KIDNEYWEEK 2018

San Diego, CA • Oct 23 – 28

Abstract Supplement

ASN LEADING THE FIGHT AGAINST KIDNEY DISEASE

KIDNEYWEEK 2018
San Diego, CA • Oct 23 – 28

Abstract Supplement

Abstract Publication
More than 4,600 abstracts are published in this supplement. Abstracts are arranged by the abstract type**, then by presentation date*, and then by chronological publication number. Abstracts with a "PUB" number will not be presented at the ASN Annual Meeting.

* TH = Thursday, FR = Friday, SA = Saturday
** OR = Oral, PO = Poster, PUB = Publication Only

The presenting author's name is underlined. For the poster sessions, the publication numbers and poster board numbers are the same.

Abstract Author Index
The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Keyword Index
The Keyword Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB) and then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Reference Format
To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 29, 2018: Page(s).

Abstract Experts
Abstract submissions were rigorously reviewed and graded by multiple experts. ASN thanks the abstract category chairs and reviewers for assistance with the abstract process. The ASN website lists all abstract experts.

Abstract Disclaimer and Copyright
The Abstract Issue of JASN® contains proprietary information belonging to the American Society of Nephrology (ASN). It is published as a service for the personal, noncommercial, and informational use only of its members and Kidney Week participants. Any commercial use is strictly prohibited. ASN's program materials and publications facilitate scientific discourse for educational purposes. ASN accepts no responsibility for any products, presentations, opinions, statements, or positions expressed, and inclusion of such material within Kidney Week and other ASN publications, or online postings does not constitute an endorsement by ASN.

ASN General Information

Kidney Week Program and Presentations
The Kidney Week program, which can be found on the ASN website and in the Kidney Week mobile app, includes:

- Plenary Sessions
- Basic/Clinical Science Sessions
- Clinical Practice Sessions
- Translational Sessions
- Special Sessions
- Educational Symposia
- Oral Abstract Sessions
- Poster Sessions

Extracellular DNA Drives Cholesterol Crystal Embolism-Related Tissue Injury

Chongxu Shi,[1] Shrikant R. Mulay,[1] Barbara M. Klinkhammer,[2] Helen Liapis,[3] Peter Boor,[2] Hans J. Anders.[1] *[1]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, Munich, Germany; [2]RWTH University Aachen, Aachen, Germany; [3]Missouri (Retired) and Arkana Laboratories, Pathology and Immunology School of Medicine, Washington University, Washington, WA.*

Background: Cholesterol crystal (CC) embolism may be an under recognized cause of acute kidney injury (AKI), especially of catheter intervention- or major surgery- related AKI. Little is known about the pathophysiology of CC embolism-related for the lack of animal models.

Methods: Injecting CC into the left renal artery of C57BL/6N, M*lkl*-/- and *CypD*-/- mice, transcutaneous measurement of GFR after CC injection 24h, quantify renal tubular and endothelial cell injury, crystal clot formation inside arteries, quantify the occlusion of renal arteries of varies sizes. Neutrophil depletion and DNase I interventions were used on mice before CC injection, all experiments same as descripted before.

Results: CC injection to mice caused a sudden drop in glomerular filtration rate (GFR) associated CC embolism and crystal clot formation leading to either partial CC or complete occlusion of numerous *interlobar arcuate*, and *interlobular arteries* documented by histology and 3D reconstructions of vascular contrast micro-CT scans. 24h after CC injection partial obstruction was associated with ischemic necrosis of respective tubular S3 segments, while complete obstruction caused large territorial infarction. Such infarcts were surrounded by massive neutrophil infiltrates apparently also derived from vessels of the renal capsule (rim sign). Necroptosis and mitochondrial permeability transition-related regulated necrosis are known to drive post-ischemic AKI but lack of *Mlkl, CypD* or both had no effect on GFR loss or infarct size probably because crystal clot obstruction remained unaffected. Crystal clots stained positive for platelets, neutrophils, fibrin, and DNA. While neutrophil depletion only partially attenuated GFR loss and infarct size recombinant DNAse I was fully protective as it reduced the number of complete vascular occlusion. *In vitro* studies revealed that CC induce membrane rupture and DNA release from endothelial cells, neutrophils, and platelets and that CC-induced activation of platelets induces neutrophil extracellular traps formation. CC embolism was found in 446 of 92,000 diagnostic kidney biopsies (0.5%).

Conclusions: CC embolism activates numerous cell types to release DNA, which is a central component of crystal clot formation, vascular occlusion, and kidney infarct-related AKI.

Mitochondrial DNA Leakage Causes Inflammation via the cGAS-STING Axis in Cisplatin-Mediated Tubular Damage

Hiroshi Maekawa,[1,2] Tzu-Ming Jao,[3] Reiko Inoue,[1] Hiroshi Nishi,[1] Tsuyoshi Inoue,[1,2] Masaomi Nangaku,[1] Reiko Inagi.[2] *[1]Div of Nephrol and Endocrinol, The Univ of Tokyo Grad Sch of Med, Tokyo, Japan; [2]Div of CKD Pathophysiol, The Univ of Tokyo Grad Sch of Med, Tokyo, Japan; [3]National Taiwan University Hospital, Taipei, Taiwan.*

Background: Cisplatin is an anti-neoplastic drug that induces tubular inflammation. However, its detailed mechanisms are not fully understood. Stimulator of interferon genes (STING) and its upstream or downstream molecules (cGAS-STING axis) play an important role in 3self/non-self DNA-triggered signal transduction, leading to inflammation. Here, we investigated the potential role of STING-mediated inflammation in cisplatin-induced tubular inflammation.

Methods: The human proximal tubular cell line, HK-2, was treated with 10 μM of cisplatin and the renal cortex of C57BL/6 mice, injected with 25 mg/kg of cisplatin for 72 h, was analyzed. The changes in cGAS-STING activation, mitochondrial DNA (mtDNA) leakage, or BAX expression were evaluated using real-time PCR, western blotting, or immunofluorescence analysis. Cisplatin and/or STING siRNA-treated HK-2 culture supernatants were analyzed using cytokine arrays and migration assays. Amlexanox and ethidium bromide (EtBr) were used for cGAS-STING axis inhibition and mtDNA depletion, respectively.

Results: In cisplatin-treated HK-2 or kidney cortex, STING expression was upregulated and translocated from the ER to the Golgi apparatus, indicating STING activation by cisplatin. Subsequently, the cGAS-STING axis(TBK-1, IRF3, and P65) was activated due to cisplatin-mediated phosphorylation. Cisplatin also induced inflammatory cytokine(IL-6, IL-8, ICAM-1, CXCL10, and GMCSF) production and neutrophil chemotaxis, which were ameliorated by STING knockdown ($P < 0.05$). Amlexanox prevented cytokine production via cGAS-STING axis inhibition (IRF3 inactivation). Interestingly, cisplatin-mediated mtDNA leakage to the cytosol activated cGAS-STING axis-mediated inflammation. In fact, EtBr-mediated mtDNA depletion inhibited the inflammation by cisplatin in HK-2. Cisplatin-induced BAX expression, which interacted with the mitochondrial permeability transition pore, suggested that mtDNA leakage was caused by the increase in BAX expression.

Conclusions: mtDNA leakage to the cytosol induces tubular inflammation by activating the cGAS-STING axis in cisplatin nephrotoxicity.

Knockout of DNA Methyltransferases in Proximal Tubules Preserves Klotho and Improves Kidney Repair after Ischemia/Reperfusion Injury

Chunyuan Guo,[1] Qingqing Wei,[1] Man J. Livingston,[2] Zheng Dong.[3] *[1]Medical College of Georgia, Augusta University, Augusta, GA; [2]Augusta University Medical College of Georgia, Augusta, GA; [3]Medical College of Georgia, Augusta, GA.*

Background: DNA methylation, catalyzed by DNA methyltransferases (DNMTs), is an important epigenetic mechanism that has been implicated in renal development, function, and disease pathogenesis. However, the role of DNA methylation in renal ischemia/reperfusion (I/R) injury and subsequent kidney repair remains largely unknown.

Methods: Mice were subjected to: i) 30 minutes of bilateral renal ischemia with 48 hours of reperfusion to examine renal I/R injury, and ii) 30 minutes of unilateral renal ischemia with 2 weeks of reperfusion to analyze post-injury kidney repair. To determine the role of DNA methylation, we established kidney proximal tubule-specific DNMT1 knockout (PT-DNMT1-KO) or DNMT1 and DNMT3a double knockout (PT-DNMT1/3a-DKO) mouse models.

Results: DNMT1 and DNMT3a were markedly increased in renal tubular cells during renal I/R injury as well as post-injury kidney repair. Knockout of DNMT1 or knockout of both DNMT1 and DNMT3a in proximal tubules did not affect renal I/R injury. However, DNMT1 and DNMT3a double knockout (PT-DNMT1/3a-DKO) promoted post-injury kidney repair and attenuated renal fibroblast activation and interstitial renal fibrosis. Two weeks after I/R injury, PT-DNMT1/3a-DKO mice showed lower kidney injury molecule-1 (Kim-1) and vimentin expression than wild type mice, suggesting better kidney repair in DKO mice. Furthermore, DKO mice showed less accumulation of fibronectin and α-SMA (myofibroblast marker) with lower levels of collagen deposition in kidneys, indicating less interstitial fibrosis. Mechanistically, post-injury kidneys showed hypermethylation of Klotho, the anti-aging gene with anti-fibrosis activity. Hypermethylation of Klotho was accompanied by a dramatic decrease of Klotho expression in kidneys. Notably, DNMT1/3a-DKO prevented Klotho hypermethylation and preserved Klotho expression in post-injury kidneys.

Conclusions: These results indicate that DNMT1 and DNMT3a-dependent DNA methylation in proximal tubules plays an important role in kidney repair following renal I/R. Changes in DNA methylation in specific genes, such as Klotho, may lead to aberrant gene expression to promote maladaptive repair and interstitial fibrosis.

Orphan Nuclear Receptor COUP-TFII Regulates Pericyte Detachment in AKI

Li Li, Pierre Galichon, Takaharu Ichimura, Joseph V. Bonventre. *Brigham and Women's Hospital/Harvard Medical School, Boston, MA.*

Background: Pericytes are essential to maintain capillary integrity. Acute kidney injury (AKI) causes pericyte detachment from capillaries, triggering endothelial cell injury, capillary rarefaction, and hypoxia, contributing to interstitial fibrosis. The molecular mechanisms underlying pericyte detachment and subsequent transition to myofibroblasts are poorly understood. We hypothesized that Chicken Ovalbumin Upstream Promoter-Transcription Factor II (COUP-TFII) is important for maintaining kidney pericyte function by preventing detachment/activation in the setting of kidney injury.

Methods: COUP-TFII mRNA was measured by quantitative real-time PCR (qRT-PCR) and protein by immunostaining at different times after unilateral ischemia reperfusion (IRI). In vitro, knockdown of COUP-TFII was attained by transfecting a small interfering RNA (siRNA) into CH310T1/2 (pericyte-like cells). Angiopoietin 1 (Ang1, a angiotrophic protein produced by pericyte to maintain vessel stability) expression was evaluated. In addition, we generated CRISPR-cas9 COUP-TFII knock out and tetracycline-inducible COUP-TFII overexpressing CH310T1/2 cells. By modulating COUP-TFII expression, we studied the effect on αSMA expression (a marker of myofibroblast) and cell migration (using scratch motility assay) in CH310T1/2 cells.

Results: COUP-TFII mRNA and protein expression initially decreased at 4 hours after IRI, returned to baseline at 24 hours, and was significantly increased at day 21 post-IRI. In vitro, knockdown of COUP-TFII by siRNA resulted in decreased Ang1 expression in CH310T1/2 cells. Furthermore, knock out of COUP-TFII resulted in increased αSMA mRNA expression and promoted migration compared to wild type CH310T1/2 cells. In contrast, over-expression of COUP-TFII decreased αSMA mRNA expression and inhibited migration compared to control-transfected cells.

Conclusions: Down regulation of COUP-TFII in AKI is an early event regulating pericyte fate. It results in: 1) decreased Ang1 expression, which is important for pericyte-endothelial crosstalk; 2) increased αSMA expression and cell migration, which is important for the pericyte to myofibroblast transdiferentiation. Maintaining COUP-TFII expression may stabilize pericytes, protect endothelial cells in the early phase of AKI, and prevent vascular rarefaction, secondary ischemia and subsequent fibrosis.

The Orphan Nuclear Receptor RORα Is a Potential Endogenous Protector in Renal Ischemia/Reperfusion Injury

Jieru Cai. *Zhongshan Hospital, Fudan University, Shanghai, China.*

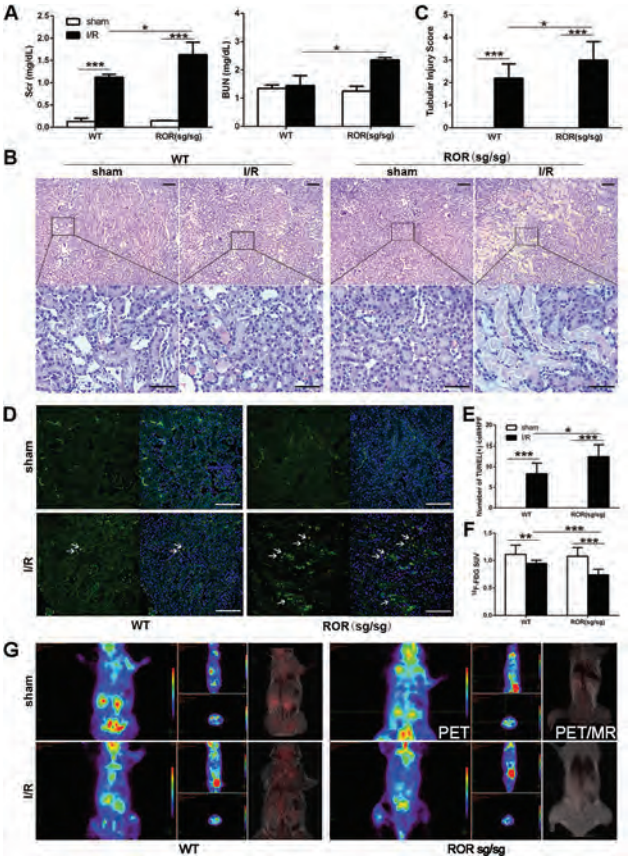
Background: Emerging evidence indicates that retinoid-related orphan receptor alpha (RORα), a member of the ROR nuclear receptor (NR) subfamily, mediates key cellular adaptions to hypoxia and contributes to the pathophysiology of many disease states. However, the effects of RORα in renal ischemia/reperfusion (I/R) injury remain unclear.

Methods: Wild-type C57BL/6 mice, ROR-deficient stagger [ROR (sg/sg)] mice and their wild-type (WT) littermates were used for in vivo studies. Renal I/R injury model was induced by bilateral renal pedicle clamping for 35 minutes. HK-2 cells and human kidney samples were used for in vitro studies. HK-2 cells were treated with hypoxia (1% oxygen) to establish the cell hypoxia/reoxygenation (H/R) model.

Results: We found that RORα was significantly down-regulated after renal I/R injury. RORα-deficient stagger mice displayed dramatically augmented renal dysfunction and morphological damage compared with wild-type (WT) mice at 24 hours post-I/R. Further study revealed that the detrimental effects of RORα deficiency were attributable to tubular epithelial cell apoptosis and, consequently, renal inflammation and oxidative stress. The proapoptotic effect of RORα deficiency was associated with aggravated mitochondrial dysfunction in renal tubular cells after I/R. However, pretreatment of WT mice with the RORα agonist SR1078 ameliorated I/R-induced renal dysfunction and damage and elicited a concomitant decrease in tubular epithelial cell apoptosis.

Conclusions: In summary, our study provides experimental evidence showing that RORα is a novel endogenous protector against renal I/R injury and that RORα activation is a promising therapeutic strategy for the prevention of acute kidney injury.

Funding: Government Support - Non-U.S.



RORα deficiency aggravates renal injury at 24 hours post-I/R.

Stress Response Gene NUPR1 Protects Renal Tubular Cells from Proliferation-Induced Energy Exhaustion

Pierre Galichon, Li Li, M. Todd Valerius, Joseph V. Bonventre. *Brigham and Women's Hospital/Harvard Medical School, Boston, MA.*

Background: Energy depletion in renal tubular cells is a hallmark of acute kidney injury associated with cell death. *NUPR1* (Nuclear protein 1, transcriptional regulator) promotes survival, increases ATP and inhibits proliferation in renal tubular cells. Although proliferation of tubular cells is necessary for kidney repair after resolution of injury, it could increase vulnerability in the context of ongoing injury. The effect of proliferation on energy in cells is unknown. We hypothesized that *NUPR1* protects renal tubular cells from proliferation-induced energy exhaustion.

Methods: Stable renal proximal tubular cell lines were generated from HK-2 cells with inducible expression of *NUPR1* (gain-of-function) or of CRISPR-dCas9-KRAB repression of *NUPR1* (loss-of-function). The cells were transfected with the fluorescent biosensor PercevalHR to visualize the intracellular ATP/ADP ratio and with the intracellular pH sensor pHRed to adjust the ATP/ADP measures. The RatioPlus plugin from Fiji was used to measure ATP/ADP and pH from dual wavelength acquisitions of PercevalHR and pHRed, and the TrackMate plugin was used for monitoring single cell trajectories. The effect of tenovin-1 (p53 agonist for G1/S arrest), rigosertib (PLK1 inhibitor for G2/M arrest), pifithrin-α (p53 inhibitor for G1/S passage) and KU55933 (ATM kinase inhibitor for G2/M passage) on the ATP/ADP ratio was assessed.

Results: *NUPR1* overexpression increased the ATP/ADP ratio in tubular cells. Conversely, *NUPR1* inhibition decreased the ATP/ADP ratio. Modeling proliferative repair after injury by a scratch assay or facilitation of cell cycle passage by pifithrin-α or KU55933 decreased ATP/ADP ratio in migrating and proliferating cells. In contrast, inhibition of proliferation by either contact inhibition, tenovin-1 or rigosertib recapitulated *NUPR1*'s protective effect on ATP/ADP levels. Proliferating cells undergo cyclic variations of the ATP/ADP ratio, with a mitotic peak followed by a sudden drop of ATP/ADP ratio and a gradual recovery.

Conclusions: *NUPR1* protects renal tubular cells from energy depletion caused by proliferation. Proliferation is associated with decreased energy, characterized by cyclic steep diminution of ATP/ADP ratio after mitosis. Delaying proliferation is a potential therapeutic goal to minimize damage during acute kidney injury and prevent maladaptive repair after injury.

C-Type Lectin Mincle Accelerates Renal Ischemia-Reperfusion Injury

Miyako Tanaka,[1,2] Marie Saka-Tanaka,[1,3] Naotake Tsuboi,[3] Shoichi Maruyama,[3] Takayoshi Suganami.[1,2] *[1]Department of Molecular Medicine and Metabolism, Research Institute of Environmental Medicine, Nagoya University, Nagoya, Japan; [2]Department of Immunometabolism, Nagoya University Graduate School of Medicine, Nagoya, Japan; [3]Department of Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Evidence has accumulated suggesting that pathogen sensors such as Toll-like receptors contribute to the pathogenesis of various non-infectious diseases. It is also known that Macrophage-inducible C-type lectin (Mincle), a pathogen sensor for *Mycobacterium tuberculosis*, can sense cell death, suggesting the role of Mincle in sterile inflammation. Indeed, we recently demonstrated that Mincle plays an important role in obesity-induced adipose tissue inflammation, thereby regulating systemic insulin resistance. In this study, we investigated the pathophysiologic role of Mincle in a mouse model of acute kidney injury.

Methods: Eight to eleven week-old male Mincle-deficient mice or wildtype mice were subjected to ischemia-reperfusion injury. After 30 minutes of ischemic period, the clamp of left kidney was released to induce reperfusion. The right side of kidney was resected at this time point.

Results: There was a marked upregulation of Mincle mRNA in the injured kidney from 6 hours after the reperfusion. Histological and flow cytometric analysis revealed that most of the Mincle-expressing cells were proinflammatory M1 macrophages infiltrating toward the damaged tubules. All of the Mincle-deficient mice were alive during the experimental period, while about half of wildtype mice died due to renal failure. Consistently, serum concentrations of BUN and creatinine along with mRNA expression of proinflammatory cytokines were significantly ameliorated in the kidney of Mincle-deficient mice compared to wildtype mice. Moreover, wildtype mice were protected against ischemia-reperfusion injury when they received bone marrow transplantation from Mincle-deficient mice.

Conclusions: This study indicates that Mincle in macrophages plays an important role in the pathogenesis of acute kidney injury. Our data also suggest that Mincle senses damaged tubular epithelial cells to accelerate inflammation.

TH-OR008

Novel Liposomal Nanocarriers of Preassembled Glycocalyx Restore Renal Microcirculation in Sepsis

Michael S. Goligorsky, Dong Sun. *New York Medical College, Valhalla, NY.*

Background: Endothelial cell dysfunction is a weighty contributor to the pathogenesis of sepsis. Endothelial glycocalyx (EG) is a guardian of endothelial functions, but during the course of sepsis its integrity is compromised. We observed that mice with the polymicrobial sepsis exhibit a drastic reduction in the global volume of EG. The loss of EG leads to leukocyte infiltration, impaired microvascular circulation, increased vascular permeability, thrombogenesis, and circulatory collapse, eventuating in the development of multiorgan dysfunction. Therapeutic attempts to prevent EG loss showed success, however, clinically more important restorative therapies of EG have been unsuccessful.

Methods: We have recently invented liposomal nanocarriers of preassembled EG (LNPEG) to expeditiously restore EG and halt vascular complications of sepsis. We used atomic force microscopy, DAF-based NO detection, flow-induced vasodilation and in vivo LPS Laser-Doppler studies.

Results: In vitro testing of LNPEG using atomic force microscopy of cultured endothelial cells showed that they increased thickness of EG and restored mechanoactivation-induced NO production, both severely affected by exposure to LPS. Ex vivo perfused isolated arterioles with degraded EG obtained from LPS-injected mice showed subnormal flow-induced dilation and exhibited increased vascular permeability, whereas perfusion of these vessels with LNPEG restored both and increased flow-induced NO production. In LPS mice,

infusion of LNPEG either systemically or into the renal artery significantly improved renal microcirculation (laser-Doppler imaging and flowmetry). Electron microscopy of kidneys localized LNPEG to be tethered to or embedded into the plasma membrane of glomerular and peritubular capillary endothelial cells. Immunostaining of EG showed its significant restoration after administration of LNPEG.

Conclusions: In conclusion, this is the first demonstration that our invented LNPEG are functionally capable of expeditiously restoring EG and halting vascular complications of sepsis. In summary, wepropose that the early loss of EG facilitates multiorgan failure in sepsis, and treatment with LNPEG has a potential to alleviate it.

TH-OR009

Human Recombinant Alkaline Phosphatase (recAP) Protection from Kidney Ischemia-Reperfusion Injury (IRI) Is Mediated by Dephosphorylation of ATP to Adenosine and Activation of Adenosine A2a Receptors

Diane L. Rosin,[5] James P. Hall,[3] Andrea G. Bree,[3] Shuqiu Zheng,[1] Iain M. Encarnacion,[1] Andrea van Elsas,[4] Bruce A. Molitoris,[2] Mark D. Okusa.[1]
[1]Division of Nephrology and Center for Immunity, Inflammation and Regenerative Medicine, University of Virginia School of Medicine, Charlottesville, VA; [2]Division of Nephrology, Indiana University School of Medicine, Indianapolis, IN; [3]Inflammation & Immunology Research Unit, Pfizer Inc., Cambridge, MA; [4]AM-Pharma B.V., Bunnik, Netherlands; [5]Department of Pharmacology, University of Virginia School of Medicine, Charlottesville, VA.

Background: Acute kidney injury (AKI) results in high mortality (up to 50%), and surviving patients are at risk for progressive chronic kidney disease (CKD). ATP released from dying cells acts as a potent pro-inflammatory 'danger' signal. Alkaline phosphatase (AP), a common endogenous enzyme that de-phosphorylates ATP, appears to play a significant anti-inflammatory role in host defense and innate immunity. Human recombinant AP (recAP) is currently in Phase 2 clinical trials for treatment of sepsis-associated AKI. We hypothesized that recAP protects kidneys from IRI by metabolizing released extracellular ATP to adenosine, producing anti-inflammatory effects through activation of adenosine A2a receptors (A2aR).

Methods: RecAP (500-2000 U/kg, iv) ± ZM-241,385 (ZM, 20, 200 mg/kg, sc) (adenosine A2a receptor antagonist) were administered 1h before renal ischemia in mice and at times after ischemia in rats; kidney injury in mice was evaluated at 24h.

Results: RecAP dose-dependently decreased kidney injury in WT mice after 26 min ischemia; the 80% decrease in plasma creatinine with 2000 U recAP/kg was prevented completely by co-administration with ZM (20 mg/kg). Enzymatically inactive (mutant) recAP was not protective, suggesting that ATP dephosphorylation is necessary for protection. RecAP also protected *CD73*$^{-/-}$ mice, which lack a 5' ectonucleotidase that de-phosphorylates AMP to adenosine and are more sensitive to IRI than WT mice (22 min ischemia); this beneficial effect of recAP in *CD73*$^{-/-}$ mice (34% of control) was partially blocked by 200 mg/kg ZM (86% of control). In rats recAP ameliorated IRI when administered *after* initiation of acute injury, an effect reversed by ZM, thus providing relevance for therapeutic dosing of recAP clinically. In a CKD ischemic rat model, recAP given after the 3rd instance of IRI also significantly reduced renal injury (61% reduction).

Conclusions: These results strongly suggest that during renal IRI recAP promotes production of adenosine from liberated ATP in injured kidney tissue, thereby amplifying endogenous mechanisms that can reverse tissue injury, in part through A2aR-dependent anti-inflammatory signaling pathways.

Inactivation of Mtorc1 in Proximal Tubular Epithelial Cells Reduces KIM-1-Mediated Kidney Fibrosis and Inflammation in Mice

Wenqing Yin,[1] Craig R. Brooks,[2] M. Todd Valerius,[3] Joseph V. Bonventre.[1]
[1]Brigham and Women's Hospital, Boston, MA; [2]Vanderbilt University Medical Center/Division of Nephrology & Hpertension, Nashville, TN; [3]Brigham and Women's Hospital, Boston, MA.

Background: Acute kidney injury (AKI) predisposes patients to progressive chronic kidney disease (CKD). Previously we reported that persistent expression, beginning prenatally, of kidney injury molecule-1 (KIM-1) in tubule epithelial cells of the nephron causes murine kidney fibrosis through a mechanism involving mTOR. Since prenatal activation of KIM-1 in this system also decreases nephron number, we tested the hypothesis that postnatal activation of KIM-1 expression specifically in proximal tubular cells (PTCs) would lead to fibrosis independent of any potential effect on kidney development, and evaluated the role of mTOR in this context.

Methods: We created proximal tubular cell specific KIM-1 overexpression transgenic mice by treating Slc34a1$^{CreERT2/+}$;CAG-Z/Kim1-AP$^{tg/+}$ (KIM-1^{PTCtg}) mice with tamoxifen beginning at 4 weeks of age to express KIM-1 in proximal tubules in a postnatal, post kidney development, context. The resulting KIM-1^{PTCtg} mice (and non-KIM-1 overexpression controls) were subjected to bilateral renal ischemia-reperfusion injury (IRI) for 26 minutes, or sham surgery, at 3 months of age and then evaluated at 3 or 6 months later for kidney fibrosis. We also created KIM-1^{PTCtg}/Raptor^{PTCko} mice, where mTORC1 is deleted at 4 weeks of age in KIM-1 overexpressing PTCs, using the same tamoxifen-inducible promoter, and these animals were then evaluated for kidney fibrosis with or without bilateral IRI.

Results: With tamoxifen-induced postnatal KIM-1 overexpression in proximal tubular cells, KIM-1^{PTCtg} mice developed fibrosis with progressive renal insufficiency at 6 months of age. Bilateral IRI in KIM-1^{PTCtg} mice at 3 months of age caused maladaptive repair and a persistence of renal insufficiency post injury, leading to progressive kidney fibrosis and renal failure with an earlier onset (5 months of age) than sham controls. In contrast, KIM-1^{PTCtg}/Raptor^{PTCko} mice subjected to bilateral IRI had less kidney fibrosis and a reduced inflammatory response, demonstrating a role for mTOR in the fibrotic response.

Conclusions: Persistent expression of KIM-1 may play an important role on the link between AKI and progressive CKD. mTORC1 is a potential therapeutic target in KIM-1-mediated kidney injury and fibrosis in mice.

Funding: NIDDK Support, Other U.S. Government Support

TH-OR011

The Hyaluronan Synthase-1 Isoenzyme Promotes Differentiation to a Distinct Subset of Myofibroblasts That Limit Fibrosis Progression

Aled P. Williams,[3,1] Adam C. Midgley,[2,1] Charlotte V. Brown,[3,1] Talea H. Roberts,[3,1] Nathanael G. Morris,[3,1] Robert Steadman,[3,1] Aled O. Phillips,[3,1] Soma Meran.[3,1]
[1]Cardiff University, Llanelli, United Kingdom; [2]Nankai University, Tianjin, China; [3]Wales Kidney Research Unit, Cardiff, United Kingdom.

Background: Renal interstitial fibrosis is a key determinant of CKD progression, and increased synthesis of the glycosaminoglycan, Hyaluronan (HA), in renal tissue correlates with fibrosis and renal outcomes. Factors that regulate HA synthesis therefore influence CKD progression. HA is synthesized by three HA Synthase enzymes (HAS1, HAS2 and HAS3). Our work has specifically shown that increased HAS2 expression is causally linked with fibrosis *in vivo* and is a critical mediator of pro-fibrotic cell phenotype *in vitro*. Furthermore, the anti-fibrotic growth factor BMP7 (Bone Morphogenetic Protein-7) prevents/reverses pro-fibrotic cell phenotype and renal fibrosis in murine models. Recent data shows BMP7 significantly increases HAS1 expression, indicating a possible protective role for this enzyme in fibrosis

Methods: Studies were performed on human proximal tubular epithelial cells our established library of scarring *versus* non-scarring primary fibroblasts. Genetic and histological analysis of kidneys from HAS1, HAS3 and HAS1/3 double knockout mice and Ischaemia Reperfusion Injury (IRI) -induced renal fibrosis were used

Results: In response to TGF-β1, cells primarily expressing the HAS2 isoenzyme assembled large pericellular HA coats tethered to the principal HA receptor CD44-standard. The cells were significantly α-smooth muscle actin (αSMA) positive and had a contractile phenotype. TGF-β1 stimulation in HAS1 isoenzyme expressing cells had negligible HA pericellular coats and enhanced cell-surface expression of the CD44 variant isoform, CD44v7/8. These cells had a limited contractile response, were pro-migratory, with low αSMA expression and laid down different matrix. Mice with IRI have elevated levels of both HAS1 and HAS2 in acute early injury, and HAS2 in late injury; whilst kidneys from HAS1/3 DKO mice were predisposed to pro-fibrotic renal injury

Conclusions: Different HAS isoenzymes have distinct and likely conflicting roles in response to pro-fibrotic stimuli. Whilst HAS2 promotes a pro-fibrotic contractile cell phenotype associated with tissue fibrosis, HAS1 appears to limit pro-fibrotic phenotypes and promotes a distinct subset of myofibroblasts that are pro-migratory and may be involved in reparative processes that limits fibrotic injury

TH-OR012

PINK1-MFN2-Parkin-Mediated Mitophagy Dependent Macrophage Reprogramming Protects against Renal Fibrosis

Divya Bhatia,[1] Kuei-Pin Chung,[1,2] Thangamani Muthukumar,[1] Augustine M. Choi,[1] Mary E. Choi.[1]
[1]Weill Cornell Medicine, New York City, NY; [2]National Taiwan University Hospital, Tapei, Taiwan.

Background: Mitophagy, by maintaining mitochondrial quality, plays critical role for normal kidney function. Kidney injury-induced mitochondrial oxidative stress triggers proinflammatory cytokine production by M1 macrophages and their reprogramming towards profibrotic/M2 phenotype. We investigated the role of mitophagy regulatory proteins: PTEN-induced kinase1 (PINK1), Mitofusin 2 (MFN2) and Parkin in macrophage reprogramming during renal fibrosis.

Methods: Renal fibrosis in wild type, PINK1 and Parkin knockout (KO) mice was induced by unilateral ureteral obstruction (UUO) (7-days) or adenine diet (14-days). Renal macrophages from mice and human kidneys were isolated by magnetic beads. Flow cytometry (F4/80, CD11b, Ly6c, CCR1, CX3CR1) and western blots (iNOS, arginase I, mannose receptor-1, fibronectin, rictor, TGFβ1, TGFβR1) were performed to determine macrophage phenotypes and fibrotic response. MitoTracker & MitoSox dyes were used to access mitochondrial membrane potential (MMP) and reactive-oxygen species (mROS). Mitophagy was suppressed by transfection of PINK1-siRNA/Mdivi1 or induced by FCCP treatment.

Results: Obstructed kidneys from PINK1/Parkin KO mice displayed higher expression of FN, MR-1, TGFβ1, TGFβRI & CD45+ mononuclear cells. Renal macrophages from obstructed kidneys of KO mice showed amplified fibrotic response. TGFβ1-treated BMDM from the KO mice displayed greater levels of mROS, rictor, Arg I but not iNOS expressing M1 macrophages. PINK1-knockdown THP-1 human macrophages showed lower phosphorylation at MFN2. Mitochondria from FCCP treated MFN2-KO macrophages showed reduced expression of Parkin and lower MMP. Inhibition of mitophagy in human primary renal macrophages resulted in: i) elevated expression of FN, MR-1, TGFβ1 & CX3CR1, ii) reduced MMP & iii) enhanced mROS production. Human fibrotic kidney showed higher relative mRNA expression of MRC1 (P=0.002), TGFβ1 (P=0.03) and a trend of decrease in Parkin (P=0.07) expression than control kidney.

Conclusions: UUO and adenine diet-induced oxidative stress and renal fibrosis were exaggerated in absence of mitophagy. Deficiency of PINK1 in macrophages resulted in decreased phosphorylation of MFN2, suppressed recruitment of Parkin to mitochondria and rictor-mediated reprogramming of macrophages towards M2/profibrotic phenotype.

Loss of Transcription Factor A (Mitochondrial, Tfam) in Tubule Cells Causes Renal Failure by Linking Metabolic Insufficiency to Enhanced Inflammation

Kiwung Chung, Shizheng Huang, Rojesh Shrestha, Chengxiang Qiu, Jihwan Park, Katalin Susztak. *University of Pennsylvania, Philadelphia, PA.*

Background: Renal tubule cells have one of the highest mitochondrial density to keep up with their high energy need. Loss and dysfunction of mitochondria has been proposed to play key role in kidney disease development. On the other hand, the key transcriptional regulator that maintains mitochondrial integrity in renal tubule cells of healthy kidneys have not been defined.

Methods: To investigate the role of Tfam on renal tubule epithelial cells (TECs), we generated and characterized tubule specific Tfam (Transcription Factor A, mitochondrial) knock-out mice (Ksp cre/Tfam $^{flox/flox}$). To perform *in vitro* mechanism studies, we cultured primary TECs from wild-type and WT/Tfam $^{flox/flox}$ mice and infected them with Ad5CMVCre adenovirus to delete Tfam.

Results: Tfam deficient mice were viable at birth but they died by 12 weeks of age. Blood chemistry indicated significant renal damage and azotemia. Structurally, the kidneys were enlarged, the tubules were dilated. There was an increase in inflammatory cells and matrix accumulation. Renal epithelial cells showed abnormally enlarged mitochondria and structural defect. Mitochondrial oxidative phosphorylation associated proteins were decreased with mild lipid accumulation. Mechanistic studies, using primary cultured tubule epithelial cells demonstrated that aberrant mtDNA packaging upon Tfam deficiency results in an escape of mtDNA into the cytosol. These events induced the activation of cytosolic DNA sensing pathway such as Stimulator of interferon genes (STING)-Cyclic GMP-AMP synthase (cGAS), and downstream NF-κB activation. The NF-κB activation was also evident in kidneys of the knock-out mice. Blunting of the NF-κB activation, reduced inflammatory gene expression, proliferation of tubule cells and protected from cellular dedifferentiation.

Conclusions: Collectively, we show Tfam maintains mitochondrial integrity and cellular metabolism at baseline. Loss of Tfam results in NF-κB activation linking metabolic signals to inflammation.

Novel Rho-Associated Coiled Kinase 2 Inhibitor (ANG4201) Reduces Renal Fibrosis and Improves Kidney Function in Subtotal Nephrectomy Mice Model

Quaisar Ali,[1] Dibyendu Dana,[1] Prakash Narayan,[2] An-Hu Li,[1] Satishkumar V. Gadhiya,[1] Jingsong Li,[1] Dong sung Lim,[1] Dawoon Jung,[1] Latha Paka,[2] Michael A. Yamin,[1] Itzhak D. Goldberg.[1] *[1]Angion Biomedica Corp., Uniondale, NY; [2]Angion Biomedica Corp, Uniondale, NY.*

Background: Rho associated coiled kinase 1 (ROCK1) and 2 (ROCK2) are implicated in variety of cellular processes including organ fibrosis. Earlier we demonstrated that kidney ROCK2 and not ROCK1 is upregulated in animal models of renal fibrosis. The present study was done to investigate if inhibiting ROCK2 reduces renal fibrosis and improves kidney function.

Methods: Using core hopping and structure based drug design approach, we synthesized highly selective (>200 fold for ROCK2 vs ROCK1), orally bioavailable ROCK2 inhibitor (ANG4201). We evaluated the antifibrotic effects of ANG4201 in subtotal nephrectomy (Nx) mice model. Adult male SV129 mice were subjected to Nx, wherein poles of one kidney were ablated and contralateral kidneys were removed after two weeks. The Nx were then randomized to vehicle or ANG4201 (20 mg/Kg, PO, BID) and treated for 8 weeks. A week prior to sacrifice, GFR was measured by using FITC-Inulin clearance method. Blood pressure was measured by direct cannulation of the carotid artery. Kidney tissues were analyzed for fibrotic, molecular and inflammatory markers.

Results: Compared to control, Nx mic exhibited increase in both renal ROCK2 expression and phosphorylation of myosin phosphatase, a downstream marker of ROCK2 activity. Treating Nx mice with ANG4201 blocked the upregulation of these proteins. The increase in ROCK2 activity correlated with increase in renal fibrosis characterized by increase in kidney hydroxyproline and α-SMA expression. Nx mice also had elevated blood pressure (MAP; ~165 mm Hg). Intervention with ANG4201 did not affect blood pressure but attenuated hydroxyproline and α-SMA expression which were confirmed with Mason's trichrome and Picrosirius red staining. The reduction in fibrosis was associated with significant improvement in GFR by ~38%, measured by FITC-Inulin clearance method. Urinary EGF, marker of renal function loss was found to be elevated in Nx and subsequently reduced with ANG4201 treatment.

Conclusions: This study demonstrates that ROCK2 upregulation contributes to renal fibrosis and renal functional loss in subtotal nephrectomy mice model. ANG4201 is highly promising orally bioavailable therapeutic ROCK2 inhibitor with potential use in chronic kidney disease.

Inhibition of Tubulointerstitial Fibrosis by Targeting the p70 Ribosomal Protein S6 Kinase 1

Ting Liu, Jinxian Xu, Caihong Dai, Jian-Kang Chen. *Medical College of Georgia at Augusta University, Augusta, GA.*

Background: Tubulointerstitial fibrosis strongly correlates with the decline of renal function in chronic kidney disease (CKD), regardless of the primary etiology. Tubulointerstitial fibrosis is the major characteristic of the patients with aristolochic acid (AA) nephropathy, which is caused by the ingestion of herbs containing AA. Studies using rapamycin suggested that activation of the target of rapamycin (mTOR) might be causally linked to renal fibrosis, but mTOR knockout caused embryonic lethality; mTOR has multiple downstream effectors, including the p70 S6 kinase 1 (S6K1). Here we report the effect of S6K1 knockout on renal fibrosis.

Methods: Induction of tubulointerstitial fibrosis was accomplished by aristolochic acid I (AAI, given at a dose of 3 mg/kg body weight by daily I.P. for 3 consecutive days) or unilateral urethra obstruction (UUO) in wild type and S6K1 knockout mice. Renal lesions, kidney function and mTOR-S6K1 signaling activities were evaluated.

Results: AAI caused a marked increase of kidney injury molecule 1 (KIM-1) and necrosis of proximal tubular epithelial cells. In addition, we observed that the S2 segment of renal proximal tubule is more susceptible to injury than the S1 and S3 segments of proximal tubule in response to AAI treatment. These lesions resulted in a significant decrease in renal function (indicated by elevated serum creatinine and BUN levels) within 3 days, peaked by day 7. AAI treatment or UUO induced massive tubulointerstitial fibrosis within 2-4 weeks, revealed by a marked reduction of renal tubules, proliferation of a-smooth muscle actin-positive cells, Masson trichrome stains, and deposition of extracellular matrix proteins including fibronectin and fibroblast-specific protein 1 (FSP1). Interestingly, mechanistic studies revealed marked activation of S6K1 and ribosomal protein S6 (rpS6) phosphorylation in the kidney in response to either AAI or UUO. Importantly, mice with global (whole animal) homozygous S6K1 knockout were viable and protected from tubulointerstitial fibrosis.

Conclusions: The present study provides the first unequivocal evidence that activation of S6K1 plays an important pathogenic role during the development of tubulointerstitial fibrosis. Thus, specifically targeting S6K1 may represent a viable strategy for the prevention and treatment of renal fibrosis.

CD47 Blockade Modulates Fibrosis in Chronic Kidney Injury

Natasha M. Rogers,[1,2] Barkha Sanganeria.[1] *[1]Westmead Institute for Medical Research, Westmead, NSW, Australia; [2]Renal Unit, Westmead Hospital, Sydney, NSW, Australia.*

Background: Acute kidney injury triggers a complex cascade of cellular esponses that can culminate in maladaptive repair and fibrosis. The matrix protein thrombospondin-1 (TSP1) is known to activate latent TGF-beta, a crucial mediator of fibrosis. We have previously reported that the TSP1 and its receptor CD47 are are induced following kidney injury. However, the role of this axis has not been characterized in chronic kidney disease.

Methods: Age and gender-matched wild-type (WT), CD47$^{-/-}$ and WT mice treated with CD47 blocking antibody (WT+αCD47Ab) were compared in two chronic kidney injury models: ischemia-reperfusion injury and contralateral nephrectomy (RN), and unilateral ureteric obstruction (UUO). All animals underwent analysis of renal function and biomolecular phenotyping. Human and murine WT and CD47$^{-/-}$ renal tubular epithelial cells (rTEC) were studied *in vitro*.

Results: WT, WT + CD47Ab, and CD47$^{-/-}$ RN mice showed no difference in serum creatinine at 4 weeks regardless of injury model, however there was clear amelioration of renal histological changes and fibrosis with blockade or global knockout of CD47, defined by light microscopy and Sirius red staining. WT RN mice showed upregulated mRNA and protein expression of TSP-1 and pro-fibrotic markers TGF-ß, SMAD2, α-smooth muscle actin (SMA), fibronectin and type I collagen. These markers were significantly abrogated in both CD47$^{-/-}$ and WT + αCD47Ab counterparts. Interestingly, both WT and CD47$^{-/-}$ UUO mice at day+7 showed equivalent increases in pro-fibrotic tendency, by histology and qPCR, regardless of overall TSP1 expression. Only treatment with αCD47Ab reduced markers of matrix protein deposition. Renal tubular epithelial cells isolated from WT mice showed robust upregulation of TSP1 and elaborated pro-fibrotic markers under hypoxic stress, which was mitigated in CD47$^{-/-}$ cells. Incubation of rTEC with exogenous TSP1 demonstrated epithelia-to-mesenchyme transition with increased expression of TGF-ß and α-SMA. Immunohistochemistry of human kidney biopsy samples showed upregulated tubular TSP1 expression in stages 3-4 CKD (eGFR 15-59ml/min), and concurrently raised plasma TSP1 levels (8-10 fold) when compared to control samples (eGFR>60ml/min).

Conclusions: These data suggest that renal tubular epithelial cells contribute to fibrosis by activating TSP1-CD47 signalling, and point to CD47 as a target to limit fibrosis following some types of renal injury.

Klotho Overexpression Improves Interstitial Fibrosis, Accumulation of Cell Cycle Arrested Cells, and Increased Levels of Oxidative Stress in the Kidneys of Aging Mice

Hiroaki Ohishi, Shigehiro Doi, Ayumu Nakashima, Takao Masaki. Department of Nephrology *Hiroshima University Hospital, Hiroshima, Japan.*

Background: Klotho is reported to suppress growth factor signaling by transforming growth factor (TGF)-β1, insulin-like growth factor (IGF)-1, and Wnt. Notably, previous studies have reported that renal function decreases with age, and that interstitial fibrosis, accumulation of cell cycle arrested cells, and increased levels of oxidative stress are major features of the aging kidney. In this study, we investigated whether klotho overexpression improves these factors in the kidneys of aging mice together with the expression of growth factor signaling molecules.

Methods: Male mice that overexpress klotho under the control of the human elongation factor 1 promoter EFmKL46 (KLTG) or wild type 129 mice (WT) were used. Mice at 2 and 24 months old were defined as young mice and aging mice, respectively. Expression of klotho, fibrotic markers (α-smooth muscle actin, vimentin, collagen I, collagen III), cell cycle markers (p16, p21, p53, proliferating cell nuclear antigen), and oxidative stress markers (8-hydroxy-2′-deoxyguanosine, manganese superoxide dismutase, catalase, 3-nitroturosine) were examined using immunohistochemistry, western blotting, and/or quantitative PCR. We also investigated the expression of TGF-β1 (Smad2/3/4), IGF-1 (c-Jun N-terminal kinase, extracellular signal-regulated kinase, p38, protein kinase B, forkhead box protein O1), and Wnt (β-catenin, RAS-related C3 botulinus toxin substrate 1) signaling molecules.

Results: Klotho expression decreased in aging WT mice, whereas it was maintained in aging KLTG mice. Although expression of fibrotic markers did not differ between young KLTG and WT mice, they were significantly suppressed in aging KLTG mice compared with aging WT mice. Similarly, aging KLTG mice demonstrated significantly less expression of cell cycle arrest markers, as well as oxidative stress markers, than aging WT mice. Furthermore, expression of TGF-β1, IGF-1, and Wnt signaling molecules increased in aging WT mice; however, this upregulation was not observed in aging KLTG mice.

Conclusions: Klotho overexpression protects against kidney aging that is characterized by interstitial fibrosis, accumulation of cell cycle arrested cells, and increased levels of oxidative stress in mice, which is accompanied by suppression of signaling for multiple growth factors.

Twist1 in Macrophages Attenuates Kidney Fibrosis after Ureteral Obstruction

Jiafa Ren,[1] Xiaohan Lu,[1] Yi Wen,[2] Jamie Privratsky,[3] Steven D. Crowley.[3] *[1]Duke University, Durham, NC; [2]Southeast University, Nanjing, China; [3]Duke University Medical Center, Durham, NC.*

Background: Macrophages play a critical role in directing kidney fibrogenesis. The transcription factor Twist1 limits pro-fibrotic cytokine production in macrophages, and we have recently found that activating type 1 angiotensin receptors in macrophages induces Twist1 but paradoxically attenuates renal fibrosis. To directly test the role of macrophage Twist1 in kidney scar formation, we subjected mice with macrophage-specific deletion ("MKO") of Twist1 and controls ("WT") to the unilateral ureteral obstruction model.

Methods: C57BL/6 mice with a floxed allele for the gene encoding Twist1 were bred with LysM-Cre mice to yield Twist1 MKO mice with robust but selective deletion of Twist1 in macrophages (>80% vs. WTs; $p < 0.0001$). Twist1 MKO and WT littermate controls underwent unilateral ureteral ligation with assessment of kidney fibrosis and macrophage phenotype at 14 days.

Results: 2 weeks after UUO, Twist1 MKO mice developed more kidney fibrosis compared to WTs as quantitated by western blots for collagen I (1.5 ± 0.1 vs 1.00 ± 0.1 au; $p = 0.01$) and α-SMA (1.5 ± 0.15 vs 1.00 ± 0.12 au; $p = 0.01$) and hydroxyproline assay (10.7 ± 0.8 vs 8.2 ± 0.6 mg/10mg; $p = 0.02$). As certain MMPs may limit renal fibrosis by degrading extracellular matrix, we profiled kidney MMP expression after UUO and found that the obstructed Twist1 MKO kidneys compared to WTs had blunted mRNA levels for MMP11 (0.65 ± 0. 05 vs 1.00 ± 0.13; $p = 0.03$) and MMP13 (0.38 ± 0.11 vs 1.00 ± 0.20; $p = 0.03$) but preserved expressions of MMP2 and 7 (0.90 ± 0.14 vs 1.1 ± 0.15; $p = 0.78$ and 0.84 ± 0.30 vs 1.0 ± 0.19; $p = 0.66$, respectively). Other gene expression patterns in the Twist1 MKO kidneys consistent with macrophage-driven fibrosis were blunted Arg-1 levels (0.14 ± 0.06 vs 1.00 ± 0.30; $p = 0.05$) and upregulation of Fizz1 (2.35 ± 0.69 vs 1.0 ± 0.19; $p = 0.03$). We therefore used flow cytometry to detect enhanced accumulation of $CD11b^{+}Ly6C^{hi}$ infiltrating monocytes in the obstructed Twist1 MKO kidneys vs WTs (271 ± 41 vs 169 ± 17 cells/mg kidney; $p = 0.049$). Consistent with a role for Twist1 to suppress inflammatory cytokines in myeloid cells, LPS-stimulated peritoneal macrophages from the Twist1 MKO cohort had upregulated IFN-γmRNA compared to WTs (5.9 ± 0.3 vs 1.0 ± 0.2 au; $p < 0.001$).

Conclusions: Twist1 suppresses myeloid cell-dependent fibrosis in the kidney, possibly through effects on matrix degradation.

TH-OR019

Smad Anchor for Receptor Activation (SARA) Prevents Pericyte Activation and Protects Kidney from Fibrosis

Xiaoyan Liang,[1] H. William Schnaper,[1] Benjamin D. Humphreys,[2] Tomoko Hayashida.[1] *[1]Northwestern University, Chicago, Illinois; [2]Washington University School of Medicine, Clayton, Missouri.*

Background: Pericytes are a major source of fibrogenic cells in injured kidneys. We previously reported that decreasing SARA expression drives cultured proximal tubular epithelial cell dedifferentiation to a pro-fibrotic phenotype, and last year at ASN showed that pericyte-specific overexpression of SARA prevents interstitial fibrosis induced by aristolochic acid (AA) in mice. Here, we characterize the actions of SARA in pericytes.

Methods: Conditional human SARA-overexpressing mice were bred with PDGFRβ-Cre mice to drive pericyte SARA expression. The offspring were further bred with Z/EGFP or COL1A1-GFP mice to mark cells where Cre or type I collagen transcription is active, respectively. Mice were given AA (2.5 mg/kg, i.p., 3x week, for 3 weeks), then sacrificed after 3 more weeks. Harvested kidneys were enzymatically digested and sorted for GFP^{+} cells to obtain pericytes that were analyzed by flow cytometry and qPCR. A pericyte line ($Gli1^{+}$-iPeri) was isolated from a $Gli1^{+}$ tdTomato Immortomouse.

Results: As anticipated, native SARA mRNA expression was 62% decreased after AA treatment in GFP^{+} cells isolated from both phenotypically wild-type ($SARA^{WT}$; PDGFRβ-Cre^{+}; Z/EGFP) and SARA-overexpressing ($SARA^{Tg}$; PDGFRβ-Cre^{+}; Z/EGFP) mice. Transgene-derived SARA was detected even after AA, only in $SARA^{Tg}$ mice. $SARA^{Wt}$ mice showed significant expansion of the renal interstitial, GFP^{+} pericyte population after AA treatment, but this did not occur in mice with SARA-overexpression in pericytes. GFP^{+} cells isolated from wild-type mice without AA were $NG2^{+}$, $CD90.1^{-}$, confirming their pericyte origin. AA treatment induced 45% of the wild-type GFP^{+} cells to become $CD90.1^{+}$, suggesting pericyte fibroblastic transition. This shift was not observed in GFP^{+} cells isolated from AA-treated, SARA-overexpressing mice. COL1A1 mRNA expression was incrased by 10 fold in GFP^{+} cells from $SARA^{Wt}$ but not $SARA^{Tg}$ littermates. The $Gli1^{+}$-iPeri cell line expressed very little SARA in culture and strongly expressed αSMA. However, transfection with SARA significantly reduced TGF-β1-induced αSMA and COL1A2 promoter activity, suggesting that re-introduction of SARA at least partially reverses the fibrotic nature of $Gli1^{+}$-iPeri cells.

Conclusions: These data suggest that SARA expression in pericytes suppresses their activation to produce extracellular matrix.

Anti-dsDNA Antibodies Bind to Ku70 in Proximal Renal Tubular Epithelial Cells and Increased Matrix Protein and Cytokine Secretion

Daniel Tak Mao Chan, Shirli S. Ho, Chi pang Tai, Caleb C. Chan, Wai-Ming Cheng, Mel Chau, Susan Yung. *The University of Hong Kong, Hong Kong, China.*

Background: Anti-dsDNA antibodies can lead to immune-mediated kidney injury through complement activation or trigger downstream pro-inflammatory or fibrotic responses after cellular binding. Immune deposition along tubular basement membrane is commonly observed. We investigated the binding of anti-dsDNA antibodies to proximal renal tubular epithelial cells (PTEC).

Methods: Human polyclonal anti-dsDNA antibodies were isolated from the sera of lupus nephritis patients using affinity chromatography and samples demonstrating high binding affinity to PTEC were studied. Cultured PTEC were incubated with serum-free medium, control IgG, or anti-dsDNA antibodies for up to 48h. PTEC plasma membrane proteins were isolated and immuno-precipitated with anti-dsDNA antibodies to identify cross-reactive antigens using LC-MS/MS. The role of Ku70 in inflammatory and fibrotic processes was investigated by gene silencing with RNAi.

Results: The 70 kDa on PTEC cell membrane that bound anti-dsDNA antibodies was identified as Ku70 by LC-MS/MS. Exogenous DNA, histones, or nucleosomes did not affect its binding by anti-dsDNA antibodies. Anti-dsDNA antibodies binding to Ku70 was accompanied by increased fibronectin and laminin expression, and increased MCP-1 and IL-6 secretion ($P<0.05$, for all). Ku70 gene silencing with ninety percent efficacy resulted in reduced PTEC binding by anti-dsDNA antibodies as shown by immunohistochemistry. Ku70 knockdown significantly decreased the expression of fibronectin, laminin, and Bax, and and also the secretion of MCP-1 and IL-6, induced by TGF-β1, MCP-1, IL-1β, and IL-6 ($P<0.05$, for all). Kidney specimens from lupus nephritis patients and NZB/W F1 mice showed markedly increased Ku70 expression in the proximal tubules.

Conclusions: Our data shows that Ku70 mediates the binding of anti-dsDNA antibodies to PTEC, which is accompanied by downstream pro-inflammatory and pro-fibrotic cellular responses.

FGF23 and Falls in SPRINT

Anna J. Jovanovich,[1,2] Charles Ginsberg,[3] Zhiying You,[4] Alfred K. Cheung,[5] Michel Chonchol,[2] Michael Shlipak,[6] Joachim H. Ix.[3] *[1]Denver VA, Denver, CO; [2]University of Colorado, Aurora, CO; [3]UCSD, San Diego, CA; [4]UC Denver, Aurora, CO; [5]University of Utah, Salt Lake City, UT; [6]San Francisco VA Medical Center, San Francisco, CA.*

Background: Fibroblast growth factor 23 (FGF23) is elevated in chronic kidney disease and associated with kidney disease progression and increased mortality. There are little data on circulating FGF23 levels and falls despite the fact that FGF23 is derived from bone and regulates phosphorus and 1,25-dihydroxyvitamin D. The purpose of this analysis was to evaluate the relationship between intact FGF23 (iFGF23) and falls in the Systolic Blood Pressure Interventional Trial (SPRINT).

Methods: SPRINT was a randomized multicenter trial evaluating the effects of standard (SBP <140 mmHg) vs. intensive (SBP <120 mmHg) blood pressure lowering on cardiovascular outcomes among older adults without diabetes. iFGF23 was measured among 2488 participants with eGFR < 60 mL/min/1.73m^2. Cox proportional hazards models adjusted for demographics, comorbidities, randomization group, baseline number of antihypertensives, eGFR, and serum calcium, phosphorus, and intact parathyroid hormone identified the relationship between baseline iFGF23 and time to first fall.

Results: Mean age was 73 ± 9 years, 40% were female, and 66% were white. Mean eGFR was 49 ± 11 mL/min/1.73m^2 and median iFGF23 was 66 [52-88] pg/mL. After full adjustment, participants with iFGF23 levels in the highest quartile (compared to the lowest) demonstrated >2-fold increased risk of falling (HR 2.00 [95% 1.20-2.67]), and a doubling of iFGF23 level was associated with an increased risk of fall (HR 2.34 [95% CI 1.28-4.28]). Intact FGF23 did not modify the relationship between randomization to intensive blood pressure lowering and fall (p for interaction 0.96).

Conclusions: Among SPRINT participants with baseline eGFR < 60 mL/min/1.73m^2, iFGF23 was significantly associated with increased risk of falls; however, FGF23 did not modify the relationship between randomization to intensive blood pressure lowering and falls. FGF23 has been associated with frailty in a large cohort of older community-dwelling adults. Our novel finding that FGF23 increases risk of fall supports a link between FGF23 and frailty. Further investigation is necessary.

Genetic Variants Associated with Circulating Fibroblast Growth Factor-23 among Patients with CKD

Cassianne Robinson-Cohen,[1] Farzana Perwad,[2] Elvis A. Akwo,[1] Loren Lipworth,[1] Myles Wolf,[5] Bryan R. Kestenbaum,[4] Adriana Hung,[3] Talat Alp Ikizler.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of California San Francisco, San Francisco, CA; [3]VA & Vanderbilt University, Nashville, TN; [4]University of Washington, Seattle, WA; [5]Duke University, Durham, NC.*

Background: Recent genome-wide association studies (GWAS) identified loci associated with differences in fibroblast growth factor 23 (FGF23) concentrations, near genes involved in vitamin D metabolism, ABO blood group system, and renal phosphate transport. These studies were conducted among individuals with preserved kidney function. It is possible that genetic contributions to circulating FGF23 may differ among individuals with mineral metabolism disturbances, such as those with chronic kidney disease (CKD), in whom the biologic implications and potential treatment options are most relevant.

Methods: We examined 5 SNPs previously identified in GWAS of FGF23 (index SNPs) and 44 putatively functional SNPs in the surrounding regions (±250kb) among unrelated individuals of European ancestry (n=1,666) who participated in the Chronic Renal Insufficiency Cohort (CRIC) Study. We additionally tested for interactions of eGFR on the SNP-FGF23 association.

Results: Two index SNPs were associated with FGF23, after adjustment for age, sex, eGFR and BMI: rs11741640 at 5q35.3/*RGS14/SLC34A1* (beta for the G allele: 5.7% higher FGF23 95% CI: 3.6,13.9, p=0.001) and rs2769071 at 9q34.2/*ABO* (beta coefficient for the G allele: 7.3% higher FGF23, 95% CI: 2.8,11.8, p=0.001). When we expanded to surrounding functional variants, 9 SNPs were associated with FGF23 (false discovery rate ≤ 0.05), all within the 5q35.3 region. The strongest association was for rs4075958 in *RGS14* (beta for the A allele: 7.3% lower FGF23, 95% CI: -11.3,-3.1, p=9x10^{-4}). Statistically significant interaction by eGFR was noted for the association of rs17216707 at 20q13.2/*CYP24A1* (p=0.019).

Conclusions: Our findings provide evidence that a subset of genetic variants associated with FGF23 under normal conditions are also associated in the setting of CKD. Larger, more comprehensive studies are needed to fully assess the generalizability of published GWAS findings and to identify potential novel associations in CKD. Both replication and lack of replication of published GWAS findings in CKD provide important information on the genetic etiology and on pathways influencing mineral metabolism disorders.

Burosumab Improves Phosphorus Metabolism and Fracture Healing in Adults with X-Linked Hypophosphatemia (XLH)

Anthony A. Portale,[1] Karl Insogna,[7] Erik Imel,[2] Peter Kamenicky,[8] Yasuo Imanishi,[4] Nobuaki Ito,[5] Farzana Perwad,[1] Lin Zhang,[6] Christina Theodore-Oklota,[3] Matt Mealiffe,[3] Javier San martin,[3] Thomas Carpenter.[7] *[1]University of California San Francisco, San Francisco, CA; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Ultragenyx Pharmaceutical Inc., Novato, CA; [4]Osaka City Univ Graduate School of Med, Abeno-ku, Japan; [5]University of Tokyo Hospital, Tokyo, Japan; [6]Ultragenyx Pharmaceutical Inc, Novato, CA; [7]Yale University, New Haven, CT; [8]Université Paris-Sud, Le Kremlin-Bicêtre, France.*

Background: In an ongoing, Phase 3, double-blind, multicenter study, we examined the efficacy and safety of burosumab, a human monoclonal antibody against FGF23, in 134 adults with XLH.

Methods: Subjects were randomized 1:1 to receive burosumab 1 mg/kg (n=68) or placebo (n=66) subcutaneously every 4 weeks (wks). After 24 wks, subjects receiving placebo crossed-over to receive burosumab, and all subjects received burosumab during wks 24-48, while remaining blinded to prior treatment.

Results: From wks 0 to 24, a significantly greater percentage of burosumab subjects than placebo subjects (94% vs 8%; p<0.0001) attained the primary endpoint of a mean serum phosphorus level within the normal range at the midpoint of dosing intervals; from wks 24-48, phosphorus was within the normal range in both groups (crossover 89%, burosumab-continuation 84%). At baseline, 65 active fractures/pseudofractures (Fx/PFx) were present in 47% (32/68) of subjects in the burosumab group and 91 Fx/PFx in 58% (38/66) of subjects in the placebo group. At wk 24, 43% (28/65) of Fx/PFx fully healed with burosumab and 8% (7/91) healed with placebo (odds ratio of full healing 16.8, p<0.0001). By wk 48, the burosumab-continuation group showed additional Fx/PFx healing, and the crossover group showed healing similar to that of the burosumab-continuation group at wk 24. At wk 48, both groups showed significant decreases from baseline (or wk 24 for crossover) in stiffness, physical functioning, and pain scores (all p<0.001). At wk 48, PTH decreased from baseline by 9% in the burosumab-continuation group and by 7% in the crossover group. Serum creatinine and calcium levels and urine calcium excretion were unchanged. Most subjects had no change in nephrocalcinosis severity score (5-point scale), and no subject had a change >±1 point. Serious AEs were reported in 15 subjects; none were assessed as drug-related.

Conclusions: Inhibition of FGF23 with burosumab was associated with improvements in serum phosphorus levels, pain, stiffness, and physical functioning, and healing of Fx/PFx in adults with XLH. The improvements seen with burosumab at wk 24 were replicated in placebo subjects who crossed over to receive burosumab from wks 24-48.

Association of Serum Calcification Propensity with Presence and Progression of Coronary Artery Calcification among Patients with CKD: The CRIC Study

Joshua D. Bundy,[1] Xuan Cai,[1] Julia J. Scialla,[2] Geoffrey A. Block,[3] Harold I. Feldman,[4] Ian H. de Boer,[5] James P. Lash,[6] Jing Chen,[7] Chi-yuan Hsu,[8] Mirela A. Dobre,[9] Jungwha Lee,[1] Panduranga S. Rao,[10] Alan S. Go,[11] Raymond R. Townsend,[4] Myles Wolf,[2] Andreas Pasch,[12] Tamara Isakova.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Duke University, Durham, NC; [3]Colorado Kidney Care, Denver, CO; [4]University of Pennsylvania School of Medicine, Villanova, PA; [5]Division of Nephrology and Kidney Research Institute, University of Washington, Seattle, WA; [6]University of Illinois at Chicago, Chicago, IL; [7]Tulane School of Medicine, New Orleans, LA; [8]University of California San Francisco, San Francisco, CA; [9]Case Western Reserve University, Cleveland, OH; [10]University of Michigan Health System, Ann Arbor, MI; [11]Kaiser Permanente Northern California, Oakland, CA; [12]University Hospital Bern, Bern, Switzerland.*

Background: Coronary artery calcification (CAC) is prevalent among patients with chronic kidney disease (CKD) and predicts the risk of cardiovascular disease and mortality. We hypothesized that a novel measure of serum calcification propensity is associated with CAC among patients with CKD stages 2-4.

Methods: Among 780 participants from the CRIC Study, CAC was measured at baseline and a follow-up visit using electron beam or multidetector computed tomography. Calcification propensity was quantified at baseline as the transformation time (T50) from primary to secondary calciprotein particles, with lower T50 corresponding to higher calcification propensity. Poisson and linear regression were used to estimate associations between T50 and CAC, with a priori stratification by absence or presence of CAC at baseline.

Results: At baseline, 460 (59%) participants had any CAC and 255 (33%) participants had CAC score ≥100 Agatston units. Over an average 3-year follow-up, 65 (20%) participants without baseline CAC developed CAC while 89 participants (19%) with baseline CAC increased ≥100 Agatston units per year. After multivariable adjustment, lower T50 was associated with more severe CAC at baseline and over follow-up among those with baseline CAC (Table).

Conclusions: Among patients with CKD, higher serum calcification propensity is associated with more severe CAC and progression of CAC. Future studies should evaluate

whether T50 predicts the risk of clinical cardiovascular disease and whether its determinants represent novel therapeutic targets.

Serum Bicarbonate Level and Coronary Artery Calcification – A Report from the Chronic Renal Insufficiency Cohort (CRIC) Study

Mirela A. Dobre,[1] Neil H. Patel,[1] Wei Yang,[6] Jing Chen,[2] L. Lee Hamm,[7] Tamara Isakova,[4] Bernard G. Jaar,[3] Ana C. Ricardo,[5] Thomas H. Hostetter,[1] Mahboob Rahman.[1] CAC *[1]Case Western Reserve University, Cleveland, OH; [2]Tulane School of Medicine, New Orleans, LA; [3]Johns Hopkins University and Nephrology Center of Maryland, Baltimore, MD; [4]Feinberg School of Medicine, Northwestern University, Chicago, IL; [5]University of Illinois at Chicago, Chicago, IL; [6]University of Pennsylvania, Philadelphia, PA; [7]Tulane University School of Medicine, New Orleans, LA.*

Background: There is a graded relationship between the severity of chronic kidney disease (CKD) and coronary artery calcification (CAC), though the mechanism is unclear. Metabolic acidosis, a common complication of CKD, contributes to decreased mineral bone content and may lead to worsening vascular calcification. We hypothesize that low serum bicarbonate level, an expression of metabolic acidosis, is a risk factor for CAC in CKD.

Methods: Serum bicarbonate and CAC were simultaneously measured in 862 CRIC participants at baseline and after 3 years. CAC was measured using electron beam or multidetector computed tomography and calculated using Agatston score. Serum bicarbonate was analyzed both as a continuous and a categorical variable by the following groups: <22 mEql/L (low), 22-26 mEq/L (normal) and >26 mEq/L (high). CAC progression was defined as follows: CAC> 0 at follow-up, if CAC=0 at baseline; annualized change ≥10 Agatston units at follow-up if 0<CAC≤100 at baseline; and annualized percent change (annualized change in CAC score divided by the baseline CAC score) ≥ 10% at follow-up, if CAC > 100 at baseline. Logistic regression models were built to study the association of interest.

Results: The mean eGFR was 43±17ml/min per 1.73m², mean serum bicarbonate was 24.4±3.3 mEq/L, and 42.7% participants had diabetes. A total of 412 (48%) participants experienced CAC progression. Participants with low bicarbonate were more likely to have CAC >400 at baseline, and to experience CAC progression, compared to those in the normal group (57.3% vs 46.2%, p=0.003). The low group had 52% higher risk of CAC progression, compared to normal group (OR1.52; 95%CI: 1.02–2.29), in models adjusted for demographics, baseline co-morbidities, medications, calcium and phosphorus. Addition of eGFR and proteinuria to these models attenuated the association (OR 1.34; 95%CI: 0.87–2.08). In fully adjusted models, each 1mEq/L lower serum bicarbonate was associated with 6% higher risk of CAC progression (OR 1.06; 95%CI: 1.01-1.12).

Conclusions: In a cohort of patients with CKD, low serum bicarbonate level was associated with CAC progression. This association may not be independent of kidney function. Further studies are needed to determine a causal link between low serum bicarbonate and CAC.

A Serum Biomarker Panel of Low Bone Turnover Identifies Higher Fracture Risk in Community Dwelling Individuals with CKD

Jan M. Hughes-Austin,[1] Ronit Katz,[2] Richard Semba,[3] Doug Bauer,[4] Mark J. Sarnak,[5] Michael Shlipak,[6] Florence Lima,[7] Hartmut H. Malluche,[7] Joachim H. Ix.[8] *[1]University of California, San Diego, La Jolla, CA; [2]University of Washington, Seattle, WA; [3]Johns Hopkins University, Baltimore, MD; [4]UCSF, San Francisco, CA; [5]Tufts Medical Center, Boston, MA; [6]San Francisco VA Medical Center, San Francisco, CA; [7]University of Kentucky, Lexington, KY; [8]UCSD, San Diego, CA.*

Background: Individuals with chronic kidney disease (CKD) can have low or high turnover bone disease, either of which could lead to low bone mineral density (BMD). We identified a panel of biomarkers on biopsy that marked low turnover bone disease. Then, in a community-dwelling cohort of persons with CKD, we determined if this panel identified a subset at high risk for fracture.

Methods: Among 58 patients with CKD stage 2-5 who had undergone bone biopsies, we used CART analysis to define a panel of serum biomarkers that could differentiate low turnover from non-low turnover bone disease. We then applied this panel of biomarkers to 676 participants in the Health ABC study who had eGFR < 60 mL/min/1.73m²and had BMD measurements at baseline. We used Cox proportional hazards models to evaluate the association of BMD with fracture risk and to determine whether biomarker defined low- vs non-low bone turnover modified the risk of fracture.

Results: CART analysis in 58 CKD patients defined cut-off points for differentiation of low bone turnover: PTH below the median, soluble a-klotho above the median, and FGF-23 below the median (AUC = 0.6, 0.7, and 0.7, respectively). Among the 676 participants with CKD in Health ABC, mean age was 75±3 years, and were 51% female and 36% African-American. Average eGFR was 48±10 mL/min/1.73m². For every standard deviation (SD=0.16 g/cm²) lower hip BMD at baseline there was higher risk for hip (HR 2.5 (1.9, 3.2)) and spine fractures (HR 1.6 (1.3, 2.1)) during follow-up. This risk differed in individuals with biomarker defined low vs non-low bone turnover ($p_{interaction}$hip= 0.05; spine= 0.07), where individuals characterized as having low bone turnover had higher risk of fracture (Table)

Conclusions: In individuals with CKD, a biomarker panel of PTH, a-klotho, and FGF-23 can be used to identify individuals more likely to have low bone turnover. In such individuals, the relationship of low BMD with risk for incident hip and spine fractures is much higher than in others.

Funding: Other NIH Support - NHLBI (K01 HL122394)

Table. Association between BMD* and incident fractures stratified by low bone turnover versus non-low bone turnover

	Hip Fractures			
	Unadjusted	Age, gender, race, and site adjusted	Fully adjusted**	P-interaction
	HR (95% CI)	HR (95% CI)	HR (95% CI)	
Low Turnover	3.05 (2.01, 4.65)	3.14 (1.91, 5.15)	5.72 (2.67, 12.25)	0.053

A MicroRNA Approach to Diagnosing Renal Osteodystrophy

Tom Nickolas,[1] Neal X. Chen,[2] Donald J. Mcmahon,[5] Pieter Evenepoel,[3] Patrick C. D'Haese,[4] Fabrice Mac-Way,[6] Sharon M. Moe.[2] *[1]Columbia University Medical Center, New York, NY; [2]Indiana University School of Medicine, Indianapolis, IN; [3]University Hospitals Leuven, Leuven, Belgium; [4]University Antwerp, Edegem, Belgium; [5]Columbia University, New York, NY; [6]CHU de Quebec, Hotel-Dieu de Quebec Hospital, Quebec, QC, Canada.*

Background: The primary goal of treating renal osteodystrophy (ROD) is reducing high bone turnover with calcitriol and/or calcimimetics while avoiding the development of low turnover. A main obstacle in managing ROD is identifying the underlying bone turnover-type. Bone biopsy, the gold standard to define turnover, is impractical for routine clinical use. Therefore, KDIGO recommends that clinical use (starting/stopping) of these agents is guided by parathyroid hormone (PTH) and bone specific alkaline phosphatase (BSAP). However, bone biopsy studies demonstrated that PTH and BSAP are poor guides for ROD treatment. We hypothesized that 4 circulating microRNAs (miRs) that regulate osteoblast (30b, 30c, 125b) and osteoclast development (155) would provide superior discrimination of low and high turnover than PTH and BSAP.

Methods: In 24 patients with CKD 3-5D, we obtained tetracycline double-labeled iliac crest bone biopsy and measured levels of intact PTH, BSAP and circulating miR-30b, 30c, 125b and 155 (evaluated independently and together as a panel). Spearman correlations assessed relationships between miRs, dynamic parameters of bone biopsy, and PTH and BSAP. Discrimination of low / high turnover were determined by receiver operator curve analysis; areas under curve were compared by χ^2.

Results: miRs moderately correlated with bone formation and adjusted apposition rate (ρ 0.43-0.51; p<0.05) by biopsy but were not correlated with PTH or BSAP. Discrimination of low vs. non-low and high vs. non-high turnover for PTH, BSAP and miRs (both individually and as a panel) are shown in the Table.

Conclusions: These data suggest that a panel of circulating miRs provide accurate non-invasive identification of low and high turnover and individually identified low turnover. Future work will discover and validate additional miR biomarkers of turnover and determine their impact on clinical decision making and outcomes.

Cholecalciferol vs Small Doses of Alfacalcidol in Hemodialysis Patients: A Randomized Placebo-Controlled Study

Pawel Kulicki,[1] Stanislaw Niemczyk,[4] Pawel Zebrowski,[3] Jolanta Malyszko,[2] Joanna Matuszkiewicz-Rowinska.[3] *[1]Medical University of Warsaw, Warsaw, Poland; [2]Warsaw Medical University, Warsaw, Poland; [3]The Medical University of Warsaw, Warsaw, Poland; [4]Military Medical Institute of Warsaw, Warsaw, Poland.*

Background: The ability of extrarenal tissues to convert 25OHD into 1,25(OH)2D and its dependence on substrate levels provide the rationale for supplementing vitamin D in dialysis patients who usually have severe depletion of both: calctriol and vitamin D. The primary aim of the study was to compare effects of cholecalciferol (CHOL, 4000 IU) with frequently used in Europe, small doses of alfacalcidol (ALFA, 0.5 microg) or placebo (PLC), given thrice weekly for 12 weeks, on serum 1,25(OH)2D in hemodialysis (HD) patients with vitamin D deficiency. Secondary outcomes were changes in serum calcium, phosphate, 25(OH)D, parathyroid hormone (PTH), fibroblast growth factor 23 (FGF23) and sclerostin during the treatment.

Methods: This was a prospective, randomized, partly double-blind (CHOL vs PLC), partly open-label (ALFA vs CHOL or PLC) study. Out of 522 patients dialyzed in 5 centers in the Mazovian Province, 93 gave informed consent and met the inclusion criteria: vitamin D and calcimimetics naïve; no history of liver or intestinal disease; serum 25(OH)D <20 ng/ml, iPTH <1000 ->110 pg/ml, calcium <10.2 and phosphate < 6.8 mg/dl. The subjects were stratified by serum iPTH, then randomized into 3 groups according to the treatment

Results: To our knowledge, this is a first study comparing head-to-head these drugs in HD population. There were no significant differences between the groups at baseline. 81 patients completed the study. CHOL normalized serum 25OHD, with a mean rise from 12.9±6.7 to 31.3±10.1 ng/ml (p<0.0001). This was accompanied by a marked increase of $1,25(OH)_2D$ (from 13.8±9.3 to 25.1±14.2 pmol/l (p<0.0001). A rise in serum 1,25(OH)2 was observed also in ALFA treated patients, however much smaller (from 13.5±10.1 to 18.5±11.0 pmol/l; p=0.02). Neither CHOL nor ALFA treatment resulted in significant changes in the remaining parameters.

Conclusions: In most HD patients treatment with CHOL in a dose of 12000 IU/week permits safe correction of vitamin D deficiency and is more effective than small doses of ALFA in rising serum 1,25(OH)2D. This together with a lack of influence on circulating iPTH question the usefulness of this treatment in HD patients.

TH-OR029

Randomized Trial to Evaluate the Effect of Cholecalciferol Supplementation on Parathyroid Hormone in Hemodialysis Patients

Laura Sola, Susana B. Gonzalez, Juan C. Diaz, Sandra D. Fleitas, Manuela Bello, Maria noel Leyun, Ricardo A. Hermo. *CASMU-IAMPP, Montevideo, Uruguay.*

Background: Vitamin D (25VD) supplementation is associated with a decrease in parathyroid hormone (iPTH) in general population, not confirmed in hemodialysis (HD) patients (Pts). The aim of the study was to evaluate if cholecalciferol supplementation can normalize 25VD levels and reduce iPTH in HD Pts with vitamin D deficiency.

Methods: Randomized, controlled trial with 2 arms: cholecalciferol vs placebo. Inclusion Criteria: Adult Pts, on HD for ≥ 3 months, 25VD < 30 ng/ml and iPTH >300 ng/ml. Randomization was done using a table of random numbers, and allocation was blinded for Pts and investigators. Intervention: Pts received one tablet with 5000 IU 25VD or placebo during dialysis thrice a week for 12 weeks. Hemoglobin (Hb), Calcium (Ca), Phosphorous (P), erythropoietin dose (IU/kg/week), Alkaline Phosphatase (AP), 25VD and iPTH were measured at 0 and 12 weeks. Assuming a dropout rate of 15%, sample size of 120 Pts was needed for a 20% reduction on iPTH in 35% of treated Pts. Analysis was done per protocol for the primary outcome. Quantitative data was expressed were compared by t test and categorical by chi square. Significant differences were considered with p values <0.05. Institutional Ethics Committee authorization was obtained.

Results: 118 Pts were randomized, 60 to 25VD and 58 to PLA with no significant differences (Table I). 17 Pts were lost of follow-up, 101 Pts completed treatment (54 with 25VD and 47 with PLA). Pts on 25VD normalized 25VD (increased x 20.9 ± 11.9) significantly more frequently than those on PLA (41 (75.9%) vs 11 (23.4%)). A 20% iPTH reduction was seen in 17 Pts (29.3%) on 25VD (x reduction 45 ± 194) and 9 Pts (19.1%) on PLA (p=0.1). A reduction on AP was seen in 25VD Pts (29.5 ± 84.8, p=0.016) and not on PLA (21.9 ± 81.3).

Conclusions: Significant increase in 25VD was observed in treated group, with a reduction on AP but with no significant effect on iPTH

Funding: Commercial Support - Celsiuss, Government Support - Non-U.S.

Multicentre Randomized Control Trial of Phosphate Control with a Modified as Compared to Standard Renal Diet

Fiona N. Byrne,[1,2] Joe Eustace,[2] Barbara A. Gillman.[3] *[1]Department of Nutrition & Dietetics, Cork University Hospital, Cork, Ireland; [2]Clinical Research Facility, University College Cork, Cork, Ireland; [3]Mater Misericordiae University Hospital, Dublin, Ireland.*

Background: The standard renal diet fails to distinguish between phytate and non phytate bound phosphorus, despite consensus that the latter is poorly absorbed. A modified renal diet based on the increased use of pulses, nuts and whole grains, the avoidance of P additives and of over-prescription of protein may offer improved or similar [P] levels as the standard renal diet but with a wider food choice.

Methods: We conducted a national, multicentre, pragmatic, parallel arm, open label, randomized controlled trial (1:1 allocation ratio) of 1 month of modified vs. standard diet in 74 prevalent anuric adults on maintenance hemodialysis with a 3 mt mean pre-dialysis serum phosphate ([P]) >1.6mmol/L and a stable phosphate binder and vitamin D prescription. Subjects with a history of severe hyperkalemia, parathyroidectomy or recent acute illness were excluded. Subjects were re-educated on the standard diet or educated on the modified diet by the renal dietitian. Analysis was on a modified intention-to-treat basis of the difference between diets in follow-up [P] minus baseline [P] using an independent sample t test and a 2 sided type 1 error rate of 0.05.

Results: We recruited 74 subjects from 13 university dialysis units. Two patients did not have a follow-up [P], due to an insufficient sample and transplantation and thus could not contribute to the primary analysis. The study population was 96% Caucasian, 69% male, 36% of subjects had diabetes. Both diets were similarly well tolerated. The modified diet resulted in a significantly higher phytate and fiber intake (both p<0.01). Baseline and follow-up [P] in modified diet arm was 2.1 (0.5) and 2.0 (0.7) mmol/L, and in the Standard Diet arm were 2.0 (0.6) and 1.9 (0.6) mmol/l; the mean (95% CI) change in $[PO_4]$ in modified vs. standard arm was 0.01 (-0.24,0.21), p=0.91. The mean (sd) difference in follow-up [K] -baseline [K] in the modified and standard arms was 0.01 (0.7) and 0.09 (0.6) mmol/L respectively; the mean (95% CI) change in $[K^+]$ modified v standard was -0.07(-0.23,0.38), p = 0.63. C terminal FGF23 (n=27) was not significantly different. Limitations of this study include its modest sample size and limited intervention period.

Conclusions: The modified renal diet was well tolerated and was associated with similar [P] control but with a wider food choice and greater fiber intake than the standard diet.

TH-OR031

Combination of Changes in eGFR and Albuminuria and the Risk of Major Clinical Outcomes in Type 2 Diabetes Mellitus (T2DM)

Min Jun,[1] Toshiaki Ohkuma,[1] Vlado Perkovic,[2] John P. Chalmers,[4] Mark Woodward.[3] ADVANCE Collaborative Group *[1]The George Institute for Global Health, UNSW Sydney, Newtown, NSW, Australia; [2]The George Institute for Global Health, Newtown, NSW, Australia; [3]Johns Hopkins University, Baltimore, MD; [4]The George Institute for Global Health, Camperdown, NSW, Australia.*

Background: Whether combining changes in eGFR and UACR more accurately predicts outcomes in T2DM compared with assessing either change alone is unknown. We assessed the association between changes in eGFR and UACR and subsequent risk of the composite of major macrovascular and renal events and all-cause mortality in the ADVANCE-ON study.

Methods: We defined eGFR and UACR change (baseline to 2 years) as ≥40% decrease, <40% decrease to <40% increase (minor change; reference) and ≥40% increase. Follow-up for outcomes commenced at the second eGFR or UACR measurement. Cox regression models (adjusted for demographics, ADVANCE randomized treatment, comorbidities and laboratory measurements [including baseline eGFR and UACR]) were used to estimate the hazard ratio (HR) and 95% confidence intervals (CIs) relating changes in eGFR and UACR to the combination endpoint.

Results: Of 8766 patients, from baseline to 2 years, 3% experienced an eGFR decrease ≥40%, 93% experienced a minor change, and 4% experienced an increase ≥40%. For UACR change, the proportions were 29%, 34% and 37%, respectively. 1% experienced both an eGFR decrease ≥40% and a UACR increase ≥40%. Over the next 7.7 years (median), 2191 composite outcome events were recorded. Strong linear associations between eGFR and UACR changes and the subsequent risk of the outcome were observed (p for trend <0.001 for each marker). For eGFR change, the HRs for a decrease ≥40% was 1.59 (95% CI: 1.28-1.97) compared with those with minor change whilst that for an increase ≥40% was 0.82 (0.64-1.04). For UACR change, the HRs were 0.96 (0.85-1.07) for a decrease ≥40% and 1.32 (1.19-1.46) for those with ≥40% increase compared to minor change. Compared to patients with minor changes, patients who experienced an eGFR decrease ≥40% and a UACR increase ≥40% had 2.31 (1.67-3.18) times the risk of the outcome, with evidence of interaction between the 2 markers (p for interaction=0.047).

Conclusions: In patients with T2DM, clinically meaningful decreases in eGFR and increases in UACR over 2 years significantly predicted, independently and in combination, increased risk of major clinical outcomes. Our results suggest that a combined assessment of clinically meaningful changes in both eGFR and UACR compared with separate assessments of the 2 markers may further improve risk stratification in T2DM.

Metformin Treatment in Patients with Type 2 Diabetes and CKD

Soie Kwon,[4,3] Yong Chul Kim,[1] Jae Yoon Park,[2] Jung Nam An,[3] Dong Ki Kim,[4] Jung Pyo Lee.[3] *[1]SNUH, Seoul, Republic of Korea; [2]Dongguk University Ilsan Hospital, Gyeonggido, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, SEOUL, Republic of Korea; [4]Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Metformin is widely used as the first pharmacological option in the patients with type 2 diabetes mellitus. However, use of this drug has not been recommend in individuals with impaired kidney function because of the perceived risk of lactic acidosis. We aimed to assess the efficacy and safety of metformin in patients with type 2 diabetic chronic kidney disease (CKD).

Methods: We conducted a retrospective, observational, cohort study of 10,426 patients with type 2 diabetic CKD who followed the nephrology clinic at two tertiary hospitals from 2001 to 2016. We compared 3,183 patients who used metformin with 7,243 who did not use metformin. Primary outcomes were all-cause-mortality and end-stage renal disease (ESRD) progression. Secondary outcomes were event of metformin associated lactic acidosis and maximal lactate level in all events of lactic acidosis. Cox multivariate analysis and propensity score matching were conducted.

Results: The patients who used metformin had more female proportion, younger, higher eGFR, higher BMI and higher HbA1c level at the time of enrollment. All-cause-mortality for metformin-user group was significantly better than that that of non-metformin user in the multivariable cox analysis (P value <0.001 adjusted hazard ratio [aHR] 0.54, 95% confidence interval [C.I.] 0.48 - 0.62). Also, MFM group has longer duration of ESRD progression. (P value < 0.001, aHR 0.47, 95% CI 0.41 – 0.53). Because two group had significantly different baseline characteristics, we did a propensity score matching by age, gender, hypertension, liver disease, BMI, Hba1c and eGFR. Metformin usage consistently has superiority in all-cause-mortality (P value <0.001, aHR 0.52, 95% CI 0.46 – 0.60) and ESRD progression (P value <0.001, aHR 0.50, 95% CI 0.43 – 0.58) in matched group. There was only one case of metformin associated lactic acidosis event in metformin user group. But there was no difference in maximal lactate level. (P value 0.966)

Conclusions: In Korean diabetic CKD patients, metformin can be safely considered. However, more researches about cumulative dose effect, dose adjustment and monitoring method are needed.

Edit Table - Uni-variate cox analysis about primary outcome in matched group

	Hazard ratio	95% CI	P value
All-cause-mortality	0.52	0.46 - 0.60	<.001
ESRD progression	0.50	0.43 - 0.58	<.001

TH-OR033

CKD Outcomes in Type 2 Diabetes and Moderate-to-Severe CKD Treated with Dulaglutide Versus Insulin Glargine: AWARD-7

Katherine R. Tuttle,[1] Mark Lakshmanan,[2] Brian Rayner,[3] Alan G. Zimmermann,[4] Brad Woodward,[2] Fady T. Botros.[2] *[1]University of Washington School of Medicine, Spokane, WA; [2]Eli Lilly and Company, Indianapolis, IN; [3]Division of Nephrology and Hypertension, Groote Schuur Hospital and University of Cape Town, Cape Town, South Africa; [4]Formerly at Eli Lilly and Company, Indianapolis, IN.*

Background: In the Assessment of Weekly AdministRation of Dulaglutide in Diabetes-7 (AWARD-7) study, dulaglutide (DU) treatment was associated with slower decline in estimated glomerular filtration rate (eGFR) compared to insulin glargine (IG) in participants with type 2 diabetes (T2D) and moderate-to-severe chronic kidney disease (CKD). The present analysis is aimed to determine CKD outcomes by treatment group.

Methods: As treatment for T2D, participants with T2D and CKD stages 3-4 were randomized (1:1:1) to receive DU 0.75 mg, DU 1.5 mg, or titrated IG, all added-on to titrated insulin lispro, for 1 year in this open-label (DU dose-blinded), phase 3 clinical study. In this prespecified exploratory analyses, proportions of participants experiencing ≥40% eGFR decline, end-stage renal disease (ESRD), or kidney disease-related death were compared between groups as composite and individual outcomes. For the composite outcome, a time-to-event analysis was conducted using a Cox proportional hazards model.

Results: The age (mean ± SD) of participants was 64.5 ± 8.5 years and 264/549 (48%) were women. At baseline, diabetes duration (mean ± SD) was 18.1 ± 8.8 years, HbA1c was 8.6 ± 1.0%, eGFR was 38 ± 13 mL/min/1.73 m^2, and median (interquartile range) urine albumin-creatinine ratio was 209 (39, 965) mg/g. HbA1c declined similarly in all groups by a mean of approximately 1% over 1 year. The composite outcome was experienced by 47/576 (8.2%) participants: 10/192 (5.2%) in DU 1.5 mg, 16/190 (8.4%) in DU 0.75 mg, and 21/194 (10.8%) in IG (p=0.046, p=0.548 versus IG, respectively). The time-to-event for the composite outcome was significantly better for DU 1.5 mg versus IG (Cox model; p=0.038). Proportions with eGFR decline ≥40% occurred in: 2/192 (1.0%) in DU 1.5 mg, 7/190 (3.7%) in DU 0.75 mg, and 6/194 (3.1%) in IG. Proportions reaching ESRD were: 8/187 (4.3%) in DU 1.5 mg, 14/184 (7.6%) in DU 0.75 mg, and 16/191 (8.4%) in IG. Between-group comparisons were not significant for individual outcomes. No kidney disease-related deaths were reported.

Conclusions: One-year treatment with DU 1.5 mg was associated with a lower rate of CKD outcomes, including the composite outcome of eGFR decline ≥40% or ESRD, compared to IG at similar levels of glycemic control.

Reduction in Albuminuria Is Associated with Cardiorenal Protection Independent of Baseline Albuminuria – A Post-Hoc Analysis of the LEADER Trial

Frederik Persson,[1] Stephen Bain,[2] Ofri Mosenzon,[3] Hiddo J. Lambers Heerspink,[4] Johannes F. Mann,[5] Itamar Raz,[6] Thomas Idorn,[7] Soren Rasmussen,[7] Bernt Johan Von Scholten,[7] Peter Rossing.[1] The LEADER Publication Committee on behalf of the LEADER Trial Investigators *[1]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [2]Institute of Life Science, Swansea University, Swansea, United Kingdom; [3]Hadassah Hebrew University Hospital, Jerusalem, Israel; [4]University Medical Center Groningen, Groningen, Netherlands; [5]KfH Kidney Center, and Friedrich Alexander University of Erlangen, Munich, Germany; [6]Hadassah Hebrew University Hospital, Jerusalem, Israel; [7]Novo Nordisk A/S, Soborg, Denmark.*

Background: We investigated association between changes in urinary albumin-to-creatinine ratio (UACR) and subsequent risk of cardiovascular (CV) and renal events in the LEADER trial according to baseline UACR.

Methods: LEADER was a randomized, double-blind, multicenter, placebo-controlled CV outcomes trial of liraglutide up to 1.8 mg/day vs placebo added to standard care for 3.5–5 years in 9340 patients with type 2 diabetes and high risk for CV disease. Using a Cox regression model including subjects with a UACR measurement at baseline and after 1 year (N=8231 [88%]) adjusted for treatment, we analyzed the risk of major adverse CV events (MACE) and adjudicated renal events (doubling of serum creatinine and estimated glomerular filtration rate ≤45 ml/min/1.73 m^2; the need for continuous renal-replacement therapy; or death from renal disease) from 1 year to end of trial in subgroups defined by first-year change in UACR: >30% reduction, 30-0% reduction, any increase, and according to absolute level of baseline UACR (normo- [<30 mg/g], micro- [30 to 300 mg/g] or macroalbuminuria [>300 mg/g]).

Results: For first MACE, the hazard ratios (HRs) according to baseline UACR groups were: HR=2.49, 95%CI (2.09;2.97) for macro- vs normoalbuminuria and HR=1.38 (1.18;1.60) for micro- vs normoalbuminuria. Correspondingly for first renal event: HR=39.4 (26.3;58.9) and HR=3.57 (2.20;5.80) (Figure). Within each subgroup the risk for CV and renal events was lower in patients with >30% UACR reduction than in those with any UACR increase. There were no interactions between groups (Figure).

Conclusions: These findings highlight the benefit of UACR reduction, even in patients with normoalbuminuria at baseline.

TH-OR035

Treatment with Dipeptidyl-Peptidase Inhibitors (DPP4_Rx) Delays Progression of Kidney Disease and Reduces Mortality

Thomas Wiegmann,[1] Olurinde Oni,[1] Peter S. Wiegmann,[2] Archana Goel,[1] Mukut Sharma,[1] Ram Sharma,[1] Maria N. Gomes,[1] Virginia J. Savin,[1] Mariana Garcia-Touza.[1] Cardiovascular and Renal Clinical Research at MidWest BioMedical Research Foundation *[1]Kansas City VA Medical Center, Kansas City, MO; [2]Midwest Biomedical Research Foundation, Kansas City, MO.*

Background: Effects of DPP4_Rx on cardiovascular morbidity are disputed and e ffects on renal function are not known.

Methods: Data from a large cohort of veterans diagnosed with type 2 diabetes mellitus (T2DM) were used to identify patients on DPP4_Rx (group 1). and without DPP4_Rx (group 2). Groups were matched for age (yrs), sex, BMI, initial renal function, follow-up time (FU, minimum 365 days). Propensity score matching (PSM) was used to adjust groups 1 and 2 with a best odds ratio about 1:2. Groups were compared to determine the effect of DPP4_Rx on the progression of CKD and all-cause mortality. Increase in serum creatinine (creat, mg/dl) over time (days) was taken as a measure of progression of CKD. Data were extracted using the Veterans Administration Informatics and Computing Infrastructure (VINCI), and analyzed using SPSS and SAS. Results were compared using t-tests, frequency tables, Kaplan Meier survival curves, hazard ratios (HR) and p values.

Results: Results show that subjects in group 1 (N=20,424) had baseline variables (creat 1.061, FU 1117, age 68.2 yrs and BMI 31.9) similar to Group 2 (N=52,118, creat 1.09, FU 1197, age 69.9, BMI 31.7). DM control improved in group 1 (HgbA1c 8.3% to 7.9%,

p < 0.001) but remained worse than group 2 (7.2% to 7.1%) A significant reduction in progression of CKD was seen in group 1. The proportion of patients exceeding creat of 1.5, 3, and 6 mg/dl was reduced by 6.5, 40.8 and 47.4%, all p<0.01 respectively. Time to ESRD (creat >6.0 mg/dl) was delayed also by 143.7 days p < 0.01. Mortality from all causes was reduced by 78.1%, but time to death was not changed.

Conclusions: We conclude that DPP4_Rx associates with a significant reduction in frequency of all-cause mortality and progression toward ESRD independent of glucose control. The data are consistent with a reduction in the number and severity of discrete morbid events that would associate with progressive renal disease and all cause mortality..

Does Glucose Control Influence the Effect of Empagliflozin on Kidney Outcomes in Type 2 Diabetes (T2D)? Insights from the EMPA-REG OUTCOME® Trial

Mark E. Cooper,[1] Silvio E. Inzucchi,[2] Bernard Zinman,[3] Stefan Hantel,[5] Maximilian von Eynatten,[5] Christoph Wanner,[4] Audrey Koitka-Weber.[1,5] *[1]Monash University, Melbourne, VIC, Australia; [2]Yale University School of Medicine, New Haven, CT; [3]Mount Sinai Hospital, Toronto, ON, Canada; [4]Würzburg University Clinic, Würzburg, Germany; [5]Boehringer Ingelheim International GmbH, Ingelheim, Germany.*

Background: In the EMPA-REG OUTCOME® trial, empagliflozin (EMPA), a selective SGLT2 inhibitor given in addition to standard of care, significantly reduced pre-specified kidney outcomes by 39% in T2D patients with established cardiovascular disease (CVD). There is evidence that intensified glycemic control in T2D prevents microvascular complications including progression of kidney disease. We sought to determine whether the renal benefits of EMPA were linked to its effect on HbA1c.

Methods: Patients were randomized (1:1:1) to EMPA 10 mg, EMPA 25 mg, or placebo (PBO). Background glucose-lowering therapy was to remain unchanged for the first 12 weeks. Kidney outcomes were analyzed in the pooled EMPA group vs PBO after adjustment by baseline HbA1c, for HbA1c control during the trial as a time-dependent factor, and by reduction in HbA1c from baseline to week 12. Differences in risk between treatment groups were assessed using a Cox proportional hazards model.

Results: A total of 7020 patients were treated. Median observation time was 3.1 years. The reduction in risk of incident or worsening nephropathy with EMPA vs PBO was found to be consistent irrespective of either HbA1c at baseline or subsequent changes in glycemic control during active study treatment (Figure).

Conclusions: In patients with T2D and established CVD, the beneficial effect of EMPA on kidney outcomes was consistent irrespective of HbA1c prior to and during therapy. EMPA-KIDNEY, the outcome study of heart and kidney protection with EMPA, will provide additional insights into potential glycemia-independent kidney effects of EMPA in patients with and without diabetes.

TH-OR037

Prediction of the Effect of Dapagliflozin on Renal and Heart Failure Outcomes Based on Short-Term Changes in Multiple Risk Markers

Nienke Idzerda,[1] David Sjostrom,[2] Bergur V. Stefansson,[3] David C. Wheeler,[4] Hiddo J. Lambers Heerspink.[1] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]AstraZeneca LP, Molndal, Sweden; [3]AstraZeneca, Molndal, Sweden; [4]University College London, London, United Kingdom.*

Background: Sodium glucose cotransporter 2 inhibition with dapagliflozin reduces blood pressure, body weight and urinary albumin:creatinine ratio (UACR) in patients with type 2 diabetes (T2DM). We previously developed an algorithm, the PRE score, to predict how short term effects of a drug on risk factors may translate into long-term changes in clinical outcomes. We applied the PRE score to clinical trials of dapagliflozin to model the effect of the drug on renal and heart failure (HF) outcomes in T2DM patients with impaired renal function.

Methods: The relationships between multiple risk markers and long-term outcome were determined by means of a multivariable Cox model in a subgroup of T2DM patients derived from the ALTITUDE trial. These relationships were applied to short-term changes in risk markers observed in a pooled database of seven dapagliflozin clinical trials to predict the expected drug-induced changes to renal and HF outcomes. Patient characteristics within the background population were matched with respect to UACR and eGFR to those from the dapagliflozin trial participants. The renal outcome was defined as a composite of end-stage renal disease (ESRD) and a sustained doubling of serum creatinine. The heart failure outcome was defined as hospitalization due to HF.

Results: A total of 372 and 136 patients had UACR>30 mg/g and UACR>200 mg/g at baseline, respectively. The PRE score predicted a renal risk reduction of 39% (95% CI 17 to 61%) and 43% (95% CI 4 to 83%) with dapagliflozin 10 mg/day for the UACR>30 mg/g and UACR>200 mg/g subgroups. The predicted reduction in HF events was 21% (95% CI 8 to 35%) and 28% (95% CI 7 to 49%), respectively. Dapagliflozin decreased albuminuria by approximately 35% in both UACR subgroups. Simulation analyses showed that even with a smaller albuminuria lowering effect of dapagliflozin (10%), the estimated renal risk reduction was still 26.5% and 26.8% in the two UACR subgroups.

Conclusions: The PRE score predicted clinically meaningful reductions in renal and HF endpoints associated with dapagliflozin therapy in patients with diabetic kidney disease. These results support a large long-term outcome trial in this population to confirm the benefits of the drug on these endpoints.

TH-OR038

Canagliflozin Induced Reduction in TNF Receptor 1 Is Associated with a Reduction in eGFR Decline

Hiddo J. Lambers Heerspink,[1] Paul Perco,[2] Skander Mulder,[1] Johannes Leierer,[2] Michael K. Hansen,[3] Andreas Heinzel,[4] Gert J. Mayer.[2] *[1]Department of Clinical Pharmacy and Pharmacology, University of Groningen, Groningen, Netherlands; [2]Department of Internal Medicine, Medical University of Innsbruck, Innsbruck, Austria; [3]Janssen Research & Development, LLC, Spring House, PA; [4]emergentec biodevelopment GmbH, Vienna, Austria.*

Background: Circulating levels of the pro-inflammatory biomarker Tumor Necrosis Factor Receptor 1 (TNFR1) predict the risk of end-stage renal disease (ESRD) in patients with type 2 diabetes. Experimental studies suggested that sodium glucose co-transporter 2 (SGLT2) inhibitors exert anti-inflammatory effects. Here we examined the effect of the SGLT2 inhibitor canagliflozin (CANA) on TNFR1 and assessed whether the change in TNFR1 is associated with eGFR decline.

Methods: TNFR1 levels were measured at baseline, 52 and 104 weeks in plasma samples of 297 patients with type 2 diabetes and urinary albumin:creatinine ratio >15 mg/g participating in a phase 3 clinical trial. Patients were randomly assigned to CANA 100 or 300 mg or glimepiride (GLIM) uptitrated to 6 to 8 mg. Repeated measure models were used to compare effects of CANA vs. GLIM on TNFR1 over 104 weeks follow-up and to assess associations between change in TNFR1 with eGFR change.

Results: During 104 weeks of follow-up, TNFR1 increased in the GLIM group but stabilized or decreased in the CANA 100 and 300 mg groups. Compared with glimepiride, treatment with CANA 100 and 300 mg dose-dependently decreased TNFR1 by 5.9% (1.3 to 10.3; p=0.013) and 9.2% (4.7 to 13.5%; p<0.001). The change in TNFR1 at week 52 (the earliest available time point) was significantly and independently associated with eGFR decline during 104 weeks follow-up (p=0.0234). In increasing tertiles of TNFR1 change, eGFR change during 104 weeks follow-up was -0.4 (95%CI -2.3 to 1.5), -4.7 (95%CI -6.5 to -2.8), and -7.1 (95%CI -9.0 to -5.2) ml/min/1.73m^2. Reductions in HbA1c were similar with GLIM and CANA during follow-up.

Conclusions: The reduction in TNFR1 with CANA and association between changes in TNFR1 and eGFR suggests that TNFR1 may be used to monitor effects of CANA on long-term kidney function.

Canagliflozin in Patients with Type 2 Diabetes and Macroalbuminuria: Data from the CANVAS Program

Vlado Perkovic,[1] Brendon L. Neuen,[1] Toshiaki Ohkuma,[1] Bruce Neal,[1] David R. Matthews,[2] Dick de Zeeuw,[3] Kenneth W. Mahaffey,[4] Greg Fulcher,[5] Richard Oh,[6] Qiang Li,[1] Meg J. Jardine.[1] *[1]The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; [2]Oxford Centre for Diabetes, Endocrinology and Metabolism and Harris Manchester College, University of Oxford, Oxford, United Kingdom; [3]University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [4]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; [5]The Royal North Shore Hospital, University of Sydney, St. Leonards, NSW, Australia; [6]Janssen Research & Development, LLC, Raritan, NJ.*

Background: High levels of albuminuria are associated with increased progressive loss of kidney function in type 2 diabetes mellitus (T2DM). SGLT2 inhibitors reduce glomerular hyperfiltration, which might therefore have particular benefits for people with T2DM and macroalbuminuria.

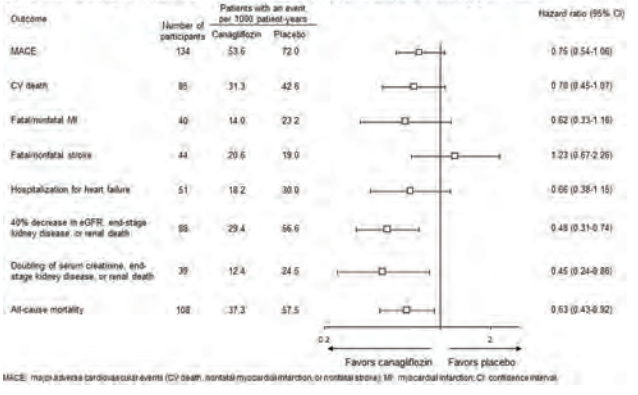
Methods: The CANagliflozin cardioVascular Assessment Study (CANVAS) Program randomized patients with T2DM and a history or high risk of cardiovascular (CV) disease to canagliflozin or placebo. This analysis assessed effects of canagliflozin on renal and CV outcomes in participants with macroalbuminuria at baseline (urinary albumin:creatinine ratio [UACR] >300 mg/g).

Results: The CANVAS Program included 760 participants (7.5%) with macroalbuminuria (mean age 64 y, BP 145/80 mmHg, HbA1c 8.5%, estimated glomerular filtration rate [eGFR] 66 mL/min/1.73 m^2, median UACR 722 mg/g). As compared with placebo, canagliflozin significantly reduced the geometric mean UACR (change from baseline to end of follow-up –36%, 95% CI –43 to –28); slowed the chronic annual decline in eGFR: –1.76 mL/min/1.73 m^2 with canagliflozin vs. –4.77 mL/min/1.73 m^2 with placebo (difference 3.01 mL/min/1.73 m^2, 95% CI 2.03-3.99); and reduced the risk of the composite outcome of end-stage kidney disease or renal death in combination with either 40% decrease in eGFR or doubling of serum creatinine (Figure). Canagliflozin also reduced the risk of all-cause mortality (Figure), while effects on CV outcomes were broadly consistent with those previously reported for the overall trial population.

Conclusions: Canagliflozin lowers albuminuria and improves outcomes in patients with T2DM and macroalbuminuria.

Funding: Commercial Support - Janssen Research & Development, LLC

Figure. Effect of canagliflozin on CV and renal outcomes in participants with UACR >300 mg/g at baseline.



MACE: major adverse cardiovascular events (CV death, nonfatal myocardial infarction, or nonfatal stroke); MI: myocardial infarction; CI: confidence interval.

Effect of Canagliflozin on Cardiovascular and Renal Outcomes across KDIGO Risk Categories: Analysis from the CANVAS Program

Brendon L. Neuen,[1] Toshiaki Ohkuma,[1] Bruce Neal,[2] David R. Matthews,[3] Dick de Zeeuw,[4] Kenneth W. Mahaffey,[5] Greg Fulcher,[6] Jaime Blais,[7] Qiang Li,[1] Meg J. Jardine,[1,8] David C. Wheeler,[9] Vlado Perkovic.[1,6] *[1]The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; [2]The George Institute for Global Health, UNSW Sydney, Sydney, NSW, Australia; [3]Oxford Centre for Diabetes, Endocrinology and Metabolism and Harris Manchester College, University of Oxford, Oxford, United Kingdom; [4]University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [5]Stanford Center for Clinical Research, Department of Medicine, Stanford University School of Medicine, Stanford, CA; [6]Royal North Shore Hospital, Sydney, NSW, Australia; [7]Janssen Scientific Affairs, LLC, Titusville, NJ; [8]Concord Repatriation General Hospital, Sydney, NSW, Australia; [9]Centre for Nephrology, University College London, London, United Kingdom.*

Background: The CANagliflozin cardioVascular Assessment Study (CANVAS) Program randomized patients with type 2 diabetes to canagliflozin or placebo and demonstrated that the drug reduced the risk of cardiovascular (CV) and renal outcomes. The Kidney Disease: Improving Global Outcomes (KDIGO) chronic kidney disease classification is a risk stratification tool based on estimated glomerular filtration rate (eGFR, mL/min/1.73 m^2) and urinary albumin:creatinine ratio (UACR, mg/g).

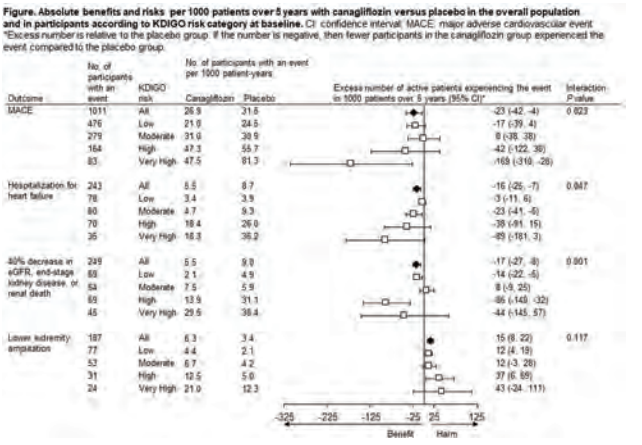
Methods: Absolute effects on CV and renal outcomes were analyzed by baseline KDIGO risk category, defined as low risk (eGFR ≥60 and UACR <30), moderate risk (eGFR 45-<60 and UACR <30, or eGFR ≥60 and UACR 30-300), high risk (eGFR 30-<45 and UACR <30, eGFR 45-<60 and UACR 30-300, or eGFR ≥60 and UACR >300), and very high risk (eGFR <30 with any UACR, eGFR 30-<45 and UACR ≥30, or eGFR 45-<60 and UACR >300).

Results: Of 10,142 participants, 10,031 (98.9%) had available baseline eGFR and UACR data. The proportion of participants in low, moderate, high, and very high risk categories was 58.6%, 25.8%, 10.6%, and 5.0%, respectively. Heterogeneity in absolute effects across KDIGO risk categories was observed for the primary outcome (CV death, nonfatal myocardial infarction, or nonfatal stroke; *P* heterogeneity=0.023), hospitalization for heart failure (*P*=0.047), and the renal composite outcome (40% decrease in eGFR, end-stage kidney disease, or renal death; *P*=0.001; Figure).

Conclusions: The absolute reduction in CV and renal outcomes with canagliflozin may be greater in patients at higher renal risk.

Funding: Commercial Support - Janssen Research & Development, LLC

Figure. Absolute benefits and risks per 1000 patients over 5 years with canagliflozin versus placebo in the overall population and in participants according to KDIGO risk category at baseline. CI: confidence interval; MACE: major adverse cardiovascular event. *Excess number is relative to the placebo group. If the number is negative, then fewer participants in the canagliflozin group experienced the event compared to the placebo group.



TH-OR041

Effects of Hyperoxia with and without Klotho Supplementation in a Murine Model of Post-Natal Nephrogenesis

Mohammed Farhan Ali,[1] Sunil kumar Batlahally venkatarayappa,[2] Merline Benny,[2] Claudia P. Rojas,[3] Naimeh Da Silva,[1] Michael Freundlich,[1] Carolyn L. Abitbol,[1] Marissa J. Defreitas,[1] Karen C. Young.[2] *[1]Department of Pediatrics, Division of Pediatric Nephrology, University of Miami, Miami, FL; [2]Department of Pediatrics, Division of Neonatology, University of Miami, Miami, FL; [3]Department of Pediatrics, Division of Pediatric Pathology, University of Miami, Miami, FL.*

Background: Preterm infants are born during active nephrogenesis and exposure to high oxygen levels has been proposed to cause kidney related injury due to oxidative stress. Studies investigating the effects of hyperoxia on nephrogenesis are limited and have not evaluated whether these effects are reversible by administration of an agent with antioxidant properties. The aim of our study was to determine whether the administration of exogenous Klotho, a multi-functional protein that is known to diminish oxidative stress and apoptosis, attenuates hyperoxia induced glomerular and tubular injury in rats during nephrogenesis.

Methods: Newborn rat pups were raised in hyperoxia (85% oxygen for 3 weeks and then recovered in room air for 3 weeks) or room air (21% oxygen for 6 weeks). Klotho was administered intraperitoneally to half of the pups in both groups every other day for the first 3 weeks. All pups were sacrificed at the end of 6 weeks and the kidneys were assessed for glomerular diameter and area using Image J software, and tubular injury using a tubular injury scoring system (0- no injury, 5- >75% of tubules injured).

Results: Hyperoxia exposed rats had greater glomerular diameter, area and tubular injury scores. The administration of Klotho attenuated tubular injury (Figure A) and prevented glomerulomegaly (Figure B).

Conclusions: The findings of this study demonstrate that hyperoxia exposure during active nephrogenesis in the neonatal rat pups results in increased glomerular size and tubular injury and that the exogenous administration of Klotho in these pups attenuates hyperoxia induced tubular injury and prevents glomerulomegaly at 6 weeks. Future studies aimed at exploring the therapeutic potential of Klotho in neonatal models of kidney injury are needed.

Increased Mortality in Underweight but Not Obese Critically Ill Patients – A Secondary Analysis of the AWARE Study

Rajit K. Basu,[2] Itay Ayalon,[1] Jessica G. Woo,[3] Ahmad Kaddourah,[3] Stuart Goldstein,[3] Jennifer M. Kaplan.[4] *[1]Dana-Dwek Children's Hospital, Tel-Aviv Medical Center, Tel-Aviv, Israel; [2]Children's Healthcare of Atlanta, Atlanta, GA; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Obesity is a significant public health problem with an increasing prevalence in both adults and children. The effect of obesity on critical care mortality is controversial and even less is known about the effect of underweight status on mortality. We investigated the prevalence and outcomes of obesity and underweight in a large, critically ill pediatric cohort.

Methods: We conducted a secondary analysis of the prospective, observational, multinational Assessment of Worldwide Acute kidney injury, Renal angina, and Epidemiology (AWARE) study data. PICU patients, 3mos to 25yrs, were eligible but only subjects with documented age, sex, height and weight were analyzed. Patients were divided into 4 groups (under, normal, overweight and obese) based on their BMI percentile-for-age and sex according to WHO (for patients 3mos- 2yrs) and CDC criteria (for patients ≥2yrs). The primary outcome was 28d mortality. We planned for an analysis of a subgroup of septic patients.

Results: A total of 3,719 patients were evaluated of which 542 (14%) had a primary diagnosis of sepsis. Twenty-nine percent of patients were underweight, 44% normal weight, 11% overweight and 16% obese. The 28d mortality rate was 3.5% for the entire cohort and 8.9% for the septic group and differed significantly by weight status (5.7%, 3%, 2.1% and 1.7% for under, normal, overweight and obese subjects, p<0.0001 and 14.9%, 6.5%, 3.5%, 5.3% in the septic group respectively, p=0.003). In a fully adjusted model, 28d mortality risk was 1.8-fold higher in underweight (adjusted Odds Ratio [OR] and 95%CI: 1.2-2.8]) compared to normal weight in the entire group and 3.4 [1.4-8.4] in the septic group with overweight and obese not having increased risk in both cohorts. Interestingly underweight patients had a significantly higher frequency of fluid overload >10% at day 3 (44.0% vs. 32.5%, 26.1%, 19.1% for under, normal, overweight and obese subjects, p<0.0001) without increased frequency of KDIGO-AKI or renal replacement therapy.

Conclusions: Underweight subjects make up a significant proportion of patients in the PICU. Underweight, not obesity, is independently associated with increased risk for mortality which may be associated to their higher frequency of fluid overload during their ICU stay.

TH-OR043

Central Blood Pressure and Measures of Vascular Health in Children with ADPKD

Paul Winyard,[1] Matko Marlais,[1,2] Haotian Gu,[3] Manish Sinha.[2] *[1]Nephro-Urology Unit, UCL GOS Institute of Child Health, London, United Kingdom; [2]Evelina London Children's Hospital, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [3]King's College London, London, United Kingdom.*

Background: Hypertension is increasingly recognised in children with Autosomal dominant polycystic kidney disease (ADPKD) but underlying cardiovascular factors such as central blood pressure (cBP) and pulse wave velocity (PWV) may change before overt hypertension. We assessed peripheral BP (pBP), cBP, pulse pressure (PP) amplification ratio, carotid-femoral PWV (PWVcf) and indexed left ventricular mass (LVMI) in children with ADPKD.

Methods: This was a two-centre prospective observational study of children with ADPKD versus age and BMI-matched healthy controls. All children underwent manual pBP, cBP using radial applanation tonometry and PWVcf with a SphygmoCor device. LVMI was measured by 2D m-mode echocardiography. 24-hour ambulatory BP monitoring (ABPM) and urine albumin: creatinine ratio was assessed in children with ADPKD. Estimated GFR was calculated in children where blood tests were performed.

Results: 47 ADPKD and 49 healthy controls (mean ages 11.4 and 11.7 years, 55% and 39% male respectively) were recruited from two paediatric nephrology centres. Children with ADPKD had significantly higher pBP (mean 112/65mmHg vs. 104/60mmHg, systolic p<0.001) and cBP (mean 97/67mmHg vs. 87/61mmHg, systolic p<0.001) compared to healthy children. There was no significant difference between clinic pBP and 24-hour ABPM. 9 children (19%) with ADPKD were on anti-hypertensive medication. Children with ADPKD had a significantly lower PP amplification ratio (1.59 vs. 1.67, p=0.04) compared to healthy children. There was no difference in PWVcf between affected and healthy children (mean 5.74m/s vs. 5.57m/s, p=0.46). Children with ADPKD had a significantly higher LVMI (mean 30.4 g/m$^{2.7}$ vs. 26.2 g/m$^{2.7}$, p=0.01), although only one had frank hypertrophy. There was significantly lower eGFR (mean 89.9ml/min/1.73m^2 vs. 101.4ml/min/1.73m^2, p<0.01) and 42% of children with ADPKD had evidence of microalbuminuria with a raised albumin:creatinine ratio.

Conclusions: This study confirmed that a significant percentage of children with ADPKD have higher blood pressure, with novel cardiovascular findings of normal PWV but significantly lower PP amplification and increased LVMI. These early cardiovascular abnormalities should be amenable to antihypertensive therapy, reinforcing the need for routine screening of children and young people with ADPKD. eGFR and microalbuminaria warrant checking at the same visit.

TH-OR044

Should RAAS Inhibition Be Discontinued in Children with Advanced CKD? Results of the 4C Study

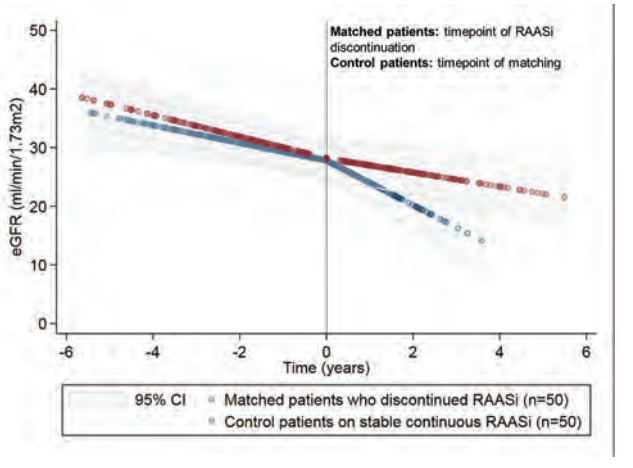
Valentina Gracchi,[1] Sophie Van den Belt,[1] Hiddo J. Lambers Heerspink,[1] Elke Wuehl,[2] Dick de Zeeuw,[1] Franz S. Schaefer.[2] 4C Study group *[1]University Medical Center Groningen, Groningen, Netherlands; [2]University of Heidelberg, Heidelberg, Germany.*

Background: RAAS inhibition (RAASi) is used for renoprotection in children with Chronic Kidney Disease (CKD). RAASi is sometimes discontinued in advanced stages of CKD. We studied the reasons and impact of RAASi discontinuation on important markers of CKD progression and on eGFR decline in the Cardiovascular Comorbidity in Children with CKD (4C) study.

Methods: 69 children with CKD (67% male, mean age 13.7 years, mean eGFR 27 ml/min/1.73m2) who discontinued RAASi during prospective follow-up were studied. Initial 6-month changes in blood pressure, albuminuria and potassium after discontinuation were assessed. The rate of eGFR decline (eGFR slope) during a median of 1.9 years before and 1.2 years after discontinuation were estimated using a linear mixed effects model.

Results: Reported reasons for RAASi discontinuation were increase in serum creatinine (33%), hyperkalemia (23%), and symptomatic hypotension (17%). After discontinuation of RAASi, blood pressure and albuminuria increased whereas potassium decreased. eGFR loss accelerated after RAASi discontinuation from -1.5 (95%CI -2.4 to -0.6) during RAASi treatment to -3.9 (95%CI -5.1 to -2.6) ml/min/1.73m^2 per year (p=0.005). In a matched control group of children who continued RAASi, renal function decline was stable before and after timepoint of matching (eGFR slope -1.8 (95%CI -2.6 to -1.1) versus -1.2 (95%CI -2.0 to -0.4) ml/min/1.73m2/year; p=0.30; Figure).

Conclusions: Discontinuation of RAASi in children with CKD is associated with an acceleration of renal function decline. These results indicate that RAASi is nephroprotective even in advanced CKD and that stopping this therapy, even for good clinical reasons, should be weighed against a potential negative impact on long term renal function.



eGFR over time in patients who discontinued RAASi (blue) and matched controles (red). Grey area: 95%CI per group.

Uric Acid, Kidney Function, and Cardiovascular Risk among Children with CKD

Shireen Hashmat,[1] Shuai Jiang,[2] Derek Ng,[3] Susan L. Furth,[6] Bradley A. Warady,[5] Cynthia G. Pan.[4] *[1]Pediatrics, University of Chicago, Chicago, IL; [2]Johns Hopkins University, Baltimore, MD; [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [4]Children's Corporate Center, Milwaukee, WI; [5]Children's Mercy Kansas City, Kansas City, MO; [6]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Previous studies have shown that high uric acid (UA) is associated with cardiovascular risk factors in adults with and without chronic kidney disease (CKD), but the relationships in children with CKD are not well characterized. We used longitudinal data from the Chronic Kidney Disease in Children (CKiD) cohort study to investigate the relationships between UA, kidney function and cardiovascular outcomes.

Methods: The primary exposure was time-varying UA measured at annual visits. The primary outcomes were blood pressure (BP; clinical and ambulatory) and markers of cardiometabolic health (ie, lipids). Multivariate linear mixed effects models described UA z-scores (scaled within the CKiD population) with BP and lipid outcomes.

Results: A total of 718 participants (mean age= 13, 60% male and 29% with a glomerular-based CKD diagnosis) with at least 1 UA measurement were included in the analysis. At baseline, 47% had a high UA based on age- and gender-specific cutpoints. The figure (below) demonstrates that the UA increased with age, as well as decreasing eGFR even when adjusted for age. Whereas UA was associated with higher clinical and ambulatory BP, the differences were not significant. In models adjusted for age,

gender, race, BMI, CKD diagnosis and eGFR, participants with one SD higher UA had significantly lower HDL (47 vs 50 mg/dL), higher LDL (93 vs 89 mg/dL) and higher total triglycerides (116 vs 110 mg/dL) at baseline compared to those with the average UA. Higher UA was also significantly associated with slower increase in HDL with time (p= 0.002). UA was not associated with longitudinal changes in clinical or ambulatory BP measurements.

Conclusions: There is a strong relationship between eGFR and UA in children with CKD. Higher UA is associated with a more severe lipid profile at baseline and over time, but is not independently associated with hypertension.

Funding: NIDDK Support

Kidney Biomarkers for CKD Risk Stratification after Pediatric Cardiac Surgery in the ASSESS-AKI Study

Jason H. Greenberg,[1] Michael Zappitelli,[2] Vernon M. Chinchilli,[3] Steven G. Coca,[4] Mark M. Wurfel,[5] Edward D. Siew,[6] Alan S. Go,[7] Paul L. Kimmel,[8] James S. Kaufman,[9] Prasad Devarajan,[10] Chirag R. Parikh.[11] ASSESS-AKI *[1]Yale University, New Haven, CT; [2]Toronto Hospital for Sick Children, University of Toronto, Toronto, ON, Canada; [3]Penn State College of Medicine, Hershey, PA; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]University of Washington, Seattle, WA; [6]Vanderbilt University School of Medicine, Nashville, TN; [7]Kaiser Permanente Northern California, Oakland, CA; [8]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [9]VA New York Harbor Healthcare System, New York, NY; [10]Cincinnati Children's Hospital, Cincinnati, OH; [11]Yale University and VAMC, New Haven, CT.*

Background: We have previously demonstrated that children who require surgery for congenital heart disease have increased risk for long-term hypertension and chronic kidney disease (CKD). Biomarkers of ongoing kidney injury and fibrosis after surgery may indicate subclinical kidney disease and assist with prognosis for long-term hypertension and CKD.

Methods: We enrolled children from 1 month to 18 years old undergoing cardiac surgery in the ASSESS-AKI Study. We used Cox proportional hazards regression to assess the association between eight urinary biomarkers (log2 transformed) measured 3 months after cardiac surgery: NGAL, KIM-1, IL-18, L-FABP, uromodulin, MCP-1, YKL-40, and albumin, with the outcomes of incident hypertension (systolic or diastolic BP ≥ 95% for age, height, and gender) and CKD (modified Schwartz eGFR<90 ml/min/1.73m²) at yearly in-person visits over 4 years.

Results: 117 children undergoing cardiac surgery were enrolled. During 48 months of follow-up there were 44 (38%) and 71 (61%) children who developed hypertension and CKD, respectively. After adjustment for sex, AKI during the index hospitalization for surgery, and pre-surgery eGFR, only urine albumin was independently associated with incident CKD (HR, 1.52; 95% CI, 1.20-1.93), but was not associated with incident hypertension (Table). None of the other 7 urinary biomarkers of injury or fibrosis were associated with either outcome.

Conclusions: At 3 months after cardiac surgery, children with higher urine albumin, but not any other tubular injury and fibrosis biomarkers, were more likely to develop CKD.

Funding: NIDDK Support

Table. Multivariate Cox proportional hazard models of the risk of incident hypertension and CKD in children after cardiac surgery with urine biomarkers

	Hypertension HR (95% CI)	CKD HR (95% CI)
Urine biomarker		
NGAL	1.07 (0.91-1.25)	1.05 (0.92-1.20)
KIM-1	0.99 (0.87-1.12)	1.05 (0.93-1.17)
IL-18	1.22 (0.98-1.52)	1.01 (0.85-1.20)
L-FABP	0.92 (0.71-1.20)	1.00 (0.81-1.24)
Uromodulin	0.79 (0.60-1.04)	1.01 (0.82-1.24)
MCP-1	0.95 (0.86-1.06)	1.02 (0.93-1.12)
YKL-40	1.06 (0.90-1.24)	1.07 (0.93-1.23)
Albumin	1.20 (0.90-1.59)	1.52 (1.20-1.93)

Effect size is expressed as the HR for a two-fold increase of each biomarker

Models are adjusted for sex, AKI during the index hospitalization, and pre-surgery eGFR

TH-OR047

Adaptation of the Kidney Failure Risk Equation to Predict Risk of ESRD in Children

Elaine Ku,[1] Elke Wuehl,[6] Erica Winnicki,[1] Mark Mitsnefes,[2] Charles E. McCulloch,[3] Bradley A. Warady,[4] Susan L. Furth,[5] Franz S. Schaefer.[6] *[1]UC San Francisco, San Francisco, CA; [2]Cincinnati Children's Hospital, Cincinnati, OH; [3]University of California San Francisco, San Francisco, CA; [4]Children's Mercy Kansas City, Kansas City, MO; [5]The Children's Hospital of Philadelphia, Philadelphia, PA; [6]University of Heidelberg, Heidelberg, Germany.*

Background: The Kidney Failure Risk Equations (KFREs) have been shown to predict ESRD risk in children with mild-to-moderate CKD in the US. Whether the KFRE accurately predicts progression to ESRD in children with more advanced CKD and children outside of the US is unknown. KFREs to predict ESRD risk in North American (NA) and non-North American (NNA) adults are currently available.

Methods: We studied 653 children from 4C study, 341 children from ESCAPE trial, and 633 children from CKiD study with an eGFR <60 mL/min/1.73 m². The primary predictors were the 4-variable (age, sex, bedside eGFR, albumin-to-creatinine ratio) NA and NNA KFRE score which provides estimates of the risk of ESRD over a 2- and 5-year horizon. C-statistics were used to compare discrimination of the risk for ESRD by the KFRE, and this predicted risk of ESRD was compared to observed failure rates.

Results: Median follow-up time was 2.8 years in 4C, 4.7 years in ESCAPE, and 3.8 years in CKiD. The NA and NNA 4-variable KFRE strongly discriminated risk of ESRD in children outside the US, with a C-statistic of 0.82 and 0.79 in 4C and 0.90 and 0.87 in ESCAPE over a 2- and 5-year horizon, respectively. The predicted risk closely matched the observed ESRD rates in CKD stage 3, but over-predicted ESRD risk in CKD stage 4-5 across all cohorts (Figure 1). After we re-calibrated the equation, performance of the KFRE in advanced CKD improved (Figure 2).

Conclusions: The KFRE is a simple tool that strongly discriminates the risk of ESRD in children with CKD in the US and internationally, although its performance was less robust in children with advanced CKD. With re-calibration, its performance in more advanced CKD was substantially improved.

Funding: NIDDK Support

Children in CKiD with Congenital, Non-Glomerular Form of Progressive CKD Will Experience Renal Replacement Therapy by 40 Years of Age

Derek Ng,[1] Matthew Matheson,[1] Bradley A. Warady,[2] Susan L. Furth,[3] Alvaro Munoz.[1] [1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD;* [2]*Children's Mercy Kansas City, Kansas City, MO;* [3]*The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: The Chronic Kidney Disease in Children (CKiD) study provides a unique opportunity to prospectively describe a life course characterization of progressive non-glomerular disease prior to renal replacement therapy (RRT). Our aim was to maximize the heterogeneous disease duration at entry in this cohort to estimate the age by which all children with congenital, non-glomerular disease will require RRT.

Methods: The times to RRT in CKiD children were characterized by parametric survival models (generalized gamma (GG) distribution). The time scale was years from NG diagnosis (age) and accounted for late entries due to heterogeneous disease duration at enrollment. Models were fit overall, and stratified by race and gender.

Results: Among 626 children, the median duration of disease at entry was 9 years (range 2 to 18) and median duration at end of follow-up was 15 years (maximum= 27). Three diagnosis groups represented 67%: obstructive uropathy (24%), hypo/dysplasia (24%) and reflux nephropathy (19%). Over approximately 25 years (capitalizing on staggered entries), 186 initiated RRT. The GG fit was excellent and demonstrated that 50% received RRT by age 18.5 and estimated that 99.6% will receive RRT by age 40 (Figure). The times to RRT did not differ significantly by race (p=0.25) or gender (p=0.40), with similar 40 year estimates of RRT for nonblacks (99.9%), blacks (98.8%), males (99.9%) and females (97.9%).

Conclusions: Practically all CKiD participants with progressive non-glomerular disease will receive RRT by 40 years old, much earlier than reports from European registries. This is likely due to a combination of access to care, organ availability and disease severity. Methodologically, these data enable handling right censored observations as interval censored, thus enriching parametric survival methods.

Racial and Ethnic Disparities in Pediatric Kidney Transplant Outcomes in the United States: Have We Made Any Progress over the Last Twenty Years?

Tanjala S. Purnell,[1] Xun Luo,[1] Karina Covarrubias,[1] Deidra C. Crews,[1] Lisa A. Cooper,[1] Sunjae Bae,[1] O. N. Ray Bignall,[2] Macey L. Henderson,[1] Allan Massie,[1] L. Ebony Boulware,[3] Dorry L. Segev.[1] [1]*Johns Hopkins University School of Medicine, Baltimore, MD;* [2]*Cincinnati Children's Hospital Medical Center, Cincinnati, OH;* [3]*Duke University School of Medicine, Durham, NC.*

Background: A recent JASN study demonstrated dramatic reductions in disparities in adult kidney transplant (KT) outcomes in the US. We examined twenty-year trends in pediatric KT outcomes to determine whether pediatric KT disparities also changed over time.

Methods: Using OPTN data, we performed Cox proportional hazards regression models to compare patient outcomes among 3,295 White, 2,049 Black, and 2,073 Hispanic children (aged 0-17 years) who received a KT in the US between January 1, 1995 and December 31, 2014. We adjusted regression models for differences in recipient, donor, and transplant center factors.

Results: From 1995 to 2014, survival after KT improved for all recipients. **(Figure 1)** However, racial/ethnic disparities in long-term survival worsened over time (p<0.05 for statistical interaction). In 1995, compared with long-term mortality in White KT recipients, the adjusted hazard ratio (aHR) for Black recipients was 0.89 (95% CI: 0.67, 1.18) and for Hispanic recipients was 0.51 (95% CI: 0.34, 0.76). In 2014, compared with White recipients, the aHR for Black recipients was 1.84 (95% CI: 1.10, 3.07) and for Hispanic recipients was 0.71 (95% CI: 0.37, 1.35).

Conclusions: In stark contrast to the prior findings of reduced disparities for adult KT recipients, we found that disparities in long-term survival among pediatric kidney transplant recipients worsened over the last two decades in the US. Strategies to elucidate and intervene on mechanisms for disparities in long-term outcomes among pediatric recipients are needed.

Prevalence of Blood Pressure Control in Children with Kidney Transplant

Pamela D. Winterberg,[1,2] Rouba Garro,[1,2] Devesh S. Dahale,[3] Jens W. Goebel,[4] David K. Hooper.[3] Improving Renal Outcomes Collaborative [1]*Department of Pediatrics, Emory University School of Medicine, Atlanta, GA;* [2]*Children's Healthcare of Atlanta, Atlanta, GA;* [3]*Cincinnati Children's Hospital Medical Center, Cincinnati, OH;* [4]*Children's Hospital Colorado, Aurora, CO.*

Background: Hypertension (HTN) is common in children following kidney transplant (KT) with reported prevalence of 60-90%. Uncontrolled blood pressure (BP) is associated with cardiovascular mortality and decreased graft survival. The Improving Renal Outcomes Collaborative (IROC) is a networked learning health system of 23 pediatric centers dedicated to improving health outcomes and longevity for children with kidney disease by sharing best practices and clinical data, and engaging in quality improvement (QI). We aimed to determine the baseline prevalence of systolic BP control and treatment within the collaborative after implementing standardized processes for BP measurement across centers.

Methods: Patient and KT characteristics were uploaded into the IROC registry via UNOS TEIDI reports. Biometric data, BP measurements, and medications are prospectively entered by centers for each clinic visit. BP percentiles are automatically calculated in the registry using the 2004 NHBPEP 4th Report to determine BP status for each visit (e.g. normal, pre-HTN, stage 1, stage 2). We examined the latest clinic visit for each patient >90 days post-transplant in the registry. Patients were classified by systolic BP control (<90th percentile) and treatment status.

Results: Of the 935 unique patients with at least 1 visit in the registry, 56% had uncontrolled systolic BP (pre-HTN or greater) and/or were on BP medications. Of the 492 pts receiving BP meds, 132 (27%) had uncontrolled systolic BP at last visit. In addition, 31 patients (3% of total) had uncontrolled systolic BP at last visit but no record of BP medication. Of those treated, 80% had one, 16% had 2, and 8% had 3 or more active BP meds. Calcium channel blockers (80%) were most commonly used for treatment of BP followed by renin-angiotensin system blockade (33%), and beta-adrenergic blockade (23%).

Conclusions: HTN is common in pediatric KT patients in the IROC registry. Nearly one-quarter of those treated for HTN have not achieved systolic BP control. Future studies within IROC will evaluate patient- and center-level factors influencing BP control.

		Visit BP Status		
		Normal BP	Uncontrolled BP	Total
BP Treatment	Meds	360 (73% treated are **well-controlled**)	132 (27% treated are **uncontrolled**)	492 (53%)
	No Meds	412 (44% of pts **no treatment required**)	31 (3% pts **untreated, uncontrolled**)	443 (47%)
	Total	772 (83%)	163 (17%)	935

TH-OR051

IL-17 Signaling in CD4+ T Cells Control TH17 Responses

Tilman Schmidt,[1] Sonja Kapffer,[1] Christian F. Krebs,[1] Hans-Joachim Paust,[2] Ulf Panzer.[1] [1]*Universitätsklinikum Hamburg-Eppendorf, Hamburg, Germany;* [2]*Hamburg University Hospital, Hamburg, Germany.*

Background: The interleukin-17 family (IL-17A-F) plays a critical role in autoimmune and chronic inflammatory diseases, such as crescentic GN. A heterodimeric receptor complex consisting of IL-17RA and a ligand specific IL-17 receptor subunit (IL-17RB-E), which is expressed by epithelial and endothelial tissue cells, mediates their biological effects. In contrast, the IL-17 receptor expression pattern and function on hematopoietic cells, e.g. $CD4^+$ T cell subsets, remains to be determined.

Methods: Crescentic GN (Nephrotoxic Nephritis, NTN) was induced in IL-17A, IFNγ and Foxp3 triple-reporter mice for *in vivo* cell sorting of renal $CD4^+$ T cell subsets and

subsequent single cell RNAseq of $CD4^+$ T cells using the 10X Single Cell system. The effect of IL-17 signaling in $CD4^+$ T cells was analyzed by CD4 T cell polarization experiments. Moreover, we generated T_H17 cell specific IL-17RA gene-deficient mice to study the role of IL-17 signaling in Th17 cells in the NTN model.

Results: mRNA expression analysis of sorted T cells revealed a predominant expression of IL-17RC and IL-17RE by IL-$17A^{positive}$ T_H17 cells, high IL-17RB expression by $Foxp3^{positive}$Tregs, whereas IL-17RA is ubiquitously expressed by all $CD4^+$ T-cell subsets, demonstrating for the first time a T cell specific expression pattern of IL-17 receptors. *In vitro* T cell polarization experiments revealed that IL-17A-RC signaling downregulates IL-17A expression of T_H17 cells. In line, competitive adoptive transfer experiments of wildtype and IL-$17RA^{-/-}$ $CD4^+$ T cells into nephritic $Rag1^{-/-}$ mice revealed that T_H17 genes were upregulated in cells lacking the IL-17RA, indicating that IL-17 signaling on $CD4^+$ T-cells is instrumental for the control of the T_H17 response. In addition, scRNAseq analysis of 12,971 renal $CD4^+$ T cells revealed that, T_H17 cells lacking the IL-17RA form a distinct cluster which is characterized by upregulation T_H17 marker genes. Most importantly, mice lacking IL-17 signaling specifically in T_H17 cells demonstrated dysregulation of T_H17 immune response with higher production of IL-17A and F after induction of NTN and an accelerated course of the disease.

Conclusions: Our findings indicate that IL-17 receptor signaling in CD4 T cells control T_H17 immune response via a self-inhibitory loop. These findings might provide new insight into the development of more efficient anti-T_H17 treatment strategies.

Bowman Capsule Provides Protective Podocyte Niche: Implications for Crescentic Glomerulonephritis

Anqun Chen,[1,2] Kyung Lee,[2] Vivette D. D'Agati,[3] Tianjun Guan,[1] John C. He,[2] Judith Agudo,[2,4] Detlef O. Schlondorff.[2] *[1]ZhongShan Hospital, Xiamen University, XiaMen, China; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Columbia University College of Physicians and Surgeons, New York, NY; [4]Department of Cancer Immunology & Virology, Dana-Farber Cancer Institute, Boston, MA.*

Background: A role for CD8+ cytotoxic T cells (CTLs) in peri-glomerular infiltrates during glomerulonephritis (GN) has been proposed, but how and if CTLs can enter Bowman's space remains unclear.

Methods: CD8+ T cells from a newly generated transgenic mouse, termed Jedi (for Just EGFP Death Inducing) T cells that are cytotoxic for any EGFP expressing cells were used. Jedi T cells and lentivirus expressing EGFP were injected into transgenic mice with podocyte-specific EGFP expression mice in normal conditions and in a nephrotoxic serum nephritis (NTSN) model. 4 days after induction of NTSN, Jedi or control CD8+T cells were injected, and the mice were sacrificed at day 12. Proteinuria and blood urea were measured. EGFP+ podocyte areas were analyzed. In biopsies from patients with crescentic GN co-staining of CD8+ T cells and Bowman's capsule were performed.

Results: In control mice, Jedi T cells could not access EGFP+ podocytes. Conversely, when we induced NTSN and injected Jedi T cells, EGFP+ podocyte transgenic mice showed enhanced proteinuria and higher blood urea levels. Morphometric analysis showed greater loss of EGFP+ podocytes, which was associated with severe crescentic and necrotizing GN. Notably, only glomeruli with disrupted Bowman's capsule displayed massive CD8+ T cell infiltrates that were in direct contact with EGFP+ podocytes, causing their apoptosis. Comparable findings were obtained in biopsies from patients with crescentic GN, where infiltration of CD8+ T cells inside Bowman's capsule also only occurred after breaches in the capsule allowed access of CD8+ T cells to the glomerular tuft, resulting in its destruction.

Conclusions: Under control conditions Bowman's capsule provides an immunologically protected niche for podocytes from CTL. However any breach in Bowman's capsule, as occurs during crescentic GN, allows access of CTLs to Bowman's space with catastrophic consequences for the glomerulus, converting a potentially reversible GN into a rapidly progressive GN leading to end stage kidney disease. Translating these mechanistic insights to human crescentic nephritis should direct future therapeutic interventions at blocking CD8+ T cells, especially in progressive stages of rapidly progressive GN.

TH-OR053

Myeloperoxidase Mediates Renal Damage in Crescentic Glomerulonephritis That Can Be Successfully Targeted In Vivo

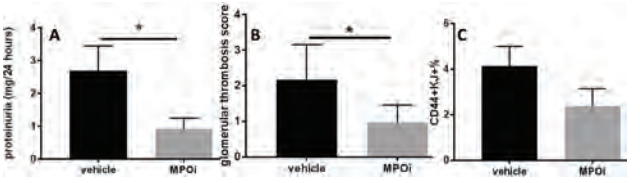
Marilina Antonelou,[1] Erik Michaëlsson,[2] Chun J. Wang,[3] Lucy S. Walker,[3] Robert J. Unwin,[2,1] Alan D. Salama.[1] *[1]Centre for Nephrology, University College London, London, United Kingdom; [2]Heart Failure Bioscience and Early Clinical Development, Cardiovascular, Renal and Metabolism (CVRM), IMED Biotech Unit, AstraZeneca, Sweden, AstraZeneca, Gothenburg, Sweden; [3]Institute of Immunity and Transplantation, University College London, London, United Kingdom.*

Background: Myeloperoxidase (MPO) released following neutrophil and monocyte activation can lead to host tissue damage by generating ROS and promoting further leukocyte activation. Extracellular glomerular MPO deposition has been shown in ANCA associated vasculitis (AAV) and may promote T and B cell glomerular targeting to enhance crescentic glomerulonephritis (CGN). MPO-deficient mice have less CGN but enhanced T cell activity (Odobasic, 2007). We investigated the role of MPO in mediating glomerular damage and leukocyte activation using a novel MPO inhibitor, AZM198.

Methods: A) We stained renal biopsies from patients with CGN due to SLE, IgA, anti-GBM disease, $ANCA^-$ and $ANCA^+$ GN, for MPO and CD15. B) We measured MPO activity in the supernatants of AAV patient neutrophils and healthy controls, stimulated by different means in the absence and presence of AZM198. C) We induced nephrotoxic nephritis (NTN) in C57BL/6 mice investigating the effect of AZM198 on CGN severity and T cell activity and D) tested the effect of AZM198 on antigen-specific T cell responses using adoptive transfer of DO11.10 lymphocytes into OVA immunised mice.

Results: All biopsies with CGN had extracellular glomerular MPO deposition. In vitro, AZM198 led to a significant reduction in MPO activity measured in the supernatants of PMA (n=16, median(IQR) 37.4(9-175.6) vs12.93(1.9-152.8)U/g, p<0.05), TNF(n=8, 229.2(130.3-950.6) vs108.5(33.3-138.1)U/g, p<0.05) and pANCA(n=6,185.8(79.9-278.9) vs114.3(45.9-340.6)U/g, p=0.19) stimulated neutrophils. In vivo, AZM198 attenuated glomerular inflammation (NTN model), defined by proteinuria (A,p=0.01) and glomerular thrombosis (B,p=0.04,vehicle n=13, MPOi n=15), while reducing CD4 activation. In the adoptive cell transfer model, AZM198 led to a non-significant reduction of CD44 and KJ expression on $CD4^+$ T cells in the draining lymph nodes (C, vehicle n=3, MPOi n=3).

Conclusions: Therapeutic MPO inhibition reduced neutrophil degranulation in patients with AAV and attenuated kidney damage in preclinical models of CGN without augmenting adaptive immune responses, suggesting it may be a novel adjunctive therapy in various forms of CGN.



TH-OR054

Proteinase 3 Promotes Giant Cell Formation and Granulomata In Vitro and In Vivo Implicating a Key Role in GPA Pathogenesis

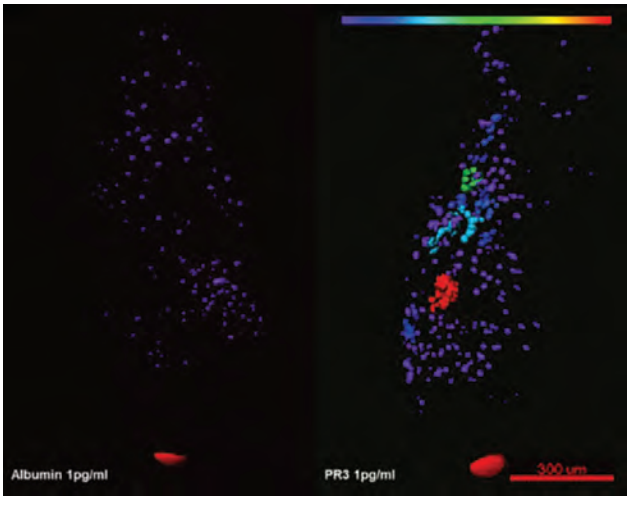
Scott R. Henderson, Maryam Khosravi, Alan J. Greig, Paul Frankel, Alan D. Salama. *University College London, London, United Kingdom.*

Background: Granulomatosis with polyangiitis (GPA) is characterised by ANCA reactivity towards proteinase 3 (PR3), PR3 deposition in granulomatous lesions and increased neutrophil membrane PR3 expression, inhibiting apoptotic cell phagocytosis by macrophages. We investigated whether persistent and excessive PR3 expression in GPA may underlie giant cell and granuloma formation.

Methods: PBMCs were isolated from healthy controls(HC)(n=10), GPA(n=10) and microscopic polyangiitis(MPA)(n=10) patients and monocytes isolated. Cells were stimulated with either enzymatically active (aPR3) or inactive PR3(iPR3) or control auto-antigen myeloperoxidase (MPO). Light, epifluorescence and confocal microscopy was used to confirm cell fusion at different time points. Mpeg:mcherry macrophage zebrafish at 24 hours post-fertilisation were injected with aPR3 or iPR3 or albumin. Fish were imaged by lightsheet microscopy 6 days later.

Results: Monocyte aggregation and giant cell formation occurred following stimulation with both aPR3 and iPR3 with a greater number (p<0.01) and size of aggregates (p<0.001) in GPA patients compared to MPA patients and HC. Typical granuloma were observed using PBMC preparations with a greater number (p<0.001) and size (p<0.001) of aggregates seen in GPA patients. There was no significant difference between aPR3 or iPR3. No effect was seen with MPO. Supernatant profiling implicated specific roles for pro-inflammatory cytokines. In zebrafish (n=9/group), both aPR3 and iPR3 were associated with a significant increase in cell fusion and aggregate volume (p<0.001) when compared to albumin injected controls (figure).

Conclusions: These models support a role for PR3 in promoting monocyte and macrophage fusion and granuloma formation *in vitro* and *in vivo*, and provide an opportunity to test specific therapeutics.



Macrophage aggregation in zebrafish (volume=purple min;red max)

Sortilin-Related Receptor (SORL1) Mediates Glomerulopathic Light Chain Interactions with Mesangial Cells (MCs)

Guillermo A. Herrera, Jiamin Teng, Xinggui Shen, Chun Zeng, Elba A. Turbat-Herrera. *Louisiana State University Health Sciences Center, Shreveport, LA.*

Background: It has been proven that glomerulopathic (G), but not tubulopathic (T) light chains (LCs) interact with mesangial cells (MCs) using a receptor membrane. Both light chain deposition disease (LCDD) and amyloid- producing (AL) LCs use the same receptor but lead to divergent downstream mesangial cell/matrix alterations. Tubulopathic LCs do not interact with MCs.

Methods: Three AL, two LCDD and one tubulopathic-LCs (10 ug/ml) were incubated with MCs for 30 minutes, cross-linked using DSTTP and subsequently, SPS-PAGE gels were run to identify bands. Bands above 70kD were cut and analyzed using mass spectroscopy (MS). Proteins obtained from various LCs cross linked to MCs were compared to identify receptors shared by the GLCs. TLC was used as a control. Fluorescein-labeled antibody to the SORL1 protein receptor and a second Texas red labeled antibody for the GLCs were used to evaluate for colocalization.

Results: Several transient MC receptors were shared by the 5 GLCs including: G-protein coupled, ligand-gated ion channel/transient receptor potential cation channel, subfamily M, and extracellular matrix linker protein receptor/cell adhesion-molecule extracellular matrix glycoprotein receptors. The one unique membrane receptor shared by the 5 GLCs was SORL1 located on chromosome 11, a lysosomal sorting receptor engaged in directing internalized proteins to the endolysosomal system and participating in microvesicular protein movement inside MCs. SORL1 was colocalized with both AL and LCDD light chains using double fluorescence labeling techniques. No localization was noted with TLC.

Conclusions: SORL1 (238 kD mw) was expressed when GLCs interact with MCs and not when TLCs were incubated with MCs or when MCs were incubated without LCs. Engagement of this receptor serves to direct GLCs, depending on their physicochemical characteristics, to various intracellular compartments where crucial pathogenetic events occur. SORL1 had not been previously identified as a MC receptor but it had been found to be present in the kidneys with no specific localization yet defined prior to this study. SORL1 was colocalized with LCDD and AL-LCs at the cell surfaces and inside MCs. There was no colocalization with TLC.

TH-OR056

Disruption of Endosomal Trafficking of Membrane Bound Nephrin Results in an Earlier Phenotype in Nephrin Deleted Adult Mice

Rakesh Verma,[1] Madhusudan M. Venkatareddy,[1] Gabriel M. Cara-Fuentes,[1] Sanjeevkumar R. Patel,[2] Puneet Garg.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of Michigan Hospitals, Ann Arbor, MI.*

Background: In a recent publication we reported that deletion of nephrin in an adult mature glomerulus results in FSGS. Following cre-induction a small fraction (10-15%) of nephrin remains at the membrane and is sufficient to maintain the slit diaphragm for 4-6 weeks. *In vitro* studies have suggested that membrane bound nephrin undergoes endocytic recycling. Vesicular trafficking is an important part of cellular development and growth, helping in maintaining a balance between synthesis, degradation and recycling of cellular components. Vps34, an important phosphoinositol kinase that generates PI3P, plays critical role in vesicular trafficking. We hypothesized that in our model recycling is responsible for maintenance of nephrin at the membrane following nephrin deletion.

Methods: Standard biochemical and cell biology techniques were used to analyze kidneys from knock out mice. Cre-loxP system was used to generate podocyte specific deletion of nephrin and vps34.

Results: Nephrin deleted adult animals have normal phenotype at 4-6 weeks age, when mice develop proteinuria. $Vps34^{fl/fl,\ cre+}$ mice have normal phenotype at birth, develop massive proteinuria and accumulation of vesicles by 3 weeks of age and majority of them die by 9 weeks of age. Immunogold EM analysis reveals accumulation of Nephrin in vesicles suggesting involvement of Vps34-dependent endocytic pathway in nephrin's maintenance at the slit diaphragm. In order to examine the role of endocytic recycling of nephrin at the membrane we generated a mouse model where both nephrin and vps34 are simultaneously deleted using tamoxifen in an adult mature mouse podocytes. These double knockout mice develop proteinuria at 1 week of age and die at 10-12 days indicating a earlier phenotype compared to deletion of vps34 or nephrin alone. Immunostaining revealed nephrin in vesicles that are EEA1 and Rab5 positive indicating nephrin localization in early endosomes and not in vesicles originating from the Golgi network.

Conclusions: We report an *in vivo* model that provides evidence for nephrin endocytosis and recycling at the membrane. A small fraction of nephrin is stably present at the membrane once production of new nephrin is stopped. Our data provides evidence of recycling of this nephrin from and to the membrane.

Induction of a Glomerular Reparative Program in Lupus Glomerulonephritis by a Novel Treg-Enhancing Cytokine Therapy

Rajkumar Venkatadri, Vikram Sabapathy, Marta Stremska, Hongyang Wang, Sun-sang J. Sung, Saleh Mohammad, Shu man Fu, Rahul Sharma. *University of Virginia School of Medicine, Charlottesville, VA.*

Background: Lupus glomerulonephritis (GN) is an autoimmune disease marked with glomerular inflammation and with reduced levels of IL-2 and T-regulatory cell as contributing factors. Earlier we showed that a novel hybrid cytokine IL233 utilizes the synergy of IL-2 and IL-33 to increase Tregs and protect mice from acute kidney injury and onset of accelerated GN in lupus prone NZM2328 mice. Here we investigated whether IL233 can reverse ongoing lupus GN and restore renal structure and function.

Methods: We made use of the recombinant hybrid cytokine (IL233) bearing activities of IL-2 and IL-33 and tested its efficacy to induce a glomerular repair program in three animal model systems: spontaneous lupus GN in NZM2328, adenovirus (Ad)-IFNa-accelerated lupus GN model and MRL/lpr mice.

Results: Treatment of NZM2328 mice after the onset of GN, induced rapid and persistent remission from severe proteinuria in Ad-IFNa-accelerated GN in NZM2328 mice as well as spontaneous lupus GN in NZM2328 and MRL/lpr mice. IL233 strongly inhibited glomerular hypertrophy and mesangial expansion and induced skewing of immune complex deposits towards IgG2b as compared to predominantly IgG2a deposits in control mice. Markers of glomerular integrity (nephrin, podocin, podocalyxin and synaptopodin) were elevated in IL233 treated animals confirming its therapeutic effects. Furthermore, IL233 treatment in mice with established GN also induced elevated levels of renal progenitor markers (Sox9, Six2, Lgr4, Lgr5 and Pax8) indicating an IL233-mediated cellular programming involving regeneration and repair.

Conclusions: We present a novel cytokine therapy of lupus GN with implications for induction of a glomerular reparative program with the use of IL233 hybrid cytokine.

Non-Classical Monocytes Act as Glomerular Sentinels, Sensing Deposited Immune Complexes and Orchestrating the Inflammatory Response via LFA-1 in Experimental Crescentic Glomerulonephritis

Kevin Woollard, Tabitha Turner-Stokes, Ana Isabel Garcia Diaz, H. Terence Cook, Charles D. Pusey. *Imperial College London, London, United Kingdom.*

Background: Non-classical monocytes (NC Mo) crawl along the resting endothelium, orchestrate the inflammatory response in some vascular beds and express high levels of FcγRIII(CD16). They may be important in triggering inflammation to immune complex (IC) deposition in glomerulonephritis (GN). Nephrotoxic Nephritis (NTN) in the WKY rat is a widely used, clinically-relevant model of crescentic GN but the distinct roles of myeloid subsets and the dynamics of their glomerular recruitment are unknown.

Methods: We developed a novel rat transgenic WKY-hCD68-GFP Mo/macrophage reporter. Mo subsets and endothelial cells were sorted from glomeruli of rats with NTN to investigate effector functions. Intravital confocal microscopy, with *in vivo* antibody labelling, was performed in the hydronephrotic kidney of anaesthetised WKY-hCD68-GFP rats, permitting high-resolution glomerular imaging and real-time, *in vivo* visualisation of myeloid recruitment and intravascular behaviour during NTN.

Results: Classical and NC Mo subsets were phenotyped as $GFP^{pos}CD43^{lo}HIS48^{hi}$ and $GFP^{pos}CD43^{hi}HIS48^{int}$ respectively and neutrophils (PMNs) as $GFP^{neg}CD43^{int}HIS48^{hi}$. RNA expression confirmed NC Mo were $CD16^{hi}CX3CR1^{hi}CD14^{lo}CCR2^{lo}$ relative to classical Mo i.e. homologous to mice and humans. During intravital imaging, NC Mo surveyed the glomerular endothelium for prolonged periods in the steady state. Classical Mo and PMNs had only transient endothelial interactions. There were subset-specific differences in the behavioural response to IC deposition during NTN: Increased recruitment of NC Mo vs. increased retention of classical Mo and PMNs. CD16 and pro-inflammatory cytokines (IL-1β, TNFα) were upregulated in NC compared to classical Mo and a unique chemokine axis was overexpressed by the endothelium and NC Mo. LFA-1 blockade inhibited the distinctive migratory phenotype of NC Mo, reducing their recruitment and the retention of PMNs.

Conclusions: LFA-1-mediated endothelial surveillance by $CD16^{hi}$ NC Mo may be an important mechanism for IC detection in GN, orchestrating the subsequent inflammatory response through a unique chemokine axis and cytokine-mediated retention of classical Mo and PMNs. Targeting NC Mo may lead to effective treatments for GN, with fewer side effects.

Classical Monocytes Promote Crescent Formation and Necrosis in ANCA-Associated Necrotizing Crescentic Glomerulonephritis

Anthony Rousselle,[2] Ralph Kettritz,[2,1] Adrian Schreiber.[2,1] *[1]Charite Berlin, Berlin, Germany; [2]ECRC, Berlin, Germany.*

Background: The binding of circulating antineutrophil cytoplasmic autoantibodies (ANCAs) to neutrophils and monocytes and their subsequent activation are key events in the development of ANCA-associated vasculitis (AAV) and necrotizing crescentic glomerulonephritis (NCGN). In contrast to neutrophils, the exact role of monocytes remains poorly described. Murine monocytes are classified into two functionally different subsets: $Ly6C^{hi}$ $CCR2^{+}$ classical (inflammatory) monocytes (CM) and $Ly6C^{lo}$ $CCR2^{-}$ non-classical (patrolling) monocytes (NCM). Differentiation of circulating $Ly6C^{hi}$ monocytes into $Ly6C^{lo}$ monocytes is controlled by the transcription factor C/EBPβ. We showed recently that global monocyte depletion protected from ANCA-induced necrotizing crescentic glomerulonephritis (NCGN) in vivo. We now studied the exact contribution of the two distinct monocyte subsets in AAV.

Methods: To assess the role of both monocyte subsets in vivo, we used our AAV murine model: $MPO^{-/-}$ mice were immunized with murine MPO, sublethally irradiated and subsequently transplanted with hematopoietic cells from either WT, $CCR2^{-/-}$, $C/EBP\beta^{+/+}$ or $C/EBP\beta^{-/-}$ mice (all MPO positive). $CCR2^{-/-}$ mice had a reduction of circulating

Ly6C^{hi} monocytes whereas C/EBPβ$^{-/-}$ mice lacked circulating Ly6C^{lo} monocytes. Mice were sacrificed and analyzed 8 weeks following transplantation. Urine was analyzed by dipstick, albuminuria by ELISA, glomerular necrosis and crescents by histology, and circulating and renal cell influx by flow cytometry.

Results: Blood composition confirmed the expected engraftment as CM and NCM were indeed significantly decreased in CCR2$^{-/-}$ and C/EBPβ$^{-/-}$ chimeric mice, respectively. WT, C/EBPβ$^{+/+}$ and C/EBPβ$^{-/-}$ chimeric mice developed urine abnormalities and glomerular necrosis and crescent formation. In contrast, CCR2$^{-/-}$ chimeric mice did neither develop erythrocyturia and albuminuria nor NCGN. Flow cytometry showed significantly reduced renal infiltration of CM CCR2$^{-/-}$. In contrast, renal neutrophil, macrophage and dendritic cell infiltration remained similar in all groups.

Conclusions: Our findings provide novel experimental evidence that classical monocytes are important contributors of kidney damage in ANCA-mediated NCGN. The exact molecular mechanisms by which classical monocytes promote kidney damage remains to be clarified.

Inflammasome Priming and Activation Glomerular Gene Expression Scores Associate with Poor Outcome in Nephrotic Syndrome

Jeffrey B. Hodgin, Laura H. Mariani, Jinghui Luo, Yingbao Yang, John R. Hartman. *University of Michigan, Ann Arbor, MI.*

Background: Recent studies have shown that the inflammasome, a cytoplasmic protein complex that processes interleukins IL-1beta and IL-18, is functional in resident cells of the glomerulus, such as the podocyte. Before activation of the NLRP3 inflammasome, a priming step occurs consisting of upregulation of NLRP3, pro-IL-1beta, and other genes. Here we interrogate glomerular mRNA of patients with nephrotic syndrome to test our hypothesis that gene expression profiles of inflammasome priming and activation (IL-1beta-regulated genes) correlate with eGFR and proteinuria at time of biopsy and outcome measures.

Methods: Using the Nephrotic Syndrome Study Cohort (NEPTUNE), a prospective longitudinal cohort study enrolling patients at time of biopsy, we correlated glomerular gene expression Z-scores of inflammasome priming (5 genes) and activation (100 genes) with clinical characteristics at enrollment (Pearson for eGFR; Spearman for UPCR). Linear GEE models of eGFR and urine protein to creatinine ratio (UPCR) were fit to associate baseline inflammasome Z-scores with disease status over time.

Results: 97 patients with NS (50 FSGS, 47 MCD) were available for analysis. At time of biopsy, both the priming (r=-0.33, p<0.001) and activation (r=-0.45, p<0.001) Z-scores negatively correlated with eGFR. Priming (r=0.23, p=0.02) and activation (r=0.28, p=0.01) Z-scores positively correlated with UPCR as well. Over a follow-up time of 45 months, baseline inflammasome priming and activation Z-scores were associated with lower eGFR over time (-12.6 mg/dL, p=0.028 and -55.4 mg/dL, p<0.001 respectively) in unadjusted models. After adjusting for baseline eGFR and UPCR, diagnosis, age, black race, immunosuppression and time, only the activation Z-score association was significant (-17.4 mg/dL, p=0.05). The inflammasome priming and activation Z-scores did not associate with UPCR over time in adjusted models.

Conclusions: Inflammasome priming and activation Z-scores based on glomerular gene expression profiles significantly correlate with eGFR and UPCR at time of biopsy and associate with lower eGFR, but not UPCR, over time. This approach offers the opportunity to discover novel molecular tests to predict outcome in nephrotic syndrome and highlight pathways for therapeutic intervention.

Label-Free Imaging of Human Kidney Biopsies Guides Downstream Interrogation

Michael J. Ferkowicz,[1] Seth Winfree,[2] Daria Barwinska,[1] Ken Dunn,[1] Katherine J. Kelly,[1] Timothy A. Sutton,[2] Michael T. Eadon,[3] Pierre C. Dagher,[1] Tarek M. El-Achkar.[1] *[1]Indiana University, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Indiana University Division of Nephrology, Indianapolis, IN.*

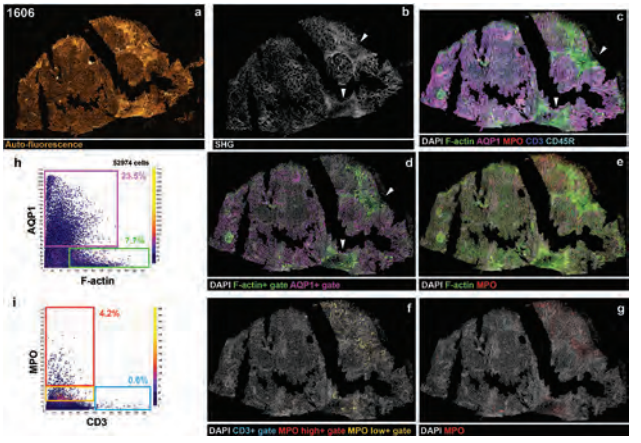
Background: Label-free (LF) imaging of human kidney biopsies is a novel and under-utilized approach to characterize kidney pathology. Unlabeled kidney biopsies have auto-fluorescence (AF) across the visible spectrum that encodes specific signatures of nephron structures and can be correlated with pathology. In addition, AF intensity can be extended using fluorescence lifetime imaging (FLIM) to resolve endogenous fluorophores in health and disease. Second harmonic generation (SHG) by collagen fibers is an LF imaging approach that can be simultaneously acquired, allowing for rapid measurement of fibrosis.

Methods: Scanning multiphoton excitation microscopy was used to rapidly collect AF, FLIM and SHG images of human kidney sections. These same sections were subsequently stained by immuno-fluorescence and imaged with spectral multi-channel three-dimensional laser scanning confocal microscopy. These volumes were then analyzed by 3D tissue cytometry (3DTC).

Results: AF provides LF imaging and identification of tubular sub-segments. Supervised machine learning approaches can automatically and accurately identify tubular sub-segments in AF images. Lifetime imaging of AF provides an additional signature. SHG provides LF imaging of collagen fibrosis. Using 3DTC, LF images can be correlatively integrated into the analysis of stained tubular and infiltrating cells from the same kidney section.

Conclusions: Thus, the label-free imaging of human kidney biopsies using AF, FLIM and SHG will complement our existing confocal spectral imaging approach. This combined multi-dimensional imaging approach will maximize the informational yield of a biopsy when combined with downstream interrogation methods.

Funding: NIDDK Support, Veterans Affairs Support



Label-free imaging informs analysis. A. SHG imaging delineates fibrosis (b) that spatially correlates with spectrally imaged F-actin+ cells (c and d) and inflammatory cells (e, in red and f, in red and yellow).

SPECTRUM: A Quantitative Pipeline for Optically Cleared Tissue Validated in Crescentic Nephritis

Victor G. Puelles,[1,2] Lena Ortz,[2] Stella Papadouri,[2] Thiago Strieder,[2] Turgay Saritas,[2] Michael Vogt,[2] Christoph Kuppe,[2] David J. Nikolic-Paterson,[3] Marcus J. Moeller.[2] *[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]RWTH Aachen University, Aachen, Germany; [3]Monash Medical Centre, Clayton, VIC, Australia.*

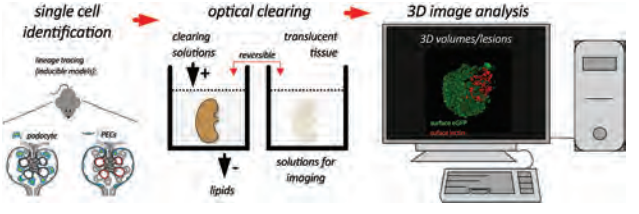
Background: Optical clearing and advanced light microscopy have revolutionised three-dimensional quantification in cell biology. Here, we present a **S**ystematic **P**ipeline of **E**nhanced **C**larification for **T**hree-dimensional **R**endering and **U**nbiased **M**orphometrics (***SPECTRUM***) as a unique tool for the comprehensive analysis of glomerular health and disease.

Methods: ***SPECTRUM*** is based on a combination of single cell identification (ie. lineage tracing), optical clearing, advanced light microscopy with single cell resolution, and 3D morphometrics. Podocytes and parietal epithelial cells (PECs) were genetically labelled with eGFP using inducible mouse systems (POD or PEC -rtTA/H2B-eGFP). Crescentic nephritis was used as a validation model. Several optical clearing protocols were optimized for kidney tissue, including aqueous, hydrogel, and solvent-based approaches. Image acquisition was based on whole structures (ie. glomeruli and lesions) using light sheet, confocal and two-photon microscopy. Subsequent tissue de-clarification with immunolabelling and classical histopathology allowed the combination of 3D and 2D analyses.

Results: While IgG deposition showed a homogeneous distribution among all analysed glomeruli, only 80% showed signs of podocyte loss (podocyte loss per glomerulus of about 60%). Only glomerular lesions showed significant increases in numbers of PECs (sign of PEC activation) in close association with reductions in glomerular capillary volume (sign of capillary injury). PEC activation was confirmed via immunofluorescence in recycled tissue samples (ie. de-novo CD44 expression). Based on 3D analysis of intraglomerular lesion location, we identified a progressive pattern from localised tubular lesions to segmental lesions and development of atubular glomeruli.

Conclusions: ***SPECTRUM*** provides new roadmap for morphometrics in the kidney. In crescentic nephritis, ***SPECTRUM*** revealed that despite of uniform IgG deposition, there was focal lesion development and podocyte loss, and allowed us to characterise for the first time the 3D evolution of extracapillary lesions.

Funding: Government Support - Non-U.S.



TH-OR063

Mass Spectrometry Imaging Rapidly Discriminates between Ischemic Injury in Renal Tissue

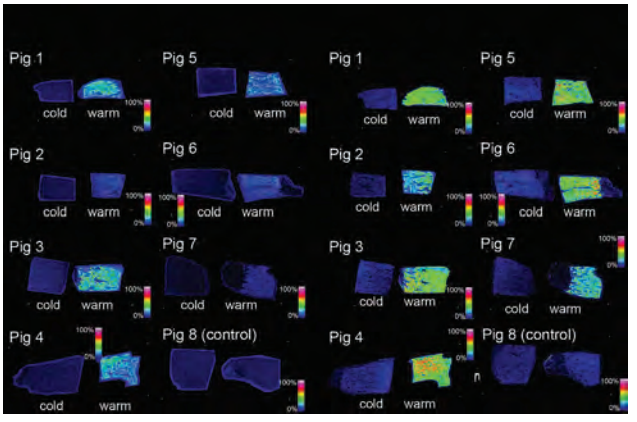
Patrick A. de Hoogt,[1] Tim C. Van smaalen,[1] Maarten G. Snoeijs,[1] Geert willem H. Schurink,[1] Carine Peutz-Kootstra,[1] Berta Cillero pastor.[2] *[1]Maastricht University Medical Center, Maastricht, Netherlands; [2]M4I, Maastricht, Netherlands.*

Background: The increasing analytical speed of mass spectrometry imaging (MSI), leads to growing interest in the medical field. When transplanting donor kidneys, ischemic injury to donor kidneys leads to significant short and long term risk for recipients. No reliable cut-offs are known to decide if a donor kidney can be safely transplanted. Thus, there is a need for new tools to rapidly and accurately assess acute ischemic injury in renal transplantation to aid in graft selection. We investigated the value of MSI to assess acute ischemic kidney tissue in a porcine model.

Methods: A perfusion model was developed where paired kidneys received warm (severe) or cold (minor) ischemia (n=8 per group). First, ischemic tissue damage was systematically assessed by two blinded pathologists. Secondly, MALDI-MSI of kidney tissues was performed to study spatial distributions and compositions of lipids in the tissues.

Results: Histopathological examination revealed no significant difference between kidneys, while MALDI-MSI was capable of a detailed discrimination of warm and cold ischemia by differential expression of characteristic lipid degradation products within 2 hours. In particular lysolipids, including lysocardiolipins, lysophosphatidylcholines and lysophosphatidylinositol, were dramatiaclly elevated after warm ischemia.

Conclusions: This study demonstrates the significant potential of MSI to differentiate and identify molecular patterns of early ischemic injury in a clinically acceptable time frame. The observed changes highlight the underlying biochemical processes of acute ischemic kidney injury and provide a molecular classification tool that can be deployed for graft viability assessment.



TH-OR064

Can Nephrectomy Tissue Be Considered as Normal? A Comparison of the Molecular Expression between Nephrectomy and Donor Kidney Tissue

Samer Mohandes, Huijuan Song, John P. Shapiro, Paolo Fadda, Jianying Zhang, Lianbo Yu, Anjali A. Satoskar, Brad H. Rovin, Samir V. Parikh. *Ohio State University Wexner Medical Center, Columbus, OH.*

Background: The molecular interrogation of kidney tissue provides important information on disease pathogenesis. Uninvolved areas of tumor nephrectomies have been used as normal reference tissue. We postulated that nephrectomy tissue may be remotely affected by the tumor and tested this by comparing compared renal transcript expression of nephrectomy tissue to biopsies of living donor (LD) kidneys at the time of implantation.

Methods: Formalin-fixed paraffin-embedded nephrectomy (n=8) and LD (n=8) tissue was laser dissected and RNA from the glomerular and tubulointerstitial (TI) compartments was extracted. The expression of 564 immune transcripts was analyzed using Nanostring technology. Transcript expression between nephrectomy and LD samples was compared. Differences are reported by fold change (FC) and p-value.

Results: Overall, 116 glomerular transcripts and 67 TI transcripts were differentially expressed between nephrectomy and LD. The top overexpressed nephrectomy glomerular transcripts were FCER1G (FC: 8.5, P: 0.02), CD45RB (FC: 7, P: 0.02), and PDCD1LG2 (FC: 5, P: 0.014), and the top TI transcripts were TNFRSF1B (FC: 6.7, P=0.01), CD45RB (FC: 6, P: 0.02), and C1R (FC: 4.9, P: 0.02). The top under-expressed glomerular transcripts included AIRE (FC: 0.1, P: 0.0001), XCL1 (FC: 0.1, P: 0.02) and IL-20 (FC: 0.13, P: 0.001), and ATM (FC: 0.15, P: 0.03), VTN (FC: 0.16, P: 0.03) and CD160 (FC: 0.17, P: 0.008) in the TI. Panther Pathway analysis revealed upregulation of inflammation mediated by cytokine/chemokines, integrin and interleukin signaling pathways in nephrectomy compared to LD.

Conclusions: To our knowledge, this is the first study comparing the gene expression between nephrectomy and LD. Despite being ostensibly unafflicted by the tumor, the gene expression of nephrectomies was different than LD and reflected overexpression of inflammatory and immune pathways. This study highlights the potential pitfall in using nephrectomy samples as controls, especially when comparing to autoimmune and inflammatory kidney diseases.

Primary Membranous Nephropathy: Glomerular RNA Sequencing from Archival Kidney Biopsies

Oystein Eikrem,[1,2] Even Koch,[1] Thomas Knoop,[2] Bjorn Egil Vikse,[1,4] Eric Schordan,[5] Hanna Debiec,[3,6] Pierre M. Ronco,[3,6] Sabine Leh,[2,1] Hans-Peter Marti.[1,2] *[1]University of Bergen, Bergen, Norway; [2]Haukeland University Hospital, Bergen, Norway; [3]Inserm UMR_S1155, Paris, France; [4]Haugesund Hospital, Haugesund, Norway; [5]Firalis S.A., Huningue, France; [6]Hôpital Tenon, Paris, France.*

Background: Our study aim was to expand the usability of archival kidney biopsies with primary membranous nephropathy (MN) by next generation sequencing of glomerular mRNA & lncRNA.

Methods: Formalin-fixed & paraffin-embedded (FFPE) renal biopsies from six female and six male adult patients (mean age 55±16 y, mean proteinuria 2.9±3.5 g/d) from the Norwegian Kidney Biopsy Registry (NKBR) with primary MN were divided into: i) PLA2R antibody positive MN (n=6), and ii) PLA2R antibody negative MN (n=6). In addition, we included iii) normal NBKR control samples (n=8; mean age 27±11 y). All subjects had eGFR>60ml/min/1.73m2. RNA inputs of 0.15-3 ng of total RNA per sample from microdissected glomerular cross-sections (High Pure FFPE Extraction kit, Roche) were used for library preparation (Truseq RNA Exome kit, Illumina) and sequenced as 75 bp paired end on a NextSeq500 by Firalis SA, France. Reads were aligned to Homo sapiens hg38 reference genome using Gencode v.26 for mRNA and LNCipedia 5.0 for lncRNA.

Results: From alignment on their databases, 3473 mRNA & 1719 lncRNA were above a threshold of 2 fragments per kilobase of exon per million reads mapped (FPKM). Principal component analyses and heatmaps with differentially regulated mRNA & lncRNA clustered anti-PLA2R positive and anti-PLA2R negative MN together with some separation from normals (esp. lncRNA). Pathways of renal inflammation and of glomerular injury were upregulated in MN (IPA analyses). Overall, 197 mRNA and 59 lncRNA were differentially regulated comparing MN combined to normal controls. Within the two MN groups, 84 mRNA and 19 lncRNA were differentially expressed. Among these 84 mRNA, subgroups of 12 mRNA (e.g. IGFBP2) and 22 mRNA (e.g. MIF) differed also between normal controls and anti-PLA2R positive or negative MN, respectively. Among the 19 lncRNA, subgroups of 4 and 2 lncRNA differed also between normal controls and anti-PLA2R positive or negative MN, respectively. Thus, these mRNA & lncRNA could represent candidates of diagnostic/prognostic markers and of therapeutic targets if confirmed later.

Conclusions: Sequencing of mRNA & lncRNA from microdissected glomerular cross-sections of FFPE kidney biopsies is feasible and potential biomarker & drug target candidates that discriminate anti-PLA2R positive from anti-PLA2R negative MN were identified.

Funding: Government Support - Non-U.S.

Predicting APOL1 Risk Category from Kidney Donor Biopsies Using Deep Learning

Jun Xu,[1] Andrew Janowczyk,[2] L. Barisoni,[4] Chengfei Cai,[1] Jeffrey J. Nirschl,[5] Matthew Palmer,[5] Michael Feldman,[5] Dhruti P. Chen,[6] John F. O'Toole,[3] Ziad S. Zaky,[3] Emilio D. Poggio,[3] John R. Sedor,[3] Anant Madabhushi.[2] *[1]Nanjing University of Information Science and Technology, Nanjing, China; [2]Case Western Reserve University, Cleveland, OH; [3]Cleveland Clinic, Cleveland, OH; [4]U. Miami, Miller School of Medicine, Miami Beach, FL; [5]University of Pennsylvania, Philadelphia, PA; [6]University of North Carolina, Chapel Hill, NC.*

Background: African Americans (AA) subjects with two *APOL1* gene variants (G1 and G2) are at higher risk (HR) to develop non-diabetic kidney disease, while individuals with 0 or 1 *APOL1* variants are at low risk (LR). Conventional visual histologic analysis of renal biopsies does not identify structural differences between LR and HR subjects with or without kidney disease. In this work we sought to evaluate whether deep-learning (DL) based analysis could help identify phenotypic representations that were predictive of *APOL1* variants from whole slide images (WSI) of kidney biopsies.

Methods: WSI's from kidney allograft implant biopsies stained with H&E from 19 *APOL1* LR and 12 *APOL1* HR AA donors were annotated by a pathologist to identify artifact-free regions of interest (ROIs). The ROIs from the training set (8 LR and 5 HR) were divided into non-overlapping 256x256 patches for processing at 40X magnification. Each patch was assigned a HR or LR label based on the subject's *APOL1* genotype. An 8 layer AlexNet model was trained to predict the likelihood that a previously unseen test input patch belongs to the *APOL1* HR genotype. This patch-wise output was then overlaid as a heatmap on the original image such that red and blue pixels predicts HR and LR class, respectively. Majority voting across the individual patches were aggregated to generated the combined prediction of *APOL1* risk status as either HR or LR. (Figure 1).

Results: The prediction accuracy of trained model was 84.67% and 91.02% for LR and HR cases respectively (n=18, LR=11, HR=7) on the test set.

Conclusions: In this preliminary study, the DL model was able to distinguish between *APOL1* HR and LR genotypes in AA patients. Future work will involve larger scale multi-site independent validation.

Funding: Other NIH Support - National Natural Scientific Foundation of China, Other U.S. Government Support, Government Support - Non-U.S.

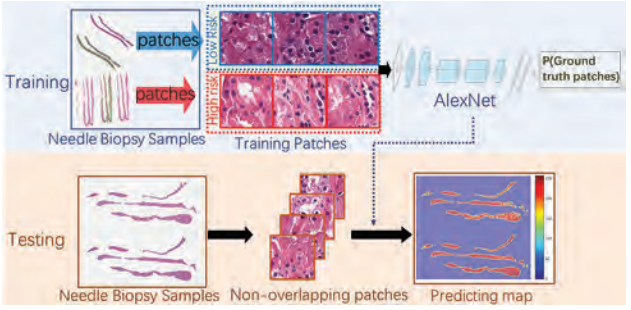

Figure 1: Flowchart illustrating the training and testing for predicting APOL1 risk status, where the bottom right image heatmap is the output from the DL classifier where redder pixels indicate higher likelihood of belonging to the HR class.

Background: Bevacizumab is a humanized monoclonal IgG1 antibody which neutralizes vascular endothelial growth factor (VEGF) and is used for treating multiple cancer types. As a known and frequent adverse event, it can lead to renal damage including proteinuria and nephrotic syndrome.

Methods: In a retrospective approach we analyzed 16 renal biopsies from patients receiving bevacizumab treatment. We observed a distinctive pseudothrombotic pattern different from the previously reported thrombotic microangiopathy (TMA). Since the newly described pattern includes some features similar to TMA and cryoglobulinemic membranoproliferative glomerulonephritis (MPGN), biopsies with these diagnoses were included for comparison. Clinical, laboratory, light microscopic, immunohistochemical (including a proximity ligation assay (PLA)), proteomic and electron microscopic features were assessed in 16 proteinuric patients after bevacizumab therapy and compared to seven cases of cryoglobulinemic MPGN and six cases of typical acute TMA.

Results: Nephrotic syndrome was present in 14 of the 16 bevacizumab-treated patients. All 16 displayed a patchy pattern of variably PAS-positive hyaline pseudothrombi occluding markedly dilated glomerular capillaries in their biopsies. Mass spectrometry based proteome analysis revealed a special protein pattern demonstrating some features of TMA and some of MPGN, including a strong accumulation of IgG in the thrombi. PLA did not show interaction of IgG with C1q, arguing for accumulation without classical complement activation. Compared to thrombi in TMA cases, the hyaline pseudothrombi did not contain clusters of CD61-positive thrombocytes. Electron microscopy of bevacizumab cases did not show extensive loss of podocyte foot processes.

Conclusions: Bevacizumab therapy can lead to a unique hyaline occlusive glomerulopathy, likely arising from endothelial leakage followed by subendothelial accumulation of serum proteins. Bevacizumab associated glomerulopathy can be diagnosed by light microscopy and is an important differential diagnosis in cancer patients with nephrotic syndrome.

A Nuclear Magnetic Resonance-Based Method for Accurate Assessment of Glomerular Filtration Rate

Jochen H. Ehrich,[1] Laurence Dubourg,[2] Sverker Hansson,[3] Tobias Steinle,[4] Jana Fruth,[4] Sebastian Höckner,[4] Eric Schiffer.[4] *[1]Hannover Medical School, Hannover, Germany; [2]Néphrologie, Dialyse, Hypertension et Exploration Fonctionnelle Rénale, Hopital E Herriot, Lyon, France; [3]Sahlgrenska University Hospital, Göteborg, Sweden; [4]numares AG, Regensburg, Germany.*

Background: Measuring glomerular filtration rate (mGFR) using renal or plasma clearance of an exogenous filtration marker (tracer) is the gold standard for assessing kidney function, but this procedure is time consuming and associated with a high burden for patients. Therefore, GFR is commonly estimated from serum creatinine ($eGFR_{creat}$) or serum cystatin C ($eGFR_{cysC}$). However, there exist different estimating equations for adult and paediatric patients and these equations often perform only moderately outside the cohort in which they were developed.

Methods: We used metabolomics based on nuclear magnetic resonance (NMR) spectroscopy and biostatistical modeling to identify metabolites correlated with mGFR and to combine these metabolites to biomarker networks for accurate GFR prediction. The biomarker networks were established and tested in two separate cohorts from two European centres. These cohorts comprised serum samples from both paediatric and adult patients with various nephrological conditions, covering the whole GFR range from hypo- to hyperfiltration.

Results: By combining creatinine with the uremic toxin myo-inositol, valine as indicator of metabolic acidosis, and a marker of oxidative stress into a metabolic network, we were able to generate reliable results over the whole GFR range. Compared to $eGFR_{creat}$ and $eGFR_{cysC}$, the marker network showed a higher correlation with mGFR (Pearson correlation coefficient r = 0.880 vs. 0.848 and 0.636) and a 31% and 41% reduction, respectively, in overall root mean square error (RMSE 19.2 vs 28.0 and 32.8) in an independent test cohort. Especially in the "creatinine blind spot" between 60-90 ml/min/1.73m^2, it more than halved the variation from 24.5 to 11.0 compared to $eGFR_{creat}$. The marker network increased the percentage of estimated GFR values within 30% of mGFR (P_{30}) from 72% (66%) observed for $eGFR_{creat}$ ($eGFR_{cysC}$) to 82%, which is within the performance range of plasma clearance methods, depending on the tracer used for mGFR measurement.

Conclusions: We developed a metabolomics-based serum test for accurate prediction of GFR in both adult and paediatric patients. It combines the precision of plasma clearance with the convenience of creatinine-based eGFR and obviates the need of invasive tracer application.

Histologic Predictors of Renal Outcome in Myeloma Cast Nephropathy: A Multicenter Study

Virginie Royal,[1] Samih H. Nasr,[2] Laure Ecotiere,[4] Stephan Troyanov,[3] Mariam P. Alexander,[2] Nelson Leung,[2] Frank Bridoux.[5] *[1]Pathology, Université de Montréal, Montreal, QC, Canada; [2]Mayo Clinic, Rochester, MN; [3]Hopital du Sacre-Coeur de Montreal, Town of Mount Royal, QC, Canada; [4]CHU Poitiers Néphrologie, Poitiers, France; [5]Hôpital Jean Bernard, CHU Poitiers, Poitiers, France.*

Background: Cast nephropathy (CN) is the main cause of acute kidney injury (AKI) in multiple myeloma (MM). Renal prognosis is poor and chronic renal impairment strongly affects survival. Whether renal biopsy can help in the management of AKI is unclear. The aim of this study was to investigate the prognostic value of renal biopsy findings in CN.

Methods: We retrospectively reviewed renal biopsies from 161 CN patients in a multicenter cohort (9 centers). Histological features, including the extent of cast formation, were independently scored by 2 pathologists. We assessed reproducibility, correlations with clinical presentation and, in patients with ⟩3 months follow-up (n=135), associations between biopsy findings, hematologic and renal outcomes.

Results: Interclass Correlation (ICC) for inter-reader concordance was good to excellent (⟩0.60) for medullary interstitial inflammation, giant cell reaction around casts, highest and mean cortical and medullary cast numbers. It was moderate (0.40-0.59) for interstitial fibrosis, cortical interstitial inflammation, tubular rupture, interstitial giant cell and Tamm-Horsfall extravasation. We found 46% of kappa CN and 54% of lambda CN. The severity of AKI correlated with higher serum free light chain level (sFLC), ß2-microglobulin, LDH and bone marrow infiltration. The presence of giant cell reaction, highest and mean medullary and cortical number of casts and medullary interstitial inflammation also correlated with a lower initial eGFR. Following therapy, renal response rate was lower with higher age, ß2-microglobulin and baseline sFLC. It was greater with a lower serum creatinine level and greater sFLC reduction. The presence of giant cell reaction, moderate or severe interstitial fibrosis, highest and mean medullary and cortical number of casts and, marginally (p=0.06), medullary interstitial inflammation, also correlated with lower renal recovery rate.

Conclusions: Histologic scoring of CN enables reproducible assessment of morphologic parameters with prognostic significance and may guide the management of MCN. Participants: G. Touchard, H. Fatima, F. Rosenblum, P. Sanders, M. Drosou, M. Rabant, C. Cohen, B. Knebelmann, B. Adam, B. Sis, C. Venner, H. Rennke, S. Motwani, R. Manso, K. Soto, A. Barraca, F. Maletta, D. Rocatello, R. Digital Pathology and Computer-Aided Quantitative Analysis for Lupus Nephritis

Srikanth Ragothaman,[2] Anthony Chang,[1] J. Michelle Kahlenberg,[2] Stephanie Wylie,[2] Jeffrey B. Hodgin.[2] *[1]UChicago Medicine, Chicago, IL; [2]University of Michigan, Ann Arbor, MI.*

Background: The kidney biopsy has allowed a better understanding of the pathogenesis of renal injury in lupus nephritis (LN) and is routinely used for patients with active LN or previously untreated disease. Currently, the ISN/RPS classification system is used to identify subgroups with different prognoses and response to treatment. However, the ISN/RPS classification suffers from poor reproducibility, raising doubts about its validity and clinical application. Thus novel approaches are required to obtain continuous, quantitative data to improve accuracy, reproducibility, and prognostic utility. We have assembled a novel computer-aided digital pathology image analysis pipeline to improve the utility of the kidney biopsy in LN.

Methods: To facilitate our analyses, we have created the University of Michigan Lupus Nephritis Digital Pathology Image Repository (DPIR). Currently it contains 200+ cases with access to clinical data over many years. Slides are scanned to whole-slide images (WSI) at 40x with Leica Biosystems AT2 scanners. We employ QuPath, a cross-platform

open source software for digital pathology and WSI image analysis, for quality control, annotation, and as a framework to run in-house algorithms on WSI. Algorithms to quantitate morphologic features of interest are designed using the image processing package FIJI, a distribution of ImageJ.

Results: Our image analysis pipeline allows supervised WSI annotation (glomeruli, vessels, etc.) and quantitation of glomerular size, glomerular cellularity, mesangial index, interstitial fibrosis and fractional interstitial area, and tubulointerstitial cellularity using PAS and trichrome stained slides. Complete analysis can be performed within one day. Preliminary data comparing glomerular cellularity to ISN/RPS classification groups reveals that cellularity varies widely within each classification group, indicating novel information beyond classification groups are captured.

Conclusions: We have generated a computer-aided, quantitative image analysis pipeline for morphologic features in a lupus nephritis biopsy. The pipeline has a short enough turnaround time suitable for clinical application and generation of an adjunct report wherever cases can be scanned to WSIs. Future studies will seek to improve turnaround time and determine which analyses best predict patient outcome and response to therapy.

The Role of Megalin in the Regulation of Renal RAS: Investigation Using LC/MS-Based Multiple-Reaction Monitoring Quantification of Angiotensin Peptides

Sawako Goto, Yutaka Yoshida, Michihiro Hosojima, Tomomichi Iida, Shoji Kuwahara, Hideyuki Kabasawa, Ryohei Kaseda, Ichiei Narita, Akihiko Saito. *Niigata University, Chuo-ku, Japan*.

Background: The mechanisms underlying the regulation of the renal renin-angiotensin system (RAS) are largely unknown. Megalin, an endocytosis receptor in proximal tubular cells, reabsorbs angiotensinogen (AGT) and angiotensin (Ang) peptides filtered through glomeruli. We have developed liquid chromatography (LC)/mass spectrometry (MS)-based multiple-reaction monitoring quantification of Ang peptides. This study aimed to investigate the role of megalin in the renal RAS by measuring Ang peptides in biological samples obtained from kidney-specific, tamoxifen-inducible conditional megalin knock-out mice (KO) and their controls (Ctl).

Methods: Stable isotope-labeled Ang peptides were added to each sample as internal standards. Under the steady condition and 30 min after AGT administration, Ang peptides were extracted by reverse phase chromatography and evaluated by LC/MS-based quantification.

Results: Under the steady condition, Ang-I and -II were quantified in the kidney and plasma without significant differences between KO and Ctl (e.g., kidney Ang-II: 573±257 in KO and 569±172 fmol/g in Ctl). High levels of Ang-I, -II, -1-7 and -1-9 were detected in KO's fresh urine (e.g., Ang-II: 3.8±4.5 pmol/mL), whereas their concentrations were below the limit of detection in Ctl. AGT administration increased kidney Ang peptides without significant increase in plasma. Kidney Ang-II and -1-9 levels in KO administered with AGT were significantly lower than those in Ctl (e.g., Ang -II: 1760±1043 in KO and 2489±836 fmol/g in Ctl, $p<0.05$); kidney Ang-I showed a similar tendency, whereas there was no difference in Ang -1-7.

Conclusions: High-level excretion of Ang peptides in KO's urine indicated that they were produced in the tubular lumen. AGT administration increased kidney Ang peptides independently of the systemic RAS. The increase of kidney Ang-I, -II, and -1-9 induced by AGT administration was suppressed in KO compared with Ctl, whereas there was no difference in Ang-1-7. Ang-I, -II and -1-9 generated in the tubular lumen may be excreted more in KO than Ctl or converted to Ang-1-7. Megalin blockade could be beneficial for modulating the renal RAS by regulating the renal handling of AGT and Ang peptides.

Cholesterol, a Repressor of Natriuretic Genes

Robert L. Repetti,[1,2] Jennifer Meth,[1] Daniel Flores,[3] Lisa M. Satlin,[3] Rajeev Rohatgi.[1,2] *[1]Northport VAMC, Northport, NY; [2]Medicine, Stony Brook University School of Medicine, Stony Brook, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Salt-sensitivity in Dahl rats is due, in part, to the reduction of hemoxygenase-1 (HO1), cyclooxygenase 2 (COX2), and nitric oxide synthase-2 (NOS2) in the renal medulla. Renal overexpression of HIF1-α, a regulator of HO1, COX2, and NOS2, enhances salt and water excretion and reduces blood pressure. Cholesterol (chol) incorporation into collecting duct (CD) cells, *in vivo or in vitro*, represses COX2 activity in response to tubular flow or fluid shear stress (FSS). We hypothesized that dietary chol ingestion represses flow responsive genes necessary to effectuate salt and water excretion.

Methods: To this end, mice were fed either a 0% or 1% chol diet for up to 12 weeks, injected with SQ isotonic saline at 5% of body weight, and urine collected at 2, 4, and 6 hrs. Kidneys were extracted to measure medullary expression of HO1, COX1, and NOS2. Mice were divided into three dietary time points: (1) 3-5 (2) 6-8 and (3) >9 weeks of diet.

Results: Urine volume was less in the chol group at the 6 hr urine collection for 6-8 wks of diet group (n=8 control and chol; $p<0.05$). Urinary [Na], [K] and osmolality were higher while Na excretion was lower at the 6 hr urine collection time point in the chol ($p<0.05$) vs. control fed mice. Renal medullary HO1 (0.76±0.09; $p<0.05$), and NOS2 (0.76±0.1; $p<0.05$) mRNA levels were reduced compared to controls (HO1, 1.00±0.02; NOS2, 1.00±0.03) while COX2 and HIF1-α were unaffected. ATP-binding cassette transporter (ABCA1), a tissue chol efflux transporter, was increased in the medulla (2.0±0.3 fold; $p<0.05$) of chol vs. control fed mice. To test the flow responsiveness of HO1, COX2, NOS2 and HIf1-α, IMCD3 cells were exposed to 0.4 dynes/cm^2 of FSS for up to 6 hours. HO1 mRNA increased by 350X fold, COX2 by 25X fold, and NOS2 by 8X fold at 6 hrs in sheared (n=4-6; $p<0.01$) vs.static (n=3-6) cells. HIF1-α mRNA increased by ~50% ($p<0.05$) at 4 and 6 hrs. Western blotting of FSS exposed cells demonstrated an increase in HIF1-α and HO1 protein compared to static cells ($p<0.05$). Similar to mouse, chol incorporation into cells raised ABCA1 mRNA levels 3.7±0.2 fold vs. untreated cells.

Conclusions: Dietary chol is associated reduced urine volume and Na excretion at 6 hrs after saline injection and suppressed flow induced HO1 and NOS2 gene expression. Studies will test whether chol incorporation into the tubule represses of natriuretic factors to reduce Na excretion..

TH-OR073

Tubular Deficiency of Heterogeneous Nuclear Ribonucleoprotein F Enhances Development of Hypertension and Kidney Injury via Elevated Renal Angiotensinogen and Attenuated SGLT2 Expression in Mice

Chao-Sheng Lo,[1] Isabelle Chenier,[1] Janos G. Filep,[3] Julie R. Ingelfinger,[2] Shao-Ling Zhang,[1] John S. Chan.[1] *[1]CRCHUM, Universite de Montreal, Montreal, QC, Canada; [2]The New England Journal of Medicine, Boston, MA; [3]Research Centre, Maisonneuve-Rosemont Hospital, Montreal, QC, Canada.*

Background: We reported previously that overexpression of the transcription factor, heterogeneous nuclear ribonucleoprotein F (hnRNP F) in renal proximal tubular cells attenuates systolic blood pressure (SBP), kidney injury and renal angiotensinogen (Agt) gene expression in mice with both type 1 and type 2 diabetes (Diabetes 2012, 2017). Here, we investigated whether deletion of hnRNP F in renal tubules would elevate SBP and aggravate kidney injury through increasing renal Agt gene expression.

Methods: Tubule-specific hnRNP F knockout (KO) mice were generated by crossbreeding Pax8-Cre mice with floxed hnRNP F mice on a C57BL/6 background. Both male and female Pax8-hnRNP F KO mice and control littermates were studied. Body weight (BW), SBP, blood glucose (BG), urinary glucose (UG) and albumin/creatinine ratio (ACR) were monitored up to 24 weeks of age. Kidneys were processed for histology. Western blotting and real-time qPCR were used to quantify hnRNP F, Agt, sodium-glucose co-transporter-2 (Sglt2) protein and mRNA expression in renal proximal tubules (RPTs), respectively.

Results: Both male and female Pax8-hnRNP F KO mice developed hypertension and elevated ACR as compared with control littermates with no detectable differences in BW and BG. Intriquingly, both male and female Pax8-hnRNP F KO mice developed glucosuria at 8 weeks of age. However, glucosuria disappeared in male Pax8-hnRNP F KO at the age of 12 weeks, whereas glucosuria was persistent in females. HnRNP F protein and mRNA expression are barely detectable in RPTs of Pax8-hnRNP F KO mice. In contrast, Agt expression was elevated, and Sglt2 expression was attenuated in RPTs of both male and female Pax8-hnRNP F KO mice as compared to controls at 8 and 24 weeks.

Conclusions: Our data demonstrate that hnRNP F plays an important role in the development of hypertension and kidney injury through modulation of renal Agt expression. Pax8-hnRNP F KO mice may provide a novel experimental model to study the development of glycosuria in non-diabetic mice.

TH-OR074

Haploinsufficiency of Transcription Factor ETS-1 Improves Renal Autoregulation in Dahl Salt Sensitive Rats

Wenguang Feng,[1] Zhengrong Guan,[1] Dongqi Xing,[1] Xingsheng Li,[1] Weizhong Ying,[1] Edward W. Inscho,[1] Paul W. Sanders.[1,2] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Birmingham Veterans Affairs Medical Center, Birmingham, AL.*

Background: The mechanisms underlying the susceptibility to hypertension-associated kidney injury are not well defined. Previously, we showed that the transcription factor ETS-1 mediates glomerular injury in Dahl Salt Sensitive (SS) rats. Hypertensive SS rats with a single functioning ETS-1 gene (ES, developed with zinc-finger nuclease (ZFN) technology), exhibit less glomerular injury. Because renal autoregulation is critical for protecting glomeruli from arterial hypertension, we hypothesized that ETS-1 transactivity is involved in afferent arteriolar autoregulatory behavior.

Methods: SS and ES rats were maintained on either a 0.3% (LS SS and LS ES) or a 4% NaCl diet (HS SS and HS ES) for one week.

Results: Assessment of serum creatinine and albuminuria revealed that renal dysfunction was present in the hypertensive HS SS rats, but was abrogated in the HS ES rats despite similar increases in telemetry mean blood pressures. Afferent arteriolar autoregulation was assessed using the *in vitro* blood-perfused juxtamedullary nephron preparation. Average baseline diameter of afferent arterioles were similar across the four groups of rats ($P>0.05$). Afferent arterioles from LS SS and LS ES rats exhibited normal autoregulatory behavior. Decreasing renal perfusion pressure from 100 to 65 mmHg increased arteriole diameter to 118 ± 2% and 119 ± 4% of baseline diameter, respectively. Stepwise increases in perfusion pressure to 170 mmHg decreased arteriolar diameter to 75.4 ± 3% and 72.9 ± 4% respectively. In contrast, pressure-mediated afferent arteriolar responses were markedly impaired in HS SS rats. Baseline diameter averaged 15.1 ± 1.2 μm and remained between 107 ± 3% and 89 ± 4% ($p< 0.05$ vs. LS SS) of baseline over the 65-170 mmHg pressure range tested. Importantly, renal autoregulation was significantly improved in HS ES rats. Baseline diameter averaged 15.6 ± 0.9 μm, and decreasing renal perfusion pressure from 100 to 65 mmHg resulted in a diameter increase to 114 ± 2% while increasing perfusion pressure to 170 mmHg resulted in a pressure-dependent vasoconstriction to 73 ± 3% ($P<0.05$ vs SS HS).

Conclusions: These results show that ETS-1 influences renal arteriolar autoregulation in SS rats and that impaired autoregulation may contribute to hypertension-induced kidney injury in SS rats.

TH-OR075

Renal Artery Stenosis Magnifies Mitochondrial Damage, Aggravating Post-Stenotic Kidney Injury in Pigs with Metabolic Syndrome

Arash Aghajani Nargesi, Hui Tang, Lilach O. Lerman, Alfonso Eirin. *Mayo Clinic Rochester MN, Rochester, MN.*

Background: Renal artery stenosis (RAS) often develops in the context of prevalent cardiovascular risk factors, and can induce hypertension, renal injury, and fibrosis. We have shown that metabolic syndrome (MetS) induces mitochondrial damage associated with glomerular hyperfiltration and tubular injury. We hypothesized that superimposition of RAS on MetS would exacerbate mitochondrial damage, aggravating post-stenotic kidney injury in swine.

Methods: Domestic pigs were studied after 16 weeks of either high-fat/high-fructose or standard diet with or without superimposed RAS (n=7 each). Single-kidney GFR was assessed in-vivo with multi-detector-CT, and renal tubular mitochondrial morphology ex vivo by electron microscopy. ATP production was measured by colorimetric/fluorimetric methods in isolated mitochondria and renal fibrosis by trichrome staining.

Results: Blood pressure was higher in MetS, Lean+RAS, and MetS+RAS compared to Lean (Table). Both RAS groups achieved significant stenosis. Single-kidney GFR was higher in MetS vs Lean, but decreased in Lean+RAS and MetS+RAS vs. their respective controls. MetS+RAS further decreased renal mitochondrial matrix density (Fig. B-C) and ATP production (Fig. D), and increased renal fibrosis (Fig. E) compared to Lean+RAS.

Conclusions: RAS superimposed on MetS aggravates mitochondrial structural damage and dysfunction, which may contribute to structural injury and dysfunction in the post-stenotic kidney.

Funding: NIDDK Support

Renal Artery Stenosis Induces Renal Cellular Senescence

Seo Rin Kim,[1] Amrutesh Puranik,[1,2] Kai Jiang,[1] Christopher M. Ferguson,[1] LaTonya J. Hickson,[1] Tamara Tchkonia,[3] James L. Kirkland,[3] Lilach O. Lerman.[1] *[1]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Colton Center for Autoimmunity, Division of Rheumatology, NYU Langone Health, New York, NY; [3]Robert and Arlene Kogod Center on Aging, Mayo Clinic, Rochester, MN.*

Background: Cellular senescence (CS) is an irreversible proliferation arrest with secretory phenotype evoked in response to stress, which can be identified by upregulation of the cyclin-dependent kinase inhibitor $p16^{INK4a}$. Renal artery stenosis (RAS) induces stenotic kidney (STK) ischemia and injury, but whether these involve activation of CS remains unclear. We studied CS in the STK of transgenic INK-ATTAC mice, in which $p16^{INK4a}$-expressing cells can be selectively eliminated by injection of AP20187.

Methods: INK-ATTAC mice were randomized to a 4-week treatment with AP20187 (3.3μg/g, IP, 3/week) or vehicle starting after 2 weeks of RAS or sham (n=6-8 each). Single kidney function (GFR) and oxygenation were studied in vivo using 16.4T magnetic resonance imaging at baseline and 6 weeks after surgery. CS was assessed by plasma levels of Activin-A, and by image cytometry analysis of $p16^{INK4a}$-positive cells in dissociated kidney tissue.

Results: After 6 weeks of RAS blood pressure, Activin-A, STK tissue hypoxia were all elevated, and plasma creatinine tended to be higher compared to sham, whereas STK RBF and GFR were decreased. The percentage of $p16^{INK4a}$-positive cells increased in the STK, many of which expressed epithelial, but not endothelial, cell markers (Fig. E). Clearance of $p16^{INK4a}$-positive cells restored blood pressure, Activin-A, and plasma creatinine levels, and prevented the fall in GFR, and rise in tissue hypoxia (Fig. A-D), whereas RBF remained unchanged.

Conclusions: Renal artery stenosis induces cellular senescence in the stenotic kidney, particularly in tubular epithelial cells, and their clearance improves renal function. These observations suggest a role for cellular senescence in pathogenesis of renal artery stenosis, supporting development of senotherapy.

Evidence for Female Protection from Kidney Injury during Angiotensin II Hypertension

Borna S. Shirvani, Luciana C. Veiras, Donna Ralph, Hillmin Lei, Alicia A. McDonough. *Keck School of Medicine of USC, Los Angeles, CA.*

Background: To address resistance to cardiovascular and kidney disease in females (F) vs. males (M), we recently defined sexual dimorphisms in renal transporters' abundance and distribution along the nephron. We reported lower proximal and higher distal Na^+ transporters' abundance and activity along nephrons of F vs. M rats and mice. This study

aimed to examine susceptibility to renal injury during Ang II Hypertension (AngII-HTN) in F vs. M Sprague Dawley rats.

Methods: Rats were either implanted with osmotic minipumps that infused 400 ng/kg/min AngII for 2 weeks or sham operated (n=6/group). Systolic blood pressure (tail-cuff) increased to 190 mmHg in both sexes. Urine was collected overnight in metabolic cages before sacrifice after which blood and kidney were collected. Quantitative immunoblotting was used to assess protein levels of kidney injury molecule-1 (KIM-1), angiotensinogen (aogen) and plasmin in urine and/or renal cortex; serum and urine albumin were quantified via ELISA and BCG method, respectively, and confocal immunohistochemistry (IHC) used to detect endocytosed albumin.

Results: Urinary albumin, similar at baseline in M and F, was 10-fold higher in M vs. F during AngII-HTN ($p<0.001$) associated with a 10% fall in serum albumin in M ($p=0.05$, no change in F). Urinary KIM-1, aogen and plasmin were markedly increased in M during AngII-HTN while near undetectable in F. Higher urinary plasmin in M vs. F correlated with twice as much cleaved (activated) epithelial Na^+ channel gamma subunit during AngII-HTN ($p<0.0001$). In renal cortex homogenates at baseline, KIM-1, aogen and megalin were higher in M vs F; during AngII-HTN cortical megalin increased in F only while KIM-1 and a'ogen were unchanged. AngII-HTN increased cortical albumin in both sexes and endocytosed albumin was evident by IHC in M PT but not F.

Conclusions: Despite similar increases in blood pressure, M vs. F rats exhibit greater susceptibility to renal injury during AngII-HTN, evident as greatly increased urinary albumin, KIM-1, aogen, plasmin associated ENaC activation, and endocytosed PT albumin.

Sex Differences in the Renal Hemodynamic Response to Angiotensin II Post-CPAP Therapy in Women and Men with Obstructive Sleep Apnea

David D. Nicholl,[1] Patrick Hanly,[1] Ann A. Zalucky,[1] George Handley,[2] Darlene Y. Sola,[1] Sofia B. Ahmed.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]Healthy Heart Sleep Company, Calgary, AB, Canada.*

Background: Women have slower loss of kidney function and chronic kidney disease (CKD) progression. The renin-angiotensin system (RAS) and the vascular effects of obstructive sleep apnea (OSA) differ by sex. OSA is associated with glomerular hypertension which can be reversed by continuous positive airway pressure (CPAP) therapy. We sought to determine whether sex differences exist in the effect of CPAP for OSA on renal hemodynamics and the renal RAS in humans.

Methods: Twenty-nine (10 female, 19 male; 49±2y) incident, otherwise healthy, OSA subjects (respiratory disturbance index [RDI]>$15h^{-1}$) with nocturnal hypoxemia (SaO_2<90% >12%/night) were studied in high-salt balance, a state of maximal RAS suppression, pre-CPAP and after 4 weeks of effective CPAP therapy (>4h/night). Renal plasma flow (RPF) and glomerular filtration rate (GFR) were measured by para-aminohippurate and inulin clearance technique at baseline and in response to Angiotensin II (AngII) challenge (3ng/kg/min x 30min, 6ng/kg/min x 30min), a marker of renal RAS activity, pre- and post-CPAP. The primary outcome was the effect of CPAP on the renal hemodynamic responses to AngII in women compared to men.

Results: CPAP corrected OSA and nocturnal hypoxemia (RDI: 44±4 vs 4±$1hr^{-1}$, $p<0.001$; duration SaO_2<90%: 45±6 vs 7±2%, $p<0.001$). In women, CPAP was associated with a significant increase in RPF (626±22 vs 718±43 mL/min, $p=0.007$) but no change in GFR (108±2 vs 105±3 mL/min, $p=0.8$), whereas in men, CPAP use was not associated with changes in renal hemodynamics (RPF: 710±37 vs 756±38 mL/min, $p=0.11$; $p=0.7$ vs women; GFR: 124±8 vs 113±6 mL/min, $p=0.085$; $p=0.5$ vs women). Pre-CPAP, there was no difference in the RPF or GFR responses to AngII between women and men. Post-CPAP, there was a significantly greater renovasoconstrictive response to AngII in women (RPF: Δ30min: -100±27 vs -161±25 mL/min, $p=0.007$; Δ60min: -138±27 vs -206±32 mL/min, $p=0.007$), but not in men (RPF: Δ30min: -142±14 vs -154±19 mL/min, $p=0.4$; Δ60min: -168±23 vs -200±23 mL/min, $p=0.053$). Post-CPAP women had a larger initial reduction in GFR in response to AngII compared to men (Δ30min: -5±3 vs 0±2 mL/min, $p=0.039$; vs men).

Conclusions: CPAP therapy for OSA is associated with altered renal hemodynamics and downregulation of renal RAS activity in women but not in men.

TH-OR079

Role of Klotho Genetic Polymorphisms in Salt-Sensitivity Hypertension: A Link between Salt and Aging?

Chiara Lanzani,[1,2] Simone Fontana,[1,2] Lorena Citterio,[1,2] Laura Zagato,[1,2] Marco Simonini,[1,2] Paolo Manunta.[1,2] *[1]Genomics of Renal Diseases and Hypertension, IRCCS San Raffaele Scientific Institute, Milan, Milan, Italy; [2]Chair and School of Nephrology, Università Vita Salute San Raffaele, Milan, Italy.*

Background: Hypertension is a common aging-related disorder. Salt intake is one of the main environmental factors contributing to the development of hypertension. Recently, an elegant paper showed that one-half Klotho transgenic mice displayed a spontaneous BP increase and a salt-sensitive hypertension in response to high Na intake. Commonly, serum levels of alpha-Klotho decrease with age and this reduction may be stronger in patients with several aging-related diseases. Aim of the study: to evaluate the role of Klotho polymorphisms in human essential hypertension and salt sensitivity.

Methods: 32 SNPs in Klotho gene identified with a previous GWA were used in the genetic analysis. Selected SNPs were studied for Pressure-natriuresis relationship (PNat) in 677 naïve essential hypertensive patients, never treated before, (NHP) by Acute salt load (NaLoad: 310 mMol in 2 h iv). Salt sensitivty (SS) is defined as mean BP increase (DMBP120) greater than 4 mm Hg at the end of infusion.

Results: We genotyped 32 SNPs within KL gene and 20 kb flanking regions. The best associated SNP with Na sensitivity resulted the missense rs9536314 common SNP, MAF 0.17 for G allele. According to salt sensitivity definition, 64% of NHPs resulted SR, while 36 % were SS. An inverse relationship was found between plasma klotho and DMBP120. Moreover KL rs9536314 GG and GT genotypes are more represented among SS. Again, GG group shows a less steep PNat curve, that is a significant increase in MBP occurred to excrete the same quantity of salt compared to salt resistant subjects.

Conclusions: In summary, this study showed, for the first time, that KLOTHO rs9536314 polymorphism is associate to salt-sensitive hypertension by activating a right shift of the pressure-natriuresis relationship in NHP. Therefore, klotho supplement in those hypertensive patient carrying the GG o mr GT variants may be potential therapeutic strategies for the treatment of salt-sensitive hypertension and kidney damage in elderly patients.

Malignant Hypertension Can Be Partially Attenuated and Reversed by a 20-Hydroxyeicosatetraenoic Acid Antagonist

Vera Certikova chabova,[1] Lenka Sedláková,[2] Ludek Cervenka.[3] *[1]1st Faculty of medicine, Charles University, Praha 2, Czechia; [2]Institute for Clinical and Experimental Medicine, Praha 4, Czechia; [3]Institute of Clinical and Experimental Medicine, Praha 4, Czechia.*

Background: 20-hydroxyeicosatetraenoic acid (20-HETE), the product of cytochrome P450-dependent ω-hydroxylase might potentiate prohypertensive actions of angiotensin II (ANG II) in Cyp1a1-Ren-2 transgenic rats, a model of ANG II-dependent malignant hypertension. Therefore, we evaluated the antihypertensive effectiveness of a 20- HETE receptor antagonist (AAA) in this model.

Methods: Malignant hypertension was induced in Cyp1a1-Ren-2 transgenic rats by activation of the renin gene using indole-3-carbinol (I3C), a natural xenobiotic. Treatment with AAA (N-disodium succinate-20-hydroxyeicosa-6(Z),15(Z)-diencarboxamide) was started either simultaneously with induction of hypertension or 10 days later, during established hypertension. Systolic blood pressure (SBP) was monitored by radiotelemetry, indices of renal and cardiac injury, and kidney ANG II levels were determined.

Results: In I3C-induced hypertensive rats, early AAA treatment reduced SBP elevation (to 161±3 vs. 199±3 mmHg in untreated I3C-induced rats), reduced albuminuria, glomerulosclerosis index and cardiac hypertrophy ($p<0.05$ in all cases). Untreated I3C-induced rats showed augmented kidney ANG II (405±14 vs. 52±3 fmol/g in noninduced rats, $p<0.05$). AAA treatment lowered it to levels not significantly different from that in noninduced rats (72±6 fmol/g). Remarkably, in TGR with established hypertension, AAA also decreased SBP (from 187±4 to 158±4 mmHg, $p<0.05$) and exhibited organoprotective effects in addition to a marked suppression of kidney ANG II levels. In conclusion, 20-HETE antagonist attenuated the development and largely reversed the established ANG II dependent malignant hypertension, likely via suppression of intrarenal ANG II levels.

Conclusions: Intrarenal ANG II activation by 20-HETE is important in the pathophysiology of this model of ANG II -dependent hypertension. 20-HETE antagonists can partially reverse both developing and established hypertension and target organ damage.

Urinary Biomarkers of Kidney Damage and Incident CKD in SPRINT

William R. Zhang,[1] Timothy Craven,[2] Rakesh Malhotra,[9] Alfred K. Cheung,[3] Michel Chonchol,[4] Paul E. Drawz,[5] Mark J. Sarnak,[6] Chirag R. Parikh,[7] Michael Shlipak,[8] Joachim H. Ix.[9] *[1]UCSF School of Medicine, San Francisco, CA; [2]Wake Forest School of Medicine, Winston-Salem, NC; [3]University of Utah, Salt Lake City, UT; [4]University of Colorado, Aurora, CO; [5]University of Minnesota, Minneapolis, MN; [6]Tufts Medical Center, Boston, MA; [7]Yale University and VAMC, New Haven, CT; [8]San Francisco VA Medical Center, San Francisco, CA; [9]UCSD, San Diego, CA.*

Background: Randomization to the intensive arm (SBP<120mmHg) in the Systolic Blood Pressure Intervention Trial (SPRINT) was associated with a 3-fold increased incidence of CKD, compared with the standard arm (SBP<140mmHg). However, it is unknown whether incident CKD in the setting of intensive SBP lowering is accompanied by intrinsic kidney injury.

Methods: Among the 162 incident CKD cases (128 in the intensive arm and 34 in the standard arm) that occurred during SPRINT follow-up and 162 controls matched on age, sex, race, baseline eGFR, and randomization arm, we measured 9 validated urinary biomarkers of kidney damage at baseline and 1 year. Linear mixed-effects models adjusting for baseline SBP and urine creatinine estimated 1-year biomarker changes to compare incident CKD cases vs. matched controls in the intensive arm; and to contrast cases in the intensive vs. standard arms.

Results: At 1 year of SPRINT follow-up, incident CKD cases vs. matched controls in the intensive arm had mean eGFR declines of -22 vs. -4 mL/min/$1.73m^2$. However, incident CKD cases in the intensive arm had either significantly greater 1-year reductions or similar changes of kidney damage biomarkers, compared with both matched controls and with cases in the standard arm (**Figure**).

Conclusions: Incident CKD cases in the intensive arm had substantial 1-year eGFR reductions yet did not have relative increases in biomarkers, compared with matched controls; rather, these cases had decreases in several biomarkers, compared with both

matched controls and cases in the standard arm. Thus, incident CKD in the setting of intensive SBP lowering may reflect hemodynamic accommodation rather than intrinsic injury.

Urinary Oxalate Excretion and the Risk of ESRD and CKD Progression

Sushrut S. Waikar,[9] Anand Srivastava,[1] Ragnar Palsson,[2] Tariq Shafi,[3] Chi-yuan Hsu,[4] Kumar Sharma,[14] James P. Lash,[5] Jing Chen,[10] Jiang He,[11] John C. Lieske,[6] Dawei Xie,[12] Xiaoming Zhang,[13] Harold I. Feldman,[7] Gary C. Curhan.[8] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Harvard, Belmont, MA; [3]Johns Hopkins University School of Medicine, Baltimore, MD; [4]University of California San Francisco, San Francisco, CA; [5]University of Illinois at Chicago, Chicago, IL; [6]Mayo Clinic, Rochester, MN; [7]University of Pennsylvania, Philadelphia, PA; [8]Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA; [9]Harvard Medical School, Boston, MA; [10]Tulane School of Medicine, New Orleans, LA; [11]Tulane School of Public Health and Tropical Medicine, New Orleans, LA; [12]University of Pennsylvania School of Medicine Center for Clinical Epidemiology and Biostatistics, Philadelphia, PA; [13]University of Pennsylvania School of Medicine, Philadelphia, PA; [14]University of Texas Health San Antonio, San Antonio, TX.*

Background: Kidney failure from oxalate nephropathy is a devastating complication of rare disorders of oxalate metabolism (e.g., primary hyperoxaluria), oxalate over-absorption (e.g., enteric hyperoxaluria), and ingestion of large amounts of oxalate or its precursors. We hypothesized that higher urinary oxalate excretion, even within the typical range of excretion, would be associated with progression of CKD.

Methods: We measured 24h urinary oxalate excretion in stored specimens from 3,123 participants of the Chronic Renal Insufficiency Cohort study. Baseline eGFR was 43 ml/min/1.73m^2. CRIC study participants were followed longitudinally for incident ESRD and/or halving of eGFR. We used Cox proportional hazards models to test whether urinary oxalate excretion was associated with two outcomes: (1) Incident ESRD; and (2) CKD progression, defined as halving of eGFR or incident ESRD. Multivariable models were adjusted for a number of demographic, clinical, and laboratory variables.

Results: The median 24h oxalate excretion in CRIC participants was 18.6 mg (IQR, 12.9 - 25.7 mg). Cross sectionally, higher oxalate excretion was correlated with lower baseline eGFR (r=-0.1, p<0.001) and greater albuminuria (r=0.15, p<0.001). In prospective multivariable-adjusted analyses, those in the highest vs lowest quintile of oxalate excretion had a 1.41-fold (95% CI 1.09-1.83) higher risk of ESRD and a 1.28-fold (95% CI 1.02-1.61) higher risk of CKD progression (p<0.001).

Conclusions: Among individuals with CKD, higher baseline urinary oxalate excretion is associated with greater risk of ESRD and CKD progression. Oxalate excretion should be tested as a potentially modifiable risk factor for progression of kidney disease.

Association of Soluble TNFR-1 Concentrations with Long-Term Decline in Kidney Function: The Multiethnic Study of Atherosclerosis

Pavan K. Bhatraju,[1,2] Leila R. Zelnick,[2] Ronit Katz,[3] Bryan R. Kestenbaum.[3] *[1]Pulmonary and Critical Care Medicine, University of Washington, Seattle, WA; [2]Kidney Research Institute, Seattle, WA; [3]University of Washington, Seattle, WA.*

Background: Tumor necrosis factor receptor-1 (TNFR-1) is a cell surface receptor predominantly expressed in the glomerular and peritubular capillary endothelium and plays a causative role in the development of endothelial cell dysfunction and inflammation. Soluble TNFR-1 (sTNFR-1) concentrations are associated with early glomerular structural lesions and kidney disease progression among persons with established diabetic kidney disease. No studies have assessed the potential impact of sTNFR-1 on long-term changes in kidney function among healthy people.

Methods: We tested associations between sTNFR-1 concentration, measured at study enrollment, and incident decline in eGFR (≥40% decline and annual proportional decline) among 2,551 participants in the Multiethnic Study of Atherosclerosis (MESA). Participants were recruited into the MESA from six U.S. communities and were free of clinical cardiovascular disease at baseline. Serum creatinine concentrations were obtained at enrollment and study years three, five, and ten.

Results: Mean age was 61 years, 53% were women, an equal proportion was White, Black, Chinese or Hispanic (≈25%). Mean baseline eGFR was 79 ± 16 mL/min/1.73m^2. Serum sTNFR-1 was inversely associated with baseline eGFR. Over a median follow-up time of 9.3 years, 110 participants developed a ≥40% decline in eGFR [adjusted hazard ratio, 1.45 (95% CI, 1.18 to 1.78) per standard deviation increment, p=0.0004] Table1. The highest sTNFR-1 tertile was associated with an adjusted annualized decline in eGFR 1.80% (95% 1.10 to 4.70) after multivariate adjustment. Associations were robust across subgroups defined by demographics, hypertension, diabetes, and baseline CKD status.

Conclusions: Serum sTNFR-1 concentrations are associated with long-term decline in eGFR among a healthy, multi-ethnic cohort. Endothelial dysfunction and inflammation may be modifiable targets for the preservation of kidney function in ambulatory patients.

Funding: NIDDK Support, Other NIH Support - Kidney Research Institute, University of Washington, Government Support - Non-U.S.

Transethnic Genome-Wide Association Studies of Kidney Function Measures Identify Associations at >300 Genomic Loci

Matthias Wuttke. CKDGen Consortium *Institute of Genetic Epidemiology, Department of Biometry, Epidemiology and Medical Bioinformatics, Faculty of Medicine and Medical Center, University of Freiburg, Freiburg, Germany.*

Background: Chronic kidney disease (CKD) affects 10% of the adult population globally. Reduced estimated glomerular filtration rate (eGFR) is the primary measure used to define CKD. Although previous[MW1] genetic studies have revealed many loci associated with eGFR, most of the genetic variation is still unexplained. The CKDGen Consortium is an international collaborative effort aimed at identifying the genetic underpinnings of renal health.

Methods: In an ongoing effort, 121 studies totaling >750,000 participants from five different ethnicities contributed genome-wide association summary statistics relating log-transformed creatinine-based eGFR (CKD-EPI formula) to ~9 million high-quality 1KGP- or HRC-imputed genetic markers, using an additive genetic model adjusted for sex and

age. Summary statistics were combined using fixed-effects inverse variance-weighted meta-analysis.

Results: Across ethnicities, 308 genomic loci (1 Mb-segments, MHC region joined) contained at least one significantly eGFR-associated SNP (p<5E-08). The LD score regression intercept was 1.04, suggesting no residual inflation of the test-statistics. Of the 308 loci, 228 were novel (mapping outside of 500 kb of previously reported index variants), and 80 were consistent with previous findings. Loci were characterized by their association with blood urea nitrogen and CKD, by tissue-specific enrichment of expressed genes, as well as by their heterogeneity correlated with ancestry. Approximate conditional meta-analysis among European-ancestry individuals identified 277 independent trait-associated variants, which together explained 7.6% of the phenotypic variance, almost doubling previous estimates. We fine-mapped 212 non-overlapping regions, of which 46 contained >1 independent SNPs. Credible sets with 99% probability for including a causal variant consisted of 7-74 SNPs (IQR). There were 20 single-SNP sets; for example, rs881858 (close to *VEGFA*) maps to open chromatin and represents a CTCF binding site.

Conclusions: Ongoing analyses include gene expression, tissue enrichment and network analyses of gene expression, and functional follow-up studies. These results of the largest genetic screen of kidney function to date will enhance the understanding of the biologic mechanisms of this trait.

TH-OR085

Genetic and Epigenetic Analysis in Genes Affecting Mitochondrial Function Are Associated with CKD in an Older Population

A.J. Mcknight,[1] Ruaidhri C. Cappa,[1] Laura J. Smyth,[1] Marisa Canadas Garre,[1] Cassio P. De campos,[3] Ryan Skelly,[1] Sharon Cruise,[1] Frank Kee,[1] Bernadette Mcguinness,[1] Catherine Godson,[2] Alexander P. Maxwell.[1] *[1]Queen's University Belfast, Belfast, United Kingdom; [2]The Conway Institute of Biomolecular and Biomedical, Belfield, Dublin, Ireland; [3]Utrecht University, Utrecht, Netherlands.*

Background: The Northern Ireland COhort for the Longitudinal study of Ageing (NICOLA) is a ten-year project exploring health and lifestyle information in 8,504 people ≥ 50 years of age via a computer assisted personal interview with an associated bioresource. Chronic kidney disease (CKD) affects ~10% of the World's population and is more prevalent in older individuals. Optimal renal function is critically dependent upon efficient mitochondria, therefore genetic and epigenetic features that lead to mitochondrial dysfunction may influence CKD.

Methods: The discovery cohort comprised 2,567 white European individuals with body mass index ranging from 18.5 - 40 kg/m^2. Genotyping was performed using Illumina's Infinium CoreExome array (n=551,839 SNPs directly typed), with data imputed to the Haplotype Reference Consortium. Methylation data was generated using Illumina's Infinium MethylationEPIC array (866,554 features with single site resolution). PLINK and Partek Genomics Suite were employed to investigate association with eGFR, serum albumin, urea and creatinine. Replication was conducted in an independent cohort of 402 individuals.

Results: SNPs that demonstrated the most evidence for association include an exonic SNP in the mitochondrial genome *MT-TL2* gene (rs2853498; A12308G; a key SNP defining mitochondrial Haplogroup U) with increased creatinine levels (P=0.000153, OR=1.185, 95% CI=1.0929-1.2812). SNPs in nuclear genes that influence mitochondrial function include rs77790196 within *SLC39A1* (P= 4.4 x10^{-07}, OR=0.0055, 95% CI=0.0007-0.0412) and rs12564199 within *JTB* (P=6.6 x10^{-07}, OR=0.006, 95% CI=0.0008-0.0449) associated with decreased eGFR. Analysis of epigenetic data identified eight genes demonstrating differential methylation with p<10^{-08} and Δβ ±0.2, including *ZBED3*, *ZNF672*, and *AHCTF1* for participants with early stage CKD compared to individuals with CKD stages 3-5.

Conclusions: These analyses have identified novel associations linking CKD with SNPs and CpG sites. This may serve as a future basis for the development of predictive multi-omic biomarkers and/or increased understanding of CKD pathogenesis.

Funding: Private Foundation Support, Government Support - Non-U.S.

Metabolomic Alterations Associated with Proteinuria

Shengyuan Luo,[1,2] Josef Coresh,[1,2] Adrienne Tin,[1,2] Casey Rebholz,[1,2] Andrew S. Levey,[3] Lesley Inker,[3] Mark J. Sarnak,[3] Morgan Grams.[1,2] *[1]Johns Hopkins University, Baltimore, MD; [2]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [3]Tufts Medical Center, Boston, MA.*

Background: Metabolomic profiling may reveal important pathophysiological mechanisms underlying proteinuria in chronic kidney disease (CKD).

Methods: Among 962 participants in the African-American Study of Hypertension and Kidney Disease (AASK) and 670 participants in the Modification of Diet in Renal Disease (MDRD) Study, we evaluated the cross-sectional association between log-transformed urine protein-to-creatinine ratio (UPCR) and known, non-drug metabolites (N =801) identified in stored serum samples (pre-randomization visit in AASK and 12-month follow-up visit in MDRD) via an untargeted approach. The metabolites with statistically significant associations (adjusted for age, sex, race, trial arm, measured GFR, history of heart disease, smoking, and BMI) after Bonferroni correction were included in a pathway analysis.

Results: In AASK and MDRD, respectively, median UPCR was 80 (IQR: 28-359) and 185 (IQR: 54-894) mg/g, mean age was 56 and 53, 39% were female, 100% and 7% were black, 0% and 5% were diabetic, and mean GFR was 48 and 28 mL/min/1.73m^2. Linear regression identified 64 metabolites associated with proteinuria in one or both cohorts, 55 of which were statistically significant in meta-analysis (p<8x10^{-4}). There were moderate within-pathway correlations among these metabolites (**Figure**). Metabolites with the lowest p-values (p<10^{-17}) included 4-hydroxychlorthalonil, 1,5-anhydroglucitol (1,5-AG), perfluoroctanesulfonic acid (PFOS), and 3-carboxy-4-methyl-5-propyl-2-furanpropanoate (CMPF), all of which negatively associated with UPCR. Pathway analysis showed over-representation of metabolites in the phosphatidylethanolamine (PE) and phosphatidylinositol (PI) pathways.

Conclusions: Metabolomic profiling identified metabolites (including 1,5-AG, CMPF and chemicals such as hydroxychlorthalonil and PFOS), as well as metabolic pathways (such as PE and PI metabolism), that were strongly associated with non-nephrotic range proteinuria in CKD.

Funding: NIDDK Support

Figure. Heatmap showing correlations among 55 metabolites associated with proteinuria.

An Investigation into the DNA Methylation Patterns of CKD in Older Individuals

Laura J. Smyth, Sharon Cruise, Jill Kilner, Alexander P. Maxwell, Bernadette Mcguinness, Frank Kee, A.J. Mcknight. On behalf of the Northern Ireland Cohort of Longitudinal Ageing collaborative group *Queen's University Belfast, Belfast, United Kingdom.*

Background: Changes in DNA methylation are associated with chronic diseases. The study assessed whether methylation status of CpG sites differs between individuals with and without CKD between the ages of 60 and 79.

Methods: Participants were recruited as part of the Northern Ireland COhort for the Longitudinal study of Ageing (NICOLA), a large-scale population-based prospective cohort study. Estimated GFR was calculated for each individual (n=1,097) using the CKD-EPI formula. CKD stages, based on eGFR, were determined and all individuals with stage 2 CKD (eGFR >60 - <90mL/min/1.73m^2) were removed to increase discrimination between CKD case and control groups. Using the Infinium HD Methylation Assay, MethylationEPIC BeadChips from Illumina, the methylation status of >850,000 CpG sites, gene bodies, promoters and CpG islands were determined in each individual. Blood-derived DNA was processed consistently within our single genetics centre. Partek Genomics Suite 7.0 was utilised for data analysis, with standard quality control applied. In total, 155 individuals had CKD stages 3, 4 or 5 and were compared with 240 individuals with eGFR >90ml/min/1.73m^2 and no evidence of renal disease.

Results: In total, 306 CpG sites were identified as having significantly different levels of methylation in individuals with CKD compared with controls (p<1x10^{-07}). Among the genes identified with altered methylation status, several, including *CLU*, *NOS3*, *IQSEC1* and *NPHP4* have been linked with CKD. High concordance between duplicate samples was also observed for this array. Three of the significantly associated CpG sites demonstrated a graduated increase in the methylation fold change with worsening renal function i.e. comparing control individuals with persons having CKD stages 3, 4 and 5 respectively.

Conclusions: Epigenetic modifications, such as DNA methylation, may represent important biomarkers for the loss of kidney function in individuals with CKD. Data from this longitudinal cohort study provides the opportunity to monitor and assess the relationship between methylation status and CKD over time with a view to identifying new biomarkers or expanding knowledge of those previously identified CKD biomarkers.

TH-OR088

Prognostic Value of Extracellular Fluid Volume in CKD: A Prospective Cohort Study

Anne-Laure Faucon,[1] Martin Flamant,[4,8] Marie Metzger,[2] Jean-Jacques Boffa,[5,9] Jean-philippe Haymann,[6,9] Pascal Houillier,[7,3] Eric Thervet,[10,3] Benedicte Stengel,[1] Guillaume Geri,[11] Emmanuelle Vidal-Petiot.[4,8] *[1]CESP, INSERM U1018, Villejuif, France; [2]CESP U1018, INSERM, Villejuif, France; [3]Paris Descartes University, Paris, France; [4]Physiology Department, Hôpital Bichat, Paris, France; [5]Nephrology Department, Hôpital Tenon, Paris, France; [6]Physiology Department, Hôpital Tenon, Paris, France; [7]Physiology Department, Hôpital Européen Georges Pompidou, Paris, France; [8]Paris-Diderot University, Paris, France; [9]Pierre et Marie Curie University, Paris, France; [10]Nephrology Department, Hôpital Européen Georges Pompidou, Paris, France; [11]Intensive care Unit, Hôpital Ambroise Paré, Paris, France.*

Background: Volume overload has been shown to be an independent risk factor for mortality in chronic dialysis patients. However, few studies have analyzed the prognostic value of extracellular fluid (ECF) volume in patients with chronic kidney disease (CKD), not on dialysis. The aim of this study was to analyze the association between ECF volume and end-stage renal disease (ESRD) and mortality in patients with non-dialysis CKD.

Methods: The NephroTest study is a prospective hospital-based tricentric cohort which included 2,084 patients with CKD stage 1-5 of various aetiologies, between 2000 and 2012. ECF volume was measured as the distribution volume of ^{51}CrEDTA, and expressed as a ratio of measured over theoretical ECF (rECF) - the latter being calculated using Moore formula. Measured glomerular filtration rate (mGFR) was assessed from the renal clearance of ^{51}Cr-EDTA. Cause-specific Cox regression models were used to estimate hazard ratios (HR, 95% confidence intervals) of ESRD and death before ESRD associated with rECF tertiles in 1,610 patients with mGFR > 15 ml/min/1.73 m^2.

Results: Mean age of patients was 58.7±15.1years, and 66.8% were men. Baseline mean mGFR was 43.7±18.7mL/min/1.73m^2, mean ECF volume and rECF were 16.1±3.8L and 0.96±0.14, respectively. After a median follow-up of 6.1 [IQR: 3.64;8.37] years, ESRD occurred in 329 (20.4%) patients and 187 (11.6%) patients died before ESRD. After adjustment for age, sex, site, ethnicity, cardiovascular risk factors, underlying renal disease, mGFR, proteinuria, 24-hour sodium excretion, diuretics and diuresis, a higher baseline rECF was significantly associated with ESRD (HR for second vs. first tertile = 1.28 [0.94;1.74], HR for third vs. first tertile = 1.51 [1.08;2.10]), and with mortality (HR for second vs. first tertile = 0.99 [0.63;1.56], HR for third vs. first tertile = 1.81 [1.17;2.80]).

Conclusions: Our data suggest that rECF volume is an independent risk factor of ESRD and mortality. Monitoring and avoiding excessive fluid overload is important for the clinical management of patients with CKD.

TH-OR089

Specific Mitochondrial Genetic Variants Are Associated with Kidney Dysfunction and Injury in Older Adults

Vasantha Jotwani,[1] Ronit Katz,[2] Mark J. Sarnak,[3] Samir M. Parikh,[4] Adrienne Tin,[5] Dan Arking,[5] Michael Shlipak,[6] Gregory J. Tranah.[7] *[1]UCSF, San Francisco, CA; [2]University of Washington, Seattle, WA; [3]Tufts Medical Center, Boston, MA; [4]Beth Israel Deaconess Medical Center, Boston, MA; [5]Johns Hopkins University School of Medicine, Baltimore, MD; [6]San Francisco VA Medical Center, San Francisco, CA; [7]Sutter Health, San Francisco, CA.*

Background: Mitochondrial dysfunction is an important contributor to acute and chronic kidney damage, due to the critical roles of mitochondria for oxidative phosphorylation. Mitochondrial genetic variation has been associated with age-related cardiovascular and functional impairments, but little is known regarding the impact of common inherited mitochondrial DNA (mtDNA) variants on kidney health.

Methods: In this study of 2,728 ambulatory older adults enrolled in the Health, Aging, and Body Composition Study, we evaluated associations of 10 common inherited mtDNA haplotypes and 137 single nucleotide polymorphisms (SNPs) with estimated glomerular filtration rate (eGFR), albumin/creatinine ratio (ACR), and urine concentrations of kidney injury molecule-1 (KIM-1) and interleukin-18 (IL-18). DNA was extracted from blood buffy coat specimens and mtDNA genotype was determined using the Illumuna 1M chip. A total of 60 SNPs with minor allele frequency >=1% were examined for associations with kidney outcomes. All analyses stratified participants by European and African ancestry and adjusted for age, sex, and mitochondrial genetic ancestry.

Results: Among persons of European ancestry (n=1,660), m.10589G>A was associated with lower eGFR (57 vs 71 ml/min/1.73m^2; p=0.009) and m.6776T>C was associated with higher ACR (98 vs 29 mg/g; p<0.0001), whereas haplogroup V (1721 vs 1172 pg/ml, p=0.0066) and m.3916G>A (2599 vs 1207 pg/ml, p<0.0001) were each associated with higher urine KIM-1. Among persons of African ancestry (n=1,137), m.15758A>G was associated with higher urine KIM-1 (3476 vs 1074 pg/ml, p<0.0001). There were no statistically significant associations of mtDNA variants with urine IL-18.

Conclusions: Specific inherited mtDNA variants are associated with kidney dysfunction and injury in older adults, suggesting that mitochondrial genetic variability may contribute to risk of kidney disease.

Provider Perception of Frailty Influences Dialysis Modality Choice for Late Stage CKD Patients Receiving Multidisciplinary Care

Ranveer S. Brar,[1,2] Reid Whitlock,[1,2] Blake Lerner,[2] Clara Bohm,[1,2] Paul Komenda,[1,2] Claudio Rigatto,[1,2] Bhanu Prasad,[3] Navdeep Tangri.[1,2] *[1]Seven Oaks General Hospital, Chronic Disease Innovation Center, Winnipeg, MB, Canada; [2]University of Manitoba, Winnipeg, MB, Canada; [3]Nephrology, Regina Qu'Appelle Health Region, Regina, SK, Canada.*

Background: Frailty is common in patients with Chronic Kidney Disease (CKD) and is associated with accelerated aging. While there have been several studies examining frailty in patients with earlier stages of CKD and those on dialysis, little is known about the prevalence and impact of frailty on decisions surrounding renal replacement therapy modalities in patients with advanced CKD (Stages G4-G5). We sought to determine the prevalence of frailty in patients with advanced CKD and the association of these measures with dialysis modality decisions and mortality.

Methods: We studied 587 patients with advanced CKD who were enrolled in multidisciplinary CKD clinics at 4 centers. We collected demographics, comorbid conditions, and laboratory results in addition to objective [Fried Frailty Criteria and Short Physical Performance Battery (SPPB)], and subjective measures (physician and nurse impression) of frailty. Our primary outcomes were choice of dialysis modality based on provider perception of frailty. Our secondary outcomes were agreement between frailty assessment tools and all-cause mortality.

Results: Our cohort had a mean age of 66.3 and 41% were female. Estimates of frailty prevalence varied as 54.8% of the cohort were considered frail according to SPPB, 33.2% according to Fried, 35.2% according to physician impression, and 32.5% according to nursing impression. Agreement between objective frailty assessments was moderate (κ = 0.42), as was agreement between subjective frailty assessments (κ = 0.47). In unadjusted and adjusted analyses, frailty measured objectively using Fried was associated with mortality (HR 2.15 [95% CI: 1.27-3.62]), and frailty measured subjectively (OR 4.20 [95% CI: 1.88-9.76) was associated with choosing in center hemodialysis.

Conclusions: Frailty is common in patients with advanced CKD, but its operational definition can classify different patients as frail. Patients classified as frail by Fried have a higher risk of death, and patients considered frail by nurses and physicians are more likely to choose in-center hemodialysis. Further research to understand the longitudinal trajectory of frailty and its impact on therapeutic choices, morbidity, mortality, and quality of life after the initiation of dialysis is needed.

Twenty-Year Trends in Mortality Due to Myocardial Infarction and Stroke in Dialysis Patients

Gurbey Ocak,[1] Marlies Noordzij,[2] Maarten B. Rookmaaker,[1] Marianne C. Verhaar,[1] Ziad Massy,[3,4] Friedo W. Dekker,[5] Kitty J. Jager.[2] *[1]Department of Nephrology and Hypertension, University Medical Center Utrecht, Utrecht, Netherlands; [2]Department of Medical Informatics, ERA-EDTA Registry, Amsterdam, Netherlands; [3]Department of Nephrology, Ambroise Pare University Hospital, Boulogne Billancourt/ Paris, France; [4]Inserm Unit 1018, CESP, Team 5, (EpReC, Renal and Cardiovascular Epidemiology), UVSQ, Villejuif, France; [5]Department of Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands.*

Background: In the last decades, important improvements have been made in the prevention and treatment of myocardial infarction and stroke resulting in reduced mortality rates in the general population. However, it is unknown whether mortality rates of myocardial infarction and stroke have also decreased with time in dialysis patients. The aim of this study was to assess the mortality rates due to myocardial infarction and stroke in a large cohort of dialysis patients as compared with the general population for three time periods.

Methods: We included incident dialysis patients from eleven European countries providing data to the ERA-EDTA Registry who started dialysis between 1994 and 2011 and followed them for three years. The causes of death in dialysis patients were compared with the causes of death in the general population in the same time period. We calculated age- and sex-standardized mortality rate ratios (SMRs) with 95% confidence intervals (CIs) by dividing the mortality rates in dialysis patients by the mortality rates in the general population for three time periods (1994-1999, 2000-2005 and 2006-2011).

Results: Of the 201,918 dialysis patients, 79,327 patients died during follow-up of whom 10.3% died due to myocardial infarction and 6.6% due to stroke. In the general population, 19,058,469 persons died during follow-up of whom 7.4% died due to myocardial infarction and 6.1% due to stroke. Compared with the general population, the SMRs of myocardial infarction for dialysis patients were **11.4 (95% CI 10.8-12.0)** between 1994 and 1999, **12.1 (95% CI 11.5-12.8)** between 2000 and 2005 and **14.0 (95% CI 13.2-14.8)** between 2006 and 2011. The SMRs of stroke were **11.0 (95% CI 10.3-11.9)** between 1994 and 1999, **11.7 (95% CI 10.8-12.6)** between 2000 and 2005 and **12.4 (95% CI 11.5-13.3)** between 2006 and 2011.

Conclusions: Mortality rate ratios for myocardial infarction and stroke increased with time. Dialysis patients seem to benefit less of improvements made in the prevention and treatment of myocardial infarction and stroke than non-dialysis patients which may be related to the underlying pathophysiological mechanisms of the atherosclerotic disease or to the limited optimal cardiovascular therapeutic strategies.

TH-OR092

International Comparisons of Mortality Among Hemodialysis Patients in the DOPPS

Keith McCullough,[1] Eric W. Young,[4] Steven M. Brunelli,[2] Daniel E. Weiner,[3] John Hartman,[5] Dino B. Capone,[6] Bruce M. Robinson.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]DaVita Clinical Research, Needham, MA; [3]Tufts Medical Center, Boston, MA; [4]Arbor Research, Ann Arbor, MI; [5]Visonex LLC, Green Bay, WI; [6]Visonex, LLC, Green Bay, WI.*

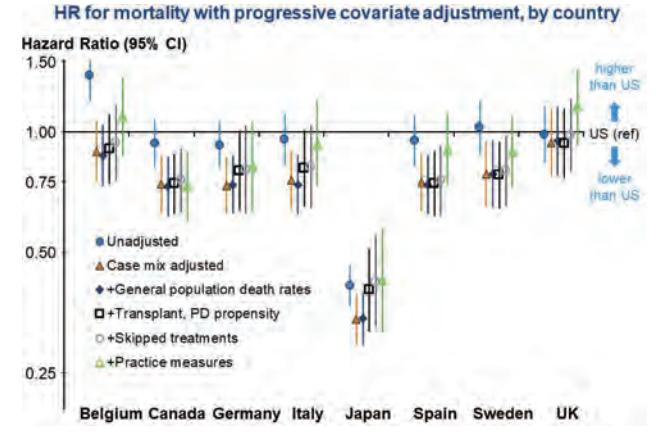
Background: Case-mix-adjusted mortality rate among hemodialysis patients has been higher in the US than in Europe or Japan, although this gap has been shrinking. Patient population and clinical practices have changed over time. We are evaluating the effects of case mix, practice patterns, and country factors on mortality rates across countries.

Methods: In DOPPS phase 5 data (2012-15) from hemodialysis facilities in Europe, Japan, and North America, Cox models with cumulative covariate adjustment were fitted to estimate adjusted hazard ratios (HR) for death. Case-mix-based propensities for transplantation or change to peritoneal dialysis (PD) were generated using models based on data from the previous DOPPS phase, while within-country general population all-cause and kidney-related death rates were based on WHO data.

Results: The unadjusted death rate in the US was generally comparable to that of many European countries (figure). Adjustment for case mix, especially age and race, results in lower hazard ratios for most European countries compared to the US, while adjustment for skipped treatments and selected practice measures (fistula use, phosphorous levels <6 mg/dl, intra-dialytic weight gain <5.7% of body weight) increased the hazard ratios for these European countries compared to the US, although most were still somewhat below that of the US. Japan Canada had consistently lower adjusted mortality than the US.

Conclusions: Unadjusted mortality in the US is comparable to that of European countries. Case-mix adjustment yields lower hazard ratios in most countries compared to US, indicating outcomes are still worse in US. Adjustment for practice measures substantially attenuates this effect in some countries, indicating that these factors may provide a means for the US to improve its outcomes. Japan has lower mortality in DOPPS data than any other country; this is not explained by any adjustment explored thus far.

Funding: NIDDK Support, Commercial Support - The DOPPS Program is supported by Amgen, Kyowa Hakko Kirin, Baxter Healthcare. Additional support for specific projects and countries is provided by AstraZeneca, European Renal Association-European Dialysis & Transplant Association (ERA-EDTA), Fresenius Medical Care Asia-Pacific Ltd, Fresenius Medical Care Canada Ltd, German Society of Nephrology (DGfN), Janssen, Japanese Society for Peritoneal Dialysis (JSPD), Keryx, Kidney Care UK, MEDICE Arzneimittel Pütter GmbH & Co KG, Proteon, and Vifor Fresenius Medical Care Renal Pharma. Public funding and support is provided for specific DOPPS projects, ancillary studies, or affiliated research projects by National Health & Medical Research Council (NHMRC) in Australia, Cancer Care Ontario (CCO) through the Ontario Renal Network (ORN) in Canada, French National Institute of Health and Medical Research (INSERM) in France, Thailand Research Foundation (TRF), Chulalongkorn University Matching Fund, King Chulalongkorn Memorial Hospital Matching Fund, and the National Research Council of Thailand (NRCT) in Thailand, National Institute for Health Research (NIHR) via the Comprehensive Clinical Research Network (CCRN) in the United Kingdom, and National Institutes of Health (NIH) in the US. All support is provided without restrictions on publications. All grants are made to Arbor Research Collaborative for Health and not to Mr. McCullough directly., Private Foundation Support, Government Support - Non-U.S.



TH-OR093

The Comparative Cardiac Safety of Selective Serotonin Reuptake Inhibitors (SSRIs) in the Hemodialysis (HD) Population

Magdalene M. Assimon, Jennifer E. Flythe. *University of North Carolina Kidney Center, Chapel Hill, NC.*

Background: HD patients may be particularly susceptible to the lethal consequences of drug-induced QT prolongation due to their tremendous cardiovascular disease burden and recurrent exposure to electrolyte shifts during HD treatments. Electrophysiologic data indicate that citalopram and escitalopram prolong the QT interval more than other SSRIs. Even though 37% of HD patients receive SSRI therapy, the relative cardiac safety of individual SSRIs in this vulnerable population is not well-established.

Methods: Data were taken from a cohort of Medicare-enrolled HD patients in the United States Renal Data System registry (2007–2014). Using a new-user design, we conducted a retrospective cohort study to assess the comparative 1-year risk of sudden cardiac death between HD patients initiating SSRIs with higher (citalopram, escitalopram) vs. lower (fluoxetine, fluvoxamine, paroxetine, sertraline) QT prolonging potential. We used propensity-score weighted survival models, adjusted for numerous demographic and clinical covariates, to estimate adjusted hazard ratios (aHRs) and their 95% confidence intervals (CIs). All analyses used an on-treatment analytic approach and treated non-sudden cardiac death as a competing event.

Results: Of 65,654 study patients, 30,932 (47.1%) started an SSRI with higher QT prolonging potential and 34,722 (52.9%) started an SSRI with lower QT prolonging potential. Initiation of an SSRI with higher (vs. lower) QT prolonging potential was associated with an increased 1-year risk of sudden cardiac death, aHR [95% CI] = 1.14 [1.05–1.25]. Observed associations were particularly elevated among females (1.21 [1.07–1.37]); individuals ≥75 years old (1.14 [1.01–1.28]); individuals with structural heart disease (1.13 [1.03–1.23]); and those concurrently using other QT prolonging medications (1.16 [1.04–1.29]). Sensitivity analyses 1) evaluating a composite outcome of sudden cardiac death *or* new-onset ventricular arrythmia, and 2) using an intent-to-treat analytic approach yielded similar results (not shown).

Conclusions: Initiation of an SSRI with higher (vs. lower) QT prolonging potential was associated with an increased risk of sudden cardiac death. When prescribing SSRIs to HD patients, providers should consider the QT prolonging potential of these agents, especially among individuals with sudden cardiac death risk factors.

TH-OR094

Association of Ultrafiltration Rate and Decline in Residual Kidney Function among Thrice-Weekly Hemodialysis Patients

Yuji Lee,[1] Yusuke Okuda,[1] Yoshitsugu Obi,[1] Jason A. Chou,[1] Elani Streja,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh,[1] Connie Rhee.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: The association between ultrafiltration rate (UFR) and decline in residual kidney function (RKF) has not been well examined in conventional hemodialysis (HD) patients with RKF.

Methods: We retrospectively reviewed a cohort of 7,753 patients who initiated thrice-weekly HD from 2007 to 2011, had available UFR and renal urea clearance (KRU) data at baseline, and had KRU data at 1 year after HD initiation. Patients were categorized into 4 UFR groups (<6, 6 to <10, 10 to <13, and ≥13 mL/h/kg). We defined rapid decline in RKF as a decline in KRU of more than 20% per year. We explored the association between UFR and rapid decline in RKF using logistic regression models with adjustments for case-mix variables, baseline RKF, and maximal change of blood pressure during dialysis.

Results: Mean ± SD UFR level was 7.0 ± 3.1 mL/h/kg. Median (interquartile range) baseline KRU was 3.5 (2.1 – 5.3) mL/min/1.72m^2. Mean annual changes of KRU were -1.1, -1.2, -1.4, and -1.6 mL/min/1.73m^2 in UFR <6, 6 to <10, 10 to <13, and ≥13 mL/h/kg groups, respectively (P = 0.004). In a cubic spline model, higher UFR was associated with increased risk for rapid decline in KRU [figure 1A]. Additionally, we found a graded association between categorized UFR and rapid decline of RKF in the fully adjusted multivariable regression models: odds ratios (95% confidence intervals) were 0.80 (0.72-0.88), 1.33 (1.14-1.57), and 1.39 (1.08-1.80) in UFR <6, 10 to <13, and ≥13 mL/h/kg groups, respectively (reference: UFR 6 to <10 mL/h/kg) [figure 1B].

Conclusions: In incident thrice-weekly HD, higher UFR was associated with rapid decline in RKF. Strategies to avoid high UFR may be useful for RKF preservation in incident HD patients.

TH-OR095

Opioid and Benzodiazepines Use in Patients on Hemodialysis

Rupam Ruchi, Shahab Bozorgmehri, Tezcan Ozrazgat-baslanti, Mark S. Segal, Sanjeev Kumar. *University of Florida, Gainesville, FL.*

Background: Opioid & Concomitant use of benzodiazepines is a public health problem. Little is known about opioids and benzodiazepine prescription in HD patients

Methods: This is retrospective study of USRDS data on ESRD patients ≥18 yrs, on HD, enrolled in Medicare & part D between 2006-2012, excluding those on PD & malignancy. We used ESRD Medicare Prescription Drug Events dataset for narcotics & benzodiazepines. We categorized narcotics into three safety classes per literature (safe, use

caution, unsafe) and analyzed their prescription pattern. We used hospitalization dataset to identify hospitalization with opioid overdose using ICD-9 CM codes, total LOS and ICU LOS

Results: Out of 2,657,352 patients, 643,859 were included, & divided into opioid (n=480,460, 74.6%) and non-opioid group. The biggest difference b/w 2 groups is in the use of benzos (30% in opioid vs 11% in non-opioid P<0.001). There is significant association between opioid & benzo use (OR = 3.27, P<0.001). 6,665,906 narcotic prescriptions were written averaging 13.8 prescriptions/patient. 52.2% patients were prescribed narcotics/year. Each patient got an average of 8 prescriptions/year. 30% of patients who got a prescription for opioid, also got a prescription for a benzo. 56.5% received prescriptions for both within a week of each other. Adverse events (A/E): 2225 patients with narcotic prescription (0.46%) had 3231 admissions with opioid overdose. 4 died. Median LOS is 4d, median ICU LOS is 2d. Benzo use prior to hospitalization was significantly higher in patients admitted for narcotic overdose as compared to others (40% vs 24%, p <0.001). Association between opioid class and A/E: Among the "safe" drugs, fentanyl & hydromorphone were associated with moderately high odds of hospitalization within 30 days (OR 3 and 2.4 respectively). This persisted at 60 & 90 days with fentanyl but decreased with hydromorphone at 90 days (1.6). Methadone was associated with a very high risk of hospitalization at 30 days (OR 5.9), that persisted at 60 & 90 days. Among the drugs to be used with caution hydrocodone had the least OR among all the drugs (1.8, 1.7 and 1.6 at 30, 60 and 90d). Oxycodone was moderate risk and oxymorphone (Opana) was high risk.

Conclusions: opioid and benzodiazpeine prescription in HD patients is very high. Drug safety based on pharmacokinetic profile in dialysis does not translate to clinical safety.

TH-OR096

Prevalence, Indications, and Risks of Muscle Relaxant Use among Hemodialysis Patients

Diana Mina, Kirsten L. Johansen, Charles E. McCulloch, Michael Steinman, Barbara A. Grimes, Julie H. Ishida. *UCSF, San Francisco, CA.*

Background: Muscle relaxants are used to treat musculoskeletal pain and cramping, which are commonly experienced symptoms among hemodialysis patients. However, epidemiologic data characterizing the prevalence, indications, and risks of muscle relaxant use in this population are lacking.

Methods: From the USRDS, we identified 140,899 adults receiving in-center hemodialysis with Medicare Part D in 2011. We determined the prevalence of muscle relaxant use and the presence of a relevant indication, defined by ICD-9 codes, within 60 days preceding the date of a prescription by examining Medicare claims data. Using Cox regression models, we investigated the association between receipt of muscle relaxants (e.g., cyclobenzaprine, baclofen), modeled as a time-varying exposure, and time to first emergency room visit or hospitalization for altered mental status (AMS), fall, and fracture defined by ICD-9 and CPT codes. We adjusted for demographics, comorbidities, duration of muscle relaxant exposure, number of medications, and concomitant medications. Exposure was time-lagged (i.e., ascertained from the prior day) for fall and fracture in order to account for possible effect/cause.

Results: Ten percent (14,312) of the cohort received muscle relaxants, and 17% (24,067) had an episode of AMS, fall, or fracture in 2011. The most common diagnoses associated with muscle relaxant use were musculoskeletal pain other than neck or back pain (72%), back pain (48%), and muscle spasticity (25%). Fourteen percent of patients with a muscle relaxant prescription lacked a relevant indication. Muscle relaxant use was significantly associated with AMS, fall, and fracture (**Table**).

Conclusions: Muscle relaxants are commonly used by hemodialysis patients. They were most frequently prescribed for musculoskeletal pain and spasticity, but a sizeable proportion of patients lacked a clear indication based on claims data. Muscle relaxants are associated with a high risk for AMS, fall, and fracture. Future research to define the appropriate use of these agents in this population is warranted.

Funding: NIDDK Support

Risk of Adverse Outcomes Associated with Muscle Relaxant Use

	Hazard Ratio (95% Confidence Interval)		
	AMS	Fall	Fracture
None	1.00 (ref)	1.00 (ref)	1.00 (ref)
Muscle Relaxant	1.68 (1.53–1.84)	1.29 (1.11–1.49)	1.30 (1.05–1.61)

Temporal Trend of the Provision of Palliative Care Encounter in Hospitalized Patients with ESRD: A Nationwide Analysis

Yumeng Wen,[1,2] Marcelo X. Hernandez Cuchillas,[1,2] David Mariuma,[1,2] Changchuan Jiang,[1,2] Di Pan.[1,2] *[1]Department of Medicine, Mount Sinai St. Luke's and Mount Sinai West, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: End stage renal disease (ESRD) is major cause of worldwide mortality and morbidity. We sought to investigate the temporal trend of the utilization of palliative care (PC) in hospitalized patients with ESRD in United States.

Methods: We conducted a retrospective study using the national inpatient sample to identify patients with ESRD admitted to hospitals from 2006 to 2014. We sought to determine the temporal trend and factors associated with utilizing palliative care in hospital. Multivariate logistic analysis was performed to calculate odds ratios, adjusting for demographics, hospital characteristics, comorbidities and code status. Analysis was performed using Stata 14.0.

Results: A cohort of 6,280,637 patients was identified from 2006 to 2014, of whom 1.65% had a PC consult referral. The incidence of PC contact increased from 0.39% in 2006 to 2.98% in 2014 (aOR 1.11, p<0.01). Patients who received PC contact, compared to who did not, were older (68.79 vs 64.28, p<0.01), had longer hospital stay (8.37 vs. 6.20 days, p<0.01) and were more likely to die in hospital (49.40% vs. 4.04%, p<0.01). Factors associated with more frequent PC referral included more cormobidities, Caucasian race (compared to minorities), teaching hospitals, larger hospitals, hospitals region other than Northeastern area, household income, medicaid or private insurance, and do not resuscitate (DNR) status (shown in Table 1).

Conclusions: The use of palliative care consultation for patients with ESRD who are admitted to hospitals is approximately 1.65%. Race, socioeconomic status, hospital size, region and teaching status all were associated with differential rates of referral. There was a significant increase in palliative care use observed from 2006 to 2014.

The Impact of the IDEAL Trial on Early Initiation of Dialysis

Thomas W. Ferguson,[1] Amit X. Garg,[2] Manish M. Sood,[3] Paul Komenda,[4] Ahsan Alam,[5] Navdeep Tangri,[1] Claudio Rigatto,[6] David M. Naimark,[7] Monica C. Beaulieu,[8] Braden J. Manns,[9] Joseph Kim.[10] *[1]Seven Oaks General Hospital, Winnipeg, MB, Canada; [2]London Health Sciences Centre, London, ON, Canada; [3]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [4]University of Manitoba, Winnipeg, MB, Canada; [5]McGill University Health Centre, Montreal, QC, Canada; [6]Chronic Disease Innovation Centre, Winnipeg, MB, Canada; [7]Sunnybrook Health Science Centre, Toronto, ON, Canada; [8]University of British Columbia, North Vancouver, BC, Canada; [9]Foothills Medical Center, Calgary, AB, Canada; [10]Toronto General Hospital, University Health Network, Toronto, ON, Canada.*

Background: In August 2010, the Initiating Dialysis Early and Late (IDEAL) trial was published and randomized patients with pre-dialysis CKD to planned initiation of dialysis in the eGFR range of 10 to 14 ml/min/1.73m^2 (early start) vs. 5 to 7 ml/min/1.73m^2 (late start). It concluded that earlier initiation was not associated with improved survival or clinical outcomes. The degree by which this information was disseminated and applied in practice is unknown. We aimed to determine the impact of the IDEAL trial on the proportion of patients who initiate dialysis early (eGFR > 10.5 ml/min/1.73m^2).

Methods: A segemented regression analysis was performed including all incident adult dialysis patients from the Canadian Organ Replacement Register (CORR) with at least 90 days of nephrologist care before starting dialysis with a recorded eGFR at dialysis initiation. The primary outcome was the change in the proportion of early dialysis starts (eGFR at initiation > 10.5 ml/min/1.73m^2). Secondary outcomes included the change in the proportion of acute inpatient dialysis initiations, the proportion of patients who received home dialysis as initial therapy, and the proportion of hemodialysis patients who started dialysis with an arteriovenous (AV) fistula.

Results: Following the IDEAL trial we observed an immediate decline in the proportion of early dialysis starts of 4.49% (95% confidence interval 1.24 to 7.74; p = 0.0080), and there was a significant decrease from the pre-trial annual slope of 2.76% (1.68 to 3.84; p = < 0.001), resulting in an annual decrease of 1.44% (0.84 to 2.16; p < 0.001) in the post-trial period. Acute inpatient dialysis initiations increased immediately following the publication by 2.86% (0.10 – 5.62; p = 0.0440), however there was no sustained change. The proportion of patients who received home dialysis as initial therapy and the proportion who initiated hemodialysis with an AV fistula did not have immediate or sustained differences.

Conclusions: The IDEAL trial had a strong and sustained impact on the timing of dialysis initiation in Canada. These changes were accompanied by no sustained effects on home dialysis as initial therapy, AV fistula construction, or acute inpatient dialysis initiation

Impact of Rescheduling a Missed Hemodialysis Treatment on Clinical Outcomes

Dena E. Cohen,[1,2] Kathryn S. Gray,[1,2] Carey Colson,[1,2] David B. Van Wyck,[2] Francesca Tentori,[1,2] Steven M. Brunelli.[1,2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]DaVita Institute for Patient Safety, Denver, CO.*

Background: Among patients treated with hemodialysis (HD), a missed treatment is associated with elevated hospitalization risk in the subsequent 30 days. It is not known whether attending a rescheduled treatment on the following day ameliorates this risk.

Methods: This retrospective study used electronic health records and 2014 USRDS claims merged via direct linkage. Eligible patients were adults receiving HD on a Monday/Wednesday/Friday schedule who, as of index, had dialysis vintage ≥90 days, available Medicare A & B claims, and had not missed a treatment for any reason in the 30 days prior to index. For each of 12 index dates, patients were classified based on attending treatment; those who did not were classified as "rescheduled" or "missed" based on whether or not they dialyzed the following day. In separate analyses, "rescheduled" and "missed" patients were each matched (1:5) to patients who attended based on index day of week and propensity score. Hospitalization was considered over the subsequent 7 and 30 days, or until censoring, and compared using generalized linear models.

Results: Prior to matching, patients who missed or rescheduled treatment were of younger age and dialysis vintage than those who attended. All characteristics were balanced after matching. Compared to attending (N=20,725), a missed treatment (N=4145) was associated with a 100% higher rate of hospitalization in the subsequent 7 days, and a 39% higher rate over 30 days. Attending a rescheduled treatment on the day after a missed treatment (N=2308) was associated with a 49% higher rate of hospitalization in the subsequent 7 days, and a 31% higher rate over 30 days, versus attending (N=11,540).

Conclusions: Rescheduling treatment attenuated but did not fully mitigate the hospitalization risk imposed by a missed treatment.

Association of Baseline eGFR and AKI-D with Early Mortality after ESRD

Raymond K. Hsu, Anna Rubinsky, Michael Shlipak, Carmen A. Peralta, Benjamin J. Lee, Chi-yuan Hsu. *UCSF & SF VA Medical Center, San Francisco, CA.*

Background: Abrupt decline in kidney function and non-recovery of dialysis-requiring AKI (AKI-D) have both been shown to be associated with adverse outcomes in patients with incident ESRD. We hypothesized that distinct patterns of transition to ESRD based on both the mean 1-year baseline eGFR and presence of AKI-D preceding ESRD would help prognosticate 90-day mortality after hemodialysis (HD) initiation.

Methods: We identified a national cohort of Veterans who initiated maintenance HD in 2009-2013 and had outpatient creatine (Cr) measured within 1 year prior to ESRD. Patients were categorized based on A) mean outpatient eGFR within 1 year prior to incident ESRD (≥ or < 30); and B) occurrence of in-hospital AKI-D leading to ESRD. AKI-D was defined using KDIGO criteria of [≥0.3mg/dL rise and/or ≥50% rise in Cr from mean 1-year baseline], *and* inpatient dialysis. The association between patterns of transition and all-cause mortality within 90 days after HD initiation were examined using multivariable Cox models.

Results: Patients with incident ESRD (N=22,815) were 69±11 years old, 98% male, 27% black, and 68% diabetic. 4114 (18%) had mean 1-year outpatient eGFR≥30; 2644 (12%) experienced AKI-D with peak inpatient Cr rise was ≥50% from baseline. Relative to refence group of mean outpatient eGFR<30 and no AKI-D, patients with mean outpatient eGFR≥30 had ~2-fold adjusted risk of 90-day mortality, regardless of presence/absence of AKI-D (Table1). Among patients with mean eGFR<30, those with AKI-D and ≥50% rise in Cr had a small increase in mortality, whereas those with AKI-D and smaller peak Cr (<50% but ≥0.3mg/dl rise) had lower 90-day adjusted mortality.

Conclusions: Nearly 1 in 5 incident ESRD patients had a mean outpatient eGFR≥30 within the 1 year prior to HD initiation. This pattern of abrupt transition to ESRD was strongly associated with early mortality regardless of whether or not AKI-D directly preceded ESRD.

Funding: NIDDK Support

Pattern of Transition	[Death in first 90 days after ESRD] / [Total N] = crude death rate	Unadjusted Hazard Ratio	Fully Adjusted Hazard Ratio**
eGFR<30*, no AKI-D	1229 / 15,484 = 7.9%	Reference	Reference
eGFR<30*, + AKI-D with peak Cr <50% from baseline	39 / 1076 = 3.6%	0.45 (0.32-0.61)	0.62 (0.45-0.86)
eGFR<30*, + AKI-D with peak Cr ≥50% from baseline	170 / 2141 = 7.9%	1.00 (0.85-1.17)	1.31 (1.11-1.55)
eGFR≥30*, no AKI-D	655 / 3611 = 18.1%	2.41 (2.19-2.65)	1.94 (1.75-2.15)
eGFR≥30*, + AKI-D with peak Cr ≥50% from baseline	82 / 503 = 16.3%	2.14 (1.71-2.68)	2.09 (1.66-2.62)

*refers to mean outpatient eGFR within 1 year prior to ESRD. **adjusted for demographics, co-morbidities, and pre-ESRD nephrology care.

TH-OR101

Anti-MicroRNA Screen Uncovers miR-17 Family within miR-17~92 Cluster as the Primary Driver of Kidney Cyst Growth

Matanel Yheskel,[1,2] Ronak Lakhia,[1] Vishal Patel.[1] *[1]University of Texas Southwestern Medical Center, Dallas, TX; [2]MD/PhD (MSTP) training program, Albert Einstein College of Medicine, Bronx, NY.*

Background: We have recently shown that inhibiting miR-17~92 is a potential novel therapeutic approach for autosomal dominant polycystic kidney disease (ADPKD). However, miR-17~92 is a polycistronic cluster that encodes microRNAs (miRNAs) belonging to the miR-17, miR-18, miR-19 and miR-25 families. The relative pathogenic contribution of these miRNA families to ADPKD progression is unknown.

Methods: We performed an *in vivo* anti-miR screen to identify drug targets within the miR-17~92 miRNA cluster. Locked nucleic acid-modified anti-miRs (12 to 16 nucleotides) were used to selectively inhibit either the miR-17, miR-18, miR-19, or miR-25 family in an orthologous model of ADPKD. miRNAs belonging to one family harbor identical seed sequence but there are minor differences in flanking nucleotides. To simultaneously inhibit all members of one family, anti-miRs were designed to Watson-Crick base pair with the majority but not the entire length of cognate mature miRNA sequence. Mice were randomly assigned to receive either 20 mg/kg of anti-miR-17, anti-miR-18, anti-miR-19, or anti-miR-25 family inhibitors, or vehicle at postnatal days (P) 10-12 and 15, and were sacrificed at P18 to assess cyst burden.

Results: Q-PCR analysis showed that anti-miRs specifically inhibit the cognate miRNA family members without affecting the expression of unrelated miRNAs. Treatment with anti-miRs against the miR-17 family reduced cyst proliferation, kidney-weight-to-body-weight ratio, and cyst index. In contrast, treatment with anti-miRs against the miR-18, 19, or 25 families did not affect cyst growth. RNA-seq analysis showed that anti-miR-17 treatment recapitulated the gene expression pattern observed after miR-17~92 genetic deletion. Additional analysis revealed that anti-miR-17 treatment was associated with upregulation of mitochondrial metabolism, suppression of the mTOR pathway, induction of autophagy, and reduction of cyst-associated inflammation (M2-like macrophages).

Conclusions: Our results argue against functional cooperation between the various miR-17~92 cluster families in promoting cyst growth and instead point to miR-17 family as the primary pathogenic component and therapeutic target for ADPKD. This new information is vital because it guides the substantial on-going drug development efforts aimed at targeting the miR-17~92 cluster for the treatment of human ADPKD.

Kidney Organoids without Cilia Establish a Human Model of Ciliopathy-Associated Polycystic Kidney Disease

Nelly M. Cruz,[1] Jonathan Himmelfarb,[2] Benjamin S. Freedman.[1] [1]*University of Washington, Seattle, WA;* [2]*Kidney Research Institute, Seattle, WA.*

Background: Primary cilia are specialized, antenna-like organelles at the plasma membrane associated with a spectrum of human syndromes called ciliopathies. Phenotypes of polycystic kidney disease (PKD) are commonly associated with ciliopathies, but how cilia function to prevent kidney cysts remains poorly understood. A major barrier to understanding ciliary function is the absence of cellular models that accurately reconstitute the complex human phenotypes of ciliopathies.

Methods: We used the CRISPR-Cas9 genome editing system to introduce mutations in two genes that are required for ciliogenesis, kinesin family member 3A (*KIF3A*) and *KIF3B*, in human pluripotent stem cells (hPSC). Genome modified *KIF3A*$^{-/-}$ or *KIF3B*$^{-/-}$ hPSC were differentiated *in vitro* into kidney organoids containing proximal tubules, distal tubules, and podocytes in nephron-like segments. Structure and composition of organoids were analyzed by immunofluorescence. To determine the mechanistic consequences of ciliary loss, a biochemical assay was used to measure ciliopathy-linked protein levels in both whole cell lysates and extracellular vesicles.

Results: We isolated four independent cell lines with indel mutations in the *KIF3A* gene and three cell lines with indels in *KIF3B*. Immunoblots confirmed that no full-length protein is produced in these mutants. The gene-edited hPSC completely lacked cilia, while ~50% of cells were ciliated in the isogenic controls. Importantly, the absence of cilia did not alter hPSC growth, pluripotency, self-renewal, or their ability to differentiate into kidney organoids. Upon differentiation, however, the cilia-deficient kidney organoids formed large cysts from tubular epithelial cells, which were absent in controls. Defects were furthermore observed in the expression of the disease-associated proteins polycystin-1 and polycystin-2 in kinesin mutants.

Conclusions: Genome modified *KIF3A*$^{-/-}$ or *KIF3B*$^{-/-}$ hPSC establish a general tool for studying the function of human cilia in diverse cell types and organoids. Our findings directly link the loss of ciliary kinesins to polycystin expression defects and kidney cyst formation in human cells. Using this new tool, it is now possible to perform phenotypic screens and mechanistic studies to reveal the functions of human cilia and test interventional strategies for ciliopathy syndromes.

Polycystin Signaling: Control of Tubule Cell Shape by Actomyosin-Dependent Apical Constriction

Alexis Hofherr,[3] Claudia Seger,[3] Eryn E. Dixon,[2] Samuel L. Svendsen,[1] Owen M. Woodward,[2] Jens G. Leipziger,[1] Michael Kottgen.[3] [1]*Aarhus University, Aarhus C, Denmark;* [2]*University of Maryland School of Medicine, Baltimore, MD;* [3]*Medical Center – University of Freiburg, Freiburg im Breisgau, Germany.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common monogenic cause of end-stage renal disease affecting approximately 1 in 500 adults. Mutations in two genes cause ADPKD. *Polycystic kidney disease 1* (*PKD1*) accounts for 85 % of patients and *PKD2* accounts for the remaining 15 % of patients. Elegant experiments in model organisms have uncovered that the respective proteins, Polycystin-1 (PC1) and transient receptor potential ion channel Polycystin-2 (TRPP2), form a receptor-ion channel complex which is essential for renal morphogenesis and maintenance. The molecular components, however, connecting the two ADPKD proteins to these processes have remained elusive. Or more specifically, the intracellular effectors translating PC1/TRPP2 receptor-ion channel activity into three-dimensional tissue organization connecting genetics, cellular output, and tissue mechanics are unknown.

Methods: We have addressed this issue for the kidney with an unbiased high-resolution mass spectrometry-based screen for TRPP2-binding proteins in polarized renal epithelial cells followed by targeted analyses of PC1/TRPP2 function *in vitro* and *in vivo*. *In vitro* analyses of PC1/TRPP2 and candidate proteins were performed using CRISPR/Cas- and TALEN-based gene-specific knock-out and knock-in Madin-Darby canine kidney (MDCK) cell models. Wild-type and mutant zebrafish, mice, and human samples were used to validate results *in vivo*.

Results: Here we identify an apical junction associated multi protein signaling complex as functional PC1/TRPP2 effector and show: 1) how the PC1/TRPP2 complex controls cellular shape by actomyosin-dependent apical constriction; 2) that this cellular contraction translates on a tissue-scale into a coordinated fine-tuning of renal tubular diameter *in vivo*; and 3) that in human ADPKD kidneys, tubular shape is lost, because of impaired signal integration disconnecting mutant cells from their healthy surroundings.

Conclusions: ADPKD is a prime example for a disease affecting renal morphogenesis and maintenance. We anticipate that our detailed characterization of the various levels of polycystin-dependent renal tubular cell shape control may help to elucidate the complex cellular machinery integrating genetic, cellular, and mechanical inputs in health and renal disease.

Role of the Mechanosensitive Ion Channel Piezo1 in Autosomal Dominant Polycystic Kidney Disease

Fouad T. Chebib,[1] Maria V. Irazabal,[2] Vicente E. Torres.[1] [1]*Mayo Clinic, Rochester, MN;* [2]*Mayo Clinic, Rochester, MN.*

Background: Disruption of intracellular calcium (iCa^{2+}) likely underlies the upregulation of cAMP signaling and the proliferative and secretory phenotype of the cystic epithelium in ADPKD. However, the mechanisms by which polycystins reduce iCa^{2+} remain elusive. Impaired flow-induced Ca^{2+} entry through ciliary polycystin complex has been previously proposed as a pathogenic mechanism, but newer evidence suggests the involvement of polycystins in modulation of other mechanosensitive ion channels such as Piezo1, the novel stretch-activated cation channel. We hypothesized that polycystins, through their physical and functional interaction with Piezo1, modulate various cellular responses to mechanical stimulation.

Methods: Wild type inner medullary collecting duct cells (mIMCD3) were stably transfected with genetically encoded biosensors, jRGeco1a and Flamindo2, to study spatiotemporal dynamics of Ca^{2+} and cAMP during live cell imaging, respectively. These cells were also cultured in 3D matrigel matrix. Metanephric embryonic kindeys were cultured and stimualted with forskolin.

Results: Piezo1 is expressed in both WT mIMCD3 cells and PKD_2 null cells (~3 fold higher than wild type). Piezo1 activation by Yoda1 increased cytoplasmic calcium and simultaneously lowered forskolin-induced cAMP (Figure 1A). Additionally, exerting physiological fluid shear stress (FSS) (ibidi pump system) led to reduction in cAMP (Figure 1B). Yoda1 significantly reduced forskolin-induced *in vitro* cystogenesis by 68% in WT and by 48% in PKD_2 null mIMCD3 cells (Figure1C). Low dose Yoda1 (750nM) prevented cyst formation in forskolin-induced cystogenesis of metanephric organ culture (Figure1D).

Conclusions: Piezo1 activation inhibits cystogenesis in matrigel matrices and metanephric organ cultures. Further studies are required to determine *in vivo* effect of Piezo1 on renal cystogenesis.

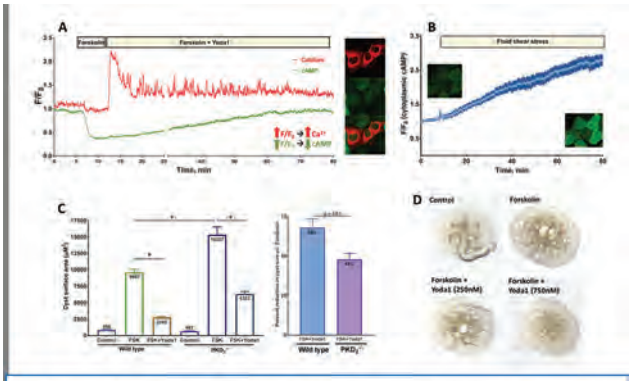

Figure 1: Effect of Piezo1 and fluid shear stress on calcium, cAMP, and cystogenesis. A) Forskolin increased cAMP levels (F/F0 decreased indicating increase in cAMP level). Treatment of cells with both forskolin and Yoda1 led to an increase in cytoplasmic calcium and simultaneously decreased cAMP back to baseline. **B)** FSS gradually decreases cAMP level (Light blue trace is mean F/F0 and dark blue is SD, n=8). **C)** mIMCD3 cells were grown in 3D matrigel and incubated with defined medium (control) +/- forskolin (10uM) and Yoda1 (10uM) for 5 days. Yoda1 reduced forskolin-induced cyst size by 68% in WT and by 48% in PKD2 null cells compared to forskolin alone. D) Yoda1 prevented forskolin-induced cyst formation at a dose of 750 nM.

TH-OR105

Enhanced Protein Folding via XBP1 Activation Ameliorates ADPKD Due to PC1 Misfolding

Matteus Krappitz,[5] Tobias Staudner,[4] Parisa Westergerling,[4] Till A. Hollmann,[2] David R. Rümmele,[3] Charlotte E. Roosendaal,[5] Bruno Eduardo Pedroso Balbo,[6] Rachel Gallagher,[1] Stefan Somlo,[5] Sorin V. Fedeles.[1] [1]*Yale University School of Medicine, New Haven, CT;* [2]*Yale School of Medicine, New Haven, CT;* [3]*Yale university, New Haven, CT;* [4]*Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany;* [5]*Yale University, New Haven, CT;* [6]*Yale University, New Haven, CT.*

Background: *Pkd1* is one of the two genes responsible for autosomal dominant polycystic kidney disease (ADPKD). In ADPKD, ~30% of mutations are missense predicted to result in reduced PC1 function. *XBP1* encodes the main chaperone modulator of the ER unfolded protein response. Here we investigated the role of XBP1 as a "genetic" chaperone therapy which may affect the levels of functional PC1 carrying patient derived missense mutations using the p.R2220W human REJ mutant (p.R2216W in mouse) as a representative candidate.

Methods: The effect of XBP1 on the expression and trafficking of the PC1-R2220W-V5 mutant was determined *in vitro*. A *Pkd1*^{R2216W} knock-in mouse model was generated. Using this backbone, *Pkd1*$^{R2216W/fl}$*;Pkhd1-Cre* and *Pkd1*$^{R2216W/fl}$*;Pkhd1-Cre;XBP1-Rosa-floxstop-TG* mice were examined by morphological, functional and biochemical analyses.

Results: Expression of XBP1 in transiently cells expressing PC1-R2220W-V5 leads to increased expression and GPS cleavage of the mutant protein. Ciliary trafficking of PC1-R2220W was markedly improved by co-expression of XBP1 as compared with PC1-

R2220W alone. At P16, *Pkd1$^{R2216W/fl}$;Pkhd1-Cre* mice developed cystic disease compared with *Pkd1$^{R2220W/+}$* animals as seen via a significant increase in renal parameters [KW/BW, 0.01±0.001 vs. 0.13±0.008, ****p<0.0001; BUN, 33.35±4.44 vs. 102.2±26.4, **p=0.0042; n=10, 7]. Expression of the conditional XBP1 transgene in *Pkd1$^{R2216W/fl}$;XBP1-TG;Pkhd1-Cre* mice at P16 led to a significant decrease in the cystic burden compared to the controls [KW/BW, 0.07±0.006 vs. 0.13±0.008, ****p<0.0001; BUN 50.57±8.47 vs. 102.2±26.49, *p=0.027, n=10, 7]. Using TUNEL and Ki67 assays we found that induction of XBP1 in the cyst lining cells led to a significant reduction in proliferation with no impact on apoptosis suggesting that the improved cystic phenotype in the *Pkd1$^{R2216W/fl}$;XBP1-TG;Pkhd1-Cre* animals is due to a reduction in cyst growth.

Conclusions: Our data raises the possibility that *in vivo* chaperone therapy for the treatment of ADPKD may have a beneficial role for a subset of PC1 missense mutations.

TH-OR106

Cystic Epithelial Cells Modify Their Microenvironment to Promote Fibrosis in Polycystic Kidney Disease

Nidhi Dwivedi, Sonali Sinha, Darren P. Wallace, James P. Calvet, Reena Rao. *University of Kansas Medical Center, Kansas City, KS.*

Background: Progressive tubulo-interstitial fibrosis accompanies cyst expansion in polycystic kidney disease (PKD) and is a major cause for loss of renal function and end stage renal disease. However, the mechanisms for development of renal fibrosis in PKD are currently unclear. A significant number of myofibroblasts, the primary producers of ECM, are often found in the pericystic areas in PKD kidneys. We tested the hypothesis that cystic epithelial cells can activate interstitial myofibroblasts and thus modify the cystic microenvironment to promote fibrosis.

Methods: Renal tubular epithelial-specific vasopressin type-2 receptors (V2R) were stimulated or inhibited in pre-weaning and adult inducible conditional Pkd1 gene knockout mice with cystic kidneys. Wild type and PKD mice were treated with the V2R agonist dDAVP, or the antagonist OPC31260 by daily intraperitoneal injections for 3 days.

Results: Treatment with dDAVP increased myofibroblast numbers and ECM deposition in PKD mouse kidneys, while OPC31260 had the opposite effect. Expression of connective tissue growth factor (CTGF), a matricellular protein, and its transcriptional regulator YAP were increased in the dDAVP treated PKD mouse kidneys. CTGF and YAP were expressed in mouse and human ADPKD renal cystic epithelium, and CTGF secreted by cultured human ADPKD epithelial cells induced myofibroblast activation and migration in vitro. In contrast, YAP inactivation by pharmacological inhibition or renal tubule specific gene deletion suppressed CTGF production and cyst expansion in vitro, and the development of fibrosis in Pkd1 knock out mice.

Conclusions: These results suggest that epithelial specific V2R stimulation can induce YAP dependent CTGF production to activate interstitial myofibroblasts and renal fibrosis in PKD.

TH-OR107

A Central Role of the Enzyme Asparagine Synthetase (ASNS) in Driving Glutamine Anaeplerosis in the Metabolic Rewiring of ADPKD

Christine Podrini,[1] Isaline Rowe,[1] Roberto Pagliarini,[1] Ana Sofia Henriques da Costa,[2] Marco Chiaravalli,[1] Hyunho Kim,[3,4] Feng Qian,[4] Christian Frezza,[2] Alessandra Boletta.[1] *[1]San Raffaele Scientific Institute, Milan, Italy; [2]MRC Cancer Unit, University of Cambridge, Cambridge, United Kingdom; [3]Center for Medical Innovation, Seoul National University Hospital, Seoul, Republic of Korea; [4]University of Maryland School of Medicine, Baltimore, MD.*

Background: We showed that the Warburg effect is a feature of PKD. However, additional pathways involved in the metabolic deregulation of ADPKD are likely present. Here, we explore global metabolomics and isotope tracing experiments to identify new targetable metabolic pathways in PKD.

Methods: 16 newborn (P4) kidneys of *Ksp-Cre;Pkd1$^{flox/-}$* mice and their respective littermate controls were collected. Metabolomics was performed with LC-mass spectrometry (MS). Tracing studies with ^{13}C-labeled carbons from glucose or glutamine were performed in *Pkd1*-mutant cells, using LC-MS.

Results: Metabolomics screen identified 488 significantly altered metabolites. PCA and HCA showed a clear separation between cystic and control samples. The alterations included glycolysis, fatty acid oxidation and biosynthesis, and massive TCA cycle. To test which energy source was fuelling the accumulation of TCA cycle metabolites, alternate labelling with [$^{13}C_6$] glucose or [$^{13}C_5$,$^{15}N_2$] glutamine was performed *in-vitro*. *Pkd1$^{-/-}$* cells had an enhanced glucose uptake, mostly used to produce lactate and minimally funneled into the TCA cycle. To compensate, *Pkd1$^{-/-}$* cells uptake more glutamine and use it both oxidatively and reductively in the TCA cycle to drive fatty acids biosynthesis. Following the fate of the $^{15}N_2$-glutamine, we found a significant increase of ^{15}N-labelled asparagine in *Pkd1$^{-/-}$* cells suggesting that they exhibit increase asparagine synthesis from glutamine. This reaction is catalyzed by Asparagine synthetase (ASNS). Indeed, *Asns* was upregulated in *Pkd1$^{-/-}$* cells and *KspCre;Pkd1* kidneys. Tracing with $^{15}N_2$ and $^{13}C_5$-glutamine showed that silencing of *Asns* reduced significantly the levels of labelled asparagine and glutamine-derived α-KG. Importantly, the down-regulation of *Asns* reduced growth in *Pkd1$^{-/-}$* cells, but not in controls. Combination with glucose starvation was lethal in *Pkd1$^{-/-}$* cells. Microarray analysis on *Pkd1* mutant kidneys (*Pkd1$^{V/V}$*) and human *PKD1* samples confirmed upregulation of ASNS and further validated the global metabolic perturbations observed.

Conclusions: Our data show that increased glutaminolysis, interlinked with asparagine metabolism is an important feature of PKD and targeting ASNS might offer a novel therapeutic opportunity.

TH-OR108

CD8+ T-Cells Regulate Progression of Autosomal Dominant Polycystic Kidney Disease

Logan C. Tyler,[1] Emily K. Kleczko,[1] Kenneth H. Marsh,[1] Darren P. Wallace,[2] Michel Chonchol,[1] Berenice Y. Gitomer,[1] Raphael A. Nemenoff,[1] Katharina Hopp.[1] *[1]University of Colorado Denver, AMC, Aurora, CO; [2]University of Kansas Medical Center, Kansas City, KS.*

Background: Therapeutic strategies to treat Autosomal Dominant Polycystic Kidney Disease (ADPKD) have largely focused on targeting abnormal renal epithelial cell signaling. In cancer, a disease with many parallels to ADPKD, modulating the activity of cells within the microenvironment, specifically CD8$^+$ T-cells, has shown remarkable therapeutic effects. However, the role of CD8$^+$ T-cells and their potential as a novel therapeutic target in ADPKD has not been well studied.

Methods: Using the murine ADPKD model *Pkd1* p.R3277C [RC], as well as stored human ADPKD/Autosomal Recessive PKD (ARPKD) kidney tissue, we explored the role of renal CD8$^+$ T-cells via flow cytometry, *in situ*/immunofluorescence (IF) imaging, qPCR, and pharmacological intervention.

Results: Using flow cytometry and IF, we previously showed that CD8$^+$ T-cells increase in numbers, become selectively activated, and localize to cystic regions in *Pkd1$^{RC/RC}$* vs. wildtype (WT) kidneys. Further, CD8$^+$ T-cell depletion worsened PKD pathology in *Pkd1$^{RC/RC}$* mice. By *in situ* hybridization we now show that *Pkd1$^{RC/RC}$* interstitial and cystic epithelial cells express higher levels of CD8$^+$ T-cell recruiting chemokines (*Cxcl9/Cxcl10*) vs. WT, implying active recruitment of CD8$^+$ T-cells to cystic lesions. We confirmed these findings in human ADPKD/ARPKD vs. healthy control kidneys and demonstrated *in vitro* that human *PKD1$^{-/-}$* renal epithelial cells have higher basal *CXCL9/10* levels, as well as a greater increase in response to IFNg vs. *PKD1$^{+/+}$* cells. To understand how CD8$^+$ T-cells may halt cyst progression, we performed TUNEL and PCNA staining in *Pkd1$^{RC/RC}$* anti-IgG and anti-CD8 treated animals. Mice depleted of CD8$^+$ T-cells had fewer apoptotic and more proliferating cystic epithelial cells vs. control, consistent with CD8$^+$ T-cell-mediated cytotoxicity and IFNg-induced reduction in proliferation.

Conclusions: These data indicate that CD8$^+$ T-cells are recruited specifically to cystic lesions via chemokine production by interstitial and cystic epithelial cells and halt ADPKD progression through modulating cyst expansion via apoptosis/proliferation. Hence, therapeutic strategies aimed at increasing CD8$^+$ T-cell numbers/activity may represent novel treatment approaches to slow ADPKD progression.

TH-OR109

CD4 T Cells Promote Cystic Kidney Disease

Kurt Zimmerman,[1] Cheng Song,[2] Michal Mrug,[1] Bradley K. Yoder.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Amgen & University of southern california, Los Angeles, CA.*

Background: The majority of renal cystic diseases are caused by mutations in proteins localized to the primary cilia or proteins required for cilia assembly. Previous data indicate that renal injury markedly accelerates cyst formation and that macrophage numbers are increased prior to and during cyst formation. Depletion of macrophages reduces renal cysts in multiple models of cystic kidney disease. These data led to the hypothesis that cilia and cilia-related proteins regulate innate immune response and cystic disease following renal injury. However, the involvement of adaptive immune cells in renal injury induced cystic disease remains unknown.

Methods: We set out to identify and define the contribution of adaptive immune cells, particularly CD4 T cells, in an ischemia reperfusion injured cilia mutant model of renal cyst formation and in human patients with autosomal dominant polycystic kidney disease (ADPKD).

Results: Our data show that CD4 T cell numbers are increased prior to the formation of renal cysts and are located in regions adjacent to cysts in conditional cilia mutant mice following injury. Further subtyping of CD4 T cells shows that IL-17A producing CD4 T cells (Th17 cells) are increased prior to the formation of renal cysts whereas T regulatory cells (Tregs) are increased during periods of rapid cyst progression. These data suggest that Th17 cells may contribute to the initial stages of cyst formation whereas Tregs may promote cyst expansion. In support of this idea, genetic deletion of adaptive immune cells (RAG1-/- mouse) or pharmacological depletion of CD4 T cells reduced renal cyst formation. These results are complemented by studies in ADPKD patients where we found an increased number of CD4 T cells in regions adjacent to developing cysts. In addition, our preliminary studies revealed the highest serum levels of IL-17A in young ADPKD patients (<30 yrs old) suggesting that, similar to the mouse model, the number of Th17 cells is also highest in early stages of ADPKD. In contrast, PKD patients with ESRD had increased numbers of Tregs, resembling our data obtained in the mouse. Finally, we point to urinary CD4 T cells as a predictor of renal function decline in ADPKD.

Conclusions: Our results suggest that CD4 T cells are an integral component of renal cystic disease and a candidate marker of the disease activity in ADPKD.

Bimodal Activation of Macrophages Promotes Proliferation Independent and Dependent Cyst Expansion in PKD

Vijayakumar R. Kakade,[1] Marcelo F. Cassini,[1] Stefan Somlo,[1] Lloyd G. Cantley.[2] *[1]Yale University, New Haven, CT; [2]Yale University School of Medicine, New Haven, CT.*

Background: Macrophages progressively accumulate adjacent to cyst lining cells in PKD. Macrophage chemoattractant protein-1 (Mcp1) is highly upregulated at the time of cyst initiation following knock-out of Pkd1, and dual deletion of *Mcp1* and *Pkd1* in renal tubules results in less renal macrophages, slower cyst growth, preserved GFR and better survival than deletion of *Pkd1* alone. The current study addresses the mechanisms by which the Mcp1-induced macrophages promote cyst growth.

Methods: Expression profiling was performed by qPCR using RNA from whole kidney and flow sorted macrophages. Multiphoton microscopy was used to analyze tubule morphology from doxycycline-treated *Mcp1$^{fl/fl}$Pkd1$^{fl/fl}$Pax8rtTA;TetOCre* mice (DKO) and *Pkd1$^{fl/fl}$Pax8rtTA;TetOCre* mice (SKO). Tubular cell responses were analyzed using Ki67, BrdU, comet assay and anti-8OHdG staining.

Results: Macrophages that accumulate at cyst initiation (8 weeks age, 2 weeks after doxy induction) express high levels of proinflammatory cytokines Tnfa, Nos2 and IL12, correlating with increased tubular cell injury as judged by Kim1 expression (SKO dCt 0.002 vs DKO dCt 0.0005, p=0.002) and oxidative DNA damage (14.4% 8OHdG$^+$ cells in SKO vs 3.6% in DKO, p=0.009). Analysis of tubular cell proliferation rates and tubule morphology in SKO and DKO kidneys during at cyst initiation shows that the macrophage-dependent component of cyst growth corresponds to decreased tubular epithelial area (tubular cell flattening consistent with injury) and enlarged tubule area (tubule/epithelial area ratio of 3.8±1.0 in SKO vs 1.04±0.02 in control and 1.4±0.5 in DKO p<0.0001) rather than proliferation. At the late cystic stage (18 weeks age), macrophages express high levels of the alternative activation genes Arg1 and Mrc1, with a 3-fold increase in Ki67+ cells in the presence of macrophages (6.4±0.6 in SKO vs. 1.8±0.8 in DKO, p<0.0001), correlating with a late acceleration in cyst growth in the SKO kidneys.

Conclusions: The results demonstrate two distinct effects of macrophages: early proinflammatory induction of tubule cell injury and tubule dilation that is proliferation independent and late alternative activation mediated induction of proliferation-dependent cyst growth.

AKI in Pediatric Sepsis Is an Independent Risk Factor for Death and New Substantive Disability

Michelle C. Starr,[1] Ron W. Reeder,[3] Jerry J. Zimmerman,[2] Russell K. Banks,[3] Sangeeta R. Hingorani.[1] Collaborative Pediatric Critical Care Research Network *[1]Seattle Children's Hospital, Seattle, WA; [2]Seattle Children's Hospital, University of Washington School of Medicine, Seattle, WA; [3]University of Utah, Salt Lake City, UT.*

Background: Acute kidney injury (AKI) is common in critically ill children. The incidence of septic AKI and its impact on PICU survivor functional status are unknown. We used data from a multicenter cohort with sepsis to evaluate functional outcomes of children with AKI.

Methods: Using the prospective Life after Pediatric Sepsis Evaluation (LAPSE) study [R01HD073362], we evaluated the association of AKI with a composite of death or new substantive functional disability at day 28 of hospitalization or discharge as a primary outcome. We defined AKI using KIDGO criteria, comparing patients with no AKI or Stage 1 AKI to those with Stage 2 or 3 AKI (Severe AKI). New substantive disability was defined as a Functional Status Scale (FSS) score increase ≥3 points from baseline to 28 days. Wilcoxon rank-sum and likelihood ratio tests were used to compare variable associations between groups. We used multivariable logistic regression to assess the association of AKI with outcomes.

Results: 176 (50.5%) of 348 patients had severe AKI; of those, 38 (21.6%) required renal replacement therapy. Patients with severe AKI had higher median PRISM III scores (excluding creatinine) (12 vs 8; p<0.001), and were treated more often with vasoactive agents (97.7 vs 91.9%; p=0.011), blood products (65.3 vs 44.8%; p<0.001), and corticosteroids (74.4 vs 61.0%; p=0.007). Twice as many patients with severe AKI died or developed new substantive disability (38.1 vs 16.3%; p<0.001). Children with severe AKI had longer PICU stays (11.7 vs 7.1 days; p<0.001), and longer duration of mechanical ventilation (11.0 vs 7.0 days; p<0.001). After adjustment for age, malignancy, and PRISM III score, severe AKI was independently associated with mortality or new substantive disability (adjusted odds ratio 2.77; 95% CI 1.63–4.81, p<0.001). Despite similar baseline FSS scores, children who survived with severe AKI had a greater sustained change in FSS scores at 28 days or hospital discharge than those without AKI (adjusted effect 1.35; 95% CI 0.27–2.43; p=0.014).

Conclusions: In critically ill children with sepsis, severe AKI is common and is independently associated with increased risk of death or new substantive disability. Survivors of sepsis with severe AKI were more likely to have persistent decreased functional status at discharge than those without severe AKI.

Long-Term Outcomes after AKI Requiring Dialysis Among Neonates and Children in Ontario: A Population-Based Study

Rahul Chanchlani,[1] Danielle M. Nash,[3] Eric McArthur,[7] Michael Zappitelli,[6] John paul Kuwornu,[8] Amit X. Garg,[3] Jason H. Greenberg,[4] Stuart Goldstein,[5] Ron Wald.[2] *[1]Pediatric Nephrology, McMaster Children Hospital, Hamilton, ON, Canada; [2]St. Michael's Hospital, Toronto, ON, Canada; [3]London Health Sciences Centre, London, ON, Canada; [4]Yale University, New Haven, CT; [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [6]Toronto Hospital for Sick Children, University of Toronto, Toronto, ON, Canada; [7]Institute for Clinical Evaluative Sciences, London, ON, Canada; [8]Government of Saskatchewan, Regina, SK, Canada.*

Background: There is limited knowledge on the long-term impact of an episode of acute kidney injury requiring dialysis (AKI-D) among neonates and children.

Methods: Using health administrative databases housed at the Institute for Clinical Evaluative Sciences, we conducted a retrospective cohort study of all hospitalized neonates and children who received dialysis for AKI across Ontario between 1996 and 2015 and survived to hospital discharge (exposed cohort). We assembled a comparator cohort (up to 4 neonates and children without AKI-D for every patient with AKI-D) matched on demographics and comorbidities. Primary outcomes were all-cause mortality and end-stage renal disease (ESRD, defined as receipt of chronic dialysis or a kidney transplant) and secondary outcomes were *de novo* CKD and hypertension. Incidence rates (IR) were calculated and Cox proportional hazards models were fitted for all outcomes.

Results: There were 466 neonates and 1641 children hospitalized with AKI-D in Ontario between 1996 and 2015, of whom 356 neonates and 1500 children, had matched counterparts without AKI-D. The median follow-up time was 9.2 years (Interquartile Range (IQR) 4.7,12.0) for neonates and 12.4 years (IQR 5.8,16.9) for children. After adjusting for confounders, survivors of AKI-D during the neonatal period had a 21-fold risk of death and a 7-fold higher risk of hypertension, as compared to neonates with no AKI-D. Similarly, children surviving an episode of AKI-D had a higher risk of death, CKD and hypertension as compared to hospitalized children who did not experience AKI-D. (Table 1).

Conclusions: Neonates and children with AKI-D remain at higher risk of long-term adverse outcomes compared to those without AKI-D suggesting that they need a close follow-up after discharge.

Multiple Episodes of AKI and Their Association with Kidney Function and Death

Edward D. Siew,[1] Kathleen D. Liu,[3] Amit X. Garg,[4] Mark M. Wurfel,[5] Vernon M. Chinchilli,[6] James S. Kaufman,[7] Paul L. Kimmel,[8] Chirag R. Parikh.[2] on behalf of the ASSESS-AKI Investigators *[1]Vanderbilt University School of Medicine, Nashville, TN; [2]Yale University and VAMC, New Haven, CT; [3]University of California at San Francisco School of Medicine, San Francisco, CA; [4]London Health Sciences Centre, London, ON, Canada; [5]University of Washington, Seattle, WA; [6]Penn State College of Medicine, Hershey, PA; [7]VA New York Harbor Healthcare System, New York, NY; [8]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD.*

Background: Recurrent AKI may mediate the risk for future CKD outcomes. Prior studies on recurrent AKI lacked appropriate controls. We compared the incidence of future AKI between hospitalized AKI and nonAKI patients and the impact of AKI on kidney disease progression.

Methods: ASSESS-AKI is a prospective multi-center study of matched AKI and non-AKI patients followed longitudinally beginning 3 months after initial hospitalization. AKI was defined as a 0.3 mg/dl or 50% increase in baseline serum creatinine during subsequent hospitalizations. The determinants of future AKI were examined using multivariate Cox regression. Outcomes included time to event for (1) a composite renal outcome of incident or progressive CKD or ESRD, and (2) the competing risk of death. Predictors of outcome were examined using a multivariable trivariate Weibull regression model, along with a zero-inflated Poisson regression model for the number of AKI events prior to the composite renal endpoint.

Results: Among 769 matched pairs of AKI and non-AKI patients, 465(30%) experienced a future AKI episode over a median follow-up of 57 months. Future AKI was more common among patients with AKI compared to nonAKI status at index hospitalizations, with 8 compared to 5 AKI episodes per 100 person-years (PYs)($p < 0.0001$). After multivariate adjustment, index AKI remained independently associated with the risk for future AKI [aHR 1.5 (95%CI:1.2-1.8)]. The rates of the composite renal outcome were 2, 5, and 6 per 100 PYs among patients with 0, 1, and ≥2 episodes of AKI ($p < 0.0001$). The rates for death prior to a CKD event were 2, 4, and 9 among patients with 0, 1, and ≥2 episodes of AKI ($p < 0.0001$). After multivariable adjustment, the presence of 1 and ≥2 episodes of AKI conferred an increased risk for the CKD outcome [aHR 3.3(2.2-4.9) and 2.8(1.8-4.2)], respectively, compared to patients without AKI. There were incremental increases in the risk of death prior to a CKD event with 1[aHR 1.7(1.2-2.6)] and ≥2[aHR 2.8(1.8-4.2)] episodes of AKI compared to no AKI.

Conclusions: AKI is an independent risk factor for future hospitalized AKI and loss of kidney function. The association between multiple AKI events and future CKD outcomes may be affected by the competing risk of death.

Post-Discharge Long-Term Cardiovascular Outcome of Dialysis Requiring AKI after Cardiac Surgery

Soojin Lee,[1] Sehoon Park,[1] Min woo Kang,[1] Yaerim Kim,[1] Jung Pyo Lee,[2] Kwon Wook Joo,[1] Chun Soo Lim,[2] Dong Ki Kim.[1] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University Boramae Medical Center, Seoul, Republic of Korea.*

Background: Dialysis requiring acute kidney injury (AKI-D) is one of the serious complications following the cardiac surgery and it is known to increase in short-term in hospital mortality. Nevertheless, long-term prognosis and risk of major cardiovascular events (MACE) has not been examined yet.

Methods: We conducted a nationwide, population-based cohort study using the data of Korean National Health Insurance System. Adult patients who underwent cardiac surgery in tertiary hospitals between 2006 and 2015 were considered. Patients previously received dialysis were excluded. Then, the patients were divided into those who underwent dialysis after cardiac surgery and those who did not.

Results: Of 52,803 patients received cardiac surgery, 1,261 underwent dialysis during the perioperative period of cardiac surgery. All-cause mortality [adjusted hazard ratio (HR) 2.93 (2.65-3.23), P<0.001], progression to end-stage renal disease (ESRD) [adjusted HR 15.95 (13.89-18.33), P<0.001] and risk of MACE [adjusted HR 2.26 (2.04-2.51), P<0.001] were increased in AKI-D group (Figure 1). In the AKI-D group, all-cause mortality [adjusted HR 1.07 (0.83-1.38), P=0.593] and the risk of MACE [adjusted HR 1.25 (0.94-1.67), P=0.126] were comparable between the continuous renal replacement therapy (CRRT) and intermittent renal replacement therapy (IRRT) group.

Conclusions: Patients required dialysis after the cardiac surgery were associated with high all-cause mortality and rate of dialysis dependence. Although AKI-D patients independently survive, they persistently had increased risk of MACE development. Despite higher patient severity in patients requiring CRRT, outcomes among these patients were not deteriorated, compared to IRRT group.

Outcomes after Left Ventricular Assist Device Implantation in Patients with AKI

Samuel A. Silver,[1,2] Jin Long,[4] Yuanchao Zheng,[4] Glenn M. Chertow.[3] *[1]Queen's University, Kingston, ON, Canada; [2]Kingston Health Sciences Center, Kingston, ON, Canada; [3]Stanford University School of Medicine, Palo Alto, CA; [4]Stanford University, Palo Alto, CA.*

Background: Left ventricular assist devices (LVAD) are increasingly used as a bridge to heart transplant and destination therapy for heart failure. Although acute kidney injury (AKI) is a common complication in these patients, there are few multicenter studies on how AKI affects LVAD outcomes. We sought to determine outcomes associated with AKI among patients receiving LVADs in a nationally representative sample of hospitalizations in the US.

Methods: Using the National Inpatient Sample from 2008 to 2013, we identified patients who received a LVAD during a hospitalization using ICD-9 code 37.66. We ascertained AKI and acute dialysis using validated ICD-9 codes. The primary outcome was in-hospital mortality. Secondary outcomes included procedural complications and discharge destination. We used logistic regression to adjust for demographics, hospital-level factors, comorbidities, and acute hospitalization details.

Results: We identified 8362 patients who received a LVAD, of whom 3760 (45%) developed AKI without dialysis (AKI-ND) and 426 (5%) developed AKI-requiring dialysis (AKI-D). In-hospital mortality increased from 4% for patients without AKI, to 12% for patients with AKI-ND, to 48% for patients with AKI-D. We observed similar increases for major bleeding (25% vs 33% vs 49%) and sepsis (9% vs 22% vs 43%). Discharge destination was home for 84% of patients without AKI, 72% of patients with AKI-ND, and 56% of patients with AKI-D. After multivariable adjustment, patients with AKI-ND and AKI-D had higher odds of mortality (OR 3.24, 95% CI 2.04-5.13 and 20.8, 95% CI 9.7-44.2), major bleeding (1.38, 95% CI 1.08-1.77 and 2.43, 95% CI 1.47-4.04), sepsis (2.69, 95% CI 1.93-3.75 and 5.75, 95% CI 3.46-9.56), and discharge to a nursing facility (2.15, 95% CI 1.51-3.07 and 5.89, 95% CI 2.67-12.99). Patients with AKI-ND and AKI-D on mechanical ventilation had a markedly increased adjusted odds of death (14.2, 95% CI 7.5-26.9 and 90.9, 95% CI 41.4-199.6). None of the patients with AKI-D received a heart transplant during the same hospitalization as LVAD implantation.

Conclusions: During a hospitalization in which a LVAD is implanted, patients with AKI are at increased risk of procedural complications and death. The prognosis is particularly poor for patients with AKI-D. This information is necessary to support shared decision-making for patients with advanced heart failure and AKI.

TH-OR116

AKI Is Associated with an Increased Risk of Dementia

Jessica B. Kendrick,[1] John R. Holmen,[2] Titte Srinivas,[6] Zhiying You,[3] Michel Chonchol,[4] Anna J. Jovanovich.[5] *[1]University of Colorado School of Medicine, Aurora, CO; [2]Intermountain Healthcare, Murray, UT; [3]UC Denver, Aurora, CO; [4]University of Colorado, Aurora, CO; [5]Denver VA / University of Colorado, Denver, CO; [6]Intermountain Medical Center, Murray, UT.*

Background: Acute kidney injury (AKI) is associated with long-term adverse outcomes including development of chronic kidney disease, cardiovascular disease and mortality. Acute neurologic complications of acute kidney injury are well described but the long-term consequences of AKI on neurologic outcomes are unclear. We tested the hypothesis that AKI, even with complete kidney function recovery, is associated with a higher risk of developing dementia.

Methods: We performed a retrospective propensity score-matched analysis of 2,082 patients without prior history of dementia from an integrated health care delivery system in Utah, who had a hospital admission between January 1, 1999 and December 31, 2009. AKI was defined by ICD-9 codes and AKI Network serum creatinine values. 1041 patients with AKI followed by complete recovery, defined as discharge creatinine <1.10 times the pre-admission baseline value, were propensity score-matched with 1041 patients without AKI during the index admission. Dementia was defined by ICD-9 codes. Demographic, baseline serum creatinine, prior inpatient visits, season of admission, and all components of the Charlson Comorbidity index were used to generate the propensity score. Proportional hazards analysis was used to compare time to dementia among patients with and without AKI.

Results: After propensity score matching, covariates were well balanced between the groups. The mean (SD) age and baseline creatinine was 61 ± 16 years and 0.9 ± 0.2 mg/dL, respectively. During a median follow-up time of 5.8 years, 97 patients developed dementia. More patients with AKI developed dementia (7.0% vs. 2.3%). Patients with AKI had more than a 3-fold increased risk of developing dementia compared to those without AKI (Hazard Ratio 3.4, 95% CI 2.14 to 5.40).

Conclusions: AKI, even with complete kidney recovery, is associated with a significantly increased risk of hospitalized dementia. Further studies are needed to examine the association of AKI with cognitive dysfunction.

Recognizing Sepsis: A High-Throughput Non-Invasive Assessment Using Machine Learning and Urinary MicroRNAs

Ferdous Kadri,[1,2] Sabyasachi Bandyopadhyay,[6,4] Lasith Adhikari,[1,2] Tezcan Ozrazgat-baslanti,[1,2] Laura Sautina,[1,3] Maria C. Lopez,[5,3] Henry V. Baker,[5,3] Mark S. Segal,[1,3] Parisa Rashidi,[4,2] Azra Bihorac.[1,2] PRISMA-P *[1]Division of Nephrology, Hypertension, and Renal Transplantation, Department of Medicine, University of Florida, Gainesville, FL; [2]Precision and Intelligent Systems in Medicine (PrismaP), University of Florida, Gainesville, FL; [3]Sepsis and Critical Illness Research Center, University of Florida, Gainesville, FL; [4]J. Crayton Pruitt Family Department of Biomedical Engineering, University of Florida, Gainesville, FL; [5]Department of Molecular Genetics and Microbiology, University of Florida, Gainesville, FL; [6]Department of Surgery, University of Florida, Gainesville, FL.*

Background: Identifying early differences between Systemic Immune Response Syndrome, SIRS, and sepsis remains at the fulcrum of surviving sepsis: without early identification, shock and eventual death ensues. MicroRNAs (miRNAs) are non-coding RNAs that regulate gene expression. Given their selective secretion and extensive role in cellular communication, miRNAs have been utilized in diagnosis, prognosis, and therapeutics in various disciplines of medicine. As the kidneys are one of critical organs affected by sepsis, we surveyed the miRNA population in urine at the time of sepsis. Here we isolate urinary exosomes to identify miRNAs that are associated with sepsis in comparison to patients with vascular disease prior to surgery serving as a control group.

Methods: We collected urine samples from 41 patients within 12 hours of sepsis onset and 29 control patients. Using exosomal isolation protocol (Norgen), we extracted miRNAs from urine supernatant. Subsequently, we utilized Affymetrix® RNA Labeling Kit and GeneChip Arrays to obtain expression values of 2,578 miRNAs in each patient. For machine learning, we randomly divided patients into 70% training set for feature selection of microRNAs and prospectively tested the performance in the validation set (30%) using area under the receiver operating curve (AUC).

Results: 94 miRNAs were dysregulated in sepsis ($\log_2$FC > 1, p-value < 0.01). 29 miRNAs were highly associated with the septic cohort. Testing the performance of these miRNAs, the validation set performed well with an AUC of 0.94 (95% CI 0.84 - 1.00). Among these, mir-455 is validated to induce hypoxia signaling, whereas mir-3201 upregulates monocyte chemoattractant protein. The mir-548 family is extensively intercalated in the network of TLR signaling, a pathway at the foundation of sepsis.

Conclusions: Uniting machine learning with miRNA arrays allowed us to identify dysregulated miRNAs and peer deeper into the specific pathways activated at the time of sepsis. Actively, we are utilizing this methodology to delineate expression patterns in septic patients as compared to SIRS+ and control groups to further define the fulcrum between SIRS and sepsis.

The Circular RNA ciRs-126 Predicts Survival in Critically Ill Patients with AKI

Malte Kölling,[1] Harald Seeger,[1] Andreas D. Kistler,[4] Jan T. Kielstein,[2] Hermann G. Haller,[3] Rudolf P. Wuthrich,[1] Johan Lorenzen.[1] *[1]University Hospital Zurich, Zurich, Switzerland; [2]Academic Teaching Hospital Braunschweig, Braunschweig, Germany; [3]Hannover Medical School, Hannover, Germany; [4]Cantonal Hospital Frauenfeld, Frauenfeld, Switzerland.*

Background: Circular RNAs (circRNAs) have recently been described as novel non-coding regulators of gene expression. They might impact on microRNA expression by their sponging activity. The detectability in blood of these RNA transcripts has been demonstrated in patients with cancer and cardiovascular disease. We tested the hypothesis, that circulating circRNAs in blood of critically ill patients with acute kidney injury (AKI) at inception of renal replacement therapy may also be dysregulated and associate with patient survival.

Methods: We performed a global circRNA expression analysis using RNA isolated from blood of patients with AKI as well as controls. This global screen revealed several dysregulated circRNAs in patients with AKI. Most highly increased circRNA-array-based transcripts as well as expression of the circRNA target miR-126-5p were confirmed in blood of 109 patients with AKI, 30 age-matched healthy controls, 25 critically-ill non-AKI patients and 20 patients on maintenance hemodialysis by quantitative realtime-PCR.

Results: Circulating concentrations of 3 novel circRNAs were amplified in blood of patients with acute kidney injury and controls. *Circular RNA sponge of miR-126* (or ciRs-126) was most highly altered compared to healthy controls and disease controls (fold change of 52.1). *CiRs-126* was shown to bioinformatically sponge miR-126-5p, which was found to be highly suppressed in AKI patients and hypoxic endothelial cells. Cox regression and Kaplan-Meier curve analysis revealed *ciRs-126* as an independent predictor of 28-day survival (p<0.01).

Conclusions: Circulating concentrations of circRNAs in patients with acute kidney injury are detectable. *CiRs-126* may potentially sponge miR-126-5p and acts as a predictor of mortality in this patient cohort.

The Furosemide Stress Test Predicts Severe AKI: A Multicenter Validation

Jay L. Koyner,[1] Oleksa G. Rewa,[2] Blaithin A. McMahon,[5] Lakhmir S. Chawla,[6] Ron Wald,[4] Kathleen D. Liu,[3] Sean M. Bagshaw.[2] Furosemide Stress Test (FST) Investigators *[1]University of Chicago, Chicago, IL; [2]University of Alberta, Edmonton, AB, Canada; [3]University of California at San Francisco School of Medicine, San Francisco, CA; [4]St. Michael's Hospital, Toronto, ON, Canada; [5]Johns Hopkins Hospital, Baltimore, MD; [6]University of California, San Diego, San Diego, CA.*

Background: The Furosemide Stress Test (FST) has been previously shown to predict which patients with Stage 1 or 2 AKI will progress to Stage 3 AKI.

Methods: We conducted a prospective multicenter validation of the FST at 5 centers across North America. Euvolemic or hypervolemic patients with Stage 1 & 2 AKI were given 1 or 1.5 mg/kg of intravenous furosemide, depending on prior exposure. Hourly urine output (UOP) was measured for 6 hours (hrs) to validate the previously published cutoff of 200 ml of urine in the first 2 hrs as well as to explore other cutoffs. We assessed the ability of the FST to predict the development of KDIGO Stage 3 AKI (primary endpoint – 200% increase in serum creatinine or receipt of renal replacement therapy (RRT)) and just the receipt of RRT, as well as occurrence of adverse events.

Results: We prospectively enrolled 92 patients with Stage 1 or 2 AKI who received a mean(SE) dose of 108(3.7) mg of furosemide. Twenty-three (25%) patients developed subsequent Stage 3 AKI, with 10 (11%) receiving RRT. There was no difference in baseline serum creatinine or eGFR, dose of furosemide, cardiovascular SOFA score or APACHE II score between those with and without Stage 3 AKI. Patients who progressed had significantly lower UOP in the 6hrs before the FST (median[IQR]) (241[93-357] compared to 336[199-578] p=0.024). The total UOP for the first 2hrs post-FST provided an AUC(SE) of 0.85(0.05) for progression to stage 3 (p<0.001) and 0.73(0.10) for RRT (p<0.05) (Table) UOP of less than 200ccs in the first 2hrs was 89.8% specific for AKI progression. In terms of adverse events, hypotension developed in 9(10%) patients post FST and 5(6%) patients developed hypokalemia and 5(6%) patients developed hypophosphatemia.

Conclusions: In this multicenter validation, the 2 hour total UOP following FST predicted the progression to Stage 3 AKI and the need for RRT. UOP of less than 200 cc in the first 2hrs post-FST is a highly specific for progression to Stage 3 AKI, while less than 400 cc is highly sensitive for AKI progression.

Funding: Commercial Support - Satellite Healthcare

Sensitivity Analysis for 2 hour UOP following FST to predict Stage 3 AKI

2 hr UOP Cutoff (ccs total)	Sensitivity	Specificity
<100	43.4%	94.2%
<200	73.9%	89.9%
<300	82.6%	84.1%
<400	87.0%	62.3%

Impact of Echocardiographic Parameters on Mortality in ICU Patients Undergoing CRRT

Panagiotis Kompotiatis,[1] Brandon M. Wiley,[2] Jacob Jentzer,[2] Kianoush Kashani.[2] *[1]Nephrology, Mayo Clinic, Rochester, MN; [2]Mayo Clinic, Rochester, MN.*

Background: Echocardiographic abnormalities have been associated with adverse outcomes in various Intensive care unit (ICU) populations. However, the impact of echocardiographic abnormalities on the prediction of mortality in patients undergoing continuous renal replacement therapy (CRRT) has not been examined.

Methods: Historical cohort study of consecutive adults admitted to the ICUs at one tertiary care hospital from December 2006, through November 2015 who underwent CRRT and had an echocardiogram done within 7 days of CRRT initiation. The primary outcome was 30-day death rate. Logistic regression was used to determine predictors of 30-day mortality.

Results: We included 1,276 patients, 1,040 (81.5%) with acute kidney injury (AKI) and 236 (18.5%) with end-stage renal disease (ESRD). Median patient age was 63 (IQR 53-73) years, and 514 (40%) were female, median Charlson score was 5 (IQR 3-7), and median SOFA score on the day of CRRT initiation was 12 (IQR 10-14). Echocardiographic parameters associated with 30-day mortality on univariate analysis included: Moderate or greater right ventricular (RV) dysfunction (OR 1.47, 95% CI: 1.08-1.60), moderate or greater tricuspid regurgitation (OR 1.67, 95% CI: 1.26 – 2.21) and right ventricular systolic pressure (RVSP) (OR 1.12 per 10 mmHg increase, 95% CI: 1.02-1.23). RV dysfunction (OR 1.54, 95% CI: 1.02-2.32) and tricuspid regurgitation (OR 1.55, 95% CI:1.02-2.32) remained significantly associated with 30-day mortality after adjusting for age, sex, SOFA score, Charlson comorbidity index, need for mechanical ventilation, type of ICU, fluid balance and AKI vs. ESRD using logistic regression analysis.

Conclusions: RV dysfunction and tricuspid regurgitation are associated with increased mortality in patients undergoing CRRT, emphasizing the importance of cardiorenal syndrome among critically-ill patients. Further study will be needed to determine if RV dysfunction is a risk marker or a modifiable risk factor in this patient population.

Impact of Obesity on Kidney Transplant Outcomes: A Paired-Kidney Analysis

Bhavna Chopra,[1] Rita L. McGill,[2] Michelle A. Josephson,[2] Pratik B. Shah,[2] Kalathil K. Sureshkumar.[1] *[1]Nephrology, Allegheny General Hospital, Pittsburgh, PA; [2]University of Chicago, Chicago, IL.*

Background: The prevalence of obesity is increasing in prospective kidney transplant recipients (KTRs). The impact of recipient obesity on long term outcomes is not clear. We sought to evaluate the associations of recipient body mass index (BMI) with transplant outcomes using a paired-kidney model.

Methods: UNOS data were used to identify all deceased donors between 1/2006 and 12/2016 in which each kidney was used for kidney-alone transplant. Recipient BMIs were classified as: 18-25, >25-30, >30-35, and >35 (reference category). Hazard ratios (HR) for graft failure (GF), death-censored GF (dcGF), and patient death were obtained by marginal survival models adjusted for pairing by donor. Odds ratios (OR) for delayed graft function (DGF) were obtained by conditional logistic regression models. Models were adjusted for recipient and transplant factors.

Results: 39,334 paired recipients were evaluated, of whom 4,949 (12.6%) had BMI>35. Median follow up was 43.9 (IQR=22.3-71.8) months, with graft failure in 11.9% and death in 11.0%. Results for adjusted models are shown in table. Compared to patients with BMI>35, patients with BMI 18-25 had lower hazards for both GF and dcGF, but not for death. Patients with BMI >25-30 had lower dcGF. No significant differences seen between BMI >30-35 and BMI>35 for GF, dcGF or death. The odds of DGF were significantly decreased in all BMI groups, compared to BMI>35.

Conclusions: Our paired kidney analysis among a large national transplantation dataset found similar long-term graft and patient outcomes among KTRs with BMI >35 compared to those with BMI 30-35, despite increased DGF. Higher rates of dcGF among all patients with BMI>30 may reflect hyperfiltration, inflammation, subtherapeutic immunosuppression, or increased post-operative complications. Non-inferior patient outcomes among patients with BMI>35 could reflect careful pre-transplant selection among very obese candidates or a survival advantage similar to that of obese dialysis patients. These data support a more favorable consideration of obese patients for kidney transplantation and suggest that the use of a BMI cut off between 35 and 40, while common, is arbitrary and unfounded.

Clinical Outcomes by Body Mass Index Categories (Reference: BMI>35)						
BMI	18-25		>25-30		>30-35	
n	10,683		13,665		10,037	
	HR (95% CI)	P	HR (95% CI)	P	HR (95% CI)	P
GF	0.92 (0.86-0.99)	0.03	0.95 (0.88-1.01)	0.1	0.99 (0.92-1.06)	0.8

Obesity Is Associated with Graft Failure in Pediatric Kidney Transplantation

Heather L. Wasik,[1] Cozumel S. Pruette,[1] Rebecca Ruebner,[1] Allan Massie.[2] *[1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins School of Medicine, Baltimore, MD.*

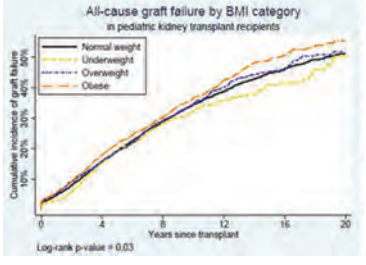
Background: Obesity is a potentially modifiable risk factor in kidney transplantation (KT), but recent studies have shown conflicting results regarding the impact of recipient obesity on graft failure in pediatric KT.

Methods: We studied first-time KT recipients 1995-2016 aged 2-17 years at transplant using SRTR data. Using recipients' height and weight at time of KT, we classified them as underweight (BMI <5th percentile), normal weight (BMI 5th to <85th percentile), overweight (BMI 85th to <95th percentile), and obese (BMI ≥ 95th percentile) based on US CDC growth reference charts. Normal weight recipients were the reference group. Survival analysis was used to compare the cumulative incidence of all-cause graft failure (ACGF) between recipients in each BMI category. Multivariable Cox models were used to compare time to ACGF between recipients in each BMI category, adjusting for recipient, donor, and transplant characteristics.

Results: Of 12,247 pediatric KT recipients, 62.7% were normal weight, 6.9% were underweight, 14.3% were overweight, and 16.1% were obese. Obese KT recipients had the highest incidence of ACGF (37% at 10 years vs 34% for normal/overweight and 32% for underweight (Figure)). After adjustment, obesity remained associated with an increased risk of ACGF ($aHR=_{1.09}1.20_{1.31}$, p<0.001).

Conclusions: Obesity at the time of transplantation is associated with increased risk of ACGF in pediatric KT recipients. Obesity may be a modifiable risk factor for graft loss in pediatric KT.

Funding: Other NIH Support - Renal Epidemiology NRSA Training Grant T32 DK007732



Weight and ACGF in pediatric KT recipients

BMI category	Adjusted hazard ratio
Underweight	$_{0.72}0.82_{0.94}$
Normal weight	Reference
Overweight	$_{0.93}1.05_{1.19}$
Obese	$_{1.09}1.20_{1.31}$

Note: Multivariable Cox regression adjusted for recipient age, recipient sex, recipient race, recipient insurance status, cause of ESRD, years of dialysis prior to KT, donor age, donor sex, donor type (living vs deceased), number of HLA mismatches, peak panel reactive antibody, transplant year

Association of Pre-Transplant Weight Loss with Mortality after Deceased Donor Kidney Transplantation

Meera N. Harhay,[1,2] Suzanne Boyle,[1] Karthik M. Ranganna,[1] Mara McAdams-DeMarco.[3] *[1]Medicine, Division of Nephrology & Hypertension, Drexel University College of Medicine, Philadelphia, PA; [2]Epidemiology and Biostatistics, Drexel University Dornsife School of Public Health, Philadelphia, PA; [3]Johns Hopkins, Baltimore, MD.*

Background: Weight loss is a recognized component of frailty, signaling vulnerability to health stressors. Whether deceased donor kidney transplant (DDKT) recipients who lost weight before DDKT are at higher risk of adverse post-transplant outcomes is unknown.

Methods: Retrospective cohort study, using national registry data, of all DDKT recipients in the United States between January 1, 2005 and December 31, 2014 who were adults (age>=18 years) at wait-listing. We used unadjusted fractional polynomial methods and adjusted Cox proportional hazards models to examine the association of relative change in body weight pre-DDKT with post-DDKT mortality.

Results: Among 96,938 DDKT recipients, there was a non-linear unadjusted relationship between relative pre-DDKT weight change and post-DDKT mortality, with a steep increase in mortality among DDKT recipients who lost 10% or more of their listing body weight compared to those with no pre-DDKT weight change (Figure). In a multivariable Cox model adjusted for recipient and allograft characteristics, waiting time, and dialysis vintage, compared to recipients with weights at DDKT within 5% of their listing weights, recipients who lost 10% or more of their listing body weight before DDKT were 14% more likely to die post-DDKT (adjusted hazard ratio 1.14, 95% confidence interval 1.08-1.21, p<0.001). Pre-DDKT weight gain was not independently associated with post-DDKT mortality after multivariable adjustment. There was no evidence of effect modification by age, dialysis vintage, or body mass index (p>0.10 for interaction terms).

Conclusions: Substantial weight loss before DDKT may indicate increased vulnerability after DDKT. Studies are needed to identify and modify unhealthy weight trajectories among DDKT candidates.

Funding: NIDDK Support

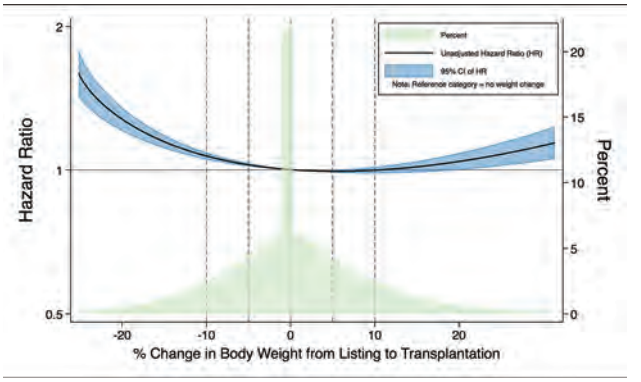

Figure demonstrates the distribution of pre-DDKT weight change (light green) among 96,938 DDKT recipients, and the unadjusted association of pre-DDKT weight change with post-DDKT mortality (black line) with 95% confidence intervals (light blue).

TH-OR124

Metabolic Acidosis Is a Risk Factor for Ischemic Cardiovascular Events in Kidney Transplant Recipients

Arjang Djamali,[2] Nancy A. Wilson,[1] Brad C. Astor.[1] *[1]University of Wisconsin, Madison, WI; [2]School of Medicine and Public Health, Madison, WI.*

Background: Metabolic acidosis is associated with disease progression and death in CKD. However, there is limited information on whether metabolic acidosis is a risk factor for poor outcomes after kidney transplantation.

Methods: We examined the association between mean total serum bicarbonate levels(TCO2) at one-year and the incidence of all-cause mortality, *de novo*ischemic, arrhythmic, or heart failure events in 2018 kidney transplant recipients.

Results: The prevalence of metabolic acidosis defined as TCO2 <24 mEq/L, was 16.9% (n=341). There were 593 deaths and 363 recipients with a CVE over a median follow-up of 3.75 years. CVE included 221 ischemic, 63 arrhythmic, and 178 heart failure events. TCO2 < 22 mEq/L was associated with increased risk of CVE (adjusted HR 2.22; 95%CI 1.41, 3.48). This association was primarily due to ischemic CVE (aHR 2.51; 95%CI 1.43, 4.40). For every 1 mEq/L TCO2 below 24 mEq/L, the risk of all CVE and ischemic events was 18% and 17% higher, respectively (aHR for all CVE 0.82; 95% CI 0.72, 0.94, and aHR for ischemic CVE 0.83; 95% CI 0.71, 0.98). Notably, TCO2 < 22 mEq/L was an independent risk factor for all-cause mortality (aHR 1.85; 95% CI 1.28, 2.68). For every 1 mEq/L TCO2 below 24 mEq/L, the risk of death was 17% higher (aHR 0.83; 95%CI 074, 0.92).

Conclusions: In summary, metabolic acidosis is a risk factor for ischemic CVE and all-cause mortality in kidney transplant recipients. Clinical trials are needed to determine the safety and efficacy of alkali therapy for CVE after renal transplantation.

TH-OR125

Kidney Recipient-Donor KIR-HLA Ligand Mismatch Is Associated with Reduced Graft Survival

Andreas Heinzel,[1] Lori Dolores Kregar,[1] Roman Reindl-Schwaighofer,[1] Alexander Kainz,[1] Kira Jelencsics,[1] Karin Hu,[1] Petra Hruba,[2] Ondrej Viklicky,[2] Georg Bohmig,[1] Brendan Keating,[3] Rainer Oberbauer.[1] *[1]Medical University of Vienna, Vienna, Vienna, Austria; [2]Institute for Clinical and Experimental Medicine, Department of Nephrology, Prague, Czechia; [3]University of Pennsylvania, Philadelphia, PA.*

Background: Differences in KIRs between recipients can lead to different KIR-HLA ligand constellations not captured by HLA matching alone. These differences may contribute to variation in allogeneic response to the renal allograft after transplantation.

Methods: We made use of the iGeneTrain consortium and genotyped 162 first kidney transplant recipients and respective HLA-DR matched deceased donors from two centers in Vienna and Prague. KIR types were imputed using KIR*IMP. HLA eplet mismatch was calculated for the HLA-A, -B, -C, -DP, -DQ, and -DR loci. The median follow-up time of the cohort was 5.8 years. KIR HLA ligand mismatches were defined based on the presence of inhibitory KIRs (2DL1, 2DL2, 2DL3 and 3DL1) and activating KIRs (2DS1 and 2DS2) in the recipient and absence or presence of the corresponding ligand in the donor, respectively. Kaplan-Meier analysis and a Cox PH model were used to assess the association of KIR-HLA ligand mismatch with death censored graft loss.

Results: Comparison of the groups of recipients with no- and at least a single KIR-HLA ligand mismatch revealed an elevated risk for graft loss following renal transplantation in the latter group (see figure 1). This association remained significant in a multivariable Cox model after adjustment for full HLA eplet mismatch and donor age (HR: 3.01 CI: 1.06 – 8.56, p-value: 0.039).

Conclusions: Presence of a KIR-HLA ligand mismatch between recipient and donor is associated with graft loss after HLA-DR matched kidney transplantation.

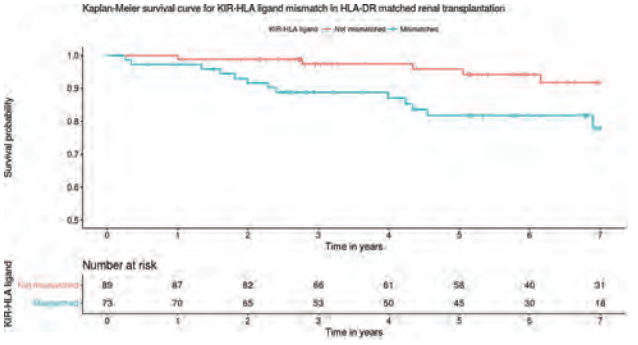

Figure 1: Kaplan-Meier survival curves comparing HLA-DR matched kidney recipient-donor pairs without and with a KIR-HLA ligand mismatch.

Risk Prediction Score for Allograft Loss in Kidney Transplant Recipients: An International Derivation and Validation Study

Alexandre Loupy, Olivier Aubert, Yassine R. Bouatou, Denis Viglietti, Carmen Lefaucheur. *Paris Translational Research Center for Organ Transplantation, Paris, France*.

Background: The field of kidney transplantation currently lacks robust models to predict long-term allograft failure, hampering patient care improvement and novel clinical trials. We aimed at developing and validating a score that predicts individual patients' risks of long-term kidney allograft failure.

Methods: This prospective international cohort study included consecutive kidney transplant recipients from a derivation cohort (n=4,000) recruited between 2005 and 2014 in four centres and a validation cohort of 3,557 kidney transplant recipients from six centres recruited in Europe (n=2,129) and North America (n=1,428) between 2002 and 2014. Thirty-three candidate prognostic factors of kidney allograft were assessed. The outcome was the long-term allograft failure (i.e. return on dialysis or pre-emptive re-transplantation); NCT03474003.

Results: Amongst the 7,557 patients included, 1,067 allograft failures occurred (14.12%) after a median follow-up time post-transplantation of 7.12 years (IQR: 3.51-8.77). In the derivation cohort, eight functional, histological and immunological prognostic factors were independently associated with allograft failure and were then combined into an integrative risk prediction score (iBox). This score exhibited accurate calibration and discrimination (C index=0.81; 95% CI, 0.79-0.83). The performance of the iBox was also confirmed in two validation cohorts from Europe (C-index=0.80; 95% CI=0.78-0.84) and the USA (C-index=0.80; 95% CI=0.76-0.84). The iBox was accurate at different times of posttransplant risk evaluation and outperformed conventional prediction model based on functional parameter assessment only. Finally, the performance of the iBox was confirmed in 3 independent randomised controlled therapeutic trials covering distinct clinical scenarios (C-index 0.87; 95% CI=0.82-0.92).

Conclusions: We developed the iBox risk prediction score, which accurately predicts kidney allograft failure and demonstrates generalisability across centres worldwide. This risk prediction score provides an accurate but simple strategy that can be easily implemented to stratify patients into clinically meaningful risk groups, which may help guide patient monitoring in everyday practice and improve the design of future clinical trials.

TH-OR127

Sclerostin Is an Independent Risk Factor of All-Cause Mortality in Older Kidney Transplant Recipients and Graft Loss in Younger Kidney Transplant Recipients

Shufei Zeng,[1,2] Wolfgang M. Pommer,[1] Mohamed M. Gaballa,[2] Ahmed A. Hasan,[2] Berthold Hocher.[3] Institute of Nutritional Science University of Potsdam *[1]Charité University Berlin, Berlin, Germany; [2]Institute of Nutritional Science University of Potsdam, Potsdam, Germany; [3]University of Potsdam, Potsdam, Germany*.

Background: Immediate graft loss and patient survival after kidney transplantation have improved over the past decade, however, long-term outcomes remain an issue and graft loss is in some centers the leading cause for imitating renal replacement therapy. Sclerostin is a hormone contributing to the bone-vascular wall cross talk and has been implicated in cardiovascular events and mortality in patients with chronic kidney disease (CKD). However, the relationship between sclerostin and mortality or graft failure in renal transplant recipients has not been analyzed so far.

Methods: 600 stable renal transplant recipients were followed for 3 years for all-cause mortality and graft failure. Blood and urine samples for analysis of sclerostin, albumin, creatinine, total cholesterol, HbA1c, 1,25$(OH)_2$D, calcium, phosphorus, iPTH, fasting blood glucose, urinary protein and clinical data were collected at baseline. We performed Kaplan Meier survival analysis and Cox regressions models considering confounding factors such as eGFR, urinary protein excretion, cold ischemia time, donor age, recipient age, time on dialysis and HbA1c.

Results: Elevated baseline serum sclerostin concentrations (>75 ng/ml) is an independent risk factor for all-cause mortality in older(>66y) stable kidney transplant recipients but not in young patients: Kaplan-Meier curves (older patients: P=0.003, log-rank test; young patients: P=0.492, log-rank test); and Cox regression (older patients: relative risk, 0.155; 95% CI, 0.043 to 0.561 ; P=0.004; young patients: relative risk, 1.330; 95% CI, 0.170-10.403; P=0.786). Elevated baseline serum sclerostin concentrations (>75 ng/ml) is an independent risk factor for graft failure in young(≤66y) stable kidney transplant recipients but not in older patients: Kaplan-Meier Curves(older patients: P=0.784, log-rank test; young patients: P=0.023, log-rank test); and Cox regression (older patients: relative risk, 0.227; 95% CI, 0.011 to 4.855 ; P=0.343; young patients: relative risk, 0.244; 95% CI, 0.063-0.944; P=0.041).

Conclusions: Our study showed for the first time that elevated baseline serum sclerostin is an independent risk factor of all-cause mortality in older patients and for graft failure in young patients after kidney transplantation.

TH-OR128

Outcomes for Kidney Transplant Recipients with Hearing, Visual, Physical, and Walking Disabilities

Alvin G. Thomas,[1,2] Jessica M. Ruck,[2] Christine E. Haugen,[2] Ashton A. Shaffer,[2] Hao Ying,[2] Jacqueline Garonzik wang,[2] Silas Norman,[3] Dorry L. Segev,[2] Mara McAdams-DeMarco.[2] *[1]UNC Chapel HIll, Chapel Hill, NC; [2]Johns Hopkins University, Baltimore, MD; [3]University of Michigan Health Systems, Ann Arbor, MI.*

Background: Lower functional status is associated with higher mortality risk in kidney transplant (KT) recipients. Physical disabilities might also affect post-KT outcomes through similar pathways, but this population has not been well characterized.

Methods: Using a prospective 2-center cohort of 500 KT recipients 6/2013-12/2017, we compared normally able recipients to recipients with self-reported hearing, visual, physical, or walking disabilities. We used hybrid registry-augmented Cox regression to assess the association between disability status and post-KT outcomes (death-censored graft failure and mortality) by adjusting for recipient, donor, and transplant characteristics in the national population (SRTR N=76,112).

Results: Among the 500 KT recipients in our cohort, 24.2% reported a disability: 9.6% had a hearing disability, 16.2% had visual disability, 8.9% had a physical disability, and 11.7% had a walking disability. Compared to recipients that did not report a disability, recipients who reported a disability were more often Black (51.2% vs. 33.8%, p<0.001), spent longer on dialysis (median 2.7 vs. 1.9 years), less often college educated (62.1% vs. 74.6%, p<0.01), less often employed (31.9% vs. 49.7%, p<0.001), and more often on public insurance (67.8% vs. 53%, p<0.01). After adjustment, visual disability was associated with a 3.98-fold higher risk of graft failure and walking disability was associated with a 4.12-fold higher risk of mortality. Other self-reported disabilities were not associated with transplant outcomes (all p>0.05, Table 1).

Conclusions: In this two-center cohort, 24% of KT recipients reported a disability. Compared to recipients without a reported disability, recipients with a visual disability were at higher risk of graft failure and recipients with a walking disability were at higher risk of mortality. These KT recipients might benefit from additional supportive care and monitoring post-transplant.

Outcomes of Kidney Transplant Patients with Atypical Hemolytic Uremic Syndrome Treated with Eculizumab: A Meta-Analysis

Maria Lourdes Gonzalez Suarez,[1] Charat Thongprayoon,[2] Michael A. Mao,[3] Wisit Cheungpasitporn.[1] *[1]University of Mississippi Medical Center, Jackson, MS; [2]Bassett Medical Center, Cooperstown, NY; [3]Mayo Clinic, Rochester, MN*.

Background: Kidney transplantation in patients with atypical hemolytic uremic syndrome (aHUS) is frequently complicated by recurrence of aHUS, often resulting in thrombotic microangiopathy (TMA) in the renal allograft and graft loss. We aimed to assess the efficacy of eculizumab in the prevention and treatment of aHUS recurrence after kidney transplantation.

Methods: Databases (MEDLINE, EMBASE and Cochrane Database) were searched through March 2018. Studies that reported outcomes of adult kidney transplant recipients with aHUS treated with eculizumab were included. Effect estimates from the individual studies were extracted and combined using random-effect, generic inverse variance method of DerSimonian and Laird. The protocol for this meta-analysis is registered with PROSPERO (International Prospective Register of Systematic Reviews; no. CRD42018089438).

Results: Fourteen studies (11 cohort studies and 3 case series) that consisted of 167 adult kidney transplant patients with aHUS who received eculizumab for prevention and/or treatment of post-transplant aHUS recurrence were included into the analysis. Among patients who received prophylactic eculizumab, the pooled estimated rates of aHUS

recurrence and allograft loss due to TMA were 7.9% (95%CI: 3.4%-17.5%, I^2 =0%) and 6.6% (95%CI: 2.8%-15.1%, I^2 =0%), respectively. Among patients who received eculizumab for treatment of post-transplant aHUS recurrence, the pooled estimated rates of allograft loss due to TMA was 24.1% (95%CI: 14.8%-36.7%, I^2 =10%). When the meta-analysis was restricted only to cohort studies with data on genetic mutations associated with aHUS, the pooled estimated incidence of allograft loss due to TMA after eculizumab therapy was 22.6% (95%CI: 13.2%-36.0%, I^2 =10%). We found no publication bias as assessed by funnel plots and Egger's regression asymmetry test (P values >0.05 for all analyses).

Conclusions: The use of eculizumab for prevention of aHUS recurrence after kidney transplantation seems to be more effective than treatment with eculizumab after post-transplant aHUS recurrence. Our findings suggest that kidney transplant patients with history of aHUS may have better allograft survival when prophylactic eculizumab is started at the time of kidney transplantation. Randomized control trials are important to further investigate this.

TH-OR130

Outcomes of Kidney Transplantation in AL Amyloidosis Patients

Avital Angel-Korman,[3] Lauren D. Stern,[1] Shayna Sarosiek,[3] John M. Sloan,[3] Gheorghe Doros,[2] Vaishali Sanchorawala,[1] Andrea Havasi.[3] *[1]Boston University School of Medicine, Brookline, MA; [2]Boston University, Boston, MA; [3]Boston University Medical Center, Boston, MA.*

Background: Therapies for AL amyloidosis have dramatically improved leading to longer patient survival (OS), however more patients reach end stage renal disease. Renal transplantation in patients with AL amyloidosis has been controversial due to lack of long term outcome data and appropriate and validated eligibility criteria.

Methods: We evaluated 52 patients with renal involvement who were followed in the Amyloidosis Center at Boston University Medical Center and underwent renal transplantation at various centers in the United States over the past 30 years.

Results: Median age at renal transplantation was 59.7 years (range 30.7-73.2) with 64% of transplantations from live donors. During a median follow up of 7.1 years (range 0-21), median OS from diagnosis was 16.6 years (range1-27.2), and from renal transplantation was 10.5 years. One, three and five-year graft survival were 92%, 87% and 80%, respectively. Patients with hematologic complete response (CR) or very good partial response (VGPR) at renal transplantation had a better OS than patients with partial response (PR) or no response (NR). Similarly, median time to graft loss in patients with CR/VGPR was 11.7 years (range 0.5-20.3) and with NR/PR was 5.3 years (range, 0.3-15) (HR 2.4, P=0.02). Seventeen patients (32%) had recurrent amyloidosis in the graft with median time from renal transplantation to recurrence of 3.7 years (range 0.3-11.9). Successful treatment mostly prevented graft loss in the setting of disease recurrence in the graft. There was a trend towards better OS and graft survival in patients who underwent high dose melphalan/stem cell transplantation at any time during their disease course vs. patients who were treated only with chemotherapy, however the difference did not reach statistical significance.

Conclusions: This is the largest study of patients undergoing renal transplantation for systemic AL amyloidosis to date. Carefully selected patients, particularly those who had achieved a CR and VGPR to plasma cell directed therapy at the time of renal transplantation demonstrated prolonged OS as well as graft survival. These good outcomes were independent of the type of treatment that was used for the underlying plasma cell dyscrasia. Overall and graft survival of the patients with AL amyloidosis were comparable to outcomes achieved in non-AL amyloidosis patients.

Kidney Organoids Generated through Heterochronic Recombination of Progenitors Show Nephron Segmentation and Vascular Connection with Host In Vivo

Ashwani K. Gupta, Michele J. Karolak, Leif Oxburgh. *Maine Medical Center Research Institute, Scarborough, ME.*

Background: In recent years procedures have been developed to differentiate human induced pluripotent stem cells (hiPSC) to renal tissues. In the present study, we investigated the potential of heterochronic recombination of hiPSC-derived kidney progenitors to increase tubular density in hiPSC-derived kidney organoids. Characterization of this technique included organoid engraftment, nephron segmentation, graft vascularization and perfusion in vivo.

Methods: hiPSC-derived kidney progenitors were treated with a WNT/β-catenin agonist for two days to induce epithelialization and were mixed with fresh progenitors, aggregated and cultured at the air-liquid interface. On day 9, these organoids were engrafted under the kidney capsule of NSG mice. Grafts were harvested after 3 weeks and nephron segmentation, vascularization and perfusion were evaluated.

Results: Heterochronic recombination of kidney progenitors induced robust tubulogenesis in kidney organoids compared with unmixed cells. Tubules stained with molecular markers for proximal and distal tubules and revealed segmentation. Podocytes ($Podxl^+$), stromal cells ($Meis1^+$) and endothelial cells ($CD31^+$) were abundant. Engrafted organoids showed differentiation of complex graft-derived glomeruli with vascular networks ($CD31^+$ $Endomucin^+$), podocytes ($Podxl^+$ $WT1^+$), mesangial cells ($Pdgfr\beta^+$), glomerular basement membrane ($Laminin^+$ Col I^+ Col IV^+), and juxtaglomerular cells ($Renin^+$). Proximal tubules (E $cadherin^-$ LTL^+), thick ascending limb of the loop of Henle ($Tamm\text{-}Horsfall\ protein^+$), distal tubule ($BRN1^+$), connecting tubule (E $cadherin^+$ $GATA3^-$ DBA^+), collecting duct ($Troma\text{-}1^+$ $GATA3^+$ DBA^+), and stromal cells ($Meis1^+$ $Pdgfr\beta^+$) were also present in the grafts. Engrafted organoids showed vascularization ($CD31^+$ $Endomucin^+$ SMA^+) and direct connections with host vasculature. All nephron structures and stromal cells in the graft were iPSC derived ($HuNu^+$), whereas endothelial cells were derived from the host ($HuNu^-$).

Conclusions: Heterochronic recombination of kidney progenitors results in vigorous differentiation of human iPSC-derived kidney tissue in vitro and in vivo.

Mechanistic Analysis of Flow-Enhanced Vascularization in Kidney Organoids

Kimberly Homan,[1] Navin R. Gupta,[5] Katharina T. Kroll,[1] David B. Kolesky,[1] Mark A. Skylar-Scott,[1] Tomoya Miyoshi,[3] Donald Mau,[4] M. Todd Valerius,[3] Thomas Ferrante,[4] Joseph V. Bonventre,[3] Jennifer A. Lewis,[2] Ryuji Morizane.[3] *[1]Harvard University, Cambridge, MA; [2]Harvard School of Engineering and Applied Sciences, Cambridge, MA; [3]Brigham and Women's Hospital, Boston, MA; [4]Wyss Institute, Boston, MA; [5]Brigham & Women's Hospital/Massachusetts General Hospital, Brighton, MA.*

Background: Multilineage cellular communication is implicated in organ development and cellular maturation. We have recently shown that fluidic shear stress (FSS) promotes the vascularization and maturation of kidney organoids derived from human pluripotent stem cells (hPSCs) *in vitro*. The addition of VEGF is deemed to facilitate vascular formation during kidney organoid development *in vivo*, however, mechanisms of organoid vascularization and maturation under FSS conditions *in vitro* have yet to be identified.

Methods: Early kidney organoids (pretubular aggregate stage) derived from hPSCs were subjected to FSS in printed millifluidic chips. During 10 days of perfusion at a FSS of 0.04 dynes/cm^2, they were given organoid media without growth factors or with either added VEGF (1, 10, 100 ng/mL) or Avastin (250 mg/mL, which inhibits VEGF). The degree, distribution, and maturation of $CD146^+$and $CD31^+$vascular networks were evaluated by immunostaining, RT-qPCR, and image analysis (ImageJ Angiotool plugin). Tubulo-vascular proximity was quantified by distance transformation and surface area contact calculations using Imaris software.

Results: FSS-induced vascularized organoids exhibit upregulated VEGF expression, compared to static controls. Interestingly, total vascular abundance was independent of VEGF signaling under high FSS; however, manipulation of the VEGF pathway reduced vascular invasion to glomeruli and tubulo-vascular surface area contact. Reducing the nephron epithelial communication with vasculature led to an increase in vascular branching and a reduction in average vessel length.

Conclusions: In developing kidney organoids under FSS, modifying the native VEGF intrinsic gradient results in random templating of the same amount of vasculature with less tubular and glomerular integration. Our results indicate that maintenance of intrinsic growth factor production may be critical to develop functional bioengineered kidneys from hPSCs *in vitro*, which may supplant current renal replacement therapies in the future.

Human Kidney Organoids Model Tubular Injury and Maladaptive Repair with Interstitial Fibrosis In Vitro

Navin R. Gupta,[1,2] Edgar Garcia,[1] Tomoya Miyoshi,[1] Pierre Galichon,[1] Koichiro Susa,[1] Lauren D. Walter,[3] Charles B. Epstein,[3] Joseph V. Bonventre,[1,2] Ryuji Morizane.[1,2] *[1]Brigham and Women's Hospital/Harvard Medical School, Boston, MA; [2]Harvard Stem Cell Institute, Cambridge, MA; [3]The Broad Institute, Cambridge, MA.*

Background: Kidney fibrosis is a unifying feature of diseases that cause progressive loss of kidney function. Upon severe or repeated tubular injury, the adaptive repair response transitions to being maladaptive and pro-fibrotic. Determining the mechanisms involved in maladaptive tubular repair is vital to developing anti-fibrotic therapies. Here we propose kidney organoids as a model for tubular adaptive and maladaptive repair with interstitial fibrosis in human tissue *in vitro*.

Methods: Kidney organoids were generated from hPSCs by our previously established protocol. Organoid maturation was determined by downregulation of developmental genes and upregulation of adult markers using immunostaining, qPCR, flow cytometry, and histone ChIP-seq for epigenetic analysis of chromatin remodeling overtime. Organoids with mature profiles were treated with repetitive cisplatin at 5μM. Cell proliferation, dedifferentiation, partial epithelial-to-mesenchymal transition (pEMT), G2/M cell cycle arrest, pro-inflammatory cytokine expression, myofibroblast activation and interstitial fibrosis were evaluated using a combination of Masson Trichrome, immunostaining, qPCR, and flow cytometry after each treatment.

Results: Organoids exhibited mature gene expression profiles by day 49 of differentiation. LTL^+ tubules exhibited adaptive repair responses following the initial cisplatin treatment, including proliferation ($Ki67^+$), dedifferentiation ($PAX2^+$ and $SOX9^+$), and pEMT (VIM^+ and $SNAIL1^+$). Upon repeated cisplatin injury, LTL^+ cells adopt a pro-fibrotic phenotype characterized by maladaptive repair processes, including further loss of an epithelial phenotype, cell cycle arrest in the G2/M phase, and upregulated pro-inflammatory cytokine expression, followed by tubular atrophy, the transdifferentiation of peritubular fibroblasts ($PDGFR\text{-}\beta^+NG2^-DESM^-$) and pericytes ($PDGFR\text{-}\beta^+NG2^+DESM^+$) into αSMA^+ myofibroblasts, and the advent of interstitial fibrosis (FN and COL1A1).

Conclusions: Human kidney organoids model the transition from adaptive to maladaptive repair in tubular epithelial cells with repeated injury. Human kidney organoids

enable the study of tubular repair, along the continuum from acute injury to fibrosis, and the screening of anti-fibrotic therapeutics in human kidney tissue.

Exo Utero Method to Regenerate Nephrons from Nephron Progenitor Cells in the Living Fetus

Shuichiro Yamanaka,[2] Yatsumu Saito,[2] Tsuyoshi Takamura,[2] Toshinari Fujimoto,[2] Susumu Tajiri,[3] Kei Matsumoto,[1,2] Takashi Yokoo.[2] *[1]The Jikei University School of Medicine, Tokyo, Japan; [2]The Jikei University School of Medicine, Tokyo, Japan, Tokyo, Japan; [3]The Jikei University School of Medicine, Tokyo, Japan., Minato-ku, Japan.*

Background: Kidney regeneration using native kidney development has been previously reported. We previously reported that neonephrons could be generated by transplanting nephron progenitor cells (NPCs) into the nephrogenic zone in mice and replacing exogenous cells with host cells. In this cell replacement method, the fetal kidney was used as a scaffold for regeneration. We postulated that direct transplantation of NPCs into the scaffold in utero may obtain a more suitable developmental environment for kidney regeneration. We tried an exo utero method for kidney regeneration was used to examine whether NPCs could be transplanted into the retroperitoneum near the fetal host kidney without fetal sacrifice in vivo, and the development of neonephrons was examined.

Methods: Using an exo utero method to dissect only the myometrial layer of the mouse fetus which has only one clear amnion, cells can be injected to the fetus in utero. This approach allows the fetus in the amniotic membrane to be returned to the uterus after cell transplantation. An exo utero method was used to transplant GFP-expressing NPCs into the retroperitoneum on E13.5. After cell transplantation, the fetus continued to develop in the mother's uterus for 6 days. Following cesarean section on E19.5, histopathological examination was performed to determine NPC differentiation into nephrons. To determine whether cell transplantation in the fetus had a negative effect on fetal growth, fetal body weight and crown-rump-length (CRL) were measured on E19 and compared with those of fetuses who did not receive NPC transplantation.

Results: Glomeruli derived from transplanted NPCs expressed the nephron differentiation markers podocin, nephrin, megalin and aquaporin 1. CD31-positive blood vessels were observed inside the glomeruli. There were no significant differences in body weight or CRL between the fetuses with and without NPC transplantation.

Conclusions: Transplantation of exogenous NPCs into the retroperitoneum using an exo utero method could differentiate into nephrons in vivo. This method, which did not adversely affect fetal growth, is potentially applicable to kidney regeneration using NPCs.

Dose Related Effects of Intra-Renal Autologous Mesenchymal Stem/Stromal Cell Infusion on Renal Hemodynamics, Function, and Cytokine Signaling in Human Atherosclerotic Renovascular Disease

Abdelrhman Abumoawad,[1] Ahmed Saad,[1] Christopher M. Ferguson,[1] Sandra Herrmann,[1] LaTonya J. Hickson,[1] Sanjay Misra,[2] Allan B. Dietz,[3] Lilach O. Lerman,[1] Stephen C. Textor.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Radiology, Mayo Clinic, Rochester, MN; [3]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN.*

Background: Preliminary data identify increased renal blood flow after intra-renal infusion of mesenchymal stem/stromal cells (MSC) in post-stenotic kidneys. The effects of cell dose on systemic effects and anti-inflammatory activity of autologous MSC in human renovascular disease (RVD) are poorly understood

Methods: We measured cortical and medullary blood flows (MDCT), GFR (iothalamate and eGFR), renal vein cytokine levels, BP, and tissue oxygenation (BOLD MR) in 21 human subjects with atherosclerotic RVD under controlled study conditions, before and 3 mo after MSC delivery. Autologous adipose-derived MSC were administered at 3 dose levels (1, 2.5 and $5.0x10^5$/MSC/kg, n=7 patients each) into one affected kidney, without vascular intervention. Cultured MSC were also studied in vitro..

Results: At the highest dose ($5x10^5$ cells/kg), systolic BP fell (140±11.8 to 128±8.18 mmHg, p<.01), as did urine protein (149±89 to 103±96 mg/dL, p<.01), while single kidney GFR rose (18±10.6 to 21±12.5 ml/min, p<.05). Serum creatinine and renal venous VEGF-A fell only in the highest dose (Figure), whereas VEGF-C and Angiopontin fell at all dose ranges. Increases in treated-kidney tissue oxygenation by BOLD MR were correlated with levels of hepatocyte growth factor secretion by MSC in vitro.

Conclusions: These data reinforce the capability of autologous MSC to improve the renal circulation in human RVD, and reveal their potential to improve renal function, decrease BP, and modify angiogenic signaling from post-stenotic kidneys. The observation that some beneficial effects are dose-dependent and related to in-vitro properties of MSC may serve to optimize this strategy and predict in-vivo efficacy.

Therapeutic Effects of Genome-Engineered Angiogenic or Anti-Inflammatory Factor Secreting-Mesenchymal Stem Cells in Mice with AKI

Hye-Jeong Park,[1] Min Jung Kong,[1] Hyo-Ju Jang,[1] Eui-Jung Park,[1] Hyo-Jung Choi,[1] Hyun Jun Jung,[2] Kwon Moo Park,[1] Tae-Hwan Kwon.[1] *[1]Kyungpook National University, Taegu, Republic of Korea; [2]NHLBI/NIH, Bethesda, MD.*

Background: Stem cell therapy has been proposed as a potential therapeutic strategy for acute kidney injury (AKI). By exploiting genome editing technology, we generated mesenchymal stem cells (MSCs) secreting angiogenic factor (angiopoietin 1: ANG1) or anti-inflammatory factor (erythropoietin: EPO) for therapeutic application in AKI.

Methods: To integrate each gene cassette into the safe harbor locus, AAVS1, of the human umbilical cord-derived MSCs (hUC-MSCs) chromosome, AAVS1-targeting Zinc Finger Nuclease (ZFN) system was exploited. For the application of stem cell therapy *in vivo*, a scaffold-free cell sheet system was established using a temperature-responsive polymer. AKI in C57BL/6 mice was established by bilateral renal pedicles occlusion for 30 min and monitored for additional 7 days after the clamps were removed.

Results: Junction PCR analysis demonstrated the ZFN-aided gene integration in hUC-MSCs. Flow cytometry and osteogenic and adipogenic differentiation assay revealed that genome editing did not affect the stemness. Protein measurement in conditioned media by ELISA and immunoblotting confirmed the production and secretion of each integrated gene product (ANG1 and EPO proteins). The *in vitro* angiogenic function of hUC-MSCs secreting ANG1 was further revealed by the increased cell migration and expression of MMP-9 and Tie-2 mRNAs in co-cultured HUVEC. As a control experiment, a mono-layered sheet of hUC-MSCs was applied to the mice kidney surface *in vivo*. Immunohistochemistry with anti-human nuclei antibody at 1 or 2 weeks after the application demonstrated that hUC-MSCs on the mice kidney surface were intact and specifically labeled. In mice subjected to bilateral renal ischemia and reperfusion, cell sheets of ANG1- or EPO-secreting hUC-MSCs applied to the kidney surface significantly ameliorated renal functional deterioration with lower BUN and creatinine levels, compared with sham control mice as well as mice treated with sheets of GFP-expressing hUC-MSCs. Moreover, treatment of EPO-secreting hUC-MSCs resulted in higher Hct levels.

Conclusions: A novel cell therapy of hUC-MSCs secreting ANG1 or EPO provides the therapeutic effects against AKI *in vivo*.

Bioprinting and Controlled Perfusion of 3D Vascularized Proximal Tubules on Chip

Neil Lin,[1] Sanlin Robinson,[5] Kimberly Homan,[2] David B. Kolesky,[2] Annie Moisan,[3] Jennifer A. Lewis.[4] *[1]Harvard University, Wyss Institute, Brookline, MA; [2]Harvard University, Cambridge, MA; [3]Roche, Basel, Switzerland; [4]Harvard School of Engineering and Applied Sciences, Cambridge, MA; [5]Havard University, Boston, MA.*

Background: Building three-dimensional human renal tissues that recapitulate native physiological functions is a grand challenge. To date, progress towards developing 3D proximal tubule (PT) on chip has resulted in significantly improved cell morphology and function, akin to that observed *in vivo*. However, absent a perfusable vasculature that is essential to sustained renal reabsorption, these microphysiological systems are unable to replicate key kidney functions, such as tubulovascular exchange.

Methods: Here, we report the bioprinting and characterization of a 3D vascularized proximal tubule (PT) on chip that contains two co-localized channels embedded within an engineered extracellular matrix (ECM). In our model, the co-localization of the independently addressable PT and vascular channels combined with the high permeability of our engineered ECM enables effective vectorial transport of solutes. Specifically, we quantitatively measured the vectorial transport of glucose and albumin using a closed-loop perfusion system.

Results: We demonstrated that glucose reabsorption from the PT lumen to the vascular lumen is substantially improved by their 3D lumen geometry and fluid flow. We also observed that the glucose reabsorption by the confluent epithelium is reduced upon administering Dapagliflozin (SGLT2 inhibitor). Finally, to explore a disease state, we

created a hyperglycemic condition by quadrupling the glucose level in the PT channel and studied its effect on confluent endothelium within the vascular channel. We found that hyperglycemia-induced endothelial dysfunction is also reduced by inhibiting glucose transporters in the PT channel.

Conclusions: We have created a 3D vascularized PT on chip model that exhibits renal reabsorptive functions *in vitro*, which is relevant for drug screening, mechanistic safety studies, and disease modeling.

TH-OR138

Endothelialization of Decellularized Porcine Kidneys Sustains In Vivo Perfusion in an Acute Porcine Model

Joseph S. Uzarski,[1] Senthuran Atputhanathan,[1] Dominique Seetapun,[1] Matthew L. Holzner,[3] Ron Shapiro,[3] Vikram Wadhera,[3] Sander Florman,[3] Jeff Ross,[2] Dylan Adamson.[3] Miromatrix Medical Inc. *[1]Miromatrix Medical Inc., Eden Prairie, MN; [2]Miromatrix Medical, Eden Prairie, MN; [3]Mount Sinai Medical Center, New York, NY.*

Background: The shortage of donor kidneys forces patients suffering from kidney failure to undergo dialysis as the only alternative to transplantation, the preferred therapy with lower morbidity and mortality rates. Recellularization of kidney extracellular matrix (ECM) scaffolds derived through decellularization is a promising strategy to produce humanized renal tissues for transplantation in a shorter time frame than donor kidneys may become available.

Methods: Porcine kidneys were decellularized via perfusion with mild detergents. The derived ECM scaffolds were repopulated with human umbilical vein endothelial cells (HUVECs) to endow the grafts with thromboresistance. Key metabolic markers were monitored to non-invasively assess cell proliferation, viability, and totality of vascular endothelialization. Re-endothelialized kidneys were functionally assessed by in vitro perfusion with heparinized porcine blood or in vivo anastomosis in an acute porcine implant. Primary epithelial cells were introduced to assess survival in co-culture.

Results: HUVECs engrafted in decellularized kidney scaffolds within both the arterial and venous vasculature. Daily metabolic analysis found that glucose consumption rate (GCR) directly correlated with graft perfusability, and grafts implanted at peak GCR (Fig 1A) sustained higher volumetric blood flow. Implanted grafts anastomosed to the porcine vasculature showed excellent perfusion of the vascular tree, as demonstrated by angiography (Fig 1B). Endothelialization sustained vascular patency during acute in vivo perfusion for up to 1 hour (Fig 1C). Co-culture of endothelialized grafts with epithelial cells showed dual survival in their respective vascular and nephron niches.

Conclusions: Effective engraftment and proliferation of human endothelial cells within porcine kidney scaffolds indicates that the renal ECM retains critical integrin adhesion sites. Sustained perfusion of endothelialized grafts during blood loops and acute implants represents an important step toward chronic transplantation of recellularized whole kidney grafts in human-scale preclinical models.

TH-OR139

A High-Throughput Microfluidic Model of Proximal Tubule with Active Transport Function

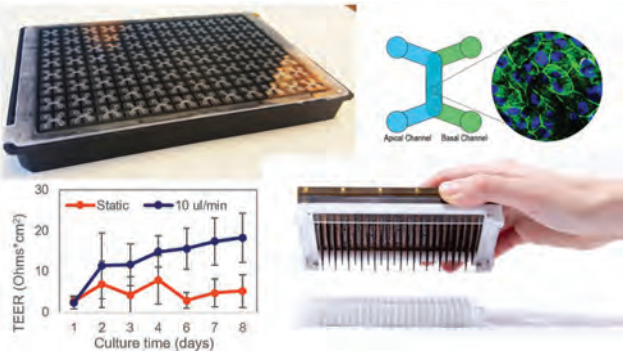
Else M. Vedula, Timothy J. Haggerty, Joseph L. Charest. *Draper, Cambridge, MA.*

Background: Models with kidney-specific function *in vitro* and high-throughput capability will speed kidney disease drug development. Microfluidic models control flow to cultured cells to generate tissue with kidney-specific function. However, high throughput is required for experiments accommodating many drug doses, assays, and biological variables. Microfluidic models have yet to achieve high throughput.

Methods: We developed an *in vitro* kidney model in a high-throughput microfluidic platform, PREDICT-96. PREDICT-96 co-cultured human renal proximal tubule epithelial cells (hRPTEC) and human microvascular endothelial cells (hMVEC) and characterized them via real-time trans-epithelial electrical resistance (TEER) and a high-content screening (HCS) approach quantifying ZO-1 expression, localization. Primary cilia, polycystin-1 (PC1), and transporter expression were characterized via confocal microscopy. Glucose reabsorption via SGLT2 and organic anion transport via OAT-1 were characterized using real-time imaging and spectrophotometric techniques.

Results: hRPTEC and hMVEC formed polarized tissue with barrier integrity and active, kidney-specific transport function. Flow increased TEER, hRPTEC thickness, primary cilia expression with co-localized PC1, and ZO-1 localization. Drug dosing modulated glucose reabsorption from the filtrate to vascular channel, indicating active kidney-specific function. OAT-1 expression and function were characterized to quantify uptake and excretion functions.

Conclusions: Microfluidic flow enhanced tissue structure/morphology, polarization, and function, resulting in *in vitro* tissue with kidney-specific function. Integrated TEER sensing and HCS-capable platform architecture supported real-time data collection. Microfluidic flow-conditioned tissue actively responded to drug dosing, indicating the ability of the model to quantify drug effects. The PREDICT-96 kidney model can generate kidney tissue, study renal toxicity, and evaluate disease progression *in vitro* to speed development of kidney therapeutics.



TH-OR140

Exposure to Fluid Shear Stress Enriches Tip Cell Populations in In Vitro Cultured Ureteric Bud Cells

Hiroshi Kimura,[1,3] Masaki Nishikawa,[4,3] Naomi Yanagawa,[4] Hiroko Nakamura,[1] Oak D. Jo,[4] Norimoto Yanagawa.[2,3] *[1]Tokai University, Hiratsuka, Japan; [2]VA Greater Los Angeles Healthcare System, North Hills, CA; [3]Department of Medicine, UCLA, Los Angeles, CA; [4]GLAVAHS at Sepulveda, North Hills, CA.*

Background: Most kidney cells are exposed to fluid shear stress (FSS) from either blood flow or urine flow. Previous studies have shown that changes in FSS may affect the function or induce injury of kidney cells. However, it remains unclear whether FSS influences kidney development when urinary flow starts in the embryonic kidneys, which occurs around embryonic age E15.5 in mouse. In this study, we evaluated the influence of FSS on *in vitro* cultured ureteric bud (UB) cells.

Methods: We used a pumpless microfluidic device, which offers the convenience of conducting parallel cell culture experiments without the need of cumbersome electronic driven equipment. We first validated the function of the device by both mathematical model and experimental measurements. UB cells dissected from E15.5 mouse embryonic kidneys were cultured in the pumpless microfluidic device and subjected to FSS for 48 hrs. Control UB cells were similarly cultured in the device and maintained under a no-flow condition.

Results: We found that the exposure to FSS for up to 48 hrs led to an increase in mRNA expression levels of UB tip cell marker genes (*Wnt11*, *Ret*, *Etv4*) with a decrease in stalk cell marker genes (*Wnt7b*, *Tacstd2*). In further support of the enrichment of UB tip cell population in response to FSS, we also found that exposure to FSS led to a remarkable reduction in the binding of lectin Dolichos Biflorus Agglutinin (DBA), which is a characteristic of UB tip cells.

Conclusions: Results of our present study show that exposure to FSS led to enrichment in UB tip cell populations. Since UB tip cells are known to be the proliferative progenitor cells that contribute to the branching morphogenesis of the collecting system in the kidney, our finding could imply an important link between the FSS from the initiation of urine flow and the development of the kidney.

FR-OR001

Relative Survival among Incident Patients on Home Versus In-Center Hemodialysis

Eric D. Weinhandl,[1,2] Kristine Kubisiak,[1] Debabrata Ray,[1] Allan J. Collins.[1,2] *[1]NxStage Medical, Inc., Victoria, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: Relatively little research has been aimed at outcomes among incident dialysis patients who undergo home hemodialysis (HHD). Percolating interest in transitional dialysis care may result in greater utilization of HHD during the first year of dialysis. We assessed relative survival among incident patients on HHD versus in-center hemodialysis (IHD).

Methods: We analyzed merged data from the United States Renal Data System. HHD patients initiated at-home treatment with the NxStage System One between January 1, 2006, and December 31, 2012, and within 3 months after dialysis initiation. IHD patients underwent treatment in a dialysis facility at 45 days after dialysis initiation. We followed HHD patients from the day of the first at-home treatment and IHD patients from the 45th day after dialysis initiation; all patients were followed until death, but for a maximum of one year. We used Cox regression to estimate the adjusted hazard ratio (AHR) of death for HHD versus IHD, with adjustment for age, race, sex, primary cause of end-stage renal disease, Medicaid enrollment, comorbid conditions, vascular access type, body mass index, estimated glomerular filtration rate (GFR), and hematocrit; all adjustment factors were ascertained from form CMS-2728.

Results: We identified 1773 HHD patients and 555,366 IHD patients. Relative to IHD patients, HHD patients were younger (mean age, 55.3 versus 60.3 years), more likely white (81.3% versus 62.7%), more likely male (71.1% versus 57.0%), less likely enrolled in Medicaid (9.5% versus 28.3%), and less likely to have heart failure (15.8% versus 31.3%). Mean estimated GFR was 10.5 and 10.4 mL/minute/1.73 m^2 in HHD and IHD patients, respectively. Survival after one year of follow-up was 91.7% and 81.4% in HHD and IHD patients, respectively. After adjustment, the AHR of death for HHD versus IHD was 0.77 (95% confidence interval, 0.66-0.91). Within age strata, corresponding AHRs of death were 0.56 (0.30-1.04) for 20-44 years, 0.74 (0.58-0.94) for 45-64 years, and 0.89 (0.70-1.13) for ≥65 years. Within estimated GFR strata, corresponding AHRs of death were 0.68 (0.51-0.90) for GFR <10 mL/minute/1.73 m^2 and 0.80 (0.65-1.00) for GFR ≥10 mL/minute/1.73 m^2.

Conclusions: Among incident patients, HHD is associated with better survival than IHD. Associations are attenuated with older age and higher estimated GFR at dialysis initiation.

Funding: Commercial Support - NxStage Medical, Inc.

FR-OR002

Efficacy of Mupirocin Prophylaxis for Prevention of Bacteremia in Home Hemodialysis Patients Using Buttonhole Technique for Cannulation

Frank Liu,[1,2] Upali Dutta,[1] Janice Herrera,[1] Joel Mallare,[1] Thomas Parker.[1] *[1]The Rogosin Institute, New York, NY; [2]Medicine/Nephrology, New York Presbyterian - Weill Cornell Medical Center, New York, NY.*

Background: Buttonhole cannulation (BC) technique is often preferred by home hemodialysis (HHD) patients but has been associated with a significant risk of bloodstream infection (BI). Despite a single center report suggesting a decrease in BI with topical mupirocin prophylaxis (MP), use of MP is not widespread, and indeed, many centers have shied away from using BC altogether. Because our patients have shown a strong preference for BC, we have continued to use BC but began mandating the use of MP in September 2013. This study is a retrospective chart review comparing the incidence of BI in patients using BC before and after we started MP.

Methods: To establish the number of treatments-at-risk for development of access-related BI, HHD billing records from January 2007 through March 2018 were reviewed to assess the total number of HHD treatments performed, as well as the access used for those treatments. Corresponding monthly QA reports were reviewed to identify episodes of BI attributable to the HD access, and confirmed by review of the underlying medical record independently by two clinicians.

Results: From January 2007 through March 2018, 133 patients performed 63,704 HHD treatments, encompassing 298.3 patient-years of observation. Of those, 50 patients performed 28,047 treatments using BC in the period prior to MP and 37 patients performed 14,702 treatments using BC in the period after MP. 21 episodes of access-related BI were observed, with 19 episodes occurring in 14 patients in the pre-MP period, and 2 episodes occurring in 2 patients in the post-MP period. Both patients who developed BI in the post-MP period admitted to non-adherence with MP at the time of BI. When analyzed by observation period, the odds ratio (OR) for BI without MP was 5 (95% confidence interval (CI) = 1.16 to 21.4; p=0.03). In an as-treated analysis, the OR for BI without MP was 21.9 (95% CI=1.3 to 361.7; p=0.03).

Conclusions: Topical mupirocin prophylaxis is effective in prevention of buttonhole cannulation-associated bloodstream infection. Buttonhole cannulation technique can be safely used for HHD if patients are adherent to a prophylaxis protocol.

FR-OR003

Increased Hemodialysis Frequency Is Associated with Improved Clinical Outcomes among Patients in Skilled Nursing Facilities

Eric D. Weinhandl,[1,2] Kathy Hocking,[3] Susan Markovich,[3] Scott Vavrinchik,[3] Allan J. Collins.[1,2] *[1]NxStage Medical, Inc., Victoria, MN; [2]University of Minnesota, Minneapolis, MN; [3]Affiliated Dialysis Centers, Glen Ellyn, IL.*

Background: In light of hemodynamic instability and frailty, dialysis patients who reside in a skilled nursing facility (SNF), either for short-term rehabilitation or long-term custodial care, may benefit from on-site, frequent hemodialysis (HD). We assessed whether increased HD frequency was associated with risks of death and hospital admission among SNF patients receiving care from a single dialysis provider in the Chicago area.

Methods: We assessed Medicare Parts A and B claims in 2011-2015 to identify HD patients at Affiliated Dialysis Centers (ADC). For each patient-week in 2011-2015, we tallied the number of HD sessions at ADC. We constructed an outcome-exposure model that measured associations of all-cause mortality, all-cause hospital admission (HA), and cause-specific (cardiovascular disease, infection, and other morbidity) HA risks during one calendar week with mean HD frequency during the preceding two calendar weeks, with frequency categorized as ≥4.5 vs. 2.5-4.4 HD sessions/week. We fit logistic generalized estimating equations, with adjustment for age, race, sex, primary cause of end-stage renal disease (ESRD), duration of ESRD, vascular access type, and calendar time.

Results: We identified 3619 unique patients and 78,047 patient-weeks. Mean age was 69.0 years; 59% and 34% of patients were white and black, respectively; 49% were female; and 53% dialyzed with a central venous catheter. Between 2011 and 2015, the percentage of two-week intervals with ≥4.5 HD sessions/week increased monotonically, from 9% in 2011 to 45% in 2015. We observed 641 deaths. The adjusted mortality risk ratio for ≥4.5 vs. 2.5-4.4 HD sessions/week was 0.66 (95% confidence interval, 0.52-0.83). The adjusted all-cause HA risk ratio for ≥4.5 vs. 2.5-4.4 HD sessions/week was 0.91 (0.81-1.02). Corresponding cause-specific HA risk ratios were 0.77 (0.62-0.97), 1.05 (0.88-1.24), and 0.86 (0.74-1.00) for cardiovascular disease, infection, and other morbidity, respectively. For all HAs excluding those attributable to infection, the adjusted risk ratio for ≥4.5 vs. 2.5-4.4 HD sessions/week was 0.83 (0.73-0.95).

Conclusions: In a large study of on-site HD in the SNF setting, increased HD frequency was associated with significantly lower risks of death and all hospital admissions excluding those attributable to infection.

A Comparison of Technique Survival in Canadian Peritoneal Dialysis and Home Hemodialysis Patients

Emilie Trinh,[1] James A. Hanley,[5] Annie-Claire Nadeau-Fredette,[2] Jeffrey Perl,[3] Christopher T. Chan.[4] *[1]McGill University Health Center, Montreal, QC, Canada; [2]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [3]St. Michael's Hospital, Toronto, ON, Canada; [4]Toronto General Hospital, Toronto, ON, Canada; [5]McGill University, Montreal, QC, Canada.*

Background: High discontinuation rates remain a challenge for both home hemodialysis (HHD) and peritoneal dialysis (PD). Our study aimed to compare the technique failure risks between HHD and PD in a Canadian cohort.

Methods: We studied adult patients who initiated either HHD or PD within 1 year of dialysis initiation between 2000-2012 in the Canadian Organ Replacement Register. Technique failure was defined as a transfer to any alternative dialysis modality for a period of ≥60 days. We compared technique survival between HHD and PD using a Fine and Gray competing risk model. Secondary outcomes assessed the trajectory of technique survival, the association of patient characteristics with technique failure, causes of technique failure and changes of technique failure rates over time

Results: 15,314 patients were treated with a home dialysis modality between 2000-2012: 14,461 on PD and 853 on HHD. The adjusted risk of technique failure was overall lower with HHD compared to PD (HR 0.79; 95% CI 0.69-0.90). However, comparisons varied over time (Figure 1a). During the first year of therapy, there was no significant difference in technique survival between HHD and PD (HR 1.13; 95% CI 0.94-1.36). Thereafter, the risk of technique failure was significantly lower with HHD. In PD and HHD, crude rates of technique failure were the highest during the first year of therapy (Figure 1b). Among HHD patients, rates were significantly lower subsequent to that. In contrast, the decrease in failure rates was not as pronounced among PD patients. Furthermore, the majority of home dialysis discontinuation occurred for medical reasons in PD (38%) while the majority of HHD patients experienced technique failure due to social reasons or inadequate resources (50%).

Conclusions: In this Canadian study of home dialysis patients, HHD was associated with superior technique survival compared to PD. However, causes and patterns of technique failure differed significantly among these modalities. Strategies to improve patient retention across all home dialysis modalities are needed.

Effect of Intensive Home Hemodialysis on Right Ventricular Systolic Pressure and Clinical Outcomes

Michael Y. Girsberger, Christopher T. Chan. *Toronto General Hospital, Toronto, ON, Canada.*

Background: Increased right ventricular systolic pressure (RVSP) is a marker of pulmonary hypertension in patients with end-stage kidney disease (ESKD). Our primary aim is to examine whether nocturnal home hemodialysis (NHD) will modify RVSP in ESKD patients. Our secondary aim is to ascertain the clinical consequence of normalization of RVSP.

Methods: We conducted a retrospective single center cohort study at the Toronto General Hospital including all patients between 1999 and 2017 with baseline and follow-up echocardiograms on intensive home hemodialysis followed for at least 1 year. Patients were categorized according to RVSP response at the end of follow-up: non-responders with increased RVSP and responders with normal RVSP. Multivariate and cox regression analysis were used to identify risk factors for increased RSVP and reaching clinical composite endpoint (death, cardiovascular hospitalisation, treatment failure), respectively.

Results: A total of 129 patients were included in the study with a mean follow-up of 4.1 years. 31% (40/129) of patients had increased RVSP (=/> 35 mmHg). 9 (10.1%) out of the 89 responders and 18 (45%) out of the 40 non-responders reached the composite endpoint of death, cardiovascular hospitalization or technique failure. Responder status is an independent predictor for reaching the composite endpoint and is associated with a survival benefit.

Conclusions: Increased RSVP is associated with adverse clinical outcomes in patients on intensive home hemodialysis.

Silicon Nanopore Membrane-Based Implantable Hemodialysis: A Preclinical Proof-of-Concept Study

Jarrett Moyer,[1] Jimmy Ly,[1] Nathan Wright,[1] Charles Blaha,[1] William H. Fissell,[2] Shuvo Roy.[1] *[1]UC San Francisco, San Francisco, CA; [2]Vanderbilt University, Nashville, TN.*

Background: Silicon nanopore membranes (SNM) are highly efficient biomimetic and blood-compatible slit-pore membranes. The high efficiency of the membrane enables hemofiltration and hemodialysis by utilizing cardiovascular perfusion pressure to circulate blood over the filters, enabling the prospect of a fully implanted hemodialysis cartridge. This alternative access strategy could offer a solution for patients with complicated conventional access, and lowers barriers to self-care home hemodialysis.

Methods: A 115 x 57 x 18 mm SNM-based parallel-plate hemodialyzer (SNMHD) was prototyped from polycarbonate and stainless steel. The device was implanted subcutaneously in the neck of a healthy Yucatan mini-pig and anastomosed to the carotid artery and jugular vein via ePTFE vascular grafts. Catheters to supply dialysate were tunneled subcutaneously and attached to the SNMHD. The animal was allowed to recover, and 3-hour hemodialysis sessions were performed on the day of surgery, and post-operative days 1, 2, and 3. Dialysate was recirculated in a counter-current fashion at 10-15 mL/min, and blood flow through the SNMHD was between 1.0-1.5 L/min, assessed by pulse wave Doppler ultrasound. Blood samples were collected at the initiation of dialysis, and dialysate sampled every hour to assess solute clearance over time. The animal was treated with daily aspirin and clopidogrel beginning three days before the implant, continuing throughout the post-operative period.

Results: The animal tolerated surgical implantation and subsequent dialysis sessions without complication. Blood flow through the dialyzer remained brisk throughout the three-day study. All dialysis sessions were completed as planned, via recirculation of normal saline through the dialysate catheters. Over the course of the study, normalized creatinine and urea clearances ranged from 11-42 mL/min/$m^2$and 26-74 mL/min/m^2, respectively. Albumin concentration in the dialysate remained below the detection limit throughout the study.

Conclusions: We demonstrated preclinical feasibility of an implantable, pumpless SNM-based hemodialyzer. Further development and refinement of the SNMHD could provide an alternative method for hemodialysis access and facilitate frequent in-home dialysis.

International Trends in Mortality Soon after Switch from Peritoneal Dialysis to In-Center Hemodialysis: Results from the INTEGRATED Study Group

Nidhi Sukul,[1] Purna Mukhopadhyay,[6] Anneke Kramer,[10] Kitty J. Jager,[5] Mark Lambie,[11] James A. Sloand,[12] Wim Van Biesen,[9] Simon J. Davies,[13] Christopher T. Chan,[4] Jeffrey Perl,[7] David W. Johnson,[8] Bruce M. Robinson,[2] Ronald L. Pisoni,[2] Rajiv Saran,[1] Annie-Claire Nadeau-Fredette.[3] *[1]University of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [4]Toronto General Hospital, Toronto, ON, Canada; [5]Academic Medical Center, Amsterdam, Netherlands; [6]Arbor Research Collabortaive for Health, Ann Arbor, MI; [7]St. Michael's Hospital, Toronto, ON, Canada; [8]Princess Alexandra Hospital, Brisbane, QLD, Australia; [9]Ghent University, Ghent, Belgium; [10]ERA-EDTA Registry, Amsterdam, Netherlands; [11]Keele University, Crewe, United Kingdom; [12]Baxter Healthcare Corporation, Northbrook, IL; [13]University Hospital of North Midlands, Stoke-on-Trent, United Kingdom.*

Background: Switching between dialysis modalities is common among patients (pts) with end-stage kidney disease (ESKD) and has been shown to be associated with adverse outcomes. This international registry study describes mortality rates after switch from peritoneal dialysis (PD) to in-center hemodialysis (HD).

Methods: Using four longstanding international registries (ANZ, CORR, ERA, USRDS), and with support from the NIDDK, this study analyzed incident PD pts, defined as starting PD within 180 days of ESKD incidence, who switched from PD to HD for ≥1 day. Pts were grouped into 3 cohorts by year of ESKD incidence (2000-2004, 2005-2009, 2010-2014). Crude mortality rates (per 100 patient-years [PY]) were calculated for the first 180 days after switch, with patients censored on the date of death, transplant, loss-to-follow up, or study end-date.

Results: In each registry, (1) mortality rate was highest during the first 30 days after switch to HD, subsequently declining to a stable rate by 120 to 180 days (Figure); (2) mortality rate decreased from the earliest to the most recent cohort, though remained high soon after switch to HD (Figure).

Conclusions: Transition from PD to HD is associated with high mortality rates internationally, especially during the first 30-day period. The lower mortality rates in recent years may reflect more timely transition and/or improved peri-transition care. Future studies should evaluate optimal timing of switch, as well as modifiable predictors of post-switch mortality, to increase the likelihood of successful transition and to improve clinical outcomes.

Funding: NIDDK Support

Peritoneal Dialysis Utilization in US markets and Associated Mortality Rate Ratios for Peritoneal Dialysis Versus Hemodialysis

Kristine Kubisiak,[1] Debabrata Ray,[1] Allan J. Collins,[1,2] Eric D. Weinhandl.[1,2]
[1]NxStage Medical, Inc., Victoria, MN; [2]University of Minnesota, Minneapolis, MN.

Background: In the United States, peritoneal dialysis (PD) is associated with lower mortality risk than in-center hemodialysis (HD) during the first year of dialysis. However, increased utilization of PD in a local area may move higher-risk patients from HD to PD, thus attenuating the mortality rate ratio (MRR). We assessed the influence of PD utilization in US markets on MRRs for PD versus HD.

Methods: We analyzed data from the United States Renal Data System. We identified incident dialysis patients in 2006-2013 and retained patients in markets with ≥500 patients. For each area, we calculated the percentage of patients on PD within 3 months of dialysis initiation. Using Poisson regression, we assessed the association of that percentage with the mortality rate between 3 and 36 months after dialysis initiation, without censoring for modality change and with fixed effects for markets.

Results: The cohort included 586,718 incident dialysis patients in 236 markets. Overall PD utilization was 8.8%. Market-specific mortality rates in PD and HD patients are displayed. Market-adjusted MRRs for PD versus HD were 0.56 with local PD utilization of 2-3% (number of markets, 12), 0.55 with utilization of 4-5% (27), 0.58 with utilization of 6-7% (47), 0.61 with utilization of 8-11% (90), 0.65 with utilization of 12-15% (42), 0.64 with utilization of 16-19% (11), and 0.77 with utilization of ≥20% (7). Compared to the market-adjusted MRR with local PD utilization of 2-3%, only the MRR with utilization of ≥20% was significantly different ($P < 0.01$).

Conclusions: Across a gradient of local PD utilization from 2% to 20%, MRRs for PD versus HD are similar. Expanded utilization of PD in incident dialysis patients may have limited negative effect on population survival.

Peritoneal Fluid Cell Free DNA Is a Versatile Analyte of Peritonitis

John R. Lee,[1] Vesh Srivatana,[2] Philip Burnham,[3] Amanda D. Renaghan,[1] Xunxi S. Guo,[1] Lars Westblade,[1] Emmanuel Y. Edusei,[1] Jeffrey I. Silberzweig,[2] Shady Y. Albakry,[1] Matthew Magruder,[1] Manikkam Suthanthiran,[1] Iwijn De Vlaminck.[3] *[1]Weill Cornell Medicine, New York, NY; [2]The Rogosin Institute, New York, NY; [3]Cornell University, Ithaca, NY.*

Background: Culture negative peritonitis is common in peritoneal dialysis (PD) patients, especially in the setting of recent antibiotic use. We investigated whether sequencing cell free DNA (cfDNA) extracted from peritoneal fluid supernatants can identify the suspected causative agent(s) in cases of peritonitis.

Methods: We recruited 7 PD subjects: 3 subjects had peritonitis and 4 subjects did not have evidence of peritonitis; and we collected 16 peritoneal fluid specimens. cfDNA was isolated using a Qiagen Circulating Nucleic Acid Kit and a single stranded library preparation was constructed for each specimen. The library was sequenced using an Illumina Next-Seq instrument (75 base pair by 75 base pair). Pathogen identification was performed using the bioinformatics program, GRAMMy.

Results: We obtained approximately 10 million cfDNA reads per specimen. Three PD subjects had an episode of culture confirmed peritonitis (*Klebsiella pneumoniae*, *Staphylococcus aureus*, and *Staphylococcus epidermidis*). cfDNA profiling identified the organisms in all 3 cases and importantly on subsequent days after antibiotic administration which had corresponding same day cultures that were negative. One of the subjects subsequently developed another episode of suspected peritonitis. The subject was treated for peritonitis with intraperitoneal antibiotics, but the peritoneal fluid cultures on admission were negative. The subject continued to have abdominal pain despite intraperitoneal antibiotics. The subject was suspected to have cholecystitis and cullture from a percutaneous cholecystotomy 4 days after admission grew *Enterococcus faecium* and *Parabacteroides distasonis*. cfDNA profiling of peritoneal fluid detected *Enterococcus faecium* and *Parabacteroides distasonis* on admission.

Conclusions: Our pilot data support the use of cfDNA profiling of peritoneal fluid to investigate peritonitis, especially in the setting of antibiotic use, and potentially as a method to investigate occult infections in abdominal organs.

Nanoparticles of Lipids with Paclitaxel Reverse Inflammation and Peritoneal Fibrosis in the Peritoneal Fibrosis Model in Uremic Rats

Elerson Costalonga,[1] Rafael Pepineli,[2] Raul C. Maranhão,[3] Irene L. Noronha.[2]
[1]School of Medicine, University of Sao Paulo, São Paulo, Brazil; [2]University of Sao Paulo, Sao Paulo, Brazil; [3]Instituto do Coração do HCFMUSP, Sao Paulo, Brazil.

Background: Increased cellular proliferation and inflammation of the peritoneal membrane (PM) are complications of long term peritoneal dialysis leading to peritoneal fibrosis (PF). Paclitaxel, a potent antiproliferative drug, has therapeutic efficacy, limited by toxicity. Nanotechnology enabled drug release systems that can concentrate the active drug on target tissues. LDE, a LDL similar nanoparticle, was associated to Paclitaxel (NanoPACLI) in order to reduce drug toxicity. NanoPACLI binds to LDL receptors, which are overexpressed on the cell surface of inflamed tissues. In this study, the effects of NanoPACLI administration in a model of experimental PF associated to uremia were analyzed.

Methods: Uremia was induced in male Wistar rats fed with adenine-containing diet during a period of 21 days. Injections of chlorhexedine gluconate (CG) were administrated intraperitoneally (IP) to induce PF. Rats (n=27) were divided into 3 groups: **Control**, normal rats receiving saline injections; **PF/CKD**, uremic rats receiving CG injections; **PF/CKD-NanoPACLI,** uremic rats with PF receiving NanoPACLI injections (IP; 4mg/kg every 3 days). The NanoPACLI treatment was initiated 7 days after PF induction. Euthanasia was performed on day 21. PM thickness, ultrafiltration (UF), inflammatory cell infiltration, and cytokine expression were analyzed.

Results: NanoPACLI significantly decreased peritoneal thickness, prevented UF failure, reduced inflammatory cellular infiltration as well as cytokine concentration in the PM.

Conclusions: NanoPACLI administration was effective in inhibiting the progression of PF and preserving UF in a model of established PF in uremic rats. These findings may be related to the anti-inflammatory effects of paclitaxel delivered locally by NanoPACLI.

Effects of NanoPACLI on PF model in uremic rats

Reducing the Incidence of Post CABG AKI by Early Intervention Guided by Novel Urinary Biomarker (TIMP-2, IGFBP-7): An Institutional Experience

Abhinav K. Tiwary,[1] Barbara A. Greco,[2] Michael J. Germain,[3] Daniel Engelman,[4] Krishna A. Agarwal,[5] Armand Golchin,[5] Cheryl Crisafi.[5] *[1]Nephrology, UMMS-Baystate, Springfield, MA; [2]Renal and Transplant Associates of New England, Springfield, MA; [3]Renal and Transplant Assoc of New England, Hampden, MA; [4]Baystate Medical Center, Springfield, MA; [5]UMMS-Baystate, Chicopee, MA.*

Background: AKI post cardiac surgery occurs in up to 25% of patients: KDIGO AKI Stage 1 (30%), Stage 2 (10-15%), Stage 3 (2-5%), RRT (1%) and adversely affects prognosis, prolongs hospital stay and increases readmission rate. KDIGO guidelines recommend preventative measures in patients at high risk for developing AKI. In two multicenter studies of critically ill patients, NephroCheck (NC), urinary tissue inhibitor of metalloproteinases-2 (TIMP2) and insulin-like growth factor-binding protein 7 (IGFBP7), was validated for risk stratification for moderate-severe AKI. These markers are believed to reflect renal tubular epithelial cell response to stress and can identify patients at risk before injury occurs allowing for interventions to prevent AKI

Methods: Urinary NC was measured in CABG pts (n = 98) at our institution the morning after surgery. All pts with NC > 0.3 (moderate positive) received a modification of the KDIGO support measures. For NC > 0.6 (high positive), nephrology consultation was added. Patients with preoperative CKD were excluded. AKI was defined as rise in creatinine by 0.3 from baseline until hospital discharge. Interventions included goal-directed therapy for optimizing volume status, hemodynamics and renal perfusion pressure, raising the PAD pressure to 14-16 using balanced crystalloid, instituting inotropes for depressed cardiac function, limiting use of diuretics, avoidance of RAAS inhibitors, NSAIDs, and nephrotoxins, extending duration of hemodynamic monitoring, and using a higher transfusion threshold

Results: The AKI incidence (STS registry stage 3 KDIGO) prior to our study was 2.36 %. During the 6-month period using NC, the incidence of Stage 3 AKI fell to 1.25%. One false positive test was seen. One pt with a positive NC had a 2-hour UF post operatively; no other patients required RRT

Conclusions: The use of NC, a urinary biomarker for renal stress, in combination with rapid renal supportive interventions resulted in a 47% relative reduction in AKI in our institution in post CABG patients.

FR-OR012

Preventing AKI and Improving Outcome in Critically Ill Patients Utilising Risk Prediction Score (PRAIOC-RISKS) – A Pilot Study

Tarek S. Abdelaziz, Wessam M. Hussin, Mohamed S. Elyamny, Moataz Fatthy, Ragai Fouda, Yasser M. Abdelhamid. *Kasr Alaini Hosp-Cairo university, Giza-Cairo, Egypt.*

Background: Early detection and management of AKI in medical ICU is an unmet goal. Our study used a risk score to identify patients at high risk of developing AKI and apply timely preventive measures.

Methods: The study was run at two separate medical intensive care units. A recently validated and published risks score, developed by Malhotra and colleagues was used. A risk score was applied to all patients admitted to the ICU during the study period. Eligible patients were adults, who had mental capacity and who did not have AKI at time of recruitment. Patients who had established AKI at the time of recruitment were excluded from the study. In the (observation) ICU, patients received the standard care. In the (intervention) ICU, high risk patients (risk score ≥5) had very early nephrology review. A package of standardized recommendations was implemented. Measures included optimizing fluid balance, mean arterial pressure, cessation and avoidance of potential nephrotoxic medications and optimal sepsis management. The primary outcome was the incidence of AKI.

Results: During 8 months, we recruited 98 patients in the intervention arm and 108 patients in the observation arm. Baseline characteristics are shown in table 1. There was statistically significant difference in AKI incidence between the two groups (26% in the observation group versus 11% in the intervention group, p=0.002). 30 day-mortality was lower in the intervention group but not statistically significant (25% in the intervention arm versus 32% in the observation arm, p=0.35).

Conclusions: It was feasible to apply very early nephrology intervention to critically ill patient at high risk of developing AKI. The incidence of AKI was significantly lower in the intervention group. Multicentre studies are needed.

	Intervention	Observation	p value
Age (years)	48.01	51	0.23
Female sex n (%)	54(55%)	63(58%)	0.740
Basline creatinine (mg/dl)	1.16	1.07	0.315

Community AKI Reporting Improves Longer-Term Patient Outcomes

Seema Jain,[2,1] Jane E. Manning,[1] Bhrigu Raj Sood.[2,1] *[1]Epsom And St. Helier University Hospitals, Epsom, United Kingdom; [2]South West Thames Renal Unit, Carshalton, United Kingdom.*

Background: More than half a million patients develop AKI in England per year. Two-thirds of these occur in the community. AKI episodes have long-term implications with regard to morbidity and mortality. To improve detection of AKI in the community, automated detection systems have been developed to generate an 'AKI Alert' alongside blood test reports. In this study, we assess the outcomes of patients 3 years after the episode of AKI was detected.

Methods: AKI alerts were generated using the UK national AKI algorithm. Only blood tests done in the community were considered. 3-year outcomes were analysed for patients with AKI alerts in December 2014. Worsening renal function was defined as an increase in CKD stage by 1 or more.

Results: 79 AKI alerts were issued over this time period. Of these, 9 were excluded from analysis as 3 were repeat alerts and data was missing for 6. The median age of the patients in which AKI was detected was 80 (Min 22, Max 94). 45 patients had pre-existing CKD with 43% of the total cohort having an eGFR 30-60 and 21% having an eGFR of less than 30. 19 of the 70 alerts were incorrect with 95% overstating the stage of AKI as defined by KDIGO criteria. In cases when AKI was reported correctly, 70% of patients died or had worse renal function 3 years after the episode of AKI. In 71% of cases where an episode of AKI was detected by the algorithm, the alert led to a repeat blood test within 4 weeks. However, in the patients that did not have a repeat blood test in this time frame, there was a higher proportion of falsely reported AKI (45% versus 16%). This might be expected as the clinician may be less likely to repeat the test if deemed not to be a true episode of AKI. Patients in which the alert resulted in a repeat blood test in 4 weeks had a lower incidence of worsening renal function (40% vs 55%) and a composite outcome of death or worsening renal function (69% vs 73%) at 3 years.

Conclusions: A high proportion of patients who have an incidence of 'community' AKI go on to develop worsening CKD or death within 3 years. In cases when the AKI alert led to further investigation, there was a lower incidence of death and progressive renal dysfunction compared to cases where no action was taken. This suggests that a community blood test-based AKI alert system leads to longer lasting improved patient outcomes.

FR-OR014

Impact of Intensive Glycemic Control in the Development of AKI after Cardiac Surgery: A Randomized Clinical Trial

Eduesley Santana-Santos,[1] Maria De Fatima Vattimo,[2] Cassiane D. da Fonseca,[3] Kleyton A. Bastos,[4] Andreia F. Menezes.[4] Grupo Interdisciplinar de Estudos em Cuidados Críticos - GIEsCC *[1]Nursing Department, Federal University of Sergipe, Aracaju, Brazil; [2]Medical and Surgical Departament, School of Nursing University of Sao Paulo, Sao Paulo, Brazil; [3]Nursing School, Federal University of Sao Paulo, Sao Paulo, Brazil; [4]Federal University of Sergipe, Aracaju - Sergipe, Brazil.*

Background: Hyperglycemia is directly linked to higher rates of morbidity and mortality in hospitalized patients and is recognized as an important risk factor for postoperative complications. We performed a randomized controlled trial to evaluate the impact of an intensive glycemic control strategy in the occurrence of acute kidney injury in patients undergoing cardiac surgery.

Methods: Were included patients who presented blood glucose greater than 200 mg/dl in the first 6 hours of admission to the ICU. Patients aged less than 18 yo, diagnosed with congenital heart disease and heart transplantation were excluded. The patients were allocated in one of the groups: conventional group (CG), glucose target between 140 and 180 mg/dl and the intensive group (IG), glucose target between 90 and 110 mg/dl. The primary endpoint was AKI defined according with KDIGO criteria. The secondary outcomes were mortality, need for dialysis, renal function recovery, hypoglycemia, ICU discharge, length of stay in ICU.

Results: Were included 95 patients, 36 (37.9%) in the IG and 59 (62.1%) in the CG. In the comparison between groups, no significant difference was observed in relation to the surgical risk (p = 0.511) and the risk for acute kidney injury (p = 0.962), measured by the EuroSCORE and Cleveland Clinic Score, respectively. Using vasoactive drugs was higher in the IG as compared to CG (97.2% vs. 83.1%; p = 0.047). There was no difference in the incidence of AKI in IG, when compared with CG (61.1% vs. 49.2%; p = 0.294, respectively). Nevertheless, the return of kidney function to the basal values was smaller in the IG as compared to CG (41.7% vs. 69.5%; p = 0.010, respectively). There was no found any difference between the groups in relation to mortality (p = 0.066), need for dialysis (p = 0.364) and episodes of hypoglycemia (p = 0.151). There was a higher number of ICU discharges in the CG, when compared with IG (98.3% vs. 86.1%; p = 0.028, respectively) as well as shorter length of stay in the ICU (4.2 ± 3.0 vs. 5.7 ± 4.2; p = 0.046, respectively).

Conclusions: The intensive glycemic control strategy used in this study was not associated with decrease in the incidence of acute kidney injury in patients undergoing cardiac surgery also influenced negatively in secondary outcomes.

FR-OR015

One-Year Mortality Follow-Up in Subjects Treated with QPI-1002 at Risk of AKI Following Cardiac Surgery (CS)

Brown,[9] A. Patel,[10] P. Chan,[11] D. P. Cafaro,[12] Yuval Mathews,[14] D. Rothenstein,[15] Elizabeth C. Squiers.[13] QRK209 AKI Study Group *[1]Quark Pharmaceuticals, Inc, Fremont, CA; [2]Charité Universitätsmedizin Berlin, Berlin, Germany; [3]Quark Pharmaceuticals, Inc, Fremont, CA; [4]McLaren Northern Michigan, Petoskey, MI; [5]University of Heidelberg, Heidelberg, Germany; [6]Duke University Medical Center, Durham, NC; [7]McMaster University, Hamilton, ON, Canada; [8]West-German Heart and Vascular Center Essen, University Duisburg-Essen, Essen, Germany; [9]New Brunswick Heart Centre, Saint John, NB, Canada; [10]Quark Pharmaceuticals, Inc, Fremont, CA; [11]Quark Pharmaceuticals, Inc, Fremont, CA; [12]Quark Pharmaceuticals, Inc, Fremont, CA; [13]Quark Pharmaceuticals, Inc, Fremont, CA; [14]Quark Pharmaceuticals, Inc, Nes Ziona, Israel; [15]Quark Pharmaceuticals, Inc, Nes Ziona, Israel*.

Background: QPI-1002 (QPI), a siRNA targeting p53, is being developed for prevention of Delayed Graft Function (DGF) (NCT#02610296) and for reduction of acute kidney injury (AKI) and its consequences following CS. In a large global Phase 2 double-blind study (N=341: QPI=165, Placebo (PL)=176) (NCT#02610283), QPI reduced the incidence, severity and duration of AKI and reduced the proportion of subjects with major adverse kidney events (MAKE) at Day 90 as previously reported (ASN 2017 Abstract SA-OR124).

Methods: For the primary study, deaths were recorded through Day 90 and causes of death adjudicated by medical dictionary for regulatory activities (MedDRA) coding in a blinded fashion by the medical monitor and safety physician. Longer term mortality was collected at Day 365

Results: Deaths: 22/176 subjects receiving PL and 13/165 subjects receiving QPI died within 365 Days after receiving study drug (p=0.1713). Causes of death were coded to System organ class (SOC): Cardiac Disorders system (3QPI/3 PL), General disorders, (1QPI/5 PL), Infectious disorders (4QPI/4PL), Neoplasm (1PL), Nervous system disorders (2PL), Respiratory disorders (2QPI/2PL), Metabolism (1QPI), Vascular (1QPI) and Not Reported/Unknown(1QPI,5PL). None of the deaths were reported as related to study drug. Eighteen subjects (10 PL and 8 QPI) died within 90 days and 17 subjects (12 PL and 5 QPI) died between D90 and D365.

Conclusions: The results indicate a survival trend through Day 365 in favor of QPI treatment. Additional studies are required to confirm these findings.

Mortality Outcomes Related to Acute Declines in eGFR following RAAS Inhibition in Patients with Heart Failure

Wendy I. McCallum,[1] Hocine Tighiouart,[1] Elaine Ku,[2] Deeb N. Salem,[1] Mark J. Sarnak.[1] *[1]Tufts Medical Center, Boston, MA; [2]University of California San Francisco Medical Center, San Francisco, CA.*

Background: Blockade of the renin-angiotensin-aldosterone system (RAAS) is beneficial for cardiovascular outcomes in heart failure with reduced ejection fraction (HFrEF). However, it is associated with acute declines in estimated glomerular filtration rate (eGFR). Whether the benefit of RAAS inhibition persists for all magnitudes and timing of acute declines remains unclear.

Methods: We performed a retrospective analysis of the Studies Of Left Ventricular Dysfunction (SOLVD) trial, in which patients with HFrEF were randomized to enalapril vs placebo. Multivariable Cox models were used to evaluate the association of % eGFR change from baseline to three follow-up time points (2 weeks, 6 weeks, 12 months) with mortality. We tested for an interaction between treatment group and % eGFR decline. In effort to separate eGFR decline secondary to RAAS inhibition from eGFR decline due to other causes, we also calculated the mortality hazard ratios for enalapril and placebo using the reference point of 0% eGFR decline on placebo.

Results: Using the 2-week follow-up time point, 6,031 participants were included in the analysis (n=3,015 in the enalapril group, n=3,016 in placebo). Compared to placebo, enalapril was associated with a lower hazard of mortality at all levels of eGFR decline, with no significant interaction between treatment assignment and eGFR decline (Figure A). When compared to patients randomized to placebo with 0% eGFR decline, up to 20% decline in the enalapril group was still associated with a lower hazard of mortality (Figure B). Declines of >20% in placebo had higher hazard of mortality compared to placebo with 0% decline, but similar declines in the enalapril group were not. Results were consistent using the time points of 6 weeks and 12 months.

Conclusions: Enalapril decreases mortality at all levels of eGFR decline when compared to placebo. In patients with HFrEF, ACE inhibitors should be continued even if there is an acute decline in GFR up to 20%.

Thrombotic Microangiopathy Frequency in Patients with Atypical HUS: Discontinuing vs Remaining on Eculizumab Treatment

Gema Ariceta,[6] Gianluigi Ardissino,[1] Lisa Sartz,[2] Fadi Fakhouri,[3] Christoph Gasteyger,[4] Imad Al-Dakkak.[5] *[1]Center for HUS Prevention, Control and Management, Milano, Italy; [2]Skåne University hospital, Lund, Sweden; [3]Centre Hospitalier Universitaire de Nantes, Nantes, France; [4]Alexion Pharma GmbH, Zurich, Switzerland; [5]Alexion, Lexington, MA; [6]Hospital Universitari Vall d'Hebron, Barcelona, Spain.*

Background: Atypical hemolytic uremic syndrome (aHUS) is characterized by thrombotic microangiopathy (TMA). Eculizumab (Ecu), a C5 inhibitor, is the first approved treatment for patients (pts) with aHUS. Using data from the Global aHUS Registry, the largest database of patients with aHUS, we report TMA rate in pts receiving ongoing Ecu vs those who discontinued Ecu.

Methods: Pts enrolled in the non-interventional Global aHUS Registry (NCT01522183) up to 1 January, 2018 were included in this study of real-world data. Pts with unknown treatment status were excluded from this analysis. Additionally, pts with a cobalamin deficiency or diacyl glycerol kinase-ε mutation were excluded from the Ecu treated group. Data were stratified according to Ecu treatment status and descriptive statistics on TMA rate were calculated.

Results: Of the 1475 pts eligible for this analysis, 532 pts were never treated with Ecu and 943 pts were treated with Ecu. Among the latter, 682 pts remained on Ecu without discontinuing treatment, 218 pts discontinued Ecu without restarting and 43 pts discontinued and restarted Ecu. Overall, pts who remained on Ecu had a lower TMA rate than pts who were never treated and pts who discontinued treatment (3.6, 27.5 and 10.7 per 100 pt-years, respectively; Table).

Conclusions: In this, the largest cohort ever analyzed in a real-world, non-randomized setting to address the question of treatment maintenance in aHUS, pts who continued to receive Ecu had a substantially lower risk of TMA than those who discontinued or never received Ecu.

Funding: Commercial Support - Alexion Pharmaceuticals

Clinical characteristics per eculizumab treatment status

Dutch Initiative to Improve Therapy and Economize Healthcare in Atypical HUS

Kioa L. Wijnsma,[1] Caroline Duineveld,[2] Jack F. Wetzels,[3] Nicole Van De Kar.[4] on behalf of the Dutch national aHUS working group *[1]Pediatric Nephrology, Radboudumc, Radboud Institute for Molecular Life Sciences, Amalia Children's Hospital, Nijmegen, Netherlands; [2]Radboudumc, Nijmegen, Netherlands; [3]Radboud University Medical Center, Nijmegen, Netherlands; [4]UMC St. Radboud Nymegen, Nijmegen, Netherlands.*

Background: With the introduction of eculizumab, a new era began for patients with atypical hemolytic uremic syndrome (aHUS); a rare but severe form of thrombotic microangiopathy (TMA). Although the results were promising, a worldwide debate started regarding optimal treatment strategy. Lifelong treatment with this highly expensive orphan drug was advised, despite any evidence. In the Netherlands, an unique and challenging initiative was undertaken by the national working group aHUS, comprising a delegation of (pediatric) nephrologists of all academic hospitals. In 2016, the new Dutch guideline for the diagnostics and treatment of aHUS, drafted by this working group, was implemented. This guideline advocates a restrictive treatment regimen and is monitored by the national, observational, CUREiHUS study. Here we present first preliminary results.

Methods: All known and suspected aHUS patients up till September 2017, were discussed in the working group and included. Patients received plasma therapy and/or eculizumab following the guideline and therapy was evaluated and tapered when patients were stable and in remission. Follow up data were only available from those registered in CUREiHUS study.

Results: In total, 69 patients with TMA have been discussed of which 44 new patients with TMA. In 27 out of the 44, aHUS was suspected and eculizumab was initiated in 25 patients. In the remaining 17 patients, other diagnoses explanatory for the TMA were present, hence no eculizumab treatment was started. Of the 32 patients included in the CUREiHUS study, therapy was adjusted in all. Only 19% of the patients experienced recurrence. After rapid initiation of eculizumab, eculizumab therapy was tapered again with good clinical outcome. A costs reduction of 55% was accomplished.

Conclusions: The new Dutch guideline on the treatment of aHUS regarding a restrictive eculizumab regimen appears safe and effective. Moreover, by critically evaluating eculizumab therapy, aHUS treatment can be economized. Although this first annual report showed promising results, the majority of patients is within their first year of follow up and continuous careful monitoring remains warranted.

FR-OR019

Renal Immune Related Adverse Events in Patients Treated with PD-1 Inhibitors: An Emerging Complication of Immunotherapy

Ilya Glezerman, Sheron Latcha, Edgar A. Jaimes. *Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: Inhibition of programmed cell death protein 1 (PD-1) immune checkpoint pathway activates patient's immune system, which is responsible for anti-tumor effect but may cause unwanted immune-related adverse events (IrAE) including renal effects.

Methods: Retrospective review of cases of acute kidney injury (AKI) or nephrotic syndrome while on treatment with PD-1 inhibitors seen at MSKCC between 2012 and 2018. Patients concurrently treated with another checkpoint therapy were excluded.

Results: Thirty-one patients were identified and twenty-three met inclusion criteria. Eight were male and the average age was 61.7 years. Fourteen patients had a biopsy while nine were treated empirically. The mean number of immunotherapy cycles prior to onset of AKI was 5.08 (1-14). In the biopsy group (Table 1), thirteen patients had AIN and one had membranous glomerulonephropathy (MGN). All had either full or partial recovery of renal function. Two patients were re-challenged with PD-1 inhibitors and tolerated 2 and 5 cycles respectively accompanied by low dose steroid therapy. One patient was re-challenged without corticosteroids and AKI recurred after 10 cycles. One patient with biopsy proven AIN received 5 additional cycles without further worsening of renal function. The patient with MGN developed a relapse after re-challenge with checkpoint inhibitor but tolerated additional 5 cycles with supportive care.

Conclusions: Most patients with renal IrAE developed AIN and all recovered kidney function. These patients can be re-challenged with PD-1 inhibitors if clinically indicated with concomitant steroid therapy support.

Polymyxin Hemoperfusion Shows No Benefits on Kidney Outcomes in Severe Sepsis Patients

Somkanya Tungsanga,[1] Nuttha Lumlertgul,[1] Nicha Thamrongsat,[1] Sadudee Peerapornratana,[2] Kriang Tungsanga,[1] Nattachai Srisawat.[1] *[1]Division of Nephrology, Department of Medicine, Chulalongkorn University, Bangkok, Thailand; [2]Chulalongkorn University, Bangkok, Thailand.*

Background: Polymyxin B Hemoperfusion (PMX-HP) has been introduced as one of the treatments for sepsis over the past 25 years. Previous randomized control trials (RCT) examining the efficacy of PMX-HP reached different conclusions. We aimed to study the effect of PMX-HP on kidney outcomes in patients with severe sepsis.

Methods: An RCT was conducted in sepsis patients who were admitted at intensive care units and had blood endotoxin activity assay (EAA) level ≥ 0.6. They were randomized into 2 groups. The PMX-HP group received standard treatment plus 2-hour PMX-HP for 2 consecutive days whereas the non PMX-HP group received only standard treatment for sepsis. The primary outcome was Major Adverse Kidney Events by 28 days (MAKE28) which consisted of mortality, renal replacement therapy (RRT) status, and persistent renal dysfunction. Secondary outcomes were the mean or median change in mHLA-DR

expression, CD11b expression, neutrophil chemotaxis, cardiovascular sequential organ failure assessment (CVS SOFA) score, vasopressor dose, and EAA level between day 3 and day 0. Other parameters included serum creatinine on day 7, ICU free days, and ventilator free days.

Results: 59 patients were randomized to PMX-HP (n=29) and non PMX-HP (n=30) groups. At baseline, clinical and immunologic parameters were comparable between groups. The MAKE28 were not significantly different between the two groups, p=1.0. The median change in mHLA-DR expression, parameter of monocyte function, was higher in PMX-HP patients than in non PMX-HP patients, p=0.027. The mean change in CD11b, sparameter of neutrophil activation, was significantly lower in PMX-HP than in non PMX-HP, p=0.002. There were no significant changes in neutrophil chemotaxis, CVS SOFA scores, vasopressor doses, or EAA levels between groups. The serum creatinine on day 7, ICU-free days, and ventilator-free days were comparable between groups.

Conclusions: PMX-HP had no benefits on kidney outcomes in severe sepsis patients. However, it showed beneficial effects on immunomodulation processes. Whether this effects should improve clinical outcomes needs further larger scale clinical trial.

Funding: Commercial Support - Toray provided Polymyxin-B cartridge and endotoxin activity assay kits for use in this study. The company had no influenced on the study design or analysis or on the comment of this article. None of the other authors have any disclosures., Private Foundation Support

Associations of Tubular Injury, Inflammation, and Repair Biomarkers with AKI in the SPRINT Trial

Michelle M. Estrella,[2] Alexandra K. Lee,[2] Alexander Bullen,[1] Vasantha Jotwani,[2] Rakesh Malhotra,[1] Chirag R. Parikh,[3] Joachim H. Ix,[1] Michael Shlipak.[2] *[1]UCSD, San Diego, CA; [2]Kidney Health Research Collaborative, UCSF & VA, San Francisco, CA; [3]Yale University and VAMC, New Haven, CT.*

Background: Randomization to intensive BP treatment (SBP <120 mmHg) in SPRINT led to higher AKI risk compared to standard BP treatment (SBP <140 mmHg). Whether a greater burden of tubular disease predisposes to AKI has not been well evaluated.

Methods: Among SPRINT participants with CKD (eGFR <60 mL/min|1.73 m^2), we measured baseline urine levels of tubular injury (NGAL, KIM1 and IL18), inflammation (IL18 and MCP1) and repair (YKL40) biomarkers using multiplex panels. Cox proportional hazards models were used to examine whether baseline biomarker levels (log_2-transformed and in quartiles) were independently associated with AKI, defined by hospital discharge AKI diagnosis listed within the top three reasons for hospitalization. We examined whether treatment arm assignment modified these associations by inclusion of interaction terms.

Results: Among 2412 CKD participants with urine biomarkers, the mean age was 73 and mean eGFR 45.9 mL/min/1.73m^2. A total of 190 AKI events occurred over a median 3.2 years of follow-up. YKL40, per 2-fold higher, was independently associated with higher risk of AKI (HR=1.09; 95% CI: 1.01-1.18). The highest versus lowest YKL40 quartile was significantly associated with risk of AKI in adjusted analyses (HR=1.82; 95% CI:1.17-2.83) (**Figure**). Treatment arm assignment did not influence this association. In contrast to YKL40, biomarkers of tubular injury and inflammation were not significantly associated with AKI risk in adjusted analyses.

Conclusions: Higher baseline urine YKL40 levels were associated with higher risk of AKI among SPRINT participants with CKD. These results suggest that CKD patients with greater activation of tubular repair mechanisms are more vulnerable to AKI.

Funding: NIDDK Support

Plasma Angiopoietin-2 Concentrations Mediate the Contribution of Genetic Variation in the Angiopoietin-2 Gene to Development of AKI Sub-Phenotypes

Pavan K. Bhatraju,[1,2] Jonathan Himmelfarb,[3] Mark M. Wurfel.[1] *[1]University of Washington, Seattle, WA; [2]Kidney Research Institute, University of Washington, Seattle, WA; [3]Kidney Research Institute, Seattle, WA.*

Background: Plasma angiopoietins 1 (Ang-1) and 2 (Ang-2), markers of endothelial stability and dysfunction, have been implicated in the development of acute kidney injury (AKI). Using latent class analysis, we previously identified two AKI sub-phenotypes (AKI-SP1 and AKI-SP2). Critically ill subjects classified as AKI-SP2 had worse clinical outcomes and higher markers of endothelial dsyfuntion (high Ang-2 and low Ang-1) compared to AKI-SP1 (low Ang-2 and high Ang-1). It is unknown whether Ang-1 and 2 are markers of disease or act as a causal mediator in the development of AKI sub-phenotypes.

Methods: A targeted genetic study was performed to identify SNPs within 50 kb of the *Angiopoietin 1 (ANGPT1)* and *Angiopoietin 2 (ANGPT2*) genes associated with AKI- SP2 in 452 AKI subjects from the iSPAAR cohort. Association testing was performed on 190 SNPs. Causal inference analysis was used to determine the role of genetic variation and circulating angiopioetins in the development of AKI-SP2.

Results: An intronic SNP, *rs2920656*, near the *ANGPT2* gene (≈ 30kb downstream to the 3' position) was associated with reduced risk of AKI-SP2 (Bonferroni, p=0.003) and decreased Ang-2 concentrations (p=0.002) adjusting for age, gender, sepsis and 5 principal components of ancestry. Causal inference analysis indicated that the total effect of the SNP (rs2920656) on AKI-SP2 was *Beta* = -0.16 (95% CI -0.23 to -0.09, p=1.0 x 10^{-4}) and the indirect effect was *Beta* = -0.07 (95% CI -0.11, -0.03, p=0.001). This suggests that for each minor allele (T allele) of the genetic variant the risk of developing AKI-SP2 decreases by 16%. When comparing the total effect to the indirect effect through a mediation analysis, 42% of the SNP's prognostic effect was mediated through Ang-2 plasma concentrations (Figure 1).

Conclusions: Our findings support the importance of *ANGPT2* in AKI pathophysiology by mediating plasma Ang-2 levels.

Funding: NIDDK Support, Other NIH Support - NHLBI

Impact of Kinetic Glomerular Filtration Rate Estimation on Medication Dosing in AKI

Yuenting D. Kwong,[1] Sheldon Chen,[2] Kathleen D. Liu.[1] *[1]University of California at San Francisco School of Medicine, San Francisco, CA; [2]MD Anderson, Houston, TX.*

Background: Medication dosing during acute kidney injury (AKI) is often based on Cockcroft-Gault (CG) creatinine clearance (CrCl) or estimated glomerular filtration rate (eGFR) equations (Dowling et al, Pharmacotherapy 2010). However, these equations are not valid in AKI as serum creatinine (SCr) is not in steady state. A kinetic estimate of CrCl or eGFR (keGFR) may be a more accurate method of estimating renal function. The aim of this study was to determine the impact of using kinetic estimates of renal function on drug dosing in critically ill patients with fluctuating SCrs.

Methods: We used data from subjects in the NIH ARDS Network Fluid and Catheters Treatment Trial (Wiedemann et al, NEJM 2006) with more than 2 serial SCrs. SCrs post-dialysis initiation were censored. Daily renal function was calculated using the 1)CG CrCl 2)MDRD and 3)CKD-EPI equations. Kinetic estimates of each formula were calculated using: [Steady State or baseline SCr X CrCl or eGFR/mean SCr at 2 time points]X(1-[(24XΔScr)/(ΔTime (h) X MaxΔSCr/day)]. We evaluated the frequency with which the kinetic estimate of each formula changed medication dosing categories (≥60, 30-59, 15-29, and <15mL/min) compared with the use of CG CrCl, $eGFR_{MDRD}$, or $eGFR_{CKD-EPI}$.

Results: Among 947 subjects, 46.0%, 28.5% and 30.0% of the population required recategorization of the dosing category if the kinetic estimate was used instead of CG CrCl, $eGFR_{MDRD}$, and $eGFR_{CKD-EPI}$, respectively. Recategorization occurred more in those with AKI by AKIN criteria. If CG CrCl was adjusted using the kinetic counterpart, 62.8% of

those with AKI would change dosing categories, compared to 25.6% of patients without AKI.

Conclusions: In a critically ill population, use of kinetic estimates of renal function would change medication dosing in the majority of subjects with AKI on at least one calendar day. Further studies will be needed to test whether use of keGFR in clinical practice would lower the incidence of medication toxicity and avoid subtherapeutic dosing during renal recovery.

Funding: Other NIH Support - T32-DK007219-41

Variable Economic Impacts of Clinical Decision Support Algorithms That Predict AKI among Postoperative Patients: A Nationwide Analysis

Felix K. Chang,[1,4] Allan D. Kirk,[2] Timothy G. Buchman,[3] Eric Elster.[1]
[1]Uniformed Services University of the Health Sciences and the Walter Reed National Military Medical Center, Bethesda, MD; [2]Duke University School of Medicine, Durham, NC; [3]Emory University, Atlanta, GA; [4]DecisionQ, Arlington, VA.

Background: New clinical decision support (CDS) algorithms are being developed to predict the likelihood of AKI among patients who undergo operative treatment. Conceptually those predictions enable early prophylactic interventions that could prevent AKI and thereby avoid its adverse health effects and associated treatment costs. We sought to assess (1) how accurate such CDS algorithms and (2) how effective their paired prophylaxes would have to be to yield a net positive economic impact.

Methods: We searched the 2014 National Inpatient Sample using ICD-9 codes to identify patients ≥18 years old with one or more operative treatments. We combined our findings with data on the incidences and treatment costs of AKI at three RIFLE classification stages. We then performed a sensitivity analysis of the costs associated with the use of CDS algorithms designed to predict AKI-R, AKI-I, and AKI-F in concert with their paired prophylaxes.

Results: We found that CDS algorithms designed to predict AKI-R yielded greater net economic benefits than those designed to predict AKI-I or AKI-F. With an algorithm accuracy of 0.75 and a prophylaxis effectiveness of 0.50, an AKI-R CDS algorithm could create an annual nationwide benefit of $11.6 billion, whereas AKI-I and AKI-F CDS algorithms could create benefits of only $8.3 billion and $4.7 billion, respectively. (**Figure**.) The area under each curve represents the combinations of algorithm accuracy and prophylaxis effectiveness that would produce a net economic benefit for each CDS algorithm.

Conclusions: Our study revealed that lower incidences of AKI-I and AKI-F relative to AKI-R in postoperative patients would likely result in higher false positive rates among CDS algorithms focused on AKI-I and AKI-F. Those higher rates, when combined with likely higher prophylaxis costs to treat potential AKI-I and AKI-F patients, add new costs that, in many cases, overwhelm the costs avoided through early intervention. Barring more effective AKI prophylaxes, future development of AKI-related CDS algorithms should focus on the prediction of AKI-R.

Defining Kidney Dysfunction in the Community Setting: The ISN 0by25 Initiative

Etienne Macedo,[6] Sanjib Kumar Sharma,[1] Ulla Hemmila,[7] Rolando Claure-Del Granado,[5] Bhupendra Shah,[1] Henry E. Mzinganjira,[8] Jorge Cerda,[2] Emmanuel A. Burdmann,[3] Michael V. Rocco,[4] Ravindra L. Mehta.[6] ISN 0by25
[1]B.P.Koirala Institute of Health Sciences, Dharan, Nepal; [2]Capital District Renal Physicians, Albany, NY; [3]University of Sao Paulo Medical School, Sao Paulo, Brazil; [4]Wake Forest School of Medicine, Winston-Salem, NC; [5]Hospital Obrero #2 Universidad Mayor de San Simon, Zona Sarco, Bolivia, Plurinational State of; [6]University of California San Diego Medical Center, La Jolla, CA; [7]College of Medicine, Malawi, Kokemäki, Finland; [8]MOH, Blantyre, Malawi.

Background: Community-acquired acute kidney injury (AKI) is common, but often unrecognized in resource-constrained settings. Limited lab assessments and unavailable informationon the prior state of kidney health contribute to this lack of recognition. In this study, we evaluated the efficacy of point of care (POC) serum creatinine (sCr) and urine dipstick tests to identify patients with kidney dysfunction at presentation to community health centres (CHC) and emergency departments (ED), as part of the International Society of Nephrology (ISN) 0by25 Pilot Feasibility Project.

Methods: Patients (pts) presenting at CHC or ED with signs or symptoms associated with high/moderate risk of developing AKI underwent sCr POC test and urine dipstick. At enrollment, pts were classified as chronic kidney disease (CKD) based on prior history, proteinuria(>1+) and/or baseline sCr within 12 mos by estimated GFR (CKD-EPI equation)) <60 mL/min/1.73 m^2; normal renal function (NRF) (no proteinuria and eGFR>75ml/min/1.73 m^2); and Acute Kidney Disease (AKD) neither meeting criteria for CKD or NRF. AKI was confirmed within 7days by sCr increase or decrease of 0.3 mg/dl or 1.5x from the enrollment value. Pt outcomes: progression of AKI, need for RRT, hospitalization, mortality and renal functional recovery, were assessed at 7days and 1, 3 and 6 mos.

Results: 3577pts were screened, 2101enrolled; 91%adults, 9%children. At enrollment, 9% were CKD and 66% AKD. At 7 days, 30% of pts fulfilled criteria for AKI: 67 from NRF (13%), AKD 470 (33%) and CKD 91 (46%). Overall mortality rate was 7.4% at 7 days and increased to 13% at 6 months. In comparison to NRF, AKD and CKD patients had higher mortality at 7 days and follow up, and the development of AKI trended for higher mortality in both AKD and CKD groups. Of 434 patients with 3 months sCr follow up, new onset CKD was encountered in 40(26%) of AKD and 54(33%) of AKI patients. Of patients dying from CKD and AKD groups, non-provision of dialysis occurred in 31 (11%).

Conclusions: Kidney dysfunction is common in CHC and is associated with adverse outcomes. POC tests can identify patients with AKD and CKD at increased risk for AKI, progression of CKD and mortality. Early implementation of targeted interventions may help improve outcomes.

Epidemiology of Pediatric AKI in a Nationally-Representative Cohort of American Children

Erica C. Bjornstad,[3,1] Amy K. Mottl,[3] Keisha L. Gibson,[3] Steve Marshall,[1] Yvonne Golightly,[1] Anthony Charles,[2] Emily Gower.[1]
[1]Epidemiology, UNC Gillings School of Public Health, Chapel Hill, NC; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]University of North Carolina Kidney Center, Chapel Hill, NC.

Background: Acute kidney injury (AKI) significantly increases morbidity and mortality for hospitalized children. However, few studies have evaluated the relationship between race/ethnicity, socioeconomic status (SES) and pediatric AKI. We proposed to evaluate those relationships with the outcome of AKI in a national pediatric cohort.

Methods: The Kids' Inpatient Database, developed by the Agency for Healthcare Research and Quality's Hospital Care and Utilization Program, is a nationally representative database of pediatric discharges from >4100 community hospitals throughout the United States. We conducted a secondary analysis of the most recent data (2012) to assess for racial disparities and socioeconomic differences in the development of pediatric AKI (age 1-20 years) using weighted sampling methods to obtain national estimates. We used logistic regression to assess the relationship between race/ethnicity and SES and the development of AKI, adjusting for comorbidities. SES was defined using three variables: type of insurance (private, Medicaid, other, no insurance), median household income of a patient's zip code in quartiles, and urbanization of patient's home address.

Results: In 2012, approximately 1.2% of all pediatric hospitalizations had an AKI episode, which is a national estimate of almost 30,000 children. After adjusting for chronic illnesses, African American children (Risk difference (RD) 0.00139, 95% CI 0.00064-0.00214) and Asian American children (RD 0.00323, 95% CI 0.00167-0.00478) were at an increased risk for AKI compared to Caucasian children. Children without insurance were more likely to have an episode of AKI compared to those with any form of insurance (e.g., Medicaid versus no insurance has RD of -0.014 with 95% CI -0.016 to -0.012). Based on these data, we estimate that one episode of AKI could be prevented if 73 children currently hospitalized without insurance were provided with Medicaid. No significant differences were seen based on urbanization or median household income.

Conclusions: AKI occurs more frequently in African American and Asian American children compared to Caucasian children. However, the most protective aspect prior to hospitalization is having insurance, regardless of race/ethnicity and type of insurance.

FR-OR027

Reduction in Nephrotoxic Antimicrobial Exposure Decreases Associated AKI in Pediatric Hematopoietic Stem Cell Transplant Patients (HSCT)

Stefanie W. Benoit, Stuart Goldstein, Devesh S. Dahale, David B. Haslam, Adam Nelson, Kori Truono, Stella M. Davies. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Exposure to nephrotoxic medications (NTMx) is a common risk factor for AKI. Quality improvement work in antimicrobial stewardship and NTMx-associated AKI (NAKI) reduction took place at Cincinnati Children's Hospital from 2013 to 2018. We hypothesized that choosing less nephrotoxic antimicrobial medications for HSCT patients would be associated with lower NAKI rates and no increase in treatment failures.

Methods: We used data from a prospective NAKI monitoring system within our electronic health record. AKI days and severity were extracted for patients exposed to 3+ NTMx or 3+ days of IV aminoglycosides (AG). AKI was defined using KDIGO creatinine criteria. We assessed rates of NTMx exposure and NAKI in all HSCT inpatients from 09/2013 to 03/2018. The percent of repeat positive cultures was used to capture treatment failures. Data were grouped and analyzed by calendar month.

Results: The HSCT division changed frontline fever treatment from piperacillin-tazobactam (pip-tazo) to cefipime, and AG use was limited. Cidofovir use decreased with availability of brincidofovir and antiviral cytotoxic T-lymphocytes. There were no other major changes in supportive care practices. Rates of NTMx exposure, NAKI, and percent of repeat positive cultures all decreased, as shown in Table 1. Mean rates of all stages of NAKI decreased >50% after 01/2016, which coincided with the divisional change from pip-tazo to cefipime. Rates of NAKI have since remained stable.

Conclusions: Reduction of nephrotoxic antimicrobial exposure may decrease the amount and severity of NAKI in HSCT patients without an increase in treatment failures.

Change in Rate of NTMx Exposure, Associated AKI, and Repeat Positive Cultures.

	Period 1: 09/2013 – 01/2016 (Mean per 1000 patient days)	Period 2: 01/2016 – 03/2018 (Mean per 1000 patient days)
Nephrotoxin Exposed Patients	25.46	14.53
All AKI	29.65	12.92
Stage 1 AKI	16.7	6.42
Stage 2 AKI	9.2	4.14
Stage 3 AKI	3.75	1.16
Percent Repeat Positive Blood Cultures	10%	7.3%

FR-OR028

Damage to the Mesangium Mediates the Loss of Podocytes in Glomerular Hypertension

Wilhelm Kriz,[1] Hermann-Josef Groene.[2] *[1]Neuroanatomy, Medical Faculty Mannheim, University Heidelberg, Mannheim, Germany; [2]German Cancer Research Center, Heidelberg, Germany.*

Background: Glomerular hypertension damages the glomerulus leading to progressive glomerular disease. It is widely believed that increased perfusion pressure exposes the tuft to increased tensile stress challenging the adhesion of podocytes to the GBM favouring their detachment. This hypothesis has been based on the view that podocyte foot processes, like pericyte processes, actively counteract the pressure-driven expansion of the GBM and fail in hypertension. Recent findings have compromised this view. Instead, counteraction of tensile stress to the filtration barrier seems to be almost exclusively performed by the GBM. The GBM displays a non-linear elasticity (Janmey and Tyler Miller 2011, J Cell Sci 124:9) meaning that its distensibility progressively decreases with increasing distension and finally reaches a limit. Thus, the expansion of a glomerular capillary and thus the expansile challenge to podocytes have an upper limit (Kriz and Lemley 2017, Ped.Nephrol 32:405). Podocytes are protected from any unphysiological pressure rises by the GBM.

Methods: High resolutiion light microscopy and transmission electron microscopy.

Results: In hypertensive models and in biopsies from patients with nephrosclerosis local disruptions of mesangial cell GBM connections are a common finding. They are consistently associated with expansions of mesangial spaces and bulging capillaries. These changes have been described in many previous studies. However, the danger that results from such local derangements of the tuft architecture to podocytes has never been adequately recognized. Here we show that such changes are topographically correlated with centrifugal displacements of capillary loops and corresponding podocytes. Depending on the location of the mesangial damage this may lead to a prolapse of podocytes into the urinary orifice with subsequent detachment of podocytes into the urine or to contacts with the parietal epithelium. Such contacts may initiate the formation of a tuft adhesion at any site of the tuft circumference, thus the committed lesion to develop focal segmental sclerosis (FSGS).

Conclusions: A combined failure of mesangial cells and podocytes underlies the development of FSGS in hypertensive glomerular diseases. The same dependence of a podocyte damage on a preceding mesangial failure is also seen in glomerular diseases, in which mesangial-cell-GBM-connections are directly damaged.

A New Spheroid Model of the Glomerulus

Jack P. Tuffin,[1] Gavin I. Welsh,[1] Timothy S. Johnson,[3] Simon C. Satchell,[1] Rachel Lennon,[2] Salman Hosawi,[4] Moin Saleem.[1] *[1]University of Bristol, Bristol, United Kingdom; [2]University of Manchester, Manchester, United Kingdom; [3]Sheffield kidney Institute, University of Sheffield, Sheffield, United Kingdom; [4]King Abdulaziz University, Manchester, United Kingdom.*

Background: 2D models of glomerular cells are limited in their ability to recreate accurate morphology and protein expression. The purpose of this project was to produce a 3D co-culture of conditionally immortalised human podocytes and glomerular endothelial cells (GEnCs), more translationally representative of glomerular health and disease for medium-throughput pharmaceutical compound screening.

Methods: Magnetic spheroid bio-printing was used to assemble podocytes and GEnCs into organised 3D structures. Fluorescence IHC techniques were used to stain and samples were imaged using confocal, lightsheet and transmission electron microscopy. Western blotting, mass spectrometry-based proteomics and transcriptomics techniques were applied.

Results: Podocytes and GEnCs in spheroid co-culture self-assembled into a glomerulus-like structure, whereby peripheral podocytes wrapped a core of endothelial cells. An organised layer of extracellular matrix formed between the two cell types. A combination of TGFβ and adriamycin caused significant podocyte effacement. TGFβ alone was sufficient to induce a significant increase in expression of the GBM protein collagen IV. Incubation with an antifibrotic compound (Nintedanib) significantly reduced both of these effects.

Conclusions: An in-vitro spheroid model demonstrating two key aspects of glomerulosclerosis (foot-process effacement and matrix dysregulation) has been developed. This model is more physiologically relevant than 2D cultures, whilst being reproducible and scalable.

Macula Densa Cells Orchestrate Podocyte Neogenesis

Georgina Gyarmati, Urvi nikhil Shroff, Anne Riquier-brison, Ina M. Schiessl, Janos Peti-Peterdi. *University of Southern California, Los Angeles, CA.*

Background: The recruitment of new podocytes from precursor cells including parietal epithelial cells (PECs) and cells of the renin lineage (CoRL) in response to glomerular

injury has been established, however the mechanism remains elusive. Here we tested the hypothesis that macula densa (MD) cells localized at the glomerular entrance are master organizers of glomerular remodeling, and can be stimulated to recruit new podocytes in the adult kidney.

Methods: Intravital multiphoton imaging (MPM) in genetic mouse models was performed to track the fate and migration pattern of mesenchymal and endothelial precursor cells. RNA seq and gene profiling was used to establish and analyze the gene profile of MD cells under control and stimulating conditions. Immunohistochemistry for podocyte, mesenchymal, and endothelial precursor cell markers p57, WT-1, and CD34 were performed in kidney sections of control WT mice and in a new genetic model of inducible MD-specific Wnt gain-of-function (gof).

Results: MPM provided "smoking gun" direct visual evidence for the migration of single CoRL from the PEC layer to the glomerular tuft (sometimes within 15 s) in the intact mouse kidney. The newly established, exclusively MD-specific secretome includes several angiogenic, patterning, growth factor, and extracellular matrix remodeling peptides including Pappa2, Ccn1, Cxcl14, Wnt10a, Sema3c, Bmp3, Egfl6, Fgf9, Vegfd, Pdgfc, Frem1, etc. In MD-Wnt(gof) mice, glomerular size and podocyte number increased from control 17±3 to 24±3 per unit glomerular volume within 5 weeks. MD-Wnt gof also developed a WT-1+ cell niche at the MD base/extraglomerular mesangium transitioning into the Bowman's capsule, and a CD34+ endothelial precursor cell niche at the glomerular vascular pole. Treatment of Ren1d-Confetti mice with GSK3b inhibitors for only 5 days caused a 3-fold increase in the density of CoRL at the glomerular vascular pole and in PEC layer.

Conclusions: These results suggest that MD cells are central players in the physiological remodeling of the glomerulus via Wnt signaling and secreted paracrine factors, that act on the mesenchymal-to-epithelial transition of glomerular precursor cells to become new podocytes. MD cells also stimulate angiogenesis simultaneously. This new mechanism protects from glomerular injury when augmented, and may be developed further to specifically treat glomerular diseases.

Glomerular Filtrate Promotes Cell Detachment in Podocyte Injury

Nobuyuki Saga,[1] Naoko Ito,[1] Kazuo Sakamoto,[1] Taiji Matsusaka,[2] Michio Nagata.[1] *[1]University of Tsukuba, Tsukuba, Japan; [2]Tokai University School of Medicine, Isehara, Japan.*

Background: Podocyte detachment is a hallmark of segmental glomerulosclerosis. Although glomerular filtrate may effectively drive cell detachment, it alone is insufficient and needs presumptive structural changes in filtration surface. We analyzed structural background that synergistically drives podocyte detachment in NEP25, a mouse model of uniform podocyte injury.

Methods: Whole glomerular profiles (73 glomeruli, n=6) in NEP25 mice with LMB2 (8-10 days) were photographed by TEM. Entire GBM in all glomeruli were classified into normal, foot process effacement (FPE) or detachment and each length per glomerulus was measured. This method enabled us to identify the localization and continuity of each change within the glomerulus. UUO was performed at day 5 in the above protocol (UUO model, n=3) to identify the effect of filtrate on detachment. Using multiphoton microscopy (MPM), decreased filtration by UUO was visualized. Glomeruli in UUO model were analyzed by TEM in the same way as above.

Results: Detachment occurred only in the glomeruli with >50% FPE lesions. The length of detachment correlated with the length of FPE. Detachment was more in deep cortex than in surface and tended to occur in limited to 1 to 2 local areas within each glomerulus. In examining 43 glomeruli with both vascular and urinary poles, detachment dominantly occurred at the side of urinary pole. Contralateral kidneys of UUO model had severe podocyte detachment, which also occurred dominantly at the urinary pole side (n=61). Filtration effectively decreased in the obstructed kidneys of UUO by MPM and these glomeruli completely lacked podocyte detachment, despite diffuse FPE by TEM (n=55). Podocyte pseudocysts were observed in the contralateral kidneys but rarely in the obstructed kidneys of UUO model.

Conclusions: 1) Podocyte detachment may be caused by synergistic effects of podocyte changes, such as FPE, with hydrostatic forces by filtrate. Biological changes in podocyte that occur in "grouping" may be an additional background. 2) From the fact that the frequency and the length of detachment positively correlated with the extent of FPE and pseudocyst, the cell reaction to strengthen cell-GBM and cell-cell attachment is also a basis for podocyte detachment.

FR-OR032

Promotion of β-Catenin/Foxo Protects against Kidney Fibrosis

David C. Harris,[1,5] Padmashree Rao,[1] Titi Chen,[1] Hong Yu,[1] Min Hu,[1] Qi Cao,[1] Yiping Wang,[1] Chow H. P'ng,[2] Brian J. Nankivell,[3] Vincent W. Lee,[1,3] Stephen I. Alexander,[4] Guoping Zheng.[1] *[1]Centre for Transplantation and Renal Research, Westmead Institute for Medical Research at University of Sydney, Westmead, NSW, Australia; [2]ICPMR, Westmead Hospital, Department of Tissue Pathology and Diagnostic Oncology, Westmead, NSW, Australia; [3]Westmead Hospital, Westmead, NSW, Australia; [4]Centre for Kidney Research, Children?s Hospital at Westmead., Westmead, NSW, Australia; [5]Sydney Medical School - University of Sydney, Duffys Forest, NSW, Australia.*

Background: Transforming growth factor β (TGF-β) is the key cytokine in the development of fibrosis. The conflicting roles of TGF-β (profibrotic versus anti-inflammatory) create a dilemma in the treatment of kidney fibrosis. β-catenin/TCF is central to various TGF-β's profibrotic signaling pathways in fibrosis. β-catenin also binds to Foxo in competition with TCF and leads to cell cycle arrest, promoting cell survival under oxidative stress. We propose that promoting β-catenin/Foxo will protect against β-catenin/TCF-mediated profibrotic changes and kidney fibrosis.

Methods: Kidney biopsies of patients with chronic kidney disease (CKD) or a kidney transplant were assessed by Proximity Ligation Assay (PLA) for β-catenin/Foxo and β-catenin/TCF interactions in relation to kidney fibrosis. Murine proximal tubular epithelial C1.1 cells were treated with TGF-β1 (3ng/ml) with or without ICG-001 (5μM), which inhibits β-catenin/TCF. CRISPR/Cas9 gene technology was used to knockout Foxo1 or TCF1. We also evaluated kidney fibrosis in murine unilateral ureteric obstruction (UUO). β-catenin/Foxo and β-catenin/TCF interactions were examined by co-immunoprecipitation (co-IP) and PLA. Profibrotic gene expressions were examined by western blot and immunofluorescence.

Results: PLA of CKD and kidney transplant patient biopsies showed that β-catenin/Foxo correlated negatively (r=-0.7405, P<0.001) and β-catenin/TCF positively (r=0.8061, P<0.001) with kidney fibrosis. TGF-β1 and ICG-001 treatment in C1.1 cells protected against TGF-β1-induced profibrotic gene expression while the protection was absent in Foxo1 KO C1.1 cells. Combined treatment with TGF-β1 and ICG-001 in C1.1 cells showed direct evidence for the promotion of β-catenin/Foxo by PLA and co-IP. UUO mice treated with TGF-β1 and ICG-001 had significantly reduced kidney fibrosis, via promotion of β-catenin/Foxo interaction as shown by PLA.

Conclusions: β-catenin/Foxo protects against TGF-β's profibrotic activity and thereby prevents kidney fibrosis.

An APOL1-Induced FSGS Mouse Model That Mimics Human FSGS Nephropathy

Avi Z. Rosenberg,[3] Hila Roshanravan,[1] Marco Delsante,[4] Maarten Hoek,[2] Myung Shin,[5] Jeffrey B. Kopp.[1] *[1]NIDDK, NIH, San Jose, CA; [2]Third Rock Ventures, Redwood City, CA; [3]Johns Hopkins University, Baltimore, MD; [4]Universita' degli Studi di Parma, Baltimore, MD; [5]Merck & Co., Inc, Kenilworth, NJ.*

Background: In the present study, the we aimed to develop a CKD model in mice expressing apolipoprotein L1 (APO1) in order to generate a robust, reproducible model of APOL1 nephropathy. As reported, a bacterial artificial chromosome (BAC) that contains either the human *APOL1* gene (BAC-APOL1 G0) or each of the renal risk variants (BAC-APOL1-G1 and -G2) were used to generate transgenic mice that constitutively expressed APOL1. At baseline, BAC-APOL1 G0, G1, and G2 mice had no renal phenotype despite genetic risk in the latter lines; therefore, we induced hypertension as second hit.

Methods: We used a combination of Saline drinking water, Angiotensin II infusion, uniNephrectomy and Deoxycorticosterone acetate pellets (SAND model)

Results: After 3 weeks, mice developed albuminuria (G0, 2205 ± 84 mg/g, G1, 3840 ± 363 mg/g, G2 3447 ± 111 mg/g, and wild type, 2085 ± 202 mg/g) and uremia, with elevated blood urea nitrogen (BUN). SAND intervention in G1 and G2 mice led to reduced cortical thickness and podocyte number compared to G0 mice. SAND G1 and G2 mouse kidneys showed focal global and segmental glomerulosclerosis (FSGS), as well as glomerular lipid accumulation by oil red O staining. Differentially expressed genes in kidney cortex were identified based on log2 fold change and false discovery rate (FDR) of <0.05. In SAND G1 mice *Aoc1*, *C1q*, *Ncam1*, *Scamp1*, and *Tbca* were downregulated and *Hmgcs2* was upregulated compared to G0 mice. We examined expression of 60 FSGS-related genes, 64 cytokines, 63 cytokine receptors, 52 chemokines and 33 chemokine receptors in order to identify additional differentially-expressed genes in G1 and G2 mice, using a cutoff of log2 fold change of <0.05. *Ccrl2* was shown to be upregulated in G1 and G2 transgenic mice compared to WT and APOL1-G0 mice

Conclusions: In summary, we have shown that with the SAND model of hypertensive nephropathy, BAC-APOL1 G1 and G2 mice manifest more severe proteinuria, FSGS, and distinct patterns of gene expression.

Funding: NIDDK Support

FR-OR034

PTEN/YAP Mediated Lipid-Accumulation in Podocytes Contributes to Glomerulosclerosis

Huizhen Wang, Yangyang Zuo, Jianteng Xie, Jing Li, Tiantian Liang, Yanhui Wang, Yifan Zhang, Wenjian Wang. *Division of Nephrology, Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China.*

Background: The pathogenetic mechanism of focal segmental glomerulosclerosis (FSGS) are largely unknown. Here, we showed that phosphatase and tensin homolog (PTEN) was down-regulated in foamy podocytes in patients with FSGS, however, whether PTEN involves in accumulation of lipid in podocytes and contributes to glomerulosclerosis is undefined.

Methods: PTEN knockout and podocyte-specific PTEN knock-in mice were established.

Results: We revealed that partially deletion of PTEN increased the lipids accumulation in glomeruli segmentally, and boosted albuminuria and glomerulosclerosis. Conversely, podocyte-specific overexpression of PTEN demonstrated a marked alleviation of lipid-retention in podocytes, serum creatinine, UACR, and characteristics of glomerulosclerosis. *In vitro*, PTEN was found down-regulated in cultured podocytes stimulated with ox-LDL. Forced expression of PTEN reduced ox-LDL influx via down-regulating scavenger receptor

A (SR-A), decreasing intracellular cholesterol content, and thus prevented podocytes from lipid loading. In contrast, inhibition of PTEN exhibited aggravated podocytes damage by more lipid accumulation. The lipid retention in ox-LDL treated podocytes was mainly attributed to the lipid uptaking other than lipid effusion or synthesis. Mechanistically, we identified PTEN as a regulator of SR-A by dephosphorylating its nuclear transcription factor, yes-associated protein (YAP), at Ser^{127} in the cytoplasm of ox-LDL treated podocytes.

Conclusions: These findings implicate a central role of PTEN in a signaling cascade that regulates podocytes lipid-loading which contributes to the glomerulosclerosis, and provide evidence for PTEN as a target for HFD-induced FSGS therapy.

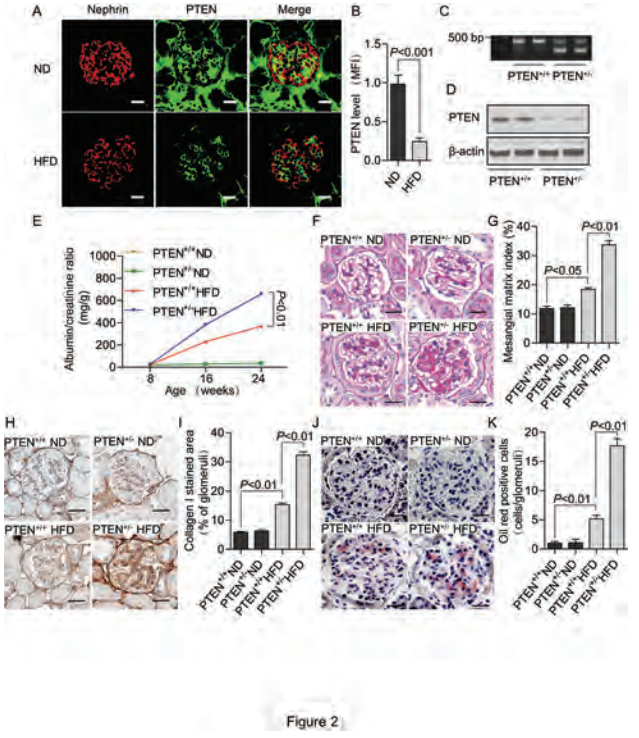

Figure 2

Knockout of PTEN aggravated renal lipid accumulation and glomerulosclerosis in FSGS mice.

FR-OR035

The Role of HDAC Activation in Proteinuric Kidney Disease Progression in Mice and Humans

Kazunori Inoue, Chirag R. Parikh, Francis P. Wilson, Shuta Ishibe. *Yale University School of Medicine, New Haven, CT.*

Background: As the incidence and prevalence of End Stage Kidney Disease due to proteinuric diseases continue to rise, alternative novel therapies are required.

Methods: An adult-onset proteinuric disease model was generated using doxycycline (DOX)-induced podocyte specific *Talin1* knockout (i*Tln1* KO) mice. Our findings were validated using podocyte specific germline *Dynamin1* and *2* KO (*Dnm* DKO) and *Tln1* KO mice treated with 2 different histone deacetylase (HDAC) inhibitors (valproic acid (VPA) and vorinostat (SAHA)). We generated DOX-induced podocyte specific *Hdac1* and *2* KO or early growth response 1 (*Egr1*) KO mice. Microarray was performed from isolated glomeruli in control and the i*Tln1* KO mice +/- VPA to unearth differentially expressed genes (DEGs). HDAC1 and 2 activities were measured using an activity assay kit. For in-vitro podocyte injury models, lipopolysaccharide (LPS) or protamine sulfate (PS) were used. Observational data in patients on VPA in the Veterans Aging Cohort Study (VACS) was analyzed for estimated glomerular filtration rate (eGFR).

Results: Using Connectivity Map database and Drug Pair Seeker, *Hdac1* and *2* genes and HDAC inhibitors were identified as potential targets regulating or reversing the 188 DEGs in control vs i*Tln1* KO mice glomeruli. Deletion of podocyte *Hdac1* and *2*, in i*Tln1* KO mice where podocyte HDAC1 and 2 are activated, and treatment with VPA, or SAHA ameliorated progression of proteinuria and kidney failure in these mice. VPA also improved survival in *Dnm* DKO and *Tln1* KO mice that die from kidney failure (*Dnm* DKO:35 (median survival (days)), *Dnm* DKO+VPA:77.5, *Tln1* KO:30.5, and *Tln1* KO+VPA:64). From our RNA profiling data, we also identified *Egr1* as a potential VPA regulated target. Loss of *Egr1* in i*Tln1* KO mice mitigated proteinuria and kidney failure (control:0.11 +/- 0.02 (plasma creatinine (mg/dl)), i*Tln1* KO:0.35 +/- 0.02, *Egr1*, i*Tln1* DKO:0.19 +/- 0.02). *Egr1 KO* podocytes stabilized the actin cytoskeleton following LPS or PS in vitro. Longitudinal analysis of VACS revealed reduction in the mean annual eGFR loss among those receiving VPA (-0.48 (ml/year) in VPA user vs -1.10 in non VPA user).

Conclusions: Our results demonstrate inhibition of HDAC1 and 2 activation not only improved proteinuric mice models but also suggests a novel therapeutic strategy in progressive proteinuric human kidney diseases.

FR-OR036

Induced Endothelial Expression of Podocyte Specific Retinoic Acid Receptor Responder 1 (Rarres1) in Glomerular Nephritis (GN) Accelerates Renal Injury

Katja Möller-Hackbarth, Dina Dabaghie, Emmanuelle Charrin, Jaakko Patrakka. *Karolinska Institutet, Sweden, Huddinge, Sweden.*

Background: Glomerular damage, including endothelial dysfunction and podocyte loss, plays an important role in the pathogenesis of diabetic nephropathy (DN). Pathogenesis of microvascular damage in the disease is still poorly understood. High throughput molecular profiling (RNA seq.) identified Rarres1 as a highly podocyte specific protein, that is consistently up-regulated in kidney tissue of DN patients.

Methods: To identify cellular localization of Rarres1, we analysed the expression in human healthy and DN kidneys using immunohistochemical methods and RNA *in situ* hybridization. *In vitro*, we over/underexpress Rarres1 in human podocytes to investigate its functional role. *In vivo*, we generated two novel transgenic mouse lines, enabling cell-specific inactivation and overexpression of Rarres1. We induced crescentic GN model by anti-glomerular basement membrane (anti-GBM) antibodies in podocyte specific knock-out (KO) and endothelial cell (EC) specific knock-in (KI) mice for Rarres1.

Results: In healthy kidney, Rarres1 is specifically expressed by podocytes and not by other glomerular cells. In DN patients, Rarres1 expression is induced in microvascular endothelial cells. *In vitro*, Rarres1 overexpression leads to elevated expression of EMT related genes and activation of NF-kB signaling by interaction with Receptor Tyrosin Kinase Axl. *In vivo*, EC specific Rarres1 KI animals were more prone to anti-GBM-induced damage as they developed higher albuminuria than control animals and showed an accelerated immune response as well as increased levels of fibrotic makers. In contrast to this, podocyte-specific KO animals showed no obvious abnormalities.

Conclusions: In summary, these results suggest that the activation of Rarres1 expression plays a pathogenic role in renal endothelial dysfunction during disease progression by promoting fibrosis and inflammation *in vitro* and *in vivo*.

FR-OR037

Characterization of a New Mechanism of Proteinuria

Andrew Beenken,[1] Andong Qiu,[4] Guangchun Jin,[3] Tian Shen,[3] Abraham D. Levitman,[3] Jonathan M. Barasch.[2] *[1]New York Presbyterian/Columbia University, New York, NY; [2]Columbia Presbyterian, New York, NY; [3]Columbia University, New York, NY; [4]Tongji University, Shanghai, China.*

Background: A central problem in biology is the mechanism by which cells regulate iron transport. This problem arises because the common oxidized form of iron (ferric-Fe3+) precipitates at physiologic pH, while the reduced form of iron (ferrous-Fe2+) is unstable in oxygenated atmospheres, and produces toxic radicals. To investigate iron transport in the kidney, we performed homology searches with yeast iron transporters and identified Spin, a novel transporter of ferrous iron.

Methods: Using in vivo LacZ reporters and by raising antibodies we found that Spin is specific to the endosomes and lysosomes of the proximal tubule. We constructed a conditional knockout of Spin driven by Megalin-Cre and found iron deposits and intense ferritin staining in the cytosol indicating defective iron localization in the KO.

Results: We saw proximal tubule dysfunction in the KO as measured by proteinuria. Western blot revealed leakage of NGAL and transferrin in the urine, and silver stain showed albuminuria. We investigated this phenotype by intraperitoneally injecting FITC-labeled dextran and found impaired endocytosis in the KO. While megalin expression was unchanged between KO and wild type as seen on confocal microscopy, autophagy appeared to be inhibited in the KO. Electron microscopy showed increased size and number of vesicles in the proximal tubules, and Western blot showed increased abundance of LC3B-II in the homogenate of kidney cortex, suggesting that the Spin KO may hinder autophagosome fusion with the lysosome. The endocytic phenotype appears to be regulated by mislocalized iron because iron deficiency can rescue endocytosis.

Conclusions: In sum, we have found a critical iron transporter that regulates the endocytic functions of the proximal tubule.

Human Nephron Segmentation: Opportunities to Replicate Cellular Programs In Vitro

Nils Lindstrom. Andrew McMahon laboratory *The University of Southern California, Los Angeles, CA.*

Background: Advances in renal bioengineering have shown how pluripotent stem cells can be differentiated into composite cell-structures called 'kidney organoids'. These technologies can, if harnessed properly, hold potential for human kidney disease modeling, nephrotoxicity screens, and renal replacement therapies. However, the intense interest into the kidney organoids have highlighted our current insufficient understanding of normal human kidney development and raised the question of whether the blueprint for nephrogenesis established in the mouse, frog, and fish, is actually applicable to the human system and the organoid.

Methods: To establish a cellular and molecular understanding of human development we have carefully scrutinized and contrasted it with mouse kidney development using a broad range of technologies including bulk RNA-sequencing (conventional and MARIS-based), single-cell RNA sequencing, in situ hybridization, immunofluorescent stains (three dimensional and two dimensional), and confocal live fate-mapping.

Results: We demonstrate significant conservation between human and mouse patterning programs alongside distinct divergences in anatomies and expression patterns (JASN 2018 PMIDs: 29449453, 29449451, 29449449). Further, our examination of the human system resulted in the proposition of a new model for how nephrons form and pattern. Mesenchymal nephron progenitors are recruited into the forming nephron over a protracted period of time and it is the order of recruitment that dictates the spatial identities and eventual fates of each cell. We demonstrate this model by high-resolution image analyses and 3D reconstructions of human nephrogenesis and confirmed it through direct visualization and cell fate analysis in the mouse kidney organ cultures. Single-cell RNA sequencing of the human nephrogenic niche revealed the molecular events occurring during these early patterning processes and predicted developmental trajectories adopted by nephron progenitor cells in forming segment-specific domains of the human nephron.

Conclusions: The temporal-recruitment model for nephron polarity and patterning provides a framework for how integrated signaling pathways drive mammalian nephrogenesis. Collectively, these studies benchmark human nephrogenesis and predicts why current organoids fall short of replicating the *in vivo* nephron.

Manipulation of Nephron Patterning Signals Enables Selective Induction of Podocytes from Human Pluripotent Stem Cells

Yasuhiro Yoshimura,[1,2] Atsuhiro Taguchi,[1,3] Masashi Mukoyama,[2] Ryuichi Nishinakamura.[1] *[1]Department of Kidney Development, Institute of Molecular Embryology and Genetics, Kumamoto University, Kumamoto, Japan; [2]Department of Nephrology, Graduate School of Medical Sciences, Kumamoto University, Kumamoto, Japan; [3]Max Planck Institute for Molecular Genetics, Berlin, Germany*.

Background: Podocytes, which play an important filtration role in the kidney, are derived from nephron progenitor cells (NPCs). Recently, we and others have established the induction methods of kidney organoids via NPCs from human induced pluripotent stem cells (hiPSCs). However, it remains a challenge to control the patterning process of nephron development and selectively induce a specific nephron segment.

Methods: We first developed a method to purify NPCs from mouse embryonic kidneys and cultured the NPCs *ex vivo* to investigate the required signals for podocyte induction. We then applied the findings obtained from mouse NPCs to hiPSC-derived NPCs to establish a method to selectively induce human podocytes.

Results: Mouse NPCs differentiation experiments identified that 1) optimal duration and strength of Wnt signaling was essential for mesenchymal-to-epithelial transition and podocyte differentiation, 2) inhibition of TGF-β signaling supported the expansion of proximal segment of renal vesicle, and 3) inhibition of TGF-β signaling in the later step enriched podocyte fraction by suppressing the differentiation of other nephron segments. The resultant protocol was successfully applied to the induction of Nephrin/Podocalyxin-positive podocytes from hiPSCs with more than 90% of efficiency. Importantly, the expression levels of Nephrin and Podocin genes in the induced podocytes were 10^5 to 10^6 times higher than that in the immortalized podocyte cell line and comparable to the sorted human adult podocytes. RNA-seq analysis further confirmed characteristic similarities between induced podocytes and human adult podocytes. Electron microscopy revealed foot process-like protrusions with Nephrin protein expression on the cell surface. Furthermore, exposure of induced podocytes to puromycin aminonucleoside reduced the expression of foot process-associated proteins, suggesting their functional responsiveness.

Conclusions: We elucidated the signals required for podocyte differentiation from NPCs and established a novel method to selectively induce human podocytes from hiPSCs. Induced podocytes exhibited gene expression profiles resembling their counterparts *in vivo* as well as morphological and functional properties of podocytes and will serve as new resources for disease modeling, nephrotoxicity testing, and regenerative medicine.

Nephron Progenitor Commitment Is a Stochastic Process Influenced by Cell Migration

Kynan T. Lawlor,[1] Luke Zappia,[1,2] James Lefevre,[4] Joo-Seop Park,[3] Nicholas A. Hamilton,[4] Alicia Oshlack,[1,2] Melissa H. Little,[1,2] Alexander N. Combes.[2,1] *[1]Murdoch Childrens Research Institute, Melbourne, VIC, Australia; [2]University of Melbourne, Parkville, VIC, Australia; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]Institute for Molecular Bioscience, The University of Queensland, Highgate Hill, QLD, Australia*.

Background: Nephrons in the mouse kidney are formed from self-renewing mesenchymal progenitors that reside within a niche defined by the cap mesenchyme and ureteric epithelial tip. As the kidney develops, progenitor cells differentiate in response to inductive cues and exit the niche to form nephrons. We previously showed that the cap mesenchyme population is highly dynamic, migrating both within and between domains in response to niche cues. In this study we examine how migrating progenitors initiate nephrogenesis in a precise, spatially regulated manner.

Methods: We used lineage tracing, live timelapse imaging, single cell RNA-seq and computational modelling to characterise the fate of commiting mouse nephron progenitors.

Results: Using a tamoxifen inducible Wnt4-CreERT2 activated reporter we show that committing cells give rise to both the nephrons and a proportion of the progenitor pool. Timelapse imaging reveals a population of cells that are labelled at sites of nephrogenesis but escape commitment and re-enter the progenitor niche. Re-entry occurs continually during kidney development, leading to an accumulation of 'escapers' over time. Single cell RNA-seq reveals that these 'escapers' exist in the same range of transcriptional states as the unlabelled progenitor pool, suggesting that progenitors may traverse the transcriptional hierarchy between self-renewal and commitment in both directions. Consistent with this plasticity, live imaging analysis of individual cell fate suggests that some cells do not commit immediately but remain within the pre-tubular aggregate through branching iterations and contribute to subsequent nephrons.

Conclusions: We propose that nephron progenitor commitment is a stochastic process where the duration of exposure to spatially defined inductive cues is dependant on migration events. Progenitor plasticity may enable robust regulation of nephrogenesis as niches grow and are remodelled during organogenesis.

High Throughput Single Cell RNA Sequencing Reveals a Roadmap to Recreate the Kidney

Alexander N. Combes,[1,2] Belinda Phipson,[3] Kynan T. Lawlor,[2] Luke Zappia,[3,4] Alicia Oshlack,[2] Melissa H. Little.[2,4] *[1]Anatomy and Neuroscience, University of Melbourne, Parkville, VIC, Australia; [2]Murdoch Children's Research Institute, Melbourne, VIC, Australia; [3]Murdoch Children's Research Institute, Parkville, NSW, Australia; [4]University of Melbourne, Melbourne, VIC, Australia*.

Background: The developing mouse kidney represents a valuable model to understand the formation and maturation of renal cell types. High throughput single cell RNA sequencing offers new opportunities to understand the formation of complex tissues.

Methods: We performed single cell RNA-seq on over 6000 cells (median 2896 genes per cell) from E18.5 kidneys on the Chromium 10x platform. Seurat was used for normalisation and clustering of cells, edgeR to test for differentially expressed genes. Findings were investigated using immunofluorescence and lineage tracing.

Results: We used single cell profiling to define cell type-specific profiles and revisit the molecular regulation of kidney development in mouse. A detailed analysis of cellular heterogeneity in the nephron lineage identified multiple *Six2*+ subpopulations including a nephron progenitor 'ground state', a putative committing state with evidence of FGF suppression and Notch activation, and cells expressing markers of both nephron progenitor and stroma. *In vivo* lineage analysis from E12.5 with inducible *Six2*CreERT2 and *Pdgfra*CreER lines supported a rare transition from nephron progenitor to stroma, but not the other way. Several markers thought to be specific to one population were expressed more broadly. For example *Hoxb7* was expressed in collecting duct, distal tubule, and in some endothelial cells. Likewise, most markers considered specific to the ureteric epithelium were also expressed in the distal tubule or connecting segment. Comparative analysis between these populations yielded unique markers for each, which should be useful for distinguishing between these cell types in kidney organoids. An analysis of signaling pathway component expression was performed for each lineage, identifying known and previously unassociated ligands and receptors with progenitor states and stages of maturation in each lineage.

Conclusions: This study offers new insight into the mechanisms of progenitor maintenance and differentiation in the stroma, the ureteric epithelium, and the nephron lineages and therefore provides a roadmap of the signals that regulate differentiation *in vivo*. This information can be used to refine strategies to direct differentiation of mature renal cell types in vitro.

Comparative Analysis of Kidney Organoid and Adult Human Kidney by Single Cell RNA-Seq

Haojia Wu, Kohei Uchimura, Erinn L. Donnelly, Yuhei Kirita, Benjamin D. Humphreys. The Humphreys Lab *Renal Division Washington University School of Medicine, Saint Louis, MO*.

Background: Kidney organoids differentiated from human pluripotent stem cells hold tremendous promise but the similarities and differences between protocols and between pluripotent cell sources is unknown. In addition, how closely organoid-derived kidney cell types model their adult human counterparts is undefined.

Methods: We used Dropseq to generate single cell transcriptomes from two different directed differentiation protocols (Morizane and Takasato), using both iPSC and hES cell lines for each. We analyzed and compared single cell gene expression from 71,390 cells isolated from 38 organoids using unbiased computational approaches. We could detect on average 1,115 genes per cell. We further compared the differentiation state of major organoid kidney cell types against 4,524 single nucleus transcriptomes that we generated from healthy adult human kidney.

Results: Both protocols generate kidney organoids that contain a diverse range of kidney cells at differing ratios but also substantial numbers of non-renal cell types such as muscle and neuron. Some organoids have up to 30% off-target cell types. Organoid-derived cell types are substantially immature compared with adult kidney cells. We could detect 16 different types of adult kidney cell types by single nucleus RNA-seq, including all glomerular cell types, all epithelial cell types including S1-S3 proximal tubule segments and type A and type B intercalated cells, as well as stroma and leukocytes. Disease-related genes predicted by GWAS are predominantly expressed in single cell types in adult kidney and organoids. We also identified lineage-specific expression of transcription factors, receptors and ligands during organoid differentiation and in adult human kidney.

Conclusions: We provide the first direct and comprehensive comparison of separate differentiation protocols using both iPSC and hES cells, revealing important differences in cell ratio, differentiation state and off-target cell types that will be important for investigators

in the organoid field to appreciate. The information provided in this comprehensive dataset will also guide future attempts to improve differentiation protocols, including reduction of off-target populations.

FR-OR043

Reciprocal Antagonism between Ppargc1a and Sim1a Regulates Boundary Formation of the Proximal Straight Segment during Vertebrate Pronephros Development

Joseph M. Chambers, Rebecca A. Wingert. *University of Notre Dame, Notre Dame, IN.*

Background: The genetic and molecular mechanisms that regulate boundary formation between adjacent segment populations are not fully understood. The pronephros of several vertebrates provides a simplified, tractable model to investigate fundamental mechanisms of segmentation, as this primitive kidney is comprised of proximal and distal segments that are conserved with mammalian nephrons, including humans.

Methods: Through a bioactive small molecule chemical genetic screen, we discovered that peroxisome proliferator-activated receptor (PPAR) signaling is essential for pronephros segmentation. Next, we found that the co-activator, *ppargc1a*, which binds activated PPARs to regulate transcription of target genes, is dynamically expressed in renal progenitors and is requisite for segmentation.

Results: *ppargc1a*$^{sa13186-/-}$ mutants with a T->A substitution that results in a putative null allele have an reduced distal tubule segment and increased proximal tubule domain, which was recapitulated in subsequent knockdown studies and rescued with *ppargc1a* overexpression. Further, *ppargc1a* acts to promote *tbx2b*, a transcription factor necessary for proper formation of the distal segment. Interestingly, *ppargc1a*$^{sa13186-/-}$ have an expanded *sim1a* domain, a transcription factor which is thought to regulate proximal segments. Conversely, *ppargc1a* expression was expanded in *sim1a* deficient embryos. This data suggests a negative regulation between the two factors. To test this interaction, we examined the proximal straight tubule domain in *sim1a* deficient, *ppargc1a* deficient, and doubly deficient embryos. While the loss of *sim1a* resulted in an abrogated proximal straight tubule, loss of *ppargc1a* resulted in expanded proximal straight tubule, but loss of both factors results in a completely restored segment boundary.

Conclusions: Taken together, this data strongly suggests that Ppargc1a and Sim1a act to counterbalance each other in an antagonistic fashion that is necessary for proper nephron segment boundary formation. These findings reveal for the first time how a layer of redundancy within the mechanism of segment boundary delineation is used to mitigate segment formation. Thus, these studies have discovered a useful paradigm to advance our understanding of nephron segmentation mechanisms.

Deletion of SWI/SNF Chromatin Remodeling Component Brg1 in Nephron Progenitors Causes Renal Hypoplasia

Michael I. Rauchman,[1,2] Ajeet P. Singh,[3] Jeannine M. Basta,[1,2] Lynn Robbins.[1,2] *[1]Internal Medicine- Nephrology, Washington University in St. Louis, St. Louis, MO; [2]VA St. Louis Healthcare System, St. Louis, MO; [3]Cornell University, Ithaca, NY.*

Background: Regulation of the self-renewal and differentiation capacity of the nephron progenitor (NPC) is a delicately balanced process. Decreased self-renewal or increased differentiation during kidney development can result in decreased nephron number at birth. When severe, this leads to childhood kidney failure. However, even moderate reductions in nephron number are associated with hypertension and chronic kidney disease in adulthood. The molecular mechanisms that modulate expression of genes for expansion of nephron progenitors are not completely understood. Mounting evidence supports a role for the SWI/SNF (SWItch/Sucrose Non-Fermentable) chromatin remodeling complex in regulating mesodermal cell fate. The SWI/SNF complex is a large evolutionarily conserved protein complex required for embryonic development. The complex is composed of 10-12 subunits including alternative core ATPase subunits BRM (Brahma) and Brg1 (Brahma related gene 1) that modulate chromatin structure on targeted loci, and regulate lineage restricted gene expression during development. We found that Brg1 associated with Sall1, suggesting that SWI/SNF has a functional role in NPCs.

Methods: We genetically deleted the Brg1 gene (*Smarca4*) in mouse NPCs.

Results: Deficiency of Brg1 in Six2+ NPCs resulted in hypoplastic kidneys by embryonic day (E) 17. The number of Six2+ NPCs was reduced in mutant kidneys as early as E14, which correlated with a significant reduction of phospho-histone H3 positive dividing Six2+ NPCs. The nephron progenitor cells were almost completely lost by the time of birth. Similar to *Sall1* mutants, global gene expression changes in E17 Brg1 mutant kidneys suggested defects in cell adhesion. RNA-seq analysis also showed downregulation of many genes required for mitochondrial respiration, suggesting reduced metabolic fitness of mutant NPCs. Brg1 is not expressed in adult kidney, however upon nephrotoxic injury with aristolochic acid Brg1 was significantly upregulated, indicating that the molecular pathways regulating kidney development may be activated for repair processes after injury.

Conclusions: Together, these data suggest that Brg1 regulates expression of genes that are required for the self-renewal and maintenance of nephron progenitor cells. Our results reveal novel functions of Brg1 in developing kidney.

FR-OR045

Inactivation of Foxi1 Rescues Most of the Hes1-Deficient Mouse Kidney Collecting Duct Defects

Malini Mukherjee,[1] Jennifer DeRiso,[2] Kameswaran Surendran.[1] *[1]Sanford Research / University of South Dakota, Sioux Falls, SD; [2]Sanford Research, Sioux Falls, SD.*

Background: The distal nephron and collecting duct segments of mammalian kidneys consist of intercalated cell types intermingled among Aqp2-expressing (principal) cell types. Notch signaling ensures that a sufficient number of cells select the Aqp2-expressing instead of an intercalated cell state. However, the precise mechanisms by which Notch patterns the collecting ducts is unknown. Here we tested whether Notch signaling simply represses Foxi1, an essential intercalated cell specific transcription factor, to allow for principal cell differentiation.

Methods: Hes1, a direct target of Notch signaling, was inactivated in developing kidney distal nephron and collecting duct segments by generating *Cdh16-Cre;Hes1*$^{f/f}$ mice and compared with *Cdh16-Cre;Hes1*$^{f/f}$*;Foxi1*$^{-/-}$ mice to determine whether the only function of Notch in developing collecting ducts is to repress Foxi1. We also tested whether Hes1 directly regulates principal cell genes in a calcium/calmodulin-dependent protein kinase-II (CaMKII) in *ex vivo* embryonic kidney cultures.

Results: Inactivation of *Hes1* resulted in fewer principal cells, and reduced principal cell specific gene expression, and ability to concentrate urine, along with increased expression of *Foxi1*. Inactivation of *Foxi1* rescues the Hes1-deficient principal cell deficiency and the ability to concentrate urine. However, detailed examination of *Cdh16-Cre;Hes1*$^{f/f}$*;Foxi1*$^{-/-}$ mouse kidneys revealed reduced expression of certain principal cell (PC) specific genes. Consistent with PC specific genes being regulated independent of Foxi1, *Foxi1* inactivation in mice does not result in increased expression of all PC specific genes. Additionally, Hes1 and PC specific genes are down-regulated upon inhibition of Notch signaling in cultured principal cells without activation of *Foxi1* expression. Hes1 can directly activate proximal promoters of *Aqp2*, *Aqp3* and *Elf5* in a CaMKII sensitive manner. The expression of PC specific genes and not *Foxi1* expression is dependent on CaMKII activity in *ex vivo* mouse embryonic kidney cultures.

Conclusions: Notch/Hes1 has at least two roles during collecting duct development: (i) principal cell fate selection by repressing Foxi1 expression and (ii) activation of principal cell gene expression in a CaMKII dependent manner.

FR-OR046

Molecular Programs of the Progenitor Population Directing Branching Morphogenesis and Differentiation of the Collecting Duct Network

Elisabeth Rutledge. Andrew McMahon Lab *University of Southern California, Los Angeles, CA.*

Background: Branching morphogenesis underpins the formation of arborized epithelial networks in many organs including the lung airways and the mammalian kidney collecting duct. Epithelial branch tip cells respond to inductive signals from the adjacent mesenchyme that regulate this process and maintain an uncommitted progenitor identity. Progenitors exit the tip to populate stalk regions where they differentiate into the regionally distinct, organ appropriate, cell types of the epithelial network.

Methods: We employed population-based and single cell RNA-sequencing (scRNA seq) screens to identify tip progenitor cell types and their differentiated progeny in the developing mouse and human kidney and validated key genes by *in situ* hybridization and immunostaining. Several tip-specific genes are being explored through knockout mouse studies to identify their role in tip-niche regulation. To establish lineages from ureteric progenitors to adult collecting duct cell types, we are combining cell fate studies with scRNA seq, facilitated by novel genetic tools.

Results: RNA sequencing has identified a tip-enriched gene set that include all known tip genes and conservation of tip progenitor profiles between the developing mouse and human kidney. Further, conservation is observed in other branching organ systems. Expression studies show that ureteric tips have a complex gene expression pattern and cell fate analysis demonstrates that subsets of cells have lineage restrictions in the establishment of mature cell types. We analyzed the role of *Adamts18*, which encodes a secreted protease in mouse tip cells within the collecting duct and lung. Adamts18 null mutants display enlarged kidneys with double ureters while all mutants exhibit reduced growth of the airways.

Conclusions: Conserved gene regulatory programs organize the kidney tip progenitor niche in mouse and human, and progenitor niches in other branching organs. Lineage-tracing and scRNA seq show mosaicism of progenitor populations and how this determines their potential to form the mature collecting duct cell types. Analyses of Adamts18 mutants give new insights into mechanisms of branching growth in several branching networks.

Adult Mouse Aqp2+ Progenitor Cells Maintain and Remodel Connecting Tubule/Collecting Duct

Chao Gao,[1] Long Zhang,[1] Lihe Chen,[2] Enuo Chen,[1] Wenzheng Zhang.[1] WZ Zhang lab *[1]Albany Medical College, Albany, NY; [2]NIH, Bethesda, MD.*

Background: Embryonic Aqp2^{+} progenitor cells generate all known cell types in the connecting tubule/collecting duct (CNT/CD). Aqp2$^{ECE/+}$ is a highly tamoxifen-inducible principal-cell-specific Cre mouse line with complete fidelity in cell specificity and no leakiness. Here we investigate weather Aqp2^{+} progenitor cells have multipotency and self-

renewal potential during CNT/CD maintenance and lithium-induced remodeling in adult mice.

Methods: *Adult Aqp2$^{ECE/+}$* RFP/+ and Aqp2ECE/+ rainbow/+ were induced with tamoxifen and examined at various time points post induction. Alternatively, tamoxifen-induced adult mice were treated with dietary LiCl for 4, 7 and 14 days, respectively. RFP or GFP co-expression with markers for PC (Aqp2), IC (V-ATPase B1, B2, CAII, AE1, and Pendrin) was investigated by immunofluorescence staining. PC to IC conversion rates ($RFP^+IC^+/(RFP^+IC^+ + RFP^+IC^-)$ and IC derivation from PC rates ($RFP^+IC^+/(RFP^+IC^+ + RFP^-IC^+)$ were determined. Uninterrupted single-colored clones in Aqp2ECE/+ rainbow/+ were grouped into single-cell and multiple-cell ones to represent regular and progenitor cell-like PC, respectively.

Results: *Aqp2$^{ECE/+}$* RFP/+ possessed no PC to IC conversion (no RFP^+ IC^+ cells) at day 1, intermediate state cells (RFP+ PC+ IC+) at day 3, and completely converted cells (RFP+ PC- IC+) at day 60 and 270 post induction. The conversion rate was 5% in the cortex and 0.02% in the medulla at day 60, which were increased to 25% and 4%, respectively, at day 270. IC derivation from PC rates were 47% and 6% in the cortex and medulla, respectively, at day 270. Lithium progressively facilitated PC-IC conversion, with the highest conversion rate reaching to 17.3% in cortex at day 14. Among the total cortical IC population, about 31% IC were derived from PC. Clone size ranged from 1-7 cells, with the largest ones observed at day 270 post induction and day 14 post lithium treatment. The majority of clones were 1-2 cells.

Conclusions: Adult $Aqp2^+$ progenitor cells possess multipotency and self-renewal potential, and contribute to CNT/CD maintenance and remodeling.

Whole Genome Bisulfate Sequencing and dCas9-Mediated Epigenome Editing Identifies a Key Role for Tumor Necrosis Factor Alpha in Progressive Diabetic Kidney Disease

Jihwan Park,[1] Yuting Guan,[1] Matthew J. Seasock,[1] Chengxiang Qiu,[1] Caroline A. Gluck,[2] Matthew Palmer,[1] Katalin Susztak.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]Nemours/AI DuPont Hospital for Children, Wilmington, DE.*

Background: Epigenetic changes have been proposed as the biological mechanism that encodes the long-lasting impact of metabolic changes on diabetic kidney disease (DKD) development. Understanding the contribution of methylation changes to DKD has been limited by a lack of comprehensive base resolution methylation data and specific methylome editing.

Methods: We have performed genome-wide based resolution methylation analysis of microdissected human control and DKD kidney tubule samples using whole genome bisulfate sequencing to identify methylation differences in human DKD kidneys. We used RNA sequencing to define transcriptional changes in the same samples. We validated results with larger array-based and animal model results. We applied dCas9-Tet1 system to define the causality of individual cytosine methylation changes and gene expression under specific sgRNAs.

Results: Methylation differences with genome-wide significance were detected in kidney tubule samples of patients with DKD. The changes were replicated by large cohort array-based methylation analysis. Differentially methylated regions (DMRs) were enriched on regulatory regions and associated with gene expression changes; however, it is likely that most changes were actually the result of cell type-specific changes rather than cell-specific changes. Pathway analysis indicated coordinated (methylation and gene expression) changes in metabolic and immune response pathways; specifically, changes in tumor necrosis factor alpha (TNFα) signaling. dCas9-Tet1 based lowering of cytosine methylation level of the TNFα DMR region resulted in an increase in TNF transcription indicating that methylation of this locus plays an important role in controlling gene expression. Increasing the TNF levels in diabetic animal models resulted in high grade albuminuria due to increased cytokine levels and cell death indicating TNFα is functionally important in DKD development.

Conclusions: Our results indicate wide spread methylation differences in DKD kidneys. We propose that epigenetic dysregulation of TNF locus likely contributes to nephropathy in patients with diabetes.

FR-OR049

Aberrant DNA Methylation of mTOR Pathway Promotes Inflammatory Activation of Immune Cells in Diabetic Kidney Disease

Guochun Chen,[1,2] Zheng Dong,[3,2] Lin Sun.[1,2] *[1]Department of Nephrology, The Second Xiangya Hospital, Changsha, China; [2]Kidney Research Institute, The Second Xiangya Hospital, Changsha, China; [3]Medical College of Georgia, Augusta, GA.*

Background: DNA methylation has been implicated in the pathogenesis of diabetic kidney disease (DKD), but the underlying mechanism is unclear. We hypothesize that aberrant DNA methylation in peripheral immune cells may contribute to the inflammation and pathological progression in DKD.

Methods: Whole DNA samples were extracted from human peripheral blood mononuclear cells (PBMCs) and applied to genome-wide methylation analysis. PBMCs were isolated from human whole blood samples to determine the expressions of DNMTs and their relationship with the inflammatory activities. At 8 weeks of age, db/db mice were treated with 5-Aza or PBS twice a week for 12 weeks. Peripheral immune cells were isolated from donor db/db mice with or without 5-Aza treatments and intravenously infused to host diabetic animals. In in-vitro studies, human PBMCs and mouse splenocytes were isolated and applied to the intervention experiments of targeting DNMT1 or mTOR pathway.

Results: The key DNA methylation enzyme DNMT1 increased along with the inflammatory activity of PBMCs in DKD patients. Inhibition of DNMT1 with 5-Aza markedly increased CD4+CD25+ regulatory T (Treg) cells in the peripheral immune cells from DKD patients and in db/db diabetic animals, leading to enhanced immunosuppressive activity. In db/db mice, adoptive transfer of Treg cells from 5-Aza-treated animals beneficially modified the inflammatory phenotype of host immune system, resulting in significant improvement of diabetic albuminuria and chronic kidney injuries. We demonstrated differentially methylated genes in diabetic PBMCs, revealing prominent DNA hypomethylation in the upstream regulatory genes of mTOR pathway. Further mRNA array confirmed the induction of genes predominantly in the positive, rather than negative, regulators of mTOR pathway in DKD. In db/db mice, mTOR activity showed a correlation with the level of global DNA methylation and the inflammatory capacity of kidney immune cells. Finally, mTOR interventions efficiently modified the regulatory effects of 5-Aza on diabetic immune cells.

Conclusions: Chronic hyperglycemia induces aberrant DNA methylation of mTOR pathway, leading to pathogenic activation of immune cells in DKD progression. Our study highlights the therapeutic potentials of targeting epigenetic events in the immune system for treatment of chronic kidney disease and DKD in particular.

FR-OR050

Histone Demethylation near the Serum Amyloid A Promoter: Metabolic Memory Associated Inflammation

Brad Dieter,[1] Katherine R. Tuttle,[2] Rick L. Meek.[3] *[1]Providence Health Care, Spokane, WA; [2]University of Washington School of Medicine, Spokane, WA; [3]Providence Sacred Heart Medical Center, Spokane, WA.*

Background: Episodic hyperglycemia increases risk of diabetic complications, also known as "metabolic memory." The study aim was to determine if serum amyloid A (SAA) mediated inflammation is due to demethylation of trimethyl histone 3 lysine 27 (H3K27Me3) near the SAA promoter in podocytes and to correlate indicators of this demethylation with SAA expression in kidneys of humans and mice with diabetes.

Methods: SAA knockout (CRISPR-Cas9) and control mouse podocytes were exposed to advanced glycation end-products (AGE, 300 μg/mL) for 7 days, followed by 7 days without AGE. H3K27Me3 near the SAA promoter was measured via chromatin immunoprecipitation (ChIP). Levels of mRNA for SAA and inflammatory mediators: (CXCL5, CCL5, and CCL2) were measured by qt-PCR. H3K27Me3 demethylation was inhibited (GSK-1, 20 uM) in podocytes exposed to AGE for 1 day. ChIP measured H3K27Me3 near the SAA promoter in the kidney cortex of db/db and wild type mice (C57BLKS). Relationships between expression of JMDJ3 mRNA (H3K27Me3 specific demethylase) and SAA mRNA were determined in kidneys of diabetic and non-diabetic humans and mice (C57- BLKS, DBA/2, eNOS-deficient C57-BLKS, Nephroseq).

Results: H3K27Me3 was reduced (95%, n=6 pooled samples) after 7-day periods of AGE exposure and AGE withdrawal in podocytes. Levels of mRNA increased for SAA (17±6-fold, p=0.025) and inflammatory mediators: CXCL5 (18±12-fold, p=0.004), CCL5 (1.6±0.6-fold, p=0.026), and CCL2 (2.0±0.7-fold, p=0.001). SAA knockout reduced expression of these mediators by ≥60% ($p<0.05$ for all). GSK-1 reduced AGE-induced expression of SAA and these mediators by ≥60% ($p<0.05$ for all). H3K27Me3 was lower in the kidney cortex of db/db mice compared to wild type mice (25±6%, p=0.049, n=6). Expression of JMDJ3 mRNA correlated with SAA mRNA in diabetic and non-diabetic kidney tissue from humans ($r=0.54$, $p<0.001$) and mice ($r=0.54$, $p<0.001$).

Conclusions: Episodic exposure to AGE, a hyperglycemia-related perturbation, caused H3K27Me3 demethylation near the SAA promoter and increased expression of inflammatory mediators in podocytes. Correlative studies showed that indicators of this histone demethylation process and increased SAA expression carried over into kidney tissue of humans and mice.

FR-OR051

Genetic Inactivation of Histone H3 K79 Methyltransferase Dot1l in Aqp2+ Progenitor Cells Causes CKD by Upregulating Endothelin-1 in Mice and Humans

Long Zhang,[1] Lihe Chen,[2] Chao Gao,[1] Enuo Chen,[1] Wenzheng Zhang.[1] *[1]Albany Medical College, Albany, NY; [2]NIH, Bethesda, MD.*

Background: Histone H3 K79 methyltransferase Dot1l represses aldosterone target genes including endothelin-1 (ET1). $Aqp2^+$ progenitor cells give rise to all known cell types in the connecting tubule and collecting duct. Here we investigate whether genetic inactivation of *Dot1l* in $Aqp2^+$ progenitor cells causes chronic kidney disease (CKD) by upregulating ET1.

Methods: $Dot1l^{f/f}$ Aqp2Cre ($Dot1l^{AC}$) and $Dot1l^{f/f}$ $ET1^{f/f}$ Aqp2Cre (DE^{AC}) mice were generated to disrupt Dot1l with or without intact ET1 in the $Aqp2^+$ progenitor cells, respectively. Aqp2Cre mice were used as WT control. Mice were analyzed at the ages of 12 and 24 months. Alternatively, two-month-old mice were subject to UUO and analyzed 14 days later. Various molecular, cellular and pathological methods were employed to assess the renal function and pathology. Cells with loss of dimethyl K79 ($H3m2K79^-$) were identified and isolated from archived kidney biopsies from patients with diabetic nephropathy (n=50) by laser capture to identify hDOT1L mutations via sequencing.

Results: At both ages, WT mice were apparently normal. $Dot1l^{AC}$ developed slight and severe symptoms mimicking human chronic kidney disease (CKD). The CKD symptoms include extreme polyuria, proteinuria, natriuresis, a variety of tubular abnormalities,

interstitial fibrosis, and mononuclear cell infiltrate. These changes were coupled with upregulated ET1 and fibrotic markers (FSP1, Collagen IV, Vimentin, and a-SMA). However, all of these phenotypic features were ameliorated by inactivation of ET1 in DE^{AC} mice. Consistently, $Dot1l^{AC}$ vs. WT developed more prominent UUO-induced kidney fibrosis, which was partially rescued in DE^{AC} mice. Some CNT/CD cells in DN were $H3m2K79^{-}$. Analysis of the microdissected $H3m2K79^{-}$ cells revealed two single-base deletions and an $E^{129}K$ mutation that is predicted to abolish the methyltransferase activity.

Conclusions: Dot1l is a new potential renoprotective factor by repressing ET1 in both mice and humans. Inactivation of Dot1l in $Aqp2^{+}$ progenitor cells is sufficient to trigger CKD development.

Single-Cell RNA-Seq of Dissected Glomeruli in a Mouse Model of Diabetic Nephropathy

Jia Fu,[1] Kemal M. Akat,[2] Kyung Lee,[1] John C. He.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]The Rockefeller University, New York, NY.*

Background: Diabetic nephropathy is the most common etiology for end-stage renal disease. In recent years, single-cell RNA-seq (scRNA-seq) has evolved into a reliable tool to interrogate gene expression changes on a single-cell level. Previous scRNA-seq studies on human and animal kidneys failed to capture glomerular cells even when sequencing thousands of cells. Here, we use scRNA-seq on microdissected glomeruli to study changes in a mouse model of diabetic nephropathy (DN).

Methods: Diabetes was induced at 8 weeks of age in IRG/Nphs2.Cre/$eNOS^{-/-}$mice (C57BL/6 background) with 50 mg/g streptozotocin (STZ) over 5 consecutive days. Single-cell suspensions of microdissected whole glomeruli from STZ-treated (DN) and control (Ctrl) mice were used for scRNA-seq on the Fluidigm C1 platform using 800-cell IFCs (v2) according to the manufacturer's instructions. Resulting libraries were sequenced on an Illumina NextSeq500.

Results: We captured 186 and 217 single-cells from control mice, and 188 and 238 single-cells from diabetic mice. After QC filtering 99 and 199 control cells, and 107 and 188 cells from DN were used for downstream analysis. K-means clustering identified 4 cell populations representing endothelial cells (marker genes Kdr, Pecam1, Emcn), podocytes (Nphs1/2, Podxl), mesangial cells (Pdgfrb, Myl9, Gata3), and leukocytes (Cd44, Cd52, Cd53, Cd74, Cd300a). The relative cell type contribution was (Ctrl %/DN %) 47%/62% for endothelial cells, 16%/7% for podocytes, 34%/15.5% for mesangial cells, and 3%/15.5% for leukocytes. Differential analysis of gene expression comparing DN and Ctrl showed genes known to be altered in diabetic glomeruli as well as several interesting candidate genes which have thus far not been demonstrated to be affected in DN.

Conclusions: Single-cell RNA-seq of glomeruli overcomes limitations of previous studies which largely missed glomerular cells altogether. This approach allowed us to confidently identify 3 major cell types of the glomerulus, and the inflammatory response associated in this DN model. The low percentage of podocytes and mesangial from diabetic glomeruli as compared those from control suggests either loss or dedifferentiated of these cells in the diseased condition.

Modelling Immune Mediated Renal Injury through the Use of Induced Pluripotent Stem Cell Derived Organoids

Thomas K. Dodd,[1] Jessica L. Davis,[1] Ciarán Kennedy,[1] Shane Clerkin,[2] Monica De gaetano,[1] Catherine Godson,[3] Orina Belton,[1] John Crean.[1] Diabetes Complications Research Centre, UCD School of Biomolecular and Biomedical Science, University College Dublin *[1]University College Dublin, Dublin, Ireland; [2]UCD, Dublin, Ireland; [3]The Conway Institute of Biomolecular and Biomedical, Belfield, Dublin, Ireland.*

Background: The role of inflammatory cells in chronic kidney disease has been well documented, with macrophage infiltration and accumulation implicated in the initiation and progression of renal injury. However, current models of disease fail to accurately reflect the initial cycles of damage and resolution. At the core of this issue remains a fundamental gap in our knowledge of how discrete inflammatory signalling networks converge and interact with renal tissue to cause fibrosis. We have found that plasticity of resident cells and infiltrating cells is reflected by significantly increased levels of the stemness regulator, miR-302 in exosomes of patients with CKD while additionally the TGFβ signalling network was identified as a mediator of macrophage reprogramming.

Methods: IPSCs were differentiated into kidney organoids over a 24 day period. Primitive streak formation was induced by treating cells with CHIR99021 8μM for 3 days. Medium was then changed to APEL medium supplemented with 200ng/ml FGF9 and Heparin 1μg/ml. On day 12, growth factors were removed and organoids were matured until day 24. Organoids were then cultured in conditioned media from peripheral blood mononuclear cells (PBMCs) polarised towards a pro-inflammatory phenotype using lipopolysaccharide 200ng/ml and Interferon γ 20ng/ml and towards a pro-resolving phenotype using interleukin 4 20ng/ml and interleukin 13 20ng/ml. Organoids were subsequently fixed, stained and imaged using confocal microscopy for known markers of renal damage. Similarly, organoids were also treated with the nephrotoxic agent Aristolochic Acid (AA) and co cultured with PBMCs.

Results: Culturing of organoids in conditioned media for a 48 hour period lead to significant increases in the expression of αSmooth Muscle Actin, Fibronectin and KIM-1. Co culture of organoids exposed to AA for up to 24 hours with PBMCs resulted in significant damage to the organoid, accompanied by migration and infiltration of differentiated cells into these damaged organoids.

Conclusions: We propose that this novel model of macrophage induced renal damage can be used to investigate the role of inflammatory pathways which result in fibrosis and that by manipulating the plasticity of resident and infiltrating cells we may inhibit or reverse the progression of fibrosis *in vivo*.

FR-OR054

The NGAL-Macrophage Therapy Improves Diabetic Kidney Disease in db/db Mice by Induction of PI3K/Akt Pathway

Roser Guiteras,[1] Anna Sola,[1] Anna Manonelles,[2] Georgina Hotter,[3] Josep M. Cruzado.[2] Nephrology and Renal Experimental Transplantation, Institut d'Investigació biomèdica de Bellvitge (IDIBELL), Hospitalet de Llobregat, Barcelona, Spain *[1]Nephrology and Experimental Transplantation, IDIBELL, Barcelona, Spain; [2]Hospital Universitari de Bellvitge, Barcelona, Spain; [3]IIBB-CSIC, Barcelona, Spain.*

Background: Alternatively activated macrophages (M2) have regenerative properties and shown promise as cell therapy in chronic kidney disease. However, M2 plasticity is one of the major hurdles to overcome. Genetically modified macrophages stabilized by neutrophil gelatinase-associated lipocalin (NGAL) are able to preserve in stable manner their M2 phenotype. Nowadays, little is known about M2 macrophage effects in diabetic kidney disease (DKD). The aim of the study was to investigate the therapeutic effect of both bone marrow-derived M2 (BM-ØM2) and Ø-NGAL macrophages in the *db/db* mice

Methods: Seventeen wk-old mice with established DKD were divided into five treatment groups with their controls: **D+BM-ØM2; D+Ø-BM; D+Ø-NGAL; D+Ø-RAW; D+SHAM and non-diabetic (ND)** (*db*/- and C57bl/6J) animals. We infused $1x10^{6}$ macrophages twice, at baseline and 2 weeks thereafter. Blood, urine samples and kidney tissue were collected. To further ascertain the mechanism by which NGAL macrophage cell therapy is involved in epithelial kidney repair, we co-cultured renal epithelial cells and macrophages *in vitro*. We assessed epithelial proliferation, repair and epithelial phenotype integrity.

Results: BM-ØM2 did not show any therapeutic effect whereas Ø-NGAL significantly reduced albuminuria and renal fibrosis in db/db mice. The Ø-NGAL therapy increased the anti-inflammatory IL-10 and reduced some pro-inflammatory cytokines, reduced the proportion of M1 glomerular macrophages and podocyte loss and was associated with a significant decrease of renal TGF-β1. Furthermore, we demonstrated *in vitro* that NGAL overexpression in macrophages enhanced epithelial markers and healthy epithelial phenotype through the induction of PI3K/Akt pathway. In addition, NGAL activated proliferation markers such as Ki67 and PCNA through the inhibition of PPAR-γ.

Conclusions: Overall, our study provides evidence that NGAL macrophage cell therapy has therapeutic effects on DKD. NGAL acts as a mediator and is a crucial player reducing inflammation, fibrosis and promoting epithelial proliferation.

Macrophage-Derived Migrasomes Transfer of IL-11 Is a Novel Mechanism of Renal Interstitial Fibrosis in Diabetic Nephropathy

Xiaodong Zhu, Yu Zhao, Yuteng Jiang, Yuqiu Liu, Xiaoliang Zhang. *Institute of Nephrology, Zhong Da Hospital, Southeast University, School of Medicine, Nanjing, China.*

Background: Migrasome is a newly discovered, migration-dependent vesicle which differ dramatically from common extracellular vesicles(EVs) and primarily aid in intercellular communications. Macrophages infiltration and fibroblasts activation have been closely associated with renal interstitial fibrosis in diabetic nephropathy(DN). Whether macrophage produce migrasomes and contribute to the pathological processes are unknown.

Methods: Macrophage migrasomes were examined in streptozotocin murine model and Raw264.7 cells by transmission/scanning electron microscopy. Migrasomes isolated from M1/M2 phenotype macrophage, high glucose treated macrophage (M1-mig, M2-mig, HG-mig)interaction with renal fibroblast were assessed and migrasome gene profiling to identify the intercellular signaling.

Results: Ultrastructural analysis revealed that macrophage produce the previously unrecognized vesicles (Fig1.*arrowhead*) that typically grow on the tips or intersections of retraction fibers(Fig1.*triangle*). The vesicles were confirmed as the newly discovered migrasome by morphology and biomarker data that distinguish them from common EVs. We noticed that activated macrophage and HG enhanced migrasome production. Released migrasomes can directly initiate fibroblasts transdifferentiation which fibrosis markers (αSMA, COL1) markedly increased in HG/M1-mig group (by 10-15fold, respectively), while migrasome inhibitor CK636 or Dynasore alleviate fibrosis in DN model. We performed migrasomes gene-profiling to determine what intercellular fibrosis messages might be delivering. Amongst the top ranking genes, notably, we found a specific enrichment of IL-11 mRNA in HG-mig and M1-mig. The knockout IL-11 migrasomes or blocking fibroblasts IL-11RA sharply decreased the fibrosis levels.

Conclusions: Our findings suggest a fundamental, but formerly unrecognized pattern via which macrophage exert their effects through migrasomes and more depth of their functional roles shall be unearthed. IL-11 in HG/M1-mig driving fibroblasts transdifferentiation may be a novel mechanism of fibrosis in DN.

Funding: Government Support - Non-U.S.

TYRO3 Is a Novel Podocyte Protective Factor in Glomerular Disease

Fang Zhong,[1] Wenjun Ju,[2] Matthias Kretzler,[3] Kyung Lee,[4] John C. He.[5] *[1]Icahn Medical School at Mount Sinai, New York, NY; [2]University of Michigan, Ann Arbor, MI; [3]U.Michigan, Ann Arbor, MI; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]Mount Sinai School of Medicine, New York, NY.*

Background: Our previous work demonstrated a protective role of protein S against podocyte loss in early diabetic kidney disease (DKD) [Zong F JASN 2018]. Protein S is known to have anti-inflammatory and anti-apoptotic effects through the activation of Tyro3, Axl, and Mer (TAM) receptors. We find that the biological effects of protein S in DKD are largely mediated by Tyro3 in podocytes. The aim of this study was to determine the role of Tyro3 in podocyte injury in glomerular disease.

Methods: Tyro3 mRNA levels were checked in different datasets of human kidneys with DKD. Tyro3 knockout mice and control WT mice were made diabetes or injected with adriamycin to induce nephropathy. Inducible podocyte-speciifc Tyro3 overexpression mice were generated and crossed with OVE26 diabetic mice or Tg26 mice or induced nephropathy with adriamycin. Albuminuria, kidney histology, and podocyte number were assessed in these mice. Western blot and PCR analysis were used to assess mechanisms of Tryo3 regulation and biological effects in cultured human podocytes.

Results: *TYRO3* mRNA expression is highly enriched in human glomeruli, and immunostaining showed that TYRO3 co-localized with podocyte marker. Glomerular *TYRO3* mRNA expression was suppressed in the progressive DKD. It was also suppressed in focal segmental glomerulosclerosis (FSGS). We showed that genetic ablation of *Tyro3* in murine models of DKD and Adriamycin-induced nephropathy (ADRN) worsened albuminuria and glomerular injury, suggesting a protective effect of TYRO3 in early DKD and FSGS. Conversely, we showed that induction of TYRO3 overexpression specifically in podocytes significantly attenuated albuminuria and kidney injury in mice with DKD, ADRN and HIV-associated nephropathy. Mechanistically, we found that TYRO3 expression was suppressed by activation of TNF-α/NF-κB pathway, which may contribute to decreased TYRO3 expression in progressive DKD and FSGS, and TYRO3 confers anti-apoptotic effects through the activation of AKT pathway in podocytes.

Conclusions: In conclusion, we demonstrate that TYRO3 has a critical role to maintain normal podocyte function and could be a potential new drug target to treat glomerular disease.

Development of a Peptide Inhibitor of a Novel Target to Retard Diabetic Nephropathy

Zhonglin Chai,[1] Mark E. Cooper.[2] *[1]Monash University Central Clinical School, Melbourne, VIC, Australia; [2]Monash University, Melbourne, VIC, Australia.*

Background: Diabetic nephropathy (DN) is the major cause of end-stage renal disease worldwide, and remains suboptimally treated medically. A large body of compelling data from our group have demonstrated a critical role of CDA1 in DN and validated CDA1/CDA1BP1 interaction as a promising target to retard diabetic nephropathy. We have developed a prototype inhibitor, CHA-061, to target this novel axis.

Methods: This study focuses on the assessment of CHA-061 for its efficacy to attenuate parameters relevant to renal fibrosis in two models of diabetes. The first model is an insulin deficient model using streptozotocin (STZ)-induced diabetes in ApoE KO mice, a model relevant to type 1 diabetes. The second is a type 2 diabetes model using db/db mice which initially become obese and subsequently diabetic as a result of the leptin receptor mutation. Both non-diabetic control and diabetic mice with established DN after diabetes was developed for 10 weeks were randomly allocated to receive either vehicle or CHA-061 treatment (10 mg/kg IP injections twice a week) for 10 weeks.

Results: The analysis of kidney tissues showed that, in the vehicle treated ApoE KO mice, diabetes was associated with >2-fold increase in gene expression of sclerotic molecules such as collagens I and III as well as proinflammatory genes such as TNFα and MCP1. Immunohistochemical staining of collagen III was increased >10-fold and the glomerulosclerosis index (GSI) as assessed by PAS staining was increased >2-fold in diabetic ApoE KO mice. These parameters were significantly attenuated in CHA-061 treated diabetic ApoE KO mice. Similarly, CDA1 expression levels were increased ~2-fold in diabetic db/db mice accompanied by >2-fold increase in gene expression of sclerotic molecules such as CTGF, fibronectin, collagens I, III and IV when compared to the non-diabetic dbh mice. CHA-061 treatment reduced these parameters in the diabetic db/db mice to levels similar to those in the non-diabetic controls. These results were consistent with our previous target validation data using CDA1 KO and CDA1BP1 KO mouse strains.

Conclusions: Taken together, the current study has demonstrated the efficacy and feasibility to pharmacologically target the novel CDA1/CDA1BP1 axis to retard nephropathy in both type 1 and type 2 diabetes by targeting not only fibrotic but also proinflammatory pathways.

Chloride-Insensitive WNK4 Mice Reveal Differential NCC Regulations by Dietary Potassium

Jen-Chi Chen,[1] Yi-Fen Lo,[1] Chou-Long Huang,[2] Shih-Hua P. Lin,[1] Chih-Jen Cheng.[1] *[1]Tri-Service General Hospital, Taipei City, Taiwan; [2]University of Iowa Carver College of Medicine, Iowa City, IA.*

Background: With-no-lysine (WNK) kinases critically regulate sodium chloride cotransporter (NCC) in the distal nephron. Earlier works reveal that intracellular chloride ion ($[Cl^-]i$) binds to a hydrophobic pocket of WNKs and inhibits autophosphorylation and activity of WNKs in non-transporting *in vitro* condition. Substitution of two leucine residues (L319, L321) surrounding the hydrophobic pocket with phenylalanine makes WNK4 less sensitive to $[Cl^-]i$. The Cl^--sensing character of WNK4 hasn't been validated *in vivo*.

Methods: We generated the Cl^--insensitive L319F/L321F WNK4 mice using CRISPR/Cas9.

Results: The Cl^--insensitive L319F/L321F WNK4 mice displayed hypertension, hyperkalemia, and metabolic acidosis along with hyperactive NCC and impaired urinary potassium excretion, mimicking pseudohypoaldosteronism type II. To test the Cl^--sensing character of WNK4 in response to dietary potassium, we fed L319F/L321F WNK4 mice diets with various potassium contents. Potassium deprivation failed to further enhance NCC in L319F/L321F WNK4 mice. Chronic potassium-rich diet still dephosphorylated NCC in L319F/L321F WNK4 mice. These results suggest that Cl^--insensitive WNK4 is an NCC stimulator, and the physiological $[Cl^-]i$ in the distal nephron suppresses WNK4 activity. Potassium deprivation enhances NCC through ameliorating Cl^--mediated inhibition on WNK4. In chronic potassium adaptation, other mechanism(s) overrides the constitutively active WNK4 to suppress NCC.

Conclusions: In sum, this study provides compelling evidence supporting that WNK4 is a bona fide NCC stimulator and Cl^- sensor in the distal convoluted tubule. The Cl^--sensing mechanism of WNK4 play an important role in potassium deprivation.

Funding: Government Support - Non-U.S.

FR-OR059

Regulated Dephosphorylation of NCC Shapes the Renal Potassium Switch Pathway

P. R. Grimm,[1] Eric J. Delpire,[2] Paul A. Welling.[1] *[1]University of Maryland School of Medicine, Baltimore, MD; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: The Renal Potassium Switch Pathway stimulates the thiazide-sensitive sodium chloride cotransporter (NCC) to limit urinary potassium loss at the expense of retaining sodium and elevating blood pressure. It has been established that low extracellular potassium ($[K^+]_o$) activates the WNK4-SPAK kinase cascade to drive NCC phosphorylation, but it remains mysterious how NCC is dephosphorylated in response to a rise in $[K^+]_o$. It has been assumed that high $[K^+]_o$ turns off WNK4-SPAK mediated NCC phosphoactivation, allowing phosphatase activity to dephosphorylate WNK4, but this remains unclear.

Methods: Kinase-activating mutations were introduced in SPAK, the terminal kinase in the WNK signaling pathway, and renal expression of the constitutively active (CA) SPAK mutant was specifically targeted in mice to the early DCT. NCC abundance (tNCC) and phosphorylation (pNCC) were evaluated in vivo and in isolated tubules, together with telemetric blood pressure (BP) measurements in response to changes in dietary potassium and $[K^+]_o$. CA-SPAK were compared to Control mice.

Results: CA-SPAK mice display NCC hyperphosphorylation and thiazide-treatable hypertension. BP remained elevated in CA-SPAK mice, compared to control, over a wide range of $[K^+]_o$, as predicted. However, BP dropped in CA-mice when $[K^+]_o$ exceeded 5mM, and this was coincident with a reduction in pNCC/tNCC, revealing a $[K^+]$-regulated dephosphorylation mechanism. Acute elevation in $[K^+]_o$ decreases pNCC in isolated DCT from WT but not CA-SPAK mice. However, chronic potassium loading for 2 or 5 days reduces pNCC abundance with an IC50 of ~4.1mM in WT. pNCC is also reduce in CA-SPAK mice under the same conditions but with a rightward shift in pNCC vs. $[K^+]_o$ curve (IC50 ~ 5.5mM), suggesting chronic activation of a protein phosphatase (PP). Subsequent RNA profiling studies revealed a network of PP-subunits are regulated to decrease pNCC in response to increased $[K^+]_o$.

Conclusions: Because CA-SPAK drives NCC phosphorylation independent and downstream of WNK, these observations provide strong support for a potassium-activated phosphatase that directly dephosphorylates NCC. Thus $[K^+]_o$–regulated phosphorylation as well as dephosphorylation of NCC shape the Renal Potassium Switch Pathway. Regulated NCC dephosphorylation provides new mechanism to explain why high dietary K^+ consumption alleviates salt-sensitive hypertension.

FR-OR060

Differential Functions of Chloride Channels Clc-k1 and Clc-k2 in Mouse Kidneys

Yi-Fen Lo, Jen-Chi Chen, Shih-Hua P. Lin, Chih-Jen Cheng. *Tri-Service General Hospital, Taipei City, Taiwan.*

Background: Two voltage-gated ClC chloride (Cl^-) channels, ClC-Ka and ClC-Kb, conduct urinary Cl^- reabsorption in renal tubules. Genetic alterations on ClC-Ka/ClC-Kb result in human diseases with abnormal blood pressure. Previous studies have shown that rodent ortholog Clc-k1 and Clc-k2 expressed in the renal medulla and cortex, respectively. The physiological roles of these two Cl^- channels have not been compared.

Methods: We created Clc-k1 knockout and Clc-k2 knockout mice sharing the same genetic background using the Ksp-Cre system.

Results: Clc-k1 deficiency resulted in polyuria with a blunted response to vasopressin and relatively normal extracellular fluid. In contrast, Clc-k2 deficiency led to uncompensated renal salt wasting, hypovolemia, and impaired renal function. The sodium transporters in distal nephron were unanimously upregulated in Clc-k1 knockout mice but downregulated in Clc-k2 knockout mice. Various vasopressors, including catecholamine, endothelin, and serotonin, were stimulated in Clc-k2 knockout mice but not in Clc-k1 knockout mice. Patchy interstitial inflammation & fibrosis, hyperplasia of juxtaglomerular apparatus, and renal scarring were observed in Clc-k2 knockout mice. High salt diet rescued the renal function and ameliorated the interstitial inflammation and fibrosis in Clc-k2 knockout mice. In embryonic kidneys, Clc-k2 transcript first expressed in the nephron progenitors on E13.5 and gradually extended into the inner medulla along with NKCC2. Clc-k1 was not detected in the embryonic kidneys and found in inner medulla on P1 after birth.

Conclusions: Clc-k1 and Clc-k2 express and function differentially in the embryonic and adult kidney. The critical roles of Clc-k2 in distal salt reabsorption and embryonic kidney explain the uncompensated salt wasting in Clc-k2 knockout mice.

FR-OR061

A Single Gastric K+ Load Induces Acute Diuresis in Mice

Samuel L. Svendsen,[1] Simon Kornvig,[1] Casper K. Larsen,[2] Iben S. Jensen,[1] Jens G. Leipziger,[1] Mads V. Sorensen.[1] *[1]Aarhus University, Aarhus, Denmark; [2]LEO Pharma, Copenhagen SV, Denmark.*

Background: K^+ balance relies on regulated renal K^+ excretion to match variable dietary K^+ intake. Upon a K^+ rich meal, rapid and effective urinary K^+ excretion is obligatory. The renal adaptation to an acute K^+ load involves an increase of the driving force for K^+ secretion by shifting the distal tubular Na^+ reabsorption from being electroneutral (NCC) to electrogenic (ENaC). In addition, K^+ secretion in the CD is stimulated by increased luminal flow. Here we asked, if a high K^+ intake acutely increases urinary flow.

Methods: Mice were K^+ challenged through gavage, diets or a combination of these. After K^+ loading urinary volume, $[K^+]_u$ and $[Na^+]_u$, plasma osmolality, $[K^+]_p$ and $[Na^+]_p$ were measured.

Results: 1) Mice switched from a 1% to a 2% K^+ diet increased their diuresis markedly within 12h. **2)** Mice switched from a 1% to a 0.01% K^+ diet had a biphasic diuretic response. During the first 12h their diuresis decreased, whereas it increased from 12 to 36h. **3)** A single K^+ load, by gastric gavage, corresponding to 25-50% of daily K^+ intake induced diuresis within 30 min. This occurred despite augmented plasma osmolality. $[K^+]_u$ remained unchanged and therefore the increased urinary K^+ excretion depended on the volume effect **4)** K^+ gavage did not changes urinary creatinine excretion suggesting a constant GFR. **5)** Subsequently, a possible direct and acute effect of a plasma $[K^+]$ ($[K^+]_{bl}$) increase was tested in isolated perfused mTALs and CDs. An acute $[K^+]_{bl}$ increase (from 3.6 to 6.5 mM) did not affect TAL NaCl absorption (measured 5 and 25 minutes post K^+ jump). In contrast, the same manoeuver reduced the CDs sensitivity to stimulated AVP-mediated water absorption (measured 10 minutes post K^+ jump).

Conclusions: Dietary K^+ load induces a rapidly on setting diuresis. This increase in urinary volume appears crucial for a powerful K^+ elimination since it appears prior to alteration in $[K^+]_u$. Based on preliminary data we suggest that the physiological mechanism of K^+-induced diuresis involves AVP desensitization of the CD.

FR-OR062

SPAK Is Rapidly Dephosphorylated in the Distal Convoluted Tubule during Acute Potassium Loading

Anindit Mukherjee,[1] Chao-Ling Yang,[3] David H. Ellison.[2] *[1]Oregon Health Science University, Portland, OR; [2]Oregon Health & Science University, Portland, OR; [3]Oregon Health and Science University, Portland, OR.*

Background: The thiazide-sensitive sodium chloride cotransporter (NCC) of the distal convoluted tubule (DCT) is phosphorylated and activated by WNK acting through SPAK. High extracellular potassium leads to rapid NCC dephosphorylation and inactivation. However, the molecular mechanism remains unknown. Here, we examined the roles of SPAK in this process: specifically, testing the hypothesis that ***SPAK is dephosphorylated by high extracellular K in cultured cells and in vivo.***

Methods: 1) SPAK-transfected HEK293 cells were treated with 0mM to 10Mm (high) KCl, for one hour. Cell extracts were analyzed by western blot. 2) Kidney slices were incubated for 30 minutes in 0 Mm K to increase NCC phosphorylation and then treated with 3mM or 10mM K for 30 minutes. Slices were snap frozen. 3) C57/BL6 mice were gavaged with either vehicle or 3% KCl for 15 mins. Blood collected was used for electrolyte measurement by iSTAT. One kidney was processed for western blot and the other kidney was either perfused for IF or cortex-rich kidney poles were isolated and snap frozen.

Results: In HEK293 cells, raising medium $[K^+]$ for one hour led to a reduction in transfected and endogenous SPAK phosphorylation at S383. This *in vitro* finding was replicated *ex vivo* in kidney slices by western blot analysis. We saw parallel decrease in NCC and SPAK phosphorylation levels in kidney slices incubated in high K (10mM) vs normal K (3mM) buffer. We used a model similar to Loffing and colleagues to test whether SPAK dephosphorylation by high K^+ occurs in a physiologically relevant setting. C57/BL6 mice gavaged with 3% KCl for 15 minutes showed an increase in plasma $[K^+]$ and a corresponding decrease in SPAK phosphorylation in the cortex, but not in whole kidney. Immunofluorescence studies also showed decreased SPAK-S383 primarily in parvalbumin-positive 'early' DCT1 upon K loading. Cytosolic total-SPAK puncta observed in control kidneys rapidly disappeared after K loading, suggesting a rapid alteration in SPAK localization as well as phosphorylation by extracellular K.

Conclusions: Although prior work suggested that SPAK is not involved in rapid NCC dephosphorylation, the current data indicate that SPAK is rapidly dephosphorylated *in vivo* primarily along the DCT during short term K treatment. Further work will be necessary to establish that this effect is essential for rapid NCC dephosphorylation.

FR-OR063

Phosphorylation of β1Pix by AMPK and Its Role in ENaC Inhibition in Kidney Epithelial Cells

Pei-Yin Ho,[1] Hui Li,[1] Lei Cheng,[2] Robert A. Fenton,[2] Kenneth R. Hallows.[1] *[1]USC/UKRO Kidney Research Center; Medicine, USC Keck School of Medicine, Los Angeles, CA; [2]Biomedicine, Aarhus university, Aarhus, Denmark.*

Background: AMP-activated kinase (AMPK) inhibits the epithelial Na^+ channel (ENaC) by increasing the binding of the ubiquitin ligase Nedd4-2 to ENaC. We recently showed that AMPK inhibits ENaC by direct phosphorylation of Nedd4-2 at a site critical for Nedd4-2 stability. We also demonstrated that the Pak-interacting exchange factor β_1Pix is required for ENaC inhibition by AMPK and for Nedd4-2 stability in mouse kidney cortical collecting duct (CCD) cells. AMPK activators increase the binding of β_1Pix to 14-3-3. Thus, AMPK may enhance Nedd4-2-dependent ENaC degradation by promoting the formation of a β_1Pix/Nedd4-2/14-3-3 complex. Here, we further investigate the mechanisms of how AMPK promotes a β_1Pix-14-3-3 interaction and whether 14-3-3 binding is important for ENaC inhibition by AMPK.

Methods: Protein mass spectrometry (MS), *in vitro* translation and phosphorylation assays were used to detect AMPK phosphorylation sites in β_1Pix. Various constructs were transiently expressed in polarized mpkCCD$_{c14}$ cells. An epithelial volt-ohmmeter was used to measure amiloride-sensitive equivalent short-circuit currents in mpkCCD$_{c14}$ cells ± combined treatment with the AMPK activators AICAR and A-769662 for 24 h. Coimmunoprecipitation assays were used to examine modulation of β_1Pix/14-3-3/Nedd4-2 interactions by AMPK.

Results: AMPK directly phosphorylates β_1Pix *in vitro*, and six potential AMPK phosphorylation sites were detected by MS. Among these sites, the Ser-71 phosphorylation site on β_1Pix was found to be functionally significant. Compared to wild-type β_1Pix, overexpression of the β_1Pix-S71A mutant significantly reduced ENaC inhibition and the binding of both β_1Pix and Nedd4-2 to 14-3-3 caused by AMPK activation in mpkCCD$_{c14}$ cells. Moreover, overexpression of a β_1Pix-Δ602-611 mutant unable to bind 14-3-3 decreased the interaction between Nedd4-2 and 14-3-3. Finally, in preliminary studies, overexpression of the R18 peptide, which inhibits 14-3-3-target interactions, reduced the binding of both β_1Pix and Nedd4-2 to 14-3-3 and attenuated ENaC inhibition by AMPK in CCD cells.

Conclusions: Our results suggest that phosphorylation of β_1Pix at Ser-71 by AMPK is involved in the formation of a β_1Pix/Nedd4-2/14-3-3 complex, which promotes ENaC degradation caused by AMPK activation.

A Pivotal Role of WNK1/OSR1 Pathway in Regulation of Renal Proximal Sodium Transport

Motonobu Nakamura,[1] Shoko Horita,[1] Nobuhiko Satoh,[1] George Seki,[2] Tomohito Mizuno,[1] Hiroyuki Tsukada,[1] Yusuke Sato,[4] Haruki Kume,[4] Masaomi Nangaku,[1] Masashi Suzuki.[3] *[1]Division of Nephrology and Endocrinology, The University of Tokyo, Tokyo, Japan; [2]Yaizu City Hospital, Yaizu, Japan; [3]Tokyo Gakugei University, Koganei, Tokyo, Japan; [4]Department of Urology, The University of Tokyo Hospital, Tokyo, Japan.*

Background: In renal proximal tubules (PTs) we and others have shown that insulin stimulates both apical Na^+/H^+ exchanger (NHE)3 and basolateral Na^+/HCO_3^- co-transporter (NBCe1) via PI3K/Akt signaling. Pioglitazone (Pio) also stimulates both NHE3 and NBCe1 via non-genomic PPARg/ERK signaling (Cell Metab 2011). In human PTs, angiotensin (Ang)II stimulates both transporters via NO/ERK signaling (JASN 2014). However, the mechanism underlying this coordinate regulation in apical and basolateral PT sodium transport is poorly understood. In this study, we investigated the role of WNK1/OSR1 pathway in regulation of PT sodium transport.

Methods: By using a pH-sensitive dye BCECF we measured the basolateral NBCe1 activity and apical NHE3 activity in freshly-isolated rat PTs as well as human PTs, the latter obtained during surgery for renal cell carcinoma. We also measured the NBCe1 activity in rat PTs incubated overnight with siRNA against WNK1, WNK3, OSR1 or SPAK. Protein phosphorylation was analyzed by Western blotting in rat and human kidney cortex tissue.

Results: In freshly-isolated rat and human PTs, insulin and Pio markedly stimulated both NHE3 and NBCe1 activities, and an OSR1/SPAK inhibitor, Closantel (10mM) completely suppressed these stimulatory effects. Closantel also completely suppressed the AngII-stimulated NBCe1 and NHE3 activities in human PTs. Immunostaining analysis confirmed the expression of OSR1 protein in rat and human PTs. In rat and human kidney cortex, Closantel suppressed the insulin-induced OSR1/SPAK phosphorylation without affecting the Akt phosphorylation. Similarly, Closantel suppressed the OSR1/SPAK phosphorylation by Pio and AngII without affecting the ERK phosphorylation. In overnight incubated rat PTs, siRNA against WNK1 but not WNK3 abolished the stimulatory effects of Pio and insulin on NBCe1. Moreover, siRNA against OSR1 but not SPAK abolished the stimulatory effects of Pio and insulin.

Conclusions: These results indicate, for the first time to our knowledge, that diverse stimuli depending on the distinct signaling cascades converge into WNK1/OSR1 pathway, which may work as a master regulator of PT sodium transport and hence represent a novel therapeutic target in hypertension and/or volume expansion.

G-protein Pathway Suppressor 2 Abolished the WNK4-Mediated Inhibition of the Large Conductance Ca2+ Activated Potassium (BK) Channels

Yunman Wang,[2] Ruidian Li,[1] Shan Chen,[1] Jia Xiao,[3] Saier Shen,[1] Xiuyan Feng,[6] Hui Cai.[4,5] *[1]Medicine/Renal, Emory University, Atlanta, GA; [2]Medicine/Renal, Emory University, Atlanta, GA; [3]Medicine/Renal, Emory University, Atlanta, GA; [4]Medicine/Renal, Emory University, Atlanta, GA; [5]Nephrology, Atlanta VA Medical Center, Decatur, GA; [6]Pathology, LSU Shreveport, Shreveport, LA.*

Background: G-protein pathway suppressor 2 (GPS2) is a multifunctional protein and transcriptional regulation factor. We have recently reported that GPS2 enhances BK channel activity and its protein expression by reducing ERK1/2 signaling-mediated degradation of the channel. Previous studies reported that WNK4 inhibits BK channel activity and protein expression through stimulating ERK 1/2 signaling pathway. Our yeast-two hybrid screening data showed that WNK4 interacts with GPS2. Thus, we hypothesized that GPS2 increases BK protein expression through interfering with the WNK4-mediated effect on BK.

Methods: Cell culture, transfection, western blot analysis, co-immunoprecipitation, and cell surface biotinylation were used in the experiments.

Results: To determine whether GPS2 modulates the WNK4-mediated inhibitory effect on BK, we first wanted to confirm whether GPS2 interacts with WNK4. In HEK293 cells cotransfected with HA-WNK4 and either myc-vector or myc-GPS2, co-immunoprecipitation (co-IP) experiments showed that myc-GPS2 co-immunoprecipitates WNK4, whereas myc-vector does not. To further confirm their interaction, we performed the reciprocal co-IP experiments in HEK293 cells cotransfected with HA-GPS2 and either myc-vector or myc-WNK4. We found that myc-WNK4 co-immunoprecipitates HA-GPS2 while myc-vector does not. To further assess the effects of GPS2 on WNK4-mediated inhibitory effects on BK, we performed the western blot analysis in HEK293 cells cotransfected with BK and WNK4 in the presence or absence of GPS2. We found that WNK4 significantly inhibits BK protein expression as expected. However, in the presence of GPS2, BK protein expression is restored to the control level. We further did cell surface biotinylation experiments in Cos-7 cells co-transfected with BK and WNK4 in combination with increasing doses of GPS2. We showed that WNK4 significantly inhibits total and surface BK protein expressions and GPS2 reversed the WNK4-mediated inhibition of BK in a dose-dependent manner. We further showed that GPS2 reversed the WNK4-mediated inhibition of BK protein expression by partially reducing the BK degradation through a lysosomal pathway.

Conclusions: These data suggested that GPS2 abolishes the WNK4-mediated inhibition of BK by partially reducing BK degradation through a lysosomal pathway.

Response of Intercalated Cell (IC) BKα Knock-Out Mice to a High K (HK) Diet

Rolando Carrisoza-Gaytan,[1] Evan C. Ray,[2] Allison L. Marciszyn,[3] Peng Wu,[4] Leah Liu,[7] Arohan R. Subramanya,[5] WenHui Wang,[4] Daniel Flores,[1] Donald E. Kohan,[6] Thomas R. Kleyman,[3] Lisa M. Satlin.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]UPMC, Pittsburgh, PA; [3]University of Pittsburgh, Pittsburgh, PA; [4]New York Medical College, Valhalla, NY; [5]University of Pittsburgh School of Medicine, Pittsburgh, PA; [6]University of Utah Health Sciences Center, Salt Lake City, UT; [7]McGill University, Montreal, QC, Canada.*

Background: Flow-induced K secretion (FIKS) in the cortical collecting duct (CCD) is mediated by BK channels, which also contribute to the renal adaptation to a high K diet (HKD). BK channels are expressed in both ICs and principal cells (PCs) in CCDs. We generated a mouse with a targeted deletion of BKα, the pore forming subunit of the BK channel, in ICs (IC-BKα-KO) by crossing floxed BKα mice with B1 V-ATPase Cre mice. Perforated cell recordings of ICs in CCDs in these KO mice revealed reduced charybdotoxin (CTX)-sensitive K currents vs. those in floxed controls, suggesting that the KO would have a limited capacity for FIKS and renal adaptation to a HKD. In fact, KO mice exhibited a higher blood [K] vs. controls (5.5±0.8 vs. 5.0±0.7 mM; p<0.05), yet rates of urinary K excretion in response to volume expansion were similar in both groups.

Methods: See results.

Results: To confirm the contribution of IC BK channels to FIKS and K adaptation, we measured net transepithelial transport (Jx, in pmol/min.mm) of Na and K, in control (n=4) and KO (n=6) microperfused CCDs from mice fed a HKD x 10 d. Similar rates of flow-stimulated JNa were observed in control and KO CCDs (43.3±6.5 and 26.9±8.3, respectively, p=NS), but FIKS, present in control CCDs (-5.0±0.6), was absent in KO tubules (-1.1±0.6; p<0.05). Although CTX-sensitive K currents in PCs were upregulated in KO mice (454±40 pA; n=6) vs. those in controls (304±28 pA; n=5; p=0.02), the failure to detect FIKS in KO CCDs underscored the critical role of ICs vs. PCs in BK channel-mediated K secretion. ROMK immunolabeling of kidney cryosections revealed a 16% increase in apical membrane relative to whole cell expression in calbindin-positive DCTs of KO mice vs. controls.

Conclusions: We conclude that in the absence of IC BKα, mice have a limited capacity for adaptation to a HKD, as evidenced by the higher blood [K], and lack of FIKS, confirming a critical role of IC BK channels in K homeostasis. We speculate that upregulation of alternate K secretory channels, including ROMK, in other segments of the nephron occurs to enable K secretion in the absence of BK channel activity in ICs.

FR-OR067

Calcineurin Homologous Protein 1 Regulates the Renal Na-K-2Cl-Cotransporter

Kerim Mutig,[1] Alexander Paliege,[2] Sebastian Bachmann.[1] *[1]Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Universitätsklinikum Dresden, Dresden, Germany.*

Background: The Na-K-2Cl-cotransporter (NKCC2) of the thick ascending limb (TAL) is essential for renal salt handling. Its activity depends on phosphorylation and dephosphorylation steps. Our previous work suggested that calcineurin is involved in dephosphorylation and deactivation of NKCC2. Calcineurin activity can be modulated by members of the calcineurin homologous protein family (CHP). Among these, CHP1 has been implicated in the regulation of several membrane proteins including ion transporters. We hypothesized that CHP1 participates in calcineurin-dependent regulation of NKCC2 activity.

Methods: Immunofluorescence, immunoblotting, co-immunoprecipitation and GST pull down assays were applied in rodent kidneys and cultured cells to characterize physical and functional interactions between NKCC2, CHP1 and calcineurin.

Results: Double labeling of CHP1 and NKCC2 revealed their close co-localization in rat TAL. Both products co-immunoprecipitated, suggesting their interaction. GST pull down assays with recombinant N-terminal NKCC2 mutants, mimicking its (de)phosphorylation at functionally relevant residues (T96, T101, T114, and S126), suggested that CHP1 and calcineurin may compete for the binding with phosphorylated NKCC2. Overexpression of CHP1 in cultured macula densa cells significantly increased NKCC2 phosphorylation at baseline and upon low-chloride stimulation. Acute stimulation of NKCC2 by administration of desmopressin in rats promoted the interaction of NKCC2 with CHP1, while attenuating its binding with calcineurin.

Conclusions: Our data suggests that CHP1 protects NKCC2 from calcineurin-dependent dephosphorylation and deactivation.

FR-OR068

APOL1 Antisense Oligonucleotide Treatment Ameliorates IFNγ-Induced Proteinuria in Genomic APOL1 Transgenic Mice

Mariam Aghajan,[1] Sheri Booten,[1] Magnus Althage,[2] Anette E. Ericsson,[2] Ingela Maxvall,[2] Angela Menschik lundin,[2] Christine Ahlström,[2] Joseph Ochaba,[1] Danielle Gattis,[1] Andy Watt,[1] Jeffery A. Engelhardt,[1] Brett P. Monia,[1] Maria chiara Magnone,[2] Shuling Guo.[1] *[1]Ionis Pharmaceuticals, Carlsbad, CA; [2]AstraZeneca, Gothenburg, Sweden.*

Background: APOL1 risk variants (G1/G2) strongly associate with CKD in African Americans. Not all individuals homozygous for the risk variants, however, develop renal disease suggesting that a second hit is required. In this study, we sought to develop a physiologically-relevant mouse model of APOL1-associated renal disease.

Methods: We generated genomic APOL1 G0 or G1 transgenic mice via random transgenesis of a human APOL1-containing fosmid, resulting in APOL1 expression in similar tissues as that identified in humans and at similar relative levels of expression. Mice were challenged with recombinant IFNγ and APOL1 induction was measured by qRT-PCR. Proteinuria was measured by albumin ELISA and normalized using urine creatinine levels measured by a clinical chemistry analyzer.

Results: Naïve APOL1 G1 Tg mice failed to show a differential renal phenotype compared to APOL1 G0 mice. A single dose of IFNγ, however, caused robust proteinuria only in G1 mice, despite inducing kidney APOL1 expression in both G0 and G1 mice. We identified an antisense oligonucleotide (IONIS-APOL1$_{Rx}$) against APOL1 that is potent with an excellent safety profile. Administration of IONIS-APOL1$_{Rx}$ to G1 Tg mice prior to IFNγ challenge prevented APOL1 induction and IFNγ-induced proteinuria in a dose-dependent manner. Treatment with a hepatocyte-targeting version of IONIS-APOL1$_{Rx}$, however, provided incomplete protection against IFNγ-induced proteinuria, suggesting that local expression of APOL1 in kidney is critical for pathogenesis. In search of a kidney-specific target engagement biomarker, we detected APOL1 mRNA in urinary shed cells from mice and humans and correlated its reduction to kidney APOL1 mRNA reduction in APOL1 Tg mice.

Conclusions: We developed a novel APOL1 transgenic mouse model that recapitulates the physiological attributes of APOL1 and exhibits a kidney phenotype in G1 mice upon IFNγ challenge. APOL1 ASO treatment in this model prevents IFNγ-induced proteinuria in G1 mice, demonstrating that the kidney disease cell type is sensitive to APOL1 ASO

treatment and that IONIS-APOL1$_{Rx}$ may be an effective therapeutic for APOL1-associated nephropathies.

Kidney Compartment Specific eQTL Studies Highlight Causal Genes and Pathways for Renal Disease Development

Chengxiang Qiu,[1] Shizheng Huang,[1] Jihwan Park,[1] Yoson Park,[1] Yi-An Ko,[1] Matthew J. Seasock,[1] Joshua S. Bryer,[1] Wenchao Song,[1] Matthew Palmer,[1] Jonathan Hill,[2] Paolo Guarnieri,[2] Julie Hawkins,[2] Carine Boustany,[2] Steven S. Pullen,[2] Katalin Susztak.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]Boehringer Ingelheim, Ridgefield, CT.*

Background: Chronic kidney disease (CKD) is a common disease condition affecting more than 1 in 10 people in the general population. Genome wide association studies (GWAS) have identified more than 100 regions where nucleotide variants are significantly and reproducibly associated with kidney function. Expression quantitative trait locus (eQTL) analysis aim to identify gene expression changes in cell and tissue samples driven by the underlying genetic variation. By combining GWAS and eQTL studies we can identify gene expression change driven by disease associated genetic variation. Genes for which expression are influenced by GWAS signals are likely candidates for disease development.

Methods: We conducted eQTL analyses separately on glomerular and tubular portions of healthy human kidney samples obtained from 151 subjects of European descent. We complemented our compartment-based eQTL studies with kidney-specific epigenome maps and single-cell RNA-sequencing results. Focusing on the *DAB2-C9* CKD GWAS locus, we induced kidney injury by folic acid administration and unilateral ureter obstruction to test the effect of *DAB2* and *C9*. To understand the mechanism of Dab2-induced kidney damage, we cultured primary renal tubule cells from Dab2$^{flox/+}$ mice and infected them with Cre-eGFP or control adenovirus.

Results: We identified eQTLs and generated a searchable public eQTL database from human whole kidney, tubules and glomeruli samples. Kidney-specific eQTLs showed significant enrichment for genetic variants associated with renal traits. We identified eQTLs at 27 genes that colocalize with CKD GWAS signals. Putative causal genes were enriched for proximal tubule expression and endolysosomal function. *DAB2* appeared to be a central gene among the putative causal genes. *In vivo* studies, using mice with reduced tubule epithelial-specific gene expression demonstrated that Dab2 protects mice from CKD development. *In vitro* results indicate that Dab2 in tubule cells plays an important role in TGFβ-induced profibrotic gene expression.

Conclusions: This in-depth follow-up analysis of CKD GWAS, defines a novel framework for CKD development, and identifies DAB2 and endolysosomal pathway as key mechanism for kidney disease pathogenesis.

FR-OR070

Allele-Specific Expression Studies Identify Tubule Epithelial DACH1 as a Kidney Disease Gene

Shizheng Huang,[1] Chengxiang Qiu,[1] Jihwan Park,[1] Yoson Park,[3] Rojesh Shrestha,[1] Hongliu Yang,[2] Richard G. Pestell,[4] Katalin Susztak.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]West China Hospital of Sichuan University, Chengdu, China; [3]Perelman School of Medicine University of Pennsylvania, Philadelphia, PA; [4]Pennsylvania cancer and regenerative medicine center, Philadelphia, PA.*

Background: Genome wide association analysis (GWAS) have identified significant associations between over 100 genetic loci and kidney disease development. However, finding causal genes, cell types and biological mechanisms underlying such associations remains a challenge. High throughput RNA-seq data allows transcriptome-wide scan of millions of variants and their impact on gene expression variation (eQTLs) in specific cells and tissues. Furthermore, incorporating allele-specific expression (ASE) analysis enables us to improve statistical power for such screening methods while controlling for biases and potential confounding factors.

Methods: We generated genotype and gene expression data of kidney tissue samples obtained from 121 healthy individuals of European descent. Additionally, we generated mice with tubule-specific dose reduction of *Dach1* (Ksp^{cre}/*Dach1*$^{flox/+}$). Kidney injury was studied in aging mice or following folic acid administration. We cultured primary renal tubule epithelial cells (TECs) from *Dach1*$^{flox/+}$ mice for Cre adenovirus infection. Furthermore, we performed single cell RNA-sequencing on control and Ksp^{cre}/Dach1$^{flox/flox}$ mouse kidneys.

Results: We identified 41 ASE loci (compared to 27 eQTL loci) with genome-wide significant associations to kidney function. Interestingly, kidney compartment-based ASE analysis identified a significant tubule-specific association between the CKD risk variant rs716877 genotype and *DACH1* level, but not in glomeruli. The GWAS risk allele was associated with decreased *DACH1* levels. By single cell RNA-sequencing analysis, we found that *Dach1* is expressed in the loop of Henle, distal convoluted tubules and collecting ducts. Mice with reduced tubule-specific Dach1 level demonstrated worsened renal damage at baseline and following nephrotoxic injury. Reducing Dach1 expression in primary TECs directly increased profibrotic gene expression. Single cell RNA-sequencing analysis of Ksp^{cre}/Dach1$^{flox/flox}$ mice indicated a significantly increased expression level of proliferating tubule cells.

Conclusions: Combining ASE and GWAS integration analysis, we identified 41 putative causal associations between genetic variation and kidney development. In particular, we show that reducing tubule epithelial *Dach1* level induces kidney fibrosis development via TEC proliferation.

FR-OR071

GWAS of Urinary Metabolite Concentrations among CKD Patients Identify 90 Loci

Anna Kottgen,[1] Peggy Sekula,[1] Robert P. Mohney,[2] Florian Kronenberg,[3] Kai-Uwe Eckardt,[4] Pascal Schlosser.[5] *[1]Medical Center - University of Freiburg, Freiburg, Germany; [2]Metabolon, Inc., Durham, NC; [3]Innsbruck Medical University, Innsbruck, Austria; [4]University Medicine-Charite, Berlin, Germany; [5]Medical Center and Faculty of Medicine, University Freiburg, Germany, Freiburg, Germany.*

Background: The kidneys play a central role in metabolite handling. Genetic studies of metabolite concentrations can identify proteins performing these functions. Reduced GFR may represent a challenge model for metabolite handling, facilitating the identification of such loci.

Methods: We carried out GWAS of the urinary concentrations of 1,172 metabolites among 1,221 European ancestry GCKD study participants with eGFR of 30-45 ml/min/1.73m^2 and UACR <30 mg/g, with further replication among 406 individuals. Dilution-corrected urinary metabolite concentrations were related to HRC-imputed genome-wide genotypes of minor allele frequency >1%, using an additive genetic model and multivariable adjustment. Statistical significance was defined as p<4.3e-11 (5e-8/1172) in a meta-analysis of discovery and replication, with concordant effect sizes.

Results: After correction for multiple testing, there were 246 genome-wide significant associations for 211 metabolites, distributed across 90 independent loci. These included previously identified loci in screens of urine (n=15) and blood (n=55) metabolite concentrations in the general population, and 20 novel loci. Associations between lead SNPs and urinary metabolite concentrations were strong, with p-values as low as <1e-550. Compared to associations of the same genetic variants and urinary metabolites in a healthy population, effects were significantly stronger among CKD patients on average (p<2e-16). The number of metabolites associated with a locus' lead variant ranged up to 30 for missense rs13538 in *NAT8*, consistent with the function of N-acetyl-transferase in detoxification reactions. Relating genome-wide genotypes to modeled relationships between metabolites (pairwise ratios, clusters) resulted in additional insights such as the identification of candidate substrates for renal transport proteins, a functional readout of renal enzymes, detoxification reactions of drugs commonly prescribed among CKD patients, and facilitated the de-orphanization of SNP-associated metabolites of previously unknown identity.

Conclusions: Our study increases the number of loci associated with urinary metabolite concentrations from 26 to 90, highlights the value of studying genetics of renal metabolism among CKD patients, and provides many novel insights into human renal (patho)physiology.

FR-OR072

Rho Guanine Nucleotide Exchange Factor β-PIX Is Required for the Maintenance of Podocyte Architecture and Glomerular Function in Adult Mice

Jun Matsuda, Mirela Maier, Lamine Aoudjit, Tomoko Takano. *Division of Nephrology, McGill University Health Centre, Montreal, QC, Canada.*

Background: Activation of Rac1 (a small GTPase) in podocytes has been implicated in the development of proteinuria and focal segmental glomerulosclerosis (FSGS). Previously, we identified Arhgef7 (β-PIX) as a predominant GEF (guanine nucleotide exchange factor) that interacts with Rac1 in human podocytes (HP) using a proximity-based ligation assay, BioID. Furthermore, we confirmed that β-PIX is expressed in podocytes both *in vitro* and *in vivo*. However, its functional role remains unknown.

Methods: Cultured mouse podocytes (MP) with β-PIX knockdown (KD) and their controls were established using shRNA. Cell size was quantified in fixed cells stained with phalloidin. Cell migration and adhesive property were studied by wound healing assay and attachment assay, respectively. Cell proliferation was studied by MTT assay. Podocyte specific β-PIX deficient (KO) mice were generated by crossing β-PIX floxed mice with NPHS2-Cre mice. Urine albumin to creatinine ratio (ACR) and renal histology were studied up to 13 weeks of age. Data are provided as the mean ± SE.

Results: Compared to control MP, β-PIX KD MP were significantly smaller. Cell motility and adhesive property were modestly decrease in β-PIX KD MP. Proliferation rate was not different. Podocyte specific β-PIX KO mice presented no obvious renal phenotype up to 2-3 weeks of age, but developed progressive proteinuria starting at around 7-8 weeks of age (8 wk: KO: 117±44 x10^2 vs Control: 49±15 μg/mg, n=7-11, p<0.01; 13 wk: 255±128 x10^2 vs 238±90 μg/mg, n=4-7, p<0.05). In addition, by PAS staining, 13-week-old KO mice showed global/segmental glomerulosclerosis, parietal cells proliferation, and tubular casts in the kidney.

Conclusions: Our findings demonstrate the previously unrecognized importance of β-PIX in maintaining podocyte function. To the best of our knowledge, this is the first evidence that a Rho GTPase GEF plays a critical role in podocytes.

FR-OR073

Tight Regulation of Crkl Isoforms Account for the Etiology and Pleiotropic Effect of the 22q11.2 Microdeletion Syndrome (DiGeorge) on Kidney and Urinary Tract Development

Jeremiah Martino, Qingxue Liu, Tze Yin Lim, Nicholas J. Steers, Vivette D. D'Agati, Simone Sanna-Cherchi. *Columbia University Medical Center, New York, NY.*

Background: We recently showed that haploinsufficiency and point mutations in *CRKL* drive kidney and urinary tract malformations in the DiGeorge, or 22q11.2, syndrome and in sporadic CAKUT, respectively. We examined the developmental necessity of two *Crkl* transcript isoforms using conditional mutant mouse models.

Methods: Bulk RNAseq data from E15.5 mouse kidneys were analyzed for expression of *Crkl* T1 and T2 expression. Phenotypic analyses were carried out on conditional mouse mutants generated by breeding *Crkl(Ex1)$^{f/f}$* or *Crkl(Ex2)$^{f/f}$* with either *Six2*-, *Hoxb7*- or *Pax2-Cre* mice to delete either both splice variants by removing the first of three exons (Ex1), or by removing T1 only via Ex2 excision.

Results: Analysis of RNAseq data show T1 and T2 expression at a mean TPM of 39.5 and 9.3, respectively, (n=4) in E15.5 mouse kidneys. This is comparable to TPM data for housekeeping (*Gapdh*=55.5) and kidney & urinary tract genes (*Pax2*=10.4, *Hoxb7*=54.9, *Six2*=24.1). The two isoforms exist also in human embryonic kidneys. At P0, phenotypic analysis of *Six2-Cre;Crkl(Ex1)$^{f/f}$* and *Six2-Cre;Crkl(Ex2)$^{f/f}$* mice shows severe renal hypoplasia. When both *Crkl* transcripts were removed in ureteric-bud derived structures via *Hoxb7-Cre*, both unilateral and bilateral ureteropelvic dilation and early hydronephrosis developed by P0. However, in *Hoxb7-Cre;Crkl(Ex2)$^{f/f}$* mice, where only T1 is absent, there was a decreased frequency and severity of obstructive phenotypes. Lastly, when bred with *Pax2-Cre* mice, both crosses show mild renal hypoplasia at P0 and E18.5.

Conclusions: These data suggest a tight regulation of both *Crkl* isoforms during mouse embryonic development with possible tissue-specific synergistic and modulatory effects. On the one hand, the presence of both *Crkl* isoforms in the metanephric mesenchyme is necessary for normal kidney development, but when inactivated in both compartments, hypoplasia was less severe. When T1 was removed from UB-derived structures, the presence of only T2 was sufficient to prevent abnormal development and obstructive uropathy, which were only observed with absence of both *Crkl* isoforms. These findings provide further insight into the pleiotropic effect of human *CRKL* mutations on kidney and urinary tract development.

The LMX1βR246Q Mutation Causes FSGS through Dysregulation of Chloride Intracellular Channel Expression and Focal Adhesion Dynamics

Gentzon Hall,[1] Maria E. Kovalik,[2] Olivia G. Gregory,[1] Brandon M. Lane,[1] Maxwell S. Lagas,[3] Guanghong Wu,[1] Megan Chryst-Stangl,[4] Liming Wang,[1] Robert F. Spurney,[1] Rasheed A. Gbadegesin.[1] *[1]Duke University Medical Center, Durham, NC; [2]Duke University, Durham, NC; [3]University of Arizona, Phoenix, AZ; [4]Duke Molecular Physiology Institute, Durham, NC.*

Background: We previously reported a heterozygous missense mutation of LMX1β as a cause of nail-platella-like renal disease in two families with hereditary FSGS. Currently, there are no targeted therapies for $LMX1\beta_{R246Q}$-induced glomerulopathy. We hypothesized that $LMX1\beta_{R246Q}$ disrupts the expression of disease-relevant molecular targets that may be amenable to pharmacotherapy. To test this hypothesis, we performed an unbiased, RNA-seq analysis in our established $LMX1\beta_{WT}$ and $LMX1\beta_{R246Q}$-overexpressing podocyte lines to uncover potential therapeutic targets.

Methods: We conducted RNA-seq, qPCR, immunoblot, immunofluorescence, and scratch wound healing assays in $LMX1\beta_{WT}$ and $LMX1\beta_{R246Q}$-overexpressing podocytes to evaluate the effects of the $LMX1\beta_{R246Q}$ mutation on podocyte dysmotility.

Results: We detected significantly reduced Chloride Intracellular Channel 5 (*CLIC5*) expression in $LMX1\beta_{R246Q}$ podocytes relative to $LMX1\beta_{WT}$ controls by RNA-seq and qPCR. CLIC5 protein expression was similarly reduced as was the expression of CLIC3 and CLIC4. Given the established roles of CLIC proteins in the regulation of foot process architecture (i.e. CLIC5) and β1-integrin recycling (i.e. CLIC3 and CLIC4), we evaluated motility in $LMX1\beta_{R246Q}$ podocytes. $LMX1\beta_{R246Q}$ podocytes displayed decreased wound closure, β1-integrin expression, FAK phosphorylation and paxillin activation. Focal adhesion density was increased in $LMX1\beta_{R246Q}$ podocytes relative to controls as evidenced by an increase in VASP staining by immunofluorescence. Gene expression of PKG II, an upstream activator of VASP, was also significantly downregulated by RNA-seq and qPCR in $LMX1\beta_{R246Q}$ podocytes. To determine the effect of NO/sGC/PKG pathway agonists on podocyte motility, we treated $LMX1\beta_{R246Q}$-overexpressing podocytes with vardenafil (PDE5 inhibitor), cinaciguat (sGC activator) or riociguat (sGC stimulator). These NO/sGC/PKG agonists ameliorated podocyte dysmotility.

Conclusions: The $LMX1\beta_{R246Q}$ mutation may cause FSGS, in part, through the dysregulation of CLIC-mediated foot process architecture and β1- integrin recycling and through impaired of PKG-mediated VASP activation in focal adhesions. NO/sGC/PKG pathway agonists may be effective in ameliorating $LMX1\beta_{R246Q}$-induced podocyte dysmotility.

Enzymatic Degradation of Cystine Decreases Nephrolithiasis in a Mouse Model of Cystinuria

Giulia Agnello,[1] Jason F. Wiggins,[1] Susan E. Alters,[1] Everett Stone,[2] James E. Wooldridge,[1] Scott W. Rowlinson.[1] *[1]Aeglea BioTherapeutics, Inc., Austin, TX; [2]University of Texas at Austin, Austin, TX.*

Background: Cystinuria is a genetic disease characterized by frequent recurrent stone formation in the kidneys requiring multiple procedural interventions with an increased risk of chronic kidney disease. Stone formation is the result of increased urinary excretion of insoluble cystine due to mutations in the *SLC3A1* and/or *SLC7A9* genes. Current disease management with hyperhydration, alkalization and cystine binding thiol drugs (CBTD) is challenging and problematic. Effectiveness is limited with continued stone formation and frequent adverse effects to CBTD requiring treatment withdrawal in some patients (Biyani and Cartledge, EAU-EBU update series 4, 2006). We investigated the potential of an alternative approach to disease management utilizing novel cystine degrading enzyme derived from human cystathionine gamma lyase (CGL).

Methods: *In vivo* efficacy of ACN00107 was tested in a murine model of cystinuria (SLC3A1-/-) that develops stones between 4 and 7 weeks of age (PMID: 28165480). ACN00107 (100 mg/kg, i.p., every other day) was administered to 5-week-old SLC3A1 -/- mice for up to 6 weeks. At specific timepoints prior to, during, and after ACN00107 treatment, bladder and kidneys were weighed and imaged by micro computed tomography (μCT) analysis.

Results: μCT analysis demonstrated a reduction in both volume and number of total kidney stones after 6 weeks of treatment which was associated with reduced kidney weights. A trend towards reduced bladder weight and total bladder stone volume compared to control was also observed.

Conclusions: This study demonstrates for the first time that enzymatic degradation of cystine reduces the propensity for kidney and bladder stone formation in a mouse model of cystinuria. Given the high morbidity, frequent requirement for procedural intervention, and the safety and tolerability profile of current medical approaches, enzymatic degradation of cystine warrants further investigation as a new potential approach for disease management.

TFCP2L1 Mutations Cause a Novel Distal Tubulopathy in Humans

Verena Klambt,[1] Max Werth,[2] Michael Kaminski,[3] Soeren S. Lienkamp,[3] Kai M. Schmidt-Ott,[4] Yvette Roske,[5] Jianhui Wang,[6] Udo Heinemann,[6] Jonathan M. Barasch,[8] Friedhelm Hildebrandt.[7] *[1]Boston Children's Hospital, Boston, MA; [2]Columbia University, New York, NY; [3]University Hospital Freiburg, Freiburg, Germany; [4]Charite - Universitaetsmedizin Berlin, Max-Delbrueck Center for Molecular Medicine, Berlin, Germany; [5]Max-Delbrück-Center for Molecular Medicine, Berlin, Germany; [6]Max Delbrück Center for Molecular Medicine, Berlin, Germany; [7]Boston Children's Hospital, Boston, MA; [8]Columbia Presbyterian, New York, NY.*

Background: An underlying monogenic cause of early-onset chronic kidney disease (CKD) can be detected in 20% of individuals. To date, >250 monogenic causative genes have been identified for the most common etiologies of CKD evident before age 25 years suggesting mechanisms of renal pathogenesis.

Methods: We performed whole exome sequencing to identify novel monogenic causes of CKD in ~1,000 families with renal tubulopathy/ echogenic kidneys.

Results: We discovered 2 different recessive, homozygous mutations in *TFCP2L1* (Transcription Factor CP2 Like 1) in 2 consanguineous families with CKD. Family B2003 with CKD at the age of 2 years, episodes of severe hypochloremic, hypokalemic alkalosis, cataracts, seizures, developmental delay, and hypotonia encoded a homozygous Ser290Phefs*5 mutation. A second child encoded a homozygous Gln168Arg mutation in A5048 with onset of CKD by 2 years of age, loss of urinary potassium and chloride, hypotonia and deafness. The variants are disease causing by SIFT, MutTaster and PolyPhen2 prediction programs and are absent from gnomAD database. Gln168Arg is located in the DNA-binding domain positioned at the start of the L10 loop pointing into the DNA minor groove. *Tfcp2l1* is a transcription factor expressed in the thick limb of Henle, distal convoluted tubule, connecting segments and especially in the intercalating cells (ICs) in collecting ducts. *Tfcp2l1* alone is sufficient to induce tubulogenesis in rat progenitors and is required for normal maturation of the distal nephron and collecting ducts in mice (Yamaguchi, Development, 2006; Werth, Elife, 2017). *Tfcp2l1* knockout mice display loss of expression of direct binding targets of Tfcp2l1 including ion transporters in different segments of the distal nephron and regulatory proteins determining cell identity. A knockout caused renal hypoplasia, polyuria, renal potassium and chloride loss (Yamaguchi, Development 133:4737, 2006) and disruption of collecting duct patterning characterized by the deletion of ICs (Werth, eLIFE, 2017). Consistently, in *Xenopus* larvae skin *tfcp2l1* localizes to *foxi1+* ICs.

Conclusions: We here identified *TFCP2L1* mutations as a potential novel cause of distal tubulopathy in humans. Modeling these mutations in mice and segment specific deletions will reveal the full functions of *Tfcp2l1*.

FR-OR077

CHRNA3 Mutations Cause Neurogenic Bladder and Dysautonomia

Franziska Kause,[1] Nina Mann,[2] Shirlee Shril,[3] Dervla M. Connaughton,[2] Caroline M. Kolvenbach,[4] Rufeng Dai,[2] Makiko Nakayama,[2] Elisa De Franco,[7] Sian Ellard,[8] Velibor Tasic,[5] Jonathan M. Beckel,[6] Friedhelm Hildebrandt.[2] Boston Children's Hospital, Division of Nephrology *[1]Boston Children's Hospital, Boston, MA; [2]Boston Children's Hospital, Boston, MA; [3]Boston Childrens Hospital, Boston, MA; [4]Harvard Medical School, Boston, MA; [5]University Children's Hospital, Skopje, Macedonia (the former Yugoslav Republic of); [6]University of Pittsburgh, Pittsburgh, PA; [7]Royal Devon and Exeter NHS Foundation Trust, Exeter, United Kingdom; [8]University of Exeter Medical School, Exeter, United Kingdom.*

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) are the most prominent cause (>45%) of chronic kidney disease (CKD) in the first 3 decades of life. Although about 40 monogenic causes have been implicated in human CAKUT so far, many causes remain unknown.

Methods: To identify novel monogenic causes of CAKUT we applied whole exome sequencing (WES) to 144 families with CAKUT.

Results: By WES, we discovered a homozygous frameshift mutation (p.Thr337Asnfs*81) in the gene *CHRNA3* (*cholinergic receptor nicotinic alpha 3 subunit*) in a patient of consanguineous descent with CKD stage 3 secondary to neurogenic bladder, vesicoureteral reflux (VUR) and bilateral hydronephrosis. Screening WES data of 703 further patients with CAKUT revealed three different homozygous recessive *CHRNA3* mutations in 3 families with neurogenic bladder (p.Ser340*; c.267+2T>G obligatory splice site mutation; p.Arg110His). *CHRNA3* codes for an ion channel subunit in the urothelium and interacts with other ion channels in the neuronal network governing bladder reflexes and smooth muscle contraction. A *Chrna3* knockout mouse has impaired bladder reflexes, a distended urinary bladder, dribbling urination, urinary tract infections, urinary stones and mydriasis (Xu *PNAS* 96:5746, 1999). Given the mydriasis in mice we inquired for constant mydriasis in the patients. This was confirmed for the index patient with p.Thr337Asnfs*81 and two affected siblings with the p.Ser340* mutation.

Conclusions: We identified *CHRNA3* recessive mutations as the first cause of neurogenic bladder in humans. The mutations caused additionally extrarenal dysautonomic phenotypes such as constant mydriasis. Our findings may disclose a pathophysiological sequence, in which neurogenic bladder secondarily causes CAKUT.

FR-OR078

Confidence in Women's Health: An International Survey of Nephrologists

Monica L. Reynolds,[1] Elizabeth M. Hendren,[4] Jarcy Zee,[3] Laura H. Mariani,[2] Michelle A. Hladunewich.[4] *[1]Nephrology, University of North Carolina, Chapel Hill, NC; [2]University of Michigan, Ann Arbor, MI; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]University of Toronto, Toronto, ON, Canada.*

Background: A broad range of women's health issues are intimately related to kidney disease, yet little is known about providers' confidence in these issues. The women's health working group of CureGN sought to assess adult Nephrologists' exposure to women's health, their confidence in counseling and management, and ways to improve future care.

Methods: A 25-question survey was disseminated via the CureGN email network, the Canadian Society of Nephrology and ASN *Kidney News*. Demographics, practice characteristics, and response prevalence were summarized with descriptive statistics. Responses across country of practice (United States vs Canada) were compared using Pearson's chi squared test.

Results: Of the 154 respondents, 58% were from the US, 53% were women, and the median age was between 41-45. The majority (77%) identified their practice setting as academic. 55% of the respondents had fellowship training in women's health, which was similar across country of training (p=0.325). Nephrologists from both countries lacked confidence across a spectrum of issues (Figure 1). Most provided contraception (64%) and pre-conception (68%) counseling to less than one woman per month though counseling occurred significantly more frequently in the US. In their career, 91% have cared for less than five pregnant women on dialysis. Only 12% had access to interdisciplinary clinics. Finally, 89% felt that interdisciplinary guidelines and/or continuing education seminars would improve knowledge.

Conclusions: As women with chronic kidney disease experience adverse maternal outcomes and remain at risk for disease progression postpartum, we must do better to bolster provider knowledge and comfort level. Further research is warranted to identify barriers to counseling about women's health issues, identify best mechanisms to enhance physician confidence, and facilitate formation of interdisciplinary clinics. Interdisciplinary guidelines and case based materials may be a starting point.

Nephrologists' Confidence Managing Women's Health

FR-OR079

The Effect of Plasma Exchange and the Effect of Reduced-Dose Oral Glucocorticoids during Remission Induction in Severe ANCA-Associated Vasculitis

Michael Walsh,[1] Peter A. Merkel,[3] David R. Jayne.[2] PEXIVAS Investigators *[1]McMaster University, Hamilton, ON, Canada; [2]University of Cambridge, Cambridge, United Kingdom; [3]University of Pennsylvania, Philadelphia, PA.*

Background: Whether plasma exchange reduces the risk of end-stage renal disease or death in anti-neutrophil cytoplasm antibodies (ANCA) -associated vasculitis is uncertain. Also uncertain is whether lower doses of oral glucocorticoids reduce the risk of infection without increasing the risk of end-stage renal disease or death.

Methods: We performed a 2-by-2 factorial randomized controlled trial to separately evaluate plasma exchange and two different regimens of oral glucocorticoids in patients with severe ANCA-associated vasculitis. Participants were randomly assigned to 7 treatments of plasma exchange or no plasma exchange. Participants were also randomly assigned to either a reduced-dose regimen that <60% of the cumulative oral glucocorticoid dose or a standard regimen by 6 months or the standard regimen. All patients received immunosuppression. Patients were followed for up to 7 years for the primary composite outcome of death from any cause or end-stage renal disease.

Results: Amongst 702 participants, the primary outcome occurred in 28% of patients allocated to plasma exchange compared to 31% in the no plasma exchange group (hazard ratio 0.86, 95% confidence interval [CI] 0.65 to 1.13; p=0.27). The primary outcome occurred in 28% of patients in the reduced glucocorticoid group and 26% in the standard glucocorticoid group (absolute risk difference 2.3%, 90% CI -3.4% to 8.0%; met non-inferiority hypothesis). Serious infections in the first year occurred less often in the reduced glucocorticoid group compared to the standard group (incidence rate ratio 0.70, 95% CI 0.52 to 0.94; p=0.02).

Conclusions: Plasma exchange did not reduce the risk of end-stage renal disease or death. Compared to a standard dose, reduced glucocorticoids did not substantially increase the risk of death or end-stage renal disease and resulted in fewer serious infections.

FR-OR080

Membranous Nephropathy: Response to Rituximab Is Dependent on Anti-PLA2R1 Epitope Spreading and Gender

Vesna Brglez,[1] Piero L. Ruggenenti,[2,3] Barbara Ruggiero,[3] Luca Perico,[3] Alessia Gennarini,[2] Christine Payre,[1] Guillaume Dolla,[1] Barbara Seitz-Polski,[1,4] Ariela Benigni,[3] Gerard J. Lambeau,[1] Giuseppe Remuzzi.[2,3] *[1]Université Côte d'Azur, CNRS, Institut de Pharmacologie Moléculaire et Cellulaire (IPMC), Valbonne, France; [2]Azienda Socio-Sanitaria Territoriale Papa Giovanni XXIII, Bergamo, Italy; [3]IRCCS - Istituto di Ricerche Farmacologiche Mario Negri, Ranica (Bergamo), Italy; [4]Pasteur University Hospital, Nice, France.*

Background: Membranous nephropathy (MN) is a rare autoimmune kidney disease, yet one of the leading causes of nephrotic syndrome (NS) in adults. Clinical evolution is complex and treatment controversial. There is a need for better biomarkers to identify patients at risk of severe disease and orient therapy. Phospholipase A2 receptor 1 (PLA2R1) was identified as the major autoantigen in 70% of patients with MN. Proteinuria and PLA2R1 antibody titer predict outcome in PLA2R1-related MN.

Methods: We evaluated the additional predictive role of PLA2R1 epitope spreading from the immunodominant CysR domain to CTLD1 and CTLD7 domains in 117 consecutive, rituximab- treated patients with PLA2R1-related MN and nephrotic syndrome. Primary outcome was complete (proteinuria <0.3 g/24h) or partial remission (proteinuria <3.0 g/24h and >50% reduction vs basal). Non-spreaders had antibodies restricted to the CysR domain while spreaders had additional antibodies to CTLD1 and/or CTLD7 domains.

Results: Higher basal anti-PLA2R1 titer associated with higher probability of spreading. All patients with titer >400 RU/ml were spreaders. Fifteen of the 79 spreaders (19%) were females vs 16 of the 38 non-spreaders (42%; p=0.008), and 15 of 31 females (48%) were spreaders vs 64 of 86 males (74%; p<0.01). During a median (IQR) follow-up of 32.2 (16.4-50.5) months, 77 patients (66%) achieved the combined endpoint of

complete or partial remission. Female gender (p=0.004), shorter duration of proteinuria (p=0.004), lower proteinuria (p=0.004), lower antibody titer (p=0.036), and no epitope spreading (p=0.009) predicted remission. Compared to spreader males, the HR (95% CI) for the endpoint was 5.15 (2.73-9.70; p<0.0001) in non-spreader females, 2.09 (1.16-3.77, p=0.014) in spreader females, and 1.85 (0.95-2.59, p=0.069) in non-spreader males.

Conclusions: In MN, anti-PLA2R1 titer and epitope spreading monitoring help to predict response to rituximab. Better response of females could be explained, at least partially, by protection against PLA2R1 epitope spreading. VB and PR contributed equally as first authors, GL and GR contributed equally as last authors.

FR-OR081

Non-Invasive Diagnosis of Primary Membranous Nephropathy using Phospholipase A2 Receptor Antibodies

Shane A. Bobart,[1] An S. De Vriese,[2] Ladan Zand,[1] Sanjeev Sethi,[1] Callen D. Giesen,[1] John C. Lieske,[1] Fernando C. Fervenza.[1] *[1]Mayo Clinic, Rochester, MN; [2]AZ Sint-Jan, Bruges, Belgium.*

Background: Kidney biopsy is the current gold standard to diagnose membranous nephropathy (MN). Approximately 70-80% of patients with primary MN have circulating anti-PLA2R antibodies. We hypothesized that PLA2R antibody testing without the need for a biopsy is a valid strategy to make a non-invasive diagnosis of MN in the setting of preserved renal function and negative work up for secondary causes such as autoimmunity, malignancy, medications and paraproteinemias.

Methods: The medical records of all Mayo Clinic patients with positive serum PLA2R antibody tests between July 2015 and December 2017 were reviewed.

Results: A total of 1065 PLA2R tests were ordered on 675 unique patients. Of these, 113 had a positive PLA2R antibody test, of which 105 had native renal biopsies performed. The primary diagnosis in all biopsies was MN. Eighty-four patients had a negative work up for secondary causes of MN. Fifty of the 84 patients had preserved renal function (eGFR >60 ml/min/1.73m^2). In none of these 50 patients, kidney biopsies provided significant information that altered diagnosis or management. Among the 34 patients with eGFR <60 ml/min/1.73m^2, additional findings that altered the treatment plan included acute interstitial nephritis (n=1), superimposed diabetic nephropathy (n=1) and cellular crescents (n=1). Potential secondary causes were identified in 21 cases (positive ANA test = 4, malignancy = 9, NSAID = 3, monoclonal protein = 5). A detailed review of the clinical data revealed that these were co-existing findings and not true secondary MN.

Conclusions: In patients with preserved renal function and no evidence of secondary causes, a positive PLA2R test confirms the diagnosis of MN. A kidney biopsy does not add significant data in this context.

FR-OR082

PLA2R1 as the Major Autoantigen in Membranous Nephropathy: From New Epitope Identification to Personalized Medicine

Joana Justino,[1] Vesna Brglez,[1] Guillaume Dolla,[1] Christelle Zaghrini,[1] Christine Payre,[1] Barbara Seitz-Polski,[2] Hanna Debiec,[3] Pierre M. Ronco,[3] Gerard J. Lambeau.[1] *[1]Institute of Molecular and Cellular Pharmacology, CNRS and University Cote d'Azur, Valbonne, France; [2]Pasteur University Hospital, Nice, France; [3]Hospital Tenon, Sorbonne University, Paris, France.*

Background: Membranous nephropathy (MN) is a rare autoimmune kidney disease yet the most common cause of nephrotic syndrome. Clinical evolution is complex and treatment controversial. There is a need for better biomarkers to identify patients at risk of severe disease and orient therapy. In 2009, PLA2R1 was identified as the major autoantigen, with circulating autoantibodies in 70% of patients. The severity of MN and clinical outcome is associated with anti-PLA2R1 titer and the presence of multiple antibodies. PLA2R1 epitopes have been identified in the CysR (CR), C1 and C7 domains and may be linked by a mechanism of epitope spreading. However, their exact number and location including controversial findings concerning their presence in the CR and C1 domains require further studies. The aim of this work was to clarify the number of PLA2R1 domains containing epitopes.

Methods: To clarify the conundrum between CR and C1 N-terminal domains, we expressed in HEK293 cells a series of CR-FnII-C1 triple domains with insertion of protease cleavage sites between each domain. Reactivities were tested with different patients' sera before and after protease cleavage. To further investigate the number of epitope domains in the distal region of PLA2R1, we expressed a series of individual PLA2R1 domains and tested their reactivity for a cohort of >150 MN patients by ELISA.

Results: The triple domain CR-FnII-C1 was recognized by all patients' sera when tested before cleavage. After cleavage releasing isolated domains, some sera had reactivities limited to CR or C1 while others reacted with both CR and C1, demonstrating the presence of independent epitopes targeted by different antibodies. The ELISA screening of a cohort of 150 patients towards individual PLA2R1 domains led us to identify C5 and C8 as two new epitope-containing domains.

Conclusions: Our results show that patient's autoantibodies can target up to 5 PLA2R1 domains: CR, C1, C5, C7 and C8 with different prevalence's. The clinical association between reactivity towards these 5 PLA2R1 domains and disease activity is currently being analyzed and may help to design new diagnosis and prognosis tools towards better personalized medicine. JJ and VB contributed equally as first authors.

FR-OR083

CD-19 Targeted Rituximab Is Safe and Effective in Adult Steroid Dependent/Resistant but Calcineurin Inhibitor Dependent Podocytopathy

Krishan Lal L. Gupta, Ritambhra N. Duseja, Raja Ramachandran. *Postgraduate Institute of Medical Education & Research, Chandigarh, India.*

Background: Minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS) are common podocytopathies causing nephrotic syndrome (NS) in children and adults. A significant proportion of patients are either steroid dependent (SD) or resistant (SR), requiring alternate therapies. Long-term calcineurin inhibitors (CNI) use is associated with dyslipidemia, impaired glucose tolerance and, nephrotoxicity. Rituximab is a potential candidate in this group of patients, with a more favourable safety profile, so the present study was undertaken to evaluate the efficacy and safety of rituximab in SD/SR MCD/FSGS dependent on CNIs to maintain remission.

Methods: This was a prospective observational study conducted from July 2014 to February 2018. SD-NS or SR-NS (biopsy proven MCD/FSGS), who were CNI dependent were enrolled. All patients received rituximab at a dose of 375 mg/m^2 at entry in the study. CD-19 levels were monitored monthly and patients having CD-19 levels >5/μL and/or >1% received additional low-dose (100 mg) of rituximab. Patients were followed up monthly for a period of 12 months, and the clinical and biochemical parameters prior to and following rituximab administration were compared. Outcome: Cumulative percentage of patients who experienced remission (Complete remission (CR), partial remission (PR)) at 6 and 12 months.

Results: A total of 24 patients was enrolled and followed for 12 months. Mean age at enrolment was 22.77±7.45 years. At the end of 6 and 12 months, 87.50% and 79.16% of the patients achieved remission, respectively. CR and PR at 6 and 12 months were observed in 14 (58.33%) and 7 (29.17%), and 13 (54.16%) and 6 (25%), patients, respectively. Relapse occurred in 7 (29.16%) patients during the follow-up, requiring steroids (4, 57.14%) or CNIs (3, 42.85%). The mean dose of rituximab was 791 mg. Rituximab was well-tolerated, with infusion reactions, respiratory tract infection and oral candidiasis in 5 (20.83%), 5 (20.83%) and 1 (4.17%) patient, respectively.

Conclusions: CD-19 targeted rituximab is a safe and effective agent in the management of adults with CNI dependent MCD/FSGS. At 12 months, over three-fourth of the patients with CNI dependent podocytopathy maintain clinical remission.

FR-OR084

Nephrotic Syndrome Is Significantly Associated with Increased Risk of Ischemic Stroke

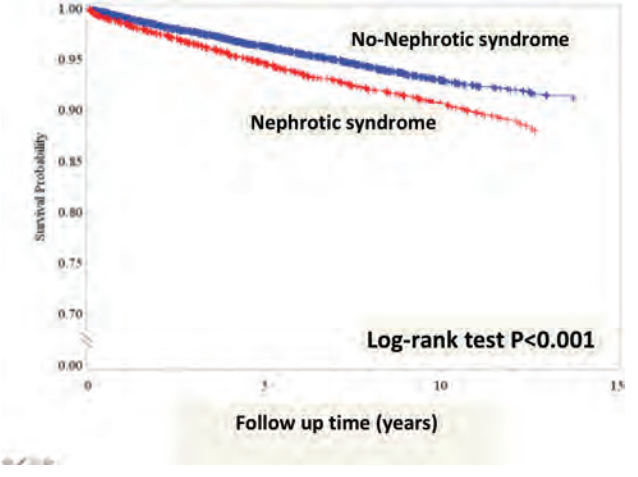
Ming-Ju Wu, Tung-Min Yu. *Taichung Veterans General Hospital, Taichung, Taiwan.*

Background: Evidence on the risk of ischemic stroke in patients with nephrotic syndrome is scarce.

Methods: We conducted a retrospective nationwide cohort study by analyzing the registry data of the National Health Insurance Research Database in Taiwan. Adult patients who were aged ranged 18 to 110 years and had received a diagnosis of nephrotic syndrome were included in the nephrotic syndrome cohort. For each patient with nephrotic syndrome, the corresponding controls were selected 1:4 on the basis of matched age, sex, Charlson comorbidity index, and index date to evaluate the risk of stroke, especially the ischemic stroke.

Results: The first three-year incidence rates of ischemic stroke were 25% and 15.9% in 3496 patients with nephrotic syndrome and 13984 comparison control cohorts, respectively. Overall, 9% patients with nephrotic syndrome developed ischemic stroke in 9.1±2.9 years follow-up period. A higher risk of stroke was observed in patients with nephrotic syndrome than in controls, adjusted hazard ratio (aHR) 1.37; 95% confidence interval (CI) 1.21-1.54, p<0.001. Regarding the risk of different stroke subtypes, including ischemic stroke and hemorrhagic stroke, the aHR for ischemic stroke was 1.38 (95% CI 1.21-1.57, p<0.001) and that for hemorrhagic stroke was 1.26 (95% CI 0.84-1.88, p=0.266) in patients with nephrotic syndrome compared with controls, after adjustment for age, sex, and comorbidities.

Conclusions: This study provides first significant evidence that patients with nephrotic syndrome had an increased risk of ischemic stroke.



FR-OR085

Treatment Response in Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits

Gauri Bhutani,[1] Wai L. Lau,[3] Maria E. Drosou,[2] Samih H. Nasr,[2] Brad C. Astor,[1] Gerald B. Appel,[3] Nelson Leung.[2] *[1]University of Wisconsin, Madison, WI; [2]Mayo Clinic, Rochester, MN; [3]Columbia University College of Physicians and Surgeons, Scarsdale, NY.*

Background: Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits (PGNMID) usually results from an occult hematologic clone, making treatment challenging.

Methods: The Mayo Clinic pathology and Columbia U. Glomerular Ctr database were used to identify patients with PGNMID. Response to each treatment (Rx) regimen for native renal disease was evaluated. "Renal response" was defined as decrease in proteinuria (UPRT) by >50% without worsening of serum creatinine (Scr); "complete remission" as return to within 10% of normal Scr with <1 g/d UPRT; "renal progression" as reaching ESRD, death or need for another Rx. Chi-square, Fisher's exact and Log-rank test were utilized for statistical analysis.

Results: Rx outcomes in 83 PGNMID patients were evaluated. Most had no known hematologic clone (87%). Median Scr at presentation was 1.6 mg/dL (1.2-2.3) with UPRT 4.12 g/d (2.71-8.07). Over a median follow up period of 2.8 yrs, 30% (25/83) reached ESRD, 5% (4/83) died and a median of 2 (1-3) and total 139 Rx were received. "Renal response" differed significantly between the Rx regimens (p=0.012). This was primarily due to worse outcomes with conservative Rx and a superior response with cyclophosphamide (Table). "Renal progression" occurred with 60% Rx regimens over a median time of 216 days (104-545). Time to progression was lesser with conservative vs immunosuppressive Rx (p=0.012) but not different among the 5 immunosuppresive regimens (p=0.369). Anti-plasma cell Rx was less often used as 1st Rx as compared to other regimens (p=0.011).

Conclusions: PGNMID results in poor renal outcomes especially when immunosuppression is not used. Cyclophosphamide was most likely to lead to renal remission in our cohort but surprisingly, anti-plasma cell Rx, which is most appropriate targeted therapy in expert opinion, was not found to have improved outcomes. This may be due to use of this Rx later in disease course. Further prospective studies are needed to identify the best Rx in PGNMID.

Rx Regimen (N=139)	Renal Response	P-value	Complete Remission	P-value
Conservative	11.8% (2/17)	0.001**	11.8% (2/17)	0.194
Steroids alone	42.1% (8/19)	0.522	15.8% (3/19)	0.344
Mycophenolate based	47.8% (11/23)	0.909	26.1% (6/23)	0.843
Cyclophosphamide based	71.4% (15/21)	0.025**	38.1% (8/21)	0.115
Anti-plasma cell	56% (14/25)	0.434	24% (6/25)	0.953
Anti-B cell	52.9% (18/34)	0.590	26.5% (9/34)	0.754

FR-OR086

Hypertension or Complement-Associated Thrombotic Microangiopathy Diagnostic Implications and Response to Eculizumab

Fernando Caravaca-Fontan,[3] Teresa Cavero escribano,[1] Santiago Rodriguez de Cordoba,[2] Manuel Praga.[1] Spanish Group for the Study of Glomerular Diseases (GLOSEN) *[1]Hospital 12 de Octubre, Madrid, Spain; [2]Consejo Superior de Investigaciones Cientificas, Madrid, Spain; [3]Hospital Universitario Ramón y Cajal, Madrid, Spain, Madrid, Spain.*

Background: Malignant hypertension is listed among the causes of secondary thrombotic microangiopathy (TMA), but the presence of pathogenic mutations in complement genes have been recently reported in patients with hypertension-induced. No studies have investigated the frequency and severity of hypertension (HTN) in primary, complement-mediated atypical hemolytic uremic syndrome (aHUS).

Methods: Seventy-five patients with primary aHUS were collected in 21 hospitals in Spain and Portugal. Primary outcome was hematologic and renal response. Patients were classified according to the severity of HTN in normal blood pressure (8 patients, 10%), stage 1 HTN (13, 17%) and stage 2 HTN (54, 72%). Among the latter, malignant HTN (defined by the presence of hypertensive retinopathy grades III/IV) was found in 24 (55%) out of 43 patients in whom retinal examination was performed.

Results: Median age was 34 years and 27 patients (36%) had history of HTN. Fifty-five (75%) patients required acute hemodialysis at presentation. Plasmapheresis was performed in 64 patients and 35 received eculizumab. Abnormalities in complement genes were found in 36 /64 patients (56%) in whom genetic study was performed (68% among patients with malignant HTN). Response was significantly lower after plasmapheresis (25%) than after eculizumab (82%), as well as the rate of dialysis discontinuation (38% and 79%, respectively). Response to eculizumab was similar in normotensive (100%), stage 1 HTN (71%), stage 2 HTN (84%) and malignant HTN patients (90%) and was independent of the presence of genetic abnormalities. Renal survival was significantly higher in patients treated with eculizumab (87% at 1, 3 and 5 years) compared to patients who did not receive this treatment (55%, 46% and 38% at 1, 3 and 5 years, respectively).

Conclusions: Severe hypertension is very common in aHUS, frequently fulfilling the criteria of malignant HTN. The efficacy of eculizumab was observed also in patients with HTN, having or not abnormalities in complement genes.

FR-OR087

Long-Term Effects of Sparsentan, a Dual Angiotensin and Endothelin Receptor Antagonist in Primary Focal Segmental Glomerulosclerosis (FSGS): Interim 84-Week Analysis of the DUET Trial

Jonathan J. Hogan,[5] Vimal K. Derebail,[6] Edward Murphy,[4] Partha C. Raguram,[7] Pablo E. Pergola,[1] Neil S. Sanghani,[2] Howard Trachtman,[3] Radko Komers.[4] *[1]Renal Associates, PA, San Antonio, TX; [2]Vanderbilt University, Nashville, TN; [3]NYU School of Medicine, New York, NY; [4]Retrophin, Inc., Portland, OR; [5]University of Pennsylvania, Philadelphia, PA; [6]UNC School of Medicine, Chapel Hill, NC; [7]Catholic Health Initiatives Franciscan, Tacoma, WA.*

Background: DUET is a phase 2, randomized, active-control study of patients (pts) 8–75 years with primary FSGS, estimated glomerular filtration rate (eGFR) >30 mL/min/1.73 m^2, and urine protein-to-creatinine ratio (UP/C) ≥1 g/g. Pts (N=109) were randomized to sparsentan (SPAR; 200, 400, or 800 mg/d) or irbesartan (IRB; 300 mg/d) for 8-week double-blind (DB) treatment in addition to current standard of care (including immunosuppressive treatments), followed by SPAR only (SPAR:SPAR, IRB:SPAR) in the open-label extension (OLE). This interim analysis was performed at Week 84.

Methods: In the OLE, UP/C, blood pressure (BP), eGFR, and FSGS partial remission endpoint (FPRE; UP/C ≤1.5 g/g and >40% UP/C reduction) were assessed every 12 weeks and compared with baseline (Week 0 for SPAR:SPAR; Week 8 for IRB:SPAR).

Results: UP/C, BP, and eGFR data are in the Table. SPAR:SPAR and transition to SPAR, at Week 8 in IRB:SPAR, led to statistically significant reductions in UP/C and BP, sustained to Week 84. FPRE was achieved by 27/45 (60%) SPAR:SPAR and 13/26 (50%) IRB:SPAR pts at Week 84. In both groups, eGFR decreased initially and stabilized with increasing follow-up duration, possibly reflecting early hemodynamic effects of the drug. During SPAR treatment, adverse events were reported in 63 (94%) SPAR:SPAR and 32 (91%) IRB:SPAR pts; headache, peripheral edema, and hypotension occurred in >20% of pts in SPAR:SPAR or IRB:SPAR.

Conclusions: Sparsentan achieved sustained protein-lowering and BP-lowering effects in primary FSGS over 84 weeks, suggesting long-term nephroprotective potential of the drug.

An Autologous Cellularized In Vivo Engineered Vascular Graft Capable of Remodeling to a Non-Thrombogenic Blood Vessel upon Arteriovenous Grafting in Adult Goats

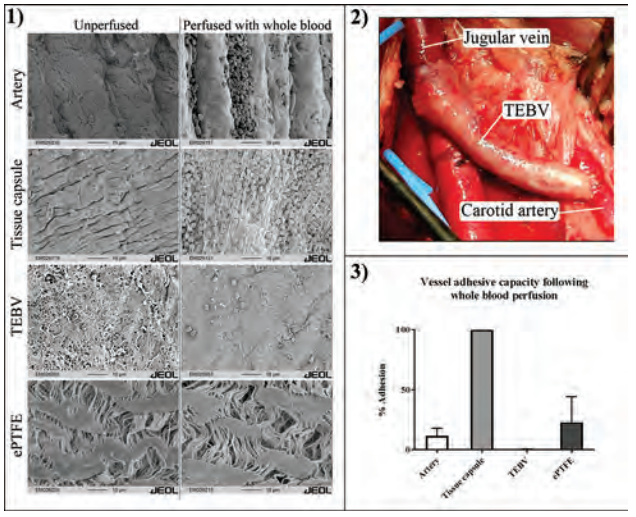
Wouter Geelhoed,[1] Koen E. van der Bogt,[2] Carolien Rothuizen,[4] Jaap Hamming,[3] Maarten S. van Agen,[8] Hetty C. de Boer,[3] Boris Hinz,[7] Ankur Kislaya,[5] Anton J. Van Zonneveld,[3] Ton J. Rabelink,[1] Lorenzo Moroni,[6] Joris I. Rotmans.[1] *[1]LUMC, Leiden, Netherlands; [2]Haaglanden Medisch Centrum/LUMC, Den Haag, Netherlands; [3]Leiden University Medical Center, Leiden, Netherlands; [4]Leiden University Medical Center/Stafsecretariat Nephrology, Leiden, Netherlands; [5]Delft University of Technology, Delft, Netherlands; [6]Maastricht University, Maastricht, Netherlands; [7]University of Toronto, Toronto, ON, Canada; [8]Leiden University Medical Centre, The Hague, Netherlands.*

Background: The durability of prosthetic vascular grafts used for hemodialysis access is poor due to venous stenosis, limiting vascular access. We present a method to create tissue engineered blood vessels (TEBVs) capable of developing *in vivo* towards a functional vascular graft.

Methods: Polymeric rods are implanted subcutaneously in goats for 1 month, resulting in the formation of fibrocellular tissue capsules (TC's) with sufficient mechanical strength to restrain arterial pressure. The TC's then are grafted as arteriovenous conduit between the carotid artery and jugular vein. After 1 or 2 months in the vasculature the grafts were harvested.

Results: *Ex vivo* perfusion showed grafts were less thrombogenic than initial TCs, and also when compared to ePTFE grafts. At 1 month the TEBVs were composed of vascular smooth muscle cell-like cells, with confirmed contractility. At 2 months, complete endothelialisation and elastin formation was also observed, while *in vivo* graft patency was comparable to ePTFE.

Conclusions: Here, we demonstrate the *in vivo* remodelling capacity of TC into TEBV, and their potential as replacements for prosthetic vascular grafts.



FR-OR089

Lysyl Oxidase Determines Postoperative Vascular Stiffness and Neointimal Formation after Arteriovenous Fistula Creation

Diana R. Hernandez,[1] Laisel Martinez,[1] Marwan Tabbara,[1] Juan C. Duque Ballesteros,[1] Loay H. Salman,[2] Roberto I. Vazquez-Padron.[1] *[1]University of Miami, Miller School of Medicine, Miami, FL; [2]Albany Medical College, Albany, NY.*

Background: The transformation of a vein to a fistula is one of the most intriguing processes in vascular biology. The desired scenario is that the fistula matures becoming a larger vessel with increased luminal area and a thicker wall. Unfortunately, arteriovenous fistulas (AVFs) frequently fail (~40%) because venous stenosis compromises blood flow. Lysyl oxidase (LOX) is the main enzyme that catalyzes the oxidative deamination of lysine/hydroxylysine residues (ε-amino groups) in proteins to facilitate spontaneous intra/intermolecular covalent crosslinks formation. The most recognized substrate of LOX is collagen. In fact, collagen tensile strength relies upon LOX mediated crosslinking. LOX is critical for vascular and connective tissue formation; however, deregulated LOX increases collagen stiffness and prevents its degradation, thereby contributing to fibrosis.

Methods: Herein, our goal was to demonstrate that upregulated LOX in the venous limb of the AVF mediates improper remodeling, which causes stenosis and failure.

Results: We first demonstrated that immature and mature collagen crosslinks (using UPLC-ESI-MS/MS) were more abundant in failed human AVFs than in fistulas that matured successfully (N=10/group, p< 0.05). Increased crosslinking correlated with vascular accumulation of LOX as determined by immunohistochemistry. Interestingly, LOX appeared in the interstitial space and in the nuclei of smooth muscle cells (SMCs) and neointimal cells, in agreement with prior reports detecting LOX within the nuclei of cultured fibroblasts. The nuclear location of LOX in SMCs was further demonstrated using cell fractioning techniques. The LOX inhibitor β-aminoproprionitrile (BAPN) decreased SMC growth in culture, which suggests a potential role of this enzyme in the postoperative expansion of the intima. Finally, we demonstrated that systemic and local inhibition of LOX with BAPN increases blood flow and elasticity, and prevents medial fibrosis and intimal hyperplasia in a rat model of AVF.

Conclusions: In conclusion, these data indicate, for the first time, the importance of LOX-mediated crosslinking in AVF failure and the potential role of this enzyme not only in vascular stiffness but also in the control of SMC fate and growth.

Inhibition of MicroRNA-92a Enhances Arteriovenous Fistula Development

Yan-Ting Shiu,[1] CS Jason Tey,[1] Yuxia He,[1] Ha D. Le,[1] Isabelle D. Falzon,[1] Zhen Chen,[2] Yun Fang,[3] Lisa Lesniewski,[1] Alfred K. Cheung.[1] *[1]University of Utah, Salt Lake City, UT; [2]City of Hope, Duarte, CA; [3]University of Chicago, Chicago, IL.*

Background: The Hemodialysis Fistula Maturation Consortium Study showed that endothelial health was associated with the development of arteriovenous fistulas (AVFs). MicroRNA (MiR)-92a is a major contributor to vascular endothelial dysfunction. We recently reported that patients with chronic kidney disease (CKD) had increased serum miR-92a levels when compared to non-CKD control subjects, and that serum miR-92a was likely derived from the endothelium. Thus, we investigated the relationship between miR-92a and AVF development in animal models.

Methods: In young male Wistar rats with normal kidney function or with adenine diet-induced CKD, we created femoral AVFs and then assessed AVF lumen diameter by ultrasound and AVF tissue miR-92a levels by RT-PCR at 4 weeks after creation. In a mouse carotid-jugular AVF model, miR-92a inhibition was achieved using genetic and pharmacological approaches: (1) whole-body knockout (miR-92a$^{-/-}$) with C57BL/6 mice used as wild-type (WT) controls; or (2) nanoparticles (NPs) that encapsulate miR-92a inhibitors and target inflamed endothelium (un-encapsulated miR-92a inhibitors and saline were used as no-NP and no-treatment controls, respectively). C57BL/6 mice received the inhibitor treatment (8 mg/kg body weight) intravenously at 1 day after AVF creation and were sacrificed 1 week later. Mouse AVF cross-sectional lumen area was quantified by histology.

Results: When compared to AVFs in non-CKD rats, AVFs in CKD rats had increased miR-92a expression (3-fold, $p<0.05$) and smaller AVF lumen diameter (1.0 ± 0.51 in CKD vs. 1.55 ± 0.65 mm in non-CKD, $p<0.05$). In the knockout study, the percent open lumen area of AVF veins was larger in miR-92a$^{-/-}$ mice (72% of total area) than in WT mice (12%). In the inhibitor study, both NP-encapsulated (41%) and un-encapsulated (23%) miR-92a inhibitors resulted in larger open lumen area than saline control (5%), and the effect of encapsulated inhibitors was more pronounced.

Conclusions: In our rat model, CKD increased the AVF tissue miR-92a levels and decreased the AVF lumen area. Further, inhibition of miR-92a improved AVF development. Nanomedicine may offer a novel and effective therapeutic approach to enhance AVF maturation in CKD patients.

Does Sex Matter? The Transcriptomics of Sex Differences in Arteriovenous Fistula Failure

Roberto I. Vazquez-Padron,[1] Laisel Martinez,[1] Diana R. Hernandez,[1] Marwan Tabbara,[1] Juan C. Duque Ballesteros,[1] Loay H. Salman.[2] *[1]University of Miami, Miller School of Medicine, Miami, FL; [2]Albany Medical College, Albany, NY.*

Background: Over 260,000 women depend on a vascular access to receive hemodialysis to prolong their lives. Since women have a higher risk of arteriovenous fistula (AVF) maturation failure compared to men, they are more likely to initiate dialysis with grafts and central venous catheters, further increasing their risk for hospitalization and complications. The reasons for sex disparities in AVF maturation have not been well studied despite the unmet clinical need.

Methods: Herein, we explored the nature of sex-related differences in AVF remodelling using high-throughput RNA sequencing of human pre-access veins and AVFs, and functional assessment of experimental fistulas.

Results: We first confirmed that women are at higher risk of maturation failure in a cohort of 161 patients. Failure was associated with female sex independently of preoperative luminal diameter (>4 mm), age and diabetes. Failure among women was associated with postoperative medial fibrosis. Interestingly, experimental AVFs in female rodents had lower blood flow and were stiffer than those in their male counterparts as determined by high precision pressure myography. The persistence of sex disparities in animal models that lack the confounding factors of human cohorts highlight the importance of sex-related biological effects in fistula maturation. Transcriptomic profiling of sex-biased AVF remodeling revealed strong pre-existing (veins) and postoperative (fistulas) sex-related differences in gene expression, and uncovered novel molecular targets of maturation failure associated with sex effects. In women's veins, 748 genes were significantly associated with nonmaturation, while 537 distinct genes were differentially expressed between men's veins that matured or failed. The transcriptomic disparity persisted after fistula creation. Only 33 out of the 763 differentially expressed genes in AVFs that matured vs. failed were common between sexes.

Conclusions: These results demonstrate that mechanisms leading to maturation or failure are sex dependent, and highlight the necessity of sex-oriented therapies in preventing hemodialysis access failure.

Temporal Activation of Notch Improves Arteriovenous Fistulas Maturation

Jizhong Cheng,[1] Qunying Guo,[1] Fengzhang Huang,[1] Xiaoguang Xiao,[1] Ming Liang,[1] Ying Qing,[1] William E. Mitch,[1] Luan D. Truong.[2] *[1]Baylor College of Medicine, Houston, TX; [2]The Methodist Hospital, Houston, TX.*

Background: maturation of arteriovenous fistula (AVFs) requires arterialization of the venous arm in order to sustain increased blood flow and repeated punctures. Proliferation and migration of vascular smooth muscle cells (VSMCs) are required for thickening the venous wall of AVFs. But excessive VSMC accumulation forms a neointima, ultimately, leading to AVF failure. Notch signaling determine the artery fate. Earlier, we demonstrated that Notch signaling in AVFs stimulates vascular remodeling, but complete inhibition of Notch signaling pathway block AVF arterialization. Does temporally controlled Notch activation balance AVF arterialization and neointima formation?

Methods: AVFs created in wild type (WT) and conditionally inducible, VSMC-specific Notch KO mice (RBP-Jk$^{VSMC-KO}$). Temporal Notch activation was controlled by addition of tamoxifen to KO Notch transcription factor, RBP-Jk, in VSMCs. The VSMCs were labeled and tracked; VSMC dedifferentiation, activation, and neointima formation were determined.

Results: in AVF anastomoses, VSMC contractile markers were decreased; proliferation and migration markers were markedly increased. These results document VSMC activation and dedifferentiation. In neointimas, activated Notch was present in VSMC nuclei and it induced VSMC contractile markers thereby promoting neointima formation. Pre-operative KO of RBP-Jk in VSMCs blocked expression of contractile markers causing non-arterialization of AVFs. However, when RBP-Jk was KO in VSMCs in day 10 or day 20 after AVF surgery, the VSMCs in the neointima expressed VSMC markers even

without RBP-Jk expression. Consequently, arterialization of the AVF was induced and the neointima area was smaller in AVFs created in RBP-Jk$^{VSMC-KO}$ mice VS. WT mice. Thus, Notch signaling is required to initiate the expression of VSMC markers. But, the signaling pathway is not required for maintaining VSMC fate. As occurred in AVF, KO or inhibition of Notch signaling suppressed PDGF-BB-induced differentiation of progenitors into VSMCs. Notch overexpression promotes PDGFRβ expression plus differentiation VSMCs from their progenitors.

Conclusions: Temporal activation of Notch improves AVF arterialization and maturation.

Targeting Zero Infection in Hemodialysis Patients: An Experience of an Intra-Hospital Hemodialysis Unit with None Catheter-Related Blood-stream Infection in 633 Days

Claudio Luders, Renata D. Lobo, Carlucci G. Ventura, Felicio Roque, Fabio E. Di nizo. *Hemodialysis, Hospital Sirio-Libanes, Sao Paulo, Brazil.*

Background: Patients undergoing hemodialysis (HD) through tunnelled central venous catheter are exposed to several risks, including infection and trombosis. Catheter-related bloodstream infection (CR-BSI) is the second major cause of death in this population. To reduce the incidence of CR-BSI we conducted an intervention study aimed in lowering these rates.

Methods: An quasi-experimental, pre-post intervention study was conducted in an intra-hospital hemodialysis unit with 15 HD machines and attending 70 patients. In 2011, we implemented an evidence-based intervention package aiming at elimination of all preventable CR-BSI, including the following measures: 1. Alcohol based gel delivery system fixed in every HD machine for hand hygiene 2. Catheter external cleaning with alcoholic chlorhexidine before manipulation for at least 1 minute 3. A scrub-the-hub protocol with strictly aseptic technic for catheter manipulation in any intervention 4. Use of chlorhexidine-impregnated dressing 5.Training all nurse staff admitted, annual re-training and evaluation of performance with infection rate feedback 6. The use of citrate 30% as lock solution.

Results: During the follow-up period (January 2011 to January 2018) a mean of 34 patients (range 30-38) used tunnelled catheter as vascular access each year. The median age was 72 years (range 20-90 years), and 35% of patients were diabetic. After implementation of the intervention package, we observed a continuous reduction in the CR-BSI rate: from 1.1/1000 catheter-days in 2010, the year before the intervention measures; to 0.6/1000, 0.6/1000, 0.1/1000, 0.1/1000, 0.2/1000, 0.2/1000 and 0.0/1000 catheter-days from 2011 to 2017, respectively. Between April 2016 and January 2018, we reached the longest period without CR-BSI events: 633 days, interrupted by a *Serratia marcenses* CR-BSI with tunnel infection in a recipient of pancreas transplant.

Conclusions: Implementation of several evidence-based practices and continuous education can reduce CR-BSI in HD patients to a very low and sustained level. Targeting zero infection proposing eliminate all preventable infection should be routine practice of all dialysis units.

FR-OR094

Arteriovenous Fistula Maturation Outcomes Following Local Perianastomotic Delivery of Sirolimus

Sriram Iyer,[12] Maria V. DeVita,[1] Nelson P. Kopyt,[2] Nirav Gandhi,[3] Naveen K. Atray,[4] Thomas D. Wooldridge,[5] Joseph J. Lee,[6] Kendra S. Hendon,[7] William D. Paulson,[8] Osman S. Khawar,[9] Robert I. Lynn,[10] Prabir Roy-Chaudhury.[11] On behalf of ACCESS Study Investigators. *[1]Lenox Hill Hospital- Northwell Health System, New York, NY; [2]Lehigh Valley Hospital, Bethlehem, PA; [3]Southern California Kidney Consultants, Anaheim, CA; [4]Capitol Nephrology, Sacramento, CA; [5]Nephrology & Hypertension Associates, LTD, Tupelo, MS; [6]Nephrology Associates Medical Group, Riverside, CA; [7]Knoxville Kidney Center, Knoxville, TN; [8]Augusta University, Augusta, GA; [9]Balboa Nephrology Medical Group, Escondido, CA; [10]Albert Einstein College of Medicine, Bronx, NY; [11]University of Arizona, Tucson, AZ; [12]Vascular Therapies, Cresskill, NJ.*

Background: Arteriovenous Fistula (AVF) creation and maturation have many obstacles limiting successful cannulation in a timely manner. Time to first cannulation and rates of AVF suitability for dialysis remain unacceptable; 80% of ESRD patients initiate dialysis with a catheter; many require use for ≥90 days. The use of locally delivered perianastomotic sirolimus may help maturation of AVF in a predictable timeframe by attenuating the development of neointimal hyperplasia. We now report the combined findings of our single arm Phase 2 trial and open label portion of our ongoing US Phase 3 multicenter, randomized controlled clinical trial (NCT02513303).

Methods: All patients underwent creation of an AVF for hemodialysis. The phase 2 trial included 30 patients. The open label phase 3 trial, to date, includes 22 patients. For all patients, after creation of a successful end-to-side vascular anastomosis, sirolimus–eluting collagen membranes (Drug product; Vascular Therapies, Cresskill, NJ) were implanted around the anastomosis and outflow vein. Time to First dialysis (TTFD) defined as use with 2 needles and 300 mL/min flow (2N/300) for 3 consecutive sessions, proportion of AVF in use with 2N on or before day 90, Fistula Suitability at 6 months (FSD6) defined as fistula use (2N/300) for two-thirds of the dialysis sessions during a 30 day period commencing on day 150, and thrombosis/abandonment rates are reported.

Results: Fifty two patients, 51 with ESRD on dialysis and 1 with CKD, were enrolled (Male 67%, mean, age 56±17 y, diabetic 42%; radiocephalic AVF 65%). There were no product related serious adverse events. By 6 months, 9 AVF were abandoned: 7 thrombosed (6 within 2 wks), 1 for central vein occlusion and 1 for pseudoaneurysm. Abandoned AVF are included in the calculations shown in Table. Median days (Q1, Q3) to first dialysis was 49 (39, 67).

Conclusions: 1. In comparison to historical controls local delivery of sirolimus resulted in improved AVF outcomes 2. 73% of sirolimus treated AVF were mature by 3 months (HFM: 25%) 3. Suitability for Dialysis at 6 months was 82% (DAC: 40%)

Funding: Commercial Support - Vascular Therapies

	Proportion of AVF in use with 2 needles on or before day 90	Fistula Suitability for Dialysis at 6 Months
No. eligible for evaluation	51	50

GlomCon Trivia: A Live Web-Based Interactive Fellows Curriculum

Pravir V. Baxi,[1] Nikhil Agrawal,[3] Xavier F. Parada,[2] Roger A. Rodby,[1] Stewart H. Lecker,[3] Ali Poyan-Mehr.[3] *[1]Rush University Medical Center, Chicago, IL; [2]Massachusetts General Hospital, Boston, MA; [3]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Sufficient exposure during nephrology training to the variety of glomerulonephritides (GN) is difficult due to their rare and heterogeneous presentations. GN diagnosis/management and renal pathology interpretation are topics recently identified as areas needing further instruction (JASN 2017; 28:1983–1990). Glomerular Disease Case Conference (GlomCon) Trivia, recipient of the 2017 ASN Innovation in Kidney Education Award, was created to enhance the GN education of trainees, and connect training programs to foster a culture of collaborative learning.

Methods: Using GlomCon's live web-based video platform, the "Trivia" series was created for nephrology training programs to provide topic-based didactic webinars. These sessions include an interactive Q&A audio/video chat forum centered around board-style Q's answered by participants in real time. Participants access the webinars via institutional video conference setup, personal computers, or smartphones. A selected number of multiple-choice Q's (MCQ) from the Webinar were shared with the general public through social media (Twitter). An anonymous survey was obtained to assess participant's perception and experience.

Results: From 9/17-5/18, 11 sessions have been held by different training programs. 100% of the survey responders agreed that the sessions enhanced awareness of GN, and 94% either "completely agreed" or "agreed" that the sessions contributed to their overall knowledge base. In terms of educational quality, 84% rated it as "outstanding" or "above average". In addition, 73% of participants "completely agreed" that the session supplemented their individual program's curriculum. On Twitter, an average of 78 people responded to each publicly presented MCQ.

Conclusions: GlomCon Trivia Interactive Fellows' Curriculum is a global initiative with the potential to 1) Enhance education in GN for trainees, 2) Allow participants to interact and collaborate beyond geographical boundaries, 3) Facilitate discussion of diagnosis and management approaches which can be region or center specific. This program adds to the expanding list of training tools with free open access, which will hopefully improve the education of our trainees and increase interest in the field of nephrology for potential applicants.

FR-OR096

Demystifying Glomerular Disease: A Worksheet Teaching Tool

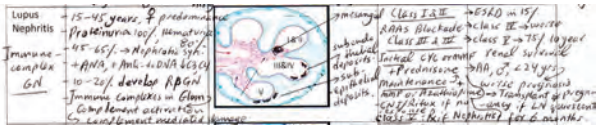
Ahmed A. Awan,[2] Sehrish Ali,[3] Prejith P. Rajendran,[1] Rajeev Raghavan.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Baylor college of medicine, Houston, TX; [3]BCM Nephrology, Sugar Land, TX.*

Background: Learners of all levels express apprehension about glomerular diseases. This may herald from an incomplete understanding of the pathophysiology, and a focus on memorization. For example, understanding that IgA Nephropathy begins with an abnormal IgA protein helps the learner conceptualize symptoms and principles of treatment. This curriculum uses active learning and is broadly applicable to students, residents, and fellows. The goals of this worksheet include: 1) Reduce anxiety when approaching glomerular disease, 2) Complete a worksheet that can be used as a study guide, 3) Use illustration to understand the pathophysiology and histologic representation of glomerular diseases.

Methods: The learner is given a 4-page worksheet with 20 glomerular diseases, arranged by order of the most frequently encountered. Each disease is represented by 1 row. The facilitator is provided a detailed written guide, and the teaching session does not require power point. The learners collectively discuss each disease, but must begin by illustrating pathophysiologic immune marker and/or key histologic appearance of the disease. Next, the clinical presentation, treatment, and prognosis are discussed. The worksheet includes select prompts and mnemonics to aid in material retention and can be completed within a 90 minute session.

Results: We piloted a total of 3 sessions with 42 independent learners - medical students (19), internal medicine residents (13), and Nephrology fellows (10). Over 90% of respondents 'did not feel comfortable treating glomerular disease' prior to the workshop. Over 90% (n=40) of participants agreed or strongly agreed that the worksheet was easy to complete. 85% of respondents plan to use use the completed worksheet as a study guide. One representative comment was 'Excellent review on a topic I struggle with!'

Conclusions: Educators need a teaching tool to help trainees demystify glomerular diseases. The glomerular worksheet can be completed on-the-fly, emphasizes pathophysiology / histology, and can be used as a study guide.



FR-OR097

Easing the Difficult Job of Giving Bad News: Using a Decision Aid to Match Patient Values to a Dialysis Modality

Meg Wise,[1] Dorian R. Schatell,[2] Betty Chewning,[1] Micah R. Chan,[1] Akhtar Ashfaq.[3] *[1]University of Wisconsin-Madison, Madison, WI; [2]Medical Education Institute, Madison, WI; [3]Clinical R&D, Medical Affairs, Opko Pharmaceuticals, Westbury, NY.*

Background: Nephrologists say telling patients they need dialysis is the worst part of the job—and patients do not want this "bad news". Yet, little is known about how nephrologists describe the options or tailor information to patients' values—or whether decision support can make this challenging topic less traumatic and more effective.

Methods: *Design:* A 2-phase prospective, intervention study of audiorecorded conversations between nephrologists and stage 4-5 non-dialysis CKD patients at 2 WI clinics. *Phase 1:* 6 nephrologists and 32 patients; no decision support offered. *Phase 2:* 6 nephrologists and 30 patients; patients used an online, values-based decision aid—*My Life, My Dialysis Choice (My Life)* before the visit and shared the 1-page summary of their values/dialysis preferences with the nephrologist. *Data:* Phase 1 vs. Phase 2: conversations for tailoring information to (1) Values, (2) Patients' surveys for dialysis preference, and (3) Nephrologists' surveys.

Results: ***Results*** *Sample:* Nephrologists had a mean age of 40 and 7.5 mean years of practice. Patients' mean eGFR was 20; mean age was 70; 90% were non-Hispanic white; 73% did not finish college. Phase 1: The dialysis conversation segment was the most difficult. 0% of nephrologists elicited patients' values. Nephrologists tailored dialysis information for only the 4 (13%) activated patients who inserted their values; 4 (13%) patients preferred home dialysis. Nephrologists said they wanted a tool to aid the dialysis discussion. Phase 2: The summary served as a dialysis conversation icebreaker. Nephrologists proactively addressed patients' values 97% of the time and tailored their modality information accordingly (P<0.001 vs. Phase 1). Nephrologists said it "alleviated the need to give bad news." 15 (50%) patients preferred home dialysis (P <0.01 vs. Phase 1).

Conclusions: Patient use of *My Life* (~20 minutes) eased a difficult conversation for both nephrologists and patients, and increased patient preference for home dialysis modalities in this small study.

Funding: Commercial Support - Amgen supported Phase 1

Conversation Analysis Results

Conversation Analysis	Phase 1: No Decision Aid n=32	Phase 2: Decision aid n=30	P value
MD elicited/addressed patients	0 (0%)	29 (97%)	<.001
Patients inserted their own values	4 (13%)	0 (0%)	<.001
POST-VISIT PATIENT SURVEY			
Would choose home dialysis	4 (13%)	15 (50%)	<.01
Undecided about a type of dialysis	12 (38%)	6 (20%)	0.134

Harnessing Technology to Enhance Medical Student Learning

Sana Waheed,[1] Beth A. Altschafl.[2] *[1]University Of Wisconsin School Of Medicine and Public Health, Madison, WI; [2]University of Wisconsin-Madison, Madison, WI.*

Background: Various studies have shown that active learning is more effective than passive learning for long-term retention of concepts for students. Moreover, in this day and age, young learners seem to be familiar, adept, and excited about engaging with online learning material. Therefore, we have designed online leaning materials which allow medical studnents to interact with them in an active manner that leads to improved long-term retention of renal pathophysiological principles.

Methods: Our medical school curriculum at the University of Wisconsin transformed in the fall of 2016 and as a part of this process we created numerous online enduring learning activities (ELA) in addition to the traditional in class lectures and medium group discussions for first year medical students. Some ELAs teach basic science concepts in an innovative way involving technologies like the lightboard. Other ELAs utilize Articulate Storyline, which allows the students to interact with online simulated cases to apply basic science concepts such as sodium, water, and acid- base balance to clinical care. Students receive immediate feedback during these activities through the use of embedded self-assessment activities. Suggested by their name, ELAs are designed to be enduring; they are stored in a in a repository and are easily searchable with the intention that students revisit their content during their clinical years.

Results: To determine if active learning promoted better long-term retention of renal pathophysiological concepts, we compared the students' scores for content taught in-class during traditional lectures to concepts that were taught through ELAs for the renal exam. Our data shows that students performed better on questions from ELA content (Table 1).

Conclusions: Our preliminary data indicates that active learning methodologies such as delivering content through online ELAs is an effective way to teach difficult renal pathophysiology concepts. Feedback indicates that students find these online activities more engaging, and the ELAs offer better student interaction with the material and this likely translates to improved long-term retention of the material in our students.

Number Of Students	Total Number of students	Mean of Students with correct response	Standard Deviation	p-Value
In- Class Content	173	130.01 (75.15%)	31.23 (18.05%)	
ELA Content	173	139.77 (80.79%)	25.19 (14.56%)	P < 0.0001

Table 1: Student scores for content taught through ELAs compared to traditional didactic format

FR-OR099

The Acute Dialysis Orders Objective Structured Clinical Examination (OSCE): Results of Administration to 117 Nephrology Fellows Nationwide

Lisa K. Prince,[1] Ruth C. Campbell,[4] Jessica B. Kendrick,[3] Laura J. Maursetter,[2] Christina M. Yuan.[1] Nephrology Education Research & Development Consortium *[1]Walter Reed National Military Medical Center, Silver Spring, MD; [2]University of Wisconsin School of Medicine & Public Health, Madison, WI; [3]University of Colorado School of Medicine, Aurora, CO; [4]Medical University of South Carolina, Charleston, SC.*

Background: Few quantitative, validated, Nephrology-specific simulations assess ACGME fellow competency performance. We developed, validated and administered a formative OSCE during 2016 and 2017 to 117 Nephrology fellows nationwide to assess medical knowledge, patient care, and systems-based practice in acute dialysis.

Methods: Fellows use institutional protocols and order sets to write dialysis orders and answer evidence based questions on 3 acute dialysis scenarios (49 test items; 58 possible points). 10 board-certified clinical nephrologists validated the test, determining a pass threshold of 46 points.

Results: The 2016 administration included 25 fellows (4 programs), and the 2017 administration included 92 fellows (15 programs). 51 first year fellows and 66 second/third year fellows completed the OSCE. All tests were scored by the 2 Principal Investigators. Median time to take the test was 65 minutes. 75% of fellows passed Scenario 1 (Acute CRRT), with 92% correctly prescribing a greater than 20 ml/kg/hr effluent dose, and 63% able to calculate CRRT clearance as effluent volume. 43% passed Scenario 2 (Urgent outpatient initiation) with 75% using a correct 3-4 meq/L K+ dialysate, but only 12% able to identify the 2 absolute, urgent indications for chronic dialysis initiation. Fellows performed poorly on Scenario 3 (Management prior to and dialysis prescription for acute hyperkalemia in ESRD). 6% passed, with only 20% correctly checking for rebound hyperkalemia with 2 separate lab draws. However, 83% were correct in not giving IV sodium bicarbonate as acute medical management for hyperkalemia. 32% of fellows passed the overall OSCE. No significant difference was found between first and second year fellow performance (overall score 42.7 ± 5 vs. 44.4 ± 4; p= 0.049; 24% vs. 39% pass rate; p= 0.082) with no correlation between second year fellow ITE and OSCE scores. The fellow satisfaction survey had a 56% response rate. 78% strongly agreed/agreed that the OSCE was useful in assessing proficiency in ordering acute renal replacement therapy.

Conclusions: The Acute Dialysis OSCE can provide quantitative data for fellow ACGME sub-competency assessments, and identify opportunities for dialysis curriculum development.

Nephrology Business Leadership University: Filling a Gap in Fellowship Education

Cynthia Miracle,[1] Emmanuel Rodriguez Vargas,[1] Samir Nangia,[2] Parin M. Makadia,[2] Scott Mullaney.[1] *[1]University of California San Diego, San Diego, CA; [2]Dallas Renal Group, P.A., Allen, TX.*

Background: Historically, fellowship training programs have not focused on the knowledge and skills fellows need to successfully transition from training to practice. Concurrently there is dissatisfaction with nephrology as a career choice and interest in nephrology has declined. As a specialty we have focused on attracting trainees into nephrology but not on ensuring fellows have the skills to navigate their career post fellowship. To address this need we developed a weeklong conference, Nephrology Business Leadership University (NBLU), in partnership with practicing nephrologists and industry experts. Our goal was to provide fellows with education in the business aspects of nephrology not taught in traditional nephrology training programs.

Methods: During NBLU fellows attended workshops on topics ranging from the job search to growing a practice to retirement planning. Fellows also participated in sessions on leadership roles in nephrology. Pre- and post-course surveys, interactive feedback sessions, and exit interviews were used to assess the program. A Pre/Post Knowledge Level Survey (5-point Likert Scale) assessed improvements in knowledge level in 24 different content domains. Scores were compared using a paired two sample means t-test. Follow up surveys will be sent at the end of the academic year to assess implementation of this knowledge into the attendees job search.

Results: 31 fellows attended NBLU, representing 22 programs in 15 different states. The pre-survey confirmed that the areas covered in NBLU were absent in traditional training; only 2 out of 30 respondents stated "yes" to having previous instruction in any

business aspects of medicine. The Knowledge Survey demonstrated statistically significant increases in knowledge in all 24 areas. Median knowledge level in the 24 areas was 1.72 prior to and 4.11 post course ($p<0.05$) .100% of surveyed fellows would recommend NBLU.

Conclusions: Education on the business aspects of nephrology is lacking in traditional fellowship training. NBLU is an innovative and effective program for educating fellows on areas they will need when they transition into practice. Fellows were satisfied with their experience and would recommend the program to others. Results of follow up will further assess if learned skills were useful during their job search and in the early days of practice.

FR-OR101

The Need for Nephropathology Teaching Worldwide: The ISN-Clinical Nephropathology Course Survey

Vanesa Bijol,[2] Kenar D. Jhaveri.[1] *[1]Nephrology, Zucker School of Medicine at Hofstra Northwell, Great Neck, NY; [2]Pathology, Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Background: The epidemiology and pathology of kidney disease is still unknown in large parts of the world that are burdened with high rates of CKD, in part due to inability to adequately process and interpret kidney biopsies. Clinical Nephropathology Certificate (CNC) Program is a joined educational initiative of the International Society of Nephrology (ISN) and American Nephrologists of Indian Origin (ANIO) primarily focusing on needs of nephrologists and pathologists in parts of the world with suboptimal nephropathology training and service. The CNC program(started 2013) includes over 40 recorded online lectures and 12 live webinars run by a pathologist and a nephrologist (one each month) made available over a one-year period.

Methods: We surveyed previous and current participants of the ISN CNC program to better understand the worldwide nephropathology practices. This voluntary survey was emailed to participants with 12 questions regarding the nephropathology service in their institutions and respective countries.

Results: The survey response was received from 293 out of 494 current or former participants (response rate 59%) from 63 countries. The data were evaluated using ISN regions and world bank economy classification. Results are summarized in Table below.

Conclusions: The survey responses suggest a large gap between the nephropathology practices in well-developed countries and the rest of the world. Even when existent in L/LM/UMIC, EM services are available for select cases and not routinely. The lack of trained nephropathologists and inability to adequately process samples is a common problem for the most of Africa, Asia, and Latin America, leading to underutilization of kidney biopsy procedures for diagnostic purposes. The lack of financial resources in these countries is still a significant limiting factor in establishing functional nephropathology laboratories. Programs like ours help bridge the education gap that exists in these countries.

Survey results stratified by world bank classification with regards to nephropathology services available in respondents' countries and institutions where they practice

WHO Nation types	n (%)	Electron microscopy in respondents' countries	Nephropathology in respondents' institutions
Low income(LI)	14 (5%) - 5 countries	None	No renal lab - 50%; LM only 36%; LM and IF 12%; EM 0%
Lower middle income(LMI)	122 (59%) - 20 countries	Available in rare labs in 7 out of 20 countries, but not routinely	No renal lab - 23%; LM only 23%; LM and IF 36%; EM 18%
Upper middle income(UMI)	36 (12%) - 12 countries	Exists in all countries but not routinely performed	No renal lab -20%; LM only 11%; LM and IF 23%; EM 46%
High income(HI)	71 (24%) - 26 countries	Commonly present and used routinely in labs in 23 out of 26 countries	No renal lab - 23%; LM only 1%; LM and IF 35%; EM 41%

FR-OR102

Impaired Renal Iron Handling Leads to Iron Overload through an ET-1 Dependent Pathway

Malgorzata Kasztan,[1] Kelly A. Hyndman,[2] David M. Pollock.[2] *[1]Medicine, University of Alabama at Birmingham, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL.*

Background: Elevated plasma endothelin-1 (ET-1) reported in sickle cell disease correlates with microalbuminuria, an independent risk factor for renal disease progression. In humanized sickle cell mice (HbSS), long-term ET_A receptor antagonism significantly attenuated renal tubular iron deposition in proximal tubules (PT). Evidence suggests a pathophysiological links between ET-1, renal iron deposition and early sickle nephropathy, therefore we hypothesize that ET-1 regulates renal iron trafficking in iron overload-associated sickle nephropathy.

Methods: To determine the involvement of ET-1 in renal iron handling mouse primary PT cells (from wild type, HbSS and control (HbAA) mice) were exposed to ET-1 and iron trafficking mediators were assessed by PCR.

Results: Expression of the iron import transporter transferrin receptor 1, TfR-1, and the iron storage protein, H-ferritin, were increased in a concentration-dependent manner by ET-1 in mouse primary PT cells. Also, ET-1 treatment resulted in a decrease in iron exporter ferroportin-1, FPN-1 (65% reduction), which was associated with a doubling in expression of hepcidin, HAMP, a key regulator of FPN-1 and iron removal from the cell. Exposure of PT cells to plasma from HbSS mice, increased cellular iron uptake compared to plasma from control HbAA mice (98±17 vs. 4±1 pg/μl, $p<0.05$). The ET_A antagonist, BQ123, completely prevented ET-1-mediated alterations in all iron mediators, suggesting involvement of ET_A receptors in iron trafficking mechanisms. Moreover, plasma ET-1 was positively correlated with renal iron deposition in HbSS mice ($R^2=0.72$, $p<0.0001$). PT cells isolated from HbSS mice showed significant elevation in expression of TfR-1, DMT-1, H-ferritin, and HAMP along with significantly lower FPN-1 expression compared to control mice. 10-week treatment (from weaning) with an ET_A receptor antagonist (ambrisentan 10mg/kg/day) prevented the induction of DMT-1, preserved FPN-1 and reduced HAMP expression in PT cells from HbSS mice.

Conclusions: These results uncover a novel role for ET-1 in PT iron trafficking and provide a rationale for the use of selective ET_A receptor blockade as a therapeutic approach in iron overload-associated sickle nephropathy.

FR-OR103

Inability to Regulate Fatty Acid Oxidation or Glycolysis Increases Renal Fibrosis

Mardiana Lee,[1,2] Peter F. Mount,[1,2] Marina Katerelos,[1,3] Kurt Gleich,[1,3] David A. Power.[1,2] *[1]Austin Health, Melbourne, VIC, Australia; [2]Medicine, The University of Melbourne, Melbourne, VIC, Australia; [3]Institute of Breathing and Sleep, Melbourne, VIC, Australia.*

Background: Changes in energy metabolism are emerging as a key contributor to renal fibrosis. Expression of genes regulating fatty acid metabolism is reduced in fibrotic kidneys and aerobic glycolysis increases in some renal disease models. We aimed to determine the role of phosphorylation events that control fatty acid oxidation (FAO) and glycolysis in renal fibrosis.

Methods: The folic acid nephropathy (FAN) and unilateral ureteric obstruction (UUO) models were induced in mice with knock-in mutations of phosphosites in acetyl CoA carboxylase 1 and 2 (ACC1/2KI mice), the major regulator of FAO, and 6-phosphofructo-2kinase/fructose-2,6-biphosphatase (PFKFB2KI mice), the major regulator of glycolysis. Metformin, which activates AMPK to increase phosphorylation of ACC and PFKFB2, was administered to mice with FAN.

Results: ACC Ser79 phosphorylation was reduced in folate-treated tubular epithelial cells ($p<0.01$) and WT mice with FAN ($p<0.05$). Mutation of these sites in ACC1/2 KI mice with FAN or UUO caused lipid accumulation (Oil Red O $p<0.01$), increased triglyceride ($p<0.01$), increased collagen (PicroSirius red $p<0.001$; Masson's Trichrome $p<0.01$; qRT-PCR $p<0.01$) and increased α-SMA (Western blot $p<0.05$; qRT-PCR $p<0.01$). Metformin administration was associated with reduced fibrosis (PicroSirius red $p<0.01$) and lipid accumulation (Oil Red O $p<0.05$) in WT mice, but not in ACC1/2KI mice. To determine the role of control of glycolysis, UUO was induced in PFKFB2KI mice. WT mice with UUO had reduced PFKFB2 Ser483 phosphorylation ($p<0.01$). PFKFB2KI UUO mice had increased collagen (Picrosirius red $p<0.001$), increased fibronectin (Western blot $p<0.05$; qRT-PCR $p<0.05$), increased α-SMA (Western blot, $p<0.05$) (Fig.1) and glycogen accumulation (PAS, $p<0.05$).

Conclusions: These data suggest that reduced phosphorylation of ACC and PFKFB2 are deleterious following renal injury. Drugs that reverse this, such as metformin, may be useful in preventing and treating renal fibrosis.

Amphiregulin Drives Kidney Fibrosis in Mice and Its Elevated Serum Levels Correlate with CKD Outcomes in Humans

Eirini Kefalogianni,[1] Manikanda raja Keerthi raja,[1] Vaia Pliaka,[4] Julian Schumacher,[1] Leonidas G. Alexopoulos,[3] Sushrut S. Waikar,[2] Andreas Herrlich.[1] *[1]Washington University in St. Louis, St. Louis, MO; [2]Harvard Medical School, Boston, MA; [3]National Technical Univ of Athens, Glyfada, Greece; [4]Protavio, Athens, Greece.*

Background: We have shown that ADAM17-released EGFR ligands in proximal tubule cells (PTCs) drive kidney fibrosis in IRI and UUO kidney injury models (Kefaloyianni et al, JCI Insight 2016). Which specific EGFR ligands are involved remains unknown. We showed that amphiregulin (AREG) is the most upregulated EGFR ligand after kidney injury in mice and the most potent EGFR ligand in inducing pro-inflammatory and pro-fibrotic genes in human PTCs (HPTCs) *in vitro*. Soluble AREG (sAREG) is significantly elevated in the urine of AKI and CKD patients and AREG protein is elevated in CKD biopsies, as compared to healthy controls. It is not known whether AREG has a key role in mediating injury-induced kidney fibrosis in mice and humans.

Methods: We used tamoxifen inducible AREG$^{fl/fl}$-Slc34a1$^{GCE+/-}$-tdTomato^{+} (AREG-PTC KO) mice and ADAM17$^{fl/fl}$-Slc34a1$^{GCE+/-}$-tdTomato^{+} (ADAM17-PTC KO) mice and their respective wt littermates, as well as HPTCs transfected with control or YAP1 siRNA. We also developed and extensively validated a sensitive bead-based ELISA for sAREG in human serum samples.

Results: We found that sAREG can uniquely sustain EGFR activation in HPTC *in vitro* via YAP1-dependent upregulation of its own transcript, followed by ADAM17-dependent release of sAREG (positive feedback). *In vivo*, AREG-PTC-KO reduced IRI-induced sustained EGFR phosphorylation, as well as upregulation of pro-inflammatory cytokines and pro-fibrotic markers. We show that in ADAM17-PTC-KO mice, which cannot release any injury-induced EGFR ligand in PTC, injection of sAREG alone is sufficient to induce production of pro-inflammatory and pro-fibrotic factors to the levels of ADAM17 wt mice. Finally, we show that sAREG serum levels correlate positively with serum creatinine and CKD stage and negatively with eGFR in a nephrectomy cohort (n=69) of patients with various diagnosis and levels of fibrosis.

Conclusions: These results suggest that AREG is a major driver of kidney fibrosis in mice and humans, acting via a YAP1-dependent positive feedback loop that sustains EGFR activation and induces pro-inflammatory and pro-fibrotic cytokines, and represents a potential functional marker of fibrosis and CKD progression.

FR-OR105

The Effects and Potential Role of Circulating Macrophage in Renal Fibrosis

Gang Xu,[2] Yuxi Wang,[3] Rui Zeng.[1] *[1]Tongji Hospital, Huazhong Univ of Science and Technology, Wuhan, China; [2]Tongji hospital affiliated to Tongji medical college, Huazhong University of Science and Technology, Wuhan, China; [3]Division of Nephrology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology Wuhan, Hubei, China, Wuhan, China.*

Background: Macrophages plays an important role in the process of renal fibrosis. Recent studies have suggested that circulative macrophages are the major source of myofibroblasts, which is contradicted with traditional view, that only a few myofibroblasts were derived from bone marrow-derived cells. In this study, we looked for changes in CKD lesions and macrophages at different stages to find better classification of macrophage

Methods: Firstly, we adopted a bone marrow transplantation (BMT) model using GFP mouse bone marrow cells. Secondly, a parabiosis + I/R model or UUO model was constructed using GFP mice. To further understand the link between macrophage with myofibroblast, CSF1r-GFP mice were adopted in parabiosis + I/R model. Otherwise, we used the chlorophosphate liposome (CL) to knockout macrophages. CCR2-/- mice were adopted to construct parabiosis + I/R models to observe the effect of circulating macrophage in renal fibrosis. To directly explore the mechanism of macrophage on renal injury, we sorted Ly6c+ inflammatory macrophages from I/R kidneys and injected under kidney capsule of immunodeficient mice. At the same time, fibrosis-related markers were detected after co-culture the sorted Ly6c+ cells with fibroblasts.

Results: BMT+I/R model found that 22.55% of renal myofibroblasts were derived from bone marrow-derived cells, and 14.6% of myofibroblasts were derived from peripheral macrophages. The parabiosis + I/R or UUO model by using CSF1r-GFP mice proved that 5-9% of myofibroblasts in the kidney expressed GFP. With the treatment of CL, operated mice had early renal injury and delayed atrophy, and renal tubular injury was alleviated. Then we used CCR2-/- mice and observed that mice knocked out of peripheral macrophages reduced renal fibrosis; CCR2-/- mice were constructed parabiosis model with WT mice, in which peripheral macrophages can be replenished, and their kidney damage and fibrosis are aggravated. The sorted Ly6c+ inflammatory macrophages direclty lead to increased fibroblast activation and fibrosis.

Conclusions: The results indicated that peripheral derived macrophages are not the main source of myofibroblasts. The sorted Ly6c+ macrophages have the effect on promoting renal fibrosis. Knockout peripheral inflammatory macrophages reduce renal fibrosis. Ly6c+ inflammatory macrophages can directly lead to normal kidney damage and fibrosis and can promote fibroblast activation.

DOT1L Inhibition Attenuates Renal Fibrosis through Suppressing Multiple Profibrotic Signaling Pathways and Preserving Expression of Smad7 and Klotho

Lirong Liu,[2] Xiaoxu Zhou,[3] Chongxiang Xiong,[2] Shougang Zhuang.[1] *[1]Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI; [2]Rhode Island Hospital, Providence, RI; [3]Rhode Island Hospital, Brown University, Providence, RI.*

Background: Disruptor of telomeric silencing-1 like (DOT1L) protein specifically catalyzes the methylation of histone H3 on lysine-79 and is implicated in leukemia and some solid tumors, but its role in tissue fibrosis remains unknown.

Methods: In this study, we examined the role of DOT1L in renal fibroblast activation, epithelial-mesenchymal transition and renal fibrosis development in vitro and in vivo.

Results: We demonstrated that injury to the kidney increased DOT1L expression and H3K79 dimethylation (H3K79me2) in renal tubules and myofibroblasts in a murine model of unilateral ureteral obstruction. Administration of EZP5676, a highly selective inhibitor of DOT1L, attenuated renal fibrosis as evidenced by decreased activation of renal interstitial fibroblasts and reduced deposition of extracellular components. Treatment with EZP5676 or DOT1L siRNA also inhibited transforming growth factor β1 and serum -induced activation of renal interstitial fibroblasts and epithelial-mesenchymal transition (EMT) in vitro. Moreover, blocking DOT1L abrogated injury-induced epithelial G2/M arrest; reduced expression of Snail and Twist, two transcription factors that drive EMT; downregulated Notch1, a transmembrane receptor protein associated with renal fibrosis; and inactivated several profibrotic signaling molecules, including Smad3, epidermal growth factor receptor, platelet growth factor receptor, STAT3, AKT as well as NF-κB in the injured kidney. Conversely, DOT1L inhibition increased expression of phosphatase and tensin homolog, a protein associated with dephosphorylation of tyrosine kinase receptors, and prevented decline in levels of klotho and Smad7, two renoprotective factors.

Conclusions: Our data indicate that targeting DOT1L inhibits activation of renal fibroblasts, EMT and renal fibrosis by suppressing activation of multiple profibrotic signaling pathways and retaining expression of renoprotective factors. DOT1L could be a novel therapeutic target for treatment of fibrotic renal diseases.

Osteocrin, a Bone-Derived Humoral Factor, Exerts a Renoprotective Role in Ischemia-Reperfusion Injury in Mice

Yoshihiko Nishiguchi,[1] Takashige Kuwabara,[1] Shuro Umemoto,[1] Daisuke Fujimoto,[1] Tomoko Kanki,[1] Yusuke Hata,[1] Hideki Yokoi,[2] Yuichiro Izumi,[1] Yutaka Kakizoe,[1] Masashi Mukoyama.[1] *[1]Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [2]Kyoto University Graduate School of Medicine, Kyoto City, Japan.*

Background: Natriuretic peptides (NPs; atrial, brain and C-type NPs: ANP, BNP and CNP) constitute the hormonal basis of the heart-kidney network, in which the remote organs influence each other under physiological and pathophysiological conditions. We recently reported that osteocrin (Ostn), originally identified as a secretory peptide in the bone and muscle, exerted bone elongation and cardioprotective effects through antagonizing NP clearance receptor NPR3. Of note, SNPs of the *Ostn* and *NPPA/NPPB* gene loci are reportedly related to a renal function decline risk by genome-wide association studies. However, the role of Ostn in the kidney has not been clarified yet.

Methods: To investigate the role of Ostn, we generated systemic Ostn knockout (KO) mice, and mated with liver-specific SAP promoter-driven Ostn-transgenic mice (KO-Tg). Wild-type (WT), KO and KO-Tg mice were subjected to ischemia-reperfusion injury (IRI) by unilateral renal artery clamping. Samples were collected at 3 weeks after IRI. Ostn expression in the kidney was evaluated by X-gal immunostaining using Ostn-LacZ knockin mice.

Results: In atrophic and fibrotic kidneys after IRI of WT, Ostn mRNA was increased in parallel with NPR3 and CNP upregulation, but not in the contralateral or pre-IRI kidneys. Furthermore, CNP expression was markedly suppressed in the contralateral kidney after IRI. These changes were either enhanced or suppressed in KO or KO-Tg, respectively, suggesting that Ostn affects the regulation of CNP and NPR3 expression in the kidney. In KO kidneys, mRNA expression of neutrophil gelatinase-associated lipocalin (NGAL) and IL-1b was further enhanced. In KO-Tg, fibrosis and atrophy were significantly ameliorated compared to WT and KO, together with the decreased expression of pro-fibrotic (aSMA, TGF-b), pro-inflammatory (IL-1b, TNFa) and tubular injury maker (NGAL, KIM-1) genes. X-gal immunostaining revealed that endogenous Ostn expression was induced by IRI in the tubular epithelial cells of corticomedullary junction in the kidney.

Conclusions: Exacerbation of IRI-induced kidney injury in Ostn-deficient mice was attenuated by ectopic overexpression of Ostn. Our data suggest a renoprotective role of Ostn, and could provide a potential therapeutic strategy against acute kidney injury.

FR-OR108

Temporal and Tissue-Specific Activation of AHR Signaling in Discrete Renal Diseases

Joshua A. Walker,[1,2] Daniel M. Roth,[1] Mostafa Belghasem,[4] Joseph Y. Tashjian,[4] Sean Richards,[1] Stephen A. Whelan,[5] Nkiruka Arinze,[1] Norman Lee,[5] Vijaya B. Kolachalama,[2] Jean M. Francis,[1] Vipul C. Chitalia.[3] *[1]Renal Section, Department of Medicine, Boston University, Boston, MA; [2]Whitaker Cardiovascular Institute, Boston University, Boston, MA; [3]Boston University School of Medicine, Boston, MA; [4]Department of Pathology and Laboratory Medicine, Boston University, Boston, MA; [5]Department of Chemistry, Chemical Instrumentation Center, Boston University, Boston, MA.*

Background: Aryl hydrocarbon receptor (AHR) signaling is emerging as an important mediator of uremic toxicity regulating several manifestations of uremic solutes. While previous studies showed AHR activation in whole organs in response to uremia, no studies have examined cell- type specific AHR activation in vivo in uremic and non-uremic conditions in discrete models of kidney diseases.

Methods: Transgenic mice containing two dioxin-response elements upstream of a beta-galactosidase (β-gal) reporter gene were subjected torenalanischemia/areperfusioninjury(I/R), andanaAdenine-induced CKD, oranda recently developed Indoxylsolute specific animal modelss. TCDD, a canonicalAHRligand served as a positive control. β-gal protein expressionswaserecompared using a recently validatedquantitativecolor-based image segmentation quantitative image analytical techniqueanalysis. Double label immunofluorescence was used to analyze cell specific expression of β-gal. mRNA was analyzed with qRT-PCR. Plasma was analyzed for levels of blood-urea nitrogen (BUN), creatinine.

Results: In all the models, β-gal expression in kidneys predominated in both the proximal and distal renal tubules, but distinctly sparedwas absent fromthe glomeruli. In I/R model, β-gal expression significantly increased within 24 hours of injury ($p<0.05$) and decreased at both 48 and 96hrs post-surgery, while renal function continued to remains significantly altered at all these time points ($p<0.01$). Along with renal tubules, CKD and solute specific AHR models showed significant increase β-gal expression in endothelial, smooth muscle cells of the aorta and liver ($p<0.05$). A trend towards increased AHR activation in cardiomyocytes and neuron cells bodies was observed. Xxx Uremic solutes

Conclusions: The current study represents the first use of this reporter animal in disease-specific models. The model demonstrated a broad sensitivity in uremic kidney diseases and also in uremia-independent mechanisms such as hypoxia. While supportive of our previous observations in uremic thrombosis, AHR activation in some of the organs provide a hypothesis-generating insight. The model demonstrated a broad sensitivity in uremic kidney diseases and also in uremia-independent mechanisms such as hypoxia.

CKD Impairs Muscle Protein Synthesis via a Demethylase Mechanism That Regulates Ribosomal Biogenesis

Liping Zhang,[1] William E. Mitch.[2] *[1]Nephrology, Baylor College of Medicine, Houston, TX; [2]Baylor College of Medicine, Houston, TX.*

Background: the report that patients with chronic kidney disease (CKD) require diets with 1.5 g protein/kg/d is based on the premise that a high protein diet will overcome a block in muscle protein synthesis. Such a diet, however, would cause metabolic acidosis, hyperphosphatemia, etc. To prevent these outcomes we are investigating mechanisms that can improve muscle protein synthesis even with dietary protein is restricted. We have identified a CKD-stimulated, chromatin-modifying, nucleolar protein, NO66 and show that it suppresses both ribosomal DNA transcription and muscle protein synthesis

Methods: we studied mice with CKD (subtotal nephrectomy) with BUN >80 mg/dL, similar to values in ESRD patients.

Results: NO66 demethylates histone proteins, H3K4ME3 and H3K36ME3, regulating growth. In muscles of both mice and patients with CKD, we found high levels of NO66 mRNA and protein. These increases were found to be stimulated by inflammation and mediated by changes in NF-κB: NO66 expression was suppressed by a NF-κB inhibitor. In support of this conclusion, we identified 3 NF-κB binding sites in the NO66 promoter. Does NO66 cause loss of muscle mass in mice with CKD? To address this possibility, we created global KO of NO66 in mice (NO66-/-) or satellite cell-specific NO66 KO (NO66-Pax7-cre) or muscle-specific NO66 KO (NO66-MCK-cre) mice. In response to CKD, NO66 KO mice developed an increase in muscle mass (28±8%) and protein synthesis (71±15%) vs. results in control mice. From a RNA-seq analysis of soleus muscles of $NO66^{-/-}$ and $NO66^{flox/flox}$ mice, we found that NO66 absence in muscle stimulates ribosomal biogenesis. Consistent with the RNA-seq results, both rRNA and the ribosomal translational capacity were increased in muscles lacking NO66 vs. results from control, $NO66^{flox/flox}$ mice. In addition, NO66 overexpression was found to suppress pre-rRNA expression in C2C12 muscle cells. Finally, a CHIP assay revealed that NO66 represses the transcription of ribosomal DNA via a demethylase mechanism

Conclusions: we have uncovered a new mechanism that regulates protein synthesis and ultimately, muscle mass

The Kidney Makes Gas in Defense against Urinary Bacteria

Katherine Xu, Tian Shen, Abraham D. Levitman, Max Werth, Jonathan M. Barasch. *Columbia University, New York, NY.*

Background: The kidney expresses a variety of powerful defense mechanisms to limit urinary infection including iron scavenging, a process called "nutritional immunity". We previously demonstrated that the intercalated cells generate the archetype of the urinary iron defense, a lipocalin called NGAL which binds Enterochelin (Strong, FHCC), a bacterial siderophore. However, because urinary bacteria can evade the bacteriostatic effects of NGAL by modifying Enterochelin and by producing additional siderophores, other mechanisms of "nutritional immunity" are anticipated.

Methods: We utilized a cell type specific method of RNA isolation (adapted from Gay, Oregon). A promiscuous form of phosphoribosyltransferase (UPRT) was cloned into the Rosa26 locus using a floxed-stop design which we activated in a cell specific fashion with HoxB7Cre or Atp6v1b1Cre. Thiouracil was introduced 12hr and 24hrs after infection. Hmox1 was detected with a luciferase based reporter (Contag et al, Stanford). CO was detected with a novel metal-based probe synthesized at Columbia (adapted from Liu, China).

Results: A survey of classical iron transporters revealed segment specific expression of megalin (proximal tubule), TfR1 (TALH), and DMT1 (TALH-DCT). Nonetheless, despite ferritin accumulation, we failed to identify the mechanism of iron import in intercalated cells. Isolation of RNA directly from intercalated and principal cells revealed synthetic (*NPAS-BMAL-ALAS*), transport (*Hrg1, Flvcr1*) and metabolic enzymes (*Hmox*) of heme metabolism. Functional reporters demonstrated Hmox expression and the production of CO gas from cortical>medullary sources *in vivo* and from AtpCre-mTmG FACS isolated intercalated cells *in vitro*. Urinary bacteria (UPEC) with heme transport mutations were not competitive in the colonization of the kidney but conversely were markedly stimulated by heme, suggesting bacterial-host competition for heme capture and metabolism. In fact, infection upregulated both heme synthetic and metabolic genes, suggesting that CO production is induced by infection. Exposure to CO terminated the growth of UPEC.

Conclusions: We have identified an unusual iron trafficking system in the collecting ducts that mirrors the nutritional requirements of UPEC to achieve pyelonephritis. Many of these components are specific to the intercalated cells, consistent with the notion that these cells defend the urinary tract.

Whole-Kidney Three-Dimensional Imaging Reveals the Progression of Renal Sympathetic Denervation after Ischemia-Reperfusion Injury

Sho Hasegawa,[1] Tetsuhiro Tanaka,[1] Etsuo A. Susaki,[2] Hirotaka Komaba,[3] Takehiko Wada,[3] Hisako Saito,[1] Mai Sugahara,[1] Lisa Uchida,[1] Marie Ito,[1] Masafumi Fukagawa,[3] Hiroki R. Ueda,[2] Masaomi Nangaku.[1] *[1]Division of Nephrology and Endocrinology, The University of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]Department of Systems Pharmacology, The University of Tokyo Graduate School of Medicine, Tokyo, Japan; [3]Division of Nephrology, Endocrinology and Metabolism, Tokai University School of Medicine, Isehara, Japan.*

Background: The sympathetic nervous system is critical in maintaining the homeostasis of renal functions. Its three-dimensional (3D) structures in the kidney, however, have not been elucidated because of the limitation of conventional imaging methods. CUBIC (Clear, Unobstructed Brain/Body Imaging Cocktails and Computational analysis) is a newly developed tissue clearing technique, which enables 3D imaging of whole-organ with single-cell resolution. Here, we apply CUBIC to the kidney research, visualizing the 3D structure of renal sympathetic nerves, showing the process of denervation after ischemia-reperfusion injury (IRI).

Methods: Eight-week-old male C57BL/6 mice were subjected to sham operation or bilateral IRI for 45 minutes, and sacrificed 28 days after surgery. The kidneys were optically cleared using CUBIC protocol. After making kidneys transparent, the sympathetic nerves were labeled with 3D immunofluorescent staining. Whole-kidney imaging was acquired by a light-sheet fluorescent microscopy.

Results: The spatial distribution of sympathetic nerves was clearly visualized. Compared with the sham group (figure 1A), the nerve density in the cortical lesion was significantly decreased in the IRI group (figure 1B).

Conclusions: The new 3D imaging technique has demonstrated the sustained renal sympathetic denervation after IRI. Dysfunction of sympathetic nerves might be related to the progression of chronic kidney disease.

The Epidemiology of CKD from 1990 to 2016 in the United States of America: An Analysis of the Global Burden of Disease Study

Benjamin C. Bowe,[1,3] Yan Xie,[1] Tingting Li,[1,2] Yan Yan,[1,2] Hong Xian,[1,3] Ziyad Al-Aly.[1,2] Clinical Epidemiology Center *[1]Clincal Epidemiology Center, VA Saint Louis Health Care System, Saint Louis, MO; [2]Washington University in St. Louis, Saint Louis, MO; [3]Saint Louis University College for Public Health & Social Justice, St. Louis, MO.*

Background: Over the last 3 decades, the United States experienced significant changes in demographic, social, and epidemiologic trends; these changes likely have contributed to changes in chronic kidney disease (CKD) epidemiology.

Methods: We used the Global Burden of Disease (GBD) study data and methodologies to describe the change in burden of CKD from 1990 to 2016 involving disability adjusted-life years (DALYs) and death.

Results: Between 1990 and 2016, CKD DALYs increased by 104.7% from 945,627 (UI: 837,774-1,053,428) to 1,935,953 (1,747,356-2,124,794). Death due to CKD increased by 149.5% from 33,080 (UI: 3 2,382-33,721) to 82,539 (UI: 80,297-84,652). All states exhibited increase in CKD burden, but there was remarkable heterogeneity in rate of change. In 2016, the burden varied greatly by state, where Mississippi (the state with the highest burden) had twice the age-standardized CKD DALY rate compared to Vermont (the state with the lowest burden), 697(UI:619-778) and 321 (UI:280-363), respectively. In the US, 37.8%, 35.6%, and 26.7% of the increase in DALYs was attributable to increased risk factor exposure, population growth, and aging, respectively. Decomposition analyses showed substantial increase in metabolic, and to a lesser extent dietary, risk factors which manifested in increase in CKD due to diabetes, and to a lesser extent hypertension. CKD due to diabetes was the primary contributor for increased probability of death due to CKD among those aged 20-54; among those aged 55-89, the increase in probability of death was driven by CKD due to diabetes and decreased probability of death from causes other than CKD. Improvement in socio-demographic (SDI) development was coupled with an increase in age-standardized DALY rates. Rate of change in burden of CKD outpaced rate of change of other non-communicable diseases, and rate of change of CKD in all SDI levels.

Conclusions: The US toll of CKD is significant, rising, and substantially variable among states; it is driven by increased risk factor exposure and demographic expansion leading to increased probability of death from CKD among working adults; the rate of change in CKD burden outpaced other diseases in the US and CKD in other areas of the world.

Cumulative All-Cause Hospitalization Trajectories and Risks of ESRD and Death in the Chronic Renal Insufficiency Cohort (CRIC) Study

Anand Srivastava,[1] Xuan Cai,[1] Jungwha Lee,[1] Rupal Mehta,[1] David I. Chu,[2] Sarah J. Schrauben,[3] Milda R. Saunders,[4] Clarissa J. Diamantidis,[5] Katherine T. Mills,[6] Jonathan J. Taliercio,[7] Tariq Shafi,[8] Chi-yuan Hsu,[9] Sushrut S. Waikar,[10] James P. Lash,[11] Tamara Isakova.[1] CRIC Study Investigators *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL; [3]Division of Renal, Electrolytes, and Hypertension, University of Pennsylvania, Philadelphia, PA; [4]University of Chicago, Chicago, IL; [5]Duke University School of Medicine, Durham, NC; [6]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [7]Glickman Urological and Kidney Institute, Cleveland, OH; [8]Johns Hopkins University School of Medicine, Baltimore, MD; [9]University of California San Francisco, San Francisco, CA; [10]Harvard Medical School, Boston, MA; [11]University of Illinois at Chicago, Chicago, IL.*

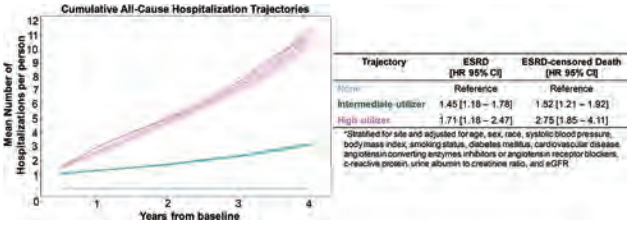
Background: Prior studies have not evaluated whether trajectories of all-cause hospitalization identify high-risk sub-phenotypes of patients with chronic kidney disease (CKD).

Methods: We evaluated data on 3012 participants of the CRIC Study who were alive and did not reach end stage renal disease (ESRD) during the first 4 years of follow up. To identify clinically distinct trajectories of cumulative all-cause hospitalization during 4 years, we performed trajectory analyses using latent class model. Trajectory analyses allow agnostic detection of subpopulations with distinct longitudinal patterns. Next, we fit multivariable-adjusted Cox proportional hazards models to assess the associations of trajectories of all-cause hospitalization with ESRD and with ESRD-censored death in participants who survived beyond their 5th annual visit.

Results: Trajectory analyses identified 3 discrete groups based on cumulative all-cause hospitalizations within the first 4 years of follow-up: none (n=1090), intermediate-utilizer (n=1785), or high-utilizer (n=137). Participants in the high-utilizer group were more likely to be black, have greater prevalence of diabetes mellitus and cardiovascular disease, have higher body mass index and albuminuria, and lower estimated glomerular filtration rate (eGFR). During a median follow-up time of 5.6 years, there were 544 ESRD events and 437 ESRD-censored deaths. High and intermediate utilizer trajectory groups were associated with a higher risk of ESRD and ESRD-censored death (Figure).

Conclusions: Trajectories of cumulative all-cause hospitalization identify subgroups of patients with CKD who have increased risks of ESRD and death independent of known risk factors including eGFR and albuminuria. Population health interventions should focus on patients with CKD with increasing cumulative all-cause hospitalizations.

Funding: NIDDK Support



Trajectory	ESRD [HR 95% CI]	ESRD-censored Death [HR 95% CI]
None	Reference	Reference
Intermediate-utilizer	1.45 [1.18 – 1.78]	1.52 [1.21 – 1.92]
High utilizer	1.71 [1.18 – 2.47]	2.75 [1.85 – 4.11]

Efficacy and Safety of Evolocumab in CKD: Data from the FOURIER Trial

David M. Charytan,[1] Marc S. Sabatine,[3] Terje R. Pedersen,[2] Kyungah Im,[3] Armando Lira Pineda,[6] Scott M. Wasserman,[6] Peter Sever,[4] Anthony C. Keech,[5] Robert P. Giugliano.[3] *[1]Brigham and Women's Hospital/Harvard Medical School, Brookline, MA; [2]Oslo University Hospital, Ullevål, Oslo, Norway; [3]TIMI Study Group, Brigham and Women's Hospital, Boston, MA; [4]Imperial College London, London, United Kingdom; [5]NHMRC Clinical Trials Centre, University of Sydney, Sydney, NSW, Australia; [6]Amgen, Thousand Oaks, CA.*

Background: The efficacy and safety of PCSK9 inhibition in patients (pts) with CKD is undefined. We analyzed outcomes by kidney function in FOURIER.

Methods: FOURIER randomized 27564 pts with stable atherosclerosis and LDL-cholesterol (C) ≥70 or non-HDL-C ≥100 mg/dL to the PCSK9 inhibitor evolocumab or placebo. The primary endpoint (CV death, MI, stroke, hospitalization for unstable angina, or coronary revascularization), key secondary endpoint (CV death, MI or stroke), and safety outcomes were analyzed by CKD stage estimated from baseline CKD-EPI eGFR.

Results: 8077 pts had eGFR ≥90 mL/min/1.73m^2, 15,034 stage 2 (eGFR 60-89), and 4443 ≥stage 3 CKD (eGFR <60). Age and comorbidity prevalence increased with worse CKD. LDL-C reduction with evolocumab vs placebo at 48 weeks was similar across CKD groups at 58.2%, 59.4% and 58.7%, respectively. In the placebo arm, the primary and key secondary endpoint rates were higher with worsening CKD, especially those with ≥stage 3 vs. preserved kidney function (primary-16.1% vs. 12.2%, P<0.01; secondary-12.8%

vs. 7.1%, P<0.001, Figure). Relative risk reduction (RRR) with evolocumab was similar regardless of CKD stage (P_{int}=0.77 and 0.75, respectively). However, the absolute RRs for the key secondary endpoint tended to be larger among those with ≥stage 3 CKD (2.5%, 95% CI: 0.4%-4.7%) compared with individuals with preserved kidney function (1.7%, 95% CI 0.5%-2.8%). Adverse events, including eGFR decline ≥30%, were similar regardless of CKD stage.

Conclusions: LDL-C lowering and the relative efficacy and safety of evolocumab was preserved across CKD groups in patients with clinically evident atherosclerosis and hyperlipidemia on statin therapy. Absolute reduction in CV death, MI or stroke with evolocumab tended to be greater with more advanced CKD.

RAAS Inhibitors and Risk of ESRD and Mortality in Advanced CKD

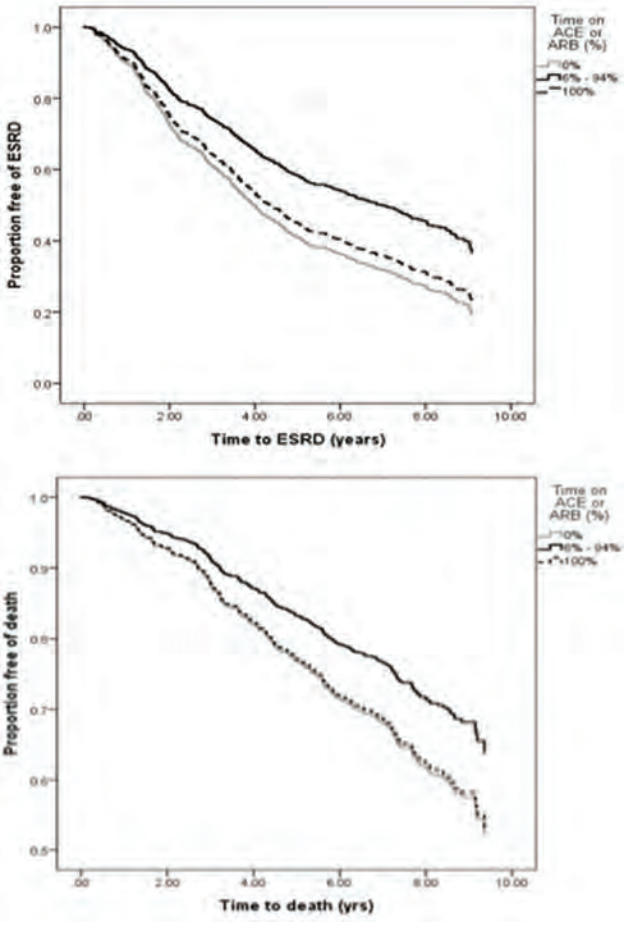
Nayan Arora, Ronit Katz, Nisha Bansal. *UW, Seattle, WA.*

Background: Inhibition of the renin-angiotensin-aldosterone system (RAASi) is standard of care in early to moderate CKD. However their use in advanced CKD is controversial due to lack of data on safety and efficacy. We described the use of RAASi among a large advanced CKD cohort and tested the association of differing patterns of RAASi use with clinical outcomes.

Methods: We identified participants of the Chronic Renal Insufficiency Cohort (CRIC) study with eGFR <30 mL/min/1.73m2. A physician reviewed all available longitudinal study visit data and classified participants into groups based on RAASi use (defined as use of ACEi or ARBs): (1) no RAASi use; (2) continuous RAASi use; and (3) treated dynamically with periods off and on RAASi during advanced CKD. Cox models were used to test the association of patterns of RAASi use with risk of ESRD and mortality, adjusting for potential confounders.

Results: Of the 761 participants with advanced CKD (mean eGFR 25 ml/min/1.73 m2), 167 (22%) did not take a RAASi throughout the study period, 319 (42%) took a RAASi continuously and 275 (36%) had a dynamic approach to RAASi use. Dynamic treatment with RAASi was associated with the lowest cumulative rates of ESRD and mortality (Figure). In multivariable models, a dynamic treatment strategy was associated with a 46% lower risk of ESRD (HR 0.54, 95% CI: 0.41,0.71) and a 23% lower risk of death (HR 0.77, 95% CI: 0.46, 0.97) compared with no RAASi use. The association of continuous ACEi/ARB use with clinical outcomes did not significantly differ from no RAASi use.

Conclusions: In a large, multi-center cohort of participants with advanced CKD, there was heterogeneity in patterns of use of RAASi. A dynamic, personalized approach to RAASi use in advanced CKD may be linked with lower risk of ESRD and mortality



KM curves for ESRD and death by patterns of RAASi use in advanced CKD

Real World Dosing Practices of Renin-Angiotensin-Aldosterone System Inhibitors Is Associated with Risk of Adverse Clinical Events in CKD Patients

Lei Qin,[2] Hans Furuland,[3] Daniel Ayoubkhani,[1] Marc L. Evans,[7] Cecilia Linde,[5] Ameet Bakhai,[6] Susan Grandy,[4] Eirini Palaka,[2] Philip McEwan.[1] *[1]Health Economics and Outcomes Research Ltd, Cardiff, United Kingdom; [2]AstraZeneca, Gaithersburg, MD; [3]University Hospital, Uppsala, Uppsala, Sweden; [4]Astrazeneca, Gaithersburg, MD; [5]Karolinska University Hospital, Stockholm, Sweden; [6]Royal Free London Hospitals NHS Foundation Trust, Barnet, United Kingdom; [7]University Hospital Llandough, Cardiff, United Kingdom.*

Background: This study estimated real-world relationships between renin-angiotensin-aldosterone system inhibitors (RAASi) dosing in chronic kidney disease (CKD) patients and the incidence of all-cause mortality and major adverse cardiovascular events (MACE).

Methods: Data from the UK Clinical Practice Research Datalink and linked Hospital Episode Statistics between Jan 2006 and Dec 2015 were used to identify adult non-dialysis patients with incident CKD stage 3+ (based on codes or eGFR ≤60 mL/min/1.73m^2). Kaplan-Meier survival curves were stratified by <50% and ≥50% of guideline-recommended RAASi dose. Adjusted odds ratios (ORs) relating RAASi dosing to mortality and MACE were estimated using Generalized Estimating Equations.

Results: 100,572 patients were included in the study (mean follow-up 6 years). Mortality rates for patients prescribed <50% and ≥50% of recommended RAASi dose were 58 and 11 events per 1,000 patient-years, respectively; the corresponding rates of MACE were 141 and 82 events respectively. Risk of mortality over time was greater for patients prescribed <50% RAASi dose compared to those prescribed ≥50% (Figure 1). Adjusted ORs for mortality and MACE were 3.77 and 1.57 (both p<0.0001), respectively, comparing patients prescribed <50% and ≥50% RAASi dose.

Conclusions: CKD patients prescribed <50% RAASi dose were at significantly higher risk of mortality and MACE compared to those prescribed ≥50%. Although adjustment for factors such as clinician risk appreciation was not possible, the results highlight the need for treatment strategies that allow the prescription of recommended RAASi doses to optimize patient benefit.

Funding: Commercial Support - AstraZeneca

FR-OR117

Benefits and Risks of Oral Anticoagulant Therapy in CKD: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

Jeffrey Ha,[1,2] Brendon L. Neuen,[1] Lap P. Cheng,[1,2] Min Jun,[1] Meg J. Jardine,[1] Martin P. Gallagher,[1] Amit X. Garg,[3] Manish M. Sood,[4] Vlado Perkovic,[1] Sunil V. Badve.[1,2] *[1]The George Institute for Global Health, Sydney, NSW, Australia; [2]St George & Sutherland Clinical School, UNSW Medicine, Sydney, NSW, Australia; [3]London Health Sciences Centre, London, ON, Canada; [4]Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

Background: The effects of anticoagulation in chronic kidney disease (CKD) are uncertain. The aim of this systematic review was to study the benefits and risks of oral anticoagulant therapy in CKD.

Methods: Electronic databases were searched for randomized controlled trials with ≥3 months follow-up in CKD patients (Stage 3-5D) that evaluated oral anticoagulant therapy. Treatment effects were summarized using random-effects meta-analysis.

Results: Nine trials (1341 participants) compared a vitamin K antagonist (VKA) to placebo, no study medication, aspirin, or low molecular weight heparin (LMWH). Twenty-three trials (27849 participants) compared a non-vitamin K oral anticoagulant (NOAC) to VKA, placebo, aspirin, or LMWH. Only 7 VKA trials (663 participants) included patients with advanced CKD, including dialysis patients. There were no clear differences in the risk of all-cause death (7 trials, RR 0.92, 95%CI 0.71, 1.18), and major bleeding (6 trials, RR 1.08, 95%CI 0.61, 1.92) between the VKA and combined control groups. Data on venous thromboembolism (VTE) and stroke or systemic embolism in atrial fibrillation (SSE-AF) with VKA were scant. Compared to VKA, NOAC reduced the risk of SSE-AF (5 trials, RR 0.82, 95%CI 0.70, 0.96), major bleeding (8 trials, RR 0.71, 95%CI 0.51, 0.97), hemorrhagic stroke (3 trials, RR 0.42, 95%CI 0.20, 0.65), and intracranial hemorrhage (3 trials, RR 0.43, 95%CI 0.26, 0.60); and had similar risk of VTE/VTE-related death (4 trials, RR 0.86, 95%CI 0.47, 1.58), and all-cause death (4 trials, RR 0.91, 95%CI 0.78, 1.06). There were no clear differences in the risk of all-cause death (6 trials, RR 0.95, 95%CI 0.82, 1.11), VTE/VTE-related death (7 trials, RR 0.56, 95%CI 0.29, 1.09), and major bleeding (14 trials, RR 1.04, 95%CI 0.74, 1.44) between the NOAC and combined control groups. Compared to placebo, the effect of NOAC on major adverse cardiovascular events was uncertain (3 trials, RR 0.85, 95%CI 0.73, 1.01).

Conclusions: NOAC have a benefit-risk profile superior to VKA in early stages of CKD, with significant reductions in SSE-AF and major bleeding. However, there is insufficient evidence to conclude whether patients with advanced CKD derive benefit from VKA or NOAC.

FR-OR118

Trends in Use of Prescription Opioids by Those with CKD in the United States, 1999 to 2014

Daniel P. Murphy, Robert N. Foley. *University of Minnesota, Minneapolis, MN.*

Background: High rates of opioid prescribing in the United States have contributed to a national opioid epidemic. Those with chronic kidney disease (CKD) likely have not been immune, and may, in fact, have an increased probability of opioid prescription due to a high prevalence of pain and frequent contact with healthcare systems. We sought to elucidate trends in prescription opioid use in the CKD population over time, by levels of kidney function, and among CKD-relevant subgroups.

Methods: We examined trends in prescription opioid use from years 1999-2014 among adult National Health and Nutrition Examination Survey participants with creatinine-based estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73m^2 or albumin-creatinine ratio (ACR) ≥ 30 mg/g. Differences in opioid use by racial/ethnic and other demographic characteristics and CKD-relevant comorbidities were described.

Results: 7.5% of the CKD population used a prescription opioid compared to 5.4% among those without CKD (P < 0.001). Both reduced eGFR and albuminuria were associated with opioid use: 8.4% among those with eGFR < 60 ml/min/1.73m^2 compared to 5.6% (P < 0.001) among those without reduced eGFR, and 7.4% among those with ACR ≥ 30 mg/g compared to 5.6% (P < 0.001) among those without albuminuria. No temporal trend in unadjusted prevalence of opioid use in the CKD population was seen. In an age, sex, and race/ethnicity adjusted model, the most recent era 2011-2014 vs. 1999-2002 was associated with increased opioid use in the CKD population (adjusted odds ratio 1.43, 95% CI 1.05-1.95). Other multivariate associations (P < 0.05) were age 40-64 years, female sex, diabetes mellitus, hypertension, BMI ≥ 30 kg/m^2, history of cancer, and arthritis. After statistical adjustment, no difference was seen among racial/ethnic minorities in the CKD population.

Conclusions: Prescription opioid use is more prevalent among the CKD population than in the general U.S. population with 28% of opioid use among those with CKD attributable to the association with CKD. Multiple comorbidities, which to varying degrees increase risk for pain and/or exposure to healthcare systems, were associated with increased prevalence of prescription opioid use.

FR-OR119

Geographic and Environmental Inequities and the Prescription Opioid Epidemic among Elderly CKD Patients in the United States

Yun Han,[1] Kevin He,[1] Jian Kang,[2] Jennifer L. Bragg-Gresham,[2] Rajiv Saran.[2] *[1]Kidney Epidemiology and Cost Center, University of Michgian, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.*

Background: CKD patients are vulnerable to opioid abuse due to high burden and suboptimal management of pain. We assessed geographic variation and the impact of environmental factors on long-term opioid use in elderly CKD patients.

Methods: We used a linked dataset from Medicare 5% sample claims data (2006-09), the American Community Survey Data (2005-09) and the Health Resources and Services Administration (HRSA) Primary Care Service Area (PCSA) data (2007). Medicare Part D enrollees age ≥65 years were included. County-level long-term opioid use was measured as % patients prescribed opioids for more than 90 days during a 1-year period after CKD diagnosis. County-level environmental factors included % of general physicians, elderly, population residing in Medically Underserved Areas (MUAs) and area deprivation index. A mixture model separating counties into different risk categories with subgroup analysis, was applied to investigate the relationship between environmental factors and county-level long-term opioid use.

Results: : The mixture model (Fig) clustered counties (n=1,794) into 4 risk subgroups. The average proportion of long-term opioid use of subgroups, which corresponded to mild, moderate, severe and very severe long-term opioid use were 3.0%, 5.3%, 13.0% and 31.2%. Counties in the Northeast and Midwest were more likely in mild and moderate risk groups, while the West andSouth counties were more likely in the severe and very severe group. Counties with aging adults and higher deprivation index were associated with greater long-term opioid use. Counties in MUAs were most likely in the very severe group.

Conclusions: Several environmental factors are associated with long-term prescription opioid use among elderly patients with CKD. This association varied across counties, highlighting the importance of allocating resources for this epidemic at county level.

Efficacy and Safety of Oral Ferric Maltol (FM) in Treating Iron-Deficiency Anemia (IDA) in Patients with CKD: Randomized Controlled Trial

Nelson P. Kopyt. AEGIS-CKD Study Group *Lehigh Valley Hospital, Allentown, PA.*

Background: IDA is common in CKD and is a leading cause of morbidity and mortality. Oral ferrous products for IDA may be poorly tolerated due to gastrointestinal (GI) adverse events (AEs). Intravenous iron can be inconvenient and has the risk of allergic

reactions or iron overload. Patients with CKD and IDA would benefit from effective, well tolerated oral iron replacement therapy. FM is an oral iron replacement therapy for IDA formulated to improve GI absorption. A phase 3 multicenter double-blind, randomized controlled trial (NCT02968368) evaluated the efficacy and safety of FM in patients with stage 3/4 CKD.

Methods: Patients aged ≥18 years with CKD (estimated GFR ≥15 to <60 mL/min/1.73 m²) and IDA (hemoglobin [Hb] ≥8.0 to <11.0 g/dL, and either ferritin <250 µg/L with transferrin saturation [TSAT] <25% or ferritin <500 µg/L with TSAT <15%) were randomized 2:1 to oral FM 30 mg or placebo twice daily for 16 weeks. The primary endpoint was change in Hb from baseline to Week 16 using analysis of covariance of the intent-to-treat population. Also reported are data on all iron parameters measured in the trial; changes from baseline in ferritin, TSAT, and serum iron were assessed at Weeks 4, 8, and 16.

Results: Of 167 patients randomized (FM 111, placebo 56), 77% completed double-blind treatment (FM 81%, placebo 70%). All iron parameters were significantly improved with FM vs placebo over 16 weeks (Table). GI disorders were the most common drug-related AEs (FM 18%, placebo 7%). Serious AEs occurred in 21% in each group; none was considered to be study-drug related. Two patients died (one in each group), both considered unrelated to study drug.

Conclusions: FM resulted in statistically significant and clinically meaningful increases in Hb concentration and all iron parameters from baseline to week 16 vs placebo, supporting the efficacy of oral FM in treating IDA in patients with stage 3 or 4 CKD. FM was generally well tolerated, with only minor differences in the safety profile and overall GI AEs vs placebo.

Funding: Commercial Support - Shield Therapeutics Ltd

Least-square mean change from baseline to Week 16

	FM (n=111)	Placebo (n=56)	p-value

Benefits and Harms of Dual Antiplatelet Therapy in CKD: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

Lap P. Cheng,[1,2] Jeffrey Ha,[1,2] Matthew H. Tong,[2] Brendon L. Neuen,[1] Min Jun,[1] Meg J. Jardine,[1] Martin P. Gallagher,[1] Manish M. Sood,[3] Amit X. Garg,[4] Vlado Perkovic,[1] Sunil V. Badve.[1,2] *[1]The George Institute for Global Health, Sydney, NSW, Australia; [2]St George & Sutherland Clinical School, UNSW Medicine, Sydney, NSW, Australia; [3]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [4]London Health Sciences Centre, London, ON, Canada.*

Background: Dual antiplatelet therapy (DAPT) is the standard of care in coronary artery disease. Despite the high burden of cardiovascular disease in chronic kidney disease (CKD), the role of DAPT in improving outcomes in CKD has not been systematically studied. The aim of this systematic review was to study the benefits and harms of DAPT in CKD.

Methods: Electronic databases were searched for randomized controlled trials (RCT) that included CKD patients (stage 3-5D or proteinuria) and evaluated the effect of DAPT on cardiovascular outcomes with ≥3 months follow up. Treatment effects were summarized using random-effects analysis.

Results: Eleven trials (13628 participants) compared DAPT to a single antiplatelet agent (6 trials), placebo (3 trials), or no study medication (2 trials). DAPT interventions were aspirin/dipyridamole (5 trials) and aspirin/P2Y12 inhibitor (6 trials). Compared to the control group, DAPT reduced the risk of major adverse cardiovascular events (4 trials, risk ratio [RR] 0.87, 95%CI 0.78, 0.97), myocardial infarction (5 trials, RR 0.76, 95%CI 0.61, 0.92), and stroke (6 trials, RR 0.81, 95%CI 0.68, 0.94). There were no differences in risk of cardiovascular death (7 trials, RR 0.95, 95%CI 0.76, 1.14), all-cause death (10 trials, RR 0.92, 95%CI 0.82, 1.03), and major bleeding (8 trials, RR 1.36, 95%CI 0.98, 1.73) between DAPT and control group. Three other trials (6239 participants) compared DAPT using aspirin/P2Y12 inhibitor to DAPT. Compared to aspirin/clopidogrel, aspirin plus ticagrelor or prasugrel reduced the risk of all-cause death (2 trials, RR 0.74, 95%CI 0.6, 0.88); and with no differences for major adverse cardiovascular events (2 trials, RR 0.88, 95%CI 0.61, 1.14), and major bleeding (3 trials, RR 0.93, 95%CI 0.37, 1.48). Overall, 4 trials included dialysis patients (1860 participants); 5 trials excluded dialysis patients (13725 participants); 2 trials did not include advanced CKD (stages 4-5) (372 participants); and 3 trials did not report the lower threshold of renal function for exclusion (3910 participants).

Conclusions: DAPT improved cardiovascular outcomes in early stages of CKD. However, there is insufficient evidence to conclude whether patients with advanced CKD derive benefit from DAPT.

FR-OR122

Skeletal Muscle Inflammation and Fibrosis Contribute to Weakness in Patients with CKD

Matthew K. Abramowitz,[1] William Paredes,[1] Kehao Zhang,[2] Camille Brightwell,[3] Julia N. Newsom,[3] Hyokjoon Kwon,[4] Matthew Custodio,[1] Rupinder singh Buttar,[8] Hina Farooq,[5] Bushra Zaidi,[7] Rima N. Pai,[6] Jeffrey E. Pessin,[1] Meredith Hawkins,[1] Christopher Fry.[3] *[1]Albert Einstein College of Medicine, New York, NY; [2]Einstein Medical School, Bronx, NY; [3]University of Texas Medical Branch, Galveston, TX; [4]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; [5]Louis A. Weiss Memorial Hospital, Chicago, IL; [6]Beth Israel Deaconess Medical Center, Boston, MA; [7]BronxCare Health System, Bronx, NY; [8]Jacobi medical center, Belmont, NY.*

Background: Muscle dysfunction is an important cause of morbidity among patients with chronic kidney disease (CKD). Although muscle fibrosis is present in a CKD rodent model, its existence in humans and its impact on physical function are currently unknown. In animal models of muscle injury, TNF-α secreted by macrophages prevents muscle fibrosis by limiting the expansion of fibro/adipogenic progenitor cells (FAPs).

Methods: We examined isometric leg extension strength and measures of skeletal muscle fibrosis and inflammation in vastus lateralis muscle from CKD patients (n=10, stage 4 and 5 CKD) and healthy, sedentary controls of similar age (n=10). Histochemistry and immunohistochemistry were used to assess muscle collagen and macrophage and FAP cell populations, and RT-qPCR was used to assess muscle-specific inflammatory marker expression.

Results: Muscle collagen content was significantly greater in CKD compared with control (18.8 ± 6.7% vs. 11.7 ± 2.0% collagen area, p=0.008), as was staining for collagen I, pro-collagen I, and a novel collagen-hybridizing peptide that binds remodeling collagen. Muscle collagen was inversely associated with leg extension strength in CKD (r= -0.74, p=0.01) but not control (r=0.40, p=0.28). FAP abundance was increased in CKD, was highly correlated with muscle collagen (r=0.84, p<0.001), and was inversely associated with TNF-α expression (r= -0.65, p=0.003). TNF-α, CD68, CCL2, and CCL5 mRNA were significantly lower in CKD than control, despite higher serum TNF-α and IL-6. Immunohistochemistry confirmed fewer CD68+ and CD11b+ macrophages in CKD muscle.

Conclusions: Skeletal muscle collagen content is increased in humans with CKD and is functionally significant. Muscle fibrosis correlated with increased FAP abundance resulting from insufficient macrophage-mediated TNF-α secretion. These data provide a foundation for future research elucidating the mechanisms responsible for this newly identified human muscle pathology.

Intramuscle Fat Infiltration in Non-Dialysis CKD: Clinical Determinants and Association with Mortality

Carla M. Avesani,[1,2] Juliana Giglio,[1] Abdul Rashid T. Qureshi,[3] Maria A. Kamimura,[4] André V. Bichels,[7] Peter Stenvinkel,[5] Bengt Lindholm,[3] Juan J. Carrero,[3] Antonio C. Cordeiro.[6] *[1]Rio de Janeiro State University, Rio de Janeiro, Brazil; [2]Clinical Science, Intervention and Technology, Division of Baxter Novum, Karolinska Institutet, Huddinge, Sweden; [3]Karolinska Institutet, Huddinge, Sweden; [4]Federal University of São Paulo, São Paulo, Brazil; [5]Karolinska University Hospital Huddinge, Stockholm, Sweden; [6]Dante Pazzanese Institute of Cardiology, Sao Caetano do Sul, Brazil; [7]Unifesp, São Paulo, Brazil.*

Background: Intramuscle fat infiltration (IFI) is an important feature of aging currently understood as a cause of muscle weakness in elderly. Compared to healthy controls, IFI has been reported elevated in chronic kidney disease (CKD) patients. Its determinants and consequences, however, are unknown.

Methods: Cross-sectional study with mortality follow-up of 195 nephrology-referred patients with non-dialysis CKD stages 3-5. Mean age was 60±11 years, 61% were men and glomerular filtration rate (creatinine clearance) was 25±12 ml/min/1.73 m². We used computed tomography (CT) scan (Slice-O-Matic software version 5.0) of the third lumbar vertebra to quantify the degree of IFI (reported as % of fat within muscle area). Muscles evaluated by CT were psoas, transversus abdominis, rectus abdominis, external and internal obliques, erector spinae and quadratus lumborum. Coronary artery calcification score (CAC) was evaluated by CT, muscle strength by dynamometry (handgrip strength, HGS) and shown as standard values to normative tables.

Results: IFI was higher in women than in men (9.7±6 vs 6.3±4%, P<0.05), and was positively correlated (Spearman test) with age (rho =0.37), Charlson comorbidity score (rho=0.19), CAC (r=0.16) and CT-derived visceral (rho=0.37) and subcutaneous fat (rho =0.57). IFI was negatively associated with HGS (rho=-0.25) and CT-derived skeletal muscle mass (rho=-0.37). In multiple linear regression analysis, male sex (ß=-0.66; P<0.01), older age (ß=0.40 per 1-SD increase; P<0.01), higher muscle mass (ß=0.48 per cm/m² increase; P<0.01) but lower muscle strength (ß=-0.15 per % decrease in HGS) were independent predictors of IFI% (r^2=0.33). During 40±13 months of follow-up, 57 patients died. Increased IFI was associated with the risk of death (adjusted hazard ratio 1.60 per 1-SD increase, 95% CI: 1.21 to 2.11) independently of sex, age, diabetes, CKD stage, CAC, subjective global assessment and standard HGS.

Conclusions: IFI is associated with lower muscle strength in non-dialysis CKD patients and predicts the risk of death, regardless of muscle stores. These data are consistent with the notion that intramuscle fat infiltration worsens muscle quality.

FR-OR124

Pro-Inflammatory Diets Increase Risk of ESRD in US Adults with CKD

Tanushree Banerjee,[5] Deidra C. Crews,[1] Nilka Rios Burrows,[2] Meda E. Pavkov,[2] Rajiv Saran,[3] Hal Morgenstern,[3] Neil R. Powe.[4] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Centers for Disease Control and Prevention, Atlanta, GA; [3]University of Michigan, Ann Arbor, MI; [4]Priscilla Chan and Mark Zuckerberg San Francisco Gen Hosp & UCSF, San Francisco, CA; [5]University of California, San Francisco, CA.*

Background: CKD progression can be accompanied by chronic low-grade inflammation marked by elevated concentrations of inflammatory markers. We hypothesized that proinflammatory diets increase risk of kidney disease progression and systemic inflammation is a mediator of progression of kidney disease.

Methods: We analyzed a cohort study of 1084 adults with CKD (eGFR 15-59 ml/min/1.73m^2) aged≥ 20 years in the 1988-1994 National Health and Nutrition Examination Survey linked with the US Renal Data System, allowing for assessment of ESRD as an outcome over a follow-up period of 14 years. The Adapted Dietary Inflammatory Index (ADII, based on 26 components) was calculated at baseline from a 24-hr dietary recall. We used regression analysis to examine the association between ADII and an inflammatory score (IS) computed from C-reactive protein, serum albumin, white blood cell count, and mean platelet volume, adjusting for demographics, body mass index, physical activity, HbA1C, systolic blood pressure, total cholesterol. The Fine Gray competing risk model was used for exploring the association between (i) IS and ESRD, and (ii) risk of incident ESRD and per standard deviation (SD) increase in ADII. The models were adjusted for the above mentioned covariates and estimated glomerular filtration rate and urinary albumin–to-creatinine ratio (ACR). IS was considered as a mediator of CKD progression using Valeri and Vanderweele's method.

Results: 120 participants with CKD (11.1%) developed ESRD. A 1 SD increase in ADII was associated with a higher IS (β [95% CI]: 1.05[0.89-1.22]). IS was also associated with ESRD (relative hazard [RH]: 1.12 [95% CI: 1.02-1.25]). ADII was associated with increased risk of incident ESRD (RH per SD increase: 1.40 [1.04-1.78]). Mediation analyses showed that 25% of the total effect of the ADII on ESRD was explained or mediated by IS. Interaction tests showed a higher risk of ESRD per SD increase in ADII in adults with ACR≥30mg/g (RH 1.55 [1.12-1.96] than those with ACR<30 mg/g (RH 0.96 [0.55-1.38]; $p_{interaction}$<0.001).

Conclusions: A proinflammatory diet is independently associated with risk of ESRD which is mediated by the inflammatory markers. These findings have implications for prevention of ESRD using dietary approaches.

FR-OR125

Multicenter Randomized Controlled Study of the Efficacy of Low-Protein Rice for Dietary Protein Restriction in Patients with CKD

Michihiro Hosojima,[1] Hideyuki Kabasawa,[1] Ryohei Kaseda,[1] Tomomi Ishikawa,[1] Yoshitsugu Obi,[2] Toshiko Murayama,[1] Shoji Kuwahara,[1] Yoshiki Suzuki,[1] Ichiei Narita,[1] Akihiko Saito.[1] *[1]Niigata University, Niigata, Japan; [2]University of California, Irvine, CA.*

Background: The benefits of dietary protein restriction in chronic kidney disease (CKD) remain unclear, largely due to poor adherence to low-protein diet in most clinical studies. Rice, a major staple food globally, is a primary source of dietary plant proteins, especially in Asia. We examined the efficacy of low-protein rice (LPR) for dietary protein restriction in CKD patients.

Methods: This open multicenter randomized controlled study aimed to compare the efficacy of dietary protein restriction [0.7 g/kg ideal body weight (IBW)/day] between CKD patients without LPR (no LPR group) and those with LPR (LPR group) to be eaten in at least 2 meals per day for 24 weeks (UMIN000015630). We enrolled 104 patients (age, 62.7 ± 10.8 years) with CKD (stages G3aA2 and G4) from Niigata University Medical & Dental Hospital and 7 affiliated hospitals from August 2014 to December 2017. Patients in both groups were given regular instruction by dietitians to meet the nutritional goal. Maroni's formula was used to estimate protein intake.

Results: Analysis of covariance was performed adjusted by protein intake at the start of the study. After 24 weeks, estimated protein intake decreased from 0.99±0.23 to 0.80±0.20 g/kg IBW/day in the LPR group and from 0.99±0.23 to 0.91±0.21 g/kg IBW/day in the no LPR group, respectively. The change was significantly higher in the LPR group than in the no LPR group by 0.11 (95% CI, 0.03 to 0.19) g/kg IBW/day (P = 0.001). Energy intake did not differ significantly between the groups; salt intake decreased significantly at 24 weeks in the LPR group. Creatinine clearance did not differ significantly between the groups, but urinary protein excretion decreased significantly at 24 weeks in the LPR group. Also, nutritional indices including diagnostic markers of protein-energy wasting and quality of life showed no significant difference between the groups.

Conclusions: LPR has potential as a feasible tool for dietary protein restriction in CKD patients. Long-term studies are needed to investigate LRP diet and suppression of CKD progression.

Dietary Fiber Intake, Myocardial Injury, and Major Adverse Cardiovascular Events among ESRD Patients: A Prospective Cohort Study

Angela Yee Moon Wang,[1,2] Mei Wang,[2] John E. Sanderson,[2] Iris Chan,[3] Christopher W. Lam,[4] Jean Woo.[5] *[1]Medicine, University of Hong Kong, Queen Mary Hospital, Hong Kong, China; [2]Chinese University of Hong Kong, Prince of Wales Hospital (Previous), Hong Kong, Hong Kong; [3]Chemical Pathology, Prince of Wales Hospital, Hong Kong, Hong Kong; [4]Macau University Science Technology, Macau, China; [5]The Chinese University of Hong Kong, Hong Kong SAR, China.*

Background: Dialysis patients are frequently advised to restrict fruits, vegetables, wholegrain or nuts intake due to their high potassium or phosphate content. The importance of fiber intake in relation to cardiovascular health in dialysis patients is not known.

Methods: Two hundred and nineteen prevalent dialysis patients was prospectively recruited from a university teaching hospital and regional dialysis center and followed for 4 years. Dietary fiber intake was estimated using a 7-day validated food frequency dietary questionnaire and examined in relation to a composite of major adverse cardiovascular events (MACE).

Results: Higher fiber intake was associated with less inflammation, lower serum cardiac troponin T, N-terminal pro-brain natriuretic peptide and less cardiac hypertrophy. During 4 years' follow-up, 127 patients were complicated with one or more MACE. Higher fiber intake (hazard ratio [HR], 0.87, 95% confidence intervals [CI], 0.80 – 0.94) and higher fiber intake density (HR, 0.85, 95% CI, 0.74 – 0.97) were associated with a lower risk of MACE on univariate analysis. In the multivariable Cox regression analysis, higher fiber intake predicted a lower risk of MACE (adjusted HR, 0.89, 95% CI, 0.81 – 0.97, P=0.008) independent of other clinical, demographic, biochemical, hemodynamic, adequacy parameters, dietary protein and energy intake, as well as inflammatory and cardiac markers. Similarly, fiber intake density retained significance in predicting MACE both as a continuous variable [adjusted HR, 0.87, 95% CI, 0.77 – 0.99] and when stratified into tertiles, adjusting for the same confounders. Those in the lower tertile of fiber intake density showed an increased hazard for MACE [adjusted HR, 1.78, 95% CI, 1.13 – 2.80] compared to those in the upper tertile.

Conclusions: Higher dietary fiber intake and fiber nutrient density were associated with less inflammation, less myocardial hypertrophy and injury and predicted a lower risk of MACE in dialysis patients. These data form an important basis for a randomized controlled trial to examine the effects of fiber supplementation on cardiovascular outcomes in dialysis patients.

Resistant Starch Supplementation Reduces Indoxyl Sulfate Levels in Hemodialysis Patients: A Randomized, Double-Blind, Crossover, Placebo-Controlled Study

Denise Mafra,[1] Marta Esgalhado,[1] Renata D. Macedo,[2] Julie ann Kemp,[1] Bruna Paiva,[1] Lia S. Nakao,[3] Diana B. Cunha,[4] Natalia A. Borges.[5] *[1]Federal University Fluminense, Rio de Janeiro, Brazil; [2]Federal Fluminense University, Rio de Janeiro, Brazil; [3]UFPR, Curitiba, Brazil; [4]State University of Rio de Janeiro, Rio de Janeiro, Brazil; [5]Universidade Federal Fluminense, Rio de Janeiro, Brazil.*

Background: Protein-bound uremic toxins produced from intestinal bacterial protein fermentation, including indoxyl sulfate (IS) and p-cresyl sulfate (p-CS), tend to accumulate in chronic kidney disease (CKD) patients. These patients have a gut microbiota imbalance that leads to loss of gut barrier integrity, facilitating the passage of IS and p-CS into the bloodstream. Both solutes are linked with the progression of renal disease, as well as, cardiovascular disease (CVD). Strategies like prebiotic supplementation may be effective to restore the balance of the gut microbiota. This study tested whether prebiotic resistant starch (RS) supplementation would reduce IS and p-CS plasma levels in hemodialysis patients (HD).

Methods: Thirty eight stable HD patients were randomized in RS (n=19) or Placebo (n=19) groups to receive alternately 9 cookies/day (dialysis days) and 1 sachet/day (non-dialysis days) containing 16 g of RS (Hi-Maize 260, Ingredion®) or manioc flour for 4 weeks and then after the washout period (4 weeks) were crossed over to the alternative for an additional 4 weeks. Fasting pre-dialysis plasma IS and p-CS were analyzed by reversed-phase high-performance liquid chromatography. Food intake was also recorded. Intention-to-treat analysis were performed in order to verify the variation of IS and p-CS plasma levels according to allocation groups, by means of mixed linear models is SAS.

Results: Twenty six patients concluded the study, 12 in RS-Placebo group (42% male, 54.8±7.9 years, 53.0±40.5 months of HD, 26.7±5.1 Kg/m^2) and 14 in Placebo-RS group (71% male, 54.2±11.9 years, 44.1±23.0 months of HD, 26.2±4.8 Kg/m^2). After 4 weeks, IS plasma levels were significantly reduced in the RS group [-6.2 (-9.7/-3.3)mg/L] compared to placebo [2.2 (-5.9/4.5)mg/L] (p=0.006). No significant alterations was observed in plasma p-CS levels or food intake (besides fiber intake has increased with RS).

Conclusions: Prebiotic RS supplementation seems to be an effective nutritional strategy to reduce plasma IS levels in CKD patients on HD. These findings support the hypothesis that prebiotics may be a new non-pharmacological intervention to modulate gut microbiota.

Funding: Government Support - Non-U.S.

Probiotic Dietary Supplementation in Hemodialysis Patients: A Double-blind, Randomized, Placebo-Controlled Trial

Sixiu Liu, Hongli Jiang. *First Affiliated Hospital of Medicine School, Xi'an Jiaotong University, Xi'an, China.*

Background: Recent studies have highlighted that gut microbiota is a key origin of uremic retention solutes in patients with chronic kidney disease, and is involved in triggering systemic microinflammation. The objective of this study was to evaluate the effects of probiotics on the gut microbiota profile and inflammatory markers in hemodialysis (HD) patients.

Methods: This was a randomized, double-blind, placebo-controlled study. Fifty HD patients were assigned to receive 1 of 2 treatments: probiotic (Pro0,n = 25; Enterococcus faecalis, Lactobacillus acidophilus, Bifidobacterium longum, 4 capsules each, twice daily, totally containing 30 billion colony-forming units per day) or placebo (PL0,n = 25) daily for 6 months. Blood samples and feces samples were collected at baseline and after intervention. The gut microbiota profile, inflammatory markers (IL-6, TNF-α and hs-CRP) and endotoxin were assessed.(Trial registration number NCT02929225.)

Results: Twenty-three patients remained in the probiotic group(Pro2) and 22 in the placebo group(PL2). Compared with the placebo group, probiotics did not induce major changes in the faecal microbiome. The alpha and beta diversity of gut microbiota in probiotic group were not significantly different from placebo group(Fig.1(A)and(B)). However, according to the Linear discriminant analysis coupled with effect size measurements (LEfSe) further identified four bacterial families that significantly changed. Particularly, Family Enterococcaceae was increased, while Ruminococcaceae was reduced in probiotic group. In addition, the plasma levels of inflammatory markers and endotoxin were not affected by probiotics.

Conclusions: In HD patients, probiotics did not significantly induce major alterations in the fecal microbiome but several specific bacteria relative abundance were restored.

Dysbiosis in Renal Failure Causes Insulin Resistance and Leaky Gut

Kiyotaka Uchiyama, Shu Wakino, Tomoaki Ito, Takaya Tajima, Ayumi Matsui, Hiroshi Itoh. *Keio University, School of Medicine, Tokyo, Japan.*

Background: Chronic Kidney disease (CKD) leads to clinically relevant insulin resistance (IR), which is a novel cardiovascular risk factor in patients with CKD. However, the pathophysiology of IR in CKD remains unclear. Recently, gut microbiota alterations have been reported to be associated with the etiology and progression of CKD. Using germ-free mice, we sought to determine whether dysbiosis in renal failure (RF) contributes to CKD-associated IR.

Methods: RF was induced in 7-week-old male ICR mice by feeding a diet containing 0.2% adenine for 6 weeks; these were compared with a control group that was fed a normal diet. Fecal microbiota transplantation (FMT) was performed by oral gavage on the 8-week-old, germ-free, male, ICR mice using cecal microbiota obtained from either the control group (control-FMT) or RF group (RF-FMT). The vehicle group was gavaged with only sterile phosphate-buffered saline. Two weeks after inoculation, glucose and insulin tolerance and intestinal microbiota and barrier function were evaluated in each group.

Results: In the mice from the RF group, whose body and adipose tissue weight were markedly lower, IR was evident where insulin stimulation failed to activate insulin signaling in skeletal muscles and adipose tissues. The expression of tight junctions in the colon was also reduced. In the RF-FMT group, glucose and insulin tolerance were impaired compared with those in the control-FMT and vehicle groups; insulin-induced signal transduction was attenuated, especially in skeletal muscles. Additionally, adipose tissue weight, adipocyte size and tight junction protein expression in the colon were lower in the RF-FMT group compared with those in the control-FMT group. These results mimicked those of the RF and the control groups. The differences in gut microbiota between the RF and control groups were mostly consistent between the RF-FMT and the control-FMT groups, including a decrease in *Bacteroides* and *Prevotella* species and an increase in *Clostridium* species in the RF and RF-FMT groups.

Conclusions: The gut microbiota from mice with RF induced IR along with impaired adipose tissue maturation, and disruption of the intestinal barrier associated with RF. Our data demonstrated for the first time, that uremic dysbiosis directly affects CKD-related metabolic abnormality.

FR-OR130

CKD Attenuates the Plasma Metabolome Response to Insulin

Baback Roshanravan,[1] Leila R. Zelnick,[2] Jessica A. Alvarez,[3] Jorge Gamboa,[4] Thomas Ziegler,[5] Kristina M. Utzschneider,[6] Steven E. Kahn,[6] Bryan R. Kestenbaum,[6] Daniel Raftery,[6] Ian H. de Boer.[7] *[1]University of Washington - Kidney Research Institute, Seattle, WA; [2]Kidney Research Institute, Seattle, WA; [3]Emory University SOM, Atlanta, GA; [4]Vanderbilt University, Nashville, TN; [5]ASN, Lilburn, GA; [6]University of Washington, Seattle, WA; [7]Division of Nephrology and Kidney Research Institute, University of Washington, Seattle, WA.*

Background: Chronic kidney disease (CKD) leads to decreased sensitivity to the metabolic effects of insulin contributing to protein energy wasting and muscle atrophy. Targeted metabolomics profiling during hyperinsulinemic euglycemic insulin clamp testing may help identify potential aberrant metabolic pathways contributing to insulin resistance among patients with CKD.

Methods: Using a targeted metabolomics profiling, we examined the plasma metabolome in 95 adults without diabetes in the fasted state (58 with moderate-severe CKD, 37 with normal glomerular filtration rate (GFR)) of whom 60 had plasma collected during a hyperinsulinemic-euglycemic clamp (40 with CKD). We assessed heterogeneity in fasting metabolites and the response to insulin to identify potential cellular metabolic pathways linking CKD with insulin resistance. Differences and changes in metabolite concentrations by CKD status and with insulin clamp testing were adjusted for potential confounders of age, sex, race/ethnicity (white versus non-white) and body weight. Pathway analysis was performed using Metaboanalyst

Results: Mean GFR among participants with CKD was 37.3 mL/min per 1.73m^{2}compared to 89.3 ml/min per 1.73m^{2}among controls. In the fasting state, differences between CKD and control subjects included significant abnormalities in tryptophan metabolism, ubiquinone biosynthesis, and the TCA cycle (Figure). Insulin infusion markedly decreased plasma metabolite levels, predominantly amino acids and their metabolites. CKD was associated with attenuated insulin-induced changes in nicotinamide, arachidonic acid, and glutamine/glutamate metabolic pathways (Figure).

Conclusions: Targeted plasma metabolomics profiling suggests broad disruption in amino acid metabolism and mitochondrial function as putative manifestations or mechanisms of the impaired anabolic effects of insulin in CKD.

Comparison of fasting (left panel) and insulin clamp (right panel) metabolic pathway differences between CKD and controls.

FR-OR131

Endurance Exercise-Derived Exosomal miRNA Exerkines Attenuate Progressive CKD

Bjoern Tampe, Michael Zeisberg. *University Medical Center Goettingen, Goettingen, Germany.*

Background: Progressive CKD is still an unmet biomedical challenge because no effective therapies are available as of yet for clinical use. While various studies across multiple organs which demonstrated that endurance exercise (EE) protects from progressive organ failure by endocrine-like signalling via specific nucleic acids (so-called exerkines), little consideration has been paid as to whether any exerkines are released in a manner other than direct discharge into the circulation. It is becoming increasingly apparent that one of the main mechanisms by which scelettal muscle cells and distant organs communicate

is by the release of cell-derived extracellular exosomes. Based on these pre-requisits, we here aimed to gain insights into the molecular mechanisms underlying successful reno-protection and to explore whether such pathways could be therapeutically targeted.

Methods: EE was performed in *C57BL/6*mice for 4 weeks before challenging with unilateral ureteral obstruction (UUO) for 7 days without EE. Exosomal miRNA signatures were analyzed by unbiased array-based approaches and confirmed by qRT-PCR in sclettal muscles, plasma exosomes and corresponding kidneys. By using miRNA mimics administered systemically, miRNA candidates for succesful protection during EE were confirmed for therapeutical implications.

Results: We identified a unique miRNA signature in muscle-derived exosomes and kidneys specifically during endurance exercise, associated with attenuation of progressive CKD. Systemic administration of miRNA mimics was equally effective to attenuate progressive CKD, supporting that endurance exercise-derived exosomal miRNAs are involved in reno-protection. On a mechanistic level, we provide evidence that exosomal miRNAs directly target and degrade *PAI-1*, associated with activation of the tPA/uPAR/plasmin pathway. Increased tPA/uPAR/plasmin stimulates ECM remodelling and degradation by activation of latent MMPs, in particular MMP-2 and MMP-9.

Conclusions: In summary, we here provide evidence that EE attenuates progressive CKD by enrichment of exosomal miRNA exerkines modulating ECM remodelling and degradation in chronically injured kidneys. Because miRNA mimics equally protect from progressive CKD, these findings further support therapeutical implications of exosomal exerkines as nature's exercise pill.

FR-OR132

Genome-Wide Non-HLA Incompatibility between Donor and Recipient Contributes to Kidney Allograft Attrition

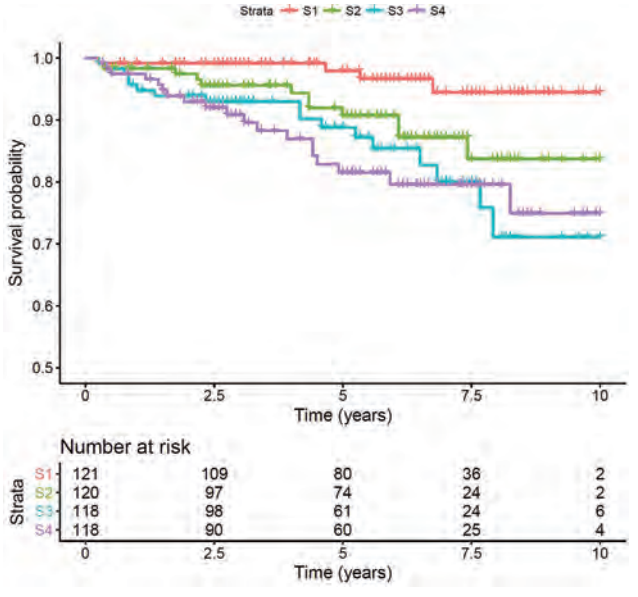
Rainer Oberbauer,[1] Roman Reindl-Schwaighofer,[1] Andreas Heinzel,[1] Petra Hruba,[2] Ondrej Viklicky,[2] Kira Jelencsics,[1] Karin Hu,[1] Alexander Kainz,[1] Michael Kammer,[1] Georg Heinze,[1] Georg Bohmig,[1] Frans Claas,[3] Farsad A. Eskandary,[1] Brendan Keating.[4] *[1]Medical University of Vienna, Vienna, Austria; [2]Institute for Clinical and Experimental Medicine, Department of Nephrology, Prague, Czechia; [3]University Leiden, Leiden, Netherlands; [4]University of Pennsylvania, Philadelphia, PA.*

Background: The introduction of HLA matching of donors and recipients was a breakthrough in kidney transplantation but epidemiological data suggest also a fundamental role of non-HLA alloimmunity.

Methods: 477 deceased donor and first kidney transplant recipient pairs from a prospective multi-center transplant cohort study were successfully genotyped and genome-wide genetic mismatches in nsSNPs were calculated to identify incompatibilities in transmembrane and secreted proteins. Association of nsSNP mismatch and graft loss was estimated in a Cox model adjusting for HLA mismatch and clinical covariates. Customized peptide arrays were generated to screen for antibodies against genotype-derived mismatched epitopes.

Results: The median nsSNP mismatch in immune-accessible transmembrane and secreted proteins between donors and recipients was 1,892 with an interquartile range (IQR) of 86. The degree of nsSNP mismatch was independently associated with graft loss in a multivariable model adjusted for HLA eplet mismatch *(HLA-A, B, C, DP, DQ, DR).* Each increase by a unit of one IQR exhibited a HR of 1.68 (95% CI 1.17-2.41, p=0.005). Five-year death censored graft survival was 98% in the quartile with the lowest mismatch but only 82% in the highest quartile (p=0.003, logrank test).(Figure). Customized peptide arrays verified a donor-specific alloimmune response to genetically predicted mismatched epitopes for selected transmembrane proteins.

Conclusions: Genetic mismatch of non-HLA haplotypes coding for transmembrane or secreted proteins is associated with an increased risk of functional graft. DSAs can be identified against genotype derived non-HLA epitopes.



FR-OR133

Single Cell Transcriptome Analysis of Human Kidney Allograft

Hemant Suryawanshi,[2] Hua Yang,[3] Milagros T. Lagman,[4] Michelle L. Lubetzky,[5] Thomas Tuschl,[7] Manikkam Suthanthiran,[6] Thangamani Muthukumar.[1] *[1]Weill Cornell Medicine, New York, NY; [2]The Rockefeller University, New York, NY; [3]Weill-Cornell, New York, NY; [4]Weill Medical College of Cornell University, New York, NY; [5]Division of Nephrology and Hypertension, New York, NY; [6]Weill Cornell Medical College, New York, NY; [7]Howard Hughes Medical Institute, New York, NY.*

Background: Unbiased transcriptome-based clustering analysis of cells within the kidney allograft may help identify cell type-specific injury and has the potential to redefine the current pathology-based classification of allograft rejection/injury.

Methods: Kidney allograft tissue obtained at the time of core needle biopsy (n=2, TK1 and TK2, Figure 1) was digested to generate single cell suspension. Droplet-based 10X Chromium platform (10X Genomics) was used to capture single cells in emulsion, followed by cDNA synthesis, sequencing, and analysis.

Results: We obtained 2,657 (TK1) and 2,207 (TK2) high-quality scRNA-seq profiles and identified 13 and 11 major cell clusters, respectively (Figure 2). In both biopsies, T cells (27% TK1 and 24% TK2) were abundant despite the differences in histopathology findings. Cell types restricted to TK1 were NK, MZB and SMC, whereas cell types restricted to TK2 were NKT, MC and IC. Only TK2 had fibrosis but we found FB cells in both the samples.

Conclusions: Our single cell expression atlas of human kidney allograft has deciphered the complex cellular environment of kidney allograft and provides a powerful step towards better understanding of the cellular basis of kidney allograft dysfunction.

Clinical and histopathological characteristics

Accelerated Podocyte Detachment Early after Kidney Transplantation and Relationship to Long-Term Allograft Loss-of-Function

Abhijit S. Naik,[1] Farsad Afshinnia,[1] Jawad Aqeel,[1] Diane M. Cibrik,[2] Milagros D. Samaniego-Picota,[3] Larysa T. Wickman,[1] Su Q. Wang,[1] Mahboob A. Chowdhury,[1] Roger C. Wiggins.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of Kansas, Kansas city, KS; [3]Henry Ford Hospital, Detriot, MI.*

Background: Kidney allograft half-life has not improved despite excellent short-term survival. Recent long-term surveillance biopsy studies identify accumulating glomerulosclerosis associated with late allograft loss. While podocyte depletion is well-known to drive proteinuria and glomerulosclerosis in animal models and human glomerular diseases, its role in renal allograft loss-of-function is not generally recognized.

Methods: To address these questions, we collected urine from 125 kidney transplant recipients in the first post-transplant year for urine pellet mRNA and protein analysis, with a median follow up of 4.5-years.

Results: Using multivariable linear models adjusted for proteinuria, transplant, recipient and donor factors, we observed that the **average rate of podocyte detachment in the first post-transplant year was significantly associated with eGFR decline**. The relationship between podocyte detachment rate and eGFR decline persisted **even among recipients who were non-proteinuric (<0.3g/g creatinine) and who had no recurrent or *de novo* glomerular disease identified on 1yr protocol biopsy**.

Conclusions: These findings support the concept that in kidney allografts **accelerated podocyte loss precedes proteinuria**, is associated with inferior long-term allograft outcomes as measured by eGFR decline. Modulating factors driving early podocyte detachment after kidney transplantation may help improve long-term outcomes.

FR-OR135

The Banff Working Group Classification of Polyomavirus Nephropathy: A Validation Study in the Modern Era

Volker Nickeleit,[1] Darshana Dadhania,[2] Adil H. Gasim,[1] Vicki G. Davis,[1] Surya V. Seshan,[2] Harsharan K. Singh.[1] *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Weill Cornell Medical College, New York, NY.*

Background: The Banff multicenter working group on polyomavirus nephropathy (PVN) recently proposed a morphologic, clinically significant PVN classification scheme with three disease classes based on the histologic degree of intra-renal PV replication and the Banff-ci score. Transplant recipients with definitive PVN managed between 1996-2010 were analyzed (JASN 29: 680, 2018). Aim: To evaluate the validity of the proposed PVN classification in the modern transplant era.

Methods: 652 consecutive adult renal allograft recipients transplanted at UNC after 1/1/2009 were enrolled. In patients with definitive PVN, the first diagnostic biopsy (index biopsy) was scored and PVN classes defined. Clinical and histologic data were statistically analyzed following the Banff working group approach (JASN 29: 680, 2018). Biopsies with TCMR (type II/III), ABMR or other severe renal diseases were excluded from some analyses.

Results: PVN affected 57/652 patients (incidence 8.7%; 39 (68%) males; median age 54 years). 2/57 patients were excluded due to recurrent disease at time of index biopsy. PVN class I: 29/55 (53%), class II: 25/55 (45%), class III: 1/55 (2%; small case number in class III precluded further statistical analysis). Class I was diagnosed earlier (median 18 weeks post grafting) than class II (24 weeks). Baseline S-Cr levels before index biopsy were similar between class I and II: class I 1.4 mg/dl, class II 1.3 mg/dl, p=0.823. At index biopsy, class I compared to II had only a minor rise of S-Cr: median % change from baseline, 10% class I, 37% class II, p=0.004. Over 12-month follow-up, class I showed minimal increase in S-Cr levels compared to baseline (+0.2 mg/dl; median change) in contrast to class II (+0.6 mg/dl; p=0.003). In the study cohort, graft failure was rare: overall 3/55 (5%); class I: 2/29 (7%), class II: 1/25 (4%), class III: 0/1 (0%).

Conclusions: The histologic classification of PVN as proposed by the Banff working group also carries clinical significance in the modern era. PVN class I characterizes cases with stable graft function. Overall graft failure rates for this single site are lower (5%) than reported by the Banff working group (30%). The PVN disease classification provides additional clinical information, therefore it should be incorporated into diagnostic and scientific communications.

Archetype Analysis Identifies Distinct Profiles in Renal Transplant Recipients with Transplant Glomerulopathy Associated with Allograft Survival

Yassine R. Bouatou,[2,1] Olivier Aubert,[2] Sarah Higgins,[3] Denis Viglietti,[2] Carmen Lefaucheur,[2] Alexandre Loupy.[2] *[1]Pathology, AMC, Amsterdam, Netherlands; [2]Paris Translational Research Center for Organ Transplantation, Paris, France; [3]Université de Sherbrooke, Sherbrooke, QC, Canada.*

Background: Transplant glomerulopathy (TG) is a common glomerular lesion observed after kidney transplantation and a well-known contributing factor for allograft loss. However, overlapping pathways, associated etiologies and clinical courses have not been addressed at a population level.

Methods: All consecutive kidney transplant recipients from 3 referral centers from France and 1 in Canada with a diagnosis of TG (Banff cg score≥1) in biopsies performed between January 2004 and January 2014 were included and assessed by light microscopy, immunohistochemistry, immunofluorescence and electron microscopy. All patients underwent circulating anti-HLA donor-specific antibodies testing at the time of TG diagnosis.

Results: Among the 8,207 post-transplant allograft biopsies performed during the inclusion period in the 4 centers, 552 presented with TG (incidence of 6.7%). The median time to TG diagnosis post-transplant was 33.18 months (IQR: 12.12 – 78.72 months). Kidney allograft survival rates after TG diagnosis were 69.4%, 57.1%, 43.3% and 25.5% at 3, 5, 7 and 10 years, respectively. Unsupervised learning method integrating clinical, functional, immunological and histological parameters revealed 5 TG archetypes characterized by distinct features, and associated etiologies. The 5 TG archetypes unraveled distinct allograft survival profiles with incremental 5-year allograft loss rates between archetypes (Fig 1).

Conclusions: A probabilistic data-driven archetypical approach applied in a large well defined multicentric cohort, refines the diagnostic and prognostic features associated with TG, reducting heterogeneity, which might help improving disease characterization and individual patient risk stratification, opening avenues for an archetype-based strategy for TG treatment.

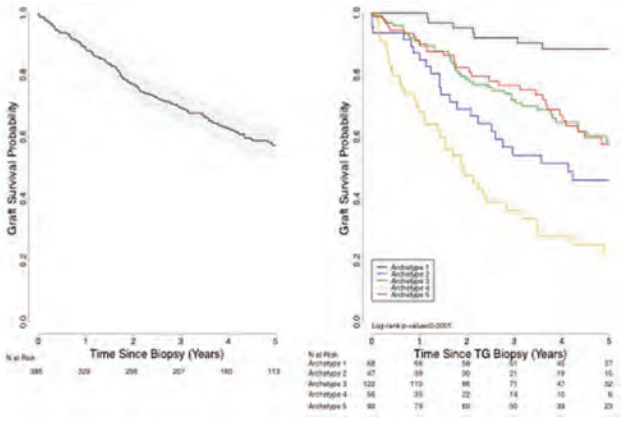

Figure 1: Kidney allograft survival after TG diagnosis overall (A) and archetype-based (B). The overall difference between the five archetypes was significant (p-value<0.0001).

FR-OR137

A Phase-I Clinical Trial of Donor-Derived MIC Cell Infusion for the Induction of Donor-Specific Hyporesponsiveness after Living Donor Kidney Transplantation (TOL-1 Study)

Christian Morath,[2,1] Anita Schmitt,[2] Christian Kleist,[2] Volker Daniel,[2] Gerhard Opelz,[2] Caner Süsal,[2] Florian Kälble,[2,1] Claudius Speer,[2,1] Luiza Pego silva,[2,1] Claudia Sommerer,[2,1] Lei Wang,[2] Angela Hückelhoven-Krauss,[2] Uta Merle,[2] Arianeb Mehrabi,[2] Carsten Mueller-Tidow,[2] Martin G. Zeier,[2,1] Michael Schmitt,[2] Matthias Schaier,[2,1] Peter Terness.[2] *[1]Nierenzentrum Heidelberg, Heidelberg, Germany; [2]Heidelberg University Hospital, Heidelberg, Germany*.

Background: MIC cells are donor-derived monocytes that gain immunosuppressive properties after incubation with the proliferation inhibitor mitomycin C.

Methods: PBMCs were harvested from living donors by leukapheresis and MIC cells were manufactured under GMP conditions. Transplant recipients received either 1.5x10E6 MIC cells/kg body weight on day -2 (N=3,group A), 1.5x10E8 MIC cells/kg body weight on day -2 (N=3,group B) or day -7 (N=4,group C) before living donor kidney transplantation. Patients received immunosuppressive therapy with CyA,EC-MPS and CS. Primary outcome measure was the frequency of adverse events (AE) on day 30.

Results: A total of 72 AEs (3 severe AEs) occurred in treated patients that were unrelated to MIC cell infusion. No positive cross match results, de novo donor specific antibodies, or rejection episodes but 2 infectious complications were recorded. Median serum creatinine on day 30 was 1.4 mg/dL with no significant proteinuria. In vitro, MIC cells were capable of inducing tolerogenic dendritic cells with low expression of costimulatory molecules CD80, CD86 and a 30% increase of immunosuppressive molecule CD103. Beyond day 30 after surgery, serum creatinine remained stable (median 1.48 mg/dL on day 180) with no significant proteinuria (median 10 g/mol creatinine on day 180) and no rejection episodes. The patients from group C who received low-dose CyA and low-dose EC-MPS during the observation phase had no or only minimal reactivity against irradiated donor lymphocytes in mixed lymphocyte culture while reactivity against 3rd party lymphocytes was preserved. CD19+ B cells increased to a median of 300/µL until day 30 but decreased to a median of 35/µL on day 180.CD19+CD24highCD38high transitional Bregs increased from a median of 2% on day 30 to a median of 20% of the total CD19+ B cell pool on day 180. There was an increase in the plasma IL-10/TNFalpha ratio from a median of 0.05 before cell therapy to a median of 0.11 on day 180.

Conclusions: MIC cell therapy represents a promising option for individualized immunosuppression after living donor kidney transplantation.

FR-OR138

The Effect of Pulse Steroids/IVIG/Rituximab on Circulating Lymphocytes and Cytokines in Kidney Transplant Recipients with Chronic Active ABMR)

Nancy A. Wilson,[1] Natalie M. Bath,[1] Sarah E. Panzer,[2] Arjang Djamali,[3] Shannon Reese.[1] *[1]University of Wisconsin, Madison, WI; [2]University of Wisconsin Madison, Madison, WI; [3]School of Medicine and Public Health, Madison, WI*.

Background: There is no information on the effect of combination therapy with pulse steroids/IVIG/Rituximab on circulating T-cell and B-cell phenotypes and cytokines in kidney transplant recipients (KTR) with chronic active antibody mediated rejection (cABMR).

Methods: We examined this questions in 8 KTR with cABMR who underwent follow up evaluation with a repeat protocol biopsy within 3 months of the initial diagnosis. PBMC subsets were identified using flow cytometry. Plasma was analyzed using Luminex 45-plex assay for cytokines. Paired Wilcoxon rank sum test was utilized to assess the effect of therapy on pre and post samples. Pre-treatment samples were also compared to a group of 11 healthy volunteers matched for age, gender, and race.

Results: Median age at the diagnosis of cABMR was 48 years. The diagnosis was made at a median of 9.8 years post-transplant. Median Scr and urine PC at biopsy were 2.43 mg/dL and 1.24 g/g. Treatment with pulse steroids/IVIG/Rituximab was associated with a statistically significant decline in ptc and mvi Banff scores ($p<0.05$) at the three-month protocol biopsy. Similarly, B cells, Naïve B cells, plamablasts, and transitional B cells were significantly reduced ($p<0.05$ for all). However, treatment was associated with a significant increase in CD3 T cells and IL17 levels ($p=0.02$ for both). There was no significant difference in other Banff scores, kidney function, and Treg or Breg populations. Compared to controls, KTR had significantly lower naïve B cells, plasmablasts, and transitional B cells, while cirtculating fractaline, IL1-alpha, IL7, IL13, IL15, PDL1, and VEGF levels were significantly increased ($p<0.04$ for all).

Conclusions: In conclusion, KTR with ABMR have significantly different circulating B cell and cytokine profiles than healthy volunteers. Short term therapy with Pulse steroids/IVIG/Rituximab effectively inhibits disease activity in cABMR. However, treatment is associated with an upregulation of T cell response suggesting a negative feedback role for B cells in cABMR.

FR-OR139

G2/M Cycle Arrest in Human Transplanted Kidneys Correlates to Fibrosis, Functional Decline, and Graft Loss

Tobias Pieters,[3] Thomas Vanhove,[4] Tri Q. Nguyen,[1] Marianne C. Verhaar,[3] Dirk R. Kuypers,[4] Roel Goldschmeding,[3] Maarten B. Rookmaaker.[2] *[1]UMC Utrecht, Utrecht, Netherlands; [2]UMCU, Utrecht, Netherlands; [3]University Medical Center Utrecht, Utrecht, Netherlands; [4]University Hospitals Leuven, Leuven, Belgium*.

Background: Kidney transplantation (KTx) is the only curative treatment of end-stage renal failure. However, some KTx recipients suffer from long-term graft loss associated with interstitial fibrosis and tubular atrophy (IF/TA), especially after delayed graft function (DGF) due to acute tubular injury (ATI). Maladaptive repair, characterized by G2/M arrested tubular cells, has emerged as a key mediator of IF/TA after ATI in animal experiments, although little is known about its role in human kidney fibrosis. In this retrospective study, we studied the relation between G2/M cell cycle arrest in tubular cells in biopsies and histological and functional outcome of kidney allografts.

Methods: We included 64 patients, of which 32 presented with DGF and 32 with early graft function (EGF). Surveillance biopsies taken at 3 months after KTx were evaluated for G2/M cell cycle arrest by staining for the G2/M marker pHH3 and the proliferation marker Ki67. ATI was quantified morphologically in the indication biopsies taken approximately 7 days after KTx in the DGF group. Renal outcome was evaluated by fibrosis 2 years after KTx (Remuzzi score), kidney function decline in 2 years (CKD-epi), and 10-year death-censored graft survival.

Results: At 3 months after KTx, DGF kidneys had more G2/M arrested cells (median 1.17 cells/mm2 [0.0-3.8] vs median 0.6 cells/mm2 [0.0-1.8]; $p<0.05$) and the number of arrested cells/mm2 correlated to acute histological damage in the 7 day biopsy ($\rho=-0.78$ $p<0.0005$), to histological severity of fibrosis in biopsies taken 2 years after transplantation ($\rho=0.52$, $p<0.01$), and to functional decline over these 2 years ($\rho = -0.44$, $p<0.01$). Finally, the amount of G2/M arrested cells was associated with a higher risk of 10- year death-censored graft survival (univariate cox regression, HR=3.98, $p<0.01$).

Conclusions: Our data suggest that in the regenerative response following ATI damaged cells in kidney allografts can get arrested in G2/M and subsequently contribute to progressive IF/TA, functional decline and eventually graft loss.

Clinical Utilization of Donor-Derived Cell-Free DNA (AlloSure) for Monitoring Kidney Transplants: The Colorado Experience

Alexander C. Wiseman,[2] James E. Cooper,[3] Scott Davis,[1] Monica Grafals,[1] Erik Stites.[1] *[1]University of Colorado, Denver, CO; [2]University of Colorado at Denver and Health Sciences Center, Denver, CO; [3]University of Colorado at Denver, Denver, CO*.

Background: Cell-free DNA is released by cellular apoptosis or damage. Donor-derived cell-free DNA (dd-cfDNA) released from kidney allografts can be differentiated from recipient cfDNA and correlates with graft injury due to rejection. Dd-cf-DNA may be an effective biomarker for monitoring immunologic risk and damage in kidney transplants. We recently implemented dd-cfDNA surveillance in all eligible kidney transplant recipients within three years of transplant at our center. Here we present our early experience.

Methods: All eligible kidney transplant recipients within three years of transplant at our center were enrolled in the surveillance protocol. Blood samples for dd-cfDNA are collected at 1, 2, 3, 4, and 6months post-transplant and then quarterly for the first 3years. A dd-cfDNA proportion of >1.0% was considered positive based on published data. Management of positive results were left to clinical discretion. Patients also undergo surveillance biopsy at 3 months post-transplant per our institutional protocol.

Results: In the first four months of the protocol, 394 samples have been collected from 256 patients. The dd-cfDNA was negative (<1.0%) in 95.2% (n=375) of samples analyzed. Nineteen samples from 18 patients were positive (>1.0%) with 13 patients undergoing subsequent biopsy. Six biopsies (46.2%) were confirmed diagnosis of rejection (2 with clinical rejection, 4 with subclinical rejection). Seven biopsies were not diagnostic of rejection (3 with no pathologic abnormality, 1 with ATN, 1 with glomerular disease, 1 with moderate glomerulitis, 1 with borderline cellular rejection). Twelve patients have had dd-cfDNA monitoring (a total of 22 samples, all <1.0%) and 3-month surveillance biopsies. Biopsies demonstrated no pathologic abnormality in 11 of 12 surveillance biopsies (91.7%).

One biopsy had moderate peritubular capillaritis, moderate glomerulitis, and negative staining for C4d. The patient has stable graft function and no DSA.

Conclusions: To our knowledge, this is the largest published series to date using dd-cfDNA to monitor immunologic risk in kidney transplant recipients. A positive dd-cfDNA (>1.0%) had a PPV of 46.2% for biopsy-proven acute rejection, and importantly, 4 out of 6 of these cases were subclinical. A negative dd-cfDNA (<1.0%) had a NPV of 91.7% on 3-month surveillance biopsies.

FR-OR141

Gene Expression Profiles of Post-Transplant Glomerular Disease

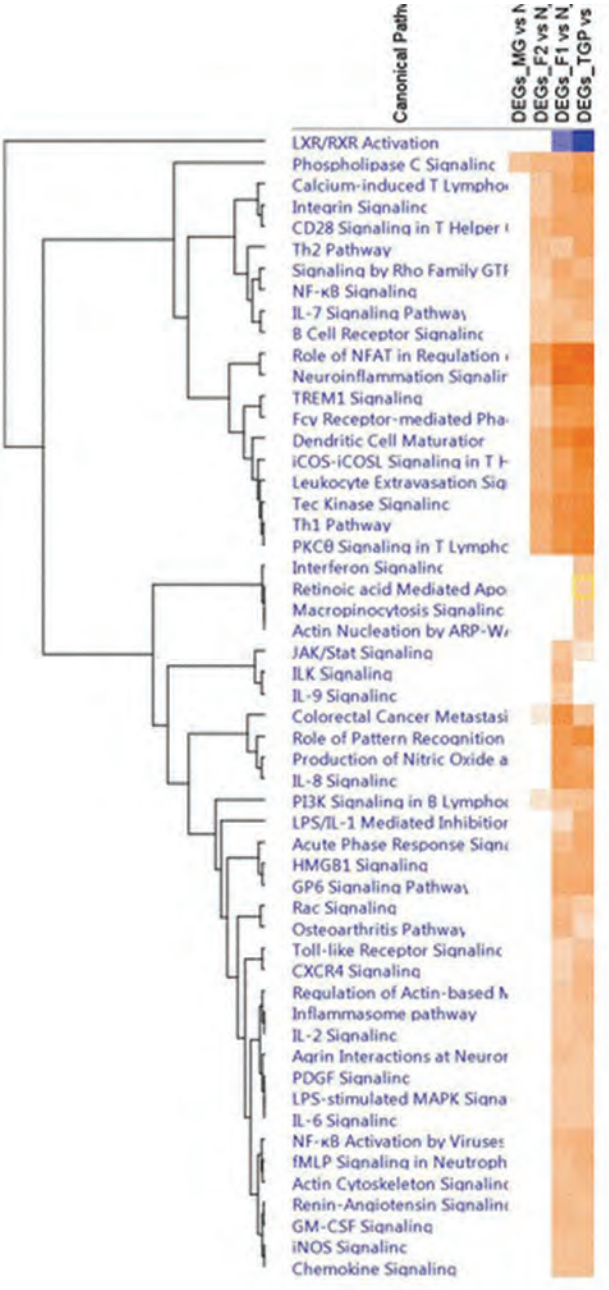
Enver Akalin,[1] Maria Ajaimy,[1] Sai Vineela Bontha,[2] Mariel Barbachan e Silva,[3] Pilib Ó Broin,[3] Valeria Mas.[2] *[1]Montefiore Medical Center, Bronx, NY; [2]University of Virginia, Charlottesville, VA; [3]National University of Ireland, Galway, Galway, Ireland.*

Background: Intragraft gene expression profiles of glomerular disease after kidney transplantation has not been well described other than transplant glomerulopathy (TG) which develops due to chronic rejection. We aimed to evaluate intragraft gene expression profiles of post-transplant glomerular disease including membranous glomerulopathy (MG), secondary or primary focal segmental glomerulosclerosis (FSGS), comparing to normal and TG biopsies.

Methods: The gene expression profiles of the 83 kidney biopsy specimens were studied by Affymetrix HuGene 1.0 ST expression arrays. TG (n=33), MG (n=10), secondary/late FSGS (n=16), and primary FSGS (n=6) were compared to normal transplant kidney biopsies (n=16).

Results: Gene Ontology analysis showed that all 4 glomerular disease groups had increased expression of gene transcripts related to activation, regulation, and differentiation of T cells, B cells, leukocytes, cytokines, chemokines, chemotaxis, and immune response compared to normal biopsies. Ingenuity Pathways Analysis demonstrated majorly overlapping differentially expressed genes between different comparisons indicating majorly common pathways and gene expression (Figure). Comparing canonical pathways the MG was least aggressive in terms of gene expression differences, followed by the secondary/late FSGS when compared to normal allografts. Primary FSGS and TG had the most differentially expressed genes, with most of them involved in inflammatory pathways and immune response. ILK signaling pathway and IL9 signaling pathway were uniquely activated in primary FSGS. All 4 groups demonstrated increased interferon gamma and rejection, cytotoxic T cell and macrophage associated pathogenesis based transcript expression.

Conclusions: Post-transplant glomerular disease including MG and FSGS had intragraft gene transcripts associated with increased immune activity similar to rejection and share overlapping gene transcripts with TG.



SA-OR001

Frailty and Age Disparities in Access to Kidney Transplantation

Christine E. Haugen,[1] Mary G. Bowring,[1] Courtenay M. Holscher,[3] Hao Ying,[4] Daniel C. Brennan,[2] Niraj Desai,[5] Jacqueline Garonzik wang,[2] Dorry L. Segev,[3] Mara McAdams-DeMarco.[2] *[1]Johns Hopkins Hospital, Baltimore, MD; [2]Johns Hopkins, Baltimore, MD; [3]Johns Hopkins University, Baltimore, MD; [4]Johns Hopkins School of Medicine, Baltimore, MD; [5]Physician, Baltimore, MD.*

Background: Older age is a known barrier to kidney transplantation (KT). One mechanism to explain age disparities is frailty, a decreased physiologic response to stressors associated with poor outcomes after KT.

Methods: We studied 3,548 KT candidates (2009-2017) in a multi-center cohort study of frailty. We estimated time to listing, waitlist mortality, and transplant rate using Cox proportional hazards, competing risks, and Poisson regression.

Results: The association between KT listing and candidate age varied by frailty status (interaction p=0.03): Older (age≥65) frail candidates were 27% less likely to be listed compared to older nonfrail candidates (aHR:0.73,95%CI:0.59-0.92,p<0.01), whereas younger (age:18-64) frail candidates were 23% less likely to be listed for KT (aHR:0.77,95%CI:0.68-0.88,p<0.001) (Figure 1A). Both older (aSHR:1.97,95%CI:1.54-2.53,p<0.001) and frail (aSHR:1.38,95%CI:1.05-1.83, p=0.02) KT candidates had higher waitlist mortality; but there was no synergistic effect (interaction p=0.12) (Figure 1B). The association between candidate age and transplant rate differed by frailty status (interaction

p=0.02): younger frail KT candidates were transplanted less frequently than younger nonfrail candidates (aIRR:0.68,95%CI:0.55-0.83,p<0.001). However, older frail KT candidates had similar transplant rates to older nonfrail candidates (aIRR:1.12,95%CI0.78-1.61,p=0.5) (Figure 1C).

Conclusions: The synergistic effect of older age and frailty is associated with a lower chance of listing, but not seen in older frail candidates with regards to waitlist mortality. Frailty assessment at KT evaluation can help guide patient counseling for candidates all of all ages, and prehabilitation strategies to improve pre-KT outcomes.

SA-OR002

Identification of Factors That Explain Racial Disparities during the Evaluation Process for Kidney Transplantation

Karly A. Murphy, Hao Ying, Dorry L. Segev, Mara McAdams-DeMarco. *Johns Hopkins University, Baltimore, MD.*

Background: Racial disparities between blacks and white patients are observed in evaluation completion rates, a step required for kidney transplantation (KT) listing. However, the role of patient-level demographics and medical comorbidities as explanatory factors for these disparities is unclear. We compared the risk of listing in black versus white adults referred to clinic for KT evaluation and identified whether the association of socio-economic factors and medical co-morbidities account for racial disparities in listing for KT.

Methods: As part of a prospective multi-center cohort study of aging and ESRD, 3,540 black and white candidates were enrolled at evaluation for KT (1/2009-12/2017). Self-reported demographic data, education, income, employment, and frailty status was collected at time of first evaluation. Medical comorbidities were ascertained from self-report and chart review. Time to listing in the first year was our primary outcome. We used multivariate Cox proportional hazard models to estimate incidence for listing and the association of patient-level factors between black and white participants. Mediation analysis was performed using percent reduction in beta coefficient for race in expanded model versus a base model, adjusted for age and sex.

Results: Among 3,540 participants, the mean age was 54.7 years (sd=13.5) with 41.2% female and 49.2% self-reported black race. Overall, 1,930 patients were listed for KT in the first year. Likelihood of listing was lower for blacks compared with whites (HR=0.77, 95% CI:0.70-0.84) after adjusting for age and gender. Racial differences in listing rates were partially explained by socio-economic factors (% reduction in beta coefficient, 38.5%) and partially explained by medical co-morbidity (% reduction in beta coefficient, 35.6%). After accounting for age, gender, patient-level socioeconomic factors, and medical comorbidity, disparity by race persisted (adjusted HR 0.89, 95% CI 0.81-0.98, % reduction in beta 47.6%).

Conclusions: Racial disparities during the listing stage of KT are partly explained by differences in patient-level socio-economic factors and medical comorbidity. Higher socio-economic status may indicate greater personal resources to navigate the transplant process and could direct future intervention.

SA-OR003

Exploring the Viability of Kidneys Discarded in the US: A Comparison of Kidney Utilization Patterns and Outcomes in the US and France

Olivier Aubert,[1] Peter P. Reese,[2] Yassine R. Bouatou,[3] Denis Viglietti,[4] Carmen Lefaucheur,[3] Alexandre Loupy.[5] *[1]Paris Translational Research Center for Organ Transplantation, Paris, France; [2]University of Pennsylvania, Philadelphia, PA; [3]Paris Transplant Group, Paris, France; [4]Saint-Louis Hospital, Paris, France; [5]INSERM, Paris, France.*

Background: Approximately 2,000 donated kidneys are discarded in the US each year. Some transplant leaders have questioned the viability of these lost organs, while others suggest instead that allocation inefficiencies or risk-aversion due to center report cards are responsible for the high discard rates. However, few studies have examined whether kidneys discarded in the US might be transplanted with acceptable outcomes in other countries.

Methods: Using UNOS registry and the Paris Transplant Group prospective cohort data from 2004 – 2014, we compared kidney quality and outcomes between the US and France.

Results: During this period, 125,936 kidneys in the US and 4,287 kidneys in the Paris Transplant Group cohort were procured for transplant. As shown in the upper panel, a much higher proportion of transplanted French kidneys were higher-risk organs (as measured by the kidney donor profile index, KDPI) compared to the US (median 65 [39-90] vs 42 [19-67] in the US, p<0.0001). During the decade, the KDPI of US kidneys only increased modestly (from a mean KDPI of 42 to 44), while in France, a steadily rising KDPI (from a mean KDPI of 54 to 67) reflected a trend of more aggressive organ use. We used the Kaplan-Meier method to estimate death-censored graft survival for higher-KDPI kidneys transplanted in France. Three and five-year survival for KDPI 80 – 90 kidneys was 88 and 83%, for KDPI 91-99 kidneys was 83 and 79% and for KDPI 100 was 81 and 78%. Finally, we fit a logistic regression model to predict kidney discard in the US (AUC 0.80) and estimated the probability that kidneys transplanted in France would have been discarded if instead allocated in the US. Many transplanted French kidneys would have had a high probability of discard in the US system. Using 951 transplanted kidneys in France randomly selected according to their probability of being discarded in the US, we calculated that the use of those kidneys in the US would have translated to a 3,000 allograft life-years saved.

Conclusions: In summary, these results provide fresh evidence that some kidneys discarded in the US are a lost opportunity that could have benefitted some wait-listed patients.

SA-OR004

Clinical Utility and Interpretation of CKD Stages in Living Kidney Donors

Allan Massie,[1] Alvin G. Thomas,[2] Jon J. Snyder,[3] Dorry L. Segev.[4] *[1]Johns Hopkins School of Medicine, Baltimore, MD; [2]UNC Chapel HIll, Chapel Hill, NC; [3]Minneapolis Medical Research Foundation, Minneapolis, MN; [4]Johns Hopkins University, Baltimore, MD.*

Background: Current definitions of chronic kidney disease (CKD) staging define any individual with estimated glomerular filtration rate (eGFR)<60 as having stage 3 or higher CKD. Nearly half of living kidney donors (LKDs) have post-donation eGFR below this threshold, but the clinical interpretation of eGFR<60 in donors is unknown, and the "CKD" label may not be appropriate. Evidence of risk associated with decreased post-donation eGFR is needed to inform international guidelines and best practices for donor followup and care management.

Methods: Using national registry data, we studied end-stage renal disease (ESRD) risk in 67,571 LKDs 1999-2015 with at least one reported postdonation serum creatinine

(SCr). eGFR was calculated via the CKD-EPI equation. Measurements with eGFR<15 were excluded from analysis. We modeled the association between eGFR category (≥60, 45-59, 30-44, 15-30, corresponding to no CKD, CKD stage 3, stage 4A, and stage 4B) using Cox regression with eGFR category as a time-varying exposure and adjusting for donor age, sex, race (black vs nonblack), BMI, and 1st-degree biological relationship to recipient.

Results: 117,051 CKD measurements were reported at median (IQR) 11 (4-14) months post-donation (90th percentile 25m post-donation). Of these, 33.9% were in the range 45-59, 5.7% were in the range 30-45, and 0.8% were in the range 15-29. Lower eGFR categories were associated with greater ESRD risk: 5-fold higher risk for eGFR 30-45 (aHR = 5.3 (2.1-13.3)) and 54-fold higher risk for eGFR 15-29 (aHR=53.7 (4.8-421.3); both p<0.001). Donors with eGFR 45-60 had elevated risk but the association was not statistically significant (aHR=1.9 (0.9-3.8), p=0.08).

Conclusions: There is insufficient evidence to support the category eGFR 45-60 as clinically meaningful "CKD stage 3" among LKDs. Nevertheless, eGFR category is associated with ESRD risk among donors with eGFR<45, and our results support current guidelines recommending longitudinal followup of renal function in living kidney donors.

Variation in Access to Transplant Referral and Evaluation Start among Dialysis Facilities

Laura J. McPherson,[1] Derek Dubay,[3] Matthew J. Ellis,[4] Heather Jones,[9] Carlos F. Zayas,[2] Laura L. Mulloy,[5] Brenda B. Thrasher,[8] Joseph A. Gulotta,[6] Shannon Wright,[7] Reem Hamoda,[1] Stephen O. Pastan,[1] Rachel E. Patzer.[1] on behalf of the Southeastern Kidney Transplant Coalition *[1]Emory University School of Medicine, Atlanta, GA; [2]Augusta University (MCG) School of Medicine, Augusta, GA; [3]Medical University of South Carolina, Charleston, SC; [4]Duke University Medical Center, Durham, NC; [5]Medical College of Georgia, Augusta, GA; [6]IPRO, Lake Success, NY; [7]IPRO ESRD Network of the South Atlantic, Morrisville, NC; [8]Carolinas Medical Center, Charlotte, NC; [9]Vidant Medical Center, Greenville, NC.*

Background: Variation exists in transplant access across US dialysis facilities. However, little is known about the proportion of end-stage renal disease (ESRD) patients who initiate or complete transplant steps prior to waitlisting. We describe dialysis facility-level variation in referral and evaluation start among dialysis facilities in ESRD Network 6 using our regional pre-transplant data registry.

Methods: In collaboration with the community-based Southeastern Kidney Transplant Coalition, patient-level data from all 9 transplant centers in ESRD Network 6 (GA, NC, and SC) on kidney transplant referral (date referral form was received by transplant center) and evaluation start (date patient started evaluation) were collected from January 1, 2012 to December 31, 2016. Referral and evaluation start data were linked with ESRD Network data, including prevalent patients by dialysis facility and year, to calculate the proportion of patients referred and starting evaluation.

Results: Among 47,804 prevalent dialysis patients from all ESRD Network 6 dialysis facilities in 2016 (n=705) with a median of 60 patients/facility, approximately 16.1% (n=7717) were referred for evaluation and 9.2% (n=4406) started an evaluation. The median proportion of patients referred in 2016 was 14.5% (IQR: 8.9-21.2%), with 48 facilities not referring any patients (Figure 1). The median proportion of patients starting an evaluation in 2016 was 7.7% (IQR: 4.2-12.2%); 67 facilities had no patients start evaluation in 2016.

Conclusions: In the Southeastern United States, a small proportion of dialysis patients are referred for kidney transplant evaluation, and fewer start the evaluation at a transplant center. There is considerable variation in the proportion of patients referred and starting evaluation across dialysis facilities in ESRD Network 6. Interventions targeting these early steps in the kidney transplant process could improve equitability in transplant.

Favorable Cardiac Remodeling Following Ligation of Arteriovenous Fistula in Stable Renal Transplant Recipients: A Randomized Controlled Study

Nitesh N. Rao,[1,2] Stephen P. McDonald,[3] Randall J. Faull,[3] Patrick T. Coates.[4] CNARTS *[1]University Of Adelaide, Adelaide, SA, Australia; [2]Nephrology, Lyell McEwin Hospital, Adelaide, SA, Australia; [3]Royal Adelaide Hospital, Adelaide, SA, Australia; [4]University of Adelaide, Adelaide, SA, Australia.*

Background: Cardiovascular morbidity and mortality remains high in recipients of kidney transplantation. Persistence of a functional arteriovenous fistula (AVF) post-transplant may contribute to maladaptive cardiovascular remodeling. In this study we aimed to determine whether ligation of AVF would improve myocardial mass in stable kidney transplant recipients, assessed at baseline and 6 months after closure using cardiac magnetic resonance imaging (CMR).

Methods: We recruited 63 adult kidney transplant recipients with stable kidney function and functioning AVF. Participants were randomly assigned to AVF ligation versus no intervention, after a baseline CMR scan followed by a repeat scan six months following AVF ligation. Primary outcome was assessment of left ventricular(LV) mass at 6 months. Secondary outcomes were changes in left and right ventricular volumes, pulmonary flows, left and right atrial areas.

Results: Of the 93 participants assessed for eligibility, 63 eligible participants underwent randomisation: 32 to the intervention and 31 to non-intervention. 54 out of 63 participants completed the study. At the end of 6 months, a decrease of 21.6 gm (95% CI -32.1to -11.0, p<0.001) was observed between the mean LV mass in the AV fistula closure group compared to no significant change in the non-intervention control group. The difference in LV mass index (gm/m^2) was a drop by 11.7 gm (95 % CI -17.2 - -6.1, p<0.001) in the intervention group from the baseline versus no change in the control group. Decrease in LV end diastolic volume, LV end systolic volume, right ventricular and bi-atrial volumes were also observed in the AVF closure group. No significant complications were noted after AVF ligation.

Conclusions: Elective ligation of AVF in adults with stable kidney transplantation and functioning AVF is associated with marked reduction in both absolute and indexed measurements of myocardial mass. (Funded by the Royal Adelaide Hospital Research Foundation grant; Australian and New Zealand clinical trials registry, number ACTRN12613001302741)

Gut Microbiota Dysbiosis Is a Novel Risk Factor for Urinary Tract Infections in Kidney Transplant Recipients

John R. Lee,[1] Matthew Magruder,[1] Adam N. Sholi,[1] Emmanuel Y. Edusei,[1] Lisa T. Zhang,[1] Shady Y. Albakry,[1] Michelle L. Lubetzky,[1] Darshana Dadhania,[1] Ying Taur,[2] Lilan Ling,[2] Philip Burnham,[3] Iwijn De Vlaminck,[3] Eric Pamer,[2] Manikkam Suthanthiran.[1] *[1]Weill Cornell Medicine, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY; [3]Cornell University, Ithaca, NY.*

Background: The gut is the presumed source of urinary tract infection (UTI) but direct evidence for this supposition is lacking.

Methods: We recruited 169 kidney transplant recipients for serial collection of fecal specimens and profiled 516 fecal specimens using 16S rRNA gene deep sequencing of the V4-V5 hypervariable region. Among the cohort, 36 subjects developed *Escherichia* bacteriuria within the first 6 months of transplantation (*Escherichia* Group) and 133 subjects did not (No *Escherichia* Group); 36 subjects developed *Enterococcus* bacteriuria (*Enterococcus* Group) and 133 subjects did not (No *Enterococcus* Group).

Results: The relative gut abundance of *Escherichia* was significantly higher in the fecal specimens in the *Escherichia* Group than in those in the No *Escherichia* Group (P<0.001, Wilcoxon rank sum test) (Fig 1A) and the relative gut abundance of *Enterococcus* was significantly higher in the fecal specimens in the *Enterococcus* Group than in those in the No *Enterococcus* Group (P<0.001) (Fig 1B). Using a Cox Regression with gut abundance as a time-dependent covariate, a relative gut abundance of 1% *Escherichia* was a risk factor for future development of *Escherichia* bacteriuria (HR= 3.2, P<0.001), and a relative gut abundance of 1% *Enterococcus* was a risk factor for future development of *Enterococcus* bacteriuria (HR = 2.6, P= 0.006). Strain analysis of the *Escherichia coli* in paired urine-fecal specimens using shotgun metagenomic sequencing revealed that the *E. coli* strain in the urine specimens was most similar to the *E. coli* strain in the fecal specimens from the same subject, supporting the gut as the source of the urine strain (Fig 1C).

Conclusions: Our findings support the hypothesis that gut microbial composition is a contributor to UTI in kidney transplant recipients. Modulating the gut microbiota may be a novel and effective strategy for preventing this frequent complication.

Funding: Other NIH Support - NIAID

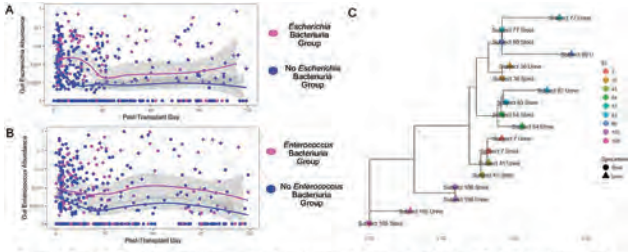

Figure 1. Panel A. Each point represents a fecal specimen with the gut abundance of *Escherichia* (y axis) and time in days after transplantation (x axis). Panel B. Each point represents a fecal specimen with the gut abundance of *Enterococcus* (y axis) and time in days after transplantation (x axis). Panel C. Consensus strains for *Escherichia coli* were constructed using Strainphlan and a phylogenetic tree was constructed based on these strains. *E. coli* in the urine specimens was most similar to *E. coli* in the fecal specimens from the same subject.

Association of Recipient APOL1 Kidney Risk Alleles and Hepatitis C Status with Kidney Transplant Outcomes

Karim H. Anis,[1] Simin Goral,[4] Jeffrey B. Kopp,[2] Cheryl A. Winkler,[3] Rui Feng,[4] Sylvia E. Rosas.[1] *[1]Joslin Diabetes Center, Boston, MA; [2]NIDDK, NIH, Bethesda, MD; [3]NCI, NIH, Frederick National Laboratory, Frederick, MD; [4]University of Pennsylvania, Philadelphia, PA.*

Background: African-Americans (AA) are more likely to have worse kidney transplant outcomes compared to non-AA transplant recipients. The mechanism is unknown but the *APOL1* risk alleles (RA) have been postulated as likely contributors. Given the high prevalence of *APOL1* RA in AA a two-hit theory has been embraced. We examined the outcomes of kidney transplant recipients (KTR) stratified by *APOL1* RA and hepatitis C virus (HCV) antibody status.

Methods: We conducted a multicenter observational prospective study of incident KTR. Incident KTR were genotyped for *APOL1* RA. Baseline characteristics and graft survival rates were compared by number of *APOL1* RA and/or by HCV antibody presence.

Results: Among 221 participants, approximately 43% had 2 *APOL1* RA. The prevalence of HCV antibody in the cohort was 17%. KTR with 2 *APOL1* RA were younger compared to those with none or one *APOL1* RA [51.8 vs 42.2 years old, P<0.0001]. Two *APOL1* RA was associated with early (prior to 1500 days) [1.98 (95% CI 1.01-3.85); P=0.045], but not late graft failure (up to 2000 days) [HR 1.39 (95% CI 0.79-2.45); P=0.25] adjusted for acute rejection and age at transplant. However, recipients with both two *APOL1* RA and HCV antibodies demonstrated lower graft survival compared to recipients with only one or none of those risk factors. [HR 2.74(95%CI 1.06-7.10); P=0.04].

Conclusions: Our study demonstrates the effect of *APOL1* risk status in KTR on graft survival. Furthermore, it illustrates that the effect of recipient *APOL1* RA on graft outcome may be altered by viral infections such as HCV and is likely time dependent.

Characteristics and Outcomes of Deceased Donor Kidney Transplants Performed in the US Based on Donor HCV NAT and Recipient HCV Ab Status

Venkatesh Kumar Ariyamuthu,[1] Cagla Keceli,[2] Bekir Tanriover,[1] Burhaneddin Sandikci,[3] Yuan Zhong,[4] Nashila AbdulRahim,[1] Ricardo M. La Hoz.[5] *[1]UT Southwestern, Richardson, TX; [2]The University of Chicago Booth School of Business, Chicago, IL; [3]University of Chicago, CHICAGO, IL; [4]University of Chicago, Booth School of Business, Chicago, IL; [5]UT Southwestern Medical Center, Dallas, TX.*

Background: HCV nucleic acid testing (NAT) testing for deceased donors has become routine since April 2014. Comparative outcomes of deceased donor renal transplants (DDRT) based on HCV NAT and antibody (Ab) testing in different donor-recipient pairs are not well known.

Methods: We queried the UNOS dataset for DDRT performed between April 2015 and September 2017. Pediatric age, multiorgan transplants, and cases with unknown HCV NAT / Ab status were excluded. The final study cohort (N=27,930) were stratified into 4 groups: 1) Donor (D) Ab-/NAT- Recipient (R) Ab- (reference group, n=27,070); 2) D Ab+/ NAT- R Ab- (n=133); 3) D Ab+ / NAT+ R Ab- (n=65); 4) D Ab+/NAT+ R Ab+ (n=662). A propensity score was calculated based on donor KDPI, recipient age, race, and underlying kidney diagnosis. An exact propensity score matching was performed 1:4 ratio between the reference group and other 3 stratified groups. Primary outcomes were overall allograft survival (failure defined as death or graft failure), acute rejection at 1 year and DGF.

Results: The results are shown in Table 1.

Conclusions: HCV NAT + kidneys do have similar outcomes compared to NAT negative donors. Utilization of HCV NAT + kidneys should be encouraged.

BK Virus Nephropathy: Characterization of an Interferon Signature and Identification of Risk Factors for Graft Failure

Darshana Dadhania,[4] Weeraporn Srisung,[1] Essa Abuhelaiqa,[1] Catherine Snopkowski,[6] Carol Y. Li,[4] John R. Lee,[2] Thangamani Muthukumar,[3] Ruchuang Ding,[5] Surya V. Seshan,[3] Manikkam Suthanthiran.[4] *[1]NYP-Weill Cornell Medical Center, New York, NY; [2]Weill Cornell Medicine-, New York, NY; [3]Weill Cornell Medical Center, New York, NY; [4]Weill Cornell Medical College, New York, NY; [5]weill Cornell Medical College, Beechhurst, NY; [6]Weill Medical College of Cornell University, New York, NY.*

Background: BK virus nephropathy(BKVN) is an important cause of allograft failure. Identification of its immune pathways may help design better therapeutics.

Methods: We measured urinary cell mRNAs in 53 BKVN patients and 43 patients with normal protocol biopsies. Among the 53 BKVN cases, 18 grafts failed within 3 years post diagnosis and none in the normal group. Levels of mRNA were measured using kinetic, quantitative polymerase-chain assays. We compared mRNA levels of 53 BKVN vs. 43 normal patients, and within BKVN group, the 18 BKVN with graft loss vs. 35 BKVN without graft loss.

Results: Among the transcripts quantified in a total of 96 renal graft recipients, urinary cell levels of 18S rRNA, IP-10 and MIG were significantly higher in the BKVN group vs. normal group (all P<0.0001)(Table 1). Of the 53 BKVN cases, 18 lost their grafts and they were more likely to have received a deceased-donor renal transplant(DDRT) (P=0.03) and a higher creatinine(SCr) at time of BKVN diagnosis (2.88+/-1.18 mg/dl vs. 1.96+/-0.69 mg/dl;P=0.005). Urinary cell levels of PAI-1 mRNA predicted graft failure(Figure 1). Multivariate analysis demonstrated that PAI-1 mRNA level (OR: 2.6;P= 0.005), biopsy SCr (OR: 9.1;P<0.001) and DDRT (OR: 8.3;P=0.01) were independent predictors of graft failure.

Conclusions: BKVN is associated with an inflammatory milieu characterized by an interferon signature. Urinary cell levels of the acute phase reactant PAI-1 offer a noninvasive means to predict graft failure after BKVN diagnosis.

Alpha 2 Adrenergic Receptor Blockade Prevents AKI to CKD Transition

Hee-Seong Jang, Babu J. Padanilam. *University of Nebraska Medical Center, Omaha, NE.*

Background: Increased sympathetic nerve activity and norepinephrine (NE) levels are of importance in the onset and the early development of end stage renal disease. We reported that renal denervation (DNx) can prevent renal fibrosis and inflammation in renal fibrogenesis models. However, the underlying mechanism by which renal denervation prevents the long-term sequelae of acute kidney injury (AKI) remains to be elucidated.

Methods: Based on our data, we hypothesized that NE mediates its effect through activation of alpha 2 adrenergic receptors (α2ARs). In this study, we investigated whether genetic or pharmacological inhibition of α2ARs prevents ischemia/reperfusion injury (IRI)-induced CKD progression.

Results: IRI resulted in severe kidney fibrosis in medullary region over 2 weeks with tubular cast and atrophy and massive macrophage infiltration. Renal DNx and pharmacological inhibition of α2AR did not affect renal functional and histological damage in the acute phase of the IRI. However, renal tubular damage, inflammation, and fibrosis progression was suppressed 2 weeks post-IRI by renal DNx and pharmacological inhibition of α2AR with downregulation of downstream targets of NE-α2AR axis, including angiotensinogen, fibrogenic factors and inflammatory cytokines. Similar with results in pharmacological inhibition of α2A-AR subtype, blockage of α2C-AR subtype by pharmacological or genetic manipulation prevented the long-term sequelae of IRI, including renal tubular atrophy, inflammation and fibrosis progression.

Conclusions: Collectively, inhibition of α2AR subtypes prevents IRI-induced AKI to CKD transition through inhibition of persistent renal tubular injury and inflammation, and fibrosis progression, suggesting that targeting α2ARs may be a potential therapeutic strategy to prevent long-term sequelae of ischemic AKI.

Regeneration of Proximal Tubules after Severe Injury Depends on Clonal Proliferation of eR1-Active Subpopulation of Proximal Tubular Cells

Yuichiro Kitai, Motoko Yanagita. *Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: Proximal tubular cells (PTC) are considered to repair injured proximal tubules by their own proliferation. However, whether this process depends on stochastic proliferation of surviving PTCs or expansion of a specific population of PTCs is still debated, and whether severity of injury affects the repair process is uncertain. In mammals, RUNX transcription factors are essential in diverse biological processes. Along with the elucidation of the roles of Runx1 in hematopoietic homeostasis and blood malignancies, a Runx1 enhancer named Runx1+24mCNE (eR1) has been identified recently, and shown to be active in adult long-term hematopoietic stem cells and gastric stem cells, but the role of eR1 in the kidney is unknown.

Methods: We first compared the proliferation of PTCs after 30- (moderate injury) and 60-min ischemia reperfusion injury (IRI) (severe injury) by bromodeoxyuridine (BrdU) labeling. We next explored the role of eR1 in kidney injury, utilizing eR1-ECFP and eR1-Cre^{ERT2} mice.

Results: As indicated by BrdU incorporation, PTCs of the superficial cortex were more proliferative in 60-min IRI than in 30-min IRI, whereas proliferation rate was comparative in the deep cortex. While ECFP$^+$ PTCs were almost absent in healthy kidneys of eR1-ECFP mice, ECFP$^+$ cells increased to about 20% of total PTCs in the superficial cortex after 60-min IRI, but not after 30-min IRI. Then, we subjected eR1-ECFP:eR1-Cre^{ERT2}:R26-tdTomato mice to 60-min IRI, and showed that ECFP$^+$ and tdTomato$^+$ PTCs mostly overlapped in acute phase even without tamoxifen. This result indicated that eR1-Cre^{ERT2} mice show leaky Cre^{ERT2} activity when eR1 was highly activated, and could be used to trace the fate of PTCs with strong eR1 activity. In acute phase of 60-min IRI, tdTomato$^+$ PTCs showed a higher rate of BrdU incorporation than other PTCs, and clustered with several tdTomato$^+$ PTCs. Clonal analysis using eR1-Cre^{ERT2}: R26-Confetti multicolor reporter mice revealed that clusters of PTCs were mostly labeled with a single color, indicating the clonal expansion of labeled cells. Notably, tdTomato$^+$ PTCs in acute phase were mostly positive for Kim-1 and vimentin, and negative for PTC markers such as aquaporin 1.

Conclusions: In severe injury, transiently dedifferentiated eR1-active PTCs clonally expand and repair superficial proximal tubules.

SA-OR013

Tubular HIF-1α Activates Macrophages via Exosomal MicroRNA-23a to Promote Tubulointerstitial Inflammation

Zuolin Li,[1] Linli Lv,[1] Jialing Ji,[2] Ye Feng,[1] Bi-Cheng Liu.[1] *[1]Institute of Nephrology, Zhong Da Hospital, Southeast University School of Medicine, Nanjing, China; [2]Nanjing Medical University, Nanjing, China.*

Background: Hypoxia is a key instigator of tubulointerstitial inflammation (TI) which has been assumed related with hypoxia inducible factor-1 (HIF-1), a master regulator response to hypoxia. While the exact mechanism of HIF-1 on this pathophysiological process is still largely unclear.

Methods: Hypoxia-related TI was induced in I/R injury and UUO models. Exosomes from hypoxic kidney and hypoxic TECs were isolated. The role of HIF-1 on miR-23a expression was studied using CHIP-PCR. Besides, exosomal miR-23a was inhibited or overexpressed to explore its functional role in macrophage. *In vivo*, TECs exosomes overexpressed or silenced miR-23a was transferred to mice via kidney parenchyma injection. Furthermore, treatment of miR-23a inhibitor in I/R model was also performed.

Results: TI was highly associated with the time-course expression of tubular HIF-1α in I/R injury and UUO mice. Meanwhile, the kidney exosomal miR-23a was markedly increased. *In vitro*, hypoxic TECs presented with higher HIF-1α and upregulation of NF-κB as well as exosomal miR-23a. HIF-1α could transcriptionally regulate miR-23a in exosomes. Exosome from hypoxic TECs could develop more severe macrophage activation compared to exosome from normal TECs. Furthermore, we demonstrated that exosomal miR-23a directly suppressed its target A20, leading to macrophage activation. Inhibition of miR-23a reversed macrophage activation. *In vivo*, TI was significantly increased when mice transferred with miR-23a enriched exosomes, which was not shown by miR-23a silenced exosomes. Furthermore, treatment of miR-23a inhibitor in I/R model could ameliorate TI significantly.

Conclusions: Our study firstly demonstrates that tubular HIF-1 regulated macrophage function via exosomal miR-23a to promote hypoxia-related TI. The finding provides a novel strategy to target HIF1α-miR-23a axis in preventing hypoxia induced kidney injury.

Arginase 1 Knockout Macrophages Fail to Promote Epithelial Proliferation and Impair Kidney Repair after AKI

Arnaud Marlier,[1] Serena M. Tharakan,[1] Søren Nielsen,[2] Lloyd G. Cantley.[1] *[1]Yale University School of Medicine, New Haven, CT; [2]Aalborg University, Aalborg, Denmark.*

Background: Renal ischemic injury induces epithelial cell death which leads to an innate immune response that includes initial proinflammatory macrophage activation that promotes additional epithelial injury followed by alternative activation that is required for

kidney repair. Alternative activation is marked by the expression of several genes including arginase 1 (Arg1), mannose receptor (Mrc1) and macrophage scavenger receptor (Msr1), but the actual function of the protein products of these genes in the injured kidney is not known. This work addresses the role of Arg1 expression by reparative macrophages in kidney repair.

Methods: AKI model: Unilateral renal ischemia reperfusion with contralateral nephrectomy in $Arg1^{f/f}$;$LysMCre^{/+}$ (Arg1ko: knock-out of Arg1 in macrophages) and $Arg1^{+/+}$;$LysMCre^{/+}$ (Arg1con: control) mice. RNA was isolated either from whole kidney or from flow sorted macrophages (CD45+F4/80+). Gene expression profiling by qPCR. Immunohistology performed on paraffin embedded kidney sections.

Results: $Arg1^{ko}$ (n=8) and $Arg1^{Ctrl}$ (n=9) mice were therefore subjected to 27 minutes of unilateral IR with contralateral nephrectomy. The initial rise in creatinine on day 1 was equivalent in the 2 groups (1.55±0.05 and 1.61±0.05 mg/dl, p=ns). 85% of the control mice survived to day 7 after IR, whereas only 37% $Arg1^{ko}$ mice survived until day 7, with mortality observed on day 3. Renal macrophage expression of Arg1 on day 7 after IR is 0.755±0.484 in control mice but only 0.020±0.012 in $Arg1^{ko}$ mice (dCt relative to Hprt1, p=0.04). Quantification of F4/80+ cells in the kidney on day 3 revealed no difference in macrophage numbers between control and $Arg1^{ko}$ mice (298±83 vs. 315±17 F4/80+ cells/mm^2, p=ns), whereas tubular cell proliferation as determined by Ki67 positivity was significantly reduced in $Arg1^{ko}$ kidneys (343±86 vs. 110±33 Ki67+ cells/mm^2, p=0.03). Finally, morphometric analysis of day 7 kidney sections showed a pronounced loss of healthy tubular mass in $Arg1^{ko}$ kidneys compared to control kidneys (normal tubule/section: 34.2%±2.7 vs. 44.7%±0.5, p=0.004).

Conclusions: These results indicate that the upregulation of macrophage Arg1 expression facilitates tubular regeneration by promoting epithelial cell proliferation and limiting nephron loss at the site of injury.

Tamm-Horsfall Protein (Uromodulin) Inhibits Systemic Oxidative Stress by Inactivating the TRPM2 Channel

Kaice A. LaFavers,[2] Shehnaz Khan,[3] Seth Winfree,[2] Takashi Hato,[1] Pierre C. Dagher,[1] Tarek M. El-Achkar,[1] Radmila Micanovic.[2] *[1]Indiana University, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN, IN; [3]Indina university of school of medicine Nephrology, Indianapolis, IN.*

Background: Tamm-Horsfall protein (THP) is produced exclusively in the thick ascending limb (TAL) of the loop of Henley. In TAL cells, THP is secreted apically in the urine but also released basolaterally in the interstitium and circulation. We previously showed that THP downregulates inflammatory signaling in S3 proximal tubules. Here, we investigate potential targets of THP on these cells and the role of systemically released THP.

Methods: We used THP+/+ and THP -/- mice. Various assays and technologies as described in results

Results: We performed laser microdissection on S3 and TAL tubules for transcriptomic studies. Bioinformatic analysis determined that, in the setting of THP deficiency, JNK stress kinase signaling is activated in S3 segments but not in TAL. JNK activation uniquely in S3 segments was confirmed by 3D tissue cytometry. Additional proteomic studies on S3 segments and human proximal tubular cell suggested that THP inhibits oxidative stress and Rac-1 activity, both known to be upstream of JNK. This was confirmed in vivo using intravital imaging and other measures of oxidative stress. Furthermore, we observed that THP deficiency increased oxidative injury not only in the kidney, but also systemically and in distant organs, such as the lungs. Since TRPM2, a nonvoltage activated nonselective cationic channel, is implicated in regulating oxidative stress, we investigated if THP modulates its activity. Indeed, TRPM2 is expressed in the kidney, lungs and other organs. In HEK-293 recombinant cells with inducible TRPM2, we show that THP specifically inhibits TRPM2 dependent calcium influx in a dose dependent manner. Furthermore, pharmacological inhibition of TRPM2 in THP-/- mice reduced systemic oxidative damage.

Conclusions: We show that THP inhibits oxidative stress not only in the kidney but also systemically in other organs. This effect is likely mediated through the circulating form of THP. Our data suggest that this effect, in part, is due to inhibition of the TRPM2 channel, which in some tissue types, conditions and experimental models, is known to cause downstream oxidant injury. These findings underscore the importance of THP in mediating a systemic cross-talk between the kidney and other organs and identify, for the first time, a molecular target for circulating THP.

SA-OR016

Inhibition of Orai1-Mediated Ca2+ Signaling Ameliorates AKI-to-CKD Transition Following Ischemia and High Salt Diet

Purvi Mehrotra,[1] Michael Sturek,[3] David P. Basile.[2] *[1]Indiana School of Medicine, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Indiana University School of Medicine, Indianapolis, IN.*

Background: Store-operated Ca^{2+}entry (SOCE) through Orai1 channels raise intracellular Ca^{2+}concentrations in T cells, which induce proliferation and cytokine production in immune cells. The Orai-1 gene has been linked to SCID, and loss-of-function mutation of Orai-1 in murine T cells shown to be protective in models of autoimmune disease, due to impaired production of the cytokine IL-17. T-helper 17 (Th17) cells increase following renal injury and exposure to high-salt diet and IL-17 blockade reduces AKI-to-CKD progression. We have recently identified Orai-1 expression in AKI primed renal T cells and hypothesize that Orai1-mediated Ca^{2+}signaling may influence Th17 differentiation and modulate CKD progression.

Methods: Rats were allowed to recover from renal ischemia for 1 week and CD4+ lymphocytes were analyzed for $Ca^{2+}$and IL-17 responses in vitro. In other studies, rats were subjected to bilateral I/R and allowed to recover 24 hours with or without SOCE antagonist YM-58483 (1mg/kg). To study CKD progression, rats following unilateral ischemia were allowed to recover for 5 weeks 0.4% NaCl diet. CKD was hastened by Unx and elevated dietary NaCl (4%) for 4 weeks. In this study, rats were fed YM-58483 or vehicle daily during the high salt treatment.

Results: AKI primed CD4+ lymphocytes manifested an induction of IL-17 production in vitro to angiotensin II and 170 mMol/L Na^+while ~30% of cells manifested an increase in cytosolic Ca^{2+}; these responses were blocked by 10mM YM-58483. Rats treated with YM-58483 were protected from bilateral ischemia as indicated by lower serum creatinine (vehicle 3.3±0.4; YM-58483 2.2±0.5 mg/dl; p£0.05) and significantly reduced by ~40% Th17 infiltration. When post ischemic rats were exposed to 4% dietary salt, there was an increase in inflammatory cells and fibrosis. YM 58483 initiated during high salt feeding significantly attenuated renal CD4+, CD8+, B cells and dendritic/macrophage cells by ~50%. Th17 cells (CD4+/IL17+) were also reduced significantly (vehicle 19425±23086, YM-58483 6494±1146 cells/g; p£0.05). In addition, YM-58343 treatment also attenuated the development of interstitial fibrosis by ~86% relative to vehicle (p< 0.05).

Conclusions: Taken together, these data suggest that Orai1 activity is enhanced by renal ischemia and that Orai1-mediated Ca^{2+}signaling increases Th17 activity and AKI-CKD progression.

Hepcidin Mitigates Sepsis-Induced AKI through Its Antibacterial and Anti-Inflammatory Effects

Yogesh M. Scindia,[1] Ewa U. Mandziak,[2] Joseph T. Leeds,[2] Valentina Loi,[3] Sundararaman Swaminathan.[2] *[1]Univerisity of Virginia, Charlottesville, VA; [2]University of Virginia, Charlottesville, VA; [3]AO Brotzu Cagliari, Cagliari, Italy.*

Background: Sepsis-induced acute kidney injury (AKI) is a common cause of in-hospital morbidity and mortality. Sepsis induces hepcidin-dependent iron sequestration to limit iron availability to pathogens. Hepcidin can limit inflammation. Therefore, we investigated if hepcidin pretreatment would mitigate endotoxin- and peritonitis-induced systemic pathology and AKI.

Methods: C57BL/6 mice were treated with saline or 50 µg hepcidin, 24 hours before LPS injection (*Escherichia coli O111:B4*, 6.5 mg/kg) or subjected to Cecal ligation and puncture (CLP) to induce peritonitis. Some mice underwent splenectomy (SPLX) and were challenged with LPS, with and without Hepcidin. Mice undergoing CLP received another dose of hepcidin, 2 hours prior to CLP. Renal injury and inflammatory markers were assessed. After CLP, mice were euthanized at different time points. Mouse macrophages (J774A) were treated with SiRNA to H-ferritin or scramble, treated with 1µg/mL Hepcidin for 4 hours, and cultured with 1 ng/mL LPS for 6 hours.

Results: LPS-induced AKI (plasma creatinine, renal NGAL and KIM-1 gene expression) were significantly reduced by hepcidin pretreatment. Hepcidin also reduced LPS-induced renal Cox-2, loss in PGC1a and enzymatic activity of cytochrome c oxidase. Hepcidin induced higher splenic H-ferritin, reduced splenocytes apoptosis, and inflammation. SPLX reduced LPS-induced AKI, and hepcidin did not provide additional protection in these settings. In CLP model, Hepcidin significantly reduced bacteremia, AKI, and mortality (colony forming units in the blood, renal NGAL and KIM-1 gene expression) and increased survival (up to 6 days in hepcidin-treated mice compared to approximately 24 hrs in PBS-treated mice). Compared to scramble siRNA, H-ferritin-deficient macrophages treated with Hepcidin secreted more LPS-induced IL-6.

Conclusions: Our results demonstrate a protective role of hepcidin in endotoxin- and peritonitis-induced pathologies and AKI, exerted through H-ferritin-dependent anti-inflammatory effects, and antibacterial property. Splenectomy protects against LPS-induced AKI.

TLR9 Mediated IL-17A Responses Are Associated with the Pathogenesis of Polymicrobial Septic AKI

Yoshitaka Naito,[2] Takayuki Tsuji,[1] Tomoyuki Fujikura,[2] Naro Ohashi,[2] Akihiko Kato,[3] Hideo Yasuda.[2] *[1]NIDDK/NIH, Bethesda, MD; [2]Hamamatsu University School of Medicine, Hamamatsu, Japan; [3]Hamamatsu University Hospital, Hamamatsu, Japan.*

Background: Toll-like receptor 9 (TLR9) contributes to the development of polymicrobial septic AKI. Recently, interleukin (IL) -17A has been shown to play a pathogenic role in septic AKI. According to the previous study, TLR 9 mediated IL-17A responses were associated with the pathogenesis of many conditions, including murine hypersensitivity pneumonitis, mycobacteria-elicited pulmonary granuloma, and neurotoxicity induced by microglia. However, its role in septic AKI remains unclear. We hypothesized that TLR9-mediated IL-17A responses are associated with the pathogenesis of polymicrobial septic AKI.

Methods: Tlr9-knockout (Tlr9KO) mice and IL-17A knockout mice (IL-17AKO) and both wild type (WT) littermates were subjected to cecal ligation and puncture (CLP) operation to induce polymicrobial sepsis. We performed functional and pathological assessment of the kidney and splenic apoptosis evaluated by immunohistochemistry of caspase 3 at 18 hours after CLP. Survival were assessed for the following 7 days after CLP. We assessed IL-17A consentrations in plasma and ascites from Tlr9KO and WT mice at 3,

6, 18 hours after CLP by enzyme-linked immunosorbent assay (ELISA) also. Furthermore, we examined IL-17A production of immune cells in spleen by flow cytometry.

Results: Although WT mice developed kidney injury at 18 hours after CLP, Tlr9KO and IL-17AKO mice exhibited decreased serum creatinine levels, expression of Kidney Injury Molecule-1 in proximal tubular cells, and improved tubular damage score in cortex. Splenic apoptosis were decreased at 18 hours after CLP in both Tlr9KO and IL-17AKO mice compared with WT mice. Mortalities were less in both Tlr9KO and IL-17AKO mice compared with WT mice after CLP. Furthermore, IL-17 A levels of both plasma and ascites were significantly higher in WT mice than Tlr9KO mice at 18 hours after CLP, and IL-17A levels in ascites tended to increase in earlier phase than in plasma. IL-17A production of splenic γδ T cells was less in Tlr9KO mice compared to WT mice at 3 hours after CLP.

Conclusions: We showed that Tlr9KO and IL-17AKO could protect against polymicrobial septic AKI, and Tlr9KO mice decreased IL-17A secretion in plasma, ascites, and splenic γδ T cells. These findings suggest that TLR9 mediate IL-17A production, and this pathway is associated with the pathogenesis of septic AKI.

Renal Ischemia Resistant Rat Strains and Ischemic Preconditioned (IPC) Kidneys Share Upregulated Mitochondria Proteins

Alexander L. Kolb,[1] Jason A. Collett,[1] Frank Witzmann,[1] Uma Aryal,[3] David P. Basile,[1] Robert L. Bacallao.[1,2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Medicine, Richard Roudebush VAMC, Indianapolis, IN; [3]Bindley Bioscience Center, Purdue University, West Lafayette, IN.*

Background: Brown-Norway (BN) rats are resistant to renal ischemia reperfusion injury as compared to Sprague-Dawley (SD) or Dahl Salt Sensitive (DS) rats. This resistance is linked to 3 chromosomes in BN rats. Also IPC kidney mitochondria have significant changes in their proteome. The study goal was to identify mitochondria proteins that are over-expressed in both IPC and genetically resistant tissues. Quantitative proteomic analysis of mitochondria was performed in IPC kidneys and compared to sham conditioned kidneys. A second set of comparisons was performed on kidney cortex mitochondria isolated from BN rats and DS rats.

Methods: Mitochondria were isolated from renal cortex of BN rats, DS rats, IPC and IPC sham treated kidneys of SD rats. 4 animals were used for each group with 3 replicant samples. Mitochondria proteomes were identifed using label free quantitative proteomic analysis using LC-MS/MS. LS-MS/MS data were collected in Thermo Q Exactive Orbitrap High Field (HF) MS coupled to Dionex UltiMate 3000 RP HPLC system. Raw data were analyzed using MaxQuant and Andromeda search engines. Highest stringency conditions were used in protein identification in all searches. Proteins were identified by searching against the rat protein sequences database from Uniprot. Relative protein quantitation was performed using the MaxQuant LQF algorithm.

Results: Greater than 1300 proteins were identified in the sham versus IPC mitochondria, 571 proteins are significantly overexpressed in the IPC group (p values <0.05). In the proteomic comparison between BN and DS rats, 1184 proteins were identified with high confidence. Of the 1184 proteins 770 proteins were expressed 1.8-fold or greater in BN versus SS rats (p values <0.05). Comparing the two groups revealed 78 common proteins. Ingenuity pathway analysis revealed enhanced pathways that include response to drug, negative regulation of apoptosis, protein transport, metabolic processes and redox homeostasis.

Conclusions: 78 endogenous mitochondria proteins are significantly overexpressed in mitochondria from kidney cells in an ischemic preconditioned state or isolated from a rat strain with genetic resistance to ischemia. These proteins represent important targets for pharmacologic exploration to develop preventative agents for acute kidney injury.

Transcriptional Trajectories of Human Kidney Disease Progression

Pietro E. Cippa, Andrew P. McMahon. McMahon Lab *University of Southern California, Los Angeles, CA.*

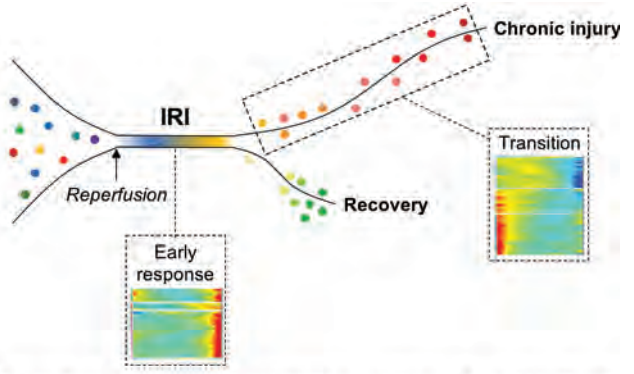
Background: The molecular understanding of the transcriptional program determining the progression from acute to chronic kidney injury in humans is limited.

Methods: We performed RNAseq-based transcriptional profiling on protocol biopsies obtained from 42 kidney transplant recipients at 4 time points (before and after reperfusion, 3 and 12 months after transplantation) and we applied machine learning techniques to identify and group patient responses over time. Our previously described mouse model of ischemia/reperfusion injury was used for data validation.

Results: In the first hours after reperfusion all patients underwent a similar response characterized by a biphasic transcriptional program under the control of immediate early response genes. In the following months we identified two main transcriptional trajectories corresponding to recovery and to a sustained injury response leading to fibrosis and renal function deterioration. The molecular map generated by this computational approach delineated the transcriptional program determining the transition from acute to chronic kidney injury: genes associated with mitochondrial dysfunction, kidney injury/repair and innate immunity were followed by genes related to fibrosis and adaptive immunity. Moreover, the computational model highlighted early markers of kidney disease progression (e.g. EP300). The characterization of a similar process in mice showed evidence for substantial similarities in the response to kidney injury across species and expanded the relevance of the findings beyond kidney transplantation.

Conclusions: The integration of multiple transcriptomes from serial biopsies in advanced computational algorithms overcame the analytical hurdles related to interindividual variability and identified shared transcriptional elements of kidney disease progression. For the first time, this new concept allowed an unsupervised analysis of the molecular mechanisms of kidney disease in a clinical setting.

Funding: Private Foundation Support, Government Support - Non-U.S.



Conceptual summary. Computational analysis of transcriptional responses in kidney tissue from renal transplant patients identified common early injury outcome with divergent longer-term outcomes: recovery versus the initiation of a chronic injury signature.

SA-OR021

Decreased KAT5 Expression Impairs DNA Repair and Induces DNA Methylation in Diabetic Nephropathy Podocytes

Akihito Hishikawa, Kaori Hayashi, Norifumi Yoshimoto, Hiroshi Itoh. *Division of Nephrology, Endocrinology and Metabolism, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan.*

Background: Podocytes are terminally differentiated cells with a very low capacity of regeneration. Therefore, the mechanism of DNA damage repair in podocytes is expected to be highly significant. We have recently reported that podocyte specific deletion of DNA double strand break (DSB) repair factor KAT5 causes glomerulosclerosis in mice (KAT5 KO mice) (ASN Kidney week 2017). Here we investigated the role of KAT5 in the pathogenesis of diabetic nephropathy (DN).

Methods: We generated tamoxifen-inducible podocyte-specific KAT5 knockout mice (iKO) to investigate the physiological role of KAT5 excluding its role in the maturation of podocytes. Expression of KAT5 was examined in streptozotocin (STZ)-induced DN mice model and the effect of KAT5 gene transfer was evaluated. We performed in vitro studies using cultured human podocytes to examine the mechanism of KAT5-associated epigenetic changes.

Results: KAT5 iKO mice showed massive albuminuria (WT 40±9 mg/gCr, iKO 2455±153 mg/gCr, p<0.01) and FSGS lesion with foot process effacement of podocytes after 12 weeks induction of KAT5 knockdown, similar to the KAT5 KO mice. Nephrin expression was significantly decreased, as shown by both isolated podocytes and glomerular immunofluorescence staining. Interestingly, thickening of glomerular basement membrane was observed in some glomeruli of KAT5 iKO mice just like in DN, which was observed especially in the glomeruli near the corticomedullary junction. Podocyte KAT5 expression was decreased in DN mice, accompanied by increased DNA DSBs and DNA methylation and restoration of decreased KAT5 by gene transfer attenuated albuminuria and glomerulosclerosis. In cultured human podocytes, knockdown of KAT5 increased DNA DSBs and decreased nephrin expression with increased DNA methylation of the nephrin promoter region. High-glucose treatment (30mM) induced KAT5 reduction and overexpression of KAT5 increased nephrin expression with decreased DNA DSBs and decreased DNA methylation at the same nephrin promoter region, indicating that KAT5-mediated DNA repair may be related to the DNA methylation status.

Conclusions: KAT5-mediated DNA repair is essential for podocyte maintenance and has relation to the changes in DNA methylation status in DN. KAT5 may be a good therapeutic target for DN.

SA-OR022

Selective Deletion of EGFR in Podocytes Protects against Nephropathy in Type II Diabetes

Yan Li,[2,1] Kensuke Sasaki,[2] Yinqiu Wang,[2] Aolei Niu,[2] Suwan Wang,[2] Xiaofeng Fan,[2] Jianchun Chen,[2] Ming-Zhi Zhang,[2] Raymond C. Harris.[2] *[1]Shanghai Ninth People's Hospital, Shanghai JiaoTong University, Shanghai, China; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: Previous studies by us and others have indicated that renal epidermal growth factor receptor (EGFR) signaling is activated in DN and EGFR inhibition protects against DN. In the present study, we examined whether selective EGFR deletion in podocytes affected development of DN in type II diabetes.

Methods: *db/db* mice with selective podocyte EGFR deletion (podocin-Cre; $EGFR^{f/f}$; *db/db*: $\mathbf{EGFR^{podKO}}$**;*db/db***) and an accelerated type II diabetic model ($eNOS^{-/-}$; *db/db* mice) with selective podocyte EGFR deletion (podocin-Cre; $EGFR^{f/f}$; $eNOS^{-/-}$; *db/db*: $\mathbf{EGFR^{podKO}}$**; $\mathbf{eNOS^{-/-}}$; *db/db***) were generated and used. Genotypes were confirmed before sacrifice. A mouse podocyte cell line was used for *in vitro* studies.

Results: Selective podocyte EGFR deletion was confirmed by reduced EGFR co-IF with WT1. Podocyte EGFR deletion had no effect on body weight and fasting blood sugar in either *db/db* or eNOS$^{-/-}$; *db/db* mice. However, podocyte EGFR deletion led to marked reduction in albuminuria in both *db/db* and eNOS$^{-/-}$; *db/db* mice [albumin vs. creatinine ratio (μg/mg): 175 ± 11 vs. 495 ± 16 in 40 week old *db/db* , $P < 0.01$; 2185 ± 175 vs. 3434 ± 418 in 20 week old eNOS$^{-/-}$; *db/db* mice, $P < 0.05$]. Glomerulosclerosis index was lower in EGFR^{podKO}; eNOS$^{-/-}$; *db/db* mice than in eNOS$^{-/-}$; *db/db* mice at 20 weeks. In eNOS$^{-/-}$; *db/db* mice, podocyte EGFR deletion produced less podocyte loss, as indicated by increased mRNA levels of podocin and higher podocyte number per glomerulus section (10.7 ± 0.5 vs. 7.0 ± 0.2, $P < 0.001$), in association with decreases in proinflammatory cytokine/chemokine levels, including iNOS, IRF5, IL-23, IL-1α, IL-1β, CCL-3, TNF-α and IL-6 as well as pro-fibrotic and fibrotic components, TGF-β1 and collagen I and IV. Both *in vivo* and in cultured podocytes exposed to high glucose, inhibition of podocyte EGFR signaling suppressed the mTOR/p70 S6K signaling pathway, leading to stimulation of a podocyte protective autophagic pathway, as indicated by increased beclin 1 and decreased rubicon, an inhibitor of beclin 1, and decreases in the autophagic substrate, p62.

Conclusions: These studies indicate that activation of a podocyte EGFR signaling pathway contributes to progression of diabetic nephropathy, at least in part due to activation of an EGFR/mTOR/p70 S6K pathway, leading to inhibition of podocyte autophagy and subsequent cell injury.

Exosome-Mediated miR-26a Treatment Attenuates Muscle Atrophy and Kidney Fibrosis in Diabetic Mice

Aiqing Zhang,[1,2] Janet D. Klein,[1] Xiaonan H. Wang.[1] *[1]Renal Medicine, Emory University, Atlanta, GA; [2]Dept of Pediatric Nephrology, 2nd affiliated hospital of Nanjing Medicial University, Nanjing, China.*

Background: The treatment of muscle wasting is well known to be accompanied by benefits in other organs. However, how the muscle communicates with these organs is less understood. Exosomes, natural carriers of many signal molecules including microRNA (miR), mediate organ to organ communication. We hypothesized that intramuscular injection of miR-26a would counteract both muscle wasting and renal fibrosis through exosome-mediated muscle-kidney crosstalk in diabetic mice.

Methods: We used an engineered exosome vector which contains an exosomal membrane protein gene - lysosomal-associated membrane protein 2b (Lamp2b) fused with kidney specific surface peptide [(KKEEE)^{3}K] for kidney targeting delivery. Exosome encapsulated miR-26a (Exo/miR26) were generated in cultured skeletal muscle satellite cells, collected from conditioned media, and injected into the tibialis anterior muscle of diabetic mice. Diabetes mellitus was induced by low dose STZ injection (5-days). A NanoSight instrument was used to quantify exosomes. MiR deep sequencing and qPCR were used to identify microRNA expression. The In-Vivo Xtreme camera system was used to detect exosomes *in vivo*.

Results: miR-26a was decreased in skeletal muscle and kidney of diabetic mice. Diabetic serum enhanced secretion of miR-26a exosomes from cultured skeletal satellite cells and HEK293 kidney cells. The delivery of exogenous Exo/miR26a into muscle increased the levels of miR-26a in skeletal muscle and kidney, as well as increasing muscle cross-sectional area and decreasing diabetes-induced upregulation of atrogin-1 and MuRF1. Interestingly, renal fibrosis lesions were partially depressed, and α-SMA, connective tissue growth factor (CTGF), fibronectin and collagen1α were decreased in diabetic kidney with intramuscular injection of Exo/miR-26a. Blood urea nitrogen was decreased in diabetic mice treated with Exo/miR26a. Using fluorescent dye labeled Exo/miR26a, we found that the fluorescence intensity in kidney was linearly correlated with skeletal muscle.

Conclusions: overexpression of miR-26a in muscle prevents diabetes-induced muscle loss and attenuates renal fibrosis via exosome-mediated muscle-kidney crosstalk. These results could provide new approaches for developing therapeutic strategies for kidney diseases with muscle wasting.

miR-379 Knockout Mice and CLASH Technique Reveal Fis1 as a Novel miR-379 Target Related to Diabetic Nephropathy

Mitsuo Kato,[1] Rama Natarajan.[2] *[1]City of Hope, Duarte, CA; [2]Beckman Research Institute of City of Hope, Duarte, CA.*

Background: We recently showed that microRNAs (miRNAs) in the miR-379 megacluster and the host noncoding RNA (lncMGC) are co-regulated by endoplasmic reticulum stress, are upregulated in kidneys of diabetic mice and promote features of early diabetic nephropathy (DN). Here we hypothesized that miR-379-mutant mice created by CRISPR-Cas9 editing (miR-379-knockout, KO) are valuable tools to examine the in vivo functions of the miR-379 cluster and miR-379 in DN. Furthermore, new miR-379 targets identified using miR-379KO mouse mesangial cells (MMC) and the CLASH technique (crosslinking, ligation, and sequencing of hybrids) can uncover new therapeutic targets for DN.

Methods: Cas9 nickase and two guide RNAs (gRNAs) were injected into mouse eggs to create miR-379KO mice. To identify new miR-379 targets, UV-crosslinked RNA-protein complexes from wild type (WT) and miR-379KO mouse mesangial cells (MMC) were sonicated, immunoprecipitated (IP) with Ago2 antibody and ligated. Hybrid RNAs were subjected to RNA sequencing (CLASH).

Results: Several founders identified by PCR were crossed with WT mice, and homozygous miR-379KO mice (harboring 36bp deletion in the miR-379 locus) were obtained. Multiple miR-379 hybrid sequences were identified by CLASH and RNA-seq. Fis-1 (mitochondrial fission) was confirmed as a bonafide miR-379 target by Ago2 IP qPCR and Fis1 3'UTR reporter assays. siRNA-mediated Fis1 knockdown reduced key mitochondrial signals in MC, suggesting Fis1 is a new player in mitochondrial dysfunction in DN. Notably, miR-379-KO mice were protected from early features of DN, and Fis1 expression was decreased in kidneys of diabetic WT but not diabetic miR-379KO mice.

Conclusions: Combination of miR-379-mutant mice created by CRISPR-Cas9 editing and CLASH technique identified Fis1 as a new miR-379 target with key mitochondrial functions in the diabetic kidney. Fis1 could be a novel therapeutic target for DN.

Mice with Drp1-S600 Knockin Mutation Exhibit Reduced Mitochondrial Fission and Attenuation of Diabetic Nephropathy

Daniel L. Galvan,[1] Jianyin Long,[3] Nathanael Green,[4] Jamie Lin,[3] Benny B. Chang,[4] Farhad R. Danesh.[2] *[1]University of Texas MD Anderson Cancer Center, Houston, TX; [2]UT MD Anderson, Houston, TX; [3]The University of Texas MD Anderson Cancer Center, Houston, TX; [4]Baylor College of Medicine, Houston, TX.*

Background: Mitochondrial fission has been linked to the pathogenesis of diabetic nephropathy (DN), but how this process affects progression of DN *in vivo* remains elusive. We have previously reported the role Dynamin-related protein1 (Drp1), a key component of mitochondrial fission, and its phosphorylation at serine 600 on mitochondrial dynamics in podocytes *in vitro*. We now report the *in vivo* consequences of S600 phosphorylation in progression of DN in a mouse model of Type 2 diabetes.

Methods: We generated a S600 phospho-dead Drp1 knockin mouse on the C57BL/6 background *via* point mutation of serine 600 to alanine. Following C57Bl6/J ES cell electroporation, selection, and screening of colonies by southern blot and PCR analysis, we identified several positive clones and generated chimeric S600A mice. We next generated heterozygous S600$^{+/A}$ and homozygous S600$^{A/A}$ mice. We crossed the Drp1-S600 mice with *Lepr$^{db/+}$* mice, a well-established model of Type 2 diabetes, to generate homozygous diabetic Drp1-S600$^{A/A}$ mice (Lepr$^{db/db}$; Drp1-S600$^{A/A}$).

Results: Diabetic Drp1-S600 mutant mice were followed over the course of 16 weeks. Diabetic mice did not exhibit any differences in their body weight or blood glucose levels. In contrast, as compared to diabetic *wild-type*, both hetero- and homozygous diabetic Drp1-S600A mice exhibited significantly reduced albuminuria. Histological analysis by Periodic-Schiff's Acid (PAS) stain and quantification of glomerular area positive for PAS stain, revealed attenuated mesangial matrix expansion in glomeruli of db/db;Drp1-S600$^{A/+;A/A}$ compared to controls. Transmission electron micrographs (TEM) also revealed reduced podocyte foot process effacement and reduced glomerular basement membrane thickening in diabetic Drp1-S600$^{A/+;A/A}$ compared to diabetic controls. TEM of podocytes also revealed elongated mitochondria and increased aspect ratio in mitochondria from *db/db*;Drp1-S600A mice compared to *wild-type* diabetic mice. Our results are consistent with preservation of mitochondrial morphology and structure in S600 mutant mice.

Conclusions: These findings demonstrate that a single phosphorylation site in Drp1 regulate mitochondrial fission and progression of DN and elucidate a potential role for targeting Drp1-S600 phosphorylation in DN.

Inhibition of Complement C5a/C5a Receptor 1 Decreases Renal Injury in Diabetic Kidney Disease via Metabolic Reprogramming

Melinda T. Coughlan,[1] Sih Min Tan,[1] Mark Ziemann,[1] Trent M. Woodruff,[2] Mark E. Cooper.[1] Department of Diabetes *[1]Monash University, Melbourne, VIC, Australia; [2]The University of Queensland, St. Lucia, QLD, Australia.*

Background: The complement system plays a central role in the activation of innate immunity, inflammation and tissue remodelling. The complement activation fragment C5a is a potent pro-inflammatory effector molecule. We have shown complement activation in patients with diabetes including renal deposition of the canonical C5a receptor C5aR1 and C5a/C5aR1 activation in experimental diabetes. This study aimed to determine whether genetic deletion or pharmacological inhibition of C5aR1 could confer renoprotection in diabetes.

Methods: Streptozotocin (STZ)-induced diabetic C57BL/6 mice were treated with the highly selective C5aR1 antagonist, PMX-53 (2mg/kg/day) in drinking water for 24 weeks (n=10). C5aR1 deficient mice (*C5ar1-/-*) and their wild type littermates were rendered diabetic with STZ and followed for 24 weeks (n=10). Kidney injury was assessed by urinary albumin excretion and glomerulosclerosis (GSI). Immunohistochemistry for Collagen IV, FoxP3+ regulatory T cells and F4/80+ cells was performed. Transcriptomics of renal cortex was performed by RNA-sequencing using the Illumina platform and pathway analyses using Gene Set Enrichment Analysis.

Results: Diabetic *C5ar1-/-* mice showed protection against renal injury with decreased albumin excretion. Treatment of diabetic mice with PMX-53 led to a reduction in proteinuria, inhibition of glomerular injury and fibrosis and resolution of inflammation via a decrease in F4/80+ macrophages and activation of FoxP3+ regulatory T cells. Transcriptomic analyses showed that the diabetes gene signature was reversed by PMX-53. Pathways that were reduced by PMX-53 in diabetic mice were related to mitochondrial function and lipid

metabolism. The top differential gene downregulated in the diabetic kidney was acyl-CoA dehydrogenase 10 *(Acad-10)*, which participates in the beta-oxidation of fatty acids in mitochondria. Blockade of C5aR signalling in diabetic mice restored *Acad-10* expression.

Conclusions: Our findings demonstrate that genetic or pharmacological disruption of C5aR1 is renoprotective in diabetes via restoration of pathways involved in fatty acid oxidation and by suppressing the pathogenic inflammatory response. This study indicates that targeting the C5a/C5aR1 pathway may provide a substantial therapeutic benefit for this devastating complication of diabetes.

Klotho Ameliorates Diabetic Nephropathy via AMPK-PGC1α Mediated Renal Mitochondrial Protection

Jinho Lee, Tsogbadrakh B. Bodokhsuren, Sohyun Yun, Hyunjin Ryu, Eunjeong Kang, Minjung Kang, Curie Ahn, Kook-Hwan Oh. *Seoul National University Hospital, Seoul, Republic of Korea.*

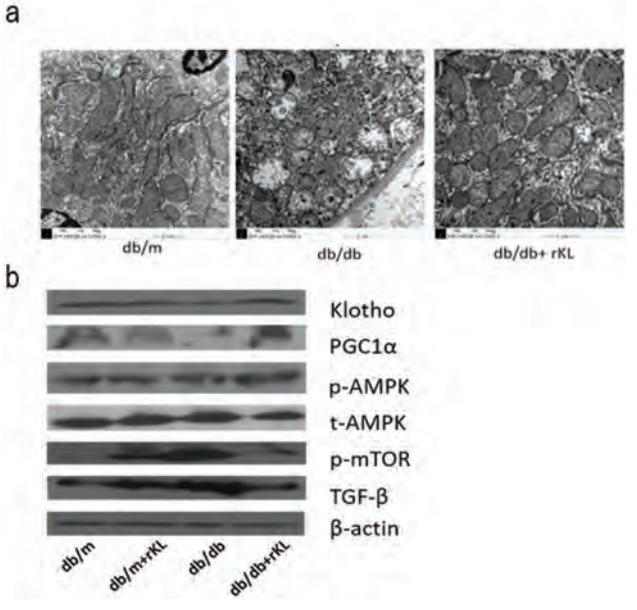
Background: Diabetic nephropathy(DN) is associated with renal mitochondrial injury, and decreased renal klotho. Klotho is known as ageing suppressor, and mitochondrial dysfunction is the hallmark of ageing. Peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC1α) is a master regulator of mitochondrial biogenesis, and adenosine monophosphate-activated protein kinase(AMPK) is known as a guardian of mitochondria. Here, we report that recombinant klotho protein (rKL) is protective against DN in db/db mice by PGC1α-AMPK mediated mitochondrial recovery in the kidney.

Methods: We injected rKL into db/db and db/m mice for 8 weeks, and collected the serum and the kidney. Also, we treated rKL to various renal tubular cells *in vitro*, with or without 30mM high glucose (HG) exposed.

Results: rKL-treated db/db mice showed recovered renal proximal tubular mitochondria, as well as significantly reduced renal ROS and serum glucose, compared to vehicle-treated db/db mice. Also, rKL increased renal p-AMPK, PGC1α, and down-regulated mTOR/TGF-β in db/db mice. Moreover, we confirmed that rKL treatment ameliorated HG-mediated cellular damage, with an increase of PGC1α-AMPK induced mitochondrial recovery in cultured renal tubular cells.

Conclusions: Our data suggest a mitochondrial protective role of klotho against diabetic kidney disease by inducing AMPK-PGC1α expression.

Funding: Government Support - Non-U.S.



a) renal mitochondiral recovery by rKL in db/db mice, and b) rKL increased renal p-AMPK and PGC1α expression in db/db mice.

Effects of Sodium Glucose Cotransporter 2 Deletion on Bone and Mineral Metabolism

Claire Gerber,[1] Valentin David,[3] Susan E. Quaggin,[1] Aline Martin,[1] Tamara Isakova.[2] *[1]Northwestern University, Chicago, IL; [2]Feinberg School of Medicine, Northwestern University, Chicago, IL; [3]Northwestern University - Feinberg School of Medicine, Chicago, IL.*

Background: Type 2 diabetes mellitus (T2DM) and chronic kidney disease are associated with an increased risk of developing bone and mineral metabolism abnormalities. A new class of glucose-lowering agents, sodium-glucose cotransporter 2 (SGLT2) inhibitors, promotes urinary glucose excretion and improves renal and cardiovascular outcomes in patients with T2DM. However, SGLT2 inhibitors are associated with increased risk of bone fractures. Because loss of SGLT2 function may decreases urinary phosphate, we hypothesize that inhibition of SGLT2 induces mineral metabolism alterations that could contribute to increased bone fragility.

Methods: Slc5a2 nonsense mutation in Sweet Pee (SP) mice results in total loss of SGLT2 function in proximal tubules. To understand the effects of loss of SGLT2 function on mineral metabolism, urine and serum was collected from fasted wild type (WT) and SP mice. Levels of fractional excretion of calcium and phosphate; serum phosphate, calcium, PTH, $1,25(OH)_2D$, and FGF23 were evaluated at 15 and 25 weeks. To determine the longitudinal impact of loss of SGLT2 function on bone metabolism, bone architecture, remodeling, and mineralization was assessed in SP mice and WT mice at 15 and 25 weeks of age.

Results: At 25 weeks, SP mice showed significantly decreased body weight compared to WT mice (21.6±3.8 vs 25.1±2.9 g, $p<0.05$). Consistently, femoral length was significantly shorter in SP mice compared to WT mice (14.1±0.4 vs 14.5±0.2 mm, $p<0.05$). Overall renal function was not impaired in SP mice compared to WT mice (blood urea nitrogen: 18±4 vs 21±5 mg/dL, NS). Fasted SP mice did not show modification of fractional excretion of calcium. Serum calcium, PTH, and $1,25(OH)_2D$ levels were similar between WT and SP mice at 15 and 25 weeks. Fractional excretion of phosphate was significantly higher at 25 weeks in SP mice compared to WT (5.5±2.0 vs 2.5±1.9 %, $p<0.05$), despite unchanged levels of FGF23. SP mice had reduced cortical bone mineral density, compared to WT mice at 25 weeks (1240±16 vs 1264±14 mg/cm^3, $p<0.05$).

Conclusions: These results suggest that loss of SGLT2 function in the absence of T2DM may contribute to bone fragility. Future studies are required to determine how loss of SGLT2 function impacts bone fragility in T2DM.

Unravelling Reno-Protective Effects of SGLT2 Inhibition in Human Proximal Tubular Cells

Markus Pirklbauer, Ramona Schupart, Lisa Fuchs, Petra Staudinger, Ulrike Corazza, Sebastian Sallaberger, Johannes Leierer, Gert J. Mayer, Herbert Schramek. *Medical University Innsbruck, Innsbruck, Austria.*

Background: Large clinical trials recently demonstrated that SGLT2 inhibitors (SGLT2i) slow the progression of kidney function decline in type 2 diabetes independently of their glucose lowering effects. However, the underlying molecular mechanisms of these beneficial renal effects are unknown. As the proximal tubule (PT) is supposed to play a role as initiator and contributor in early pathogenesis of diabetic kidney disease, we conducted a systematic molecular approach to study the effects of SGLT2i on gene expression in human PT cells. Utilizing two SGLT2i, namely empagliflocin and canagliflocin, we investigated their effects on differential gene expression in the presence and absence of TGF-ß1, a well established pro-fibrotic ligand.

Methods: human proximal tubular cell culture (HK-2 and RPTEC/TERT1), microarray hybridization, pathway enrichment analysis, real-time PCR, ELISA

Results: Microarray hybridization analysis identified 94 genes that were both upregulated by TGF-ß1 and downregulated by two SGLT2i in HK-2 and RPTEC/TERT1 cells (n=2). Functional annotation of these genes revealed 152 involved pathways in 7 annotation clusters (EASE score < 0,05). Within the top-ranked clusters (enrichment score > 3), annotations for extracellular matrix organisation ($p=6,4x10^{-7}$) and extracellular space ($p=2,8x10^{-6}$) showed the highest significance. Differential gene expression of 3 annotated genes of interest within this pathway, namely thrombospondin 1 (THBS1), tenascin C (TNC) and platelet derived growth factor subunit B (PDGFB), was verified on mRNA level in HK-2 and RPTEC/TERT1 cells: While TGF-ß1 significantly induced mRNA expression of THBS1 (5-fold), TNC (8-fold) and PDGFB (4,2-fold), SGLT2i significantly downregulated basal mRNA expression of THBS1 (0,2-fold), TNC (0,5-fold) and PDGFB (0,5-fold). Administration of SGLT2i in the presence of TGF-ß1 resulted in a significant inhibition of TGF-ß1-induced THBS1 and TNC mRNA expression by approximately 50 % (n=4; $p<0,05$). TGF-ß1-induced PDGFB protein expression was almost completely blocked in the presence of SGLT2i (n=6; $p<0,001$).

Conclusions: We conclude that SGLT2i block basal and TGF-ß1-induced expression of key mediators of renal fibrosis and kidney disease progression, namely of THBS1, TNC and PDGFB in two independent human PT cell lines.

SA-OR030

Dysregulated Translation and Differential p53 Isoform Expression in the Kidney during Diabetes

Bernhard Maier, Takashi Hato, Timothy A. Sutton, Pierre C. Dagher. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Over 30 million people in the US have diabetes and it remains the leading cause of ESRD. Critically missing from investigation into the pathogenesis of diabetic nephropathy (DN) is the detailed examination of translation, the fundamental process linking gene expression to the synthesis of functional proteins. In this study we use a mouse model of diabetes to examine differential and sequential changes in global translation as well as expression of p53, an important regulator of transcription and translation during cell stress, in the kidney.

Methods: Transcriptional (RNA-seq) and translational (polysome, Ribo-seq) profiling are used to study changes in the translatome during progression of diabetes in the kidney of db/db (B6.BKS(D)-Lepr ^{db}/J) mice. p53 isoform expression is examined by biochemical, proteomic, and translational profiling in db/db mice and nondiabetic background (WT) mice.

Results: Transcriptional profiling reveals that pathways regulating translation are the most differentially altered in the kidney of db/db mice as the diabetic state progresses from 8 weeks to 12 weeks old. Significant changes are observed broadly across ribosomal proteins and regulators of both ribosomal biogenesis and translation. Direct analysis of translation by polysome profiling demonstrates translational activity is increased by 50% in 12 week-old compared to 8 week-old db/db mice. In addition, Ribo-seq confirms the increase in translational activity in the kidney from db/db mice as compared to WT mice. Further analysis of Ribo-seq data reveals four general variations of ribosomal kinetics in the kidney of db/db mice as compared to WT mice. Given the relationship between cell stress and altered translation, we examined p53 isoform expression in the kidney of db/db mice. Immunoblotting reveals the presence of a ~44kDa band consistent with ΔNp53, a translationally-regulated (IRES-mediated) p53 isoform modulating aging and metabolism, in the kidney of db/db mice that is absent in WT mice. Proteomic analysis and ribosome footprint profiling (Ribo-seq), an indispensable method to examine IRES-mediated generation of proteins, further substantiate the differential generation of ΔNp53 in the kidney of db/db mice.

Conclusions: Dysregulated translation in the diabetic state is associated with ΔNp53 expression that can in turn alter translation and contribute to DN.

The Renal Na-Cl and Na-K-2Cl Cotransporters Are Increased in Urinary Exosomes of Patients with Severe Preeclampsia

Elba O. Medina,[1] L. M. Perez-Navarro,[1] Jesús C. Briones,[1] Ivonne Hurtado,[2] Fabiola Gallardo,[2] Rafael Valdez-Ortiz,[1] Lorena L. Rojas,[2] Gerardo Gamba.[2,3]
[1]Hospital General de México Dr. Eduardo Liceaga, México, Mexico; [2]INCMNSZ, Mexico, Mexico; [3]IIB, UNAM, Mexico City, Mexico.

Background: Arterial hypertension (AH) in preeclampsia (PE) is in part due to increased sodium reabsorption in the kidney. One of the major pathways for salt reabsorption is the Na-Cl cotransporter (NCC), whose expression and activity is modulated by female hormones (AJP Renal, 2015). Here we assessed the presence of NCC and NKCC2 in urinary exosomes of women with PE as compared with women with healthy pregnant (HP).

Methods: We included ten women diagnosed with severe PE (ACOG 2013; SBP ≥160mmHg or DBP ≥ 110mmHg, protein/creatinine ratio > than 0.3mg/dl), which were matched with a HP patients by age and gestation weeks. The urine sample was taken at the time of detection of arterial hypertension with criteria of severity. Urinary exosomes were used for Western Blot analysis for total and phosphorylated NCC, NKCC2 and the kinase SPAK. Serum and urinary electrolytes were measured.

Results: Mean age (years), gestation (weeks) and mean blood pressure (mmHg) were 28 ± 4.6, 36 ± 3.7 and 123 ± 11 for PE group and 25 ± 6.7, 37 ± 3.9 and 83 ± 8.5 in HP, respectively. A remarkable increase in the expression of NCC was found in PE group vs HP, 3.0 ± 0.77 vs 1.0 ± 0.7321 ($p<0.01$, Fig 1). There was no difference in the expression of NKCC2, but a significant increase in the phosphorylated form was observed in PE group (2.56 ± 1.11 *vs* 1.00 ± 0.15, p=0.015, Fig. 1). Additionally, increase in the expression and activation of SPAK/OSR1 were observed in the PE group. Serum K^+ was similar between PE and HP groups (p=NS).

Conclusions: Our data revealed increased expression/activation of NCC and NKCC2 in PE, suggesting the participation of these cotransporters in the development of AH. The increased phosphorylation of SPAK/OSR1 suggests that these kinases are responsible for NCC and NKCC2 activation.

Funding: Government Support - Non-U.S.

SA-OR032

Intense Renal Sodium Retention in Healthy Individuals Subjected to a Potassium Deprived Diet

Andrew Kowalski,[1] Daniel Batlle.[2] Northwestern University Feinberg School of Medicine *[1]Northwestern University, Lombard, IL; [2]Northwestern University Feinberg Medical School, Chicago, IL.*

Background: Diets poor in potassium (K) have been associated with hypertension, cardiovascular disease and all-cause mortality. Our study aims to quantify sodium (Na) balance in the setting of total dietary potassium deprivation of brief duration while keeping dietary sodium constant.

Methods: 10 male healthy volunteers were studied in the clinical research unit while on a strict calorie and electrolyte balanced liquid diet for a 10 day control period followed by a 5 day study period with total dietary K deprivation. The Na intake was kept constant throughout the entire study period (1.8 mEq/KBW) and the intake of K was reduced from 1.5 mEq/KBW to 0 mEq/KBW. Body weights, systolic and diastolic blood pressure (SBP, DBP), serum and 24 hour urine electrolytes were collected daily.

Results: At the end of the control period, urinary K was 81 ± 8.6 mEq/24hrs and fell to 16 ± 1.68 mEq/24Hr (p=0.0006) by day 5 of the K deprived diet. After 5 days on a K deprived diet the cumulative K deficit was -132 ±10 mEq with a fall in plasma K from 4.54 ±0.15 to 3.68 ±0.05 mEq/dL (p=0.0016) by the end of the study period. Urinary Na excretion fell on day one on the K deprived diet, and by day 5 renal Na retention resulted in a positive Na balance of 507 ± 3.8 mEq/L. Bodyweight did not significantly increase during the initial 5 days of the study diet (from 91.6 ± 5.2kg to 91.8 ± 5.3kg; p=0.71). SBP at the end of 5 day increased slightly, but not significantly from 111.2 ± 2 .58 mmHg to 115.49 ± 2.94 mmHg; p=0.083, and DBP decreased but not significantly from 72.6 ± 1.6 mmHg to 71.3 ± 2.4mmHg; p=0.50. There was a marked fall in hematocrit by day 5 with a fall from 45.6 ± 0.53% to 42 ± 0.44% (p=0.01). From the change in hematocrit and body weight plasma volume was estimated to have increased by 192mL (from 3483 ± 379 mL to 3675 ± 409 mL; p=0.005) over the 5 day period.

Conclusions: This study shows that total dietary K deprivation is a potent stimulus for the kidney to rapidly retain Na over a very short period of time. Even more striking was the observed magnitude of the positive Na balance of 507 mEq/L with only a small increase in plasma volume along with no significant increase in body weight or blood pressure. This observation supports recent evidence of a large Na reservoir with the ability to store significant amounts of Na, thus limiting its impact on body weight and blood pressure.

Sodium Concentration in Tissues of Dialysis Patients

Elena Qirjazi,[1,2] Alireza Akbari,[3,2] Timothy J. Scholl,[2,3] Christopher W. McIntyre.[4,2]
[1]Nephrology, Western University, London, ON, Canada; [2]Medical Biophysics, Western University, London, ON, Canada; [3]Robarts Research Institute, Western University, London, ON, Canada; [4]London Health Sciences Centre, London, ON, Canada.

Background: Dialysis patients are unable to fully remove sodium (^{23}Na). Thus, ^{23}Na is buffered in the skin, muscle and skeleton (osmotically inactive, but not biologically inert). We measured ^{23}Na content in these reservoirs using novel ^{23}Na MRI, in dialysis patients and healthy controls.

Methods: We undertook a pilot cross-sectional study of 26 subjects (10 controls and 16 dialysis - 9 peritoneal dialysis and 7 hemodialysis - patients). Subjects participated in a study session, which included collection of baseline information, bloodwork and a ^{23}Na MRI study using a multinuclear-capable 3.0T MRI (Discovery MR750, General Electric Healthcare). An axial proton T1-weighted fast-low-angle-shot sequence was acquired to delineate the anatomy; followed by a ^{23}Na MR image obtained with a custom-made lower-leg ^{23}Na coil and ^{23}Na-optimized pulse sequence (DA-3DPR). Maps of absolute tissue ^{23}Na concentration were generated using calibration vials of known ^{23}Na concentration included in the field-of-view. Four regions of interest were drawn, highlighting different tissues: 1) pre-tibial skin, 2) posterior leg skin (included because ^{23}Na distribution in skin was inhomogeneous), 3) soleus muscle, and 4) tibia.

Results: ^{23}Na concentrations in the different tissues for both groups are shown in Fig. 1. Dialysis patients had statistically significant higher ^{23}Na levels in all four regions ($p<0.05$). Dialysis modality and gender did not have a significant effect.

Conclusions: Dialysis patients have significantly higher ^{23}Na level in their skin, muscle and bone compared to healthy controls.

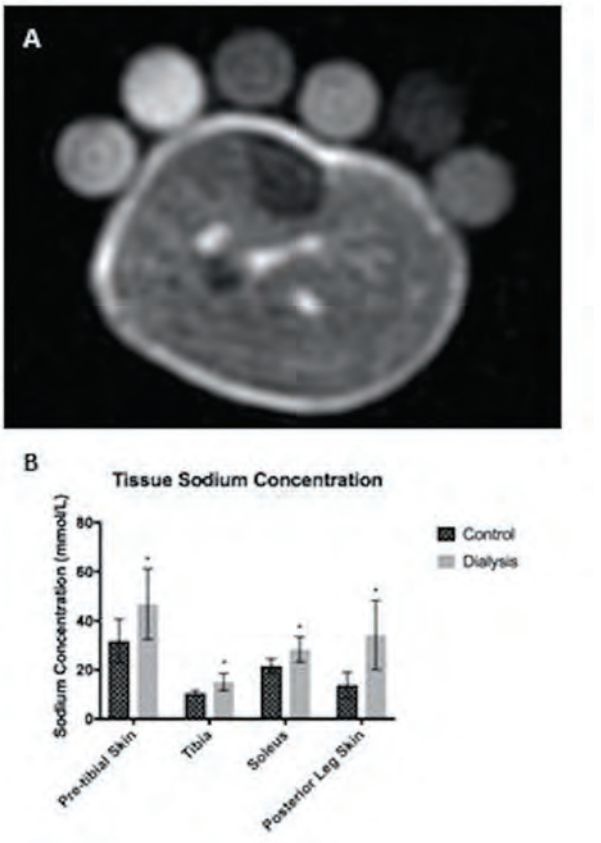

Fig. 1: A: ^{23}Na concentration map of the lower leg and calibration vials for a dialysis patient. B: ^{23}Na concentration in different tissues in dialysis patients and controls. Error bars = standard deviation. * = statistically significant differences ($p<0.05$)

SA-OR034

Incidence and Outcomes of Hyperkalemia in Solid Organ Transplant Recipients

Masaaki Yamada, Karthikeyan Meganathan, Taranpreet Kaur, Silvi Shah, Amit Govil, Charuhas V. Thakar. *University of Cincinnati, Cincinnati, OH.*

Background: Hyperkalemia is a serious complication resulting in a critical adverse event. Solid organ transplant (SOT) recipients can experience hyperkalemia contributed by both pathophysiological and medication related mechanisms. We examined incidence and outcomes of hyperkalemia in SOT recipients receiving acute care.

Methods: In a multi-center national sample (Cerner Health Facts database, 1/1/2000 to 6/30/2016), we examined patients with first hospitalization after transplant surgery or during the study period, whichever occurred earlier. Based on the peak potassium (K) level in mEq/L during the index admission, we classified K as normal ≤5.0, mild 5.1-5.5, moderate 5.6-6.0, and severe >6.0; hyperkalemia was defined as moderate or severe K groups. By logistic regression, we analyzed the effect of hyperkalemia and its severity on in-hospital mortality/hospice discharge and 30-day readmissions after adjustment for major confounders.

Results: Of the 14,684 SOT recipients, 65% kidney; 8% heart; 17% liver; and 10% other transplants. The cohort was 60% male with median age of 56 years (Q1, Q3, 45, 64) and median creatinine of 1.6 mg/dL (Q1, Q3, 1.2, 2.7). Overall, 16% experienced hyperkalemia (K levels: 69% normal; 15% mild; 8% moderate; 8% severe); frequency of hyperkalemia across organ type ranged between 13% and 17%. Overall in-hospital mortality was 2.6%; hyperkalemia group 6.1% vs. others 2.0% ($p<0.001$); mortality by K class was 1.6%, 3.7%, 5.4% and 6.8%, respectively ($p<0.001$). Hyperkalemia increased the risk of death [adjusted odds ratio (aOR), 3.1; 95% confidence interval (CI), 2.5-4.0]; compared to normal level, the severity of K class was associated with a graded increase in risk of death: mild K, aOR 2.2; 95% CI, 1.7-3.0; moderate K, aOR 3.4; 95% CI, 2.4-4.7; severe K, aOR 4.6; 95% CI, 3.3-6.2. There was a synergistic interaction between hyperkalemia and type of SOT, which was statistically significant ($p=0.025$). Hyperkalemia also increased risk of 30-day readmissions, 27% vs. others 18% ($p<0.001$); aOR 1.5; 95% CI, 1.4-1.7.

Conclusions: Hyperkalemia occurs in 1-in-6 SOT recipients during acute care; it is associated with a 3-fold increase in the risk of hospital mortality and 1.4-fold increase in the risk of readmission. Hyperkalemia prevention or treatment during acute care may improve patient survival in transplant recipients.

Urine Citrate Excretion Reliably and Non-Invasively Identifies Acid Retention in CKD 2 Patients without Metabolic Acidosis

Nimrit Goraya,[1,2] Jan Simoni,[6] Lauren N. Sager,[3] Nicolaos E. Madias,[4] Donald E. Wesson.[5,2] *[1]Internal Medicine, Baylor Scott and White Health, Temple, TX; [2]Internal Medicine, Texas A&M HSC College of Medicine, Temple, TX; [3]Reaserch Institute, Baylor Scott & White, Temple, TX; [4]Medicine, Tufts University School of Medicine, Boston, MA; [5]Baylor Scott and White Health and Wellness Center, Dallas, TX; [6]Surgery, Texas Tech University Health Sciences Center, Lubbock, TX.*

Background: Dietary acid (H^+) reduction slows eGFR decline in CKD stage 2 (eGFR=60-89 ml/min/1.73 m^2, CKD 2) patients without metabolic acidosis (conventionally defined as plasma total CO_2 <22 mM) (Mahajan et al, Kid Int, 2010) but who have H^+ retention identified using cumbersome and invasive methods. Earlier studies from this laboratory supported the potential utility of urine citrate excretion to non-invasively identify H^+ retention in such patients but its reliability to do so was not assessed.

Methods: We measured H^+ retention and 8-hour urine citrate excretion ($U_{citrate}V$) in macroalbuminuric, non-diabetic CKD 2 (n=40) and CKD stage 1 (eGFR >90 ml/min/1.73 m^2, CKD 1, n=26) patients with hypertension-associated nephropathy but without metabolic acidosis (mean plasma total CO_2 25.9±0.8 and 26.4±0.6 mM, respectively). H^+ retention was measured by comparing observed to the expected increase in plasma [HCO_3] in response to retained HCO_3 (dose minus $U_{HCO3}V$) 6 hours after oral $NaHCO_3$ bolus (0.5 mmol/kg bw), assuming 50% body weight HCO_3 apparent space of distribution.

Results: H^+ retention was higher in CKD 2 than CKD 1 (28.1±9.4 vs. 5.2±12.0 mmol, respectively, $p<0.01$) but $U_{citrate}V$ was lower in CKD 2 than CKD 1 (187±40 vs. 335±125 mg, respectively, $p<0.01$). Overall Pearson correlation for $U_{citrate}V$ with H^+ retention was -0.76 ($p<0.001$) and a mixed effects regression model showed lower $U_{citrate}V$ to be strongly predictive of higher H^+ retention ($p<0.001$). Using the 90th percentile of H^+ retention in CKD 1 (19.5 mmol) as normal, $U_{citrate}V$ of 230 mg in CKD 2 patients had sensitivity 93.7%, specificity 62.5%, positive predictive value 90.9%, negative predictive value 71.4%, and an accuracy of 87.5% to predict H^+ retention.

Conclusions: Lower $U_{citrate}V$ reliably identifies CKD 2 patients with higher H^+ retention in the absence of metabolic acidosis by acid-base parameters. Because <2% of CKD 2 patients have metabolic acidosis (Shah et al, AJKD, 2009), follow-up studies should further refine this simple, non-invasive method to identify CKD 2 patients who are candidates for dietary H^+ reduction which might reduce their risk for nephropathy progression.

A Multicenter, Randomized Pilot Study of Oral Sodium Bicarbonate Supplementation in Non- to Mildly-Acidotic CKD: The BASE Pilot Study

Kalani L. Raphael,[1] Tamara Isakova,[2] Joachim H. Ix,[3] Dominic S. Raj,[4] Myles Wolf,[5] Linda F. Fried,[6] Jennifer J. Gassman,[7] Brett Larive,[7] Kevin C. Abbott,[8] Susan R. Mendley,[8] Geoffrey A. Block,[9] Ping Li,[4] John P. Middleton,[5] Stuart M. Sprague,[10] Donald E. Wesson,[11] Alfred K. Cheung.[12] The CKD Pilot Studies Consortium *[1]VA Salt Lake City Health Care System, Salt Lake City, UT; [2]Feinberg School of Medicine, Northwestern University, Chicago, IL; [3]UCSD, San Diego, CA; [4]GWU Medical Faculty Associates, Washington, DC; [5]Duke University, Durham, NC; [6]VA Pittsburgh Healthcare System, Pittsburgh, PA; [7]Cleveland Clinic, Cleveland, OH; [8]The National Institutes of Health, NIDDK, Bethesda, MD; [9]Colorado Kidney Care, Denver, CO; [10]NorthShore University HealthSystem University of Chicago Pritzker School of Medicine, Chicago, IL; [11]Baylor Scott and White Health and Wellness Center, Dallas, TX; [12]University of Utah, Salt Lake City, UT.*

Background: Chronic oral $NaHCO_3$ may preserve GFR in CKD, even in those with normal serum (S) HCO_3^-. However, definitive proof of efficacy and the optimal dose have not been demonstrated. We performed a randomized, double-blinded, placebo-controlled multicenter pilot study to determine the safety, tolerability, compliance, and pharmacodynamics of two doses of oral $NaHCO_3$ and the feasibility to conduct a multicenter Phase-3 trial.

Methods: Individuals (n=194) with mean age 68 yrs, eGFR 37 ml/min/1.73m^2, ACR 530 mg/g, and S-HCO_3^- 24 meq/L (range 20-28 meq/L) were randomized to higher-dose (HD) (0.8 meq/kg-LBW/d; n=90) or lower-dose (LD) (0.5 meq/kg-LBW/d; n=52) $NaHCO_3$ or placebo (Plac; n=52) for 28 weeks. The dose was adjusted depending on clinical and laboratory side-effects. The prescribed dose at study completion was the primary outcome. Feasibility for a Phase 3 trial was defined a priori as ≥67% of participants completing the study on full dose and ≥80% on ≥25% of the dose. Pharmacodynamics were assessed by S-HCO_3^-, 24-hour urine NH_4^+ (U-NH_4^+) and pH (U-pH).

Results: 87% in HD, 98% in LD, and 88% in Plac completed the study on full dose, while 91% in HD, 98% in LD, and 94% in Plac completed the study on ≥25% of the dose. Compliance by pill count was ≥88%, with >80% of participants having ≥80% compliance in all arms during follow-up. BP, weight, and S-K^+ were similar between Plac, LD and HD during follow-up. Table 1 shows dose-response effects of $NaHCO_3$ on S-HCO_3^-, U-pH and U-NH_4^+.

Conclusions: In persons with non- to mildly-acidotic stage 3/4 CKD, safety, tolerability and compliance of HD and LD NaHCO3 were each comparable to Plac. $NaHCO_3$ had a mild effect on S-HCO_3^- and substantial dose-dependent effects on U-NH_4^+ and U-pH, but no significant effect on BP, weight, or S-K^+. A Phase-3 multicenter trial using $NaHCO_3$ 0.8 meq/kg-LBW/d is feasible.

The Effects of Sodium Bicarbonate in CKD Stages 3 and 4: A Randomized, Placebo-Controlled, Multi-Center Clinical Trial

Michal L. Melamed,[1] Edward J. Horwitz,[2] Mirela A. Dobre,[2] Matthew K. Abramowitz,[1] Yungtai Lo,[1] Thomas H. Hostetter.[2] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Case Western Reserve University, Cleveland, OH.*

Background: The chronic metabolic acidosis associated with kidney disease may contribute to muscle dysfunction, bone disease and progression of kidney disease.

Methods: We enrolled 149 patients with CKD stages 3 and 4 and randomized them to either placebo or sodium bicarbonate (NaBicarb) (0.4 mEq/kg ideal body weight/day) between 7/2011 and 4/2016 at 3 clinical sites across the US. Participants were seen at baseline, 2, 6, 12 and 24 months. The dual primary outcomes were muscle function assessed by sit-to-stand-to-sit test and bone mineral density. At each visit, blood pressure (BP), weight, a 5-repetition sit-to-stand-to-sit test, and laboratory studies were conducted. Bone mineral density scans were performed at baseline, 12 and 24 months.

Results: Of the 149 participants, 74 were on NaBicarb, 75 were on placebo. Mean age was 61.0 years (standard deviation(SD) 12.6), 54% were women, 58% were non-Hispanic black, 13% were Hispanic and 27% were non-Hispanic white, 62% had diabetes mellitus and 93% had hypertension at baseline. Baseline serum bicarbonate level was 23.5 (SD 1.7) mEq/L, baseline eGFR was 36.3 (SD 11.2) ml/min/1.73m^2 and baseline systolic BP was 137 (SD 17) mmHg. There were no differences in baseline characteristics by treatment group. 104 participants completed the 24 months study. At 2, 6, 12 and 24 months, the mean serum bicarbonate levels in the NaBicarb arm were 26.4 mEq/L (SD 2.2), 25.5 mEq/L (SD 2.3), 25.6 mEq/L (SD 2.6) and 24.4 mEq/L (SD 2.8). These were significantly higher than in the placebo group (p<0.001). NaBicarb caused a significant decrease in serum potassium levels by approximately 0.1 mEq/L (p= 0.047). There were 14 patients in the NaBicarb group who had a potassium level >5.0 mEq/L over the course of the study compared to 30 patients in the placebo group (p=0.005). There were no significant differences in sit-to-stand-to-sit time, bone mineral density, BP or weight between the randomized groups.

Conclusions: NaBicarb therapy in patients with CKD stages 3 and 4 significantly increases serum bicarbonate and decreases serum potassium levels. There were no differences in muscle function or bone mineral density between the randomized groups. Larger trials are required to evaluate effects on kidney function.

Therapeutic Efficacy and Safety of Human Adipose-Derived Stem Cells for Anti-GBM Nephritis

Yuko Shimamura, Naotake Tsuboi, Yutaka Kamimura, Shoichi Maruyama. *Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Mesenchymal stem cells (MSCs), which exert immunomodulatory function, would be one of the promising therapeutic agents for inflammatory disorders. We have been intensively studied adipose derived stem cells (ASCs) cultured under low serum conditions (LASCs) and recently demonstrated that systemic administration of syngeneic LASCs ameliorated anti-GBM nephritis in rats more effectively than ACSs grown under high serum conditions (HASCs). In the current study, we investigated therapeutic potency of human LASCs for rat anti-GBM nephritis.

Methods: Anti-GBM nephritis was induced by intravenous injection of TF78, a monoclonal anti-glomerular basement membrane antibody, to female WKY/NCrj rats. 2×10^6 human LASCs, HASCs or bone marrow derived MSCs (BMMSCs) were administrated to them on day 0, 2, 4 and sacrificed on day 7. Therapeutic efficacy was evaluated by proteinuria during observation period and serum creatinine (sCr), BUN, histological renal damage on day 7. Distribution of administrated MSCs was observed by In Vivo Imaging System. The clotting time after addition of MSCs into plasma was measured. The expression of tissue factor on the MSC surface was analyzed by flow cytometry.

Results: ASC-treatment demonstrated significant amelioration in TF78-induced renal dysfunction. Histologically, crescent formation and accumulations of CD68$^+$ or CD163$^+$ macrophages in inflamed glomeruli were significantly decreased in ASC-treated groups compared with the BMMSC-treated group. Although the therapeutic efficacy of HASC slightly surpassed that of LASC, therapy-related animal death caused by pulmonary accumulations of administrated-ASCs occurred in 4 out of 12 HASC-treated rats, while none in LASC-treated animals. Procoagulant function, which has emerged as a critical aspect in clinical application of ASCs, was remarkably diminished in LASCs compared with HASCs as evidenced with similar clotting time and tissue factor expression to BMMSCs.

Conclusions: Human ASCs have therapeutic potential for anti-GBM nephritis as well as syngeneic ASCs compared with BMMSCs. Although HASCs shows slightly superior efficacy, it has a serious safety drawback compared with LASCs. From a comprehensive perspective, LASCs would be advantageous in therapeutic potential for clinical use.

SA-OR039

Neutralizing the Th1 Effector Cytokines, TNFα and IFNγ, in Experimental Autoimmune Myeloperoxidase ANCA Associated Glomerulonephritis (MPO-ANCA GN)

Kei Nagai,[1,2] A. Richard Kitching,[2] Stephen R. Holdsworth,[2] Poh-Yi Gan.[2] *[1]University of Tsukuba, Tsukuba-city, Japan; [2]Monash University, Monash Medical Centre, Melbourne, VIC, Australia.*

Background: Anti-cytokine monoclonal antibody (mAb) therapies have been effective in many autoimmune diseases but have not been successfully trialled in MPO-ANCA associated vasculitis. This study assessed the efficacy of blocking key CD4$^+$ Th1 subset signature effector cytokines, TNFα and IFNγ in MPO-ANCA GN. Assessing therapeutic efficacy of these anti-cytokine mAbs is now complicated by our recent discovery that Th subset dominance during the development of MPO autoimmunity is biphasic with initial transient Th17 dominance followed by persistent Th1 responses.

Methods: Anti-MPO autoimmunity was induced in C57BL/6 mice by MPO immunization and GN triggered using anti-GBM Ig during early and late development of anti-MPO autoimmunity, and GN assessed 4 days later (days 20 and 32, respectively). mAb treatment began 4hrs post GN triggering.

Results: Administration of anti-TNFα mAb early in anti-MPO development (day 20) had no effect on kidney injury compared with vehicle treated controls: albuminuria [5.7±1.7 vs 5.5±1.7 mg/24hr, P=0.9]; glomerular segmental necrosis [GSN: 50±4 vs 43±3%, P=0.1]. Similarly, anti-IFNγ mAb was ineffective in attenuating GN at this timepoint [GSN: 48±6 vs 45±3%, P=0.53]. Failure of these treatments is concordant with our observation that early developing anti-MPO autoimmunity is Th17 dominant. In contrast, anti-TNFα therapy during established anti-MPO GN (day 32) markedly attenuated kidney injury [GSN: 27±2 vs 50±4%, P=0.01]. TNFα blockade acts locally in the kidney as systemic MPO specific IFNγ and IL-17 recall responses from lymph nodes draining MPO immunization sites were similar to vehicle treated controls. Neutralizing IFNγ at this late timepoint induced a phenotypic switch from Th1 responses to a protective Th2 with increased in serum MPO-ANCA [1.19±0.25 vs 0.48±0.13 OD_{450nm}, P=0.02], increased IL-4 production from MPO challenged LN cells and increased the proportion of activated M2 macrophages [F4/80$^+$CD206$^+$: 29.3±3.2 vs 16.0±0.9%, P=0.01]. However, 4 days of anti-IFNγ treatment was insufficient to improve GN.

Conclusions: In conclusion, Th1 anti-MPO effector responses direct established anti-MPO nephritogenic autoimmunity and glomerular injury (day 32). Therapeutic TNFα neutralizing mAb initiated after triggering GN effectively attenuates kidney injury.

BB-Cl-Amidine Limits Neutrophil Extracellular Trap Formation and Inflammation in Murine Experimental Myeloperoxidase Anti-Neutrophil Cytoplasmic Antibody Associated Glomerulonephritis

Kim M. O'Sullivan,[1] Poh-Yi Gan,[1] A. Richard Kitching,[2] Stephen R. Holdsworth.[2] Centre for Inflammatory Diseases *[1]Monash University, Monash Medical Centre, Melbourne, VIC, Australia; [2]Monash University, Monash Health, Clayton, VIC, Australia.*

Background: Accumulating evidence suggests that dysregulation of neutrophil extracellular traps (NETs) could be associated with the pathogenesis of anti-neutrophil cytoplasmic antibody (ANCA) vasculitis. Peptidyl arginine deiminases (PADs) are enzymes that generate citrullinated proteins, which are pro-inflammatory in both innate and adaptive immune responses. Citrullination of histone 3 (H3Cit) by PAD2 and PAD4 facilitates generation of both macrophage extracellular traps (METs) and NETs. BB-Cl-amidine is a second generation pan (PAD) inhibitor which reduces citrullination of H3Cit and subsequent NET formation. This study investigates the contribution of NETs in the pathogenesis of experimental anti-myeloperoxidase ANCA associated glomerulonephritis (MPO-ANCA GN) and the therapeutic possibility of BB-Cl amidine disrupting NET formation in vivo, and attenuating anti-MPO GN.

Methods: Experimental anti-MPO GN was induced in C57BL/6 mice by myeloperoxidase (MPO) immunisation and GN triggered using a subnephritogenic dose of anti-glomerular basement membrane globulin. BB-Cl-amidine treatment (1mg/kg/daily, n=6 or vehicle, n=7) was administered to disrupt NET formation after the establishment of MPO autoimmunity until termination of the experiment.

Results: NET accumulation identified by co-localisation of extracellular DNA, H3Cit, PAD4, and MPO, was prominent in glomeruli of untreated (vehicle) mice compared to BB-Cl-amidine treated mice (2.1 ± 0.4 vs 0.4 ± 0.1, P=0.004). Histological assessment of kidneys demonstrated prominent glomerular segmental necrosis in the untreated group versus a reduction in mice receiving BB-Cl-amidine (88 ± 3% vs 41 ± 3%, P=0.004). BB-Cl-amidine significantly attenuated glomerular leukocyte infiltration; CD4 T cells (1.2 ± 0.3 vs 0.3 ± 0.1, P=0.03), macrophages (1 ± 0.1 vs 0.4 ± 0.06, P=0.008) and neutrophils (3 ± 0.5 vs 1.6 ±0.3, P=0.03), compared to untreated mice. BB-Cl-amidine treated mice had increased numbers of CD4+FoxP3+ T regulatory cells in lymph nodes compared to the untreated mice (7.1 ± 0.9% vs 3.7 ± 0.3% P= 0.001).

Conclusions: PAD inhibtion with BB-Cl-amidine successfully attenuates in vivo formation of NET formation in experimental anti-MPO GN, reduces kidney injury, glomerular pathology, and supresses inflammation.

Tolerogenic Dendritic Cells Attenuate Autoimmune Vasculitis by Inducing Interleukin 10-Expressing Regulatory T Cells

Stephen R. Holdsworth, A. Richard Kitching, Dragana Odobasic. *Department of Medicine, Monash University, Clayton, VIC, Australia*.

Background: Tolerogenic dendritic cells (DCs) are an attractive immunoregulatory tool for the treatment of inflammatory diseases, but their therapeutic efficacy has not been tested in autoimmune renal vasculitis. These studies sought to determine whether tolerogenic DCs can suppress experimental anti-myeloperoxidase (MPO)-associated vasculitis.

Methods: Tolerogenic DCs (BAY-DCs) were generated by culturing bone-marrow cells with an NFkB inhibitor BAY-11-7082. MPO-pulsed BAY-DCs or vehicle were administered to mice with established anti-MPO or anti-methylated bovine serum albumin (mBSA) immunity, after which immune responses and vasculitis were assessed. BAY-DCs were also transferred to DREG mice (expressing diphtheria toxin [DT] receptor under the Foxp3 promotor) in which foxp3+ regulatory T cells (Tregs) were depleted using DT. BAY-DC-induced Tregs or vehicle were administered, with or without a neutralizing anti-IL-10 receptor antibody, to mice with established anti-MPO immunity, and immune responses and vasculitis assessed.

Results: MPO-pulsed BAY-DCs attenuated established anti-MPO T cell autoimmunity (proliferation, IL-17A/IFNg production) and, after glomerulonephritis was triggered by anti-basement membrane globulin, vasculitis (glomerular injury and leukocyte accumulation), in association with an induction of IL-10-producing Tregs in lymph nodes. MPO-pulsed BAY-DCs did not affect immune responses against mBSA. They also failed to inhibit anti-MPO responses in Treg-depleted DREG mice, showing that Tregs are required for BAY-DC-mediated effects on MPO-specific immunity. Furthermore, Treg transfer/IL-10 receptor blocking experiments showed that BAY-DC-induced Tregs suppressed established anti-MPO immunity and glomerulonephritis via IL-10.

Conclusions: Tolerogenic BAY-DCs attenuate established anti-MPO autoimmunity and consequently vasculitis in an antigen-specific manner by inducing IL-10-expressing Tregs. This suggests that tolerogenic DCs may represent a novel therapeutic option for the treatment of autoimmune renal vasculitis.

SA-OR042

Targeting CD103+ Dendritic Cells Using Flt3 Inhibitors for Treatment of Kidney Disease: Relevance to Human Kidney Disease

David C. Harris,[4,1] Titi Chen,[1,2] Qi Cao,[5] Padmashree Rao,[8,2] Natasha M. Rogers,[10,2] Guoping Zheng,[6] Vincent W. Lee,[3,2] Hong Yu,[7] Yiping Wang.[9] *[1]The Westmead Institute for Medical Research, Westmead, NSW, Australia; [2]University of Sydney, Sydney, NSW, Australia; [3]Westmead Hospital, Sydney, NSW, Australia; [4]Sydney Medical School - University of Sydney, Duffys Forest, NSW, Australia; [5]Centre for Transplant and Renal Research, Westmead Millennium Institute, University of Sydney, Westmead, NSW, Australia; [6]The University of Sydney, Westmead, NSW, Australia; [7]Westmead Institute for Medical Research Australia, Hornsby, NSW, Australia; [8]Westmead Millenium Institute for Medical Research, Parramatta, NSW, Australia; [9]Centre for Transplantation and Renal Research, Westmead Millennium Institute, The University of Sydney, Westmead, NSW, Australia; [10]Westmead Institute for Medical Research, Westmead, NSW, Australia*.

Background: Whereas CD103+ dendritic cells (DCs) were previously considered to be a minor DC subset in kidney disease. we and others have proven that they have a major role. Flt3 is a receptor specifically expressed on tissue CD103+ DCs. Flt 3 inhibitors are currently used for cancer treatment. In this study, our aims are 1. To examine CD141+ DCs (human homologue of mice CD103+ DCs) in human kidney diseases. 2. To explore the role of CD103+ DCs and therapeutic potential of targeting CD103+ DCs by repurposing Flt3 inhibitors in experimental kidney diseases.

Methods: For a human study, we included 294 patients who underwent kidney biopsies from 01/07/2016 to 01/04/2017. For animal experiments, we are using Adriamycin Nephropathy (AN), anti-GBM disease and ischemia reperfusion injury (IRI).

Results: In humans, the number and proportion of CD141+ DCs were significantly increased in proliferative glomerulonephritis and acute tubular necrosis (ATN). CD141+ DCs were found mainly in tubulointerstitium, except in lupus nephritis where they were also present in glomeruli. CD141+ DC numbers correlated with increasing severity of ATN ($P<0.001$) as well as increasing severity of fibrosis in IgA nephropathy ($P=0.025$), but not in diabetic nephropathy. In murine AN, anti-GBM disease and IRI, the number and proportion of kidney CD103+ DCs were significantly increased. In AN, CD103+ DCs played a pathogenic role through activation of CD8+ T cells. Treatment with a Flt3 inhibitor specifically depleted CD103+ DCs and significantly reduced renal injury. The effect of Flt3 inhibition is currently being studied in anti-GBM disease and IRI.

Conclusions: Kidney CD103+ DC numbers correlate with severity of human kidney disease. In experimental kidney disease, CD103+ DCs play a pathogenic role through activation of CD8+ T cells. Targeting CD103+DCs with Flt3 inhibitors effectively reduces renal injury, suggesting a novel therapeutic strategy with accelerated translational potential through drug repurposing.

SA-OR043

Epigenetic Changes in Dendritic Cells in Patients with Systemic Lupus Erythematosus (SLE) with Renal Involvement

Alicja Debska-Slizien,[1] Michal Komorniczak,[1] Anna Wardowska,[2] Barbara Bullo-Piontecka,[1] Piotr Trzonkowski.[2] *[1]Clinic and Department of Nephrology, Transplantology and Internal Diseases, Medical University of Gdansk, Gdansk, Poland; [2]Department of Clinical Immunology and Transplantology, Medical University of Gdansk, Gdansk, Poland*.

Background: SLE is a systemic autoimmune disease that affects the kidneys in about 50% of patients. The pathogenesis of lupus is still unclear and requires further research. There is a mounting evidence that changes in the dendritic cell (DC) function is associated with SLE development.

Methods: 51 patients with lupus nephritis were enrolled to the project. The study group (SG) consisted of 9 men and 42 women, the average age was 44.05 (range: 21-69) years. The control group (CG) consisted of 22 people with no history of autoimmune diseases (5 male and 17 female) with average age 35 (range: 22-60) years. Each participant of the study was cytometrically examined for DCs subpopulations (mDC - myeloid DC, pDC - plasmacytoid DC), including DC activity assessed. The global DNA methylation, histone H3 methylation was estimated. Cytokine profile analysis of both groups was performed with Luminex platform.

Results: In the SG as compare to CG, the percentage of DCs ($HLA\text{-}DR^+$ Lin^{2-}) was significantly lower ($p=0.0259$) and it was accompanied by a significant decrease in the $CD123^+$ pDCs subpopulation ($p=0.006$). There were no statistical differences between the SG and CG in the mDCs ($CD11c^+$) subpopulations ($p=0.133$). However, in the mDCs subpopulation a significant increase in the expression of activation markers was found in SG (for $CD80^+$ $p=0.002$). The study of epigenetic changes in DCs did not show significant differences in the global DNA methylation between groups. However, a statistically significant decrease in methylation histone H3K27me3 in mDCs was found in CG ($p=0.0005$), which suggests increasing transcriptional activity of DCs in this group. The strongest increase in activity was present in INF-inducible genes such as IRF8 (pDC $p=0.0002$; mDC $p=0.037$). In both subpopulations of DCs, the second strongly activated gene in patients with SLE was the TNF gene (pDC $p=0.0049$; mDC $p=0.0198$). Changes in gene activity translate directly into the cytokine profile. The level of proinflammatory cytokines was statistically higher in SG: TNFα ($p=0.0007$), IL8 ($p=0.0029$).

Conclusions: DCs are vital factors in the pathogenesis of SLE. Epigenetic and transcriptomic studies of DCs and analysis of serum proteins have demonstrated their significant role in the genetic modification of the autoimmune process.

Transcriptomic and Proteomic Profiling Identifies Patients with Elevated Inflammatory and Immune Signaling in Nephrotic Syndrome

Sean Eddy,[1] Habib Hamidi,[1] Laura H. Mariani,[1] John R. Hartman,[1] Heather N. Reich,[2] Richard A. Lafayette,[3] Matthias Kretzler.[1] NEPTUNE Consortium *[1]University of Michigan, Ann Arbor, MI; [2]Toronto General Hospital, Toronto, ON, Canada; [3]Stanford University, Stanford, CA*.

Background: Despite the high cost associated with renal disease, the reliability and availability of information to guide patient care using a precision medicine approach prior to reaching end-stage is relatively sparse. To address this, patient specific profiles were generated for major signaling pathways to understand the diversity of patient level signaling in a nephrotic syndrome cohort.

Methods: Transcriptomic profiles were generated from isolated glomeruli (glom) and tubulointerstitium (TI) samples from subjects with nephrotic syndrome in the NEPTUNE cohort. Patient-specific transcriptional profiles were generated from a curated set of genes for activated TNF, JAK-STAT, and major immune cell types. Patient-specific profiles were correlated with urine biomarker profiles generated from a panel of 54 markers to identify relevant surrogate markers. NMF clustering was used to identify disease-relevant molecular subtypes. Patient-specific profiles and clustering approaches were utilized in a blinded retrospective analysis to evaluate the use of high dimensional data to predict patient outcomes and help guide treatment decisions.

Results: Across the cohort, TNF and JAK-STAT pathway activation profiles in the tubulointerstitium were both positively correlated with IFTA ($p<0.001$). In select cases, profiles were identified with high pathway activation with little to no IFTA. MCP-1 and TIMP1 were identified as biomarkers for TNF activation with a C-statistic of 0.86. Urine IP-10 was correlated with intrarenal JAK-STAT activation ($p<0.001$), and together with immune cell signatures were predictive of intrarenal inflammation and immune activation. NMF clustering of glom and TI profiles from subjects each revealed four patient clusters that were associated with outcome; the poorest prognosis cluster was enriched for inflammatory and innate immunity pathways. In individual cases, profiling results were qualitatively consistent with pathology descriptors.

Conclusions: Patient-specific transcriptional and urine biomarker profiles were identified that can indicate degree of intrarenal signaling and damage, and by combing data from other domains, can be used to identify patients that may be best suited for targeted therapy approaches and/or pharmacodynamic patient monitoring in clinical settings.

SA-OR045

Molecular Profiling of Serial Kidney Biopsies to Identify Markers That Predict Long Term Outcomes in Lupus Nephritis

Samir V. Parikh,[2] Ana Malvar,[1] Huijuan Song,[2] John P. Shapiro,[2] Valeria G. Alberton,[1] Bruno J. Lococo,[1] Isabelle Ayoub,[2] Anjali A. Satoskar,[2] Paolo Fadda,[2] Jianying Zhang,[2] Lianbo Yu,[2] Brad H. Rovin.[2] *[1]Hospital Fernandez, Buenos Aires, Argentina; [2]Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Proliferative lupus nephritis (LN) is treated with induction therapy followed by prolonged maintenance therapy for several years. The intra-renal molecular changes that occur during this treatment period is unknown. Here we present results of molecular profiling of the LN glomeruli using protocol kidney biopsies to identify markers of long term response.

Methods: A protocol kidney biopsy was done at flare (Bx1), after induction therapy (Bx2) and after 3 years of maintenance therapy (Bx3) in 9 LN patients. Controls were living donor transplant biopsies (n=6). Glomeruli were laser dissected and RNA was extracted and analyzed by nanostring. Transcript expression from LN glomeruli was compared to controls, and complete responders (CR, n=5) were compared to non-responders (NR, n=4). Response was determined by proteinuria level and renal function at Bx3. All patients were treated with standard induction and maintenance therapy for LN.

Results: There were 110 differentially expressed glomerular transcripts between NR and CR. Pathway analysis revealed upregulation of several T cell pathways in NR compared to CR including Th1, Th2, NFAT, ICOS-ICOSL, CD28 and PKC signaling in T lymphocytes. Additionally, toll-like receptor, trem1, complement, and interferon signaling were upregulated in NR. The expression of 8 glomerular transcripts significantly increased in NR and decreased in CR from Bx1 to Bx3. This included *HLA-DQA1* (FC:3.9 P: 0.03), *LAIR1* (FC:4.2, P:0.004), *GBP1* (FC:2.7, P:0.001), *CCR1* (FC: 3.4 P:0.04), *JAK1* (FC:2.0, P:0.02), *C1R* (FC:2.5, P:0.01), *CTSC* (FC:2.6, P:0.04), and *C1QA* (FC:4.2, P:0.01).

Conclusions: Transcript expression from serial kidney biopsies in LN after prolonged maintenance therapy predicts T cell activation and persistent inflammation in NR compared to CR glomeruli. These pathways could be specifically targeted to improve response in NR. Several glomerular transcripts were identified to predict response in this cohort. These transcripts should be studied further to determine their utility as predictive markers of long-term outcomes in LN.

The Influence of Microbiome Composition on the Development and Progression of IgA Nephropathy

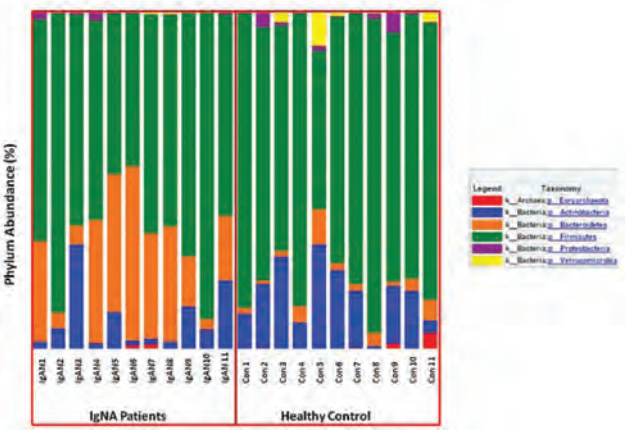
Farid M. Nakhoul,[1,2] Farber Evgeny,[1] Omri Koren,[4] Younes Bathish,[7] Anaam Hnut,[3] Ido Zellner,[6] Sophia Tehawkho,[8] Inbal Dahan.[5] *[1]Nephrology %Hypertension, Baruch Padeh Poriya Medical Ctr., Lower Galilee, Israel; [2]Azieli Faculty of Medicine, Bar-Ilan, Israel; [3]Nephrology %Hypertension, Baruch Padeh Poriya Med Ctr, Lower Galilee, Israel; [4]F, Azrieli Faculty of Medicine, Tzfat, Israel; [5]Diabetes %Metabolism Lab, Lower Galilee, Israel; [6]Azrieli Faculty of Medicine, Tzfat, Israel; [7]Nephrology Division, Ezfat, Israel; [8]Baruch Padeh Poriya Med Ctr, Lower Galilee, Israel.*

Background: IgA Nephropathy (IgAN) is an auto-immune dis., characterized by abnormal deposition of IgA1 antibody with aberrant O-glycosylation in the glomerular mesangium, resulting in local inflammation. Aberrantly glycosylated IgA1 may be synthesized in response to a mucosal infection and may include deregulated innate immune responses. IgAN usually characterized with variability in its manifestation between different patients. The human microbiome is involved in normal host physiology & several metabolic diseases. It was shown that IgAN patients had an altered fecal microbiota, but the exact relationship between microbiome composition and IgAN is still understood.

Methods: Stool sample from 26 IgAN patients and 26 healthy control individuals subjected to microbiome array and to taxonomic analysis, to characterize their microbiome compositions. Creatinine, albumin and urine proteinuria levels are used for evaluate the renal function of each IgAN patient. The clinical and laboratory evaluations will be crossed with the taxonomic data using statistical analysis.

Results: Preliminary result with 11 IgAN patients and 11 healthy controls, there are significant differences in the microbiome composition between the two groups. IgAN patients have a significant increase in the Bacteroides phylum accompanied with a significant decrease in the amount of both the Actinobacteria and Verrucomicrobia phyla, compared with the healthy individuals (Fig.1). At the genus level, there is a significant increase in the Prevotella bacteria in the IgAN subjects compared with the healthy individuals.

Conclusions: 1. A strong association between specific bacteria population and IgAN 2. To isolate specific population of bacteria that leads to IgAN or even aggravate its manifestation. 3. Develop disease-specific therapies based on microbiome modulations and manipulations by modifying the gut microbiota through diet, antibiotic Tx, probiotic interventions, fecal transplants.



SA-OR047

Molecular Phenotype of Lupus Nephritis Histological Lesions

Salem Almaani,[1] Stephenie Prokopec,[4] Carmen Avila-Casado,[6] Joan Wither,[3] James W. Scholey,[5] Heather N. Reich.[2] *[1]The Ohio State University, Columbus, OH; [2]Toronto General Hospital, Toronto, ON, Canada; [3]University Health Network, Toronto, ON, Canada; [4]Ontario Institute for Cancer Research, Toronto, ON, Canada; [5]University of Toronto, Toronto, ON, Canada; [6]University Health Network, University of Toronto, Toronto, ON, Canada.*

Background: The current classification of lupus nephritis (LN) solely relies on histological features and does not incorporate any information about molecular changes that characterize pathologic features. Inclusion of molecular phenotype in histologic scoring may provide insights into disease pathogenesis, prognosis, and aid in surveillance. As a first step towards achieving a more comprehensive molecular-histopathological description of kidney tissue in LN, we evaluated the transcriptional changes associated with various histologic phenotypes in LN.

Methods: 54 kidney biopsies from 53 sequential patients were dissected and separated into glomerular and interstitial compartments. RNA was extracted and amplified. cDNA was hybridized to affymetrix Genechips, processed and data normalized. Descriptive statistics were used for patient demographics. Differential mRNA expression was evaluated according to the presence or absence of the histologic lesion of interest using Wilcoxon Rank Sum test, then using Spearman's Rank Correlation, mRNA expression levels were correlated with lesion severity (on a semiquantitative scale). Pathway analysis of significant transcripts was later performed. A subset of transcripts were validated in an indepndent population.

Results: Histological lesions in LN demonstrated different patterns of expression. The most notable glomerular transcripts reflecting disease activity were osteopontin (OPN) and fibronectin (FN1), which correlated with cellular proliferation, and galectin 3 (LGALS3) which correlated with cellular crescents. On the other hand, interstitial podocin, TLR4, and ITGA1 expression were associated with interstitial fibrosis, and glomerular expression of NEAT1 and CYTIP were associated with glomerular sclerosis. Interestingly, cluster analysis demonstrated clear separation based on tissue type (glomerular vs interstitial), and not by ISN/RPS class or NIH activity and chronicity indices. OPN, FN1, and LGALS3 correlated with proteinuria in the validation cohort.

Conclusions: Histological lesions of LN demonstrate different patterns of expression that do not reflect distinct immunological/inflammatory processes. Some of the identified gene transcripts (OPN, FN1, LGALS3) deserve further evaluation as biomarkers of LN activity, as they correlated with histological activity and proteinuria in two independent cohorts.

SA-OR048

Genomic Characterization of Monogenic Hypertension in a Multiethnic Cohort

Kipp W. Johnson, Steven G. Coca, Ron Do, Girish N. Nadkarni. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Hypertension is a major risk factor for adverse outcomes, but secondary hypertension may not be not appropriately diagnosed. We sought to ascertain prevalence of monogenic hypertension mutations, and their associations with blood pressure and clinical outcomes.

Methods: In 10,782 individuals of predominantly African (n=4,502) or Hispanic/Latino (n=4,621) ancestry, we examined Clinvar mutations pathogenic for secondary hypertension with systolic, diastolic, and mean arterial blood pressures; hypertension-associated composite clinical outcome; acute systolic blood pressure elevation rates, and appropriate diagnosis.

Results: 536 individuals (4.9%) possessed pathogenic mutations. Individuals with pathogenic mutations had 11% increased risk for adverse outcomes (95% CI 1.01-1.20) and had elevated mean arterial (2±0.36 mmHg; p<0.01), systolic (3.22±0.55 mmHg, p<0.001), and diastolic (1.19±0.34) blood pressures. Individuals with a pheochromocytoma and paraganglioma-associated mutation had 2.5-fold higher rates (95% CI 1.8-3.4) for acute

SBP elevations above 200 mmHg. Only 4.5% of individuals with pathogenic mutation had appropriate diagnoses of secondary hypertension and 5.4% received appropriate biochemical evaluations. The majority were diagnosed with essential hypertension (65.9%). (Figure 1)

Conclusions: Pathogenic mutations were more frequent in Hispanic Americans. Individuals with pathogenic monogenic mutations for secondary hypertension have higher blood pressures, increased rates of acute blood pressure elevation, and elevated risk for adverse clinical outcomes. The majority of individuals with pathogenic mutations were not appropriately evaluated or diagnosed. These results suggest a need for diversity in the study of rare genetic diseases, and that a genotypic approach for diagnosis of hypertension may be beneficial.

The New 2017 ACC/AHA Guideline for High Blood Pressure in Adults: How It Impacts Mexican Population and Healthcare System? An Analysis of the SALMEX Cohort

Armando Jezael Martinez-Rueda,[1] Antonio Olivas-Martínez,[1] Jorge I. Fonseca-Correa,[2] Olynka Vega,[2] Ricardo Correa-Rotter.[2] *[1]Department of Internal Medicine, National Medical Science and Nutrition Institute Salvador Zubirán, Mexico City, Mexico; [2]Department of Nephrology and Mineral Metabolism, National Medical Science and Nutrition Institute Salvador Zubirán, Mexico City, Mexico.*

Background: The new 2017 ACC/AHA High Blood Pressure Guidelines for Adults lower the threshold to define hypertension (HT). The impact of these new definitions on populations and health systems is poorly understood.

Methods: SALMEX was a cross-sectional study to evaluate Na^+ and K^+ intake as well as chronic non-communicable diseases prevalence in adults. Participants were recruited from 2010 to 2012. We included data from all subjects aged 20-64 yrs (n=990). HT prevalence and pharmacological treatment (TX) requirement were determined according to both: JNC 7 and 2017 ACC/AHA. Data was extrapolated to sex- and age-adjusted Mexico City's (CDMX) population and annual costs of medical follow-up was calculated. The need for pharmacologic TX was assessed with the Atherosclerotic Cardiovascular Disease (ASCVD) score, and compared to Framingham scores (lipids and BMI).

Results: HT prevalence in the SALMEX cohort increased from 16.2% to 37.4% (18% to 39.3% adjusted to CDMX population). The proportion of subjects requiring pharmacological and non-pharmacological TX increased from 17.7% to 19.0% and from 17.7% to 37.4%, respectively (19.4% to 21.8% for pharmacological and 19.4% to 39.3% for non-pharmacological TX, adjusted to CDMX population). Medical follow-up annual costs for hypertensive subjects in CDMX would increase an estimated $59,278,928 USD. The indication to initiate pharmacological TX was similar when assessed by Framingham risk score with serum lipids values or with BMI, as compared to the ASCVD score, with correlation kappa indexes of 0.981 and 0.972 respectively.

Conclusions: The adoption of the new HT guidelines in Mexican population not only has implications on its prevalence but also on medical follow-up costs. Further pharmacoeconomic analysis is required to evaluate the potential impact of this new HT definition. Framingham BMI score represents the most cost-effective alternative to assess cardiovascular risk at diagnosis.

The DASH Diet and Blood Pressure among Black Americans with and without CKD: The Jackson Heart Study

Crystal C. Tyson,[1] Clementina A. Davenport,[1] Pao-Hwa Lin,[1] Julia J. Scialla,[1] Rasheeda K. Hall,[1] Clarissa J. Diamantidis,[1] Joseph Lunyera,[1] Nrupen A. Bhavsar,[1] Casey Rebholz,[2] Jane F. Pendergast,[1] L. Ebony Boulware,[1] Laura P. Svetkey.[1] *[1]Duke University Medical Center, Durham, NC; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.*

Background: Hypertension control rates are low among Black Americans, particularly among Blacks with CKD. CKD raises blood pressure (BP) through complex mechanisms. Therefore, therapies may have a different effect on BP for those with and without CKD. The DASH diet lowers BP in adults without CKD but its effect in CKD is not clear. Our preliminary data showed that markers of kidney dysfunction are associated with better BP response to the DASH diet. We tested the hypothesis that greater DASH diet accordance has a stronger association with lower BP among Blacks with CKD compared to those without CKD.

Methods: This cohort study of Jackson Heart Study participants involved 3135 Black adults enrolled between 2000 and 2004 (Exam 1) with data on office BP and habitual diet from food frequency questionnaires. We examined the cross-sectional relation of a modified-DASH diet score (excluding sodium intake; range 0-8) to SBP and DBP using linear models adjusting for demographic, behavioral, and clinical factors. We tested for interaction between the DASH score and CKD status (defined as eGFR <60 ml/min/1.73 m^2 and/or urine albumin-to-creatinine ratio ≥30 mg/g).

Results: Mean age was 55 years, 60% had hypertension, and 19% had CKD. Overall, the median DASH score was 1.0 (interquartile range [IQR]: 0.5-2.0), which was similar among participants with and without CKD (1.0 [IQR: 0.5-2] and 1.0 [IQR: 0.5-1.5], respectively). Among those *without* CKD, the DASH score was not associated with SBP (-0.4 [95% confidence interval: -1.0, 0.1] mmHg) or DBP (-0.1 [-0.4, 0.2] mmHg). Among those *with* CKD, a higher DASH score by one point was associated with lower SBP (-1.6 [-2.6, -0.5] mmHg) and DBP (-0.9 [-1.5, -0.3] mmHg; Figure).

Conclusions: CKD status modified the relation of the DASH score to SBP and DBP. Despite poor diet quality overall, greater DASH diet accordance was more strongly associated with lower BP among Blacks with CKD compared to those without CKD.

Long-Term Kidney Effects of Intensive (INT) SBP Lowering in Persons with Type 2 Diabetes Mellitus (T2DM): ACCORD BP and ACCORDION

Srinivasan Beddhu,[1] Robert E. Boucher,[1] Guo Wei,[1] Alfred K. Cheung,[1] Glenn M. Chertow,[2] Walter T. Ambrosius,[3] William C. Cushman,[4] Paul K. Whelton,[5] Tom Greene.[1] *[1]University of Utah, Salt Lake City, UT; [2]Stanford University School of Medicine, Palo Alto, CA; [3]Wake Forest School of Medicine, Winston-Salem, NC; [4]Memphis VA Medical Center, Memphis, TN; [5]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA.*

Background: We recently reported that INT SBP lowering increased the risk of incident CKD in T2DM. It is unclear whether this risk persists long-term after discontinuation of INT SBP control.

Methods: ACCORD BP tested the effects of SBP goal < 120 vs. < 140 mm Hg on CV outcomes in T2DM. ACCORDION was a long-term, post-trial, off-intervention, cohort follow-up of ACCORD participants. We examined the long-term trajectories of SBP and

eGFR using mixed models. In separate Cox regression models, we related the intervention to incident CKD (defined as a >30% decrease in eGFR to a value <60 ml/min/1.73 m²) in participants without CKD at baseline (N = 4305) and to a composite of 50% decline in eGFR or incident stage IV CKD (<30 ml/min/1.73 m²) in all participants (N = 4733).

Results: SBP and eGFR trajectories are depicted in Fig 1. Mean differences in SBP and eGFR between the treatment arms are also summarized in Fig 1. INT SBP lowering resulted in increased risk of incident CKD in ACCORD BP which attenuated after the intervention was discontinued during ACCORDION (Fig 2), interaction p = 0.02; the pattern was similar for 50% decline/ stage IV CKD but the interaction p value (0.24) was not significant.

Conclusions: In persons with T2DM, INT SBP lowering resulted in a decline in eGFR and higher risk of kidney events which appeared to attenuate after discontinuation of the intervention.

The Effect of Intensive Blood Pressure Lowering on Kidney Tubule Injury in a Subgroup of Participants in the ACCORD Trial

Girish N. Nadkarni,[1] Kinsuk Chauhan,[1] Joachim H. Ix,[2] Michael Shlipak,[3] Chirag R. Parikh,[4] Steven G. Coca.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]UCSD, San Diego, CA; [3]San Francisco VA Medical Center, San Francisco, CA; [4]Yale University and VAMC, New Haven, CT.*

Background: Randomization to the intensive (SBP<120 mm Hg) arm in the ACCORD-BP trial resulted in more rapid decline in estimated glomerular filtration rate (eGFR) than in the standard arm (SBP <140 mm Hg). Whether this change reflects hemodynamic effects or accelerated intrinsic kidney damage is unknown.

Methods: Longitudinal sub-group analysis of 529 participants in the ACCORD-Blood Pressure clinical trial. We measured urine biomarkers of tubule injury (kidney injury molecule-1 [KIM-1], interleukin-18 [IL-18]), repair (YKL-40) and inflammation (monocyte chemoattractant protein [MCP-1]) at baseline and year 2. We compared changes between arms using ANCOVA.

Results: Of the 529 participants, 260 were randomized to intensive and 269 to standard blood pressure arm. Mean age was 62 ± 6.5 and eGFR 90 ml/min/1.73m². Baseline clinical characteristics, eGFR, urinary albumin-to-creatinine ratio (ACR), and all 4 biomarkers were similar between arms. Compared to the standard arm, eGFR was 9.2 ml/min/1.73m² lower in the intensive arm at year 2. Despite the reduction in eGFR, ACR was 30% lower in the intensive arm and 4 urinary biomarkers were unchanged or lower at year 2 in the intensive arm (Figure). Moreover, participants in the intensive arm with the largest declines in eGFR had greater reductions in urine IL-18 and YKL-40. In a subgroup analysis stratified by incident CKD development (sustained 30% decline and eGFR < 60 ml/min/1.73 m², n=77), ACR and 4 biomarkers were flat to decreased in the intensive arm, whereas the urinary biomarkers were unchanged or increased in those that developed CKD in standard arm.

Conclusions: Among a subgrop from the ACCORD trial, randomization to intensive BP control reduced eGFR but did not increase injury markers. These findings support the hypothesis that eGFR decline in intensive BP arm of ACCORD predominantly reflect hemodynamic alterations.

SA-OR053

Modification of Effect of Intensive Blood Pressure Lowering on Cardiovascular (CV) Outcomes by Baseline eGFR in the Secondary Prevention of Small Subcortical Strokes (SPS3) Trial

Adhish Agarwal, Man Li, Jianing Ma, Alfred K. Cheung. *University of Utah, Salt Lake City, UT.*

Background: The SPRINT trial reported CV benefits of intensive (INT) systolic blood pressure (SBP) target of <120 mm Hg vs. <140 mm Hg in patients with and without CKD. However, SPRINT excluded patients with a history of stroke. The SPS3 trial examined the CV effects of INT SBP control in patients with previous stroke and found a non-significant reduction in all (recurrent) stroke (hazard ratio [HR] 0.81, 95% CI 0.64-1.03) and the CV composite outcome of myocardial infarction (MI) or vascular death (HR 0.84, 95% CI 0.68-1.04). We conducted a post hoc analysis of the SPS3 trial to examine whether baseline eGFR modified the effects of INT SBP control on CV events in patients with a history of stroke.

Methods: 3,020 patients with recent MRI-defined symptomatic lacunar infarctions were randomized to a SBP target of <130 mm Hg vs. 130-149 mm Hg. Among 3,017 patients with valid baseline eGFR measurements, we evaluated the effects of INT SBP control on the risk of recurrent stroke and CV composite outcome (stroke, acute MI or death) during the 3.7 years of mean follow-up in two strata defined by baseline eGFR (<60 or ≥60 ml/min/1.73m²) using Cox proportional models. We also tested the interaction between treatment group and baseline eGFR.

Results: Non-significant rate reduction by INT SBP control was seen for all (recurrent) stroke and the composite outcome in both eGFR strata. In the eGFR <60 ml/min/1.73m² subgroup (N=303, mean eGFR 51.22 ml/min/1.73m²), the HR was 0.84 (95% CI, 0.46-1.56) for all stroke, and 0.92 (95% CI, 0.58-1.44) for the CV composite outcome. In the eGFR ≥60 ml/min/1.73m² subgroup (N=2714, mean eGFR 90.08 ml/min/1.73m²), the HR was 0.83 (95%, 0.64-1.07) for all stroke, and 0.90 (95%, 0.74-1.09) for the CV composite outcome. Baseline eGFR did not significantly modify the effect of INT SBP control on either all stroke ($P_{interaction}$=0.74) or the CV composite outcome ($P_{interaction}$=0.45).

Conclusions: Baseline eGFR did not modify the effects of INT SBP lowering on CV events among patients with previous stroke. Studies with adequate statistical power in patients with a wide range of kidney functions are needed to provide conclusive evidence of SBP targets in CKD.

SA-OR054

Influence of Intensive Glycemia Intervention on the Effects of Intensive Systolic Blood Pressure (SBP) Lowering in Type 2 Diabetes Mellitus: Reconciling Results from ACCORD BP and SPRINT

Srinivasan Beddhu,[1] Tom Greene,[1] Alfred K. Cheung,[1] Glenn M. Chertow,[2] Holly J. Kramer,[3] Paul L. Kimmel,[4] Robert E. Boucher,[1] Lawrence J. Fine,[5] Guo Wei,[1] Chong Zhang,[1] Mahboob Rahman,[6] Suzanne Oparil,[7] Walter T. Ambrosius,[8] Adam Bress,[1] Jeffrey A. Cutler,[5] Paul K. Whelton,[9] William C. Cushman.[10] *[1]University of Utah School of Medicine, Salt Lake City, UT; [2]Stanford University School of Medicine, Palo Alto, CA; [3]Loyola University Medical Center, Maywood, IL; [4]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [5]NHLBI, Washington, DC; [6]Case Western Reserve University, Cleveland, OH; [7]University of Alabama at Birmingham, Birmingham, AL; [8]Wake Forest School of Medicine, Winston-Salem, NC; [9]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [10]Memphis VA Medical Center, Memphis, TN.*

Background: Intensive systolic blood pressure (SBP) lowering significantly reduced cardiovascular disease (CVD) events in the Systolic Blood Pressure Intervention Trial (SPRINT) but not in the Action to Control Cardiovascular Risk in Diabetes Blood Pressure trial (ACCORD BP).

Methods: SPRINT (N =9361) tested the effects of intensive (<120 mm Hg) versus standard (<140 mm Hg) SBP goals on CVD events and all-cause mortality. Using 2x2 factorial design, ACCORD BP (N = 4733) tested the same SBP intervention in addition to an intensive versus standard glycemia intervention. We compared the effects of intensive SBP lowering on the composite CVD endpoint and all-cause mortality in SPRINT with its effects within each of the glycemia arms in ACCORD BP.

Results: As shown in the figure, intensive SBP lowering decreased the hazard of the composite CVD endpoint similarly in SPRINT and the ACCORD BP standard glycemia

arm (interaction p=0.87). However, the effect of intensive SBP lowering on the composite CVD endpoint in the ACCORD BP intensive glycemia arm was significantly different from SPRINT. Patterns were similar for all-cause mortality.

Conclusions: The effects of intensive SBP control on CVD events and all-cause mortality were similar in persons without diabetes and in persons with diabetes on standard glycemic control. An interaction between intensive SBP lowering and intensive glycemic control may have masked beneficial effects of intensive SBP lowering in ACCORD BP.

Safety and Efficacy of High Dose Spironolactone in Loop Diuretic Resistant Acute Decompensated Heart Failure

Shweta Bansal,[1] Anand Prasad,[2] Sonja D. Brune,[2] Chakradhar Velagapudi.[1] *[1]University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]UT Health San Antonio, San Antonio, TX.*

Background: Secondary hyperaldosteronism plays a key role in pathogenesis of volume overload and resistance to loop diuretics. However, Athena-HF trial failed to show response to high dose spironolactone in ADHF subjects. We aim to evaluate the safety and efficacy of high dose spironolactone with patiromer exclusively in loop diuretic resistant ADHF subjects.

Methods: ADHF subjects admitted with one symptom and one sign of hypervolemia were given spironolactone 100mg daily if they lost <1lb/day despite IV furosemide>160mg/day (at least one dose of 80mg/day) or equivalent dose of other loop diuretics or remained significantly dyspneic despite 48hrs after admission. The dose was up titrated to 200mg based on response with no change in dose of loop diuretic. Subjects received oral patiromer if serum potassium was >4.3mEq/L. They were followed until achievement of euvolemia or hospital discharge.

Results: Twenty of 48 enrolled subjects with ADHF were loop diuretic resistant. One subject was withdrawn due to mechanical ventilation. The mean±SD age was 61±15yr, 60% male, and 50% Hispanics. Nine did not respond to furosemide >160 mg/day and ten remained symptomatic after 48hrs. Median[IQR] dose of furosemide was 160[120,230] mg/day a day before intervention. Mean ejection fraction was 27.9±19% and 14 subjects had pulmonary hypertension with mean PASP 47.3±11.5 mmHg. All 19 subjects except one responded to addition of spironolactone. Mean±SD weight change was -3.0±3.4lb on day1 and -6.5±4.5lb by day2 ($p<0.001$, ANOVA) on spironolactone. Mean urine output increased from 1712±686 ml a day prior to spironolactone to 2732±1374ml on day1 and 3439±1565 ml ($p=0.002$, ANOVA) on day2 on spironolactone. Eight subjects required 200mg dose. One subject sustained worsening renal function in setting of hypotension due to worsening of underlying cardiac dysfunction. None of the subjects had serum potassium >5.5mEq/d. Three subjects were given patiromer for protocol indication and it was well-tolerated.

Conclusions: Addition of high dose spironolactone to ADHF patients resistant to loop diuretic provided significant decongestion without causing hyperkalemia or worsening renal function. A larger randomized trial is warranted in loop diuretic resisant ADHF patients.

Elevated Tissue Na+ Deposition in Hemodialysis Patients with Cardiovascular Disease Detected by 23Na-Magnetic Resonance Imaging

Anna-Carolina Friedrich,[1] Christoph Kopp,[1] Peter Linz,[2] Armin M. Nagel,[2] Jens Titze,[3,1] Anke Dahlmann.[1] *[1]Dept. of Nephrology and Hypertension, Erlangen, Germany; [2]University Hospital Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Erlangen, Germany; [3]Duke - National University of Singapore, Singapore, Singapore.*

Background: Disturbances in Na^+ homeostasis with accumulation of Na+ in tissues are present in salt sensitive hypertension and correlate with left ventricular hypertrophy. Tissue Na^+ distribution could be recently visualized in vivo by ^{23}Na-magnetic resonance imaging (^{23}Na-MRI). We used ^{23}Na-MRI to quantify Na^+ in skin and muscle of hemodialysis (HD) patients either with or without concomitant cardiovascular disease (CVD). We hypothesized that tissue Na^+ might accumulate to a higher extent in HD patients co-diagnosed with CVD.

Methods: We used ^{23}Na-MRI at 3.0 Tesla to quantify Na^+ content in skeletal muscle and skin of the left lower leg. We determined tissue Na^+ content using a Na^+ volume coil in 19 HD patients with a positive history of a CV event (MI, CABG, arrhythmia, stroke or PAD IV) and in 41 age-matched control HD patients. Additionally, total body water content, including extra- and intracellular water space, were determined using Body Composition Monitoring technique (BCM).

Results: Compared to control HD patients ^{23}Na-MRI detected an increased Na^+ content in muscle tissue (20.97 ± 3.60 vs. 24.59 ± 7.10 mmol/L, $p<0.05$) and skin tissue (21.95 ± 7.26 vs. 29.80 ± 10.91 mmol/L, $p<0.05$) of HD+CVD patients. Simultaneously measured excess extracellular water content detected by BCM was significantly higher in the HD+CVD group (1.17 ± 1.48 vs. 2.31 ± 1.61 liter, $p<0.05$). .

Conclusions: ^{23}Na-MRI detected increased Na^+ in muscle and skin tissue as well as higher excess extracellular water content in HD+CVD patients. Our findings provide evidence that the history of a cardiovascular event is associated with disturbances in tissue Na^+ and water content in HD patients.

SA-OR057

Balancing eGFR Loss and Albuminuria Suppression during Intensive BP Control

Elaine Ku,[1] Charles E. McCulloch,[1] Mark J. Sarnak,[3] Jennifer J. Gassman,[2] Chi-yuan Hsu.[1] *[1]University of California San Francisco, San Francisco, CA; [2]Cleveland Clinic, Cleveland, OH; [3]Tufts Medical Center, Boston, MA.*

Background: Intensive BP lowering often lowers GFR. This GFR decline is thought to be hemodynamic, benign, and potentially necessary for albuminuria (ACR) suppression. We hypothesized that the Kidney Failure Risk Equation (KFRE) which predicts 5-yr risk of ESRD (using age, sex, eGFR, ACR) could help guide the risk-benefit tradeoff between eGFR loss vs. ACR suppression during intensive BP lowering.

Methods: We determined the tradeoff between GFR loss and ACR suppression that could be theoretically tolerated during intensive BP lowering to maintain the same predicted 5-year ESRD risk (based on the mathematical relationship of eGFR and ACR in the KFRE). We then determined the % of participants in African American Study of Kidney Disease and Modification of Diet in Renal Disease (MDRD) trials (two trials of intensive BP lowering) who achieved adequate ACR suppression during intervention. We confirmed that the KFRE predicted risk of ESRD (henceforth KFRE score) at baseline and at 6 mos (after intensification of BP control) both provided good risk discrimination for ESRD.

Results: To maintain the same KFRE score, substantial ACR suppression was needed to counter even small declines in eGFR (Table). For example, a 3 mL/min/1.73 m^2 decline in eGFR would require 50% ACR suppression to maintain the same KFRE score. Only 21% of 1523 trial participants had sufficient suppression of ACR that maintained or improved their KFRE score given the large magnitude of eGFR changes that occurred during BP lowering. The KFRE score discriminated risk of ESRD before and after intensive BP lowering well, with C-statistic of 0.85 (strict BP) and 0.87 (usual BP) at baseline, and c=0.88 for both treatment arms at 6 mos. Every 10% worsening of KFRE score predicted higher observed risk of ESRD (HR 1.93 [95% CI 1.66-2.25]) in the strict BP arm.

Conclusions: De-intensification of BP control should be considered when aggressive BP lowering leads to declines in eGFR without sufficiently large corresponding ACR suppression to maintain (or improve) the same predicted ESRD risk by the KFRE.

Clinical Significance of Crescent Formation in IgA Nephropathy – A Multicenter Validation Study

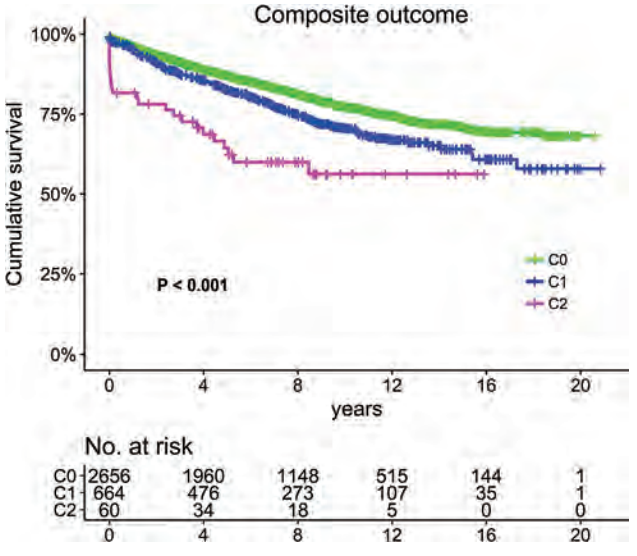
Sehoon Park,[1] Chung Hee Baek,[2] Su-Kil Park,[2] Hee Gyung Kang,[3] Hyesun Hyun,[4] Eujin Park,[5] Seung Hyeok Han,[6] Dong-Ryeol Ryu,[7] Dong Ki Kim,[1] Kook-Hwan Oh,[1] Kwon Wook Joo,[1] Yon Su Kim,[8] Ho Jun Chin,[9] Hajeong Lee.[8] Korean Glomerular Disease Study Group *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Asan Medical Center, Songpa-gu, Seoul, Republic of Korea; [3]Seoul National University Children's Hospital, Seoul, Republic of Korea; [4]St. Vincent's Hospital, The Catholic University College of Medicine, Suwon, Republic of Korea; [5]Hallym University Kangnam Sacred Heart Hospital, Seoul, Republic of Korea; [6]Yonsei University College of Medicine, Seoul, Republic of Korea; [7]Ewha Womans University, Seoul, Republic of Korea; [8]Seoul National University College of Medicine, Seoul, Republic of Korea; [9]Seoul National University Bundang Hospital, Seong nam, Republic of Korea.*

Background: Additional validation study was warranted to confirm the clinical significance of C score, which was recently added to the Oxford classification for immunoglobulin A (IgAN).

Methods: We performed a multicenter retrospective cohort study in four hospitals in Korea. Patients who had biopsied glomeruli less than eight or inadequate follow-up information were excluded. Clinicopathologic parameters, including the degree of cellular or fibrocellular crescents, were collected and included in multivariable model for Cox regression analysis. The main outcome was a composite renal outcome, defined as a merge of progression to end-stage renal disease (ESRD) and halving of estimated glomerular filtration rate (eGFR) from baseline.

Results: Among included 3,380 biopsy-confirmed IgAN patients, there were 664 (19.6%) patients with C1 and 60 (1.8%) patients with C2 scores in the study population. Although C0 and C1 patients shared similar baseline characteristics, C2 patients frequently had more clinicopathologic risk factors for poor prognosis of IgAN. Both C1 [adjusted HR 1.33 (1.11-1.58), P=0.002] and C2 [adjusted HR 2.24 (1.46-3.43), P<0.001] scores were associated with increased risk of the composite outcome. C2 was a strong predictive parameter associated with both progression of ESRD and halving of eGFR, whereas C1 was mainly associated with the increased risk of halving of eGFR. Notably, the proportion of crescent showed a linear association with the risk of adverse renal outcome.

Conclusions: The C score in the Oxford classification is a valid predictive parameter for IgAN prognosis. Additional clinical attention is necessary for IgAN patients with identified cellular or fibrocellular crescents



SA-OR059

Percentage of Glomerular Crescents Predicts Renal Outcomes in Children with IgA Vasculitis – A Midwest Pediatric Nephrology Consortium Study

Scott E. Wenderfer,[1] Michelle N. Rheault,[2] David T. Selewski,[3] Cheryl L. Tran,[4] Cynthia G. Pan,[5] Meredith Seamon,[6] Raoul D. Nelson,[6] Katherine Twombley,[7] Ali Mirza Onder,[8] Joseph T. Flynn,[9] Joseph G. Maliakkal,[10] William E. Smoyer,[11] Guillermo Hidalgo.[12] *[1]Pediatrics, Baylor College of Medicine, Houston, TX; [2]University of Minnesota, Minneapolis, MN; [3]University of Michigan, Ann Arbor, MI; [4]Mayo Clinic, Rochester, MN; [5]Medical College of Wisconsin, Milwaukee, WI; [6]The University of Utah, Salt Lake City, UT; [7]Medical University of South Carolina, Charleston, SC; [8]University of Tennessee, Memphis, TN; [9]Seattle Children's Hospital, Seattle, WA; [10]Saint Louis University School of Medicine, St. Louis, MO; [11]Nationwide Children's Hospital, Columbus, OH; [12]Eastern Carolina University, Greenville, NC.*

Background: While crescents on kidney biopsy predict poor outcome for children with IgA vasculitis, evidence-based thresholds for %crescents most predictive of renal risk are not established. The International Study of Kidney Disease in Children (ISKDC) used 50% and 75% thresholds to grade severity of crescentic glomerulonephritis. MEST-C scoring for IgA nephropathy has also been proposed for IgA vasculitis: 1 point for any glomerular crescent and 2 when crescents involve >25% of glomeruli.

Methods: To test the validity of 25, 50, and 75% thresholds for crescents in IgA vasculitis, we identified 62 patients (13 centers) in the IRB-approved Midwest Pediatric Nephrology Consortium Glomerulonephritis with Crescents Registry (18% of total). Enrollment included patients <21 yo with >1 crescentic glomerulus on biopsy from 2004-16. Primary outcome was end stage kidney disease (ESKD) at 1 year. Secondary outcomes included estimated glomerular filtration rate (eGFR) at 1 year and change in eGFR over time. Crescents were defined by local renal pathologist.

Results: The cohort was 47% female, 53% white, 3% black, 18% Hispanic, and 3% Asian. Median age at biopsy was 8 years (range 6-11) with 2.6 years median follow-up (IQR 1.7-4.8). A median of 36 glomeruli were sampled per biopsy (IQR 27-57). The median %crescents was 10.8 (IQR 7-18%, max 83%). Cellular crescents were seen in 95% of biopsies; fibrous crescents in 27%; both in 23%. Only 2% of children had crescents in >50% of glomeruli, and only one in >75% of glomeruli. One child with 13% cellular and 3% fibrous crescents advanced to ESKD at 26 months post-biopsy. Median change in eGFR was +2.8 mL/min/1.73m^2/year (IQR -20 to +24) at 1 year and -1.5 (IQR -7 to +6) at latest follow-up. Change in eGFR was 2-fold greater for children with >25% crescents (-3.6) vs. those with <25% (-1.6).

Conclusions: Children with higher %crescents present with lower GFRs but most have significant recovery of eGFR at 1 year. Utility of the ISKDC thresholds for grading crescents in IgAV is limited, due to low prevalence of biopsies with crescents >50%. Long term, the 25% threshold for cellular crescents appears to predict worsening GFR decline.

SA-OR060

Relationship between Complement Activation and the Oxford Classification Score and Their Combined Effects on Renal Outcome in Early Stage IgA nephropathy

Seon yeong Lee, Seohyun Park, Yooju Nam, Joohwan Kim, Ki Heon Nam, Tae-Hyun Yoo, Seung Hyeok Han. *Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.*

Background: Complement activation has been highlighted in the pathogenesis of IgA nephropathy. However, it is unknown how the complement is connected to the downstream phenotype of IgA nephropathy. In this study, we investigated the association of the mesangial C3 deposition with the Oxford classification and their joint effects on the prognosis of IgA nephropathy.

Methods: We included 408 patients with biopsy-proven early stage IgA nephropathy [T0 and estimated glomerular filtration rate (eGFR) ≥30 ml/min/1.73m^2] between 2009 and 2016 at Yonsei University Health System. C3 deposit was defined as the immunofluorescence intensity of C3 ≥2+ within the mesangium. The study subjects were classified according to the combination of C3 deposits and each lesion of the Oxford classification. The primary endpoint was the development of a ≥ 30% decline in eGFR during follow-up.

Results: Among the Oxford lesions, M1 (mesangial proliferation), S1 (segmental sclerosis), and crescent were significantly correlated with C3 deposit, whereas E1 (endocapillary proliferation) was not. During a median follow-up of 32.5 (18.0 – 61.8) months, primary endpoint occurred in 32 patients (7.9%). In individual multivariable-adjusted analyses, the presence of M1, S1, and C3 deposit was significantly associated with increased risk of primary outcome. In combined analyses with C3 deposit and each of the Oxford lesions, HRs were significantly higher in the presence of C3/M1 and C3/S1, and C3/crescent than in the presence of each single lesion alone.

Conclusions: C3 deposition was significantly associated with the Oxford M-, S-, and crescent scores. In addition, risk of adverse renal outcome was consistently highest when C3 deposition was added to each score. These findings suggest that complement activation can strengthen the significance of the Oxford score and the presence of both components portends a poorer prognosis in IgA nephropathy.

SA-OR061

Relationship between IgA1 Lectin-Binding Specificities, Mesangial C4d Deposits, and Clinical Phenotypes in IgA Nephropathy

Luisa Martin-conde,[1] Elias A. Jatem,[5] Clara Carnicer,[6] Maria Molina,[1] Cristina Martínez,[4] Laura Colàs-Campàs,[3] Alicia G. Carrasco,[7] Alfonso Segarra.[2] *[1]University Hospital Arnau de Vilanova, Lleida, Spain; [2]Servicio Nefrologia Hospital Vall D'Hebron, Barcelona, Spain; [3]IRB Lleida - University of Lleida, Lleida, Spain; [4]Vall d'Hebron Institute of Research, Barcelona, Spain; [5]Hospital Universitari Arnau de Vilanova, Lleida, Spain; [6]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [7]Vascular and Renal Translational Research Group. IRB Lleida, Lleida, Spain.*

Background: The reason why mesangial C4d deposits are detected in only certain biopsies of IgA nephropathy, remains unclear. In this study, we analyse the association between different patterns of IgA1 glycosilation, mesangial C4 deposition and clinical phenotypes, in IgA nephropathy

Methods: This cross-sectional study included 145 patients with idiopathic IgA nephropathy. We measured the serum levels of three different IgA1 lectin-binding specificities, using enzyme-linked-immunosorbent assays, and we analysed the relationship between these specificities, C4d mesangial deposits and clinical profiles at diagnosis.

Results: C4d-positive vs. Cd4-negative patients had higher proteinuria (median: 3.1 g/g [0.9-4.2] vs. 1.8 g/g [1-2.2]; p=0.000), hematuria (223 cel/µL [32-278] vs 99 cel/µL [25-186], p=0.000), and higher levels of IgA1 with ability to bind Helix Aspersa (HAA IgA1) (150.6 ± 52 U vs 96.2 ± 64.1 U, p= 0,000), Triticum vulgaris (TVIgA1) (85.1 ± 31.7 U vs 42.2 ± 26.9U, p= 0.000) and Canavalia ensiformis (ConAIgA1) (32.5 ± 18U vs 16.7 ± 9.38U, p=0.000) but similar levels of total galactose-deficient IgA1 (338 ± 64 U vs 324 ± 43U p: 0.15). The levels of HAAIgA1, TVIgA1 and ConAIgA1 were all associated with the mesangial deposition of C4d, extracapillary proliferation and the presence of acute kidney injury. HAAIgA1, TVIgA1 and ConAIgA1 had a similar ability to discriminate between C4d positive ad C4d-negative biopsies (AUC: 0.72 ± 0.04, 0.83 ± 0.03 and 0.81 ± 0.04, respectively, p=0.000 in all cases). In logistic models, TVIgA1 and ConAIgA1 were the only independent predictors of mesangial C4d deposits

Conclusions: In IgA nephropathy, the severity of the disease is associated with the level of desialylation of galactose-deficient IgA1 whereas C4d deposits are associated with elevated levels of IgA1 glycoforms involving aberrantly glycosilated N-linked glycan residues.

SA-OR062

An Open-Label Pilot Study of ACTH in the Treatment of IgA Nephropathy at High Risk of Progression

Ladan Zand,[1] Pietro A. Canetta,[4] Richard A. Lafayette,[2] Nabeel Aslam,[3] Sanjeev Sethi,[1] Nelson Leung,[1] Fernando C. Fervenza.[1] *[1]Mayo Clinic, Rochester, MN; [2]Stanford University, Stanford, CA; [3]Mayo Clinic Florida, Jacksonville, FL; [4]Columbia Universtiry, New York, NY.*

Background: Patients with IgAN and elevated proteinuria despite renin-angiotensin inhibition (RASI) are at risk of progressive CKD, and therapeutic options are limited. ACTH has been shown to lower proteinuria in certain proteinuric kidney diseases. We hypothesized that it may be effective in lowering proteinuria and preserving renal function in patients with IgAN at high risk of progression.

Methods: We conducted a prospective open-label pilot study in patients with IgAN using ACTH (H.P. Acthar® Gel) at a dose of 80 units SC twice weekly for a total of 6 months (m) and followed patients for a total of 12m. Patients had to have urinary protein (UP) > 1 g/24 hr despite adequate RASI & eGFR >30 ml/min at enrollment. Secondary IgAN & those with hepatitis were excluded. Glucocorticoids could not have been used for the prior 3m. Primary endpoint was defined as achieving CR (24 hr UP <300 mg & ≤10% reduction in eGFR) or PR (≥50% reduction in UP and ≤25% reduction in eGFR).

Results: Twenty patients were enrolled. One was removed from the study at 3m as he was hepatitis B positive. Another patient withdrew at 6m due to progression of IgAN but was included in the analysis at 12m. At baseline, the mean age was 34.5 ± 10.5 yrs with 11 males & 8 females, 14 Caucasian & 5 Asians. At 12m there was a statistically significant decline in 24hr UP from 2.8 to 1.9 g (P=0.006) and significant increase in serum albumin (3.79 to 3.93, P=0.02). There was no significant change in eGFR (65.5 to 61.1 ml/min, P=0.1). There were 8 PRs (42%). There were total of 4 infections (1 pneumonia, 1 otitis media, and 2 sinus infections) that required antibiotics. Most common adverse events included acne, hot flashes, and anxiety.

Conclusions: Patient with IgAN with >1 g/24 hr UP and eGFR >30ml/min had a significant reduction in 24hr UP with stable eGFR at 12m follow up after being treated with 6 months of ACTH.

Patients' clinical and renal charactersitics

	Baseline (n=19)	12 months (n=19)	P value
sBP (mmHg)	124.2 ± 20.2	118.8 ± 11.1	0.24
dBP (mmHg)	76.0 ± 8.2	76.6 ± 9.8	1.0
BMI (kg/m2)	27.7 ± 7.4	28.5 ± 7.0	0.18
Serum creatinine (mg/dL)	1.40 ± 0.49	1.55 ± 0.64	0.1
eGFR - CKD-EPI (ml/min)	65.5 ± 28.8	61.1 ± 31.1	0.1
Serum albumin (g/dL)	3.79 ± 0.54	3.93 ± 0.39	0.02
24 hour urinary proteia (mg)	2821 ± 1234	1963 ± 1668	0.006

SA-OR063

Using Long Term Outcome Data to Redefine Proteinuria and eGFR End Points for Lupus Nephritis Trials

Hannah R. Wilson,[2] Tabitha Turner-Stokes,[2] Iara Dasilva Santos,[1,2] Megan Griffith,[2] Jeremy B. Levy,[2] Tom Cairns,[2] H. Terence Cook,[2] Liz Lightstone.[2] *[1]Fundacio Puigvert, Barcelona, Spain; [2]Imperial College London, Hammersmith Hospital, London, United Kingdom.*

Background: Lupus Nephritis (LN) is a common & severe manifestation of systemic lupus erythematosus (SLE) that can lead to renal failure (ESRF). Reviews of Euro-Lupus Nephritis & MAINTAIN cohorts suggest a less stringent cut off proteinuria at 1yr (<0.8g/d & <0.7g/d respectively) better predicted good renal outcome at 7yrs than usual complete remission (CR) criteria (<0.5g/d). This cut-off has yet to be validated using urinary protein creatinine ratio (uPCR) or in a larger real world cohort.

Methods: Data were reviewed for LN biopsies 1/1/1996 to 1/1/2016. Definition CR:uPCR (mg/mmol) <50 & estimated glomerular filtration rate (eGFR mls/min/1.73m^2) ≥60, or if b/l <60, no fall >20%; Partial remission (PR):uPCR <300 with ≥50% improvement & eGFR as CR; Non-remission (NR):no PR by 1yr. Factors predicting good outcome, defined as 1-46yr survival with eGFR >60, assessed by multiple logistic regression (LR) with correction & receiver operating characteristic (ROC) curves.

Results: 476 patients had 819 biopsies. Median age diagnosis:SLE 29yrs; LN 32yrs. Female:82%. Ethnicity:32% S Asian, 27% Black, 26% White& 3% SE Asian. At latest f/up since diagnosis LN (median 9yrs(0-46): majority, 293(62%) had good outcome; ESRF: 68(14%), median 5yrs(0-43); died: 31(7%), 7yrs(0-19). LR identified 1yr eGFR and uPCR as predictors of good outcome: eGFR odds ratio (OR) 2.186 (95% CI 1.529-3.126) p<0.001 for each rise 10; uPCR OR 0.547 (0.356-0.841) p=0.006 for increase between ranges (0-50,50-100,100-300,300-500,500-1000,>1000). ROC curves identified 1yr uPCR <68 (AUC0.70,p<0.0001,sens 67%,spec 65%) & eGFR >80.5 (AUC 0.83,p<0.0001,sens 77%,spec 76%) predictive of good outcome. Standard CR&NR definitions fail to predict good outcome; in contrast, achieving uPCR & eGFR identified by ROC curves strongly predicted good outcome OR 5.68 (95% CI 2.367-13.635, p<0.001); OR good outcome if not achieved 0.42 (95% CI 0.188-0.926, p=0.032).

Conclusions: Our "real world" multi-ethnic cohort, the largest to date, support Eurolupus and MAINTAIN data: less stringent proteinuria thresholds (<68mg/mmol) and excellent renal function (>80.5ml/min/m^2) at 1yr better predict long term outcome than current trial endpoints. As the key outcome that matters to patients, we argue it is time to change definitions of success of treatments in LN trials.

SA-OR064

Infectious Complications in Lupus Nephritis Treatment: A Systematic Review and Meta-Analysis

Kah Mean Thong,[1,2] Daniel Tak Mao Chan.[1] *[1]Queen Mary Hospital, Pokfulam, HKSAR, China; [2]Hospital Raja Permaisuri Bainun, Ipoh, Malaysia.*

Background: Infection is an important concern in lupus nephritis treatment, but few studies have primarily focused on this complication. We investigated the incidence rate of infections, their associated risk factors, and outcomes reported in the literature.

Methods: Randomized controlled trials (RCTs) on lupus nephritis Class III/IV/V published between January 1980 and December 2016 and identified from Pubmed/Medline were included in the meta-analysis. Infection risk associated with different immunosuppressive medications was presented as risk ratio (RR) with 95% confidence interval (CI) using the Mantel-Haenszel method.

Results: Thirty-two RCTs involving 3834 patients were included. Estimated incidence rates of overall and serious infections were both higher during the induction phase than maintenance phase. The rate of serious infections ranged from 8.2-50 per 100 patient-years during the induction phase, and 3.5 per 100 patient-years during maintenance phase. The rates of serious infections were 4.1-25% in Asia and 4.4-8.5% in non-Asian countries; with infection-related mortality rates of 0-6.7% in Asian, compared to 0-2.1% in non-Asian locations. Mycophenolate mofetil as induction treatment was associated with lower overall infection risks than cyclophosphamide in non-Asian countries (RR, 0.60; 95% CI, 0.48–0.75; p<0.001). Recent data (since 2011), predominantly from Asia, suggested that tacrolimus used as induction immunosuppression was associated with lower rates of overall infections compared with mycophenolate mofetil (RR, 0.50; 95% CI, 0.33–0.76; p=0.001).

Conclusions: Infection remains a serious complication in patients with lupus nephritis, especially in Asia, but the reported rates varied markedly. Mycophenolate mofetil was associated with lower infection rates in non-Asian patients, compared with cyclophosphamide; and further experience is required to confirm the infection risk associated with tacrolimus.

Lupus Nephritis Flare after Withdrawal of Immunosuppression Is Predicted by Kidney Biopsy Findings during Maintenance Therapy: A Prospective Observational Cohort Study

Marcelo A. De Rosa,[2] Jorge E. Toblli,[5] Graciela E. De Rosa,[6] Federico Fuentes,[3] Haikady N. Nagaraja,[4] Ryan R. Nash,[4] Brad H. Rovin.[1] *[1]Ohio State University Wexner Medical Center, Columbus, OH; [2]University of Buenos Aires, Buenos Aires, Argentina; [3]Hospital de Clínicas, Buenos Aires, Argentina; [4]The Ohio State University, Columbus, OH; [5]Laboratory of Experimental Medicine Hospital Aleman, Buenos Aires, Argentina; [6]Hospital de Clinicas, Buenos Aires, Argentina.*

Background: The optimal duration of maintenance immunosuppressive therapy in lupus nephritis (LN) is unclear. Withdrawal of immunosuppression is generally based on a patient achieving a sustained clinical remission (CR). However, a significant proportion of patients in CR continue to have persistent histologic activity on kidney biopsy. We postulated that patients with ongoing histologic activity are at risk of LN flare when maintenance therapy is tapered, and designed a prospective observational study to test this hypothesis.

Methods: Patients with Class III/IV±V LN on maintenance therapy who had received at least 3 years of immunosuppression and were in complete CR for at least the last year of treatment were recruited to undergo a kidney biopsy. Maintenance therapy was withdrawan after the kidney biopsy and patients were followed prospectively for 2 years. The primary endpoint of the trial was LN flare.

Results: Out of 44 recruited patients, 36 completed the study. Patients withdrew due to pregnancy, non-renal lupus flare, or by choice. Biopsy showed that 20 patients (55.6%) had achieved complete histologic remission with an NIH activity index (AI) of 0, nine patients (25%) had an AI of 1 or 2, and 7 patients had an AI between 3 and 5. LN flared in 11 patients (30.5%), all but one flare (91%) occurred in patients with persistent histologic activity, and everyone with an AI>2 flared. In multivariable analysis AI and duration of SLE were independent predictors of LN flare, and these variables could discriminate between future flare and no-flare with 100% sensitivity, 88% specificity, an 8.3% misclassification rate, and an area under the ROC curve of 0.98. Among the individual components of the AI, endocapillary proliferation and subendothelial deposits were both significantly associated with the odds of future flare, but endocapillary proliferation was a more robust marker.

Conclusions: Persistent histologic activity in kidney biopsies of LN patients in complete CR on maintenance immunosuppression, especially persistent endocapillary proliferation, is a risk factor for future LN relapse. A kidney biopsy during maintenance immunosuppression may help inform the decision of whether to withdraw or continue maintenance therapy in LN.

SA-OR066

A Phase III Study of Abatacept on Standard of Care in Patients with Active Class III or IV Lupus Nephritis

Gerald B. Appel,[3] Mary A. Dooley,[11] David Wofsy,[7] Tsutomu Takeuchi,[10] Ana Malvar,[2] Andrea Doria,[9] Juanita Romero-Díaz,[4] Daniel Tak Mao Chan,[5] Ayanbola O. Elegbe,[8] Richard Furie,[6] David R. Jayne,[1] Michael Maldonado.[8] *[1]University of Cambridge, Cambridge, United Kingdom; [2]Hospital Fernández, Buenos Aires, Argentina; [3]Columbia University Medical Center, New York, NY; [4]Instituto Nacional de Ciencias Médicas y Nutrición, Mexico City, Mexico; [5]University of Hong Kong, Hong Kong, Hong Kong; [6]Northwell Health, Great Neck, NY; [7]University of California San Francisco, San Francisco, CA; [8]Bristol-Myers Squibb, Princeton, NJ; [9]University of Padova, Padova, Italy; [10]Keio University, Minato, Tokyo, Japan; [11]University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Novel treatments (tx) for active class III or IV lupus nephritis (LN) are needed. This study compared IV abatacept (ABA) vs placebo (pbo) on background therapy for tx of active proliferative LN.

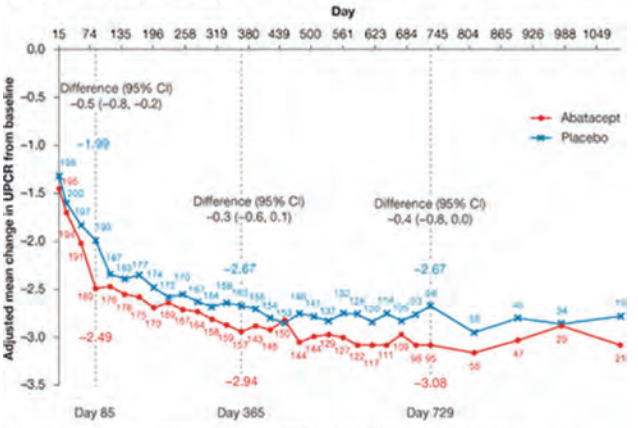
Methods: This was a 24-month (M), randomized, Phase III, double-blind study with long-term extension. Patients (pts) were randomized to pbo or IV ABA every 4 wks on background of MMF + corticosteroids (CS). Primary endpoint: complete response (CR; UPCR ≤0.5, preserved eGFR, no cellular casts, CS ≤10 mg/day) at Year (Yr) 1. We report all blinded data up to Yr 3 of tx.

Results: 405 pts were randomized (ABA n=202; pbo n=203). At baseline: mean age=33 yrs, UPCR=3.78, eGFR=95 mL/min. ABA 77%, pbo 79% completed Yr 1; fewer discontinued during Yr 2 (ABA 14%, pbo 22%). There were no differences between tx arms in CR rates at Yr 1 (ABA 35.1%, pbo 33.5%, p=0.73; primary endpoint). Sustained CR (two successive visits) were more frequent and occurred earlier in ABA pts. CR rates were higher and non-response rates lower in ABA arm in Yr 2 and 3. Benefits were driven by improvement in proteinuria, seen as early as 3 M and sustained up to 3 yrs (Figure). There was no between-group difference in eGFR over 3 yrs. Safety in Yr 1 was consistent with the known profile of ABA (serious AE [SAE] rate ABA 24%, pbo 19%). SAE rates after Yr 1 were lower (ABA 6%, pbo 13%). More sustained improvements in SLE-related biomarkers (C3, C4, anti-dsDNA) were seen in ABA-treated pts over 3 yrs.

Conclusions: The study failed to meet its primary endpoint. Up to 3 yrs of tx, abatacept-treated pts had more rapid improvement in proteinuria, which led to earlier, sustained CR with a favorable safety profile. Writing assistance provided by Caudex.

Funding: Commercial Support - Bristol-Myers Squibb

Figure: Adjusted Mean Change in UPCR Over Time (all Patients)



Adjusted mean change is estimated from longitudinal model repeated mixed model which includes stratification factors (race, ACEi/ARBs use) treatment group, time, time*treatment group interaction and baseline UPCR as continuous covariate
ACEi=angiotensin-converting enzyme inhibitor; ARBs=angiotensin receptor blockers; UPCR=urine protein-to-creatinine ratio

SA-OR067

Correlation of Albuminuria and Hypoalbuminemia with Area Under the Curve Levels of Mycophenolic Acid in Lupus Nephritis

Negiin Pourafshar,[1] Xuerong Wen,[3] Rajesh Mohandas,[2] Mark S. Segal.[2] *[1]University of Virginia, Charlottesville, VA; [2]University of Florida, Gainesville, FL; [3]University of Rhode Island, Kingston, RI.*

Background: Mycophenolate mofetil (MMF) is the mainstay of therapy for lupus nephritis (LN). Studies have shown targeting an area under the curve (AUC) leads to better outcomes in these patients. Therefore, it is critical to identify factors modifying AUC of MMF. Mycophenolic acid (MPA) the active metabolite of MMF binds avidly to albumin. Since patients with lupus often have profound albuminuria and hypoalbuminemia, we hypothesized that it might influence MPA-AUC.

Methods: 51 subjects with biopsy confirmed LN on 1500 mg of MMF twice daily, were included in this study. MPA levels were obtained at 0, 1, 2 and 4 hours. The MPA-AUC values calculated using the linear trapezoidal rule. Spearman correlations were used for correlations between urine albumin creatinine ratio (UACR), serum albumin and MPA-AUC.

Results: Subjects mean age was 33±13 years. The mean serum albumin was 3.3± 0.9 g/dL. 90 % of patients had albuminuria with a median of median of 874 mcg/mg [IQR: 365, 2150]. In univariate analysis there was a statistically significant correlation between AUC and UACR (Rho=-0.34, P=0.02) and serum albumin (Rho=0.48, P=0.004) (Figure-1A and 1B). In multivariate analyses serum albumin remained an independent predictor of AUC when controlled for age and proteinuria [R^2=0.21 p=0.03], but not for renal function[p=0.06]. Hypoalbuminuria was a predictor of AUC only for an eGFR > 60 ml/min/1.73 mt2.

Conclusions: Our results reveal that hypoalbuminemia is associated with lower therapeutic levels of MMF, particularly in those with normal renal function. Patients with hypoalbuminemia are more likely to have severe disease warranting higher doses of MMF. We will discuss the implications of these findings with regard to the monitoring of MMF-AUC to ensure adequate therapeutic doses in such patients.

A Randomized Controlled Trial of Albumin Versus Saline for the Prevention of Intradialytic Hypotension in Hypoalbuminemic Patients

Etienne Macedo, Bethany E. Karl, Lea D. Jacinto, Euyhyun Lee, Ravindra L. Mehta. *University of California San Diego Medical Center, La Jolla, CA.*

Background: Intradialytic hypotension (IDH) is a frequent complication in hypoalbuminemic patients with AKI or ESRD limiting adequate fluid removal and increasing the risk for vascular access thrombosis, early hemodialysis (HD) termination, and mortality. Albumin infusion before and during therapy has been used for preventing and treating hypotension with varying results. We evaluated the efficacy of albumin infusion in preventing intradialytic hypotension during HD.

Methods: A randomized, crossover trial was performed in 65 patients with albumin<3g/dl with AKI or ESRD who required HD during hospitalization. Patients were randomized to receive 100mL of either 0.9% sodium chloride or 25% albumin intravenously prior to their first dialysis session and alternated between the two solutions for up to 6 sessions. Patients' vital signs and ultrafiltration removal rate were recorded every 15 to 30 minutes during HD. All symptoms associated with hypotension as well as interventions during the dialysis were recorded. IDH was assessed by different definitions reported in the literature (Table).

Results: 65 patients completed 249 sessions; mean age was 58(+/-12), 46(70%) were male with a mean weight of 76 (+/-18) kg. Presence of IDH was lower during albumin sessions based on all definitions. The risk of hypotension was significantly decreased based on the KDOQI, decrease in systolic blood pressure (SBP)<30 and 20mmHg and a nadir<90mmHg definitions.

Conclusions: In hypoalbuminemic patients who need IHD, administration of albumin before dialysis results in fewer episodes of intradialytic hypotension. Albumin infusion may be of benefit to improve safety of IHD in high-risk patients

Intradialytic hypotension definition and frequency in NS and Albumin groups

Term	Definition	Albumin	NS	P

Thirst, Xerostomia, and Inter-Dialytic Weight Gain in the Sodium Lowering in Dialysate (SoLID) Trail

Brenda M. Luey,[3] Joanna L. Dunlop,[1] Mark R. Marshall.[1,2] for the SoLID trial investigators *[1]Renal Medicine, Middlemore Hospital, Auckland, New Zealand; [2]School of Medicine, University of Auckland, Auckland, New Zealand; [3]Middlemore Clinical Trials, Auckland, New Zealand.*

Background: A number of observational studies and clinical trials have shown that lower dialysate [Na^+] is associated with reduced fluid intake in hemodialysis (HD) patients. We report the effect of lower dialysate [Na^+] on thirst, xerostomia, and inter-dialytic weight gain (IDWG) in the Sodium Lowering in Dialysate (SoLID) trial (ACTRN12611000975998, www.solid.org.nz).

Methods: The SoLID trial randomised 99 participants on home or self-care HD from 11 sites in New Zealand to the control group (dialysate [Na^+] of 140mM) or intervention group (135mM) for 12 months. Thirst and xerostomia were scored by validated inventories - the Dialysis Thirst Inventory or DTI (Bots 2004), and the Xerostomia Inventory or XI (Thomson 2011). IDWG was measured as the weight gain between dialysis sessions averaged over a two-week period. Outcomes were ascertained at baseline, 6 and 12 months, and analysed using generalized linear models on an intention-to-treat basis.

Results: Results are tabulated in Table 1. IDWG was lower in the intervention group compared to the control group at all time-points There was little or no difference in thirst and xerostomia between the control and intervention groups at either 6 or 12 months.

Conclusions: In the SoLID trial, lower dialysate [Na^+] clearly reduced fluid intake, consistent with previous clinical trials. The intervention did not change DTI and XI, however, despite previous observational studies showing positive correlation between DTI and XI with IDWG (Bots 2004). Further research is underway to determine the relationship between IDWG and the individual items within the DTI and XI instruments. It may be that the DTI and XI are invalid in prospective settings due to recall bias or other reasons, and that other methods are more suitable for determining the longitudinal effects of different interventions on thirst and xerostomia.

Funding: Commercial Support - Fresenius Medical Care (Australia), Private Foundation Support, Government Support - Non-U.S.

Mean difference (p-value) in outcomes between control and intervention group at 6 and 12 months

	Dialysis Thirst Inventory (DTI) score	Xerostomia Inventory (XI) score	IDWG in kg
6 months	-1.22 (0.38)	-0.62 (0.53)	-0.559 (0.001)
12 months	0.57 (0.68)	0.38 (0.70)	-0.569 (<0.0005)

Subgroup Analysis of Impact of Extended Hours Dialysis on Quality of Life in the Active Dialysis Trial

Brendan Smyth,[1,2] Oliver van den Broek-Best,[3] Kirsten Howard,[2] Kris Rogers,[1] Nicholas A. Gray,[4,5] Janak R. de Zoysa,[6,7] Christopher T. Chan,[8] Alan Cass,[9] Martin P. Gallagher,[1,10] Vlado Perkovic,[1] Meg J. Jardine.[1,10] *[1]The George Institute for Global Health, UNSW, Sydney, NSW, Australia; [2]Sydney School of Public Health, University of Sydney, Sydney, NSW, Australia; [3]Sydney Medical School, University of Sydney, Sydney, NSW, Australia; [4]Sunshine Coast University Hospital, Birtinya, QLD, Australia; [5]Sunshine Coast Clinical School, University of Queensland, Birtinya, QLD, Australia; [6]Waitemata District Health Board, Auckland, New Zealand; [7]Department of Medicine, University of Auckland, Auckland, New Zealand; [8]Toronto General Hospital, Toronto, ON, Canada; [9]Menzies School of Health Research, Darwin, NT, Australia; [10]Renal Unit, Concord Repatriation General Hospital, Sydney, NSW, Australia.*

Background: The ACTIVE Dialysis trial of extended hours (≥24 hours per week) versus standard hours (≤18 hours per week) haemodialysis demonstrated a significant improvement in QOL as measured by Short Form-36 (SF-36) Physical Component Summary (PCS) and Mental Component Summary (MCS). We aimed to determine if the effect of extended hours dialysis on quality of life (QOL) in the ACTIVE Dialysis trial differed according to pre-specified subgroups.

Methods: The ACTIVE Dialysis trial was an open-label randomised, blinded endpoint assessment trial. Two hundred participants were enrolled from four countries and randomised to 12 months of standard or extended hours dialysis. The SF-36 was administered by a blinded interviewer at 3-month intervals. Mean difference between extended and standard arms was assessed by mixed linear regression. The overall effect sizes (Cohen's *d*: where 0.2-0.5 is a small effect, 0.5-0.8 a moderate effect and >0.8 a large effect) were calculated as the ratio of mean difference to standard deviation. Subgroup variables were added to the regression model with an interaction with treatment group to test for effect modification.

Results: Extended hours dialysis was associated with significant improvement in PCS (2.30 [95% CI 0.55-4.06]; p=0.010) and MCS (2.54 [95% CI 0.48-4.60]; p=0.016). The effect size on both measures was small (PCS 0.24 [95%CI 0.06-0.42; p=0.010], MCS 0.24 [95%CI 0.04-0.43; p=0.016]). The effect of extended hours dialysis did not vary significantly by baseline score, region (China vs Australia, Canada, New Zealand), dialysis location (home vs in-centre/satellite) or dialysis vintage (≤6 months vs >6 months).

Conclusions: Extended hours dialysis leads to a small improvement in physical and mental QOL. These effects did not differ significantly between key demographic and clinical subgroups.

Bioelectrical Impedance Analysis (BIA) Versus Clinical Criteria for Setting Ultrafiltration (UF) in Chronic Hemodialysis (HD) Patients

Jeffrey P. Mora,[1] Romina A. Danguilan,[2] Concesa Casasola.[1] *[1]National Kidney and Transplant Institute, Quezon City, Philippines; [2]National Kidney and Transplant Institute, Quezon City, Philippines.*

Background: This study compared the laboratory, echocardiographic and clinical outcomes of patients where dry weight (DW) was determined using BIA or clinical evaluation, thus guiding UF.

Methods: A prospective randomized study involving chronic stable HD patients, 21 in BIA and 21 in Clinical-group, managed based on a structured protocol to set UF. The effect on volume status and CV indices after 3 months was evaluated. BIA was done fortnightly for BIA-grp while hypo- or hypervolemia was observed every HD session for the other group. CBC, electrolytes were done monthly, inferior vena cava (IVC) size and collapsibility index (CI), Left ventricular (LV) size, cardiac index and ejection fraction were done at baseline and month 3. Intradialytic events were noted.

Results: DW decreased by 1.12 kg in BIA-grp (p=0.012). Lab results were similar in both groups. IVC and LV size decreased by 0.1 cm in BIA-grp but remained unchanged in Clinical-grp, although not significant (p=0.2183, p=1.000). IVC CI significantly increased to 49.5% in BIA-grp but dropped to 40.8% in Clinical-grp (p=0.0186) suggesting a decrease in right atrial (RA) pressure and attainment of euvolemia in the former group. There was a non-significant increase (4%) in the EF in BIA compared to Clinical (2%) group (p=0.527). Significant change in diastolic BP (7 mmHg drop) and MAP (8 mmHg drop) were seen in the BIA-grp (p=0.034, p=0.043). Intradialytic episodes of muscle cramps, chest pain/palpitations, and dizziness occurred only in BIA-grp (p=0.000).

Conclusions: BIA-guided determination of UF resulted in a significantly reduced dry weight, DBP, MAP, and RA pressure in a chronic HD population while other cardiac indices had a tendency to improve. All these may result in improved cardiac function and CV outcomes.

Online Haemodiafiltration Improves Inflammatory State in Dialysis Patients: A Longitudinal Study

Anil Bhalla, Ganesh Dhanuka, Ashwani Gupta, Aakash Shingada, Lovy Gaur, Anurag Gupta, Vinant Bhargava, Anant Joshi, Devinder S. Rana. *Nephrology, Sir Ganga Ram Hospital, New Delhi, India.*

Background: We conducted this study to evaluate and compare the effect of online haemodiafiltration(OL-HDF) and conventional haemodialysis(C-HD) on the level of inflammatory markers (hs-CRP,IL1, IL6 and TNF- α) in Chronic Kidney Disease V (D).

Methods: In this prospective observational study we measured levels of hs-CRP, IL-1, IL-6 and TNF-alpha at baseline, 3months and 6 months. 60 patients (5 excluded, underwent transplant) with CKD V on C-HD for minimum 3 months were included. Study population was divided in two groups; 27 patients were continued on C-HD; 28 patients shifted on OL-HDF. Follow-up period was 6 months after randomization.

Results: Mean age was 50.22yrs. Mean Kt/v and dry weight were similar in both groups at baseline. Kt/v (P=0.78) & dry weight (P=0.591) remained stable in both groups after 6 months. Mean hs-CRP levels were similar in both groups at baseline (2.66±1.86 mg/dl vs 2.60±1.96 mg/dl; p=0.916) and at 6 months, there was significant reduction of hsCRP in the HDF group by 33%(p-0.007). Mean IL-1 levels were similar at baseline in both groups (177.30±41.86pg/ml vs 166.57±30.29pg/ml; p=0.280) and at 6 months, IL- 1 levels in HDF group decreased significantly (p<0.001) by 13 %. Mean IL-6 levels were similar at baseline in both groups (14.18±9.46pg/ml vs 12.74±7.63pg/ml; p=0.536) and at 6 months IL-6 levels in HDF group decreased significantly (p=0.001) by 33%. Mean TNF-α levels were similar at baseline in both groups (15.47±7.60pg/ml vs 14.87±7.48pg/ml; p=0.771) and at 6 months, TNF-α levels in HDF group decreased significantly (p=0.017) by 22 %. Mean Haemoglobin was similar in both groups at baseline (8.90±1.50gm/dl vs 9.16±1.33 gm/dl; p=0.498). At 6 months, haemoglobin was stable in HD group(p=0.426), while in HDF group it increased significantly (p=0.001) to 10.05±1.53gm/dl. This was associated with a significant decrease on rhEPO requirement in HDF group by 14% (p – 0.043). Mean S. phosphorous was similar in both groups at baseline (6.12±1.72mg/dl vs 6.07±2.05mg/dl; p=0.923). At the end of 6 month reduction in phosphorous in HDF group was significantly higher (p<0.001).

Conclusions: This study showed that CKD related inflammation improved significantly with online-HDF, with significantly decreased level of hs-CRP : 33%, IL-1 : 13%, IL-6 : 33%, THF- α : 22% after 6 months.

SA-OR073

Using IVC Collapsibility and Lung Ultrasound to Determine Ultrafiltration Goal in Hemodialysis Patients

Siddhartha Kattamanchi,[1] Manasi Bapat,[3] Girish N. Nadkarni,[2] Joji E. Tokita,[4] Steven G. Coca.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Ichan School of Medicine, New York, NY; [3]Icahn School of Medicine, Mount Sinai Hospital, NY, New York, NY; [4]Mount Sinai School of Medicine, New York, NY.*

Background: Intra-dialytic hypotension (IDH) and pulmonary congestion are two problems at the opposite ends of the spectrum of the problems related to volume status management in ESRD patients. Current clinical assessment tools to predetermine ultrafiltration (UF) goal in hospitalized patients are inadequate. We sought to determine the utility of employment of hand-held ultrasound at the bedside to adjust goal UF in hospitalized HD patients.

Methods: Hospitalized patients receiving HD for AKI or ESRD in the MSH inpatient dialysis unit were eligible for participation in this pilot study at Mount Sinai Hospital. HD encounters were randomized to the ultrasound-assisted UF goal (intervention group) vs. standard of care to determine UF goal (control arm). In the intervention group, the UF rate ordered by the treating nephrologists was additionally adjusted based upon IVC collapsibility and lung ultrasound patterns assessed immediately prior to the start of HD, as shown in the **Table**. The primary outcomes were A. Intradialytic hypotension (IDH) and B. Moderate to severe congestion on the end of HD.

Results: There were 26 HD encounters in the intervention arm and 26 in the control arm. Based on the US findings, the UF goal was changed in 12 out of 26 (46%) HD patients in the intervention group; Among those 12, 6 patients were classified as hypervolemic and had their UF goal increased, and 6 patients were classified as hypovolemic and had their UF goal decreased. IDH was observed in 1 patient in the intervention arm vs. 4 patients in the control arm. Post-dialysis pulmonary congestion was seen in 2 patients in the intervention arm vs. 4 patients in control group.

Conclusions: This pilot study suggests that adjusting UF goal based on US findings may improve precision of the optimal UF for that HD session and has the potential to decrease incidence of IDH and post-dialysis pulmonary congestion.

Intervention Arm Protocol for UF Adjustment

CVP based on IVC	Lung US	INTERPRETATION	UF adjustment
>10	B line pattern	Hypervolemic	1L more than last time
6-10	A line pattern	Euvolemic	UF not adjusted
≤6	A line pattern	Hypovolemic	≤1L

SA-OR074

The Relationship between Non-Transferrin Bound Iron (NTBI) and Iron Utilization for Erythropoiesis in Maintenance Hemodialysis Patients

Takahiro Kuragano, Takeshi Nakanishi. *Hyogo College of Mediicne, Nishinomiya, Japan.*

Background: The relationship between non-transferrin bound iron (NTBI) derived oxidation stress and arteriosclerosis in maintenance hemodialysis (MHD) patients has been reported. In this study, we investigated the determinant of serum NTBI and the relationship between NTBI and iron utilization for erythropoiesis in MHD patients who did not receive the iron preparations.

Methods: Study design: multicenter cross-sectional study. We evaluated the blood levels of hemoglobin (Hb), β2-microglobulin (βMG), total cholesterol, triglyceride, iron, hepcidin, ferritin, total iron binding capacity (TIBC), NTBI, Interleukin(IL)-6, tumor necrosis factor (TNF)-α, and high sensitive (hs) CRP in 126 MHD patients who did not receive the iron preparations for the past three months. To evaluate the relationship between serum NITB and iron utilization for erythropoiesis, patients were divided into 4 groups according to Hb and ferritin levels (Hb<10 g/dL and ferritin<50 ng/mL, Hb<10 g/dL and ferritin≥50 ng/mL, Hb≥10 g/dL nad ferritin<50 ng/mL, and Hb>10 g/dL and ferritin≥50 ng/mL).

Results: There was no significant difference in the NTBI levels in patients with or without diabetes and hepatitis C. Moreover, there was no significant correlation among NTBI, age, hemodialysis duration, and inflammation index (IL-6, TNF-α, hsCRP). In multivariate analysis, only serum ferritin was selected as a significant (β=0.69, p<0.0001) predictor of serum NTBI levels. Even after adjusting according to the dose of ESA, the serum NTBI of patients with Hb<10 g/dL and ferritin≥50 ng/mL (0.72± 0.5(μM Fe)) had significantly higher levels than other groups ((Hb<10 g/dL and ferritin<50 ng/mL: 0.57±0.35 (μM Fe), Hb≥10 g/dL and ferritin<50 ng/mL: 0.58±0.28 (μM Fe), and Hb>10 g/dL and ferritin≥50 ng/mL:0.62±0.41 (μM Fe).

Conclusions: In this study, we revealed that serum NTBI levels in MHD patients were related to the iron storage and iron utilization for erythropoiesis. Although, repleted iron storage patients with anemia who suspected dysutilization of iron for erythropoiesis already showed significantly higher serum NTBI levels; iron administration to these patients might cause further higher NTBI levels related with arteriosclerosis of MHD patients.

SA-OR075

Phase 3, Multicenter, Open-Label Study of Intermittent Oral Roxadustat in Peritoneal Dialysis CKD Patients with Anemia

Tadao Akizawa,[1] Tetsuro Otsuka,[2] Michael Reusch,[3] Mai Ueno.[2] *[1]Showa University School of Medicine, Tokyo, Japan; [2]Astellas Pharma Inc., Tokyo, Japan; [3]Astellas Pharma Europe B.V., Leiden, Netherlands.*

Background: Roxadustat is an oral HIF-PHI in late-stage development for treatment of anemia in CKD. This Phase 3 study evaluated the efficacy and safety of roxadustat in Japanese CKD patients on peritoneal dialysis (PD).

Methods: This 24-week, randomized, open-label study enrolled adult, Japanese, anemic CKD patients on PD into two groups based on prior ESA treatment. Patients not treated with ESA (ESA Untreated) were randomized to roxadustat 50mg or 70mg; patients treated with prior ESA (ESA Treated) were switched to roxadustat 70mg or 100mg depending on prior ESA dose. Dose was adjusted throughout the study to maintain a target hemoglobin (Hb) level of 10.0-12.0 g/dL. Efficacy endpoints were maintenance rate of target Hb level at Weeks 18-24, cumulative response rate at the end of treatment (two Hb thresholds, 10.0 g/dL and 10.5 g/dL; and Hb increase, ≥1.0 g/dL), average Hb levels at Weeks 18-24 and its change from baseline, and rate of rise in Hb levels from Week 0 to Week 4. Safety was assessed by occurrence of adverse events (AEs).

Results: 56 patients were enrolled (ESA Untreated, n=13; ESA Treated, n=43). Maintenance rates were 92.3% (95% CI: 64.0, 99.8; ESA Untreated) and 74.4% (95% CI: 58.8, 86.5; ESA Treated). Maintenance rates of patients with at least one Hb value at Weeks 18-24 were 92.3% (95% CI: 64.0, 99.8; ESA Untreated) and 86.5% (95% CI: 71.2, 95.5; ESA Treated). In the ESA Untreated Group, cumulative response rate for both Hb thresholds was 100%. Mean of average Hb levels at Weeks 18-24 were 11.05 g/dL (95% CI: 10.67, 11.42; ESA Untreated) and 10.93 g/dL (95% CI: 10.73, 11.13; ESA Treated); mean change in average Hb at Weeks 18–24 from baseline was 1.69 g/dL (95% CI: 1.06, 2.33; ESA Untreated) and 0.14 g/dL (95% CI: –0.12, 0.39; ESA Treated). In the ESA Untreated Group, mean (SD) rate of rise in Hb levels from Week 0 to Week 4 was 0.193 (0.203) and 0.556 (0.408) g/dL/week with roxadustat 50mg and 70mg, respectively. The most common AEs were nasopharyngitis, back pain, catheter site infection, diarrhea, vomiting, abdominal pain, conjunctivitis, constipation, nausea, and pruritus.

Conclusions: Roxadustat was well tolerated and effective in achieving and maintaining Hb levels within the target range in Japanese CKD patients on PD previously treated or untreated with ESA.

Effect of Intradialytic Exercise on Physical Performance and Echocardiographic Findings in Maintenance Hemodialysis Patients

Ji-Hyung Cho, Jun Chul Kim. *Department of Internal Medicine, CHA Gumi Medical Center, CHA University School of Medicine, Gumi, Republic of Korea.*

Background: Poor physical performance (PP) is frequently observed and related to a high risk of mortality, cardiovascular events, and hospitalizations in dialysis patients. We aimed to investigate the effect of intradialytic exercise (IDE) on PP and echocardiographic findings in maintenance hemodialysis (MHD) patients.

Methods: This study randomly assigned ambulatory MHD patients aged≥20 years on dialysis≥6 months, to 4 groups: aerobic exercise (AE), resistance exercise (RE), combination exercise (CE), and control. A stationary bike was used for AE at moderate intensity and a TheraBand®/theraball for RE at vigorous intensity. A 12-week IDE program (3 times/week) was completed in the AE (n=11), RE (n=10), and CE (n=12) groups. The control group (n=13) received only warm-up stretching. At baseline and 12-week follow-up, a sit-to-stand for 30 seconds test (STS30), a 6-minute walk test (6-MWT), and echocardiography were performed in all patients.

Results: We observed significant increases in STS30 (times/30 s) and 6-MWT (meters) in the AE (18.7±5.4 vs 16.5±4.8 and 459±122 vs 434±111, respectively), RE (24.6±4.9 vs 21.0±5.0 and 530±106 vs 510±102, respectively), and CE (24.8±10.7 vs 21.6±9.6 and 514±165 vs 492±167, respectively) groups at 12 weeks compared with baseline, while no improvement was observed in the control group. When comparing between-group changes in STS30 and 6-MWT, there were significant increases in the AE (2.3±2.2 vs -0.5±2.2 and 25±29 vs -26±41, respectively), RE (3.6±2.7 vs -0.5±2.2 and 20±21 vs -26±41, respectively), and CE (3.3±3.1 vs -0.5±2.2 and 22±12 vs -26±41, respectively) groups compared with the control group. In the echocardiographic analysis, the 12-week IDE group interventions (AE, RE, and CE) showed no significant change on left ventricular (LV) ejection fraction (%) (2.5±5.2, -0.7±5.3, and -0.3±5.4 vs 0.3±3.9, respectively), LV mass index (g/m^2) (-1.5±16.7, 0.8±16.3, and -0.5±32.0 vs -11.7±30.1, respectively), and myocardial performance index (0.09±0.19, -0.02±0.18, and 0.12±0.21 vs 0.08±0.18, respectively) compared with the control group.

Conclusions: Although IDE does not affect the echocardiographic parameters measured, it appears to be clinically beneficial in improving PP. It may suggest that IDE can also contribute to improve PP even before any significant benefits in cardiac function is achieved in MHD patients.

SA-OR077

Effects of Age and Hemodialysis on Frailty Prevalence, Gait, and Balance in Diabetic Patients: A Randomized Controlled Trial

Abdullah Hamad,[1] He Zhou,[2] Fadwa S. Al-Ali,[1] Rania A. Ibrahim,[1] Talal Talal,[3] Bijan Najafi.[2] *[1]Hamad Medical Corporation, Doha, Qatar; [2]Baylor College of Medicine, Houston, TX; [3]hamad medical corp, Doha, Qatar.*

Background: Motor skills deteriorates with aging. Some conditions may magnify this deterioration. This study examined whether diabetes and hemodialysis (HD) would negatively impact gait, balance, and physical frailty beyond aging.

Methods: Seventy-three elderly adults with diabetes (age=71.4±5.4 years, BMI=30.8±5.9, 49% were on HD) and seventy-eight mid-age adults with diabetes (age=56.7±5.7 years, BMI=31.1±7.2, 50% were on HD) were recruited. Gait and balance performances were objectively measured using validated wearable sensors at HD clinic. Frailty status was determined by Fried Frailty Criteria.

Results: Aging deteriorated motor-functions (gait and balance) in people with diabetes irrespective of dialysis (9%-46% deterioration, Cohen's *d*effect size=0.22-0.42), with largest effect size observed for double support in gait performance (p=0.011). In addition, deteriorations in gait and balance caused by aging were more pronounced among diabetics with HD (19%-65% deterioration, d=0.41-0.75, p<0.05), when compared to diabetics without HD (1%-14% deterioration, d=0.01-0.20, p>0.05). The largest effect size for gait deterioration among diabetics with HD was observed in double support test (d=0.75,p = 0.002, Fig. 1), and the largest effect size for balance deterioration was observed in ankle stability test (d=0.48, p = 0.042, Fig. 1). Diabetics with HD, irrespective of age, had 3 times higher prevalence of frailty than diabetics without HD (42% vs. 14%, p=0.017).

Conclusions: Our study showed that HD deteriorates gait and balance and magnifies prevalence of frailty by factor of 3 beyond aging in people with diabetes. Immobility caused by prolonged HD (4-hour, 3 times per week) and post-dialysis exhaustion may contribute to poorer motor function in older diabetics leading to frailty. This study demonstrated practicality of wearable sensors to assess motor performance in dialysis clinics with opportunity to capture early deterioration.

Funding: Government Support - Non-U.S.

Higher eGFR at Ten Years in CKD Stage 2 Patients Treated with Chronic Oral NaHCO3 Despite No Metabolic Acidosis Is Associated with Prevented Worsening of Underlying Acid Retention

Nimrit Goraya,[1,2] Jan Simoni,[5] Lauren N. Sager,[3] Donald E. Wesson.[4,2] *[1]Internal Medicine, Baylor Scott and White Health, Temple, TX; [2]Texas A&M HSC College of Medicine, Temple, TX; [3]Biostatistics, Baylor Scott & White, Temple, TX; [4]Baylor Scott and White Health and Wellness Center, Dallas, TX; [5]Surgery, Texas Tech University Health Sciences Center, Lubbock, TX.*

Background: Chronic oral $NaHCO_3$ but not eqimolar NaCl preserves eGFR compared to placebo in CKD stage 2 (eGFR=60-89 ml/min/1.73 m^2, CKD 2) patients (Mahajan et al, KI, 2010) without metabolic acidosis (conventionally defined as plasma total CO_2 <22 mM). Because amelioration of underlying H^+ retention with dietary alkali in experimental CKD models without metabolic acidosis helped preserved GFR (Wesson et al, Kid Int 2010), we explored if eGFR preservation in CKD 2 patients without metabolic acidosis receiving $NaHCO_3$ was associated with amelioration of underlying acid (H^+) retention.

Methods: We randomized 120 CKD 2 non-diabetic, macroalbuminuric subjects with hypertension-associated nephropathy without metabolic acidosis (plasma total CO_2 > 24 mM) to receive 0.5 meq/kg bw/day $NaHCO_3$ (HCO3, n=40), 0.5 meq/kg bw/day NaCl (NaCl, n=40), or to usual care (UC, n=40) and assessed them yearly for 10 years. We measured Cystatin C-based estimated GFR (eGFR) and H^+ retention by comparing observed to expected increase in plasma total CO_2 in response to retained HCO_3 (dose minus $U_{HCO3}V$) 2 hours after oral $NaHCO_3$ bolus (0.5 mmol/kg bw), assuming 50% body weight HCO_3 apparent space of distribution.

Results: Baseline eGFR was not different among groups, was lower than their respective baseline for each group at 10 years, but the 10-year value was higher ($p<0.01$) in HCO_3 (60.3±4.8 ml/min/1.73 m^2) than NaCl and UC (52.2±5.8 and 51.4±4.6 ml/min/1.73 m^2, respectively). Baseline H^+ retention was not different among groups and the 10-year vs. baseline value was not different for HCO_3 (15.7±12.6 vs. 18.1±14.87 mmol, p=0.90). By contrast, 10-year H^+ retention was higher than baseline in NaCl (27.5±15.2 vs. 19.2±16.7 mmol, respectively, $p<0.01$) and UC (22.1±11.2 vs. 17.4±9.9 mmol, $p<0.01$)

Conclusions: Better eGFR preservation in $NaHCO_3$-treated CKD 2 patients without metabolic acidosis was associated with no worsening of underlying H^+ retention whereas H^+ retention worsened in NaCl and UC with less eGFR preservation. The data support that worsening H^+ retention, without metabolic acidosis, contributed to nephropathy progression in CKD. The data suggest that more aggressive $NaHCO_3$ dosing might reduce H^+ retention, rather than preserve its level, possibly yielding even greater eGFR protection.

SA-OR079

Serial FGF23 Concentrations and Risk of ESRD: The Chronic Renal Insufficiency Cohort (CRIC) Study

Rupal Mehta,[1] Xuan Cai,[1] Jungwha Lee,[1] Dawei Xie,[2] Xue Wang,[3] Julia J. Scialla,[4] Amanda H. Anderson,[3] Jonathan J. Taliercio,[5] Mirela A. Dobre,[6] Jing Chen,[7] Michael J. Fischer,[8] Susan P. Steigerwalt,[9] Mary B. Leonard,[10] Chi-yuan Hsu,[11] Ian H. de Boer,[12] James P. Lash,[13] Harold I. Feldman,[3] Myles Wolf,[4] Tamara Isakova.[1] CRIC Study Investigators *[1]Northwestern Univesrsity, Feinberg School of Medicine, Chicago, IL; [2]University of Pennsylvania School of Medicine Center for Clinical Epidemiology and Biostatistics, Philadelphia, PA; [3]University of Pennsylvania, Philadelphia, PA; [4]Duke University, Durham, NC; [5]Glickman Urological and Kidney Institute, Cleveland, OH; [6]Case Western Reserve University, Cleveland, OH; [7]Tulane School of Medicine, New Orleans, LA; [8]University of Illinois Hospital and Health Sciences Center, Chicago, IL; [9]University of Michigan, Ann Arbor, MI; [10]Stanford School of Medicine, Stanford, CA; [11]University of California San Francisco, San Francisco, CA; [12]Division of Nephrology and Kidney Research Institute, University of Washington, Seattle, WA; [13]University of Illinois at Chicago, Chicago, IL.*

Background: Studies using a single FGF23 value suggest that elevated plasma FGF23 is associated with increased risk of ESRD in patients with CKD. However, the data are inconsistent and do not include serial assessments of FGF23.

Methods: To test the association between serial plasma FGF23 and ESRD risk, we performed a case-cohort study within the CRIC Study. We included 1597 individuals with serial FGF23 measurements: 1135 randomly selected individuals, of whom 266 reached ESRD, and 462 individuals outside the random subcohort who also reached ESRD. FGF23 values were available at 2–5 annual time points in all individuals (mean 4.0 ± 1.2). We used weighted Cox proportional hazards models adjusted for baseline and time-varying covariates. To account for the possibility that eGFR could be a time-dependent confounder, we used marginal structural models. We performed group-based trajectory modeling and adjusted the analyses for baseline and final eGFR and eGFR trajectory.

Results: In all models using baseline and time-varying FGF23, elevated plasma FGF23 was independently associated with increased risk of ESRD (Figure). In group-based trajectory analyses, compared to individuals with plasma FGF23 in the stable trajectory group, individuals in the slowly and rapidly rising trajectory groups were at ~3-fold and ~22-fold greater risk of ESRD (Table).

Conclusions: In multiple modeling approaches using serial FGF23 measurements, elevated plasma FGF23 was independently associated with risk of ESRD. Mechanistic studies are needed to test whether exposure to elevated and rising FGF23 levels contributes to accelerated CKD progression.

Febuxostat for Patients with CKD Stage G3 with Asymptomatic Hyperuricemia: A Randomized Trial

Yugo Shibagaki,[1] Iwao Ohno,[2] Naohiko Imai,[1] Shunya Uchida,[3] Shoichi Maruyama,[4] Sadayoshi Ito,[5] Hirofumi Makino,[6] Yasuo Ohashi,[7] Tatsuo Hosoya,[2] Kenjiro Kimura.[8] FEATHER Study Investigators *[1]St. Marianna University, Kawasaki, Japan; [2]The Jikei University School of Medicine, Tokyo, Japan; [3]Teikyo University School of Medicine, Tokyo, Japan; [4]Nagoya University Graduate School of Medicine, Nagoya, Japan; [5]Tohoku Graduate School of Medicine, Sendai Miyagi, Japan; [6]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [7]University of Tokyo, Tokyo, Japan; [8]Tokyo Takanawa Hospital, Tokyo, Japan.*

Background: Epidemiological and clinical studies have suggested that urate-lowering therapy may slow the progression of chronic kidney disease (CKD). However, clinical evidence is still scarce.

Methods: We conducted a randomized, double-blind, placebo-controlled trial in patients with CKD stage G3 [estimated glomerular filtration rate (eGFR) < 60 and ≧ 30 ml/min/1.73m^2] with asymptomatic hyperuricemia (n = 467) at 55 sites in Japan. Participants were randomly assigned, in a 1:1 ratio, to receive febuxostat (loading daily dose: 10 mg on days 1 to 28; maintenance daily dose: 40 mg at weeks 8 to 108) or placebo. The primary endpoint was the slope (mL/min/1.73 m^2 per year) of the eGFR. The mean eGFR slope, time-course changes in eGFR, and serum uric acid from baseline through week 108 were measured.

Results: Among 443 patients who underwent randomization, 220 received febuxostat and 222 received placebo. No significant difference was found in the mean eGFR slope between febuxostat (0.23 ± 5.26) and placebo (-0.47 ± 4.48) (difference, 0.70 mL/min/1.73 m^2 per year; 95% confidence interval, -0.21 to 1.62) (Figure). A subgroup analysis revealed a significant between-group difference in the kidney function decline-suppressing effect in patients who were negative for proteinuria (difference, 1.79; 95% confidence interval, 0.55 to 3.03) and whose serum creatinine concentration was lower than the median (difference, 1.76; 95% confidence interval, 0.44 to 3.07). The incidence of gouty arthritis was significantly lower (P = 0.007) in the febuxostat group [0.91% (2/219)] than in the placebo group [5.86% (13/222)]. Adverse events specific to febuxostat did not occur.

Conclusions: Febuxostat failed to show a statistically significant renoprotective effect as compared with placebo in Japanese patients with CKD stage G3 with asymptomatic hyperuricemia.

Reduction in Albuminuria with Dapagliflozin Cannot Be Predicted by Baseline Clinical Characteristics or Changes in Most Other Risk Markers

Hiddo J. Lambers Heerspink,[1] David Sjostrom,[2] Silvio E. Inzucchi,[3] Melissa Hallow,[4] Valerie Cain,[5] Peter Rossing,[6] Bergur V. Stefansson,[2] Peter Sartipy.[2] *[1]Clinical Pharmacy and Pharmacology, University of Groningen, Groningen, Netherlands; [2]AstraZeneca, Gothenburg, Sweden; [3]Section of Endocrinology, Yale University School of Medicine, New Haven, CT; [4]Department of Epidemiology and Biostatistics, University of Georgia School of Public Health, Athens, GA; [5]Bogier Clinical and IT Solutions, Inc., Raleigh, NC; [6]Steno Diabetes Center, Copenhagen, Gentofte, Denmark.*

Background: The sodium glucose co-transporter 2 inhibitor dapagliflozin (DAPA) has been shown to decrease the urine albumin:creatinine ratio (UACR). This effect varies markedly among individual patients. This study assessed the baseline characteristics and concurrent changes in other cardiovascular risk markers that could be associated with UACR response to DAPA.

Methods: A pooled analysis of 11 phase 3, randomized, controlled clinical trials was performed. UACR change from baseline post 24 weeks treatment with DAPA (10 mg/day) in 531 patients with type 2 diabetes and UACR ≥30 mg/g was determined. UACR response was defined as >30% reduction from baseline at 24-weeks and UACR non-response was defined as ≤30% reduction at 24-weeks.

Results: A total of 288 (54%) patients were classified as responders and 243 (46%) as non-responders. At 24 weeks, the UACR adjusted mean change from baseline appeared to be bimodal: −71.2% (95% CI: −73.7 to −68.3) in responders and 25.9% (95% CI: 17.1 to 35.4) in non-responders (Table). Baseline UACR, HbA1c, estimated glomerular filtration rate (eGFR), systolic blood pressure (SBP), body weight, cardiovascular disease history, and concomitant anti-diabetic medication use were similar between responders and non-responders. Changes in HbA1c, body weight, and haematocrit were also similar between the two groups. Responders showed a numerically larger reduction in SBP and eGFR compared to non-responders (Table). The incidence of hypoglycaemia and other adverse events was similar between the two groups.

Conclusions: UACR reduction to DAPA is an individual characteristic that cannot be predicted by baseline clinical features. It is associated with a modestly larger concurrent reduction in SBP and eGFR. Whether UACR responders compared to non-responders show improved long-term renal and cardiovascular outcomes remains to be determined.

Funding: Commercial Support - AstraZeneca, Gaithersburg, MD, USA.

Table: Adjusted mean change from baseline at week 24*

	UACR responders (N=288)	UACR non-responders (N=243)
UACR† (%)	−71.2 (−73.7, −68.3)	25.9 (17.1, 35.4)
HbA1c (%)	−0.9 (−1.1, −0.7)	−0.7 (−0.9, −0.6)
Body weight (kg)	−2.3 (−2.8, −1.9)	−2.3 (−2.8, −1.9)
Haematocrit (%)	2.0 (1.7, 2.3)	2.6 (2.2, 2.9)
SBP (mm Hg)	−8.7 (−10.2, −7.2)	−3.5 (−5.3, −1.8)
eGFR (mL/min/1.73 m²)	−2.4 (−4.0, −0.8)	−0.3 (−1.9, 1.3)

Change in Albuminuria and GFR as End Points for Clinical Trials in Early Stages of CKD: A Scientific Workshop Collaboration by the NKF, EMA, and FDA

Andrew S. Levey. Planning and Operations Committees and Analytic Group *Tufts Medical Center, Boston, MA.*

Background: The workshop was held on March 15-16, 2018. We used observational studies, clinical trials and simulations to address the research aims (Table). At the ASN meeting, we will present updated and more detailed results.

Methods: For observational studies, we included 20 studies comprising 585,723 participants with 7047 clinical endpoints (ESKD) for ACR change (or equivalent PCR change) and 14 studies, 3,373,368 participants, 14348 endpoints for eGFR slope. For clinical trials, we included 43 trials comprising 30,078 participants with 3939 clinical endpoints (ESKD, eGFR <15 and Scr doubling) for ACR change and 47 trials, 59,074 participants, 6883 endpoints for eGFR slope. For simulations, we performed 1000 independent simulations for >1200 scenarios for parameters related to eGFR trajectories and study design to compare power and type 1 error for eGFR slope with the clinical endpoint (ESKD or Scr doubling).

Results: For observational studies, after adjustment for measurement error, relationships between change in ACR or eGFR slope and the clinical endpoint were strong and consistent. For clinical trials, relationships of treatment effects on change in ACR and eGFR slopes with the clinical endpoint were moderately strong and strong, respectively. The magnitude of relationships was similar across cohorts and trials for both ACR change and eGFR slope (30% ACR reduction or eGFR slope improvement by 0.5-1.0 ml/min/1.73 m2 per year were associated with a HR of approximately 0.7 for the clinical endpoint). For simulations, eGFR slope can substantially reduce the required sample size and duration of followup compared to the clinical endpoint in some circumstances, particularly when baseline eGFR is high.

Conclusions: These analyses suggest that both change in albuminuria and GFR slope can fulfill criteria for surrogacy for use as endpoints in clinical trials for CKD progression under some conditions (characteristics of the clinical population, intervention and trial design), with stronger support for GFR slope than for albuminuria change. Implementation requires understanding conditions under which one or the other surrogate is likely to perform well and restricting its use to those settings.

Funding: Private Foundation Support

NKF-EMA-FDA Workshop Research Aims

1. Examine associations of changes in ACR with subsequent adverse outcomes (ESRD and mortality), and examine consistency of associations across subgroups (level of ACR and GFR, disease, and interventions) as well as implications of measurement error.
2. Examine associations of slope of GFR with subsequent adverse outcomes (ESRD and mortality), and examine consistency of associations across subgroups (level of ACR and GFR disease, intervention) as well as implications of measurement error.
3. Examine associations of treatment effects on early change in ACR with treatment effects on established endpoints, and consistency across subgroups (level of ACR and GFR, disease, and intervention)
4. Examine associations of treatment effects on GFR slope (acute, chronic and total slope) with treatment effects on established endpoints, and consistency across subgroups (level of ACR and GFR, disease, and intervention).
5. Develop methods to combine early change in ACR and GFR for combined endpoint

SA-OR083

Change in Albuminuria and Subsequent Risk of ESRD: A Consortium Meta-Analysis

Josef Coresh.[1,2] CKD Prognosis Consortium and CKD Epidemiology Collaboration *[1]CKD Prognosis Consortium, Baltimore, MD; [2]CKD Epidemiology Collaboration, Boston, MA.*

Background: A recent NKF-FDA-EMA Workshop evaluated candidate surrogate endpoints for clinical trials to slow kidney disease progression, particularly among participants with relatively preserved baseline glomerular filtration rate (GFR). Here we analyze the strength and consistency of the association between changes in albuminuria and end-stage kidney disease (ESKD) risk across a wide range of cohort studies.

Methods: We included 20 studies with 585,732 individuals and 7,047 ESKD events. Using linear regression of log albuminuria, we quantified the percent change in albuminuria during a baseline period of 1, 2, and 3 years. Associations with subsequent ESKD were quantified using Cox regression in each cohort, followed by random-effects meta-analysis. Further adjustment for regression dilution was used to take into account the high variability of albuminuria to relate risk to true reductions in albuminuria.

Results: Change in urine albumin-to-creatinine ratio (ACR) was strongly related to ESKD risk (**Figure**). The adjusted hazard ratio of ESKD following a 30% decrease in ACR during a 2-year baseline period was 0.83 (95% CI 0.74-0.94); after further adjustment for regression dilution it was 0.77 (95% CI 0.65-0.92). Adjusted hazard ratios were relatively consistent across subgroups and study types but were somewhat stronger at higher ACR (p-interaction<0.05). Among persons with ACR >300 mg/g, a true reduction in ACR of 30% over 2-years was estimated to confer >1% absolute reduction in 10-year ESKD risk even at preserved GFR (**Figure**). Results were similar and slightly stronger for PCR.

Conclusions: Change in albuminuria was consistently associated with later risk of ESKD across a wide range of settings lending support to its use as a surrogate endpoint for CKD progression trials. Adjustment for high ACR variability was needed to demonstrate the similar magnitude of observational associations to clinical trials.

Funding: NIDDK Support, Private Foundation Support

Early Albuminuria Change as Surrogate End Point for Kidney Disease Progression – Individual Patient Meta-Analysis of Randomized Controlled Trials: A Report from an NKF-FDA-EMA Workshop

Hiddo J. Lambers Heerspink. Chronic Kidney Disease-Epidemiology Collaboration *University Medical Center Groningen, Groningen, Netherlands.*

Background: A recent NKF-FDA-EMA Workshop evaluated candidate surrogate endpoints for clinical trials to slow kidney disease progression. Change in albuminuria (UACR) may have advantages as it occurs earlier than kidney failure or GFR decline.

Methods: Using a pooled dataset including 30078 patients from 43 RCTs with UACR data at baseline and 6 months post-randomization, we estimated treatment effects on UACR and the composite clinical end point of ESRD, eGFR < 15 or doubling of serum creatinine using separate intent-to-treat analyses in each RCT. We then performed Bayesian mixed models to relate the treatment effects on UACR to treatment effects on the clinical endpoint and to compute the predicted hazard ratio for the clinical endpoint given a specified magnitude of treatment effect on UACR.

Results: Treatment reduced 6-month UACR by a geometric mean ratio (GMR) 22% (95%CI18-26). The figure shows a statistically significant association of treatment effects on change in UACR compared to that of the clinical endpoint. The association was strengthened when analyses were restricted to those with baseline UACR > 30mg/g [R^2 47% (95%CI 2-96) vs 72% (5-99)]. For a 30% true change in UACR, the HR for the clinical endpoint was predicted to be 0.68 (95%CI 0.47-0.95) vs 0.93 (0.63-1.35) with no treatment effect on UACR. Results were consistent by subgroups of baseline eGFR, and disease.

Conclusions: In conjunction with results from epidemiological studies presented at the workshop, the moderately strong association between treatment effects on early changes in albuminuria and treatment effects on the clinical endpoint for UACR > 30mg/g supports the use of sufficiently large reductions (~> 30%) in albuminuria as a surrogate end point for kidney failure in clinical trials of kidney disease progression.

Performance of eGFR-Based Surrogate End Points by Statistical Simulation: A Report from an NKF-FDA-EMA Workshop

Tom Greene,[1] Jian Ying.[2] CKD-Epidemiology Collaboration *[1]University of Utah, Salt Lake City, UT; [2]Univrsity of Utah, Salt Lake City, UT.*

Background: Analyses at the individual and trial level support the validity of 30% or 40% eGFR declines and eGFR slope as surrogate endpoints for randomized clinical trials (RCTs) of CKD. We apply statistical simulation to determine conditions in which eGFR-based surrogate endpoints a) increase statistical power, allowing shorter follow-up or reduced sample size compared to the clinical endpoint of doubling of SCR or kidney failure (CEP), and b) preserve low risk of false positive conclusions if the treatment does not affect the CEP (Type 1 error).

Methods: Using a dataset of 59,074 patients from 47 RCTs, we determined input parameters for simulations of eGFR trajectories and the relationships of these trajectories with kidney failure and death. 1,000 independent simulations were performed for > 1,200 scenarios for eGFR trajectories and specific study designs. We compared the total sample size (N) required for 90% power and evaluated Type 1 error for mean eGFR slope from baseline (total slope) and from 3 months follow-up (chronic) and for composite time-to-events endpoints based on 30%, 40% declines or kidney failure vs. the CEP.

Results: The table displays the required N for each endpoint for 9 scenarios defined by the acute effect of the treatment on eGFR and the type of long-term treatment effect (uniform across fast and slow progressors), proportional (greater for fast progressors), or intermediate. Other simulations show that in the absence of a positive acute effect, Type 1 error favoring the treatment is preserved for each method except chronic slope. Type 1 error for chronic slope may be inflated if a negative acute effect attenuates as eGFR declines.

Conclusions: eGFR-based surrogate endpoints can substantially reduce the required N vs. the clinical endpoint, particularly when baseline eGFR is high and there is no acute effect. The optimum eGFR-based endpoint depends on the rate of eGFR decline, type of treatment effect and study design.

Funding: Private Foundation Support

Acute Effect (ml/min/1.73m²)	Long Term Effect	Baseline eGFR (ml/min/1.73m²)	Ratio of Required N vs. CEP				Total N required for CEP
			Chronic Slope	Total Slope	30% eGFR decline	40% eGFR decline	
None	Uniform	42.5	0.29	0.26	0.52	0.63	5,210
None	Intermediate	42.5	0.55	0.47	0.79	0.77	2,490

GFR Slope as a Surrogate End Point for Kidney Disease Progression – Individual Patient Meta-Analysis of RCTs: A Report from an NKF-FDA-EMA Workshop

Lesley Inker. Chronic Kidney Disease-Epidemiology Collaboration *Tufts Medical Center, Boston, MA.*

Background: A recent NKF-FDA-EMA Workshop evaluated candidate surrogate endpoints for clinical trials to slow kidney disease progression. GFR slope may provide an advantage over time to event endpoints by increasing power but has limitations, in particular when early acute changes differ from longer term changes.

Methods: Using a pooled dataset of 59074 participants from 47 studies, we computed GFR slope from randomization to 1, 2, and 3 years (total slope[TS]) as well as after excluding the initial 3 months after randomization (chronic slope[CS]). We performed Bayesian mixed models to relate the treatment effects on GFR slope to those on the clinical endpoint (CE), defined as ESKD, eGFR<15 or doubling of creatinine and to compute predicted hazard ratio (HR) for the clinical endpoint given a specified magnitude of treatment effect on slope.

Results: The figure shows associations of treatment effects on 3-year TS and CS compared to that of CE. For TS, associations weaken but persist at 2 years [R^2 0.82 (0.46, 0.97)], and deteriorate at 1 year [R^2 0.47 (0.09, 0.78)], likely related to presence of acute effects. For CS, sensitivity analyses using truncated data seem to show similar associations with follow-up time of 18-24 months. Results were consistent across eGFR, ACR and disease subgroups. For a 0.75 ml mean difference in 3-year TS and CS, predicted HR on the CE was 0.69 (0.59, 0.81) and 0.72 (0.60, 0.87), respectively.

Conclusions: Treatment effects on 3-year TS and CS have strong associations with those on the CE. TS over lesser time periods needs to consider presence of acute effect. These results, combined with analyses of epidemiological associations and simulation studies presented at the Workshop, support the use of GFR slope as a surrogate endpoint in clinical trials of kidney disease progression.

SA-OR087

Association between GFR Slope and Subsequent ESKD and the Impact of Adjustment for Measurement Error: Meta-Analysis of Observational Studies

Morgan Grams. CKD Prognosis Consortium *CKD Prognosis Consortium (CKD-PC), Baltimore, MD.*

Background: A recent NKF-FDA-EMA Workshop evaluated candidate surrogate endpoints for clinical trials to slow kidney disease progression, particularly among participants with relatively preserved baseline glomerular filtration rate (GFR). Here, we investigate difference in GFR slope as a candidate surrogate endpoint using observational studies assembled by the CKD-PC.

Methods: We evaluated the strength of association between GFR slope and the clinical endpoint of end-stage kidney disease (ESKD), including the impact of error in slope measurement and the length of the observation period in which slope is observed, using random-effects meta-analysis of 14 cohorts including 3,373,368 participants followed for a mean of 4.4 years.

Results: In covariate-adjusted analyses, a reduction in eGFR decline of 0.75 ml/min/1.73 m^2/year was protective for ESKD in participants with baseline GFR ≥60 ml/min/1.73 m^2 (adjusted hazard ratio using 1-year slope, 0.93, 95% CI: 0.92-0.94). Associations were stronger among participants with GFR <60 ml/min/1.73 m^2 (0.88, 95% CI: 0.86-0.91), when slopes were observed over longer observation periods (2-year slope, 0.80, 95% CI: 0.78-0.82; 3-year slope, 0.71, 95% CI: 0.69-0.74), and when adjusted for measurement error (1-year slope 0.80, 95% CI 0.77-0.83; 2-year slope, 0.71, 95% CI: 0.69-0.74; 3-year slope, 0.64, 95% CI: 0.60-0.67). Compared to a control group with baseline GFR of 60 ml/min/1.73 m^2 and an expected 2-year GFR decline of 3 ml/min/1.73 m^2/year, an intervention that slows GFR decline by 0.75 ml/min/1.73 m^2/year would be expected to result in an absolute 10-year risk reduction of ESKD of 1.3% (0.9% to 3.6% risk reduction for a baseline eGFR of 75 to 45 ml/min/1.73 m^2, respectively).

Conclusions: Slope of GFR is associated with subsequent ESKD, with stronger associations after adjustment for measurement error as well as when observed over longer periods. These results, combined with analyses of clinical trials and simulation studies, may support the use of GFR slope as a surrogate endpoint in clinical trials.

SA-OR088

CyTOF Analysis Identifies Antibody-Secreting and Memory B Cells >1 Year Prior to Antibody-Mediated Rejection (AMR) Development in Pediatric Kidney Transplant Recipients

Clara Fischman,[1] Miguel Fribourg,[1] Fabrizio Ginevri,[2] Patrizia Comoli,[2] Michela Cioni,[2] Arcangelo Nocera,[2] Chiara Cantarelli,[1,3] Laura Perin,[4] Paolo Cravedi.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]IRCCS G Gaslini, Genoa, Italy; [3]Az. Osp. Univ. Parma, Gattatico (Reggio Emilia), Italy; [4]Childrens Hospital Los Angeles, Los Angeles, CA.*

Background: Development of anti-HLA donor specific antibodies (DSA) is associated with antibody mediated rejection (AMR) and reduced graft survival. Changes in circulating T and B cells before AMR development have not been investigated systematically.

Methods: We used time-of-flight mass cytometry (CyTOF) to comprehensively characterize T and B cells in prospectively collected PBMC from 10 pediatric kidney transplant recipients who developed DSA and 11 matched controls who did not develop DSA. PBMC were obtained at 2 months post-transplant, 3 months prior to DSA development, and at DSA detection (PBMC from controls were collected at the same time-points).

Results: DSA^+ and DSA^- patients had similar baseline characteristics and comparable T cell frequencies across the different time-points. Patients who developed DSA had significantly more B cells with an antibody-secreting phenotype ($CD27^+CD38^+$) compared to DSA^- controls 3 months prior to DSA detection (p=0.01; **Figure 1A,B**). Within DSA^+ patients, only those that developed AMR (n=5; 18±3.6 months post-DSA detection) had increased B cells with a memory phenotype ($CD27^+CD95^+IgD^-$) at the time of DSA detection (p=0.009; **Figure 1A,C**). There was no difference in DSA titers between patients who developed AMR and those who did not (13,687±4,159 vs. 11,375±1,894 MFI, respectively; p=0.63).

Conclusions: Our extensive phenotypic analysis by CyTOF showed that, while circulating T cells do not differ between patients with or without DSA, antibody-secreting and memory B cells are detectable prior to the development of DSA and AMR, offering a potential target for this serious condition.

Funding: NIDDK Support, Private Foundation Support

Concerns over the Safety and Maturity of Nephron-Like Structures after Renal Subscapular Transplantation of Kidney Organoids Derived from Human iPS Cells

Yong Kyun Kim,[2,1] Benjamin S. Freedman.[1] *[1]Division of Nephrology, Kidney Research Institute, and Institute for Stem Cell and Regenerative Medicine, Department of Medicine, University of Washington, Seattle, WA; [2]Cell Death Disease Research Center and Department of Internal Medicine, College of Medicine, Catholic University of Korea, Seoul, Republic of Korea.*

Background: For chronic kidney disease, regeneration of lost nephrons in human kidney organoids derived from induced pluripotent stem (iPS) cells is proposed to be an attractive potential therapeutic option, but it remains unclear whether kidney organoids transplanted into kidneys *in vivo* would be safe or functional.

Methods: Kidney organoids were differentiated from the CMC11 iPS cell line using the protocols decribed previously. The harvested kidney organoids were transplanted into subcapsular space of kidneys of immunodeficient male NOD/SCID mice.

Results: Kidney organoid grafts survived for months after transplantation and were vascularized from host mouse endothelial cells. Transplantation of kidney organoids into mouse kidneys revealed nephron-like structures with more mature characteristics, compared with kidney organoids *in vitro*, but they remained immature. Ultrastructural analysis revealed the filtration barrier-like structures, capillary lumens and tubules with brush border in the transplanted kidney organoids, which were more mature than those of the kidney organoids in vitro but not organized as adult mammalian kidneys. Stroma of transplanted kidney organoid grafts were filled with vimentin-positive mesenchymal cells, and cells in nephron-like structures were similarly not fully differentiated. Chondrogenesis and cystogenesis were observed in the transplanted kidney organoid grafts in the long term, characteristics reminiscent of teratoma tumors.

Conclusions: Our data suggest that kidney organoids derived from iPS cells may be transplantable but strategies for overcoming the immaturity and maldifferentiation are needed before they can be used in humans as a therapeutic option for nephron loss.

MicroRNA Expression in Human Kidney Allografts Is Associated with Future Development of Fibrosis

Hua Yang,[1] Lucile Amrouche,[2] Kemal M. Akat,[3] Carol Y. Li,[4] Claire Tinel,[5] Dany Anglicheau,[6] Thangamani Muthukumar.[1] *[1]Weill-Cornell, New York, NY; [2]Necker hospital, Paris, France; [3]The Rockefeller University, New York, NY; [4]Weill Cornell Medical College, New York, NY; [5]CHU Dijon, Dijon, France; [6]Necker Hospital, Paris, France.*

Background: Biomarkers that foretell tubulointerstitial fibrosis (IFTA) of the kidney allograft may help redefine management of kidney transplant recipients.

Methods: We studied 16 kidney allograft surveillance biopsies from 16 recipients at 3 months post–transplantation. All biopsies had Banff ci score (interstitial fibrosis) and ct score (tubular atrophy) of zero. Based on the presence of IFTA in the 12-month surveillance biopsy, 10 recipients were classified as 'Progression to IFTA' (Group A, ci score ≥2 and ct score ≥2) and 6 as 'No Progression to IFTA', (Group B, ci/ct scores=0). We did RNA sequencing of the 16 biopsies and compared the differential abundance of miRNA between Group A and Group B. We did qRT-PCR assay of the top differentially abundant miRNAs.

Results: Sixteen miRNAs were differentially abundant between the groups; 11 increased and 5 decreased in Group A comapred to Group B (Figure 1). All 16 miRNAs,

as reported in prior studies, were associated with organ fibrosis. By qRT-PCR assay, the miRNAs discriminated the groups with high degree of accuracy (Figure 2).

Conclusions: miRNA expression in kidney allograft in 3-month surveillance biopsies is associated with IFTA in 12-month surveillance biopsies.

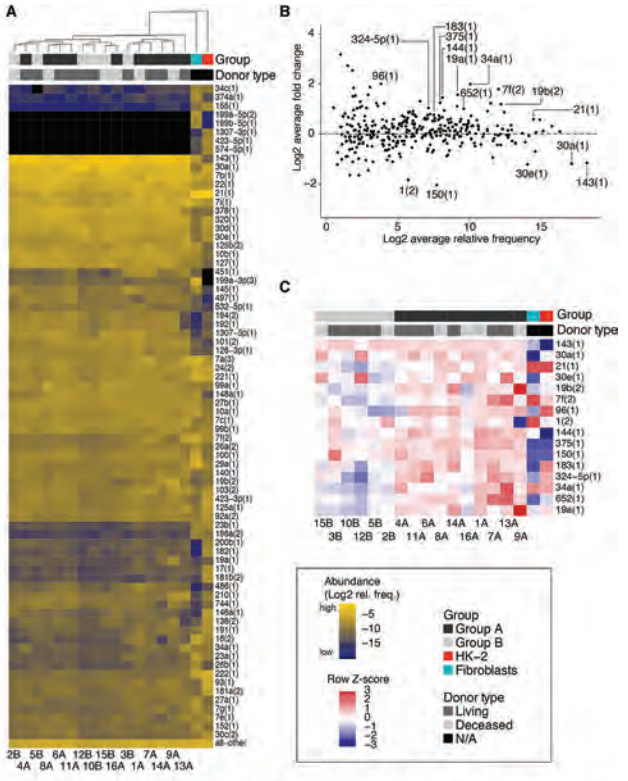

Figure 1. Kidney Allograft MicroRNA Profiles Generated by Small RNA Sequencing.
(A) Heat map after unsupervised clustering of the cumulative top 90% abundant individual miRNAs of 16 kidney allograft biopsy samples obtained at 3 months after transplantation.
(B) MA-plot showing the result of the differential analysis between Groups A and B.
(C) Heat map of 16 differentially expressed miRNAs selected for qRT-PCR.

miRNA	Area Under ROC	95%CI	P
96-5p	0.98	0.93-1.00	0.002
34a-5p	0.98	0.91-1.00	0.002
183-5p	0.95	0.85-1.00	0.003
21-5p	0.93	0.81-1.00	0.005
652-3p	0.93	0.79-1.00	0.006
375	0.89	0.73-1.00	0.01
7f-5p	0.86	0.67-1.00	0.02
324-5p	0.82	0.58-1.00	0.04
144-3p	0.78	0.51-1.00	0.07
19a-3p	0.76	0.51-1.00	0.09
19b-3p	0.73	0.45-0.99	0.14

Figure 2. Discrimination between Group A and Group B by miRNAs.
qRT-PCR assay of the 11 miRNAs increased in Group A (Progression to Fibrosis) comapred to Group B (No Progression to Fibrosis). At the time of reverse transcription we spiked the RNA sample with 1ul of 1nmol synthetic cel-miR-54 (Integrated DNA Technologies). We did qRT-PCR assay in QuantStudio™ 6 Flex Real-Time PCR System (ThermoFisher Scientific). Absolute levels of miRNAs were measured in PCR assays by the incorporation of a customized 73-bp BAK amplicon-based standard curve. The spike-in control, cel-miR-54 copies, and the endogenous control, RNU-44 copies, were not different between Group A and Group B (P=0.1 and P=0.15, respectively). For each sample, we created ratios of individual miRNAs to miR-143, the most abundant miRNA in kidney, in the same sample. We did receiver operating characteristic (ROC) curve analysis and assessed the ability of the miRNAs to discrimiante Group A and Group B by the area under the ROC curve.

Change of Gut Microbiome after Kidney Transplantation and Its Impact on Acute Rejection

Ji Eun Kim,[3] Hyunjeong Cho,[1] Ji In Park,[2] Dong Ki Kim,[3] Seung Hee Yang,[4] Jung Pyo Lee,[5] Yon Su Kim,[6] Hajeong Lee.[6] *[1]Internal Medicine, Chungbuk National University Hospital, Cheongju-si, Chungcheongbuk-do, Republic of Korea; [2]Kangwon National University Hospital, Chuncheon-si, Republic of Korea; [3]Seoul National University Hospital, Seoul, Republic of Korea; [4]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [5]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [6]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Gut microbiota regulates immune responses and its dysbiosis is associated with various kinds of diseases, although very few studies have been conducted in kidney transplantation recipients. The purpose of this study is to analyze the changes of gut microbiome after renal transplantation and to evaluate the association between bacterial composition and post-transplantation outcomes.

Methods: We prospectively enrolled renal transplant recipients at 2 tertiary centers. We gathered their fresh feces before and three-month after receiving transplantation. The Illumina MiSeq system was used for sequencing of the 16S rRNA V4-V5 variable region from the extracted stool DNA. We explored gut microbiome profile change before and after transplantation and its impact on transplantation outcomes such as acute rejection (AR) and infection occurrences.

Results: From 76 recipients, we analyzed 76 feces before transplantation and 39 feces after transplantation. Microbial diversity decreased significantly in three months after transplantation than pre-transplantation period ($p<0.001$). At the phylum level, *Proteobacteria* significantly increased in post-transplantation state ($p=0.046$). At the genus level, relative proportions of *Oscillibacter* ($p=0.001$), *Subdoligranulum* ($p=0.018$), and *Alistipes* ($p=0.005$) significantly decreased, whereas the genera *Clostridium_g24* significantly increased ($p=0.016$) in post-transplantation period. When we compared gut microbiome profiles between patients with and without transplantation outcomes, both observed operational taxonomic unit ($p=0.029$) and microbial diversity ($p=0.014$) were significantly lower in AR group. AR group tended to have lower phylum *Bacteroidetes*, higher phylum *Proteobacteria*, and lower abundance of the genera *Faecalibacterium* than non-AR group, although insignificant. Recipients with infection episodes had lesser the genera *Oscillibacter* ($p=0.019$) than those without. In addition, they had higher abundance of the genera *Bacteroides* ($p=0.037$) than those without.

Conclusions: In this study, we demonstrate significant sequential changes as well as a decreased diversity of gut microbiota after kidney transplantation. Interestingly, transplantation outcomes including AR and infection episodes were associated with changes of gut microbiota in recipients.

SA-OR092

Histone Deacetylase-8 Inhibition Is Protective in Renal Ischemia-Reperfusion Injury

Seth Concors,[1] David D. Aufhauser,[2] Zhonglin Wang,[2] Douglas R. Murken,[2] Guanghui Ge,[4] Tricia Bhatti,[5] Wayne W. Hancock,[3] Matthew H. Levine.[2] *[1]University of Pennsylvania Health System, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA; [3]Children's Hospital of Philadelphia and University of Pennsylvania, Philadelphia, PA; [4]University of Pennsylvania, Philadelphia, PA; [5]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Ischemia/reperfusion injury (IRI) is a major source of morbidity in renal transplantation and other surgical scenarios, and has no specific therapy. In renal transplantation, IRI contributes to poor outcomes and early graft loss. Histone deacetylases (HDACs) regulate diverse cellular processes. We have previously shown that class I HDAC 1 and 2 have reciprocal effects on renal ischemia-reperfusion injury (IRI) with HDAC1 deletion increasing vulnerability and HDAC2 protection providing profound protection. HDAC8, another Class I HDAC, is structurally distinct from other members and is specifically targetable, making it a molecule of interest in IRI.

Methods: Whole-body tamoxifen-inducible HDAC -8 deficient (HDAC8 KO), and tamoxifen-treated WT female mice, as well as B6 female mice treated with specific HDAC8 inhibitor (OJ-1) or DMSO control were used. Mice were subjected to warm renal IRI through unilateral clamping of the renal pedicle and contralateral nephrectomy under strict temperature control. Creatinine and BUN were examined at 24-, 48-, 72-, and 96-h post IRI.

Results: HDAC8 KO (Figure 1A& 1B) and inhibitor-treated (Figure 1C & 1D) mice developed significantly less renal injury after renal IRI than controls, with significantly decreased post-operative BUN and Cr ($p<0.0001$ for all).

Conclusions: HDAC8 knockout and pharmacologic inhibition appears to be proactive in a standard model of renal warm IRI. The benefit of short term HDAC8 pharmacologic inhibition represents an important finding, demonstrating highly novel translational potential. Further clinical correlation and mechanistic understanding is needed for this candidate molecule.

Funding: NIDDK Support

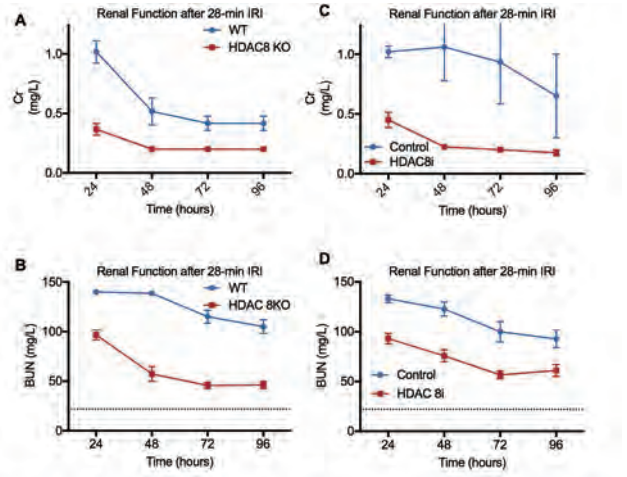

Figure 1. A&B) HDAC8 KO demonstrated significantly improved BUN (p<0.0001) and Cr (p< 0.0001) at each time point post IRI. C&D) HDAC8 inhibition demonstrated significantly improved BUN and Cr (p<0.0001) relative to DMSO control

SA-OR093

Urinary Microvesicular Biomarkers for Delayed Graft Function and Overall Outcome after Living Donor Kidney Transplantation

Fabian Braun,[1] Markus M. Rinschen,[5] Denise Buchner,[6] Andreas Beyer,[4] Dirk L. Stippel,[4] Christine E. Kurschat,[2] Bernhard Schermer,[2] Thomas Benzing,[4] Roman-Ulrich Mueller.[3] *[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]University Hospital Cologne, Cologne, Germany; [3]Dept. 2 of Internal Medicine, University of Cologne, Koeln, Germany; [4]University of Cologne, Köln, Germany; [5]CECAD, Cologne, Germany; [6]Department of General, Visceral and Cancer Surgery, Division of Transplantation Surgery, Transplant Center Cologne, University Hospital of Cologne, Cologne, Germany.*

Background: With a cargo of specific proteins and nucleic acids, urinary microvesicles represent a source for cellular material, that can be isolated easily and non-invasively. Despite this, their application in routine diagnostics are still a subject of investigation. Kidney biopsies remain the gold standard procedure in the diagnosis of transplant failure. We hypothesize that the addition of non-invasive biomarkers could benefit this method minimize the risk of a sampling error.

Methods: Via a protocol of differential centrifugation, we isolated urinary microvesicles from living kidney transplant recipients and their donors over the course of 40 kidney transplantations. Urine samples were collected on day -1 (donor sample), 0, 1 and 3 months after transplantation (recipient samples). Microvesicular protein content was measured using quantitative mass spectrometry. We detected proteins, that linearly change their abundance corresponding to clinical parameters, e.g. GFR measured at 6 and 12 Months after transplantation in a set of 20 transplantations, by linear regression models. These results were validated in a cohort of 20 additional transplantations.

Results: We identified >1500 proteins present in at least 50% of the first sample set. In hierarchical clustering analysis, the proteomic profiles depicted a clear clustering by time point of urine collection. Microvesicular proteins of glomerular (e.g. nephrin, podocin) or tubular origin (e.g. V-ATPase and Slc transporters) were regulated over the course of transplantation. Overall, specific proteomic time course patterns were apparent over the course of transplantation. Depending on low statistical error and high stability in a leave-one-out cross-validation of the linear models correlating to GFR values after transplantation, we created a list of 64 candidate proteins. This candidate list was validated in a targeted proteomics analysis in the samples of the follow-up cohort.

Conclusions: With this study, we present the first analysis of the changes in the human urinary microvesicular proteome over the course of kidney transplantation. We believe, the validated biomarkers of all 40 Transplantations to hold the potential to further aid the diagnosis of graft survival and possibly transplant rejection.

Simvastatin Modulates the Immunoregulatory Phenotype of Vascular Endothelial Cells

Timna Agur,[1,2] Chandra C. Ghosh,[1,2] Johannes Wedel,[1,2] David M. Briscoe.[1,2] *[1]Transplant Research Program and the Division of Nephrology, Boston Children's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Evidence suggests that HMG-CoA reductase inhibitors (statins) reduce the incidence of acute and chronic allograft rejection and have immunomodulatory effects. However, their mechanism of function to regulate alloimmunity is poorly understood. We hypothesize that statins modulate the immunogenicity of donor graft endothelial cells (EC) and the costimulation of recipient CD4+ Teffector cells thereby promoting a pro-tolerogenic intragraft microenvironment.

Methods: Pooled populations of CD4+T cells and memory CD45RO+ subsets were isolated from PBMC, and were co-cultured with untreated human umbilical vein EC (HUVEC) or EC pre-treated with simvastatin (Simva, 0.1-10μM for 24 hrs) in the presence of mitogen (PHA 0.1-0.3μg/ml). The ability of EC to transcostimulate CD4+T cell proliferation was measured after 72 hours using either [3H] thymidine incorporation or CFSE dilution by FACS. Released cytokines were analyzed by Luminex and by ELISPOT, and the direct effect of Simva on the phenotype of EC was evaluated by RNAseq and validated by qPCR. Controls were Simva-treated fibroblasts.

Results: We found a significant reduction ($P<0.001$, n=6) in the proliferation of CD4+T cells following coculture with Simva-pretreated EC vs. untreated cells. Furthermore, inhibition of memory CD4+T cell proliferation was dose dependent using up to five concentrations of simva (0.1-10μM, n=3). Multianalyte luminex assays of coculture supernatants revealed a reduction in several pro-inflammatory cytokines, and ELISPOT assays confirmed a notable effect on the reduction of IL-2, IFNg and IL-6 production following coculture with Simva-pretreated EC vs. untreated cells. In contrast, fibroblasts pretreated with Simva failed to inhibit PHA-induced proliferation of CD4+T cells as a control, indicating that there are cell intrinsic effects of Simva on the EC phenotype. To determine mechanism, we evaluated RNAseq and performed mRNA gene arrays on Simva-treated EC vs untreated and found increased expression of immunoregulatory genes including LGALS family molecules and reduced expression of IL-6, IL-8 and OX40L.

Conclusions: Simvastatin modulates the immunogenicity of EC and their function in the activation of memory $CD4^+$T cells. These studies support the use of simvastatin as an adjunct immunomodulatory therapy to augment tolerance and promote long-term graft survival.

Single Cell RNA-Seq of Sequential Kidney Biopsies in Antibody Mediated Rejection Reveals a Highly Diverse Inflammatory Response

Andrew F. Malone, Sai Mukund Ramakrishnan, Haojia Wu, Erinn L. Donnelly, Benjamin D. Humphreys. *Washington University School of Medicine, Saint Louis, MO.*

Background: Antibody mediated rejection (AMR) remains a major cause of allograft failure yet current treatments are suboptimal reflecting our poor understanding of this disease process. To better understand the impact of current AMR treatments we performed single cell RNA-seq on human kidney biopsies both at AMR diagnosis and at 1 month post treatment.

Methods: Single cell suspensions were prepared by enzymatic digestion. The 10X Genomics platform was used for library preparation. Libraries were sequenced to a depth of ~50k reads/cell. Gene-cell matrices were obtained using CellRanger and the downstream analyses were done using R and Seurat.

Results: 11,592 cells (1,841 genes/cell) and 5,581 cells (1,253 genes/cell) from the pre- and post-treatment biopsy, respectively, were included in the final analysis of each biopsy. AMR treatment included rituximab, bortezomib, IVIG, high dose steroids and tocilizumab. Allograft function did not return to baseline and post treatment histology showed no improvement in Banff scores. We detected all major epithelial cell types. A combined analysis of all immune cells from both biopsies revealed 16 separate immune cell clusters (Fig A). These included distinct monocyte(x8), dendritic cell(x3), CD8 T cell, NK cell, B cell and plasma cell clusters. Treatment resulted in a modest reduction in B cell and plasma cell proportions of 0.56 to 0.44 and 0.6 to 0.4, respectively (Fig B; red, pre-treatment cells; blue, post-treatment cells). By contrast, the number of these cells expressing TNFRSF17 (BMCA, B cell maturation antigen) increased from 1.2% to 24.9%, before and after treatment. Furthermore, the number of TNFSF13B (BAFF, B cell activating factor) expressing cells remained high after treatment (42% to 32%).

Conclusions: Aggressive anti-B cell and anti-plasma cell therapy failed to substantially reduce intra-graft antibody secreting cell numbers. Elevated intra-graft antibody secreting cell number may be maintained by BAFF-BCMA signaling. scRNA-seq provides a quantitative description of the cellular landscape in rejection.

SA-OR096

IgG Glycosylation Causes Podocyte Injury in Transplant Glomerulopathy via Calcium Calmodulin Kinase IV

Rhea Bhargava,[1] Kayaho Maeda,[3] Martha Pavlakis,[2] George C. Tsokos.[1] *[1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Beth Isreal Deaconess Medical Center, Harvard Medical School, Brookline, MA.*

Background: Transplant glomerulopathy(TG) is a major cause of late allograft loss. Increase in urine podocin/creatinine ratio in TG signifies acceleration of podocyte detachment from glomerular basement membrane. We evaluated the mechanism by which antibodies lead to podocyte injury in transplant glomerulopathy. We focused on calcium calmodulin kinase IV(CAMKIV), a serine threonine kinase which we have shown to be upregulated in immune podocytopathies.

Methods: Expression of CaMKIV in transplant biopsy kidney specimens was evaluated by immunofluorescence. Immortalized human podocytes were examined for actin cytoskeleton changes after exposure to IgG from patients with TG versus controls. We subjected IgG from TG patients to deglycosylation and silenced the podocyte expressed neonatal Fc receptor (FcRn) by CRISPR technology and siRNA.

Results: CaMKIV was increased in podocytes of transplant kidney biopsies from patients with TG but not in samples without TG. Culture of podocytes in the presence of IgG from TG patients or patients who eventually developed TG, led to increased CAMKIV expression in a dose dependent manner along with reduction in expression of nephrin and alpha actinin 4, podocyte migration and significant actin cytoskeleton changes. This was not seen with IgG from normal transplant subjects. Silencing of FcRn reduced the entry of IgG into podocytes. IgG from patients with TG subjected to N-deglycosylation failed to increase the expression of CaMKIV. CAMKIV deficiency or pharmacologic inhibition preserved nephrin and alpha actinin 4 expression and prevented the disruption of actin cytoskeleton in podocytes. CAMKIV inhibited GSK3beta by phosphorylating it at serine 9 which led to stabilization of transcription factor SNAIL and subsequent repression of nephrin transcription.

Conclusions: We conclude that targeting CaMKIV may represent a novel biomarker for the early detection of transplant glomerulopathy and a pathway for development of novel therapeutics in this disease. Furthermore, glycosylated IgG from patients with TG enters podocytes through the FcRn causing an increase in CaMK4 and transcriptional repression of nephrin. The ability of IgG in the sera of patients with TG vs controls to disrupt structure and function of podocytes can serve as a bioassay for impending TG. Targeting the glycosylation of IgG may prevent allograft failure.

SA-OR097

Late B Lymphocyte Action in Dysfunctional Tissue Repair Following Kidney Injury and Transplantation

Pietro E. Cippa, Andrew P. McMahon. McMahon Lab *University of Southern California, Los Angeles, CA.*

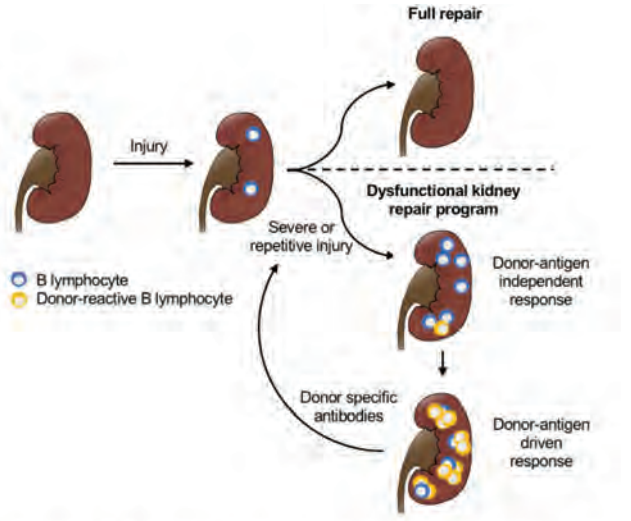
Background: Immune-mediated injury contributes to unsatisfactory long-term outcomes after kidney transplantation, but the mechanisms initiating late immunoreactivity are poorly understood.

Methods: In this translational study, we combined transcriptional profiling of serial protocol biopsies after kidney transplantation in humans (RNAseq analysis from 163 protocol biopsies) with the extensive characterization of immunological processes up to 18 months after ischemia/reperfusion injury (IRI) in mice (RNAseq, immunofluorescence, B cell receptor analysis and autoantibody detection).

Results: In human kidney allografts, a transcriptional B cell signature correlated with fibrosis and reduced graft function. The presence of a B cell signature at 1 year was associated with an injury/repair response earlier after transplantation, not primarily related to episodes of allograft rejection. In the mouse model, we identified a sustained immune response in the absence of foreign antigens in conjunction with the transition to chronic kidney disease. The late intrarenal response after IRI was characterized by the appearance of ectopic lymphoid structures hosting the proliferation and maturation of B lymphocytes into antibody secreting cells. The B cell receptor analysis was consistent with a process of clonal expansion and affinity maturation of B lymphocytes in the damaged kidney. In the absence of foreign antigens this process resulted in the production of systemically detectable broadly-reacting antibodies.

Conclusions: These findings highlight stage specific immunological responses to kidney injury shared between the mouse and human kidney and suggest a new disease model for chronic forms of injury and rejection after transplantation with dysfunctional kidney repair as the *primum movens* of late B cell mediated immunity.

Funding: Private Foundation Support, Government Support - Non-U.S.



New model to understand late alloreactivity after kidney transplantation. Severe or repetitive kidney injury induces a dysfunctional repair program leading to a sustained immune response in the kidney. Over time, the local immune response leads to the recruitment and activation of donor reactive B cell clones, which differentiate to plasma cells and produce donor specific antibodies, further contributing to tissue injury in a deleterious feedback mechanism.

SA-OR098

Glycerol-3-Phosphate Is a Novel FGF23 Regulator Derived from the Injured Kidney

Petra Simic,[1] Wondong Kim,[1] Bryan R. Kestenbaum,[2] Ian H. de Boer,[3] David E. Leaf,[4] Sushrut S. Waikar,[4] Robert Gerszten,[7] Ravi I. Thadhani,[8] Clary B. Clish,[6] Harald Jüppner,[1] Marc N. Wein,[5] Eugene P. Rhee.[1] *[1]Massachusetts General Hospital, Brookline, MA; [2]University of Washington, Seattle, WA; [3]Division of Nephrology and Kidney Research Institute, University of Washington, Seattle, WA; [4]Harvard Medical School, Boston, MA; [5]MGH Endocrine Unit, Boston, MA; [6]Broad Institute of MIT and Harvard, Cambridge, MA; [7]Beth Israel Deaconess Medical Center, Boston, MA; [8]Cedars-Sinai, Los Angeles, CA.*

Background: Disorders of FGF23 are associated with significant morbidity and mortality, but an understanding of what regulates FGF23 in bone is lacking. Because the kidney is the major end-organ of FGF23 action, we hypothesized that it releases a factor that regulates bone FGF23 synthesis.

Methods: Using aptamer based proteomics and liquid chromatography-mass spectrometry (LC-MS) based metabolomics, we profiled >1600 molecules in renal venous plasma obtained from human subjects. After identifying the molecule that has the strongest correlation with FGF23, we used *in vitro* techniques and genetically modified mice to investigate its effects on bone FGF23 production. Further, we examined the association between the molecule and FGF23 levels in an ischemia-reperfusion (IRI) model of acute kidney injury (AKI) in mice, and in 26 individuals who did (cases) or did not (controls) develop AKI after cardiac surgery.

Results: Renal vein glycerol-3-phosphate (G-3-P) had the strongest correlation with circulating intact FGF23 (iFGF23) levels (r^2 = 0.76, P = 5.2x10^{-6}) in humans. Injection of G-3-P, as well as its downstream product lysophosphatidic acid (LPA) in mice increased plasma iFGF23 and c-terminal FGF23 (cFGF23) levels at 24 hours. G-3-P increased LPA levels in bone marrow and in osteoblast cell culture, and this effect on LPA as well as G-3-P's stimulatory effect on FGF23 production, were blocked with the glycerol-3-phosphate acyltransferase (GPAT) inhibitor FSG67 *in vivo* and *Gpat2* knock-down *in vitro*. The stimulatory effect of G-3-P and LPA on FGF23 production were similarly abrogated in *Lpar1* deficient cells and mice. In mice subjected to IRI, kidney tissue G-3-P levels rose rapidly; the increase in iFGF23 levels following IRI was significantly attenuated with GPAT inhibition or *Lpar1* deletion. In humans undergoing cardiac surgery, plasma G-3-P levels increased significantly and correlated with the plasma iFGF23 levels (r^2 = 0.31) in AKI cases but not controls.

Conclusions: Our findings establish G-3-P as a molecule released from the injured kidney, that is converted to LPA via GPAT-2 in bone where it triggers FGF23 production through LPAR1. This is a novel mechanism in mineral metabolism and outlines potential targets to modulate FGF23 production during kidney injury.

DMP1 Prevents Bone Alterations, FGF23 Elevations, and Cardiac Hypertrophy in Mice with CKD

Corey Dussold,[1] Claire Gerber,[1] Samantha Neuburg,[1] Xueyan Wang,[1] Connor Francis,[1] Lixin Qi,[1] Ying Liu,[3] Chaoyuan Li,[3] Jian Feng,[3] Myles Wolf,[2] Valentin David,[1] Aline Martin.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Duke University, Durham, NC; [3]Texas A&M-Baylor College of Dentistry, Dallas, TX.*

Background: Disordered bone and mineral metabolism is a common complication of CKD. Excessive secretion of the osteocyte-derived hormone fibroblast growth factor 23 (FGF23) during CKD progression is independently associated with increased risk of cardiovascular disease and mortality, perhaps by contributing to development of left ventricular hypertrophy (LVH). Dentin matrix protein 1 (DMP1), an extracellular matrix protein produced by osteocytes, is an established inhibitor of FGF23 production and a promoter of bone mineralization. We hypothesized that overexpression of DMP1 in CKD would improve bone health and prevent FGF23 elevations and consequent adverse cardiovascular outcomes in CKD.

Methods: We studied the Col4a3^{KO} mouse, an established model of progressive CKD, which typically shows a shortened lifespan (21.4±0.6 weeks). We overexpressed DMP1 (DMP1$^{Tg\text{-}3.6Kb\ Colla1\ promoter}$) in the bone of WT (DMP1^{Tg}) and Col4a3^{KO} (Col4a3^{KO}/DMP1^{Tg}) mice and we assessed renal function, serum FGF23 and phosphate (Pi) levels, bone and cardiac phenotype in 20 week-old mice, and overall survival.

Results: Col4a3^{KO} mice showed impaired renal function (blood urea nitrogen: 94±18 vs 25±2 mg/dL), reduced bone mineral density (BMD: 1154±14 vs 1194±5 mg/cm^3), altered osteocyte morphology and connectivity, an 8-fold increase in serum FGF23 levels, hyperphosphatemia (serum Pi: 9.2±0.6 vs 6.2±0.2 mg/dL), and LVH (LV Mass: 124±7 vs 101±4 mg) ($p<0.05$ vs WT for each). Overexpression of DMP1 in Col4a3^{KO}/DMP1^{Tg} did not improve renal function but corrected the reduction in BMD by 40% and fully prevented osteocyte alterations. Col4a3^{KO}/DMP1^{Tg} also showed lower FGF23 levels (631±124 vs 1161±196 pg/mL) resulting in higher serum phosphate levels (11.4±1.0 mg/dL) ($p<0.05$ vs Col4a3^{KO} for each). As opposed to Col4a3^{KO}, Col4a3^{KO}/DMP1^{Tg} mice did not have LVH (LV Mass: 93±5 mg; NS vs WT) and showed improved survival (24.2±0.9 weeks; $p<0.05$ vs Col4a3^{KO}).

Conclusions: DMP1 prevented CKD-associated osteocyte alterations, FGF23 elevations and LVH, and improved survival, despite persistently impaired renal function and worsened hyperphosphatemia. This supports the contribution of FGF23 excess to cardiac injury in CKD and suggests that DMP1 represents a novel therapeutic approach to improve bone and cardiac outcomes in CKD.

The Osteocyte Is Not the Only Source of FGF23 in Folic Acid-Induced AKI

Marta Christov,[1] Zhiqiang Cheng,[5] Seham M. Rabadi,[1] Jenna Hwong,[7] Hanson Ho,[4,2] Amanda L. Herberger,[6] Harald Jüppner,[3] Wenhan Chang.[2] *[1]New York Medical College, Valhalla, NY; [2]Endocrine Unit, SF-VAMC, University of California San Francisco, San Francisco, CA; [3]Massachusetts General Hospital, Boston, MA; [4]Adaptive Biotechnology, South San francisco, CA; [5]UCSF, San Francisco, CA; [6]University of California, San Francisco/ San Francisco Veterans Affairs Medical Center, San Francsicso, CA; [7]SFVAMC, San Francisco, CA.*

Background: Fibroblast growth factor 23 (FGF23) is thought to be produced predominantly by osteocytes in bone and to exert a phosphate-regulating action in the kidneys. Its levels increase with development of chronic kidney disease and acute kidney injury (AKI) and are linked to morbidity and mortality. Recently, other tissues were reported to be additional sources of FGF23 in kidney injury or iron deficiency. However, it is unclear to what extent the extra-skeletal sources contribute to the baseline and the massively elevated serum FGF23 levels in AKI.

Methods: FGF23$^{fl/fl}$ mice carrying loxP sequences flanking exon 1 of *Fgf23* gene were bred with Zp3-Cre and DMP1-Cre lines to produce global (FGF23-null) and osteocyte-specific FGF23 (^{Ocy}FGF23-KO) KO mice, respectively. AKI was induced after a single folic acid (FA) injection in adult male and female ^{Ocy}FGF23-KO and control mice and circulating intact and c-terminal FGF23, PTH, and mineral levels as well as Fgf23 mRNA expression in various tissues were determined 24 hours after induction of AKI.

Results: The FGF23-null mice recapitulated serum and skeletal phenotypes of the previously reported germ-line FGF23 KO mice, validating our gene KO strategy. Basal serum FGF23 and PTH levels in the ^{Ocy}FGF23-KO mice were 39-50% and 48-67% lower (depending on sexes) compared to control mice, respectively. While serum cFGF23 levels were increased by AKI more robustly in control (6904±1272 pg/ml) vs ^{Ocy}FGF23-KO mice (3178±836.1 pg/ml) ($p<0.05$), the fold-change over baseline value was similar between the 2 groups (35 in control vs 41 fold in KO mice, p=0.69). Accordingly, AKI induced higher PTH levels in control (2583±339.5 pg/ml) vs ^{Ocy}FGF23-KO mice (1349±363.9 pg/ml, $p<0.05$), despite no difference in phosphate, calcium, and BUN levels between the two mouse groups after 24 hrs of AKI. As expected, FA did not increase FGF23 mRNA levels in the bone of ^{Ocy}FGF23-KO mice, but raised FGF23 mRNA levels in their kidney and spleen by 5-10 fold.

Conclusions: We conclude that although the osteocytes contribute greatly to baseline FGF23 levels and to the increase of FGF23 in AKI, extra-skeletal tissues, particularly spleen and kidney, are also significant sources of FGF23 at physiological and injury states.

Dietary Phosphate Restriction Attenuates Renal Cystic Disease in pcy/pcy Mice

Cassandra R. Johnson, Ogorchukwu F. Omede, Emily A. Daniel, Darren P. Wallace, Jason R. Stubbs. *University of Kansas Medical Center, Kansas City, KS.*

Background: Abnormalities in phosphate metabolism strongly predict future development and progression of chronic kidney disease (CKD); however, the mechanism remains undefined. Previously, we showed that dietary phosphate restriction reduced tubular injury in mice with glomerulonephritis. Here, we determined if dietary phosphate restriction slows renal cyst growth and fibrosis in *pcy/pcy* mice, a slowly progressive model of polycystic kidney disease (PKD).

Methods: At 7 weeks of age, *pcy/pcy* mice were randomized to receive either a control phosphate (0.54%) or low phosphate (0.02%) diet (n=10/group) until 20 weeks of age. All other major dietary constituents, including protein source and content were comparable between diets. Mice were sacrificed for measurement of kidney weight to body weight (KW/BW), cystic index (% cystic area), and renal expression of early markers of fibrosis.

Results: *Pcy/pcy* mice that received the low phosphate diet had a 25% lower KW/BW (low phosphate 2.9±0.3% vs. control 4.3±0.6%; $P<0.001$) and 30% lower cystic index (low phosphate 21.7±6.6% vs. control 31.5±4.4%; $P<0.01$). When examining the renal gene expression of markers of fibrosis, *pcy/pcy* mice fed the low phosphate diet had a 50% reduction in the expression of collagen 1a1 ($P<0.05$) and a 40% reduction in the expression a-smooth muscle actin ($P<0.01$).

Conclusions: Dietary phosphate restriction attenuates PKD progression and renal gene expression for early markers of fibrosis in *pcy/pcy* mice.

Funding: NIDDK Support

Dietary Magnesium Prevents Vascular Calcification and Bone Mineralization in Klotho Knock-Out Mice

Anique D. Ter Braake,[1] Wynand Alkema,[3] Joost Hoenderop,[4] Jeroen H. De Baaij.[2] *[1]Physiology, Radboud University Medical Center, Nijmegen, Netherlands; [2]Physiology, Radboud University Medical Center, Nijmegen, Netherlands; [3]Center for Molecular and Biomolecular Informatics, Radboud University Medical Center, Nijmegen, Netherlands; [4]Physiology, Radboud University Medical Center, Nijmegen, Netherlands.*

Background: Klotho is a key modulator of the phosphate (Pi) and calcium (Ca^{2+}) balance and is diminished in chronic kidney disease (CKD). Klotho knock-out ($^{-/-}$) mice are therefore an important model for CKD, mimicking all essential features including hyperphosphatemia and development of calcification. In CKD, serum magnesium (Mg^{2+}) inversely correlates with incidence and severity of vascular calcification. The mechanisms by which Mg^{2+}prevents vascular calcification are poorly understood. Therefore, this study aims to determine the effects of Mg^{2+}on development of aortic calcification using Klotho$^{-/-}$mice.

Methods: Klotho$^{-/-}$and Klotho$^{+/+}$mice were fed a normal (0.05% w/w) or high (0.48% w/w) Mg^{2+}diet from birth. Aortic calcification was detected by Von Kossa staining and RNA-sequencing was performed. Serum electrolyte and hormone concentrations were determined. MicroCT was used to study bone integrity.

Results: Von Kossa staining revealed that aortic calcification developed extensively in Klotho$^{-/-}$mice on a normal Mg^{2+}diet and was absent in Klotho$^{+/+}$mice. Strikingly, high Mg^{2+}diet prevented calcification in Klotho$^{-/-}$mice. Moreover, Mg^{2+}rescued increased expression of RUNX2 and osteopontin as well as upregulation of matrix gla protein, demonstrating the preventive effect of Mg^{2+}on pro-osteogenic signaling. Potential novel mechanisms by which Mg^{2+}prevented calcification were studied by RNA sequencing, revealing that pathways mediating inflammation and extracellular matrix remodeling enriched in Klotho$^{-/-}$mice were reversed by Mg^{2+}. Though Mg^{2+}prevented calcification, klotho$^{-/-}$mice on high Mg^{2+}diet had reduced weight and smaller stature. Interestingly, high Mg^{2+}impaired bone formation in Klotho$^{-/-}$mice as femoral mineral-bone density decreased by 20% compared to mice on normal Mg^{2+} diet. High Mg^{2+}did not change known mineralization modulators parathyroid hormone, 1.25-dihydroxyvitamin D and Ca^{2+}in serum. Interestingly, Mg^{2+}prevented calcification despite increasing fibroblast growth factor-23 and Pi concentration in Klotho$^{-/-}$mice.

Conclusions: This study shows that Mg^{2+}prevented vascular calcification in Klotho$^{-/-}$mice. Importantly, Mg^{2+}prevented mineralization in the aortic media as well as bone,

potentially involving anti-inflammatory signaling and disruption of extracellular matrix remodeling.

Cinacalcet Ameliorates Cardiac Valve Calcification in CKD via Suppressing Endothelial-to-Osteoblast Transition

Li-ting Wang, Kai-yun Song, Li-Hua Ni, Xiao-chen Wang, Meng Zuo, Yu-xia Zhang, Bi-Cheng Liu, Ri-ning Tang. *Institute of Nephrology, ZhongDa Hospital, school of medicine, Southeast University, Nanjing, China.*

Background: Clinical studies found cinacalcet (CINA) markedly ameliorated cardiac valve calcification in chronic kidney disease (CKD) patients, but it underlying mechanisms are still unknown. Previous studies demonstrated endothelial cell participate in ectopic calcification in part by mediating endothelial-to-mesenchymal transition (EndMT) that could be transitioned into mesenchymal stem cells and further differentiated into osteoblast. Thus we investigated whether cinacalcet ameliorated cardiac valve calcification in two CKD models via suppression of endothelial-to-osteoblast transition.

Methods: SD rats were randomly divided into three group: control group (CTL, n=10), CKD group(n=30), and CINA treatment group(n=30). CKD group were established by 5/6 nephrectomy (n=15) or 0.75% adenine (n=15) for 4 weeks, both followed with 2.0% phosphorus diet for next 8 weeks. Meanwhile, rats of CINA treatment group were orally administered CINA (10 mg/kg one day). The expression of EndMT and osteoblast markers in valve was examined with the use of western blot, real time PCR, immunofluorescence staining and immunohistochemistry. Pathological examinations of the valves included histological characterization and Von Kossa staining. And we finished echocardiography for three groups. Besides, the important makers of Notch signal pathway were also detected in our study with the use of western blot and real time PCR.

Results: In CKD rats, CINA treatment significantly decreased the serum PTH concentration, calcium but did not affect the elevated levels of serum creatinine, blood urea nitrogen and phosphorus. Besides, CINA significantly attenuated aortic valve calcification, and inhibited the expression of osteogenic markers (osteopontin and osterix). Moreover, CINA treatment largely abolished the up-regulation of mesenchymal markers (FSP1 and α-SMA), stem cell markers (CD44 and CD10) and down-regulation of the endothelial marker (CD31, E-cadherin), which accompanied calcification in CKD aortic valve samples. Besides, Notch signal pathway was activated with Notch1, NICD, HES and HEY increased, while CINA could ameliorates this process.

Conclusions: These findings suggest CINA could attenuate valve calcification by abrogating Notch mediated endothelial-to-osteoblast transition in rats with CKD.

SA-OR104

Pharmacokinetic and Pharmacodynamic Evaluation of a New Vascular Calcification Inhibitor (INS-3001) in Rats

Marc P. Maillard,[1] David Mordasini,[1] Dany Spaggiari,[3] Olivier Phan,[1] Mattias E. Ivarsson,[2] Roberto Maj,[2] Laurent A. Décosterd,[3] Michel Burnier.[1] *[1]Service of nephrology, Lausanne University Hospital, Lausanne, Switzerland; [2]Inositec Inc., Zurich, Switzerland; [3]Service of clinical pharmacology, Lausanne University Hospital, Lausanne, Switzerland.*

Background: Morbidity and mortality of patients with CKD increase with the progression of vascular calcifications. In the context of the development of drugs capable of reducing pathological crystallization, *myo*-inositol hexaphosphate (IP6) has been shown to be a promising candidate but needs to be administered *via* intravenous infusion. This study demonstrates the *in vivo* inhibitory effect of an IP6 analog (INS-3001), and characterizes its pharmacokinetic profile in uremic and non-uremic rats.

Methods: Efficacy of INS-3001 versus IP6 to prevent severe vascular calcification was studied in non-uremic rats (vitamin D3 model, n = 5 – 11/group), while the PK of INS-3001 was determined after after single i.v. or s.c dosing of 10mg/kg in uremic rats (adenine diet model) and non-uremic controls (n = 6/group). Vascular calcifications were visualized by von Kossa staining and calcium tissue content measured by ICP-MS. INS-3001 concentrations in EDTA plasma were measured using a HILIC-MS/MS bioanalytical method.

Results: INS-3001 significantly blunted carotid calcification reducing the amount of calcium in tissues by a factor of two compared to controls (p=0.017) while a numerical decrease was observed at the level of abdominal aorta (p>0.05). Treatment with IP6 could not be completed due to the appearance of necrotic lesions at the injection site. INS-3001 displayed high s.c. bioavailability. In the s.c. group, uremic rats displayed higher AUC, mean residence time and Tmax than non-uremic controls (1327.1 vs 802.3 μg/mL*min; 124 vs 66 min; 23 vs 50 min, respectively) whereas Cmax remained unchanged (8348 vs 8325 ng/mL). Similar trends were observed following i.v. administration.

Conclusions: IINS-3001 is a potent inhibitor of vascular calcification after Vitamin D overdose in rats, in addition INS-3001 has a beneficial effect on the renal function of animals in this model. The uremic state appeared to significantly influence the rat plasma PKs of INS-3001 after s.c. and i.v. administration. The data suggests that uremia extends plasma exposure of INS-3001 without increasing peak plasma levels and that therapeutic levels can be attained following s.c. administration in the context of uremia.

Inhibition of Tissue-Nonspecific Alkaline Phosphatase Protects against Medial Arterial Calcification in the CKD-MBD Mouse Model

Takashi Tani,[1,2] Meguji Fujiwara,[2] Hideo Orimo,[2] Akira Shimizu,[3] Shuichi Tsuruoka,[1] Anthony B. Pinkerton,[4] Jose luis Millan.[4] *[1]Department of Nephrology, Graduate School of Medicine, Nippon Medical School, Tokyo, Japan; [2]Department of Metabolism and Nutrition, Graduate School of Medicine, Nippon Medical School, Tokyo, Japan; [3]Department of Analytic Human Pathology, Graduate School of Medicine, Nippon Medical School, Tokyo, Japan; [4]Sanford Burnham Prebys Medical Discovery Institute, La Jolla, CA.*

Background: Medial arterial calcification (MAC), the main manifestation of chronic kidney disease - mineral and bone disorder (CKD-MBD), is a serious complication of patients with CKD. The overexpression of tissue-nonspecific alkaline phosphatase (TNAP) on vascular smooth muscle cells is reported to accelerate MAC formation. The aim of this study was to assess the inhibitory effect of SBI-425, novel and potent pharmacological TNAP inhibitor, on MAC formation in a CKD-MBD mouse model.

Methods: Eight-week-old C57/BL6J male mice in CKD groups (Vehicle, SBI-10 and SBI-30) (n=10 each) mice were fed a 0.2% adenine and 0.8% phosphorus (Pi) diet for 6 weeks to induce CKD, followed by a high phosphorus (0.2% adenine and 1.8% Pi) diet for 6 weeks. Mice in the SBI-10 and SBI-30 groups were administrated 10mg/kg and 30mg/kg of SBI-425 by gavage once per day, respectively, from 14 to 20 weeks of age. Control group mice (n=6) were fed a standard chow (0.8% Pi) from 8 to 20 weeks of age. At sacrifice, animals were scanned by computed tomography (CT) and aorta, kidney and blood samples were harvested.

Results: In contrast to major MAC formation in the vehicle group, administration of SBI-425 drastically halted MAC formation confirmed by aortic calcification volume (CT imaging), percentage calcified area in histology (positive Von Kossa staining) and aortic tissue calcium content (OCPC assay). Aortic tissue mRNA expression of osteoblastic trans-differentiation-related genes including TNAP were upregulated in the Vehicle group, while they were suppressed to Control levels in the SBI-10 and SBI-30 groups. Plasma and aortic tissue TNAP activities were increased in the Vehicle group, and they were suppressed by SBI-425 administration. Blood levels of urea nitrogen and creatinine, phosphorus, intact PTH and FGF-23 were higher in the CKD groups than in the Control group and were comparable between CKD groups. Plasma pyrophosphate (PPi) levels were shown to be higher in SBI-10 and SBI-30 group than the others.

Conclusions: These results showed that TNAP inhibition protects the vascular media from MAC formation in a mouse model of CKD-MBD. As PPi is a potent protective agent for calcification, elevated PPi concentrations in the SBI-425 treated groups, resulting from TNAP activity suppression, reduced MAC.

SA-OR106

The Direct Inhibitory Effect of Ferric Citrate on Phosphate-Induced Calcification and Osteoblastic Trans-Differentiation via Suppression of HIF1a Expression in Human Vascular Smooth Muscle Cells

Masanori Tokumoto,[1] Shunsuke Yamada,[2] Toshiaki Nakano,[2] Kazuhiko Tsuruya,[3] Takanari Kitazono,[2] Hiroaki Ooboshi.[1] *[1]Department of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; [2]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [3]Department of Nephrology, Nara Medical School, Kashihara, Japan.*

Background: Vascular calcification is a life-threatening pathophysiological abnormality in chronic kidney disease (CKD). Phosphate (P) is known as its main inducer, and it was recently reported that P enhances HIF1a expression, leading to osteoblastic trans-differentiation and calcification of cultured vascular smooth muscle cells (VSMCs). Because iron degrades HIF1a via activation of proryl hydroxylase (PHD), we examined direct effects of ferric citrate (FC), an iron-containing P binder, on P-induced calcification, osteoblastic trans-differentiation, and HIF1a expression in VSMCs.

Methods: Human VSMCs were cultured in DMEM plus 10%FCS and 2.0mM P with 0, 1, 5, 10, 50, 100, or 500mM FC for one or two weeks. The precipitated calcium (Ca) contents and expression of calcification inducers or inhibitors were evaluated.

Results: At 1 week, moderate to high concentrations (>=5mM) of FC equally decreased P-induced calcification by about 80% (p<0.01), while, at 2 weeks, FC inhibited calcification in a concentration-dependent manner and high concentrations (>=50mM) of FC reduced calcification by almost 90% (p<0.01). Moderate to high concentrations (>=5mM) of FC not only suppressed expression of osteoblastic trans-differentiation inducers (BMP2, RUNX2, SOX9, MSX2, PiT1, and MMP2), but also increased expression of calcification inhibitors, OPG and MGP (p<0.01). Moreover, moderate to high concentrations of FC inhibited expression of HIF1a and VEGF, a downstream gene of HIF1 (p<0.01). Expression of HIF1a and VEGF positively correlated with precipitated Ca content and expression of BMP2, RUNX2, SOX9, MSX2, PiT1, and MMP2, respectively (p<0.01), and negatively correlated with OPG and MGP expression (p<0.01).

Conclusions: FC, an iron-containing P binder, can directly inhibit P-induced calcification and osteoblastic trans-differentiation via suppression of HIF1a expression in cultured human VSMCs.

Sucroferric Oxyhydroxide (PA21) Improves Mineral Homeostasis, Reduces Vascular Calcification, and Exerts a Beneficial Effect on Renal Function in a Rat Model with CKD

Anja Verhulst,[1] Ellen Neven,[1] Sebastian Walpen,[3] Britt Opdebeeck,[2] Felix W. Funk,[4] Patrick C. D'Haese.[2] *[1]University of Antwerp, Wilryk, Belgium; [2]University Antwerp, Edegem, Belgium; [3]Vifor Fresenius Medical Care Renal Pharma, Glattbrugg, Switzerland; [4]Vifor Pharma Management Ltd., Glattbrugg, Switzerland.*

Background: PA21 (or sucroferric oxyhydroxide) is an efficacious, well-tolerated iron-based phosphate binder and a promising alternative to existing compounds. We aimed to evaluate the effect of PA21 on renal function, mineral homeostasis and vascular calcification in a CKD rat model.

Methods: To induce stable CKD, 64 male Wistar rats were administered a 0.25% adenine diet during for 8 weeks. CKD rats were assigned to 4 treatment groups: (i) vehicle (n=16), (ii) 2.5 g/kg/day PA21 (n=16), (iii) 5.0 g/kg/day PA21 (n=16) and (iv) 3.0 g/kg/day $CaCO_3$ (n=16). Evolution in renal function and mineral metabolism was followed by measurement of serum creatinine, phosphorus, calcium, 1,25 $(OH)_2$ vitamin D, PTH and FGF-23. Serum ionized calcium, iron, hematocrit, hemoglobin, pH and bicarbonate were also measured. Calcification was assessed by determining the calcium content in the arteries.

Results: Vehicle treated CKD rats developed severe renal impairment, with creatinine values around 3.5-4 mg/dL, and anemia as indicated by decreased serum hematocrit and hemoglobin levels. CKD went along with hyperphosphatemia, hypocalcemia, low 1,25 $(OH)_2$ vitamin D and high PTH and FGF-23 levels. Both PA21 and $CaCO_3$ treatment showed efficient phosphate binding capacity and prevented the pronounced increase in serum PTH. CKD rats treated with 2.5 or 5 g/kg PA21 showed significant lower serum creatinine and phosphorus levels and higher ionized calcium levels after 8 weeks of daily treatment as compared to vehicle treated CKD rats. The better preserved renal function with PA21 treatment went along with less severe anemia. Both PA21 doses prevented the dramatic increase in FGF-23, whereas $CaCO_3$ did not. Daily treatment with PA21 did not increase circulating iron levels. Finally, PA21 treatment significantly reduced the calcium content in the aorta as well as the carotid and femoral arteries, whereas $CaCO_3$ did not affect calcification in the arteries.

Conclusions: In contrast to $CaCO_3$, treatment with PA21 had, aside from its phosphate lowering capacity, a beneficial impact on the development towards severe CKD and prevented the pronounced rise in serum FGF-23. Arterial calcification was significantly reduced by PA21 treatment.

Interventions in Patient Pathways Reduce the Incidence and Complications of AKI

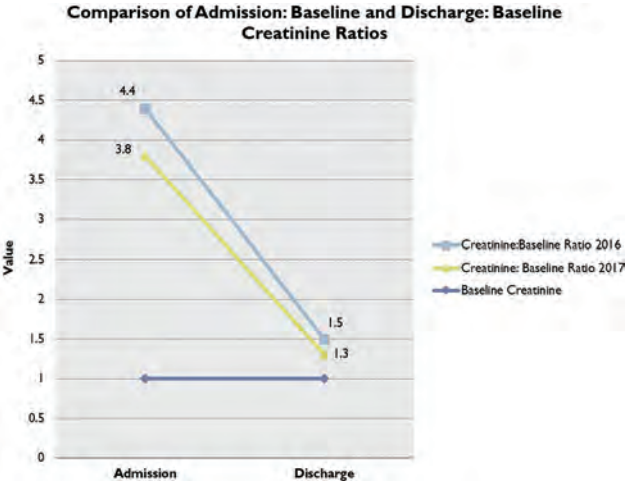
Madeline Brazell,[3] Jonathan A. Chernick,[3] Anna Robinson,[5] Philip H. Jones,[4] Philippa L. Gaunt,[6] Shalabh Srivastava.[1,2] *[1]Nephrology, City Hospitals Sunderland and South Tyneside NHS FT, Sunderland, United Kingdom; [2]Nephrology, Newcastle University, Newcastle Upon Tyne, United Kingdom; [3]South Tyneside NHS Foundation Trust, Gateshead, United Kingdom; [4]South Tyneside District Hospital, Co Durham, United Kingdom; [5]NHS England, Newcastle, United Kingdom; [6]South Tyneside NHS Foundation Trust, England, Gateshead, United Kingdom.*

Background: We investigated the management and outcomes of patients developing AKI-3 in the South Tyneside area of the North East of England (population:153,700, census 2011). We proactively introduced interventions to aide early recognition and management of AKI. These interventions included intensive education for clinical staff in the community and hospitals, the launch of a nephrology outreach service in the South Tyneside Hospital and an online AKI health pathway tool. The study aims to scrutinize any changes in outcomes since interventions were delivered.

Methods: Methods: Data was gathered by interrogating the regional pathology database for all patients who developed AKI 3 during the periods of 1st October 16 – 31st December 2016 and subsequently from 1st October 2017 – 31st December 2017. Paediatric patients, palliative care patients and those on renal replacement therapy were excluded.

Results: We demonstrate an overall reduction of 17% in the development of AKI3 during the study period (68 vs 82 cases) additionally; we demonstrate a 29% reduction in the development of AKI-3 in hospital. The discharge to baseline creatinine ratio improved from 1.5:1 to 1.3:1. The admission to baseline creatinine ratio improved from 3.8:1 to 4.4:1. The overall mortality rates remain at 30.88% and the overall hospital stay did not change (16.1 days vs 16.2 days).

Conclusions: In conclusion, we demonstrate a significant improvement in the incidence of AKI-3. There is early recognition of AKI and significant improvement in the renal function on discharge. We recognise that there was no improvement in overall mortality and the total number of in-patient days did not improve. Our data suggests that simple interventions at multiple levels in a patient's pathway can lead to significant improvement in outcomes.



Comparison of Admission: Baseline and Discharge: Baseline Creatinine Ratios

TH-PO002

Real-Time, Model-Driven Diagnostic and Therapeutic Evaluation of Patients at Risk of AKI: A Pilot and Feasibility Study

Francis P. Wilson,[1] Ugochukwu C. Ugwuowo,[2] Melissa Martin,[1] Aditya Biswas,[2] Yu Yamamoto.[2] *[1]Yale School of Medicine, New Haven, CT; [2]Yale University, New Haven, CT.*

Background: Acute kidney injury is typically defined by a rise in serum creatinine, but this is a late marker of the syndrome. Real-time, updated modeling of AKI risk using electronic health record (EHR) parameters may allow for targeting of diagnostic and therapeutic interventions earlier in the course of AKI.

Methods: We deployed a time-updated AKI prognostic model into the EHR of a large, tertiary care hospital. The model alerted study team members when any hospitalized adult had a greater than 30% risk of developing AKI within the next 48 hours: the "pre-AKI Alert". Study personnel took urine and blood samples, examined the medical record, and followed patients for the development of creatinine-defined AKI. Our primary goal was to determine the feasibility of providing tailored pre-AKI recommendations in this clinical setting.

Results: Of 98 patients who met eligibility criteria, 68 were unable or refused to consent to study participation. Of the 30 who were enrolled, 5 developed AKI within 24 hours, 1 additional patient within 48 hours, and 1 later during the subsequent hospital admission. Lower-than-expected AKI rates were seen due to difficulty obtaining consent from the highest-risk patients. At the time of pre-AKI alert, 3 patients were receiving a potentially nephrotoxic agent, 24 had at least one electrolyte abnormality that could be addressed, and 3 had mean arterial pressure < 65mmHg (Table). Oxygen saturation was significantly lower in those who went on to develop AKI compared to those who did not with median (IQR) SPO2 94 (92 - 94) compated to 97 (95-98), p=0.03.

Conclusions: A real-time updated model successfully identified a group of patients at high risk for AKI, many of whom had nephrotoxin, electrolyte, blood pressure, or oxygenation abnormalities that could be proactively addressed. Model-based pre-AKI interventions are feasible and their efficacy should be explored in a larger study.

Funding: NIDDK Support

Characteristics at Pre-AKI Alert

Epidemiology of Emergency Department AKI

David A. Foxwell,[2,1] Sara Pradhan,[2] Soha Zouwail,[3] Timothy H. Rainer,[2] Aled O. Phillips.[2] *[1]Wales Kidney Research Unit (WKRU), Cardiff, United Kingdom; [2]Cardiff University School of Medicine, Cardiff, United Kingdom; [3]University Hospital of Wales, Cardiff, United Kingdom.*

Background: The epidemiology of Acute Kidney Injury (AKI) diagnosed in the Emergency Department (ED) is poorly described. This study describes the incidence, demographics and outcomes of patients diagnosed with AKI in the ED (ED-AKI).

Methods: Between April and August 2016 20,421 adult patients attended the ED of a University Teaching Hospital (UK) and had a serum creatinine measurement. Using an electronic AKI reporting system, 548 incident ED-AKI patients were identified and compared to a randomly selected cohort of non-AKI ED patients (n=571). Admission, short term and 12-month follow-up data was collated and compared.

Results: 572 patients had a confirmed eAlert AKI (548 incident cases), giving an incidence of ED-AKI of 2.8%. ED-AKI was associated with a 24.4% inpatient mortality of which 22.3% of deaths occurred in the first 24-hours and 58% within 7 days. Progression of admission AKI stage to a higher AKI stage was associated with a 38.8% mortality compared to a 21.4% mortality in those who did not progress (p<0.001). In multivariate analysis ED-AKI was an independent risk factor for mortality (HR, 6.293; 95% CI, 1.887 to 20.790, p=0.003). For those discharged from hospital 20.4% of ED-AKI patients were re-admitted within 30-days (non-AKI 7.6%, p<0.001). At 90-days following hospital discharge 10.0% of the discharged ED-AKI group died (non-AKI discharged 90-day mortality 1.4%, p<0.001). 12-months post discharge 17.8% of ED-AKI group developed CKD progression or de-novo CKD compared to 6.0% in the non-AKI cohort.

Conclusions: AKI diagnosed in the ED is a strong independent predictor of death. ED-AKI mortality is predominantly in the first days following presentation, but for those surviving to discharge there is significant long-term morbidity and mortality

TH-PO004

Derivation of a Prediction Model for Emergency Department AKI

David A. Foxwell,[2,1] Sara Pradhan,[2] Soha Zouwail,[3] Timothy H. Rainer,[2] Aled O. Phillips.[2] *[1]Wales Kidney Research Unit (WKRU), Cardiff, United Kingdom; [2]Cardiff University School of Medicine, Cardiff, United Kingdom; [3]University Hospital of Wales, Cardiff, United Kingdom.*

Background: Acute Kidney Injury (AKI) is an independent risk factor for death. Over 50% of community acquired AKI cases are identified in the Emergency Department (ED), which is the main route for acute hospital admissions. Accurate risk stratification is essential to facilitate prompt medical investigation and treatment. This study aimed to derive a hospital front-door model for predicting AKI in the ED (ED-AKI).

Methods: Between April and August 2016 20,421 adult patients attended the ED of a University Teaching Hospital in Wales and had a serum creatinine measurement. A retrospective analysis was conducted on 1119 cases (548 incident ED-AKI patients and 571 randomly selected non-AKI ED patients). Univariate and stepwise backwards removal of insignificant variables in a multivariate analyses were used to derive a pragmatic model for predicting and risk-stratifying AKI. The primary outcome was ED-AKI.

Results: An 18-point model using four variables was derived for assessing patients on ED arrival, where 0 is low chance of ED-AKI and 18 a high chance. The adjusted odds ratios for AKI were: age 1.03; male gender 1.45; known Chronic Kidney Disease 2.08; and number of comorbidities (from 0 to 10) 1.31. At a score of >2, the sensitivity was 99.8% (95%CI 99.0-11.0), and specificity was 5.1% (95%CI 3.4-7.2). At a score of >5.5, the sensitivity was 85.8% (95%CI 82.6-88.6), and specificity was 52.7% (95%CI 48.5-56.9). At a score of >11, the sensitivity was 15.0% (95%CI 12.1-18.2), and specificity was 96.5% (95%CI 94.6-97.8). The probability of AKI increased with score groups (chi-squared <0.0001). The AUROC was 0.745 (95%CI 0.720-0.772; p<0.0001; R^2 18%). There were positive correlations between the score and peak creatinine (r=0.415; p<0.0001) but not with AKI stage.

Conclusions: A simple, pragmatic 18-point score for predicting probability of ED-AKI on ED arrival has been derived. This now requires refinement and prospective validation.

TH-PO005

Comparison of Community and In-Hospital Acquired AKI in the Clinical Emergency Department at a University Tertiary Hospital

Lia J. Marçal,[2] Flávia B. Azevedo,[2] Veronica Torres,[2] Graziela R. de Souza,[2] Leila Antonangelo,[2] Dirce M. Zanetta,[1] Luis Yu,[2] Emmanuel A. Burdmann.[2] *[1]University of São Paulo, S Paulo, Brazil; [2]University of Sao Paulo Medical School, Sao Paulo, Brazil.*

Background: Prospective studies comparing frequency and outcomes of community and in-hospital (IH) acquired acute kidney injury (AKI) in patients (pts) admitted to the Emergency Department (ED) are scarce, especially in developing countries.

Methods: This study aimed to compare the frequency, characteristics and outcomes of community AKI (CAKI) vs. IH acquired AKI diagnosed by RIFLE or/and KDIGO (serum creatinine criteria - SCr) in pts admitted to the ED through a referred emergency room (ER) of a tertiary university hospital. All pts ≥ 18 years old hospitalized in the ED were included. Exclusion criteria: decline to sign the informed consent, IH < 48 h, chronic kidney disease stage 5, pts on palliative care and renal transplant. Pts were assessed until the hospitalization day 7 or discharge. SCr(mg/dl) was assessed at admission and daily or every 48h. Pts were divided in the following groups: non-AKI, community-acquired AKI (CAKI), AKI by RIFLE (ARIFLE), AKI by KDIGO (AKDIGO) and ARIFLE negative AKDIGO positive (K+R-). The assessed outcomes were length of IH stay (LoS, d), and IH mortality. Data are presented as median (minimum-maximum values) or percent (%). Statistical significance is set at p<0.05.

Results: A total of 788 pts were included, mean age 63 y (18-98y), 55.1% were male, LoS was 8d (2-132) and IH mortality was 16.7%. A total of 231 pts (29.3%) developed IH AKDIGO – mostly KDIGO I (69.7%) and 167 pts (13.6%) presented CAKI, resulting in 398 AKI pts (50.5%) Causes of hospitalization were pulmonary (36.2%), cardiovascular (11.3%), gastric (16.3%) and others (36,2%). Major outcomes among AKI groups and Non-AKI group (IMAGE1):

Outcomes vs. AKI	NON- AKI	CAKI	ARIFLE	AKDIGO	K+ R -
% (N)	49.5 (390)	21.1(167)	18.8(148)	29.4 (231)	10.5 (83)
AGE (Y)	57 (18-95)	64 (18-98) ***	64 (18-98) *	65 (18-98) ***	66 (20-95) **
LOS (D)	5.0 (2-132)	9 (1-132)	10 (2 - 95) *	9 (2 -95)	8 (2-78)
IH MORTALITY (%)	9.5% (37)	17.4(29) &	31.1(46) &	28.5 (66) &	24.1(20) &

* p<0.05 vs Non-AKI; **p<0,01 vs no AKI; ***p<0,001 vs no AKI; & IH mortality was significantly different among groups (p<0.0001).

Conclusions: The frequency of AKI at reference ER admission and IH acquired in the first 7d of hospitalization was strikingly high in the clinical ED. CAKI showed high frequency and mortality. KDIGO criteria diagnosed more pts than RIFLE criteria IH pts. IH mortality of AKI pts was significantly higher than non-AKI pts at the ED.

Transition of Hospital-Associated AKI to Acute Kidney Disease and CKD

Kevin Ho, David Riviello, Jason Brown, Sara Saunders, Ion D. Bucaloiu, Gurmukteshwar Singh, Jamie A. Green, H. Lester Kirchner. *Geisinger, Danville, PA.*

Background: Acute kidney injury (AKI) is closely tied bidirectionally to the pathogenesis and public health burdens of chronic kidney disease (CKD) together with increased risks for hospital readmission, endstage kidney disease, and death. Bridging transient AKI and CKD, acute kidney disease (AKD) may represent a potentially modifiable stage in the natural history of kidney disease.

Methods: We performed a retrospective analysis of hospitalization data from the electronic health records for Geisinger, a large healthcare delivery system in Central Pennsylvania and New Jersey, 2013-2017 inclusive of baseline SCr and eGFR values 12-18 months preceding hospital admission. We examined AKI events (KDOQI criteria, duration 7 days or less), length of stay, AKD (persistent AKI based on SCr during Days 8 to 89 post-AKI start date), incident CKD (patients with baseline eGFR <60ml/min/1.73m^2), and CKD progression (eGFR ≥5 ml/min below baseline eGFR).

Results: Of 282,418 patient admissions, we identified 53,741 hospital admissions characterized by AKI events (19.0%). Length of stay (LOS) was increased following an AKI event (5.8 days) and exceeded 7 days in 24.7% of AKI patients versus a LOS of 3.7 days in non-AKI patients. Among admissions with AKI events, AKI transitioned to acute kidney disease in 38.2% of occurrences. Moreover in 35,190 patients admitted with a baseline eGFR ≥60 ml/min, 18.8% of patients developed incident CKD following either AKI or AKD within 1 year of the AKI start date. Combining AKI and AKD occurrences in 9,245 patients with baseline CKD prior to hospital admission, 29.0% of patients exhibited post-AKI/AKD progression of their CKD within 1 year of the AKI event.

Conclusions: Hospital-associated acute kidney injury is observed to occur in conjunction with increased hospital length of stay, a relatively high transition rate to acute kidney disease, and both incident and progression of chronic kidney disease within 1 year of an event. Close clinical follow-up of AKI survivors is needed to promote renal recovery and/or delay progression of kidney disease.

Background: AKI is frequent and predictors of renal recovery are incompletely understood. We aimed to determine the association between clinical characteristics and risk factors for AKI with renal recovery.

Methods: This prospective observational study was conducted among intensive care unit patients from 25 centers in 9 countries. AKI was defined as an increase in creatinine of at least 0.3 mg/dl within 48 hours, and renal recovery, as a creatinine at hospital discharge within less than 0.5 mg/dl of reference creatinine.

Results: Between 2008 and 2018, 14,460 patients were screened, of whom 4,241 (29%) developed AKI. A total of 2,009 (47%) of AKI patients had sufficient data. Median age was 64 years (IQR 50-74), 63% were male, 67% were Caucasian, 19% Asian and

7% were Black. Thirty-two percent came from emerging countries and 44% had CKD. Thirty-six percent underwent surgery, 47% had sepsis, and 47% received vasopressors. APACHE III scores at ICU admission was 61 (IQR 43-83). Within the first 7 days of AKI, 43% had hypotension, 14% received iodinated contrast, 26% required anesthesia and 72% received nephrotoxins (including any antibiotics). In-hospital mortality was 20%, and 19% received dialysis during hospital stay. Seven percent of 1613 survivors were dialysis-dependent at discharge, while 72% recovered their renal function. A lower probability of renal recovery was associated with older age, residence in an emerging country, presence of diabetes and liver disease, medical reason for ICU admission and provision of dialysis, while administration of vasopressors was associated with a better probability of renal recovery. Additional risk factors for AKI were not associated with a lower probability of renal recovery.

Conclusions: In our study, older age, residence in an emerging country, diagnosis of diabetes and liver disease, medical reason for ICU admission, as well as severe AKI were independently associated with a lower renal function at hospital discharge. However, ongoing risk factors for AKI within days of diagnosis did not modify renal prognosis at discharge.

TH-PO008

Post-Discharge Major Adverse Cardiovascular Events of Intensive Care Unit Survivors Who Received Acute Renal Replacement Therapy: A Nationwide Population Based Study

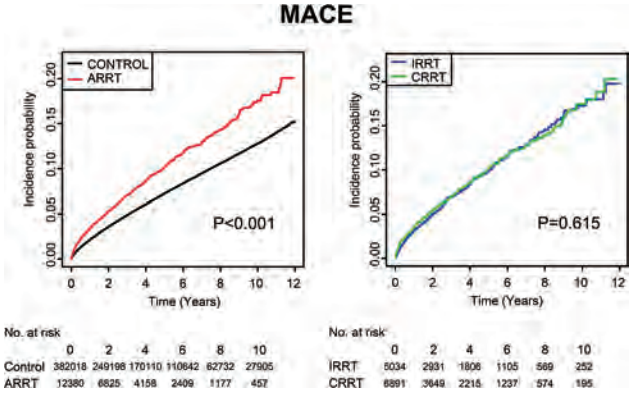
Sehoon Park,[1] Soojin Lee,[2] Min woo Kang,[1] Yaerim Kim,[1] Jung Nam An,[3] Kwon Wook Joo,[1] Chun Soo Lim,[3] Yon Su Kim,[4] Dong Ki Kim.[1] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Seoul national university hospital, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, Seoul, Republic of Korea; [4]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: The long-term risk of a major adverse cardiovascular events (MACE) in intensive care unit (ICU) survivors who underwent acute renal replacement therapy (ARRT) requires further investigation.

Methods: We performed a nationwide population-based study using the claims database of Korea, including ICU survivors in over 40 government-designated tertiary hospitals from 2005 to 2016. The study group consisted of ICU survivors who underwent ARRT, and the control group consisted of those without ARRT. Patients were excluded if they 1) were under age 20, 2) expired within 30 days after discharge, 3) received ICU care for less than 24 hours, 4) had a previous ICU admission, 5) had a history of MACE or MACE-related cardio/cerebrovascular diseases. The outcomes of the patients who received CRRT were compared with those of patients who received only intermittent renal replacement therapy (IRRT). The main outcome was MACE, including acute myocardial infarction, revascularization, and acute ischemic stroke. Patient mortality and progression to end-stage renal disease were also evaluated.

Results: We included 12,380 ARRT patients and 382,018 patients in the control group. Among the study group, 6,891 patients were included in the CRRT group, and 5,034 in the IRRT group. The risks of MACE [adjusted hazard ratio (HR) 1.463 (1.323-1.619), P<0.001], all-cause mortality [adjusted HR 1.323 (1.256-1.393), P<0.001], and end-stage renal disease [adjusted HR 18.110 (15.779-20.786), P<0.001] were higher in the ARRT patients than the control group. When we compared the CRRT patients to the IRRT patients, the risk of a MACE was comparable [adjusted HR 1.049 (0.888-1.239), P=0.575].

Conclusions: Clinicians should note the increased risk of a long-term MACE in ARRT survivors and consider appropriate risk factor management. Receiving CRRT did not increase the risk of MACE when compared to receiving IRRT only.



TH-PO009

Simple Postoperative-AKI Risk (SPARK) Classification in Major Non-Cardiovascular Surgery

Sehoon Park,[1] Hyunjeong Cho,[2] Seokwoo Park,[1] Soojin Lee,[3] Sejoong Kim,[4] Dong Ki Kim,[1] Kwon Wook Joo,[1] Yon Su Kim,[5] Hajeong Lee.[5] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Chungbuk National University Hospital, Cheongju-si, ChungcheongBuk-Do, Republic of Korea; [3]Seoul national university hospital, Seoul, Republic of Korea; [4]Seoul National University Bundang Hospital, Seongnam, Gyeonggi-do, Republic of Korea; [5]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: We aimed to develop a patient-oriented outcome-based postoperative acute kidney injury (PO-AKI) risk index and classification for planning PO-AKI monitoring before performing major non-cardiac surgery.

Methods: We performed an observational cohort study in two tertiary referral hospitals, each consisting a discovery and validation cohort. Patients who underwent a major non-cardiac operation (≥ 1 hour) were included. We fitted a proportional logistic regression model for an ordinal outcome consisting of the following three categories: no PO-AKI, low-stage AKI, and critical AKI. Critical AKI was defined as KDIGO AKI stage ≥ 2, post-AKI death, or renal failure within 90 days after surgery. PO-AKI events not fulfilling the definition of critical AKI were defined as low-stage AKI.

Results: A total of 50,792 and 39,537 patients were included in the discovery and validation cohorts, respectively. After building a robust model with variables that could be collected or estimated when surgery was scheduled, further simplification was performed. The final Simple PO-AKI RisK (SPARK) index included scores of the following ten variables: age, sex, eGFR, surgery duration, emergency operation, diabetes mellitus, renin-angiotensin-aldosterone system blockades, hypoalbuminemia, anemia, and hyponatremia. The calibration and discrimination results were acceptable. The AUC for low-stage AKI and critical AKI was 0.701 and 0.779 in the validation cohort. When we designated cutoff values to define four classifications, the incidences of the outcomes showed class-dependent increments.

Conclusions: The SPARK index and classification prior to surgery reflects not only the risk of PO-AKI but also the severity and patient-oriented outcomes associated with PO-AKI.

Risk factors	Scores
Age (years)	
< 40	0
≥40 and <60	6
≥60 and <80	9
≥80	14
eGFR (mL/min/1.73 m^2)	
≥ 60	0
≥ 45 and <60	7
≥ 30 and <45	13
≥ 15 and <30	21
Urine albuminuria (≥ 1+)	5
Sex	
Female	0
Male	7
Surgical duration (hours)	×4
Emergency operation	8
Diabetes mellitus	4
RAAS blockade use	5
Hypoalbuminemia (< 3.5 g/dL)	8
Anemia (<12 g/dL female, 13 g/dL male)	3
Hyponatremia (<135 mEq/L)	4

SPARK class	Score	AKI	Critical AKI
A	< 20	less likely	minimal
B	≥ 20 and < 40	possible	less likely
C	≥ 40 and < 60	at risk	possible
D	≥ 60	definite risk	at risk

TH-PO010

Geographic Correlation Between Dialysis-Requiring AKI and Recovery from ESRD

Zijin Chen,[1,2] Benjamin J. Lee,[2] Charles E. McCulloch,[2] Rajiv Saran,[3] Michael Heung,[3] Meda E. Pavkov,[4] Nilka Rios Burrows,[4] Chi-yuan Hsu.[2] CDC CKD Surveillance Team *[1]Ruijin Hospital affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China; [2]University of California San Francisco, San Francisco, CA; [3]University of Michigan, Ann Arbor, MI; [4]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: We recently reported that about 5% of incident end stage renal disease (ESRD) patients in the U.S. recover enough kidney function to discontinue maintenance

dialysis (Lee AJKD 2017). Large geographic variations in rates of renal recovery among ESRD patients have also been reported (Mohan PLoS One 2013). We hypothesized that this may be related to variation in rates of dialysis-requiring acute kidney injury (AKI-D).

Methods: Incidence rates of AKI-D hospitalization in 2011 for AZ, AR, CA, FL, IA, KY, MA, MD, MI, NJ, NM, NY, NV, OR, RI, SC, VT and WA were calculated from the State Inpatient Database using validated diagnostic and procedure codes. Rates of renal recovery among ESRD patients in 2011 were calculated using U.S. Renal Data System data. U.S. Census data were used to define underlying population sizes. Correlation (unadjusted) was determined using Pearson's r.

Results: We found a positive correlation between rate of renal recovery and incidence of AKI-D, both overall (Figure) and in subgroups (Table).

Conclusions: Rates of renal recovery among incident ESRD patients varied considerably across states and correlated with geographic variation in AKI-D incidence. These findings support the hypothesis that renal recovery among ESRD patients mostly represents recovery from AKI-D. When reporting counts of "end-stage" renal disease, subtracting those who recovered renal function (which ranges in magnitude from 3% to 8% in the sampled states) might be a consideration.

Population-Based Trends in Pediatric AKI (2008-2016): The Kaiser Permanente Experience

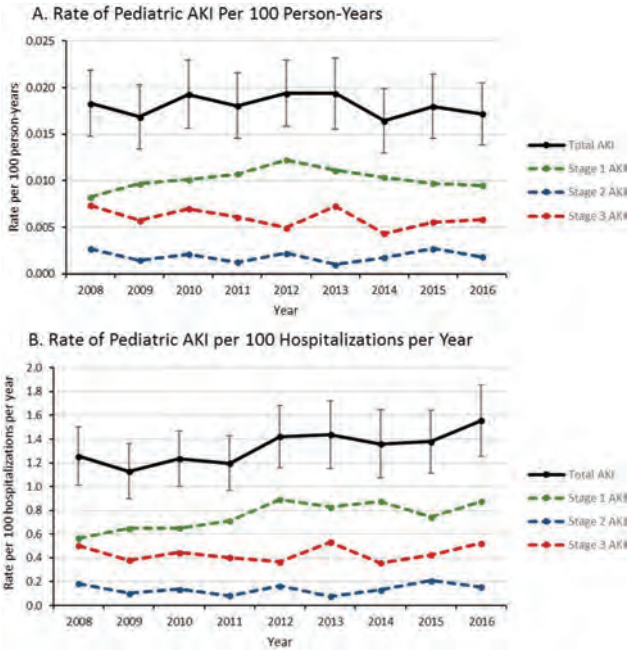
Rishi V. Parikh,[1] Thida C. Tan,[1] Elaine Ku,[2] Tracy Y. Jonelis,[1] Alan S. Go.[1]
[1]Kaiser Permanente Northern California, Oakland, CA; [2]University of California San Francisco, San Francisco, CA.

Background: Acute kidney injury (AKI) may lead to long-term consequences in children but its epidemiology has not been well-described outside of ICU settings. We evaluated recent temporal trends in rates of AKI in a large, diverse pediatric population receiving care within an integrated healthcare delivery system.

Methods: We identified calendar year-based cohorts from 2008-2016 of Kaiser Permanente Northern California members <18 years old. We excluded those <1 year old or who received prior renal replacement therapy before entry into a yearly cohort. Hospitalized AKI was identified and its severity assessed using KDIGO criteria. Baseline SCr was defined as the most recent outpatient, non-emergency department value 7-365 days before admission, and eGFR was calculated using the bedside Schwartz equation. We examined age- and sex-adjusted incidence of AKI per 100 person-years and per 100 hospitalizations per year, directly standardized to the 2008 population. Trends were evaluated using Poisson regression.

Results: Among 1,500,546 pediatric members, mean age was 9.8 years and 48.9% were female. The age-and sex-adjusted incidence of hospitalized AKI did not change significantly across the study period. There were 69,645 hospitalizations during the study period, with the hospitalization rate in the population declining from 1.45 per 100 PY in 2008 to 1.12 per 100 PY in 2016 (p<0.001). Among hospitalizations, the age-and sex-adjusted incidence of Stage 1 AKI increased from 2008 to 2016, with borderline significance.

Conclusions: Population-level pediatric AKI incidence did not significantly change between 2008-2016, but Stage 1 AKI incidence slightly increased over time among the subset of hospitalized children.



TH-PO012

Theophylline Use to Mitigate AKI in Infants Undergoing Total Body Cooling for Perinatal Asphyxia

Kyle Merrill, Jennifer G. Jetton, Jonathan M. Klein, Jason Misurac. *University of Iowa, Iowa City, IA.*

Background: Perinatal asphyxia is a common cause of acute kidney injury (AKI) and hypoxic ischemic encephalopathy (HIE). Theophylline is protective against AKI in infants with HIE who are not treated with total body cooling. However, there is a paucity of information on the effect of theophylline to protect against AKI in infants with HIE treated with total body cooling.

Methods: Single-center retrospective cohort analysis of infants diagnosed with HIE treated with total body cooling from 1/2007 to 12/2017. Inclusion criteria were: moderate or severe HIE, gestational age > 36 weeks, measurement of at least two serum creatinine (SCr) values at least 12h apart, and absence of prenatally diagnosed renal disease. Included infants were stratified based on receipt of theophylline and theophylline dose strategy: either a single dose of 5-8 mg/kg on day of life (DOL) 0 (standardized) or multiple doses (non-standardized). AKI was defined according to a Kidney Disease: Improving Global Outcomes (KDIGO) definition modified for neonates: SCr ≥50% above the lowest previous baseline; increase in SCr of ≥0.3 mg/dL within 48h; or urine output (UOP) ≤1 ml/kg/h for 24h.

Results: There were 116 infants who met the inclusion criteria. Among included infants, SCr was missing on 374/812 days (46%) from DOL 0-6, limiting the detection of AKI by SCr. AKI incidence was 63/116 (54%). There was no significant difference in AKI incidence between groups (χ^2=0.18, p=0.91). AKI severity was higher in the no theophylline group but the difference was not significant (χ^2=3.9, p=0.42). UOP was different between groups on DOL 1 (p=0.008) but not on DOL 2-6.

Conclusions: In this cohort of infants with HIE treated with total body cooling, theophylline administration was not associated with a significant difference in the incidence or severity of AKI.

	No Theophylline (n=58)	Standardized Theophylline (n=46)	Non-standardized Theophylline (n=12)
AKI (UOP or SCr)	32/58 (55%)	24/46 (52%)	7/12 (58%)

Hyponatremia and AKI in Critically Ill Children

Cassandra L. Formeck,[3,1] Emily L. Joyce,[3,1] Priyanka Priyanka,[1] Shashank Badavanahalli Rajashekar,[1] Juan Carlos Ayus,[2] John A. Kellum,[1] Michael L. Moritz.[3] *[1]The University of Pittsburgh, Pittsburgh, PA; [2]Renal Consultants of Houston, Houston, TX; [3]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA.*

Background: Hyponatremia is associated with increased morbidity and mortality in hospitalized patients for unknown reasons. Hyponatremia is also associated with osmotic cellular stress. Renal tubular epithelial are exposed to numerous stressors in critically ill patients. We hypothesized that hyponatremia would be associated with a greater rate of acute kidney injury (AKI) in critically ill children. Our objective was to evaluate the association between hyponatremia and AKI, controlling for sepsis, a primary coexposure.

Methods: Using a pediatric ICU database of 12,806 admissions, we included patients with a measured sodium value within 6 hours of ICU admission, and excluded patients with AKI or significant chronic renal dysfunction. We analyzed the association between hyponatremia (serum Na < 135 mEq/L), sepsis and known nephrotoxic drug exposure within 48 hours of ICU admission, on the development of stage 2 or 3 AKI within 7 days. For the primary analysis, we stratified by the presence or absence of sepsis at ICU admission, and compared rates of AKI in patients with and without expsoure to hyponatremia or 3 or more nephrotoxic medications.

Results: A total of 5,300 patients (male 58%; mean age 7.5 years) were included in the analysis. 16.1% of patients had hyponatremia, 7.0% nephrotoxic medication exposure and 30.1% developed sepsis. The incidence of stage 2 or 3 AKI was 8.8% in hyponatremic patients with sepsis compared to 14.7% in hyponatremic patients without sepsis. Patients with hyponatremia and nephrotoxic medication exposure were at increased risk for AKI in the absence of sepsis (p <0.001, p 0.008). Patients with hyponatremia, with and without sepsis, were more likely to develop AKI compared to patients with normonatremia (RR 1.11, RR 1.82). In children without sepsis, patients with hyponatremia were at higher risk of developing AKI than patients with exposure to 3 or more nephrotoxic medications (RR 1.82, RR 1.57).

Conclusions: Hyponatremia is a significant risk factor for AKI in critically in children in the absence of sepsis.

Hyperuricemia Is Associated with AKI and All-Cause Mortality in Hospitalized Patients

Min woo Kang,[1] Minjung Kang,[2] Soie Kwon,[3] Ho Jun Chin,[4] Dong Ki Kim,[1] Kwon Wook Joo,[1] Yon Su Kim,[5] Sejoong Kim,[4] Seung Seok Han.[5] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea; [3]Seoul national university, Seoul, Republic of Korea; [4]Seoul National University Bundang Hospital, Seong nam, Republic of Korea; [5]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Hyperuricemia as a risk factor of high morbidity and mortality has been documented in several disease status. Nevertheless, the relationship between uric acid (UA) and the risks of acute kidney injury (AKI) and mortality remains unresolved in hospitalized patients.

Methods: All patients (aged ≥ 17 years old) admitted to Seoul National University Bundang Hospital from January 2013 to December 2013 were retrospectively reviewed. UA at the time of admission was categorized based on the quartiles. Odds ratio (OR) for AKI and hazard ratio (HR) for all-cause mortality were calculated after adjustment of multiple variables. All the analyses were stratified by gender.

Results: The 4th quartile UA group (male, UA ≥ 6.8 mg/dL; female, UA ≥ 5.4 mg/dL) showed a higher risk of AKI than the 1st quartile group (male, UA < 4.4 mg/dL; female, UA < 3.5 mg/dL) as following ORs: 2.3 (1.76-2.90) in males (P < 0.001); and 2.5 (1.86-3.32) in females (P < 0.001). There were more patients who did not recover from AKI in the 4th quartiles than in the 1st quartiles, as following ORs: 1.5 (1.11-1.95) in males (P < 0.001); and 2.5 (1.63-3.98) in females (P < 0.001). The 4th quartile group had a higher risk of all-cause mortality than the 1st quartile group, as following HRs: 1.5 (1.30-1.71) in males (P < 0.001); and 1.3 (1.08-1.52) in females (P = 0.004). The in-hospital mortality risk was also higher in the 4th quartile than in the 1st quartile, which was only significant in males: OR, 2.4 (1.56-3.77) (P < 0.001).

Conclusions: Hyperuricemia increases the risks of AKI and all-cause mortality in hospitalized patients.

Improvement of the Renal Angina Index Clinical Application Through Multiple Baseline Creatinine estimation Methods

Jean-Philippe Roy,[1,2] Stuart Goldstein.[3] *[1]Division of Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Center for Acute Care Nephrology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: The Renal Angina Index (RAI) is a validated screening tool used at 12h of pediatric intensive care unit (PICU) admission that predicts severe AKI on PICU day 3. A baseline serum creatinine (SCr) value is essential for AKI diagnosis as well as RAI, yet, is often not available. In this situation, our RAI algorithm uses a validated height-dependent imputation method (Baseline SCr (mg/dL) = 0.413 x height (cm) / 120ml/min/1.73m^2), yet patient height often is not available in the medical record within 12 hours of PICU admission. To improve the reliability of the RAI algorithm, we compared the height-dependent method with an age-based, height-independent baseline SCr calculation.

Methods: In April 2017, we implemented an electronic algorithm to automatically generate an RAI score for every patient (pt) admitted to our PICU. We reviewed 157 pt records from May 2017, selecting those who had an appropriate calculation of their RAI at 12h. We compared the RAI using an age-based SCr imputation method of Pottel to the RAI using a SCr imputed by the height-dependent method. Our primary outcome was a change in fulfillment of the RAI positivity threshold (RAI≥8). A secondary outcome compared height-based imputed and age-based baseline SCr to assess for a discrepancy of >25% between the two methods.

Results: We found 15/157 false positive RAI results on screening due to a lack of previously measured SCr and height, 42 without SCr measurement within 12h of their admission, leaving 100 that had sufficient data for RAI calculation. Only 2/100 pt had the RAI reclassified when using the Pottel imputed baseline SCr (one in each direction). 20% of pt had a discrepancy of 25% or more between the two methods. A Cochrane-Mantel-Haenszel Chi-square test confirmed that being small for age (<3rd percentile of height) or being older (≥14 years old) were both independently associated with an overestimation of the baseline SCr when using the age-based method.

Conclusions: The age-based method to estimate baseline SCr offers a viable height-independent alternative for RAI calculation. While being less precise than a height-based approach, this lack of precision rarely leads to reclassification of pt RAI status.

TH-PO016

U-Shape Association of Serum Albumin Level and AKI Risk in Hospitalized Patients

Wisit Cheungpasitporn,[1] Charat Thongprayoon,[2] Michael A. Mao,[3] Ankit Sakhuja,[4] Kianoush Kashani.[3,4] *[1]Nephrology, University of Mississippi Medical Center, Jackson, MS; [2]Bassett Medical Center, Cooperstown, NY; [3]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [4]Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, MN.*

Background: While an association between hypoalbuminemia and increased risk of acute kidney injury (AKI) is well-established, the risk of AKI development and its severity among patients with elevated serum albumin is unclear. The aim of this study was to evaluate the risk of AKI in hospitalized patients stratified by various admission serum albumin levels.

Methods: This single-center retrospective study was conducted at a tertiary referral hospital. All adult hospitalized patients who had admission albumin levels available between January 2009 and December 2013 were enrolled. Admission albumin was categorized based on its distribution into six groups (≤2.4, 2.5-2.9, 3.0-3.4, 3.5-3.9, 4.0-4.4, and ≥4.5 mg/dL). The primary outcome was the incidence of hospital-acquired AKI (HAKI). Logistic regression analysis was performed to obtain the odds ratio of AKI for various admission albumin strata using the albumin 3.5 to 3.9 mg/dL (lowest incidence of AKI) as the reference group.

Results: Of the total 9,552 studied patients, HAKI occurred in 1,556 (16.3%) patients. The incidence of HAKI among patients with admission albumin ≤2.4, 2.5-2.9, 3.0-3.4, 3.5-3.9, 4.0-4.4, and ≥4.5 mg/dL was 18.3%, 14.3%, 15.5%, 14.2%, 16.7%, and 26.0%, respectively. After adjusting for potential confounders, admission serum albumin levels ≤2.4 and ≥4.5 mg/dL were associated with an increased risk of HAKI with odds ratios of 1.52 (95% CI 1.18-1.94) and 2.16 (95% CI 1.74-2.69), respectively. While stage 1 HAKI was significantly more frequent among patients with admission albumin ≥4.5 mg/dL (23.0% vs. 11.6%, P<0.001), incidence of stage 3 HAKI was higher in those with albumin ≤2.4 mg/dL (2.8% vs 0.3%, P<0.001).

Conclusions: Admission serum albumin levels ≤2.4 and ≥4.5 mg/dL were associated with an increased risk for HAKI. Patients with admission albumin ≥4.5 mg/dL had HAKI with a lower intensity when compared with those who had admission albumin levels ≤2.4 mg/dL.

TH-PO017

Admission Calcium-Phosphate Product Levels and Risk of AKI in Hospitalized Patients

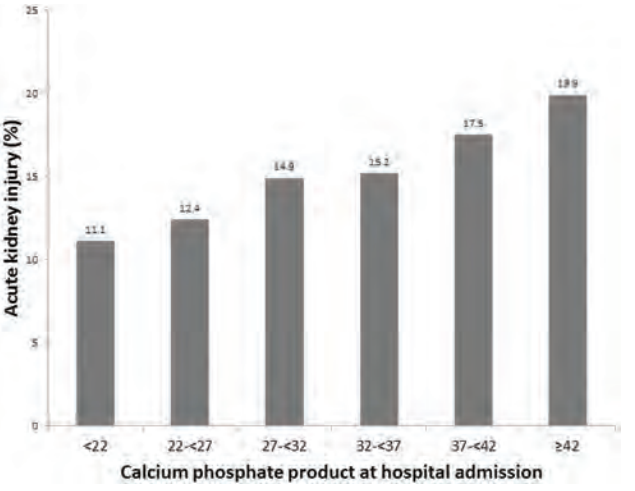
Michael A. Mao,[1] Wisit Cheungpasitporn,[2] Charat Thongprayoon,[3] Stephen B. Erickson.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Nephrology, University of Mississippi Medical Center, Jackson, MS; [3]Bassett Medical Center, Cooperstown, NY.*

Background: An increased serum calcium-phosphate product (CaP) can result in acute kidney injury (AKI) due to tubular and interstitial calcium phosphate deposits. In addition, CaP of >55 mg^2/dL^2 is associated with systemic calcification. However, the risk of AKI development among hospitalized patients with different calcium-phosphate product levels on admission remains unclear.

Methods: All adult hospitalized patients who had both admission serum calcium and phosphate levels available between years 2009 and 2013 were enrolled. Admission CaP was categorized based on its distribution into six groups (<22, 22-<27, 27-<32, 32-<37, 37-<42 and ≥42 mg^2/dL^2). The odds ratio (OR) of in-hospital mortality by admission CaP, using the CaP category of <22 mg^2/dL^2 as the reference group, was obtained by logistic regression analysis.

Results: After excluding patients with end stage renal disease (ESRD), without serum creatinine measurement, and those with AKI at presentation, a total of 9,864 patients were studied. In-hospital AKI occurred in 1,478 (15.0%) patients. The incidence of AKI among patients with admission CaP <22, 22-<27, 27-<32, 32-<37, 37-<42 and ≥42 mg^2/dL^2 was 11.1%, 12.4%, 14.9%, 15.2%, 17.5%, and 19.9%, respectively. After adjusting for potential confounders, CaP >37 mg^2/dL^2 was associated with an increased risk of developing AKI, with ORs of 1.53 (95% CI 1.19-1.96) and 1.63 (95% CI 1.25-2.14) in patients with admission CaP 37-<42 and ≥42, respectively. Among a subgroup of patients with available serum albumin, after adjusting for potential confounders, corrected CaP >27 mg^2/dL^2 was associated with an increased risk of developing AKI with ORs of 1.50 (95% CI 1.06-2.15), 1.49 (95% CI 1.06-2.13), 1.85 (95% CI 1.30-2.67) and 1.69 (95% CI 1.16-2.49) when CaP were within 27-<32, 32-<37, 37-<42 and ≥42 mg^2/dL^2, respectively.

Conclusions: Elevated admission CaP was associated with an increased risk for in-hospital AKI.



TH-PO018

Lower Serum Bicarbonate Is Associated with an Increased Risk of AKI

Neil R. Shah,[2] Zhiying You,[3] Anna J. Jovanovich,[4] Michel Chonchol,[2] Jessica B. Kendrick.[1] *[1]University of Colorado School of Medicine, Aurora, CO; [2]University of Colorado, Denver, CO; [3]UC Denver, Aurora, CO; [4]Denver VA / University of Colorado, Denver, CO.*

Background: Lower serum bicarbonate levels are associated with an increased risk of kidney disease progression. Whether lower serum bicarbonate levels are associated with an increased risk of developing acute kidney injury (AKI) is unclear. We tested the hypothesis that lower serum bicarbonate levels are associated with a higher risk of developing AKI.

Methods: We included 8,393 patients from the Systolic Blood Pressure Intervention Trial (SPRINT). Serum bicarbonate levels were measured at baseline in the SPRINT study. AKI was a predetermined adjudicated adverse event that was determined by hospital admission and discharge records with AKI as a recorded diagnosis. Serum bicarbonate was examined in clinically significant cutoffs ≤ 24, 25-28 and >28 mEq/L, with 25-28 mEq/L as the reference group. Cox proportional hazard models were used to examine the association between serum bicarbonate and development of AKI.

Results: The mean (SD) age, estimated glomerular filtration rate (eGFR), and serum bicarbonate level at baseline were 68 (9) years, 77 (23) ml/min/1.73m2 and 26.3 (2.6) mEq/L, respectively. Participants with serum bicarbonate levels ≤ 24 mEq/L were more likely to be male and to have lower baseline eGFR. After a median follow-up time of 3.3 years, 293 participants developed AKI. More patients in the lower bicarbonate group developed AKI (6.1% vs 2.8% in the 25-28 mEq/L and 2.1% in the >28 mEq/L). A bicarbonate level ≤ 24 mEq/L was associated with a significantly increased risk of AKI compared to those with a bicarbonate level of 25-28 mEq/L after full adjustment (HR 1.42, 95% CI 1.1 to 1.8).

Conclusions: Lower serum bicarbonate levels are an independent risk factor for the development of AKI.

Funding: Other NIH Support - NHLBI

Hazard Ratio (95%CI) of AKI

Serum Bicarbonate mEq/L	Unadjusted	Model 1*	Model 2**
≤ 24	2.11 (1.7-2.7)	1.42 (1.1-1.8)	1.42 (1.1-1.8)
25-28	1.00	1.00	1.00
> 28	1.14 (0.8-1.6)	0.99 (0.7-1.4)	1.01 (0.7-1.4)

*Model 1: adjusted for age, gender, race, treatment assignment, smoking status, history of cardiovascular disease, heart failure, baseline body mass index, blood pressure and eGFR.

**Model 2: adjusted for model 1 plus class of antihypertensive medication.

TH-PO019

Risk Factors for Community-Acquired Kidney Disease

Etienne Macedo,[6] Ulla Hemmila,[7] Sanjib Kumar Sharma,[2] Rolando Claure-Del Granado,[1] Henry E. Mzinganjira,[8] Bijay Bartaula,[2] Michael V. Rocco,[3] Emmanuel A. Burdmann,[4] Jorge Cerda,[5] Ravindra L. Mehta.[6] ISN 0by25 *[1]Hospital Obrero#2-Universidad Mayor de San Simon, Zona Sarco, Bolivia, Plurinational State of; [2]B P Koirala Institute of Health Sciences, Dharan, Nepal; [3]Wake Forest School of Medicine, Winston-Salem, NC; [4]University of Sao Paulo Medical School, Sao Paulo, Brazil; [5]Capital District Renal Physicians, Albany, NY; [6]University of California San Diego Medical Center, La Jolla, CA; [7]College of Medicine, Malawi, Kokemäki, Finland; [8]MOH, Blantyre, Malawi.*

Background: Risk factors for the development of AKI in the community, either presenting to Community Health Center (CHC) or emergency departments (ED), have not been well studied in Low and Lower-Middle Income Countries (LLMIC). A key limitation is the heterogeneity of diseases and a lack of a standardized approach to evaluating renal

dysfunction. We evaluated the risk factors associated with acute kidney disease (AKD) within the International Society of Nephrology 0by25 Pilot Feasibility Project, designed to improve detection and management of community acquired-AKI in LLMIC.

Methods: Patients (pts) presenting to CHC or ED were screened for signs or symptoms *a priori* associated with risk of developing AKI. Pts with high/moderate risk underwent a serum creatinine (sCr) POC test and a urine dipstick. Pts were classified as chronic kidney disease (CKD) based on prior history, proteinuria (>1+) and/or baseline sCr within 12 mos by estimated GFR (CKD-EPI equation)) <60 mL/min/1.73 m^2; normal renal function (NRF) (negative proteinuria and eGFR>75ml/min/1.73 m^2); Acute Kidney Disease (AKD) neither meeting criteria for CKD or NRF. AKI was confirmed within 7 days by sCr increase or decrease of 0.3mg/dl, or 1.5x from the reference value.

Results: 3,577 pts were screened; 319 CKD and 379 children <12 years old were excluded from this analysis. Of 2,879 remaining pts, 1248 (43%) were classified as AKD at enrollment; 496 had NRF; and 1,135 with low risk for AKI, were assumed to have a normal renal function. Over the first 7 days, 438(3.5%) from AKD and 58(35%) from NRF group met criteria for AKI. In comparison to NRF, pts with AKD had a higher frequency of diabetes (13% AKD vs. 9%NRF), hypertension (22%AKD vs.16%NRF) and chronic liver disease (5%AKD vs. 2%NRF). Dehydration associated with vomiting and low oral intake was the most common risk factor for AKD, followed by diarrhea, hypotension and appetite loss. Pts with AKD were more often hospitalized and had high mortality rates; 9% at 7 days and 15% at 6months.

Conclusions: Comorbidities and a set of signs and symptoms can identify adult patients at risk for AKD and can be used to select patients that may benefit from POC testing in CHC. Crucially, identification of kidney dysfunction can help discriminate patients who may benefit from higher levels of care.

TH-PO020

National AKI Risk Estimates After a Variety of Inpatient Surgeries

Mohammed J. Saeed,[1] Tarek Alhamad.[2] *[1]Capital Health, Trenton, NJ; [2]Washington University in St. Louis, St. Louis, MO.*

Background: Postoperative acute kidney injury (AKI) is not well studied in non-cardiac procedures. Our aim was to quantify the risk of AKI and dialysis-requiring AKI (AKI-D) after various inpatient surgeries.

Methods: We used the National Inpatient Sample (NIS), which is a nationally representative sample of hospitalizations in the United States and includes records from all payers (including the uninsured). We identified 37 types of surgeries from 1/1/2013 to 9/30/2015 in adults (age ≥18 years) on first 2 days of hospitalization, excluding patients with end stage renal disease. Procedures, AKI and AKI-D were defined using ICD-9-CM diagnosis and procedure codes. Certain same-day surgery combinations were identified as well. Weighted frequencies and proportions of AKI and AKI-D were calculated for each surgery with 95% confidence intervals (CI).

Results: Our study sample of 2,504,894 surgical hospitalizations represented 12,524,470 hospitalizations when weighted. AKI and AKI-D risk was plotted in figure 1 sorted by AKI risk. Surgeries with the highest AKI-D percentages were heart transplant (2.6%, 95% CI 1.0-4.2), liver transplant (3.7%, 95% CI 2.4-4.9) and abdominal aortic aneurysm repair (4.2%, 95% CI 3.4-5.0). Small bowel surgery had the highest AKI risk among bowel surgeries (8.7%, 95% CI 8.3-9.0) and had even higher risk when combined with colon surgery (18.3%, 95% CI 17.4-19.3) or with exploratory laparotomy (14.2%, 95% CI 13.5-14.8). Exploratory laparotomy combined with an abdominal procedure (except gastric and cesarean procedures) had significantly higher AKI risk (range of percentage difference 0.4-5.5).

Conclusions: Using nationally representative data, we estimated the risk of AKI and AKI-D in a large population of surgical hospitalizations including certain same-day surgery combinations.

TH-PO021

Predictors for AKI in Old Age

Natalie Ebert,[3] Doerte Huscher,[4] Jens Gaedeke,[2] Markus van der Giet,[2] Martin K. Kuhlmann,[1] Nina Mielke,[3] Elke Schaeffner.[3] Berlin Initiative Study (BIS) *[1]Vivantes Klinikum im Friedrichshain, Berlin, Germany; [2]Dept. of Nephrology, Charité, Berlin, Germany; [3]Institute of Public Health, Charité Universitaetsmedizin Berlin, Berlin, Germany; [4]Institute for Biostatistics and Clinical Epidemiology, Charité Universitätsmedizin Berlin, Berlin, Germany.*

Background: Acute kidney injury (AKI) is a feared condition especially in old age. Data on incidence rates however as well as predictors are scarce. The Berlin Initiative Study (BIS) evaluates the incidence of AKI and potential predictors in older adults.

Methods: The BIS is a prospective population-based cohort initiated in 2009 whose participants are members of a German insurance company with the largest fraction of older adults. Patients are documented biannually by a standardized questionnaire. All intermediate hospitalizations with referral and acute ICD-10 (N17.xx) diagnoses were provided by the insurance company. N17.xx events during hospitalizations were identified. From the group without incident AKI 16 patients with prevalent events were excluded. Multivariate Cox-PH regression analysis was used to detect predictors for the first incident AKI.

Results: As of May 04, 2018, 2053 participants (47.4% male, mean age 80.3 at inclusion) were observed for 7.4±0.4 years. Of those, 189 (9.2%) experienced at least one AKI during the observation. In total, 292 events were observed (incidence ratio / 100.000 person-yrs: 1900). At baseline, patients with incident AKI were about 2.4 years older, more frequently male (57 vs. 47%), had a worse waist-hip-ratio (WHR, median 1.0 vs. 0.9), $eGFR_{(BIS2)}$ (median 49 vs. 60 mL/min per 1.73m^2) and albumin-creatinine ratio (median 17 vs. 10 mg/g) and suffered more often from comorbidities at baseline (hypertension 91 vs. 77%, diabetes 40 vs. 25%, myocardial infaction 22.0 vs 13%, stroke 15 vs. 8%, anemia 32 vs. 16%). Of the 189 patients with AKI, 26 (13.8%) were admitted to the hospital with an N17.xx ICD-10 code, all other patients with other primary referral diagnoses; the median number of hospitalization during the observation period was 7 (median duration of stay 11 days). Of the patients without AKI, 41% had hospitalizations with a median number of 4 (median duration of 7.6 days). In the multivariate model, $eGFR_{(BIS2)}$ (OR=0.873 [0.83;0.92] per 5 units), waist-hip-ratio (OR=1.47 [1.24;1.74] per 0.1 units), hypertension (OR=2.00 [1.18;3.38]), diabetes (OR=1.61 [1.19;2.18]), and anemia (OR=1.52 [1.09;2.12]) were predictive for AKI in older adults.

Conclusions: With 1900 per 100.000 person-yrs AKI is frequent in a representative sample ≥70 yrs. Potential predictors apart from $eGFR_{(BIS2)}$ were WHR, hypertension, diabetes and anemia.

Funding: Veterans Affairs Support

TH-PO022

AKI Mortality and Weekend Nephrologist Consultation

Ana carolina N. Tome,[3] Rodrigo J. Ramalho,[1] Emerson Q. Lima.[2] Hospital de Base / FAMERP - São José do Rio Preto - Brazil *[1]Hospital de Base/FAMERP, Sao Jose Rio Preto, Brazil; [2]FAMERP, São José do Rio Preto, Brazil; [3]Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto, Brazil.*

Background: Admission to the hospital on weekends (WKD) is associated with increased mortality for acute illnesses than weekdays (WDAY). Previous analysis showed that this phenomenom also occurs in patients with acute kidney injury (AKI). However, there is still no data about this association and nephrologist consultation. Aim: analyse the impact of the day of the week of nephrologist consultation on the mortality in patients with AKI.

Methods: Database of patients over 18 years with AKI between 1srt January 2012 and 28st February 2018. Patients were analyzed according to the day of the week of first nephrologist consultation.

Results: During the period 6177 patients diagnosed with AKI were attended. The mean age was 64.1±15.7 years. They were classified in KDIGO I (46.3%), KDIGO II (26.5%) e KDIGO III (27.2%) at the nephrologist's called. The mean SOFA was 7.3 ± 4.7, 34.1% dialyzed and global mortality was 37.1%. WDAY called group has 4761 (77.1%) and WKD, 1416 (22.9%) patients. SOFA (7.8±4.7 *vs* 7.1±4.6, p<0.001) and mortality (41.5% *vs* 35.8%, p <0,001) were higher on WKD group. The following mortality risk factors were identified: age (OR 1.02; IC 1.02-1.03; p<0.001), obstructive AKI (OR 0.39; IC 0.26-0.58; p<0.001), sepsis (OR 1.26; IC 1.10-1.45; p=0.001), liver disease (OR 1.40; IC 1.11-1.77; p=0.004), cancer (OR 1.17; IC 1.19-2.62; p=0.005), dialysis (OR 1.54; IC 1.31-1.80; p<0.001), SOFA at the moment of the call (OR 1.18; IC 1.16-1.20; p<0.001) and at the first dialysis (OR 1.07; IC 1.05-1.08, p<0.001). In the model with only patients hospitalized in intensive care unit (ICU) (3283 patients; 53.14%), nephrologist consultation at WKD (OR 1.22; IC 1.02-1.46; p=0.028), age (OR 1.01; IC 1.01-1.02; p<0.001), obstructive AKI (OR 0.51; IC 0.27-0.96; p=0.037), cancer (OR 2.30; IC 1.34-3.94; p=0.002), dialysis (OR 1.57; IC 1.31-1.88; p<0.001), SOFA at the moment of the call (OR 1.11; IC 1.09-1.13; p<0.001) and at the first dialysis (OR 1.08; IC 1.07-1.10; p<0.001) were identified as risk factors of mortality.

Conclusions: First nephrologist consultation at WKD was associated a higher mortality, particularly those hospitalized in ICU. This association can be due to the highest severity of this population.

TH-PO023

Incidence and Risk Factors of AKI After Coronary Artery Bypass Grafting

Ahmad Salha,[1] Jose O. Valencia,[1] Bayiha daho Klaud francheska,[1] Racquel M. Lowe-Jones,[1] Joe Wang,[2] Robin Kanagasabay,[1] Debasish Banerjee.[1] *[1]St George's University Hospital NHS Foundation Trust, London, United Kingdom; [2]Epsom & St Helier Hospital NHS Trust, London, United Kingdom.*

Background: Acute kidney injury (AKI) Post-coronary artery bypass graft (CABG) is common, but the exact incidence remains controversial, and contributing risk factors varies in different studies. We aimed to investigate the true incidence and risk factors of AKI post Cardiopulmonary bypass (CPB) CABG; in a large inner-city, multi-ethnic, population.

Methods: We examined 2413 patients undergoing first time CPB CABG in a large tertiary care, UK hospital. Creatinine measurements (on isotope dilution mass spectroscopy or spectrometry) were derived from hospital records, pre-surgery and post-surgery days 1,2,3 and 4. AKI was defined as a rise of serum creatinine 26.4 μmol/L or 50% or 1.5-fold from baseline creatinine.. All data for the study was recorded prospectively, as a part of institutional audit process. All statistics were done using SPSS 17 and p value<0.05 was considered significant.

Results: Baseline characteristics of the patients are shown in table 1. The incidence of AKI was 23%. Majority of new AKI cases occurred on the second day post-operatively with 19% occurring on day 2 compared to 6%, 9% and 3% occurring on days 1, 3 and 4 respectively. Patients who developed AKI were older, with higher proportion of blacks, diabetics, hypertensives, higher CCS score (Canadian Cardiovascular Society grading of angina) and higher NYHA class compared to non-AKI patients (table 2). Incidence of AKI was associated with increased in-hospital mortality (4.4% vs 0.5%; p=0.000) and length of stay (8[IQR5] vs 6[IQR3] days; p=0.000). On multiple regression analysis, the independent predictors of AKI were age, CCS score 3-4, hypertension, emergency nature of surgery, insulin dependent diabetes and raised pre-operative creatinine (table 3).

Conclusions: In a multi-ethnic, inner-city population the incidence of AKI was 23% in first time CPB CABG patients and the independent risk factors were age, CCS score 3-4, hypertension, emergency surgery, diabetes and CKD.

Patient-Centered AKI: Baseline Characteristics of the Change AKI Study

Clarissa J. Diamantidis,[1] L. Ebony Boulware,[1] Aviel N. Alkon,[3] Joseph Lunyera,[1] Jennie Riley,[2] Cassandra Bowman,[3] Jennifer St. Clair Russell.[1] *[1]Duke University School of Medicine, Durham, NC; [2]Duke Un, Durham, NC; [3]Duke University, Durham, NC.*

Background: Hospital-related AKI carries a threat of poor outcomes that persist after discharge, yet few interventions support patient-centered AKI awareness and self-management beyond the hospital. We describe the study protocol and baseline characteristics of the ongoing Change AKI Study, a pilot study testing the feasibility and acceptance of an mHealth-based educational intervention for AKI survivors.

Methods: Hospitalized AKI survivors at Duke University Hospital seen by the inpatient nephrology service were recruited in 2017-2018. Eligible participants complete baseline surveys including questions regarding their outpatient safety behaviors (e.g. regular use of pain medication such as NSAIDs), perceived AKI knowledge (e.g. "Which of the following statements best describe how much you know about what causes AKI?"), and perceived risk of AKI outcomes (e.g. "How likely do you think it is that you will develop AKI in the future?"). Participants are then randomized to receive an mHealth educational program promoting AKI awareness/self-management, or usual care. Surveys are repeated by phone 1-month after discharge to evaluate changes in behaviors, perceived knowledge, and perceived risk.

Results: To date, 56 participants have completed baseline (28 intervention, 28 control). Half (50%) are female, 57% are aged 45-64 years old, and 42% are Black. Most have completed high school (98%), with a high proportion reporting a history of hypertension (61%) and diabetes (50%). Over half reported regular pain medication prior to hospitalization. Despite receiving a nephrology consult, only 28 (50%) report being aware of their AKI diagnosis – 23% report being told by their primary hospital team. Perceived AKI-related knowledge was variable: what kidneys do (95%), what is AKI (36%) causes of AKI (59%), what to do after AKI (48%). Most (70%) were concerned about recurrent AKI, 52% felt it was likely. While 63% reported confidence in knowing what questions to ask their outpatient provider about AKI, only 50% felt confident they had information to lower their future AKI risk.

Conclusions: AKI awareness, perceived knowledge, and self-management are suboptimal among hospitalized survivors receiving inpatient nephrology care. Interventions designed to improve these patient-centered outcomes may prevent recurrence.

TH-PO025

Risk Factors for AKI in High-Risk Populations: Systematic Review and Meta-Analyses

Waleed Zafar,[1] Andres Garcia-Arce,[1] Yirui Hu,[1] Sara J. Kwiecien,[1] Gurmukteshwar Singh,[2] Sara Saunders,[1] Ion D. Bucaloiu,[3] H. Lester Kirchner,[4] Kevin Ho.[3] *[1]Geisinger, Dnville, PA; [2]Geisinger Medical Center- Nephrology, Danville, PA; [3]Geisinger Medical Center, Danville, PA; [4]Geisinger Clinic, Danville, PA.*

Background: Predictive models help identify patients at increased risk for Acute kidney injury (AKI) for preventive care. It is unclear how various risk factors perform in different clinical settings. We systematically reviewed predictive models for AKI in four high risk settings and performed meta-analyses of common AKI risk factors

Methods: We searched MedLine, EMBASE, CINAHL and Cochrane Library, and performed hand searches of the retrieved reference lists, from 2010 through 2017 for English language studies of prediction models for hospital-acquired AKI (KDIGO, AKIN or RIFLE criteria) in adult hospital populations, patients undergoing cardiac surgery, patients in intensive care unit (ICU) and those undergoing contrast procedures. PRISMA-P 2015 statement was used for data extraction and study appraisal. For the meta-analyses of risk factors, studies with insufficient or non-standardized data and unadjusted risk factors were excluded. Random effects meta-analyses were used to assess pooled adjusted odds ratio (OR) for diabetes (DM), congestive heart failure (CHF) and chronic kidney disease (CKD) for developing AKI

Results: 74 studies testing AKI prediction models in the four clinical settings were included. Of these, 10 were in the general hospital setting, 8 were in the ICU, 27 in

percutaneous coronary interventions, and 29 in cardiac surgery. There was considerable heterogeneity among studies in the choice and definition of predictors. Meta-analyses included 14 studies reporting diabetes (135955 patients), 16 studies reporting CKD (137846 patients) and 22 studies reporting CHF (180224 patients). Stratified analyses based on high-risk clinical settings were consistent with the overall results (Table 1)

Conclusions: In the combined as well as sub-populations, DM, CKD, and CHF are associated with increased risk for AKI. Analyses of differential risk levels in sub-populations was limited by heterogeneity. Using uniform definitions for AKI and its risk factors in the development of predictive models for AKI is essential for their clinical application

Funding: Private Foundation Support

Meta-analyses results

	Overall estimate OR (95% CI)	Percutaneous coronary intervention OR (95% CI)	Cardiac surgery OR (95% CI)
Diabetes	1.72 (1.38-2.14)	1.86 (1.47-2.34)	1.26 (1.01-1.56)
CKD	1.47 (1.32-1.64)	2.53 (1.10-5.83)	1.31 (1.15-1.51)
CHF	1.78 (1.54-2.06)	2.07 (1.62-2.65)	1.55 (1.31-1.83)

TH-PO026

Frequency and Consequences of AKI in Patients with CKD in Public Nephrology Practices in Queensland, Australia

Wendy E. Hoy,[1,2] Jianzhen Zhang,[1,2] Zaimin Wang,[1,2] Anne Cameron (Salisbury),[3,1] Helen G. Healy,[4,2] Sree Krishna Venuthurupalli,[5,2] Andrew J. Mallett.[4,2] NHMRC CKD.CRE and CKD.QLD Collaborative *[1]Faculty of Medicine, The University of Queensland, Brisbane, QLD, Australia; [2]NHMRC CKD.CRE and CKD.QLD Collaborative, The University of Queensland, Brisbane, QLD, Australia; [3]CKD.QLD and the NHMRC CKD.CRE, Brisbane, NSW, Australia; [4]Kidney Health Service, MNHHS, Queensland Health, Brisbane, QLD, Australia; [5]Renal Service, DDHHS, Queensland Health, Toowoomba, QLD, Australia.*

Background: It is recognised that acute kidney injury (AKI) contributes to, and complicates, CKD and can exacerbate its progression. We describe acute kidney injury (AKI) documented in hospital episodes in patients enrolled in the CKD.QLD registry, based in the public nephrology sector in Queensland.

Methods: Queensland Health supplied data on CKD.QLD patients on admissions to all Queensland hospitals, public and private, as well as associated costs, and deaths, from May 2011 to June 2016. We describe the frequency of AKI and associated conditions, recognised by ICD codes.

Results: Among 6,365 CKD.QLD patients, 2,198 (34.5%) had a total of 4,711 hospital encounters with an AKI diagnosis. 550 patients had three or more AKI-related admissions. 64.9% of AKI admissions were through the emergency department. People with AKI were somewhat older (68.2 vs 64.6 yr) and more often male (57.1% vs 52%), than those without AKI, p<0.001 for both. Leading diagnoses associated with AKI were congestive heart failure, urinary tract infection, myocardial infarction, dehydration, pneumonia and COPD, gastroenteritis/colitis, and sepsis, and diabetic nephropathy was the leading underlying renal condition. Of those with AKI, 553 (25.2%) subsequently died in the 5 year interval and 238 (10.8%) started renal replacement therapy (RRT), compared with 282 (12.8%) who died and 295 (13.4%) who started RRT among those who did not have AKI, p<0.001 for each. Adjusted for all other significant factors, the hazard ratio (95%CI) of AKI patients relative to those without AKI for death without RRT was 3.32 (CI 2.8-3.9), p<0.001, and for RRT was 1.21 (CI 1-1.5), p=0.06.

Conclusions: AKI that comes to clinical attention is very common among these CKD patients. It usually presents through unplanned, emergency admissions. It is associated with strikingly increased rates of death but only marginally increased rates of RRT. Preventable causes of AKI should be better understood and addressed.

Characteristics of Patients Readmitted to Hospital One Year Following an Episode of AKI

Andrew J. Lewington,[1] Steven Goorachan,[3] Fazeel Ahmad,[4] Adrian G. Miller.[2] *[1]Leeds Teaching Hospitals, Leeds, United Kingdom; [2]Leeds teaching Hospitals NHS Trust, Leeds, United Kingdom; [3]St. James Hospital, Leeds, United Kingdom; [4]Leeds teaching Hospitals, Leeds, United Kingdom.*

Background: Acute kidney injury (AKI) is a risk factor for further episodes of AKI. We have analysed the characteristics of a cohort of patients who had an AKI identified by an AKI e-alert and who were readmitted within a 1 year

Methods: Data was gathered on patients admitted to a teaching hospital who had an AKI e-alert (2015 - 2017) and who were subsequently readmitted within 1 year. The electronic health care records (EHR) of these patients were reviewed

Results: 2010 patients were identified of which 1513 patients had an initial length of stay〈 30 days. Initial review of 302 patient EHR from this subgroup (n=1513) excluded 52 patients who did not have a clinical episode of AKI. The remaining cohort (n=251) had a mean age of 73 yrs (25-99 yrs) with 135 (54%) males and 116 (46%) females. The mean length of stay was 16 days and the cause of AKI was poorly documented in the EHR. The reason for admission was multifactorial (30%) sepsis (26%), cardiac failure (15%), hypovolaemia (8%), malignancy (8%) obstruction (5%), trauma (5%) and abdominal surgery (3%). The 1 yr mortality was 37% and this increased with age; 20.9% (〈 60 yrs), 33.3% (〈 60-79 yrs) and 42.2% (〉80yrs). At 3 months recovery of kidney function to the original eGFR occurred in 20.3% of patients. 10.7% of patients experienced a reduction in kidney function to〈 50% of their baseline eGFR. Recovery of eGFR to baseline at 3 months did not result in improvement in 1 year mortality rate 32.8% versus 29.2% in those patients whose kidney function did not return to baseline eGFR. The mean time to readmission was 68.4 days (range 1-336 days). The cause for readmission was the same in only 20% of patients. Only 23.9% of those readmitted had a further episode of AKI either at the time of readmission or throughout the subsequent length of hospital stay.

Conclusions: Acute kidney injury has been identified as a risk factor for recurrent episodes of AKI. In our ongoing analysis of a large cohort of patients only 23.9% of those readmitted had an episode of AKI at the time of readmission or throughout the subsequent length of hospital stay. The reason for readmission was the same for only 20% of the patients. Nearly 80% of patients fail to fully recover kidney function by 3 months. Further analysis of the characteristics of this cohort are ongoing and will be presented.

TH-PO028

Temporal Trends in the Inpatient Mortality of Patients with AKI After Coronary Revascularization in a Nationwide Study

Siddartha Bhandary,[1] Jaeil Ahn,[3] Wen Shen.[2] *[1]Providence Hospital, Washington, DC; [2]Nephrology, Georgetown University, Washington, DC; [3]Georgetown University, Washington, DC.*

Background: The major modalities of coronary revascularization - coronary artery bypass grafting (CABG) and percutaneous coronary intervention (PCI) both carry high risk of acute kidney injury (AKI). Our previous studies have shown that both CABG and PCI were associated with increasing temporal trends in AKI incidence over the years; and in-hospital mortality after CABG was more than 40% higher than that of PCI. In this study, we compared the temporal trends of total in-hospital mortality, and in-hospital mortality associated with AKI after CABG vs PCI.

Methods: We generated a propensity-matched cohort of 274,464 hospitalizations that had first time CABG or PCI for multi-vessel coronary disease in 2004 to 2012 from the National Inpatient Sample. Patients received concomitant valvular repair or both CABG and PCI on same admission, history of organ transplant, CKD stage V or ESRD on dialysis were excluded. Both groups were propensity score matched. The odds ratios were estimated by the random intercept logistic regression model.

Results: The temporal trends of in-hospital mortality in CABG-AKI group had been decreasing from 16.52 % in 2004 to 6.51% in 2012 whereas in the PCI- AKI group, the in-hospital mortality has been stable, 14.17% in 2004 to 13.11% in 2012. Compared to PCI-AKI group, the likelihood of in-hospital death for CABG- AKI group in 2004 was 20 % higher (OR 1.20, 95% CI 0.89-1.61, P=0.35). But after 2004, the odds reversed.. From 2005 to 2012, the odds of in-hospital death in the patients with post-CABG AKI became 23%-54% lower than the PCI-AKI group (OR 0.77, 95% CI 0.60-0.99, P=0.05; OR 0.46, 95%CI 0.36-0.59, P<0.0001). Interestingly, when we compared the overall in-hospital mortality between both groups irrespective of the kidney function, CABG was associated with higher in-hospital mortality from 2004-2010 than PCI group with down-trending ORs. In 2011 and 2012, PCI was associated with higher in-hospital mortality.

Conclusions: CABG patients with post procedural AKI have shown a decreasing temporal trends in in-hospital mortality over the years whereas the in-hospital mortality remains high in the PCI patients with AKI.

TH-PO029

Incidence and Outcomes of Dialysis-Requiring AKI in Taiwan—A Nationwide Study 2003-2014

Jinn-Yang Chen. *Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: Dialysis-requiring acute kidney injury (AKI-D) is associated with high morbidity and mortality. Despite increasing incidence of AKI-D, information pertaining to trends and prognosis remains limited due to underreporting of discharge code of AKI code and differences in definition. We identify first in-hospital dialysis using procedure code to evaluate the time trend and outcome of AKI-D over a twelve-year period in Taiwan.

Methods: In a retrospective nationwide study based on National Health Insurance Database 2000-2015, all adults requiring the first hospitalized dialysis treatment between 2003 and 2014 were identified. Patients with previous renal transplantation or chronic dialysis were excluded. Through cross-linking of several administrative datasets, information pertaining to comorbidity, concurrent surgical interventions and sepsis, and clinical outcome were ascertained.

Results: A total of 203,071 first hospitalized dialysis was retrieved. Among them, 22,746 patients (11.2%) had advanced chronic kidney disease (CKD); 121,054 patients (59.6%) had history of CKD; 59,271 patients (29.2%) received dialysis during admission without documented CKD. Among patients without pre-existing CKD, 46.7% had sepsis; 6.6% were related to cardiac surgery; 91.2% had been admitted to ICU and 42.5% received CRRT. Patients without pre-existing CKD showed the highest in-hospital mortality (71.1%). However, only 47% of patients without pre-existing CKD could be identified with ICD-9 code of acute kidney injury (584). Time trend analysis showed that there were decreased trends of in-hospital mortality and increased trends of long-term dialysis from 2003 to 2014. For those who was discharged without receiving regular dialysis, 25% and 12% of patients died within 1 and 2 years after discharge.

Conclusions: In a nationwide retrospective study of 1st hospitalized dialysis treatment using procedure code, we found AKI-D was underreported and associated with high mortality. For the AKI-D survivors, high mortality was also noted.

TH-PO030

Kinetic Estimated Glomerular Filtration Rate (KeGFR) in Liver Transplantation: An Early Predictor of Significant AKI

Antonio Olivas-Martínez,[1] Armando Jezael Martinez-Rueda,[1] Gerardo Zavala-Garcia,[1] Silvana Bazua-Valenti,[2,3] Ignacio García juárez,[3] Ricardo Correa-Rotter.[4] *[1]Department of Internal Medicine, National Medical Science and Nutrition Institute Salvador Zubirán, Mexico City, Mexico; [2]Instituto de Investigaciones Biomedicas, UNAM, Mexico City, Mexico; [3]National Medical Science and Nutrition Institute Salvador Zubirán, Mexico City, Mexico; [4]Department of Nephrology and Mineral Metabolism, National Medical Science and Nutrition Institute Salvador Zubirán, Mexico City, Mexico.*

Background: Acute kidney injury (AKI) is a common clinical problem in patients undergoing liver transplantation (LT) and up to 20% of these patients progress to CKD. Kinetic estimated glomerular filtration rate (KeGFR) is a recommended formula in non-steady states. Aim: to evaluate the diagnostic yield of KeGFR for early prediction of AKI in patients following LT.

Methods: We retrospectively studied all patients who underwent LT from 06/ 2017 to 04/2018. Clinical data and all SCr measurements during the first 5 days after transplantation were recorded. SCr before surgery was considered as baseline. Significant AKI was defined as an increase of at least 2 times in SCr baseline or requirement of renal replacement therapy (RRT). Early decline of eGFR was defined as a decreased of more than 50% from baseline eGFR in the first postoperative 24 hours. Early decline of eGFR was evaluated by the KeGFR, Cockfort-Gault, CKD-EPI, and MDRD-4 formulas and compared with the development of significant AKI in the first 5 postoperative days.

Results: Forty nine patients were included, mean age of 47.3 ± 11.68 y, 55.1% were female. Median baseline SCr was 0.7 mg/dL (range 0.43 - 3.03). Three patients had significant AKI prior transplantation. Twenty-four (49.0%) patients developed significant AKI in the first 5 days postoperative, of which 33.3% required RRT and 12.5% died. Diagnostic performance of studied formulas is shown in Table 1.

Conclusions: KeGFR was the only formula that predicted significant AKI within the first 24 hours, with a high sensitivity (87%) and a strong negative likelihood ratio (0.17) and improved area under the curve (0.846). The KeGFR formula is an affordable diagnostic tool, which improves our capability of significantly detecting AKI in patients following liver transplantation.

Table 1. Diagnostic performance (early decline in eGFR) at 24 hours following liver transplantation

Formula	Se (%)	Sp (%)	PPV (%)	NPV (%)	+LR	-LR	Diagnostic yield (%)	AUC†
Kinetic eGFR	87.5	72.0	75.0	85.7	3.13	0.17	79.6	0.846
Cockroft-Gault	25.0	100.0	100.0	58.1	∞	0.75	63.3	0.774
CKD-EPI	25.0	100.0	100.0	58.1	∞	0.75	63.3	0.787
MDRD-4	29.2	96.0	87.5	58.5	7.29	0.74	63.3	0.776

Se: sensitivity, Sp: specificity, PPV: positive predictive value, NPV: negative predictive value, +LR: positive likelihood ratio, -LR: negative likelihood ratio, AUC: area under the curve, †AUC obtained from ROC analysis using the maximum proportional decline in eGFR from baseline in the first 24 hours for each patient.

TH-PO031

Using Kinetic Glomerular Filtration Rate to Predict AKI

Rolando Claure-Del Granado,[1] Cristian G. Sanchez,[1] Josee Bouchard,[3] Ravindra L. Mehta.[2] *[1]Hospital Obrero #2 - C.N.S.; Universidad Mayor de San Simon, School of Medicine, Cochabamba, Bolivia, Plurinational State of; [2]University of California San Diego Medical Center, La Jolla, CA; [3]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada.*

Background: Monitoring renal function changes during critical illness is difficult as current MDRD and CKD-EPI GFR estimating equations usually under or overestimate renal function during an episode of acute kidney injury (AKI). The kinetic glomerular filtration rate (KeGFR) equation (J Am Soc Nephrol 2013; 24: 877–888) has been developed to better evaluate rapid changes in renal function. We hypothesized that changes in KeGFR would predict the development of AKI in critically ill patients.

Methods: We prospectively evaluated 208 patients admitted to our general ICU. Serum creatinine (sCr) was measured daily for 7 days. KeGFR was calculated from the change in consecutive values of sCr (ICU baseline sCr and 24 h ICU sCr). In patientswith no baseline sCr available we back calculated sCr using MDRD equation (for an eGFR = 75 ml/m/1.73m^2). Patients diagnosed with AKI in the first 24 hours after ICU admission according to the KDIGO definition were excluded. AKI was defined as an increase of sCr value 1.5 times the baseline value or 0.3 mg/dl above the baseline within 48 hours to 7 days after ICU admission. The predictive performance of KeGFR was assessed by the receiver operator characteristic analysis to determine the area under the curve (AUC).

Results: From 208 patients enrolled in the study 98 patients developed AKI (47 %). Age, baseline serum creatinine, and eGFR (CKD-EPI) were not different between patients with and without AKI. At 24 h post ICU admission AKI patients had lower KeGFR (47.7 ml/m vs. 81.1 ml/m; p < 0.0001); at this time point KeGFR predicted AKI with an AUC of 0.778 (95% CI 0.689 - 0.867; p < 0.001). A KeGFR reduction from a baseline eGFR (ICU admission) ≥ 22.6% had a sensitivity of 95.3% and a specificity of 87.5% for predicting subsequent AKI development within 48 h and 7 days of ICU admission with an AUC of 0.969 (95% CI 0.932 – 1.000; p < 0.001). This reduction in KeGFR percentage from a baseline eGFR had an odds ratio of 4.5 (95% CI 1.675 – 12.090; p = 0.002) for subsequent development of AKI after 48 h of ICU admission.

Conclusions: The use of KeGFR accounts for non-steady state conditions and could improve clinical risk prediction models for AKI development in the ICU. sCr measurements, which can be obtained at modest cost, remain useful to guide early management of AKI if performed frequently.

TH-PO032

Early Biomarkers in the Detection and Risk Stratification of Sepsis Patients

Vishal G. Patel,[1] R. w. m. anusha Madushani,[2] Tezcan Ozrazgat-baslanti,[2] Lasith Adhikari,[2] Quran Wu,[2] Nicholas Lysak,[2] Sabyasachi Bandyopadhyay,[2] Azra Bihorac.[2] *[1]University of Florida College of Medicine, Lake Worth, FL; [2]University of Florida, Gainesville, FL.*

Background: Treatment of sepsis requires early hemodynamic support and antibiotic initiation, making timely diagnosis and risk stratification critical to improving survival. The reliance on clinical judgment, rather than diagnostic guidelines, to diagnosis and risk stratify sepsis patients results in a wide range of clinical outcomes.

Methods: In a prospective cohort study of 157 sepsis patients in a surgical ICU, we used 42 biomarkers that includes laboratory and vital measurements as well as age and Charlson comorbidity index using the earliest measurement within 48 hours of sepsis onset. We used hierarchical clustering to group patients with similar clinical characteristics. We compared clinical characteristics and outcomes between two main clusters identified using Fisher's exact test for categorical variables and student's t-test or Wilcoxon rank sum test for continuous variables as appropriate. Composite biomarker mosaic images were created using clustering variables.

Results: We identified two main clusters with 18 and 139 subjects in Clusters I and II, respectively. Cluster I consisted of more septic shock patients (78% vs 17%) who had early multiorgan failure and acute physiologic derangements in the first 24 hours of sepsis onset (median APACHE II score of 30 vs 16 and total SOFA score of 13 vs 5, respectively, p<.0001). Chronic diseases that differentiated the two clusters were cardiovascular and renal diseases (p<.0001). Renal biomarkers were significantly elevated two to three folds with higher prevalence of AKI (93% vs 45%) in cluster I compared to cluster II (p<0.01). Cluster I had significantly higher hospital mortality of (33% vs 2.2%, p<.0001) and one year mortality (50% vs 18%, p=0.005).

Conclusions: Using early biomarkers, we were able to identify two major clusters that had clinically different profiles which were reflected in composite biomarker mosaic images. We would be able identify patients at risk for adverse outcomes using our clustering and imaging methodology in order to improve hospital and long-term outcomes.

TH-PO033

Identification of AKI Subtypes in Patients with Sepsis Using Unsupervised Clustering

Lili Chan, Kumardeep Chaudhary, Aine Duffy, Priti Poojary, Aparna Saha, Kinsuk Chauhan, Ron Do, Tielman T. Van Vleck, Steven G. Coca, Girish N. Nadkarni. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Acute kidney injury is highly prevalent in critically ill patients. Physicians recognize that subphenotypes of sepsis associated AKI exist. Our goal was to identify subphenotypes of AKI in patients admitted to the intensive care unit with sepsis.

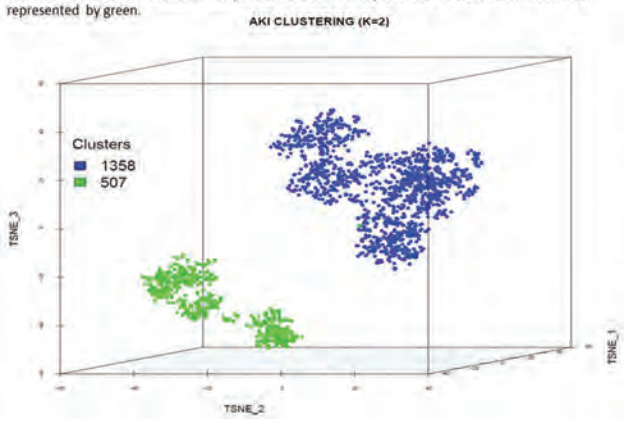
Methods: This was a retrospective analysis using the Medical Information Mart for Intensive Care (MIMIC)-III database. We identified AKI using the Kidney Disease Improving Global Outcomes criteria and sepsis utilizing the Clinical Classification Software. We used unsupervised machine learning to identify clusters using laboratory results and vital signs prior to AKI diagnosis.

Results: 1,865 patients were identified with sepsis associated AKI. After data processing and feature selection, 59 features, of which 28 were measures of variability, remained for inclusion into our unsupervised machine learning model. We utilized k-means clustering with k ranging from 2 – 10; k=2 had the highest silhouette score (0.62). Cluster 1 had 1,358 patients while Cluster 2 had 507 patients. There were no significant differences between clusters on age or gender. Small but significant differences were found on comorbidities, several laboratory results, and vital sign parameters. In-hospital mortality was significantly higher in cluster 2 patients (25%) vs. cluster 1 (20%, p=0.008). Features with the largest differences between clusters included basophil variability, eosinophil variability, ALT variability, and Creatine Kinase values.

Conclusions: To our knowledge this is the first study to identify two distinct subphenotypes of sepsis associated AKI utilizing electronic medical record data. Variability among laboratory values was important for clustering. Future studies in other cohorts and additional features are needed to validate and expand on the results of our study.

Funding: NIDDK Support, Government Support - Non-U.S.

Figure 1: 3-D Representation of clusters utilizing t-Distributed Stochastic Neighbor Embedding (t-SNE) method. This method condenses the 59 features into 3 transformed values which allows for 3-D representation. Each dot represents a single patient. The separation between two dots represents differences of features between two patients. Cluster 1 is represented in blue, while Cluster 2 is represented by green.



TH-PO034

AKI Predicts 30 Day Mortality in Community Acquired Infection

Dimitrios J. Poulikakos,[1] James Tollitt,[2] James Ritchie,[3] Philip A. Kalra,[5] Smeeta Sinha.[4] *[1]Salford Hospital, Manchester, United Kingdom; [2]Salford Royal NHS Trust, Salford, United Kingdom; [3]Salford Royal Hospital, Chorlton, United Kingdom; [4]Salford Royal NHS Foundation Trust, Salford, United Kingdom; [5]Salford Royal Hospital NHS Trust, Salford, United Kingdom.*

Background: The National Institute for Health and Care Excellence has recently introduced new guidance for sepsis that risk stratifies patients to high, moderate and low risk based on clinical observations from the National Early Warning Score (NEWS). Laboratory assessment for Acute Kidney Injury (AKI) is mandated in patients with moderate risk, and if present warrants intravenous antibiotics within one hour. Our aim was to evaluate the association between AKI in suspected community acquired (CA) infection (I) and 30 day mortality.

Methods: Data of hospital admissions with CA-I (defined as prescription of antibiotics within 24 hours from A&E arrival) were extracted from the Electronic Patient Records from 07/2013 to 02/2018. Dialysis patients were excluded. CA-AKI was defined as AKI alerting within 24 hours. NEWS score was analysed in groups 0 (low risk), 1-4 (moderate risk) and >4 (high risk). A binary logistic model was used to assess associations with 30 day mortality. The model was tested separately in each group of NEWS. AKI 2 and 3 were analysed together as AKI2&3.

Results: There were 3764 patients aged 61 ±22 years, 2047 (54.4%) females, 292 (7.8%) CA- AKI {AKI 1, 201 (5.3%), AKI 2 60 (1.6%) and AKI 3 31 (0.8%)}. Lactate was tested in 1382 (36.7%) patients and was above 2 in 398 (10.6%) cases. NEWS was 0 in 1140 (30.3%), 1-4 in 2150 (57.1%) and >4 in 474 (12.6%) cases. 316 patients (8.4%) died within 30 days. In logistic regression analysis for the whole cohort age (OR 1.07 CI 1.06-1.08, p=<0.001), male (OR 1.48, CI 1.15-1.91, p= 0.002), lactate (OR 1.67, CI 1.19-2.34, p= 0.003), NEWS 1-4 (OR 2.23, CI 1.54-3.29, p=0<.001), NEWS>4 (OR 4.58, CI 2.99-7.01, p=0<.001), AKI 1 (OR 2.14 CI 1.44-3.20, p=<0.001) and AKI2&3 (OR 4.12 CI 2.46-6.90, p=<0.001) were associated with 30 day mortality. AKI2&3 retained a significant association in NEWS=0 group (20(1.8%) cases of AKI2&3 OR 5.41 CI 1.62-18.13, p =0.006),(Table 1)

Conclusions: CA-AKI is associated with an increased risk for mortality in CA-I even in patients with normal clinical observations. Convergence of sepsis and AKI guidance should be prospectively assessed.

Association of AKI on Outcomes in Patients with ARDS - Secondary Analysis of LUNG-SAFE Patient Cohort

Bairbre A. McNicholas,[1] Emanuele Rezoagli,[1] Elsa Guiard,[3] Giacomo Bellani,[4] Matthew D. Griffin,[1] Tài Pham,[2] John G. Laffey.[1] *[1]National University of Ireland, Galway, Galway, Ireland; [2]University of Toronto, Toronto, ON, Canada; [3]Toronto General Hospital UHN, Toronto, ON, Canada; [4]University of Milan-Bicocca, Monza, Italy.*

Background: The impact of Acute Kidney Injury (AKI) in Adult Respiratory Distress Syndrome (ARDS) is poorly understood. We addressed this in a secondary analysis of the large observational study to understand the global impact of severe acute respiratory failure (LUNG SAFE) patient cohort. LUNG SAFE was an international, multicentre, prospective cohort study of patients with severe respiratory failure conducted during 4 consecutive weeks in winter 2014, in 459 intensive-care units (ICU) in 50 countries across six continents.

Methods: Patients undergoing invasive mechanical ventilation (IMV) with a diagnosis of ARDS at D1 or D2 post onset of acute hypoxic respiratory failure (AHRF) with no history of chronic kidney disease (eGFR<60ml/min/1.73m2) and not transferred from another ICU were included in the analysis. Patients were categorised based on worst serum creatinine (Scr) or urine output between D1-D7 post diagnosis of ARDS into (1) no AKI Serum creatinine <1.5mg/dl or urine output >0.5mL/kg/h (2) Moderate AKI: Scr 1.5-4mg/dl or min urine output<0.5mL/kg/h or (3) severe AKI: Scr >4mg/dl or Renal Replacement Therapy (RRT) during D1-D7 following onset of ARDS.

Results: 2016 patients were included in the analysis; 1193 (59%) with no AKI, 619 (31%) moderate AKI and 204 (10%) with severe AKI. RRT was required in 1.2% of patient with no AKI, 24.6% of moderate AKI and 100% of severe AKI over the 28 day follow-up period. Sequential organ failure assessment score was higher with worsening category of AKI (8.8±3.8, no AKI, 11.5±3.7 moderate AKI, 12.2±3.8 severe AKI, p<0.001). Lower pH, PaO2-FiO2 ratio and higher positive end-expiratory pressure were noted with advancing AKI category. Ventilatory free days was lower and ICU mortality and hospital mortality was higher with advancing AKI category (table 1).

Conclusions: The development of AKI, even in those who do not require RRT is associated with a substantial increase in mortality in patients with ARDS, with over half of these patients dying in hospital.

Funding: Government Support - Non-U.S.

Association of AKI on outcomes in patients with ARDS

Category of AKI	No AKI N=1193	Moderate AKI N=619	Severe AKI N=204	P-value
Ventilator Free days, median (IQR), days	17.0 [0.0;23.0]	0.0 [0.0;19.0]	0.0 [0.0;12.0]	<.001
ICU Mortality No. (%)	306(25.6%)	276(44.6%)	116(56.9%)	<.001
Hospital Mortality, No. (%)	355(29.9%)	310(50.2%)	125(61.3%)	<.001

TH-PO036

Assessment of Fluid and Nutritional Status Using Bioimpedance Methods in AKI Patients Treated with Continuous Renal Replacement Therapy

Huijuan Mao. *First Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Bioelectrical impedance analysis is an essential method for maintenance hemodialysis patients to assess nutritional and fluid status, however, there is still a lack of research on the value of bioelectrical impedance analysis in evaluating the prognosis of acute kidney injury (AKI) patients treated with continuous renal replacement therapy (CRRT).

Methods: Patients with severe AKI treated with CRRT in the first affiliated hospital of Nanjing medical university from 2014 to 2017 were prospectively enrolled. They were divided into death group and survival group according to 28-day survival. Logistic regression was used to analyze 28-day survival and Lean Tissue Index (LTI), Fat Tissue Index (FTI), the ratio of extracellular water(ECW) and body cell mass (BCM) (ECW/BCM), and overhydration (OH) were recorded.

Results: A total of 145 patients were included. The average age was 62.6±15.6 ys, average APACHE II score 21.7±6.5, SOFA score 9.4±3.6, and body mass index of 24.1±4.3 kg/m2. The pre-CRRT body composition analysis parameters were as followed:OH 3.9 ± 3.1L, LTI 12.4 ± 3.4kg/m2, FTI 10.3 ± 4.5kg/m2, ECW 18.0 ± 4.2L, BCM 18.6 ± 7.3L. The 28-day mortality rate was 44.8%.The pre-CRRT OH values and ECW/BCM values in survival group and death group were 3.4±3.2L, 4.6±3.0L and 1.0±0.4,1.1±0.4 (P<0.05), respectively. The changes of OH values and ECW/BCM values between CRRT 1st day and CRRT 7th day were 1.4±2.2L, 3.0±3.0L and 0.08±0.22,0.25±0.27 (P<0.05), respectively in two groups. Univariate and multivariate logistic regression analysis showed that pre-CRRT high OH values and high ECW/BCM values were associated with 28-day death, while LTI values and FTI values were not significant correlated with 28-day death; After CRRT initiation, the changes of OH values and ECW/BCM values between CRRT 7th-1st day were significantly associated with 28-day mortality.

Conclusions: The pre-CRRT fluid status(indicators of OH and ECW/BCM)were associated with 28-day mortality in patients with AKI, while the nutritional indicators LTI and FTI were not significantly related to short-term mortality. The correction of fluid overload by CRRT within 7 days may reduce the 28-day risk of death.

TH-PO037

Body Composition for Predicting Exertional Rhabdomyolysis-Induced AKI During Intensive Physical Training Program for Military Recruits

Chaken Maniyan, Bancha Satirapoj, Naowanit Nata, Amnart Chaiprasert, Ouppatham Supasyndh. *Phramongkutklao hospital, Bangkok, Thailand.*

Background: Exertional rhabdomyolysis-induced acute kidney injury (AKI) is a life-threatening condition. The risk factors for developing this condition are partially documented and changing in the body composition of these population is still poorly understood.

Methods: A prospective cohort study in the military recruits between May to July 2017 were conducted. Demographic and laboratory data including body mass index (BMI), serum creatinine, electrolyte, creatine phosphokinase (CPK), and body composition using dual frequency body impedance analysis (BIA) were measured before training and every 2 weeks until program had been completed.

Results: Total of 301 participants with mean age of 22 ± 2.5 years old were included. The incidence of exertional rhabdomyolysis-induced AKI was 19.2 %. At baseline, subjects who developed exertional rhabdomyolysis-induced AKI had lower frequency of exercise before recruitment (1.02 ± 0.13 times/week vs 3.49 ± 0.93 times/week, p <0.001), lower total body water (TBW) (45.08 ± 2.95 % vs 54.31 ± 5.21%, p < 0.001) and lower plasma potassium (3.6 ± 0.3 mEq/L vs 4.0± 0.4 mEq/L, p < 0.001). Along the course of training, AKI group had a significant loss of muscle mass (-5.65 ± 2.55% vs -4.06 ±1.75%, p < 0.001) and fat mass (-3 ± 1.41% vs -2.17 ± 0.98% p < 0.001) in the first 2 week. Moreover, there was a statistically significant increased in percentage of TBW at week 2 (2.57 ± 4.95% VS 0.24 ± 2.41 P<0.001) in AKI group compared with non-AKI group. Multivariate analysis revealed that low baseline of total body water (OR 5.51 (5.15-10.75), p < 0.01) and increased TBW at week 2 (OR 2.46 (1.49-2.97, p < 0.01) were the strong independent predictors for exertional rhabdomyolysis-induced AKI.

Conclusions: The study demonstrates that lack of adequate exercise before recruitment, low baseline potassium, low baseline TBW and increased TBW in early training period are the additional risk factors for exertional rhabdomyolysis-induced AKI. To our best knowledge this is the first study which explore the body composition change for prediction of exertional rhabdomyolysis induced. Early detection of these parameters should be implemented for AKI prevention program.

TH-PO038

Trajectories of AKI in Chronic Critical Illness After Sepsis

Tezcan Ozrazgat-baslanti,[1] Tyler J. Loftus,[2] Quran Wu,[1] Zhongkai Wang,[1] Nicholas Lysak,[1] Laura Sautina,[1] Scott Brakenridge,[1] Babette A. Brumback,[1] Philip A. Efron,[1] Lyle L. Moldawer,[1] Frederick A. Moore,[1] Mark S. Segal,[1] Azra Bihorac.[1] Sepsis and Critical Illness Research Center Investigators *[1]University of Florida, Gainesville, FL; [2]University of Florida Health, Gainesville, FL.*

Background: Acute kidney injury (AKI) is one of the most common complications among hospitalized patients. Besides the severity of an initial episode of AKI, the timing and duration of renal recovery are required to characterize the natural history of this complex condition and its effect on kidney health. We have determined the epidemiology of persistent AKI and renal recovery, the development of chronic critical illness (CCI), hospital outcomes, and long-term survival in sepsis patients. We hypothesize that patients with persistent AKI, especially those without renal recovery, have worse hospital and long-term outcomes after sepsis.

Methods: In the prospective observational study of 245 sepsis patients, AKI types were adjudicated using KDIGO criteria and ADQI recommendations. In contrast to rapidly reversed AKI, persistent AKI is characterized by the persistence of KDIGO creatinine beyond 48 hours of the onset. Patients whose renal function did not completely recover at discharge were considered to have no recovery. Development of CCI and six-month survival were compared using Fisher's exact and log-rank test, respectively.

Results: Two percent (6/245) had preexisting end-stage renal disease (ESRD) and 15% (36/245) had pre-existing chronic kidney disease (CKD). Among non-ESRD subjects, while about 46% (109/239) developed AKI within 48 hours of sepsis onset, overall 59% (140/239) developed AKI; 28% (39/140) having rapidly reversed AKI and 72% (101/140) having persistent AKI. Among 101 patients who had persistent AKI, 41% (58/140) did not recover at discharge and they had had longer ICU stay, more days on mechanical ventilation, greater prevalence of CCI (55%), and higher hospital mortality (27%). Patients with no recovery had lower 6-month cumulative survival (43%) compared to patients with recovery (88%) and no AKI (94%) (p<0.0001). Among CCI patients, survival was significantly worse for patients with no complete recovery compared to patients who recovered (p=0.0003) or did not develop AKI among patients with CCI (p=0.0001). Among non-CCI patients survival was similar across groups.

Conclusions: Among critically ill septic patients, persistent AKI and absence of renal recovery are significant risk factors for adverse outcomes and long-term mortality.

Improved Mortality of Critically Ill Patients with AKI: Population-Based Cohort Study in Korea Between 2008 and 2015

Subin Hwang,[1] Ho seok Koo,[1] Jung eun Lee,[2] Wooseong Huh,[2] Yoon-Goo Kim,[2] Dae Joong Kim,[2] Ha Young Oh,[2] Hye Ryoun Jang.[2] *[1]Department of Internal Medicine, Inje University Seoul Paik Hospital, Inje University School of Medicine, Seoul, Republic of Korea; [2]Division of Nephrology, Department of Internal Medicine, Samsung Medical Center Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Although there is still no specific treatment facilitating renal tubule regeneration in acute kidney injury (AKI), the rapid increase aging population with more comorbidities and advance in critical care management were expected to change the epidemiology of AKI. However, few recent studies dissecting the current epidemiology characteristics of critically ill patients with AKI. We investigated the recent epidemiologic changes of AKI in critically ill patients.

Methods: All adult admissions to intensive care units (ICU) in Korea from 2008 to 2015 were screened using the national health insurance review and assessment database, and a total of 1,744,235 patients were included. The clinical characteristics and change in incidence and mortality rate of AKI were analyzed.

Results: The incidence of AKI increased from 7.4% in 2008 to 8.3% in 2015 (p for trend <.001). The age-standardized AKI rates in were 7018.6 per 100,000 person-years. The in-hospital mortality was significantly decreased from 39.1% in 2008 to 37.2% in 2015 (p for trend <.001) with 2427.6 deaths per 100,000 person-years. Patients with AKI showed higher in-hospital mortality, prolonged ICU length of stay, and higher total cost. Multivariable analysis showed increased risk of in-hospital mortality (OR 6.25), mechanical ventilation (OR=4.63), ECMO (OR=18.22), and vasopressor requirement (OR=4.02) in AKI patients.

Conclusions: Recent advances in medical management for AKI have attenuated in-hospital mortality of critically ill patients with AKI despite increase of the elderly population as well as the incidence of AKI.

TH-PO040

Association of Serum Potassium Level at the Initiation of Renal Replacement Therapy with All-Cause Mortality Among Burn Intensive Care Unit Patients with AKI

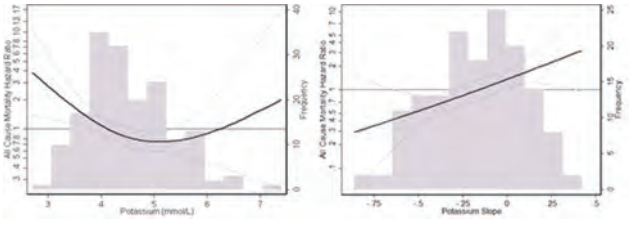
Jui-Ting Hsiung,[1] Kamyar Kalantar-Zadeh,[1] Elani Streja,[1] Hamid Moradi,[1] Victor C. Joe,[2] Julie A. Rizzo,[3] Ian J. Stewart,[4] Kevin Chung.[5] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, Orange, CA; [2]Burn Center, University of California, Irvine, Orange, CA; [3]Burn Center, US Army Institute of Surgical Research, Fort Sam Houston, TX; [4]David Grant Medical Center, Travis Air Force Base, CA; [5]Department of Medicine, Brooke Army Medical Center, Fort Sam Houston, TX.*

Background: Burn injury is associated with serious complications including acute kidney injury (AKI) requiring renal replacement therapy (RRT). There is little data on the association between baseline serum potassium (K) and outcomes in burn patients initiated on RRT. Therefore, we evaluated the association of K at the RRT initiation with survival in a cohort of burn patients.

Methods: We examined 170 burn patients enrolled in a multicenter observational study in eight burn centers across the United States. We used Cox regression models with adjustments for covariates including severity of illness, laboratory values, urine output, total burn surface area, and vasopressor requirement to evaluate the association of K level at RRT initiation with in-hospital all-cause mortality. We further explored the association between K slope, from the initiation to 48 hours after beginning of RRT, and mortality, using the same multilevel Cox models. Patients without either baseline or 48 hours K measurements were excluded from the slope analysis.

Results: The cohort was comprised of 169 AKI patients who required RRT and had a baseline K. 20% of patients were female with a mean±SD age of 51±17 years. Hypokalemia was associated with a higher risk of subsequent mortality. 150 patients were included in the slope analysis. There was a linear association between increasing K slope and higher mortality based on the result of restricted cubic splines.

Conclusions: While baseline hypokalemia at the time of RRT initiation was associated with higher risk of mortality, increasing K at 48 hours was also associated with worse outcomes in patients with burn-associated AKI. This finding may be due to inadequate dialysis, ongoing tissue destruction, or both. Future investigations are needed to examine the mechanisms which can explain these observations.



TH-PO041

Comparison Between Creatinine vs Urinary Output Criteria in RIFLE and KDIGO Definitions for AKI Post Major Elective Non-Vascular Abdominal Surgeries

Graziela R. de Souza,[1] Lia J. Marçal,[4] Luis Yu,[3] Leila Antonangelo,[4] Dirce M. Zanetta,[4] Emmanuel A. Burdmann.[5] *[1]São Paulo University, São Paulo, Brazil; [3]University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [4]University of São Paulo, S Paulo, Brazil; [5]University of Sao Paulo Medical School, Sao Paulo, Brazil.*

Background: Most of the studies using RIFLE and KDIGO AKI definitions are solely based on serum creatinine (SCr) changes. However, the urinary output (UO) criteria may be more sensitive especially for surgical patients. Therefore, the aim of this study was to compare the efficacy of SCr and UO criteria for RIFLE and KDIGO AKI diagnosis and outcome of patients (pts) submitted to major elective non vascular abdominal surgeries (MENVAS) admitted to the ICU.

Methods: Two hundred and twenty five pts were prospectively evaluated, peri-operatively, from the ICU admission until 7 days of hospitalization. Serum creatinine (mg/dl) was measured before surgery and once a day until day 7 or ICU discharge. Hourly UO (ml/kg/h) was measured daily. AKI was diagnosed using either SCr or UO according to RIFLE and KDIGO definitions. Data are presented as mean ± SD or frequencies. Statistical significance was set at $p<0.05$.

Results: A total of 225 pts were analysed, 126 (56%) developed AKI. Most frequent types of surgery were: hepatectomy, sleeve gastroplasty, gastrectomy, hepatectomy + cholecystectomy, gastroduodenopancreatectomy and, adrenalectomy. AKI pts were older 57.6 ± 1.2 vs. 50.8 ± 1.6 Non -AKI ($p = 0.0007$). Duration (min) of surgery in AKI pts was 365.6 ± 18.3 vs. 341.5 ± 16.8 Non-AKI (NS). The AKI diagnoses according to RIFLE were: 118 by UO and 38 by SCr criteria. According to KDIGO definition: 118 by UO and 39 by SCr criteria. In addition, 31 pts fullfilled both criteria simultaneously. Using the SCr criteria alone for AKI diagnosis, a total of 87 patients in RIFLE group and KDIGO group would be overlooked while only one additional patient was diagnosed by KDIGO. AKI pts (KDIGO definition) diagnosed by UO or SCr criteria changes, presented, compared to Non-AKI pts: hospital LoS 21.4 ± 1.9 vs. 25.6 ± 3.8 ($p <0.0004$), ICU LoS 3.6 ± 0.3 vs 5.8 ± 0.97 ($p < 0.0001$). Mortality in the AKI group was 10.2% vs. 2.0 % in Non-AKI ($p=0.0149$).

Conclusions: Utilization of SCr criteria instead of UO for RIFLE and KDIGO definitions in surgical patients would overlook a very high number of AKI patients (69%). Urinary output criteria seems to be pivotal for early AKI recognition in these patients. Furthermore, AKI post MENVAS is frequent and carries worse outcome and mortality.

TH-PO042

FGF23 and AKI in SPRINT

Anna J. Jovanovich,[1,2] Charles Ginsberg,[3] Zhiying You,[4] Alfred K. Cheung,[5] Michel Chonchol,[2] Michael Shlipak,[6] Joachim H. Ix.[3] *[1]Denver VA, Denver, CO; [2]University of Colorado, Aurora, CO; [3]UCSD, San Diego, CA; [4]UC Denver, Aurora, CO; [5]University of Utah, Salt Lake City, UT; [6]San Francisco VA Medical Center, San Francisco, CA.*

Background: Fibroblast growth factor 23 (FGF23) is elevated in chronic kidney disease and associated with kidney disease progression and increased mortality but data on FGF23 in humans with acute kidney injury (AKI) are limited. We hypothesize that high circulating intact FGF23 (iFGF23) concentrations will identify individuals at high risk of AKI and may modify the relationship between randomization to intensive blood pressure lowering and AKI in the Systolic Blood Pressure Interventional Trial (SPRINT).

Methods: The SPRINT study was a randomized multicenter trial evaluating the effects of standard (SBP <140 mmHg) vs. intensive (SBP <120 mmHg) blood pressure lowering on cardiovascular outcomes in older adults without diabetes. iFGF23 was measured in 2488 subjects with GFR < 60 mL/min/1.73m^2. Cox proportional hazards models adjusted for demographics, comorbidities, randomization group, and baseline number of antihypertensives, eGFR, and serum calcium and phosphorus identified the relationship between baseline iFGF23 and time to first AKI event.

Results: Mean age was 73 ± 9 years, 40% were female, and 66% were white. At baseline, mean eGFR was 49 ± 11 mL/min/1.73m^2 and median FGF23 was 66 [52-88] pg/mL. After full adjustment, there was no significant association between baseline iFGF23 and time to first AKI event; HR for Q4 (vs. Q1) was 0.93 (95% CI 0.60-1.44) and HR for iFGF23 modeled as a continuous variable was 0.96 (95% CI 0.75-1.23). FGF23 did not modify the relationship between randomization to intensive blood pressure lowering and AKI (p for interaction 0.12).

Conclusions: Among SPRINT participants with baseline eGFR < 60 mL/min/1.73m^2, there was no significant association between baseline iFGF23 and AKI events. iFGF23 did not modify the relationship between randomization to intensive blood pressure lowering and AKI.

TH-PO043

Exosomal Mitochondrial DNA Is a Prognostic Factor in Septic AKI Patients

Naoko Tsuji, Takayuki Tsuji, Akihiko Kato, Hideo Yasuda. *1st Depertment of Medicine, Hamamatsu University School of Medicine, Hamamatsu, Japan.*

Background: We reported the amount of circulating mitochondrial DNA (mtDNA) was increasing in septic rodent models and contributed development of AKI via toll-like receptor 9. The levels of mtDNA in septic patients have varied according to reports, which might occur because of the difference of the blood plasma fraction due to different centrifugal processing. We assayed mtDNA according to blood plasma fractions and evaluated whether mtDNA in circulating exosome was a prognostic factor in septic shock and septic AKI patients.

Methods: Septic patients who needed polymyxin B immobilized hemoperfusion (PMX) in intensive care unit of Hamamatsu University School of Medicine from November 2013 to March 2017 were enrolled. Patient's plasma was collected from just before the PMX initiation followed by centrifugation at 17,000g for 15 minutes to remove dead cell and cell debris. Exosome was obtained by ultracentrifugation at 200,000g for 1 hour. We extracted exosomal DNA and quantified exosomal mtDNA (Ex-mtDNA) by using real-time PCR. We prospectively observed their outcomes.

Results: The level of Ex-mtDNA in septic shock patients with hospital death (n=6) was significantly higher than those survivors (n=16) and health volunteers (n=4) (log2.80±1.19 vs log0.91±0.81 vs log-0.56±1.09, $p<0.05$). The ROC curve analysis revealed that Ex-mtDNA is the best prediction for in-hospital death compared with total mtDNA and blood lactic acid and SOFA score and urine volume [AUC: 0.90 (0.74-1.08) vs 0.86 (0.69-1.03), 0.80 (0.58-1.03), 0.84 (0.64-1.06)] and has high sensitivity and specificity and also odds ratio [0.83 (0.36-1.00), 0.93 (0.66-1.00), 65.0 (2.27-125), $p<0.05$, cut-off value: log1.91] The level of Ex-mtDNA in AKI patients was also higher than those in non-AKI patients (log1.84±1.20 vs log0.63±1.10, $p<0.05$) but was not better prediction than blood lactic acid and SOFA score [AUC: 0.76 (0.53-1.00) vs 0.82 (0.63-1.01), 0.85 (0.67-1.02)].

Conclusions: Ex-mtDNA has a potential as a good predictor of survival and AKI in septic shock patients.

TH-PO044

Exosomal MicroRNAs in Urine Are Associated with Children's Blood Pressure and Renal Biomarkers: An Exploratory Cross-Sectional Study

Alison P. Sanders,[1] Daniel Flores,[1] Vasily Aushev,[1] Gleicy M. Hair,[1] Ivan Pantic,[2] Andrea A. Baccarelli,[4] Lisa M. Satlin,[1] Martha M. Tellez-Rojo,[3] Robert O. Wright,[1] Paul Curtin.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]National Institute of Perinatology, Mexico City, Mexico; [3]National Institute of Public Health, Cuernavaca, Mexico; [4]Columbia University, New York, NY.*

Background: Urinary extracellular microRNAs are potential biomarkers of renal health and disease that may originate from epithelial cells in the renal or urogenital tract. Traditional analytical methods examine individual miRNA biomarkers; here we employ a mixtures approach to identify combinations of miRNAs associated with renal health.

Methods: We assessed the association between a mixture of exosomal miRNAs and systolic blood pressure (SBP), as well as 8 protein biomarkers measured in spot urine samples collected from 103 healthy children aged 4-5 years. We performed differential centrifugation and visualized exosomes using electron microscopy. miRNA were extracted and analyzed for 754 miRNAs using OpenArray qPCR. Expression data were normalized using the global mean. A miRNA was considered 'detectable' if it produced reliable qPCR signal in ≥70% of participant samples. We applied weighted quantile sum (WQS) regression to create a composite renal biomarker index of 252 'detectable' miRNAs, and tested for association between the miRNA mixture with either SBP or the 8 protein biomarkers, adjusting for age, BMI, sex, and parental report of indoor smoking. We analyzed the levels of 8 proteins (albumin, cystatin C, clusterin, osteopontin (OPN), α-1-microglobulin (A1M), kidney injury molecule-1 (KIM-1), TFF (trefoil factor 3), β2-microglobulin (β2M)). We considered substantive contributors to the mixture index as those with ≥ 2% weight.

Results: Increased SBP was associated with the miRNA index (β: 0.08, 95%CI: 0.1, 1.5; $p=0.02$), driven by miR-590 and miR-885 (out of 13 total miRNA with weights ≥2%). Seven proteins (albumin, A1M, KIM1, TFF3, B2M and clusterin were positively associated with the miRNA mixture. Levels of cystatin C were not associated with the miRNA index. Notably, the associations of A1M, clusterin, and KIM-1 with the miRNA mixture were consistently driven by miR-574; the associations of TFF and OPN were consistently driven by miR-146b. The mRNA targets of miR-146b and miR-574 are enriched for nephrotoxic functions including renal inflammation, nephritis, tubule damage, and necrosis.

Conclusions: These findings highlight combinations of exosomal miRNAs as potential sensitive and non-invasive early life biomarkers of renal health.

Urine Biomarkers and AKI Associations with CKD and Hypertension 3 Months Post-Cisplatin in Children

Kelly McMahon,[1] Tom D. Blydt-Hansen,[2] Maury N. Pinsk,[3] Cherry Mammen,[2] Louis Huynh,[4] Mariya Yordanova,[1] Frédérik Crépeau-Hubert,[1] Shahrad R. Rassekh,[2] Kirk R. Schultz,[2] Prasad Devarajan,[5] Michael Zappitelli.[6]
[1]McGill University, Montreal, QC, Canada; [2]British Columbia's Children's Hospital, Vancouver, BC, Canada; [3]University of Manitoba, Winnipeg, MB, Canada; [4]School of Medicine, Queen's University, Kingston, ON, Canada; [5]Cincinnati Children's Hospital, Cincinnati, OH; [6]Toronto Hospital for Sick Children, University of Toronto, Toronto, ON, Canada.

Background: Cisplatin (CisP) causes acute kidney injury (AKI) and may lead to chronic kidney disease (CKD) and hypertension (HTN) in children. Aims: 1) Describe 3-month post-CisP CKD/HTN; 2) Determine if a) AKI during CisP treatment and b) urine neutrophil gelatinase-associated lipocalin (uNGAL) and kidney injury molecule-1 (uKIM-1) near end of CisP therapy are associated with 3-month CKD/HTN.

Methods: 12-site prospective pediatric study. Exposures: a) Serum creatinine (SCr)-AKI during CisP therapy (KDIGO definition); b) Electrolyte AKI(eAKI): low serum Mg^{++}, K^{+} or PO_4^{-} during therapy; c)uNGAL/KIM-1 at discharge from a late CisP cycle. Outcomes: a) CKD: urine albumin/creatinine ratio≥3mg/mmol(≥7.5mg/mmol if <2 years old), urine protein/creatinine ratio≥15mg/mmol or SCr-estimated glomerular filtration rate<90mL/min/1.73m^2; b) HTN: blood pressure≥95thpercentile (adults:≥140/90mmHg) or treated for HTN. Univariate tests and multiple logistic regression were performed to evaluate exposure-outcome relations and adjusted associations.

Results: Of 154/158 with 3-month data: 77(50%) boys; median[IQR] age: 6[3-12] years. 96/142(68%) had CKD; 14/141(10%) had HTN; 100/154(65%) had CKD or HTN. SCr-AKI, ≥Stage 2 SCr-AKI and eAKI+SCr-AKI were associated with 3-month HTN(Table). AKI was not associated with CKD(Table). Adjusting for age and gender, only ≥Stage 2 SCr-AKI was associated with 3-month HTN (adjOR 4.4(95% CI 1.1-18.4)). Biomarkers were not associated with CKD or HTN(Table).

Conclusions: CKD and HTN are common 3 months after CisP. AKI is associated with 3-month HTN. Ongoing 3-year follow-up will determine if associations change and/or persist. Measures to reduce HTN after cancer therapy are needed.

Funding: Government Support - Non-U.S.

Association of different AKI phenotypes with 3 month CKD and HTN

AKI Exposure	% with outcome	
	%With CKD	% With HTN
SCr-AKI	45/61 (74%)	10/61 (16%)*
No SCr-AKI	51/81 (63%)	4/80 (5%)
≥ Stage 2 SCr-AKI	13/19 (68%)	5/18 (28%)*
< Stage 2 SCr-AKI	83/123 (67%)	9/123 (7%)
eAKI	91/134 (68%)	14/135 (10%)
No eAKI	5/8 (63%)	0/6 (0%)
eAKI + SCr-AKI	43/57 (75%)	10/59 (17%)*
No eAKI + SCr-AKI	53/85 (62%)	4/82 (5%)

Table: AKI *vs.* non-AKI prevalence of CKD and HTN at 3 months post CisP therapy completion (**TOP**) and end of CisP NGAL and KIM-1 concentrations between patients with *vs.* without CKD and HTN (**bottom**).
Legend:
SCr-AKI: AKI defined using the KDIGO definition (peak SCr throughout CisP therapy over baseline/pre-cisplatin treatment SCr.
eAKI: presence of low serum phosphate, magnesium or potassium throughout treatment.
eAKI+SCR-AKI: presence of both AKI phenotypes throughout treatment.
*Indicates significant difference between AKI *vs.* non-AKI groups.

Association of late CisP therapy biomarkers with 3 month CKD and HTN

TH-PO046

Markers of Kidney Tubule Cell Function and Risk of AKI

Alexander Bullen,[1] Cheryl A. Anderson,[9] Alfred K. Cheung,[2] Michelle M. Estrella,[3] Pranav S. Garimella,[9] Vasantha Jotwani,[3] James P. Lash,[4] Javier A. Neyra,[5] Henry A. Punzi,[6] Ronit Katz,[7] Michael Shlipak,[8] Joachim H. Ix.[1]
[1]UCSD, San Diego, CA; [2]University of Utah, Salt Lake City, UT; [3]University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA; [4]University of Illinois at Chicago, Chicago, IL; [5]University of Kentucky Medical Center, Lexington, KY; [6]Punzi Medical Center, Carrollton, TX; [7]University of Washington, Seattle, WA; [8]San Francisco VA Medical Center, San Francisco, CA; [9]University of California San Diego, La Jolla, CA.

Background: Novel biomarkers can quantify kidney tubular functions including proximal tubule reabsorption (alpha 1 microglobulin [a1m], and beta 2 microglobulin [b2m]) and tubule protein synthesis (uromodulin [umod]). Associations of tubule function measures with acute kidney injury (AKI) risk are uncertain. We evaluated associations of markers of kidney tubular function with AKI risk in participants with chronic kidney disease (CKD) in the SPRINT Trial.

Methods: Among 2351 participants with CKD (eGFR<60 ml/min), urine a1m, b2m and umod were measured by multiplex immunoassay (MesoScale Diagnostics) at the randomization visit. Cox proportional hazard models evaluated log-transformed biomarker levels as risk factors for AKI during 3.8 years mean follow-up. Sequential models adjusted for demographics, randomization arm, and urine creatinine (Model 1); baseline eGFR, uACR, and AKI risk factors (Model 2); and the other tubule function biomarkers (Model 3).

Results: Lower urine umod and higher a1m levels were each associated with higher AKI risk (Table). The association with uromodulin was independent of baseline eGFR and uACR (Model 2). Adjustment for all 3 tubule function markers strengthened associations of a1m which was independently associated with AKI in the final model. Results were similar in analyses stratified by randomization arm.

Conclusions: Assessment of tubule function by measurement of urine umod and a1m provides information of AKI risk independent of eGFR and albuminuria in persons with hypertension and CKD but without diabetes. Future studies should evaluate if dynamic changes in these markers can predict AKI risk in those exposed to intensive blood pressure lowering.

Combination of ITRAQ-Based Quantitative Proteomics and Parallel Reaction Monitoring Identifies Biomarkers for the Early Diagnosis of AKI Following Percutaneous Coronary Intervention

Lulu Huang,[1] Fangfang Zhou,[1] Qun Luo,[2] Gen Shen,[1] Honghua Ye,[1] Yumei Li.[1]
[1]Ningbo NO.2 Hospital, Ningbo, China; [2]Ningbo No.2 Hospital, Ningbo, China.

Background: In this study, we used Isobaric Tags for Relative and Absolute Quantitation(ITRAQ) to identify novel diagnostic biomarkers and to explore the underlying mechanisms of acute kidney injury (AKI) following percutaneous coronary intervention (PCI).

Methods: 114 patients (>60yrs) admitted for elective PCI were included in the study. We identified 14 elderly patients with PCI-AKI, 14 patients of whom did not develop AKI were selected as controls, matched by age, gender. Urine samples were collected before PCI, and 24 hours post-PCI. Blood collected for serum creatinine (Scr) concentrations and biochemical analysis. Isobaric Tags for Relative and Absolute Quantitation (ITRAQ) technology followed by Liquid Chromatography tandem Mass Spectrometry (LC-MS/MS) was used to discover differentially expressed proteins (DEPs) in a training set of PCI-AKI (n=6) and controls (n=6). DEPs were then investigated in an independent cohort of PCI-AKI (n=8) and controls (n=8) using parallel reaction monitoring (PRM). We also identified DEPs potentially involved in PCI-AKI pathogenesis by analyzing biological processes, cellular components, molecular functions, Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways and protein-protein interactions (PPI).

Results: Comparing to patients before PCI, a total of 167 DEPs (106 upregulated proteins and 61 downregulated proteins) were identified in the urine of PCI-AKI patients (24h post-PCI). Among the upregulated proteins, 12 proteins were overlapped in both comparisons of AKI-24h/AKI-Pre and AKI-24h/CON-24h. Using the PRM approach, we successfully confirmed the differential accumulation of Haptoglobin (HPT), apolipoproteins A-I (APOA1) and Peroxiredoxin-2 (PRDX2) at 24h post-PCI comparing to pre-PCI and controls in the validation set. And they were earlier than Scr for diagnosis PCI-AKI. GO and KEGG pathway analysis described that these proteins were mainly involved in the peroxisome pathway(PRDX2), and the PPARγ signaling pathway (APOA1).

Conclusions: Our research showed HPT, APOA1 and PRDX2 were potential urine biomarkers and may play key roles in the pathogenesis of PCI-AKI. And these biomarkers might be prospective to made into "AKI panel" similar to myocardial enzyme for the diagnosis of PCI-AKI in the future.

TH-PO048

Identification of Urine Potential Biomarkers of AKI Patients with Cirrhosis by iTRAQ-Based Quantitative Proteomics

Lulu Huang,[1] Fangfang Zhou,[1] Qun Luo,[2] Zemin Wang,[1] Yumei Li,[1] Wenhong Zhou.[1] *[1]Ningbo NO.2 Hospital, Ningbo, China; [2]Ningbo No.2 Hospital, Ningbo, China.*

Background: To identify novel diagnostic biomarkers and to explore the underlying mechanisms of acute kidney injury (AKI) patients with cirrhosis.

Methods: We performed a prospective nested case-control study. We collected urine samples of cirrhotic patients with risk factors of AKI (bacterial infections, bleeding from oesophageal varices, large volume paracentesis (>3L/d), increased dosage of diuretics, and receiving contrast medium) at the time of risk factors occurred and 1d after the risk factors. Blood was collected for serum creatinine (Scr) concentrations and biochemical analysis. iTRAQ technique followed by Liquid Chromatography tandem Mass Spectrometry (LC-MS/MS) was used to screen differentially expressed proteins (DEPs). And DEPs were also

analyzed by Gene Ontology (GO),Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways and protein-protein interactions (PPI) analysis.

Results: 90 cirrhotic patients with risk factors of AKI were included in the study. Among these patients, 11 patients were diagnosed as AKI (KDIGO AKI criteria, 2012), and 9 patients were selected as controls (matched by age and gender). Using iTRAQ approach,a total of 289 DEPs (64 upregulated proteins and 225 downregulated proteins) were identified in the urine of AKI group (1d after risk factors occurred) comparing to controls. 20 biological process, 20 cellular components, 20 molecular functions and 20 significant KEGG pathways were identified. Among them, renin-angiotensin system pathways, and apoptosis pathways may play a role in the pathogenesis of AKI with cirrhosis. Combined with the PPI results, alpha-1-antitrypsin precursor(SERPINA1), S100 calcium binding A9(S100A9)and mucin-5AC(MUC5AC)were significantly up-regulated at 1d after risk factors occurred in AKI group. And they were earlier than Scr which significantly rose in both comparisons of AKI-48h/AKI-Pre and AKI-48h/CON-48h till at 48h for diagnosis of AKI with cirrhosis.

Conclusions: iTRAQ technology was useful in the selection of DEPs from proteomes, and might provide a theoretical basis for the study of biomarkers and mechanisms in AKI with cirrhosis. The identified panel of SERPINA1, S100A9 and MUC5AC proteins might serve as potential biomarkers and thereby aid in the detection of AKI with cirrhosis.

TH-PO049

Predictive Value of Current Biomarkers for Early Reversal of AKI

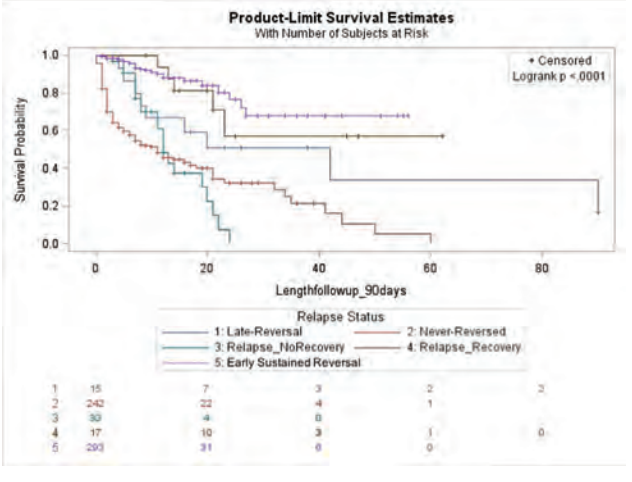
Sadudee Peerapornratana,[2,1] Priyanka Priyanka,[3] John A. Kellum.[2] Center for Critical Care Nephrology, The CRISMA Laboratory, Department of Critical Care Medicine, University of Pittsburgh *[1]Chulalongkorn University, Bangkok, Thailand; [2]University of Pittsburgh, Pittsburgh, PA; [3]The University of Pittsburgh, Pittsburgh, PA.*

Background: Acute kidney injury (AKI) is associated with various recovery patterns. Early reversal of AKI is common in critically ill patients and associated with good outcomes. The predictive role of current biomarkers for reversal of AKI is still unknown.

Methods: Using data from an ancillary study to a large randomized trial, including 1,341 patients with septic shock we focused on patients with stage 2 or 3 AKI at presentation or manifesting within the first day of hospital admission. Early reversal of AKI was defined as no longer meet any criteria for AKI (for at least 24 hours) on any day within the 7 days after first documented AKI. Any subsequent AKI episode after initial reversal was considered a relapse. Final recovery status was then assessed at hospital discharge. Several urinary biomarkers were measured at 24 hours after enrollment and used for prediction of early reversal.

Results: Among the 604 patients with KDIGO stage 2 or 3 AKI, 345 (57.1%) patients had early reversal of renal function. Of these, 50 (14.5%) patients had a relapse of AKI during their hospital stay after early reversal. A total of 327 (54.1%) patients finally had recovery at hospital discharge. About 40% of patients never reversed AKI. None of the urinary biomarkers TIMP-2●IGFBP7, NGAL, Kim-1, L-FABP, or type IV collagen were predictive of early reversal of AKI (C-statistics: 0.37, 0.45, 0.49, 0.48, 0.45, respectively). Patients who had early sustained reversal of renal function experienced the best survival at day 90, while those who had relapse of AKI and those who never recovered had the worst outcomes.

Conclusions: Currently available AKI biomarkers are not useful for prediction of early reversal of renal function after AKI. Novel predictive biomarkers for renal recovery are needed.



Survival by recovery patterns.

TH-PO050

Circulating Cardiac Stress, Vascular Dysfunction, and Inflammatory Biomarkers Predict AKI in French Type 2 Diabetes Patients: The SURDIAGENE Cohort

Benedicte Sautenet,[1] Pierre Jean Saulnier,[3] Gand Elise,[3] Ronan Roussel,[6] Stephanie Ragot,[5] Gilberto Velho,[6] Samy Hadjadj.[3] *[1]CHRU Tours, Tours, France; [3]CHU Poitiers, Poitiers, France; [5]University of Poitiers, Poitiers, France; [6]INSERM, Paris, France.*

Background: Acute kidney injury (AKI) is related to chronic kidney disease and death in patients from the general population, with or without type 2 diabetes. Nevertheless AKI biomarkers are rarely validated in diabetes population. We aimed to explore the individual and combined prognostic value of 8 circulating candidate markers for AKI.

Methods: We prospectively followed-up 1345 (565 women/780 men) type 2 diabetes participants of a French single-centre hospital-based cohort (SURDIAGENE) with baseline GFR≥30 ml/min/1.73m2 and no renal replacement to onset of AKI, death, or December 31, 2015. Intrahospital AKI was diagnosed and staged using the KDIGO criteria. We assessed 3 markers of cardiac and endothelial dysfunction (mid-regional-pro-adrenomedullin [MRproADM], angiopoietinlike-2 [ANGPTL2], N-terminal prohormone brain natriuretic peptide [NTproBNP]), 1 of oxidative stress (fluorescent advanced glycation endproducts [AGE], carbonyls), 1 for cardio-renal pathways (copeptin [CTproAVP]), and 1 of inflammation (soluble TNF receptor 1 [TNFR1]). Cox models were used to estimate the risk of AKI for each biomarker at baseline after adjustement for usual risk factors: sex, diabetes duration, HbA1c, systolic blood pressure, GFR, ACR, use of antihypertensive, and history of cardiovascular disease. Hazard ratios were reported per 1 SD increment of the logarithm of the biomarker concentration.

Results: At baseline, mean±SD age was 64±11 years, diabetes duration 14±10 years, HbA1c 7.8±1.6%, and eGFR 77±21 ml/min/1.73m^2, and median (IQR) ACR 3 (1-10) mg/mmol. During a median follow-up of 4.7 years, 449 (33%) patients developed an AKI. In univariate analysis, each biomarker was significantly associated with AKI, and 6 remained associated after multivariable adjustment (Table). The addition of a multimarker score summing standardized and weighted values of these 6 markers to the model including usual risk factors significantly improved C-statistics (0.724 to 0.759, $P<0.0001$), and 5-year risk-predictive performance (relative integrated discrimination improvement index=0.435, $P<0.0001$).

Conclusions: A panel of 6 biomarkers representing cardiac, vascular and inflammatory pathways improved the prediction of AKI over usual risk factors in patients with type 2 diabetes.

TH-PO051

Heat Shock Protein 72 (Hsp72) Is a Useful Biomarker for AKI in Liver Transplant

Armando Jezael Martinez-Rueda,[1] Silvana Bazua-Valenti,[1,2] Antonio Olivas-Martínez,[1] Jose V. Jimenez,[1] Diego L. Carrillo Perez,[1] Leoneli I. Grajeda-Medina,[1] Juan A. Ortega-Trejo,[1,2] Andrea Sanchez-Navarro,[1,2] Rosalba Pérez-villalva,[1,2] Ignacio García juárez,[1] Luis E. Morales-Buenrostro,[1] Norma Bobadilla,[1,2] Gerardo Gamba.[1,2] *[1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico; [2]Instituto de Investigaciones Biomedicas, UNAM, Mexico City, Mexico.*

Background: Acute Kidney Injury (AKI) after liver transplantation (LT) is a frequent complication and an important risk factor for mortality. We have shown that Hsp72 is an early AKI biomarker in animal models of ischemic acute renal injury and in a variety of critically ill patients in the ICU (EMBO MM 2011 and Plos One 2014). Since the LT program in our institute performs one transplant per week, we designed the present study to determine the incidence and risk factors of AKI during the postoperative period of LT, and to assess whether Hsp72 can be a useful tool to predict AKI.

Methods: We conducted a single-center prospective and observational study for LT patients (N=26). AKI was defined as a two-fold increase in baseline serum creatinine (SCr). Urine samples were collected before LT and at 0, 6, 12, 24 and 48 hours after. Urinary samples were resolved in SDS-PAGE gels and analyzed by western blot with a monoclonal anti-Hsp72 antibody. Hsp72 values were adjusted to urinary creatinine concentration.

Results: The mean age of our cohort was 49±10.58 years with 57.7% females. Hepatitis C infection was the main etiology for cirrhosis (42.3%). 14 patients (53.8%) developed AKI in the 5 days post-LT, and four of them required dialysis. Multivariate analysis showed that AKI was associated with encephalopathy prior to LT (OR 10.99, p=0.029). Based on SCr, AKI was diagnosed with a median of 24 h post-LT. Conversely, Hsp72 levels significantly increased at 6 h post-LT in patients that developed AKI vs. the non-AKI (p=0.042). The AUC-ROC analysis revealed that at 6 h Hsp72 predicts AKI with an AUC of 0.732.

Conclusions: Our observations indicate that urinary Hsp72 increases in patients that develop AKI in the post-LT several hours before they reach AKI criteria based on SCr, suggesting that Hsp72 could be a useful biomarker for the development of AKI.

TH-PO052

Utilizing Neutrophil Lymphocyte Ratio to Detect Early AKI

Asif Khan, Elie El-Charabaty, Suzanne E. El Sayegh. *Staten Island University Hospital, Brooklyn, NY.*

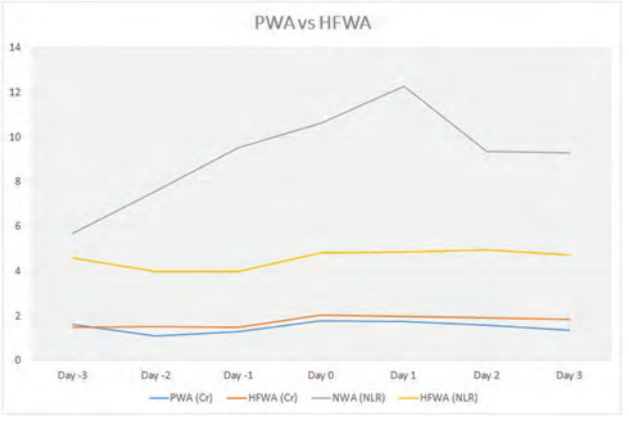
Background: The ability to detect early Acute Kidney Injury (AKI) prior to elevation of Cr has always been a challenge to physician. Traditionally, serum Cr level is used

to diagnose AKI. However, it has been shown to be poor predictor of AKI occurrence. Multiple inflammatory markers for AKI have been studied, but they are expensive and their clinical values remain limited. NLR has been found to be strongly associated with inflammatory states in last decade, thus can potentially be used as marker for AKI. Our primary objective is to investigate the role of NLR in prediction of early AKI prior elevation of Cr. We compared NLR's predictive power of AKI in both inflammatory and non-inflammatory conditions.

Methods: Retrospective study included 413 patients with age ≥ 18 who were admitted with the diagnosis of pneumonia without AKI (PWOA) and those admitted with pneumonia who developed AKI (PWA) as well as the patients admitted with diagnosis of heart failure without AKI (HFWOA) and those admitted with heart failure who developed AKI (HFWA). NLR and renal function were compared from 3 days before Day 0, and 3 days after Day 0. Day 0 represents as the day of diagnosis of AKI in PWA and HFWA groups; Day 0 is also represented by day of diagnosis of pneumonia or heart failure in PWOA and HFWOA groups. Subjects with ESRD, contrast induced AKI, drug induced AKI, hematologic proliferative diseases, on immunosuppressive agents or chronic steroid were excluded from the study.

Results: Patients in PWOA group has significantly hight NLR value (p value <0.0001) and longer lenght of stay (pvalue: <0.01) when compared to HFWOA, owing to higher sensitivity of NLR. Significant rise in NLR was also observed 72 hours earlier than serum Cr in PWA group (p value <0.0001). Thus, NLR not only strongly associated with AKI rather than infectious process, but also able to predict AKI significantly earlier than serum Cr level.

Conclusions: Our result suggests that NLR that was found to be associated with inflammatory conditions, can potentially be utilized as a marker to detect early AKI.



PWA vs HFWA

TH-PO053

Remote Ischemic Preconditioning in the Prevention of Contrast Induced Nephropathy in Patients Undergoing Peripheral Angiography: A Pilot Randomized Controlled Trial

Debajyoti M. Roy,[1] Tjun Y. Tang,[2] Tarchoon Aw.[3] [1]*Changi General Hospital, Singapore, Singapore;* [2]*Singapore General Hospital, Singapore, Singapore;* [3]*Changi Hospital, Singapore, Singapore.*

Background: Contrast induced nephropathy (CIN) is a leading cause of hospital acquired acute Kidney injury (AKI). Remote ischemic preconditioning (RIPC) has been found to be protective against AKI in patients undergoing coronary surgery This project aims to evaluate the potential of RIPC prior to vascular angiography in preventing CIN.

Methods: This study is a single centre, experimental, randomised controlled trial of the effect of RIPC with the induction of brief episodes of upper limb ischemia followed by reperfusion using blood pressure cuffs to determine protection against CIN in advanced peripheral arterial disease undergoing elective angiography. The inclusion criteria for this study are: patients above age of 21 yrs undergoing elective peripheral arterial angiography/ angioplasty who have an eGFR≥ 45ml/min and have given written informed consent. There are two arms of this trial: Control and preconditioned arm (RIPC). Patients will be randomised 1:1. Group 1(Control arm) : IV hydration with 0.9% normal saline (1ml/kg/ hour) prior to angiographic procedure Group 2 (RIPC) : patients will receive IV hydration prior to procedure, similar to control group. Additionally patients will receive RIPC, where a blood pressure cuff will be placed around one arm of the patientand inflated to a pressure of 250mm Hg for 5 minutes, deflated and allow arm to re-perfuse for 5 min. This is repeated for atotal of 3 ischemia-reperfusion cycles. Patients in both arms had serial measurements of serum creatinine as wellas serum cystatin and urinary NGAL at 2 hours, 24 hours, 48 and 72 hours post procedure

Results: There was no signicant differences between Control and RIPC groups with regards baseline characteristics. There was no reduction in development CIN in the RIPC group compared to Control.

Conclusions: RIPC did not offer any protection against development of CIN in our group of patients with eGFR >45ml/min over and above the standard therapy ie. intravenous hydration. The protective effect of RIPC in patients with more advanced chronic kidney disease needs further study

	RIPC (n = 19)			Control (n = 20)			p-value

TH-PO054

The Effect of Remote Ischemic Preconditioning for Preventing Contrast-Induced AKI in CKD Patients Undergoing Elective Coronary Angiography

Tatiporn Tusnapituk,[1,2] Thanit Chirananthavat.[3] [1]*Police general hospital, Bangkok, Thailand;* [2]*Internal medicine, Phrae hospital, Phrae, Thailand;* [3]*Police General Hospital, Nonthaburi, Thailand.*

Background: Despite the increasing use of pre- and post-hydration protocols and low-osmolar contrast media, the incidence of Contrast-Induced Acute Kidney Injury (CI-AKI) is still significant. The underlying mechanism has been attributed in part to ischemic kidney injury. Remote ischemic preconditioning (RIPC) is a non-invasive, safe, and low-cost method to reduce ischemic reperfusion injury. We aim to investigate whether RIPC, as an adjunct to standard preventive measures, reduces CI-AKI in chronic kidney disease (CKD) patients who are in high risk of CI-AKI.

Methods: This randomized double-blind control trial compared standard care with or without ischemic preconditioning (4 cycles of intermittent arm ischemia) in patients with impaired renal function (estimated glomerular filtration rate, eGFR < 60 mL /min/1.73 m2 by CKD-EPI equation) undergoing elective coronary angiography in the Police General Hospital between May 2017 and February 2018. The primary outcome was the incidence of CI-AKI, defined as an increase in serum creatinine > 0.3 mg/dL or 1.5 times above baseline at 48 hours after contrast medium exposure.

Results: A total of 50 patients, 55 episodes were enrolled, out of which 28 were in the RIPC group, and 27 were in the control group. The medians of contrast media volume, serum creatinine, and eGFR at baseline did not differ between the groups. The primary outcome, CI-AKI, occurred in a total of 7 episodes, consisting of 2 (7%) in the RIPC group and 5 (18%) in the control group, with no significant difference between the two groups (p=0.21).

Conclusions: RIPC cannot reduce the incidence of CI-AKI after contrast administration in CKD patients who are at risk of CI-AKI.

TH-PO055

AKI Is Common in Patients Receiving Immune Checkpoint-Inhibitors (CPIs)

Harish Shanthanu Seethapathy,[2] Donald F. Chute,[2] Yaa Oppong,[2] Frank B. Cortazar,[2] David E. Leaf,[1] Kerry Reynolds,[2] Meghan E. Sise.[2] [1]*Brigham and Women's Hospital, Boston, MA;* [2]*Massachusetts General Hospital, Boston, MA.*

Background: Immune CPI use for first-line or salvage cancer immunotherapy is rapidly increasing. Because acute interstitial nephritis may complicate CPI therapy, the American Society of Clinical Oncology suggests holding CPIs and evaluating any patient (pt) whose serum creatinine (SCr) rises at least 1.5-fold above baseline (BL) i.e., ≥ grade 1 AKI. Empiric steroid therapy is recommended for pts with a Grade ≥ 2 AKI without an alternate cause. We sought to determine the frequency, severity, and predictors of AKI in a real-world population receiving CPIs.

Methods: We included all pts on CPIs from 2011-2017 at our institution. We determined CPI start date by oncology infusion records. BL SCr was established by averaging all SCr values during the 6 months prior to CPI start date. We compared all SCr values within 6 months after starting CPIs to the BL SCr to determine the fold-change from BL. We used logistic regression to determine if age, sex, race, hypertension, diabetes, cirrhosis or baseline CKD (GFR < 60) predicted AKI.

Results: 1843 pts started CPI therapy. 1039 (56%) had sufficient data to determine a BL SCr and had ≥1 SCr checked within 6 months of starting CPIs. Average age was 63 (SD, 13) yrs, 60% were male and 91% were Caucasian. The mean BL SCr was 0.9 (SD, 0.4) mg/dl, and 175 (17%) had CKD at BL. Pts had a median of 7 (IQR, 2-14) SCr values measured during the BL period, and 12 (IQR, 8-18) SCr values measured in the 6 months after CPI. 140 pts (13.5%) had an AKI event within 6 months of starting CPI therapy; 79 (56%) were grade 1 (>1.5-2-fold rise in SCr), 46 (33%) were grade 2 (>2-3-fold rise in SCr) and 15 (11%) were grade 3 (>3-fold rise in SCr or needed dialysis). Of the 140 pts with AKI, 42 (30%) had multiple AKI events within the first 6 months of starting CPIs. The first AKI event occurred on average 67 (SD, 52) days after starting CPIs. 69 pts (6.6% of the total cohort) had a sustained AKI event lasting > 48 hours. No baseline pt characteristics, including BL SCr, predicted AKI in a multivariable models.

Conclusions: AKI events are common in pts receiving CPIs. BL CKD does not appear to be a risk factor for AKI after CPIs. Nephrologists are likely to be increasingly called upon to evaluate the cause of AKI and assist oncologists in determining the best course of therapy in pts receiving CPIs.

TH-PO056

Incidence of AKI Among Critically Ill Patients with Brief Empiric Use of Anti-Pseudomonal Beta-Lactams with Vancomycin

Diana J. Schreier,[1] Kianoush Kashani,[2] Ankit Sakhuja,[2] Kristin C. Mara,[4] Mohammad samie Tootooni,[5] Heather A. Personett,[1] Sarah Leung,[1] Andrew D. Rule,[2] James Steckelberg,[3] Aaron J. Tande,[3] Erin F. Barreto.[1] *[1]Department of Pharmacy, Mayo Clinic, Rochester, MN; [2]Division of Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester, MN; [3]Division of Infectious Diseases, Mayo Clinic, Rochester, MN; [4]Division of Biomedical Statistics and Informatics, Mayo Clinic, Rochester, MN; [5]Department of Health Sciences Research, Mayo Clinic, Rochester, MN.*

Background: Nephrotoxins contribute to 20-40% of acute kidney injury (AKI) cases in the intensive care unit (ICU). The combination of piperacillin/tazobactam and vancomycin (PTZ/VAN) has been identified as nephrotoxic, but existing studies focus on extended durations of therapy rather than the brief empiric courses often used in the ICU. The objective of this study was to compare the risk of AKI with a short course of PTZ/VAN to other anti-pseudomonal beta-lactam/vancomycin combinations

Methods: Retrospective cohort of 3299 ICU patients that received at least 24 hours, but no more than 72 hours of an antipseudomonal beta-lactam and vancomycin [(PTZ/VAN, cefepime (CEF/VAN), or meropenem (MER/VAN)]. The risk of developing stage 2 or 3 AKI was compared between antibiotic groups with multivariable logistic regression adjusted for relevant confounders. We also compared the risk of persistent kidney dysfunction, dialysis dependence, or death at 60-days between groups.

Results: The overall incidence of stage 2 or 3 AKI was 9%. Brief exposure to PTZ/VAN did not confer a greater risk of stage 2 or 3 AKI after adjustment for demographics, baseline serum creatinine, AKI risk prediction score, severity of illness, or sepsis [PTZ/VAN vs. CEF/VAN: adjusted OR, 95% CI 1.11 (0.85, 1.45); PTZ/VAN vs. MER/VAN 1.04 (0.71, 1.42)]. No significant differences were noted between groups at 60-day follow up in the outcomes of persistent kidney dysfunction (P = 0.081), new dialysis dependence (P = 0.15), or death (P = 0.091).

Conclusions: Short courses of PTZ/VAN were not associated with a greater risk of short- or long-term adverse renal outcomes compared to other empiric broad-spectrum combinations.

TH-PO057

AKI After Intravenous Vancomycin Compared to Other Common Intravenous Antibiotics

Martina M. Gaggl,[2,1] Til Stürmer,[5] Abhijit V. Kshirsagar,[3] J. Bradley Layton.[4] *[1]Medical Universitiy of Vienna, Vienna, Austria; [2]Department of Epidemiology, Gillings School of Global Public Health, Chapel Hill, NC; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]RTI Health Solutions, Research Triangle Park, NC; [5]UNC Gillings School of Global Publich Health, Chapel Hill, NC.*

Background: Vancomycin is a mainstay treatment for Gram-positive infection, but it may be associated with nephrotoxicity and acute kidney injury (AKI). AKI contributes to short-term morbidity, mortality, and increased risk of chronic kidney disease (CKD). The study aimed to evaluate the 2-week risk of AKI after ≥3 days of intravenous (IV) vancomycin treatment compared to patients treated with a comparator using U.S. commercial claims data.

Methods: From Truven MaketScan claims data (United States), we identified patients with a first hospitalization with IV vancomycin or comparator treatments with similar clinical indications (**table 1**) for ≥3 days with a treatment onset ≤ five days after hospital admission (2000-2015). Patients with claims for prior AKI, CKD, or use of immunosuppressive medications were excluded. We estimated incidence rates (IR) and hazard ratios (HR) with cox-regression adjusted for age, sex, main diagnosis, surgical procedure, and 1-year history of comorbidities and co-medication.

Results: We identified 32,997 hospitalized patients with vancomycin or comparator mono-therapy. The mean age was 50 (±15) years and 60% were female. Covariates were evenly distributed across treatment cohorts. Vancomycin was used in 5,449 (17%) patients and in 83% a comparator. Overall, there were 129 cases of AKI, and the IR of AKI was 9.32 (95% CI: 7.84-11.07) per 100 person-years. The crude HR comparing vancomycin vs. comparators was 1.04 (95% CI: 0.85-1.90). After adjustment the HR for vancomycin vs. all comparators was 0.74 (95% CI 0.45-1.21). Similarly, separate adjusted models for individual comparators did not result in elevated HR for vancomycin.

Conclusions: Our study using US claims data did not demonstrate an association between treatment with vancomycin alone and an increased risk of AKI compared to other commonly used intravenous antibiotics in hospitalized patients.

Table 1.

	N	Cases	Person-years	Incidence rate* (95%CI)	Crude HR (95%CI)		Adjusted HR (95%CI)	
Vancomycin (Index group)	5,449	22	229	9.62	(6.34-14.62)			
Comparators	27,548	107	1156	9.25	(7.66-11.18)	1.04	(0.85-1.90)	0.74	(0.45-1.21)
Cefazolin	20,124	58	846	6.86	(5.30-8.87)	1.40	(0.86-2.29)	1.01	(0.55-1.83)
Linezolid	251	6	10	57.63	(25.89-128.28)	0.17	(0.07-0.42)	0.17	(0.01-0.46)
Piperacillin	3,885	25	162	15.39	(10.40-22.78)	0.63	(0.35-1.11)	0.47	(0.24-0.91)
Cefepime	433	2	18	11.07	(2.77-44.28)	0.87	(0.45-3.70)	0.80	(0.19-3.69)

Levetiracetam and the Risk of AKI: A Population-Based Cohort Study

Kevin Yau,[1,2] Eric McArthur,[2] Racquel Jandoc,[2] Flory T. Muanda,[1,2] Chirag R. Parikh,[3] Ron Wald,[4] Amit X. Garg.[1,2] *[1]Western University, London, ON, Canada; [2]Institute for Clinical Evaluative Sciences, London, ON, Canada; [3]Yale University and VAMC, New Haven, CT; [4]St. Michael's Hospital, Toronto, ON, Canada.*

Background: Regulatory agencies warn about the risk of acute kidney injury (AKI) with levetiracetam use based on information contained in case reports. We conducted this population-based cohort study to determine whether new levetiracetam use versus non-use is associated with AKI.

Methods: We performed a population-based retrospective cohort study in Ontario, Canada. Adults who received a new outpatient prescription for levetiracetam from an outpatient pharmacy between January 1, 2004 and March 1, 2017 were matched to two non-users on stage of chronic kidney disease, recorded seizure in the prior 90 days, and logit of a propensity score for levetiracetam use. The primary outcome was a hospital encounter (emergency department visit or hospitalization) with AKI within 30 days of cohort entry. Secondary outcomes were AKI within 180 days and change in the serum concentration of creatinine. We assessed the primary outcome using health care diagnosis codes. We evaluated the change in the concentration of serum creatinine in a subpopulation with laboratory measurements.

Results: We matched 3,980 levetiracetam users to 7,960 non-users (mean age 55 years, 51% women). Levetiracetam use was not significantly associated with a higher risk of AKI within 30 days (13 [0.33%] events in levetiracetam users and 21 [0.26%] events in non-users [odds ratio, 1.24; 95% CI, 0.62-2.47]). Similarly, there was no significant association with AKI within 180 days (odds ratio, 0.70; 95% CI, 0.43-1.13). The change in the concentration of serum creatinine did not significantly differ between levetiracetam users and non-users.

Conclusions: In this population-based study it is reassuring that levetiracetam use was not associated with a higher risk of AKI.

Funding: Private Foundation Support, Government Support - Non-U.S.

Outcomes Assessed Using Database Codes

	Levetiracetam users (n=3,980)	Non-users (n=7,960)	OR (95% CI)	P-Value
Acute kidney injury (30 days)	13 (0.33%)	21 (0.26%)	1.24 (0.62-2.47)	0.55
Acute kidney injury (180 days)	23 (1.15%)	65 (1.63%)	0.70 (0.43-1.13)	0.15
Rhabdomyolysis (180 days)	10 (0.50%)	14 (0.35%)	1.43 (0.64-3.22)	0.39
Acute dialysis (180 days)	0 (0.00%)	≤5 (≤0.06%)	-	-
Acute interstitial nephritis (180 days)	5 (≤0.12%)	≤5 (≤0.06%)	-	-

To comply with privacy regulations to minimize the chance of identifying a study patient, numbers of patients were suppressed in the case of 1 to 5 patients (reported as ≤5).

Longer-Interval Regimen of Colistin Reduces Nephrotoxicity in Kidney-on-a-Chip

Kipyo Kim, Ji Young Ryu, Hyung Eun Son, Ho Jun Chin, Sejoong Kim. *Seoul National University Bundang Hospital, Gyeonggi-do, Republic of Korea.*

Background: Potential nephrotoxicity of colistin is of growing concerns due to relative high incidence and recent extensive use; however, which dosing regimen is less nephrotoxic remained uncertain. Previous animal and clinical studies have showed conflicting results for less toxic dosing regimen. We investigated whether bolus-mimicking regimens or continuous infusion regimen of colistin may be less nephrotoxic using microfluidic organ-on-a-chip device applying the Pharmakokinetic profile of colistin.

Methods: We introduced colistin to the kidney epithelial cells on kidney-on-a-chips under physiological shear stress condition(1 dyn/cm^2) and separated chip devices into two groups: bolus-mimicking regimen group and continuous infusion regimen group. Two drug treatment regimens were given the same total colistin dose over a 48 h period. Bolus-like regimen mimicked pharmacokinetic profiles for human bolus injection with starting colistin concentration of 1138 μg/ml and reducing by half every 9 h known as half-life of colistin in critically ill patients. Continuous Infusion regimen groups were exposed at colistin concentration of 400 μg/ml for 48 h.

Results: The bolus-mimicking regimen injured 1.64% out of total observed cells, whereas the continuous infusion regimen damaged 3.44% after 48-hour colistin exposed period. ($P < 0.05$). Bolus-mimicking regimen sustained lower transmembrane permeability of FITC-albumin and tight junction protein expression ZO-1 and occludin compared to the prolonged exposed regimen.

Conclusions: We found that a bolus-mimicking regimen dramatically alleviates kidney injury compared to the continuous infused regimen. Longer interval regimens may help to reduce nephrotoxicity in long-term colistin-using patients. In addition, kidney-on-a-chip experiments could be useful for selecting optimal dosing regimen of nephrotoxic drugs.

Funding: Government Support - Non-U.S.

The Characteristic of Drug Spectrum That Induced AKI and Clinicopathological Features of Drug-Induced AKI

Yu Cui,[1] Xiabing Lang,[2] Lan Lan.[2] *[1]Zhejiang university, Hangzhou, China; [2]Zhejiang University, Hangzhou, China.*

Background: To analyze the changes and characteristics of drug spectrum, and to analyze the kidney pathological characteristics of drug-induced acute kidney injury.

Methods: Retrospective analysis the characteristics of the patients of our center in 2012 January to October 2016, who were diagnosed of drug-induced AKI. According to the data of medical history and clinical manifestations, record the related drugs, analysis of the changes of drug composition and the renal pathological characteristics.

Results: There are 228 patients diagnosed drug-induced AKI, and 51 patients underwent renal biopsy. In 228 patients, 70 patients were caused by antibacterial and antiviral drugs, 63 patients were caused by non-steroidal anti-inflammatory drugs, 17 patients were caused by Chinese herbal medicine, and other drugs including the ACEI / ARB drugs, proton pump inhibitors, weight-loss drugs, lipid-lowering drugs, anti-hepatitis B virus medicine, antidepressants, albumin, platinum chemotherapy drugs, colchicine, calcineurin inhibitors. 14 patients cannot named which drugs. There were 31 patients had 2 or 3 types of drugs used before kidney injury. The antibiotics and antiviral drugs were the most frequently drugs associated with AKI, including cephalosporins, acyclovir, azithromycin, clindamycin, levofloxacin. In the 51 underwent renal biopsy patients, 12 patients showed allergic interstitial nephritis, 19 cases of patients showed interstitial nephritis, 8 patients showed renal tubular epithelial cell injury, and 2 cases showed Minimal Change Nephropathy, 2 cases showed IgA nephropathy, 2 cases of mild mesangial hyperplasia with glomerulosclerosis.

Conclusions: The first three types of drugs induce AKI were antibiotics and antiviral drugs, non- steroidal anti-inflammatory drugs and Chinese herbal medicine. In the group of antibacterial drugs and antiviral drugs, the most common drugs were cephalosporins, acyclovir, clindamycin, azithromycin and levofloxacin, but not aminoglycosides. Allergic interstitial nephritis, interstitial nephritis and tubular epithelial cell injury is the main pathological manifestations of drug - induced AKI, but some patients had no obvious changes of the pathological performance.

TH-PO061

NSAID Use and NSAID-Associated AKI Before and After Implementation of Pennsylvania's Prescription Drug Monitoring Program

Evan C. Ray,[1] Andrew Bilderback,[3] Amanda Schwenk,[2] Dilhari Dealmeida,[2] John A. Kellum.[2] *[1]Internal Medicine - Renal Electrolyte, University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA; [3]UPMC, Pittsburgh, PA.*

Background: Few studies describe the influence of prescription drug monitoring programs (PDMPs) on NSAID use or NSAID-associated adverse effects. We asked whether implementation of Pennsylvania's PDMP, designed to reduce narcotic use, was associated with changes in inpatient NSAID administration or NSAID-related Acute Kidney Injury (AKI) in western Pennsylvania (UPMC) hospitals.

Methods: We examined retrospective data from 16 UPMC hospitals in three PA PDMP phases: pre-PDMP (Jan 1-Aug 25, 2016), voluntary PDMP participation (Aug 26-Dec 31, 2016), and mandatory PDMP participation (Jan 1-Dec 31, 2017). Patients with ICD-10 codes indicating ESRD or kidney transplant were excluded. Outcomes included percent of admissions with any NSAID use and with prolonged NSAID use (≥ 4 days) and frequency of NSAID-associated AKI. AKI was defined by presence of both a creatinine-based electronic flag and an ICD-10 code for atraumatic, non-obstructive AKI. Outcomes were compared during each phase using chi-square tests, and interrupted time-series analyses were used to examine the impact of each phase over time.

Results: Inpatient visits in the pre-, voluntary, and mandatory PDMP phases totaled 95,550; 52,344; and 151,251, respectively. Across the three phases, hospitalizations with any NSAID use increased (77.1% pre- vs 78.3% voluntary vs 79.5% mandatory PDMP, p<0.001). Additionally, hospitalizations with prolonged NSAID use increased across the three phases (32.1% pre- vs 32.6% voluntary vs 33.9% mandatory PDMP, p=0.001). In interrupted time series analysis, receipt of any NSAIDs increased 1.4% with implementation of the voluntary phase (p <0.001), and AKI incidence increased 0.7% with implementation of the mandatory phase (p=0.06). Across all phases, patients with CKD were particularly susceptible to NSAID-associated AKI with prolonged NSAID use, as 42.0% of CKD patients receiving NSAIDs for ≥ 4 days experienced AKI, compared to 29.9% of CKD patients receiving < 4 days of NSAIDs (p = 0.001).

Conclusions: We find that implementation of the PA PDMP was associated with a significant increase in NSAID use and duration in inpatient UPMC facilities and a marginally significant and temporally correlated increase in AKI. Further analyses will examine whether AKI increased more dramatically in specific high-risk patient subsets.

Bortezomib-Induced Tumor Lysis Syndrome in Patients with Untreated Symptomatic Multiple Myeloma: A Retrospective Study

Masahiro Kondo,[1] Yuji Hotta,[2] Karen Yamauchi,[2] Akimasa Sanagawa,[1,2] Hirokazu Komatsu,[3] Shinsuke Iida,[3] Kazunori Kimura.[1,2] *[1]Pharmacy, Nagoya City University Hospital, Nagoya, Japan; [2]Hospital Pharmacy, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; [3]Hematology and Oncology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan.*

Background: Tumor lysis syndrome (TLS) causes acute kidney injury (AKI) and is a complication of cancer chemotherapy. TLS risk is classified by malignant disease type. Although multiple myeloma (MM) is a low-risk disease, treatment by novel therapies, including bortezomib (Bor), may increase TLS risk. Thus, we evaluated the association between Bor-based therapy and TLS in MM patients.

Methods: We retrospectively reviewed patients who received first-line therapy for untreated symptomatic MM between May 2007 and December 2017. Patients treated by Bor-based therapy comprised the Bor group; all remaining patients (i.e., those treated by conventional anti-cancer agents) comprised the Non-Bor group. Incidences of laboratory and clinical TLS (LTLS and CTLS) during first-line therapy were compared between groups.

Results: There were 129 and 75 patients in Bor and Non-Bor groups, respectively. Baseline laboratory data were similar between groups. More patients received prophylactic administration for hyperuricemia in Bor group than in Non-Bor group. However, LTLS incidence was significantly higher in Bor group than in Non-Bor group (12.4% vs. 4.0%, P<0.05); CTLS was observed in eight patients (6.2%) in Bor group and one (1.3%) in Non-Bor group [Table]; these patients were diagnosed with CTLS due to elevated serum creatinine. Three CTLS patients with AKI were in Bor group. No CTLS patients died or referred for dialysis during treatment period.

Conclusions: Bor-based therapy may increase risk of AKI in LTLS and CTLS, even with prophylactic interventions. TLS risk must be further evaluated in low-risk diseases such as MM, as an increasing number of novel therapies can achieve tumor shrinkage.

Table. The incidences of laboratory TLS and clinical TLS in patients treated by bortezomib-based regimen (Bor group) and Non-bortezomib-based regimen (Non-Bor group).

	No. of patients (%)		P value
	Bor group (n=129)	Non-Bor group (n=75)	
Laboratory TLS	16 (12.4)	3 (4.0)	<0.05*
Clinical TLS	8 (6.2)	1 (1.3)	0.159

All nine patients were diagnosed with CTLS due to elevated serum creatinine >1.5 × upper limit of normal range.

TLS: Tumor lysis syndrome

P values were determined by Fischer's exact test.

TH-PO063

Risk of AKI and Hyperkalemia Among Older Patients Prescribed Non-Steroidal Anti-Inflammatory Drugs

Danielle M. Nash,[2,1] Amit X. Garg.[3,1] *[1]Institute for Clinical Evaluative Sciences, London, ON, Canada; [2]Department of Health Research Methods, Evidence and Impact, McMaster University, Hamilton, ON, Canada; [3]Medicine, Western University, London, ON, Canada.*

Background: Non-steroidal anti-inflammatory drugs (NSAIDs) are used to treat pain and inflammation. Clinical guidelines caution against NSAID use in older patients due to high risk of acute kidney injury, but better evidence is needed to inform clinical care for those most at risk. The objective of this study was to determine the risk of acute kidney injury and hyperkalemia associated with long-term prescription NSAID use among older patients, and risk factors associated with these outcomes.

Methods: We conducted a population-based retrospective cohort study using linked healthcare data from Ontario, Canada. We identified patients >66 years with a new NSAID prescription with a day supply >14 days between 2007 and 2015. We propensity-score matched NSAID users to non-users and performed conditional logistic regression on 30-day risk of acute kidney injury, hyperkalemia, all-cause mortality, and hospital encounter with ventricular arrhythmia. We also developed a logistic regression model of predictors for acute kidney injury or hyperkalemia among NSAID users.

Results: We identified 61,219 eligible NSAID users and 156,589 eligible non-users. We matched 46,107 NSAID users to 46,107 non-users (mean age 74 years, 58% female). NSAID users were significantly more likely to develop acute kidney injury and hyperkalemia compared to non-users (see Table). Our prediction model included six baseline factors that were significantly associated with acute kidney injury or hyperkalemia (C-statistic adjusted for Harrell's optimism: 0.72, 95% CI: 0.70-0.74): older age, male gender, lower baseline estimated glomerular filtration rate, higher baseline serum potassium, angiotensin converting enzyme inhibitor or angiotensin receptor blocker prescription, and diuretic prescription. This model will be available as an online calculator through the QxMD Calculate application.

Conclusions: Older patients prescribed NSAIDs for more than 14 days are at greater risk for acute kidney injury and hyperkalemia compared to non-users. We have developed an online calculator to help inform clinical decision making for NSAID prescribing in this population.

Funding: Government Support - Non-U.S.

Outcome	NSAID users, n (%)	Non-users, n (%)	Odds ratio (95% CI)	Risk difference (95% CI)	Number needed to harm (95% CI)
Acute kidney injury	380 (0.82)	272 (0.59)	1.41 (1.20-1.65)	0.23 (0.13-0.34)	427 (292-787)
Hyperkalemia	184 (0.40)	123 (0.27)	1.50 (1.20-1.89)	0.13 (0.06-0.20)	756 (485-1715)
All-cause mortality	66 (0.14)	79 (0.17)	0.83 (0.60-1.16)	-0.03 (-0.08-0.02)	N/A
Hospital encounter with ventricular arrhythmia	71 (0.15)	76 (0.16)	0.93 (0.67-1.29)	-0.0001 (-0.06-0.70)	N/A

TH-PO064

Routine Laboratory Monitoring Following Initiation of an ACEi or ARB and the Association with Adverse Outcomes

Danielle M. Nash,[2,1] Rishi V. Parikh,[5] Amit X. Garg,[3,1] Alan S. Go.[5,4] *[1]Institute for Clinical Evaluative Sciences, London, ON, Canada; [2]Health Research Methods, Evidence and Impact, McMaster University, Hamilton, ON, Canada; [3]Medicine, Western University, London, ON, Canada; [4]Epidemiology and Biostatistics, University of California, San Francisco, CA; [5]Kaiser Permanente Northern California, Oakland, CA.*

Background: Clinical guidelines recommend serum creatinine and potassium monitoring shortly after initiating an Angiotensin Converting Enzyme Inhibitor (ACEi) or Angiotensin Receptor Blocker (ARB). However, it is unclear if monitoring prevents adverse outcomes. The objective of this study was to identify the association between obtaining laboratory monitoring shortly after initiating an ACEi or ARB prescription and adverse outcomes across two large North American regions.

Methods: We conducted two population-based retrospective cohort studies using healthcare data from Kaiser Permanente Northern California and the Institute for Clinical Evaluative Sciences, Ontario, Canada. We included patients initiating an ACEi or ARB prescription between 2007 and 2015. We compared patients with both outpatient serum creatinine and potassium tests in the 30 days following the prescription date to a group without such tests, where we randomly assigned a test date. Patients with and without follow-up tests were matched using high dimensional propensity scores to have similar indicators of baseline health. We assessed outcomes of all-cause mortality and hospitalization with acute kidney injury or hyperkalemia within 30 days of the test date using Cox proportional hazards regression.

Results: In the Kaiser cohort, 55,487 (34%) eligible patients received follow-up outpatient serum creatinine and potassium tests (mean 12 days after ACEi / ARB initiation). The final cohort included 54,274 patients with follow-up tests matched to 54,274 without tests (mean age 63 years). There was no significant difference in 30-day all-cause mortality between patients with follow-up tests compared to patients without tests (see Table). Patients with follow-up tests were more likely to be hospitalized with acute kidney injury, but not hyperkalemia, compared to patients without tests. The findings were similar in the Ontario cohort (mean age 75 years).

Conclusions: Routinely measuring serum creatinine and potassium after initiation of an ACEi or ARB does not appear to prevent adverse outcomes compared to no such measurements.

Funding: Government Support - Non-U.S.

Outcome	Kaiser Permanente Northern California Cohort				Ontario Cohort			
	Follow-up test, n (%)	No follow-up tests, n (%)	Hazard Ratio (HR) (95% CI)	Adjusted HR (95% CI)	Follow-up tests, n (%)	No follow-up tests, n (%)	HR (95% CI)	Adjusted HR (95% CI)

TH-PO065

Incidence, Pathology Findings, and Outcomes of Patients with Kidney Biopsy Proven Acute Interstitial Nephritis

Neelofar R. Khan,[1] Vanesa Bijol,[2] Rimda Wanchoo,[1] Kenar D. Jhaveri,[1] Nupur N. Uppal.[1] *[1]Zucker School of Medicine at Hofstra Northwell, Great Neck, NY; [2]Pathology, Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Background: Acute interstitial Nephritis (AIN) is a common cause of AKI. However, there have been no recent studies that have reviewed the incidence, and/ or etiology of AIN.

Methods: Using our Health System's kidney biopsy database, we reviewed charts of total 322 patients who underwent kidney biopsies in last 1 year. Patients with pathological diagnosis of AIN were analyzed for related clinical presentations and concurrent pathological findings. Patients with pure AIN were then compared to patients with AIN and associated kidney pathology findings using students t-tests and chi-square.

Results: AIN was present in 13% (42/322) patients. 38% had pure tubulo-interstitial diseases (Pure AIN) and 62% also had findings of other kidney diseases. 44% had simultaneous glomerular pathologies including primary and secondary FSGS (3 cases with collapsing glomerulopathy, 2 with secondary FSGS and 1 with primary FSGS), diabetic nephropathy, membranous nephropathy, immune complex GNs and lupus nephritis. To our surprise, concurrent oxalate deposition was seen in 12% patients. Mean age of patients with AIN was 54.2 years and 61% were females. Overall mean peak Scr was 3.9mg/dl and last known mean Scr post treatment was 2.5mg/dl. Mean proteinuria was 2.8 grams for both groups. There was no statistical difference in both groups in terms of age, proteinuria at baseline, and change Scr. Pure AIN group presented with a higher mean Scr (4.8) compared to AIN with concurrent glomerular disease group(3.2)(p= 0.09). Urine eosinophils were present only in 2 of 11 patients who were tested, and up trending peripheral eosinophilia was seen in only 9 patients. 10/42 patients received treatment with corticosteroids only. 11 patients required hemodialysis(HD). Pure AIN group was more likely to require HD (64% vs. 36%). Beta lactam antibiotics (13.9%), NSAIDs (11.6%) and proton pump inhibitors (6.9%) were most common agents causing AIN.

Conclusions: AIN remains a prevalent cause of AKI. AIN with concurrent kidney pathology is more common than pure AIN. Patients with Pure AIN presented with higher Scr and were more likely to require treatment with HD. Although few patients with AIN were noted to have up-trending peripheral eosinophil counts, neither eosinophiluria nor peripheral eosinophilia were associated with predicting the kidney biopsy findings.

TH-PO066

Prevention of Cisplatin-Induced AKI by Magnesium Supplementation: A Systematic Review and Meta-Analysis

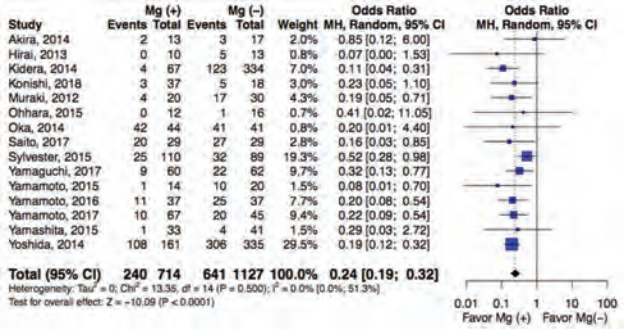
Aghiles Hamroun,[1] Remi Lenain,[1] Jean joel R. Bigna,[2] Mehdi Maanaoui,[1] Linh Bui,[1] Paul Chamley,[1] Francois Glowacki.[1] *[1]Nephrology, Lille University Hospital Center, Lille, France; [2]University of Paris Saclay, Paris, France.*

Background: Cisplatin-induced AKI (CIA) is a serious adverse event that affects 30-40% of exposed patients. To date, no prevention method has demonstrated its indisputable effectiveness. Nevertheless, magnesium appears to play a nephroprotective role, partly through its action on the Organic Cation Transporter 2 (OCT2), a renal proximal tubular receptor. The aim of this work is therefore to study the potential nephroprotective effect of magnesium supplementation on CIA.

Methods: After a systematic review on Pubmed, Embase and Web of Science, from January 1978 to January 2018, without language restriction, we performed a meta-analysis with a random effect model. Primary outcome was the occurrence of a CIA, according AKI-KDIGO classification and grading (2012). Heterogeneity between studies was quantified (I^2) and the analysis completed by a meta-regression to adjust the results for potential confounders. This study is registered in the PROSPERO International Prospective Register of systematic reviews, registration number CRD42018090612.

Results: Within the 1125 eligible records, 15 studies fulfilling the selection criteria were included in this work (4 prospective and 11 retrospective cohort studies), for a total of 1841 patients. The meta-analysis showed a significant nephroprotective effect of magnesium supplementation on grade 2 (OR=0.22, 95% CI 0.14-0.33, I^2=0.0%), grade 3 (OR=0.25, 95% CI 0,08-0.76, I^2=0.0%) and all combined grades of CIA (OR=0.24, 95% CI 0.19-0.32, I^2=0.0%). This effect remained after adjustment for all potential confounding factors (sex, age, cumulative dose of Cisplatin, baseline renal function, performance status index, type of cancer, stage of disease and type of comolecule).

Conclusions: Today, relatively unknown, magnesium supplementation could become, in the future, an effective method of low-cost prevention for CIA. In any case, these promising results encourage the implementation of a large-scale randomized trial.



TH-PO067

High Incidence of Early AKI in Cord Blood Transplantation (CBT) Recipients

Victoria Gutgarts,[1,2] Junting Zheng,[4] Sean Devlin,[4] Alexandra Jacob,[3] Molly A. Maloy,[3] Valkal Bhatt,[3] Ioannis Politikos,[3] Ilya Glezerman,[2] Thangamani Muthukumar,[1] Edgar A. Jaimes,[2] Insara Jaffer Sathick,[2] Juliet N. Barker.[5] *[1]Nephrology, Weill Cornell, New York, NY; [2]Nephrology, Memorial Sloan Kettering Cancer Center, New York, NY; [3]Adult Bone Marrow Transplantation Service, Memorial Sloan Kettering Cancer Center, New York, NY; [4]Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY; [5]Hematology/Oncology, Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: CBT can be curative in patients with high-risk hematologic malignancies but may be associated with a risk of acute kidney injury (AKI).

Methods: We analyzed AKI incidence and risk factors in adult CBT recipients (18-65 years) transplanted for hematologic malignancies with cyclophosphamide/ fludarabine/ thiotepa / TBI 400, cyclosporine (CSA)/ mycophenolate mofetil and double unit CB grafts from 2006-2016. Maximum grade AKI (KDIGO criteria 1, 2 or 3) was calculated using day 0 - +100 creatinines. If patients had multiple episodes, the highest AKI grade was analyzed.

Results: 154 patients (median age 51 years) were transplanted. No patient had chronic kidney disease. Median age-adjusted hematopoietic cell transplantation comorbidity index (aaHCT-CI) was 3 (range 0-9). 58 (38%) patients also received haploidentical CD34+ cells. 96% engrafted, 74% had grade II-IV acute graft-*vs*-host disease (aGVHD), and 138 (90%) were alive/ disease-free at day 100. 125 patients had AKI (41 grade 1, 62 grade 2, 22 grade 3) for a grade 1-3 cumulative incidence of 82% (median onset 30 days, range 0-96) and 54 % for grade 2/3. High-toxic CSA levels (3 day average greater than 350) were seen immediately prior to AKI in 11/41 (27%) patients with grade 1 *vs* 33/84 (39%) of grade 2-3 patients. There were 29 patients who did not have an AKI event. Significant variables associated with AKI are shown in Table 1.

Conclusions: CBT recipients are at significant risk for AKI. Early recognition and prompt intervention are critical to lessen severe injury. Strategies to mitigate AKI are required as well as analysis of the effect of AKI on long-term renal function.

Table 1a: Association between pre/ post CBT characteristics & AKI

TH-PO068

AKI in Hospitalized Patients with Solid Organ Cancer Who Undergo Cancer Treatment

Marianne Camargo,[1] Yuanchao Zheng,[2] Margaret R. Stedman,[2] Glenn M. Chertow.[3] *[1]Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [2]Stanford University, Palo Alto, CA; [3]Stanford University School of Medicine, Palo Alto, CA.*

Background: Acute Kidney Injury (AKI) is common in patients with cancer and associated with interruptions in therapy, increased testing and procedures, and higher healthcare costs. However, the epidemiology of AKI complicating solid organ cancer is not well-understood. We aimed to explore correlates and consequences of AKI in patients hospitalized for treatment of solid organ cancer in the United States.

Methods: Using the National Inpatient Sample (NIS) database from 2012 we included patients over the age of 20 with a primary diagnosis of solid organ cancer with a concomitant diagnosis code for cancer treatment category (surgery, chemotherapy or radiation). We excluded patients with a diagnosis code for end-stage renal disease (ESRD), or if they had a procedure code for dialysis without associated AKI. In our analysis we created separate models for the interaction between cancer type and treatment category and the outcomes: AKI, hospitalization length of stay (LOS) and cost. Multivariate models were adjusted for age, sex, comorbidities, region, primary payer, bedsize and teaching status of the hospital.

Results: The weighted sample had 321,345 hospital admissions for solid organ cancer treatment. Approximately half were for women and >60% were for persons over the age of 60. More than half had hypertension, more than one in five had diabetes. Overall, 5.5% of patients who underwent surgical treatment had AKI, compared to 11% and 9% of patients who received chemotherapy and radiation therapy (XRT) respectively. After adjustment for covariates, patients with the highest risk of AKI were those admitted for kidney and liver cancer XRT who had a 32% (CI 13%-50%), and 23% (CI 7%-40%) probability of AKI respectively, followed by admissions for XRT of colon cancer 19% (CI 11%-27%), and chemotherapy for prostate cancer 18% (CI 2%-34%). After adjusting for cancer type, treatment type, and covariates, hospitalizations with AKI had on average, double LOS (CI 1.92-2.11) and 1.78 times higher hospitalization costs (CI 1.70-1.86).

Conclusions: The probability of AKI in hospitalized patients with solid organ cancer is significantly different among different cancer types and treatment modalities. Presence of AKI is associated with increases in hospitalization costs and LOS. Further analysis will evaluate risk factors and inform clinical decision making.

TH-PO069

AKI Drives Papillary Renal Cell Carcinoma Formation from Tubular Progenitor Cells

Anna J. Peired,[1] Giulia Antonelli,[1] Maria Lucia Angelotti,[1] Alessandro Sisti,[1] Marco Allinovi,[1,2] Paola Romagnani.[1,2] *[1]Department of Biomedical, Experimental and Clinical Sciences "Mario Serio", University of Florence, Florence, Italy; [2]Nephrology Unit, Meyer Children's University Hospital, Florence, Italy.*

Background: Renal cell carcinoma (RCC) accounts for 2% of all cancers, with about 190,000 new cases per year worldwide. As the Notch pathway has a critical role in kidney injury and repair, and Notch hyperexpression was reported in patients with RCC, we hypothesized that a persistent activation of the Notch pathway may drive tubular epithelial cell (TEC) hyperplasia, leading to cancer formation. Other risk factors for RCC include obesity, diabetes, hypertension and genetic factors, but the majority of cancers occur in apparent absence of clear risk factors. As tissue injury is an important cofactor for many types of cancers, we proposed to verify whether acute kidney injury (AKI) plays a role in RCC development.

Methods: We developed mouse models in which the intracellular domain of Notch 1 (NICD1) is expressed constitutively by all Pax8+ TECs (Pax8/NICD1) or only by Pax2+ renal progenitors (Pax2/NICD1) upon induction in adult mice. Both models were further bred with Confetti mice, allowing clonal analysis of the lesions. Following induction, the mice were either left to age for 9 months or underwent unilateral ischemia-reperfusion injury (IRI), an experimental model of AKI, and were sacrificed at 28 days.

Results: At 9 months, Pax8/NICD1 mice presented a significant decline of renal excretory function as well as numerous, multicentric and progressive pretumoral and tumoral lesions. Histological analysis indicate the presence of papillary RCCs (pRCCs). In Pax8/NICD1/Confetti mice, we observed that most of the pRCCs were mono- or biclonal, suggesting that they could originate from a local stem cell/progenitor population. Pax2/NICD1 mice presented exclusively papillary tumors. Lineage tracing in Pax2/NICD1/Confetti mice identified single Pax2+ tubular progenitors as the source of pRCCs. Mice subjected to IRI presented mono- and biclonal papillary tumors in only 28 days, indicating that AKI strongly accelerated the development of pRCCs.

Conclusions: These mouse models represent useful new tools to study the mechanisms of tumor development in the kidney and indicate Pax2+ renal progenitors as the cell of origin of pRCC. Additionally, this study provides the first experimental demonstration of the link between AKI and the development of papillary tumors, with important clinical implications for RCC patients.

TH-PO070

Epidemiology and Outcomes of AKI in Hospitalized Cancer Patients in China

Yichun Cheng,[1] Sheng Nie,[2] Diankun Liu,[2] Yanqin Li,[2] Long Wang,[2] Mengqi Xiong,[2] Shuwang Ge,[1] Gang Xu.[3] *[1]Department of Nephrology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China; [2]National Clinical Research Center for Kidney Disease, State Key Laboratory of Organ Failure Research, Nanfang Hospital, Southern Medical University, Guangzhou, China; [3]Tongji hospital affiliated to Tongji medical college, Huazhong University of Science and Technology, Wuhan, China*.

Background: Acute kidney injury (AKI) is a common complication in cancer patients, but the data are lacking in Asian countries. We aimed to assed the epidemiology, correlated risk factors and outcomes of AKI in cancer patients from China.

Methods: We conducted a nationwide cohort study of cancer patients who were admitted to 25 general and children hospitals across China from January 1, 2013 to December 31, 2015. We obtained patient-level data from the electronic hospitalization information system and laboratory databases of all inpatients who had at least two serum creatinine tests within any 7-day window during their first 30 days of hospitalization. AKI was defined and staged according to Kidney Disease Improving Global Outcomes criteria. Incidence rate and risk factor profiles for AKI were examined. Outcomes of interest included in-hospital mortality, length of stay and daily costs.

Results: A total of 136,834 adult cancer patients were assessed in our study. The overall incidence of AKI was 7.6%, of which 1.6% were community acquired and 5.9% hospital acquired. The top three cancer types with high incidence of AKI were bladder cancer, leukemia, and lymphoma. Risk factors for community-acquired and hospital-acquired AKI were similar, including age, increased baseline serum creatinine, shock and urinary tract obstruction. In-hospital occurred in 12.0 % with AKI versus 0.9% cancer patients without AKI. After adjustment for confounders, the severe AKI was associated with higher risk of in-hospital death, prolonged length of stay and higher daily costs.

Conclusions: Clinicians should increase their awareness of AKI in hospitalized cancer patients.

TH-PO071

AKI in Stem Cell Transplant Patients: Role of Hemoglobinuria

Panagiotis Kompotiatis, Sandhya Manohar, Nelson Leung. *Mayo Clinic, Rochester, MN*.

Background: The available evidence regarding the risk factors of hemoglobinuria shortly after hematopoietic stem cell transplant (HSCT) and its association with outcomes including acute kidney injury (AKI), mortality, and engraftment is very limited.

Methods: The objectives of this study were: 1. Identify risk factors of hemoglobinuria within 24 hours of HSCT **2.** Assess whether hemoglobinuria is a risk factor for early post-HSCT AKI **3.** Assess outcomes (mortality, engraftment, and infection) with AKI as the predictor in the group of patients with post-HSCT hemoglobinuria. **Methods:** Retrospective cohort study of adults that underwent hematopoietic stem cell transplantation from January 6, 1999, to November 6, 2017. Patients that underwent bone marrow transplantation (BMT) or peripheral blood stem cell transplantation (PBSCT) were included in the study (n= 5992). Of these, we identified 50 patients that developed gross hemoglobinuria within 24 hours after HSCT (In 7 out of 50 patients gross hemoglobinuria was confirmed with urinalysis).

Results: Univariable analysis showed that post-HSCT hemoglobinuria was associated with graft type (BMT vs. PBSCT, OR 12.99 CI 7.3-23.16), underlying disease (lymphoma OR 13.82, CI 4.2-45.43, acute leukemia OR 7.79, CI 1.94-31.22, reference group: multiple myeloma) and fludarabine-based conditioning regimen (OR 2.4, CI 1.09-5.47). In multivariable analysis these associations persisted for all predictors except for acute leukemia. Of the 11 patients that underwent allogeneic HSCT and had hemoglobinuria, only one had a transplant with ABO mismatch (bidirectional). ABO incompatibility hence, was not included in the analysis. Additionally, post-HSCT hemoglobinuria was also associated with early (48-72h) posttransplant AKI (OR 6.3, CI 3.4 -11.7) in univariable analysis. Finally, AKI in patients with hemoglobinuria was associated with delayed platelet engraftment (P= 0.049) but not white blood cells (WBC) engraftment (P=0.11), infection (P=0.77) or 100-day mortality (P=0.52).

Conclusions: Our study demonstrated a significant association between post-HSCT hemoglobinuria and graft type (BMT), fludarabine-based conditioning regimen and underlying disease (lymphoma). Hemoglobinuria was also associated with early post-Tx AKI. Future studies should focus on preventing post-HSCT hemoglobinuria induced AKI in these high-risk patients.

TH-PO072

Temporal Trends and Impact on Mortality of AKI in Cancer Patients

Young Lee Jung,[1] Minsu Park,[2] Eunjeong Kang,[3] Dong Ki Kim,[3] Kwon Wook Joo,[3] Kook-Hwan Oh,[3] Yon Su Kim,[4] Hajeong Lee.[4] *[1]Seoul National unioversity Hospital, Bucheon, Republic of Korea; [2]Yonsei University College of Medicine, Seoul, Republic of Korea; [3]Seoul National University Hospital, Seoul, Republic of Korea; [4]Seoul National University College of Medicine, Seoul, Republic of Korea*.

Background: Recently, overall death rate in cancer patients has been improved in virtue of advanced preventive and treatment modalities. Acute kidney injury (AKI) is one of serious complication associated with worse outcomes, although its temporal trend and impact on outcome remain unclear in cancer patients.

Methods: This study retrospectively assembled newly diagnosed cancer patients at Seoul National University Hospital between January 2005 and December 2013. Among a total of 98,284 incident cases of cancer, we excluded patients with multiple primary cancer, age under 18 years-old, advanced renal dysfunction with eGFR less than 15 ml/min/1.73m^2. We evaluated annual trends of AKI occurrence within the first year after diagnosis of cancer.

Results: We finally included 68,302 patients after exclusion, and 14,152 (23.4%) patients in them developed AKI within the first year after cancer diagnosis. Overall incidence of AKI was highest in lung cancer (289.5 /1000 person-year), followed by genitourinary tract cancer (260.8/1000 person-year) and hematologic malignancies (217.1 /1000 person-year). As times go by, cancer patients has been older, more hypertensive and more diabetic, and exposed more radiocontrast. With this trend, annual AKI development has increased from 21.0% to 27.8% (P for trend <0.001). On the contrary, 5-year mortality has decreased from 42.9% to 26.5% (P for trend <0.001). Multivariate analysis showed adjusted odd ratio of AKI on mortality has been increasing continuously.

Conclusions: Although overall death rate has decreased, AKI incidence and the impact of AKI on mortality have been increasing over time in cancer patients. Our study suggested that appropriate preventive strategy and adequate management for AKI in patients with malignancy, which is an important role of nephrologists.

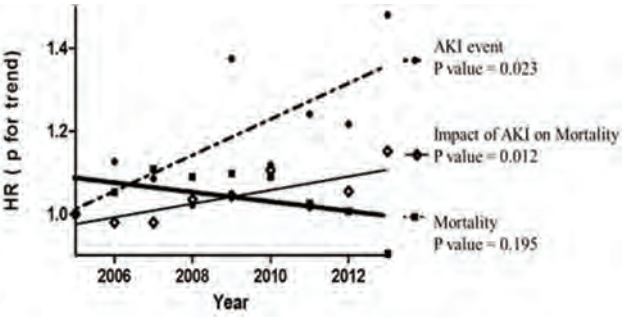

Figure 1. Temporal trends of AKI incidence and Impact on Mortality from 2005 to 2013.

TH-PO073

Partial Nephrectomy Is Associated with Increased Risk of AKI Compared to Radical Nephrectomy for Renal Cell Cancer

Pradeep Arora,[1] James W. Lohr,[1] Csaba Gajdos,[2] Oussama Darwish,[2] Hasan H. Dosluoglu,[2] Leili Pourafkari,[3] Nader D. Nader.[3] *[1]Nephrology, VAMC, Buffalo, NY; [2]Surgery, VAMC, Buffalo, NY; [3]Anesthesiology, VAMC, Buffalo, NY*.

Background: Acute kidney injury (AKI) is a common complication after major surgery including partial (PN) or radical nephrectomy (RN).

Methods: We evaluated if nephron-sparing surgery is associated with lower incidence of acute kidney injury (AKI). We used data from the national surgical quality improvement program (NSQIP) from Jan 2005 to Dec 2013. The primary endpoint was the occurrence of AKI as defined as over 200% increase in serum creatinine within 72 hours after surgery which is coded by the NSQIP. The main secondary endpoint was the occurrence of progressive kidney failure (PKF) as defined as a need for renal replacement therapy during the course of hospital stay or within 30 days of surgery. In order to identify the confounding variables for the occurrence of AKI and PKF, initially univariate analyses were performed and those factors and covariates which had a trend of significance (P<0.10) were included in multivariable binary logistic regression model. Propensity weighted analyses were then performed between the PN and RN groups for the occurrence of AKI and PKF, using confounding factors and covariates which were significant contributors of AKI and PKF.

Results: There were more male patients in both groups and the RN patients were older. PN patients had lower preoperative weight. Patients who underwent RN had higher prevalence of hypertension, CAD, CHF, dyspnea on exertion, dependent functional status, CKD as defined by eGFR <60 ml/min/1.73m^2, disseminated neoplastic disease, significant weight loss of history of bleeding episodes. PN patients had higher serum hematocrit, but lower serum creatinine values. AKI was observed in a total of 143 patients. Multivariable analysis showed increasing age, female gender, eGFR <60 ml/min/1.73m2 and increased operative times were significantly associated with increased risk of AKI. Post-operative progressive renal failure, occurred in 149 patients. In multivariable analysis only age, sex, GFR weight loss serum albumin and operative time were significant. Propensity analysis showed increased risk of AKI with PN compared to RN (OR: 1.683 (95% CI;1.073-3.181). PN also had a trend in increasing the risk of postoperative progressive kidney failure (OR: 1.683(95% CI:0.980-2.229)

Conclusions: PN was associated with increased risk of AKI.

TH-PO074

Burden and In-Hospital Mortality of Dialysis-Requiring AKI (AKI-D) Among Hospitalized Adults with Granulomatosis with Polyangiitis (GPA)

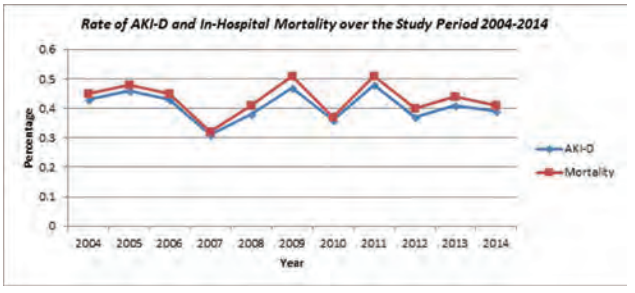
Boonphiphop Boonpheng,[1] Billy Brooks,[1] Pratyaksha Sankhyan,[1] William S. Moore.[2,1] *[1]East Tennessee State University, Johnson City, TN; [2]Mountain Home VA Medical Center, Mountain Home, TN*.

Background: To describe the incidence of acute kidney injury (AKI) requiring renal replacement therapy (dialysis-requiring AKI, AKI-D) and the impact on in-hospital mortality among hospitalized adults with granulomatosis with polyangiitis (GPA).

Methods: We reviewed the Healthcare Cost and Utilization Project's Nationwide Inpatient Sample (NIS) Database, a large nationally representative sample of inpatient hospital admissions, to identify all adult hospitalizations with AKI-D and primary or secondary diagnosis of granulomatosis with polyangiitis (GPA) from 2004–2014. We investigated the trend of AKI-D in each disease for each year and performed multivariate logistic regression to evaluate the impact of AKI-D and co-morbidities on in-hospital mortality.

Results: Among 339,856 hospitalizations with AKI-D, the proportion of GPA as an associated diagnosis remained stable at 0.31-0.47% per year. From 2004-2014, AKI-D complicated 0.32% of hospitalizations with GPA as a primary or secondary diagnosis. The age-adjusted odds of in-hospital mortality associated with AKI-D in patients with GPA decreased over the study period, from 0.92 (95% CI 0.88–0.96) in 2008 to 0.79 (95% CI 0.75–0.82) in 2014. Compared to other causes of AKI-D, GPA was significantly associated with lower in-hospital mortality with adjusted OR 0.64 (95% CI 0.55 - 0.76).

Conclusions: These data suggest that the incidence of dialysis-requiring AKI among hospitalized adults with GPA remained stable; however, the in-hospital mortality seemed to decrease and significantly lower than other causes of severe acute kidney injury.



TH-PO075

AKI in Pediatric Cancer Patients: Incidence and Outcome

Peong Gang Park,[1] Eunjeong Kang,[2] Minsu Park,[2] Hajeong Lee,[2] Yo Han Ahn,[3] IL-Soo Ha,[1] Hae Il Cheong,[1] Hyung-Jin Yoon,[2] Hee Gyung Kang.[1] *[1]Seoul National University Children's Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Seoul National University Bundang Hospital, Seongnam, Kyunggi-do, Republic of Korea.*

Background: Pediatric patients with cancer are known to experience acute kidney injury (AKI) but its incidence and clinical impact has not been well established. The purpose of this study is to analyze the incidence of AKI within 1 year of diagnosis of cancer in children, and to assess its impact on the development of impaired renal function and the development of proteinuria.

Methods: Retrospective review of medical records was done on patients who were diagnosed and treated for cancer at Seoul National University Hospital between 2004 and 2013. Patients who were 18 years old or younger at diagnosis of cancer and who had their Cr levels measured at least two times within one year of diagnosis were eligible. AKI was defined according to the Kidney Disease: Improving Global Outcomes (KDIGO) criteria: stage 1 as 0.3 mg/dL rise of Cr within two days or 1.5 times rise within seven days, stage 2 as two times rise, stage 3 as three times rise or Cr above 4 mg/dL. Impaired renal functionof eGFR of cancer survivors less than 90ml/min/1.73m^2, and development of proteinuria were also assessed.

Results: Among 2,170 candidate patients assessed, 1,868 patients were eligible. Patients were diagnosed with cancer at a median age of 7.9 years old. Their median initial eGFR at diagnosis was 90.0ml/min/1.73^2. A total of 983 patients (52.6%) developed AKI and the cumulative incidence of AKI within two weeks, three months, and one year of diagnosis were 28.9%, 39.6%, 53.6%, respectively. The 1-year cumulative incidence of AKI was the highest in patients with acute myeloid leukemia (88.4%) and lowest in patients treated for retinoblastoma (14.1%). Within the 1 year of cancer diagnosis, AKI occurred once in 520 (27.8%), 2-3 times in 349 (18.7%), more than 4 times in 114 (6.1%) patients. 18.7%, 22.1%, and 11.8% of the patients had stage 1, stage 2, and stage 3 AKI respectively. 22.6% of the survivors had impaired renal function. Male sex, lower eGFR at diagnosis, frequent AKI occurrence and nephrectomy was independent risk factor. Also, 8.2% of the survivors developed proteinuria and female gender, older age were the associated independent risk factors.

Conclusions: Current study showed that AKI occurred in a relatively large percentage of pediatric patients with cancer and that it may adversely affect their long-term renal function.

TH-PO076

Platelet Count and Serum Creatinine in the Differential Diagnosis of TMA: An Analysis from the CESAR Study

Ulf Schoenermarck,[1] Bernd Schroppel,[5] Daniel Schmidbauer,[4] Michael Jeglitsch,[3] Wolfgang Ries.[2] *[1]University Hospital Munich-Grosshadern, Muenchen, Germany; [2]Diako Flensburg, Flensburg, Germany; [3]Alexion, Munich, Germany; [4]CRI - The Clinical Research Institute GmbH, Munich, Germany; [5]University of Ulm, Ulm, Germany.*

Background: Thrombotic thrombocytopenic purpura (TTP), Shiga toxin-producing *E. coli* hemolytic uremic syndrome (STEC-HUS), and atypical HUS (aHUS) require a fast differential diagnosis in order to initiate urgent therapy. TTP may be excluded by an ADAMTS13 activity assay result of >5–10%, however, this test is not immediately available at many centers. Data from the CESAR study[1] were used to assess whether routine laboratory parameters can be used to predict/rule out TTP.

Methods: CESAR was a cross-sectional, multicenter, epidemiologic study of the relative incidence of aHUS, TTP and STEC-HUS in Germany. We developed an algorithm to predict severe ADAMTS13 deficiency in adult patients at clinical presentation. All available variables were analyzed for correlation with final diagnosis. Thresholds were identified maximizing the sum of sensitivity and specificity (Youden Index: J=sensitivity+specificity-1) and then rounding to the nearest easy-to-recall value.

Results: A total of 219 adult patients with a mean (SD) age of 56.2 (18.9) years were enrolled, of whom 31 (14%) were diagnosed with TTP. Platelet (Plt) and serum creatinine (SCr) levels significantly correlated with TTP diagnosis ($p<0.01$). Multivariate analysis (Table 1) revealed that if Plt and SCr levels are above threshold values (Plt: 30 x 10^9/L and SCr: 1.8 mg/dL), TTP is almost certainly ruled out (negative predictive value 98.1 and 92.3 for one or both values, respectively, above threshold).

Conclusions: This analysis shows that Plt and SCr are strong predictors to rule out a diagnosis of TTP. This finding confirms previous studies[2] and may help to accelerate differential diagnosis of TMA. [1]Schoenermarck U, et al. 2017; presented at ASN Kidney Week [SA-PO421] [2]Coppo P, et al. PLoS One 2010;5(4):e10208.

Table. Multivariate analysis to predict TTP diagnosis

Criteria	Specificity	Sensitivity	PPV	NPV
Plt ≤30x10^9/L	84.0	61.3	38.8	92.9
SCr ≥1.8 mg/dL	54.8	90.3	25.0	97.1
Plt ≤30x10^9/L AND SCr ≥1.8 mg/dL	90.8	54.8	50.0	92.3
Plt ≤30x10^9/L OR SCr ≥1.8 mg/dL	54.6	93.5	25.7	98.1

Values expressed as %. NPV, negative predictive value; Plt, platelets; PPV, positive predictive value; SCr, serum creatinine.

TH-PO077

Outcomes of Renal Function After Urinary Diversion for AKI among Patients with Obstructive Uropathy Secondary to Malignancy Admitted in a Tertiary Hospital

Renee glorien E. Comonsad.[1,2] *[1]Philippine Society of Nephrology, Cagayan de Oro City, Philippines; [2]Medicine, Philippine General Hospital, Manila, Philippines.*

Background: Acute kidney injury secondary to malignant obstructive uropathy is associated with poor prognosis. Urinary diversion with percutaneous nephrostomy or DJ ureteral stenting have been used to manage this potentially life-threatening condition. The study aimed to compare the renal function outcomes of patients with malignant obstructive uropathy and to determine the predictors of poor renal function after urinary diversion.

Methods: A retrospective cohort study was conducted to collect data on 112 patients admitted in a tertiary training hospital in Metro Manila from January 2015 to January 2018. EpiInfo 6 was used to compute for the sample size. Both descriptive and inferential statistics were used to describe the baseline patient characteristics and to compare the pre- and post-urinary diversion renal function outcomes.

Results: The mean age of patients was 51.52 ± 11 years with majority being females, 96/112 (85.71%). The mean number of days from admission to urinary diversion was 10.31 ± 13.08 days while the mean hospital days from admission to discharge was 24.45 ± 16.38 days. In paired t-test, there was a significant improvement in the post-urinary diversion renal function parameters including BUN, creatinine, GFR, sodium, potassium, and calcium (all p-value < 0.05) but not albumin (p-value 0.0785). Recovery of renal function (i.e. creatinine reduction of more than 25% from baseline) was achieved by 79/103 (76.7%) of patients. On multiple linear regression, for every one year increase in age, there was a corresponding 0.81 ml/min/1.73 m^2 reduction in GFR (95% CI -1.35 - -0.27, p-value 0.004) while for every one day delay in urinary diversion from admission, there was a corresponding 1.09 ml/min/1.73 m^2 reduction in GFR (95% CI -1.86 - -0.31, p-value 0.007). On multiple logistic regression, the significant predictors of poor GFR (<60 ml/min/1.73 m^2) post-urinary diversion were age (OR 1.11, 95% CI 1.03-1.19, p-value 0.006) and number of days delay from admission to urinary diversion (OR 1.24, 95% CI 1.02-1.51, p-value 0.034).

Conclusions: Prompt urinary diversion significantly improved renal function outcomes. Urinary diversion should not be delayed especially in the older patient population.

TH-PO078

Immunophenotypic Analysis of Humanized Mouse Kidney in Comparison with Human Kidney

Sanjeev Noel,[1] Johanna T. Kurzhagen,[1] Sul A Lee,[1] Mohanraj Sadasivam,[1] Abdel Hamad,[1] Phillip M. Pierorazio,[2] Hamid Rabb.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Brady Urological Institute, Johns Hopkins University, Baltimore, MD.*

Background: Most positive intervention studies in mice fail in human trials, in part due to fundamental differences between mice and humans. Humanizing mouse tissue aims to bring the mouse experimental model closer to human responses. Given the strong data supporting immune cells in acute kidney injury pathogenesis and repair, it is important to test relevance to humans. However, there is little information on immune phenotype of humanized mouse kidney in comparison to normal human kidney. We evaluated immune cell composition in the kidneys of two humanized mice strains and compared it to that of normal human kidney tissue.

Methods: For humanization, 4 week old NOG and NOGEXL female mice were irradiate (100 cGy) and $1x10^5$ human cord blood derived CD34+ hematopoietic stem cells transferred intravenously. Kidneys were harvested from well perfused humanized NOG (huNOG) and huNOGEXL mice, 20 weeks post engraftment. Normal human kidney samples were collected from visibly unaffected portion of nephrectomies from renal cell carcinoma. Kidney mononuclear cells isolated from mouse and human kidneys were analyzed for human CD45, TCR, CD4, CD8, CD20, CD16, CD14, CD11c and CD206 using flow cytometry. n=3/group each humanized mouse strain and human kidney.

Results: The frequency (mean%±SEM) of human CD45+ cells was higher (p=0.04) in huNOG (12.5±2.9) mouse kidney compared to normal human kidney (6.4±1.3). Similarly, the frequency of CD11c+ cells was higher (p=0.02) in huNOG (28.0±4.1) kidney compared to normal human kidney (17.8±1.4). The frequency of CD16+ cells was significantly reduced in both huNOG (7.6±5.5, p=0.03) and huNOGEXL (4.9±1.0, p=0.01) kidney compared to human kidney (31.5±6.3). CD8 T cell frequency was significantly lower (p=0.03) in huNOGEXL (17.2±2.6) compared to human kidney (34.8±4.4). There was no statistically significant difference in the frequency of TCR+, CD4+, CD20+, CD14+ and CD206+ cells between humanized mice kidney and human kidney.

Conclusions: These data demonstrate that huNOG and huNOGEXL kidneys have significant numbers of human immune cells. Furthermore, there are key similarities and differences between different background strains compared to human kidney. Humanizing mice to study kidney disease is a useful approach however it is important to know key strengths and limitations of this approach.

Role of Toll Like Receptors in the Pathogenesis of Myeloma Kidney

Rohit Upadhyay,[1] Wei-zhong Ying,[2] Paul W. Sanders,[2] Edgar A. Jaimes,[3] Vecihi Batuman.[1] *[1]Tulane University, New Orleans, LA; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Memorial Sloan-Kettering Cancer Center, New York, NY.*

Background: Free light chains (FLCs) lead to kidney injury (KI) in myeloma patients. We previously demonstrated that inflammatory pathways triggered by endocytosis of FLCs in proximal tubule cells (PTCs) lead to KI. The role of innate immunity mediated by toll-like receptors (TLR) in FLC-associated KI has not been previously investigated. Here we present our initial observations on the role of TLRs in FLC-induced KI in PTCs *in-vitro*.

Methods: Human kidney PTCs cultures were exposed to κ and λ FLCs. Cell supernatant and pellets were used for ELISA and gene expression studies. Cell proliferation was checked through MTS assay. Data were analyzed using one-way ANOVA with post hoc Tukey test and P values <0.05 were considered significant.

Results: Both κ and λ FLCs induced TNFα secretion and suppressed proliferation of PTCs in a dose- and time-dependent manner. Several innate-immunity (TLRs 2, 3, 4, 6, 9, HMGB1, MYD88, TICAM1), inflammatory (IL6, IL18, IL1B, IL2, TNFα, TGFβ), apoptotic (BCL2, TP53), and KI markers (HAVCR1, ABCB1, LCN2) were assayed. Increased lipocalin 2 (LCN2) and decreased TP53 appeared as the most prominent KI biomarkers for both FLC subtypes. FLCs increased the expression of TLRs 2, 3, 4, 6 and 9, with marked increases in TLR4 gene and in HMGB1 protein levels. Our data show that HMGB1 significantly increases the expression of TLR4 gene in PTCs with or without FLCs exposure. Knock-down of HMGB1 through R, S- Sulforaphane inhibits FLC-induced TLR4 expression suggesting HMGB1 as a likely candidate damage-associated molecular pattern (DAMP) activating TLR4 in FLC exposed PTCs.

Conclusions: PTCs exposed to FLCs release HMGB1, which induces TLR4 expression and downstream inflammation leading to KI. TLRs may be novel diagnostic biomarkers and therapeutic targets for KI in myeloma.

Kidney Proximal Tubular TLR9 Exacerbates Ischemic AKI

Sang Jun Han,[1] Mihwa Kim,[2] H. Thomas Lee.[3] *[1]Columbia University Medical Center, New York, NY; [2]Columbia University, New York, NY; [3]Department of Anesthesiology, New York, NY.*

Background: Ischemic acute kidney injury (AKI) is a major clinical problem. Although Toll-like receptor 9 (TLR9) mediates cell death and inflammation in the liver, the role for kidney TLR9 in ischemic AKI is unknown. Here, we tested the hypothesis that renal proximal tubular TLR9 activation exacerbates ischemic AKI by promoting renal tubular apoptosis and inflammation.

Methods: Wild type mice (WT, TLR9fl/fl) or renal proximal tubular TLR9 null mice (TLR9fl/fl PEPCK Cre) were subjected to sham surgery or 30min kidney ischemia/reperfusion (IR) injury. A separate cohort of mice was pretreated with a selective TLR9 agonist (1mg/kg ODN-1668) or control ODN and subjected to 20min renal IR injury. Cultured mouse proximal tubule cells or immortalized human proximal tubule (HK-2) cells were treated with a selective TLR9 agonist (1-5 μM ODN-BW006) to determine whether TLR9 activation induces renal proximal tubular pro-inflammatory cytokines and NFκB activation in vitro.

Results: Renal proximal tubular TLR9 null mice were protected against renal IR injury with decreased plasma creatinine (1.8±0.2mg/dL), NGAL mRNA (362.6±61.6 fold increase over sham), neutrophil infiltration and TUNEL positive cells compared to WT mice (Cr=2.6±0.1mg/dL, NGAL=667.6±122.3 fold increase over sham, N=8 for all groups). In addition, renal proximal tubular TLR9 deletion reduced pro-inflammatory cytokine synthesis, caspase 3 and 8 activation when compared to WT mice after renal IR injury. Consistent with this, a selective TLR9 agonist exacerbated renal IR injury in WT mice (Cr=1.4±0.1mg/dL, 0.93±0.04mg/dL of vehicle) but not in renal proximal tubular TLR9 null mice (Cr=0.7±0.02mg/dL, 0.73±0.02mg/dL of vehicle, N=5 for all groups). In HK-2 cells, a TLR9 selective ligand induced NFκB activation, pro-inflammatory cytokine mRNA synthesis as well as caspase 3 and 8 activation. In primary cultures of mouse proximal tubule cells from TLR9fl/fl PEPCK Cre mice, TLR9 selective ligand induced significantly less pro-inflammatory cytokine mRNA synthesis compared to cells from WT mice.

Conclusions: Taken together, our studies suggest that renal proximal tubular TLR9 activation exacerbates ischemic AKI by promoting renal tubular inflammation and apoptosis after IR via NFκB, caspase 3, and 8 activation. Our studies provide novel insight to the pathophysiology of kidney proximal tubule TLR9 in ischemic AKI, suggesting a potential therapy for ischemic AKI.

TH-PO081

Role of Interleukin-4 Receptor-JAK3-STAT6 Signaling in the AKI-to-CKD transition

Jonatan Barrera-Chimal,[1,2] Gabriel R. Estrela,[2] Soumaya El moghrabi,[2] Peter Kolkhof,[3] Frederic Jaisser.[2] *[1]UNAM, Instituto de Investigaciones Biomedicas - Instituto Nacional de Cardiologia, Ignacio Chavez, Mexico City, Mexico; [2]INSERM U1138 - Centre de Recherche des Cordeliers, Paris, France; [3]BAYER AG, Wuppertal, Germany.*

Background: Mineralocorticoid receptor (MR) antagonism is highly efficient to prevent both acute injury and the progression to chronic kidney disease (CKD) after an ischemic episode by enhancing a macrophage M2 polarization in the early post-ischemic phase and might be therefore an efficient repair mechanism. Interleukin-4 (IL-4) receptor activation in myeloid cells appears to be part of the protective mechanism. The exact contribution of IL-4 receptor downstream signaling potentially through JAK3-STAT6 in renal protection mediated by finerenone remains unclear. We tested the involvement of IL-4 receptor signaling induced by MR inhibition in the development of kidney fibrosis after an ischemic acute kidney injury (AKI) episode.

Methods: Thirty male C57/B6 mice were divided in: sham, renal ischemia for 22.5 min (IR), IR plus treatment with the non-steroidal MR antagonist finerenone (10 mg/kg) at -48, -24 and -1 h before IR and two groups of mice subjected to IR and receiving finerenone plus a STAT6 or JAK3 inhibitor. The mice were followed-up during 4 weeks to test for AKI to CKD transition. In another set of mice, the macrophages were sorted from kidneys after 24 h of reperfusion and flow cytometry characterization was performed.

Results: The progression of AKI to CKD after 4 weeks of renal ischemia in the untreated mice was characterized by a 40% increase in plasma creatinine, a 6-fold increase in proteinuria, severe tubule-interstitial fibrosis and increased mRNA levels of NGAL, Kim-1, alpha-SMA, fibronectin, TGF-beta and collagen-I. The mice that received finerenone were protected against all these alterations. MR inhibition promoted increased IL-4 receptor expression and phosphorylation in the whole kidney and in isolated macrophages. The protective effect conferred by MR antagonism was partially reversed by STAT6 inhibition as evidenced by a 5-fold increase in proteinuria and by the JAK3 inhibitor which partially reversed the tubule-interstitial fibrosis protection, and completely prevented the reduction in Kim-1 and fibrosis related gene expression.

Conclusions: Finerenone modulates the IL-4 receptor-JAK3-STAT6 signaling pathway, leading to macrophage phenotype switching and protection against AKI to CKD transition.

Mineralocorticoid Receptor Antagonism Prevents the Acute and Chronic Effects of Ischemic AKI in the Large White Pig

Jonatan Barrera-Chimal,[2,1] Sebastien Giraud,[4] Sihem Kaaki,[4] Frederic Jaisser,[1] Thierry Hauet.[3] *[1]INSERM U1138, Paris Cedex 13, France; [2]UNAM, Instituto de Investigaciones Biomedicas - Instituto Nacional de Cardiologia, Ignacio Chavez, Mexico City, Mexico; [3]Inserm / Université de Poitiers / CHU de Poitiers, Poitiers, France; [4]INSERM U1082- CHU de Poitiers, service de biochimie, Poitiers, France.*

Background: In rodent models of kidney ischemia/reperfusion (IR), mineralocorticoid receptor (MR) antagonism has shown beneficial effects against acute kidney injury (AKI) and its progression to chronic kidney disease (CKD); whether these findings might be translated to the human pathology remains to be clarified. The Large White pig is a useful

preclinical animal model to test the effectiveness of therapeutic strategies aimed to protect against AKI due to the kidney similarities between the human and the pig. In this study we evaluated the effect of MR antagonism against the acute and chronic effects of ischemic AKI in the Large White pig.

Methods: Eighteen Large White male pigs were divided in three groups: sham, pigs that received vehicle and underwent bilateral renal ischemia for 60 min and a group of pigs subjected to renal ischemia and receiving Soludactone (potassium canreonate). Soludactone (7mg/kg, i.v.) or vehicle doses were given at 48 h, 24 h and 30 min before the induction of the ischemia and 24 h and 48 h after reperfusion. Urine collection and blood sampling was carried out at days 1, 3, 5, 7, 11, 14 and 90. Kidney biopsies were taken at days 14 and 90.

Results: Renal IR induced kidney dysfunction in the untreated pigs at day 1 (plasma creatinine: 443±7 mmol/L). In contrast, the pigs that received canrenoate showed an impressive prevention of plasma creatinine elevation (145±3 mmol/L). Tubular injury was evidenced by a significant increase in urinary NGAL, KIM-1, L-FABP and NAG excretion and by histological abnormalities at day 14 (tubular injury and increased inflammatory infiltrate). Canreonate treatment decreased by 50% the excretion of these markers and prevented the histological damage. At day 90, the untreated pigs presented kidney fibrosis which was absent in the canreonate-treated pigs. Plasma creatinine was higher in untreated pigs at day 90 (120±2 mmol/L) as compared to the treated pigs (92±4 mmol/L)

Conclusions: MR antagonism is effective against the acute and chronic kidney dysfunction and structural injury in a preclinical model of AKI in the Large White pig. These findings support clinical trials testing the potential benefits of MRAs in AKI.

TH-PO083

Knockout of Interleukin-36 Receptor Prevents Fibrosis in Mice Models of AKI-to-CKD Progression

Ogasawara Masami, Yoshio Terada, Hirofumi Nishikawa, Yoshinori Taniguchi. *Kochi University, Nankoku, Japan.*

Background: IL-36, a newly named member of the IL-1 cytokine family, includes 3 isoforms, IL-36α, IL-36β, and IL-36γ, all of which bind to a heterodimer containing IL-36 receptor (IL-36R). Little is known about the role of the IL-36 axis in fibrosis during AKI to CKD progression. We examined IL-36 function using mice AKI to CKD models and clinical samples.

Methods: We evaluated IL-36 function in two models of AKI to CKD progression by using IL-36R knockout (KO) and wild-type (WT) mice. First model, left renal ischemia was performed for 35min and right kidney was removed 21days later, and left kidney analyses at 28 days (IRI). Second model, we used aristolochic acid toxic nephropathy (AAN) in mice at 28 days. We evaluate the renal function and histological analysis of KO and WT mice in both models. Fibrotic changes were evaluated by RT-PCR, Western blot analysis, and immunohistological analysis of collagen type IV, CTGF, and Masson trichrome staining. In clinical study, we performed immunohistological examination of IL-36α in AKI to CKD patients and minimal change renal biopsy sample.

Results: IL-36R was found to be expressed in the kidney mainly in proximal tubules in WT mice. IL-36R KO mice had significantly lower Cr and BUN at 28 days compared to WT mice in both models. Immunohistological examination showed mild tubular injury and fibrotic change in IL-36R KO mice compared to WT mice in both models. IL-36α/β/γ levels were increased after IRI and AAN, and IL-36α was expressed in lymphocytes and renal tubular cells. Immunohistologial analysis of collagen type IV and CTGF, and Masson trichrome staining revealed that massive fibrotic changes were observed in WT mice compared to KO mice in both models. Protein expression of collagen type IV and CTGF were also increased in WT mice compared to KO mice. Notably, IL-36α staining in renal-biopsy samples of AKI to CKD patients was enhanced.

Conclusions: Our results demonstrate that IL-36α is up-regulated in renal tissues in both mouse and human AKI to CKD transition, and that IL-36α stimulates collagen type IV and CTGF in AKI to CKD transition models. Thus, IL-36α/IL-36R blockage could serve as a potential therapeutic target in AKI to CKD transition.

TH-PO084

Deficiency of IKKα in Macrophages Mitigate the Fibrosis Progression of Kidney After Renal Ischemia-Reperfusion Injury

Feng Zhang,[1] Xin Wan.[2] *[1]Nanjing Medical University, Nanjing, China; [2]Nanjing First Hospital, Nanjing, China.*

Background: Acute kidney injury (AKI) could lead to chronic kidney disease (CKD) and the macrophages play key roles in this process. The aim of this study was to the discovery the role of IκB kinase α (IKKα) in macrophages in the process of AKI-to-CKD transition.

Methods: We crossed lyz2-Cre mice with IKKa floxed mice to generate mice with IKKα ablation in macrophage (Mac IKKa-/-). Mice renal ischemia/reperfusion injury (IRI) model was induced by clamping the renal artery for 45 min. Treated mice were evaluated for blood biochemistry, tissue histopathology and epithelial mesenchymal transition (EMT) markers. Macrophages isolated from peritoneal cavity for co-culturing with tubular epithelial cells (TEC)and flow cytometry analysis.

Results: We found that mice with Mac IKKa-/- significantly alleviated the fibrosis and ameliorated the kidney function loss after IRI compare with wide type (WT) mice. The expression of EMT markers and the infiltration of M2 macrophages were decreased in kidneys of Mac IKKa-/- mice after IRI. The in vitro experiment showed that the IRI TECs co-cultured with IKKa-/- macrophages (KO MΦ) downregulated the EMT accompany with downregulating Wnt/β-catenin signal.

Conclusions: These data support the hypothesis that IKKα was involved in mediating the macrophage polarization and elevating the fibrotic promoting inflammatory factor in macrophages. So knockdown the IKKα in macrophage may be a potential method that can be used to alleviate the AKI-to-CKD transition after IRI.

TH-PO085

Divergent Sphingosine 1-Phosphate (S1P) Signaling Pathways Control Pericyte Function in AKI to CKD Transition

Kinga P. Rudnicka,[1] Shinji Tanaka,[1] Shuqiu Zheng,[1] Amandeep Bajwa,[1] Junlan Yao,[1] Diane L. Rosin,[2] Mark D. Okusa.[1] *[1]Division of Nephrology, CIIR, University of Virginia, Charlottesville, VA; [2]Departament of Pharmacology, University of Virginia, Charlottesville, VA.*

Background: Acute kidney injury (AKI) can lead to chronic kidney disease (CKD). S1P, a sphingolipid that regulates AKI and fibrosis, is produced by two different kinases, sphingosine kinase (SphK) 1 and 2, and after its export can bind to S1P1-S1P5 receptors. S1P1, a key player during AKI and CKD, is expressed in both endothelial cells (EC) and pericytes (PC; *Foxd1Cre*$^{+}$) and plays an important role in angiogenesis and EC-PC communication. We showed previously that EC S1P1 is protective after ischemia reperfusion injury (IRI) and that the global *Sphk2 KO* has less fibrosis after AKI, however the role of S1P signaling in pericytes is unknown.

Methods: Folic acid (FA; 250 mg/kg) or vehicle (0.3 M $NaHCO_3$, Veh) was given ip to 12-14 wk old male *Foxd1Cre*$^{+}$*Sphk2*$^{fl/fl}$ (*Sphk2KO*), *Foxd1Cre*$^{-}$ *Sphk2*$^{fl/fl}$ (WT control), *Foxd1Cre*$^{+}$*S1P1*$^{fl/fl}$ (*S1P1KO*), and *Foxd1Cre*$^{-}$*S1P1*$^{fl/fl}$ (WT) mice. For IRI kidneys were clamped for 26 min ischemia followed by 24h reperfusion (8-10 wk old mice). AKI (24-72h) was assessed by plasma creatinine (PCr), blood urea nitrogen (BUN), qPCR (*Kim-1* and *Ngal*) and histology (H&E staining). 14 days after injection of FA or Veh to *Sphk2* mice, PCr and BUN were measured, and kidneys were analyzed for fibrosis by picrosirius red staining and by qPCR for expression of fibrotic markers.

Results: After bilateral IRI, in *S1P1KO* mice PCr was lower than in WT (0.91 vs. 0.55). After FA, in *S1P1KO* mice PCr was lower (0.78 vs. 0.23 mg/dl, $p<0.05$), as was ATN score (78.6 vs. 53.6%, $p<0.05$), Kim1 (0.63 vs. 0.33 $p<0.01$) and Ngal (0.85 vs. 0.50, $p<0.05$). There was no difference between Sphk2KO and its WT control in PCr, BUN, *Kim-1, Ngal* or histology (days 1-3). However, by day 14, FA-treated *Sphk2KO* mice had less fibrosis (by histology), smaller increases in BUN (39.6 vs. 55.5 mg/dL, $p<0.05$), and smaller increases in expression of fibrosis-related genes (Col1a1, Col3a1, Acta2, fibronectin, and vimentin) than WT control mice.

Conclusions: These divergent results suggest that: 1) sphingolipid signaling through *SphK2* and *S1P1* in perivascular cells is critical in controlling the phenotype in AKI and CKD and 2) controlling intracellular S1P through sphingosine kinases and extracellular *S1P1* may serve as specific therapeutic targets in both AKI and AKI-CKD transition.

TH-PO086

Neutrophil Depletion Alters Macrophage (Mo) Phenotype and Modulates Inflammation in Unilateral Ureteral Obstructed (UUO) Kidney

Siddhartha S. Ghosh,[1] Austin J. Gonzalez,[2] Richard Krieg,[3] Todd W. Gehr.[2] *[1]VCU Medical Ctr, Richmond, VA; [2]Virginia Commonwealth University, Fredericksburg, VA; [3]VCU, Richmond, VA.*

Background: UUO is a model to study inflammation and fibrosis in the kidney. Neutrophils (Neu) are the first line of defense in response to injury. Mo closely coordinate with Neu to regulate inflammation. This study investigated if neutrophil depletion can alter macrophage infiltration and inflammation in UUO fibrosis.

Methods: UUO surgery was done by the method adapted from the Vanderbilt O'Brien Center. Neutrophil depletion was done by injecting clone 1A8 to a cohort of five mice labeled (ND), 3 days pre and 2 days post UUO. An equal number of mice underwent UUO but did not receive any treatment (UT). Contralateral kidneys were used as control (C). Mice were sacrificed 3 days and 10 days after UUO. Neu, Mo, and macrophage phenotype M1 and M2 were determined by flow cytometry. Inflammation markers MCP1, IL1β, and fibrosis marker α-smooth muscle actin (SMA) were assessed by immunoblot.

Results: There was no significant influx of Mo and trace levels of inflammatory markers in C, hence comparison was made between ND and UT. 3 days after UUO, Neu levels in the blood and kidney of UT were 28% and 60% respectively. In contrast, Neu levels in ND blood and kidney was <1% and <12% respectively, suggesting significant neutrophil depletion. 3 Day UUO: Mo influx in the kidney of ND was significantly lower than UT. The M1 phenotype in UT was 1.5 fold higher ($p<0.05$) and M2 phenotype was 2 fold lower than ND ($p<0.05$). Kidney MCP-1 and IL-1β of UT was 3 fold ($p<0.01$) and 2.5 fold ($p<0.01$) higher than ND, respectively. Kidney SMA was not significantly altered between the groups. 10-day UUO: The M1 phenotype in UT was still 1.5 fold higher ($p<0.05$) than ND but the difference in M2 phenotype between UT and ND was not significant. MCP-1 and IL-1β were 2 and 1.5 ($p<0.05$) fold higher in UT, suggesting sustained inflammation in UT. SMA levels in the ND kidney were 1.8 fold higher than UT but was not statistically significant.

Conclusions: Chronic inflammation frequently leads to fibrosis, however, the mechanisms are not clearly understood. In the ND cohort the decrease in M1 phenotype (thought to be proinflammatory) and increase in M2 (reparative type) following neutrophil depletion can explain the reduced inflammation but not fibrosis. This suggests controlling inflammation at an early stage may not positively modulate fibrosis.

TH-PO087

Selenoprotein-T Exerts a Protective Role in Cisplatin-Induced AKI by Suppression of ER Stress

Hua Su, Chun Zhang. *Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

Background: Selenium (Se) is an essential trace element with important roles in human health. Acute kidney injury (AKI) as well as chronic kidney disease are often associated with low serum and tissue levels of Se. Se is incorporated with a wide range of Se-dependent enzymes, also known as selenoproteins, at its active site. Selenoprotein-T (Sel-T), a member of the selenoprotein family, is a novel thioredoxin-like enzyme. However, it's role, especially in ER stress, during renal disease remains unexplored. In this study, we aim to explore the role of Sel-T in the pathogenesis of cisplatin-induced AKI.

Methods: Twenty C57 mice were randomly divided into four groups (n=8-10): sham, AKI-1d, AKI-2d and AKI-4d. Western blot or immunohistochemistry was used to detect the expression of Sel-T, NGAL, cleaved-caspase-3, caspase-12, Bax, Bcl-2 and GRP78. In vitro, NRK-52E cells were exposed to cisplatin (20uM) for 6h, 12h and 24h respectively. Lentivirus transfection or non-specific Sel-T agonists, PACAP and db-cAMP, were utilized to regulate Sel-T before cisplatin stimuli. Flow cytometry and commercial kit were adopted individually for apoptosis and ROS detection.

Results: Comparing to sham groups, the expression of Sel-T was significantly down-regulated in the AKI-4d group. Meanwhile, the levels of NGAL, cleaved-caspase-3 and Bax were increased with the reduction of Bcl-2. Consistently, in vitro Sel-T was lessened, especially after 24h of cisplatin exposure. And Sel-T deficiency aggravated cisplatin induced ER-stress as well as cell apoptosis and ROS generation in NRK-52E cells. Pretreatment of non-specific Sel-T agonists ameliorated the ER stress in cisplatin group.

Conclusions: Sel-T deficiency is occurred in cisplatin-induced AKI in which ER stress-associated apoptosis and oxidative stress are the underlying mechanisms. Hopefully, Sel-T agonists may be effective remedies for cisplatin-induced AKI.

TH-PO088

TGF-β Promotes Fibrosis After Severe AKI by Enhancing Renal Macrophage Infiltration

Sungjin Chung,[2,1] Jessica M. Overstreet,[2] Yan Li,[2] Yinqiu Wang,[2] Aolei Niu,[2] Leslie S. Gewin,[2] Ming-Zhi Zhang,[2] Raymond C. Harris.[2] *[1]The Catholic University of Korea College of Medicine, Seoul, Republic of Korea; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: TGF-β, a central mediator of renal fibrosis, signals through a heterotetrameric receptor complex composed of two type I and two type II transmembrane subunits. Although macrophages are implicated as mediators of renal fibrosis and produce TGF-β1, macrophage TGF-β1 deletion did not prevent fibrosis after severe renal I/R injury. The current studies investigated the role of macrophage TGF-β signaling in post AKI fibrosis.

Methods: Male C57BL/6 wild type (WT, $Tgfbr2^{f/f}$) or LysM-Cre;$Tgfbr2^{f/f}$ ($TGF\beta RII^{-/-}$) mice underwent uninephrectomy plus 29 min renal I/R and were sacrificed after 4 weeks. Both in vitro and in vivo chemotaxis assays were performed.

Results: At 4 weeks after injury, there was increased renal expression of TGF-ß1 and tubulointerstitial fibrosis in WT mice. TGFßRII-/- mice had markedly decreased renal fibrosis and decreased renal macrophages. TGF-ß is a potent chemoattractant. The *in vitro* chemotactic response to a known chemotaxin, f-Met-Leu-Phe, was not different between isolated bone marrow monocytes (BMMs) from WT and TGFßRII-/- mice. Although TGF-ß was also a potent chemoattractant to WT BMMs, TGFßRII-/- BMMs did not respond. The SMAD inhibitor, SIS3, markedly inhibited the chemotactic response to TGF-ß in WT BMMs, but had minimal effect in TGFßRII-/- BMMs. To confirm these findings in an *in vivo* setting, we utilized a chemotaxis assay using matrigel plugs. Matrigel suffused with either f-Met-Leu-Phe or TGF-ß1 was injected subcutaneously into the subscapular regions of WT or TGFßRII-/- mice. After 6 days, f-Met-Leu-Phe induced equal numbers of macrophage infiltration into the matrigel plugs of WT and TGFßRII-/- mice. TGF-ß also induced matrigel macrophage infiltration in WT mice but not in TGFßRII-/- mice. To determine macrophage infiltration into post AKI kidneys, we determined the number of PKH26 labeled BMMs infiltrating into WT kidneys for 3 days 12 days after AKI. There were significantly more PKH26 labeled WT BMMs than TGFßRII-/- BMMs.

Conclusions: Macrophage TGFßRII deletion protects against the development of tubulointerstitial fibrosis following severe ischemic renal injury. Chemoattraction of macrophage to the injured kidney through a TGF-β/TGFßRII axis is a heretofore undescribed mechanism by which TGF-ß can mediate renal fibrosis during progressive renal injury.

TH-PO089

Inhibition of H3K4 Trimethylation Attenuates Renal Senescence in Mice with Ischemic Reperfusion Injury

Hironori Shimoda, Shigehiro Doi, Ayumu Nakashima, Takao Masaki. *Hiroshima University Hospital, Hiroshima, Japan.*

Background: Renal senescence is induced by not only aging, but also various stimuli, and plays important roles in the development of renal inflammation and fibrosis. Recently, accumulation of $p16^{INK4a}$-positive cells in the kidney has been considered a molecular feature of renal senescence, which is regulated by Mixed-lineage leukemia 1 (MLL1)/WD-40 repeat protein 5 (WDR5)-mediated histone 3 lysine 4 trimethylation (H3K4me3). In this study, we investigated whether MLL1/WDR5 complex inhibitor MM-102 attenuates renal senescence together with renal inflammation and fibrosis in ischemic reperfusion injury (IRI) mice and cultured renal fibroblasts.

Methods: Male C57BL/6 mice were subjected to IRI (renal pedicle was clamped for 30 minutes), and administered MM-102 every 24 hours for 7 days postoperatively. Expression of MLL1, WDR5, H3K4me3, and $p16^{INK4a}$ was examined by western blotting and immunohistochemistry. Senescence-associated β-galactosidase (SA-β-gal) staining was performed as a senescence marker. Renal fibrosis was examined by the expression of transforming growth factor (TGF)-β1, α-smooth muscle actin (αSMA), and collagens. The effect of MM-102 on inflammation was investigated by the expression of nuclear factor-κB (NF-κB), interleukin-1β (IL-1β), interleukin-6 (IL-6), tumor necrosis factor α (TNFα), and CD11b. For the *in vitro* study, TGF-β1-stimulated normal renal fibroblasts with and without MM-102 preincubation were examined for expression of MLL1, WDR5, H3K4me3, and $p16^{INK4a}$. Chromatin immunoprecipitation assays were performed to clarify the status of $p16^{INK4a}$ gene promoter as an H3K4me3-enrichment region.

Results: MM-102 suppressed expression of $p16^{INK4a}$ and β-gal in IRI mice, accompanied by decreased expression of MLL1 and WDR5 as well as H3K4me3. MM-102 also attenuated renal fibrosis and inflammation in the kidneys of IRI mice. In the *in vitro* study, TGF-β1 induced expression of MLL1, WDR5, H3K4me3 and $p16^{INK4a}$. Finally, the $p16^{INK4a}$ promoter was revealed to be an H3K4me3 site in renal fibroblasts.

Conclusions: The MLL1/WDR5 inhibitor MM-102 ameliorates IRI-induced renal senescence together with renal fibrosis and inflammation through a reduction in H3K4me3.

Funding: Government Support - Non-U.S.

Long-Term Sequelae of AKI: A Year-Long Male and Female Murine Model

Danielle Soranno,[1] Sarah Faubel.[2] *[1]Pediatrics, Medicine and Bioengineering, University of Colorado, Aurora, CO; [2]University of Colorado Denver, Denver, CO.*

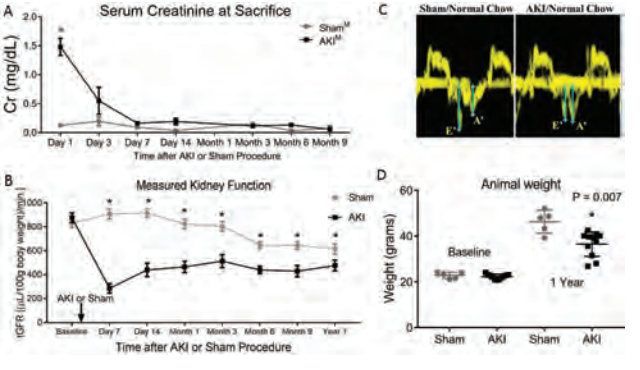
Background: There is growing appreciation that acute kidney injury (AKI) leads to systemic sequelae as well as chronic kidney disease (CKD), however most murine models of disease evaluate AKI and CKD as distinct entities, thus limiting their translational value. Herein, we performed a 1 year study of male and female BLK6 mice to determine the long-term renal and systemic sequelae of AKI.

Methods: Male and female adult BLK6 mice underwent bilateral ischemia reperfusion injury or sham procedure. Female mice underwent longer clamp times (34 min compared to 24 min) to overcome the protective effects of estrogen. Renal and systemic outcomes were tracked longitudinally in the males (1, 3, 7, 14 days, 1, 3, 6, 9, and 12 months) and at 12 months in the females.

Results: Measurements of glomerular filtration rate (tGFR), systemic inflammation, and diastolic dysfunction remained abnormal for the duration of the study.

Conclusions: Despite early normalization of serum and urine biomarkers of renal function, long-term renal and systemic sequelae were evident in both the male and female cohorts following AKI.

Funding: Private Foundation Support



Representative data from the male cohort of AKI vs sham. (A) serum creatinine normalizes within several days following bilateral ischemia-reperfusion injury. (B) Measured transcutaneous glomerular filtration rate (tGFR) remains persistently low in the AKI group compared to sham. (C) Echocardiography demonstrates diastolic dysfunction with inversion of A' E' following AKI. (D) 1 year after AKI, mice weigh less than mice that underwent sham procedure.

AKI to CKD Transition After Acute Cardiorenal Syndrome in the Mouse

Katsuyuki Matsushita,[1] Turgay Saritas,[1] James A. McCormick,[1] Michael Hutchens.[2,1] *[1]Oregon Health & Science University, Portland, OR; [2]Portland VA Medical Center, Portland, OR.*

Background: Acute cardiorenal syndrome (CRS type 1, CRS1) is an common cause of acute kidney injury (AKI) with high mortality and significant potential to transition to chronic kidney disease (CKD). Mechanistic data from translational models is lacking. We report AKI-to-CKD transition following CRS1 in a mouse model, accompanied by long-term renal inflammation.

Methods: CRS1 was modeled in male C57BL/6 mice (n=16) using potassium-induced 8 minute cardiac arrest followed by cardiopulmonary resuscitation (CA/CPR) and compared with sham (n=8). α-smooth muscle antibody, KIM-1, cleaved caspase-3, Ki-67, macrophage F4/80, and CD3 were quantified from immunohistology 1, 7, 14, and 60 days later. Glomerular filtration rate (GFR) was measured by FITC-sinistrin transcutaneous clearance and serum urea nitrogen by autoanalyzer.

Results: Sham survival was 100%. 24h survival after CA/CPR was 100% and 60 day survival was 88%. CA/CPR induced severe AKI with near-zero GFR at 24h, and early macrophage infiltration demonstrated by robust F4/80 signal. 7 days after CA/CPR, KIM-1, F4/80, and CD3 revealed severe tubular injury, predominantly of proximal tubules, and inflammation with extensive cell proliferation, although GFR was recovering. At 14 days, GFR had normalized, but at 60 days GFR was again significantly below baseline, accompanied by elevated serum urea nitrogen, continued macrophage and t-cell infiltrate, apoptotic cell death, and widespread tubulointerstitial fibrosis.

Conclusions: Acute cardiorenal syndrome induces extensive tubular injury and inflammation in the renal cortex and outer medulla which progresses to renal fibrosis and chronic kidney disease despite initial functional recovery. We present a clinically relevant mouse model of AKI-CKD transition which we expect to provide insight into the the mechanisms underlying renal sequelae of cardiac arrest.

Binding of Cell Surface Carboxypeptidase M Contributes to Tubulo-Protective Effects of Fibrinopeptide Bß15-42

Inga Soerensen-Zender, Song Rong, Sascha David, Hermann G. Haller, Roland Schmitt. *Hannover Medical School, Hannover, Germany.*

Background: Acute and chronic kidney disease is often associated with activation of the coagulation cascade and with parallel activation of the fibrinolytic system. During fibrinolysis the peptide Bβ15-42 is cleaved off the end of the fibrin Bβ chain. Previous studies have demonstrated a protective effect of Bβ15-42 in sepsis, myocardial infarction and renal ischemia/reperfusion. The responsible molecular mechanism was attributed to binding of Bβ15-42 to endothelial VE-cadherin. Our preliminary work had shown that Bβ15-42 also has a direct protective effect on renal tubular cells. It was the goal of the present study to clarify this VE-cadherin independent mechanism.

Methods: Repetitive doses of Bβ15-42 (3 mg / kg i.v.) or control peptide were tested in vivo in unilateral ureteral obstruction (UUO) and in aristolochic acid nephropathy (AAN). Kidneys were examined at different time points by histomorphology and damage marker expression. In vitro, renal tubular cells were stressed by AA or staurosporine before treatment with Bβ15-42 or control peptide. Target proteins were knocked-down by siRNA and cell damage was quantified by LDH release and qPCR. Bβ15-42 binding partners were identified by ligand-receptor capture (LRC) technology LRC-TriCEPS. Carboxypeptidase M activity was measured by Dansyl-Ala-Arg-OH trifluoroacetate assay.

Results: In vivo, Bβ15-42 improved the tubular damage pattern after induction of AAN and after UUO. To identify potential new Bβ15-42 interaction partners on tubular cells, we used LRC-TriCEPS and found the membrane protein carboxypeptidase M (CBPM) as a highly specific binding partner. Despite its strong tubular expression the physiological role of renal CBPM which modifies a variety of candidate signal peptides by C-terminal cleavage is unknown. CBPM enzymatic activity was significantly inhibited by Bβ15-42, both in vitro and in vivo. Knockdown of CBPM by siRNA resulted in a marked reduction in the protective effect of Bβ15-42.

Conclusions: The fibrinopeptide Bβ15-42 has a direct protective effect on tubular epithelial cells, which is largely determined by binding to CBPM and inhibition of CBPM enzymatic activity. Our results show a novel mode of action for Bβ15-42 and suggest that CBPM may represent a new target that can be used therapeutically for nephroprotection.

TH-PO093

Loss of Proximal Tubular Krüppel-Like Factor 6 Is Protective Against Renal Injury

Sian Piret,[1] Yiqing Guo,[1] Monica P. Revelo Penafiel,[3] Sandeep K. Mallipattu.[2] *[1]Stony Brook University, Oyster Bay, NY; [2]Stony Brook Medicine, Stony Brook, NY; [3]University of Utah, Murray, UT.*

Background: Transcriptional regulators of DNA-damage pathways leading to kidney fibrosis are relatively unknown. Krüppel-like factor 6 (KLF6), a zinc finger transcription factor, has diverse roles in various tissues. KLF6 is highly expressed in the proximal tubule (PT) and upregulated in renal ischemia-reperfusion injury and sepsis models, but its specific role in PT DNA damage and tubulointerstitial fibrosis is unknown. Our aim was to investigate the role of PT KLF6 in the setting of DNA damage, using the PT-specific DNA damaging toxin aristolochic acid I (AAI).

Methods: PT-specific *Klf6* knockdown (*Klf6^{PTKO}*) mice were generated by breeding *Klf6$^{fl/fl}$* and *Pepck*-Cre mice. *Klf6$^{fl/fl}$* littermates were used as controls. Mice were given 3mg/kg AAI or vehicle DMSO i.p. every 3 days for 3 weeks (active phase), followed by 3 weeks without injections (remodeling phase), and euthanized. Renal damage was assessed by: serum creatinine and urea nitrogen (SUN); histology (H&E, PAS and trichrome staining with blinded scoring for inflammation and fibrosis); IF for deposition of collagen 1A1 (COL1A1); and qRT-PCR for vimentin and E-cadherin expression. RNA-Seq was undertaken in active and remodeling phase samples. Data were analyzed using ANOVA with corrections for multiple comparisons.

Results: AAI caused renal damage and significantly increased serum creatinine and SUN in all mice. These were significantly lower in *Klf6^{PTKO}* mice versus *Klf6$^{fl/fl}$* mice in the acute phase, with lower vimentin expression, and preserved PT area and E-cadherin expression. In the remodeling phase, *Klf6^{PTKO}* kidneys had maintained weight, preserved PT area and less inflammation, fibrosis, COL1A1 deposition and vimentin expression, compared to *Klf6$^{fl/fl}$* kidneys. RNA-Seq combined with ENCODE ChIP-Seq data showed that many integrin signaling components that contribute to fibrosis were upregulated by AAI in *Klf6$^{fl/fl}$* mice, which was reversed in *Klf6^{PTKO}* mice with AAI, and contain KLF6 binding sites. Likely protective genes were upregulated by AAI and upregulated further in *Klf6^{PTKO}* mice, e.g. Gas6, which has a predicted KLF6 binding site.

Conclusions: PT-specific loss of KLF6 protects against renal injury and fibrosis in the setting of DNA damage. This may have relevance for DNA damaging nephrotoxic chemotherapeutic drugs e.g. cisplatin.

TH-PO094

Using Transdermal Measurement of GFR to Evaluate Long-Term Outcomes in Mouse Models of AKI

Lauren N. Scarfe, Charlene Finney, Anna Menshikh, Rachel Delgado, Mark P. de Caestecker. *Vanderbilt University Medical Center, Nashville, TN.*

Background: There are no specific treatments for patients with acute kidney injury (AKI). In part this relates to the preclinical studies that have been used to assess therapeutic efficacy: these are often short-term studies, commonly using cisplatin or ischemia reperfusion (IR) injury. However, to identify target populations with meaningful long-term outcomes, therapeutic efficacy should be tested in a range of models over longer periods, including the long-term effects of therapy on the development of progressive chronic kidney disease (CKD) after episodes of AKI.

Methods: We established a range of mouse models of AKI that reflect the diverse injuries seen in human AKI and allow long-term functional analyses of CKD progression: 1) unilateral IR with a delayed contralateral nephrectomy (Nx), modeling profound renal hypoperfusion; 2) repeat-dosing cisplatin, modeling the injury in patients receiving cisplatin chemotherapy; 3) reversible UUO with delayed contralateral Nx, modeling the relief of urinary obstruction; and 4) rhabdomyolysis, modeling crush injury, sepsis and cardiopulmonary bypass-associated AKI. We are currently developing new models in female and diabetic mice, to recapitulate more complex clinical scenarios. To evaluate the effects of these injuries on CKD progression, we used transdermal monitors to assess glomerular filtration rate (GFR) in conscious mice by detecting the clearance of exogenous FITC-sinistrin through the skin 26-46 days after the initial injury.

Results: Here, we present for the first time, data on the long-term effects of AKI on GFR in multiple mouse models of AKI. GFR was significantly reduced in several models, but not in the rhabdomyolysis model (Table).

Conclusions: We have assessed the use of transdermal GFR measurement in a range of mouse models of AKI. This method of assessing renal function is more clinically relevant than standard methods and will be useful for preclinical efficacy testing of novel therapeutics on long-term renal outcomes in mouse models of AKI.

Funding: NIDDK Support, Other U.S. Government Support

Transdermal GFR measurement in a range of mouse models of AKI

Injury Model	Mean GFR (µl/min)		p-value

Myo-Inositol Oxygenase Promotes Ferroptosis in Cisplatin-Induced AKI

Fei Deng,[2] Isha Sharma,[3] Lin Sun,[4] Yashpal S. Kanwar.[1] *[1]Northwestern University Medical School, Chicago, IL; [2]Northwestern University, Chicago, IL; [3]Northwestern University, Chicago, IL; [4]Second Xiangya Hospital Central South University, Changsha, China.*

Background: Over-expression of myo-inositol oxygenase (MIOX), a kidney tubular specific enzyme, exacerbates renal redox injury in cisplatin-induced AKI. Recently, a newly coined term, i.e., ferroptosis, has been reported, which is closely associated with lipid peroxidation and it plays a significant role in the pathogenesis of AKI. Whether or not MIOX exacerbates tubular damage by accelerating ferroptosis in cisplatin-induced AKI needs to be investigated.

Methods: CD1 mice were subjected to intraperitoneal cisplatin injection with or without Fer-1, a potent ferroptosis inhibitor. Samples were collected for various studies three days later.

Results: Fer-1 substantially decreased the blood creatinine and urine protein excretion, and ameliorated renal pathological changes in cisplatin-treated mice. Wild-type (WT) mice, MIOX-overexpressing transgenic (MIOX-TG) mice and MIOX-Null (MIOX-KO) mice were injected with cisplatin. In comparison to cisplatin-treated WT mice, MIOX-TG mice had a relatively greater increase in blood creatinine and urine protein excretion, and severe renal pathological changes. These perturbations were minimal in cisplatin-treated MIOX-KO mice. Various ferroptosis metabolic sensors, including lipid peroxidation, GPX4 activity, NADPH, GSH, ferritinophage, mitochondrial deformation and lysosomal permeability, had undergone severe perturbations in MIOX-TG compared to WT mice, and these were not observed in MIOX-KO mice. In vitro studies revealed that cisplatin-induced HK-2 cell death was considerably reduced by Fer-1, DFO (iron cleator), and VAD (apoptosis inhibitor), but not by Nec-1 (necroptosis inhibitor). Also, cisplatin-treated HK-2 cells had severe perturbations in ferroptosis metabolic sensors, which were further accentuated by transfection of MIOX-pcDNA, while ameliorated by MIOX-siRNA.

Conclusions: In conclusion, these findings indicate that ferroptosis, conceivably integral to the pathogenesis of cisplatin-induced AKI, is modulated by the expression of MIOX.

Cisplatin-Induced AKI Is Attenuated in Hepatic Sulfotransferase (Sult) 1a1-Deficient Mice by Suppressing Production of Indoxyl Sulfate (IS) and Oxidative Stress

Rika Fujino,[1] Keisuke Matsushita,[2] Nao Gunda,[2] Hirofumi Jono,[1,2] Hideyuki Saito.[1,2] *[1]Pharmacy, Kumamoto University Hospital, Kumamoto, Japan; [2]Kumamoto University Graduate School of Pharmaceutical Sciences, Kumamoto, Japan.*

Background: The toxicological process leading to cisplatin-induced AKI is caused by several mechanisms, including inflammatory responses, oxidative stress and apoptosis in renal tubules. We have reported that IS, a sulfate-conjugated uremic solute, accumulates extensively in serum and kidney of animal models of cisplatin AKI. IS is derived from the liver through metabolic process by hepatic CYP2A6/2E1 and Sult1a1, however, pathophysiological role of Sult1a1 in cisplatin AKI has not been elucidated. We generated the Sult1a1 gene-deficient mice (Sult1a1$^{-/-}$), and evaluated the toxico-pharmacological role of IS in cisplatin AKI.

Methods: C57BL/6 mice (WT) and Sult1a1$^{-/-}$ were treated with cisplatin (20 mg/kg) by intraperitoneal injection. In additional experiments, Sult1a1$^{-/-}$ were treated with IS after cisplatin administration. Gene expression of Sult1a1 and other Sult species were determined by qRT-PCR. IS and indoxyl-β-D-glucuronide (IG) levels were determined by LC-MS/MS. Accumulation of IS and 4-hydroxy-2-nonenal (4-HNE), an oxidative stress marker, in renal tissue were examined immunohistochemically. BUN, serum creatinine, Kim-1 and Ngal were determined. Cisplatin concentration in serum and kidney was measured as the ^{194}Pt levels using ICP-MS.

Results: Sult1a1 mRNA expression was not detected in the liver of Sult1a1$^{-/-}$, and was significantly elevated (5.9-fold) in WT liver with cisplatin AKI, whereas mRNA expression of other Sult gene family members were not significantly differed between WT and Sult1a1$^{-/-}$ after cisplatin treatment. In cisplatin-treated Sult1a1$^{-/-}$, kidney injury markers, renal IS level and 4-HNE accumulation were markedly reduced compared with those in WT kidney. IG concentrations in serum and kidney were elevated in cisplatin-treated Sult1a1$^{-/-}$, suggesting that glucuronidation serves as an alternative detoxification pathway for indoxyl. Administration of IS to cisplatin-treated Sult1a1$^{-/-}$ reproduced severe AKI as observed in WT. Renal accumulation of ^{194}Pt showed no significant difference between Sult1a1$^{-/-}$ and WT.

Conclusions: IS could be one of exacerbation factors in cisplatin AKI by accelerating oxidative stress. Hepatic Sult1a1 was the enzyme responsible for deriving IS, suggesting a potent preventive target for cisplatin nephropathy.

MUTYH, a DNA Repair Enzyme, Protects Against Cisplatin-Induced AKI

Aihua Zhang, Yunwen Yang, Yue Zhang, Guixia Ding, Songming Huang, Zhanjun Jia. *Children's Hospital of Nanjing Medical University, Nanjing, China.*

Background: MutY homolog (MUTYH) is a DNA Repair Enzyme and plays a key role in base excision repair (BER) for mitochondria (type I MUTYH works for mitochondrial DNA repair) and nuclear genome (type II MUTYH works for nuclear DNA repair). The current study aimed to evaluate the role of MUTYH in cisplatin-induced acute kidney injury.

Methods: *In Vivo*, Male MUTYH-/- mice and littermate WT controls were treated with cisplatin (20 mg/kg, ip). *In vitro*, mouse proximal tubular cells (mPTCs) with stable overexpression of MUTYH I or II were treated with cisplatin (5 mg/mL).

Results: In WT mice, cisplatin strikingly reduced MUTYH protein expression by 40%. MUTYH deficiency aggravated cisplatin-induced renal dysfunction (Scr: MUTYH -/- 112.5±18.8 vs. WT 33.60±9.14 mM, p<0.01; BUN: MUTYH -/- 67.65±4.0 vs. WT 37.83±4.99 mM p<0.01). Meanwhile, the renal tubular injury markers of KIM-1 and NGAL in MUTYH -/- mice were also further enhance by 191% and 94.11%, respectively, as compared with the WT mice after cisplatin treatment. The levels of cleaved caspase-3 and the number of TUNEL-positive cells in the kidneys of cisplatin-treated MUTYH-/- mice were higher than those in the kidneys of WT mice, showing the aggravated apoptotic response. Moreover, MUTYH deficiency resulted in the accumulation of 8-OHdG (indicating more severe DNA damage) and the aggravation of mitochondrial dysfunction. *In vitro*, Overexpression of type II MUTYH strikingly ameliorated cell apoptosis and oxidative stress induced by cisplatin, while MUTYH I overexpression showed a marginal role against cisplatin-induced cell injury.

Conclusions: MUTYH II but not MUTYH I played a significant role in protecting against cisplatin-induced acute kidney injury. Targeting type II MUTYH could be a promising strategy for the treatment of AKI.

TH-PO098

Treatment of Cisplatin-Induced AKI with Renal Selective Nanotherapy

Edgar A. Jaimes,[1] Ryan M. Williams,[2] Elizabeth Mercer,[3] Daniel A. Heller.[2] *[1]Memorial Sloan-Kettering Cancer Center, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY; [3]Indiana University School of Medicine, Evansville, IN.*

Background: Acute kidney injury (AKI) occurs in up to 30% of patients treated with cisplatin and up to 25% of patients in intensive care. AKI is linked to increased morbidity and mortality. Unfortunately there are no effective interventions for the treatment or prevention of AKI in humans. In prior work, we developed mesoscale nanoparticles (MNPs) that selectively localize to the kidneys primarily to the proximal tubular epithelium. We hypothesize that these MNPs can be used a delivery platform of small molecules for the treatment of AKI.

Methods: We synthesized nanoparticles from poly(lactic-*co*-glycolic acid) and polyethylene glycol (PLGA-PEG) which were encapsulated with the reactive oxygen species scavenger edaravone. The particles are approximately 400 nm in diameter with a negative surface charge. AKI was induced wit cisplatin induction (25 mg/kg IP) followed by intravenous injection of therapeutic MNPs (50mg/kg) loaded with edaravone(3.9 mcg/100 mg MNP) or the free drug alone 24 hours after induction of AKI. Mice were sacrificed after 72 hours.

Results: Compared to cisplatin alone, mice treated with drug-encapsulating MNPs had a significant reduction in serum creatinine. We stained for the renal injury marker NGAL, DNA-damage induced protein p53, TUNEL for apoptosis, and nitrotyrosine for oxidative stress. In each, we found significantly increased injury and staining in mice with cisplatin alone or cisplatin plus dose-matched free drug, with reduced or baseline levels in mice receiving therapeutic MNPs.

Conclusions: These studies demonstrate the therapeutic efficacy of our MNP as a delivery system of drugs to the proximal tubules for the treatment of cisplatin induced AKI. This approach may result in the development of novel therapeutic strategies for patients affected by AKI of different etiologies.

TH-PO099

C-Terminal Binding Protein 2 (CtBP2), a NADH-Dependent Transcription Regulator Contributes to Renal Cell Dysfunction and AKI

Ji Young Kim, Yuntao Bai, Laura A. Jayne, Navjotsingh P. Pabla. *The Ohio State University, Columbus, OH.*

Background: Worldwide, acute kidney injury (AKI) occurs in more than 13 million patients annually. AKI is associated with high short-term morbidity, a long-term risk of chronic kidney disease (CKD) as well as adverse cardiovascular events. Mechanistically, renal tubular cell dysfunction and cell death is the hallmark and the underlying cause of AKI. However, the transcriptional regulators that control shifts in epithelial cell gene expression that triggers renal tubular cell death and dysfunction remain underexplored. Here we have examined the role of NADH-dependent transcription regulator C-terminal binding protein 2 (CtBP2) in the pathogenesis of AKI.

Methods: We have used three AKI-associated mouse models, namely cisplatin nephrotoxicity (30 mg/kg, i.p.), rhabdomyolysis (50% glycerol, 7.5 ml/kg, i.m.) and ischemia reperfusion injury (30 bilateral ischemia) and determined the mRNA and protein expression of CtBP2 during kidney injury. Furthermore, we have examined the effect of CtBP2 inhibition on AKI by using a pharmacological inhibitor (MTOB) and CtBP2-specific siRNA knockdown (hydrodynamic intravenous injection). Finally, to uncover the associated mechanisms, we carried out chromatin-immuno-precipitation (ChIP) experiments and gene expression analysis to identify CtBP2 target genes in renal epithelial cells.

Results: Renal protein expression analysis showed that CtBP2 levels are very low in normal murine kidneys. However during the early phase of cisplatin, ischemia or rhabdomyolysis induced AKI, there is a striking increase in CtBP2 protein expression in renal epithelial cells. Functional *in vivo* studies showed that pharmacological or genetic inhibition of CtBP2 function significantly mitigates renal impairment (BUN, Serum Creatinine and renal damage score, Control vs. CtBP2 inhibition group, $p>0.05$) in all the three mouse models of AKI. Through ChIP and RNA expression analysis, we have identified a CtBP2 target gene expression signature that likely contributes to renal dysfunction associated with AKI.

Conclusions: Here we have identified CtBP2 as an essential regulator of renal dysfunction and AKI. Future development of CtBP2 targeting small molecules could provide a therapeutic strategy for the prevention or treatment of AKI.

TH-PO100

PGC1α in Complex Models of AKI

Mei T. Tran, Samir M. Parikh. *Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Acute kidney injury (AKI) in patients is often complex, arising in the context of background chronic kidney disease (CKD) or even recent AKI from a different etiology. In experimental models of simple AKI, we have identified a critical role for the mitochondrial biogenesis regulator PPAR-γ coactivator-1α (PGC1α) in resistance to and recovery from AKI. Renal PGC1α expression is markedly reduced in both septic and post-ischemic mice. And PGC1α knockout (KO) mice suffer worse renal function and overall survival after transient renal ischemia, whereas PGC1α induction in the renal tubule improves AKI recovery and survival. The potential role for PGC1α in a more translatable "multi-hit" experimental model of AKI, however, remains unexplored.

Methods: 1st AKI insult: PGC1α KO and WT mice underwent 15 minutes of bilateral renal ischemia. Serum creatinine measurements were collected at 24 hours, 1 month, and 6 months after ischemia reperfusion injury (IRI). 2nd AKI insult: Six months following the initial renal IRI, mice were administered cisplatin (intraperitoneal, 10 mg/kg), then monitored for 72 hours post-injection.

Results: PGC1α KO mice exhibited increased serum creatinine relative to WT littermates at 24 hours after IRI. At 1 month and 6 months post-IRI, creatinine in both genotypes had recovered to normal levels. However, 6-month survival in KO mice was 83% compared to 100% survival in WT mice. Within 48 hours of the second AKI insult, survival was 33% in KO versus 75% in WT.

Conclusions: PGC1α may impact both kidney function and overall survival after AKI. Despite KO survivors of the initial AKI insult recovering to indistinguishable and normal serum creatinine as compared to control littermates, PGC1α KO mice suffered worse outcomes after the second insult. The results suggest that PGC1α, and by extension mitochondrial homeostasis, may have important effects on the renal response to cumulative insults. Given the increasingly appreciated connections between AKI and CKD, models of repeated AKI may illuminate mechanisms of transition from acute insult to chronic impairment.

Dysregulated Tubular Autophagy Promotes Maladaptive Kidney Repair and Interstitial Fibrosis During AKI-CKD Transition

Man J. Livingston, Zheng Dong. *Augusta University Medical College of Georgia, Augusta, GA.*

Background: Tubular cell injury is a key pathological feature of AKI. Renal tubules have the capacity to regenerate after injury, but kidney repair following severe AKI is often incomplete, leading to interstitial fibrosis and CKD. The mechanisms underlying AKI-CKD transition are poorly understood. Autophagy is induced in tubular cells during AKI and protects against injury. Recent work further reveals a profibrotic role of tubular autophagy in UUO. However, the role of autophagy in kidney repair and fibrosis after AKI remains unknown.

Methods: We established an inducible, conditional knockout mouse model where *Atg7* can be ablated specifically from renal tubules at a desired time. Using this model we examined the role of tubular autophagy in the development of chronic renal pathologies after ischemic AKI.

Results: Mice underwent 30-min unilateral renal ischemia followed by reperfusion for up to 4 wks. Autophagy was persistently activated in proximal tubules of post-ischemic kidneys, as indicated by LC3-II accumulation and increased formation of both autophagosomes and autolysosomes. We generated a doxycycline-inducible, renal tubule-specific *Atg7* knockout mouse model (i*Atg7* KO) where *Atg7* was specifically deleted from renal tubules only during the recovery phase after AKI without affecting initial injury. The inducible *Atg7* KO blocked autophagy in renal tubules and also suppressed post-ischemic fibrosis. Proliferation and activation of fibroblasts was inhibited in i*Atg7* KO mice, so was the accumulation of ECM components. Wild-type (WT) mice had 10.1% interstitial fibrosis 2-wk after AKI and 17.5% at 4-wk, which were reduced to 6.7% at 2-wk and 9.9% at 4-wk respectively in i*Atg7* KO mice. AKI in WT mice led to decreased staining of brush border marker LTL and increased expression of vimentin in renal tubules indicating tubular degeneration, which were reversed in i*Atg7* KO mice. Renal tubules in WT mice displayed remarkable senescent changes after ischemic AKI, which were significantly attenuated by autophagy deficiency. Under these conditions, G_2/M cell cycle arrest was also induced in renal tubules of WT but suppressed in i*Atg7* KO kidneys.

Conclusions: These results suggest that autophagy in renal tubules may contribute to maladaptive kidney repair during AKI-CKD transition by promoting interstitial fibrosis via tubular atrophy, senescence, and cell cycle arrest.

TH-PO102

Metabolic Reprogramming in Sepsis-Associated AKI

Ying Li,[2] Prabhleen Singh.[1] [1]*UC San Diego & VA San Diego Healthcare System, San Diego, CA;* [2]*University of California, San Diego, Santee, CA.*

Background: AKI significantly contributes to the morbidity and mortality. Therapeutic strategies are limited due to incomplete understanding of its pathogenesis. Changes in tubular metabolism in response to cellular stress during sepsis may play an important role. A sepsis-associated AKI (s-AKI) model induced by cecal ligation and puncture (CLP) was used to investigate the early and late changes in mitochondrial function and tubular metabolism in s-AKI.

Methods: C57bl/6 mice underwent CLP or sham surgery. Mitochondrial biogenesis, content and dynamics were examined at 4 hours (4 h') and 24 hours (24 h') post CLP. Mitochondrial respiration is freshly isolated proximal tubules was examined with XF96 Seahorse analyzer. Expression of glycolytic enzymes and other assays of tublar metabolism were performed. Lastly, the role of AMP-activated protein kinase (AMPK), the principal cellualr metabolic sensor, was also investigated.

Results: Mitochondrial DNA copy number, PGC1α and Tfam expression were increased at 4 h' but significantly decreased at 24h' post-CLP. Mitochondrial fusion proteins were unchanged at 4' but decreased significantly at 24h' in CLP kidneys. Basal respiration in proximal tubules was significantly diminished in CLP at 4h'. At 24h', a significantly increased maximum respiration rate was observed, suggesting a shift to glycolytic metabolism. The expression of phosphofructokinase (PFK), a rate-limiting glycolytic enzyme, was significantly elevated, while carnitine palmitoyltransferase I (CPT1), a rate-limiting enzyme of lipid oxidation, was dramatically reduced at 24h'. Treatment with AICAR, an AMPK activator, prevented CLP-induced alteration of mitochondrial function (dynamics and biogenesis) and improved GFR.

Conclusions: Our novel findings demonstrate early changes in mitochondrial function and metabolic preprogramming in s-AKI. Mitochondrial dysfunction with a shift to glycolytic metabolism with dimished fatty oxidation under cellular stress is seen. Activation of AMPK improves mitochondrial function by improving mitochondrial biogenesis and

fusion. Additional effects on tubular metabolic reprogramming with AMPK activation is being investigated.

Hsp70 Induction by GGA Treatment Attenuates the Proapoptotic Unfolded Protein Response and Inhibits Gentamicin-Induced Renal Cell Death

Chinaemere Igwebuike,[1] Leah Huiting,[1] Hui Feng,[1] Zhiyong Wang,[2] Andrea Havasi,[2] John H. Schwartz,[2] Michael Sherman,[3] Steven C. Borkan.[2] *[1]Boston Univerisity School of Medicine, Boston, MA; [2]Boston Medical Center, Boston, MA; [3]Ariel University, Jerusalem, Israel.*

Background: Exposure to nephrotoxic antibiotics damages the proximal tubule epithelial cells and causes substantial morbidity and mortality. Gentamicin is a common nephrotoxic antibiotic that promotes proximal tubule damage and acute kidney injury (AKI). However, the lack of a unifying mechanism for gentamicin-induced renal cell injury limits AKI therapy. We hypothesize that computational analysis of an unbiased, broad-based shRNA cell signal screen will identify a "best fit" mechanism(s) of renal cell injury as well as targeted drugs to ameliorate gentamicin-induced AKI.

Methods: Dual shRNA screens of 25,000 individually barcoded signal pathway genes were performed in gentamicin-exposed human proximal tubule cells. Differentially expressed shRNAs were analyzed by Ingenuity Pathways Analysis (IPA) software. Predictions based on computational data were then tested using Unfolded Protein Response (UPR) markers: ATF6, CHOP, BiP and XBP1. Additionally, protein ubiquitination, protein misfolding (thioflavin T staining), oxidative stress (4HNE), mitochondrial integrity (MitoTracker), endoplasmic reticulum (ER)-mitochondrial association (ER Tracker), and cell death (cleaved PARP and propidium iodide staining) were measured.

Results: Interference RNA screening detected 226 differentially expressed shRNAs. Pathway analysis of these shRNAs identified the UPR as the "best fit" mechanism of cell injury and suggested Hsp70 as a potential cytoprotectant. Gentamicin exposure increased protein ubiquitination, protein misfolding, oxidative stress, activated all 3 UPR arms, caused mitochondrial fragmentation followed by mitochondria-ER dissociation, and finally, induced cell death. Chemical induction of Hsp70, a protein that regulates several UPR steps, markedly reduced protein ubiquitination, misfolding, oxidative stress, suppressed both mitochondrial fragmentation and dissociation from ER, and dramatically improved renal cell survival.

Conclusions: This study suggests that the proapoptotic UPR contributes to gentamicin-induced renal cell injury. Hsp70 induction by chemical treatment ameliorates the proapoptotic UPR events and significantly improves renal cell survival during gentamicin exposure.

Sex-Specific Regulation of Sirtuin-3 Mediates Differences in Ischemia-Reperfusion Kidney Injury

Jenny S. Pan,[2,1] Chengtai Yu,[1] Qingtian Li,[1] David Sheikh-Hamad.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Nephrology, Michael E. DeBakey VAMC, Houston, TX.*

Background: Sex influences susceptibility to kidney ischemia-reperfusion injury (IRI), and sex hormones play a crucial role. We previously showed that a pathway from stanniocalcin-1 (STC1) mediated AMPK activation to induction of mitochondrial sirtuin-3 (mtSIRT3) suppresses ROS and confers resistance to kidney IRI. Current observations reveal increased baseline kidney expression of STC1 and SIRT3, and AMPK activation in female vs male mice. We hypothesized that SIRT3 mediates sex differences in response to IRI.

Methods: Male and female wild-type (WT) or SIRT3 transgenic (Tg) mice were subjected to bilateral kidney IR (clamping of renal pedicles for 30 min). Male or female WT mice were treated with testosterone for 2 weeks (s.c. implantation of 21-day release, 200mg pellet). HEK cells were treated with 17β-estradiol, testosterone or vehicle.

Results: pAMPK and mtSIRT3 expression are higher in kidneys of WT female mice vs. males; pAMPK and SIRT3 decline with age but sex differences persist. At age 6 months, male WT kidneys display tubular vacuolization, which is absent in male SIRT3Tg mice. Male SIRT3Tg mice demonstrate resistance to IR [preserved creatinine clearance (CrCl) and morphology; less ROS] and better survival vs WT males; outcomes similar to WT females. In WT females, kidney mtSIRT3 expression correlates positively with plasma estradiol and negatively with testosterone levels. In WT males, kidney mtSIRT3 only correlates negatively with plasma testosterone. Testosterone administration to 6 months-old WT males causes kidney injury (decreased CrCl; increased tubular vacuolization), and decreases kidney mtSIRT3 expression with no effect on whole cell SIRT3. Testosterone administration to WT females increases whole cell- and mtSIRT3 (maybe due to associated rise in plasma estradiol) and causes no measurable kidney injury. In HEK cells, estradiol dose-dependently increases SIRT3 mRNA, whole cell- and mtSIRT3 protein, and ERβ and ERRα mRNA. Testosterone dose-dependently decreases mtSIRT3 protein expression with no effect on whole cell SIRT3 protein or SIRT3 mRNA.

Conclusions: The data suggest: 1) SIRT3 ameliorates kidney IRI; 2) decreased SIRT3 expression underlies increased susceptibility to ischemic injury in male mice; 3) sex steroids regulate mtSIRT3 expression, estrogen via transcriptional regulation and testosterone via reduced mitochondrial targeting.

Pubertal Surge of Sex Hormones Induces Kidney Maturation but Confers Ischemic Vulnerability to Postnatal Kidney

Yuichiro Kitai, Yuki Sato, Motoko Yanagita. *Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: While neonatal kidney is still immature and maturation continues after birth, comprehensive studies on postnatal kidney maturation are limited, and how kidney maturation affects disease susceptibility has not been evaluated.

Methods: We set out to characterize female kidney maturation from infancy to adulthood by morphological analysis and comprehensive gene expression analysis. We also aimed to assess the impact of pubertal sex hormones on postnatal kidney maturation and disease susceptibility.

Results: Comprehensive analysis revealed the increase of transcripts encoding transporters and metabolic enzymes during puberty, associated with the elongation of brush borders of proximal tubules in the deep cortex. Upregulated transporters included solute carriers that transport sodium, organic anion, phosphate, glucose and amino acids, and the most enriched motif near the transcription start sites of these genes was the binding motif of *hepatocyte nuclear factor 4a*, a transcription factor essential for proximal tubule differentiation, presumably indicating the differentiation of proximal tubule during puberty. Notably, the maturation of adult mice was attenuated by the ovariectomy before puberty, whereas the administration of estrogen, but not progesterone reversed these changes. Unexpectedly, adult mice ovariectomized before puberty unexpectedly showed tolerance to renal ischemia, whereas adult mice ovariectomized after puberty were vulnerable to renal ischemia. Latter result was consistent with recent studies on the protective effects of estrogen against injury. Importantly, insulin-like growth factor 1 receptor (IGF-1R) protein in the kidney decreased during puberty, whereas kidneys of adult mice ovariectomized before puberty showed high expression of IGF-1R like infant kidney, indicating that pubertal sex hormone surge decreases IGF-1R expression. In vivo knockdown of IGF-1R in proximal tubules substantially reduced renal IGF-1R expression, and significantly attenuated ischemic tolerance of adult mice ovariectomized before puberty, implying that IGF-1R signaling in proximal tubule contributes to the tolerance of these mice.

Conclusions: Pubertal sex hormones accelerate kidney maturation but paradoxically confer ischemic vulnerability to postnatal kidney, possibly by inhibiting IGF-1R signaling in proximal tubules.

TH-PO106

Remote Ischemic Preconditioning Confers Renoprotection Against Septic AKI via Exosomal miR-21

Tianyi Pan.[1,2] AKI *[1]zhongshan hospital affiliated to Fudan University, Shanghai, China; [2]Institute of Biomedical Sciences, Shanghai, China.*

Background: Renal ischemic preconditioning is beneficial for multiple organs in response to ischemic injury. Whether limb remote ischemia preconditioning (limb rIPC) functions as a protective effector against sepsis-associated AKI is unclear, and the underlying mechanism has not been fully elucidated. Our study aimed to explore the protective role of limb rIPC in mice with AKI induced bycecal ligation and puncture (CLP).

Methods: In vivo, we preconditioned CLP-challenged mice with remote ischemia and reperfusion in the bilateral femoral arteries, which were subjected to 4 cycles of clamping for 5 minutes and unclamping for 5 minutes. Organ function and indicators of inflammation and apoptosis were examined, and the potential mechanism was determined. In vitro, we extracted myocyte-derived exosomes under hypoxia and re-oxygen preprocessing, and these exosomes were pre-added to lipopolysaccharide (LPS)-treated mouse tubular epithelial cells (mTECs).

Results: In vivo, limb rIPC protected polymicrobial septic mice from multiple organ dysfunction and morphological damage, via anti-inflammatory and anti-apoptotic effects. However, limb rIPC could not attenuate CLP-induced renal injury in miR-21 knockout mice. rIPC enhanced local miR-21 expression in ischemic limbs in a hif-1α dependent way, and miR-21 expression in serum exosomes and remote organs, such as the kidney and lung, was up-regulated. This beneficial effector was potentially transmitted in circulation by exosomal transfer. Meanwhile, an elevation in miR-21 was detected in exosomes derived from myocytes with hypoxia and re-oxygen pretreatment. The exosomal preconditioning resulted in renal protection and a reduction in inflammatory cytokines and in mTEC apoptosis in response to septic injury. We further found that high miR-21 expression inhibited miR-21 target genes, exerting anti-inflammation and anti-apoptosis effects.

Conclusions: Enhanced exosomal miR-21 that is induced by limb remote ischemia preconditioning contributes to renoprotection against sepsis. Our data suggest a novel and promising therapeutic strategy for septic AKI.

Myeloid Heavy Chain Ferritin Mitigates Ischemic AKI

Laurence M. Black, Amie Traylor, Kayla R. Mccullough, Jeremie M. Lever, Yanlin Jiang, Gunars Osis, Abolfazl Zarjou, Subhashini Bolisetty. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Acute kidney injury (AKI) stimulates crosstalk between damaged renal tubular epithelium and infiltrating inflammatory cells by chemokine and cytokine release. Perpetual inflammation drives worsened kidney function, structural damage and fibrosis, highlighting the importance of understanding immune cell trafficking in AKI. Heavy chain ferritin (FtH), a protein with ferroxidase activity responsible for iron metabolism, is implicated in macrophage polarization. Here, we investigate the role of myeloid FtH in immune cell trafficking and resolution of AKI.

Methods: We subjected mice deficient in myeloid FtH ($FtH^{LysM-/-}$) and floxed controls ($FtH^{fl/fl}$) to bilateral renal ischemia-reperfusion injury (IR, 20 minutes). We measured renal function, structural damage, chemokine and cytokine expression, and inflammatory cell infiltration.

Results: $FtH^{fl/fl}$ and $FtH^{LysM-/-}$ mice experience similar functional (serum creatinine; SCr levels ($FtH^{fl/fl}$ 1.6 ± 0.11 mg/dL; $FtH^{LysM-/-}$ 1.3 ± 0.12 mg/dL) and structural damage at day 1. At day 2, only $FtH^{LysM-/-}$ mice continue to worsen (2.4 ± 0.38 mg/dL), which subsequently results in significant mortality. $FtH^{LysM-/-}$ mice also exhibit elevated levels of *growth differentiation factor-15*, a marker of renal injury, at day 2 while $FtH^{fl/fl}$ levels are significantly decreased. Interestingly, day 2 after IR, while chemokine and cytokine expression in $FtH^{fl/fl}$ mice is reduced, levels of intrarenal inflammatory markers, such as *CXCL2* and *IL-6*, and serum IL-5 remain elevated in $FtH^{LysM-/-}$ mice. Following IR, the absolute number of intrarenal $F4/80^{int/low}$ $CD11b^{+}$ $Ly6C^{low/neg}$ $CD11c^{+}$ mononuclear phagocytes in $FtH^{fl/fl}$ mice increases, while this cell population does not change from sham levels in $FtH^{LysM-/-}$ mice. After IR, $FtH^{fl/fl}$ mice have a robust induction of neutrophil elastase, an enzyme important for digestion of cellular debris, while it is significantly blunted in $FtH^{LysM-/-}$ mice.

Conclusions: Our findings demonstrate that, while deletion of myeloid FtH does not influence the ischemic insult to the kidney, it regulates the resolution of AKI potentially via activation of pro-resolving macrophages. This study underscores the significance of harnessing macrophages in immunotherapy for AKI resolution and prevention of chronic kidney disease.

The Role of Hemopexin as a Protectant Against AKI

Anthony J. Croatt,[1] John D. Belcher,[2] Joseph P. Grande,[1] Raymond F. Regan,[3] Gregory M. Vercellotti,[2] Karl A. Nath.[1] *[1]Mayo Clinic, Rochester, MN; [2]University of Minnesota, Minneaplis, MN; [3]Thomas Jefferson University, Philadelphia, PA.*

Background: In ischemic and nephrotoxic acute kidney injury (AKI), renal heme content and plasma heme levels are increased. Heme is prooxidant, proinflammatory, and nephrotoxic. Levels of heme are restrained by degradation by heme oxygenase (HO) and by the binding of heme to hemopexin (HPX). HPX is also anti-inflammatory. We questioned whether induction of HPX occurs in AKI and its functional significance.

Methods: Renal HPX mRNA and protein expression was assessed by RT-PCR and western analysis respectively. Renal function was evaluated by serum creatinine and blood urea nitrogen (BUN). Multiple AKI models were employed, including glycerol-induced, heme protein-mediated AKI, and AKI induced by either acute ischemia, endotoxin, or hemoglobin.

Results: HPX mRNA and protein were vigorously induced in the kidney exposed to hemoglobin, along with the receptor for the HPX-heme complex CD91. We thus examined the effect of glycerol-induced, heme protein-mediated AKI in $HPX^{+/+}$ and $HPX^{-/-}$ mice. Renal function was comparable in these mice prior to the administration of hypertonic glycerol and on days 1 and 2 after the induction of AKI. However, $HPX^{-/-}$ mice as compared to $HPX^{+/+}$ mice exhibited significantly higher BUN at day 3 (166 ± 24 vs 104 ± 17 mg/dl) and day 4 (142 ± 23 vs 82 ± 11 mg/dl) following the induction of AKI; similarly, serum creatinine values were also higher on day 3 (1.4 ± 0.2 vs 0.8 ± 0.1 mg/dl) and day 4 (1.2 ± 0.2 vs 0.7 ± 0.1 mg/dl) in $HPX^{-/-}$ mice compared with $HPX^{+/+}$ mice. In ischemia-induced AKI, HPX mRNA and protein are also vigorously induced in the kidney, along with CD91. However, no differences were observed in renal function in $HPX^{+/+}$ and $HPX^{-/-}$ mice at days 1 and 2 following ischemia. No differences in renal function were observed in $HPX^{+/+}$ and $HPX^{-/-}$ mice at days 1 and 2 following endotoxin-induced AKI, and at days 1 and 7 following hemoglobin-induced AKI.

Conclusions: HPX is significantly induced in both nephrotoxic and ischemic models of AKI. A beneficial, functional effect of such induction is observed in glycerol-induced, heme protein-mediated AKI, but only in the recovery phase of such AKI. We suggest that when HO-1, the potent, broad-based protectant in AKI, is intact, HPX provides a secondary backup system for guarding against heme toxicity.

Trib1 Is Involved in Renal Recovery and Regeneration in a Mouse Model of Ischemia/Reperfusion Injury

Xiangcheng Xie,[1] Ming Wang,[2] Xiu Yang,[3] Wei Wei.[4] *[1]Hangzhou First People's Hospital, Nanjing Medical University, Hangzhou, China; [2]Hangzhou First People's Hospital, Hangzhou, China; [3]Hangzhou First People's Hospital, Hangzhou, China; [4]Hangzhou First People?s Hospital, Hangzhou, China.*

Background: Acute kidney injury (AKI) is one of the most common serious complications in hospitalized patients. Despite tremendous effort has been made, AKI is still strongly associated with poor outcomes. Maladaptive repair after AKI exhibit a persistently increased risk of progression to chronic kidney disease (CKD). Macrophages are implicated in the initial injury after ischemic/reperfusion (I/R) and also participate in tubular repair after I/R. Macrophages are classified into two subsets, M1 (inflammatory) and M2 (anti-inflammatory). M1 macrophages play a pathogenic role in boosting inflammatory and kidney injury, whereas M2 macrophages exhibit an anti-inflammatory and wound healing. Evidence demonstrates that macrophage polarization plays a critical role in the process of kidney recovery and chronic fibrosis, hence, enhancement of M1 to M2 phenotype transition might promote renal recovery after I/R. Trib1 is critical for the differentiation of macrophages, therefore, we aimed to investigate the role of trib1 in the process of kidney recovery following I/R and the link between trib1 and macrophage phenotype.

Methods: We used lentiviral vector mediated RNA interfering (RNAi) to knock down expression of trib1 in mice to investigate the role of trib1 in the process of renal repair.

Results: Our results showed that mice with down regulation of trib1 showed markedly reduced renal function, severe renal pathological damage, and exacerbated inflammation. Inhibition the expression of trib1 resulted in an impaired ability to form M2 macrophages in the kidney, whereas coincided with increased M1 macrophages. Expression of TNF-α, IL-6, and IL-12 increased markedly in the trib1 suppressed mice accompanied with a decreased expression of IL-4 and IL-10. Inhibition of Trib1 led to reduced PCNA and Ki67-positive proliferating tubular cells.

Conclusions: Our results showed that trib1 is involved in kidney recovery and regeneration through the regulation of macrophage polarization. This might be a viable therapeutic option to enhance renal repair after I/R injury.

Arginase 2 as a Mediator of Ischemia-Reperfusion Injury in the Kidney Through Regulation of Nitrosative Stress

Masatoshi Hara,[1] Kumiko Torisu,[1] Yasuhiro Kawai,[1] Kazuhiko Tsuruya,[2] Toshiaki Nakano,[1] Takanari Kitazono.[1] *[1]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka City, Japan; [2]Nara Medical University, Kashihara, Japan.*

Background: Arginase 2 (Arg2) is expressed exclusively in the kidney and catabolizes the hydrolysis of L-arginine, which is common substrate for nitric oxide synthase, to produce L- ornithine and urea. There were several reports that administration of arginase blockade protected hepatic and myocardial ischemia-reperfusion injury. However, the role of Arg2 for renal ischemia-reperfusion injury is still poorly unknown.

Methods: Human renal tubular epithelial cells, (HK-2 cells) were cultured under 6-hour hypoxic condition (1% O_2) and subsequent 24-hour reoxygenation (21% O_2) (H/R). To knockdown Arg2, cells were transfected with *Arg2* siRNA. Eight to ten week-old wild type (WT) and Arg2 knockout (Arg2KO) male mice were subjected to clamping of bilateral renal pedicles for 28 minutes and euthanized 24 hours after reperfusion (I/R).

Results: The level of *Arg2* mRNA and ARG2 protein was increased at 24 h after I/R in mouse kidney. Immunohistochemistry revealed that ARG2 was localized specifically in renal proximal tubules and increased after I/R. In HK-2 cells, the immunofluorescent signals of ARG2 were significantly elevated after H/R. ARG2 distributed in a punctate pattern throughout the cytoplasm and partly colocalized with mitochondrial marker. *Arg2* knockdown in HK-2 cells resulted in attenuated 3-nitorotyrosine (3-NT) formation after H/R, though the extent of apoptosis was not changed. Arg2KO mice were markedly resistant to ischemic kidney injury as measured by serum urea nitrogen (WT 150 ± 23 vs Arg2KO 106 ± 34 mg/dL, p <0.05) and creatinine (WT 1.06 ± 0.65 vs Arg2KO 0.43 ± 0.45 mg/dL, p <0.05). The level of 3-NT in ARG2KO kidney was decreased as compared to WT at 24-h reperfusion.

Conclusions: Arg 2 was strongly induced after renal I/R injury particularly in tubular epithelial cells. Suppressing Arg2 by knockdown or knockout method resulted in reduced 3-NT in renal tubular cells. Deficiency of ARG2 significantly alleviated I/R injury in mouse kidney. Our results suggest that ARG2 is a cause of nitrosative stress and inhibition of ARG2 may be beneficial for treatment of renal I/R injury.

TH-PO111

Lowering of Pathological Asymmetric Dimethyl Arginine by a Novel Dimethylarginine Dimethylaminohydrolase Improves Kidney Function After Ischemia-Reperfusion Injury

Young Lee,[2,1] Purvi Mehrotra,[1] David P. Basile,[1] Jaipal Singh.[1,2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana Center for Biomedical Innovation, Indianapolis, IN.*

Background: Asymmetric dimethyl arginine (ADMA) is an endogenously produced inhibitor of nitric oxide synthase (NOS) which contributes to endothelial dysfunction, endothelial to mesenchymal transition, reduced organ perfusion, and fibrosis. High

levels of ADMA are produced in patients with kidney disease and in response to renal ischemia which may contribute to the pathogenesis of kidney disease. In this study, we have investigated ADMA lowering and therapeutic efficacy of novel dimethylarginine dimethylaminohydrolase (DDAH) in the setting of acute kidney injury produced by ischemia-reperfusion (I/R).

Methods: DDAH gene was cloned and expressed in E. coli to generate recombinant DDAH (rDDAH). In vivo circulating DDAH activity was determined at various times after i.v. administration to rats using a colorimetric assay. I/R injury in rats was produced by renal artery ligation for 40 min followed by reperfusion in male Sprague-Dawley rats. The effect of I/R injury on renal DDAH was measured by changes in DDAH mRNA and enzymatic activity. rDDAH was post-translationally modified by PEGylation (M-DDAH) to achieve prolonged in vivo activity. The effect of M-DDAH on I/R injury in rats was determined by changes in creatinine and histology.

Results: DDAH mRNA expression and activity rapidly declined following renal I/R injury in rats, and were ~20% of the values in sham-operated controls within 6 hours ($P<0.05$). Reduction in DDAH was accompanied by increased ADMA in the kidney from 0.14±0.05 uM/mg protein at baseline to 0.42±0.09 uM/mg protein at 6h ($P<0.05$). Native rDDAH was rapidly cleared within 15 min after i.v. administration to rats, whereas PEGylated DDAH (M-DDAH) exhibited 15-fold greater in vivo half-life than the native rDDAH. M-DDAH treatment attenuated the degree of renal injury in the I/R model as indicated by reduced serum creatinine (2.23±0.38 mg/dL I/R vs 1.15±0.17 mg/dL M-DDAH, $P<0.05$) and the degree of renal tubular damage.

Conclusions: Our studies are first to synthesize a novel pharmacologically viable DDAH molecule which lowered ADMA in rats. M-DDAH significantly improved renal function in a model of I/R in rats, suggesting that M-DDAH may offer a new therapeutic approach for improving endothelial function in the setting of AKI.

TH-PO112

GDF15 Marked Stressed Tubular Epithelium and Alleviated Ischemic AKI

Jing Liu,[2] Sanjeev Kumar,[2,1] Michael Gao,[2] Jinjin Guo,[2] Pietro E. Cippa,[2] Andrew P. McMahon.[2] *[1]Cedars Sinai Medical Center, Los Angeles, CA; [2]Keck School of Medicine of the University of Southern California, Los Angeles, CA.*

Background: Renal ischemia reperfusion injury (IRI) frequently triggers tubular damage leading to acute kidney injury (AKI) in varied clinical settings including kidney transplantation. We identified *Gdf15* (Growth/differentiation factor 15) as one of the genes rapidly activated in the mouse nephron following ischemic AKI; a similar induction is observed after transplant of the human kidney. First identified as an autocrine regulatory molecule associated with macrophage activation, *Gdf15* was induced by proinflammatory cytokines and activated by various stressors including inflammation, oxidative stress and DNA damage. The role for endogenous GDF15 in ischemic kidneys is unclear.

Methods: To study *Gdf15* expression and function in the mouse kidney, we generated a mouse line ($Gdf15^{nuGFP\text{-}CE}$)producing a truncated GDF15 missing C-term 210 a.a. and fused with P2A-nuclearGFP-F2A-CREERT2. We examined GFP and tamoxifen dependent TDT expression in $Gdf15^{nuGFP\text{-}CE/+}$, $R26^{TDT/+}$ mice and compared the acute and chronic renal response to IRI in *Gdf15* heterozygous and *Gdf15* null mice by qRT-PCR, histology and immunofluorescence. To validate the clinical relevance of our findings, we performed a *GDF15*-related single nucleotide polymorphism association study in a cohort of kidney transplant recipients.

Results: In steady state, GDF15 was produced mainly by the Apq1- thin descending limb of the Henle's loop (tDLH), by the S3 segment of the proximal tubule and by principal cells in the collecting duct. After moderate bilateral renal IRI, Gdf15 was predominantly activated in proximal tubules, Aqp1+ tDLH, principal cells in the collecting ducts and connecting tubules. Moreover, GDF15 deficiency exacerbated acute tubular injury, enhanced inflammatory response and facilitated adaptive immunity following ischemia. Consistently with the immune-regulatory effect observed in the mouse model, we found that single nucleotide polymorphisms previously linked to lower circulating GDF15 concentration, were associated with an increased incidence of biopsy proven acute rejection in the first year after kidney transplantation.

Conclusions: GDF15 is a functionally relevant, conserved element with reno-protective and immune-regulatory properties in the immediate response to ischemic AKI.

Proximal Tubule β2 Adrenergic Receptor Is Responsible for Formoterol-Induced Recovery of Mitochondrial and Renal Function After AKI

Robert B. Cameron,[1,4] Whitney S. Gibbs,[1] Tess Dupre,[4] Siennah R. Miller,[4] Judit Megyesi,[3] Rick G. Schnellmann.[2] *[1]Medical University of South Carolina, Charleston, SC; [2]University of Arizona, Tucson, AZ; [3]University of Arkansas for Medical Science, Little Rock, AR; [4]University of Arizona College of Pharmacy, Tucson, AZ.*

Background: Numerous cell types play a role in the pathogenesis of AKI, including immune, endothelial, and renal proximal tubule cells. Our laboratory demonstrated that the β_2 adrenergic receptor (β_2AR) agonist formoterol stimulates mitochondrial biogenesis (MB) and accelerates the recovery of renal and mitochondrial function in mice following ischemia-reperfusion injury (IRI). However, the cell type(s) responsible for this recovery remains unknown.

Methods: $ADRB2^{Flox/Flox}$ (WT) mice were mated with γGT-Cre mice to generate γGT-Cre:$ADRB2^{Flox/Flox}$ (KO) mice with proximal tubule deletion of the β_2AR. These mice were subjected to renal IRI and were treated once daily with formoterol or vehicle beginning at 24 h and euthanized at 144 h.

Results: Compared to WT, KO mice had 80% lower renal cortical ADRB2 mRNA and DNA. At 24 h following IRI, WT and KO mice had a similar loss of renal function as measured by serum creatinine. At 144 h following IRI, both WT and KO mice treated with vehicle exhibited persistent renal dysfunction as measured by elevated serum creatinine (SCr), KIM-1 protein, and tubular necrosis. Following treatment with formoterol, WT mice, but not KO mice, exhibited accelerated recovery of renal function. Treatment with formoterol increased mitochondrial protein expression and mtDNA copy number in WT but not KO mice. Sham-operated KO mice also had fewer mitochondria than WT mice as assessed by transmission electron microscopy. Formoterol restored mitochondrial number and density in WT but not KO mice.

Conclusions: Following AKI, formoterol activates the β_2AR and stimulates MB in proximal tubule cells to accelerate the recovery of renal function. The β_2AR also regulates mitochondrial homeostasis in healthy proximal tubule cells. These data underscore the importance of the proximal tubule cell as a therapeutic target for AKI. Thus, targeting compounds that induce MB in renal proximal tubule cells may provide more effective treatments for AKI.

Inhibition of Semaphorin-3a Suppresses Lipopolysaccharide-Induced AKI

Xiaofang Tian,[1] Hua Gan,[2] Yizhou Zeng,[3] Hongfei Zhao,[4] Rong Tang,[5] Yunfeng Xia.[6] *[1]Nephrology, The First Affiliated hospital of Chongqing Medical University, Chongqing, China; [2]Nephrology, The First Affiliated hospital of Chongqing Medical University, Chongqing, China; [3]Urology, The First Affiliated hospital of Chongqing Medical University, Chongqing, China; [4]Nephrology, The First Affiliated hospital of Chongqing Medical University, Chongqing, China; [5]Cardiology, The First Affiliated hospital of Chongqing Medical University, Chongqing, China; [6]Nephrology, The First Affiliated hospital of Chongqing Medical University, Chongqing, China.*

Background: Acute kidney injury (AKI) is a common and catastrophic complication in sepsis-associated patients. Endotoxin is a common cause of sepsis-associated AKI. Lipopolysaccharide (LPS) is the major component of endotoxin derived from gram-negative bacteria and has been found to be involved in the pathogenesis of AKI. Semaphorin-3a (Sema3A), a soluble axon guidance cue, appears to play an important role in the development of AKI. However, the role of Sema3A in sepsis related AKI remains unknown.

Methods: Lipopolysaccharide (LPS) was used to simulate sepsis-associated AKI in male C57BL/6 mice and NRK-52E cells (rat tubular epithelial cells). The role of Sema3A in LPS-induced AKI was investigated in *vivo* and in *vitro*. Firstly, mice were intraperitoneally injected by LPS with different times to examine Sema3A expression. Next, (-)-Epigallocatechin-3-gallate (EGCG) was administrated to inhibit Sema3A. Then, Renal function, kidney injury, inflammation, and apoptosis were measured to investigate the effect of Sema3A in LPS-induced AKI. Furthermore, to explore the mechanism of Sema3A regulates inflammation and apoptosis in *vitro*, NSC23766 (a specific Rac1 inhibitor) and SP600125 (a specific JNK inhibitor) were used. Then, the mRNA expression of IL-6 and TNF-α, cell apoptosis, the expression of Rac1/NF-κBp65 and JNK signaling molecules were examined.

Results: The expression of Sema3A was upregulated in renal tubular epithelial cells (TECs) in LPS induced AKI model. Similar change was found in NRK-52E cells incubated with LPS (5μg/ml). Notably, inhibition of Sema3A by EGCG significantly reduced renal inflammation and the apoptosis of TECs in LPS induced AKI mice. EGCG intervention also ameliorated LPS-induced inflammation and apoptosis in NRK-52E cells in *vitro*. Our results also indicated that Rac1/NF-κBp65 and JNK signaling were involved in Sema3A-mediated inflammation and apoptosis of TECs, respectively.

Conclusions: Our results suggested that the upregulation of Sema3A probably play a pathogenic role in LPS-induced AKI, which promote renal inflammation and TECs apoptosis. Rac1/NF-κBp65 and JNK signaling pathways might be involved in the inflammation and cell apoptosis respectively.

TH-PO115

PAC-Mediated AKI Protection Is Critically Dependent on Cell-Derived Microvesicles

Daniel Patschan. *University Hospital Göttingen, Goettingen, Germany.*

Background: Acute Kidney Injury (AKI) significantly worsens the prognosis of hospitalized patients. In recent years, cell-based strategies have been established as reliable option for improving AKI outcomes in experimental AKI. Own studies focused on so-called Proangiogenic Cells (PACs). Mechanisms that contribute to PAC-mediated AKI protection include production / secretion of extracellular vesicles (EV). In addition, the cells act by paracrinic processes (secretome). The current study evaluated whether AKI may be preventable by the administration of either PAC-derived EV and / or the secretome alone.

Methods: AKI was induced in male C57/Bl6N mice (8-12 weeks) by bilateral renal ischemia (IRI - 40 minutes). Syngeneic murine PACs were stimulated with either melatonine, Angiopoietin-1 or -2, or with Bone Morphogenetic Protein-5 (BMP-5) for one hour respectively. PAC-derived EV and the vesicle-depleted supernatant were subsequently collected and i.v. injected post-ischemia. Mice were analyzed 48 hours later.

Results: IRI induced significant kidney excretory dysfunction as reflected by higher serum cystatin C levels. The only measure that improved AKI was the injection of EV, collected from native PACs. The following conditions worsened post-ischemic renal function even further: EV+Ang-1, EV+BMP-5, EV+melatonin, and EV+secretome+Ang-1.

Conclusions: Together, our data show that PAC-mediated AKI protection critically depends on the availability of cell-derived EV. The secretome, either collected from native or preconditioned cells does not prevent mice from ischemia-induced dysfunction. Certain PAC preconditioning protocols may even worsen the renal prognosis of EV(/secretome)-treated animals.

TH-PO116

Early Inflammatory Response to Pyelonephritis Induced by Uro-Pathogenic E. coli Requires P2Y2 Receptor Activation

Mette G. Christensen, Jacob R. Therkildsen, Rikke Norregaard, Helle A. Praetorius. *Aarhus University, Aarhus, Denmark.*

Background: Urinary tract infections are exceedingly common and severe infections including pyelonephritis are often caused by *E. coli* that produces the pore-forming virulence-factor alpha-hemolysin (HlyA). We have previously demonstrated that HlyA releases cellular ATP directly through its membrane pore and that the associated erythrocyte lysis is completely prevented by blocking ATP-signalling. Renal epithelia are not lysed by the toxin. Instead the released ATP causes $P2Y_2$-receptor dependent intracellular [Ca^{2+}] oscillations followed by epithelial IL-6 release. Thus, we speculated that $P2Y_2$ receptor deficient mice may be more susceptible to pyelonephritis as a result of inadequate epithelial-induced immune activation.

Methods: Acute pyelonephritis was induced by injecting 100 million HlyA-producing, uropathogenic *E. coli* into the urinary bladder of balb/c mice. After 24 hours, pyelonephritis was confirmed by culture of the right kidney, the urine and plasma were collected and the left kidney was isolated for histology after perfusion fixation.

Results: The mice showed relatively modest change in overall behaviour in response to the renal infection compared to vehicle controls and the survival or degree of infection was similar in $P2Y_2^{-/-}$ and $P2Y_2^{+/+}$ mice after 24 h. The $P2Y_2^{+/+}$ mice with confirmed pyelonephritis, showed marked elevation of plasma IL-6 (42.0±7.3 pg/ml) compared to control (12.2±4.5 pg/ml, p=0.001). Preliminary data show reduced plasma IL-6 in $P2Y_2^{-/-}$ mice with confirmed pyelonephritis (24.7±10.3 pg/ml). Similarly, we found significant elevation in keratinocyte chemoattractant (KC, a murine homologue of IL-8) in plasma of $P2Y_2^{+/+}$ mice subjected to HlyA-producing *E. coli* (91.3±27.4 pg/ml) compared to control (23.9±7.1 pg/ml, p=0.003). In contrast, plasma KC were markedly lower in $P2Y_2^{-/-}$ mice with pyelonephritis (33.6±14.7 pg/ml). These changes are likely to reflect early interaction between bacteria and renal epithelium, since the degree of neutrophil infiltration had not increased in pyelonephritic kidneys at this early time point.

Conclusions: These results indicate that ATP signalling via the $P2Y_2$ receptor plays a pivotal role in the early response to pyelonephritis with HlyA-producing *E. coli*. Data on ATP release to the urine, survival and immune reaction after 3 days are pending.

The Effect of Adenosine Kinase on Acute Renal Injury

Chang Ying Xing, Wei Cao, Yanggang Yuan, Bo Zhang, Huijuan Mao. *First Affiliated Hospital of Nanjing Medical University, Nanjing, China*.

Background: Numerous studies have demonstrated that several mechanisms, including necrosis, apoptosis, inflammatory reaction and oxidative stress are closely linked to acute kidney injury. Adenosine, emerging as a key regulatory molecule, is mostly protective in the pathophysiology of inflammatory diseases. Previous study showed that some of the adenosine receptors led to renal-protection against ischemia-reperfusion injury. However, these adenosine receptors agonists lack a useful therapeutic index due to cardiovascular side effects. We hypothesized that inhibition of adenosine kinase exacerbates extracellular adenosine levels to reduce cisplatin and ischemia reperfusion-induced renal injury.

Methods: 1.(1)C57BL/6 mice(24g, 6-8week, male) were randomly divided into 4 groups: Control, ABT-702, Cisplatin, and ABT-702+ Cisplatin, (2)C57BL/6 mice were randomly divided into 4 groups: sham operation group (Sham), ABT-702, ischemia-reperfusion (IR), ABT-702 +IR group (ABT-702+IR), kidney pathological changes, and protective effects were observed. 2.(1) HK-2 cells were pretreated with 1uM ABT-702 then incubated with cisplatin at 20uM concentration for 24 h. (2) HK-2 cells were treated with the ADK small interfered RNA, then incubated with Cocl2 at 250uM concentration for 12 h to induce chemical hypoxia, followed by reperfusion for 24 h. The apoptosis-associated protein (cleaved caspase-3, Bcl-2, Bax), ROS, and four types of adenosine receptors were detected. Four receptors antagonists were added before ABT-702 to detect the changes in cell viability.

Results: In this study, inhibition of adenosine kinase could markedly attenuate cisplatin-induced and renal ischemia reperfusion-induced acute kidney injury, tubular cell apoptosis, oxidative stress and inflammation in the kidneys. Consistent to in vivo results, the inhibition of ADK suppressed cisplatin and Cocl2-induced apoptosis, ROS production and inflammation in HK2 cell. Additionally, the protective effect of ADK inhibition was abolished byA1 or A2Badenosine receptors inhibition and enhanced by A2Aor A3 adenosine receptors inhibitor.

Conclusions: Inhibition of ADK increases adenosine and attenuates acute renal injury by anti-inflammatory, antioxidant stress and anti-apoptosis mechanism and partly dependents on A1 and A2b receptors to protect HK2 cells injury.

Acute and Chronic Renal Ischemia-Reperfusion Injury and Angiotensin II-Induced Hypertension Are Attenuated in Mice with Proximal Tubule-Selective Deletion of Angiotensin AT1a Receptors

Xiao C. Li,[1] Jian F. Zhang,[2] Xiao W. Zheng,[2] Jia L. Zhuo.[1] *[1]The University of Mississippi Medical Center, Jackson, MS; [2]Guangxi Medical University, Nanning, China.*

Background: The present study tested the hypothesis that genetic deletion of angiotensin II (ANG II) AT_{1a} receptors selectively in the proximal tubule of the kidney attenuates renal ischemia-reperfusion injury and ANG II-induced hypertension in mice.

Methods: Proximal tubule-specific AT_{1a} receptor-knockout mice (PT-AT_{1a}-KO) were generated using the standard Cre/LoxP recombination approach. Adult male C57BL/6J (WT), global AT_{1a}-KO, and PT-AT_{1a}-KO mice were subjected to sham surgery or 45 min bilateral renal ischemia, followed by reperfusion for 24 h or 7 days. ANG II-dependent hypertension was induced by infusing ANG II at 1.5 mg/kg/day, i.p., for 2 weeks. Systolic blood pressure (SBP), renal function, glomerular, tubuointerstital, and perivascular fibrotic responses were determined and compared

Results: Basal systolic blood pressure was 22 ± 5 mmHg lower in global AT_{1a}-KO or 11 ± 3 mmHg lower in PT-AT_{1a}-KO mice ($p<0.05$ vs. WT). WT mice developed significant glomerular, cortical tubulointerstitial and perivascular injury 24 h or 7 days after renal ischemia-reperfusion was induced ($p<0.01$). Ischemia and reperfusion renal injury was not prevented in global AT_{1a}-KO mice (n.s. vs. WT), but it was significantly attenuated in PT-AT_{1a}-KO mice 24 h or 7 days after renal ischemia-reperfusion was induced ($p<0.05$ vs. WT or AT_{1a}-KO). WT developed severe ANG II-induced hypertension, as expected, but it was significantly attenuated in PT-AT_{1a}-KO mice ($p<0.01$ vs. WT).

Conclusions: We concluded that AT^{1a} receptors in the proximal tubule of the kidney play a key role in the pathogenesis of renal ischemia-reperfusion injury and ANG II-dependent hypertension.

Necroptosis and Ferroptosis Inhibitors Have Significant Benefit in Acute Ischemic Kidney Injury In-Vivo and In-Vitro

Kevin M. Gallagher,[1] Allison M. Beal,[3] Yuen bun Tam,[1] James A. Ross,[1] Lorna Marson,[2] John Bertin,[3] Stephen J. Wigmore,[1] Jeremy Hughes,[2] Ewen M. Harrison.[1] *[1]University of Edinburgh, Edinburgh, United Kingdom; [2]The Queens Medical Research Institute, Edinburgh, United Kingdom; [3]GlaxoSmithKline, Collegeville, PA.*

Background: We aimed to determine if necroptosis or ferroptosis inhibitors are beneficial in murine ischemia reperfusion injury, and if necroptosis or ferroptosis occur in human tubular cells.

Methods: Mice were subjected to 18m of bilateral renal ischemia with 24 or 48h reperfusion. Highly specific RIPK1 inhibitor, GSK547a, or ferroptosis inhibitor Liproxstatin-1 were given from 4h *after* injury. Outputs included creatinine, acute tubular necrosis (ATN) score, phosphorylated MLKL (pMLKL, end effector of necroptosis) stain, TUNEL stain and qPCR. Human renal tubular cells (HK-2) underwent 3 models of ischemia in-vitro +/- necroptosis/ferroptosis inhibitors.

Results: With drug given 4h *after* injury, both RIPK1 inhibitor and liproxstatin-1 significantly reduced serum creatinine (mmol/L)(Vehicle:239.8 (+/- 51.8), RIPK1 inhibitor:103.9 (+/- 48.2) $p<0.001$, Liproxstatin-1:43.1 (+/-14.4) $p<0.001$) and ATN score (Vehicle: 3/4 (3-4), RIPK1 inhibitor: 2/4 (1-2) $p=0.008$, Liproxstatin 1: 2/4 (1-2) $p<0.001$)(9/group) 48h after injury. 24h after injury there was extensive pMLKL in vehicle treated injured kidneys. pMLKL, ATN score and TUNEL stain were significantly reduced by RIPK1 inhibition(N=6). There was median 5-fold increase in renal RIPK3 expression 48h after injury compared to sham animals, this was significantly reduced by RIPK1 inhibition ($p=0.004$) but not by liproxstatin-1 ($p=0.67$) (N=9). A20 (necroptosis inhibitor) expression was significantly higher vs vehicle in RIPK1 inhibitor ($p=0.02$) and liproxstatin-1 ($p=0.01$) treated kidneys. Despite less ATN, Liproxstatin-1, but not RIPK1 inhibitor treated kidneys demonstrated *higher* expression of MCP-1 ($p=0.002$) and TNF-α ($p<0.001$) compared to vehicle. In in-vitro ischemic HK2 cell injury, there was evidence of both necroptosis (MLKL phosphorylation) and ferroptosis (iron dependent lipid peroxidation) with associated benefit for cell survival from necroptosis and ferroptosis inhibitors (N=3-6), although to different extents depending on the type and severity of injury.

Conclusions: Both necroptosis and ferroptosis contribute to ischemic kidney injury. There may be differential effects of related inhibitors on inflammatory genes. Further study is required to determine if this impacts long term renal function after an ischemic injury.

Novel Imaging Technique Visualizing Spatiotemporal ATP Dynamics During AKI Predicts Renal Prognosis and Provides Proof-of-Concept for Hypothermia

Shigenori Yamamoto,[1] Motoko Yanagita,[2] Shinya Yamamoto,[3] Masamichi Yamamoto.[3,4] *[1]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [3]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [4]Japan Science and Technology Agency, PRESTO, Tokyo, Japan.*

Background: The kidney constantly utilizes adenosine 5' triphosphate (ATP), and mitochondrial dysfunction, which leads to ATP depletion, plays an important role in the pathogenesis of kidney diseases. In spite of importance of ATP dynamics, however, lack of technology to visualize *in vivo* ATP dynamics has hindered further analysis. Here we enabled the visualization of spatiotemporal renal ATP dynamics and analyzed whether the ATP dynamics during AKI could predict the renal prognosis.

Methods: To enable intravital ATP imaging, we generated a novel mouse line, which expressed the FRET-based ATP biosensor systemically. We monitored renal ATP dynamics in both warm and cold ischemic reperfusion (IR) models with two-photon microscope. Furthermore, we performed the quantification of fibrosis two weeks after IR, and assessed the correlation between the ATP recovery in acute phase and fibrosis in chronic phase.

Results: The ATP level of proximal tubules (PTs) rapidly decreased to the basal level in only 2 minutes after ischemia induction, whereas that of distal tubules (DTs) was maintained even after 30 minutes. The ATP dynamics in PTs after reperfusion was variable depending on the duration of ischemic time. The longer ischemic time led to slower and more insufficient ATP recovery in PTs. The ATP recovery after 15, 30, and 60 minute-warm IR took 2, 5, and 30 minutes to reach a peak plateau, and the % ATP recovery were 90%, 83%, and 69%, respectively, while the ATP recovery after 30 and 60 minute-cold IR took 2 and 4 minutes, and the % ATP recovery were 90% and 87%, indicating rapid and complete ATP recovery in cold ischemia. Interestingly, the fibrosis in chronic phase was inversely well correlated with the ATP recovery of PTs in acute phase in both warm and cold IR.

Conclusions: We, for the first time, succeeded in visualizing the spatiotemporal ATP dynamics in the kidney and revealed the tolerance of DTs to ischemia from the point of ATP dynamics. After reperfusion, the ATP recovery in PTs was variable depending on the severity of injury, and the ATP dynamics in acute phase might determine the outcome in chronic phase. In addition, cold ischemia results in much more rapid and complete ATP recovery than warm ischemia, which provides proof of concept for renal hypothermia.

No-Reflow in Experimental AKI

Jesus H. Dominguez,[3,1] Danhui Xie,[1,2] James M. Dominguez,[1,2] Katherine J. Kelly.[1,2] *[1]Indiana University, Indianapolis, IN; [2]Medicine/Nephrology, Roudebush Veterans' Affairs Medical Center, Indianapolis, IN; [3]VAMC, Indianapolis, IN.*

Background: In acute kidney injury (AKI), multiple redundant pathways contribute to renal failure. Renal microvascular congestion has been observed in clinical AKI. We sought to test the hypothesis that inadequate reperfusion, activation of coagulation and microthrombi are significant factors that result in renal failure following ischemia. We have previously (Dominguez et al, J Am Soc Neph 28:3533) demonstrated improvement in multiple abnormal pathways of injury with exosome therapy.

Methods: The role of activated coagulation, microthrombi formation and fibrinolysis were examined in a model of ischemic AKI using multiphoton, intravital imaging performed 48 hours postischemia. Four groups of rats were studied: sham surgery, bilateral renal ischemia/reperfusion (IR)/vehicle, IR/exosomes, IR/urokinase. Exosomes derived from renal tubular epithelia, urokinase or vehicle (0.9% NaCl) was administered 24 hours postischemia when renal failure was established.

Results: Diffuse renal microvascular thrombi resulted in a heterogeneous decrease in intrarenal blood flow within postischemic kidneys. Administration of exosomes after renal failure occurred, resulted in improved renal blood flow and decreased inflammation, fibrin formation and immunoreactive tissue factor. Urokinase, given after renal failure, improved intrarenal blood flow and decreased renal fibrin and tissue factor, but had less effect on inflammation. Renal function improved rapidly in both the exosome and urokinase groups.

Conclusions: Our data indicate that the no-reflow phenomenon follows global renal ischemia and contributes to heterogeneous, ongoing ischemia leading to a cycle of inflammation, tissue injury and postischemic renal failure. In this model, fibrinolysis improves renal function postischemia.

Selective Decontamination of Digestive Tract Attenuates Kidney Ischemia/Reperfusion Injury and Distant Organ Damage via Immune Modulatory Effect

Jihyun Yang, Sang-Kyung Jo, Sewon Oh, Junyong Lee, Myung-Gyu Kim. *Korea University Anam Hospital, Seoul, Republic of Korea.*

Background: Emerging evidence suggests the critical role of gut as an amplifier of systemic inflammation in diverse pathological conditions. Selective decontamination of digestive tract (SDD) is known to inhibit colonization by aerobic gram-negative bacilli while preserving anaerobic microflora and is currently being used to prevent infection and also to reduce mortality in critically ill patients. We aimed this study to examine the effect of SDD on the severity of kidney injury as well as on distant organ damage and also the underlying mechanisms.

Methods: We used male C57L/B6 mouse bilateral ischemia/reperfusion injury(IRI) after SDD, which was the mixture of three antibiotics (neomycin 25mg/kg, ampicillin 60mg/kg, and metronidazole 25mg/kg) given by orogastric gavage once daily for 12 days. The renal function, colon immunity, local and systemic inflammation level was assessed. We measured liver function test to check distant organ injury.

Results: Kidney IRI but not bilateral nephrectomy provoked increased intestinal permeability. The "leaky gut" following IRI was accompanied by increased colon apoptosis, decreased claudin-1 expression. Ly6G+ neutrophil infiltration and M1proinflammatory macrophages increased in colon after kidney IRI. SDD before IRI but not bilateral nephrectomy resulted in significant attenuation of kidney injury and inflammation as well as distant organ injury. The protective effect of SDD was associated with better preservation of intestinal permeability, reduced colon apoptosis and restored claudin-1 expression. SDD also led to the expansion of M2 anti-inflammatory macrophages and Tregs in colon. Spleen Tregs and Foxp3 expression were also increased in SDD mice. Mesenteric lymph node cells from SDD mice showed reduced proliferative response upon TCR stimulation, suggesting the state of immune tolerance compared to control mice.

Conclusions: Our results showed the critical role of intestine as an amplifier of kidney injury, inflammation and distant organ damage after IRI. We also showed the protective effect of SDD might be partially mediated by immune modulatory effect through expansion of M2 macrophages and Tregs. Strategies aimed at restoring intestinal integrity, microbiome and intestinal mucosal tolerance could be novel therapeutics in acute kidney injury.

TH-PO123

Spatially-Preserved, Multiplexed Expression Analysis of the Normal and Injured Human Kidney

Nikhil Singh, Judith Kliegel, Gilbert W. Moeckel, Brian Shuch, Lloyd G. Cantley. *Yale University, New Haven, CT.*

Background: Tissue obtained by renal biopsy is a useful substrate for understanding the biology of human acute tubular injury (ATI) with preservation of spatial context - including interactions between resident renal cells and those of the immune system. However, the small amount of tissue obtained in biopsies places a practical limitation on the number of markers that can be analyzed by conventional immunostaining, thereby limiting discovery.

Methods: Imaging mass cytometry (IMC) is a mass spectrometry-based technology that allows for simultaneous analysis of up to 40 protein and mRNA markers on a single section of formalin-fixed paraffin-embedded tissue, with no spectral overlap or background fluorescence. Using a prototype imaging mass cytometer and human kidney obtained by nephrectomy, we have sought to validate a panel of metal-conjugated monoclonal antibodies for use in mapping the human kidney with IMC, while also developing technology to simultaneously interrogate mRNA targets.

Results: We have developed and validated a panel of over 20 metal-conjugated monoclonal antibodies detectable by IMC in the kidney. We have successfully generated two-dimensional reconstructions to 1 micron resolution of reference and injured kidneys simultaneously stained with over 15 metal-tagged antibodies, better defining the spatial relationships between cell types.

Conclusions: With our current panel of antibodies, we will be able to interrogate true normal biopsies from living kidney donors and banked biopsies from patients with ATI. This will allow us to construct semi-quantitative two-dimensional atlases of the resident cell types, immune cells, and markers of cellular injury, stress, activation, regeneration and death in the normal and acutely injured human kidney.

Funding: NIDDK Support, Private Foundation Support

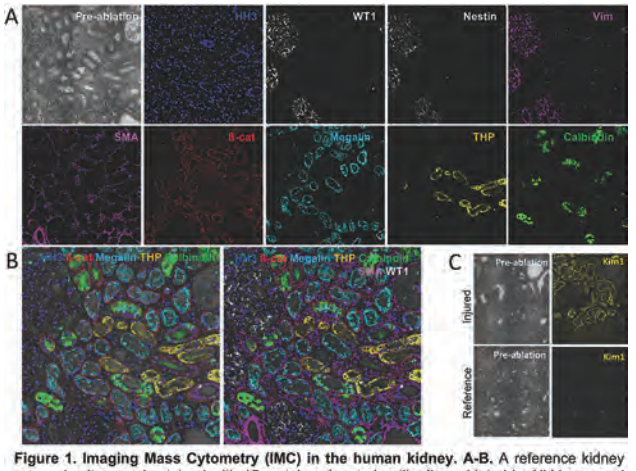

Figure 1. Imaging Mass Cytometry (IMC) in the human kidney. A-B. A reference kidney was simultaneously stained with 15 metal-conjugated antibodies, ablated by UV laser, and atomized particles detected in an imaging mass cytometer; reconstructed false-colored IMC images are shown for 9 markers: histone H3 (a pan-nuclear marker), cytoplasmic WT1 (podocytes), Nestin (podocytes), Vimentin (fibroblasts, podocytes and mesangium), alpha SMA (smooth muscle), ß-catenin (tubular epithelium), Megalin (proximal tubule), Tamm-Horsfall protein (thick ascending loop of Henle) and calbindin (distal convoluted tubule). "Pre-ablation" image is a light microscopic image generated from the tissue area of interest prior to UV laser ablation and IMC. **B.** Merged images overlayed onto the pre-ablation image in A for the indicated markers. **C.** An injured versus reference human kidney stained with a metal-conjugted antibody to Kim1, an injury marker. Note positive staining in the injured kidney and absence of epithelial staining in the reference kidney.

TH-PO124

An Unbiased Functional Genomic Screen Identifies Fibroblast Growth Factor 9 as a Novel Regulator of AKI

Yuntao Bai,[1] Ji Young Kim,[1] Laura A. Jayne,[2] Navjotsingh P. Pabla.[1] *[1]The Ohio State University, Columbus, OH; [2]The Ohio State University, Columbus, OH.*

Background: Renal epithelial cell death and dysfunction are the hallmark and underlying cause of acute kidney injury (AKI), a common disorder characterized by sudden loss of renal function, high mortality and lack of therapeutic options. Identification of therapeutic strategies to prevent AKI is an essential but unmet medical need. Here we have used an unbiased functional genomic screen to identify therapeutic and druggable targets for AKI.

Methods: In this study, we carried out an unbiased siRNA-based high throughput screen (HTS) using a mouse renal tubular cell line. In this screen, 5169 druggable genomic genes (number of 384-well plates: 68; quadruplicate) were silenced in BUMPT cells and their effect on cisplatin-mediated cell death was examined by Cell Titer Glo assay. The siRNAs that significantly protected cells from cisplatin-induced cell death were selected for confirmatory secondary screens. Subsequently, by using a pharmacological inhibitor and renal tubule specific knock-out mice (GGT-Cre and FGF9 flox mice), one of the top hits from these screens was validated as a potential therapeutic target in three mouse models of AKI, namely cisplatin-, ischemia-, and rhabdomyolysis-induced AKI. In these mouse models, renal impairment was determined by accumulation of nitrogenous waste (blood urea nitrogen and serum creatinine), biomarkers of kidney injury (KIM1 and NGAL expression) and histological analysis (H&E staining and renal damage score).

Results: Our primary and confirmatory screens identified FGF9 as one of the regulators of renal cell death and injury. Infigratinib, a pan inhibitor of FGF9 receptors, mitigated kidney injury (KIM1, NGAL and renal damage score) and significantly improved renal function (blood urine nitrogen and creatinine) in three mouse AKI models (Vehicle vs. Infigratinib group, $p \leq 0.01$). Furthermore, renal tubule specific FGF9 knock-out mice exhibited significant protection from AKI as compared to their control littermates.

Conclusions: Using a novel HTS mediated functional genomic screen, we have identified FGF9 associated signaling network as a crucial modulator of renal dysfunction and AKI. Proof-of-principle experiments also suggest that pharmacological or genitic inhibition of FGF9 signaling can mitigate AKI.

TH-PO125

Translating Ribosome Affinity Purification (TRAP) Molecular Profiling of Kidney Cell Types: A Data Resource

Jie Huang,[1] John Vekich,[1] Konstantin Bobkov,[2] Corine Holub,[1] Debashree Das,[1] Pranali Taskar,[3] Mats I. Ekstrand,[1] Eun ji Yoo,[1] Naishan Chen,[1] Huey-Jing Huang,[1] Sara J. Mcsweeney,[5] David C. Bedford,[4] Joseph P. Doyle.[1] *[1]Takeda California, Inc., San Diego, CA; [2]SGI, San Diego, CA; [3]NGM Biopharmaceuticals, Santa Clara, CA; [4]Mission Therapeutics Ltd, Cambridge, United Kingdom; [5]Clinical Network Services, Bishop?s Stortford, United Kingdom.*

Background: The Translating Ribosome Affinity Purification (TRAP) methodology was developed in the labs of Nathaniel Heintz and Paul Greengard at Rockefeller University in order to overcome the inherent cellular complexity of tissues and to obtain cell-type specific translational profiles of critically relevant cell types in these tissues (Doyle et al., Heimann et al., Cell, 2008). Using bacTRAP transgenic mouse lines licensed from Rockefeller University or generated at Takeda, California, we here apply the TRAP methodology to profile relevant kidney cell types, both in a basal state as well as in models of acute kidney injury.

Methods: We employed the TRAP methodology in order to obtain translational profiling data from multiple kidney cell types. Transgenic mice expressing the EGFP-ribosomal L10a fusion protein under kidney cell type specific promoters were generated using standard techniques and characterized for EGFP-L10a expression in the cell types of interest. For collection of TRAP samples, whole kidneys were isolated from several mice, homogenized, and processed following standard TRAP protocols. Total tissue mRNA and cell-type enriched TRAP mRNA samples were amplified, libraries prepared, and sequenced following routine protocols.

Results: We have collected kidney TRAP data covering two general areas: 1. Baseline data, collected from unperturbed transgenic bacTRAP mice, targeting specific cell types (podocytes, proximal tubule epithelial cells (PTECs) and subsets of PTECs, and perivascular mesenchymal cells) 2. Data from disease model studies (sepsis, bilateral ischemia-reperfusion).

Conclusions: Here we demonstrate that bacTRAP is a powerful tool for translational profiling of kidney cell types. In order to make best use of our kidney TRAP datasets, we are making this data available to the greater scientific community. This data is an invaluable resource for identification of potential drug targets and biomarkers for kidney disease, as well as for elucidating the mechanism of action for kidney disorders and drug response. In addition to the RNAseq data, we have access to many TRAP mouse lines on the C57Bl6/J strain which are also available. Details of data and transgenic mouse lines will be available at this poster session.

Optogenetic Stimulation of Either Efferent or Afferent Vagus Neurons Protects Kidneys from Ischemia-Reperfusion Injury

Shinji Tanaka,[1] Chikara Abe,[2,3] Diane L. Rosin,[2] Patrice G. Guyenet,[2] Mark D. Okusa.[1] *[1]Medicine, University of Virginia, Charlottesville, VA; [2]Pharmacology, University of Virginia, Charlottesville, VA; [3]Physiology, Gifu University Graduate School of Medicine, Gifu, Japan.*

Background: We recently reported that electrical vagus nerve stimulation (VNS) in the neck protects mouse kidneys from ischemia-reperfusion injury (IRI) by activating the cholinergic anti-inflammatory pathway (CAP). Stimulation of vagal efferent neurons is believed to be essential to the activation of CAP. However, we found that electrical stimulation of the cephalic end of a divided vagus nerve was equally effective against IRI. It is therefore still unclear whether afferent or efferent VNS is most important in ameliorating renal IRI.

Methods: Channelrhodopsin-2 (ChR2) is a light-sensitive, non-selective cation channel that is opened only during blue light application. We crossed *loxP-STOP-loxP ChR2* mice with choline acetyltransferase (*Chat*)-*cre* and vesicular glutamate transporter 2 (*Vglut2*)-*cre* mice to generate *Chat-ChR2* and *Vglut2-ChR2* mice expressing ChR2 in vagal efferent and afferent neurons, respectively. Illumination of the cervical vagus nerve with blue laser selectively stimulated vagal efferent and afferent neurons ("efferent VNS" and "afferent VNS") in *Chat-ChR2* and *Vglut2-ChR2* mice, respectively. Optogenetic stimulation with blue laser (wavelength: 473 nm) of left cervical vagus nerve was performed with 50 Hz (10 sec) to observe physiological changes and with 5 Hz (10 min) in renal IRI experiments to minimize physiological changes. IRI surgery was performed 24 h after optogenetic VNS; mice were euthanized 24 h later.

Results: Blue laser (50 Hz) applied to the cervical vagus nerve, decreased heart rate markedly (300→180 bpm) with no change in respiratory rate in *Chat-ChR2* mice and completely paused breathing by activation of Hering-Breuer inflation reflex in *Vglut2-ChR2* mice, proving selective efferent VNS and afferent VNS. Both efferent VNS (plasma Cr: 1.53±0.20 vs. 0.48±0.05 mg/dL) and afferent VNS (plasma Cr: 1.09±0.22 vs. 0.44±0.06 mg/dL) with 5 Hz protected kidneys from IRI, improved kidney histology and decreased renal *Kim-1* expression. Splenectomy abolished the protective effect in both groups.

Conclusions: Afferent VNS as well as efferent VNS protects the kidneys from IRI. In both cases protection requires the spleen. These results support the hypothesis that CAP underlies the beneficial effect of efferent VNS on IRI and propose that a sympathetic reflex mediates the protective effect of afferent VNS.

Enhancer and Super-Enhancer Dynamics in Kidney Repair

Julia Wilflingseder,[1,2] Michaela Willi,[2] Takaharu Ichimura,[1] Chaochen Wang,[2] Hannes Olauson,[3] M. Todd Valerius,[1] Reinhold Erben,[4] Lothar Hennighausen,[2] Joseph V. Bonventre.[1] *[1]Brigham & Women's Hospital/Harvard Medical School, Boston, MA; [2]NIDDK, National Institute of Health, Bethesda, MD; [3]Clinical Sciences, Karolinska Institute, Stockholm, Sweden; [4]Physiology, University of Veterinary Medicine, Vienna, Austria.*

Background: The endogenous repair process of the mammalian kidney allows rapid recovery after acute kidney injury (AKI) through robust proliferation of tubular epithelial cells. There is currently limited understanding of which transcriptional regulators activate these repair programs. Here we investigate the existence of enhancer dynamics in the regenerating mouse kidney.

Methods: RNA-seq and ChIP-seq (H3K27ac, H3K4m3, BRD4, MED1, POL2) were performed on samples from repairing kidney cortex 4 hours and 2 days after ischemia/reperfusion injury (IRI) to identify activated genes, transcription factors, enhancer and

super-enhancer dynamics. Further, we investigated the role of super-enhancer activation after IRI through pharmacological BET inhibition via the small chemical compound JQ1 in vitro and in AKI models *in vivo*.

Results: AKI leads to genome-wide alterations in enhancer repertoire *in vivo*. We identified 16,781 enhancer sites (H3K27ac / BRD4 positive, H3K4me3 negative) active in Sham and IRI samples; 6,512 lost and 9,774 gained after IRI. The lost and gained enhancer sites could be annotated to 62% and 63% of down- and up-regulated transcripts after AKI, respectively. The top 5 transcription factor binding motifs enriched in lost enhancer sites are Hnf4a, Esrrb, PPARE, RXR and Esrra. In contrast Fra1, Fosl2, Atf3, Jun-AP1 and BATF binding motifs are enriched in gained enhancer sites after injury. Both transcription factor groups show corresponding mRNA changes after injury. Super-enhancer analysis reveals 164 lost and 216 gained super-enhancer sites after IRI. 385 super-enhancers maintain activity before and after injury. Pharmacological inhibition of super-enhancer activity by BRD4 inhibition (JQ1 50 mg/kg/day) before IRI led to suppression of 40% of injury-induced transcripts associated with cell cycle regulation, and significantly increased mortality between days 2 and 3 after AKI.

Conclusions: These results are the first demonstration of enhancer and super-enhancer function in the repairing kidney. In addition, our data call attention to potential caveats for use of small molecule inhibitors of BET proteins that are already being tested in clinical trials. Our comprehensive analysis of enhancer changes after kidney injury *in vivo* has the potential to identify new targets for therapeutic intervention.

Application of New Hypertension Guidelines to Renal Transplant Recipients: Impact on Cardiovascular Outcome and Graft Survival

Nikolaos Pagonas,[1] Felix S. Seibert,[1] Frederic Bauer,[1] Benjamin Rohn,[1] Richard Viebahn,[2] Nina Babel,[1] Timm H. Westhoff.[1] *[1]Medical Department I, Ruhr-University Bochum, Germany, Herne, Germany; [2]Dept. of Surgery, Ruhr-University Bochum, Bochum, Germany.*

Background: Based on data of the SPRINT trial, American national guidelines recently reduced the blood pressure goal from 140/90 mm Hg to 130/80 mm Hg for subjects with increased cardiovascular risk, e. g. those with chronic kidney disease. To date it remains elusive whether renal transplant recipients benefit from these goals as well.

Methods: We performed a retrospective analysis of 877 patients who underwent kidney transplantation between 1997 and 2011 in three transplant centers in Germany (Berlin and Bochum) with a follow-up of 12 - 120 months. Blood pressure was obtained at regular follow-up examinations in the transplant outpatient clinic. Patient and graft survival was defined as composite endpoint. Subjects were stratified according to mean systolic blood pressure values < 130 mmHg, 130-139 mmHg, or ≥ 140 mmHg.

Results: Mean SBP of the overall follow-up period was significantly associated with patient and graft survival. Cumulative survival was significantly higher for those patients with a systolic blood pressure (SBP) < 130 mmHg than those with 130-140 mmHg. Survival was lowest in renal transplant recipients with a mean SBP ≥ 140 mmHg. Analogously, mean SBP of the first 12 months posttransplant < 130 mmHg was associated with better cumulative patient and graft survival than higher blood pressure values in Kaplan Maier analyses.

Conclusions: Renal transplant recipients who achieve a mean systolic blood pressure < 130 mmHg have a significantly lower mortality and a better allograft outcome than with the conservative blood pressure goal < 140 mmHg. The new blood pressure targets should be considered suitable for renal transplant recipients as well.

TH-PO129

Progression of Cardiovascular Calcification in Renal Transplant Recipients

Maria Yaseen, Amr E. Mohamed, Bilal Ashqar, Waleed Hassan, Radwa Awad, Conor Lowry, Roberto Gedaly, Daniel Davenport, Florence Lima, Hartmut H. Malluche. *University of Kentucky, Lexington, KY.*

Background: Cardiovascular disease is the leading cause of death in renal transplant patients. We conducted a study to determine the progression of cardiovascular calcification in renal transplant recipients.

Methods: 192-slice computed tomography was used to longitudinally examine abdominal and thoracic aortic calcification (AAC, TAC) and CAC in 34 renal transplant recipients at time of transplantation, at 6 months (n=28), and at 12 months (n=24). Univariate analyses were used to assess risk factors for CAC progression. Transplant patients were matched to 50 dialysis patients. Linear regression was used to adjust for baseline CAC in evaluating groups' calcification progression.

Results: Boxplots for AAC, TAC and CAC scores are shown in fig. 1. Pre-transplant square root of CAC volume (SqrtCACVol) correlated with serum calcium (r=.44, p=.012), magnesium (r=.43, p=.018), male gender (r=.56, p=.001), CAD (r=.49, p=.004) and age (r=.65, p < .001), but not with presence of diabetes, phosphorous, or dialysis vintage. None of these variables were associated with 1-year changes in SqrtCACVol. In the matched groups, transplant patients gained less SqrtCACVol compared to dialysis patient (Transplant: 1.3, 95% CI -0.4 - 3.1; Dialysis: 3.9, 95% CI 1.9 – 5.9, fig. 2), though this difference was not significant (p = 0.07).

Conclusions: Renal transplantation does not stop or reverse vascular calcification; however the rate of progression was less compared to dialysis patients.

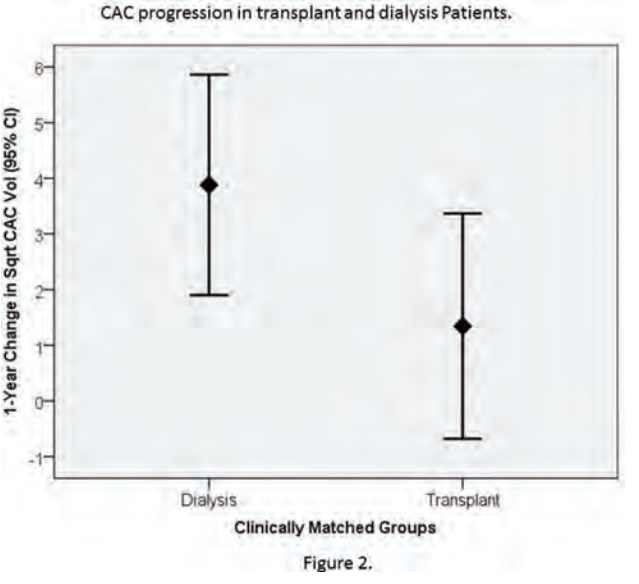

Figure 2.

TH-PO130

Vascular Calcification Slows but Does Not Regress After Renal Transplantation

Harish R. Alappan,[2] Payaswini Vasanth,[1] Shumila Manzoor,[3] W. Charles O'Neill.[1] *[1]Emory University, Atlanta, GA; [2]Emory University - Undergraduate, Atlanta, GA; [3]Renal Division,Department Of Medicine, Emory University, Atlanta, GA.*

Background: While prevention of uremic vascular calcification has been extensively studied, it is not clear whether this lesion is reversible. To address this, we measured the change in breast arterial calcification (BAC), a marker of generalized medial arterial calcification, after successful kidney transplantation (Tx) in women without other risk factors for medial arterial calcification.

Methods: Women with kidney transplantation between 2009 and 2016 who had BAC and at least 2 digital mammograms performed at this institution after Tx were included. Women with diabetes, warfarin use, or serum creatinine > 1.4 were excluded. Breast arterial calcification (BAC) was measured on serial mammograms and linear regression was performed on each patient. Comparison was made to randomly selected cohorts of women with ESRD or eGFR ≥ 60 ml/min/1.73 m^2.

Results: Characteristics of the final cohort of 16 patients (with ranges) were: mean age at Tx, 56 (39-67); mean pre-Tx ESRD duration, 7.0 years (0.3-14); mean serum creatinine at most recent mammogram, 1.05 mg/dl (0.60-1.40); median baseline BAC, 41 mm/breast (2-776); mean number of mammograms, 3.6 (2-6). The slopes of BAC vs. time showed a mean increase of 5.3 ± 2.6 mm/breast/y or 9.8 ± 5.2 %/y, which was significantly ≥0 (p<0.05). This was significantly less than the rate of 18.1 ± 5.6 mm/breast/y in 23 ESRD women (p=0.017) and similar to the rate of 4.3 ± 0.7 mm/breast/y in 43 women with eGFR ≥ 60 ml/min/1.73 m^2. The rate decreased in all 3 patients in whom it could also be measured pre-Tx. The post-Tx slope was negative in 7 patients but within the error of the measurement. In the 10 patients with >2 mammograms, none showed consistent decreases in BAC with each mammogram. There was no difference in age, pre-Tx ESRD duration, baseline BAC, or serum creatinine between patients with positive and negative slopes.

Conclusions: We conclude that medial arterial calcification significantly slows but does not regress after renal transplantation. This irreversibility emphasizes the importance of strategies to prevent vascular calcification during CKD and ESRD.

Factors Associated with Coronary Artery Calcification Score in Renal Transplant Recipients

Jennifer S. Lees,[1,2] Elaine Rutherford,[1,2] Giles Roditi,[2] Alan G. Jardine,[1,2] Patrick B. Mark.[1,2] *[1]Institute of Cardiovascular and Medical Sciences, University of Glasgow, Glasgow, United Kingdom; [2]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom.*

Background: Coronary artery calcification (CAC) is associated with cardiovascular morbidity. The presence and severity of CAC amongst renal transplant patients may vary because of heterogeneity within the population. We sought to determine factors associated with CAC using baseline data from a clinical trial.

Methods: Prevalent renal transplant patients recruited to a clinical trial of vitamin K supplementation (ViKTORIES: ISRCTN22012044) were included. Biochemical tests were performed and demographic data recorded at the baseline visit. Coronary artery calcification (CAC) was determined by non-contrast CT coronary calcium (Agatston) score; score >160 was considered high. Binary logistic regression analysis was used to determine factors associated with high CAC score. Analyses were conducted using *stats* and *oddsratio* for R statistical software.

Results: There were 68 trial participants included: 70.6% were male; 97.1% were Caucasian. Patients with high CAC score (58.8%; median score 1269, IQR 502-3245) were older (60.8 vs 54.7 years; p=0.01) with similar systolic blood pressure (152 vs 144 mmHg; p=0.08) and proteinuria (urine protein creatinine ratio 98 vs 72 mg/mmol; p=0.56), but had longer time since renal transplant (11.2 vs 7.4 years; p=0.05) and time since first renal replacement therapy (17.0 vs 9.8 years; p=0.002). There was no difference in graft function (GFR 50.6 vs 54.2 ml/min; p=0.54) and both groups had controlled calcium, phosphate and parathyroid hormone. Vitamin D insufficiency (vitamin D <30 ng/nl) was common in both groups (71.4 vs 65.0%; p=0.58). On binary logistic regression analysis, factors associated with high CAC score were older age (OR 1.18 per 10-year increase; 95% CI 1.05-1.33), longer duration of non-transplant RRT (OR 1.02 per year; 95% CI 1.01-1.04) and current or previous smoking history (OR 1.35; 95% CI 1.09-1.67).

Conclusions: In a diverse group of renal transplant recipients, high CAC score was associated with older age, dialysis vintage and smoking status, but not with traditional markers of CKD mineral and bone disorder or vitamin D insufficiency. These offer few modifiable risk factors for intervention, though smoking cessation may be worthwhile. Activity of calcification inhibitors may be important in this patient group and warrant further study.

TH-PO132

High Molecular Weight Adiponectin Inhibits Vascular Calcification in Renal Allograft Recipients

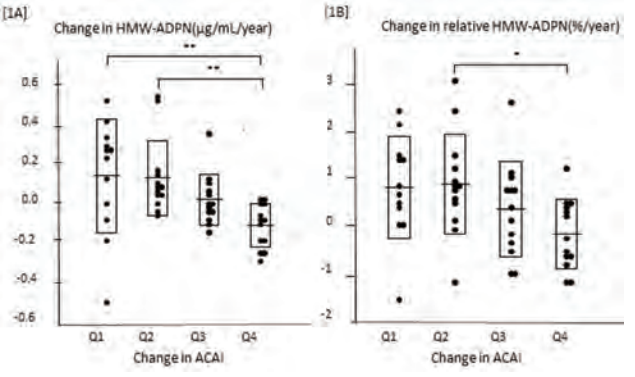
Kanae Nomura, Hiroki Adachi, Keiichiro Okada, Keiji Fujimoto, Hitoshi Yokoyama. *Kanazawa medical university, Kahoku, Japan.*

Background: Adiponectin (ADPN) prevents the development/recurrence of cardiovascular events via its anti-atherogenic effects. However, few long-term studies have examined the changes in serum ADPN levels and arterial calcification seen in renal allograft recipients.

Methods: The effects of the serum ADPN level on arterial calcification were examined in 51 Japanese renal allograft recipients. Abdominal aorta calcification was evaluated on computed tomography using the aortic calcification area index (ACAI). The change in the ACAI and serum high-molecular-weight (HMW) - ADPN fractions were studied over an 8-year period. The arterial expression of ADPN, ADPN receptors (AdipoR)1 and 2, and T-cadherin (cadherin-13) were also examined by immunohistochemistry.

Results: 1) The change in the ACAI were grouped into quartiles and compared with the alterations in the serum levels of each ADPN fraction over an 8-year period. The change in the ACAI was much lower in the patients with highly elevated HMW-ADPN levels. 2) Multiple regression analysis demonstrated that an advanced age at transplant and a history of cardiovascular complications were associated with an increased change in the ACAI, while higher HMW-ADPN concentrations were associated with improvements in the ACAI. Serum HDL-C level was also identified as a positive factor to increase serum HMW-ADPN level. 3) In immunohistochemical examinations, ADPN was detected on CD31-positive arterial endothelial cells from renal allograft biopsy samples. ADPN co-localized with T-cadherin and AdipoR1, but only partially co-localized with AdipoR2.

Conclusions: Both HMW-ADPN and HDL-C might inhibit the progression of vascular calcification by promoting ADPN binding to vascular endothelial cells via T-cadherin and AdipoR in Japanese renal allograft recipients.



TH-PO133

Serum Calcification Propensity and Fetuin-A: Biomarkers of Cardiovascular Disease in Long-Term Kidney Transplant Recipients

Andrew Bostom. For The FAVORIT Study Investigators *Memorial Hospital of Rhode Island, Chepachet, RI.*

Background: "T50," shortened transformation time from primary to secondary calciprotein particles, may reflect deranged mineral metabolism predisposing to vascular calcification, and cardiovascular disease [CVD]. The glycoprotein fetuin-A is a major T50 determinant.

Methods: The FAVORIT cohort, is a completed, large, multiethnic controlled clinical trial cohort of chronic, stable kidney transplant recipients (KTRs). We conducted a longitudinal case-cohort analysis using a randomly selected subcohort of patients, and all individual cases who developed CVD. Serum T50 and fetuin-A were determined in this total of n=685 FAVORIT trial participants at randomization.

Results: 311 incident or recurrent CVD events occurred during a median surveillance of 2.18-years. Shorter T50 (minutes), or reduced fetuin-A concentrations (g/L) were associated with CVD after adjustment for treatment assignment, systolic blood pressure, age, sex, race, pre-existing CVD and diabetes, smoking, body mass index, total cholesterol/HDL cholesterol, kidney allograft vintage and type, calcineurin inhibitor, or lipid lowering drug use, estimated glomerular filtration rate, and urinary albumin/creatinine: tertile 1 (lowest) to tertile 3 (highest) comparisons, T50, [HR= 1.86; 95% CI= (1.20, 2.89)]; fetuin-A, [HR=2.25, 95% CI= (1.38, 3.69)]. Elevated high sensitivity c-reactive protein [hsCRP] was an effect modifier of both these associations.

Conclusions: Shortened T50, as well as reduced fetuin-A levels, ostensible promoters of vascular calcification, remained associated with greater risk for CVD outcomes, after adjustment for major CVD risk factors, measures of kidney function and damage, and KTR clinical characteristics and demographics, in a large, multiethnic cohort of long-term KTRs. Increased hs-CRP was an effect modifier of these CVD risk associations.

Impact of Hypertension and White Coat Hypertension on Renal Function and Blood Pressure Post Kidney Donation

Aruni Ratnayake, Pauline A. Swift, Peter A. Andrews, Mysore K. Phanish. *Epsom and St Helier University Hospitals NHS Trust, London, United Kingdom.*

Background: The effects of nephrectomy on blood pressure (BP) and renal function in kidney donors with hypertension (HTN) and white coat HTN are unclear. This study is a pilot of a planned larger project aimed at investigating this in UK kidney donor population.

Methods: Living donors with HTN and white-coat HTN (BP >140/90 but normal ABPM) between January 2010 to December 2014 were identified. Matched normotensive donors were chosen as controls.

Results: N=30, 10 in each category. Table 1 shows demographics pre-donation. There was no significant difference in percentage reduction of eGFR post-donation across all donor groups (Figure 1). No donor had proteinuria pre-donation. Post-donation, donors with normal BP and white coat HTN did not develop proteinuria. However 20% donors

in HTN group developed proteinuria. All normotensive donors had normal BP readings post-donation. No donors in the white coat HTN group took anti-hypertensive medication pre-donation; post-donation, 40% required medication. All donors in HTN group took anti-hypertensive medications pre-donation; of these, 70% had raised BP post-donation needing uptitration of medications.

Conclusions: There was no significant difference in change in renal function across all 3 groups. Our observations of higher incidence of proteinuria and uptitration of BP medications in donors with HTN, and significant proportion of donors with white coat HTN requiring antihypertensive medications post-donation merits further investigation. Our future work will investigate the impact of pre-donation HTN and white coat HTN on renal function and cardiovascular health in a large cohort of kidney donors.

Association Between Malnutrition – Inflammation Score and Bone Fractures in Prevalent Kidney Transplant Recipients

Miklos Z. Molnar,[1,4] Abduzhappar Gaipov,[1] Orsolya Cseprekál,[2] Praveen Kumar Potukuchi,[1] Kairat Kabulbayev,[5] Manish Talwar,[6] James D. Eason,[7] Istvan Mucsi,[3] Csaba P. Kovesdy.[1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]Semmelweis University, Budapest, Hungary; [3]University of Toronto, Toronto, ON, Canada; [4]Transplant Nephrology- Methodist Le Bonheur, Memphis, TN; [5]Kazakh national medical university, Almaty, Kazakhstan; [6]UTHSC, Germantown, TN; [7]University of TN/Methodist Transplant Institute, Memphis, TN.*

Background: Kidney transplant recipients (KTR) have a 4-fold higher risk of fracture compared to the general population. Chronic inflammation and protein energy wasting (PEW) syndrome are common in KTR and associated with poor outcomes. The presence of inflammation and PEW syndrome can directly affect bone resorption and bone formation, leading to bone loss and fractures. We assessed the association between Malnutrition-Inflammation Score (MIS) a marker of PEW and bone fractures in KTR.

Methods: This prospective cohort study included 839 prevalent KTR. MIS is a semiquantitative instrument for the evaluation of Malnutrition–Inflammation Complex Syndrome, was calculated at the study entry. Self-reported history of fractures was recorded during the 2-year follow-up period. The association between MIS and bone fractures was examined in logistic regression analyses with adjustment for age, gender, eGFR, smoking habits, history of pre-transplant bone fractures and acute rejection.

Results: Mean age was 51±13 years and 56% of patients were males. Fifty-five (7%) patients experienced bone fractures during the follow-up period. In logistic regressions, MIS score showed linear association with increased risk of fracture (Figure 1). Each 1-point higher MIS was associated with 23% higher risk of bone fractures (odds ratio (OR) and 95%CI: 1.23, 1.12–1.34), which remained significant after multivariable adjustments (OR: 1.17, 95%CI: 1.06–1.29).

Conclusions: The MIS is independently associated with new bone fractures in prevalent KTR.

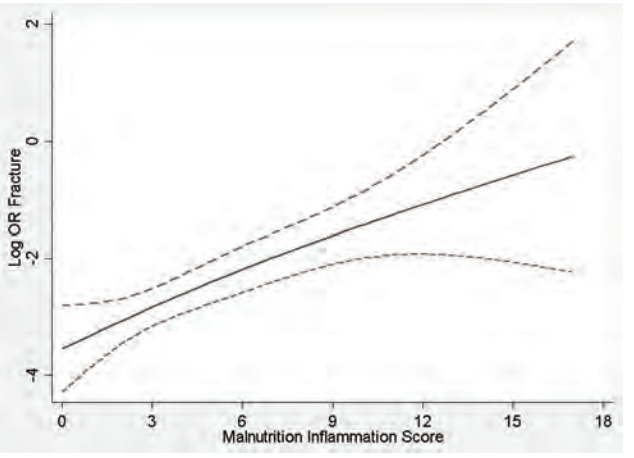

Figure 1. An association of MIS with bone fractures using cubic splines

TH-PO136

Association Between Serum Pre-Albumin Level and Outcomes in Prevalent Kidney Transplant Recipients

Miklos Z. Molnar,[1,3] Abduzhappar Gaipov,[1] Christopher D. Jackson,[1] Manish Talwar,[1,3] Vasanthi Balaraman,[1,3] Arijit Chakravarty,[1,3] Orsolya Cseprekál,[2] Zoltan Mathe,[2] Adam Remport,[2] Csaba P. Kovesdy,[1] James D. Eason,[1,5] Istvan Mucsi.[4] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]Semmelweis University, Budapest, Hungary; [3]Transplant Nephrology- Methodist Le Bonheur, Memphis, TN; [4]University of Toronto, Toronto, ON, Canada; [5]University of TN/Methodist Transplant Institute, Memphis, TN.*

Background: Prealbumin, a transport protein mostly synthesized in the liver, is a marker of nutrition. While decreased prealbumin levels are associated with increased mortality in end stage kidney disease patients, its association with mortality in kidney transplant recipients remains unknown. We evaluated the association between prealbumin levels and outcomes in kidney transplant recipients.

Methods: This prospective cohort study included 991 kidney transplant recipients enrolled from December 31, 2006 to December 31, 2007 and followed over a 6-year period. Sociodemographic, past medical history, clinical and laboratory data were collected at the study entry. Associations between prealbumin levels and death with functioning graft, all-cause mortality and graft loss were examined using survival models.

Results: Serum prealbumin levels showed significant negative correlation with eGFR (R=-0.28, p<0.001), and hsCRP (R=-0.24, p<0.001) (Figure 1). Each 5 mg/dL lower serum prealbumin level was associated with 20% higher risk of death with functioning graft (Hazard Ratio (HR) [95% Confidence Interval (CI)]: 1.20 [1.08–1.35], p=0.001), which persisted after multivariable adjustments (HR [95%CI]: 1.13 [1.00–1.28], p=0.039) (Figure 2). Qualitatively similar trend was observed in all-cause mortality; however, there was no association between prealbumin levels and graft loss (Figure 2).

Conclusions: Lower serum prealbumin level is associated with increased risk of death with functioning graft and all-cause mortality in prevalent kidney transplant recipients.

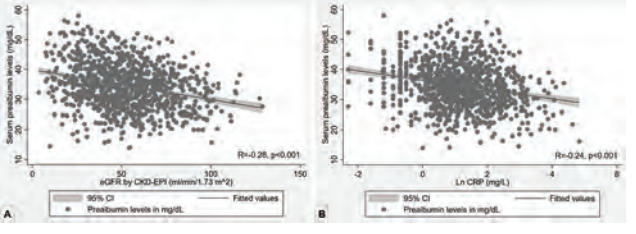

Figure 1: Association between serum prealbumin level with eGFR (panel A) and serum C-reactive protein (panel B).

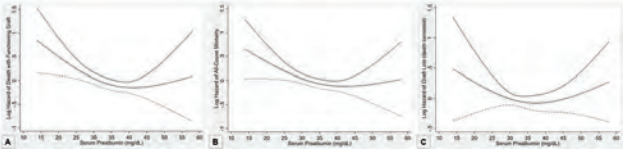

Figure 2: An adjusted association of serum prealbumin levels with death with functioning graft (panel A), all-cause mortality (panel B) and death censored graft loss (panel C) using cubic splines

Myocardial Perfusion Reserve Is Preserved in Patients with Kidney Transplant

Johanna M. Päivärinta,[2,1] Kaj P. Metsarinne,[2] Juhani Knuuti,[4,3] Eliisa Löyttyniemi,[3] Niina S. Koivuviita.[2] *[1]Department of Medicine, University of Turku, Turku, Finland; [2]Turku University Central Hospital, Turku, Finland; [3]University of Turku, Turku, Finland; [4]PET center, Turku, Finland.*

Background: Chronic kidney disease (CKD) has been associated with decreased myocardial perfusion reserve (MPR), the ratio of stress and rest perfusion. MPR reflects the capacity of vascular bed to increase perfusion and reflects the endothelial function and microvascular responsiveness. The effect of kidney transplantation on MPR is unknown. In this study our aim was to assess MPR of kidney transplant patients.

Methods: 10 healthy subjects and 19 kidney transplant patients without manifest atherosclerotic disease and with mild to moderate kidney impairment were included in the study. The average age of kidney transplant patients was 37 +/-23 months. Myocardial perfusion (MP) was measured by means of [^{15}O]H_2O PET (positron emission tomography) at rest and during adenosine infusion.

Results: MP was statistically significantly higher at rest in the kidney transplant patients than in the healthy controls (p=0.0015). After correction by cardiac work load (basal MP_{corr}, corrected basal myocardial blood flow, [(MP/own RPP)xRPP average of the healthy]) the difference between the groups disappeared. Coronary vascular resistance (CVR) at rest and CVR and MP at stress were comparable between the groups. Although MPR was reduced, MPR_{corr} (=stress flow/basal MP_{corr}) did not differ between the kidney transplant patients and the healthy controls.

Conclusions: MP and CVR during stress are preserved in the kidney transplant patients with mild to moderate CKD. The reduced MPR is explained by increased resting MP which is likely linked with increased cardiac workload due to sympathetic overactivation in the transplant patients.

Arterial Stiffness and Immunosuppressive Regimen in Renal Transplants Recipients

Zbigniew Heleniak,[1] Jakub Ruszkowski,[1] Fabian Halleck,[2] Sarah M. Illersperger,[2] Susanne Brakemeier,[2] Alicja Debska-Slizien,[1] Klemens Budde.[3] *[1]Nephrology, Transplantology and Internal Medicine, Medical University of Gdansk, Gdansk, Poland; [2]Charité Universitätsmedizin Berlin, Berlin, Germany; [3]Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: Reduction of cardiovascular influences on the long-term survival rates of renal transplant recipients (RTRs) The aim of the study was to assess the relation between immunosuppression and pulse wave velocity in RTRs.

Methods: 103 RTRs, who were visiting outpatient clinic in February 2018 were enrolled into the study. eGFR was calculated with the CKD-EPI formula. Arterial stiffness was assessed by means of brachial-ankle and carotid-femoral pulse wave velocity (baPWV, cfPWV) measured by ABI-system 100. Patient characteristics and results were described by median and interquartile range (IQR) for continuous variables and by frequencies for categorical variables.

Results: Median age of 103 studied RTRs was 53 (37-61) years, 64 (62.1%) patients were male. Details are presented in figure 1. The immunosuppressive regimen was as follow: calcineurin inhibitors (CNI) (68.9/17.5% on TAC/CsA, respectively), antiproliferative agents (48.5/47.6% on MPS/MMF, respectively), steroids (39.8/7.8/3.9% on methylprednisolone/prednisolone/prednisone, respectively), belatacept (6.8%). There was linear correlation between CsA level and cfPWV (p <0,05). CsA concentration/dose (C/D) ratio correlated with baPWV (p<0,05). Neither tacrolimus daily dose nor concentration correlated with baPWV and cfPWV, respectively. C/D ratio of TAC correlated with cfPWV p<0,05). There were observed linear correlations between age of the patients, duration of renal replacement therapy and baPWV, cfPWV (p<0,05). eGFR correlated negatively with cfPWV (p<0,05)

Conclusions: CsA and TAC were administered in the majority of the study population. CNI increased the arterial stiffness. Both CsA and TAC C/D ratio had the influence on PWV. Age, RRT duration time and eGFR correlated with arterial stiffness markers

Parameter	Median (IQR) value	unit
Time after KTx	61 (22-110)	month
Total time of RRT	134 (73-188)	month
eGFR	52 (38-72)	ml/min/1,73m^2
Creatinine level	1.41 (1.05-1.88)	mg/dl

TH-PO139

Progression of Endothelial Dysfunction, Atherosclerosis, and Arterial Stiffness in Kidney Transplant Patients

Joey Junarta,[1] Nina Hojs,[2] Racquel M. Lowe-Jones,[1] Juan carlos Kaski,[1] Debasish Banerjee.[1] *[1]St. George's, University of London, London, United Kingdom; [2]University Clinical Centre Maribor, Maribor, Slovenia.*

Background: Cardiovascular events are the commonest cause of mortality and morbidity in kidney transplant recipients, yet little is known about the changes in vascular structure and function with time. This pilot study investigated changes vascular structure and function over time, in stable kidney transplant patients (KTxPs) compared to controls.

Methods: Brachial artery flow-mediated dilation (FMD), nitroglycerine-mediated dilation (NMD), carotid-femoral pulse wave velocity (cf-PWV), ankle-brachial pressure index (ABPI), and common carotid artery intima-media thickness (CCA-IMT) were assessed in 18 KTxPs and 17 controls at baseline and 3-6 months after. All subjects were recruited after written consent and all measurements were done in our vascular laboratory under standard conditions.

Results: There were more dyslipidaemics in KTxPs compared to controls (10 vs. 3; *P*=0.02). There was no difference in age (51.28 ± 13.29 vs. 45.82 ± 10.85; *P*=0.19), body mass index (25.56 ± 5.18 vs. 24.59 ± 2.59; *P*=0.49), or diabetes status (3 vs. 0; *P*=0.08). No difference existed in vascular markers between KTxPs and controls at baseline: FMD (4.34 ± 3.45 vs. 4.63 ± 3.02 %; *P*=0.79), NMD (15.15 ± 6.08 vs. 16.00 ± 5.47 %; *P*=0.67), cf-PWV (7.83 ± 1.76 vs. 6.96 ± 1.26 m/s; *P*=0.10), ABPI (1.27 ± 0.15 vs. 1.18 ± 0.08; *P*=0.47), CCA-IMT (5.73 ± 0.95 vs. 5.54 ± 1.08 mm; *P*=0.05). Vascular measurements did not change in controls upon follow-up (see table 1). In KTxPs, FMD decreased (-1.52 ± 2.74 %; *P*=0.03), cf-PWV increased (0.62 ± 1.06 m/s; *P*=0.03), and CCA-IMT increased (0.35 ± 0.53 mm; *P*=0.02).

Conclusions: Markers of vascular structure and function worsened in stable kidney transplant patients follow-up. We propose that after initial improvement in cardiovascular health immediate post-transplant; the newly acquired cardio-vascular risk factors, immunosuppression and persistent mild CKD may cause further deterioration explaining the elevated risk for CV events.

Table 1. Changes in cardiovascular structure and function from baseline to second visit

Parameter	Healthy controls (n=17)			KTxPs (n=18)			Between-group comparison
	Baseline visit	Second visit	P-value	Baseline visit	Second visit	P-value	Baseline results P-value
Brachial FMD (%)	4.63 ± 3.02	3.51 ± 2.73	0.33	4.34 ± 3.45	2.82 ± 2.18	0.03	0.79
Brachial NMD (%)	16.00 ± 5.47	17.17 ± 5.18	0.31	15.15 ± 6.08	15.74 ± 3.88	0.68	0.67

TH-PO140

Incidence of Cardiovascular Diseases in Pediatric Solid Organ Transplant Recipients

Sandeep Brar,[1,2] Stephanie Dixon,[5,8] John M. Paterson,[5,7] Joseph Kim,[1,2] Diane Hebert,[1,3] Jade S. Dirk,[5] Emma J. Hahn,[6] Rulan S. Parekh,[3,1] Rahul Chanchlani.[4] *[1]Department of Medicine, University of Toronto, Toronto, ON, Canada; [2]Division of Nephrology and the Kidney Transplant Program, University Health Network, Toronto, ON, Canada; [3]The Hospital For Sick Children, Toronto, ON, Canada; [4]McMaster Children's Hospital, Hamilton, ON, Canada; [5]Institute for Clinical Evaluative Sciences, London, ON, Canada; [6]Institute of Clinical Evaluative Sciences, London, ON, Canada; [7]Institute of Health Policy, Management, and Evaluation, Toronto, ON, Canada; [8]Department of Epidemiology and Biostatistics, Western University, Toronto, ON, Canada.*

Background: Cardiovascular disease (CVD) is a long-term complication in pediatric solid organ transplant (SOT) recipients; however, the incidence is not well described.

Methods: We conducted a cohort study comparing CVD rates in children with SOT (heart, liver, lung, kidney, small bowel) at the Hospital for Sick Children in Toronto,

Canada (n = 979) with a random sample of healthy, non-transplanted children in Ontario (n = 1,000,000) between 1993 and 2014 using provincial health administrative data. Outcomes included non-fatal CVD events, CVD-specific death, and a composite of non-fatal and fatal CVD events. Non-fatal CVD events were defined as atherosclerotic (acute myocardial infarction, stroke, peripheral vascular disease, carotid endarterectomy, percutaneous coronary intervention, coronary artery bypass grafting) and non-atherosclerotic (congestive heart failure, arrhythmia, cardiac defibrillation, insertion of pacemaker, out of hospital cardiac arrest).

Results: Among SOT recipients, 41% had a kidney transplant, 32% had a liver transplant and 22% had a cardiac transplant. The remaining 5% had lung, small bowel or multi-organ transplants. Mean age at index was 7.7 and 8.1 years in the transplant and non-transplant group, respectively. During an overall median follow-up time of 11.0 years (interquartile range: 5.7-17.5 years), CVD events were at least 50 times more likely to occur in SOT recipients versus healthy, non-transplanted children (table).

Conclusions: The increased incidence of CVD in children post transplantation highlights the need for surveillance and prevention during transition into early adulthood.

Events and incidence rate ratios for cardiovascular outcomes in pediatric solid organ transplant recipients

Outcome	Number of events	Event rate per 1000 person-years	Incidence rate ratio (per 1000 person-years) (95% CI)
Non-fatal composite			
Non-transplant	5727	0.5	Reference
Transplant	260	32.5	68.2 (60.2, 77.2)
Non-fatal, atherosclerotic CVD			
Non-transplant	3104	0.3	Reference
Transplant	167	19.5	75.7 (64.8, 88.4)
Non-fatal, non-atherosclerotic CVD			
Non-transplant	4422	0.4	Reference
Transplant	167	19.5	52.9 (45.5, 61.5)
CVD-specific death			
Non-transplant	633	0.1	Reference
Transplant	76	9.5	180.3 (142.1, 228.7)
Non-fatal and fatal composite			
Non-transplant	6072	0.5	Reference
Transplant	278	34.7	68.8 (61.0, 77.5)

TH-PO141

Obesity as a Predictor of Renal Allograft Function

Nathan A. Luke,[3] Ekamol Tantisattamo.[1,2] *[1]Division of Nephrology and Hypertension, Department of Medicine, University of California Irvine School of Medicine, Orange, CA; [2]Multi-Organ Transplant Center, Division of Nephrology, Department of Internal Medicine, William Beaumont Hospital, Oakland University William Beaumont School of Medicine, Royal Oak, MI; [3]Oakland University William Beaumont School of Medicine, Rochester, MI.*

Background: While being underweight in ESRD is associated with increased morbidity and mortality, obesity in these patients leads to unfavorable post-transplant outcomes. The aim of this study is to explore associations between pre-transplant obesity and early readmission (ERA), as well as renal allograft function at 12 months post-transplantation.

Methods: Demographic data of 84 patients receiving a kidney transplantation from January to December 2014 were retrieved. The patients were categorized into non-obese and obese groups based on BMI. ERA, defined as any admission within 30 days after the discharge date from transplant admission, and eGFR was associated with pre-transplant obesity status.

Results: Of all 83 patients, 53 were non-obese and the remaining 30 patients were obese with mean BMIs of 24.65±3.08 and 34.12±2.98, respectively (95% CI -10.85, -8.09, p <0.001). Pre-transplant diabetes were lower in the non-obese group than in the obese group (30% vs 60%, p 0.015); otherwise, all other baseline characteristics between non-obese and obese groups were similar. There were 19, 4, and 2 patients who had 1, 2, and 3 ERA, respectively. One patient died at the early post-transplant period. The remaining 57 patients were never readmitted. Obese patients had 33% higher odds of being readmitted when compared to non-obese patients (OR 1.33, 95% CI 0.50, 3.51, p 0.562). Among 50 non-obese and 28 obese patients with functioning allografts at 12 months post-transplantation, mean eGFR at 12 months was 59.4±19.55 and 50.9±15.81 ml/min/1.73 m^2, respectively. Obese patients had a decrease in eGFR of 8.56 ml/min/1.73 m^2 at 12 months post-transplantation compared to non-obese patients (95% CI -17.17 to 0.04, p 0.051). After adjusted for all variables including age, race, type of kidney transplantation, induction immunosuppressive medications, pre-transplant diabetes, hypertension, hyperlipidemia, and smoking, obese patients had a significant decrease in eGFR at 12 months post-transplantation by 10.10 ml/min/1.73 $m^2$when compared to non-obese patients (95% CI -20.18 to -0.02, p-value 0.0495).

Conclusions: Although ESRD patients who are underweight are at risk of poor outcomes during the pre-transplant period, pre-transplant obesity increases the risk of poorer renal allograft function. Patients who will undergo a kidney transplantation should control and maintain their weight in a normal range.

TH-PO142

Overweight and Size Mismatch Are Risk Factors of De Novo Focal Segmental Glomerulosclerosis After Kidney Transplantation from Parent to Child

Tomo Suzuki,[3] Masahiko Yazawa,[3] Daisuke Ichikawa,[3] Naohiko Imai,[3] Hideo Sasaki,[1] Yuhji Marui,[1] Junki Koike,[2] Yugo Shibagaki.[3] *[1]Department of Urology, St. Marianna university school of medicine, Kawasaki, Japan; [2]St. Marianna University, Kawasaki, Japan; [3]St Marianna University Hospital, Kawasaki, Japan.*

Background: Proteinuria among transplant recipients is an important factor for allograft and patient survival. In addition, the mean age of donor is increasing in Japan. The aging donor is a risk factor of de novo focal segmental glomerulosclerosis (FSGS) due to podocytopenia and loss of nephron number. The aim of this study is to evaluate the risk factor in de novo FSGS after kidney transplantation (KTx) from parent to child.

Methods: This is an observational case control study. The subjects were 45 patients who underwent KTx from parent to child between 2009 Apr to 2016 Aug in our Hospital and whose allograft survived to have allograft biopsy not showing FSGS at both 0 and 12 months. Cases of recurrent FSGS (N=1), IgA nephropathy (N=1), and nephrosclerosis of 0h biopsy (N=1) and those without protocol biopsy at 12 months (N=3) were excluded, leaving total of 39 patients. We examined clinical and histological features, with all values are expressed as mean ± standard error (SE).

Results: Five out of 39 recipients showed FSGS in biopsy which was done after > 12 months (FSGS group). Comparing FSGS group vs non-FSGS group, male accounted for 100% vs 61.8 %, the ages were 41.2 ± 3.3 vs 35.0 ± 1.3 (p=0.088), body weight (BW) were 74.9 ± 6.1 vs 59.5 ± 2.4 kg (P=0.024), body mass index (BMI) were 26.2 ± 2.0 vs 21.9 ± 0.8 kg/m^2(P = 0.049), the donor age was 68.8 ± 3.2 vs 62.4 ± 1.2 (p=0.069), and the donor eGFR was 72.3 ± 6.2 vs 77.6 ± 2.4 ml/min/1.73m^2, respectively. So, there were significant differences for BW and BMI of recipients. Before KTx, the difference between the recipient and donor's BW was significantly higher in FSGS group [18.3 ± 7.3 vs 1.4 ± 2.8 kg (p=0.038)]. At protocol biopsy of 12 months after KTx, BW and BMI in FSGS group were also significantly higher than non-FSGS group [BW; 78.0 ± 6.1 vs 60.6 ± 2.3 kg (P=0.012), BMI; 27.3 ± 1.9 vs 22.3 ± 0.8 kg (P=0.027)]. The duration to FSGS diagnosis after KTx was 1066 ± 277 day. The Columbia classification of FSGS group was all NOS variant (no perihilar). The range of foot process effacement was not diffuse, indicating these FSGS were secondary.

Conclusions: Overweight of the recipient and size mismatch are risk factors of de novo FSGS after 12 months post-KTx from parent to child.

TH-PO143

Obesity Is a Risk Factor for ESRD in Prior Living Kidney Donors

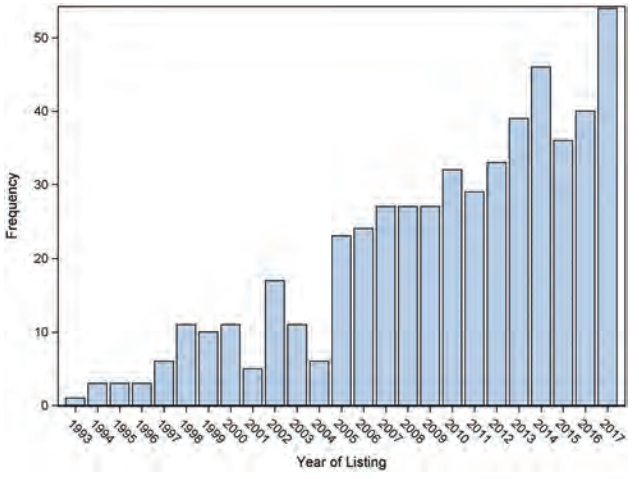
Amarpali Brar,[1] Angelika C. Gruessner,[1] Rahul M. Jindal,[3] Robert Nee,[2] Dimitre Stefanov,[1] Moro O. Salifu.[1] *[1]SUNY Downstate Medical Center, Brooklyn, NY; [2]Walter Reed National Military Medical Center, Vienna, VA; [3]Uniformed Services University of Health Sciences, Silver Spring, MD.*

Background: Living donors undergo extensive evaluation prior to donation. Despite that some living kidney donors (LKDs) progress to end stage renal disease (ESRD). We evaluated the trends and characteristics of LKDs who were waitlisted for kidney transplantation.

Methods: We used the United Network for Organ Sharing data to identify 524 LKDs who were listed for kidney transplantation from 1993-2017. For qualitative variables, frequencies were computed and the tests of association were performed using the chi-square test.

Results: In this cohort, 59.8% (n=313) were men and 40.2% (n= 211) women. Cause of ESRD was diabetes in 17.5%, hypertension in 32% and other in 44%. Forty six % were White, 38.5% Black, 10% Hispanic, 2.2% Asian, 1.9 % Native -American and 1.1% were multiracial. Mean age at listing was 55 yrs ±11.4. **Figure 1** shows the increasing number of prior LKDs who waitlisted from 1993- 2017. The number of Black LKDs who waitlisted were disproportionately higher (38.5%) as compared to the proportion of Black LKDs in this time period varying from 8% to 12%. Hypertension as a cause of ESRD was observed to be much higher in Blacks (41.1%) and Hispanics (32%) as compared to Whites (26%), p= 0.02. Mean BMI at time of waitlisting was 29.5 ± 5.2 kg/m^2. Among LKDs who were listed for transplantation, majority were overweight (36%) or obese (43.%). Forty-one percent of (n=100) white, 46% (n=93) black, 46 % Hispanic (n=24) and 25.3% (n=7) multiracial prior LKDs were obese (>30kg/m^2) at time of wait listing, p=0.18.

Conclusions: Transplantation centers now approve more medically complex obese LKDs without supporting data. Informed consent with obese individuals are critical in those considering LKD. Life style changes and modifications should be addressed in those with normal BMI at time of donation to avoid future obesity. Long-term studies are needed to understand risks associated with hypertension and obesity focused on minority LKDs



TH-PO144

Association of Visceral Obesity After Kidney Transplantation with Graft Survival in Living Kidney Transplant Recipients: A Retrospective Cohort Study

Reibin Tai,[1] Yasushi Ohashi,[2] Masaki Muramatsu,[1] Takeshi Kawamura,[2] Nobuyuki Shiraga,[3] Seiichiro Shishido,[1] Ken Sakai.[1] *[1]Nephrology, School of Medicine, Faculty of Medicine, Toho University, Tokyo, Japan; [2]Nephrology, Sakura Medical Center, School of Medicine, Toho University, Chiba, Japan; [3]Radiology, School of Medicine, Faculty of Medicine, Toho University, Tokyo, Japan.*

Background: Excessive weight gain is common after kidney transplantation. However, the relationship between visceral obesity and kidney allograft outcome remains unclear. We measured the visceral fat area by computed tomography and examined the relation with the kidney allograft survival.

Methods: We identified 254 recipients who underwent living kidney transplantation from 2004 to 2014. Of those, 196 recipients evaluated metabolic risk factors and visceral fat area at the level of the umbilicus on abdominal computed tomography before transplantation and 12 months after transplantation and were followed until February 2018. Visceral obesity was defined as visceral fat area of ≥100cm^2. Metabolic syndrome was defined by the NCEP ATP III criteria modified for the Japanese population. Treatment-resistant hypertension was defined as an office blood pressure of ≥130/80 mmHg, despite receiving ≥3 antihypertensives including diuretics, or ≥4 drugs usage. The adverse graft outcomes were defined as a decline of 50% or more of estimate glomerular filtration rate with baseline one month after transplantation or initiation of renal replacement therapy.

Results: Recipients with visceral obesity were seen in 69 (35.2%) at 12 months post-transplantation. Compared to recipients with no visceral obesity, they were more likely to be male, older, have a higher weight gain from 1 month to 12 months after kidney transplantation (7.0 ± 7.5 vs. 4.6 ± 8.8%, P <0.05), prevalence of metabolic syndrome (23.2 vs. 3.9%, P <0.01), and treatment-resistant hypertention (17.4 vs. 7.1%, P <0.05), and have a lower glomerular filtration (44 ± 12 vs. 48 ± 15 ml/min/1.73m^2, P <0.05). During median 9.5-year follow-up, they also had higher adverse graft outcome (3.2 vs 1.3 per 100 patient-years, P <0.05). In multivariate analysis, visceral obesity independently remained as a risk factor for kidney allograft outcome (hazard ratio, 2.27 ; 95% confidence interval, 1.11–4.72, P=0.033).

Conclusions: Visceral obesity at 1 year post-transplantation becomes a risk factor for metabolic syndrome and graft survival, which emphasizes the importance of management of obesity after transplantation.

TH-PO145

Effect of Obesity on Transplant Outcome One Year Post Kidney Transplant

Muna Alnimri,[1] Golnaz G. Friedman.[2] *[1]University of California Davis, Sacramento, CA; [2]University of California, Davis Health, Sacramento, CA.*

Background: Kidney transplant is the preferred option of treatment for patients with Chronic kidney disease, studies have shown poor outcome for obese patients BMI≥30kg/m2 and more perioperative complications, the aim of this study is to compare outcomes of obese patients BMI ≥30kg/m2 to patients with BMI<30kg/m2.

Methods: A retrospective single center cohort study of adult kidney transplant recipients between 1/2014 - 1/2016 compairing 308 patient BMI<30 to110 patients BMI≥30, one year patient and graft survival, incidence of delayed graft function, average hospital stay, wound and cardiac complications, new onset diabetes after transplant (NODAT), proteinuria and rejection.

Results: Table1 shows obese patient with BMI≥30kg/m2 were older, diabetics, on peritoneal dialysis, had higher incidence of delayed graft function worse patient suvival in one year, other complcations were not significantly different among both groups

Conclusions: Kidney transplant recipients with BMI ≥30kg/m2 have higher incidence of mortality, delayed graft function than patients with BMI <30kg/m2. Dietery counseling and referral for bariatric surgery is recommended for weight loss to improve post transplant outcome.

Advanced Glycation End Products and Risk of Late Graft Failure and Cardiovascular Mortality in Renal Transplant Recipients: A Prospective Cohort Study

Camilo G. Sotomayor,[1] Antonio Gomes Neto,[1] Marco van Londen,[1] Reinold O. Gans,[1] Stefan P. Berger,[1] Ramon Rodrigo,[2] Stephan J. Bakker.[1] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]Faculty of Medicine, University of Chile, Institute of Biomedical Sciences, Molecular and Clinical Pharmacology Program, Santiago, Chile.*

Background: Advanced glycation endproducts (AGE) have been implicated in the pathogenesis of chronic transplant dysfunction and cardiovascular (CV) disease of renal transplant recipients (RTR), but no prospective studies have been performed to date. We investigated the association of plasma AGE levels with graft failure (GF) and CV mortality in a cohort of RTR with long-term follow-up.

Methods: Tandem mass spectrometry was performed to simultaneously measure the AGE N$^{\varepsilon}$-(Carboxymethyl)lysine (CML) and N$^{\varepsilon}$-(Carboxyethyl)lysine (CEL) levels in hydrolysates of plasma proteins. Multivariate-adjusted Cox-proportional hazards regression analysis was used to assess prospective associations with clinical outcomes.

Results: We included 555 RTR (mean (SD) age 51±12 years old, 56% males). During median follow-up for 6.9 [IQR, 6.2-7.2] years, 67 (12%) RTR developed GF, and 122 (22%) died (52% were due to CV causes). In analyses adjusted for potential confounders, including age, sex, estimated Glomerular Filtration Rate (eGFR) and proteinuria, CML levels were not independently associated with GF, but they were with CV mortality (Table 1). In similar analyses, CEL levels were independently associated with GF and CV mortality (Table 1). The association of CML levels with GF was modified by renal function (P_{int}<0.001), with a significant and independent association in RTR with eGFR≤45 mL/min/1.73m^2 (HR, 1.75; 95% CI, 1.06-2.89; P=0.03).

Conclusions: High plasma levels of the AGE CML and CEL were independently associated with increased risk of GF and premature CV mortality. These results strengthen the quest for studying AGE-targeted interventions as potential therapeutic strategy to improve long-term outcomes in RTR.

Funding: Government Support - Non-U.S.

Table 1. Multivariate-adjusted associations of plasma CML and CEL levels with GF and CV mortality in RTR.

Outcomes	CML, µmol/L		CEL, µmol/L	
	HR (95% CI)	P value	HR (95% CI)	P value
Graft Failure	1.44 (0.89-2.33)	0.14	2.71 (1.26-5.81)	0.01
Cardiovascular mortality	1.90 (1.22-2.95)	0.004	2.77 (1.13-6.83)	0.03

Hazard ratios are adjusted for age, sex, eGFR, proteinuria, primary renal disease, pre-transplant dialysis vintage, time between transplantation and inclusion, BMI, total cholesterol, systolic blood pressure, personal history of diabetes mellitus and CV disease, and familiar history of CV disease.

TH-PO147

Fruit and Vegetable Consumption and Cardiovascular Mortality in Renal Transplant Recipients: A Prospective Cohort Study

Camilo G. Sotomayor,[1] Antonio Gomes Neto,[1] Michele F. Eisenga,[1] Josephine Anderson,[1] Ilja M. Nolte,[2] Martin H. De Borst,[1] Maryse Osté,[1] Ramon Rodrigo,[3] Reinold O. Gans,[4] Stefan P. Berger,[1] Stephan J. Bakker.[1] *[1]Division of Nephrology, Internal Medicine, University Medical Center Groningen, Groningen, Netherlands; [2]Department of Epidemiology, University Medical Center Groningen, Groningen, Netherlands; [3]Molecular and Clinical Pharmacology Program, Institute of Biomedical Sciences, Faculty of Medicine, University of Chile, Santiago, Chile; [4]Internal Medicine, University Medical Center Groningen, Groningen, Netherlands.*

Background: We investigated the associations of fruit and vegetable (F&V) consumption after kidney transplantation with risk of CV mortality in an extensively phenotyped cohort of renal transplant recipients (RTR) with long-term follow-up.

Methods: F&V consumption were assessed by means of an item-specific food-frequency questionnaire. Multivariable-adjusted Cox-proportional hazards regression analysis was performed to assess the risk of CV mortality.

Results: We included 400 RTR (age 52±12 (SD) years old, 54% males). At a median follow-up of 7.2 [interquartile range, 6.7-7.6] years, 93 (23%) patients died, of which 49 (53%) were due to CV disease. Overall, fruit consumption was not associated with CV mortality, whereas vegetable consumption was inversely associated with risk of CV mortality (Table 1). This association remained independent of adjustment for several potential confounders. The association of fruit consumption with CV mortality was significantly modified by renal function (P_{int}=0.01) and proteinuria (P_{int}=0.01), with significant inverse associations in patients with estimated Glomerular Filtration Rate (eGFR)>45 mL/min/1.73m^2 (HR, 0.56; 95% CI, 0.35-0.92; *P*=0.02) or absence of proteinuria (HR, 0.62; 95% CI, 0.41-0.92; *P*=0.02).

Conclusions: In RTR, a relatively high vegetable consumption is independently and strongly associated with lower risk of premature CV mortality. A relatively high fruit consumption is also associated with lower risk of premature CV mortality, although particularly in RTR with eGFR>45 mL/min/1.73m^2 or absence of proteinuria. Further studies are warranted to investigate whether increasing F&V consumption may open opportunities for interventional pathways to decrease the burden of CV mortality in RTR.

Funding: Government Support - Non-U.S.

Table 1. Association of fruit and vegetable consumption with CV and all-cause mortality of RTR

Outcome	Fruit consumption, servings/day		Vegetable consumption, tablespoons/day	
	HR (95% CI)	P value	HR (95% CI)	P value
Cardiovascular mortality	0.90 (0.64-1.27)	0.55	0.50 (0.35-0.72)	<.001
All-cause mortality	0.91 (0.71-1.16)	0.45	0.73 (0.56-0.95)	0.02

Hazard ratios are adjusted for age, sex, income, educational level, physical activity, eGFR, proteinuria, time since transplantation, primary renal disease, total cholesterol, blood pressure, BMI, diabetes and smoking status.

The Incidence and Related Factors of Post-Transplantation Diabetes Mellitus within 1-Year After Kidney Transplantation: Korean Cohort Study for Outcome in Patients with Kidney Transplantation (KNOW-KT)

Seungyeup Han,[1,2] Seong Sik Kang,[1,2] Hayeon Park,[1] Jin hyuk Paek,[1,2] Sang Mok Yeo,[1] Woo Yeong Park,[1,2] Kyubok Jin,[1,2] Sung Bae Park.[1,2] KNOW-KT Study Group *[1]Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Keimyung University Kidney Institute, Daegu, Republic of Korea.*

Background: Posttransplantation diabetes mellitus (PTDM) is associated with poor graft survival and greater mortality. The incidence of PTDM after kidney transplantation (KT) reported to date is varied from 10-74% and varies by country and race. There are few nationwide cohort study reports on the incidence of PTDM and associated risk factors in Korea. The purpose of this study was to evaluate incidence and related factors of PTDM early after KT in Korea.

Methods: A total of 1,080 recipients were enrolled in KoreaN cohort study for Outcome in patients With Kidney Transplantation (KNOW-KT) between July 2012 and August 2016. This study included 723 recipients, excluding 273 patients with pretransplant DM and 84 patients lost of follow-up within 1-year after KT. We evaluated associated factors of PTDM within 1-year after KT.

Results: Among the 723 recipients, 85 (11.8%) was diagnosed and treated with PTDM. In the univariate logistic regression analysis, pretransplantation variables that showed significant associations with PTDM were older recipient age, end-stage renal disease due to polycystic kidney disease, smoking history, high body mass index, waist–hip ratio (WHR), HbA1C levels, numbers of HLA total and HLA-DR mismatches and lower transferrin saturation. Posttransplant variables that were significantly associated with PTDM were high WHR, triglyceride/high density lipoprotein ratio, and serum triglyceride levels, low serum albumin levels, acute rejection, statin use, and vitamin D replacement. In the multivariate logistic regression analysis, predictors of PTDM were older recipient age, high WHR and HbA1C before KT, and statin use after KT.

Conclusions: In Korean cohort study, the incidence of PTDM was 11.8%. Risk factors for PTDM within 1-year after KT were older recipient age, higher WHR and HbA1C before KT. To prevent PTDM, it is important to control the overweight and abdominal obesity through life style modification prior to KT.

TH-PO149

Withdrawal of Antihypertensive Medication One Year After Kidney Transplantation: Korean Cohort Study for Outcome in Patients with Kidney Transplantation (KNOW-KT)

Seungyeup Han,[1,2] Seong Sik Kang,[1,2] Hayeon Park,[1] Jin hyuk Paek,[1,2] Sang Mok Yeo,[1] Woo Yeong Park,[1,2] Kyubok Jin,[1,2] Sung Bae Park.[1,2] KNOW-KT Study Group *[1]Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Keimyung University Kidney Institute, Daegu, Republic of Korea.*

Background: Cardiovascular disease (CVD) is a major cause of graft and patient loss in kidney transplant (KT) recipients. Inadequate control of hypertension in KT recipient is associated with an increased risk of CVD. Therefore blood pressure control after KT is important and it is also important to evaluate the related factors. The purpose of this study was to evaluate the incidence and related factors of withdrawing antihypertensive (AH) medication early after KT.

Methods: A total of 1,080 patients were enrolled in KoreaN cohort study for Outcome in patients With Kidney Transplantation (KNOW-KT) between July 2012 and August 2016. The study included 857 recipients who had been treated for hypertension prior to KT and followed-up for 1-year after KT. We evaluated associated factors of withdrawing AH medication within 1-year after KT.

Results: Among 857 the recipients, 278 (32.4%) withdrawn AH medication within 1-year after KT. The medication withdrawn (MW) group was younger than the medication continued (MC) group and the proportion of female, nondiabetic patients, and non-smokers were higher. In the pre-transplant evaluation, the MW group had lower systolic blood pressure (SBP), body mass index (BMI), triglyceride/high density lipoprotein (TG/HDL) ratio, and serum TG levels and showed thinner left ventricular posterior wall thickness (LVPWT) and smaller left atrial diameter in echocardiography. One year after KT, the MW group had lower BMI, TG/HDL ratio, and serum TG levels and had a lower incidence of delayed graft function (DGF), acute rejection (AR), and coronary artery disease (CAD). In multivariate logistic regression analysis, predictors of withdrawing AH medication after KT were female, lower SBP before KT and thin LVPWT in pre-transplant echocardiography.

Conclusions: In a Korean cohort study, 32.4% of recipients who were treated with hypertension before KT stopped AH medication 1-year after KT. For better control of BP and prevention of additional administration of AH medication after KT, it is important not only to prevent DGF, AR, and CAD after KT, but also to control SBP and prevent cardiovascular remodeling before KT.

TH-PO150

New Onset Diabetic Foot Ulcer After Renal Transplantation Increases Risk of Transplant Failure

Angelica Sharma,[3] Siew Cohen,[1] Luigi Gnudi,[3,1] Prashanth R. Vas,[2] Janaka J. Karalliedde.[3,1] *[1]Guy's and St Thomas' NHS Trust, London, United Kingdom; [2]King's College Hospital, London, United Kingdom; [3]King's College London, UK, London, United Kingdom.*

Background: Patients with diabetic kidney disease are at high risk of diabetic foot ulcers (DFU). Whether this risk is modified after renal transplant is unclear. There is a paucity of information on the burden and risk factors for DFU development after transplantation and impact of DFU on renal transplant viabilty.

Methods: We evaluated the incidence and predictors of new onset DFU post renal transplant in a single centre retrospective study. Patients who underwent renal transplant for diabetic kidney disease between 2004-2016 were evaluated. In total 144 (66% male, 26% Type 1, 74% Type 2) diabetic patients were evaluated. Median (range) follow up was 6 (3 to 13) years. Median (range) age was 62 (28 to 80) years and duration of diabetes 23 (7-60) years. Electronic patient medical notes were reviewed.

Results: Over the follow up period 22 (15%) patients developed a new DFU. Patients with a DFU were of similar age, body mass index, diabetes duration and had similar pre-transplant haemoglobin, as compared to those without a DFU. Patents who developed a DFU were more likely to have Type 1 than Type 2 diabetes (29% vs. 10%), history of peripheral vascular disease (PVD) [32 % vs. 8%], had higher pre-transplant HbA1c, mean ± standard deviation (7.5 ±1.2% vs. 6.8±1.4%) and serum creatinine (809±243µmol/l vs. 660±202µmol/l) p<0.05 for all. Of the cohort 8 patients had a history of DFU pre-transplant and all 8 developed a new onset DFU post-transplant. Median (range) duration of healing was 5 (1-26) weeks. Nearly 50% of all DFU occurred within the first 1000 days post-transplant. Of the 22 cases, 6 needed a minor amputation; no major amputations were documented. Mortality was 27.3% in patients with DFU compared to 20.3% without DFU p=0.25. Patients with DFU had more than twofold increased risk of transplant failure as compared to those without DFU (50% vs 23.3% p=0.02).

Conclusions: Nearly 1 in 7 patients post renal transplant develop a new onset DFU. Type 1 diabetes, higher pre-transplant HbA1c, serum creatinine and history of PVD and prior DFU are associated with increased risk of new onset DFU post-transplant. DFU increases risk of transplant failure nearly twofold. Our results indicate a high burden of DFU post-transplant and emphasises the requirement for regular foot surveillance by renal and diabetes clinical teams in this high-risk population.

Glucose Metabolism After Renal Transplantation: Oral Glucose Tolerance Test-Derived Insulin Release and Insulin Sensitivity Under Tacrolimus versus Belatacept-Based Immunosuppression

Manfred Hecking,[4] Martin Müller,[1] Michael Haidinger,[1] Elisabeth Schwaiger,[2] Giovanni Pacini,[6] Andrea Tura,[5] Johannes Werzowa,[1] Marcus D. Saemann.[3]
[1]Medical University of Vienna, Vienna, Austria; [2]Medical University Vienna, Vienna, Austria; [3]Wilhelminen Hospital, Vienna, Austria; [4]Medical University of Vienna, Nephrology & Dialysis, Vienna, Austria; [5]CNR Institu of Neuroscience, Padova, Italy; [6]Institute of Neuroscience, National Research Council, Padova, Italy.

Background: In our previous oral glucose tolerance test (OGTT)-based study (PMID23656979), calcineurin inhibitor-treated kidney transplant recipients (KTRs) showed lower insulin release but higher insulin sensitivity than non-KTRs. We aimed at refining our analysis, using only Tacrolimus-treated KTRs (Tac-KTRs) vs Belatacept-treated KTRs (Bela-KTRs) as controls.

Methods: We revisited our database and analysed indices of insulin release and insulin sensitivity from OGTTs of 67 Tac- vs 26 Bela-KTRs.

Results: Our center's outpatient records showed 38 Tac-KTRs vs 0 Bela-KTRs among 113 KTRs with treated posttransplant diabetes mellitus. The randomly assigned OGTTs among KTRs with unknown glycemic status differed between Tac- vs Bela-KTRs: 11 vs 0 diabetics (2-h glucose [2-h G] ≥200 mg/dL), 24 vs 2 prediabetics (2-h G 140-199) and 32 vs 24 with normal glucose tolerance (NGT) (2-h G <140) [*p<0.01*]. Tac- vs Bela-KTRs with NGT had similar age, body mass index, 0-h and 2-h G, but higher HbA1c and insulin sensitivity and lower insulin release (Table and Figure).

Conclusions: In line with our previous study, impaired insulin release was the main pathophysiological feature for diabetes development in Tac-KTRs, while Bela-KTRs had no impaired glucose metabolism. It is tempting to speculate that impaired insulin secretion, due to beta-cell damage, in Tac-KTRs is compensated by increased insulin sensitivity, but this mechanism seems more complex and deserves further study.

Table: Characteristics and OGTT-derived indices of stable kidney transplant recipients (time since transplantation >6 month) with different immunosuppression randomly assigned to an OGTT

Empagliflozin in Posttransplantation Diabetes Mellitus: Effect on Glucose Metabolism and Fluid Volume

Manfred Hecking,[1] Elisabeth Schwaiger,[1] Lorenzo Signorini,[2] Robin Ristl,[3] Andrea Tura,[4] Giovanni Pacini,[4] Chantal M. Kopecky,[1] Marlies Antlanger,[1] Johannes Werzowa,[5] Marcus D. Saemann.[6] *[1]Medical University of Vienna, Nephrology & Dialysis, Vienna, Austria; [2]Azienda ospedaliera universitaria integrata - ospedale civile di Verona, Sommacampagna, Italy; [3]Center for Medical Statistics, Informatics and Intelligent Systems, Medical University Vienna, Vienna, Austria; [4]Institute of Neuroscience, Padova, Italy; [5]1st Medical Department, Hanusch Hospital, Vienna, Austria; [6]Wilhelminen Hospital, Vienna, Austria*.

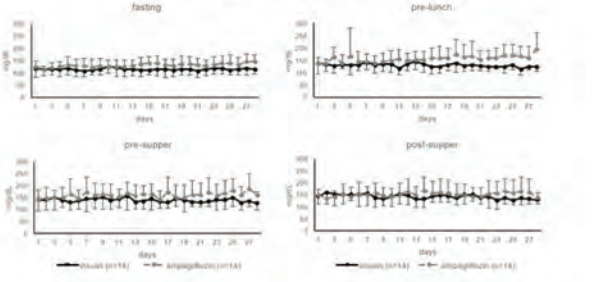
Background: Empagliflozin decreases cardiovascular morbidity and mortality in type 2 diabetics, but safety and efficacy in patients with posttransplant diabetes mellitus (PTDM) is unknown.

Methods: We conducted a prospective non-inferiority trial, converting stable kidney transplant recipients with PTDM from insulin (<40 IU/day) to 10 mg empagliflozin, aiming at eliminating exogenous insulin. Oral glucose tolerance tests, fluid volume status and adverse events were compared from baseline to 4 weeks after empagliflozin conversion (clinicaltrials.gov:NCT03113110).

Results: 14 patients (the required sample size, using change in intra-individual 2-hour glucose as primary endpoint) completed the study visits. The primary endpoint was negative (*p=0.06*) but glucose control was clinically inferior after insulin withdrawal (27.2±10.5 IU/day; Figure & Table). Insulin sensitivity and bioimpedance spectroscopy-derived extracellular fluid volume decreased with empagliflozin therapy. No patient developed ketoacidosis, 3 had bacterial urinary tract infections (UTIs).

Conclusions: Despite risk of UTIs and moderatly inferior glucose control under empagliflozin monotherapy following exogenous insulin therapy, empagliflozin is a valuable antidiabetic for PTDM patients which should be studied as add-on therapy. Plasma volume contraction might contribute to the cardiovascular risk reduction observed in type 2 diabetics.

Patients' self-monitored blood glucose profiles



Self-monitored blood glucose profiles over 28 days. During the first three days of empagliflozin treatment, the insulin dosage was washed out. Comparisons between empagliflozin and insulin treatment were calculated using a mixed linear model. Mean differences: fasting [19.4 mg/dl (95%CI -0.5-37.3) p=0.06], pre-lunch [24.4 mg/dl (95%CI -0.19-48.9) p=0.05], pre-supper [mean 20.7 mg/dl (95%CI -4.2-45.7) p=0.1] and post-supper [mean 7.9 (95%CI -21.0-36.8) p=0.6]. Means and standard deviations of blood glucose levels are displayed as bold lines (blood glucose levels during insulin treatment) and dotted lines (blood glucose levels during empagliflozin treatment).

Cardiovascular Events After Kidney Transplantation: Seven-Year Follow-Up of the Vienna Treat-to-Target Trial of Basal Insulin in Post-Transplant Hyperglycemia (TIP)

Manfred Hecking,[2] David Topitz,[1] Marcus D. Saemann.[3] *[1]Medical University of Vienna, Vienna, Austria; [2]Medical University of Vienna, Nephrology & Dialysis, Vienna, Austria; [3]Wilhelminen Hospital, Vienna, Austria.*

Background: In our previous proof-of-concept clinical trial, basal insulin therapy early after kidney transplantation significantly reduced the odds of posttransplant diabetes mellitus (PTDM) throughout 1 year of follow-up (PMID22343119). We investigated whether the occurrence of cardiovascular events (CVEs) differed by insulin therapy, respectively by oral glucose tolerance test (OGTT)-derived glycemic status.

Methods: We obtained ethics approval for following up on the Vienna TIP-study patients, in order to compare CVEs in those who had received insulin versus standard of care control treatment; and in patients with normal glucose tolerance (NGT, 2-hour glucose [2-h G] <140 mg/dL), versus in prediabetics (2-h G 140-199) plus diabetics (2-h G ≥200), per OGTT-result at 3, 6 and 12 months posttransplantation.

Results: Seven of the original 50 TIP-study patients were lost to follow-up. Occurrence of CVEs differed by diabetic status, but not by treatment status (Figure). None of the patients with NGT experienced any CVE, but NGT patients were significantly younger (Table).

Conclusions: The present results lead to the hypothesis that PTDM might be a read-out for older, potentially sicker patients, and that CVE occurrence might not be modifiable by antidiabetic treatment.

	Insulin	Control	p*	Diab. + prediab.	NGT	p*
N patients	22	21		36	7	
Males (%)	14 (64)	14 (66)	1,0	24 (67)	4 (57)	0,68
Females (%)	8 (36)	7 (34)	1.0	12 (33)	3 (43)	0,68
Age ± SD	54±12,1	56,6±13,3	0,55	**57,3±12,1**	**45,6±10,9**	**0,02**
Inclusion [months] ± SD	76,6±15,1	76,6±10,1	1,0	75,9±13,8	80,1±3,2	0,42
Height [cm] ± SD	168,7±8	171,3±3	0,33	170±8,1	171,3±10	0,67
Weight [kg] ± SD	73±12,3	80,6±13,8	0,06	76,6±14	77,1±10,9	0,92
2-h G month 3 [mg/dL]	156	205	0,07	**195**	**107**	**<0,01**
2-h G month 6 [mg/dL]	149	156	0,62	**160**	**117**	**<0,01**
2-h G month 12 [mg/dL]	151	157	0,77	**163**	**112**	**<0,01**

Diab. + prediab. = diabetics + prediabetics; NGT = normal glucose tolerance; SD = standard deviation, 2-h G = 2-hour glucose at the oral glucose tolerance test. *p-values were determined, using the unpaired two-tailed Student t test for continuous variables, and the unadjusted chi square test for categorical variables. †Determined at transplantation. **OGTTs in the original TIP-study were not performed in patients who were receiving anti-diabetic therapy (accounting for the lack of signifcance between 2-h G in insulin treatment-versus control patients; for further details, please refer to PMID22343119).

TH-PO154

High Incidence of Recurrent Diabetic Nephropathy in Kidney Transplant Alone (KTA) Recipients

Aleksandra Kukla,[1] Martha Catalina Morales Alvarez,[3] Andrew J. Bentall,[1] Mariam P. Alexander,[1] Naim S. Issa,[2] Walter Park,[4] Matthew R. D'Costa,[1] Mark D. Stegall.[1] *[1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic, Rochester, MN; [3]Mount Sinai Beth Israel, Rochester, MN; [4]The Mayo Clinic, Rochester, MN.*

Background: Improving long-term kidney allograft survival is a major challenge. Recurrent diabetic nephropathy (RDN) in kidney transplant recipients is not well studied. We aimed to determine the incidence, timing and severity of recurrent diabetic nephropathy (RDN) in recipients with pre-transplant type 1 (T1DM) and type 2 diabetes (T2DM).

Methods: We studied 118 diabetic transplant recipients (recs) -T1DM (simultaneous kidney pancreas [SPK] and KTA), and T2DM (all KTA) transplanted between 2002 and 2009. Recs with SPK had functioning pancreas allograft at 5y post transplant. All recs underwent surveillance protocol kidney biopsy at 4 months, 1y, 2 y and 5 y post transplant. RDN was diagnosed based on light microscopy according to Banff 2015 criteria (MM score) and/or as described by pathologist if MM score was not assigned. Advanced RDN was diagnosed if MM score was >1. Patients with immune complex diseases were excluded.

Results: We identified 52 T1DM (46% SPK and 54% KTA) and 66 T2DM (all KTA) recs. T1DM were younger (47y ± 1.3 vs. 62.1y±1.2 for T2DM; p<0.001). BMI was comparable (31.2 T1DM vs. 33.2 T2DM). The earliest RDN was seen at 1 year post transplant. At 5 years, the incidence of RDN was only 4.3% in T1DM SPK, compared to 34% in T1DM with KTA and 46% in T2DM with KTA (p<0.05). BMI was higher in those with RDN (34.5 vs 29.9; p<0.05) regardless od diabetes type. 13 (11%) recs developed advanced RDN (mm>1) at 5 years. Those recs were more likely to be T2DM (74% vs. 26% for T2DM and T1DM, respectively, p<0.05). Mean HbA1C in this group at 5 y was 8.12%±1.8. Creatinine has not changed over the 5 years post transplant (mean delta creatinine 0.03 ± 0.38). Mean albuminuria at 5 y was 52 mg/24h ± 345. 7 (53 %) of recs with advanced RDN did not have significant albuminuria at 5 years (30 mg/24 h or less).

Conclusions: Histologic changes of RDN can be seen as early as 1 year post kidney transplant and have high incidence at 5 years. HIgh BMI is a risk factor. Pancreas transplantation is associated with histological protection. Advanced RDN is significantly more common in T2DM recipients and may be clinically silent. Future studies should focus on identifying risk factors for RDN, its impact on graft survival and development of better noninvasive biomarkers of histologic injury.

Liraglutide May Be Safe After Kidney Transplantation

Nizar M. Attallah,[1] Lina Yassine.[2] *[1]Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates; [2]Imperial College of London Diabetes Center Abu Dhabi, Abu Dhabi, United Arab Emirates.*

Background: Kidney transplant has offered better outcomes for patients with end stage renal disease (ESRD). Diabetes is a common comorbidity in patients with renal transplants which requires treatment. Diabetes is the most common cause of ESRD. Patients could develop post-transplant DM (PTDM), or have pre-existing diabetes mellitus. Management of DM after transplant (whether the patient had it from before or after the transplant) is challenging. Different medications could be used to manage PTDM. Those medications have good safety and efficacy record in the general population and patients with mild degrees of kidney disease.

Methods: We conducted a retrospective single center analysis of safety and efficacy of Liraglitude after kidney transplant. The study was approved by institutional review board. We collected data (demographics, laboratory tests and any symptoms or hospitalizations) for 32 consecutive patients for 18 months.

Results: All 32 patients received subcutaneous Liraglitude at an average of 1.2 mg/day throughout the study period. Patients' average age was 64. 18 were females and all from Middle Eastern decent and had kidney transplant on average 32 months when they were included in the study. 13 patients had DM before the transplant and the rest had PTDM. 15 patients were on metformin and 10 were on insulin while the rest were not on any other medications. Average baseline creatinine was 1.2 mg/dL (106.3 mmol/L) and glycated hemoglobin (HbA1c) of 8.4 g/dL while creatinine was 1.1 mg/dL (97.5 mmol/L) and HbA1c was 7.2 g/dL at the end. HbA1c dropped 1.2 on average within 6 weeks of initiating Liraglitude and was maintained for the rest of the study. Urine protein did not change significantly throughout the study. One patient developed acute myocardial infarction during the study and another patient was hospitalized with acute pancreatitis. A third patient developed an opportunistic infection. Ten patients developed nausea and vomiting following the initiation of Liraglitude but that resolved 4 weeks later with lowering the dose. No allergic reactions or hypoglycemia episodes were reported. The average weight dropped 2.4 kg during the study and body mass index changed from 28.6 to 27.8. Only one patient stopped the medication due to acute pancreatitis.

Conclusions: In this retrospective analysis, Liraglitude seems to be safe and efficacious after kidney transplant. It can be considered to manage DM after transplant.

TH-PO156

Linagliptin May Be Safe After Kidney Transplant

Nizar M. Attallah,[1] Lina Yassine.[2] *[1]Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates; [2]Imperial College of London Diabetes Center Abu Dhabi, Abu Dhabi, United Arab Emirates.*

Background: The incidence and prevalence of end-stage renal disease (ESRD) is increasing. The most common cause of ESRD is diabetes mellitus (DM). Kidney transplantation offers better quality of life and survival for patients with ESRD. Patients could develop post-transplant DM (PTDM). Management of DM after transplantation (whether the patient had it from before or after the transplant) is a challenge. Different medications could be used to manage PTDM. Those medications have good safety and efficacy record in general population and patients with mild degrees of kidney disease.

Methods: We conducted a retrospective single center analysis of safety and efficacy of Linagliptin post kidney transplantation. The study was approved by institutional review board. We collected data (demographics, laboratory tests and any symptoms or hospitalizations) for 28 consecutive patients for 16 months.

Results: All 28 patients were initiated on Linagliptin throughout the study period. Patients' average age was 62. Fifteen were females and all from Middle Eastern decent and had kidney transplant on average of 25 months when they were included in the study. Twelve patients had DM before the transplant and the rest had PTDM. 13 patients were on metformin and 8 were on insulin while the rest were not on any other medications at the start of the study. Baseline average creatinine was 1.5 mg/dL (132.9 mmol/L) and glycated hemoglobin (HbA1c) of 8.2 g/dL at the start of the study while creatinine was 1.6 mg/dL (141.8 mmol/L) and HbA1c was 7.4 g/dL at the end. HbA1c dropped 0.8 on average within 5 weeks of starting Linagliptin and was maintained at the same level for the rest of the study. Urine protein did not change significantly throughout the study. Two patients developed acute myocardial infarction during the study and a third patient was hospitalized with an opportunistic infection. Two patients had urinary tract infections. 3 patients had nausea and vomiting after starting Linagliptin but that resolved 2 weeks later. No allergic reactions, hypoglycemia or acute pancreatitis episodes were reported. The average weight and body mass index did not change throughout the study. None of the patients stopped the medication.

Conclusions: In this retrospective analysis, Linagliptin seems to be safe and efficacious after kidney transplantation. It can be considered in the management of diabetes post kidney transplantation.

TH-PO157

Serum Bicarbonate Levels Are Associated with Graft Survival and Mortality in Swiss Kidney Transplant Recipients

Anna Wiegand,[1] Sandar F. Lim,[2] Rudolf P. Wuthrich,[1] Leonhard Held,[2] Nilufar Mohebbi.[1] *[1]Division of Nephrology, University Hospital Zürich, Zürich, Switzerland; [2]Epidemiology, Biostatistics and Prevention Institute, University of Zurich, Zurich, Switzerland.*

Background: Metabolic acidosis (MA) is a frequent complication of chronic kidney disease (CKD) and an independent risk factor for kidney disease progression. MA is also highly prevalent after kidney transplantation (12%-58%). A recent study has shown that MA after kidney transplantation was associated with increased risk of graft loss and death indicating an impact of MA on long-term graft function. However, the cohort had a fairly low prevalence of MA. Also a cut-off value for bicarbonate of 22 mEq/L, as commonly used for the definition of MA, may be questionable since kidney outcome and mortality have been shown to correlate best with TCO_2 values of 24-28 mEq/L. Thus, we wanted to investigate if serum bicarbonate is associated with graft outcome and mortality in Swiss kidney transplant recipients (KTRs).

Methods: We performed a single-center retrospective study including adult (≥ 18 years) patients that have been subjected to *de novo* kidney transplantation between 1999 and 2015. Cox proportional hazard model was used to analyze a possible association between time-dependent serum bicarbonate measurements and graft loss (defined as re-entry to dialysis or second kidney transplantation) or death

Results: 430 KTRs were included in the analysis with a mean age of 50.9±13.4 years. Mean observation time was 4.7±2.8 years. 284 (66%) were male and 318 (74%) had received a deceased donor kidney transplant. Mean bicarbonate and eGFR levels one year post-transplant were 22.7±3.1 mmol/L and 61±26 ml/min, respectively. Prevalence of MA (defined as bicarbonate <22 mmol/L) was 51.2% after transplantation and decreased to 30.8% one year post-transplant. 14 (3%) patients died and 31 (7%) suffered from graft failure. Higher bicarbonate levels were associated with significantly lower hazards for graft failure (HR=0.88; 95% CI, 0.79-0.98; p=0.022) and mortality (HR=0.79; 95% CI, 0.66-0.93; p=0.006) after adjusting for potential confounders such as age, type of donor and time-varying eGFR.

Conclusions: Our analysis showed that higher serum bicarbonate levels are associated with long-term graft and patient survival in Swiss KTRs. Thus, serum bicarbonate may serve as a predictor for graft and patient outcome after kidney transplantation as has been previously shown for patients with CKD.

TH-PO158

Prevalence of Gout in the Surviving US Solid Organ Transplant Population

Mark D. Brigham,[1] Thilan Tudor,[1] Gavin Miyasato,[1] Jeffrey Kent,[2] Brian Lamoreaux,[2] Richard J. Johnson.[3] *[1]Trinity Partners, Waltham, MA; [2]Horizon Pharma, Lake Forest, IL; [3]University of Colorado Denver, Aurora, CO.*

Background: Although incidence and survival are frequent topics within the solid organ transplant (SOT) literature, there are no recent publications on the total size of the surviving SOT population. Existing studies of gout in SOT have focused on the incident SOT population. This analysis was performed to characterize the prevalent SOT population and the prevalence of gout within it.

Methods: 2017 U.S. population sizes of kidney, heart, liver, and lung recipients were estimated by combining Organ Procurement and Transplantation Network (OPTN) primary transplant cohort sizes (1988-2017) with previously published survival rates for each annual cohort's time since transplant (0-29 yrs), adjusted for recent improvements in 1-5 yr survival. Gout among prevalent SOT patients was assessed via 2 administrative claims databases: Medicare Fee-For-Service Limited Data Set (5% sample) and a commercial claims sample (IQVIA™ Real-World Data Adjudicated Claims – US). Definitions used were – SOT: a claim with an SOT procedure code OR any claim with a history of SOT status code; Gout: ≥1 claim with any gout diagnosis code. Total gout prevalence was calculated by weighting Medicare and commercially insured patient estimates by OPTN payer distribution.

Results: 637,231 U.S. patients received a primary kidney (393,953), liver (142,186), heart (66,637), or lung (34,455) transplant between 1988 and 2017. An estimated 355,000 (55.8%) recipients were alive in 2017, comprising nearly two-thirds (233,000) kidney, as well as 78,700 liver, 29,300 heart, and 14,700 lung recipients. Gout was identified in 11% of prevalent SOT patients in 2016. Higher rates of gout were seen in kidney (13%) and heart (13%) recipients compared to liver (6.4%) and lung (5.3%) recipients (p<0.0001 in both datasets).

Conclusions: Hundreds of thousands of U.S. patients are living with an organ transplant today and these numbers are likely to increase. Within the SOT clinical picture, gout is a frequent co-morbidity of which physicians should be aware. This study suggests a markedly higher rate of gout for the most common SOT types (11%) compared to established rates reported for the general population (e.g. 3.9%). Kidney recipients, with the largest surviving population and high rates of gout, bear much of this disease burden.

TH-PO159

Gout Severity in Kidney Transplant Recipients

Lauren Radeck,[1] Clive M. Mendonca,[1] Isabel Lang,[1] Jeffrey Kent,[2] Brian Lamoreaux,[2] Richard J. Johnson.[3] *[1]Trinity Partners, Waltham, MA; [2]Horizon Pharma, Lake Forest, IL; [3]University of Colorado Denver, Aurora, CO.*

Background: Gout is a frequent co-morbidity of solid organ transplant (SOT), especially among kidney recipients. Less well understood are any differences in gout severity and treatment success between gout patients with and without SOT. This retrospective analysis of medical patient chart data was performed to compare disease severity and treatment history in recent gout case examples with vs. without a history of kidney transplant.

Methods: An online survey was completed using a panel of board certified U.S. nephrologists. Respondents were asked to pull de-identified patient charts for their 3 most recent gout patients. Measures evaluated included: SUA level, numbers of swollen/tender joints (at visit), visible tophi (at visit), gout flare events (prior 12 months), gout drug treatment history, and presence of "severe, uncontrolled gout" defined as: SUA ≥7.0 mg/dL, 1 or more visible tophi AND 2 or more gout flares, and history of xanthine oxidase inhibitor treatment. Case examples were weighted by number of visits in last 12 months and respondents' overall gout treatment volume.

Results: 23 out of 299 (7.7%) Rx-treated patients had a history of kidney transplant (N=104 nephrologist respondents). Compared to non-SOT patients, SOT patients were more likely to meet severe uncontrolled gout criteria (25% vs. 7%, p<0.05). Univariate analysis found that SOT patients, compared to non-SOT patients had: higher prevalence of visible tophi (32% vs. 13%, p<0.01), lower allopurinol treatment rates (28% vs. 50%, p<0.05), and higher rates of failure or contraindication to febuxostat (22% vs. 4%, p<0.01).

Conclusions: This study provides preliminary evidence that gout is more severe and poses more challenges for pharmacologic management in kidney transplant patients compared to other nephrology gout patients. Although gout has been linked to a higher all-cause mortality rate among kidney recipients in the literature, to our knowledge there are no published comparisons of gout severity among such patients vs. the general nephrology patient population. Further investigation of symptom severity and unmet need in appropriate, effective treatment options in transplant recipients with gout is warranted.

TH-PO160

Immunosuppressant Use and Gout in the Prevalent Solid Organ Transplant Population

Andrew Milgroom,[1] Mara Onita Lenco,[1] Kevin Francis,[1] Jeffrey Kent,[2] Brian Lamoreaux,[2] Richard J. Johnson.[3] *[1]Trinity Partners, Waltham, MA; [2]Horizon Pharma, Lake Forest, IL; [3]University of Colorado Denver, Aurora, CO.*

Background: Gout is a frequent co-morbidity of solid organ transplant (SOT). Cyclosporine (CsA) is often cited as the main cause of gout in SOT, as other immunosuppressant (IS) regimens were associated with lower gout rates (e.g. 1980s studies of azathioprine monotherapy). In most guidelines & institutions, tacrolimus (TAC) has replaced CsA in SOT IS regimens. However, two questions are largely unknown: (1) to what degree is CsA still used among prevalent SOT patients? (2) can CsA fully explain high rates of gout still seen among SOT patients? This retrospective patient claims data analysis was performed to evaluate IS use and gout in the prevalent SOT population.

Methods: IS regimens and gout prevalence among prevalent SOT patients were assessed via commercial claims data (IQVIA™ Real-World Data Adjudicated Claims – US). Definitions used were – SOT: claim with an SOT procedure code OR any claim with a history of SOT status code; IS: ≥1 claim for a given IS drug in the calendar year; Gout: ≥1 claim with any gout diagnosis code. IS use at time of transplant for 2016 recipients was obtained from the Organ Procurement and Transplantation Network (OPTN).

Results: The proportion of prevalent SOT patients on CsA declined from 2012 to 2016: heart 22% to 18%, kidney 21% to 17%, lung 16% to 11%, liver 15% to 12% (all p<0.01). TAC use increased: heart 66% to 73%, kidney 67% to 74%, lung 75% to 80%, liver 77% to 82% (all p<0.01). CsA use was higher in prevalent vs. incident SOT populations (e.g. 17% vs. 1.7% kidney 2016, p<0.0001). 2016 gout prevalence was 16% vs. 8% among CsA vs. non-CsA patients. Among all SOT patients with gout, 69% and 26% were on TAC and CsA, respectively.

Conclusions: Despite declining CsA use, gout remains a problem in SOT patients. For one, this study finds that many prevalent SOT patients still receive CsA. Additionally, gout prevalence in the non-CsA population was much higher (8%) than established rates reported in the general population (e.g. 3.9%). This suggests CsA is not the sole driver of gout in SOT. In fact, this analysis finds that post SOT, more than twice as many gout sufferers are on TAC than on CsA. Physicians should be aware that with any transplant IS regimen including calcineurin inhibitors, gout is likely to remain a frequent co-morbidity of SOT.

TH-PO161

Role of Coronary Interventions in High Cardiovascular Risk Patients on Kidney Transplant Waitlist

Bayiha daho Klaud francheska, Maria Fernandez, Ahmad Salha, Racquel M. Lowe-Jones, Debasish Banerjee. *St George's University Hospitals NHS Foundation Trust, London, United Kingdom.*

Background: High cardiovascular risk patients on the kidney transplant list often undergo cardiac interventions to improve their outcome and survival following

transplantation. However the benefits of these interventions are currently unknown and were explored in this study.

Methods: The study, approved by hospital Clinical Effectiveness and Audits Committee, included 164 episodes in 126 patients discussed in discussed in a multidisciplinary cardio-renal MDT, between 1-10-2014 to 30-09-2017 and followed until 23-05-2018.

Results: 126 patients were discussed in the multidisciplinary meeting, some more one than once. Clinical characteristics of the 164 patient episodes were; age 61±8years, BMI 28±5kg/m^2, cholesterol 4.0±1.1mmol/L, 61% diabetes, 96% hypertension, 63% haemodialysis and 27% pre-dialysis. After discussion 96 cardiac procedures were suggested and performed, including stress echocardiogram (68%), echocardiogram (9%), coronary angiogram (13%), percutaneous coronary intervention (4%), and coronary artery bypass graft (4%). The non-invasive tests resulted in further 19 angiograms, 10 PCI and 1 CABG. Thirty-five percent of patients had no cardiac intervention performed; 44% had a single intervention and 21% had multiple interventions. 28 patients had an event (death, ACS or stroke) during follow-up, who were more likely to be diabetic, the clinical characteristics are in table 1. 37% (n= 13) of patients who had invasive cardiac intervention developed an event, while 16% (n=7) of patients who did not receive any cardiac tests or intervention developed an event (p=0.246). Of the 91 patients who did not have invasive procedures, only 15 (16%) had an event as opposed to 13 (37%) in the remaining cohort who had invasive procedures done (Figure 1).

Conclusions: Out of 126, events occurred in 28 patients, mainly cardiovascular. Cardiac interventions including angiograms, CI or CABG were unable to lower the CV event rate in high-risk patients on transplant waitlist..

	Patients with no events (n=98)	Patients with events (n=28)	P value
Age	61 ± 8.8	62.6 ± 6.3	0.256
Men (%)	60	60.7	0.543
Diabetes (%)	53.1	75	0.009
Haemodialysis (%)	57.1	78.6	0.014
BMI	27.9 ± 4.8	28.5 ± 5.2	0.506
Cholesterol	4.14 ± 1.1	3.7 ± 1.2	0.025
Positive DSE (%)	11.2	14.3	0.532
Angio/PCI/CABG (%)	19.4	46.4	0.246

TH-PO162

Non-Skeletal Effects of High Doses Versus Minimum Recommended Intake of Vitamin D3 in Renal Transplant Recipients in a Prospective, Multicenter, Double-Blind, Randomized Study

Marie Courbebaisse,[1,2] Sandra Colas,[3] Rebecca Sberro-Soussan,[4,2] Valerie Moal,[11] Yannick Le Meur,[7] Nassim Kamar,[5] Laetitia Albano,[10] Antoine Thierry,[15] Jacques Dantal,[9] Julien Allard,[6] Karine Moreau,[8] Corinne Alberti,[13,14] Eric Thervet.[12,2] *[1]European Georges Pompidou Hospital, APHP, Paris, France; [2]Paris Descartes University, Paris, France; [3]URC/CIC Necker-Cochin, Paris, France; [4]Necker Hospital, APHP, PARIS, France; [5]Toulouse University Hospital, Toulouse, France; [6]University Hospital Limoges, LImoges, France; [7]University Hospital, Brest, Brest, France; [8]Pellegrin Hospital, Bordeaux, France; [9]Institut de Transplantation Urologie Néphrologie, Nantes, France; [10]Hôpital Pasteur CHU de Nice, Nice, France; [11]Assistance Publique Hopitaux de Marseille, Marseille, France; [12]European Georges Pompidou Hospital, APHP, Paris, France; [13]Robert Debré Hospital, Paris, France; [14]Paris-Diderot University, Paris, France; [15]CHU La Miletrie, Poitiers, France.*

Background: High doses of vitamin D_3 (cholecalciferol, CL) have been advocated to reduce the risk of diabetes mellitus (DM), major cardiovascular events (MACE), and cancer, which are frequent complications in renal transplant recipients (RTR).

Methods: The VITALE study is a prospective, multicenter (30 French transplantation departments), double-blind, controlled trial (NCT01431430). Adult RTR with serum 25(OH)-vitamin D levels (25OHD) <30 ng/mL, were randomized between 12 and 48 months after transplantation to receive either high doses (HD, 100,000 IU) or low doses (LD, 12,000 IU corresponding to the minimum recommended intake, MRI) of CL every 2 weeks for 2 months then monthly for 22 months. The primary objective was to evaluate the effect of HD vs LD on a composite endpoint: DM, MACE, de novo cancer, and patient death. The sample size calculation was based on the assumption of an incidence of a first event of the composite endpoint of 22% in the LD group *versus* 13% in the HD group. The inclusion of a total of 480 RTR was required to test this hypothesis with a power of 80%.

Results: Between January 2012 and December 2013, 536 RTR (mean (SD) age 50.8 (13.7) years, 335 males) were included. Baseline clinical and biological characteristics did not differ between HD (n=269) and LD (n=267) groups. In the HD and the LD group, 25OHD was 20.2 (8.1) vs 19.2 (7.0) ng/mL at D0 and 43.1 (12.8) vs 25.1 (7.4) ng/mL after 24 months (<0.0001). The intention to treat analysis showed that the number of events of the composite endpoint did not differ between HD and LD groups (15% vs 16%, respectively). There was also no difference for infections (51% vs 47%), acute rejection episodes (3% vs 2%) and graft loss (0.37% in both groups). The number of patients with incident hypercalcemia or hyperphosphatemia did not differ between groups (17% vs 13%, p=0.24, and 5% vs 4%, p=0.41, in HD and LD group respectively). Of note, evolution of valvular calcifications was not significantly different between groups (p= 0.59).

Conclusions: In conclusion, HD of CL are well-tolerated but do not reduce the incidence of non-skeletal complications in RTR when compared to the MRI.

TH-PO163

A Prospective Observational Study Comparing Bone Loss in Renal Transplant and Dialysis Patients

Waleed Hassan, Maria Yaseen, Hasan Ashqar, Amr E. Mohamed, Conor Lowry, Roberto Gedaly, Daniel Davenport, Florence Lima, Hartmut H. Malluche. *University of Kentucky, Lexington, KY.*

Background: Bone loss has been reported with chronic dialysis and after renal transplantation. This study compared the differences in longitudinal changes in BMD between dialysis and transplant patients using quantitative computed tomography (QCT).

Methods: Total hip BMD was assessed using QCT in 29 renal transplant recipients at the time of transplantation, at 6 months (n=25), and at 12 months (n=19). In addition 50 dialysis patients of similar gender, age, race, dialysis vintage, diabetes, non-smoking status, coronary artery disease, and exercise were studied. BMD at baseline and after 12 months was compared between the two groups.

Results: In transplant patients, total hip BMD by QCT decreased from a mean of 0.88 g/mm^3 at time of transplantation to 0.83 g/mm^3 at 6 months after transplant, then stabilized at 0.83 g/mm^3 at 12 months for an average loss of 0.05 ± SE 0.02 g/mm^3 (fig. 1). While the average dialysis patient lost 0.02 ± SE 0.01 g/mm^3 of BMD at the hip over 12 months (p= 0.07, Figure 2). The average bone loss was higher for transplant patients with normal baseline BMD compared to patients with low BMD (Normal: -0.05 g/mm3; Low: -0.02, p=0.314).

Conclusions: Significant bone loss occurs in renal transplant recipients during the first 6 months then stabilized at 12 months. This bone loss is more than what is observed in matched dialysis patients. Normal BMD is still of concern because bone loss may be higher compared to patients with low BMD.

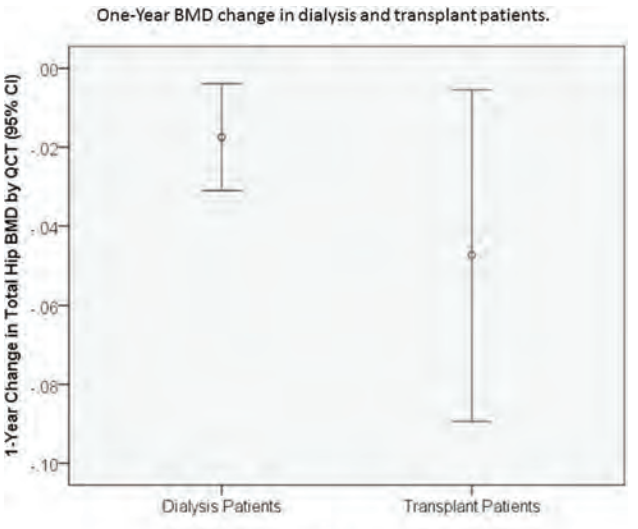

Figure 2

TH-PO164

Association of Post-Transplant Calcium and Phosphate Levels with Graft Outcomes

Julio L. Chevarria,[1] Donal J. Sexton,[2] Chaudhry Adeel Ebad,[1] Claire Kennedy,[1] Susan L. Murray,[1] Peter J. Conlon.[3] *[1]Beaumont Hospital, Dublin, Ireland; [2]The Irish Longitudinal Study on Ageing (TILDA), Trinity College Dublin., Dublin, Ireland; [3]Beaumont Hospital, Dublin 9, Co Dublin, Ireland.*

Background: Alterations in Ca and P are observed with varying impact on post-transplant outcomes and its implications in graft function are unclear. Our study assesses the relation between serum P and Ca during the first year and graft outcomes

Methods: Longitudinal single centre cohort study, we analyse 1524 first transplants, since 1991 to 2016. Our data was prospectively collected in the national kidney transplant registry. The primary outcome was graft failure and association with P and Ca on first year. We include patients >18 years and immunosuppression MMF + CNI + steroids. We categorized the P and Ca as low, normal or high. The analysis include Kaplan Meier and cox regression

Results: The age was 47.9 y (SD13.9), donor age 43.2 (SD13.3), 64.4% male, 59% HD, 29.5% PD, and 10.1% pre emptied, HLA mean 3.35 (SD1.5), time to fail 8.2 y (SD5.0), 297 grafts failed (18.4%), 85.1% has P<0.7 mmol/L the first year 0.52 (SD0.15), reached at 26.9 (SD46) days, 35.9% Ca >2.6 mmol/L, reached at 74.7 (85.9) days. The KM analysis show increase graft failure with low P or Ca pre transplant (p:0.03), better outcomes with low P at 1, 6 and 12 m (p:0.014, 0.04, 0.004), and high Ca at 1 month, but not so at 6 and 12 m (p:0.03, 0.7 and 0.6). Cox regression show HR 0.60; 95% CI 0.29 to 1.26 with low P and HR 0.71; 95% CI 0.52 to 0.98 with high Ca for graft failure

Conclusions: The derangements in Ca and P are frequent post transplant and develop the first months. The post transplant hypercalcemia is associated with better graft outcomes however the hypophosphatemia not. Futures trials will investigate if the treatment of these conditions would be a risk factor in these patients

TH-PO165

Effects of Denosumab on Bone Metabolism and Bone Mineral Density in Kidney Transplant Patients: A Meta-Analysis

Prakrati C. Acharya,[1] Charat Thongprayoon,[2] Aldo E. Torres Ortiz,[1] Maria Lourdes Gonzalez Suarez,[1] Wisit Cheungpasitporn.[1] *[1]University of Mississippi Medical Center, Ridgeland, MS; [2]Bassett Medical Center, Cooperstown, NY.*

Background: The uses of immunosuppressive agents, are associated with increased risks of bone loss in kidney transplant (KTx) patients. Denosumab, a potent anti-resorptive agent, has been shown to increase bone mineral density (BMD) in patients with CKD. However, its effects on bone metabolism and BMD in KTx patients remain unclear.

Methods: A literature search was conducted using MEDLINE, EMBASE and Cochrane Database from inception through April 2018 to identify studies evaluating the effects of denosumab on changes in bone metabolism and BMD from baseline to post-treatment course in KTx patients. Study results were pooled and analyzed using a random effects model. The protocol for this meta-analysis is registered with PROSPERO (CRD42018095055).

Results: 5 studies (a clinical trial and 4 cohort studies) with a total of 162 KTx patients were identified. Majority of patients had baseline eGFR ≥ 30 mL/min/1.73 m2. After the treatment (≥6 to 12 months), there were significant increases in BMD with standardized mean differences (SMDs) of 3.26 (95%CI 0.88-5.64) and 1.83 (95%CI 0.43 to 3.22) for lumbar spine and femoral neck, respectively. There were also significant increases in T scores with SMDs of 0.92 (95%CI 0.58 to 1.25) and 1.14 (95%CI 0.17 to 2.10) for lumbar spine and femoral neck, respectively. There were no significant changes in serum Ca or PTH from baseline to post-treatment course (≥ 6 months) with mean differences (MDs) of 0.52 (95%CI, -0.13 to 1.16) mmol/L and -13.24 (95% CI, -43.85 to 17.37) ng/L, respectively. Data from a clinical trial demonstrated that asymptomatic hypocalcemia occurred more common in denosumab group (12 episodes in 39 patients) than in control (1 episode in 42 patients). From cohort studies, the pooled incidence of hypocalcemia following denosumab treatment was 1.7% (95%CI 0.4% to 6.6%). All reported hypocalcemic episodes were mild and asymptomatic, but majority of patients required Ca and Vit D supplements.

Conclusions: Among KTX patients with good allograft function, denosumab effectively increases BMD and T scores in the lumbar spine and femur neck. From baseline to post-treatment, there are no differences in serum Ca and PTH. However, mild hypocalcemia can occur following denosumab treatment, requiring monitoring and titration of Ca and Vit D supplements.

TH-PO166

Safety and Efficacy of Patiromer in Kidney and Liver Transplant Recipients

Rickinder Grewal, Akram Audi, Jeremy G. Taylor, Jennifer I. Melaragno, David M. Dewolfe. *University of Rochester Medical Center, Rochester, NY.*

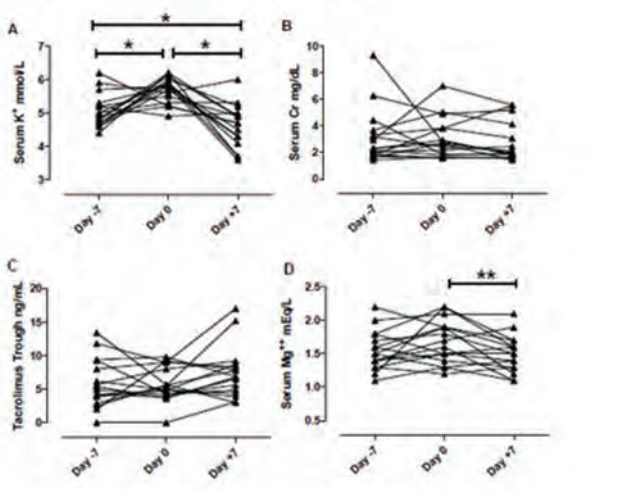
Background: Patiromer has been FDA approved for the management of chronic hyperkalemia, however, there is a paucity of data regarding its safety and efficacy in transplant recipients.

Methods: We retrospectively reviewed the use of patiromer in 16 transplant recipients at our center from 2016 to 2018 including 9 Kidney, 6 Liver, and 1 Kidney after Liver recipients. Patiromer was given mid-day, separated from immune suppression medications by 3 hours. It was started a median of 24 (8-548) days (d) post-transplant and used for a median of 44 (1-160) d. Maximum dose used was 8.4 g/d in 7, 16.8 g/d in 6, and 25.2 g/d in 3 patients. In 5 (31.3%) patients, patiromer was added to other therapies for hyperkalemia: fludrocortisone in 3, diuretics in 3, and discontinuation of sulfamethoxazole/trimethoprim in 2 for an alternative agent.

Results: Mean serum K decreased (Fig. 1A) though serum Cr did not change (Fig. 1B). Patiromer did not appear to interfere with tacrolimus absorption as 13 (81.3%) patients were within goal tacrolimus trough range 1 week after starting patiromer and no change in mean tacrolimus troughs was seen (Fig. 1C). Serum magnesium decreased from initiation to 1 week later but post-initiation levels were not different from pre-initiation levels (Fig. 1D). 10 (62.5%) patients required magnesium repletion. There were no adverse events attributed to patiromer and no observed episodes of rejection. 1 patient stopped patiromer due to intolerance, but later resumed the medication without issue. 3 patients were readmitted with hyperkalemia: 1 in the setting of AKI, 1 after self-discontinuing patiromer, and 1 after provider-instructed dose reduction.

Conclusions: In this observational cohort, patiromer appears to be both safe and effective for treating hyperkalemia in kidney and liver transplant recipients.

Figure 1: Serum Values Before and After Patiromer Initiation



*= P<0.01. ** = P<0.05 A: Serum K 7 days before (5.06±0.50), on day of (5.69±0.38) and 7 days after (4.61±0.65) initiation of patiromer. B: Serum Cr 7 days before (3.15±2.06), on day of (3.05±1.52) and 7 days after (2.74±1.49) initiation of patiromer. C: Tacrolimus trough 7 days before (5.86±3.66), on day of (5.78±2.61) and 7 days after (7.45±3.91) initiation of patiromer. D: Serum Mg 7 days before (1.55±0.29), on day of (1.69±0.28) and 7 days after (1.50±0.07) initiation of patiromer.

TH-PO167

Potential Beneficial Association of Renin-Angiotensin-Aldosterone-System Blockade and Graft Prognosis in Allograft IgA Nephropathy

Sehoon Park,[1] Chung Hee Baek,[2] Hyunjeong Cho,[3] Mi-yeon Yu,[4] Yong Chul Kim,[5] Jung Pyo Lee,[6] Yon Su Kim,[7] Su-Kil Park,[2] Curie Ahn,[1] Hajeong Lee.[7]
[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Asan Medical Center, Songpa-gu, seoul, Republic of Korea; [3]Chungbuk National University Hospital, Cheongju-si, Chungcheongbuk-do, Republic of Korea; [4]Seoul National University, Jong-no gu, Republic of Korea; [5]SNUH, Seoul, Republic of Korea; [6]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [7]Seoul National University College of Medicine, Seoul, Republic of Korea.

Background: Clinical evidence supporting suggestions of using renin-angiotensin-aldosterone-system blockades (RAASB) for proteinuric recurrent glomerulonephritis after renal transplant was scarce. For allograft IgA nephropathy (IgAN), benefits of RAASB for graft prognosis remained controversial although the medication is consisting the mainstay for treatment of native IgAN.

Methods: We performed a bi-center retrospective cohort study on kidney transplant recipients diagnosed for IgAN in allograft biopsy. The included patients were stratified according to their prescribed maintenance hypertensive medication types within 6 months from their diagnosis. Patients those had follow-up duration less than 6 months were not considered in the analysis. The main outcome was 5-year death-censored-graft-failure (DCGF). Additional adjustment for other variables including presence of acute rejection or time-averaged eGFR after 3 months from diagnosis of allograft IgAN was performed, as clinicians may prescribe RAASB to those who were at stable allograft function.

Results: Among 558 patients with allograft IgAN, there were 38 patients who only received RAASB, and 33 patients who received single agent of CCB or BB. The other 121 patients were prescribed for other medications, mostly combination therapies. The RAASB group had relatively higher eGFR at the time of diagnosis for allograft IgAN but had higher degree of albuminuria and worse pathologic findings. The group of patients who received single antihypertensive agent other than RAASB (calcium channel blockers (CCB) or beta blockers (BB)) had significantly increased risk of DCGF (adjusted HR 2.68, 95% CI 1.08-6.67, P=0.03) than those who received single RAASB agent, and this was also similar in patients who received multiple antihypertensive medications (adjusted HR 2.20, 95% CI 1.02-4.74, P=0.04). In addition, this possible beneficial association of RAASB usage and graft prognosis was more prominent in patients who had albuminuria at the time of allograft IgAN diagnosis.

Conclusions: Usage of RAASB during the time of allograft IgAN diagnosis was associated with better prognosis compared with using other antihypertensive drugs. Our study is one of evidences encouraging the usage of RAASB in allograft IgAN patients.

TH-PO168

Relationship of Systolic Blood Pressure with GFR Decline in Kidney Transplant Recipients: The FAVORIT Trial

Rakesh Malhotra,[1] Ronit Katz,[2] Daniel E. Weiner,[3] Andrew S. Levey,[3] Alfred K. Cheung,[4] Andrew Bostom,[6] Joachim H. Ix.[5]
[1]UCSD, San Diego, CA; [2]University of Washington, Seattle, WA; [3]Tufts Medical Center, Boston, MA; [4]University of Utah, Salt Lake City, UT; [5]UCSD, San Diego, CA; [6]Rhode Island Hospital, Providence, RI.

Background: In chronic kidney disease, intensive systolic blood pressure (SBP) control reduces mortality, but increases rate of estimated glomerular filtration (eGFR) decline and acute kidney injury risk. The optimal blood pressure target in KTRs is uncertain. Prior observational studies from FAVORIT demonstrate lower mortality at lower SBP levels, but the relationship of SBP with kidney allograft function is largely unknown. We investigated the relationship of baseline SBP with risk of kidney allograft failure and eGFR slope during long-term follow-up among stable KTRs.

Methods: The FAVORIT trial, a multicenter, double-blind, randomized trial examining the effect of B-vitamin therapy on CVD and mortality, recruited KTRs who were at least 6 months post-transplant. SBP was measured at baseline, and subsequent eGFR values and kidney failure events were assessed. Cox proportional hazards and multivariable linear regression models were used to determine association of SBP with time to ≥50% eGFR decline or dialysis dependence, and annualized eGFR decline, respectively. Restricted cubic spline plots were developed to evaluate the functional form of the relationships. Models were adjusted for demographics, transplant characteristics, baseline eGFR, urine ACR and comorbidities.

Results: Among 3,598 KTRs, mean age was 52±9 years, mean baseline SBP was 136±20 mmHg and mean eGFR was 49±18 ml/min/1.73m^2. There were 369 ≥50% eGFR decline or dialysis dependence events during mean follow-up of 4.0±1.5 years. The relationships of SBP with both ≥50% eGFR decline or dialysis (SBP: $P_{\text{nonlinearity}} = 0.2$) and annualized eGFR slope (SBP: $P_{\text{nonlinearity}} = 0.8$) were linear without evidence of J or U shaped relationships (figure).

Conclusions: In a large sample of stable KTRs, we found no evidence of threshold at which lower baseline SBP was related to higher risk of eGFR decline. While reassuring in light of prior findings of mortality benefit at lower SBP, future trials are required to establish optimal BP targets in KTRs.

Funding: NIDDK Support

Figure: Adjusted spline plots for risk of ≥ 50% eGFR decline or hemodialysis dependence and annualized eGFR decline over the range of baseline systolic blood pressure

Triglyceride to HDL-Cholesterol Ratio and Risk of Major Cardiovascular Events in Renal Transplantation Recipients

Ji Eun Kim,[1] Mi-yeon Yu,[1] Yong Chul Kim,[1] Jung Pyo Lee,[2] Yon Su Kim,[1] Hajeong Lee.[1]
[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University Boramae Medical Center, Seoul, Republic of Korea.

Background: Dyslipidemia is common in renal transplant recipients(RTRs). Recent studies have shown that TG/HDL-C ratio may be a better predictor of cardiovascular(CV) events and CV mortality than other lipid parameters. We analyzed the TG/HDL of the first year of transplantation to identify the risk factors for major cardiovascular events(MACE). MACE was defined as heart failure, coronary artery disease with percutaneous coronary artery intervention(PCI), and cerebrovascular disease confirmed as an imaging study.

Methods: We retrospectively included 1301 RTRs who had lipid profile after 1 year of transplantation between 2000-2018. We identified TG/HDL from the lipid profile at 1 year and classified it into 3 groups as follows: low; less than 1, moderate; 1 to 2.5, high; 2.5 or more. After then, we explored an association between TG/HDL group and MACE.

Results: The mean age of included patients was 40.9 years and male sex was 61.7%. The prevalence of diabetes was 29.1%. Statin was prescribed in 30.3% of RTRs within 1 year after transplantation. RTRs with higher TG/HDL tended to be more men, more obese and diabetic. Proportion receiving statin was lowest in moderate TG/HDL group. During follow-up, 80 patients experienced MACE. Time to MACE occurrence was 92.7 month. As expected high TG/HDL group showed elevated MACE risk even after adjustment with age, sex, BMI, DM, prior history of CVD, and statin use (adjusted HR 1.98 [1.20-3.29] p=0.008), compared with moderate TG/HDL group. Interestingly, also low TG/HDL group revealed higher risk of MACE, compared to moderate TG/HDL group (adjusted HR 2.14[1.03-4.47] p=0.041). These associations were represented similarly in statin users, whereas only low TG/HDL group, not high TG/HDL group, showed elevated MACE risk in non-statin users.

Conclusions: High TG/HDL of 2.5 or more may be a risk factor for cardiovascular events in RTRs, especially in patients requiring statin therapy. Additionally, our study suggested low TG/HDL may paradoxically increase cardiovascular risk, especially in low risk patients.

TH-PO170

Pre-Transplant NT-proBNP, Dialysis Duration, and Post-Transplant Mortality in Renal Transplant Recipients

Stanley M. Yeung,[1] Marco van Londen,[1] Uzma Nakshbandi,[2] Mohammad Y. Said,[1] Michele F. Eisenga,[1] Bouke Hepkema,[1] Ilja M. Nolte,[2] Stefan P. Berger,[3] Martin H. De Borst,[1] Stephan J. Bakker.[1] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]UMCG, Groningen, Netherlands; [3]University of Groningen Medical Center, Groningen, Netherlands.*

Background: Pre-transplant dialysis duration is associated with increased mortality in renal transplant recipients (RTRs) due to intradialytic volume overload and subsequent progression of left ventricular hypertrophy. As a result, the cardiovascular system could deteriorate into a worse state in potential RTRs. N-terminal pro brain natriuretic peptide (NT-proBNP), a protein released by stretch of ventricular cells caused by volume overload, is a prognostic predictor of mortality in end-stage renal disease patients. The aim is to assess if dialysis duration (DD) is independently associated with mortality in RTRs and if NT-proBNP explains the association between DD with mortality in RTRs.

Methods: 648 patients, transplanted (1995-2005) in the University Medical Center Groningen, were prospectively analyzed after exclusion of 225 patients without sera NT-proBNP and 39 patients with graft failure within 1 year after transplantation. Multivariable Cox regression models were used to study the association of DD and NT-proBNP with all-cause mortality. Mediation analysis was performed to evaluate whether the associations between DD and mortality were mediated by NT-proBNP.

Results: In multivariable Cox regression DD was associated with increased risk for post-transplant mortality, independent of potential confounders including age, gender, creatinine, diastolic blood pressure, diabetic nephropathy, donor type, delayed graft function, pre-emptive transplantation and CMV seropositivity (Hazard ratio [HR]: 1.39; 95% confidence interval [CI]: 1.11-1.75; *P*=0.004). This association weakened after adjustment for NT-proBNP (HR: 1.25; 95% CI: 0.99-1.58; *P*=0.06). NT-proBNP was independently associated with all-cause mortality in RTRs (HR: 1.46; 95% CI: 1.23-1.74; *P*=<0.001). In mediation analysis NT-proBNP was found to explain 47.3% of the effect of DD on all-cause mortality in RTRs.

Conclusions: DD is a predictor of mortality in RTRs and variation in NT-proBNP at the time of transplantation to a large extent captures and mediates the effect of DD on mortality risk in RTRs. Future studies are needed to evaluate the potential value of NT-proBNP as check of cardiac patency of patients on the transplantation waiting list.

TH-PO171

Epidemiology and Prognostic Importance of Atrial Fibrillation in Kidney Transplant (KT): A Meta-Analysis

Nadeen J. Khoury,[1] Charat Thongprayoon,[2] Tarun J. Bathini,[3] Ronpichai Chokesuwattanaskul,[4] Wisit Cheungpasitporn.[5] *[1]Henry Ford Health, Detroit, MI; [2]Bassett Medical Center, Cooperstown, NY; [3]Bassett medical center, Cooperstown, NY; [4]King Chulalongkorn Memorial Hospital, Lansing, MI; [5]University of Mississippi, Mississippi, MS.*

Background: This meta-analysis was conducted with aims to summarize all available evidence on prevalence of pre-existing atrial fibrillation (AF) and/or incidence of AF following kidney transplantation and the outcomes of KT recipients with AF.

Methods: A literature search was conducted utilizing MEDLINE, EMBASE and Cochrane Database from inception through March 2018. We included studies that reported 1) prevalence of pre-existing AF or incidence of AF following kidney transplantation or 2) outcomes of KT recipients with AF. Effect estimates from the individual study were extracted and combined utilizing random-effect, generic inverse variance method of DerSimonian and Laird. The protocol for this meta-analysis is registered with PROSPERO (International Prospective Register of Systematic Reviews; no. CRD42018086192).

Results: 8 cohort studies with 137,709 kidney transplant recipients were enrolled. Overall, the pooled estimated prevalence of pre-existing AF in patients undergoing kidney transplantation was 7.0% (95%CI: 5.6%-8.8%) and pooled estimated incidence of AF following kidney transplantation was 4.9% (95%CI: 1.7%-13.0%). Meta-regression analyses were performed and showed no significant correlations between year of study and either prevalence of pre-existing AF (p =0.93) or post-operative AF after kidney transplantation (p =0.16). The pooled OR of mortality among KT recipients with AF was 1.86 (3 studies; 95%CI: 1.03-3.35). In addition, AF is also associated with death-censored allograft loss (2 studies; OR: 1.55, 95%CI: 1.02-2.35) and stroke (3 studies; OR: 2.54, 95%CI: 1.11-5.78) among KT recipients.

Conclusions: The overall estimated incidence of AF following kidney transplantation is 4.9%. Despite advances in medicine, incidence of AF following KT doesn't seem to decrease over time. In addition, there is a significant association of AF with increased mortality, allograft loss, and stroke after kidney transplantation.

TH-PO172

Autoantibodies to Apolipoprotein A-1 as Independent Predictors of Cardiovascular Mortality in Renal Transplant Recipients

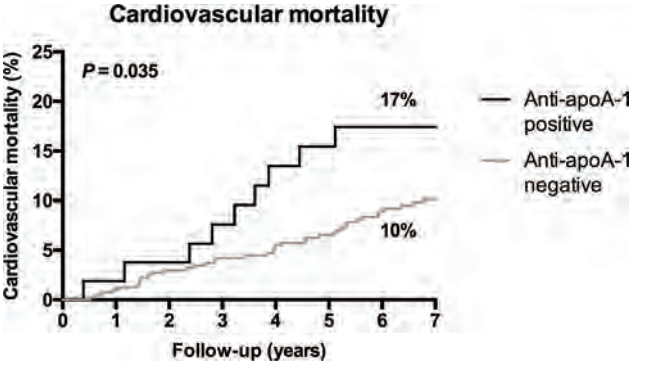
Josephine Anderson,[1] Sabrina Pagano,[2] Wijtske Annema,[2,1] Stephan J. Bakker,[3] Nicolas Vuilleumier,[2] Uwe J. Tietge.[3] *[1]University Medical Centre Groningen, Groningen, Netherlands; [2]Geneva University Hospital, Geneva, Switzerland; [3]University Medical Center Groningen, Groningen, Netherlands.*

Background: The aim of this study was to determine i) the prognostic value of autoantibodies against apoA-1 (anti-apoA-1 IgG) for incidence of cardiovascular disease (CVD) specific mortality, all-cause mortality and graft failure in renal transplant recipients (RTR), patients known to have a high CVD burden only partly explained by traditional CVD risk factors, and ii) to delineate the relationship of anti-apoA-1 IgG with HDL functionality.

Methods: 462 prospectively included RTR were followed for 7.0 years. Baseline anti-apoA-1 IgG were determined and associations with incidence of CVD mortality (n=48), all-cause mortality (n=92) and graft failure (n=39) were tested.

Results: HDL functionality assessed in vitro by measuring anti-oxidative and cholesterol efflux capacity was not associated with anti-apoA-1 IgG levels. Kaplan–Meier analyses demonstrated significant associations of anti-apoA-1 IgG with CVD mortality (log rank test among tertiles: P=0.048). Adjusted Cox regression analysis showed that for each standard deviation increase of log transformed anti-apoA-1 IgG values, there was a 4-fold increase (hazard ratio [HR]: 4.00; 95% confidence interval [95%CI]:1.32-12.11; p=0.01) in risk for CVD mortality and a more than 2-fold increase for all-cause mortality (HR:2.69, 95%CI:1.25-5.83; P=0.01), independent of CVD risk factors, renal and HDL function. The association with all-cause mortality disappeared after excluding cases of CVD specific mortality. The sensitivity, specificity, positive predictive value, and negative predictive value of anti-apoA-1 positivity for CVD mortality were 18.0%, 89.3%, 17.0%, and 90.0%, respectively.

Conclusions: In conclusion, this prospective study demonstrates that in RTR, anti-apoA-1 IgG are independent predictors of CVD mortality. In RTR, anti-apoA-1 IgG are not associated with HDL functionality.



TH-PO173

High-Quality 3D MRA for Transplant Renal Artery Stenosis with NATIVE TrueFISP

Juan C. Infante,[2,1] Marissa J. Defreitas,[2] Wendy R. Glaberson,[2] Carolyn L. Abitbol.[2] *[1]Radiology, Jackson Memorial Hospital, Miami, FL; [2]University of Miami/Jackson Memorial Hospital, Miami, FL.*

Introduction: Renal artery stenosis is a common complication after transplantation. In our institution, we have experienced a high rate of false-positive Doppler ultrasound and "confirmatory" non-contrast time-of-flight MRA studies that needlessly go to invasive catheterization. We present one of many of our cases which show the utility of high-quality 3D MRA using a non-flow dependent non-contrast technique, NATIVE TrueFISP.

Case Description: A 13-year-old male with a history of idiopathic dilated cardiomyopathy and end-stage renal disease underwent a combined cardiac transplant and deceased donor kidney transplant. Two months after the transplant, the patient was admitted for respiratory distress, pulmonary edema, and worsening cardiac function. On admission, the patient was mildly hypertensive. Further investigation showed an increase in serum creatinine to 1.6 mg/dl. A Doppler study showed elevated peak systolic velocity of the transplant renal artery anastomosis, up to 434 cm/sec. To confirm the sonographic suspicion of renal artery stenosis, a non-contrast 3D MRA was requested which showed tight juxta-anastomic stenosis (see Figure 1A). A diagnostic angiogram confirmed the pre-invasive imaging findings with nearly 1:1 correlation with the MRA 3D volume-rendered images (see Figure 1B). Angioplasty of this lesion was achieved by serial balloon dilation. Follow-up ultrasounds up to six-months post angioplasty show interval normalization of the renal artery velocities and blood pressure.

Discussion: The correct diagnosis of post-transplant renal artery stenosis is critical to avoid unnecessary, risky, costly, and time-consuming procedures. Under the supervision of a qualified radiologist, we have found our initial experience with NATIVE TrueFISP MRA technique to be reliable in evaluating transplant renal artery stenosis without the need for intravenous contrast.

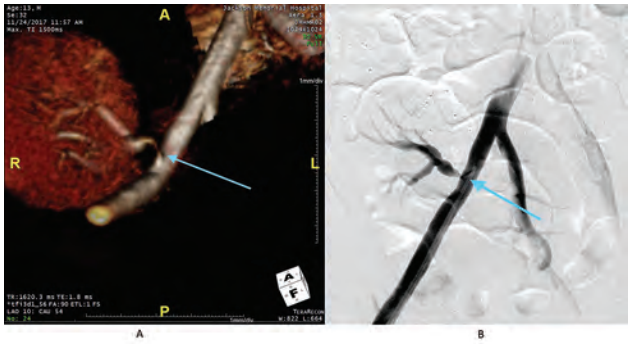


Figure 1 (A) 3D volume-rendered MRA shows tight juxta-anastomotic narrowing. (B) Conventional angiogram shows nearly 1:1 correlation of the stenosis as compared with the MRA.

TH-PO174

Clinical Outcomes of Adult Kidney Transplant Recipients with Post-Transplant Metabolic Acidosis: A Retrospective Cohort Study

Erika bianca V. Isidro. *Section of Nephrology, St. Luke's Medical Center, Quezon City, Philippines.*

Background: Metabolic acidosis as defined as serum bicarbonate of <22 mmol/L is commonly seen in patients with advanced chronic kidney disease, and is observed among Kidney transplant recipients (KTRs) due to maladaptive changes during early post-transplant causing subacute kidney injury despite preserved estimated glomerular filtration rate. Post-transplant metabolic acidosis is potentially an early marker of chronic allograft nephropathy, and eventual graft loss. However, graft survival is not well studied due to lack of periodic determination of serum bicarbonate post-transplant. This study aims to determine clinical outcome of graft loss among patients with post-transplant metabolic acidosis.

Methods: This is a single-centered retrospective cohort study, which included 132 eligible subjects from January 1995-December 2012 at the St. Luke's Medical Center, Quezon City. Laboratory measurements were determined at 12 months post-transplant, which included serum bicarbonate, creatinine, and proteinuria. Clinical outcomes were determined as graft loss, either by death or death censored graft failure, based on follow-up records.

Results: A total of 132 recipients were analyzed for baseline characteristics according to serum bicarbonate at 12 months post-transplant. The low serum bicarbonate (<22 mmol/L) group included 26 patients, with an incidence rate of 19.7%. Risk factors for metabolic acidosis include: eGFR of 15- 30 ml/min, deceased donor status, presence of one DR mismatch, acute rejection, presence of proteinuria, and use of alkalinizing agents. Graft loss, death, and death censored graft failure were not significantly associated with post-transplant metabolic acidosis, with the following risk ratios for graft loss (HR=2.293, 95% CI 0.849-6.191, p=NS), mortality (HR=1.885, 95% CI 0.311 -11.436, p=NS), and death censored graft failure, (HR=2.502, 95% CI 0.759-8.246, p=NS). The mean allograft survival with metabolic acidosis is 124.8 months, compared with 134.1 months in the group without metabolic acidosis.

Conclusions: Post-transplant metabolic acidosis has fairly high incidence rate of 19.7%. Graft loss, death, and death censored graft failure were not significantly associated with post-transplant metabolic acidosis. Periodic monitoring of serum bicarbonate is recommended to yield a well-represented large prospective cohort study in the future.

TH-PO175

Phosphate levels: Early Determining Factors and Influence in Long Term Graft Outcome in a Cohort of Renal Transplanted Patients

Carlo M. Alfieri,[1] Maria Teresa Gandolfo,[1] Donata Cresseri,[1] Mariarosaria Campise,[1] Valentina Binda,[1] Masami Ikehata,[1] Federica Tripodi,[1] Marianna Tangredi,[1] Silvia Malvica,[1] Piergiorgio Messa.[1,2] *[1]Fondazione IRCCS Ca' Granda Ospedale Policlinico Milan, Milan, Italy; [2]Università degli Studi di Milano, Milan, Italy.*

Background: Renal transplantation (RTx) only partially corrects certain metabolic alterations, especially in mineral metabolism (MM). We aim to examine the effect of RTx during the 1st year of RTx on P levels, exploring the factors related and influencing P levels after 1 month (T1) and 12 months (T2) of RTx. The impact on long term graft outcome of 1st year average P levels (P-avr) will also be explored.

Methods: In 132 RTx pts (age: 48[37;58] yrs – 87 males), up to the 476 transplanted in our unit between 2006 and 2015, clinical parameters, blood and urinary samples were collected at T1 and T2. In addition, in all the patients intact FGF23 (iFGF23) was tested at T1 and T2. Median follow up (FU) was 5[3-9] yrs.

Results: 84% percent of patients received a kidney from a deceased donor; 68% and 23% of patients were treated with haemodialysis and peritoneal dialysis before RTx. Dialysis vintage was 49[27-64] mths. Cold ischemia time was 13[11-16]h. MM parameters at T1 were: Ca 9.7[9.3-10.2]mg/dL, iPTH 68[42-114]pg/mL, ALP 94[72-127]U/L, 25OHVitD 12[8-17]ng/mL. Between T1 and T2, an increase of P levels was noted (T1:2.3[1.9-2.8] mg/dL – T2 3.1[2.7-3.6] mg/dL, p<0.001). iFGF23 was reduced (T1: 80[6-1360] pg/mL–T2 62[14-489] pg/mL, p=0.01). P-avr was 2.7[2.3-3.1]mg/dL. Thirty-five percent and 11% of patients were treated with active and native vitamin D during the first year of RTx. In multivariate analysis, T1-iFGF-23, T2-ALP and T2-Ca resulted the most influencing parameters of T1-P, T2-P and P-av (p=0.009, p=0.03 and p=0.002 resp.). No relationship between T2-P and T2-iFGF23 as like as between P-av and renal function was found. No influence of immunosuppressive therapy was found. During FU, 8 patients restarted dialysis (D+). D+ were different to those patients with functioning graft only for higher T2-PTH (p=0.01) and P-av (p<0.0001). In Cox and ROC curve analysis, P-av was the best predicting and discriminatory factor for graft loss (Cox: p<0.0001; ROC: AUC 0.71±0.10– p=0.04).

Conclusions: Our data confirm that RTx has an impact to MM from the beginning, and that P levels are influenced by different factors at T1 and T2. However, independently to renal function, P-av might influence long-term graft outcome.

TH-PO176

Early Post-Transplant Hypophosphatemia Predicts Better Graft Function After Kidney Transplantation

Kentaro Nakai, Yusuke Kuroki, Yukiko Ishimatsu, Megumi Inoue, Chiaki Kohara, Shutaro Yamamoto, Keita Takae, Takehiro Nishiki, Kentaro Motoyama, Koji Mitsuiki. *Japanese red cross fukuoka hospital, Fukuoka, Japan.*

Background: Hyperphosphatemia is a well-established and independent risk factor for fracture, cardiovascular disease, and mortality in dialyzed and non-dialyzed patients with chronic kidney disease. Recent studies showed that high serum phosphate is associated with rapid decline in kidney function. Kidney transplantation dramatically decreases serum phosphate levels; however, the association of hypophosphatemia with graft survival remains unclear.

Methods: This was a single-center, retrospective study comprising 90 patients who underwent a kidney transplant at our institution between 2008 and 2016. Patients were divided into two groups, with and without hypophosphatemia. The hypophosphatemia was defined as those with less than or equal to the lowest quartile of serum phosphate levels at 3 months post-transplant. The endpoints were defined as 30% decrease in the eGFR. The cumulative kidney survival rates were calculated for each group using the Kaplan–Meier method, and the adjusted hazard ratio (HR) was calculated using the Cox regression model.

Results: No significant differences were observed in age, diabetes, living donor, pre-emptive kidney transplantation, ABO incompatibility, donor-specific antigen, or biochemical parameters of mineral bone disorders at transplantation between the two groups. The proportion of male recipients was higher in the hypophosphatemia group than in the control group (88% vs. 65%). The hypophosphatemia group received a higher proportion of cinacalcet prescriptions during the dialysis period than the control group (33% vs. 14%). The median follow-up duration was 47.5 months, and the 90 transplantations resulted in 6 cases of graft loss, 2 of mortality, and 37 of 30% decline in eGFR. The Kaplan–Meier analysis revealed that patients in the hypophosphatemia group had a significantly lower risk of 30% decline in eGFR than those in the control group. After adjusting for confounding factors, hypophosphatemia was associated with a significantly lower risk of 30% decline in eGFR [HR, 0.37; 95% confidence interval (CI), 0.14–0.88] compared with the control group.

Conclusions: The results of the present study suggested that hypophosphatemia at 3 months post transplant is a favorable sign for the successful outcome of transplantation.

TH-PO177

To Study the Effect of Variable Protein Intake on Nitrogen Balance in Renal Transplant Recipients with Underlying Graft Dysfunction

Rasika A. Sirsat, Neha Shah, Alan F. Almeida, J. Kothari, Mayuri Trivedi. *P. D. Hinduja Hospital and Medical Research Centre, Mumbai, India.*

Background: It is essential to determine the optimum nutrition (protein intake) in renal transplant recipients on steroids with renal dysfunction to maintain a neutral nitrogen balance. It was our aim to study the effect of variable protein intake [i.e.higher (1.2g/kg/d) and lower (0.8g/kg/d) protein intake] on nitrogen balance, body composition, glomerular filtration rate and proteinuria in renal transplant recipients with low eGFR (15–44 ml/min/1.73m^2).

Methods: This prospective, open-labelled, randomized, cross-over, interventional study enrolled 35 patients who were ≥ 4 months post-transplant and who had an eGFR between 15 - 44 ml/min/1.73m^2. Thirty-two patients completed the study. The subjects were randomised to either Group 1 [Diet: proteins (1.2 g/kg/day) and 35 kcal/kg/day] or Group 2 [Diet: proteins (0.8 g/kg/day with 50% first class proteins) and 35 kcal/kg/day] for one month. The subjects crossed over to the other diet for the second month. The body composition analysis, sr. creatinine, blood urea nitrogen, sr. protein, sr. albumin, 24 hours proteinuria, GFR measurement (24 hours creatinine clearance), three day diet recall and nitrogen balance estimation were performed at baseline and at the end of the first and second months. Statistical analysis was performed using SPSS version 21.

Results: The three day diet recall showed that the daily protein and energy consumption was 1.2 g/kg and 36.47 kcal/kg with the higher protein diet and 0.94 g/kg protein with 31.94 kcal/kg with the lower protein diet. The nitrogen balance was positive with both the diets, +3.61 g/d with the higher protein diet (p=0.0002) and +1.66 g/d with the lower protein diet. The waist hip ratio showed a significant decrease on the higher protein diet (p=0.011) and increase on the lower protein diet (p=0.011). There was significant gain in muscle mass (0.70 kg gain; p=0.0317) with the higher protein diet. Significant increase was noted in blood urea nitrogen (p=0.0048) and GFR (p=0.0114) with the higher protein diet. 24 hours urinary protein excretion increased significantly after consuming the higher protein diet (320mg/d, p=0.010).

Conclusions: Renal transplant recipients remained in positive nitrogen balance with both diets. Muscle mass and proteinuria increased significantly with the higher protein diet.

The Efficacy of Exercise Training in Kidney Transplant Recipients: A Systematic Review and Meta-Analysis

Hideyo Oguchi,[1] Makoto Tsujita,[8] Masahiko Yazawa,[5] Takehiko Kawaguchi,[3] Junichi Hoshino,[7] Masahiro Kohzuki,[10] Osamu Ito,[9] Kunihiro Yamagata,[6] Yugo Shibagaki,[2] Tadashi Sofue.[4] *[1]Department of Nephrology, Toho University Faculty of Medicine, Tokyo, Japan; [2]St Marianna University Hospital, Kawasaki, Japan; [3]National Hospital Organization Chiba-East Hospital, Chiba, Japan; [4]Kagawa University, Kita-gun, Japan; [5]Division of Nephrology and Hypertension, Department of Internal Medicine, St.Marianna University School of Medicine, Kawasaki, Japan; [6]University of Tsukuba, Tsukuba, Japan; [7]Toranomon Hospital, Tokyo, Japan; [8]Nagoya Daini Red Cross Hospital, Nagoya, Japan; [9]Tohoku Medical Pharmacetical University Faculty of Medicine, Sendai, Japan; [10]Tohoku University Graduate School of Medicine, Sendai, Japan.*

Background: The effectiveness of exercise in kidney transplant recipients is not well established. We therefore performed a systematic review of the effects of exercise training in kidney transplantation recipients.

Methods: We searched two electronic databases for articles up to April 2017. Inclusion criteria were as follows: randomized controlled trial and kidney transplant recipients aged 18 years or older. The main outcomes were allograft function (estimated glomerular filtration rate, eGFR), exercise tolerance (VO2 peak), and quality of life (QOL).

Results: After screening of 1,303 references in PubMed and Ichushi, six randomized control trials were analyzed. For kidney transplant recipients, supervised exercise training was shown to significantly improve VO2 peak (mean difference, 2.42; 95% confidence interval (95%CI) 0.22–4.63) and QOL (mean difference, 7.23; 95%CI 0.94–13.52). However, exercise training did not improve allograft kidney function (mean difference, 6.22; 95%CI -13.00–25.44). No reporting bias was observed in any of the outcomes.

Conclusions: Exercise training for kidney transplant recipients significantly improved exercise tolerability and QOL, but a significant improvement was not obtained with respect to allograft kidney function.

TH-PO179

Fibroblast Growth Factor 23 and Arterial Stiffness in SPRINT

Anna J. Jovanovich,[1,2] Zhiying You,[3] Charles Ginsberg,[4] Joachim H. Ix,[4] Mark A. Supiano,[5] Michael Shlipak,[6] Alfred K. Cheung,[7] Michel Chonchol,[2] Kristen L. Nowak.[8] *[1]Denver VA, Denver, CO; [2]University of Colorado, Aurora, CO; [3]UC Denver, Aurora, CO; [4]UCSD, San Diego, CA; [5]University of Utah Geriatrics Division, Salt Lake City, UT; [6]San Francisco VA Medical Center, San Francisco, CA; [7]University of Utah, Salt Lake City, UT; [8]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO.*

Background: Fibroblast growth factor 23 (FGF23) and arterial stiffness are both associated with cardiovascular disease and mortality in chronic kidney disease (CKD). The relationship between FGF23 and arterial stiffness needs further investigation. We hypothesized that higher serum FGF23 levels would be associated with greater arterial stiffness in participants with CKD in the Systolic Blood Pressure Intervention Trial (SPRINT).

Methods: The SPRINT study was a randomized multicenter trial evaluating the effects of standard (SBP <140 mmHg) vs. intensive (SBP <120 mmHg) blood pressure lowering on cardiovascular outcomes among older adults without diabetes. Intact FGF23 (iFGF23) was measured at baseline among 2384 participants with an estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73m^2. Multivariable linear regression determined the association between baseline iFGF23 and pulse pressure (PP; a surrogate measure of arterial stiffness) (N = 2384) and aortic pulse wave velocity (aPWV) (N = 202), the latter of which was measured in an ancillary study. Models were adjusted for demographics, comorbidities, randomization group, baseline number of antihypertensives, eGFR, albuminuria, and serum calcium and phosphorus.

Results: In the PP analysis, mean age was 73 ± 9 years, mean eGFR was 49 ± 11 mL/min/1.73m^2, and median iFGF23 level was 71 [53-95] ng/mL. There was no significant association between baseline iFGF23 and PP (β: -0.08, 95% CI: -1.06 to 0.89). Notably, baseline serum phosphorus was significantly associated with PP (β: 1.33, 95% CI: 0.23 to 2.43) in the fully adjusted model. In the ancillary study, mean age was 73 ± 10 years, mean eGFR was 47 ± 12 mL/min/1.73m^2, and median iFGF23 level was 71 [53-95] ng/mL. In the unadjusted model, higher iFGF23 was significantly associated with lower aPWV (β: -0.009, 95% CI: -0.02 to -0.003). However, in the fully adjusted model, this association was no longer significant (β: -0.003, 95% CI: -0.01 to 0.004).

Conclusions: Among SPRINT participants with baseline eGFR < 60 mL/min/1.73m^2, iFGF23 was not associated with arterial stiffness as measured by PP and aPWV. However, higher serum phosphorus was associated with increased PP. The analysis of aPWV was limited due to a smaller sample size.

TH-PO180

Fibroblast Growth Factor 23 (FGF23) and Cystic Liver Disease in Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Anna J. Jovanovich,[2] Zhiying You,[4] Berenice Y. Gitomer,[5] Myles Wolf,[6] Isidro B. Salusky,[7] Michel Chonchol,[1] Kristen L. Nowak.[3] *[1]University of Colorado, Aurora, CO; [2]Denver VA / University of Colorado, Denver, CO; [3]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO; [4]UC Denver, Aurora, CO; [5]Div. Renal Diseases and Hypertension, Aurora, CO; [6]Duke University, Durham, NC; [7]Mattel Children's Hospital, Los Angeles, CA.*

Background: Previous studies have demonstrated that the cystic liver from ADPKD patients markedly expresses FGF23 mRNA and protein. Epidemiological studies have reported an elevation in circulating FGF23 levels in adult ADPKD patients compared to non-ADPKD patients with similar kidney function. We hypothesize that elevated serum iFGF23 levels are associated with greater increases in cystic liver volume in early ADPKD.

Methods: 440 participants with early ADPKD and normal kidney function (mean eGFR 92± 18mL/min/1.73m^2) who participated in HALT Study A were included in this analysis. The cross-sectional and longitudinal (5-year) association of iFGF23 with liver volume, measured as baseline total liver volume and change in total liver volume by magnetic resonance imaging, respectively, were evaluated using linear regression models. iFGF23 levels were measured using stored serum samples obtained at baseline

Results: Participants had a mean (SD) age of 37 ± 8 years. Mean (SD) serum phosphate level and the median (IQR) iFGF23 level were 3.4 ± 0.5 mg/dL and 43 (33–56) pg/mL, respectively. The median (IQR) baseline liver volume was 1790 (1572-2088)ml. After adjustment for age, sex, body mass index, randomization group, systolic blood pressure, estimated glomerular filtration rate, urinary albumin excretion, serum calcium, phosphate, parathyroid hormone level and PKD genotype, higher circulating iFGF23 levels were not associated with liver volume at baseline (ß=35.39, [95% CI -86.75 to 157.53; p=0.60] per doubling in iFGF23). Similarly, higher circulating iFGF23 was not associated with greater percentage increase in liver volume (ß=-1.94, [95% CI -17.04 to 13.15; p=0.80]) per doubling in iFGF23.

Conclusions: Our results indicate that circulating iFGF23 is not independently associated with liver volume in ADPKD patients. FGF23 does not appear to represent a valid therapeutic target or a pertinent biomarker for liver cysts progression in patents with early ADPKD.

The Effect of Intensive Blood Pressure Lowering on Markers of Mineral Metabolism in Persons with CKD in SPRINT

Charles Ginsberg,[1] Ronit Katz,[2] Michel Chonchol,[3] Alexander Bullen,[1] William R. Zhang,[4] Michael Shlipak,[5] Joachim H. Ix.[1] *[1]UCSD, San Diego, CA; [2]University of Washington, Seattle, WA; [3]University of Colorado, Aurora, CO; [4]UCSF School of Medicine, San Francisco, CA; [5]San Francisco VA Medical Center, San Francisco, CA.*

Background: Serum fibroblast growth factor 23 (FGF23) and parathyroid hormone (PTH) concentrations are high in chronic kidney disease (CKD) and have been associated with increased cardiovascular disease (CVD) risk. The SPRINT trial demonstrated that intensive blood pressure (BP) lowering reduced risk of CVD despite more rapid eGFR decline. The effects of intensive blood pressure lowering on serum FGF23 and PTH are currently unknown.

Methods: Among individuals with CKD (eGFR < 60ml/min/1.73m^2), we randomly selected 1000 participants and measured serum intact FGF23 (iFGF23; Kainos ELISA), intact PTH (iPTH), calcium, phosphate, and urine phosphate/creatinine at baseline and year 1. Thirteen were missing serum samples, resulting in 987 for analysis. We used linear mixed models to assess the effect of intensive BP lowering on iFGF23 and iPTH, in addition to changes in serum calcium, phosphate and fractional excretion of phosphate (FePhos).

Results: Mean age was 72±9 years, 42% were female, and mean eGFR was 46±10 ml/min/1.73m^2. Demographics, baseline BP, kidney function, iFGF23, and iPTH were well-balanced across arms. Randomization to the intensive arm resulted in an increase in iFGF23 over 1 year compared with the standard BP arm (p=0.01) but no change in PTH [-1.6% (95% CI -6.1, 2.9]. After adjustment for 1 year changes in eGFR and albuminuria, persons in the intensive arm experienced an 11.2% (95% CI 6.2, 17.5) increase in serum iFGF23 compared with the standard arm. Randomization to the intensive arm did not impact calcium and phosphate or FePhos

Conclusions: In SPRINT participants with CKD, compared with the standard arm, randomization to the intensive BP arm led to an increase in iFGF23 that was independent of changes in eGFR. Future studies should determine whether increasing iFGF23 in persons receiving intensive BP therapy impacts CVD risk.

TH-PO182

Change in FGF23 and PTH1-84 and Subsequent Cardiovascular and Renal Events in Patients with Advanced CKD

Mark Canney,[1] Ognjenka Djurdjev,[2] Mila Tang,[1] Claudia Zierold,[3] Frank A. Blocki,[3] Fabrizio Bonelli,[3] Adeera Levin.[1] *[1]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada; [2]BC Renal Agency, Vancouver, BC, Canada; [3]DiaSorin, Stillwater, MN.*

Background: Elevated levels of parathyroid hormone (PTH1-84) and fibroblast growth factor 23 (FGF23), measured at a single time, are associated with increased risk of cardiovascular (CV) and renal events in patients with CKD. Few studies have examined the longitudinal association between bone mineral biomarkers (BMB) and outcomes. We sought to describe changes in PTH1-84 and FGF23 over time and their association with subsequent CV and renal events.

Methods: Using data from a prospective cohort of 1078 patients with advanced CKD in Canada under the care of nephrologists (2008-2013), we measured serial PTH1-84 and FGF23 (3 time-points) in a central laboratory using sensitive DiaSorin assays. Adjudicated CV (coronary artery disease, congestive heart failure, stroke, sudden cardiac death) and renal outcomes (initiation of renal replacement therapy (RRT)) were recorded over 3 years of follow-up after the last BMB measurement. We used group-based trajectory models to characterize patterns of change in BMB, and Cox regression models to relate these changes to CV and renal outcomes.

Results: Mean age was 69.9, 62% were male, 45% were diabetic and 45% had pre-existing CV disease. Mean eGFR was 27mL/min/1.73m^2; 28%, 34% and 38% had eGFR <20, 20-29 & >30mL/min/1.73m^2 respectively. We identified 3 distinct patterns of BMB change over time: low & stable (reference group), mid-level & stable, high & slowly rising. The proportions of patients in each category for PTH1-84 were 26%, 55% and 20% respectively. A small subgroup of patients (6%) had a high & rising pattern for FGF23. During median follow-up of 29 months, 11% experienced a CV event and 13% initiated RRT. Compared with the reference group, patients with mid-level & stable and high & rising patterns of each BMB had higher risk of CV events and RRT (Table). In multivariable models, only the high & rising patterns of PTH1-84 and FGF-23 demonstrated increased risk of CV events.

Conclusions: The majority of patients with advanced CKD had stable BMB values over time. A subgroup of patients had a high & rising pattern of change in PTH1-84 and FGF23 which conferred increased risk of CV events.

Funding: Commercial Support - DiaSorin

Table 1: Associations of BMB Change Patterns with Cardiovascular and Renal Outcomes

BMB Change Pattern (% patients)	CV Event (Unadjusted) HR	95% CI	CV Event (Adjusted) HR	95% CI	RRT (Unadjusted) HR	95% CI	RRT (Adjusted) HR	95% CI

TH-PO183

Adjustment for ProBNP Substantially Attenuates Prognostic Implications of Plasma FGF23 Levels in CKD

Insa E. Emrich,[1] Vincent Brandenburg,[2] Alexander Sellier,[1] Sarah Seiler-Mussler,[4] Gunnar H. Heine.[3] *[1]Saarland University Medical Center, Homburg (Saar), Germany; [2]Nephrology, Rhein-Maas Klinikum, Würselen, Germany; [3]Saarland University Faculty of Medicine, Homburg, Germany; [4]Gemeinschaftspraxis Dr. Schürfeld, Dr. Möller, Dr. Henrich, Saarlouis, Germany.*

Background: Various epidemiological studies linked high plasma levels of the phosphatonin FGF23 with cardiovascular events in non-dialysis CKD. It remains enigmatic whether high FGF23 exerts adverse cardiovascular effects, or whether it reflects detrimental effects of residual confounders. Earlier epidemiological studies adjusted for chronic kidney disease – mineral bone disease (CKD-MBD) regulators of FGF23 rather than for recently discovered non-CKD-MBD regulators, among which iron deficiency and heart failure are of particular importance. Moreover, they used c-terminal FGF23 assays (cFGF23) rather than more specific intact FGF23 assays (iFGF23).

Methods: The *CARE FOR HOMe* study analyzed plasma ferritin, hepcidin, iFGF23, cFGF23 and proBNP along with conventional risk factors, among 575 CKD G2-G4 patients. The participants were followed 5.1 ± 2.1 years for the occurrence of atherosclerotic events and hospitalization for acute decompensated heart failure, respectively.

Results: cFGF23 correlated strongly with high iFGF23, fairly with high proBNP and weakly with low ferritin; correlation coefficients of iFGF23 with proBNP and ferritin were numerically lower. In Kaplan-Meier analyses, both endpoints were predicted by cFGF23 and iFGF23. In Cox regression models, cFGF23 remained an outcome predictor after adjustment for conventional risk factors and iron deficiency. This prediction was largely eliminated when further adjusting for proBNP. iFGF23 was less consistently associated with adverse outcome in partly adjusted models, and failed to predict outcome in fully adjusted models.

Conclusions: In summary, iron deficiency and heart failure affect plasma FGF23. As adjustment for proBNP virtually eliminates the prognostic implications of plasma FGF23, we speculate that high FGF23, rather than exerting detrimental cardiovascular effects, merely mirrors prevalent heart disease.

TH-PO184

Effect of Renal Transplantation on Carotid Intimal Medial Thickness (CIMT), Left Ventricular Mass Index (LVMI), and CKD-MBD Markers: A Longitudinal Study

Sandeep Mahajan. *All India Institute of Medical Sciences, New Delhi, India.*

Background: Various nontraditional risk factors (NTRFs) including serum markers of CKD-MBD (serum calcium, phosphorus, intact PTH, vitamin D & FGF-23) & increased LVMI have been implicated for high cardiovascular (CV) mortality in CKD. Renal transplant (RT) by correcting uremic milieu improves most NTRFs. However compared to general population, CV mortality remains high post RT. This could be due to new risk factors or legacy effect of previous CKD period. CIMT is marker of structural atherosclerosis & has been shown to decrease after correction of risk factors in some clinical settings. This prospective, longitudinal study in CKD 5D patients looks at any change in CIMT & LVMI post RT & their correlation with changes in CKD-MBD markers.

Methods: 83 consecutive, eligible & consenting patients aged 18-65 years undergoing first live RT were enrolled. All investigations, CIMT & LVMI assessments were done at baseline (≤1 week prior to RT) & at 6 & 12 months post RT. Patients with pre-transplant diabetes, established coronary/valvular heart disease & those having persistent eGFR <40 ml/min post RT were excluded

Results: 74 patients completed study, 91.8% were male, mean age was 35.5±10.6 years & median dialysis vintage was 14 months. All were on MMF, steroids & calcineurin inhibitors. At baseline CIMT did not correlate with any of CKD-MBD parameters while LVMI correlated positively with FGF-23 (correlation coefficient 0.57, p-value <0.001). There was a significant reduction in CIMT & LVMI at 6 & 12 months post RT & improvement some CKD-MBD markers (table). There was however no correlation between changes in CIMT & LVMI & changes in CKD-MBD markers

Conclusions: In low risk CKD-5D population we document a significant decline in CIMT & LVMI post RT. Though there was significant improvement in CKD-MBD markers post RT they did not correlate with change in CIMT & LVMI

Parameter	Baseline	6 month	12 month	P-value I vs II, I vs III
CIMT mm	0.57±0.07	0.55±0.08	0.55±0.07	0.001, 0.001
LVMI g/m2	161.9±14.4	160.8±12	149.3±13.6	<.001, <0.001
S. Calcium mg/dl	9.2±1.4	9±0.8	9±0.7	0.16, 0.3
S. Phosphorus mg/dl	5±1.6	2.9±0.8	3.3±0.6	<.001, <0.001
Intact PTH pg/dl median (range)	57.8 (9.3-1297.7)	33 (3-297)	12.9 (3-210)	0.29, 0.01
25 (OH) Vit D ng/dl median (range)	10.5 (4.9-52.6)	10.5 (4.9-52.6)	16.6 (3.9-38.2)	0.54, 0.08
Intact FGF-23 pg/dl median (range)	2649.2 (157.8-3244.2)	72.2 (2.3-2481.3)	68.6 (5.7-2939.5)	<.001, <0.001

TH-PO185

FGF23 as a Risk Factor for Cardiovascular Events and Mortality in Patients in the EVOLVE Trial

Mark D. Danese,[2] Glenn M. Chertow,[3] Kerry Cooper,[7] Marc Halperin,[4] William W. Stark,[1] David C. Wheeler,[5] Geoffrey A. Block.[6] *[1]Amgen INC, Newbury Park, CA; [2]Outcomes Insights, Inc., Westlake Village, CA, CA; [3]Stanford University School of Medicine, Palo Alto, CA; [4]Outcomes Insights, Inc, Westlake Village, CA; [5]University College London, London, United Kingdom; [6]Colorado Kidney Care, Denver, CO; [7]Amgen Inc., Thousand Oaks, CA.*

Background: Risk factors for all-cause mortality and cardiovascular events in dialysis patients with CKD-MBD have not been fully elucidated. Historically, analyses using mineral metabolism biomarkers to predict clinical outcomes have used neither FGF23 nor clinically-adjudicated events.

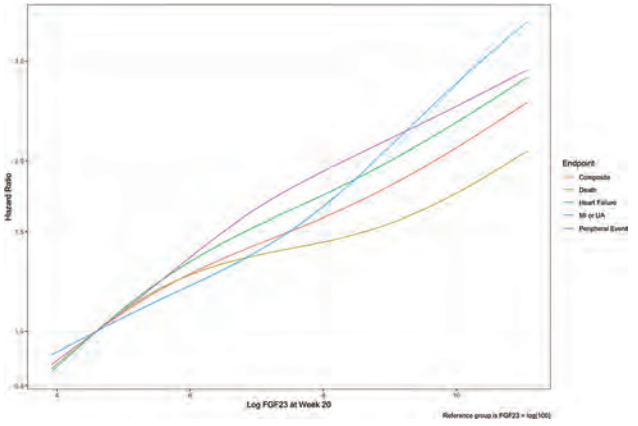
Methods: We evaluated FGF23 and other risk factors using data from EVOLVE, a randomized, double-blind placebo-controlled, event-driven trial (N=3883 with CKD-MBD) in which subjects were followed for up to 64 months. EVOLVE compared cinacalcet to placebo with a composite endpoint of death, myocardial infarction, hospitalization for unstable angina, heart failure (HF), or peripheral vascular event. Inclusion criteria included PTH ≥300 pg/mL, calcium ≥8.4 mg/dL, and phosphorus ≥5.3 mg/dL. Our study quantified FGF23-associated risk following dose titration (week

20). We used Cox proportional hazards models to estimate the relative risk of the composite endpoint and its components, adjusting for age, albumin, race, sex, smoking status, Hb, P, Ca, PTH, and alkaline phosphatase as well as history of diabetes, coronary artery disease, HF, and stroke. Laboratory values and age were modeled using penalized splines to allow for a flexible relationship between the measure and risk (e.g., S or U-shaped).

Results: We included 2,411 patients who were event-free at week 20, and had an FGF23 measure. There were 1100 events (526 deaths and 574 non-fatal events). In adjusted models, higher log FGF23 was associated with a higher risk of the composite endpoint and its components. See Figure.

Conclusions: FGF23 appears to be an important, independent risk factor for mortality and CV events in addition to those traditionally associated with CKD-MBD.

Funding: Commercial Support - This study was funded by Amgen, Inc.



Association of Log(FGF23) with the Composite Endpoint and its Components

TH-PO186

Interactions Between FGF23 and Genotype in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Laura K. Grau,[1] Berenice Y. Gitomer,[1] Michel Chonchol,[1] Myles Wolf,[2] Peter C. Harris,[3] Godela M. Brosnahan,[1] Vicente E. Torres,[3] Theodore I. Steinman,[6] Alan S. Yu,[4] Arlene B. Chapman,[5] Kristen L. Nowak.[1] *[1]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO; [2]Duke University, Durham, NC; [3]Mayo Clinic, Rochester, MN; [4]University of Kansas Medical Center, Kansas City, KS; [5]University of Chicago, Chicago, IL; [6]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Among individuals with ADPKD, higher serum intact fibroblast growth factor 23 (iFGF23) was associated with disease progression in participants in the HALT-PKD study. PKD mutation is also an important determinant of ADPKD progression. We hypothesized that serum levels of iFGF23 and vitamin D metabolites (1,25-dihydroxyvitamin D [1,25$(OH)_2$D] and 25-hydroxyvitamin D [25[OH]D]) differed in adults with ADPKD according to ADPKD mutation and that the interaction between genotype and mineral metabolites would predict clinical endpoints.

Methods: 921 individuals with ADPKD who participated in the HALT-PKD study A or B and had measurement of mineral metabolites (1,25$(OH)_2$D, 25(OH)D, and iFGF23) were categorized by PKD mutation (PKD1 truncating, PKD1 non-truncating, PKD2, or no mutation detected [NMD]). The longitudinal (5-yr) association of the interactions of genotype * iFGF23 and genotype * 1,25$(OH)_2$D with clinical endpoints of (a) 50% decline in eGFR; b) end-stage renal disease (ESRD); c) composite of 50% decline in eGFR, ESRD, or death) were evaluated using cox proportional hazards regression.

Results: Median (IQR) 1,25$(OH)_2$D differed (PKD1 truncating: 31.0 (24.4, 39.1); PKD1 non-truncating: 32.0 (24.8, 40.1), PKD2: 33.9 (24.8,41.0); NMD: 38.2 (27.8, 46.4) pg/ml; p=0.01) and iFGF23 tended to differ (PKD1 truncating: 55.9 (40.5, 76.2); PKD1 non-truncating: 49.9 (37.7, 72.2); PKD2: 48.6 (33.9, 69.8); NMD: 49.8 (39.7, 65.8) pg/ml; p=0.07) according to PKD genotype. There was a significant interaction between FGF23 and genotype ($p<0.01$) for the composite endpoint in the fully adjusted models (Figure), but no significant interaction between 1,25$(OH)_2$D and genotype for clinical endpoints.

Conclusions: ADPKD genotype interacts significantly with FGF23 to influence clinical endpoints, with the worst outcomes in individuals with a PKD1 truncating or non-truncating mutation and the highest tertile of iFGF23.

TH-PO187

Association of Serum Bicarbonate Levels with Serum Fibroblast Growth Factor-23 Levels

Jessica B. Kendrick,[1] Zhiying You,[2] Berenice Y. Gitomer,[3] Michel Chonchol,[4] Judith Blaine.[5] *[1]University of Colorado School of Medicine, Aurora, CO; [2]UC Denver, Aurora, CO; [3]Div. Renal Diseases and Hypertension, Aurora, CO; [4]University of Colorado, Aurora, CO; [5]University of Colorado Denver, Aurora, CO.*

Background: The regulation of fibroblast growth factor-23 (FGF23) is not understood. *In vitro* studies have found that metabolic acidosis increases FGF23. However, small pilot studies have found that treatment of low bicarbonate levels with sodium bicarbonate increases FGF23 levels. We tested the hypothesis that lower serum bicarbonate levels are associated with higher levels of FGF23.

Methods: We included 822 patients from the HALT-PKD Study A (n=540; mean eGFR = 91±17 ml/min per 1.73 m2) and B (n=462; mean eGFR = 48±12 ml/min per 1.73 m2) with serum bicarbonate and FGF23 levels measured at baseline. Bicarbonate was examined as a continuous variable and in categories (≤ 24, 25-28 and >28 mEq/L, with 25-28 mEq/L as the reference group). We used linear regression models to examine the cross-sectional association between baseline serum bicarbonate and FGF23 levels.

Results: The mean (SD) age and estimated glomerular filtration rate (eGFR) was 43 ± 10 years and 70 ± 26 ml/min/1.73m2. The mean (SD) serum bicarbonate level was 26.7 ± 2.4 mEq/L and the median (IQR) serum FGF23 level was 53 (39-74) pg/mL. Participants with bicarbonate levels ≤ 24 mEq/L had lower baseline eGFR and higher systolic blood pressure. In unadjusted analysis, every 1 mEq/L increase in serum bicarbonate was associated with a decrease of 1.25 pg/mL in FGF23 levels (β -1.25, 95% CI -2.48 to -0.01). However, after adjustment for demographics, randomization group, baseline eGFR, smoking, cardiac history, body mass index, blood pressure, serum calcium and phosphorus, the association was no longer significant (p=0.20). A serum bicarbonate ≤ 24 mEq/L trended towards an increased risk of higher FGF23 in unadjusted analysis but it did not reach statistical significance (p=0.05).

Conclusions: Serum bicarbonate levels are not associated with FGF23 levels in patients with polycystic kidney disease. Further studies are needed to examine the relationship between metabolic acidosis and FGF23 in other causes of kidney disease.

Funding: Other NIH Support - NHLBI

Genome-Wide Association Study Reveals That Distinct Genetic Factors Regulate Intact and C-Terminal FGF23 Levels in Humans

William T. Barrington,[1] Mark R. Hanudel,[1] Renata C. Pereira,[4] Sarada Charugundla,[1] Markku H. Laakso,[5] Aldons J. Lusis,[2] Isidro B. Salusky.[2,3] *[1]UCLA, Los Angeles, CA; [2]UCLA, Los Angeles, CA; [3]Mattel Children's Hospital, Los Angeles, CA; [4]University of California, Los Angeles, CA; [5]University of Eastern Finland, Kuopio, Finland.*

Background: Elevated fibroblast growth factor 23 (FGF23) levels have been associated with chronic kidney disease (CKD) progression, cardiovascular disease (CVD) and increased mortality. FGF23 also directly induces cardiac myocyte hypertrophy. Recently, non-mineral factors such as iron, anemia, inflammation and erythropoietin (EPO) have been identified in FGF23 production. Such factors are also associated with CKD progression, CVD and mortality. Thus, several lines of evidence suggest that FGF23 could play an important link. However, no studies have examined genetic factors underlying FGF23 levels in humans. We conducted the first-ever genome-wide association study (GWAS) study of FGF23.

Methods: We measured both the active, intact form (iFGF23), and the total amount of FGF23 as measured by c-terminal form (cFGF23) via ELISA in a population of 1,400 Finnish men aged 58+7 (SD) yrs. and eGFR 85+15 ml/min/1.73 m^2. We performed GWAS mapping using a linear mixed model removing, SNPs with less than 5% minor allele frequency.

Results: We identified suggestive loci for cFGF23 on chromosomes 3 ($p = 4.3 \times 10^{-7}$) and 21 ($p = 8.9 \times 10^{-8}$), and suggestive for iFGF23 levels on chromosomes 7 ($p = 3.6 \times 10^{-6}$), 12 ($p = 3.6 \times 10^{-6}$) and chromosome 18 ($p = 4.5 \times 10^{-6}$). The locus influencing iFGF23 levels on chromosome 7 is near the erythropoietin (*EPO*) gene, which stimulates hematopoiesis

and is deregulated in CKD patients. It is known that serum EPO and recombinant EPO administration are associated with FGF23 levels. Genetic manipulation of FGF23 has been shown to regulate erythropoiesis through EPO, indicating that regulation of EPO and FGF23 is complex. Our results show that genetic variants near *EPO* regulate iFGF23, raising the possibility that iFGF23 is genetically controlled by EPO. In contrast, the cFGF23 levels were not associated with the locus near *EPO* possibly due interindividual variation in FGF23 cleavage.

Conclusions: Our results improve the understanding of the complex regulation between FGF23 and EPO. Our results provide evidence that complex and distinct genetic factors are involved in the regulation iFGF23 and cFGF23 that may help identify populations with different FGF23 levels at similar GFR, and indicate that natural genetic variation near *EPO* is involved in the regulation of FGF23.

Effects of Induced Whole-Body Hypoxia on FGF23 in Obese Men

Bhupesh Panwar,[1] Courtney M. Peterson,[2] Eric Ravussin,[3] Orlando M. Gutierrez.[1]
[1]The University of Alabama at Birmingham, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Pennington Biomedical Research Center, Louisiana State University, Baton Rouge, LA.

Background: Higher fibroblast growth factor 23 (FGF23) is associated with higher risk of heart disease and mortality in patients with chronic kidney disease (CKD). Recent evidence shows that Hypoxia Inducible Factor 1α (HIF-1α) is a direct transcriptional activator of FGF23. No study has directly tested the effect of induced hypoxia on FGF23 levels.

Methods: In a single-arm study design, 8 healthy obese men (BMI: 32.7 ± 3.7 kg/m^2; age: 28 ± 3 years) were exposed to 10 consecutive nights of moderate hypoxia (15 ± 0.5% O_2, simulating oxygen tension at 2400 m elevation) using hypoxic tents. Blood specimens and skeletal muscle and adipose biopsies were taken at baseline and after 10 days of hypoxic exposure. The primary outcomes were change in plasma intact FGF23 (iFGF23), c-terminal FGF23 (cFGF23) and FGF23 ratio (cFGF23:iFGF23). Paired t-test analysis was used to examine changes in log transformed values for iFGF23, cFGF23 and the FGF23 ratio. We also examined associations of muscle and adipose HIF-1α expression with FGF23.

Results: There were no statistically significant changes in either cFGF23 or iFGF23 after induced hypoxia. There was a statistically significant increase in the FGF23 ratio (1.05±0.11 to 1.08±0.11) post exposure to hypoxia (p=0.02)**(Table).** HIF-1α expression in muscle was significantly associated with iFGF23 (r=0.86,*p*<0.05) but not cFGF23 (r=0.11,*P*=0.45).

Conclusions: Exposure to hypoxia significantly increased the FGF23 ratio in obese men. In addition, muscle expression of HIF-1α was associated with iFGF23 plasma levels, suggesting that hypoxia influences FGF23 transcription and cleavage in humans.

Geometric mean Change (95%CI) in plasma FGF23 and arithmetic mean change (±SD) in FGF23 ratio with exposure to hypoxia.

	Baseline	Post-Exposure	p-value
cFGF23	71.1 (26.4,190.9)	75.3 (27.1,209.2)	0.48
iFGF23	58.9 (18.5,188.3)	55.2 (16.0,189.8)	0.38
FGF23 Ratio	1.05 ± 0.11	1.08 ± 0.11	0.02

TH-PO190

FGF23, Erythropoietin, and Erythroferrone Levels in Autosomal Dominant Polycystic Kidney Disease Patients

Mark R. Hanudel,[1] Isidro B. Salusky,[1] Renata C. Pereira,[1] Wei Wang,[2] Zhiying You,[2] Berenice Y. Gitomer,[2] Kristen L. Nowak,[2] Michel Chonchol.[2]
[1]UCLA, Los Angeles, CA; [2]University of Colorado Anschutz Medical Campus, Aurora, CO.

Background: Circulating FGF23 levels are higher in patients with autosomal dominant polycystic kidney disease (ADPKD) compared to patients with similar kidney function and other causes of CKD. Although bone is the major source of FGF23, erythropoietic bone marrow cells may also express FGF23 in response to erythropoietin (EPO), levels of which increase in ADPKD. We tested whether serum EPO levels in ADPKD patients are associated with circulating and bone FGF23. We also assessed serum levels of the EPO-responsive hormone erythroferrone (ERFE).

Methods: 20 adult subjects with ADPKD and normal kidney function (mean ± SD eGFR 97 ± 29 ml/min/1.73m^2) and 9 healthy controls participated in the study. We measured circulating C-terminal (total) FGF23 (cFGF23), intact FGF23 (iFGF23), EPO, ERFE, phosphate, calcium, PTH, 25D, 1,25D, iron, ferritin, hepcidin, and hemoglobin. Quantitative bone FGF23 levels were determined by immunohistochemical staining from bone biopsies.

Results: Circulating total FGF23 was higher in ADPKD subjects than in controls (geometric mean (95% CI) 109 (78, 153) vs. 73 (56, 95) RU/ml, p=0.050). Intact FGF23 tended to be higher (67 (57, 80) vs. 51 (39, 67) pg/ml, p=0.073). Quantitative bone FGF23 levels did not differ between the groups. Serum EPO levels were higher in ADPKD subjects (11.1 ± 6.7 vs. 6.1 ± 3.8 mIU/ml, p=0.019). Consistent with increased EPO, serum ERFE levels were also increased (17.6 ± 7.4 vs. 7.6 ± 6.2 ng/ml, p=0.001). The ADPKD subjects had higher phosphate (4.0 ± 0.5 vs. 3.6 ± 0.4 mg/dl, p=0.036) and lower 1,25D (44 (39, 49) vs. 61 (45, 82) pg/ml, p=0.039). Serum calcium, PTH, 25D, iron, ferritin, hepcidin, and hemoglobin did not differ between the groups. In the ADPKD subjects, EPO correlated with Log cFGF23 (r=0.55, p=0.021), and tended to correlate with Log iFGF23 (r=0.42, p=0.069), but not bone FGF23. After adjusting for phosphate, EPO remained associated with Log cFGF23 (β=0.58, p=0.011) and Log iFGF23 (β=0.44, p=0.053).

Conclusions: ADPKD patients with normal kidney function have increased EPO levels, which are associated with increased ERFE, and may contribute to increased circulating FGF23. EPO-induced marrow FGF23 expression has been demonstrated in rodents, and may explain the observation that EPO is associated with circulating FGF23 but not bone FGF23.

Associations of Food Environment with Bone Mineral Disorders in the Chronic Renal Insufficiency Cohort (CRIC) Study

Jessica M. Madrigal,[1] Esteban A. Cedillo-Couvert,[2] Ana C. Ricardo,[1] Lawrence J. Appel,[5] Cheryl A. Anderson,[6] Rajat Deo,[3] L. Lee Hamm,[7] Daohang Sha,[3] Jesse Y. Hsu,[3] Shannon Zenk,[1] Milda R. Saunders,[4] Victoria Persky,[1] James P. Lash.[1] CRIC Investigators
[1]University of Illinois at Chicago, Chicago, IL; [2]South Texas Renal Care Group, San Antonio, IL; [3]University of Pennsylvania, Philadelphia, PA; [4]University of Chicago, Chicago, IL; [5]Johns Hopkins Medical Institutions, Baltimore, MD; [6]University of California San Diego, La Jolla, CA; [7]Tulane University School of Medicine, New Orleans, LA.

Background: Access to fast food outlets may influence eating behaviors and contribute to disordered mineral metabolism through increased consumption of phosphates. The influence of food outlet density on mineral disorders has not been studied in chronic kidney disease (CKD).

Methods: Baseline cross-sectional analysis of the association between food outlet density (within 1 km of census block group) and phosphate ≥5.3 mg/dL, fibroblast growth factor 23 (FGF23) ≥100 RU/mL, and parathyroid hormone (PTH) ≥100 pg/mL using multivariable logistic regression. Data on food outlets included a count of fast food restaurants (unhealthy), convenience stores (unhealthy), and grocery stores (healthy). A food outlet index was categorized as *no food outlets*; *only unhealthy outlets*; *few healthy food outlets* (a ratio of healthy to unhealthy ≤0.2); or *mostly healthy (*a ratio of >0.2).

Results: The study included 2,484 participants with CKD (mean age 58 years, 46% female, 42% white, 39% black, and mean eGFR 44 ml/min/1.73 m^2). A total of 455 (18%) participants had no food outlets within 1 km, 973 (39%) had only unhealthy food, 716 (29%) had few healthy food outlets, and 340 (14%) had mostly healthy outlets. Hyperphosphatemia was rare (n=50, 2%); 73% and 41% of participants had excess FGF23 and PTH, respectively. The table summarizes analyses. Compared to persons living in an area with only unhealthy food, increased availability of healthy food outlets was significantly associated with increased odds of hyperphosphatemia [OR=2.3 (1.1, 4.9)].

Conclusions: Our results highlight the possibility that changes to the food environment at the neighborhood level may impact important health indicators in CKD. Increased food availability may influence behaviors, and access to healthy food may not prevent unhealthy choices.

Effect of Ferric Citrate Hydrate on FGF23 and Serum α-Klotho in Hemodialysis Patients with Hyperphosphatemia and Controlled Serum Phosphate Levels: ASTRIO Study, Supplementary Analysis

Keitaro Yokoyama,[1] Masafumi Fukagawa,[2] Masaaki Nakayama,[3] Ito Kyoko,[4] Koji Hanaki,[5] Hideki Hirakata.[6]
[1]Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; [2]Tokai University School of Medicine, Isehara, Japan; [3]St Luke's International Hospital, Tokyo, Japan; [4]Torii Pharmaceutical Co., Ltd, Tokyo, Japan; [5]Japan Tobacco Inc., Tokyo, Japan; [6]Fukuoka Renal Clinic, Fukuoka City, Japan.

Background: Elevated serum Fibroblast Growth Factor (FGF) 23 level is an independent risk factor for the progression to ESRD, and high FGF23 levels are reportedly associated with cardiovascular events. There is growing interest in α-klotho, a co-receptor for FGF23, as a biomarker of kidney function, because low α-klotho levels have been associated with adverse kidney disease outcome. However, the effect of phosphate binders (PBs) on α-klotho has not been extensively evaluated.

Methods: ASTRIO was a prospective, randomized, multicenter, 24-week study. 93 HD patients who had been taking non-iron based PBs were randomized to Ferric Citrate

Hydrate (FC) group (n=45) or Control group (n=48). In Control, patients maintained treatment with their existing PBs. Serum P and Hb were controlled within 3.5 to 6.0 mg/dL and 10.0 to 12.0 g/dL, respectively. The primary endpoint was change in ESA dose; we also evaluated serum FGF23 and α-klotho.

Results: Serum P was maintained in both groups. C-terminal FGF23 (cFGF23) significantly decreased in FC compared to Control (p=0.04). There were no statistical differences in the changes in intact FGF23 (iFGF23) and α-klotho between groups. Serum ferritin and TSAT were significantly increased in FC compared to Control.

Conclusions: In this study, while there was no difference in the change of serum P between the groups, cFGF23 significantly decreased in FC compared to Control, but did not change iFGF23 and α-klotho.

Parameter	FC (N=40) Mean (SD) Change (from baseline to EOT**)	Control (N=42) Mean (SD) Change (from baseline to EOT**)	Adjusted Mean Difference (FC minus Control)	p-value

Soluble Klotho Is Associated with Cardiovascular Disease Events in Patients with Hemodialysis: Prospective Cohort Study

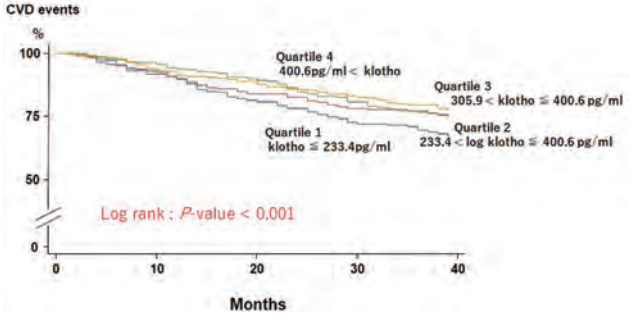
Akio Nakashima, Ichiro Ohkido, Keitaro Yokoyama, Takashi Yokoo. *Division of Nephrology and Hypertension, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan.*

Background: Patients with hemodialysis are higher mortality and their main cause of death is CVD events. Mineral bone disorder recently has been regarded as the important risk factors of CVD events. Klotho, which is known as an antiaging gene, serves as the cofactor for fibro blast growth factor 23 (FGF23) and regulate phosphorus and vitamin D metabolism. We aimed to evaluate whether serum soluble klotho levels are associated with CVD events in hemodialysis patients.

Methods: This prospective cohort study analyzed 1029 hemodialysis patients. We divided the study population into four groups based on serum Klotho levels. In this study, we defined the primary outcome was cardiovascular events, defined as a composite of death due to cardiac disease, sudden death, ischemic heart disease, heart failure requiring hospitalization and cerebral vascular events including cerebral hemorrhage and cerebral infarction. Association between Klotho levels and CVD events were analyzed using Cox proportional hazard model.

Results: The median soluble Klotho level was 305.9 (233.4-400.6) pg/ml. Their mean age (±standard deviation) was 63.1 (±11.9) years and median dialysis vintage was 109 (38-153) months. During follow up, 394 CVD events occurred. CVD events were more frequent in the lowest than highest soluble Klotho quartile [hazard ratio, 1.50; 95% confidence interval, 1.04-2.18; *P*-value, 0.032]. These associations were confirmed in patients with higher age (>65 years), higher phosphate levels (> 6.0mg/dl), or cinacalcet.

Conclusions: In this study, we found that soluble klotho is associated with CVD events in hemodialysis patients.



TH-PO194

Association of Serum Mineral Parameters with Mortality in Hemodialysis Patients: Data Analysis from Korean ESRD Registry

Yunmi Kim,[1] Kyung Don Yoo,[1] Hyo Jin Kim,[2] Junga Koh,[5] Yeonsil Yu,[3] Yeong Hoon Kim,[6] Kook-Hwan Oh.[4] *[1]Dongguk University Gyeongju Hospital, Gyeongsangbuk-do, Republic of Korea; [2]Dongguk University College of Medicine, Gyeongju-si, GyeongSangBuk-do, Republic of Korea; [3]JHospital, Seongnam-si, Republic of Korea; [4]Seoul National University Hospital, Seoul, Republic of Korea; [5]Gangneung Dongin Hospital, Gangneung-si, Gangwon-do, Republic of Korea; [6]Inje University Medical School, Busan, Republic of Korea.*

Background: We investigated the association between mineral metabolism parameters and mortality in Korean hemodialysis patients to identify optimal targets in Korean population.

Methods: Among hemodialysis patients registered in the End-stage renal disease Registry of the Korean Society of Nephrology between March 2012 and June 2017, those with serum calcium, phosphorus, and intact parathyroid hormone (iPTH) measured at enrollment were included. Analysis for the association of serum levels of calcium, phosphorus, and iPTH with all-cause mortality was conducted.

Results: Among the total 21,433 enrolled patients, 3,135 (14.6%) patients died during 24.8 ± 14.5 months follow-up period. After multivariable adjustment, patients in the 1st quintile of corrected calcium was associated with lower mortality (HR, 0.84; 95% CI, 0.71-0.99; *P*=0.003), while those in the 5th quintile of corrected calcium was associated with higher mortality (HR, 1.39; 95% CI, 1.20-1.61; *P*<0.001) compared with those in the 3rd quintile. For phosphorus, only the lowest quintile was significantly associated with increased mortality (HR, 1.24; 95% CI, 1.08-1.43; *P*=0.003). The lowest (HR, 1.18; 95% CI, 1.02-1.36; *P*=0.026) and the highest quintile of iPTH (HR, 1.24; 95% CI, 1.05-1.46; *P*=0.013) were associated with increased mortality. Regarding target counts achieved according to the KDOQI guideline, patients who achieved none of the mineral parameter targets had higher mortality than those who achieved all of the 3 targets (HR, 1.37; 95% CI, 1.12-1.67; *P*=0.003).

Conclusions: In Korean hemodialysis patients, high serum calcium, low phosphorus, as well as high and low iPTH levels were associated with increased all-cause mortality.

TH-PO195

Changes in Serum Phosphorus (sP) Among Patients with Hyperphosphatemia (sP >5.5 mg/dL) Switched to Sucroferric Oxyhydroxide for Two Years

Stuart M. Sprague,[1] Vidhya Parameswaran,[2] Linda Ficociello,[2] Claudy Mullon,[2] Robert J. Kossmann.[2] *[1]NorthShore University HealthSystem University of Chicago Pritzker School of Medicine, Chicago, IL; [2]Fresenius Medical Care Renal Therapies Group, Waltham, MA.*

Background: Hemodialysis (HD) patients are advised to keep sP levels ≤ 5.5 mg/dl through diet modification and use of phosphate binders (PB). Sucroferric oxyhydroxide (SO) has been prescribed to hemodialysis patients for the control of sP as part of routine clinical care. This database analysis retrospectively analyzed sP and PB pill burden in patients who had a mean sP level > 5.5 mg/dl at baseline and were prescribed SO for up to two years.

Methods: The analysis included adult HD patients with sP > 5.5 mg/dl at baseline (3-month, -Q1) who were switched to SO as part of routine care for up to two years (Q1-Q8). Patients were stratified into 3 groups based on baseline sP: Group 1: sP 5.6-7 mg/dl, Group 2: sP 7.1-8.5 mg/dl, and Group 3: sP >8.5 mg/dl. Mixed effects linear regression was used for significance testing.

Results: There were 2067, 1381, and 479 patients in Groups 1, 2, and 3, respectively. 84% had recorded PB prescriptions at baseline with the majority prescribed sevelamer. Table 1 shows the percent of patients who achieved sP ≤5.5 mg/dl and mean sP levels by group. In Groups 1 and 2, 42% and 22% of patients had sP ≤5.5 mg/dl after 2 years of follow-up. In the group with the highest baseline sP level, Group 3, sP ≤ 5.5 mg/d was achieved in 8.3% of patients, and the mean sP for this group decreased from 9.36 mg/dl to 7.62 at Q8, a 19% reduction in sP (-1.74 mg/dl). On average, the PB pill burden was reduced in groups 1, 2, and 3 from 8.7, 9.7, and 9.9 PB pills/day at baseline to 4.9, 5.3 and 5.4 SO pills/day at Q8, respectively.

Conclusions: Patients with elevated sP levels at baseline switched to sucroferric oxyhydroxide for up to two years as part of routine care, experienced significant reductions in sP along with a >40% reduction in PB pills/day and increase in patients with sP ≤5.5 mg/dl.

TH-PO196

Serum Phosphorus (sP) Lowering Effect of Sucroferric Oxyhydroxide (SO) in Phosphate-Binder (PB) Naïve Hemodialysis Patients (pts) over 12 Months

Kamyar Kalantar-Zadeh,[1] Linda Ficociello,[2] Vidhya Parameswaran,[2] Claudy Mullon,[2] Robert J. Kossmann,[2] Stuart M. Sprague.[3] *[1]University of California Irvine, School of Medicine, Orange, CA; [2]Fresenius Medical Care Renal Therapies Group, Waltham, MA; [3]NorthShore University HealthSystem University of Chicago Pritzker School of Medicine, Chicago, IL.*

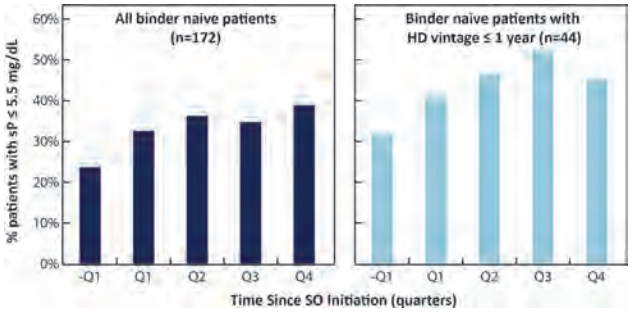
Background: Achieving recommended levels of sP ≤5.5 mg/dL by restricting dietary phosphate alone can be a major challenge and may compromise nutritional status leading to poor outcomes in hemodialysis (HD) pts. Whereas most HD pts are prescribed PB therapy to control sP, the efficacy and bill burden vary substantially across agents. We hypothesize that SO can effectively control sP with a low PB pill burden in pts naïve to PB.

Methods: Data, rendered de-identified, were extracted for all adult, HD pts with their first SO prescription between 3/1/2014-3/1/2015 and SO prescription for 12 months. 172 adult HD pts with SO prescribed as a first-line PB were identified. A subset of 44 pts prescribed SO as late as one year after dialysis start were also analyzed. Baseline (BL) was defined as the 3 months before SO (-Q1) and SO follow-up was divided into quarters (Q1-Q4).

Results: Pts were 54 (±14) years old with a dialysis vintage of 49 (±52) months. Comparing BL vs SO follow-up (Q1-Q4) among all 172 pts, there were consistent improvements in pts achieving target sP ≤5.5 mg/dL (increased from 23.7% at BL to 32.6%-38.8% during SO treatment, p<0.0001) [Figure]. Pts were prescribed between 4.0–4.1 SO pills/day. For the subset of 44 pts prescribed SO during the first year of dialysis, 31.8% of pts had sP ≤5.5 mg/dl at BL and during SO follow-up, 40.9%-52.4% of pts had a sP ≤5.5 mg/dl, a 29%-65% increase from baseline. Mean PB pills/day for this subset ranged from 3.7 to 3.9 pills/day during Q1-Q4.

Conclusions: SO was effective in achieving sP ≤5.5 mg/dL as a first line PB with a low pill burden (4.0–4.1 pills/day) in HD pts. This was confirmed in a subset of pts who began HD as late as one year of starting SO.

Funding: Commercial Support - Fresenius Medical Care Renal Therapies Group



TH-PO197

Serum Phosphorus and Phosphate Binder (PB) Pills/Day Among Hemodialysis Patients Prescribed Sucroferric Oxyhydroxide (SO) for a Year Compared to Patients Who Discontinue SO and Are Prescribed Other PB

Daniel W. Coyne,[1] Linda Ficociello,[2] Vidhya Parameswaran,[2] Claudy Mullon,[2] Robert J. Kossmann.[2] *[1]Washington University School of Medicine, St. Louis, MO; [2]Fresenius Medical Care Renal Therapies Group, Waltham, MA.*

Background: The high pill burden of most PBs has been associated with hemodialysis (HD) patients' lack of adherence to prescribed therapy. SO is an iron-based PB indicated for the control of serum phosphorus (sP) in patients with chronic kidney disease on dialysis with a starting dose of 3 pills/day. This retrospective database analysis compared sP levels and PB pills/day for patients who continued use of SO and patients who discontinued SO.

Methods: Analysis included adult, HD patients prescribed PB for 12 months as part of routine care with sP measurements recorded during the quarter (Q) before and 4 Q after switch to SO. Continued use of SO was defined as SO monotherapy for 12 months (cSO-Pt). Discontinuing SO (dSO-Pt) was defined as discontinuation of SO within 90 days of initiation followed by a switch to other PB(s). Pre-SO baseline was 6 months (-Q2 and -Q1) and follow-up was 12 months (Q1 to Q4). Statistical analysis was conducted using chi-square test.

Results: 653 cSO-Pt and 2294 dSO-Pt were analyzed. 74% of dSO-Pt had a switch to sevelamer after discontinuing SO. Up to 38.4% of cSO-Pt achieved sP ≤5.5 mg/dL compared to up to 34.4% for dSO-Pt [Figure]. During a 12-month follow-up, crude mean sP was 6.19 mg/dL for cSO-Pt and 6.37 mg/dL for dSO-Pt (p<0.0001). After controlling for age, gender, baseline sP, and baseline serum albumin, the follow-up mean sP was 6.22 mg/dL for cSO-Pt and 6.39 mg/dL for dSO-Pt, p<0.0001. The mean PB pill/day was 4.8 for cSO-Pt and 9.2 for dSO-Pt.

Conclusions: During a 12-month follow-up, SO patients had a lower mean sP, were more likely to achieve in-sP ≤5.5 mg/dl, and were prescribed 50% fewer pills/day than patients who discontinued SO and were prescribed other PB(s).

Hepcidin, Iron Indices, and Bone Mineral Metabolism in Non-Dialysis CKD

Sung Woo Lee,[1] Su Ah Sung.[2] *[1]Eulji General Hospital, Seoul, Republic of Korea; [2]Eulji Medical Center, Seoul, Republic of Korea.*

Background: There have been some small studies which have reported that intravenous iron replacement was associated with levels of bone mineral metabolism markers. Disordered bone mineral metabolisms are also well-known risk factors of erythropoietin (EPO) resistance. Hepcidin is a key peptide for the EPO resistance and iron metbolism. Although the intimate association between hepcidin, iron indices, and bone mineral metabolism was expected, particularly in non-dialysis chronic kidney disease (CKD) patients, it has been studied sparsely. Therefore, we performed this study.

Methods: We reviewed data of 2,238 patients from a large-scale multicenter prospective Korean study (2,011–2,016), and excluded 214 patients with missing data on markers and related-medications of iron and bone mineral metabolism, hemoglobin, blood pressure and causes of CKD. Multivariate linear regression analysis was used to identify the association between iron and bone mineral metabolism.

Results: The proportion of CKD stage 1-5 were 16.2%, 18.7%, 37.1%, 21.6%, and 6.4%, respectively. Per each 10% increase in transferrin saturation (TSAT), there was a 0.013 mmol/l decrease in phosphorus [95% confidence interval (CI) -0.021—0.004; *P* = 0.003] and a 0.022 nmol/l increase in logarithmic 25-hydroxyvitamin D (Ln-25OHD) levels (95% CI 0.005–0.040; *P* = 0.019). A 1 pmol/l increase in Ln-ferritin was associated with a 0.080 ng/l decrease in Ln-intact parathyroid hormone (Ln-iPTH) (95% CI -0.122—0.039; *P* <0.001). Meanwhile, beta (95% CI) per 1 unit increase in phosphorus, Ln-25OHD, and Ln-iPTH for the square root of the serum hepcidin were 0.594 (0.257–0.932; *P*= 0.001), -0.270 (-0.431—0.108; *P* = 0.001), and 0.115 (0.004–0.226; *P* = 0.042), respectively. In subgroup analysis, the relationship between phosphorus, 25OHD, and hepcidin was strongest in the positive-inflammation group.

Conclusions: Increased TSAT was associated with decreased and increased phosphorus and 25OHD levels, respectively, while increased ferritin was associated with decreased iPTH levels. Increased phosphorus and iPTH and decreased 25OHD were independently associated with increased hepcidin levels.

TH-PO199

Effects of Patiromer on Markers of Mineral Metabolism in Patients with Hyperkalemia and Hyperphosphatemia

David A. Bushinsky,[1] David M. Spiegel,[2] Jinwei Yuan,[2] Suzette Warren,[2] Jeanene Fogli,[2] Pablo E. Pergola.[3] *[1]University of Rochester Medical Center, Rochester, NY; [2]Relypsa, Inc., a Vifor Pharma Group Company, Redwood City, CA; [3]Renal Associates, PA, San Antonio, TX.*

Background: Patiromer (PAT) is a once-daily K binder for hyperkalemia (HK) treatment; Ca is the counterexchange ion. In TOURMALINE (NCT02694744) patients (pts) with serum K >5.0 mEq/L were randomized to PAT 8.4 g QD without/with food for 4 wks, with doses adjusted to achieve/maintain serum K 3.8-5.0 mEq/L (target range). The primary endpoint (% of pts in target range at wk 3/4) was met in 83% dosed without food and 87% with food, with overlapping 95% CIs. We report the effects of PAT on markers of mineral metabolism in the pts with baseline (BL) hyperphosphatemia (HyperP, serum phosphate >4.8 mg/dL).

Methods: BL and wk 4 serum and 24-hr urine phosphate and Ca, and other markers, are reported for all HyperP pts combined (without/with food). Time-corrected 24-hr urine phosphate/Ca values were normalized to each pt's mean of the time-corrected urine creatinine (Cr) level.

Results: 16 pts had HyperP; 11 dosed without and 5 with food. All had CKD (median [Q1, Q3] eGFR 18.0 [11.5, 20.5] mL/min/1.73m^2) and hypertension; 14/16 had diabetes. Two pts were on stable doses of sevelamer during the study. The primary endpoint was met in 14/16 pts (10/11 without and 4/5 with food in target range). There were significant reductions in serum and 24-hr urine phosphate (Table). Mean serum Mg decreased significantly. Mean serum Ca and 24-hr urine Ca were not different from BL at wk 4. Serum PTH levels decreased at wk 4 (P=0.19). Overall, 15/16 had ≥1 post-BL serum phosphate assessment; 9/15 had serum phosphate in the normal range by wk 4.

Conclusions: The decrease in serum and urine phosphate in the small number of HyperP pts in this study supports that intestinal phosphate is bound to some of the released Ca when PAT is used to lower serum K. These findings suggest that PAT may aid in the management of HyperP in pts with CKD requiring both K and phosphate binders.

Effects of Lanthanum Carbonate on Mineral Metabolism in Normophosphatemic Patients with CKD: Secondary Analysis of the COMBINE Trial

Tamara Isakova,[1] Brett Larive,[8] Jennifer J. Gassman,[8] Kalani L. Raphael,[4] Alfred K. Cheung,[5] Dominic S. Raj,[6] Linda F. Fried,[7] John P. Middleton,[3] Kevin C. Abbott,[11] Susan R. Mendley,[12] Geoffrey A. Block,[10] Joachim H. Ix,[2] Myles Wolf,[3] Stuart M. Sprague.[9] CKD Optimal Management with Binders and NicotinamidE (COMBINE) Investigators *[1]Feinberg School of Medicine, Northwestern University, Chicago, IL; [2]UCSD, San Diego, CA; [3]Duke University, Durham, NC; [4]VA Salt Lake City Health Care System, Salt Lake City, UT; [5]University of Utah, Salt Lake City, UT; [6]GWU Medical Faculty Associates, Washington, DC; [7]VA Pittsburgh Healthcare System, Pittsburgh, PA; [8]Cleveland Clinic, Cleveland, OH; [9]NorthShore University HealthSystem University of Chicago Pritzker School of Medicine, Chicago, IL; [10]Colorado Kidney Care, Denver, CO; [11]The National Institutes of Health, NIDDK, Bethesda, MD; [12]NIDDK/NIH, Bethesda, MD.*

Background: Disordered mineral metabolism is a nearly universal complication of reduced kidney function that develops early in the course of CKD and is associated with adverse clinical outcomes. Strategies aimed at reducing dietary phosphate absorption may prevent abnormalities in markers of mineral metabolism, but data from large and long-term interventional studies are lacking.

Methods: The COMBINE trial was a randomized, double-blinded, 12-month, 4-group parallel trial of nicotinamide and lanthanum carbonate vs. placebo in 205 CKD stage 3–4 patients that tested the effects of active therapies on serum phosphate and FGF23 levels and on safety and tolerability. The primary results demonstrated that compared to placebo (n=51), lanthanum carbonate (n=50), nicotinamide (n=51) or dual treatment (n=53) did not significantly lower serum phosphate or FGF23. To determine the efficacy of each individual therapy, we performed secondary analyses to test the main effects of lanthanum carbonate (treated, n=103 vs. untreated, n=102) and nicotinamide (treated, n=104 vs. untreated, n=101).

Results: At baseline, mean eGFR was 33±7 ml/min/1.73m^2, serum phosphate was 3.7±0.5 mg/dL, FGF23 was 103.6 [IQR 76.8, 145.1] pg/ml, and PTH was 96 ± 64 pg/ml. Baseline characteristics were well-balanced across comparison groups. In intention to treat analyses, the overall 12-month effect of lanthanum carbonate treatment on serum phosphate was -0.051 mg/dL (95% CI= -0.191 to 0.089, P=0.48); FGF23 was -14.0% (95% CI= -24.2 to -3.7, P=0.0077); PTH was -6.7% pg/mL (95% CI= -20.1 to 6.9, P=0.33); FEPI was -3.56 (95% CI= -5.76 to -1.36, P=0.0016); and 24 hr urine phosphate/creatinine was -0.042 mg/dL (95% CI= -0.081 to -0.003, P=0.033). No significant effects were observed with nicotinamide treatment.

Conclusions: In a secondary analysis of the COMBINE trial, we demonstrated that lanthanum carbonate treatment decreased urinary phosphate excretion and reduced FGF23 levels. Our findings provide support for targeting dietary phosphate absorption to modify FGF23 levels in patients with CKD stages 3-4.

Effectiveness of Sucroferric Oxyhydroxide in Phosphate Binder-Naïve and -Experienced Patients: A Real-World Retrospective Database Analysis

Charles Chazot,[4] Rosa Ramos,[5] Attilio Di Benedetto,[6] Manuel A. Ferreira,[3] Birgit Kagermeier,[2] Hans-Juergen Arens,[7] Sebastian Walpen,[1] Viatcheslav Rakov,[1] Stefano Stuard.[2] *[1]Vifor Fresenius Medical Care Renal Pharma, Glattbrugg, Switzerland; [2]Clinical & Therapeutical Governance, Fresenius Medical Care, Bad Homburg, Germany; [3]Nova Medical School, Lisbon, Portugal; [4]NephroCare France, Fresnes, France; [5]Nephrology, NephroCare Spain, Madrid, Spain; [6]Medical Direction, NephroCare Italy, Naples, Italy; [7]Contract Clinical Services, Fresenius Medical Care, Bad Homburg, Germany.*

Background: Retrospective analysis of a clinical database (EuCliD5) assessed the real-world effectiveness of an iron-based phosphate binder (PB), sucroferric oxyhydroxide (SFOH), to control serum phosphorus (sP) levels in hemodialysis (HD) patients (pts) in European countries.

Methods: De-identified data were extracted from electronic records for adult HD pts in 4 countries (France, Italy, Spain, Portugal) who were newly prescribed SFOH as part of routine care between Jan 2016 and Oct 2017. Baseline (BL) was defined as the 3-month period prior to SFOH prescription. Mean PB pill burden and sP levels were analyzed for Months 1–3 (Q1) and Months 4–6 (Q2) of SFOH treatment using mean values from the BL period as the reference. Effectiveness of SFOH for control of sP levels was evaluated for pts who had not received PB therapy during BL (PB-naïve) and those who had (PB-experienced).

Results: 1347 pts were included (mean age: 61.6 years; 63.5% male), of whom 605 pts were PB-experienced and 742 were PB-naïve. Characteristics of pts in these subgroups were generally comparable; median dialysis vintage was longer in PB-experienced vs. -naïve pts (50 vs. 34 months). The % of pts with sP control (≤5.5 mg/dL) during BL was lower in the PB-experienced (31.6%) vs. the PB-naïve (44.9%) subgroup (**Figure**). In both subgroups, the % pts achieving sP ≤5.5 mg/dL increased significantly from BL through Q1 and Q2. For PB-experienced pts, these sP improvements were achieved with a reduction in PB pill burden.

Conclusions: In routine practice, SFOH therapy improved sP control in both PB-naïve and PB-experienced HD pts, with a relatively low daily pill burden.

Association Between Serum Phosphorus level and Decline of Glomerular Filtration Rate in Heathy Individuals

Mengjing Wang,[1] Li Ni,[2] Minmin Zhang,[3] Jiaying Zhang,[4] Guoxin Ye,[5] Weichen Zhang,[6] Weisheng Chen,[6] Xiaofeng Wang,[4] Jing Chen.[7] *[1]Huashan hospital, Fudan University, Shanghai, China; [2]huashan hospital,Fudan University, Shanghai, China; [3]Huashan Hospital, Fudan Univerisy, Shanghai, China; [4]Fudan University, Shanghai, China; [5]Division of Nephrology, Huashan Hospital, Shanghai Medical College, Fudan University, Shanghai, China; [6]Huashan Hospital, Shanghai, China; [7]Huashan Hospital,Fudan University, Shanghai, China.*

Background: High serum phosphorus levels are strongly and independently associated with a more rapid decline of renal function in patients with advanced chronic kidney disease (CKD). We hypothesized that phosphorus was also associated with decline of Glomerular Filtration Rate (GFR) in heathy individuals.

Methods: We identified 1,340 healthy individuals with measured serum creatinine from the Rugao aging cohort over the period of Nov 2014 (baseline) to Nov 2017 (2nd follow-up). The association of phosphorus at the 2nd follow-up (Nov 2017), which was not measured at the baseline, with decrease of GFR between baseline and 2nd follow-up was examined using logistic models with adjustment for baseline demographics characteristics and laboratory variables.

Results: The mean age (mean±SD) of the cohort was 75±4 years old and included 55% females, 7% diabetics, and 44% hypertension. Mean GFR estimated by CKD-EPI equation at baseline and the 2nd follow-up was 88.0 (±10) and 85.9 (±12) ml/min/1.73m^2, respectively, with an average of 2 ml/min/1.73m^2 decrease across the 3 years. Mean serum phosphorus level was 1.17(±0.16) mmol/l. Serum phosphorus was not associated with GFR at the baseline (P=0.1) or at the 2nd follow up (P=0.5). However, each 1-mmol/l increase in phosphorus concentrations was associated with approximately 3-fold increased risk for rapid GFR decline (defined as at least 4.5ml/min/1.73m^2 decrease during the 3 years) after adjusted for age, gender, smoking, hypertension, cardiovascular disease, BMI, Low-density lipoprotein, triglyceride, albumin, and baseline GFR (OR 3.1, 95%CI 1.3-7.2, P = 0.01).

Conclusions: Higher phosphorus levels are associated with GFR decline in heathy individuals. Further studies are needed to validate this finding.

TH-PO203

Using Machine Learning to Help Predict Elevated Serum Phosphate Levels in Patients with ESRD

Andrew Long,[1] Tommy C. Blanchard,[1] Joanna Willetts,[1] Sheetal Chaudhuri,[1] Michael R. O'Connell,[1] Kathleen Belmonte,[2] Marissa A. Lee,[1] Len A. Usvyat,[1] Terry L. Ketchersid,[1] Franklin W. Maddux.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]Fresenius Kidney Care, Waltham, MA.*

Background: According to USRDS, over two-thirds of patients treated with hemodialysis had serum phosphate (PO_4) greater than the KDIGO guidelines of 4.5 mg/dl (USRDS 2017, KDIGO 2009). In practice, most clinicians try to achieve PO_4 levels between 3.0 and 5.5 mg/dl (Handbook on dialysis 2015). Proactively identifying patients who may transition from the normal clinical range to greater than 5.5 mg/dl may help clinicians target their interventions and avoid elevated PO_4 levels.

Methods: We built a machine learning model with over 1000 variables to predict which HD patients will realize a PO_4 lab value greater than 5.5mg/dl during the following month. We restrict our model to patients using a pharmacy specializing in renal medications with all PO_4 draws less than 5.5 mg/dl in the last 180 days. Some of the variables included in this model are history of lab values, treatment vital signs, treatment no shows, comprehensive assessments from dieticians and social workers, and PO_4 binder medication possession ratios. To train the XGBoost machine learning model, we utilized data from patients who were treated in Fresenius Medical Care North America clinics between January 2016 and October 2017. The results shown below are from un-seen test data with 16639 patients in 2017.

Results: For the patients enrolled in the specialty pharmacy who have all PO_4 values less than 5.5 mg/dl in the previous 180 days, the prevalence of having next month's lab draw greater than 5.5 mg/dl is approximately 10%. Results from the test data include area under the receiver operating curve (AUROC) of 0.75, sensitivity of 72% and specificity of 66%. The confusion matrix for test data is shown in Table 1.

Conclusions: We created a predictive model to help identify patients who may unexpectedly have elevated PO_4 lab values in the next month. Identifying these patients may help to target interventions that mitigate negative consequences associated with high PO_4 levels.

Funding: Commercial Support - Fresenius Medical Care North America

Confusion matrix for test data (n = 16639)

		Actual PO4 >5.5 mg/dl	
		Positive	Negative
Prediction for PO4 >5.5 mg/dl	Positive	7.3%	30.6%
	Negative	2.9%	59.1%

TH-PO204

Safety, Efficacy, and Cost-Effectiveness of Mg/Al Type Hydrotalcite Drug versus Conventional Phosphate Binders in Hemodialysis CKD Patients with Hyperphosphatemia

Yingying Chen, Lan Chen, Tianjun Guan, Yisheng Ling. *Department of Nephrology, Zhongshan Hospital, Xiamen University, Xiamen, China.*

Background: Hyperphosphatemia is a risk factor for the increased of mortality rates in chronic kidney disease (CKD) patients and associated to several clinical diseases. In this study, we assess safety, efficacy and clinical cost between Mg/Al hydrtoalcite (Talcid) and conventional non-calcium, non-aluminum phosphate binders (Lanthanum carbonate, LC) for hemodialysis (HD) chronic kidney disease (CKD) patients with hyperphosphatemia.

Methods: In this open-label, randomized, parallel-group study, 64 maintenance hemodialysis patients were matched to our selected procedure. Serum phosphate levels were over 1.78 mmol/L (5.5 mg/dl) and they were randomized to treat Talcid 1000 mg three times/day or LC 500 mg two or three times/day for 6 months. Serum calcium, phosphate, parathyroid hormone (iPTH) and alkaline phosphatase (ALP) levels were examined serially for 6 months.

Results: In hemodialysis patients with hyperphophatemia, both Talcid and LC significantly moderated serum phosphate levels, from 2.323±0.392 to 1.702±0.360 mmol/L(P<0.01) and from 2.379±0.393 to 1.890±0.403 mmol/l (P<0.01), respectively. Serum calcium and intact parathyroid hormone (iPTH) level in the both groups did not significantly change when comparing to baseline parameters during the study. No severely adverse events were reported on both groups. Total cost of 6-month treatment with Talcid was 839.79±96.97 RMB while 6-month treatment with LC was 10292.96±4018.10 RMB (P<0.01).

Conclusions: The efficacy and safety of hydrotalcite are similar to LC but it presents higher reaching-target rate and lower economic burden in hemodialysis CKD patients with hyperphosphatemia. It can be severed as another option for dialysis patients with hyperphosphatemia patients.

Comparisons of the daily average cost and total cost between Talcid group and LC group during 6 months treatment.

6 months	Talcid group	LC group	p-value
Average dose / day(mg)	2687.50±310.34	1191.31±465.06	<.001 **
Total cost(RMB)	839.79±96.97	10292.96±4018.10	<.001 **

Data are presented as mean+SD

TH-PO205

Acute Mineral Metabolism Disorders Following Kidney Donation Are Not Different Compared to Those Observed in Other Surgical Procedures

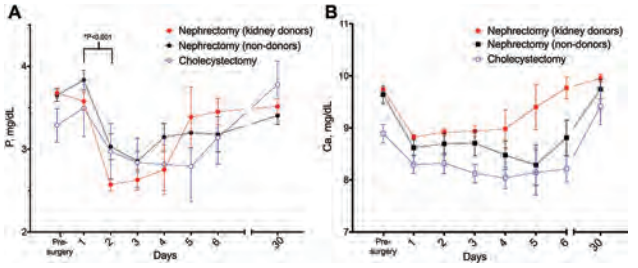
Jorge I. Fonseca-Correa,[1] Luis Tamez Pedroza,[1,3] Lucas Porto-Silva,[1,2] Josefina Alberú,[1] Ricardo Correa-Rotter,[1] Juan Carlos Ramirez-Sandoval.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; [2]Benemérita Universidad Autónoma de Puebla, Ciudad de México, Mexico; [3]Universidad Autonoma de Baja California, Ciudad de M?xico, Mexico.*

Background: Emerging studies have suggested that living kidney donors (LKD) have acute mineral metabolism (MM) abnormalities after unilateral nephrectomy related to loss of eGFR, in particular significant disturbances in P and Ca. Nevertheless, these changes have not been compared to controls undergoing other major surgical procedures. Our aim was to analyze acute MM abnormalities (serum Ca y P levels) in 3 groups: following laparoscopic (LN) vs. open nephrectomy (ON) and elective laparoscopic cholecystectomy (LC).

Methods: Single-center retrospective cohort study (n=293). Biochemical parameters were evaluated before and after surgery on days 1-6 and 30, in 100 consecutive LKD undergoing LN, compared with 91 subjects undergoing ON for kidney cancer or urolithiasis, and 102 subjects with gallstone disease undergoing elective LC. We excluded cases with CKD G4.

Results: LN group was younger compared to ON and LC groups (41±19, 58±14, and 58±19 years; p<0.001), and eGFR was higher in LN compared to ON and LC (101±17, 79±23, and 85±28 mL/min/1.73m^2; p<0.001). As expected, only LN and ON reduced eGFR by day 2: -11.4 (-27 to 6) and -14 (-51 to 3) mL/min/1.73m^2 respectively. Serum P levels did not change significantly from baseline to day 1, but decreased by day 2 in all groups (LN=-1.2 [-1.6 to -0.2], ON=-1.0 [-1.7 to -0.1] and LC=-0.6 [-1.0 to 0.0] mg/dL) before normalizing by day 30 (Figure). Serum P decline was not modified by concurrent changes in eGFR in any group. Moderate hypophosphatemia (reduction to 1-2 mg/dL) was similarly present in all groups (LN 14%, ON 7%, and LC 12%; p=0.16). No hypophosphatemia <1 mg/dL occurred during follow-up. Transient non-corrected hypocalcemia and hypoalbuminemia appeared by day 3 in all groups.

Conclusions: Acute MM disturbances (serum P and Ca) occur after surgical procedures independent of changes in eGFR, and are not related to kidney donation or nephrectomy indicated for other causes. Postoperative slight hypophosphatemia is frequent and appears to be a multifactorial.



TH-PO206

Hyperphosphatemia and Acid-Base Equilibrium Disorders Are Newly Recognized Risk Factors for Mönckeberg's Sclerosis of Vascular Access Artery

Takashi Tani,[1,2] Tomohiro Kaneko,[1] Mariko Ikeda,[1] Hideo Orimo,[2] Akira Shimizu,[3] Shuichi Tsuruoka.[1] *[1]Department of Nephrology, Graduate School of Medicine, Nippon Medical School, Tokyo, Japan; [2]Department of Metabolism and Nutrition, Graduate School of Medicine, Nippon Medical School, Tokyo, Japan; [3]Department of Analytic Human Pathology, Graduate School of Medicine, Nippion Medical School, Tokyo, Japan.*

Background: Medial arterial calcification (MAC), also known as Mönckeberg's sclerosis, in vascular access (VA) artery is reported to be observed with high frequency in end-stage renal disease (ESRD) patients with advanced age and/or diabetic nephropathy. MAC in VA artery is also associated with increased risk of VA failure and cardio-vascular disease (CVD) events. The purpose of this study was to clarify risk factors for MAC formation in VA arteries of patients with ESRD.

Methods: Forty-one patients with ESRD, who underwent VA operation at the initiation of hemodialysis therapy, were enrolled in this study. In addition to clinical information (primary disease, age, gender, blood biochemical and computed tomography (CT) imaging findings etc.), the presence of calcification was examined pathologically by Von Kossa staining of arterial specimens (radical artery).

Results: MAC was observed in 21 patients (51.2%), and their serum phosphorus (Pi) (6.2 *vs* 4.9), Ca x Pi product (53.3 *vs* 42.4), blood urea nitrogen (79.7 *vs* 60.7), urinary osmolality (U-OSM) (333 *vs* 246) levels were significantly higher, while HCO_3^- (20.1 *vs* 23.0), base excess (-5.45 *vs* -2.33) and urinary pH (5.80 *vs* 6.47) levels were significantly lower than the averages of 20 patients without MAC formation (48.8%). Other biochemical parameters (e.g. i-PTH, FGF-23, α-klotho and pyrophosphate) and patients' age, gender and treatment history did not differ between MAC positive and MAC negative patients. The ROC analysis revealed that the area under curve for serum phosphorus and U-OSM were the highest, 0.771 and 0.874, respectively. By Fisher's test, a serum phosphorus level of 4.8 mg/dl or more significantly increased the probability of MAC (66.7% *vs* 17.65%, $p<0.0037$), and its odds ratio was 9.33 times. The U-OSM of 312 mOsm or more significantly increased the incidence of MAC (76.9% *vs* 9.1%, $p<0.0013$) with an odds ratio of 33.3.

Conclusions: It was shown that higher serum phosphorus level and severer renal dysfunction and acid-base equilibrium disorders at the start of hemodialysis were risk factors for MAC in VA artery. Particularly, patients with hyperphosphatemia over 4.8 mg/dl were highly likely to display MAC in VA artery, so that attention should be paid to potential VA failure and CVD events.

TH-PO207

Intestinal Phosphorus Absorption Assessment by Kinetic Modeling of 33P Radiotracer in Hemodialysis Patients

Kathleen M. Hill Gallant,[1,2] Elizabeth Stremke,[1] Laurie Trevino,[4] Sharon M. Moe,[2] Meryl E. Wastney.[3] *[1]Purdue University, West Lafayette, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Metabolic Modeling Services, Blenheim, New Zealand; [4]Indiana University, Indianapolis, IN.*

Background: Intestinal phosphorus (P) absorption is an important component of P homeostasis. In CKD, limiting P absorption is the goal of many pharmacologic therapies. 24-hr urine P has been used as a surrogate for P absorption, but recent balance studies demonstrate that this measure is highly variable and not related to net P absorption (Stremke, CJASN 2018). Further, 24-hr urine P is not useful in oliguric/anuric patients. Changes in serum P are equally problematic due to diurnal variation, fluxes with dialysis, and erratic dietary intake. We tested a ^{33}P absorption method as a sensitive and direct assessment of P absorption in humans that can be used for clinical research in hemodialysis (HD) patients.

Methods: HD patients with stage 5D CKD were enrolled. Following 10 days of controlled study diet (~800 mg/d P), patients underwent HD and then were admitted as inpatients to a clinical research center for 2 days for P absorption testing. ^{33}P radiotracer was administered PO with a meal containing a load of ~300 mg P, and blood sampled over 24-hr. The next day, a second dose of ^{33}P was administered by IV and blood sampled for another 24-hr, followed by a second HD treatment. Serum ^{33}P activity was measured by liquid scintillation, adjusted for decay and expressed as % of dose. The ^{33}P data were analyzed by compartmental modeling using WinSAAM software. Intestinal absorption was calculated as the fraction moving into blood vs. moving down the intestinal tract into stool. Descriptive results from 14 unique subjects are presented.

Results: Serum P increased during the 48-hr of study that was during an interdialytic interval. To estimate how much additional P (i.e., over absorption) was entering the system, a second model was used. Average fractional P absorption was 58±17%. The absorption test was well-tolerated by patients in the study. Complications were limited to difficulties with venous access in some patients.

Conclusions: Fractional P absorption can be estimated directly by a test using oral and IV ^{33}P administration; the test is feasible and well-tolerated in HD patients. This novel methodology can be used for clinical studies aimed at assessing physiology, pathophysiology, or interventions related to P absorption in HD patients.

Phosphate Binders for Preventing and Treating CKD-Mineral and Bone Disorder (CKD-MBD)

Suetonia Palmer,[2] Marinella Ruospo,[1] Patrizia Natale,[1,3] Mariacristina Vecchio,[4] Giovanni F. Strippoli.[3,1] Cochrane Kidney Transplant *[1]Diaverum, Bari, Italy; [2]University of Otago, Christchurch, New Zealand; [3]University of Bari, Bari, Italy; [4]Danone research, Palaiseau Cedex, France.*

Background: Phosphate binders are used to reduce positive phosphate balance for people with CKD to prevent tissue calcification, cardiovascular events and mortality, and bone complications. In this Cochrane review we aimed to update the available evidence for phosphate binders to manage CKD-MBD.

Methods: We searched the Cochrane Kidney and Transplant Specialised Register through 30 November 2017 for all randomized trials (RCTs) of adults with any stage of CKD comparing a phosphate binder with another phosphate binder, placebo or usual care. Key outcomes were cardiovascular events, all-cause and cause-specific mortality, symptomatic bone disease, adverse events, and surrogate measures of vascular calcification. We used random-effects meta-analysis, the Cochrane risk of bias tool, and the GRADE process to adjudicate evidence certainty.

Results: 104 RCTs (13,744 adults) were eligible. Placebo-controlled RCTs were generally in CKD G3-5 not requiring dialysis, while active comparator RCTs involved CKD 5D on dialysis. In CKD 3a to 5, compared with placebo or usual care, sevelamer, lanthanum, iron, and calcium-based phosphate binders had uncertain effects with respect to all-cause and cardiovascular mortality, myocardial infarction, stroke, fracture, or coronary artery calcification. In patients on dialysis, sevelamer may decrease all-cause mortality (RR 0.53, CI 0.30-0.91; low certainty evidence) and induce less hypercalcemia (RR 0.30, CI 0.20-0.43) compared with calcium-based binders, while the evidence indicates that sevelamer had uncertain effects with respect to cardiovascular mortality, myocardial infarction, stroke, or fracture, coronary artery calcification, or fracture. Compared with calcium, lanthanum had uncertain effects with respect to all-cause or cardiovascular mortality, myocardial infarction, stroke, fracture, or coronary artery calcification.

Conclusions: For patients with CKD G3a to 5 not requiring dialysis, there is no evidence that phosphate binders improve clinical vascular and bone outcomes. For dialysis patients, sevelamer lowers all-cause mortality compared to calcium-based binders and incurs less treatment-related hypercalcemia. Data for patient-centered outcomes of lanthanum and iron-based binder treatment and placebo-controlled trials in the dialysis setting are limited.

TH-PO209

Hidden Hypocalcemia at the Initiation of Dialysis as a Risk Factor for Cardiovascular Disease and All-Cause Mortality

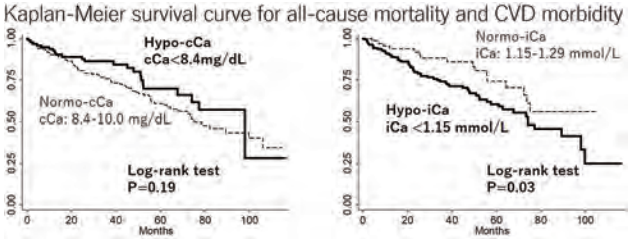
Satoshi Yamaguchi,[1] Takayuki Hamano,[2] Yohei Doi,[1] Keiichi Kubota,[1] Tatsufumi Oka,[1] Yusuke Sakaguchi,[2] Isao Matsui,[1] Yoshitaka Isaka.[1] *[1]Nephrology, Osaka Univ Graduate School of Medicine, Osaka, Japan; [2]Inter-Organ Communication Research in Kidney Disease, Osaka Univ Graduate School of Medicine, Osaka, Japan.*

Background: Lower corrected calcium (cCa) levels were reported to be associated with better prognosis among incident dialysis patients. On the other hand, hypocalcemia (HypoCa) often leads to arrhythmia and heart failure. Prognostic importance of true calcium (Ca) status defined by ionized calcium (iCa) remains to be revealed.

Methods: We performed a retrospective cohort study of incident hemodialysis (HD) patients. We collected the latest data just before the initiation of HD. We divided patients into 3 categories: Apparent HypoCa (low iCa: <1.15 mmol/L and low cCa: <8.4 mg/dL), Hidden HypoCa (low iCa and normal cCa), and Normocalcemia (NormoCa: normal iCa and normal cCa). The primary outcome was the composite outcome of all-cause death and cardiovascular diseases (CVD) after the initiation of HD. Using log-rank tests, Kaplan-Meier curves, and cox proportional hazards models, we examined whether Ca status predicts the primary outcome.

Results: Among the enrolled 321 patients, 75% of the patients showed true HypoCa defined as iCa <1.15 mmol/L, 57% of whom showed Hidden HypoCa. Over a median follow-up period of 31.5 months, 31% of the patients reached the primary endpoint. The risk for the primary outcome was not significantly different between HypoCa and normocalcemia defined by cCa. In contrast, patients with true HypoCa had higher risk than patients with normal iCa levels (Figure). In univariate analysis, Hidden HypoCa was significantly associated with increased risk for death or CVD compared with NormoCa (hazard ratio [HR], 2.35; 95% confidence interval [CI], 1.27-4.32), whereas Apparent HypoCa was not. Even after adjustment for age, sex, eGFR, diabetes, QTc prolongation, serum albumin, phosphate, and ALP levels, Hidden HypoCa was associated with significantly higher risk (HR, 2.28; 95% CI, 1.08-4.80).

Conclusions: Hidden HypoCa at the initiation of dialysis was a significant risk factor of the combined outcome of all-cause mortality and CVD morbidity, independently of QTc prolongation, phosphate, and ALP, suggesting the importance of measuring iCa.



TH-PO210

Combined Impact of Phosphorous and Calcium on Mortality Risk in 109,205 Hemodialysis Patients

Antonio Aguirre,[1] Christina Park,[1] Jui-Ting Hsiung,[1] Carola-Ellen Kleine,[1] Connie Rhee,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh,[1] Elani Streja.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: Mineral and bone disorder (MBD) is highly prevalent in patients with chronic kidney disease (CKD). Serum phosphorus (Phos), calcium (Ca) and calcium phosphorus product have been shown to be independently associated with mortality risk in hemodialysis patients. We sought to examine whether evaluating the combination of Phos and Ca can better predict mortality rates among dialysis patients.

Methods: Our analytical cohort consists of 109,205 incident hemodialysis patients receiving treatment from a large dialysis organization between 2007 and 2011. Associations between combined serum Phos and Ca values for the first dialysis quarter (dialysis start + 91 days) and mortality were estimated using Cox proportional hazard models with adjustment for demographics and markers of malnutrition and inflammation.

Results: Mean patient age was 63 ±15 years, while 44% were female, 32% were African American, and 58% were diabetic. The mean amount of Phos in the total cohort was 4.9 ± 1.1 mg/dL and the mean amount for Ca was 9.1 ± 0.6 mg/dL. Compared to the reference group (Phos ≥10.2 mg/dL and Ca ≥7 mg/dL), all-cause mortality tended to be lowest in patients with Phos 3.5-<5.5 mg/dL and Ca 8.4-<9.5 mg/dL (Hazard Ratio 0.60, 95% CI 0.44, 0.82). Besides, patients in the highest Phos group (≥ 7mg/dL) had the highest mortality risk across all strata of serum Ca. (Figure 1)

Conclusions: In hemodialysis patients, keeping serum Phos and Ca within or close to the physiological range might result in better survival. Further studies are needed to examine this association.

TH-PO211

Association Between Serum Magnesium and Arterial Calcification in Incident Hemodialysis Patients

Wei Chen,[1,3] Jessica Fitzpatrick,[4] Jose M. Monroy-Trujillo,[5] Stephen M. Sozio,[5] Bernard G. Jaar,[5] Michelle M. Estrella,[2] Tong tong Wu,[1] Michal L. Melamed,[3] Rulan S. Parekh,[4,5] David A. Bushinsky.[1] PACE study team *[1]University of Rochester School of Medicine, Rochester, NY; [2]University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA; [3]Albert Einstein College of Medicine, Bronx, NY; [4]The Hospital For Sick Children, Toronto, ON, Canada; [5]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Animal studies demonstrate that magnesium (Mg) supplementation inhibits arterial calcification in CKD. In humans, both CKD and diabetes mellitus (DM) are independent risk factors for arterial calcification; however, it is unknown if Mg influences calcification in CKD patients and whether DM alters this potential relationship. We tested the hypotheses that higher serum Mg concentration was associated with lower coronary artery calcification (CAC) and thoracic aortic calcification (TAC) scores in incident hemodialysis (HD) patients and that these associations, if any, were modified by DM.

Methods: We performed cross-sectional analyses of 367 incident HD patients in the Predictors of Arrhythmic and Cardiovascular Risk in ESRD (PACE) cohort. Serum Mg was measured on a non-HD day. CAC and TAC were quantified with computed tomography, which was done at a median time of 3.6 months after initiation of HD. We used logistic regression to study the association of Mg with CAC (>0 vs. 0) and TAC (>0 vs. 0) scores among all participants and linear regression for log-transformed CAC among those with CAC >0. Models were tested for interaction with DM status and adjusted for age, sex, race, smoking, body mass index, serum calcium, phosphate, parathyroid hormone, albumin, hemoglobin, low-density lipoprotein and Kt/V.

Results: Mean age was 55 years; 40% were female; 72% were black and 58% had DM. Mean serum Mg was 1.8±0.2 mEq/L; 63% had CAC >0 and 50% had TAC >0. DM did not modify the association between Mg and CAC. Among all participants, Mg was not associated with CAC. However, among those with CAC >0, per 0.1 mEq/L higher Mg, CAC score was 15% lower [% change: -15% (95% CI: -25%, -3%), p=0.02]. DM modified the association between Mg and TAC (p for interaction=0.003). Per 0.1 mEq/L higher serum Mg, the odds of having TAC >0 was 34% lower [OR: 0.66 (95% CI: 0.47, 0.92), p=0.02] among non-diabetics, but was 55% greater [OR: 1.55 (95% CI 1.08, 2.23), p=0.02] among diabetics.

Conclusions: Consistent with animal studies, higher serum Mg was associated with a lower CAC score among incident HD patients with CAC >0 and with a lower odds of having TAC >0 among non-diabetics. Why Mg was associated with a higher odds of having TAC >0 among diabetics remains to be elucidated.

TH-PO212

Serum Magnesium Value at 1 Year After Initiation of Hemodialysis Is a Significant Predictive Factor of All-Cause Mortality

Takayuki Fujii,[1] Kaiji Saito,[1] Junya Koshizaka,[2] Nobuaki Yamauchi,[2] Noriko Terasaki,[1] Tanaka Hiroaki,[1] Satoshi Suzuki.[1] *[1]Seirei Sakura Citizen Hospital, SAKURA-SHI, Japan; [2]Seirei Sakura Citizen Hospital, SAKURA-SHI, Japan.*

Background: Recent studies reported that higher levels of serum magnesium (Mg) were associated with better prognosis in patients undergoing hemodialysis. However, it remains unclear which measurement point of the serum Mg value is crucial for vital prognosis after initiation of hemodialysis. In this study, we evaluated the association of serum Mg for 3 years after initiation of hemodialysis with subsequent all-cause mortality.

Methods: We conducted a single-center retrospective cohort study in 205 patients who initiated hemodialysis between March 2004 and May 2014 and could be followed-up for at least three years or more. We analyzed the influence of annual serum Mg value on all-cause mortality for 3 years using Cox's hazard proportional model. The hazard ratio (HR) of all-cause mortality was adjusted for demographic data, 3-year-averaged laboratory data and medications.

Results: The median follow-up period was 6.1years and fifty patients reached the outcome. Since the median of 3-year-averaged Mg level was 2.6mg/dl, we evaluated the significance of Mg≥2.6mg/dL versus Mg<2.6mg/dL using Cox's proportional hazard model. Although, at the time of initiation of hemodialysis, HR of Mg≥2.6mg/dL was 1.15[0.52-2.26], HRs of Mg≥2.6mg/dL at 1 year, 2 years and 3 years after initiation of hemodialysis, were 0.33[0.15-0.74], 0.41[0.15-0.74] and 0.30[0.16-0.53] and found to be significant factors in univariate analysis. Even adjusted for age, presence of diabetes, 3-year-averaged serum albumin and phosphorus and use of non-calcium containing phosphate binder, which were also significant factors in univariate analysis, HRs of Mg≥2.6mg/dL at 1 year, 2 years and 3 years were 0.48[0.26-0.87], 0.45[0.25-0.82] and 0.50[0.26-0.96], respectively, showing that Mg≥2.6mg/dL was a significantly better prognostic factor at 1 year or longer after hemodialysis initiation.

Conclusions: In this study, we found that higher levels of serum Mg at 1 year or later after initiation of hemodialysis were associated with subsequent better prognosis.

TH-PO213

Hypomagnesemia and Body Composition in Maintenance Hemodialysis Patients

Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Kazuomi Yamashita,[1] Kyoka Ono,[1] Kohji Usui,[2] Michiko Arita,[3] Takayuki Naito,[4] Shigehiro Doi,[5] Takao Masaki,[5] Kenichiro Shigemoto.[1] *[1]Division of Nephrology, Ichiyokai Harada Hospital, Hiroshima, Japan; [2]Ichiyokai Ichiyokai Clinic, Hiroshima, Japan; [3]Ichiyokai East Clinic, Hiroshima, Japan; [4]Ichiyokai Yokokawa Clinic, Hiroshima, Japan; [5]Hiroshima University Hospital, Hiroshima, Japan.*

Background: The aim of this study was to investigate the relationships between serum magnesium (Mg) levels and body composition, clinical parameters, or survival in maintenance hemodialysis (MHD) patients.

Methods: The subjects were 215 MHD patients on dialysate Mg of 1.0 mEq/L. Pre-dialysis laboratory data collection and post-dialysis body composition analysis with the Body Composition Monitor® (Fresenius Medical Care) were performed at the baseline. The patients were divided into serum Mg tertiles [T1-3]. Kaplan-Meier survival, and logistic regression analyses for T1 were examined.

Results: Among all patients, the mean age was 72±12 years, 39.1% were diabetics, and the median dialysis vintage was 44 (8-96) months. The serum Mg values of T1 (n=67),

T2 (n=76) and T3 (n=72) were <2.3, 2.3-2.5 and >2.5 mg/dl, respectively. The differences in body cell mass index (BCMI) among T1, T2, and T3 were significant (5.7±1.9, 6.4±2.1, 6.6±2.2 kg/m^2, p<0.05), as were those in overhydration/extracellular water ratio (OH/ECW) (15.1±16.5, 7.1±11.1, 9.1±14.2%, p<0.01), but no significant differences were seen for the body mass index (20.2±5.3, 22.1±6.4, 20.3±4.9 kg/m^2), lean tissue index (11.2±2.6, 12.0±3.3, 12.1±3.0 kg/m^2), or fat tissue index (8.0±3.7, 9.1±4.4, 8.7±4.6 kg/m^2). T1 exhibited a significantly greater age (75±11, 73±12, 69±13 years), a shorter dialysis vintage, and lower normalized protein nitrogen appearance (nPNA), serum albumin (3.2±0.5, 3.3±0.4, 3.4±0.5 g/dl) and uric acid values (6.5±1.7, 6.9±1.4, 7.2±1.4 mg/dl) but higher C-reactive protein levels (1.4±2.4, 1.1±2.7, 0.9±1.9 mg/dl) compared with T2 and T3 (p<0.05). During the 3 years, 47 (21.9%) patients died. Three-year survival rates were 57.7% and 67.9% in T1 and T2+T3, respectively (p<0.05). Multivariate analyses included all significant variables in the univariate analyses showed that T1 was significantly associated with the BCMI [Odds ratio (OR) 0.83, 95% confidence interval (CI) 0.70-0.97] or OH/ECW [OR (95%CI): 1.03 (1.01-1.06)], respectively, independent of age, dialysis vintage, nPNA, serum albumin and uric acid levels (p<0.05).

Conclusions: Hypomagnesemia is associated with lower 3-year survival rate, and worse body composition parameters such as BCMI and OH/ECW, which reflect muscle depletion and overhydration, respectively, in MHD patients.

TH-PO214

Hypomagnesemia May Not Cause Increased Mortality as Agent Provocateur in Maintenance Hemodialysis Patients

Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Kazuomi Yamashita,[1] Chie Tanji,[2] Kohji Usui,[2] Takayuki Naito,[3] Shigehiro Doi,[4] Takao Masaki,[4] Kenichiro Shigemoto.[1] *[1]Division of Nephrology, Ichiyokai Harada Hospital, Hiroshima, Japan; [2]Ichiyokai Ichiyokai Clinic, Hiroshima, Japan; [3]Ichiyokai Yokokawa Clinic, Hiroshima, Japan; [4]Hiroshima University Hospital, Hiroshima, Japan.*

Background: It is unclear whether hypomagnesemia causes increased mortality as agent provocateur or bystander in maintenance hemodialysis (MHD) patients. This study aimed to investigate the associations between hypomagnesemia and mortality, and to study the factors related to hypomagnesemia in MHD patients.

Methods: The subjects were 353 Japanese MHD patients. Laboratory parameters including the serum magnesium (Mg), coronary artery calcium score (CACS) and medication use were studied at baseline. The subjects were stratified into baseline Mg level quartiles (Q). Kaplan-Meier survival, Cox proportional hazards models for the factors associated with mortality and logistic regression analyses for Q1 were examined.

Results: Among all patients), the median age was 68 (60-78), 39.7% were diabetics, and the median dialysis vintage was 75 (32-151) months. The Mg values of Q1 (n=86), Q2 (n=97), Q3 (n=99), and Q4 (n=71) were <2.2, 2.2-2.4, 2.5-2.7, and >2.7 mg/dl, respectively. The patients in Q1 exhibited significantly lower serum albumin, phosphate, uric acid, fibroblast growth factor 23, Kt/V_{urea} and normalized protein nitrogen appearance (nPNA) levels (P<0.01), but significantly higher serum high sensitivity C-reactive protein (hsCRP) levels (P<0.05) than the patients in Q2-4. During the 3 years, 91 patients died. The 3-year cumulative survival rate was 54.4%, 70.3%, 84.3%, and 85.2% in Q1, Q2, Q3, and Q4, respectively (P<0.05), and 3-year cardiovascular (CV) mortality was also significantly higher in Q1/Q2 than in Q3/Q4 (P<0.05). The Q1 was significantly associated with 3-year all-cause mortality [Hazard ratio (HR) 2.09, 95% confidence interval (CI) 0.96-4.49, P<0.01] and 3-year CV mortality [HR (95%CI): 3.03 (1.02-8.84), P<0.05], independent of Log (CACS+1), age, dialysis vintage, serum hsCRP and uric acid but the significance was lost in the model which included serum albumin, nPNA and medication use. The most significant determinant of Q1 was serum albumin levels (g/dl) [Odds ratio (95% CI): 0.10 (0.02-0.37), p<0.01], and Q1 was not found to be related to CACS or medication use including sevelamer or proton pump inhibitor.

Conclusions: Hypomagnesemia per se may not cause increased 3-year all-cause and CV mortality as agent provocateur but associated with malnutrition in MHD patients.

Funding: Private Foundation Support

TH-PO215

The Influence of Age on PTH/Vitamin D Relationship in Non-dialytic CKD

Ricardo Madureira,[1] Eduardo J. de Sa Carneiro Filho,[2] Rosilene M. Elias,[2,3] Maria Dalboni,[3] Rosa M. Moyses.[2,3] *[1]Hospital Sírio Libanês, São Paulo, Brazil; [2]Universidade de Sao Paulo, Sao Paulo, Brazil; [3]Pós-Graduação em Medicina, UNINOVE, Sao Paulo, Brazil.*

Background: Hypovitaminosis D is recognized as a worldwide epidemic. It is associated with elevation in parathormone (PTH), increasing the risk of fractures. Studies on general population have reported that the relationship between PTH and 25vitamin D (PTH/vitD) is influenced by aging. However, in chronic kidney disease (CKD) patients, the effect of on PTH/vitD remains unknown. This study aims to analyze the impact of age (≥ 65 years old) on PTH/vitD in non-dialytic CKD patients.

Methods: This is a cross-sectional study that analysed data from digital medical records of stage 3 CKD patients of outpatient Nephrology service of Hospital das Clínicas, Universidade de São Paulo. PTH/vitD was analyzed for the following categories: renal function, sex, furosemide and hydrochlorothiazide intake, serum calcium, oral cholecalciferol supplementation, phosphate binder and omeprazole.

Results: 1178 patients (506 women and 672 men) with glomerular filtration rate (GFR) = 44.03 ± 8.74 mL/min/1.73m2 were analyzed. Elderly and women accounted for 57 and 48.7% of total patients, respectively. PTH/vitD was higher in women [2.81(1.79-4.18) vs. 2.5 (1.6-3.97), p<0.0001], elderly [2.83(1.91-4.38) vs. 2.33 (1.54-3.61); p<0.0001], CKD stage 3b [2.9 (1.95-4.55) vs. 2.34 (1.49-3.52), p<0.0001], furosemide [3.48 (2.22-5.58) vs. 2.5 (1.59-3.69), p<0.0001] and cholecalciferol users [2.9 (1.82-4.44) vs. 2.46 (1.57-3.55), p<0.0001]; and lower in hydrochlorothiazide users [2.54 (1.6-3.66) vs. 2.7 (1.7-4.3), p = 0.018]. We did not find any association with phosphate binders or omeprazole. There was a correlation between PTH/vitD and serum calcium (r= -0.140; p <0.0001). The multivariate analysis revealed that PTH/vitD was dependent on eGFR, sex, furosemide intake, serum calcium and age.

Conclusions: Our data shows that, elderly patients with CKD present higher PTH levels when compared with young adults with similar eGFR, calcium and vitamin D levels. Prospective studies are required to determine whether cholecalciferol reposition has an impact on vitamin D and PTH levels in this population.

Evaluation of Intact and Biointact PTH Assays in Chronic Hemodialysis Patients

Carolin Berner,[1] Rodrig Marculescu,[2] Henrik Sliwka,[2] Christian Bieglmayer,[4] Manfred Hecking.[3] *[1]Medical University Vienna, Vienna, Austria; [2]Medical University of Vienna, Vienna, Austria; [3]Medical University of Vienna, Nephrology & Dialysis, Vienna, Austria; [4]Medical University of Vienna, Vienna, Austria.*

Background: Clinical management of chronic kidney disease - mineral and bone disorder is largely based on parathyroid hormone (PTH) concentrations, measured at regular intervals. The existence of PTH fragments, detected by first and second generation (“intact”) PTH (i-PTH) assays, led to the development of third generation (“biointact”) whole PTH (w-PTH) assays detecting only full length PTH. Despite efforts to use only w-PTH assays, i-PTH assays, which are usually less costly, are still being used and marketed, such that it may be indispensable to convert PTH values from one assay to another. We aimed at assessing the technical performance of a novel i-PTH assay, in comparison to 2 widely used w-PTH assays and to another i-PTH assay.

Methods: PTH levels of 134 patients on chronic hemodialysis were measured at 2 timepoints within 3 months, using: the novel new i-PTH assay by Siemens Healthcare (SH) and Roche Diagnostic (RD), respectively; the w-PTH assay by RD and DiaSorin (DS), respectively. All concentrations were measured in pg/ml by automated analyzers: Advia Centaur CP (SH), Cobas e 602 (RD) and Liaison XL (DS). Statistical methods included Passing-Bablok regression analyses and Bland Altmann plots.

Results: The i-PTH SH was slightly higher calibrated than i-PTH RD. Compared with w-PTH assays, the i-PTH SH assay yielded 2.5-fold higher results, while i-PTH RD was about 2-fold higher. Among the w-PTH(1-84) assays a rather good concordance was observed, with a mean bias of 12 ± 45.6 pg/mL (±2 SD) by Bland Altmann plots. In contrast, there was a substantial bias of -88.7 ± 183.4 pg/mL between the two iPTH assays (RD minus SH).

Conclusions: The table provided above enables method conversions, which are of interest, if a laboratory switches the assay or if a patient changes the treatment center.

TH-PO217

Peritoneal Dialysis Mineral Metabolism Disorders: Results from the BRAZPDII

Cesar A. Truyts,[2] Lucas A. Nunes,[2] Melani Custodio,[2] Rosa M. Moyses,[3] Roberto Pecoits-Filho,[1] Vanda Jorgetti,[2] Thyago P. Moraes.[1] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Universidade de São Paulo, São Paulo, Brazil; [3]Universidade Nove de Julho, São Paulo, Brazil.*

Background: Few studies evaluate mineral and bone disorders (MBD) in patients treated with peritoneal dialysis (PD), and the main guideline guiding their treatment were based on studies performed in patients treated with hemodialysis. BRAZPDII is a cohort of patients from 114 dialysis centers in Brazil, which contains data from 9.905 patients on peritoneal dialysis. We analyzed biochemical markers related to MBD (calcium (Ca), phosphorus (P) and parathormone (PTH)), categorized patients in accordance with the targets proposed guideline Kidney Disease: Improving Global Outcomes (KDIGO), and

compared the survival index between the groups which maintained the biochemical markers within or without the normal ranges

Methods: We recruited 844 patients from BRAZPDII, who had MBD biomarker data, and followed them up for 24 months. Cox proporcional was used to eliminate potencial variable confounders, and Kaplan-Meier estimator was used to compare the survival rate between the groups.

Results: Patients with Ca and P within the normal range using KDIGO definitions (8.4-10.2mg/dL and 3.5-5.5mg/dL, respectively) were associated with lower mortality (p<0.05; HR 1.63 and 1.79, respectively). PTH levels were not associated with mortality, regardless of the ranges proposed by KDIGO guideline (150-600).

Conclusions: Keeping calcium and phosphate within the range as suggested by KDIGO was associated with lower mortality in PD patients. PTH levels were not associated with mortality risks.

Funding: Commercial Support - Baxter

Relative risk of mortality and biochemical parameters out of range (KDIGO)

Biochemical parameter	HR	95% CI	p-value
Calcium	1.63	1.12-2.38	0.01
Phosphate	1.79	1.26-2.54	0.001
PTH	0.99	0.99-1.00	0.56

Hypoparathyroidism and Malnutrition – Two Sides of the Same Coin?

Petr Taborsky,[1] Lidmila Francova,[2] Ivan Rychlik.[3] *[1]Fresenius Medical Care, Prague, Czechia; [2]Charles University, 3rd Faculty of Medicine, Prague, Czechia; [3]Charles University, 3rd Faculty of Medicine, Prague, Czechia.*

Background: Chronic kidney disease-mineral and bone disorder has been recognized as a risk factor for dialysis patients survival. Clinical guidelines identify secondary hyperparathyroidism (SHPT) as the main target for therapeutic measures leaving aside the low level of parathyroid hormone (PTH). We used data from Czech Registry of dialysis patients (RDP) to analyze occurence of hypoparathyroidism in incident hemodialysis patients and its association with clinical outcomes.

Methods: In RDP we found 4878 patients who started dialysis from 2012 to 2015. Data of 576 patients treated by hemodialysis (HD) and 2615 patients treated by hemodiafiltration (HDF) were examined using multivariable regression, log-rank test and Cox survival models. Patients treated by peritoneal dialysis and patients with incomplete data were excluded. Laboratory values are recorded in RDP every 3 months in all patients, for analysis we used their respective mean values over entire follow-up.

Results: Mean follow-up of 3191 patients was 1394 days, 3-years survival 71% in all patients, 74% in HDF and 55% in HD subgroups. Mean age of patients was 65.3 years, proportion of diabetics 45%. Mean PTH < 150 pg/ml was found in 31.8% of patients, PTH 150-600 pg/ml in 64.4% and PTH > 600 pg/ml in 3.8% patients. We merged patients with PTH > 150 pg/ml into single group and compared all variables between subgroups with discriminating value of PTH 150 pg/ml (low PTH vs high PTH). Low PTH was associated with lower BMI, lower albumin and phosphate level, higher age and Kt/V. 3-years survival was significantly better in high PTH group, 65% vs 74%, this association was preserved after adjustment for mean serum calcium, phosphate, Kt/V, dialysis method (HD vs HDF), age, BMI and diagnosis of diabetes. The difference in survival between low and high PTH group dissapeared after adjustment for serum albumin. The same proportion of patients treated with phosphate binders was found in both groups. Proportion of patients treated with PTH-lowering drugs (cinacalcet, paricalcitol, calcitriol) was significantly lower in low PTH group.

Conclusions: In our study one third of incident dialysis patients have low PTH which was associated with decreased survival. Low PTH behaves as a marker of malnutrion not related to diabetes and treatment of SHPT. Whether therapeutic measures increasing PTH translate into better patient outcome warrants prospective studies.

TH-PO219

Factors Affecting Progressive Vascular Calcification in Hemodialysis Patients

Dong-Young Lee,[1] Beom Kim,[2] Kyoung hyoub Moon,[3] Hye won Kim.[4] *[1]Internal medicine, Veterans Health Service medical center, Seoul, Republic of Korea; [2]Veterans Health Service Medical Center, Seoul, Republic of Korea; [3]Vetrans Health Service Medical Center, Seoul, Republic of Korea; [4]Korea university Anam Hospital, Seoul, Republic of Korea.*

Background: It is known that patients who have done dialysis due to end stage renal disease have progressive vascular calcification, and that the more severe it is, the more frequent the occurrence and resulting death of cardiovascular disease. But so far very little is known about the causes of progressive vascular calcification. We aimed to investigate the risk factors for progressive abdominal aortic calcification in patients doing hemodialysis.

Methods: We conducted cross-sectional study of 281 subjects at six centers who agreed to this study and underwent lateral lumbar radiography. Kauppila score was used to measure abdominal aortic calcification, and progressive vascular calcification was defined as a median vascular calcification score of 7 or more. Radiographs of the lateral lumbar spine were analyzed by two staff members and the identities of the Kauppila scores between the two were 91%.

Results: The mean age of the 281 hemodialysis patients was 62.7 years, and 250 patients (89%) had calcification. The distribution of the abdominal aortic calcification score was 49.5% in 0-6, 28.5% in 7-12, 17.1% in 13-18, and 5% in 19-24. The risk factors for progressive vascular calcification were Kt / V (OR 8.2, 95% CI 2.39-28.1), cardiovascular disease (OR 2.54, 95% CI 1.27-5.06), DM (OR 2.38, 95% CI 1.21-4.68), age (OR 1.05, 95% CI 1.03-1.08), serum Ca (OR 1.63 1.13-2.34), total CO2 (OR 1.15, 95% CI 1.04-1.27), serum Na (OR 0.86 95% CI 0.79-0.93) and serum chloride (OR 0.88, 95% CI 0.82-0.94).

Conclusions: Several factors were associated with progressive vascular calcification. Further longitudinal studies are needed to determine the association of these factors with progressive vascular calcification.

TH-PO220

Trabecular Bone Score May Manifest as CKD-Mineral and Bone Disorder (CKD-MBD) Phenotype Reciprocal to Major Cardiovascular Outcome

Hyojin Yun, Inwhee Park, Gyu Tae Shin, Heungsoo Kim, Jong Cheol Jeong. *Ajou University School of Medicine, Suwon, Republic of Korea.*

Background: In general population, trabecular bone score (TBS) represents bone microarchitecture and predicts fracture risk independent of bone mineral density (BMD). A few studies reported that TBS is significantly reduced in dialysis patients. Chronic kidney disease-mineral and bone disorder (CKD-MBD) are accompanied by increased fracture risk and cardiovascular morbidity and mortality. We investigated whether TBS is associated with comorbidity related to CKD-MBD or frailty in hemodialysis patients.

Methods: In this cross-sectional study, TBS was obtained using the TBS iNsight software program (Med-Imaps) with BMD dual energy x-ray absorptiometry (DXA) images (L1–L4) from prevalent hemodialysis patients. For frailty evaluation, Tilburg frailty indicator was used. Hand grip test and bio-impedance (InBody) were measured. Patient generated subjective global assessment (PG-SGA) was measured as nutritional assessment. History of major adverse cardiovascular event (MACE) was collected. Demographic, clinical, laboratory and biomarker data were also collected.

Results: Total 57 patients were enrolled. Mean age of population was 56.8 ± 15.9 years old. Female was 50.9%. Diabetes mellitus (DM) was 40.4% and MACE was prevalent in 36.8 %. Mean TBS value was 1.44 ± 0.10. TBS was significantly reduced in MACE group (1.48 ± 0.10 vs. 1.38 ± 0.08, p<0.01). Multivariable regression analysis was conducted adjusting age, sex, dialysis vintage, DM, MACE, phase angle and intact parathyroid hormone. Age (ß=-0.003; p<0.01) and MACE (ß =-0.053; p=0.02) were significant predictors of TBS. α-klotho neither showed any significant difference in MACE outcome (MACE vs. no MACE, 474.0 ± 370.0 pg/mL vs. 582.8 ± 740.1 pg/mL, p=0.54), nor association with TBS (r=-0.001, p=0.41). During the period of follow up after TBS measure (about 20 months), 4 deaths, 7 new onset fractures, and 6 new onset MACEs were recorded. Lower TBS was associated with mortality (p<0.05) or new onset fracture (p<0.01, by log-rank test).

Conclusions: TBS was associated with age and MACE in hemodialysis patients. TBS may manifest as phenotype of frailty, also may manifest as CKD-MBD phenotype reciprocal to MACE.

TH-PO221

Progression of Abdominal Aortic Calcification in Kidney Transplantation Recipients and Hemodialysis Patients

Keiji Kono,[1] Hideki Fujii,[1] Nozomi Yamada,[3] Kentaro Watanabe,[1] Shuhei Watanabe,[1] Kimihiko Goto,[1] Shunsuke Goto,[2] Shinichi Nishi.[1] *[1]Kobe University Graduate School of Medicine, Kobe, Japan; [2]Kobe University Graduate School of Medicne, Kobe, Japan; [3]Kobe University, Kobe, Japan.*

Background: Vascular calcification is a critical complication of chronic kidney disease (CKD), and its mechanism is multifactorial. It has been reported that kidney transplantation (KT) may slow down the progression of vascular calcification along with the improvement of kidney function. However, there is a paucity of data about the comparison of the progression of vascular calcification between KT and hemodialysis (HD) patients. The aim of the present study is to compare the progression of abdominal aortic calcification between KT recipients and incident HD patients.

Methods: Ninety-one patients who underwent KT from January 2008 to January 2016 and 56 patients who initiated hemodialysis from December 2012 to June 2014 in our institutes were included in this study. We assessed the abdominal aortic calcification index (ACI) using a non-contrast computed tomography. The timing of assessment of the baseline and follow-up ACI was as follows; KT group: at the time of KT and at 1~2 years after KT, incident HD group: at the time of HD initiaion and at 1 year after HD initiation, respectively. The progression of ACI (ΔACI (%/year)) was calculated and compared between KT recipients and incident HD patients.

Results: The KT group included 17 pre-emptive KT (PKT) recipients (Living donor; n= 17, Deceased donor; n= 0) and 74 non-PKT recipients (Living donor; n= 69, Deceased donor; n= 5). The dialysis vintage was 51.2±55.6 months in the KT group. The KT group had significantly lower ΔACI compared to the incident HD group. Even after excluding the patients with pre ACI=0 (KT; n=34, incident HD; n=4), its relationship remained significant among the two groups. The baseline characteristics showed that the incident HD group had significantly higher prevalence of diabetes mellitus (DM) and higher age and body mass index (BMI) compared to the KT group. After adjustment for these traditional risk factors for vascular calcification using a propensity score matching, baseline ACI was comparable among the two groups, but the KT group had significantly lower ΔACI compared to the incident HD group.

Conclusions: Our findings suggest that KT slows the progression of ACI compared to HD initiation.

TH-PO222

Progression of Medial Arterial Calcification in CKD and ESRD

W. Charles O'Neill, Shumila Manzoor. *Renal Division,Department Of Medicine, Emory University, ATLANTA, GA.*

Background: Medial arterial calcification, as distinguished from atherosclerotic calcification, is common in chronic kidney disease (CKD) and portends poor clinical outcomes, but its progression relative to the severity of CKD and the role of other risk factors is unknown. Calcification of breast arteries detected by mammography, a marker of generalized medial calcification, was used to measure progression in women with CKD and end-stage renal disease (ESRD).

Methods: Women with and without CKD were identified from a computerized search of medical records. Subjects with current warfarin use, which is associated with medial arterial calcification, were excluded. Estimated glomerular filtration rate (eGFR) was determined by the four-variable MDRD formula and ESRD was defined as chronic outpatient hemodialysis. The lengths of calcified segments of breast arteries on digital mammograms were summed and expressed as millimeters per breast. Results are presented as medians and interquartile ranges with analysis by the Mann-Whitney U or Kruskall-Wallis test.

Results: Progression of calcification was measured in 60 control subjects (estimated glomerular filtration rate (eGFR) ≥ 90 ml/min/1.73 m^2) and 137 subjects with CKD (eGFR <90 ml/min/1.73 m^2) divided into tertiles by eGFR (Table). Progression in control subjects was linear over time and independent of age. An increased rate of progression was observed only in the lowest CKD tertile (eGFR <40 ml/min/1.73 m^2), p=0.006. Progression accelerated markedly in ESRD (n=36), with a median of 20 mm/breast/y (7.4-51), p=0.006 vs CKD 3rd tertile. Diabetes significantly augmented progression in CKD (2-fold, p=0.029) and ESRD (4.4-fold, p=0.004) but not in the absence of CKD:4.0 (1.1-8.5) vs. 3.9 (0.7-7.8) mm/breast/y.

Conclusions: CKD is a risk factor for medial arterial calcification but only when advanced (eGFR < 40 ml/min/m^2). This is consistent with hyperphosphatemia rather than earlier derangements in mineral metabolism as a contributing factor. Progression is markedly accelerated in ESRD patients, suggesting the possibility of dialysis-specific effects. Diabetes is a significant risk factor in the presence of CKD or ESRD.

The Prognostic Value of Serum Galectin 3 to Abdominal Aortic Calcification Progression in Maintenance Hemodialysis Patients

Zhiyu Wang,[1] Zijin Chen,[2] Haijin Yu,[3] Xiaonong Chen.[3] *[1]Dapartment of Nephrology, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China; [2]Ruijin Hospital affilliated to Shanghai Jiaotong University, Shanghai, China; [3]Division of Nephrology, Ruijin Hospital, Shanghai Jiao Tong University, Shanghai, China.*

Background: Heterotopic vascular calcification is one of the complications of maintenance hemodialysis (MHD) patients contributed to adverse prognosis. Basic research results indicated the relation of Galectin-3 (Gal-3) with cardiovascular calcification. However whether serum Gal-3 is associated with uremic vascular calcification has not been investigated yet.

Methods: A prospective cohort study was performed. Eligible patients undergoing hemodialysis during July 2014 enrolled from Blood Purification Center of Ruijin Hospital were followed up for 3 years. Twice AAC assessment have been performed at the baseline and after 3-year follow-up respectively. Baseline laboratory measurement results, clinical data and blood samples were collected. Serum Gal-3 was detected by quantified ELISA kits. SPSS 23.0 and Medcalc 11.4.2.0 were used to analyze data.

Results: 152 patients were recruited. Mean Gal-3 concentration was 29.24±10.15ng/ml. All patients has finished first lateral lumbar X-ray examination and 104 patients finished repetitive examination 3 years later. Serum Gal-3 was positively associated with blood phosphonium, baseline abdominal aortic calcification score (AACS), andΔAACS of MHD patients. Logistic regression analysis indicated that serum Gal-3 was an independent risk factor to both severe AAC and AAC progression in 3 years. ROC analysis revealed a significant prognostic value of serum Gal-3 to severe AAC and AAC progression in 3 years. High serum Gal-3 was one of the characteristics of patients with rapid AAC progression.

Conclusions: Serum Gal-3 is a novel biomarker of vascular calcification in uremic patients. Our research first demonstrated that serum Gal-3 was a promising biomarker predicting severe AAC and AAC progression in 3years of MHD patients. Serum Gal-3 maybe a potential intervention target for vascular calcification of MHD patients.

Funding: Government Support - Non-U.S.

Ankle-Brachial Index Predicts Vascular Calcification in Hemodialysis Patients with Severe Hyperparathyroidism

Maurilo Leite,[1] Alinie D. Pichone,[1] Carlos P. Gomes.[2] *[1]Federal University of Rio de Janeiro, Niteroi, RJ, Brazil; [2]UFRJ, Rio de Janeiro, Brazil.*

Background: Vascular calcification, which is a common complication of secondary hyperparathyroidism (sHPT), is related with high mortality in chronic kidney disease (CKD) patients. Besides the increase of intact parathyroid hormone (iPTH), high levels of phosphorus induce phenotypic changes in vascular smooth muscle cells (VSMC) that differentiate on osteoblast-like cells causing calcification at the media of arterial wall. This study aims to correlate ankle-brachial index (ABI) with biochemical abnormalities and presence of vascular calcification on X-Ray exams.

Methods: We analyzed thirty hemodialysis (HD) patients over eighteen years of age and with iPTH higher than 1000pg/ml. All patients underwent an assessment of their clinical history, laboratory data and radiographic evaluation. ABI was measured by portable Doppler Medpej®DF 7001.

Results: The age was 44.8±8.7yo, 70% women, HD vintage 136.8±61.6 months, serum phosphorus 6.1±1.0mg/dl and iPTH 2883.7±1165.2pg/ml. 66% of patients had Adragão Score>3, 76% had arteriovenous fistula (AVF) calcification and 52% had lumbar aortic calcification. Adragão Score correlated with AVF calcification (r=0.5;p<0.01) and lumbar aorta (r=0.70;p<0.01). The ABI was 1.79±0.96 and correlated with Adragão score (r=0.54;p<0.01), AVF calcification (r=0.47;p<0,05) and phosphorus level (r=0.84;p<0.05). In sHPT evaluation, we routinely use a simple vascular calcification score on plain radiographic films of pelvis and hands (Adragão score). We verified significant correlation between this score compared to AVF and lumbar aortic calcifications. Moreover, ABI, a simple clinical tool performed at bedside, was strongly correlated with serum phosphorus, Adragão score and AVF calcification. All this findings corroborate with the role of phosphorus in osteoblastic differentiation of VSMC and vessel stiffness caused by media calcification.

Conclusions: We observed high prevalence of vascular calcification in hemodialysis patients with severe hyperparathyroidism using conventional image methods and the ABI was a practice tool for this diagnosis in this population.

Enarodustat (JTZ-951), an Oral HIF-PH Inhibitor, Elevates and Maintains Hemoglobin Levels over 30 Weeks in Japanese Anemic Patients with CKD Not on Dialysis

Tadao Akizawa,[1] Yuya Miyazawa,[2] Atsushi Matsui,[2] Ryosuke Koretomo,[2] Masanobu Arai.[2] *[1]Showa University School of Medicine, Tokyo, Japan; [2]Japan Tobacco Inc., Tokyo, Japan.*

Background: The dose response in Hb and safety of enarodustat administered for 6 weeks in anemic patients with CKD not on dialysis (ND-CKD) was assessed in a placebo-controlled, randomized, double-blind manner (period I). In addition, the maintenance dosage and safety of long-term treatment with enarodustat was assessed in an open-label manner for 24 weeks (period II).

Methods: ESA naïve subjects (G1) and subjects receiving a stable dose of ESAs (G2), who have protocol specified Hb criteria, were respectively randomized in 1:1:1:1 ratio to receive either enarodustat doses of 2, 4, 6 mg or placebo once daily. Subjects, who completed the period I and were eligible for the period II, received long-term treatment with enarodustat that was adjusted in the range of 2 to 8 mg to maintain Hb in a target range of 10.0-12.0. Use of IV iron was prohibited by the end of period I.

Results: The weekly Hb elevation rate in G1 was significantly increased with dose. In G2, the changes in Hb from baseline at endpoint were also increased with dose. In period II, the proportion of subjects who maintained Hb level within the target range at end of treatment in G1 and G2 were 71.4% and 83.1%, respectively. While Hb levels over the course of Period II stayed in a target range, more than 70% subjects experienced ≤ 1 dose adjustment during the period II. Median hepcidin and ferritin levels were decreased across all the enarodustat arms during period I in contrast with increase in TIBC levels. These parameters remained stable during period II. Enarodustat was generally well tolerated.

Conclusions: Enarodustat corrected and maintained Hb levels in anemic patients with ND-CKD with minimum dose adjustment requirement. Furthermore, better iron availability and utilization by enarodustat are suggested to be contributed to erythropoietic responses, which is expected to provide alternative and more physiologic treatment option to ESA for anemic patients with CKD. The efficacy and safety compared with ESA and long-term studies are being examined in phase 3 studies.

Enarodustat (JTZ-951), an Oral HIF-PH Inhibitor, Maintains Hemoglobin Levels Switching from ESAs over 30 Weeks in Japanese Anemic Patients with CKD Receiving Maintenance Hemodialysis

Tadao Akizawa,[1] Yuya Miyazawa,[2] Kazuo Maeda,[2] Ryosuke Koretomo,[2] Masanobu Arai.[2] *[1]Showa University School of Medicine, Tokyo, Japan; [2]Japan Tobacco Inc., Tokyo, Japan.*

Background: The dose response in Hb and safety of enarodustat administered for 6 weeks was assessed in anemic patients with CKD receiving maintenance hemodialysis (HD-CKD) in a placebo-controlled, randomized, double-blind manner (period I). In addition, the maintenance dosage and safety of long-term treatment with enarodustat was assessed in an open-label manner for 24 weeks (period II).

Methods: Subjects, who have been receiving a stable dose of ESAs and have protocol specified Hb criteria, were randomized in 1:1:1:1 ratio to receive either enarodustat doses of 2, 4, 6 mg or placebo once daily and switched from ESAs. Subjects, who completed the period I and were eligible for the period II, received long-term treatment with enarodustat that was adjusted in the range of 2 to 8 mg to maintain Hb in a target range of 10.0-12.0. Use of IV iron was prohibited by the end of period I.

Results: In period I, the changes in Hb from baseline at endpoint were increased with dose. In period II, the proportion of subjects who maintained Hb level within the target range on Ext Week 24 and end of treatment were 70.9% and 65.1%, respectively. Beside Hb levels were within a target range, approximately 80% subjects experienced ≤ 2 dose adjustments during period II. Mean prescribed dose was 4.30 mg/day. Median hepcidin and ferritin levels were decreased across all the enarodustat arms during period I in contrast with increase in TIBC levels. These parameters remained stable during period II. Enarodustat was generally well tolerated.

Conclusions: Enarodustat maintained Hb levels in anemic patients with HD-CKD switching from ESAs with minimum dose adjustment requirement. Furthermore, iron availability and utilization by enarodustat are suggested to be contributed to erythropoietic responses, which is expected to provide alternative and more physiologic treatment option to ESA for anemic patients with CKD. The efficacy and safety compared with ESA and long-term studies are being examined in phase 3 studies.

Efficacy and Safety of Daprodustat on Anemia Management in Japanese Hemodialysis Patients Not Using Erythropoiesis-Stimulating Agents

Taku Fujii,[1] Yoshiharu Tsubakihara,[2] Tadao Akizawa,[3] Masaomi Nangaku,[4] Tomohiro Onoue,[6] Taeko Yonekawa,[1] Yukihiro Endo,[5] Alexander R. Cobitz.[1] *[1]GlaxoSmithKline, Tokyo, Japan; [2]Graduate School of Health Care Science, Jikei Institute, Yodogawa-ku, Osaka, Japan; [3]Showa University School of Medicine, Tokyo, Japan; [4]the University of Tokyo School of Medicine, Tokyo, Japan; [5]GlaxoSmithKline, Tokyo, Japan; [6]GlaxoSmithKline, Tokyo, Japan.*

Background: This Phase 3, open-label, non-comparative, multi-center study (funded by GlaxoSmithKline) examined the efficacy and safety of daprodustat (Hypoxia Inducible Factor-Prolyl Hydroxylase Inhibitor) over the 24 weeks in 28 Japanese hemodialysis (HD) subjects not using erythropoiesis stimulating agents (ESA).

Methods: Subjects on newly started dialysis or maintenance dialysis with hemoglobin (Hgb) of 8.0-<10.0 g/dL not using ESA were enrolled to receive daily oral daprodustat. After the first 4 weeks of the fixed starting dose of 4 mg, doses were adjusted monthly to achieve a Hgb target of 10.0–12.0 g/dL over the 24 weeks, utilizing doses ranging from 1-24 mg. The primary endpoint was to evaluate Hgb at Week 4. All subjects received the full ophthalmologic examinations (best corrected visual acuity, intraocular pressure, an anterior segment exam, and a fundoscopic exam) at baseline, Week 12 and the end of study.

Results: The mean baseline Hgb value was 9.10 g/dL. After the first 4 weeks, the mean change in Hgb from baseline was 0.79 g/dL (95%CI: 0.53, 1.05). No subjects experienced a rapid Hgb increase, defined as > 2 g/dL over the first 4 weeks. The mean Hgb value increased and reached the target range (10-12 g/dL) at Week 8 (10.76 g/dL), and was maintained within the target range at Week 24 (11.12 g/dL). At Week 24, 23 subjects (82%) had a Hgb value within the target range, and 18 (64%) subjects reached the lower target Hgb value without a dose adjustment. Ninety-two percentage of on-therapy AEs were reported as either mild or moderate in severity. There were no AEs leading to withdrawal/discontinuation of study treatment and no pre-defined ocular AEs of special interest were reported from the full ophthalmologic exam.

Conclusions: Daprodustat 4mg safely and effectively increased Hgb over the initial first 4 weeks of treatment. Daprodustat had an ability to achieve and maintain Hgb within target range and was generally well tolerated over the 24-week of treatment.

Randomized, Placebo-Controlled Phase 2 Trials of Vadadustat, an Oral Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitor (HIF-PHI), to Treat Anemia of CKD

Masaomi Nangaku,[1] Zeeshan Khawaja,[2] Wenli Luo,[2] Svetlana Garafola,[2] Emil deGoma,[2] Yasuhiro Komatsu.[3] *[1]University of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]Akebia Therapeutics, Inc., Cambridge, MA; [3]Gunma University, Graduate School of Medicine, Maebashi, Gunma, Japan.*

Background: The HIF-PHI vadadustat (VDT) was investigated in two phase 2, randomized, double-blind, placebo-controlled trials in Japanese subjects with anemia due to non-dialysis-dependent (NDD) or dialysis-dependent (DD) CKD.

Methods: Trials consisted of a 6-wk fixed-dose, placebo-controlled, primary efficacy period and a 10-wk dose adjustment period. In each trial, subjects were randomized to VDT 150 mg, 300 mg, 600 mg, or placebo. After 6 wks, subjects randomized to placebo were switched to VDT, and all subjects had their dose adjusted according to Hb response. For the primary efficacy analysis in each study, an ANCOVA model was used in the MITT population to compare mean change in Hb from baseline to Wk 6 between the VDT and placebo groups. Last observation carried forward (LOCF) was used for missing Hb data.

Results: Fifty-one and 60 subjects were randomized in the NDD and DD studies, respectively. Mean changes in Hb from baseline to Wk 6 were statistically significant in all VDT treatment arms compared with placebo (Table). Treatment with VDT 300 mg or 600 mg was associated with statistically significant increases in total iron binding capacity and decreases in ferritin and hepcidin from baseline to Wk 6 compared with placebo (P<0.01). Incidence of AEs during the 6-wk period in the VDT groups (150 mg, 300 mg, 600 mg) and placebo was 33%, 58%, 54%, and 36% (NDD study) and 53%, 73%, 40%, and 40% (DD study). During the 16-wk treatment period and 2-wk follow-up, the most common AEs reported were hypertension and viral upper respiratory infection (NDD study) and nasopharyngitis, diarrhea, and headache (DD study). 13 SAEs in 11 subjects (NDD study) and 10 SAEs in 7 subjects (DD study) were reported. No deaths were reported.

Conclusions: These data support continued development of VDT for patients with renal anemia.

Effects of Dosing Frequency on the Efficiency of EPO Administration in Hemodialysis Patients

Sabrina Rogg,[1] Doris H. Fuertinger,[1,2] Stefan Volkwein,[3] Peter Kotanko.[2,4]
[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Renal Research Institute, New York, NY; [3]University of Konstanz, Konstanz, Germany; [4]Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Achieving target hemoglobin (Hgb) levels in hemodialysis (HD) patients treated with short-acting erythropoietin (EPO) is challenging. It is highly desirable to keep drug doses low to mitigate adverse events and to reduce costs. Based on a mathematical model of erythropoiesis we developed a model predictive control (MPC) algorithm for patient-level EPO dose optimization.

Methods: Using an individualized model of erythropoiesis (Fuertinger et al, PLoS ONE 2018) an MPC algorithm is designed for computation of EPO doses at predefined dosing frequencies. The MPC aims to stabilize Hgb levels at 10.5 g/dl. Hgb variability and total amount of administered EPO are compared in an in-silico study in 60 chronic HD patients over a period of 150 days for a thrice weekly versus a daily EPO administration regimen.

Results: Daily and thrice weekly administration maintain Hgb levels equally within the target Hgb range of 10-12 g/dl except one patient reaching the target range only via daily administration. Compared to thrice weekly EPO administration, the daily administration scheme reduces Hgb variability by 8.9% and lowers the cumulative EPO dose by 18.1%. Figure 1 shows the results obtained in a single patient.

Conclusions: Our analysis shows a clear potential for reducing the risk of adverse events and saving costs by increasing the EPO dosing frequency and thereby reducing the required amount of EPO to correct the patient's anemia. Clinical studies are warranted to validate these findings.

Recombinant Erythropoietin Reduces Endothelium-Mediated Vasodilation in Patients with CKD – A Prospective Controlled Study

Zoe D. Sun,[1] Viknesh Selvarajah,[1,2] Annette Hubsch,[1] Nicholas R. Pritchard,[2] Joseph Cheriyan,[1,3] Ian Wilkinson,[1,3] Thomas F. Hiemstra.[1,3] *[1]1Division of Experimental Medicine and Immunotherapeutics, Department of Medicine, University of Cambridge, Cambridge, United Kingdom; [2]Department of Nephrology, Cambridge University Hopitals NHS Foundation Trust, Cambridge, United Kingdom; [3]Cambridge Clinical Trials Unit, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom.*

Background: Recombinant erythropoietin (rhEPO) is used for the treatment of CKD-associated anaemia, despite the hypertension and cardiovascular risks. Postulated mechanisms include endothelial dysfunction. Given the emergence of non-rhEPO treatments, elucidating the vascular effects of rhEPO in CKD-associated anaemia is important for comparative studies with non-rhEPO treatments.

Methods: We conducted a single centre open-label prospective non-randomised matched-control study in pre-dialysis rhEPO-naïve patients with CKD (n=12) and matched-healthy controls (n=12) to assess the effect of rhEPO on endothelial function (NCT02987465). Forearm blood flow responses to intra-arterial acetylcholine (ACh endothelium-dependent vasodilator), noradrenaline (NA) and BQ123 (ETA receptor antagonist) were assessed using venous occlusion plethysmography in CKD patients before and 6-weeks after rhEPO and in controls at baseline. Blood pressure, blood parameters and aortic stiffness (carotid-femoral pulse-wave velocity PWV) were measured. The primary outcome was change in log-transformed forearm blood flow compared using mixed-effects ANOVA.

Results: Baseline characteristics were similar between CKD patients and controls (age±SD 65±16 vs 64±16 years, male 83% vs male 83%). Although median eGFR (16, IQR 13-25 vs 83, IQR 78-90 ml/min, p<0.001) and haemoglobin (Hb 97±11 g/L vs 140±9 g/L, p<0.001) were lower, mean arterial pressure (110±21 vs 92±9 mmHg, p=0.02) and PWV (11.5±4.8 vs 8.3±2.2 m/s, p=0.04) were higher in patients with CKD. Response to ACh did not differ significantly between CKD patients and controls at baseline. In the CKD group, rhEPO increased haemoglobin (Hb) to 110 ± 17g/L (p<0.001) after 6 weeks, and reduced endothelium-dependent vasodilation by 23% (95% CI, 5% to 40%, p=0.009). The response to BQ123 did not differ after rhEPO treatment (-5%, 95% CI, -13% to 2%, p=0.15), but there was a greater vasoconstrictor response to NA (10%, 95% CI, 2% to 17%, p=0.01). Blood pressure and arterial stiffness did not change significantly after rhEPO.

Conclusions: Endothelium-dependent vasodilation is impaired after rhEPO treatment in patients with CKD, and NA-induced vasoconstriction is enhanced, suggesting possible mechanisms for rhEPO-associated hypertension and adverse cardiovascular outcomes.

Erythropoietin Stimulating Agents (ESA) Hyporesponsiveness and Outcomes: Patient Characteristics and Major Adverse Cardiovascular Events (MACE)

Helen T. Smith,[1] Borut Cizman,[1] Rebecca M. Lisle,[1] Yong Chen,[1] Zhou Zhou,[2] Mark Meiselbach,[2] Julie Reiff,[2] Jipan Xie,[2] Eric Wu,[2] Daniel W. Coyne.[3] *[1]GSK, London, United Kingdom; [2]Analysis Group, Boston, MA; [3]Washington University School of Medicine, St. Louis, MO.*

Background: Studies of ESA hyporesponsivness prior to 2011 showed increased morbidity and mortality potentially associated with high doses of ESA. US ESRD payment change (bundling), introduced in 2011, contributed to lower ESA use and lower targeted hemoglobin and may have altered the relationship of ESA hyporesponse to clinical outcomes.

Methods: Using the CROWNWEB clinical database from 2012-14, we characterised ESA hyporesponder patients (HR) on dialysis and, using inpatient diagnosis codes, evaluated rates of MACE in this population compared to ESA normoresponders (NR). MACE outcomes were modelled using negative binomial regressions. HR were identified using ESA resistance index (ERI) or dose; for epoetin alfa an ERI of ≥2.0 U/kg/wk/g/L or dose of ≥450 U/kg/wk was used.

Results: 119,742 patients met inclusion criteria; 43% (51,544) were classified as HR. At baseline, most were on hemodialysis (HD) (95.7% HR and 97.0% NR) and receiving epoetin alfa (97.0% HR and 95.6% NR); the mean dose (U/kg/wk) in the 2 months prior to index date was 336.0 in HR and 69.5 in NR. HR had a longer dialysis duration (5.7 vs. 4.9 years) and more comorbidities, with a Charlson Comorbidity Index of 3.8 vs. 3.2. Heart failure and coronary artery disease were more common in HR vs. NR, 47.8% vs. 36.3% and 41.1% vs. 35.0%, respectively. However, rates of T2DM were similar (51.5% in HR vs. 53.9% in NR). Over one year of follow up, 23% of patients died (24.1% HR vs. 22.6% NR). MACE and thromboembolic event-related hospitalizations were significantly higher for HR vs. NR (0.14 vs. 0.09 hospitalizations per patient-month). Non-adjusted and adjusted models for MACE incidence rate ratio comparing HR vs. NR are presented in the table below.

Conclusions: Our analysis showed ESA HR and NR have similar one year mortality rates despite epoetin alfa doses 4.8 times higher in HR. However, ESA hyporesponsivness was associated with increased risk of MACE and thromboembolic event related hospitalizations.

Funding: Commercial Support - GlaxoSmithKline

MACE event model results

	Unadjusted model HR vs. NR		Adjusted model HR vs. NR

Effects of Erythropoietin-Stimulating Agents on Blood Pressure in Patients with Non-Dialysis CKD and Renal Anemia

Kohji Ohki, Hiromichi Wakui, Sho Kinguchi, Takahiro Yamaji, Kazushi Uneda, Kotaro Haruhara, Ryu Kobayashi, Kengo Azushima, Yoshiyuki Toya, Kouichi Tamura. *Yokohama City University, Yokohama, Japan.*

Background: Erythropoietin-stimulating agents (ESAs) are widely used for treating renal anemia in patients with non-dialysis chronic kidney disease (CKD). Elevation of blood pressure (BP) is an adverse event of ESA treatment. Rigorous BP control has an important role in managing and treating non-dialysis CKD. Therefore, investigating the effects of ESA treatment on BP is important. This randomized, open-label, parallel-group, controlled study investigated that the effects of two main long-acting ESAs (continuous erythropoietin receptor activator [CERA] and darbepoetin alfa [DA]) on office BP and the ambulatory BP profile in 36 patients with non-dialysis CKD and renal anemia. We also examined the relationships of ESAs with progression of CKD and CVD events.

Methods: Participants were randomly assigned to receive CERA or DA treatment. The doses of ESAs were adjusted to maintain hemoglobin levels within the target range of 10–12 g/dL. In both groups, the antihypertensive therapy was aimed at achieving the target office BP. The primary outcomes were office BP and the ambulatory BP profile at 24 weeks after randomization.

Results: Hemoglobin levels of the two groups were within the target range at 24 weeks after randomization. There were no significant differences in office BP and the ambulatory BP profile, including short-term BP variability, between the CERA and DA groups. Although

some patients required an increase in antihypertensive agents in the CERA and DA groups, the rate of these patients was comparable between the two groups. ESA treatment did not increase BP in both groups. There were no significant differences in vascular function, renal function, and the urinary protein/creatinine ratio between the CERA and DA groups.

Conclusions: Our results suggest that CERA and DA have similar effects on BP in patients with non-dialysis CKD and renal anemia. ESAs can improve anemia without worsening the BP profile with adequate use of antihypertensive agents.

Real-World Experience with C.E.R.A. in Pediatric Dialysis Patients Fits Modeling-Based Predictions: Results from the IPDN Registries

Franz S. Schaefer,[1] Pascal Chanu,[2] Laura Benner,[3] Nicolas Frey,[4] Hui Kim Yap,[5] Karel Vondrak,[6] Paula A. Coccia,[7] IL-Soo Ha,[8] Rainer Büscher,[9] Heiko Billing,[10] Claus Peter Schmitt,[11] Charlotte Samaille,[12] Bradley A. Warady.[13] *[1]University of Heidelberg, Heidelberg, Germany; [2]Roche/Genentech, Lyon, France; [3]Institute of Medical Biometry and Informatics, University of Heidelberg, Heidelberg, Germany; [4]F. Hoffmann-La Roche Ltd, Basel, Switzerland; [5]National University Hospital, Singapore, Singapore; [6]University Hospital Prague-Motol, Prague 5, Czechia; [7]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; [8]Seoul National University Children's Hospital, Seoul, Republic of Korea; [9]University Children's Hospital, Essen, Germany; [10]University Tuebingen, Tuebingen, Germany; [11]Center for Pediatric and Adolescent Medicine, Heidelberg, Germany; [12]CHRU Lille, Lille, France; [13]Children's Mercy Kansas City, Kansas City, MO.*

Background: The International Pediatric Dialysis Network (IPDN, www.pedpd.org) maintains two global registries with children on chronic peritoneal dialysis (IPPN) and hemodialysis (IPHN). We compared registry data to PK/PD modeling and simulation results to validate the modeling approach for Continuous Erythropoiesis Receptor Activator (C.E.R.A.) in children and to examine the use of C.E.R.A. in pediatric patients (pts).

Methods: Among a total of 3225 (IPPN) and 673 (IPHN) pts registered by April 2018 with at least one update, 126 (IPPN) and 32 (IPHN) pts received C.E.R.A. sc (IPPN) or iv (IPHN) and were included in a retrospective assessment of pts characteristics, efficacy (Hb, ferritin) and safety (hospitalization in past 6 months). A model-based evaluation of clinical trial data was conducted in parallel. Subsequent prospective simulations in pediatric pts were performed, i.e. without adjusting for baseline characteristics of IPDN pts.

Results: The mean age (SD) of pts at last visit was 12.0 (6.4; IPPN) yrs and 14.2 (5.3; IPHN) yrs. With median [Q1;Q3] monthly doses (µg/kg body weight) of 3.0 [2.2;4.9] for IPPN and 1.7 [1.1;3.0] for IPHN, mean (SD) Hb levels (g/dL) were 10.8 (1.7; IPPN) and 10.5 (1.8; IPHN). Mean (SD) ferritin levels (µg/L) were 264 (289; IPPN) and 499 (3339; IPHN). In pts with longitudinal follow-up, Hb and ferritin levels were stable during C.E.R.A. treatment. The most common causes of 132 (IPPN) and 41 (IPHN) reported hospitalizations were hypertension and peritonitis (n=19, both) in IPPN and hypertension (n=7) and pyelonephritis (n=5) in IPHN. Results of prospective simulations were in excellent accordance with observed IPDN data: simulated mean [95% CI] Hb levels (g/dL) were 10.9 [10.5;11.3] for sc and 11.0 [10.6;11.3] for iv. Simulated median [95% CI] doses (µg/kg every 4 weeks) after Hb stabilization were 2.7 [2.0;3.9] for sc and 2.3 [1.6;3.2] for iv.

Conclusions: The real-world outcomes regarding steady state C.E.R.A. doses and Hb responses confirm simulations based on models developed with adult and pediatric clinical trial data. With C.E.R.A. the Hb and ferritin levels were within clinical target ranges in peritoneal and hemodialysis settings. No new safety signals were observed.

TH-PO234

Simultaneous Dosing of Iron and ESA Using Model Predictive Control (MPC)

Michael E. Brier, Adam E. Gaweda. *University of Louisville, Louisville, KY.*

Background: Advances have been made to assist the dosing of erythropoietic stimulating agents (ESA) beyond the use of a "paper protocol". These methods have been dependent on either assuming that iron stores are replete or that a separate iron dosing protocol is followed. Since ESA response is influenced by the iron status and changes as patients become iron replete, it would be beneficial to perform these dosing procedures in parallel. We tested the hypothesis that we could develop a MPC algorithm for the simultaneous dosing of both ESA and iron.

Methods: ESA dose prediction was performed using our previously published work (J Am Soc Nephrol 25:159-66 2014). Dose determination is based on an estimate of the red blood cell life span, sensitivity to the ESA and dose of ESA. Further, a close-loop design was used to "feed back" the error between observed and desired Hb. A second MPC model was developed for Iron dosing that determines the dose of iron based on baseline ferritin, iron and Tsat sensitivity to iron administration based on our previously published model (Clin J Am Soc Nephrol 5:576-81, 2010). The current model was developed in Matlab/Simulink. We simulated several iron deficient states with ferritin between 80 and 120 with ESA sensitivity values from 0.1 to 2.0. Simulations were performed to determine the impact of iron supplementation on ESA dose.

Results: The results of the simulations are shown in the following table where the effect of simultaneous iron dosing on total ESA dose is shown. Total iron administered was independent of ESA dosing in this simulation and resulted in 10,000, 8,000 and 4,000 mg over 2 years for ferritins of 80, 100, and 120, respectively.

Conclusions: We simulated the effect of concurrent ESA and iron dosing in ESRD using advanced computational approach. The algorithm optimizes both, ESA and iron dose. Further work needs to be performed on the dynamics of the response during all phases of iron repletion and in the face of elevated ferritin levels due to inflammation.

Funding: NIDDK Support

Effects of Targeting 11 to 13 g/dL of Hb on Renal Outcome in Non-Diabetic Patients with Advanced CKD: A Randomized Control Study, PREDICT

Enyu Imai,[1,2] Terumasa Hayashi,[9] Shoichi Maruyama,[8] Ichiei Narita,[10] Hideki Hirakata,[5] Kenichiro Tanabe,[6] Satoshi Morita,[11] Masaomi Nangaku,[3] Yoshiharu Tsubakihara,[4] Tadao Akizawa.[7] *[1]Nakayamadera Imai Clinic, Takarazuka, Japan; [2]Nephrology, Fujita Health University, Toyoake, Japan; [3]the University of Tokyo School of Medicine, Tokyo, Japan; [4]Graduate School of Health Care Science, Jikei Institute, Yodogawa-ku, Osaka, Japan; [5]Fukuoka Renal Clinic, Fukuoka City, Japan; [6]Foundation for Biomedical Research and Innovation at Kobe, Kobe, Japan; [7]Showa University School of Medicine, Tokyo, Japan; [8]Nagoya University Graduate School of Medicine, Nagoya, Japan; [9]Osaka General Medical Center, Osaka, Japan; [10]Niigata University, Niigata, Japan; [11]Kyoto University, Kyoto, Japan.*

Background: Anemia, a common complication of chronic kidney disease (CKD) is associated with high mortality. Target hemoglobin (Hb) levels using erythropoiesis stimulating agent for CKD remain controversial between 10 and 12g/dL, especially in non-diabetic patients with CKD.

Methods: The open-label randomized controlled trial, PREDICT, aims to study the impact of targeting Hb levels of 11–13 g/dL using darbepoetin alfa with reference to a low Hb target of 9–11 g/dL. The primary outcome is a renal composite endpoint (starting chronic dialysis, kidney transplantation, eGFR 6 mL/min/1.73m^2 or less, and 50% decrease in eGFR).

Results: The study enrolled 479 non-diabetic Japanese patients with eGFR 8–20 mL/min/1.73m^2. Of the 479 patients evaluated, 239 were assigned to maintain high Hb and 240 were assigned to maintain low Hb. Mean Hb level reached at 11.0g/dL at 16 week in high Hb group and maintained at 11.1g/dl during the study, while it was maintained at 10.0 g/dL in low Hb group. Mean doses of darbepoetin alfa in high and low Hb groups were 317 and 185µg/12 weeks, respectively. The renal composite endpoint occurred 105 (43.9%) in high Hb group and 116 (48.3%) in low Hb group (p=0.315 for log-rank test, Cox HR 0.78, p=0.075). Mean GFR reduction rate from baseline was significantly lower in high Hb group than in low Hb group at 24 week (-3.1 vs -11.0 %, p=0.001), 48 week (-11.0 vs -17.6 %, p=0.016), and 72 week (-9.34 vs -18.3%, p=0.024). Cardiovascular events occurred in 19 patients (7.9%) assigned to high Hb group and in 16 patients (6.7%) to low Hb group (HR 1.07, p=0.841). All cause death occurred 14 patients (5.9%) in high Hb group and 11 patients (4.6%) in low Hb group (HR 1.28, p=0.561).

Conclusions: Maintaining Hb at 11-13g/dL compared with Hb 9-11 g/dL by use of darbepoetin alfa did not improve renal outcome in patients with advanced CKD without diabetes, while it did not exacerbate cardiovascular outcome or all cause death. (ClinicalTrials.gov No. NCT01581073).

TH-PO236

Effect of Epoetin on Cardiovascular Disease in Patients Who Initiate Dialysis

Jong hoon Lee,[1] Seung Yun Chae,[1] Insoo Kim,[1] Byung ha Chung,[2] Cheol Whee Park,[1] Chul Woo Yang,[1] Yong-Soo Kim,[1] Bumsoon Choi.[1] *[1]Seoul St. Mary's hospital, Seoul, Republic of Korea; [2]Seoul St. Mary's Hospital, Seoul, Republic of Korea.*

Background: Anemia is a common complication in chronic kidney disease (CKD) patients and is a risk factor for increasing the incidence of cardiovascular disease (CVD). Epoetin used to treat these anemia has also been shown to increase CVD incidence in CKD patients. However, the risk of CVD of Epoetin use in dialysis patients has not yet been determined.

Methods: Data were collected from a prospective observational study in Clinical Research Center for ESRD (CRC-ESRD) registry. A total of 857 patients were enrolled in this study, all of whom received Epoetin and were enrolled in the registry at initiation of dialysis. The relationship between the incidence and mortality of CVD and Epoetin dose was analyzed. The patients were divided into groups by median hemoglobin (Hb) value and dialysis modality, and were analyzed.

Results: A mean dose of Epoetin was 4454.2±5114.0 IU/week. Median Hb level was 10.7g/dL and mean Hb level was 10.9±1.1 g/dL. There was no difference in Hb levels between hemodialysis (HD) patients and peritoneal dialysis (PD) patients. However, Epoetin dose was 4850.1±5370.5 IU/week in HD patients, which was significantly higher than 2753.2±3335.7 IU/week in PD patients (p<0.001). In the low Hb group, the mean Hb was 10.1±0.6 g/dL and the epoetin dose was 6206.2±5651.5 U/week. In the high Hg group,

the mean Hb was 11.7±0.8 g/dL and the epoetin dose was 2732.1±3811.8 IU/week. Hb level and epoetin dose were significantly different between the two groups. The dose of Epoetin has a correlation with CVD event in HD patients ($p<0.001$), but not in PD patients ($p>0.05$). The incidence of CVD was 77 cases in the low Hb group which is significantly high than 49 cases in the high Hb group ($p=0.003$). The Epoetin dose and CVD incidence were related in low Hb and high Hb group, respectively (each $p<0.05$). The CVD mortality was also associated with Epoetin dose in HD patients ($p=0.009$).

Conclusions: Epoetin dose is associated with CVD incidence and mortality in patients who initially initiate hemodialysis.

TH-PO237

Renal Outcome by Different Target Hemoglobin Levels Using Epoetin Beta Pegol in Predialysis CKD Patients with ESA Hyporesponsiveness: A Multicenter Open-Label Randomized Controlled Study (RADIANCE-CKD)

Terumasa Hayashi,[1] Hiroyasu Yamamoto,[2] Kazuhiko Tsuruya,[3] Hiroki Hase,[8] Shinichi Nishi,[4] Kunihiro Yamagata,[5] Masaomi Nangaku,[6] Takashi Wada,[7] Yukari Uemura,[10] Yasuo Ohashi,[9] Hideki Hirakata.[11] *[1]Osaka General Medical Center, Osaka, Japan; [2]Division of Nephrology and Hypertension, Department of Internal Medicine, Jikei University School of Medicine, Tokyo, Japan; [3]Nara Medical University, Kashihara, Japan; [4]Kobe University Graduate School of Medicine, Kobe, Japan; [5]University of Tsukuba, Tsukuba, Japan; [6]the University of Tokyo School of Medicine, Tokyo, Japan; [7]Kanazawa University, Ishikawa, Japan; [8]Toho University Ohashi Medical Center, Tokyo, Japan; [9]University of Tokyo, Tokyo, Japan; [10]Tokyo University Hospital, Tokyo, Japan; [11]Fukuoka Renal Clinic, Fukuoka City, Japan.*

Background: Although ESA hyporesponsiveness has emerged with respect to a poor renal and overall survival in CKD patients, appropriate ESA treatments to patients with ESA hyporesponsiveness remain uncertain.

Methods: We randomly assigned 362 predialysis CKD patients with ESA hyporesponsiveness to the intensive treatment group (target hemoglobin [Hb] level ≧ 11g/dl) and conservative treatment group (target Hb level; baseline Hb levels ± 1g/dl) using epoetin beta pegol (CERA). The primary renal composite endpoint was a transition to renal replacement therapy, a reduction of eGFR to less than 6ml/min/1.73m2 or a reduction of eGFR more than 30%. The observation period was 21 months from the assignment.

Results: Mean age was 74.7 years and 58.6% were male. Mean baseline eGFR in the intensive and conservative groups were 15.3 and 15.9ml/min/1.73m2, respectively. Mean baseline hemoglobin level was similar of 9.9g/dl in both groups despite an appropriate and similar median dose of ESA (86 and 100 μg/month for CERA, P 0.913; 120 and 80 μg/month for darbepoetin alfa, P 0.136, respectively). Mean Hb levels during observation period in each group were 10.44 and 10.05 g/dl ($P < 0.0001$) and median doses of CERA were 120.0 and 96.3 μg/month, respectively ($P < 0.0001$). Kaplan-Meier analysis showed no significant difference in the primary end point between the two groups (99 and 109 events; log-rank test, P 0.837). Cox proportional hazards analysis also showed no significant difference between the two groups (Hazard ratio, 0.972; 95% confidence interval, 0.74 to 1.28; $P = 0.84$. The incidence of cardiovascular events (CVEs) was not different in both groups [20 (10.9%) and 24 (13.4%) patients, respectively (P 0.522)]. Heart failure accounted for approximately 65% of CVEs in both groups.

Conclusions: Although there was no significant difference in renal outcome, our results suggest that targeting Hb level of 11g/dl or higher using CERA may be safe in terms of CVEs in predialysis Japanese CKD patients with ESA hyporesponsiveness. This study is funded by Chugai Pharmaceutical Co., Ltd.

The Pursuit of a More Physiologic Iron and ESA Treatment: Results from a Triferic and Individualized ESA Protocol QA Project

Yossi Chait,[1] Jonathan Slater,[2] Brian H. Nathanson,[3] Michael J. Germain.[2] *[1]University of Massachusetts, Amherst, MA; [2]Renal and Transplant Assoc of New England, Springfield, MA; [3]OptiStatim, LLC, Longmeadow, MA.*

Background: We implemented a new standard of care (SOC) anemia protocol using a web-based tool that individualizes Aranesp treatments and uses Triferic for iron supplementation. The objective was to observe changes in anemia parameters.

Methods: A QA project was conducted in a single hemodialysis (HD) clinic in 6/16-4/18: the standard bi-weekly Aranesp protocol and Venofer (phase A), Triferic replacing Venofer (phase B, 2 months "washout"+6 months), a new web-based weekly Aranesp dose titration tool and Triferic (phase C, 2 months "washout"+6 months). Target Hgb range was 9-11 g/dL with means 10 and 10.2 in phases A-B and C, respectively, and Tsat>30%. Monthly stats included patients who *received at least one Aranesp dose during the recent 3-months period.* We compared clinic-level monthly means for anemia related variables corresponding to standard SOC (6 months prior to phase B) and phases B and C using ANOVA with repeated measures and Cuzick's nonparametric test for trend.

Results: A total of 105 patients were treated at the clinic during the 3 project phases. Monthly totals varied due to transfers, transplantation, and death (11, 10.5%). Demographics mean (SD) age 61.6 (15.4) years, 52 female (50%), 35 Latino (33%), 25 (24%) white, 20 (19%) black, 6 (6%) Asian, and 19 (18%) unknown. Anemia results for each phase are shown in Figure 1. Hgb means increased with the higher target mean; mean ferritin levels were significantly lower in phase C vs phase A or phase B ($p<0.001$); Tsat levels modestly decreased compared to phase A but remained on target; and mean Aranesp and mean total iron (Venofer and/or Triferic) were lower but statistically similar across protocols.

Conclusions: A more frequent dosing schedule, which integrates Triferic for iron management with a web-based tool for individualized Aranesp treatments, performed better than a standard anemia protocol in HD patients. Patients were more likely to have Hgb in the target range or higher, lower but not significantly different dosages of Aranesp and total iron, reduced Ferritin levels and maintain Tsat levels on target.

Intravenous Ferric Carboxymaltose Is Efficacious and Safe in Management of Iron Deficiency Anemia Among Hemodialysis Patients

Mahmoud H. Imam, Mohammed Shawki. *Internal Medicine Department, Faculty of medicine,Benha University, Benha, Egypt.*

Background: Anemia has a high prevalence among hemodialysis patients. Therapy mainly includes erythropoietin (EPO) and iron supplementation. Ferric carboxymaltose is a recent intravenous iron that proved to be efficacious among nondialysis CKD patients with no data regarding its use among dialysis patients. The aim of this study is to assess the efficacy and safety of Ferric carboxymaltose among hemodialysis patients.

Methods: In this prospective randomized study, 104 patients on maintenance hemodialysis were recruited. Inclusion criteria included: anemia (hemoglobin less than 10 gm/dL) and inadequate iron status (ferritin level < 200 mg/dL and TSAT < 20%). Exclusion criteria included: patient received other forms of iron within the last 4 weeks or a patient has recent blood loss event. Patients were randomized to receive either intravenous Ferric carboxymaltose (once weekly)or Iron *Sucrose* (three times weekly). Hemoglobin hematocrit, ferritin, and TSAT were recorded at baseline and after 4 and 8 weeks. The dose of EPO was kept the same as before the study for patients already on EPO and on a fixed initial EPO dose for naive patients. Adverse effects including pain at injection site, allergy, fever were documented. ANOVA test was performed to compare the means of hemoglobin and iron studies. Chi x2 test was performed to compare the frequency of adverse effects between the two groups. Linear regression analysis was done to assess the likelihood of response to IV Ferric carboxymaltose.

Results: The mean age of patients was 56.4 ± 12.2 years. Female patients were 46%. In the Ferric carboxymaltose group, the mean ferritin increased from 148 ± 34 to 634 ± 154 ng/mL (95% CI: -527.07 to -444.92, p. value < 0.001). in Iron *Sucrose* group, mean ferritin increased from 134 ± 42 to 596 ± 112 ng/mL (95% CI: -491.8 to -432.12; p-value < 0.001). There was no significant difference in the increase in both ferritin and TSAT between the two groups. In addition, There was no difference in the frequency of adverse effects among the two groups.

Conclusions: Intravenous Ferric carboxymaltose is efficacious in restoring iron repletion with tolerable adverse effects.

Real World Experience: A Conversion of Haemodialysis Patients from Iron Sucrose to Iron Isomaltoside

Jorge Jesus Silva,[1] James Burton.[1,2] *[1]John Walls' Renal Unit, University Hospitals of Leicester, Leicester, United Kingdom; [2]Department of Infection, Immunity & Inflammation, University of Leicester, Leicester, United Kingdom.*

Background: Anaemia is common in haemodialysis (HD) patients, and associated with significant morbidity and mortality. Intravenous (IV) iron combined with erythropoietin (EPO) is the mainstay treatment of anaemia in these patients. Iron isomaltoside 100, 5% (Diafer) is the newest IV iron available to HD patients in the UK. **Objective:** To assess the efficacy and safety of converting patients from iron sucrose (IS) to iron isomaltoside (IIM).

Methods: The clinical notes of 880 HD patients were retrospectively reviewed for the period between September 2015 - April 2017. 633 were prescribed IIM of which 97 patients made a direct switch from IS to IIM. Haemoglobin (Hb), ferritin (FER), transferrin saturation (TSAT), and EPO dose were collected 1 month before conversion (T-1), month of first IIM dose (T0), 6 (T6) and 12 (T12) months post conversion. ANOVA or Friedman tests were used for statistical analyses with post-hoc adjustment for multiple comparisons using T0 as control.

Results: Differences in clinical variables are shown in the table. There was a statistically significant effect on Hb over time although after converting (T0), there was no significant change at 6 or 12 months. There were significant improvements in ferritin and TSAT over time, which remained at 6 months for both ($P<0.01$) and at 12 months for TSAT ($P<0.05$). There was an overall decrease in weekly iron dose that was significant at 12 months ($P=0.02$) and no change in EPO dose. In total there were 28,125 prescriptions of IIM and 8,145 of IS with no difference in reported adverse events during the audit period (6 each, none required adrenaline).

Conclusions: Hb, TSAT and FER were maintained at satisfactory levels for at least 12 months post-conversion, indicating that the drugs have similar efficacy with no difference in reported adverse events.

	T -1	T0	T6	T12	P value
Hb (g/L) (M / SD)	108.5±13.7	112±13.7	114.3±12.2	111.7±10.9	<.01
Ferritin (ug/L) (mdn / IQR)	305 (204-398)	288 (204-404)	374 (255-490)	338 (220-447)	0.01
TSAT (%) (mdn / IQR)	21.5 (16-28)	20 (15-27)	25.5 (19-34)	24 (16-32)	<.001
Weekly Fe dose (mg) (mdn / IQR)	50 (50-100)	50 (50-50)	50 (25-100)	50 (25-50)	<.001
Weekly EPO dose (U) (mdn / IQR)	9000 (4000-12000)	9000 (4000-12000)	6000 (3000-12000)	8000 (3000-12000)	0.4

TH-PO241

When It Comes to Intravenous Iron, More or Less, Outcomes Are Same

Srikanth Thiruvarudsothy,[1,2] Theesitha Srikanth,[3] Jennine Michaud,[2] Michael Yudd.[2] *[1]Rutgers New Jersey Medical School, Newark, NJ; [2]Nephrology, Veterans Administration, East Orange, NJ; [3]West China School of Medicine, Chengdu, China.*

Background: Intravenous (IV) iron supplementation is required in the management of anemia in most chronic hemodialysis patients. Although iron supplementation will replete iron stores and provide available iron to maximize effectiveness of erythropoietin stimulating agents (ESAs), it is a potent oxidant and known for having several potentially toxic side effects including worsening of infections and iron overload. Thus, lower doses of iron would be preferable, provided anemia is adequately managed and ESA requirements are not increased as a result.

Methods: In a single hemodialysis unit of 48 male veterans, we prospectively treated patients with standard dosing of IV sodium ferric gluconate (loading dose: 1000mg when transferrin saturation (Tsat) <20% and/or ferritin <100 μg/L or maintenance dose: 500mg when Tsat 20-50% and ferritin 100-800 μg/L), to maintain a hemoglobin (hb) level of 10-11 g/dL. Iron loading dose was 125mg IV with each dialysis treatment X 8 doses and maintenance dose was 125mg IV weekly X 4 weeks. The subsequent six months, iron dosing was reduced by half, and all other treatments were continued per protocol. Hb and iron parameters were assessed throughout the treatment periods, along with dosing requirements of erythropoietin and iron.

Results: There were no differences seen in the hb and iron profile during the standard vs reduced dosing periods, hb (mean 10.46 g/dL SD 1.57 vs mean 10.41 g/dL SD 1.39, p=0.72), Tsat (mean 22.83% SD 11.99 vs mean 24.76% SD 12.69, p=0.086) and ferritin (mean 565 μg/L SD 410 vs mean 606 μg/L SD 419, p=0.11). During the 6 month standard dosing period, 19.1% of the patients received IV iron and 23.8% during the reduced dosing period. The average amount of iron administered was 126.6mg/month in the standard dosing group and 51.2mg/month in the reduced dosing group. Erythropoietin dosage was similar during the two periods: 16,517 units/week (SD 8413) vs 14,064 units/week (SD 8612) respectively, p=0.055, however, more patients required erythropoietin treatment (32.8% vs 52.4%).

Conclusions: In our study population, iron stores were equally maintained during the standard dosing compared to a 50% reduction in IV iron administration, but more patients required ESA therapy. Implementation of a lower dosing IV iron regimen may mitigate potential adverse effects of iron supplementation without effecting iron stores.

TH-PO242

Risk of Infection Post Intravenous Iron Therapy in Patients with Anemia of CKD

Summer Dyer,[1] Chai L. Low,[1] Hugh V. Nguyen.[2] *[1]VA San Diego Healthcare System, Cardiff, CA; [2]VA San Diego, San Diego, CA.*

Background: The use of intravenous (IV) iron therapy has escalated in the treatment of anemia of chronic kidney disease (CKD) in order to optimize hemoglobin outcomes with the use of erythropoiesis-stimulating agents. The risk of infection associated with IV iron administration in patients with non-dialysis-dependent CKD has not been well defined. The purpose of this study was to investigate the risk of infection in patients with non-dialysis-dependent CKD who have received IV iron versus those patients who have not received IV iron within 3 months post index date.

Methods: This was a retrospective cohort, single center study of patients receiving care at the VA San Diego Healthcare System. Patients were included if they were enrolled in an outpatient CKD clinic from January 1, 2014 to June 1, 2017. Patients were excluded if they had end stage renal disease, active infection, or had an active prescription for immunosuppression therapy. The treatment arm included patients who had received at least one dose of IV iron for treatment of anemia of CKD. The control arm included patients enrolled in CKD clinic who did not receive IV iron during the study period. Control patients were matched to the treatment arm patients in a 3:1 ratio based on the season of their index date. Infection was defined as prescription of IV or PO antibiotic within 3 months post index date. Chi square test was performed to determine statistical significance for our primary outcome.

Results: 33 out of the 411 (8.0%) control patients and 22 out of the 136 (16.2%) IV iron patients developed at least one infection over the course of 3 months after the index date (p=0.006). CKD patients who received IV iron where twice as likely to develop an infection versus CKD patients who did not receive IV iron (OR=2.21, 95% CI 1.2-3.9).

Conclusions: This study provides support that the use of IV iron is associated with increased infection risk in the non-dialysis-dependent CKD population. This study however is limited in the ability to account for all baseline confounding variables between our study populations as it is retrospective in nature. A prospective study will be imperative to further investigate this increased risk of infections associated with IV iron therapy. Thoughtful consideration of the risks and benefits are warranted in prescribing IV iron for the treatment of iron deficiency anemia in CKD.

TH-PO243

Effect of Intravenous Ferumoxytol on Serial Platelet Counts in CKD Patients with Iron Deficiency Anemia

Terry Le,[1] Vittal Chundru,[1] Neville R. Dossabhoy.[1,2] *[1]LSU Shreveport School of Medicine, Shreveport, LA; [2]VA Medical Center, Shreveport, LA.*

Background: Iron deficiency often leads to reactive thrombocytosis; theoretically, its correction should lead to a lowering of the platelet count (PLT). Only a few studies have investigated this aspect, with some showing a reduction in PLT, whereas others did not. We investigated the effect of iron repletion with intravenous (IV) ferumoxytol (Fm) on serial PLT counts in CKD patients with iron deficiency anemia (IDA).

Methods: We conducted a retrospective chart review, including all patients with CKD and IDA who were treated with IV ferumoxytol at our medical center during a 24-month period. Patient demographics were recorded, as were baseline laboratory values for creatinine, eGFR, hemoglobin (Hgb), hematocrit (HCT), iron, transferrin saturation, ferritin and PLT. The serial counts for Hgb, HCT and PLT continued to be recorded at 1, 2, 3, 4, 6, 8, 12 and 16 weeks after the Fm dose. If data was unavailable at the exact time point, the nearest date was used if within a week.

Results: A total of 264 doses of IV ferumoxytol (each 510 mg) were given in 119 patients with age 57±13 years, Creatinine 3.1±1.5 mg/dL, eGFR 26±12 mL/min, Hgb 10.2±1.3 g/dL, T-sat 16.5±6 % and PLT 242±85. All CKD stages were represented in the study sample. Hgb and Fe stores improved post-dose. The change in post-dose PLT over time is depicted in the table below. In fact, PLT were reduced compared to baseline throughout the 16-week period of follow-up, reaching statistical significance at weeks 3, 6, 8, 12 and 16.

Conclusions: Correction of iron deficiency significantly lowered PLT in CKD patients with IDA who received IV ferumoxytol. This finding stands in contrast to some previous evidence that PLT counts were not significantly reduced with IV iron dextran used as total dose infusion. Our findings may help guide choice of IV iron therapy, given the possibility that increased PLT in the short-term post-dose period may contribute to the thrombotic events noted in clinical trials of erythropoiesis stimulating agents in CKD patients.

	Baseline	Week 1	Week 2	Week 3	Week 4	Week 6	Week 8	Week 12	Week 16
N	264.00	51.00	56.00	45.00	54.00	79.00	108.00	130.00	121.00
PLT	241.73	218.16	219.73	200.44	220.28	208.19	217.15	212.66	222.43

TH-PO244

Once Daily versus Twice Daily Oral Iron for Iron Repletion in CKD: A Randomized, Controlled, Open Label Trial

Vivek Kumar,[1] Vivek D. Sood,[2] Samir Malhotra,[2] Krishan Lal L. Gupta,[3] Kajal Kamboj.[4] *[1]Postgraduate Institute of Medical Education and Research, Chandigarh, India; [2]PGIMER, New Delhi, India; [3]Postgraduate Institute of Medical Education & Research, Chandigarh, India; [4]Nephrology, PGIMER Chandigarh, Chandigarh, India.*

Background: In healthy individuals, the amount of iron absorbed with once daily (OD) dosing has been shown to be as good as with twice daily (BD) dosing despite double cumulative dose with BD dosing. Increase in serum hepcidin impairs absorption from subsequent dose when multiple doses are given. Oral iron supplementation, given as divided daily doses, is commonly prescribed in pre-dialysis CKD as iron deficiency and anemia are common. Therefore, in view of recent findings of impaired iron absorption with multiple daily dosing in normal individuals, we decided to compare iron repletion by OD versus BD oral iron dosing in subjects with stage G3-4 CKD and iron deficiency. The primary objective was difference in change in % transferrin saturation (%TS) between groups over 12 weeks. The main secondary objectives were differences in change in serum ferritin and blood hemoglobin over 12 weeks.

Methods: In this open label, randomized, controlled trial (CTRI/2017/02/007799 at ctri.nic.in), stable adult subjects with CKD stage G3-4 and iron deficiency (%TS <30 % and serum ferritin <500 ng/ml) were randomized (1:1) to receive tablets of ferrous ascorbate (equivalent to 100 mg elemental iron) in either OD (one tablet daily, total 100 mg) or BD (one tablet twice daily, total 200 mg) dosage. Hemoglobin <9 g/dL, iron use in last 3 months, previous gastrointestinal disease, bleeding or use of anti-acid drugs were exclusion criteria. Repeated measure ANOVA was used to assess change in % TSAT and serum ferritin over 2, 6 and 12 weeks in either dosage group and test the interaction of dosage form with change in % TSAT and serum ferritin in study population.

Results: Out of 328 screened subjects, 80 were enrolled. At baseline, the groups were similar except for higher hemoglobin and eGFR in the OD group. In both groups, there were significant effects (increase) of the dosage group on % TS and serum ferritin. However, there were no interaction between the dosage group and change in %TS [Wilks' Lambda=0.951, F (3, 222) = 1.359, p=0.258] or change in serum ferritin [Wilks' Lambda=0.916, F (2.533, 187.450) = 2.666, p=0.059] or change in hemoglobin. Interestingly, there was significant interaction of dosage group with change in MCHC with significant rise in OD group ($p < 0.001$).

Conclusions: Iron incorporation in hemoglobin might be better with OD dosing.

Effect of Oral Ferric Maltol on Iron Parameters in Patients with CKD and Varying Degrees of Inflammation; A Randomized, Controlled Trial

Nelson P. Kopyt. AEGIS-CKD Study Group *Lehigh Valley Hospital, Allentown, PA.*

Background: The incidence of anemia increases with the severity or stage of CKD. Further, some patients with CKD have chronic inflammation, which can reduce the absorption and utilization of iron, including that from oral ferrous iron products. Alternative intravenous iron administration can be inconvenient and has the risk of allergic reactions or iron overload. Patients with CKD and iron-deficiency anemia (IDA) would benefit from an oral iron replacement therapy that is effective irrespective of the degree of underlying inflammation.

Methods: In this phase 3, multicenter, randomized, controlled trial (NCT02968368), patients aged ≥18 years with CKD (estimated glomerular filtration rate ≥15 to <60 mL/min/1.73 m²) and IDA were randomized 2:1 to ferric maltol or placebo orally 30 mg twice daily for 16 weeks. IDA was defined as hemoglobin ≥8.0 g/dL to <11.0 g/dL, and either ferritin <250 µg/L with transferrin saturation (TSAT) <25% or ferritin <500 µg/L with TSAT <15%. Changes in iron storage indices were assessed at weeks 4, 8, and 16 for different levels of high-sensitivity C-reactive protein (hsCRP).

Results: 111 patients were randomized to ferric maltol and 56 to placebo. In the intent-to-treat population (last observation carried forward), the mean change in ferritin from baseline to week 16 for ferric maltol vs placebo was 25.32 vs –3.67 µg/L for those with hsCRP <1 mg/L, 32.54 vs –3.88 µg/L for those with hsCRP ≥1 to ≤3 mg/L, and 23.78 vs –12.87 µg/L for those with hsCRP >3 mg/dL. Corresponding changes in TSAT concentrations from baseline to week 16 were 3.95% vs –1.89% in ferric maltol recipients vs placebo recipients with hsCRP <1 mg/L, 3.31% vs –0.12% in those with hsCRP ≥1 to ≤3 mg/L, and 3.86% vs –0.97% in those with hsCRP >3 mg/dL.

Conclusions: Ferric maltol improved iron parameters – ferritin and TSAT – from baseline to week 16 vs placebo in patients with IDA and CKD irrespective of the degree of chronic inflammation.

TH-PO246

Effect of Oral Iron on Serum Hepcidin and Erythroferrone in CKD Patients

Bhupesh Panwar,[2] Rebecca L. Womack,[3] Orlando M. Gutierrez.[1] *[1]UAB School of Medicine, Birmingham, AL; [2]The University of Alabama at Birmingham, Birmingham, AL; [3]University of Alabama at Birmingham, Birmingham, AL.*

Background: Hepcidin regulates iron metabolism by blocking iron egress from iron-handling cells. Erythroferrone (ERFE) is a hormone that is stimulated by erythropoietin and directly inhibits hepcidin production. Despite the key role of both hormones in iron metabolism, little is known about the change in hepcidin and ERFE in response to oral iron in CKD patients.

Methods: A total of 24 patients with stage 3b-4 CKD and iron deficiency were randomized to take either ferric citrate (FC;n=12, 2 gms tid with meals) or ferrous sulfate (FS;n=12, 325 mg tid) for 12 weeks. Follow-up visits were done 2, 6 and 12 weeks after baseline, at which time serum samples were collected to measure hepcidin and ERFE. Linear mixed models were used to examine changes in hepcidin and ERFE overtime and whether this differed by treatment arm.

Results: There were no significant differences in baseline characteristics by treatment arm [Figure1]. Serum TSAT and ferritin increased by 10% and 37%, respectively, in the FC arm and 0.1% and 6%, respectively, in the FS arm after 12 weeks. The change in serum hepcidin differed by randomization arm (P=0.03). Hepcidin concentrations significantly increased in participants taking FC but not those taking FS [Figure2]. There was no significant change in serum ERFE over time in either group.

Conclusions: Treatment with FC, but not FS, increased serum hepcidin in CKD patients. Neither drug significantly changed ERFE.

Oral Iron Administration (OIA) Transiently Increased Serum Malondialdehyde Modified Low-Density Lipoprotein (MDA-LDL) and Non-Transferrin Bound Iron (NTBI) in Hemodialysis (HD) Patients

Noriko Saito,[1] Kazuhide Saito,[2] Tetsuo Morioka,[1] Hisaki Shimada,[1] Katsuya Ikuta,[4] Yutaka Kohgo,[3] Shigeru Miyazaki.[1] *[1]Nephrology, Shinraku-en Hospital, Niigata, Japan; [2]Urology, Niigata University, Niigata, Japan; [3]International University of Health and Welfare, Nasushiobara, Japan; [4]Asahikawa Medical University, Asahikawa, Japan.*

Background: Intravenous iron administration may increase NTBI which appears in iron overload and cause organ damage through free radical production. OIA is not considered to increase NTBI because of slow iron adsorption rate. Aim of this study is to assess the kinetics of transferrin saturation(TSAT), NTBI and MDA-LDL in HD patients after OIA.

Methods: 16 HD patients without any iron load within 4 weeks, whose Hb<12g/dl, ferritin<100ng/ml and CRP<1.0mg/dl and 8 healthy volunteers were enrolled. Both groups received oral ferrous sulfate 105mg. We evaluated the following markers before and at 1,2,3,4 and 48 hours(hrs) after OIA : MDA-LDL, NTBI, Hepcidin-25(HPC), serum iron(Fe), TSAT, ferritin and standard hematological parameters. Vitamin C(VC) and selenium(Se) were measured before and 48hrs. Other 9 HD patients without OIA were also enrolled as HD control. MDA-LDL was measured by ELISA. NTBI was measured by recently described reliable method(Clin Chim Acta437:129-135, 2014).

Results: 1. Fe before OIA was 30(24-49)µg/dl and significantly increased at 1hr and reached the peak level of 272(104-320)µg/dl at 4hrs (medians(interquartile range)). 2. MDA-LDL before OIA was 97(68-124)U/L and significantly increased to 116(73-166)U/L at 1hr and reached the peak level of 121(81-165)U/L at 3hrs and decreased to 117(79-134) U/L at 48hrs, not significantly different from the level before OIA. 3. TSAT before OIA was 12(7-17)% and significantly increased at 2hrs, reached the peak level of 70(34-80)% at 4hrs. 4. NTBI before OIA was 0.02(0-0.10)µM and significantly increased to 0.15(0.03-0.56) µM at 4hrs. 5. HPC before OIA was very low (0.55(0.14-1.78)ng/ml) and unchanged during 48hrs. 6. In healthy and HD controls Fe, MDA-LDL, TSAT, NTBI and HPC were not significantly changed during 48hrs. 7. VC before OIA in HD patients was 3.0(1.8-6.2) mg/ml and significantly lower than that in healthy volunteers (7.7(6.5-10.7) mg/ml). 8. Se before OIA in HD patients was 14.5(12.5-16.1) mg/dl and significantly lower than that in healthy volunteers (18.4(17.6-20.3) mg/dl).

Conclusions: Fe and MDA-LDL at 1hr, TSAT at 2hrs, and NTBI at 4hrs significantly increased after OIA in HD patients. The lower anti-oxidant level in HD patients may influence the early increase of MDA-LDL.

Economic Burden of Anemia-Related Transfusions in Medicare Dialysis Patients

David T. Gilbertson,[1] Suying Li,[1] Tara Matsuda,[2] Yi Peng,[1] Vasily Belozeroff,[2] Nisha Bhatt,[2] James B. Wetmore.[3] *[1]Chronic Disease Research Group, Minneapolis, MN; [2]Amgen, Thousand Oaks, CA; [3]Hennepin County Medical Center, Minneapolis, MN.*

Background: Red blood cell transfusions are unwanted outcomes of poor anemia management, and remain important enough that Medicare has instituted a quality measure to ensure adequate care of dialysis patients. Previous studies investigated the burden of transfusions in Medicare dialysis patients, but did not investigate anemia-related transfusions (in the absence of another acute medical indication), or costs of inpatient transfusions due to anemia. We estimated Medicare spending for both inpatient and outpatient transfusions administered solely to manage anemia.

Methods: We used the USRDS dataset to analyze patients receiving dialysis in 2014. We included Medicare Parts A/B patients on dialysis at the beginning of 2014 and those initiating dialysis during 2014. Transfusions were identified using an algorithm requiring

ICD-9 procedure and/or revenue center codes. We identified hospitalizations with 0- or 1-day stays with anemia as the principal diagnosis and no evidence of another reason for the hospitalization based on other diagnosis, procedure, and DRG codes. We identified outpatient, emergency department (ED), and observation (Obs) stays that appeared to be solely for transfusions. We calculated associated total Medicare paid costs by identifying costs directly associated with the transfusion and related costs for screening or monitoring in the pre- (day -3 to day -1) and post- (day 1 to day 3) period, and post-transfusion-related complications.

Results: We identified 9669 transfusions associated with anemia in the absence of other acute illness: 974 inpatient, 1264 ED/Obs, 7431 other outpatient. Total Medicare payments for these transfusions were $13.78 million: $7.37 million inpatient, $1.47 million ED/Obs, $4.95 million other outpatient. Inpatient transfusions accounted for 10% of total anemia-related transfusions, but for over 50% of total transfusion costs.

Conclusions: Costs related to anemia-induced transfusions are substantial. Savings can be potentially achieved by more closely following anemia treatment guidelines, and using outpatient settings in lieu of more expensive care settings.

Funding: Commercial Support - Amgen

Setting for Transfusions	N	Transfusion Costs	Related Costs	Total Costs	Costs per Transfusion
Inpatient	974	$7,362,817	$4,271	$7,367,088	$7,564
ED/Obs	1,264	$1,451,228	$15,392	$1,466,620	$1,160
Other outpatient	7,431	$4,741,086	$206,339	$4,947,425	$666
Total	9,669	$13,555,131	$226,002	$13,781,133	$1,425

Anemia Treatment Patterns in CKD: Results from Three International Surveys Among Physicians

James Jackson,[1] Heleen van Haalen,[2] Hanna Salehi,[1] Gary R. Milligan,[1] Rebecca Moon.[1] *[1]Adelphi Real World, Macclesfield, United Kingdom; [2]AstraZeneca, Gothenburg, Sweden.*

Background: Patients with chronic kidney disease (CKD) are at risk of developing anemia. We describe the use of anemia medications, internationally and in the US, by year, by Hb level and across CKD stages.

Methods: Data were drawn from the 2012, 2015 & 2018 Adelphi CKD Disease Specific Programmes. The real-world, point in time surveys included data from physicians (mostly nephrologists) and a random sample of their CKD patients across France, Germany, Italy, Spain, United Kingdom (EU5; included in 2012 and 2015), US (all years) and China (2015 only). Disease and treatment information, including oral iron, IV iron and erythropoiesis-stimulating agents (ESAs), was provided by the physicians and was analyzed descriptively. Blood transfusions were not considered.

Results: Data were available from 5488 non-dialysis (NDD) and 3490 dialysis (DD) patients (1350 and 1255 from the US, respectively). The overall prevalence across regions of Hb<10 g/dL was 8%, 7%, 15%, 20%, and 19% in patients CKD stage 3a, 3b, 4, 5 and dialysis, respectively, which increased slightly over time. Across regions, these patients were more likely to be treated for anemia in higher CKD stages. Although treatment rates varied by practice type, the overall proportion of US patients prescribed anemia medication increased to 42% of NDD patients (and varied by Hb levels; **figure**) and 80% of DD patients in 2018. The proportional use of ESAs in US NDD patients decreased from 75% to 49%, yet was stable in DD patients. In 2015, proportional ESA use in NDD patients was higher in EU5 countries than in the US.

Conclusions: CKD-anemia is most often treated in DD patients. Medication rates in NDD patients increased over time, yet anemia prevalence also increased, suggesting that anemia management can be optimized.

Associations of Hemoglobin Levels and Quality of Life in Patients with CKD: Pooled Results from Three International Surveys

James Jackson,[1] Heleen van Haalen,[4] Hanna Salehi,[1] Gary R. Milligan,[2] Rebecca Moon.[3] *[1]Adelphi Real World, Macclesfield, United Kingdom; [2]Adelphi Real World, Macclesfield, United Kingdom; [3]Adelphi Real World, Macclesfield, United Kingdom; [4]AstraZeneca, Gothenburg, Sweden.*

Background: Anemia is a common comorbidity in patients with chronic kidney disease (CKD), which can affect patients' quality of life (QoL). The current study aims to determine the burden of anemia in CKD, by analyzing patients' QoL by CKD stage and hemoglobin (Hb) levels.

Methods: Data were drawn from the 2012, 2015 & 2018 Adelphi CKD Disease Specific Programmes. The real-world, point in time surveys included data from physicians and a random sample of their CKD patients across France, Germany, Italy, Spain, United Kingdom (EU5), USA and China. Data were pooled to create a large cross-sectional dataset. Patient demographics, disease characteristics and concomitant conditions were provided by the physicians. Patients completed the Kidney Disease Quality of Life Instrument (KDQOL), including the short form 12 (SF-12), and the EuroQol Visual Analog Scale (EQ VAS). Multivariable analyses were performed on SF-12 and EQ VAS scores, adjusting for age, sex, CKD stage, common comorbidities and CV risk.

Results: KDQOL and EQ VAS results were available for 2781 and 2789 NDD patients and 1749-1726 DD patients, respectively. As CKD stage increased, patients' QoL deteriorated across all KDQOL domains. In the total population, lower Hb levels were associated with lower KDQOL and EQ VAS scores (Table). This association was also apparent within CKD stages. Adjusted analyses showed statistically significant positive associations between Hb level and the SF-12 physical and mental summary scales as well as EQ VAS scores (all $p<0.001$), which were numerically strongest in patients not on dialysis.

Conclusions: This study revealed a consistent relation between lower Hb level and deteriorated QoL, which was significant when adjusted for potential confounding factors. Anemia should be recognized as a contributing factor to lower QoL in patients with CKD.

Incidence, Prevalence, and Correlates of Anemia and Iron Deficiency in US Veterans with Non-Dialysis Dependent CKD (NDD-CKD)

Carl P. Walther, Peter Richardson, Maulin Shah, Sreedhar A. Mandayam, Wolfgang C. Winkelmayer, Sankar D. Navaneethan. *Baylor College of Medicine, Houston, TX.*

Background: Anemia in CKD is often multifactorial, including from low erythropoietin production, absolute (true) iron deficiency, and functional iron deficiency related to a chronic inflammatory state. However, there is limited evidence regarding the incidence, prevalence, and correlates of anemia and iron deficiency in NDD-CKD, which is the objective of this study.

Methods: We identified persons with NDD-CKD receiving care through the Veterans Affairs healthcare system from 2005-2015. Eligible patients had ≥2 eGFRs <60ml/min/1.73m^2 separate by >90 days and a Hgb measured within 180 days of the 2nd measured eGFR. We calculated incidence and prevalence of anemia (Hgb<12g/dl), characterized concurrent iron parameters (iron deficiency: absolute, transferrin saturation [TSAT] ≤20% and ferritin <100ng/ml; functional, TSAT ≤20% and ferritin ≥100ng/ml), and identified correlates of iron deficiency status using logistic regression.

Results: We included 944,175 persons with NDD-CKD and measured Hgb. At incident eGFR <60, 78.4% were non-anemic, 16.9% had mild (Hgb 10-<12g/dl), 4% moderate (Hgb 8-<10g/dl), and 0.6% severe anemia (Hgb <8g/dl). Incidence of anemia among 686,649 at-risk patients was 110.3 (95%CI; 109.9-110.7) per 1000 patient years. Iron parameter measurement varied with presence and severity of anemia: the proportion with both transferrin saturation and ferritin varied from 37.1% in the severely anemic, to 5.2% among those without anemia (Table). In the multivariable analysis, the only significant predictor of absolute iron deficiency anemia was prior GI bleed, and there were no significant predictors of functional iron deficiency.

Conclusions: One in five patients had anemia at CKD diagnosis; among those without it, 11 of 100 developed it for each year of follow-up. Prevalence of both absolute and functional iron deficiency increased with severity of anemia at incident CKD. Outcomes associated with absolute and functional iron deficiency anemia merit further studies.

The Impact of Newly Developed Inflammation, Characterized by Rise in C-Reactive Protein, on Anemia Management Practices in Hemodialysis Patients: A Before-After Design in the DOPPS

Angelo Karaboyas,[1] Hal Morgenstern,[2] Raymond C. Vanholder,[6] Nancy L. Fleischer,[2] Douglas E. Schaubel,[2] Elke Schaeffner,[4] Tadao Akizawa,[3] Nafeesa N. Dhalwani,[5] Marvin Sinsakul,[7] Ronald L. Pisoni,[1] Bruce M. Robinson.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]Showa University School of Medicine, Tokyo, Japan; [4]Charite, Berlin, Germany; [5]Evidera, London, United Kingdom; [6]University Hospital Gent, Gent, Belgium; [7]AstraZeneca, Gaithersburg, MD.*

Background: Inflammation, as assessed by a rising C-reactive protein (CRP), may lower hemoglobin (Hgb) level and lead to increased ESA dose to support the unmet need.

Methods: Using data from Dialysis Outcomes and Practice Patterns Study (DOPPS) phases 4-6 (2009-2018) in 10 countries where CRP is routinely measured, we identified hemodialysis patients who had a new inflammation event, defined here as CRP >10 mg/L following a 3-month period with all available CRP measurements ≤5 mg/L. In a "before-after" design treating patients as their own controls, we used adjusted linear mixed models to estimate within-patient effects of inflammation on changes in Hgb and log-transformed ESA dose, comparing mean values from the 3 months "before" vs. "after" observing high CRP. Sensitivity analyses used different CRP thresholds as a proxy for a new inflammation event (e.g., ≤3 to >10 mg/L, ≤5 to >20 mg/L).

Results: Among 12389 patients, 40158 CRP values (21% of all measurements) were >10 mg/L, and 3752 measurements (from 2976 patients) met the eligibility criteria (Fig). In the "before" vs. "after" periods, mean Hgb was 11.2 vs. 10.9 g/dL and mean ESA dose was 6347 vs. 6994 units/week. In 56% of the cases, patients experienced either a Hgb drop of >0.5 g/dL (40% of cases) or a >20% increase in ESA dose (33% of cases). In adjusted models, the average within-patient change was 0.26 g/dL (95% CI: 0.22, 0.30) lower Hgb and an 8.6% (95% CI: 6.4, 10.8) increase in ESA dose. Results were robust to sensitivity analyses varying the CRP thresholds.

Conclusions: After patients experienced an inflammation event, Hgb levels declined and ESA doses rose, suggestive of increased ESA resistance. Routine measurement of CRP is not practiced in the US but could help identify inflamed patients. These patients may benefit from proactive adjustment of medications or, in the future, anemia therapies that may be less subject to effects of inflammation.

Factors Associated with Anemia in Nondialysis CKD

Lucas A. Zanetti,[2] Alexandre K. Samorano,[2] Thais Tiemi Kato,[2] Maria Eugenia F. Canziani,[1] Miguel Angelo Goes.[1] *[1]Federal University of Sao Paulo, Sao Paulo, Brazil; [2]Faculdade das Américas, São Caetano do Sul, Brazil.*

Background: Anemia is common among chronic kidney disease (CKD) patients with increased hospitalizations and mortality and is associated with inflammatory cytokines and iron status. **Objective**: To assess factors associated with anemia in nondialysis CKD patients.

Methods: We analyzed 100 nondialysis CKD outpatients no erythropoiesis-stimulating agent. Anemia was defined as hemoglobin (Hb) concentration <13.0 g/dL for men and <12.0 g/dL for women. Thus, 63 patients were in anemia group and 37 in non-anemia group. We performed analyzes of demographic data, CKD-EPI, Hb concentration, albumin, iron status, serum sFas, iPTH, inflammatory cytokines and erythropoietin (Epo) levels. We used correlations to all variables. We performed comparisons between two groups and multiple linear regression was used to determine the factors associated with Hb concentration when p<0.1.

Results: The primary causes of CKD were diabetes and hypertension followed by chronic glomerulonephritis. We observed in all patient together positive correlation between Hb and transferrin saturation (r=0.20, p=0.04), Hb and CKD-EPI (r=0.42, p<0.001), Hb and albumin (r=0.39, p=0.003). There was negative correlation between Hb and sFas (r=-0.50, p<0.001). We observed lower CKD-EPI (48±23, 27±10 mL/min; p=0.001), Hb (14.1±1.4, 10.9±1.6 g/dL; p<0.001) and serum Epo (14.2±9.5, 9.4±4.7 pg/mL; p=0.08) in anemia group. We found higher levels of sFas (3575±1109, 2533±1025 pg/mL; p<0.001), IFNg (7.1±5.9, 5.7±3.2 pg/mL; p=0.09) and iPTH (271±47.3, 110±47.8 pg/mL; p=0.003) in anemia group. Albumin (b = 3.518, 95%CI 1.059-3.873; p<0.001) and sFas (b = -0.252, 95%CI -0.852-0.17; p=0.001) were independently associated with Hb concentration.

Conclusions: This study shows that levels of albumin and sFas were associated with anemia in nondialysis CKD outpatients.

TH-PO254

Serum Soluble-Fas Is a Predictor of Need for Erythropoiesis-Stimulating Agents in Nondialysis CKD

Marcella A. Barros,[3] Thais D. Takahashi,[4] Bruna Hernandez,[2] Lucas A. Zanetti,[2] Maria Eugenia F. Canziani,[1] Miguel Angelo Goes.[1] *[1]Federal University of Sao Paulo, Sao Paulo, Brazil; [2]Faculdade das Américas, São Caetano do Sul, Brazil; [3]UNIFESP, Sao Paulo, Brazil; [4]INICIAÇÃO CIENTÍFICA UNIFESP, POÁ, Brazil.*

Background: Erythropoiesis-stimulating agents (ESAs) are commonly used to treat anemia in chronic kidney disease (CKD). Soluble-Fas (sFas) and inflammatory cytokines are associated with renal anemia. **Objective**: To assess predictor factors of need for ESAs in nondialysis CKD patients.

Methods: We retrospectively analyzed and identified 80 nondialysis CKD outpatients with Hb>10g/dl. Thus, CKD outpatients that needed ESA up to 48 months after enrolment in nephrology office were identified. Initiated ESA when Hb values <9.0-10.0 g/dL with iron store replete. Demographic data, ESA use, CKD-EPI, Hb concentration, albumin, iron status, serum sFas, iPTH, inflammatory cytokines and erythropoietin (Epo) levels were recorded. 24 patients needed ESA and 56 patients no needed ESA in this period. We performed comparisons between two groups (ESA and non-ESA). Binary logistic regression was used to determine the impact of factors on ESA need.

Results: The primary causes of CKD were diabetes and hypertension. ACEi were used more in ESA group (46%, 20%; p=0.04). At baseline we observed lower CKD-EPI (42±22, 29±12 mL/min; p=0.01), serum Epo (10.8±1.8, 8.8±2.4 pg/mL; p=0.07) and Hb (13.5±1.7 g/dl, 12±1.8; p=0.09) in ESA group. We found higher levels of serum sFas levels (3537± 578, 2751±1258 pg/mL; p=0.005) in ESA group. We did not observed difference in levels of iPTH, albumin, iron status and inflammatory cytokines. Serum sFas (b = 1.002, 95%CI 1.001-1.004; p=0.01) was independently associated with Hb concentration.

Conclusions: In this study serum sFas was a predictor of need for ESA in nondialysis CKD outpatients within 48 months.

TH-PO255

Estimated Glomerular Filtration Rate (eGFR) and Hemoglobin (Hb) Levels Associated with Anemia Therapy in CKD Patients in a US Commercial Insured/Medicare Advantage Population

Haechung Chung,[2] Julia Catini,[1] Shaum Kabadi,[1] Vincent Willey.[2] *[1]AstraZeneca, Gaithersburg, MD; [2]HealthCore Inc., Wimlington, DE.*

Background: Little is known about the eGFR and Hb levels that trigger initiation of anemia treatment in non-dialysis-dependent CKD patients in the real-world setting. The study objective was to explore Hb and eGFR levels prior to anemia treatment in non-dialysis CKD patients and assess the trigger for anemia treatment based on these test results.

Methods: CKD patients treated for anemia were identified in the HealthCore Integrated Research Database from 1/1/07 to 6/30/15 by the presence of ≥ 1 medical claim each with a CKD and anemia diagnosis. Patients were required to have ≥ 12 months of health plan eligibility prior to their first CKD claim, during which they could not have any claims for CKD or anemia. These patients were 1:1 propensity score matched to CKD patients not treated for anemia. An anemia "at-risk" period was defined as the period between the first CKD diagnosis and anemia treatment date or "pseudo" treatment date assigned to the untreated group. Patients in both groups had an eGFR during the at risk-period and an Hb outpatient result within 90 days prior to treatment/pseudo treatment date. Hb and eGFR levels associated with anemia treatment were evaluated; trigger values were assessed using logistic regression with Youden's J index.

Results: We identified a total of 1724 matched pairs (anemia treated/untreated), with a mean age of 65 years. Anemia treatments included darbepoetin (9.6%), epoetin (24.8%), prescription iron (31.6%) and blood transfusion (60.9%). The mean Hb during the at-risk period was 10.0 and 12.5 g/dL for the anemia treated/untreated cohorts. The mean eGFR during the at-risk period was 41.0 and 52.5 mL/min for the anemia treated/untreated cohorts, with 1/3 of patients in the treated group at stage 4/5 CKD and another 1/3 at stage 3b. The trigger point for anemia treatment was 10.3 g/dL for Hb and 33.3 mL/min/1.73 m^2 for eGFR, with Hb being a stronger predictor of anemia treatment than eGFR. Type of anemia treatment received depended on Hb level.

Conclusions: Two thirds of patients in the anemia-treated group were stage 3b CKD or worse when treatment was initiated, with Hb being the main impetus for therapy. Future research on the interplay among renal function, Hb levels, and anemia treatment initiation is warranted.

Role of Soluble Transferrin Receptors, Serum Ferritin, and Inflammatory Markers in Assessment of Functional Iron Deficiency in Anemia of CKD

Om P. Kalra,[1] Neha Garg,[2] Anil K. Yadav,[2] Usha Rusia,[2] Meera Sikka,[2] Mrinalini Kotru.[2] *[1]Pt. B.D. Sharma University of Health Sciences, Rohtak, Haryana, India; [2]University College of Medical Sciences and GTB Hospital, Delhi, India.*

Background: Anemia in chronic kidney disease (CKD) is multifactorial and functional iron deficiency (FID) is very common. The presence of coexisting inflammation may alter transferrin saturation (TSAT) and serum ferritin (SF) values, thus affecting their utility in assessment of iron stores. Interleukin-6 (IL-6) is the prime mediator of FID through hepcidin induction and has a direct role in the pathogenesis of anemia in CKD. The present study was conducted to explore the role of soluble transferrin receptors (sTfR), SF, IL-6 and high-sensitive C- reactive protein (hsCRP) in anemia of CKD. ESR was measured by Westergren method.

Methods: A total of 77 patients of CKD {Stage 3 (n=31), 4 (n=17) and 5 (n=29)} of either sex, aged >18 years with hemoglobin (Hb) <11 g/dL were studied. Patients with active bleed, chronic infection, systemic disorders, history of recent blood transfusion and those receiving iron supplements were excluded. Hb, serum iron (SI), total iron binding capacity (TIBC) were measured in all the cases and TSAT was calculated. SF, sTfR, hsCRP and IL-6 were measured by ELISA technique.

Results: Taking sTfR/log ferritin (cut-off >1) as gold standard, CKD patients were divided into two groups:- Group-A: Iron deficient erythropoiesis (IDE) (n=31) and Group-B: Non-iron deficient erythropoiesis (NIDE) (n=46). No statistically significant difference was found in the values of Hb, MCV, MCH, MCHC, SI, TIBC, TSAT and SF between the two groups. All patients had raised IL-6 while hsCRP was raised in 60/77 (79.93%) patients. A positive correlation was found between hsCRP and SF (r=0.311, p=0.006) and between ESR and SF (r=0.451, p=0.000); however, no correlation was found with sTfR, indicating that sTfR levels are not affected by inflammation. The criteria i.e. TSAT <20% and SF>100 μg/L showed a sensitivity of only 6.45% in detection of FID. On the other hand, SF levels from 12 to 70 μg/L were able to identify 14/19 (73.7%) cases of FID. Further, sTfR showed significantly higher values in the IDE group (p=0.000).

Conclusions: hsCRP, ESR and IL-6 levels were raised in majority of the patients of CKD with anemia and were not useful in the diagnosis of FID; however, raised sTfR levels and SF values between 12 to 70 μg/L were found to be useful for assessment of IDE (p=0.000).

TH-PO257

Efficient Management of Renal Anemia Is Achieved by Low Ferritin Levels and Moderate Transferrin Saturation Analyzed by Combination of the Hemoglobin Content of Reticulocytes and Iron Markers

Chie Ogawa,[1,2] Ken Tsuchiya,[3,2] Fumiyoshi Kanda,[1] Kunimi Maeda.[1,2] *[1]Maeda Institute of Renal Research, Kawasaki, Japan; [2]Biomarker Society, INC, Kawasaki, Japan; [3]Tokyo Women's Medical University, Shinjuku-ku, Japan.*

Background: Excessive iron induces negative iron metabolism by production of hepcidin25 (Hep25), but the optimal iron levels for hematopoiesis on hemodialysis (HD) patients is unclear. The hemoglobin content of reticulocytes (CHr) is sensitive indicator of used iron for hematopoiesis. The previous studies indicated CHr level increased by iron therapy in iron deficiency patients, whereas showed no change in iron sufficiency patients. So we investigated the relation among CHr level, iron status, reticulocytes counts and Hep25.

Methods: 181 outpatients on maintenance HD treated with recombinant human erythropoietin were enrolled and examined CHr, serum ferritin(s-ft), transferrin saturation (TSAT), reticulocytes (Ret) counts and Hep 25. The sample was comprised of 115 men with a mean (SD) age of 59.9 (13.8) years, and mean HD duration of 8.6 (6.8) years. CHr and Hep 25 was measured using ADVIA 120 hematology system and LC-MS/MS assay. As management of anemia, the target Hb level was 10–11 g/dL according to the Japanese guidelines. We performed sensitivity analysis using the generalized linear regression model including the interaction term to determine the optimal cut-off values, which correlation coefficients show greatest changes, of s-ft, TSAT and Hep25 for CHr. The correlation between CHr and Ret count was evaluated in four groups classified by iron status.

Results: The optimal cut-off values of s-ft and TSAT for CHr were showed 50 ng/mL (≤50 ng/mL, r=0.47 vs >50 ng/mL, r=0.22; F-statistic, 17.64) and 24% (≤24%, r=0.58 vs >24%, r=0.08; F-statistic, 34.45), respectively. Moreover, two values were suggested for the optimal cut-off of CHr and Hep25. The under and upper values were 20 ng/mL (≤20 ng/mL, r=0.52 vs >20 ng/mL, r=-0.01; F-statistic, 21.12) and 70 ng/mL (≤70 ng/mL, r=0.36 vs >70 ng/mL, r=-0.45; F-statistic, 24.52), respectively. As the Ret count increased, CHr most greatly decrease in the "s-ft ≤50 ng/mL and TSAT ≤ 24%" group, however showed almost no change in the "s-ft >50 ng/mL and TSAT > 24%" group.

Conclusions: This study showed that the iron status of s-ft >50 ng/mL or/and TSAT > 24% had almost no influence on CHr, indicator of used iron for hematopoiesis. However, high level of Hep25 may impair the efficiency of iron use for hematopoiesis.

Red Blood Cell Volume Is Not Always Decreased in Anemic CKD Patients

Sophie M. De Seigneux,[1] Belen Ponte,[3] Pierre-Yves F. Martin,[4] Carsten Lundby.[2] *[1]Nephrology, University Hospital of geneva, Geneva, Switzerland; [2]Copenhagen University Hospital, Copenhagen, Denmark; [3]University Hospital of Geneva, Geneva, Switzerland; [4]Hospital Universitaire de Geneve, Geneva City, Switzerland.*

Background: Anemia is defined according to blood hemoglobin concentration ([Hb]), which can be considered a marker of total red blood cell volume (RBCV). However, alterations of plasma volume (PV) may also modify [Hb] without concomitant changes in RBCV. Since anemia and fluid retention are frequent complications of chronic kidney disease (CKD), we hypothesized that anemia during CKD may in part be related to expanded PV without a simultaneous decrease in RBCV.

Methods: To test this hypothesis, we quantified in 50 consecutive stable stage 3-5 CKD outpatients not on dialysis and 7 controls in the same age cathergory: hemoglobin mass, RBCV, PV and total blood volume (BV) using an automated carbon monoxide device. Epo was measured by Elisa. Predicted values for PV, RBCV, and BV were calculated according to nadler's formula for each patient.

Results: CKD patients were divided into anemic and non-anemic patients based on their hemoglobin [Hb] values. While we demonstrated that RBCV was within the predicted range in anemic patients (+8%, p=0.35) but higher than predicted in non-anemic (+14.5%, p=0.02) patients, both BV and PV were higher than predicted values for non-anemic (+15.5% and +19%, p<0.01) and anemic patients (+ 10.5 and +22%, p<0.01), respectively. Anemic patients had a higher PV than controls (p<0.01) whereas their RBCV was not different, whereas non anemic CKD patients had higher RBCV than controls (p<0.01). Thus the cause for anemia in the large majority of the investigated patient population was related mainly to hemodilution and not to a limited erythropoiesis, as also confirmed by the erythropoietin values. [Hb] based anemia over-diagnosed anemia in 20 of the 26 anemic patients.

Conclusions: In conclusion, anemia in CKD as diagnosed by low [Hb] is not necessarily only associated to low RBCV but may also reflect increased plasma volume. This finding could have implications for the treatment of CKD patients and may explain the increased mortality associted to normalization of [Hb] values by rhEpo treatment in the predialysis CKD population.

Estimation of Pre-Dialysis Hemoglobin Concentration Using Intradialytic Crit-Line Monitor Readings

Ohnmar Thwin,[1] Priscila Preciado,[1] Xia Tao,[1] Samir D. Patel,[3] Mirell Tapia,[1] Lemuel Rivera,[1] Stephan Thijssen,[1] Peter Kotanko.[1] *[1]Renal Research Institute, New York, NY; [3]Renal Research Institute, Weehawken, NJ.*

Background: Anemia is a major complication in hemodialysis (HD) patients. The Crit-Line monitor (CLM) is widely use to determine oxygen saturation, hematocrit and hemoglobin (Hgb) levels. It would be desirable to use CLM to estimate pre-HD Hgb values to reduce blood draws. However, due to hemodilution by the priming fluid, the initial Hgb values at the HD start are consistently lower than pre-HD values. A high initial ultrafiltration rate (UFR) allows rapid removal of the priming fluid while limiting the impact associated with saline extravasation and vascular refill. Our goal was to implements a high initial UFR to evaluate the agreement between the two measurements.

Methods: Prospective, observational study in chronic HD patients. Subjects were studied 3 times. Two pre-HD blood samples were drawn, measured in triplicate by Spectra East Laboratories (Rockleigh, NJ, USA), and the average used for comparison to CLM. Initial UFR was set to 3 L/hr for 8 minutes and then returned to prescribed rate. Hgb was recorded continuously with CLM. Difference of CLM to lab Hgb value was calculated as CLM reading at each time point minus averaged lab value

Results: We included 27 subjects (56.4±15 years, 70% males, 63% African-Americans) and a total of 61 treatments. With rapid ultrafiltration, the difference between CLM and lab values decreased and reached minimal at approximately 6 minutes (Fig.1), and about 75% of subjects had CLM Hgb values that were within ±0.5 g/dL of the corresponding lab reference Hgb

Conclusions: With a high initial UFR, 75% of CLM Hgb values were within ±0.5 g/dL difference of the averaged lab measurement at minute 6. Of note, the lab values are afflicted with some degree of measurement variability contributing to the data spread. Next steps should include development of mixed effects models for prediction of an individualized time point at which to read CLM Hgb, to further increase the agreement between the two methods.

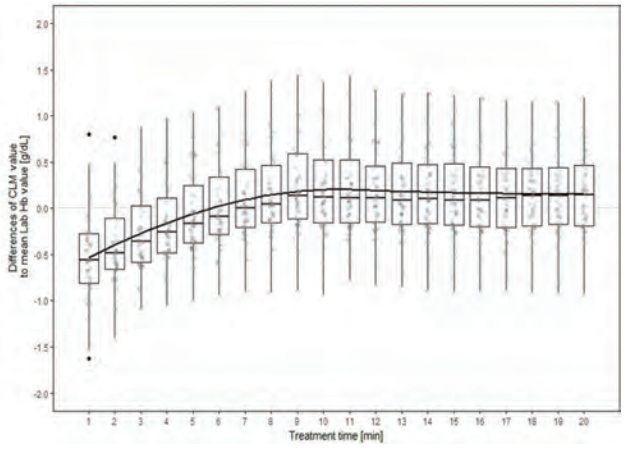

Fig.1. Delta of lab and CLM Hgb values at each time point for the first 20 minutes of HD

Reduced Hemoglobin Level Increases Risk of Incident Heart Failure and Atherosclerotic Events in CKD: The CRIC Study

Santosh Saraf,[1] Jesse Y. Hsu,[2] Ana C. Ricardo,[1] Mayank Kansal,[1] Jing Chen,[3] Michael J. Fischer,[4] Jiang He,[5] Rupal Mehta,[6] Thida C. Tan,[7] Alan S. Go,[7] James P. Lash.[1] On behalf of the CRIC investigators *[1]University of Illinois at Chicago, Chicago, IL; [2]University of Pennsylvania, Philadelphia, PA; [3]Tulane School of Medicine, New Orleans, LA; [4]University of Illinois Hospital and Health Sciences Center, Chicago, IL; [5]Tulane School of Public Health and Tropical Medicine, New Orleans, LA; [6]Northwestern Univesrsity, Feinberg School of Medicine, Chicago, IL; [7]Kaiser Permanente Northern California, Oakland, CA.*

Background: Anemia may exacerbate cardiac ischemia or contribute to abnormal left ventricular remodeling but data regarding the impact of anemia on cardiovascular outcomes in chronic kidney disease (CKD) have been inconsistent.

Methods: We used Cox proportional hazards to examine the association of hemoglobin (Hgb) level (per 1 gm decrease) with incident heart failure, atherosclerotic events (myocardial infarction, stroke, or peripheral artery disease), and all-cause death among participants with CKD in the Chronic Renal Insufficiency Cohort Study.

Results: Among 3,919 participants with CKD (mean age 58 yrs, 45% women, 42% white, 42% black, 13% Hispanic, mean eGFR 45 ml/min/1.73 m^2, median proteinuria 0.19 g/24h, and mean entry Hgb 12.6±1.8), 1,859 (47.4%) participants had anemia (defined using WHO criteria of Hgb <12 g/dL in women and <13 g/dL in men) at study entry. Compared to individuals without anemia, those with anemia were older, more likely to be black or Hispanic, have prior clinical cardiovascular disease, and had a lower mean eGFR at baseline. Over a median follow-up of 8.8 years, we observed 757 heart failure events, 692 atherosclerotic events, and 1148 deaths. In multivariable analyses, lower Hgb was associated with significantly higher rates of heart failure and atherosclerotic events that may be partially explained by subclinical cardiac ischemia.

Conclusions: In a large, diverse CKD cohort, lower Hgb was independently associated with an increased risk for heart failure and atherosclerotic events.

Association of Anemia with Clinical Outcomes in Patients with Severe CKD: A Danish Population-Based Study

Reimar W. Thomsen,[1] Uffe Heide-Jørgensen,[1] Gunnar Toft,[1] Marvin Sinsakul,[2] Heleen van Haalen,[2] Lars Pedersen,[1] Henrik T. Sorensen.[1] *[1]Aarhus University Hospital, Aarhus, Denmark; [2]AstraZeneca, Gothenburg, Sweden.*

Background: Real-world evidence is limited on clinical outcomes associated with anemia in patients with chronic kidney disease (CKD). We investigated the association of anemia with incident dialysis, adverse cardiovascular (CV) outcomes and death in patients with severe CKD.

Methods: We linked laboratory and healthcare databases to identify individuals with stage 4 or 5 CKD (eGFR <30) in Northern Denmark on 1 Jan 2012. We classified patients by anemia grade using lowest hemoglobin (Hb) value in 2011 (grade 1: Hb 10 to <12/<13 g/dL; grade 2+: Hb <10 g/dL). Patients were stratified by dialysis status on 1 Jan 2012 and followed for incident dialysis, first CV event (myocardial infarction, stroke, and heart failure hospitalization) and all-cause death. We computed incidence rates and derived risk curves and adjusted hazard ratios (HRs) through cumulative incidence function and Cox proportional hazards regression.

Results: Of 4,120 patients with severe CKD (median age 77 years), 45% had no anemia, 41% had grade 1 anemia, and 14% had grade 2+ anemia. Incidence rates for dialysis, CV events and death increased with increasing anemia severity (Table). After controlling for baseline differences in age, gender, CV history, other comorbidities, eGFR level and CKD duration, HRs for incident dialysis were increased for patients with grade 1 and particularly with grade 2+ anemia. Moreover, HRs for CV events and death were elevated among both non-dialysis and dialysis patients. A similar risk pattern for CV events and death was observed when non-dialysis patients were censored at dialysis initiation.

Conclusions: In routine clinical care patients with severe CKD, the presence and severity of anemia was associated with increased risks of incident dialysis, CV events and death.

Delta-He It Is a Novel Biomarker of Mortality in Prevalent Hemodialysis Patients: A Multivariate Regression Predictive Model Development

Manuel B. Sánchez. *Nephrology, Hospital Juan Ramon Jimenez, Huelva, Spain.*

Background: Delta-He is a marker of iron availability, which has been suggested as a marker of the inflammation. It is calculated as the difference between the hemoglobin content of reticulocytes (Ret-He) reflects the incorporation of iron into the erythroid progenitor cells over the previous 2–4 days, and the hemoglobin content of erythrocytes (RBC-He). Under normal conditions, Delta-He has a positive value. As iron homeostasis and inflammation are related through the action of Hepcidin, an acute inflammatory response suppresses the availability of iron to erythropoietic progenitor cells and rapidly induces a decrease in Ret-He, leading to a negative value of Delta-He.

Methods: 78 patients prevalent in Hemodialysis were followed during 1 year. We have analyzed time to the event (mortality from any cause). Has been acknowledged Mortality as Dependente Variable and Delta-He Dicotomized as independent variable. Time in Hemodialysis, KtV, the treatment with erythropoiesis-stimulating agents (ESA) and Fe iv therapy was taken into account, PCR, RET-He and Delta-He. We have realise the determinations through the Sysmex XE 500. A survival study was carried out trougt using Multivariate Regression Cox Model . The predictive model is developed with the regression coefficients. Internal validity was realise by Bootstrap. The model is presented as a nomogram.

Results: 22/78 patients (28.2%) presented exitus. 19/78 patients (24.4%) had Delta-He Negative and require a higher weekly dose of ESA. The delta He has a protective effect against mortality, that is, the greater the value of Delta-He, the less mortality, for each unit that increases Delta He above 0 the mortality decreases by 27%. Discrimination: Index C: 0.74, Calibration: I. Brier: 0.171, R2 Nagelkerke: 0.22.

Conclusions: Delta-He Negative is a predictive factor of all-cause mortality at one year in patients on hemodialysis, associated with inflammation and hypo-responsiveness to ESA.

TH-PO263

The Association of the Difference in Hemoglobin Levels Before and After Hemodialysis with the Risk of 1-Year Mortality in Patients Undergoing Hemodialysis: Results from the Japanese Renal Data Registry

Hiroki Nishiwaki,[1] Takeshi Hasegawa,[1] Takayuki Hamano,[2] Ikuto Masakane.[3] The Japanese Society for Dialysis Therapy, Committee of Renal Data Registry
[1]Showa University Fujigaoka Hospital, Yokohama, Japan; [2]Osaka University Graduate School of Medicine, Suita, Japan; [3]Honcho-Yabuki Clinic, Yamagata, Japan.

Background: Few clinical studies have directly examined the associations of hemoglobin (Hb) levels after hemodialysis (HD) and of the difference in Hb levels before and after HD (ΔHb) with patient outcomes. The present study aimed to determine ΔHb and post-HD Hb levels with nationwide data and to examine their associations with all-cause mortality in patients undergoing HD.

Methods: Study Design: Retrospective cohort study Setting and Participants: This study is based on data from 2008 and 2009 recorded in the Japanese Renal Data Registry. Exposures: The ΔHb and the absolute post-HD Hb value. Outcomes: 1-year mortality Analytical Approach: The ΔHb and post-HD Hb level as categorical variables using Cox regression for 1-year mortality, adjusting for potential confounders.

Results: Eligible patients were 38,636 patients. The median ΔHb was 1.0 g/dl (first quartile, 0.4 g/dl; third quartile, 1.5 g/dl), and the median post-HD Hb level was 11.3 g/dl 1.0 g/dl (first quartile, 10.3 g/dl; third quartile, 12.4 g/dl). The median pre-HD Hb level was 10.4 g/dl (first quartile, 9.6 g/dl; third quartile, 11.1 g/dl). The risk of mortality was lower with a ΔHb of 0 to 1.0 g/dl (adjusted hazard ratio [aHR], 0.82; 95% confidence interval [CI], 0.74–0.92) or > 1.0 g/dl (aHR, 0.62; 95% CI, 0.55–0.70) than with a ΔHb < 0 g/dl. The risk for mortality was also lower with a post-HD Hb of 10 to 11 g/dl (aHR, 0.79; 95% CI, 0.71–0.89), 11 to 12 g/dl (aHR, 0.72; 95% CI, 0.64–0.80), or > 12 g/dl (aHR, 0.71; 95% CI, 0.64–0.80) than with a post-HD Hb < 10 g/dl.

Conclusions: Both a low ΔHb and a low post-HD Hb level were associated with a higher risk of 1-year mortality.

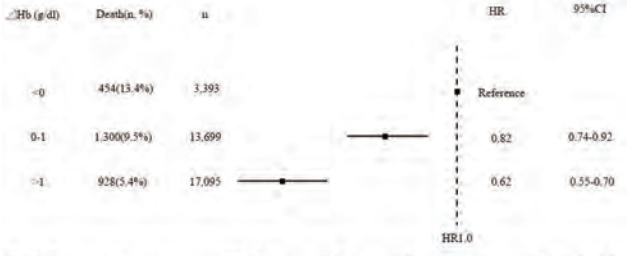

Figure1: The association between categorized △Hb of all patients and all-cause mortality(1-year) in cox proportional hazard model. The model was adjusted with age, gender, dialysis vintage, cause of end stage renal disease, history of cardiovascular disease or amputation, body mass index, serum albumin level, time of dialysis session, blood urea nitro, serum creatinine, serum sodium, serum potassium, adjusted calcium, phosphate, C-reactive protein, PCR, Kt/V, the amount of fluid removal, and type of blood access.

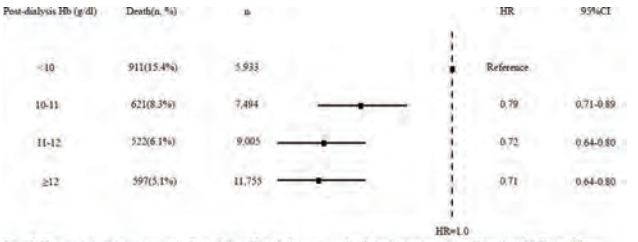

Figure2: The association between categorized post-dialysis Hb and all-cause mortality(1-year) in cox proportional hazard model. The model was adjusted with age, gender, dialysis vintage, cause of end stage renal disease, history of cardiovascular disease or amputation, body mass index, serum albumin level, time of dialysis session, blood urea nitro, serum creatinine, serum sodium, serum potassium, adjusted calcium, phosphate, C-reactive protein, PCR, Kt/V, the amount of fluid removal, and type of blood access. TH-PO264

Differential Effect of Hemoglobin Level on Patient Mortality According to Patient Age in ESRD Patients

Eun jeong Ko,[4] Bumsoon Choi,[1] Cheol Whee Park,[2] Chul Woo Yang,[3] Byung ha Chung.[3] *[1]Division of Nephrology, Department of Internal Medicine, Seoul, Republic of Korea; [2]The Catholic University of Korea, Seoul, Republic of Korea; [3]Seoul St. Mary's Hospital, Seoul, Republic of Korea; [4]Seoul St.Mary's Hospital, Seoul, Republic of Korea.*

Background: In chronic dialysis patients, achieving an adequate hemoglobin (Hb) concentration is very important because lower than 10 g/dL or higher than 12g/dl can be associated with increased patient mortality. However, it has not been confirmed that it can be applied irrespective of patient age. Therefore, the aim of this study is to investigate the impact of Hb level on the clinical outcomes of dialysis patients according to patient age using the Clinical Research Center registry for end-stage renal disease (CRC-ESRD) data.

Methods: A total of 3,409 patients form CRC-ESRD were included. They were divided into three group by age, age < 40 (n=488), 40<age≤60 (n=1,650), and age >60 (n=1,271). We compared the overall mortality, cardiovascular mortality, all-cause and cardiovascular hospitalization according to mean Hb level.

Results: In age <40 group, Hb ≥12 g/dl group showed higher all-cause mortality (adjusted HR 3.894, 95% CI 1.037-14.624; p=0.044) compared to 10≤Hb <12 g/dl group, whereas HR of cardiovascular hospitalization was higher in Hb < 10g/dl group (adjusted HR 2.268; 95% CI 1.044-4.926, p=0.039). Meanwhile, in age≥60 group, all-cause and cardiovascular mortality was higher in Hb <10 g/dl (adjusted HR 2.098, 95% CI 1.567-2.808, p<0.001 and adjusted HR 2.796, 95% CI 1.669-4.686, p<0.001) compared to 10≤ Hb < 12g/dl group, however the difference between 10≤ Hb < 12g/dl group and Hb ≥ 12g/dl was not significant. In 40<age≤ 60 group, Hb <10g/dl showed higher all-cause mortality (adjusted HR 1.719, 95% CI 1.158-2.252, p=0.007), all-cause hospitalization (adjusted HR 1.572, 95% CI 1.213-2.036, p=0.001) and cardiovascular hospitalization (adjusted HR 1.455, 95% CI 1.037-2.043, p=0.030) compared to 10≤Hb <12 g/dl group, whereas there was no significant difference between 10≤Hb <12 and Hb ≥ 12 g/dl group

Conclusions: Thus, in elderly patient on dialysis, the effect of low or higher hemoglobin level than 10 - 12 g/dL in elderly patients was different from that in young patient.

Measuring Quality of Life in Patients with CKD Anemia – SF36 and KDQOL

Roberto Pecoits-Filho,[1,2] Bruce S. Spinowitz,[3] Pablo E. Pergola,[4] Samuel Rochette,[5] Philippe Thompson-Leduc,[5] Patrick Lefebvre,[5] Ana Bozas,[6] Gigi Shafai,[6] Myrlene Sanon,[7] Holly Krasa.[7] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]George Institute for Global Health, Newtown, NSW, Australia; [3]New York Hospital Medical Center of Queens, New Rochelle, NY; [4]Renal Associates, PA, San Antonio, TX; [5]Analysis Group, Inc., Montreal, QC, Canada; [6]Akebia Therapeutics, Inc., Cambridge, MA; [7]Otsuka Pharmaceutical Development & Commercialization, Inc., Rockville, MD.*

Background: Anemia of chronic kidney disease (CKD) has deleterious impacts on patients' quality of life (QoL). The Standardized Outcomes in Nephrology (SONG) initiative identified QoL components as essential trial outcomes to be reported in hemodialysis and peritoneal dialysis-dependent (DD) patients. Resolving anemia of CKD may lead to more important QoL benefits in non-DD (NDD) patients than in DD patients (Eriksson 2016). QoL is frequently assessed using the 36-item general Short Form (SF-36) and the CKD-targeted Kidney Disease QoL (KDQoL), the latter being preferred in US dialysis clinics (Peipert 2017). It is unclear to which extent QoL tools are used to study anemia of CKD, and specifically in NDD patients. Therefore, we aimed to describe the evidence on treatments for anemia of CKD in which SF-36 and/or KDQoL were used, in both DD and NDD patients.

Methods: Studies included in a broader systematic literature review of treatments for anemia of CKD were reviewed. The Cochrane Library, MEDLINE, EMBASE, NHS EED, and NHS HTA were searched for English publications. Studies published between 1/1/2000-3/17/2017 meeting the following criteria were included: adult patients; focus is anemia of CKD; patients receiving iron, red blood cell transfusions, erythropoiesis-stimulating agents (ESA); results on QoL. Studies that used SF-36 or KDQoL were retained and qualitatively synthesized.

Results: 1,625 publications were identified and 17 met the eligibility criteria. All studies focused on ESA, with or without iron replacement. SF-36 was used more frequently than KDQoL (11/17, 64.7%) across studies. Notably, KDQoL was used more frequently

(vs. SF-36) in studies on DD patients (4 vs. 2) than in studies on NDD patients (1 vs. 8; 2 studies with mixed DD/NDD patients). Both tools showed QoL improvements (SF-36: 8/11, KDQoL: 4/6). QoL domains improved (e.g., vitality, physical/social functioning) and magnitude of results varied widely.

Conclusions: KDQoL was less frequently used in the NDD population than in DD patients (as expected, given CMS guidelines). Findings highlight how QoL treatment benefits are variable, and that there is a lack of standardized use of adapted QoL tools in studies of NDD patients.

Associations of Anemia with Quality of Life in CKD Stage 3-5 Patients: Results from CKDopps in the US and Brazil

Nidhi Sukul,[1] Daniel G. Muenz,[2] Elodie Speyer,[3] Antonio A. Lopes,[4] Koichi Asahi,[5] Junichi Hoshino,[6] Nafeesa N. Dhalwani,[7] Heleen van Haalen,[8] Roberto Pecoits-Filho,[9] Brian Bieber,[2] Bruce M. Robinson,[2] Ronald L. Pisoni.[2] *[1]University of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]CESP Inserm U1018, VILLEJUIF Cedex, France; [4]Faculdade de Medicina da Universidade Federal da Bahia, Salvador, Brazil; [5]Department of Chronic Kidney Disease Initiatives, Fukushima Medical University School of Medicine, Fukushima, Japan; [6]Toranomon Hospital, Tokyo, Japan; [7]Evidera, London, United Kingdom; [8]AstraZeneca, Gothenburg, Sweden; [9]Pontificia Universidade Catolica do Parana, Curitiba, Brazil.*

Background: The risk of anemia increases with chronic kidney disease (CKD) progression. Some studies suggest that anemia is associated with poorer quality of life (QOL) among non-dialysis CKD patients. Using the Chronic Kidney Disease Outcomes and Practice Patterns Study (CKDopps), we report the associations of anemia with QOL outcomes among CKD patients in the US and Brazil.

Methods: We analyzed CKDopps data on patient characteristics, laboratory measurements and the Kidney Disease QOL-36 (KDQOL-36) survey collected prospectively for stage 3-5 CKD patients (N=1212) at 22 US and 15 Brazilian nephrologist-run clinics from 2014-2018. Hemoglobin (Hgb) levels, reported closest in time to KDQOL-36 completion (median gap: 13 days, IQR: 1-57 days), were modelled separately as continuous and categorical exposures in GEE linear regression models for each QOL outcome, adjusting for country, age, sex, race, smoking history, eGFR, serum albumin, and 13 comorbidities, and accounting for clustering by clinic.

Results: More severe anemia was most strongly associated with poorer scores for QOL domains of general health, physical role, emotional role, burden, effects of kidney disease, as well as the physical and mental component summary scores. Weak to moderate associations were observed with the domains of energy, physical function, and pain.

Conclusions: These findings show moderate associations between anemia and poorer outcomes on several QOL domains in CKD stage 3-5 patients from the US and Brazil, even after accounting for numerous comorbidities. Longitudinal studies would be valuable to understand how patient QOL and well-being are impacted by anemia and its treatment over time.

Relationship Between Anemia Profile and Nutritional Status as Assessed by Subjective Global Assessment in Incident Dialysis Patients

Seung Yun Chae, Byung ha Chung, Bumsoon Choi, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim, Tae Hyun Ban. *Seoul St. Mary's hospital, Seoul, SEOUL, Republic of Korea.*

Background: Anemia is a major complication in patients with end-stage renal disease (ESRD). Subjective global assessment (SGA) is a useful tool assessing nutritional status. We investigated an association with changes of anemia, iron and erythropoietin (ESA) prescription rate, and prescribed ESA dosage after assessing nutritional status using SGA over time in incident ESRD patients.

Methods: The cohort was prospectively collected in 36 centers of the Clinical Research Center for ESRD in Republic of Korea. The incident ESRD patients started hemodialysis or peritoneal dialysis between November 2008 and Feburary 2014. We excluded patients who were younger than 18 years old, or had an underlying liver disease and malignancy. Finally, we included 898 incident ESRD patients in this study. Nutritional status was calssified to well nourished (WN, SGA A) or malnourished (MN, SGA B or C). The patients based on the change of nutritional status was divided into four groups as following: group 1, WN to WN; group 2, WN to MN; group 3, MN to WN; and group 4, MN to MN. Data between baseline and 12 months after dialysis initiation was analyzed.

Results: Serum hemoglobin and hematocrit levels, iron and ESA prescription rate, and ESA dosage were improved in all the patients at 1 year after dialysis commencement (P<0.05 for all). In subgroup analysis based on dialysis modality, serum hemoglobin and hematocrit levels of the hemodialysis patients were ameliorated in all the groups (P<0.001 for all). In addition, iron and ESA prescription rate, and ESA dosage were more definitely reduced in group 1 and 3 than the other groups (P<0.001 for both). However, these trends in the patients with peritoneal dialysis diminished or dissipated in all the groups.

Conclusions: Maintaining proper nutritional status based on SGA improved anemia in the incident dialysis patients, with reducing iron and ESA usage in especially hemodialysis patients.

TH-PO268

Different Effects of Iron Indices on Mortality in Patients with Autosomal Dominant Polycystic Kidney Disease After Long-Term Hemodialysis: A Nationwide Population-Based Study

Shu-Ching Yeh.[1,2] *[1]Taipei Medical University Hospital, Taipei, Taiwan; [2]Taipei Medical University, Taipei, Taiwan.*

Background: Iron supplementation and erythropoietin stimulating agents (ESAs) are essential for maintaining hemoglobin levels in hemodialysis (HD) patients. However, patients with autosomal-dominant polycystic kidney disease (PKD) have higher endogenous erythropoietin levels, so their recommended iron indices for HD patients may be different.

Methods: This cohort study from the Taiwan Renal Registry Data System (TWRDS) enrolled 84,219 HD patients with valid baseline iron profiles. We stratified mortality risk by presence of PKD recorded as underlying disease. The primary outcome was 3-year all-cause mortality. Predictors included time-averaged and baseline serum ferritin levels and transferrin saturation (TSAT, %). Cox regression multivariate analysis adjusting age, comorbidities, important relevant laboratories was used to pursue estimated all-cause hazard ratio (HR) of mortality.

Results: We enrolled 1346 HD patients with PKD and 82,873 HD patients without PKD. Mean ages were 56.2±13.2 and 61.7±13.5 years and follow-up durations were 2.62±0.89 and 2.28±1.04 years, respectively. Mortality risks for ferritin >800 ng/mL (HR=1.32; 95% confidence interval (CI)=1.21-1.43) or TSAT >50% (HR=1.34; 95% CI=1.18-1.52) were significantly higher among patients without PKD than those with normal iron indices. However, a U-shape curve between mortality and Ferritin/TSAT levels was not observed in patients with PKD. In sensitivity test, PKD patients underwent regular ESAs therapy showed no difference with non-ESAs user.

Conclusions: Iron indices affect mortality differently among patients with and without PKD. Iron supplementation, recommended serum ferritin levels, or TSAT should be monitored in HD patients especially without PKD. Clinicians should consider to treat anemia in HD patients individually, especially in PKD.

TH-PO269

C-Reactive Protein Levels Might Affect the Association of Ferritin and Survival in Hemodialysis Patients

Shunji Suzuki,[1] Norio Hanafusa,[2] Hiroshi Kawaguchi,[3] Ken Tsuchiya,[2] Kosaku Nitta.[2] *[1]Tokyo Woman Medical University, Shinjuku-ku, Japan; [2]Tokyo Women's Medical University, Shinjuku-ku, Japan; [3]Tokiwa-kai Medical Corporation, Iwaki, Japan.*

Background: Ferritin is associated with survival in hemodialysis (HD) patients; higher ferritin levels are associated with worse survival. Inflammatory status is also associated with worse survival in the same population. Serum ferritin itself increases in the presence of inflammation. Therefore, we hypothesized that inflammation affects the association between ferritin and survival. We investigated the interaction of C-reactive protein (CRP) and ferritin for dialysis patient survival.

Methods: All patients who were receiving hemodialysis HD treatment thrice a week at Jyoban Hospital, Fukushima, Japan were included in the study. The study period was set as July 2012 through August 2014. Baseline laboratory data including CRP, ferritin, and other clinical indices were collected in July 2012. CRP and ferritin were dichotomized in

the subsequent analysis. The study outcome was set as all-cause mortality. Analyses were conducted using Cox's proportional hazard models. Interaction between CRP and ferritin was also included in the study. Analyses stratified by CRP levels were also conducted.

Results: This study examined 397 patients, 258 of whom were male; 44.6% were diabetic. Their average age was 70.6 years, with an average of 3.6 years using on HDhemodialysis. During the observation period, 73 patients died. Examination of the entire population demonstrated that high CRP (>0.2 mg/dl), but not high ferritin (>200 ng/ml), is associated with worse survival: HR 3.31 (95%CI 1.35–14.5) and HR 0.64 (95%CI 0.15–1.54), respectively. Interaction of CRP and ferritin was also significant. Stratified analysis demonstrated that high ferritin was associated with better survival (HR 0.17, 95%CI 0.01–0.81) only in the low-CRP stratum, but not (HR 2.24, 95%CI 0.94–4.77) in the high-CRP stratum.

Conclusions: Results demonstrated that inflammation status might affect the association between ferritin and survival in hemodialysis HD patients. Iron dosing might be individualized in light of inflammation results.

TH-PO270

Iron Rather than Erythropoietin Mediates the Role of Fibroblast Growth Factor 23 in Renal Anemia in Humans

Bernhard O. Bielesz, Fabian P. Hammerle, Thomas J. Reiter, Marija Bojic, Andreas Gleiss, Rodrig Marculescu. *Medical University of Vienna, Vienna, Austria.*

Background: Renal anemia is an almost universal complication of chronic kidney disease (CKD). In animal experiments, Fibroblast growth factor 23 (FGF23), a well-known key-player in mineral metabolism, has been causally implicated by suppressing erythropoietin (EPO). We assessed whether FGF23 might contribute to anemia by inducing relative EPO deficiency.

Methods: Hemoglobin, EPO, iron, and mineral metabolism parameters, including both intact (Diasorin) and c-terminal (Immutopics) FGF23 were measured in 225 non-dialysis CKD (stage 1-5, median eGFR 30 ml/min/1.75m^2) patients not on erythrocyte stimulating agent or intravenous iron therapy. To approximate relative EPO deficiency, EPO values from 5483 patients collected at the General Hospital of Vienna with CRP<1 mg/dl and GFR>60 (median eGFR 87) were chosen as reference population for modelling of gender-specific EPO-standard deviation scores (EPO-SDS) stratified to corresponding hemoglobin levels. Analysis was performed by multiple linear regression.

Results: Both intact and c-terminal FGF23 were associated with hemoglobin in univariate analysis but only cFGF23 remained significant after adjustment. Inclusion of EPO-SDS did not alter the association of cFGF23 with hemoglobin. In contrast, iron indices largely displace this interaction.

Conclusions: In patients with predominantly moderate to severe renal function impairment, relative EPO deficiency fails to explain the association of cFGF23 with anemia, which rather seems to be mediated by iron metabolism.

TH-PO271

Iron Overload in Patients on Hemodialysis: Hepatic, Myocardial, and Bone Tissue Deposit

Lucas A. Nunes,[1] Cesar A. Truyts,[3] Luciene dos Reis,[5] Rosse C. Osorio,[7] Hilton M. Leao-Filho,[1] Rosa M. Moyses,[4] Rosilene M. Elias,[2] Carlos E. Rochitte,[6] Vanda Jorgetti,[2] Melani Custodio.[1] *[1]Universidade de São Paulo, Belem, Brazil; [2]Universidade de Sao Paulo, Sao Paulo, Brazil; [3]university of sao paulo, Jacarei, Brazil; [4]Universidade Nove de Julho, São Paulo, Brazil; [5]University of Sao Paulo - Medical School - Nephrology Division, Sao Paulo, Brazil; [6]Heart Institute (InCor) University of São Paulo Medical School, São Paulo, Brazil; [7]INCOR, Salvador, Brazil.*

Background: Anemia is commonly observed among ESRD patients on hemodialysis patients, most of the time requesting intravenous correction of iron deficiency (Fe). However, excessive Fe supplementation leads to increased risk of Fe overload with consequent deposition in organs and tissues such as liver, heart and bone tissue. The objective of the current study was to evaluate this issue in a cross-sectional cohort of ESRD on hemodialysis.

Methods: We included 28 adult patients (16 men), on hemodialysis for at least 3 months, and with serum ferritin levels ≥1,000 mg/l. Serum ferritin, transferrin saturation index (STI), Fe, C reactive protein (CRP), Calcium (Ca), phosphorus (P), parathyroid hormone (PTH) and alkaline phosphatase (AP) levels were recorded. T2* image acquisition of Magnetic Resonance Imaging (MRI) 1,5 Tesla, were used for the assessment of Fe of liver, and heart. R2* were used only of liver. Bone biopsy was also performed

Results: Mean age was was 54±13 years (57% men). Laboratorial values are depicted at the Table 1. T2* [Reference value(RV) > 16 ms] and R2* (RV < 60 s^{-1} ms) MRI of liver showed 6.95 ms [IQR 3.57] and 143.85 s^{-1} ms [IQR 84.52], respectively. MRI T2* of the heart did not show presence of Fe. Bone biopsy revealed that 100% of patients had Fe deposition.

Conclusions: These data detail the Fe distribution throughout the bone and liver but not myocardial in selected high-risk patients on hemodialysis (serum ferritin levels ≥1,000 ng/ml). The impact of Fe deposition on these tissues whether the use of chelation therapy would change this scenario should be evaluated in subsequent studies.

Socio-Demographic Characteristics, Out of Pocket Expenditure and Quality of Life of Hemodialysis Patients in India

Abhinav Bassi,[2] Oommen John,[2,4] Kamal D. Shah,[1] Sradha S. Kotwal,[3,4] Rohina Joshi,[3] Sanjay K. Singh,[2] Sumathi Kolli,[1] Prasanna K. Thota,[1] Beverley M. Essue,[5] Stephen Jan,[3,4] Martin P. Gallagher,[3,4] John Knight,[3,4] Vivekanand Jha.[2,4] *[1]NephroPlus Dialysis Centres, Hyderabad, India; [2]George Institute for Global Health, New Delhi, India; [3]The George Institute for Global Health, Sydney, NSW, Australia; [4]University of New South Wales, Sydney, NSW, Australia; [5]University of Sydney, Sydney, NSW, Australia.*

Background: The Dialysis Outcomes in India (DOI) Study is following a cohort of incident dialysis patients to evaluate the impact of socio-demographic and economic factors on clinical outcomes among end stage kidney disease (ESKD) patients initiated on hemodialysis in India. Here we present the baseline socio-demographic and clinical characteristics and Quality of Life (QoL) in the enrolled subjects.

Methods: A total of 1000 subjects were recruited between Nov 2016 & Mar 2018 in 18 facilities across 10 states in India. Routine medical records were utilized for collection of demographic and clinical information. Structured interviews were conducted to collect socio-economic parameters, including out-of-pocket expenses (OoP), with QoL measured using Euroqol-5D-3L®.

Results: Mean age (±standard deviation) of enrolled subjects was 54±16 years, and there were 341 females. Nearly two-thirds of the participants had school education or less (female 73% and males 62%). Over 80% of the female subjects worked within the home and 44% of the males were either retired or not working. A history of hypertension was reported in 64% of subjects (duration 7±6 years) and diabetes in 50% (duration 8±7 years). Mean monthly family income was reported as US$ 602±408. Only one-third of the subjects had health insurance. The mean monthly OoP expenditure was US$ 491±299 for uninsured subjects and US$ 191±103 for insured subjects. Nearly 9% of the subjects had to change their occupation due to kidney disease and treatment schedules. Mean distance travelled to the dialysis unit was 25±15 kms (female 15±9 and males 21±14 km, respectively). Over 16% of the patients reported severe anxiety/depression and 14% reported severe problems related to activities of daily living. Mean QoL Score on the VAS Scale (0-100), was reported at 58 ± 18 (male) and 64 ± 14 (female).

Conclusions: Our study found high dialysis-related OoP expenditure, particularly in those who were uninsured. Low levels of health insurance coverage represents a major challenge for policy makers in mitigating the economic burden of dialysis treatment. High number of participants leaving the workforce highlights the challenges related to maintaining employment for patients undergoing dialysis.

TH-PO273

Marginal Cost of Frailty Among Dialysis Patients

John Sy,[1] Elani Streja,[3] Kirsten L. Johansen.[2] *[1]Long Beach VA Medical Center, Long Beach, CA; [2]University of California, San Franicsco, San Francisco, CA; [3]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA.*

Background: Patients on dialysis incur disproportionately high costs compared to other Medicare beneficiaries, and frail individuals may cost more. We examined the extent to which frailty contributes to higher costs among dialysis patients.

Methods: The ACTIVE/ADIPOSE study enrolled adult hemodialysis patients from June 2009 to August 2011. Individuals utilizing Medicare as the primary payer with active claims were selected for inclusion. Frailty was assessed at baseline and annually for 2 years using Fried's frailty phenotype. Baseline demographic data and costs were derived from linkage with the USRDS and Medicare claims (Part A, B, and D) standard analysis files. We used generalized estimating equations incorporating time-updated frailty to estimate the marginal cost of being frail at the beginning of each year of follow-up, adjusting for age, gender, body mass index (BMI), and comorbid conditions (diabetes, coronary artery disease, and congestive heart failure). All costs were adjusted for inflation to 2017 US dollars and reported per patient per year (pppy).

Results: Among 771 individuals enrolled in the ACTIVE/ADIPOSE study, 345 met inclusion criteria with an average age of 56.1 years and BMI of 29 kg/m^2. 28% of patients were considered frail at baseline, whereas 54% were frail at any time point. Over mean 2.3 years of follow up, frail individuals incurred 23% (95% CI 10-37%) higher costs compared with non-frail individuals ($101,000 pppy, 95% CI $89,000-$116,000, vs $83,000 pppy, 95% CI $75,000 – $91,000). The difference in costs between frail and non-frail patients appears to be driven primarily by higher hospitalization expenditures (26% higher, 95% CI 11%-43%). Neither physician/supplier costs (12% higher, 95% CI 2% lower to 29% higher) nor were expenditures for pharmacy benefits (2% higher, 95% CI 8% lower to 13% higher) statistically different between frail and non-frail individuals.

Conclusions: Frail dialysis patients incur a significantly higher cost relative their non-frail counterparts, primarily driven by higher hospitalization costs. Efforts to address frailty and its association with hospitalizations may lead to a significant reduction in health care expenditure among dialysis patients.

TH-PO274

The Health and Economic Consequences of Missed Dialysis at the Robley Rex Veterans Affairs Medical Center

Liza Cholin,[1] Jordan Burlen,[1] Farrah Harden,[1] Nevin Murthy,[1] Michael E. Brier,[1] Eleanor D. Lederer.[2] *[1]University of Louisville, Louisville, KY; [2]University of Louisville; Robley Rex VA Medical Center, Louisville, KY.*

Background: Non-adherence to hemodialysis (HD) is associated with increased morbidity and mortality risk, as well as increased health care costs. These patients frequently present to the emergency department (ED) needing urgent HD for volume overload, hyperkalemia, or uremic symptoms. At present, the Robley Rex VAMC does not offer outpatient HD, necessitating full hospital admission for patients who present with urgent need for HD. We hypothesized that offering outpatient HD to patients who missed their scheduled appointments would reduce costs attributed to missed HD hospital admissions, even taking into account increased dialysis nurse overtime utilization.

Methods: We conducted a retrospective analysis of established HD patients evaluated in the ED of the Robley Rex VAMC, between October 2015 and May 2017, for complications secondary to missed dialysis. Individuals that were admitted for any reason other than urgent HD were excluded. The costs for ED evaluation, hospitalization, and dialysis labor costs were obtained. We calculated costs of the full inpatient admission including dialysis and compared those results with the projected cost providing a single outpatient dialysis treatment for each presentation.

Results: There were 92 individual admissions resulting in 209 inpatient dialysis treatments, indicating that patients were often kept for additional HD treatments. The total cost for these admissions was $729,360.93, which roughly equates to $7,927.84 spent per admission. The cost for an outpatient dialysis session (including ED cost) ranges between $1,032.12 and $1,177 accounting for standard labor versus time-and-a-half labor, respectively. Thus, the total expected range for an equivalent 209 HD sessions, if they were to be done as an outpatient, would be between $215,713.08 and $245,993. This results in total savings ranging from $483,367.93 to $513,647.85.

Conclusions: Forming outpatient dialysis capabilities in an acute dialysis unit would help reduce health-care spending in patients being admitted to VA hospitals for missed HD. Further research is still needed in identifying possible reversible barriers in non-adherent patients.

TH-PO275

Fast Track Dialysis: A Novel Triage and Communication Pathway to Reduce Resource Utilization for ESRD Patients Presenting with Missed HD

Tahsin Masud,[1] Ethan Molitch-Hou,[3] Kyle P. James,[2] Christopher M. O'Donnell.[3] *[1]Renal, Emory University, Atlanta, GA; [2]Hospital medicine, Emory University Hospital Midtown, Atlanta, GA; [3]Hospital Medicine, Emory University Hospital Midtown, Atlanta, GA.*

Background: Many end stage renal disease (ESRD) patients present to emergency department (ED) with complaints related to missed hemodialysis (HD) or have no established dialysis clinic. Provision of inpatient HD necessitates short stay admission, use of extra resources, coordination between multiple specialties, resulting in substantial cost.

Methods: A multidisciplinary team sought to improve the flow of ESRD patients through the ED by creating a unique triage pathway, Fast Track Dialysis (FTD). FTD care was facilitated with standardized communication between ED, Nephrology, Hospitalist and Nursing. The FTD pathway emphasized use of venous blood gasses for potassium levels, limited telemetry, chest X-ray, and peripheral IV lines. Patients eligible for FTD were identified by ED providers. Exclusions were BP > 200/100, heart rate > 120/ minute, hypoxia requiring oxygen > 4 L/min, potassium > 6.5 mEq/L and clinical concern that would require admission beyond one session of HD, and dialysis access issues requiring immediate intervention. A six-month historical control group (Pre-FTD) was compared with a six-month FTD cohort with hospital stay < 48 hours. The historical group was filtered by admitting diagnosis (ICD-10 codes) related to dialysis conditions, stay < 48 hours, and above exclusion criteria. Outcome measures were time parameters from triage to ED discharge, HD start, and hospital discharge. The estimates of cost were obtained from hospital generated billing.

Results: FTD led to significant reduction in all time parameters studied (Table). The billing cost was lower but reached significance level after excluding 3 outliers who require additional diagnostic testing for head injury, paracentesis and chest pain.

Conclusions: The implementation of a novel patient care pathway intended to identify, triage, and facilitate the care of low risk ESRD patients that required urgent HD led to a reduction in resource utilization.

	Pre-FTD (1/1/17-6/30/17)	95% CI	FTD (9/25/17-3/16/18)	95% CI	p-value
Age, years(SD)	58.6 (13.2)		53.2 (10.1)		<.01
Males, n(%)	44 (53.7)		52 (68.4)		0.23
Triage to ED discharge (Hrs)	7.2	5.90-8.43	4.1	3.34-4.83	<.01
Triage to HD start (Hrs)	12.8	9.15-16.6	5.2	3.52-6.86	<.01
Triage to hospital discharge (Hrs)	26.2	24.28-28.05	14.3	12.4-25.4	0.01

TH-PO276

Cost Savings Associated with Post-Hospital Medication Therapy Management Program Dialysis Patients

Harold J. Manley,[1,2] Gideon N. Aweh,[1] Daniel E. Weiner,[3,1] Eduardo K. Lacson.[1,3] *[1]Dialysis Clinic, Inc., Nashville, TN; [2]Reach MTM, Albany, NY; [3]Tufts Medical Center, Boston, MA.*

Background: Dialysis Clinic, Inc. implemented a medication therapy management (MTM) program for End-Stage Renal Disease Seamless Care Organization patients following hospital discharge. Prior results suggested a 56% reduction in readmission rate with MTM compared to no MTM. We determined the potential impact of the MTM process on costs associated with readmision.

Methods: We used a propensity score (PS) to match MTM 1:1 to non-MTM discharges based on clinical characteristics and on the day post-discharge MTM was initiated. Actual readmission costs were obtained from claims data; the percent difference between MTM and non-MTM groups were calculated and used to estimate cost impact if MTM process applied to non-MTM discharges. Readmission rates after MTM completed, or similar time at risk in matched non-MTM patients, was determined. Cost estimates incorporated MTM implementation time (median, interquartile range) and assumed 25%, 50% or 75% of reported MTM program impact on readmission rate.

Results: In the original cohort, there were 162 discharges with 17 readmissions costing $253,652 in the MTM group and 586 discharges with 170 readmissions costing $2,161,163 in the non-MTM group. Median time to complete MTM was 11 days. There were 135 PS matched pairs used, with 26 (19.26%) readmissions in MTM patients and 50 (37.04%) in non-MTM patients (p=0.0002). Readmission costs were $202,659 vs. $580,549, respectively (p<0.001). MTM was associated with 12%, 26%, or 49% cost savings if implemented ≥14 days, ≥11 days or ≥7 days post discharge, respectively. Extrapolating results to the entire non-MTM group, savings ranges from $117,586 to $600,642 (see Table). Cost savings with MTM performed within 11 days of discharge assuming 50% impact approximates $286,020.

Conclusions: MTM process is associated with fewer readmissions and lower inpatient costs. The statements contained in this document are solely those of the authors and do not necessarily reflect the views or policies of CMS. The authors assume responsibility for the accuracy and completeness of the information contained in this document.

Savings estimates if MTM process implemented in 586 no-MTM discharges

	≥14 days	≥11 days	≥7 days
25%	$117,586	$143,010	$200,214
50%	$235,172	$286,020	$400,428
75%	$352,758	$429,030	$600,642

TH-PO277

In-Center Hemodialysis Consumer Assessment of Healthcare Providers and Systems (ICH CAHPS) Survey Response and Long-Term Clinical Outcomes

Taimur Dad,[1] Hocine Tighiouart,[1] Megan Grobert,[2] Eduardo K. Lacson,[1] Klemens B. Meyer,[1] Daniel E. Weiner,[1] Michelle M. Richardson.[3] *[1]Tufts Medical Center, Boston, MA; [2]Dialysis Clinic Inc, Nashville, TN; [3]New England Medical Center, Boston, MA.*

Background: The In-Center Hemodialysis Consumer Assessment of Healthcare Providers and Systems (ICH CAHPS) survey, introduced into the ESRD Quality Incentive Program, is the only patient-reported outcome measure currently used for value-based reimbursement in dialysis. It is administered twice yearly to assess hemodialysis patient experience. Current response rates are approximately 30%. The relationship between response status and long-term clinical outcomes is unknown.

Methods: All Dialysis Clinic Inc. (DCI) hemodialysis patients age 18 and older treated at their facility for at least 3 months as of August 2012 were eligible for the survey. Covariates included patient demographic, clinical, and treatment related characteristics. Outcomes included mortality, kidney transplantation, and all cause-hospitalization.

Results: Among 10,395 eligible patients who survived the 3-month survey administration, 3,794 (36%) responded to the survey. Over median follow-up of 30 months, 4,178 patients died, 5,336 patients were hospitalized at least once, and 717 patients received a transplant. In multivariable models, survey response was associated with lower mortality (HR 0.80; 95% CI: 0.74-0.85) and hospitalization (HR 0.84; CI: 0.79-0.89) and higher likelihood for kidney transplant (HR 1.15; 95% CI: 0.98-1.35). Sensitivity analyses evaluating the receipt of transplant with competing risk for death, or a composite outcome of death or hospitalization, yielded similar results.

Conclusions: Response to the ICH CAHPS survey is associated with a lower risk for mortality and hospitalization and higher likelihood for kidney transplantation. These findings raise concern about survey result generalizability and use for quality improvement since experiences of high-risk patients are less likely to be captured.

TH-PO278

Do the Better Medical Results Mean a Higher Costs for the Dialysis Clinic?

Wojciech Marcinkowski,[4] Jacek P. Zawierucha,[1] Jolanta Malyszko,[2] Jacek S. Malyszko.[3] *[1]Fresenius Medical Care Polska S.A., Poznan, Poland; [2]Warsaw Medical University, Warsaw, Poland; [3]Nephrology Department, Bialystok, Poland; [4]Fresenius, Krakow, Poland.*

Background: The quality of care for hemodialyzed patients is determined by commonly accepted biochemical parameters controlled periodically. In everyday practice evaluation includes, among other things, the dose of dialysis provided, the control of anemia, the control of calcium-phosphate balance, and the patients' nutrition status. Obtaining good results is related to, among other things, the time of dialysis sessions, water consumption, electricity, prescribed pharmacotherapy. The aim of the study was to retrospectively assess the correlation between the obtained medical results and the costs directly related to the dialysis treatment of patients with chronic renal failure.

Methods: The analysis included 5,500 patients treated in 68 centers in the years 2014-2016. Medical evaluation was based on the percentage of patients achieving the individual target in particular categories: weekly dialysis time > 240 minutes, single-pool kt/v > 1.4, dialysis with arteriovenous fistula, relative overhydration < 13% (female) or <15% (male), Hb concentration in the range of 10-12 g/dl or > 12 g/dl without the use of erythropoiesis stimulating agents (ESA), albumin > 35 g/l, phosphate concentration < 5.5 mmol/l, patient's protection against new HBV infection and the percentage of patients active on the waiting list for kidney transplantation > 7%. For reaching the clinic target in a single category the center was awarded 1 point. The clinic medical result was the sum of points. The assessment was made on a monthly basis. Monthly treatment costs were also assessed. Costs of dialyzers and dialysis lines, electricity, water, concentrates, ESA, iron, anticoagulation, dialysis fluid concentrates, hygiene and dressing agents were included. The medical results were then correlated with the costs incurred in individual months in subsequent years.

Results: The correlation coefficient r between medical results and costs in 2014, 2015 and 2016 was -0.35 ($p < 0.005$), -0.42 ($p < 0.001$) and -0.51 ($p < 0.001$), respectively.

Conclusions: A statistically significant negative correlation between medical results and costs directly related to the treatment of hemodialyzed patients in three consecutive years suggests that better medical results are obtained in centers that better control medical expenses. Better medical care does not necessarily means higher costs for dialysis centers.

TH-PO279

Dialysis Facility Acquisitions and Patient Health Outcomes

Kevin F. Erickson,[1] Bo Zhao,[1] Wolfgang C. Winkelmayer,[1] Glenn M. Chertow,[2] Vivian Ho.[3] *[1]Baylor College of Medicine, Bellaire, TX; [2]Stanford University School of Medicine, Palo Alto, CA; [3]Baker Institute for Public Policy, Houston, TX.*

Background: Mergers and acquisitions among healthcare providers are increasingly common. Although dialysis markets have undergone several decades of mergers and acquisitions, their effects on patient health outcomes are unknown.

Methods: We identified patients initiating in-center hemodialysis between 2001 and 2013 from a national ESRD registry and used difference-in-differences (DID) models to estimate the associations among dialysis facility acquisitions, mortality and hospitalization. We used multivariable Cox models and negative binomial models (with predicted marginal effects) to examine mortality and hospital days, respectively. All analyses adjusted for observed differences in patient and geographic characteristics. In addition to examining all facility ownership types, we conducted stratified analyses of facilities that were independently-owned and chain-owned prior to acquisition.

Results: When examining all facility ownership types, dialysis facility acquisitions were independently associated with 0.63 additional hospital days per patient-year (95% CI 0.00 to 1.27; p=0.07). When examining independently-owned facilities, acquisitions led to 2.01 additional adjusted hospitalization days per patient-year (95% CI 0.53 to 3.48) and a nominally significant 13% relative increase in adjusted mortality (95% CI 4% to 22%).

Conclusions: Acquisition of independently-owned dialysis facilities by large dialysis organizations led to higher adjusted mortality and an increase in adjusted hospital days per patient-year.

TH-PO280

The Impact of Debility on Inpatient Mortality and Hospital Costs of ESRD Patients in the United States: A Nationwide Study

Mark A. Nader,[1,2] Oussama Hassan,[3] Rodrigo Aguilar Campos,[4] Rehan Shafique,[1] Carmen E. Cervantes,[5] Ricardo Correa,[6] Prabin Sharma,[7] Hieu Q. Vo,[9] Omar Hamze,[11] Judit Gordon,[8] Ping Li.[10] *[1]Nephrology and Hypertension, Kidney Care consultants, Memphis, TN; [2]Nephrology and Hypertension, Georgetown University, Washington, DC; [3]Royal London Hospital, Austin, TX; [4]Georgetown University Hospital, Washington, DC; [5]Aventura Hospital and Medical Center, Aventura, FL; [6]University of Arizona, Phoenix, AZ; [7]Yale University Bridgeport Hospital, Bridgeport, CT; [8]Medstar Georgeotown University Hospital, Washington, DC; [9]University of Tennessee, Memphis, TN; [10]Nephrology and Hypertension, George Washington University, Washington, DC; [11]Kidney Care Consultants, Memphis, TN.*

Background: Patients on dialysis often suffer from muscle wasting and reduced exercise tolerance compared with the general population. The impact for this debility on the in-patient dialysis population remains unclear. The purpose of the current study was to determine the inpatient mortality and cost effects of debility between dialysis patients.

Methods: Data was extracted from the 2005 to 2012 Nationwide Inpatient Sample (NIS). Using propensity score matching, end stage renal disease (ESRD) patients with debility were matched with ESRD patients without debility at a 1:1 ratio. We compared inpatient mortality, length of stay and total hospital charges between both groups. Analyses were performed using SAS version 9.3 (SAS Institute, Cary, NC, USA).

Results: Among 1,070,450 hospitalized ESRD patients during 2005 to 2012; only 16,810 (1.57%) were identified with debility. These patients were associated with significantly higher rate of gastrointestinal bleed (2.01 vs 1.77%; p=0.02), obesity (11.92 vs 8.37%), acute CHF (39.12 vs 33.94%; p=0.0001), Atrial fibrillation (23.11 vs 15.06%; p=0.0001) and CAD (41.74 vs 33.99; p=0.0001). Surprisingly, ESRD patients with debility had a significantly lower in-hospital mortality compared with ESRD patients without debility before (4.52 vs 5.09%; p=0.001) and after matching (4.53 vs 6.17%, $p = 0.0001$). Mean length of stay for those with debility was 11.12 days compared with 7.53 days ($p < 0.0001$). Similarly, mean hospital charges were greater for those who had debility compared with control ($69,596 vs $57,752; $p < 0.001$).

Conclusions: Debility in dialysis patients appears to have a lower in hospital mortality compared to more conditioned ESRD patients. It does however increase the costs and length of stay. Interventions to lower debility may help reduce hospital expenditures.

TH-PO281

Can Dialysis Facility Compare (DFC) Star Ratings Inform Patient Choice of Dialysis Facility? Geographic Co-Location of Facilities by Star Rating Category

Stephen Salerno, Garrett W. Gremel, Richard A. Hirth, Yi Li, Claudia Dahlerus, Lan Tong, J. M. Messana. *University of Michigan, Kidney Epidemiology and Cost Center, Ann Arbor, MI.*

Background: Beginning in 2015, Medicare's DFC site implemented a Star Rating system summarizing the selected clinical quality measures reported on DFC. The Star Ratings are intended to provide an easily interpretable summary of dialysis facility's quality performance and to assist consumer decision-making. We hypothesize that patients' choice of dialysis facility might be influenced by the reported Star Ratings, particularly for those whose choice is not limited by distance to a dialysis facility.

Methods: Based on facilities' zip codes and their reported Star Ratings on DFC, we geocoded all 6000+ dialysis facilities in the contiguous U.S.. Facilities with lower star rating performance were defined as those with 1 or 2 Stars; higher star rating performance was defined by 3 to 5 Stars. Distances between two facilities were calculated based on the spherical distance between the centroids of their zip codes using the geosphere package in R.

Results: Fig. 1 shows the locations of dialysis facilities and Star category. A clear geographic pattern for distribution of lower performing facilities is not apparent. Fig. 2 demonstrates that 84% of facilities with lower star rating are within 10 miles of facilities with higher performance.

Conclusions: These results demonstrate that most patients receiving dialysis care in lower star rating facilities have the option to transfer care to higher star rating facilities based on their geographic proximity. Whether the availability of a higher star rating facility in close proximity contributes to the patient's choice of a new or transfer facility remains unanswered by these analyses. Subsequent analyses will stratify lower and higher star rating

facilities to evaluate if patients' choice of dialysis provider is associated with higher rated facilities in close proximity.

Medicare Payments for Ambulance Transport Between Skilled Nursing and Dialysis Facilities

Debabrata Ray,[1] Kristine Kubisiak,[1] Allan J. Collins,[1,2] Eric D. Weinhandl.[1,2] *[1]NxStage Medical, Inc., Victoria, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: Most dialysis patients receiving care in a skilled nursing facility (SNF) undergo hemodialysis in off-site dialysis facilities and thus require transportation before and after each session. In specific circumstances, Medicare Part B provides coverage for ambulance transport between such facilities. However, Medicare payments to ambulance service providers have been scrutinized by the federal government. By year, we aimed to quantify trends in Medicare expenditures on ambulance transport between SNFs and dialysis facilities.

Methods: We analyzed data from the United States Renal Data System. We searched Medicare Part B claims in payment years 2011-2015 for ambulance transport and retained such claims with an origin/destination code pair that indicated transport between SNF and dialysis facility. We tallied the number of patients with ≥1 ambulance transport between SNF and dialysis facility, the cumulative number of patient-days with ambulance transport, and cumulative Medicare payments for ambulance transport.

Results: Ambulance transport utilization was similar in 2011 and 2012 and subsequently increased to an apex in 2014: 24,327 patients with ≥1 transport between SNF and dialysis facility and 783,786 patient-days with transport (32.2 days per patient). In 2015, utilization fell to 21,601 patients with ≥1 transport between SNF and dialysis facility and 643,808 patient-days with transport (29.8 days per patient). Cumulative Medicare payments for ambulance transport increased from $305.7 million in 2011 to $312.4 million in 2013; thereafter, payments fell to $285.4 million in 2014 and $235.3 million in 2015. In 2015, the Medicare payment rate for ambulance transport was $365 per patient-day, down from $411 per patient-day in 2012. As a share of all Medicare Parts A and B payments among beneficiaries with end-stage renal disease, cumulative Medicare payments for ambulance transport between SNFs and dialysis facilities fell from nearly 1.1% in 2011-2013 to 0.8% in 2015.

Conclusions: Medicare expenditures for ambulance transport between SNFs and dialysis facilities are falling, initially due to lower per-diem payments and later due to lower utilization. Nevertheless, even in 2015, the per-diem Medicare payment for ambulance transport remained more than 50% higher than the base-level Medicare payment ($239) for an outpatient hemodialysis session.

TH-PO283

The 13-Year Experience of Performing In-Center Short Daily Hemodialysis - Who Pays for It?

Mateus Pascoal, Andre Fernandes, Adolfo Simon, Kelia Xavier, Vilber Bello, Juliane Lauar, Istenio Pascoal. *Centro Brasiliense de Nefrologia & Dialise, BRASILIA, Brazil.*

Background: Conventional hemodialysis (CHD: 4h3x/wk) has been associated with poor quality of life and high morbidity, hospitalization and mortality rates. An ideal hemodialysis prescription requires ultrapure dialysate, single-use biocompatible membranes, on-line blood monitoring and more frequent and/or longer treatments. Hospitalization represents a significant financial burden, accounting for 40% of total dialysis expenditures. We have successfully run an in-center short daily hemodialysis program (SDHD: 2h6-7x/wk) complying with all requirements for an ideal prescription in the last 13 years. This study aims to demonstrate how we have configured dialysis delivery, improved outcomes and managed resources to achieve an optimal sustainable dialysis practice.

Methods: Operational (productive efficiency, patient compliance and payers coverage), clinical (hospitalization, kidney transplantation and survival rates) and economic (supply dialysis cost, cost-savings and net savings) landscapes were assessed in 176 consecutive unselected private-insured patients (108M/68F; mean age 57.6±19.0 yrs, range 8-97) receiving in-center SDHD treatments (6-7x/wk; lasting 117.2±8.8min, range 105-150; ultrapure dialysate and single-use high-flux dialyzer) from Jun/05 to May/18. Reimbursement has been largely based on patient outcomes and hospitalization rates.

Results: Our in-center SDHD program operates five 2-hour shifts a day (67% higher productivity without increasing fixed costs), the average missed treatment rate was 1.47% and an incremental negotiated approach reached universal insurance coverage for daily regimen. Average hospital stay (2.97 days per patient-year), kidney transplantation rate (7.5%) and mortality rate (7.3%) were better than reported for CHD hospital stay (12 days per patient-year), kidney transplantation rate (4.6%) and mortality rate (19.9%). Daily hemodialysis consumables costs doubled, adding 25% for patient overall cost. Conversely, hospital total length of stay was 75% lower, reducing overall costs by 30% and offseting the additional supply cost.

Conclusions: Our dialysis care redesign has markedly improved patient outcomes and dramatically reduced hospital stays and expenses. With clinical and economic variables combined, it has been possible to sustain a distinctive yet affordable maintenance hemodialysis program.

TH-PO284

Estimated Revenue Gains Associated with Relative Blood Volume Monitoring (RBV-M) in Hemodialysis (HD) Clinics: An Economic Model Using Real-World Data and a Case Size of 12 Medicare Incident Patients

Melissa M. Rosen,[1] Yisha Li,[1] Linda Ficociello,[1] Paul Balter,[2] Claudy Mullon,[1] Robert J. Kossmann,[1] Gary G. Singer.[3] *[1]Fresenius Medical Care Renal Therapies Group (RTG), Waltham, MA; [2]Nephrology Associates of Northern Illinois and Indiana (NANI), Oak Brook, IL; [3]Midwest Nephrology Associates, Saint Peters, MO.*

Background: There are over 100,000 new HD patients (pts) per year (USRDS). For these pts, the first 90 days following HD initiation are associated with elevated hospitalization and mortality rates, along with high healthcare costs. We conducted an economic analysis for incident HD pts using data from a fluid management (FM) quality improvement project (QIP) using RBV-M.

Methods: RBV-M was performed using Crit-Line® Monitors in 9 Renal Research Institute (RRI) Clinics. The QIP was associated with an average of 5.3 fewer hospital days and an estimated reduction of 2.5 missed treatments (txs) per year in incident HD pts (n=1068). Revenue gains from fewer missed txs were calculated using a cost minimization model from a facility level perspective. We assumed that HD clinics continuously served 12 Medicare incident pts with 2 monitors and disposable supplies associated with RBV-M. It was also assumed that pts received HD 3 times per week and HD txs were reimbursed at $350 per patient (i.e. standard Medicare reimbursement amount plus the onset of dialysis adjustment).

Results: Implementing a FM initiative with RBV-M has the potential to generate additional revenue from reducing 2.5 missed txs per year. This translated into gains of $2,048, annually per clinic (with 12 Medicare incident pts) in the implementation year, after accounting for the cost of the monitors and disposable supplies. Once the machines are paid for, either in the second year or if the clinic already owns monitors, annual gains are $6,048, including the cost of disposable supplies. These results do not include potential savings associated with averted hospitalizations or other benefits of the QIP.

Conclusions: RBV-M QI initiatives have the potential to reduce missed txs in incident pts and increase revenue in HD clinics. Assuming a reimbursement of $350 per dialysis treatment and 12 incident pts per clinic, potential revenue gains associated with RBV-M were found to be $2,048 in the start year and $6,048 in the year following implementation (or for clinics who already own monitors). Future cost-effectiveness studies of FM initiatives should consider the additional value gained from including prevalent HD pts who are also likely to benefit from RBV-M.

TH-PO285

Analytical Methods for Assessing Clinic-Level Outcomes

V. Shane Pankratz,[2] Huan Jiang,[1] S. Paine,[1] Ambreen Gul,[1] Dana Miskulin,[3] Philip Zager.[1] *[1]Dialysis Clinic, Inc., Albuquerque, NM; [2]UNM Health Sciences Center, Albuquerque, NM; [3]Tufts Medical Center, Boston, MA.*

Background: Patient outcomes from dialysis units are important indicators of the quality of care provided by each unit. Clinical outcomes for dialysis providers are typically assessed on a per-clinic level. However, the number of patients in each clinic varies greatly, and this can impact the validity of ratings. Different analytical approaches might enhance the estimated ratings.

Methods: Using 2009-2017 data from Dialysis Clinic, Inc. (DCI) clinics, as well as simulated data, we assessed the impact of different estimation approaches (fixed vs. random clinic effects) on ratings based on clinic-level mortality.

Results: Simulations demonstrate that random effects estimates are shrunk towards the overall mean, and have lower standard errors than fixed effects estimates, and that random effects estimates more reliably provide estimates that agree with truth, particularly for smaller clinics. Estimates of mortality from DCI clinics illustrate the degree of shrinkage that is induced through the application of random effects methods (Figure 1).

Conclusions: Random effects approaches are more likely to provide correct rankings of clinics than fixed effects estimates, and might reliably be used to obtain stabilized estimates of mortality rates. However, obtaining estimates in this way may require larger numbers of patients per unit than are often treated within individual clinics. Enhancing information content, either by aggregating across years or by incorporating other data types into an aggregated rating measure, would enable more accurate estimation of clinic performance.

The Centers for Medicare & Medicaid Services ESRD Quality Incentive Program (QIP): Measurement, Monitoring, and Evaluation

Jeffrey Pearson,[1] Dominick Esposito,[2] Adebola O. Adeleye,[3] Delia Houseal,[3] Marc Turenne,[1] Alissa Kapke,[1] Meg G. Tucker,[2] Whitney B. Schott,[2] Josh Chen,[2] Amanda Szymanski,[1] Eric W. Young,[1] Alan B. Leichtman.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Insight Policy Research, Arlington, VA; [3]Centers for Medicare and Medicaid Services, Woodlawn, MD.*

Background: Mandated in 2008, QIP is Medicare's premier value-based purchasing program. Congress designed QIP to link dialysis facility quality with payment. Initially QIP used measures of anemia and hemodialysis adequacy; it now includes a broad set of clinical, safety, and reporting measures. With the recent Meaningful Measures Initiative, CMS is interested in a measure set that reflects the highest priorities for quality measurement and improvement. We describe ongoing monitoring of QIP measures and evaluation of QIP influence on quality, overall and among subgroups of patients and facilities.

Methods: We used Medicare claims, CROWNWeb, and other CMS data to monitor monthly trends in QIP measures during 2010-17.

Results: Performance has improved over time under the QIP for most quality indicators, and has remained relatively stable for the remainder (figure). Smaller recent changes for some indicators may reflect diminishing opportunities for improvement where performance levels are already relatively high (e.g. hemodialysis adequacy, hypercalcemia). Performance was lower for some patient subgroups (e.g. black race, young adults) for some indicators (e.g. fistula use, readmissions, emergency department visits). Many indicators varied by facility characteristics, including ownership, hospital-based vs freestanding, and size. For example, facilities not affiliated with large chains often had consistently lower performance (e.g. peritoneal dialysis adequacy, hospitalizations) or took longer to achieve similar performance levels (e.g. hemodialysis adequacy, fistula use).

Conclusions: In the era of the QIP, overall performance has improved on many indicators of quality of care. Variation in performance on some indicators based on patient and facility characteristics suggests continued opportunities for improvement.

National Trends in QIP Measures, 2010-17

TH-PO287

A Case Study of the Barriers to the Practice of Person-Centered Care within the Context of Hemodialysis Services

Rachel A. Lewis, Marcello Tonelli. *University of Calgary, Calgary, AB, Canada.*

Background: People dependent upon hemodialysis have a high illness and treatment burden. This can be accentuated by care delivery systems that are disease specific, episodic, process focused and fragmented. Person-centered care (PCC) has been shown to provide a number of benefits including: improved health outcomes; increased patient satisfaction; and a reduction in healthcare utilization. Although conceptually PCC is widely supported, its translation into practice is proving to be a challenge. This research explores stakeholder perspectives of how care is provided within hemodialysis services. It particularly focuses on factors that inhibit PCC.

Methods: A case study approach was used that included semi-structured interviews and observation of clinical encounters, including physician rounding. Data was coded inductively and categorized into emergent themes using Nvivo®. Interpretive description was used to analyse the data. A total of 48 people were interviewed: 20 patients, 5 family members, 9 nurses, 6 physicians, 5 managers and 3 social workers. 30 hours of observation were undertaken.

Results: Care was largely limited to the technical aspects of dialysis treatment and whilst there was evidence of PCC, this was episodic and specific to individual clinicians and/or patients. Patients did not perceive their care as individualized, were not involved in decisions regarding it and felt the staff did not have time to listen to their concerns. Nurses described an oppressive and stressful environment with a culture of bullying. The routinization of nursing care and micromanagement, reduced their autonomy and scope of practice. Physician scheduling required reviewing a large number of patients within a short time span; care was often limited to addressing immediate issues and physicians had some concerns regarding continuity. Many of the healthcare professionals alluded to the lack of multi-professional working.

Conclusions: A complex mix of individual, environmental and organizational barriers mitigate against the adoption and practice of PCC within hemodialysis services. In particular, how professionals' practised was often constrained by care processes aimed at meeting demand. This was accentuated by the absence of integrated work practices.

TH-PO288

Patient-Nephrologist Prognostic Awareness and Discordance in ESRD on Renal Replacement Therapy

Sassine Ghanem,[1] Nicholas Fuca,[1] Samer Saouma,[1] Sami U. Hossri,[1] Frank Forte.[2] SIUH Medicine/Nephrology *[1]Staten Island University Hospital, Staten Island, NY; [2]Staten island university hospital Nothwell Health, Staten island, NY.*

Background: The one-year mortality rate of patients with ESRD on renal replacement therapy is 20-25%, comparable to many cancers. Several studies have documented that patients with cancer commonly overestimate their likelihood of survival relative to their physicians however it is unclear if this translates into other terminal illnesses.

Methods: Patients with ESRD on RRT age 18 years and older with no cognitive defect were interviewed to evaluate their prognostic estimates at one and five years. Their past medical history and demographic data were abstracted from medical charts. Each patient's nephrologist was then interviewed regarding the prognostic estimate of the patient. Both patient and nephrologist estimates were then compared and a difference of greater than 20% divided the patients into two groups, prognostic concordance or discordance.

Results: 77% of the patients were found to be in prognostic discordance with their nephrologists. This group was older, had more comorbidities, a lower albumin level and a worse prognostic score. The majority of these patients were in disagreement with their nephrologists regarding whether a discussion about prognosis had occurred. The goals of care for 55% of patients was oriented towards an end of life focused on relieving pain and discomfort even if that meant a shorter duration of life.

Conclusions: Communication of prognosis and discussions related to life expectancy and planning for end of life care are lacking in routine care of ESRD patients. ESRD patients therefore tend to overestimate their prognosis, while half of the patients interviewed preferred an end of life care oriented towards symptom control, not longevity, this may lead to overutilization of invasive procedures and higher healthcare costs as well as a delay in palliative or hospice measures.

Table 5: Brief Perception Illness Questionnaire comparison of concordant & discordant patients

Brief Illness Perception Questionnaire: Mean of answers on a scale of 1-10	Concordant Group	Discordant Group	*p* - value
How much does your illness affect your life?	7.40	4.98	0.014
How long do you think your illness will continue?	6.33	7.37	0.200
How much control do you feel you have over your illness?	4.87	5.29	0.833
How much do you think your treatment can help your illness?	7.80	8.49	0.267
How much symptoms do you experience from your illness?	5.60	3.63	0.038
How concerned are you about your illness?	7.73	7.49	0.335
How well do you feel you understand your illness?	8.00	8.50	0.194
How much does your illness affect you emotionally? (e.g. does it make you angry, scared, upset or depressed?)	5.07	3.67	0.087

Table 6: Reporting of prognostic discussion discordance

Nephrologist reports having discussion	Patient reports having discussion		
	Yes	No	Total
Yes	13	17	30
No	18	18	33
Total	31	35	66

Table 7: Prognostic awareness comparison of concordant and discordant patients

Prognostic awareness (Patient) frequency and percentage		Concordant Group	Discordant Group	*p*-value
Do you believe that hemodialysis is extending your life?	Yes	15 (100%)	48 (94%)	N/A
	No	0 (0%)	3 (6%)	
Did your physician discuss your prognosis with you?	Yes	6 (40%)	25 (49%)	0.57
	No	9 (60%)	26 (51%)	
Would you like your physician to discuss this with you?	Yes	9 (82%)	18 (51%)	0.09
	No	2 (18%)	17 (49%)	
If you were seriously ill, would you prefer care to: Extend life, even if it meant more pain and discomfort		7 (47%)	22 (45%)	1.00
Relieve pain and discomfort, even it if meant not living as long?		8 (53%)	27 (55%)	
Are you aware that increased weight gain between dialysis sessions affects your prognosis negatively?	Yes	6 (40%)	20 (40%)	1.00
	No	9 (60%)	30 (60%)	
Are you aware that an uncontrolled phosphorus level affects your prognosis negatively?	Yes	3 (20%)	9 (18%)	1.00
	No	12 (80%)	42 (82%)	
Are you aware that a low albumin level affects your prognosis negatively?	Yes	5 (33%)	30 (58%)	0.76
	No	10 (67%)	21 (42%)	
Would you be interested in an educational course or information pamphlet regarding factors that might improve the course of your disease and life expectancy?	Yes	3 (20%)	24 (48%)	0.04
	No	12 (80%)	26 (52%)	
Prognostic awareness (Nephrologist) frequency and percentage				
Would you be surprised if this patient died within the following year?	Yes	11 (73%)	19 (37%)	0.02
	No	4 (27%)	32 (63%)	
Did you have a discussion with this patient regarding his/her prognosis?	Yes	7 (53%)	23 (45%)	1.00
	No	8 (47%)	28 (55%)	

TH-PO289

The Primary Cares Survey of In-Unit Dialysis Patient Primary Care Choices

Alan Perlman,[1,2] David L. Epstein,[1,2] Thomas Parker,[1] Daniel Levine,[1] Jonathan T. Lin,[1,2] Xunxi S. Guo,[2] Omar Farrukh,[2] Victoria Gutgarts,[2] Molly R. Phillips,[1] Weeraporn Srisung,[2] Perola Lamba,[2] Samuel Baskharoun,[3] Frank Liu.[1,2] *[1]Rogosin Institute, New York, NY; [2]NYP-Weill Cornell, New York, NY; [3]Frank H. Netter MD School of Medicine, New Haven, CT.*

Background: The complexity of primary care(PC) management of patients undergoing chronic dialysis often leads to confusion by the patient, nephrologist and traditional PC practitioners regarding the responsibility for the management of their care. In addition to renal failure, dialysis patients have a significant number of co-morbid medical conditions and require numerous medications. Common beliefs regarding PC by patients and their practitioners are not well characterized. Centers for Medicare and Medicaid Services(CMS) has advanced the notion of the patient centered model of care. With the implementation of the ESRD Seamless Care Organizations(ESCO), CMS has placed the dialysis facility and providers as the principal coordinators of patient care, thus implying that PC provisions are incorporated. Ultimately, patients preferences are integral to care delivery and may prove intrinsic to the success or failure of the ESCO model. The objective of the survey is to characterize attitudes amongst dialysis patients regarding PC provisions.

Methods: The PRIMARY CARES (**Primary C**are **A**ttitudes and **Re**nal Replacement **S**election) survey was performed in 7 HD units in the NYC area representing a diverse population of ethnicities, languages (5) and socioeconomic categories with the objective of assessing factors influencing the utilization of PC services.

Results: 832 patients were approached and 511 completed the survey. Of these, 396 (77%) completed the question regarding having someone whom they consider to be their PC provider(PCP) with 44% reporting their PCP was their internist(IM) or family practitioner(FP) vs 45% reporting their nephrologist as their PCP. Regarding which practitioner they would seek for first management of an acute issue, 48% stated their IM/FP vs 38% their nephrologist. Regarding patient preference for PCP, 41% reported their IM/FP vs 44% for nephrologist.

Conclusions: Our results indicate that a significant percentage of dialysis patients identify, utilize and prefer non-nephrology practitioners rather than their nephrologists for acute medical care and PC needs. In the ESCO model, patient preference for, and utilization of, services outside the purview of the dialysis center is likely to have important consequences on the overall success of the program.

TH-PO290

Obstetric Outcomes in Poor CKD Pregnant Women in Mexico

Margarita Ibarra-Hernández,[1,2] Maria de la luz Alcantar Vallin,[1,2] Patricia M. Jimenez,[1] Francisco V. Villagrana,[1] Jose D. Diaz-Avila,[1] Giorgina B. Piccoli,[3] Guillermo Garcia-Garcia.[1,2] *[1]Hospital Civil de Guadalajara FAA, Guadalajara, Mexico; [2]CUCS University of Guadalajara, Guadalajara, Mexico; [3]University of Torino, Torino, Italy.*

Background: CKD affects up to 6% of women of childbearing age. Despite that adverse obstetric outcomes are common in CKD pregnant women, the number of successful preganancies has increased over time, especially in high-income countries. We report outcomes in CKD pregnant women, followed at our integrated Obstetric and Renal Clinic.

Methods: Prospective study in CKD pregnant women followed between June 2013-December 2017. CKD was defined as per KDIGO guidelines. Dialysis was initiated when BUN was ≥ 45 mg/dL or when RRT was clinically indicated. Outcomes were compared between patients who required RRT vs conservative treatment.

Results: Table 1

Conclusions: Poor CKD pregnant women have a high rate of adverse obstetric outcomes. However, an integrated nephrological and obstetric prenatal care throughout all stages of CKD, could lead to successful pregancies, even in resource-constrained settings like ours.

TH-PO291

Sex- and Age-Associated Differences in the Prevalence of Comorbidities in Dialysis Patients

Sophia Rosen, Dugan Maddux, John W. Larkin, Len A. Usvyat, Franklin W. Maddux, Marta Reviriego-Mendoza. *Fresenius Medical Care North America, Waltham, MA.*

Background: In dialysis patients, the presence of non-renal comorbidities is associated with decreased quality of life and poorer outcomes. The prevalence of comorbidities in dialysis may vary by sex and age. We aimed to investigate the prevalence of the common comorbidities in dialysis patients within different age groups for both women and men.

Methods: We analyzed data from all hemodialysis (HD) patients at a large dialysis provider in 2016. Patients were grouped in 14 five-year age categories from 25 years old (y/o) to 95 y/o. For each age-group, we plotted the percent (%) of patients with an active comorbidity of anemia, diabetes (DM), cardiovascular disease (CVD), hyperparathyroidism (HPT), gastrointestinal (GI) bleeding, hypertension (HTN), and infection.

Results: Overall, we studied data from 230,091 patients; 43% were female. When compared to men in the same age group, we observed that: i) Anemia appears to affect a higher % of women 50 y/o and over 65 y/o, ii) Women suffer more infections at younger ages (25 y/o) and >75 y/o, iii) HTN is more prevalent in younger women (30-35 y/o) and in women >65 y/o when compared to men, iv) women show higher or similar prevalence of HPT at all ages, v) DM is more prevalent in women of most ages and, vi) CVD appear similar in men and women with a slight increase in men at age 75-85 y/o. No differences in GI bleeding were noted (Figure 1).

Conclusions: In this analysis we noted that the prevalence of comorbidities in dialysis patients varies by sex and age with a higher percent of women affected by anemia, HTN and DM. Further analyses are needed to elucidate if these differences affect dialysis outcomes.

Gender-Specific Differences Associated with Sociocultural Attributes in Dialysis Patients: A National Cohort Analysis

Sophia Rosen,[1] Maria E. Ferris,[2] Nwamaka D. Eneanya,[3] Carly R. Van Zandt,[1] Priscila Preciado,[4] John W. Larkin,[1] Len A. Usvyat,[1] Franklin W. Maddux,[1] Dugan Maddux,[1] Marta Reviriego-Mendoza.[1] *[1]Fresenius Medical Care North America, Waltham, MA; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]Massachusetts General Hospital, Boston, MA; [4]Renal Research Institute, New York, NY.*

Background: Women and men have physiological differences that distinctly affect their health, treatment regimens, and clinical outcomes. Sociocultural factors may also play a significant role on these differences. We investigated whether certain sociocultural and certain clinical factors varied between men and women on dialysis.

Methods: All adult patients from a large dialysis provider who had a comprehensive social worker assessment and/or patient health questionnaire-2 (PHQ2) completed in 2016 were included. The association between sex, age (as of Jan 1, 2016) and sociocultural and clinical attributes noted in Table 1 was investigated. Chi-square and t-tests were used as appropriate.

Results: We included data from 209,378 patients. In both age groups, housing barriers and PHQ2 scores were greater in women, and physical component scores were higher for men. Food security was lower in younger women, but there was no difference by sex in older patients. In both age groups, married and unmarried men tended to rely on their spouse/partner while women tended to rely on a family member other than spouse/partner (Table 1).

Conclusions: Our analysis shows that among dialysis patients, several sociocultural and clinical factors differ between men and women. Further investigation is warranted to elucidate whether these factors influence sex disparities in health outcomes.

TH-PO293

Are Hemoglobin Levels Affected by Sex, Age, and Race in Dialysis Patients?

Marta Reviriego-Mendoza, Sophia Rosen, Dugan Maddux, John W. Larkin, Len A. Usvyat, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: In the general population, women have lower reference ranges for hemoglobin (Hgb) levels compared to men, yet no differences are considered for anemia targets in people with chronic kidney disease (CKD). We aimed to explore if differences exist in Hgb levels between men and women initiating dialysis within different age groups and races.

Methods: Data from all incident patients in the United States Renal Data System (USRDS) from 2011-2015 was utilized via the RenDER system. Patients' were separated by sex, race (Asian (ASN), Black (BLK) and White (WHT), and age groups (0-19 years old (y/o), 20-39, 40-55, 56-79 and 80+). Average Hgb levels were obtained from the 2728 Medical Evidence form and compared among categories. The sex gap in Hgb levels $((Female_{Hgb}\text{-}Male_{Hgb})/Male_{Hgb})$ is evaluated for each category.

Results: Data from a total of 481,823 patients was analyzed; 203,804 (42%) were women. Although anemia targets do not differ between men and women with CKD, women tend to have lower levels of Hgb when starting dialysis, and this difference is greater for younger women. Young BLK women show a -4% and a -5.3% difference at ages 0-19 and 20-39, respectively, when compared to men. For young WHT women, Hgb levels differ from men by a -5.3% for the 0-19 y/o group, and a -3.3% for the 20-39 y/o group. However, young ASN women tend to have a smaller gap/difference in Hgb levels when compared to men (between -1 to 1% for 0-19 y/o and 20-39 y/o). The sex gap/difference in Hgb levels becomes less apparent in older age groups of women for the races analyzed (Figure 1).

Conclusions: Findings suggest that there may be differences in Hgb levels between the sexes that vary with age and race, which are most noticeable in WHT and BLK patients. More analyses are necessary to investigate if these sex, age and race dependent differences in Hgb levels affect health outcomes.

Funding: Commercial Support - Fresenius Medical Care North America

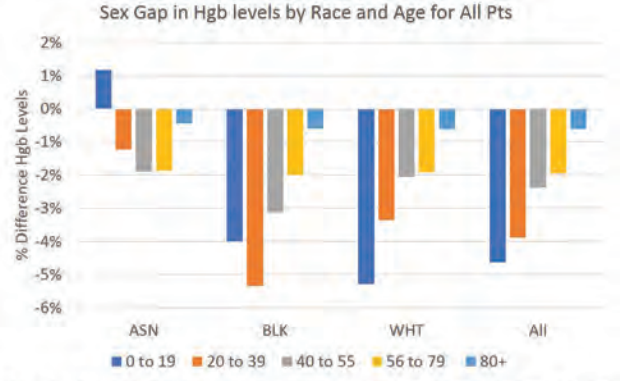

Figure 1: Gap/difference between mean Hgb levels measured in females and males by age and race. Negative values reflect females have a lower mean Hgb levels versus males.

TH-PO294

Evaluation of Diabetes-Related Knowledge Among African American Dialysis Patients

Mary O. Muoneke,[1] Jason Cobb,[2] James L. Bailey,[2] Janice P. Lea.[1] Emory University Hospital *[1]Emory University, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA.*

Background: Diabetic nephropathy is the leading cause of End Stage Renal Disease (ESRD) in the United States, accounting for nearly half of all cases. Although training patients with diabetes on self-management may help improve their health outcomes, the vast majority of U.S. dialysis clinics do not provide diabetes self-management education. As part of a diabetes education program introduction assessment, we examined baseline diabetes-related knowledge and care practices among patients with diabetes at the Emory dialysis clinic. Our overall aim is to introduce diabetes education in the clinic and subsequently assess the impact on clinical outcomes among dialysis patients with diabetes.

Methods: A questionnaire assessing diabetes knowledge and practices was administered on all ESRD patients with diabetes attending the clinic. Data on endocrinology care, most recent HbA1c results and history of amputations were also obtained. Introduction of regular foot checks during dialysis treatment with appropriate referrals to podiatry has now been introduced as a routine clinical practice in the clinic. Review of a diabetes curriculum and recruitment of a specialist diabetes educator is ongoing.

Results: Of the 155 patients, 87 (56%) have a diagnosis of diabetes. 85 (98%) were African Americans, 50 (58%) are males. The mean age was 63 years. The average HbA1C was 6.5%. Only 20 (25%) of the patients were aware of their most recent HbA1C results. About 12 (16%) had a history of limb amputations. A history of vascular studies was documented in 38 (48%) of the patients. Approximately 65 (82%) and 60 (76%) of the patients practiced self-foot and glucose checks respectively. About half of all patients

reported receiving endocrinology care. A total of 17 (20%) patients had abnormal foot examination and were referred for podiatry evaluation

Conclusions: A small proportion of the African American Diabetic ESRD patients were aware of factors that could impact their outcome. Introducing diabetes self-management education at dialysis clinics may help improve patient knowledge and potential clinical outcomes.

TH-PO295

The Impact of Race and Ethnicity upon Health-Related Quality of Life and Mortality in Dialysis Patients

Sara S. Kalantar,[1] Amy S. You,[2] Alejandra Novoa,[3] Kimberly M. Juarez,[1] Tracy Nakata,[4] Connie Rhee.[1] *[1]University of California Irvine, Huntington Beach, CA; [2]University of California, Irvine, Orange, CA; [3]UC Irvine Health, Orange, CA; [4]UC Irvine, Orange, CA.*

Background: While health-related quality of life (HRQOL) has been increasingly recognized as a strong predictor of mortality among hemodialysis (HD) patients, differences in these associations across diverse racial/ethnic groups have not been thoroughly investigated.

Methods: We examined the relationship between HRQOL and mortality among a prospective cohort of racially/ethnically diverse HD patients recruited across 18 dialysis units over 2011-16. Using Short Form 36 (SF36) surveys administered every 6 months, HRQOL was ascertained by 36 questions summarized as 2 physical and mental health dimension and 8 subscale scores. Associations of time-varying SF36 scores with all-cause mortality were estimated using multivariable Cox models in the overall cohort and within racial/ethnic subgroups.

Results: Among 753 HD patients who met eligibility criteria, the lowest quartiles (Q) of physical and mental health dimension scores were associated with higher mortality in the overall cohort (ref: highest Q): HRs (95% CIs): 2.18 (1.43-3.32) and 1.56 (1.06-2.28), respectively. In analyses stratified by race/ethnicity, among Blacks and Hispanics the lowest Q of physical health dimension scores was significantly associated with higher mortality, whereas in Non-Hispanic Whites and Asian/Pacific Islanders point estimates of the lowest Q suggested higher death risk but did not reach statistical significance. The lowest Q of physical functioning, energy/fatigue, and pain subscale scores were associated with higher mortality in the overall cohort, and were particularly pronounced in Blacks and Hispanics.

Conclusions: Lower self-reported HRQOL scores, particularly related to impaired physical health dimension and subscales, were associated with higher mortality in HD patients, including those of minority background. Further studies are needed to determine whether interventions that augment physical function improve the survival of these diverse populations.

TH-PO296

Quality of Life Reported by Patients with Expanded Hemodialysis by the TheraNova Dialyzer in RTS Colombia

Mauricio Sanabria,[1] Alfonso Bunch,[1] Ricardo Sanchez,[2] Jasmin Vesga,[1] Angela S. Rivera,[3] Lars-Goran Nilsson,[4] Adriana M. Suarez,[1] Juan Alarcon,[1] Mauricio Guerrero,[1] Jorge A. Diaz,[1] David Varon,[1] Rafael A. Gomez,[1] Freddy Ardila,[1] Roberto D'Achiardi,[1] Eduardo Zuniga.[1] *[1]RTS, Bogota, Colombia; [2]Universidad Nacional de Colombia, Bogotá, Colombia; [3]Baxter, Bogota, Colombia; [4]Baxter International Inc., Lund, Sweden.*

Background: Patients on hemodialysis have a lower quality of life compared to the general healthy population. Some factors such as restrictions on diet and physical activity, presence of symptoms and time consumed in treatment greatly affect the level of quality of life perceived by patients. The purpose this study was to evaluate changes in quality of life and prevalence of restless legs in the first six months after initiating a change in dialysis therapy from high-flux HD to expanded hemodialysis(HDx) with Theranova dialyzer.

Methods: Cross-sectional study in prevalent hemodialysis patients older than 18 years, enrolled between September 1st and November 30th, 2017, when converted to HDx, in 12 renal clinics of the Renal Therapy Services (RTS) Colombia network. KDQOL ™ 36 and the diagnostic criteria of restless legs were administered 2 times, at baseline and 6 months later. For the analysis, descriptive statistics, ANOVA and Mc Nemar test were used.

Results: 666 patients were evaluated, 61.4% (n =409) were men, the mean age was 59.8 years (SD = 15.3), 60.3%(402) were more than 3 years old in dialysis. We found significant improvements in a large part of the dimensions of quality of life in the time. Details are presented in table 1 In addition, we observed significant reduction of the diagnosis of restless legs. See table 2.

Conclusions: The expanded hemodialysis positively impacts on quality of life and diagnosis of restless legs The results reported by the patients are a valuable intervention that can guide health interventions in search of better clinical results.

TH-PO297

Impact of Extended Hours Dialysis on Quality of Life Measured by EQ-5D and SF-6D Utility Instruments

Brendan Smyth,[1,5] Kirsten Howard,[1] Janak R. de Zoysa,[2,6] Nicholas A. Gray,[3,7] Alan Cass,[4] Martin P. Gallagher,[5,8] Vlado Perkovic,[5] Meg J. Jardine.[5,8] *[1]Sydney School of Public Health, University of Sydney, Sydney, NSW, Australia; [2]Waitemata District Health Board, AUCKLAND, New Zealand; [3]Sunshine Coast University Hospital, Birtinya, QLD, Australia; [4]Menzies School of Health Research, Darwin, NT, Australia; [5]The George Institute for Global Health, UNSW, Newtown, NSW, Australia; [6]Department of Medicine, University of Auckland, Auckland, New Zealand; [7]Sunshine Coast Clinical School, University of Queensland, Birtinya, QLD, Australia; [8]Renal Unit, Concord Repatriation General Hospital, Sydney, NSW, Australia.*

Background: Health economic evaluations often rely on measurements of health utility. Validated health utility assessment tools are available but whether they perform similarly is rarely assessed. We aimed to estimate the effect of extended hours dialysis on utility-based quality of life (QOL) using two multi-attribute utility instruments.

Methods: The ACTIVE Dialysis trial randomised 200 participants to extended hours (≥24 hours/week) or standard hours (≤18 hours/week) haemodialysis for 12 months. Utility-based QOL was assessed every three months by the EuroQOL-5 Dimensions (EQ-5D) and Short Form-6 Dimensions (SF-6D). The mean difference in utility weights between groups was obtained by mixed linear regression. Quality adjusted life years (QALYs), a measure that combines survival and quality of life, were calculated.

Results: Extended dialysis hours did not improve utility-based QOL measured by the EQ-5D (0.036 [95%CI -0.022, 0.093]; p=0.223) but did significantly improve it when measured by the SF-6D (0.027 [95%CI 0.003, 0.052]; p=0.026). There was no significant difference in mean QALYs gained per patient from extended over standard dialysis as measured by the SF-6D (0.015 [95%CI -0.070, 0.041]) or the EQ-5D (0.029 [95%CI -0.108, 0.049]) - equivalent to a mean per patient gain of 5.5 (95%CI -25.6, 15.0) and 10.6 (95%CI -39.4, 17.9) days of perfect health, respectively.

Conclusions: The EQ-5D and SF-6D resulted in distinct interpretations of utility-based QOL differences in extended hours dialysis, although the significant improvement in utility-based QOL found with the SF-6D did not translate into a significant gain in QALYs. These results emphasise the need for a better understanding of the impact of different scoring algorithms and instrument properties on the performance of multi-attribute utility instruments to measure QOL in dialysis patients.

TH-PO298

The Symptom Profile of Hemodialysis Patients in Ontario

Alysha Glazer,[2] Marnie Mackinnon,[2] Esti Heale,[2] Carey Moolji,[2] Jane Ip,[3] Yingbo Na,[3] Yanqing Xu,[4] Peter G. Blake,[5] Michael Walsh.[1] *[1]McMaster University, Hamilton, ON, Canada; [2]Ontario Renal Network, Toronto, ON, Canada; [3]Cancer Care Ontario, Toronto, ON, Canada; [4]Bristol-Myers Squibb, Lawrenceville, NJ; [5]London Health Sciences Centre, London, ON, Canada.*

Background: People requiring dialysis reportedly experience a high symptom burden. However, there are few large studies assessing symptoms of this patient population over time. The Ontario Renal Network (ORN) is pilot testing a standardized provincial approach

to symptom screening, assessment, and management using the Edmonton Symptom Assessment System Revised: Renal (ESAS-r:Renal).

Methods: Eight Regional Renal Programs in Ontario were selected to participate in a one year pilot project. Participating programs routinely assess patients undergoing in-facility hemodialysis with ESAS-r:Renal every 4 to 6 weeks. The ESAS-r:Renal questionnaire asks patients to self-report the severity of 12 symptoms between 0 (no symptom) and 10 (worst possible symptom).

Results: Between April 1 and December 31, 2017, there were 5,839 screening attempts by 1,267 patients with 90% of the questionnaires fully completed and 5% partially completed. Forty-two percent of patients were female, 48% had diabetes (Type 1 or 2), and 32% were on dialysis for 5 or more years. Patients frequently reported changes in symptom scores over time. Tiredness was the most common symptom reported (76% of all surveys) and nausea the least reported (26% of all surveys). Scores of 7 or greater were recorded frequently (pain [14%], tiredness [22%], drowsiness [12%], nausea [3%], poor appetite [7%], shortness of breath [6%], depression [7%], anxiety [6%], poor wellbeing [11%], itching [12%], problems sleeping [17%], and restless legs [13%]).

Conclusions: Patients receiving in-facility dialysis frequently have symptoms. The degree to which the symptoms reported through ESAS-r:Renal can be modified and improved requires further research.

TH-PO299

What Patients and Caregivers Want in a Personalized Mobile Dialysis Unit

Larry Kessler,[1] Ji-Eun Kim,[1] Zach Mccauley,[1] Glenda V. Roberts,[2] Linda N. Boyle.[1] *[1]University of Washington, Seattle, WA; [2]Kidney Research Institute at the University of Washington, Seattle, WA.*

Background: The Center for Dialysis Innovation (CDI) at the University of Washington (UW) is designing an Ambulatory Kidney to Improve Vitality (AKTIV), a personalized and ambulatory device that will function as an artificial kidney for ESRD patients. Project objectives include developing, testing, and conducting clinical trials demonstrating feasibility of AKTIV to improve the current thrice-weekly hemodialysis treatment. Modern theory of device/product construction calls for user input during conception and design. As we develop the technical aspects of AKTIV, user input is crucial to ensure that engineers and clinicians have target parameters for their final output. Our first set of interviews gathered data from patients and their caregivers and focused on ways to increase the usability of a mobile and self-contained dialysis device.

Methods: At the National Kidney Foundation meeting in Portland in March 2018, we interviewed 26 patients and caregivers with a pre-interview survey and semi-structured interview about their design and feature preferences for a novel, personalized mobile dialysis unit. The 26 participants were between the ages of 24 and 82 years (M = 60.2, SD = 13.9), of which 14 were female, and 19 were patients. Content analysis was performed on the interviews.

Results: Participants chose the belt type for most preferred and the distributed type (parts of the device are separated from each other on the body) for least preferred compared to backpack, vest, and shoulder bag types ($F(4, 124) = 2.80$, $p < 0.05$). Participants reported that the most important features of a wearable dialysis unit were its accuracy and safety, compared to ease of use, comfort, compact, and simplicity to operate ($F(5, 143) = 13.14$, $p < 0.001$). Such preferences varied based on age, gender, and familiarity with wearable devices. Based on this input, we will design up to three different prototypes that were ranked the most preferred.

Conclusions: The interest and motivation of patients and caregivers to be involved in the creation of a personalized and mobile dialysis unit that works essentially as an artificial kidney is extremely high. From qualitative analysis and discussions, the dominant impression we have is patients want the device to be as unobtrusive as possible. We summarize by quoting a patient, "I don't want to be identified as a dialysis patient when I walk into a room."

TH-PO300

Patient Satisfaction Score in Relation to Hemodialysis Guidelines and Practices: A European Multicenter Analysis

Maciej B. Drozdz,[1] Joao M. Frazao,[2] Szymon Brzosko,[3,4] Fatima F. Silva,[5] Werner Kleophas,[6] Abdulkareem Alsuwaida,[7,8] Mahesh Krishnan,[9] Stefan H. Jacobson.[10] *[1]DaVita Poland, Krakow, Poland; [2]Nephrology and Infectiology Research and Development Group, INEB, and School of Medicine, Porto University, Portugal, Porto, Portugal; [3]DaVita Poland, Bialystok, Poland; [4]Department of Nephrology, Medical University of Bialystok, Bialystok, Poland; [5]Davita Portugal, Alfragide, Portugal; [6]DaVita Germany, Dusseldorf, Germany; [7]King Saud University, Riyadh, Saudi Arabia; [8]DaVita Saudi Arabia, Riyadh, Saudi Arabia; [9]DaVita, Inc, Denver, CO; [10]Danderyd Hospital, Stockholm, Sweden.*

Background: Understanding patient values and exploring their preferences is critical to caring for the dialysis population. Little is known about the factors that influence patient satisfaction compared with other measured clinical indices of care. We investigated these factors in an international European multicenter descriptive analysis.

Methods: We enrolled 845 HD patients from 13 DaVita centers in Poland (8 centers, n=453) and Portugal (5 centers, n=392). An anonymous patient survey was conducted (14 questions; 5-grade scale: "agree completely" to "disagree") focusing on patient satisfaction with their care at the local facility. Practices, demographic, and laboratory data were analyzed for the same month that the survey was performed and correlated to the survey results at the facility level.

Results: The survey response rate was 81% (range 72-100%). Mean (SD) age was 68 (14) years; 53% were male. Mean Charlson comorbidity index was 7.1 (3.0); 76.3% used AVF, 16.5% used CVC. Mean (SD) Kt/V was 1.8 (0.4), albumin was 39.5 (4.3) g/L, phosphorus was 4.7 (1.3) mg/dL and PTH was 512 (481) pg/mL Mean (SD) patient satisfaction score (0-10) was high 9.1 (1.6) and the net promoter score was 71. High scores (> 90% agree) were observed for all but one of the 14 questions ("*I'm happy with my transportation provider";* 85% agree). Spearman correlation analyses at the facility level showed that patients involved in decision making had higher Kt/V ($p=0.02$). Patients who agreed that their "*chairs and linen were comfortable"* had lower phosphorus ($p=0.02$) and higher Kt/V ($p<0.001$). Patients "*happy with their transportation provider"* had higher Kt/V ($p=0.002$) and lower phosphorus ($p<0.05$) and patients who agreed that their "*treatment started on time"* had higher Kt/V ($p=0.05$). The overall satisfaction score was higher with low Kt/V ($p=0.004$) and high phosphorus ($p<0.05$).

Conclusions: Patient satisfaction surveys provide a critical perspective on the quality of patient-centered healthcare delivery. Information derived from direct evaluation of patient experience of care can be used to identify areas for improvement and support changes in care provision with the aim of improving the overall quality of care for patients.

TH-PO301

Assessing a Modified Edmonton Symptom Assessment System as a Patient Report Outcome Measure for Patients on Dialysis in Canada

Juliana Wu,[1] Michael Terner,[1] Michael Manno,[1] Helen Chiu,[2] Ognjenka Djurdjev,[2] Adeera Levin.[3] *[1]Canadian Institute for Health Information, Toronto, ON, Canada; [2]BC Renal Agency, Vancouver, BC, Canada; [3]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada.*

Background: Patients with end-stage renal disease (ESRD) often experience heavy symptom burden that is under-recognized in the absence of routine and systematic assessment and management, resulting in poor quality of life. In Canada, British Columbia has implemented a modified Edmonton Symptom Assessment System (mESAS) to monitor symptom burden in patients with ESRD. Completion of the mESAS was voluntary. Implementation started in 2010 and was staggered across facilities. We investigated whether the mESAS functions as a patient-reported outcome measure (PROM) for patients on dialysis, specifically whether the mESAS is feasible to use in routine assessment and is responsive to changes in patient symptoms over time.

Methods: The dataset comprised 3,573 patients from 7 dialysis facilities in British Columbia, 62% of whom had completed at least 1 assessment. Of these, 77% completed more than one assessment that can be used for longitudinal analysis. The dataset included assessments performed between March 2010 and April 2016. We used descriptive statistics to examine mESAS practice and changes in symptom scores over time.

Results: Of the patients with more than 1 mESAS assessment, the majority (69%) of adjacent assessments were completed within a 3 ± 1.5 month timeframe, and an additional 16% were completed within a 6 ± 1.5 month timeframe. For symptoms that were scored within the severe category (between 7 and 10 on the scale), the majority improved to below the severe category in a subsequent assessment. Across years, the proportion of symptom scores in the severe category demonstrated a change to lower scores using the mESAS. The results for improved symptoms scores across centres and years varied between 68 and 93%.

Conclusions: There was sufficient data available for analysis of mESAS scores and changes in scores over time. Serial collection of this data allows a real time opportunity to assess symptom burden at a specific point in time as well as the responsiveness of mESAS over time. There is also important value in collecting PROMs in renal patients to further explore how PROMs can be used to evaluate symptom management strategies and thereby optimize patient quality of life.

TH-PO302

A Multicenter Survey in Toronto of Opinions on Driving Safety in Hemodialysis Patients

Bourne L. Auguste,[1] Lauren A. Glick,[1] Christopher T. Chan,[3] Karthik K. Tennankore,[2] Darren A. Yuen.[1] *[1]University of Toronto, Toronto, ON, Canada; [2]Dalhousie University/NS Health Authority, Halifax, NS, Canada; [3]Toronto General Hospital, Toronto, ON, Canada.*

Background: Hemodialysis patients are at an increased risk of adverse health events from operating a motor vehicle and may have their license withdrawn due to safety concerns. However, little is known about the perspectives of nephrology health care practitioners towards driving safety for hemodialysis patients and their awareness of best practice. The purpose of this study was to survey health care practitioners to identify their opinions towards driving practice and safety for hemodialysis patients.

Methods: We developed a 16-item questionnaire about driving safety using a Delphi model with input from 4 nephrologists, 2 nurse practitioners, 2 social workers and 1 nephrology fellow. The questionnaire was distributed amongst the 3 academic hemodialysis centers affiliated with the University of Toronto in Toronto, Canada. All voluntary participants were healthcare professionals caring for dialysis patients. Questionnaires were emailed to participants and their responses were completed on a secure website link.

Results: The survey was distributed to 154 persons with a response rate of 39%. 52% (31) of responders were hemodialysis nurses, 15% (9) were nephrologists and other responders included fellows and other allied healthcare professionals. 60% (36) of responders had greater than 10-years of experience. 88.3% of responders knew of at least one patient who drove regularly. 80% of responders never reported a patient to the provincial

driving authority despite safety concerns. Responses were unchanged despite participants being presented with 3 clinical hypothetical scenarios of unstable patients that drove to hemodialysis sessions. This suggests that participants did not recognize the safety concerns in hypothetical situations where reporting should have occurred. Participants likely did not report patients due to the lack of clear guidelines along with no current mandated reporting requirements. This was further supported by 97% of all responders agreeing that more robust driving guidelines are warranted.

Conclusions: Our preliminary results underscore the lack of clarity, consistency and knowledge with regards to driving safety in hemodialysis patients. Larger national scale surveys will further support the prevalent opinion in Toronto that more comprehensive driving guidelines for hemodialysis patients are warranted.

TH-PO303

Employment 6 Months Prior to and at Dialysis Start: Validation Evidence for CMS-2728 Data

Nancy G. Kutner,[1] Rebecca H. Zhang.[2] *[1]Emory University School of Medicine, Atlanta, GA; [2]Emory University, Atlanta, GA.*

Background: The CMS-2728 is a unique source of patient employment status 6 months prior and at dialysis start. A USRDS analysis of patients 18-54 initiating in-center hemodialysis (HD) or home dialysis 1996-2013 showed a persistent pattern of job loss in the 6-month pre-dialysis interval (CJASN 2018). The CMS-2728 employment field has not been independently validated, however. We compared incident patients' interview responses obtained approximately 2 months after dialysis start with corresponding employment information from their CMS-2728 report.

Methods: Patients who began in-center HD or home dialysis July 1996-August 1997, English- or Spanish-speaking and without documented cognitive impairment, were recruited for a study of health behaviors/quality of life from 26 dialysis clinics serving the Atlanta GA 23-county area. Participants represented eligible patients in age, race and functional status but the cohort included fewer women. Structured in-person interviews were conducted at a non-dialysis facility location convenient for the patient 67.3 ± 19.5 days after dialysis start. 95/226 study participants were ages 20-54 (median 43) with women 47%; blacks 58%; non-Hispanic whites 35%; and Hispanic, Asian, other 7%. CMS-2728 employment status options include: unemployed, employed full time (FT), employed part time (PT), homemaker, retired (age/preference), retired (disability), medical leave of absence, and student. The patient interview asked: Are you working now (hours/week)? job being held? retired or stopped working; when? keeping house? student (FT, PT)? Using FT, PT, or student to define employment (CJASN 2018), we identified the unadjusted proportion of patients employed 6 months prior and at dialysis start, reported by the CMS-2728 and by patients.

Results: Compared with their CMS-2728 data, 8% more patients reported being employed 6 months prior, while 6% fewer patients reported current employment. Potential job maintenance opportunities were suggested by patients who reported having switched from FT to PT work, said their prior job was "being held," cited a medical leave of absence, or reported being "let go" from their job (in all, 14% of the cohort).

Conclusions: Our study suggests that CMS-2728 employment fields have good validity. Effective interventions are needed to help patients remain in the workforce as they transition to dialysis.

TH-PO304

Reducing Polypharmacy in Dialysis Patients

Travis R. Jameson,[1] Julia Schneider,[2] Holly J. Kramer.[2] *[1]Nephrology, Loyola University Medical Center, MAYWOOD, IL; [2]Loyola University Medical Center, Maywood, IL.*

Background: Polypharmacy is a freqent problem for patients receiving maintenance dialysis and may increase risk of adverse events and drug interactions. Previous studies have identified 4 drug classes (proton pump inhibitors [PPI], alpha 1 blockers [A1B], diuretics, and statins) in which use may not be necessary in patients receiving maintenance dialysis. This study examined overall medication use and use of 4 non-essential drug classes.

Methods: This study was comprised of 168 patients receiving maintenance dialysis at a single dialysis unit. The mean age was 60.4 (SD 15.8) and median dialysis vintage was 2.4 years with a range of 0.2 to 13.9 years. Overall 49.1% were male. Diabetes mellitus (49.1%) and hypertention (18.0%) were the two main causes of end stage renal disease. The average number of prescribed medications was 11 (SD 5) and ranged from 2-26 medications but was higher among women (11[SD 4]) than among men (10[SD 5]).

Results: Of the 4 non-essential drugs, 51.5% were taking at least one of these drugs, 36.9% were taking at least 2, and 11.5% were taking at least three non-essential medications. Statin use was most common at 56.3% overall and among patients age 70+ years, 75% were using statins. PPI and diuretic use wee noted in 32.5% and 31.7% respectively. A1B use was noted in 8.5% of men with a dialysis vintage of 2.4 years. If the 4 non-essential drugs were eliminated, the average number of medications would decrease to 9 (SD 4) overall, to 9 (SD 5) among men and to 10 (SD 4) for women.

Conclusions: In conclusion, use of non-essential medications is common among patients receiving maintenance dialysis. Elimination of non-essential medications would lead to a reduction of about 1 medication on average. Targeted de-prescribing may help reduce polypharmacy in this patient population.

TH-PO305

Long-Term Follow-Up of Respiratory Function in Maintenance Hemodialysis Patients Following an In - Center Exercise Program for 24 Months

Andreas Bozikas,[1] Maroula Papacharalambous,[5] Pinelopi Pisanidou,[1] Styliani Vakiani,[1] Antigoni Martika,[1] Iliana Kiriakoutzik,[1] Eleni Kitoukidi,[1] Ioannis Akrivopoulos,[3] Soultana Falakidou,[2] Stergios Papastergiou,[4] Sofia Spaia.[2] *[1]Nephrology, General Hospital of Thessaloniki "Agios Pavlos", Thessaloniki, Greece; [2]Hemodialysis Unit, General Hospital of Thessaloniki "Agios Pavlos", Thessaloniki, Greece; [3]Physicotherapy, General Hospital of Thessaloniki "Agios Pavlos", Thessaloniki, Greece; [4]Orthopedic, General Hospital of Thessaloniki "Agios Pavlos", Thessaloniki, Greece; [5]Pneumonologist, General Hospital of Thessaloniki "Agios Pavlos", Thessaloniki, Greece.*

Background: In spite the well documented benefit of physical exercise on hemodialysis patients (HD) only few reports concern the long-term effect on respiratory function. We designed this study to investigate the effects of continuous moderate-intensity programme applied during hemodialysis sessions by a physiotherapist, on parameters in spirometry.

Methods: We enrolled 60 maintenance HD patients in this study. 44 stable HD patients participated in a 20 – 30 minute exercise program of moderate intensity targeting muscle strengthening and elasticity, articular flexibility in every session for 24 months. 16 HD patients who did not participated served as controls. Spirometry: Forced Vital Capacity (FVC), FVC %, Forced Expiratory Volume in One second (FEV1), FEV1 % and Forced Expiratory Flow over middle half of the FVC – that is, average flow from 25 % of the FVC to 75 % of the FVC during forced expiration (FEF 25 – 75 %) was performed at 0, 12 and 24 months along with biochemical tests: Hct, CRP, Chol, TG, LDL, HDL, TP, Alb, HbA1C and dialysis adequacy (Urr, Kt/V).

Results: Overwhelming acceptance of the program resulted in continuous and constant participation. 7 patients (12 %) were found with undiagnosed COPD in the beginning of the study. Respiratory indices were comparable either the test was performed before or after the HD session. FEV1/FVC index was improved at 12 months and remained improved at 24 months only in the exercising group (76.6 ± 10 v s79.6 ± 8 vs 81.5 ± 7, $p<0.05$).

Conclusions: Adaptation of a thrice weekly exercise program under physiotherapist guidance resulted in the enthusiastic participation of patients and it is one of the longest that have been reported. Patients following the long term exercise improved FEV1/FVC over the follow-up period. Evaluation of respiratory function should be performed in all patients starting dialysis since it reveals latent morbidity. In spite the reports of deterioration of pulmonary function in the long term of maintenance HD the latter remained stable in the control group.

TH-PO306

Aerobic versus Anaerobic Exercise and Oral Nutritional Supplementation Related to Nutritional Status and Physical Function of Adult Haemodialysis Patients: AVANTE Study

Geovana Martin-Alemañy,[1] L. M. Perez-Navarro,[1] Angeles Espinosa-Cuevas,[2] Rafael Valdez-Ortiz.[3] *[1]Hospital General de México, Dr. Eduardo Liceaga, Mexico, City, Mexico; [2]National Medical Science and Nutrition Institute, Mexico, Mexico; [3]Hospital General de Mexico, Mexico City, Mexico.*

Background: Protein energy wasting affects the nutritional status (NS) and physical function (PF) of dialysis patients. Oral nutritional supplementation (ONS) and resistance exercise (RE) or aerobic exercise (AE), have been shown to be effective for NS and PF. Nevertheless, the combination of RE and AE with ONS has not been completely elucidated. The aim of this study was to assess the effect of a 12-week intradialytic RE or AE program combined with ONS versus ONS without exercise on PF and NS indicators.

Methods: Patients were divided in to three groups: 1) ONS, 2) ONS + RE and 3) ONS + AE. Anthropometrics [body mass index (BMI), body weight (BW), midarm circunference (MAC), arm muscle circumference (AMC) and arm muscle area (AMA)], PF tests [sit to stand, time up and go and six minute walk tests (6 MWT)] and quality of life (QOL) by KDQOL-SF36 were recorded.

Results: All groups had statistical significant increases in BW, BMI, MAC, AMC and AMA ($p<0.05$). All patients significantly improved the three different PF tests and muscle strength; however, groups with AE and RE increased 43 and 42 metres respectively the distance walked in six minutes; while the ONS group increased 11 metres ($p<0.05$). Regarding QOL, the group with ONS + RE shown to have more areas of improvement at the end of the study (sleep, general health and social function, $p<0.05$), followed by the group with ONS + AE (emotional role, $p<0.05$).

Conclusions: The effect of RE or AE combined with ONS versus ONS without exercise improves the PF and NS; however, PF measured with the 6 MWT and QOL was better at the end of the study in both groups with exercise. No statistical significant differences were observed between groups at the end of the study. All interventions have a positive effects on NS and PF.

Funding: Private Foundation Support

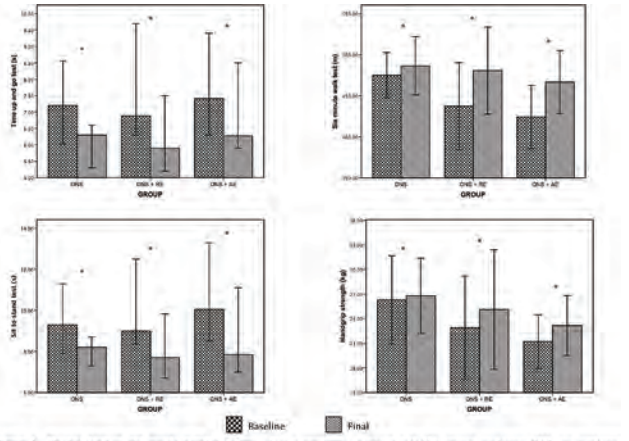

Figure 2. Physical function and muscle strenght changes. Data is represented in median with 95% interval confidence. ONS, oral nutritional supplementation; ONS + RE, oral nutritional supplementation plus resistance exercise; ONS + AE, oral nutritional supplementation plus aerobic exercise. The asterik indicates p<0.05 for the comparison from baseline of each group. No statistical significance difference was observed between groups.

TH-PO307

Dialysis Therapy and Gait Speed: A Repeated Measures Analysis of US Patients on Chronic Dialysis

Christopher A. Carlos,[1] Barbara A. Grimes,[3] Kirsten L. Johansen.[2] *[1]University of California, San Francisco, San Francisco, CA; [2]University of California, San Franicsco, San Francisco, CA; [3]UCSF, San Francisco, CA.*

Background: Slow gait speed, a patient-centered yet understudied clinical outcome, is a common and independent predictor of future disability, hospitalizations and death among patients with chronic kidney disease. Prior studies have shown that improper fluid management is a likely contributor to physical impairment, but lack of data on the relative importance of the many fluid-related components of dialysis therapy (e.g. baseline fluid overload, blood pressure, and ultrafiltration rate) has limited consensus and evidence-based guideline development. Analyses are needed to understand which managed aspects of dialysis therapy are most associated with functional status declines.

Methods: We measured gait speed at baseline, 12 months, and 24 months, among 652 patients on hemodialysis recruited in the ACTIVE/ADIPOSE cohort study. We used linear mixed effects modeling to examine associations between demographic, comorbid, social, and laboratory data with gait speed trajectory. We then added degree of bioimpedance-measured predialysis volume overload (defined as a fluid state >= 15% relative to extracellular water volume in men and >=13% in women), dialysis treatment time, ultrafiltration rate, and predialysis systolic blood pressure to ascertain whether treatment-related factors were associated with gait speed or its change over time.

Results: Mean gait speed at baseline was 0.94 m/s and declined an average of 0.08 m/s per year. In adjusted analysis, nonwhite race (-0.14 m/s, 95% CI -0.19 to -0.08), female sex (-0.10 m/s, 95% CI -0.13 to -0.06), and BMI > 35 kg/m2 (-0.09 m/s, 95% CI -0.15 to -0.03) were associated with slower gait speeds. Predialysis volume overload was associated with slower gait speed (-0.06 m/s, 95% CI -0.11 to -0.01), but was not a statistically meaningful predictor of future gait speed trajectory. Dialysis treatment time, ultrafiltration rate, and predialysis systolic blood pressure were not independently associated with gait speed.

Conclusions: Certain factors place patients on dialysis at increased risk of slowed gait speed, including a state of predialysis volume overload. Interventions that focus on limiting states of volume overload, compared to other managed aspects of the dialysis treatment, may be more meaningful in limiting gait speed impairment.

TH-PO308

Intradialytic Activities and Health-Related Quality of Life

Fatima M. Warsame,[1] Hao Ying,[2] Christine E. Haugen,[3] Alvin G. Thomas,[4] Deidra C. Crews,[5] Tariq Shafi,[5] Bernard G. Jaar,[6] Dorry L. Segev,[1] Mara McAdams-DeMarco.[7] *[1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins School of Medicine, Baltimore, MD; [3]Surgery, Johns Hopkins Hospital, Baltimore, MD; [4]UNC Chapel HIll, Chapel Hill, NC; [5]Johns Hopkins University School of Medicine, Baltimore, MD; [6]Johns Hopkins University and Nephrology Center of Maryland, Baltimore, MD; [7]Johns Hopkins, Baltimore, MD.*

Background: Given the time burden and physiologic effects of hemodialysis, patients who spend dialysis time physically or intellectually engaged may have better health-related quality of life (HRQOL). We sought to characterize the association between intradialytic activities and HRQOL and explore patients' interest in performing intradialytic interventions.

Methods: In a prospective cohort study of 431 prevalent hemodialysis patients, an activity score was assigned on a scale of 0-5 points for each active intradialytic task (read, electronic games, puzzles, chat, other-physical/cognitive). We quantified the association between KDQOL components and activity using adjusted linear regression.

Results: The two most common intradialytic activities reported by patients were passive [watching TV (87.9%) and sleeping (72.4%)]. Patients who were female (aOR=1.85, 95%CI:1.28, 2.66; p=0.001), nonfrail (aOR=1.70, 95%CI:1.06-2.70; p=0.03), and nonsmokers (aOR=2.61, 95%CI:1.39, 4.90; p=0.003) had a higher intradialytic activity. Additionally, higher intradialytic activity was associated with better mental HRQOL (+0.83 points, 95%CI: +0.04, +1.62; p=0.04) and kidney disease-specific HRQOL (+1.70 points, 95%CI: +0.47, +2.93; p=0.007), but not physical HRQOL. Each one-point increase in the activity index was associated with a 1.29-fold and 1.25-fold increased odds of interest in intradialytic cognitive training and physical exercise.

Conclusions: Hemodialysis patients with more active intradialytic activities report better mental and kidney disease-specific HRQOL and increased interest in participating in intradialytic interventions. Dialysis providers may consider offering patients with low levels of activity additional support and opportunities to engage in beneficial intradialytic activities.

Funding: NIDDK Support, Other NIH Support - National Institute on Aging, Private Foundation Support

The Association Between Handgrip Strength (HGS) and Predialysis Sodium (sNa) in Patients with CKD Stage 5D

Periklis P. Kyriazis,[1] Anastasia Markaki,[2] Eleftheria-Kleio Dermitzaki,[3] Dimitra Lygerou,[3] Aspasia Spyridaki,[2] Emmanouil Psylinakis,[2] Panagiotis T. Kanellos,[2] Argyro Gioume,[2] Konstantina Kyriakidi,[2] Nikolaos Kalemikiarakis.[2] *[1]Internal Medicine, Baystate Medical Center/ University of Massachussetts, Springfield, MA; [2]Nutrition & Dietetics, Technological Educational Institute of Crete, Siteia, Greece; [3]Nephrology, University Hospital of Heraklion, Heraklion, Greece.*

Background: HGS is a useful tool for continuous and systematic assessment of muscle function related to nutritional status. Reduced HGS has been associated with adverse clinical outcomes in patients with stage 5D CKD. In the same patients, low sNa has been associated with malnutrition and mortality. Here, we investigated the role of sNa on muscle mass and function in stage 5D CKD patients.

Methods: We evaluated 73 CKD stage 5D (45 on hemodialysis and 28 on peritoneal dialysis) patients (43 men and 30 women) with HGS, bioimpedance analysis (BIA), anthropometric measurements and malnutrition inflammation score (MIS). According to the diagnostic criteria for sarcopenia established by EWGSOP, patients were diagnosed with reduced HGS, if HGS was below 30 Kg and 20 Kg in men and women, respectively. Predialysis sNa values were defined as the mean of all predialysis measurements available during the preceding 6 months.

Results: Patients with reduced (n=28) as compared to the those with normal HGS (n=45) were older in age (p=0.006), had lower skeletal muscle index (SMI) (p=0.004), mid-arm muscle circumference (MAMC) (p=0.043), sNa (137±2.3 vs. 139.5 ± 2.2 mmol/L; p=0.004), serum albumin (sAlb) (p=0.029) and higher MIS (5.13±2.62 vs. 3.82±2.34; p=0.034). In multivariate logistic analysis, after controlling for age, SMI, MAMC, sAlb and MIS, each increase in sNa by 1 mmol/l was associated with 28 % (OR= 0.72, 95% CI: 0.55-0.94; p <0.05) lower odds of having reduced HGS. sNa was positively associated with HGS (r=0.384; p<0.001) and SMI (r=0.295; p<0.05). In a forward stepwise multivariate (sex, SMI, MAMC, sALB, MIS) model (R^2= 0.499; p<0.001), sNa, along with SMI and sex, emerged as a strong independent predictor of HGS (B=0.791; p<0.05) explaining about 3 % of its variance.

Conclusions: Our results show that a) sNa is strongly associated with both muscle mass and muscle function, b) sNa impacts on muscle strength independently of muscle mass, nutritional status and inflammatory state and c) irrespective of the mechanism(s) underlying the HGS-sNa association, optimizing predialysis sNa may improve HGS and thus clinical outcomes in 5D CKD patients.

TH-PO310

Utility of Regular Management of Physical Activity and Physical Function in Hemodialysis Patients

Shohei Yamamoto,[1] Ryota Matsuzawa,[2] Yoshifumi Abe,[1] Manae Harada,[1,3] Takaaki Watanabe,[1,3] Yuta Suzuki,[1] Kentaro Kamiya,[1] Atsushi Yoshida,[3] Atsuhiko Matsunaga.[1] *[1]Kitasato University Graduate School of Medical Sciences, Sagamihara, Japan; [2]Kitasato University Hospital, Sagamihara, Japan; [3]Sagami Circulatory Organ Clinic, Sagamihara, Japan.*

Background: Several clinical practice guidelines recommend regular assessment of physical activity and physical function as part of routine care in hemodialysis patients. However, there is no clear evidence to support these recommendations. We investigated whether the proportion of attendance at a regular program for management of physical activity and physical function can predict all-cause mortality and cardiovascular events in hemodialysis patients.

Methods: This retrospective cohort study consisted of 266 hemodialysis patients participating in the management program at least once. Participants were tracked for 3 years after their first attendance at the management program to determine their attendance proportion. The main study outcomes included all-cause mortality and a composite of fatal and nonfatal cardiovascular events.

Results: Median patient age was 64.5 (interquartile range, 56.8–72.0) years, 45% were women, and the median time on hemodialysis was 35.5 (interquartile range, 12.0–114.3) months at baseline. Sixty-five patients died over a median follow-up of 79 months (Figure 1A). The incidence of cardiovascular events was 60 over a median follow-up of 68 months (Figure 1B). Even after adjusting for any of the prognostic models, participants who attended ≦75% of sessions (n=140) had higher risks of mortality (hazard ratio (HR), 1.79 ; 95% confidence interval (CI) : 1.00–3.36 ; P = 0.049) and cardiovascular events (HR, 1.84 ; 95% CI : 1.07–3.48 ; P=0.03) than those attending >75% of sessions (n=126).

Conclusions: Hemodialysis patients in whom physical activity and physical function could be assessed more regularly had better prognosis than those with only intermittent assessment.

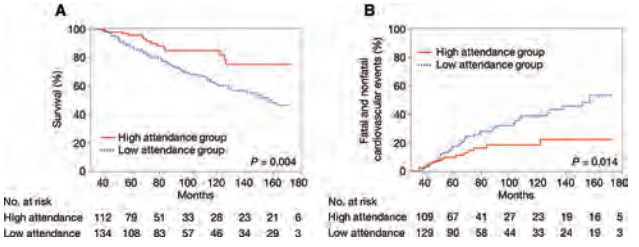

Figure 1. Kaplan–Meier analysis of survival (A) and cardiovascular events (B) in 266 patients undergoing hemodialysis. The High attendance group (attended >75% of all available sessions in the management program) had significantly better survival and lower incidence of cardiovascular disease than the Low attendance group (≤75% attendance).

TH-PO311

A Retrospective Study on the Decline of Muscle Mass in Maintenance Hemodialysis Patients in China

Yiqi Song,[1] Qian Zhang,[1] Li Ni,[2] Jing Chen.[3] *[1]Division of Nephrology, National Clinical Research Center for Aging and Medicine, Huashan Hospital, Fudan University, Shanghai, China; [2]huashan hospital,Fudan University, Shanghai, China; [3]Huashan Hospital, Shanghai, China.*

Background: Sarcopenia is characterized by age-related decline of skeletal muscle plus low muscle strength and/or physical performance. Studys have demonstrated that sarcopenia was associated with adverse health outcomes, such as disability, hospital admission, poorer quality of life and mortality. A high prevalence of sarcopenia is also observed in maintenance hemodialysis (MHD) patients, which need for further investigation. Hence, this study aimed to analyze the risk factors that affect the speed of muscle mass decline in MHD patients.

Methods: The retrospective study was performed in hemodialysis center of Huashan hospital, Fudan university in Shanghai, China. MHD patients suffered muscle mass loss in the past three years were eligible to participate in this study. Patients were divided into low speed group and high speed group according to the speed of muscle mass decline. Univariate linear regression analysis was conducted to assess the associations between muscle mass decline speed and the variables. These variables included age, gender, dialysis vintage, body mass index, normalized protein catabolic rate, serum levels of albumin, hsCRP, 25(OH)D, CO_2-CP. Variables with P≤0.20 were included in the multivariate logistic analysis.

Results: A total of 47 MHD patients were included in this study, of which 23 were male and 24 were female. Mean patient age was 59.30±12.49 years. The mean dialysis duration was 7.24±4.88 years. The low speed group showed shorter dialysis vintage, higher level of serum 25(OH)D and lower Log NT-proBNP, compared with the high speed gruop. There were no significant differences in albumin, prealbumin, cholesterol, nPCR, CO_2-CP, hsCRP, BMI, deltoid skin fold thickness, grip strength and daily steps. Multivariate linear regression analysis showed that dialysis vintage (β=0.309, P=0.017), 25 (OH) D(β=-0.370, P=0.004), Log NT-proBNP (β=0.339,P=0.011) were risk factors associated with muscle mass decline speed in MHD patients.

Conclusions: Risk factors associated with the muscle mass decline speed in maintenance hemodialysis patients include dialysis vintage, 25 (OH)D, and log NT-proBNP. Higher levels of 25 (OH) D contributes to the maintenance of muscle mass.

TH-PO312

Fatigue on Hemodialysis Day Is Associated with Post-Hemodialysis Amino Acids Depletion

Subrata Debnath,[1] Jason O'Connor,[3] Shweta Bansal,[2] Carlos Lorenzo,[4] Kumar Sharma.[5] *[1]Medicine, University of Texas Health San Anotonio, San Antonio, TX; [2]Medicine, University of Texas Health San Antonio, San Antonio, TX; [3]Pharmacology, University of Texas Health San Antonio, San Antonio, TX; [4]Medicine, University of Texas Health San Antonio, San Antonio, TX; [5]Medicine, University of Texas Health San Antonio, San Antonio, TX.*

Background: End-stage renal disease (ESRD) patients on maintenance hemodialysis (HD) endure debilitating fatigue. Kidney function is essential for the synthesis, balance, and interorgan exchange of several amino acids (AA) notably aromatic amino acids (AAA) such as phenylalanine, tyrosine, and tryptophan and branched-chain amino acids (BCAA): leucine, isoleucine and valine. Dysregulation of these AA has been implicated in the genesis of fatigue as they may affect neurotransmitters. The relationship of AA with fatigue in HD patients is not known.

Methods: In a cross-sectional study, we examined the relationship between AA and fatigue in a well-characterized cohort of HD patients with T2 diabetes (N=119). The mean±SD age was 54.77±12.76 yr and 48% were female. Mean serum albumin was 3.46±0.38 g/dl, Hgb 11.04±1.43 mg/dl, and HgbA1c 6.93±1.86%. Fatigue on HD day was assessed by the 9-item Brief Fatigue Inventory (BFI) which measures fatigue severity and fatigue impact on daily functioning. BFI has internal consistency coefficient 0.96 and scores range from 0 to 90, lower score = less fatigue. BFI item #3 (Please rate your fatigue that best describes your WORST level of fatigue) was chosen to represent fatigue severity for conceptual simplicity. Free AA in pre- and post-HD plasma were quantified using HPLC-mass spectrometry.

Results: BCAA and AAA levels decreased significantly post HD (p<0.0001 and 0.0009, respectively). Post-HD AA, except for tyrosine, correlated with BFI item #3 and global fatigue scores (mean of all BFI 9 items). On Pearson correlation, post-HD BCAA and AAA levels correlated negatively with worst fatigue (r=–0.24, p=0.015 and r=–0.26, p=0.009, respectively) and global fatigue (r=–0.26, p=0.008 and r=–0.26, p=0.01, respectively). These correlations remained significant after adjustments for HD duration, dialysis shift, and intradialytic changes in body weight and blood pressure. Fatigue intensity, categorized into mild (1-3), moderate (4-6), and severe (≥7) based on BFI item #3 score, inversely related to post-HD AA levels: BCAA (p for trend 0.028) and AAA (p for trend 0.008).

Conclusions: HD procedure depletes BCAA and AAA. Post-HD levels of both BCAA and AAA correlate with fatigue on HD day in ESRD patients. Depleted AA may contribute to impaired neurotransmitters synthesis.

Preliminary Analysis of the Effect of Blood Flow Rate Reduction on Post-Dialysis Fatigue

Vishal Duggal,[1,2] Graham E. Abra,[1] Marc Reiterman,[2] Wael F. Hussein,[2] Brigitte Schiller.[2] *[1]Stanford University, Palo Alto, CA; [2]Satellite Healthcare, San Jose, CA.*

Background: Post-dialysis fatigue is a common complaint among patients undergoing maintenance hemodialysis (HD). It is not known whether hemodialysis blood flow rate (Qb) affects post-dialysis fatigue. We aimed to determine if a reduction in Qb affected the time to recover from HD treatments in patients with significant baseline post-dialysis fatigue.

Methods: We conducted a randomized, controlled trial of patients undergoing maintenance HD ≥3x/week who reported post-dialysis fatigue ≥6 hours at baseline. Preliminary data included 94 subjects randomized to Qb reduction of up to 100 mL/min (minimum Qb 300 mL/min; intervention group, 47 subjects) or to usual care (control group, 47 subjects). Patients with borderline dialysis adequacy were excluded. Subjects were surveyed weekly for 4 weeks regarding their dialysis recovery time (DRT) using the validated question "How long did it take you to recover from dialysis?" Primary outcome was change in DRT.

Results: Mean age was 65.1±12.7 years, 62.8% were men, median vintage was 3.73 years (IQR 2.0–6.7), and 68.1% of subjects had diabetes. Baseline characteristics in post-randomization groups were fairly balanced. Prescribed Qb was reduced from 398±39.8 mL/min to 314±23.1 mL/min in the intervention arm. Prescribed Qb was 389±41.6 mL/min in controls. During the intervention period, median DRTs decreased in both groups (Figure 1). Repeated measures analysis performed on the difference from each time point to baseline did not show a significant difference between intervention and control arms [$F(1,67) = 0.74$, $p = 0.39$].

Conclusions: In maintenance hemodialysis patients with a baseline post-dialysis recovery time of 6 or more hours, we did not observe an effect of Qb reduction of up to 100 mL/min on post-dialysis recovery time.

Association of Psychosocial Factors with Adherence to Treatment Among Prevalent Dialysis Patients

Joshua B. Ang,[1] Janice P. Lea,[4] Olufunmilola Adisa,[3] Abyalew Sahlie,[1] Catherine I. Obadina,[2] Laura Plantinga.[1] *[1]Emory University, Atlanta, GA; [2]Emory University School of Medicine, Marietta, GA; [3]Emory School of Medicine, Buford, GA; [4]Emory University, Atlanta, GA.*

Background: Dialysis patients are expected to adhere to dialysis treatments, medications, and dietary and fluid restrictions; these may be complicated by patient psychosocial issues. The aim of this study was to examine the relationship between social worker-assessed psychosocial factors and patients' perceived ease of adherence to treatment among prevalent dialysis patients.

Methods: Data were extracted from the initial comprehensive assessment performed by social workers for patients starting dialysis treatment at three outpatient Emory Dialysis centers. Exposures were social worker-assessed psychosocial factors, primarily depression/anxiety. Outcome was patient-perceived ease of adherence across five categories: ability to come to dialysis, complete dialysis, take medications, follow dietary restrictions, and follow fluid restrictions. Responses were dichotomized as "easy" vs. "not easy." Statistical analysis was performed using ANOVA, *t* test, and Pearson's chi-square.

Results: Of 1334 patients, 205 (15.4%) were reported to have depression/anxiety. Compared to those without depression/anxiety, patients with depression/anxiety were significantly less likely to find adherence across all categories to be easy vs. not easy (Table; $P<0.001$ for all). Daily vs. less frequent social support was associated with greater perceived ease of adherence to coming to (75.5% vs. 65.2%, $P=0.001$) and completing (75.6% vs. 64.3%, $P<0.001$) dialysis. Memory impairment vs. none was associated with lower ease of adherence in the same categories (66.2% vs. 74.4%, $P=0.03$; 64.7% vs. 74.7%, $P=0.01$). History of substance abuse, marital status, living alone, employment, community-dwelling status, and ambulatory assistance were not associated with ease of adherence.

Conclusions: Our results suggest that patients who have depression/anxiety, infrequent social support, or memory impairment are more likely to perceive adherence to various aspects of dialysis treatment as difficult. Further investigation of perceived and actual adherence by these psychosocial factors, which could inform targeted interventions to improve adherence, is warranted.

Table 1. Ease of adherence by presence of depression/anxiety

Category	% of patients reporting "easy" vs. "not easy"	
	Depression/anxiety	No depression/anxiety
Coming to Dialysis Visits (N=1044)	53.4	75.5
Completing dialysis (N=1058)	54.3	75.5
Adherence to Medications (N=1089)	63.9	83.3
Adherence to Diet Restrictions (N=1076)	42.5	65.3
Adherence to Fluid Restrictions (N=1066)	51.0	68.9

TH-PO315

The Psychological Burden Associated with Functional Dependency in Hemodialysis Patients

Gabriel B. Gutierrez Peredo, Marcelo Lopes, Gildete B. Lopes, Antonio A. Lopes. *UNIVERSIDADE FEDERAL DA BAHIA, Salvador, Brazil.*

Background: Functional dependency is highly prevalent in maintenance hemodialysis (MHD) patients. We investigated associations between functional dependency and the psychological burden reported by MHD patients

Methods: Cross section of 235 MHD patients treated in Salvador, Brazil. Responses to Katz's and Lawton-Brody's functional status questionnaires were used to create 3 groups: highly dependent (n=44), mild dependent (n=109) and independent (n=82). Using KDQOL-SF patients were asked how true was the 4 questions of the kidney disease burden (KDB) scale: 1) disease interferes too much with life, 2) too much time dealing with the disease, 3) feel frustrated with the disease, 4) feel like a burden on my family. Responses varied from definitely true to false; definitive/mostly true defined higher burden. The KDB score (range from 0 to 100) was determined based on patient's responses; higher scores indicate lower burden. Regression models adjusted for age and comorbidities were used to estimate associations of functional status with KDB scores.

Results: Mean age was 51.2±12.4 yr and significantly higher in highly dependent patients ($P<0.001$). The Table shows score differences and the Figure shows the trend in % of responses for each KDB question, by functional status.

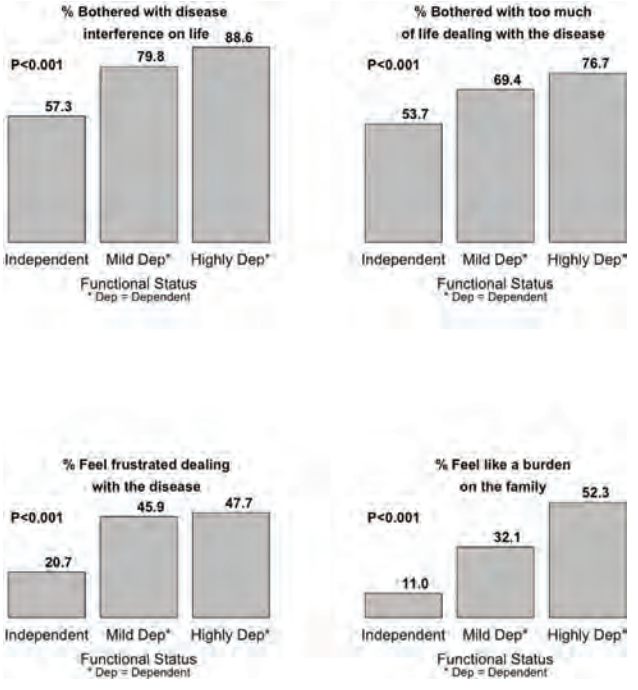
Conclusions: The results indicate that functional dependency represents a strong psychological burden for MHD patients.

Funding: Government Support - Non-U.S.

MEANS AND ADJUSTED DIFFERENCES OF THE KIDNEY DISEASE BURDEN SCORE

FUNCTIONAL STATUS	MEAN KDB SCORE	DIFFERENCE (95% CI)
Independent	64.4±27.2	Reference = 0
Mild Dependent	44.6±26.5	-18.5 (-27.7, -9.36)
Highly Dependent	35.0±25.7	-25.5 (-35.3, -15.7)

KDB = kidney disease burden



Percentages of True or Definitely True Responses for each Item of the Kidney Disease Burden Scale, by Functional Status

TH-PO316

Deep Cerebral Microbleeds Associate with Cognitive Impairment in Dialysis Patients: A Cross-sectional Observational Study

Qian Yujun,[1] Ke Zheng,[2] Xuemei Li.[2] *[1]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China, Beijing, China; [2]Peking Union Medical College Hospital, Beijing, China.*

Background: Cerebral microbleeds (CMBs) are common in dialysis patients, and different location of CMBs resulted from different pathologies. The relationship between CMBs and cognitive impairment (CI) in dialysis patients was controversial. This study aimed to explore whether the distribution of CMBs affects cognitive function in dialysis patients.

Methods: In this cross-sectional study, we enrolled a total of 189 dialysis patients. Patients were divided into 4 groups: without-MBs group, strictly lobar group, strictly deep group, and mixed group. A wide range of cognitive tests were administered to evaluate cognitive function.

Results: In our study, the prevalence of CMBs was 32.8%, 35.2% in HD patients and 29.7% in PD patients. 17 subjects (9.0%) classified as lobar group, 14 subjects (7.4%) as mixed group, and 31 subjects (16.4%) as deep group. Mean arterial pressure (MAP) was significantly associated with the lobar group and deep group. Dialysis vintage was associated with deep group only. Self-reported stroke history and current antiplatelet medication had relevance to the lobar group. There was a significant association between deep CMBs and impaired cognitive function, involving overall cognitive function, memory, language ability and executive function.

Conclusions: Deep CMBs are closely associated with global and specific cognitive impairment in dialysis patients.

TH-PO317

Memory Deficit in Hemodialysis Patients: Clinical Characteristics and Cerebral Imaging Findings

Wenjin Liu,[1] Lulu Wang,[1] Junwei Yang.[2] *[1]Nanjing Medical University, Nanjing, China; [2]Center for Kidney Disease, Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: The current study aimed to investigate the characteristics of memory deficit in dialysis patients, as well as using magnetic resonance imaging (MRI) to explore associated cerebral structural and functional changes.

Methods: Sixty patients on maintenance hemodialysis and 60 healthy controls were included. Patients and controls were frequency-matched by age, sex and education. All subjects underwent evaluation of global cognition (The Montreal Cognitive Assessment, MoCA) and episodic memory (Auditory Verbal Learning Test, AVLT). Brain structure and function were evaluated using MRI with 3DT1 and BOLD (blood-oxygen-level dependent) sequences. Voxel-based morphometry (VBM) was used to calculate grey matter volume while ReHo (regional homogeneity) was calculated to assess brain activity.

Results: Compared with controls, patients had significantly lower scores of MoCA and AVLT (learning memory, short delayed recall, long delayed recall). The memory curve plot based on AVLT results demonstrate that patients had a similar memory curve from learning memory to short delayed memory, whereas their memory declined significantly from short delayed recall to long delayed recall while the controls' memory remained stable during this period. Multiple stepwise regression analysis revealed that end-stage renal disease is associated with memory deficit independently. VBM revealed that dialysis patients have significantly reduced grey matter volume in the following area: right cerebellum anterior lobe, bilateral cerebellum posterior lobe, right hippocampus, amygdala, parahippocampus gyrus, left medial frontal gyrus, left fusiform gyrus, bilateral caudate and subcallosal gyrus and left insula. fMRI showed that ReHo declined in dialysis in the left middle and inferior frontal gyrus, as well as in the right supra marginal gyrus. Correlation analysis demonstrated that ReHo of left middle/inferior frontal gyrus correlated with learning memory test score ($r=0.34, p=0.02$).

Conclusions: Our study reveals memory deficit with a special pattern in dialysis patients, as well as that dialysis patients are with diffuse cerebral atrophy and reduced brain functional activity in certain areas. Cerebral functional changes are associated with memory alterations in the patients.

TH-PO318

Orthostatic Blood Pressure Decline as a Possible Explanation for Memory Deficit in Dialysis Patients

Wenjin Liu,[1] Lulu Wang,[1] Junwei Yang.[2] *[1]Nanjing Medical University, Nanjing, China; [2]Center for Kidney Disease, Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Memory deficit is usually ignored by nephrologists but can be detrimental to patients' quality of life as well as prognosis. A better understanding of the mechanisms underlying this condition could improve the care of CKD patients. Here we sought to test the hypothesis that orthostatic blood pressure decline contributes to memory deficit in patients with end-stage renal disease.

Methods: Sixty patients on maintenance hemodialysis and 60 healthy controls (without CKD, cardiovascular diseases or neurologic diseases) were included. Patients and controls were frequency-matched by age, sex and education. The Montreal Cognitive Assessment (MoCA) was used to assess global cognition while the Auditory Verbal Learning Test (AVLT) was used for episodic memory evaluation. Seated and standing blood pressure were measured. Frequency domain heart rate variability (HRV) were recorded and analyzed.

Results: Compared with controls, patients had significantly lower scores of MoCA and AVLT (learning memory, short delayed recall, long delayed recall). They also exhibited rapid blood pressure decline upon standing, with a delayed compensatory rebound following. Correlation analyses showed that orthostatic blood pressure decline was not associated with cognition or memory in the controls, whereas it was correlated significantly to both short recall and delayed recall scores in the patients. Multiple stepwise regression analysis revealed that orthostatic blood pressure decline is an independent predictor for memory deficit (both short recall and delayed recall). The association between orthostatic blood pressure decline and short recall remained significant after adjusting for HRV.

Conclusions: Our study reveals significant memory deficit and overt orthostatic blood pressure decline upon standing in patients receiving maintenance hemodialysis. Orthostatic blood pressure decline is associated independently with memory test scores in a reverse fashion in hemodialysis patients and this association remained significant even after adjusting for heart rate variability, suggesting that orthostatic blood pressure decline possibly induce memory deficit directly, rather than merely a reflection of general cerebral injury.

Improved Thinking Through Dialysis: A Pilot Study Using the BrainCheck Assessment Platform

Horacio E. Adrogue,[2,1] Alexander H. Adrogue,[3] Yael Katz,[3] Karina Soto-Ruiz,[3] Benjamin Flores,[3] David M. Eagleman.[3] *[1]Dialyspa Medical Center, Houston, TX; [2]Nephrology, Houston Methodist Hospital, Houston, TX; [3]BrainCheck, Inc., Houston, TX.*

Background: It is estimated that 27-67% of the ESRD population is plagued by cognitive dysfunction. This impairment not only decreases QOL and dialysis compliance, but also increases depression and mortality. Drew et al demonstrated that each 1 SD higher executive function score was associated with a 35% lower hazard of mortality. We tested hemodialysis patients with a novel, mobile and digital neurocognitive test, BrainCheck, in an effort to evaluate cognitive improvement after dialysis treatment.

Methods: We prospectively consented and enrolled patients at Dialyspa dialysis center in Houston, TX and administered BrainCheck before and after dialysis. Their performance pre and post-dialysis was shared with the patients in real-time. We also compared the neurocognitive performance of our patients against age-matched controls without ESRD.

Results: We enrolled a total of 29 patients, 17 (58.6%) female. Their ages ranged from 25 to 88, average was 59 years. 11 (37.9%) were African American, 9 (31%) Hispanics, 7 (24.1%) White, and 2 (6.9%) Asians. The educational level breakdown was 12 (41.4%) had some college education, 8 (27.6%) completed high school, 5 (17.2%) had a college degree and 4 (13.8%) a graduate degree. Our findings show that patients who are compliant with dialysis have cognitive function similar to the non-dialysis population. We also found that sharing cognitive performance results with patients could be used as a motivator to increase compliance.

Conclusions: Standard dialysis practice appears to help patients regain cognitive function to levels similar to their non-ESRD counterparts. While more data is needed, this study shows that a brief cognitive test could be used to promote compliance with dialysis treatment. This could translate into QOL gains and decreased mortality in this patient population.

Depressive Symptoms as a Function of Race, Gender, and Perceived Social Support in End-Stage Kidney Disease

Marcus G. Wild,[2] Devika Nair,[2] Ebele Umeukeje,[1] Kerri L. Cavanaugh,[1] Ken Wallston.[1] Behavioral Medicine in Chronic Conditions Research Group *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University, Nashville, TN.*

Background: Depression negatively impacts physical health and quality of life, and the prevalence of depressive symptoms in individuals receiving maintenance hemodialysis (HD) is 2-3 times higher than in the general population. Further, women and members of minority groups are at an increased risk for depression. Perceived social support (PSS) is found to have protective effects against depression. Yet, the effects of social support, gender, and race on depressive symptoms in HD patients is not well described.

Methods: 117 patients (55% female, 72% self-reported African American (AA)) receiving in-center HD completed questionnaires assessing depressive symptoms and PSS. A 2x2x2 ANOVA was conducted to assess the main effects of PSS, gender, and race on depressive symptoms. Two-way interactions of race x PSS, gender x PSS, and race x gender, as well as the three-way interaction of race, gender, and PSS were also evaluated. Age and self-rated overall health were included as covariates.

Results: Analyses revealed significant main effects of age ($p<.01$), overall health ($p<.01$), and PSS ($p<.01$) on depressive symptoms. There was a significant interaction between PSS and race ($p<.05$), such that AAs had lower levels of depressive symptoms at low levels of PSS and higher levels of depressive symptoms at higher levels of PSS, as compared to whites. Further, there was a significant 3-way interaction among PSS, race, and gender (See Figure 1).

Conclusions: Gender and race are important modifiers of the effects of PSS on depressive symptoms. Patient characteristics such as race and gender should be taken into account when creating tailored, social support-based interventions to treat depression in HD patients.

Funding: NIDDK Support

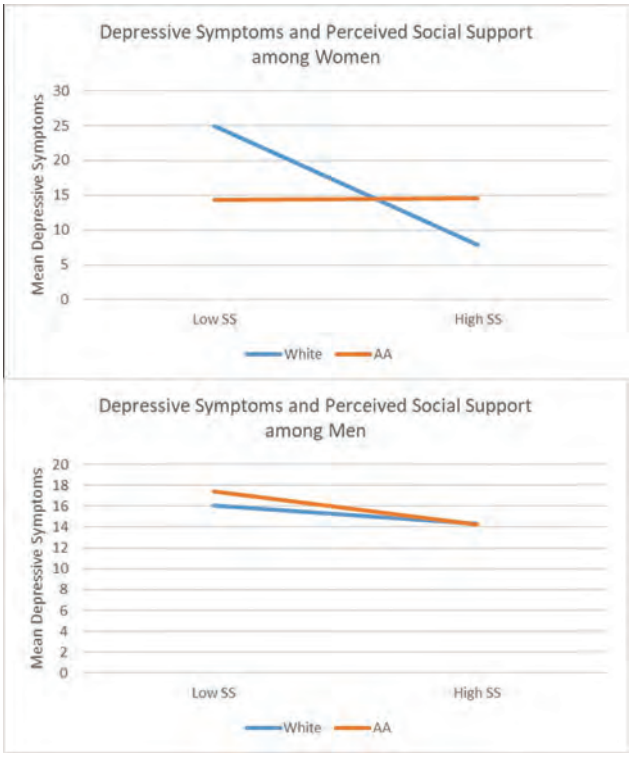

Figure 1. Effect on depressive symptoms of the interaction of PSS, gender, and race.

TH-PO321

Acceptance of Erectile Dysfunction Treatment by Patients on Hemodialysis and Their Renal Providers

Amoghavarsha Puli,[1] Hossam Abdalla,[1] Steven D. Weisbord.[1,2] *[1]University of Pittsburgh Medical Center, PIttsburgh, PA; [2]VA Pittsburgh Healthcare System, PIttsburgh, PA.*

Background: Erectile Dysfunction (ED) is highly prevalent in men receiving chronic hemodialysis (HD). Past studies demonstrate that treatment of ED with phosphodiesterase-5 inhibitors is safe and effective in this population. However, it is unknown whether these medications and other therapies are routinely used. We sought to investigate the acceptance of treatment for ED among men on chronic HD and their renal providers.

Methods: As part of a clinical trial of symptom management in patients on chronic hemodialysis, we assessed erectile dysfunction monthly using the Sexual Health Inventory of Men (SHIM) tool. For men with erectile dysfunction (SHIM score < 22), trained research nurses provided treatment recommendations and if patients and providers accepted them, helped facilitate their implementation. We assessed patients' acceptance of recommendations, reasons for refusal, and providers implementation of therapy. All data was analyzed at the level of monthly assessments.

Results: Of the 101 patients followed for up to 12 months, 46 of 47 (98%) men met criteria for erectile dysfunction. These 46 patients reported ED on 426 monthly assessments. In 49 of the 426 (11.5%) assessments, patients accepted the recommendation for treatment. On 59 assessments (14%) patients were already on treatment or had received a prescription. On 11 monthly assessments (2.5%) patients reported having financial obstacles precluding treatment. On 260 (61%) monthly assessments, patients refused the treatment recommendations. The primary reason patients refused the recommendations was no desire to discuss treatment options (53%) and not interested in being sexually active or not having a partner (38%). In 14 of the 27 assessments (51%) where patients accepted the recommendation, renal providers were unwilling to provide treatment.

Conclusions: Despite the high prevalence of ED in the hemodialysis population, a large majority of patients are not interested in pursuing treatment. For patients interested in treatment, renal providers are commonly unwilling to modify or initiate therapy. Future efforts should focus on identifying patients interested in treatment and improving the provision of therapy for these individuals.

Management of Uremic Pruritus in Hemodialysis: Effectiveness of a Quality Improvement Treatment Algorithm

Karthik K. Tennankore,[1] Erin P. Westby,[1] Kailee L. Mccarron,[2] Marsha Wood,[2] Tabassum ata Quraishi,[2] Jo-Anne S. Wilson,[1] Jaclyn Y. Tran,[2] Amanda J. Vinson,[1] Samuel A. Silver.[3] *[1]Dalhousie University/NS Health Authority, Halifax, NS, Canada; [2]Nova Scotia Health Authority, Halifax, NS, Canada; [3]Queen's University, Kingston, ON, Canada.*

Background: Uremic pruritus (UP) is highly prevalent among dialysis patients and associated with significant morbidity. However, management of UP is inconsistent across centres and many patients remain inadequately treated. The purpose of this study was to analyze the effectiveness of a UP treatment algorithm for chronic dialysis patients.

Methods: We analyzed a cross-section of in-center hemodialysis patients at a tertiary care center and assessed pruritus character (localized or generalized) and severity (0; no itch to 10; worst imagineable itch) using a numerical rating scale (NRS). Those with generalized pruritus rated as moderate to severe (NRS ≥4) were entered into a treatment algorithm consisting of hydrous emollients (all patients) and step-wise use of a topical agent (menthol 0.5%/camphor 0.5% cream), gabapentin (dose increased from 100-300 mg 3X/week) and UV-light. UP severity was recaptured at entry into the algorithm, and assessed at one month after the topical agent and two week intervals after each dose increase of gabapentin.

Results: Overall, 64/196 patients (33%) rated their pruritus as ≥4, and 56/64 entered the algorithm. A total of 39/56 patients (70%) had a persistent pruritus score of ≥4 on reassessment and were prescribed the topical agent; 16/39 patients had a complete response at one month post initiation, 2/39 could not afford the topical, 2/39 developed side effects necessitating discontinuation and 3/39 did not fill the prescription due to other delays. A total of 11 non-responders/non-users of the topical agent received gabapentin; 3/11 patients had a complete and sustained pruritus score of <3 at last follow-up while 3/11 patients failed to respond and were referred for UV light treatment. The remainder had not completed titration of gabapentin or experienced spontaneous remission. Overall, the mean pruritus score fell from 6.5 ± 2.1 to 2.9 ± 1.9 (P<0.001) for those who initiated treatment with the topical agent and had an assessment of their pruritus severity (N=31/39) at four months.

Conclusions: Implementation of a treatment algorithm for UP management effectively reduced UP severity in a cross-section of in-center hemodialysis patients. Future external validation of the algorithm is needed prior to widespread implementation.

Comparison of Retinal Neurodegenerative Changes in Patients with CKD Undergoing Hemodialysis versus Healthy Controls Assessed by Spectral-Domain Optical Coherence Tomography

Susanne Jung,[1] Agnes Bosch,[4] Christian Ott,[2] Dennis Kannenkeril,[4] Thomas Dienemann,[4] Joanna M. Harazny,[3] Roland E. Schmieder.[4] *[1]Departments of Cardiology, Nephrology and Hypertension, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany; [2]Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany; [3]University Erlangen-Nueremberg, Erlangen, Germany; [4]University Hospital Erlangen, Erlangen, Germany.*

Background: Spectral-domain optical coherence tomography (SD-OCT) represents a reliable tool for retinal layer volume measurement. The aim of this study is to evaluate retinal changes indicating neurodegenerative processes in patients with chronic kidney disease (CKD) undergoing hemodialysis (HD) compared to healthy controls.

Methods: In a prospective observational single center study, we included a total of 70 subjects–32 CKD patients undergoing HD and 38 healthy controls. Circular scans of the optic disc area to determine retinal nerve fiber layer (RNFL) thickness were obtained by SD-OCT and macular retinal layer volumes of both eyes including total retinal volume but also each layer were evaluated.

Results: The group of CKD patients (11 females, 21 males, aged 60.3±15 years) was compared to healthy controls (28 females, 10 males, aged 57.9±10 years). The age- and gender-adjusted temporal superior RNFL sector of the right eye was significantly thinner in HD patients as were several retinal layer volumes such as total retinal volume, ganglion cell layer (GCL), ganglion cell layer + inner plexiform layer (GCL-IPL) and inner retinal layer volume (IRL, comprising RNFL, GCL and IPL) of the right eye and IPL volume of both eyes. To eliminate additive effects of HD and diabetes, we performed a subgroup analysis excluding patients with diabetes mellitus (n=25). The temporal superior RNFL sector was still significantly thinner than in the control group (p=0.021) as were GCL (p=0.014) and GCL-IPL volume of the right eye (p=0.024).

Conclusions: In patients undergoing HD, we observed a decrease in temporal RNFL thickness and retinal layer volumes indicating neurodegenerative retinal alterations in patients with CKD. Thereby, SD-OCT represents a valuable high-resolution imaging technique to explore retinal neurodegenerative changes.

RNFL thickness and retinal volumes

SD-OCT scan	Hemodialysis (n=32)	Healthy controls (n=38)	age-/gender-adjusted p value
Temporal superior right sector of the circular RNFL scan [µm]	122.58±26.73	138.53±20.35	0.016
Total retinal volume right [mm^3]	8.22±0.45	8.51±0.41	0.037
GCL volume right [mm^3]	0.96±0.10	1.05±0.08	0.003
IPL volume right/left [mm^3]	0.83±0.08/0.82±0.07	0.88±0.07/0.88±0.07	0.017/0.044
IRL volume right [mm^3]	6.00±0.43	6.27±0.38	0.042
GCL-IPL volume right [mm^3]	1.79±0.67	1.93±0.15	0.005

TH-PO324

The Effects of Repetitive Transcranial Magnetic Stimulation (rTMS) on Improvement of Mental Health and Clinical Parameters in Hemodialysis Patients – Pilot Study

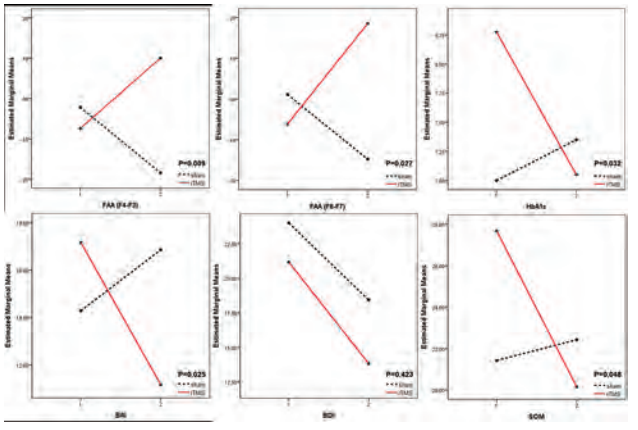
Jin Ho Hwang, Seongyup Yeo. *Department of Internal Medicine, Chung-Ang University Hospital, Seoul, Republic of Korea.*

Background: The prevalence of major depressive disorder in patients with ESRD is higher than in diabetes or congestive heart failure. However, it is difficult to prescribe antidepressant treatment because of concern about potential adverse effects in CKD patients. Here, we studied the therapeutic effect of rTMS as a nonpharmacologic treatment in depressed hemodialysis patients.

Methods: The patients with more than 5 points in Patient health Questionnair-9 were randomized to rTMS group and sham group. The rTMS group was stimulated on the left dorsolateral prefrontal cortex for 20 minutes, three times a week. We collected and analyzed the clinical indices before and after TMS treatment, and also collected data of quantitative electroencephalogram (qEEG), and the results of various psychiatric questionnaires (Beck's depression index-II [BDI-II], Beck's anxiety index [BAI] and SCL-90R-Somatization subscales [SCL-90R-SOM]).

Results: In this study, a total of 13 patients were randomized, 7 patients assigned to the sham group and 6 were assigned to the rTMS group. When laboratory findings were compared 1 month after TMS, hemoglobin A1c was significantly improved in rTMS group (8.3% to 7.1%, P=0.046 by pared t-test, P=0.032 by mixed ANOVA). Although there was no statistical significance, serum potassium and intact PTH also showed an improving tendency. The frontal alpha asymmetry (FAA) F4-F3 (P=0.009), and F8-F7 (P=0.027) values in qEEG was significantly improved in the rTMS group than the others. The BDI-II score was improved both with sham (24.0 to 18.4, P=0.009) and rTMS group (21.2 to 13.8, P=0.005), the BAI (rTMS: 11.2±6.1 vs. sham: 16.9±13.0; F 6.7, P=0.025) and SCL-90R-SOM scores (rTMS: 20.2±5.4 vs. sham: 22.4±5.6; F 4.9, P=0.048) showed prominent improvement after rTMS.

Conclusions: In hemodialysis patients, rTMS may improve depression, anxiety, and somatization symptoms, which may lead to improvements in clinical measures.



TH-PO325

Interventions to Improve Sleep Quality in People with CKD: A Cochrane Systematic Review

Patrizia Natale,[1,2] Suetonia Palmer,[3] Marinella Ruospo,[1] Valeria M. Saglimbene,[1,4] Jorgen B. Hegbrant,[5] Giovanni F. Strippoli.[1,2] *[1]Diaverum, Bari, Italy; [2]Emergency and Organ Transplantation, University of Bari, Bari, Italy; [3]University of Otago, Christchurch, New Zealand; [4]School of Public Health, University of Sydney, Sydney, Italy; [5]Diaverum Renal Services Group, Lund, Sweden.*

Background: Sleep quality is lower for people with chronic kidney disease (CKD). The prevalence of sleep disorder ranges from 45% to 80% in adults with end-stage kidney disease (ESKD) and half of patients with earlier stages of CKD. People with CKD have identified the importance of research focused on better treatments to reduce symptoms of CKD. This Cochrane review evaluates the benefits and harms of interventions to improve sleep quality for adults and children with CKD.

Methods: We searched the Cochrane Kidney Transplant Specialised Register for randomized trials reporting treatment on sleep quality for people with CKD through April 2018. Two authors independently screened citations for eligibility, extracted data, and assessed risk of bias using the Cochrane tool. Evidence certainty was adjudicated using GRADE. Sleep quality was measured by validated sleep scores.

Results: Sixty-seven studies (3427 participants) met review eligibility criteria. Sixty-one studies (3201 participants) involved dialysis patients, three studies involved 104 transplant recipients, and one study involved 45 patients with CKD. Median trial duration was 5 weeks. Mean trial age was 54.3 years. Interventions included acupressure, aromatherapy, benzodiazepine therapy, cognitive-behavioral therapy, dopaminergic agonists, education, exercise, light therapy, massage, melatonin, music therapy, peritoneal dialysis technique, reflexology, relaxation, and telephone support. Methodological reporting was incomplete for most studies. Relaxation had uncertain effects on sleep quality (mean difference [MD] -1.62, 95% confidence interval [CI] -5.03, 1.79; very low certainty evidence). Exercise may provide improvements in sleep quality (standardized MD -1.10, -2.26, 0.05; very low certainty). Acupressure compared to no treatment may improve sleep quality (MD -1.27, -2.13, -0.40; very low certainty) and sleep latency (MD -0.59, -0.92, -0.27; moderate certainty), although effects were smaller than clinically important changes in sleep scores. Effects of other interventions on sleep quality were very uncertain. Evidence in children was absent.

Conclusions: Exercise and acupressure may provide small clinical improvements in sleep quality for people with CKD, although limitations in existing trials reduce the certainty of these findings.

TH-PO326

Association of Self-Reported Sleep Quality with Frailty in Patients on Hemodialysis

Kendra E. Wulczyn,[1] Barbara A. Grimes,[2] Kirsten L. Johansen.[3] *[1]University of California San Francisco, San Francisco, CA; [2]UCSF, San Francisco, CA; [3]University of California, San Franicsco, San Francisco, CA.*

Background: Poor sleep quality is associated with frailty in the elderly, yet the relationship has not been examined in patients on hemodialysis, among whom the prevalence of both poor sleep quality and frailty is higher. We examine the association of sleep quality with frailty in patients on hemodialysis over a two-year period.

Methods: We used ordinal generalized estimating equation analysis to examine the association between self-reported sleep quality and frailty and change in frailty over time in a cohort of 762 hemodialysis patients. Frailty was measured using the Fried frailty phenotype and modeled according to the number of components met. Participants rated sleep quality on a Likert scale in 3 domains: sleep initiation, sleep maintenance, and returning to sleep. A score of 16 or greater on the Center for Epidemiologic Studies-Depression scale indicated depressive symptoms. Measures were conducted at baseline, 12, and 24 mos.

Results: Self-reported difficulty with sleep initiation, sleep maintenance, and trouble returning to sleep were associated with significantly higher odds of being frail in multivariate analysis (table). Impaired sleep maintenance and trouble returning to sleep were also associated with worsening frailty over time. Addition of the inflammatory marker IL-6 did not weaken the association between sleep quality and frailty. The addition of depression to the multivariate model markedly attenuated the association between sleep quality and frailty in all three sleep domains.

Conclusions: Poor sleep quality was associated with higher odds of frailty in patients on hemodialysis, and impaired sleep maintenance and trouble returning to sleep were associated with worsening frailty over time. Our analyses suggest that inflammation does not solely account for these findings and that depression may play a large role in the causal pathway between sleep and frailty.

Funding: NIDDK Support

Odds ratio of higher frailty score and change in frailty over time

Variable	Multivariate‡		Addition of IL-6		Addition of Depression	
	Frailty	Change in Frailty	Frailty	Change in Frailty	Frailty	Change in Frailty
Sleep initiation	1.6* (1.2 - 2.1)	1.2 (0.9 - 1.6)	1.5* (1.2 - 2.0)	1.1 (0.9 - 1.5)	1.1 (0.9 - 1.5)	0.9 (0.7 - 1.2)
Sleep maintenance	1.6* (1.2 - 2.1)	1.5* (1.2 - 1.9)	1.5* (1.2 - 2.0)	1.5* (1.2 - 1.9)	1.2 (1.0 - 1.6)	1.3* (1.0 - 1.6)
Trouble returning to sleep	1.7* (1.3 - 2.2)	1.3* (1.0 - 1.7)	1.7* (1.3 - 2.2)	1.3 (1.0 - 1.6)	1.3 (1.0 - 1.7)	1.1 (0.8 - 1.4)

Dialysis After Displacement

Madhavi E. Ryali,[1] Sejal K. Kalawadia,[2] Wadah Atassi,[2] Cybele Ghossein.[3] *[1]Nephrology Associates of Northern Illinois, Elmhurst, IL; [2]Nephrology Associates of Northern Illinois and Indiana (NANI), Blue Island, IL; [3]Northwestern University- Feinberg School of Medicine, Chicago, IL.*

Background: The Syrian war and the influx of approximately 1.5 million refugees into neighboring Lebanon has led to a humanitarian crisis. Refugees have a multitude of chronic medical and psychosocial problems and few resources. End stage renal disease (ESRD) refugees patients have the additional stressor of trying to obtain life-saving therapy under extreme hardship. Here we report on the current experience of ESRD Syrian refugee patients in Lebanon.

Methods: As part of a medical mission through the Syrian American Medical Society (SAMS), four US nephrologists along with ground staff evaluated the dialysis services provided to refugees in Lebanon. The Lebanese government covers dialytic services for their citizens but Syrian refugees depend on Non Government Organizations (NGO) or personal finances to cover their treatments. Two NGOs currently fund the majority of HD treatments for Syrian refugees in Lebanon – Norwegian Aid Committee (NORWAC) and SAMS. Hemodialysis (HD) is the only available dialysis option. Each dialysis session costs approximately $100 per 4 hour treatment session but does not include transportation and oral medications. Patients travel up to 6 hours by bus round-trip to receive HD. Transplantation is not an option due to costs.

Results: There are currently 218 Syrian refugees in Lebanon who require HD, and this number grows by 1-2 monthly. 114 are covered by NORWAC, 37 are covered by SAMS, and 67 patients are on a waiting for list for a sponsored dialysis chair. Waiting list patients wait for NGO coverage, self-pay for an HD session intermittently if they are able to afford it, or die waiting.

Conclusions: The primary obstacle for providing Syrian refugees in need with HD in Lebanon is cost. This vulnerable population mortality risk is high given the limited financial resources available to them and the chronicity of their condition.

Vibration Perception Threshold as a Measure of Peripheral Neuropathy in Dialysis Patients: A Pilot Project

Paras Dedhia,[1] Rachana H. Jasani,[1] Viswanath Billa,[2] J. Kothari,[1] Shrirang Bichu,[3] Rajesh B. Kumar.[1] *[1]Apex Kidney Care, Mumbai, India; [2]Bombay Hospital, Mumbai, India; [3]Bombay Hospital Near Liberty Theater New Marine Lines, Mumbai, India.*

Background: Dialysis patients are at increased risk of fall due to neuropathy and myopathy. Also, significant percentages of dialysis patients are diabetic; making them vulnerable to neuropathy, foot ulcers and fall.

Methods: Vibration perception threshold (VPT) was measured by handheld digital biothesiometer in prevalent dialysis patients. The biothesiometer probe, which vibrates at amplitude proportional to the square of the applied voltage, was applied perpendicular to the test site. VPT value was defined as the voltage level at which subject first felt vibration sense. Measurements were taken at 6 points of plantar aspects of both feet at great toe, 1st metatarsal, 3rd metatarsal, 5th metatarsal, instep and heel. Average of these 6 points was further graded as normal (<15 volts), mild (16-20 volts), moderate (21-25 volts) and severe (>26 volts). All patients were on thrice a week hemodialysis.

Results: Of the 304 subjects, 59.5% were males. Average age was 51.1± 14.1 years and average dialysis vintage was 4.6 ± 3.8 years. 65 % subjects had hypertension, 31.9% had diabetes, 13% subjects had ischemic heart disease. VPT was found to be normal in 41.1%, mild impairment of VPT in 21.3%, moderate in 11.1% and severe impairment in 24.6% of subjects.

Conclusions: Moderate to severe vibration perception threshold impairment was found in 1-in-3 dialysis patients. This calls for quality improvement program to assess prevalence of neuroapthy and to decrease the burden of morbidities and falls.

TH-PO329

Association Between Psychosocial Factors and Receipt of Nocturnal In-Center Hemodialysis Among Prevalent Dialysis Patients

Zhaoli Tang,[1] Adam S. Wilk,[1] Courtney E. Hoge,[1] Laura Plantinga,[2,1] Janice P. Lea.[3,2] *[1]Rollins School of Public Health, Emory University, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA; [3]Emory Dialysis Centers, Atlanta, GA.*

Background: Compared to traditional in-center hemodialysis (HD), nocturnal dialysis (ND) is characterized by longer sessions and nighttime administration, which may lead to better outcomes for some patients. Given the importance of patient choice in the decision to initiate ND, we explored associations between patients' psychosocial factors and their receipt of ND.

Methods: Among HD patients at a medium-sized dialysis organization, we identified ND patients as those for whom ≥80% of dialysis sessions were ND sessions—starting at 6:30 pm or later and lasting ≥5 hours—over the 3 months (≥20 sessions total) after their first ND session. We extracted dialysis session data from electronic medical records and psychosocial data from social worker assessments typically performed at dialysis start. We performed descriptive analyses of ND and non-ND patients among all HD patients. We also analyzed the subsample of patients whose available psychosocial assessment data were more timely: i.e., patients whose psychosocial assessment was conducted between 1 year before and 1 month after their first ND session (for ND patients) or within the first year of dialysis at the dialysis organization (for non-ND patients). We tested associations of psychosocial factors with ND receipt in logistic regression models.

Results: We identified 64 ND patients in the total sample (5.5% of 1,169 HD patients). ND versus non-ND patients had greater full or part-time employment (26.8% vs. 8.5%, p<0.01), were less likely to require ambulatory assistance (14.1% vs. 41.2%, p<0.01), and were more likely to live alone (33.3% vs. 19.3%, p<0.01). Factors not associated with ND status included being married (26.7% vs. 30.9%, p=0.49) and having daily access to support at home (70.0% vs. 71.6%, p=0.79). For the subsample of 25 ND patients with timely psychosocial data (3.2% of 792 subsample HD patients), the relationships between ND and psychosocial characteristics were similar. Regression results were also qualitatively similar for both samples.

Conclusions: Patient psychosocial characteristics strongly predict receipt of ND care. It may be important to account for differences in psychosocial factors, which are typically unmeasured, when comparing outcomes for ND and non-ND patients.

TH-PO330

Altered Fingerprint Patterns: Revelation of an Unexplored Phenomenon in Patients Receiving Maintenance Hemodialysis

Hari K. Mogili,[2] Indirakshi J. Jamalpuri,[2] Abhilash Koratala.[1] *[1]University of Florida, Gainesville, FL; [2]Sri venkateswara institute of medical sciences, TIRUPATI, India.*

Background: Epidermal ridge patterns on fingers, commonly known as fingerprints, are not only unique to each individual, but are also thought to remain unchanged over time. As such, they are one of the most commonly used means for identification. In our maintenance hemodialysis [HD] program, an unexpectedly high number of patients reported experiencing difficulty using fingerprints as a biometric for identification. This observation prompted a study to explore whether there are alterations in the papillary ridges in HD population and if so, evaluate its magnitude.

Methods: In this cross-sectional study, a total of 300 subjects including 150 patients receiving HD and an equal number of healthy controls [HC] were enrolled from October 2016 to March 2017. The fingerprints were obtained from all 10 fingers and were analyzed for clarity and pattern. They were classified as intact, partially lost, and completely lost. Based on their occupation, the subjects were categorized into 3 groups: 'Blue-collar' [BC], 'White-collar' [WC], and 'unemployed' [UE]. The patterns of fingerprints (i.e. loops, whorls, and arches) were identified and compared for each group.

Results: The mean age of the HD population and the HC were 46.8 and 47.2 years respectively (72% men in each group). The BC, WC, and UE proportions in the HD group were 70, 30, and 23% respectively, while they were 38, 62, and 20 in the HC. Fingerprint clarity was normal in 76.6 and 98.7% of the HD population and HC respectively (p<0.009). Partially lost fingerprints were detected in 13.3% of the HD group and 1.3% of the HC (p<0.001). While the prints were completely lost in 10% of the HD group, none of the HC was found with found to have lost patterns. Loss of fingerprints was more common in those with BC than WC.

Conclusions: While patients receiving maintenance HD can host a multitude of specific and non-specific skin conditions, to our knowledge, this is the first study on altered fingerprints in this patient population. It shows that compared to HC, a significant number of HD patients lose their fingerprint patterns partially or completely over time. Future studies are needed to confirm these findings, identify the pathophysiology and contributing factors, and explore its potential correlation with common comorbidities in this setting.

TH-PO331

Physician Attribution of Long-Term Catheter Use: A New Way of Looking at Clinical Performance Measures

Jonathan H. Segal, Abhijit S. Naik, Tammie A. Nahra, Mia Wang, Jingya Gao, Kathryn Sleeman, J. M. Messana. *University of Michigan Kidney Epidemiology and Cost Center, Ann Arbor, MI.*

Background: Quality metrics in national ESRD programs are traditionally calculated at the dialysis facility level. With the Medicare Quality Payment Program, there is interest in physician-level metrics that could complement existing facility-level measures without increasing provider reporting burden. Our objective was to develop methodology to attribute patient outcomes to either individual physicians or group practices and then compare long-term catheter (LTC) use at the facility and provider-level.

Methods: We used NPI numbers to determine the single provider who received the Monthly Capitated Payment (MCP) from 2016 Medicare physician supplier claims, and identified hemodialysis (HD) patient months from Medicare dialysis facility claims. A group practice arrangement was inferred if multiple practitioners shared a common Tax Identification Number (TIN) and provided MCP services to a specific patient in the year. The percent of total HD patient-months with a LTC from CROWNWeb was then assigned to a practitioner or group practice.

Results: 9307 providers were identified by NPI caring for 338,718 eligible patients. Using NPI alone, 61% of patients were associated with only one MCP practitioner, while using the TIN matching algorithm an additional 33% of patients stayed within a single group practice during 2016 (See Figure). The mean LTC rate of 14.4% at the provider level for 2 of 3 consecutive months was similar to the LTC facility rate of 13.4%. The LTC rate of 9.7% at the provider level for 3 of 3 consecutive months was less sensitive but more specific.

Conclusions: MCP claims can identify the responsible practitioner for a patient's care during a given month. The TIN matching algorithm may allow development of a low-burden patient attribution paradigm for ESRD practitioner quality metrics. This approach yields similar results as the facility-level measure of LTC use and could help align dialysis facility and MCP practitioner quality initiatives.

Dialysate Potassium (K) Concentration and Total Dialysate Volume per Week During More Frequent Hemodialysis (MFHD) Determine Serum K After Transfer from In-Center Hemodialysis (ICHD): Model Predictions

J. Ken Leypoldt,[1] Eric D. Weinhandl,[2] Michael A. Kraus,[3] Allan J. Collins.[2] *[1]Unaffiliated, San Clemente, CA; [2]NxStage Medical, Inc., Victoria, MN; [3]NxStage Medical, Inc, FISHERS, IN.*

Background: Low dialysate K concentrations during ICHD induce rapid intradialytic K removal and low postdialysis serum K concentrations; low dialysate K concentrations are also associated with a higher risk of sudden cardiac arrest. Using a mathematical model, we evaluated the effect of the MFHD prescription on predialysis serum K concentration (Kpre), postdialysis serum K concentration (Kpost) and intradialytic decrease in serum K concentration (ΔKintra) after transfer from ICHD.

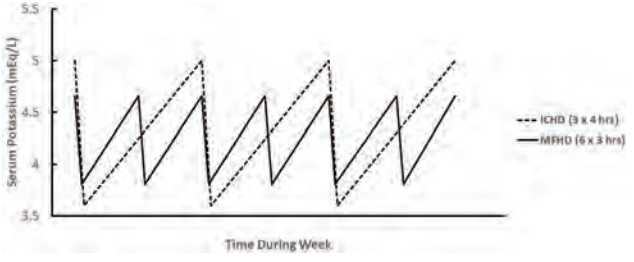
Methods: The mathematical model was modified from one previously published (Agar et al, Hemodial Int 2015) by accounting for colonic K clearance. MFHD prescriptions included treatment frequencies of 3.5, 4, 5 and 6 treatments per week, dialysate volumes of 20-60 L/treatment and treatment durations of 120-240 min. Predialysis serum K concentration during ICHD was assumed between 4.0 and 5.5 mEq/L with a dialysate K concentration of 2 mEq/L.

Results: Model-predicted Kpre, Kpost, and ΔKintra during MFHD were primarily dependent on total dialysate volume per week (TDV) and dialysate K concentration. A schematic weekly profile of serum K during ICHD and MFHD is illustrated in the figure. The range of TDV on MFHD with dialysate K concentrations of 1 and 2 mEq/L required to decrease Kpre, Kpost and ΔKintra below that during ICHD are tabulated.

Conclusions: We conclude that transfer from ICHD to MFHD with low TDV can result in a lower Kpre without reducing Kpost or ΔKintra for dialysate K and MFHD prescriptions typically seen in clinical practice. As with any hemodialysis therapy, additional vigilance is required for patients persistently presenting with hypokalemia or those prescribed high TDV.

Funding: Commercial Support - NxStage Medical

	TDV required to decrease K value below that during ICHD		
MFHD Dialysate K	Kpre	Kpost	ΔKintra
1 mEq/L	80-120 L	120-200 L	>360 L
2 mEq/L	120-175 L	300 L	>360 L



TH-PO333

Effect of Dialysate Potassium (K) Bath During Daily Hemodialysis (DHD) on Serum K Concentration After Transfer from In-Center Hemodialysis (ICHD)

J. Ken Leypoldt,[1] Michael A. Kraus,[4] Bertrand L. Jaber,[2] Eric D. Weinhandl,[3] Allan J. Collins.[3] *[1]Unaffiliated, San Clemente, CA; [2]St. Elizabeth's Medical Center, Boston, MA; [3]NxStage Medical, Inc., Victoria, MN; [4]NxStage Medical, Inc, FISHERS, IN.*

Background: The choice of the dialysate K bath influences serum K concentration during thrice-weekly ICHD; however, the prescription of the dialysate K bath during DHD has not been extensively studied. We examined the effect of the dialysate K bath during DHD on serum K concentration after transfer from ICHD.

Methods: This post hoc analysis evaluated patients who transferred from ICHD to DHD during the FREEDOM Study (N=345). DHD was performed at low dialysate flow rates; treatment frequency per week and dialysate volume per session were 5.9±0.2 and 22.2±4.0 L, respectively. The change in serum K concentration after transfer from ICHD to DHD (ΔK) was calculated based on the average serum K concentration from the last 3 months of ICHD and the first 3 months of DHD.

Results: ICHD serum K concentration was 5.3±0.7, 4.8±0.6 and 4.4±0.5 mEq/L with ICHD dialysate K bath of 1, 2 and 3 mEq/L, respectively. Mean±SD (N) serum ΔK for combinations of ICHD and DHD dialysate K baths are tabulated. By multiple linear regression, ΔK was inversely associated with both higher ICHD dialysate K bath (P<0.001) and ICHD serum K concentration (P<0.001) when DHD dialysate K bath was 1 mEq/L; no such associations were noted when DHD dialysate K bath was 2 mEq/L.

Conclusions: Transfer from ICHD to DHD at low dialysate flow rates with a dialysate K bath of 1 mEq/L resulted in decreased serum K concentrations, but no changes in serum K concentration occurred with a dialysate K bath of 2 mEq/L. Control of serum K concentration during DHD at low dialysate flow rates is effective; however, the choice of the dialysate K bath can be informed when transfer is from ICHD to DHD.

Funding: Commercial Support - NxStage Medical

Misclassification of Acid-Base Status Using Serum Bicarbonate in Hemodialysis

Tyler Woodell,[1] Dena E. Rifkin,[2] David H. Ellison,[1] Jessica W. Weiss.[1] *[1]Oregon Health & Science University, Portland, OR; [2]University of California, San Diego, La Jolla, CA.*

Background: Acid-base status is a potentially modifiable determinant of mortality among ESRD patients. Little is known about how acid-base status changes during hemodialysis, when potential imbalance is directly attributable to treatment. How serum bicarbonate performs in ESRD patients at estimating acid-base status compared to the gold standard – pH – is unknown.

Methods: In a cohort of veterans with ESRD, we prospectively assessed acid-base status monthly at the beginning and end of routine hemodialysis for three months by measuring bicarbonate (as total CO2) and pH. Bias of measured bicarbonate was evaluated with Bland-Altman plots and concordance correlation coefficients comparing measured bicarbonate to that calculated from the Henderson-Hasselbalch equation using pH and pCO2. Categorizing measured bicarbonate and pH, we determined the proportion of pre-dialysis paired samples for which measured bicarbonate misclassified acid-base status (i.e. measured bicarbonate < 24 mmol/L when pH > 7.40, or vice versa).

Results: Among 25 participants, mean pH was 7.41 (± 0.04) pre-dialysis and 7.48 (± 0.05) post-dialysis; 75% of post-dialysis pH measurements were ≥ 7.45. Compared to calculated bicarbonate, measured bicarbonate produced lower estimates of acid-base status both pre-dialysis (mean difference ranged from -1.52 [95% CIs -1.91 to -1.13] to -1.35 [95% CIs -1.69 to -1.00] mmol/L) and post-dialysis (mean difference ranged from -2.70 [95% CIs -3.41 to -1.99] to -0.80 [95% CIs -1.29 to -0.31] mmol/L). There was considerable month-to-month variability in concordance both pre-dialysis (ranging from 0.61 [95% CIs 0.42 to 0.79] to 0.85 [95% CIs 0.76-0.95]) and post-dialysis (0.44 [95% CIs 0.25-0.64] to 0.87 [95% CIs 0.77-0.97]). Compared to pH, 21 of 71 (30%) pre-dialysis bicarbonate samples misclassified acid-base status.

Conclusions: The majority of patients became alkalemic during hemodialysis despite arriving with normal acid base status – a finding currently under recognized in clinical practice. Measured bicarbonate suggested a more acidemic state than was measured by pH. Serum bicarbonate measurements misclassified acid base status in 30% of cases. If confirmed, this observation could impact how physicians prescribe dialysate bicarbonate.

Hepatic Response to Cooler Hemodialysis

Elena Qirjazi,[1,2] Raanan Marants,[2] Megan A. Mio,[3] Brad Urquhart,[3] Ting Lee,[2,4] Christopher W. McIntyre.[1,2] *[1]Nephrology, Western University, London, ON, Canada; [2]Medical Biophysics, Western University, London, ON, Canada; [3]Physiology and Pharmacology, Western University, London, ON, Canada; [4]Lawson Health Research Institute, London, ON, Canada.*

Background: Hemodialysis (HD) exerts significant hemodynamic effects on vulnerable vascular beds. The liver has preserved blood flow during dialysis due to its dual blood supply. Even so, its excretory function is lower, despite an increase in toxin-rich portal vein flow. Extracorporeal cooling has a protective effect on multiple organs during dialysis, but its effect on the liver is unknown. We used CT perfusion imaging to examine the effect of cooling on hepatic blood flow and detoxifying function during HD.

Methods: In this pilot randomized cross-over study, 16 HD patients underwent two HD study sessions – one at standard dialysis temperature (36.5 degrees Celsius), and one at cooler dialysis (35 degrees Celsius; order of the sessions was randomly allocated). Participants had dynamic contrast-enhanced CT studies of their liver using a 256-slice GE

scanner pre (baseline), 3 hours into (peak hemodynamic stress), and post HD. Perfusion maps of total liver, hepatic arterial and portal venous blood flow were generated and analyzed by CT Perfusion (GE Healthcare). Furthermore, subjects had non- invasive pulse dye densitometry (Nihon Kohden) measurements of indocyanine green (ICG) clearance as a marker of liver excretory function and serial blood sampling to assess endotoxin levels.

Results: The cohort had an average age of 63years old (range 47-84 years), 37.5% were female and the average dialysis vintage was 66.5 months (range 9-305 months). An increase in portal vein blood flow at peak HD stress compared to baseline was seen in 62.5% (10/16) of subjects with standard HD (118.6±10.0%). Cooler HD prevented this perfusion change in the portal vein (95.7±12.6%, p=0.03). Total liver blood flow and hepatic arterial flow were not statistically different amongst standard vs. cooler HD treatments. Standard HD also resulted in a significant decrease in ICG clearance at peak stress relative to baseline (85.5±10.4%, p=0.02), which was absent in the cooler HD sessions (92.6±12.1%, p=0.25). Cooler HD also had a trend of increased clearance of uremic toxins: indoxyl sulfate, hippuric acid and phenyl sulfate.

Conclusions: In a subgroup of patients, standard HD causes significant increases in toxin-rich portal vein blood flow at peak hemodynamic stress, which can be mitigated by extracorporeal cooling. Cooler HD also preserves the liver detoxifying function, which usually decreases with standard treatment.
