] Donald Blatherwick,[2] Teresa S. Marshall,[2] George Boutsalis.[2] *[1]Medscape Education, Nicholasville, KY; [2]Medscape, Medford, NJ.*

Background: Identifying clinical gaps related to hyperkalemia and its management can inform the development of tools to advance best practices for nephrologists

Methods: Medscape conducted surveys in 2015, 2016, and 2018. The first two were CME-accredited activities consisting of 25 multiple choice, knowledge- and case-based questions aboout hyperkalemia assessment and management. These online surveys were available without compensation or fee. The third online, 14-question, survey was incentivized for nephrologists with monetary compensation for completion. In all surveys, respondents' confidentiality was maintained and responses were de-identified and aggregated prior to analyses. Data collection occurred in 9/22 - 11/22/2015, 11/21 – 12/21/2016, and 4/20 – 4/26/2018.

Results: Participation by nephrologists: 394 in 2015, 131 in 2016, and 50 in 2018 **Significant Changes:** Competence related to management of hyperkalemia rose significantly (P =.018) from 44% in 2016 to 66% in 2018* Competence regarding clinical use of potassium binders grew significantly (P <.001), from 63% to 92% (2016 to 2018, respectively) Nephrologists who reported being very confident increased significantly (P =.04), from 35% to 45% to 60% (2015, 2016, and 2018, respectively)* **Modest Changes:** Hyperkalemia risk assessment understanding grew (58% to 72%, P =.083) as well as recognition of strategies to minimize hyperkalemia risk with RAAS inhibitors (25% to 30%, P =.381) from 2016 – 2018* Knowledge of the mechanism of action of patiromer trended upward each year, 46% to 50% to 56% (2015, 2016, and 2018 respectively, P=.377) * **Ongoing Gap:** Confusion remains around the mechanism of action of ZS9, 49%

(2015), 39% (2016), and 44% 2018, *P* =.046)* Understanding related to the physiology of hyperkalemia and potassium excretion remains low (55% vs 54%, P - .885) from 2015 to 2018* * *results indicate a need for further education*

Conclusions: These surveys demonstrate some improvement in clinical knowledge, competence, and confidence by nephrologists related to hyperkalemia from 2015 to 2018, as well as continued gaps that need to be addressed to improve patient care. Future education in the area of hyperkalemia should focus on improving risk assessment for hyperkalemia, understanding available treatment options, management of hyperkalemia, and also reinforce important points to further increase confidence.

FR-PO311

Calcium-Phosphate Product and Its Impact on Mortality in Hospitalized Patients

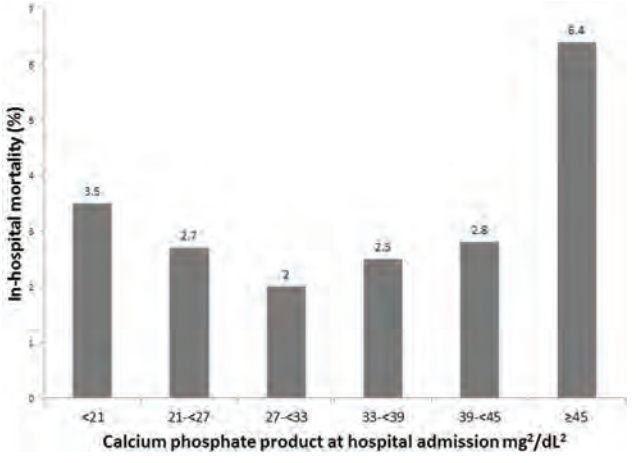
Michael A. Mao,[1] Charat Thongprayoon,[2] Wisit Cheungpasitporn,[3] Stephen B. Erickson.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Bassett Medical Center, Cooperstown, NY; [3]Nephrology, University of Mississippi Medical Center, Jackson, MS.*

Background: Calcium-phosphate product (CaP) of >55 mg^2/dL^2 is associated with acute or subacute calcification of vascular, cardiac, and other soft tissues. However, the relationship between admission CaP and in-hospital mortality in all hospitalized patients is unclear.

Methods: All adult hospitalized patients who had both admission serum calcium and phosphate levels available between years 2009 and 2013 were enrolled. Admission CaP was categorized based on its distribution into six groups (<21, 21-<27, 27-<33, 33-<39, 39-<45 and ≥45 mg^2/dL^2). The odds ratio (OR) of in-hospital mortality by admission CaP, using the CaP category of 27-<33 mg^2/dL^2 as the reference group, was obtained by logistic regression analysis.

Results: 14,772 patients were studied. The lowest incidence of in-hospital mortality was associated with an admission CaP within 27-<33 mg^2/dL^2. A U-shaped curve emerged demonstrating higher in-hospital mortality associated with both CaP <27 and ≥33 mg^2/dL^2. After adjusting for potential confounders, both CaP <21 and ≥39 mg^2/dL^2 were associated with an increased risk of in-hospital mortality with ORs of 1.60 (95% CI 1.07-2.37), 1.53 (95% CI 1.07-2.18) and 3.46 (95% CI 2.51-4.79) when CaP were within <21, 39-<45 and ≥45 mg^2/dL^2, respectively. Among a subgroup of patients with available serum albumin, the lowest incidence of in-hospital mortality was associated with corrected CaP within 33-<39 mg^2/dL^2. After adjusting for potential confounders, corrected CaP 39-<45 and ≥45 mg^2/dL^2 were associated with an increased risk of in-hospital mortality with ORs of 2.15 (95% CI 1.39-3.33) and 3.90 (95% CI 2.60-5.94) when CaP were within 39-<45and ≥45 mg^2/dL^2, respectively.

Conclusions: CaP levels on admission are associated with in-hospital mortality. Highest mortality risk is observed in hospitalized patients with admission CaP ≥45 mg^2/dL^2.



Admission calcium phosphate product levels and hospital mortality

Outcome	Calcium phosphate product at hospital admission (mg^2/dL^2)					
	<21	21-<27	27-<33	33-<39	39-<45	≥45
Hospital Mortality	41 (8.5)	59 (2.7)	78 (2.0)	91 (2.5)	58 (2.8)	118 (6.4)
Mortality, OR (95%CI)						
Model 1: unadjusted	1.78 (1.20-2.60)	1.32 (0.94-1.87)	1 (ref)	1.25 (0.92-1.70)	1.42 (1.003-2.00)	3.34 (2.50-4.48)
Model 2#	1.60 (1.07-2.37)	1.34 (0.94-1.89)	1 (ref)	1.35 (0.99-1.84)	1.53 (1.07-2.18)	3.46 (2.51-4.79)

FR-PO312

A Structural Equation Model on Regulatory Network of Phosphate Metabolism in Healthy Individuals

Guoxin Ye,[1] Mengjing Wang,[2] Jiaying Zhang,[2] Weisheng Chen,[3] Jing Chen.[3] *[1]Division of Nephrology, Huashan Hospital, Shanghai Medical College, Fudan University, Shanghai, China; [2]Huashan hospital, Fudan University, Shanghai, China; [3]Huashan Hospital, Shanghai, China.*

Background: Basic and clinical studies reveal that the homeostasis of phosphate is maintained by a regulatory network. The factors in the network may change along with the dietary intake of phosphate. The aim of our study was to explore the variation of phosphatoninin with the change of diet.

Methods: A cross-over trial of 6 healthy volunteers was conducted. Each of them was given diet strictly: regular Pi diet (1500 mg/d), low Pi diet (LPD, 500 mg/d) and high Pi diet (HPD, 2300 mg/d), with a wash out period after diet intervention. The data were traditionally detected by ANOVA. In order to overcome limitations of the traditional correlation analysis, we used structural equation model (SEM) as a general framework for a new paradigm of analysis of multiple correlations.

Results: Pi was significantly higher in HPD. In contrast, Ca was lower in HPD. Meanwhile, LDP increased 1,25(OH)D and 25(OH)D. HPD leaded to increasing level of iPTH. With the gradual escalation of Pi intake, the FGF23 were upward trend. However, klotho didn't appear to be affected by dietary intervention by ANOVA. With the traditional comparison, it was difficult to reveal the overall phosphate network regulation. By SEM, we developed 3 networks for phosphate regulation. When healthy individual with regular Pi diet, Ca, Pi, iPTH, FGF23 and klotho formed a precise regulatory network. When HPD or LPD, vitamin D was closely associated with other phosphatonin, suggesting vitamin D played a prominent role in HPD or LPD. FGF23 and klotho had a close relationship in the network, especially in high Pi loads.

Conclusions: By SEM, the importance of klotho in phosphate regulation is revealed with the network diagrams. Meanwhile, the network demonstrates the importance of vitamin D in abnormal phosphate metabolism which need further investigation.

Recurrent GATM Mutations Causing Autosomal Dominant Renal Fanconi Syndrome with Progressive Renal Failure

Ming-Tso Yan,[1,2] Shih-Hua P. Lin.[3,1] *[1]National Defense Medical Center, Taipei, Taiwan; [2]Cathay General Hospital, Taipei, Taiwan; [3]Tri-Service General Hospital, Neihu, Taiwan.*

Background: Inherited renal Fanconi syndrome without extrarenal manifestations, described as Fanconi renotubular syndrome (FRTS), have been reported to be caused by genetic defects in uncertain loci of chromosome 15 (type I), *SLC34A1* (type II) and *EHHADH* (type III). In Type I characterized by autosomal dominant inheritance with late onset FRTS and progressive renal failure, its causative gene mutation is just reported to be caused by *GATM* encoding arginine-glycine aminotransferase (AGAT), an enzyme catalyzing rate-limiting step of creatine biosynthesis.

Methods: A Chinese family with typical autosomal dominant FRTS and progressive renal failure was enrolled. The affected father (age 60 and serum creatinine 6.1 mg/dl with eGFR 12 ml/min) and daughter (age 31, and serum creatinine 1.3 mg/dl, eGFR 50 ml/min) exhibited severe hypophosphatemia and hyperchloremic metabolic acidosis with distinctively osteomalacia as well as hypokalemia despite potassium, alkali, and vitamin D therapy. Sanger's sequencing demonstrated no pathogenic mutations in *SLC34A1* and *EHHADH*. Whole exome sequencing was performed in this family.

Results: Whole exome sequencing discovered a possible culprit missense mutation (p.Thr336Ile) in *GATM*, which mutation was identical to recent report, supporting the pathogenic role of *GATM* mutation in this unique type of FRTS. Localization of T336I mutation on 4th β-sheet was suggested to transform 4th β-sheet into a novel additional interaction surface, resulting in formation of linear AGAT multimer rather than physiological

homodimer by interaction between 2nd β-sheet. Because biallelic mutations in *GATM* causes cerebral creatine deficiency syndrome (CCDS) with neurological symptoms but not FRTS, the role of diminished total AGAT activity in pathogenesis of FRTS is unlikely.

Conclusions: *Uniallelic GATM* mutation clustering to a specific region may play a role in pathogenesis of autosomal dominant FRTS. Generation of GATM T336I knock-in mice is warranted to elucidate the mechanism of FRTS and assess the therapeutic role of creatine administration.

FR-PO314

Intrapartum PDE-5 Inhibition Lowers Blood Pressure and Renal Injury in Young Adult Offspring of Preeclamptic Dahl S Rats

Hannah R. Turbeville, Sean Didion, Michael R. Garrett, Jennifer M. Sasser. *University of Mississippi Medical Center, Jackson, MS.*

Background: Up to 10% of pregnancies are complicated by preeclampsia, and up to 15 million Americans are offspring of preeclamptic pregnancies. The Developmental Origins of Health and Disease hypothesis proposes that an adverse intrauterine environment programs the fetus to develop high blood pressure (BP) from early childhood, and evidence shows that offspring of preeclamptic pregnancies have increased risk of hypertension and CKD. Animal models of hypertension in pregnancy have shown that sildenafil citrate, a phosphodiesterase-5 (PDE-5) inhibitor that prolongs NO-cGMP signaling, improves the maternal syndrome of preeclampsia; however, the effects of perinatal use on long term fetal outcomes have not been reported. Here, we test the hypothesis that PDE-5 inhibition during preeclamptic pregnancy improves long-term BP and renal injury in the offspring.

Methods: Female Dahl S rats (n=16) on a 0.3% salt diet, a previously characterized model of preeclampsia, were mated and treated orally with sildenafil (50 mg/kg/day) or vehicle from gestational day 10 to delivery. Lactating dams and offspring were on normal chow for the duration of the study, and measurements were made at 11 weeks of age.

Results: Systolic BP (n=5-9/group, tail cuff) was greater in Dahl S rats of untreated mothers compared to offspring of sildenafil treated dams (VEH: 177±4 mmHg; SLD: 158±2 mmHg; p=0.0001). BP data were pooled due to lack of significant sex differences between treated groups. Tubulointerstitial fibrosis (n=3/group) was measured in kidney sections stained with Masson's trichrome. Tubulointerstitial fibrosis is increased in male Dahl S offspring of untreated mothers as compared with offspring of sildenafil treated dams (Area: VEH: 9.0 ±0.6%; SLD: 5.0 ±0.6%, p=0.006), but no differences were observed in female rats (VEH: 5.3 ±0.7%; SLD: 6.0 ±0.6%). Urine was collected for measurement of urinary protein (Bradford assay), but no significant differences in proteinuria were observed (VEH male: 87 ±23 mg/day; SLD male: 138 ±18 mg/day; VEH female: 64 ±9 mg/day; SLD female: 53 ±7mg/day).

Conclusions: These data support the hypothesis that use of a PDE-5 inhibitor during preeclamptic pregnancy improves the long-term BP and renal injury in the offspring.

FR-PO315

The Role of Renal Claudin-4 Protein in Salt-Induced Hypertension of Spontaneous Hypertensive and Dahl Salt Rats

Gheun-Ho Kim, Sua Kim, Chor ho Jo. *Hanyang University, Seoul, Republic of Korea.*

Background: Claudin proteins in the kidney act as Na^+ barrier or Cl^- channel, and hypotension was reported from renal claudin-4 knockout mice due to urinary Cl^- loss. Our previous study showed that salt-sensitive hypertension was associated with upregulation ofclaudin-4 in Dahl salt rats (DSR). Here we extended our work to see if any changes in renal claudin proteins precede the development of salt-sensitive hypertension in spontaneous hypertensive rats (SHR) and DSR.

Methods: Time course studies were undertaken over two weeks for SHR and one week for DSR. SHR were randomly divided into normal salt-loaded (SN, n=4) and high salt-loaded (SH, n=4) rats at each time point. High salt was offered with 8% NaCl diet. Wistar Kyoto rats (WKR) served as controls and were given normal salt diet. DSR were classified into salt-resistant (SR, n=6) and salt-sensitive (SS, n=6) rats, and both groups were given 8% NaCl diet. Systolic blood pressure (SBP), urine sodium excretion, and renal protein expression of claudin-2, claudin-4, claudin-7, claudin-8, and claudin-10 were serially followed.

Results: At baseline, SBP was higher in SHR than in WKR (137 ± 1 vs. 118 ± 1 mmHg, P<0.05). SBP was not different between SN and SH at Day 7, but was higher in SH than in SN (162 ± 1 vs. 156 ± 1 mmHg, P<0.05) at Day 14. WKR had lower SBPs throughout the period (114 ± 1 mmHg at Day 14). At baseline, claudin-4 (123 ± 1 vs. 100 ± 2%, P<0.05) expression increased in SHR compared with WKR. The expression of claudin-4 was not different between SN and SH at baseline, but increased in SH compared with SN from Day 7 (185 ± 4 vs. 130 ± 2%, P<0.05) to Day 14. In DSR, SBP was not significantly different between SR and SS through Day 3, but increased in SScompared with SR (141 ± 2 vs. 119 ± 1 mmHg, P<0.05) at Day 7. From baseline (174 ± 3 vs. 100 ± 3%, P<0.05) to Day 3 (240 ± 4 vs. 100 ± 3%, P<0.05), claudin-4 expression increased in SS compared with SR. Immunofluorescence localization of claudins in the kidney was compatible with the results of immunoblot analysis.

Conclusions: In response to high salt intake, the increase in renal claudin-4 protein preceded the elevation of SBP in both SHR and DSR. Claudin-4 expression also increased in SHR compared with WKR. These findings suggest the contributory role of renal claudin-4 in salt-sensitive hypertension.

Role of Na/K-ATPase Signaling in Susceptibility to Hypertension in Salt-Sensitive Animal Models

Yanling Yan,[1] Muhammad A. Chaudhry,[2] Ying Nie,[8] Shuyan Sun,[7] Fang Bai,[3] Rebecca Pratt,[2] Cameron Brickman,[4] Komal Sodhi,[5] Jung Han Kim,[2] Deepak K. Malhotra,[6] Zi-jian Xie,[8] Joseph I. Shapiro,[2,6] Jiang Liu.[3] *[1]Marshall University, Joan C. Edwards School of Medicine, Huntington, WV; [2]Marshall University School of Medicine, Huntington, WV; [3]Marshall University JCE School of Medicine, Huntington, WV; [4]Marshall University JCESOM, Huntington, WV; [5]Marshall University Joan C. Edwards School of Medicine, Huntington, WV; [6]The University of Toledo, Toledo, OH; [7]Shijiangzhuang Medical School, Proctorville, OH; [8]Marshall University, Huntington, WV.*

Background: Previous studies from our and our collaborative laboratories have indicated that Na/K-ATPase acts as a receptor for reactive oxygen species (ROS), regulating renal Na^+ handling and blood pressure (JBC, 2011; JAHA, 2016). In the present work, the Na/K-ATPase signaling was investigated in the animal models of salt-sensitive hypertension.

Methods: Studies were conducted with tissues from rats and mice made hypertensive by the salt administration. Na/K-ATPase signaling including phosphorylation of c-Src and ERK1/2 and protein carbonylation (DNP, commonly used as a marker for ROS) was assessed by Western blot(WB). Renal function curve was constructed with high salt diets (HS, 2, 4, and 8% NaCl). Urinary and plasma Na^+ levels were measured by flame photometry.

Results: In the Dahl salt-sensitive hypertensive rat (S), the renal proximal tubules (RPTs) contained significantly more protein carbonylation than did the control (Dahl salt-resistant rat, R) RPTs (Fig. A. NC, Normal chow). Qualitatively similar effects were observed on the Na/K-ATPase signaling from the kidney cortex of three obese rat and mouse models (Fig. B-D). As did Dahl S rat, (Fig. A and in JBC, 2011), Na/K-ATPase signaling was not able to be stimulated by HS (Fig. D), leading to blunted urinary Na^+ excretion and salt-sensitive hypertension in obese TALLYHO/JngJ (TH) mice. More importantly, pNaKtide as an antagonist of Na/K-ATPase signaling attenuated protein carbonylation and c-Src phosphorylation stimulated by a high-fat diet (HF, Fig. C).

Conclusions: All four forms of salt-sensitive hypertension showed significant elevation of baseline Na/K-ATPase signaling when compared to their respective controls, indicating that this aberration in Na/K-ATPase signaling may represent a common signaling defect fundamental to the salt-sensitive hypertensive syndrome irrespective of etiology.

FR-PO317

Tubulo-Glomerular Feedback Independent Hypertension and Kidney Interstitial Fibrosis in DOCA-Salt Mice

Xiaoxiao Shi, Xiaoyan Peng, Dongli Tian, Peng Xia, Yubing Wen, Limeng Chen. Peking Union Medical College Hospital Kidney Lab *Peking Union Medical College Hospital, Beijing, China.*

Background: Sodium transporters and tubulo-glomerular feedback (TGF) play important roles in sodium balance and blood pressure maintanence. Renal adenosine-A1 adenosine receptor (A1AR) pathway, which is mediated by Na-K-Cl cotransporter 2 (NKCC2), is involved in the classic TGF mechanism. This study was to observe the role of sodium transporters and A1AR in salt-sensitive hypertension and associated kidney injury.

Methods: Deoxycorticosterone acetate (DOCA)-salt hypertensive mouse model was established by removal of left kidney, implantation of a DOCA pellet (200mg, 60-day release), and feeding with high salt diet (8%NaCl). Arterial blood pressure and urine electrolyte excretion were determined. Pathological changes, protein and mRNA expression of sodium transporters and adenosine-A1AR pathway were measured in mice kidney.

Results: DOCA-salt and uni-nephrectomy treatment in wildtype C57BL/6J mice led to continuous higher blood pressure, accompanied by obvious tubulo-interstitial injury and interstitial fibrosis at different ages (4w, 8w). In DOCA-salt wildtype mice, the Na^+-Cl^- cotransporter (NCC) and NKCC2 upregulation (1.6-1.75 times) were observed in kidney, with activation of adenosine-A1AR pathway (mRNA expression of adenosine synthetase CD73 and A1AR about 2-3 times increased). DOCA-salt mice also showed signs of glomerular hyperperfusion and hyperfiltration, which included polyuria, increased urine sodium excretion and kidney enlargement. Compared with DOCA-salt wildtype mice, the DOCA-salt $A1AR^{-/-}$ mice presented more severe glomerular hyperperfusion and hyperfiltration (including polyuria and increased urine sodium excretion). However, DOCA-salt $A1AR^{-/-}$ mice showed the same degree of hypertension (4w: 125.7±7.4 vs. 127.4±18.8 mmHg; 8w: 135.3±5.2 vs. 141.7±9.5 mmHg; $P>0.05$ both) and renal interstitial fibrosis (4w: 2.05±1.73% vs. 1.52±1.44%; 8w: 10.35±4.86 vs. 9.42±5.95%; $P>0.05$ both), which were compliant with the change of NCC protein expression (4w 1.65 ± 0.19 vs. 1.70 ± 0.18; 8w 1.47 ± 0.21 vs 1.00 ± 0.34, $P>0.05$ both).

Conclusions: DOCA-salt treatment in mice induced hypertension and kidney interstitial fibrosis. The mechanism may lie in NCC activation, instead of NKCC2 associated TGF.

FR-PO318

In Obese ZSF1 Rats Salt-Sensitivity of Blood Pressure Is Positively Related to Free Sodium in Skin and Negatively to Bound Sodium in Skin

Isabel T. Nguyen,[1] Anne-Maj Samuelsson,[2] Jaap A. Joles,[1] Marianne C. Verhaar.[1] *[1]University Medical Center Utrecht, Utrecht, Netherlands; [2]University of Bergen, Bergen, Norway.*

Background: Last year we reported that blood pressure in Zucker fatty/spontaneously hypertensive heart failure F1 hybrid (ZSF1) rats exposed to deoxycorticosterone acetate (DOCA) and fed a high salt diet is more salt-sensitive in obese than in lean ZSF1 rats ($p<0.0001$). Moreover, obese females were even more salt-sensitive than obese males ($p<0.01$). Only male obese ZSF1 were hyperglycemic and manifested glycosuria (Nguyen et al. ASN 2017). This follow-up study dissects the role of free and bound sodium in the skin on the differences in salt-sensitivity between female and male obese ZSF1 rats.

Methods: Male and female ZSF1 rats, lean (N=4-6/subgroup) and obese (N=6-8/subgroup), were either implanted with a DOCA pellet and fed a high salt diet (6% NaCl) or with a placebo pellet and fed a normal salt diet from 19 weeks of age. Every two weeks, from 18 (i.e prior to pellet implantation) to 26 weeks of age, systolic blood pressure (SBP) and 24-hours urine was collected. To further elucidate the diverging natriuresis-pressure relations in the obese ZSF1, skin sodium content was determined at 26 weeks (N=2-4/group).

Results: On placebo, obese male ZSF1 showed more free sodium in skin than obese females (p=0.03). However, on DOCA+salt, obese females showed higher free sodium compared to obese males (p=0.053). The interaction between sex and DOCA+salt on free sodium in skin was very significant (p=0.002). For bound sodium in skin changes were in the reverse direction (interaction: p=0.036). Overall (N=6), the increase in blood pressure/natriuresis on DOCA+salt from week 18 to week 26 correlated positively with free sodium in skin (r=0.91, P=0.01; Figure 1A) and tended to correlate negatively with bound sodium in skin (r=0.69, P=0.13; Figure 1B).

Conclusions: Our results indicate that in obese ZSF1 rats inverse relations exist between salt sensitivity of blood pressure and free versus bound sodium in the skin. Compartmentalization of sodium in the skin is influenced by sex, which in this model may be associated with differences in glycemia.

Funding: Private Foundation Support

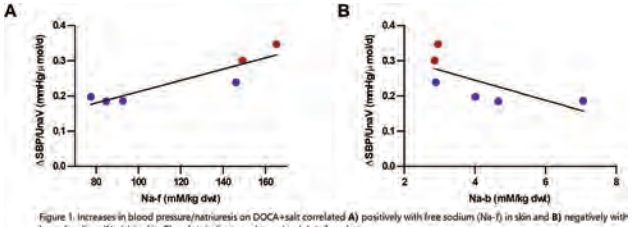

Figure 1. Increases in blood pressure/natriuresis on DOCA+salt correlated **A)** positively with free sodium (Na-f) in skin and **B)** negatively with bound sodium (Na-b) in skin. Blue dots indicate males and red dots females.

Deletion of SPAK (Stk39) Reduces Hypertension, NKCC2 Phosphorylation and NKCC2 Activity in Dahl Salt-Sensitive Rats

Jose A. Garcia-Pedraza,[1,2] Tang-Dong Liao,[1] Pablo A. Ortiz.[1] *[1]Henry Ford Hospital, Detroit, MI; [2]University of Salamanca, Salamanca, Spain.*

Background: The Na/K/2Cl cotransporter NKCC2 mediates the NaCl reabsorption in the thick ascending limb (TAL), playing a crucial role in blood pressure regulation. NKCC2 can be phosphorylated by the SPAK kinase (*Stk39*) at $Thr^{96,101}$ and this is thought to activate NKCC2. We found that NKCC2 phosphorylation was 5-fold higher in TALs from Dahl salt-sensitive (DSS) rats. However, the role of SPAK in NKCC2 function and salt-sensitive hypertension remain unclear. We hypothesized that SPAK is involved in salt-sensitive hypertension in part by increasing NKCC2 phosphorylation and activity.

Methods: To test this, we generated SPAK knockout (KO) rats in a DSS genetic background *via* Crispr/Cas9 targeting. We used telemetry to measure systolic blood pressure (SBP) on normal (0.22% Na) or high salt diet (4% Na).

Results: At baseline, SPAK-KO had lower SBP than wild-type DSS (WT) rats (SPAK-KO: 139±1, WT: 153±2 mmHg; p<0.05). After 4 weeks on high salt, SBP rose reaching 162±3 in SPAK-KO and 183±3 mmHg in WT rats (p<0.05). The increase in SBP after feeding a high salt diet was lower in SPAK-KO than WT rats at 7 days (10±1 *vs* 15±1 mmHg, p<0.05), 14 days (14±2 *vs* 19±2 mmHg, p<0.05), and 28 days (22±3 *vs* 30±2 mmHg, p<0.05). We measured total and phospho-NKCC2 in isolated TALs. On normal salt diet, phospho-NKCC2 ($Thr^{96,101}$) over total NKCC2 was 61±25% lower in SPAK-KO (p<0.05), whereas total NKCC2 was not different. After 4 weeks on high salt, phospho-NKCC2 was 62±13% lower in SPAK-KO (p<0.05) whereas total NKCC2 was not different. SPAK-KO rats had a decreased bumetanide-induced natriuresis while on a normal salt diet (UNa WT: 1271±55; UNa SPAK-KO: 843±80 μmol/12h; p<0.05). Lymphocyte infiltration (CD3+) into the kidney after 4 weeks on high salt diet was not different between strains, whereas CD68+ macrophages were lower in SPAK-KO (WT: 266±35, SPAK-KO: 150±6 CD68+/mm^2, p<0.05).

Conclusions: We conclude that SPAK-KO DSS rats exhibit lower SBP at baseline and reduced salt-sensitivity in part caused by lower NKCC2 phosphorylation and activity. In addition, decreased macrophage infiltration in SPAK KO rats supports a potential role for SPAK in renal inflammation during salt-sensitive hypertension.

FR-PO320

Exogenous Mineralocorticoid Administration and Acute Salt Loading Effects on NCC Expression and Activity in Hypertensives with Raised Aldosterone/Renin Ratio (ARR)

Aihua Wu,[2] Martin Wolley,[2,1] Diane Cowley,[2] Richard Gordon,[2] Robert Fenton,[3] Michael Stowasser.[2] *[1]Department of Nephrology, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [2]Endocrine Hypertension Research Centre, The University of Queensland Diamantina Institute, Greenslopes and Princess Alexandra Hospitals, Brisbane, QLD, Australia; [3]Department of Biomedicine, Aarhus University, Aarhus, Denmark.*

Background: Primary aldosteronism (PA) is a common form of hypertension (HTN) caused by autonomous aldosterone (Aldo) production. Aldo is the major endogenous mineralocorticoid regulating sodium (Na) reabsorption by stimulating the Na-Cl cotransporter (NCC) and the epithelial Na channel (ENaC) in the renal distal tubule. Potassium (K) may also regulate NCC. Exogenous mineralocorticoid and salt loading suppress plasma Aldo, and affect differently NCC and ENaC in human and murine studies.

Methods: Urine samples were collected before and after fludrocortisone suppression testing (FST; fludrocortisone administration and orally salt loading for 4 days) from 13 subjects (10 with HTN and raised ARR and 3 cured of PA by unilateral adrenalectomy); and saline suppression testing (SST; 2L saline infusion over 4h) from 9 subjects (5 with HTN and raised ARR and 4 cured of PA). Urinary exosomes were analysed by immunoblotting.

Results: Significant increases in abundances of NCC (mean 2.97 fold, p=0.04) and pNCC (mean 2.06 fold, p=0.03) by day 4 of FST were observed in 10 with HTN and raised ARR, yet no clear trends of NCC and pNCC were observed in the 3 cured of PA. There were no significant changes in abundance of prostasin, cleaved γ-ENaC and NKCC2 post FST in all 13 subjects, but cleaved γ-ENaC rose post FST (mean 1.17 fold, p=0.05) among the 10 with HTN and raised ARR. There were trends observed towards decreases in abundance of NCC (p=0.09) and pNCC (p=0.07) in 5 with HTN and raised ARR undergoing SST, but not in 4 cure of PA where NCC and pNCC were already low at baseline. The abundances of cleaved γ-ENaC and NKCC2 were unchanged. Plasma Aldo droped in both subjects with HTN and raised ARR (from 328.6 to 180.8 pM, p=0.07) and subjects cured of PA (from 153.75 to 57.25 pM, p=0.05) after SST, but plasma K was unchanged.

Conclusions: Variation of NCC abundance and phosphorylation during FST and SST is detectable in human urinary exosomes. Exogenous mineralocorticoid administration is associated with increases in exosomal NCC and pNCC. The decreases in NCC and pNCC abundance during SST in HTN with raised ARR suggest acute salt loading may induce salt excretion by reducing NCC expression and activity, which may relate to a reduction in plasma Aldo but is independent of plasma K.

Stimulatory Effects of NaCl on Tonic Highly Sensitive Cultured Neurons with Renal Afferents

Kristina Rodionova,[2,1] Amelie Dietz,[2] Martin Hindermann,[2] Tilmann Ditting,[2,1] Christian Ott,[2,1] Roland E. Schmieder,[2] Kerstin U. Amann,[3] Roland Veelken.[2,1] *[1]Medical Department 4, Paracelsus Private Medical School, Nuremberg, Germany; [2]Dept. of Nephrology, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany; [3]Dept. of Nephropathology, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany.*

Background: An important regulatory role of afferent nerve fibers from the kidney has been postulated for a while especially in developing hypertension and counterregulation of salt loading. However, it is not known how salt will act on renal afferent nerves. Hence we wanted to test the hypothesis that even short exposure to low NaCl concentrations will already induce significant action potential generation in cultured neurons with renal axons.

Methods: Over 180 cultured dorsal root ganglion neurons (Th11-L2) of rats with renal afferents *in vitro* were investigated in current clamp mode to asses action potential (AP) generation and classify neurons as tonic (high AP generation upon stimulation) and phasic (AP ≤ 5 upon stimulation). Furthermore, experiments in voltage clamp mode to assess inward currents have been performed. Cultured neurons were exposed to short periods of superfused boli with increasing NaCl concentrations (0.3%, 3%, 4.5%, 10%).

Results: Renal neurons exhibited significant production of action potentials to NaCl superperfusion that was impaired with increasing concentrations of NaCl (0.3%: 36+/-

9.6 APs/10s; 3%: 14.5+/-3.6 APs/10s; 4.5%: 7.8+/-0.7 APs/10s; p<0.05; mean+/-SEM). Superfusion with 10 % NaCl increased AP generation in tonic neurons (15.9+/-3.1 APs/10s, p<0.05; mean+/-SEM) likely due to unspecific e.g. osmotic effects. Phasic neurons were not affected by NaCl. Classification of renal neurons according to their firing pattern (tonic or phasic) revealed the majority of renal neurons to be tonic as previously described.

Conclusions: Superfusion with NaCl in a low concentration led to marked increases of action potential production in tonic, highly active neurons (a characteristic feature of renal innervation) that was impaired with higher superpefused NaCl concentrations in a dose-dependent manner. Hence, NaCl likely influences renal sympathetic nerve activity via the stimulation of renal afferents. However, this effect might be not uniform for all forms and stages of salt loading and hypertension.

Funding: Clinical Revenue Support, Government Support - Non-U.S.

FR-PO322

Neurogenic SP Facilitates Action Potential Production in Tonic Highly Sensitive Cultured Neurons with Renal Afferents

Kristina Rodionova,[1,3] Tilmann Ditting,[1,3] Johannes Schätzl,[1] Martin Hindermann,[1] Christian Ott,[1,3] Roland E. Schmieder,[1] Kerstin U. Amann,[2] Roland Veelken.[1,3] *[1]Dept. of Nephrology, Friedrich-Alexander-University Erlangen Nürnberg, Erlangen, Germany; [2]Dept. of Nephropathology, Univestiy of Erlangen-Nuremberg, Erlangen, Germany; [3]Medical Department 4, Paracelsus Private Medical School, Nuremberg, Germany*.

Background: Release of the proinflammatory peptide SP from afferent nerves has been shown to influence local inflammation. But SP is also involved in a powerful sympathoinhibitory afferent renal nerve pathway with a long time-constant. Hence we wanted to test the hypothesis that SP also influences action potential production related to TRPV1 receptor stimulation in cultured neurons with afferent axons from the kidney in vivo.

Methods: Cultured dorsal root ganglion neurons (Th11-L2) of rats with renal afferents *in vivo* were investigated in current clamp mode to asses action potential (AP) generation and classify neurons as tonic (high AP generation upon stimulation) and phasic (AP ≤ 5 upon stimulation). Furthermore experiments in voltage clamp mode to assess inward currents. For stimulation of TRPV1 receptors acid of pH 6 was used with and without the addition of SP (0.5 µmol) or CGRP (0.5 µmol).

Results: More than 92 DRG neurons with renal afferents were tested. Addition of SP did not change action potential generation nor inward currents. Proton stimulation (pH 6) of TRPV1 significantly increased action potential production in tonic neurons (0 APs/10s vs. 9.57+/-1.89 APs/10s, p<0.05, mean+/- SEM) and augmented long-term inward currents (baseline -361.7 +/- 89.6 pA vs. -1393.3+/-337.3 pA, p<0.05, mean +/- SEM). The co-stimulation of renal neurons with protons (pH 6) and SP increased the number of action potentials per 10 seconds in tonic neurons (9.57 +/-1.89 APs/10s vs. 16.86+/2.3 APs/10s, p<0.05, mean+/- SEM) as compared to a co-stimulation with CGRP, that was not effective in this respect (13.19+/-1,62 APs/10s vs. 9.57 +/-1.89 APs/10s).

Conclusions: SP in contrast to CGRP facilitated action potential production in tonic, highly active neurons with axons from the kidney (a characteristic feature of renal innervation). Hence, SP might increase the sensitivity of afferent renal nerve pathways thus influencing renal sympathetic nerve control.

FR-PO323

Increased Renal Protein Expressions of SLC4A4 and SLC4A5 in Salt-Sensitive C57Bl/6J Mice

Xiaoyan Wang, Xiaobo Ma, Laureano D. Asico, Pedro A. Jose. Hypertension & Renal Diseases *George Washington University School of Medicine, Washington, DC*.

Background: C57Bl/6J mice are salt-sensitive caused, in part, by the dysfunction of the renal dopamine D_1 receptor. However, the role of renal ion transporters in salt-sensitive mice is not well understood.

Methods: Therefore, we studied the effect of varying amounts of sodium intake on the blood pressure (BP) and renal expression of exchanger/transporters/channels for sodium and other ions in salt-sensitive C57Bl/6J mice and salt-resistant BALB/c mice.

Results: We found that 4% NaCl diet given for 1 wk increased the BP (ΔBP=+20 mm Hg) of C57Bl/6J (male, 3 months old, n=5) but not of sex-and age-matched BALB/c mice (n=5). C57Bl/6J mice on high NaCl intake (1.6%, 4%, 6%) had higher BP (ΔBP=+20 mm Hg) relative to when they were on low or normal NaCl intake (<0.09%, 0.6%, 0.8%). The dietary salt-induced increase in BP was observed in anesthetized and conscious, unanesthetized mice, measured by telemetry. There were no differences in water/food intake, urinary excretion, and serum concentrations of Na^+, K^+, and Cl^- between the two mouse strains. However, high salt intake (4%NaCl) increased the renal protein expressions of SLC4A5 (NBCe2) (162±8% *vs.* 100±5%) and SLC4A4 (NBC1) (163±12%) compared with normal salt diet in C57Bl/6J mice, which was not observed in BALB/c mice. By contrast, the 4% NaCl diet increased renal SLC26A6 (Pendrin L1) in both C57Bl/6J (190±1%) and BALB/c (161±8%) mice. Increased NaCl intake did not affect the renal protein expression of NHE3 in either mouse strain. Renal protein expressions of NCC and αENaC, but not of NKCC2 and γENaC, were decreased by high salt diet in BALB/c, but not in C57Bl/6J mice.

Conclusions: We conclude that the salt sensitivity of BP in C57Bl/6J mice is associated with increased renal protein expressions of SLC4A4 and SLC4A5 and impaired salt-mediated down-regulation of NCC and αENaC.

FR-PO324

Up-regulation of SGLT-5 as a Cause of Fructose-Induced Volume-Dependent Hypertension

Hiroaki Hara,[1] Kaori Takayanagi,[1] Yuka Kitamura,[1] Takatsugu Iwashita,[1] Taisuke Shimizu,[1] Masaaki Terao,[1] Ryo Yamamoto,[1] Yoshimi Okada,[1] Tomonari Ogawa,[1] Koichi Kanozawa,[1] Hajime Hasegawa.[2] Department of Nephrology & Hypertension, Saitama Medical Center, Saitama Medical University *[1]Saitama Medical Center, Saitama Medical University, Kawagoe, Japan; [2]School of Medicine, Saitama Medical University, Kawagoe, Japan*.

Background: Excessive intake of fructose causes a variety of adverse conditions including obesity, hepatic steatosis, insulin resistance, uric acid overproduction and hypertension which is the most common and significant pathological setting. Cause of the hypertension is not known at present. This study aimed to elucidate the underlying mechanism of fructose-induced hypertension by rat model.

Methods: Male SD rats (7 weeks old) were fed by food containing 60% glucose (GLU) and 60% fructose (FRU) for 3, 6 and 12 weeks. Histological, immunohistological and molecular biological analysis, and gene chip study were applied. No difference of calorie and salt intake of individual animal was daily checked by the measured weight of remaining food.

Results: Mean blood pressure and fractional sodium excretion (FENa) of FRU were both significantly higher (BP 12w-GLU: 94.8±3.4 vs 12w-FRU: 103.7±1.2 mmHg; FENa 12w-GLU: 0.084±0.011 vs 12w-FRU: 0.059±0.08%), suggesting that fructose caused ECF volume-dependent hypertension. Glomerular expansion in FRU (glomerular surface area in 12w-GLU: 7495±181 vs 12w-FRU: 9831±164 µm2) was agreed with the increase in the ECF volume. The expression of GLUT-5, fructose entry pathway, and ketohexokinase, phosphatase of fructose, in the proximal tubule were both up-regulated by fructose. As a candidate of fructose-induced salt reabsorption pathway, NHE3 was focused first because it is principal salt reabsorption pathway of proximal tubule. However, gene expression analysis, immunohistochemistry and immunoblotting of whole and phosphorylated NHE3 indicated negative results. To explore salt transporting molecules responding to fructose, gene chip analysis was conducted, and *Slc5a10*, corresponding to SGLT-5, showed significant up-regulation. The result was confirmed by RT-PCR (12w-GLU: 75.0±5.8% vs 12w-FLU: 230.1±16.0%), and SGLT-1 mRNA was also confirmed to be up-regulated (12w-GLU: 127.9±15.1% vs 12w-FLU: 214.8 ±37.4%).

Conclusions: Excess intake of fructose caused volume-dependent hypertension due to increased salt reabsorption through fructose-induced up-regulation of SGLT-1 and 5.

FR-PO325

Sympathetic Nervous System Regulation of the NCC Is Mediated by α1-Adrenoceptors and OxSR1 to Drive Hypertension

Franco J. Puleo, Alissa Frame, Richard D. Wainford. *Boston University, Boston, MA.*

Background: Recent studies suggest that Sympathetic nervous system (SNS) release of norepinephrine (NE) mediates acute sodium chloride cotransporter (NCC) upregulation via synergistic α1 and β adrenoceptor pathways and oxidative stress responsive 1 (OXSR1) signaling in NCC regulation. **Hypothesis:** NE increases NCC activity via an α1-adrenoceptor and OxSR1 pathway to drive neurogenic or salt sensitive hypertension (HTN, SSH).

Methods: Male Sprague-Dawley (SD) rats receiving a continuous s.c. saline, NE (600ng/min), or NE + terazosin (α1 antagonist, 10mg/kg/day) infusion were fed a 0.6% (NS) or 4% NaCl (HS) diet for 14 days. Naïve or 14 day s.c. terazosin infused spontaneous hypertensive rats (SHR) and Wister Kyoto (WKY) rats were also assessed (N=4/gp). On day 14 basal MAP and NCC activity (peak natriuresis to hydrochlorothiazide [HCTZ]; 2mg/kg) were assessed. NCC, phosphoNCC, and OXSR1 protein levels were assayed via immunoblotting. Expression of adrenoceptor mRNA (α1A-D, β1, β2) was assessed via qPCR using kidney samples from separate groups of rats (N=6/gp).

Results: SD rats remain normotensive on a HS diet and NCC expression and activity is downregulated. NE infusion prevents HS-evoked NCC downregulation, leads to increased OXSR1 expression, and drives SSH. The SHR model of neurogenic HTN shows increased NCC activity and high BP. SHR and NE-infused SD rats show increased expression of α1-adrenoceptor-1D mRNA (SHR: 1.4±0.1 fold increase vs. WKY rats, NE-infused SD rats on NS: 2.2 ±0.5 fold increase, on HS: 2.2±0.4 fold increase vs. respective SD rat diet group). Antagonism of α1-adrenoceptors 1) abolishes SSH and restores HS evoked downregulation of NCC activity in NE-infused SD rats, 2) reduces NCC activity and BP in SHR.

Conclusions: SNS release of NE can modulate NCC activity via an α1-adrenoceptor pathway to evoke SSH and neurogenic HTN. Taken together, we propose a model whereby SNS release of NE activates a linear α1-adrenoceptor pathway that stimulates OxSR1-mediated NCC regulation. Thus, sympathetically driven increases in renal expression of α1-adrenoceptors may contribute to SSH and HTN by driving increases in NCC mediated sodium reabsorption and BP.

Increased Proximal Tubule Sodium Avidity Among African Americans vs Whites with CKD Correlates with Blood Pressure

Anna L. Zisman,[1] Brianna Lambert,[1] Stuart M. Sprague,[2] Fredric L. Coe,[1] Elaine M. Worcester.[1] *[1]University of Chicago, Chicago, IL; [2]NorthShore University HealthSystem University of Chicago Pritzker School of Medicine, Chicago, IL.*

Background: Since African Americans (AA) adapt to higher sodium (Na) intake mainly with a fall in Na reabsorption in the distal nephron and whites (W) via a fall in the higher capacity proximal tubule (PT), AA might be less efficient in adaptation to Na loads. This could lead to greater fluid and Na retention and hypertension both with high Na diet and chronic kidney disease (CKD), which has not been previously studied. We sought to compare patterns of nephron segment Na reabsorption using endogenous lithium and iohexol clearances in individuals across race and levels of kidney function.

Methods: 17 subjects (7 male; 10 AA, 9 of the total with CKD with mean GFR 55 ml/min) were recruited. Subjects with CKD, if treated for hypertension, were weaned off all medication for at least one week prior to study date using a low sodium diet. Subjects could participate in the study day only if their blood pressures (BP) remained <150/90 during the washout. All subjects were placed on an 80 meq/day sodium diet for 1 week prior to study date. Subjects were admitted to the CRC and continuous iohexol infusion (with bolus) was initiated. Urine and serum laboratory measurements including basic chemistries and lithium were collected at baseline and during six 40-minute clearance periods, with a standardized meal served after the 3rd clearance period. BPs were measured with each blood draw.

Results: Fractional excretion of lithium (FELi) was markedly higher in CKD (0.28 vs. 0.15, p<0.0001) and in W (0.27 vs. 0.17, p<0.0001) (Figure). This correlated to mean systolic BP (CKD AA 135 mmHg vs control AA 116 mmHg, p<0.05, and vs W CKD 115 mmMg p<0.001).

Conclusions: PT sodium avidity is significantly higher in AA subjects in health and in CKD and directly correlates with BP.

Mineralocorticoid Receptor Antagonism by Finerenone Improves Diastolic Dysfunction Induced by CKD in Mice

Benjamin Bonnard,[1] Marie Pieronne-Deperrois,[2] Zoubir Djerada,[2] Soumaya El moghrabi,[1] Peter Kolkhof,[3] Antoine Ouvrard-Pascaud,[2] Paul Mulder,[2] Frederic Jaisser,[1,4] Smail Messaoudi.[1] *[1]Cordeliers Institute, Paris VI-University, INSERM U1138, Paris Cedex 13, France; [2]Normandie Univ, UNIROUEN, FHU- REMOD-VHF, INSERM 1096, Paris, France; [3]Cardiology Research, BAYER AG, Wuppertal, Germany; [4]Clinical Investigation Centre 1433, INSERM, Vandoeuvre-lès-Nancy, France.*

Background: Managing the cardiovascular complications of renal failure is a major therapeutic challenge in clinical practice. Mineralocorticoid Receptor (MR) blockade is a highly effective strategy for the management of heart failure, but the use of MR antagonists (MRA) is limited by their side effects rendering them contraindicated in patients with renal failure. Finerenone is a new non-steroidal MRA that has demonstrated in more than 2000 patients with heart failure and additional chronic kidney disease (CKD) as well as in patients with diabetic kidney disease that neither hyperkalemia nor reductions in kidney function were limiting factors to its use. The aim of this study is to characterize the effects of finerenone on the cardiac complications of renal failure in a mouse model of CKD.

Methods: CKD was induced by subtotal nephrectomy (Nx), and finerenone was administered at a low dose (2.5 mg/kg/d) from week 4 to week 10 post-Nx. Cardiac function was assessed by echocardiography and invasive hemodynamic while cardiac fibrosis was measured by Sirius Red staining.

Results: Renal failure induced cardiac systolic and diastolic dysfunctions as well as minor changes on cardiac structure in untreated CKD mice. We also observed alterations in the phosphorylation of proteins playing key roles in the calcium handling (phospholamban, calmodulin kinase II) in these mice. Finerenone prevented most of these lesions without interfering with renal dysfunction.

Conclusions: The benefits of finerenone suggest that MR plays a key role in the development of diastolic dysfunction induced by CKD, thus providing a rationale for further clinical studies with MRAs in patients with CKD.

FR-PO328

Systemic Succinate Homeostasis and Local Succinate Signaling Control Blood Pressure and Modify Risks for Calcium Oxalate Lithogenesis

Ehud Ohana, Ahlam Khamaysi, Liana Shimshilashvili. *Ben Gurion university of the Negev, Beer Sheva, Israel.*

Background: Succinate and citrate are important metabolic signaling molecules. In the kidney, low urinary citrate increases the risk for developing kidney stones, while an elevation of luminal succinate in the juxtaglomerular apparatus increases renin secretion and can cause hypertension. Although the association between kidney stone formation and hypertension is well established in humans, the molecular mechanisms that link these pathophysiologies remain elusive.

Methods: We have utilized electrophysiological measurements, fluorescent imaging and radiolabeled molecules to monitor transport rptoein activity in live cells. In addition we utilized biochemical assays to monitor protein expression and interaction. Finally, slc26a6-/- mice were utilized to test the physiological effects of impaired succinate and citrate homeostasis.

Results: Here, we reveal an intimate relationship between succinate and citrate/oxalate *in vivo* and study the molecular mechanism of this association. Deletion of the succinate/citrate transport inhibitor, the slc26a6 transporter, in male mice resulted in 40% decrease in urinary excretion of succinate, elevated plasma renin and activity-dependent hypertension. Structural modeling confirmed by mutational analysis identified the NaDC-1/slc26a6 interacting surfaces that mediate inhibition of the succinate/citrate transporter, NaDC-1, by slc26a6. This interaction is regulated by the scaffolding protein IRBIT, which interacts with the NaDC-1/slc26a6 complex and is released upon stimulation of the succinate receptor, SUCNR1 to inhibit succinate transport by NaDC-1.

Conclusions: These findings reveal a succinate/citrate homeostatic pathway regulated by IRBIT that controls blood pressure and biochemical risk of calcium-oxalate stone formation and provides a novel potential molecular link between these syndromes. This may have significant clinical implications for stone formation and the associated hypertension.

FR-PO329

Succinate Transport Is Mediated and Regulated by the slc26a6/NaDC-1 Transporters

Ahlam Khamaysi, Ehud Ohana. *Department of Clinical Biochemistry and Pharmacology, Ben Gurion university of the Negev, Beer Sheva, Israel.*

Background: The slc26a6/NaDC-1 system controls citrate absorption from the urinary lumen. Urinary citrate chelates free Ca^{2+} thus protecting against Ca^{2+}-oxalate crystallization. Since the slc26a6/NaDC-1 complex mediates and regulates both citrate and succinate transport, a major question that we asked here is whether the same mechanism controls succinate homeostasis and which molecular determinants mediate slc26a6-NaDC-1 interaction and regulation.

Methods: We monitored protein-protein interaction by coimmunoprecipiatation. Succinate transport was monitored using electrophysiological measurements.

Results: Our structural modeling confirmed by mutational analysis identified the slc26a6/NaDC-1 interacting surfaces that mediate regulation of NaDC-1 by slc26a6. To test our model, we monitored the effects of slc26a6 (E613A) and NaDC-1(K107A, R108A) on NaDC-1–slc26a6 interaction by co-immunoprecipitation (coIP). The slc26a6(E613A) mutant showed reduced interaction with NaDC-1 and reduced inhibition of NaDC-1 activity, assayed as Na+-dependent succinate currents. Although expression of slc26a6 was not affected by the (E613A) mutation, slc26a6(E613A) had ~30% lower Cl^-/oxalate exchange activity. The role of NaDC-1(K107) and NaDC-1(R108) in the NaDC-1–slc26a6 interaction is shown. While NaDC-1(R108A) was inactive (not shown), NaDC-1(K107A) retained its activity. Importantly, however, the interaction between NaDC-1(K107A) and slc26a6 was reduced and NaDC-1(K107A) was not inhibited by slc26a6, which strongly inhibits WT NaDC-1.

Conclusions: These results suggest that NaDC-1-mediated succinate transport is controlled by the interaction between the two transporters, and that their interaction is mediated by E613 at the slc26a6-STAS domain and K107 at the NaDC-1 H4c region.

FR-PO330

Succinate Signaling Regulates Succinate Transport

Liana Shimshilashvili,[1] Ahlam Khamaysi,[2] Ehud Ohana.[3] *[1]Clinical biochemestry and pharmacology, Ben Gurion University of the Negev, Beer sheva, Israel; [2]Clinical biochemestry and pharmacology, Ben Gurion University of the Negev, Beer sheva, Israel; [3]Clinical biochemestry and pharmacology, Ben Gurion university of the Negev, Beer sheva, Israel.*

Background: The SUCNR1 acts as an extracellular succinate sensor and is widely expressed in a variety of epithelial tissues namely the kidney, liver and the intestine. SUCNR1 is a G_q coupled receptor which regulates renin secretion when stimulated in the macula densa. In general, G_q coupled receptors elevate intracellular IP3, that subsequently binds the IP3 receptor (IP3R) and releases IRBIT. IRBIT is the master transport regulator, interacting and modulating the NBC, Slc26a6 and succinate transporters. Here we asked whether succinate receptor stimulation regulates succinate transport via the IP3- IRBIT pathway.

Methods: We monitored SUCNR1 and NaDC-1 mediated succinate transport using fluorescent ion imaging and electrophysiological measurements, respectively. Protein expression was monitored using biochemical techniques.

Results: We found that SUCNR1 activity in transfected human embryonic kidney cells (HEK293) results in intracellular Ca^{2+} release, which is abolished by PLC inhibitor. Moreover, SUCNR1 activity is desensitized by succinate overstimulation. SUCNR1 is expected to result in IRBIT release. We found that IRBIT interacts with the succinate transporter NaDC-1 and regulates succinate transport.

Conclusions: Together, our results suggest that succinate signaling may regulate succinate transport across cellular membranes.

FR-PO331

Low Doses of Intrarenal Bradykinin Induce a Monophasic Sympathoinhibitory Response

Martin Hindermann,[3] Tilmann Ditting,[3,2] Kristina Rodionova,[3,2] Christina Forray,[3] Christian Ott,[3,2] Roland E. Schmieder,[3] Kerstin U. Amann,[1] Roland Veelken.[3,2] *[1]Dept. of Nephropathology, University of Erlangen-Nürnberg, Erlangen, Germany; [2]Medical Department 4, Paracelsus Private Medical School, Nuremberg, Germany; [3]Dept. of Nephrology, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany.*

Background: As recently reported intrarenally administered bradykinin induced a biphasic renal sympathetic nerve response (RSNA) with increases and decreases of RSNA but not uniform sympathoexcitation as previously assumed. The high doses necessary to evoke this biphasic response to bradykinin did not suggest a major physiological role of this observation in renal salt and water handling. Hence, we wanted to test the hypothesis that significantly lower doses of intrarenal bradykinin as previously used will induce a merely monophasic renal sympathoinhibition.

Methods: Groups of anesthetized SD rats (n=6-12) were equipped with femoral catheters (blood pressure (BP) & heart rate (HR) recording, drug application), a renal arterial catheter for one time intrarenal administration (IRA) of Bradykinin (BK 5 nM, 5 µl) or Capsaicin (CAP 1 nM, 10 µl) and a bipolar electrode for RSNA recordings; eventually an intravenous (iv) bolus of the NK1-receptor blocker RP67580 (10*10-3M, 15 µl) was given

Results: IRA Bradykinin and IRA CAP decreased RSNA from baseline 3.8±1.2 µV*sec to 1.3±0.7 µV*sec (5 µl, 5 nM BK, $p<0.05$) and 4.0±0.6 µV*sec to 1.6±0.4 µV*sec (10 µl, 1 nM CAP, $p<0.01$). After reaching the lowest point of RSNA activity at 95 min, both groups showed a slight re-increase of RSNA within the following 55 min (from 1.3±0.7 µV*sec up to 2.4±1.3 µV*sec (BK) and from 1.6±0.4 µV*sec up to 1.9±0.4 µV*sec (CAP)). Suppressed RSNA in both groups could be unmasked by systemic (i.v.) administration of the NK1-blocker (1.4±0.4 µV*sec to 5.0±1.9 µV*sec; $p<0.05$ (BK); 3.5±0.6 µV*sec to 9.7±1.7 µV*sec; $p<0.01$ (CAP)).

Conclusions: Bradykinin is able to reduce renal sympathetic nerve activity in doses that are significantly lower than doses inducing a biphasic sympathoexcitatory/-inhibitory response suggesting a physiological role of bradykinin in renal sympathetic nerve control and hence in neurogenic salt and water handling.

NAD(P)H Oxidase 4 Modulates Generation of Hydrogen Peroxide in Rat Aorta and Kidney Glomerulus During High Salt Intake

Xingsheng Li,[1,2] Wei-zhong Ying,[1,2] Paul W. Sanders.[1,2] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Birmingham Veterans Affairs Medical Center, Birmingham, AL.*

Background: NAD(P)H Oxidase 4 (Nox4) is a unique member of a family of oxidoreductases, because it is a constitutively active enzyme that produces specifically hydrogen peroxide (H_2O_2). The purpose of present study is to test the hypothesis that high-salt intake increases H_2O_2 generation in the aorta and kidney glomerulus through Nox4.

Methods: Sprague-Dawley rats were randomly assigned to receive a low-salt (LS, 0.3% sodium chloride) or high-salt (HS, 8% sodium chloride) diet for 7 days. Additional groups of rats on the LS and HS diets received a Nox4 inhibitor (GKT136901, 60mg/g BW) by gavage in the final two days. Fresh aortic rings and kidney glomeruli were prepared for H_2O_2 measurement using Amplex Red ELISA or C_2DCF fluorescence staining for confocal microscopy. Expression of kidney Nox4 protein was accessed by immunohistochemistry in fixed kidney tissue.

Results: Compared with animals maintained on the LS diet, HS enhanced H_2O_2 generation in the aorta ($P=0.019$); animals that received the HS diet had a 47.4% higher H_2O_2 production than animals on the LS diet. Serial scanning using confocal microscopy of aortic specimens stained with C_2DCF demonstrated that intracellular levels of H_2O_2 in both endothelial and smooth muscle layers of the HS-treated animals were higher than the LS group. Treatment of rats with the Nox4 inhibitor reduced intracellular H_2O_2 levels remarkably in both low- and high-salt treated animals. Production of H_2O_2 by kidney glomeruli in rats that received HS was also higher than LS animals ($P<0.001$), and co-incubation with the Nox4 inhibitor (50µM) inhibited H_2O_2 generation in glomeruli of animals receiving both the LS and HS diets ($P<0.001$). Immunohistochemistry of kidney sections showed that Nox4 protein expression was increased in animals that received HS diet, particularly in outer cortex and medulla. CONCLUSION: In summary, rat aortae and kidney glomeruli from rats on a HS diet showed enhanced H_2O_2 generation, which was attenuated by introducing the Nox4 inhibitor. We conclude that Nox4 participated in the modulation of the salt-dependent increase in H_2O_2.

Conclusions: In summary, rat aortae and kidney glomeruli from rats on a high-salt diet showed enhanced H_2O_2 generation, which was attenuated by introducing the Nox4 inhibitor. We conclude that Nox4 participated in the modulation of the salt-dependent increase in H_2O_2.

PeroxisomeProliferator-ActivatedReceptorαAttenuatesHypercholesterolemia-Induced Serum Sulfatide Abnormalities

Yuji Kamijo, Daiki Aomura, Shigekazu Kurihara, Takayuki Nimura, Makoto Harada. *Department of Nephrology, Shinshu University School of Medicine, Matsumoto, Japan.*

Background: As chronic kidney disease (CKD) patients often develop accompanying cardiovascular disease (CVD), an understanding of the developmental mechanisms of CVD is important for nephrologists. Our past studies have demonstrated that serum levels of sulfatides, which belong to glycosphingolipids regulated by peroxisome proliferator-acitvated receptor α (PPARα) and exert anti-platelet and anticoagulation activities, were decreased in end-stage CKD patients and that serum levels of sulfatides in CKD patients with CVD were lower than in those without. Thus, reduced serum sulfatides in CKD patients is potentially related to CVD development. It is also unknown whether hypercholesterolemia, an important CKD risk factor, affects serum levels of sulfatides with or without PPARα involvement.

Methods: We fed a high-cholesterol (HC) diet to wild-type (WT) and *Ppara*-null (KO) mice and examined the serum level changes of cholesterol and sulfatides, sulfatide metabolism, and oxidative stress, another important factor influencing serum sulfatide levels.

Results: The HC diet caused identical levels of hypercholesterolemia in WT and KO mice. Serum levels of sulfatides and the expression level of CST, a major sulfatide synthase, were significantly decreased in both groups due to cholesterol overload, with significantly lower levels in the KO group. On the other hand, oxidative stress was significantly increased in both groups by cholesterol overload, with significantly higher levels in KO mice.

Conclusions: Hypercholesterolemia via cholesterol overload induced a reduction of serum sulfatide levels, suppression of sulfatide synthase expression, and an increase in oxidative stress. PPARα attenuated serum sulfatide abnormalities by maintaining sulfatide synthesis and reducing oxidative stress. PPARα activation therapy may therefore be useful for preventing CVD in CKD patients with hypercholesterolemia.

FR-PO334

Macrophage Myeloperoxidase Deficiency Attenuates CKD Accelerated Atherosclerosis

Anna V. Mathew, Lixia Zeng, Vetalise K. Cheofor, Nancy F. Roeser, Jaeman Byun, Subramaniam Pennathur. *University of Michigan, Ann Arbor, MI.*

Background: Increased myeloperoxidase (MPO) expression and activity are associated with cardiovascular disease in chronic kidney disease (CKD). We recently demonstrated the presence and catalytic activity of myeloperoxidase in vascular lesions of CKD mice. However, it is not known if modulation of MPO alters development and progression of exaggerated atherosclerosis in CKD.

Methods: Male and female LDL receptor-deficient mice were subjected to sham or 5/6 nephrectomy surgery (CKD). These mice were then irradiated and transplanted with bone marrow from MPO knock-out (MPOKO) mice to induce macrophage MPO deficiency. The mice were then maintained on a high-fat diet for 16 weeks. The extent of atherosclerosis was then assessed with oil red O staining of *en face* aortic sections.

Results: As anticipated, the CKD mice had significantly higher plasma creatinine, lower hematocrit, and decreased body weight when compared to the sham animals within the same group. After radiation, the MPOKO mice have decreased hematocrit and body weight but did not have any change in renal function compared to non-irradiated mice. Quantification of aortic oil red O stained lesional area revealed that CKD MPOKO mice had significantly decreased aortic plaque area compared to CKD mice with normal MPO expression. Both sham mice and CKD mice with MPOKO marrow showed decreased atherosclerosis compared to their wildtype counterparts and had no significant change in atherosclerosis when compared with each other.

Conclusions: Our studies demonstrate attenuation of atherosclerosis with macrophage MPO deficiency in CKD mouse model of atherosclerosis. These results strongly implicate macrophage-derived MPO in the pathogenesis of CKD accelerated atherosclerosis.

FR-PO335

Interleukin-11 Expression Correlates with Hypertensive Kidney Injury in Rat Renovascular Hypertension

Karl F. Hilgers,[1] Roland Veelken,[1] Kerstin U. Amann,[2] Andrea Hartner.[3] *[1]University of Erlangen, Erlangen, Germany; [2]University Hospital Erlangen, Erlangen, Germany; [3]University Hospital of Erlangen, Erlangen, Germany.*

Background: Interleukin-11 (IL-11) was recently identified as a crucial determinant of cardiovascular fibrosis (Schafer et al. 2017, Nature 552:110). We examined IL-11 expression in the heart and the kidney exposed to high blood pressure in renovascular hypertensive rats.

Methods: Two-kidney, one-clip renovascular hypertension (2K1C) was induced in rats; controls (CON) were sham operated. IL-11 expression was measured by RT-PCR in the left ventricle and the right kidney (exposed to high blood pressure). The correlation of renal IL-11 expression with several biomarkers of kidney injury was assessed. We further investigated IL-11 expression in 2K1C rats grouped into rats with malignant versus non-malignant hypertension (based on weight loss, and the number of typical fibrinoid necrosis and onion skin lesions per kidney section of the nonclipped kidney).

Results: At 35 days after clipping, mean arterial pressure was 207±4 mmHg in 2K1C versus 113±3 mmHg in CON (p=0.004). IL-11 expression in the right kidney was elevated 19.6±3.3-fold in 2K1C (N=17) compared to CON (N=8, p<0.001). In left ventricular tissue there was only a non-significant trend towards higher IL-11 expression in 2K1C compared to CON (2-fold, p=0.121). IL-11 in the right kidney in 2K1C correlated with the expression of TGFβ (r=0.72, p=0.001), TIMP-1 (r=0.71, p=0.001), collagen 1 (r=0.68, p=0.001), PDGF (r=0.81, p<0.001) as well as with serum creatinine (r=0.52, p=0.036). There were also correlations with parameters of inflammation including MCP-1 expression (r=0.78, p<0.001) and macrophage infiltration (ED-1 staining, r=0.73, p=0.001) but no correlation with mean arterial pressure (p=0.299). Rats with malignant 2K1C (N=8) had the highest levels of IL-11 expression in the kidney (28.3±3.7-fold versus 11.9±4.1-fold in non-malignant 2K1C, N=9; p<0.01 by ANOVA and Bonferroni; CON N=6).

Conclusions: Expression of IL-11 in the kidney of renovascular hypertensive rats is markedly increased and correlates with parameters of fibrosis, inflammation and loss of function.

FR-PO336

Dysregulation of a Pro-Inflammatory Signaling Pathway Exacerbates Vascular Calcification Induced by Saturated Fatty Acids

Audrey L. Keenan,[1] Shohei Kohno,[2] Yuji Shiozaki,[2] Shinobu Miyazaki-anzai,[3] Makoto Miyazaki.[3] *[1]University of Colorado AMC, Aurora, CO; [2]University of Colorado Denver, Aurora, CO; [3]University of Colorado-Denver, Aurora, CO.*

Background: Vascular calcification is closely associated with cardiovascular mortality in patients with chronic kidney disease (CKD). We previously reported that saturated fatty acids (SFAs) such as stearic acid promote osteoblastic differentiation and mineralization of vascular smooth muscle cells (VSMCs). We recently found that profound activation of aortic IKKb and NFkB-mediated inflammation occurs in mouse models of vascular calcification such as SMC-specific SCD1/2 knockout mice. However, the pathological relevance of a pro-inflammatory signaling pathway to SFA-mediated vascular calcification in CKD is unknown. In this study, we investigated the role of the IKKb-NFkB pathway in the development of vascular calcification induced by SFAs.

Methods: We generated several in vitro models of IKKb-NFkB pathway activation or suppression using a mouse VSMC line, including VSMCs overexpressing constitutively active IKKb (IKKbCA) and IkBa (IKKb deficient) VSMCs (IkBaKO). For in vivo study, we generated SMC-specific IKKb knockout mice by crossing IKKb floxed mice with an SMC-specific Cre transgenic mouse line, SMMHC-Cre$^{(ER)T2}$, to generate SMC-IKKbKO mice.

Results: IKKbCA significantly increased levels of phosphorylated (active) p65, and reduced levels of IkBa protein, a negative regulator of NFkB, resulting in increased expression of NFkB target genes, including IL-6, MCP-1 and iNOS. Importantly, IKKb activation increased the matrix calcium of VSMCs. In addition to IKKbCA, IkBaKO significantly increased expression of NFkB target genes and matrix calcium induced by stearate treatment compared with wild type VSMCs. We next examined whether IKKb inhibition inhibits calcification of VSMCs. shIKKb inhibited stearate-induced up-regulation of NFkB target genes. Unexpectedly, however, IKKb knockdown significantly accelerated stearate-induced vascular calcification. Consistent with the in vitro study, SMC-IKKbKO mice had significantly larger calcified medial lesions under 5/6 nephrectomy.

Conclusions: This study suggests that the IKKb-NFkB pathway positively and negatively regulates mineralization of VSMCs.

New Myeloid-Derived Cells Attributing to Cardio-Renal Syndrome

Akihiro Sagara,[1] Norihiko Sakai,[1] Yasunori Iwata,[1] Kengo Furuichi,[1] Yasuhiko Yamamoto,[2] Takashi Wada.[1] *[1]Nephrology, Kanazawa University Hospital, Kanazawa, Japan; [2]Kanazawa University Graduate School of Medical Sciences, Kanazawa, Japan.*

Background: Cardiovascular disease is connected to chronic kidney disease (CKD), which is well-known as cardio-renal syndrome (CRS). Dysregulation of tissue repair is a pathological process leading to the end stage of organ failure characterized by tissue fibrosis. However, it remains unknown how fibrosis occurs in CRS under CKD.

Methods: To identify bone marrow (BM)-derived cells responsible for the development of CRS, continuous angiotensin II (AII) infusion plus unilateral ureteral obstruction (UUO) (AII+UUO) CRS model was employed using CAG-GFP mice and Col1a2 (Col)-GFP mice, with procedures of parabiosis and bone-marrow transplantation. Flow cytometry was used to identify recruited and migrated cells into the hearts or kidneys and gene expression analyses were followed by cell sorting. We also used immunohistochemistry and co-culture system of sorted cells with mouse embryonic fibroblasts (MEFs) from Col-Luciferase mice.

Results: We newly identified a cluster of myeloid cells, CD45$^+$Sca1$^+$ cells, in the hearts as well as kidneys of the CRS model. The cell type was a globular and mononuclear and this population was significantly increased in number along with the exacerbation of fibrosis. The CD45$^+$Sca1$^+$ cells had an activating potential for collagen production of the cultured MEFs and an ability of producing type 1 collagen by themselves. GeneChip analyses and flow cytometry showed the subpopulation of the CD45$^+$Sca1$^+$ cells, which expressed CCR8.

Conclusions: We could find a new population of myeloid-derived fibrosis-inducing cells, which were associated with cardiac and kidney fibrosis using our CRS model. Further studies are needed to elucidate the full role of this cell population in CRS under CKD.

Renin-Angiotensin System Mediates Renal Vasoconstriction Induced by Acute Renal Venous Pressure Elevation in Rats

Xiaohua Huang,[1] Shereen M. Hamza,[1] Wenqing Zhuang,[3] William A. Cupples,[2] Branko Braam.[1] *[1]University of Alberta, Edmonton, AB, Canada; [2]Simon Fraser University, Burnaby, BC, Canada; [3]Univ. of Alberta, Edmonton, AB, Canada.*

Background: Combined cardiac/renal dysfunction is characterized by elevated renal venous pressure (RVP). Renin-angiotensin system (RAS) is presumably an important mediator of worsening kidney function at a high RVP. In the present study, our hypothesis is that acute RVP elevation increases vascular tone leading to decreased renal vascular conductance (RVC) can be abolished when endogenous angiotensin II (ANG II) is inhibited. Our objective is to evaluate RVP induced renal hemodynamic response during ANG II inhibition.

Methods: Male Lewis rats (350-450g) received a regular sodium diet were randomized as time control or subjected to RVP increase to 20 mmHg. EndogenousANG II was blocked using Enalapril infusion and mean arterial pressure (MAP) was restored by continuous, constant ANG II (ANG II "clamped", n=18) or vasopressin (AVP)(n=11) infusion. To increase RVP, the left renal vein was partially occluded for 120 min following 60 min baseline. MAP, renal blood flow (RBF) and GFR were continuously monitored.

Results: When ANG II was clamped, elevating RVP (0.4±0.3 to 19.6±0.3 mmHg) induced a reduction of MAP by experiment end (Δ -22±4 mmHg, P<0.05). The RVP-induced RVC reduction previously observed in intact rats was completely inhibited (Δ 0.011±0.005 ml/min. mmHg). ANG II clamp did not prevent the decrease of both RBF (Δ -1.9±0.4ml/min, P<0.05), and ipsilateral GFR (Δ -0.77±0.18 ml/min, P<0.05). In AVP-infused animals, RVP increase (0.1±0.4 to 19.6±0.6 mmHg) did not impact MAP (Δ -5.6±4.0 mmHg). Although RBF decreased (Δ -1.3±0.7ml/min, P<0.05), RVC did not decrease (Δ 0.022±0.011 ml/min. mmHg) and the reduction of GFR was attenuated (Δ -0.45±0.15 ml/min).

Conclusions: RVP induced renal vasoconstriction was abolished and reduction in RBF and GFR was attenuated when ANG II was fixed or inhibited. This suggests a primary role for the RAS in the vasoconstriction induced by increased RVP.

FR-PO339

Hypertension and Proteinuria After Antiangiogenic Drugs: Role of the Renin-Angiotensin-Aldosterone System

Roman A. Shingarev,[1] Sheron Latcha,[1] Insara Jaffer Sathick,[1] Minolfa C. Prieto,[2] Edgar A. Jaimes.[1] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Tulane University, New Orleans, LA.*

Background: Antiangiogenic drugs (AAD) are an effective treatment for many cancers. Hypertension (HTN) and proteinuria (PTN) are frequent side effects of AAD and are common reasons for therapy discontinuation. These effects are thought to be due at least in part to blockade of VEGF in the vasculature and podocytes, but the mechanisms involved are not well understood. Renin-angiotensin-aldosterone system (RAAS) blockade is commonly used for treatment despite the lack of evidence of RAAS activation in this setting. Here, we examine the link bewteen the development of HTN and PTN and intrarenal (IR) RAAS activation.

Methods: Urine albumin/creatinine ratio (ACR) and blood pressure (BP) were measured in 28 prospectively enrolled patients before AAD and on subsequent follow-up visit. Urine angiotensinogen (uAGT) was used as marker of IR RAAS activation and quantified by ELISA, corrected for urine creatinine and assessed for association with HTN and PTN. HTN was defined as BP ≥ 140/90. PTN was defined as > "trace" on urinalysis.

Results: HTN was present in 8 patients at the study start with 50% developing worsening HTN. New HTN developed in 12 patients (60%) and PTN in 10 patients (36%). Mean fold uAGT increase was significantly correlated with fold increase in urine ACR (r=0.39, p=0.04). A 6-fold increase in uAGT was associated with development of HTN and/or PTN, RR= 1.5 (95% confidence interval, 1.1-2.02). Mean fold uAGT increase was greater in patients with incident HTN vs non-HTN and with incident PTN vs non-PTN; however, this trend did not reach statistical significance. Mean baseline uAGT was not predictive of subsequent HTN or PTN.

Conclusions: This study suggests that IR RAAS activation after AAD drugs is responsible at least in part for the development of HTN and PTN in these patients. Larger studies will be needed to better determine whether IR RAAS activation mediates the development of isolated HTN without PTN after AAD.

Association of Hypertension and Proteinuria with Urine Angiotensinogen

Outcome	Neither HTN nor PTN	HTN and/or PTN	Non-HTN	HTN	Non-PTN	PTN
n (%)	7 (25)	21 (75)	12 (43)	16 (57)	18 (64)	10 (36)

ReninNull Cells Synthesize Osteopontin, a Likely Cause of Concentric Renal Arteriolar Hypertrophy

Hirofumi Watanabe, Maria Luisa S. Sequeira Lopez, Roberto Ariel Gomez. *Department of Pediatrics, Child Health Research Center, University of Virginia School of Medicine, Charlottesville, VA.*

Background: *Ren1^c* gene knockout (Ren1KO) mice develop renal failure and a characteristic renal vascular lesion consisting of concentric arteriolar hypertrophy. Recently, we discovered that in Ren1KO mice, the cells programmed for the renin phenotype (*Renin^{null}* cells) survive and increase in numbers along the renal arterial tree, maintain the molecular program of the renin phenotype, and integrate in a chaotic, disorderly manner inside the vessel wall, thus contributing to the vascular abnormality. However, how *Renin^{null}* cells are involved in vascular hypertrophy remains to be elucidated.

Methods: We performed transcriptome analysis of renin cells. To isolate renin cells, we generated mice that express yellow fluorescent protein (YFP) under the control of 5 Kb of the 5' regulatory region of the *Ren1^c* gene. YFP-positive cells sorted from the kidneys of Ren1KO mice were processed for single-cell RNA sequencing (scRNA-seq) and compared to cells similarly processed from wild type mice kidneys. RNAs differentially expressed were verified by *in situ* hybridization using digoxigenin-labeled RNA probes. Plasma osteopontin (OPN) level was examined by ELISA.

Results: Differential expression analysis of scRNA-seq showed 364 genes significantly upregulated in *Ren1^c* wild type cells and 1395 genes significantly upregulated in Ren1KO cells. We identified transcripts of 107 genes corresponding to putative secreted proteins whose expression were found to be enhanced in the cells from Ren1KO mice. Using *in situ* hybridization, the expression of the several identified genes was detected in the hypertrophic arterioles at higher level in Ren1KO mice than control mice. *Spp1* gene that encodes OPN is one of the most significantly upregulated genes in *Renin^{null}* cells. With ELISA, we found that plasma OPN level was elevated in Ren1KO mice than control mice.

Conclusions: *Renin^{null}* cells in the hypertrophic arterioles in Ren1KO mice express secreted protein genes including *Spp1* gene. Further study for the function of these genes may elucidate the mechanisms of vascular hypertrophy.

Mitochondrial NADP+ Dependent Isocitrate Dehydrogenase (IDH2) Deficiency Aggravates High Fat Diet-Induced Hypertension

Mi Ra Noh,[1] Min Jung Kong,[2] Jee in Kim,[3] Kwon Moo Park.[4] *[1]Department of Anatomy and BK21 Plus, School of Medicine, Kyungpook National University, Daegu, Republic of Korea; [2]Kyungpook Nationcal University, Daegu, DaeJeon, Republic of Korea; [3]Keimyung University, Daegu, Republic of Korea; [4]Kyungpook National University, Daegu, Republic of Korea.*

Background: Obesity is a major risk factor for essential hypertension. Oxidative stress is an important pathogenic mechanism of obesity-induced hypertension. Mitochondrial $NADP^+$-dependent isocitrate dehydrogenase (IDH2) plays as a major antioxidant system by production of NADPH, which is an essential player in the glutathione (GSH) and thioredoxin systems for peroxide detoxification antioxidant system. Here, we investigated the role of IDH2 in high fat diet (HFD)-induced hypertension using *Idh2* gene-deleted (*Idh2$^{-/-}$*) mice and wild-type (*Idh2$^{+/+}$*) littermates.

Methods: Eight-week-old *Idh2$^{-/-}$*and *Idh2$^{+/+}$* mice were fed a normal diet (ND) or a HFD for 12 weeks.

Results: HFD accelerated the increase in body weight and mean blood pressure (MBP) compared to those in the ND group in both mice. MBP was higher in *Idh2$^{-/-}$* mice than in *Idh2$^{+/+}$*. Also, the level of cholesterol was greater in *Idh2$^{-/-}$* mice than in *Idh2$^{+/+}$* mice. Whereas, the lipid accumulation in the kidney was greater in *Idh2$^{+/+}$* HFD mice than in *Idh2$^{-/-}$* HFD mice. mRNA levels of renin, angiotensinogen, angiotensin converting enzyme, and angiotensin II receptor type I increased in the HFD mouse kidneys and these increases were higher in *Idh2$^{-/-}$* mouse kidneys than in *Idh2$^{+/+}$* mouse kidneys. However, there were no differences in this renin angiotensin system between ND groups. Mitochondrial damage was observed after HFD feeding in both mice and this damage was more severe in the *Idh2$^{-/-}$* mice than *Idh2$^{+/+}$* mice.

Conclusions: These results indicate that HFD-induced hypertension is worsened by IDH2 gene deletion with greater oxidative stress in the kidneys, suggesting that mitochondrial redox balance is associated with obesity-induced hypertension.

FR-PO342

A New Role of Sox6 in Blood Pressure Regulation

Mohammad Saleem,[1] Conrad Hodgkinson,[2] Jose Gomez.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Medicine, Duke University, Durham, NC.*

Background: Hypertension afflicts about 50% of the U.S. adult population, of which half are unresponsive to treatment. As such, new therapies to treat this disease and its complications are necessary. Renin catalyzes the rate limiting step in the renin angiotensin aldosterone system (RAAS) and is produced and stored by Juxtaglomerular (JG) cells in the kidney. The transcriptional mechanisms that govern renin expression are of great importance to develop new treatments for hypertension. Gene expression profiling indicated that the transcription factor Sox6 is highly expressed in JG cells compared to renal Mesenchymal Stromal Cells (MSCs) in the adult kidney. Moreover, *in vitro* Sox6 knockdown decreased the differentiation of renal MSCs into renin producing cells. These results support a previously undefined role for Sox6 in blood pressure control. Several human genetic studies associate Sox6 with hypertension. We hypothesized that Sox6 is a new transcription factor involved in renin expression control.

Methods: Ren1dCre/Sox6$^{fl/fl}$ (Sox6KO mouse), in which Sox6 is deleted specifically in renin expressing cells was used. *In vivo:* JG cell expansion was induced by 10 days of low sodium diet (0.01% Na) and furosemide (0.1 mg/g body weight). Plasma renin concentration measured by elisa. Expression of genes involved in vasoconstriction, calcium (Ca^{2+}) and sodium (Na) metabolism was measured by qRT-PCR.

Results: *In vivo*, at base line specific Sox6 knock-out animals did not alter plasma renin concentration (575±492 ng/mL Sox6-wt vs 984±400 ng/mL Sox6-KO, N=7-11). However, the expression of several genes involved in vasoconstriction, Ca^{2+} and Na metabolism were solely expressed in the Sox6-KO mice. In contrast to the basal state, Sox6 knockout had a dramatic effect during JG cell expansion. As expected, in wild-type mice plasma renin concentration increased during JG cell expansion. Interestingly, there was a concomitant increase in Sox6 expression. In contrast, specific knock out of Sox6 in renin expressing cells halted the increase in the amount of plasma renin concentration during JG cell expansion (186±123 ug/mL Sox6-wt vs 135±68 ug/mL Sox6-KO, N=17-18, $P<0.05$).

Conclusions: These results support a novel role of Sox6 in renin cell fate and thereby in renal development and blood pressure regulation. This opens new possibilities of renin regulation and the development of new therapeutic targets for hypertension.

The Effect of Microgravity on Central Aortic Blood Pressure

Felix S. Seibert,[1] Fabian Bernhard,[1] Ulrik Stervbo,[1] Benjamin Rohn,[1] Nikolaos Pagonas,[1] Frederic Bauer,[1] Nina Babel,[1] Joachim Jankowski,[2] Timm H. Westhoff.[1] *[1]Ruhr-University Bochum, Germany, Herne, Germany; [2]RWTH Aachen, Aachen, Germany.*

Background: Blood pressure has been traditionally measured at peripheral arteries. In the past decade evidence has grown, that central aortic blood pressure may be a more powerful predictor for cardiovascular events, but data on its regulation are rare. The present work examines the impact of microgravity on central blood pressure for the first time.

Methods: We performed seven parabolic flights with 22 seconds of weightlessness in each parabola. Hemodynamic parameters including central systolic blood pressure were measured non-invasively in a free-floating position in 20 healthy subjects (19-43 years of age).

Results: Arterial elasticity at rest was normal in all participants (augmentation index 14% [interquartile range IQR 10-22], pulse wave velocity 5.2 m/s [IQR 5.0-5.4]). Transition of 1g to 0g led to a significant increase of central systolic blood pressure from 124 (IQR 118-133) to 127 (IQR 119-133) mmHg ($p=0.017$). Cardiac index augmented significantly from 2.5 (IQR 2.2-2.8) to 2.7 (IQR 2.3-3.0) l/min/m2 ($p<0.001$), whilst peripheral vascular resistance showed a decrease from 1.30 (IQR 1.14-1.48) to 1.25 (IQR 1.15-1.40) s*mmHg/ml ($p=0.037$). Peripheral systolic blood pressure did not change significantly ($p>0.05$).

Conclusions: Whereas there is a multitude of studies on the effects of microgravity on peripheral blood pressure, this study provides first data on central aortic blood pressure. An acute loss of gravity leads to a central blood volume shift with an augmentation of cardiac output. In healthy subjects with normal arterial stiffness the compensatory decrease of peripheral resistance does not outweigh this effect resulting in an increase of central blood pressure.

MicroRNAs May Predict End-Organ Damage in Severe Hypertension: An Experimental Animal Model

Knut Asbjørn R. Langlo,[2,1] Gustavo J. Silva,[3] Tina S. Overrein,[4] Ulrik Wisloff,[5,6] Natale Rolim,[7] Stein I. Hallan.[8,1] *[1]Department of Nephrology, Clinic of Medicine, St. Olavs Hospital HF, Trondheim, Norway; [2]K.G. Jebsen Center of Exercise in Medicine, Department of Circulation and Medical Imaging, Faculty of Medicine and Health Sciences, Norwegian University of Science and Technology, Trondheim, Norway; [3]K.G. Jebsen Center of Exercise in Medicine, Department of Circulation and Medical Imaging, Faculty of Medicine and Health Sciences, Norwegian University of Science and Technology, Trondheim, Norway; [4]Division of Pathology and Medical Genetics, Department of Laboratory Medicine, St. Olavs Hospital, Trondheim, Norway; [5]K.G. Jebsen Center of Exercise in Medicine, Department of Circulation and Medical Imaging, Faculty of Medicine and Health Sciences, Norwegian University of Science and Technology, Trondheim, Norway; [6]School of Human Movement & Nutrition Sciences, University of Queensland, Brisbane, QLD, Australia; [7]NTNU, Trondheim, Norway; [8]Department of Clinical and Molecular Medicine, Faculty of Medicine, Norwegian University of Science and Technology, Trondheim, Norway.*

Background: Severe hypertension is a potentially life-threatening condition if complicated by vital organ failure. The clinical challenge is to differentiate patients in risk of these serious complications from those with solely severely elevated blood pressure. Therefore, we aimed to investigate how hypertension-induced end-organ damage altered the level of circulating microRNAs (miRs) in an experimental model of severe hypertension.

Methods: Dahl salt-sensitive rats were randomized in low-salt (LS, N=20: 0.3% NaCl) or high-salt (HS, N=60: 8% NaCl) diet. Mean systolic blood pressure was 152 mmHg (SD 18,2) in the LS group and 205 mmHg (SD 19,9) in the HS group (p<0,001). Hypertensive encephalopathy (HE) and thrombotic microangiopathy (TMA) were accessed by histology, heart failure with preserved ejection fraction (HFpEF) by echocardiography and endothelial dysfunction (ED) by acetylcholine-induced relaxation.

Results: Partial least squares discriminant analysis (PLS-DA) analysis (VIP-score cut-off at 1.2) predicted 28 miRs for ED, 29 miRs for HE, 30 miRs for HFpEF, and 24 miRs for TMA. ROC curve further identified the miRs that better separate disease from non-disease animals: miR-28-5p for ED (AUC=0.778), miR-151-5p for HE (AUC=0.779), let7c-5p for HFpEF (AUC=0.897), and miR-21-5p for TMA (AUC=0.971). Additionally, we have identified a common signature of circulating miRs using (PLS-DA VIP-score above 1,0) for all 4 outcomes (let-7b-5p, miR-21-5p, miR-484, let-7a-5p, miR-130b-3p, let-7e-5p, and miR-342-3p). Interestingly, KEGG analysis revealed an enrichment of pathways related to TGF-beta signaling (p=3.58E-08), adherens junction (p=6.62E-08), HIF-1 signaling (p=4.43E-04), p53 signaling (p=3,280E-03), and ECM-receptor interaction (p=8.11E-03).

Conclusions: This shows that miRs may serve as biomarkers to identify serious end-organ failure in severe hypertension. Analysis also show that different hypertension induced end-organ failures may be caused by common pathways.

Circulating Extracellular miRNAs in Early Pregnancy and Preeclampsia in Women with Chronic Hypertension

Line Malha,[1] Klaas E. Max,[2] Thangamani Muthukumar,[1] Hua Yang,[1] Phyllis August,[1] Thomas Tuschl,[2] Manikkam Suthanthiran.[1] *[1]Weill Cornell Medical College, New York, NY; [2]Rockefeller University, New York, NY.*

Background: Women with chronic hypertension (cHTN) are at an increased risk for developing preeclampsia (PE). Development of biomarkers that foretell PE is an unmet objective. We aim to investigate the hypothesis that circulating extracellular miRNA profiles are predictive of PE in women with cHTN.

Methods: Circulating miRNAs in 57 cell-free EDTA plasma samples collected during 9 to 19 weeks of pregnancy from women with cHTN (RO1 HL 48846. PI: P. August), were characterized by small RNA-derived barcoded cDNA sequencing. 39 samples had >1 million reads (30 samples from women who did not develop PE [No PE group] and 9 samples from women who subsequently developed PE [PE group]). We performed differential expression analysis to identify miRNAs discerning the two groups. Criteria for the selection of predictive miRNA included a base mean >5, an absolute fold change (FC) between groups >2, and an unadjusted P <0.05.

Results: Age, gestational age, race, parity, body mass index and baseline blood pressure were not different between the two groups. The PE group was more likely to have a previous history of PE (6/10 vs. 3/24, *P*<0.001). Differential gene expression analysis identified 19 miRNAs in agreement with the above criteria (Table 1).

Conclusions: Validation that circulating levels of 19 miRNAs in plasma may predict the development of PE in women with cHTN may inform pathogenesis and help design prophylactic strategies.

Funding: Other NIH Support - RO1 HL 48846. PI: P. August

Long-Lasting RNAi Therapeutics Targeting Angiotensinogen Induces a Robust and Durable Antihypertensive Effect

Estrellita Uijl,[1] Katrina M. Mirabito Colafella,[3] Ewout J. Hoorn,[2] Jae B. Kim,[4] Donald J. Foster,[4] Alexander H. Danser.[2] *[1]Erasmus Medical Center, Rotterdam, Netherlands; [2]Erasmus Medical Center, Rotterdam, Netherlands; [3]Monash University, Clayton, NSW, Australia; [4]Alnylam Pharmaceuticals, Cambridge, MA.*

Background: All angiotensin stems from angiotensinogen (AGT). A single dose of small interfering ribonucleic acids (siRNA) targeting AGT may provide long-lasting blood pressure reductions, as it would abolish angiotensin generation. Here we assessed efficacy of AGT siRNA in spontaneously hypertensive rats (SHRs).

Methods: SHRs were treated for 4 weeks with vehicle, siRNA (10 mg/kg; s.c. every 2 weeks), valsartan (31 mg/kg/day; oral), captopril (100 mg/kg/day; oral), valsartan+siRNA, or captopril+valsartan (all groups n=8). Mean arterial pressure (MAP) was measured via radiotelemetry.

Results: Baseline MAP was 137±2 mmHg. ΔMAP was largest after valsartan+siRNA (-67±3 mmHg; P<0.01 vs. captopril+valsartan), followed by captopril+valsartan, captopril, siRNA and valsartan (-55±4, -24±2, -14±1, and -9±2 mmHg, respectively). Valsartan+siRNA reduced cardiac hypertrophy the most (P<0.05 vs. captopril+valsartan). No treatment affected glomerular filtration rate or albuminuria. After 4 weeks, siRNA lowered AGT by 98.6%, which increased to 99.9% in combination with valsartan. All treatments increased renin, the highest rise occurring after valsartan+siRNA. Yet, only valsartan+siRNA lowered angiotensin II. No treatment altered aldosterone. Plasma K^+ tended to increase in all groups, significance being reached only in the valsartan+siRNA group. Both types of dual blockade attenuated normal growth from the second week of treatment onwards.

Conclusions: In conclusion, due to renin upregulation, circulating angiotensin II remained intact even with only 1.4% of AGT left, relative to pretreatment. Consequently, AGT siRNA caused a similar antihypertensive effect as valsartan and captopril. Importantly, when combining siRNA+valsartan, angiotensin II collapsed, and blood pressure decreased synergistically. Given the potential for a low dosing frequency, this novel treatment may address medication adherence problems in patients with resistant hypertension and further development is warranted.

FR-PO347

Impact of Dialysis Access on Right Heart Function

Jamie L. Kennedy, Laura Holsten, Idil Aktan, Andrew D. Mihalek, Sula Mazimba, Brendan T. Bowman, Alden M. Doyle, Thu H. Le. *University of Virginia, Charlottesville, VA.*

Background: Arteriovenous shunts (AVS) are the preferred hemodialysis (HD) access over central venous catheters (CVC) due to lower rates of infection and venous complications. However, AVS may be associated with a higher prevalence of pulmonary hypertension (PH), which is linked to poor kidney transplant outcomes. We assessed the relationship between dialysis access and right heart (RH) function (RHF) in a cohort of patients referred to our center for kidney transplantation.

Methods: We conducted a retrospective analysis of patients who underwent transthoracic echocardiogram (TTE) evaluation. We assessed the frequency of PH with estimated pulmonary artery systolic pressure (PASP) ≥ 50 mmHg, right ventricular (RV) dysfunction, and moderate or greater tricuspid regurgitation (TR). Analyses were performed with SAS, using either chi square, ANOVA, or Fisher's exact test.

Results: We identified 448 patients with TTE and known dialysis access: 69.2% AVS, 19.4% CVC, and 11.4% peritoneal dialysis (PD). Demographics and comorbid conditions were similar across access groups, with the exception of gender and dialysis duration (See Table). The prevalence of RH dysfunction (PH, TR, and RV dysfunction) was lowest in PD patients. Among HD patients, TR was significantly more common in CVC than AVS patients, whereas PH and RV dysfunction were not different. Linear regression modeling of estimated PASP found access, age, and diabetes as significant predictors, and again favored PD over CVC and AVS.

Conclusions: PD patients were less likely to have RH dysfunction than HD patients. The effect of CVC vs AVS was less clear; TR was more common in CVC patients while there was no difference in PH and RV dysfunction. Dialysis access decisions are not randomized, possibly leading to differences unaccounted for in our analysis.

	CVC (n=87)	AVS (n=310)	PD (n=51)	P value
Age (mean ± SD)	55.8 ± 17.5	56.3 ± 13.4	55.9 ± 12.8	0.9424
Male (%)	49.4	59.5	70.6	0.047
Months on Dialysis (mean ± SD)	31.3 ± 28.7	40.2 ± 30.2	28.5 ± 15.5	0.0028

Carotid Intima-Media Thickness Is a Risk Factor to Cognitive Impairment in Dialysis Patients

Ke Zheng,[1] Qian Yujun,[2] Haiyun Wang,[1] Xuemei Li.[1] *[1]Peking Union Medical College Hospital, Beijing, China; [2]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China, Beijing, China.*

Background: Carotid atherosclerosis is closely related to cardiovascular and cerebrovascular disease. Carotid intima-media thickness (cIMT) measurement by ultrasound is the most widely used noninvasive imaging method to assess carotid atherosclerosis, and was considered as a risk factor and predictor of CV disease. With growing concern about the cognitive impairment (CI) and cerebral small vascular disease (CSVD) problem in ESRD 5D patients, some studies were designed to explore the risk factors of them, without convincing conclusion. In this study, we evaluated the relationship between CIMT and CSVD, CI.

Methods: In this retrospective studies, we analyzed the carotid artery ultrasound results of our dialysis cohort of 2013~2014 CSVD/CI study in which the CSVD were assessed by magnetic resonance imaging and cognitive function were assessed by a cognitive test battery (including: global cognitive function, verbal memory, language ability and executive function). According to cIMT measurement, patients were divided into normal cIMT group (cIMT<1mm) and increased cIMT group (cIMT≥1mm). Multivariable analysis was used to explore the relevance between cIMT and CSVD, CI.

Results: 73 dialysis patients (HD and PD) of our CSVD/CI study cohort of 4 received carotid artery ultrasonography. 54.8% (40/73) was diagnosed as increased cIMT. Compared with normal cIMT group, increased cIMT group, was older (62.4yr vs 52.5yr, p<0.001), with lower serum albumin level (37.4g/Lvs39.4g/L,p=0.046) and lower SCr level (860.7umol/L vs 1007.8umol/L, P=0.010). There were no difference of the prevalence of 3 typical features of CSVD (lacunes, CMBs, and WMHs) between two groups. After multivariable analysis, patients with increased cIMT had a 1.27 fold risk of MMSE score reduce, 2.30 fold risk of MoCA score reduce, 23.53 fold risk of Trails A time delay and 61.56 fold risk of Trails B time delay, but cIMT was not relative to CSVD.

Conclusions: Increased cIMT was an independent risk factor of impairment of global cognitive function, executive function,and the impact of cIMT was not induced by CSVD. Carotid artery ultrasonography may be a useful tool of screening high risk of impaired cognitive function patients.

Impact of Hybrid Therapy with Peritoneal Dialysis and Hemodialysis on Cardiac Events

Masataka Banshodani, Misaki Moriishi, Sadanori Shintaku, Shinichiro Tsuchiya, Hideki Kawanishi. *Tsuchiya General Hospital, Hiroshima, Japan.*

Background: The impact of hybrid therapy with peritoneal dialysis (PD) and hemodialysis on cardiac events in PD patients remains unclear.

Methods: PD patients, who underwent the hybrid therapy for at least 3 years, were divided into low cardiac function (LCF, left ventricular ejection fraction [LVEF] < 60%) and normal cardiac function (NCF, LVEF ≥ 60%) groups by cardiac function at the initiation of the hybrid therapy. In these patients, emergency hospitalization rate for cardiovascular diseases (CVDs) (hospitalizations/patient-dialysis years) and echocardiographic parameters (mean ± standard deviation) were evaluated.

Results: The mean age and PD vintage at the initiation of the hybrid therapy in both groups were the followings: LCF group (n = 29), 57.0 ± 11.8 and 3.6 ± 3.3 years; NCF group (n = 64), 58.0 ± 10.8 (P = 0.7) and 4.5 ± 3.2 (P = 0.2) years. The 1-year emergency hospitalization rate for CVDs significantly decreased after the initiation of the hybrid therapy in both groups: LCF group, 0.36 to 0.11 (P = 0.02); NCF group, 0.45 to 0.09 (P < 0.001). In longitudinal analyses for 3 years after the initiation of the hybrid therapy using generalized linear mixed models, in LCF group, LVEF (44.1 ± 15.0%) significantly improved 1 (53.2 ± 18.2%), 2 (55.5 ± 16.7%), and 3 (57.7 ± 17.0%) years after the initiation (every P < 0.05), whereas, in NCF group, LVEF (68.4 ± 5.5%) was maintained at the same level 1 (67.1 ± 7.9%), 2 (66.9 ± 8.7%), and 3 (68.1 ± 9.0%) years after the initiation (every P > 0.05). Moreover, in LCF group, LV mass index (LVMI) (189.1 ± 41.2 g/m^2) decreased 1 (177.7 ± 35.3 g/m^2, P = 0.8), 2 (159.5 ± 44.8 g/m^2, P = 0.008), and 3 (166.4 ± 46.8 g/m^2, P = 0.05) years after the initiation, whereas, in NCF group, LVMI (156.8 ± 44.7 g/m^2) was maintained at the same level 1 (152.8 ± 40.4 g/m^2), 2 (154.6 ± 54.4 g/m^2), and 3 (158.5 ± 52.2 g/m^2) years after the initiation (every P > 0.05).

Conclusions: The hybrid therapy may decrease CVDs and improve cardiac function in PD patients with LCF.

FR-PO350

No Association Was Observed Between Aortic Arch Calcification and Mortality in Hemodialysis Patients

Toma Hamada. Team Yokochi *Division of Nephrology, Kanto rosai hospital, Kanagawa prefecture Nakahara ward kizuki sumiyoshicho 1-1, Japan.*

Background: Vascular Calcification (VC) is common in end-stage renal disease. Previous reports have shown that Aortic Arch Calcification (AoAC) score is associated with poor outcomes in general population. We assessed the utility of AoAC score at initiation of hemodialysis.

Methods: In this study, 115 patients who initiated Hemodialysis in our facility from January 2010 to December 2013 were retrospectively analyzed. The follow-up period was 3 years, and we excluded patients who underwent renal transplantation, transfered to other hospital, and lost to follow up. Two nephrologists retrospectively reviewed chest X-rays to count AoAC score. Using specific scale, we counted the calcification parts from 0 to 16. Patients were classified into 2 groups based on AoAC score : High AoAC score (HC) group (AoAC score ≧ 7) and Low AoAc score (LC) group (AoAC score < 7), and we compared clinical characteristics and outcomes among both groups. Analyses were performed using JMP.

Results: Overall 155 patients were included in the study, 66 % of them were male, mean age was 70.0 ± 10.6 years, mean AoAC score was 6.5 ± 3.6. There was highly significant correlationship between the two nephrologist's AoAC score (r = 0.95, p < 0.05). AoAC score was correlated with age (r = 0.42, p < 0.05) and alkaline phosphatase (ALP) (r = 0.21, p < 0.05), was not correlated with serum phosphate (p = 0.75) and calcium (p =0.50). Kaplan-Meier analysis showed that all-cause mortality rates were significantly higher in HC group compared with LC group (p < 0.05). Logistic regression analysis revealed that HC group patients were significantly high to die within 3 years after initiation of hemodialysis (unadjusted odds ratio 2.90; 95 % CI 1.16 – 7.78; p < 0.05). But, after adjustment for age, sex, presence of diabetes, serum phosphate, calcium, ALP, HC group did not have higher mortality compared with LC group (adjusted odds ratio 1.71; 95 % CI 0.61 – 4.99; p = 0.30).

Conclusions: These results suggested that the severity of Aortic Arch Calcification at initiation of hemodialysis was not an independent risk factor for mortality. But it is well-known, the progression of calcification is associated with poor outcomes, further studies are needed to solve the mechanism of this mysterious discrepancy.

FR-PO351

A Systematic Review of Interventions Targeting Arterial Stiffness in ESRD

Rosendo A. Rodriguez,[2] Richard Hae,[3] Matthew Spence,[3] Beverley J. Shea,[4] Mohsen Agharazii,[5] Kevin D. Burns.[1] *[1]Medicine, Kidney Research Centre, Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada; [2]Medicine, Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada; [3]Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada; [4]Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada; [5]CHUQ-HDQ, Quebec City, QC, Canada.*

Background: Increased carotid-femoral pulse wave velocity (cf-PWV) in end-stage renal disease (ESRD) patients is indicative of both increased arterial stiffness and high risk for cardiovascular and overall mortality. Several strategies have been studied to decrease arterial stiffness in ESRD, using cf-PWV as a monitoring tool. We conducted a systematic review to explore the effect of these interventions on cf-PWV in ESRD patients.

Methods: MEDLINE, EMBASE and EBM databases were searched for all randomised and observational studies that evaluated interventions to improve arterial stiffness in adults with ESRD. The primary outcome was a reduction of cf-PWV and secondarily, the effects on blood pressure (BP). Study screening, selection, data collection and assessment of methodological quality were performed by two independent reviewers. Study-level effect estimates and pooled estimates were provided by computing the mean differences (MD) and 95% confidence intervals (CI) using the DerSimonian and Laird method and the random effects model.

Results: From 6,607 citations identified, 68 studies met eligibility criteria (randomised: 29; observational studies: 39), and 33 studies were suitable for meta-analysis of 7 interventions (Table). Bio-electrical impedance-guided ultrafiltration (UF), low calcium dialysate, intra-dialytic exercise and calcium channel blockers (CCB) effectively reduced cf-PWV, but only UF and CCB decreased BP compared to standard care. Cholecalciferol or cinacalcet did not affect cf-PWV or BP. Kidney transplantation decreased BP but not cf-PWV compared to dialysis.

Conclusions: Bio-impedance guided UF, low calcium dialysate, exercise and CCB reduce arterial stiffness in ESRD patients. The effectiveness of combining these strategies in decreasing adverse cardiovascular events in ESRD patients requires further study in randomised clinical trials.

Funding: Government Support - Non-U.S.

Intervention	Comparator	# of studies	cf-PWV MD (m/s) [95% CI]	Systolic BP MD (mm Hg) [95% CI]
Bio-impedance guided UF	Clinically guided UF	3	-1.93 [-3.54; -0.31]; **p=0.02**	-4.21 [-7.44, -0.97]; **p=0.01**
Low calcium dialysate	Standard calcium dialysate	7	-1.75 [-2.38, -1.13]; **p<0.0001**	-1.0 [-9.59, 7.59]; p=0.82
Intra-dialytic exercise	No exercise	4	-1.11 [-1.98, -0.24]; **p=0.01**	0.36 [-8.76, 9.49]; p=0.94

FR-PO352

Leucine-Rich a-2-Glycoprotein 1 Predicts Cardiovascular Diseases in ESRD Patients

Feng-Jung Yang.[2,1] *[1]Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei, Taiwan; [2]Internal medicine, National Taiwan University Hospital Yulin Branch, Douliu, Taiwan.*

Background: Plasma Leucine-Rich a-2-Glycoprotein 1 leucine rich α-2 glycoprotein (LRG-1) as a novel serum biomarker for various inflammatory diseases such as rheumatoid arthritis and inflammatory bowel disease. Patients with end-stage renal disease (ESRD) are associated with several health-related adverse outcomes including inflammation, atherosclerosis and premature mortality in individuals. Whether level of Plasma Leucine-Rich a-2-Glycoprotein 1may associate with the clinical status of hemodialysis patients is unknown.

Methods: The immunity in ESRD study (iESRD) recruited 169 hemodialysis patients from southern Taiwan. By history taking and detailed chart reviews, baseline co-morbidities were recorded. Peripheral blood was sampled before hemodialysis session and processed immediately. Plasma levels of LRG1 and high-sensitivity C reactive protein were determined by ELISA. Peripheral blood monocyte and T cell differentiation subsets were determined by multicolor flow cytometry.

Results: Among these patients, 100% were LRG-1-seropositive. In the univariate analysis, log level of LRGwas independently associated with the existence of cardiovascular diseases including stroke and peripheral arterial occlusive disease (OR=111.9 95% CI=2.3-5283.3, p=0.016). In a multivariate-adjusted logistic regression model, log level of LRG was independently associated with the existence of cardiovascular diseases including stroke and peripheral arterial occlusive disease (OR=150.9 95% CI=2.3-9684.8, p=0.018) afteradjusting for gender, hemoglobin, DM, hypertension and hs-CRP. Level of LRG-1 positively correlated with both IL-6, CRP and WBC, indicating the accumulation of these cytokines participate in the progression of atherosclerosis.

Conclusions: LRG-1positively correlates with the existence of cardiovascular diseases in ESRD patients. Role of LRG-1 and the associated inflammation response should be further investigated in the pathogenesis of atherosclerosis in this patient population.

FR-PO353

Prognostic Value of Left Atrial Volume Index (LAVi) in ESRD Patients

Shahbaz Sarwar, Sidra Saleem, Haris Naveed, Afshan Ittifaq, Asad Mahmood, Abeera Mansur. *DHMC, Lahore, Pakistan.*

Background: Cardiovascular Disease is the leading cause of death in End Stage Renal Disease (ESRD) patients. Echocardiographic estimation reveals that left atrial volume Index (LAVi) is increased in diastolic dysfunction of left ventricle, hypertensive heart disease and chronic kidney disease patients. LAVi is an established independent risk predictor for mortality in atherosclerotic heart disease. However, LAVi has not been extensively studied in ESRD population. The aim of this study is to assess the impact of LAVi on cardiovascular mortality in hemodialysis patients.

Methods: From January 1, 2013, through April 30, 2018, we evaluated echocardiographic findings of 91 ESRD patients on maintenance hemodialysis. LAVi was categorized as 1 and 2 (1 < 40 mL/m2 and 2 ≥40 mL/m2). All patients had an ejection fraction of greater than 40%. Patient information was collected and data analysed using SPSS version 22 for windows software package.

Results: Out of 91 patients, 34 patients(37.4%) had LAVi greater than 40 ml/m2. Among 34 patients with LAVi greater than 40ml/m2, 64.7% encountered death. The proportion of death was significantly more in LAVi group 2 than in LAVi group 1 (P=0.007). Unadjusted logistic regression analysis revealed that cardiovascular mortality in LAVi group 2 was 3.4 times higher as compared to LAVi 1 (OR=3.39; 95%CI: 1.39-8.25). In survival analysis the patients with increased LAVi (group 2) were at a greater risk of mortality. Although this group also showed an observable difference in survival and a hazard ratio of 1.5 it was not significant(p=0.197).

Conclusions: Increased LAVI is an independent predictor of cardiovascular mortality in End Stage Renal Disease patients.

	Alive			Number of deaths		Crude OR (95%CI)	P Value	Adjusted OR (95%CI)	P Value
	Group	Number	Percentage	Number	Percentage				
Lavi Group	1	37	64.9%	20	35.1%	3.39 (1.39-8.25)	0.007	3.72 (1.44-9.58)	0.006
	2	12	35.3%	22	64.7%				

FR-PO354

Higher Hemodialysis Product Is Associated with Lower Systolic Blood Pressure in Home Hemodialysis Patients

Eric D. Weinhandl,[1,2] Kristine Kubisiak,[1] Debabrata Ray,[1] Allan J. Collins.[1,2] *[1]NxStage Medical, Inc., Victoria, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: Emerging data has clarified that 24-hour ambulatory blood pressure is linearly associated with risk of cardiovascular events. Randomized clinical trials consistently show that increasing hemodialysis (HD) frequency reduces systolic blood pressure (SBP). Thus, the HD prescription may be calibrated to target blood pressure and corresponding cardiovascular risk. We assessed whether Scribner and Oreopoulous' hemodialysis product (HDP) is associated with pre-dialysis SBP in a cohort of home hemodialysis (HHD) patients.

Methods: We analyzed data from US patients who have undergone HHD with the NxStage System One and used Nx2me Connected Health. Data regarding HD frequency, session duration, and pre-dialysis SBP were organized into calendar weeks. We retained all calendar weeks with ≥3 HD sessions. For each calendar week, we calculated the HDP as equal to (mean session duration, in hours) × (number of HD sessions)^2. We fit generalized estimating equations to model separately the associations of pre-dialysis SBP with HDP, HD frequency, and HD hours per week, with adjustment for age and sex.

Results: We analyzed data from 769 patients, 34,340 calendar weeks, and 142,210 HD sessions. Mean age was 54.3 years; 66.4% of calendar weeks were accumulated in male patients. Mean treatment frequency was 4.1 sessions per week, mean (standard deviation) HDP was 56 (28) points, and mean HDP with 3, 4, 5, 6, and 7 sessions was 32, 52, 75, 97, and 122 points, respectively. Mean (standard deviation) pre-dialysis SBP was 135.1 (22.6) mmHg. In a multivariate model, each 10-point increment in the HDP was associated with a 1.5-mmHg decrement (95% confidence interval, 1.1-2.0) in pre-dialysis SBP. Each 5-year increment in age was associated with a 0.4-mmHg increment in pre-dialysis SBP (P = 0.25), and male versus female sex was associated with a 4.8-mmHg increment (P = 0.004). Goodness of fit was best with HDP, moderate with HD frequency, and worst with HD hours per week.

Conclusions: The HDP is a simple-to-use formula that be used to calibrate both treatment frequency and session duration to target a specific change in pre-dialysis SBP. Increased HDP is associated with decreased pre-dialysis SBP, implying that schedules of 3 sessions/week × 3.5 hours/session and 6 sessions/week × 8 hours/sessions are associated with highest and lowest SBP, respectively.

FR-PO355

Effect of Coronary Revascularization on the Association of Elevated Troponin with Post-Dialysis Mortality in Patients with Advanced CKD

Santhosh K. Koshy,[2,1] Lekha K. George,[1] Miklos Z. Molnar,[1] Praveen Kumar Potukuchi,[1] Abduzhappar Gaipov,[1] Manyoo Agarwal,[3] Koshy K. George,[4] Kamyar Kalantar-Zadeh,[5] Csaba P. Kovesdy.[6,1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]Regional One Health - University of TN Health Sciences Ctr, Memphis, TN; [3]University of Tennessee Health Science Center, Memphis, TN; [4]University of Queensland, Memphis, TN; [5]University of California Irvine, School of Medicine, Orange, CA; [6]Memphis VA Medical Center, Memphis, TN.*

Background: Coronary revascularization (CR), supported by its long-term mortality benefit, is indicated for high risk acute coronary syndrome as evidenced by elevated troponin. Patients with CKD often present with higher and sustained levels of troponin due to reduced clearance, causing diagnostic uncertainty and potentially resulting in fewer patients receiving CR. The incidence of CR and its benefits on long-term mortality in patients with advanced CKD and elevated troponin levels is unclear.

Methods: We examined 16,759 US veterans who had troponin measured during the 3 years prior to start of dialysis. We examined the association between troponin level and future CR, and whether or not future CR modifies the association between troponin levels and subsequent mortality. We modelled the risk of mortality associated with the highest recorded troponin level in time-dependent Cox models including the interaction between troponin and future CR, while adjusting for demographics, comorbidities, smoking status, blood pressure, BMI and baseline eGFR.

Results: Patients were 66±10 years old, 97% male, 37% African-American and 77% diabetic. CR was performed in only 326 patients (2%) following a troponin measurement, and higher troponin was associated with future CR (multivariable adjusted hazard ratio and 95%CI in fourth [>0.25 ng/ml] vs. first quartile [<0.03 ng/ml] of troponin: 6.35 [4.26-9.46]). Death occurred in 11,315 patients (67%). Higher troponin was associated with linearly higher mortality in patients who did not undergo CR (Figure). Patients who underwent CR experienced numerically lower risk of death associated with troponin levels compared to those without CR (Figure), but the interaction was not statistically significant.

Conclusions: CR may be associated with lower post-dialysis mortality in patients with advanced CKD and elevated troponin. The potential benefit of CR in this population needs to be explored further in large prospective studies.

FR-PO356

Effects of a Comprehensive Volume Reduction Protocol on Hydration Status and Blood Pressure Control in Hemodialysis Patients

Ken Wilund,[1] Luis M. Perez,[2] Brett Burrows,[1] Alana P. Harris,[1] Jennifer L. Barnes,[3] Lauren Chan.[4] *[1]University of Illinois at Urbana-Champaign, Urbana, IL; [2]University of Illinois, Urbana, IL; [3]Illinois State University, Normal, IL; [4]Oregon State University, Tigard, OR.*

Background: Chronic volume overload remains one of the most vexing problems in hemodialysis (HD) therapy. The purpose of this study was to investigate the impacts of comprehensive volume reduction protocol focused on reducing dietary sodium intake, blood pressure medications, and post-dialysis weight, on HD patient's hydration status and blood pressure.

Methods: Twenty-three maintenance HD patients (age = 56 ± 13.3y, 48% female) completed a 6-month comprehensive volume control protocol consisting of: 1) weekly intradialytic counseling to reduce dietary sodium intake and interdialytic weight gain (IDWG); 2) persistent reductions in post-dialysis weight; and 3) reductions in prescribed blood pressure (BP) medications. The primary outcome was volume overload (VO) measured by bioelectrical impedance spectroscopy. Secondary outcomes included: IDWG, estimated dry weight (EDW), BP, BP medication prescriptions, and dietary sodium intake.

Results: From baseline (BL) to 6 months (6m), significant improvements were noted in VO (BL 3.9 ± 3.9L (BL) vs 6m 2.6 ± 3.4L, p=0.003), post-dialysis weight (BL 89.4 ± 23.1 kg vs 6m 87.6± 22.2 kg; p = 0.012), and EDW (BL 89.0 ± 23.2 vs 6m 86.7 ± 22.5 kg., p=0.009). There was also a trend for a reduction in monthly averaged IDWG (p = 0.053), and dietary sodium intake (BL 2.9 ± 1.6 vs 6m 2.3 ± 1.1 g/day, p=0.13). Neither systolic BP (BL 160 ± 25 vs. 6m 156 ± 23 mmHg, p=0.56) nor diastolic BP (BL 81 ± 20 vs 6m 79 ± 15 mmHg, p= 0.73) changed, though there was a significant reduction in the total number of BP medications prescribed (BL 3.0 ± 1.0 vs 6m 1.5 ± 1.0 BP meds; p<0.01).

Conclusions: Our comprehensive volume reduction protocol significantly improved HD patient's hydration status. While BP did not change, the reduction in prescribed BP medication number suggests improved BP control. Despite these overall positive findings, the magnitude of change in most variables was modest, and cultural changes in hemodialysis clinics may be necessary to realize more robust results.

FR-PO357

Trajectories of Adherence to Thienopyridines After Coronary Stenting in Patients on Dialysis

Benjamin Lidgard,[1] Tara I. Chang,[2] Maria E. Montez-Rath,[2] Wolfgang C. Winkelmayer,[3] Jenny I. Shen.[4] *[1]Harbor UCLA Medical Center, Carson, CA; [2]Stanford University School of Medicine, Palo Alto, CA; [3]Baylor College of Medicine, Houston, TX; [4]LaBiomed at Harbor-UCLA, Torrance, CA.*

Background: Adherence to medications often fluctuates over time. We identified distinct trajectories of adherence to thienopyridines after percutaneous intervention (PCI) with stenting in patients on dialysis and hypothesized that better adherence would be associated with lower risk of cardiovascular events.

Methods: Using the U.S. Renal Data System, we identified all adult patients on dialysis who underwent PCI with stenting from July 2007 to December 2012, filled a discharge prescription for a thieneopyridine, and survived the following 6 months. We applied group-based trajectory modeling to categorize patients into patterns of thienopyridine adherence in the 6 months after discharge. We used Cox regression to estimate the hazard ratios for the composite outcome of myocardial infarction, revascularization, and death associated with each trajectory.

Results: Among 8,296 patients, we identified 4 distinct trajectories of adherence: 1) consistently high adherence, 2) high adherence with gradual decline, 3) moderate adherence with gradual improvement, and 4) moderate adherence with rapid decline (**Figure**). The unadjusted risk of the composite outcome was significantly lower for those with consistently high adherence (**Table**).

Conclusions: Consistently high adherence to thienopyridines was associated with a lower unadjusted risk of cardiovascular events than other trajectories of adherence. Further work to identify correlates of these trajectories may help inform interventions to improve adherence and potentially reduce adverse outcomes.

Funding: NIDDK Support

Hazard Ratios for CV Outcomes

Trajectory (vs. Group 1)	HR (95% Confidence Interval)
Group 1 (consistently high adherence)	reference group
2 (high adherence with gradual decline)	1.15 (1.05-1.25)
3 (moderate adherence with gradual improvement)	1.32 (1.04-1.21)
4 (moderate adherence with rapid decline)	1.19 (1.11-1.28)

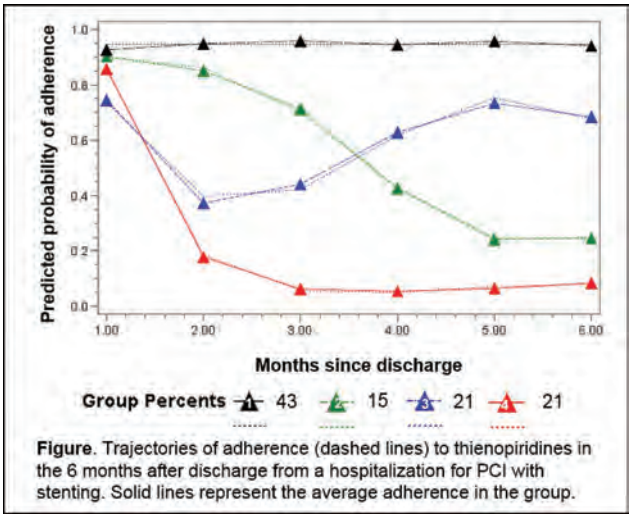

Figure. Trajectories of adherence (dashed lines) to thienopiridines in the 6 months after discharge from a hospitalization for PCI with stenting. Solid lines represent the average adherence in the group.

FR-PO358

The Safety and Efficacy of Clonidine in Hemodialysis Patients: A Systematic Review and Meta-Analysis

Gwendolyn Derk,[1] Amy B. Pai,[2] Ruopeng An,[3] Ken Wilund.[1] Renal and Cardiovascular Disease Research Laboratory UIUC *[1]University of Illinois, Urbana, IL; [2]University of Michigan, Ann Arbor, MI; [3]Univresity of Illinois at Urbana-Champaign, Champaign, IL.*

Background: The United States Renal Data System data shows that 20% of hemodialysis (HD) patients are prescribed clonidine to treat hypertension. Clonidine is a centrally acting alpha 2 adrenergic agonist, and the balance between potential efficacy and its known adverse effects is unknown in HD patients. This study systematically reviewed existing evidence and performed a meta-analysis on the safety and efficacy of clonidine in HD patients.

Methods: Keyword and reference search was conducted through February 2018 in PubMed Cochrane Library, Web of Science, Scopus, and ClinicalTrials.gov databases. Inclusion criteria were - study design: randomized controlled trials, cohort studies, prospective studies, retrospective studies or case series; subjects: adult HD patients; main outcome: blood pressure and safety; language: English; and article type: peer-reviewed publications.

Results: Eight studies met the inclusion criteria, including two prospective pre-post studies, one double-blind controlled trial, one single blinded placebo-controlled trial, one crossover open-label clinical trial, one retrospective analysis, and two case report series. Study durations ranged from 2 to 8 weeks, with a total sample size of 23. Risk of bias was high for all included studies. Significant side effects and adverse events include hypotension, lightheadedness, drowsiness, dry mouth, and rebound hypertension for oral clonidine, as well as contact dermatitis for patch application. Meta-analysis (random effect model) found short-term clonidine use to be associated with significant improvement in systolic blood pressure (pooled effect: -12.985, 95% CI[7.878, 18.092], p<0.001) while changes in diastolic blood pressure were not statistically significant (-11.119, 95% CI[-22.725, 0.487], p=0.060). There is currently no data on the long-term efficacy of clonidine in dialysis patients.

Conclusions: Despite its widespread use, there is no evidence supporting the long-term use of clonidine in the HD population and significant safety concerns. There is low-quality evidence demonstrating the efficacy of clonidine in lowering blood pressure in HD patients in the short term. Clonidine is poorly tolerated and has a potentially dangerous adverse effect profile. Future studies on anti-hypertensives with known cardiovascular benefits should be studied more rigorously in the HD population.

FR-PO359

Arterial Stiffness as a Risk Factor for Subclinical Coronary Artery Calcification in Predialysis CKD: From the KNOW-CKD Study

Young Youl Hyun,[1] Su Ah Sung,[4] Seung Hyeok Han,[2] Soo Wan Kim,[3] Kook-Hwan Oh,[5] Curie Ahn.[5] KNOW-CKD Study Investigators *[1]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [2]Yonsei University College of Medicine, Seoul, Republic of Korea; [3]Chonnam National University Medical School, Gwangju, Republic of Korea; [4]Eulji Medical Center, Seoul, Republic of Korea; [5]Seoul National University Hospital, Seoul, Republic of Korea*.

Background: Both arterial stiffness and coronary artery calcification (CAC) are important predictors of cardiovascular disease (CVD) in the general population and in chronic kidney disease (CKD) patients. Recent studies on arterial stiffness and CAC in subjects with preserved renal function have verified the association between the two. However, the relationship is not well evaluated in CKD patients.

Methods: This cross-sectional study analyzed 1,385 predialysis CKD patients from the KNOW-CKD cohort. Participants were divided into four groups according to brachial-ankle pulse wave velocity (baPWV) quartile. Coronary artery calcium score (CACS) were assessed using cardiac computed tomography and CAC was defined as a CACS >100.

Results: CAC prevalence was higher in the higher baPWV groups (6.4%, 9.8%, 23.7%, and 43.8% for the 1st to 4th quartiles of baPWV, respectively, P<0.001). In Tobit regression analyses (Table) that were fully adjusted for traditional and renal cardiovascular risk factors, the CACS ratio comparing the highest and lowest baPWV quartiles was 3.03 (95% CI, 1.59–6.87). Similarly, the OR for CAC in the highest baPWV quartile compared to the lowest quartile was 1.98 (95% CI, 1.09–3.60) in a fully adjusted multivariate logistic model. Results were consistent across analyses with different cutoffs for CAC or with different clinically relevant subgroups.

Conclusions: Increased arterial stiffness measured by high baPWV was associated with CAC in a predialysis CKD cohort. Further studies are required to explore the role of arterial stiffness in the development of CAC and cardiovascular disease in CKD.

Funding: Government Support - Non-U.S.

Multivariate-adjusted CACS ratios according to baPWV

baPWV quartile	Model 1		Model 2		Model 3	
	Ratios (95% CI)	P	Ratios (95% CI)	P	Ratios (95% CI)	P
1	Reference		Reference		Reference	
2	1.29 (0.67–2.50)	0.448	1.11 (0.59–2.09)	0.740	1.11 (0.59–2.08)	0.745
3	3.91 (1.99–7.68)	<.001	2.08 (1.08–4.01)	0.029	2.03 (1.05–3.92)	0.034

FR-PO360

Vascular Abnormalities in CKD Patients

Nina Hojs,[1,2] Joey Junarta,[6] Robin Ramphul,[3] Racquel M. Lowe-Jones,[7] Juan carlos Kaski,[5] Debasish Banerjee.[4] *[1]University Clinical Centre Maribor, Maribor, Slovenia; [2]Faculty of Medicine, University of Maribor, Maribor, Slovenia; [3]St. George's University Hospitals NHS Foundation Trust, Worthing, United Kingdom; [4]St Georges Hospital and St Georges University of London, Wimbledon, United Kingdom; [5]SGUL, LONDON, United Kingdom; [6]St. George's, University of London, London, United Kingdom; [7]St George's University Hospital, London, United Kingdom*.

Background: CKD patients suffer from excess vascular events. The exact nature of vascular abnormalities and their progression is unknown. The aim of our study was to compare vascular abnormalities and its progression in 3-6 months in different CKD groups and healthy controls.

Methods: A detailed vascular assessment was performed in clinically stable patients (21 CKD stage 2-4, 14 haemodialysis (HD), 22 transplant (TX)) and 21 healthy controls in a quiet, temperature controlled vascular laboratory; at baseline and 3-6 months. Data were analysed with SPSS version 25, P value <0.05 was considered significant.

Results: The carotid intima media thickness (CIMT) differed significantly between all groups at baseline and after 3-6 months. As expected, the lowest values were present in healthy controls and the highest in CKD2-4 and HD patients. Ankle brachial index (ABI) significantly differed between groups at baseline, but not after 3-6 months. Brachial flow mediated dilatation (FMD) didn't differ between groups at baseline or on follow up. Pulse wave velocities (PWV) were significantly different between different groups, with the highest values in HD and CKD2-4 patients and the lowest values in healthy controls. During 3-6 months CIMT increased significantly only in TX patients. ABI significantly decreased in 3-6 months in the CKD2-4 patients. FMD decreased in 3-6 months in TX patients. PWV didn't change significantly in 3-6 months in all groups.

Conclusions: CKD2-4, HD, TX patients and healthy controls differ significantly in CIMT, ABI and PWV, with the most abnormal values present in HD patients. Progression of cardiovascular disease in this short term follow up was variable, with worsening of FMD and CIMT in TX patients.

	CKD2-4	HD	TX	Controls	ANOVA P value
CIMT1 (mm)	7.05±1.44	6.86±1.33	5.89±0.92	5.55 ±1.03	0.000*
CIMT2 (mm)	7.42±1.54	7.08±0.76	6.13±0.98	5.723±1.34	0.001*

The Make-Up of Cardiovascular Disease as Kidney Function Declines: Results from a Population-Based Australian Cohort Study (EXTEND45)

Louisa Sukkar,[1,2] Brendan Smyth,[1] Amy Kang,[1] Min Jun,[3] Celine Foote,[1] Kris Rogers,[1] Brendon L. Neuen,[1] Martin P. Gallagher,[1] Alan Cass,[6] Carol A. Pollock,[4] Germaine Wong,[4] John Knight,[1] David Peiris,[1] Meg J. Jardine.[5] EXTEND45 Steering Committee *[1]The George Institute for Global Health, Sydney, NSW, Australia; [2]School of Public Health, The University of Sydney, Sydney, NSW, Australia; [3]The George Institute for Global Health, UNSW Sydney, Newtown, NSW, Australia; [4]The University of Sydney, St. Leonards, NSW, Australia; [5]The George Institute for Global Health, UNSW, Newtown, NSW, Australia; [6]Menzies School of Health Research, Darwin, NT, Australia*.

Background: The pathophysiological process behind cardiovascular morbidity differs between people with Chronic Kidney Disease and the general population. We aimed to examine the relative contributions of myocardial and endoluminal disease to cardiovascular morbidity as kidney function declined.

Methods: Based on data from the EXTEND45 study (the 45 and Up Study linked to hospital and community pathology datasets by the Centre for Health Record and Linkage[CHeReL]), we identified a population-based cohort (2006-2014) of 41,099 people aged ≥45 years who had a measure of kidney function(estimated glomerular filtration rate[eGFR]). Cardiac hospitalisations were identified using ICD-10 codes and classified into endoluminal (all coronary artery diseaxse including complications), myocardial (all cardiac failure and arrhythmias) or other (all valvular disease and infective cardiac processes). We compared the proportion of endoluminal, myocardial and other causes of hospitalisation by KDIGO stage using the Chi-squared test and the trend in proportions between endoluminal and myocardial causes using the Cochran-Armitage trend test.

Results: Of 41,099 participants 3,177 experienced ≥1 hospitalised cardiac event(1901, 837, 439 endoluminal, myocardial and other respectively) over a median follow-up of 1.9 years. Endoluminal causes as a total proportion of cardiac hospitalisation decreased as kidney function declined(64.5%, 61.8%, 57.2%, 53.1%, 50% for Stages 1, 2, 3a, 3b, and 4-5, respectively) while myocardial(26.7%, 25.5%, 27.0%, 28.1%, 29.6% respectively) causes increased(P-value 0.0005) and this trend was significant(P= 0.02). Other causes were also found to increase(8.8%, 12.7%, 15.9%, 18.8%, 20.5% respectively, P-value 0.0005).

Conclusions: The trend towards a decrease in the proportion of endoluminal and an increase in myocardial causes of hospitalisation with kidney function decline was significant. Understanding risk factors that lead to this divergence in cardiovascular morbidity may help reduce the burden.

Funding: Commercial Support - The EXTEND45 Study is funded through peer-reviewed (NSW Cardiovascular Research Network Collaborative Project Grant) and unrestricted industry (from MSD, Amgen and Eli Lilly) research grants.

Vascular Endothelial Growth Factor C Is Associated with Atherosclerotic Change in Kidney Arteries

Kei Takahashi, Satoru Sanada, Mitsuhiro Sato, Toshinobu Sato, Yoshio Taguma. *Japan Community Health Care Organization Sendai Hospital, Sendai, Japan*.

Background: Vascular endothelial growth factor (VEGF) contains five members in humans. Among them, VEGF-C is known to has a crucial role in lymphangiogenesis, however, some studies have shown that the VEGF-C is associated with atherosclerosis as well. In this study, we observed the VEGF-C expression in kidney arteries using kidney biopsy samples.

Methods: VEGF-A, B and C expressions on arteries greater than intralobular artery were assessed by immunofluorescence histochemistry using 185 kidney biopsy specimens obtained at Japan Community Health Care Organization Sendai Hospital. Atherosclerotic change was scored semi quantitatively. Results were compared with patients' baseline characteristics.

Results: One hundred sixty three specimens which contained more than one interlobular artery were eligible for the study. The age of participants ranged from 14 to 85 and biopsy result included various diseases such as glomerulonephritis, diabetes and hereditary disorders. VEGF-A was positive, and VEGF-B was negative in all arterial samples, whereas VEGF-C was positive in 87 and negative 76 samples. VEGF-C positive

group was older (61.0±14.1 vs 46.6±19.9, p<0.001), showed higher cardio-ankle vascular index (8.39±1.36 vs 7.45±1.43, p<0.001) and higher prevalence of hypertension (72.4 vs 40.8%, p<0.001) compared to that of negative group. Body mass index, serum HbA1c level and serum cholesterol level did not show a statistical significance between the two groups.

Conclusions: VEGF-C expression on the artery could be associated with atherosclerosis in the kidney. This new finding is enabled by kidney biopsy which can obtain arterial samples from a wide age range.

FR-PO363

Fibroblast Growth Factor 23 Is Associated with Biomarkers of Cardiomyocyte Stress/Injury in Patients with CKD

Ana Coloma,[1,2] Pedro Azcarate,[3] Jose M. Valdivielso,[4] Enrique Ramalle-Gomara,[5] Emma H. Loza,[1] Javier Diez.[6] *[1]Nephrology, Hospital San Pedro, Logroño, Spain; [2]Nephrology, Hospital Universitari de Bellvitge, Hospitalet de Llobregat, Spain; [3]Cardiology, Hospital San Pedro, Logroño, Spain; [4]IRBLLEIDA, Lleida, Spain; [5]La Rioja Regional Authority - Logroño - Spain, Logroño, Spain; [6]Centre of Applied Medical Research, University of Navarra, Pamplona, Spain.*

Background: High levels of fibroblast growth factor 23 (FGF23) has been related with left ventricular hypertrophy (LVH) in adults with CKD. In this cross-sectional study, we aimed to determinate the associations between c-terminal FGF23 (ctFGF23), intact FGF23 (iFGF23), serum αKlotho, cystatin C, high sensitive troponin T (hsTnT), prothormone brain natriuretic peptide (NT-proBNP) levels and structural and functional cardiac changes in patients with chronic kidney disease (CKD).

Methods: We enrolled patients with CKD and left ventricular ejection fraction (LVEF) >50%. Patients with atrial fibrillation, history of heart failure, myocardial infarction, pulmonary hypertension, cardiomyopathies, LVEF <50% or parathyroidectomy were excluded. Laboratory parameters including serum creatinine, 24h-proteinuria, mineral bone disorder (calcium, parathormone (PTH), phosphate, tubular reabsorption of phosphate (TRP), phosphate clearance), iFGF23, ctFGF23, serum αklotho, hs-TnT, NT-proBNP were measured. Echocardiographic parameters including LV mass index, relative wall thickness (RWT), volume end-diastolic (VTD), early diastolic mitral annulus velocity (e' velocity), E/e', left atrial volume index (LAVI) and global longitudinal strain (GLS) were measured by the same cardiologist at the same day of blood extraction. The cardiologist was blind for the stage of CKD in each patient.

Results: 120 patients were included. FGF23 was related with 2 biomarkers of cardiomyocyte stress/injury: hsTnT (p<0.05) and NT-proBNP (p<0.05), without finding an association with structural and functional cardiac parameters. However, cystatin C, hsTnT and NT-proBNP were associated with LV mass (p<0.05), RWT (p<0.001), VTD (p<0.001), e'velocity (p<0.001), E/e' (p<0.001), LAVI (p<0.001). We also found that FGF23 was associated with αKlotho (p<0.05), creatinine based-estimated glomerular filtration rate (p<0.001), 24h proteinuria (p<0.001), cystatin C (p<0.001), PTH (p<0.001), TRP (p<0.05).

Conclusions: FGF23 was not associated with structural and functional cardiac changes, but it was associated with two biomarkers of cardiomyocyte stress/injury: hsTnT and NT-proBNP. This finding suggests a relation between FGF23 and remodeling of cardiac tissue in patients with chronic kidney disease.

Longitudinal Changes of Cardiac Structure and Function in Mild to Moderate CKD: Results from the Korean Cohort Study for Outcomes in Patients with CKD (KNOW-CKD)

Eunjeong Kang,[1] Hyunjin Ryu,[1] Minjung Kang,[2] Curie Ahn,[1] Kook-Hwan Oh.[1] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Abnormal left ventricular (LV) structure and function are associated with increased risk of adverse outcomes among patients with chronic kidney disease (CKD). However, little is unknown regarding the natural longitudinal changes in cardiac structure and function especially in early CKD patients.

Methods: This was a longitudinal study of a subset of participants of the KoreaN Cohort Study for Outcome in Patients With Chronic Kidney Disease (KNOW-CKD) who were enrolled from 2011 to 2012. Patients with CKD at stages from G1 to G3b were included if they had serial echocardiograms performed at baseline and again after 4 years. Age, sex, diabetes, CKD stages, hemoglobin, albumin, lipid profile, systolic blood pressure, and baseline LV mass index were included as covariates in the multivariable analysis for risk factors of *de novo* LV hypertrophy (LVH).

Results: A total of 378 patients (57.7% male) were enrolled. The numbers of patients with diabetes and hypertension were 65 (17.2%) and 360 (95.2%), respectively. During the follow-up period for 4 years, mean (SD) estimated glomerular filtration rate was declined from 64.1±27.1mL/min/1.73m^2 to 54.8±30.8 mL/min/1.73m^2. Over 4 years, there was no significant change of LV structure and function among overall subjects. Our subjects were divided into two subgroups based on the baseline eGFR; subgroup I (eGFR ≥60 ml/min/1.73m^2) and subgroup II (30 < eGFR <60 ml/min/1.73m^2). Mean age (SD) was 46.5±11.2 years in subgroup I, and 55.4±10.8 years in subgroup II (*P*<0.001). In subgroup analysis, the prevalence of LVH for subgroup I was similar between baseline and follow-up (18.5% vs. 19.9%). However, for subgroup II, LVH increased from 26.2% at baseline to 52.3% at 4 years. There was no significant change over time in the prevalence of systolic and diastolic dysfunction according to CKD stage. In multivariable logistic regression analysis, only age was associated with development of *de novo* LVH (odds ratio 1.602; 95% confidence interval 1.021-1.105, *P*=0.003).

Conclusions: In conclusion, LV structure and function of mild to moderate CKD patients (eGFR >30ml/min/1.73m^2) did not change significantly over 4 years.

Lanosterol Synthase and Endogenous Ouabain Cooperate in Blood Pressure Control

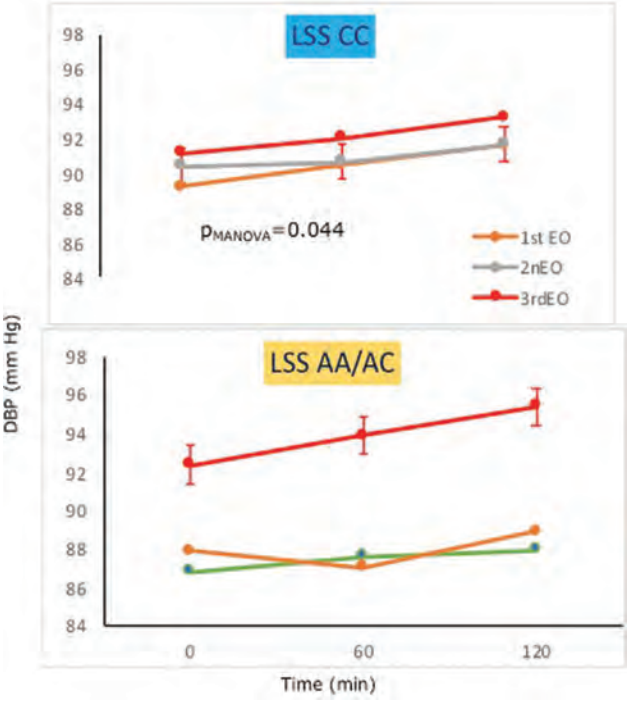
Chiara Lanzani,[1,2] Simone Fontana,[1,2] Marco Simonini,[1,2] Elena Brioni,[1,2] Elisabetta Messaggio,[1,2] Ermira Cuka,[1,2] Simona Delli carpini,[1,2] Lorena Citterio,[1,2] Laura Zagato,[1,2] John Hamlyn,[3] Paolo Manunta.[1,2] *[1]Genomics of Renal Diseases and Hypertension, IRCCS San Raffaele Scientific Institute, Milan, Italy; [2]Chair and School of Nephrology, Università Vita Salute San Raffaele, Milan, Italy; [3]University of Maryland, Baltimore, Baltimore, MD.*

Background: Endogenous Ouabain (EO) is stress hormone secreted from the adrenal glands in response to hemodynamic stimuli. Long term body sodium has been shown to modulate plasma EO levels according to Lanosterol synthase gene polymorphisms. The present study explores the effect of acute saline load according to LSS Gene variants and circulating EO levels in a large cohort of naïve hypertensive patients (NHPs).

Methods: Basal EO was measured in 713 NHPs for acute saline test phenotypes. For the analysis, patients were divided in groups according to tertile distributions of basal EO : 1st group EO <167 pmol/L; 2nd group EO >167 pmol/L and < 268 pmol/L; 3rd group EO >268 pmol/L. In the three groups, we evaluated 1) changes in EO, 2) interaction with LSS variants and 2) blood pressure effects.

Results: Circulating EO was higher among Salt Sensitive NHPs, (geometric mean 224.04 vs 199.81 pM/L,p =0.005) no significant modification was observed during acute maneuvers. However, a significant modulation (p=0.044) was observed between elevated circulating EO and the LSS A variant, and the DBP rise after saline infusion.

Conclusions: These results confirm the role of EO in salt sensitive hypertension. Patients carrying at least one LSS A variant in the presence of elevated EO show an modulatory effect on diastolic BP. The higher affinity of the LSS A variant at tissue levels may account for the enhanced vascular response in these patients. The present findings support a role for LSS and EO in salt adaptation.



FR-PO366

Pharmacologic Control of Arterial Hypertension and Risk of All-Cause Mortality in Older Adults

Antonios Douros,[1] Markus van der Giet,[1] Natalie Ebert,[1] Jens Gaedeke,[2] Martin K. Kuhlmann,[3] Alice Schneider,[1] Elke Schaeffner.[1] Berlin Initiative Study (BIS) Team *[1]Charite Universitätsmedizin Berlin, Berlin, Germany; [2]Dept. of Nephrology, Charité, Berlin, Germany; [3]Vivantes Klinikum im Friedrichshain, Berlin, Germany.*

Background: Hypertension is highly prevalent in older adults and can increase the risk of mortality. Real world data on the effects of disease control in this age group are scarce. Thus, the objective of this population-based analysis was to assess whether pharmacologic control of hypertension has an impact on the risk of all-cause mortality in patients ≥70 yrs.

Methods: All patients were participants in the Berlin Initiative Study (BIS). Demographics, lifestyle factors, medication use, and comorbidities were ascertained in face-to-face interviews. Mortality was assessed using health insurance data including the exact date of death. Cox prop. hazards models yielded adjusted hazard ratios (HRs) with 95% confidence intervals (CIs) of all-cause mortality associated with systolic blood pressure (SBP) <140 mmHg and diastolic blood pressure (DBP) <90 mmHg ('good' disease control) compared to SBP ≥140 mmHg and/or DBP ≥90 mmHg ('poor' disease control). In secondary analyses we assessed the risk of all-cause mortality after stratifying by age (70-79 vs ≥80 yrs) and previous cardiovascular (CV) events.

Results: Among the 2069 participants of the BIS, 1628 (79%) were treated with antihypertensive drugs at baseline. Of those, 636 (39%) showed good disease control (mean age 81 yrs, 51% female) and 992 (61%) poor disease control (mean age 81 yrs, 53% female). Baseline characteristics were comparable between patients with good and poor disease control except for previous myocardial infarction (23% vs 15%) and albuminuria (23% vs 33%). During a follow-up of 8853 person-yrs, 469 patients died. Compared with poor disease control, good disease control was associated with an increased risk of all-cause mortality (HR, 1.27; 95% CI, 1.04-1.55). This effect was augmented in patients ≥80 yrs (HR, 1.41; 95% CI, 1.13-1.76) and patients with previous CV events (HR, 1.68; 95% CI, 1.19-2.38) (Figure).

Conclusions: Reducing BP below 140/90 mmHg could increase the risk of mortality in older adults, in particular among octogenarians and patients with previous CV event.

FR-PO367

Influence of Pre-Diabetes Status on the Effects of Intensive Systolic Blood Pressure (SBP) Lowering in the Systolic Blood Pressure Intervention Trial (SPRINT)

Naveen Rathi, Guo Wei, Robert E. Boucher, Tom Greene, Srinivasan Beddhu. *University of Utah, Salt Lake City, UT.*

Background: Intensive lowering of SBP increased the risk of incident CKD in people with type 2 diabetes mellitus. Hence, we examined the hypothesis that pre-diabetes increases the risk of incident CKD with intensive SBP lowering in persons without diabetes.

Methods: SPRINT tested the effects of intensive (<120 mm Hg) versus standard (<140 mm Hg) SBP goals on CVD outcomes. Diabetes was an exclusion criteria. Based on fasting blood glucose (FBG), we defined normoglycemic group as FBG < 100 mg/dl and pre-diabetes group as FBG ≥ 100 mg/dl in SPRINT participants without CKD at baseline. We defined incident CKD as ≥ 30% decline in eGFR to < 60 ml/min/1.73 m^2 with a second confirmatory value. We examined in Cox regression models whether the risk for incident CKD with intensive SBP lowering differed by pre-diabetes status.

Results: Of the 6678 non-CKD SPRINT participants, 2829 (42.3%) had prediabetes. The baseline characteristics are summarized in the Table. Over 21155 total years of follow-up, there were 164 incident CKD events. The incidence of CKD was higher in the intensive arm compared to standard SBP arm within normoglycemia and pre-diabetes group (Fig 1), with similar hazard ratios (interaction p = 0.47).

Conclusions: Intensive SBP lowering increased the risk of incident CKD in persons with normoglycemia and prediabetes. There was no evidence that the presence of pre-diabetes modified the risk of incident CKD with intensive SBP lowering.

Associations of Early Decline in eGFR with Cardiovascular Disease (CVD) Events in the Systolic Blood Pressure Intervention Trial (SPRINT)

Srinivasan Beddhu,[1] Paul L. Kimmel,[2] Glenn M. Chertow,[3] Alfred K. Cheung,[1] Guo Wei,[1] Robert E. Boucher,[1] Michel Chonchol,[4] Barry I. Freedman,[5] Joachim H. Ix,[6] Michael V. Rocco,[5] Paul K. Whelton,[7] Tom Greene.[1] *[1]University of Utah, Salt Lake City, UT; [2]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [3]Stanford University School of Medicine, Palo Alto, CA; [4]University of Colorado, Aurora, CO; [5]Wake Forest School of Medicine, Winston-Salem, NC; [6]UCSD, San Diego, CA; [7]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA.*

Background: SPRINT examined the cardiovascular effects of intensive (INT) vs. standard (STD) SBP goals (<120 vs. <140 mm Hg). INT SBP lowering resulted in early ↓ in eGFR but the clinical implications are unclear.

Methods: In a post-hoc analysis, based on % change in eGFR from baseline to 6 months, we defined four ΔeGFR groups (Table). Using -5 to +5% group as the reference, we related ΔeGFR groups to CVD events that occurred after 6 months in Cox regression models.

Results: 15% in the STD vs. 26% in the INT SBP arms (p<0.001) had >10% ↓ in eGFR. Key baseline characteristics are summarized in the Table. Unadjusted Kaplan-Meier plots suggested higher incidence of CVD events in the group with >10% ↓ in eGFR within the STD SBP arm, which attenuated in an adjusted Cox regression model (Fig 1). There was no evidence that ΔeGFR groups associated with CVD events in the INT arm (Fig 2).

Conclusions: INT SBP lowering resulted in a higher proportion of persons with >10% ↓ in eGFR but there is no clear evidence that greater ↓ in eGFR was associated with worse CVD outcome in either arm during the trial. Further investigation of the implications of early eGFR ↓ on CVD is warranted.

Ambulatory Blood Pressure (ABP) Is More Important Risk Factor to Renal Outcome in CKD Patients Than Office Blood Pressures

Hyung Eun Son,[1] Ho Jun Chin.[1,2] [1]*Internal medicine, Seoul National University Bundang Hospital, Seongnam, Gyeong-gido, Republic of Korea;* [2]*Medicine, Seoul National University, Seoul, Republic of Korea.*

Background: The prognosis of CKD is strongly associated with blood pressure. However, there are few clinical data suggesting which methods is better for measuring blood pressure and what is the target level of blood pressure to prevent CKD progression.

Methods: We enrolled 387 hypertensive CKD patients from three tertiary referral hospitals in Korea who underwent ABP monitoring and followed for 38.0 months. The primary renal outcome was an incident end stage renal disease (ESRD) which data was collected from the ESRD registry of the Korean Society of nephrology.

Results: The mean office blood pressure was 131.9/79.4 mmHg and the mean ABPs was 131.9/79.4 mmHg. The estimated glomerular filtration rate (GFR) and urine protein to creatinine ratio (UPCR) was 45.0 ± 21.6 ml/min/1.73 m^2 and 1.545 ± 2.278 mg/mg creatinine, respectively. There were 13.4 % (52/387) incident ESRD. The risk factors for an incident ESRD were age, GFR, UPCR, product of calcium by phosphorous at renal biopsy and parameters of blood pressures, such as ambulatory systolic blood pressure (ASBP), ambulatory diastolic pressure (ADBP), ABP grouped by the criteria of 120/80, 130/80, and 140/90 mmHg. The rate of incident ESRD in patients with ABP < 120/80 mmHg was 1.2 %, with ABP 120/80-129/79 mmHg, 12.0 %, with 130/80-139/89 mmHg, 10.2 %, and, with ABP ≧ 140/90 mmHg, 25.4 % (p<0.001). The risk ratios of an incident ESRD in patients with ABP 120/79-129/79, 130/80-139/89, and ABP ≧ 140/90 mmHg were 10.643 (95% CI: 1.032-86.980, p=0.027), 7.489 (95% CI: 0.928-60.408, p=0.059), and 13.518 (95% CI: 1.792-101.952, p=0.012) compared to the risk of ESRD in patients with ABP < 120/80 mmHg, respectively (p for trend=0.002), adjusted by risk factors using the Cox's hazard proportional model.

Conclusions: Office blood pressure was not appropriate measurement to guide BP control in CKD patients. Lower criteria of ambulatory blood pressure would be recommended for prevention of ESRD in CKD patients.

Effect of Chronotherapy on BP Pattern and Renal Function in CKD III-IV: A RCT

Vaibhav Tiwari,[1] Raju K. Sahu.[2] [1]*nephrology, ipgmer, Kolkata, India;* [2]*IPGME&R Kolkata, Kolkata, India.*

Background: There is higher prevalence of non dipping pattern in antihypertensive CKD patients. we studied the effect of shifting antihypertensives to night time on blood pressure profile of CKD III-IV patients

Methods: Study Design: single centre, prospective, RCT **Setting and participants:** CKD III-IV with non dipping pattern on ABPM **Intervention:** the intervention group received all the antihypertensives in the night time, control group continued to take medication in the morning. Both groups were followed for 1 year **Outcomes:** primary outcome was the reversion to dipper status. Secondary outcomes were changes in eGFR and cardiac structure.

Results: 39 patients in bedtime group and 36 patients in awakening group were analysed. 10 patients (24%) reverted to dipping pattern in bedtime group as compared to none in the awakening group. Mean eGFR decrease from 34.59±12.43 to 34.41±11.82 ml/min/1.73m^2 in Bedtime group (p=0.5), in awakening group eGFR decrease from 32.46±13.42 to 29.91±9.97 ml/min/1.73m^2 (p=0.03). Between group difference in eGFRs was significant at 1 year (5.22 [95% CI,4.3-6.1]ml/min/1.73m^2; p= 0.02). Cardiac structure changes showed no significant changes in either group.

Conclusions: Bedtime administration of antihypertensives reverted non dippers to dippers and slowed the decline in eGFR in CKD III-IV compared to morning administration of antihypertensives.

Baseline Characteristics

Variables	Awakening group	Bedtime group
Creatinine, mg/dL	2.32±0.68	2.18±0.58
No. of hypertension medications	2.58±1.1	2.67±0.96
Awake systolic mean, mmHg	131.64±13.13	133.31±13.47
Sleep systolic mean, mmHg	124.94±13.14	126.49±13.83
24 hour systolic mean, mmHg	128.72±13.29	130.92±13.21
Awake diastolic mean, mmHg	84.36±11.67	83.21±11.67
Asleep diastolic mean, mmHg	76.31±12.55	78.36±13.67
24 hour diastolic mean, mmHg	79.28±11.43	80.59±11.24

Non-Dipping Blood Pressure Profile Does Not Predict a Risk for Developing CKD in Normotensives

Tomoharu Ida, Tetsuro Kusaba, Keiichi Tamagaki. *Kyoto Prefectural University of Medicine, Kyoto, Japan.*

Background: Lack of nocturnal blood pressure (BP) fall (non-dipper), a potent risk of future kidney dysfunction, is frequently observed in chronic kidney disease (CKD) patients. However, whether non-dipping pattern of BP profile in normotensive CKD patients is still a risk for progression of kidney disease is unknown. The aim of our retrospective cohort study is to elucidate the impact of non-dipping BP profile with normotensives on the incidence of ESRD and the CKD progression.

Methods: 1198 CKD patients (age:68.6 ± 12.0, eGFR:33.1 ± 18.2 ml/min/1.73m^2, avg ± SD) who underwent ambulatory BP monitoring (ABPM) were enrolled into our analysis. According to their nocturnal BP dipping pattern (>10%: dipper or <10%: non-dipper) and the average 24hr BP (>130/80 mmHg: hypertensive or <130/80 mmHg: normotensive), the patients were divided into 4 groups. Primary composite outcomes including 40% reduction of eGFR from baseline or reaching ESRD were assessed. We also performed the multivariate regression analysis of the factors considered to have significant relationship for the incidence of primary outcomes.

Results: 86.3% of patients were non-dipper and half of them were normotensive. The average observation period was 4.76 ± 2.75 (avg ± SD) years. Overall, the composite outcomes occurred in 45.6% of patients and it was highest in hypertensive non-dipper group (60.0%). In normotensive patients, there was no difference in the incidence of primary outcome between non-dipper (32.0%) and dipper (29.6%). Multivariate regression analysis showed that amount of urinary protein (95% CI 0.74-0.91) and 24hr BP (95% CI 0.67-0.81), not BP dipping rate (95% CI 0.98-1.01), were relevant for the incidence of primary outcomes.

Conclusions: ABPM based analysis demonstrated that non-dipping pattern of BP does not predict the risk for the kidney disease progression in normotensive CKD patients.

Association of Major Adverse Cardiac Events in Patients Taking Direct Oral Anticoagulants (DOACs) in Patients with CKD

Justin M. Ashley,[7] Eric McArthur,[2] Marisa Battistella,[3] Amber O. Molnar,[4] Min Jun,[5] Amit X. Garg,[6] Thomas Mavrakanas,[8] Manish M. Sood.[1] *[1]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]Institute for Clinical Evaluative Sciences, London, ON, Canada; [3]University Health Network, Toronto, ON, Canada; [4]McMaster University, Hamilton, ON, Canada; [5]The George Institute for Global Health, UNSW Sydney, Newtown, NSW, Australia; [6]London Health Sciences Centre, London, ON, Canada; [7]The Ottawa Hospital, Ottawa, ON, Canada; [8]McGill University, Montreal, QC, Canada.*

Background: Clinical trials provide conflicting evidence for the use of DOACs in the prevention of major adverse cardiac events (MACE). Patients with chronic kidney disease (CKD) are at an exceptionally high risk for MACE. We set out to assess the association of DOAC use compared to no oral anticoagulant or warfarin, and MACE, hemorrhage and all-cause mortality in patients with CKD.

Methods: Population-based retrospective cohort study of 241, 045 eligible adults of advanced age (≥ 66 years) in Ontario, Canada from 2009-2016. A high dimensional propensity score was used to match new DOAC use to either no anticoagulant or warfarin. The study outcomes were major cardiac events (MACE), hemorrhage requiring hospitalization and all-cause mortality. DOAC exposure was modeled using Cox and Fine & Gray sub-distribution hazards models to examine the association with outcomes. Outcomes by level of kidney function, albuminuria and DOAC type were also examined.

Results: We matched 6,039 DOAC (mean [SD] age, 77.2 [7.0] years; 44.9% women), users with a high dimensional propensity score to non-anticoagulant users. There were a total of 560 (46% DOAC users) MACE, 178 hemorrhages (47% DOAC users) and 768 (31.3% DOAC users) deaths during the follow-up time. DOAC use, compared to no anticoagulant use, was associated with a higher risk of MACE (sHR 1.20 95%CI 1.04-1.39) and hemorrhage requiring hospitalization (sHR 1.36 95%CI 1.03-1.80) whereas all-cause mortality was lower (sHR 0.74 95%CI 0.61-0.91). Among DOAC and non-anticoagulant use, the risk of hemorrhage and all-cause mortality differed by DOAC type whereas all-cause mortality differed by eGFR. We further matched 5,581 DOAC to warfarin users. There were a total of 460 (56% DOAC users) MACE, 177 hemorrhages (49% DOAC users) and 581 (61% DOAC users) deaths during the follow-up time. DOAC use, compared to warfarin use, was associated with a comparable risk of MACE, hemorrhage and all-cause mortality. Among DOAC and warfarin users, the risk of all-cause mortality but not MACE or hemorrhage differed by eGFR.

Conclusions: DOACs did not lower the risk of major cardiac events compared to no DOAC use or warfarin in patients with or without CKD. Further studies to determine if specific DOAC dosages reduce MACE in CKD are required.

FR-PO373

Duration of Dual Antiplatelet Therapy in Patients with CKD and Drug-Eluting Stents: A Meta-Analysis

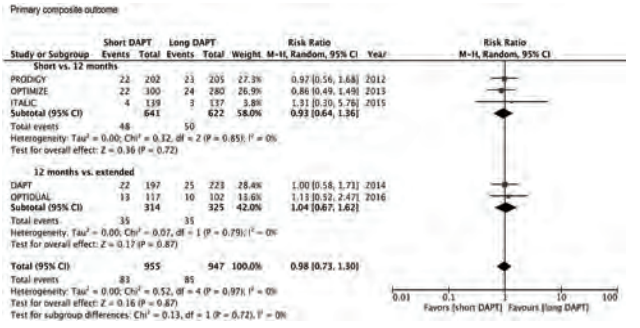
Thomas Mavrakanas,[1,2] Yiannis Chatzizisis,[7] Karim Gariani,[11] Dean J. Kereiakes,[10] Giuseppe Gargiulo,[4] Fausto Feres,[6] Marie claude Morice,[12] Jean-Louis Georges,[8] Marco Valgimigli,[9] Deepak L. Bhatt,[5] Laura Mauri,[5] David M. Charytan.[3] *[1]Brigham & Women's Hospital, Boston, MA; [2]Geneva University Hospitals, Geneva, Switzerland; [3]Brigham and Women's Hospital/ Harvard Medical School, Brookline, MA; [4]Bern University Hospital, Bern, Switzerland; [5]Brigham and Women's Hospital, Newton, MA; [6]Instituto Dante Pazzanese de Cardiologia, São Paulo, Brazil; [7]UNMC, Omaha, NE; [8]Centre Hospitalier de Versailles, LE CHESNAY, France; [9]University Hospital Bern, Bern, Switzerland; [10]The Christ Hospital, Cincinnati, OH; [11]Geneva University Hospital, Geneva, Switzerland; [12]Générale de Santé - Institut Cardiovasculaire Paris Sud, MASSY, France.*

Background: Whether prolonged dual antiplatelet therapy (DAPT) is more protective in chronic kidney disease (CKD) patients with drug-eluting stents (DES) compared with shorter DAPT is uncertain. This meta-analysis examined whether shorter DAPT in patients with DES and CKD is associated with lower mortality or major adverse cardiovascular event rates compared with longer DAPT.

Methods: A Medline literature research was conducted to identify randomized trials in patients with DES comparing different DAPT duration strategies. The primary outcome was a composite of all-cause mortality, myocardial infarction, stroke, or stent thrombosis (definite- probable). The secondary outcome was major bleeding. A random-effects model was used.

Results: Five randomized controlled trials were included (1,902 CKD patients). Short DAPT (≤6 months) was associated with a similar incidence of the primary outcome, compared with 12-months DAPT among patients with CKD (Figure). Twelve-months DAPT was also associated with a similar incidence of the primary outcome compared with extended DAPT (≥30 months) in the CKD subgroup (Figure). Numerically lower major bleeding event rates were detected with shorter vs. 12-month DAPT (RR 0.68, 95% CI 0.29-1.60, p=0.38) and 12-month vs. extended DAPT (RR 0.82, 95% CI 0.34-1.94, p=0.65) in CKD patients.

Conclusions: Short DAPT may be preferred to longer DAPT in CKD patients with DES.



Forest plot showing the impact of short (≤6 months), 12-month, and extended (>=30 months) dual antiplatelet therapy on the composite primary outcome, a composite of all-cause mortality, myocardial infarction, stroke, and stent thrombosis (definite or probable) in patients with chronic kidney disease.

FR-PO374

Direct Oral Anticoagulants vs Warfarin: Stroke Outcomes in CKD Patients

Drake A. Edgett,[1,2] Alissa Dratch,[1,2] Elani Streja,[1,2] Ekamol Tantisattamo,[2] Kamyar Kalantar-Zadeh,[1,2] Wei Ling Lau.[2,3] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]University of California, Irvine School of Medicine, Orange, CA; [3]Visiting Fellow at OptumLabs, San Francisco, CA.*

Background: CKD patients are at higher risk of ischemic and hemorrhagic stroke. For over 50 years warfarin was the only oral anticoagulant available for stroke prevention. Direct Oral Anticoagulants (DOACs) became available in the past decade but outcomes data in CKD is limited. In this project we examined ischemic stroke outcomes associated with warfarin vs. DOAC therapy in the OptumLabs® Data Warehouse (OLDW).

Methods: This was a retrospective analysis of de-identified claims and electronic health record data for privately insured and Medicare Advantage enrollees in a large, private, U.S. health plan. Adults aged ≥18 years with claims data between 10/1/2010-11/30/2017 were included. Stroke events were captured between index prescription date and censor date (earliest date of index medication stopped, death, or end of follow up). Cox models were used to calculate hazard ratios of time to first stroke. Poisson models were used for stroke incident rate ratios. Associations were evaluated with multivariable adjustment for age, gender, race and baseline comorbidities (diabetes, hypertension, heart failure, myocardial infarction, prior stroke, antiplatelet medications).

Results: The cohort included 340,732 patients of which 90% were non-CKD, 9% were CKD stage 3-4, and 1% were CKD stage 5/ESRD. Patients had a mean±SD age of 67±13 years, and included 30% diabetics, 10% African-Americans and 6% Hispanic. Patients on warfarin were more likely to be older, African-American, ESRD, and have pre-existing comorbidities. Across all strata, patients on warfarin had a faster time to first stroke and a higher incidence of stroke events [Table].

Conclusions: In a large nationwide database, DOACs were associated with a lower risk of ischemic stroke as compared to warfarin therapy. Randomized controlled trials are warranted to further investigate this observed superiority of the newer anticoagulant therapies.

Subgroup	n	Ischemic Stroke outcomes Median (interquartile range) of follow up: 65 (31, 196) days	
		Incident Rate Ratio warfarin vs. DOACs (95% CI)	Hazard Ratio warfarin vs. DOACs (95% CI)
Non-CKD	304,956	1.64 (1.63, 1.66)	1.23 (1.20, 1.27)
CKD 3-4	31,189	1.29 (1.25, 1.32)	1.17 (1.11, 1.26)
CKD 5/ESRD	4,587	2.21 (1.99, 2.44)	1.45 (1.15, 1.83)

FR-PO375

Kidney Failure and Mortality in Older Live Kidney Donors with Hypertension

Fawaz Al Ammary,[1] Xun Luo,[1] Allan Massie,[1] Macey L. Henderson,[1] Deidra C. Crews,[1] Jacqueline Garonzik wang,[1] Daniel C. Brennan,[1] Alexander C. Wiseman,[2] Dorry L. Segev.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]University of Colorado at Denver and Health Sciences Center, Denver, CO.*

Background: Hypertension in otherwise healthy, screened older live kidney donor candidates has been viewed as safe. However, hypertension guidelines have evolved and long-term outcomes for these donors have not been explored, which may bring this practice into question.

Methods: We used a US cohort of 24,533 older donors (≥50-year-old), including 2265 with predonation hypertension, to quantify the 15-year end-stage renal disease (ESRD) and mortality risk in donors with hypertension vs. those without hypertension. From 2004-2016, hypertension was defined as documented predonation use of antihypertensive therapy, regardless of systolic/diastolic blood pressure (SBP/DBP); from 1999-2003, when there was no documentation of antihypertensive therapy, hypertension was defined as predonation SBP≥140 or DBP≥90 mmHg.

Results: Older donors were 88.1% white, 5.6% Hispanic, and 6.3% black. Estimated 15-year ESRD risk was 77 per 10,000 (95%CI:38-155) for donors with hypertension (mean SBP=137.7 mmHg) vs. 21 per 10,000 (95%CI:12-37) for donors without hypertension (mean SBP=123.4 mmHg); (adjusted hazard ratio [HR] 3.04; 95%CI:1.28-7.22; *P*=.01). In the years when predonation use of antihypertensive therapy was available, risk of ESRD was 6.21-fold higher (95%CI:1.20-32.17; *P*=.03) for donors using antihypertensive therapy (mean SBP=131.9 mmHg) vs. those not using antihypertensive therapy (mean SBP=123.9 mmHg); this inference remained similar after further adjustment for SBP<125. There was no evidence of association between donor hypertension and 15-year mortality risk (HR 1.18; 95%CI:0.84-1.66; *P*=0.34).

Conclusions: Older kidney donor candidates with hypertension may be viewed as potentially high-risk for ESRD. These findings may help inform discussion with older candidates considering kidney donation; long-term monitoring is warranted. .

FR-PO376

High Variability of Initial 24-Hour Systolic Blood Pressure After ICU Admission Is Associated with Mortality

Soon hyo Kwon,[1] Moo Yong Park,[2] Hyoungnae Kim,[2] Hyunjin Noh.[2] *[1]Soonchunhyang University, Seoul, Republic of Korea; [2]Soonchunhyang University Hospital, Seoul, Republic of Korea*.

Background: Increased blood pressure variability predicts long-term outcomes in cardiovascular and kidney disease. This study aimed to determine whether variability of initial 24-hour systolic blood pressure (SBP) affects mortality in critically ill patients.

Methods: In a retrospective study, we enrolled patients who had been admitted to 2 adult intensive care units (ICU) in a single center between Nov. 2015 and Oct. 2017. All patients were under active treatment. Variability of patients' blood pressure was assessed by initial 24-hour SBP coefficient of variation (CV) after ICU admission. CV was measured as standard deviation of SBP divided by mean of SBP. Patients were categorized into two groups based on SBP CV. The effect of SBP variability on 90 day mortality was analyzed.

Results: Of the 451 patients (male 56 %) were analyzed, 25.7% of patients died within 90 days. The mean SBP CV was 7.6 ± 1.4 % in low CV group (n=225) and 13.6 ± 3.2 % in high CV group (n=226). In Kaplan-Meier survival analysis, 90 day mortality of high CV group was higher than that of low CV group (p = 0.001) (Figure 1). A Cox analysis showed that high CV in SBP was an independent risk factor for death compared to low CV in SBP (HR 1.87; 95% CI, 1.26-2.77; p = 0.002) after adjust of age, sex, comorbidities, inotropic agents and SBP.

Conclusions: Higher SBP variability in critically ill patients was associated with high mortality. This suggests that variability of blood pressure would be helpful for prediction of prognosis and treatment in ICU patients.

FR-PO377

AKI Followed by Complete Recovery Is Associated with Higher Stroke Risk

Joao P. Teixeira,[2] Zhiying You,[3] Benjamin Griffin,[2] John R. Holmen,[4] Titte Srinivas,[5] Michel Chonchol,[2] Sarah Faubel,[6] Anna J. Jovanovich.[1,2] *[1]Denver VA, Denver, CO; [2]University of Colorado, Aurora, CO; [3]UC Denver, Aurora, CO; [4]Intermountain Healthcare, Murray, UT; [5]Intermountain Medical Center, Murray, UT; [6]University of Colorado Denver, Denver, CO*.

Background: Acute kidney injury (AKI) has been shown to be associated with a future increased risk of adverse cardiovascular events. However, there are fewer data specifically analyzing the risk of stroke after AKI and they have been somewhat mixed. While severe (stage III) AKI has been shown to be independently associated with an increased risk of future stroke, the effects of less severe AKI or AKI with recovery are unclear. We aim to determine the risk of stroke following an admission complicated by AKI with complete recovery in a propensity score-matched cohort of cases and controls.

Methods: We identified 1139 AKI cases (AKI Network definition) with complete kidney function recovery at the time of discharge, defined as serum creatinine <1.10 times the pre-admit baseline value, during a hospitalization between January 1, 1999 and December 31, 2009 from an integrated health care delivery system. We matched 1139 controls (no AKI during index admit) based on a propensity score including age, sex, race, prior inpatient visits, season of admission, baseline creatinine, and all components of the Charlson Comorbidity index. The primary outcome was time to post-discharge stroke, as defined by ICD-9 codes. Cox proportional hazards models were adjusted for history of prior stroke and atrial fibrillation and censored for death.

Results: Baseline characteristics among the cases and controls were similar: age 62 ± 17 years, 46% female, 92% white, serum creatinine 0.9 ± 0.2 mg/dL. During a median [IQR] post-discharge follow-up of 68 [17-92] months, 99 cases and 36 controls had a stroke. In the unadjusted model, AKI with recovery was associated with a greater than 3-fold increased risk of stroke (HR 3.08 [95% CI, 2.10 – 4.52]; p <0.0001). This association did not change after adjusting for prior stroke and atrial fibrillation (HR 3.27 [95% CI, 2.21 – 4.2]; p <0.0001).

Conclusions: Among patients from an integrated health care delivery system, AKI followed by complete recovery was independently associated with an increased risk of incident stroke. These data add to prior studies linking AKI with an increased long-term risk of cardiovascular events.

FR-PO378

Health Plan Coverage Duration and Annualized Healthcare Costs in Patients with ADPKD in a Managed Care Population

Myrlene Sanon,[1] Robert A. Stellhorn,[1] Efstathios N. Michalopoulos,[2] Christina Pao,[1] Dorothee Oberdhan.[2] *[1]Otsuka Pharmaceutical Development & Commercialization, Inc., Princeton, NJ; [2]Otsuka Pharmaceutical Development & Commercialization, Inc., Rockville, MD*.

Background: ADPKD is a rare inherited systemic disease characterized by progressive kidney enlargement and worsening of kidney function leading to end stage renal disease, and transplant. Hypertension occurs in 70% of patients and contributes to disease progression, and cardiovascular morbidity and mortality. Even for long-term progressive diseases, US health plans often focus on short-term outcomes rather than prevention due to patients' short retention in health plans. This study assesses health plan retention rates and direct healthcare costs of ADPKD patients with hypertension.

Methods: Patients diagnosed with ADPKD were selected from the Optum Clinformatics 2007-2017 US research database. ADPKD was identified using ICD9/10 codes: 753.12, 753.13, Q61.2, and Q61.3. Patients were required to have continuous medical and pharmacy benefits for 6 months pre- index date (baseline period) and ≥6 months post-index date. The index date was the date of ADPKD diagnosis. Duration of plan coverage was reported for the overall population and annual healthcare costs reported in patients with and without hypertension.

Results: A total of 9,361 patients met inclusion criteria, of whom 85% had hypertension. Mean enrollment duration was 36.5 months with a median of 28.1 months. Forty-three percent of patients had 1-2 years coverage, 18% 2-3 years coverage, 12% 3-4 years coverage, 8% 4-5 years coverage, and 18% greater than 5 years coverage. Mean annual direct healthcare costs were higher for patients with ADPKD and hypertension ($50,850) compared with ADPKD only ($16,135), p<0.001. In patients with ADPKD and hypertension, outpatient costs were the primary source of costs with a mean of $18,025, followed by inpatient costs ($15,957), pharmacy costs ($8,022), emergency room visits ($1,476), office visits ($993), and home health costs ($504).

Conclusions: The study findings indicate that most patients with ADPKD retain their health plan coverage for a relatively long period, including those with the most prevalent comorbid condition in this population. Direct healthcare costs were higher among patients with comorbid hypertension. Since these patients incur higher healthcare cost, health plans and decision makers may benefit from earlier disease management strategies for ADPKD.

FR-PO379

Clinical Feature and Diagnosis of Primary Hyperaldosteronism

Ryotaro Shioda, Hitoshi Suzuki, Yasuhiko Kanaguchi, Tomohito Gohda, Yusuke Suzuki. *Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: Primary aldosteronism(PA) is the most common form of secondary hypertension, with an estimated prevalence of 10% of hypertensive patients. Patients with PA have higher cardiovascular morbidity and mortality than age- and sex-matched patients with essential hypertension and the same degree of blood pressure elevation. Early checkup is extremely important to prevent cardiovascular event, stroke and renal dysfunction.

Methods: We retrospectively analyzed the clinical features of the patient with PA who were diagnosed from 2014 to 2018.

Results: We analyzed 36 cases with PA who were not treated with RAS inhibitor or diuretic drug at the time of screening test for PA. The average age was 49 years old. The cases of serum K < 3.5 were only 20%, and adrenal adenoma detected by CT scan was 42.9%. The median of aldosterone-to-renin ratio (ARR) was 841.9 (206-4370), however, in cases with adrenal adenoma, the median ARR was significantly high level with 1299.4 (300-4370). The correct diagnostic rate of diagnoses of saline test, furosemide test and captopril test was 77.1, 71.4 and 65.7%, respectively. There was a trend that the accuracy of captopril test was low in patients with low eGFR. The correct diagnostic rate of combination of saline and furosemide tests would be the best. The 90 percentile of the serum potassium in patients with PA was 4.4 mEq/L, however, those in patients with over 40 years old were 4.5 mEq/L.

Conclusions: Present study suggested that screening test for PA should be performed in cases with serum potassium was less than 4.3 mEq/L in hypertensive patients. Especially, in cases with over 40 years old, the screening of the PA with ARR should be performed. In addition, the correct diagnostic rate of diagnoses of captopril test was low compared with other screening test. Combination of salin and furosemide tests suggested to be proposed in present study.

FR-PO380

A Cross-Talk Between TGFbeta Receptor (TGFbR) and PDGF Receptor-Beta (PDGFRb) Controls mTORC1-Mediated Mesangial Cell (MC) Hypertrophy and Fibrotic Protein Expression

Soumya Maity,[3] Falguni Das,[4] Nandini Ghosh-choudhury,[4] Meenalakshmi M. Mariappan,[1] Balakuntalam S. Kasinath,[1] Goutam Ghosh-Choudhury.[2] *[1]University of Texas Health Science Center, San Antonio, TX; [2]Medicine, UT Health San Antonio, San Antonio, TX; [3]University of Texas Health Science Center at San Antonio, San Antonio, TX; [4]UTHSCSA, SAN ANTONIO, TX.*

Background: TGFb induces MC hypertrophy and matrix protein expression via noncanonical mTORC1 during the progression of diabetic nephropathy. The mechanism of mTORC1 activation is not clear. Since its activation requires tyrosine kinase activity, we considered a cross-talk between TGFb serine-threonine kinase and PDGFRb tyrosine kinase in this process.

Methods: Human glomerular MCs in culture and OVE 26 diabetic mice were used. PDGFRb inhibitor, activation/inactivation-specific phospho-antibodies, siRNA and plasmid-derived expression vector transfection, ^{35}S-Methionine incorporation and immunoblotting were used.

Results: In MCs, TGFb increased the activating phosphorylation of PDGFRb in a time-dependent manner. This phosphorylation was inhibited by the TGFbRI and PDGFRb inhibitors SB431542 and JNJ, respectively. Importantly, JNJ did not have any effect on TGFb-stimulated phosphorylation of receptor-specific Smad 3 while SB inhibited its phosphorylation. JNJ also inhibited the phosphorylation of PDGFRb at Tyr-751, the PI 3 kinase binding site, in response to TGFb, resulting in inhibition of Akt phosphorylation at both Thr-308 and Ser-473. Transfection of siRNA against PDGFRb confirmed these results. Importantly, JNJ and siRNA targeting PDGFRb blocked the phosphorylation of the Akt substrate PRAS40, a negative regulator of mTORC1 activation. To determine the mTORC1 activity, we measured the phosphorylation of S6 kinase and rps6. Inhibition of PDGFRb as well as its siRNA mitigated TGFb-induced mTORC1 activity that resulted in attenuation of MC hypertrophy. Similarly, JNJ and siPDGFRb inhibited TGFb-stimulated fibronectin expression in MCs. Finally, in the renal cortex of OVE 26 diabetic mice, expression of TGFb was significantly increased concomitant with phosphorylation of PDGFRb, which were associated with increased Akt phosphorylation and mTORC1 activation that lead to increased fibronectin expression.

Conclusions: Our results provide the first evidence for a functional role of PDGFRb downstream of TGFbR to activate Akt/mTORC1 axis for MC hypertrophy and matrix protein expression. We propose to test PDGFRb-specific inhibitor in preclinical models of diabetic nephropathy.

Quercetin Ameliorates Podocytes Injury via Inhibition of Oxidative Stress and TGF-β1/Smad Pathway in DN Rats

Fanfan Gao,[1] Hongli Jiang.[2] Dialysis Department of Nephrology Hospital, First Affiliated Hospital of Medicine School, Xi'an Jiaotong University, Xi'an 710061, Shaanxi, China *[1]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [2]First Affiliated Hospital of Medicine School, Xi?an Jiaotong University, Xi?an, China.*

Background: An increasing number of investigations revealed that podocytes play a crucial role in the development and progression of diabetic nephropathy (DN). The bioflavonoid quercetin, an antioxidant, may be a potential alternative to ameliorate podocytes injury in DN rats. The aim of this study was to investigate the protective effect and underlying mechanism of quercetin on podocyte injury in rats with diabetic nephropathy.

Methods: SD rats (180-220g) were randomly divided into four groups: normal control (NC), diabetic nephropathy (DN), DN treated with low-dose quercetin (DN+LQ) and DN treated with high-dose quercetin (DN+HQ). All diabetic rats were induced by a single intraperitoneal injection of streptozotocin at concentration 60 mg/kg, and quercetin was administered daily with an oral dose of 50 mg/kg (DN+LQ) or 100 mg/kg (DN+HQ) 1 week after STZ injection, NC and DN rats were administered vehicle only. Blood glucose and body weight were measured every 2 weeks, and albuminuria was measured every 4 weeks. All animals were sacrificed after 12 weeks of treatments. Then HE, PAS staining and electron microscope were performed to observe kidney tissue and podocytes. Immunohistochemical stainig and western blotting were performed to explore the expression of podocin, nephrin, desmin, TGF-β1, p-Smad2, and p-Smad3 and Smad7. The contents of SOD, GSH and MDA were examined by ELISA.

Results: In the present study, quercetin markedly decreased blood glucose levels, kidney-to-body weight ratio, albuminuria, creatinine clearance rate, blood urea nitrogen, triglycerides and significantly attenuated oxidative stress compared with the DN group. Moreover, quercetin was observed to inhibit podocyte effacement and decrease the thickness of glomerular basement membranes. Mechanistically, quercetin significantly increased the expression of podocyte-specific markers nephrin and podocin and decreased expression of the podocyte injury marker desmin in DN rats. Quercetin also inhibited activation of the TGF-β1/Smad signaling pathway in DN rats by decreasing expression of TGF-β1, p-Smad2, and p-Smad3, and increasing Smad7 expression.

Conclusions: Quercetin administration ameliorated podocytes injury in DN rats, possibly by inhibiting oxidative stress and the TGF-β1/Smad signaling pathway. Thus, quercetin may be manipulated to act as a potential drug for prevention of early diabetic nephropathy.

TGF-β1 Increases LTBP-2 via RelA, and Elevated LTBP-2 Stimulates TGF-β1 Secretion via ERK, Forming a Positive Feedback Vicious Loop and Resulting in the De-Differentiation of Proximal Tubules

Kazuhiro Hasegawa, Shu Wakino, Hiroshi Itoh. *Keio University, Tokyo, Japan.*

Background: Latent transforming growth factor-β-1 binding protein-2 (LTBP-2) does not bind to transforming growth factor-β1 (TGF-β1) unlike other LTBPs. Reportedly, serum LTBP-2 levels were elevated statistically; thus, it is considered as a potential prognostic marker in the progressive stages of diabetic kidney disease. Although LTBP-2 seems to regulate the TGF-β1 bioactivity, except direct bindings, the effect of LTBP-2 in the kidneys is unclear.

Methods: We evaluated the regulatory mechanism of the LTBP-2 expression and primary function of LTBP-2.

Results: In wild-type mice, **LTBP-2** is expressed only in **proximal tubules (PTs)**. Diabetic nephropathy, such as STZ and *db/db* mice, demonstrated remarkably upregulated LTBP-2 in PTs. UUO models also marginally increased LTBP-2 immunostaining in collecting tubules but not in PTs. By treating humoral factors that are considered crucial mediators in the pathogenesis of diabetic renal injury or renal fibrosis, such as high glucose, AGE, angiotensin II, TGF-β1, TNF-α, and interleukin 6, only the **TGF-β1** administration markedly elevated the LTBP-2 mRNA and protein expression in time- and dose-dependent way in cultured PTs. TRANSFAC analysis, luciferase assays, and EMSA revealed that the promoter region spanning –1666 to –1436, especially the **RelA** binding site, was essential for the basal LTBP-2 gene promoter activity and TGF-β1–induced LTBP-2 gene upregulation. **Erk** phosphorylation was markedly elevated by the transfection of LTBP-2 cDNA vector into HK-2 cells, resulting in the de-differentiation of PTs such as reducing E-cadherin expression, increasing fibronectin expression, and TGF-β1 secretion. Conversely, LTBP-2 siRNA administration under TGF-β1 treatment silenced Erk phosphorylation, resulting in blocking the de-differentiation of PTs. When cells were treated with Erk inhibitor, these phenotypic changes were prevented.

Conclusions: Renal fibrogenetic changes in diabetic nephropathy were attributed to the upregulation of LTBP-2 via the RelA activation by TGF-β1. Elevated LTBP-2 triggers the stimulation of TGF-β1 secretion via Erk signaling, forming a **positive feedback vicious loop** and resulting in the **de-differentiation** of PTs. Overall, silencing LTBP-2 is a novel therapeutic target for blocking diabetic tubulopathy or fibrotic changes.

Smad3 Regulates Cell Fate Through Silencing of Enhancer and Superenhancer Elements During the Specification of iPSC Derived Kidney Organoids

Jessica L. Davis, Thomas K. Dodd, Ciarán Kennedy, Shane Clerkin, Darrell C. Andrews, Catherine Godson, John Crean. *University College Dublin, Dublin, Ireland.*

Background: Critical pathological features of diabetic nephropathy are now accepted to include dysregulation of epigenetic processes as evidenced by the observed differential methylation in patients with or without progressive disease. We recently demonstrated a novel direct interaction between Smad3 and EZH2, the enzymatic component of the PRC2 complex, during cell fate specification and TGFβ mediated epithelial dedifferentiation. Targeting this interaction in iPSC derived renal organoids protected against TGFβ mediated tubular epithelial dedifferentiation. Here we further delineate the molecular mechanism underlying this interaction.

Methods: Co-localisation of Smad3 and EZH2 was analysed and visualised using ChIP-Atlas (www.chip-atlas.org). Putative superenhancers (SE) were identified using the Illumina BaseSpace platform. Differential expression of SE target genes in healthy and CKD kidney samples were analysed using Nephroseq (www.nephroseq.org). Target genes were further analysed during the specification of iPSC derived kidney organoids and during TGFβ mediated epithelial dedifferentiation using quantitative real-time PCR.

Results: ChIP-seq identified Smad3 and EZH2 co-localisation at specific loci in human ESCs, and newly occupied enhancers in ESCs and iPSCs treated with activin A. Bioinformatic analysis of these sites identified 243 putative SEs potentially regulated by Smad3/EZH2. Further analysis identified a number of these putative SE target genes that are silenced in normal adult kidney but whose expression is significantly increased during disease. These included critical determinants of cell fate including ZIC3, ZIC5, and DPPA4. Further analysis by RT-PCR indicated a TGFβ dependent downregulation of genes within this cohort suggesting a novel mechanism of gene repression during both development and disease. Functional analysis of enhancer reporter activity verified a Smad3/EZH2 dependent mechanism.

Conclusions: We propose that this complex forms a molecular switch that regulates enhancer and/or promoter access through epigenetic mechanisms and controls gene silencing, informing the fundamental mechanisms through which subsets of genes are switched on and off during fate specification and during the pathogenesis of diabetic nephropathy.

FR-PO384

LRG1 Promotes DN Progression by Enhancing TGF-β-Induced Angiogenesis

Quan Hong,[1,2] Lu Zhang,[1,4] Jia Fu,[1] Wenjun Ju,[3] Xiangmei Chen,[2] Steven G. Coca,[1] Detlef O. Schlondorff,[1] John C. He,[1] Kyung Lee,[1] Matthias Kretzler.[3] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Chinese PLA General Hospital, Bei Jing, China; [3]University of Michigan, Ann Arbor, MI; [4]Xiamen University Affiliated The First Hospital, Amoy, China.*

Background: Glomerular endothelial dysfunction and neoangiogenesis have long been implicated in pathogenesis of diabetic nephropathy (DN). However, specific molecular pathways contributing to these processes in the early stages of DN injury is not well understood. Our recent transcriptomic profiling of isolated glomerular endothelial cells identified number of pro-angiogenic genes that were upregulated in the diabetic mice, including leucine-rich alpha-2 glycoprotein-1 (LRG1). LRG1, a secreted glycoprotein belonging to a leucine-rich repeat family, was previously shown to promote neovascularization in models of ocular disease by potentiating the TGF-β/ALK1 signaling in endothelial cells. However its role in kidney cells, particularly in the setting of DN, was not known.

Methods: We analyzed the expression pattern of LRG1 in murine and human diabetic kidneys in comparison to normal kidneys by utilizing the RNA-sequencing data of isolated glomeruli and by RNA in situ hybridization. We examined the effects of high glucose conditions on LRG1 cultured murine glomerular endothelial cells (mGECs) in vitro. We then examined the effects of genetic ablation of *Lrg1* in DN progression in diabetic mice at 12 weeks and at later time point of 20 weeks post diabetes induction.

Results: We found that *LRG1* mRNA expression is significantly increased in glomeruli of mouse and human diabetic kidneys and that its expression localizes predominantly with the glomerular endothelial cells (GECs). High glucose conditions led to the upregulation of LRG1 expression in cultured mGECs, and shRNA-mediated knockdown of *Lrg1* led to reduction in endothelial tube formation in vitro. Genetic ablation of *Lrg1* in mice markedly attenuated diabetes-induced angiogenesis, albuminuria and glomerulopathy at 12 and 20 weeks of diabetes. These improvements were associated with reduced ALK1-Smad1/5/8 activation and with reduced number of GECs in glomeruli of diabetic mice. Moreover, we found that plasma LRG1 levels were associated with worsened renal outcome in type 2 diabetic patient cohort from Bio*Me* Biobank.

Conclusions: Together, our results identify LRG1 as a potential novel pathogenic mediator of glomerular angiogenesis in diabetic kidneys and a risk factor of DN progression, and suggest that LRG1 may be a promising therapeutic target against the disease progression.

Mesangial Matrix Expansion Attenuated by All-Trans Retinoic Acid Through Direct Suppression of Bone Morphogenetic Protein 4 in Mouse Diabetic Nephropathy

Masanori Tamaki, Tatsuya Tominaga, Yui Fujita, Seiji Kishi, Taichi Murakami, Kojiro Nagai, Hideharu Abe, Toshio Doi. *Department of Nephrology, Tokushima University, Tokushima, Japan.*

Background: Diabetic nephropathy (DN) leads to mesangial matrix expansion, resulting in glomerulosclerosis and renal failure. Collagen IV (COL4), a major component of the mesangial matrix, is positively regulated by bone morphogenetic protein 4 (BMP4)/suppressor of mothers against decapentaplegic (Smad1) signaling. All-trans retinoic acid (atRA) treatment has a beneficial effect on several kidney disease models, although the effect on mesangial matrix expansion in DN remains unclear. AtRA is a representative ligand for retinoic acid receptor (RAR), which heterodimerizes with retinoid X receptor (RXR). Because RAR/RXR heterodimer binds to RA response element (RARE) and regulates various gene transcriptions, the therapeutic effect of atRA on DN through BMP4 regulation by RAR/RXR–RARE was investigated in the present study.

Methods: Streptozotocin was given to male ICR mice at 12 weeks old for diabetes induction. Both control mice and diabetic mice were given all-*trans* retinoic acid (atRA, 15 μg/gBW) intraperitoneally thrice weekly from 16 weeks old to 24 weeks old. Animal kidneys were harvested at 24 weeks. AtRA or specific agonists for each subtype of RAR were added to cultured mouse mesangial cells for 24 h (from 1 nM to 1 μM). The RAR binding capacity to RARE, suggested by genome analysis, was confirmed by ChIP analysis. The functional role of the putative RARE was confirmed by a reporter assay.

Results: Mesangial matrix expansion worsened in diabetic mice and was associated with increased BMP4, phosphorylated Smad1, and COL4. These levels were attenuated after atRA administration. In cultured mesangial cells, BMP4 and COL4 expression levels were significantly decreased by atRA or low concentrations (1 nM) of RARα agonist but not by 1 nM of RARβ or γ agonists. Two putative regions with significant homology to RARE were identified around the mouse *Bmp4* gene. ChIP analysis and subsequent reporter assays indicated the binding of one putative RARE of the *Bmp4* gene to RARα and RXR, resulting in suppression of BMP4 expression.

Conclusions: AtRA directly suppressed BMP4 via RARα/RXR heterodimer binding to a unique RARE, resulting in amelioration of mesangial matrix expansion in diabetic mice. These findings provide a novel regulatory mechanism for treatment of DN.

The Hippo Pathway in the Regulation of the Epithelial-to-Mesenchymal Transition of Renal Proximal Tubular Epithelial Cell in Diabetic Nephropathy

Chenyang Qi, Zhigang Zhang, Huijuan Wu. *Department of Pathology, School of Basic Medical Sciences, Fudan University, Shanghai, China.*

Background: Diabetic nephropathy (DN) is a major cause of end-stage renal disease in the world. Epithelial-to-mesenchymal transition (EMT) of renal proximal tubular epithelial cells (PTECs) is an important mechanism in the progression of interstitial fibrosis in DN. Recently, Hippo pathway was recognized as a regulator of cell proliferation, differentiation and apoptosis and may be potential therapeutic targets in many kidney diseases.

Methods: In order to study whether the Hippo pathway regulate EMT of PTECs in DN, we cultivated the db/db type 2 diabetic model mice and normal or high glucose stimulated HK-2 cells (human PTECs). We detected the levels of Hippo pathway and EMT of HK-2 cells and PTECs in db/db mice. We administrated verteporfin, a YAP inhibitor, and detected the change of EMT.

Results: Compared with the littermates, db/db mice developed microalbuminuria at the age of 20 weeks and showed obvious kidney hypertrophy from the 4th week. Then, we found that the expression of phosphorylated YAP at serine 127 (p-YAP-S127) in PTECs was obviously increased. While, the total YAP level did not change significantly. We also found that the protein levels of epithelial markers (Ecadherin, ZO-1, and CK-18) were significantly decreased in db/db mice, while the mesenchymal markers (Vimentin, α-SMA) was elevated and these changes were consistent with EMT. Similar changes have been found in HK-2 cells. In high glucose stimulated HK-2 cells, p-YAP-S127/total YAP ratio was increased, epithelial markers were decreased and the mesenchymal markers was elevated (i.e., the onset of EMT). At the same time, we extracted the nuclear and cytoplasmic fraction in normal or high glucose stimulated HK-2 cells. The total YAP level in the cytoplasm was increased, while that in the nucleus was decreased. In addition, administration of verteporfin, which could reduce the level of p-YAP, elevated the epithelial markers and decreased mesenchymal markers (i.e., reversed the EMT) in high glucose stimulated HK-2 cells.

Conclusions: In conclusion, high glucose reduced the YAP nuclear translocation, thus more p-YAP was anchored in the cytoplasm and induced EMT of PTECs. Verteporfin could reverse the EMT, which suggested that Hippo pathway can regulate the EMT in PTECs. This study would provide a new potential therapeutic target for DN.

Blockade of RIPK3 Alleviates Renal Fibrogenesis Through TLR2/4 Signalling in Streptozotocin-Induced Diabetic Model

Ying Shi, Chunling Huang, Xinming Chen, Carol A. Pollock. *University of Sydney, Sydney, NSW, Australia*.

Background: Current therapies for renal fibrosis are largely ineffective. Therefore, identification of novel therapeutic targets is essential. RIPK3 is identified as a crucial regulator of TLRs signalling activation, which has been well recognised to be involved in renal fibrogenesis. To date, the function of RIPK3 in renal fibrosis remains unclear.

Methods: C57BL/6 wild-type mice and C57BL/6 RIPK3 gene knock out (RIPK3-/-) mice were used in the study. streptozotocin (55 mg/kg/day) was administrated to induce diabetic model by i.p. for 5 consecutive days. After 24 weeks treatment, mice were sacrificed and urinary albumin creatinine ratio (UACR) was measured by ELISA. Kidney histological change and ECM deposition were assessed by PAS, picrosirius red staining and immunohistochemistry. Collagen IV, Fibronectin, α-SMA, TGF-β, TNF α, IL-1 β, TLR2. TLR4, MCP-1, F4/80 mRNA expression level were assessed by quantitative RT-PCR analysis.

Results: RIPK3 deletion reduced UACR compared to the increased level of diabetic group. Both Immunohistochemical staining and PCR revealed that the absence of RIPK3 decreased the diabetic induced collagen IV and Fibronectin within kidney cortex. In addition, diabetes induced the TLR2/4 signalling activation and resulted in an increase of MCP-1 and F4/80 gene expression. However, genetic ablation of RIPK3 decreased TLR2/4 mRNA expression levels and the downstream TNF α and IL-1 β transcription associating with less MCP-1 and F4/80 gene expression. Moreover, diabetes upregulated TGF-β and α-SMA mRNA expression within kidney, whereas this effect was blocked by RIPK3 deletion.

Conclusions: RIPK3 is crucial in renal fibrosis by mediating TLR2/4 signalling. Our data suggest that RIPK3 blockade may be a potential novel target in renal fibrosis.

Grem1 Plays a Vital Role in Nicotine Exacerbated Diabetic Nephropathy

Hongxiu Wen,[2,1] Xiqian Lan,[2,1] Vinod Kumar,[3] Seyedeh Shadafarin Marashi Shoshtari,[4] Rukhsana Aslam,[5] Ali Hussain,[6] Ashwani Malhotra,[7] Pravin C. Singhal.[8] *[1]Feinstein Institute for Medical Research, Manhasset, NY; [2]Key Laboratory for Aging and Regenerative Medicine, School of Pharmacy, Southwest Medical University, Luzhou, China; [3]Fienstine Institute for Medical Research, NEW YORK, NY; [4]The Feinstein Institute for Medical Research, Manhasset, NY; [5]Feinstein Institute for medical research, Glenoaks, NY; [6]Feinstein Institute of Medical Research, New York, NY; [7]Feinstein Institute Medical Research and NSLIJ, MANHASSET, NY; [8]North Shore LIJ Health System, Great Neck, NY*.

Background: Increasing evidences have demonstrated that cigarette smoking promotes the progression of diabetic nephropathy (DN), but the underlying molecular mechanisms are far from clear. Nicotine, a major component for smoking addiction, has been reported to be an independent component to cause kidney cell injury to accelerate the progression of DN. This study has been designed to evaluate the role of nicotine in DN and to explore the underlying molecular mechanisms.

Methods: *In vivo* studies, diabetic mice were developed through the administration of three doses of streptozotocin (STZ, 50 mg/kg body weight, intraperitonelly). These mice were fed with either nicotine (100 μg/ml) or vehicle (PBS) in their drinking water for 5 months. At the end of the experimental period, kidney function biomarkers (proteinuria, blood urea nitrogen [BUN]) were collected and kidneys were harvested for histological changes and molecular analysis (immunohistochemistry, real-time PCR, and Western blotting). The kidney transcriptomes of these mice were compared through RNA seq analysis, and the results were further confirmed by real-time PCR, Western blotting, and immunohistochemical studies. *In vitro* studies, human podocytes were treated with high glucose (30 mM) with or without nicotine (10 μM), followed by morphologic assay for apoptosis. The effect of high glucose with or without nicotine was also evaluated on podocytes-silenced for specific genes.

Results: *In vivo* studies, STZ-receiving mice displayed a higher level of blood glucose and associated kidney injury, however, nicotine further exacerbated this effect of hyperglycemia. Interestingly, nicotine alone didn't cause an over kidney injury. RNA seq analysis revealed that nicotine dramatically exacerbated the expression of Grem1, a DAN family member, which has been demonstrated to play a vital role in the pathogenesis of DN. *In vitro* studies, combined use of nicotine and high glucose displayed an increase in podocyte apoptosis as well as the expression of Grem1; while silencing of Grem1 decreased the number of cells with apoptosis.

Conclusions: Grem1 might play an important role in nicotine-exacerbated DN. Our study has highlighted novel molecular targets for the therapy and prevention of smoking boosted DN.

FR-PO389

Grem2 Mediates Podocyte Apoptosis in High Glucose Milieu

Hongxiu Wen,[2,1] Xiqian Lan,[2,1] Vinod Kumar,[1] Abheepsa Mishra,[1] Rukhsana Aslam,[1] Seyedeh Shadafarin Marashi Shoshtari,[1] Ali Hussain,[1] Ashwani Malhotra,[1] Pravin C. Singhal.[1] *[1]The Feinstein Institute for Medical Research, Northwell Health, MANHASSET, NY; [2]Key Laboratory for Aging and Regenerative Medicine, School of Pharmacy, Southwest Medical University, Luzhou, China*.

Background: The DAN family members (Grem1, Grem2, Grem3, Cerberus, NBL1, SOST, and USAG1) are highly expressed during development where they have an important role in kidney formation and morphogenesis; in adults, however, increased DAN protein levels are often associated with severe disease-states, including renal fibrosis. Grem1, SOST, and USAG1 have been demonstrated to be upregulated and play a critical role in the progression of diabetic nephropathy (DN); other DAN family members have not been reported to be related to renal disease, and their expression in DN kidneys has not be yet investigated. In this study, we investigated the expression and the role of Grem2 in type 2 DN mice.

Methods: *In vivo* studies, 14-weeks-old BTBR ob/ob (a type 2 diabetic mouse model) and control (BTBR, wild-type) mice were evaluated for renal function biomarkers (proteinuria and blood urea nitrogen [BUN]). Kidneys were harvested and renal tissues were analyzed by real-time PCR, Western blotting, and immunohistochemistry studies. *In vitro* studies, human podocytes transfected with Grem2 plasmid were evaluate for apoptosis (morphologic assay and Western blotting). To evaluate the Grem1-mediated downstream signaling, the phosphorylation status of Smad2/3 and Smad1/5/8 was assessed; additionally, SIS3, an inhibitor for Samd3, and BMP-7, an agonist for Smad1/5/8 were used to treat the cells.

Results: *In vivo* studies, the diabetic mice showed elevated levels of and proteinuria BUN. Real-time PCR and Western blotting analysis showed an increased expression of Grem2 in diabetic kidneys. Immuno-histochemical studies showed enhanced Grem2 expression both by tubular and glomerular cells. *In vitro* studies, high glucose increased Grem2 expression in cultured human podocytes, and silencing of Grem2 partially suppressed high glucose-induced apoptosis. Overexpression of Grem2 promoted podocyte apoptosis morphologically as well as by an increased Bax/Bcl2 ratio. Overexpression of Grem2 increased the phosphorylation of Smad2/3 and decreased the phosphorylation of Smad1/5/8, while addition of SIS3 or BMP-7 attenuated Grem2-induced podocyte apoptosis.

Conclusions: High glucose increases Grem2 expression in kidney cells. Grem2 mediates podocyte apoptosis through Smads. Grem2 plays an important role for the progression of DN.

FR-PO390

Activation of Pro-Fibrotic Genes by Nicotine in a Mouse Model of Diabetes: Implications for Diabetic Nephropathy in Smokers

Wenguang Feng,[2] Edgar A. Jaimes.[1] *[1]Memorial Sloan-Kettering Cancer Center, New York, NY; [2]University of Alabama at Birmingham, Birmingham, AL*.

Background: Tobacco use is a well-recognized, preventable risk factor for CKD progression, especially in diabetics; however, the mechanisms involved are not completely understood. We and others have demonstrated that nicotine acetylcholine receptors (nAChR) are present in rat, mouse, and human kidneys, and that the systemic administration of nicotine worsens the severity of renal injury in animal models of CKD. In these studies we hypothesize that siganling via the α7-nAChR promotes the gene expression of pro-fibrotic pathways in diabetic mice receiving nicotine.

Methods: Diabetes (DM) was induced by low dose STZ injection in male eNOS$^{-/-}$ mice (n=6 per group). After confirmation of diabetes nicotine was admnistered in the drinking water (Nic, 100 μg/mL) for 10 weeks. A group of mice was treated with the specific α7nAChR blocker IC200610 (NB, 2 mg/kg IP) 5 days a week for 10 weeks. An additonal group of mice double knockout for eNOS and α7nAChR was also made diabetic (DKDM) and treated with nicotine (Nic, 100 μg/mL). After euthanasia renal cortex mRNA expression for genes involved in fibrosis and inflammation was determined by RT-PCR.

Results: Diabetes resulted in increased expression of genes linked to fibrosis and inflammation (table). The administration of nicotine increased the expression of CTGF, COL1 and MMP2 three genes that have been linked to progression of CKD. The administration of a specific α7nAChR blocker or genetic deletion of α7nAChR reduced the expression of these genes suggesting that these effects are mediated via signaling activated by this receptor.

Conclusions: The administration of nicotine to diabetic mice results in increased expression of CTGF and MMP2 two genes involved in the pathogenesis of progressive CKD including diabetic nephropathy. In addition these effects appear to be mediated by the α7nAChR which could potentailly be a therapeutic target for diabetes with CKD who use nicotine containing tobacco products.

Modulation of GSK-3β Expression by AMPK Ameliorates Diabetic Kidney Injury by Promoting IR Phosphorylation Cascade

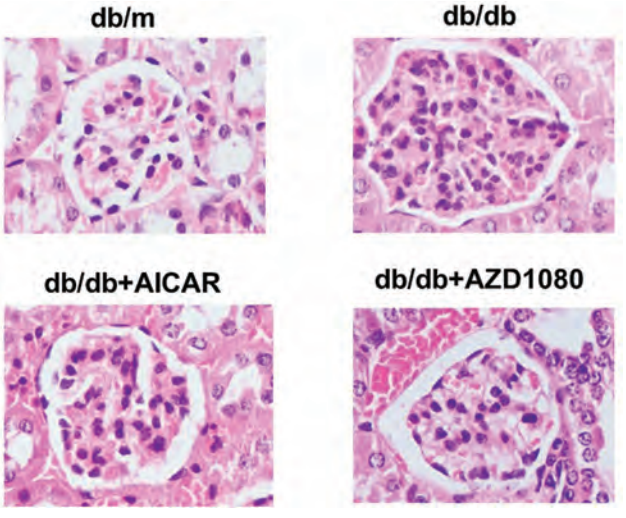
Bo Zhang, Suyan Duan, Yanggang Yuan. *The First Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Insulin resistance is a systemic disorder that affects many organs and insulin-regulated pathways. Insulin signaling to the glomerular podocyte is important for normal kidney function and is implicated in the pathogenesis of diabetic nephropathy (DN). It has recently been found that GSK-3β may play a role in the pathogenesis of diabetes and DN; however, the specific mechanism is still unknown. We aimed to investigate whether GSK-3β has a role in the amelioration of podocyte injury and insulin resistance, thus suppressing the progression of DN. Moreover, the molecular mechanisms responsible for the effects were examined.

Methods: Podocyte insulin responses were investigated with western blotting, cellular glucose uptake assays and fluorescent imaging of the insulin receptor signalling. Quantitative (q)RT-PCR was employed to investigate changes in mRNA. Cell viability and motility were detected by CCK-8 and wound healing assay. Db/db mice injected with different treatment were also generated. ELISA measurements were also used.

Results: Our results demonstrated that AMPK modulates podocyte IR level and enhances insulin-stimulated phosphorylation of PI3K/Akt cascades in high-glucose condition and diabetic db/db mice. Plus, AMPK prevented hyperglycemia-induced increase of GSK3β phosphorylation, ameliorated glucose uptake into podocytes, and impaired podocyte viability and motility. Moreover, treatments for modulation of key proteins in AMPK- PI3K/Akt -GSK3β signalling results in a reduction of proteinuria and significant improvement in renal function and pathological damage in db/db mice.

Conclusions: These findings evoke a novel therapeutic concept for DN, implying that the pharmacologic activation of AMPK might suppress the progression of DN and podocyte injury, also rescue podocyte insulin resistance. AMPK-PI3K/Akt- GSK3β pathway may be exploited as a therapeutic target for protection against podocyte injury and insulin resistance in DN.



Representative HE staining of diabetic kidney in each group

Circulating Soluble Nogo-B Ameliorates Diabetic Glomerulopathy Partly by Modulating GSK3β/βcatenin Signaling

Carlo alberto Ricciardi,[1] Ivan Hernandez,[1] Georgia E. Fouli,[1] Anthea E. Hayward,[1] David A. Long,[2] Luigi Gnudi.[1] *[1]King's College London, London, United Kingdom; [2]University College London, London, United Kingdom.*

Background: Early diabetic glomerulopathy (DG) is characterised by albuminuria, endothelial cell (EC) proliferation, EC glycocalyx disruption and podocyte loss. Nogo-B, expressed in glomerular EC and podocytes, is downregulated in diabetes. A 200-aminoacid N-terminus soluble Nogo-B (sNogo-B) is found in the circulation and (as Nogo-B) binds to its receptor NgBR promoting vascular integrity. Activation of GSK3β/βcatenin pathway promotes vascular stability; conversely, inactivation of GSK3β with βcatenin cellular accumulation, as seen in diabetes, promotes VEGFR2 signaling and ECs proliferation/vascular permeability. We investigated whether, in diabetes, sNogo-B overexpression modulates GSK3β/βcatenin and VEGFA signaling towards a stable glomerular capillary.

Methods: Adult DBA2J male mice were made diabetic with streptozotocin; sNogo-B overexpression was initiated after induction of diabetes by adeno-associated vector (AAV) (AAV driving the expression of green fluorescent protein-GFP served as control). Mice with glycemia >22 mM were considered diabetic. Mice were killed after 12-14 weeks of diabetes and kidney tissue collected for electron microscopy and immunofluorescence, respectively for podocyte number and EC proliferation/glycocalyx determination; renal cortex lysate was utilised for VEGFA/VEGFR2 phosphorylation levels (ELISA), and AKT, GSK3β/βcatenin signaling (western immunoblotting). Abuminuria was measured by ELISA.

Results: Diabetes (D) resulted in albuminuria, glomerular EC proliferation, EC glycocalyx disruption and podocyte loss when compared to non-diabetic (ND) mice (ND-GFP *vs* D-GFP, $p<0.01$); sNogo-B overexpression ameliorated diabetes-mediated albuminuria and vasculature anatomical alterations and was paralleled by inhibition of diabetes-mediated AKT^{ser473} and $GSK3\beta^{ser9}$ phosphorylation (D-GFP *vs* D-sNogo-B, $p<0.05$). βcatenin was highly expressed in kidney cortex lysate of D-GFP mice (ND-GFP *vs* D-GFP, $p<0.001$) and was downregulated in D-sNogo-B mice (D-GFP *vs* D-sNogo-B, $p<0.01$), an event paralleled by a normalisation of diabetes-mediated VEGFA/VEGFR2 receptor system activation (D-GFP *vs* D-sNogo-B, $p<0.04$).

Conclusions: sNogo-B overexpression in diabetic mice promotes a healthy vasculature *via* activation of GSK3β/βcatenin pathway; sNogo-B could represent a targetable pathway for the treatment of DG.

FR-PO393

Deacetylation of S6 Kinase (S6K) by High Glucose Drives Mesangial Cell (MC) Hypertrophy and Matrix Expansion in Diabetic Nephropathy (DN)

Falguni Das, Nandini Ghosh-choudhury, Balakuntalam S. Kasinath, Goutam Ghosh-Choudhury. *UTHSCSA, SAN ANTONIO, TX.*

Background: Hyperglycemia increases mTORC1-dependent S6K Thr-389 phosphorylation/activation to induce glomerular MC hypertrophy and matrix protein expansion in DN. S6K is acetylated in the C-terminal lysines (K484/485/493). We investigated the mechanism of S6K acetylation in relation to MC hypertrophy and fibronectin expression.

Methods: Human MCs in culture and streptozotocin (STZ)-induced diabetic rats were used. Activation/inactivation-specific phospho-antibodies, siRNA and plasmid-derived expression vector transfection and immunoblotting were employed.

Results: In MCs, 25 mM glucose (HG) decreased acetylation of multiple proteins including S6K concomitant with its increase in phosphorylation/activation. Consequently, HG increased phosphorylation of the S6K substrates rps6 and eEF2 kinase that resulted in dephosphorylation of eEF2. To determine the mechanism of S6K deacetylation, we considered the class I histone deacetylase-1 (HDAC1). Trichostatin-A (TSA), a pan HDAC inhibitor, blocked all of the HG-stimulated effects. HG increased the association of S6K with HDAC1. Expression of HDAC1 decreased the acetylation of S6K and increased the phosphorylation of S6K, rps6, eEF2 kinase, and dephosphorylation of eEF2, resulting in MC hypertrophy and expression of fibronectin, similar to HG. In contrast, siRNA against HDAC1 prevented these effects induced by HG. To study the precise mechanism, an acetylation mimetic triple mutant (TKA) was used. Expression of TKA blocked HG-stimulated phosphorylation of S6K, rps6, eEF2 kinase and inhibited the dephosphorylation of eEF2 resulting in attenuation of MC hypertrophy and fibronectin expression. In contrast, acetylation deficient mutant S6K (TKR) induced above phosphorylation events, and MC hypertrophy and fibronectin expression, similar to HG. Finally, in the renal glomeruli of STZ-induced diabetic rats, acetylation of S6K was significantly reduced concomitant with increased HDAC1, S6K activation, phosphorylation of rps6 and eEF2 kinase, dephosphorylation of eEF2, renal hypertrophy and fibronectin expression.

Conclusions: Our data for the first time show a role of S6K deacetylation in MC hypertrophy and matrix expansion, two pathologic features of DN. The results also furnish a molecular basis underlying the association between S6K and HDAC1 in DN.

DcR2 Interacts with Peroxiredoxin 1 and Accelerates Senescence of Renal Tubular Epithelial Cell in Diabetic Nephropathy

Jia Chen, Yani He. *Daping Hospital, Chongqing, China.*

Background: Diabetic nephropathy (DN) is the leading cause of end-stage renal disease (ESRD). The extent of tubulointerstitial lesions ultimate determines the rate of attrition of renal function, and premature senescence of RTECis a prominent renal histological change in DN. Decoy receptor 2 (DcR2) is a transmembrane receptor of cellular senescent marker, but the interaction proteins and the role of DcR2 are not clear.

Methods: 139 DN patients which diagnosed by renal biopsy were enrolled. Renal DcR2 and senescent markers, P16 and SA-β-gal were detected with immunostaining. The degree of cell senescence were evaluated after regulation of DcR2 expression. Co-IP combining with LC-MS/MS were screened the interaction proteins for DcR2 in renal tissue and high glucose (HG) induced-proximal tubular epithelial cells (PTECs). The interaction of DcR2 and PRDX1 was detected by Co-IP and pull down assay. Peroxidase activity of PRDX1 was assessed by the kits of ROS and specific 2-cys peroxidase activity. The level of PRDX1 phosphorylation was detected through WB.

Results: DcR2 was primarily expressed in renal proximal tubules, and co-expression with senescent markers P16 and SA-β-gal. Overexpression of DcR2 accelerate whereas knockdown inhibited the expression of P16 and SA-β-gal. Quantitative proteomics identified 135 differentially expressed proteins (DEPs) in renal tissue and 59 DEPs in HG. Peroxiredoxin 1 (PRDX1), an enzyme of oxidative stress, was screened not only in renal tissue but also in HG-induced cells. The interaction of DcR2 and PRDX1 was verified in vivo and in vitro. DcR2 can inhibited the peroxidase activity of PRDX1 through promote the phosphorylation of PRDX1.

Conclusions: DcR2 accelerates tubular cell senescence through interacting with a new partner PRDX1, and DcR2 can affect the peroxidase activity of PRDX1 through regulating the phosphorylation of PRDX1 in DN.

SMPDL3b Modulates Insulin Signaling in Lipid Raft Domains and Interferes with Diabetic Kidney Disease

Alla Mitrofanova,[1] Shamroop Kumar Mallela,[1] Gloria Michelle Ducasa,[1] Tae-Hyun Yoo,[2] Judith T. Molina David,[3] Mengyuan Ge,[3] Jin Ju Kim,[3] Christopher E. Pedigo,[7] Christian Faul,[4] Yu Ishimoto,[5] Reiko Inagi,[6] Sandra M. Merscher,[3] Alessia Fornoni.[3] *[1]University of Miami School of Medicine, Miami, FL; [2]Yonsei University College of Medicine, Seoul, Republic of Korea; [3]University of Miami, Miami, FL; [4]The University of Alabama at Birmingham, Birmingham, AL; [5]Tokyo University, Hongo, Japan; [6]The University of Tokyo Graduate School of Medicine, Bunkyo-ku, Japan; [7]Yale University, New Haven, CT.*

Background: SMPDL3b is a recently identified phosphodiesterase localized in lipid raft domains that regulates lipid composition and plasma membrane fluidity. As SMPDL3b is upregulated in diabetes while insulin receptor signaling is impaired, our study was aimed at testing the hypothesis that SMPDL3b affects the generation of sphingolipids involved in the regulation of insulin receptor signaling.

Methods: For *in vitro* studies, control and SMPDL3b overexpressing human podocytes were used. Cells were treated with insulin (0.1 and 1 nM, 30 min) or ceramide-1-phosphate (C1P; 100 uM, 1h) and analyzed by Western blotting or PCR. Lipidomic analysis was performed using LC-MS analysis and TLC plates. Co-immunoprecipitation experiments were performed using HEK293 cells. For *in vivo* studies, podocyte-specific *Smpdl3b* deficient diabetic db/db mice were produced using Cre-LoxP technology. Starting at 4 weeks of age, vital parameters (weight, glycemia, urine) were measured bi-weekly. For C1P replacement therapy, diabetic mice were IP injected with 30 mg/kg C1P daily for 28 days. Mice from all experiments were sacrificed for in-depth phenotypical analysis. All animal studies were performed in accordance with the NIH IACUC Guide. For statistical analysis One-Way ANOVA followed by Bonferroni's posttest or Student t-test were used.

Results: SMPDL3b binds to both IR isoforms (IRA and IRB) and, when in excess, competes with the binding of IRB to caveolin-1 and alters pro-survival insulin signaling in podocytes. *In vivo*, we demonstrated that kidneys of diabetic db/db mice are characterized by SMPDL3b excess and C1P deficiency, whereas podocyte-specific *Smpdl3b* deficient diabetic db/db mice show a normal C1P content and are protected from the development of diabetic kidney disease (DKD). Exogenous administration of C1P is sufficient to restore proper IR signaling *in vitro* and to protect from DKD *in vivo*.

Conclusions: Taken together, we identified new sphingolipid modulator of insulin signaling and demonstrated that replacement of deficient active sphingolipid species such as C1P may represent a novel approach to treat diabetic complications such as DKD.

LXR/mTOR/Nox4 Signaling Axes: Novel Therapeutic Targets in Diabetic Nephropathy

Sahar Alkhansa,[2] Stephanie A. Eid,[2] Christopher El mouhayyar,[3] Neamah Mahjoub,[2] Rasha Barakat,[4] Assaad Antoine Eid.[1] *[1]American University of Beirut/Faculty of Medicine, Beirut, Lebanon; [2]American University of Beirut, Beirut, Lebanon; [3]American Univeristy of Beirut, Naccache, Lebanon; [4]Universite Paris Descartes, Amioun, Lebanon.*

Background: Podocyte injury has emerged as a key mediator in the initiation of Diabetic Nephropathy (DN). The molecular mechanism by which hyperglycemia induces podocyte injury is multi-factorial and not well defined. Recent studies have described the potentiality of defective autophagy mechanisms on the onset and development of diabetes. Our lab has described the importance of renal NADPH Oxidases (Noxs) in the progression of podocyte injury. Yet, a mechanistic pathway between Nox-induced ROS production and the alteration in autophagy has yet to be clarified. Liver-X-receptor (LXR) and the mTOR pathway have recently been linked to autophagy and oxidative stress. In this study we aim to assess the role of Nox/LXR/mTOR axes on autophagy and their possible links to podocyte depletion and injury.

Methods: Pharmacological means were utilized to alter the expression of Noxs, LXR and the mTOR signaling pathways, while podocyte depletion/loss, autophagy alteration and glomerular injury were assessed as the corresponding biological output both *in vitro* and *in vivo*.

Results: Our results reveal that high glucose (HG) induces defective autophagy in both podocytes and isolated glomeruli of type 2 diabetic mice. HG reduces LXR mRNA levels and protein expression and activates the mTORC1/p70S6kinase pathway. HG also increases the levels of Nox4 and Nox activity and induces ROS production. Activation of the LXR pathway using an LXR activator T0, decreases HG-induced Nox4 expression, Nox activity, inactivates the mTORC1 pathway, and restores autophagy protein levels. In parallel, inactivation of the mTORC1 pathway using low dose rapamycin, mimicked the effect of T0 on ROS production and podocytes injury but did not alter the LXR pathway, suggesting that mTORC1 is downstream of LXR and Noxs are the final common pathway altered in our experimental model. More importantly, our results display the role of Nox4 in autophagy, where inactivation of Nox4, using GKT, a potent Nox1 and Nox4 inhibitor, restores homeostatic autophagy levels, and reduces podocytes and glomerular injury.

Conclusions: Thus, LXR activation, mTOR and/or NADPH oxidase inhibition may represent a therapeutic modality for diabetic kidney disease.

FR-PO397

High Glucose–Induced Apoptosis and Necroptosis in Podocytes Is Regulated by UCHL1 via the RIPK1/RIPK3 Pathway

Yuyin Xu,[1] Chenyang Qi,[2] Huijuan Wu,[2] Zhigang Zhang.[2] *[1]Departmen of pathology, School of basic medical science, Fudan University, Shanghai, China; [2]Department of Pathology, School of Basic Medical Sciences, Fudan University, Shanghai, China.*

Background: Depletion of podocytes plays a critical role in the pathogenesis of diabetic nephropathy (DN). Many investigations suggested its close association with apoptosis. However, the complex mechanism of podocyte loss in DN remains unclear. Recently, necroptosis has emerged as an important cell death model in cell injury related to many pathological conditions, which is regulated through the receptor interacting kinase 1/3 (RIPK1/RIPK3) pathway. It has been revealed that the molecular pathways to regulate apoptosis and necroptosis are closely related. Therefore, it is speculated that apoptosis and necroptosis may occur simultaneously during the process of podocyte injury in DN.

Methods: Immunofluorescence staining, trypan blue staining, Hoechst staining, TUNEL and ELISA were used to detect apoptosis and necroptosis of podocytes *in vitro and in vivo*. The ultrastructures of the two cell death patterns were observed under scanning electron microscope (SEM). After stimulation of podocytes with high glucose (HG), the expression of UCHL1 and RIPK1/RIPK3 pathway and the regulation effect of UCHL1 on apoptosis and necroptosis of podocytes were detected by western blot. The endogenous binding of UCHL1 with RIPK1 or RIPK3 and the ubiquitination of RIPK1 and RIPK3 proteins was detected by IP experiment.

Results: The present study demonstrated that necroptosis was involved in HG-induced podocyte injury both *in vitro* and *in vivo*. HG could induce both apoptosis and necroptosis in podocytes, which was dependent on HG concentration and treatment duration. This novel study explored the explicitly different morphological characteristics of apoptotic and necroptotic cells using SEM examination with TUNEL and Trypan blue double staining. The inhibition of apoptosis by z-VAD-fmk could enhance the necroptosis process, which was inhibited by Necrostatin-1(Nec-1). The present study also showed that ubiquitin carboxyl-terminal hydrolase L1 (UCHL1) had a central role in regulating the two modes of cell death via mediating the ubiquitination states of the RIPK1/RIPK3 pathway.

Conclusions: These data suggested that necroptosis might be a major contributor to podocyte loss rather than apoptosis in HG treatment. The discovery of the novel function of UCHL1 may assist in developing strategies for treating podocyte damage induced by HG.

Amodiaquine and Chloroquine Attenuate Mitochondrial Abnormalities in Diabetic Tubulopathy Presumably by AMPK Phosphorylation

So-young Lee,[1] Dong Ho Yang,[2] Jun mo Kang,[2] Min ji Sung,[2] Yubum Choi,[2] Wooyeol Ahn,[3] Su Woong Jung,[4] Soonchul Lee.[5] *[1]Internal Medicine, CHA Bundang Medical Center, CHA Univ., Seongnam, Gyeonggi-do, Republic of Korea; [2]Internal Medicine, Bundang CHA medical center, CHA university, Seongnam, Gyeonggi-do, Republic of Korea; [3]CHA University, Seongnam, Gyeonggi-do, Republic of Korea; [4]Internal Medicine, Kyung Hee University Hospital at Gangdong, Kyung Hee University, Seongnam, Gyeonggi-do, Republic of Korea; [5]Orthopaedic Surgery, CHA Bundang Medical Center, CHA university, Seongnam, Gyeonggi-do, Republic of Korea.*

Background: The activity of 5' AMP-activated protein kinase (AMPK), the major energy-sensing enzyme, was recently observed to be reduced in the kidneys of both diabetic mice and humans. Several previous studies showed that AMPK activators attenuate diabetic nephropathy, resulting in decreased albuminuria in diabetic mice. Chloroquine (CQ), an antimalaric drug, has also been considered an essential therapy in patients with systemic lupus erythematosus (SLE). It was reported that withdrawal of amodiaquine (AQ), a derivative of chloroquine is related to lupus flares after medication cessation. Although the mechanisms by which these agents act on SLE are unclear, a recent study reported that chloroquine increased AMPK phosphorylation in myotube cells. We investigated the effects of CQ and AQ on AMPK phosphorylation in renal tubular cells in a diabetic environment in vivo and in vitro. We also examined whether CQ- or AQ-mediated AMPK activity restoration attenuated diabetic tubulopathy by normalizing mitochondrial fragmentation.

Methods: Human renal proximal epithelial cells (HKC8) were incubated in high-glucose conditions. Diabetes was induced with streptozotocin in male C57/BL6J mice.

Results: Treatment with CQ or AQ abolished high-glucose-induced phospho-AMPK and phosph-PGC1α down-regulation in HKC8 cells. Improvements in functional mitochondrial mass and balanced fusion/fission protein expression were observed in HKC8 cells after treatment with CQ or AQ in high-glucose conditions. Moreover, decreased mitochondrial ROS production and reduced apoptotic and fibrotic protein expression were noted in HKC8 cells after treatment with CQ or AQ, even in high-glucose conditions. CQ and AQ treatment effectively mitigated albuminuria and renal histopathologic changes and increased AMPK activity in the kidneys of diabetic mice. Electron microscopy analysis showed that mitochondrial fragmentation was decreased, and 8-OHdG content was low in the renal tubular cells of the CQ and AQ treatment groups compared with those of the diabetic control group.

Conclusions: Our results suggest that CQ and AQ may be useful treatments for patients with diabetic kidney disease. This work was supported by a National Research Foundation grant of Korea (NRF-2016R1C1B1013814) funded by the Korea government.

Sirt6 Protects Podocytes from High Glucose-Induced Mitochondrial Dysfunction and Apoptosis Through AMPK Activation

Guohua Ding, Yanqin Fan. Division of Nephrology, Renmin Hospital of Wuhan University, Wuhan, Hubei, China *Renmin Hospital of Wuhan University, Wuhan, China*.

Background: Previous studies have shown that mitochondrial dysfunction plays an important role in podocyte injury. Sirt6 has been revealed with essential roles in the regulation of mitochondrial function. However, the pathological features and molecular mechanism of mitochondrial damage in podocytes under high glucose (HG) condition remains unknown. The present study aims to observe the changes of podocyte mitochondria under HG and to evaluate whether Sirt6 contributes to HG-induced podocytes apoptosis through modulating mitochondrial function.

Methods: In vivo study, transmission electron microscope (TEM) was used to identify ultrastructure changes of podocyte mitochondria in diabetic mice. Co-localization expression of Sirt6 and WT-1 was evaluated in glomeruli by double immunolabeling. Western blot was performed to assess Sirt6 and p-AMPK expression in glomeruli. In vitro study, conditionally immortalized human podocytes were exposed to HG (30mM) for 24 h. Mitochondria ultrastructure was observed by TEM. Mitochondrial number and ROS production were respectively evaluated by Mito Green and MitoSox Red staining. Mitochondrial membrane potential was determined by JC-1 staining. Flow cytometry was used to assess podocyte apoptosis. Western blot was performed to evaluate Sirt6 and p-AMPK expression.pcDNA3.1 SIRT6 was transfect to podocytes to evaluate the effect of Sirt6 over-expression on mitochondrial function and podocyte apoptosis under HG stimulation.

Results: Ultrastructural changes of podocytes in diabetic mice included mitochondria swelling, vacuoles formation, and mitochondrial cristae fracture. Double immunolabeling of Sirt6 and WT-1in glomeruli was obviously decreased in diabetic animals. In addition, p-AMPK expression was reduced in diabetic mice compared with controls. In cultured podocytes, TEM studies showed mitochondria swelling and cristae fracture under HG treatment. HG induced decrease in mitochondrial number and increase in mitochondrial ROS production. Furthermore, HG induced decreased mitochondrial membrane potential. All these changes were significantly alleviated by pcDNA3.1 SIRT6 transfection. Sirt6 overexpression also stimulated p-AMPK expression and alleviated HG-induced podocyte apoptosis.

Conclusions: These results indicate that Sirt6 could protect podocytes from high glucose-induced mitochondrial damage and apoptosis via AMPK activation.

Renoprotective Function of Liver Type Fatty Acid Binding Protein (L-FABP) in Diabetic Kidney Disease via Activation of Mitochondrial Function

Shiika Watanabe,[1] Takeshi Sugaya,[1] Daisuke Ichikawa,[1] Kenjiro Kimura,[2] Yugo Shibagaki,[1] Atsuko Ikemori.[1] *[1]St. Marianna University School of Medicine, Kawasaki, Japan; [2]Tokyo Takanawa Hospital, Tokyo, Japan*.

Background: Tubulointerstitial damage (TID) in diabetic kidney disease (DKD) is one feature of histopathology observed in the diabetic patients with early progressive renal decline. Therefore, TID is a therapeutic target in order to prevent the progression of DKD. Recently, TID in DKD is reported to be associated with renal mitochondrial injury. Renal liver type fatty acid binding protein (L-FABP) has an anti-oxidant effect as a scavenger of reactive oxygen species. However, the interaction between renal L-FABP and mitochondrial function has not been investigated yet. Therefore, the aim of this study is to reveal the renoprotective potential of renal L-FABP via activation of mitochondrial function in streptozotocin-induced DKD.

Methods: To evaluate the role of renal L-FABP, we used human L-FABP chromosomal transgenic (Tg) mice because L-FABP is not expressed in the kidneys of wild-type (WT) mice. The (Tg) mice and wild-type (WT) mice were divided into two groups: diabetic mice were injected with STZ; control mice were injected with a citrate buffer alone. At 19 weeks after these injections, the mice were killed and the kidney, and urine were isolated for analysis.

Results: The expression of renal L-FABP and the level of urinary L-FABP increased significantly in diabetic Tg mice compared to control Tg mice. Urinary albumin levels, the expression of α-smooth muscle actin in the interstitium and the level of renal oxidative protein were significantly lower in diabetic Tg kidneys compared with diabetic WT kidneys. The expression of mitochondrial superoxide dismutase 2 was significantly higher in diabetic Tg kidneys compared with diabetic WT kidneys. In the diabetic Tg kidneys, the expression of PPARγ co-activator 1α(PGC-1α) was significantly higher than that of diabetic WT kidneys.

Conclusions: In conclusion, renal L-FABP could activate mitochondrial function by acceleration of mitochondrial biogenesis due to rise of PGC-1α expression, and attenuate renal oxidative stress, and consequently, the renal fibrosis were prevented. Increase in renal L-FABP expression may be a promising treatment against TID in DKD.

FR-PO401

Disruption of Renal Tubular Mitochondrial Quality Control by KCa3.1 in Diabetic Nephropathy

Chunling Huang, Hao Yi, Ying Shi, Qinghua Cao, Xinming Chen, Carol A. Pollock. *kolling institute, the University of Sydney, St. Leonards, NSW, Australia*.

Background: Mitochondrial dysfunction is involved in the pathogenesis of diabetic nephropathy. Mitochondrial quality control is characterized by repairing of mitochondrial damage through mitophagy and fission/fusion. It has been shown that blockade of KCa3.1, a potassium channel, ameliorates diabetic renal fibrosis and KCa3.1 activation contributes to dysfunctional tubular autophagy in diabetic nephropathy through PI3K/Akt/mTOR signaling pathways. However, the role of KCa3.1 in mitochondrial quality control is not yet known. Therefore, the aim of the study is to identify the role of KCa3.1 in mitochondrial quality control in diabetic nephropathy.

Methods: In vitro human proximal tubular cells (HK2 cells) transfected with scrambled siRNA or KCa3.1 siRNA were exposed to TGF-β1 for 48h. Mitochondrial function and mitochondrial ROS (mtROS) production were assessed. In vivo, diabetes was induced in KCa3.1+/+ and KCa3.1-/- mice by streptozotocin injection. The pro-fission protein dynamin-related protein 1 (Drp1) and pro-fussion protein mitofusin 2 (Mfn2) as well as BCL2 interacting protein 3 (BNIP3) (a mitophagy regulator) were examined by western blotting in HK2 cells and mice kidneys.

Results: The in vitro results showed that TGF-β1 significantly inhibited mitochondrial ATP production rate, compared to the controls, which were significantly reversed by KCa3.1 siRNA in HK2 cells. KCa3.1 gene silencing inhibited TGF-β1-induced significant increase in MitoSOX Red fluorescence in HK2 cells. TGF-β1 significantly increased the expression of Drp1 and BNIP3 in HK2 cells, which were attenuated by KCa3.1 gene silencing. The expression of Mfn2 was not overtly apparent on TGF-β1 stimulation. Consistently, the in vivo results showed significantly increased Drp1 and BNIP3 expression in diabetic KCa3.1 +/+ mice, which were significantly reduced in diabetic KCa3.1-/- mice.

Conclusions: KCa3.1 mediates dysregulation of mitochondrial quality control in diabetic nephropathy.

FR-PO402

Urothelial-Specific Insulin Receptor Deletion Suppresses Host Defenses of the Kidney and Bladder

Matthew J. Murtha,[2] Laura Schwartz,[3] Kristin Bender,[5] Birong Li,[6] Tad Eichler,[4] John D. Spencer.[1] *[1]The Research Institute at Nationwide Children's, Columbus, OH; [2]Ohio State University Hospital, Columbus, OH; [3]Nationwide Children's Hospital, Columbus, OH; [4]The Research Institute at Nationwide Childrens Hospital, COLUMBUS, OH; [5]The Research Institute at Nationwide Children's Hospital, Columbus, OH; [6]Nationwide Children's Hospital, Columbus, OH*.

Background: In people with diabetes mellitus (DM), urinary tract infection (UTI) is more common and has worse outcomes. With DM, UTI is more likely to cause acute kidney injury, which increases the risk of chronic and end-stage kidney disease. The mechanisms that predispose diabetics to UTI remain elusive. To investigate the significance of insulin signaling on kidney and urothelial host defense, we genetically deleted the insulin receptor (IR) in murine urothelium.

Methods: Urothelial-specific IR knock-out mice (IRKO) were generated by breeding homozygous mice for the floxed *Insr* gene (insulin receptor gene) with transgenic mice that have tamoxifen-inducible Cre recombinase under the Uroplakin 2 (Upk2) promoter. Littermates lacking the Upk2-Cre transgene served as controls (IRflox). To determine if urothelial-specific IR deletion impacts host defense, female mice were transurethrally infected with uropathogenic *E. coli* (UPEC). At 24, 48, and 72 hrs post infection, UPEC burden was enumerated in urine, bladder, and kidney. To assess why IRKO mice have increased UTI susceptibility, human urothelial cells were assayed *in vitro* using siRNA to silence IR and investigate if silencing IR disrupts urothelial barrier formation.

Results: PCR confirmed urothelial-specific Cre-LoxP recombination and IR transcript deletion in bladders of IRKO mice. Compared to IRflox, IRKO mice exhibit normal development, no evidence of hyperglycemia, and normal bladder/kidney histology. Following transurethral UPEC infection, the bladders of IRKO mice developed significantly pronounced and prolonged inflammation and edema. This was accompanied by significantly greater UPEC burden in the urine, bladder, and kidneys at all time points. siRNA-mediated *INSR* silencing in human bladder cells *in vitro* resulted in marked differences in urothelial proliferation and migration.

Conclusions: These results suggest that intact insulin signaling is critical for UTI defense. Also, they indicate that hyperglycemia alone does not explain increased UPEC susceptibility. Finally, they indicate that abnormal bladder defenses, including a reduced ability to regenerate an impermeable urothelial barrier, increases the likelihood for significant bladder and kidney infection. Additional studies are warranted to identify how IR deletion impacts urothelial defenses.

Genetic Regulation of Diabetic Kidney Disease Traits and Transcriptome Signature in Mice

Xiuju Wu,[2] John M. Basgen,[3] Daria Merkurjev,[4] Aldons J. Lusis,[5] Susanne B. Nicholas.[1] *[1]Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Human Genetics, David Geffen School of Medicine at UCLA, Los Angeles, CA; [3]Charles Drew University, Minnetonka, MN; [4]Human Genetics, David Geffen School of Medicine at UCLA, Los Angeles, CA; [5]Human Genetics, David Geffen School of Medicine at UCLA, Los Angeles, CA.*

Background: Diabetic kidney disease (DKD) is the leading cause of chronic kidney disease and end-stage renal disease. Thus far, the genetic factors contributing to hallmark features of DKD remain poorly understood. Our goal was to assess DKD and associated molecular markers in an intercross between two strains of mice differing in albuminuria on the background of the diabetes-inducing *Ins2*^{Akita} mutation.

Methods: We generated F2 mice from a cross between maternal CBA/J and paternal C57BL/6J-Ins2^{Akita} mice. We measured albumin-to-creatinine ratio (ACR) on 24-h urine from F2 mice at age 7 and 20 weeks. Kidney morphometry was quantified by light and electron microscopy at 20 weeks. We performed RNA sequencing on kidney cortex to identify transcripts associated with physiologic and structural traits. Linkage analysis identified causal loci of physiologic and molecular traits.

Results: We observed 20-fold variation in ACR among 87 diabetic F2 mice at age 20 weeks. Plasma glucose (p=1.7×10^{-6}), kidney weight (p=1.0×10^{-6}), glomerular volume (p=2.1×10^{-11}), glomerular basement membrane width (p=2.2×10^{-5}), total mesangial cell (1×10^{-2}) and total mesangial matrix (p=1.5×10^{-4}) increased significantly in diabetic F2 mice versus non-diabetic mice. We detected a significant quantitative trait locus for ACR on chromosome 4 (LOD=3.79, p=0.030) and a locus for volume fraction of mesangial cell and total mesangial cell on chromosome 14, LOD=3.79, p=0.031. We identified regulatory pathways enriched for oxidative stress (p=1.23×10^{-14}), fatty acid metabolism (p=6.86×10^{-11}) and mitochondrial function (p=4.51×10^{-12}) associated with ACR.

Conclusions: The study identified a genetic basis for increases in volume fraction of mesangial cell, total mesangial cell and ACR, and regulatory pathways associated with oxidative stress, fatty acid metabolism and mitochondrial function in DKD. The study provides further insight to the genetic determination of DKD traits.

Integrated Epigenetic Analysis for Kidney Function and Functional Decline Defines Novel Biological Pathways for Patients with Diabetic Kidney Disease

Xin Sheng,[1] Chengxiang Qiu,[2] Caroline A. Gluck,[3] Raymond R. Townsend,[4] Katalin Susztak.[2] *[1]university of pennsylvania, Philadelpiha, PA; [2]University of Pennsylvania, Philadelphia, PA; [3]Nemours/AI DuPont Hospital for Children, Wilmington, DE; [4]University of Pennsylvania School of Medicine, Villanova, PA.*

Background: Poor metabolic control induces epigenetic changes, which play an important role in development and progression of diabetic kidney disease (DKD). Prior studies failed to integrate epigenetic information with genotype and transcriptomic data. Here we performed an integrated epigenetic, genetic and transcriptomic analysis in CRIC (Chronic Renal Insufficiency Cohort).

Methods: We analyzed genome wide cytosine methylation changes in blood samples of 473 patients with DKD from the CRIC. Subjects were matched for baseline features but showed differences in their kidney function decline. We adopted linear regression model adjusted for age, sex, batch, genetic background, hypertension, cell type heterogeneity and glucose control for eGFR and eGFR slope. To distinguish between genetically or environmentally driven methylation differences, we catalogued genotype-driven methylation changes by performing mQTL (methylation quantitative trait) analysis. To define genetically driven gene expression changes, we performed expression of quantitative trait analysis (eQTL). Bayesian co-localization analysis was adopted to identify causal genes by integrating GWAS, mQTL and eQTL datasets.

Results: We identified that methylation level of 2 probes significantly associated with baseline kidney function (eGFR). Methylation level of 9 probes significantly association with kidney function decline. We were able to replicate the association for 3 of the 11 probes in the ARIC (Atherosclerosis Risk in Communities Study) and FHS (Framingham Heart Study) cohorts. We found that methylation of 6 of the 11 loci were driven by genetic variation (mQTL SNP). To understand functional consequences of methylation changes, we integrated the results with RNA-seq data using expression of quantitative trait (eQTL) analysis. We found that the expression of (Lyzosome) LYZ significantly associated with the genetic variation and methylation differences. Transcript level of LYZ in the kidney also strongly correlated with kidney function.

Conclusions: We identified and replicated significant methylation changes associated with kidney function and functional decline. Integrated genetic, epigenetic and transcriptomic analysis defines genetically and potentially environmentally driven changes and novel biological mechanisms for DKD.

FR-PO405

Inhibition of P2X7 Receptor Delays the Progression of Diabetic Nephropathy and Represses Klotho Expression

Elisa M. Higa,[1] Maria jose D. Fernandes,[2] Robson S. Serralha,[1] Deyse Lima,[1] Giovana Punaro,[1] Adelson Rodrigues.[1] Laboratory of Nitric Oxide and Oxidative Stress *[1]Medicine, Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [2]Neurology, Neurosurgery and Neuroscience, Universidade Federal de Sao Paulo, Sao Paulo, Brazil.*

Background: Previous studies in our laboratory have suggested that P2X$_7$ could contribute to the progression of diabetic nephropathy and modulate klotho expression. Aim of this study was to investigate the role of P2X$_7$ knockdown in the onset of diabetic nephropathy and its possible relationship with klotho, in rats.

Methods: Seven-week-old male Wistar rats weighing 210g were all uninephrectomized; two-thirds were induced to diabetes with 60mg/kg streptozotocin i.v., and one-third received its vehicle (control rats). At 4th day of the fifth week of the protocol, half of the diabetic rats received a small interfering RNA targeting for P2X$_7$ mRNA, and the other half received its vehicle. Euthanasia was made at the eighth week.

Results: Diabetic animals reproduced all classic symptoms of the disease; besides, they showed reduced renal function and low NO bioavailability; also SOD1, SOD2 and catalase were increased, probably due to the oxidative stress factors which were elevated in this situation. Metabolic data of diabetic rats did not change by silencing P2X$_7$ receptor. For the other hand, silencing P2X$_7$ was able to increase plasma and membrane forms of klotho, which in turn could have contributed to balance oxidative and nitrosative profile, ultimately improving the renal function.

Conclusions: These findings suggest that the management of P2X$_7$ receptor can benefit the kidneys or perhaps even other organs involved in diabetic nephropathy. Maneuvers like silencing P2X$_7$ can be used as an adjuvant therapy in diabetes mellitus, improving the quality of life of these patients.

FR-PO406

Effects of Chronic Renal Impairment on Glucose Homeostasis: Role of Class II PI3K-C2β

Samira Alliouachene, Julius E. Kieswich, Muhammad M. Yaqoob. Diabetic Kidney Disease group *Queen Mary University, London, United Kingdom.*

Background: Chronic kidney impairment may result in multiple metabolic derangements leading to insulin resistance and Type 2 diabetes. However the underlying mechanisms involved in the crosstalk between the kidney and insulin target tissues remains unknown. Therefore to help elucidate this we studied the effect of reduced kidney mass on whole-body glucose homeostasis in lean and obese mice.

Methods: Mice underwent unilateral nephrectomy (UniNX) or sham operation at 7-week old followed by either normal chow or high fat diet (HFD). 16 weeks after surgery, glucose homeostasis was assessed.

Results: Unexpectedly, despite mild proteinuria and uremia, glucose tolerance and insulin sensitivity were improved in UniNX animals both on normal and HFD without enhanced insulin secretion. This correlated with a significant increase in *in vivo* insulin stimulated-Akt signaling in metabolic tissues (liver, muscle and adipose tissue) both under normal and HFD in UniNX conditions. Furthermore, we observed a significant decrease of HFD-induced liver steatosis in UniNX animals. Taken together this unanticipated data show a beneficial impact of UniNX on glucose homeostasis. To get greater insight into the molecular mechanisms involved, we investigated the role of the class II PI3K-C2β, a lipid kinase previously reported as a potential drug target for insulin sensitization. We observed that class II PI3K-C2β inactivation positive effect was accentuated by UniNX with a significant improvement of glucose metabolism and a complete protection against HFD-induced obesity and hepatic steatosis. In conclusion this study highlights an unexpected beneficial synergistic effect of PI3K-C2β inactivation and UniNX to protect against obesity, insulin resistance and hepatic steatosis.

Conclusions: Taken together this data reveal the possibility that kidney donors taking PI3K-C2β inhibitors could be fully protected against obesity, insulin resistance and diabetes. This study could encourage living kidney donations in addition to improving our understanding of the molecular mechanisms involved in the crosstalk between the kidney and insulin target tissues.

FR-PO407

Proximal Tubular Uptake of Free Fatty Acid (FFA) by Kidney Injury Molecule-1 (KIM-1) Mediates Tubulointerstitial Disease in Diabetic Mice

Yutaro Mori,[1] Jae Hyung Chang,[1] Shan Mou,[1,2] Huiping Zhao,[1,4] Jiahua Li,[1] Pierre Galichon,[1] Craig R. Brooks,[1] Sheng Xiao,[3] Venkata Sabbisetti,[1] Suetonia Palmer,[1] Vijay K. Kuchroo,[3] Takaharu Ichimura,[1] Joseph V. Bonventre.[1] *[1]Renal Division, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Brookline, MA; [2]Renal Division, Renji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [3]Center for Neurologic Disease, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [4]Department of Nephrology, Peking University People's Hospital, Beijing, China.*

Background: Diabetic kidney disease (DKD) is associated with tubulointerstitial damage which predicts progression of chronic kidney disease. KIM-1, a scavenger receptor, is the most upregulated proximal tubule protein in many forms of kidney injury.

Dysregulated lipid metabolism is a primary feature of DKD. We hypothesized that KIM-1-mediated uptake of FFAs contributes to tubulointerstitial damage in DKD.

Methods: Renal epithelial cells expressing KIM-1 (LLC-PK1 cells and mouse primary renal epithelial cells) were exposed to palmitate followed by measurement of FFA uptake, cell death and pro-inflammatory and pro-fibrotic effects *in vitro*. *In vivo*, two animal models were used to evaluate the role of KIM-1-mediated FFA uptake. A DKD model induced by unilateral nephrectomy, streptozotocin and high fat diet (UNx-STZ-HFD DKD) was studied in wild-type or KIM-1$^{\Delta mucin}$ (functional knockout of KIM-1 lacking a mucin domain) mice. A second new model was created whereby KIM-1 or KIM-1$^{\Delta mucin}$ was upregulated by aristolochic acid and the effect of subsequent injection of FFA was determined (AA-FFA model).

Results: FFA was taken up by the wild-type KIM-1 expressing cells but not by control or KIM-1$^{\Delta mucin}$ expressing cells, leading to cell death in cells expressing wild-type KIM-1. mRNAs of IL-1β and NLRP3 were increased after FFA treatment only in cells expressing wild-type KIM-1 but not controls. Conditioned media harvested from FFA-treated cells expressing wild-type KIM-1 stimulated greater αSMA expression in mouse fibroblasts, compared to media from KIM-1$^{\Delta mucin}$ cells. In the UNx-STZ-HFD DKD model, wild-type mice showed greater proximal tubular atrophy, macrophage infiltration, fibrosis and albuminuria when compared with KIM-1$^{\Delta mucin}$ mice. In the AA-FFA model, wild-type mice showed more macrophage infiltration, αSMA expression and loss of brush border when compared with KIM-1$^{\Delta mucin}$ mice.

Conclusions: KIM-1 mediates the proximal tubular uptake of FFA, which leads to cell death and pro-inflammatory and pro-fibrotic responses in diabetic mice. Our findings support the role of KIM-1 as a therapeutic target for DKD.

Diabetic Condition Induces Hypertrophy and Apoptosis in Parietal Epithelial Cells Through Mitotic Catastrophe

Takahisa Kawaguchi, Kazuhiro Hasegawa, Shu Wakino, Hiroshi Itoh. *Keio University, Tokyo, Japan.*

Background: Podocyte hypertrophy and apoptosis are two hallmarks of diabetic glomeruli; however, little information is available about changes in parietal epithelial cells (PECs). We hypothesized that diabetes induces hypertrophy and apoptosis in PECs in a similar manner and causes damage. This study aimed to elucidate the effects of a diabetic condition on PECs in vitro and in vivo.

Methods: Conditionally immortalized mouse PECs were exposed to 5 mmol/L glucose (NG), 30 mmol/L glucose (HG), and angiotensin-II (AT-II) at the dosage of 10^{-6} mol/L or aldosterone at 10^{-7} mol/L. Hypertrophy and cell cycle analysis were assessed by flow cytometry. Podocyte apoptosis was ascertained by Annexin V/PI staining, Hoechst 33342 staining, and caspase 3/7 staining. For in vivo studies, streptozotocin-induced diabetic mice, db/db diabetic mice, and BTBR ob/ob mice were used as diabetic mouse models. Histomorphology of the renal tissue was observed using light microscopy and transmission electron microscopy (TEM). PEC apoptosis was assessed using the TUNEL assay and cleaved caspase-3 staining.

Results: In cultured PECs, HG induced hypertrophy, whereas AT-II and aldosterone failed to induce hypertrophy. Flow cytometry revealed that HG also induced PEC apoptosis in a dose-dependent manner and S-phase arrest of PECs, suggesting mitotic catastrophe of PECs. In TEM, PECs exhibited enlargement of both the cytoplasm and nucleus at the ultrastructural level in all diabetic mouse models. PAX 8 staining revealed PEC nuclear hypertrophy in diabetic mice, whereas the cell number of PECs remained unaltered, suggesting that PECs in diabetic condition underwent DNA replication with a mitotic defect. However, an increase in apoptotic PECs was not observed in diabetic glomeruli.

Conclusions: PECs in diabetic condition are in a state of dysregulation of proliferation similar to mitotic catastrophe. As PECs are considered a precursor of podocytes, this injury to PECs might impair glomerular regeneration. Nevertheless, further studies are warranted to elucidate the potential pathological role of morphological changes in PECs in diabetic kidney disease.

ENaC and MARCKS Proteolysis in Diabetes Associated Hypertension

Kubra M. Tuna,[1] Zinah M. Ghazi,[2] Qiang Yue,[2] Douglas C. Eaton,[4] Abdel A. Alli.[1] *[1]University of Florida, Gainesville, FL; [2]Emory University, Atlanta, GA; [4]Emory University Medical School, Atlanta, GA.*

Background: The majority of T2DM patients present with hypertension and diabetic nephropathy progresses more rapidly in hypertensive diabetic patients compared to those without hypertension. Thus, there is an urgent need to better understand the mechanisms contributing to diabetes associated hypertension in order to reduce morbidity and mortality in these patients. Proteolysis of both the epithelial sodium channel (ENaC) and the myristoylated alanine-rich C-kinase substrate (MARCKS) is necessary for high levels of ENaC activity.

Methods: Here we use salt-loaded db/db mice and control mice to test the hypothesis that increased proteolysis of ENaC and MARCKS plays an essential role in the pathogenesis of hypertension secondary to diabetes. Cleaved ENaC and MARCKS was assessed by Western blotting. Protease activity was measured by zymography and fluorometric assays. ENaC activity was assessed by electrophysiology. Blood pressure was measured by telemetry.

Results: Western blots using validated antibodies showed both ENaC and MARCKS proteolysis is increased in the diabetic db/db kidneys compared to kidneys from C57B6 wild-type mice. Western blot and zymography analyses showed increased expression and activity of proteases including cathepsins in the diabetic db/db kidneys compared to controls. ENaC activity was increased in split-open tubules from salt-loaded diabetic db/db mice compared to controls. Telemetry studies showed mean arterial pressure was increased in these diabetic db/db mice after salt-loading and the blood pressure was restored by daily injections with amiloride.

Conclusions: This project will contribute to our understanding of the protease-dependent regulation of ENaC and MARCKS in the development of diabetes associated hypertension and potentially lead to novel drug targets and therapeutics.

RNA Binding Proteins Tristetraprolin and Human Antigen R Mediate Diabetic Tubulopathy via Modulation of Inflammation and Apoptosis of Renal Tubular Epithelial Cells

Jia Guo,[1,2] Fei Cheng,[3] Rujun Gong,[4] Zhangsuo Liu.[5] *[1]The university of Toledo, medical center, Toledo, OH; [2]The first affiliated hospital of Zhengzhou University, Zhengzhou, China; [3]The First Affiliated Hospital of Zhengzhou University, ZhengZhou, China; [4]University of Toledo Medical Center, Toledo, OH; [5]The first affiliated hospital of zhengzhou university, Zhengzhou, China.*

Background: Inflammatory components have been involved in diabetic tubulopathy, a key constituent of diabetic nephropathy (DN) pathology, with undefined molecular mechanisms. RNA binding proteins Tristetraprolin (TTP) and Human antigen R (HuR) have been implicated in inflammatory response in a variety of diseases and exert opposite modulatory effects on a number of inflammatory mediators. Nevertheless, their role in diabetic tubulopathy remains unknown. Evidence suggests that the expression and activity of TTP and HuR are regulated by phosphorylation that is catalyzed by a number of kinases, including GSK3β, a cell signaling transducer with a nephropathic action. The aim of this study was to examine the role of GSK3β -regulated TTP and HuR in diabetic tubulopathy by using an in vitro model of renal tubular epithelial cells (HK-2).

Methods: The mRNA or protein expressions were measured by qRT-PCR or immunoblotting. Apoptosis was analyzed by TUNEL staining. The subcellular localization of TTP, HuR and GSK3β was determined by immunofluorescence staining. GSK3β was silenced by RNA interference to examine the modulatory effect on TTP and HuR expression.

Results: After exposure of HK-2 cells to high ambient glucose (HG, 30Mm glucose), both mRNA and protein expressions of TTP were decreased, while those of HuR were increased, associated with an up-regulation of KIM-1 and TNF-α, loss of E-cadherin and augmented cellular apoptosis, implying that TTP and HuR were oppositely regulated upon high glucose-induced renal tubular cell injury. Tubular cell injury coincided with GSK3β hyperactivity, marked by GSK3β overexpression and suppressed phosphorylation of GSK3β at serine 9. Dual color fluorescent immunocytochemistry staining demonstrated that GSK3β is co-localized with TTP and HuR respectively in different subcellular compartments of HK-2 cells. Moreover, GSK3β seems to be essential for high glucose-induced TTP and HuR dysregulation, because silencing of GSK3β substantially reinstated TTP expression and offset HuR overexpression, concomitant with an improved cellular injury and apoptosis.

Conclusions: The GSK3β regulated RNA binding proteins TTP and HuR play a crucial role in mediating inflammation and apoptosis renal tubular cell injury in diabetes.

The Effects of Modulating Autophagy on Macrophages Adhesion and Migration in Diabetic Nephropathy

Yuteng Jiang, Xiaodong Zhu, Yu Zhao, Yuqiu Liu, Beibei Wu, Xiaoliang Zhang. *Institute of Nephrology, Zhong Da Hospital, Southeast University, School of Medicine, Nanjing, China.*

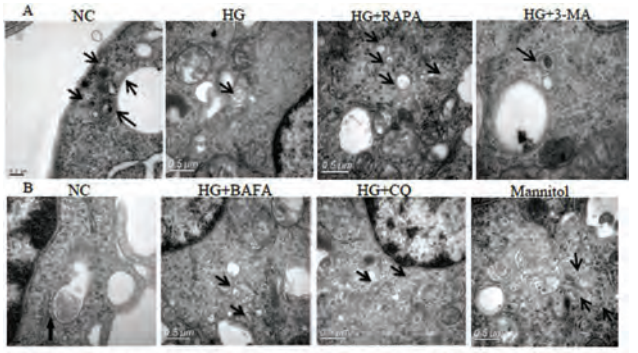
Background: Macrophage infiltration is an important histopathological feature of various chronic renal diseases including diabetic nephropathy. This study aims to investigate the impact of macrophages adhesion and migration by modulating autophagy.

Methods: In vivo, rats were randomly distributed into control (NC) and diabetic nephropathy (DN) groups. The pathological changes in renal tissue were assessed, and expression of CD68, LC3, P62 were analysed. In vitro, RAW264.7 cells were divided into normal and high glucose (HG, 30mM) groups. The capacity for macrophage adhesion and migration and the expression of autophagy markers were observed with and without autophagy modulators (rapamycin, 3-methyladenine, chloroquine, and bafilomycin A1 for RAPA, 3-MA, CQ, BAFA). The numbers of autophagosomes and the process of degradation and fusion of autophagosome-lysosome were observed by electron microscopy.

Results: In vivo, renal injury is aggravated in diabetic rat compared with NC group. The expression levels of CD68 and P62 of renal tissues increased in DN group, while expression level of LC3 decreased. In vitro, HG or 3-MA reduce the numbers of autophagosomes with less expression of LC3 and Beclin-1, but increase expression of P62. HG or 3-MA promote the adhesion and migration capacity of macrophages. Moreover, CQ and BAFA inhibit the process of degradation and fusion of the autophagosome-lysosome as well as the expression of LC3 and Beclin-1. We notice an increase expression of P62 by CQ and BAFA stimulaion. These effects further facilitate the adhesion and migration capacity of macrophages. However, RAPA increases the numbers of macrophage autophagosomes, resulting in an increase expression of LC3 and Beclin-1, whereas a reduction expression of P62, which lead to inhibition of adhesion and migration of macrophages induced by HG ($P<0.05$).

Conclusions: Modulating the function of autophagy can affect the adhesion and migration capacity of macrophages in diabetic nephropathy.

Funding: Government Support - Non-U.S.



A: the change in the numbers of autophagosomes of macrophage; B: the change in degradation and fusion of autophagosome-lysosome.

FR-PO412

The Possible Mechanisms of Effects of NF-κB Inhibitor Parthenolide on Promoting Renal Tubules Albumin Reabsorption in Type 2 Diabetic Nephropathy

Qiufa Hao,[1] Xuemei Li.[2] *[1]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China, Beijing, China., Beijing, China; [2]Peking Union Medical College Hospital, Beijing, China.*

Background: Increased albuminuria caused by albumin reabsorption reduction of renal tubules is highlighted as the cause of early stage of diabetic nephropathy. The underlying mechanism has not been fully figured out. We aimed to observe whether reducing inflammation thereby remodeling impaired insulin signaling could improve renal tubules albumin uptake in diabetic nephropathy.

Methods: 1)8-weeks db/m and db/db mice were used as control(C group) and diabetic nephropathy model(DN group). Parthenolide(PTN 1mg/kg) was used intraperitoneally every other day to db/db mice as treatment group(DN+PTN group). After 8-weeks treatment, urine, blood and kidney samples were collected. Expressions of NF-κB, insulin signaling protein pAKT/AKT and albumin receptors amnionless(AMN) and cubilin in kidneys were detected by immunohistochemistry and immunoblotting. 2)HKC cells were treated with TNF-α(25ng/ml), PTN(5μM) and insulin(100nM). Albumin uptake and expressions of NF-κB, pAKT/AKT, AMN and cubilin were tested by fluorometric assay and immunoblotting.

Results: 1)Compared with DN group, DN+PTN group showed decreased insulin resistance index levels($P<0.05$) and slightly reduced urine albumin creatinine ratio levels($P>0.05$). 2)NF-κB expression increased and phosphorylation of AKT decreased in DN group compared with C group ($P<0.05$). PTN reduced NF-κB expression and ameliorated decline of AKT phosphorylation($P<0.05$). Compared with C group, AMN and cubilin expressions decreased in DN group($P<0.05$), and PTN attenuated reduction of cubilin expression($P<0.05$). 3)Insulin promoted AMN and cubilin expressions and albumin uptake of HKC cells($P<0.05$). In TNF-α group, NF-κB expression increased and AKT phosphorylation decreased compared with insulin group($P<0.05$). In TNF-α+PTN group, PTN reduced NF-κB expression and AKT phosphorylation($P<0.05$). AMN and cubilin expressions decreased in TNF-α group($P<0.05$), and PTN attenuated reduction of cubilin expression($P<0.05$).

Conclusions: The study observed in diabetic nephropathy PTN could ameliorate insulin resistance and slightly reduce albuminuria. We found albuminuria with albumin receptors reduction was induced by inflammation impaired insulin signaling in renal tubules. PTN could reduce inflammation, remodel impaired insulin signaling, and then increase albumin uptake by ameliorating albumin receptors expressions.

PKC-δ Reduced DUSP4 Expression Causing NOX4 and Progressive Diabetic Nephropathy

Marina Rousseau,[1] Benoit Denhez,[1] Farah Lizotte,[1] Pedro M. Geraldes.[2] *[1]University of Sherbrooke, Sherbrooke, QC, Canada; [2]University of Sherbooke, Sherbrooke, QC, Canada.*

Background: Diabetic nephropathy is characterized by the loss of an important epithelial cell called podocytes. Podocytes are specialized cells that have a critical role in maintaining the integrity of the glomerular filtration barrier. A promising insight in the initiation of glomerular pathology begins with the loss of expression of the dual specificity phosphatase 4 (DUSP4), known for its role in MAPK inhibition. We have observed that cultured podocytes exposed to high glucose (HG; 25 mM) concentrations and glomeruli of diabetic (*Ins2*$^{+/C96Y}$) mice exhibited significant reduction of DUSP4 which complied with glomerularsclerosis, podocyte foot process effacement and podocyte cell death. However, the exact mechanism of diabetes-induced DUSP4 reduction remained unknown but protein kinase C (PKC) activation has been shown to regulate DUSP expression in macrophages.

Methods: Non-diabetic (NDM) and diabetic (DM) mice with the deletion of DUSP4 (D4KO) and PKC-δ (*Prckd*$^{-/-}$) were used after 6 months of diabetes. Mouse podocytes were exposed to normal (NG; 5.6 mM) or high (HG; 25 mM) glucose levels for 72 hours with or without the overexpression of DUSP4 and PKC-δ adenoviral vector to evaluate the oxidative stress pathway. Human blood and kidney sample were collected to measure DUSP4 mRNA levels and estimated glomerular filtration rate using the CKD-EPI formula.

Results: By overexpressing the dominant negative form of PKC-δ specifically, we were able to reestablish DUSP4 expression levels in podocytes. In addition, decreased DUSP4 expression observed in renal cortex of DM mice were not seen in DM mice that did not possess the PKC-δ gene. Podocytes exposed to HG concentrations showed a 52% increase of NOX4 expression which was prevented with the overexpression of DUSP4. DM mice had a 30% increase in NOX4 expression in the glomeruli, which was exacerbated by 31% in DM mice with a specific deletion in DUSP4. Interestingly, in humans, decreased mRNA expression of DUSP4 in the renal cortex of diabetic patients correlated with eGFR level decline.

Conclusions: Reduction of DUSP4 expression induced by PKC-δ activation increased NOX4 expression and podocyte dysfunction in diabetic nephropathy.

Funding: Government Support - Non-U.S.

FR-PO414

Parkin Inhibits Accelerating Senescence of Renal Tubular Cells by Promoting GATA4 Degradation in Diabetic Nephropathy

Kehong Chen,[1] Yani He.[2] *[1]Daping hospital, Chongqing, Chongqing, China; [2]Daping Hospital, Chongqing, China.*

Background: Accelerating senescence of renal tubular epithelial cell (RTEC) plays a fundamental role in the pathogenesis of diabetic nephropathy (DN). Parkin, as an E3 ubiquitin ligase, can promote protein ubiquitination and degradation. Parkin gene mutation can accelerate neuron senescence in several neuropsychiatric disorders. GATA binding factor 4 (GATA4), as a substrate of E3 ubiquitin ligase, is a key regulatory factor for senescence phenotype. We investigated the role of Parkin in accelerating senescence of RTEC and its mechanism.

Methods: 149 cases of patients with DN diagnosed by renal biopsy were recruited in our study. Renal Parkin expression was detected by immunohistochemistry. In vivo, we generated Parkin overexpressed streptozotocin-induced DN mice. In vitro, knockdown and overexpression experiments were performed by parkin siRNA or Parkin overexpressed adenovirus in high glucose (HG) stimulated mouse primary RTEC.

Results: Expression of parkin was gradually decreased with development of tubulointerstitial injury and negatively correlated with renal tissue injury scores (tubular atrophy and interstitial fibrosis, renal interstitial inflammation score), renal function injury parameter Scr. Parkin positive tubular epithelial cell did not express senescent marker P16. Compared to wild type DN mice, parkin overexpressed DN mice had lower renal tissue injury scores and better renal function. P16 and GATA4 expression of renal tubules were inhibited in parkin overexpressed DN mice. In vitro, parkin overexpression inhibited HG-induced GATA4 expression and RTEC senescence, whereas parkin knockdown enhanced GATA4 expression in RTECs under HG conditions. Furthermore, we found parkin co-immunoprecipitated with GATA4. Parkin overexpression increased GATA4 ubiquitination under HG conditions, whereas parkin knockdown decreased GATA4 ubiquitination.

Conclusions: Parkin may inhibit HG-induced RTEC senescence by promoting GATA4 ubiquitination and degradation. Parkin is a potential anti-senescence factor in the development of DN.

FR-PO415

ARF6: A Possible Molecular Target for Diabetic Kidney Disease?

Jamie Lin,[2] Nathanael Green,[1] Daniel L. Galvan,[2] Jianyin Long,[2] Benny B. Chang,[1] Farhad R. Danesh.[2] *[1]Baylor College of Medicine, Houston, TX; [2]The University of Texas MD Anderson Cancer Center, Houston, TX.*

Background: Podocytes are key target cells that determine the progression of diabetic kidney disease (DKD), the leading cause of renal failure in the U.S. It is now clear that small GTPase proteins have quintessential roles that govern podocyte health – too much or too little GTPase activity can make the podocyte more susceptible to injury. We recently discovered that ADP-ribosylation factor 6 (ARF6), a Ras-family small GTPase protein, is present in human podocytes and involved in podocyte response to *in vivo* glomerular injury models; however, its role in DKD is unknown. Since ARF6 is involved in diverse cellular events (e.g. actin rearrangement or endocytic trafficking), we postulate that alterations in ARF6 activity might have injury-specific effects on kidney function and that glucose-induced activation of ARF6 in podocytes contributes to the progression of DKD.

Methods: We used an integrated genetic and pharmacologic approach by taking advantage of the CRISPR-Cas9 system to generate an ARF6-gene deleted mouse podocyte line as well as a selective ARF6 inhibitor, NAV2729 (R&D Systems). Mouse podocyte cell lines were cultured under normal glucose (NG, 5mM) or high glucose (HG, 25 mM) conditions for 48 hours.

Results: Podocytes cultured under HG conditions expressed significantly higher Arf6 mRNA and protein levels compared to podocytes cultured under NG conditions. Isolated podocytes from diabetic (Lepr$^{db/db}$) mice had increased ARF6 expression compared to control (Lepr$^{db/+}$) mice. Furthermore, we generated an ARF6-gene deleted mouse podocyte cell line in which we found that ARF6 knockout podocytes had augmented mitochondrial ROS production. To determine whether ARF6 might serve as a molecular target for pharmacologic inhibition in DKD, diabetic and control mice were treated with an ARF6 inhibitor (NAV2729) or vehicle (DMSO) at a dose of 60 mg/kg starting at 8 weeks of age. NAV2729-treated diabetic mice demonstrated significant improvement in the urine albumin to creatinine ratio (UACR) compared to diabetic mice treated with vehicle suggesting a nephro-protective effect of ARF6 inhibition.

Conclusions: These results suggest that ARF6 is an important protein involved in podocyte health. ARF6 expression is increased under diabetic conditions. Inhibition of ARF6 might prevent podocyte injury and DKD progression.

Inhibition of Vascular Endothelial Growth Factor Receptor-2 Phosphorylation by Calcium Dobesilate Requires Interaction with Heparan Sulfate Binding Site

Florence Njau,[1] Nelli Shushakova,[2] Hermann G. Haller.[1] *[1]Hannover Medical School, Hannover, Germany; [2]Nephrology and Hypertensiology, Hannover, Germany*.

Background: Inhibition of vascular endothelial growth factor (VEGF) is a therapeutic option in diabetic microangiopathy. However, VEGF is needed at physiological concentrations for the maintenance of glomerular integrity. Since VEGF exerts its effects on endothelial cells via binding to (1) the VEGF-receptor and (2) to heparan-sulfate (HS) as co-receptor partial blockade of VEGF may be a possible strategy. We tested the hypothesis that the small molecule calcium dobesilate (CaD) (1) inhibits VEGF signaling in endothelial cells, (2) that this effect is mediated via interference between CaD and heparan-sulfate (HS) binding sites and (3) CaD ameliorates diabetic nephropathy (DN) in a diabetic mouse model via inhibition of VEGF.

Methods: In vitro, the effect of CaD on VEGF signaling in endothelial cells (EC) together with the role of heparin was analyzed by Western blotting. EC function was assessed by migration, proliferation and permeability assays. Streptozotocin-treated mice (STZ) were treated with CaD and functional parameters as well as renal histology and inflammatory cells infiltration (immunohistochemistry) were measured at 6 and 12 weeks of hyperglycemia.

Results: CaD inhibited $VEGF_{165}$-induced phosphorylation of VEGFR-2 kinase and suppressed the activity of VEGFR-2 mediated signaling cascades both in vitro and in diabetic animals. The effects of CaD in vitro were abrogated by exogenous heparin, suggesting the involvement of heparin-like domain in the interaction with CaD. $VEGF_{121}$, which does not bind to heparin, was not inhibited by CaD. CaD restored tight junction protein expression and decreased VEGF-induced migration, proliferation and permeability in endothelial cells. CaD ameliorated glomerular pathology, reduced albuminuria and inflammatory cells infiltration in STZ-treated mice and reduced VEGF signaling in diabetic kidneys.

Conclusions: Our results suggest that CaD inhibits VEGFR-2 phosphorylation through the interaction between CaD and HS binding sites both in cultured endothelial cells and in vivo. CaD is a partial VEGF inhibitor without the negative effects of complete VEGF blockade and could be useful as therapeutic strategy in diabetic nephropathy.

FR-PO417

The Use of Type 2 Hypoglycemic Agents in Type 1 Diabetic Animals: Unveiling Novel Signaling Pathways

Batoul Dia,[2] Patricia Bou assi,[2] Christopher El mouhayyar,[3] Rasha Barakat,[4] Neamah Mahjoub,[2] Assaad Antoine Eid.[1] *[1]American University of Beirut/ Faculty of Medicine, Beirut, Lebanon; [2]American University of Beirut, Beirut, Lebanon; [3]American Univeristy of Beirut, Naccache, Lebanon; [4]Universite Paris Descartes, Amioun, Lebanon*.

Background: Diabetic nephropathy (DN) is the leading cause of end stage renal disease. The AMPk activator, metformin, or the GLP1-agonist, liraglutide are hypoglycemic agents that are typically prescribed to type 2 diabetic patients. With their distinct mechanisms of action, these hypoglycemic drugs are utilized in our study to dissect the molecular pathway through which DN may ensue in type1 diabetes. Oxidative stress is known to be the unifying mechanisms that mediates the pathogenesis of DN, however, the role of the DUOX subfamily of enzymes, a poorly studied cellular source of reactive oxygen species (ROS), and their mechanism of action has not been previously characterized in DN. In this study, we aim to examine the expression of DUOXs in the diabetic renal system and reveal their crosstalk with AMPK/GLP-1 signaling in type 1 diabetic animals.

Methods: Monotherapy and combination therapy of metformin and liraglutide were used to assess their effects on glomerular injury in STZ-induced type-1 diabetic animals. ROS production, proteins and mRNA levels of DUOX, AMPK, mTOR, and autophagy markers were examined and correlated with morphological alterations observed histologically in addition to albuminuria.

Results: Our results showed that metformin or liraglutide monotherapy or their combination did not affect glycaemia. However, a decrease in albuminuria, glomerulosclerosis, and tubulointerstitial fibrosis was evident, especially when the drugs were used in combination. Elevated ROS production correlated with NADPH oxidase activity in diabetic animals compared to non-diabetic animals. The administration of the metformin or liraglutide was shown to partially reverse DUOX-derived ROS production, the expression of fibronectin, COL IV, nephrin, DUOX1, DUOX2, AMPK, mTOR and autophagy markers LC3A and LC3B in the type 1 diabetic animals. An effect that was more pronounced when the drugs were used in combination.

Conclusions: These findings shed light on the crosstalk between the AMPK and GLP1 signaling pathways with the NADPH-oxidases and their role in restoration of autophagy, a potential reno-protective mechanism in DN.

FR-PO418

Renin Producing Cells in the Diabetic Kidney

Jeannette Tang,[1] Mina Shirazi,[1] Minghao Ye,[1] Jan Wysocki,[1] Patricia G. Vallés,[2] Maria Luisa S. Sequeira Lopez,[3] Roberto Ariel Gomez,[3] Daniel Batlle.[4] *[1]Northwestern University, Chicago, IL; [2]Notti Pediatric Hospital School of Medicine, Mendoza, Argentina; [3]University of Virginia, Charlottesville, VA; [4]Northwestern University Feinberg Medical School, Chicago, IL*.

Background: Urinary renin is increased in patients with diabetes and models of diabetic kidney disease but its source is not clear. The intensity of renin staining in the collecting tubule is increased in the STZ model of diabetes and in Angiotensin (Ang) II-induced hypertension which could lead to RAS activation locally at this site. We examined the distribution of renin expressing cells using a renin reporter mouse made diabetic by STZ to trace the localization of renin lineage cells (RLC).

Methods: The Ren1d-Cre; mT/mG, a double transgenic reporter mouse model, expresses both Cre-recombinase from the endogenous renin locus (Ren1D) and the mT/mG cassette from the Rosa26 locus (mRenCre-mT/mG). The membrane-directed tomato protein (mT) is expressed ubiquitously and fluorescents in red, while the membrane-targeted green fluorescent protein (mG) is found only in those cells undergoing Cre-recombination. In RLC the mT/mG construct switches from red fluorescent to green fluorescent (mG), while all non-RLC remain mT positive. Ren1d-Cre;mT/mG were made diabetic using STZ. Animals were studied 11-12 weeks after STZ injection.

Results: In WT mice made diabetic by STZ, renin staining by immunohistochemistry was increased in the collecting tubule and by immunofluorescence aquaporin 2 (AQP2), a marker of principal cells, co-localized with renin protein. In the renin reporter mice AQP2 co-localized with green fluorescent protein (GFP+) reflecting that renin producing cells are or had been present at this site. A quantitative comparison of this GFP+ cells between kidney sections of STZ treated and untreated reporter mice, however, revealed no significant differences. Within the glomerulus, RLC were strongly present in parietal areas and within the glomerulus but no significant differences were found between diabetic and non-diabetic renin reporter mice.

Conclusions: In collecting tubules from diabetic mice there is an increased expression of renin which cannot be attributed to increased number of renin producing cells at that site. Alternative explanations such as increased uptake of filtered renin and impaired reabsorption mainly in the proximal tubule need to be considered as the source of collecting tubule renin.

Inhibition of Glucose Transporters Ameliorates Fibrogenic Signaling in a Cellular Model of Diabetic Nephropathy

Xinlu Pan,[3,2] Deborah L. Baines,[2] Mysore K. Phanish,[1] Mark E. Dockrell.[3,2] *[1]Epsom and St Helier University Hospitals NHS Trust, London, United Kingdom; [2]St George's, University of London, London, United Kingdom; [3]South West Thames Institute for Renal Research, London, United Kingdom*.

Background: Diabetic Nephropathy (DN) is the leading cause of kidney failure. Prolonged exposure to elevated glucose strongly facilitates the progression of DN. Tubulointerstitial fibrosis is a key prognostic marker of DN. Approximately 90% of glucose in the glomerular ultra-filtrate is reabsorbed by the low affinity Na+/glucose co-transporter SGLT2. Following the advent of therapeutics targeting glucose uptake at this specific site, we propose a role for SGLT2 in regulating DN.

Methods: Primary PTEC were grown on collagen IV coated/uncoated culture dishes. On reaching 80% confluence, they were treated with D-Glucose at either 5.5 mM (normoglycaemic control), 25mM (hyperglycaemia) or 5.5 mM D-Glucose + 19.5 mM L-Glucose (osmotic control). Cells were treated with TGFβ1, 0.75ng/ml or vehicle. After 24 h, cells were lysed. Heparin pull down was applied to the media to isolate heparin-binding proteins. Dapagliflozin (0.1, 1 & 10μm) was administered to cells treated with high glucose in combination with TGF-β1. Western blot was then used to detect the level of Connective Tissue Growth Factor (CTGF) and EDA fibronectin protein.

Results: There was no obvious cytotoxic effect of any of the treatments. Western blotting demonstrated that primary PTEC secreted CTGF, mwt 36 & 38kDa. Neither TGF-β1 alone nor raised glucose induced a significant increase in CTGF; however the combination of both did ($p<0.05$ compared to all other treatments) at 24h. EDA+ fibronectin protein was unchanged. Dapagliflozin at all three concentrations significantly attenuated CTGF protein secretion, reducing the expression to approximately basal levels.

Conclusions: A combination of raised D-Glucose and TGF-β1, similar to that expected in DN, induced a significant increase in CTGF, an important pro-fibrotic marker. Dapagliflozin successfully reduced this outcome, thus confirming SGLT2 function. Interestingly, high glucose and TGF-β1 alone under these conditions did not produce a significant increase in CTGF, suggesting an additive effect in the upregulation of CTGF. Glucose-induced CTGF expression in vascular smooth muscle cells is associated with cellular damage and death. These phenomenon were not observed in our primary renal cells. This suggests a more precise controlled mechanism for glucose-induced CTGF in PTEC.

FR-PO420

Endoglin as Potential Target to Slow Down Progressive Diabetic Nephropathy via Inhibition of Fibrosis Formation

Tessa Gerrits,[1] Malu Zandbergen,[1] Jan A. Bruijn,[2] Hans J. Baelde,[3] Marion Scharpfenecker.[3] *[1]LUMC, Leiden, Netherlands; [2]Leiden University Medical Center, Dept.Pathology, Leiden, Netherlands; [3]Leiden University Medical Center, Leiden, Netherlands.*

Background: Diabetic nephropathy (DN) is a complication of diabetes, resulting in progressive decline of renal function and proteinuria. Progressive DN is histologically characterized by glomerular matrix expansion and interstitial fibrosis, in which TGF-β plays an important role. Endoglin, a co-receptor of TGF-β, mostly known for regulating endothelial cell functions, is also described in human fibrotic tissues such as liver, heart and intestine. To investigate the role of endoglin in progressive DN, we measured endoglin expression in biopsies of patients with DN and characterized the endoglin-expressing cell type in the interstitium. We also investigated the effect of endoglin knockdown on extracellular matrix production in kidney fibroblasts *in vitro*.

Methods: Kidney biopsy material of 11 patients with DN was collected. As control, tumor free tissue of 7 patients with a renal tumor was used. Sequential sections were stained for endoglin and Sirius Red. The positively stained interstitial area was quantified using ImageJ. Immunofluorescent double stainings for endoglin and CD31, CD68, vimentin or a-SMA were performed on biopsy material from a patient with and without DN. A human kidney fibroblast cell line (TK173) was transduced with a lentiviral vector expressing an shRNA against endoglin.

Results: Endoglin was significantly upregulated in patients with DN compared to controls ($p<0.001$). Also, the Sirius red-positive area was significantly increased in patients with DN ($p<0.001$). Immunofluorescence showed co-expression of endoglin with the endothelial marker CD31. Endoglin also co-localized with the myofibroblast marker a-SMA. Co-localization with fibroblast (vimentin) or macrophage (CD68) markers was not observed. In cell culture, endoglin knockdown in fibroblast resulted in reduced PAI-1, CTGF and fibronectin expression after stimulation with TGF-β ($p<0.05$).

Conclusions: Endoglin is upregulated in the interstitium of DN patients and is expressed in myofibroblasts. *In vitro*, endoglin is involved in TGF-β dependent matrix production. Therefore, endoglin might play a role in the development of fibrosis and thus the progression towards end-stage renal disease in DN.

Inhibitor of Growth 2 Regulates the High Glucose Induced Cell Cycle Arrest and Epithelial-to-Mesenchymal Transition in HK-2 Cells

Wei Xin,[1] Ruijuan Yan,[3] Yuan Ma,[2] Tingting Lv,[2] Liyong Chen,[1] Qiang Wan.[3] *[1]Shandong Provincial Hospital affiliated to Shandong University, Jinan, China; [2]Medical school, Shandong University, Ji'Nan, China; [3]Shandong Provincial Qianfoshan Hospital affiliated to Shandong University, Jinan, China.*

Background: Cell cycle dysregulation has been linked to various kidney injuries in recent years; however, its involvement in the fibrosis of diabetic kidney disease (DKD) is far from being clarified. ING2 (inhibitor of growth 2) is the second member of the inhibitor of growth family and participates in the regulation of many cellular processes, yet the role of ING2 in the process of DKD remains largely unknown. In the present study, we aimed to investigate the involvement of ING2 in the cell cycle arrest and epithelial-to-mesenchymal transition (EMT) process in diabetic conditions and the underlying mechanism for it.

Methods: The human proximal tubular epithelial cells (HK-2) were stimulated with high glucose and diabetic mice were generated by streptozotocin injection. ING2 expression was detected by western blotting and immunofluorescent staining in vitro and immunohistochemistry staining in vivo. The expression of ING2 was silenced by siRNA transfection. Cell proliferation was analyzed by CCK-8 and EdU assay. Cell cycle arrest was measured by flow cytometry. The EMT markers were detected by qPCR and western blotting. The p53 activation by high glucose was proved by chromatin immunoprecipitation (ChIP) and the downstream p21 expression was detected by qPCR and western blotting.

Results: We first revealed that the expression of ING2 was increased both in diabetic mouse kidney in vivo and in high glucose stimulated HK-2 cells in vitro. ING2 downregulation ameliorated the reduced proliferation and cell cycle arrest induced by high glucose in HK-2 cells. Moreover, p53 was activated under hyperglycemia condition and ING2 knockdown suppressed p21 expression by reducing p53 acetylation and finally alleviated the expression of EMT markers in the high glucose stimulated HK-2 cells.

Conclusions: Our study demonstrated that cell cycle regulation is bound up with the EMT of high glucose cultured HK-2 cells, suggesting a novel function of ING2 as a potential therapeutic strategy targeting cell cycle arrest for the kidney fibrosis in DKD.

FR-PO422

Role of CD13 in Renal Proximal Tubular Handling of Albumin

Robin H. Lo, Claire Gerber, Emily R. Shearier, Mallika Ghosh, Linda H. Shapiro. *Center for Vascular Biology, University of Connecticut School of Medicine, Farmington, CT.*

Background: Albuminuria, a complication of disease states that damage glomerular function such as diabetic nephropathy (DN), promotes renal damage by triggering pro-inflammatory and pro-fibrotic pathways leading to chronic kidney disease (CKD). Understanding how the kidney handles urinary albumin may thus be beneficial for identifying therapeutic mechanisms to limit disease progression. Urinary proteins are normally efficiently resorbed via the Megalin-Cubilin receptor complex and the neonatal Fc Receptor (FcRn) in the proximal tubule. CD13, a multifunctional cell surface molecule, negatively regulates clathrin-dependent endocytosis in various cell types. Like the albumin endocytic receptors, CD13 is expressed abundantly on the apical surface of proximal tubule epithelial cells. Here, we examined the role of CD13 in renal proximal tubular handling of albumin in two murine models of albuminuria as well as in unchallenged mice.

Methods: WT and CD13 KO C57/B16 mice were used for both a streptozotocin (STZ) induced DN model (50 mg/kg daily for 5 days) and albumin overload (AO) model (bovine serum albumin; increasing daily doses from 2 mg/g to 10 mg/g on day 5, final 10 mg/g dose on day 8). Urine and serum were collected at basal, 8, 12, 16, and 20 weeks post STZ-treatment in the DN model and day 8 in the AO model for ELISA analysis. Kidneys were collected for immunofluorescence, flow cytometry, and electron microscopy analysis. Relationship of CD13 to Megalin, Cubilin, and FcRn was analyzed by co-immunofluorescence of kidney sections and western blotting of brush border membrane fractions.

Results: Compared to WT, CD13 KO mice exhibited significantly decreased albuminuria in both 20 week STZ-induced DN and AO models, as well as increased cellular uptake of albumin in the proximal tubules even in unchallenged conditions. Furthermore, we identified possible mechanisms by which CD13 regulates albumin endocytosis, including 1) co-localization of CD13 and FcRn, 2) elevated levels of cubilin at the brush border of CD13 KO proximal tubules, and 3) maintenance of cristae integrity in CD13 KO mitochondria after 20 week STZ-induced DN.

Conclusions: Our results suggest that CD13 serves as a key mediator for albumin endocytosis in the proximal tubule and may be a potential therapeutic target for preventing albuminuria-induced damage in renal disease.

The iBEAT MRI Biomarker Panel: Prognostic Imaging Biomarkers for DKD

Kanishka Sharma,[1] Fotios Tagkalakis,[1] Irvin Teh,[1] Virva Saunavaara,[5] Dmitry Kuznetsov,[6] Michael W. Mansfield,[1] Mark Gilchrist,[3] Roberto De blasi,[7] Mark Ibberson,[6] Anil K. Karihaloo,[2] Nicolas Grenier,[4] Steven Sourbron.[1] BEAt-DKD Work Package 4 *[1]University of Leeds, Leeds, United Kingdom; [2]Novo Nordisk, Seattle, WA; [3]Royal Devon and Exeter Hospital, Devon, United Kingdom; [4]Pellegrin Hospital, Bordeaux, France; [5]Turku PET centre c/o Turku University Hospital, Turku, Finland; [6]SIB, Lausanne, Switzerland; [7]Pia Fondazione Panico, Tricase, Italy.*

Background: Advances in functional Magnetic Resonance Imaging (MRI) have provided novel renal imaging biomarkers that inform on parenchymal perfusion, oxygenation, filtration, fibrosis, inflammation, and tissue composition. We present a novel panel of MRI biomarkers designed to help predict DKD progression. The panel has been developed for iBEAT, a new cohort study in 500 patients with T2 diabetes and eGFR>30 mL/min, starting mid 2018. iBEAT is part of the BEAt-DKD project (www.beat-dkd.eu) funded by IMI-JU (No 115974).

Methods: iBEAT will collect MRI in 5 sites at 3 Tesla scanners of 2 vendors; studies will be uploaded into a central database. QC and MRI post-processing will be performed centrally, and MRI biomarkers will be integrated with clinical data, demographics, blood-, urine-, and biopsy biomarkers, endothelial function, and nuclear medicine gold-standards. The MRI protocol was developed through a 6-month process involving measurements on volunteers and a reference object developed by NIST.

Results: The iBEAT MRI panel characterizes both kidney parenchyma and general body composition. The latter includes liver fat (%, insulin resistance), pancreatic fat (%, insulin secretion), liver iron (mg/g, diabetes risk), visceral fat (mL, diabetes risk). Renal biomarkers cover three groups: (1) *Anatomical biomarkers* include kidney volume (mL, increased in hyperfiltration), renal sinus fat (mL, predictor of albuminuria), cortical volume (mL, surrogate for nephron number); (2) *Microstructure biomarkers* include T2* (ms, oxygenation), T1 (ms, fibrosis), T2 (ms, inflammation, oedema), blood volume (%, glomerular hypertrophy), tubular volume (%, tubular obstruction), fractional anisotropy (%, tubular dilatation, glomerulosclerosis); (3) *Dynamic biomarkers* include cortical and medullary perfusion (ml/min/g), filtration fraction (%, hyperfiltration), tubular flow (ml/min/g, concentrating capacity), GFR density (ml/min/g).

Conclusions: The iBEAT MRI biomarker panel is designed to capture DKD progression on the level of renal tissue dynamics, microstructure and anatomy, as well as broader risk factors for diabetes. The iBEAT study will determine the utility of these biomarkers for DKD prognosis, and whether they may become part of the clinical endpoint in future trial designs.

Background: BEAt-DKD (Biomarker Enterprise to Attack DKD) is a public-private partnership committed to deliver more effective patient stratification, DKD prevention and management (www.beat-dkd.eu; IMI-JU No 115974). We report here on an early milestone in BEAt-DKD, the design and setup of a clinical study (iBEAT) to explore the utility of imaging biomarkers.

Methods: iBEAT was developed as a collaborative project with central coordination between sept 2016 and June 2018. iBEAT will be run by 7 core sites including 5 recruiting centres, one of whom is the coordinating site (Leeds), a central biobank (Lund), a data management centre (Lausanne), and an image processing and QA centre (Leeds)

Results: iBEAT is a 4-year prospective observational cohort study in 500 patients with Type 2 diabetes and eGFR>30mL/min, aiming to identify MRI & Ultrasound (US) biomarkers that can improve DKD prognosis. MRI and US will be collected at baseline only. Demographics, clinical, family and medication history, blood (70mL) and urine will be collected annually. Additional data will be collected by four sites to address ancillary objectives (100 patients per site): Kidney biopsies, digitalized and characterized by histology and EM (Bari); PET-based renal blood flow (Turku); glycocalyx and microvascular assessments (Exeter); 2-year follow-up MRI and US (Bordeaux). Biopsies and biofluids including urinary vesicles and sediment will be used for biomarker discovery using state of the art omics, and stored for validation studies. A parsimonious set of baseline biomarkers associated with eGFR (primary) and eGFR slope over time (secondary) will be identified.

Conclusions: iBEAT is the largest functional imaging biomarker study in DKD performed to date. The study will test the utility of imaging biomarkers for DKD prognosis, and may also help improve our understanding of disease pathogenesis.

FR-PO425

Magnetic Resonance Elastography (MRE) with Arterial Spin Labeling (ASL) Kidney Blood Flow for Noninvasive Evaluation of Diabetic Nephropathy

Robert S. Brown,[1] Maryellen Sun,[3] Isaac E. Stillman,[1] Teresa L. Russell,[1] Sylvia E. Rosas,[2] Jesse L. Wei.[1] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Joslin Diabetes Center, Boston, MA; [3]Lowell General Hospital, Lowell, MA.*

Background: Noninvasive quantitative measurement of fibrosis in chronic kidney disease (CKD) would be advantageous diagnostically and therapeutically but standard radiologic imaging is too variable for clinical usage. Using MRE, by applying a vibratory force, shear waves are generated that can measure kidney parenchymal shear stiffness that may correlate with tissue fibrosis.

Methods: We used novel 3-dimensional MRE with ASL kidney blood flow rates to study 30 diabetic patients with stage 0 to 5 CKD compared to 13 control individuals without CKD.

Results: MRE cortical shear stiffness at 90 Hz was surprisingly decreased significantly below normal in diabetic nephropathy (DN) of stages 3-5 CKD. Likewise, cortical ASL blood flow decreased progressively from 480±136 ml/min/100g tissue in controls to 152±32 ml/min/100g in stage 5 CKD. Calculation of a surrogate filtration fraction (sFF = eGFR/ASL) decreased progressively from 0.21±0.07 in controls to 0.10±0.02 in Stage 4-5 CKD. To account for the effect of decreased blood flow which has been shown to decrease MRE kidney shear stiffness, we calculated a novel shear stiffness index normalized to blood flow (SSI = MR shear stiffness/ASL blood flow, Pa/ml/min/100g cortical tissue). The SSI increased progressively from 12±3 in the controls to 26±4 in stage 5 CKD. This significant increase of the SSI also correlated with the grade II-V interstitial fibrosis in DN graded 'blindly' by biopsy in 5 patients.

Conclusions: MRE coupled with ASL blood flow rates can noninvasively measure kidney tissue perfusion, quantitate a sFF proportional to measured filtration fractions, and calculate a novel shear stiffness index that correlates with the degree of kidney fibrosis in worsening diabetic nephropathy.

Functional Magnetic Resonance Imaging (MRI) Is Promising in Predicting the Prognosis of Diabetic Kidney Disease (DKD): Confirmed by the Cohort Study

Jing Li, Huizhen Wang, Jianteng Xie, Tiantian Liang, Yifan Zhang, Yanhui Wang, Wenjian Wang. *Division of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China.*

Background: DKD, the major cause of CKD and ESRD globally, which prognosis is determined by tissue hypoxia or fibrosis. However, assess the two aspects noninvasively is difficult. Whether functional MRI is available for predicting outcomings has not been proven.

Methods: we performed a corhort study in 67 DKD patients, measuring their renal oxygenation by blood oxygenation level-dependent(BOLD) MRI and fibrosis by intravoxel incoherent motion (IVIM) diffusion weighted imaging (DWI). 10 diabetes mellitus were recruited as control. The correlation were caculated by pearson linear analysis. Student's t-test and one-way ANOVA were used to assess the difference among groups. the area under the curve (AUC) were built to assess the discriminative accuracy of MRI values with GFR. finally, Kaplan-Meier analysis was used to evaluate the prognosis after follow up.

Results: Differences were discovered in MRI values between DKD groups and controls. There is strong positive corelation between cortex ADC (p<0.0001)or D value (p<0.0001)and GFR, but negative correlation found in cortex R2* (p=0.0008). AUC (identify with eGFR) of cortex D, was 0.86 (95% CI 0.79–0.93) stronger than the AUC of the cortex ADC (AUC: 0.84, 95% CI 0.77–0.92) or cortex R2* (AUC: 0.67, 95% CI: 0.57–0.77). A further increase in the AUC was obtained taking ECT-GFR as a standard. Follow-up period was 22.4±12.7 months, Kaplan-Meier curve according to cortex D over time showed a significantly different prognosis(Log-rank=23.26; P<0.0001), in contrast, that cortex R2* value is less accurate(Log-rank=16.7; p=0.001).

Conclusions: Cortex D value is in good agreement with the decline of renal function, Thus, cortex D value is an ideal biomarker for predicting the prognosis, cortex R2* is less accurate than cortex D but also helpful in judging prognosis.

Magnetic Resonance Imaging Allows a Novel Non-Invasive Functional and Pathophysiologic Assessment of CKD in Diabetic Nephropathy

Kianoush Makvandi,[1] Gert Jensen,[1] Paul Hockings,[2] Tim Unnerstall,[3] Henrik Leonhardt,[3] Lisa Jarl,[2] Anna Frödén löwenmark,[2] Camilla Englund,[2] Susan Francis,[4] Johannes Hulthe,[2] Seema Baid-Agrawal.[1] *[1]Department of Nephrology, Sahlgrenska University Hospital, Gothenburg, Sweden; [2]Antaros Medical, Molndal, Sweden; [3]Department of Radiology, Sahlgrenska University Hospital, Gothenburg, Sweden; [4]Sir Peter Mansfield Imaging Centre, Nottingham, United Kingdom.*

Background: Magnetic resonance imaging (MRI) has great potential to non-invasively assess functional and morphologic changes in the kidney that may improve diagnosis, prognosis and treatment in patients with chronic kidney disease (CKD). We investigated in diabetic nephropathy (DN) patients if non-contrast MRI using multiple techniques could differentiate a) CKD3-4 stages from healthy controls and b) CKD3 from CKD4 stages.

Methods: An interim analysis of the ongoing study evaluated 18 CKD4, 10 CKD3 patients with DN staged using measured GFR and 20 age- and gender-matched healthy controls. The MRI session included following techniques: R_2* for assessment of renal hypoxia, apparent diffusion coefficient (ADC) for fibrosis, arterial spin labelling (ASL) for cortical perfusion, renal artery blood flow (peak velocity maximum and minimum, mean arterial flow [MAF], renal artery resistive index [RARI), PC perfusion (MAF/kidney volume), and kidney volume corrected for body surface area (BSA).

Results: Several of these parameters (highlighted in the table) were highly sensitive and specific to differentiate healthy vs CKD3-4 and CKD3 vs CKD4. By multivariate analysis, the combination of mean arterial flow and R2* medulla showed a strong predictive ability to separate healthy from CKD patients.

Conclusions: A comprehensive non-contrast MRI protocol was developed, which as a single non-invasive tool could improve our understanding of the function and underlying pathophysiology of CKD including DN, obviating potential user-dependent errors and risky use of contrast agents. Longitudinal follow-up will assess whether these findings can identify patients at risk for progression of CKD.

High Repeatability and Sensitivity of MR Imaging Biomarkers of CKD

Paul Hockings,[1] Kianoush Makvandi,[2] Tim Unnerstall,[3] Henrik Leonhardt,[3] Anna Frödén löwenmark,[1] Lisa Jarl,[1] Camilla Englund,[1] Susan Francis,[4] Gert Jensen,[2] Fredrik Erlandsson,[5] Anna K. Sundgren andersson,[5] Johannes Hulthe,[1] Seema Baid-Agrawal.[2] *[1]Antaros Medical, Molndal, Sweden; [2]Department of Nephrology, Sahlgrenska University Hospital, Gothenburg, Sweden; [3]Department of Radiology, Sahlgrenska University Hospital, Gothenburg, Sweden; [4]Sir Peter Mansfield Magnetic Resonance Center, Nottingham, United Kingdom; [5]AstraZeneca, Gaithersburg, MD.*

Background: New drug development tools are needed for monitoring response to therapy in chronic kidney disease (CKD) with increased precision and repeatability. We evaluated 18 CKD4 and 10 CKD3 subjects with type 2 diabetic nephropathy, and 20 age- and sex-matched healthy volunteers with a wide range of non-contrast magnetic resonance Imaging (MRI) techniques. Measured GFR (mGFR) was assessed using iohexol clearance. Half of the subjects were re-scanned after 2-4 weeks to assess repeatability.

Methods: MRI techniques included R_{2*} for assessment of renal hypoxia, apparent diffusion coefficient (ADC) for fibrosis, $R_1$for interstitial water balance, arterial spin labelling (ASL) for cortical perfusion, renal artery blood flow (peak systolic velocity, end diastolic velocity, mean arterial flow, and renal artery resistive index (RARI)), global perfusion (mean arterial flow/kidney volume), and kidney volume corrected for body surface area.

Results: see Table

Conclusions: Several MR parameters correlate strongly with mGFR indicating that these biomarkers are biologically relevant while providing additional information on pathophysiology. Given the known relationship between MRI biomarkers and mGFR plus the intra-subject CoV, the number of subjects needed to detect, e.g. a 2 ml/min/1.73m^2 change in mGFR can be calculated. To conclude, a 30 min non-contrast MRI protocol characterising important aspects of CKD with a high repeatability and sensitivity was identified. Repeatability data allows future CKD intervention studies to be correctly powered.

Funding: Commercial Support - Antaros Medical; AstraZeneca

Myocardial Flow Reserve Assessed by Cardiac 82Rb PET/CT Is Associated with Albumin Excretion in Patients with Type 1 Diabetes

Emilie Hein Zobel,[1] Signe Abitz Winther,[3] Bernt Johan Von Scholten,[2] Lene Holmvang,[5] Andreas Kjaer,[4] Peter Rossing,[3] Tine Hansen.[1] *[1]Steno Diabetes Center, Gentofte, Denmark; [2]Novo Nordisk A/S, Soborg, Denmark; [3]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [4]Rigshospitalet, Copenhagen, Denmark; [5]Rigshopitalet, Copenhagen Ø, Denmark.*

Background: To evaluate myocardial flow reserve (MFR) and coronary artery calcium (CAC) in persons with type 1 diabetes with or without albuminuria and in non-diabetic controls. MFR reflects the function of large epicardial arteries and myocardial microcirculation. CAC represents structural aspects of atherosclerosis. In addition we evaluated the association of MFR and CAC with retinopathy, another microvascular complication

Methods: Cross-sectional study in type 1 diabetes, stratified by normoalbuminuria (n=30) and macroalbuminuria (n=30), and in non-diabetic controls (n=30). MFR (pharmacological stress flow/rest flow) was evaluated by cardiac ^{82}Rb positron emission tomography/computed tomography.

Results: MFR was similar in patients with normomalbuminuria (NORMO) and controls (3.1 ± 0.8 vs. 3.0 ± 0.79; p=0.74). Patients with macroalbuminuria (MACRO) had lower (impaired) MFR compared to NORMO (2.1 ± 0.9 vs. 3.1 ± 0.8; $p < 0.0001$). The CAC score (median[IQR]) was higher in NORMO compared to controls (72[22-247] vs. 0[0-81], p=0.018), and comparable between MACRO and NORMO. MFR was comparable in patients with diabetes and simplex or no retinopathy (n=24 and n=12, 2.8 ± 0.84 vs. 3.3 ± 0.77, p=0.11), but lower in proliferative (n=24) compared to simplex retinopathy (2.1 ± 0.97 vs. 2.8 ± 0.84, p=0.02). The CAC score was comparable between groups of retinopathy.

Conclusions: Myocardial microvascular function was comparable in non-diabetic controls and patients with type 1 diabetes and normoalbuminuria; but impaired in the presence of microvascular complications (macroalbuminuria and proliferative retinopathy). Coronary calcification was elevated in diabetes, however not explained by albuminuria.

FR-PO430

Pulse Wave Velocity Is an Independent Risk Factor for Cardiovascular Events, Mortality and Decline in Renal Function in Patients with Type 1 Diabetes

Marie Frimodt-Moller,[1] Simone Theilade,[1] Signe Abitz Winther,[1] Nete Tofte,[1] Tarunveer S. Ahluwalia,[1] Peter Rossing.[1,2] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]University of Copenhagen, Copenhagen, Denmark.*

Background: The prognostic significance of carotid-femoral pulse wave velocity (cfPWV), the gold standard measure of arterial stiffness, remains to be determined in patients with type 1 diabetes (T1D). We investigated the predictive value of cfPWV for development of cardiovascular events (CVE), mortality and decline in renal function in T1D.

Methods: At baseline cfPWV was measured using the SphygmoCor device in 652 patients with T1D and various degrees of albuminuria, ranging from normo- (<30 mg/24h), micro- (30-299 mg/24) to macroalbuminuria (≥300 mg/24h. Endpoints were traced through National Registers and patient records until 31st December 2016 comprising: composite CVE, mortality, progression from normo- to micro/macroalbuminuria or from micro- to macroalbuminuria, and decline in estimated glomerular filtration rate (eGFR) ≥30%. Median follow-up ranged from 5.2 to 6.2 years. Slope estimates of eGFR and urinary albumin creatinine rate (UACR) were calculated for a median of 5.5 years. Adjustment included sex, age, mean arterial pressure, LDL cholesterol, smoking, HbA_{1c}, UACR and eGFR at baseline. Hazard ratios (HR) were calculated per 1 standard derivation (SD) increase in cfPWV.

Results: Of the 652 participants (56% male); mean±SD age was 54±13 years, cfPWV 10.5±3.38 m/s and eGFR 81±26 ml/min/1.73m^2. Median numbers of eGFR and UACR measures during follow-up were 6.0 and 17.0, respectively. After adjustment, higher cfPWV remained significantly associated with all endpoints: composite CVE (n=81; HR:1.31; p=0.045); mortality (n=48; HR:1.39; p=0.033); progression in albuminuria (n=31; HR:1.16; p=0.012); and decline in eGFR ≥ 30% (n=90; HR: 1.39; p=0.015). Higher cfPWV was associated with a steeper decline in eGFR and a steeper increase in UACR after adjustments (p≤0.009).

Conclusions: In patients with T1D, higher arterial stiffness was consistently associated with a higher risk of CVE, mortality and decline in renal function, independent of other risk factors. Measurement of cfPWV may have a promising role in risk stratification in T1D.

FR-PO431

Exome Wide Association Study Identifies a Rare Coding Variant in Cubilin Gene and Suggestive Variants in Additional Genes Associated with Albuminuria Among 33,985 Europeans with and Without Diabetes

Tarunveer S. Ahluwalia,[1,11] Christina-Alexandra Schulz,[2] Tea Skaaby,[3] Niina Sandholm,[4] Jette Bork-Jensen,[11] Natalie R. Van zuydam,[8] Peter Almgren,[2] Betina H. Thuesen,[3] Marit E. Jørgensen,[1] Ivan Brandslund,[5] Cramer K. Christensen,[9] Allan Linneberg,[3] Emma Ahlqvist,[2] Per-Henrik Groop,[6,4] Samy Hadjadj,[7] Leif Groop,[2] Niels Grarup,[11] Marju Orho-Melander,[2] Mark McCarthy,[8] Olle Melander,[2] Peter Rossing,[1,10] Tuomas O. Kilpelainen,[11] Torben Hansen.[11] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Department of Clinical Sciences in Malmö, Lund University, Malmö, Sweden; [3]Center for Clinical Research and Prevention, Bipebjerg and Frederiksberg Hospital, The Capital Region, Copenhagen, Denmark; [4]Folkhalsan Institute of Genetics, Folkhalsan Research Center, Helsinki, Finland; [5]Lillebaelt hospital,University of South Denmark, Vejle, Denmark; [6]University of Helsinki and Helsinki University Hospital, Helsinki, Finland; [7]CHU Poitiers, CIC and Endocrinology Department, Poitiers, France; [8]Wellcome Center Human Genetics, University of Oxford, Oxford, United Kingdom; [9]Lillebaelt Hospital, Horsens, Denmark; [10]University of copenhagen, Copenhagen, Denmark; [11]Novo Nordisk Foundation Center for Basic Metabolic Research, Section of Metabolic Genetics, University of Copenhagen, Copenhagen, Denmark.*

Background: Identification of rare coding variants associated with albuminuria may provide new options for preventing chronic kidney disease (CKD) and end-stage renal failure, especially in diabetic patients. With the increasing burden of CKD reaching about 15% in the US, efforts to identify underlying genetic factors for albuminuria have been limited, majority focusing just common variants.

Methods: We performed an exome-wide association study to identify coding variants in a two-phase (discovery and replication) approach employing 33,985 individuals of European ancestry (15,872 with and 18,111 without diabetes). Additive genetic models using linear regression on natural log transformed Albuminuria levels was performed for 263,894 single nucleotide polymorphisms (SNPs), adjusted for age, sex, and population substructure. Meta analyses conducted using fixed effects inverse variance method.

Results: We identify a rare (MAF: 0.8%) missense variant in Cubilin gene (*CUBN*, p=1.3 × 10^{-11}) associated with albuminuria in the combined European (EUR) meta-analyses. The rare *CUBN* variant had 3 times stronger effect in individuals with diabetes compared to those without ($p_{interaction}$: 5.4 × 10^{-4}, β_{DM}: 0.69, β_{nonDM}: 0.20) in the discovery meta-analyses. This *CUBN* rare variant is an independent signal for albuminuria after conditional analyses with the previously known albuminuria common SNP (LD: r^2 = 0.0002, D' = 1.0, $p_{condition}$: 8.5 × 10^{-7}). Gene-aggregate tests based on rare (MAF<0.01) and common variants suggest three additional genes associated with albuminuria (*HES1, CDC73,* and *GRM5*) after correction for multiple testing ($p_{bonferroni}$<2.7 × 10^{-6}).

Conclusions: The current study identifies a rare coding variant in the *CUBN* locus and suggestive variants in 3 other genes associated with albuminuria in individuals with and without diabetes, implicated in renal dysfunction. These highlight novel genes and pathways as potential targets towards diabetes related kidney disease prevention.

FR-PO432

TCF7L2 and ACE Polymorphisms Confer Genetic Susceptibility to Diabetes Mellitus Type 2/Diabetic Nephropathy in Chilean Patients

Paola Krall,[1] Natalia C. Peralta,[1] Daniela P. Nualart,[1] Carolina Lavoz,[1] Osvaldo A. Elgueta,[2] Leopoldo G. Ardiles,[1] Claudio A. Flores,[1] Sergio A. Mezzano.[1] *[1]Universidad Austral de Chile, Valdivia, Chile; [2]Cesfam Externo Valdivia, Valdivia, Chile.*

Background: Diabetes mellitus type 2 (DMT2) is a chronic disease that is the leading cause of end-stage renal disease due to diabetic nephropathy (DN). A role in DN has been described for Gremlin (GREM1) and for an indel (I/D) in the Angiotensin-converting-enzyme (*ACE*) gene. Chile has the highest prevalence of DMT2 in Latin America, but the genetic susceptibility to develop DMT2 or DN remains undetermined. The aim of this work is to explore in a cohort of Chilean subjects, the association of polymorphisms in genes related to *GREM1* and *ACE* with DMT2 or DN.

Methods: A retrospective case-control study was performed in 140 control subjects and DMT2 patients without DN (n=80) or with DN (n=101), categorized as those with early DN (1-7 yrs after DMT2 diagnosis) and late DN (8-15 yrs after DMT2 diagnosis). The genotype in the following polymorphisms was determined: rs1129456 (*GREM1*), rs7903146 (*TCF7L2*), rs34231037 (*VEGFR2*), rs4819554 (*IL-17RA*), indel (18 pb) in the *VEGF* gene and the indel (~300pb) in the *ACE* gene. Allelic and genotypic frequencies were analyzed to determine Odds ratio (OR).

Results: The analysis showed that the T allele (*TCF7L2*) was associated with DMT2 (OR=1.53, IC 95%=1.08-2.18, p=0.009). Additionally, a significant association was identified between the D allele (*ACE*) and the development of DN (OR=1.62, IC 95%=1.06-2.47, p=0.01), as well as with an early development of DN (OR=2.22, IC 95%= 1.10- 4.46, p=0.01).

Conclusions: Our results demonstrate that particular variants in *TCF7L2* (T allele) and *ACE* (D allele) are highly prevalent in the study cohort (30-50%) and present a potential clinical value as risk alleles for DMT2 and DN of early development. TCF7L2 is a transcription factor controlling the GREM1 expression. Although the SNP in *GREM1* was not associated with DMT2/ DN, further studies are required to determine if the *TCF7L2* genotype is associated with GREM1 expression in the diabetic kidney. A larger study with multi-center individuals' recruitment is required to validate *TCF7L2* and *ACE* as genetic markers of susceptibility in the Chilean population, in order to consider them as input to design more effective strategies to prevent DMT2 and DN. *Grant FONDECYT Regular 116-0465*

Genome-Wide DNA Methylation Analysis for Diabetic Kidney Disease

Laura J. Smyth, Jill Kilner, Chris C. Patterson, Christopher J. Wooster, Gareth J. McKay, Alexander P. Maxwell, A.J. Mcknight. Epidemiology and Public Health Research Group *Queen's University Belfast, Belfast, United Kingdom.*

Background: Diabetic kidney disease (DKD) is a serious complication of diabetes, characterised by progressive development of proteinuria and loss of renal function. Increasing evidence suggests that epigenetic alterations, including DNA methylation, are involved in the development and progression of DKD. This investigation compared methylation profiles from individuals with type 1 diabetes (T1D) and DKD to individuals with T1D and no evidence of renal failure, to identify potential methylation-based biomarkers of DKD.

Methods: Using the Zymo EZ DNA methylation kit to bisulphite treat the DNA and the Infinium HD Methylation Assay, MethylationEPIC BeadChips from Illumina, the methylation status of >850,000 CpG sites, gene bodies, promoters and CpG islands have been determined for 106 individuals with T1D. Of these, 66 individuals had DKD and 40 controls had no evidence of renal disease. Cases and controls for this analysis were matched carefully for ethnicity, sex, age (≤1 year), and duration of diabetes. We also considered 192 individuals with Illumina's HumanMethylation27K array data and 250 individuals with HumanMethylation450K array data for DKD. DNA obtained from each individual was treated consistently, with standard quality control applied.

Results: Methylation data was analysed using Genome Studio and Partek Genomics Suite v7.0. From the EPIC array, 891 CpG sites were identified as having significantly different levels of methylation in cases compared with controls, 9 of which had a significance level of p≤9.75x10^{-08}. Among the genes identified, several including *BCL2, CUX1, FKBP5, FBXO5, PRKAG2* and *PSD3* have been linked with T1D. High concordance (R^2=0.994) between duplicate samples (n=7) was observed. Across data from all arrays, top-ranked genes with differential methylation profiles included *CUX1, FKBP5* and *PRKAG2*.

Conclusions: We have previously reported *CUX1, FKBP5,* and *PRKAG2* genes associated with CKD, supported by changes in gene expression using RNA-Seq (Smyth *et al.,* Epigenetics, 2014). This project supports meta-analysis of independent cohorts across arrays and demonstrates blood-derived methylation signatures may serve as minimally invasive biomarkers of DKD.

Gene Expression Profiles of Hyperfiltration in Early Diabetic Kidney Disease

Vidar T. Stefansson,[1] Viji Nair,[2] Laura H. Mariani,[2] Toralf Melsom,[1,4] Bjorn O. Eriksen,[1,4] Robert G. Nelson,[3] Matthias Kretzler.[2] *[1]UiT The Arctic University of Norway, Tromso, Norway; [2]University of Michigan, Ann Arbor, MI; [3]National Institutes of Health, Phoenix, AZ; [4]University Hospital of North Norway, Tromso, Norway.*

Background: Hyperfiltration (HF) is a state of high glomerular filtration rate (GFR) seen in early diabetic kidney disease. Prolonged HF damages glomeruli, eventually leading to a vicious cycle of fibrosis and an increased filtration load for remaining glomeruli. Previous definitions of HF based on GFR cut-points have not convincingly captured microstructural and gene expression signatures in individuals. We used novel methods of capturing individual HF to elicit morphometric and gene expression profiles from kidney biopsies.

Methods: 111 Pima Indians with type 2 diabetes had a research kidney biopsy between 2002-2007 and 9-29 iothalamate GFR and albumin-creatinine ratio (ACR) measurements between 1989 and 2017. Those with mean GFR <60ml/min/1.73m^2 or ACR >300mg/g around the time of biopsy were excluded. Subjects who had their highest ever recorded GFR measurement within two years of biopsy were categorized as having HF. Eigengene-based weighted gene co-expression network analysis modules were constructed from glomerular transcriptomes. Pathway analyses and downstream targets were identified.

Results: The interquartile range of GFR among HF subjects was 138.1-203.5. One module uniquely associated with HF. Individual genes of interest included KDR, ICAM2 and PECAM1. Main pathways included Hepatic Fibrosis and the Th2 Pathway. Downstream targets included angiogenesis and endothelial cell proliferation.

Conclusions: A new method of capturing individual HF in early diabetic kidney disease correlated with clinical and morphological data and yielded novel findings in gene expression analyses. These pathways may be potential targets for further research on diagnosis and treatment of HF.

Funding: NIDDK Support, Government Support - Non-U.S.

Summary statistics at the time of biopsy

	GFR peak >2 years prior to biopsy	GFR peak within 2 years of biopsy	GFR peak >2 years after biopsy	p-value (*=quadratic trend)

Genes Related to the Different Stages of Diabetic Kidney Disease: A Clariom™ D Assay in Patients with Biopsy Proven Diabetic Nephropathy

Suyan Duan,[2] Bo Zhang,[1] Yanggang Yuan.[3] *[1]The first affiliated hosptial of Nanjing Medical University, Nanjing, China; [2]The First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [3]the First Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Diabetic kidney disease (DKD) is the leading cause of end-stage renal disease. A great number of metabolites, cytokines, proteins and transcription factors play a role in the accumulation of extracellular matrix and mesangial proliferation in the glomerulus. The integrative analysis of the proteomic and transcriptomic features of bioptic samples among different categories of patients affected by diabetic nephropathy, especially based on the accurate classification of the histopathological changes in the glomerular and tubulointerstitial compartment, could lead to the identification of new early biomarkers.

Methods: Microarray data obtained from glomeruli isolated from normal kidneys (n = 2) and kidneys from patients with DN (n = 4) were used for the Clariom™ D Assay.

Results: Two patients were diagnosed as type IIb stage DN with moderate proteinuria, while other two patients were diagnosed as type IV stage DN with massive proteinuria. In the present study, differentially expressed genes (DEGs) between healthy controls and patients with different stages of DN were also analyzed. To investigate the function changes in the course of DN progression, GO enrichment and KEGG pathway analyses were performed for both up- and down-regulated DEGs. GO provides 3 structured networks of de ned terms to describe gene product attributes: cellular compartment (CC), biological process (BP) and molecular function (MF). Results show that signaling pathways are altered by the up-regulated DEGs (Fig1,2).

Conclusions: In conclusion, our transcriptome based analysis suggests that the association between gene expression and renal pathology is mediated by structural changes and that there may be differences in pathways that lead to protenuria.

Integrating Plasma Proteomic with Tissue Transcriptomic Profiles in Early Diabetic Kidney Disease Identifies IFNG Activation as a Predictor of Disease Progression

Viji Nair,[1] Helen C. Looker,[4] Robert G. Nelson,[3] Wenjun Ju,[1] Matthias Kretzler.[2] *[1]University of Michigan, Ann Arbor, MI; [2]U.Michigan, Ann Arbor, MI; [3]National Institutes of Health, Phoenix, AZ; [4]NIH, Phoenix, AZ.*

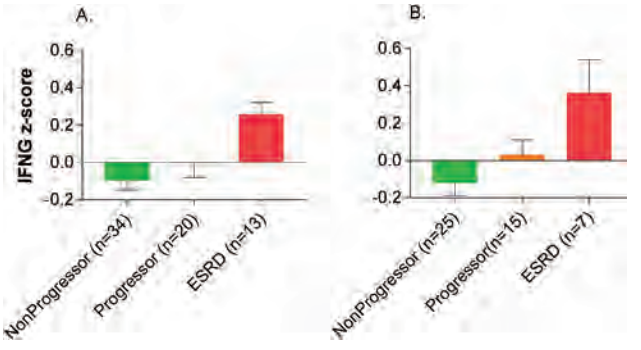
Background: Circulating proteins may act through their downstream signaling pathways in the kidneys to promote intrarenal impairment and progression to end-stage renal disease (ESRD) in persons with diabetic kidney disease (DKD).

Methods: Targeted plasma proteomics (SOMAscan) were obtained in (n=162) Pima Indians with type 2 diabetes and early DKD and compared to subsequent genome-wide transcriptomics of protocol kidney biopsies performed on average 2.3 years (n=74) and 11.2 years (n=57) later.

Results: 317 out of 550 plasma proteins were differentially expressed between 56 patients who progressed to ESRD and those who did not after a median follow up of 11 years (FDR<0.2). 114 genes in the glomeruli (Glom) (13 ESRD vs 54 of non-ESRD) and 182 in the tubulointerstitium (TI) (7 ESRD vs 40 non-ESRD) were differentially expressed (FDR<0.2). Interferon gamma (IFNG) was identified as the top ESRD-associated plasma cytokines and the top up-stream regulator of intrarenal ESRD-associated genes in both Glom and TI. An activation score (Z score) was generated for the IFNG signaling pathway based on the expression of IFNG downstream genes (Glom and TI). IFNG Z-scores in Glom and TI were inversely associated with measured GFR decline (r=-0.55 and -0.59, p<0.0001 respectively). Patients who progressed to ESRD had a significantly higher Z-score than those who did not (**Figure**). Circulating IFNG was associated with intrarenal IFNG pathway score in biopsies obtained 11.2 years later (r= 0.47 and 0.40, p<0.002, glom and TI respectively).

Conclusions: Increased circulating IFNG early in DKD precedes intrarenal IFNG pathway activation and subsequent clinical outcome a decade later, providing a strong rationale for targeting systemic inflammatory pathways in DKD progression.

Funding: NIDDK Support, Commercial Support - Boehringer Ingelheim



Intrarenal IFNG pathway Z scores in Glom (A) and TI (B) are significantly higher in ESRD/ progressors compared to non progressors (median FU 11 ± 2.5 Years). Progressors were defined as measured GFR slope more than -3 mL/min

FR-PO437

Circulating MicroRNA Profiles and Risk of ESRD in Patients with Diabetes and CKD: An RNA-Sequencing Based Study

Eiichiro Satake,[3] Marcus G. Pezzolesi,[2] Christopher Simeone,[1] Zaipul I Md Dom,[3] Hiroki Kobayashi,[3] Adam Smiles,[1] Monika A. Niewczas,[3] Andrzej S. Krolewski.[3] *[1]Joslin Diabetes Center, Boston, MA; [2]University of Utah, Salt Lake City, UT; [3]Joslin Diabetes Center, Harvard Medical School, Boston, MA.*

Background: MicroRNAs (miRNAs) are endogenous, short non-coding RNA molecules that are involved in gene regulation and play important roles in the pathogenesis of various diseases including diabetic kidney disease (DKD). However, miRNA signatures associated with DKD has not been fully established.

Methods: Using High Throughput Genomics (HTG) edge sequence platform, the expression of 2,083 mature miRNAs were examined in baseline plasma specimens from 239 patients with type 1 diabetes (T1D) and CKD stages 3 & 4 to find miRNAs associated with progression to ESRD during 7-15 years of follow-up. The findings in T1D were validated using the same technology in the replication panel of 136 patients with type 2 diabetes (T2D) and the same CKD stages.

Results: Cox proportional hazard model analysis revealed that 15 miRNAs were strongly associated with renal function decline and time to ESRD in both T1D and T2D. Using Spearman's rank test, 3 candidate miRNAs were significantly associated with declining renal function after adjusting for age, sex, type of diabetes, duration of diabetes, HbA1c, eGFR and ACR (p<0.05). In pathway analysis, 6 KEGG pathways (Endocytosis, FoxO signaling, mTOR signaling, Neurotrophin signaling, Rap1 signaling and Ras signaling) were significantly enriched by genes targeted by all 3 miRNAs (P<0.01).

Conclusions: We investigated plasma miRNA profiles associated with ESRD in patients with diabetes using RNA-sequencing based platform. Our results suggest that these

miRNAs are associated with declining renal function in patients with diabetes and have potential to serve as circulating biomarkers, and possibly therapeutic targets for DKD.

FR-PO438

Urinary Exosomal CCL21 mRNA as Biomarker of Diabetic Nephropathy

Ye Feng, Linli Lv, Xin Zhong, Bi-Cheng Liu. *Zhong Da Hospital, Southeast University Medical School, Nanjing, China.*

Background: Diabetic nephropathy (DN) is one of the common complications of diabetes characterized by variable histological changes and clinical course. Currently, renal biopsy and pathological assessment remains the standard approach in the diagnosis and prognosis of DN. Given the invasive procedures and unpredictable post-operative complications of biopsy, novel and noninvasive biomarkers are needed. We aimed to find noninvasive biomarkers reflecting the histological injury and progression of renal function in DN.

Methods: A screening cohort of 4 biopsy-proven DN patients and 4 diabetic patients with normal renal function(DM) and a validation cohort of patients with 28 biopsy-proven DN patients and 24 DM patients were enrolled in our study. We isolated exosomes from urine samples at the time of renal biopsy. Urinary exosomes was identified by Western blotting (using Alix, CD63 and CD9 as exosomal markers). Kidney histological damage of DN patients was scored according to Tervaet standard. Urinary exosome profile of the packing inflammatory response related genes were assessed and its correlation with clinic and histological injury parameters were analyzed.

Results: Known exosome markers including Alix, CD63 and CD9 were identified by Western blotting. Profile of the packing inflammatory related mRNA revealed CCL-21 was remarkably upregulated in urinary exosomes of DN patients compared with DM patients($p<0.05$). Validation study confirmed the findings and found the correlation of CCL-21 with levels of proteinuria ($r=0.590$, $p<0.05$) and eGFR ($r=0.591$, $p<0.05$). Furthermore, CCL21 was positively correlated with tubulointerstitial damage. DN patients with severe tubulointerstitial damge showed the highest expression of CCL-21 compared with DN patients with mild and moderate damage. Impressively, CCL21 showed good performance in discriminating patients with different levels of tubulointersitial inflammation.

Conclusions: In summary, urinary exosomal CCL-21 mRNA may be promising noninvasive biomarkers of diabetic nephropathy reflecting renal histological injury and renal function deterioration.

FR-PO439

Urine Synaptopodin Predicts Progression of Diabetic Nephropathy in Patients with Type 2 Diabetes

Nam-Jun Cho,[1] Eun-Young Lee,[1] Choon Hee Chung,[2] Minhwan Kang.[1] *[1]Soonchunhyang University Cheonan Hospital, Cheonan, Republic of Korea; [2]Yonsei University Wonju College of Medicine, Wonju, Republic of Korea.*

Background: Synaptopodin, a protein that plays an important role in the maintenance of the structure of podocyte, is known as a marker that reflects the damage of glomerulus. Although some studies reported that urine synaptopodin was elevated in diverse kidney diseases, the clinical role of urine synaptopodin in the diabetic patients remains unclear. We hypothesized that urine levels of synaptopodin would be associated with severity and prognosis of diabetic nephropathy.

Methods: A total of 145 patients with type 2 diabetes and 25 healthy control subjects were enrolled. They were followed up with estimated glomerular filtration rate (eGFR), urine albumin-to-creatinine ratio (UACR) and urine protein-to-creatinine ratio. The participants with baseline eGFR less than 60 mL/min/1.73 m^2 were excluded. Urine levels of synaptopodin were assessed by enzyme-linked immunosorbent assays.

Results: The mean age of the study participants was 56.2 ± 10.5 years and their median follow-up was 36 (24–40) months. Urine synaptopodin levels, presented as urine synaptopodin-to-creatinine ratio, were significantly higher in patients with diabetes (256.0 [142.0–481.7] pg/mg) than healthy control (129.2 [96.5–289.1] pg/mg). Among diabetic patients, urine synaptopodin levels were increased according to albuminuria stages (normoalbuminuria, 234.3 [140.1–470.7] pg/mg; microalbuminuria, 258.3 [143.8–424.6] pg/mg; and macroalbuminuria, 341.8 [178.7–570.6] pg/mg). Urine synaptopodin in diabetic patients was not significantly correlated with baseline eGFR. However, urine synaptopodin was negatively correlated with changes of eGFR ($R = 0.209$, $p = 0.023$). Moreover, in the normoalbuminuric subgroup of diabetic patients, urine synaptopodin was significantly associated with changes of UACR ($R = 0.272$, $p = 0.045$). This finding was also valid after adjusting for age, sex, body mass index, glycated hemoglobin level, eGFR, and follow-up duration.

Conclusions: Our study presented that urine synaptopodin in patients with type 2 diabetes reflected the severity of diabetic nephropathy and predicted progression of the disease. These results suggest that urine synaptopodin would be a useful early biomarker for diabetic nephropathy.

FR-PO440

Urinary Excretion of Podocyte mRNA as a Risk Prediction Biomarker for Progression of Diabetic Nephropathy: 2-Year Follow-Up Study

Akihiro Fukuda,[1,2] Yuji Sato,[2] Akihiro Minakawa,[2] Masao Kikuchi,[2] Shouichi Fujimoto.[2] *[1]Oita University, Yufu, Japan; [2]University of Miyazaki, Kiyotake, Japan.*

Background: Recent studies suggest that podocyte injury has already occurred at the early stage of diabetic nephropathy. Podocyte cell lineage-specific mRNA can be recovered from urine pellets. We previously reported that urinary excretion of podocyte mRNA could be an early diagnostic biomarker for diabetic nephropathy. Here, we examine whether it can be used as a risk prediction biomarker for progression of diabetic nephropathy.

Methods: For our previous study, outpatients at various stages of diabetes (n=83, normoalbuminuria group, n=31, microalbuminuria group, n=31, macroalbuminuria group) were enrolled from January to June 2015 and spot urine samples were collected. For the present study, we performed a prospective observational cohort study of these participants using data from a 2-year follow-up period (2015–2017). Renal outcome was defined as a decrease in the estimated glomerular filtration rate (eGFR) of >4% per year. Predictors used were baseline urinary excretion of podocyte mRNA (podocin/aquaporin 2 mRNA ratio), podocin mRNA/creatinine ratio (UPodCre), podocin/nephrin mRNA ratio, and albumin/creatinine ratio (UAlbCre). A logistic regression analysis was used to calculate the odds ratios (ORs) for eGFR decrease, with adjustments made for age, sex, duration of diabetes, body mass index, systolic blood pressure, eGFR, low density lipoprotein cholesterol, serum albumin, glycated hemoglobin, and usage of insulin or a renin-angiotensin system inhibitor.

Results: Of the 145 patients, 31 were excluded because of lack of follow-up or data. UPodCre and UAlbCre were significantly associated with decreased eGFR in univariable analysis [OR, 2.95 (95% CI, 1.18–7.34) and OR, 2.70 (95% CI, 1.67–4.36), respectively], and remained significantly associated with decreased eGFR in multivariable analysis adjusted for the above confounding factors [OR, 2.97 (95% CI, 1.07–8.27) and OR, 3.98 (95% CI, 1.94–8.15), respectively].

Conclusions: Urinary excretion of podocyte mRNA was independently associated with eGFR decline in addition to albuminuria in diabetic patients. Results from this and our previous study suggest that urinary excretion of podocyte mRNA could be used as early diagnostic and risk prediction biomarker for progression of diabetic nephropathy.

Identification of New Protein Biomarkers for Diabetic Kidney Disease by Proximity Extension Assays

Anja Thorenz,[1] Berthold Hocher,[2,3] Oleg Tsuprykov,[2,4] Mira Pavkovic.[1] *[1]Bayer AG, Wuppertal, Germany; [2]University of Potsdam, Potsdam, Germany; [3]Key Laboratory of Study and Discovery of Small Targeted Molecules of Hunan Province, Hunan Normal University, Changsha, China; [4]IFLB, Institute for Laboratory Medicine, Berlin, Germany.*

Background: Diabetic kidney disease (DKD) is a complication of diabetes and the leading cause of kidney failure in developed countries. To treat DKD more effectively, it is essential to identify new drug targets and to judge the success of such developments using reliable markers. The olink proximity extension assay (PEA) allows measuring 92 proteins across 96 samples per panel simultaneously using only 1µl of plasma. To identify novel protein biomarkers for DKD the olink PEA was selected and evaluated in this study.

Methods: Plasma from DKD patients with different CKD stages (0,2,4) (n=62,mean age 70y) as well as healthy controls (n=9,mean age 62y) were used for protein profiling with the olink PEA. Plasma was obtained from informed and consenting donors. Here, two antibodies labeled with unique, partially complementary oligonucleotides bind pair-wise to the target protein. The formed double-stranded sequence is detected and quantified using RT-PCR. Relevant proteins were verified with ELISA for evaluation of the olink PEA.

Results: The CKD marker FGF23 showed higher expression in plasma of CKD4 patients (n=36,mean age 74y) than in CKD2 patients (n=20,mean age 69y) and CKD0 (n=6, mean age 61y) when measured with olink PEA. This was also seen in the FGF23 ELISA. Also markers as VCAM1 and PECAM1 had similar expression patterns in the olink PEA and ELISA measurements. Correlation analysis showed significant correlation between the 2 methods when FGF23 ($p<0.001$,$r=0.922$), VCAM1 ($p<0.001$,$r=0.84$) and PECAM1 ($p<0.001$,$r=0.851$) were compared. The olink PEA also identified other differentially expressed proteins in the observed groups. Even differences between CKD stages were detected. 48 proteins out of 192 proteins were significantly different among the groups (panel CV2 and 3). Stem cell factor (SCF) which contributes to renal fibrosis was significantly upregulated in plasma of CKD2 patients compared to CKD0 patients and even higher in CKD4 patients.

Conclusions: The olink PEA and ELISA showed similar patterns and correlated significantly for FGF23, VCAM1 and PECAM1 in plasma of DKD patients. Moreover, other proteins which were different between DKD patients with different CKD stages and control groups were identified. Therefore, the olink PEA might be a promising tool to identify novel biomarkers for possible new drug targets and treatment evaluation for DKD.

FR-PO442

High-Throughput Proteomic Search Reveals Novel Plasma Biomarkers of Time to ESRD in Type 1 Diabetes Patients with Persistent Proteinuria and CKD Stage 1-2

Jan Skupien,[1] Adam Smiles,[2] Andrzej S. Krolewski.[2] *[1]Jagiellonian University Medical College, Krakow, Poland; [2]Joslin Diabetes Center, Boston, MA.*

Background: The risk of end-stage renal disease (ESRD) reaches 30-50% in patients with type 1 diabetes and persistent proteinuria. An intensive research effort is needed to identify and evaluate interventions that improve prognosis in these patients. To better understand the disease process, identify novel drug targets and improve end-point definitions in clinical trials new biomarkers of renal function decline and ESRD risk are desperately needed.

Methods: We assayed baseline plasma specimens using an Olink proteomic platform (Uppsala, Sweden) in a group of 82 patients with type 1 diabetes and CKD stage 1-2 from Joslin Proteinuria cohort and replicated the findings in an additionally ascertained sample of

76 patients with similar baseline characteristics. Using an accelerated failure time survival regression model we sought association of 454 proteins with time to ESRD. Association was considered significant if false discovery rate-adjusted p-value <0.01 and a p-value <0.01 in the replication set.

Results: We identified 31 plasma proteins significantly associated with time to ESRD. The largest number of them represented tumor necrosis factor signaling pathway. All markers were associated with increased risk of ESRD, i.e. their higher concentration was associated with shorter time to ESRD. Most proteins were highly correlated and redundant as biomarkers. Three of them were independently associated with time to ESRD and are shown in the Table. Using these three proteins we estimated patients' time to ESRD. The median predicted time in patients with ESRD was 9.7 years (observed 8.2 years) and in those without ESRD the median predicted time was 15.8 years.

Conclusions: There are multiple novel biomarkers of fast progression to ESRD in patients with type 1 diabetes and proteinuria. These proteins should be further investigated for their biologic role and therapeutic potential. They may serve in the future for predicting time to ESRD in diabetic kidney disease.

Funding: NIDDK Support, Private Foundation Support

Multivariate predictive model of time to ESRD

Protein	Effect of doubling concentration on ESRD time	P-value
HAVCR1	-23.3%	<.001
WFDC2	-29.5%	0.001
PGLYRP1	-13.3%	0.049

FR-PO443

Pre-ESRD Determinants of Post-ESRD Mortality in Patients with Type 1 Diabetes (T1D)

Adam Smiles,[1] Jan Skupien,[2] Alessandro Doria,[3] Andrzej S. Krolewski.[1] [1]*Joslin Diabetes Center, Boston, MA;* [2]*Jagiellonian University Medical College, Krakow, Poland;* [3]*Joslin Diabetes Center - Harvard Medical School, Boston, MA.*

Background: We reported that in T1D patients the patterns of estimated glomerular filtration rate decline (eGFR slopes) preceding the onset of ESRD were linear but varied greatly among individuals. The slopes could be grouped to fast, moderate and slow (Skupien et al. *Diabetes Care*). In this study we investigated in the same cohort whether post-ESRD mortality was influenced by the pre-ESRD eGFR slopes. In addition we sought whether plasma concentrations of 568 proteins during pre-ESRD period were associated with post-ESRD mortality.

Methods: A cohort of 206 T1D patients who developed ESRD while attending the Joslin Clinic were matched against the United States Renal Data System and National Death Index registries to ascertain dates of starting dialysis, renal transplant and mortality. Plasma samples obtained from these patients when they had had CKD stage 2-4 were assayed on the SOMAscan proteomics platform. Relative concentrations of 568 proteins were measured. Cox proportional hazard model for time to mortality was used, and proteins with a p value of <0.005 were selected.

Results: There were 75 deaths while on dialysis during 441 person-years (py) of follow-up (17.0 deaths/100 py) and 40 deaths after transplant during 1204 person-years (3.3 deaths/100 py). Total mortality was 115 deaths during 1644 person-years (7.0 deaths/100 py) Patients with fast (< -10 ml/min/yr) and moderate (-5 -10 ml/min/yr) renal decline had a two times higher post-ESRD mortality than in those with slow (> -5 ml/min/yr) renal decline. This pattern was similar for mortality during time spent on dialysis and after receiving renal transplant (see Table). We identified 4 plasma proteins whose elevated level was associated with increasing risk of post-ESRD mortality: CCL3L1, CCL18, IL5RA, PRSS22 and 3 plasma proteins whose higher levels were associated with decreasing risk of post-ESRD mortality: VIP, IL11 and IFNL1.

Conclusions: Disease processes that determine post-ESRD mortality begin long before the onset of ESRD. The candidate proteins identified should be investigated further for their potential role as predictors and determinants of post-ESRD mortality.

Funding: NIDDK Support, Private Foundation Support

Mortality Rates (Deaths/100 Person-Years)

Pre-ESRD eGFR slope	Mortality during Dialysis	Mortality after Transplant	Total Mortality	p value compared to Slow
Fast Decline	18.3	4.6	8.7	0.0008
Moderate Decline	18.3	4.0	7.4	0.014
Slow Decline	13.3	0.6	3.9	

FR-PO444

DUPDN - Diagnostic Urinary Panel for Diabetic Nephropathy: A Model to Predict Progressive CKD

Mysore K. Phanish,[2] Mark E. Dockrell.[1] [1]*South West Thames Institute for Renal Research, Surrey, United Kingdom;* [2]*Epsom and St helier University Hospitals NHS Trust, Carshalton, London, United Kingdom.*

Background: CKD in patients with diabetes is detected and monitored using eGFR and albuminuria. Both have limitations and a significant proportion of patients with type2 diabetes have CKD without albuminuria. We tested a panel of urinary biomarkers that reflect areas of injury and pathogenic mechanisms to develop a model to predict progressive CKD.

Methods: 400 patients with diabetes and CKD were recruited and 388 included in analysis. 50% of patients had ACR <3. A random urine sample was collected at baseline and analysed for a panel of biomarkers - ACR, inflammatory cytokines-IL1β, IL6, MCP1, Markers of proximal tubular injury/damage- NAG and RBP, NGAL, Fibronectin (Fn). Patients were followed for 5y. Logistic regression analysis was done to test the association of individual and combination of biomarkers with presence of CKD stage 3 or 4 aand progression to CKD st 3 or 4. ROC AUC results were obtained for each combination of biomarkers to measure their sensitivity and specificity to CKD stages and progression. A mixed model was used for the association of biomarkers with the trajectory of eGFR over 5y. Models with the same numbers of observations were compared using the AIC goodness-of-fit measure.

Results: Comparisons between CKD stages demonstrated significant differences in urinary RBP, NAG, MCP1, IL6. In multivariate analysis, at all levels of ACR, urinary RBP demonstrated better correlation with CKD stage 3 and 4 compared to ACR but this effect was not seen after adjusting for age, sex and race. Adjusted ACR predicted CKD stage 3 as well as any other combination of markers with AUC of 83%. For progression to stage 3 or 4 CKD, unadjusted and adjusted ACR was a poor predictor (With an AUC of 62-67%). Addition of RBP and MCP1 as covariates with adjustment for age, sex and race in patients with ACR of <3 improves the ROC AUC to 75%. Urinary Fn was raised in diabetic patients with early CKD compared to healthy controls. Using 1,243 observations of eGFR over 5y we arrived at 2 models with best AIC values: 1. where the eGFR gradient against time in yrs is associated with baseline ACR and RBP/Cre: 2. where the eGFR gradient against time in yrs is associated with baseline MCP1/Cre and RBP/Cre. This final model showed best AIC value.

Conclusions: Our study suggests that models that include RBP and MCP1 in addition to or instead of ACR improve prediction of future eGFR.

Plasma Lipids Are Associated with Diabetic Kidney Disease: A Study of Plasma Lipidomics in Type 1 Diabetes

Nete Tofte,[1] Tommi Suvitaival,[1] Linda Ahonen,[1] Simone Theilade,[1] Signe Abitz Winther,[1] Marie Frimodt-Moller,[1] Tarunveer S. Ahluwalia,[1] Peter Rossing.[1,2] [1]*Steno Diabetes Center Copenhagen, Copenhagen, Denmark;* [2]*University of Copenhagen, Copenhagen, Denmark.*

Background: The pathophysiology of diabetic kidney disease (DKD) is incompletely understood. The study aim was to perform lipidomics analyses to evaluate associations between plasma lipids and measures of DKD.

Methods: In total, the study comprised 668 patients with T1D with varying albuminuria status. Non-targeted lipidomics analyses were performed on plasma samples using ultra-high performance liquid chromatography quadrupole time-of-flight mass spectrometry. Cross-sectional associations between single lipid species and low eGFR or albuminuria were analysed. Longitudinal data on urinary albumin excretion (UAE) and estimated glomerular filtration rate (eGFR) were obtained from electronic records over a median of 5.5 years. eGFR slopes and hazard ratios for progression in albuminuria status (progression from normo- to micro/macroalbuminuria or from micro-to macroalbuminuria) were calculated. Adjustments included age, gender, HbA1c, systolic blood pressure, smoking, BMI, statin treatment, plasma triglycerides, total plasma cholesterol and baseline eGFR and/or UAE, where appropriate. Results were corrected for multiple testing.

Results: A total of 121 lipids from 4 different lipid classes (phosphatidylcholines (PCs), lysophosphatidylcholines (LPCs), triacylglycerols (TGs), and sphingomyelins (SMs)) were included in the analyses. In a crude model adjusted for baseline eGFR, PC(36:4) had the strongest association to eGFR decline ($p<0.01$) and 10 medium-and-short-chain TGs were weakly associated to eGFR decline ($p<0.10$). Among these lipids, the association between PC(36:4) and eGFR decline remained significant after adjusting for clinical variables (β=-0.08360; p=0.0004). Similar associations were seen in the cross-sectional analyses between lipids and eGFR. In cross-sectional analyses of macro- vs normoalbuminuria, PC, SMs and medium-chain-length TGs were decreased ($p<0.05$), however, no lipids were significantly associated with change in albuminuria status in longitudinal analyses.

Conclusions: Alterations in the plasma lipid levels were associated with decreased eGFR and macroalbuminuria in this T1D study cohort, indicating broad changes in the lipidome in individuals with DKD. Further, the PC(36:4) was discovered to have a significant association to future eGFR decline.

Plasma Metabolomics Identifies Markers of Impaired Kidney Function: A Meta-Analysis of 1,984 Europeans with Type 2 Diabetes

Nete Tofte,[1] Tarunveer S. Ahluwalia,[1] Nicole Vogelzangs,[2] Dennis O. Mook-Kanamori,[3] Adela Brahimaj,[7] Jana Nano,[5] Ko Willems van dijk,[3] Marie Frimodt-Moller,[1] Carla J. Van der kallen,[2] Ilja C. Arts,[2] Joline Beulens,[8] Amber A. Van der heijden,[6] Giel Nijpels,[9] Marleen V. Greevenbroek,[2] Coen Stehouwer,[4] Peter Rossing,[1] Leen M. 't Hart.[3] [1]*Steno Diabetes Center Copenhagen, Copenhagen, Denmark;* [2]*Maastricht University, Maastricht, Netherlands;* [3]*Leiden University Medical Center, Leiden, Netherlands;* [4]*University Hospital Maastricht, Maastricht, Netherlands;* [5]*Erasmuc Medical Center, Rotterdam, Netherlands;* [6]*VUMC, Amsterdam, Netherlands;* [7]*Erasmus MC, Rotterdam, Netherlands;* [8]*VUmc, Amsterdam, Netherlands;* [9]*VU University, Amsterdam, Netherlands.*

Background: There is a need for novel biomarkers and better understanding of the pathophysiology of diabetic kidney disease. The aim was to investigate the associations between plasma metabolites and measures of kidney function.

Methods: Blood metabolites (*n=235*) were measured by nuclear magnetic resonance spectroscopy (NMR) in 1,984 type 2 diabetes (T2D) cases among three independent Dutch studies (the Hoorn Diabetes Care System (DCS, *n=995*) cohort, the Maastricht Study

(MS, *n=848*) and the Cohort of Diabetes and Atherosclerosis Maastricht study (CODAM, *n=141*)) with mean ± SD age 59.7 ± 8.8. Linear regression based associations were tested between single plasma metabolites and estimated glomerular filtration rate (eGFR) and urinary albumin-to-creatinine ratio (UACR) in each study. Covariate adjustments included age, sex, systolic blood pressure, body mass index, medication (lipid-lowering, glucose-lowering, anti-hypertensive), smoking, diabetes duration, HbA1c, and eGFR or UACR, where appropriate. A fixed effect meta-analysis of the 3 study sets was performed. A Bonferroni's correction of $p_{bonferroni} = 1.0 \times 10^{-4}$ was considered significant.

Results: After adjustment for multiple testing, 82 metabolites associated significantly with eGFR while two with UACR. Alteration of several lipoprotein subclasses of VLDL and HDL as well as amino acids (phenylalanine, isoleucine and glutamine) and glycoprotein acetyls were associated with lower eGFR. Higher UACR levels were significantly associated with glycoprotein acetyls and cholesterol esters in very small VLDL.

Conclusions: The current study identifies plasma metabolites associated with decreased eGFR and albuminuria among T2D cases of European origin. These findings implicate an involvement of lipid and amino acid metabolism in the pathogenesis of DKD.

FR-PO447

A Biomarker of Type VI Collagen Formation Is Associated with Diabetic Kidney Disease and Is a Risk Factor for Mortality in Elderly Women

Federica Genovese,[1] Nadja Sparding,[1,2] Morten A. Karsdal,[1] Cecilie liv Bager.[1] *[1]Nordic Bioscience, Herlev, Denmark; [2]Biomedical Sciences, Faculty of Health and Medical Science, University of Copenhagen, Copenhagen, Denmark.*

Background: Diabetic kidney disease (DKD) is the leading cause of chronic dialysis and accounts for at large proportion of all cases of chronic kidney disease (CKD). Renal fibrosis is the hallmark of CKD and is caused by changes in the balance of extracellular matrix (ECM) remodeling. Type VI collagen is a crucial ECM molecule for the control of tissue organization. In this study, we investigated the association of PRO-C6 (collagen type VI formation) with DKD and with mortality in patients with DKD.

Methods: The study population included 5855 postmenopausal women from the Prospective Epidemiological Risk Factor Study (PERF) cohort. The women were examined at baseline (BL year, 2000) and serum PRO-C6 were measured. The dialysis, diagnosis and mortality information were extracted from Danish Health Registries at end of study (2015). DKD was defined as eGFR <60 ml/min/1.73m^2, dialysis, or a renal diagnose (ICD10). Healthy women were defined as women with no history of chronic diseases (ICD10 chapter II, IX, X, XI, XIII, XIV). Women with DKD were stratified into quintiles based on BL PRO-C6 levels and compared with an ANOVA test. Cox regression was used to explore the association with all-cause mortality with 15 years of follow-up.

Results: A total of 75 and 308 women were diagnosed with DKD and diabetes at BL, and 450 were healthy. Serum PRO-C6 levels were higher in women with DKD (mean=10.7 ng/ml (SD=3.7), p<0.0001) and diabetic (mean=8.7 ng/ml (SD=2.7), p=0.004) compared to the healthy group (mean= 8.0 ng/mL (SD=3.0)). Levels of PRO-C6 were higher in women with DKD compared to the diabetic group (p<0.0001). The women with DKD were older (age, 74.6) than the diabetic women (age, 71.3) (p<0.0001), but the effect of age did not affect the independent association of PRO-C6 with DKD. Finally, DKD women in the 5th quintile of PRO-C6 had an increased risk of all-cause mortality compared to women in the 3th quintile (HR=2.6 (95% CI=0.9-7.3), p=0.08). The borderline-significance was probably due to lack of power.

Conclusions: In this study, we demonstrated that PRO-C6, a biomarker of collagen type VI formation, was increased in serum of post-menopausal women with DKD compared to women with diabetes without kidney involvement and healthy women. In addition, PRO-C6 was associated with mortality in women with DKD.

FR-PO448

The Implications of Immunoglobulin G and Complement 3 in Differentiating Nondiabetic Renal Disease from Diabetic Nephropathy in Patients with Type 2 Diabetes Mellitus: A Single-Center Study in China

Junlin Zhang. *Nephrology, West China Hospital of Sichuan University, Chengdu, China.*

Background: Heavy proteinuria caused by nondiabetic renal disease (NDRD) is common in type 2 diabetes mellitus (T2DM). The aim of this study was to investigate specific predictors for NDRD in addition to traditional indicators in T2DM.

Methods: A total of 341 patients with T2DM who underwent renal biopsy were retrospectively included. Eligible patients were divided into a nephrotic-range group (n=194) and a non-nephrotic-range group (n=147) based on proteinuria level. Risk factors for NDRD were evaluated using logistic regression, and the diagnostic implications of these variables were assessed by subgroup.

Results: Multivariate logistic regression indicated that reduced serum IgG (OR, 0.762; 95%CI, 0.628–0.924; *p*=0.006) was an independent predictor of NDRD in the nephrotic-range group. However, in the non-nephrotic-range group, increased C3 level was an independent risk factor for NDRD (OR, 1.313; 95%CI, 1.028–1.678; *p*=0.029). In the nephrotic-range group, the optimal cutoff value of IgG for predicting NDRD was 734.0 mg/dl, with 67.8% sensitivity and 74.8% specificity, and IgG ≤734.0 mg/dl was the best predictor of NDRD. In the non-nephrotic-range group, the optimal cutoff value of C3 for predicting NDRD was 122.0 mg/dl with low sensitivity (30.9%) but high specificity (97.8%).

Conclusions: At different levels of proteinuria, reduced IgG and increased C3 levels were independent indicators of NDRD in T2DM. Insights into these factors will help to advance the clinical management of NDRD.

FR-PO449

Cathepsin D: A Potential Biomarker for Diabetic Kidney Disease

Viktor Drel,[1] Tomas Vaisar,[2] Jiwan J. Kim,[1] Erkka A. Valo,[3] Jing Zhang,[4] Tarunveer S. Ahluwalia,[5] Janet Snell-Bergeon,[6] Peter Rossing,[5] Per-Henrik Groop,[3] Loki Natarajan,[4] Andrew N. Hoofnagle,[2] Ian H. de Boer,[2] Manjula Darshi,[1] Kumar Sharma.[1] *[1]University of Texas Health San Antonio, San Antonio, TX; [2]University of Washington, Seattle, WA; [3]Folkhälsan Research Center, Helsinki, Finland; [4]University of California San Diego, La Jolla, CA; [5]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [6]University of Colorado Denver, Aurora, CO.*

Background: Cathepsins are lysosomal proteases that play important roles in a wide range of physiological and pathological processes. Recent studies have suggested that dysregulation of cathepsin D (Cat D) can lead to development of fibrosis and induce apoptosis in the podocytes and tubular cells in acute kidney injury murine models. In the current study we analyzed if changes in Cat D are associated with the development and progression of diabetic kidney disease (DKD) in type I diabetic mouse models and in humans.

Methods: Cat D protein levels in urine were measured by liquid-chromatography mass spectroscopy in four diverse cohorts (CACTI, EDC, Finn-Diane, and Steno) with long-standing type I diabetes and normal kidney function (eGFR≥60ml/min/1.73m^2). Subjects were classified into slow decliners/controls with eGFR decline ≤1ml/min/1.73m^2/yr or rapid progressors/cases with eGFR decline of ≥3ml/min/1.73m^2/yr. Cat D activity in urine samples of patients with established kidney disease (eGFR<40ml/min/1.73m^2) and in type 1 DKD mouse model (Akita) was measured biochemically. Immunohistochemistry in mouse kidney tissues were performed with FFPE embedded kidney sections.

Results: Baseline mean eGFR and median ACR in controls (n=351) and cases (n=270) were 91.97 (sd 18.68) and 9.44 (IQR 30), and 98.37 (sd 25.44) and 33.49 (IQR 283.01), respectively. Cat D protein levels in urine were significantly elevated in cases as compared to controls [mean 1.18 au (1.07-1.3) in controls vs 1.56 au (1.37 to 1.57) in cases, p<001, FDR q=0.01). Immunohistochemical analysis identified predominant localization of Cat D to tubules in akita kidney sections and increased as compared to controls. Cat D activity was significantly elevated in urine (p<0.001) samples of of akita mice (n=6 each WT and akita, p<0.001) and in patients with established DKD (n=10 each control and DKD, p<0.0001). Cat D activity also correlated significantly (R^2: 0.855, p<0.0001) with albumin/creatinine in akita mouse urine.

Conclusions: The current data indicate that Cathepsin D may play vital role in the pathogenesis of diabetic kidney disease and its level as well as activity in urine can serve as biomarker of the diabetic nephropathy.

FR-PO450

Plasma Endostatin and Kidney Outcomes in Patients with Type 2 Diabetes

Kinsuk Chauhan,[1] Girish N. Nadkarni,[1] Lili Chan,[1] Chirag R. Parikh,[2] Steven G. Coca.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Yale University and VAMC, New Haven, CT.*

Background: Additional biomarkers are needed for prognostication of kidney function decline in patients with type 2 diabetes. There are limited data on the association of markers of endothelial dysfunction with longitudinal kidney function decline. We assessed the association of plasma endostatin, an inhibitor of angiogensesis, and kidney outcomes in two settings: a clinical trial and a contemporary clinical cohort.

Methods: We used banked plasma specimens from a nested matched case-control study (187 cases:187 controls) in the Action to Control Cardiovascular Disease (ACCORD) trial and a diverse cohort of patients with type 2 patients from the EMR and USRDS-linked Mount Sinai Bio*Me* Biobank (n=871). We measured endostatin in plasma specimens banked from the time of enrollment in ACCORD and Bio*Me* and examined its association with a composite kidney outcome of sustained 40% decline in eGFR or ESRD, as well as the clinical utility.

Results: Baseline eGFR was 90 ml/min/1.73 m^2 in ACCORD and 66 ml/min/1.73 m^2 in Bio*Me*. Baseline plasma endostatin levels were higher for participants that achieved the composite kidney endpoint (median 42 ng/ml in 187 ACCORD cases and 45 ng/ml in 121 participants reaching the endpoint in Bio*Me*) vs. those without the CKD endpoint in both cohorts (median 36 and 38 ng/ml, respectively). Each $\log_2$ increment in plasma endostatin was independently associated with the kidney outcome in both cohorts (adjusted OR 2.5; 95% CI 1.5-4.3 in ACCORD and adjusted HR 2.6; 95% CI 1.8-3.8). Participants in the highest quartile (>48 ng/ml in both cohorts) vs. lowest quartile of plasma endostatin (< 32 ng/ml in ACCORD and < 31 ng/ml in Bio*Me*) had approximately 4-fold higher risk for the kidney outcome (adjusted OR 3.6; 95% CI 1.8-7.3 in ACCORD and adjusted HR 4.4; 95% CI 2.3-8.5 in Bio*Me*). In Bio*Me*, at a predicted probability threshold of 30% using clinical variables (age, sex, BMI, history of CVD,CHF, baseline eGFR, baseline mean arterial pressure, and ACEi/ARB usage) plus endostatin, the NPV was 0.90 (95% CI 0.89-0.91) and the PPV was 0.45 (95% CI 0.37-0.54) for the outcome of composite kidney endpoint.

Conclusions: Higher baseline plasma endostatin associated with kidney outcomes during follow-up in patients with type 2 diabetes from two diverse cohorts.

Serum Soluble Tumor Necrosis Factor Receptor 1 (sTNFR1) Associates with Decline in Estimated Glomerular Filtration Rate (eGFR) Slope in a Phase 2 Study of Selonsertib in Diabetic Kidney Disease (DKD)

Jacqueline Tarrant,[1] Andrew Billin,[2] Yuanyuan Xiao,[1] Matthew Peach,[2] Fang Chen,[1] Scott D. Patterson,[2] John Sundy,[5] Uptal D. Patel,[2] Pablo E. Pergola,[3] Glenn M. Chertow.[4] *[1]Gilead Sciences, Foster City, CA; [2]Gilead Sciences, Inc., Foster Cuty, CA; [3]Renal Associates, PA, San Antonio, TX; [4]Stanford University School of Medicine, Palo Alto, CA; [5]Gilead Sciences, Inc, Belmont, CA.*

Background: Circulating sTNFR1 is a promising biomarker of DKD severity and risk of progression. We investigated the disease associations and predictive effect of sTNFR1 in a Phase 2 study of selonsertib (SEL), a small molecule inhibitor of apoptosis signal-regulating kinase 1 (ASK1), in DKD.

Methods: In this study, 333 patients with moderate-to-advanced DKD (UACR 600 mg/g for stage 3a, UACR 300 mg/g for stage 3b, UACR 150 mg/g for stage 4) were randomized 1:1:1:1 to receive SEL (2, 6, or 18 mg) or matching placebo (PBO) orally once daily for 48 weeks (W48). The analysis population (full analysis set) excluded 2 sites for technical deviations and patients with baseline eGFR 20 mL/min/1.73m^2. Serum sTNFR1 was measured at baseline (BL) and W48 by ELISA. Spearman correlation was used to assess association between markers, and a random slope model for differences in chronic eGFR slope (W4-W48) between treatments.

Results: Serum sTNFR1 was inversely correlated with eGFR at BL (N=261; r=-0.74; p<0.001) and at W48 (N=215; r=-0.75; p<0.001), in addition to change of sTNFR1 and change of eGFR at W48 (N=215; r=-0.35; p=0.0016). There was no significant relation between sTNFR1 and UACR at BL (N=261; r=0.12). We found a trend for a relatively lower increase in sTNFR1 from BL to W48 in the 18mg SEL group (median=0.12 ng/mL, Q1-Q3: -0.43 to 0.53 ng/mL; N=49) compared to PBO (median=0.31 ng/mL, Q1-Q3: -0.17 to 0.66 ng/mL; N=49). Applying a BL 4.3 ng/mL sTNFR1 cutpoint retrospectively (identified by Yamanounchi M, *et al. Kidney Int* 2017), 51% of our overall population were potentially at high risk for progression to end stage renal disease. The subgroup >4.3 ng/mL sTNFR1 had an apparent therapeutic benefit from SEL 18 mg compared to PBO when comparing eGFR chronic slope (W4 to 48) difference (p=0.029), however this was no different from the benefit shown overall (p=0.036).

Conclusions: Serum sTNFR1 was directly correlated with eGFR at BL and change at W48 in patients with moderate-to-advanced DKD. The subgroup with BL sTNFR1>4.3 ng/mL had similar treatment benefit to SEL compared to the overall trial population

Serum Soluble CD163 Associates with Estimated GFR and History of Ischemic Heart Disease in Adults with Diabetes

Tomas P. Griffin,[1,2] Daniel Dempsey,[3] Aisling Morrin,[3] Md Nahidul Islam,[2,4] Sarah M. Moran,[3] Paula M. O'Shea,[4] Jason Wyse,[3] Mark A. Little,[3] Matthew D. Griffin.[2,5] *[1]Centre for Endocrinology, Diabetes and Metabolism, Saolta University Health Care Group (SUHCG), Galway University Hospitals, Galway, Ireland; [2]Regenerative Medicine Institute, at CÚRAM SFI Research Centre, School of Medicine, National University of Ireland Galway (NUIG), Galway, Ireland; [3]Trinity Health Kidney Centre, Trinity College Dublin, Dublin, Ireland; [4]Department of Clinical Biochemistry, Saolta University Health Care Group (SUHCG), Galway University Hospitals, Galway, Ireland; [5]Department of Nephrology, Saolta University Health Care Group (SUHCG), Galway University Hospitals, Galway, Ireland.*

Background: CD163 is a scavenger receptor for haptoglobin-haemoglobin complexes that is expressed by monocytes/macrophages and undergoes ectodomain shedding into blood as soluble CD163(sCD163) in an inflammatory milieu. Activation of monocytes/macrophages is implicated not only in the pathophysiology of diabetes but also in the development of glomerular injury in diabetic kidney disease. The aim of this study was to determine the relationships between serum sCD163 and clinical/biochemical parameters in a cohort of diabetic patients with a broad range of renal functional parameters.

Methods: A total of 201 adults with diabetes (eGFR[CKD-EPI] range 10-143mL/min/1.73m^2) were recruited to a prospective cohort study. Subjects had serum collected at 1-4 timepoints(stored at -80^{o}C). Clinical, anthropometric and biochemical data were recorded at each timepoint. Serum sCD163 concentration was quantified using R&D ELISA(DY1607). To analyse the longitudinal relationships between relevant clinical/laboratory parameters and sCD163, a linear mixed model was fitted in R.

Results: Of 23 parameters included in the model, there were significant associations between serum sCD163 and eGFR, ALT, diuretic use and history of ischaemic heart disease(IHD). The highest value coefficients of association with serum sCD163 were for eGFR(negative) and IHD(positive) (Fig 1). Parameters for which no significant association was observed included BMI, HbA1c, urine ACR and lipids.

Conclusions: In adults with diabetes, serum sCD163 associated most closely with eGFR and IHD. Thus, variation in serum sCD163 among adult diabetic patients may reflect, in part, the role of monocyte/macrophage activation in renal and cardiovascular complications of diabetes.

Soluble Urokinase Plasminogen Activator Receptor Predicts Kidney Function Decline and Mortality in Patients with Type 1 Diabetes

Viktor Rotbain Curovic,[1] Simone Theilade,[1] Signe Abitz Winther,[1] Nete Tofte,[1] Jesper Eugen-Olsen,[3] Frederik Persson,[1] Tine Hansen,[1] Jørgen L. Jeppesen,[2] Peter Rossing.[1,2] *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]University of Copenhagen, Copenhagen, Denmark; [3]Clinical Research Center, Hvidovre Hospital, Copenhagen, Denmark.*

Background: Soluble urokinase plasminogen activator receptor (suPAR) is an important inflammatory biomarker. The predictive qualities of suPAR in relation to complications in patients with type 1 diabetes (T1D) are unknown. We investigated the prognostic ability of suPAR for the development of decline in renal function, end stage renal disease (ESRD), progression in albuminuric status and mortality in T1D.

Methods: 667 patients with T1D and various degrees of diabetic kidney disease were included in a prospective study. suPAR was measured with commercial ELISA kits. Patients were traced through the National Death Register, the National Health Register and electronic laboratory records. Endpoints were: eGFR-decline ≥30%, development of ESRD, progression to higher albuminuric status and mortality. Follow-up ranged from 5.2 to 6.2 years. Results were adjusted for sex, age, LDL cholesterol, HbA1c, systolic blood pressure, BMI, smoking status, urinary albumin excretion rate, eGFR, prescribed renin-angiotensin-aldosterone system inhibitors, and CRP. Hazard ratio (HR) is shown per doubling of suPAR and presented with 95% confidence interval (CI). Relative integrated discrimination (rIDI) was calculated to assess predictive contribution of suPAR to known risk factors.

Results: Of 667 participants, 368 (55%) were male; mean±SD age was 55±13 years and eGFR 88±25 ml/min/1.73m2. Median (interquartile range) of suPAR was 3.4 (2.7-4.5) ng/ml. There were 93 cases of eGFR-decline ≥30%, 26 cases of ESRD, 36 cases of progression in albuminuria and 58 deaths. Adjusted HR (95% CI) for the respective endpoints were 2.96 (1.70-5.16, p<0.001), 2.99 (0.75-11.9; p=0.12), 1.41 (0.60-3.35; p=0.43) and 4.42 (2.05-8.62, p<0.001). rIDI analysis showed contribution of 18.6% (p=0.009) for eGFR-decline, 5.5% (p=0.29) for ESRD, 1.1% (p=0.68) for progression in albuminuria and 23.8% (p<0.001) for mortality.

Conclusions: Higher suPAR level is independently associated with an increased risk of eGFR-decline and mortality in patients with T1D. In addition, it is a sizeable contributor in the risk stratification of the same based on rIDI. Our results suggest that suPAR may have an important role in identifying T1D patients at early risk of kidney function decline and death.

FR-PO454

Uric Acid Is an Independent Risk Factor for Decline in Kidney Function, Cardiovascular Event, and Mortality in Patients with Type 1 Diabetes

Sascha Pilemann-lyberg, Tine Hansen, Nete Tofte, Signe Abitz Winther, Simone Theilade, Tarunveer S. Ahluwalia, Peter Rossing. *Steno Diabetes Center Copenhagen, Gentofte, Denmark.*

Background: Previous studies have provided inconclusive results to the role of uric acid (UA) for risk prediction. Here we aimed to improve power and precision of the predictive value of UA for risk of decline in kidney function, cardiovascular event (CVE) and mortality in patients with type 1 diabetes (T1D).

Methods: UA was measured in 670 patients with T1D and various degrees of albuminuria, ranging from normo- (<30 mg/24 h) to macroalbuminuria (≥300 mg/24 h). Patients were traced through national registers to gather data on CVE and mortality. Endpoints: mortality, CVE and eGFR-decline of ≥30%. Median follow-up ranged from 5.1 to 6.2 years. Slope estimates of eGFR and urinary albumin excretion rate (UAER) were

calculated for a median of 5.5 years. We applied Cox regressions and linear regression models. Adjustment included sex, age, body mass index, HDL cholesterol, smoking, HbA_{1c}, mean arterial pressure, UAER, treatment with RAAS blockers and eGFR. Hazard ratio (HR) were calculated per doubling of UA and presented with 95% confidence interval (CI). Relative integrated discrimination (rIDI) was calculated to assess predictive contribution of UA to known risk factors.

Results: Of the 670 patients, 372 (55%) were male, mean ± SD age was 55±13 years and eGFR 82±26 ml/min/1.73m^2. Median (IQR) uric acid was 5.04 (3.87-6.22) mg/dl. Higher UA was associated with higher risk of decline in eGFR of ≥30% (n=89; HR: 3.14 (1.69-5.82), p<0.001), CVE (n=94; HR: 2.43 (1.31-4.52), p=0.005) and mortality (n=58; HR: 2.81 (1.23-6.43), p=0.014) in adjusted analyses. Adding UA to the adjusted model including conventional risk factors improved the rIDI by 12.8% for decline in eGFR of ≥30% (p<0.001), 8.7% for CVE (p=0.008) and 10.8% (p=0.040) for mortality. Higher UA was also associated with steeper decline in eGFR (p<0.0014) and steeper increase in UACR (p<0.0016) in adjusted analysis.

Conclusions: In T1D, higher UA is associated with higher risk of decline in kidney function, CVE and mortality, independently of other risk factors. Our results suggest that UA have a promising role in risk stratification among T1D.

FR-PO455

Diagnostic Efficacy of sPLA2R-Ab for Membranous Nephropathy in Diabetes Kidney Disease

Qian Wang, Zheyi Dong, Xiangmei Chen, Xiaomin Liu, Weiguang Zhang. *Chinese PLA General Hospital, Beijing, China.*

Background: The pathological types of diabetes kidney disease (DKD) are various, among which, membranous nephropathy(MN) accounts for a large proportion of non-diabetic renal diseases (NDRD). Serum anti-phospholipidase A2 receptor antibody(sPLA2R-Ab) is used for the diagnosis of MN, the diagnostic efficacy of sPLA2R-Ab for MN in DKD need to be further verified.

Methods: Screened on patients with type 2 diabetes mellitus who underwent a renal biopsy and had a valid sPLA2R-Ab test results, hospitalized in the general hospital of the people's liberation army of China between May 1st, 2016 and January 30th, 2018. Eligible patients were divided into two groups according to the pathological results: MN group and non-MN group. Patients'clinical characteristics and laboratory datas were collected.

Results: The study included 252 patients:59 (23.4%) in the MN group and 193 (76.6%) in the non-MN group. The baseline were compared between the two groups: age, history of diabetes, creatinine, GFR and blood pressure were statistically significant. MN group was older, lower blood pressure, shorter history of diabetes and better renal function than non-MN group. The positive value of SPLA2R-Ab was defined respectively as≥20, > 12, > 2: sPLA2R-Ab achieved a good diagnostic efficiency with sensitivity of 59.3%, 66.1% and 83.1%, specificity of 100%, 98.96% and 93.26%, positive predictive values of 100%, 95.12% and 79.0%, negative predictive values of 88.9%, 90.52% and 94.74%, and accuracy of 90%, 91.27% and 90.87% for MN in DKD respectively.

Conclusions: SPLA2R-Ab has a good diagnostic accuracy for MN in DKD, and the positive threshold may be reduced to 12, which can increase the accuracy of diagnosis.

Table1 The diagnostic efficacy of sPLA2R-Ab for MN in DKD

positive threshold	sPLA2R-Ab	renal pathological	renal pathological	Total
		MN	non-MN	
≥20	positive	35	0	35
≥20	negative	24	193	217
≥20	Total	59	193	252
>12	positive	39	2	41
>12	negative	20	191	211
>12	Total	59	193	252
>2	positive	49	13	62
>2	negative	10	180	190
>2	Total	59	193	252

FR-PO456

Urinary Biomarkers of Tubular Injury Predict Renal Progression and ESRD in Type 2 Diabetes Mellitus: A Prospective Cohort Study

Pimanong Pooluea,[2] Pamila Tasanavipas,[2] Amnart Chaiprasert,[2] Theerasak Tangwonglert,[1] Naowanit Nata,[1] Ouppatham Supasyndh,[2] Bancha Satirapoj.[1] *[1]Phramongkutklao hospital, Bangkok, Thailand; [2]Phramongkutklao Hospital, Bangkok, Thailand.*

Background: Diabetic kidney disease (DKD) typically evolves over many years. The diagnosis, evaluation and treatment are based mainly on biomarkers that assess kidney function. New potential tubular biomarkers in DKD could improve risk stratification and prediction.

Methods: A prospective cohort study, a total of 257 type 2 diabetic patients were included. The baseline values of urine albumin creatinine ratio (UACR), urine Cystatin-C to creatinine ratio (UCYS), urine angiotensinogen to creatinine ratio (UANG), urine NGAL to creatinine ratio (UNGAL) and urine KIM-1 to creatinine ratio (UKIM) were measured. The composite outcome was a rapid glomerular filtration rate (GFR) decline or incident of ESRD at 3 year follow-up.

Results: The median follow-up period was 40.8 monthsand the composite outcome were noted in 26.1%. Urine tubular biomarkers of UCYS, UANG, UNGAL and UKIM were significantly higher among patients with rapid GFR decline or new onset of ESRD. Using univariate followed by multivariate COX proportional hazard regression analysis, the number of patients reached the composite renal endpoint was higher among those in the highest quartiles of UCYS (HR 3.86, 95% CI, 1.95-7.66), UANG (HR 3.93, 95% CI, 1.95-7.88) UKIM (HR 3.41, 95% CI, 1.66-7.01) and UNGAL (HR 3.25, 95% CI, 1.58-6.71) than in those in the lowest quartiles. In addition, the highest quartile of UCYS, UANG, UKIM and UNGAL were associated with a 2.53 to 2.96-fold increased risk of rapid GFR decline or ESRD compared with the lowest quartile in adjusted models. All biomarkers predicted composite outcome with ROC for UACR = 0.731; 95% CI 0.65-0.81, UCYS = 0.64; 95% CI 0.56-0.72, UANG = 0.635; 95% CI 0.55-0.72, UKIM = 0.611; 95% CI 0.53-0.69 and UNGAL = 0.598; 95% CI 0.52-0.68. Highest ROC for integrated with UACR, UANG and UNGAL = 0.751; 95% CI 0.68-0.82.

Conclusions: The study supported that type 2 diabetic patients with high levels of urine tubular biomarkers (Cystatin-C, angiotensinogen, KIM-1 and NGAL) had more incidence of ESRD and rapid GFR decline. These tubular biomarkers may be independent predictors of the renal progression in DKD.

Clinical Value of Urinary C5b-9 Complement Complex in Overt Diabetic Nephropathy

Karyne Pelletier,[1] Arnaud Bonnefoy,[2] Hugo Chapdelaine,[3] Matthieu Lejars,[2] Vincent Pichette,[5] Francois Madore,[1] Soumeya Brachemi,[4] Stephan Troyanov.[1] *[1]Hôpital Sacré-Coeur de Montréal, Montreal, QC, Canada; [2]CHU Sainte-Justine, Montréal, France; [3]Institut de Recherches Cliniques de Montréal, Montreal, QC, Canada; [4]Service de néphrologie, CHUM, Montreal, QC, Canada; [5]Université de Montréal, Montreal, QC, Canada.*

Background: Experimental studies support a role of complement activation through the lectin pathway in diabetic nephropathy (DN). We evaluated urinary levels of C5b-9 membrane attack complex (MAC) in patients with overt DN, tested associations with eGFR decline, proteinuria and inflammatory biomarkers.

Methods: This is a prospective observational cohort study of patients with overt DN followed for 2.1 years (1.6-2.8) from hospitals affiliated with the University of Montreal. We obtained repeated measurements of proteinuria, urinary MAC and inflammatory biomarkers expressed as urinary creatinine ratios. We also compare levels to patients with MGN, FSGS, AAV and IgAN.

Results: The diabetic cohort (n=83) was 80% male. The initial eGFR was 25 ± 9 mL/min/1.73m^2 with an eGFR decline of 2.9 ± 3.0 mL/min/1.73m^2/year. The median MAC-to-creatinine ratio was 1.89 (0.48-10.37) mg/mmol. The highest quartile was associated with a rate of decline in renal function of -5.1 ±mL/min/1.73m^2/year compared to -2.2 ± 2.6 (p < 0.001) (Figure 1). Urinary C5b-9 was also associated with inflammatory biomarkers and with the proteinuria (Spearman's rho 0.80, p<0.001). Furthermore, at comparable levels of proteinuria, the patients with DN in this study had similar or higher levels of urinary MAC than patients with other immunologic glomerulonephritis (n=62).

Conclusions: Complement MAC is present in the urine of patients with overt DN and higher levels correlate with a more rapid rate of renal function decline. At similar proteinurias, patients with DN had similar or higher levels compared to those with MGN, FSGS, AAV and IgAN. These findings support that urinary C5b-9 excretion in DN is not solely caused by a passive filtration of plasma C5b-9, but is locally expressed and implicated in the pathogenesis of DN.

Funding: Government Support - Non-U.S.

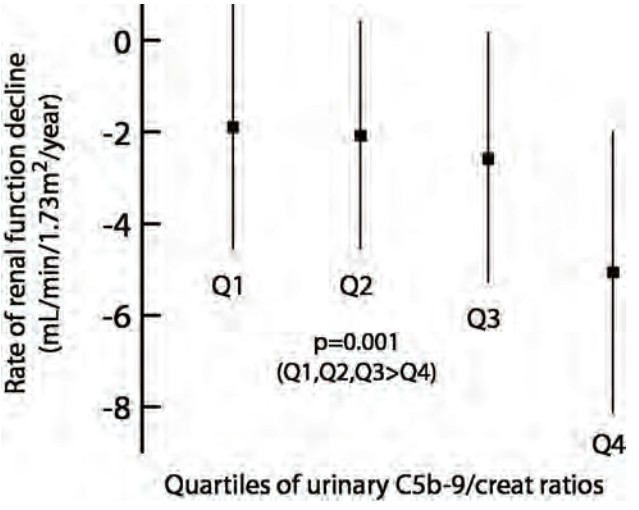

Figure 1. Rate of renal function decline according to urinary C5b-9 quartiles

FR-PO458

Associations of Urinary NGAL and RBP with Nephropathy and Their Roles in Normoalbuminuric Renal Insufficiency in T2DM

Hao Zhang,[2] Aimei Li,[1] Bin Yi,[2] Wei Zhang.[1] *[1]the Third Xiangya Hospital, Central South University, Changsha, China; [2]The Third Xiangya Hospital of Central South University, Changsha, China.*

Background: Diabetic nephropathy(DN)is an important complication of diabetes mellitus and has become the leading cause of end-stage renal disease (ESRD) worldwide. At present, the diagnosis of DN mainly depends on glomerular filtration rate (GFR) and albuminuria, but both of them have limitations. In addition, some patients follow a non-albuminuric pathway to renal impairment. The aim of this study was to investigate novel biomarkers in urine to reflect renal damage in T2DM.

Methods: This is a cross-sectional study recruiting 269 type 2 diabetic patients and 30 control subjects. Urinary neutrophil gelatinase-associated lipocalin (NGAL), retinol binding protein (RBP), plasminogen activator inhibitor-1(PAI-1), vascular cell adhesion molecule-1 (VCAM-1), E-cadherin, as well as urinary albumin excretion were measured in urine. Glomerular filtration rate (GFR) was estimated via CKD-EPI combined creatinine–cystatin C equation. The patients were further categorized based on urine albumin/creatinine ratio (UACR) or eGFR. Their correlations with UACR and eGFR were analyzed. Plasma TNF-α, IL-6, ET-1 and 8-OHdG was tested in patients with normoalbuminuria. The associations of TNF-α, IL-6, ET-1 and 8-OHdG with eGFR and urinary biomarker were analyzed. Sensitivity, specificity, and area under the curve (AUC) were calculated as measures of diagnostic accuracy.

Results: It was observed that the levels of urinary NGAL, RBP and PAI-1 were significantly elevated and correlated with UACR and eGFR in T2DM. In T2DM patients with UACR<30mg/g, plasma TNF-α, IL-6 and 8-OHdG were increased in patients with renal insufficiency, and plasma TNF-α and 8-OHdG were negatively correlated with eGFR. Urinary NGAL and RBP were statistically elevated in patients with renal insufficiency and inversely correlated with eGFR. In addition, urinary NGAL showed a positive correlation with plasma TNF-α and 8-OHdG, and urinary RBP showed a positive correlation with plasma 8-OHdG.

Conclusions: In conclusion, the results indicate that urinary NGAL, RBP and PAI-1 may serve as novel biomarkers for the diagnosis of nephropathy in T2DM and urinary NGAL and RBP may be promising biomarkers for diagnosing renal impairment in T2DM patients with normoalbuminuric.

Urine Metabolites Predict Kidney Function Decline in Type I Diabetic Subjects

Manjula Darshi,[1] Erkka A. Valo,[2] Jing Zhang,[3] Jiwan J. Kim,[1] Rintaro Saito,[4] Daniel Montemayor,[1] Tarunveer S. Ahluwalia,[5] Janet Snell-Bergeon,[6] Peter Rossing,[5] Per-Henrik Groop,[2] Loki Natarajan,[3] Kumar Sharma.[1] *[1]University of Texas Health San Antonio, San Antonio, TX; [2]Folkhälsan Institute of Genetics, Folkhälsan Research Center, Helsinki, Helsinki, Finland; [3]University of California San Diego, La Jolla, CA; [4]Institute for Advanced Biosciences, Keio University, Tsuruoka, Yamagata, Japan; [5]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [6]University of Colorado Denver, Aurora, CO.*

Background: Diabetes is the most common cause of chronic kidney disease (CKD) and end-stage renal failure. Albuminuria and eGFR are widely approved biomarkers to identify kidney disease progression. However, due to considerable heterogeneity not all subjects progress at the same rate. In the current study, we evaluated a set of urinary metabolites toward prediction of rapid progression of CKD in patients with type I diabetes.

Methods: We used a nested case-control study in four diverse cohorts (CACTI, EDC, FinnDiane, and Steno) with long-standing type I diabetes and normal kidney function. Subjects were classified into slow decliners/controls with eGFR decline ≤1ml/min/1.73m^2/yr or rapid progressors/cases with eGFR decline of ≥3ml/min/1.73m^2/yr. Thirty four urine metabolites were measured by gas chromatography-mass spectrometry. Logistic regression and Random Forest models were used to predict rapid eGFR decline. Area under the curve (AUC) were used to assess model performance.

Results: Baseline mean eGFR and median ACR in controls (n=340) and cases (n=212) were 91.97 (sd 18.68) and 9.44 (IQR 30), and 98.37 (sd 25.44) and 33.49 (IQR 283.01), respectively. Analysis with clinical variables revealed age, baseline ACR, and baseline eGFR to be significant predictors of rapid decline. Among the metabolites, three were univariately associated with rapid decline (FDR p=0.015, 0.025, 0.025). A model to predict eGFR decline using clinical variables had an AUC of 0.71 (95% CI 0.63-0.79); no significant improvements in AUC were observed with added metabolites. In a stratified analysis of eGFR≥60 ml/min/1.73m^2 and combined micro- and macroalbuminuria (MA+) group, metabolites significantly improved the AUC from 0.69 with clinical variables (0.45-0.84) to 0.76 (0.61-0.89) when combined with metabolites. Random Forest selected 6 metabolites as top 7 variables and the metabolites significantly improved the AUC from 0.61 (0.44-0.76) to 0.75 (0.61-0.89), 95% CI.

Conclusions: In subjects with albuminuria and normal eGFR (≥60 3ml/min/1.73m^2) clinical variables are not optimal to predict kidney function decline and urine metabolites may be useful as prognostic biomarkers for loss of renal function.

Funding: Other NIH Support - Juvenile Diabetic Research Foundation

FR-PO460

Developing Prognostic Models for Kidney Function Decline Based on Clinical and Metabolite Profiles in an Albuminuria-Stratified Analysis in the CRIC Cohort

Brian Kwan,[1] Tobias Fuhrer,[2] Jing Zhang,[3] Manjula Darshi,[4] Daniel Montemayor,[4] Kumar Sharma,[4] Loki Natarajan.[1] *[1]Department of Family Medicine and Public Health, University of California, San Diego, La Jolla, CA; [2]Institute of Molecular Systems Biology, ETH Zurich, Zurich, Switzerland; [3]Moores Cancer Center, University of California, San Diego, La Jolla, CA; [4]Center for Renal Precision Medicine, Division of Nephrology, Department of Medicine, University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: There is significant heterogeneity in the rate of kidney function decline among Type 2 diabetics, signaling a critical need to better identify patients at high risk of rapid kidney function decline. We previously identified a metabolomic signature of chronic kidney disease (CKD) using cross-sectional analysis. Metabolomic analysis combined with novel statistical methods could provide clinically useful signatures of CKD using longitudinal cohorts.

Methods: We studied 1003 Type 2 diabetics with up to 10 years of follow-up. The median eGFR decline per year (-1.84 ml/min/1.73m^2/yr) cutoff delineated fast vs slow CKD progression. An untargeted flow-injection mass spectrometry method was used to assay an a priori 16-metabolite set, implicated in mitochondrial dysfunction in CKD. Models for fast vs slow decline were built with the 16-metabolite subset and standard clinical variables (e.g. age, race, HbA1c, MAP) as predictors. The accuracy (i.e. % of fast and slow decliners correctly identified by the model) of clinical-only, metabolite-only, and clinical-metabolite statistical models were compared using 5-fold cross-validation. Analyses were stratified by albumin/creatinine ratio (ACR): normal (ACR <30 mg/g), microalbuminuria (ACR 30-300 mg/g), macroalbuminuria (ACR >300 mg/g).

Results: There were significant differences in eGFR decline (p <0.001) between albuminuria groups: mean eGFR slopes (ml/min/1.73m^2/yr) were -0.43 in normo-, -1.47 in micro-, and -3.03 in macro-ACR groups. As expected, study entry eGFR, diabetes control (HbA1c) and blood pressure (MAP) were worse (p <0.001) as albuminuria increased. Predictive accuracy of models was 84% normo-, 64% in micro-, 82% in macro-groups. Given the high accuracy, we further investigated the models for the normo- and macro-groups. After adjusting for clinical variables, prognostic metabolites were (i) 2-methyl acetoacetate for normo-ACR and (ii) pyruvic and homovanillic acids for the macro-ACR groups.

Conclusions: The accuracy of the models differed by ACR level. Several a priori metabolites predicted CKD progression, and interestingly, prognostic metabolites varied by ACR status. Our findings suggest that metabolites may offer insights into CKD progression in Type 2 diabetes within albuminuria groups.

Validation of a Systems Biology Derived Urinary Metabolite Panel for Prediction of Albuminuria Response to Spironolactone Therapy in Type 2 Diabetes

Skander Mulder,[1] Hiddo J. Lambers Heerspink,[1] Paul Perco,[2] Robert D. Toto,[3] Michelle Pena.[1] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]Medical University Innsbruck, Innsbruck, Austria; [3]University of Texas Southwestern Medical Center, Dallas, TX.*

Background: The mineralocorticoid receptor antagonist spironolactone significantly reduces albuminuria in patients with diabetic kidney disease, albeit with a large between individual variability. We previously identified a panel of systems biology derived urinary metabolites for prediction of albuminuria response to spironolactone therapy.[1] Here we validate this metabolite panel in an external cohort.

Methods: Data and samples were used from a randomized placebo controlled double blind clinical trial.[2] Patients with diabetes, hypertension, and albuminuria (urine albumin-to-creatinine ratio ≥300 mg/g) who all received lisinopril 80 mg/day were randomly assigned to placebo (n=23) or spironolactone 25 mg/day (n=20) for 48 weeks. Urine samples were obtained at baseline, 24 and 48 weeks, and LC-MS metabolomics measurements were performed on the baseline samples. We used leave-one-out cross-validated optimism corrected ridge regression to predict albuminuria response to spironolactone.

Results: After 12 weeks of therapy, spironolactone reduced UACR relative to placebo by median -57%, with large variability (5th to 95th percentile -136% to +4%). A clear separation between the spironolactone and placebo arms was observed in the predicted treatment effect by the metabolite panel (Figure). The metabolite panel was able to predict albuminuria response to spironolactone (R^2 = 0.30, p-value <0.01).

Conclusions: We validated a previously identified panel of 18 urinary biogenic amines and organic acids to predict albuminuria response to spironolactone. These results suggest that this urinary metabolite panel may be used as a tool to tailor optimal therapy in diabetes and move in the direction of personalized medicine. **References** 1. Pena et al. Urinary Metabolomics Predict Albuminuria Response to Spironolactone Therapy in Type 2 Diabetes. J Am Soc Nephrol 27, 2016: 557A 2. Mehdi et al. J Am Soc Nephrol. 2009 Dec;20(12):2641-50

Increasing Baseline Albuminuria Is Associated with a Continuously Increased Risk of Cardiovascular (CV) and Renal Outcomes in the LEADER Trial

Ofri Mosenzon,[1] Stephen Bain,[2] Frederik Persson,[5] Hiddo J. Lambers Heerspink,[3] Johannes F. Mann,[4] Peter Rossing,[5] Thomas Idorn,[6] Soren Rasmussen,[6] Bernt Johan Von Scholten,[6] Itamar Raz.[1] The LEADER Publication Committee on behalf of the LEADER Trial Investigators *[1]Hadassah Hebrew University Hospital, Jerusalem, Israel; [2]Institute of Life Science, Swansea University, Swansea, United Kingdom; [3]University Medical Center Groningen, Groningen, Netherlands; [4]KfH Kidney Center, and Friedrich Alexander University of Erlangen, Munich, Germany; [5]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [6]Novo Nordisk A/S, Soborg, Denmark.*

Background: Albuminuria is a known risk factor for CV disease, but the lower limit from which it is a risk factor is not well defined.

Methods: We assessed CV and renal outcomes by increasing levels of baseline urinary albumin-to-creatinine ratio (UACR) in the LEADER trial. LEADER was a randomized, double-blind, placebo-controlled CV outcomes trial of liraglutide up to 1.8 mg/day vs placebo added to standard care for 3.5–5 years in 9340 patients with type 2 diabetes and high risk for CV disease. We analyzed the risk of major adverse CV events (MACE), expanded MACE, all-cause death, and adjudicated renal events (doubling of serum creatinine and estimated glomerular filtration rate ≤45 ml/min/1.73 m^2; the need for continuous renal-replacement therapy; or death from renal disease) by baseline UACR irrespective of treatment group; UACR < lower limit of quantification (LLoQ) (G0; n=1598), 0 to <15 mg/g (G1; n=2905), 15 to <30 mg/g (G2; n=1196), 30 to <100 mg/g (G3; n=1609), 100 to <300 mg/g (G4; n=845), and ≥300 mg/g (G5; n=960).

Results: The risk of MACE, expanded MACE, all-cause death and renal events increased with increasing baseline UACR (Figure), statistically significant for all subgroups with UACR ≥30 mg/g compared to G0. Interestingly, in patients at the higher part of the normoalbuminuric range (G2), a trend towards increased risk for CV events and all-cause death was observed.

Conclusions: In LEADER, baseline UACR≥30 mg/g was associated with increased risk of death, and CV and renal events, emphasizing the importance of albuminuria as a modifiable risk factor.

Association of Anthropometric Measures of Obesity and CKD in Elderly Women Admitted in a Tertiary Care Government Teaching Hospital

Muntazir Ali P. Sayed,[1] Renu M. Bharne,[2] Adil A. Akbani,[3] Rajashri Salamwade.[4] Team Kolhapurkars *[1]RCSM Government Medical College Kolhapur, India., Mumbai, India; [2]RCSM Government Medical College and CPR Hospital, Kolhapur, Maharashtra, India, Thane, India; [3]RCSM Government Medical College, Kolhapur, Maharashtra, India, Karanja lad, India; [4]RCSM Government Medical College and CPR General Hospital Kolhapur, Mumbai, India.*

Background: There is growing evidence which suggests that obesity is an important contributor to the development of CKD. However, the relationship between obesity and CKD is complex and not completely understood, and the best anthropometric index of obesity in predicting CKD is controversial. We carried out this study to determine the best anthropometric index of obesity in predicting CKD in a population of elderly women admitted in RCSM Government Medical College and CPR General Hospital, the only tertiary care government teaching hospital in the city of Kolhapur, India.

Methods: We carried out this study for the duration of 3 years from May 2015 to April 2018 at our institute. Anthropometric indices of obesity including body mass index (BMI), waist circumference (WC), waist-to-height ratio (WheiR) and waist-to-hip-ratio (WHR), were obtained in 1706 selected females. Biochemical measurements including blood glucose, lipid profile, and 2-h postprandial blood glucose were performed. GFR was estimated by using CKD-EPI equation. Adequate statistical tests were carried out and for all tests, a p-value <0.05 was considered statistically significant.

Results: The prevalence of CKD stage ≥ 3 was 36.64%. Overweight and obesity was found in 54.16% and 34.88% of participants, respectively. Increased central fat distribution, as defined by WheiR, WC and WHR, was found in 84.34%, 89.86% and 86.52% individuals, respectively. Univariate linear regression analysis showed positive correlations between CKD and age (p<0.001), BMI (p<0.0001), WC (p<0.0001), WHR (p<0.005), WheiR (p<0.0001), diabetes (p<0.005), as well as triglicerydes (p<0.003); however there was a negative correlation between CKD and HDL level (p=0.025). Multivariable analysis demonstrated that hypertension, diabetes, WC and WheiR were independent predictors of CKD. The area under the receiver operating characteristics curve was best for WheiR (0.638), followed by WC (0.619), BMI (0.603), and WHR (0.598).

Conclusions: Abdominal obesity is an important predictor of CKD. Of commonly used anthropometric parameters of obesity, WheiR ≥ 0.6 is particularly associated with CKD in elderly females. However, the value for these obesity indices is limited in screening CKD and further research in this regard is highly encouraged.

FR-PO464

Diabetic Retinopathy Is Associated with Renal Function Deterioration in Korean Population with Type 2 Diabetes

Hayne C. Park,[1] Jung-woo Noh,[2] Chaehoon Han,[1] Young joo Shin,[1] Youngki Lee.[1] Hallym University Kidney Research Institute *[1]Kangnam Sacred Heart Hospital, Seoul, Seoul, Republic of Korea; [2]Dr. Chun & Cho's Medical Clinic & Dialysis Center, Seoul, Republic of Korea.*

Background: Although both retinopathy and nephropathy are major diabetic microvascular complications, a few studies have examined the relationship between retinal structural changes and renal functions in patients with diabetes. We investigated whether diabetic retinopathy (DR) status has adverse effects on kidney function in patients with type 2 diabetes.

Methods: We enrolled 2,139 patients with type 2 diabetes who had undergone fundus exam and serial renal function evaluation from August 2006 to February 2014. DR status was classified to no DR, non-proliferative DR (NPDR), and proliferative DR (PDR). Cox regression analysis was used to evaluate the hazard ratio for renal function decline according to DR status.

Results: The mean age of the study participants was 58.3±11.3 years and 1,124 (52.5%) were women. The mean follow-up period was 3.1±2.9 years. DR was associated with the change in estimated glomerular filtration rate (eGFR) and the development of renal dysfunction (decreased eGFR⟩20%) (no DR group 2.23±24.51; NPDR group -2.82±24.11; PDR group -4.82±46.63 mL/min/1.73m^2/year, P⟨0.001). After adjustments for other risk factors, DR was an independent predictor for renal function deterioration (HR 1.917, 95% CI 1.470–2.498, P⟨0.001). In addition, the progression of DR (new-onset DR or progression of DR status) was associated with the change in eGFR (no DR progression group 0.86±19.77, DR progression group -1.75±14.24 mL/min/1.73m^2/year; P⟨0.001). After adjustments for risk factors, however, DR progression was not an independent predictor for renal function deterioration (HR 1.374, 95% CI 0.748–2.523, P=0.305). On the other hands, DR was associated with the development of proteinuria during follow-up periods (no DR group 6.2%; NPDR group 17.5%; PDR group 30.1%, P⟨0.001). Progression of DR was also associated with the development of proteinuria during follow-up periods (no DR progression group 9.1%; DR progression group 17.1%, P=0.013). Multivariate analysis demonstrated that the status of DR as well as eGFR and HbA1c is an independent predictor for development of proteinuria.

Conclusions: Our findings showed a strong association between DR and progressive renal dysfunction after adjustment for traditional and non-traditional risk factors in Korean patients with type 2 diabetes.

FR-PO465

Impact of Diabetic Retinopathy and Diabetic Kidney Disease on All-Cause and Cardiovascular Mortality

Charumathi Sabanayagam,[1,2] Miao li Chee,[1] Riswana Mohamed,[1] Ching-Yu Cheng,[1,2] Su-chi Lim,[3] E shyong Tai,[4] Thomas M. Coffman,[5] Tien Yin Wong.[1,2] *[1]Singapore Eye Research Institute, Singapore, Singapore; [2]Duke-NUS Medical School, Singapore, Singapore; [3]Khoo Teck Puat Hospital, Singapore, Singapore; [4]National University of Singapore, Singapore, Singapore; [5]Duke University Medical Center, Durham, NC.*

Background: The relationship between diabetic microvascular complications including diabetic retinopathy (DR), and diabetic kidney disease (DKD), and mortality in populations are not clear.

Methods: We examined the association between DR, DKD and mortality among 2880 Chinese, Malay and Indian adults (aged 40-80 years) with diabetes who participated in the Singapore Epidemiology of Eye Diseases study (baseline, 2004-2011). Information on mortality was obtained by linkage with National Death Registry until May 2017. DR was ascertained from retinal photographs and DKD from estimated glomerular filtration rate (≤60 ml/min/1.73 m²). Associations of DR and DKD with each outcome separately and jointly were examined using multivariate Cox proportional hazards regression models.

Results: Over a median follow-up of 8.8 years, 580 deaths occurred (20.1%) of which 254 (8.8%) were due to CVD. DR and DKD were significantly associated with all-cause and CVD mortality separately and jointly. In joint models including both DR and DKD, 58.9% had neither DR nor DKD (DR^-DKD^-), 11.8% had DKD alone (DKD^+ DR^-), 21% had DR alone (DR^+ DKD^-), and 8.3% had both DR and DKD (DKD^+DR^+). Beyond the background risk (12% and 4.2% in DR^-DKD^-), excess risk of absolute all-cause and CVD mortality were 27.1%, 12.6% in DKD^+ DR^-, 6.5%, 5.2% in DR^+DKD^- and 5% and 5.3% in DKD^+DR^+. In multivariable models, compared to DR^-DKD^-, hazard ratio (95% confidence interval) of all-cause and CVD mortality were 1.89 (1.40-2.57), 2.26 (1.42-3.61) for DKD^+ DR^-, 1.38 (1.03-1.86), 1.64 (1.06-2.56) for DR^+DKD^-; 2.76 (2.05-3.72), 3.41 (2.19-5.32) for DKD^+DR^+. No significant interaction was observed between DR and DKD on additive or multiplicative scale for either outcome (all p>0.1).

Conclusions: Our results suggest that risks of all-cause and CVD deaths were significantly higher in those with DKD and DR, but DKD largely contributed to the excess risk. Our findings emphasize the need for assessing the presence of DR and DKD in diabetic populations to assess mortality risk associated with type 2 diabetes.

FR-PO466

Non-Proteinuric versus Proteinuric Phenotypes in Diabetic Nephropathy: A Propensity Score Matched Analysis of a Nationwide, Biopsy-Based Cohort Study

Masayuki Yamanouchi,[1,2] Kengo Furuichi,[3] Junichi Hoshino,[2] Yoshifumi Ubara,[2] Takashi Wada.[1,3] *[1]Department of Nephrology and Laboratory Medicine, Faculty of Medicine, Institute of Medical, Pharmaceutical and Health Sciences, Graduate School of Medical Sciences, Kanazawa University, Kanazawa, Japan; [2]Nephrology Center, Toranomon Hospital, Tokyo, Japan; [3]Division of Nephrology, Kanazawa University, Kanazawa, Japan.*

Background: Several cross-sectional studies have recently shown that a proportion of patients with type 2 diabetes mellitus develop loss of renal function without overt proteinuria or even without microalbuminuria, suggesting the existence of non-proteinuric phenotype of diabetic nephropathy. Their clinicopathological characteristics and renal prognosis, however, are scarce.

Methods: We retrospectively assessed patients with type 2 diabetes mellitus, who underwent clinical renal biopsy from Jan 1, 1985 to Dec 31, 2016 and had follow-up data until Dec 31, 2017, from the Japan's nationwide multicenter renal biopsy registry. Among 795 patients, we restricted 526 patients with reduced renal function (defined as estimated glomerular filtration rate <60 mL/min/1.73m²) and had a pathological diagnosis of diabetic nephropathy as the only glomerular disease diagnosis. 88 were non-proteinurics (urine albumin to creatinine ratio (UACR) <300 mg/gCre), and 438 patients were proteinurics (UACR ≥300 mg/gCre). For comparative analyses, we derived one-to-one paired cohorts of those without proteinuria versus those with proteinuria using propensity-score matching (matched by age, gender, and baseline eGFR). The primary endpoint was progression of CKD defined as new-onset ESRD, decrease of eGFR by ≥ 50%, or doubling of serum creatinine.

Results: In the matched analyses (82 patients in each group), patients with non-proteinuric diabetic nephropathy had lower systolic blood pressure and total cholesterol level, higher serum albumin level, and less frequent typical pathological lesions. After a median follow-up of 3.0 years (IQR 1.0-6.6) from the date of renal biopsy, 65 (40%) of the 164 matched patients had renal events. The 5-year CKD progression-free survival for all patients was 63.3% (95% CI, 53.3-71.7): 86.7% (95% CI, 72.5-93.8) for the non-proteinuric diabetic nephropathygroup and 43.2% (95% CI, 30.2-55.6) for the proteinuric diabetic nephropathygroup (log-rank test p<0.001). The lower renal risk in non-proteinuric diabetic nephropathy group was consistent across all subgroup analysis.

Conclusions: Patients with non-proteinuric diabetic nephropathy had lower blood pressure and less typical morphological changes, and were at lower risk of CKD progression.

FR-PO467

Histological Findings Associated with Proteinuria in Diabetic Nephropathy

Masahiro Eriguchi,[1] Masaru Matsui,[3,1] Miho Tagawa,[1] Ken-ichi Samejima,[2] Kazuhiko Tsuruya,[1] Katsuhiko Morimoto,[4] Masatoshi Nishimoto.[1] *[1]Nara Medical University, Kashihara, Japan; [2]First Department of Internal Medicine, Nara Medical University, KASHIHARA, Japan; [3]Nara Prefecture General Medical Center, Nara, Japan; [4]Nara Prefecture Western Medical Center, Ikoma-gun, Nara, Japan.*

Background: Regardless of the causes of renal diseases, proteinuria is the strongest predictor of renal prognosis among clinical parameters. Diabetic kidney disease (DKD) patients are rarely examined by renal biopsy. Determination of the histological lesions that are responsible for proteinuria in DKD will be useful for the future research to identify the intervention to the specific lesions.

Methods: This is a serial cross-sectional study of 347 adults with biopsy-proven diabetic nephropathy (DN) from 1981 to 2014. Predictors were histological findings in renal pathology and outcome variable was proteinuria. DN was evaluated by two renal pathologists according to 9 glomerular lesions; mesangial expansion, exudative lesion, nodular sclerosis, microaneurysm, duplication of the basement membrane, perihilar neovascularization, glomerulomegaly, global sclerosis, and segmental sclerosis, 2 tubulointerstitial lesions; interstitial fibrosis tubular atrophy (IFTA) and inflammatory cell infiltration, and 2 vascular lesions; arteriolar hyalinosis and intimal thickening of large artery. In addition to histological findings, age, sex, body mass index, estimated glomerular filtration rate (eGFR), systolic blood pressure and use of renin-angiotensin system blockers were used for adjustment. Statistical analyses were performed using multivariate general linear model and two-way analyses of covariate and variance.

Results: Hypertension and diabetic retinopathy were observed in 65% and 46% of patients, respectively, with mean age of 58 ± 11. Median level of proteinuria at the time of renal biopsy was 0.50 g/day (25th and 75th percentile: 0.20 and 2.7 g/day) and mean eGFR was 62.4 ± 32.6 mL/min/1.73m². Twelve out of thirteen histological lesions were significantly correlated with each other and proteinuria levels. However, after multivariate adjustment nodular sclerosis and IFTA remained significant predictors for proteinuria levels. Two-way analyses of covariate and variance showed that IFTA and glomerular lesions had a synergetic effect on increased multivariate adjusted proteinuria levels.

Conclusions: Nodular sclerosis and IFTA were significant predictors of proteinuria levels and had a synergetic effect on increased proteinuria in DN patients. These two lesions might be relevant targets for developing new therapy in DKD patients.

Comparison of Renal Outcomes Between Diffuse and Nodular Diabetic Nephropathy: A Meta-Analysis

Qiqi Feng,[1] Jialing Rao,[2] Weiyan Lai.[1] *[1]The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]The Third Affiliated Hospital of Sun Yet-sen University, Guangzhou, China.*

Background: The diffuse (DIF) type and the nodular (NOD) type of glomerulosclerosis have long been recognized as the pathological characteristics of diabetic nephropathy (DN). However, the relationship between pathological changes and renal outcomes is not fully elucidated so far. The present meta-analysis was designed to compare the renal outcomes between the two pathological types of DN.

Methods: We reviewed relevant studies that compared the renal outcomes between DIF and NOD in Medline, Embase, Cochrane Library, CNKI and other sources from 1950 to 2015.

Results: Of 3615 citations identified, only four retrospective cohort studies involving 596 patients were included in the meta-analysis. Pooled analysis of relative risk (RR) in the fixed-effects model showed that NOD had higher risk for developing ESRD than DIF did (RR 1.86, 95%CI 1.28-2.70, P = 0.001, P for heterogeneity = 0.12, I^2 = 48%). The sensitivity analysis showed that the heterogeneity among studies was decreased when studies with type 1 diabetic patients were excluded (P for heterogeneity = 0.34, I^2 = 0%).

Conclusions: The present meta-analysis revealed that renal outcomes were closely related to pathological changes of DN, and NOD had higher risk for developing ESRD than DIF.

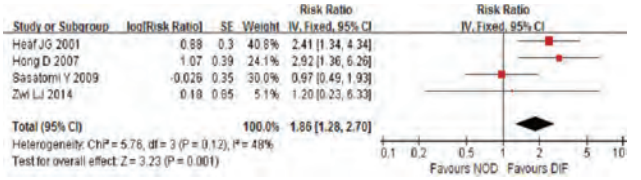

Fig. 1 Comparison of renal outcomes between the diffuse (DIF) type of diabetic nephropathy and the nodular (NOD) type

FR-PO469

Assessment of the Relationship Between the 2010 Pathologic Classification and Renal Outcomes in Patients with Diabetic Nephropathy: A Meta-Analysis

Qiqi Feng,[1] Tan-qi Lou.[2] [1]*The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China;* [2]*The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.*

Background: The pathologic classification for diabetic nephropathy (DN) established by the Renal Pathology Society in 2010 has received extensive attention. However, its relationship with renal prognosis requires further study.

Methods: Original cohort studies were identified by searching PubMed, Embase, the Cochrane Library, CNKI and other resource. Hazard ratios (HRs) were pooled using the RevMan 5.3 software.

Results: Of the 1549 relevant articles, six retrospective or prospective cohort studies with a total of 803 participants were finally included in the meta-analysis. The pooled HRs revealed that the risks for renal end-points of Class I and IIa were obviously lower than those of Class IIb, III and IV, and in turn, the risks of Class IIb and III were lower than that of Class IV. But there were no significant differences between Class I and IIa, and between Class IIb and III. The pooled HRs for tubular, interstitial and vascular changes showed that interstitial fibrosis and tubular atrophy (IFTA) and interstitial inflammation were significantly correlated to renal outcomes while arteriolar hyalinosis and arteriosclerosis were not (Table 1). Subgroup analyses and sensitivity analyses indicated that different types of diabetes generated heterogeneity.

Conclusions: The present meta-analysis revealed that 1) the glomerular classes were not completely associated with renal prognosis in that the renal outcomes were benign in Class I and IIa, moderate but similar in Class IIb and III and severe in Class IV; 2) the tubular and interstitial lesions were independent variables associated with renal outcomes while vascular changes were not.

Table 1 Results of statistical pooling

	N	HR (95%CI)	P-value	Heterogeneity	
				P-value	I2 (%)
Glomerular classes					
I vs IIa	206	0.39 (0.08, 1.87)	0.24	0.99	0
IIb vs IIa	266	2.64 (1.53, 4.54)	0.0005**	0.88	0
III vs IIa	422	3.06 (1.92, 4.89)	<0.00001**	0.23	30
IV vs IIa	272	7.54 (4.22, 13.45)	<0.00001**	0.68	0
III vs IIb	425	1.01 (0.53, 1.92)	0.98	0.05	59
IV vs IIb	256	2.98 (1.88, 4.71)	<0.00001**	0.67	0
IV vs III	417	2.11 (1.67, 2.68)	<0.00001**	0.63	0
Interstitial and vascular scorings					
IFTA	519	1.74 (1.37, 2.20)	<0.00001**	0.30	18
Interstitial inflammation	474	1.62 (1.09, 2.40)	0.02*	0.10	64
Arteriolar hyalinosis	519	0.81 (0.49, 1.35)	0.43	0.84	0
Arteriosclerosis	519	1.04 (0.61, 1.77)	0.88	0.63	0

Note: interstitial fibrosis and tubular atrophy, IFTA; *P<0.05, **P<0.01.

FR-PO470

Diabetic Fibrillosis, Not an Uncommon Entity: A Case Series

Sree bhushan Raju. *NIMS, Hydrabad, India.*

Background: Diabetic Fibrillosis (DF) is a rare glomerular abnormality detected in electron microscopy as random nonbranching fibrillary deposits in mesangium. There are few case reports available related to this entity and we report a case series of this interesting association.

Methods: We reviewed all the cases of type 2 diabetic patients who underwent renal biopsy for various indications in last one year (April 2017 to march 2018). Cases which were reported as DF in electron microscopy were collected. Clinical course, investigation reports and biopsy findings were analysed.

Results: DF was reported in 5 (3.7 %) out of 134 cases of diabetic nephropathy. The mean age was 55.6±.6 years (46-65). All five had both hypertension and diabetes. Mean duration of diabetes was 12± 2.7years. All five had increased serum creatinine with mean of 6.9±3.5 mg/dl. Three patients had nephrotic and two had subnephrotic range proteinuria (mean 3±1.3 g/day). Autoimmune and myeloma workup was negative. Light microscopy showed diabetic nephropathy class IV with arteriolar hyalinosis in all 5 cases. The Immunofluorescence and congo red stain was negative in all. GBM thickening is seen in all cases with mean thickness ranging from 426 to 714 nm. Random non branching fibrillary deposition is seen in mesangium of all cases. No spherular microparticles or tubuloreticular inclusions were seen.

Conclusions: diabetic fibrillosis is not an uncommon entity with a prevalence of 3.7 % in our case series. The clinical significance of this entity is yet to be determined. The observations made in this series needs to be elicited with a larger series of cases to know the impact on long term kidney function.

Renal Biopsy in Diabetic Patients: Preliminary Results of the Spanish Multicenter Study BIODIAB-GLOSEN-GEENDIAB

Sheila Bermejo,[1,2] Noemí Esparza,[4] Marian Goicoechea,[5] Meritxell Ibernon,[6] Tania Linares,[7] Ana Coloma,[3] Adoración Martin,[8] Rosa Garcia Osuna,[9] Montserrat M. Diaz Encarnacion,[10] Nuria Garcia-Fernandez,[11] Nadia Martin Alemany,[12] Katia Lopez-Revuelta,[13] Sandra Elias,[14] Irene Agraz,[15] Julio Pascual,[16] Manuel Praga,[17] Xavier Fulladosa,[18] Maria Jose Soler.[19] GLOSEN, GLOMCAT, GEENDIAB [1]*Parc de Salut Mar, Barcelona, Spain;* [2]*Fundació Althaia, Manresa, Spain;* [3]*Hospital San Pedro, Logro?o, Spain;* [4]*Hospital Universitario Insular de Gran Canaria, Las Palmas, Spain;* [5]*Hospital General Universitario Gregorio Marañon, Madrid, Spain;* [6]*Hospital Sant Joan Despí Moises Broggi, Sant Joan Despí, Spain;* [7]*Hospital Gregorio Marañón, Madrid, Spain;* [8]*Agencia Sanitaria Hospital de Poniente, Ameria, Spain;* [9]*Hospital De Dalamos, Palamos, Spain;* [10]*Fundación Pugvert, Barcelona, Spain;* [11]*Clinica Universidad de Navarra, Pamplona, Spain;* [12]*University Hospital Dr. Josep Trueta, Girona, Spain;* [13]*Hospital Universitario Fundación Alcorcón, Alcorcon - Madrid, Spain;* [14]*Hospital Universitario Ramón y Cajal, Madrd, Spain;* [15]*Hospital valle d'Hebron, Barcelona, Spain;* [16]*Hospital del Mar, Parc de Salut Mar, Barcelona, Spain;* [17]*Hospital 12 de Octubre, Pozuelo De Alarcon, Spain;* [18]*Hospital Universitari De Bellvitge, L'Hospitalet de Llobregat, Spain;* [19]*Parc de Salut Mar. Fundació IMIM, Barcelona, Spain.*

Background: The diabetic patient with kidney disease has a high prevalence of non-diabetic nephropathy(NDN) and the renal and patient survival in relation to the presence of diabetic nephropathy(DN) or NDN has not been widely studied. The objectives of the study are: to determine the capacity of the clinical and analytical data in the prediction in the histological result(DN or NDN) and to find differences in renal and patient survival.

Methods: Spanish retrospective descriptive multicenter study of the pathological result of biopsies performed in diabetic patients in 2002-2014.

Results: 16 centers participated including 692 patients:511 men(73.8%), mean age of 62±12years, evolution of diabetes mellitus 10.5(3.7-15.3)years, serum creatinine 2,8±2,2mg/dl, glomerular filtration rate MDRD-4 of 37,7±26.8mL/min/1,73m^2, glycosylated hemoglobin 7±1,7% and proteinuria of 3.91(1.1-5)gr/24h. 40.6% of patients had DN,48.6%NDN and 10.8%ND plus NDN. The most frequent NDN was nephroangiosclerosis(12.7%). Multivariate logistic regression analysis: age(OR1,026,1,003-1,033,p=0.021), microhematuria(OR 1.523,1.047-2.214,p=0.028), creatinine(OR:1,149,1,045-1,164,p=0.004) and diabetic retinopathy (DR)(OR0.434,0.311-0.604p<0.001) were independently associated with NDN. We obtained the ROC curve model:(95% CI):0.683(0.636-0.731). 35.2%(n=184) of patients needed renal replacement therapy(RRT),47.3% of them presented DN,38.6% NDN and 14.1% DN and NDN. The overall mortality of the studied patients was 18.7%(n=98), of them 42% presented DN,46% NDN and 12% DN and NDN. In the analysis of survival with Kaplan-Meier curves: Patients with DN or DN+NDN presented worse renal prognosis than NDN patients(p<0.001). In the multivariate analysis of Cox adjusted by confusing variables, DN was confirmed as a risk factor for RRT.

Conclusions: The most frequent NDN is nephroangiosclerosis. Elder patients with microhematuria, worse renal function and absence of DR are high risk for NDN. DN has worse renal prognosis than NDN. The histological diagnosis of renal involvement in the diabetic can facilitate an effective treatment and an improvement in the renal prognosis.

FR-PO472

Activation of the Free-Fatty Acid Receptor GPR40 Improves Anemia in Mouse Models of Kidney Disease via a Novel EPO-Independent Mechanism of Action

Jean-Francois Thibodeau,[1,3] Chet E. Holterman,[3] Pierre Laurin,[1] Richard L. Hébert,[2,3] Chris R. Kennedy,[2,3] Brigitte Grouix,[1] Lyne Gagnon.[1] [1]*Prometic Biosciences Inc., Laval, QC, Canada;* [2]*Department of Cellular and Molecular Medicine, Faculty of Medicine, University of Ottawa, Ottawa, ON, Canada;* [3]*Kidney Research Centre, Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

Background: The prevalence of anemia increases with the progression of chronic kidney disease (CKD) and leads to reduced quality of life and increased cardiovascular risk. Yet, the use of erythropoiesis stimulating agents is associated with negative outcomes in CKD patients. Here we present an alternative pathway for the treatment of anemia secondary to kidney disease through activation of GPR40, in mediating *in vitro* stimulation of bone marrow cells, particularly the colony-forming-unit-erythrocytes (CFU-E) generation; and the anti-anemic effects of PBI-4050 in models of renal injury.

Methods: *In vitro*, murine bone marrow cells were assayed for CFU-E in the presence or absence of PBI-4050 (agonist of GPR40) and/or GW1100 (GPR40 antagonist). PBI-4050 was tested in ischemia-reperfusion (IR) AKI in WT mice. In addition, we used an adenine-induced CKD model whereby male wild type (WT) and GPR40$^{-/-}$ mice were fed a diet supplemented with 0.25% adenine for one week and treated for three weeks with PBI-4050 (200 mg/kg).

Results: PBI-4050 increased the formation of CFU-E in a GPR40 dependent manner as GW1100 blocked this increase. In addition, GPR40 antagonism led to a significant decrease in CFU-E counts. Furthermore, PBI-4050 showed comparable activity to EPO regarding CFU-E count. After 14 days following IR-AKI, PBI-4050 maintained hematocrit. In adenine-CKD mice, Hct, Hb and mean corpuscular volume were significantly decreased

in CKD-mice, while PBI-4050 maintained these levels and led to significantly higher plasma erythropoietin levels. In parallel, signs of anemia were present to similar degrees in both untreated WT and GPR40$^{-/-}$ mice. Interestingly, PBI-4050 treatment in adenine-fed GPR40$^{-/-}$ mice failed to improve Hct levels.

Conclusions: Taken together, our data suggest treatment of anemia through a novel alternative pathway which is EPO-independent. Treatment with PBI-4050 may provide therapeutic benefit by maintaining adequate Hct and Hb levels, while also improving renal and cardiovascular outcomes.

Fludrocortisone Stimulates Erythropoietin (Epo) Protein Expression in the Distal Tubules of Mouse Kidney

Yukiko Yasuoka,[3] Tomomi Oshima,[3] Yuichiro Izumi,[2] Yuichi Sato,[4] Noriko Takahashi,[3] Hiroshi Nonoguchi,[1] Katsumasa Kawahara.[3] *[1]Kitasato University Medical Center, Kitamoto, Japan; [2]Kumamoto University, Kumamoto, Japan; [3]Kitasato University, School of Medicine, Sagamihara, Japan; [4]Kitasato University, School of Allied Health Sciences, Sagamihara, Japan.*

Background: Although normal plasma Epo concentration is very low, Epo mRNA was expressed in the kidney tubules under normal condition (Nagai, Yasuoka, et al, 2014). We further showed that fludrocortisone, an aldosterone receptor agonist, stimulated Epo mRNA expression in the distal nephron (Yasuoka, et al, ASN 2017). In this study, we investigated the localization of Epo protein-producing cells in the kidney and liver after fludrocortisone injection.

Methods: Fludrocortisone (2.5 mg/100 g BW) or Angiotensin II (0.5 μg/100 g BW) was once applied to mice (C57BL/6J, male, 10 weeks). After 2, 4, 6 and 72 hr, kidneys were examined by Western blot and immunohistochemistry using anti-Epo antibodies.

Results: Under normal (basal) conditions, Epo staining was widely found along the nephron (proximal tubules < thick ascending limbs < collecting ducts). Fludrocortisone significantly increased Epo production in the medullary thick ascending limb, and cortical and outer medullary collecting ducts, particularly in type A of intercalated cells after 4-6 hr. Western blot showed that Epo protein expression was increased by 5-fold in the kidney but not changed in the liver. Angiotensin II stimulated Epo mRNA expression in proximal and distal tubules but not in the interstitial cells. Epo staining decreased to the basal level after 72 hr, but was not detected in the interstitial cells.

Conclusions: Renin-angiotensin-aldosterone system regulates Epo production by the nephron.

Enarodustat (JTZ-951), an Oral HIF-PH Inhibitor, Stabilizes HIF-α Protein and Induces Erythropoiesis with Hardly Influence the Function of Vascular Endothelial Growth Factor

Kenji Fukui, Yuichi Shinozaki, Hatsue Kobayashi, Katsuya Deai, Hiromi Yoshiuchi, Akira Matsuo, Mutsuyoshi Matsushita. *Biological and Pharmacological Research Laboratories, Central Pharmaceutical Research Institute, Japan Tobacco Inc., Osaka, Japan.*

Background: Renal anemia is principally caused by decreased erythropoietin (EPO) production in the kidney due to renal dysfunction. The production of EPO cannot be increased in response to hypoxia in the chronic kidney disease (CKD) kidney. The EPO production is regulated by hypoxia-inducible factor (HIF) -α, and it was hydroxylated by HIF-prolyl hydroxylase (PHD) and degradated by the ubiquitin-proteasome system. Several PHD inhibitors, including enarodustat are under clinical trials as treatment for renal anemia.

Methods: The enzyme inhibitory activity in human PHD enzymes was investigated by HTRF assay system. The expression of HIF proteins, EPO mRNA levels, and EPO proteins were evaluated by Western blotting, qPCR, and ELISA, respectively. Normal rats and 5/6-nephrectomized rats were used in *in vivo* experiment.

Results: Enarodustat had inhibitory effects on human PHD 1-3, but had no inhibitory effects on various receptors or enzymes. In Hep3B cells, enarodustat increased HIF-1α and HIF-2α protein levels, EPO mRNA levels, and EPO production. In normal rats, after a single oral dose of enarodustat, the plasma concentrations of enarodustat reached Cmax by one hour after administration, and then decreased rapidly. The liver and kidney EPO mRNA levels and plasma EPO concentrations also increased, and then both decreased by 24 hours. In 5/6-nephrectomized rats, repeated oral doses of enarodustat once daily showed the erythropoiesis stimulating effect in proportion to the doses from 1 mg/kg. The administration of enarodustat at the high dose (over 30 mg/kg) increased plasma vascular endothelial growth factor (VEGF), however, retinal VEGF mRNA levels and the retinal vascular permeability were not changed. Finally, we evaluated the effect of enarodustat in the colorectal cancer cell-inoculated mice model. Although enarodustat dosing at the high dose increased the plasma VEGF, it showed no effect on the tumor growth.

Conclusions: Enarodustat stabilizes HIF-α protein and induces erythropoiesis with hardly influence the unexpected function, and it is expected to become a new orally drug that can maintain the hemoglobin concentrations in CKD patients with renal anemia.

A Dose-Dependent Biphasic Effect of HIF Stabilizer (MK-8617) on Renal Fibrosis

Zuolin Li,[1] Linli Lv,[1] Jialing Ji,[2] Tao-Tao Tang,[1] Cao Jingyuan,[1] Bi-Cheng Liu.[1] *[1]Zhong Da Hospital, Southeast University, Nanjing, China; [2]Nanjing Medical University, Nanjing, China.*

Background: HIF stabilizer is a novel drug for renal anemia. Previous clinical trials have demonstrated HIF stabilizer could elevate hemoglobin (Hb) levels effectively in CKD patients. As a critical transcription factor, HIF has been involved in regulating hundreds of genes, which raised too much concern by clinician for its potential adverse effect. Here we firstly demonstrated the dose dependent biphasic effect of MK-8617(HIF stabilizer, Selleck) on renal fibrosis.

Methods: CKD-anemia model was induced by in mice undergoing 5/6 nephrectomy (5/6Nx). 5/6Nx mice were treated with MK-8617 orally at low dose (1.5mg/kg/d, group A), middle dose (5mg/kg/d, group B) and high dose (12.5mg/kg/d, group C) for 12weeks respectively. The 5/6Nx mice not treated with MK-8617 served as Ctrl group.

Results: Hb level was significantly elevated in all three groups with MK-8617 treatment for 12 weeks compared with that in Ctrl group. However, Hb level in group C was lower than that of the other two groups. Compared with the Ctrl group, the Scr and BUN were significantly decreased in group A and B respectively. It is of note that there was no significant reduction of Scr and BUN in group C. The VEGF mRNA and protein expression were significantly increased in both remnant kidney and liver in mice with Group C, but not in group A & B. However, the number of glomerular endothelial cells was significantly decreased in group C. More impressively, mice in group C showed a serious renal fibrosis with macrophage infiltration, but in contrast, mice in group A & B showed the attenuation of renal fibrosis compared to the Ctrl group. Furthermore, we identified there was a transdifferention of macrophage to myofibroblast in group C.

Conclusions: Although the significant improvement of renal anemia with MK-8617 in 5/6Nx mice, the dose dependent biphasic effect on renal fibrosis has been found, which implied that cautious should be taken when long term use this kind of drug to treat renal anemia, specifically when the dose is high. And the exact mechanism is also to be clarified.

Hypoxia Increases Erythrocyte Death Rate and Oxidative Stress Induced by Indoxyl Sulfate

Andrea N. Moreno-Amaral,[1] Gabriela F. Dias,[1] Sara S. Tozoni,[1] Natalia Borges Bonan,[4] Roberto Pecoits-Filho,[2] Peter Kotanko.[3] CARe - CKD Anemia Research Group *[1]Pontifícia Universidade Católica do Paraná, Curitiba, Brazil; [2]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [3]Renal Research Institute, New York, NY; [4]PUC-PR, CURITIBA, Brazil.*

Background: Prolonged intradialytic hypoxemia has been associated with higher erythropoietin requirements and poor clinical outcomes in dialysis patients. We analyzed the erythrocyte (RBC) response to indoxyl sulfate under hypoxic conditions.

Methods: RBC from 10 healthy subjects were incubated for 24h with buffer (CON-RBC) or IS (0.01; 0.09; and 0.17 mM) in normoxia (22% O_2) or hypoxia (5% O_2) conditions. Flow cytometry was used to determine: a) Eryptosis by phosphatidylserine exposure (PS) (by Annexin-Phycoerythrin) and intracellular Ca^{2+}influx (by Fluo-3AM), b) reactive oxygen species (ROS) production (by DCFH-DA probe) and reduced glutathione (GSH) content (by ThiolTracker Violet).

Results: Eryptosis increased in an IS dose-dependent manner in both normoxia and hypoxia, but the effect was more pronounced with hypoxia (Table 1). Similarly, IS exposure increased ROS production and decrease GSH content in an IS dose-dependent manner, and the response was also amplified by hypoxia (Table 1).

Conclusions: IS exposure increased eryptosis and oxidative stress and, this effect was amplified by hypoxia. These results suggest that the eryptotic effect of uremia may be aggravated by hypoxia. This may represent a novel mechanism in the development of renal anemia.

FR-PO477

Inflammation Contributes to Anemia of CKD Through Both Iron and HIF/EPO-R Pathways

Daniel Landau,[1,2] Inbar Bandach,[4] Yael Segev.[3] *[1]Tel Aviv University, Petach Tikva, Israel; [2]Pediatrics B, Schneider Children's Medical Center, Petach Tikva, Israel; [3]Ben Gurion University, Beer-Sheva, Israel; [4]Microbiology and Immunology, Ben Gurion University, Beer Sheva, Israel.*

Background: Anemia of chronic kidney disease (CKD), originally thought to be due to impaired renal erythropoietin (EPO) synthesis as well as iron malabsorption, may also be due to EPO resistance, clinically associated with inflammation. The key pro-inflammatory cytokine Interleukin (IL-1) is normally controlled by a receptor antagonist (IL1Ra). IL1Ra-KO (RaKO) mice show arthritis and excessive inflammation. The aim of this study was to characterize the anemic state of RaKO mice with adenine induced-CKD.

Methods: Wild-type (WT) and RaKO mice were fed with 0.2% adenine or control diets, leading to 4 groups: WT, WT-CKD, RaKO, RaKO-CKD. Mice were sacrificed after 10 weeks. For a control model of anemia (CA), WT mice were bled every two days for a week.

Results: Higher levels of S-creat and histologic kidney inflammation were seen in RAKO-CKD Vs WT-CKD. Kidney IL-6 and phospho-STAT3 were increased in both CKD groups, especially in RAKO-CKD. Arthritis, associated with increased liver CRP, was more accentuated in RAKO-CKD Vs RaKO. Hct levels were decreased in CKD groups, especially in RAKO-CKD. The response to bleeding induced anemia (CA) included: no evidence for inflammation, low liver hepcidin, elevated renal HIF2 and increased EPO controlled bone marrow (BM) EPO-R and transferrin receptor (TFR). Serum iron and MCV levels were significantly reduced in both CKD groups and were even lower in RAKO-CKD Vs WT-CKD. Liver hepcidin mRNA levels were increased in RAKO-CKD in comparison to all other groups. Serum EPO levels were not increased. Renal HIF2 and BM EPO-R mRNA levels were significantly decreased in both CKD groups, especially in RAKO-CKD.

Conclusions: Exaggerated arthritis and inflammation were associated with higher degree of renal insufficiency and anemia in RAKO-CKD Vs WT-CKD. In addition to the well-known hepcidin mediated decreased iron absorption, the normal response to anemia induced hypoxia is deranged in CKD and even more accentuated when inflammation is increased in CKD-RaKO: renal HIF2 and EPO, BM EPO-R and TFR are not upregulated, which further exacerbate anemic tendency. Altogether, this supports the key role of inflammation in CKD-associated anemia. Novel treatments to reduce inflammation may attenuate the anemic state or increase the response to exogenous EPO.

FR-PO478

Hypervitaminosis A Contributes to Abnormal Iron Metabolism in CKD

Serina Kabutoya,[1] Masashi Masuda,[2] Yuichiro Adachi,[2] Yilimulati Yimamu,[1] Hisami Okumura,[3] Hironori Yamamoto,[4] Yutaka Taketani.[3] *[1]Tokushima university, Tokushima, Japan; [2]Tokushima University, Tokushima, Japan; [3]University of Tokushima, Tokushima, Japan; [4]Dept. of Health and Nutrition, Jin-ai University, Echizen city, Fukui, Japan.*

Background: Anemia is the major features of chronic kidney disease (CKD). Hepcidin (HAMP) is the principal iron regulatory hormone and its overproduction contributes to anemia. HAMP blocks iron fluxes to the blood by degradation of the iron exporter ferroportin (FPN) at the plasma membrane of macrophages. It has been reported plasma vitamin A and its metabolites, all-trans retinoic acid (ATRA), are increased in CKD patients. Several reports showed both hypervitaminosis A and vitamin A deficiency (VAD) results in iron deposition in the liver and reduces serum iron levels in rats, which suggests an inappropriate vitamin A levels may affect iron metabolism disorder. However, the molecular mechanism behind the regulation of iron metabolism by ATRA have been unclear. In this study, we investigated whether hypervitaminosis A can be involved in abnormal iron metabolism in CKD and its molecular mechanism.

Methods: Five-week-old male C57BL/6J mice were treated 5/6 nephrectomy operation to induce CKD and they were fed VAD diet for nine weeks. Iron deposition of tissues was evaluated by Berlin blue stain. Gene expressions were evaluated by RT-PCR, Western blotting.

Results: Berlin blue stain showed VAD diet did not affect hepatic iron deposition, but reduced hepatic HAMP protein levels in CKD mice. Furthermore, VAD decreased the expression of hepatic p-STAT3 protein, transcription factor which activates HAMP transcription, in CKD mice. In spleen, VAD inhibited iron deposition and increased FPN mRNA levels in CKD mice. To understand the more detailed mechanism of abnormal iron metabolism by hypervitaminosis A, we evaluated iron-related gene expression in response to ATRA *in vitro*. The expression of HAMP mRNA and protein were increased by ATRA in HepG2 cells. Ro 41-5253, RAR antagonist, reduced HAMP mRNA levels increased by ATRA in HepG2 cells. Both ATRA and TTNPB, RAR agonist, increased p-STAT3 protein levels in HepG2 cells. Finally, we investigated whether VAD-increased splenic FPN mRNA expression in CKD was not only via HAMP action but also a direct action of ATRA. Interestingly, ATRA reduced the levels of FPN mRNA and protein in Raw264 cells.

Conclusions: We suggest CKD-induced hypervitaminosis A may contribute to abnormal iron metabolism through the indirect regulation of hepatic HAMP and the direct regulation of splenic FPN.

FR-PO479

Ferric Carboxymaltose Restores Iron Status and Transiently Increases FGF23 in a Mouse Model of Iron Deficiency

Maralee Capella,[1] Claire Gerber,[1] Guillaume Courbon,[1] Samantha Neuburg,[1] Connor Francis,[3] Corey Dussold,[1] Xueyan Wang,[1] Lixin Qi,[1] Myles Wolf,[2] Aline Martin,[1] Valentin David.[1] *[1]Northwestern University - Feinberg School of Medicine, Chicago, IL; [2]Duke University, Durham, NC; [3]University of Florida College of Medicine, Gainesville, FL.*

Background: Iron deficiency stimulates FGF23 transcription and cleavage, resulting in high circulating levels of total FGF23 (tFGF23) due to increased FGF23 fragments but relatively normal levels of biologically active intact FGF23 (iFGF23), and hence no hypophosphatemia. While this suggests that treating iron deficiency will decrease circulating levels of FGF23, recent publications have shown transient asymptomatic hypophosphataemia secondary to iFGF23 increase, in response to certain intravenous iron preparations such as ferric carboxymaltose (FCM).

Methods: We investigated whether treatment with FCM could impact FGF23 production in a mouse model of dietary iron deficiency. To induce iron deficiency, we fed 3 week-old C57BL6 mice an iron deficient diet (ID) for 3 weeks or a diet containing an adequate amount of iron (Ctr). Subsequently, six week old ID mice were treated with a single iv dose of 30mg/Kg FCM or saline vehicle (Veh). We then performed biochemical analyses of urine and serum from mice collected at different time points up to 2 weeks post injection.

Results: Compared to Ctr mice, six-week old ID animals showed evidence of iron deficiency anemia including low serum iron (23±6 vs 53±18 μg/dL), low red blood cells (7.9 ±0.3 vs 8.4±0.3 M/μL), and hemoglobin (10.0±0.2 vs 13.2 ±0.6 g/dL) ($p<0.05$, ID vs Ctr). FCM treatment rapidly increased serum iron levels 6 hours post-injection (290±21 vs 28±20 μg/dL) and hemoglobin (11.6±0.4 vs. 10.0±0.4 g/dL) after 48 hours ($p<0.05$, FCM vs Veh). As shown previously, tFGF23 was increased in ID animals (1013±143 vs 202±14 pg/mL) while iFGF23 was only slightly elevated (132±8 vs 82±5 pg/mL) ($p<0.05$, ID vs Ctr). FCM administration, led to a transient increase in tFGF23 (2448±269 vs 1343±256 pg/mL) and iFGF23 (193±13 vs 124±8 pg/mL) compared to iron deficient vehicle mice ($p<0.05$, FCM vs Veh). However, one week after FCM treatment, tFGF23 (378±76 vs 1142±186 pg/mL) and iFGF23 (112±7 vs 163±6 pg/mL) levels were corrected ($p<0.05$, FCM vs Veh), likely due to partial correction of iron deficiency.

Conclusions: Our data show that FCM administration to iron deficient mice corrects iron deficiency anemia and transiently increases iFGF23. The causes of this increase remain to be elucidated.

Role of Reduced [Ca2+]i in the Denser Bone Phenotype of Mouse Familial Hypocalciuric Hypercalcemia (FHH) Induced by Deleting the Gene Encoding Canonical Transient Receptor Potential 1 (TRPC 1) Channel

Bonnie Eby,[2] Marta Onopiuk,[5] Marybeth Humphrey,[4,6] Leonidas Tsiokas,[3] Kai Lau.[1,6] *[1]University of Oklahoma Health Science Center, Oklahoma City, OK; [2]University of Oklahoma Heath Sciences Center, Oklahoma City, OK; [3]University of Oklahoma Health Sciences Center, Oklahoma City, OK; [4]University of Oklahoma, Oklahoma City, OK; [5]OUHSC, Oklahoma City, OK; [6]Medicine, VA Hospital & Medical Center, Oklahoma City, OK.*

Background: In reporting the 80% increased bone mass in FHH, we noted +/- mice have similar hypercalcemia (11 vs 10.7 mg %), calcitriol, & calcitonin as null, but no hyperparathyroidism (HPT) or hypocalciuria. We asked if gene dosage causes these & the bone phenotype. In parathyroid gland (PTG), renal cells & osteocytes from null mice, we found lower $[Ca^{2+}]_i$ & blunted response to CaSR agonists, shifting right Ca set point for PTH release. We tested the hypothesis that reduced $[Ca^{2+}]_i$ alters secretion of cytokines & phosphatonins to produce greater renal Ca & P retention & more bone mineral accretion.

Methods: We did metabolic studies in ♂ littermates of all 3 genotypes & measured blood chemistry as published & cytokines by mouse ELISA.

Results: At 6.5 mon, plasma leptin in null (2.34), but not +/- (1.78), was 75% higher than wild-type (wt) (1.3 ng/ml), compatible with known increased leptin secretion by low $[Ca^{2+}]_i$ in adipocytes. Given published positive feedback between PTH by PTG & leptin by adipocytes, the data suggest leptin could aggravate the HPT in null mice. Plasma adiponectin was reduced in null (5.36 vs 6.17 in +/- vs 6.39 μg/ml in wt), consistent with its known inhibition by low $[Ca^{2+}]_i$ & with the published hypocalciuric effects if downregulated. Indeed, despite hypercalcemia, urine Ca (50 in null vs 79 in +/- vs 84 μg/d in wt) & Ca clearance (0.68 vs 1.08 vs 1.25 μl/min) were lower in null. Consistent with the low $[Ca^{2+}]_i$ we found in osteocytes, FGF-23 was down in null (51% at 4 mon & 32 % by 5 mon). At 8 mon, P clearance was reduced in null (48 vs 60 in +/- vs 67 μl/min in wt). Thus, serum P was elevated in null (7.4 vs. 6.2 in +/- vs 6.3 mg % in wt). At 12 mon, urine P stayed 50% lower in null, consistent with the anti-phosphaturia of reduced FGF-23.

Conclusions: Our data support this model of bone phenotype in null mice. 1. Disturbed $[Ca^{2+}]_i$ homeostasis from losing both alleles shifts Ca set point to cause HPT. 2. Reduced $[Ca^{2+}]_i$ in adipocytes triggers leptin, aggravates HPT, & inhibits adiponectin. 3. Reduced $[Ca^{2+}]_i$ in osteocytes inhibits FGF-23. 4. In concert, these hypocalciuric & anti-phophaturic

factors promote renal Ca & P retention to favor bone formation, independent of any other renal & skeletal effects of TRPC1 deficiency.

Cross-Talk Between Vascular and Bone Tissues: Does Vascular Calcification Induce Bone Loss?

Maria L. Mace,[1] Eva Gravesen,[3] Anders Nordholm,[1] Marya Morevati,[3] Patrick C. D'Haese,[2] Klaus Olgaard,[3,4] Ewa Lewin.[1,4] *[1]Herlev Hospital, Herlev, Denmark; [2]University Antwerp, Edegem, Belgium; [3]Rigshospitalet, Copenhagen, Denmark; [4]University of Copenhagen, Copenhagen, Denmark.*

Background: Disturbances in bone homeostasis have been associated with development of vascular calcification. Results of epidemiological studies in general population and in CKD patients showed more severe progressive vascular calcifications were associated with greater bone loss and fractures. Our question was whether the presence of severe vascular calcification may have an impact on bone metabolism.

Methods: A novel model of isogenic aorta transplantation was used (ATX). Severe uremic vascular calcifications were induced in DA rats by 5/6 nephrectomy, high P diet and calcitriol. After 14 weeks the calcified abdominal aorta of the uremic rat was transplanted into a normal DA rat (n=16). Control groups were ATX of a normal aorta to normal rat (n=9) and age-matched rat (n=6). Rats were sacrificed 4 weeks after ATX and plasma biochemistry, bone and vessels were analyzed.

Results: The uremic donor rat suffered from severe kidney disease with disturbed mineral balance and its aorta had a high calcium content of 15.7±0.8 µg Ca/mg vs. none in the normal aorta. Control, normal ATX and calcified ATX rats had same levels of creatinine, Ca^{2+}, phosphate, PTH, FGF23 and sclerostin. The calcified ATX rats had significant changes in mRNA of several bone markers compared to normal ATX and control rats such as alkaline phosphatase (3.26±0.29 vs. 1.56±0.32 & 0.86±0.12, both p<0.001), sclerostin (3.60±0.68 vs. 1.41±0.34 & 1.04±0.27, both p<0.01), RUNX2 (1.53±0.09 vs. 0.80±0.18 & 0.44±0.11, p<0.01, p<0.001), Osteocalcin (0.54±0.06 vs. 0.92±0.14 & 1.19±0.06, p<0.05, p<0.001), RANKL (0.40±0.05 vs. 1.91±0.36 & 2.43±0.30, p<0.01, p<0.001), cathepsin K (2.36±0.24 vs. 1.19±0.23 & 1.01±0.07, p<0.01, p<0.001), beta catenin (3.15±0.25 vs. 1.28±0.26 & 1.03±0.13, both p<0.001), collagen I (8.50±0.93 vs. 4.06±2.02 & 3.25±0.88, p<0.05, p<0.001), osteopontin (1.46±0.18 vs. 0.69±0.17 & 0.49±0.06, both p<0.01). Finally, bone mineral density (BMD) was significantly lower in calcified ATX rats compared to normal ATX and control rats (1576±5 vs. 1592±5 & 1613±6 mg/cc, both p<0.05).

Conclusions: These novel findings indicate the existence of a tissue crosstalk between vessels and bone. The presence of vascular calcifications has an impact on several pathways in bone and decrease BMD. Vascular calcification does induce bone loss.

FR-PO482

The Phosphate Binding Therapy Fermagate Attenuates Vascular Calcification in Experimental Adenine-Induced CKD

Cynthia M. Pruss, Paul S. Jeronimo, Kimberly J. Laverty, Emilie C. Ward, Mandy E. Turner, Bruno A. Svajger, Martin P. Petkovich, Rachel M. Holden, Michael A. Adams. *Queen's University, Kingston, ON, Canada.*

Background: Hyperphosphatemia, common in chronic kidney disease (CKD), is linked to vascular calcification (VC), which further increases cardiovascular risk. Some evidence suggests oral magnesium (Mg) inhibits VC. Fermagate is a calcium-free, magnesium-releasing phosphate binder that controls hyperphosphatemia. This study determined if fermagate treatment compared to untreated control could impact VC in the adenine-induced CKD rat model.

Methods: Male Sprague Dawley rats were fed a 0.25% adenine, 0.5% phosphate (PO_4) diet to induce CKD (creatinine >250 uM) over 4-5 weeks, then fed 0.5% PO_4 without adenine diet. At 6 weeks CKD, two dietary PO_4 regimens were tested: moderate PO_4 (0.75%P) diet (5g 8AM and 4PM ±fermagate (FER n=9) untreated control (CON n=6), 10g diet overnight, or a combination of high and low PO_4 (1-0.5%P): high (1%P 5g 8AM, 4PM ±fermagate) and 10g low (0.5%P) PO_4 diet overnight (FER n=8, CON n=10) with the same amount of daily dietary PO_4. Serum calcium (Ca), magnesium (Mg), PO_4, FGF-23, parathyroid hormone (PTH), vitamin D metabolome, and tissue Ca and PO_4 were determined.

Results: In both studies, fermagate increased serum Mg (203% 0.75%P, p<0.0001; 163% 0.5-1%P, p<0.0001, % control, 2-way ANOVA) and had lower levels of serum PO_4 (67% 0.75%P, p<0.001; 64% 0.5-1%P, p<0.001), and PTH (31% 0.75%P, p<0.001; 16% 0.5-1%P, p<0.001). The proportion of VC was significantly reduced in arterial tissues with fermagate treatment (79%/65% in CON vs. 35% FER(0.75%P) and 13% FER(0.5-1%P), respectively, p<0.001). This inhibition was also evident on a per animal basis (100%/70% CON had VC vs. 33% FER(0.75%P) and 13%(FER 0.5-1%P), p<0.05, respectively). Fermagate treatment did not significantly alter Mg levels in the vasculature tissue, serum Ca, FGF-23, or serum vitamin D metabolome.

Conclusions: These results demonstrate that fermagate effectively reduces the bioavailability of dietary PO_4, decreases serum PO_4, increases serum Mg, and effectively limits the development and progression of CKD-induced vascular calcification.

FR-PO483

TNAP Inhibition: A Novel Strategy to Prevent the Development of Vascular Calcification?

Britt Opdebeeck,[1] Anja Verhulst,[2] Patrick C. D'Haese,[1] Ellen Neven.[2] *[1]University Antwerp, Wilrijk, Belgium; [2]University of Antwerp, Wilryk, Belgium.*

Background: Vascular media calcification (VC) is frequently seen in chronic kidney disease patients. Pyrophosphate (PPi) is a well-known calcification inhibitor that binds to nascent hydroxyapatite crystals and prevents further incorporation of inorganic phosphate (Pi) into these crystals. However, the enzyme tissue non-specific alkaline phosphatase (TNAP), which is highly expressed in calcified arteries, degrades extracellular PPi into Pi ions, by which PPi loses its ability to block VC. Here, we aimed to evaluate whether a TNAP-inhibitor is able to prevent the development of arterial calcification in a rat model of warfarin-induced VC.

Methods: To induce VC, rats received a diet containing 0.30% warfarin and 0.15% vitK1 throughout the entire study and were subjected to the following daily treatments: (i) vehicle (n=10) or (ii) 10 mg/kg/day TNAP-inhibitor (n=10) administered via an i.p. catheter from start of the study until sacrifice at wk7. Calcium (Ca) and phosphorus (P) levels were determined in serum and urine samples being important determinants of VC. To evaluate osteo/chondrogenic switch of vascular smooth muscle cells (VSMCs), aortic mRNA expression of runx2, TNAP, SOX9, collagen1 and 2 was analyzed by qPCR. At sacrifice, VC was evaluated by measurement of the total Ca content in the arteries and quantification of the area % calcification on Von Kossa stained aortic sections.

Results: No difference in serum Ca and P levels was observed between both study groups. Warfarin exposure resulted in distinct calcification in the aorta and peripheral arteries in vehicle treated rats. Importantly, daily treatment with a TNAP-inhibitor significantly reduced VC as indicated by a significant decrease in calcium content in the aorta (mean ± SEM; vehicle 3.84±0.64 mg Ca/g wet tissue vs TNAP-inhibitor 0.70±0.23 mg Ca/g wet tissue) and peripheral arteries and a distinct reduction in area % calcification on Von Kossa stained aortic sections as compared to vehicle condition. TNAP-inhibitor treatment did not alter the mRNA expression of osteo/chondrogenic marker genes runx2, TNAP, SOX9, collagen1 and 2.

Conclusions: Treatment with a TNAP-inhibitor significantly reduced the development of VC in the aorta and peripheral vessels of warfarin exposed rats most probably by directly interfering with the apatite formation rather than promoting osteo/chondrogenic conversion of VSMCs.

Protein Bound Uremic Toxins Promote Vascular Calcification by Glucose Mediated Activation of Inflammation and Coagulation Pathways

Britt Opdebeeck,[1] Annelies De maré,[2] Bjorn Meijers,[4] Anja Verhulst,[2] Pieter Evenepoel,[4] Patrick C. D'Haese,[3] Ellen Neven.[2] *[1]Laboratory of Pathophysiology, University of Antwerp, Wilrijk, Belgium; [2]University of Antwerp, Wilryk, Belgium; [3]University Antwerp, Edegem, Belgium; [4]University Hospitals Leuven, Leuven, Belgium.*

Background: Protein-bound uremic toxins indoxyl sulfate (IS) and p-cresyl sulfate (PCS) have been associated with cardiovascular morbidity and mortality in patients with chronic kidney disease (CKD). We aimed to provide direct evidence for a role of these toxins in CKD-related vascular calcification.

Methods: To induce CKD, rats were orally dosed with adenine sulfate for 10 days and continuously exposed to either vehicle, IS or PCS (150 mg/kg/day) until 7 weeks after CKD induction. Vascular calcification was assessed by measurement of arterial calcium content and through histochemical evaluation of Von Kossa stained sections. Quantitative mass spectrometric proteomics was further employed to investigate the mechanistic pathways underlying IS and PCS-mediated vascular calcification.

Results: IS and PCS exposure did not worsen renal function, fibrosis, or inflammation. Calcification in the aorta, carotid and femoral arteries was significantly increased by exposure to both toxins, for which serum levels similar to CKD patients were reached. Arterial calcification was not associated with changes in bone metabolism inherent to CKD. Unbiased proteomic analyses of arterial samples coupled to functional bioinformatics annotation analysis revealed that calcification events were likely associated with acute phase response signaling, coagulation and glucometabolic signaling pathways, while escape from calcification was linked with liver X receptors and farnesoid X/liver X receptor signaling pathways. Further metabolic linkage to these pathways also revealed that IS/PCS exposure engendered a pro-diabetic state, evidenced by elevated resting glucose and reduced glucose transporter (Glut1) transcript expression.

Conclusions: We demonstrate that both IS and PCS directly promote vascular calcification via activation of inflammation and coagulation pathways in the arterial wall which was strongly associated with impaired glucose homeostasis.

Calcium-Sensing Receptor Signal Modulation: Identification of CaRS875 as a Novel Phosphorlyation Site and the Contribution of Both Intracellular Domains to Homodimer Signaling

Lenah S. Binmahfouz,[2] Arthur D. Conigrave,[3] Donald T. Ward.[1] Ward *[1]The University of Manchester, Manchester, United Kingdom; [2]The University of Manchester, Manchester, United Kingdom; [3]University of Sydney, Sydney, NSW, Australia*.

Background: The calcium-sensing receptor (CaR) controls parathyroid hormone secretion and renal Ca^{2+} reabsorption and its function is inhibited by protein kinase C (PKC) phosphorylation on CaR^{T888}. However, the equivalent PKC site in metabotropic glutamate receptor-5 aligns instead to CaR^{S875}, not previously considered a PKC site. Thus, we examined whether a) CaR^{S875} represents a novel PKC site, b) mutation of CaR^{T888} can rescue loss-of-function (LOF) CaR mutants and c) whether one or both intracellular domains (ICD) of the CaR homodimer contribute to signaling.

Methods: The non-phosphorylatable mutation CaR^{S875A} was introduced into both wild-type human CaR and CaR^{T888A} to test whether this heightens signaling. Then CaR^{T888A} was introduced into two loss-of-function (LOF) mutants, CaR^{S170A} (extracellular domain, ECD) and CaR^{F801A} (intracellular domain, ICD) to determine a) whether it can rescue their lost function and b) whether its addition to both monomers enhances the benefit. If so then this would indicate that both ICDs of the dimer contribute to signaling.

Results: In HEK-293 cells, CaR^{S875A} exhibited significantly enhanced signaling vs wild-type CaR (EC_{50}, 3.4 ± 0.2 mM WT vs. 1.6±0.1 S875A; P<0.001) while the phosphomimetic CaR^{S875D} mutant reduced Ca^{2+}_o potency (4.7±0.2 mM S875D vs 3.4±0.2 WT; P<0.01). When combined with T888A, the Ca^{2+}_o responsiveness of the double mutant $CaR^{S875A/T888A}$ was further left-shifted relative to CaR^{T888A} alone (2.1±0.4 S875A/T888A vs. 2.6±0.1 T888A; P<0.01) demonstrating the sites' additive effects. Next, the LOF homodimers CaR^{S170A} (ECD) and CaR^{F801A} (ICD) exhibited no Ca^{2+}_o responsiveness up to 40mM, whereas co-mutation with T888A significantly rescued their Ca^{2+}_o responsiveness. It is known that heterodimerisation of CaR^{S170A} and CaR^{F801A} permits partial rescue of their function. However, additional co-mutation with T888A not only enhanced the rescue but gave maximal rescue when present on both monomers.

Conclusions: Thus, CaR^{S875} is a novel PKC site that, together with CaR^{T888}, shapes the CaR signalling that underpins Ca^{2+}_o homeostasis. Furthermore, removal of inhibitory signaling at CaR^{T888} can rescue both ECD and ICD loss-of-function mutants, and, both ICDs of the dimer contribute to CaR signalling.

FR-PO486

INS-3001 Efficiently Inhibits Severe Vascular Calcifications by Direct Interference with Vessel Wall Calcification

Anja Verhulst,[1] Mattias E. Ivarsson,[3] Roberto Maj,[4] Ellen Neven,[5] Patrick C. D'Haese.[2] *[1]Pathophysiology, University of Antwerp, Antwerp, Belgium; [2]University Antwerp, Edegem, Belgium; [3]Inositec Inc., Zurich, Switzerland; [4]Inositec AG, Zurich, Switzerland; [5]University of Antwerp, Wilryk, Belgium*.

Background: Prevention/treatment of vascular calcification currently is based on controlling its most important risk factors. A new therapeutic approach with potential higher efficacy consists in the administration of molecules directly interfering with the calcification process in the vessel wall, such as INS-3001. This abstract reports about the administration of INS-3001 in a rat model of vitamin D-warfarin induced vascular calcifications (pooled data of 3 independent studies).

Methods: Calcification was induced in male rats (8 weeks) by warfarin (3mg/g diet) administration during 6 days and by 4 consecutive daily administrations of vitD3 (100.000 IU/kg) starting on day 1 of the warfarin administration. Rats were randomly assigned to different groups: vehicle, and INS-3001 groups of 12, 25, 2x25, 50 and 2x50 mg/kg/day. Treatment was administrated sc. for 7 days (starting together with vitD). Animals were sacrificed on the 8th day. Vascular calcification was evaluated on Von Kossa stained tissue sections of the thoracic/abdominal aorta and by measurement of the total Ca content of the thoracic/abdominal aorta and the carotid/femoral arteries by atomic absorption spectrometry.

Results: Mortality rate was 38% (15/40) in the vehicle group, similar -33% (4/12) and 44% (5/12)- in the 1x25 and 1x12.5 mg/kg/day dose groups, numerically lower -15% (3/19), 21% (4/19)- in the 2x50, 1x50 mg/kg/day dose groups and significantly lower 0% (0/18) in the 2x25 mg/kg/day dose group. In the abdominal aorta, significantly lower Von Kossa positivity (area%) was measured in the INS-3001 groups compared to the vehicle group (3±5%, 6±4%, 8±7%, 15±3%, 20±3% and 28±10% in respectively the 2x50, 50, 2x25, 25, 12.5 mg/kg/day and the vehicle group). Total Ca content of the abdominal aorta was also significantly lower in the INS-3001 (not the 12.5 and 25 mg/kg/day) groups compared to the vehicle group (2.8±3.7, 6.1±5.0, 7.4±6.9, 14.9±7.0, 15.6±9.4 and 14.9±7.5 mg/g tissue in respectively the 2x50, 50, 2x25, 25, 12.5 mg/kg/day and the vehicle group. Similar reductions in area% Von Kossa positivity and total Ca content were seen in the thoracic part of the aorta, and the arteria femoralis and carotis.

Conclusions: In conclusion, INS-3001 is a promising molecule for the treatment of CKD and non-CKD induced vascular calcifications.

FR-PO487

Identification and In Vitro Characterisation of a Novel Inhibitor of Vascular Calcification

Antonia E. Schantl,[1] Mattias E. Ivarsson,[2] Bastien Castagner,[3] Jean-Christophe Leroux.[1] *[1]ETH Zurich, Zurich, Switzerland; [2]Inositec Inc., Zurich, Switzerland; [3]McGill University, Montreal, QC, Canada*.

Background: Vascular calcification (VC) is the pathological deposition of calcium and phosphate minerals in the walls of the cardiovascular system. At present, there is no approved pharmacological treatment and affected individuals are left at great risk of experiencing cardiovascular events and death. Herein, we describe a new class of inhibitors of VC based on the previously reported inhibitor *myo*-inositol hexaphosphate (IP6), with improved drug-like properties.

Methods: Multi-step syntheses, starting from protected *myo*-inositol species, via selective PEGylation, phosphorylation or sulfation were employed to afford a library of novel IP6 derivatives. Activity was compared in a serum calcification propensity assay, and stability was monitored in serum. *In vitro* efficacy experiments were performed on primary human vascular smooth muscle cells (VSMCs), treated with either calciprotein particles (CPPs) (50 μg/mL) or calcification medium (2.7 mM calcium and 2.5 mM phosphate, CaP), respectively. Subsequently, calcification of the cell monolayer, cell viability and expression of cell markers were assessed.

Results: Synthesis and screening of twelve monodispersed PEGylated IP6 derivatives revealed IP4-di-PEG_2 (INS-3001) to be almost 10-fold more potent than IP6 in delaying serum calcification propensity, with activity in the low μM range. This activity was retained following 4 h incubation in fresh human serum. VSMC calcification was largely abolished by 1 μM INS-3001 in the CaP setup (Figure 1), and 30 μM INS-3001 in the CPP setup, respectively.

Conclusions: INS-3001 was superior to natural IP6 with regard to serum calcification propensity, *in vitro* stability and efficacy in cell culture models. Thus, the presented *in vitro* data provides support for the further development of INS-3001 as an inhibitor of vascular calcification.

Hyperphosphatemia Is a Negative Modulator of the Calcium-Sensing Receptor

Patricia Pacios centeno,[3] Chia-Ling Tu,[5] Amanda L. Herberger,[6] Wenhan Chang,[4] Arthur D. Conigrave,[2] Donald T. Ward.[1] Ward *[1]University of Manchester, Manchester, United Kingdom; [2]University of Sydney, Sydney, NSW, Australia; [3]The University of Manchester, Manchester, United Kingdom; [4]Endocrine Unit, SF-VAMC, University of California San Francisco, San Francisco, CA; [5]San Francisco VA Medical Center, San Francisco, CA; [6]University of California, San Francisco/ San Francisco Veterans Affairs Medical Center, San Francsicso, CA.*

Background: Chronic kidney disease (CKD) is associated with hyperphosphataemia and secondary hyperparathyroidism (SHPT). The key controller of parathyroid hormone (PTH) secretion is the calcium-sensing receptor (CaSR), whose crystallised extracellular domain has revealed four putative phosphate-binding sites in its inactive conformation. Our aim was to determine whether extracellular phosphate, at concentrations found in CKD, can inhibit CaSR and increase PTH secretion, and thus potentially contribute to the aetiology of SHPT.

Methods: CaSR activity was measured as Ca^{2+}_i mobilisation (Fura-2) and extracellular signal-regulated kinase (ERK) phosphorylation in HEK-293 cells stably transfected with human CaSR. The HEPES buffer contained 0.5mM $CaCl_2$ with phosphate added as Na_2HPO_4 and KH_2PO_4 in a 4:1 ratio (pH 7.4). PTH secretion was measured in dispersed human parathyroid cells obtained ethically following neck surgery and in cultures of intact mouse parathyroid glands.

Results: Raising phosphate concentration from 0.8 mM (physiological) to 2 mM (CKD-like) inhibited CaSR-induced Ca^{2+}_i mobilisation (-52 ± 4%; P<0.001) and ERK activation

(-18 ± 3%; P<0.01). Raised phosphate concentration (2 mM) inhibited the maximal (E_{max}) Ca^{2+}_o response suggesting non-competitive antagonism (-32 ± 3%; P<0.001). Further, phosphate attenuated CaSR activity with an IC_{50} of 1.2 mM (95%CI 1.0 to 1.4). Mutation of $CaSR^{R62}$ (a putative phosphate-binding site) to alanine ablated this inhibitory effect. Finally, pathophysiologic phosphate concentrations elicited rapid (within minutes) and reversible increases in PTH secretion in freshly-isolated human parathyroid cells (+39 ± 10%, 0.8 vs 2mM, P<0.05; +58 ± 15%, 0.8 vs 3mM; P<0.001) consistent with a receptor-mediated action (with thanks to Ryan Mun). Similarly, in cultures of mouse parathyroid glands phosphate again elicited rapid, concentration-dependent increases in PTH secretion (by up to 180%, 3 vs 0.8mM).

Conclusions: Therefore CaSR is able to sense pathophysiologic deviations in phosphate concentration apparently via non-competitive antagonism at $CaSR^{R62}$ resulting in increased PTH secretion. This mechanism may help explain the contribution of hyperphosphatemia to SHPT.

FR-PO489

Impact of Modifying Calcitriol Dosing on the Vitamin D Metabolome and Vascular Calcification in Experimental CKD

Bruno A. Svajger,[1] Cynthia M. Pruss,[1] Kimberly J. Laverty,[1] Jason Zelt,[1] Emilie C. Ward,[2] Mandy E. Turner,[3] Glenville Jones,[4] Martin P. Petkovich,[1] Rachel M. Holden,[1] Michael A. Adams.[1] *[1]Queen's University, Kingston, ON, Canada; [2]Queen's University, Kingston, ON, Canada; [3]Queen's University at Kingston, Kingston, ON, Canada; [4]Queens University, Kingston, ON, Canada.*

Background: Calcitriol (CAL) and other vitamin D analogs are used to manage SHPT in CKD although treatment can result in PTH over-suppression and lead to vascular calcification (VC). This study sought to determine whether modifying CAL dosing frequency and magnitude could provide a better treatment profile (PTH, FGF23, VC) in experimental CKD.

Methods: Experimental CKD (e-CKD) was induced by 0.25% dietary adenine in adult male Sprague-Dawley rats (n=42). At 4 weeks (W), e-CKD rats were divided into 5 groups and treated with oral CAL as follows: 0ng/kg (e-CKD control, n=8), 5ng/kg x 4, q6h (n=9), 20ng/kg once daily (n=8), 20ng/kg x 4, q6h (n=9), or 80ng/kg once daily (n=8). After 3W treatment, rats were sacrificed, tissues and blood were collected and assessed for vitamin D metabolome, PTH, FGF-23 and VC. Sub-analysis according to PTH level: (i) over suppressed (OS), (ii) target, and (iii) mildly suppressed (MS) was performed.

Results: CAL treatment in e-CKD rats markedly increased the levels of 1,25-$(OH)_2D_3$ in a dose-dependent manner (4-6X). In contrast, both circulating 25-OH-D_3 and 24,25-$(OH)_2D_3$ fell significantly (10-30%), particularly at the higher CAL dose. Sub-analysis based on PTH suppression revealed a greater fall in 25-OH-D_3 and 24,25-(OH)2D3 levels in Target and OS groups compared to the MS and untreated e-CKD. Overall, in e-CKD, the CAL treatment induced markedly increased VC (94% in Tx vs. 29% of vessels in unTx) and FGF-23 (8-20 X increase in Tx vs. unTx) regardless of treatment profile.

Conclusions: CAL suppressed PTH early in e-CKD treatment as expected, but PTH became progressively refractory over the 3 weeks of treatment. Even in the absence of overt PTH over suppression, all animals in the CAL treatment group had significant vascular calcification. All CAL treatment groups induced similar changes in the circulating vitamin D metabolome, with increased 1,25-$(OH)_2D_3$ but decreased 25-OH-D_3 and corresponding 24,25-$(OH)_2D_3$. The CAL treatment induced varying alterations in the vitamin D metabolome which were reflected, in part, on how PTH levels were modified in response to CAL. These findings suggest that how calcitriol is administered as well as the level of PTH suppression should be re-examined to minimize VC in CKD.

FR-PO490

Significant Differences Exist in Intestinal Phosphate Absorption Between Species

Yasuhiro Ichida,[1] Naoto Hosokawa,[1] Ryushi Takemoto,[2] Takafumi Koike,[2] Tasuku Nakatogawa,[2] Mayumi Hiranuma,[2] Hitoshi Arakawa,[2] Yukihito Miura,[2] Hiroko Azabu,[2] Shuichi Ohtomo,[1] Naoshi Horiba.[1] *[1]Chugai Pharmaceutical Co. Ltd., Gotemba, Shizuoka, Japan; [2]Chugai Research Institute for Medical Science, Inc., Gotemba, Japan.*

Background: The efficacy of a NaPi-IIb specific inhibitor was recently reported to be different between rat and human. In addition, intestinal phosphate absorption was previously reported to be different between rat and mouse. This study analyzed intestinal phosphate absorption in dog, monkey, and rat and also investigated the concentrations of phosphate and related hormones in serum. The results showed significant differences in the intestinal phosphate absorption between the three species.

Methods: Fecal and urinary phosphate excretion were compared in dog, monkey, and rat after paired feeding. Phosphate uptake by intestinal brush border membrane vesicles (BBMV) and the mRNA expression of NaPi-IIb, PiT-1, and PiT-2 were also evaluated in duodenum, jejunum, and ileum of each species. In addition, the ALP activity in each intestinal segment and the concentration of serum phosphate and FGF23 were measured.

Results: The intestinal phosphate absorption rate, as calculated from food intake and fecal excretion, was highest in dog out of the three species, as were urinary fractional excretion of phosphate and serum concentration of FGF23. Accordingly, phosphate uptake with BBMV and mRNA expression of NaPi-IIb were also highest in dog. Surprisingly, urinary phosphate excretion was lowest in monkey, and the intestinal phosphate absorption rate in monkey was by far the lowest out of the three species. Dog and rat showed positive correlations between phosphate uptake with BBMV and mRNA expression of NaPi-IIb in each intestinal segment. Although phosphate uptake in BBMV was high in monkey, mRNA expression of NaPi-IIb was not detected in any of the intestinal segments, and intestinal ALP activity was low.

Conclusions: These results suggest that, whereas NaPi-IIb is the major contributor to intestinal phosphate absorption in dog and rat, monkey phosphate degrades only slightly in the intestine, and its contribution to intestinal phosphate absorption might be through a sodium-dependent phosphate transporter other than NaPi-IIb. In conclusion, there are significant differences in intestinal phosphate absorption between dog, monkey, and rat. Further analysis is needed to elucidate the phosphate absorption in human.

FR-PO491

Oxidative Stress and Autophagy Are Involved in Matrix Vesicles (MV)-Induced Calcification of Recipient Vascular Smooth Muscle Cells (VSMC)

Neal X. Chen,[1] Kalisha O'Neill,[1] Sharon M. Moe.[1,2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Roudebush VA Medical Center, Indianapolis, IN.*

Background: Oxidative stress is increased in patients with CKD and is associated with vascular calcification. Oxidative stress can also increase autophagy. We have previously demonstrated that cellular derived MV, but not media derived MV, increase calcification of recipient normal rat VSMC when endocytosed, in association with increased intracellular calcium and NOX production. We hypothesize that this increased oxidative stress in recipient VSMC cells may lead to inappropriate autophagy that induces vascular calcification and thus extends calcification lesions.

Methods: Cellular or media derived MV were co-cultured with recipient VSMC in the calcification inducing media (high phosphorus) and alteration of oxidative stress (ROS production) and autophagy were examined by confocal microscopy and Western blot, respectively. Calcification was determined by biochemical assay. In some experiments, inhibitors for autophagy (3-MA) and oxidative stress (NOX1/4 inhibitor GKT137831) were added to the MV-VSMC cultures.

Results: The addition of cellular MV, but not media MV, to recipient normal VSMC increased ROS production by 95% at 24 h and increased the expression of autophagy markers LC3II and Atg5 at 1 and 3 days during calcification. Pretreatment with GKT137831 significantly blocked cellular MV-induced ROS production in recipient VSMC. Furthermore, inhibition of autophagy with 3-MA decreased MV-induced calcification of recipient VSMC by 425%, a magnitude similar to the inhibition induced by blockade of NOX1/4 activity.

Conclusions: Cellular derived MV induced ROS production and increased autophagy in recipient VSMC during calcification (high phosphorus media). These results suggest that normal VSMC may endocytose cellular MV from calcifying VSMC leading to increased ROS and autophagy in the recipient VSMC, resulting in increased calcification.

FR-PO492

Effect of Advanced Glycation End-Products (AGE) Lowering Drug ALT-711 on a Rat Model of CKD-Mineral Bone Disorder (CKD-MBD)

Neal X. Chen,[1] Shruthi Srinivasan,[1] Loretta O. Aromeh,[1] Kalisha O'Neill,[1] Keith Avin,[2] Matthew R. Allen,[1] Tom Nickolas,[4] Joseph M. Wallace,[5] Sharon M. Moe.[1,3] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University-Indianapolis, Indianapolis, IN; [3]Roudebush VA Medical Center, Indianapolis, IN; [4]Columbia University Medical Center, New York, NY; [5]Indiana University Purdue University Indianapolis, Indianapolis, IN.*

Background: Reduced bone quality is a key determinant of skeletal fragility in CKD. We hypothesized that the increased formation of AGEs that occur in advanced CKD due to oxidative stress may be responsible for the impaired bone fragility. To test this hypothesis, we evaluated the efficacy of an AGE breaker (ALT-711) on CKD-MBD and bone AGEs in a slowly progressive rat model of CKD, the Cy/+ rat.

Methods: We compared five groups of animals [1: Normal (NL); 2: CKD; 3:CKD+ALT-711; 4: CKD+ 3% calcium in drinking water (Ca, lowering PTH and reducing bone remodeling); and 5: CKD+ALT-711+Ca]. Treatment was started at 25 weeks of age (~50% kidney function) and ended at 35 weeks (~15% function). Blood, kidney weight, and heart weight were examined at sacrifice and aorta calcification determined biochemically. Bone AGE content was determined in demineralized femur shaft using fluorescence plate reader, normalized by collagen (hydroxyproline) content.

Results: As expected, there was progressive decline in kidney function over time in all 4 CKD groups compared to NL. The serum levels of calcium and FGF23 were higher, and phosphorus and PTH lower in CKD animals treated with calcium consistent with resolution of secondary hyperparathyroidism. The administration of ALT did not alter BUN, calcium, PTH or FGF23 levels but did reduce serum phosphorus levels in CKD animals. Heart weight and left ventricular mass index (LVMI) increased in all of the CKD animal groups compared to NL. Treatment with ALT-711, calcium, or ALT+Ca all reduced the heart weight and LVMI in CKD animals. There was increased vascular calcification in all of the CKD animal groups but no effect of ALT-711 treatment. Serum 8-OHdG levels (marker of DNA oxidation) was elevated in CKD compared to NL and not lowered by ALT-711. Bone AGE levels were increased in CKD compared to NL but not reduced by ALT treatment.

Conclusions: In a progressive rat model of CKD, there is increased AGE accumulation in bone. Starting treatment with an AGE breaker early in the course of CKD failed to improve bone AGE levels, but did reduce heart weight. Interestingly, there was also an interaction with secondary hyperparathyroidism in the pathogenesis of AGEs and response to ALT. Bone biomechanical testing is in progress.

FR-PO493

Specific Knockdown of WNT8b Expression Protects Against Phosphate-Induced Calcification in Vascular Smooth Muscle Cells by Inhibiting the Wnt/β-Catenin Signaling Pathway

Li Yao, Zitong Sheng, Tianhua Xu, Pengzhi Wan, Tian Binyao. *The First Affiliated Hospital of China Medical University, Shenyang, China*.

Background: In the last 10 years, the prevalence, significance, and regulatory mechanisms of vascular calcification have gained increasing recognition. The aim of this work is to study the action of WNT8b on the disease development of phosphate-induced vascular calcification through its effect on vascular smooth muscle cells (VSMCs) in vitro by inactivating the Wnt/β-catenin signaling pathway.

Methods: In order to find out the effect of WNT8b on the Wnt/β-catenin signaling pathway and vascular calcification in vitro, β-glycerophosphate (GP) induced T/G HA-VSMCs were treated with siRNA against WNT8b, LiCl (Wnt agonists), and both, respectively. The mRNA and protein levels of WNT8b, α-SMA, calcification associated molecules, the Wnt signaling pathway related molecules were determined by reverse transcription quantitative polymerase chain reaction (RT-qPCR) and western blot analysis. TOP/FOP-Flash reporter assay was performed to detect transcription activity mediated by β-catenin.

Results: si-WNT8b reduced calcium deposition and activity of ALP, increased α-SMA level, and dropped BMP2, Pit1, MSX2, and Runx2 levels, while stimulation of LiCl worsened β-GP-induced calcium deposition, increased activity of ALP, reduced α-SMA expression level. si-WNT8b resulted in reductions in WNT8b, Fzd4, β-catenin, p-GSK-3β, and cyclin-D, whereas enhancement of p-β-catenin and GSK-3β, indicating si-WNT8b could alter the Wnt/β-catenin signaling pathway thus to hamper the vascular calcification in T/G HA-VSMC, which further demonstrated by TOP/FOP FLASH assay and detection of β-catenin expression level in the nucleus.

Conclusions: Taken together, we conclude that WNT8b knockdown abolishes phosphate-induced vascular calcification in VSMCs by inhibiting the Wnt/β-catenin signaling pathway.

FR-PO494

High Phosphate Diet Before Pregnancy Dysregulates Phosphate Metabolism in Neonatal Offspring Mice

Mayu Hayashi,[1] Shiori Fukuda,[1] Maki Kishimoto,[1] Hironori Yamamoto,[2] Masashi Masuda,[1] Yutaka Taketani.[1] *[1]Tokushima University, Tokushima, Japan; [2]Dept. of Health and Nutrition, Jin-ai University, Echizen city, Fukui, Japan*.

Background: Excess intake of dietary phosphate (Pi) increases fibroblast growth factor 23 (FGF23) and parathyroid hormone (PTH) to maintain plasma Pi level. FGF23, is a potent phosphaturic factor, binds to α-klotho / FGFR complex in the kidney to promote excretion of Pi into urine. In addition, excess intake of dietary Pi also decreases in renal α-klotho expression. Downregulation or lack of α-klotho induces a premature aging-like phenotype such as ectopic calcification and osteoporosis resulted from hyperphosphatemia. Recent the theory of developmental origins of health and disease indicates that early exposure of dietary or environmental factors determines the risk of various diseases in adulthood. Thus, excess intake of dietary Pi during or before pregnant period may affect the gene expression of α-klotho or other Pi regulating factors related to future health risks in offsprings.

Methods: To investigate that, we used C57BL/6J female mice aged 8 weeks old. Mice were fed with either control Pi (CP) or high Pi (HP) diet for 21 days before pregnancy. At the end of diet control, they were mated with male mice and become pregnant. After the delivery, both groups were fed with CP diet. Neonatal offspring mice (at 3 weeks old when they were weaning) were subjected to analysis.

Results: As a result, although the no difference of Pi and calcium levels in breast milk between two groups, the offspring mice in HP diet group revealed plasma FGF23 concentration was significantly elevated, urinary Pi excretion tended to increase and urinary calcium excretion tended to decrease. Renal α-klotho mRNA expression level was not changed in the both groups. But interestingly, renal mRNA expression level of NaPi2c and CYP27B1, which are known to be suppressed by the FGF23/α-klotho signal was decreased in HP diet group. Femur mRNA expression level of Phex, which is known to FGF23 secretory suppression factor at the bone was increased in HP diet group. In addition, femur mRNA expression level of DNA methyltransferase (DNMT1) was significantly increased in HP diet group.

Conclusions: In conclusion, excessive dietary Pi intake before pregnant causes abnormal Pi metabolism, and it may be due to epigenetic modification through DNA methylation at bone.

FR-PO495

Nox1 Induces Osteoblastic Transition of Vascular Smooth Muscle Cells and Contributes to Vascular Calcification in Early CKD Rats with Normal Serum Phosphorus

Hui Xu. *Nephrology Department, Xiangya Hospital, Central South University, Changsha, Hunan, China, ChangSha, China*.

Background: Vascular calcification (VC) is a major cause of mortality in patients with chronic kidney disease (CKD). While higher levels of serum phosphorus contribute to VC, but in early CKD patients with normal phosphorus have VC, and reduction of serum P by using various P binder is not effective in preventing VC progression in patients with CKD. So, we think some other factors contribute to VC, especially in Early CKD.

Methods: In CKD dialysis patients with VC (n=11) and dialysis CKD patients without VC (n=13), serum 8-OHdG was measured. We use CKD5 and early CKD rats to test the Vascular calcification and Nox1, we also use the serum of early CKD patients to incubate **primary VSMCs** , SM22α expression and RUNX2 expression, calcium deposition in primary rat VSMCs and Nox1 are measured.

Results: In a rat model for the stage 5 CKD (CKD5), robust increases of VC and 8-OHdG, significant reductions of smooth muscle 22 alpha (SM22α) expression, and an upregulation in RUNX2 expression in vascular smooth muscle cells (VSMCs) were demonstrated. Inhibition of 8-OHdG using MnTMPyP dramatically reduced these events without normalization hyperphosphatemia. In CKD patients with VC (n=11) but not in CKD patients without VC (n=13), 8-OHdG was significantly elevated. While the serum levels of calcium and phosphate were not altered in animal models in the early stage CKD (ECKD), 8-OHdG, VC, SM22α downregulation, RUNX2 upregulation, and NADPH oxidase 1 (NOX1) expression in VSMCs were all significantly changed. More importantly serum (10%) derived from patients with ECKD (n=30) or CKD5 (n=30) significantly induced SM22α downregulation, RUNX2 upregulation, NOX1 upregulation along with a robust 8-OHdG, and calcium deposition in primary rat VSMCs. These alterations were all reduced by MnTMPyP and a specific NOX1 inhibitor (ML171).

Conclusions: Collectively, we provide evidence for an important role of Nox1 in promoting VC development in early CKD patients, which was at least in part through induction of osteoblastic transition in VSMCs.

FR-PO496

Polymer Characterization of VS-505, a Novel Non-Absorbed, Calcium- and Aluminum-Free Phosphate Binder

J. Ruth Wu-Wong,[1] Yung-wu Chen,[1] Tony Zhang,[2] Jin Tian.[2] *[1]Vidasym, Chicago, IL; [2]Alebund, Shanghai, China*.

Background: Inadequate control of phosphate in chronic kidney disease can lead to pathologies of clinical importance. VS-505 is a novel phosphate binder, which has been evaluated in hemodialysis subjects with hyperphosphatemia for 8 weeks (ClinicalTrials.gov Identifier #: NCT02469467) with the following results: (1) significantly reduced plasma phosphorus (Pi) in the treatment group (median Pi change -2.40 mg/dl), (2) no changes of iron parameters, and (3) no change of Ca levels, but a significant reduction in iPTH and CaxPi over the treatment period.

Methods: In this study, VS-505 was characterized by FT/IR spectroscopy (Fourier Transform Infrared), XPS (X-ray Photoelectron Spectroscopy), and ^{57}Fe Mössbauer spectroscopy. VS-505 is not soluble in regular NMR solution/solvent, and thus was analyzed by a 750 MHz solid-state NMR spectroscopy. In 5% EDTA, VS-505 was partially solubilized, and the solubilized material was analyzed by size exclusion chromatograph.

Results: VS-505 has a high density (1.95 vs. 1.27 g/cm^3 for sevelamer, by helium pycnometer) with a reduced pill size. When exposed to simulated gastric fluid, VS-505 exhibits a low swell volume (0.4 vs. 4 cm^3/ml/0.1 g for sevelamer), and low iron release (<3% Fe^{+3} vs. 53% for sucroferric oxyhydroxide) after 2 hr of incubation at 37°C. FTIR spectrum of VS-505 conforms with that of gum Arabic, indicating that gum Arabic is the main component in VS-505. Results from XPS show the presence of Fe, C and O in VS-505, devoid of chloride and other impurities. Mössbauer spectroscopy results indicate that all Fe atoms in VS-505 are in the high-spin Fe^{+3} state. Solid-state NMR results show significant differences in chemical shifts between gum Arabic and VS-505, implicating the presence of tight complex between iron ion and gum Arabic. Results from the size exclusion chromatograph with solubilized material in 5% EDTA indicate that gum Arabic in VS-505 maintains its original molecular weight with chelated iron ion.

Conclusions: The characterization shows that VS-505 is a stable complex with 30% iron ion chelated to 70% gum Arabic (by weight). While effectively binding phosphate, VS-505 releases <3% of its iron content in gastric fluid, and doesn't significantly affect blood iron parameters in both pre-clinical and clinical studies.

FR-PO497

Discovery of a Novel NPT2b Inhibitor That Inhibits Intestinal Phosphate Absorption in Mice and Rats

Xiaojun Wang, Yanping Xu, Xiaohong Yu, Asim B. Dey, Hong Y. Zhang, Charity Zink, Dariusz Wodka, Gina Porter, William F. Matter, Leah L. Porras, Charles A. Reidy, Jeffrey A. Peterson, Brian Mattioni, John Wetterau. *Eli Lilly and Company, Indianapolis, IN*.

Background: Hyperphosphatemia in CKD and ESRD contributes to bone, kidney and CV diseases. Inhibition of the intestinal phosphate (Pi) transporter, NPT2b, may be an approach to augment current therapies for hyperphosphatemia.

Methods: Utilizing radiolabeled Pi uptake assays in CHO cells over-expressing various Pi transporters, and a mouse model, we discovered a novel NPT2b inhibitor, LY3358966. Due to the insoluble nature of the compound at acidic and neutral pH, the sodium salt of the compound was formulated in PVP-VA for further characterization. An amorphous solid dose formulation suitable for clinical development was prepared by spray dry dispersion and incorporated into a capsule and further tested for activity in mice.

Results: LY3358966 inhibited Pi uptake in CHO cells over-expressing human, mouse and rat NPT2b with an IC50 of 32.4, 43.9, and 26.8 nM, respectively. Formulated in PVP-VA and dosed in water, the compound has desirable PK properties for a drug target found on the luminal surface of the small intestine, with low bioavailability, and very low serum free drug concentrations. LY3358966 acutely (15 min) inhibited Pi absorption in mice with an ED50 of 0.15 mg/kg and Emax of 73%. Four hours after dosing the inhibitor, the ED50 was 1.12 mg/kg and Emax was 79%. In contrast, it acutely inhibited Pi absorption with an ED50 of 0.051 mg/kg and an Emax of only 19% in rats. Importantly, a solid dose formulation of

LY3358966 incorporated into a capsule effectively inhibited Pi uptake in mice. Following three 10 mg/kg doses of LY3358966 and radiolabeled Pi, mouse feces were collected for 48 hours. Compared to placebo treated animals, there was a significant increase in radiolabeled Pi recovered in feces (8.6% of the dose, $p < 0.0001$).

Conclusions: LY3358966 is a potent NPT2b inhibitor with desirable PK properties that inhibits Pi absorption in mice when dosed in a solid dose formulation acceptable for clinical development. Using a pharmacological approach, we achieved an inhibition of Pi absorption in mice comparable to that reported in NPT2b knockout mouse models. The NPT2b inhibitor had less effect on acute Pi absorption in rats.

Stronger Phosphate Lowering Effects of a Novel PiT-1/PiT-2/NaPi-IIb Triple Inhibitor EOS789 in Hyperphosphatemia Than a NaPi-IIb Inhibitor

Shuichi Ohtomo,[1] Yoshinori Tsuboi,[1] Yasuhiro Ichida,[1] Hitoshi Hagita,[2] Manami Iida,[1] Naoshi Horiba.[1] *[1]Chugai Pharmaceutical Co. Ltd., Gotemba, Shizuoka, Japan; [2]Chugai Research Institute for Medical Science, Inc., Gotemba, Japan.*

Background: EOS789 is a novel inhibitor of the sodium-dependent phosphate co-transporters PiT-1, PiT-2, and NaPi-IIb, which play central roles in intestinal phosphate absorption.

Methods: The in vitro inhibitory activity and the in vivo potency of EOS789 were evaluated.

Results: The in vitro IC_{50} values of EOS789 on human or rat NaPi-IIa, NaPi-IIb, NaPi-IIc, PiT-1, and PiT-2 were between 1 and 10 μM, and its IC_{50} value on sodium-dependent phosphate uptake in rat small intestinal brush border membrane vesicles was 3.1 μM. The inhibitory effect of EOS789 on intestinal phosphorus uptake was evaluated in healthy rats by fecal phosphorus excretion rate. EOS789 dose-dependently increased the fecal phosphorus excretion rate and inversely decreased the urinary phosphorus excretion rate. The effects of EOS789 on serum phosphorus, FGF23, and intact PTH concentrations were evaluated in a hyperphosphatemia model of adenine-induced nephritis rats. After 14 days food admixture dosing of EOS789 with a dose between 0.015% and 0.5%, the serum phosphorus, FGF23, and intact PTH concentrations were decreased dose-dependently. Notably, EOS789 at the highest dose decreased these serum parameters to below their values in normal control rats. In addition, EOS789 exhibited a more potent effect on serum phosphorus than a NaPi-IIb-selective inhibitor in hyperphosphatemia rats. The effect of EOS789 on the progression of chronic kidney disease was also evaluated in chronic anti-Thy1.1 nephritis rats. During the experimental period, dietary dosing of EOS789 provided a sustained suppression of serum phosphorus, FGF23, and intact PTH. After 16 weeks of dosing, EOS789 significantly decreased serum creatinine concentration in parallel with suppression of fibrosis-related mRNA and pro-inflammatory cytokine mRNA expressions. In addition, EOS789 significantly ameliorated ectopic calcification of the thoracic aorta.

Conclusions: This series of data suggests that EOS789 has a robust lowering effect on serum phosphorus under hyperphosphatemic conditions, and that EOS789 treatment can ameliorate renal function deterioration and protect the cardiovascular system from ectopic calcification.

FR-PO499

Combination Treatment with Tenapanor and Sevelamer Synergistically Reduces Urinary Phosphate Excretion in Rats

Andrew J. King, Jill N. Kohler, Cyra Fung, Zhengfeng Jiang, Allison Quach, Padmapriya Kumaraswamy, David P. Rosenbaum. *Ardelyx, Fremont, CA.*

Background: Many chronic kidney disease (CKD) patients on dialysis fail to achieve target serum phosphate (P) levels, despite treatment with available P binding agents. Tenapanor is a first-in-class, minimally absorbed small molecule NHE3 inhibitor that reduces intestinal P absorption and is under investigation as a novel treatment for hyperphosphatemia in CKD patients on dialysis. This study evaluated the effect of tenapanor and varying doses of sevelamer carbonate administered alone and in combination on urinary P excretion, an index of intestinal P absorption, in rats.

Methods: Male Sprague Dawley rats were assigned to groups dosed orally with vehicle or tenapanor (0.3 mg/kg/day) and provided with a diet containing varying amounts of sevelamer (0-3% w/w) for 11 days. 24-hour urinary P excretion was measured over the final 4 days. The effect of the addition of tenapanor (0.3 mg/kg/day) or vehicle for 7-days on 24-hour urinary P excretion in rats (n=6/group) already on a stable dose of sevelamer (1.5% w/w) for 6 days was also assessed.

Results: In combination with tenapanor, sevelamer dose-dependently decreased urinary P excretion such that the combination effect was significantly greater than either tenapanor or the equivalent dose of sevelamer alone across all sevelamer dose levels (**Figure**). The BLISS statistical model of independence indicated that the drug combination interaction between tenapanor and sevelamer was synergistic. On a stable sevelamer dose (1.5% w/w) that reduced urinary P excretion by 42 ± 3% (*P<0.001*), the addition of tenapanor reduced residual urinary P excretion by 37 ± 6% (*P<0.05*).

Conclusions: The combination of tenapanor and sevelamer results in greater reductions in intestinal P absorption than when either agent is administered alone. Clinical evaluation of the potential for the combination of tenapanor and sevelamer to more effectively achieve serum P target levels in hyperphosphatemic CKD patients on dialysis is warranted.

FR-PO500

Effects of Ferric Citrate on Phosphate Metabolism in Alport Mice with CKD

Komuraiah Myakala,[1] Xiaoxin Wang,[2] Moshe Levi.[2] *[1]Biochemistry, Georgetown University, Washington, DC; [2]Georgetown University, Washington, DC.*

Background: The maintenance of phosphate (Pi) homeostasis depends on the absorption of Pi across the intestine, reabsorption by the kidney and resorption by the bone. The mechanisms however still remain unknown and the role of intestinal Pi transport is subject of ongoing debate. Hyperphosphatemia is a common occurrence and plays important roles in cardiovascular and metabolic bone disease. Normalizing the serum Pi by reducing the dietary Pi intake can resolve the biochemical changes which may improve the clinical outcomes in CKD. To investigate the role of intestinal Pi absorption, we studied the effects of the Pi-binder Ferric Citrate (FC) on reducing intestinal absorption of Pi in a mouse model of progressive CKD

Methods: 4-week old wild type (WT) and Col4a3 knockout (Alport, CKD) mice (n=6 to 8 per group) were fed with control diet (0.9% Pi, 0.6% Ca^{2+}) or control diet supplemented with 2% or 3% ferric citrate (FC) for 5 to 6 weeks. Tissues were harvested and serum biochemistry was measured at 9-10 weeks old mice. To determine the intestinal Pi transport mechanism in CKD, we isolated apical brush border membrane vesicles (BBMVs) from the ileum and studied sodium gradient dependent Pi (Na^+/Pi) transport and NaPi-2b protein abundance.

Results: Serum BUN and Pi were increased significantly in Alport CKD mice compared to WT. In parallel to Pi, serum FGF23 levels were markedly increased in CKD mice. Dietary FC administration in CKD mice significantly reduces the serum Pi levels along with a significant decrease in intact FGF23. In addition, serum calcium (Ca^{2+}) was reduced significantly in CKD mice compared to WT. FC diet improved Ca^{2+} levels in CKD mice. The excretion of Pi in the urine was increased in CKD mice compared to WT mice and in contrast, urinary Pi was reduced in both wild type and CKD mice fed with FC. BBMV Na^+/Pi cotransport activity was comparable between WT and CKD mice fed with control diet. However, BBMV Na^+/Pi transport activity was increased in both WT and CKD mice fed with FC diet. This was associated with a 2-fold increase in BBMV NaPi-2b protein abundance.

Conclusions: Our data indicates that, the administration of FC improved the dysregulated Pi metabolism in CKD. However, the resultant increase in NaPi-2b protein abundance suggest that FC or any other Pi binder needs to be administered at all times with the diet.

FR-PO501

Effects of Low-Dose Ferric Citrate on Hematologic and FGF23 Parameters in High-Hepcidin Murine Models with and Without CKD

Mark R. Hanudel, Maxime Rappaport, Victoria R. Gabayan, Isidro B. Salusky, Elizabeta Nemeth, Tomas Ganz. *UCLA, Los Angeles, CA.*

Background: Ferric citrate (FC) is an effective phosphate binder and iron supplement in CKD patients. FC-delivered iron is enterally absorbed, despite high hepcidin levels, but the specific absorption mechanism and its regulation remain unknown. We assessed the effects of FC in *Tmprss6* knockout (TKO) mice, a model characterized by high hepcidin levels and resultant iron-refractory iron-deficiency anemia, without or with the addition of adenine-induced CKD, which exacerbates anemia and iron restriction.

Methods: Wild-type (WT) and TKO mice were fed diets with or without 0.2% adenine for 6 weeks (to induce CKD), with or without 0.1% FC for the last 3 of the 6 weeks (corresponding to an adult human FC dose of ~2 tablets thrice daily). Blood and tissues were then collected for analysis.

Results: In the absence of CKD, TKO mice compared to WT mice had significantly higher serum hepcidin, lower liver iron, lower serum iron, lower hemoglobin, higher serum erythropoietin (EPO), higher bone and marrow *Fgf23* mRNA, and higher plasma C-terminal (total) FGF23, but no difference in circulating intact FGF23. In TKO mice, despite high serum hepcidin, FC administration significantly decreased serum phosphate, increased liver iron, increased serum iron, increased hemoglobin, decreased serum EPO, decreased bone and marrow *Fgf23* mRNA, and decreased plasma total FGF23. With adenine-induced CKD, TKO mice had the highest hepcidin levels. FC treatment caused no significant changes in serum phosphate, liver iron, or serum iron, but significantly increased hemoglobin, with a trend towards lower serum EPO. FC therapy significantly decreased bone *Fgf23* mRNA,

marrow *Fgf23* mRNA, and plasma total FGF23, but not intact FGF23. Despite the very high hepcidin levels, FC increased duodenal ferroportin protein in the CKD TKO mice.

Conclusions: In the high-hepcidin TKO mice, low-dose FC was sufficient to increase enteral iron absorption and ferroportin expression, improve the anemia of both iron deficiency and CKD, and decrease FGF23 expression. FC may decrease FGF23 expression through decreased enteral phosphate absorption, improved iron status, and/or decreased EPO levels. Although murine FC dosing needs to be optimized, the models of FC absorption despite high hepcidin levels will facilitate examination of the mechanisms involved.

FR-PO502

Vitamin D Increases Bone FGF23 Expression by Increasing Numbers of Early Osteocytes

Renata C. Pereira,[2] Kathleen Noche,[5] Barbara Gales,[4] Isidro B. Salusky,[3] Katherine Wesseling-Perry.[1] *[1]David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]University of California, Los Angeles, CA; [3]Mattel Children's Hospital, Los Angeles, CA; [4]University of California Los Angeles, Los Angeles, CA; [5]UCLA, Los Angeles, CA.*

Background: Vitamin D directly stimulates osteoblast maturation and FGF23 expression. FGF23 is expressed in early osteocytes at the trabecular periphery. Whether the vitamin D-mediated increase in bone FGF23 expression reflects increased numbers of early osteocytes or an increase in per-osteocyte expression is unknown.

Methods: We evaluated markers of osteocyte maturity and FGF23 expression by immunohistochemistry (IH) and immunofluorescence (IF) and osteocyte apoptosis by TUNEL staining in iliac crest of 11 dialysis pts age 15.8±0.8 years who underwent bone biopsy before and after 8 mos of doxercalciferol (D) therapy. Bone protein expression was evaluated by Ariol scanning of IH. Numbers of FGF23-expressing osteocytes were counted and normalized by bone area. RNA was extracted from cores and evaluated by qRT-PCR.

Results: FGF23 co-localized with e11/gp38, a marker of early osteocytes (**Fig 1A**). Numbers of FGF23-expressing osteocytes correlated with FGF23 protein expression ($r=0.83$, $p<0.001$). Numbers of FGF23-expressing osteocytes increased by 226 (83, 440)% and FGF23 mRNA increased by 226 (124, 320)% in response to D. Expression of sclerostin, a mature osteocyte marker, increased in cortical bone in response to D ($p<0.05$). Osteocyte apoptosis was low at baseline but increased with D (**Fig 1B**).

Conclusions: The co-localization of FGF23 with e11/gp38 suggests that increased numbers of FGF23-expressing osteocytes reflect a D-mediated increase in early osteocytes. The tight relationships between FGF23 RNA message, FGF23 protein, and numbers of FGF23-expressing osteocytes suggest that D-mediated increases in FGF23 expression are due to increased numbers of FGF23-expressing osteocytes in CKD bone. Increased osteocyte apoptosis suggests that D is associated with increased osteocyte turnover. Further studies into altered osteocyte maturation, the effects of medications on osteocyte biology, and their implications for clinical bone disease in CKD patients are warranted.

FR-PO503

Primary CKD Osteoblasts Are Resistant to the Pro-Maturation Effects of 1,25D In Vitro

Renata C. Pereira,[2] Isidro B. Salusky,[3] Anne M. Delany,[4] Katherine Wesseling-Perry.[1] *[1]David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]University of California, Los Angeles, CA; [3]Mattel Children's Hospital, Los Angeles, CA; [4]University of Connecticut Health Center, Farmington, CT.*

Background: Osteoblast maturation and bone mineralization are integrally linked processes. Pediatric CKD patients have a high prevalence of skeletal mineralization defects *in vivo* and primary CKD osteoblasts demonstrate intrinsic impairments in maturation *in vitro*. 1,25D simultaneously stimulates osteoblast maturation and bone FGF23 expression while overexpression of FGF23 in primary rodent osteoblasts impairs their maturation and mineralization. However, the independent effects of 1,25D and FGF23 on osteoblast differentiation in CKD are unknown.

Methods: To investigate this, primary osteoblasts from 6 adolescent dialysis patients and 3 healthy adolescent controls were grown to confluence and stimulated to mineralize in differentiation media for 2 weeks. Mineralization was quantified by staining cultures with 1% Alizarin Red S; gene expression was evaluated by qPCR in parallel cultures.

Results: Mineralization was greater in healthy control than in CKD osteoblasts. 1,25D increased mineralization of CKD osteoblasts (**Fig A**). FGF23 did not affect mineralization in either CKD or healthy control cultures (**Fig B**). *Runx2* (early osteoblast marker) expression was similar in healthy control and CKD osteoblasts at baseline and increased in both groups with time. 1,25D increased *Runx2* in control, but not CKD, osteoblasts (**Fig C**). Osteocalcin (*Bglap*) (mature osteoblast marker) expression was higher in control than in CKD osteoblasts at baseline. 1,25D stimulated *Bglap* in both groups (**Fig D**). FGF23 did not affect *Runx2* or *Bglap*.

Conclusions: These data suggest that CKD osteoblasts are resistant to the pro-maturation effects of 1,25D. This 1,25D resistance may contribute to the mineralization defects that persist in pediatric CKD patients despite current renal osteodystrophy therapies. The mechanism behind CKD osteoblast maturation resistance, which appears unrelated to exogenous FGF23, requires further evaluation.

FR-PO504

1,25-Dihydroxyvitamin D Stimulation Increases FGF23 Expression in Calcified Vessels Under High Phosphate Condition

Masaki Ohya, Kazuki Kawakami, Tomohiro Sonou, Mitsuru Yashiro, Toru Mima, Shigeo Negi, Takashi Shigematsu. *Wakayama Medical University, Wakayama, Japan.*

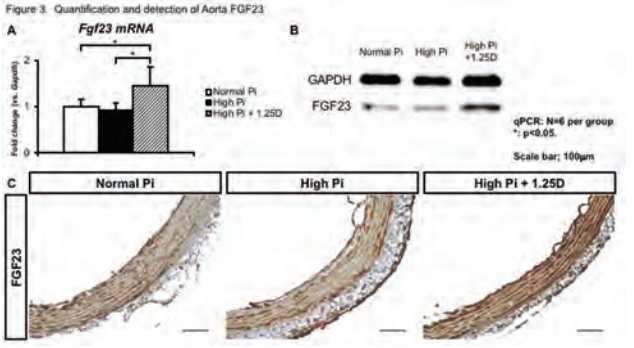
Background: Elevated fibroblast growth factor 23 (FGF23) is observed in patients with end stage renal disease (ESRD) or chronic kidney disease (CKD). Vascular calcification is also a commonly observed in patients with ESRD or CKD, which leads to increased cardiovascular events and mortality. Expression of FGF23 in bone is elevated by the factors as serum Pi, parathyroid hormone (PTH), and 1,25-Dihydroxyvitamin D, and is suppressed by dentin matrix protein-1 (DMP1). We hypothesized that 1,25-Dihydroxyvitamin D stimulates FGF23 expression in Pi-induced calcified vessels.

Methods: We performed aortic tissue culture in the medium with normal phosphate (0.9mM), high P (3.8mM)i, and high Pi with 1,25Dihydroxyvitamin D (1,25D) for 10 days, subsequently von kossa staining, quantification of calcium contents and gene expression of *Fgf23*, *Dmp1*, and other osteocyte/osteoblast marker; alkaline phosphatase (*Alp*), dickkopf-related protein 1 (*Dkk1*), and scrolostin, and immunostaining of FGF23 and DMP1 in the cultured aorta.

Results: Aortic ring cultured in the medium with high Pi and high Pi+1,25D showed calcium deposition and increased calcium contents significantly. Quantitative PCR demonstrated that increased*Alp*and *Dkk1*expression and unchanged *Sost* expression in high Pi+1,25D medium. Expression of FGF23 in aorta ring is not altered under the high Pi condition, but is increased under the high Pi+1,25D condition. DMP1 expression in aorta is increased under the high Pi condition while the up-regulation is attenuated under the high Pi+1,25D condition.

Conclusions: These results suggest that 1,25Dihydroxyvitamin stimulation increases FGF23 expression in calcified vessels under high phosphate condition.

Funding: Government Support - Non-U.S.



A. Quantification of *Fgf23*gene expression. B. Immunoblot image of FGF23 protein. C. Immunohistochmical images of FGF23 expression. Normal Pi; 0.9 mmol/L phosphate, High Pi; 3.8 mmol/L phosphate, High Pi+1.25D; 3.8 mmol/L phosphate and 100 nmol/L 1,25-Dihydroxyvitamin D_3.

FR-PO505

Osteocytes Are the Major Source of Circulating FGF23 During Acute Inflammation

Guillaume Courbon,[1] Claire Gerber,[1] Samantha Neuburg,[1] Maralee Capella,[1] Corey Dussold,[1] Xueyan Wang,[1] Lixin Qi,[1] Wenhan Chang,[2] Myles Wolf,[3] Aline Martin,[1] Valentin David.[1] *[1]Northwestern University - Feinberg School of Medicine, Chicago, IL; [2]Endocrine Unit, SF-VAMC, University of California San Francisco, San Francisco, CA; [3]Duke University, Durham, NC.*

Background: Inflammation is a novel mechanism that stimulates fibroblast growth factor (FGF) 23 production in bone cells and extraosseous tissues, however the contribution of osteocytes to circulating FGF23 levels during acute inflammation is unknown.

Methods: To investigate the effects of inflammation on FGF23 production, wild-type (WT) mice and mice with a conditional deletion (cKO) of Fgf23 in osteocytes (Fgf23fl/fl;DMP1-Cre+) received a single injection of interleukin-1β (IL-1β) or saline (Ctr). We measured FGF23 mRNA and circulating intact and total protein (cFGF23 which includes intact and cleaved proteins) up to 6 hours post injection.

Results: In WT mice, injection of IL-1β increased circulating levels of intact and total FGF23 (12-fold and 62-fold, respectively, $p<0.001$ vs Ctr). IL-1β increased *Fgf23* mRNA expression by 60 fold in bone, 7 fold in spleen and by 300 fold in kidney ($p<0.05$ vs. Ctr), suggesting that extraosseous production of FGF23 may contribute to circulating FGF23 levels. In line with these findings, cKO-Ctr mice did not show a significant reduction in circulating FGF23 compared to WT-Ctr mice, suggesting that extraosseous FGF23 production is sufficient to maintain relatively normal circulating FGF23 levels. However, cKO mice showed a markedly reduced FGF23 secretion in response to IL-1β injection compared to WT- IL-1β mice for both intact (-80%) and total FGF23 (-92%, $p<0.001$). Consistent with these data, bone *Fgf23* mRNA and protein expression levels were also dramatically reduced by 80% ($p<0.01$) in cKO- IL-1β mice compared to WT- IL-1β. Finally, IL-1β treatment of primary osteocytes cultures from WT and cKO animals increased *Fgf23* mRNA expression and protein secretion by 10 fold in WT mice ($p<0.05$ vs. Ctr) but failed to increase FGF23 in cKO cultures.

Conclusions: These results suggest that *Fgf23* expression is increased in bone and extraskeletal tissues during acute inflammation, however osteocytes are the major secretory source for the circulating FGF23 protein.

FR-PO506

Soluble Klotho Regulates TRPC6 Calcium Signaling via Lipid Rafts and Independently of FGFR-FGF23 Pathway

Jian Xie, Sung Wan An, Chou-Long Huang. *Carver school of Medicine, University of Iowa, Iowa City, IA.*

Background: Membranous Klotho interacts with fibroblast growth factor receptor (FGFR) to form coreceptors for FGF23. The ectodomain of membranous klotho is shed (soluble klotho, sKL) and functions as a circulating endocrine or local paracrine factor. sKL protects the heart by inhibiting growth factor-stimulated, PI3K-dependent TRPC6-mediated Ca entry. Lipid rafts are membrane microdomain important in many cellular processes including growth factor signaling and membrane trafficking. We have shown that sKL binds to sialogangliosides of membrane lipid rafts to inhibit cardiac Ca signaling. Regulation of lipid raft formation and function may underlie pleiotropic actions of sKL. A recent X-ray crystal structure of sKL in ternary complex with FGFR and FGF23 suggests that function of sKL is mediated by FGFR and FGF23. The physiological circulating levels of sKL and FGF23 are ~30 pM and 2 pM (50 pg/ml), respectively. Yet many in vitro assays examining the function of sKL, FGF23, and FGFR based on formation of the ternary complex utilize supraphysiological levels of sKL and FGF23. For example, in cell proliferation assay based on sKL-FGF23-FGFR ternary complex, 100 fold higher sKL (3 nM) and 4,000 fold higher FGF23 (200 ng/ml = 4 nM) are commonly used. Here, we examine whether sKL can function independently of FGFR-FGF23.

Methods: Computer modeling of sKL structure with and without FGFR-FGF23. Whole-cell patch-clamp recording of TRPC6 channels in L6 myoblast cell line lacking endogenous FGF receptors.

Results: Computer modeling of sKL structure suggests potential binding sites for sialic acids of gangliosides in the absence of FGFR-FGF23. sKL inhibits TRPC6 channel in L6 cells. We identified amino acid sequence unrelated to sKL but structurally conserved for binding sialic acid known as carbohydrate binding motif (CBM). Purified recombinant CBM inhibits TRPC6 expressed in L6 cells and in HEK293 cells.

Conclusions: Our results support the hypothesis that sKL protects the heart by downregulating TRPC6-mediated calcium signaling in lipid rafts. sKL can exert actions independently of FGFR-FGF23 signaling pathway.

Valsartan Mitigated CKD-MBD in Uremic Rats by Activation Klotho

Ao Cheng. *Department of Neprology, The Fist Affiliated Hospital of Xiamen University, Xiamen, China.*

Background: Valsartan as the most commonly one of ARB drugs, can effectively lower blood pressure and remit the progression of chronic kidney disease. In addition, we also observed that the ARB drugs could ameliorate the calcium and phosphorus metabolism in patients. The main purpose of this experiment is to explore whether valsartan could mitigate calcium and phosphorus metabolism and secondary hyperparathyroidism and seek the underlying signal pathway in uremic rats.

Methods: Animal Experiment: The rats were divided into three groups: sham group, 5/6 nephrectomy group, 5/6 nephrectomy + calcitriol group. 1) Through serum biochemical tests, to detect the levels of BUN, Creatine, Ca and P in various groups and determine expression of Klotho, TGFβ1, iPHT in serum. 2) By HE, Masson staining of renal tussues, Observation of fibrosis and collagen deposition in parathyroid tissue and renal tissue. 3) Detection expression of Klotho, TGFβ1, iPHT in parathyroid tussue by Immunohistochemical staining. 4) Detection expression of AT1, Klotho, TGFβ1, iPHT, E-cadherin and α-SMA in renal tussue by Immunohistochemical staining. 5) Using PCR and Western-Bloting detect expression of Klotho, TGFβ1, E-cadherin and α-SMA in renal tussues.

Results: (1) Valsartan could effectively reduce the elevated creatinine, BUN, improve the calcium and phosphorus metabolism and lessen iPTH in the 5/6 nephrectomy rats; (2) Valsartan can distinctly reduce parathyroid hyperplasia and iPTH expression, increased Klotho expression in parathyroid tissue; (3) Valsartan might ameliorate kidney injury and fibrosis by light microscopy; (4) In renal tissue, Valsartan may induce Klotho and E-cadherin expression and reduce iPTH, TGFβ1 and α-SMA expression.

Conclusions: Valsartan could suspress parathyroid hyperplasia and ameliorate kidney injury and fibrosis in uremic rats. Valsartan might delay the progression CKD-MBD in ESRD by increasing the expression of Klotho, reducing iPHT, improving calcium and phosphorus metabolism.

FR-PO508

Comparison of Four Commercially Available ELISA Kits for Serum and Urinary Klotho in Mice

Naoto Hamano,[1] Hirotaka Komaba,[1,2] Takehiko Wada,[1] Masafumi Fukagawa.[1] *[1]Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan; [2]The Institute of Medical Sciences, Tokai University, Isehara, Japan.*

Background: Klotho is a transmembrane protein that serves as a co-receptor for fibroblast growth factor 23 (FGF23). Klotho is cleaved and released into body fluids, including serum, urine, and cerebrospinal fluid. Soluble Klotho has been implicated in diverse of biological activities and an increasing number of studies measured serum or urinary soluble Klotho levels using commercially available ELISA kits. However, the sensitivity and specificity of these kits have been poorly studied.

Methods: We assessed the diagnostic accuracy of 4 commercially available ELISA kits for soluble Klotho using serum and urine from 3-week-old *Klotho* homozygous knockout (*Klotho*$^{-/-}$), heterozygous knockout (*Klotho*$^{-/+}$), and wild type littermate mice. We measured serum soluble Klotho with 4 kits and urinary soluble Klotho with 2 kits following the instructions of manufacturers.

Results: *Klotho*$^{-/-}$ mice showed hyperphosphatemia, high 1,25-dihydroxyvitamin D, low PTH, increased fractional excretion of phosphate, and markedly elevated FGF23, as described previously. All 4 kits for serum soluble Klotho measurements appeared to be inaccurate, with false positive results with sera from *Klotho*$^{-/-}$ mice. As for urinary soluble Klotho measurements, we found that only a kit from Immuno-Biological Laboratories Co., Ltd. provided reasonable results. With this assay, mean±SD creatinine-adjusted urinary soluble Klotho levels in *Klotho*$^{-/-}$ mice, *Klotho*$^{-/+}$ mice, and wild type mice were 5±2, 218±38, and 290±149 pg/g creatinine, respectively ($P<0.001$).

Conclusions: These results indicate that appropriate choice of the assay is important for accurately measuring soluble Klotho levels. For validating the function of ELISA kits, measurement of target elements with specimens of knockout animals would provide valuable information.

FR-PO509

Sclerostin, a Potential Mediator in the Bone-Vascular Axis

Annelies De maré,[1] Britt Opdebeeck,[2] Ellen Neven,[1] Patrick C. D'Haese,[2] Anja Verhulst.[1] *[1]University of Antwerp, Wilrijk, Belgium; [2]University Antwerp, Wilrijk, Belgium.*

Background: The Wnt/β-catenin signaling, one of the most important bone anabolic pathways, might also be a major player in the crosstalk within the bone-vascular-axis. When pathologically disturbed, this axis results in the concomitant occurrence of disturbed bone metabolism and vascular calcification (VC). A hallmark of these VCs is the transdifferentiation of vascular smooth muscle cells (VSMCs) towards bone-forming (osteochondrogenic) cells. In the current study we investigated parameters related to the Wnt/β-catenin signaling cascade and its inhibitor sclerostin.

Methods: Rats were given 0.3mg warfarin/g diet to induce VC. Rats not receiving warfarin were included as controls. Rats were sacrificed at different time-points, i.e. after 4, 6, 8 and 10 weeks of warfarin treatment, to follow up the development of VC. At sacrifice; VC, aortic mRNA expression and immunohistochemistry, bone status and serum biochemistry were analyzed.

Results: Results showed a time-dependent increase in VC in warfarin-treated rats. Aortic calcium concentration significantly differed from controls in 4-wk treated rats (p=0.0286), reaching a 50-fold increase in 10-wk treated rats (p=0.0061). Furthermore, aortic mRNA levels of osteochondrogenic transdifferentiation markers (Sox9, p=0.0317 and Cbfa1, p=0.0635) and β -catenin (regulating target gene transcription, p=0.0159) were upregulated. Interestingly, this went along with an upregulation of aortic mRNA expression (p=0.0159) and protein levels of sclerostin, as well as serum levels of this protein which became significant (p=0.0381) in 10-wk treated rats compared to controls. Finally, a mild but significant (p= 0.0095) decrease in bone formation parameters was observed in 10-wk treated warfarin rats.

Conclusions: Our results support the hypothesis that VSMCs transdifferentiate towards osteochondrogenic cells and thereby also express genes/proteins associated with the Wnt/β-catenin signaling, including its inhibitor sclerostin. The latter thereby may act as a negative feedback protein to prevent excessive (vascular) calcifications, similar to its function in bone. Sclerostin might also spillover from the vessels to the circulation (high serum sclerostin levels) causing mild inhibition of bone formation.

FR-PO510

Accumulation of Activated β-Catenin in Uremic Hyperparathyroid Glands

Ping Wen, Dawei Hou, Jinlong Cao, Junwei Yang. *Second Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: Parathyroid proliferation may become nodular mainly in cases of advanced uremic hyperparathyroidism. The ubiquitously expressed multifunctional protein β-catenin displays important functions in the canonical Wnt signaling pathway by regulating cell proliferation and differentiation. Activation of Wnt/β-catenin pathway leads to stimulate aerobic glycolysis, called Warburg effect, which is validated the dominant metabolic style in tumor tissue. While hyperplasic parathyroid glands display similar pathology characteristics of tumor, the aim of this study is to evaluate whether the Wnt/β-catenin signaling pathway is activated in hyperplastic glands from sHPT patients and if Warburg effect is activated by β-catenin pathway.

Methods: Serum iPTH levels were measured by radio-immunity method. Hyperplastic parathyroid glands from sHPT patients (n=36) were acquired from patients during the operation. Normal parathyroid tissue (n=3) was obtained from glands inadvertently removed in conjunction with thyroid surgery. Real time RT-PCR and immunohistochemistry were performed to detect PCNA and activated β-catenin, and glycolytic enzymes.

Results: 1. The average serum iPTH level was 1264.59±576.29 pg/ml of sHPT patients and 42.0±20.95 pg/ml of normal controls respectively. 2. HE staining revealed 5 diffuse hyperplasic glands and 31 nodular hyperplasic glands. 3. The mRNA and protein expression of PCNA was dramatically up-regulated compared to normal controls. 4. The expressions of activated β-catenin were increased in hyperplastic glands compared to normal glands. There was no difference between diffuse hyperplasic and nodular hyperplasic glands. Semiquantitative analysis didn't reveal association between β-catenin and iPTH level. 5. The expressions of glycolytic enzymes: HK2, PFK and LDH were not up-regulated in hyperplasic glands compared to the normal glands. Semiquantitative analysis didn't reveal associations between expressions of glycolytic enzymes and iPTH level.

Conclusions: Our results strongly suggest that modifications in the Wnt/β-catenin signaling pathway may be involved in the development of sHPT. However, aerobic glycolysis was not activated by β-catenin in hyperplasic glands. The precise mechanism is needed to be explored.

FR-PO511

In Silico Model of PTH-Induced Self-Limiting Anti-Apoptotic Signaling Pathways in Osteoblasts

Alhaji Cherif,[1] Doris H. Fuertinger,[2] Stephan Thijssen,[1] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Cyclical and continuous stimulations of cell receptors result in differential responses with important clinical and therapeutic implications. An example of such differential response is seen in the anabolic and catabolic outcomes of intermittent and continuous elevations of parathyroid hormones (PTH), respectively, where chronic level of PTH, as seen in hyperparathyroidism, leads to catabolic effects on bone, whereas cyclical administration of PTH or analogs, as seen in osteoporotic therapy, stimulates osteoblastic activities resulting in anabolic gains. The goal is to develop an *in silico* model describing the proteasomal proteolysis mechanism limiting the anti-apoptotic effect of PTH in osteoblasts, in order to understand quantitatively the differential clinical responses.

Methods: We develop a model to describe the underlying PTH-induced intracellular osteoblastic signaling pathway, namely, Runx-2-CREB-Bcl-2 signaling pathway. The model incorporates multiple scale to capture scale differences between the anti-apoptotic and degradative enzymatic activities. The model is used to evaluate apoptotic activities under the conditions of continuously and intermittently elevated PTH, respectively.

Results: *In silico* result shows that continuously elevated PTH increases degradative enzymatic activities and blunt the anti-apoptotic effects associated with the Runx-2-CREB-Bcl-2 signaling pathway. The directional difference between CREB and Runx-2 equilibrates Bcl-2 level, thereby nullifying its anti-apoptotic effects on osteoblasts. Consequently, PTH-mediated osteoclastic activities via RANK-RANKL-OPG pathway exert catabolic loss. The model also predicts that intermittency of PTH increases CREB while only intermittently decreasing Runx-2, resulting in a net increase in Bcl-2. This, in conjunction with downstream inhibition of cytokine-mediated osteoblastic apoptosis, leads to anabolic gains. Employing global sensitivity analysis, different anti-apoptotic therapeutic directions are outlined.

Conclusions: There is a great need to understand the mechanisms underlying differential osteoanabolic and catabolic responses induced by intermittent and continuous levels of PTH, respectively, in order to provide new therapeutic options for patients. With our model, we can demonstrate importance of Runx-2-CREB-Bcl-2 signaling in limiting the osteoblastic apoptosis.

FR-PO512

Severe CKD, Even Without a High-Phosphorus Diet, Affects the Expression of Only CaSR, VDR, and Gcm2 in the Parathyroid Glands in Rats but Not of Other Key Genes Involved in Parathyroid Function

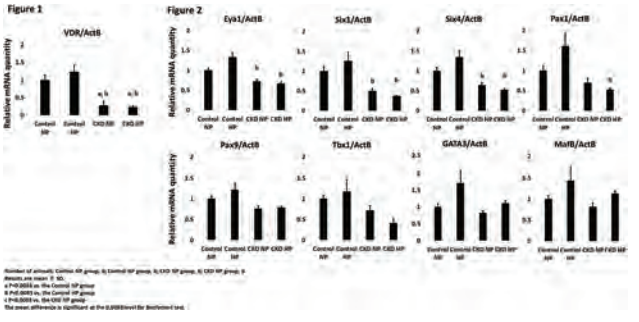
Taketo Uchiyama,[1] Ichiro Ohkido,[1] Sahoko Kamejima,[2] Akio Nakashima,[3] Takashi Yokoo.[4] *[1]Division of Nephrology and Hypertension, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan; [2]Jikei University School of Medicine, Tokyo, Japan; [3]Division of Kidney and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; [4]The Jikei University School of Medicine, Tokyo, Japan.*

Background: Secondary hyperparathyroidism (SHPT) is a common complication of chronic kidney disease (CKD), which disrupts mineral homeostasis. It occurs during the early course of progressive renal insufficiency, and is associated with mortality and cardiovascular events. Downregulation of calcium-sensing receptor (*CaSR*) and vitamin D receptor (*VDR*) occurs throughout this process. Previously, we reported that glial cells missing 2 (*Gcm2*), which directly regulates *CaSR* and is related to hyper- and hypoparathyroidism, may be responsible for the reduction in mRNA and protein levels of *CaSR* (ASN 2017). However, as many other important genes regulate parathyroid function, we aimed to investigate the role of these genes in SHPT progression.

Methods: CKD was induced in rats with 0.75% adenine-containing diet. CKD and control rats were maintained for 2 weeks on diets with 0.7% (normal; NP) or 1.3% (high; HP) phosphorus. For gene expression analysis, quantitative real-time polymerase chain reaction (PCR) was performed with TaqMan probes. Protein expressions was analyzed by immunohistochemistry and Western blotting. DNA methylation analysis was performed by restriction digestion and quantitative PCR.

Results: *VDR* mRNA and protein expression levels were reduced in CKD rats fed NP and HP diets. There was no significant difference in the DNA methylation status of *VDR* promoters among the four groups (Figure 1) as same as *CaSR* (ASN 2017). There were no significant differences in the gene expression levels of *MafB*, *GATA3*, *Eya1*, *Tbx1*, *Pax1*, *Pax9*, *Six1, Six4* (Figure 2), although the Gcm2 gene and protein expression levels were significantly decreased.

Conclusions: CKD NP and HP rats showed significant reductions in *CaSR*, *VDR* and *Gcm2* gene and protein expressions. Our data suggested that compared with *CaSR* and *VDR*, *Gcm2* plays a major role in SHPT progression and may be an important therapeutic target for SHPT.



FR-PO513

Effect of Ovariectomy on the Progression of CKD-Mineral Bone Disorder (CKD-MBD) in Cy/+ Rats

Colby Vorland,[1] Pamela Lachcik,[1] Courtney N. Nelson,[1] Neal X. Chen,[2] Sharon M. Moe,[2] Kathleen M. Hill Gallant.[1,2] *[1]Purdue University, West Lafayette, IN; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: There is increasing interest in sex as a biologic variable, yet studies have generally not examined the role of sex in the pathogenesis of CKD-MBD despite experimental and epidemiological evidence suggesting that estrogen is protective to kidney function and bone and thus CKD-MBD. In the Cy/+ rat model of CKD-MBD, a spontaneous genetic mutation causes progressive kidney function decline in males prior to 20 weeks of age, but kidney function is maintained in females past 80 weeks of age making it impractical to study these females as a model of CKD. Therefore, ovariectomy to mimic a post-menopausal state may accelerate the initiation of the CKD-MBD phenotype and enable the use of female Cy/+ rats in research.

Methods: Sixteen female Cy/+ rats were randomized to either ovariectomy (OVX) (n=8) or sham surgery (n=8) at 15 weeks of age. A casein-based diet was initiated at 24 weeks of age to promote kidney function decline as is done in studies with male Cy/+ rats. Blood was sampled at 10, 20, 25, 30, and 35 weeks of age, and analyzed for BUN, plasma phosphorus, and plasma calcium.

Results: Data collected on all n=16 through 25 weeks show that OVX rats have higher body weights ($p<0.0001$) (and lower uterine weights for n=4 that completed the 35 weeks of the study) confirming the success of the OVX procedure. Plasma phosphorus decreased over time in both groups ($p<0.0001$), but was not different between groups ($p=0.46$). Plasma calcium was not different between groups ($p=0.38$) and did not change over time ($p=0.57$). Plasma BUN decreased slightly over time in both groups ($p<0.01$) but remained in normal ranges, and there is no difference between OVX and sham ($p=0.23$). In n=2 OVX and n=2 sham that have completed the 35 weeks of the study, preliminary analysis shows no appreciable difference in BUN, phosphorus, or calcium between groups.

Conclusions: Analyses will continue through 35 weeks, however at 25 weeks of age, there is currently no indication that OVX accelerates kidney function decline in female Cy/+ rats. This is in contrast to Cy/+ male rats which can be phenotyped based on elevated BUN as early as 10 weeks of age, and by 25 weeks of age exhibit a ~50% reduction in kidney function (Moe et al. 2011).

FR-PO514

Advanced Glycation End-Products (AGEs) Accumulation and Skeletal Complications in CKD Patients

Noemi A. Roza,[3,1] Kelcia R. Quadros,[3,1] André B. Esteves,[3,1] Renata A. Franca,[3,1] Cynthia M. Borges,[3,1] Cinthia E. Carbonara,[3,1] Fabiana S. Antonialli,[3,1] Luciene dos Reis,[2] Vanda Jorgetti,[2] Rodrigo B. de Oliveira.[3,1] Laboratory for Evaluation of Mineral and Bone Disorder in Nephrology (LEMON) *[1]State University of Campinas, Campinas, Brazil; [2]University of Sao Paulo - Medical School - Nephrology Division, Sao Paulo, Brazil; [3]School of Medical Sciences, Campinas, Brazil.*

Background: Chronic kidney disease (CKD) has high rates of mortality related to uremic toxins and bone complications. Fractures risk is higher in CKD patients than general population and is dependent of cortical bone quality. We aim to investigate the relationships between advanced glycation end-products (AGEs) and bone in a cohort of patients at different stages of CKD.

Methods: 86 CKD patients (stages 3-4, N=26; hemodialysis, N=32; peritoneal dialysis, N=28) were included. AGEs levels were measured in serum (for glycated hemoglobin and pentosidine), skin (through AGE-Reader device), and cortical bone (by immunohistochemistry). Fracture risk was predicted using FRAX tool. Bone histomorphometry was performed to measure cortical porosity, thickness and volume.

Results: Age was 51±13 yrs., 48 (56%) male, 41 (48%) Caucasian and 16 (19%) diabetics; GFR was 6 (5-17) mL/min, body mass index (BMI) was 26±5 kg/m^2 and waist circumference 92±12 cm. AGEs levels in skin were 3.0±0.7 AU (reference: < 2.0 AU) and were positively correlated with age ($R=0.68$; $P=0.001$), glycated hemoglobin ($R=0.28$; $P=0.04$), risk for major osteoporotic fracture ($R=0.54$; $P=0.001$), hip fractures ($R=0.53$; $P=0.001$), Framingham risk ($R=0.53$; $P=0.001$). AGEs deposition in cortical bone were positively correlated with major osteoporotic fracture risk ($R=0.50$; $P=0.001$). Cortical thickness were negatively correlated with serum pentosidine ($R=-0.30$; $P=0.04$) and glycated hemoglobin levels ($R=-0.31$; $P=0.03$), Framingham Risk ($R=-0.33$; $P=0.02$), age ($R=-0.43$; $P=0.03$), BMI ($R=-0.43$; $P=0.03$), waist circumference ($R=-0.38$; $P=0.01$), and LDL-cholesterol ($R=-0.34$; $P=0.02$). Cortical porosity were positively correlated with cholesterol levels ($R=0.30$; $P=0.04$) and Framingham Risk ($R=0.32$; $P=0.03$).

Conclusions: AGEs were detected in cortical bone of CKD patients at different stages and correlates with their risk for major osteoporotic fractures; this risk was also related with AGEs accumulation in skin. Serum levels of pentosidine and glycated hemoglobin were associated to low thickness of cortical bone. Finally, there seems to be a relationship between poor quality of cortical bone and factors linked to cardiovascular disease.

FR-PO515

PTH Suppression Normalizes CKD-Induced Elevations in Cortical Bone Perfusion in an Animal Model of Progressive CKD

Mohammad W. Aref,[1] Elizabeth A. Swallow,[2] Neal X. Chen,[3] Sharon M. Moe,[3] Matthew R. Allen.[3] *[1]IU School of Medicine, Indianapolis, IN; [2]Indiana University, Indianapolis, IN; [3]Indiana University School of Medicine, Indianapolis, IN.*

Background: Patients with chronic kidney disease (CKD) have accelerated bone loss, vascular calcification and abnormal biochemistries, together contributing to an increased risk of cardiovascular disease and fracture-associated mortality. Despite evidence of vascular pathologies and dysfunction in CKD, our group has shown that cortical bone tissue perfusion is higher in a rat model of high-turnover CKD. The goal of this experiment was to test the hypothesis that suppression of high turnover through calcium-induced suppression of PTH would normalize cortical bone vascular perfusion in the setting of CKD.

Methods: 35-week-old animals in one of three groups: normal (NL), Cy/+ (CKD), and Cy/+ treated with 3% calcium water (CKD+Ca) for 10 weeks (n=6/group) underwent intra-cardiac fluorescent microsphere injection to assess bone tissue perfusion.

Results: CKD animals had serum blood urea nitrogen (BUN) and PTH levels significantly higher than NL (+182% and +958%; $p<0.05$). CKD+Ca animals had BUN levels that were similar to CKD, while PTH levels were significantly lower and comparable to NL. Dynamic bone histomorphometry of the proximal tibia demonstrated that active remodeling surfaces were significantly increased in the CKD animals compared to normal (+88%); levels were normalized to NL levels by calcium supplementation. MicroCT analysis of the proximal tibia cortical porosity showed a trend toward higher values in CKD (+401%; $p=0.0962$) but not CKD+Ca (+111%; $p = 0.3787$) compared to NL. Both femoral cortex (+220%, $p=0.0083$) and tibial cortex (+336, $p=0.0009$) tissue perfusion were significantly higher in CKD animals when compared to NL; perfusion was normalized to those of NL in CKD+Ca animals.

Conclusions: These data demonstrate that the combination of bone remodeling suppression and serum PTH reduction normalizes cortical bone perfusion in the setting of CKD. Further work will focus on uncoupling the effects of PTH reduction and turnover suppression on cortical bone perfusion in the setting of CKD.

FR-PO516

Inflammation and Bone Loss in Patients with New Onset of Lupus Nephritis: The Pathways to Increased Osteoclastogenesis

Ana P. De Lima,[3] Wagner Dominguez,[4] Cristiane B. Dias,[5] Luciene dos Reis,[4] Vanda Jorgetti,[2] Viktoria Woronik.[1] *[1]Nephrology, University of São Paulo, São Paulo, Brazil; [2]Universidade de Sao Paulo, Sao Paulo, Brazil; [3]Universidade de São Paulo, São Paulo, Brazil; [4]University of Sao Paulo - Medical School - Nephrology Division, Sao Paulo, Brazil; [5]University of Sao Paulo, Brazil, São Paulo, Brazil.*

Background: The pathogenesis of lupus nephritis (LN) comprises immune complexes deposition, abnormalities of complement system,T,B and regulatory cells-TREG, unbalance of Th1/Th2 subsets and IL17. Bone loss is present in newly diagnosed LN patients without an expressive dose of corticosteroids. Some evidences indicate an increased osteoclastogenesis as the main disturb of the remodeling process. Although the pathways that lead to bone loss are not completely understood, some systems are involved such as RANK-L/OPG, Wnt/βcatenin and Th17/IL17. In this context osteoblasts seems to play a remarkable role in mediating the crosstalk between bone and immune systems as well as osteoclast response. Vitamin D (VitD) is well-known for its role in bone mineralization but studies have been revealing its anti-inflammatory actions such as redirecting Th1 to Th2 response, suppressing Th17 and stimulating TREG. This study aimed to determine the pathways involved in abnormal osteoclastogenesis observed in women at the diagnosis of proliferative LN as well as evaluating if vitD can reverse this response.

Methods: We cultured the human osteoblastic cell line hFOB 1.19. Once mature, we divided cultures into those supplemented with serum from healthy controls (n=15) and LN patients (n-15) instead of fetal bovine serum. Then 1,25-dihydroxyvitaminD was added in two subgroups at 10^{-9}M e 10^{-7}M while vitD was absent in one subgroup in both healthy and LN women. After 48h of vitD addition, hFOB cultures were trypsinized. Flow Cytometry and multiplex assays were performed to test CD166, CD54, RANK-L, OPG, CD14, TLR4, NFκB, SOST, DKK1, βcatenin, IL6, IL1β, TNFα, IL2, IL17A, IL17F, IL21 and IL22.

Results: There was a tendency of DKK1 to be higher in LN patients than healthy controls at baseline without vitD (668.6x460.4pg/mg, p0.07) but at vitD 10^{-7}M the difference became significant (673.0x456.6pg/mg, p0.02). Without vitD, OPG was higher in the healthy group than LN (298.7x 178.8pg/mg, p0.003).

Conclusions: Osteoblasts cultured with LN serum tend to have lower levels of OPG, which can corroborate to increased osteoclastogenesis by inhibition of RANK-L action. Although DKK-1, an inhibitor of wnt/βcatenin pathway, tend to be higher in osteoblasts cultured with LN serum, no difference was observed in βcatenin levels among the groups.

FR-PO517

Validation of a Small Caliber Bone Biopsy for the Diagnosis of Renal Osteodystrophy

Etienne Novel-Catin,[1] Solenne Pelletier,[1] Denis Fouque,[1] Jean-Paul Roux,[3] Roland Chapurlat,[3] Tom Nickolas,[2] Marie-helene Lafage-proust.[4] *[1]University Center Hospital - Lyon Sud, Saint Priest, France; [2]Columbia University Medical Center, New York, NY; [3]inserm UMR 1033, lyon Cedex 08, France; [4]INSERM U1059-CHU, SAINT-ETIENNE, France.*

Background: Histomorphometric analysis of a transiliac bone biopsy is the gold standard for the diagnosis of renal osteodystrophy (ROD). This procedure is usually performed with an 8mm-diameter trephine. However, this procedure is progressively forgone due to its invasiveness and cost as well as to the increasing lack of experts able to carry it out. Our objective was to validate ROD diagnosis on halved bone samples, mimicking those obtained with a 4mm Jamshidi needle, a procedure of increasing popularity that has not been endorsed yet.

Methods: Fifty two bone biopsies performed in CKD patients with 8mm Meunier-Bordier trephines were included. Quantitative histomorphometric analysis of the complete bone samples was performed including assessment of bone mass (Bone volume, BV/TV,%), turnover (Bone Formation Rate, BFR, $\mu m^3/\mu m^2/d$, mineralizing surface, MS/BS,%, and Mineral Apposition Rate, MAR, μm/d), resorption (TRAP positive osteoclastic surface, OcS/BS, %), mineralization (osteoid surface, OS/BS %, osteoid thickness OTh, μm and Mineralization Lag Time, MLT, days). Each histological section was then divided lengthwise in two 4mm-wide hemi-biopsies. Histomorphometric analysis was repeated this time on one randomly chosen hemi-biopsy for each sample, blind form initial results. Diagnoses were classified as Osteitis Fibrosa (OF), Adynamic bone disease (ABD), Mixed uremic bone disease (MUO), Osteomalacia (OM) or other. Correlation of each parameter between the whole biopsy and the corresponding hemi-biopsy was studied using Pearson's test. Concordance between the ROD diagnosis obtained from the whole biopsy and the hemi biopsy was analyzed.

Results: Fifty two biopsies were analyzed including 39 OF, 3 ABD, 3 MUO, 3 OM and 4 Other. Correlations between whole 8mm-wide biopsies and the corresponding hemi-biopsies was for BV/TV, r=0.97, p<0.001, OS/BS, r=0.98, p<0.001, Oc.S/BS, r=0.98, p<0.001, and BFR/BS, r=0.93, p<0.001. Final diagnosis was concordant between the whole biopsy and the hemi-biopsies in 97% of cases.

Conclusions: Four mm wide bone biopsies allow for an accurate assessment of ROD in CKD patients. The replacement of Meunier/Bordier trephines with disposable Jamshidi-type needles could improve the procedure's feasibility at the patient's bedside, as well as decrease both its invasiveness and cost.

FR-PO518

Multiple Lower Doses of Zoledronate Reduces Skeletal Accumulation in the Setting of CKD

Elizabeth A. Swallow,[1] Mohammad W. Aref,[2] Spencer Sacks,[3] Demi R. Lehmkuhler,[1] Neal X. Chen,[4] Sharon M. Moe,[4] Matthew R. Allen.[4] *[1]Indiana University, Indianapolis, IN; [2]IU School of Medicine, Indianapolis, IN; [3]Marian University, Indianapolis, IN; [4]Indiana University School of Medicine, Indianapolis, IN.*

Background: Chronic Kidney Disease (CKD) results in a dramatic increase in skeletal fracture risk. Bisphosphates (BP) are an effective and common treatment for reducing fracture risk but they are not recommended in advanced CKD. We have recently shown higher skeletal accumulation of zoledronate (ZOL) in the setting of CKD. This study aimed to test the hypothesis that more frequent, lower dose administration of ZOL would alter skeletal accumulation profiles in CKD.

Methods: At 25 weeks of age, normal (NL) and CKD (Cy/+) rats were divided into control groups (no dosing), a single dose of a fluorescent-tagged ZOL (FAM-ZOL), or ten weekly doses of FAM-ZOL each at $1/10^{th}$ the dose of the single dose group. A subset of CKD animals were provided 3% calcium (Ca) in drinking water to lower PTH and bone remodelling. At 35 weeks of age, serum, tibia, ulna, radius, vertebra, femora, and mandible were collected. Bulk fluorescence levels were assessed using Spectral CT and data compared using 2-way ANOVA.

Results: At 35 weeks of age, all CKD groups had significantly higher blood urea nitrogen (BUN) compared to NL. Parathyroid hormone (PTH) levels were 10-fold greater in CKD animals compared to NL; Ca supplementation normalized PTH levels to those of NL. At all skeletal sites assessed CKD and CKD+Ca animals had higher FAM-ZOL levels compared to NL (+89 to +167%). The vertebra, radius, and ulna all showed significant dosing effects with the multiple dosed animals accumulating 20-32% less FAM-ZOL than those given a single dose. At the distal femur, there was a significant interaction between factors, with CKD+Ca animals having a 40% reduction in FAM-ZOL retention with multiple FAM-ZOL doses versus a single dose.

Conclusions: More frequent, lower dose administration result in significantly less zoledronic acid accumulation compared to a single dose at multiple skeletal sites.

FR-PO519

Effects of Fetuin-A-Containing Calciprotein Particle (CPP) on Posttranslational Modifications of Fetuin-A in HepG2 Cells

Hideki Uedono,[1] Akinobu Ochi,[1] Shinya Nakatani,[1] Akihiro Tsuda,[1] Katsuhito Mori,[1] Masanori Emoto,[1] Masaaki Inaba,[1] Tetsuo Shoji.[2] *[1]Osaka City University Graduate School of Medicine, Osaka, Japan; [2]Osaka City University Graduate School, Osaka, Japan.*

Background: Fetuin-A is a liver-derived circulating glycoprotein that has potent calcification-inhibitory capacity. Under calcification stress such as CKD, fetuin-A prevent ectopic calcification by forming colloidal complexes that comprise calcium, phosphate and fetuin-A, termed fetuin-A-containing calciprotein particle (CPP). Recent reports suggest that CPP may have physiological and pathological functions including induction of inflammation. The objective of this study was to investigate the effects of CPP on fetuin-A expression in hepatocytes.

Methods: Synthetic CPP was prepared as previously reported. Because fetuin-A is posttranslationally modified, the molecular weight (MW) of fetuin-A is known to be approximately 60 kDa (fully modified fetuin-A: FM-Fet), which is much higher than deduced MW based on amino acid sequence. We focused on the effects of synthetic CPP on FM-Fet expression using the human hepatoma HepG2 cell line.

Results: CPP increased protein expression of FM-Fet in dose- (462% increase by 100 μg/mL CPP for 24hr) and time-dependent manner. However, CPP did not affect the mRNA expression of fetuin-A. Although we focused on the effects of CPP on degradation pathways of fetuin-A such as the lysosome and the ubiquitin-proteasome system, these pathways were not involved in CPP-induced FM-Fet expression. Since FM-Fet contains N-linked and O-linked glycosylation sites, cell lysates containing CPP-induced FM-Fet were incubated with N-glycosidase PNGase F (peptide-N-glycosidase F) and/or O-glycosidase. Treatment with N-glycosidase and/or O-glycosidase increased the considerable mobility of 60 kDa form of FM-Fet, suggesting that CPP modulate N- and O- glycosidations of fetuin-A. After HepG2 cells were pretreated for 30 min with or without 1 μg/mL brefeldin A, which blocks the transport of proteins from the endoplasmic reticulum to the Golgi complex, cells were incubated in 100 μg/mL CPP for 24 hr. Treatment with brefeldin-A inhibited CPP-induced FM-Fet expression concomitant appearance of approximately 50-55 kDa form.

Conclusions: CPP could upregulate posttranslational modifications of fetuin-A in HepG2 cells. These findings suggest a positive feedback loop between increased CPP which may reflect fetuin-A deficiency in advanced CKD and up-regulation of secreted fetuin-A.

PPARγ Mediates Impaired Circadian Rhythmicity of Human Vascular Smooth Muscle Cells Cultured Under High Phosphate Environment

Ningning Wang,[1] Qingting Wang,[2] Ying Cui.[1] *[1]Department of Nephrology, The First Affiliated Hospital with Nanjing Medical University, Nanjing, China; [2]Nephrology, the First Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: The onset of cardiovascular disease (CVD) in chronic kidney disease(CKD) patients often vary by time-of-day. Peroxisome proliferator-activated receptor γ (PPARγ) has been confirmed to play an important role in vascular smooth muscle cells (VSMC) by acting as a peripheral factor participating in regulation of cardiovascular circadian rhythms. It has been reported that hyperphosphatemia plays a vital role in abnormal cardiovascular circadian rhythms. Here we aim to investigate the role of PPARγ in the biorhythm regulation of human aortic vascular smooth muscle cells (HASMCs) under high phosphate environment in vitro.

Methods: The HASMCs were divided into (1) normal control group (1.0 mmol/L phosphorus), (2) high phosphorus group (2.5 mmol/L phosphorus), (3)PPARγ activator rosiglitazone group (10 μmol/L), and (4) high phosphorus(2.5 mmol/L phosphorus) + rosiglitazone group (10 μmol/L) (n=3). The timing of the beginning stimulated was counted as time 0. Thereafter, cells were collected every 4 hours for a total of 28 hours. The mRNA expressions of PPARγ, Bmal1, Per2 and Rev-erbα in different groups of cells at different time points were detected by quantitative polymerase chain reaction (qRT-PCR).

Results: The mRNA expressions of PPARγ and clock genes Bmal1, Per2, Rev-erbα showed circadian rhythm in control group of HASMCs. A high-phosphorus environment could inhibit the expression of above genes, thereby destroying the normal biorhythm of HASMCs. After activating PPARγ by rosiglitazone, the expression of clock genes were up-regulated, and the inhibited biorhythm of HASMCs by high-phosphorus environment could be reversed(Fig1).

Conclusions: Expression of PPARγ and clock genes Bmal1, Per2, Rev-erbα in HASMCs has circadian rhythm. High phosphorus environment destroys their normal biological rhythms by inhibiting PPARγ. We uncovered a vital role of PPARγ in vascular rhythms disorders under high phosphate environment, suggesting the new treatment target of CVD in CKD patients.

NMR Metabolomic Profiling in Distinguishing Kidney Stone Formers from Controls

Aleksandar Denic, Ivan Vuckovic, Lisa E. Vaughan, Felicity T. Enders, Slobodan Macura, John C. Lieske, Andrew D. Rule. *Mayo Clinic, Rochester, MN.*

Background: NMR-based urine metabolomics has shown considerable potential in biomarker discovery. It is not fully understood why some individuals develop kidney stones and others do not. We hypothesized that certain urine metabolites can distinguish kidney stone formers from controls.

Methods: We used high resolution NMR spectroscopy to study urines of 255 adult first-time incident symptomatic stone formers (SF), and 255 age and sex-matched controls. This was split into a training dataset (2/3, n=171 SF/control each) and a test dataset (1/3, n=84 SF/control each). NMR spectra were normalized by total spectrum area. Sex and metabolites from NMR data were used in PLS discrimination analysis to fit a model that distinguishes stone formers from controls in the training dataset. Variables with VIP>0.8 were selected for inclusion and cross-validation was used to determine number of components in the final model.

Results: Among the 108 metabolites included in the final model, those with the strongest positive association with SF were 1,6-Anhydro-D-glucose, glucuronate, lactose and an unknown compound, while those with the strongest negative association were 2 unknown compounds and scyllo-inositol. The area under the curve for detecting stone formers with the metabolite panel was 0.66 in the training dataset and 0.57 in the validation dataset **(Figure).** Sensitivity and specificity were 78%/50% and 76%/36% in the training and validation sets, respectively.

Conclusions: This study found that a panel of urine metabolites could potentially discriminate those at risk for symptomatic kidney stones. Further studies are needed to identify the unknown compounds. Understanding the differential expression of these metabolites could shed new insights into the biology of kidney stone formation.

Matrix Protein Differences Between Various Stone Types

Jeffrey Wesson. *VA Medical Center, Milwaukee, WI.*

Background: Enrichment of highly anionic and highly cationic proteins was observed in calcium oxalate monohydrate (COM) stone matrix, but ittle is known about protein distributions other stone types. In this study, stone matrix proteins have been quantitatively identified in other stone types, including uric acid (UA), calcium oxalate dihydrate (COD), and basic calcium phosphate (BCP) using a previously reported method.

Methods: Stone matrix proteins were isolated from 11 COM stones (>60% COM content), 6 UA stone samples (>95% UA content), 6 COD stones (>50% COD content), and 5 BCP stones (>50% BCP content) by dissolution in sequential washes with an EDTA/SDS solution at pH=8 with dithiothreitol added. The solubilized proteins from each stone were concentrated and desalted by ultradiafiltration. Proteomic analysis was performed at the Medical College of Wisconsin Innovation Center using non-labelled, quantitative mass spectrometry methods and reported as spectral counts (SC), including only proteins with 2 or more peptide matches at >85% confidence, after removing keratin and redundant proteins.

Results: All samples contained >1,000 SC, but the total protein signal was slightly smaller in COM compared to other stone types. More than 400 unique proteins were identified in each stone type, but a smaller subset were both frequent and abundant in each stone type: 69 proteins in ≥7 of 11 COM stones (89% SC); 126 proteins in ≥4 of 6 COD stones (85% SC); 108 proteins in ≥3 of 5 BCP stones (92% SC), and 51 proteins in ≥4 of 6 UA stones (67% SC). Most abundant proteins were common between the different stone types, and all stone types were enriched in strongly cationic proteins. Calcium containing stones were also enriched in strongly anionic proteins, more prominently in COM compared to COD or BCP. UA stones exhibited a markedly different proteome compared to calcium stones, with fewer nuclear proteins and more inflammatory components.

Conclusions: Stone matrix proteins exhibit distinctly different patterns in each stone type, implying that unique crystal interactions with proteins and/or cell surfaces control their pathogenesis. The prominence of strongly anionic proteins in calcium stones, particularly in COM suggests that polyanion-polycation aggregation is a plausible mechanism for COM stone formation. Conversely, UA stone formation may be more dependent on inflammatory pathways, but the link to crystal aggregation is unkown.

Common CLDN2 Variants Are Associated with Kidney Stone Risk and Reduced Claudin-2 Expression in Human Tissue

Joshua N. Curry,[1] Chizu Tanikawa,[3] Yoichiro Kamatani,[4] Koichi Matsuda,[3] Alan S. Yu.[2] *[1]University of Kansas School of Medicine, Kansas City, KS; [2]University of Kansas Medical Center, Kansas City, KS; [3]The University of Tokyo, Minato-ku, Tokyo, Japan; [4]RIKEN Center for Integrative Medical Sciences, Yokohama, Japan.*

Background: The majority of calcium reabsorption in the proximal tubule (PT) occurs by an unknown route, although many studies suggest it is a passive process. The claudin family of proteins are tight junction proteins that in part modulate paracellular permeability and passive reabsorption in the kidney. The isoform claudin-2 forms cation-selective pores *in vitro* and is highly expressed in the PT. We previously showed that *Cldn2*$^{-/y}$ mice exhibit hypercalciuria and nephrocalcinosis, both of which are major risk factors for the development of kidney stones. We hypothesized that *CLDN2* polymorphisms would associate with susceptibility for nephrolithiasis. To date, genome-wide association studies of nephrolithiasis have excluded *CLDN2* from their analyses due to its location on the X chromosome.

Methods: Twelve SNPs in the *CLDN2* locus passed our inclusion criteria and were assessed by logistic methods for disease association in two separate patient populations. Meta-analysis of the 2 studies was subsequently conducted using METAL with a total of 11,130 kidney stone cases and 187,639 controls. Using the dataset from the Genotype-Tissue Expression (GTEx) project, we analyzed *cis*-acting eQTLs in the *CLDN2* locus. GTEx has insufficient kidney samples for eQTL analysis, but human kidney cortex and pancreas both exclusively express the same transcript (ENST00000540876.1). Thus, we analyzed pancreatic claudin-2 expression in association with *CLDN2* risk variants.

Results: Our findings show that 9 *CLDN2* SNPs were associated with nephrolithiasis with p-values of 0.0462-0.0055. Given our findings in *Cldn2*$^{-/y}$ mice, we predicted that *CLDN2* risk variants for kidney stones would lead to reduced claudin-2 expression. In 6 of the 7 *CLDN2* SNPs available for eQTL analysis using GTEx, nephrolithiasis risk alleles were strongly associated with decreased pancreatic claudin-2 expression.

Conclusions: Our present findings suggest that common *CLDN2* variants lead to reduced claudin-2 expression and thereby increase the risk for human kidney stone formation.

Urinary Stone Forming Crystals Activate Renal Medullary Epithelial Cells to Shed Extracellular Vesicles Containing Specific MicroRNAs and Proteins

Guotao Chen,[4] Muthuvel Jayachandran,[1] Jing jing Han,[2] Zejfa Haskic,[3] John C. Lieske.[1] *[1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic College of Medicine (Rochester), Rochester, MN; [3]Mayo clinic, Rochester, MN; [4]Department of Nephrology, The Bishan Hospital, Chongqing City, P.R. China, Chongqing city, China.*

Background: The majority (~80%) of urinary stones are comprised of calcium oxalate (CaOx) and/or hydroxyapatite (HA). Our previous studies suggest that populations of urinary extracellular vesicles (EVs) and their contents differ in stone formers. This study was designed to examined whether CaOx or HA crystals activate human renal medullary epithelial cells (HRMdEC) to shed EVs containing specific microRNAs (miRNAs) and their target proteins.

Methods: HRMdEC grown in 6-well tissue culture plates were synchronized by incubation in RenaLife Basal Medium without fetal bovine serum for one hour before exposure to CaOx monohydrate (COM) or HA crystals (100μg/mL). Aliquots of medium (250μL) were collected at 0, 0.5, 1, 3, 6, 12, and 24 hour (h). Populations of EVs in medium were analyzed by digital flow cytometer. Cells were harvested at 24h to determine expression of miRNAs identified previously in the urinary EVs of stone formers and their target proteins using qPCR and Western blotting, respectively. Data were analyzed by Student's t-test or Wilcoxon rank sum test.

Results: The total number of EVs (exosomes and microvesicles) in the medium was significantly increased ($P<0.05$) by 3h and progressively increased out to 24h after addition of COM or HA crystals. Cellular expression of preselected miR-1299, miR-146b-5p and miR-483-5p were increased whereas miR-532-5p and 664a-3p were decreased significantly ($P<0.05$) in response to COM crystals. Expression of miR-146b-5p was increased whereas miR-532-3p was decreased significantly ($P<0.05$) in response to HA crystals. Cellular expression of miR-146-5p and miR-532-3p targeted matrix matalloproteinase-16 was increased significantly ($P<0.05$) following COM crystal treatment.

Conclusions: Exposure of cultured renal medullary epithelial cells to urinary stone forming crystals activates them to shed EVs and express specific miRNAs and target proteins. The response to COM crystals was more robust that to HA. Further analysis of intra- and inter-cellular signaling pathways via EVs and miRNAs could elucidate novel cellular mechanisms in early urinary stone pathogenesis.

FR-PO525

Specific Inflammatory and Renal Cellular Injury Markers Are Found in Urinary Extracellular Vesicles and Proteins Associated with Nephrocalcinosis and Stones in Type 1 Primary Hyperoxaluria Patients

Muthuvel Jayachandran, Stanislav Yuzhakov, Andrew D. Rule, Dawn S. Milliner, John C. Lieske. *Mayo Clinic, Rochester, MN.*

Background: Our previous study showed that specific inflammatory (MCP-1) and renal cell injury (NGAL) molecule associated urinary extracellular vesicles (EVs) were significantly lower in calcium oxalate (CaOx) stone formers compared matched controls. Primary hyperoxaluria type 1 (PH1) can cause nephrocalcinosis (NC), CaOx stones, and chronic kidney disease but specific populations of urinary EVs contribution in these disease processes are not well known.

Methods: Bio-banked urine from PH1 patients without (n=10) and with nephrocalcinosis (n=6) or stones (n=9) and age-/sex-matched (± 5 years) living kidney donors (n=25) was studied. All patients had an eGFR > 40 and no prior kidney or liver transplantation. Urinary EVs were analyzed by digital flow cytometry and analyzed as EVs/μL urine or EVs /mg creatinine. A customized protein array was used to identify specific proteins in urine.

Results: Compared to healthy controls, PH1 patients excreted significantly greater EVs and EVs with surface biomarkers of inflammation (ICAM-1, MCP-1, tissue factor, VCAM-1), renal injury (β2-microglobulin (β2-M), clusterin, KIM-1, Laminin α-5, NGAL), of glomerular origin (juxtaglomerular, mesangial, podocyte, and parietal cells), and of tubular origin (proximal and distal tubule, collecting duct) (all $P<0.05$). PH1 patients with NC had fewer total EVs than PH1 patients without NC or stones ($P<0.05$). PH1 patients with kidney stones had fewer total EVs, and subgroups of EVs with biomarkers of inflammation, renal injury, glomerular origin, specific renal tubular and papillary origin compared to PH1 patients without NC or stones (all $P<0.05$). Excretion of soluble urinary MCP-1, CRP, and osteopontin were all significantly lower in PH1 patients with NC compared to PH1 patients without either NC or stones, or patients with stones alone ($P<0.05$). A similar trend for decreased urinary excretion of soluble CD14, endoglin, E-selectin, ICAM-1, PDGFRβ, and osteoprotegrin was observed in PH1 patients with NC compared to the other groups.

Conclusions: This study suggests that inflammation-associated EVs and proteins released from specific populations of renal parenchyma of PH1 patients may contribute nephrocalcinosis and stone pathogenesis.

Characterization of Oxalobacter Formigenes-Derived Factors as Potential Novel Therapeutic Agents for Hyperoxalemia, Hyperoxaluria, and Related Kidney Stones

Hatim A. Hassan,[1] Donna L. Arvans,[4] Changsoo Chang,[2] Christine Tesar,[5] Gyorgy Babnigg,[2] Altayeb Alshaikh,[1] Mark W. Musch,[3] Eugene B. Chang,[1] Andrzej Joachimiak.[2] *[1]University of Chicago, Chicago, IL; [2]Argonne National Laboratory, Argonne, IL; [3]U Chicago, Chicago, IL; [4]University of Chicago, LEMONT, IL; [5]Argonne National Lab, Argonne, IL.*

Background: Most kidney stones are composed of calcium oxalate, and small increases in urine oxalate significantly enhance the risk for stone formation. Hyperoxaluria is a major risk factor for calcium oxalate kidney stones (COKS) and it has no specific therapy. The gut bacterium *Oxalobacter formigenes* (*Of*) induces colonic oxalate secretion and reduces urinary oxalate excretion via an unknown secretagogue. Given the difficulties with recolonization, *Of* alone is not therapeutically feasible and underscores the need to identify the secretagogue inducing colonic oxalate secretion. We previously identified *Of*-derived factors secreted in its culture conditioned medium (CM) that stimulate (>2.8-fold) oxalate transport by human intestinal Caco2-BBE (C2) cells, and reduce (>32.5%) urinary oxalate excretion in hyperoxaluric mice by stimulating (>42%) distal colonic oxalate secretion. The *in vivo* retention of biologic activity reflects the therapeutic potential of these factors and support the pursuit of their characterization.

Methods: Using Mass spectrometry we identified multiple protiens in a family of a regulatory protein as the major *Of*-derived factors, and we have obtained the crystal structures for 5 of these proteins.

Results: The identified proteins closely recapitulate the effects of the *Of*-derived factors and stimulate (1.4-2.4-fold) oxalate transport by C2 cells via PKA and stimulation of the oxalate transporters SLC26A6 and SLC26A2 similar to CM. We also identified 35-amino acid peptides (P8+9) within one of these proteins that significantly stimulate (>2.4-fold) oxalate transport by C2 cells. P8+9 peptides also stimulated oxalate transport by human sigmoid colon (1.8-fold) and ileum (2-fold) organoids (*ex vivo* intestinal epithelia models fully mimicking the *in vivo* physiological responses), strongly suggesting that P8+9 peptides will stimulate oxalate transport in human colonic and ileal epithelia *in vivo*.

Conclusions: We identifed *Of*-derived peptides with singificant potential to stimulate oxalate transport in human colonic and ileal epithelia *in vivo*. Future studies will evaluate the therapeutic potential of these peptides in reducing urine and plasma oxalate levels in hyperoxaluric and hyperoxalemic mice, respectively.

FR-PO527

The Combination of Chlorthalidone and Potassium Citrate Is More Effective Than Either Agent Alone in Decreasing Calcium Oxalate Stone Formation in Genetic Hypercalciuric Stone-Forming Rats

Nancy S. Krieger,[1] John R. Asplin,[2] Ignacio Granja,[4] Evan Multala,[6] Courtney A. Flotteron,[7] Luojing Chen,[5] David A. Bushinsky.[3] *[1]Univ. of Rochester Medical Center, Rochester, NY; [2]Litholink Corp, Chicago, IL; [3]Univ. of Rochester Medical Center, Rochester, NY; [4]Litholink Corp, Chicago, IL; [5]Univ. of Rochester Medical Center, Rochester, NY; [6]Univ. of Rochester Medical Center, Rochester, NY; [7]Univ. of Rochester Medical Center, Rochester, NY.*

Background: To study human idiopathic hypercalciuria (IH) we developed an animal model, genetic hypercalciuric stone-forming (GHS) rats, whose pathophysiology parallels that of human IH. All GHS rats spontaneously form calcium phosphate (CaP) stones while there is no stone formation in the founder rats. When the oxalate precursor, hydroxyproline, is added to the diet, only calcium oxalate (CaOx) stones form. Previously, we demonstrated that chlorthalidone (CTD) alone was superior to potassium citrate (KCit) alone or in combination with CTD, in reducing CaP stone formation. In the current study we tested the hypothesis that CTD and KCit combined would effectively reduce CaOx stone formation in GHS rats.

Methods: 113th generation GHS rats were fed a fixed amount of a normal Ca (1.2%) and P (0.65%) diet with 5% hydroxyproline added, housed in metabolic cages and divided into four groups. Diets were supplemented with KCl (4 mmol/d) as control, KCit (4 mmol/d), CTD (4-5mg/kg/d)+KCl, or KCit+CTD. Urine (u) was collected at 6,12, and 18 wks for analyses and kidney stone formation was determined by X-ray at 18 weeks.

Results: Compared to the KCl control, KCit reduced uCa (KCl= 17.2±0.3 mg/d, KCit=14.4±0.3), CTD reduced it further (CTD=13.0±0.6) and KCit+CTD reduced it even further (KCit+CTD=9.3±0.4). The combination of KCit+CTD decreased uOx compared to all other groups (KCl=3.4±0.2 mg/d, K Cit=3.5±0.2, CTD=3.5±0.1, KCit+CTD= 2.7±0.1). Compared to KCl (108.7±2.2 mg/d), KCit and CTD+KCit increased uCit (KCit=146.6±2.6, KCit+CTD=129.9±3.3). There were no significant differences in CaOx supersaturation (ss) in any group. CTD did not change uCaP ss (KCl= 4.3±0.3, CTD=2.3±0.2), while KCit alone, or in combination with CTD, increased it (KCit=10.3±0.6, KCit+CTD=11.5±0.9). Compared to KCl (stone formation with a range of 0-4: KCl=2.1±0.1), KCit did not alter stone formation (2.0±0.3), while there was less stone formation in rats fed CTD alone (CTD=1.6±0.2). The combination of KCit+CTD (0.8±0.2) resulted in significantly fewer stones than KCl, CTD or KCit alone.

Conclusions: Thus in GHS rats fed a diet that results solely in CaOx stone formation, the combination of KCit+CTD prevented stone formation better than either agent alone.

Neutrophil Infiltration and NETosis in the Pathogenesis of Human Kidney Brushite Stones

Mohammad S. Makki,[4] Seth Winfree,[4] Frank Witzmann,[3] Elaine M. Worcester,[2] James Williams,[4] Tarek M. El-Achkar.[1] *[1]Indiana University, Indianapolis, IN; [2]University of Chicago, Chicago, IL; [3]Indiana University School of Medicine, Indianapolis, IN; [4]Indiana University School of Medicine, Indianapolis, IN.*

Background: The pathogenesis of kidney stones in humans is poorly understood. There are multiple types of kidney stones, and the role of inflammation in promoting specific stone types is not well established. Here, we applied a combination of unbiased omics and quantitative large-scale 3D imaging on kidney stones and papillae from two types of stone forming patients: calcium oxalate and brushite. Our goal was to uncover a specific inflammatory signature that could differentially associate with a specific type of stone disease and infer how they are formed.

Methods: Kidney stones were obtained from a well-characterized cohort of patients in a high volume clinic. Stones were further processed for label free quantitative mass spectrometry to quantify differentially expressed proteins. Papillary biopsies were obtained at the time of percutaneous nephrolithotomy and processed for histology and large scale 3D imaging. 3D tissue cytometry and analysis was done using Volumetric Tissue Cytometry and Analysis Software (VTEA).

Results: Brushite stones have differentially increased neutrophil proteins such as myeloperoxidase and elastase compared to calcium oxalate evaluated by LC/MS. To determine if this observation is driven by changes in the kidney papillae, we confirmed that the number (6.91 ±1.19% vs. 1.35 ± 0.28%; $p=3.2x10^{-5}$) and the density of neutrophils ($10.1x10^3$ ±$6.2x10^3/mm^3$ vs. $0.91x10^3$ ±$0.67x10^3/mm^3$; $p<0.05$) were increased in the papillae from brushite vs. calcium oxalate patients, respectively. To explain how neutrophil proteins are transitioning from the tissue to the stone matrix, we investigated whether Neutrophil Extracellular Trap (NET) formation, whereby neutrophils expel their DNA and their cytoplasmic content, is more common in brushite stones. Indeed, histone citrullination of neutrophils, a marker of NETosis, was increased in brushite compared the calcium oxalate papillae (1.3 ± 0.28% vs. 0.07 ±0.04%; $p<0.05$).

Conclusions: Our work supports that increased neutrophil infiltration and NETosis may be an important factor in the pathogenesis of brushite stones. We propose that metabolic changes or ascending infections could trigger a hyper-inflammatory response that leads to the release of NET proteins in the urine, which promote brushite stone formation.

FR-PO529

Inositol Phosphate Analogs as Inhibitors of Renal Calcium Oxalate Crystallization

Anna Kletzmayr,[1] Mattias E. Ivarsson,[2] Bastien Castagner,[3] Jean-Christophe Leroux.[1] Drug Delivery and Formulation *[1]ETH Zurich, Zurich, Switzerland; [2]Inositec Inc., Zurich, Switzerland; [3]McGill University, Montreal, QC, Canada.*

Background: Nephrocalcinosis and nephrolithiasis can be triggered by calcium oxalate (CaOx) crystallization, a main symptom in different forms of hyperoxaluria. To date, treatment options for pathologies involving renal CaOx crystallization are scarce, mostly aiming at slowing down disease progression, rather than directly targeting crystal growth and deposition. Inositol hexaphosphate (IP6) was previously shown to inhibit crystallization of calcium salts. Its clinical use, however, may be hampered by its low urine exposure following parenteral dosing. In this project, we aim at developing inhibitors against renal CaOx crystallization, based on IP6 analogs.

Methods: Potency of compounds to inhibit CaOx crystallization was assessed by light scattering measurements. Effects on the CaOx crystal morphology were characterized by light microscopy, followed by an automated image analysis and machine learning approach to classify different CaOx hydrate forms. *In vitro* cell experiments were performed using RPTEC human proximal tubular cells. Adhesion of CaOx crystals to a cell monolayer was determined by light microscopy and CaOx induced cellular toxicity *in vitro* was measured with a viability stain.

Results: In the initial screening of a small library of IP6 analogs, a subgroup of compounds that included IP5-mono-PEG_2 (INS-2001), showed inhibitory potential in the low micromolar range. Light microscopy experiments performed in human urine, confirmed the dose-dependent reduction in size of CaOx monohydrate crystals upon the addition of INS-2001. This compound also significantly reduced CaOx adhesion to renal epithelial cells at submicromolar concentrations. Additionally, protective effects of INS-2001 on CaOx induced cellular toxicity *in vitro* were observed.

Conclusions: The data generated with INS-2001 provide a starting point for further optimization of the IP6 analogs for treatment of renal CaOx crystallization. In subsequent steps, inhibitory effects of INS-2001 and related compounds on CaOx-induced fibrosis and inflammation *in vitro*, and *in vivo* efficacy will be characterized in depth.

FR-PO530

Effect of Alanine Supplementation on Oxalate Synthesis

Sonia Fargue,[1] Ross P. Holmes,[2] John Knight.[3] *[1]Urology, University of Alabama at Birmingham, Birmingham, AL; [2]UAB, Birmingham, AL; [3]University of Alabama at Birmingham, Birmingham, AL.*

Background: Alanine:glyoxylate aminotransferase (AGT) is the enzyme deficient in type 1 primary hyperoxaluria, which are a group of severe inherited kidney stone disorders characterized by an excessive endogenous synthesis of oxalate. The high Km of AGT for alanine (30 mM) and the lower level of alanine in human plasma (200-600 μM) suggest that AGT metabolic function, and therefore oxalate synthesis, could be improved by alanine supplementation. In support of this hypothesis, cells expressing normal or pathogenic variants of AGT and supplemented with L-alanine, have decreased synthesis of oxalate when incubated with an oxalate precursor, glycolate. In order to test whether L-alanine could improve AGT metabolic efficiency *in vivo*, we investigated the effect of L-alanine supplementation on the urinary excretion of oxalate in normal mice and mice deficient in AGT or Glyoxylate reductase (GR, deficient in primary hyperoxaluria type 2).

Methods: Wt, Gr Ko and Agt Ko mice were fed a low oxalate diet. Three 24 hr urines were collected in metabolic cages at baseline and after 1 week of equilibration with the low oxalate diet supplemented with 5-10% alanine. Plasma and liver alanine were measured by high-pressure liquid chromatography after extraction of the tissues. Urine oxalate was measured by ion chromatography coupled with mass spectrometry, urine creatinine was measured on a chemical analyzer. Statistical analysis was done with Student's paired t-test.

Results: Urinary oxalate was higher in Gr and Agt Ko compared with Wt mice at baseline (152 ±35, 215 ± 13 compared with 48 ± 5 μg oxalate/day, in GR KO, Agt Ko and Wt, respectively, $p<0.005$). Supplementation with L-alanine in the diet resulted in a 20-30% decrease in urinary oxalate in both Gr Ko and Wt animals (106 ± 20 and 36 ± 2 μg oxalate/day after supplementation, $p<0.002$ and $p<0.001$, respectively). There was no significant change in urinary excretion of oxalate in Agt Ko mice.

Conclusions: The urinary excretion of oxalate was decreased by dietary L-alanine supplementation in Wt and Gr Ko mice, which express functional Agt. These results suggest that L-alanine could prove useful as an adjunct therapy in PH2 and PH3, for which no specific treatment is currently available, and potentially idiopathic hyperoxaluria.

FR-PO531

The Role of the Microbiota in Mammalian Oxalate Metabolism

Lama Nazzal,[1] Menghan Liu,[1] Melody Ho,[1] Ignacio Granja,[2] John R. Asplin,[2] David S. Goldfarb,[1,3] Martin J. Blaser.[1] *[1]New York University School of Medicine, New York, NY; [2]Litholink Corporation, Chicago, IL; [3]New York Harbor VAMC, Hastings on Hudson, NY.*

Background: Kidney stones represent a disease of worldwide prevalence with significant public health implications. About 60–80% of stones are composed of calcium oxalate (CaOx); hyperoxaluria is a major risk factor for CaOx stones. Oxalate is an end-product of mammalian digestion and as with urea, must be excreted. We obtain oxalate from diet, or from endogenous production. Certain intestinal bacteria have the ability to degrade oxalate, protecting against oxalate nephropathy, including nephrolithiasis. To understand the role of the gut microbiome in oxalate metabolism, we compared conventional mice with germ-free mice (that lack a microbiota). In addition to the stress of endogenous oxalate production, we challenged groups with dietary and metabolic (via hydroxyproline (Hyp) supplementation) oxalate loads.

Methods: Conventional (CO) and germ-free (GF) mice were fed normal chow diets supplemented with either 1% Oxalate (Ox), 1% Hydroxyproline (Hyp) or were unsupplemented (NC) for 6 weeks (n=3-4/mice group). After 6 weeks, we obtained 48-hour urine collections for measurement of the oxalate/creatinine ratio (Uox/cr).

Results: In CO mice, Uox/cr increased with the Ox diet compared with NC (0.57 + 0.17 vs 0.16 + 0.05, p= 0.03 by Student's t test), but not with the Hyp diet (0.14 +0.03 vs 0.16 +0.05, p=ns). However, in germ-free mice, both dietary Hyp and Ox led to increased Uox/cr compared to NC diet (0.50 ± 0.04, 0.85 ± 0.11, vs. 0.31± 0.06, $p<0.05$ by ANOVA, respectively). Uox/Cr was lower in CO mice than GF mice when receiving Hyp (p=0.01, by Student's t test), Ox (p=0.06), and NC diets (0.06).

Conclusions: In conclusion, oxalate excretion was higher in the germ-free than in the conventional mice under all three dietary conditions (Ox, Hyp, NC), providing direct evidence that the normal gut microbiome plays a protective (symbiotic) role in oxalate metabolism. With the metabolic stress of the Hyp diet, the CO mice but not the germ-free mice could compensate. Since mice are not colonized with *O. formigenes,* this work indicates that other members of their microbiota have the functional capacity to alter oxalate metabolism.

FR-PO532

Intermuscular Fat in Patients with CKD Inversely Correlates with Physical Activity and Mitochondrial Function

Jorge Gamboa,[1] Chad A. Keller,[4] Baback Roshanravan,[2] Talat Alp Ikizler.[3] *[1]Vanderbilt University, Nashville, TN; [2]University of Washington - Kidney Research Institute, Seattle, WA; [3]Vanderbilt University Medical Center, Nashville, TN; [4]Vanderbilt University, Nashville, TN.*

Background: Patients with chronic kidney disease (CKD) have higher prevalence of sarcopenia, defined as reduction in muscle mass and/or muscle strength. Muscle quality (in particular, fat infiltration) may provide insight into the links between muscle metabolic health and physical functioning beyond traditional muscle mass assessment. We hypothesize that intermuscular fat is increased in patients with chronic kidney disease and it is inversely associated with physical activity and mitochondrial function.

Methods: In a cross-sectional study, we evaluated 51 subjects (20 with CKD stage 3-4, 15 with CKD stage 5 on hemodialysis, and 16 matched controls with no history of CKD). Intermuscular fat was evaluated in the quadriceps muscle using sequential thigh magnetic resonance images. Physical performance was measured using the six-minute walk test. Mitochondrial function was evaluated by measuring phosphocreatine (PCr) recovery after exercise using ^{31}phosphorus magnetic resonance spectroscopy (^{31}P-MRS). A longer PCR

recovery results in a greater time constant tau (τ), which indicates worsening mitochondrial function.

Results: Groups were matched by gender, body mass index, and history of diabetes and hypertension. Patients with CKD stage 5 were younger than patients with CKD stage 3-4 (47.7±11.7 vs. 63.6±9.0) but had similar age compared to controls (46.9±9.5). Intermuscular fat was greater in patients with CKD stage 5 compared to patients with CKD stage 3-4 and controls (**Figure 1A**). We also found a negative correlation between quadriceps intermuscular fat and physical performance (**Figure 1B**). In addition, mitochondrial dysfunction (greater time constant τ) was associated with increased intermuscular fat (**Figure 1C**).

Conclusions: CKD is associated with greater intermuscular fat which associates with poor physical performance and impaired mitochondrial function. Future studies should evaluate the effectiveness of interventions that not only increase muscle mass but also improve muscle quality in patients with CKD.

Impaired Muscle Mitochondrial Energetics Is Associated with Poor Physical Performance and Reduced Objective Physical Activity in CKD

Baback Roshanravan,[1] Sophia Liu,[3] Kushang V. Patel,[3] Jorge Gamboa,[2] Amir S. Ali,[3] Jonathan Himmelfarb,[1] Ian H. de Boer,[1] Kevin Conley,[3] Bryan R. Kestenbaum.[1] *[1]University of Washington - Kidney Research Institute, Seattle, WA; [2]Vanderbilt University, Nashville, TN; [3]University of Washington, Seattle, WA.*

Background: Persons with chronic kidney disease (CKD) are at increased risk of impaired mobility function that is central to living independently. The abnormal uremic milieu of CKD may contribute to reduced ambulatory physical performance and sedentarism by impairing skeletal muscle mitochondrial metabolism.

Methods: We performed a cross-sectional analysis of 48 participants (37 with CKD not treated with dialysis and 11 matched, clinic-based controls without CKD) from the Muscle Mitochondrial ENergetics and Dysfunction (MEND) study. Persons were excluded from MEND if they used medications that influenced mitochondrial metabolism or had mobility disability. We measured mitochondrial capacity during the recovery from exercise of the tibialis anterior leg muscle as ATPmax using ^{31}Phosphorus magnetic resonance spectroscopy. We assessed ambulatory physical performance by the 6-minute walk and timed up and go tests and we quantified usual physical activity levels using digital accelerometry over a two-week period. Results were adjusted for age, sex, weight, diabetes, and leg muscle size.

Results: Among persons with CKD, the mean GFR was 36 ±15 ml/min; mean age was 62 ±15yr; 50% were female, and 30% had diabetes. After adjustment, patients with CKD had a 0.181mM/sec (1SD) lower muscle ATPmax compared with controls (95% CI 0.06-0.297 lower; P=0.003). Among those with CKD greater muscle ATPmax was associated with greater 6 minute walk distance **(A)**, faster timed up and go performance **(B)** and greater usual physical activity **(C)** (Figure).

Conclusions: CKD is associated with lower muscle mitochondrial capacity measured by ATPmax manifesting as poor ambulatory physical performance. Among CKD patients, mitochondrial capacity is associated with objective measurements of physical performance and activity.

Factors Associated with Functional Impairment in Mild to Moderate CKD

Natasha J. McIntyre,[1] James E. Morris,[2] Simon D. Fraser,[2] Scott Harris,[2] Adam Shardlow,[1] Paul J. Roderick,[2] Christopher W. McIntyre,[3] Richard J. Fluck,[4] Maarten W. Taal.[1] *[1]University of Nottingham, Nottingham, United Kingdom; [2]University of Southampton, Southampton, United Kingdom; [3]London Health Sciences Centre, London, ON, Canada; [4]Royal Derby Hospital, Derby, United Kingdom.*

Background: Chronic kidney disease (CKD) is associated with functional impairment (reduced physical ability to perform normal activities and independently self-care) and may impact on quality of life. Additional factors related to functional impairment in CKD are less well described and may help identify those needing assessment and intervention. This study explored factors associated with functional impairment in people with mild to moderate CKD and comorbidities.

Methods: Data were analysed from 1013 patients at 5y follow up in the Renal Risk in Derby cohort study, comprising patients with CKD stage 3 at recruitment in primary care (baseline n=1741). Data included: age, sex, socioeconomic status (SES) based on index of multiple deprivation (IMD); comorbidities; renal function (estimated glomerular filtration rate (eGFR)); Karnofsky Performance Status (KPS). Functional impairment was defined as KPS score ≤70 (at best, unable to do active work or normal activities but can self-care; possible KPS score 0-100 in intervals of 10, lower score represents lower function). Binary logistic regression analyses assessed associations with functional impairment.

Results: Cohort characteristics were: median age 77y, 62% female, mean eGFR 54 ml/min/1.73m^2. 23% scored ≤70 on the KPS indicating low levels of functional impairment. On univariable analysis, functional impairment was associated with older age, lower SES, multiple comorbidities, and lower eGFR. In a multivariable model, these factors remained independently associated, and female sex became associated, with the outcome.

Conclusions: In addition to lower eGFR, older age, female sex, lower SES and multiple comorbidities were independent risk factors for clinician-assessed functional impairment in mild to moderate CKD. Persons with these risk factors should be considered for further functional status assessment and interventions to improve impairment.

Association of Subjective Health Assessments with Frailty, ADLs, and iADLs in Advanced CKD

Nicolas Baddour,[1] Cassianne Robinson-Cohen,[2] Loren Lipworth,[2] Aihua Bian,[3] Thomas G. Stewart,[2] Khaled Abdel-Kader.[2] *[1]Vanderbilt University School of Medicine, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Vanderbilt University, Nashville, TN.*

Background: Subjective health measures (i.e., patient self-rated health (SRH) and the provider surprise question (SQ)) predict key outcomes such as mortality. How these measures relate to frailty and functional status has not been studied in chronic kidney disease (CKD).

Methods: We approached 293 and enrolled 271 outpatients ≥ 60 years of age with non-dialysis dependent CKD stage 4 or 5. Patients were assessed with the SRH questionnaire: "In general, would you say your health is: excellent, very good, good, fair, or poor." Providers completed patient assessments with the SQ using a 5-point Likert scale: "Would you be surprised if this patient died in the next 12 months?" Frailty was measured using Fried Frailty phenotype and the Clinical Frailty Scale. Activities of daily living (ADLs) and instrumental ADLs (iADLs) were assessed using Katz and Lawton measures. Correlations were evaluated using Spearman's rank correlation. We used cutoff responses of 'poor' or 'fair' for SRH and 1 or 2 (i.e., not surprised) for the SQ to determine test-characteristics.

Results: About 15% of patients were frail by both Fried Frailty phenotype and Clinical Frailty Scale and 8% and 29% of patients had at least 1 ADL or iADL deficit, respectively. Both SRH and SQ were fairly to moderately correlated with clinical frailty score, Fried Frailty phenotype, iADLs, and weakly correlated with ADLs [Table 1]. SRH (of excellent, very good or good) had a negative predictive value (95% confidence interval) of 0.92 (0.86 to 0.96), 0.92 (0.87 to 0.96), 0.96 (0.91 to 0.98), and 0.83 (0.76 to 0.89) for Fried Frailty phenotype, Clinical Frailty scale, ADL deficiency, and iADL deficiency respectively. SQ had a negative predictive value of 0.87 (0.82 to 0.91), 0.90 (0.86 to 0.94), 0.79 (0.73 to 0.84), and 0.95 (0.92 to 0.98) for Fried Frailty, Clinical Frailty, ADL deficiency, and iADL deficiency respectively.

Conclusions: Single question patient or provider subjective health measures are correlated with frailty and functional status. These measures also may serve as useful tools to rule out frailty and disability in this population.

Funding: Private Foundation Support

Profiles of Physical Activity in Hemodialysis Patients Randomized into the HDFIT Trial

John W. Larkin,[1,2] Priscila B. Gonçalves,[1] Hao Han,[2] Jochen G. Raimann,[3] Maggie Han,[3] Carlos E. Poli de Figueiredo,[4] Americo L. Cuvello neto,[7] Ana Beatriz L. Barra,[5] Len A. Usvyat,[2] Peter Kotanko,[3] Maria Eugenia F. Canziani,[6] Roberto Pecoits-Filho.[1] HDFIT Study Investigators *[1]Pontifícia Universidade Católica do Paraná, Curitiba, Brazil; [2]Fresenius Medical Care North America, Waltham, MA; [3]Renal Research Institute, New York, NY; [4]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Brazil; [5]Fresenius Medical Care, Rio de Janeiro, Brazil; [6]Universidade Federal de São Paulo, Sao Paulo, Brazil; [7]Hospital Alemão Oswaldo Cruz, Sao Paulo, Brazil.*

Background: Profiles of physical activity (PA) are poorly understood in dialysis patients. We characterized granular profiles of PA in hemodialysis (HD) patients.

Methods: PA was measured with the Actigraph (www.actigraphcorp.com) monitor over 1 week in patients treated with high-flux HD during the baseline period of the HDFIT randomized controlled study, which is a 6-month study of the impacts of modality (HDF vs HD) on PA levels (ClinicalTrials.gov: NCT02787161). Granular PA levels were captured in blocks including a HD period (Block A), 2-hour (hr) post-HD period (Block B; includes 30min data slices), and 2-to-24hr post-HD period (Block C; includes 4.5hr data slices) captured over 24hr periods relative to the start time of HD on dialysis days, and concurrent periods on non-HD days and the long interdialytic day.

Results: We recruited 195 HD patients from 13 sites during October 2016 to 2017. Patients were: age 53±15 years, 71% male, 59% white race, post-HD weight 76±16 Kg, 29% with diabetic nephropathy, 26% with hypertensive nephrosclerosis, and 16% with chronic glomerulonephritis. Patients took a mean of 4,725 steps/24hrs. On non-HD days and the long interdialytic day, patients took 1,387 and 1,105 more steps/24hrs vs HD days respectively (both p<0.001). During concurrent times to the HD session on non-HD days and the long interdialytic day, patients performed 1,351 and 1,082 more steps respectively (both p<0.001). Surprisingly, on HD days patients performed more steps in each 30 min slice during the 2hr post-HD period vs concurrent times on non-HD days and the long interdialytic day (all p<0.05). On non-HD days, patients performed more steps during the 2 to 6.5hr post-HD period (p<0.05).

Conclusions: Findings revel PA levels tend to be lower on HD days primarily due to sitting/lying during HD treatments, albeit patients had higher post-HD PA levels compared to concurrent times on non-HD days that may be related to transportation from the clinic. Offering intradialytic exercise programs could help increase PA during HD, potentially above sedentary levels (i.e. >5,000 steps/day or equivalents) with potential benefits as observed in the general population.

Decline in Functional Status and Mortality in Patients on Hemodialysis: Results from the Japan Dialysis Outcome and Practice Patterns Study (J-DOPPS)

Ryota Matsuzawa,[1] Tsukasa Kamitani,[2] Baback Roshanravan,[3] Shingo Fukuma,[4] Nobuhiko Joki,[5] Masafumi Fukagawa.[6] J-CLIP *[1]Kitasato University Hospital, Sagamihara, Japan; [2]Kyoto university, Kyoto, Japan; [3]University of Washington - Kidney Research Institute, Seattle, WA; [4]Kyoto University, Kyoto, Japan; [5]TOHO University Ohashi Medical Center, Tokyo, Japan; [6]Tokai University School of Medicine, Isehara, Japan.*

Background: Poor functional status — the limitation in activities of daily living (ADL) — is strongly associated with adverse clinical outcomes among end-stage renal disease (ESRD) patients treated with hemodialysis (HD). Little is known in regard to the association of change in functional status and adverse clinical outcomes in this population. The current investigation tests the association of decline in functional status with all-cause mortality among HD patients using data from the Japan Dialysis Outcome and Practice Patterns Study (J-DOPPS).

Methods: We studied 817 ESRD patients on HD with repeat measures of functional status enrolled in the J-DOPPS. Information on age, sex, body mass index, smoke, dialysis vintage, comorbidities and laboratory data was collected. The assessments of functional status were conducted twice over a one-year baseline period (2012-2013), and functional status score was calculated based on Katz index and Lawton-Brody instrumental ADL scale. We classified patients into 2 groups based on having or not at least 1 point declined in functional status score during the baseline period. A Cox regression analysis was conducted to evaluate the association between the decline in functional status and the all-cause mortality during the follow-up period (2013-2015) with adjustment for potential confounders.

Results: Over this period, 163 (20.0%) patients showed decline in functional status score, and 44 (5.4%) patients died. Using Cox regression analysis adjusting for potential confounders including baseline functional status, the declined in functional status score was significantly associated with higher mortality (adjusted hazard ratio, 2.68; 95% confidence interval, 1.31-5.50).

Conclusions: Decline in functional status was strongly associated with mortality among patients treated with HD. These findings underscore the importance of interventions directed at preventing deterioration in functional status over time among HD patients.

FR-PO538

Predictors of Mobility Impairment over Time in Incident Dialysis Patients

Ranjani N. Moorthi,[1] William F. Fadel,[4] Alissa A. Cranor,[1] Judy Hindi,[4] Kathleen A. Lane,[1] Ravi I. Thadhani,[3] Keith Avin,[2] Sharon M. Moe.[1,5] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University-Indianapolis, Indianapolis, IN; [3]Cedars-Sinai, Los Angeles, CA; [4]Indiana University, Indianapolis, IN; [5]Roudebush VAMC, Indianapolis, IN.*

Background: Sarcopenia involves loss of muscle strength and/or mass that leads to loss in physical function (mobility impairment). Mobility impairment can be quantified by gait speed measures. In CKD, mobility loss is associated with hospitalizations, functional dependence and mortality. The trajectory of mobility over time in new dialysis patients is not well-characterized. We hypothesized that there are decreases in mobility over time in incident dialysis patients, independent of changes in muscle strength.

Methods: Gait speed was assessed in 195 subjects who were incident to outpatient dialysis by the 4-meter walk test at baseline, 6, 12 and 24 months. Maximum handgrip strength of 3 trials in both upper limbs was recorded at similar time points. Appendicular lean mass/ ht2 was measured by DXA. Mixed effects models were used to analyze changes in gait speed and identify predictors of change among covariates which included demographics, walking aids, self-reported health status, ESRD cause, time-varying muscle strength, baseline lean mass and physical activity.

Results: The mean age of the cohort was 54.3+/-13 years, with 53.3% male, 72.4% black and with a median of 93.7+/-72 days since dialysis start. There was an average decrease in gait speed of 0.023 m/s/yr. Lower grip strength at baseline was associated with lower gait speed trajectory over time (Figure). Age, use of walking aids, lower grip strength, diabetic nephropathy as cause of ESRD, self-reported poor ambulation and lower health utility were significantly associated with poor mobility over time in the adjusted mixed effects model (all p<0.05). Baseline lean mass or step counts did not affect these relationships.

Conclusions: There is loss of mobility with time in patients relatively new to dialysis. Loss of muscle strength is an independent risk factor for mobility impairment over time. Identifying risk factors for mobility loss may be used to target interventions like physical therapy, gait training and exercise.

Gait Speed Trajectory by Baseline Grip Strength

FR-PO539

The Effect of Exercise Intervention on Physical Activity in Patients with Non-Dialysis-Dependent CKD: A Systematic Review

Naohiko Fujii. The NDD-CKD Team of the Committee of the Guideline for Renal Rehabilitation *Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Japan.*

Background: As the population of chronic kidney disease (CKD) grows larger and older worldwide, frailty has become one of emerging problems that may affect the prognosis of patients with CKD and their quality of life. Many observational studies suggest that frailty should be a clinically-relevant mortality risk in both dialysis-dependent and non-dialysis-dependent (NDD) CKD. However, it is not well understood whether this vulnerable state is modifiable by lifestyle intervention, or exercise, in patients with NDD-CKD independent of diet and drug therapy. We performed a systematic review to evaluate the benefits and limitations of exercise intervention among patients with NDD-CKD on exercise tolerance.

Methods: We searched PubMed and the Japanese medical publication library "Ichushi" databases for randomized controlled trials (RCTs) or intervention trials targeting patients with NDD-CKD published until April 2017. Outcomes of interest included indices of exercise tolerance, such as VO_2 peak and 6-min walking test (6MWT). Two or three reviewers independently screened the title and abstract of extracted papers from the databases and reviewed the full-text of articles that met the prespecified inclusion and exclusion criteria. Data quality and risk of bias were evaluated by GRADE system. Any disagreements between the reviewers were resolved by discussion. Data syntheses and meta-analyses were performed using Review Manager version 5.3.

Results: After the full-text review of 50 selected articles, 14 RCTs and two intervention trials were included in meta-analysis. Four of them conducted resistance exercise, and others did aerobic exercise or exercise with reduced workload. Nine studies reported changes in VO_2 peak, six in 6MWT, and the rest measured other indices. Overall, VO_2 peak and 6MWT were significantly improved by 3.2 [inter quartile range (IQR): 1.5 – 5.0] mL/kg/min (N = 296, $I^2 = 0.67$) and 51 [22 - 80] m (N = 241, $I^2 = 0.27$), respectively. There was no report on adverse event regarding exercise intervention.

Conclusions: Moderate exercise intervention among patients with NDD-CKD is beneficial for exercise tolerance measured by VO_2 peak and 6MWT. These results should be verified by other objective indices for mobility and in other CKD populations especially with frailty.

FR-PO540

Physical Performance in Nocturnal Hemodialysis Patients: Systematic Review of the Literature

Manouk Dam, Peter J. Weijs, Frans J. van Ittersum, Brigit C. van Jaarsveld. *VU University Medical Center, Amsterdam, Netherlands.*

Background: Hemodialysis (HD) pts have poor physical performance, leading to a diminished quality of life (QOL) and overall health. This low activity level can be explained by lack of energy due to insufficient metabolic clearance and shortage of time by time-consuming HD sessions. Nocturnal hemodialysis (NHD) improves metabolic control and results in largely increased spare time. Whether NHD stimulates pts to a more active lifestyle and increased muscle mass and strength, is unclear. Our aim is to investigate whether physical performance improves when pts switch from conventional HD to NHD.

Methods: A systematic literature search, with help of a specialized librarian, was conducted in multiple databases: MEDLINE, Embase, CINAHL, PhycInfo and Web of Science. Databases were searched until January 2018. Primary outcomes of interest were physical performance, activity, strength and muscle mass in NHD, either at home or in-center. Two reviewers performed data extraction and assessment of methodological quality independently, with the Newcastle-Ottawa scale.

Results: The search yielded 10 studies meeting the inclusion criteria including 2 RCTs. A total of 526 NHD pts were evaluated with a mean follow-up duration of 15,3 months. Physical performance was assessed with objective measurements in 7 studies: short-physical performance battery (1x), exercise spirometry (1x), 6-min walk test (6MWT, 1x), (skeletal) muscle mass using dual-energy X-ray absorptiometry (2x) and bioelectrical impedance analysis (BIA, 2x). In 5 studies physical performance was assessed subjectively, with a physical component score (PCS) of a QOL questionnaire. Of the objective outcomes, 3 studies found significant improvements in physical performance using exercise spirometry, 6MWT and BIA. Of the subjective outcomes, 2 studies showed a better PCS. The remaining 6 studies showed no improvement in physical performance nor PCS.

Conclusions: A limited amount of studies investigate whether physical performance improves after switching from CHD to NHD and a minority of these assess physical performance with objective measurements. As current literature regarding physical performance emphasizes the importance of physical activity on clinical outcomes, it is essential to conduct better research in larger study groups, to investigate whether NHD can improve physical performance of pts with ESRD.

FR-PO541

Physical Activity and Sedentary Behaviour in Hemodialysis: Preliminary Data from a Pilot Study

Keigan More,[1] Alec Cranston,[2] Chris M. Blanchard,[3] Olga Theou,[3] Amanda J. Vinson,[4] Christine Dipchand,[4] Karthik K. Tennankore.[4] *[1]Department of Medicine, Dalhousie University, Halifax, NS, Canada; [2]Nova Scotia Health Authority, Halifax, NS, Canada; [3]Dalhousie University, Halifax, NS, Canada; [4]Dalhousie University/NS Health Authority, Halifax, NS, Canada.*

Background: Dialysis patients have reduced moderate to vigorous physical activity (MVPA), defined as activities that use ≥3 metabolic equivalents (METS). This has been shown in both self-reported surveys and objective accelerometer studies. Less attention has been directed towards sedentary behavior (SB), which is characterized by low energy expenditure (≤ 1.5 METS). Furthermore, locations where MVPA or SB occur are largely unknown for dialysis patients. **Objective:** To determine the number of minutes per day of MVPA and SB for in-center hemodialysis patients using accelerometers and to identify locations where MVPA and SB occur using global positioning software (GPS).

Methods: We analyzed a cross-section of adult in-center hemodialysis patients at tertiary care dialysis program, recruited over a three-month period. Patients were fit with the Actigraph GT3X accelerometer and Qstarz BT-Q1000X GPS receiver and were instructed to wear these devices for ≥10 hours/day for ≥4 days/week. Minutes of physical activity at various intensities and SB were described as was time spent at each activity level across different locations.

Results: Overall, 50 patients consented to participate in the study; 47 were fit with both devices, and 37 met the minimum accelerometer wear time of ≥4 days/week. Mean age of the cohort was 61±15 years. Diabetes (46%), coronary artery disease (34%), and heart failure (21%) were highly prevalent. Among those who fulfilled valid days, median wear time was 755 minutes/day (IQR 720-794), median sedentary time was 544 minutes/day (IQR 487-583), and median MVPA time was 2 minutes/day (IQR 1-9). The cohort spent 73% (IQR 64-78) of their wear time in a sedentary state, and only 0.3% (IQR 0.1-1.2) in MVPA. Only three patients met Canadian guidelines for weekly MVPA (≥150 minutes/week in bouts of ≥ 10 minutes). The majority of SB occurred in the home, hospital, and during transport, whereas most MVPA occurred at home.

Conclusions: Hemodialysis patients exhibit substantial SB and minimal MVPA across a multitude of locations. The home environment may represent an ideal location for behavior interventions as the majority of SB and MVPA occurs at home. Further studies are needed to determine the effects of these behaviors on clinical outcomes as well as to determine barriers to MVPA and facilitators of SB.

FR-PO542

The Effect of Intradialytic and Home-Based Exercise on Physical Function and Quality of Life in Hemodialysis Patients

Brett Burrows,[1] Luis M. Perez,[1] Lauren Chan,[2] Alana P. Harris,[1] Jennifer L. Barnes,[2] Ken Wilund.[1] *[1]University of Illinois at Urbana-Champaign, Urbana, IL; [2]Illinois State University, Normal, IL.*

Background: It's well established that hemodialysis (HD) patients are less active and have greater muscle atrophy compared to healthy people. Previous research has associated lack of physical activity with reduced physical function (PF) and quality of life (QOL) and increased mortality. Preceding research also states that HD patients' QOL may be negatively influenced by significant increases in intradialytic weight gain thus increasing the likelihood of a hypotensive event. HD patient's specifically cite sleep problems and fatigue as negative effects of hemodialysis on QOL. The aim of this study was to determine the effect of a 6-month physical exercise program on HD patients' PF and QOL.

Methods: HD patients (n=22) were enrolled in a larger volume control (VC) pilot trial with assessments at baseline (BL) and 6-months (6m). Nine HD patients were randomized into a volume control and exercise group (VCE). During regularly scheduled HD treatments, over the 6-month trial, VCE performed thrice weekly moderate intensity, progressive intradialytic cycling for 15-30 min per session. Additionally, VCE was given a progressive individualized home exercise prescription that consisted of total body resistance exercises and balance exercises, which the HD patients were asked to complete twice a week. Thera-bands of various resistance were given to perform the exercises at home. Before randomization, BL assessments were taken including; BP, short physical performance battery (SPPB), and self-reported Kidney Disease Quality of Life (KDQoL).

Results: SPPB total score did not improve BL to 6m between groups (VCE 9.4 to 10.1, VC 8.5 to 8.9; p=.71). The symptoms and sleep subsets, of the KDQoL, were significantly different between groups from BL to 6m (symptoms: VCE 73.2 to 85.0, VC 71.1 to 67.1; p=0.02, sleep: VCE 60.8 to 71.4, VC 58.5 to 50.9; p=0.02). Fatigue, part of the symptoms subset, was found to be reduced in VCE from BL to 6m (VCE 54.2 to 75.0, VC 51.7 to 40.0; p=0.05).

Conclusions: Despite no improvement in the SPPB between groups, specific QOL parameters such as sleep and fatigue improved significantly. These findings suggest novel benefits in QOL from an intradialytic cycling and home-based exercise program in HD patients.

Feasibility of Intradialytic Exercise in a Rural Community Hemodialysis Unit: Mixed Methods Analysis of Implementation

Malgorzata E. Kaminska,[1] Robin K. Roots,[2] Anurag Singh.[3] *[1]University Of Northern British Columbia, Prince George, BC, Canada; [2]University of British Columbia, Prince George, BC, Canada; [3]Department of Internal Medicine, Division of Nephrology, University Hospital of Northern British Columbia, Prince George, BC, Canada.*

Background: The use of leg cycle ergometers (LCEs) during hemodialysis (HD) has been shown to have a number of benefits including improved adequacy of HD and blood pressure reduction while also improving exercise capacity, physical function and quality of life in patients with end stage kidney disease. LCEs have been implemented at several dialysis centres in major Canadian cities, however no known location in British Columbia. Furthermore, a gap exists in the literature with respect to the feasibility of implementing such programs in small or rural HD centres. We examined the feasibility of implementing LCEs concurrent with HD in a rural community centre.

Methods: Study participants included patients and clinical care providers (CCPs) recruited from a remotely located community HD unit in northern British Columbia. Descriptive statistics were used to indicate frequency, intensity and length of cycle utilization. Barriers and facilitators to participation were captured in individual semi-structured interviews conducted with patient and CCPs at the end of the study period. Transcribed interviews were coded and analyzed using a theoretical framework scaffolded by constructs of acceptability and feasibility of implementation (O'Cathian et al. 2015).

Results: Of 14 eligible patients, 9 enrolled of which 6 actively participated in the study. Over 1 to 4 months patients used LCEs an average of 85% (63%-100%) of their dialysis sessions. Duration of LCEs use increased over time from a low of 15 minutes to an average of 1 hour (15-120 minutes) at an "easy" rate on the Perceived Exertion Scale with no adverse events reported. Thematic analysis of 14 interviews (9 patients; 5 CCPs) identified key elements for successful implementation: patient and CCP orientation and a structured

support process aided in acceptability, resulting in minimal disruption to workflow and generating motivation to participate and a positive patient and CCP experience.

Conclusions: Exercising during HD is acceptable, feasible, and safe when implemented in a rural community HD unit using a structured team-based approach. It does not add workload for clinical staff and can be incorporated in the workflow. Patients reported an overall positive experience and recommended the creation of an education tool to aid in recruitment.

FR-PO544

Effect of Acute and Chronic Intradialytic Bicycle Ergometer Exercise on Nrf2 mRNA Expression in Hemodialysis Patients

Denise Mafra,[1] Jessyca S. Brito,[2] Greicielle S. Da silva,[2] Drielly V. Reis,[2] Bruna kelly S. Souza,[4] Ludmila F. Cardozo,[3] Natalia A. Borges.[2] *[1]Federal University Fluminense, Rio de Janeiro, Brazil; [2]Universidade Federal Fluminense, RIO DE JANEIRO, Brazil; [3]Federal Fluminense University, Niterói, Brazil; [4]Universidade Federal Fluminense, RIO DE JANEIRO, Brazil.*

Background: Hemodialysis (HD) patients have a constant state of oxidative stress, which results from an imbalance between reactive oxygen species production and endogenous antioxidant defense mechanisms, leading to increased cardiovascular risk. Physical exercise may reduce cardiovascular risk through its beneficial effects on nuclear factor erythroid 2-related factor 2 (Nrf2) expression that regulates several antioxidant genes. The aim of the present study was to verify the effect of acute and chronic intradialytic bicycle ergometer exercise on Nrf2 mRNA expression in HD patients.

Methods: Eleven HD patients were studied (7 men, 47.5 ± 6.7 yrs, 25.4 ± 12.3 months of dialysis, BMI of 23.7 ± 2.2 Kg/m^2). The physical exercise program was individualized and performed on an adapted stationary bicycle, consisting in heating (5 minutes), 35 minutes of aerobic training at target heart rate, and cool down (load reduction for 5 minutes). The acute effect (single session) was assessed after the first exercise session and the chronic effect after 3 months of the exercise program with 3 sessions per week. Peripheral blood mononuclear cells were isolated and processed for the evaluation of expression of Nrf2 and NAD(P)H:quinoneoxidoreductase 1 (NQO1) by quantitative real-time polymerase chain reaction.

Results: No significant changes were observed after a single exercise session in Nrf2 mRNA expression [from 0.38 (0.15 - 2.84) to 1.92 (0.65 - 2.48), p=0.21] or NQO1 mRNA expression [from 0.31 (0.16 -1.20) to 0.85 (0.43 - 1.98), p=0.17]. After 3 months of the exercise program there was a significant increase in Nrf2 mRNA expression [from 0.38 (0.15 -2.84) to 1.63 (0.64 - 3.25), p=0.04] and no significant change in NQO1 mRNA expression [from 0.31(0.16 -1.20) to 1.97 (0.45 - 3.88), p=0.17].

Conclusions: These results suggest that acute intradialytic bicycle ergometer exercise was unable to change Nrf2 but three months exercise program seems to modulate this transcription factor which could improve long-term endogenous antioxidant defense in HD patients.

Effect of Resistant Starch Supplementation on the Indole-3-Acetic Acid Levels and Aryl Hydrocarbon Receptor Expression in Hemodialysis Patients

Denise Mafra,[1] Renata D. Macedo,[2] Ludmila F. Cardozo,[2] Natalia A. Borges,[1] Lia S. Nakao,[3] Mariana Z. Jardim,[1] Bruna Paiva,[1] Julie ann Kemp,[1] Marta Esgalhado.[1] *[1]Federal University Fluminense, Rio de Janeiro, Brazil; [2]Federal Fluminense University, Niterói, Brazil; [3]UFPR, Curitiba, Brazil.*

Background: Researchers have investigated the role of the gut microbiota in the pathogenesis of chronic kidney disease (CKD) and cardiovascular disease (CVD). The gut microbiota imbalance favors bacterial growth producing uremic toxins, such as indole-3-acetic acid (IAA). This toxin leads to inflammation and, the aryl hydrocarbon receptor (AhR) has been pointed as an important ligand of IAA, triggering inflammatory signaling responses. Thus, the use of prebiotics, such as resistant starch (RS), may be an effective non-pharmacological strategy to restore gut microbiota balance, reducing IAA levels and AhR expression, and consequently decreasing inflammation in CKD. The aim of this study was evaluate the effect of RS supplementation on IAA levels and AhR expression in hemodialysis patients (HD).

Methods: Randomized, double-blind, placebo-controlled clinical trial including 43 HD patients (53.4% male, 58.2 ± 9.5 years, 25.7 ± 3.8 kg/m^2, 37.5 ± 26.9 months of HD). The patients were supplemented with 16g/day of RS (HI-MAIZE 260) or placebo in the form of cookies (for consumption on the day of dialysis) and *sachet* (for daily consumption without dialysis) for 4 weeks. Blood samples were collected before and after the supplementation period. IAA plasma levels were measured by high performance liquid chromatography and, peripheral blood mononuclear cells were isolated and analyses of quantitative real time polymerase chain reaction was performed to evaluate the AhR mRNA expression.

Results: Thirty one patients completed the study, 15 in the RS group and 16 in the placebo group. No differences were found in IAA levels (2329.5 (1112-3451)mg/L vs 1667 (1191 - 2934)mg/L; p=0.16) or in AhR mRNA expression (1.08 ± 0.5 vs 1.12 ± 0.45, p=0.81) after RS supplementation. However, there was a positive correlation (r=0.48; p=0.03) between IAA and AhR at the baseline.

Conclusions: Although RS supplementation did not influence IAA levels or AhR expression, the positive association between this toxin and the AhR confirm a possible interaction between them. Future therapeutic strategies can be discovered in the sense of modulating this complex pathway.

Presarcopenia and Sarcopenia as Predictors of Hospitalization-Free Survival in Patients with CKD

So-young Lee,[1] Dong Ho Yang,[3] Min ji Sung,[2] Jun mo Kang,[3] Yubum Choi,[4] Wooyeol Ahn,[5] Soonchul Lee.[6] *[1]Internal Medicine, CHA Bundang Medical Center, CHA Univ., Seongnam, Gyeonggi-do, Republic of Korea; [2]Internal Medicine, CHA Bundang Medical Center, Cha university, Seongnam, Gyeonggi-do, Republic of Korea; [3]Internal Medicine, CHA Bundang Medical Center, CHA University, Seongnam, Gyeonggi-do, Republic of Korea; [4]Internal Medicine, CHA Bundang Medical Center, CHA University, Seongnam, Gyeonggi-do, Republic of Korea; [5]CHA University, Seongnam-si, Republic of Korea; [6]Orthopaedic Surgery, CHA Bundang Medical Center, CHA university, Seongnam, Gyeonggi-do, Republic of Korea.*

Background: Sarcopenia is defined as the degenerative loss of skeletal muscle mass, and strength associated with aging. In this article, we compared prevalence of sarcopenia using three different skeletal muscle mass indices in predialysis and dialysis patients with chronic kidney disease (CKD), and sought to the relationship with clinical outcomes.

Methods: 179 patients were recruited (114 male, 65 female, 103 predialysis, 76 dialysis) and followed prospectively for up to 3 years. Appendicular skeletal muscle mass (ASM) was measured by bioimpedance analysis (Inbody 620, In-body, Seoul, Korea). Weight (wt) adjusted, height square (ht^2) adjusted, or body mass index (BMI) adjusted ASM were assessed in all subjects. Hand grip strength and walking speed were measured. Frailty phenotypes were examed in all subjects. Sarcopenia was considered present when subjects had low handgrip strength accompanied by low adjusted ASM. Those who showed only low hand grip or muscle volume loss were categorized as presarcopenia.

Results: 9.5%, 4.5%, or 2.8% of the patients had sarcopenia, while 55.9%, 57.5%, or 58.7% of the patients were categorized as presarcopenic status according to three different indices (ASM/wt, ASM/ht^2, or ASM/BMI respectively). ASM/wt index showed significant correlation with age, handgrip strength, HOMA-IR and frailty score. During follow-up, 56 patients were hospitalized (cardiovascular 30.3%; infectious disease 23.2%). Multivariate cox proportional hazards models also demonstrated that the risk of hospitalization was significantly higher for CKD patients who were categorized as sarcopenic (hazard ratio [HR], 9.11 ; 95% confidence interval [CI], 2.295 – 25.182; P < 0.001) or presarcopenic (HR, 2.48 ; 95% CI, 1.180 – 5.230; P = 0.017) than normal status according to ASM/wt index

Conclusions: ASM/wt index showed best relationship with age, muscle strength, insulin resistance and frailty. Sarcopenia and presarcopenia defined using ASM/wt index predicted poorer hospitalization-free survival in patients with CKD. This work was supported by a National Research Foundation grant of Korea (NRF-2016R1C1B1013814) funded by the Korea government.

Relative Sarcopenia and Mortality and the Modifying Effects of CKD and Adiposity

Susan Ziolkowski,[1] Jin Long,[3] Glenn M. Chertow,[1] Mary B. Leonard.[2] *[1]Stanford University School of Medicine, Palo Alto, CA; [2]Stanford School of Medicine, Stanford, CA; [3]Stanford University, Palo Alto, CA.*

Background: Conventional definitions of sarcopenia based on lean mass may fail to capture low lean mass relative to higher fat mass, i.e., relative sarcopenia. The objective of this study is to determine the associations of sarcopenia and relative sarcopenia with mortality independent of co-morbidities, and whether chronic kidney disease (CKD) and adiposity alter these associations.

Methods: Dual energy X-ray absorptiometry (DXA)-derived appendicular lean mass index (ALMI, kg/m2) and fat mass index (FMI, kg/m2) were assessed in 14,850 NHANES participants from 1999-2006 and were linked to death certificate data in the National Death Index with follow up through 2011. Sarcopenia was defined using sex and race/ethnicity-specific standard deviation scores compared with young adults (T-scores) as an ALMI T-score < –2 and relative sarcopenia as fat-adjusted ALMI ($ALMI_{FMI}$) T-score < –2. Glomerular filtration rate (GFR) was estimated using creatinine- (eGFRCr) and cystatin C- (eGFRCys) based regression equations.

Results: Three (3.0) percent of NHANES participants met criteria for sarcopenia and 8.7% met criteria for relative sarcopenia. Sarcopenia and relative sarcopenia were independently associated with mortality (HR sarcopenia 2.89, 95% CI, 2.17 to 3.86; HR relative sarcopenia 2.62, 95% CI, 2.14 to 3.20). The corresponding population attributable risks were 6.2% (95% CI, 4.3% to 7.5%) and 25.8% (95% CI, 17.3% to 31.2%), respectively. The risk of mortality associated with relative sarcopenia was attenuated among persons with higher FMI (p for interaction <0.01) and was not affected by CKD status for either sarcopenia or relative sarcopenia.

Conclusions: Sarcopenia and relative sarcopenia are significantly associated with mortality regardless of CKD status. Relative sarcopenia is nearly 3-fold more prevalent amplifying its associated mortality risk at the population level. The association between relative sarcopenia and mortality is attenuated in persons with higher FMI.

CKD and the Adiposity Paradox: Valid or Confounded?

Susan Ziolkowski,[3] Jin Long,[2] Glenn M. Chertow,[3] Mary B. Leonard.[1] *[1]Stanford School of Medicine, Stanford, CA; [2]Stanford University, Palo Alto, CA; [3]Stanford University School of Medicine, Palo Alto, CA.*

Background: Obesity is associated with decreased mortality risk in in patients with end-stage renal disease and mild to moderate chronic kidney disease (CKD), a phenomenon termed the obesity paradox. Indices of obesity, including Quételet's (body mass) index (BMI, kg/m^2) and % body fat (%BF) are confounded by muscle mass, while DXA derived fat mass index (FMI, kg/m^2) overcomes this limitation. We aimed to compare the associations between adiposity and mortality in persons with CKD using alternative estimates of adiposity, and to determine whether muscle mass, inflammation and recent weight loss modify these associations.

Methods: DXA-derived FMI, BMI, and %BF were calculated in 2,852 NHANES participants with CKD from 1999-2006, used to define obesity according to established cut-offs, and linked to death certificate data in the National Death Index with follow up through 2011. Cox proportional hazards models assessed associations between mortality and estimates of adiposity. Sequential models adjusted for percent weight change since the maximum reported weight and interactions with measures of inflammation and muscle mass.

Results: In adjusted models, obesity based on FMI (obese$_{FMI}$) was associated with lower mortality (HR 0.82, 95% CI, 0.70 to 0.97). As continuous variables, higher FMI, BMI and %BF were associated with lower mortality. The protective effect of obesity was less pronounced among those with higher lean mass. The prevalence of >10% weight loss was 20% in obese$_{FMI}$ participants, compared with 40.4% in the non-obese$_{FMI}$ participants. Prior weight loss was strongly associated with mortality, and the protective effect of obesity was no longer significant after adjustment for prior weight loss. Inflammation did not modify these associations.

Conclusions: These data demonstrated an apparent protective effect of high fat mass in CKD, particularly among persons with low muscle mass. The prevalence of prior weight loss was two-fold less among obese compared to non-obese persons and confounded these associations.

FR-PO549

Pre-ESRD 24 Hour Urine Creatinine Changes and Post-ESRD Mortality

Csaba P. Kovesdy,[2,1] Praveen Kumar Potukuchi,[1] Chi-Yang Chiu,[1] Adnan Naseer,[2] Oguz Akbilgic,[1] Fridtjof Thomas,[1] Melissa Soohoo,[3] Elani Streja,[3] Miklos Z. Molnar,[1] Kamyar Kalantar-Zadeh.[3] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]Memphis VA Medical Center, Memphis, TN; [3]University of California at Irvine, Orange, CA.*

Background: Protein-energy wasting (PEW) is common in CKD and ESRD. The temporal dynamics of PEW in patients with progressive loss of kidney function, and its association with future outcomes, is unclear.

Methods: We examined changes in 24-hour urine creatinine (24hrUC; a surrogate of muscle mass) over the last 3 years prior to renal replacement therapy in a national cohort of 701 incident ESRD US veterans with 2 or more 24hrUC measurements. We estimated 24hrUC slopes in mixed effects models, and we examined their association with post-dialysis all-cause mortality using Cox models adjusted for confounders. To assess the temporal dynamics of pre-ESRD changes in 24hrUC and its association with changing eGFR, we separately fitted in mixed effects models penalized spline regressions of 24hrUC on time and on eGFR.

Results: Patients were 63±10 years old, 97% male, 35% African-American. Mean baseline eGFR and 24hrUC were 26±16 ml/min/1.73m2 and 1294±290 mg, respectively. The mean slope of 24hrUC vs. time was -77±45 mg/year. Decline in 24hrUC started to accelerate in the last 2 years prior to ESRD, and once eGFR was <25 ml/min/1.73m2 (Figure). 444 patients died (mortality rate 191/1000 patient-years, 95%CI: 174-209) over a median follow-up time of 3 years. More severe decreases in 24hrUC were associated with higher mortality (Figure).

Conclusions: Patients with advanced CKD lose an average of 6% of their muscle mass each year. Loss of muscle mass starts to accelerate once eGFR falls below 25 ml/min/1.73m2, and more loss of muscle mass is associated with higher mortality after ESRD transition.

FR-PO550

Change in Body Composition over Time and Its Association with Survival Among Patients on Hemodialysis

Cynthia Delgado,[1] Janet Chiang,[4] Barbara A. Grimes,[3] George A. Kaysen,[5] Mark Segal,[3] Kirsten L. Johansen.[2] *[1]Veterans Affairs Medical Center, San Francisco, CA; [2]University of California, San Franicsco, San Francisco, CA; [3]UCSF, San Francisco, CA; [4]University of California, San Francisco, San Francisco, CA; [5]University of California, Davis, Davis, CA.*

Background: Patients with ESRD who have a higher body mass index have better survival, a phenomenon known as the obesity paradox. Accounting for body composition and for changes over time may help to elucidate this paradoxical association.

Methods: We leveraged repeated measures of body composition (at baseline, 12, and 24 months) by whole-body bioimpedance spectroscopy (BIS) from 286 prevalent ESRD patients from 7 dialysis facilities in the USRDS ACTIVE/ADIPOSE study to examine the obesity paradox. We performed BIS to estimate intracellular water as a proxy for muscle mass (ICW/m^2), extracellular water (ECW/m^2), and fat mass (FM/m^2). Death data were ascertained through linkage with the USRDS through June 2016. We used linear mixed models to examine change in body composition over time and Cox models with BIS-derived estimates as time-varying predictors to examine survival after adjusting for covariates.

Results: Results: Participants' mean age was 59 ± 15, and 66% were male. Over time, only ICW/m^2 declined (-0.08 95%CI -0.13, -0.04 L/m^2/year) and neither ECW/m^2 (0.02 95%CI -0.03, 0.06 L/m^2/year) nor FM/m^2 (-0.07 95%CI -0.20, 0.05 L/m^2/year) changed significantly. In survival analysis with body composition parameters as time-varying predictors, ICW/m^2 was associated with lower mortality (HR 0.67, 95%CI 0.49, 0.93). Higher ECW/m^2 was associated with higher mortality (HR 1.75 95%CI 1.19, 2.60). Fat mass was not associated with survival (HR 0.99 95%CI 0.93, 1.06).

Conclusions: In this cohort of participants with repeated measures of body composition, muscle mass declined over time. Higher muscle mass was associated with better survival, but higher fat mas was not associated with survival independent of muscle mass.

FR-PO551

Abdominal Obesity in Normal Weight versus Overweight and Obese Hemodialysis Patients: Associations with Nutrition, Inflammation, Muscle Strength, and Quality of Life

Ilia Beberashvili,[1] Ada Azar,[2] Ramzia Abu hamad,[1] Inna Sinuani,[3] Leonid Feldman,[1] Shai Efrati.[1] *[1]Nephrology Division, Zerifin, Israel; [2]Nutrition Department, Zerifin, Israel; [3]Department of Pathology and Cytology, Assuta Ashdod Medical Center, Ashdod, Israel.*

Background: The biological basis of abdominal obesity leading to more severe outcomes in maintenance hemodialysis (MHD) patients with normal body mass index (BMI) is unclear. We compared the phenotype of abdominal obesity in different BMI categories of MHD patients.

Methods: We performed a cross-sectional study of 188 MHD patients (52.7% women; mean age, 69.4±11.5 years) with abdominal obesity in different BMI groups using WHO criteria. Appetite and dietary intake, body composition, handgrip strength, malnutrition-inflammation score (MIS), inflammatory biomarkers, adipokines and health-related quality of life (QoL) questionnaires were studied.

Results: According to multivariable analyses, abdominally obese patients with normal BMIs consumed less protein per day (p=0.04), had lower measurements of surrogates of lean (p<0.001) and fat mass (p<0.001), higher total cholesterol, TNF-α (p<0.05), and adiponectin to leptin ratios (p=0.003) compared to overweight and obese patients with abdominal obesity. Multivariable analyses showed no differences in handgrip strength among the study groups. The abdominally obese study participants with normal weight had significantly lower scores in role-physical (p=0.003) and pain (p=0.04) scales after multivariable adjustments.

Conclusions: Normal weight MHD patients with abdominal obesity exhibit a more proatherogenic profile in terms of inflammatory markers and adipokines expression, lower body composition reserves and lower physical ability compared to abdominal obesity patients with overweight and obesity. This at least partially explains the abdominal obesity paradox in MHD population in which worse clinical outcomes are seen in abdominally obese patients with normal BMIs, as opposed to overweight and obese patients who are also abdominally obese.

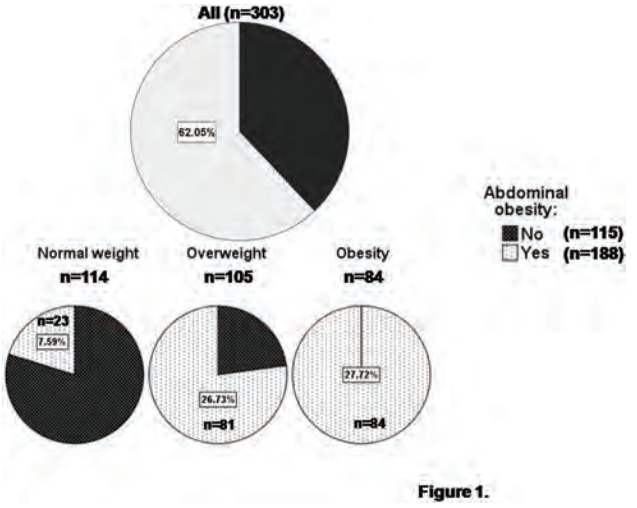

Figure 1.

FR-PO552

Effects of Body Fat Accumulation During PD on Mortality and Technique Failure: Is There a Difference by PD Duration?

Jwa-kyung Kim,[1] Narae Joo,[2] Youngsu Kim,[3] Sung gyun Kim.[1] *[1]Hallym University, Seoul, Republic of Korea; [2]Halyym University Sacred Heart Hospital, AnYang, Republic of Korea; [3]Hallym Univ. Sacred Heart Hospital, Angyang, Republic of Korea.*

Background: Significant body fat accumulation is an inevitable but potentially serious problem in maintenance peritoneal dialysis (PD) patients. Whether excessive fat gain predicts long-term outcomes in these patients is still unknown.

Methods: In this prospective observational study of 296 patients, the association between excessive fat accumulation and patient survival and PD failure rates was analyzed. Patients were classified by dialysis duration at time of study enrollment into short- (<2years) and long-term (>2years) groups. Body weight (BW) and body composition analysis were measured twice, 12.8 ± 4.6 months apart. Excessive fat accumulation was defined as a 1-year change in body fat percentage (ΔPBF) over the highest quartile (5.0% for men, 5.4% for women).

Results: A substantial 1-year increase in BW and PBF were only observed in the short-term group (p<0.001, 0.027), whereas, in the long-term group, the changes were insignificant. In the short-term group, the ΔPBF was closely associated with unfavorable baseline metabolic profiles, including old age, diabetes, obesity, elevated blood pressure and edema. Accordingly, mortality rate in patients with excessive fat accumulation was significantly higher than in those without (P=0.007). The risk of technical failure was also increased with excessive fat gain. After adjusting for diabetes, obesity, and fluid status, it increased the incident risk of PD failure by 2.22-fold (95% CI 1.08–4.54). However, in the long-term group, fat gain did not impact on prognosis.

Conclusions: Excessive fat accumulation occurring primarily during the early period of PD was associated with baseline unhealthy metabolic profiles, higher mortality and PD failure rate independent of baseline obesity and fluid status.

FR-PO553

The Association Between Obesity and CKD in the Human Hereditary and Health in Africa Kidney Disease Research Network

Titilayo O. Ilori,[1] Charlotte Osafo,[2] Shikhar Kumar,[5] Rulan S. Parekh,[3] Dwomoa Adu,[7] Rasheed A. Gbadegesin,[6] Akinlolu O. Ojo.[4] H3Africa Kidney Disease Study *[1]Nephrology, University of Arizona, Tucson, AZ; [2]University of Ghana Medical School, ACCRA, Ghana; [3]The Hospital For Sick Children, Toronto, ON, Canada; [4]University of Arizona Health Sciences, Tucson, AZ; [5]The university of arizona, Tucson, AZ; [6]Duke University Medical Center, Durham, NC; [7]University of Ghana, Accra, Ghana.*

Background: There is very little existing data on the relationship between obesity and CKD in Africans. We estimated the prevalence of obesity among cases (eGFR<60ml/min/1.73m^2) and controls (eGFR>60ml/min/1.73m^2) in the Human Hereditary and Health in Africa Kidney Disease Research Network (H3A-KDRN) and determined the association between obesity (measured by body mass index (BMI) and waist circumference) and CKD.

Methods: In this case-control study, we estimated the prevalence of obesity in cases and controls using BMI ≥30kg/m^2 and waist circumference ≥88cm in women and ≥102cm in men as definitions for obesity. Using logistic regression, we estimated crude and adjusted prevalence odds ratios and 95% confidence intervals for CKD in the entire cohort.

Results: The prevalence of obesity using BMI was 28.2% in the cases vs 21.5% in the controls (p<0.0000001) while the prevalence of obesity by waist circumference was 22.8% in cases and 26.2% in controls (p<0.01). Cases with a higher BMI were more likely to have higher eGFR (p<0.001) while controls with a higher BMI had a lower eGFR (p<0.0001). Compared to those with normal BMI, underweight individuals were 1.43 times more likely to have CKD, OR=1.43 (95% CI 1.11, 1.83). Overweight OR =0.87 (0.77,0.99) and obesity class I OR=0.81 (95% CI 0.68,0.95) were both associated with lower odds of CKD in the crude analyses. After adjusting for age, gender, country, hemoglobin and ACR underweight OR=1.61(95% CI 1.31, 1.98), overweight OR=0.85 (95% CI 0.74,0.97) and class I obesity OR=0.82 (95% CI 0.68, 0.99) remained associated with CKD. Compared to those with a normal waist circumference (80-87.9cm in women and 94-101.9cm in men), individuals with a waist circumference of <80cm in women and <94cm in men were more likely to have CKD (OR=1.24, 95% CI 1.05,1.48) in the crude and some adjusted models OR=1.20 (95% CI 1.01, 1.44). No other waist circumference categories were associated with CKD.

Conclusions: The findings in this stud mimics the risk factor paradox for obesity. Underweight individuals were more likely to have CKD but obese and overweight were less likely to have CKD. We will need further prospective studies to determine if higher BMI is protective of CKD in Africans or if these findings are reflective of reverse causality.

FR-PO554

Effect Modification of GFR and BMI on Insulin Sensitivity Among Nondiabetic Patients

Elvis A. Akwo,[1] Aseel Alsouqi,[1] Victoria Whitfield,[1] Talat Alp Ikizler,[1,2] Adriana Hung.[2,1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Veterans Affairs CSR&D, Nashville, TN.*

Background: Insulin resistance (IR) is highly prevalent in patients with CKD. The reason for this phenomenon is unknown. We studied the interaction between estimated glomerular filtration rate (eGFR) and body mass index (BMI) as determinants of peripheral and central insulin sensitivity (IS).

Methods: In a cross-sectional study of 150 patients, 56 CKD and 94 with normal GFR, we used hyperinsulinemic euglycemic glucose clamp to measure IS (peripheral or skeletal muscle IS) as insulin sensitivity index (ISI) and the homeostasis assessment of insulin resistance (HOMA-IR) (central or liver IS). eGFR estimated by CKD-EPI and body mass index (BMI) were estimated at baseline. Linear regression models with robust standard errors (to relax homoscedasticity assumptions) and interaction terms were used to investigate GFR and BMI as predictors of IS.

Results: The mean age was 53.9 (14.5) yrs; 50.7% were female and 36.7% African-American. Log ISI was positively correlated (r = 0.39, p < 0.0001) with eGFR and inversely correlated (- 0.30, p < 0.0001) with BMI. In multivariable models adjusted for age, sex and race, a 10 ml/min/1.73m2 increase in eGFR was associated with a greater increase in ISI among non-obese (0.48; 95% CI: 0.25, 0.70) compared to obese participants (0.18; 95% CI: 0.02, 0.35) (p-interaction = 0.04). Patients with low GFR had lower ISI (insulin resistant) even with normal BMI (Fig. 1a). Log HOMA-IR was inversely correlated with eGFR (r = - 0.49, p < 0.0001) and positively correlated with BMI (r = 0.52, p < 0.0001). HOMA-IR was higher for persons with lower GFR compared to higher GFR, at any BMI value. For example, at a BMI of 30 and a GFR of 30 ml/min/1.73m2, HOMA-IR was 4.8 compared to 1.2 at a GFR of 120 ml/min/1.73m2 (Fig. 1b).

Conclusions: GFR and BMI are both predictors of IS but the magnitude of the effect of BMI on IS varies across GFR levels and type of IS (peripheral versus central). The effect of BMI on central or liver IS (HOMA-IR) is more pronounced at lower GFR with small changes in BMI translating into greater variations in IS. Conversely, at low GFR, skeletal muscle IS is less affected by BMI.

FR-PO555

Density of Brown Adipose Tissue in Japanese Hemodialysis Patients: Association with Protein-Energy Wasting

Yoshihiko Kanno,[1] Miho Nagai,[1] Yuko Kurosawa,[1] Sayuri Fuse,[1] Takashi Ishizu,[2] Takafumi Hamaoka.[1] *[1]Tokyo Medical University, Tokyo, Japan; [2]Tsukuba Central Hospital, Ushiku, Japan.*

Background: Patients receiving chronic hemodialysis are on catabolic status in energy-consuming cycle, according to complex factors due to the pathogenesis of original disease, renal failure and dialysis therapy. Nutritional disorder in CKD patients with decreases of skeletal muscle and body fat has proposed to be called as Protein-Energy wasting (PEW) by International Society of Renal Nutrition and Metabolism (ISRNM). On the other hand, the pathogenesis of PEW is still unknown. In recent years, the importance of energy metabolism control via brown adipose tissue (BAT) gathers attraction, despite the difficulty in measuring its density. We have developed its portable measuring system, and investigated BAT densities and nutritional states in Japanese HD patients.

Methods: We assessed BAT densities in Japanese HD patients (66.5 ± 10.4 years) and healthy adults (65.3 ± 10.4 years) based on total hemoglobin concentrations in the supraclavicular region measured with near-infrared time-resolved spectroscopy. We also

assessed correlation between BAT densities and bioelectrical impedance analysis for the evaluation of body composition in HD patients.

Results: The BAT density in 33 HD patients was 75.6 ± 31.4 μM, which tended to be higher (p = 0.059) compared with 61.1 ± 4.3 μM in healthy subjects of the matched age over 40 years old. Furthermore, BAT density and body fat mass were negatively correlated in HD patients. BAT in healthy subjects were negatively correlates visceral fat area in previous studies. But in our study, despite the fact that the visceral fat area was significantly higher in HD patients, BAT tended to be higher in HD patients. The stimulation by cold and consequently increase in sympathetic nerve activity directly to BAT causes an increase in BAT density. It is known that muscle sympathetic nerve activity is elevated in patients with CKD complicated hypertension. It may be involved as a cause of increase in BAT density.

Conclusions: BAT may be one of the principal factors for malnutrition with energy-consuming cycles in HD patients.

FR-PO556

Glucose (Glu) Disposal in Diabetic (D) and Non-Diabetic (ND) Patients During Hemodialysis (HD)

Longin Niemczyk,[1] Stanislaw Niemczyk,[2] Anna Wojtecka,[2] Katarzyna Szamotulska,[3] Daniel Schneditz.[4] *[1]Medical University of Warsaw, Warszawa, Poland; [2]Military Medical Institute of Warsaw, Warsaw, Poland; [3]National Research Institute of Mother and Child, Warsaw, Poland; [4]Medical University of Graz, Graz, Austria.*

Background: It was the purpose to examine whether intra-venous (iv) Glu administered during HD caused a characteristic response suitable to detect impaired Glu tolerance in HD patients (pts) during routine treatment.

Methods: About 30 min into treatment (baseline T0), a 40% Glu solution (100.1±22.0 mL) was directly injected into the venous line of the extracorporeal circulation at a dose of 0.5 g/kg dry weight. Blood samples were drawn from the arterial line at T0, and 5, 10, 20, 30, 60 min after injection (T5, T10, T20, T30, T60). Glu (mmol/L) and insulin (Ins; mU/L) levels were measured. In addition, relative blood volume (RBV; %) was continuously measured by ultrasonic technique for quantification of osmotic volume effects.

Results: 25 ND and 9 D pts were studied (61±13 years, dry weight 80.6±17.6 kg, UF volume 2.47±0.92 L, 12 female). The increase and time course in Glu was largely comparable between D and ND pts; Ins significantly increased in ND pts only (Tab. 1). The RBV effect of Glu peaked around 6 min after injection and was 105.16±1.30 vs. 105.90±1.52% in ND and D pts, respectively, and also showed a comparable time course (Fig. 1).

Conclusions: In spite of significant difference in Ins secretion, infusion of Glu amount comparable to that of an iv Glu tolerance test did not produce major differences in Glu disposal during HD. It appears that Glu is removed faster by HD than it can be disposed in the large but slowly perfused Ins-dependent muscle and skin compartment. This may have implications for iv nutrition during extracorporeal treatments.

Lipoprotein Subfraction Analyses in a Cohort of the Palm Tocotrienols in Chronic Hemodialysis Study (PATCH)

Eno Latifi, Dina A. Tallman, Deepinder Kaur, Pramod Khosla. The PATCH Investigators *Wayne State University, Detroit, MI.*

Background: Dyslipidemia (D) is one of the characteristics of end-stage renal disease patients who develop cardiovascular disease (CVD). The PATCH clinical trials [NCT02358967, NCT02913690] are double-blind one-year intervention trials (300 mg tocotrienols or placebo daily) in hemodialysis patients in USA, Malaysia and Bangladesh (currently some 400 patients are enrolled). A pilot study showed improvement in D with tocotrienols. The aim of this preliminary analysis is to evaluate and characterize lipoprotein subfractions in the PATCH Michigan cohort.

Methods: The Michigan cohort includes 138 patients enrolled across various dialysis clinics in Michigan (recruitment ends Dec 2018). Subject are 95% African Americans (Age 59 ± 13 yrs., 64% men, dialysis vintage 65±63 months). Blood was collected at baseline and plasma isolated for lipid determination and lipoprotein subfraction analyses using a gel-electrophoresis method (Quantimetrix Lipoprint™).

Results: Baseline plasma lipids (n=124) revealed HDL-C, LDL-C and Triglyceride (TAG) values (mg/dL) of 49±18, 79±39 and 95±51, respectively. The values were not influenced by the dialysis shift during blood collection. The percentage of large, intermediate and small HDL particles were 39.4±15.6, 46.9±9.5 and 13.6±8.4, respectively. The percentage of large, intermediate and small LDL particles were 15.0±4.3, 8.1±3.9 and 2.4±3.3, respectively. Eight percent of subjects were D (TAG 201±54, HDL-C 33±5, LDL-C 133±17 mg/dL), 48% were normolipemic [N] (TAG 64±25, HDL-C 61±18, LDL-C 55±23 mg/dL), while the rest had mixed D (TAG 110±36, HDL-C 40±11, LDL-C 96±38 mg/dL). Dyslipidemic subjects had significantly greater proportion of small HDL particles than N subjects (22.5%±4.5% vs 9.1%±6.9%), while large HDL (24.6%±8.9% vs 48.3%±13.9%) and intermediate HDL (52.9%±6.6% vs 42.4%±8.7%) were significantly lower. D subjects had significantly smaller LDL particle sizes compared to N subjects.

Conclusions: Changes in circulating lipoproteins reflect alterations in LDL and HDL particle sizes that can be readily detected. The role of these compositional changes in CVD in HDL patients is as yet, unresolved. (Supported by the Malaysian Palm Oil Board/ Government of Malaysia)

FR-PO558

Glycosylated Hemoglobin A1c as a Predictive Marker of Poor Sleep in ESRD Population

Tarek A. Fouda,[2] Mostafa F. Elshirbeny,[3] Ahmad Kaddourah,[1] Abdullah Hamad,[1] Mohamed Y. Mohamed,[1] Rania A. Ibrahim,[1] Fadwa S. Al-Ali.[1] *[1]Hamad Medical Corporation, Doha, Qatar; [2]Hamad medical cooporation, Doha, Qatar; [3]HMC, Doha, Qatar.*

Background: Patients on dialysis experience higher rates of sleep disorders compared to general population. Self-directed questionnaires can help to diagnose sleep disorders. We aim in this study to describe the epidemiology of sleep disorders in ESRD population and determine the clinical and laboratory biomarkers that can predict it.

Methods: We conducted a prospective cross-sectional study in ESRD patients on dialysis in the main dialysis unit in the state of Qatar. All adult patients on dialysis for at least one month were eligible. Enrolled patients underwent sleep disorder screening using the Pittsburgh Sleep Quality Index (PSQI), a validated questionnaire to measure the quality and patterns of sleep in adults. PSQI score ≥5 indicates poor sleep. Logistic and regression models were employed to evaluate the association between poor sleep scores and different commonly used clinical and laboratory markers.

Results: 253 patients on dialysis (62% on hemodialysis and 38% on peritoneal dialysis) were enrolled. 115 (44.6%) were male. Median PSQI score was 10 (interquartilerange(IQR): 6-18). Diabetic patients had significantly higher median score of PSQI of 10 (IQR: 7-18.75) compared to non-diabetics (Median 9, IQR: 5-16.5) (P=0.02). 84% of diabetics had PSQI ≥ 5 compared to 73% in non-diabetic (P=0.03). Using univariate linear regression model, PSQI scores correlated significantly with Hb1AC levels (β1= 0.9, P=0.006) (even after adjusting for BMI (β1= 0.6, P=0.03)). For every 0.9 unit increase in Hb1AC, the PSQI increases by 1. The receiver operating characteristic (ROC) using Hb1AC as a predictor for sleep disorder showed AUC of 0.65. Utilizing a cut-off value of 5.1, the predictive diagnostic utility of Hb1AC was 80% for sensitivity and 89% specificity. Univariate analysis of other clinical markers including hemoglobin level, anemia, PTH, KT/v, hypertension, and phosphorus revealed no statistical correlation with PSQI scores.

Conclusions: Our data shows high prevalence of sleep disorders in ESRD population and diabetic patients are at higher risk. Utilizing Hb1AC in diabetics with ESRD can predict patients at increased risk of sleep disorder. Our statistical models suggest that controlled diabetes is associated with better sleep quality, however, further investigational work is needed.

FR-PO559

Intra-Individual Variability in High Density Lipoprotein Cholesterol and Risk of ESRD: A Nationwide Population-Based Study

Eun Sil Koh, Seok Joon Shin, Cheol Whee Park, Sungjin Chung. *The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.*

Background: Recent studies demonstrated an association between low high density lipoprotein – cholesterol (HDL-C) and progression of chronic kidney disease (CKD). However, some of the results showed the inconsistencies between HDL-C and renal

function outcomes. We investigated the association between HDL-C variability and the risk of end-stage renal disease (ESRD).

Methods: Using nationally representative data from the Korean National Health Insurance System, 3 718 355 subjects who were free of ESRD and who underwent ≥3 health examinations during 2005 to 2010 were followed to the end of 2015. HDL-C variability was measured using the coefficient of variation (CV), standard deviation (SD) and the variability independent of the mean (VIM). The primary outcome was the development of ESRD, defined as a combination of the relevant disease code and the initiation of renal replacement therapy.

Results: There were 2095 cases of ESRD during a median follow up of 4.8 years. There was a graded association between a higher HDL-C variability and incident ESRD. In the multivariable adjusted model, the hazard ratios and 95% confidence intervals comparing the highest versus lowest quartiles of VIM of HDL-C were 1.60 (95% confidence interval, 1.39–1.84). The results were consistent when the variability of HDL-C was modeled using SD and CV and were independent of preexisting CKD.

Conclusions: Increasing HDL-C variability was associated with an increasing incidence of ESRD. This findings suggest that HDL-C variability is an important risk factor of CKD progression in the general population.

FR-PO560

The Impact of Onset Age on Metabolic Disorders in Urolithiasis

Wen Wen, Yuehong Li, Qi Chen. *Beijing Tsinghua Changgung Hospital, Medical center, Tsinghua University, Beijing, China*.

Background: Urolithiasis is related with metabolic disease, such as hyperuricemia, diabetes, dyslipidemia and hypertension. We aim to explore the association between the metabolic diseases and the stone type, clinical and laboratory features, the onset age with urolithiasis patients.

Methods: Clinical data were retrospectively collected from 707 patients with urolithiasis surgery in Beijing Tsinghua Changgung Hospital from December 2015 to August 2017. Their demographic data, clinical manifestations, laboratory tests and examinations were analyzed retrospectively.

Results: (1) 446 males and 261 females (18 to 94 years old) from 28 provinces in China were included in our study. The urolithiasis patients with onset age > 30 years old are more likely common to diabetes mellitus, hypertension, gout, hyperlipidemia and metabolic syndrome. (2) The onset age of urolithiasis is positively associated with BMI (r=0.100, *P*=0.011), iPTH (r=0.089, *P*=0.049), TG (r=0.083, *P*=0.033), globulin (r=0.077, *P*=0.046) and IgG (r=0.077, *P*= 0.040), while it is negatively related to urine phosphorous (r=-0.109, *P*=0.027) and HDL-C (r=-0.099, *P*=0.010). (3) Correlation analysis showed that the level of TC and LDL-C were both positively associated with serum calcium, phosphorus, alkaline phosphatase (ALP), globulin and white blood cell (WBC) (*P*<0.05). The level of TG is positively associated with serum calcium, magnesium, 25-OH-VitD_3, while negatively associated with urine PH (*P*<0.05). HDL-C was negatively associated with urine uric acid (*P*<0.05). Fast glucose was positively associated with serum ALP, globulin and the count of urine bacterium (*P*<0.05). Serum uric acid was positively associated with serum calcium, phosphorous and urine phosphorus (*P*<0.05). (4) The incidence of urinary infection (70.3% vs. 62.2%, *P*=0.025) and amorphous calcium phosphate (1% vs. 0%, *P*=0.043) is significantly higher in patients with hyperlipidemia.

Conclusions: The urolithiasis patients with onset age > 30 years old are more likely associated with metabolic disorders and urinary infections. Elevation of serum lipid, glucose and urate acid may add risks to urolithiasis by impacting urine PH, calcium-phosphorus metabolism and infectious status.

Exosomal MicroRNAs Profiling in Obese Patient Using MicroRNA-Sequencing

Soon hyo Kwon, Hyoungnae Kim, Moo Yong Park, Hyunjin Noh. *Soonchunhyang University Hospital, Seoul, Republic of Korea*.

Background: Exosomal micro RNAs (miR) are valuable biomarker and regulate biological process of obesity. Bariatric surgery has beneficial effect on obese patients. However the mechanisms of this surgery are not clear. We investigated to identify exosomal miR signature associated with obesity and examine exosomal miR changes after bariatric surgery.

Methods: Healthy volunteers (HV, n=18) and non-diabetic obese patients (n=16) were enrolled prospectively. We assessed the miR profile of serum exosome from HV and obese patients using RNA sequencing (RNA-seq) cross sectionally. To evaluate the effect of bariatric surgery, we conducted exosomal miR analysis in 12 obese patients 6 months after surgery.

Results: RNA-seq analysis showed 224 obesity-related microRNAs. Using >2 and <-2-fold changes as cut-offs, we identified that the expression of 72 (up-regulation=57, down-regulation=15) exosomal miR in obese patients compared to HV (table 1). Biological pathway analysis was suggestive of modulation of signaling pathways including the Wnt pathway, fatty acid biosynthesis, AMPK signaling, p38 MAPK signaling, and AMPK signaling in exosome from obesity patients. Bariatric surgery induced weight reduction led to a marked change in the Wnt pathway and fatty acid biosynthesis pathway.

Conclusions: Obesity leads a different miR pattern in serum exosome compared to healthy volunteers. Weight loss after bariatric also induces changes in exosomal miR profiles.

Funding: Government Support - Non-U.S.

Cognitive Impairments in Renal Transplant Recipients: Impact on Daily Life Functioning

Aaltje L. Ziengs, Antonio Gomes Neto, Anne M. Buunk, Michele F. Eisenga, Coby Annema, Stephan J. Bakker, Gerjan Navis, Joke M. Spikman. *University Medical Center Groningen, Groningen, Netherlands*.

Background: After kidney transplantation, there is a heavy demand on the cognitive capacities of kidney transplant recipients (KTR) in order to increase survival chance with the donor organ. However, until now, it has been insufficiently examined to what extent cognitive functioning is affected in KTR. In this study, we aimed to examine the prevalence of cognitive impairment in KTR in the chronic stage. In particular, we assessed to what extent cognitive impairments affects daily life functioning post-transplant.

Methods: This study was conducted as part of the Transplantlines Biobank and Cohort Study at the University Medical Center Groningen. We included 120 KTR and 85 age, sex and education matched healthy controls (HC). Cognitive functions were assessed with tests measuring memory (15 Words Test (15WT), Wechsler Adult Intelligence Scale subtest Digit Span (Forward and Backward; DS FW, DS BW), Word Fluency (WF)), attention and mental speed (Trail Making Test part A (TMT-A)) and executive functioning (Trail Making Test part B (TMT-B), Dutch version of the Controlled Word Association Test (COWAT)). A questionnaire was used to examine participation in daily life (Utrecht Scale for Evaluation of Rehabilitation - Participation).

Results: Mean age of KTR was 56.9 ± 12.4 years, 69 were male, at a median time of 11 [1-41] years post-transplantation. KTR performed significantly worse on tasks measuring memory ($p < 0.01$ (15WT); $p < 0.001$ (WF); $p < 0.05$ (DS BW)), attention and mental speed ($p < 0.01$ (TMT-A) and executive functioning ($p < 0.001$ (TMT-B); $p < 0.001$ (COWAT)), compared to HC. Furthermore, daily life participation was significantly correlated with mental speed ($r = -0.36$, $p < 0.001$) and working memory ($r = 0.21$, $p < 0.05$).

Conclusions: This study shows cognitive impairments in multiple domains in KTR post-transplantation. Moreover, cognitive dysfunctioning interferes negatively with participation in everyday life. Administering early neuropsychological assessment in KTR is clinically highly relevant to detect cognitive impairments and to allow for timely counselling or treatment.

FR-PO563

Health-Related Hope, Disease Stage, and Disease Self-Management over a Very Wide Range of CKD Severity

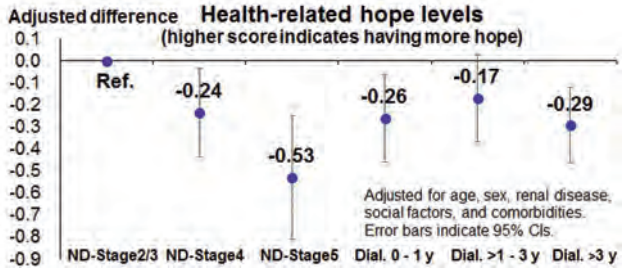
Noriaki Kurita,[1] Takafumi Wakita,[5] Yoshitaka Ishibashi,[2] Tomo Suzuki,[4] Hiroo Kawarazaki,[3] Yugo Shibagaki,[4] Masahiko Yazawa.[4] *[1]Department of Innovative Research and Education for Clinicians and Trainees, Fukushima Medical University Hospital, Fukushima, Japan; [2]Japanese Red Cross Medical Center, Tokyo, Japan; [3]Inagi Municipal Hospital, Tokyo, Japan; [4]Division of Nephrology and Hypertension, Department of Internal Medicine, St.Marianna University School of Medicine, Kawasaki, Japan; [5]Kansai University, Suita, Japan*.

Background: Disease experience varies at different stages of CKD. Patients who experience hope might more effectively adjust to their health condition. The aims of this study were to quantify the associations of health-related hope with disease stage, and with psychological and medical indices of CKD self-management.

Methods: Data were collected from 461 adult CKD patients in Japan. The range of disease severity was very wide: Included were patients at stage 2-3 who were not receiving dialysis (ND stage 2-3) and those at ND stages 4 and 5. Also included were patients receiving dialysis. Health-related hope (HR hope) was measured with a recently developed 18-item scale focusing on how people experience their health and how healthcare affects hope. General linear models were used to examine the associations of HR hope with CKD stage, blood pressure (BP), and serum levels of phosphorus and potassium. The burdens of water and diet restriction were measured with the Kidney Disease Quality of Life questionnaire. Generalized ordered logit models were used to examine the associations of HR hope with the likelihood of reporting that water or diet restriction was burdensome.

Results: Patients at ND stages 4 and 5 had lower levels of HR hope than those at ND stage 2-3 (Figure). With ND stage 2-3 as the reference, patients at all further stages had lower levels of HR-hope. The lowest level of HR-hope was among patients with disease at ND stage 5. Higher levels of HR hope were significantly associated with lower likelihoods of reporting that water and diet restrictions were burdensome (adjusted OR 0.53 and 0.57 for water restriction and diet restriction, respectively). Higher levels of HR hope were also significantly associated with lower systolic BP (adjusted mean difference -5.8 mmHg). HR hope levels were not associated with diastolic BP or with serum levels of phosphorus or potassium.

Conclusions: Among CKD patients, higher HR hope is associated with less-severe disease, lower systolic BP, and lower perceived burden of water restriction and diet restriction.



FR-PO564

Exploring Beliefs about Treatment in Advanced CKD and Relationship with Well-Being and Outcome

Zoe C. Pittman,[1] Maarten W. Taal,[1] Christopher W. McIntyre.[2] *[1]Royal Derby Hospital, Derby, United Kingdom; [2]London Health Sciences Centre, London, ON, Canada.*

Background: The beliefs that individuals hold about treatments affect treatment adherence. We aimed to examine this in both dialysis and non-dialysis dependant CKD patients and to include reference to other aspects of a treatment.

Methods: The Beliefs about Medicines Questionnaire (BMQ) explores individuals' beliefs about the necessity and concerns of treatments. We adapted the BMQ for beliefs about dialysis, fluid restriction, medicines and dietary restrictions. Individuals from HD (29), PD (10), CKD 4/5 (5) and transplant (13) clinics completed all relevant BMQ questionnaires and the illness intrusiveness ratings scale (IIRS), PHQ-9 (cut point PHQ ≥ 10 for depression screening in dialysis), dialysis recovery time (DRT) and measures of treatment tolerability (TT) and burden (TB). BMQ outputs are reported as mean ± SD, necessity score (max 25) and necessity minus concerns score (N-C) (range ±20, 0 = balanced beliefs).

Results: Dialysis: necessity 11.2 ± 4.8 and N-C -3.7 ± 4.7. N-C correlated with renal replacement therapy vintage (r=0.332 p=0.045) and TT (r=0.478, p=0.003) but not with TB, DRT, IIRS or PHQ-9 or age. Dietary restriction: necessity 15.2 ± 4.7 and N-C -1.2 ± 4.0. N-C correlated with serum potassium (r=0.376 p=0.015) and phosphate (r=0.332 p=0.040) but not with number of phosphate binders. Medicines: necessity 12.5 ± 4.3 and N-C -4.5 ± 4.8. N-C correlated with serum phosphate (r=0.384, p=0.005) but not with total number of medications or binders prescribed. Fluid restriction: necessity 13.3 ± 4.1, N-C -1.3 ± 4.0. No correlations were seen, including with interdialytic weight gains or systolic blood pressure. There was variable but significant correlation between all N-C scales; Dialysis: Medicines (r=0.718), Diet (r=0.550), Fluid (r=0.588); Medicines: Fluid (r=0.416), Diet (r=0.601); Fluid: Diet (r=0.601).

Conclusions: Individuals have a sophisticated way of thinking about the treatments that they are prescribed. These beliefs are not dependent on knowledge but impact on behaviours that affect measurable outcomes such as serum potassium and phosphate. The variation in correlation between some scales suggest that these thought processes are related, however they are not fixed character traits, and therefore may be amenable to education that takes into account individual beliefs in order to address them directly.

FR-PO565

Illness Perceptions in Renal Disease Correlate with Well-Being Markers

Zoe C. Pittman,[1] Maarten W. Taal,[1] Christopher W. McIntyre.[2] *[1]Royal Derby Hospital, Derby, United Kingdom; [2]London Health Sciences Centre, London, ON, Canada.*

Background: Individuals' perception of their illness correlates with both mortality and quality of life in dialysis patients. Improved understanding of illness perception and its relationship with outcomes will allow improved targeting of information and education. We therefore examined illness perceptions in both advanced CKD and dialysis, and how these relate to other markers of wellbeing.

Methods: The revised illness perceptions questionnaire (IPQr) offers a robust mechanism for examining individual's perception of illness. Persons from HD (29), PD (10), CKD 4/5 (5) and transplant (13) clinics were recruited for a study of understanding and illness perceptions. Questionnaires included the IPQr, illness intrusiveness ratings scale (IIRS), PHQ-9 (cut point PHQ ≥ 10 for depression screening in dialysis), dialysis recovery time (DRT) and measures of treatment tolerability (TT) and burden (TB), including number of tablets (total (NT) and phosphate binders (NB)). Additional background data were collected.

Results: Mean±SD values for individual IPQr subscales (max allowed) were Chronicity (30) 17.15±2.74, Cyclical (20) 9.91±3.97, Consequences (30) 19.11±3.59, Personal Control (30) 17.95±3.83, Treatment Control (25), 14.98±3.24, Understanding (25) 12.98±3.95, Emotional response (30) 15.54±4.98. Subscale analysis did not show any effect from dialysis status, gender or dialysis vintage. There were no correlations with chronicity, treatment control or understanding. However, subscales did demonstrate correlation with: 1)Perception of negative consequences; Age (r=-0.411), PHQ-9 (r=0.289), IIRS (r=0.550), TT (r=0.376), TB (r=0.331) 2)Emotional response; Age (r=-0.305), PHQ-9 (r=0.476), IIRS (r=0.476), TT (r=0.419), TB (r=0.450), NB (r=0.292). 3)Increased perception of the cyclical nature of the condition; PHQ-9 (r=0.308), IIRS (r=0.359), TT (r=0.395), TB (r=0.298). 4)Perception of treatment control correlated with age (r=0.282).

Conclusions: This study shows that individuals' perceptions of the consequences and emotional burdens of kidney disease are high and correlate with depressive symptoms and measures of consequence such as illness intrusiveness, treatment tolerability and treatment burden. Perceptions did not differ with dialysis status or dialysis vintage, suggesting that this is not a treatment effect. Further work will look at other predictors and outcomes.

FR-PO566

Cancer Screening in ESRD Patients

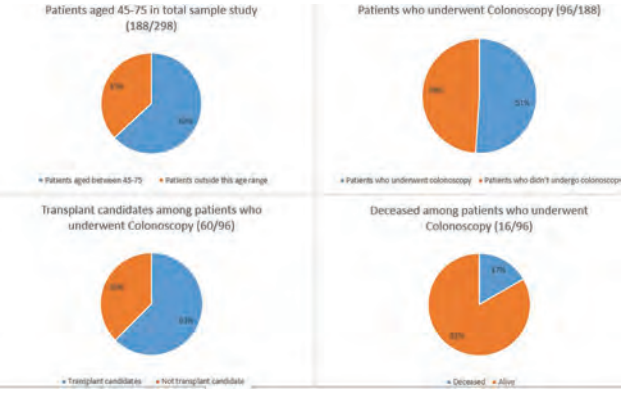
Anusha Sundararajan, Deepak Kana kadayakkara, Gregory K. Buller. *Internal Medicine, Yale New Haven Health Bridgeport Hospital, Bridgeport, CT.*

Background: As primary care physicians, we order health maintenance investigations as part of preventive work up which include cancer screening tests. ESRD patients form a special subset of population where regular cancer screening guidelines should not be applied as mortality is higher. The 2012 ASN 'choosing wisely' campaign recommended against regular cancer screening in ESRD patients. We initiated a project in our institution to assess the frequency of cancer screening tests- with focus on colorectal cancer screening in our ESRD population.

Methods: We did a retrospective study which included ESRD patients on hemodialysis (based on ICD codes) from a single center from 2012-2017 and excluded patients who had already received transplant or had prior malignancy. We had a total of 298 patients.

Results: Among the total 298 patients, 188 patients were between 45-75 year age group- out of which 96 patients (51%) underwent colonoscopy; out of 96 patients who underwent colonoscopy, 36 (37.5 %) were not transplant candidates and 16 (16.6%) died within the next 5 years. We also calculated Charlson comorbidity index of the patients to assess their 10 year survival likelihood.

Conclusions: Although patients who were undergoing transplant evaluation and patients with higher life expectancy had higher screening probability, the above numbers suggest that overscreening is still present. Hence, more individualized decision making including transplant likelihood and overall comorbidities of patients have to be considered before ordering cancer screening tests to avoid unnecessary cost and patient burden. These results can also help modify current practice- Providers can be alerted by EMR in ESRD population before ordering cancer screening tests to check if they will really benefit from them.



FR-PO567

Relationships Between Satisfaction Scores and Outcomes in Dialysis Patients

Yue Jiao, John W. Larkin, Marta Reviriego-Mendoza, Amy Barry, Judy L. Green, Len A. Usvyat, Jeffrey L. Hymes, Angela McClure, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Patient satisfaction is an important aspect of the quality of care provided, yet the associations to outcomes are unknown. We determined correlations between Net Promoter Score (NPS) satisfaction survey scores and clinical outcomes in hemodialysis (HD) patients.

Methods: We used clinic level data from a large dialysis provider in 2015 and 2017. NPS index assesses consumer satisfaction with a company's services via their willingness to recommend it to others; scores range from -100 to 100. We calculated Pearson's correlation coefficient (R) between annual NPS and end-of-year quality metrics that include readmission and hospital day rates per patient year, as well as the percent (%) of patients: nonadherent with HD treatments, with arteriovenous fistula (AVF), with hemoglobin (HgB) ≥10.0 to ≤11.0g/dL, with albumin (Alb) ≥4.0g/dL, and with calcium (Ca) ≤10.0mg/dL & phosphate ≥3.0 to ≤5.5mg/dL & parathyroid hormone ≥150 to ≤600pg/mL for a composite mineral bone disorder (MBD) measure. NPS was further compared to an overall composite quality score that aggregated the above metrics and others (e.g. Kt/V). We also calculated R between changes in NPS and changes in quality metrics.

Results: We analyzed data from 2,287 in-center HD clinics. Mean NPS scores were 49.0 in 2015 and 61.3 in 2017. We found higher NPS was related to: a lower % of patients nonadherent with HD treatments (R= -0.19 in 2015 & -0.18 in 2017; both p<0.001), a higher % of patients with AVF (R= 0.11 in 2015 & 0.12 in 2017; both p<0.001), a higher % of patients with HgB ≥10.0 to ≤11.0g/dL (R= 0.09 in 2015 & 0.10 in 2017; both p<0.001), a

higher % of patients with MBD laboratories in goal range (R= 0.14 in 2015 & 0.16 in 2017; both p<0.001), and a higher overall composite quality score (R= 0.13 in 2015 & 0.15 in 2017; both p<0.001). NPS was not related to readmission and hospital day rates, or the % of patients with Alb ≥4.0g/dL. The 12.3-point increase in NPS from 2015 to 2017 was related to improvements in the overall composite quality score (R= 0.06; p=0.01).

Conclusions: NPS scores were related, albeit weakly, to several quality metrics including treatment nonadherence, AVF use, anemia and MBD laboratories, and overall composite quality scores. Increases in NPS over time were weakly related to better overall composite quality scores.

FR-PO568

Depressive Disorders Are a Risk Factor for Falls and Fall-Related Injuries Among Adults with Kidney Disease

Brandon Kistler,[1] Jagdish Khubchandani,[1] Paul N. Bennett,[2] Ken Wilund,[3] Jacob J. Sosnoff.[4] *[1]Ball State University, Muncie, IN; [2]Satellite Healthcare, San Jose, CA; [3]University of Illinois, Urbana, IL; [4]University of Illinois at Urbana-Champaign, Urbana, IL.*

Background: Depressive disorders are common among patients with chronic kidney disease (CKD) and especially those who have advanced to end stage kidney disease (ESKD). In addition, depression and pharmacotherapy for depression have been associated with impaired gait and increased propensity for falls in older adults. Therefore, the purpose of this study was to determine the relationship between depressive disorders, falls, and fall-related injuries in a large cohort of US adults with CKD.

Methods: We analyzed the 2016 US Behavioral Risk Factor Surveillance System data using complex sample survey data analysis procedures in STATA software accounting for the multistage cluster study design.

Results: Among 354,829 adults, 16,675 (4.5%) reported CKD, 61,543 (16.8%) reported a history of a depressive disorder, 102,456 (28.5%) reported a fall, and 38.7% of those who fell reported a fall-related injury. Compared to adults without CKD or depression, adults with depression (OR=2.88, 95% CI=2.76-2.99), adults with CKD (OR=1.74, 95%CI=1.60-1.90), and adults with both CKD and depression (OR=4.17, 95%CI=3.69-4.71) had increased odds of suffering a fall. These results remained significant after accounting for demographic characteristics and comorbidities commonly associated with falls such as diabetes, arthritis, asthma, and cardiovascular conditions. Similarly, adults with depression (OR=2.02, 95%CI=1.90-2.14), CKD (OR=1.37, 95%CI=1.19-1.57), and CKD with depression (OR=2.89, 95%CI=2.47-3.38) had a higher risk of suffering an injury from a fall. Among only CKD patients, those who had been diagnosed with depression had higher odds of falling (OR=2.39, 95%CI=2.08-2.76) and suffering an injury (OR=2.11, 95%CI=1.72-2.59) even after adjusting for demographics and comorbidities commonly associated with falls.

Conclusions: Among adults with a self-reported diagnosis of CKD, depression is a risk factor for suffering a fall and fall-related injury. It is unknown if this increased propensity for falling is related to medications, depression, or an interplay of these and other factors. Given the high prevalence of depression within the CKD population, this relationship warrants further examination in order to prevent and decrease fall-related injuries in this population.

FR-PO569

Hospital Admission Rates Are Associated with Depressive Affect and Antidepressant Use in Dialysis Patients

Billy Kim,[1] Marissa A. Lee,[1] Sheetal Chaudhuri,[2] Hao Han,[2] Marta Reviriego-Mendoza,[2] John W. Larkin,[2] Len A. Usvyat,[2] Terry L. Ketchersid,[2] Franklin W. Maddux.[2] *[1]Fresenius Rx, Nashville, TN; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: Depression is a common mental health disorder and the leading cause of disability worldwide (WHO 2017). In the general population, antidepressant use has been associated with adverse drug events and frequent emergency room visits (Shehab N, et al. 2016). Little is known about the effects of antidepressant use, drug dialyzability, and associated outcomes in hemodialysis (HD) patients. We aimed to determine if hospitalization rates differ in HD patients by use of antidepressants and the presence of depressive affect (DA).

Methods: We analyzed data from a large dialysis provider on HD patients treated during 2016 to 2018. We stratified patients by antidepressant use and compared hospitalization rates per patient year (ppy). Furthermore, we captured data on patients who completed DA screening via the patient health questionnaire-2 (PHQ2) and compared hospitalization rates for those who were DA positive (PHQ2 score ≥3) or negative, and using an antidepressant or not.

Results: In a population of 268,443 HD patients, 26% of patients were using an antidepressant. Hospitalization rates were higher in those using an antidepressant versus patients not taking any antidepressants (2.18 vs 1.41 admissions ppy, respectively). Overall, there was a 75% response rate to the PHQ2 survey. Among those who completed the PHQ2, 9% were DA positive. Antidepressants were used by 41% of DA positive patients and 22% of DA negative patients. In DA positive patients, hospitalization rates were higher for those using an antidepressant versus patients not using antidepressants (2.66 vs 2.29 admissions ppy, respectively). Similarly, DA negative patients using antidepressants had higher hospitalization rates versus those not using antidepressants (2.4 vs 1.9 admissions ppy, respectively).

Conclusions: Findings indicate that patients taking antidepressants may have higher hospitalization rates when compared to those not taking any medication, irrespective of DA. Antidepressant-related hospitalization rates may be due to drug adverse events and could in part be confounded by indication. Treatment adherence and the presence of major depressive episodes are not addressed in this analysis. Further analyses are warranted.

FR-PO570

Association of Chronic Insomnia with Protein Energy Wasting in CKD

Jun Ling Lu,[1] Amado X. Freire,[1] Miklos Z. Molnar,[1] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[3,1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]University of California Irvine, School of Medicine, Orange, CA; [3]Memphis VA Medical Center, Memphis, TN.*

Background: Chronic insomnia is highly prevalent. Its effects on the sympatho-adrenal system could potentially cause multi-systems abnormalities. It is unknown if chronic insomnia plays a role in the development of protein energy wasting (PEW) in patients with chronic kidney disease (CKD).

Methods: In a national cohort of 229,236 CKD patients, we examined associations between chronic insomnia (defined as the presence of ICD9 codes 307.42, 307.49 and 780.52 and long-term use of insomnia medications) and PEW defined as the concomitant presence of serum albumin <3.8 g/dl or serum cholesterol <100 mg/dl, weight loss of 5% or more over 3 months, and neutrophil-to-lymphocyte ratio (NLR) >4.0. Associations were examined in crude logistic regression models (Model 1) and after adjustments for age, gender, race (Model 2), BMI, blood pressure, eGFR, chronic pain (Model 3), and comorbidities and socio-economic status (Model 4).

Results: 13,215 patients (5.8% of the cohort) had chronic insomnia and 1,412 (0.6% of the cohort) had PEW. 152 chronic insomnia patients (1.2%) vs. 1,260 patients in control group (0.6%) had PEW. Insomnia was associated with higher odds of PEW events in both unadjusted (Model 1) and in multivariable adjusted models (odds ratio in Model 4: 1.5 [95%CI: 1.3, 1.9], p<0.001), Figure 1. Results were consistent in subgroup analyses.

Conclusions: Chronic insomnia is associated with higher risk of PEW in CKD patients. Further studies are needed to determine underlying mechanisms of action and the effects of interventions.

FR-PO571

Hypokalemia: A Diagnostic Challenge

Smitha R. Anam,[1,2] James I. McMillan,[1,2] Zhiwei Zhang.[1] *[1]Nephrology, VA Loma Linda Healthcare system, Loma Linda, CA; [2]Nephrology, Loma Linda University Medical Center, Loma Linda, CA.*

Introduction: Hypokalemia, a very common clinical problem is generally due to decreased oral intake, urinary loss, gastrointestinal loss or transcellular shifts. Here we present a challenging case of refractory hypokalemia.

Case Description: A 72-year-old man with new diagnosis of prostate adenocarcinoma not yet on treatment presented with hematuria, new hypertension and hypokalemia. He denied poor oral intake, vomiting or diarrhea. He denied medications or herbal, dietary supplements. There was no family history of hypokalemia or hypertension. Laboratory: Serum Na 145mmol/L, K 2.0mmol/L, HCO3 34mmol/L, Plasma Renin 0.62ng/ml/hr, Aldosterone< 1ng/dl, Cortisol 38.8mcg/dl, ACTH 81pg/ml, Urine K 88.5mmol/L. Cystoscopy: large friable prostate, likely the cause of hematuria so palliative TURP was performed. Androgen deprivation therapy (Bicalutamide) was begun. Refractory hypokalemia persisted despite aggressive potassium replacement.

Discussion: In our patient, inappropriately high urine K, Hypokalemia and Chloride-resistant metabolic alkalosis and Hypertension suggested mineralocorticoid excess. However low plasma renin and aldosterone indicated pseudohyperaldosteronism. Differential diagnosis included Liddle's, Gellers syndromes, Syndrome of apparent mineralocorticoid excess or chronic licorice use, Cushing syndrome and Congenital adrenal hyperplasia. Patient's age and pertinent history excluded several of these leading us to a diagnosis of ACTH-dependent Cushing's syndrome. This was further confirmed by overnight dexamethasone suppression test. ACTH-dependent Cushing's syndrome could be due to Cushing's disease but MRI of brain was negative, making this unlikely. Ectopic ACTH producing tumor was felt more likely. A high grade prostatic adenocarcinoma with a neuroendocrine component was found in prostate tissue. The basic mechanism for hypokalemia is mineralocorticoid receptor (MR) activation by excess cortisol, leading to sodium reabsorption via ENaC. Treatment strategies focus on decreasing tumor burden and inhibition of MR or ENaC. Since some reports indicated spironolactone may

potentially promote prostate cancer, we instead recommended ENaC inhibitor triamterene. Chemotherapy (Etoposide/Carboplatin) was then initiated with resolution of hypokalemia after 5 days of treatment. He was off triamterene and potassium replacement by the end of 3rd cycle of chemotherapy.

FR-PO572

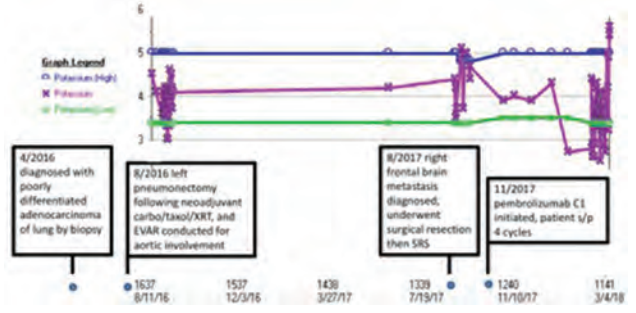
Hypokalemia as the Smoking Gun of Paraneoplastic Syndrome

Katherine M. Scovner,[1] Li Li,[2] Joseph V. Bonventre.[2] *[1]BWH/MGH, Boston, MA; [2]Brigham and Women's Hospital, Brookline, MA.*

Introduction: Ectopic secretion of ACTH (EAS) is commonly associated with small cell lung cancer but rare with other lung cancers. The present case is that of an individual with EAS leading to hypokalemia in the setting of lung adenocarcinoma.

Case Description: A 66-year-old woman presents with metastatic lung adenocarcinoma (poorly differentiated) diagnosed 2 years prior to admission. She had been treated with carboplatin and taxol. She presents with hypokalemia (K 2.6mmol/L despite K supplementation of 80meq per day). Hypokalemia was noted at the time of carboplatin therapy but resolved following its discontinuation. Hypokalemia was noted again at the time of the diagnosis of brain metastasis. Other labs were notable for Mg 1.8mg/dL, bicarbonate 33mmol/L, pH 7.51, and WBC 34.4K/uL with neutrophil predominance. Urine K was 92mmol/L and transtubular K gradient ((urine K/plasma K)/(urine osm/plasma osm)) was 26.2. Plasma cortisol was 46.5ug/dL at 7pm when ACTH was 67pg/mL. Morning cortisol after 1mg and 8mg dexamethasone were 38.1ug/dL and 32.9ug/dL respectively. Urine free cortisol was 650mcg/24 hours. Renin and aldosterone levels were both below lower limits of assay detection. Brain MRI showed no pituitary pathology to suggest Cushing disease. She was thus diagnosed with EAS. The patient underwent bilateral laparoscopic adrenalectomy, and potassium normalized. She then pursued hospice care as there were no more chemotherapeutic options.

Discussion: Although rare among non-small cell lung cancer patients, 13 cases of EAS with non-small cell lung cancer had been reported as of 2012. Hypokalemia due to platinum-based chemotherapy tends to coexist with hypomagnesemia (platinum decreases Mg, which inhibits the Na+K+ATPase and K is lost in urine through potassium channels in the thick ascending limb). The patient had hypokalemia as well as leukocytosis at the time of diagnosis of brain metastasis. Trends in K and WBC over time may help predict progression of malignancy in the setting of EAS. Bilateral adrenalectomy represents an option for control of EAS, but expected survival post-operatively should be considered before proceeding.



FR-PO573

Abiraterone Induced Hypokalemia in Treatment of Castration Resistant Prostate Cancer

Waleed Asfar, Milos N. Budisavljevic, Andrew B. Elliott. *Medical University of South Carolina, Charleston, SC.*

Introduction: Abiraterone was approved in combination with prednisone for the treatment of metastatic Castration Resistant Prostate Cancer (CRPC) who recieved chemotherapy. In 2018 FDA expanded the indication to include chemotherapy naive patients. Most common side effects associated with abiraterone include fatigue, diarrhea, hypertension, elevated liver enzymes, and hypokalemia. Abiraterone inhibits CYP17A1, the rate limiting hydroxylase in androgen and steroids synthetic pathway. This causes ACTH level to increase, leading to secondary excess in mineralocorticoids. This secondary excess manifests as hypertension, hypokalemia, and fluid overload. Prednisone is co-administered to suppress the hypothalamic-pituitary-adrenal axis and diminish the symptoms of mineralocorticoid excess.

Case Description: We Describe a case of a 65 year old male with history of hypertension, dyslipidemia, hypothyroidism and prostate cancer. He was diagnosed with Prostate cancer in 2005 and recieved total prostatectomy. In 2012 he developed biochemical relapse and recieved radiation and androgen depreviation therapy. In 2015 he was found to have bone metastasis and recieved radiation therapy to the cervical spine and started on abiraterone and prednisone therapy early 2016. He was later found to have avascular necrosis of the left femoral head and decided to stop prednisone as he was worried about his bone health. He was found to have Hypokalemia and worsening control of blood pressure on follow up with primary care, his serum potassium was 2.5 with a serum bicarb of 25. He was started on oral potassium supplementation but his Hypokalemia persisted. He was seen by nephrology as an outpatient, his exam was significant for elevated BP and trace lower extremity edema. serum aldosterone to renin was low at 2.9. He was started on aldactone with improvement in his serum potassium on follow up.

Discussion: With the recent expansion of the FDA approval more prostate cancer patients will be treated with abiraterone, understanding the mechanism of action of abiraterone and resulting side effects is crucial as it can prevent dangerous arrhythmias and outcomes. Nephrology input is needed in manging these patient along with primary care. Patient with contraindications to steroids should be started on eplerenone or aldactone therapy.

FR-PO574

A Rare Mutation Causing Hypertension and Hypokalemia During Pregnancy

Meghana Chalasani,[1] Laith Al-Rabadi,[2] Josephine Abraham.[1] *[1]University of Utah, Salt Lake City, UT; [2]University of Utah hospital, Salt Lake, UT.*

Introduction: Geller syndrome is a rare autosomal dominant condition characterized by severe early-onset hypertension and hypokalemia in pregnancy due to a gain-of-function mutation that causes upregulated mineralocorticoid activity.

Case Description: A 42-year old woman presented to her obstetrician during her 29th week of pregnancy (G1P0) and was found to be hypertensive (172/109 mm Hg). Patient was diagnosed with hypertension in her late thirties which she initially managed with exercise but later required hydrochlorothiazide and atenolol for 3 years. Both were stopped when she became pregnant and she did not require initiation of any other agents. At week 29, patient presented to her obstetrician with hypertension. She was also noted then to have hypokalemia (2.9 mmol/L) and hypomagnesemia (1.4 mmol/L) both of which were repleted intravenously. Repeat labs three days later revealed a potassium of 2.9 mmol/L and a magnesium of 1.4 mmol/L. Nephrology was consulted for further evaluation. Patient denied using diuretics or any over-the-counter supplements. Lab work was notable for a trans-tubular potassium gradient (TTKG) of 6.7 consistent with renal potassium wasting. Extensive chart review was conducted including patient's routine labs prior to pregnancy. Potassium levels pre-partum were consistently around 4 mmol/L. Patient was treated with oral potassium and magnesium supplements with frequent labs and instructions to discontinue supplements after delivery of fetus. Repeat labs four weeks post-partum revealed potassium of 3.8 mmol/L and magnesium of 2.0 mmol/L. Blood pressure also improved to 144/86 mm Hg.

Discussion: Geller syndrome is a rare autosomal dominant condition in which a gain-of-function mutation causes upregulation of mineralocorticoid activity by progesterone during pregnancy. The progesterone-high environment of pregnancy, particularly in the second and third trimesters, is likely the reason our patient suddenly developed hypertension and hypokalemia at 29 weeks. Although genetic testing is still pending, we are fairly confident in our diagnosis particularly because our patient's blood pressure and potassium levels improved post-partum. It is important that clinicians are aware of this rare entity as treatment with aldosterone antagonists which theoretically sound ideal to treat hypertension with hypokalemia can in fact exacerbate the hypertension.

FR-PO575

Supratherapeutic Posaconazole: An Emerging Cause of Apparent Mineralocorticoid Excess (AME)

Narisorn Atsava-Svate,[1] Alkesh Jani.[2] *[1]University of Colorado Denver, Denver, CO; [2]University of Denver Colorado, Aurora, CO.*

Introduction: Apparent mineralocorticoid excess (AME) causes severe hypertension accompanied by metabolic alkalosis with hypokalemia. Substances which are well known to cause AME include glycyrrhizic and glycyrrhetinic acid found in licorice. These compounds competitively inhibit the enzyme called 11 Beta Hydroxysteroid Dehydrogenase type 2 (11β-HSD2). Lack of 11β- HSD2 caused higher cortisol available to bind the mineralocorticoid receptor, and results in ENaC-mediated Na reabsorption. Posaconazole, the broad-spectrum azole group antifungal agent, is commonly used for prophylaxis in patients with AML and severe neutropenia. Literature review revealed that posaconazole at supratherapeutic level can also inhibit 11β- HSD2 and cause apparent mineralocorticoid excess (AME).

Case Description: A 37 years old Caucasian female with refractory acute myelogenous leukemia (AML) with normal baseline blood pressure(100-120/65-80mmHg). She had neutropenia after third re-induction chemotherapy with G-CLAM regimen. She was then started on oral posaconazole 300 mg daily for fungal prophylaxis. One month later she then developed refractory hypokalemia with metabolic alkalosis and new onset hypertension (180/110mmHg). We were giving her potassium replacement 60-80 mEq/day, but her serum potassium level remained less than 3.3 mEq/L. Her serum cortisol level was 18.2 mcg/dL, plasma renin activity <0.167 ng/mL/h, plasma aldosterone level < 1ng/dL. Serum posaconazole level was 1800 ng/mL. Discontinuation of posaconazole, with documented normal therapeutic posacoanzole level, resulted in improvement of hypertension, refractory hypokalemia and metabolic alkalosis. All clinical features resolved within 2 weeks after discontinuation of posaconazole.

Discussion: We suggest that posaconazole level should be part of laboratory investigations in patients who are treated with posaconazole and have new onset of hypertension, hypokalemia and metabolic alkalosis. Posaconazole, at supratherapeutic level, inhibits 11 Beta Hydroxysteroid Dehydrogenase type 2 and causes apparent mineralocorticoid excess (AME).

FR-PO576

Urinary Exosome Analysis in a Case of Licorice-Induced Pseudoaldosteronism

Shinichiro Asakawa,[1] Osamu Yamazaki,[1] Yuto Hayama,[1] Masaki Yamanaka,[1] Emiko Kuribayashi-Okuma,[1] Yoshihide Fujigaki,[2] Shigeru Shibata.[1] Teikyo University School of Medicine *[1]Teikyo University School of Medicine, Tokyo, Japan; [2]Teikyo University School of Medicine, Department of Internal Medicine, Tokyo, Japan*.

Introduction: Excessive licorice intake can cause a syndrome mimicking hypermineralocorticoidism. Glycyrrhizin, the active metabolite of licorice, inhibits 11bHSD2 that converts cortisol to inactive cortisone, resulting in epithelial Na^+ channel (ENaC) activation in principal cells. However, the contributions of other Na and Cl transporters including Na-Cl cotransporter (NCC) in distal convoluted tubules and the Cl/HCO_3 exchanger pendrin in intercalated cells remain unknown.

Case Description: A 74-year-old woman with type 2 diabetes was referred for muscle weakness, leg edema, and polyuria. She reported that she had been taking herbal medicine containing licorice (6 g/day). Her BP was 162/78 mmHg and work up revealed severe hypokalemia (1.9 mEq/L), mild hypernatremia (147 mEq/L), and metabolic alkalosis (pH 7.513, and HCO_3 43.2 mmol/L). Urinary potassium level was 84.0 mEq/gCr, indicating the urinary potassium loss. Serum magnesium level was 1.9 mg/dL. Her serum aldosterone level was below the detection limit (< 10 pg/mL) with low plasma renin activity (0.3 ng/mL/hour). Serum cortisol and adrenocorticotropic hormone were normal. Abdominal CT scan and Doppler ultrasound of renal arteries revealed no abnormality. She stopped taking licorice and received KCl 40 mmol of DIV and 24 mmol oral in first 24 hrs. However, hypokalemia persisted, and the patient received 25mg of spironolactone orally from day 3. On day 10, serum potassium returned to normal, and was discharged on day 13. To address the contribution of Na and Cl transport mechanisms in the distal nephron, we isolated exosomes from pre- and post-treatment urine samples. Comparison of the pre- and post-treatment samples revealed that active, cleaved form of ENaCγ was markedly increased, whereas uncleaved form was undetectable in the pre-treatment sample, consistent with the increased activity of ENaC. Of note, both pendrin and NCC levels were profoundly increased in the pre-treatment sample, and were reduced after the treatment. In contrast, NKCC2 levels were lower in the pre-treatment sample than in the post-treatment sample.

Discussion: These data indicate that not only ENaC but NCC and pendrin are involved in licorice-induced fluid and electrolyte abnormalities.

FR-PO577

Hypokalemic Tetraparesis as First Manifestation of MGRS

Nicola Lepori,[1] Matteo Floris,[1] Andrea Angioi,[1] Riccardo Cao,[1] Alice Atzeni,[1] Anna Maria Asunis,[2] Doloretta Piras,[1] Gianfranca Cabiddu,[1] Antonello Pani.[1] *[1]Nephrology, Ospedale Brotzu, Cagliari, Italy; [2]Anatomic Pathology, Ospedale Brotzu, Cagliari, Italy*.

Introduction: Renal potassium wasting is a frequent cause of hypokalemia; it can be consequence of medications, endogenous hormone production, inherited or acquired renal tubular defects

Case Description: A 50 y/o woman was admitted to our Hospital with limb weakness, muscle cramps progressing to tetraparesis, associated with severe hypokalemia (1,6 mEq/L). She denied diarrhea or vomiting; pharmacologic and past medical history were unremarkable. Labs showed normal renal function, hyperchloremic metabolic acidosis, urinary potassium wasting (88 mmol/24h) and alkaline urine. A diagnosis of hypokaliemic tetraparesis due to distal renal tubular acidosis (type 1 RTA) was made. IV NaHCO3 and KCl replacement resolved the tetraparesis. Further investigations were made: SPEP showed a IgMK monoclonal protein, ANA (1:640) and ENA-SSA were positive (689 U/ml) while antiDNAds were negative. At that time, she rejected a renal biopsy and any follow-up. Two months later, she was admitted to our Department with hypertension (170/90 mmHg) and swelling. Labs showed normal kidney function, hypokalemia, slightly increased CRP levels. Urinalysis revealed microscopic hematuria and proteinuria (3.6 g/24h). Serology revealed very low C3 and C4, positive ANA (1:320), ENA-SSA (314 U/ml), type 1 cryoglobulins (IgMk). Suspecting an MGRS, a renal biopsy was performed: light microscopy showed an MPGN pattern with coarse pseudothrombi and a diffuse interstitial infiltration of lymphomonocytes, kappa+. IF was coherent with serology, showing IgMK (+++) and C3 (++) subendothelial deposits, and kappa+ cytoplasmic droplets in proximal tubules. Type 1 cryoglobulinemia and kappa light chains induced chronic tubular interstitial nephritis (resulting in type 1 RTA) was diagnosed. After three courses of dexamethazone, rituximab and cyclophosphamide, microscopic hematuria disappeared, proteinuria improved to 0,15 g/24h and serum potassium levels persisted steady without potassium supplements

Discussion: We described an unusual presentation of MGRS, with severe hypokalemia due to diffuse tubular injury mediated by kappa light chain, followed by a full blown type 1 cryoglobulinemia. Searching for a monoclonal protein should be an essential part investigating an acquired tubular disfunction

FR-PO578

Neck Down Paralysis in a Young Male Triggered by High-Dose Steroids

Sohaib Zahid, Swathi Lavudi, Tina Y. Ko, Khaled Nashar, Kalathil K. Sureshkumar. AGH Nephrology *Nephrology, Allegheny Health Network, Pittsburgh, PA*.

Introduction: Derangements in electrolyte homeostasis can result in a variety of clinical manifestations. Herein we present a unique case of sudden severe symptomatic hypokalemia in an otherwise healthy young male triggered by high dose steroid.

Case Description: A 30 year old caucasian male with no significant medical history was given intravenous high dose steroids for allergic skin rash in the ER. The next day he presented with sudden onset of bilateral upper and lower extremity weakness and palpitations. Vitals were normal except for tachycardia. Physical examination confirmed bilateral upper and lower extremity weakness with diminished reflexes. CBC and BMP were unremarkable except for potassium (K) 1.4 meq/L. EKG revealed atrial fibrillation. He was given IV and oral K replacement. Further workup showed TSH of 0.007mcU/ml(0.4-4.0) with free T4 of 4.28 ng/dl(0.7-1.9) and free T3 of 11.19 pg/ml(1.76-3.68). He was started on propranolol and methimazole. His symptoms completely resolved within twelve hours of treatment and he was discharged home in a stable condition.

Discussion: Hypokalemic periodic paralysis (HPP) is a rare autosomal dominant neuromuscular disorder with prevalence of 1 in 100,000. Male to female ratio is approximately 4:1. Genetic mutations have been identified that affect skeletal muscle sarcolemma calcium and sodium channels, resulting in inadequate depolarization. Acquired HPP has been described in association with hyperthyroidism and can be precipitated by administration of intravenous steroids as in our patient. Thyroid hormones increase tissue responsiveness to beta-adrenergic stimulation, resulting in increase sodium-potassium ATPase activity on skeletal muscle membrane resulting in hypokalemia. High dose steroid likely modulated the K lowering effect of thyroid hormones in our patient. It is important to differentiate thyrotoxic periodic paralysis (TPP) from HPP as the former requires administration of non selective beta blocker along with K replacement to ameliorate the acute attack whereas the latter corrects with K replacement alone.

FR-PO579

Symptomatic Hypophosphatemia from Parenteral Iron Administration

Sohaib Zahid, Swathi Lavudi, Kalathil K. Sureshkumar, Tina Y. Ko. AGH Nephrology *Nephrololgy, Allegheny Health Network, Pittsburgh, PA*.

Introduction: Fibroblast growth factor 23 (FGF23) plays a crucial role in phosphate and vitamin D homeostasis. Herein we present a case of severe symptomatic hypophosphatemia following the administration of intravenous (IV) ferric carboxymaltose likely triggerred by inappropriate FGF23 activity.

Case Description: A 31 year old female received two doses of IV ferric carboxymaltose for iron deficiency anemia. Four days later, she presented with numbness, tingling and muscle cramps. Evaluation revealed severe hypophosphatemia with serum phosphorus level of 1.0 mg/dl. Serum potassium, calcium, iPTH, 25 hyrdoxy, and 1,25 dihydroxyvitamin D levels were normal. A 24 hour urine collection revealed calcium of 27 mg (100 -250mg) and phosphorus of 1.8 g (0.4- 1.3 g) with a high fractional excretion of phosphorus >5%. Serum FGF23 level was inappropriately elevated at 97 RU/ml (44-215) for the degree of hypophosphatemia. Patient was given IV and oral phosphorus supplementation repeatedly without clinically significant improvement. Serum phosphorus levels were normalized with resolution of symptoms three weeks later.

Discussion: FGF23 is secreted primarily by bone, thymus, heart, brain and, in low levels, by several other tissues. It reduces serum phosphorus levels by decreasing expression of type IIa sodium/phosphate cotransporters, resulting in decreased renal phosphate reabsorption. It also down regulates the gene transcription of 1α-hydroxylase thereby reducing the bioactive 1,25-dihydroxy vitamin D (1,25-2OH-VitD) further decreasing the phosphate reabsorption in the gut. Ferric carboxymaltose is a newer iron formulation increasingly prescribed due to its effectiveness and shorter infusion time. There have been reports of hypophosphatemia associated with use of IV iron preparations including saccharated ferric oxide and ferric citrate hydrate. Studies have shown that IV iron may reduce peripheral degradation, secretion, and clearance of FGF23 resulting in inappropriately elevated FGF23 levels. Data is scarce with use of IV ferric carboxymaltose and hypophosphatemia. Our case highlights the importance of understanding the side effect profile of commonly administered medications and formulations so that an early diagnosis could be established.

FR-PO580

A Case of Diabetic Ketoacidosis Concurrently with Severe Hypokalemia Induced by Distal Renal Tubular Acidosis Due to Toluene Intoxication

Kazuki Aihara,[1] Yosuke Nakagawa,[1] Naoto Hamano,[1] Masahiro Koizumi,[1] Takehiko Wada,[2] Masafumi Fukagawa.[1] Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan *[1]Tokai University School of Medicine, Isehara, Kanagawa, Japan; [2]Tokai University, Isehara, Japan*.

Introduction: Diabetic ketoacidosis (DKA) is a high anion gap metabolic acidosis due to excessive blood concentration of ketone bodies. Hyperkalemia is often accompanied with DKA because of extracellular potassium shift caused by lack of insulin action as well as reduced renal potassium excretion caused by acute prerenal kidney injury. Here, we report a case of DKA complicated by severe hypokalemia resulting from distal renal tubular acidosis type 1 (RTA-1) due to toluene intoxication.

Case Description: A 37-year-old male who had been treated with basal supported oral therapy for type 2 diabetes mellitus for 7 years experienced appetite loss. He took only isotonic drinks for 5 days and nausea and vomiting developed, followed by muscle weakness and difficulty of walking. He was referred to our hospital with his laboratory findings of hyperglycemia and high anion gap metabolic acidosis with ketonemia, which was diagnosed as DKA. In the meantime, normal anion gap metabolic acidosis was thought to be exist as well. In addition, he had severe hypokalemia and inappropriately high urinary excretion levels of potassium despite acute kidney injury due to volume depletion. He was treated with fluid resuscitation and continuous venous insulin infusion plus a large amount of potassium supplementation (Figure 1). After his general status improved, he stayed out of the hospital for trial. However, he came back in a haze with an odor of organic solvent and urinalysis revealed elevated levels of potassium and urinary hippuric acid concentration (23.65 g/L). Finally, he confessed to abuse of toluene for more than 20 years.

Discussion: It is known that toluene intoxication can be the cause of RTA-1 which gives rise to normal anion gap metabolic acidosis and hypokalemia. We should take toluene intoxication account if severe hypokalemia is accompanied with DKA.

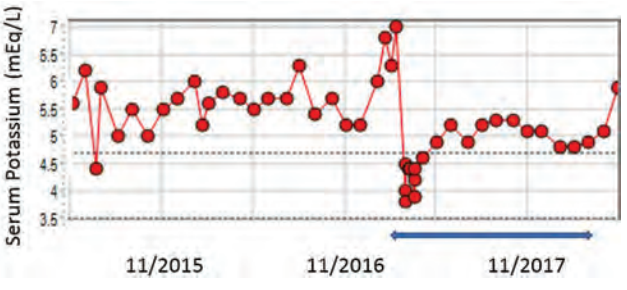
Use of Patiromer for Long-Term Management of Hyperkalemia in an ESRD Patient

Sylvester Barnes,[1,2] Julia Schneider,[1,2] David J. Leehey.[1,2] *[1]Hines VA, Hines, IL; [2]Loyola University Medical Center, Maywood, IL.*

Introduction: Hemodialysis patients generally undergo dialysis with a dialysate potassium concentration of either 2 or 3 mEq/L. Use of lower dialysate potassium concentrations (< 2 mEq/L) may lead to post-dialysis hypokalemia and an increased risk of arrhythmia. This leads to a dilemma when pre-dialysis hyperkalemia is not controlled despite use of a 2 mEq/L potassium dialysate. A possible solution is the use of potassium binding agents in order to decrease pre-dialysis serum potassium concentrations.

Case Description: A 60-YOM with ESRD due to IgA nephropathy was being maintained on hemodialysis on a MWF schedule for 4h each treatment using an AVF. He was very compliant with dialysis and with dietary restrictions. However he had persistent pre-dialysis hyperkalemia (peak K of 7 mEq/L and average around 5.5 mEq/L) despite use of a 2 mEq/L potassium dialysate. His Kt/V was 1.6. No access recirculation was present. He did not take RAAS inhibitors or other medications known to cause hyperkalemia. He had previously been prescribed maintenance sodium polystyrene sulfonate which was poorly tolerated. In February 2017 he was scheduled for laparoscopic cholecystectomy, and assistance was requested in lowering his serum potassium levels pre-operatively. He was begun on patiromer 8.4g every Saturday and Sunday which resulted in a marked decrease in his pre-dialysis serum potassium concentrations. He was subsequently maintained on patiromer for over one year (until March 2018) with no further episodes of hyperkalemia (see Figure; arrow depicts duration of patiromer therapy). At the patient's request the drug was then stopped, leading to an increase in pre-dialysis serum potassium level.

Discussion: Hyperkalemia can be a persistent problem for patients on chronic hemodialysis. Most guidelines recommend that very low potassium dialysates (< 2 mEq/L) be avoided. In this patient, use of patiromer twice weekly resulted in a long-term stable lowering of the pre-dialysis potassium concentration. To our knowledge this is the longest reported use of scheduled patiromer in a dialysis patient.



FR-PO582

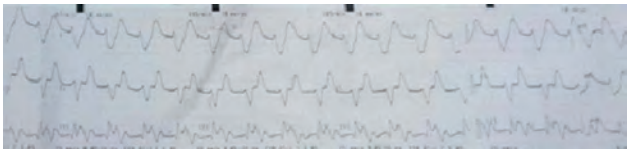
Loquat Induced Severe Hyperkalemia Presenting as Secondary Hyperkalemic Paralysis and Cardiac Conduction Abnormalities

Raja M. Rashid,[1] Zahid Nabi.[2] *[1]CPSP, Islamabad, Pakistan; [2]KRL Hospital, Islamabad, Pakistan.*

Introduction: Severe hyperkalemia is attributed to 3-5% deaths and a quarter of emergency dialysis sessions in ESRD patients. It generally manifests as cardiac abnormalities and rarely as secondary hyperkalemic paralysis. Missed dialysis sessions and dietary indiscretions to known potassium rich food are common causes. Loquat (Nispero, Eriobotrya japonica) is an often overlooked fruit for having moderate to high potassium content (266mg/100gram) that caused life threatening hyperkalemia in our patient.

Case Description: 27 year old male with ESRD secondary to diabetic nephropathy on thrice weekly maintenance hemodialysis for past 1.5 years presented in ER with restlessness, feeling of unease and weakness in limbs and inability to walk. There was no history of current or preceding fever and any such episode in the past. Examination revealed an alert yet restless individual, afebrile with pulse of 62 bpm and blood pressure of 90/60mmhg, flaccid paraparesis, hypotonia and diminished reflexes. His immediate EKG is shown in Fig. 1. Calcium gluconate was infused, transcelluar shifting measures were instituted and dialysis session of 4 hours was carried out within 30 minutes of presentation with constant cardiac monitoring. EKG changes necessitated repetition of calcium gluconate, thrice over an hour, changing serum calcium from 8.8 mg/dl pre-dialysis to 9.4mg/dl afterwards. Non hemolized and repeated samples confirmed pre dialysis serum potassium of 9.6mmol/L and post dialysis concentration of 5.2mmol/L. His symptoms improved after 80 mins of dialytic therapy. Patient was not on Beta blockers, ACE inhibitors or NSAIDs. The family and patient denied taking any unusual substance except for repeated large servings of loquat since his last dialysis session.

Discussion: Context specific and dietary education curtailing multicultural cuisines can prevent potassium catastrophes. In the ER, secondary hyperkalemic paralysis should be considered in differentials of acute paralysis. IV Calcium for myocardial stability is to be repeated judiciously unless pressing EKG changes vanish. Unambiguous EKG changes in pertinent clinical setting are sufficient in dialysis population to warrant urgent hemodialysis administration.



FR-PO583

SIADH as the Initial Presentation in Guillain Barre Syndrome

Nicholas Fuca,[1] Divya Asti,[2] Bindu Mudduluru,[2] Elie El-Charabaty.[1] SIUH Internal Medicine / Nephrology *[1]Staten Island University Hospital, Staten Island, NY; [2]Northwell Health, Staten Island, NY.*

Introduction: Guillain-Barre Syndrome (GBS) is an autoimmune disease damaging the peripheral nervous system that commonly presents as rapidly progressive symmetrical motor weakness. Autonomic dysfunction occurs in about 70% of GBS patients. Although there is a known association of SIADH in GBS patients, it usually occurs late in the disease course when there is maximal motor deficit. SIADH as an initial finding in patients with GBS is rare which is reported in this case.

Case Description: 72-year old female with history of dyslipidemia presented with subjective complaints of bilateral lower extremity weakness and difficulty ambulating. Her initial neurological exam was normal, with no deficits. She was found to have hyponatremia at 128 mEq/l that continued to drop to 115 mEq/l despite normal saline. Her serum Osmolality was 245 Osm/L, with elevated Urine Osmolality 702 Osm/L, suggestive of SIADH. Fluid restriction 1L daily was initiated, and her sodium continued to decline to 113 mEq/l. By day 6 she was found to have lower extremity weakness with strength 1/5. CSF analysis showed an albuminocytologic dissociation (total protein 288 & WBC 3) – suggestive of GBS. Therapeutic Plasmapheresis Exchange and oral Tolvaptan was initiated. Her sodium stabilized 134-137 mEq/l. With aggressive treatment and physical therapy, she regained her strength and walked without assistance at discharge.

Discussion: GBS commonly presents as progressive symmetrical muscle weakness with absent/decreased deep tendon reflexes. Incidence of SIADH in GBS is ~4.8%. Pathogenesis of SIADH in GBS is hypothesized to be: (1) Resetting of the osmoreceptor (2) Increased sensitivity of ADH at renal tubules. Hyponatremia in our case was present on admission prior to motor deficits from GBS. Urine and serum studies confirmed SIADH requiring tolvaptan. Her GBS was treated with plasmapheresis and her sodium stabilized only after treatment of the underlying GBS. Only 2 cases of GBS with SIADH at presentation have been reported. Observational and prospective studies have shown hyponatremia in GBS is associated with poor outcomes and increase mortality. Our case report emphasizes that SIADH may precede the development of profound motor deficit in GBS. Physicians should be aware of this rare presentation to prevent delays in treatment. Further studies are necessary to understand the cause behind SIADH in GBS and its impact on prognosis.

FR-PO584

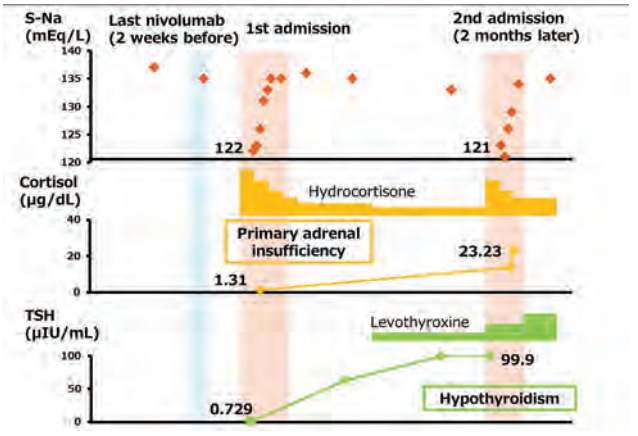
Hyponatremia Due to Nivolumab-Induced Sequential Primary Adrenal Insufficiency and Hypothyroidism

Raku Son, Masahiko Nagahama, Masaaki Nakayama. *St. Luke's international hospital, Tokyo, Japan.*

Introduction: Hyponatremia is the most common electrolyte disorders in lung cancer patients. Here we present a case of hyponatremia due to both primary adrenal insufficiency and hypothyroidism in a patient treated by nivolumab, a novel and increasingly used immune checkpoint agent.

Case Description: A 77-year old Asian man diagnosed as Stage IV non-small cell lung cancer on 6 courses of nivolumab for 4 months presented with 1-week general malaise. Laboratory test showed serum sodium (S-Na) 122 mEq/L. Cortisol, renin, aldosterone were 1.31 microg/dL, 1.1 ng/ml/hr and 23 pg/ml, respectively. Brain MRI denied hypophysitis. Positron emission tomography (PET) scan showed no adrenal metastasis but raised suspect of thyroiditis, though TSH was within normal limit. After treatment with hydrocortisone for primary adrenal insufficiency, S-Na was improved to 136 mEq/L. One month after discharge, laboratory follow-up revealed TSH of 62.7 micro IU/ml with low free T4 and T3. Levothyroxine was started but TSH remained high at 99.9 micro IU/ml. Two months after discharge he again presented with S-Na 121 mEq/L accompanied with loss of appetite. Laboratory test revealed cortisol 23.23 microg/dL, renin 7.5 ng/ml/hr and aldosterone 115 pg/ml. We increased both levothyroxine and hydrocortisone and S-Na returned to 135 mEq/L.

Discussion: Hyponatremia in lung cancer patients is commonly attributed to SIADH or hypovolemia. However, immune checkpoint agent including nivolumab can cause hypophysitis, primary adrenal insufficiency and hypothyroidism, or even more than one as in our patient. Any patient on a checkpoint inhibitor presenting with hyponatremia should undergo full work-up of endocrine disorders.



FR-PO585

A Rare Case of Hypophysitis Induced Hyponatremia

Alia Hasan, Mala Sachdeva, Rimda Wanchoo, Kenar D. Jhaveri. *Nephrology, Zucker School of Medicine at Hofstra Northwell, GREAT NECK, NY.*

Introduction: Immune checkpoint inhibitors are associated with a few electrolyte disorders. CTLA-4 antagonists are known to cause hypophysitis and as a result hyponatremia with an incidence of 3.2%. PD-1 inhibitors are not commonly associated with hyponatremia from hypophysitis. We report a case of hyponatremia associated with hypophysitis secondary to pembrolizumab therapy.

Case Description: A 69 year old male was diagnosed with non small cell lung cancer with metastatic lesions. Given the tumor was PDL1 positive, the patient was initiated on pembrolizumab therapy. 4 months into therapy, the patient was noted to have orthostatic hypotension and presented with a blood pressure of 90/50 mmHg and a sodium concentration of 125mmol/L. A trial of normal saline lead to improvement in blood pressure but worsening of hyponatremia to 123mmol/L. Serum osmolarity was 260mosm/Kg and urine osmolarity of 475mosm/Kg. Urine Na was 45mmol/L. An am cortisol repeated 3 times showed a very low value. ACTH was also suppressed. A thyroid panel revealed a low TSH and a low T4 level. FSH, LH and other hormones were in normal limits. An MRI of the brain did not show any pituitary lesions and a CT scan of the adrenals revealed no new findings. Given the hormonal abnormalities, a diagnosis of hypophysitis was made. This led to secondary adrenal insufficiency, hypotension and hyponatremia. The patient responded to corticosteroid therapy and Na improved to 133 mmol/L on discharge. The patient was also started on fludrocortisone and levothyroxine therapy.

Discussion: In contrast to CTLA4 antagonists, PD1 and PDL1 inhibitors are more commonly assocaited with thyroid and adrenalitis causing hyponatremia. Hypophysitis with PD-1 inhibitors is rare occuring <1% of patients. The mean onset of endocrine side effects is 9 weeks after initiation (range 5-36 weeks) of immunotherapy. Since the endocrine effects of immune checkpoint inhibitors are classified as toxic adverse events, it is recommended both discontinuation of the immune checkpoint inhibitor medication and 'high-dose' glucocorticoid treatment as in our patient. Our case highlights the potentially life threatening complication of checkpoint inhibitors and the urgent need for awareness amongsts hospitalists, nephrologists and oncologists for prompt recognition and treatment.

FR-PO586

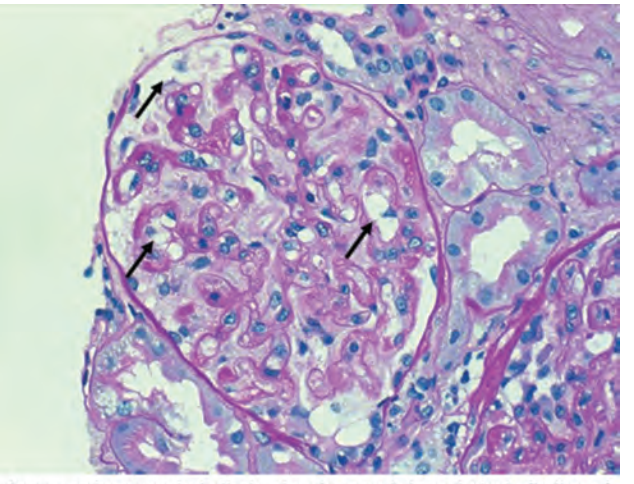
Hyponatremia in Pregnancy and the Role of Renal Biopsy

Nathaniel Pedley, Pietro A. Canetta, Russell J. Crew, Michael B. Stokes, Pascale Khairallah. *Columbia University Medical Center, New York, NY.*

Introduction: Preeclampsia is a serious pregnancy complication that may mimic nephrotic syndrome. Severe hyponatremia in preeclampsia is rare and presents a unique clinical challenge as it increases the risk of seizures, mimicking eclampsia. It can also lead to several maternal and fetal adverse events.

Case Description: We report the case of a 35yo G1P0 female who presented at 21 weeks of gestation with anasarca and vomiting. The pregnancy was conceived via in vitro fertilization and was uneventful until the day of presentation. She was found to be hypertensive to 152/84mm Hg with 4+ proteinuria on urine dispstick. Her labs were significant for creatinine of 0.7 mg/dL, serum albumin of 2.5 g/dL, Na of 117 mmol/L, and proteinuria of 12.5 g/g. Serum osmolality was 233 mOsm/Kg, UNa was <20 mmol/L and UOsm was 235 mOsm/Kg. Severe hyponatremia was secondary to low effective circulating volume from hypovolemia in the setting of vomiting and anasarca, and improved with albumin infusions. The combination of severe hyponatremia and proteinuria prompted a renal biopsy to identify the underlying cause of nephrotic syndrome. The biopsy showed diffuse severe glomerular thrombotic microangiopathy with endotheliosis, consistent with preeclampsia. The pregnancy was terminated with normalization of Na levels within 3 days postpartum and reduction in proteinuria to 2 g/g within 2 weeks postpartum.

Discussion: This case is the earliest by gestational age at which preeclampsia-induced hyponatremia has been reported. The rarity of this complication, combined with the early gestational age of preeclampsia onset and the desire of the patient to maintain her pregnancy, necessitated a definitive diagnosis to explain her clinical picture. The renal biopsy proved critical in determining the diagnosis and best course of therapeutic action.



Arrows point to endotheliosis, the characteristic pathologic finding of preeclampsia. It is a variant of thrombotic microangiopathy with damaged swollen endothelial cells.

FR-PO587

Evaluating Preeclampsia as a Rare Cause of Severe Hyponatremia

Shreemayee De,[1] Aimen Liaqat.[2] [1]*Newark Beth Israel Medical Center, Edison, NJ;* [2]*Saint Barnabas Medical Center, West Orange, NJ.*

Introduction: During normal pregnancy, resetting of osmostat can take place resulting in decrease of plasma osmolality by about 10 mOsm/kg, and mild decrease in serum sodium concentration by 4-5 meq/L. This phenomenon has been associated with increased production of hCG. Preeclampsia is a multisystem disorder defined by hypertension and proteinuria, but not classically associated with severe hyponatremia. However, there are rare incidences where severe hyponatremia is a complication of preeclampsia that can result in serious complications such as convulsions and cerebral edema.

Case Description: The first case is about a 32-year old female of 27-week gestation who presented with preeclampsia with severe features. Due to worsening epigastric pain, HELLP syndrome and elevated blood pressure, patient had emergent C-section at 28-week gestation. Patient was also found to have severe hyponatremia with lowest serum sodium concentration of 120 meq/L on the day of C-section. She was initially treated with fluid restriction and diuretics; this resulted in overcorrection of sodium by 10 meq/L that was treated with hypotonic fluid and one dose of desmopressin. Gradually the correction of sodium slowed down and eventually corrected to 142 meq/L on the day of discharge. The second case is about a 29-year old female of 33-week gestation who also presented with preeclampsia with severe features. Due to breech presentation of the fetus and preeclampsia, patient had C-section at 34-week gestation. Patient initially had normal serum sodium concentration. Overtime sodium concentration decreased to 126 meq/L one day prior to C-section. Gradually, sodium improved appropriately with diuretics and fluid restriction to 136 meq/L 2 days after C-section.

Discussion: The pathogenesis of preeclampsia associated severe hyponatremia has been widely postulated. It is important to understand the etiology of severe hyponatremia based on history and physical exam, which can help guide treatment. The main mechanism

is yet to be understood. There is a theory that preeclampsia can stimulate non-osmotic release of ADH. Another theory suggests that defective placenta in preeclamptic patients is unable to produce enough vasopressinase that would rapidly inactivate ADH. Although the incidence of preeclampsia associated severe hyponatremia is reported rarely, it is a serious complication that needs to be addressed soon and managed promptly.

FR-PO588

Correction of Hyponatremia Using D5W Pre-Blood Pump on Patients on Continuous Renal Replacement Therapy: A Case Series

Cassiopia L. Lippold, Ami Patel. *University of Baltimore, Baltimore, MD.*

Introduction: Patients with severe hyponatremia and renal failure who require continuous renal replacement therapy (CRRT) are at risk of overcorrection of their sodium (Na) level. Herein, we present three cases of using a calculated amount of dextrose 5% solution (D5W) pre-filter as pre-blood pump (PBP) to prevent overcorrection of hyponatremia.

Case Description: Case 1: 53 year old female with end-stage liver disease secondary to alcohol and lupus presented with abdominal pain and vomiting with serum Na level of 114 mEq/L, which was overcorrected to 138 mEq/L by day 2. She was initially treated with free water flushes via a nasogastric tube and peripheral D5W, which improved her serum Na to 129 mEq/L. On day 4, she was started on continuous venovenous hemofiltration (CVVH) for oliguric renal failure with replacement rate around 1.5 L per hour, and added D5W PBP at 35 ml/hr, to keep her serum sodium at 135 mEq/L on the following day. Achieved Na was around 135-137 mEq/L. Case 2: 39 year old male presented with alcohol withdrawal and hemorrhagic shock due to a variceal bleed. His admitting Na was 100 mEq/L, which corrected to 119 mEq/L by day 2. Patient was started on CVVH for acidosis, oliguric renal failure, and volume overload. Initial prescription was 2 L per hour replacement rate, D5W 500 ml per hour as PBP to aim for a goal Na of 112 mEq/l. The patient's Na level improved to 112-115 mEq/L by day 3-4. Subsequently, D5W PBP was slowly titrated downward to aim for slow correction of hyponatremia. Case 3: 45 year old male presented with acute alcoholic hepatitis, oliguric renal failure, and hyponatremia of 124 mEq/L. Patient was started on CVVH with D5W 100 ml per hour as PBP to achieve a goal Na of 131 mEq/L. In the next 24 hours, his Na was 127 mEq/L, and D5W was titrated downward with eventual slow correction of his hyponatremia.

Discussion: Slow correction of hyponatremia can safely be accomplished with the above calculation in patients with renal failure requiring CRRT using D5W PBP.

	D5W PBP (ml/hr)	Replacement Rate (L/hr)	Goal Na (mEq/L)	Achieved Na (mEq/L)
Patient 1	35	1.5	136	135-137
Patient 2	500	2	112	112-115
Patient 3	100	1.5	131	127

$$Rate\ of\ D5W\left(\frac{L}{hour}\right) = Replacement\ rate\left(\frac{L}{hour}\right)\left(\frac{140}{goal\ sodium} - 1\right)$$

FR-PO589

Syndrome of Inappropriate Antidiuresis (SIAD) in a Patient with Systemic Sclerosis: Cyclophosphamide (CYC) Use and Scleroderma Renal Crisis (SRC)

Marcelo D. Silveira, Victor F. Seabra, Marcia Fernanda Arantes de Oliveira, Camila E. Rodrigues, Bernardo V. Reichert, Antonio C. Seguro, Lucia Andrade. *University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Introduction: Hyponatremia is the most common electrolyte disorder and is often caused by SIAD, which can in turn be caused by the use of CYC, especially at moderate or high doses. To our knowledge, there has been only one reported case of hyponatremic hypertensive syndrome caused by SRC. The proposed mechanism is alteration of the osmoregulatory system, involving release of antidiuretic hormone (ADH) secondary to peripheral hyperstimulation of the renin-angiotensin system (RAS). We describe a case of SIAD associated with the use of low-dose CYC and aggravated after SRC.

Case Description: A 50-year-old male patient with a 2-year history of systemic arterial hypertension (controlled with losartan, 100 mg/day) presented with pulmonary interstitial disease and a 1-year history of progressive skin thickening. Skin biopsy showed sclerosing dermatitis, consistent with scleroderma. A mixed nucleolar and cytoplasmic reticular pattern of antinuclear antibodies was found. After an initial dose of CYC (500 mg), he developed asymptomatic hyponatremia (plasma sodium, 125-130 mEq/L). His condition was aggravated during an episode of hypertensive crisis and acute kidney injury, suggestive of SRC. During the hypertensive crisis, he presented to the emergency room with hypertension (200/120 mmHg), worsening of renal function (creatinine increasing from 1.0 to 1.5 to 2.5 mg/dl), and hyponatremia (Na, 121 mEq/L), as well as the following: plasma osmolality, 270 mOsm/kg; urine osmolality, 419 mOsm/kg; ADH, 1.5 pg/ml (reference: 1.0-13.3 pg/ml); schizocytes 0.6% (reference: absent); and lactate dehydrogenase, 259 U/L (reference: 135-220 U/L). Plasma sodium levels improved after blood pressure control with captopril (200 mg/day), fluid restriction and increased protein intake. There was also partial improvement of renal function (creatinine decreasing from 2.5 to 1.5 mg/dl).

Discussion: In this case, low-dose CYC use led to SIAD, with worsening of hyponatremia and increased plasma ADH, inconsistent with a hypo-osmolar state, in a patient whose condition was consistent with SRC. There was a significant increase in plasma renin activity, suggesting peripheral hyperstimulation of the RAS, which can deregulate the central osmoregulatory system.

FR-PO590

Osmotic Demyelination Syndrome Associated with Acute Severe Hypernatremia and Hyperglycemia

Fumiaki Tanemoto, Masahiko Nagahama, Yugo Ito, Masaaki Nakayama. *St. Luke's International Hospital, Tokyo, Japan.*

Introduction: The association between hyponatremic osmotic disturbance and osmotic demyelination syndrome (ODS) are well-established and studied. It has been increasingly recognized that ODS can occur in the setting of hypernatremia. In case of hypernatremic ODS, there is no consensus on how rapid or slow to correct plasma sodium. We report a case of ODS accompanied by acute hypernatremia and hyperglycemia.

Case Description: A 63-year-old female with a history of hypertension and dementia was brought to the ER with coma. Laboratory data were significant for plasma sodium of 189 mEq/L, plasma glucose of 629 mg/dL, serum bicarbonate of 22 mEq/L, BUN of 63 mg/dL, and plasma osmolality of 412 mosmol/kg. Head CT did not reveal any abnormalities. She was diagnosed with hyperosmolar hyperglycemic syndrome (HHS) and hypernatremia, and was admitted to ICU. Since there were 2 target components of hypertonicity simultaneously, hypernatremia and hyperglycemia, a great attention was paid to lower the tonicity appropriately to avoid cerebral edema. The upper limit of a correction rate of plasma tonicity during correction of hyperglycemia was set as 3 mosmol/kg per hour and that of plasma sodium was 10 mEq/L per day according to clinical guidelines. Although those correction rates were strictly kept, her neurological symptoms were not improved significantly. Brain MRI was performed to ascertain more precise information on day 6, which was consistent with ODS. With continuation of those correction rates of plasma tonicity and plasma sodium, her neurological symptoms as well as ODS findings in MRIs were improved gradually. The patient was sent to a rehab facility with good condition on day 65.

Discussion: ODS usually occurs in patients with overly rapid correction of chronic hyponatremia. However, ODS also results from a rapid increase in tonicity in patients with acute hypernatremia or HHS. Since onset of hypernatremia is unclear in most of the cases, serial imaging with different modalities may be warranted for detecting subtle neurological findings associated with hypernatremia, such as cerebral edema or even ODS. Although the appropriate correction rate of plasma sodium with hypernatremic ODS is not known, this case suggests that adhering to clinical guidelines may improve the prognosis of it.

FR-PO591

Central Diabetes Insipidus in a Patient with Newly Diagnosed AML

Osama El Shamy,[1] Siddhartha Kattamanchi,[3] Steven G. Coca.[2] *[1]Mount Sinai Hospital, Hasbrouck Heights, NJ; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Mount Sinai Medical Center, New Rochelle, NY.*

Introduction: Central diabetes insipidus (CDI) has been reported as both a rare complication of AML that may precede its diagnosis, and a may be a manifestation of its relapse. The exact mechanism by which diabetes insipidus and AML are connected remains elusive. The prevalence of cytogenic abnormalities in AML has been implicated as a possible cause. Here we describe a case of AML-induced CDI with monosomy 7 and without evidence on imaging of pituitary infiltration

Case Description: A 28 y/o woman was transferred from an outside hospital with significant leukocytosis (WBC 163,000) in the setting of a non-healing dental extraction and worsening odynophagia. She was found to have a new diagnosis of AML (diagnosed by peripheral blood smear and a deletion of D7S522 (7q31) locus via FISH) and a left neck soft tissue infection. The patient was started on the 7+2 chemotherapy protocol (Cytarabine and Idarubicin) on 4/17/18. The renal service was consulted for AKI in the setting of polyuria (approximately 2.5 to 3 liters per day). Labs were notable for a serum creatinine of 2.1 mg/dL, serum sodium of 152 meq/L, and urine osm of 190 mosm/L. She was started on ddAVP, and was continued for several days, over which time her urine output decreased, urine osmolality increased, with concomitant improvements in serum sodium and serum creatinine. Re-induction chemotherapy for persistent blasts was started 2 weeks later with clinical response over the next 10 days as evidenced by only 0.3% blasts. ddAVP was able to be discontinued as well at this point, as the resolution of the CDI coincided with the re-induction chemotherapy and subsequently confirmed low blast count and undetectable B cells

Discussion: A review of the literature reveals that CDI is a rare complication of AML, which can occur anytime during the course of AML. Although the exact mechanism connecting AML and CDI is unknown, some proposed theories include infiltration of hypothalamic pituitary stalk and abnormal expression of GP130 on neutrophils and platelets in patients with deletions on chromosome 7 or monosomy 7. The deficient GP 130 leads to abnormalities in glycosylation of neutrophils and platelets which can lead to CDI via two mechanisms: 1) decreased pre-pro-vasopressin which results in less active ADH production and 2) the dysfuctional platelets may affect ADH function and transport. Successful treatment of AML can rapidly reverse CDI.

FR-PO592

X-Linked Recessive Nephrogenic Diabetes Insipidus Cured with Bilateral Native Nephrectomy Following Living Donor Renal Transplant

Gautam Rangavajla,[2] Juan Pablo Arroyo,[1] Anthony J. Langone.[1] *[1]Nephrology, Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University School of Medicine, Nashville, TN.*

Introduction: X-linked recessive nephrogenic diabetes insipidus (X-NDI) is the most common subtype of congenital nephrogenic diabetes insipidus (CNDI) and is caused by mutations in the AVPR2 gene. This results in dehydration which increases the risk of urinary

tract damage. Current treatment for CNDI aims to reduce free water loss through low-solute diets, HCTZ and potassium-sparing diuretics, as well as NSAIDs. Diuretics enhance sodium and water reabsorption in the proximal nephron, and NSAIDs inhibit prostaglandin-meditated free water excretion. However, this treatment only reduces urine output by 25-50%, leaving a considerable aquaresis that impacts quality of life.

Case Description: A 19 year-old man with X-NDI with an AVPR2 mutation and neurogenic bladder underwent a Mitrofanoff procedure for neurogenic bladder at age 6. Despite intermittent catheterization several times a day, he developed recurrent UTIs, and eventually CKD IV secondary to chronic hydronephrosis. He had poor quality of life given need for q1-2 hr catheterizations with aprox. 600 cc of urine each time. Pre-transplant his creatinine baseline was 8.5 mg/dL. His medications included amiloride, HCTZ, and oxybutynin. He underwent a living related kidney transplant and was discharged on standard immunosuppression and antibiotics, amiloride, and HCTZ. He continued urinary catheterizations following discharge, with Cr stabilizing to a baseline of 1.7. His urine output continued at above 3L per day. He then underwent bilateral native nephrectomy in an attempt to cure his X-NDI and improve his quality of life. Labs following bilateral nephrectomy showed normal serum (289 mOsm) and urine (528 mOsm) osmolality with a urine output of 1.6L per day, and his Cr decreased to 1.1 mg/dL on discharge.

Discussion: Current research into new therapeutic strategies for X-NDI focuses on AVPR2 chaperones, methods to biochemically bypass the AVPR2 receptor, and existing drugs that affect AVPR2's signaling pathway. This case represents, to our knowledge, the first X-NDI patient cured with bilateral native nephrectomy following living related donor transplant for X-NDI complications. This suggests a role for renal transplantation and native nephrectomy as a definitive treatment of X-NDI and possibly CNDI, with a marked improvement in patients' quality of life.

FR-PO593

Hypophosphatemia and Phosphate Wasting Due to Oncogenic Osteomalacia in a Patient with Natural Killer T-Cell Lymphoma

John P. Canterbury, Juan Carlos Q. Velez. *Ochsner Clinic Foundation, Jefferson, LA.*

Introduction: Hypophosphatemia is common electrolyte disorder in hospitalized patients. Urinary phosphate wasting can be caused by oncogenic osteomalacia (OncOsteom), en entity characterized by production of phosphatonins, like fibroblast growth factor 23 (FGF-23). Mesenchymal tumors are the most common cause of OncOsteom and other malignancies are rarely associated. Here we present an unusual case OncOsteom in a patient with Natural Killer T-cell (NKT) lymphoma.

Case Description: A 33 year-old woman was admitted to the hospital with fever, chills, productive cough and myalgias. She had a remote history of mycobacterium *avium complex* infection and was actively being treated for hepatitis B virus with tenofovir and for hemophagocytic lymphohistiocytosis with etoposide. Upon arrival, the patient was normotensive but in respiratory distress. Examination showed sinus tachycardia and diffuse rales on lung auscultation. Laboratory data revealed serum electrolytes (mEq/L): Na 137, K 3.7, Cl 106, and CO_2 23. Others serum chemistries (mg/dL): creatinine 0.4, urea nitrogen 16, calcium 7.7 (serum albumin was 1.6 g/dL, corrected calcium 9.6) and phosphorus 1.5. Intravenous sodium phosphate was aggressively supplemented. Urine phosphate was 63 mg/dL, no glucosuria. Discontinuation of tenofovir did not lead to resolution of hypophosphatemia and the patient continued to require constant IV phosphate replacement for 12 additional days. A diagnosis of OncOsteom was entertained and a FGF-23 level was obtained and found to be elevated at 1940 RU/mL. A 1,25 (OH) vitamin D level was 48 ng/mL and 25 (OH) vitamin D was 8 ng/mL. A bone marrow biopsy was performed and the patient was diagnosed with NKT lymphoma. She continued to deteriorate clinically and expired 1 week later.

Discussion: Hypophosphatemia secondary to OncOsteom is an ominous disorder associated with significant morbidity. It is typically encountered in patients with mesenchymal tumors. Our case is the first reported in a patient with NKT lymphoma. The teaching point is that OncOsteom should be considered in cases of refractory urinary phosphate wasting in the presence of a lymphoproliferative disorder and measurement of FGF-23 level should be considered in those cases to reach a diagnosis.

FR-PO594

Case Report and Literature Review of Fanconi Syndrome Induced by Deferasirox in a Patient with Beta Thalassemia

Akika Ando, Santosh Saraf, Frances F. Tian, James P. Lash, Ana C. Ricardo. Division of Nephrology, Division of Hematology/Oncology, Department of Medicine, University of Illinois at Chicago *University of Illinois at Chicago, Chicago, IL.*

Introduction: Deferasirox (DFRA) is an oral iron chelating agent used to treat transfusion-related iron overload. Fanconi syndrome has been reported in less than 1% of patients receiving DFRA. There is a limited number of cases of Fanconi syndrome reported among patients with beta thalassemia treated with DFRA. Therapy with DFRA was permanently discontinued in all of the reported cases, except one in whom DFRA therapy was resumed after improvement of renal tubular function, resulting in recurrence of Fanconi syndrome. We report the case of a patient who developed Fanconi syndrome while receiving DFRA therapy who was rechallenged with the medication but has no signs of renal dysfunction after 6 months of therapy.

Case Description: A 25-year-old woman with medical history of beta thalassemia major and transfusion-related iron overload requiring iron chelation therapy, presented to the emergency department with generalized pain, nausea, and headaches for 24 hours. The patient had been receiving DFRA for 12 months prior to presentation. On admission, she was found to have hypophosphatemia (<1.0 mg/dL), hypokalemia (2.7 mEq/L), and non-anion gap metabolic acidosis (serum bicarbonate level 15 mEq/L). She was also found to have a urine pH of 5.5, glucosuria without hyperglycemia, and 100 mg/dL proteinuria based on urine disptick. Based on her clinical presentation, the patient was diagnosed with Fanconi syndrome. Her symptoms resolved within 1 week of discontinuing DFRA. Due to intolerance to alternative chelating agents, DFRA was restarted 1 year after Fanconi syndrome was diagnosed at 50% of the recommended dose and 3 months later, increased up to the full recommended starting dose. After 6 months of therapy, the patient has no symptoms or signs of Fanconi syndrome recurrence.

Discussion: As demonstrated in our case and prior reports in the literature, DFRA-induced Fanconi syndrome is reversible once DFRA therapy is discontinued. Plasmapheresis was attempted in one case, but did not significantly impact recovery time. Recovery can usually take several weeks to months. One case demonstrated the development of mild tubular damage after DFRA was restarted. Based on our case report, rechallenge with DFRA may be safe with close monitoring.

FR-PO595

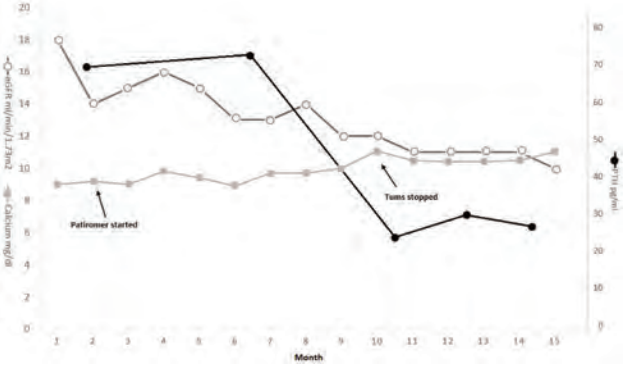
Patiromer Associated Hypercalcemia

Adil Ghaffar,[1] Hemant Magoo,[1,2] Ashish Verma.[1,2] *[1]Internal Medicine, Saint Vincent Hospital, Worcester, MA; [2]Renal and Transplant Associates of New England, Worcester, MA.*

Introduction: Patiromer calcium sorbitex is a non-absorbable cation exchange polymer approved for management of chronic hyperkalemia in patients with chronic kidney disease. We report a case of hypercalcemia in a patient with chronic kidney disease stage 5 (CKD 5) treated with patiromer.

Case Description: A 75-year-old Caucasian male had Hypertension and CKD 5 (GFR of 10 ml/min/1.73m^2) secondary to biopsy proven Focal Segmental Glomerulosclerosis. He had chronic hyperkalemia despite discontinuation of RAAS inhibition. Patient was initiated on patiromer 8.4 grams daily. This has been continued for over a year now. Prior to patiromer's introduction, corrected calcium was in the 8.5 to 8.9 mg/dl range. Eight months into treatment with patiromer, calcium was between 10.5 to 11.1. iPTH was 23-29 pg/ml. 25-hydroxy vitamin D was low at 9ng/ml. TSH was normal and serum immunofixation was negative. Patient had been taking prn TUMS (calcium carbonate) otc for reflux symptoms that was discontinued upon discovery of hypercalcemia. However, hypercalcemia has persisted several months after discontinuation of TUMS.

Discussion: Patiromer binds free potassium and magnesium ions in the gut and releases calcium ions in exchange. This helps correct hyperkalemia in these patients without sodium loading, a problem with sodium polysterene sulfonate. Though 10% of the patients did develop hypomagnesemia (below 1.4mg/dL), significant hypercalcemia has not been reported in any clinical study or subsequently. The amount of calcium released from patiromer that may be systemically absorbed is modest and did not lead to significant hypercalcemia in clinical studies. However, patients with advanced CKD may be more vulnerable due to their limited ability to excrete calcium in the urine. Prolonged treatment with Patiromer may increase the risk of hypercalcemia as noted in our patient and should be monitored for, besides hypomagnesemia.



FR-PO596

SPECT/CT with Technetium 99m-Methyl Diphosphonate for the Diagnosis of Severe Symptomatic Hypercalcemia After Rhabdomyolysis Induced AKI in 2 Patients with Cirrhosis

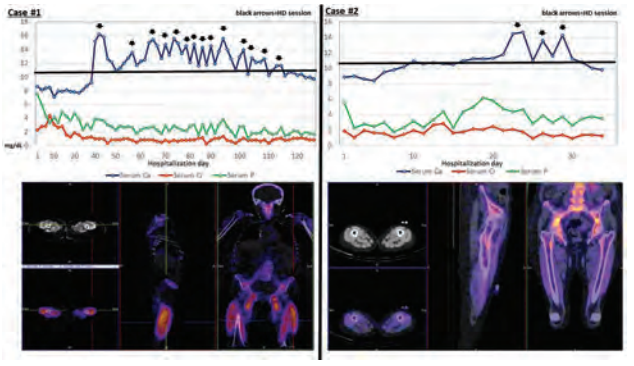
Silvia Ramirez,[1] Ismael A. Gómez Ruiz,[2] Abraham Cohen-Bucay,[3] Ricardo Correa-Rotter.[4] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico; [3]Boston University Medical Center, Boston, MA; [4]Institutor Nacional de la Nutricion, Mexico City, Mexico.*

Introduction: Rhabdomyolysis induced acute kidney injury (RI-AKI) is often complicated by multiple electrolyte abnormalities. Hypercalcemia (HC) due to soft tissue mobilization of calcium deposits in the recovery phase of RI-AKI has been described yet severe HC is rare. We present two patients with cirrhosis who developed RI-AKI and severe HC, both with SPECT/CT deposit images

Case Description: Case 1: 56-yr-old female, primary biliary cholangitis Child-Pugh B cirrhosis who developed exertional RI-AKI that required hemodialysis (HD). She was

hypocalcemic during the oliguric phase; during the recovery phase developed severe HC (peak of 16.2 mg/dl) with neurological symptoms. She required intermittent 13 sessions of HD in addition to volume replacement, diphosphonates, and diuretics and recovered in 8 weeks. Plasma levels of 25-OH and 1-25(OH)2 vitamin D were low, iPTH appropriately suppressed. A SPECT/CT with $^{99}Tc^{m}$-methyl diphosphonate ($^{99}Tc^{m}$-MDP) demonstrated extensive soft tissue tracer accumulation (Fig1). Case 2: 65-yr-old female, Child-Pugh B cirrhosis secondary to hepatitis C, who developed exertional RI-AKI that required HD. Normocalcemic during the oliguric phase yet during the recovery phase developed severe symptomatic HC (peak 14.7 mg/dl), requiring 3 intermittent HD sessions. HC lasted for 2 weeks. Plasma levels of 25-OH and 1-25(OH) vitamin D were low, iPTH level appropriately suppressed and a SPECT/CT with $^{99}Tc^{m}$-MDP demonstrated soft tissue tracer accumulation. The evolution of serum calcium, phosphorus, and creatinine levels are showed in Fig1. Both patients had full renal and neurological recovery.

Discussion: SPECT/CT with $^{99}Tc^{m}$-MDP is a useful tool to identify soft tissue calcium deposits in patients with HC after RI-AKI. Intermittent HD is an effective treatment for severe HC. Since both of our patients were cirrhotic, we postulate that cirrhosis might be a risk factor for HC during the recovery phase of RI-AKI.



FR-PO597

Hypercalcemia in ESRD Patients Secondary to Immobilization: A Case Series

Sanjeev Gupta, Yorg Al Azzi. *Westchester county medical center, White Plains, NY.*

Introduction: Immobilization is a well-known cause of hypercalcemia. However, there is scarce data available about hypercalcemia secondary to immobilization in end-stage renal disease (ESRD) patients as ESRD is often associated with hypocalcemia. We are presenting 3 cases of hypercalcemia in ESRD patients due to prolonged immobilization.

Case Description: 1: A 59-year-old man with the history of diabetes mellitus admitted for liver and heart transplant. Hospital course was complicated by sepsis, ventilator dependent respiratory failure (VDRF) and renal failure requiring hemodialysis (HD). He was initially hypocalcemic with elevated PTH and calcitriol was started. However, later he developed hypercalcemia with highest serum calcium level being 12.7mg/dl. Calcitriol was withheld and low calcium bath was used but hypercalcemia didn't resolve. Work-up came back negative [PTH-28 pg/ml, 25(OH)D-7 pg/ml and $1,25(OH)_2$ D-22 pg/ml]. 2: A 61-year-old man with the history of CHF and ESRD secondary to polycystic kidney disease on HD admitted with pericardial effusion. Hospital stay was complicated by hemothorax and VDRF. A few months later he became hypercalcemic with calcium level elevated up to 11.6 mg/dl. Work-up was negative [PTH-28 pg/ml, 25(OH)D-44 pg/ml and $1,25(OH)_2$ D-40 pg/ml]. 3: A 59-year-old lady with the history of atrial fibrillation, dilated cardiomyopathy, chronic heart failure and CKD admitted with CHF exacerbation. Hospital course was complicated by V. fibrillation arrest requiring AICD, renal failure requiring HD and VDRF. The patient remained ventilator dependent and developed hypercalcemia with a serum calcium of 11.2 mg/dl while on HD. Again, work-up was negative [PTH-74 pg/ml, 25(OH)D-26 pg/ml and $1,25(OH)_2$ D-24 pg/ml]. All of our patients had the extensive workup to rule out malignancy as a part of renal transplant evaluation and hypercalcemia was attributed to immobilization.

Discussion: Hypercalcemia due to immobilization is a result of diminished bone formation and increased bone resorption. Immobilization could be a common cause of hypercalcemia in ESRD patients than in the general population as ERSD is a low bone turnover disease and patients tend to be sicker. Immobilization should be considered a cause of hypercalcemia in ESRD patients especially when they are bed-bound and a conservative approach can be considered rather than an invasive or expansive approach of excluding malignancy.

FR-PO598

Successful Treatment of Tuberculosis-Associated Hypercalcemia with Denosumab in a Liver Transplant Patient with AKI

Aldo E. Torres Ortiz, Prakrati C. Acharya, Wisit Cheungpasitporn. *Nephrology, University of Mississippi Medical Center, Jackson, MS.*

Introduction: Denosumab, a human monoclonal antibody that inhibits RANKL, has recently been approved for treatment of malignancy-related hypercalcemia. To our knowledge, we present the first case of successful treatment of tuberculosis (TB)-associated hypercalcemia with denosumab.

Case Description: A 65-year-old African-American woman was admitted to the hospital with a 5-day history of vomiting. She also had a 3-month history of nonproductive cough. She underwent orthotopic liver transplantation for HCV-associated cirrhosis 8 months prior to admission and was maintained on tacrolimus, prednisone and mycophenolate mofetil. At presentation, she was found to have AKI with serum Cr 4.7 mg/dL (baseline Cr 2.2 mg/dL). Physical exam revealed bilateral crackles. Laboratory testing showed high serum Ca of 13 mg/dL. Phos was 4.4 mg/dL and PTH was suppressed at 7.8 pg/mL. She had elevated 1,25(OH)2 VitD (113 pg/mL) with low 25-OH-VitD level (14 ng/mL). Work-up confirmed the diagnosis of TB by demonstration of AFB in BAL. Liver biopsy also showed granulomas containing AFB. HyperCa showed only transient response to IV 0.9% NaCl. A high dose of steroids was not considered due to active TB. Zolendronic acid was not given due to potential AKI side effect. Thus, denosomab 120 mg SC injection was given. Ca started to decrease within 48 hours and normalized (Ca 10.2 mg/dL) on day 7 post-treatment with improvement in Cr of 2.1 mg/dL. However, asymptomatic hypoCa occurred on day 16 and reached nadir on day 27 (Ca 7.6 mg/dL). HypoCa subsequently improved with up-titration of Ca and active vitamin D supplements. At 4 months F/U, she remained normocalcemic (without Ca or Vit D supplement). PTH (47 pg/mL) and 1,25(OH)2 VitD (41 pg/mL) levels were normalized. 25-OH-VitD level increased to 19 ng/mL. Her Cr continued to improve (1.7 mg/dL).

Discussion: We report on the first experience in treatment of granulomatous disease-associated hypercalcemia with denosumab. Our patient had an improvement in hypercalcemia, however, hypocalcemia can occur following denosumab injection and requires close monitoring and treatment. Our patient developed asymptomatic hypocalcemia, which subsequently improved with up-titration of Ca and Vit D supplements. Further studies are needed to evaluate safety and efficacy in similar clinical scenarios.

FR-PO599

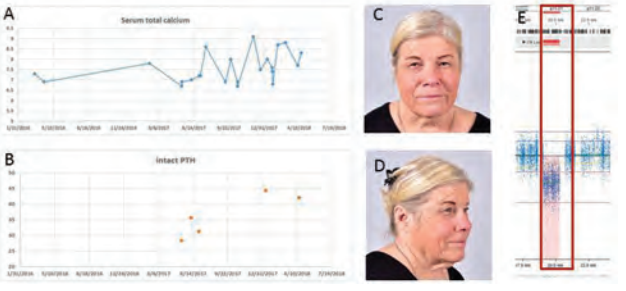
22q11.2 Deletion Syndrome Presenting with Chronic Hypocalcemia

Xiangling Wang,[1] Maren T. Scheuner,[2] Enrica Fung.[3] *[1]Loma Linda University, Loma Linda, CA; [2]VA Greater Los Angeles Healthcare System, Los Angeles, CA; [3]Loma Linda VA, Redlands, CA.*

Introduction: 22q11.2 deletion syndrome, also known as DiGeorge syndrome, is a genetic disorder characterized with distinguishing facial features and congenital anomalies. Hypocalcemia can be seen in up to 50% of patients. However, it can be challenging to reach the diagnosis in adult patients who have no or mild congenital anomalies. Here we report one female who was diagnosed with 22q11.2 deletion syndrome after symptomatic hypocalcemia for more than 40 years.

Case Description: The patient was a 66 years old Caucasian female who was the product of an uncomplicated twin pregnancy. She had frequent ear infections and nasal speech requiring speech therapy during childhood. She completed a college education and denied history of developmental delay. She experienced seizures and muscles spasms at the age of 22 while in the military service. Hypocalcemia was diagnosed and she was treated with calcium and vitamin D supplementation. Since then, she has only had episodes of muscle spasms. Family history was significant for one son with hypocalcemia and another son who died from congenital heart disease at age 6 weeks. Since her transfer to our facility in 2016, she had fluctuating levels of total serum calcium (Figure 1A) with normal range intact PTH (Figure 1B). Urine calcium excretion was low. On physical exam, she had short stature with mild facial dysmorphism, including hypertelorism and square nasal root (Figure 1C and 1D). Chromosomal microarray showed 22q11.2 deletion (Figure 1E). Diagnosis was established and she received genetic counseling about the mode of inheritance and the possibility that her son had the same diagnosis. In follow up, she continues to have intermittent asymptomatic hypocalcemia despite supplementation of calcium.

Discussion: This case highlights the importance to consider 22q11.2 deletion syndrome in chronic hypocalcemia patients who have inappropriately normal or low levels of PTH. Chromosomal microarray is available to establish the diagnosis in most cases.



FR-PO600

A Case of Pseudohypoparathyroidism Presenting with Symptomatic Hypocalcemia After Acute Hepatitis Due to Epstein-Barr Virus

Ritsuko Itayama, Yosuke Nakagawa, Yudai Isozaki, Hiroo Takahashi, Hirotaka Komaba, Masahiro Koizumi, Takehiko Wada, Masafumi Fukagawa. *Tokai University School of Medicine, Isehara, Japan.*

Introduction: Pseudohypoparathyroidism (PHP) type 1b is characterized by isolated resistance to parathyroid hormone without the features of Albright hereditary osteodystrophy (AHO). In PHP type 1b, most cases are sporadic and the timing of development of symptomatic hypocalcemia is quite variable. The initial manifestations of hypocalcemia such as tetany, muscle cramps and convulsion usually occur in childhood or adolescence, but they may be delayed until adulthood. Here, we report a young adult case of PHP type 1b which presenting with hypocalcemic tetany after acute hepatitis due to Epstein-Barr virus infection.

Case Description: A 24-year-old man who had been previously healthy was admitted to the hospital because of nausea and appetite loss followed by tetany for three days. He had been well until two weeks prior to the admission, when he got a febrile pharyngitis with lymphadenopathy. The symptoms were improved by taking some antipyretics and antibiotics, however, general fatigue and appetite loss steadily developed with tetany and weakness. Laboratory test revealed significantly elevated transaminases which indicated acute hepatitis, as well as hypocalcemia, hyperphosphatemia and increased level of intact PTH. Head computed tomography showed bilateral basal ganglia calcification. On the basis of PTH-resistant hypocalcemia without the features of AHO, he was given diagnosis of PHP type 1b and started on calcium and calcitriol. He was symptomatically improved with treatment and his laboratory findings returned to normal range. At the same time, acute hepatitis, which had been proved to be caused by primary Epstein-Bar virus infection, recovered spontaneously.

Discussion: It is unknown what factor triggers symptomatic hypocalcemia in PHP type 1b. In our case, it was considered that decreased synthesis of 25-OH vitamin D in the liver due to acute hepatitis provoked PTH resistance followed by symptomatic hypocalcemia. PHP type 1b might be overlooked and should be taken into account if asymptomatic hypocalcemia is identified.

FR-PO601

A Rare Case of Hypoparathyroidism Complicating Pregnancy

Elliott Antman,[2] Anip Bansal,[2] John M. Carson.[1] [1]*NYU Winthrop Hospital, Mineola, NY;* [2]*University of Colorado School of Medicine, Denver, CO.*

Introduction: Heterozygous activating mutations in the calcium sensing receptor (CaSR) which increase CaSR sensitivity to extracellular Ca cause autosomal dominant hypocalcemia (ADH). ADH results in hypocalcemia with low-normal parathyroid hormone (PTH) levels and is often diagnosed as hypoparathyroidism. This case describes the complicated course of a pregnant woman with ADH.

Case Description: A 31 year old female was diagnosed with autoimmune hypoparathyroidism at age 22 when she presented with paresthesias and cramping in both hands with a serum Ca of 5.5mg/dL, phosphate of 6.1mg/dL and PTH of 10pg/mL. Genetic testing for DiGeorge syndrome was negative. She had no family history of calcium or other electrolyte disorders. Her symptoms improved with oral Ca supplementation and calcitriol. Three years later a renal sonogram demonstrated medullary nephrocalcinosis. Her 24 hour urine Ca ranged 300 to 700mg and a thiazide (HCTZ) was added. Due to persistent hyperphosphatemia, the calcitriol was replaced by recombinant PTH. After starting HCTZ and recombinant PTH she developed symptomatic hypomagnesemia which persisted after stopping HCTZ. A 24hr urine magnesium (Mg) was 204mg. Her 24hr urine potassium was 140mEq while hypokalemic and off HCTZ. At age 29 she had a pregnancy complicated by exacerbation of hypomagnesemia and unexpected intrauterine fetal demise (IUFD) at 35 weeks. At the time, her serum Mg level was 1.3mg/dL. Other electrolyte levels were normal. A fetal ultrasound 10 days prior showed mild polyhydramnios and otherwise normal fetus. The cause of IUFD was uncertain but attributed to the hypomagnesemia. A year later she became pregnant again with exacerbation of hypomagnesemia. ADH was suspected and genetic testing was sent midterm. At 34 weeks she developed polyhydramnios, was induced, and delivered uneventfully. Two days post-partum, her newborn became bradycardic and seized with a serum Ca of 5.9mg/dL. PTH was 12pg/mL. Soon after, the mother's genetic testing confirmed a CaSR activating mutation consistent with ADH type 1.

Discussion: ADH should be considered in the differential for hypoparathyroidism as its diagnosis has significant genetic/family planning implications. Treatment of ADH (thiazides, recombinant PTH) may exacerbate renal Mg wasting associated with this disease, as does pregnancy. Calcilytics, allosteric antagonists of the CaSR, are an emerging therapy that may benefit patients with ADH.

FR-PO602

IV Iron Therapy Induced Acute Hypophosphatemia in CKD Patients

Annise Chung,[1] Ping Li.[2] [1]*Internal Medicine - Nephrology, Medstar Georgetown University Hospital, Washington, DC;* [2]*Nephrology, DC VA Medical Center, Washington, DC.*

Introduction: Intravenous (IV) iron-induced hypophosphatemia is a well-documented side effect in iron deficient patients. Single dosing studies suggest that decreases in serum phosphate are asymptomatic and fully reversible with phosphate repletion. Long term complications such as arrhythmias, muscular weakness, osteomalacia and bone fractures have also been documented. We report a case of hypophosphatemia with a newer formulation of IV iron: ferric carboxymaltose (FCM) induced severe acute hypophosphatemia.

Case Description: A 97 year old male with past medical history of atrial fibrillation, iron deficient anemia, hypothyroidism, chronic kidney disease III, and hypertension was referred to renal clinic for acute hypophosphatemia. The patient had been on oral iron supplementation for iron deficient anemia and it was not effective. He received IV FCM for iron deficient anemia twice in the previous month. The patient was sent to the emergency department after he was found to have a phosphate level of 0.8 mg/dL by routine lab work. Patient initially received both oral and intravenous phosphate repletion in the emergency department and subsequently received oral phosphate supplementation. However, the hypophosphatemia persisted in the presence of oral phosphate supplementation. Laboratory data showed calcium was 7.9 mg/dl, phosphate 1.5mg/dl, magnesium 2.1 mg/ml, intact parathyroid hormone 295pg/ml and 25-OH, vitamin D 30.8 ng/ml. His serum creatinine was at his baseline of 1.5-1.8 mg/dL. In addition, intact FGF23 level was found to be 1424 RU/ml (reference range < 180). Parathyroid scan showed no adenoma in parathyroid glands. Based on the above temporal association, patient was suspected of FCM induced, FGF23 mediated renal phosphate wasting. IV FCM was stopped and patient received oral active vitamin D, calcium and phosphate supplementation. The acute hypophosphatemia improved.

Discussion: This case highlights the association between FCM and low serum phosphate levels. Although there has been a growing body of literature on the association, many nephrologists may not be aware of the hypophosphatemic side effects of FCM. In the recently published phase 3 study of IV ferumoxytol versus FCM, hypophosphatemia was seen in 38.7% of the FCM group 2 weeks after treatment. In patients who receive IV FCM for iron deficient anemia, serum phosphate levels should be monitored.

FR-PO603

Hypomagnesemia: Beware of Zebras

Mohammad wisam Baqdunes, Kalathil K. Sureshkumar. *Allegheny General hospital, Wexford, PA.*

Introduction: Hypomagnesemia can be the initial and predominant manifestation of the rare17q12 deletion syndrome.

Case Description: A 62 year old male with 17 years history of severe hypomagnesemia of unclear etiology requiring daily IV and oral magnesium replacement and recent diagnosis of type 2 diabetes mellitus presented to our clinic for further evaluation. Patient experienced weakness, myalgia and cognitive deficits. Physical examination revealed macrocephaly along with brachydactyly of the hands and feet. He was found to have severe hypomagnesemia, hypocalcemia and hypokalemia with evidence for renal magnesium wasting requiring aggressive replacement with preserved renal function. Computed tomography scan of abdomen and pelvis showed bilateral kidney cysts. Because of the morphological and electrolyte abnormalities, chromosomal micro array was performed which showed a 1.5 mega-bases loss at chromosome 17q12 involving 20 genes. Per genetic analysist, patient's history, clinical findings and genetic analysis were consistent with17q12 deletion syndrome.

Discussion: Hypomagnesemia can be a presenting manifestation of 17q12 deletion syndrome also known as autosomal dominant tubulo-interstitial kidney disease sub type HNF-IB caused by a mutation in hepatocyte nuclear factor 1 beta. Classic features of 17q12 deletion syndrome are variable combinations of the following findings: structural or functional abnormalities of the kidney and urinary tract (80-85%), maturity onset diabetes of the young type 5 (MODY5) from beta-cell dysfunction (40%), and neurodevelopmental or neuropsychiatric disorders (50%). Renal abnormalities include tubular interstitial disease, characterized by reduced urine concentrating ability, hyperuricemia, hypomagnesemia, hypokalemia with bland urine sediment and tubular interstitial fibrosis on renal histology. Family members should be tested because of the autosomal dominant inheritance.

FR-PO604

Severe Hypomagnesemia as the Initial Indicator of HNF1β-Associated Renal Disease

Nina Mann,[1] Michael A. Ferguson,[1] Deborah R. Stein.[2] [1]*Boston Children's Hospital, Boston, MA;* [2]*Children's Hospital Boston, Boston, MA.*

Introduction: Mutations in *HNF1*β (hepatocyte nuclear factor-1-beta) are known to cause Renal Cysts and Diabetes Syndrome (RCAD), so-named for two common clinical manifestations, maturity-onset diabetes of the young (MODY) and renal cystic disease. However, it has become increasingly recognized that HNF1β-associated disease can lead to a wide spectrum of clinical manifestations affecting multiple organ systems, with varying degrees of renal involvement. Due to the clinical heterogeneity, a high index of suspicion is required in making the diagnosis. Here, we present a case in which severe hypomagnesemia led to a diagnosis of RCAD.

Case Description: A 13-year-old Caucasian girl with newly diagnosed insulin-dependent diabetes mellitus presented with one month of intermittent lower abdominal pain, dysuria, and urinary frequency, and one day of paresthesias. On initial assessment, she appeared tired, but otherwise had an unremarkable physical examination. Laboratory studies revealed severe hypomagnesemia (0.6 mg/dL (normal range 1.5 to 2.2 mg/dL)) and hypocalcemia (ionized calcium of 0.75 mmol/L (normal 1.14 to 1.29 mmol/L)), as well as mild acute kidney injury (Creatinine 1.0 mg/dL) and metabolic alkalosis (bicarbonate 31 mmol/L and venous pH 7.5). Urinalysis revealed 3+ protein and 2+ glucose. Fractional excretion of magnesium was inappropriately elevated at 11%, and urinary calcium was undetectable. A renal ultrasound demonstrated a single 1.3 cm simple cyst in the right kidney. The patient received IV calcium and magnesium supplementation, and was ultimately transitioned to enteral magnesium oxide supplements. Subsequent genetic testing revealed a large deletion of chromosome 17q12. Upon retrospective chart review, it was found that at the time of her initial presentation with diabetes mellitus one month prior, the patient had mild hypomagnesemia and, unusually, a metabolic alkalosis.

Discussion: Mutations in *HNF1*β can lead to impaired magnesium handling in the distal convoluted tubule, but hypomagnesemia remains an under-recognized manifestation of HNF1β-associated disease. This case highlights that hypomagnesemia should be an indicator to test for mutations in *HNF1*β, particularly if present in conjunction with early-onset diabetes or urinary tract malformations.

FR-PO605

A Puzzling Case of Metformin (MF) Associated Lactic Acidosis (MALA)

Rhea Thurston, Bassem B. Ibrahim, Jacques A. Durr, Hansang Park. *University of South Florida Morsani College of Medicine, Tampa, FL.*

Introduction: MF, a biguanide used to treat type 2 diabetes mellitus, increases intestinal glucose utilization and lactate production. It inhibits the mitochondrial respiratory chain complex 1, which clears lactate by the liver and kidney. MF is highly cationic, not protein-bound and is eliminated unchanged by the kidneys. Its apparent volume of distribution (AVD) is enormous (up to 1000 L). MALA can occur with overdose or in cases associated with reduced kidney or liver function. The incidence of MALA without acute overdose is ~ 6.3 cases per 100,000 patient years. Normal therapeutic MF levels are 1-2 μg/mL and rarely exceed peak levels of 5 μg/mL, above which MF can cause MALA.

Case Description: A 70 year old female with a history of hypertension, type 2 diabetes mellitus and cerebral vascular accident, presented to the emergency room (ER) with a two day history of abdominal pain, nausea and vomiting. She was confused with Kussmaul breathing. Among her medications was MF/Januvia 1000/50 mg BID. Blood pressure was 98/59, pulse 96, RR 27, and temperature 89.4^{0}F. Initial arterial blood gas analysis revealed a pH of 6.88. Her serum bicarbonate was < 5 mmol/L, serum glucose 115 mg/dL and potassium 5.4 mmol/L. Initially her anion gap could not be calculated, but when her bicarbonate could be measured, it was as high as 52 mmol/L. Her admission serum creatinine was 8.1 mg/dL with a normal baseline (1 mg/dL). Her serum lactate was elevated at 33.8 mmol/L. A CT of her abdomen and pelvis did not show any acute pathology. She was immediately intubated, started on pressor support and bicarbonate infusion with continuous renal replacement therapy (RRT). Emergent exploratory laparotomy ruled out ischemic bowel. The patient had only 2-3 hrs of RRT because of repeat dialysis line clothing. In spite of this, her acid-base and electrolyte abnormalities spontaneously improved and RRT was discontinued. The patient was managed only with IV fluids, including dextrose/insulin, as a presumed enzymatic defect could not be excluded. Although the MF level was toxic (37 μg/mL), a prompt recovery ensued.

Discussion: Mortality from MALA is ~ 50%, and given MF's large AVD, an extended dialysis time (preferably hemodialysis) is required. Our patient had virtually no dialysis and her massive lactic acidosis corrected spontaneously over 2 days with only IV fluid therapy. The role of dextrose/insulin is unknown.

FR-PO606

Treatment of Severe Metformin-Associated Lactic Acidosis (MALA) with Continuous High Flux Hemodialysis and Tris-Hydroxymethyl Aminomethane (THAM)

Abhinav K. Tiwary,[1] Daniel L. Landry,[3] Marat Abdullin,[3] Bogdan Tiru,[2] Kostas Papamarkakis,[2] Gregory L. Braden.[3] *[1]Nephrology, UMMS-Baystate, Springfield, MA; [2]Baystate Medical Center, Springfield, MA; [3]Kidney Care and Transplant Services of New England, Springfield, MA.*

Introduction: Hemodialysis is the preferred modality for severe lactic acidosis due to MALA. We report a case of ingestion of 480 grams of metformin. After 33 hours of high flux hemodialysis (HFHD) his severe MALA was reversed by THAM. This is the first case report of the use of THAM to treat severe MALA not responding to HFHD alone.

Case Description: A 43-year-old suicidal man with type 2 diabetes ingested the largest reported dose of metformin, 480000 mgs. Initial serum potassium was 4.9 mmol/L, bicarbonate (HCO3) 16 mmol/L, anion gap 22, serum lactate 6.2 mmol/L, & an ABG showed a ph 7.16, pCO2 36, PO2 247 & HCO3 12 mmol/L. He was intubated for airway support & activated charcoal & polyethylene glycol given by NG tube. Repeat labs showed a potassium of 7.4 mmol/L, lactate of 6.6 mmol/L, & pH of 7.06. Emergent high flux HFHD was initiated. After 12 hours of dialysis the metformin dialyzer clearance was 416 ml/min which is significantly better than earlier reports of 68-228 ml/min. Due to a persistent lactate of 22.6 - 31.4 mmol/L we continued HFHD for a total of 33 hours. The next day the serum ph was only 7.11 and the serum HCO3 10' mmol/L. A dose of THAM was calculated as follows: THAM (ml of 0.3 mol/L solution) = lean body weight (kg) x base deficit (mmol/L). We chose 3 times the usual base deficit to increase serum HCO3 by 15 mmol/L rather than the usual 5. We gave 1280 ml of THAM over 12 hours, enough to increase the serum HCO3 by 15 mmol/L. Levophed & vasopressin for hemodynamic support were rapidly weaned. The serum lactate corrected dramatically after THAM from 31.4 to 6.2 mmol/L. In fact, over the next 24-hours, the serum lactate normalized along with pH & HCO3 levels.

Discussion: Our study is the first successful use of THAM with continuous HFHD in a patient with severe MALA complicated by anuria. THAM rapidly equilibrates into the intracellular space of liver, muscle & intestine. We hypothesize that the rapid increase in tissue pH inhibits lactate dehydrogenase & increases the activity of pyruvate dehydrogenase & pyruvate carboxylase leading to rapid inhibition of lactate production & enhanced metabolism of lactate. Our case supports the use of THAM to augment continuous HFHD for the correction of severe acidemia associated with MALA.

FR-PO607

Severe Lactic Acidosis in a Patient with Advanced Hepatic Malignancy Due to Warburg Effect

Avinash G. Adiga, Kumar Rohit. *Nephrology, NYU Langone Medical Center, New York, NY.*

Introduction: Lactic acidosis is one of the most common cause of metabolic acidosis in hospitalized pateints and is either due to overproduction or reduced metabolism of lactate. Impaired tissue oxygenation, either from decreased oxygen delivery or a defect in mitochondrial oxygen utilization usually causes increased lactate production. Causes of lactic acidosis can be divided into those associated with impaired tissue oxygenation as type-A and those without obvious systemic impairment in oxygenation as type B lactic acidosis. We report a case of severe type B lactic acidosis in a patient with extensive hepatic malignancy most likely from Warburg effect.

Case Description: 62 years old male with history of hypertension, hypothyroidism and advanced hepatic metastatic gall bladder cancer admitted to the hospital due to failure to thrive. On examination BP was 128/80mmhg, HR 90/min, temperature was 95.3F. Patient was lethargic, abdomen was soft, distended and multiple bulky masses were appreciated in the right upper quadrant. Labs revealed Na:134, K: 4.2, Cl: 94, bicarb <10, BUN 53mg/dl, creatinine 3.0mg/dl, anion gap 24. ABG showed pH 7.11, pCO2:9.7, HCO3: 3, lactate >22 suggesting severe high anion gap metabolic acidosis due to lactate. He also had evidence of tumor lysis syndrome with LDH 2331, uric acid 14.1, phosphorus 9.1. CAT scan of abdomen showed infiltrative tumor replacing majority of both hepatic lobes with some sparing of superior right hepatic lobe.

Discussion: Metabolic modifcation is a typical hallmark of cancer cells, despite presence of adequate oxygen, tumor cells generate energy from aerobic glycolysis instead od mitochondrial oxidative phosphorylation. This phenomenon is defined as "Warburg effect", this leads to increased glycolysis, accumulation of ATP and lactate production by tumor cells. Warburg effect confers advantage to cell growth by providing carbon sources that are required for rapid cell proliferation and also by decreasing reactive oxygen species. This effect is more commonly seen in hematologic malignancies like lymphoma and leukemia, but can rarely be seen in solid malignancies. Our patient had features of tumor lysis and severe type B lactic acidosis, by excluding other causes of type B lactic acidosis it was attributed most likely due to Warburg effect. In addition impaired hepatic and renal clearance of lactate contributed to very high lactate levels.

FR-PO608

Severe Chloride Deficiency Metabolic Alkalosis from Excessive Sweating

Himabindu Yerneni,[1] Martin Sedlacek,[2] Tomonori A. Oyadomari.[3] *[1]Dartmouth Hitchcock medical center, Hanover, NH; [2]Dartmouth-Hitchock Medical Center, Lebanon, NH; [3]Dartmouth Hitchcock Medical Center, Lebanon, NH.*

Introduction: Most cases of chloride deficiency metabolic alkalosis are due to chloride loss from the gastrointestinal tract or the urine and secondary hyperaldosteronism contributes to hypokalemia.We are presenting a case of chloride deficient metabolic alkalosis from an unusual source.

Case Description: A 32 y/o man presented with generalized weakness, fatigue and failure to thrive since several days. He was severely volume depleted with hypotension and orthostatic BP changes, subjective weight loss and decreased skin turgor. Laboratory testing revealed a severe hypokalemic metabolic alkalosis with CO2 50 mmol/L, Chloride 70 mmol/L, sodium 126 mmol/L, potassium 2.1 mmol/L, magnesium 0.78 mmol/l BUN 18 mg/dl creatinine 0.7 mg/dl. A spot urine sodium was 10 mmol/L, Chloride <10 mmol/L and potassium 26 mmol/L. The patient had no nausea, vomiting or diarrhea and denied any use of diuretics. He had a history of multi substance abuse and incarceration and recently started working as a painter. The patient reported that painting under the hot roof in summer" was killing him". He had previous care in our institution because of cystic fibrosis. The patient's symptoms and metabolic abnormalities resolved with saline and the patient was discharged.

Discussion: Cystic fibrosis is an inherited disorder characterized by excessive chloride content in sweat with resulting pulmonary and gastrointestinal complications. Chloride deficiency metabolic alkalosis is a rare complication of cystic fibrosis precipitated by environmental stressors leading to excessive sweating, in this case by painting under a hot roof in summer.

FR-PO609

CVVH as Therapy for Severe Metabolic Alkalosis

Harish Shanthanu Seethapathy, John Y. Choi, Andrew Z. Fenves. *Massachusetts General Hospital, Boston, MA.*

Introduction: Untreated severe metabolic alkalosis (pH>7.6) can lead to devastating clinical consequences such as seizures and coma. We describe the use of continuous veno-venous hemofiltration (CVVH) in the management of a patient with severe metabolic alkalosis.

Case Description: A 51-year-old male with advanced diffuse large B-cell Lymphoma was admitted for high-dose methotrexate infusion as part of his 6th cycle of chemotherapy (R-CHOP plus methotrexate). He received oral and intravenous sodium bicarbonate to maintain high urine flow rates (>100cc/hour) and a urine pH>7.5 to aid methotrexate excretion. He sustained an AKI (peak Cr of 2.5mg/dL; baseline 0.8mg/dL) two days after the infusion. Serum methotrexate levels, which were followed q12h were persistently high (>6umol/L) and isotonic sodium bicarbonate (250cc/hour) was continued. A week later, he developed altered mental status and respiratory failure requiring ventilator support. An arterial blood gas showed a pH of 7.60, pCO2 of 51mmHg and his HCO3 was 46mmol/L. He had received a total of 20L of isotonic sodium bicarbonate. His pH worsened to 7.69 on

the ventilator and we were consulted. We initiated CVVH on a citrate bath with a blood flow of 150mL/min and a replacement fluid rate at 800mL/min. Our aim was slow and steady correction of alkalosis - we achieved that over the next 12 hours with a drop in his pH from 7.69 to 7.52. CVVH was terminated after 24 hours. In the next few days, he was extubated and his mental status and renal function returned to baseline.

Discussion: Metabolic alkalosis has traditionally been treated with an acid such as hydrochloric acid (HCl) or an acid precursor such as ammonium chloride (NH4Cl). Issues with availability and the need for reconstitution and specific guidelines for administration (in the case of HCl) limit their use. CVVH is readily available and most ICUs can initiate CVVH within a few hours. There are no specific prescription guidelines to treat metabolic alkalosis. While conventional hemodialysis has been described as a treatment modality, effects of rapid correction of pH are unknown. We successfully achieved a gradual correction of alkalosis using a bicarbonate free bath with slow clearance parameters and constant monitoring. To our knowledge, this is one of the first cases describing the use of CVVH for correction of metabolic alkalosis in the setting of AKI.

FR-PO610

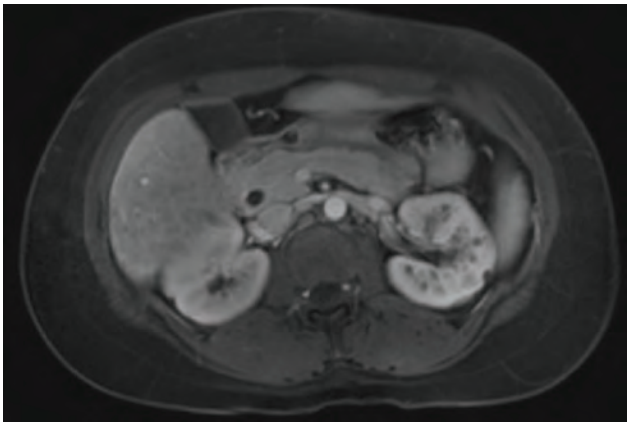
Autosomal Recessive Polycystic Kidney Disease (ARPKD) Presenting in Adulthood

Ravi Kodali, Neera K. Dahl. Yale University *Yale School of Medicine, Madison, CT.*

Introduction: ARPKD is characterized by multiple renal cysts arising from the collecting ducts, variable degree of progressive renal failure and congenital hepatic fibrosis. It is caused by mutations in PKHD1 gene located on chromosome 6p21. It is mostly diagnosed in infancy or childhood with only few cases being diagnosed as adults. Here we present a case of ARPKD that was diagnosed in adulthood.

Case Description: A 37-year-old female with past medical history significant for congenital hepatic fibrosis is referred to polycystic kidney disease clinic for evaluation of cystic kidney disease. Family history is significant for cystic kidney disease in two of her cousins (both on the paternal side). Neither of her parents had a history of kidney cysts. Her renal function was normal. Abdominal MRI revealed a cirrhotic liver with extensive fibrocystic changes and splenomegaly. It also showed several sub-centimeter cysts in both kidneys (Figure 1). Whole exome sequencing showed compound heterozygous variants of PKHD1; one, c.3761_3762delCCinsG is known to be pathogenic. The other, c.9107T>G, is a variant of unknown significance (VUS). This is a rare variant (2/100,000) which has previously been detected in at least 2 ARPKD patients, with clinical presentations of hepatic fibrosis.

Discussion: There are more than 750 different mutations described in PKHD1 gene. Most common amongst these is a missense mutation in exon 3. Our patient has a compound heterozygous mutation. The first allele had a mutation in exon 32. This involves deletion of two nucleotides and addition of a third nucleotide leading to a frameshift mutation which leads to a premature stop codon. This is a known pathogenic mutation. Less is known about the second variant, c.9107T>G although it has been described in ARPKD patients presenting with hepatic fibrosis and normal kidney function. Adult onset ARPKD is rare, and notable. The combination of hepatic fibrosis, splenomegaly and kidney cysts are consistent with ARPKD, although in this patient the liver findings dominate.



FR-PO611

Gastrointestinal Bleed in ESRD: An Unexpected Cause

Ravi Kodali, Eric Chang, Ursula C. Brewster. Yale University *Yale University School of Medicine, New Haven, CT.*

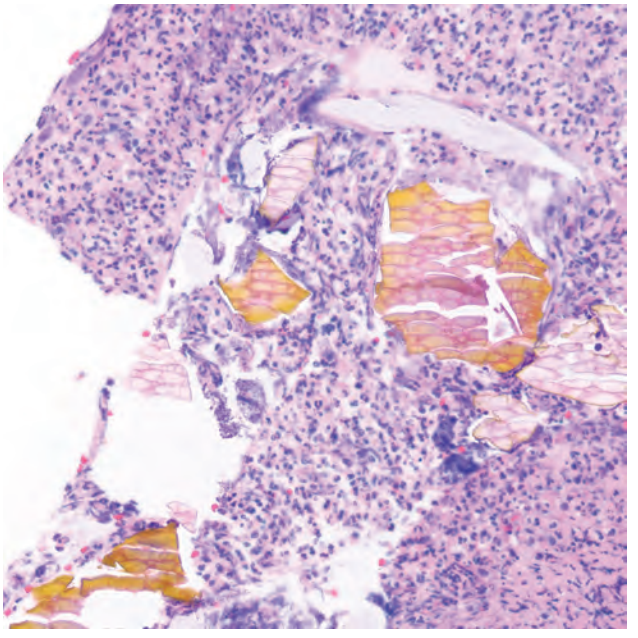
Introduction: ESRD patients have a fivefold higher risk of gastrointestinal (GI) bleed compared to those without CKD. Common causes include angiodysplasia, peptic ulcer disease, diverticular disease, ischemic colitis. A lesser known causes of GI bleed in this population is sevelamer induced GI ulcer.

Case Description: A 59-year-old African American man with type 2 diabetes mellitus, HTN, ESRD on hemodialysis, presented with severe headache and right sided weakness. He had intraventricular hemorrhage from severe hypertension. Routine labs showed hyperphosphatemia, so he was continued on sevelamer. On hospitalization day 20, he had multiple episodes of dark tarry stools with hemoglobin drop. Upper GI endoscopy revealed a large ulcer in the duodenum; he was started on pantoprazole. GI bleed recurred over the next weeks. A colonoscopy revealed a 3-5 cm segment of ulcerated and friable mucosa in the ascending colon. Biopsy of the colonic ulcer revealed presence of "fish scale" crystals previously associated with sevelamer, with inflammatory changes (Fig 1). A diagnosis of sevelamer induced colonic ulcer was made and sevelamer was stopped.

Discussion: Here we report 6 cases from our institution of GI ulcerations with deposition of sevelamer (Table 1). This is an underappreciated association and should be suspected in the right clinical scenario. Given the continued increase in use of sevelamer as a phosphate binder, it is important for the nephrologists to be cognizant of this entity.

Table 1

	Age (years)	Dialysis vintage (years)	Time on sevelamer (years)	Presenting symptoms	Location of lesion
Patient 1	59	5	5 years intermittent use	Melena, hgb drop	Ascending colon
Patient 2	58	7	5	Abdominal Pain, diarrhea	Transverse colon
Patient 3	50	3 (PD)	3	Sigmoid perforation	Sigmoid colon
Patient 4	56	2	2	Rectosigmoid colitis	Colon NOS (random biopsy)
Patient 5	75	3	2	Rectal ulcers, hematochezia	Rectosigmoid colon
Patient 6	69	3	3	Heme positive stools, anemia	Colon



Sevelamer crystals in biopsy from colon

FR-PO612

A Case of Early Onset Autosomal Dominant Polycystic Kidney Disease Caused by GANAB Mutation

Elizabeth Waldrop, Mohammed A. Al-Obaide, Tetyana L. Vasylyeva. *Texas Tech University Health Sciences Center, Amarillo, TX.*

Introduction: Autosomal Dominant Polycystic Kidney Disease (ADPKD) typically results from mutations in the *PKD1* and *PKD2* genes, which code for polycystin 1 and polycystin 2 respectively. Mutations in these genes promote renal cystic dysplasia and are a significant cause of End-Stage Kidney Disease (ESKD). *PKD3* is related to *GANAB* gene mutation and represents mid- and late adulthood. We report a description of a case of ADPKD in a 12-year-old female with dual mutations in *PKD1* and *GANAB* genes and presented bilateral renal cysts in adolescence.

Case Description: A 12-year-old female presented to the local emergency room with persistent intense left flank pain. Dipstick showed large blood and abdominal CT showed 4 mm obstructing calculus in proximal left ureter, nephrolithiasis with minimal scaring in upper pole of left kidney, multiple bilateral renal cysts with the dominant on the left kidney at 2.8 mm. Non-calcified 2 mm right lower lobe pulmonary nodules was also identified. Renal function was preserved with BUN of 11 mg/dl and creatinine of 0.6 mg/dl, electrolytes were within normal range. The patient was treated with pain control medications and hydration with improvement and was referred to a nephrologist. Renal ultrasound (RUS) showed multiple bilateral cysts. The right kidney measured 10.5 cm x 4.9 cm x 4.8 cm and the left kidney measured 9.8 cm x 4.7 cm x 5.0 cm. Renal cysts were present bilaterally with some displaying thick internal septation. The largest cyst was present in the left kidney, measuring 3.3 mm. Using genomic DNA from the submitted specimens, the exonic regions and flanking splice junctions captured and sequenced by NGS and compared to the human genome build of non-mutated genes of interest. The results returned positive for *GANAB*, variant p.R61X generated nonsense mutation; and *PKD1*, variant p.P61L generated missense mutation. The *GANAB* mutation classified as pathogenic variant and the *PKD1* mutation classified as a variant of uncertain significance.

Discussion: The presented case is the first reported pediatric case with dual mutation (PKD1 and GANAB) and nephrolithiasis. The data present unreported novel *GANAB* mutations to expand the mutation spectrum reported by Porath et al., 2017. Knowledge of spectrum variety in pediatric patients with cystic kidney disease might direct early diagnostic and open prospective for gene therapy.

FR-PO613

Long Term Effect of High Dose Tolvaptan Treatment for Autosomal Dominant Polycystic Kidney Disease Patient

Yuri Machiba,[1] Shinya Nakatani,[1] Eiji Ishimura,[2] Hideki Uedono,[1] Ayumi Nakatani,[1] Akihiro Tsuda,[1] Katsuhito Mori,[1] Masaaki Inaba.[1] *[1]Osaka City University Graduate School of Medicine, Osaka, Japan; [2]Meijibashi Hospital, Matsubara-shi, Japan.*

Introduction: Based on the results of Tolvaptan Efficacy and Safety in Management of Autosomal Dominant Polycystic Kidney Disease and Its Outcome (TEMPO) 3:4 trial, tolvaptan was firstly approved by regulatory authority in Japan (March, 2014), as a therapy for Autosomal dominant polycystic kidney disease (ADPKD) patients. However, to date, the long term efficacy and safety of high dose tolvaptan is unknown. Here, we present a Japanese case with ADPKD, who have continued a high dose of tolvaptan (a total daily dose of 120 mg) for 9 years from the beginning of the TEMPO 3:4 trial.

Case Description: A 36-year-old man was diagnosed with ADPKD in 2008. His estimated glomerular filtration rate was 57.3 mL/ min/1.73 m^2 calculated as Japanese formul, and the total kidney volume (TKV) was 1499 mL.Tolvaptan was started at a dose of 60 mg/day (with 45 mg given in the morning and 15 mg in the evening), with weekly increase by 30mg/day, and finally to 120 mg/day divided into 90 mg in the morning and 30 mg in the evening. The rate of eGFR decline during tolvaptan treatment was - 3.01 mL/min/1.73 m^2 per year (57.3 mL/ min/1.73 m^2 before the treatment of tolvaptan; and 34.4 mL/ min/1.73 m^2 9 years later). The TKV increased by 6.17 %/year (1499mL before the treatment; and 2328 mL 9years later). During 9-year period, the patient has showed no tolvaptan-related adverse events, such as liver dysfunction, and hypernatremia, which were more common adverse events in tolvaptan group of the TEMPO 3:4 trial[9]. Tolvaptan treatment is continuing in this patient, and his condition is stable now.

Discussion: The *post hoc* exploratory analysis of the TEMPO3:4 trial also revealed that tolvaptan decrease the rate of eGFR by - 3.70 mL/min/1.73m^2 /year (n=151, 95% confidential interval:- 4.04 to - 3.36 mL/min/1.73m^2 /year) in the tolvaptan group and - 5.36 mL/min/1.73m^2 year (n=84, 95% confidential interval:- 6.19 to - 4.53 mL/min/1.73m^2 / year) in the placebo group, in ADPKD patients with CKD stage 33. In our patient, during 9-year period, the rate of eGFR decline was -3.01ml/min/1.73 m^2 /year, which was similar to the results of the previous study. Thus, high dose of tolvaptan treatment for the protection of kidney function could be maintained in longer term, even in patients with CKD stage 3.

FR-PO614

A Case of Autosomal Dominant Alport Syndrome Diagnosed by a Second Renal Biopsy

Tomohiko Asakawa,[1] Kandai Nozu,[2] Makoto Araki.[1] *[1]Suwa Central Hospital, Chino, Japan; [2]Kobe University, Kobe, Japan.*

Introduction: Typically, Alport syndrome is diagnosed by a renal biopsy and is characterized by Alport symptoms, including kidney disease, hearing loss, and eye abnormalities. However, symptoms and signs are characteristic of X-linked Alport syndrome that are not applicable to the autosomal dominant condition.

Case Description: A male patient experienced asymptomatic hematuria since childhood. His mother had chronic hemodialysis because of unknown renal disease. He received a renal biopsy at the age of 16 years; however, light and electron microscopic findings revealed minor abnormalities and the immunofluorescence staining of type IV collagen α5 chain was normal. Since then, he received conservative treatment ; however, hematuria and proteinuria tended to increase over time. Therefore, he received a second renal biopsy at the age of 23 years. While light microscopy revealed focal glomerulosclerosis in some glomeruli, electron microscopy revealed irregular thickening and thinning with a reticulated change in the glomerular basement membrane. Although renal biopsy findings suggested Alport syndrome, he reported no hearing loss or visual impairment. Therefore, genetic analysis revealed a single-base deletion of type IV collagen a3 chain [exon26 c.1826delC, p(Pro 609Leufs*138)], which, along with a family history, confirmed the diagnosis of autosomal dominant Alport syndrome. Currently, the patient is receiving conservative treatment, including renin–angiotensin system inhibitors.

Discussion: A renal biopsy cannot diagnose Alport syndrome at an early stage because of an unclear change in the basement membrane. Besides, autosomal dominant Alport syndrome lacks eyes and ears abnormalities, which delays the diagnosis unless positive suspicion. Recent advancements in sequence technology have revealed autosomal dominant Alport syndrome to be a relatively frequent disorder (19%–31% of Alport syndrome cases). Thus, in patients with family history of renal impairment, we should consider the possibility of autosomal dominant Alport syndrome, even if absence of Alport symptom except hematuria.

FR-PO615

A Case Report of a Novel Variant of X-Linked Alport Syndrome

Robert M. Gaeta, Christina M. Yuan, Robert Nee, John S. Thurlow. *Walter Reed National Military Medical Center, Bethesda, MD.*

Introduction: X-linked Alport syndrome is a rare hereditary disorder caused by COL4A5 gene variants. We describe a case of a 28 year old Caucasian male with a family history of end-stage renal disease (ESRD) presenting with episodic gross hematuria and nephrotic range proteinuria. Renal biopsy showed focal segmental glomerulosclerosis with non-diagnostic ultrastructural findings. Next Generation Sequencing showed a COL4A5 missense likely pathogenic variant, substituting adenine for guanine at nucleotide 901(c.901G>A) of coding DNA predicting a glycine to serine substitution at amino acid 301 (p.Glyc301Ser).

Case Description: A 28 year-old Caucasian male with recent diagnosis of hypertension and a family history of ESRD presented with episodic gross hematuria and nephrotic range proteinuria (7.7g/g). Blood pressure was 146/92 mmHg. Physical examination was unremarkable with no lower extremity edema. All other laboratory testing and renal ultrasound was unremarkable. Renal biopsy showed FSGS with non-diagnostic ultrastructural findings (figure 2). NGS and Sanger Sequencing revealed a COL4A5 missense variant, substituing adenine for guanine at nucleotide 901(c.901G>A) of coding DNA predicting a glycine to serine substitution at amino acid 301 (p.Glyc301Ser).

Discussion: The pathogenicity for this novel missense variant is strongly suspected based on its location in a conserved GLY-Xaa-Yaa triple helical domain in the COL4A5 gene. Knebelmann et al first reported a similar missense variant substituting arginine for glycine at position 325 in a large kindred of X-linked Alport syndrome. The variant genotype has implications for individual prognosis. A study of 175 X-linked AS families showed that rate of progression of renal and extra-renal manifestations was associated with mutation type. Those with Gly-Xaa-Yaa variants reached ESRD at a median of 33 years versus 25 years for truncating mutations. Correct diagnosis allowed for appropriate genetic counseling and treatment, including ACE inhibitor therapy and the avoidance of immunosuppression. The views expressed in this presentation are those of the authors and do not necessarily reflect the official policy or position of the Department of the Navy, the Department of the Army, the Department of Defense, nor the US Government.

FR-PO616

A New Pathogenic Stop Codon Variant in the COL4A5 Gene

Claudio Perez-Ledezma,[1] Asif A. Sharfuddin,[2] Carrie L. Phillips,[3] Michael T. Eadon.[1] *[1]Indiana University School of Medicine, Division of Nephrology, Indianapolis, IN; [2]Division of Transplant Nephrology, Indiana University School of Medicine, Indianapolis, IN; [3]Pathology, Indiana University School of Medicine, Indianapolis, IN.*

Introduction: X-linked Alport syndrome (AS) is a progressive form of renal failure caused by pathogenic variants in the *COL4A5*gene. More than 702 variants have been described and a further 400 are estimated to be known to individual laboratories but have not been published.

Case Description: We present the case of a 30 year-old man with a history of AS diagnosed at age 8 years (hearing loss, vision deficit, and proteinuria) who presented for discussion of inheritance patterns of his disease as part of family planning with his current partner. AS was biopsy-proven at age 14 years, which showed thinned and multi-laminated glomerular basement membranes. He experienced an acute decline in renal function at age 22 years, requiring dialysis for 2 years before undergoing a living-related renal transplant. He and his significant other have no known family history of chronic kidney disease. He notes a history of hypertension in his maternal grandfather. Since a pedigree was not possible, it was unclear whether he had X-linked, autosomal recessive, or autosomal dominant inheritance. Thus, the patient underwent sequencing of COL4A3, COL4A4, COL4A5, and COL4A6 genes to determine his specific mutation. A hemizygous stop codon variant was found in exon 52 of the COL4A5 gene, designated c.4829C>A, resulting in premature protein termination (p.Ser1610*) after TCA to TAA conversion. He was referred for genetic counseling.

Discussion: About 65% of AS cases are caused by COL4A5mutations and are inherited in an X-linked pattern. The patient's variant c.4829C>Aappears to be pathogenic in this given clinical context and has never been previously reported. The description and reporting of COL4A5 variants and clinical associations help to predict phenotype and understanding of collagen type IV biochemistry, which may ultimately inform therapy.

FR-PO617

Biallelic PKD1 Mutations in a Child with Aggressive Autosomal Dominant Polycystic Kidney Disease and Congenital Hepatic Fibrosis

Rosanna Fulchiero,[1] Callie Diamonstein,[5] Catherine S. Chao,[4] Haresh Mani,[3] Natalie S. Hauser,[3] Patricia Seo-Mayer.[2,1] *[1]Inova Fairfax Children's Hospital, Falls Church, VA; [2]Pediatric Specialists of Virginia (Inova-CNMC) and Georgetown University School of Medicine, Fairfax, VA; [3]Inova Fairfax Hospital, Falls Church, VA; [4]Pediatric Specialists of Virginia, Oak Hill, VA; [5]Inova Translational Medicine Institute, Falls Church, VA.*

Introduction: Autosomal recessive polycystic kidney disease (ARPKD) is generally characterized by neonatal detection of enlarged kidneys and pulmonary hypoplasia. Autosomal dominant PKD (ADPKD) usually manifests in adulthood with hypertension and nephromegaly. Both have gastrointestinal manifestations - congenital hepatic fibrosis (CHF) is common in ARPKD, while ADPKD patients more typically have polycystic liver

disease. CHF has been rarely reported in cases of ADPKD, but specific modifier genes have not been identified. We report the case of a child with aggressive ADPKD and CHF in the context of a biallelic mutation of PKD1.

Case Description: We report the case of a term male infant of African descent presenting with neonatal nephromegaly, pulmonary hypoplasia and hypertension. ARPKD was suspected initially, but genetic testing did not identify a pathogenic mutation in PKD2 or PKHD1. Instead, two variants on the PKD1 gene were identified (c.11249G>A and c.6395T>G), one of which was previously unreported. His course was complicated by anemia, hypertension, respiratory insufficiency and progressive CKD. At 20 months of age, he became acutely ill with fever, ascites, and worsening abdominal distension and was diagnosed with spontaneous bacterial peritonitis. Liver imaging showed hepatomegaly with normal liver function tests. Renal function deteriorated, requiring hemodialysis and ultimately, nephrectomies. Kidney biopsy showed diffuse cysts involving all segments of the nephron, complete obliteration of the cortex and glomerulocystic changes. Liver biopsy demonstrated CHF, with diffuse ductal plate malformation, tortuous peripheral ductal profiles and expanded portal tracts. Doppler ultrasound did not reveal portal hypertension.

Discussion: Our patient has a previously unreported variant of PKD1, and biallelic or "double dominant" ADPKD. This case is significant due to his neonatal presentation, early deterioration of renal function, and CHF, all of which are unusual in ADPKD. This suggests that biallelic ADPKD has unique clinical characteristics. This case emphasizes the importance of considering a wider differential diagnosis when evaluating children with nephromegaly and cystic kidney disease; and the importance of monitoring for CHF and related sequelae, even in the context of ADPKD.

FR-PO618

Mutation in NOTCH2 Gene Causing Liver and Renal Failure in Newborn

Thu Tran, Rasmey Chhin, Tetyana L. Vasylyeva. *Pediatrics, Texas Tech University Health Sciences Center, Amarillo, TX, Amarillo, TX.*

Introduction: Alagille syndrome is an autosomal dominant disorder known to cause a multi-organ dysfunction and often presents as neonatal liver disease. The majority of cases are related to the mutation of the JAG1 gene and only a small percentage, <1%, is due to mutation of the *NOTCH2* gene. We present a patient who was diagnosed with neonatal giant cell hepatitis and renal tubular dysgenesis later found to have *NOTCH2* gene mutation.

Case Description: The patient delivered at 39 weeks gestation via cesarean section due to being large for gestational age and appeared "swollen" on ultrasound. At 6 weeks of life, he was found to have elevated transaminases, hyperbilirubinemia, clay colored stools, rust colored urine and ascites. A liver biopsy was done and read as neonatal giant cell hepatitis with marked hemosiderosis, bile duct paucity, and acute microabscess. At 5 months of life, he was admitted for acute kidney failure when found to have oliguria, hyperkalemia, rising creatinine levels and coagulation levels indicative of disseminated intravascular coagulation. He underwent orthotopic liver transplantation at that time. A biopsy was done on the explanted liver and found hepatocellular necrosis with syncytial giant cell transformation and diffuse fibrosis with marked hemosiderosis which was highly concerning for possible embryonal hepatoblastoma versus neonatal hemochromatosis. He required a prolonged period of continuous renal replacement therapy and dialysis which prompted a fine needle biopsy of the kidneys revealing renal tubular dysgenesis. Repeated biopsy at the age of 4 years showed glomeruli with podocyte hypertrophy and fetal glomerular appearance. Whole exome sequencing was later done and revealed he had an unclassified variant detected of phenotype H2032N which is found in the *NOTCH2* gene and known to be linked to Alagille syndrome.

Discussion: Alagille syndrome is characterized by bile duct paucity but has the classical involvement of 5 main systems including: liver, dysmorphic facies, congenital heart disease, skeletal anomalies, and ophthalmic defects. Both the *JAG1* gene and the *NOTCH2* genes are involved with the Notch receptors. *JAG1* gene is responsible for up to 95% of cases while the *NOTCH2* gene is involved in <1% of cases. This case highlights the extensive multisystem involvement that can be seen in Alagille syndrome and the extremely rare presentation of the NOTCH2 gene mutation.

FR-PO619

C3 Gene Mutation Abnormality Associated with Atypical Hemolytic Uremic Syndrome in a Patient With Polycystic Kidney Disease

Vineet K. Jassal, Tushar Chopra, Negiin Pourafshar. *University of Virginia Div. of Nephrology, Charlottesville, VA.*

Introduction: Atypical HUS (aHUS) is a disorder involving dysregulation of the serum complement system, resulting in endothelial cell injury and has been effectively treated with blockade of the complement system. The optimal therapy remains unknown, but advances in genetic testing help determine which patients would benefit from complement system blockade. We report a case of an aHUS patient that benefited from genetic testing after being on dialysis.

Case Description: 35-year-old female with a past medical history of obesity, gestational hypertension, history of a miscarriage, diabetes mellitus, and polycystic kidney disease presented with diarhea, acute renal failure, and uremic symptoms after eating uncooked meat. Her serum creatinine (sCr) was 11 mg/dL, platelet count 82 k/μL and labs concerning for microangiopathic hemolytic anemia. A kidney biopsy showed severe acute thrombotic angiopathy; extensive endothelial cell injury and prominent fibrinoid necrosis of vascular walls. There were mild chronic changes in the parenchyma including focal glomerulosclerosis, tubular atrophy and interstitial fibrosis. Genetic testing revealed a variant of unknown significance in the C3 gene. She required hemodialysis, and started on eculizumab, along with prednisone and plasmapheresis. A month later, her kidney function improved to be off dialysis and one year later her sCr is stable 3.0 mg/dl with continued use of eculizumab.

Discussion: Our case highlights the difficulty in recognition of mutations of complement cascade that can be trigged to cause thrombotic microangiopathy. We herein, present a case of atypical hemolytic uremic syndrome that is uncommonly associated with C3 gene mutation. Genetic susceptibility to aHUS has been well recognized with mutations in genes involving complement factor I, membrane cofactor protein, and CFH (complement factor H). These mutations affect the binding regions of C3b that interrelate with CFH, CD46, and complement receptor 1, with resultant dysregulation of the alternative complement pathway. Patients with C3 mutations usually progress to severe disease and ESRD within the first year following presentation. Therefore proper diagnosis and management (including the use of eculizumab) in this group of patients would have a great impact on prognosis of their renal disease.

FR-PO620

Atypical Hemolytic Uremic Syndrome (HUS): DGKE and Other Mutations in West Virginia Children's Hospital

Kayla Duvall,[1] Oulimata K. Grossman.[2] *[1]WVU School of Medicine, Morgantown, WV; [2]West Virginia University Health Sciences, Morgantown, WV.*

Introduction: HUS is a thrombotic microangiopathy (TMA) presenting with thrombocytopenia, anemia, and end organ involvement with normal ADAMTS13. Microvascular injury, platelet consumption and intravascular hemolysis lead to end organ damage. Renal biopsy is pathognomonic. Typical HUS presents acutely after E. coli (STEC) related bloody diarrhea with good prognosis despite severity. Atypical HUS (aHUS) has incidence projected at 0.53 per million. Here we focus on etiologies related to complement dysregulation. AHUS is a chronic and progressive disease leading to acute kidney injury (AKI), end stage renal disease (ESRD), and even death. Early treatment with complement blockade (Eculizumab) has improved prognosis. Although a rare disease, this reports 3 cases managed in our institution to highlight the varied presentation and management.

Case Description: Patient A had TMA at 8 months old with proteinuria and progressed to ESRD at 19 years. Renal biopsy showed chronic TMA. This patient received Eculizumab for 4 months after renal transplant. Patient B was diagnosed at 3 years old with acute gastroenteritis, neurologic symptoms, and nephrotic syndrome. Renal biopsy showed acute TMA. Symptoms resolved with Eculizumab. Patient C presented at 10 years old with abdominal pain, gross hematuria, and proteinuria. Renal biopsy showed IgA nephropathy and no TMA lesions. This patient improved without Eculizumab.

Discussion: Despite similarities in presentation, it is vital to differentiate aHUS from HUS as early treatment with Eculizumab is recommended in aHUS to prevent morbidity. Genetics will determine who benefits from this treatment. Mutation in CFH gene is a major cause in up to 25% of cases, has poor prognosis, and requires plasma treatment. Patient B had such treatment and did have a secondary mutation on CFH compared to patient C who did not require treatment. MCP mutations are generally known to be associated with glomerulopathies and have better prognosis. DGKE, a rarely reported mutation, presents in infancy with ESRD by age 20 years and is not known to respond to Eculizumab without a secondary mutation. Extending our review on prior and future cases will give more insight to this very rare disease.

Genetics of Cases

	Patient A	Patient B	Patient C
Major genetic mutation for gene mutation on Membrane cofactor protein (MCP, Complement factors I, B, H, CFHR4-6, Thrombomodulin, Diacydiacylglycerol kinase epsilon (DGKE)	Homozygous nonsense DGKE mutation(c.966G>A, p.Trp322StopiExon6	Heterozygous missense variant (c.1058C>T, p.Ala353Val) Exon 8 MCP/CD46. Minor genetic mutation(s)	Heterozygous missense variant of PLG (c.112A>G, p.Lys38Glu) on Exon2, (c.1469G>A, p.ARg49 Gln) on Exon 12. Heterozygous MCP/CD46	Heterozygous for CFH C>T polymorphism	Heterozygous missense variant (c.754G>A, p.Gly252Ser) CFB exon

FR-PO621

A Case of Familial Infantile Nephrotic Syndrome Secondary to Membranous Nephropathy

Ashley E. Rawson,[1] Amy C. Wilson,[1] Anne Kouri,[1] Myda Khalid,[1] Corina Nailescu,[1] Carrie L. Phillips,[2] David S. Hains.[1] Indiana University School of Medicine Pediatric Nephrology *[1]Indiana University School of Medicine Pediatric Nephrology, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN.*

Introduction: Infantile nephrotic syndrome (NS) is defined as NS onset between 3-12 months of life. It is often caused by genetic alterations of proteins involved in forming the podocyte slit diaphragm and glomerular basement membrane. Over 95% of cases are autosomal recessive and can be attributed to mutations in NPHS1, NPHS2, NPHS3, WT1, and LAMB2. Biopsy findings are usually negative for immune deposition. In very rare cases membranous nephropathy causes infantile NS; however, there are no documented cases of dominant inheritance. We describe a case of familial infantile NS with a variable histologic phenotype and atypical inheritance pattern.

Case Description: A 9-month-old male presented with 2 weeks of diffuse swelling. He had massive proteinuria with a urine protein: creatinine ratio of 22.18. His renal function, complement levels, metabolic work-up and ANA were unremarkable. Family history included a half-brother (same mother) with steroid resistant NS who presented at 1 year of age and died of sepsis at 2 years of age 8 years prior to this case. The half-brother had a kidney biopsy revealing type III membranoproliferative glomerulonephritis but genetic

evaluation was not sent. Genetic evaluation on our current patient is pending; however, because of the biopsy findings of the half-brother, a biopsy was performed and consistent with membranous nephropathy. Immunofluorescence was positive for glomerular labeling of IgG (3+), IgA (2+), and C3 (4+). Additionally, glomerular capillary loops diffusely labeled with PLA2R (3+) antibody and tubular basement membranes labeled with IgG in a granular pattern. Patient currently maintains normal albumin levels on albumin infusions, furosemide, and ACE-inhibition.

Discussion: Infantile membranous nephropathy with tubular basement membrane antibodies is not currently reported in the literature. Some pediatric case reports exist but staining of the tubular basement membranes with IgG is typically in a linear pattern. The granular pattern seen in our patient is very unusual and usually seen in patients with SLE. Familial cases of these findings have not been reported. The presence of NS in half-brother suggests a dominant inheritance pattern and may suggest a novel gene mutation for infantile NS. The half-brother with a different histological pattern suggests a variable phenotype.

FR-PO622

Renal Manifestation in a Patient with Seckel Syndrome: An Interdisciplinary Challenge

Henrike Stopfkuchen, Anja K. Büscher, Ilja Finkelberg, Peter F. Hoyer, Rainer Büscher. *Paediatric Nephrology, University Hospital Essen, Essen, Germany*.

Introduction: Seckel syndrome (SCKL) ist the extremly rare manifestation of an proportionate dwarfism, presenting with microcephaly, osteodysplasia, bird head-like appearance and psychomotorical retardation. Approximately 20 cases worldwide are described. This genetically heterogeneous syndrome ist inherited autosomal-recessive and the gene located on chromosomal region 3q22.1-q24 (OMIM no. 210600). A renal manifestation is not described so far.

Case Description: We present the case of a 34 years old Lebanese woman diagnosed with Seckel syndrome in early childhood. Parents are first degree relatives. Intrauterine growth retardation was observed, several other family members are diagnosed with unclear dwarfism, but nobody else with Seckle syndrome. Birth weight was 1500 g (< 3rd percentile, gestational age 36 weeks). Besides the typical stigma of the syndrome, the patient did well and the family doctor in Lebanon was not seen on a regular basis. A chronic Hepatitis B infection remained clinically unapparent and was not treated. The family moved to Germany when the girl was 16 years old. The patient was first seen in our hospital at the age of 34 years presenting with a first transitorily ischemic attack and dexter hemiparesis. Further laboratory results revealed a so far unapparent chronic renal failure. Kidneys were dysplastic with volumina of 17 and 23 ml. Due to the low weight of 15.0 kg and a height of 107.6 cm, peritoneal dialysis was initiated by the paediatric dialysis department. Besides several internal, neurological and gynecological ailments such as progessive heart failure and dysmenorrhea, the patient remained under paediatric care due to the habit. Continuous cyclic peritoneal dialysis was continued for 5 years, the patient did well and was listed as kidney recipient with Eurotransplant. A second ischemic attack and severe heart failure with shortening fraction < 10% occured in April 2018 and the patient passed away few days later.

Discussion: Take-away lesson: Regardless the age, treatment of multi-morbid patients with rare diseases is an enormous interdisciplinary challenge. Preservation of quality of life has highest priority and needs individual definitions and solutions.

FR-PO623

A 5-Month-Old Female with One Week of Anuria

Angelina M. Dixon,[1] Hannah R. Lively-Endicott,[2] Samir S. El-Dahr.[1] *[1]Tulane University School of Medicine, New Orleans, LA; [2]University of Queensland/ Ochsner Clinical School, New Orleans, LA.*

Introduction: Anuric AKI is typically associated with worse outcomes than AKI with preserved urine volume. Anuria usually suggests obstruction, but it can also be seen in ATN or AIN. Acute vascular catastrophe can also cause anuria; however, it must affect both kidneys or a single functioning kidney.

Case Description: We present the case of a 5-month-old, ex-24-week female transferred to our PICU from an outside hospital NICU with anuria. Ten days prior to transfer the patient's creatinine had risen from 0.3 to 2.0 in five days with oliguria, and seven days prior to transfer the patient was noted to be anuric. A renal US demonstrated obliteration of the renal venous flow suggestive of thrombosis of the IVC and bilateral (BL) renal veins as well as high resistive flow in the main renal artery. Upon admission, the patient had a BUN of 219 mg/dl and creatinine of 6.8 mg/dl. She was placed on CRRT. A repeat US confirmed IVC and BL renal vein thrombi, so a heparin drip was started. Subsequent catheterization demonstrated BL renal artery thrombi as well, so the patient underwent mechanical thrombectomy of her IVC and right renal vein in addition to site-directed TPA to her IVC, renal veins, and renal arteries. Ultimately, anticoagulation was not sustainable due to the development of severe coagulopathy, so the decision to withdraw support was made. The etiology of this patient's BL renal artery thrombi is still unclear. Our patient had a normal hypercoagulability workup; however, she had multiple central venous lines placed, including a catheter placed immediately before her creatinine began to drastically rise. In addition, she had a known PFO. Therefore, the most likely etiology of in this patient was central-line associated thrombus formation.

Discussion: Renal vascular occlusion leads to renal infarct in hours as collateral vasculature can only maintain adequate perfusion for a short period of time. Therefore, early diagnosis and treatment is imperative. Treatment is controversial and depends on the acuity of the situation. Most patients are treated with systemic anticoagulation. In recent reports, supportive care is recommended for unilateral vascular occlusion without extension into the IVC where thrombolytic agents were used for bilateral cases. The long-term benefit of this approach is still unclear.

FR-PO624

LOANing a Kidney: Role of Whole Exome Sequencing (WES) in Diagnosis of Microscopic Hematuria in Potential Kidney Donors

Sarthak Virmani, Neera K. Dahl. *Yale School of Medicine, New Haven, CT.*

Introduction: Kidney donors with microscopic hematuria present a particular challenge to transplant clinics, with some advocating for donor kidney biopsies. Only those with no glomerular lesions by biopsy are deemed to be suitable donors. We used WES instead of a more invasive kidney biopsy to determine a donor's eligibility for transplant. Subsequent confirmatory testing in her sibling, the recipient, led to an unexpected finding.

Case Description: A 62-year-old French Canadian woman was referred to our transplant center for evaluation as a potential kidney donor to her 60-year-old younger sister with ESRD from biopsy proven FSGS. Years earlier, their mother had also developed ESRD of unknown etiology. Routine evaluation of the donor showed microscopic hematuria. Further inquiry revealed a long-standing history of microscopic hematuria in at least 3 other first degree family members. This prompted WES of the potential donor. An autosomal recessive homozygous variant (cA740G) in the INVS gene, associated with nephronophthisis was found. This variant was classified a variant of unknown significance (VUS). Her sister, the potential recipient, was also found to have the same homozygous mutation. However, in addition to his mutation, a likely pathogenic frameshift variant in the COL4A4 gene (P1235fs) was also found to be present. This led to a reformed diagnosis of autosomal dominant Later Onset Alport Nephropathy (LOAN) in the proposed recipient and cleared her sister for donation.

Discussion: COL4A4 mutations can differentiate the patients with familial microscopic hematuria into benign familial hematuria or LOAN presenting histologically as FSGS. About 25 % of patients above the age of 50 with COL4A3/A4 mutation, who are labelled as having thin basement membrane nephropathy, have been found to have proteinuria, hematuria, hypertension and progression to ESRD making this differentiation improtant. This case highlights the importance of WES in differentiating various familial microscopic hematuria syndromes and helps obviate the need for renal biopsies, especially in patients being considered for transplant.

FR-PO625

The Clinical Impact of Whole-Exome Sequencing by Japan's Initiative on Rare and Undiagnosed Diseases (IRUD) Project on Renal Genetic Diseases

Akira Ishii,[1] Kanna Shinkawa,[1] Atsushi Fukatsu,[2] Naoko Nakagawa,[3] Takahito Wada,[3] Naoya Kondo,[1] Kaoru Sakai,[1] Shuichiro Endo,[1] Hideki Yokoi,[1] Takeshi Matsubara,[1] Shinji Kosugi,[3] Kenjiro Kosaki,[4] Motoko Yanagita.[1] *[1]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Fukatsu Medical Clinic, Anjo, Japan; [3]Department of Medical Ethics/Medical Genetics, Kyoto University School of Public Health, Kyoto, Japan; [4]Center for Medical Genetics, Keio University School of Medicine, Tokyo, Japan*.

Introduction: There exist many patients who are suffering from rare, undiagnosed kidney diseases. In 2015, the Japan Agency for Medical Research and Development (AMED) launched the Initiative on Rare and Undiagnosed Diseases (IRUD). IRUD is a national project to analyze whole-exome sequence by using next-generation sequencer.

Case Description: Case 1: A 30-year-old woman, who was diagnosed with Retinitis Pigmentosa, developed renal dysfunction (serum creatinine level, 4.8 mg/dl). She had hypokalemia and metabolic acidosis, and her 31-year-old brother also had same symptoms and was receiving hemodialysis. Her brother was suspected of having Nephronophthisis and the genetic examination was performed but could not find the *NPHP* gene mutation. Therefore, we examined exome sequencing by IRUD. By genetic analysis, she had compound heterozygous missense variants in *ALMS1* gene c.[4331A>T];[7973C>G] which were also found in her brother, but it seemed atypical presentations as Alstrom syndrome because they did not show neither obesity nor type 2 diabetes. Case 2: A 57-year-old man, who was diagnosed with hematuria 37 years ago, developed proteinuria and renal dysfunction (serum creatinine level, 3.5 mg/dl). Her mother and younger sister also had hematuria and proteinuria and his three sons also had hematuria. From his family history of renal disease including women, Alport syndrome which is probably due to *COL4A3* or *COL4A4* mutation was suspected. Exome sequencing found deletion and missense variants in *COL4A4* gene c.[1323_1340del]; [2045A>G] in the patient. These mutations had not been reported so far as responsible genes in Alport syndrome.

Discussion: These genetic mutations found in the two cases were predicted to cause the phenotypes of diseases. Whole-exome sequencing by IRUD is a powerful tool for diagnosis of rare and atypical renal genetic diseases. Sharing and accumulating the genetic data of diseases will be important for further elucidation of the pathology.

FR-PO626

Proximal Tubule Histopathologic Variability in Renal Tubular Dysgenesis: A Case Report

Seon Lee, Nirupama Gupta, William L. Clapp, Lawrence R. Shoemaker. *University of Florida- College of Medicine, Gainesville, FL.*

Introduction: Renal tubular dysgenesis (RTD) is a rare autosomal recessive disorder that presents with antenatal oligohydramnios and anuric renal failure, despite normal renal sonography. Mutations of 4 genes that code for integral proteins of the renin-angiotensin system (RAS) are responsible for RTD. The function of these proteins is necessary for proper fetal renal tubular development. The pathologic hallmarks of RTD include a

paucity of proximal tubules (PT) with aberrant developmental features, detectable by light microscopy and immunohistochemistry (IHC).

Case Description: A 32-week gestational age neonate delivered by urgent C-section for prolonged rupture of membranes and oligohydramnios had anuric renal failure since birth and severe hypotension refractory to vasopressors. Imaging revealed a normal renal sonogram and a large anterior skull ossification defect. Blood tests revealed markedly low renin activity, but normal cortisol, aldosterone, and angiotensin converting enzyme levels. Review of renal biopsy performed on DOL 20 revealed a paucity of PT. In contrast to prior reports, several developmentally mature PT were detected that stained positive with IHC targeted for PT-specific markers CD10 and CD15. Genetic confirmation was sought on DOL 23. The patient had a homozygous nonsense mutation in the *REN* gene, c.127C>T, which results in termination of coding of transcripts at the level of the pro-peptide of renin. This pathogenic mutation, which prevents any renin production, was previously identified and described in another patient with RTD.

Discussion: This case brings to question whether there exists a meager degree of biological redundancy in the fetal RAS that may obscure correlation of genotype and phenotype. For example in this case, might there be alternate enzymes (other than renin) capable of activating RAS? Recognition of the mild histopathologic variability in these rare cases supports early genetic testing for RTD in neonates with unexplained anuria. Furthermore, the finding of relatively mature PT in this case, associated with a mutation that prevents any renin production, suggests a greater complexity of the biology of the fetal RAS than currently appreciated.

FR-PO627

A Surprise Diagnosis: Oxalate Nephropathy

Deep Shah, Kim Jordan. *Ohiohealth Riverside Methodist Hospital, Columbus, OH.*

Introduction: Hyperoxaluria can cause acute kidney injury (AKI) or chronic kidney disease (CKD) from oxalate crystal deposition. We present a surprising diagnosis of oxalate nephropathy in an elderly female.

Case Description: A 75-year-old female presented with dyspnea, weight gain, and edema. She had diastolic heart failure, CKD stage 3 attributed to insulin-requiring diabetes, and prior partial colectomy for ulcerative colitis. Furosemide was increased two weeks prior because of symptoms, but no other medication changes were noted. Admission serum creatinine was 8.1 mg/dl, (1.6 mg/dl baseline). AKI was attributed to cardiorenal syndrome, but she failed to improve with intravenous furosemide, and hemodialysis was started. Echocardiography showed mild left ventricular hypertrophy and atrial dilation, EF 60-65%, and grade 2 diastolic dysfunction. Protein and moderate blood were noted on urinalyis, but casts and crystals were not reported. Renal ultrasound found mild asymmetry in kidney size, few simple renal cysts, and hyperechoic cortices. Serum complement levels, anti-GBM, ANA, ANCA, urine protein electrophoresis and serum immunofixaton studies were normal. Kidney biopsy revealed acute tubular necrosis with prominent oxalate crystals, urine eosinophils, mild fibrosis, and interstitial changes consistent with oxalate nephropathy. The patient reported consumption of one gallon of iced tea daily for 20 years. While on hemodialysis, plasma oxalate was 15.4 micromol/L (normal <11) with urinary oxalate excretion of 11.4 mg/24 h (normal <40 mg/24 h). Calcium supplementation was started and she was instructed to maintain high water intake, avoid iced tea consumption, and begin a low oxalate, low vitamin C, calcium-enriched diet. The patient remains on hemodialysis post-discharge.

Discussion: Hyperoxaluria can be primary from enzymatic deficiency, or secondary from gastrointestinal disease, malabsorption syndromes, excessive vitamin C ingestion, and ethylene glycol toxicity. However, ingestion of oxalate-rich foods, including spinach, beets, rhubarb, peanuts, star fruit, and iced tea should also be considered. Despite documented excess dietary oxalate intake in individuals in the United States, reports speculate that oxalate nephropathy is under-recognized. Physicians should consider oxalate nephropathy in the right clinical scenario, in this case, excessive iced tea and underlying gastrointestinal disease.

FR-PO628

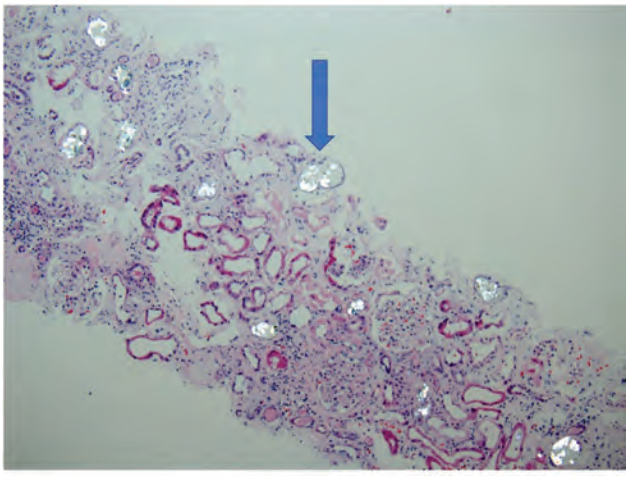
ESRD Secondary to Oxalate Nephropathy Post Whipple's Procedure: A Report of an Interesting Case

Azka Arif,[6,1] Ahmad Hassan,[3] Leena Syed,[4] Muhammad Moosa Niazi,[3] Talal A. Khan.[5,2] *[1]Internal Medicine, Freeman Health System, Joplin, MO; [2]Nephrology, Kansas City University of Biomedical Sciences, Joplin, MO; [3]Rawalpindi Medical College, Rawalpindi, Pakistan; [4]Quaid-e-Azam Medical College, Bahawalpur, Pakistan; [5]Nephrology, Freeman Health System, Joplin, MO; [6]Internal Medicine, Kansas City University of Biomedical Sciences Graduate Education Program, Joplin, MO.*

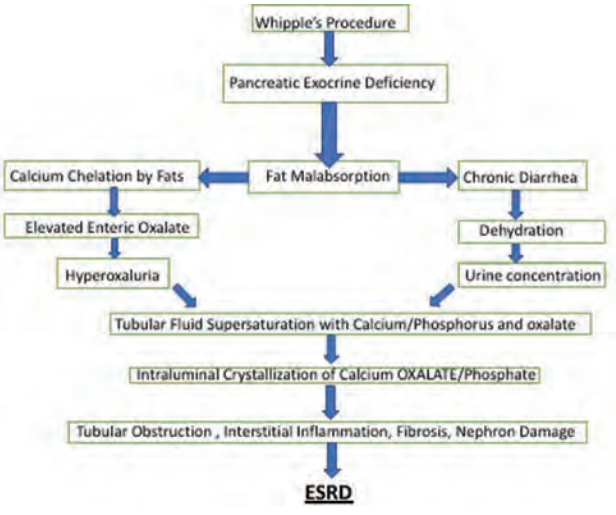
Introduction: HTN & DM are the two most common causes of ESRD. Secondary Oxalate Nephropathy is one of the rare causes of ESRD, We present an interesting case of ESRD secondary to oxalate nephropathy resulting from Pancreatic Exocrine deficiency.

Case Description: 77-year-old male with recently diagnosed HTN, presented to ER with generalized weakness, nausea, vomiting & swelling. Initial labs showed BUN of 109mg/dl, creatinine of 14.8 mg/dL. No recent IV contrast exposure, no NSAIDs use, no evidence of hematuria, had 0.5 g of proteinuria & negative urine eosinophils. Immune workup was negative. Renal ultrasound was negative for hydronephrosis. He was urgently dialyzed & later on underwent kidney biopsy which showed evidence of oxalate nephropathy & significantly advanced fibrosis. Patient had history of Whipple's procedure in 1996, he was not on any pancreatic enzyme supplementation. He had history of chronic recurrent diarrhea. His serum lipase was <10 U/L & serum Albumin was 2.8mg/dl. He was deemed ESRD & continued hemodialysis. He was started on pancreatic enzymes and his diarrhea improved.

Discussion: Our case represents one of the rare complications of pancreatic exocrine insufficiency resulting from Whipple's procedure. Pancreatic insufficiency is associated with fat malabsorption causing calcium chelation. Resulting Hyperoxaluria causes oxalate nephropathy. Our case presents a rare yet unfortunate long-term complication of pancreatic insufficiency post Whipple's procedure. Patients especially after Gut related surgeries should be monitored for any hyperoxaluria which can result in lifelong morbidity.



Oxalate Crystals Under Polarized Light in Renal Biopsy specimen



Mechanism of Oxalate Nephropathy

FR-PO629

Oxalate Nephropathy in Patient with Diabetic Kidney Disease

Hristo Shivarov,[1] Maria V. DeVita.[2] *[1]Lenox Hill Hospital - Northwell Health System, New York, NY; [2]Lenox Hill Hospital- Northwell Health System, New York, NY.*

Introduction: Secondary oxalate nephropathy is an uncommon condition that causes acute kidney injury with the potential for progression to end-stage renal disease. The diagnosis is based on high clinical suspicion and the findings from kidney biopsy.

Case Description: 54 year old female with significant past medical history for Diabetes mellitus type I since age of 10, proliferative diabetic retinopathy, diabetic kidney disease, CKD stage 3b, HTN. She presented into the ED with abdominal pain, nausea and vomiting for less than 1 week. Laboratory work showed severe deterioration of her kidney function BUN 129 mg/dl and serum creatinine of 10.4 mg/dl and severe anemia – hemoglobin 6.6 g/dl. Baseline creatinine of 1.82 mg/dl, eGFR 31 ml/min one month prior. Furosemide and Enalapril were discontinued, rehydration therapy was initiated in the next two days without significant improvement in renal function, The evaluation for secondary causes for worsening of the renal function were negative: C3 and C4, hepatitis status, free light chains, UA – bland sediment <5 RBC, 5-10 WBC, no casts, proteinuria +, 34 mg/24 h. The patient was started on hemodialysis. Because of relatively fast progression of the renal failure inconsistent with diabetic nephropathy a renal biopsy was performed. The histological findings were consistent with widespread tubular oxalate crystal deposition, diffuse and nodular diabetes glomerulosclerosis and severe arterial sclerosis. After that a detailed history of her dietary habits was taken. The patient acknowledge for recent change

in her diet habits including increased intake of green leafy vegetables, copious amount of green tea and almonds.

Discussion: A diet rich of oxalate can cause irreversible acute oxalate nephropathy, which can lead to ESRD in a patient with impaired renal function. Patients with predisposing conditions such as CKD and diabetic kidney disease are particularly at risk. Heightened awareness of the potential for acute oxalate nephropathy following a high green diet in susceptible individuals is needed to reduce the incidence of this preventable condition

FR-PO630

Acute Renal Failure Due to Dietary Hyperoxaluria

Prerna Kumar, Youness Hussein, Douglas L. Somers. *University of Iowa, Iowa City, IA.*

Introduction: We present a case of rapid drop in GFR attaining CKD stage 5 from CKD stage 3 caused by excessive dietary oxalate intake.

Case Description: A 51-year-old male with the PMH of chronic kidney disease stage 3b, benign prostatic hypertrophy and kidney stones was admitted in February 2018 for unintentional weight loss, abdominal discomfort, and a creatinine of 6.9. Patient reportedly lost 14 lbs over 4 months. Detailed interviewing revealed a recent change in his diet. He was on a "Microbiome-intense diet" for two months in December 2017 to accompany his wife in her weight loss regimen. This diet included whole meals of raw fruits and vegetables, and later included eggs and cheese, as well as a lot of almonds, spinach, kale and berries. Pertinent positives on physical exam included BP of 100/60 mm Hg and dry mucous membranes. Labs: BUN 111, Creatinine 6mg/dL (baseline 2.0) and eGFR 8 mL/min/1.73m2. Chart review revealed a history of oxalate kidney stones in 2014 with high oxalate excretion. Prior CT abdomen/pelvis without contrast showed bilateral non-obstructing renal stones. Patient denied taking any herbal products, over the counter drugs including NDSAIDs, or any "diet pills". Family history was negative for renal stones. 24-hour urine collection for stone analysis demonstrated high urinary oxalate excretion. Renal biopsy showed chronic interstitial nephritis, with intraparenchymal deposition of oxalate and phosphate He was discharged with recommendations to stop the microbiome diet and restart potassium citrate.

Discussion: Oxalate is widely found in both plants and animals and is normally excreted by the kidneys.. Increased oxalate excretion in the urine causes supersaturation and deposition of calcium oxalate crystals in the renal tissue. The most common cause of hyperoxaluria is excessive oxalate absorption from the gastrointestinal tract, enteric hyperoxaluria from fat malabsorption or excessive endogenous oxalate production (primary hyperoxaluria). The diagnosis of dietary hyperoxaluria in this patient was suggested by the patient's extreme diet which altered the gut flora and consequently, the oxalate homeostasis. Most commonly implicated vegetables and fruits are peanuts, celery, carrots, parsley, beets, spinach, nuts and rubarb. As patient's GFR fell, his serum oxalate increased leading to more deposition.

FR-PO631

Gastrointestinal Bleeding Secondary to Gastric Mucosal Calcinosis in an ESRD Patient

Anum Malik,[1] Jonathan J. Taliercio,[2] Laura Ferreira Provenzano.[1] *[1]Cleveland Clinic, Beachwood, OH; [2]Glickman Urological and Kidney Institute, Cleveland, OH.*

Introduction: Gastric mucosal calcinosis (GMC) is a pathological process of calcium salt deposition in normal tissues from prolonged periods of hypercalcemia or hyperphosphatemia. The gastric mucosa, kidneys and lungs are preferred sites for deposition. We describe a rare case of upper gastrointestinal bleeding (UGIB) secondary to GMC in a peritoneal dialysis (PD) patient.

Case Description: A 21 year old male with a history of ESRD secondary to anti-glomerular basement membrane disease on PD was transferred to our facility for work up of an UGIB. He has a complex cardiac history including congenital transposition of the great arteries requiring surgical repair in childhood and left ventricular thrombus on warfarin. He was listed for a combined heart-kidney transplant. He presented to the emergency department due to a syncopal episode which was attributed to hemorrhagic shock upon discovery of a hemoglobin 5.2g/dL from a baseline 9 g/dL and guaiac positive stools. His INR was 5.9 and his coagulopathy was reversed and transfused blood. An EGD demonstrated non-bleeding gastric ulcers which were biopsied. Pathology revealed diffuse calcification of the lamina propria with a mononuclear inflammatory infiltrate diagnostic of GMC. On review of his dialysis and bone mineral disease (BMD) history he a low average transporter without residual renal function on PD for 3 years. PD prescription was 10 hours of CCPD with 8 exchanges, fill volume of 1.8L of 2.5% dextrose dialysate per exchange, with a last fill of 1.5L of 2.5% dextrose. His last Kt/V was consistently > 1.7 for the last year. His serum calcium levels have been within goal but he has been hyperphosphatemic with average level of 8-9mg/dL and PTH 501 pg/ml attributable to noncompliance with multiple calcium and non-calcium binders. He had no signs of calciphylaxis. Despite these findings, he continues to do well post discharge.

Discussion: We report a unique case of GMC in the setting of hyperphosphatemia in an ESRD patient with a dialysis vintage of only 3 years and an adequate Kt/V. On literature review, there is no other reported cases of GMC in a PD patient and only one reported case in a hemodialysis patient. Our case also highlights the importance of recognizing GMC as an possible etiology of UGIB in ESRD patients, especially those with poorly controlled BMD.

FR-PO632

Spontaneous, Non-Traumatic Rupture of an Acquired Renal Cyst in ESRD Patient with Large Retroperitoneal Hemorrhage - A Case Report

Abbas Raza,[1] Sandeep Aggarwal,[2] Muhammad O. Hanif.[1] *[1]Drexel University, Philadelphia, PA; [2]Drexel University College of Medicine, Philadelphia, PA.*

Introduction: Acquired Cystic Kidney Disease (ACKD) is asymptomatic in most patients. However, the renal cyst may be associated with back pain, infection, and malignant transformation. Cyst rupture and bleeding secondary to ACKD are considered unlikely because of reduced renal parenchymal blood supply in atrophic kidneys. We present a case of an End Stage Renal Disease (ESRD) patient with a previously unrecognized cystic condition who presented with extensive retroperitoneal hemorrhage.

Case Description: A 31-year-old male with the medical history of ESRD for 5 years due to hypertension and no history of smoking presented with acute onset of left flank pain. Patient denies any traumatic event prior to the onset of pain. Blood work showed a hemoglobin of 9.5 g/dl with normal coagulation profile and platelets. Imaging showed large heterogeneously attenuating, ruptured left renal/perinephric hematoma measuring 10x12x27 cm occupying most of the left retroperitoneal space and extending across the midline. There were multiple foci of active extravasation and no normal renal parenchymal tissue was visualized. (Figure-1). The patient had an emergent fluoroscopy guided coil and Gelfoam embolization of the superior and inferior pole left renal arteries with successful hemostasis. The patient remained hemodynamically stable for the rest of the stay.

Discussion: To our knowledge, it is the first reported case of ACKD associated massive hemorrhage. Although rare, hemorrhage due to ruptured renal cyst should be suspected when an ESRD patient presents with acute back pain and symptoms of shock. Screening for ACKD has been proposed but larger scale trials are required for consensus and guideline development.

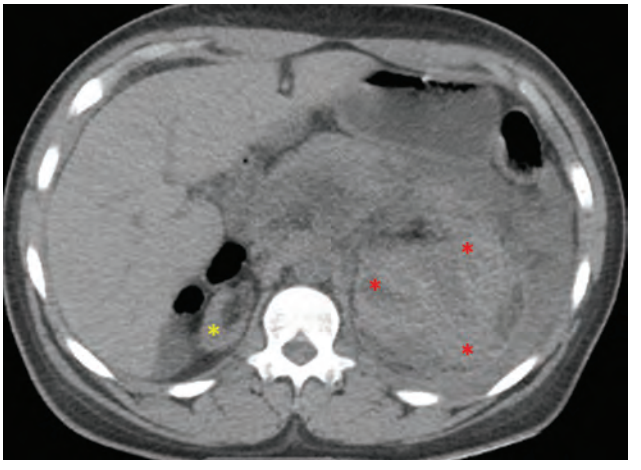


Figure 1: CT scan image. Red asterisk on the left of the patient indicating the area of retroperitoneal hemorrhage. Note right atrophic kidney (yellow asterisk).

FR-PO633

A Concrete Cause of Abdominal Pain

Jimmy D. Gentry, Peter Hanna, Rishi Naik, Lori Wanko, Edward Gould. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Sevelamer hydrochloride is a non-calcium based phosphate binder routinely used in the treatment of hyperphosphatemia in patients with impaired renal excretion of phosphorus. Sevelamer is commonly associated with mild gastrointestinal (GI) symptoms - most commonly, constipation, nausea and bloating. Here we describe a case of a more serious sevelamer concretion masquerading as a gastric malignancy in a patient presenting with abdominal pain.

Case Description: Our patient is a 48 year-old female with a history of hypertension, DM2, morbid obesity, and ESRD on hemodialysis three times a week, who presented with sharp left flank pain of two weeks duration as well as nausea and early satiety. A contrasted CT scan raised concern for invasive gastric malignancy. She underwent endoscopy with biopsy for diagnostic purposes. Visual examination revealed a discolored infiltrative mass. Histologic examination revealed irregularly shaped "fish-scales" consistent with sevelamer crystals and other debris all consistent with sevelamer concretion. After multidisciplinary discussion the decision was made to forego surgical removal and treat conservatively. Prior to presentation, she had been on 3200mg three times daily of sevelamer; this was discontinued with plan for repeat EGD to ensure resolution of the gastric mass and healing of the gastric ulcer.

Discussion: Resin-based phosphate binders such as sevelamer can crystallize leading to the formation of concretions. Since the first description of this in 2013 there have been seventeen reported cases of GI lesions attributable to sevelamer. Eighty-one percent of these were in the intestine and the most frequent presentation is GI bleeding. Pathology ranges from acute inflammation to chronic mucosal injury, strictures, ulcerations, and necrosis, many of which show sevelamer at least in close proximity to inflammation or ulceration on histology. Gastric involvement is rare, and when present is usually in the form of an ulceration. We could not identify previous reports of a gastric mass due to sevelamer. Given the frequency of sevelamer use, it is critical for clinicians to remain attentive to the

possibility of sevelamer concretions as a cause for GI symptoms and pathology in patients using it for phosphorous elimination.

FR-PO634

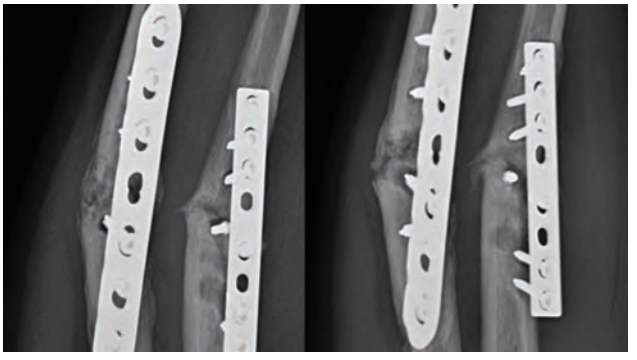
Normohormonal Primary Hyperparathyroidism Presenting as Fracture Non-Union

Amita Maibam, Madhumathi Rao. *University of Kentucky, Lexington, KY.*

Introduction: Primary hyperparathyroidism (PHPT) is a rare cause of poor fracture healing. We present a patient with osteopenia and fracture non-union with mild hypercalcemia in the setting of hydrochlorthiazide (HCTZ) treatment and normal intact parathyroid hormone (iPTH) level.

Case Description: A 54-year-old Caucasian female with history of hypertension, hypothyroidism and depression presented with progressive pain and deformity of the left forearm, 8 months after open reduction and internal fixation of fractures of left radius and ulna. X-ray showed fracture non-union (Figure:1, left); laboratory evaluation revealed mild hypercalcemia (10.5 mg/dl), non-suppressed iPTH (41 pg/ml), and elevated serum creatinine (1.3 mg/dl). Repeat serum calcium after stopping HCTZ, remained 10.5 mg/dl though iPTH increased to 64 pg/ml (range 14-66) Urine calcium was 851 mg/d and bone densitometry showed osteopenia of lumbar spine. A right inferior parathyroid adenoma was demonstrated on nuclear scan establishing a diagnosis of PHPT. The remainder of the work up for hypercalcemia was also significant for a diagnosis of monoclonal gammopathy of undetermined significance (MGUS) confirmed by bone marrow aspiration. Patient underwent parathyroidectomy with prompt reversal of biochemical abnormalities. At 4 weeks after surgery, repeat calcium was 9.6 mg/dl and iPTH level 27 pg/ml; bone pain was improved, and forearm X-ray showed evidence of healing with new bone formation and reversal of cystic changes (Figure:1, right).

Discussion: Normohormonal PHPT accounts for about 5 % of parathyroid explorations and should be considered in patients with fracture non-union and should be corrected before any further orthopedic intervention is undertaken. Mild hypercalcemia in the setting of thiazide treatment and normal iPTH levels may confound the diagnosis and require a high degree of suspicion. The reported association between PHPT and MGUS was also notable in this patient.



Left Forearm XRAY showing fracture site before (left) and after (right) parathyroidectomy.

Lytic Lesions in A Dialysis Patient: It's Not Always Cancer

Victoria Gutgarts,[1,5] David L. Epstein,[3] Narasimhan P. Agaram,[2] Juliet N. Barker,[4] Insara Jaffer Sathick.[1] *[1]Nephrology, Memorial Sloan Kettering Cancer Center, New York, NY; [2]Pathology, Memorial Sloan Kettering Cancer Center, New York, NY; [3]Nephrology, The Rogosin Institute, New York, NY; [4]Hematology/Oncology, Memorial Sloan Kettering Cancer Center, New York, NY; [5]Nephrology, Weill Cornell Medical Center, New York, NY.*

Introduction: Secondary hyperparathyroidism is a known complicaiton of end stage renal disease (ESRD). Increased production of parathyroid hormone (PTH) leads to excess osteoclast activity and fibroblast proliferation. In severe cases, patients are at risk of developing bone lesions called brown tumors.

Case Description: A 31 year old female with history of Hodgkins lymphoma treated with umbilical cord transplant and ESRD due to hypertension on dialysis for six years, presented for kidney transplant evaluation. She had no systemic complaints and an unremarkable physical exam. Laboratory values were significant for elevated PTH 1874 pg/ml. As part of her transplant evaluation, she underwent CT scan showing multiple bony lesions concerning for malignancy. PET scan confirmed FDG avid lytic lesions (Figure 1a). Biopsy of the right iliac crest (Figure 1b) revealed a giant cell rich lesion with osteoclasts and hemosiderin pigment deposition. Despite being medically managed with cinacalcet and doxercalciferol, the patient developed diffuse lytic bone lesions consistent with brown tumor of hyperparathyroidism.

Discussion: Brown tumor is a rare finding in ESRD patients and has an estimated incidence of 1.7 %. Clinically, they can be silent unless there is compression of surrounding structures. CT or PET imaging reveals the lesions, but histopathology is necessary to identify the giant cell granulomas with brown colored hemosiderin deposits from which the tumor gets its name from. Treatment begins with pharmacologic therapy to lower PTH, but can be ineffective, and parathyroidectomy and evaluation for kidney transplantation should be considered. This case underlines the importance of recognizing Brown tumor as a complication and important differential diagnosis of a patient with imaging showing lytic lesions. Prevention and early diagnosis are essential to reduce the prevalence of high turnover bone disease.

Figure 1a: PET scan demonstrating multiple FDG avid lytic lesions of the scapula, clavicle, sternum, femoral condyles, and right iliac crest. 1b: Right iliac crest histopathology with giant cell rich lesion comprised of osteoclasts, fibroblast like cells, and hemosiderin pigment deposition.

FR-PO636

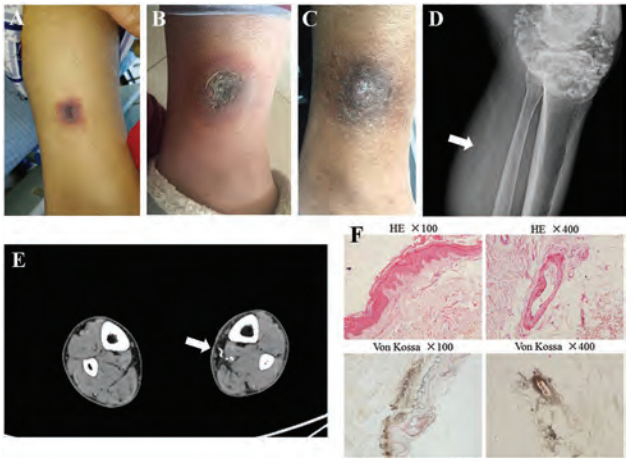
A Case Report of Early Calciphylaxis Based on Single Cutaneous Erythema and Literature Review

Yuqiu Liu, Haifeng Ni, Xiaoliang Zhang. *Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, China.*

Introduction: We analyzed the clinical information of a patient with single cutaneous erythema leading to calciphylaxis, and reviewed literatures. Improve clinical understanding of calciphylaxis to reduce the occurrence of missed diagnosis and misdiagnosis.

Case Description: A 36-year-old male patient with hemodialysis for 5 years had focal purple-black skin changes in the left leg recently(Fig. A). Then the wound was enlarged and ulcerated with mild pain(Fig. B). X-rays showed the large vessel calcification(Fig. D). There was multiple subcutaneous small vessel calcification by further plain CT scanning of suspicious vessel calcification area. In particular, small blood vessels deep in the skin lesions were significantly calcified(Fig. E). Imaging evidence strongly suggests a diagnosis of calciphylaxis. A skin biopsy was performed on the rough skin of the patient's left lower leg. The pathology showed extensive calcium deposits in the subcutaneous soft tissue with calcification of the small vessel wall(Fig. F). The calciphylaxis was diagnosed and was still in the early stage of disease. After comprehensive treatment based on sodium thiosulfate for three months, the necrosis area was gradually scabbed and the wound healed(Fig.C).

Discussion: Calciphylaxis is a fatal vascular disease characterized by systemic arteriole calcification with endothelial destruction and thrombosis, resulting in peripheral tissue ischemic necrosis. This patient presented with a single, early-onset skin lesion and lacked typical skin lesions. Imaging examinations have a high guiding significance in the diagnosis of calciphylaxis in this case. Recently, the prevalence of calciphylaxis in dialysis patients has been increasing, and a combination of diagnostic techniques has helped early detection. Skin biopsy helps diagnose early and atypical patients, while imaging is a non-invasive test that can be used as an early screening and efficacy monitoring tool.



FR-PO637

Dramatic Improvement in Dialysis Related Tumoral Calcinosis Following Renal Transplantation

Win Win Moe, Kamal Nayyar, Ruby Zhao, Nobuyuki (Bill) Miyawaki, James Drakakis. *NYU Winthrop Hospital, Mineola, NY.*

Introduction: Tumoral calcinosis (TC) is an uncommon and serious complication of dialysis. It is usually associated with high serum calcium and phosphorus product. Management of this ectopic calcification syndrome involves dietary phosphorus restriction,

non-calcium based binders, low calcium dialysis, and parathyroidectomy. Here, we present a case of extensive TC which failed to respond to conservative measures in a patient on long-standing dialysis, only clinically and radiographically improved after a successful renal transplant.

Case Description: A 56 year old male with history of HIV on HAART therapy with resultant end-stage-renal-disease (ESRD) on dialysis for 8 years, presented with hip pain and difficulty ambulating. CT scan revealed abundant metastatic calcium deposition within the adductor compartment of the right thigh, enlarging within the vastus intermedius and iliopsoas tendon and invading the femur. Biopsy revealed benign fibrous tissue and marked granular calcification. He was initially on hemodialysis (HD) but later switched to peritoneal dialysis (PD) due to limited vascular access. While on PD, clearances were sub-optimal and phosphorus ranged 8-10 mg/dL. PTH was elevated (300-400 pg/mL) despite attempts to suppress with calcimimetic. He then switched back to an intense HD regimen via a femoral dialysis catheter and was given low calcium dialysate and sodium thiosulfate. However, he did not improve and a request for medical urgency to receive compassionate points on the deceased donor wait list was filed. Shortly after, he received a functioning kidney transplant and imaging began to show resolution. In fact, a CT scan done 3 years later revealed the deposition to be 2.9 x 1.0 x 3.2 cm, compared with14 x 14 x 10 cm at time of initial diagnosis.

Discussion: There is known morbidity associated with extraosseous tumoral calcification associated with ESRD, often carrying with it a poor prognostic significance. Several medical and surgical (i.e, parathyroidectomy) treatment options are available, but responses may be limited. Renal transplantation has been described as being useful to treat TC and several cases of complete dissolution have been reported. This case similarly illustrates success after kidney transplantation and highlights the need for awareness in diagnosis and urgency to help facilitate an effective treatment strategy.

FR-PO638

Calciphylaxis Patient Characteristics and Outcomes: Case Series of 7 Patients

Mariam Zakher,[1] Loay H. Salman,[1] Swati Mehta,[1] Sabrina Daoui,[2] Rachid Daoui,[3] Rafia I. Chaudhry.[1] *[1]Albany Medical College, Albany, NY; [2]363, Saratoga Springs, NY; [3]Nephrology, Saratoga Hospital, Saratoga, NY.*

Introduction: Calcific uremic arteriolopathy (CUA) also known as calciphylaxis is a rare, life-threatening ischemic small-vessel vasculopathy, primarily a complication of advanced CKD or ESRD. The pathogenesis involves intimal hypertrophy and medial calcification, resulting in endovascular fibrosis and thrombosis of small arteries and arterioles. We reviewed historical cases to assess patient characteristics, treatment modalities employed and clinical outcomes.

Case Description: We present 7 cases of calciphylaxis diagnosed between 2013 and 2017. Median age at time of diagnosis was 57.7 (42-76), 57% were male, 57% were Caucasian, 71% smokers, and 100% obese. Patients had been on dialysis for an average of 5.2 years prior to diagnosis. Only 1 patient was on peritoneal dialysis; the rest were on in-center hemodialysis (3 days/week). Comorbid conditions included DM (4/7), HTN (4/7), concomitant anticoagulation with warfarin (2/7), vitamin D analogue (4/7), oral calcium supplements (2/7), and calcitriol (2/7). Calciphylaxis was confirmed by skin biopsy in 7 cases. Mean calcium, phosphorus and PTH levels were 9.15, 5.6, and 322.9, respectively. All patients received sodium thiosulfate 25 mg 3 days/ week, along with increased daily dialysis (average of 5.2 treatments/ week for 4.3 hours over 7.2 months). 5/7 patients were reported to have complete resolution after an average of 7.64 months. One patient continues to receive treatment. Two patients died, including one patient who chose to discontinue dialysis 3.8 years after diagnosis, and the second patient did not tolerate sodium thiosulfate (metabolic acidosis and hypotension) and died from sepsis 8 days after diagnosis. Complications of sodium thiosulfate included metabolic acidosis (6/7), hypotension (4/7), and hypocalcemia (2/7).

Discussion: Previously reported risk factors include high BMI, female sex, DM, PD, higher serum calcium, phosphorus, and parathyroid hormone, and combined therapy with calcium salts and vitamin D, cinacalcet, warfarin and calcitriol. Mortality rate is reported at 27% at 6 months after CUA diagnosis, and 45% at 12 months. Data on the dose and duration of increased intensity dialysis as well as treatment are lacking, and while CUA is associated with a high rates of mortality, we have a 71% survival rate with emphasis on maximizing dialysis (daily).

FR-PO639

Penile Calciphylaxis: A Clinico-Radiologic Diagnosis

Gajapathiraju Chamarthi,[2] Abhilash Koratala.[1] *[1]Nephrology, University of Florida, Gainesville, FL; [2]University of Flroida, Gainesville, FL.*

Introduction: Calciphylaxis, also known as calcific uremic arteriolopathy (CUA) is a rare and serious disorder typically seen in ESRD patients that presents with skin ischemia and necrosis and histologically characterized by calcification of dermal arterioles. While most lesions occur on the lower extremities followed by the lower abdomen, rare sites such as breast and penis have been reported. Herein, we present a case of penile calciphylaxis that was diagnosed clinically.

Case Description: A 34-year-old man with end-stage renal disease (ESRD) secondary to diabetes mellitus, on hemodialysis for 2 years was seen for worsening pain and blackening of the skin in the penile region that started a month ago. He denied having any fever, painful urination, discharge from the urethra or unprotected sexual intercourse in the recent past. Physical examination revealed mild edema and superficial necrosis of the foreskin and glans penis [Figure 1A]. Laboratory data demonstrated a high blood urea nitrogen of 100 mg/dL, serum creatinine 12.2 mg/dL, parathyroid hormone (PTH) 400 pg/mL and calcium-phosphorus product of 111 mg/dL. He was not on therapeutic anticoagulation and work up for hypercoagulable disorders was negative. Plain radiographs of the pelvis demonstrated widespread vascular calcification [Figure 1B], suggestive of CUA.

Discussion: High calcium-phosphate product, elevated PTH, hypoalbuminemia, diabetes, obesity, warfarin use, female sex and protein C or S deficiency are among the risk factors for CUA and skin biopsy is the gold standard of diagnosis. However, biopsy is not typically recommended for penile lesions because of the risk for progression of necrosis and therefore, penile CUA essentially remains a clinico-radiologic diagnosis. Treatment includes aggressive risk factor control, intensification of hemodialysis regimen, supportive wound care and administration of intravenous sodium thiosulfate with dialysis, all of which we instituted in our patient. The prognosis remains poor despite treatment and the main cause of mortality in these patients is sepsis.

FR-PO640

Non-Uremic Calciphylaxis: Early Diagnosis of a Rare Entity and Successful Treatment with Sodium Thiosulfate

Rocio Eleid,[1] Gautam M. Phadke.[2] *[1]University of North Dakota, Fargo, ND; [2]University of North Dakota School of Medicine, Fargo, ND.*

Introduction: Calciphylaxis is a rare cutaneous disease, with varied lesions: from bullae to necrotic ulcers. Pain out of proportion to clinical examination is a distinct finding. Key finding is Vitamin K deficiency, contributing to progressive microvascular calicifcation and microthrombi. Diabetes, liver cirrhosis and patients on warfarin are Vitamin K deficient.

Case Description: A 64 yo male with DM2, HTN and cirrhosis was referred to the Nephrology Clinic for evaluation of AKI, hematuria, nephrotic range proteinuria. Kidney biopsy showed Nodular Diabetic Nephropathy, secondary IgA nephropathy (liver cirrhosis) and ATN. His Ca was 9.6 mg/dl, Phos 4.1 mg/dl, vitamin D 15ng/dl, and PTH 129 pg/ml. Three months after initial evaluation, measured GFR (Iohexol) was 19 ml/min/1.73m^2 and he presented with left lower extremity, painful, necrotic ulcers. Despite surgical debridement, lesions increased in size and he developed new lesions on the right leg. Skin biopsy via telescoping technique showed intraluminal occlusion of small and medium sized vessels with calcified appearing material consistent with calciphylaxis. Sodium thiosulfate was started at 12.5 g twice/week, it was increased to 25 g twice/week and that dose was kept for 7months. Patient lesions improved and thiosulfate was discontinued.

Discussion: This illustrates the importance of an early diagnosis and treatment of non uremic calciphylaxis with attention to “at risk” patients: liver cirrhosis, in our case. The patient is currently been referred for simultaneous liver-kidney transplantation.

FR-PO641

A Case of Delayed Onset Hungry Bone Syndrome After Subtotal Parathyroidectomy in ESRD Patient with Secondary Hyperparathyroidism

Samer Kareem, Aromma Kapoor, Michael D. Klein. *Nephrology, Westchester Medical center, Valhalla, NY.*

Introduction: Hungry bone syndrome (HBS) is an important postoperative complication of parathyroidectomy done for severe hyperparathyroidism of renal origin; occuring in 27.8 to 72% of cases. It is marked by hypocalcemia (most severe in the first 24-48 hrs) associated with hypophosphatemia, hypomagnesemia and elevated Alkaline phosphatase. We are reporting a case where hungry bone syndrome is seen to develop more than one week post-op, and did not respond to standard management despite normal magnesium and Phosphorus levels.

Case Description: 52 yr old male with ESRD on HD underwent subtotal parathyroidectomy for management of severe secondary hyperparathyroidism (PTH 2024 pg/ml) in spite of high dose of cinacalcet and calcitriol. Post -op PTH dropped to 63.5 pg/ml. The lowest reading of Ca was 8.2mg/dl in the immediate post-op period and was treated with Ca and vitamin D analogs as per standard guidelines. Two weeks later patient reported symptoms of tetany on dialysis and serum Ca was 6.8 mg/dl. Serum Phos remained 3.3 -4.5mg/dl range and ALP 282 u/l with a normal Magnesium. Calcium was persistently low despite treatment with IV calcium ; requiring a prolonged hospital stay.

Discussion: HBS is characterised by prolonged and severe postoperative hypocalcemia and hypophosphatemia as a result of extensive and accelerated remineralisation of bone following sudden decrease of parathyroid hormone. This syndrome should be anticipated when there is evidence of severe parathyroid bone disease with marked elevation of serum ALP and PTH levels. Other factors that predict the development of HBS include old age, high BMI, and high pre-op BUN. HBS is seen within 24 hrs of a total parathyroidectomy in patients with SHPT. The post operative fall in serum calcium has been strongly correlated with the severity of bone disease which can be diagnosed only with pre-operative bone biopsy not by serum chemistries. This case shows that patients might develop severe hypocalcemia in the later time despite a normal serum calcium postoperatively. We recommend, patients undergoing total parathyroidectomy should have their serum calcium and phosphate levels closely monitored in the following 2 weeks to safeguard against the development of severe and symptomatic hypocalcemia and to provide guidance on the intensity of calcium supplementation.

FR-PO642

Hyperparathyroidism Induced Erythropoietin Resistance After Successful Renal Transplantation

Juan Pablo Arroyo,[1] Laura Binari,[2] Anthony J. Langone.[1] *[1]Nephrology, Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Resistance to erythropoietin (EPO) in the CKD-ESRD population is pervasive. Common causes include iron deficiency, chronic inflammation, medications and hyperparathyroidism. Most if not all of these conditions resolve after successful renal transplant. Post-transplant anemia can occur due to multiple factors including immunosuppressant medications, dapsone, TMP-SMX, RAAS antagonists, and viral infections (CMV, Parvovirus). We report a case of hyperparathyroidism-induced EPO resistance in a patient which was successfully treated with subtotal parathyroidectomy three-years after her transplant.

Case Description: A 36-year-old woman with a history of ESRD secondary to hypertension underwent a successful deceased donor kidney transplant managed with tacrolimus, mycophenolate mofetil and prednisone complicated by refractory anemia and hyperparathyroidism. Three years post transplantation with baseline creatinine of 1 mg/dL, she continued to require 40,000 units of subcutaneous epoetin alfa twice weekly for refractory anemia. Her hemoglobin oscillated between 6 – 7 g/dL during this time. She underwent an extensive workup that included: multiple iron panels all with >20% saturation, negative parvovirus PCR, and a bone marrow biopsy that showed mild hypocellularity. Her blood pressure management did not include ACEi/ARBs. Her initial immunosuppressive regimen included sirolimus; her anemia, however, persisted after switching to tacrolimus. Her NT-PTH was noted to be consistently above 1750 pg/mL and subsequently referred for parathyroidectomy following a sestamibi scan demonstrating multigland hyperplasia. One month following her parathyroidectomy, her anemia resolved completely and was able to stop epoetin alfa injections.

Discussion: Although hyperparathyroidism is a known cause of EPO resistance in the CKD-ESRD population, it is thought to contribute minimally to the overall burden of EPO resistance. This case highlights that isolated hyperparathyroidism in the absence of other common causes for EPO resistance (iron deficiency, medications, infection/inflammation) can cause severe EPO resistance, and must be addressed when evaluating anemia in renal transplant patients despite stable creatinine.

FR-PO643

Laparoscopic Gastric Sleeve Surgery in a Patient on Peritoneal Dialysis

Anthony Nguyen,[2] Farshid Yazdi,[1] Mihran V. Naljayan.[2] *[1]Louisiana State University Health Sciences Center New Orleans, New Orleans, LA; [2]LSUHSC School of Medicine, New Orleans, LA.*

Introduction: The high prevalence of obesity along with its potential resulting conditions make obesity a major public health concern. Morbid obesity is a limiting factor for a dialysis patient to obtain a kidney transplant. While an obese patient may elect to undergo bariatric surgery to induce weight loss, there is little data on this type of surgery involving a PD patient. We present a rare case of a patient with end-stage kidney disease (ESKD) on PD who underwent laparoscopic gastric sleeve surgery while maintained on PD.

Case Description: A 66-year-old morbidly obese female patient with ESKD on PD underwent laparoscopic gastric sleeve surgery. Prior to her surgery, she was 124 kg and was on continuous cyclic peritoneal dialysis (CCPD) for 9 hours with 4 cycles of 3000 mL 2.5% dextrose solution with 500 mL icodextrin last fill. Her adequacy prior to surgery was residual renal (RR) Kt/V 0.45 and PD Kt/V 1.56 for a total of 2.01. She cycled the night before her surgery and did not do a last fill. She received clindamycin 600 mg IV perioperatively (allergy to cefazolin) and post operatively, she held PD the first night, then initiated 1000 mL 2.5% dextrose for 6 cycles over 12 hours. At day 5 post operatively, it was increased to 1500 mL for 6 cycles over 12 hours due to low drain alarms. After 3 weeks, it was increased to 2500 mL alternating 1.5% and 2.5% dextrose for 4 cycles over 9 hours. Her adequacy 4 weeks postoperatively was RR Kt/V 1.03, PD Kt/V 1.11, and total 2.15. Two months postoperatively she was 113 kg.

Discussion: One particularly interesting observation regarding this case is the fact that the patient's RR Kt/V improved after her surgery also leading to an increase in her total adequacy. This case illustrates how PD patients undergoing bariatric surgery can successfully be maintained on PD post-operatively without having to transition temporarily to hemodialysis and without sacrificing renal adequacy. Being allowed to continue PD as opposed to hemodialysis allows for the patient to avoid potential complications involved with a catheter and leads to a goal weight suitable for transplantation.

FR-PO644

Rapid Diagnosis of Fungal Peritonitis in a Peritoneal Dialysis Patient using a Multiplex PCR-based Identification Panel

Divya Shankaranarayanan,[1] John R. Lee,[1] Lars Westblade,[2] Stephen G. Jenkins,[2] Vesh Srivatana.[1,3] *[1]Department of Nephrology, Weill Cornell Medicine, New York CIty, NY; [2]Department of Microbiology, Weill Cornell Medicine, New York City, NY; [3]The Rogosin Institute, New York, NY.*

Introduction: Fungal peritonitis can be difficult to detect using conventional culture methods and delayed diagnosis can lead to significant morbidity and mortality. The FilmArray® blood culture identification panel (BCID; BioFire Diagnostics, LLC.) is an US FDA approved test for rapid identification of common bacterial and fungal pathogens in positive blood culture broths. We present a case of peritoneal dialysis (PD) peritonitis

with Candida albicans that was detected using the BCID panel prior to conventional fungal culture results.

Case Description: The patient is a 50-year-old female with history of end stage renal disease (ESRD) secondary to membranoproliferative glomerulonephritis on PD for 7 years. She was admitted with abdominal pain and cloudy PD fluid concerning for peritonitis. She had been discharged ten days prior after being treated for Clostridioides difficile colitis. She reportedly had a breach in aseptic techniques while performing PD exchanges since her hospital discharge. On presentation, her PD effluent had 5,150 white blood cells (WBC/μL) with 94% polymorphonuclear (PMN) cells. She was started on empiric intraperitoneal antibiotics as well as oral fluconazole for prophylaxis for fungal peritonitis. Initially, her WBC count in the PD fluid and clinical condition improved and PD fluid cultures were negative. However, on the 5th hospital day she had worsening symptoms and increasing WBC count in the PD fluid. The BCID panel was able to detect Candida albicans on a PD fluid sample that was saved at the time of her presentation. Treatment was escalated to intraperitoneal antifungal therapy, and subsequent PD fluid cultures confirmed Candida Albicans peritonitis. Her PD catheter was eventually removed on the 7th day of her hospitalization and she was switched to hemodialysis.

Discussion: Rapid diagnosis of fungal peritonitis in PD patients can lead to life saving therapy and definitive PD catheter removal. In this case, initial conventional PD fluid cultures were non diagnostic, but the BCID enabled rapid identification of a Candida albicans infection. This case illustrates a potential use and supports future studies on rapid PCR based diagnostic techniques for diagnosing PD peritonitis.

FR-PO645

A Rare Presentation of an Unusual Fungus: Trichoderma Peritonitis

Jeremy Carlson, Peter P. Staiano, Leighton R. James. *UF Health, Jacksonville, FL.*

Introduction: Peritoneal Dialysis (PD) can be an attractive modality for end stage renal disease (ESRD) patients. It does, however, require patients be responsible enough to safely perform their own dialysis care, otherwise they can develop peritonitis. Often there is a bacterial source, however, in rare cases fungal infections are seen and in these cases, mortality is higher. Trichoderma is an opportunistic fungus normally found on decaying wood, and it's presence in humans is especially rare and mainly limited to case reports, most of which surfacing in the last 10 years. This likely reflects the increasing number of relatively immunocompromised patients on PD and recent improvements in identifying pathogens. Presented is a rare case of PD associated Trichoderma peritonitis.

Case Description: A 48 year old Hispanic male with past medical history of diabetes mellitus, hypertension, and 1.5 years of PD presented to his nephrologist's office with decreased appetite, abdominal pain, and cloudy effluent from his PD catheter. He was on his 3rd week of treatment with vancomycin and meropenem for gas gangrene diabetic foot ulcer infection. Intraperitoneal vancomycin was initiated for presumed PD peritonitis. PD effluent studies showed 1984 WBCs and mold culture growth, indicating fungal infection. He was immediately admitted for PD catheter removal, anti-fungal therapy with amphotericin B, and hemodialysis preparation with a tunnel catheter. Cultures finalized during his admission showed Trichoderma species susceptible to voriconazole, which he was switched to and discharged with a 1 month course.

Discussion: Peritonitis is a feared complication in PD patients as it can permanently ruin PD access as well as quickly develop into florid sepsis and death. This is especially true in fungal peritonitis cases, where all cause mortality is worse compared to bacterial counterparts. Nephrologists must remain vigilant in monitoring for signs and symptoms of peritonitis (mainly abdominal pain, fever, and cloudy effluent) at every office visit and maintain a low threshold for treatment and admission. Risk factors specifically for fungal peritonitis include: HIV co-infection, recent treatment with antibiotics, or recent abdominal surgery/peritonitis. It is imperative when fungal peritonitis is diagnosed the catheter is removed and strong antifungals are started until susceptibilites are returned.

FR-PO646

Spontaneous Rupture of Peritoneal Dialysis Catheter with No Drainage Problem

Ricardo Rodriguez-Santos,[1] Shweta Bansal,[2] Ashley Garcia-Everett.[1] *[1]UTHSCSA, Helotes, TX; [2]University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Introduction: Background: Spontaneous rupture of the intraperitoneal portion of peritoneal dialysis (PD) catheter is a rare complication and usually presents with drainage failure and PD related infection. Here we present a case of PD catheter rupture who presents with peritonitis; however, intact out- and in-flow.

Case Description: Case report: A 32-year female with end stage renal disease due to hypertension on PD for 5 years presented with 2 days of mild grade fever, nausea, abdominal pain and cloudy peritoneal fluid. She was managed on CCPD with a two-cuff coiled Tenckhoff catheter. She practiced daily exit site care using topical exsept and alternative gentamicin/bactroban cream. She had 2 episodes of exit site infections with pseudomonas and coagulase negative staphylococcus, respectively 3 years prior to presentation but no peritonitis. On examination, she was afebrile, tachycardiac and had diffuse abdominal tenderness; however, no findings of exit site infection. PD fluid revealed 12,000 WBC/μl with 98% neutrophils and culture grew Pseudomonas aeuroginosa. CT scan done for abdominal pain showed discontinuity of the PD catheter within the anterior abdominal wall soft tissue. Later, fluoroscopic study with gastrograffin confirmed the fracture site in subcutaneous fat with pooling of contrast around the site and drainage of a portion of contrast into peritoneal cavity suggestive of a track. Of note, the patient had an episode of exit site trauma with mild bleeding 8 months prior to the presentation but no infection. Since then she had intermittent issues with long drain time (about 30 minutes) which improved somewhat with laxatives. In addition, she maintained good solute and volume clearance throughout this period. Finally, she underwent surgical removal of the fractured catheter and found to have abscess around the fracture site which was evacuated. The patient had an uneventful recovery and PD was resumed successfully with a new catheter after few months.

Discussion: Conclusion: This is a rare case of PD catheter rupture which likely occurred slowly over time allowing the formation of a soft tissue track and uninterrupted PD therapy but with long drain time. This case highlights the need to be vigilant about these rare events even with mild catheter flow issues.

FR-PO647

Physical Examination of the Hemodialysis Vascular Access: An Unforgettable Tool

Jessita singh natasha Albert messiah dhas,[1] Jason C. George,[1] Steven R. Bonebrake,[2] Luis L. Nadal,[3] Ion D. Bucaloiu.[1] *[1]Geisinger Medical Center, Danville, PA; [2]Geisinger, Danville, PA; [3]Geisinger Health System, Danville, PA.*

Introduction: Hemodialysis (HD) access failure is an important cause of morbidity and mortality in HD patients. We present a case of false-negative fistulography in an end stage renal disease patient presenting with life-threatening hyperkalemia.

Case Description: A 66-year-old man on chronic HD for 5 years via right brachiocephalic fistula presented with one day of profound weakness. There were no missed HD sessions and no major dietary indiscretions by history. Initial labs showed serum potassium of 8.7 mmol/L (non-hemolyzed), serum bicarbonate 23 mmol/L, glucose 98 mg/dL. EKG showed widened QRS complex and he promptly received intravenous calcium gluconate and insulin. On physical exam his fistula was well-developed and had a harsh, pulsatile bruit. He underwent an emergent, 4-hour HD session with 2K dialysate, blood flow of 400 mL/minute, and dialysate flow of 800 mL/min. Labs 4 hours after HD showed serum potassium 6.1 mmol/L. Reflux fistulography showed no stenosis at the anastamotic segment. Given recurrent hyperkalemia despite an additional 3.5 hours of HD the following day, the case was reviewed with Interventional Radiology and variable contrast densities were noted along different fistula segments. Repeat fistulography via retrograde access was obtained, during which a wire and catheter were advanced across the anastomosis, placing the catheter retrograde in the brachial artery prior to infusing contrast. A hemodynamically significant anastomotic and juxta-anastomotic narrowing was identified and successfully treated with angioplasty. Back pressure generated by reflux angiography masked the stenoses that were apparent when retrograde approach was utilized. After another 4-hour HD session, the patient's hyperkalemia resolved.

Discussion: Thorough assessment of the HD vascular access includes both physical and radiological data. Retrograde arterial catheterization and angiography in a dialysis access circuit provides better physiologic imaging when stenosis is suspected at the anastomosis and/or juxta-anastomotic segment. This case illustrates the importance of correlating clinical and physical examination data with subtle angiographic findings and raises awareness among nephrologists of potential pitfalls in the diagnosis and management of HD access failure with important patient safety implications.

FR-PO648

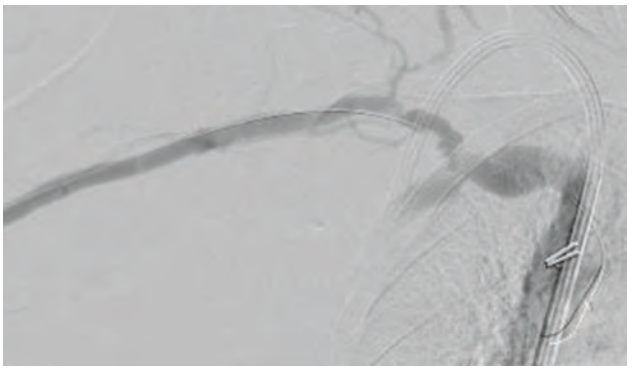
Arteriovenous Fistula (AVF) Pseudo-Stenosis

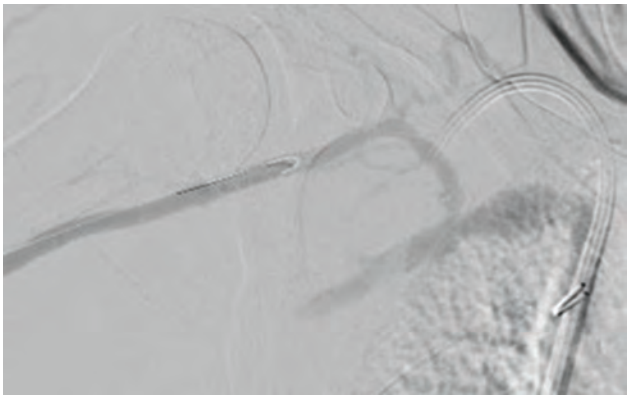
Robert Valleau,[1,2] David J. Leehey,[2] Mohamed A. Rahman,[3] Aparna Natarajan,[1,2] Julia Schneider.[1,2] *[1]Nephrology, Loyola University Medical Center, Maywood, IL; [2]Hines VA Hospital, Hines, IL; [3]Nephrology Associates of Northern IL, Elk Groove Village, IL.*

Introduction: Pseudo-stenosis of an AVF has not yet been described in the literature, though it has been noted in the coronaries. It is the false visual appearance of stenosis seen during interventions involving the use of guidewire.

Case Description: Patient 1. 81-year-old male with a brachio-basilic AVF was referred for a fistulogram for high venous pressures noted during dialysis. A fistulogram with guidewire insertion and contrast injection showed multiple areas of apparent stenosis of the basilic vein. After retraction of the guidewire and repeat contrast injection, these areas of apparent stenosis were no longer observed. Patient 2. 83-year-old male with a brachio-cephalic AVF was referred for a fistulogram because of arm pain. A fistulogram with guidewire insertion and contrast injection showed high-grade stenosis at the cephalic arch which was sucessfully dilated with a balloon. Distal to the area of stenosis, the cephalic vein appeared tortuous with multiple areas of stenosis seen while the guidewire was in place (Fig1). Once the guidwire was removed and contrast re-injected, these areas of apparent stenosis were absent (Fig2).

Discussion: Pseudo-stenosis (accordion effect) is well-described in the coronary arteries and is characterized by pseudo-narrowing of the coronary vessels which disappears after guidewire withdrawal. Although the exact mechanism is unclear, the theory is that advancing a guidewire, thereby shortening a tortuous artery, induces folds of the vessel wall which creates the false impression of narrowing. This phenomenon has not previously been reported in an AVF. It is important to recognize this phenomenon to avoid unnecessary interventions.





FR-PO649

Airway Compromise and Failed Extubation Due to Central Venous Stenosis in a Hemodialysis Patient

Karthik Kovvuru. *Nephrology, University of Mississippi Medical Center, Jackson, MS.*

Introduction: Central Venous Stenosis (CVS) in hemodialysis (HD) patients is common and is not always easy to manage. We encountered a patient who presented with a unique complication of central venous stenosis.

Case Description: 57 Yr old Female pt with HIV and ESRD on HD for more than eight years via left AV fistula presented to the hospital for large bloody bowel movement and hypotension (80/50). She was given a liter of fluid and three units of red blood cells with improvement of blood pressure to (110/70). She was admitted to floor and started on maintenance IV fluids at 75cc/hr. Dialysis was held for two days due to stable labs, clinical euvolemia and borderline blood pressures. Pt developed shortness of breath, difficulty breathing and got intubated. During intubation it was noted that pts airway was swollen, angioedema was clinically diagnosed and started on Rx. Chest x ray did not show any fluid in the lungs and she continued to remain clinically euvolemic other than swollen face and left arm. No precipitant for angioedema could be found and the swelling did not resolve with medical treatment. CT scan of the chest was performed which showed subcutaneous edema throughout the neck bilaterally (left greater than right), subcutaneous edema of upper chest wall, mucosal edema of base of tongue and supraglottic larynx, Extensive collateral venous vessels in left anterior upper chest with narrowing of brachiocephalic vein. Angiogram showed occlusion at the level of left brachiocephalic vein which was difficult to open. Left arm AV fistula doppler showed wide patency with flow of 2.4 Liter per min. Pt was trached and weaned off ventilator after aggressive removal of volume with help of midodrine and cold dialysate. However she could not be decannulated due to persistence of edema from CVS. After 8 months of hospital stay she was sent to hospice care.

Discussion: Our patient developed upper airway edema secondary to CVS and high flow AV fistula on the same side. The volume resuscitation she received for GI bleed resulted in worsening airway edema leading to intubation. Once intubated the positive pressure in the chest cavity will decrease venous return worsening the airway edema leading to failed extubation. CVS should be considered as potential cause of airway edema and failing extubation in hemodialysis patients.

FR-PO650

Potential Anaphylactic Shock Related to Tunneled Hemodialysis Catheter Material

Andrew B. Elliott,[1] Fredrik Jenssen,[1] Neville R. Dossabhoy,[2] Tibor Fulop,[1] Waleed Asfar.[1] *[1]Medical University of South Carolina, Charleston, SC; [2]LSUHSC-Shreveport, Shreveport, LA.*

Introduction: We report a most concerning case of likely allergic reaction related to tunneled dialysis catheter (TDC) polyurethane material, manifesting with anaphylactic shock and culminating in the patient's death.

Case Description: The index case of a 57-year-old male veteran with end-stage renal disease, diabetes mellitus, obesity, and sleep apnea had been receiving in-center maintenance hemodialysis for nine years. Due to an interval left arterio-venous upper extremity fistula malfunction, he received a tunneled dialysis catheter (TDC) [major manufacturer; 23 cm, 14.5 French dual-lumen catheter] in the right internal jugular position. Of note, this was his first catheter access. Shortly after TDC placement, he complained of diffuse and severe itching; however, no hives or respiratory difficulties were observed. Approximately 12 hours after TDC placement, he presented for his scheduled chronic dialysis. Immediately after start (1-2 min), he complained of intolerable whole body itching and requested termination of treatment; blood was not returned. Diffuse swelling of the tongue and face was observed with almost immediate full-blown hemodynamic collapse and cardiovascular arrest. A prolonged resuscitation attempt failed. Subsequent autopsy revealed severe cardiomegaly and atherosclerosis, but no clear or competing immediate cause of death. An extensive investigation of dialysis machine and water supply ruled out bacterial or chemical contamination. No other patients experienced any problems in the unit. Aside from the catheter use in this patient, there was no technological change in the facility (filter, sterilization) and his dialysis prescription was unchanged. An institutional Root Cause Analysis was also performed, which failed to disclose any other competing cause for cardiovascular arrest.

Discussion: To our knowledge, this is the first report of possible anaphylactic shock related to TDC polyurethane material. Diffuse itching soon after TDC placement (not related only to insertion site) should raise clinical suspicion and may indicate risk of hemodynamic collapse after blood starts flowing through the catheter. Also it is important to consider other entities that may cause allergic reaction that has not been discovered in this setting and possible differences in cleaning of VA dialysis machines vs other outpatient units to see differences arise.

FR-PO651

Volume of Distribution in a Severely Underweight Female Is Better Approximated by Ideal Body Weight Than Actual Body Weight

Benjamin Griffin,[1] Joao P. Teixeira,[1] Sophia L. Ambruso,[1] Stuart L. Linas,[1] James F. Dylewski.[2] *[1]University of Colorado, Aurora, CO; [2]University of Colorado Hospital, Aurora, CO.*

Introduction: Guidelines recommend that patients treated with continuous renal replacement therapy (CRRT) be delivered an effluent dose of 20-25 mL/kg/hr. There is debate, especially at the extremes of BMI, as to whether actual, adjusted, or ideal body weight (IBW) should be used in these dose calculations.

Case Description: The patient is a 50 year-old woman with a history of anorexia who was admitted with altered mental status. Initial vital signs were significant for weight of 27 kg, BMI 10.1 kg/m2, and BP 70/34 mmHg. Labs showed lactate 21 mg/dL, bicarbonate (HCO_3^-) 2 mmol/L, and creatinine 2.1 mg/dL. Arterial blood gas (ABG) showed an initial pH 6.55, PCO_2 32 mmHg, and calculated HCO_3^- 3 mg/dL. Protocolized sepsis management was initiated, and she was intubated. Shortly thereafter, she became anuric and was initiated on CRRT. The initial dialysate dose, prescribed using actual weight, was 800 ml/hr. Labs 2 hours later revealed pH 6.84, pCO_2 10 mmHg, and calculated HCO_3^- 3 mg/dL. The dialysate dose, recalculated using her IBW of 58 kg, was increased to 1750 ml/hr. Six hours later, pH was 6.83 with calculated HCO_3^- 3 mg/dL. Lactate remained elevated at 20 mg/dL. Her CRRT prescription was changed to 1500 mL/hr of dialysate with 250 mL/hr of post-filter concentrated bicarbonate solution (6 ampules in 1 L of water or 300 mEq/L of sodium bicarbonate). After 4 hours, pH was 7.39, pCO_2 was 15 mmHg, and measured serum HCO_3^- was 9 mg/dL. Sodium had risen from 143 to 147 mmol/L. Notably, lactate remained elevated at 18 mg/dL. When using appropriate formulas to estimate the expected rate of change in sodium and bicarbonate and comparing to the observed changes, the effective volumes of distribution were those of a typical patient with a weight in the range of 55 – 70 kg, in line with her IBW. Ultimately the patient was found to be surreptitiously taking metformin (later confirmed with serum testing). Her acidosis resolved with 48 hours of CRRT and she was transferred to the floor the next day.

Discussion: This case illustrates the challenges of dosing CRRT in severely underweight patients and suggests that IBW, rather than actual body weight, gives a better approximation of the volumes of distribution of sodium or bicarbonate and therefore may be more appropriate for dosing of CRRT.

FR-PO652

Does a Very High Nephrocheck Level (Above 10) Predict the Need of Early RRT?

Sanjeev Gupta,[1] Anastasios Papanagnou,[2] Savneek S. Chugh.[3] *[1]Westchester county medical center, White Plains, NY; [2]Westchester Medical Center, Bayside, NY; [3]New York Medical College, Hartsdale, NY.*

Introduction: Studies have shown that elevated levels of TIMP-2 (tissue inhibitor of metalloproteinase) and IGFBP7 (insulin-like growth factor binding protein) predict AKI early on compared to other biomarkers, and early intervention can prevent AKI or its progression. It is, however, unknown if elevated levels of these biomarkers can predict the need for RRT. We present two cases of high Nephrocheck levels (above 10) who required RRT within 24 hours.

Case Description: (1) 51 y/o woman with a PMH of DVT and DM-2 was transferred to our hospital with complaints of nausea, dizziness, and abdominal pain. She was found to have wide complex tachycardia; she was subsequently cardioverted and started on amiodarone, as well as lidocaine drip. 2D Echo showed an EF of 10% with SBP in the 80s. Emergent cardiac catheterization did not reveal any CAD; an IABP was placed and the patient was transferred to our facility for ECMO placement. Her BUN/Cr initially was 20/0.91 which increased to 33/3.3. Nephrocheck was performed showing a level of more

than 10; her Cr worsened the following day and the patient became anuric; CVVHD was started. (2) 52 y/o woman with a PMH of sickle cell disease and asthma was transferred to our hospital for further management of septic shock. On admission, her Cr was 1.5 which worsened to 2.3. Nephrocheck was done showing a level of more than 10; the patient was placed on HD shortly thereafter.

Discussion: Nephrocheck has a high negative predictive value, ruling out potential AKI if the value is negative; however, it has a low positive predictive value. A high Nephrocheck level is indicative of significant kidney injury; however, no studies have been done, thus far, examining the correlation between a high Nephrocheck level predicting the need for early or late RRT. Both of our patients with Nephrocheck levels above 10 required RRT within 24 hours of admission. Therefore, Nephrocheck can be used an early surrogate marker of kidney injury, seen prior to elevations in serum Cr; this data can be helpful to triage the patients with severe AKI requiring RRT.

FR-PO653

Hemodialysis for Urea Cycle Disorder Associated Hyperammonemia - Does It Have a Role?

Angel F. Delgado Garrastegui,[1] Agustin G. Velazquez perez,[2] Apoorva Cheeti,[4] Bharat Sachdeva,[3] Neeraj Singh.[5] *[1]LSU Health Shreveport, Shreveport, LA; [2]LSU health shreveport, Shreveport, LA; [3]Lousiana State University - Shreveport, Amritsar, India; [4]Willis-Knighton Health System, Shreveport, AL; [5]LSU Health Sciences Center, Shreveport, LA.*

Introduction: Hemodialysis for hyperammonemia is rarely performed. We report a patient who presented with acute encephalopathy, nausea and vomiting associated with elevated levels of serum ammonia and normal hepatic workup and responded only to hemodialysis.

Case Description: A 20 year old Caucasian male with no significant past medical history presented with nausea, vomiting and altered mental status of one day duration. On admission, his vitals were stable and examination was unremarkable except for disorientation. Laboratory work-up revealed normal CBC and BMP and liver function tests except for elevated serum ammonia at 144 mmol/L (normal11-32mmol/L): Head CT, EEG and CSF fluid analysis were negative. Further liver work up including hepatitis panel, HIV screen, alfa-feto-protein, calcinoembrionic antigen, smooth muscle ab, alpha-1 antitrypsin, anti-mitochondrial ab, antinuclear ab, ceruloplasmin level, hemochromatosis panel, liver ultrasound and a liver biopsy was normal. On admission, patient was started on intravenous fluids, vitamin B12, lactulose, rifaximin and protein restriction, but failed to respond and serum ammonia levels trended up to 275 mmol/L on day 3. He was initiated on hemodialysis and underwent a total of 2 dialysis sessions with reduction in ammonia levels to <9umol/L and improvement in mentation by day 5. The urine organic acid gas chromatography test showed highly elevated orotic and uracil levels suggesitive of a urea cycle defect, possibly OTC (ornithine transcarbamylase deficiency), citrullinemia, argininosuccinic aciduria, argininemia or Hyperammoninemia-Hyperornithinemia-Homocitrullinuria syndrome. Genetic testing was negative for the most common mutations but did not rule out a urea cycle defect. The patient was discharged on L carnitine, lactulose and a low protein diet and has not had a recurrent episode of hyperammonemia till last follow-up.

Discussion: Serum Ammonia is a small molecule, with a molecular weight less than that of urea and as such its clearance by a dialyzer membrane is greater than the clearance rate for urea. Hemodialysis can be effectively utilized to treat hyperammonemia associated with urea cycle defect in medically refractory cases.

FR-PO654

Back from the Cold!

Sandeep Padala, Muhammad O. Saleem, Azeem Mohammed. *Augusta University, Augusta, GA.*

Introduction: Continuous Renal replacement therapy (CRRT) can modulate core body temperature through modulation of the replacement fluid temperature. Although this has been theorized to be helpful in hypotension, there are no guidelines for a temperature setting during CRRT. We present a case where maintaining an optimal temperature during CRRT was of paramount importance to the overall patient management.

Case Description: A 32-year-old African American male presented to the emergency room with recurrent syncope and was notably pale and lethargic on arrival. Lab tests revealed hemolytic anemia with hemoglobin of 3.3 g/dL, LDH of 991 U/L, haptoglobin of 1 mg/dL, positive C3 and total bilirubin of 4.3 mg/dL. A peripheral smear showing severe anemia, prominent agglutination and several granulocytes containing intracytoplasmic cryoglobulins was conclusive for cold agglutinin disease. Although steroids and plasmapheresis were started, patient's condition worsened with the development of multiorgan failure, shock and oliguric renal failure from acute tubular necrosis. We instituted emergent initiation of CRRT for correction of malignant hyperkalemia and acidosis in the setting of hemodynamic instability. Patient underwent 5 days of CRRT with concomitant plasmapheresis. To assist with the overall therapeutic warming strategy, the Replacement fluid was heated on an external heating device and via the CRRT machine to the maximum temperature of 38 C. He improved significantly with resolution of acidosis, and electrolyte derangements; he ultimately required rituximab to truncate the autoimmune hemolytic anemia. A repeat cold agglutinin assay confirmed IgG+ cold agglutinin disease with a positive Mycoplasma IgM thought to be the likely trigger of the autoimmune hemolytic anemia.

Discussion: This case provides a unique perspective on temperature control during CRRT. Typically, cooling of dialysate or replacement fluid is used to bolster blood pressure in times of hemodynamic shock. In this setting, the reverse was utilized as a therapeutic benefit. While often overlooked as a part of the routine CRRT order set, this case highlights the important impact that temperature modulation can have on overall patient management, and should be carefully considered when approaching the CRRT prescription.

FR-PO655

Emergent Hemodialysis: Not Only for AKI

Emmanuelle Cordero Torres, Loay H. Salman, Rafia I. Chaudhry, Mauricio Monrroy. Albany Medical Center Nephrology and Hypertension *Albany Medical College, Albany, NY.*

Introduction: Severe hypothermia, i.e. core body temperature <28°C, is associated with a mortality rate of 50% despite optimal medical care. Commonly used external and internal rewarming techniques may not be effective in achieving the desired core body temperature, and more invasive rewarming modalities i.e. extra corporeal membrane oxygenation (ECMO) and cardiopulmonary bypass (CPB) are not available in all institutions. Hemodialysis (HD) is a safe, effective, and readily available option for the emergent management of hypothermia when conventional techniques have failed.

Case Description: A 78-year-old woman found unconscious, was airlifted to our institution with severe hypothermia (core body temperature of 28°C). She was unresponsive, requiring intubation for airway protection. Initial vital signs included BP 167/87 HR 40 RR 18 T 28°C. External rewarming with thermal blankets, and internal rewarming with 40 °C NS infusion resulted in increase in core body temperature from 28°C to 31°C over 5 hours. The patient remained unresponsive and bradycardic. Nephrology was consulted for role of extracorporeal renal replacement therapy in the setting of persistent hypothermia. We initiated hemodialysis via a right femoral HD catheter, with HD blood flow (Qb) of 300 ml/min, dialysate flow (Qd) 600 ml/min, and dialysate temperature of 37°C. The achieved Qb was 250 ml/min. The patient's core body temperature was monitored via bladder probe, and rose from 32°C to 36.5°C after 3 hours of treatment i.e. hourly increase of 1.5°C. She regained consciousness soon after HD was completed, and was extubated. Frostbite lesions were evident in fingers and toes, although no other sequela of hypothermia persisted. No further complications, including electrolyte abnormalities, developed during, and after rewarming with HD.

Discussion: Hemodialysis is an effective therapeutic option to improve core body temperature, after external and internal rewarming techniques have failed. The rate of core body temperature increase can be closely monitored, and the ability to adjust the dialysate temperature offers the advantage to achieve a safe rate of correction (0.5 to 2°C). Timely rewarming can minimize duration and severity of adverse events including bradycardia and QT prolongation, which may result in a cardiac arrest if untreated. Furthermore, possible electrolyte derangements are simultaneously addressed with HD.

FR-PO656

Adverse Events During Hemodialysis in HeartWare LVAD Recipients

Tapati Stalam. *University of Maryland Medical Center, BALTIMORE, MD.*

Introduction: Over the past decade, implantable left ventricular assist devices have become an acceptable alternative to support patients with advanced heart failure, either as a bridge to transplantation or as destination therapy for patients who are not candidates for heart transplantation. As the number of LVAD implantation increases, greater number of LVAD recipients requiring long term renal replacement therapy, usually chronic hemodialysis (HD), will be seen. This is due to common simultaneous chronic kidney disease in patients with heart failure, but more frequently due to irreversible acute kidney injury occurring in the peri-implantation period. We looked at 92 HD sessions in HeartWare LVAD recipients between 2015 and 2017 and assessed adverse events requiring early termination of HD sessions.

Case Description: Between 2015 and 2017 at the University of Maryland Medical Center, 7 patients required HD after LVAD implantation. These 7 patients had a total of 92 HD sessions during their hospitalizations. The average age of the patients was 46 +/- 11.9 years old. Two patients had ESRD and were on HD prior to LVAD implantation. The remaining 5 patients had CKD but were not on HD. The pre-LVAD creatinine average for all 7 patients was 2.55 +/- 1.8. After LVAD implantation, all of the patients were initially on continuous renal replacement therapy before being transitioned to HD. During HD all patients were on midodrine, vasopressors, or fludrocortisone to help increase blood pressure. There were 7 HD sessions that required early termination due to symptomatic hypotension (3), asymptomatic hypotension (2), sinus tachycardia and cramping and discomfort. The average duration of all HD sessions was 172 minutes and the average duration of HD sessions that were terminated early was 148 minutes.

Discussion: 7 out of 92 sessions required early termination and the most common reasons (5 out of 7) were related to hypotension. Complications related to blood pressure was also found to be the most common reason for termination of HD in a previous study of HD sessions in Heartmate LVAD patients. As a result of continuous-flow technology, in most LVAD recipients, there is an absence of pulse, precluding the standard assessment of blood pressure and making assessment of blood pressure during dialysis difficult. There needs to be more research on how to address this in addition to how to optimize and change LVAD settings during HD sessions.

FR-PO657

Full Vessel and Empty Chambers: Volume Management in a Patient with Total Artificial Heart

Maria Andrievskaya, Stanley Frinak, Jerry Yee, Junior Uduman. *Division of Nephrology and Hypertension, Henry Ford Hospital, Detroit, MI.*

Introduction: Total Artificial Heart (TAH) is a pulsatile device that is FDA approved as a bridge to transplant among individuals with biventricular failure. Renal failure requiring renal replacement therapy (RRT) is seen in 15 to 20% of these patients. Given the mechanical constraints of these devices, volume management in dialysis dependent patients is challenging as they are prone to deleterious effects of volume overload and contraction.

We describe the use of blood volume monitor as a tool to guide ultrafiltration management in a patient with TAH.

Case Description: A 50 year-old male with non-ischemic cardiomyopathy was admitted with decompensated biventricular failure and acute kidney injury (AKI) requiring RRT. He was evaluated for advanced heart failure therapies. His hospital course was prolonged with multiple cardiac and medical complications warranting percutaneous cardiac support devices. He was eventually listed for heart-kidney transplantation and underwent TAH implantation as a bridge to transplant. The ventricular chambers of the TAH have limited pre-load capability, thus 6 to 7 days a week of dialysis therapy has been a requirement to avoid volume overload. Similarly, excess ultrafiltration can also lead to unstable hemodynamics. Four months post-operatively the patient remained on a step-down inpatient unit, without invasive hemodynamic monitoring capabilities, while awaiting organ transplantation. It was difficult to maintain an adequate fluid balance without additional hemodynamic monitoring. In addition to fill volumes reported on the patient's TAH monitor, (Companion 2 Driver- SynCardia) blood volume monitoring with the Crit-line III™ was utilized for real time fluid management. Each dialysis treatment was 3-3.5 hours duration with ultrafiltration of 2-3 liters per session. The average blood volume change was between -7 to 8%, allowing safe ultrafiltration without untoward hemodynamic instability.

Discussion: A clinical trial for TAH as destination therapy is currently underway and more widespread adoption of TAH is likely. Understanding the mechanics and hemodynamic effects of TAH is important for nephrologists caring for dialysis dependent patients. This index case describes the feasibility and utility of employing a blood volume monitor to assist in safe volume management.

FR-PO658

Intraperitoneal Filling Transiently Decreases Hepato-Splanchnic Perfusion During Regular Peritoneal Dialysis

Werner Ribitsch, Thomas A. Lehner, Notburga Sauseng, Alexander R. Rosenkranz, Daniel Schneditz. *Medical University of Graz, Graz, Austria.*

Background: Peritoneal dialysis (PD) is considered a hemodynamic more tolerable treatment mode compared to hemodialysis (HD). However, during PD intra-abdominal pressure (IAP) reaches values close to intra-abdominal hypertension (IAH, defined as IAP>12 mmHg) known to cause local venous congestion. It was the aim to investigate whether a standardized PD filling reduced hepato-splanchnic blood flow (Qh).

Methods: Measurements were done during a peritoneal equilibration test (PET) with 2L of 2.27% glucose dialysate. Subjects remained fasting and assumed a supine body position throughout the duration of the study. Data were obtained in the drained state at baseline (T0), immediately after instillation of dialysate (T1), as well as 2 h after instillation (T2). IAP was measured by Durand's approach. Qh was determined from kinetics of indocyanine-green (ICG) dye venously injected and transcutaneously measured by pulse-dye-densitometry (DDG-2001, Nihon-Kohden, Japan). Mean arterial pressure (MAP) and total peripheral resistance (TPR) were derived from continuous arterial pulse analysis (Finometer, Finapres Medical Systems, The Netherlands). Plasma glucose (G) and insulin (I) concentrations were measured by standard techniques. Variables obtained at T0, T1, and T2 were compared by non-parametric Friedman-test.

Results: Ten patients (58.6±14.8 years; 87.5±18.8 kg dry body mass; 172±9 cm; 8 male; 8 non-diabetics) were studied after a 13.9±4.3 h fasting period. IAP increased after filling and remained elevated (Tab. 1). Qh fell by about 13.4±17.6% at T1 but returned close to baseline values at T2. MAP increased at T1 and T2. TPR (in peripheral resistance units, PRU) remained unaffected.

Conclusions: The increase in IAP during PD causes a small and transient decrease in Qh. The subsequent rebound coincides with the absorption of glucose and is likely due to the vasodilatory effects of glucose and insulin which appears to compensate for the pressure induced flow congestion in the splanchnic circulation.

Table 1

	IAP, mmHg	Qh, L/min	MAP, mmHg	TPR, PRU	G, mmoL/L	I, mU/L
T0	6.9±3.2	1.25±0.57	106.2±17.7	1.13±0.33	5.8±1.5	13.9±17.3

FR-PO659

Prevalence and Prognosis of Coexisting Frailty and Cognitive Impairment in Continuous Ambulatory Peritoneal Dialysis Patients: A Prospective Cohort Study from a Single Center in China

Chunyan Yi, Xiao Yang, Xueqing Yu. *Nephrology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.*

Background: The aim of this study was to investigate the prevalence of coexisting frailty and cognitive impairment as well as its association with clinical outcomes in continuous ambulatory peritoneal dialysis (CAPD) patients.

Methods: Patients on CAPD from January 1, 2014 and December 31, 2016 were recruited. Frailty was assessed by clinical frailty scale (CFS), and cognitive function was assessed by the Montreal Cognitive Assessment (MoCA). All patients were followed up until cessation of PD or December 31, 2017.

Results: A total of 880 CAPD patients were recruited, with a median vintage of PD 24.9 (6.0-52.4) months. The mean age was 48.5±14.6 years, 352 (40%) patients were female and 147 (26.7%) patients with diabetic nephropathy. Coexisting frailty and cognitive impairment was present in 205 (23.3%) patients. Pathway models showed that CFS score was negatively associated with MoCA score (β=-0.14, P<0.001); diabetes mellitus and cardiovascular disease are positively associated with CFS score (β=0.14, p<0.001; β=0.12, P<0.001) while negatively associated with MoCA score (β=-0.14, p<0.001; β=-0.08, P<0.01); serum albumin was negatively associated with CFS score (β=-0.09, P<0.01) while positively associated with MoCA score (β=0.05, P<0.05). Coexisting frailty and cognitive impairment was associated with increased mortality (HR 2.34; 95% CI 1.16-4.72; P<0.05) and had higher peritonitis rate (0.22 vs. 0.11 episodes per patient year, P<0.05).

Conclusions: Coexistence of frailty and cognitive impairment was common in CAPD patients, which increased the risk of adverse outcomes. A significant relationship between frailty and cognitive impairment was demonstrated.

FR-PO660

Peritoneal Dialysis in the Elderly: An Opportunity Not to Miss

Jakob D. Ohman, Vivian Gama, Tripti Singh, Brad C. Astor, Sana Waheed. *University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Background: End Stage Renal Disease (ESRD) prevalence is steadily increasing in the United States with 700,000 patients currently requiring some form of renal replacement therapy, with a steeper increase in prevalence in the older population (age > 65 years). The rate of peritoneal dialysis (PD) utilization in the US is low at 7% of the ESRD population. The aim of this study is to find the rate of utilization of PD in older patients and examine the outcomes of PD compared to hemodialysis (HD) in old patients segmented into chronological age groups in order to study modality-based survival as age advances.

Methods: We utilized the United States Renal Data System (USRDS) to track the survival of patients with ESRD who started dialysis between 2001-2014. Survival of patients on PD and HD was compared in three age groups: age 65-74, age 75-84, and age >85. Comparisons of PD and HD were adjusted for sex, year of initiation of dialysis and number of comorbidities, and mortality rates were calculated.

Results: A total of 743,229 patients were analyzed in the 3 different age categories. Prevalence of PD use was lower as age progressed, with 6%, 4%, and 3% of patients using PD in the three age groups: 65-74 (N=21,776), 75-84 (N=11,978), >85 (N=2,426), respectively, (Table 1). PD was associated with lower mortality compared to HD across all age groups after adjustment for sex, race and number of comorbidities, (Table 2).

Conclusions: PD is underutilized in the older population but overall is associated with a lower mortality in these patients. Despite comorbidity adjustments, it is possible that PD patients are inherently healthier than HD patients. However, the results of this study should encourage providers to strongly consider PD as an option in older patients.

Table 1: Patient demographics taken from USRDS on dialysis, separated into three ascending age brackets: 65-74 years, 75-84 years, and >85 years.

	Age 65-74	Age 75-84	Age >85	p-value
Mean Age	69.4	79.1	87.6	< 0.001
Total N	362,925	299,452	80,852	< 0.001
% Female	45.7%	45.8%	46.3%	< 0.001
Race				
• Caucasian	69.22%	76.53%	79.51%	< 0.001
• Black	24.49%	18.19%	15.38%	< 0.001
• Asian	3.31%	3.33%	3.79%	< 0.001
• other	2.99%	1.95%	1.32%	< 0.001
Modality				
• % HD	94%	96%	97%	< 0.001
• % PD	6%	4%	3%	< 0.001

Table 2: Hazard Ratios for ESRD patients on peritoneal dialysis compared to hemodialysis in three ascending age brackets: 65-74 years, 75-84 years, and >85 years.

Age	HR (PD/HD)	CI (95%)	p-value
65-74	0.89	0.88-0.91	< 0.001
75-84	0.94	0.92-0.96	< 0.001
>85	0.91	0.87-0.96	< 0.001

FR-PO661

Prevalence and Outcome Impact of Depression and Frailty Among Peritoneal Dialysis Population in a Local Dialysis Centre

Gordon C. Chan,[2] Cheuk-Chun Szeto.[1] [1]*The Chinese University of Hong Kong, Shatin, China;* [2]*Prince of Wales Hospital, Hong Kong, China.*

Background: Depression and frailty are increasingly being recognized as contributing factors to the adverse clinical outcome of peritoneal dialysis (PD) patients. Depressed patients have multiple physical and psychological symptoms, and have poor adherence to dialysis and medical therapy. Frailty refers to a state of increased vulnerability caused by decline in physical reserve and function, and is caused by malnutrition, chronic inflammation, and repeated infection. However, the interaction between depression and frailty in PD patients remains uncertain. We determine the prevalence of depression and frailty in prevalent PD patients. We further dissect the internal relationship between depression and frailty, and their relative contribution to the adverse clinical outcome in PD patients.

Methods: This is a prospective observational study. We recruited 267 prevalent PD patients between 2015 and 2016. Depression was identified by Patient Health Questionnaire (PHQ-9). Frailty was identified by a validated Frailty Score. All cases were followed for one year. Outcome measures included number and duration of hospitalisation, peritonitis rate, and all-cause mortality.

Results: Of the 267 patients, 197 patients (73.8%) were depressed, and 157 (58.8%) were frail. There was a substantial overlap between depression and frailty. Although depression and frailty were associated the number and duration of hospitalisation by univariate analysis, the association became insignificant after adjusting for confounding factors by multivariate analysis. Both depression and frailty were associated with one-year mortality by univariate analysis, but only frailty was an independent predictor of patient survival by multivariate analysis (adjusted hazard ratio 1.424, 95% confidence interval 1.011-2.005. p = 0.043).

Conclusions: Depression and frailty were common among Chinese PD patients. Frailty, but not depression, was an independent predictor of one-year mortality. Further studies are needed to determine the benefit of treatment for frailty in PD patients.

Factors Affecting Selection of Dialysis Modality in Elderly Patients with CKD: Prospective Cohort Study of Korea

Jang-Hee Cho,[1,2] Hee-Yeon Jung,[1,2] Ji-Young Choi,[1,2] Sun-Hee Park,[1,2] Chan-Duck Kim,[1,2] Se-Hee Yoon,[3,2] Yong-Lim Kim.[1,2] Clinical Research Center for End Stage Renal Disease (CRC for ESRD) Investigators *[1]Kyungpook National University Hospital, Daegu, Republic of Korea; [2]Clinical Research Center for End Stage Renal Disease, CRC for ESRD, Republic of Korea; [3]Konyang University Hospital, Daejeon, Republic of Korea.*

Background: Several factors associated with dialysis modality selection have been reported in many studies. However, the factors affecting selection of dialysis modality in elderly patients with chronic kidney disease is not known. We investigated which factors are associated with selection of dialysis modality in elderly patients compared to younger patients.

Methods: This study included 2,238 incident dialysis patients from a multicenter prospective cohort study in Korea from August 2008 to July 2015 (NCT00931970). We surveyed demographic, referral, dialysis planning, socioeconomic, and clinical data. Using multivariate regression analyses, variables significantly associated with the chosen dialysis modality were analyzed. The differences in the factors were compared between elderly (≥65 years) and younger (<65 years) groups.

Results: Of the enrolled patients, 1,537 (68.7%) and 701 (31.3%) selected hemodialysis (HD) and peritoneal dialysis (PD) respectively. The percentage of HD was higher in elderly patients compared to younger patients (82.3% vs. 62.2%, p<0.001). In elderly group, patients choosing PD was younger than patients choosing HD (70.4±4.4 vs. 72.2±5.4, p<0.001). Patients with planned dialysis (p<0.001), employed status (p=0.042), married status (p=0.023), and congestive heart failure (p=0.003) were more common in elderly PD patients. However, patients with tumor were more common in elderly HD patients. Multivariate analysis showed that planned dialysis (p<0.001) and congestive heart failure (p=0.003) were independent factors for selecting PD and tumor (p=0.01) was for selecting HD in elderly group. In younger group, planned dialysis (p<0.001), employed status (p<0.001), and independent economic status (p=0.043) were revealed as the independent factors for choosing PD whereas peripheral vascular disease (p=0.019) and tumor (p=0.02) were independent factors for choosing HD.

Conclusions: As age of patients with chronic kidney disease increases, HD was more frequently selected modality than PD. Dialysis planning and specific comorbidities were associated with selection of dialysis modality in elderly patients. However, elderly patients were less affected by socioeconomic status compared to younger patients.

FR-PO663

Barriers and Facilitators to Home Dialysis in Older Veterans: Perspectives from Patients and Caregivers

Michael J. Fischer,[1,6] Lindsey A. Jones,[3] Cindi Fiandaca,[6] Timothy P. Hogan,[4] Bridget M. Smith,[5] Elisa J. Gordon.[2] *[1]Jesse Brown VAMC, Chicago, IL; [2]Northwestern University, Chicago, IL; [3]Department of Veterans Affairs, Hines, IL; [4]Veterans Health Administration, Bedford, MA; [5]Hines VA Hospital, Hines, IL; [6]Edward Hines Jr. VA Hospital, Hines, IL.*

Background: Home-based dialysis - hemodialysis (HD) or peritoneal dialysis (PD) – often confers greater survival and quality of life, and lower morbidity than in-center hemodialysis for patients with end-stage renal disease (ESRD). However, home dialysis is underutilized, especially among older adults. To understand this underutilization, we assessed barriers and facilitators to home dialysis from the perspectives of older Veterans and their caregivers.

Methods: Semi-structured telephone interviews were conducted and audio-recorded separately with Veterans receiving home dialysis through VA and their informal caregivers in five VA facility-based programs during 2017-2018. Transcribed interviews were analyzed using content analysis to identify themes emerging from the data.

Results: Out of 82 Veterans on home dialysis (78 PD, 4 HD), 63 (77%) had informal caregivers. We interviewed 20 Veterans (24% participation rate) and their 20 caregivers (32% participation rate). Most Veterans were male (100%), white (77%), with an average age of 64 years. Most caregivers were female (95%), white (78%), with an average age of 63 years. Most Veterans (54%) believed that they needed their caregiver to assist in performing home dialysis. Key patient-level barriers included unsuitable home environment, lack of self-efficacy in administering home dialysis treatments, and physical disability. Important facilitators included having sufficient space at home, knowledge/training on performing home dialysis, and caregiver support. Significant caregiver-level barriers included unsuitable home environment, lack of self-efficacy in administering home dialysis treatments, and competing job duties. Common facilitators included personal devotion to the Veteran, knowledge/training of the home dialysis procedure, and VA dialysis staff support. Veterans and caregivers similarly supported interventions to foster home dialysis, including telemedicine applications and paid stipends for caregivers.

Conclusions: Informal caregivers play a key role in supporting home dialysis for older adults. Interventions should address both patient and caregiver barriers to increase use of home dialysis.

Association Between Receiving Public Assistance and Long-Term Peritoneal Dialysis Outcomes in Adults

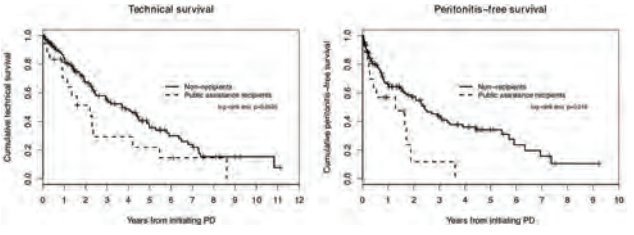
Daisuke Komukai,[1] Yutaka Nakajima,[2] Hiroshi Kashiwaba,[1] Takeshi Suzuki,[1] Ai Kato,[1] Susumu Uda,[1] Kanji Shishido.[2] *[1]Department of nephrology, Kawasaki Saiwai Hospital, Kawasaki, Japan; [2]Kawasaki Clinic, Kawasaki, Japan.*

Background: Public assistance (PA) in Japan is available as part of the financial support system for the poor. With the increasing number of elderly people living in households, the number of elderly people receiving PA has increased. Although the role of peritoneal dialysis (PD) is substantial in the treatment of end-stage renal disease (ESRD) in the elderly, the effects of the long-term PD on PA recipients remain unknown.

Methods: We reviewed medical records for 147 patients who had initiated PD between 2005 and 2018 at Kawasaki Saiwai Hospital and had remained in care at a related facility. We examined patient characteristics, including age, sex, ESRD etiology, and serum creatinine and albumin levels at the PD induction. Data on PD prescription and the method of connection were also collected. The long-term technical survival and peritonitis-free survival rates were calculated using Kaplan–Meier method, and predictors of technical and peritonitis-free survival were determined using Cox regression analysis.

Results: PD was initiated in 88 males and 59 females, of which 18 received PA. At the induction, mean patient age was 63.1 years and mean estimated glomerular filtration rate (eGFR) was 5.9 ml/min/1.73m^2. In the Kaplan–Meier analysis, the overall median time for technical survival was 1158 days: 806 days for the recipients and 1357 days for non-recipients. Although there was no statistical difference in the technical survival rate between the two groups, the outcome appeared to be unfavorable in the PA recipients. The peritonitis-free survival was significantly shorter in the PA recipients than in the non-recipients. In Cox regression analysis, PA was associated with short technical [HR 2.16; 95%CI 1.06–4.40] and peritonitis-free survival [HR 3.13; 95%CI 1.55–6.34] after adjustments for age, sex, estimated GFR at the induction, the presence of diabetes, connection method, and the presence of people living together.

Conclusions: Receiving PA was associated with unfavorable technical survival outcomes and significantly poor peritonitis-free survival outcomes.



FR-PO665

Quality of Life and Emotional Distress Changes Between Peritoneal Dialysis Patients Versus Hemodialysis Patients and Their Families

Takeyuki Hiramatsu, Shota Okumura, Yuko Asano, Masatsuna Mabuchi, Katsuhiko Suzuki, Daiki Iguchi, Shinji Furuta. *Konan Kosei Hospital, Konan Aichi, Japan.*

Background: In Japan, hemodialysis (HD) is the most popular modality for the end stage renal disease (ESRD) patients. While, the number of peritoneal dialysis (PD) patients accounts for 2.8%. We investigated the reason of low PD penetration through the prospective assessment of quality of life(QOL) and emotional distress(ED) of patients and their families.

Methods: Fifty one incident patients (31 PD, 20 HD) were recruited. The SF-36 and CES-D were assessed in all patients and their families at the start of dialysis and every year for 2 years.

Results: The background characteristic was similar between two groups. The CES-D in PD was not changed, but was significantly increased in HD at 2 years. As for families, the CES-D results showed the same trend as patient's. Summary of physical components and role of social components (RS) in SF-36 at 2 years in PD but not in HD revealed significant improvement,. The summary of mental components (MC) were not changed in both groups. But MC in PD were significantly higher than that in HD at 2 years. The summary of RS was significantly improved at 2 years in PD and retained higher than that in HD. In the family's test, all SF-36 scores were not changed in PD, but MC was decreased in HD, followed significant lower at 2 years than in PD.

Conclusions: In this study, PD provided better QOL and ED due to preservation of residual renal function and lesser hospital visiting. However, HD is more prevalent in Japan instead of burdening the families. It might be considered that most Japanese tend to or depend on others and select HD modality. Moreover, ESRD patients were not well educated according to PD. Finally, it is important to inform patients of PD where PD provides better QOL and better effect on emotional change.

FR-PO666

Estimating Total Small Solute Clearance in Patients Treated with Continuous Ambulatory Peritoneal Dialysis Without Urine and Dialysate Collection

Li Fan,[1] Dominik Steubl,[2,11] Lesley Inker,[2] Hocine Tighiouart,[2] Amy B. Karger,[6] John H. Eckfeldt,[7] Hao Zhang,[8] Jing Hu,[3] Yunhua Liao,[9] Tariq Shafi,[4] Wei Chen,[10] Xueqing Yu,[5] Andrew S. Levey.[2] *[1]Department of Nephrology, The First Affiliated Hospital of Sun Yat-sen University; Key Laboratory of Nephrology, Ministry of Health; Guangdong Provincial Key Laboratory of Nephrology, Guangzhou, China; [2]Tufts Medical Center, Boston, MA; [3]The third Xiangya hospital of Central South Univercity, Changsha, China; [4]Johns Hopkins University School of Medicine, Baltimore, MD; [5]Department of Nephrology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [6]University of Minnesota, Minneapolis, MN; [7]University of Minnesota Medical School, Minneapolis, MN; [8]The Third Xiangya Hospital of Central South University, Changsha, China; [9]The First Affiliated Hospital of Guangxi Medical University, Nanning, China; [10]The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [11]Nephrology, Klinikum rechts der Isar, Technische Universitaet Munich, Munich, Germany*.

Background: Higher total (kidney plus dialysis) clearance of small solutes is associated with lower mortality in peritoneal dialysis (PD) patients. Measurement of total clearance (mCL) is recommended to monitor and adjust dialysis dose, but is difficult and prone to errors due to the requirement for timed fluid collections. We hypothesized that equations (eCl) could be developed to estimate mCl using serum concentrations of endogenous filtration markers.

Methods: Using 2/3 of the participants in the Guangzhou PD Study (N=980), we used linear regression to develop eCl equations. Reference tests were mCl for urea nitrogen (mCl_{UN}, ml/min) and average mCl for UN and creatinine (mCl_{UN-Cr}, ml/min/1.73 m^2). Index tests were various eCl equations using UN, creatinine, low-molecular-weight-proteins (LMWP) [beta-trace-protein (BTP), beta-2-microglobulin (B2M), cystatin C], demographic variables and body size. We validated the equations in the remaining 1/3 of the cohort (n=322) and refitted equations in the combined dataset. We analyzed the predictive value of the equations to detect a weekly total standard Kt/V (mCl_{UN} per week indexed for total body water) >1.7 using receiver-operating-characteristic curve.

Results: Mean age of the cohort was 50±15 years, 53% were male; mCl_{UN} was 6.9±1.8 ml/min, mCl_{UN-Cr} 7.5±2.8 ml/min/17.3 m^2. Creatinine but not UN contributed to eCl (Table). LMWP did not improve accuracy for mCl_{UN} (range 87.6-88.6%). BTP and B2M improved accuracy for mCl_{UN-Cr} (range 81.6-82.0 vs. 79.7%), however, differences were small. The area-under-the-curve for predicting a weekly kt/V >1.7 was similar for all equations (range 0.791-0.802).

Conclusions: Total small solute clearance can be estimated moderately well [TMC1] in CAPD patients from serum concentration of creatinine and demographic variables without urine and dialysate collection. Equations to estimate total clearance need to be evaluated in other cohorts.

Funding: Commercial Support - Siemens, Dialysis Clinic Inc., Private Foundation Support

Table: Performance total clearance estimating equations in the entire dataset (n=980)

Markers	Co-Variables	RMSE (95%-CI)[a]	ΔRMSE[b]	Accuracy (95%-CI)[c]
Equations estimating mCl_{UN}, ml/min		ml/min	%	%
Creatinine	Age, Sex, Height, Weight	0.205 (0.192, 0.219)	-	87.6 (85.5, 89.5)

Factors Associated with Peritoneal Membrane Permeability in Patients Starting Peritoneal Dialysis

Paraskevi Tseke,[1] Emilios Andrikos,[3] Konstaninos Perrakis,[9] Olga Balafa,[6] Vassilios Liakopoulos,[2] Christine Melexopoulou,[8] Chrhstos Katsinas,[13] Vasileios Margellos,[4] Marios Theodoridis,[11] Chrysostomos Dimitriadis,[10] Evangelia Dounousi,[12] Theofanis Apostolou,[4] Ploumis S. Passadakis,[7] George I. Tsirpanlis.[5] *[1]General Hospital "Alexandra", Athens, Greece; [2]Nephrology, AHEPA, University Hospital, Thessaloniki, Greece; [3]G.Hatzikosta General Hospital, Ioannina, Greece; [4]"Ant. Mpilis" Nephrology Department Evaggelismos Hospital, Athens, Greece; [5]Nephrology, G. Genimatas General Hospital, Athens, Greece; [6]University Hospital, Ioannina, Greece; [7]Democritus University of Thrace, Alexandroupolis, Greece; [8]Laiko Hospital, Ethniko Kapodistriako University, Athens, Greece; [9]University Hospital of Hrakleio, University of Crete, Hrakleio, Greece; [10]Ippokrateio Hospital of Thessaloniki, Thessaloniki, Greece; [11]Univesity Hospital of Alexandroupolis, Alexandroupolis, Evros, Greece; [12]University of Ioannina, Ioannina, Greece; [13]"Bodosakio" General Hospital, Ptolemaida, Greece.*

Background: Peritoneal membrane transport characteristics vary in peritoneal dialysis (PD) patients and have been related to patient and technique survival.

Methods: Data from PD patients from 10 PD units in Greece were retrospectively analyzed. Patients with a history of early catheter dysfunction or leakage were excluded. 163 patiens (100 male and 63 female) were finally included, whose first PET test was performed within 2 months after PD catheter insertion. Patients were divided into 4 sub-groups according to 4 hr D/P creatinine ratio; fast as 1SD above mean, average fast as between mean and mean+1SD, average slow as mean-1SD and slow as below 1SD from the mean. Ordinal regression analysis was performed to identify risk factors for faster membrane permeability.

Results: The median age of the study group was 58.2 (range 21-88) years. The etiology of ESRD was unknown in 26.5%, diabetes mellitus in 19.5%, hypertension/nephrosclerosis in 18%, glumerolonephritis in 17.2%, polycystic kidney disease in 10.5%. Gender and BMI did not differ significantly between sub-groups of patients (p>0.05). In univariate analysis age (p=0.02), the history of diabetes mellitus (p=0.03) and lipidemia (p=0.03), as well as hemoglobin (p=0.03) and albumin concentrations (p=0.01) were significantly different among the four sub-groups. In multivariate analysis only the presence of diabetes mellitus (OR=1.98, p= 0.045) and hemoglobin levels (OR: 0.76, p=0.01) were independently associated with higher membrane permeability.

Conclusions: Diabetes mellitus and anemia are independent predictors of membrane transport characteristics in patients starting PD.

FR-PO668

Risk Factors for Loss of Residual Renal Function During the First Year of Chronic Automated Peritoneal Dialysis (APD) in Children

Qian Shen.[1,2] *[1]Department of Nephrology, Children's Hospital of Fudan univeristiy, Shanghai, China; [2]Shanghai Kidney Development & Pediatric Kidney Disease Research Center, Shanghai, China*.

Background: In chronic dialyzed patients, preservation of residual renal function is associated with better survival, lower morbidity, and greater quality of life. The aim of this study was to assess risk factors for loss of residual renal function (RRF) in children during the first year of chronic automated peritoneal dialysis (APD).

Methods: The study group included 56 children (33 boys and 23 girls, median age 9.58 years) with end-stage renal disease (ESRD) at Children's Hospital of Fudan University from Jan 2008 to Dec 2015 who commenced APD as the initial method of renal replacement therapy for at least 12 months with significant initial residual renal function (daily diuresis more than 100ml/m^2/day). Patient characteristics and potential risk factors of developing oligoanuria (under 100 ml/m^2/day) including gender, BMI and age at APD, etiology of ESRD, baseline daily diuresis and residual glomerular filtration rate (rGFR), PD fluid volume, glucose load, ultrafiltration, peritoneal permeability, dialysis adequacy, blood pressure, biochemical parameters, medications used and dialysis-related peritonitis frequency were analyzed.

Results: 1. Mean diuresis before initiation of APD was 692.0±315.9 (mL/m^2/day) and mean rGFR was 7.48±2.93 (mL/min/1.73 m^2). An average decline of daily urine volume was 376.2±354.6 (mL/m^2/day) in the first year of APD and 23 (41.14%) children became oligoanuria. 2. Risk factors associated with loss of RRF: Children who lost RRF during the first year frequently exhibited a lower baseline rGFR (P=0.02), were exposed to higher dialysate glucose (P<0.001), higher PD fluid volume (P=0.002) and achieved higher daily ultrafiltration volume (P<0.001). The use of RAS antagonists (ACEI/ARB) tended to increase the risk of becoming oligoanuria (P=0.003).

Conclusions: The important risk factors for rapid RRF loss in children during the first year of chronic APD include lower baseline rGFR, higher glucose load, higher PD fluid volume, higher ultrafiltration and administration of RAS antagonists.

FR-PO669

Simultaneous Optimization of Ultrafiltration and Solute Transport in Automated Peritoneal Dialysis (APD)

Karin E. Bergling,[1] Anders P. Wieslander,[2] Carl M. Öberg.[1,3] Renal Physiology & Peritoneal Dialysis Group *[1]Department of Clinical Sciences, Lund University, Lund, Sweden; [2]Baxter, Lund, Sweden; [3]Lund University Hospital, Department of Nephrology, Lund, Sweden.*

Background: In a recent study we found that the treatment with APD could be improved in terms of shorter treatment times and markedly (> 20%) lower glucose absorption using optimized bi-modal treatment regimens, combining cycles with a high glucose concentration and cycles using low or no glucose.

Methods: We further explored this novel concept *in silico* by using a sparse linear regression model with constraints to find the shortest possible treatment time given a set of clinical treatment goals. We created optimal regimes giving the same Kt/V urea and/or weekly creatinine clearance and UF as a standard (6 × 2 L 1.36%) and an adapted (2 × 1.5L 1.36% + 3 × 3L 1.36%) regime.

Results: Compared to the non-optimized (standard and adapted, see Figure A) regimes, optimized regimes for creatinine (35 L/week; see Figure B and C) and UF (0.5 L/day) demonstrated marked reductions (up to 40%) in glucose absorption (G abs), having a similar sodium and phosphate removal (see Table). Optimizing for urea Kt/V (1.40 / week; PD-only; see Figure A) and UF (0.5 L/day) leads to a slightly lower creatinine and phosphate removal but leads to a shorter treatment time. Larger fill volumes of 1200 mL/m^2 (UF cycles) and 1400 mL/m^2 (Clearance cycles) can be applied to shorten the total treatment time.

Conclusions: These simulations suggest that great reductions in treatment time and in glucose absorption are possible using a novel optimization technique for APD prescription. Further studies are needed to evaluate the feasibility of these novel regimens.

Funding: Private Foundation Support

Regime	Sodium Removal (mmol/d) †	Urea Kt/V †	Phosphate Clearance (L/w) †
Standard 6 x 2 L 1.36%	53	1.38	29
Adapted APD	54	1.40	31
Optimized 12 L ‡	51	1.40	30
Optimized 23.6 L *	59	1.56	30
Optimized 32.8 L *	55	1.64	31

FR-PO670

A Time-Varying Analysis: The Relationship Between Serum Uric Acid and Residual Renal Function Loss in CAPD Patients

Yang C. Lun. *zhong-shan university, Guangzhou, China.*

Background: Residual renal function(RRF) is significantly associated with mortality and quality of life in peritoneal dialysis(PD) patients. A number of studies demonstrated that pre-dialysis serum uric acid(UA) was predictor of RRF loss in PD patients. However, the relationship between serum uric acid and RRF loss in patients over time are unknown.

Methods: This is a single-center, retroperspective cohort study. Total 201 CAPD patients who started PD between January1, 2008 and April 30, 2016 at the third affiliated hospital of Sun-Yat Sun University were eligible for the study with follow-up through December 31, 2016. Urine volume, biochemical and therapeutic information was collected within 1 month of PD commencement and at every 3-month intervals thereafter. Cox proportional hazard regression models and penalized splines analysis were employed to analyze the association between uric acid and RRF loss and to identify independent risk factors of RRF loss.

Results: During the period of first five years in PD, 86 patients became anuria. Multivariate Cox regression analysis showed that uric acid, 5-year peritonitis rate, ultrafiltration and phosphorous were independent risk factors of RRF loss while KT/V urea was a protective factor. Using Cox proportional hazard regression models and penalized splines analysis, when compared to patients with UA 403-455umol/L, patients with UA>455umol/L (HR=1.99, 95%CI 1.021-3.345; p<0.05) or UA<403umol/L (HR=2.12, 95%CI 1.005-3.611; p<0.05), UA levels conferred a higher risk of RRF loss, while it showed a U-shaped relationship between continuous UA levels and RRF loss.

Conclusions: A U-shaped relationship between UA levels and RRF loss was found in patients over time. Uric acid, 5-year peritonitis rate, ultrafiltration, phosphorous, and KT/V urea were independent risk factors for RRF loss in CAPD patients.

FR-PO671

Early Complications of Urgent-Start Peritoneal Dialysis

Ying Wang, Haiyun Wang, Ying Ma, Yang Li, Bingyan Liu, Zijuan Zhou, Wei Yang, Xuemei Li, Limeng Chen. *Peking Union Medical College Hospital, Beijing, China.*

Background: Urgent-start peritoneal dialysis (PD) would be an effective option for patients need unplanned dialysis. However, the early catheter-related complications in urgent-start PD have not been well investigated and the previous results were inconsistent.

Methods: In this retrospective study, end stage renal disease (ESRD) patients were included if they were over 18 years old and received regular PD in our PD center between 1 March 1996 and 30 September 2016. Urgent-start PD was defined as initiation of PD within 2 weeks of catheter insertion. The time from placement-to-PD was determined by the nephrologists based on the clinical condition of each patient. Patients were divided into two groups according to whether PD was started urgently or not. The outcome was mechanical and infectious complications and technique survival in the first 6 months.

Results: A total of 667 patients (203 urgent-start, 464 conventional-start) were included. The mean age of the study patients was 59.6±15.4 years old, and 49.8% of the patients were female. Diabetes was the primary cause of ESRD (36.1%) and was followed by glomerulonephropathy (25.6%) and hypertension (20.5%). The time from catheter insertion to PD initiation was 8.1±4.5 and 18.6±12.7 days in urgent-start and conventional-start PD group, respectively. Compared with conventional-start patients, urgent-start patients had lower serum albumin, Kt/v, Ccr and eGFR levels at the start of PD, and otherwise there was no significant difference between the two groups. The rate of mechanical complications at 1 month, 3 months, and 6 months after PD commencement was 9.4%, 16.7%, and 18.2% in the urgent-start PD group, respectively. The rate of infectious complications at the same time points was 11.8%, 13.8%, and 20.7% in the urgent-start group. Technique survival was 96.9% and 98.4% in urgent-start and conventional-start PD group, respectively. There was no difference in the rate of mechanical and infectious complications and technique survival between urgent- and conventional-start PD patients at either time point.

Conclusions: Urgent-start PD patients had similar rates of catheter-related complications and technique survival compared with conventional-start PD patients.

FR-PO672

Low-Volume Tidal Peritoneal Dialysis Is a Preferable Mode in Patients Initiating Urgent-Start Automated Peritoneal Dialysis

Jianteng Xie, Huizhen Wang, Jing Li, Tiantian Liang, Yanhui Wang, Yifan Zhang, Wenjian Wang. *Division of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, GuangZhou, China.*

Background: To evaluate the safety of low-volume tidal peritoneal dialysis (TPD) and intermittent peritoneal dialysis (IPD) in end-stage renal disease (ESRD) patients initiating automated peritoneal dialysis (APD) after an acute catheter insertion.

Methods: Clinical outcomes of patients who received either TPD or IPD using an APD system were compared in a randomized, open-label, prospective control study in a single-center setting. From May 2011 to May 2013, 49 patients were enrolled and 27 patients received low-volume TPD treatment whereas 22 patients underwent low-volume IPD right after Tenckhoff catheter insertion. The incidence of complications during the 14-day APD treatment were observed. After APD treatment, all the patients were transferred to continuous ambulatory peritoneal dialysis (CAPD) and followed up for 2 years.

Results: The IPD group demonstrated a significantly high incidence of catheter-related complications than the TPD group after adjusting for age, gender, baseline diabetes, systolic blood pressure, and body mass index. However, the short duration of APD treatment with either IPD or TPD mode did not affect the long-time technical survival.

Conclusions: In patients immediately after catheter insertion, low-volume TPD mode demonstrated a lower incidence of catheter-related complications compared to IPD. However, definitive conclusions about TPD benefit cannot be made, owing to early termination of the trial.

Characteristics	TPD (n=27)	IPD (n=22)	*p*-Value
Female, n (%)	16(59.3)	16(72.7)	0.325

Clinical Outcomes Associated with Peritoneal Dialysis Catheter Placement by Interventional Radiology

Gabrielle Côté,[1] Yannick Begin,[1] Mathieu Rousseau-Gagnon,[2] Mohsen Agharazii,[2] Fabrice Mac-Way.[2] *[1]Université Laval, Québec, QC, Canada; [2]CHU de Quebec, Hotel-Dieu de Quebec Hospital, Quebec, QC, Canada.*

Background: Fluoroscopy-guided peritoneal dialysis (PD) catheter insertion by interventional radiologist (IR) has been reported as an appropriate alternative to surgical insertion to increase access to PD. The objective of this study was to report clinical outcomes and complications associated with PD catheter insertion by IR.

Methods: We conducted a single-center retrospective study of all patients who had PD catheter insertion by IR from January 2014 to January 2018. The primary outcomes were to report the complications related to catheter insertion within the first 3 months and the number of active PD patients at 3 months. Secondary outcomes were to evaluate the impact on the prevalent number of PD patients and on the waiting time for PD catheter insertion.

Results: 56 patients with a median age of 55 years old (20-85) were included in this study. Patients with severe obesity (IMC>35), polycystic kidney disease and previous major surgery were not eligible for IR and were referred for laparoscopic insertion. Among these 56 patients, 1 had kidney transplantation, 1 had renal recovery and 2 were deemed unable to learn the procedure. Therefore, 52 completed the training and began PD. Among these 52 patients, 49 (94%) were on active PD at 3 months (catheter removed due to an acute intestinal perforation post-insertion (n=1), refractory peritonitis (n=1) and a pleural leak (n=1)). Within 3 months, catheter malposition occurred in 12 (21%) patients but only 3 of them needed surgical or IR repositioning. Three patients (5%) experienced peri-catheter leaks where PD was successfully restarted after temporary cessation for 4 weeks. Finally, 1 patient developed peritonitis and 1 had exit site infection that were successfully treated with antibiotics. Since the introduction of this technique, the number of prevalent PD patients in our center increased from 60 to 84 while the average time for PD catheter insertion has decreased from 4.5 to 1.5 months.

Conclusions: Insertion of PD catheter by IR is associated with a low complication rate while it improves access to PD therapy. Its use should therefore be encouraged as an alternative to surgical placement in most patients.

FR-PO674

Peritoneal Dialysis After Renal Transplant Failure: A Different Beast Altogether

Vivian Gama,[1] Jakob D. Ohman,[1] Tripti Singh,[1] Brad C. Astor,[2] Sana Waheed.[3] *[1]University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]University of Wisconsin, Madison, WI; [3]University Of Wisconsin School Of Medicine and Public Health, Madison, WI.*

Background: The number of patients starting dialysis after graft failure (DAGF) has been steadily increasing in the United States. This population differs significantly from those with native End Stage Renal Disease (ESRD) and little is known about the outcomes of DAGF patients on peritoneal dialysis (PD). We undertook this study to examine characteristics and survival of DAGF patients on PD compared to the native ESRD population on PD.

Methods: We analyzed the United States Renal Data System (USRDS) to assess characteristics and survival of DAGF and native ESRD patients on PD. Mortality rates were compared after adjustment for age, sex, number of comorbidities, and year of dialysis initiation.

Results: A total of 7.46% of DAGF and 7.09% of native ESRD patients used PD (p=0.01) and a total of 108,194 patients on PD were analyzed (Table 1). The mean age for DAGF patients on PD was significantly lower than native ESRD patients on PD (p<0.001). DAGF patients on PD were more likely to be employed than their counterparts with native ESRD (p<0.001). Those with DAGF had higher mortality than those with native ESRD (Table 2). This trend was even more significant after adjustment for age, sex, number of comorbidities, and year of dialysis initiation (p<0.001).

Conclusions: DAGF patients on PD have much worse outcomes compared to their native ESRD counterparts. The results of this study should encourage providers to consider DAGF PD patients as a high risk group and focus on risk reduction. Further research regarding the timing and cause of mortality in DAGF population on PD is needed.

Table 1. Patient demographics obtained from USRDS separated into Native ESRD patients on PD and DAGF patients on PD

Characteristic	All Patients on PD	Native ESRD patients on PD	DAGF Patients on PD	p Value

FR-PO675

Bedside Peritoneal Dialysis Catheter Repositioning - A Novel Technique

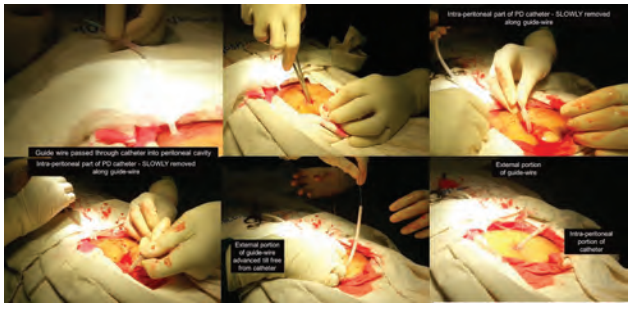
Santosh Varughese,[1] Suceena Alexander,[2] Anna T. Valson,[2] Shibu Jacob,[3] Shailesh T. Kakde,[4] Anjali Mohapatra,[3] Vinoi G. David.[5] *[1]Nephrology, Christian Medical College, Vellore, India; [2]Christian Medical College, Vellore, India; [3]Christian Medical College, Vellore, Vellore, India; [4]Christian medical college, Vellore. Tamil Nadu, India; [5]Royal Adelaide Hospital, Adelaide, SA, Australia.*

Introduction: Malfunction of peritoneal dialysis (PD) catheters usually need surgical repositioning, requiring anaesthesia, operating time, longer hospital stay and surgical expertise. This novel technique obviates need for surgical intervention.

Case Description: The abdomen is scrubbed and cleaned. PD catheter distal to exit site is meticulously cleaned, titanium adaptor and transfer set removed, the former soaked in povidone-iodine. A guidewire is passed through catheter into peritoneal cavity. A 5mm incision is made over previous healed incision scar. Soft tissue is dissected until deep cuff is visible. With blunt dissection, cuff is gently separated from subcutaneous tissue where it had become anchored. Taking care to retain guide wire's position inside peritoneum, intra-peritoneal part of PD catheter is removed. External portion of guidewire is advanced through PD catheter till free from catheter. Proximal end of guidewire is in peritoneum

and distal end free. PD catheter is searched for occluding clots, and if present, are gently milked out and catheter flushed with saline. A dilator is advanced along guidewire to ensure adequate space for PD catheter at linea alba. Peel-away sheath and dilator are then advanced into peritoneum. The dilator and guide wire are removed leaving only sheath in place. The catheter is then re-introduced into peritoneum through the sheath, which is separated leaving catheter in place. Peritoneal cavity is filled with PD fluid and good inflow and outflow are ensured. Subcutaneous tissue and skin are closed in layers. In the 18 patients so far. we have had an immediate technical success of 100% and a month later 12 catheters were functioning well (66.67%). Six months later, the catheters remained functional except in one patient who died due to heart disease.

Discussion: This novel technique allows for preservation of the catheter, exit site and tunnel. This reduces costs and duration of hospital stay and does not require specialized surgical expertise, operating room time or a dedicated anaesthetist.



Steps of repositioning

FR-PO676

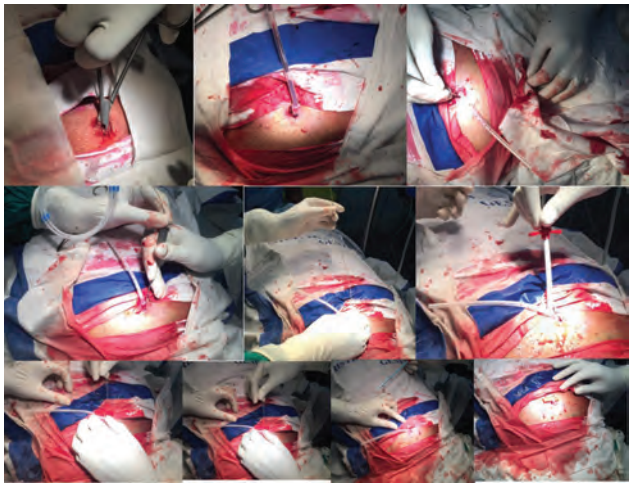
Percutaneous Re-Positioning of Peritoneal Dialysis Catheter Accidentally Placed in the Pre-Peritoneal Subcutaneous Space Leaving the Tunnel and Exit-Site Intact - A Novel Idea

Santosh Varughese. *Nephrology, Christian Medical College, Vellore, India.*

Introduction: Percutnaeously placement of peritoneal dialysis (PD) catheters may be accidenatly be placed in the pre-peritoneal subcutanous space if the introducer needle does not pierce the peritoneal membrane in the initial part of the procedure. If this happens, the catheter insertion has to be redone either percutaneously or surgcially. The catheter often has to be replaced as part of it has been externalized and is unsterile.

Case Description: 70 year old man with end stage renal disease underwent bedside PD catheter insertion. Unfortunately, the cathteter was accidetally placed in the pre-peritoneal subsutaneous space. The inflow and outflow of PD fluid was present as the pre-peritoneal subcutaneous space had expanded with the PD fluid, but was slow. The problem was identified on CT scan and PD catheter re-insertion was planned. A week later, a novel technique was attempted in which the exit site and tunnel were untouched. The skin and subcutanousl sutured over the origical catether insertion site were undone and the deep cuff of the catheter was dissected and the intrabdominal part of the cathteter was exteriorized. A veress needle was advanced till it reached the peritoneal space, the position of which was confirmed using a guidewire. The track was dilated using a peel-away sheath-dilator assembly. The dilator was removed and the intra-abdomina portion of the catheter was slid in. The wound was closed in layers after ensuring good inflow and outflow. Peritoneal dialysis exchanges were begun the same day.

Discussion: Compared to using a new PD catheter and tunnel, this novel technique allows for a simple bedside repositioning technique, saving time, operating room time, reducing hospital stay and possibly avoiding unnecessary hemodialysis.



Steps of procedure

FR-PO677

Long-Term Outcomes in Peritoneal Dialysis Patients Who Initiated Immediately After Catheter Insertion Using Percutaneous Catheter Placement Method

Young kyung Ko,[2] Young-Il Jo.[1] [1]*Nephrology, Konkuk University Medical Center, Seoul, Republic of Korea;* [2]*Nephrology, Konkuk University Medical Center, Gwangjin-gu, seoul, Republic of Korea.*

Background: The aim of this study was to evaluate the long-term outcomes in peritoneal dialysis (PD) patients who initiated immediately after catheter insertion using percutaneous catheter placement method without a break-in procedure.

Methods: We conducted a retrospective study including all incident PD patients in our hospital who began PD therapy between January 2002 and December 2017. PD catheter (swan neck or non-swan neck) were used and inserted by a nephrologist using percutaneous catheter placement method with guidewire. PD therapy initiated immediately after catheter insertion without a break-in procedure. Demographic and clinical data including ESI, peritonitis, pericatheter leakage, and catheter dysfunction during the study period were collected. Event-free survival rates of clinical events and patient survival rates were calculated using Kaplan-Meier analysis.

Results: One-hundred thirty seven patients began PD during the study period, and 127 of these patients were included in the final analysis. During the follow-up period, 83 patients were withdrawn from PD. Reasons for discontinuing PD were transfers to hemodialysis(42.3%), kidney transplantation (18.8%), follow-up loss(21.7%), or death(17.6%). The survival rates were 96.7%, 94.3%, 91.3%, 91.3% and 86.8% at 1, 2, 3, 4 and 5 years after PD initiation, respectively [Fig. 1]. In the Cox multivariate model, DM was related to patient survival. The technique survival rates were 90.9%, 83.7%, 81.2%, 73.5% and 69.6% at 1, 2, 3, 4 and 5 years after PD initiation, respectively [Fig. 1]. The risk factor for technique survival was catheter migration (95% CI 0.113-0.701, p=0.006). Event-free survival rates of variable clinical events were shown in Fig 1.

Conclusions: Our study showed that long-term outcomes including patient survival rates and event-free survival rates were comparatively high in PD patients who initiated immediately dialysis after catheter implantation using percutaneous method

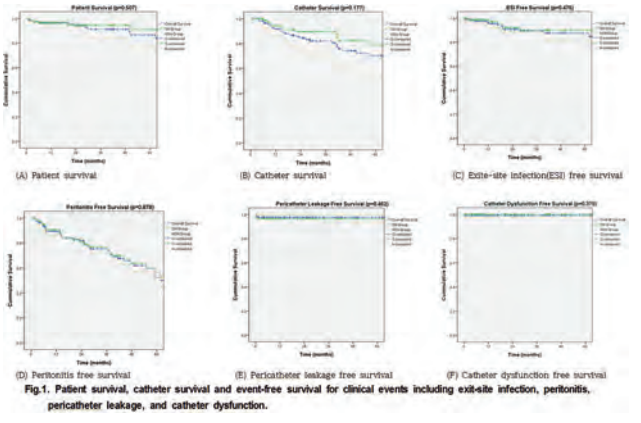


Fig.1. Patient survival, catheter survival and event-free survival for clinical events including exit-site infection, peritonitis, pericatheter leakage, and catheter dysfunction.

FR-PO678

Laparoscopic Peritoneal Dialysis Catheter Insertion Using Nitrous Oxide Under Conscious Sedation

Nalinee Saiprasertkit, Joanne M. Bargman. *Toronto General Hospital, Toronto, ON, Canada.*

Background: The conventional laparoscopic peritoneal dialysis catheter implantation using carbon dioxide (CO2) for peritoneal insufflation necessitates general anesthesia (GA) due to CO2-induced peritoneal pain. However, end stage kidney disease (ESKD) patients are not generally ideal candidates for GA. Using nitrous oxide (N20) as an insufflation agent offers several advantages, including PD catheter insertion under regional anesthesia.

Methods: We performed a retrospective cohort study in ESKD patients who underwent laparoscopic PD catheter insertion with N2O under regional anesthesia from Jan 1, 2008 to May 31, 2018. Patient demographics, treatment outcomes and adverse events were collected from our electronic databases.

Results: There were 152 patients, mean age was 68.2 ± 13.2 years; 41.5% women. Most common cause of ESKD was diabetic nephropathy (25.6%). Only 2 patients had unsuccessful catheter insertion due to extensive intra-abdominal adhesions. One patient required unexpected hospitalization due to intraoperative bleeding requiring a blood transfusion. Mean follow up was 26.6±23.1 months. One-year and 2-year catheter survival rates were 90.1% and 84.9%. Mean catheter survival was 51.0 ± 7.6 months.

Conclusions: Laparoscopic implantation of PD catheter with N2O insufflation and local anesthesia is feasible and can be performed safely in end-stage renal failure patients.

FR-PO679

Bedside Peritoneal Dialysis Catheter Insertion Program at the University Health Network – An Improvement Initiative to Grow PD Prevalence

Ali Z. Ibrahim, Rory F. McQuillan. *University of Toronto, Toronto, ON, Canada*.

Background: Peritoneal dialysis (PD) is underutilized in many jurisdictions, despite known societal and individual benefits, cost efficiency, and safety. One identified cause is lack of timely access to PD catheter insertion, which lends itself to quality improvement and innovation.

Methods: At the University Health Network at the University of Toronto, we sought to initiate a nephrologist-led bedside PD catheter insertion program directed at late presenting ESKD patients, beginning in January 2013, with appropriate support from a nursing education and infrastructure perspective. This included the implementation of a "Dialysis Start Unit" for patients needing Intermittent Peritoneal Dialysis while waiting for training with a nursing educator, as well as a dialysis catheter coordinator who was involved in both the bedside and surgical PD insertion programs. Specifically, the program aimed to help grow the PD program, while maintaining literature standards for catheter function, adverse events, and technique survival.

Results: The nephrology division at UHN has been able to create sustainable growth at a rate of 35% in its PD population using a safe, resource conscious, and effective way. This growth has come with no cost by way of patient adverse events or sacrifice of technique survival. Indeed, PD catheter failure rates have been consistently falling with more experience within the program, and within the last 2 years have been well below the accepted literature standards of 25%, at a rate of 5-7%. This is in keeping with available evidence that operator expertise, experience and interest have a large bearing on the success of any insertion technique. The rise in PD population was also accompanied by stability of home hemodialysis (HHD) and in-centre intermittent hemodialysis (IHD) numbers, while continuing to have a sustained rise in PD patient numbers.

Conclusions: Using a well-coordinated multi-disciplinary initiative to insert PD catheters at the bedside, the nephrology division at UHN was able to increase PD prevalence in a safe manner, which can be replicated in a similar context using similar resources and planning

FR-PO680

Abdominal Rectus Thickening as a Predictor of Peritoneal Catheter Primary Dysfunction

Pablo Maggiani, Guillermo Navarro Blackaller, Jonathan Chavez, Maria de la luz Alcantar Vallin, Guillermo Garcia-Garcia, Elsa edith Carreon bautista. *Hospital Civil De Guadalajara, University of Guadalajara, Zapopan, Mexico*.

Background: Percutaneous insertion of peritoneal dialysis (PD) catheters by nephrologists are an effective alternative to open surgical techniques. Complications following PD catheter insertion requiring manipulation or replacement are about 20%. Previous studies show that ultrasound measurements of skin depth to the peritoneum with values> 5.5 cm ($p < 0.001$) are associated at percutaneous DP catheter dysfunction.

Methods: We conducted a cross-sectional study of 46 patients who had their first percutaneous peritoneal dialysis (PD) catheter and had a primary PD catheter dysfunction (PDC) defined as PD catheter removal when the PDC never worked due to a problem related to the catheter. They were divided into 2 groups: Group A patients who presented DPC dysfunction (20 patients) and Group B without DPC dysfunction (26 patients). We perform ultrasound measurement of the abdominal wall to all patients after DPC was inserted. We mesured distance from the surface of the skin to the parietal peritoneum (SPP) and the thickness of the rectus abdominis (RAT) in centimeters (cm) in the sagittal plane, on the medial border of the rectus abdominus muscle at the level of the umbilicus, just above the scar of the procedure. Body mass index (BMI), central obesity (CO) was calculated.

Results: The mean age was 44.3 years (SD +/- 13.6). The BMI of Group A 24.9 kg / m2 (SD +/- 5.5) and Group B 24.4kg / m2 (SD +/- 4.1), central obesity (OC) of group A 93.6cm (SD +/- 16.8) and Group B 90.5 cm (SD +/- 11.2), SPP Group A 2.7 cm (SD +/- 0.94), Group B 2.2 cm (SD +/- 0.7), Group A RAT 1,005 cm (SD +/- 0.2), Group B 0.7cm (SD +/- 0.15). Of the 46 patients, 43% (20) had primary PDC dysfunction (group A). The RAT $\geq$ 1 cm was the only variable that was significantly associated with the primary dysfunction of the PD catheter (RR: 6.8, IC 95% 2.7-16.0) OR: 100, (IC 95% 10.23 .977.1, $p < 0.0001$), a sensitivity of 80%, specificity 96%, PPV of 94% NPV of 86%, with an AUC 0.86.

Conclusions: It was also observed that 94.4% (17) of patients with CO who did not have primary PDC dysfunction had a RAT <1 cm. No significant association was observed between primary PDC dysfunction and other risk factors, such as age, BMI, CO and SPP. The RAT $\geq$ 1cm is an very good predictor of the risk of primary dysfunction of the PD catheter.

FR-PO681

Comparison of Different Techniques for Peritoneal Dialysis Catheter Insertion: A Systematic Review and Network Meta-Analysis

Lichuan Yang. *West China Hospital of Sichuan University, Chengdu city, China*.

Background: Peritoneal dialysis (PD) is one of the important treatment methods of end-stage renal disease (ESRD). Various techniques had been applied to the PD catheter insertion, including open surgery, laparoscopy and percutaneous techniques. However, the best technique, regarding both the catheter survival and catheter related complications, is still controversial. Previous studies did not compare the three techniques at the same time. Therefore, we did a systematic review and network meta-analysis to identify the best insertion method.

Methods: We systematically searched PubMed, Embase, Cochrane library, CNKI, WanFang and VIP database for randomized controlled trial, case-control study and cohort study until December 2017. Quality assessment and data extraction were conducted by two reviewers independently. We performed a direct meta-analysis and Bayesian network meta-analysis to pooled odds ratios (OR) or weighted mean differences (WMD) with 95% credible intervals (CrI) with random effects model. The node-splitting method was used to assess the inconsistency. We estimated the potential ranking probability of treatments by calculating the surface under the cumulative ranking curve for each intervention. Meta data is analysed by Addis software version 1.16.5.

Results: Forty studies involving 6494 patients were included (10 RCTs and 30 retrospective studies). The surface under the cumulative ranking curve (SUCRA) ranking from the network analysis showed that laparoscopy had the lowest occurrence of PD catheter displacement and obstruction, followed by percutaneous insertion and open surgery. Percutaneous insertion had the lowest occurrence of hernia, exit-site and tunnel infections. Open surgery had the lowest incident of bleeding.

Conclusions: Considering about the dysfunction of PD catheter, laparoscopy may be the best technique for PD catheter insertion. Different technique has the advantage of their own and more RCTs with larger sample size, comparing laparoscopy and percutaneous insertion directly are needed in the further.

Stakeholder Priorities for Remote Management in Peritoneal Dialysis

Lalita Subramanian,[1] Tony Cuttitta,[1] Rosalind H. Kirk,[5,1] Rachel Perlman,[2,1] Yanko Restovic,[4] Allison D. Jeter,[2,4] Rachel Tocco,[1] Kimberly Fox,[1] Nicholas W. Moore,[1] Jeffrey Perl,[3,1] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]UM Health Center, Ann Arbor, MI; [3]University of Toronto, Toronto, ON, Canada; [4]RM4PD project, Stakeholder Advisory Panel, Ann Arbor, MI; [5]Independent Qualitative Research Consultant, Edinburgh, United Kingdom.*

Background: Remote management (RM) technologies alert and enable health care providers to manage a range of health-related changes including remote follow-up, where appropriate. In this study, an Advisory Group including patients, social workers, nurses, nephrologists, alongside researchers, developed and reviewed interviews and responses from patients, care partners and clinicians on using remote management (RM) technologies that may influence priorities for patient care and engagement in peritoneal dialysis (PD) treatment for kidney failure.

Methods: Thirty semi-structured phone interviews were conducted in the United States and United Kingdom between October 2017 and January 2018. These aimed to assess effects of RM on PD treatment from patients', care partners' and clinicians' perspectives. NVivo11 was used to organize and analyze the data to identify remote management priorities. Sample quotes illustrating the variations in perspectives among the three groups are shown in Table

Results: Sample quotes illustrating the variations in perspectives among the three groups are shown in the Table. Clinicians tended to view RM as a tool with the potential to significantly change management and delivery of PD care while patients and care partners frequently perceived RM as having some benefits but not necessarily addressing some of the more immediate needs with their care.

Conclusions: There were variations in aspects of RM that were most valued by patients, care partners and clinicians. Opportunities for further technological innovations might exist in addressing patient and care partner priorities for PD care.

Table: Sample quotes on priorities for remote management and PD care

Clinician	"[RM enables us] to better understand how each of them dialyze, to be able to identify problems and to change how we manage our day... not necessarily burden families with unnecessary phone calls" "I really enjoy this because it [RM] does allow us to sort of dissect out all the important components of their prescription and then to discuss them with the family and give them some visual information as well to sort of compliment what we're telling them..." "...in that first phase there's a potential to be more gradual about introducing the treatment and more responsive to problems that the patient's experiencing, anticipating those sorts of problems. I think that's the potential benefit of remote technologies"
Patient	"It would be great if, ya know, you had your blood pressure cuff and that information could also be directly transmitted so you don't have to actually enter anything." "And the Smart machine tells you, it tells me when my treatment is going to be over, which is really good, I never knew with the other machine.." "...my car was going to be towed and he banged on my door and I couldn't even go to the door, you know and I realize I couldn't disconnect when I'm in dual mode... I'm on there nine hours, it's a long time to be trapped"
Care Partner	"If the RM enables us to individualize the treatment of care I would say maybe that would be a benefit..." "It [RM] does kind of cut down on the requirements for me to make sure that we are relaying all of his vitals and input and output for treatment." "..just maybe being able to, like, message, like, last night my husband was having some issues with severe itching so be able to maybe message the team and say 'hey he's having this, do we need to do something different, is this normal?'"

Comparison of Hospitalization Rate in Automatized Peritoneal Dialysis Patients with and Without Remote Management Program in Colombia

Angela S. Rivera,[3] Mauricio Sanabria,[2] Jasmin Vesga,[1] Adriana M. Suarez,[1] Alfonso Bunch.[1] *[1]RTS, Bogota, Colombia; [2]RTS Baxter, Bogota, Colombia; [3]Baxter, Bogota, Colombia*.

Background: The remote monitoring technology specifically designed to be integrated into APD systems (such as ShareSourceä, Baxter Healthcare) gives both patients and their clinical team a powerful tool that can enhance communication, potentially improve adherence to the treatment, optimize fluid balance; and address potential complications of therapy in near real-time. The purpose of this study was to compare the hospitalization rate in incident adult patients in Automated Peritoneal Dialysis (APD) with and without HomeChoice Claria® & Shaaresource®.

Methods: Multicenter observational retrospective cohort study in incident adult patients in Automated Peritoneal Dialysis (APD) with HomeChoice Claria and Sharesource®, enrolled between October 1st, 2016 to October 31th, 2017 with follow up of 1 year, in 46

renal clinics of the Renal Therapy Services (RTS) Colombia network. For the analysis, descriptive statistics and incidence rate were used

Results: 954 patients were evaluated, 56.6% were men, the mean age was 59.63 years (SD = 16.12). See table 1 We found a decrease statistically significant in days and hospitalization rate with the monitoring program for APD patients. Details are presented in table 2 y 3

Conclusions: A remote monitoring program for APD patients may be easily and efficiently implemented in healthcare settings improving clinical outcomes.

Funding: Commercial Support - Baxter Healthcare Corporation

Table1. Baseline clinical and demographic characteristics

Variables	With Claria N= 90 % N	Without Claria N= 864 % N
Age [mean;SD] year	56.83 17.14	59.92 15.99
Male	58.89 53	56.37 487
History Diabetes Mellitus	38.89 35	46.30 400
Charlson Index >= 4	13.33 12	13.43 116
Educational level		
None	8.89 8	17.13 148
Elementary school	23.35 21	41.09 355
High School/Technical diploma	50.00 45	33.8 292
University degree	17.78 16	7.99 69

Table 2. Hospitalization rate

Year	N	Person-Time (Years)	Events	Rate	95% CI		P
2017 without Claria	864	604.18	484	0.80	0.73	0.87	0.0159
2017 with Claria	90	71.7	41	0.57	0.41	0.77	

Table 3. Hospital days rate

Year	N	Person-Time (Years)	Days	Hospital days Rate	95% CI		P
2017 without Claria	864	604.18	4357	7.21	6.99	7.42	0.0000
2017 with Claria	90	71.7	394	5.49	4.96	6.06

Impact of Peritoneal Dialysis (PD) Remote Monitoring on PD Services

Heidy Hendra, Georgina J. Pharro, Sarah Lewis, Tina Mccornack, Gowrie Balasubramaniam. *Southend University Hospital NHS Foundation Trust, Chelmsford, United Kingdom.*

Background: Remote monitoring to manage renal patients is increasing. HomeChoice Claria with Sharesource™ (Baxter Healthcare Ltd) is a web-based, two-way connectivity platform enabling remote monitoring of automated peritoneal dialysis (APD). We introduced it in 10/2015 and reviewed it's impact after 12-months.

Methods: 48 patients were studied; median age 62.8 years (24 – 90), 30 males. Patients and clinical information were identified from the electronic patient records system and medical records. We investigated the number of patient on PD, months on treatment, outpatient attendances, remote consultations, home visits and staff travel. We also looked at take-up/ drop-off rates. Continuous variables were analysed by the independent samples t-test.

Results: Average number of patients on active PD increased by 14%, patient months on treatment increased by 12% as patients spent 4 months longer on treatment on average. Outpatient attendances increased by 34%. 60 remote consultations were performed, averaging 0.2 remote consultations/ patient/ month. The number of home visits per month increased by 41% and the visits per patient increased by 29%. The mean nurse mileage/ month increased by 57% and mileage/ patient/ month increased by 43% in 2015/16 (Results shown in Table 1). There was a net loss of 9 patients 12 months prior to implementation and a net gain of 2 patients 12 months after implementation.

Conclusions: More service was delivered with the same number of nursing staff. There was a rise in PD-related OP attendances per patient, mean home visits/ month and mileage/ patient in 2015/6; this may be due to increased visit for educational purposes during system exchange as data collected across the year showed a reduction. Further study involving longer period of observation is needed to validate the result.

Summary of results

	Pre ShareSource (01/10/14 – 30/09/15)	Post ShareSource (01/10/15 – 30/09/16)	p-value
No. patients on active PD (mean)	21.5	24.5	0.05
Number of months on treatment (mean)	32.8	36.8	0.001
Outpatient attendances/ month (mean)	61.6	82.3	0.08
No. home visits/ month (mean)	11.3	15.8	0.03
No. visits/ patient (mean)	0.5	0.7	0.42
Mileage/ patient/ month (mean)	6.4	9.2	0.07
Nurse mileage/ month (mean)	139	217.8	0.02
PD related blood tests/ month (mean)	36.8	36.1	0.89
PD catheter removal	9	6	
Net take on drop on-off rate	-9	+2

Cost Consequence Analysis of a Remote Monitoring Program to Improve Clinical Practice of Automatized Peritoneal Dialysis in Colombia

Juan G. Ariza,[1] Alfonso Bunch,[2] Mauricio Sanabria,[3] Angela S. Rivera,[4] Jasmin Vesga.[2] RTS Renal Therapy Services *[1]BAXTER, BOGOTA, Colombia; [2]RTS, Bogota, Colombia; [3]RTS Baxter, Bogota, Colombia; [4]Baxter, Bogota, Colombia.*

Background: To estimate from the payer perspective, the cost and clinical consequences of a Remote Monitoring (RM) standardized program, supported in *Claria Sharesource* technology, to improve the clinical practice and control of incident patients in automatized peritoneal dialysis (APD) currently treated in the Renal Therapy Services (RTS) setting in Colombia.

Methods: A one year Markov analytic model, structured in five health states, was used to project costs and clinical outcomes from a cohort of 100 APD patients with and without RM. Real world outcomes required as model inputs such as rates of hospitalization, peritonitis, technique failure and mortality were estimated from retrospective patient level registries and RTS medical records. Renal care ambulatory costs were estimated from referent national tariffs. Inpatient care costs were obtained from administrative database in a referent health care provider. Model results were reported as the RM incremental effect in: overall direct costs, patient months in control, one year persistence in APD, hospitalization episodes, days of hospitalization, peritonitis episodes, technique failure episodes and death episodes. Both deterministic and probabilistic sensitivity analyses were done to analyze the effect of information uncertainty in the model results.

Results: *In comparison with APD without RM, the implementation of a standardized RM program in 100 APD patients during one year resulted in*: Overall savings USD $ 16,169; 73 additional patient months in control; 25 hospitalization episodes avoided; 243 hospitalization days avoided; 17 peritonitis episodes avoided; 7 technique failure episodes avoided; 7 death episodes avoided and 13 additional patients persisted in APD technique after one year. *Deterministic sensitivity analysis*: RM tariff, hospitalization rate and hospitalization episode costs were the most sensitive drivers of model results. *Probabilistic sensitivity analysis:* With 66% of chance, the RM standardized program was a cost-saving dominant intervention.

Conclusions: From the payer perspective, RM is a cost saving dominant alternative, improving patient time in control, burden of hospitalization, risk of complications, persistence in APD technique and mortality.

Associations Between Use of a Patient Portal with Hospitalization Rates and Modality Failure in Peritoneal Dialysis Patients

Carlos Muchiutti, Bryan Fore, Sheetal Chaudhuri, Sophia Rosen, Hao Han, Marta Reviriego-Mendoza, John W. Larkin, Len A. Usvyat, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Peritoneal dialysis (PD) patients often have their clinical status assessed monthly, which limits the clinicians view of the patients' health state. A large dialysis provider has recently constructed a connected health program for PD patients to enter their clinical parameters or complaints daily. This portal provides automated alerts to clinicians for abnormal findings, as well as non-adherence with reporting. We analysed outcomes for hospital admission rate and modality failure in patients who were using the portal versus those who were not.
