Background: The effects of modest changes in dialysate sodium concentrations on inter-dialytic weight gain (IDWG), blood pressure and intra-dialytic hypotension (IDH) are uncertain. We studied the association between a change in sodium dialysate from 142 to 140 mmol/L and IDWG, blood pressure and IDH in in-centre hemodialysis patients.

Methods: The dialysate sodium concentration was changed from 142 mmol/L to 140 mmol/L in four dialysis units in Hamilton, Canada as part of a policy change. We assessed changes in IDWG, pre- and post- treatment systolic blood pressures, intra-dialytic change in systolic blood pressure, ultrafiltration volume, and frequency of intra-dialytic hypotension (intra-dialytic SBP < 90 mmHg) 8 weeks before and in two 8 week blocks after switching dialysate sodium from 142 to 140 mmol/L. All analyses were done using mixed-effects models in which patients were considered random intercepts and dialysate sodium was considered a fixed effect. All models were adjusted for age and sex.

Results: Analyses included a total of 559 patients. Compared to the 8 weeks before changing the dialysate sodium, 8 to 16 weeks after the change to 140 mmol/L the mean ultrafiltration volume decreased by 0.11 L (95% confidence interval [CI] 0.07 to 0.12, p<0.001), the mean IDWG decreased by 0.10 kg (95% CI 0.02 to 0.18, p=0.01) and the mean pre-dialysis systolic blood pressure fell by 2.8 mmHg (95% CI 2.3 to 2.3, p<0.001). The odds of intra-dialytic hypotension were not significantly different (odds ratio 1.07, 95% CI 0.97 to 1.18, p=0.17).

Conclusions: Decreasing dialysate sodium from 142 to 140 mmol/L was associated with a reduced pre-dialysis SBP and IDWG without increasing the risk of IDH. Large randomized trials to understand the effects of modest changes in dialysate sodium on patient-important outcomes are needed to inform this fundamental component of dialysis care.

TH-PO337

Effects of Ultrafiltration Rate on Decline in Residual Kidney Function Among Patients Receiving Less-Frequent Hemodialysis

Yuji Lee,[1] Yusuke Okuda,[1] Yoshitsugu Obi,[1] Connie Rhee,[1] Elani Streja,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN*.

Background: High ultrafiltration rate (UFR) may lead to poor preservation of residual kindey function (RKF) by causing hemodynamic instability. However, there are no data about the association between UFR and decline in RKF in patients receiving less-frequent hemodialysis (HD).

Methods: This study included the patients who started less-frequent HD from 2007 to 2011 and had available UFR and renal urea clearance (KRU) data at baseline and KRU data at 1 year after less-frequent HD initiation. Less-frequent HD was defined as dialysis with a consistent treatment schedule of <3 times per week for 6 or more continuous weeks. Patients were grouped into 4 UFR categories (<6, 6 to <10, 10 to <13, and ≥13 mL/h/kg). We defined rapid decline in RKF as a decline in KRU of more than 20% per year. We explored the association between UFR and rapid decline in RKF using logistic regression models with adjustments for case-mix variables, baseline RKF, and maximal change of blood pressure during dialysis.

Results: Among eligible patients, mean (SD) UFR level was 7.0 (4.7) mL/h/kg. Median (interquartile range) baseline KRU was 5.6 (3.6 – 7.7) mL/min/1.72m^2. In adjusted cubic spline models, we found a nonlinear association between higher UFR and the risk for rapid decline in KRU. In an adjusted logistic regression analysis, UFR ≥13 mL/h/kg had a 2.1-fold higher risk of rapid decline in RKF compared to UFR of 6 to <10 mL/h/kg (odds ratio (OR) and 95% confidence intervals (CI): 2.09 (1.14 – 3.82)). In subgroup analyses based on vintage, the association between UFR and decline of KRU was attenuated in patients who started less-frequent HD more than 6 months after dialysis initiation [Figure 1].

Conclusions: High UFR increased the risk for rapid decline in RKF among patients receiving less-frequent HD.

Association of Treatment Time and One Year Change in Residual Renal Urea Clearance in Hemodialysis Patients

Steven Nguyen,[1] Yuji Lee,[1] Christina Park,[1] Jui-Ting Hsiung,[1] Connie Rhee,[1] Csaba P. Kovesdy,[2] Kamyar Kalantar-Zadeh,[1] Elani Streja.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN*.

Background: Longer hemodialysis (HD) treatment time has been associated with lower mortality risk. However, there are scant data regarding the effects of increased treatment time with regards to residual renal function (KrU).

Methods: We retrospectively examined associations of baseline (first 91 days of dialysis) HD treatment time and 1-year renal residual urea clearance change in 6,659 patients receiving thrice weekly HD at a large dialysis organization between 2007-2011 and who survived the first year of dialysis and had available KrU data in the first and fifth patient-quarters. Patients were grouped into 4 exposure categories based on average treatment duration during the baseline quarter. Significant KrU loss was defined as a drop ≥20% ([KrU quarter 5 - baseline KrU quarter] / baseline KrU). Logistic regression models were used with covariate adjustment for case-mix, markers of malnutrition and inflammation, and ultrafiltration volume.

Results: The mean age of patients in the cohort was 62±14 years and 35% were female. Treatment duration of <3 hours was associated with higher risk for KrU loss. Longer treatment durations were linearly associated with lower risk of significant KrU loss. These trends persisted across all models of adjustment. In the shortest duration category (<3 hours), the fully adjusted odds ratio (OR) was 1.40 (95% CI, 1.16, 1.69). In the longest duration category (>4 hours), the OR was 0.81 (95% CI, 0.68, 0.98). [Figure]

Conclusions: Among HD patients, shorter treatment duration was found to be associated with higher odds of loss of KrU whereas longer treatment duration was found to be associated with lower odds of KrU loss. Further studies are needed to understand the relationship between treatment time and KrU loss.

TH-PO339

Incremental and Twice Weekly Hemodialysis in Australia and New Zealand

Martin Wolley,[2,1] Carmel M. Hawley,[5] Mark R. Marshall,[4] Matthew A. Roberts.[3]
[1]Department of Nephrology, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [2]Faculty of Medicine, University of Queensland, Brisbane, QLD, Australia; [3]Eastern Health, Blackburn, VIC, Australia; [4]Middlemore Hospital, Auckland, New Zealand; [5]Princess Alexandra Hospital, Brisbane, QLD, Australia.

Background: Most patients with end stage kidney failure starting hemodialysis do so at a standard frequency of three times a week, with occasional patients starting at a twice weekly frequency ("incremental dialysis"). Incremental dialysis may preserve residual kidney function, and has been associated with reduced mortality in dialysis patients. In this study we aimed to report the prevalence of incremental dialysis in an Australian and New Zealand incident dialysis cohort, and outcomes associated with this approach.

Methods: A cohort of incident adult patients starting hemodialysis between 2004 and 2015 was created. We constructed multivariate Cox proportional hazards models with a primary exposure of dialysis frequency at the first survey date. The primary outcome was all-cause mortality with secondary outcomes of cardiovascular and non-cardiovascular mortality.

Results: The cohort comprised 27513 subjects with complete dialysis frequency data, with 970528 patient months of follow up. Of these, 850 started on twice weekly hemodialysis and 783 had complete data for analysis. Compared to patients starting on conventional dialysis, those started on incremental dialysis were older (67 vs 62 years, p<0.001), had a lower BMI (26.1 vs 27.7 kg/m^2, p<0.001), were more likely to be female (45% vs 38%, p<0.001) had a higher eGFR at dialysis start (7.59 vs 6.66ml/min P<0.001) and were less likely to have diabetes (39.2% vs 50.2%, p<0.001). In a multivariate cox model, incremental start dialysis was not associated with reduced hazards for all-cause mortality (HR 1.03, 95% CI 0.92 – 1.16) but in death cause-specific models was associated with an increased risk for non-cardiovascular mortality (HR 1.25, 95% 1.11 – 1.42) but not cardiovascular mortality (HR 0.87, 95% CI 0.71 – 1.07).

Conclusions: In this cohort, incremental dialysis was used infrequently and there was evidence of patient level differences which imply specific selection criteria are used in practice. Outcomes overall were similar, but cause specific mortality risks demonstrated increased non-cardiovascular mortality risks in the incremental cohort, likely reflecting the differences in patient characteristics. A prospective trial to test the safety and efficacy of incremental dialysis should be considered.

TH-PO340

Short Frequent Haemodialysis at Home and Loss of Residual Renal Function

Hannah K. Beckwith,[1,2] Raja mohammed Kaja kamal,[1] Roger N. Greenwood,[1] Ken Farrington,[1,3] Enric Vilar.[1,3] *[1]Renal Department, Lister Hospital, Stevenage, United Kingdom; [2]Imperial College London, London, United Kingdom; [3]University of Hertfordshire, Hertfordshire, United Kingdom.*

Background: The importance of preserving residual renal function (RRF) in dialysis patients has long been recognised with benefits in survival, nutrition and biochemical parameters. Frequent nocturnal haemodialysis (FNH) may accelerate loss of RRF but effects of short frequent haemodialysis (SFHD) are less clear. We studied rate of loss of RRF in our cohort of home SFHD patients, comparing to matched thrice-weekly in-centre haemodialysis (ICHD) patients.

Methods: We identified 2 cohorts of patients at our centre both of whom had intermittent measures of residual renal urea clearance (KrU). The SFHD cohort comprised patients initiating SFHD at home between 2009-2017. A separate control historical cohort of ICHD patients was used of those commencing dialysis 1989-2009. Vintage from time of HD initiation was calculated for the SFHD cohort. Each patient was matched against 3 patients in the ICHD control cohort for KrU (±0.5ml/min) at the equivalent vintage (±6 months). Only KrU data after SFHD initiation was used in the SFHD cohort, and from the equivalent vintage time in matched controls. We compared trajectories of KrU decline in both cohorts, correcting for potential confounding variables.

Results: 1073 patients were in the control cohort and 84 patients in the SFHD cohort. 24 patients on SFHD had ≥2 KrU measures following initiation but only 22 patients could be matched with 66 control patients according to the above criteria. KrU at SFHD initiation was 2.3ml/min(IQR 1.3-5.4) in the SFHD group and 1.7(IQR 1.0-4.9) in the control group,p=0.25. Patients in the SFHD group were younger than control patients at the equivalent vintage time (50±SD17 v 64±SD14 years,p<0.001). There was no significant difference in frequency of diabetes, cardiac disease, peripheral vascular disease or gender between SFHD and control ICHD patients. Slope of decline in kidney function was -0.8ml/min/yr(IQR -1.8 to 0.1) in the SFHD group and -0.5(IQR -1.2 to -0.1) in the ICHD control group(p=0.60). Using multiple linear regression to determine predictors of slope of decline in KrU, neither group (SFHD or ICHD) nor age or gender were independent predictors of KrU slope.

Conclusions: We did not find evidence that SFHD at home was associated with an increased rate of decline in RRF. Patients with RRF on home HD might benefit from SFHD rather than FNH, but this needs further exploration.

TH-PO341

Residual Renal Function Loss in Hemodialysis Patients: Is Kidney Stunning the Culprit and Can Dialysate Cooling Help?

Raanan Marants,[1] Elena Qirjazi,[1] Claire Grant,[3] Ting Lee,[1] Christopher W. McIntyre.[2] The Lilibeth Caberto Kidney Clinical Research Unit *[1]University of Western Ontario, London, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada; [3]University of Nottingham, Nottingham, United Kingdom.*

Background: Residual renal function (RRF) declines in patients with ESRD after hemodialysis (HD) initiation, necessitating more aggressive fluid removal in subsequent sessions. It has been postulated that recurrent HD-induced renal ischemic insults lead to RRF decline, while dialysate cooling (DC), a feasible intervention which does not burden patient treatment, has been shown to ameliorate HD-induced circulatory stress in the heart and brain. The purpose of this work was to assess the effects of HD on renal hemodynamics using CT perfusion imaging and to explore DC as a protective intervention against renal intradialytic circulatory stress and RRF decline.

Methods: 26 patients provided written informed consent. All patients received standard (36.5°C) HD and a subgroup of 15 patients were randomized to receive either standard or cooled (35°C) HD first in a 2-visit crossover study design. For each visit, CT perfusion imaging was performed at three timepoints (before, 3 hrs into, and after HD) on a 256-slice CT scanner (GE Healthcare) without interrupting HD treatment. Parametric renal perfusion maps were generated and used to measure kidney blood flow.

Results: Renal perfusion loss ('kidney stunning') was observed in 63% (33/52) of kidneys during standard HD but declined to 50% of kidneys during cooled HD. The drop in renal perfusion at 3 hrs into HD was statistically significant (p<0.05) for the standard HD case but not for the cooled HD case. Figure 1 summarizes the per kidney perfusion measurements.

Conclusions: HD causes an acute drop in renal perfusion, and it may be these recurring ischemic insults over many sessions which result in irreversible renal tissue damage and RRF reduction. However, DC ameliorates these perfusion changes and may help slow RRF decline in HD patients.

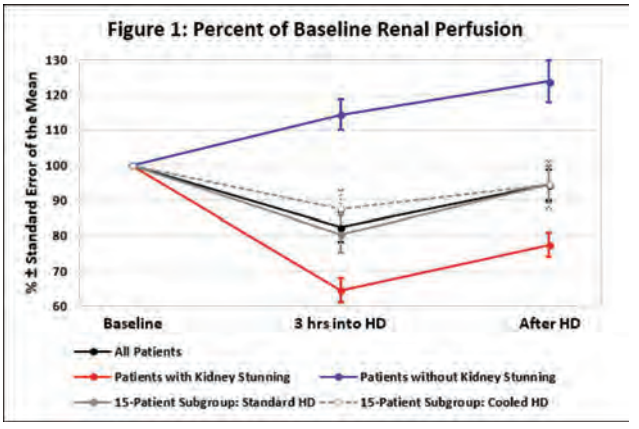

Figure 1: Percent of baseline renal perfusion before, 3 hours into, and after HD. Results are given as average ± standard error of the mean for 26 patients (52 kidneys).

TH-PO342

Allo-Hemodialysis: Intermittent Donation of Kidney Function as a Novel Treatment for Patients with Kidney Failure in Limited Resource Settings

Peter Kotanko,[1,2] Vaibhav Maheshwari,[1] Stephan Thijssen.[1] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: A global report suggests that 2.2 to 7.1 million people might have died in 2010 prematurely because renal replacement therapy could not be accessed (Liyanage *et al*, Lancet, 2015); the authors noted the largest treatment gaps in low-income countries. Current hemodialysis (HD) is expensive and technically challenging. HD requires a substantial amount of water (300 to 1000 L of tap water per HD, depending on dialysate flow rate, treatment time, and reverse osmosis system rejection rate), a dialyzer, blood lines, and a sophisticated dialysis machine with pumps, heating, and ultrafiltration control systems to safely deliver HD, mostly in-centers. In our research, we systematically questioned long-held paradigms and conceptualized a novel treatment option that may have the potential to increase access to HD and reduce the loss of human life owing to kidney failure.

Methods: We conceptually reduced HD to its essential components, the dialyzer, blood lines, a pump, and ultrafiltration control. While - as in traditional HD - on the dialyzer's blood side the patient's blood flows, the dialysate side is connected to the circulation of a healthy subject ("buddy") and perfused with his/her blood (hence called *allo*HD). Because the "most physiologic dialysate i.e. physiosate" is provided by the buddy, the complexity of HD is substantially reduced. We employed extensive mathematical modeling to explore the feasibility of the *allo*HD.

Results: Our model simulations show that fluid and urea transferred into the buddy are cleared effectively by the buddy's kidneys, while bicarbonate diffuse into the patient. We show that a child can sufficiently be treated by an adult buddy with 3-4 weekly treatments. We show that blood flow rates are a key factor, thus *allo*HD may require catheters or

permanent vascular access in buddy. We also address a host of ethical, societal, biological, and technical questions in our ongoing research.

Conclusions: While dialyzing one human against another may seem unthinkable at first, we challenge the kidney community to rethink pre-conceived notions and reflect on the proposed concept. Prototyping of an *allo*HD device is underway that may be used for bench testing and, ultimately, *in vivo* studies in animals and humans. We believe that *allo*HD holds promise to ease the human burden of kidney disease.

TH-PO343

Renal Survival in Patients with Multiple Myeloma Requiring Renal Replacement Therapy – A Single Centre Experience

Aruni Ratnayake, Mukunthan Srikantharajah, Simon C. Stern, David Makanjuola. *Epsom and St Helier University Hospitals NHS Trust, London, United Kingdom.*

Background: Renal impairment is a recognised complication of multiple myeloma (MM). The incidence of renal impairment at diagnosis of MM ranges between 20-50%; of these, approximately 10% present with acute kidney injury (AKI) requiring renal replacement therapy (RRT). Advances in MM treatments have improved overall patient survival and can result in complete or partial recovery of renal function. We reviewed outcomes of patients with MM requiring RRT over a 14 year period.

Methods: Patients diagnosed with MM requiring RRT between January 2003 and December 2017 were identified. Patient data was obtained from electronic records.

Results: 38 patients met the inclusion criteria. Median age was 62 years (range 45-86); 53% were male, 76% were Caucasian. Median follow up time was 37 months (range 6–168 months). 55% required RRT at presentation with a new diagnosis of MM. Of the rest, 21% started RRT within a year of diagnosis and 24% started RRT >12 months after diagnosis. Additional factors contributing to initiating RRT included infection (21%), hypercalcaemia (13%) and fluid overload (10%). Median creatinine at start of RRT was 550µmol/l (range 235-1372µmol/l). 37% of all patients had a renal biopsy, which identified cast nephropathy (43%), amyloidosis (43%), light chain deposition disease (7%), and other diagnoses (7%). 44% of patients requiring RRT at presentation recovered sufficient renal function to stop RRT, with a median time to dialysis independence of 1 month (range 1 week - 21 months) and median eGFR 42 mls/minute (range 12-78mls/minute). Only 6% of the cohort who required dialysis later (not at presentation) recovered adequate renal function to stop dialysis. Overall 1 year survival was 93% (N=36), and 5 year survival was 48% (N=21). 47% of all patients had died by the end of 2017; of these, 94% were dialysis-dependent at time of death, with a median time on dialysis of 1 year (range <1 week to 8 years).

Conclusions: In our cohort, more patients (55%) presented with AKI requiring RRT at the time of diagnosis of myeloma than in published literature (10% in Evison et al, British Journal of Haematology 2016); 44% of these patients became dialysis-independent. Our data demonstrates a positive correlation between recovery of renal function and reduced mortality, further reinforcing the importance of prompt treatment of myeloma.

TH-PO344

Effect of Hemofiltration on Anemia, Adequacy, and Bone Mineral Disease in Hemodialysis Patients

Mostafa A. Abdelkhalek,[1,2] Tarek M. Demerdash,[1,3] Mohammed M. Assem,[1,3] Muhammad Awais,[1] Mahmoud M. Shaheen,[1,3] Ayman Sabri,[1] Hany A. Salama,[1] Ibrahim A. Jubran,[1] Saad S. Alobaili,[1] Wisam H. Al-Badr,[1] Abdulkareem Alsuwaida,[1] Abdullah Kashgary.[1,4] *[1]DaVita-Saudi Arabia, Riyadh, Saudi Arabia; [2]Mansoura University, Mansoura, Egypt; [3]Cairo University, Cairo, Egypt; [4]King Abdulaziz University, Jeddah, Saudi Arabia.*

Background: Hemofiltration (HF) is not associated with lower mortality risk compared to standard hemodialysis (HD). However, there are many critical clinical outcomes in dialysis patients in addition to mortality; the impact of HF on these other outcomes is not clear.

Methods: This retrospective study included all patients referred to DaVita clinics in the Kingdom of Saudi Arabia. High-flux HD was the initial modality in all patients. Those who did not achieve adequacy targets or who had poorly controlled phosphorus were switched to post-dilution HF using 18-23L exchange per treatment. Patients dialyzing with a central venous catheter, patients who dialyzed less than 90 days at DaVita, and those with interrupted HF were excluded.

Results: Of the 1115 patients, 215 (19%) were on HF and 900 on high-flux HD; median follow-up was 6 months for all patients. The HF group showed a significant reduction in serum phosphate ($p<0.001$), a significant increase in serum calcium ($p<0.012$) and a significant improvement in Kt/V ($p<0.0001$). The HF group had significantly higher hemoglobin level than the HD group ($p=0.024$), with a significant reduction in weekly erythropoietin (ESA) dose after starting HF ($p<0.001$).

Conclusions: HF improved anemia, ESA dose, dialysis adequacy, and phosphate control in this retrospective analysis of a cohort selected for failure to meet Kt/V and phosphorus targets. Thus, HF can enable achievement of adequate dialysis care in some patients. Randomized-controlled clinical trials are necessary to confirm these findings.

Funding: Commercial Support - DaVita

Comparison of anemia, mineral bone disorder, and adequacy parameters before and after initiation of HF

Parameters	Before HF	After HF	P-value
Serum phosphate, mg/dL, mean ± SD	5.5 ± 1.58	5.15 ± 1.53	<.001
Serum calcium, mg/dL, mean ± SD	8.92 ± 0.82	9.1 ± 0.68	0.01
Kt/V, mean ± SD	1.53 ± 0.36	1.7 ± 0.43	<.001
Hemoglobin, g/dL, mean ± SD	11.15 ± 1.16	11.3 ± 1.08	0.3
PTH, pg/ml, median (IQR)	554 (556-85)	537 (579-55)	0.6
ESA dose, IU/week, median	10000	4000	0.001

TH-PO345

A Bi-National Cross-Sectional Survey of Clinician Attitudes Towards Haemodiafiltration in Australia and New Zealand

Emily J. See,[2] James Hedley,[3] John W. Agar,[4] Carmel M. Hawley,[1] David W. Johnson,[1] Vincent W. Lee,[5] Kathy Mac,[5] Kevan Polkinghorne,[2] Kannaiyan S. Rabindranath,[6] Kamal Sud,[7] Angela C. Webster.[3] *[1]Princess Alexandra Hospital, Greenslopes, QLD, Australia; [2]Monash Health, Melbourne, VIC, Australia; [3]University of Sydney, Camperdown, NSW, Australia; [4]University Hospital Geelong, Geelong, VIC, Australia; [5]Westmead Hospital, Westmead, NSW, Australia; [6]Waikato Hospital, Hamilton, New Zealand; [7]Nepean Hospital, Castle Hill, NSW, Australia.*

Background: High convection volume hemodiafiltration may improve survival compared to high-flux hemodialysis, however there is significant variation in its use. Clinician attitudes towards hemodiafiltration are poorly understood but may explain differences in practice patterns.

Methods: A 17-question online survey was administered from February 2017 to January 2018. Clinicians involved in the care of hemodialysis patients were invited to participate via the Australian and New Zealand Society of Nephrology. The survey addressed domains of clinician knowledge; hemodiafiltration prescription; perceived benefits, harms, and barriers to use; and indications and contraindications.

Results: Eighty-two responses were received from clinicians affiliated with 49 of 81 hemodialysis units (60% unit response rate). Hemodiafiltration was prescribed by 87% of respondents, but generally to less than 25% of patients. The percentage of respondents prescribing hemodiafiltration to most of their patients was greater for those in privately funded (60%) than publicly funded units (28%). Only 26% of respondents considered the level of evidence supporting the superiority of hemodiafiltration over high-flux hemodialysis to be high. Its key benefits were perceived to be superior middle molecule clearance, hemodynamic stability, phosphate clearance, and amyloid prevention. Common indications included frequent intradialytic symptoms, intradialytic hypotension, and uremic polyneuropathy. Few respondents (14%) agreed hemodiafiltration conveyed harm to patients, however 25% considered frequent circuit clotting to be a relative contraindication. Although most respondents (63%) believed hemodiafiltration was more expensive than high-flux hemodialysis, this was not a barrier to its use. Three-quarters of respondents prescribed post-dilution hemodiafiltration, but only 55% targeted a convection volume greater than 20L.

Conclusions: Most clinicians in Australia and New Zealand prescribe hemodiafiltration, but generally to a small proportion of patients, and high convection volumes are not routinely targeted. Although no specific barriers to its use were identified, the majority of clinicians did not consider the level of evidence supporting its use to be high.

TH-PO346

Effect of Centre and Patient Related Factors on Uptake of Haemodiafiltration in Australia and New Zealand: A Cohort Study Using ANZDATA

Kathy Mac,[1] James Hedley,[3] Vincent W. Lee,[2] John W. Agar,[4] Carmel M. Hawley,[5] David W. Johnson,[5] Emily J. See,[5] Kevan Polkinghorne,[7] Kannaiyan S. Rabindranath,[6] Kamal Sud,[8] Angela C. Webster.[3] *[1]Centre for Transplant and Renal Research, Westmead Hospital, Westmead, NSW, Australia; [2]Westmead Hospital, Westmead, NSW, Australia; [3]University of Sydney, Camperdown, NSW, Australia; [4]University Hospital Geelong, Geelong, VIC, Australia; [5]Princess Alexandra Hospital, Brisbane, QLD, Australia; [6]Waikato Hospital, Hamilton, New Zealand; [7]Monash Medical Centre and Monash University, Melbourne, VIC, Australia; [8]Nepean Hospital, Castle Hill, NSW, Australia.*

Background: We described the use of haemodiafiltration (HDF) in Australia and New Zealand over time, and any patient or centre-related associations with use of HDF.

Methods: We included all incident patients commencing haemodialysis in Australia and New Zealand between 2000-2014. The primary outcome was commencement of HDF over time, which was evaluated using multivariable logistic regression stratified by country.

Results: Of 27,433 patients starting haemodialysis, 3,339 (14.4%) of 23,194 patients in Australia and 810 (19.1%) of 4,239 in New Zealand received HDF. Uptake increased over time in both countries but was more rapid in New Zealand. In Australia, HDF use was more likely in males (OR 1.13, 95%CI 1.03-1.24, $p=0.009$) with BMI>30 kg/m^2(OR 1.46, 95%CI 1.33-1.61), and less likely in older patients (reference <40 years; 40-54 years OR 0.85, 95% confidence interval [CI] 0.72-0.99; 55-69 years OR 0.79, 95% CI 0.67-0.91; >70 years OR 0.48, 95% CI 0.41-0.56) and those with chronic lung disease (OR 0.84, 95%CI 0.76-0.94, $p<0.001$), cerebrovascular disease (OR 0.76, 95%CI 0.67-0.85, $p<0.001$) or peripheral vascular disease (OR 0.77, 95%CI 0.70-0.85, $p<0.001$). Larger centres (defined by number of new patients/year) were more likely to prescribe HDF: 36-147/year OR 26.75 (95%CI 18.54-38.59); 17-35/year OR 7.51 (95%CI

5.35-10.55); 7-16/year OR 3.00 (95%CI 2.19-4.13; <6/year reference. HDF was used more in private dialysis clinics (public OR 0.13, 95%CI 0.05-0.32). In New Zealand, where there is no private dialysis, HDF use was more likely in Maori and Pacific Islanders (OR 1.32, 95%CI 1.05 – 1.66) compared to Caucasians and less likely in males (OR 0.76, 95%CI 0.62 – 0.94, p=0.01). In both countries, centres with higher HD:PD patient ratios were significantly more likely to prescribe HDF. Centre differences explained 36% of variability in HDF uptake in Australia and 48% in New Zealand.

Conclusions: HDF uptake has increased over time, and was associated with similar centre characteristics, but different patient characteristics in each country.

TH-PO347

The Effect of Frequent Hemodialysis on Phosphate and Fibroblast Growth Factor 23: Results from the Frequent Hemodialysis Network Trials

Christopher T. Chan,[1] George A. Kaysen,[5] Gerald J. Beck,[4] Michael V. Rocco,[2] Alan S. Kliger.[3] FHN Trials Group *[1]Toronto General Hospital, Toronto, ON, Canada; [2]Wake Forest School of Medicine, Winston-Salem, NC; [3]Yale New Haven Health System, New Haven, CT; [4]Cleveland Clinic Foundation, Cleveland, OH; [5]Medicine, UC Davis, Sacramento, CA.*

Background: Hyperphosphatemia is associated with elevations in fibroblast growth factor 23 (FGF23) and blood pressure in patients with end-stage kidney disease (ESKD). We aimed to ascertain whether reduction in phosphate by frequent hemodialysis is associated with specific changes in biomarker profile amongst patients enrolled in the Frequent Hemodialysis Network (FHN) trials.

Methods: This was a post hoc observational cohort study. We hypothesized that reduction in phosphate is associated with changes in FGF23. We further hypothesized that changes in FGF23 may correlate with variations in blood pressure and markers of collagen turnover.

Results: Among 332 randomized patients, 243 had biomarker data available. Of these, 124 were assigned 3 times a week hemodialysis (94 [Daily Trial] and 30 [Nocturnal Trial]) and 119 patients were assigned to 6 times a week hemodialysis (87 [Daily Trial] and 32 [Nocturnal Trial]). Frequent hemodialysis lowered phosphate, blood pressures, logFGF23 and tissue inhibitors of metalloproteinase (TIMP) - 2 levels. The fall in phosphate correlated to the changes in FGF23 (r = 0.48, p <0.001 [Daily Trial] and r = 0.55, p < 0.001 [Nocturnal Trial]) and trended with changes in systolic blood pressure (r = 0.18, p = 0.057 [Daily Trial] and (r = 0.31, p = 0.04) [Nocturnal Trial].

Conclusions: Reduction of serum phosphate by frequent hemodialysis may modulate FGF23 levels and systolic blood pressure. Frequent hemodialysis may affect pathological mediators of chronic kidney disease – mineral bone-metabolism disorder.

TH-PO348

Comparison of the Removal of Uremic Toxins with Medium Cut-Off and High-Flux Dialyzers: A Randomized Clinical Trial

Mohamed Belmouaz, Marc Bauwens, Iseline Bouteau, Antoine Thierry, Laure Ecotiere, Frank Bridoux. *Nephrology, CHU POITIERS, Poitiers, France.*

Background: Accumulation of middle weight toxins (500 Da-60 kDa) in hemodialysis (HD) patients results in increased morbidity and mortality. Conventional high-flux (HF) dialyzers allow efficient removal of beta2 microglobulin (11.8 kDa), but their effect on higher molecular weight molecules is not well established. Whether new generation of medium cut-off (MCO) dialyzer improve removal of middle to high molecular weight uremic toxins remains to be demonstrated.

Methods: Theranova, a randomized, open-label, cross-over study (NCT03211676) was designed to compare MCO-HD to HF-HD on the epuration of middle weight uremic toxins. Forty six patients treated with HF dialyzer Elisio 21H™ for more than 6 months were randomized to either continue on this membrane (n=22) or to receive the Theranova 500™ dialyzer (n=24). After 3 months, patients crossed over to the other dialyzer during 3 other months. Primary outcome was myoglobin (17 kDa) reduction ratio (RR) at 3 months. Secondary outcomes were RR, pre and post dialysis levels of beta2 microglobulin, prolactin, hepcidin, leptin, retinol binding protein, alpha 1 glycoprotein, fibroblast growth factor-23, hyaluronic acid, homocystein and cytokines (IL6, IL1-beta, TNF-alpha) at 3 and 6 months. Nutritional and inflammatory parameters, level of albumin and oxidative stress mediators (8-iso-Prostaglandin, oxidized LDL, superoxide dismutase), anemia parameters and erythropoietin resistance index were also determined.

Results: Forty patients completed the study. Mean age was 76 ± 9 years (male gender 74%). MCO-HD provides higher median RR of myoglobin [59% vs 36%, p<0.0001] whereas beta2 microglobulin RR was similar [77% vs 69%, p=0.7], as compared to HF-HD. Mean pre-dialysis beta2 microglobulin levels [26.9 mg/l vs 28.4 mg/l, p =0.001] and post dialysis myoglobin levels [76 µg/l vs 126 µg/l, p<0.0001] were significantly lower with MCO-HD. Pre and post dialysis albumin levels were significantly lower with MCO-HD [36.9 g/l vs 38.2 g/l, p=0.004] and [40 g/l vs 42.3 g/l, p=0.004].

Conclusions: These preliminary data indicate that MCO-HD provides significant removal of myoglobin and decrease in beta2 microglobulin pre dialysis level, with higher albumin loss than HF-HD. Complete results will be presented during the meeting.

Six Months Evaluation of the Expanded Hemodialysis (Hdx) on Removal Efficiency, Anemia, and Quality of Life

Giuseppe Gernone. *ASL BA - "S. Maria degli Angeli" Hospital - Putignano (Bari) - Italy, Putignano, Italy.*

Background: The High-Flux (HF) dialysers in standard-hemodialysis (HD) allow the removal of a wider spectrum of uremic toxin. However the HD can remove mostly low molecular weight solutes while the HDF can remove solutes around 15kDa, so-called Middle Molecules (MM), improving morbidity and mortality by exchange volumes >15L per session. The new medium cut-off (MCO) filter Theranova® is designed to expand the removal of toxins up to 45kDa in HD compared to HF membranes (HemoDialysis eXpanded, HDx) even with conventional blood flows and without exchange fluid infusion. The aim of this study is to evaluate the performance of HDx and its impact on anemia and quality of life (QoL) in hemodialysis patients (pts).

Methods: 13 stable HD pts were enrolled (M/F 10/3, age 70.8±9) with Qb ≤300 ml/min in a six months' observational case-control study. Each patient was evaluated first with HF filter (T0) and then in HDx for six months. Pre-dialysis (T0-T6) were evaluated: urea, phosphate (P), beta2-microglobulin (B2m), myoglobin (Myo), free light-chains K and λ (FLC-K and FLC-λ), C-Reactive Protein (CRP), hemoglobin (Hb) and albumin. Furthermore Kt/V, dose of EPO, ERI and SF-36 questionnaire were evaluated at the beginning and end of observation. We treat hemodialysis pts according to the KDIGO Guideline for Anemia in CKD. The values have been reported as mean±SD.

Results: HDx (Qb= 275 ± 41 ml/min, TT 215 ± 21 m) shows a significant increase in KT/V (T0 1,31 ± 0,23; T6 1,55 ± 0,17; p= 0.001) with relevant RR of: Urea 69%; P 56%; B2m 63%; Myo 55%; FLC-k 61%; FLC-λ 59%. There is a significant reduction at 6 months for FLC-λ (Tab.1). HDx reduced ERI (T0 9.8 ± 10.5; T6 4.4 ± 5.5; p <0.05) and EPO dose (T0 7692 ± 8518; T6 3615 ± 4464, p <0.05), keeping the Hb unchanged. QoL is significantly improved (ISF: T0 27.3 ± 10.1; T6 40.2 ± 8.4 p= 0.0001) (ISM: T0 43.8 ± 14.2; T6 51.1 ± 9.8 p= 0.001).

Conclusions: HDx effectively removes uremic toxins up to 45kDa, even with Qb <300 ml/min, without reducing serum albumin and with promising results on inflammation. Reduction of ERI and improvement of QoL are encouraging and suggest the use of HDx even in pts who cannot benefit from convective techniques because of vascular access or intolerance to high volumes of exchange.

Middle Molecules Elimination in Expanded Hemodialysis: Only Convective Transport?

Nicolás Macías,[1] Almudena Vega,[1] Soraya Abad,[1] Ana M. Garcia Prieto,[1] Esther Torres aguilera,[1] Alba Santos,[4] Ines Aragoncillo,[3] Jose Luno.[2] *[1]Hospital Gregorio Marañón., Madrid, Spain; [2]Hospital General Universitario Gregorio Marañón, Madrid, Spain; [3]Hospital Gregorio Marañón, Madrid, Spain; [4]Gregorio Mara?on Hospital, Madrid, Spain.*

Background: Hemodialysis using high flux membranes leads to convective transport by internal filtration(IF) [Direct Filtration(DF)/Backfiltration(BF)] and allows middle molecules(MM) elimination. The development of High Retention Onset dialyzers has achieved greater elimination of MM and their depurative capacity could be similar to high convective volumes of online hemodiafiltration. The aim of the study was to assess solute transport mechanisms in expanded hemodialysis(HDx) with Theranova 500(Baxter).

Methods: We analyzed fourteen HDx sessions with similar dialysis conditions: blood flow 400 ml/min, dialysate flow 700 ml/min, dialysate temperature 35.5C and 240 minutes length. Pressures at the inlet and the output of both dialyzer compartments(P_{bi}, P_{bo}, P_{di}, P_{do}) were collected hourly with DBB-EXA monitor(Nikkiso) to estimate convective volume(CV) using different semi-empirical methods previously used to model IF. Blood viscosity data and uremic toxins with various molecular weight were measured pre-dialysis, at 1 hour(pre-filter and post-filter) and post-dialysis to calculate molecules reduction over time and dialyzer *in vivo* clearances.

Results: Ultrafiltration was 1.47±0.9 L and Kt/V 1.74±0.3. Hydrodynamic data (average P_{bi}:259±39, P_{bo}:155±27, P_{di}:271±30, P_{do}:145±29 mmHg, monitor TMP 1.8±4

mmHg, oncotic pressure 20,8±3,4 mmHg, blood viscosity 1,51±0,10 cP) allowed to estimate DF and BF rates and volumes. Models showed a DF flow range from 18.2±4.5 to 29.8±3.1 ml/min and BF flow range from 16.8±1.8 to 26.6±2.3 ml/min. The highest calculated CV was 7160.2±738.9 ml/session. Global, convective and diffusive clearances and molecules RR are summarized in Table. CV was correlated with urea(r:-0.785,p=0.001), creatinine(r:-0.675,p=0.008) and myoglobin(r:0.587,p=0.027) clearances.

Conclusions: Results suggest that diffusive transport is a main mechanism of middle molecules elimination in HDx with Theranova 500. HDx offers a potential advantage achieving efficient depuration of middle molecules without the need for high convective transport volumes.

	MW (Da)	Reduction ratio (%)			Clearances (ml/min) at 60 min		
		[0 – 240 min]	[0 – 60 min]	[60 – 240 min]	Global	Convective*	Diffusive

Albumin (g/dL)	66200	10.9 ± 5.9	6.5 ± 8.2	5.1 ± 6.2	-9.4 ± 17.1	-	-

* Convective clearances were calculated using the following theoretical sieving coefficients: Sc 0.90 for Beta-2 microglobulin, Sc 0.88 for cystatin C, Sc 0.79 for myoglobin, Sc 0.67 for prolactin, Sc 0.01 for albumin, Sc → 1 for urea, creatinine and phosphates.

TH-PO351

Higher In Vivo β2 Microglobulin Clearance in Expanded Hemodialysis: Preliminary Results of a Cross-Over Trial

Isis S. Cordeiro, Benedito J. Pereira, Marcelo D. Silveira, Lilian Cordeiro, Hugo Abensur, Rosilene M. Elias, Bruno C. Silva. *Renal Division, University of São Paulo, São Paulo, Brazil*.

Background: In conventional hemodialysis (HD), β2 microglobulin (β2M), a medium-range molecule (MRM), tend to accumulate in tissues. Online hemodiafiltration (olHDF) increases MRM clearance at expense of more complex dialysis machines. The development of medium cut-off with high albumin retention onset membranes allowed a new therapy, known as expanded hemodialysis (HDx). However, so far, *in vivo* extraction of MRM in this modality is unknown.

Methods: Prospective trial, in which 8 patients switched from HD to olHDF or HDx for 1 month, and then crossed to the other modality for another month, after a washout period of 2 weeks. Pre- and post-dialysis urea, albumin, phosphorus, and β2M were measured in blood and in a sample of homogeneously collected spent dialysate, throughout dialysis procedure. High-flux Diacap™ dialyzers (BBraun, Germany) were used both in HD and in olHDF, while Theranova 400™ dialyzers (Gambro, Germany) in HDx. Ongoing trial is registered at NCT03274518.

Results: Mean age was 48 ± 13 years (75% men), and dialysis duration was 225 ± 12 minutes. Total convection volume in olHDF was 20.3 ± 1.1L. β2M clearance was higher in HDx in comparison to high-flux HD and olHDF (62.2 ± 10.2 *vs.* 36.5 ± 2.6, p = 0.012 and 45.5 ± 18.3 ml/min, p = 0.026 respectively). β2M extraction during dialysis was higher in HDx in comparison to olHDF (196.4 ± 31.3 *vs.* 122.1 ± 43.8 mg, p=0.023). Pre-dialysis serum β2M was not different among the three modalities.

Conclusions: Preliminary results of this trial indicate that *in vivo* clearance and total mass extraction of β2M is higher in HDx in comparison to olHDF.

Medium-Range Molecule Extraction and Intradialytic Hemodynamics: Comparison of Two Convective Dialysis Methods

Isis S. Cordeiro, Marina Romagnoli, Rodrigo S. Adao, Telma Dos santos, Mariana H. de Mendonça, Edilene M. Santos, Bruno C. Silva. *Renal Division, University of São Paulo, São Paulo, Brazil*.

Background: Online hemodiafiltration (olHDF) improves intradialytic hemodynamic (IH) stability in comparison to hemodialysis (HD), possibly by lowering dialysate temperature (DT) and increasing medium-range molecule extraction. Using medium cut-off dialyzers in HD machines (HDx) might exert similar effects on IH.

Methods: Prospective trial, in which 8 patients switched from olHDF to HDx. DT was set to 36 °C. Pre-dialysis Beta2 microglobulin (β2M) was measured both in blood and spent dialysate. IH was assessed by Finometer™ during the first and the last 15 minutes of each dialysis session. High-flux Diacap™ dialyzers (BBraun) were used in olHDF, and Theranova 400™ (Gambro) in HDx.

Results: Total convection volume in olHDF was 20.3±1.1L. Post *minus* pre dialysis variation of systolic blood pressure (ΔSBP), diastolic blood pressure (ΔDBP), stroke volume (ΔSV), cardiac output (ΔCO) and peripheral arterial resistance (ΔPAR) were similar between olHDF and HDx. Positive ΔPAR, indicating increased post-dialysis vascular tonus, was observed both in olHDF and HDx (table), yet correlation between ΔPAR and β2M extraction was observed in HDx (r=0.785, p=0.021), but not in olHDF (r=-0.096, p=0.85).

Conclusions: At a same DT, olHDF and HDx led to similar IH stability. β2M extraction was associated with increased intradialytic PAR only in HDx.

Study data, according to dialysis modality

	olHDF	HDx	p
Ultrafiltration (L)	2.77 ± 0.9	2.90 ± 1.0	ns
β2M (ug/ml)	23.2 ± 6.9	27.8 ± 5.5	ns

Trial Evaluating Mid Cut-Off Value Membrane Clearance of Albumin and Light Chains in Hemodialysis Patients (REMOVAL-HD): A Safety and Efficacy Study

Rathika Krishnasamy,[1] Colin A. Hutchison.[1,2] on behalf of the REMOVAL-HD investigators *[1]Australasian Kidney Trials Network, The University of Queensland, Brisbane, QLD, Australia; [2]Department of Medicine, Hawke's Bay District Health Board, Hawke's Bay Hospital, Hawkes Bay, New Zealand*.

Background: A medium cut-off (MCO) dialyzer is a novel form of hemodialysis (HD) therapy designed to increase clearances of larger middle molecules and uremic toxins but may result in short-term loss of albumin. The safety and efficacy profile following sustained use of this dialyzer has not been established.

Methods: REMOVAL-HD is an investigator led, single-arm, multi-center device study that examined the safety, efficacy and patient-centered outcomes of MCO dialyzer use in chronic HD patients over 6 months. The primary outcome was change in serum albumin between baseline and 6 months. Secondary outcomes included 4-weekly trends in serum albumin, six-minute walk test (6MWT), malnutrition inflammation score (MIS) and symptom burden using restless leg syndrome rating scale and Edmonton Symptom Assessment System Revised (ESAS-R) measured at baseline, 3 and 6 months.

Results: Of 92 enrolled participants, 87 completed the required protocol and were included for analysis. Participants had a mean age of 67± 15 years, 63% were men and 51% were diabetic. The average serum albumin decreased by 1.06 g/L (95% confidence interval [CI] 0.43,1.69], or 2.92%, from baseline. The trend in serum albumin during the intervention period is shown in Figure 1. A sustained, unexplained reduction in serum albumin (>25%) was not observed in any participant. Functional and nutritional assessment using 6MWT (Δ5.7m 95% CI -29.9, 41.3) and MIS (Δ-0.4 95%CI -0.9, 0.1) were stable throughout the treatment period. Similarly, there was no significant change in patient-reported symptom burden.

Conclusions: Regular HD using the MCO dialyzer in a chronic HD population resulted in a small but acceptable reduction in serum albumin. Future randomised controlled trials should now assess the impact of the MCO dialyzer on clinical and long-term patient-centered outcomes.

Increasing the Removal of Protein-Bound Uremic Toxins by Hemolipodialysis

Yuanyuan Shi, Yifeng Wang, Qiuyu Zhu, Feng Ding. *Shanghai Ninth People?s Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, China.*

Background: Protein-bound uremic toxins (PBUTs) accumulate at high plasma levels and cause various deleterious effects in ESRD patients because their removal by conventional hemodialysis (HD) is severely limited by their low free-fraction levels in plasma. Here, we assessed the extent to which solute removal can be increased by adding liposomes to the dialysate.

Methods: A reservoir that contained PBUTs and artificial plasma was used for determinating the adsorption capacity of liposomes for p-cresyl sulfate (PCS), indoxyl sulfate (IS) and hippuric acid (HA). The effect of adding liposomes to the dialysate was then quantified and compared with the effect of adding bovine serum albumin (BSA) to the dialysate and dialysate without addition of any sorbent in a rapid equilibrium dialysis (RED) setup and an in vitro closed HD model respectively. Finally, male Sprague-Dawley rats were subjected to 5/6 nephrectomy and fed for 20 weeks to establish the end stage renal failure. They received HD for 240 min at a blood and dialysate flow rate of 1.0 and 5.0 mL/min, respectively. Removal of solutes was determined by reduction ratios (RRs) and total solute removal (TSR) in dialysate.

Results: The uptake of liposomes by direct incubation in vitro showed an obvious dose-response relationship for PCS and IS but not for HA. The percent removal of both PCS and IS but not of HA was gradually increased with the increased concentration of liposomes in the RED setup. In vitro closed HD circulation showed that adding liposomes to the dialysate markedly increased the clearance of PBUTs without greatly altering that of urea and creatinine. The difference was more noticeable for strongly albumin bound compounds. In vivo experiments in uremic rats demonstrated that adding liposomes to the dialysate resulted in higher reduction ratios (RRs) and more total solute removal (TSR) for several PBUTs compared to the conventional dialysate, which was approximately similar to the addition of BSA to the dialysate. There were no significant differences in RRs and TSR of blood urea nitrogen and creatinine with addition of liposomes or BSA to dialysate compared to conventional dialysis.

Conclusions: As an adjunct to conventional hemodialysis, adding liposomes to the conventional dialysate may significantly improve the removal of protein-bound uremic solutes without greatly altering the removal of small, water-soluble solutes.

TH-PO355

Bias Between In Vitro and In Vivo Mass-Transfer Coefficient of Urea (KoA) Is Larger in Pediatric Than in Adult Patients on Chronic Hemodialysis

Verena Gotta,[1] Olivera Marsenic Couloures,[2] Marc Pfister.[3] *[1]University of Basel Children's Hospital, Basel, Switzerland; [2]Yale University, New Haven, CT; [3]University of Basel Children's Hospital, Basel, Switzerland, Hilterfingen, Switzerland.*

Background: Hemodialysis (HD) prescription with respect to blood flow (Q_B) dialysate flow (Q_D) and filter KoA significantly differs between pediatric and adult patients. This may explain why urea dialytic clearance (K_D) has been observed to be significantly underpredicted from Q_B, Q_D and KoA in pediatric HD patients using a mechanistic equation. The objective of this analysis was to evaluate factors that could explain this bias, assuming that it results from a bias between reported *in vitro* determined KoA and actual *in vivo* KoA.

Methods: An urea kinetic model previously developed in adult patients was scaled to 923 paediatric and young adult patients aged 1-29 years based on *a priori* physiologic knowledge (inter-compartmental clearance and volumes of distribution; "base model"). Utilizing data from 2676 HD sessions of those patients with pre- and post-HD urea concentration measurements, a mixed effect modelling approach was applied to evaluate the relationship between individual estimates of KoA correction factors (f_{KoA}) required for unbiased prediction of K_D (as indicated by unbiased post-HD urea predictions), and prescription related parameters (Q_B, Q_D, Q_D/Q_B ratio, filter reuse, low/high-flux, ultra-filtration rate, duration of treatment).

Results: Q_D/Q_B ratio was the parameter most strongly associated with individual estimates of f_{KoA} (≈ -10%, 10%, 100% and 200% increased *in vivo* KoA estimated at Q_D/Q_B ratios of 1.5, 2, 5, and 10, respectively; p<0.001), explaining 18% of inter-individual variability (decrease from 42.8 to 35.1%). Inclusion of Q_D/Q_B ratio as a covariate removed bias observed with Q_B and Q_D. A proposed correction equation for Q_B (true Q_B lower than nominal Q_B at rates >200 mL/min) also corrected bias observed at Q_B > 300 mL/min, but did not reduce inter-individual variability. Inclusion of session duration, low-flux filters, and ultra-filtration rate did further improve the model fit, however with small reductions in inter-individual variability.

Conclusions: While *in vivo* KoA has been reported to be *lower* in adult patients than established *in vitro*, the opposite was observed for pediatric patients in the present study. The observed bias could best be explained by high Q_D/Q_B ratios used in pediatric patients indicating that dialyzers require specific characterization under pediatric conditions.

Intracellular ATP and Inorganic Phosphate Depletion During Maintenance Hemodialysis

Guillaume Chazot,[1] Sandrine Lemoine,[1] Gabriel Kocevar,[2] Emilie Kalbacher,[1] Gabrielle L. Normand,[1] Dominique Sappey-Marinier,[3] Olivier Rouviere,[4] Laurent Juillard.[3,1] *[1]Nephrology and Renal Functional Explorations, Hôpital Edouard Herriot, Hospices Civils de Lyon, Lyon, France; [2]CREATIS (UMR 5220 CNRS & U 1044 INSERM), Université Claude Bernard Lyon 1, France, Villeurbanne, France; [3]University of Lyon, Lyon, France; [4]Hospices Civils de Lyon, Department of Urinary and Vascular Imaging, Hôpital E. Herriot, Lyon, France; Université de Lyon, Lyon, France; Université Ly, Lyon, France.*

Background: The origin of depurated phosphate during hemodialysis (HD) remains unknown. Using phosphorus magnetic resonance spectroscopy (^{31}P-MRS), we previously showed in an acute kidney failure model in pig, an increase of intracellular inorganic phosphate (Pi) concentration during hemodialysis associated with a decrease in ATP. This result strongly supports the hypothesis that depurated phosphate could come from the intracellular space. The aim of this study was to measure intracellular Pi in patients during maintenance HD using ^{31}P-MRS.

Methods: Eleven maintenance HD patients were included in the CIPHEMO (Intracellular ATP and Pi Concentrations measurements in HEMOdialysis patients) study, a single-center prospective trial. They underwent a ^{31}P-MRS exam using a 3-Tesla system and a surface coil placed over the calf muscle region for measuring Pi and ATP contents during a standard hemodialysis session (4 hours). ^{31}P-MR spectra were acquired before, during (every 152 seconds) and after the HD session. Phosphatemia, depurated phosphate and calcemia were monitored during HD and parathyroid hormone levels were measured at the beginning and at the end of the session. Calcium balance was also measured.

Results: Intracellular Pi and βATP kinetics can be described in 2 phases. During the first hour of HD, phosphatemia decreased rapidly (-41%, p<0.001) whereas intracellular Pi didn't change (p=0.9) and intracellular βATP decreased (-17%, p=0.038). After 1 hour of HD, phosphatemia decreased slowly, intracellular Pi decreased (p=0.001) and βATP remained constant until the end of the session (p=0.46). Depurated phosphate is nearly constant during the session. Calcemia increased (p<0.01) and parathyroid hormone decreased (p<0.05) during HD. Calcium balance is positive (mean of 17.1 mmol).

Conclusions: This study showed a significant decrease in both intracellular ATP and Pi during hemodialysis. These findings, reported for the first time in HD patients, support the hypothesis that a large part of depurated phosphate could come from the intracellular space in patients on maintenance hemodialysis.

TH-PO357

Removal of Large-Middle Molecules on Expanded Hemodialysis (HDx): A Multicentric Observational Study of 6 Months Follow-Up

Vincenzo Cantaluppi,[1] Gabriele Donati,[2] Antonio Lacquaniti,[3] Francesco Cosa,[4] Giuseppe Gernone,[5] Marita Marengo,[6] Ugo Teatini.[7,8] *[1]University of Piemonte Orientale (UPO), Novara, Italy; [2]Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [3]Papardo Hospital, Messina, Italy; [4]Ospedale Civile Di Legnano, Taranto, Italy; [5]ASL BA - "S. Maria degli Angeli" Hospital - Putignano (Bari) - Italy, Putignano, Italy; [6]S.C. Nefrologia e Dialisi, ASLCNI, Savigliano, Italy; [7]ASST Rhodense, Milano, Italy; [8]ASST Rhodense, Milano, Italy.*

Background: Hemo**D**ialysis e**x**panded (HDx) may potentially represent an innovative way to remove uremic toxins of Large-Medium Molecular weight (LMMs, ≤45 Kda) thanks to the membrane medium cut-off (MCO, Theranova®, Baxter). LMMs are involved in the pathogenic mechanisms of organ dysfunction associated with uremia including inflammation, malnutrition and atherosclerosis. The aim of this study was to evaluate the efficacy of LMMs removal in HDx during an observational multicentric study of 6 months follow-up.

Methods: 41 HD stable patients (age 67,6±13,4) were dialyzed in HDx with Theranova® 400 (1.7 m^2). Each patient was evaluated at baseline with standard HD (T0), 3 months (T3) and 6 months (T6) after HDx. In the first session of the week (for each period), we evaluated the following pre-dialysis parameters: Urea, Creatinine (Creat), Phosphate (P), Beta2-microglobulin (B2m), Myoglobin (Myo), Free Light Chains (FLC-k, FLC-λ),

Hemoglobin (Hb), Albumin and C Reactive Protein (CRP). Data are reported as mean ± standard deviation (SD).

Results: HDx therapy was well tolerated without evidence of major adverse side effects. The main results of the study are summarized in Figure 1. After 3 months of HDx (T3), we observed a significant decrease of pre-dialysis levels of urea (p=0,008), B2m (p=0,003), FLC-k (p=0,026), FLC-λ (p=0,001). No significant differences of the other uremic toxins between the periods (T3 vs. T6) were observed. Albumin levels remained stable during all the study period. A significant decrease of CRP was observed at T3 and T6, suggesting a positive effect of HDx on inflammatory parameters correlated with a worse outcome.

Conclusions: HDx therapy provided high removal of different LMMs, leading to a significant reduction of molecules involved in uremia-associated organ dysfunction in the first 3 months of treatment (T0-T3). Long-term studies with a larger sample size are needed to evaluate the clinical impact of HDx. However, our preliminary data suggest that HDx may improve LMMs removal and inflammatory parameters.

TH-PO358

Comparison Between Online Clearance Monitoring (OCM) and Calculated kt/V in Adult Population on Hemodialysis

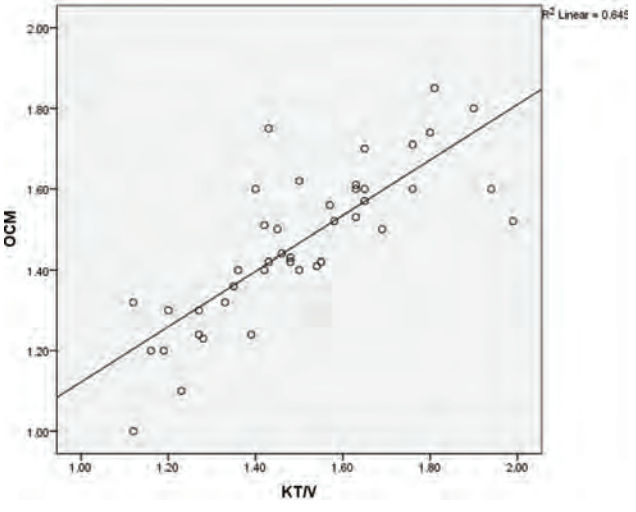
Sidra Saleem, Haris Naveed, Asad Mahmood, Zain Rasool, Abeera Mansur. *DHMC, Lahore, Pakistan.*

Background: Morbidity and mortality in hemodialysis patients is closely correlated to the delivered dialysis dose. The delivered dose is measured in maintenance hemodialysis patients either by blood samples to calculate Kt/V single pool or by measuring the ionic dialysance in real time using OCM. The aim of this study was to compare the quality of dialysis delivered by calculated kt/V obtained with the formula of lowrie(L) and Daugridas(D) with the results measured by Online Clearance Monitoring(OCM).

Methods: Using Fresenius 4008S machines equipped with OCM, we prospectively studied 42 hemodialysis patients from February 1, 2018 to April 30, 2018. All patients were on hemodialysis for more than three months. Pre and post dialysis urea samples were collected for estimation of Single pool Kt/V and compared with OCM. Patient information was collected and all data analysed using SPSS for windows software package.

Results: The average age of the patients was 56.07 ±13.89 years and the mean duration of dialysis was 28.34 ±34.95 months. Mean blood flow rate was 307.67 ±45.87 mL/min. The mean Kt/V was 1.499 ±0.222 (p=0.000) and the mean OCM was 1.465 ±0.190 (p=0.000). We found a positive correlation between the two parameters i.e a Pearson's Correlation: 0.83 (p=0.000) and an R square value of 0.645. We found that OCM is a good indicator of Kt/V. However, it underestimated Kt/V by 2.07%±8.53%.

Conclusions: Online Kt/V calculated by ionic dialysance is a useful method to estimate dialysis dose without the need of blood samples, however it slightly underestimates Kt/V. In clinical practice Kt/V is done on a monthly basis. Any change in the dialysis prescription would entail repeat labs. OCM can be performed at each dialysis session at no extra cost and in real time. Thus, it can prove to be a helpful tool in the assessment of dialysis adequacy.



TH-PO359

Comparison of Removal Efficiency and Biocompatibility Between Pre- and Post-Dilution On-line Hemodiafiltration

Kenji Sakurai,[1] Takeshi Saito,[1] Hiromi Hosoya,[1] Yoshitaka Kurihara,[1] Daisuke Ishii,[2] Kazunari Yoshida,[3] Kenichi Kokubo,[4] Toru Hyodo.[5] *[1]Hashimoto Clinic, Sagamihara, Japan; [2]Kitasato University Hospital, Sagamihara Kanagawa, Japan; [3]Department of Urology Kitasato University School of Medicine, Sagamihara, Japan; [4]Kitasato University School of Allied Health Sciences, Sagamihara, Japan; [5]Eijin Clinic and Cambodian Association of Nephrology, Hiratsuka, Japan.*

Background: In Japan in late-2016, 329,609 patients received dialysis, 24.2% of whom received hemodiafiltration (HDF). In 79% of HDF, the on-line mode is used, which is mostly performed with the pre-dilution mode (pre-HDF). However, in Europe, all HDF sessions use the post-dilution mode (post-HDF). We previously assessed differences in biocompatibility between pre- and post-HDF based on inflammatory markers and lymphocyte stimulation tests, and reported that pre-HDF is less physically stressful. Here, we used a more biocompatible hemodiafilter to study whether biocompatibility would differ between pre- and post-HDF, and assessed the solute removal efficiency of both modes.

Methods: Eight stable dialysis patients were included in this study. HDF was performed with Fineflux 210S eco (asymmetric triacetate membrane, NIPRO) at a blood flow rate of 250 mL/min and a total dialysate flow rate of 500 mL/min for 4 h/session. The substitution fluid volumes were 60 and 12 L/session for pre- and post-HDF, respectively. To test removal efficiency, urea, creatinine, b_2-microglobulin (MG) (MW:11.8kDa) and a_1-MG (MW:33kDa) levels were measured to determine the reduction rates. Albumin (Alb) leakage was also measured. To test biocompatibility, hs CRP, interleukin (IL)-6, tumor necrosis factor (TNF)-a, pentraxin (PTX)-3, intercellular adhesion molecule (ICAM)-1, and cluster of differentiation 62 platelet (CD62P; a platelet cell surface marker) levels were measured.

Results: Post-HDF was more efficient at removing small-molecular-weight solutes than pre-HDF. The reduction rate of b_2-MG was 81.2±2.6% for both modes. The reduction rates of a_1-MG were 33.1±5.8% for pre-HDF and 37.4±3.9% for post-HDF, showing a significant difference ($p<0.05$). Alb leakages (g/session) were 2.8 for pre-HDF and 3.4 for post-HDF ($p<0.05$). No differences between the two modes were observed in the rates of changes in CRP, IL-6, TNF-a, ICAM-1, and PTX-3 levels. Increases in the expression rates of CD62P were 164.7±24.1% for pre-HDF and 210.7±44.2% for post-HDF ($p<0.05$).

Conclusions: The percent change in the CD62P expression rate was smaller for pre-HDF than for post-HDF; platelets may have been less activated during pre-HDF than during post-HDF under this study's conditions. Post-HDF was more efficient at removing solutes.

Using Binding Competitors of Albumin to Promote the Removal of Protein-Bound Uremic Toxins in Hemodialysis: Proof of Concept and Screening of Candidates

Nans Florens,[1,2] Dan Yi,[2] Laurent Soulère,[3] Laurent Juillard,[1,2] Christophe O. Soulage.[2] *[1]Hospices Civils de Lyon, Lyon, France; [2]CarMeN, INSERM u1060, INSA LYON, VILLEURBANNE, France; [3]INSA LYON, Villeurbanne, France.*

Background: Protein-bound uremic toxins (PBUT) remain a concerning burden as their removal in hemodialysis is limited by their strong interaction with albumin. Despite interesting animal data, the limitation of their intestinal production is disappointing. By enhancing their circulating free-fraction during hemodialysis, the use of binding competitors could be undertaken. The aim of this work was to evaluate the displacing capabilities of some selected solutes and to identify potential candidates for an *in vivo* development.

Methods: Displacement capacity of a fluorescent probe (dansylsarcosine) specific to Sudlow's site II on albumin was tested in spectrofluorimetry. Displacement capacity was then expressed as a concentration displacer/albumin ratio. Short chain fatty acids were provided by Sigma-Aldrich. The selection of potential candidate solutes was realized by an in-silico screening (virtual screening and docking) of 12,055 compounds from Asinex chemotech library. The effect on the free-fraction of indoxyl-sulfate (IS) was tested after an addition of a 1mM solution of octanoic C8 in a solution of bovine serum albumin previously incubated with a solution of IS.

Results: Among the short chain fatty acids tested, C8 and C10 were the more prone to displace dansylsarcosine from site II of albumin (75% for C8 ; displacer/albumin ratio of 5). In silico sreening identify 10 potential candidates among which N-phelyl-glycine and N-phenyl-N-benzenesulfonyl glycine (PBSG) were the best candidates. Indeed, the displacement obtained was roughly 60% for a displacer/albumin ratio between 50 and 250. The addition of a 1mM solution of C8 to a solution of bovine serum albumin permitted an increase of 22% of the free-fraction of IS ($p<0.05$).

Conclusions: C8 permitted a significant increase in the free fraction of IS in vitro. Nevertheless, significant concentrations of short chain fatty acids can lead to a significant hemolysis. Hence, we identified two interesting solutes that could be interesting to promote the removal of PBT: N-phenyl-glycine and PBSG. Those hydrophilic solutes need to prove their safety under physiological conditions and their effects on other compounds bound onto site II of albumin need further investigations.

A Novel Post-Dilution CVVHDF-RCA with Personalized Initial Calcium Dosing and Fixed Citrate to Blood Flow Ratio

Lenar T. Yessayan, Michael Heung, Ryann Sohaney, Vidhit Puri, Benjamin Wagner, Balazs Szamosfalvi. *University of Michigan, Ann Arbor, MI.*

Background: Regional citrate anticoagulation (RCA) use is limited by concerns of electrolyte complications. We describe a novel approach for post-dilution CVVHDF that minimizes nurse workload, achieves desired circuit anticoagulant activity, and avoids life-threatening hypocalcemia even in patients with fulminant liver failure.

Methods: Post-dilution CVVHDF was performed using Prismaflex machines at one of three blood flow rates 60, 100, or 150ml/min based on patient's body weight. Acid citrate dextrose-A solution (113 mmol/L) was infused into the arterial limb of the extracorporeal circuit at one of three rates 150, 250, 300 ml/h depending on blood flow rate. Equal dialysate/replacement flow rates are determined from a table according to body weight (for 25-30 ml/kg/h total effluent) in those with expected normal citrate metabolism and modified according to weight and circuit plasma flow in those with absent citrate metabolism. Dialysate/replacement fluid electrolyte concentrations were as follows: Na 136-151, K 2-4, Ca 0, and HCO3 25-45 mEq/L, phosphate 0 to 1.36 mmol/L. Initial calcium chloride solution (136 mmol/L) infusion rate was determined according to a dosing table based on effluent rate and daily serum albumin and titrated thereafter according to systemic ionized calcium (iCa) every 6 hours. Circuit iCa was obtained every 12 hours. RCA effectiveness was measured in terms of circuit iCa and filter life. Electrolyte trends for 30 consecutive patients are reported.

Results: The protocol achieves adequate circuit anticoagulation (circuit iCa <0.4 mM in >95% of measured samples). The risk of clinically significant hypocalcemia is less than 1%. The risk of hypernatremia or metabolic alkalosis is abrogated. Clinically significant hypophosphatemia is avoided by spiking commercial solutions with sodium or potassium phosphate.

Conclusions: The approach achieves desired circuit anticoagulant activity, avoids life-threatening hypocalcemia and poses no risks related to RCA.

TH-PO362

Pre-Filter CVVH Results in Longer Filter Life Than CVVHD

Benjamin Griffin,[1] Nigel Arruda,[1] Isaac Teitelbaum,[2] Sophia L. Ambruso,[1] Joao P. Teixeira,[1] Katja M. Gist,[3] Anna J. Jovanovich,[4] Sarah Faubel.[5] *[1]University of Colorado, Aurora, CO; [2]University of Colorado Health Science Center, Aurora, CO; [3]University of Colorado, Children's Hospital Colorado, Aurora, CO; [4]Denver VA / University of Colorado, Denver, CO; [5]University of Colorado Denver, Denver, CO.*

Background: Continuous renal replacement therapy (CRRT) is used to treat severe acute kidney injury (AKI) in hemodynamically unstable patients. The two main CRRT modalities are continuous venovenous hemofiltration (CVVH, convective clearance) and continuous venovenous hemodialysis (CVVHD, diffusive clearance). Filtration fraction, an estimate of hemoconcentration through a filter, is thought to be a major determinant of filter clotting risk in CRRT. In theory, CVVHD produces less hemoconcentration, and therefore less potential for filter clotting, than either pre-filter or post-filter CVVH. However, data to support this claim remain limited. The purpose of this study was to examine filter life in patients treated with either pre-filter CVVH or CVVHD.

Methods: We conducted a retrospective analysis of adult patients initiated on CRRT at the University of Colorado Hospital (UCH) between 2014 and 2016. Filter life was recorded for all filters, which were changed if clinically warranted or after a maximum of 72 hours. Cox regression was used to evaluate time to filter loss in CVVH versus CVVHD, and the model was adjusted for blood flow rate, anticoagulation type, replacement or dialysis fluid flow rate, ultrafiltration rate, and patient weight.

Results: A total of 415 filters from 160 patients were included in the analysis, of which 275 were used in a CVVH circuit and 140 in a CVVHD circuit. The average filter life in those undergoing pre-filter CVVH was 42 hours (SD 25.2) compared to 35 hours (SD 24.3) in CVVHD ($p = 0.01$). Cox regression showed a hazard ratio of 1.3 (CI 1.03 – 1.65, $p=0.028$) for filter loss with CVVHD.

Conclusions: Contrary to out hypothesis, pre-filter CVVH had a longer average filter life than CVVHD, and this pattern remained significant in a Cox regression model. CVVHD results in less hemoconcentration than CVVH, but is not associated with increased filter life. Pre-filter CRRT may be associated with longer filter life through dilution of clotting factors, but further investigation into the mechanism of filter clotting in these CRRT modalities is needed.

Multipoint Dilution Hemofiltration (MPD-HF): A New Technology for Maximum Convective Clearance

Vienna L. Mott, Violet G. Finley, Daniel Rossetti, Jose Santos, Christopher Dibiasio, Dorit S. Berlin, Joseph L. Charest. *Draper, Cambridge, MA.*

Background: Convection-based renal replacement therapies (RRT) have the potential to improve patient outcomes when compared to diffusion-based RRT such as hemodialysis (HD), but have limited clearance rates. We propose and characterize Multipoint Dilution HF (MPD-HF), a purely convective blood purification technology which removes the fundamental filtration limit associated with convective RRT. In MPD-HF, filtration of liquid and solutes occurs along the length of the hollow fibers that convey the blood and substitution fluid is pushed into the fibers at multiple points along their length. Since multiple filtration and dilution steps are contained within one pass of the blood through the hollow fiber, the fraction of fluid that can be filtered may be increased to allow a high clearance rate.

Methods: We designed, simulated, fabricated, and tested MPD-HF cartridges comprising commercial Fresenius F200NR hollow fibers passed through 3 filtration and 2 infusion chambers, quantifying clearance of molecules across a range of molecular weights.

Results: Figure 1 shows steady state clearance versus molecular weight for the *in vitro* MPD-HF experiment, a COMSOL model prediction of the MPD-HF, an FX CorDiax 800 HDF dialyzer and an F160 dialyzer. *In vitro* tests yielded an average steady state filtrate fraction of 68%, exceeding commercial HDF cartridge filtrate fractions by a factor of approximately 3 and matching the COMSOL model.

Conclusions: MPD-HF offers substantial increases in the filtrate fraction relative to both HD and HDF. Extrapolating the MPD-HF to 5 or more filtration and dilution chambers allows for a theoretical 100% fluid fraction removal in a single pass, yielding clearance rates higher than HD and HDF.

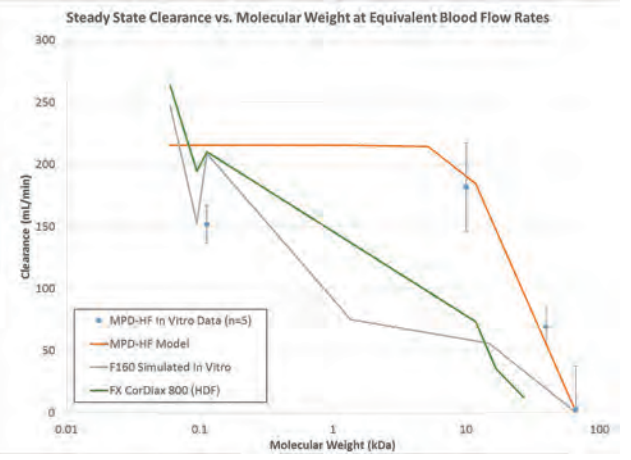

Figure 1. MPD-HF Model and In Vitro Performance

TH-PO364

Measured Dialysate Sodium Deviates Frequently and Sometimes Substantially from Ordered Dialysate Sodium in Acute Care Hemodialysis

Vishwa C. Sheth, Heejung Bang, Burl R. Don, Vincent Paracuelles, Maureen Craig, Andrew I. Chin. University of California, Davis *University of California Davis, Sacramento, CA.*

Background: It is unknown if measured dialysate sodium (meas $_D$Na) differs from the ordered $_D$Na (ord $_D$Na) in the acute care setting where hemodialysis (HD) dialysate is created at the point of care via individual acid and bicarbonate concentrates

Methods: We examined HD treatments in an acute care setting where meas $_D$Na was obtained at HD start. An absolute difference between meas $_D$Na and ord $_D$Na >2 mEq/L was considered out of range. Factors in a simple/univariate logistic regression model with random intercept for each dialysis machine included: machine factors (ID#, model, hours of use) and dialysate factors (ord $_D$Na, additives in acid or bicarb jug, dialysate flow rate)

Results: There were 1230 HD treatments on 21 unique Fresenius machines in a 3-mo period. After exclusions (machine ID# unknown, machine <20 HD's), 1196 treatments were analyzed. The difference between meas $_D$Na and ord $_D$Na was close to normally distributed but skewed towards meas $_D$Na <ord $_D$Na; meas $_D$Na was out of range in 46.8% (n=560) of the cases (Fig 1). In the logistic regression analysis, there was a significant effect of machine ID# clustering, with an ICC of 0.20-0.25, on out of range $_D$Na. Other factors (machine model, hours of use, dialysate flow, ord $_D$Na, additives in acid or bicarb jug) were not associated with $_D$Na out of range, when machine clustering was taken into account. In 227 treatments where the meas $_D$Na was out of range (91.5% were <ord $_D$Na), the nurse made a manual $_D$Na adjustment based on the difference between meas $_D$Na and ord $_D$Na. A subsequent meas $_D$Na level was checked during HD. After this adjustment, the meas $_D$Na was within range of the originally ord $_D$Na in 176 (77.5%) of the treatments.

Conclusions: Measured $_D$Na was >2 mEq/L off from ordered $_D$Na in about half of the treatments, with a bias towards a lower level. There appears to be a difference between dialysis machines, with some having a higher % of treatments with out of range $_D$Na, despite consistent and rigorous machine maintenance and testing

Efficacy and Safety of Oxabact® OC5 in Dialysis Patients with Primary Hyperoxaluria Type 1 (PH1): A Phase II, Prospective, Open-Label Study

Bernd Hoppe,[1] Bastian Dehmel,[2] Ulrike Herberg.[3] *[1]University Hospital Bonn, Bonn, Germany; [2]OxThera AB, Thousand Oaks, CA; [3]University of Bonn, Bonn, Germany.*

Background: In PH1, endogenous overproduction of oxalate in the liver and, therefore, extremely elevated urinary oxalate excretion lead to early end-stage renal disease with patients requiring dialysis and/or liver (±kidney transplantation). Removal of oxalate via dialysis is insufficient and cannot match the endogenous production. Oxabact®, a formulation of an oxalate-metabolizing bacterium (*Oxalobacter formigenes*), induces active secretion of oxalate in the intestinal lumen and generates reductions in plasma and urinary oxalate (Pox and Uox, respectively) in patients with PH1 at various stages of renal impairment. This Phase II, prospective, open-label study investigated efficacy and safety of an improved Oxabact® formulation, OC5, in patients with PH1 treated with a stable dialysis regimen.

Methods: After a 4-week baseline period, patients received OC5 (one oral capsule containing ≥10^9 CFU lyophilized *O.formigenes*, twice a day) for 6 weeks and were monitored for an additional 4 weeks (initial treatment), before they started an extended treatment at the same dose until transplantation or a maximum of 36 months. Total and free Pox were evaluated monthly. Traditional and Speckle-Tracking Echocardiography were performed at baseline and then every 6 months. Fecal analyses for *O. formigenes* and standard safety assessments were conducted. This is the interim analysis of the study's first 12 months.

Results: To date, 12 subjects have been enrolled and six subjects with a mean (SD) age of 30.5 (14.0) years have received OC5 for up to 12 months. Total Pox (mean at baseline 153.48 µmol/L, maximum mean decrease: 43.52 µmol/L at Week 44) and total:free Pox ratio (mean at baseline 1.468, 1.223 at Week 52; p <0.05) decreased. Cardiac parameters clearly indicated that systemic oxalosis did not worsen under treatment. *O.formigenes* genotype 1 was detectable in all patients. Six subjects reported 52 adverse events; most were mild or moderate (88.5%) and not related (90.4%) to treatment. Two subjects experienced serious adverse events, unrelated to treatment.

Conclusions: A 52-week treatment regimen with OC5 in patients with PH1 undergoing dialysis was safe, reduced Pox, and provided evidence that systemic oxalate deposition was attenuated, which would be of a substantial clinical significance for future transplantation outcome.

TH-PO366

Low Rates of Outpatient Intensified Hemodialysis in Pregnant Women with ESRD

Andrea L. Oliverio,[1] Jennifer L. Bragg-Gresham,[1,2] Rajiv Saran,[1,2] Michael Heung.[1,2] *[1]University of Michigan, Ann Arbor, MI; [2]U-M Kidney Epidemiology and Cost Center, Ann Arbor, MI.*

Background: Pregnancy is a rare event for women on hemodialysis (HD). Observational data suggests that increasing HD hours per week to >20-36hrs and targeting pre-HD BUN<50 during pregnancy improves likelihood of successful delivery. We aimed to characterize pre-delivery HD regimens of pregnant women with ESRD in the US and to identify patient characteristics associated with receipt of intensified HD.

Methods: Deliveries were identified using inpatient claims data from USRDS for all women age 18-44 undergoing HD with Medicare as primary payer in 2012-2015 (n=390). 41 weeks of preceding outpatient HD treatment data in CROWNWeb was examined, including: number of sessions per week, prescribed and delivered HD time, Kt/V, ultrafiltration rate, and pre-HD BUN. We stratified women into "intensified HD" group (5+ sessions per week; INT-HD) vs. "standard HD" (<5 sessions; STD-HD). Comparison of demographic and treatment variables were made for women receiving INT-HD vs. STD-HD using student's t-test.

Results: There was no difference in age, ethnicity, or dialysis vintage of women who received INT-HD vs. STD-HD (Table), nor were there individual patient characteristics which predicted receipt of INT-HD. 39.2% of women in the STD-HD group did not achieve the recommended pre-HD BUN<50 compared to 17.2% of women in the INT-HD group (p<0.0001). Only 12.8% of women were dialyzed at least 5 times per week as outpatients, and less than 5% received ≥20 hrs (1200 minutes) per week. The average total treatment time per week for all delivering women was 745.5 min.

Conclusions: Experts advocate for at least 20 hours (if no residual renal function >36 hours) of HD per week in order to improve pregnancy outcomes. We observed that very few women with ESRD on HD in the US are receiving >20 hrs of HD per week in the outpatient setting and a significant proportion do not achieve the recommended pre-HD BUN.

Demographics and Treatment Characteristics in Delivering Women by Group

TH-PO367

Pregnancy Delivery Rates Amongst Women of Child-Bearing Age with ESRD: 2002-2015

Andrea L. Oliverio,[1] Jennifer L. Bragg-Gresham,[1,2] Rajiv Saran,[1,2] Michael Heung.[1,2] *[1]University of Michigan, Ann Arbor, MI; [2]U-M Kidney Epidemiology and Cost Center, Ann Arbor, MI.*

Background: Fertility is depressed in women with advanced CKD and ESRD and improves after transplant. Women with ESRD are at higher risk for pregnancy complications and loss. We sought to identify trends in delivery incidence amongst women with ESRD receiving renal replacement therapy (RRT) in the United States Renal Data System (USRDS).

Methods: We identified deliveries from inpatient claims of all prevalent female ESRD patients aged 18-44 yrs (n=650,282) between 2002-2015. Treatment modality at time of delivery was taken from treatment history files. Modality assignment for non-pregnant women was defined as last modality reported in each year. Rates were expressed as number of delivering women for every woman of child-bearing age receiving that RRT modality within each year. Logistic regression examined associations between patient characteristics and delivery.

Results: 1833 deliveries were observed over the study period. Delivery rates increased overall from 0.23% to 0.34% from 2002-2015 (Figure). Rates were highest for transplant patients, while PD patients had significantly lower rates. Older age was associated with lower odds of delivery (OR=0.91 for each additional year, 95% CI: 0.91-0.92). Black and Hispanic women (compared to White) were more likely to deliver (OR=1.46, 95% CI: 1.29-1.65 and OR=1.44, 95% CI:1.26-1.65, respectively), as were women whose primary cause of ESRD (compared to diabetes) was glomerulonephritis (OR=1.78, 95% CI=1.49-2.13) and hypertension (OR=1.65, 95% CI: 1.35-2.02). For each additional year after ESRD diagnosis, the odds of delivery were lower by 3% (OR=0.98, 95% CI: 0.97-0.99).

Conclusions: The absolute number of deliveries for women of childbearing age with ESRD remains low, but is increasing. The rate of delivery in women receiving HD nearly doubled between 2002 and 2015. Further work is needed to identify factors contributing to this increase. Younger women with shorter ESRD vintage are more likely to deliver and it may be prudent to focus family planning counseling to this subset of patients.

Switching Dialysis Modalities for a Better Outcome: Analysis from the United States Renal Data System (USRDS)

Farah Abifaraj,[1] Yasir Lal,[2] Wayne G. Fischer,[2] John Badalamenti,[2] Hania Kassem.[2] *[1]Internal Medicine, University of Texas Medical Branch at Galveston, Galveston, TX; [2]University of Texas Medical Branch, Galveston, TX.*

Background: Since 2011, the prospective payment system dialysis bundle has created more incentive for providers to place patients (pts) on Peritoneal Dialysis (PD) leading

to more pts switching from Hemodialysis (HD) to PD. Previous studies showed that, compared to pts who started with HD, those who started with PD were more likely to be white, younger, non-diabetic, and with less prevalence of obesity and other comorbidities. They were also described to have either better or similar survival. However, patient factors and outcome in those who switch from HD to PD have not been well described. In this study, we compared demographics and survival between pts on HD and those switched from HD to PD.

Methods: Using the USRDS, we analyzed demographics and mortality for 594,872 pts from May 2012 till December 2015. Kidney transplant recipients were excluded. Pts were divided into: HD only, PD only, and HD-to-PD switch groups. Comparison of continuous demographic variables, such as age, BMI, and albumin, was based on t-tests (pooled variances). Comparison of demographic categorical variables, such as sex, race, region, and presence of diabetes, was based on Contingency Analysis. Survival Analyses were performed using Kaplan-Meier curves. A Cox Proportional Hazards model was used to estimate the effects of predictor variables on pts survival as well as on PD modality survival after the switch.

Results: Comparing the HD only (n= 574,606) and switch groups (n= 20,266), we found that switch pts were more likely to be younger at time of 1st ESRD service (5.0 years, $p<0.01$), males, white, non-diabetics, and to have a higher serum albumin (0.05 g/dl, $p<0.01$). Average BMI was surprisingly higher in the switch group (0.4 kg/m^2, $p<0.01$). The switch group had better survival than both the HD only and PD only groups. Among pts who switched, non-diabetics and those with a higher serum albumin had better overall survival as well as PD modality survival. BMI and sex had no significant effect on either.

Conclusions: Demographics in pts who transitioned from HD to PD were similar to those previously reported in pts initiated on PD. Additionally, the HD to PD group had improved survival. These findings provide insight into the demographics influencing the decision to switch pts to PD and the positive impact on survival among those pts.

TH-PO369

Factors Affecting Initial Dialysis Modality in Pediatric ESRD

Celina Brunson,[1] Justine Shults,[3] Sandra Amaral.[2] *[1]The Children's Hospital of Philadelphia, Philadelphia, PA; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]Perelman School of Medicine University of Pennsylvania, Philadellphia, PA.*

Background: Children from minority and immigrant backgrounds are more likely to be placed on hemodialysis (HD) vs. peritoneal dialysis (PD) at onset of end stage renal disease (ESRD). We hypothesize that social determinants of health (SDOH), beyond the effect of race/ethnicity, influence initial dialysis modality.

Methods: We performed a retrospective cohort study of children 1-18 years who started dialysis between 2000-2012 using the US Renal Data System database. Using national census and American community survey data based on the patient's residence zip code, we derived a community level health risk score comprised of 17 items representing the five elements of SDOH defined by Healthy People 2020. (Table 1) Used a multivariable logistic regression model to identify associations between dialysis modality (HD vs. PD) and the health risk score, adjusting for age at incident ESRD, race, sex and ESRD cause.

Results: Among 5,607 patients, 3,472 (61.9%) had HD as their initial modality vs. 2,135 (31.8%) who were started on PD. Patients in the lower quintile for risk score (more favorable community based on the included variables) were more likely to be placed on PD (OR 1.456, p-value 0.000, 95%CI 1.21-1.75) vs those in the highest quintile of risk score (OR 1.267, p-value 0.014, 95% CI 1.049-1.53) when adjusting for age at incident ESRD, race, sex and ESRD cause. In this multivariable model, race was not associated with initial dialysis modality.

Conclusions: Children with highest risk scores were less likely to be placed on PD vs patients in neighborhoods with lower risk. Race was not associated in our model with initial dialysis modality unlike earlier studies looking at similar associations. Our findings suggest that it may be informative to examine SDOH along with race when examining inequities in health care access. Next steps will include differential weighting of variables within the risk score to determine whether there are modifiable factors that impact initial dialysis modality for children.

Developing Consensus-Based Outcome Domains for Trials in Peritoneal Dialysis: An International Delphi Survey

Karine E. Manera,[1,2] Allison Tong,[1,2] Jonathan C. Craig,[1,2] David W. Johnson.[3,4] on behalf of the SONG-PD Steering Group *[1]Sydney School of Public Health, The University of Sydney, Sydney, NSW, Australia; [2]Centre for Kidney Research, The Children's Hospital at Westmead, Westmead, NSW, Australia; [3]Princess Alexandra Hospital, Brisbane, QLD, Australia; [4]University of Queensland, Brisbane, QLD, Australia.*

Background: Major inconsistencies in the reporting of outcomes, the omission of patient-reported outcomes, and frequent reporting of surrogate outcomes in trials impedes evidence-informed decision making by patients and their clinicians.

Methods: In an international online 3-round Delphi survey, patients/caregivers and health professionals rated the importance of outcomes using a 9-point Likert scale and provided comments. In rounds 2 and 3, participants re-rated the outcomes after reviewing the scores and comments of other respondents. For each outcome we calculated the mean, median, and proportion rating 7-9 (critically important).

Results: In total, 873 participants (207 [24%] patients/caregivers and 666 [76%] health professionals) from 68 countries completed round 1, and 530 (61%) completed round 3. The top outcomes based on a threshold (mean >8; median ≥8; proportion >85% in both groups) were PD-infection, membrane functioning, PD failure, cardiovascular disease, mortality, catheter complications, and ability to do usual activities. Compared with health professionals, patients/caregivers gave higher priority to 6 outcomes: blood pressure (mean difference of 0.4), fatigue (0.3), membrane functioning (0.3), impact on family/friends (0.1), peritoneal thickening [EPS] (0.1), and usual activities (0.1).

Conclusions: Clinical outcomes were highly prioritised by both stakeholder groups. Patients/caregivers gave higher priority to lifestyle-related outcomes than health professionals. This process will inform a core outcome set to improve the consistency and relevance of outcomes reported in trials in peritoneal dialysis.

TH-PO371

Regional Variation in Peritoneal Dialysis (PD) Time on Therapy (ToT): Results from the Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS)

Jeffrey Perl,[1] Junhui Zhao,[2] Bruce M. Robinson,[2] Simon J. Davies,[3] Hideki Kawanishi,[4] David W. Johnson,[5] James A. Sloand,[6] Mauricio Sanabria,[7] Talerngsak Kanjanabuch,[8] Yong-Lim Kim,[9] Jenny I. Shen,[10] Ronald L. Pisoni.[2] *[1]St. Michael's Hospital, Toronto, ON, Canada; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Keele University, Stoke-on-Trent, United Kingdom; [4]Tsuchiya General Hospital, Hiroshima, Japan; [5]Princess Alexandra Hospital, Brisbane, QLD, Australia; [6]JAS Renaissance, Chicago, IL; [7]RTS Baxter, Bogota, Colombia; [8]Chulalongkorn University, Bangkok, Thailand; [9]School of Medicine, Kyungpook National University Hospital, Daegu, Republic of Korea; [10]LaBiomed at Harbor-UCLA, Torrance, CA.*

Background: Transition to hemodialysis (HD) carries significant morbidity and reduced quality of life for PD patients. PDOPPS seeks to identify practices aimed at meaningfully prolonging technique survival on PD. Here we describe PD discontinuation and death rate in PDOPPS.

Methods: PDOPPS is a prospective cohort study of randomly selected patients across national samples of PD facilities from Australia/New Zealand (A/NZ), Canada, Japan, Thailand, the UK, and the US. The study population included 20532 patients who were followed until death (on PD) or permanent switch to HD, based on initial designation as a permanent transfer or a temporary transfer with no return at 12 weeks. ToT (from PD start to death or permanent transfer to HD) and hazard ratios (HR) were estimated using Cox models based on PD vintage at study entry (age, sex, and diabetes adjusted).

Results: 16% of patients transferred to HD and 13% of patients died. Median (IQR) ToT was 3.0 (1.3-5.7) years, ranging from 2.3 (1.1-4.4) in the UK to 4.5 (2.3-9.0) in Japan. Relative to the US, HR (95% CI) for transfer to HD were similar in Japan, Canada, and A/NZ, lower in Thailand (0.5, 0.3-0.7), and higher in the UK (1.5, 1.0-2.0). Compared to the US, HR for death was lower in Japan (0.4, 0.3-0.5), higher in Thailand (1.9, 1.4-2.5), and similar in A/NZ, Canada, and the UK. Variation in death, and transfer to HD (was seen across facilities [figure].

Conclusions: In PDOPPS, rates of permanent transfer to HD, and death vary significantly by country and facility. Future work will identify reasons for variation in PD outcomes, and identify practices to reduce the risk of PD attrition.

TH-PO372

Differing Attitudes Towards Peritoneal Dialysis (PD) Among PD and Hemodialysis (HD) Medical Directors

Jenny I. Shen,[1] Martin J. Schreiber,[2] Junhui Zhao,[3] Bruce M. Robinson,[3] Ronald L. Pisoni,[3] Rajnish Mehrotra,[4] Matthew J. Oliver,[5] Tadashi Tomo,[6] Kriang Tungsanga,[7] Isaac Teitelbaum,[8] Arshia Ghaffari,[9] Mark Lambie,[10] Jeffrey Perl.[11] *[1]LaBiomed at Harbor-UCLA, Torrance, CA; [2]DaVita HealthCare Partners Inc., Cleveland, OH; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]University of Washington, Seattle, WA; [5]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [6]Oita University Hospital, Yufu, Japan; [7]Chulalongkorn University, Bangkok, Thailand; [8]University of Colorado School of Medicine, Aurora, CO; [9]University of Southern California, Los Angeles, CA; [10]Keele University, Crewe, United Kingdom; [11]St. Michael's Hospital, Toronto, ON, Canada.*

Background: Negative perceptions towards PD may be limiting its use. We compared differences in attitudes towards PD among medical directors in PD vs. HD units.

Methods: PDOPPS and DOPPS are international prospective cohort studies based on national samples of PD and HD patients. From 2014-18 we asked medical directors of dialysis units in Canada, Japan, US, and UK: 1) to rate the level of training and support for PD in their units, 2) whether certain patient factors would influence recommendations to use PD, and 3) to cite potential reasons PD was not more widely used in their program.

Results: 178 (74%) HD and 134 (67%) PD directors responded. PD directors agreed more than HD directors that their nephrologists and nursing staff were well trained in and were enthusiastic about PD (72-96% vs. 59-72%, by country). HD directors were less likely to recommend PD among certain patients (Figure). Among PD medical directors (78%), a leading reason for the lack of PD utilization was due to the myth that "in-center HD would result in the highest quality of care compared to PD" compared to 29% of HD medical directors. Among HD medical directors, leading reasons included patient fears about PD (68%), and comfort with facility HD (75%) as major barriers to PD growth.

Conclusions: Compared to HD medical directors, PD medical directors feel their units have higher levels of trained, enthusiastic staff towards PD, are more likely to recommend PD, and have different opinions regarding drivers of low PD use. Given the majority of patients receive HD, educating HD physicians and staff about PD may lead to consideration of more patients for PD, and greater PD utilization.

Changes over Time in Outcomes of Incident Peritoneal Dialysis Patients in Southern China

Yuan Peng,[1,2] Chunyan Yi,[1,2] Meiju Wu,[1,2] Xueqing Yu,[1,2] Xiao Yang.[1,2] *[1]The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [2]Department of Nephrology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.*

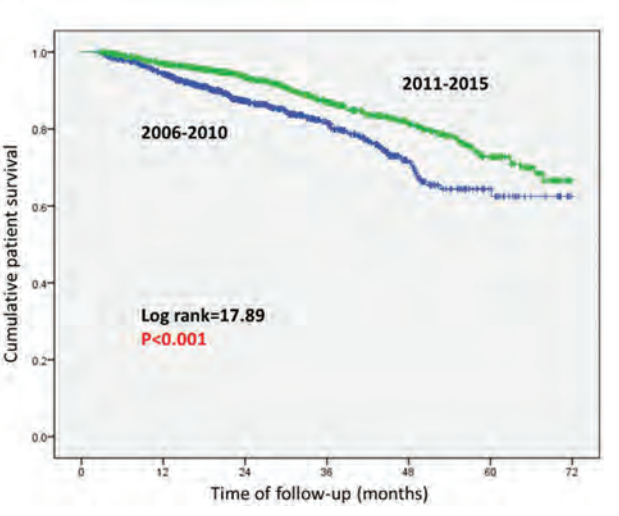
Background: The present study was to investigate the changes in outcomes of incident patients who stated peritoneal dialysis (PD) between 2006-2010 and 2011-2015 in Southern China.

Methods: In this single center retrospective cohort study, incident PD patients from January 1, 2005, to December 31, 2015 at the PD center of The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China were enrolled. Collected baseline data include demographic characteristics and clinical outcomes. Patients initiated PD during 2006-2010 and 2011-2015 were followed-up until December 31, 2011 and December 31, 2016, respectively. The outcomes were compared between the two incident cohorts.

Results: A total of 2021 incident PD patients were enrolled, with mean age 47.2±15.2 years, 40.6% were female. Compared with the 2006–2010 cohort (n=1073), patients initiating PD during 2011-2015(n=948) were younger (46.2±14.8 vs 48.1±15.5 years, p=0.006), had similar baseline eGFR(5.81±2.41 vs. 5.81±2.89 ml/min/1.73m^2, p=0.109) and comparable percentage of diabetes mellitus (24.9% vs 25.7%,p=0.682). The overall peritonitis rate between 2011 and 2015 was lower than 2006-2010 (0.157 vs. 0.160 per patient year, p=0.001). By the end of 1, 3 and 5 years, patients survival rates were 94%, 82% and 63% in 2006-2010 and 97%, 87% and 73% in 2010-2015, respectively (p<0.001); and technique survival rates were 98%, 92% and 85% in 2006-2010 and 98%, 90% and 80% in 2010-2015, respectively (p=0.204). After multivariable-adjusted, patients starting PD in 2011-2015 was associated with lower risk of all-cause mortality (HR 0.76, 95%CI 0.60-0.97, p=0.029).

Conclusions: Peritonitis episodes and patient survival on PD continues to improve, while technical survival remains unchanged. Patients initiating PD between 2010 and 2015 was associated with better patient survival.

Funding: Government Support - Non-U.S.



Cumulative patient survival according to era of PD initiation

The Effect of Combined Therapy with Peritoneal Dialysis and Hemodialysis: A Prospective Multicenter Study in Japan

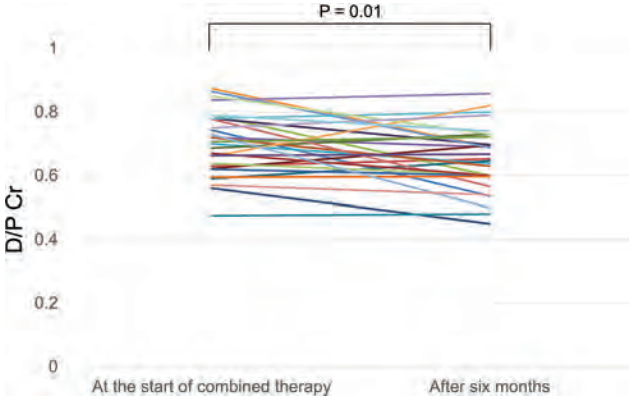
Yukio Maruyama,[1] Keitaro Yokoyama,[1] Yoshihide Tanaka,[2] Ken Sakai,[2] Yoshihiko Kanno,[3] Tsutomu Sanaka,[4] Tsutomu Sakurada,[5] Munekazu Ryuzaki,[6] Masaaki Nakayama,[7] Chieko Higuchi,[8] Teruhiko Maeba,[9] Tatsuo Hosoya.[1] EARTH (Evaluation on the Adequacy of Renal Replacement Therapy) Study Group *[1]Division of Nephrology and Hypertension, The Jikei University School of Medicine, Tokyo, Japan; [2]Toho University School of Medicine, Tokyo, Japan; [3]Tokyo Medical University, Tokyo, Japan; [4]Edogwa Hospital, Medical Center, Tokyo, Japan; [5]St. Marianna University School of Medicine, Kawasaki, Japan; [6]Tokyo Saiseikai Central Hospital, Tokyo, Japan; [7]St Luke's International Hospital, Tokyo, Japan; [8]Division of Internal Medicine, Tokyo Women's Medical University Medical Center East, Tokyo, Japan; [9]Asao Kidney Clinic, Kawasaki, Japan.*

Background: Combined therapy with peritoneal dialysis (PD) and hemodialysis (HD) was widely performed to correct underdialysis and/or overhydration in Japan. However, its clinical result was only reported in retrospective observational studies. We conducted a prospective study to investigate its clinical efficacy in Japan.

Methods: In this prospective multicenter study, we recruited 42 patients started PD from January 1, 2011 to December 31, 2016 (61±9 years, 35 males, and 14 diabetes), and collected clinical information at the start of combined therapy and six months after initiation, prospectively. The changes in parameters between the start of combined therapy and six months later were evaluated using a paired t-test or the Wilcoxon signed-rank test.

Results: Two cases transferred to HD within six months. In the remaining cases, body weight, urine volume, and serum creatinine levels decreased, whereas hemoglobin and serum albumin levels increased. Additionally, dialysate-to-plasma ratio of creatinine (D/P Cr), obtained from a peritoneal equilibration test (PET) decreased significantly from 0.71 ± 0.10 to 0.66 ± 0.10 (P = 0.01) (Figure 1).

Conclusions: In this prospective observational study, both underdialysis and overhydration appear to have been improved by switching from PD alone to combined therapy. Additionally combined therapy could limit further deterioration of the peritoneal membrane. Long-term patient and technical survival will be clarified by the results of ongoing our larger prospective study.



TH-PO375

Peritoneal Dialysis Utilization in US Markets and Associated Hospitalization Rate Ratios for Peritoneal Dialysis versus Hemodialysis

Kristine Kubisiak,[1] Debabrata Ray,[1] Allan J. Collins,[1,2] Eric D. Weinhandl.[1,2] *[1]NxStage Medical, Inc., Victoria, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: In the United States, peritoneal dialysis (PD) is associated with lower hospitalization risk than in-center hemodialysis (HD) during the first and second years of dialysis. However, increased utilization of PD in a local area may move higher-risk patients from HD to PD, thus attenuating the hospital admission (HA) rate ratio (RR). We assessed the influence of PD utilization in US markets on HA RRs for PD versus HD.

Methods: We analyzed data from the United States Renal Data System. We identified incident dialysis patients in 2006-2013 and retained patients in markets with ≥500 patients. For each area, we calculated the percentage of patients on PD within 3 months of dialysis initiation. Using Poisson regression, we assessed the association of that percentage with the admission rate between 3 and 36 months after dialysis initiation, without censoring for modality change and with fixed effects for markets; only the subset of Medicare patients were included in the model.

Results: The cohort included 323,045 incident dialysis patients in 236 markets. Overall PD utilization was 8.8%. Market-specific HA rates in PD and HD patients are displayed. Market-adjusted HA RRs for PD versus HD were 0.81 with local PD utilization of 2-3% (number of markets, 12), 0.86 with utilization of 4-5% (27), 0.86 with utilization of 6-7% (47), 0.82 with utilization of 8-11% (90), 0.90 with utilization of 12-15% (42), and 0.95 with utilization of ≥16% (18). Compared to the market-adjusted HA RR with local PD utilization of 2-3%, RRs with utilization of ≥12% were significantly different ($P < 0.05$).

Conclusions: Across a gradient of local PD utilization from 2% to 12%, HA RRs for PD versus HD are similar. Local PD utilization ≥12% is associated with attenuated RRs.

TH-PO376

Incremental Peritoneal Dialysis Is Beneficial in Preserving Residual Renal Function, Compared to Full-Dose Peritoneal Dialysis

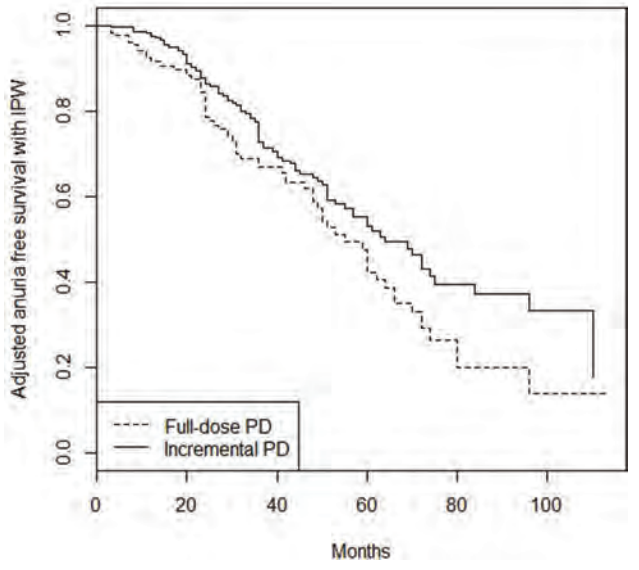
Yeonhee Lee, Seokwoo Park, Seung Seok Han, Hajeong Lee, Dong Ki Kim, Kwon Wook Joo, Curie Ahn, Kook-Hwan Oh. *Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Maintaining residual renal function (RRF) is a crucial issue in peritoneal dialysis (PD). Incremental dialysis is the practice of initiating PD exchanges less than four times a day in consideration of RRF, and increasing dialysis dose step-wisely as the RRF decreases. Effects of incremental PD on the RRF and technique survival have not been widely studied yet. The aim of this study was to compare the outcomes of incremental PD and full-dose PD in terms of RRF preservation and other outcomes.

Methods: Data were extracted from a retrospective PD cohort (16 years of age or older) who started PD between 2007 and 2015 in the PD Unit of Seoul National University Hospital. Full-dose PD was defined as a maximal 4 dwell-times per day for continuous ambulatory peritoneal dialysis (CAPD) and as nightly dialysis sessions for automated peritoneal dialysis (APD). Incremental PD was defined as all other PD except full-dose PD. Outcomes were compared with the use of propensity scores and inverse-probability-weighting (IPW) adjustment to reduce treatment selection bias between incremental and full-dose PD groups. Multivariate time-dependent Cox analyses were performed.

Results: Among 443 included patients, 277 underwent incremental PD and 132 underwent conventional full-dose PD. After IPW adjustment, Incremental PD group exhibited a lower risk of developing anuria (hazard ratio [HR] 0.99; 95% CI, 0.983-0.998). Patient survival, technical survival and peritonitis free survival was similar (Log rank test, $P>0.05$).

Conclusions: In this observational study, incremental PD was beneficial for preserving residual renal function compared to conventional full-dose PD and showed similar patient survival.



Adjusted, weighted anuria free survival curve

TH-PO377

Early Mortality Hazard of Peritoneal Dialysis Is Also Present in Dialysis Modality Converted Patients

Jong Cheol Jeong,[1] Sejoong Kim,[2] Dong-Chan Jin,[3] Ki Young Na.[2] *[1]Ajou University Hospital, Suwon, Republic of Korea; [2]Seoul National University Bundang Hospital, Seongnam, GyeongGi-Do, Republic of Korea; [3]The catholic university of Korea, Suwon, Republic of Korea.*

Background: Peritoneal dialysis showed increased mortality in previous registry reports from east Asian countries. However, hazard pattern according to time have never been investigated. Also, there have been few reports about the outcome of dialysis modality converted patients. We examined 22,210 incident dialysis patients from Korean Society of Nephrology registry.

Methods: We evaluated whether hazard ratio of peritoneal dialysis has time-dependent nature. Survival analysis was performed using a non-proportional hazard fractional polynomial model. Treatment effect of peritoneal dialysis was tested by using inverse probability weighted regression adjustment

Results: During a median follow up of 7.9 years (from 0 to 13.9 years), 13,218/22,210 (59.5%) patients died. Peritoneal dialysis showed significantly elevated hazard ratio till 8 years after dialysis initiation, which has its peak value reaching 1.4 at 3 years. Multivariable analysis adjusted for age at dialysis initiation, sex, and cause of end stage renal disease was conducted. The average treatment effect of peritoneal dialysis showed -0.946 (95% C.I. -1.356 - -0.536, p<0.001) of beta, which is interpreted as -0.946 years less survival in average peritoneal dialysis group. Within those patients who died before 8 years, death related to diabetes was more prevalent in peritoneal dialysis group (35.5% vs 27.8%, p<0.001) For the dialysis modality converted patients, 1,561 patients were analyzed. Peritoneal dialysis converted from hemodialysis showed worse survival with an early bimodal peak of increased hazard ratio.

Conclusions: Peritoneal dialysis showed increased early mortality hazard. Early death within 8 years of peritoneal dialysis might be associated with metabolic risk. This phenomenon was also present for the dialysis modality converted patients.

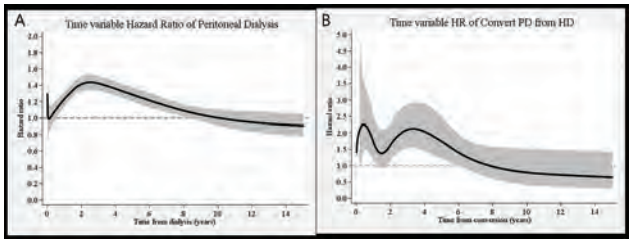


Figure A. Early mortality hazard is elevated in peritoneal dialysis. B. Bimodal peak of early mortality hazard of peritoneal dialysis. HR, hazard ratio; PD, peritoneal dialysis; HD, hemodialysis

TH-PO378

Dialysis Modality and Bleeding Risk

Gurbey Ocak,[1] Alferso C. Abrahams,[1] Maarten B. Rookmaaker,[1] Marianne C. Verhaar,[1] Friedo W. Dekker,[2] Merel Van diepen.[2] *[1]Department of Nephrology and Hypertension, University Medical Center Utrecht, Utrecht, Netherlands; [2]Department of Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands.*

Background: Bleeding as a manifestation and complication of renal failure was already recognized in the 18th century. However, there is limited information whether bleeding risks are different for peritoneal dialysis patients and hemodialysis patients. From a clinical point of view, there could be a preferred dialysis modality for patients with bleeding problems. Therefore, the aim of this study was to investigate the association between dialysis modality and bleeding risk.

Methods: In total, 1745 incident dialysis patients from the NECOSAD study were prospectively followed for major bleeding events within three years of dialysis. Hazard ratios (HRs) with 95% confidence intervals (CIs) were calculated for hemodialysis as compared with peritoneal dialysis using Cox proportional hazard analyses. Hazard ratios were adjusted for age, sex, primary kidney disease, antiplatelet drug use, vitamin K antagonist use, EPO use, prior history of bleeding, cardiovascular disease, systolic blood pressure, residual GFR and albumin levels.

Results: Of the 1745 dialysis patients, 1211 started with hemodialysis and 534 started with peritoneal dialysis. A total of 183 patients had a bleeding event during a median follow-up of 2.2 years (interquartile range 1.0-3.0). The bleeding rate was 60.8 per 1000 person-years for hemodialysis patients and 34.6 per 1000 person-years for peritoneal dialysis patients. The crude hazard ratio of bleeding was **1.7 (95% CI 1.2-2.5)** for hemodialysis patients as compared with peritoneal dialysis. Hemodialysis patients as compared with peritoneal dialysis patients had a **1.5-fold (95% CI 1.0-2.2)** increased bleeding risk after adjustment for age, sex, primary kidney disease, prior history of bleeding and cardiovascular disease. After additional adjustment for antiplatelet drug use, vitamin K antagonist use, EPO use, systolic blood pressure, residual GFR and albumin levels, the HR did not change 1.5 (95% CI 1.0-2.4).

Conclusions: In this large prospective cohort of incidence dialysis patients with detailed information, hemodialysis as compared with peritoneal dialysis was associated with an increased bleeding risk. An explanation could be the use of heparin for hemodialysis sessions to prevent clotting of dialysis lines and dialyzers. Future studies should examine whether starting or switching to peritoneal dialysis could be beneficial for patients with bleeding problems.

TH-PO379

Anemia and Mortality in a Mexican PD Cohort

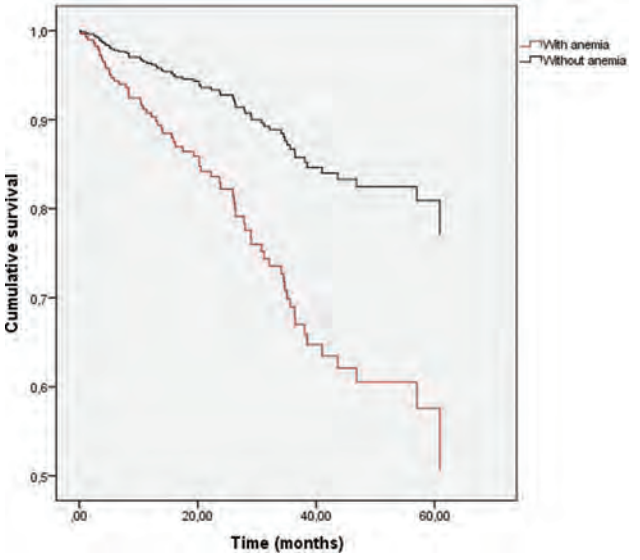
Javier Soto-Vargas, Judith J. Velasco, Renato Parra Michel, Jorge fernando Topete reyes, Leonardo Pazarin-Villaseñor, Mario A. García Cárdenas, Julio A. Gutierrez-Prieto. *Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Especialidad en Nefrologia, Hospital General Regional No 46 del IMSS, GUADALAJARA, Mexico.*

Background: The impact of anemia and its management on mortality is controversial in PD patients, despite of being considered and important part of the adequacy therapeutic plan, and the recommendations are based on evidence derived from HD patients. Thus, our aim was to study the association of anemia in all-cause mortality in a PD cohort.

Methods: During January 2012 to December 2017 we included 802 prevalent PD patients to investigate the impact of anemia (Hgb <10 g/dL) in all-cause mortality. We collected relevant information as demographic characteristics, anthropometric, biochemical, type (i.e. automatized PD or continuous ambulatory PD), dose of dialysis, peritoneal transport rate, as well as residual kidney function and comorbidities, and used them as covariates for a multivariate analysis.

Results: The median follow-up was 23 months (IQR 23-36.4). During the study period, there were 109 (13.6%) deaths. The median age was 47.9 years (IQR 28.3-64.4), 270 (33.7%) were female, and the main etiology of CKD was unknown in 383 (48.7%) patients, and T2D in 336 (42.7%), twenty (4.5%) had a previous kidney transplant, and 71 (14.5%) were initially on HD and then transferred to PD. The prevalence of anemia was 25.2% (202 patients), with a median Hgb level of 11 g/dL (IQR 9.7-12.0). In a binary logistic regression model adjusted for the variables afore mentioned, anemia was associated with all-cause mortality (OR 2.9 CI 95% 1.62-5.25 p<0.001), and this association was confirmed in a multivariate Cox regression (HR 2.5 CI 95% 1.6-4.2 p<0.001).

Conclusions: The presence of anemia is associated with a twofold increased risk for all-cause mortality in PD patients.



Cumulative survival in patients with and without anemia

Mean Corpuscular Volume and Mortality in Peritoneal Dialysis

Sara S. Kalantar,[1] Carola-Ellen Kleine,[1] Christina Park,[1] Jui-Ting Hsiung,[1] Csaba P. Kovesdy,[2] Elani Streja.[1] *[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, Orange, CA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: Normocytic and normochromic anemia is a common sequela in chronic kidney disease, however some patients with end-stage renal disease present with macrocytic anemia. In hemodialysis patients abnormal mean corpuscular volume (MCV) was associated with mortality, while so far this association has not been explored in peritoneal dialysis (PD) patients.

Methods: We retrospectively examined a cohort of 14,251 incident PD patients from a large dialysis organization from 2007 to 2011 with MCV measurement within the first 91 days of PD treatment. PD patients were grouped into five *a priori* selected MCV categories. Using Cox models, we explored the association between baseline serum MCV and all-cause death with adjustments for case-mix variables and laboratory markers of malnutrition and inflammation (MICS).

Results: Mean age was 56±16 years and 43% of study participants were women. Higher MCV levels trended towards higher mortality across all levels of adjustment, although the association was attenuated after adjustment of case-mix and MICS variables. The highest MCV category (≥96 fL) was significantly associated with a higher risk of all-cause mortality when compared to the reference group (90-<93 fL) in the fully adjusted model (HR 1.29, 95%Cl 1.11-1.49). Lower MCV categories trended towards lower mortality. [figure1]

Conclusions: In incident PD patients, macrocytosis/higher MCV was associated with higher all-cause mortality risk. The underlying mechanisms of the observed MCV-mortality association remains unclear and should be explored in further studies.

Renin-Angiotensin System Blockade and Mortality in Peritoneal Dialysis Patients

Godhy E. Hernandez Gonzalez, Javier Soto-Vargas, Denisse Arellano-Mendez, Omar I. Delgado-Ayon, Carlos Daniel Jiménez Mejía, Leonardo Pazarin-Villaseñor, Renato Parra Michel, Julio A. Gutierrez-Prieto. *Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Especialidad en Nefrologia, Hospital General Regional No 46 del IMSS, Guadalajara, Mexico.*

Background: Renin-Angiotensin System (RAS) blockade in Peritoneal dialysis (PD) patients has not been widely examined, however, its use in hemodialysis (HD) patients has been associated with risk reduction in all-cause and cardiovascular mortality. Moreover, mortality in PD patients still represents a challenge for the clinician. Our objective was to determine if RAS blockade improve survival or reduce all-cause mortality in PD patients.

Methods: A total of 248 adult PD patients were prospectively enrolled from January to October 2017. The preliminary findings of 85 patients are presented here. Sixty-four (75%) with RAS blockade and 21 (25%) without it were analysed. The mean follow-up was 13.5±3.4 months. We performed a survival and multivariate analysis adjusted for age, gender and diabetes mellitus, between groups to estimate the all-cause mortality risk.

Results: The median age was 42 years (IQR 27-62) and 64 (74.4%) were male. There were no significant differences in baseline characteristics between groups (e.g. residual renal function, etiology of CKD, comorbidities, type of peritoneal transport and dyslipidemia profile). Four deaths were recorded during follow-up, one (1.6%) in the RAS blockade group and 3 (14.3%) in the control group (p=0.02). Patients with RAS blockade had higher serum potassium (p =0.01) as well as reduced risk for all-cause mortality compared with the group without RAS blockade (OR 0.05, CI 95% 0.03-0.85, p=0.04) in the multivariate analysis.

Conclusions: In this prospective cohort of PD patients, the use of RAS blockers was associated with all-cause mortality risk reduction and higher serum potassium.

All-cause mortality Risk according Use of RAS blockade

	Coefficient	P	OR	CI 95%
RAS blockade	-3.05	0.039	0.05	0.03-0.85

Multivariate model adjusted for age, gender and diabetes mellitus.

Baseline Echocardiographic Parameters Predict Mortality in Peritoneal Dialysis Patients

Rodolfo Mario Orihuela,[1,2] Lucino Bahena,[6] Rocio B. Cruz,[7] Ricardo Correa-Rotter,[3] Luis E. Morales-Buenrostro,[5] Abraham Cohen-Bucay.[4] Departamento de Nefrología Hospital Central Militar *[1]Nefrología, Hospital Central Militar, Ciudad de México, Mexico; [2]Nefrología y Metabolismo mineral, Instituto Nacional de Ciencias Medicas y Nutrición, Ciudad de México, Mexico; [3]Institutor Nacional de la Nutricion, Mexico City, Mexico; [4]Boston University Medical Center, Boston, MA; [5]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; [6]Hospital central militar, México, DF, Mexico; [7]Hospital Central Militar, Mexico City, Mexico.*

Background: Patients with end-stage renal disease (ESRD) have high mortality rates and the leading cause of death is CV disease. Multiple baseline factors including age, comorbidities and frailty, have been associated with higher mortality risk. Here we evaluate the prognostic value of baseline echocardiographic structural and functional cardiac abnormalities in incident peritoneal dialysis (PD) patients.

Methods: Prospective cohort study of patients with CKD5 that started PD between 2014 and 2016 at Hospital Central Militar in Mexico City, Mexico. A bi-dimensional transthoracic echocardiogram was performed within 7-14 days before starting PD. The primary objective was to correlate structural and functional echocardiographic parameters with the primary outcome of death by any cause.

Results: We included 138 patients, 44.9% were male, median age 52.3 +/- 15.3, the cause of ESRD was DM in 71%. During a median follow up of 26.8 months 73 patients (52%) died, with a median survival of 30.8 months. In univariate analysis we identified age (p=0.001), DM (p=0.001), residual urine volume (RUV) (p,0.001), serum albumin (p<0.001) and B-type natriuretic peptide (BNP) (p=0.001) as risk factors for mortality. By Kaplan-Meier method we identified the following echocardiographic parameters to be correlated with higher mortality: left atrium volume >20 (p=0.007), mitral insufficiency (p=0.001), LV ejection fraction (EF) <53% (p=0.017), LV hypokinesis (p=0.001) and diastolic dysfunction with a restrictive pattern (p<0.001). Multivariate analysis identified age >50y (OR=2.05, p=0.046), gender (OR=0.53, p=0.010), RUV (OR=0.99, p=0.002), LV EF (OR=0.97, p=0.042), and diastolic dysfunction with a restrictive pattern (OR=3.08, p=0.003) as independent risk factors for mortality.

Conclusions: Baseline echochardiogram (lower LV EF and diastolic dysfunction) at dialysis initiation is a strong predictor of mortality in PD patients, in particular in those with DM. We hereby confirm high mortality rate in patients that start PD, and the previously reported correlation of age, gender, and RUV with mortality.

TH-PO383

A Fast Decline of Residual Renal Function in the First Year Is a Predictor for Early Withdrawal from Peritoneal Dialysis in Non-Diabetic Patients

Fei Han. *First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China.*

Background: Little is known about the relationship of residual renal function (RRF) decline in early period with survival in peritoneal dialysis (PD).

Methods: Total of 567 patients who began PD between January 1, 2005, and June 30, 2013 was investigated. The rate of decline of RRF was determined by the "slope of the trend equation" of serial RRFs. A composite end-point of all-cause mortality and transfer to hemodialysis was used, survival status was censored on June 30, 2016.

Results: The median of "the slope of RRF decline equation" was 0.308 (0.001-2.111) mL/min/1.73 m^2/month. In the median follow-up period of 43 months (12 to 120 months), 65 patients died, 90 patients transferred to HD, and 171 patients underwent kidney transplantation. Male, high baseline RRF, high baseline peritoneal Kt/V urea, low serum albumin and low uric acid were independently associated with the rate of RRF in the first year of PD. RRF decline in the first year remained a predictor of composite end-point (HR, 2.74, *P* =0.001). When the patients were divided into high RRF decline group (>0.308 mL/min/1.73m^2/month) and low RRF decline group (≤0.308 mL/min/1.73m^2/month) at the first three years of PD period, end-point events incidence was higher in high RRF decline group (23.2%) than in low RRF decline group (11.0%) (log-rank test P < 0.001). There were 189 patients in low RRF decline group and 171 patients in high RRF decline group maintaining PD for more than 3 years, in a median follow-up of 54 months (range 37 to 120 months), no significant difference of survival was observed (30.9% in high group vs 46.4% in low group, log-rank test P=0.883). In high RRF decline group, there were 92 patients reaching composited end-point and 112 patients maintaining PD; multivariate Cox regression model showed high peritoneal Kt/V urea after 1 year of PD period and high albumin level were the protective factor for composite end-point (HR, 0.29, P = 0.001; HR, 0.94, P=0.022, respectively), while fast RRF decline remained the risk factor for composite end-point (HR, 3.28, P=0.004).

Conclusions: A faster RRF decline in the first year was a predictor for all-cause mortality and transfer to hemodialysis in non-diabetic PD patients, mainly in the first three year. For patients with faster RRF decline, increase the PD dose was effective to improve survival.

TH-PO384

The Effect of Traditional Chinese Medicine (TCM) Practice on Mortality Risk in a Large Cohort of Patients on Continuous Ambulatory Peritoneal Dialysis (CAPD) from China

Pei Ming,[5] Mark R. Marshall,[1] Haiming Li,[2] Tao Feng,[4] Qiang Yao,[3] Hongtao Yang.[5] *[1]Middlemore Hospital, Auckland, New Zealand; [2]Baxter China, Shanghai, China; [3]Baxter, Shanghai, China; [4]Baxter (China) Investment Co., Ltd, Guangzhou, China; [5]First teaching hospital of Tianjin university of TCM, Tianjin, China, Tianjin, China.*

Background: We report mortality risk in a cohort of patients on CAPD from China, comparing outcomes between hospitals classified as TCM hospitals versus conventional ones.

Methods: Data were sourced from the Baxter Healthcare (China) support program database, comprising an inception cohort commencing PD between Jan-2005 and September-2015, followed until death, dropout, loss to follow-up, or November-2015, whichever occurred first. The primary outcome was death. The primary exposure was official classification of the treating hospital as TCM versus conventional, although we separated TCM further according to whether the hospital was affiliated with the China TCM PD Federation (TCM-PDF) or not. We made comparison using Cox proportional hazards models with shared frailty by center, censoring for kidney transplantation and change to HD, adjusting for age, gender, employment, insurance, primary renal disease, size of PD program.

Results: We modelled 100,558 subjects from 1,134 centres over 241,051patient-years. CAPD patients at TCM hospitals were younger, more likely female, with hypertension as kidney disease, urban, unemployed, from larger programs, and treated with < 4 exchanges per day. The modelling results are presented in Table 1.

Conclusions: TCM is associated with better outcomes for PD patients in China. TCM interventions include traditional diet therapy optimizing digestive tract symptoms and therefore nutrition, traditional medications to increase urinary volume and ameliorate the micro-inflammatory state, the use of enemas to reduce accumulation of uremic toxins and maintain bowel habit, and traditional Wu Style Tai Chi Chuan athletics. However, the indentified benefit with TCM appears to be restricted to hospital with an affiliation with the TCM-PDF, and we believe this is due to greater standardization of management, and a greater focus on continuing medical education and scholarly activities in affiliated centers.

TH-PO385

Impact of CMS-Kidney Disease Education Policy on Home Dialysis Rates

Ashutosh M. Shukla,[1] Shahab Bozorgmehri,[2] Rajesh Mohandas,[2] Tezcan Ozrazgat-baslanti.[2] *[1]Department of Nephrology, Hypertension, and Transplantation, University of Florida, Gainesville, FL; [2]University of Florida, Gainesville, FL.*

Background: Multiple US and international studies have shown that Kidney disease education (KDE) improves informed selection of home dialysis (HoD) in CKD patients. In 2010, Center for Medicare and Medicaid Services (CMS) approved reimbursement for the KDE services for patients with advanced stage 4 & 5 pre-dialysis CKD. No data is available on the efficacy of this policy change on the patient use of HoD.

Methods: we evaluated the effect of the use of CMS KDE billing code during the pre-dialysis period on the rates of post-ESRD HoD use, and factors associated with HoD use.

Results: Out of 369,938 Medicare enrollees between 2010 and 2014, who were 18 years and older and started dialysis first time after 2010, we identified 3,681 patients (1% of included cohort) in whom KDE services were billed for a total of 6,166 times. KDE services were provided with a median of 218 (25^{th}, 75^{th}:74-462) days prior to the initiation of dialysis therapies. Of the 3,681 KDE recipients, 15% (n=538) used HoD as the initial dialysis modality and 25% (n=903) used HoD at any time after KDE. Twelve percent (n=365) of those initiating dialysis with in-center hemodialysis switched to HoD at a median of 216 (25^{th}, 75^{th}:74-581) days after dialysis initiation. Multivariate logistic regression model showed that younger age, white race, non-diabetes renal disease, employment, absence of congestive heart failure, and atherosclerotic disease, higher MDRD eGFR, albumin>3g/dl, not having a need for assistance with daily activities, prior renal care, and group rather than individual KDE were independently associated with higher odds of HoD therapy. Gender, overall diabetes, cystic kidney disease, BMI, or number of KDE services did not have any impact on the use of HoD therapies.

Conclusions: Despite being recognized by CMS, KDE services are vastly underutilized for the patients with incident ESRD. Use of KDE services is associated with marginal improvements in the HoD rates among incident ESRD patients. A significant proportion of those receiving KDE and using HoD therapy need to initiate with in-center hemodialysis. Better pre-ESRD care coordination may be needed among those who choose HoD but require in-center initiation of dialysis.

TH-PO386

Increased Peritoneal Dialysis as Initial Treatment Modality: A Canadian Costing Analysis

Thomas W. Ferguson,[1] Reid Whitlock,[2] Navdeep Tangri,[1] Claudio Rigatto,[3] Michelle S. DiNella,[4] Paul Komenda.[2] *[1]Seven Oaks General Hospital, Winnipeg, MB, Canada; [2]University of Manitoba, Winnipeg, MB, Canada; [3]Chronic Disease Innovation Centre, Winnipeg, MB, Canada; [4]Seven Oaks General Hospital Research Centre, Winnipeg, MB, Canada.*

Background: Kidney failure is increasing in prevalence in Canada. Patients with kidney failure are often treated with dialysis: either hemodialysis (HD) or peritoneal dialysis (PD). There are economic considerations relevant to these therapies, with HD provided in hospital costing over $60,000 and home dialysis (HD or PD) costing between $35,000 and $45,000 per patient annually. Increasing home PD as a modality choice may afford the health care system substantial cost savings.

Methods: We aimed to evaluate the cost-utility of scenarios in which the number of patients offered PD as initial treatment modality is increased to 30% and 40% of incident dialysis starts (baseline Canadian incidence: 20.8%). We accomplished this by performing an incremental cost-utility analysis from the perspective of the Canadian public health payer including all costs related to treating kidney failure with dialysis in the Canadian adult incident dialysis population using data from the Canadian Organ Replacement Register (CORR) between 2004 and 2013. Threshold analysis was performed on the relative risk of infections and hospitalizations from increased PD prescription. Second order Monte Carlo simulations were performed to evaluate parameter uncertainty. Our outcomes were expressed as cost per quality adjusted life years.

Results: Increasing initial uptake of PD to 30% resulted in an average cost savings of $3,132, and increasing uptake to 40% resulted in an average cost savings of $6,529 ($33,970 per new additional PD patient initial therapy over a lifetime horizon). The models were robust to changes in the risk of infection and hospitalization, requiring over 10-fold

increased risk of infection, 7.6-fold increased risk of cardiovascular-related hospitalization, or 2.5-fold increased risk of all-cause hospitalization to reach cost neutrality. Retrospectively applying these findings to the Canadian incident dialysis population for the 10 years between 2004 and 2013 would have resulted in cost savings of $123.1 million and $256.7 million in the 30% and 40% scenarios respectively.

Conclusions: Policy recommendations to increase the initial prescription of home peritoneal dialysis should be considered and are highly cost-effective.

Funding: Commercial Support - Baxter Canada Inc.

TH-PO387

Health-Related Quality of Life: Seeking Novel Targets for Effective Interventions

Juliya Hemmett,[3,2] Kiersten Colbran,[1] Dilraj S. Sanghera,[1] Saad Chahine,[2] Christopher W. McIntyre.[3,2] *[1]Schulich School of Medicine & Dentristy, Sarnia, ON, Canada; [2]Western University, London, ON, Canada; [3]London Health Sciences Centre, London, ON, Canada.*

Background: Understanding patients' perceived quality of life (QOL) is important in order to provide quality care for chronic kidney disease (CKD) patients. QOL is shaped by several factors including patients' beliefs, symptoms, and behaviours, and yet the interaction between these is not well studied. We studied the interaction between these factors using well-established instruments, to help identify priority targets to meaningfully improve patient care.

Methods: The sample of study were patients with CKD and end-stage renal disease (ESRD). This was a single-phase, cross-sectional survey-based study of adult patients from two centers in London, ON. Patients were recruited in three cohorts: in-center hemodialysis (cHD), CKD (eGFR <30 ml/min), and home dialysis (peritoneal (PD) and home hemodialysis (HHD)). Each set of surveys included the KDQOL-36SF, Illness Intrusiveness Scale (IIS), Dialysis Recovery Time (DRT), Grit Scale, Physical and Emotional Symptom (PES) Questionnaire, BMQ, and PHQ-9. Demographic information was also collected. Surveys were individually scored results from the three cohorts were compared and analyzed using correlation and regression techniques.

Results: Seventy two patients (24 cHD, 24 home dialysis (19 PD, 5 HHD), and 24 CKD) completed the survey package. The cohorts were well balanced with respect to age and comorbidities. There was no difference between the cohorts with respect to any of the surveys except for DRT (cHD=384.63 mins, SD 411.13 versus home dialysis= 142.75 mins, SD 404.46). Physical QOL (pQOL) and mental QOL (mQOL) were not significantly related (R^2=0.045). IIS was significantly associated with decreased pQOL (R^2=0.27, p<0.001). The linear combination of depression, PES, and grit were significantly associated with mQOL (R^2=0.54, p<0.001). While depression (b=-0.31) and PES (b=-0.31) were negatively associated with mQOL, grit (b=0.34) was found to be partially protective.

Conclusions: Using a rigorous series of validated questionnaires, we did not find a significant difference between CKD and ESRD patients on home and in-center dialysis modalities with regards to pQOL or mQOL. We have identified several targets for potential patient education and engagement strategies. Further studies are required to identify how to best integrate this knowledge into practice.

TH-PO388

Development of a Novel Connection Device for Patients on Peritoneal Dialysis (PD)

Sandra B. Neumann. *Peripal AG, Zurich, Switzerland.*

Background: The dialysis population has changed significantly with an increasing age, multi morbidity and frailty. At the same time, home care is a major trend in health care systems for clinical and financial reasons.. Overall PD usage is decreasing due to difficulties preparing elderly patients for PD without additional support. A first need finding suggested that there exists the need to develop a novel auto-connect device for PD patients, to overcome current hurdles to PD use. The aim was to understand how such a device could support home care patients and what functionalities would be required to better standardize the therapy.

Methods: The user interface of functional prototypes were tested with more than 30 PD patients, nurses and doctors. Based on the feedback of the test persons, we optimized and iterated the functional prototypes six times over a period of 18 months.

Results: During the tests we identified the following needs for an auto-connect device: (1) a connecting mechanism to accommodate both continuous ambulatory PD (CAPD), as well as automated PD therapy, (2) a therapy guidance that leads the patient through drain, flush, fill, preventing user errors, (3) an antiseptic environment that may better protect the patients from infections, (4) a user interface that was suited for the respective users. After six generations, it was felt that these were merged in a final product design.

Conclusions: The new prototypic device could allow more patients to be treated at home, better protect these patients from infections, further standardize the PD therapy, and support assisted home care models.

TH-PO389

Racial and Ethnic Disparities in Treatment Modalities for ESRD Vary by Patient Age

Adam S. Wilk,[1] Wairimu Magua,[2] Janet Cummings,[1] Laura Plantinga,[2,1] Harold A. Franch,[3,2] Rachel E. Patzer,[4,2] Janice P. Lea.[3,2] *[1]Rollins School of Public Health, Emory University, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA; [3]Emory Dialysis Centers, Atlanta, GA; [4]Emory Transplant Center, Atlanta, GA.*

Background: Black patients present with end-stage renal disease (ESRD) at younger ages than whites, while younger patients are more likely to undergo transplantation (Tx) and to use peritoneal dialysis (PD) or home hemodialysis (HHD) versus in-center hemodialysis (HD). It is unknown whether disparities in treatment modality use across racial/ethnic groups are consistent among all ages.

Methods: We used 2011-2015 USRDS data to identify treatment modalities—Tx, HD, PD, HHD, or Other—at day 90 of therapy (persisting for ≥60 days) for all incident US ESRD patients. We compared use of each modality between racial/ethnic groups (Hispanic, non-Hispanic [NH] Black, NH White, Other) pairwise using t tests, both overall and stratified by age: 22-44, 45-64, 65-74, and 75-99. We computed relative risks (RRs) across groups and tested whether age modified these RRs in multinomial logit models, controlling for patient factors. Missing data, discontinued dialysis/recovered function, and lost follow up (e.g., died before day 90) were excluded.

Results: During 2011-2015, 81.5% of 552,896 patients used HD at day 90, 10.0% used PD, 0.7% used HHD, 2.8% underwent Tx, and 4.9% were classified as Other. NH Blacks and Hispanics were less likely to use PD and Tx and more likely to use HD versus NH Whites (all p<0.01). Tx disparities were greatest among age 22-44 for NH Blacks (RR 0.144) and among age 45-64 for Hispanics (RR 0.318), and were smallest among age 75+ (RRs 0.269 and 0.444, respectively) (all p<0.01; see Table). PD disparities were greatest among age 75+ (RRs 0.476 and 0.625, respectively) and smallest among age 22-44 (RRs 0.691 and 0.825, respectively) (all p<0.01). HHD disparities varied across groups by age. Results were similar in adjusted multinomial logit models.

Conclusions: There are large racial/ethnic disparities in HD, PD, and Tx use by incident ESRD patients. Tx disparities are worse for younger patients, and PD disparities are worse for older patients.

Impacts of Medicare Bundled Payment on Utilization of Peritoneal Dialysis and Changes in Treatment Modality

Virginia Wang,[1,2] Cynthia Coffman,[1,2] Linda L. Sanders,[1] Richard A. Hirth,[3] Shoou-Yih D. Lee,[3] Caroline E. Sloan,[1,2] Matthew L. Maciejewski.[1,2] *[1]Duke Univ, Durham, NC; [2]Durham VA HCS, Durham, NC; [3]U of Michigan, Ann Arbor, MI.*

Background: In 2011, Medicare implemented a new policy that bundled reimbursement for dialysis treatment and ancillary services, removing incentives that made HD a more profitable therapy than PD under the prior payment model. This study examined whether

2011 Medicare ESRD bundled payment (BP) was associated with increased rates of PD utilization and modality switches.

Methods: We used USRDS and Medicare data to identify all US patients with ESRD initiating dialysis (n=619,130) and outpatient dialysis facilities (n=6,433) before (2006-2010) and after (2011-2013) BP. We used logistic models to examine the BP effect on two outcomes of interest observed 90 days after dialysis initiation up to 2 years: any patient utilization of PD and change in treatment modality (HD-PD and PD-HD), adjusting for patient, dialysis provider, and regional characteristics.

Results: Observed **PD utilization** increased from 12.5% in 2006, to 15.0% in 2010 (the year prior to policy change), and to 18.7% in 2013. In adjusted models, BP was associated with increases in PD use in the pre- vs. post-BP era (OR=1.6; 95% CI 1.5,1.6; p<0.0001) and an estimated BP effect of 5 percentage points in PD use between pre and post policy periods (14% pre vs 19% post, for fixed values of covariates). Observed rates of **modality switches** increased from 6.1% in 2006, to 7.5% in 2010 and 9.0% in 2013. Of those initiating HD in the first 90 days, 4.7% switched to PD up to 2 years later in the pre-policy period and 6.3% in the post-policy period. Of those initiating PD in the first 90 days, 24.6% switched to HD in the pre-policy period and 24.1% in post-policy. In adjusted models, BP was associated with higher rates of modality switches for both PD-HD (OR=1.1 95% CI 1.0,1.1; p=0.009) and HD-PD (OR=1.4 95% CI 1.4,1.5; p<0.0001). There was an estimated 0.4 percentage point BP effect on PD-HD switches (18.0% pre vs 18.4% post) and 1.7 percentage points for HD-PD switches (4.4% pre vs 6.1% post).

Conclusions: ESRD bundled payment was associated with increased PD use without a substantial increase in modality failure, achieving a secondary goal of payment reform. More work is needed to determine whether increased use and HD-PD modality switches from payment reform also led to changes in patient characteristics associated with modality use.

Identification of Factors That Are Associated with Risk of Modality Failure Among Patients Treated with Peritoneal Dialysis

Steven M. Brunelli,[1,2] Dena E. Cohen,[1,2] Kathryn S. Gray,[1,2] Michelle Cassin,[3] Bram Van hout,[3] Julie A. Rodriguez,[3] David B. Van Wyck,[2] Martin J. Schreiber.[3] *[1]DaVita Clinical Research, Minneapolis, MN; [2]DaVita Institute for Patient Safety, Denver, CO; [3]DaVita Kidney Care, Denver, CO.*

Background: Treatment with peritoneal dialysis (PD) is associated with better quality of life and clinical outcomes compared to in-center hemodialysis (ICHD). However, a substantial number of patients who initiate PD later fail the modality and switch to ICHD. Identification of factors that are associated with greater risk of modality failure may facilitate targeted interventions to retain patients on PD.

Methods: This retrospective, observational study considered adult patients who, during 2014-2016, were either prevalent on PD or initiated the modality during that time. Data were derived from deidentified electronic health records. The index event was considered as the first of at least 3 consecutive PD treatments (exclusive of training treatments). Follow-up time began on the first day of the calendar month after index and continued until modality failure, or until censoring for study end (31 July 2017) or loss to follow-up. Exposures were time-updated on a monthly basis. In this time to event analysis, Cox regression models (with robust variance estimators) were each tested on a bivariable basis against outcome, followed by joint modeling where multiple potential factors were entered into the model simultaneously. Models were adjusted for age, sex, race, history of congestive heart failure or amputation, and Charlson comorbidity index. Interactions were tested using likelihood ratio testing.

Results: This analysis considered a total of 303,126 patient-months. Factors associated with increased risk of PD modality failure included use of continuous ambulatory PD, total daily exchange volume >12L, indication that the patient needed support for treatment, weight >100kg, change in weight of >2kg, low serum albumin or change in albumin >0.4mg/dL, Kt/V<1.7, hospital admission, and clinical indications of peritonitis. Factors associated with a lower risk of modality failure were receipt of ≥4 retraining sessions, residing >20 miles from the treatment center, albumin>4.0 mg/dL, and treatment in a facility with >150 patients or a facility in which ICHD was not available.

Conclusions: Modifiable factors may contribute to the risk of modality failure among patients treated with PD. Programs targeting these factors may improve time on therapy for patients using this modality.

TH-PO392

Trends in the Rate of Conversion from Peritoneal Dialysis to Hemodialysis

Eric D. Weinhandl,[1,2] Kristine Kubisiak,[1] Debabrata Ray,[1] Allan J. Collins.[1,2] *[1]NxStage Medical, Inc., Victoria, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: Conversion from peritoneal dialysis (PD) to hemodialysis (HD) is frequently necessitated by medical complications, including peritonitis and ultrafiltration failure. Conversion can be disruptive to the patient, as it usually involves a transition from dialysis in the home to dialysis in a facility and may require placement of a permanent vascular access. In addition, high rates of conversion impose stress on dialysis providers, as high rates necessitate additional training in order to maintain program size. We assessed rates of conversion from PD to HD among US incident patients in 2006-2015.

Methods: We analyzed data from the United States Renal Data System. For each calendar year from 2006 to 2015, we identified all patients that initiated PD within 3 months after dialysis initiation. We retained patients with age between 20 and 99 years and non-missing data regarding race, sex, and primary cause of end-stage renal disease (ESRD). We followed patients from first date of PD until the earliest of conversion to HD (defined as treatment with HD for ≥2 months), death, kidney transplant, or recovery of renal function, but for a maximum of one year. We calculated crude rates of conversion from PD to HD in each per-annum cohort and used Fine-Gray regression to estimate the relative hazard of conversion from PD to HD as a function of PD initiation year, with adjustment for age, race, sex, and primary cause of ESRD.

Results: The number of incident patients on PD reached a nadir of 7924 in the 2008 cohort and monotonically increased thereafter, with 14,273 incident patients on PD in the 2015 cohort. Mean age increased slightly during the study era and reached 59.0 years in the 2015 cohort. The rate of conversion from PD to HD was 20.8 events per 100 patient-years in the 2006 cohort and reached a low of 17.6 events per 100 patient-years in 3 subsequent cohorts: 2010, 2013, and 2015. By Fine-Gray regression, with the 2010-2011 cohorts as referent, the adjusted hazard ratios of conversion from PD to HD were 1.10 ($P < 0.001$) in both the 2006-2007 and 2008-2009 cohorts and 0.99 ($P > 0.5$) in both the 2012-2013 and 2014-2015 cohorts.

Conclusions: Although the number of incident patients on PD grew every year from 2008 to 2015, the rate of conversion from PD to HD during the first year after initiation of PD was essentially unchanged between 2010 and 2015.

TH-PO393

Prescription Patterns in Dialysis Patients – Differences Between Hemodialysis and Peritoneal Dialysis and Opportunities for Deprescription

Judith G. Marin,[1] Laura M. Beresford,[2] Gabriela Espino-Hernandez,[3] Monica C. Beaulieu.[2] *[1]Providence Health, North Vancouver, BC, Canada; [2]University of British Columbia, North Vancouver, BC, Canada; [3]Cancer Care Ontario, Toronto, ON, Canada.*

Background: Dialysis patients are at high risk for polypharmacy with many comorbidities and complications from their disease and treatment. The prescribing patterns and burden of polypharmacy in dialysis patients, and specifically the difference between hemodialysis and peritoneal dialysis prescribing, are not well characterized. The objectives of this study were to review prescribing patterns for dialysis patients, to analyse any differences in prescribing patterns between hemodialysis (HD) and peritoneal dialysis (PD), and to identify potential opportunities for deprescription.

Methods: We completed a retrospective analysis of demographic and medication data for patients who were on chronic dialysis from June 3rd 2015 to October 1st 2015. Both prescription and non-prescription medications were collected. Medications were classified by indication - (1) renal complications, (2) cardiovascular (CV), (3) diabetes (DM), or (4) symptom management. Medications were also classified as "Potentially Inappropriate Medications" (PIMs) or not. Ethics approval was granted from the University of British Columbia Research and Ethics Board.

Results: 3017 patients met inclusion/exclusion criteria (2,243 HD, 774 PD). The mean (SD) age was 66.2 (14.8) years. The HD group had more patients over 80 years old (22.1% vs 12.5%) and more patients with DM and CV disease. The mean number (SD) of prescribed medications was 17.71 (5.72) with more medications in the HD group versus the PD group. The mean number of medications increased with dialysis vintage in both groups. HD patients were on more medications for renal complication and symptom management than PD patients. Patients on HD were prescribed more PIMs than patients on PD (5.37 (2.83) vs 4.02 (2.37)).

Conclusions: This is the first study to review and characterize both the prescription and non-prescription medication use in HD and PD patients. Patients in both groups experienced polypharmacy and prescription of PIMs. Patients on HD received more overall medications and more PIMs compared to PD patients. There are opportunities for future systematic and patient informed deprescription initiatives in both patient groups.

TH-PO394

A Peritonitis Surveillance System Developed by a Large Dialysis Organization to Improve the Accuracy and Consistency of Peritonitis Rate Reporting in the United States

Martin J. Schreiber, Levi Njord, Meredith L. Zywno, Bram Van hout, Julie A. Rodriguez, Michelle Cassin, James R. Tetley. *DaVita, Inc, Denver, CO.*

Background: Peritonitis (PTN) remains a major reason for hospitalization of peritoneal dialysis (PD) patients and may result in transfer to in-center hemodialysis. In August 2015, a standardized approach to PTN surveillance was introduced by a large dialysis organization (LDO) to improve the consistency and accuracy of PTN event identification across affiliated programs in the US. The goal of this analysis was to examine the impact of this new surveillance system on the reporting of PTN events since 2015.

Methods: Under the surveillance system, patients with PTN are identified following 6 hierarchical business rules that include the 4 standard diagnostic rules for PTN (based on positive culture, positive cell count, abdominal pain) as well as hospitalization for infection and receipt of intraperitoneal (IP) antibiotics (>8 days, >2 vancomycin doses within 8 days, or >5 doses of non-vancomycin within 8 days). An exemption process exists for PTN events based on the IP antibiotic dosing rule alone. Episodes occurring within 28 days of identification of a prior episode with the same causal organism were considered relapse episodes and were not included in calculations of PTN rates.

Results: During the period August 2015 to December 2017, 10,814 cases of PTN were identified under the surveillance system. Of these, 6280 (58.1%) were identified by standard diagnostic rules, an additional 2793 (25.8%) were identified based on hospitalization, and

a further 1741 (16.1%) were identified based on receipt of IP antibiotics. Exemption filings have remained relatively constant over time. The average time to first PTN event was 19.4 months, with 8.6% of events occurring in the first 90 days on PD. Among PD patients overall, 88% experienced no episodes of PTN, 10% developed 1 episode/year, and 2% were observed to have 2 or more PTN events/year.

Conclusions: A consistent approach to identifying PTN events combining standard criteria with infection-related hospitalizations and IP antibiotic dosing is necessary to compare rates between practices in the US and across LDOs and different countries.

TH-PO395

Analysis of After-Hours Oral Antibiotic Protocol for the Treatment of Suspected Peritonitis in Peritoneal Dialysis Patients

Martin J. Schreiber,[1] David A. Pegues,[2] Bram Van hout,[1] Julie A. Rodriguez,[1] Michelle Cassin,[1] Aaron Huwe,[1] Levi Njord,[1] George R. Aronoff.[1] *[1]DaVita, Inc, Denver, CO; [2]Hospital of the University of Pennsylvania, Philadelphia, PA.*

Background: Delays in initiating antibacterial therapy for the treatment of peritonitis may lead to increased risk of peritoneal dialysis (PD) failure. Because intraperitoneal (IP) antibiotic treatment is not available after business hours at most dialysis centers, it is important to have a protocol in place for oral "bridge" therapy until a patient can receive IP treatment. The current analysis was conducted, following FDA fluoroquinolone alert notifications, to evaluate the probability of activity of selected oral antibiotic agents against observed PD infections.

Methods: Causative organisms and oral antibiotic susceptibility were analyzed for all peritonitis cases identified during 2016 among PD patients treated by an LDO. Based on these findings, we determined the probability of activity of selected oral antibiotic agents (cefazolin, cefdinir, ciprofloxacin, trimethoprim/sulfamethoxazole [TMP/SMX]) against infections overall, gram-positive infections, and gram-negative infections.

Results: A total of 4534 cases of peritonitis were analyzed. Causative organisms were: coagulase-negative *Staphylococcus* (41.4%), gram-negative rods (21.2%), *Staphylococcus aureus* (8.1%), *Streptococcus* (9.9%), *Enterococcus* (5.5%), fungal (3.9%), other (12.5%). Assuming this distribution of pathogens for PD infections overall, TMP/SMX was predicted to be the most active agent (57.2% of episodes susceptible), followed by cefdinir (50.6%), ciprofloxacin (42%), and cefazolin (39.4%). Among gram-positive infections alone, 74.3% would be expected to be susceptible to TMP/SMX, and 62.7% to cefdinir. Among gram-negative infections, ciprofloxacin was predicted to be the most active agent (84.3% of episodes susceptible).

Conclusions: Early initiation of treatment for peritonitis is critical to avoid PD failure. Designing a strategy for early therapy administered at home, until a patient can receive IP treatment, can potentially improve outcomes. Based on the current analyses, TMP/SMX and cefdinir are predicted to be the most active oral agents for the treatment of suspected gram-positive infections. Ciprofloxacin should be used only in the case of suspected high-risk, gram-negative infections.

Serum Galactomannan and (1→3)-β-D-Glucan Testing for Rapid Detection of Fungal Peritonitis

Talerngsak Kanjanabuch,[1] Tamonwan Chamroensakchai,[2] Thunvarat Saejew.[2] *[1]Medicine, Pathumwan, Thailand; [2]chulalongkorn hospital, Bangkok, Thailand.*

Background: Fungal peritonitis is one of the most serious complications of peritoneal dialysis. Early detection of the causative organism is a key determining outcome; however, routine culture is time consuming and KOH staining has very low sensitivity. Hence serum (1→3)-β-D-glucan (BG) or galactomannan (GM), both fungal cell wall components, may be candidate biomarkers of fungal peritonitis.

Methods: A comparative multi-centered cross-sectional analysis of paired serum and peritoneal dialysis fluid (PDF) BG (Fungitell, Cape Cod, MA, USA) and GM (Platelia Aspergillus Ag kits, Bio-rad, France) from all PD patients with and without fungal peritonitis (23 cases, 8 cases with bacteria and 23 cases control identified by culture), over a 1 year period, was performed.

Results: PDF and serum of the fungal peritonitis group showed very high GM (2.42±2.15, 1.85±1.22) and BG (410.0±158.3, 355.9±246.9) compared to bacterial peritonitis (0.28±0.12, 0.34±0.14), (7.81±0, 7.81 ±0) and healthy control (0.42±0.16, 0.39±0.10), (7.81 ± 0, 7.81±0), respectively. A GM cut-off value at at 0.5 and BG at 80 pg/ml. showed positive predictive value (PPV) of GM test was 95.45% and negative predictive value (NPV) was 93.75%. The sensitivity and specificity of GM testing in PDF and serum were 91.3% and 96.8% respectively.

Conclusions: BG and GM in peritoneal dialysis fluid and serum with provisional cut-off values were applicable as surrogate biomarkers for the diagnosis of fungal peritonitis in PD patients.

TH-PO397

Smartphone-Based Point-of-Care Diagnostics for Early Detection of Peritonitis

Nadja Grobe,[1] Xia Tao,[1] Mia G. Garbaccio,[1] Maricar Villarama,[2] Christopher Hanrahan,[2] Stephan Thijssen,[1] Peter Kotanko.[1] *[1]Renal Research Institute, New York, NY; [2]RRI/Avantus, New York, NY.*

Background: Peritonitis is a serious complication in peritoneal dialysis (PD) and associated with significant morbidity and mortality. Diagnostic criteria include turbid effluent with >100 leukocytes/μl, abdominal pain, and a positive culture. Since accurate diagnosis and a short time-to-treatment are essential for therapy success, we developed a smartphone-based system to measure turbidity in PD fluid. Its use was evaluated in the settings of continuous ambulatory PD (CAPD) and continuous cycling PD (CCPD).

Methods: Total cells of one normal PD effluent were isolated, concentrated, and characterized by count, differential, Wright-Giemsa staining, and flow cytometry. PD effluent was spiked with known amounts of cells isolated from the PD effluent ranging from 5 to 90 leukocytes/μl. Solutions were analyzed in a cuvette (CAPD setup) or pumped through a drain line at 100 ml/min (CCPD setup). Turbidity was measured using the light sensor of a commercially available smartphone. An app (developed in-house) recorded illuminance in real time.

Results: PD effluent contained a total of 159 cells/μl of which 94.4% were red blood cells, 2.5 % leukocytes and 3.1% platelets. The differential showed 7.7% neutrophils, 71% lymphocytes, 18.7% monocytes, 0.8% eosinophils and 1.8% basophils. The PD effluent cell population was confirmed by Wright-Giemsa stain. Flow cytometry showed 20% peritoneal debris. Using the light sensor of the smartphone, a decrease in illuminance was detected with increasing cell concentration. At 90 leukocytes/μl, illuminance was decreased by 15% and 13% in CAPD and CCPD, respectively. The figure exemplifies the tight relationship between cell concentration in the PD effluent and illuminance in the CCPD setting.

Conclusions: A sensitive method to detect an increase of leukocytes in PD effluent was developed. This smartphone-based approach may aid in earlier detection of peritonitis in PD patients since even minor cloudiness can be measured.

Relationship between cell concentration in the PD effluent and illuminance.

TH-PO398

Relative Dialysate White Blood Cell Change Can Predict Treatment Failure in Peritoneal Dialysis-Related Peritonitis: Development and Validation Studies

Pichaya Tantiyavarong,[1,2] Natapol Khumsiri,[1] Krittapong Somboon,[3] Piyatida Chuengsaman.[4] *[1]Division of Nephrology, Department of Medicine, Thammsat University Hospital, Pathum thani, Thailand; [2]Division of Clinical Epidemiology, Faculty of Medicine, Thammsat University, Pathumthani, Thailand; [3]Department of Medicine, Kalasin Hospital, Kalasin, Thailand; [4]Banphaeo-Pattanakarn Peritoneal Dialysis Center, Banphaeo Hospital, Bangkok, Thailand.*

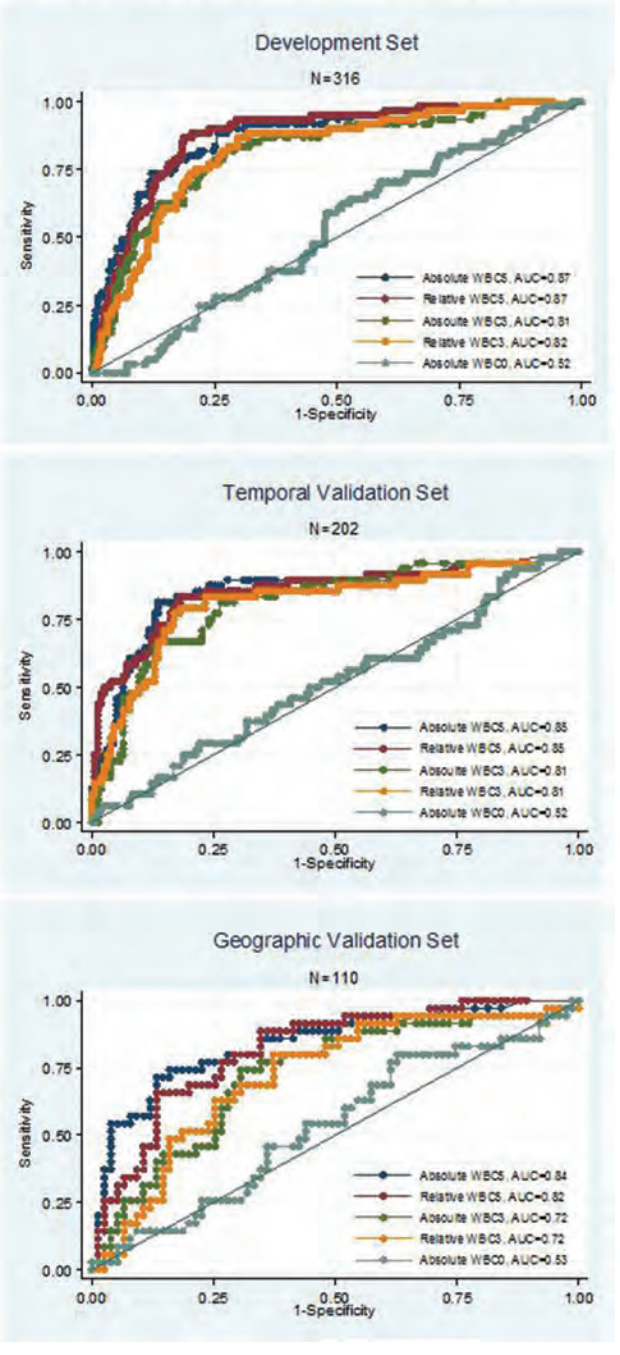
Background: Absolute dialysate white blood cell count (aWBC) can predict treatment failure; however, no study explores predictive ability of relative dialysate white blood cell count (rWBC).

Methods: In this study, there were 3 cohorts. The first (Development set) and second cohorts (Temporal validation set) were conducted in Banphaeo Hospital in different periods. The third cohort (Geographic validation set) was conducted in Kalasin Hospital. Treatment failure was defined as either peritonitis-associated death or transferring to hemodialysis according to physician's judgment. Area under receiving-operating characteristics curve (AUC) of rWBC and aWBC on day 0, 3 and 5 after initial antibiotic treatment were compared. Finally, we defined a cut point of remaining rWBC on day 3 and 5 of ≥33% and ≥15% as a non-response criteria, and compared predictive probability to aWBC criteria (aWBC on day 3 and 5 of ≥1,090 and ≥100 cell/mm^3).

Results: There were 316 (cohort 1), 202 (cohort 2) and 110 (cohort 3) episodes of PD-related peritonitis included for analysis. The majority of initial antibiotic regimens in all cohorts were intraperitoneal Cefazolin and Ceftazidime. Overall treatment failure rate was 19%, 24% and 32%, respectively. Discriminative ability showed similar AUC of rWBC and aWBC on day 3 and day 5 (Figure 1). Baseline WBC had poor AUC. Using a defined cut-off criteria, rWBC ≥15% on day 5 had a better predictive ability comparing to aWBC ≥100 cell/mm^3 in the development set (52% *vs* 44%) and in two validation sets (61% *vs* 55% and 57% *vs* 51%).

Conclusions: rWBC ≥15% on day 5 showed a good predictive probability. We suggest to use this pattern as an alternative criteria to predict treatment failure in PD-related peritonitis.

Figure 1. Receiving-operating characteristics curve



TH-PO399

Association Between Serum Diamine Oxidase, D-Lactic Acid, and Peritoneal Dialysis Related Peritonitis

Jieshuang Jia.[1,2] *[1]Shanghai general hospital, Shanghai, China; [2]school of medicine, Shanghai Jiaotong University, Shanghai, China.*

Background: Abdominal infection is one of serious complications of peritoneal dialysis patients. Studies have shown dysfunctional intestinal barrier seriously affects the efficacy of peritoneal dialysis, and increases serum diamine oxidase(DAO) and D-lactic acid(DLA) levels.

Methods: To investigate the changes of DAO and DLA in patients with peritoneal dialysis-associated abdominal infection, and to find predictable indicators of abdominal infection. We collected 45 peritoneal dialysis patients from January 2017 to January 2018. They include 30 patients without abdominal infection and 15 patients with abdominal infection. We observe the serum levels of DAO, DLA, albumin(ALB), hemoglobin(Hb), interleukin-6(IL-6), and tumor necrosis Factorα(TNFα).

Results: 1. In the patients with abdominal infection, the levels of DAO 18.7±4.9(U/L), DLA 40.1±10.2(mg/L), IL-6 12.8±3.5(pg/ml), TNFα18.9±6.7 (pg/ml)(P<0.05) after abdominal infection were significantly higher than those before abdominal infection. 2. In the patients without infection, the levels of DAO 2±0.5 (U/L), DLA 10±2 (mg/L), IL-6 2.8±2.1 (pg/ml) and TNFα4.2±3.4 (pg/ml) (P<0.05) were obviously lower than those of pre-infection indicators in patients with abdominal infection.3. In patients with abodminal infection, pre-infection serum ALB 25.1±5.6 (g/L), Hb 90±10.7 (g/L) (P<0.05) decreased compared with the data in non-infection group. 4. According to the medical histories we found that in the 15 cases of abdominal infection, 10 cases had a history of diarrhea. Among them, 3 cases of patients had taken drugs regulating intestinal flora;In contrast to patients without drugs, the interval of abdominal infection were prolonged from 1.5 ± 2 months to 10±5.3 months (P>0.05), the levels of DAO, DLA, IL-6 and TNFα were decreased(P<0.05), and ALB and Hb levels were decreased(P>0.05).

Conclusions: Serum DAO, DLA levels may be predictors of peritoneal dialysis abdominal infection;Intestinal barrier disorders induces elevated DAO and DLA which induce the increase of inflammatory cytokines IL-6 and TNFα, affect the nutritional status of patients, decrease ALB and Hb level and promote the abdominal infection; drugs regulating intestinal bacteria prolong the period of infection but the data are not statistically significant. Large sample studies are needed. The mechanism how intestinal barrier dysfunction induced abdominal infection needs further study.

A New Initiative to Measure the Provincial Rate of Peritoneal Dialysis Related Peritonitis in Ontario

Philip McFarlane,[1] Angie Yeung,[2] Janet L. Graham,[5] Jane Ip,[2] Arsh Jain,[3] Monisha Patel,[4] Gihad E. Nesrallah.[6] *[1]St. Michael's Hospital, Toronto, ON, Canada; [2]Cancer Care Ontario, Toronto, ON, Canada; [3]London Health Sciences Center, London, ON, Canada; [4]Ontario Renal Network, Toronto, ON, Canada; [5]The Ottawa Hospital, Ottawa, ON, Canada; [6]The University of Western Ontario, Toronto, ON, Canada.*

Background: Peritonitis is an important complication of peritoneal dialysis (PD), as it is the most common cause of PD technique failure. In April 2016, the Ontario Renal Network (ORN, which funds dialysis in Ontario) launched a provincial quality improvement (QI) initiative with the aim to shift from local monitoring of peritonitis rates to a province-wide standardized tracking system. The initiative was launched with the objectives of defining a provincial average rate of peritonitis, and an individualized rate for each of the Regional Renal Programs (RRP), comparing provincial rates against the ISPD benchmark of 0.67 cases per annualized patient and sharing provincial data and developing program-level QI plans to help minimize peritonitis risk.

Methods: All 26 RRPs in Ontario collected and reported data from May 2016 – December 2017 using a tracking tool incorporating indicator methodology developed by an expert panel. Reported peritonitis events formed the numerator for the rate calculation, while the denominator was derived from the Ontario Renal Reporting System database (ORRS) to calculate person-time on PD. The peritonitis rate is expressed as number of infections per year at risk, combining patient-time from all PD patients at each RRP.

Results: Over a period of 20 months (May 2016 to December 2017), 888 unique peritonitis cases were reported over a total of 1,426,243 patient days (3908 annualized patients). Program-level peritonitis rates ranged from 0.10 – 0.44 and the provincial average was 0.23 episodes/365 PD catheter-days. Quarterly reports were shared with the programs for data validation, comparison and monitoring purposes. The initiative enabled consistent measurement and reporting of peritonitis that allowed programs to benchmark themselves against their peers, and design local quality improvement plans.

Conclusions: The risk of peritonitis is deemed to be relatively low in Ontario, and consistently below ISPD targets. This initiative has produced a sustainable system of data collection for monitoring the risk of peritonitis, and is part of a larger strategy to ensure that all patients receiving dialysis therapy experience as few complications as possible for safe and individualized dialysis access.

TH-PO401

Significant Decrease in PD Peritonitis Rate Using FMC Multiple Tubing Segment Set with Stay Safe Pin Technology Compared to Baxter MiniCap Extended Life PD Transfer Set

Harish R. Alappan,[1] Jennifer Thompson,[2] Raj Alappan.[3] *[1]Emory University - Undergraduate, Atlanta, GA; [2]Davita, Columbus, GA; [3]Renal Associates, LLC, Columbus, GA.*

Background: Peritoneal Dialysis Peritonitis (PDP) is a common and serious complication of Peritoneal Dialysis (PD) resulting in structural & functional alteration in membrane function and membrane failure. Reporting PDP rates varies by country. As of 2016, ISPD recommends a rate < 0.5 episodes/year at risk. Any measures to reduce PDP rate is of utmost importance. We analyzed our PDP data retrospectively, comparing Baxter to FMC transfer sets for PDP. Our center has one of the lowest PDP rates compared to ISPD's 2016 PDP recommendation.

Methods: PD data from Davita Home Dialysis Center, Columbus GA was retrospectively analyzed from Aug. 2013 to Dec. 2017. During this period a total of 111 PD patient data was available for analysis. Baxter transfer sets were used initially from Aug. 2013, and then transitioned to FMC transfer set from 2016 onwards. During this period (53

months) there were 39 PDP episodes; of these 32 were single episode. PDP rate per year and per month was calculated for overall study group and between Baxter and FMC Sets.

Results: Total of 111 patients, mean age is 57.82 ± 1.89 yrs, 68(61%) male, 66 (59.5%) used Baxter & 45(40.5%) used FMC transfer set. Mean BMI was 32.15, nPR 0.727, Albumin 3.41 g/dL, HB 10.25 g/dL, PTH 465.93, with a mean K^+ of 4.35 mmol/dL. 21 PDP episodes (53.8%) were due to Staph species. For a total of 159.67 PD years, overall PDP rate in the cohort was 0.244/year, and 1 PDP in every 4.304 years or 1 in every 51.65 months. First PDP occurred at a mean of 465.2 days from the start of PD. Baxter patient had higher KTV at 2.101 ± 0.11, versus FMC 1.746 ± 0.11 (p=0.035).

Conclusions: Data from our center indicates our PDP rate is significantly lower in comparison to ISPD data, suggesting both Baxter and FMC transfer sets are equally effective in achieving such a low PDP rate. Baxter's higher KTV rate correlates to higher PDP rate. Between the two, the FMC transfer set was more effective in reducing PDP, with the lowest rate and more delayed occurrence of PDP. We recommend a large prospective study to validate our data.

Data	Over All (n=111)	Baxter (n=68)		FMC (n=45)		
			SEM		*SEM*	*p-Values*

Apartment vs Single Family Home and Its Effect on Peritonitis Among Peritoneal Dialysis Patients, A Single Center Study in an Urban Population

Omar Farrukh,[1] Vesh Srivatana.[2] *[1]NYP-Weill Cornell, New York, NY; [2]The Rogosin Institute, New York, NY.*

Background: Peritonitis is a significant complication among patients undergoing Peritoneal Dialysis (PD). It can lead to significant morbidity, loss of ultrafiltration, permanent membrane damage, and treatment failure. Social aspects including geographical location and educational status have been implicated in the risk of developing peritonitis however no studies have assessed the impact of living space on peritonitis risk. We hypothesize that nephrologists may not offer PD to patients with small living quarters due to a perceived increased risk of peritonitis. This issue is exacerbated in urban populations where most patients live in apartments and not single family homes. Our aim was to determine if home size has any impact on PD peritonitis.

Methods: A retrospective review of prevalent patients undergoing Peritoneal Dialysis between 1998 and 2005 in a single center in an urban population. Inclusion Criteria were all adult patients with complete follow up and housing information for the duration of PD treatment. Data collected for each individual patient included Race, Gender, Age at time of initiation of PD, Presence of Diabetes, BMI, Type of living quarters (House vs Apartment), occurence of Peritonitis and time to first peritonitis or PD discontinuation.

Results: A total of 85 patients met the inclusion criteria and had 35 individual episodes of PD peritonitis. A Univariate Logistic Regression between type of living quarters and Peritonitis had an Odds Ratio 0.53, 95% Confidence Interval, 0.22 to 1.27, p=0.158. We then performed a multivariate logistic regression to control for known independent risk factors for peritonitis including, age, gender, race, diabetes, BMI and residual renal function and found an Odds Ratio 0.48, 95% confidence interval, 0.18 to 1.28. p=0.144. A Cox Regression analysis was then performed to assess the time to peritonitis in relation to living in an apartment with a Hazard Ratio 0.65, 95% confidence interval 0.33 to 1.24, p= 0.186.

Conclusions: To our knowledge this is the first study to examine the effect of living quarters on PD peritonitis in an urban population. Our data suggests that there is no increased risk of peritonitis based on living quarters and should not be a contraindication for PD.

TH-PO403

Development of Risk Prediction Model for Infection-Related Mortality in Peritoneal Dialysis Patients

Hiroaki Tsujikawa,[1] Shigeru Tanaka,[2] Hidetoshi Kanai,[3] Kazuhiko Tsuruya,[4,6] Toshiaki Nakano,[1] Takanari Kitazono.[5] *[1]Department of Medicine and Clinical Science, Kyushu University, Fukuoka, Japan; [2]Fukuoka Dental College, Fukuoka, Japan; [3]Kokura Memorial Hospital, Kita Kyushu, Japan; [4]Nara Medical University, Kashihara, Japan; [5]Department of Medicine and Clinical Science, Fukuoka, Japan; [6]Department of Integrated Therapy for Chronic Kidney Disease, Kyushu University, Fukuoka, Japan.*

Background: The risk assessment for infection-related mortality remains limited in patients on peritoneal dialysis (PD). The aim of this study was to develop a risk model to predict the 2-year infection-related mortality risks in PD patients.

Methods: A total of 606 patients who started and continued PD over 90 days from Fukuoka PD Registry Study in Japan were enrolled into the study. Participants were enrolled from January 1, 2006 to December 31, 2016 and followed up until December 31, 2017. To create a prediction rule, the score for each variable was weighted by the regression coefficients calculated using a Cox proportional hazards adjusted by the risk factors for infection-related mortality, including demographic, comorbidities and laboratory data.

Results: During a follow-up period (median, 2.2 years), a total of 138 patients died; 58 of these patients died of infectious disease. The final model for infection-related mortality consisted of six factors, including age, sex, serum albumin, serum creatinine, total cholesterol and renal Kt/V. The incidence of infection-related mortality increased linearly with an increase in the total risk score (P for trend <0.001). Furthermore, the prediction model showed adequate discrimination [c-statistic=0.73 (0.67–0.79)] and calibration (Hosmer-Lemeshow test, P=0.66).

Conclusions: In this study, we developed a new prediction model using clinical measures for infection-related mortality in PD patients.

Peritonitis Before Peritoneal Dialysis Training: A Single Center Experience

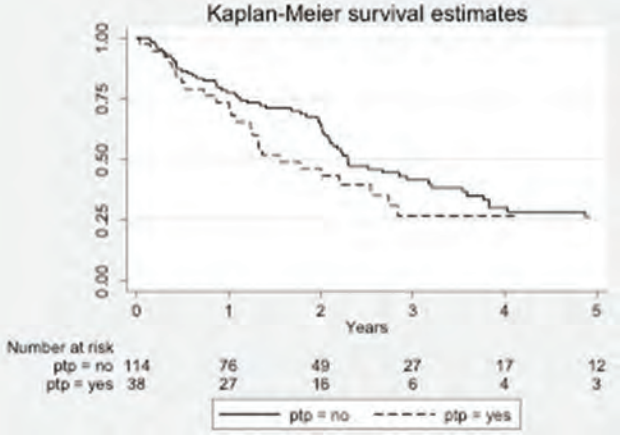
Saw Yu Mon,[1,2] Usman Mahmood,[3] Carmel M. Hawley,[1,2] David W. Johnson,[1,2] Magid Fahim,[1,2] Yeoung Jee Cho.[1,2] *[1]Department of Nephrology, Princess Alexandra Hospital, Brisbane, QLD, Australia; [2]School of Medicine, University of Queensland, Brisbane, QLD, Australia; [3]Toowoomba Hospital, Toowoomba, QLD, Australia.*

Background: Peritoneal dialysis (PD)-related peritonitis is an important risk factor for death and technique failure in PD patients. The predictors and outcomes of peritonitis prior to commencing PD (pre-training peritonitis [PTP]) are poorly understood. The aim of this study was to examine risk factors and long-term patient outcomes in those who experience PTP.

Methods: This single-center, matched case-control study included patients commencing PD from 1January 2005 to 31December 2015. PTP patients were matched 1:3 with those who developed peritonitis after PD training, based on tertiles of age and diabetic status. We examined risk factors for PTP, immediate and long-term outcomes, including technique and patient survival.

Results: Thirty-eight patients with PTP were identified and matched to 114 control patients. Compared to controls, PTP patients were significantly more likely to have history of hypertension (100% vs 89%, p=0.04), late nephrologist referral (21% vs 9%,p=0.04), open surgical PD catheter insertion (82% vs 44%,p<0.001), and pre-training exit site infection (34% vs 2%,p<0.001). PTP patients experienced comparable rates of peritonitis cure (58% vs 65%, p=0.50), temporary haemodialysis transfer (13% vs 11%,p=0.77), technique survival (HR 1.47, 95% CI 0.94-2.29,p=0.09) and patient survival (HR 1.35, 95% CI 0.52-3.49,p=0.54). There was a significant two-way interaction between history of ischaemic heart disease (IHD) and PTP status (p=0.02), such that technique failure risk was increased in PTP patients with IHD (HR 2.82, 95% CI 1.37-5.84,p=0.005) but not those without IHD (HR 0.88, 95% CI 0.41-1.92,p=0.75).

Conclusions: The risk of PTP was increased by factors relating to patient, catheter insertion approach and clinical events. Patient outcomes were comparable between PTP and post-training peritonitis, except for a greater risk of technique failure in patients with PTP and IHD.



Technique survival for PTP group compared with non-PTP group

TH-PO405

Feasibility of Resuming Peritoneal Dialysis After Catheter Removal Due to Severe Peritonitis

María C. Chediak, Haridian Sosa Barrios, Victor Burguera, Melissa Cintra Cabrera, Milagros Fernandez lucas, Maite Rivera. *Nephrology, Hospital Ramón y Cajal, Madrid, Spain.*

Background: The resumption of peritoneal dialysis (PD) after a peritonitis requiring peritoneal catheter (PC) removal is unlikely and remains poorly studied. We analyzed the characteristics and outcomes of patients resuming PD after peritonitis.

Methods: We reviewed all episodes of peritonitis between 1996 and 2017 and identified the cases in which the catheter was removed. We compared the data of patients who restarted PD after PC removal (Group 1) with those who did not (Group 2) and identified the causes.

Results: Of 483 peritonitis episodes, PC was removed in 48 patients (16.9%). Of these, 18 (37.5%) resumed PD and 30 (62.5%) did not. The median duration of PD before catheter removal was 24.5 months (range 14.2-40) and the number of previous peritonitis episodes was 2 (range 1-3). The indications for catheter removal were: refractory and relapsing peritonitis; fungal, mycobacterial and polymicrobial peritonitis. The organisms identified were: S. aureus 20.8% (n=10), Candida sp 18.8% (n=9), P. aeruginosa 14.6% (n=7), other Gram-negative bacilli 20.8% (n=10), mixed growth 8.3% (n=4), Mycobacterium sp 6.3% (n=3), other Gram-positive 4.2% (n=2) and no growth 6.3% (n=3). Group 1 (n=18): 89.9% (n=16) were male, median age was 53 years (range 44 – 64) and Charlson Index was 4 (range 2 – 6). PD was resumed successfully in all with a median duration of PD afterwards of 14.1 months (range 4-69). Group 2 (n=30): 60% (n=18) were male, median age was 64 years (range 48 – 76) and Charlson Index was 6 (range 4 – 8). Causes of no reinsertion were: death due to peritonitis 16.7% (n = 5), transplantation 6.7% (n = 2) and transfer to hemodialysis (HD) 76.6% (n = 23). HD- switch was due to non- medical reasons in 47.8% (n = 11), including fear of peritonitis 10.4% (n=5), family decision 36.3% (n = 4) and social dependence in 18.2% (n = 2). Group 1 was younger (p = 0.041), had a higher proportion of men (p = 0.049) and a lower Charlson index (p = 0.045). No other statistically significant difference was found between both groups.

Conclusions: Resuming PD after PC removal is feasible. A high proportion of patients do not restart PD for non-medical reasons, mostly fear of peritonitis and family decision.

TH-PO406

Linoleic Acid Co-Treatment Inhibits Bacterial Biofilm Formation in Continuous Ambulatory Peritoneal Dialysis (CAPD) Catheter

Gang Jee Ko,[1] Shin-Young Ahn,[1] Eunjung Cho,[1] Young-Joo Kwon,[1] Eunji Cha,[2] Han shin Kim,[2] Hee deung Park.[2] *[1]Department of Internal Medicine, Korea University College of Medicine, Guro Hospital, Seoul, Republic of Korea; [2]School of Civil, Environmental and Architectural Engineering, Korea University, Seoul, Republic of Korea.*

Background: Peritonitis is a serious complication in patients receiving PD responsible for significant morbidity and technical failure. Biofilm formation of catheter is considered as an underlying mechanism for relapsing, recurrent and intractable peritonitis. However, little has been known to prevent it. Here we aimed to investigate the protective effect of linoleic acid (LA) on catheter biofilm formation, which is one of the elements of ginger extract demonstrated an inhibitory effect on biofilm of industrial and environmental settings such as water pipes system.

Methods: Biofilm was formed by overnight culture of S.aureus and P. aeruginosa (PA 14) with and without treatment of LA, and quantified by measurement of OD at 595nm after staining of crystal violet. The amount of extracellular polymeric substance (EPS) attached to biofilm was also examined. Additive therapeutic effect of LA on biofilm formation was examined by co-treatment of antibiotics (cefazolin(CF) for S.aureus and tobramycin(TM) for P.aeruginosa) with LA. Intracellular cyclic digulanylate (c-di-GMP) and related gene activity under LA treatment were also examined. Cellular and functional toxicity of LA was assessed using human mesothelial cells and mice.

Results: LA treatment reduced biofilm formation (0, 10 and 100nM: 1.41±0.17, 0.95±0.11, 0.64±0.07, p<0.001, respectively), and EPS production was also markedly decreased. After LA treatment, reduction of c-di-GMP, secondary messenger of microorganism, and related gene activities were observed. Bacterial biofilm inhibitory effect was synergistically increased by co-treatment of LA (25nM) with antibiotics (CF *vs.* CF+LA: 0.60±0.03 *vs.* 0.13±0.19, TM *vs.* TM+LA 0.18±0.05 *vs.* 0.06±0.04). Cytotoxicity measured by LDH and MTS assay was not increased, and liver and renal functional and histologic abnormalities were not observed in mice after LA treatment.

Conclusions: Co-treatment of LA with antibiotics was effective to inhibit bacterial biofilm formation in catheter. It should be studied further as a therapeutic strategy to reduce recurrent peritonitis.

TH-PO407

Predictive Values of Different Blood Pressure Measurements for Left Ventricular Diastolic Dysfunction in Peritoneal Dialysis Patients

Yun Jung Oh,[1] Su mi Lee,[2] Jiwon Ryu,[1] Chungsik Lee.[1] *[1]Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea; [2]Internal Medicine, Dong-A University Hospital, BUSAN, Republic of Korea.*

Background: Cardiovascular diseases (CVDs) are main causes of death in end stage renal disease (ESRD) patients and one of the CVDs, left ventricular diastolic dysfunction is suggested to be associated with increased mortality in these patients. Hypertension is known to be implicated in the pathogenesis of diastolic dysfunction and an important modifiable risk factor for diastolic heart failure. In this study, we compared different methods of blood pressure (BP) measurement and evaluated comparative values of BP measurement for predicting diastolic heart dysfunction in patients on peritoneal dialysis (PD).

Methods: A total of 52 prevalent PD patients were enrolled. We measured ambulatory BP, office BP, home BP, and central BP. The ambulatory BP was recorded for 24 hours, office BP was measured at least in two visits, and home BP was measured for one week. The central BP was estimated using radial artery tonometry. Patients underwent transthoracic echocardiography and the presence of diastolic dysfunction was determined according to 2016 American Society of Echocardiography and European Association of Cardiovascular imaging (ASE/EACVI) guideline.

Results: Left ventricular diastolic dysfunction was best predicted by ambulatory systolic BP (area under the curve (AUC), 0.845; 95% CI, 0.726-0.964). The office systolic BP (AUC, 0.661; 95% CI, 0.457-0.866), home systolic BP (AUC, 0.661; 95% CI, 0.481-0.842), and central systolic BP (AUC, 0.623; 95% CI, 0.441-0.805) were inferior to ambulatory systolic BP monitoring in predicting diastolic dysfunction. In multivariate analysis adjusted for age, sex, PD vintage, diabetes and coronary artery disease, only ambulatory systolic BP had significantly increased OR for diastolic dysfunction (OR, 1.094; 95% CI 1.004-1.192). The other adjusted ORs of office, home, and central systolic BP for diastolic dysfunction were not statistically significant.

Conclusions: Ambulatory systolic BP was the strongest predictor of left ventricular diastolic dysfunction in comparison with the other BP measurements including office, home, and central systolic BP, in ESRD patients on PD.

TH-PO408

A Machine Learning Model to Predict Patient Risk of Peritonitis Episodes

Tommy C. Blanchard, Joanna Willetts, Michael R. O'Connell, Sheetal Chaudhuri, Len A. Usvyat, Brian C. Ellison, Judith Moran, Melissa Herman, Susan M. Dunphy, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Peritonitis infections are one of the primary complications in the use of peritoneal dialysis. Predicting what patients are at a higher risk of peritonitis is of great interest so that cases of peritonitis can be caught early, or patients can be given additional training to prevent peritonitis infections altogether.

Methods: We analyzed data of 36,329 peritoneal dialysis patients who were treated by a large dialysis provider from 2016-2017. We had 10,522 cases of peritonitis over this period. We trained a machine learning model (XGBoost boosted tree model) to predict which patients will be diagnosed with a peritonitis infection in the next month based on patients' history of peritonitis, symptoms noted by nurses during assessments, routine clinical laboratory values, and demographic data.

Results: Our machine learning model achieved an area under the ROC curve of 0.736. The features that were found to be most important for prediction were: whether the patient has had a previous peritoneal infection, how long the patient has been on peritoneal dialysis days since previous infection, changes in potassium levels, and albumin levels (Table 1).

Conclusions: We built a machine learning model that was able to predict which patients will have a peritonitis infection in the next month. This model can be used to allocate resources to try to catch infections early or prevent them. Future work can expand the features the model has access to in order to improve the model performance.

Funding: Commercial Support - Fresenius Medical Care

Variable	Mean value for peritonitis	Mean value for uninfected
Vintage	647 days	621 days
Previous infection	32%	13%
Days since infection	102	153
Change in potassium	.052	.028
Albumin	3.34	3.48

Short Patient and Technique Survival Following First Peritonitis in Peritoneal Dialysis Patients: Does Timing of First Peritonitis Matter?

Wael A. Al-Bader,[1,2] Hossam A. Nassef.[3] *[1]Medicine, Kuwait University, Kuwait, Kuwait; [2]Nephrology, Al-Sabah Hospital, Kuwait, Kuwait; [3]Ministry of Health, Kuwait, Kuwait.*

Background: To investigate whether patient and technique survival in peritoneal dialysis (PD) are related to timing of first peritonitis.

Methods: In this retrospective study, 144 patients on peritoneal dialysis who were 18 years of age and older and had at least one episode of peritonitis between 2004 and 2016 were included. They were divided into early peritonitis (EP) group (n = 97) which included patients who had their first peritonitis within 12 months from start of PD therapy, and late peritonitis (LP) group (n = 47) which included patients who had their first peritonitis after 12 months from start of PD therapy. Technique and patient survival of both groups were compared in terms of time following first incident peritonitis using Cox proportional hazard model.

Results: EP group had shorter time on PD therapy compared to LP group (median 16.7 ± 13.1 vs 39.8 ± 20.1 months respectively, p < 0.001). However, EP and LP groups had similar patient survival in relation to time following first incident peritonitis (16 % vs 19 % at 24 months, HR: 0.96, CI 95%: 0.84 – 1.23, p = 0.9) and similar technique survival (16% for both groups at 24 months, HR: 1, CI 95%: .96 – 1.04, p = 0.7). There was no difference in causal microorganisms between both groups (p = 0.45).

Conclusions: Incident first peritonitis is associated with short patient and technique survival independently of time taken to develop the event.

Funding: Government Support - Non-U.S.

Exit-Site Infection Associated with Baseline Body Mass Index in Patients Initiating Peritoneal Dialysis

Hironori Nakamura, Anayama Mariko, Yasushi Makino, Masaki Nagasawa. *Department of nephrology, Sinonoi General Hospital, Nagano, Japan.*

Background: The International Society for Peritoneal Dialysis (PD) guidelines recommend the monitoring of PD-related infections as well as the incidence of peritonitis. However, the incidence rate of PD-related infections or the associated clinical factors have not been well investigated.

Methods: Forty-seven patients who initiated PD between 2012 and 2017 were retrospectively reviewed. The clinical data were compared between the patients developing exit-site infection (ESI) and those who did not during the initial 60 days after initiating PD. Kaplan–Meier analysis and Cox proportional hazards model were used to identify the factors associated with ESIs using the time to initial ESI from data in the cohort. An ESI was defined as the presence of purulent drainage with positive culture results, and was counted as one occurrence when the infection lasted for <4 weeks.

Results: The number of annual ESI events and their annual incidence rates between 2012 and 2017 were 1, 6, 18, 32, 20, and 36 and 0.83, 0.86, 1.36, 1.09, and 1.59 (per patient-years), respectively. The body mass index (BMI) in patients who developed ESIs before the initial 60 days (25.9 ± 4.4 kg/m^2) was significantly higher than that of patients who did not develop ESIs (21.7 ± 2.8 kg/m^2); the occurrence of diabetes mellitus (DM) was also significantly higher (9/16 vs. 7/31) and the D/P Cr was significantly lower (0.57 ± 0.08 vs. 0.66 ± 0.10) in patients with ESIs than in those without ESIs. There were no significant differences in variables, such as age, sex, stepwise PD initiation, presence of caregiver, and serum albumin, between the two groups. Kaplan–Meier revealed that the high BMI group divided by the median value and the occurrence of DM indicated a higher rate of ESI (Log-Rank: p = 0.006 and 0.026, respectively) compared with the group with low BMI and that without DM. The Cox proportional hazards model revealed that ESI events during the 2 years were significantly affected by the patients' BMI [hazard ratio (HR), 1.236; 95% confidence interval (95% CI), 1.07–1.41; p = 0.002] but not by the presence of DM (HR, 0.952; 95% CI, 0.29–3.03; p = 0.934).

Conclusions: Our findings suggest that ESIs are associated with baseline BMI of patients initiating PD in our study population. Body weight control at the time of PD initiation can potentially diminish the risk of ESI.

Estimating Residual Kidney Function in Dialysis Patients Without Urine Collection

Dominik Steubl,[1,12] Li Fan,[3] Lesley Inker,[1] Hocine Tighiouart,[1] Friedo W. Dekker,[6] Amy B. Karger,[7] John H. Eckfeldt,[8] Hao Zhang,[9] Jing Hu,[2] Yunhua Liao,[10] Tariq Shafi,[4] Wei Chen,[11] Xueqing Yu,[5] Andrew S. Levey.[1] *[1]Tufts Medical Center, Boston, MA; [2]The third Xiangya hospital of Central South Univercity, Changsha, China; [3]Department of Nephrology, The First Affiliated Hospital of Sun Yat-sen University; Key Laboratory of Nephrology, Ministry of Health; Guangdong Provincial Key Laboratory of Nephrology, Guangzhou, China; [4]Johns Hopkins University School of Medicine, Baltimore, MD; [5]Department of Nephrology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [6]Leiden University Medical Center, Leiden, Netherlands; [7]University of Minnesota, Minneapolis, MN; [8]University of Minnesota Medical School, Minneapolis, MN; [9]The Third Xiangya Hospital of Central South University, Changsha, China; [10]The First Affiliated Hospital of Guangxi Medical University, Nanning, China; [11]The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [12]Nephrology, Klinikum rechts der Isar, Technische Universitaet Muenchen, Munich, Germany.*

Background: Measurement of RKF is recommended for adjustment of the dialysis prescription, but timed urine collections are difficult and prone to errors. Few equations to estimate RKF in dialysis patients using serum concentrations of low molecular weight proteins (LMWP) have been externally validated (Shafi T et al, Kidney Int 2016).

Methods: We developed RKF estimating equations using linear regression analysis in 823 peritoneal dialysis patients in the Guangzhou PD Study. The reference tests were measured clearance of urea nitrogen (UN) (mCl_{UN}, ml/min) and average clearance of UN and creatinine (mCl_{UN-cr}, ml/min/1.73 m^2). The index tests were estimated clearance (eCl) using UN and creatinine (eCl_{UN-cr}), beta-trace-protein (eCl_{BTP}), beta-2-microglobulin (eCl_{B2M}), cystatin C (eCl_{cys}) and combinations. Equations were then externally validated in 826 hemo- and peritoneal dialysis patients in the NECOSAD study and also compared to published validated equations.

Results: In external validation, bias was within ±1.0 (Table). Precision and accuracy were significantly better for eCl_{BTP}, eCl_{B2M} and $eCl_{BTP\text{-}B2M}$ than $eCl_{UN\text{-}cr}$. The area-under-the-curve for predicting mCl_{UN} >2.0 ml/min for eCl_{B2M} and $eCl_{BTP\text{-}B2M}$ was 0.853 and 0.848, respectively (Figure). Results were similar to other validated equations.

Conclusions: These results confirm the validity and extend the generalizability of estimation of RKF from serum concentrations of LMWPs without urine collection.

Funding: Commercial Support - Siemens, Dialysis Clinic Inc., Private Foundation Support

TH-PO412

Lipid Level and Its Impact on Cardiovascular Mortality in Peritoneal Dialysis Patients

Yong kyu Lee, Elani Streja, Hamid Moradi, Kamyar Kalantar-Zadeh. *Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, Orange, CA.*

Background: Peritoneal dialysis (PD) patients show different characteristics in terms of lipid profile and qualitative function compared to hemodialysis (HD) patients, however there are limited large-scale studies regarding the influence of lipid level on cardiovascular mortality in PD patients. The guideline for lipid control, which is focused on cardiovascular mortality in HD patients, needs validation with respect to its application in PD patients.

Methods: 7,543 PD patients were selected from a national cohort of patients treated by a large dialysis organization during 2007-2011. We sought to verify the relationship between lipid levels—including total cholesterol, LDL cholesterol, and triglyceride levels—and cardiovascular mortality. Lipid levels were divided into 6 strata and 3 different hierarchical adjustment models were applied to observe the change in relationship after adjustment.

Results: Total cholesterol, LDL cholesterol, and triglyceride showed a consistent trend, whereby patients in the lowest stratum were observed to have highest cardiovascular mortality: hazard ratios were 2.183 (1.634-2.916), 1.513 (1.166-1.963), and 1.788 (1.348-2.373), respectively in case-mix adjusted models. Cardiovascular mortality risk showed a reversed J-shaped association with inflection at a total cholesterol level of 200-230mg/dL, LDL cholesterol level of 100-120mg/dL, and triglyceride level of 200-250mg/dL.

Conclusions: In contrast to conventional belief, PD patients with low total cholesterol, LDL cholesterol, and triglyceride levels showed higher cardiovascular mortality.

TH-PO413

HDL Cholesterol Level and Its Impact on Cardiovascular Mortality in Peritoneal Dialysis Patients

Yong kyu Lee, Elani Streja, Kamyar Kalantar-Zadeh, Hamid Moradi. *Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, Orange, CA.*

Background: HDL cholesterol is traditionally believed to be beneficial in preventing cardiovascular mortality by reverse cholesterol transport and restricting LDL cholesterol oxidation. However, in ESRD patients, the effect of HDL cholesterol was shown to deviate due to its qualitative and quantitative alteration.

Methods: 7,839 peritoneal dialysis (PD) patients were selected from a national cohort of patients treated at a large dialysis organization during 2007~2011. We sought to verify the relationship between HDL cholesterol and total cholesterol/HDL cholesterol ratio and all-cause mortality. Each exposure parameter was divided into 6 strata and 3 different hierarchical adjustment models were applied to observe the change in relationship after adjustment.

Results: Although patients with low HDL cholesterol showed higher all-cause mortality risk in the unadjusted model, the risk was attenuated after adjustment, with a hazard ratio of 1.235 (0.970-1.573) in the case-mix adjusted model. However, patients with low total cholesterol/HDL ratio showed higher all-cause mortality risk which was robust even after adjustment for case-mix and markers of malnutrition/inflammation (MICS), with a hazard ratio of 1.433 (1.183-1.736) in the case-mix adjusted model. Both showed a reversed J-shaped association with the inflection point at 50-60mg/dL for HDL cholesterol and 4-5 for total cholesterol:HDL cholesterol ratio. The highest HDL cholesterol level group showed a mortality risk of 1.090 (0.836-1.421) and the highest total cholesterol:HDL cholesterol ratio group showed a mortality risk of 1.178 (0.940-1.477).

Conclusions: PD patients with low HDL cholesterol and total cholesterol:HDL cholesterol ratio showed higher all-cause mortality. However, higher HDL cholesterol and total cholesterol:HDL cholesterol ratios showed neither the beneficial effect observed in the general population nor the deleterious effect observed in HD patients.

Serum Osteopontin Level Is Positively Associated with Central Arterial Stiffness in Patients with Peritoneal Dialysis

Wei-Chen Lin, Bang-Gee Hsu. *Buddhist Tzu Chi General Hospital, Hualien, Taiwan.*

Background: Osteopontin (OPN) is generally regarded as a proinflammatory and proatherogenic molecule and is associated with atherosclerosis. The aim of this study was to evaluate the relationship between serum OPN on central arterial stiffness by measuring of carotid-femoral pulse wave velocity (cfPWV) values in patients with peritoneal dialysis (PD).

Methods: Fasting blood samples were obtained from 70 PD participates in the study. Carotid-femoral pulse wave velocity was measured by a validated tonometry system. cfPWV values of > 10 m/s were used to define the high central arterial stiffness group, while values ≤ 10 m/s were regarded as the control group, according to the ESH-ESC 2013 guidelines. Serum OPN levels were measured using a commercial enzyme-linked immunosorbent assay kit.

Results: Twenty-two patients (31.4%) had high central arterial stiffness and were of older age (P = 0.001) and had longer PD vintage (P = 0.024), higher C-reactive protein (P = 0.005) and OPN levels (p < 0.001) compared to subjects with control group. Multivariate logistic regression analysis of the factors significantly associated with central arterial stiffness revealed that OPN (odds ratio: 1.044, 95% confidence interval: 1.020–1.069, P < 0.001) and PD vintage (odds ratio: 1.027, 95% confidence interval: 1.007–1.047, P = 0.009) were the independent predictors of central arterial stiffness in PD patients. Multivariate forward stepwise linear regression analysis also showed that OPN level (β = 0.477, adjusted R^2 change = 0.269, P = 0.001) was positively associated with cfPWV values in PD patients.

Conclusions: In this study, serum OPN level was positively associated with cfPWV values in PD patients and was the independent predictors of central arterial stiffness in PD patients.

TH-PO415

Serum Osteoprotegerin Level Is Positively Associated with Peripheral Artery Disease in Patients with Peritoneal Dialysis

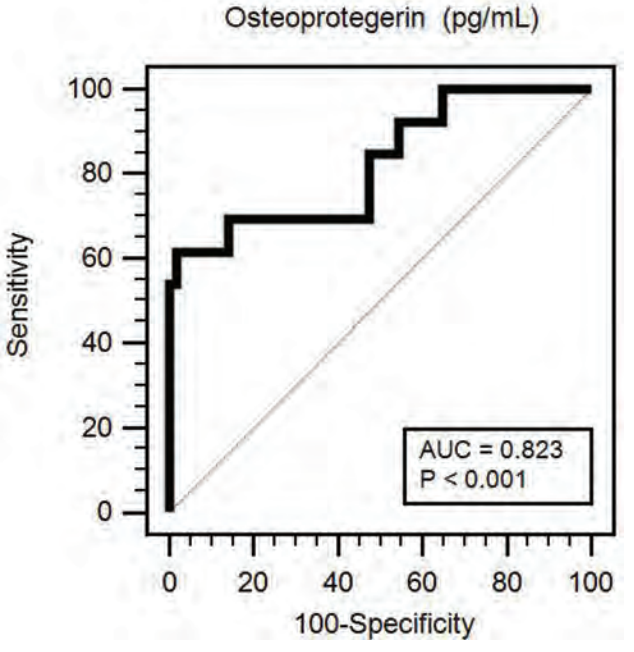
Wei-Chen Lin,[2] Bang-Gee Hsu.[1] *[1]Division of Nephrology, Buddhist Tzu Chi General Hospital, Hualien, Taiwan; [2]Buddhist Tzu Chi General Hospital, Hualien, Taiwan.*

Background: Osteoprotegerin (OPG) levels may be a potential biomarker of complications and severity of cardiovascular disease. Peripheral arterial disease (PAD) is associated with an increased risk of death in peritoneal dialysis (PD) patients. Our aim was to evaluate the relationship between serum OPG levels and PAD by ankle-brachial index (ABI) among PD patients.

Methods: Fasting blood samples were obtained from 70 PD patients. The ABI values were measured using an ABI-form device (VaSera VS-1000). Serum OPG levels were measured using a commercial enzyme-linked immunosorbent assay kit. Left or right ABI values that were < 0.9 were included in the low ABI group.

Results: Among 70 PD patients, 13 patients (18.6%) were in the low ABI group. Compared with patients in the normal ABI group, patients in the low ABI group had higher prevalence of diabetes (p = 0.044), higher serum C reactive protein (CRP) (P < 0.001), and higher serum OPG level (P < 0.001), while lower serum creatinine level (P = 0.013) and peritoneal Kt/V (P = 0.048). According to the multivariate logistic regression analysis, OPG (Odds ratio [OR]: 1.027, 95% confidence interval [CI]: 1.010-1.045, P = 0.002) and CRP (each increase of 0.1 mg/dL, OR: 1.102, 95% CI: 1.006-1.207, P = 0.037) were the independent predictors of PAD in PD patients. The area under the receiver operating characteristic (ROC) curve (AUC) indicates the diagnostic power of OPG at predicting PAD of PD patients was 0.823 (95% CI: 0.714-0.904, P < 0.001).

Conclusions: In this study, serum OPG level was proved to be involved in the pathogenetic process of PAD in PD patients.



TH-PO416

Relationship Between Hypomagnesemia and Abdominal Calcification Index in Peritoneal Dialysis Patients: A Cross-Sectional Study

Kenji Harada,[1] Hidetoshi Kanai,[2] Shigeru Tanaka.[3] *[1]Kokura memorial hospital, Kitakyusyu city, Japan; [2]Kokura Memorial Hospital, Kita Kyushu, Japan; [3]Fukuoka Dental College, Fukuoka, Japan.*

Background: Several previous reports have reported that hypomagnesemia was associated with high mortality in hemodialysis (HD) patients. However, the influence of hypomagnesemia on the prognosis of peritoneal dialysis (PD) remains unclear. We investigated relationship between abdominal calcification index (ACI) and cardiovascular risk factors in PD patients.

Methods: A total of 184 PD patients were included in the current study. ACI was calculated calculated as average calcification area of consecutive 20 slices of abdominal aorta measured by abdominal plain CT (computerized tomography). We evaluated relationships between ACI and cardiovascular risk factors, including serum phospahte, serum calcium, whole parathyroid hormone, serum agnesium, lipid status, Hemoglobin A1c (HbA1c), blood pressure (BP), peritoneal function, echocardiographic findings.

Results: The overall, mean age was 64.9 years old, male/female was 132/52, average PD vintage was 12 months. Median value of magnesium was 1.92±0.3 mg/dl. We deviated participants into two groups; low magnesium (Mg<1.9) group and high magnesium (Mg≥2) group. Low magnesium group had a lower HbA1c and higher ACI. There was no difference in age, sex, ejection fraction, BP, peritoneal function, past history of cardiovascular disease between two groups. In the multiple regression analysis, hypomagnesemia was an independent predictor for high ACI (β=-2.73, P<0.007).

Conclusions: Hypomagnesemia at initiation of PD was strongly correlated with high ACI and its relationship did not change even after adjusting by plausible cardiovascular risk factors, hypomagnesemia was an independent predictor for high ACI. These results suggest that hypomagnesemia might be involved in calcification progression in PD patients.

TH-PO417

Concentric Left Ventricular Hypertrophy at Peritoneal Dialysis Initiation May Predict Death and Cardiovascular Disease in Patients Using Neutral-pH Solution

Yoshifumi Hamasaki,[1] Teruhiko Yoshida,[2,3] Akihiko Matsumoto,[1] Rei Isshiki,[1] Eisei Noiri,[2] Masaomi Nangaku.[2] *[1]The University of Tokyo Hospital, Tokyo, Japan; [2]The University of Tokyo, Tokyo, Japan; [3]National Institute of Diabetes and Digestive and Kidney Diseases, NIH, Bethesda, MD.*

Background: Left ventricular hypertrophy (LVH) is known as one of the risk factors of mortality and cardiovascular disease (CVD) in the patients undergoing peritoneal dialysis (PD). Concentric LVH (cLVH) is the most frequent left ventricular geometry model in dialysis patients. The relationship between cLVH at PD initiation and prognosis is not well known. We investigated whether cLVH at PD initiation is associated with mortality and incidence of CVD in PD patients.

Methods: The data from patients who started PD at The University of Tokyo Hospital were collected retrospectively. Clinical parameters measured at PD initiation were obtained. The definition of cLVH was as follows; left ventricular mass index is ≧115 g/m^2 and relative wall thickness is ≧0.42. All patients were divided into two groups with and without cLVH. Morality, incidence of CVD, technique survival rate were compared between two groups. We also investigated the relationship between clinical parameters and cLVH at PD initiation.

Results: A total of 126 patients was included and mean follow-up period was 44 months. The mean age was 58.5±11.8 y.o., male was 76%, and automated PD was selected in more than 90% patients. All patients were treated using neutral-pH PD solution. Twenty-six patients (21%) had cLVH at PD initiation. Kaplan-Meier analysis revealed that cLVH group had significant higher mortality, higher incidence of CVD, and lower technique survival rate compared with non-cLVH group (Log rank: p < 0.01, = 0.02, and < 0.01, respectively). The result of Cox proportional hazards model demonstrated that age and cLVH were independent predictors of mortality (hazard ratio, 1.08 and 3.67; 95%CI, 1.04 to 1.14 and 1.18 to 11.46; p < 0.01 and = 0.02; respectively). Age, hemoglobin, and geriatric nutrition risk index (GNRI) were independently correlated with cLVH (odds ratio [95% confidence interval]: 1.07 [1.02-1.11], 0.53 [0.30-0.93], and 0.92 [0.86-0.99], respectively).

Conclusions: Concentric LVH at PD initiation may be a possible predictor of mortality and CVD in patients using neutral-pH PD solution.

TH-PO418

Peritoneal Ultrafiltration on Refractory Heart Failure

Tomas Alexis Becerra-Gamba,[1] Gabriela Leal,[3] Bernardo Moguel.[2] Instituto Nacional de Cardiología "Ignacio Chávez" *[1]Nephrology, Instituto Nacional de Cardiología, Mexico City, Mexico; [2]Instituto Nacional de Cardiologia, Mexico City, Mexico; [3]Instituto Nacional de Cardiología, México, Mexico.*

Background: Fluid Overload (FO) in Heart Failure (HF) is a major risk factor for morbidity and mortality.

Methods: The primary outcome of this study was to evaluate the safety and efficacy of Icodextrin for peritoneal ultrafiltration in Refractory HF (RHF) patients with FO and to assess the change in New York Heart Association (NHYA) Class, body composition measurement by electrical bio-impedance, length of hospital stay (LHS) and hospital costs (HC) in a 1 year follow up.

Results: we included a total of 6 patients with RHF and FO, table 1 shows baseline and post-intervention characteristics of participants. During the follow up we registered 1 episode of peritonitis and 1 mechanical dysfunction of peritoneal catheter. The median of LHS in one year previous treatment was 35 (RIC 23-50) vs 3 (RIC 2-25) days in 1 year follow-up (p 0.07). Also, a 1 year HC pre-intervention was $6,804.82 (RIC $4,308.62 - 11,579.14) vs $676.56 (RIC $420.69 –4,093.65) US dollars (p 0.06). At 6 months follow up we registered 2 deaths (34%).

Conclusions: we observed a better FO control and an improvement of symptoms (NYHA class), also a decrease of LHS and HC. The limitation of this study is the sample size but with a tendency towards statistical significance.

Pilot Study to Determine Whether Cooled Peritoneal Dialysis Confers Cardioprotective Effect

Shemer Ratner,[1] Aaron So,[2] Tanya Tamasi,[1] Christopher W. McIntyre.[1] *[1]London Health Sciences Centre, London, ON, Canada; [2]Lawson Health Research Institute, London, ON, Canada.*

Background: Despite lack of dialysis induced ischema (characteristic of hemodialysis), patients receiving peritoneal dialysis (PD) also suffer excess cardiac morbidity and mortality- driven by high rates of heart failure and sudden cardiac death. Currently there are no effective primary prevention therapies. Moderate hypothermia is well established in animal models to provide protection against demand ischemia. Furthermore, perfusion heterogeneity disrupts the passage of myocardial depolarization increasing the risk of ventricular re-entrant circuits. The aim of this study was to explore PD as a method of delivering a cooling intervention and test whether or not it could reduce segmental or global stress induced cardiac ischemia.

Methods: We studied 6 patients at 2 study visits. Myocardial perfusion was measured using high resolution 256 slice CT scanning at rest and with adenosine stress. The first visit was done on patients' usual PD regimen, second visit utilised peritoneal dialyzate cooled to 32-33 ^{0} C, to reduce body temperature by 0.5 ^{0} C. Myocardial Perfusion was assessed using the American Heart Association segmentation model with ANOVA test, and perfusion pattern heterogeneity was measured by standard deviation of segmental perfusion.

Results: Cooled dialysate was tolerated well by all patients. No symptoms of cold or drain pain were reported. Cooling significantly decreased rest and trended towards decreased stress global and segmental cardiac perfusion (mean values being 75.53 to 165.83 mL/min/100g). Pharmacological stress was associated with an increase in perfusion heterogeneity (mean increase in SD from 10.87 to 21.09). However, cooling the dialysate significantly reduced this effect by 25%.

Conclusions: Moderate hypothermia can be safely delivered using PD. It provides significant reduction in a potential key risk factor for cardiac sudden death and warrants further investigation to reduce cardiovascular attrition in PD patients.

TH-PO420

Lower Risk of Hospitalizations in Cardiorenal Patients Using Once-Nightly Icodextrin Peritoneal Exchanges

Ravleen K. Saini,[1] Jaibir Bhullar,[1] Shaheen Jadidi,[2] Anis A. Rauf,[4] Rayaan A. Rauf.[3] *[1]Avalon University School of Medicine, Youngstown, OH; [2]Midwestern University, Downers Grove, IL; [3]Advocate Good Samaritan Hospital, Downers Grove, IL; [4]Nephrology Associates of Northern Illinois and Indiana, Oakrook, IL.*

Background: The purpose of this study is to investigate the benefits of using a nightly icodextrin peritoneal dialysis (PD) solution in the cardiorenal (diuretic-resistant congestive heart failure) patient. Icodextrin is a glucose polymer that has been used as a replacement for the glucose traditionally used in the PD long dwells, as the oncotic pressure gradient can be maintained at adequate ultrafiltration (UF) values for 8-12 hours during sleep. Icodextrin-based solutions (ICO) are well tolerated, lack the metabolic side effects of glucose, and enhance the clearance of small and middle-sized molecules as a consequence of increased convective flow. Patients using one exchange nightly lead a more "normal" life when compared to patients using continuous cycling peritoneal dialysis (CCPD) with glucose solutions, as CCPD requires a nightly cycler apparatus which restricts the patient ability to ambulate at night.

Methods: This study provides data from a sample size of 11 individuals (9 males and 2 females) currently on once-nightly icodextrin peritoneal exchanges. Hospital admissions over an equal date range before and after starting extraneal dialysis treatment were compared.

Results: In our study, we observed that patients using once-nightly icodextrin exchange had fewer hospitalizations (p=0.0149), and reported an overall better quality of life after initiation of icodextrin peritoneal dialysis with decreased hospital admissions for CHF and progressive chronic kidney disease.

Conclusions: By augmenting UF in the cardiorenal patient with recurrent episodes of decompensated heart failure through once-nightly icodextrin exchanges, patients receive adequate clearance with preserved residual renal function as well as fewer hospitalizations. In addition, patients report more restful sleep and a better quality of life as a result of not being attached to a machine at night. They also enjoy being able to travel with their solutions delivered to their destination without having to carry a cycler.

TH-PO421

Association Between Use of Alpha-Blockers in Older Adults and Hypotension and Hypotension-Related Clinical Events

Swapnil Hiremath,[2] Marcel Ruzicka,[2] William Petrcich,[3] Gregory L. Hundemer,[4] Kevin D. Burns,[5] Cedric A. Edwards,[5] Amit X. Garg,[6] Manish M. Sood.[1] *[1]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]University of Ottawa, Ottawa, ON, Canada; [3]Institute for Clinical Evaluative Sciences, Ottawa, ON, Canada; [4]Massachusetts General Hospital, Arlington, MA; [5]The Ottawa Hospital - Riverside Campus, Ottawa, ON, Canada; [6]London Health Sciences Centre, London, ON, Canada.*

Background: Alpha- blockers (AB) are effective and commonly prescribed medications as part of a multi-drug regiment in the management of hypertension. Little is known regarding the risk of hypotension and hypotension-related clinical outcomes in older adults with ongoing AB use. We set out to assess the risk of hypotension and related adverse events with AB use compared to other anti-hypertensives in the older adults.

Methods: A population-based, retrospective cohort study of 933,033 older adults (≥ 66 years) prescribed an anti-hypertensive medication between 1995 and 2015 in Ontario, Canada. A high dimensional propensity score was used to match the dispensing of AB compared to other anti-hypertensives. AB exposure was modeled as a time-varying and cumulative covariate using extended, conditional Cox proportional hazards to examine the association with outcomes. Study outcomes were hospital admissions or emergency room visits for hypotension, related events (syncope, fractures, falls), major adverse

cardiovascular events (MACE) and all-cause mortality. We examined subgroups of age, total number of anti-hypertensives and concurrent beta-blocker use.

Results: Among 69,092 matched patients prescribed AB (mean age 75.1 SD 6.5 years) with a median follow up 3.7 (IQR 1.4 to 9.5) years, the incident rate of hypotension and related events were significantly higher compared to other anti-hypertensives (hypotension 1.15 vs. 0.39, syncope 1.47 vs. 0.46, falls 4.37 vs. 1.37, fractures 2.23 vs. 0.69 per 100 person-years of follow-up). In time-varying exposure models with additional adjustment for the total number of anti-hypertensives, the higher risk persisted (hypotension HR 1.34 95%CI 1.26-1.43, syncope HR 1.49 95%CI 1.41-1.57, falls HR 1.27 95%CI 1.23-1.32, HR fractures 1.41 95%CI 1.34-1.48). Secondary outcomes of MACE and all-cause mortality were higher or similar among AB users (MACE IR 7.03 vs. 2.31, mortality 6.54 vs 6.37 per 100 person-years follow-up).

Conclusions: Treatment of hypertension in older adults with AB is associated with a higher risk of hypotension, hypotension-related events and MACE. Our findings suggest that AB should be used with caution, even as add on therapy for hypertension in older adults.

TH-PO422

Beta Blocker (BB) Use Patterns at ESRD Transition and Mortality Outcomes Among Congestive Heart Failure (CHF) Patients Starting Hemodialysis (HD)

John J. Sim,[1] Hui Zhou,[2] Jiaxiao Shi,[2] Sally F. Shaw,[2] Ming-Sum Lee,[1] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh,[4] Steven J. Jacobsen.[2] *[1]Nephrology and Hypertension, Kaiser Permanente Los Angeles Medical Center, Pasadena, CA; [2]Kaiser Permanente Southern California, Pasadena, CA; [3]University of Tennessee Health Science Center, Memphis, TN; [4]University of California Irvine, School of Medicine, Orange, CA.*

Background: While BB have demonstrated benefit in CHF, there is uncertainty among HD pts. Comparative BB outcomes (beta selective, dialyzability, lipophilic) in the ESRD transition period are lacking; while studies on newly initiated BB after ESRD are conflicting and overall sparse. Among CHF patients on BB at ESRD transition, we evaluated BB use patterns and 1-year mortality.

Methods: A retrospective cohort study (1/1/2007-6/30/2016) within Kaiser Permanente Southern California (an integrated health system) of CKD patients with CHF who transitioned to HD while on BB. BB use and type [dialyzable (D) vs non dialyzable (ND)] were evaluated. Multivariable regressions were used to estimate 1-year mortality HR based on post ESRD transition BB use and type.

Results: A total of 2756 pts w CHF on BB transitioned to HD (age 68 yrs, 57% males, 31% whites, 23% blacks, and 34% Hispanics). Within 120 days post transition, 25% of pts discontinued BB, 38% were on D BB, and 24% were on ND BB. Post ESRD transition, 6.5% switched their BB dialyzable types (similar both directions). Mean blood pressure w/ in 120days post transition was 130/65mmHg but lowest among ND BB pts. Mortality rates were 126.5 (per 1000 person-yrs), 205.7, and 223.2 for D BB, ND BB, and pts off BB, respectively. 1-yr mortality HR's were 1.37 (1.07-1.74) and 1.66 (1.32-2.09) for ND BB and off BB compared to D BB pts. Carvedilol (ND) pts had a mortality HR of 1.32 (1.00-1.73) vs metoprolol (D).

Conclusions: Among CHF pts on BB who transitioned to HD, 25% discontinued BB while 6.5% switched BB dialyzability types. The highest short-term mortality were observed in pts off BB followed by ND BB compared to D BB. Given the vulnerable state of ESRD transition and the high-risk CHF ESRD population, BB use may be an area of focus to help improve ESRD transition outcomes.

TH-PO423

Use of Calcium Channel Blockers Before Dialysis until Dialysis Initiation Is Associated with All-Cause Mortality During Maintenance Dialysis

Daijo Inaguma, Yukio Yuzawa, Midori Hasegawa, Kazuo Takahashi. *Nephrology, Fujita Health University School of Medicine, Toyoake, Japan.*

Background: Angiotensin-converting enzyme inhibitors and angiotensin receptor blockers are reno-protective renin-angiotensin system blockade agents (RASBs) that are recommended for patients with chronic kidney disease (CKD), especially for diabetic nephropathy. However, a meta-analysis of CKD patients including those on dialysis demonstrated no significant difference in mortality between those on RASBs or calcium channel blockers (CCBs). Therefore, we examined whether the use of CCBs was associated with all-cause mortality and cardiovascular (CV) events in patients with incident dialysis.

Methods: The subjects were patients in 17 centers participating in the Aichi Cohort Study of Prognosis in Patients Newly Initiated into Dialysis between October 2011 and September 2013. We enrolled 1,520 subjects in the study. Baseline was defined as the time at which dialysis was initiated. Survival prognosis and incidence of CV events as of September 30, 2016, were determined from medical records. We classified patients into two groups according to the use of CCBs at the time of dialysis initiation: those who received CCBs (CCB group; n = 1,199) and those did not receive CCBs (non-CCB group; n = 321). Study outcomes included mortality and the incidence of CV events in the two groups. Factors contributing to all-cause mortality were examined using multivariate Cox proportional hazards regression analysis. In addition, we compared all-cause mortality stratified by use of RASBs.

Results: A log-rank test showed significant differences in all-cause mortality and the incidence of CV events between the two groups (p = 0.001 and p = 0.003, respectively). Multivariate stepwise Cox proportional hazards analysis revealed that all-cause mortality and the incidence of CV events were significantly lower in the CCB group than in the non-CCB group (hazard ratio [HR] = 0.62, 95% confidence interval [CI]: 0.46 – 0.85, p = 0.003 and HR = 0.74, 95% CI = 0.56 – 0.98, p = 0.037) (Table). All-cause mortality rates were significantly lower in the CCB group than in the non-CCB group among patients who did not receive RASBs (HR = 0.70, 95% CI: 0.52 – 0.95, p = 0.021).

Conclusions: The use of CCBs in patients before dialysis initiation was associated with reduction in all-cause mortality and CV events during maintenance dialysis.

TH-PO424

Effect of Aspirin on Cardiovascular Disease Outcomes in ALLHAT Participants with and Without CKD

Michael Bond,[1] Niraj Desai,[2,1] Brigid Wilson,[2,3] Mahboob Rahman.[1,2] *[1]Case Western Reserve University/University Hospitals Cleveland Medical Center, Cleveland, OH; [2]Louis Stokes Cleveland Department of Veterans Affairs Medical Center, Cleveland, OH; [3]Case Western Reserve University School of Medicine, Cleveland, OH.*

Background: Those with chronic kidney disease (CKD) are at increased risk of cardiovascular disease (CVD), as well as increased CVD-related and all-cause mortality. In the general population, aspirin is effective in the secondary prevention of CVD, for those at high risk of occlusive vascular events. For patients with CKD, however, it remains unclear whether aspirin is useful in either the primary or secondary prevention of CVD.

Methods: We performed a secondary analysis of the randomized controlled trial, Antihypertensive and Lipid-Lowering Treatment to Prevent Heart Attack Trial (ALLHAT) to assess the effect of baseline aspirin use on the initial primary endpoint, nonfatal myocardial infarction (MI), or fatal coronary heart disease (CHD) and secondary end points, all-cause mortality and stroke. Differences in baseline characteristics between subjects with and without aspirin use were examined and then used to generate a propensity-matched analysis population. Using conditional logistic regression models, we estimated the effect of aspirin on the outcomes. We created additional models testing for differences in the effect of aspirin across 3 levels of kidney function (eGFR $\geq$ 90, 60-89, and <60).

Results: The ALLHAT trial (n=33,537) contained 11,250 participants with complete data who reported using aspirin at baseline. There were significant differences in the race, sex, and cardiovascular disease history of aspirin versus non-aspirin users. The propensity-matched dataset included 6,894 non-aspirin users matched with replacement to aspirin users and achieved an analysis population (n=22,500) with balance across possible confounders. The risk of the primary study endpoint (OR = 0.98, 95% CI = 0.90-1.06) and stroke (OR = 0.92, 95% CI = 0.82-1.03), was not significantly different between aspirin users/non-users. Aspirin users were at significantly lower risk of all-cause mortality compared to non-users (OR = 0.75, 95% CI = 0.70-0.80). There were no significant interactions between aspirin and baseline eGFR kidney function for these three endpoints.

Conclusions: Aspirin use is not associated with decreased odds of non-fatal MI, fatal CHD or stroke but is associated with decreased odds of all-cause mortality for participants in the ALLHAT trial. These results are consistent across baseline eGFR.

Association of Hyperuricemia and Serum Uric Acid Lowering Medication with Mortality in Hemodialysis Patients

Benjamin Rohn,[2] Felix S. Seibert,[5] Nina Babel,[4] Frederic Bauer,[3] Timm H. Westhoff.[1] *[1]Ruhr-University Bochum, Germany, Herne, Germany; [2]Marien Hospital Herne, Herne, Germany; [3]Ruhr-University Bochum, Herne, Germany; [4]Ruhr University Bochum, Herne, Germany; [5]University Hospital Marien Hospital Herne, Herne, Germany.*

Background: In the general population hyperuricemia is associated with increased cardiovascular risk and mortality. It is unknown whether this association exists in hemodialysis patients as well and whether this population benefits from serum uric acid (SUA) lowering medication.

Methods: We performed a retrospective analysis of 601 patients on chronic hemodialysis therapy in five dialysis outpatient centers for a maximum follow-up of 100 months (mean follow-up 41 months). Death was defined as primary endpoint. Hyper- and normouricemic subjects differed in age. Therefore a Cox regression analysis adjusted for age was performed in addition to Kaplan Meier survival analyses.

Results: Kaplan Meier survival curves showed a higher cumulative survival rate for those subjects with a higher than median SUA concentration both based on mean annual SUA concentrations and baseline SUA concentrations (three months after the initiation of dialysis, p<0.05 each). Groups showed no significant difference in survival anymore after adjustment for age in Cox regression analyses (p>0.05 each). SUA lowering therapy (allopurinol or febuxostat) revealed no effect on cumulative survival, neither in Kaplan Meier nor in Cox regression analysis (p>0.05 each). Body mass index had no impact on

survival rates. There were 22 symptomatic gout attacks during the follow-up corresponding to an incidence of 1/93.3 patient years. Among those with prior symptomatic hyperuricemia (10.1% of overall population) 47.5% continued on medication, 52.5% discontinued. Only 6 subjects with prior symptomatic hyperuricemia developed additional gout attacks after the initiation of hemodialysis (1/342.2 patient years), all of them despite medication.

Conclusions: The present analysis shows that – in contrast to the general population – hyperuricemia is not associated with increased mortality in patients undergoing hemodialysis. A "reversed epidemiology phenomenon" of better survival with higher SUA concentrations disappears after adjustment for age. SUA lowering therapy is neither associated with a survival benefit nor a significant reduction of gout free patient years. These data indicate that SUA lowering medication might be dispensable after the initiation of dialysis.

TH-PO426

Association Between Warfarin Use and Clinical Outcomes in Late-Stage CKD Patients with Atrial Fibrillation

Manyoo Agarwal,[2] Praveen Kumar Potukuchi,[1] Adnan Naseer,[5] Miklos Z. Molnar,[1] Lekha K. George,[1] Santhosh K. Koshy,[3,1] Fridtjof Thomas,[1] Kamyar Kalantar-Zadeh,[4] Csaba P. Kovesdy.[5,1] *[1]University of Tennessee Health Science Center, Memphis, TN; [2]University of Tennessee Health Science Center, Memphis, TN; [3]Regional One Health - University of TN Health Sciences Ctr, Memphis, TN; [4]University of California Irvine, School of Medicine, Orange, CA; [5]Memphis VA Medical Center, Memphis, TN.*

Background: The effect of warfarin on clinical outcomes in late-stage chronic kidney disease (CKD) patients with atrial fibrillation (AF) is unclear.

Methods: We examined a national cohort of 23,201 US veterans with incident end stage renal disease (ESRD) who developed incident AF prior to initiating renal replacement therapy. We examined the association of warfarin therapy following the diagnosis of AF with cerebrovascular accidents (CVA) (ischemic stroke or transient ischemic attack), hemorrhagic strokes, post-dialysis fatal bleeding and all-cause mortality in multivariable adjusted time dependent Cox models adjusting for demographic characteristics and comorbidities.

Results: Patients were 77±9 year old, 95% male, 13% African-American, 99% hypertensive, 79% diabetic, and 88%, 88% and 64% had histories of ischemic heart disease, congestive heart failure and CVA, respectively. 5,632 (24.3%) patients received treatment with warfarin during the study period. As shown in the Table, the risk of all outcomes except all-cause mortality were higher in those exposed to warfarin when compared to those not exposed to warfarin. These differences in outcomes remained significant even after multivariable adjustment, except fatal bleeding events, which showed no significant associaiton (Table).

Conclusions: Warfarin use in advanced CKD is associated with higher risk of ischemic and hemorrhagic CVA, but lower risk of mortality after ESRD transition. Randomized controlled trials are needed to determine the risks and benefit of warfarin therapy in patients with incident AF and advanced CKD.

Funding: NIDDK Support, Veterans Affairs Support

	Overall (1000 patient years [95% CI])	No-Warfarin Exposure (1000 patient years [95% CI])	Warfarin Exposure (1000 patient years [95% CI])	Adjusted Hazard Ratio for Warfarin Exposure (95% CI)
All-cause mortality	469.7 [463.0-476.4]	496.2 [487.9-504.6]	416.3 [405.6- 427.4]	0.93 [0.90- 0.96]
Ischemic CVA	65.5 [64.3- 66.8]	61.6 [60.3-62.9]	97.7 [93.1-102.4]	1.39 [1.31- 1.48]
Hemorrhagic Stroke	8.6 [8.2 – 9.1]	7.6 [7.2-8.0]	15.5 [14.1-17.1]	1.52 [1.32- 1.75]
Fatal Bleeding Event	7.4 [6.6- 8.3]	8.1 [7.1-9.3]	6.1 [4.9-7.6]	0.86 [0.62 – 1.19]

Hyperkalemia and Renin-Angiotensin Aldosterone System Inhibitor (RAASi) Therapy in CKD: A General Practice-Based, Observational Study

Min Jun, Meg J. Jardine, Vlado Perkovic, Quentin Pilard, Laurent Billot, Anthony Rodgers, Kris Rogers, Martin P. Gallagher. *The George Institute for Global Health, UNSW, Newtown, NSW, Australia.*

Background: Data on hyperkalemia frequency among chronic kidney disease (CKD) patients receiving RAASis and its impact on subsequent RAASi treatment are limited. We sought to assess the incidence of clinically significant hyperkalemia in CKD patients who were prescribed a RAASi and the proportion of patients with RAASi medication change after experiencing incident hyperkalemia.

Methods: We conducted a retrospective, population-based cohort study (1 January 2013-30 June 2017) using Australian national general practice data from the NPS MedicineWise's MedicineInsight program. The study included adults aged ≥18 years who received ≥1 RAASi prescription during the study period and had CKD (estimated glomerular filtration rate [eGFR] <60 ml/min/1.73m^2). Study outcomes included incident clinically significant hyperkalemia (serum potassium >6 mmol/L or a record of hyperkalemia diagnosis) and among patients who experienced incident hyperkalemia, the proportion who had RAASi medication changes (cessation or dose reduction during the 210-day period after the incident hyperkalemia event).

Results: Among 20,184 CKD patients with a median follow-up of 3.9 years, 1,992 (9.9%) patients experienced an episode of hyperkalemia. The overall incidence rate was 3.1 (95% CI: 2.9-3.2) per 100 person-years. Rates progressively increased with worsening eGFR (e.g. 3.5-fold increase in patients with eGFR <15 vs. 45-59 ml/min/1.73m^2). Among patients who experienced incident hyperkalemia, 47% had changes made to their RAASi treatment regimen following the first occurrence of hyperkalemia (discontinuation: 37% and dose reduction: 10%). In the full multivariable model, higher levels of serum potassium at the time of the hyperkalemia event was significantly associated with a greater likelihood of medication change (per 0.1 mmol/L increase: odds ratio [OR] 1.05, 95% CI: 1.02-1.08).

Conclusions: In this analysis of adult RAASi users with CKD, hyperkalemia and subsequent RAASi treatment changes were common. Further assessment of strategies for hyperkalemia management and optimal RAASi use among people with CKD are warranted.

Funding: Other U.S. Government Support, Commercial Support - This study was funded by AstraZeneca Pty Ltd and commissioned by VentureWise (a wholly owned commercial subsidiary of NPS MedicineWise). The Feasibility of Interventions to Increase Potassium Intake for Hypertension: A Systematic Review of the Evidence

Maryam Zaree,[2] Marcel Ruzicka,[2] Swapnil Hiremath.[1] *[1]University of Ottawa, Ottawa, ON, Canada; [2]University of Ottawa Faculty of Medicine, Windsor, ON, Canada.*

Background: Increased potassium (K) intake has been reported to decrease blood pressure (BP) in animal studies as well as clinical trials. On this basis, major organizations including the American Heart Association recommend increasing K intake, preferably by diet, as a non pharmacological mean of reducing BP. However, it is not clear if the interventions for efficaciously increasing K intake are reproducible or feasible for translation into public health. Hence, we conducted a systematic review of the evidence to review this from randomized controlled trials (RCTs).

Methods: We conducted a literature search using an information specialist of MEDLINE, EMBASE and Cochrane CENTRAL till November 2017. Two reviewers selected RCTs that were in adults, with an intervention aimed at increasing K intake, with blood pressure as an outcome. From RCTs which reported both a significant change in BP and K using 24 hour urine K, we evaluated the interventions for ease of reproducibility and feasibility based on prespecified criteria.

Results: The initial search retrieved 1199 non-duplicate citations. After applying eligibility criteria, 90 studies were selected for inclusion. In 31 studies, the change in BP or K was not significant. Of the remaining 59 studies which reported a significant change in K and BP, 47 reported a change in K based on 24 hour urinary K measurement. 32/47 studies used a K supplement, with details provided on dose and administration to make it both reproducible and feasible. 15/47 studies used a dietary intervention, of which in 4, the intervention was not described in sufficient detail to be reproducible. The remaining 11 studies were feeding trials, with intervention consisting of provision of prepared meals, or of food items on a daily basis to make them unfeasible for routine clinical practice.

Conclusions: Dietary potassium interventions from trials in which there was a significant change in K based on 24 hour urine, and a significant change in BP, and which describe methods insufficient detail to be reproduced, are not feasible for routine clinical practice.

Variation in Use of Antihypertensive Medications After Kidney Transplant and Associated Outcomes: A National Study

Hala Yamout,[1,2] Rosemary Ouseph,[8] Mark Schnitzler,[13] Vikas R. Dharnidharka,[3] Abhijit S. Naik,[4] Ngan Lam,[5] Farrukh M. Koraishy,[6,1] Huiling Xiao,[7] Zidong Zhang,[6] Henry B. Randall,[12] Dorry L. Segev,[9] Bertram L. Kasiske,[10] Gregory P. Hess,[11] Krista L. Lentine.[6] *[1]Nephrology, VA St. Louis HealthCare System, Saint Louis, MO; [2]Nephrology, St. Louis University, Saint Louis, MO; [3]Washington University School of Medicine, St Louis, MO; [4]University of Michigan, Ann Arbor, MI; [5]University of Alberta, Edmonton, AB, Canada; [6]Saint Louis University, Saint Louis, MO; [7]St. Louis University, St. Louis, MO; [8]St Louis University, St Louis, MO; [9]Johns Hopkins University, Baltimore, MD; [10]Hennepin County Medical Center, Minneapolis, MN; [11]LDI University of Pennsylvania/Symphony Health, Conshohocken, PA; [12]SSM Health/SLUH, St. Louis, MO; [13]Saint Louis Univ, St Louis, MO.*

Background: Hypertension is a common comorbidity in kidney transplant (KTx) recipients. Impact of antihypertensive medication (AHM) regimen on patient and graft outcomes is not clear.

Methods: A novel database linking SRTR registry data for 54,153 KTx recipients with AHM fill records from a large pharmaceutical claims warehouse (2008-2015) was used. Mutually exclusive regimens were defined hierarchically as based in: Angiotensin converting enzyme inhibitor/angiotensin receptor blockers (ACEi/ARB), dihydropyridine calcium channel blockers (DHP-CCB), beta blockers (BB) and vasodilators/others. Associations (adjusted hazard ratio, $_{95\%\ LCL}$ aHR $_{95\%\ UCL}$) of AHM regimen 7-12 months post-transplant with patient and graft survival over 5 years were quantified by multivariate Cox regression with adjustment for recipient, donor and transplant factors, and clustering for center.

Results: The most common AHM post-transplant was DHP-CCB, followed by BB, ACEi/ARB, and diuretics. Regimen patterns varied by transplant centers (**Fig 1**). In bi-level hierarchical modeling, compared to DHP-CCB-based treatment, ACEi/ARB use was more common in those with diabetes, obesity, and mTORi-based immunosuppression.

Unadjusted survival varied with AHM treatment (**Fig 2**). Compared to DHP-CCB reference, adjusted mortality was higher in those on NDHP-CCB (aHR $_{1.11}1.24_{1.37)}$ and 'other' agents (aHR $_{1.11}1.24_{1.37}$, but lower in those on ACEi/ARB (aHR $_{1.44}1.69_{1.99}$).

Conclusions: While associations may in part reflect unobserved selection factors, controlled studies are needed to determine optimal AHM regimens after KTx, reduce unjustified practice variation, and inform evidence-based best practices.

Effect of Vitamin D Repletion on Cardiorenal Biomarkers and Vascular Function in a High-Risk African American Cohort

Satyesh K. Sinha,[2,1] Jae eun Lee,[3] Ling Sun,[1] Keith C. Norris,[1] Susanne B. Nicholas.[1] *[1]Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Charles R Drew University of Medicine and Science, Los Angeles, CA; [3]Jackson State Univerity, Madison, MS.*

Background: African Americans (AAs) suffer disproportionately from cardiovascular disease and chronic kidney disease (CKD), and eighty percent of AAs are vitamin D deficient. The effects of vitamin D on vascular and renal health in patients with CKD have been contradictory in part due to different study designs. We previously showed that vitamin D repletion significantly decreased markers of inflammation and oxidative stress in a high-risk cohort of AAs with controlled hypertension and preserved renal function. In this study, we examined the effect of vitamin D on c-terminal fibroblast growth factor-23 (cFGF23), plasminogen activator inhibitor-1 (PAI-1), and vascular and renal function in a subset of the cohort.

Methods: We performed a randomized, placebo-controlled study of high-risk AAs (N=65) with vitamin D deficiency treated with 100,000 IU vitamin D3 or placebo every 4 weeks for 12 weeks. We measured eGFR (MDRD) albumin-to-creatinine ratio (ACR), and quantified plasma cardiorenal biomarkers (cFGF23 and PAI-1 by ELISA) and determinants of vascular function (pulse wave velocity, augmentation index, ambulatory systolic and diastolic blood pressure). We performed multiple regression analysis controlling for the placebo-treated group to understand the relationship between FGF23 and PAI-1 with cardiovascular and renal risk factors.

Results: Vitamin D3 levels increased (p<0.0001) and iPTH levels decreased (p=0.0060) with vitamin D3 repletion. There was no change in systolic/diastolic blood pressure and no correlation between vitamin D3 repletion and levels of cFGF23 or PAI-1. However, logPAI-1 was associated with improved augmentation index (p=0.045) and a trend for improved ACR (p=0.074), and reduced PAI-1 levels were associated with improved eGFR (p<0.0300). There was a trend for reduced FGF23 with improved augmentation index (p=0.078); and for logcFGF23 with improved pulse wave velocity (p<0.069).

Conclusions: Vitamin D3 repletion may modulate vascular and renal function in AAs with controlled hypertension and vitamin D3 deficiency. Further study may provide a better understanding of the genetic predisposition of vitamin D repletion on vascular and renal function in high-risk AAs with vitamin D deficiency.

Clinical Factors Associated with Choice of Oral P2Y12 Inhibitors (P2Y) in Chronic Dialysis

Nishank Jain,[1,2] Deepa Raghavan,[2] Milind A. Phadnis,[3] Huizhong Cui,[3] Suzanne L. Hunt,[3] Jonathan D. Mahnken,[4] Theresa I. Shireman,[5] Rafia Rasu.[6] *[1]Little Rock VA Hospital, Little Rock, AR; [2]University of Arkansas for Medical Sciences, Little Rock, AR; [3]University of Kansas Medical Center, Kansas City, KS; [4]The University of Kansas Medical Center, Kansas City, MO; [5]Brown University School of Public Health, Providence, RI; [6]University of Kansas, Kansas City, KS.*

Background: Due to systematic exclusion of patients on chronic dialysis in P2Y clinical trials, risk factors associated with their choice remain unknown.

Methods: Using U.S. Renal Data System data, we identified dialysis patients who received new P2Y prescriptions, and analyzed trends in P2Y use and clinical risk factors associated with their choice using regression models.

Results: From 2011 to 2014, 36,590 ESRD patients received P2Y (95% clopidogrel, 3% prasugrel and 2% ticagrelor) with a proportional decrease in clopidogrel use, no change in prasugrel use and a proportional increase in ticagrelor use (p-for trend <0.0001, 0.61 and <0.0001). Median age was 64.0 years, 18% were ≥75 years, 54% men, 36% African American, 19% Hispanic and 93% on hemodialysis. History of atherosclerotic heart disease (ASHD) and thrombotic cardiovascular (CV) events were associated with choice of ticagrelor over clopidogrel [adjusted OR 5.43 (3.23, 9.15) and 2.13 (1.73, 2.62)] and prasugrel over clopidogrel [10.24 (6.66, 15.74) and 1.88 (1.63, 2.16)]. Severity of comorbidities and presence of diabetes mellitus were not associated with P2Y choice. Of the clinical events occuring 90-days prior to the index date of P2Y, percutaneous coronary intervention was the strongest independent factor favoring ticagrelor over others, adjusted OR 10.21 (8.09, 12.89) and 1.75 (1.32, 2.30).

Conclusions: Ticagrelor has gained popularity while prasugrel use remained unchanged in dialysis patients. In the absence of outcomes data in dialysis patients, clinicians favored use of ticagrelor over other P2Ys when patients had history of ASHD or CV events or were undergoing coronary revascularization. These findings suggest presence of channeling bias in prescribing P2Y to this patient population.

TH-PO432

48-Hour Ambulatory BP (ABPM) Monitoring and the Estimated Risk of Death in the Hemodialysis Population: A Multicenter, International Study

Francesca Mallamaci. on behalf of the TACTIC study working group* *G.O.M. Bianchi Melacrino Morelli Reggio Calabria, Reggio Calabria, Italy.*

Background: ABPM extended to 44h or 48h has been proposed by consensus documents by the ASN and the ESH and the ERA-EDTA (EURECAm) as the ideal metric for estimating the BP-related health burden in ESRD but information on the relationship between this metric and the risk of death is still restricted to a limited number of single center studies.

Methods: We investigated the relationship between 48h ABPM and the probability of death as estimated by the ARO risk score in a cohort of 278 hemodialysis patients in 7 centers in 3 European countries. The ARO risk score is a well-validated instrument based on 14 risk factors for death specific to the hemodialysis population (KI 87, 996–1008, 2015).

Results: Average 48h diastolic BP robustly correlated in an inverse fashion with the estimated risk of death at 1 year (r=-0.350, P<0.001) and at 2 years (r=-0.331, P<0.001) and these associations were confirmed in separate analyses of day-time and night-time average values (P<0.001). Furthermore, 48h pulse pressure was a direct predictor of the estimated death risk at 1 year (r=0.330, P<0.001) and at 2 years (r=0.293, P<0.001) and again this metric predicted the estimated risk of death in separate analyses of day and night time recordings.

Conclusions: In a multicenter study in 3 countries 48h diastolic and Pulse Pressure correlated strongly with the estimated risk of death and this was true for both average daytime and night-time values. Extended ABPM recordings reflect the health burden of BP in the hemodialysis population. *Torino C, Sarafidis PA, Ekart R, Loutradis C, Karpetas A, Raptis V, Bikos A, Papagianni A, Balafa O, Siamopoulos K, Pisani G, Morosetti M, Del Giudice A, Aucella F, Di Lullo L, Battaglia G, Tripepi R, Tripepi G, London G, Zoccali C.

Ambulatory Blood Pressure Monitoring: Assessing Capacity and Practice Patterns of the Improving Renal Outcomes Collaborative (IROC)

Charles D. Varnell,[1] Devesh S. Dahale,[2] David K. Hooper.[1] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Cincinnati Childrens Hospital Medical Center, Cincinnati, OH.*

Background: Ambulatory Blood Pressure Monitoring (ABPM) is recommended for assessment of hypertension in patients with a kidney transplant (KTx) and/or chronic kidney disease (CKD). IROC is a multicenter learning health system comprised of patients and families, clinicians, and researchers from 23 pediatric nephrology centers, working together to improve health of patients with kidney disease.

Methods: 23 IROC centers were surveyed from July to December 2017 and asked to report the number of transplant and CKD patients under their care, their center's protocol for ABPM, ABPM unit availability vs need, ABPM return mechanism, challenges and barriers to performing ABPM.

Results: All centers responded to the survey and cumulatively care for approximately 4256 CKD and 2497 KTx patients. There were an average (std dev) of 109 (+/- 51) KTx and 224 (+/- 114) CKD patients at each center. 17 (74%) centers report intending to use the IROC protocol: yearly if last ABPM was abnormal OR every 3 years if last ABPM was normal for patients ≥ 7 years old and 1 year post-transplant. One center reported once a year screening regardless of last ABPM result. Five centers reported using other protocols. With regard to ABPM device needs, 16 (70%) of centers report a shortage of units, 1 center reports just enough units, and 6 (26%) of centers report excess units. The majority of centers (20/23, 87%) report ABPM devices are returned by the patient or through courier/postal service. The main barriers to performing ABPM per protocol are insurance approval, workflow, and shortage of ABPMs.

Conclusions: Three-quarters of IROC centers plan to use the recommended IROC ABPM protocol, however many centers report a shortage of ABPM units for the number of patients cared for. In order to decrease the negative impact of barriers to performing ABPM according to recommendations and standards, structured quality improvement is underway to optimize workflow and utilization of existing ABPM units.

TH-PO434

Magnitude of the Difference Between Clinic and ABPM BPs Predicts Mortality Risk

Elaine Ku,[1] Raymond K. Hsu,[1] Delphine S. Tuot,[1] Se ri Bae,[1] Michael S. Lipkowitz,[2] Barbara A. Grimes,[1] Matthew R. Weir.[3] *[1]University of California, San Francisco, San Francisco, CA; [2]Georgetown University Medical Center, Washington, DC; [3]University of Maryland School of Medicine, Baltimore, MD.*

Background: Ambulatory blood pressure (ABP) monitoring is recommended for the detection of masked and white coat hypertension in patients with CKD. Our objective was to determine whether the magnitude of the difference between ambulatory and clinic BP's has prognostic implications.

Methods: We examined data from 610 participants of the African American Study of Kidney Disease and Hypertension (AASK) Cohort Study, who had completed the AASK Trial and had both clinic BP and ABP performed at Cohort entry. We performed multivariable Cox proportional hazards models to determine the association between absolute systolic BP (SBP) difference between clinic and awake ABPs with death.

Results: Mean age was 61 years, 38% were female, and mean eGFR was 39. During median follow-up of 10 years, 33% died; 30% developed ESRD. The association between the clinic-awake SBP difference and risk of death is shown in Figure1 and Table1. Higher clinic-versus-awake SBP (white coat phenomenon) was associated with higher mortality risk compared to 0-5mm Hg clinic-awake SBP difference. A ≤ -5 mmHg lower clinic-versus-awake SBP (masked phenomenon) was also associated with higher mortality. Additonal adjustment for clinic SBP or ambulatory SBP did not change these findings.

Conclusions: Our data revealed a U-shaped, independent association between the magnitude of the difference between clinic and ambulatory SBP and mortality in black patients with CKD. Further studies are needed to examine whether interventions to lower clinic-ABP differences will improve patient outcomes.

Funding: NIDDK Support

Difference between clinic and mean awake ABP and long-term risk of death

Absolute SBP difference between clinic BP and awake ABP	N	Unadjusted Model	Adjusted Model*
"White Coat Effect"			
≥ 10 mm Hg	104	2.30 (1.27-4.18)	2.31 (1.27-4.22)
5 to <10 mm Hg	58	2.07 (1.07-4.02)	1.84 (0.94-3.56)
0 to <5 mm Hg	77	Reference	Reference
"Masked Effect"			
-5 to <0 mm Hg	91	1.04 (0.54-2.02)	1.15 (0.59-2.24)
≤ -5 mm Hg	280	1.82 (1.06-3.13)	1.82 (1.05-3.15)

Office Blood Pressure Measurement (OBPM) in Children: The SPA Project

Gianluigi Ardissino,[1] Silvia Ghiglia,[5] Sebastiano A. Lava,[3,1] Selena Longhi,[1] Laura Martelli,[1] Michela Perrone,[1] Patrizia Salice,[4] Sandra Piantanida.[2] The SPA Project *[1]Center for HUS Prevention, Control and Management, Milano, Italy; [2]Polo Materno Infantile- Ospedale F. del Ponte - Varese, COMERIO, Italy; [3]University Children's Hospital, Inselspital, Bern, Switzerland; [4]Fondazione Policlinico IRCCS Ca' Granda Milano, MILANO, Italy; [5]Cardiology Unit. Ospedale Policlinico, MILANO, Italy.*

Background: If blood pressure (BP) measurement still remains challenging in adults, it is even more in children. Current guidelines suggest to measure office BP with three readings and average them when the first BP is elevated otherwise to perform only one BP reading (AAP 2017) or to measure BP 3 times every 3 min using the average of the last two (ESH 2016).

Methods: Since 2010, we regularly perform unattended multiple OBPM (mOBPM) with a validated (OMRON M3) device: after 5 min rest, at least 10 automated readings are taken every 3 min on the non-dominant arm. Readings <5th or >95th centile and mOBPM with coefficient of variation (CV)>15% are discarded.

Results: 286 healthy, non-obese children (141 females; median BMI 15.4 Kg/m2 IQR 14.5-16.4), median age 5.7 (IQR 5.3-6.1) years, were analyzed. The median CVs of included mOBPMs were 7% (IQR 5-9) for systolic and 4% (IQR 3-6) for diastolic BP. The readings #1-10 were compared with the mean of all 10 measurements (Wilcoxon matched-paired-signed-rank-test, significance assigned at $p<0.01$). The first 3 measurements were significantly different from the mean, while the readings #4-10 were not. Based on the mean, only 11 subjects had a systolic or diastolic BP >90th centile (n=5 >95th c.le) while single measurement significantly over-estimated high BP (Fig.1).

Conclusions: Although most guidelines advice ≥2 BP readings, these findings suggest that mOBPM should include ideally 10, but at least 4 repeated measurements.

Multiple Spot Urine Sampling Is More Precise, Accurate, and Simpler Compared to 24-Hours Collection for Estimating Sodium Excretion

Gianluigi Ardissino,[1] Selena Longhi,[1,2] Laura Martelli,[1,3] Antenore Giussani,[8,1] Giovanni R. Pieri,[6,1] Patrizia Salice,[10] Roberto Romano,[9] Marta Brambilla,[5] Michela Perrone,[1] Francesca Tel,[1,4] Florjan Mehmeti,[7,1] Silvia Ghiglia.[11] *[1]Center for HUS Prevention, Control and Management, Milano, Italy; [2]Università degli Studi Milano Bicocca, Milano, Italy; [3]Ospedale Papa Giovanni XXIII, Bergamo, Bergamo, Italy; [4]Ospedale dei Bambini V.Buzzi, MILANO, Italy; [5]Università degli Studi di Milano, Italy, MILANO, Italy; [6]IRCCS San Matteo Pavia, Lacchiarella, Italy; [7]Pediatric Nephrology and dialisys unit, Milano, Italy; [8]Fondazione IRCCS Cà granda policlinico Milano, Milano, Italy; [9]Università degli Studi di Milano, Campobasso, Italy; [10]Fondazione Policlinico IRCCS Ca' Granda Milano, MILANO, Italy; [11]Cardiology Unit. Ospedale Policlinico, MILANO, Italy.*

Background: The estimate of Sodium (Na) intake is of important for monitoring hypertensive patients on Na restriction. 24 hours urinary collection (24-hrsUC) is inaccurate because of errors in time and/or volume measuring. In addition, the urinary collection is unpractical and often done during weekends thus is not representative of the usual Na intake. Since spot urine sampling (SUS) is not affected by any of the above mentioned sources of error, we hypothesized that the mean urinary Sodium-to-urinary Creatinine ratio (uNa-to-uCrR) of multiple SUS, collected in different days, is more precise and accurate for estimating the average Na excretion compared to 24-hrsUC.

Methods: A total of 301 urine samples (1 for each voiding) and the related 52 24-hrsUC performed in different days in 10 heathy subjects (age range 3-65, 6 females, up to 11 voidings per day) were collected. For the purpose of comparison, uNa excretion in mEq/Kg/day from each sample was derived multiplying by 2 each uNa-to-uCrR (the mean conversion constant obtained from all ratios as determined from 24-hrsUCs). We calculated Lin's correlation coefficient, mean bias, and 95% limits of agreement (LOA), of uNa for: 1) The single 24-hrsUC, using the individual overall 24-hrsUC average as reference; 2) 1000 random samples of means of 4 spot urine samples (1 per subject in 4 different days) using the individual overall 24-hrsUC average as reference. Statistical analysis was performed using Stata 15.

Results: 1) The single 24-hrs-UC urine collections showed a Lin's coefficient of 0.78, with 95% limits of agreement (LOA) of +1.39 mq/Kg/die (difference between upper and lower LOA: 2.78). 2) In the 1000 random samples the average Lin's coefficient was 0.82. Difference between upper and lower LOA was smaller than 2.78 in 58.2% of samples.

Conclusions: Sodium excretion can be estimated, on average, more precisely, accurately and practically, as the mean of 4 uNa-to-uCrR in different days, then with a single 24-hrsUC. In details the mean of 4 spot samples (expressed as mean ((uNa-to-uCr) x 2) will provide a more reliable estimate (in mEq/kg/day) in as many as 58% of determinations.

TH-PO437

Evaluating Blood Pressure Control in a VA Renal Clinic: A Performance Improvement (PI) Initiative

Maryyam Ali,[1] Yoav Segal,[2,1] Ashish Malhotra,[2] Scott Reule.[2,1] *[1]U of MN Renal Division, Minneapolis, MN; [2]Minneapolis VAMC, Minneapolis, MN.*

Background: The suboptimal control of hypertension in adult Americans highlights a major need for performance improvement activities at the practice level to achieve better blood pressure (BP) control and meet national benchmarks. We evaluated factors associated with poor BP control among hypertensives referred to our Veterans Administration Renal Clinic with the goal of defining potential correctable characteristics of the persistently hypertensive patient. This abstract presents the data of our baseline assessment - the essential first step in a PI initiative.

Methods: *Study cohort*: Veterans followed at the Renal Clinic in September 2017, including new consults and follow-up appointments. *Site:* VA Health Care System, Minneapolis, Minnesota *Study Type:* Retrospective, as a part of PI initiative *Methodology*: Manual review of medical records beginning September 2017. Patient follow-up: 3 months *Data recorded*: Demography, co-morbidities and medications control of BP defined by JNC 8 guidelines as a core clinical metric, unless a different goal was documented by the provider. *Statistics*: Chi-square analysis for unadjusted comparisons of patients by BP control and logistic regression for odds ratio (OR) calculations.

Results: A total of 105 veterans were included in the final study cohort. Compared to those not achieving goal BP (n = 55), those achieving BP goal (n = 50) had an average BP of 129/75 mmHg (vs. 151/82 mmHg) with a mean age of 68.2 years (vs. 69.8 years). The average medication number was 3.1 (vs. 2.4). Those not achieving BP goal during follow-up period were less likely to receive any intervention (43.6% vs. 68%; OR 0.36) and more likely to remain uncontrolled on subsequent clinic follow up (81.8% vs. 40%; OR 6.67). No significant differences by comorbidity or individual provider were observed.

Conclusions: Veterans not achieving BP goals in Renal Clinic were less likely to receive any intervention, a finding that did not vary by comorbidity. This data signifies a preliminary step to design future quality improvement interventions to identify high-risk groups and direct efforts to improve our population-level cardiovascular outcomes.

What New Guideline Brought to Turkish Hypertension Profile?

Serpil muge Deger,[1] Ulver Derici,[3] Sukru Sindel,[3] Sule Sengul,[2] Mehmet T. Akpolat,[5] Yunus Erdem,[6] Mustafa Arici,[7] Oktay Karatan,[2] Cetin Turgan,[4] Enver Hasanoglu,[3] Sehsuvar Erturk,[2] Sali Caglar.[4] *[1]Nephrology, Yuksek ihtisas University Faculty of Medicine, ANKARA, Turkey; [2]Ankara University School of Medicine, Ankara, Turkey; [3]Gazi University Faculty of Medicine, ANKARA, Turkey; [4]Hacettepe University Faculty of Medicine, ANKARA, Turkey; [5]Liv Hospital ULUS-ISTANBUL, ISTANBUL, Turkey; [6]Hacettepe University Faculty of Medicine, ANKARA, Turkey; [7]Hacettepe University Medical Faculty, Sihhiye-Ankara, Turkey.*

Background: 2017 ACC/AHA guideline lowered the numbers for the diagnosis of HT to 130/80 mmHg for adult population with the aim for the early diagnosis of life threatening complications of HT such as heart attack and/ or stroke. Turkey is a developing Euroasian country with the population of 82 million and has dominance of relatively younger age. Although, young population is predominating, cardiovascular disease is still major public health concern in Turkey. In 2003, the first large sample sized (n=4910) epidemiological study (PatenT study) showed the prevalence of HT as 31.8% in Turkey. After nine years, PatenT 2 trial showed prevalence of hypertension as 30.3 %.This study aimed to determine to assess current epidemiology of hypertension including, prevalence, awareness and control rates among Turkish adults, using criteria from the 2017 ACC/AHA guideline and the Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC7).

Methods: We analyzed data from PatenT 2 study (n= 5437). Blood pressure measurements were performed three times and awareness and treatment were assessed by self-reporting and control was defined as SBP/DBP less than 140/90 mmHg.

Results: According to the 2017 ACC/AHA and JNC7 guidelines, the crude prevalence of hypertension among Turkish adults was 48.4% and 30.3%, respectively and the awareness rate of the hypertension diagnosis was 34.2 % and 54.7 %, respectively. The control rate in hypertensives was 28.7 % according to the JNC 7, 17.9 % according to the 2017 ACC/AHA guideline.

Conclusions: Compared with the JNC7 guideline, the 2017 ACC/ AHA guideline results in a considerable increase in the prevalence of hypertension and substantial decrease in control rates and awareness of hypertension in Turkish adults.

New Guidelines Shift Prevalence of Elevated Blood Pressure (BP) Among US Adults Both with and Without CKD

Joanne E. Rodrigue,[2] Tanushree Banerjee,[6] Kirsten L. Johansen,[1] Jennifer L. Bragg-Gresham,[4] Sharon Saydah,[5] Nilka Rios Burrows,[5] Rajiv Saran,[4] Neil R. Powe.[3] *[1]University of California, San Franicsco, San Francisco, CA; [2]University of California San Francisco, San Francisco, CA; [3]Priscilla Chan and Mark Zuckerberg San Francisco Gen Hosp & UCSF, San Francisco, CA; [4]University of Michigan, Ann Arbor, MI; [5]Centers for Disease Control and Prevention, Atlanta, GA; [6]San Francisco General Hospital, San Francisco, CA.*

Background: In 2017, the American College of Cardiology/American Heart Association (ACC/AHA) published guidelines that redefine criteria for hypertension (HTN) using a lower threshold of BP. We sought to determine the number of individuals reclassified as having HTN by prior treatment with antihypertensive medication (Rx) and presence or absence of CKD.

Methods: We used National Health and Nutrition Examination Survey data (1999-2014) to estimate the total number of non-pregnant adults aged ≥20 years who would have been reclassified from having pre-HTN (systolic BP [SBP] 120-139 mmHg) per the 2003 Seventh Report of the Joint National Committee (JNC7) BP guidelines to having elevated BP (SBP 120-129 mmHg) or stage 1 HTN (SBP 130-139 mmHg) per 2017 ACC/AHA definitions. BP measures were averaged from three readings taken during medical examination, and medication use was obtained from the household interview. We further examined the number of people with and without CKD having HTN status reclassified. CKD was defined as having an estimated glomerular filtration rate (eGFR) between 15-59 ml/min/1.73m^2 or eGFR ≥60 mL/min/1.73m^2 with urine albumin to creatinine ratio ≥30 mg/g.

Results: About two-thirds of people initially defined as having pre-HTN in the JNC7 were reclassified to stage 1 HTN according to the ACC/AHA guidelines. The proportion was similar among individuals with and without CKD; among those receiving and not receiving pharmacologic treatment for HTN; and over time. This represents approximately one-quarter to one-third of all adults with CKD (28 M; 16 M on Rx) or without CKD (173 M; 36 M on Rx).

Conclusions: According to the latest guidelines, during the period 1999-2014, a large proportion of people would have been reclassified from pre-HTN to stage 1 HTN. In addition, these results suggest that the new guidelines may stimulate intensification of therapy for individuals already being treated for HTN, whether or not they have CKD.

Funding: Other U.S. Government Support

Pre-HTN Reclassified by New BP Guideline n (% of 201M U.S. adults)

Survey Years	Treated with Rx		Not Treated with Rx	
1999-2014	Elevated BP	Stage 1 HTN	Elevated BP	Stage 1 HTN
CKD	2 M (14.7)	4 M (28.5)	2 M (14.5)	4 M (29.5)
No CKD	6 M (17.6)	12 M (34.2)	22 M (15.9)	32 M (23.1)

Applying the New Intensive Blood Pressure Categories to Non-Dialysis CKD Population from PATRIOTIC Survey

Ying Zheng, Weiguang Zhang, Guangyan Cai, Xiangmei Chen. *Chinese PLA General Hospital, Beijing, China.*

Background: The 2017 high blood pressure clinical practice guideline reported by the American College of Cardiology/American Heart Association put forward new categories of blood pressure (BP). This study aimed to assess the applicability of the new guideline in non-dialysis chronic kidney disease (CKD) population.

Methods: This is a nationwide, multicenter, cross-sectional study with a large sample. A total of 8927 non-dialysis CKD patients in 61 tertiary hospitals in all 31 provinces, municipalities, and autonomous regions of China (except Hong Kong, Macao, and Taiwan) were analyzed. The categories of BP were defined as normal BP (<120/80 mmHg), elevated BP (systolic BP 120–130 mmHg and diastolic BP <80 mmHg), and stages 1 (systolic BP 130–139 mmHg or diastolic BP 80–89 mmHg) and stage 2 (systolic BP ≥140 mmHg or diastolic BP ≥90 mmHg) hypertension. The prevalence and control of hypertension were estimated using a new definition, and the association between the main target organs' injury and new categories of BP was analyzed.

Results: The prevalence, awareness, and treatment of hypertension in non-dialysis CKD patients were 79.8%, 72.4%, and 68.3%, respectively. Approximately 11.9% had BP <130/80 mmHg, and 6.6% had BP <120/80 mmHg. Subgroups via categories of BP had significant difference in age, sex, body mass index (BMI) categories, primary causes, and CKD stages (P <0.001). After multivariable adjustment, only stage 2 hypertension was associated with decreased renal function (odds ratio [OR] 2.4, 95% confidence interval [CI] 1.9–3.0, P<0.001), cardiovascular disease (OR 2.0, 95% CI 1.3–3.1, P=0.001), and cerebrovascular disease (OR 2.7, 95% CI 1.2–5.8, P=0.015).

Conclusions: Using the new definition of hypertension, the higher prevalence and lower control of hypertension were shown in non-dialysis CKD participants. More studies are necessary to confirm the applicability of new categories of BP in CKD population because only stage 2 hypertension showed statistical association with the main target organs' injury.

TH-PO441

Screening and Management of Albuminuria in a Large Integrated Health System

Waleed Zafar,[1] Jamie A. Green,[2] Ion D. Bucaloiu,[2] Alex R. Chang.[2] *[1]Geisinger, Dnville, PA; [2]Geisinger Medical Center, Danville, PA.*

Background: Kidney Disease Improving Global Outcomes (KDIGO) guidelines recommend albuminuria screening in patients with hypertension or diabetes for appropriate risk stratification. Little is known about factors associated with adherence to KDIGO-recommended treatment goals for patients with albuminuria.

Methods: We used data from 212,068 adults ≥ 18 years of age with eGFR ≥ 15 ml/min/1.73m^2, who were seen by a primary care provider between 2015-2016 in a large, integrated health system. Patients were categorized as having severely increased albuminuria per KDIGO guidelines (ACR 300+ mg/g, PCR 500+ mg/g, or urine dipstick 1+), using quantitative tests if available. We then examined associations between sociodemographic and clinical factors with attainment of KDIGO-recommended goals [renin-angiotensin-aldosterone system (RAAS) inhibition, blood pressure (BP) goal <130/80, and statin treatment] in patients with severely increased albuminuria.

Results: Mean age was 55.2 years, 55.7% were female, 19% were current smokers, and 13.0% had baseline eGFR < 60 ml/min/1.73m^2. Among 87193 patients with hypertension, 70.5% were screened using any method, 41.3% were screened with ACR or PCR, and 9.9% had severely increased albuminuria. Among 33655 patients with diabetes, 91.3% were screened using any method, 82.9% were screened with ACR or PCR, and 10.4% had severely increased albuminuria. Of the 22153 patients with 1+ or greater protein on dipstick, only 40.2% also completed an ACR or PCR. Adherence to KDIGO-recommended goals was low in severely albuminuric patients (30.8% taking RAAS inhibitors, 33.8% taking statins, 48.2% with clinic BP <130/80); only 7.8% achieved all 3 goals. Factors associated with attainment of all 3 KDIGO-recommended goals in severely albuminuric patients included older age, cardiovascular risk factors, cardiovascular disease, and quantitative protein testing (Table). CKD was not associated with attainment of these goals.

Conclusions: Adherence to KDIGO guidelines for albuminuria remains suboptimal. Future research is needed to improve screening and management of albuminuria.

Funding: NIDDK Support

Factors associated with Achievement of KDIGO-recommended Goals (RAAS inhibition, statins, clinic BP < 130/80) in 17,121 patients with severely increased albuminuria

	Adjusted odds ratio (95% confidence interval)	p-value
Male	1.11 (0.98-1.25)	0.10
Age 60 years or older	1.58 (1.36-1.84)	<0.01
Current or former smoker (compared to never smoker)	1.14 (1.00-1.29)	0.04
Hypertension	4.39 (3.49-5.52)	<0.01
Diabetes	1.45 (1.24-1.70)	<0.01
Dyslipidemia	4.77 (3.83-5.93)	<0.01
Myocardial infarction	1.53 (1.24-1.88)	<0.01
Stroke	1.25 (1.05-1.49)	0.01
Congestive heart failure	1.21 (1.03-1.43)	0.02
eGFR less than 60 ml/min/1.73 m^2 at baseline	1.04 (0.88-1.22)	0.43
Any protein quantification (ACR or PCR)	1.21 (1.03-1.42)	0.02

CKD Screening Rate and Blood Pressure (BP) Control in Veterans with Hypertension

Shweta Bansal,[1,3] Luci Leykum,[2] Jacqueline Pugh.[4] *[1]University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]General Internal Medicine, UTHSCSA, SAN ANTONIO, TX; [3]Renal Section, STVHCS, San Antonio, TX; [4]STVHCS, SAN ANTONIO, TX.*

Background: Hypertension (HTN) control is a key strategy to prevent CKD progression. Earlier recognition of CKD (by eGFR and albuminuria) and volume optimization using diuretics are important to achieve adequate BP control. Prevalence of CKD is a third higher in Veterans; however, CKD screening rate in hypertensive Veterans, HTN control and utilization of diuretics in Veterans with CKD is unclear.

Methods: We analyzed Veterans Integrated Service Network corporate Data Warehouse for Veterans seen at least twice in primary clinics with ICD-9 codes for HTN and diabetes. The Final cohort of 241,235 subjects was examined for serum creatinine/eGFR reported at least twice 90 days apart, urine protein and ICD-9 for CKD. BP readings from last two clinic visits were averaged to evaluate the HTN control.

Results: Ten percent of final cohort did not have any CKD screening procedures. Figure 1 shows the percentage of hypertensive subjects with (N=92,129) or without diabetes (N=128,099) with available serum creatinine or urine protein measurements or both. CKD (eGFR<60 ml/min and/or ACR>30mg/g) was present in 27.2% subjects but only 6% had CKD ICD-9 code in the chart. Table 1 demonstrates the HTN control and baseline characteristics in these 27.2% subjects.

Conclusions: While hypertensive Veterans get eGFR checked, identification of albuminuria is suboptimal and despite screening procedures the recognition of CKD is low. Only one third CKD Veterans had BP <130/80 mmHg and 29% were on diuretics. These results warrant exploration of factors responsible for these low rates and design interventions to address those factors to improve HTN control.

Prediction Model for Cardiovascular Death Including Proteinuria and Estimated Glomerular Filtration Rate in a General Population

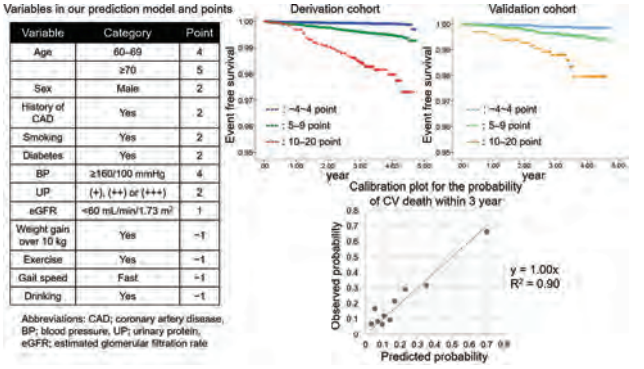
Masatoshi Nishimoto,[1] Miho Tagawa,[1] Kazuhiko Tsuruya,[1] Masaru Matsui,[1] Masahiro Eriguchi,[1] Ken-ichi Samejima,[1] Kunitoshi Iseki,[2] Chiho Iseki,[2] Koichi Asahi,[2] Kunihiro Yamagata,[2] Tsuneo Konta,[2] Shouichi Fujimoto,[2] Ichiei Narita,[2] Masato Kasahara,[2] Yugo Shibagaki,[2] Toshiki Moriyama,[2] Masahide Kondo,[2] Tsuyoshi Watanabe.[2] *[1]Nara Medical University, Kashihara, Japan; [2]Steering Committee of Research on Design of the Comprehensive Health Care System for Chronic Kidney Disease (CKD) Based on the Individual Risk Assessment by Specific Health Check, Fukushima, Japan.*

Background: There are several prediction models for coronary or cardiovascular (CV) events, some of which include estimated glomerular filtration rate (eGFR). However, there has been no prediction model for CV death that includes proteinuria and eGFR.

Methods: This was a longitudinal cohort study. Inclusion criteria was subjects aged 40–74 years in a Japanese nationwide Specific Health Checkup database in 2008. Exclusion criteria were subjects with missing data. The exposures of interest were demographics, comorbidities, blood pressure, laboratory data, and lifestyle factors. Outcome variable was CV death. Subjects were randomly assigned to derivation and validation cohorts by 2:1 ratio. Points for prediction model were determined based on regression coefficients derived from the Cox proportional hazards model in the derivation cohort. The model was validated by Kaplan-Meier curves and calibration plot in the validation cohort.

Results: Among 295,297 subjects, data for 120,823 were available for analysis (80,549 and 40,274 in the derivation and validation cohorts, respectively). During a mean follow-up of 3.6 years, there were 204 and 106 CV deaths in the derivation and validation cohorts, respectively. Proteinuria and eGFR were significantly associated with CV death and were included in the model. Other variables included in our prediction model were shown in the figure. Kaplan-Meier curves of 3 risk groups defined by points in the prediction model were matched between the derivation and the validation cohorts, and calibration plot was well calibrated ($y = 1.00x$, $R^2 = 0.90$).

Conclusions: Our prediction model for CV death including proteinuria and eGFR was well calibrated. External validation in another cohort is required before clinical use.



TH-PO444

Prevalence of Cardiovascular Risk Factors and Association with CKD in sub-Saharan Africa

Timothy O. Olanrewaju,[1] Charlotte Osafo,[2] Manmak Mamven,[3] Titilayo O. Ilori,[4] Yemi R. Raji,[5] Fatiu A. Arogundade,[6] Ifeoma I. Ulasi,[7] Rasheed A. Gbadegesin,[8] Rulan S. Parekh,[9] Adebowale A. Adeyemo,[10] Babatunde L. Salako,[11] Dwomoa Adu,[12] Akinlolu O. Ojo.[13] H3Africa Kidney Disease Research Network Investigators *[1]University of Ilorin and University of Ilorin Teaching Hospital, Ilorin, Nigeria; [2]University of Ghana Medical School, Accra, Ghana; [3]University of Abuja, Abuja, Nigeria; [4]Emory University School of Medicine, Chandler, AZ; [5]University of Ibadan and University College Hospital, Ibadan, Nigeria; [6]Obafemi Awolowo University / Teaching Hospitals Complex, Ile-Ife, Nigeria; [7]College of Medicine, University of Nigeria, Enugu, Nigeria; [8]Duke University Medical Center, Durham, NC; [9]The Hospital For Sick Children, Toronto, ON, Canada; [10]National Institutes of Health, Bethesda, MD; [11]College of Medicine, University of Ibadan, Ibadan, Nigeria; [12]University of Ghana, Accra, Ghana; [13]University of Arizona Health Sciences, Tucson, AZ.*

Background: Cardiovascular disease (CVD) risk factors are also risk factors for initiation and progression of CKD. The epidemiology of CVD risk factors and their associations with CKD have not been defined in a well-characterized cohort of patients with CKD in sub-Saharan Africa which may differ from high income countries.

Methods: We studied 919 patients with CKD from diabetes, hypertension, sickle cell disease, HIV, and unknown causes compared with 3504 healthy participants with no CKD from the H3Africa Kidney Disease Research Network. We determined the prevalence of self-reported hypertension, diabetes, smoking, and dyslipidaemia in sub-Saharan African population, and their relationship with CKD risk. Multivariate logistic regression method was used to determine association between the risk factors and CKD.

Results: The mean age was 45.7±15.5years and 59.4%% were females. Patients with CKD were older (48.9±15.8years) than the control participants (45.6±14.9years), p=0.001; they have lower BMI (25.3±5.4kg/m^2 versus 26.4±6.1kg/m^2, p=0.001), lower hemoglobin, (11.3±2.1g/dL versus 13.3±1.7g/dL, p=0.001) and higher Albumin-Creatinine Ratio (65.1±37.6mg/g versus 6.2±4.1mg/g, p=0.001). Compared with the control participants, patients with CKD have higher prevalence of hypertension (68.87% versus 31.44%, p=0.001); diabetes (28.61% versus 18.46%, p=0.001), dyslipidaemia (11.42% versus 5.96%, p=0.001); and smoking (7.39% versus 3.11%, p=0.001). Table 1 shows the odds of each CVD risk factor and having CKD.

Conclusions: Traditional CVD risk factors are prevalent and consistently associated with CKD especially hypertension in middle aged adults in sub-Saharan Africa. Prevention and optimal treatment of these risk factors may reduce CKD progression in sub-Saharan Africa.

Funding: Other NIH Support - National Human Genome Research Institute (1U54-HG006939-01)

Table 1: Association of self-reported cardiovascular risk factors with CKD in Sub-Saharan Africa

CVD risk factors	Unadjusted Odd ratio (95% CI)	*Adjusted Odd ratio (95% CI)	P value
Hypertension	4.74 (4.04-5.57)	5.18 (4.34-6.19)	0.001
Diabetes	1.47 (1.44-2.02)	1.47 (1.22-1.76)	0.001

Arterial Stiffness and Kidney Function Decline in SPRINT

Kristen L. Nowak,[1] Anna J. Jovanovich,[1,2] Zhiying You,[1] Michel Chonchol,[1] Mark A. Supiano.[3] *[1]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO; [2]Denver VA, Denver, CO; [3]University of Utah and VA Salt Lake City, Salt Lake City, UT.*

Background: Arterial stiffness increases with advancing age and chronic kidney disease. Arterial stiffness may contribute to a decline in kidney function; however, evidence is inconsistent. We hypothesized that greater baseline arterial stiffness was independently associated with rapid decline in kidney function over the longitudinal follow-up period in the Systolic Blood Pressure Intervention Trial (SPRINT).

Methods: 538 adults who participated in an ancillary study of SPRINT which measured arterial stiffness (aortic pulse-wave velocity [aPWV]) were included in this analysis. Multivariable logistic regression was used to examine the association between baseline aPWV and rapid decline in kidney function (estimated glomerular filtration [eGFR] decline >3 ml/min/1.73m^2/yr) over the follow-up period (median of 3.7 yrs).

Results: Mean age was 72±3 years with a mean baseline aPWV of 10.6±2.6 m/sec and eGFR of 67±21 ml/min/1.73 m^2. 109 participants had rapid decline in renal function over the follow-up period. After adjustment demographics, randomization group, co-morbid conditions, smoking, body-mass index, estimated glomerular filtration rate, urinary albumin to creatinine ratio, antihypertensive medications, systolic blood pressure, and heart rate, baseline aPWV was not associated with increased odds of rapid decline in kidney function (OR: 1.03, 95% CI: 0.93-1.13 per unit increase in aPWV). In the fully adjusted model, baseline aPWV above the median also did not associate with rapid decline in kidney function (OR: 0.92, 95% CI: 0.56-1.51).

Conclusions: Among adults at high risk for cardiovascular events, greater arterial stiffness is not associated with rapid decline in kidney function.

Plasma Sodium Is Associated with Arterial Stiffness in SPRINT

Kristen L. Nowak,[1] Anna J. Jovanovich,[1,2] Zhiying You,[1] Mark A. Supiano,[3] Michel Chonchol.[1] *[1]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO; [2]Denver VA, Denver, CO; [3]University of Utah and VA Salt Lake City, Salt Lake City, UT.*

Background: High dietary sodium may induce small yet physiologically relevant increases in plasma sodium concentrations, which associates with increased systolic blood pressure. Cellular data suggests this is mediated by increased endothelial cell stiffnes, as measured by atomic force microscopy. We hypothesized that higher plasma sodium levels were associated with greater arterial stiffness in participants in the Systolic Blood Pressure Intervention Trial (SPRINT).

Methods: 8,004 adults who participated in SPRINT were included in the analysis of the association of plasma sodium level with pulse pressure (PP), a surrogate measure of arterial stiffness. 542 adults who participated in an ancillary study of SPRINT which measured aortic pulse-wave velocity (aPWV) were included in the analysis of the association of plasma sodium with aPWV. Multivariable linear regression was used to examine the association between baseline plasma sodium levels and a) PP and b) aPWV.

Results: Mean age was 68±9 years with a mean serum sodium level of 140±3 mmol/L. In the PP analysis, after adjustment for demographics, randomization group, co-morbid conditions, smoking, body-mass index, estimated glomerular filtration rate, urinary albumin to creatinine ratio, antihypertensive medications, and heart rate, higher plasma sodium was associated with increased baseline PP (tertile 3 [≥141 mmol] vs. tertile 2 [139-141 mmol]; β: 1.11, 95% CI: 0.49-1.73). In the ancillary study, higher plasma sodium was associated with increased baseline aPWV in the unadjusted analysis (tertile 3 vs. tertile 2; β: 0.53, 95% CI: 0.02-1.03). However, in the fully adjusted model, this association was no longer significant (β: 0.39, 95% CI: -0.10-0.88).

Conclusions: Among adults at high risk for cardiovascular events, higher plasma sodium was independently associated with baseline arterial stiffness as measured by PP, but not by aPWV. The latter analysis may have been limited in power due to a smaller samples size.

Impact of Cardiovascular Events on Mortality and Decline of Renal Function in Patients with CKD

Andrew J. Mallett,[1,2] Andrew S. Jeyaruban,[1,2] Anne Cameron (Salisbury),[2] Jianzhen Zhang,[2] Helen G. Healy,[1,2] Wendy E. Hoy.[2] on behalf of the CKD.QLD consortium *[1]Kidney Health Service, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [2]CKD.QLD and the NHMRC CKD.CRE, The University of Queensland, Brisbane, QLD, Australia.*

Background: CVEs are common and significant complications amongst patients with CKD. The association of CKD and CVE is well publicised. However, the impact of CVE on subsequent kidney survival is not well described. We aimed to study the impact of new cardiovascular events (CVE) on mortality and deterioration of kidney function in a prevalent chronic kidney disease (CKD) patient cohort.

Methods: A retrospective cohort study of 1,123 patients of a tertiary teaching hospital, registered in the CKD.QLD registry between January 2011 and August 2017 and with a minimum of 2 years follow up time. CVE data (ischaemic heart disease (IHD), stroke and peripheral vascular disease (PVD)), renal function (eGFR CKD-EPI) and mortality events were extracted from integrated medical records. Subjects who progressed to end stage kidney disease were imputed an eGFR 8mL/min/1.73m^2 at the date of kidney replacement therapy (KRT). Delta eGFR (mL/min/1.73 m^2/year, (CKD-EPI)was calculated as the difference between latest eGFR compared to at time of incident CVE.

Results: 222 patients had at least one incident CVE which included IHD (n=144), stroke (n=51) or PVD (n=40). CVE events had a significant ($p<0.05$) impact on mortality, even after adjusting for age, gender and/or history of prior IHD, stroke and/or PVD. Kaplan-Meier analysis showed survival was reduced by 700 days (2867 (SE=67) vs 2167 (SE=61)) in the CVE cohort ($p<0.01$). There was no significant change in the absolute mean delta eGFR in subjects with and without CVE, adjusted for age (2.6mL/min/1.73 m^2/year (SE=0.4) vs 1.7mL/min/1.73 m^2/year (SE=0.2); p=0.2). Nor was there a significant different in progression to KRT, adjusting for age, gender and previous IHD, stroke and PVD (CVE 11.5% vs no CVE 10.4%; p=0.6).

Conclusions: New cardiovascular events are a flag for premature mortality in the CKD cohort as they are for the general population. However, patients with the shortest survival could have been excluded due to the exclusion criteria of the study. Moreover, incident CVE do not seem to have a significant association with accelerated progression of renal dysfunction or transition to KRT in CKD patients.

TH-PO448

Association of Blood Pressure with Urinary Sodium, Potassium, and Sodium/Potassium Ratio in CKD - The French CKD-REIN Cohort Study

Natalia Alencar de Pinho,[1] Jean Kabore,[3] Tilman B. Drueke,[1] Maurice Laville,[4] Bruce M. Robinson,[5] Ziad Massy,[2] Benedicte Stengel.[1] *[1]Inserm /CESP, Villejuif, France; [2]Ambroise Pare University Hospital and Inserm U1018 Eq5, Boulogne Billancourt/ Paris cedex, France; [3]Institute for Research in Health Science, Ouagadougou, Burkina Faso; [4]Université de Lyon, Pierre-Bénite, France; [5]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: The urinary sodium-to-potassium ratio (uNa/K) has been repeatedly shown to be more closely linked to blood pressure (BP) than urinary sodium or potassium excretion alone, both in general population and in patients with arterial hypertension. Whether this is also true for patients with CKD is unknown.

Methods: We assessed associations of BP with spot urine sodium/creatinine (uNa/Cr), potassium/creatinine (uK/Cr), and uNa/K in 1658 patients with CKD stages 3 or 4 under nephrology care. We used the mean of 2 office BP readings for analyses. Urinary Na, K, and creatinine concentrations were measured in second-void urine samples and expressed in mmol/L. Associations of BP with uNa/Cr, uK/Cr, and uNa/K modeled by 4-knot splines were assessed using generalized linear models adjusted for age, gender, eGFR, albuminuria, diabetes, heart failure, dyslipidemia, body mass index, and number of antihypertensive drugs.

Results: Median (IQR) age was 68 (59-76) years; most patients were men (65.3%), had CKD stage 3 (54.9%), and albuminuria (71.7%). Mean systolic (SBP) and diastolic (DBP) BP were 141 and 78 mm Hg, respectively. More than 90% of the patients had a history of arterial hypertension, and only 34% among them had controlled BP <140/90 mmHg. Median (IQR) uNa/Cr, uK/Cr, and uNa/K were 11.6 (7.9-16.3), 5.3 (4.1-7.0), and 2.2 (1.5-3.1), respectively. Spot uNa/Cr and uNa/K were positively associated with SBP (p 0.004 for both urinary indices) and with pulse pressure (p 0.002 and 0.019, respectively). The mean difference (β) in SBP between the highest and the lowest quartile (Q4-Q1) was 4.48 (95%CI 1.81-7.16) mmHg for uNa/Cr and 4.47 (95%CI 1.91-7.03) mmHg for uNa/K. Spot uK/Cr was not associated with any of the BP indices. The higher the quartile of uNa/K, but not of uNa/Cr, the higher the likelihood of uncontrolled (p 0.066) or apparently treatment resistant hypertension (p 0.033).

Conclusions: The positive association of urinary sodium, but not potassium, excretion with SBP and pulse pressure suggests a predominant role of sodium intake in determining BP level in many patients with CKD stages 3-4. In contrast with the general population, spot uNa/K does not appear to be more informative than uNa/Cr in such patients.

TH-PO449

Renal Impairment Modifies the Association Between Sodium Intake and Risk of Stroke – An Analysis of INTERSTROKE

Conor S. Judge,[1] Andrew Smyth,[2] Martin O'donnell.[2] Conor Stephen Judge *[1]Health Research Board Clinical Research Facility, Galway, Ireland; [2]NUI Galway, Galway, Ireland.*

Background: Stroke is the second most common cause of death and the third most common cause of disability worldwide (1). Excess sodium intake, and renal impairment, are associated with an increased risk of stroke. We performed an analysis of the INTERSTROKE case-control study to investigate the relationship between estimated urinary sodium excretion (used as a surrogate for intake) and stroke.

Methods: INTERSTROKE was a standardized international case-control study that recruited 26,919 participants in 32 countries (2). We included participants with urine samples collected and measurement of spot urine sodium, potassium, and creatinine. 24-hour urinary sodium excretion was estimated using the Kawasaki, Intersalt, and Tanaka equations (7–9). Multivariable unconditional logistic regression was performed to compare the risk of stroke across four quartiles (<3.2 g/day, 3.2–4.4 g/day, 4.4–5.8 g/day, >5.8 g/day) of estimated 24-hour urinary sodium excretion using 3.2–4.4g/day as the reference quartile, as this was the category with lowest risk.

Results: Of the 26,945 participants, 13,483 were cases and 13,462 were controls. 23,258 participants had urine collected and processed. Mean eGFR (CKD-EPI) was 79.83 (23.49) ml/min/1.73m^2. Mean 24-hour estimated sodium excretion was 3.56 (1.95) g/day

for cases and 3.43 (1.56) g/day for controls (p<0.001). After adjustment for age, sex, hypertension, diabetes, ethnicity, and region, <3.2 g/day (OR 1.38 [1.28-1.48]) and >5.8 g/day (OR 1.67 [1.55-1.79]) of sodium excretion were both associated with increased odds of stroke (ischaemic stroke and intracerebral hemorrhage). 4.4 – 5.8 g/day was not significant (OR 1.05 [0.97-1.13]). The pattern of association across quartiles was consistent with 24-hour sodium excretion estimated with Intersalt and Tanaka equations. The magnitude of association increases across each CKD stage (Table 1).

Conclusions: Our data report that renal function amplifies the association of sodium intake with stroke, and suggest that moderate stroke intake is associated with lowest stroke risk in all stages of renal impairment.

Risk of stroke by 24hr estimated sodium excretion (Tanaka) and CKD stage (CKD-EPI)				
CKD Stage (Participants)	24 hr Estimated Sodium Excretion (Tanaka)			
	<3.2 g/day	3.2–4.4 g/day	4.4–5.8 g/day	>5.8 g/day
>90 (7690)	1.36 [1.18-1.56]	Ref.	0.94 [0.82-1.07]	1.76 [1.55-2.00]

TH-PO450

Age, Tissue Sodium, and Blood Pressure Associations in Healthy, Hypertensive, and Hemodialysis Subjects

Luis M. Perez,[1] Hsin-Yu Fang,[2] Brett Burrows,[3] Gwendolyn Derk,[2] Ryan J. Larsen,[3] Ken Wilund.[2] Renal and Cardiovascular Research Laboratory *[1]Division of Nutritional Sciences, University of Illinois, Urbana, IL; [2]Department of Kinesiology and Community Health, University of Illinois, Urbana, IL; [3]Bioiengineering, University of Illinois at Urbana-Champaign, Urbana, IL.*

Background: Sodium magnetic resonance imaging (^{23}Na MRI) can non-invasively quantify sodium (Na) concentrations in tissues such as the skin and muscle. However, previous tissue Na studies in healthy subjects and hemodialysis patients reported only one lower leg concentration. We used ^{23}Na MRI to quantify tissue Na in the anterior (AT) and posterior (PT) muscle regions of the leg in healthy, hypertensive (HTN), and HD subjects. We also examined group differences in tissue Na concentrations and the association of tissue Na to age and blood pressure (BP).

Methods: We recruited 22 subjects (45±18 years, 26.0±3.7 kg/m^2, 50% male, 64% white, 50% HTN, 27% HD) from the University of Illinois and a dialysis clinic in central Illinois. ^{23}Na MRI was performed on a Siemens TIM Trio/Prisma II 3T system (birdcage head coil). We conducted ^{23}Na MRI region of interest (ROI) analysis in a double-randomized and blinded manner for tissue Na concentrations. We also collected height, weight, and standardized BP.

Results: Across groups, Na concentration was significantly different (p<0.05) and lower in AT compared to PT (AT 18.6±5.1 mM, PT 26.0±4.9 mM; p< 0.05). PT Na was correlated both with age (R=0.64, p<0.01) and SBP (R=0.57, p<0.01). AT Na was also correlated with age (R=0.68, p<0.01), SBP (R=0.70, p<0.01), and with PT Na (R=0.62, p<0.01). Regression analysis demonstrated a significant relation between both age and SBP with both AT Na and PT Na (Table 1).

Conclusions: Na concentration in the calf differs depending on the site of quantification, with AT having a lower concentration than PT. This was a consistent finding across subject groups, despite differing Na concentrations by group. AT and PT are correlated with each other as well as age and SBP. Lower leg Na concentrations could differ due to muscle fiber type differences or because the AT region is smaller muscle group, thus more difficult to quantify than the PT region.

Age and BP Regression by Tissue Sodium

	Model A: AT Tissue Na, mM			Model B: PT Tissue Na, mM		
	Beta	P-value	Adj. R^2	Beta	P-value	Adj. R^2
Model 1:						
Age, years	0.18	<.01	0.43	0.16	<.01	0.40
Model 2:						
BP, mmHg	0.16	<.01	0.46	0.13	<.01	0.29

TH-PO451

Estimating the Association Between Urinary Cadmium and Hypertension: Bias Introduced by Missing Data on Renal Function

Martina M. Gaggl,[1,2] Tiansheng Wang,[2] Nora Franceschini.[2] *[1]Medical Universitiy of Vienna, Vienna, Austria; [2]Department of Epidemiology, Gillings School of Global Public Health, UNC, Chapel Hill, NC.*

Background: Cadmium exposure is associated with hypertension and ultimately all-cause mortality. Reduced renal function leads to decreased urinary cadmium excretion, and is aside from smoking an important confounder of the causal relationship of urinary cadmium and hypertension. The current project aimed to demonstrate an easily applicable method to overcome missing data to establish an unbiased association between urinary cadmium and hypertension in a large U.S. cohort of postmenopausal women sampled between 1993-1998.

Methods: Data were derived from the Women's health Initiative. Filtered urinary cadmium was measured by Inductively Coupled Mass Spectrometry and normalized to urine creatinine (μg/g). Hypertension was defined as a systolic blood pressure (SBP) >140 mmHg or a diastolic BP (DBP) > 90 mmHg or use of antihypertensive medication. Estimated glomerular filtration rate (eGFR) was calculated using the CKD-EPI equation. We estimated the odds of having hypertension in relation to log-transformed urinary cadmium adjusted for age, ethnicity/race, education, U.S. region, smoking, body mass index, and anemia (hemoglobin<12g/dL). Because of 76% missing data on eGFR, we performed analysis (1) unadjusted for eGFR, (2) adjusted for eGFR but restricted to a complete sample, and (3) adjusted for eGFR with imputed eGFR values. We performed multiple imputation (SAS 9.4. Proc MI) using a Monte-Carlo-Chain method (100 iterations) and estimated variance with Rubin's formula.

Results: In 1460 women aged 63(±7) years, the mean urinary cadmium was 0.61(±46)μg/g and 44% had hypertension. Eight percent were current, 37% were past, and 54% were never smokers. The unadjusted odds ratio (OR) for prevalent hypertension was 0.84 (95% CI 0.73 – 0.96). The OR for model 1 was 0.92 (95% CI 0.78-1.07), whereas in model 2 restricted to complete sample on eGFR OR was 0.63 (95% CI 0.42-0.94). After imputation for eGFR (model 3), the OR was 0.91 (95% CI 0.77-1.07), which is similar to estimates obtained in model 1. Assumptions of missing out of randomness and normal distribution were met for the imputation.

Conclusions: Our example demonstrates that using a study sample without missing data may provide biased estimates of association, and imputation of important confounders and covariates can be used if missing is random.

TH-PO452

Relationship Between Ankle Brachial Blood Index (ABI) and Cardiac Ankle Vascular Index (CAVI) and Prognosis in Maintenance Hemodialysis Patients

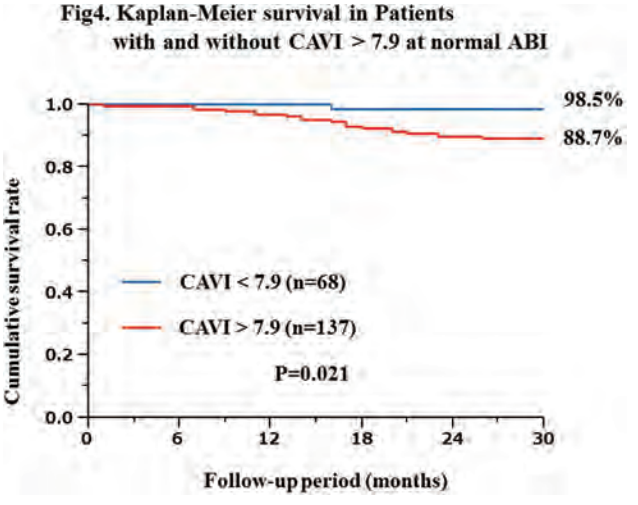
Kaoru Yasuda,[1] Shoichi Maruyama,[2] Kunio Morozumi.[3] *[1]Masuko Memorial Hospital, Department of Nephrology, Nagoya, Japan; [2]Nagoya University Graduate School of Medicine, Nagoya, Japan; [3]Masuko Memorial Hospital, Nagoya, Japan.*

Background: Ankle brachial blood index (ABI) and cardiac ankle vascular index (CAVI) are both indicators of systemic atherosclerosis. We investigate the relationship between ABI and CAVI in maintenance hemodialysis patients and their prognosis.

Methods: We measured ABI and CAVI for 297 patients undergoing maintenance hemodialysis treatment at Masuko memorial hospital. The cut-off value of CAVI was calculated by ROC analysis.

Results: During the observation period (median 28 months), 47 cases (15.8%) died. In 2-year survival rate, the ABI abnormal group (<0.9, n = 92) was significantly lower than in the normal group (> 0.9, n = 205) (67.7% vs. 92.6%, p <0.0001, adjusted hazard ratio 2.18). There was no difference in the survival rate between the CAVI abnormal group (> 9.0, n = 91) and the normal group (<9.0, n = 114) in the ABI normal group (91.1% vs. 93.6%, p = 0.74). However, when a new cut-off value (7.9) by ROC analysis was used, 2-year survival rate in the CAVI abnormality group (n = 137) was significantly lower than that in the normal group (n = 68) (88.7% vs. 98.5%, p = 0.021).

Conclusions: CAVI as a prognostic indicator should have a lower Cut-off value in maintenance hemodialysis patients with increased arteriosclerosis than the Cut-off value used by general population. In addition, it was suggested that even with normal ABI patients, it is possible to stratify prognostic risk by measuring CAVI.



TH-PO453

Clinical Features of Dialysis Patients at Risk of Lower Limb Amputation

Karen G. Butler, Michael R. O'Connell, Sheetal Chaudhuri, Hao Han, Marta Reviriego-Mendoza, Dugan Maddux, John W. Larkin, Len A. Usvyat, Terry L. Ketchersid, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Dialysis patients are at elevated risk for peripheral artery disease (PAD), lower extremity ulcers, and lower limb amputations (LLA) (Garimella et al, 2017). As part

of a quality improvement project for the current foot check process, a large dialysis provider piloted a Limb Preservation Project (LPP) capturing clinical features of patients' limbs at risk for amputation to streamline processes for specialist referral. We analyzed what features were more common in patients with LLA.

Methods: LPP was deployed at 9 dialysis clinics during Sept 2017 to Jan 2018. Dialysis clinics received a monthly list of patients considered high risk for foot ulcer who then received screening for dermatologic, mechanical and vascular changes in lower extremities.

Results: Among 571 patients considered high risk, there were 458 remarkable features documented. In those without a prior amputation (n=496), there were 356 features documented, and for those with a prior amputation (n=75), 102 were features documented. Patients with a prior amputation most frequently had bandaged wound on their non-amputated limb (23.53%), an open wound/ulcer on their amputated limb (18.63%), and abnormal nails (11.76%). Patients without a prior amputation most frequently had abnormal nails (36.25%), skin cracks/fissures (16.01%), and a bandaged wound (10.11%).

Conclusions: Results suggest that regardless of amputation status, the presence of abnormal nails and bandaged wounds may be a common clinical feature in dialysis patients at risk of lower extremity vascular disease.

Figure 1: Clinical Features	# of Features for Patients without Amputation	% of Features for Patients without Amputation	# of Features for Patients with Amputation	% of Features for Patients with Amputation	Odds Ratio
Skin cracks/fissures on amputated limb(s)	0	0.00%	9	8.82%	0
Vascular insufficiency with skin and/or temperature changes on amputated limb(s)	0	0.00%	6	5.88%	0
Open wound/ulcer on amputated limb(s)	0	0.00%	19	18.63%	0

Interarm Difference in Blood Pressure: Prevalence, Risk Factors, and Relevance for Diagnosis of Disease of the Aorta Among Patients Referred to Specialized Regional Hypertension Center

Januvi Jegatheswaran, Swapnil Hiremath, Cedric A. Edwards, Marcel Ruzicka. *University of Ottawa, Ottawa, ON, Canada.*

Background: Initial evaluation of hypertension (HTN) should include assessment of blood pressure (BP) in both arms. The prevalence of high interarm BP difference ranges from 3% in the general adult population to about 10% in the patients with HTN. However, we lack proper estimates of its prevalence, and existing practice of follow up for these patients in a referred population.

Methods: We performed a retrospective chart review of all prevalent patients followed at the Hypertension Center at the Ottawa Hospital. BP data from the first visit were used for assessment for interarm BP difference. We considered interarm difference in either systolic or diastolic BP in excess of 10 mmHg for casual BP by mercury sphygmomanometry to be clinically significant.

Results: 493 patients of 580 patients were included in this study based on available data. The prevalence of clinically significant interarm difference in systolic or diastolic BP was 16.2% and was similar among men and women. These patients were more likely to be smokers (current or previous; 53.5% vs 36.8%) with peripheral arterial disease (PAD, 15% vs 8%). None of these patients had undergone further investigations of ascending aorta/aortic arch.

Conclusions: A significant proportion of referred patients have a high interarm difference in systolic or diastolic BP. No clinical investigations were ordered to evaluate for ascending aorta/aortic arch disease reflecting the physicians' lack of understanding of its clinical relevance. The association with smoking and PAD suggests underlying aortic/large vessel disease as a potential mechanism in some patients.

Demographics	All patients in Hypertension clinic included in study	Patients with interarm SBP or DBP difference ≥10mmg	Patients without interarm SBP or DBP difference ≥10mmg

Association of Vascular Calcification with Brain Atrophy in Patients with CKD: Cross-Sectional and Longitudinal Analyses

Kazuhiko Tsuruya,[1,2] Hisako Yoshida,[3,2] Toshiaki Nakano,[4] Takanari Kitazono.[4] *[1]Department of Nephrology, Nara Medical University, Kashihara, Japan; [2]Department of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; [3]Osaka City University Graduate School of Medicine, Osaka, Japan; [4]Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

Background: It has been reported that brain atrophy (BA) progresses rapidly in chronic kidney disease (CKD) patients, especially in patients on hemodialysis (HD). We previously demonstrated that BA progressed more rapidly in patients on peritoneal dialysis (PD) compared with patients with non-dialysis dependent CKD (ND) (Tsuruya K, et al. AJKD, 2015). Vascular calcification (VC) has been considered to be an independent risk factor for cardiovascular disease including cerebrovascular disease; however, it remains unclear whether VC affects BA. Thus, we examined the association between VC and BA by cross-sectional and longitudinal analyses among CKD patients.

Methods: In the present study, 157 CKD (90 ND, 42 PD, and 25 HD) patients aged 62 (mean) ± 10 (SD) years (men 91, diabetes 46) were recruited and underwent MRI scanning at baseline and after two years. T1-weighted MRI images were analyzed with statistical parametric mapping software. Total gray matter (GM), total white matter (WM), and cerebrospinal fluid (CSF) were segmented and each volume was quantified using MRI voxel-based morphometry. GM ratio (GMR), calculated by normalization of GM volume to intracranial volume determined by summation of GM, WM, and CSF volume, and annual reduction rate of GMR (ARR-GMR) were used to evaluate BA. At baseline, all participants underwent multidetector computed tomography to assess coronary artery calcification score (CACS) and the values were transformed into the square root values (SR-CACS) to reduce the skewed distribution. We examined the associations of SR-CACS with GMR and ARR-GMR using multiple regression analysis.

Results: The mean GMR significantly decreased from 40.0% at baseline to 39.2% after 2 years, and the mean ARR-GMR was 0.38 percentage-point. SR-CACS was significantly negatively associated with GMR and positively associated with ARR-GMR. The association with GMR remained significant even after adjustment for age, sex, diabetes, systolic blood pressure, hemoglobin, dialysis status (ND, PD, or HD), current smoking, and regular drinking (Model-1), and the association with ARR-GMR also remained significant even after adjustment for Model-1 and baseline GMR (Model-2).

Conclusions: CACS was significantly associated with rapid progression of BA in CKD patients. This study suggests that VC might affect BA.

TH-PO456

Prevalence of Abdominal Aortic Calcifications in CKD Patients in the Arabian Gulf Region

Ali AlSahow,[1] Fadwa S. Al-Ali,[4] Basset El Essawy,[2] Anas M. Al Yousef,[3] Mohamed N. Husain.[5] *[1]Nephrology, Jahra Hospital, Jahra, Kuwait; [2]Nephrology, Ibrahim Bin Hamad Obaidallah Hospital, Ras AlKhaimah, United Arab Emirates; [3]Nephrology, Farwaniya Hospital, Sabah AlNaser, Kuwait; [4]Nephrology, Hamad Hospital, Doha, Qatar; [5]Nephrology, Salmanyia Hospital, Manama, Bahrain.*

Background: Abdominal aortic calcification (AAC) is an important risk factor for cardiovascular disease (CVD). CVD is the commones complication of chronic kidney disease (CKD). In the Arabian Gulf, few studies were conducted on CKD patients. Aim was to determine AAC prevalence in dialysis and non-dialysis CKD patients and determine relevant predictive factors.

Methods: We performed a multi-center, multi-national chart review of 546 adult CKD patients who have had a plain abdominal x-ray within 6 months prior to study entry. We collected data about patients' demographics, CKD stage, medical history and comorbidities, lipid profile, current medications and reviewed X-rays for AAC presence.

Results: A total of 544 CKD patients were eligible for analysis including 325 (59.7%) dialysis patients and 219 (40.3%) non-dialysis patients. 290 (53.3%) patients were males and 369 (67.8%) were diabetics. Mean age was 57.98 years (SD ± 15.39). Table 1 describes the distribution of patients according to CKD stage and AAC prevalence in each stage. Overall, AAC was reported in 203 (37.3%, 95% CI=33.2%: 41.4%) patients. AAC prevalence among dialysis patients (126 patients, 38.8%) did not differ significantly from that among non-dialysis patients (77 patients, 35.2%) (p=0.393). Higher risk of AAC development was associated with age, as mean age for AAC group was 66 for non AAC group was 53 (p< 0.001); diabetes, as 45.3% of diabetics developed AAC, compared to 20.6% of non-diabetics developing AAC (p< 0.001), with diabetic patients 2.1 times more likely to have AAC than non-diabetic patients; and longer dialysis vintage, which was 1.92 years in AAC group compared to 1.18 years in non AAC group (p= 0.003). Gender, hypertension and CVD had no associations with AAC.

Conclusions: Our study shows that AAC is present in more than one third of CKD patients in the Arabian Gulf. Risk is higher with older age, diabetes, and longer dialysis vintage.

Funding: Commercial Support - Sanofi

AAC Prevalence

CKD Stage	Number of patients	Patients with AAC
Non Dialysis	219 40.3% of all	77 35.2% of non dialysis
CKD 2	29 13.2% % of non dialysis	5 17.2% % of Corresponding CKD stage
CKD 3	81 37%	33 40.7%
CKD 4	45 24.7%	22 40.7%
CKD 5	55 25.1%	17 30.9%
Dialysis	325 59.7% of total	126 38.8% of all dialysis
Total	544	203 37.3% of total

Thyroid Status and Coronary Artery Calcification in a Prospective Hemodialysis Cohort

Connie Rhee,[1] Alejandra Novoa,[2] Amy S. You,[1] Tracy Nakata,[1] Kamyar Kalantar-Zadeh.[3] *[1]University of California, Irvine, Orange, CA; [2]UC Irvine Health, Orange, CA; [3]University of California Irvine, School of Medicine, Orange, CA.*

Background: In the general population, hypothyroidism is a known risk factor for coronary heart disease (CHD) and death. Experimental data suggest that low levels of circulating thyroid hormone (e.g., triiodothyronine [T3]) are causally associated with vascular calcification via downregulation of matrix Gla and klotho (i.e., vascular calcification inhibitors), and human studies suggest that low T3 levels are associated with higher risk of coronary artery calcification (CAC). However, little is known about the association of thyroid status, defined by serum thyrotropin (TSH) as the most sensitive and specific biochemical metric of thyroid function, with risk of CAC in the hemodialysis population.

Methods: In a secondary analysis of 104 patients from the Anti-Inflammatory and Anti-Oxidative Nutrition in Hypoalbuminemic Dialysis Patients (AIONID) trial, we examined the association of serum TSH levels with total Agatston CAC score. Cross-sectional associations of thyroid status with CAC score (total Agatston score >100, threshold for which moderate non-obstructive coronary artery disease highly likely) were estimated using logistic regression models adjusted for age, sex, and race.

Results: We observed that increasingly higher increments of serum TSH (defined as change in 1 standard deviation = 1.9mIU/L) were associated with a 3-fold higher risk of higher CAC score: OR (95%CI) 3.05 (1.26-7.37). When categorized as tertiles, the highest TSH tertile was also associated with a higher risk of higher CAC burden (ref: lowest tertile): OR (95%CI) 5.53 (1.44-26.3). Similarly TSH levels >3mIU/L were associated with a higher risk of higher CAC score (ref: ≤3mIU/L): OR (95%CI) 10.82 (1.78-65.8).

Conclusions: These data indicate that higher serum TSH levels are associated with higher risk of CAC in hemodialysis patients. Further studies are needed to determine of thyroid hormone supplementation ameliorates CHD burden in this population.

Repeat Intravascular Ultrasound Guided Renal Artery Angioplasty in a Patient with Fibromuscular Dysplasia

Avantika Chenna. *Nephrology, Southwest georgia nephrology----, Albany, GA.*

Introduction: Fibromuscular dysplasia (FMD) is one of the etiologies of renal artery stenosis (RAS) and secondary hypertension. Balloon angioplasty has emerged is emerging as a mainsstay of treatment in patients with FMD usually show substantial clinical response to renal angioplasty without stenting.

Case Description: We report a case of 32 -year-old male case of secondary hypertension from RAS due to with repeat intravascular ultrasound guided renal artery angioplasty. Her blood pressure (BP) was 165/95 with heart rate of 89 bts/min on presentation with chronic headaches. Her physcial exam was within normal limits. Labs revealed sodium of 138, potassium of 4.6, chloride of 97 and bicarbonate of 23 mmol/l respectively. BUN was 13 and creatinine was 0.87 mg/dl respectively. Secondary hypertension workup was negative except borderline elevated renin level. Doppler renal ultrasound showed increased velocity in the proximal portion of left renal artery concerning for left RAS. Patient's medications were adjusted including maximum dose of lisinopril without improvement in home blood pressure readings. Renal angiography was performed which revealed classic beaded appearance of bilateral renal artery showing FMD. Therefore, percutaneous transluminal angioplasty of bilateral renal arteries was performed. BP improved temporarily for a month after the procedure but slowly started to go up with average BP being 150's systolic and 100's diastolic. Doppler renal ultrasound showed increased velocities in bilateral renal arteries. Therefore percutaneous transluminal angioplasty of bilateral renal arteries was performed again. BP improved after the second balloon angioplasty and was now sustained. 3 months after follow up her BP improved to systolic 110-120 and diastolic of 70-80 mm hg without requiring any antihypertensives.

Discussion: This is the only case reported in medical literature to the best of our knowledge where repeat balloon angioplasty was attempted with successful and sustained BP control. Through this case we propose that repeat intravascular ultrasound guided renal artery angioplasty can be considered in patients with bilateral RAS due to FMD in whom the first attempt fails to control BP without stent placement. Further studies are needed to study the long term benefits of this procedure on BP control and kidney function.

TH-PO459

Impact of Ageing and Cardiovascular Risk Factors on Retinal Neurodegeneration Assessed by Spectral-Domain Optical Coherence Tomography

Susanne Jung,[1] Agnes Bosch,[3] Nikolas L. Kohler,[1] Christian Ott,[1] Dennis Kannenkeril,[3] Thomas Dienemann,[3] Joanna M. Harazny,[2] Roland E. Schmieder.[3] *[1]Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany; [2]University Erlangen-Nueremberg, Erlangen, Germany; [3]University Hospital Erlangen, Erlangen, Germany.*

Background: Spectral-domain optical coherence tomography (SD-OCT) has become a reliable imaging technique for the evaluation of retinal layer volumes. The aim of this study is to characterize age-related neuroretinal alterations and thereby identify risk factors for the process of retinal ageing.

Methods: This was a prospective observational single center study including 62 healthy subjects–25 young (aged<40 years) and 37 elderly healthy individuals (aged≥40 years). Macular retinal layer volumes of both eyes were evaluated by SD-OCT, comprising total retinal volume and each layer separately.

Results: In the group of young subjects (12 females/13 males, aged 25.1±3.5years) fasting plasma glucose (FPG) and HbA1c were significantly lower than in elderly subjects (28 females/9 males, aged 58.2±10years). There were no significant differences in systolic (SBP) and diastolic blood pressure (DBP). Gender-adjusted retinal layer volumes of both eyes including total retinal, RNFL, ganglion cell layer (GCL), inner plexiform layer (IPL), GCL-IPL, inner retinal layer (IRL, comprising RNFL, GCL-IPL) and outer nuclear layer

(ONL) volume were lower in the group of elderly subjects compared to young individuals. Additionally, partial correlation analysis revealed a significant negative correlation between retinal layer volumes and age (r range: -0.633 to -0.272, p range: <0.001-0.032), SBP (r range: -0.319 to -0.266, p range: 0.014-0.036), DBP (r range: -0.386 to -0.275, p range: 0.004-0.035), FPG (r range: -0.448 to -0.297, p range: 0.001-0.036) and HbA1c (r range: -0.433 to -0.286, p range: 0.002-0.044).

Conclusions: In this study, we detected significant differences in retinal layer volumes indicating age-related retinal neurodegenerative processes and identified risk factors for retinal ageing such as hypertension and a dysregulated glucose metabolism.

Retinal layer volumes

Retinal layer volume [mm^3]	Young subjects Right eye / left eye	Elderly subjects Right eye / left eye	Gender-adjusted p value Right eye / left eye
Total retina	8.86±0.40 / 8.80±0.37	8.47±0.35 / 8.46±0.35	< 0.001 / 0.001
Retinal nerve fiber layer (RNFL)	1.00±0.14 / 0.93±0.08	0.91±0.11 / 0.86±0.12	0.007 / 0.005
Ganglion cell layer (GCL)	1.14±0.07 / 1.13±0.07	1.04±0.07 /1.04±0.09	< 0.001

TH-PO460

Serum Magnesium Levels and Subsequent Risk of Peripheral Artery Disease

Steven Menez,[1] Ning Ding,[2] Morgan Grams,[2] Pamela L. Lutsey,[6] Elizabeth Selvin,[2] Josef Coresh,[3] Bernard G. Jaar,[4] Kunihiro Matsushita.[5] *[1]Medicine, Div. of Nephrology, Johns Hopkins Medicine, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD; [3]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [4]Johns Hopkins University and Nephrology Center of Maryland, Baltimore, MD; [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [6]University of Minnesota, Minneapolis, MN.*

Background: Hypomagnesemia has been associated with increased risk of several cardiovascular phenotypes presumably through its interaction with calcium and phosphate, but its relation to peripheral artery disease (PAD) is not well established. Magnesium (Mg) homeostasis is tightly regulated by the kidney, and thus the relationship between Mg and PAD may be weaker in CKD.

Methods: Using data from the Atherosclerosis Risk in Communities (ARIC) Study, we investigated the association of serum Mg with incident PAD in 14,293 participants free of prevalent PAD at baseline (mean age 54.6 years [SD 5.7], 26.2% black, 1.2% with GFR<60 mL/min/1.73m^2, 9.5% with DM). We used multivariable Cox models to quantify the association of Mg (< vs. ≥ the median value of 1.6 mEq/L) with incident PAD accounting for potential confounders. We further evaluated these associations, stratified by GFR above and below 60 mL/min/1.73m^2.

Results: Over a median follow-up time of 25.9 years, a total of 620 cases of incident PAD were observed. In fully adjusted models, the association between higher Mg and PAD was significant (HR=0.80, 95% CI: 0.67 – 0.95) (Table). Modeled continuously, the risk of PAD decreased significantly with every 0.1 mEq/L increase in Mg (HR 0.49, 95% CI: 0.30 – 0.82). In stratified analysis, this association persisted for participants with GFR above 60 mL/min/1.73m^2 but not for those with GFR<60. The interaction between Mg and GFR for PAD risk was significant (p=0.01). Among other electrolytes, higher calcium trended towards lower risk of PAD (HR=0.86, 95% CI: 0.72 – 1.01).

Conclusions: Higher serum Mg is independently associated with a lower hazard of incident PAD, though this association was not seen in individuals with reduced GFR. Our results suggest potential contribution of low serum Mg levels in the development of PAD independent of other calcium-phosphate metabolism.

Funding: Other NIH Support - The project described was supported by Grant Number T32 HL007024 from the National Heart, Lung, and Blood Institute, National Institutes of Health

Multivariable Cox Proportional Hazards Models for Incident PAD

Dialysis Modality and Risk of Atrial Fibrillation: A Systematic Review and Meta-Analysis

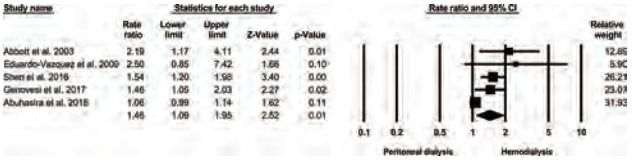
Boonphiphop Boonpheng,[1] Charat Thongprayoon,[2] Emmanuel Addo-Yobo,[1] Wisit Cheungpasitporn.[3] *[1]East Tennessee State University, Johnson City, TN; [2]Bassett Medical Center, Cooperstown, NY; [3]University of Mississippi Medical Center, Jackson, MS.*

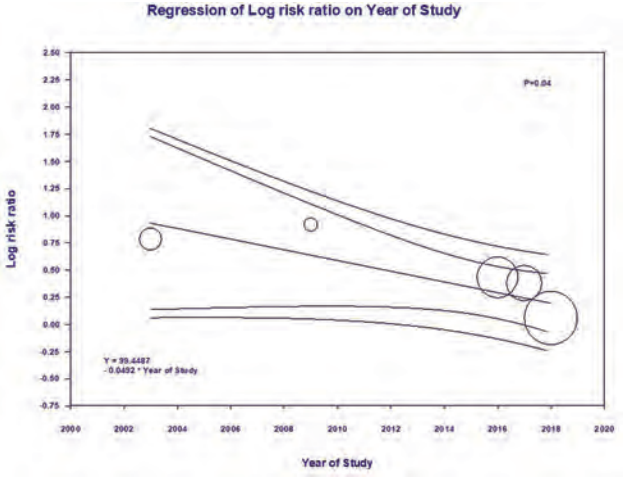
Background: Several studies have demonstrated that end- stage renal disease (ESRD) patients on dialysis are at higher risk for atrial fibrillation, which can be associated with stroke and increased mortality. However, the risk of atrial fibrillation in patients on different renal replacement modality remains unclear. We performed this meta-analysis to assess the risks of atrial fibrillation in ESRD patients on hemodialysis (HD) compared to peritoneal dialysis (PD).

Methods: A systematic review was conducted in MEDLINE, EMBASE, Cochrane databases from inception through April 2018 to identify studies that evaluated the risk of atrial fibrillation of patients on different dialysis modalities. Effect estimates from the individual study were extracted and combined using random-effect, generic inverse variance method of DerSimonian and Laird.

Results: 5 observational studies with a total of 22,779 dialysis patients (19,623 on HD and 3,156 on PD) were enrolled. Compared with PD, HD was associated with significantly increased risk of atrial fibrillation with pooled rate ratio of 1.46 (95% CI, 1.09-1.95). Meta-regression showed significant negative correlations between risk of AF among HD patients and year of study (slopes = -0.049, P = 0.04).

Conclusions: HD status is associated with 46% higher risk of atrial fibrillation compared to PD. However, compared to those on PD, there are potential reductions in the risk of atrial fibrillation among ESRD patients on HD overtime.





TH-PO462

Sex Disparities in Cardiovascular Events in Incident Dialysis Patients

Silvi Shah,[1] Annette Christianson,[2] Karthikeyan Meganathan,[1] Anthony C. Leonard,[1] Charuhas V. Thakar.[1] *[1]University of Cincinnati, Cincinnati, OH; [2]Cincinnati VA, Cincinnati, OH.*

Background: Cardiovascular events remains the leading cause of mortality in patients with end stage renal disease (ESRD) and the risk of cardiovascular events is 10 to 20 times higher in ESRD as compared to general population. Sex disparities in the major cardiovascular events in dialysis patients have not been studied.

Methods: We evaluated 96,729 patients who initiated dialysis between 1/1/2007 and 12/31/2008 from the United States Renal Data System with linked claims for Medicare Part A and Part B or Medicare Primary Other as the primary payer for the entire one year post dialysis initiation. Using ICD-9 codes, we identified hospitalizations for major adverse cardiovascular events (MACE), defined by unstable angina, acute myocardial infarction (MI), congestive heart failure (CHF), and stroke. Using case mix adjusted logistic regression models, we examined the impact of sex on MACE as the primary outcome.

Results: The mean age was 70±12 years. In the study cohort, 45.2% were women and 61.4% were white patients. All cause one-year mortality was 43.3%. Overall, women had higher frequency of MACE as compared to men (41.8% vs. 38.3%, p value<0.0001). Additionally, women had higher incidence of acute hospitalizations with CHF (36.7% vs. 33.1%, p value<0.0001), and stroke (5.8% vs. 4.5%, p value < 0.001) as compared to men. The frequency of unstable angina (7.3% vs. 7.5%, p value = 0.20) and acute MI (2.6% vs. 2.5%, p value = 0.26) was comparable between women and men. In the adjusted analyses, women had higher odds of MACE as compared to men (OR, 1.16; 95% CI, 1.13-1.19). As compared to men, women also had higher adjusted odds of CHF (OR, 1.17; 95% CI, 1.14-1.21) and stroke (OR, 1.28; 95% CI, 1.20-1.35). Odds of acute MI (OR, 1.08; 95% CI, 1.00-1.18) and angina (OR, 0.99; 95% CI, 0.94-1.04) did not differ significantly between men and women.

Conclusions: Women are 16% more likely to have acute hospitalizations with MACE as compared to men in the first year after incident ESRD. Additionally, women experience 17% higher rates of hospitalization with CHF and 28% higher rates of hospitalization with stroke. Further studies are needed to better delineate the factors associated with this sex disparity in the risk of MACE, and its treatment approaches.

TH-PO463

The Cut-Off Value of NT-Pro BNP to Diagnose Cardiac Insufficiency with Both Decreased and Preserved Ejection Fraction Value in Patients with Stage 3 to 5D CKD

Zi Li. *Department of Medicine-Nephrology, West China Hospital of Sichuan University, Chengdu, China.*

Background: BNP and NT-Pro-BNP are widely used in clinical work for the diagnosis of heart failure even in patients with chronic kidney disease(CKD). Previous research focused on the heart failure with decreased ejection fraction (EF). However, heart failure/ insufficiency with preserved EF occurs in a large amout CKD patients especially in the early period. This research is to explore the diagnosis cut-off value of NT-Pro BNP for cardiac insufficiency in CKD patients with stage 3 to 5D, and to analyze its probable influential factors.

Methods: CKD patients with 3 to 5D stages who were hospitalized in the department of nephrology, which belongs to an affiliated hospital of our university, from April 2016 to April 2017 were enrolled. All the patients measured plasma NT-Pro BNP and completed echocardiography within 1 month. Criteria for heart insufficiency included both the patients' symptoms, the 2013 ACCF/AHA heart failure guideline and recommendations and the American Society of Echocardiography as well. Informations of age, sex, weight, height, BMI, blood pressure, NT-ProBNP, GFR, serum electrolytes, index of echocardiography were collected. According to GFR, the patients are divided into three groups: CKD3, CKD4, CKD5 (non-dialysis, hemodialysis, and peritoneal dialysis). SPSS software is used for data analysis.

Results: (1) A total of 396 patients met our inclusion crtieria. NT-Pro BNP was negatively correlated with GFR, EF, sodium, potassium or chloride and positively correlated with E/A, LV, LA, RV, RA, IVS, LVPW, EDD, ESD, EDV, ESV and CKD stages ($p<0.05$). (2) Linear correlation analysis showed ESV, EF, ESD, EDV, E/A, NT-Pro BNP, LV, LA, E/e' correlated with heart failure; multi-factor logistic regression analysis showed that the factors affecting heart failure included E/A, ESV and NT-pro BNP. The diagnostic cut-point value of NT-pro BNP for heart insufficiency increased with the increase of CKD stage (CKD stage 3: 3654.0pg/ml; CKD stage 4: 7584.5pg/ml; CKD stage 5 non-dialysis: 9465.5pg/ml; peritoneal dialysis: 18667.5pg/ml; hemodialysis: 29362.0pg/ml).

Conclusions: NT-Pro BNP cut-off values for cardiac insufficiency should be established according to different CKD stages and considering both decreased and preserved EF value in order to improve early diagnosis and treatment of heart insufficiency.

TH-PO464

N-Terminal Pro-B-Type Natriuretic Peptide and Cardiac Troponin T for Detection of Left Ventricular Hypertrophy in Non-Dialysis CKD Patients

Han Zhang, Jing Chen. *Zhongshan Hospital, Fudan University, Shanghai, China.*

Background: The mortality of cardiovascular disease (CVD) in the patients with chronic kidney disease (CKD) is significantly higher than in the general population. Plasma N-terminal pro-B-type natriuretic peptide (NT-proBNP) and cardiac troponin T (cTnT) have been shown to be powerful predictors of cardiovascular mortality. In subjects with albuminuria or impaired renal function, the use of these cardiac biomarkers has been debated. In this cross-section study, we tried to investigate whether these two biomarkers could predict left ventricular hypertrophy (LVH) in subjects with CKD patients and the prediction power of both.

Methods: A total of 1320 pre-dialysis CKD patients were recruited in this study. NT-pro-BNP and cTnT were all measured on the Roche cobas E602 (Roche Diagnostics). Left ventricular mass index (LVMI) were determined by an echocardiographic examination.

Results: Participants in high NT-proBNP group, as well as participants in high cTnT group, had a worse cardiovascular risk profile and had more LVH. Participants with high cardiac biomarkers had also more often a lower eGFR and higher proteinuria. Multivariable-adjusted association of NT-proBNP level and LVH was OR 1.233(95%CI 1.131 to 1.345) for per 1000pg/ml increase. Multivariable-adjusted association of cTnT level and LVH was OR 1.005(95%CI 1.001 to 1.010)for per 100ng/L increase. Then we identified optimal threshold value for NT-ProBNP and cTnT. The 90th percentile of NT-proBNP had moderately high positive likehood ratios for detecting LVH, 50th percentile of NT-proBNP had moderately low negtive likehood ratios for detecting LVH. The 90th percentile and 50th percentile of cTnT had optimal positive likehood ratios and negtive likehood ratios separately for detecting LVH.

Conclusions: NT-proBNP and cTnT both are independent factors associated with the echocardiographic parameters of LVH in CKD patients. The diagnostic performance of NT-proBNP is significantly superior than cTnT.

Association of NT-proBNP and cTnT with LVH

Variables	NT-proBNP(per 1000pg/ml)	cTnT(per 100ng/L)
Demographic-adjusted	1.373(1.262-1.495)**	1.014(1.009-1.020)**
Multivariate-adjusted	1.233(1.131-1.345)**	1.005(1.001-1.010)*

Data are presented as OR (95% CI).*P<0.05, **P<0.001.

Left ventricular hypertrophy was defined as LVM/height2.7 >47 g/m2.7 for women and >50 g/m2.7 for men.

TH-PO465

ADAM17 as a Predictor of CV Events in CKD Patients

Vanesa Palau,[1] Marta Riera,[1] David Benito,[1] Jose M. Valdivielso,[3] Angels Betriu,[3] Elvira Fernandez,[3] Julio Pascual,[1,2] Maria Jose Soler.[1,2] *[1]Hospital del Mar Medical Research Institute (IMIM), Barcelona, Spain; [2]Parc de Salut Mar. Fundació IMIM, Barcelona, Spain; [3]IRB LLEIDA, LLEIDA, Spain.*

Background: Previous studies have demonstrated a positive correlation between ADAM17 and TNFα in cardiovascular (CV) disease. Increased expression of TNFα and ADAM17 has important implications in advanced cardiac dysfunction. We studied the relationship between baseline circulating ADAM17 activity, cardiovascular events and mortality in CKD patients from the NEFRONA study after 48 months of follow-up.

Methods: 2,570 patients without history of previous CV disease from the observational and multicenter NEFRONA study were divided into three groups: non-dialysis CKD stage 3-5 patients (CKD3-5, n=1,463), hemodialysis or peritoneal dialysis patients (CKD5D, n=538) and control patients (CONT, n=569). Baseline circulating ADAM17 activity was analyzed using a fluorimetric assay in plasma samples. Survival was analyzed by Kaplan-Meier curves for the following events: CV event, CV mortality, non-CV mortality and all mortality causes according to ADAM17 activity, diabetes, age, smoking and dialysis requirement. Cox regression analyses were used to identify risk factors for these events.

Results: Circulating ADAM17 activity was higher in patients with CV events and in patients with CV mortality, non-CV mortality and all-cause mortality ($p<0.05$). In the unadjusted Cox model, circulating ADAM17 activity was a risk factor for CV events, CV mortality and all-cause mortality in CKD patients. However, circulating ADAM17 was not a risk factor for non-CV mortality. In the multivariate Cox regression model, circulating ADAM17 activity, older age, male sex, diabetes and dialysis were identified as independent risk factors for CV events.

Conclusions: Higher levels of circulating ADAM17 activity correlated with a worst survival rate in patients with CV events, CV death and all mortality causes. Circulating ADAM17 activity could be an independent predictor for CV events in CKD patients without previous history of CV disease.

α-Adducin Polymorphism's Influence on Ischemic Strokes

Paola Casanova, Lino Merlino, Chiara Lanzani, Laura Zagato, Simona Delli carpini, Elisabetta Messaggio, Paolo Manunta, Marco Simonini. *San Raffaele Scientific Institute, Milan, Italy.*

Background: rs4961 Gly460Trp variant of the alpha Adducin gene (ADD1) has been associated with renal sodium retention and salt sensitive hypertension. Previous studies indicated ADD1 Gly460Trp as associated to higher risk of cardiovascular diseases. The aim of this study is to assess whether there is a correlation between this ADD1 variant and the development of ischemic strokes

Methods: 212 patients with ischemic stroke (IS) were recruited from San Raffaele Hospital in Milan and divided into four categories according to Oxford Classification. These patients were compared to a cohort of elder general population (EGP, 128 patients) and a cohort of hypertensive patients (HYP, 2404 patients), both with no history of strokes.

Results: In IS group mean age at strokes' diagnosis was 72.34±11.9, 61% men, 39% women. The incidence of CV risk factors was: hypertension 66%, diabetes 22%, hypercholesterolemia 40% and hypertriglyceridemia 13%, previous stroke 14%, CKD 16%. Two comparable populations were selected with similar age (71.28±6.9 years for EGP) and with the same incidence of risk factors (for HYP population). Notably, the presence of subjects homozygous for ADD1 mutated allele (rs4961 TrpTrp) is more than double in patients bearing ischemic stroke than in the two others (6.1% IS vs. 2.3% EP, $p=0.049$; 6.1% IS vs. 2.2 HYP, $p = 0.009$; fig.1). There was no statistically difference among the various types of stroke.

Conclusions: These data suggest a correlation between mutated alpha-Adducin and the increased incidence of all types of ischemic stroke. No correlation was found with the other hypertension-related genes analysed (as ADD2, ADD3). rs4961 alpha-Adducin polymorphism should be considered as an independent risk factor for ischemic strokes, even if these events donot appear directly linked to hypertension. Finally, alpha-Adducin polymorphism itself might be a candidate gene in the pathogenesis of stroke.

APOL1 Genotypes and Vascular and Endothelial Function in the Multi-Ethnic Study of Atherosclerosis (MESA)

Teresa K. Chen,[1] Ronit Katz,[2] Michelle M. Estrella,[3] Wendy S. Post,[9] Holly J. Kramer,[4] Jerome I. Rotter,[8] Bamidele O. Tayo,[6] Josyf Mychaleckyj,[7] Christina Wassel,[10] Carmen A. Peralta.[5] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]University of Washington, Seattle, WA; [3]University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA; [4]Loyola University Medical Center, Maywood, IL; [5]University of California San Francisco/SFVAMC, San Francisco, CA; [6]Loyola University Chicago Stritch School of Medicine, Maywood, IL; [7]University of Virginia, Charlottesville, VA; [8]LABioMed at Harbor-UCLA Medical Center, Torrance, CA; [9]Johns Hopkins University, Baltimore, MD; [10]Premier, Inc, Charlotte, NC.*

Background: The *APOL1* high-risk genotypes, present in 13% of U.S. blacks, are associated with an increased risk for hypertension-attributed kidney disease. Biopsy studies show differences in kidney vasculature by *APOL1* status, but less is known about the variants' associations with systemic vascular and endothelial function.

Methods: Using a recessive genetic model, we examined the cross-sectional associations of *APOL1* risk genotypes (high=2 risk alleles; low=0-1 risk allele) with subclinical measures of vascular and endothelial function in MESA. Outcomes included measures of vascular (small and large arterial elasticity [SAE, LAE] by HDI PulseWave CR-2000 and ascending aortic distensibility [AAD] by magnetic resonance imaging) and endothelial (by brachial artery Doppler flow-mediated dilation [FMD]) function. We constructed linear regression models, adjusting for age, sex, and genetic global ancestry.

Results: We included African-American MESA participants with available *APOL1* genotyping and measurements of SAE (n=1586), LAE (n=1586), AAD (n=985), and FMD (n= 777) at Exam 1 (2000-2002). Mean age was 62 years, 54% were female, 59% had hypertension, mean systolic blood pressure was 131 ± 22 mmHg, and mean $eGFR_{CysC}$ was 90 ± 20 ml/min/1.73 m^2. Mean (SD) SAE, LAE, AAD, and FMD were 4.2 (2.5) ml/mmHg*100, 13.5 (5.8) ml/mmHg*100, 1.7 (1.3) 1/mmHg*1000, and 0.2 (0.1) mm, respectively. In linear regression models, the *APOL1* high-risk genotypes were not associated with SAE, LAE, AAD, or FMD, though there was a trend of lower AAD among *APOL1* high- vs. low-risk individuals (Table).

Conclusions: Among African Americans in MESA, the *APOL1* high-risk genotypes were not associated with subclinical measures of vascular or endothelial function. Further studies are needed to clarify the potential role of *APOL1* in vascular changes.

Plasma Sphingolipid and Mortality Risk in Incident Hemodialysis Patients

Jessica Fitzpatrick,[1] Stephen M. Sozio,[2] Bernard G. Jaar,[3] Michelle M. Estrella,[4] Jose M. Monroy-Trujillo,[7] Rulan S. Parekh,[5] Mark Mitsnefes.[6] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]Johns Hopkins University and Nephrology Center of Maryland, Baltimore, MD; [4]University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA; [5]The Hospital For Sick Children, Toronto, ON, Canada; [6]Cincinnati Children's Hospital, Cincinnati, OH; [7]Johns Hopkins University, Baltimore, MD.*

Background: ESRD patients receiving hemodialysis (HD) are at high risk of mortality, particularly cardiovascular (CVD) mortality. Plasma sphingolipids have been identified as predictors of CVD mortality in the general population. Despite the high prevalence of dyslipidemia in HD, no studies have examined the associations of sphingolipids with mortality risk in this population.

Methods: This study included 368 incident HD patients enrolled in the Predictors of Arrhythmic and Cardiovascular Risk in ESRD (PACE) study. Plasma sphingolipid (ceramides, glucosylceramides and lactosylceramides) levels were measured at baseline by liquid chromatography-tandem mass spectrometry. Proportional hazards regression was used to examine the association of sphingolipids with CVD mortality and all-cause mortality.

Results: At baseline, mean age was 55 years, 39% were female, 72% were African American, 58% had diabetes, and the mean comorbidity index was 5.2. Over a median 2.5 years (IQR: 1.4-3.5 years) of follow-up, there were 78 deaths from all causes, of which 33 were from CVD. The highest tertile of glucosylceramide C16GC (0.81-5.88 μM) was associated with increased risk of all-cause (HR: 1.81; 95%CI: 1.02-3.22) and CVD mortality (HR: 2.63, 95%CI: 1.08-6.55) as compared to the lowest tertile (0.03-0.40 μM) after adjusting for demographics and comorbidity.[Figure] There was no evidence of association between other sphingolipids and risk of all-cause or CVD mortality.

Conclusions: Glucosylceramide C16GC was associated with CVD and all-cause mortality among adults incident to HD. These results suggest that glycosphingolipid imbalance may contribute to increased mortality risk in ESRD. Further studies are needed to confirm these new and important findings.

Funding: NIDDK Support

Plasma Sphingolipids and Cardiovascular Disease Risk in Incident Hemodialysis Patients

Jessica Fitzpatrick,[1] Stephen M. Sozio,[2] Bernard G. Jaar,[3] Michelle M. Estrella,[5] Jose M. Monroy-Trujillo,[4] Rulan S. Parekh,[6] Mark Mitsnefes.[7] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]Johns Hopkins University and Nephrology Center of Maryland, Baltimore, MD; [4]Johns Hopkins University, Baltimore, MD; [5]University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA; [6]The Hospital For Sick Children, Toronto, ON, Canada; [7]Cincinnati Children's Hospital, Cincinnati, OH.*

Background: Risk of cardiovascular (CVD) morbidity is high in adults with ESRD undergoing hemodialysis (HD). Many CVD risk factors are prevalent in ESRD, including dyslipidemia. Recent studies identified plasma sphingolipids as independent predictors of CVD in the general population; however, no studies have examined this association in HD patients.

Methods: This study included 368 incident HD patients enrolled in the Predictors of Arrhythmic and Cardiovascular Risk in ESRD (PACE) study. At baseline, plasma sphingolipid (ceramides, glucosylceramides and lactosylceramides) levels were measured by liquid chromatography-tandem mass spectrometry. We examined the cross-sectional association of sphingolipids with intermediate CVD outcomes (uncontrolled hypertension [SBP ≥140 mm Hg or DBP ≥90 mm Hg], left ventricular hypertrophy [left ventricular mass index >51 g/m$^{2.7}$], and low ejection fraction [ejection fraction <55%]) using multiple logistic regression.

Results: At baseline, mean age was 55 years, 39% were female, 72% were African American, 58% had diabetes, 36% had coronary artery disease, and 41% had congestive heart failure. Higher glucosylceramide C16GC was consistently associated with higher odds of uncontrolled hypertension, left ventricular hypertrophy, and low ejection fraction independent of demographic, CVD, and dialysis factors.[Table] No other sphingolipid was consistently associated with these intermediate CVD outcomes.

Conclusions: Glucosylceramide C16GC was consistently associated with intermediate CVD outcomes. These results suggest that abnormal glycosphingolipid metabolism may contribute to increased CVD risk in ESRD. Additional studies in other dialysis cohorts are needed to confirm our results.

FGF-23, Hypertension, and Dyslipidemia in Glomerular Disease

Christine B. Sethna,[1] Mary B. Leonard,[5] Kevin E. Meyers,[6] Tammy M. Brady,[3] Andrew N. Hoofnagle,[4] Myles Wolf,[7] Michelle Denburg.[2] *[1]Cohen Children's Medical Center of NY, New Hyde Park, NY; [2]The Children's Hospital of Philadelphia, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; [3]Johns Hopkins University, Baltimore, MD; [4]University of Washington, Seattle, WA; [5]Stanford School of Medicine, Stanford, CA; [6]The Children Hospital of Philadelphia and University of Pennsylvania, Philadelphia, PA; [7]Duke University, Durham, NC.*

Background: Fibroblast growth factor-23 (FGF-23) has direct effects on vasculature and myocardium and is a risk factor for cardiovascular disease (CVD); however, the impact on CVD in glomerular disease (GD) has not been addressed.

Methods: Plasma intact FGF-23, casual blood pressure (BP) and serum lipids were measured cross-sectionally in Nephrotic Syndrome Study Network (NEPTUNE) participants. Multiple regression analyzed the association of FGF-23 with BP and lipids adjusted for age, sex, black race, glomerular diagnosis, estimated glomerular filtration rate (eGFR), urine protein:creatinine (UPC), obesity and phosphorus (+ height in BP models). FGF-23 was divided into tertiles (<100,≥170 pg/ml). Hypertension (HTN) was defined as BP ≥130/80 mmHg for adults and per established definitions in children (Flynn 2017). BP index (BPi) was calculated as BP÷130/80 for adults and 95th %tile for children. Dyslipidemia (DLP) was defined as abnormal triglycerides, HDL or non-HDL for age (AHA 2013, Daniels 2011).

Results: 204 adults (46±16 yr, 60% M, 23% black) and 93 children (9.6±5 yr, 59% M, 42% black) with median eGFR of 78.4 (IQR 50,104.9) ml/min/1.73m^2 and UPC 1.83 (IQR 0.57,3.8) were evaluated. Diagnoses included membranous 17%, minimal change 24%, FSGS 33% and IgA 14%. Median FGF-23 was 73 (IQR 50,110) pg/ml, PTH 38 (IQR 26,59) pg/ml and phosphorus 3.9 (IQR 3.4,4.4) mg/dl. HTN was present in 68% and DLP in 75%; mean SBPi was 0.83±0.15 and DBPi 0.94±0.18. The highest tertile of FGF-23 was associated with HTN, SBP, DBP, SBPi and DBPi, vs. the lowest tertile in adjusted models (Table 1). FGF-23 was not associated with DLP.

Conclusions: In NEPTUNE, FGF-23 was directly associated with HTN and BP. Further study of FGF-23 as a therapeutic target for reducing CVD in GD is warranted.

Funding: Other NIH Support - NCAS, Private Foundation Support

Table 1. Association of FGF-23 with BP and Lipids (adjusted models)

	FGF-23 Highest compared to Lowest Tertile	P value
	OR (95% CI)	
Hypertension	7.33 (1.27, 42.4)	**0.03**
Dyslipidemia	0.85 (0.26, 2.8)	0.79
	β (95% CI)	
SBP	8.97 (0.99- 16.95)	**0.03**

Clinical Characteristics Enhancing the Predictive Ability of C-Reactive Protein on Incident Hypertension

Dong-Young Lee,[1] Kyoung hyoub Moon.[2] *[1]Veterans Health Service medical center, Seoul, Republic of Korea; [2]Vetrans Health Service Medical Center, Seoul, Republic of Korea.*

Background: Previous studies have demonstrated that the elevated CRP predicts the development of cardiovascular disease. However, it is still argued whether elevated CRP was independently associated with the elevation of blood pressure. This study was to investigate the predictability of CRP level on incident hypertension according to the clinical characteristics in normotensive general Korean population.

Methods: We examined 7,481 normotensive subjects from Korean Genome and Epidemiology Study (KoGES). They were stratified into 4 groups by quintiles of their baseline CRP levels, and followed-up for 10 years to monitor the incident hypertension. Cox proportional hazards model was used to calculate the hazard ratios (HRs) and 95% confidential interval (CI) for hypertension according to quintiles of CRP level. Additionally, subgroup analysis was performed by gender, obesity/non-obesity, dysglycemia/normal glycemia and middle (40-54 years) /old age (55-69 years).

Results: In all participants, compared to group of quintile 1, adjusted HRs for hypertension significantly increased in group of quintile 4 (1.22 [95% CI 1.04-1.43]). In subgroup analyses, women, obese and middle-aged subgroup showed the statistically significant HRs for hypertension at quintile 4 (women subgroup: 1.37 [95% CI 1.09-1.72]; obese subgroup: 1.33 [95% CI 1.07-1.66]; middle-aged subgroup: 1.31 [95% CI 1.07-1.59]), and dysglycemic subgroup had the statistically significant HRs for T2DM at both quintile 3 (1.33 [95% CI 1.04-1.71]) and quintile 4 (1.34 [95% CI 1.04-1.73]).

Conclusions: Our results suggest that the predictability of CRP on hypertension is enhanced in clinical conditions including women, obesity, dysglycemia and middle age.

TH-PO472

Hypertension and Dyslipidemia in Childhood Nephrotic Syndrome

Elizabeth Thomas,[1] Kevin E. Meyers,[2] Tammy M. Brady,[3] Debbie S. Gipson,[5] Frederick J. Kaskel,[4] Tarak Srivastava,[7] Keisha L. Gibson,[8] Cheryl L. Tran,[11] Kimberly J. Reidy,[6] Rebecca Levy,[9] Christine B. Sethna.[10] NEPTUNE Pediatric Working Group *[1]Cohen Children Medical Center, Glen Oaks, NY; [2]The Children Hospital of Philadelphia and University of Pennsylvania, Philadelphia, PA; [3]Johns Hopkins University, Baltimore, MD; [4]Children's Hospital at Montefiore, Bronx, NY; [5]University of Michigan Mott Children's Hospital, Ann Arbor, MI; [6]Children's Hospital at Montefiore/ Albert Einstein College of Medicine, Bronxville, NY; [7]Childrens's Mercy Hospital, Kansas City, MO; [8]University of North Carolina Kidney Center, Chapel Hill, NC; [9]Montefiore Medical Center, New York, NY; [10]Cohen Children's Medical Center of NY, New Hyde Park, NY; [11]Mayo Clinic, Rochester, MN.*

Background: Children with nephrotic syndrome (NS) often have hypertension (HTN) and dyslipidemia (DLP). However, these CVD risk factors have not been well described over time and in relation to renal outcomes in NS.

Methods: Longitudinal analysis of children with new onset NS in the Nephrotic Syndrome Study Network (NEPTUNE) was conducted. HTN and DLP were defined as per established definitions (Flynn 2017, Daniels 2011). BP was indexed (BPi) to the 95%. Generalized Estimating Equation models compared HTN and DLP among those reaching complete remission (CR) (urine protein:creatinine [UPC] <0.3) vs. no CR. Regression models examined the association of baseline BP and lipids with outcomes of CR, 40% eGFR drop, eGFR <90 ml/min/1.73m^2 at last follow up and eGFR slope adjusted for age, sex, race, follow up, medications, eGFR and obesity.

Results: 81 children (4.3±2.3 yr, 63% M, 24% black) with mean baseline eGFR 112±48 ml/min/1.73m^2 and UPC 4.5±9.2 were evaluated. At baseline, 58% had HTN and 81% had DLP (Table). Among CR, DLP decreased over time (*Q*10.8, p=0.01) but HTN did not change (*Q*10.8, p=0.39). For no CR, HTN and DLP did not change over time. In adjusted models, no CR had greater odds of HTN (OR 3.4 CI1.16-10.8) and greater LDL

(β 35 CI 2.9,68) over time. For outcomes, baseline elevated total cholesterol (HR 1.01 CI 1.00-1.01), greater LDL (HR 1.01 CI1.0-1.02) and triglycerides (HR 1.01 CI 1.001-1.01) were associated with increased risk of 40% eGFR drop. Baseline BP and lipids were not associated with other outcomes.

Conclusions: In NEPTUNE, HTN and DLP were prevalent in children with new onset NS and were worse over time in those with no CR. In addition, baseline lipids were found to independently predict poorer renal outcomes.

Pericytes Detachment and Peritubular Capillaries Injury in Malignant Hypertensive Nephrosclerosis Patients

Peng Xia,[1] Jiaxin Lang,[1] Min Lin,[2] Yubing Wen,[1] Xiaoxiao Shi,[1] Lubin Xu,[1] Yumo Zhao,[2] Ming-Xi Li,[1] Xuemei Li,[1] Xuewang Li,[1] Limeng Chen.[1] *[1]Peking Union Medical College Hospital, Beijing, China; [2]Peking Union Medical College, Beijing, China.*

Background: Peritubular capillary (PTC) injury contributes to the progression of various kidney disease. However, its impact on renal prognosis has not been well reported in malignant hypertensive nephrosclerosis (MHN) patients. The disintegration of interstitial pericytes may cause PTC loss and expansion of interstitium. This study investigated the role of PTC loss and pericytes distribution in MHN patients.

Methods: One hundred patients with essential MHN confirmed by renal biopsy from Jan. 2003 to Jun. 2016 in Peking Union Medical College Hospital were recruited. Clinical data and pathologic findings carefully reviewed. IHC and immunofluorescence staining of CD34 and PDGFRβ were used to evaluate PTC loss and pericytes distribution. The primary end point was defined as renal replacement therapy, kidney transplant as well as death. Cox regression was used to identify factors related to prognosis.

Results: The patients were mostly young males (male 88%; age 34.9±8.5ys) with significantly elevated blood pressure (225.2±26.4/152.0±25.0 mmHg), decreased eGFR (22.1±15.2 mL/min/1.73 m²) and proteinuria (median 1.4 g/d). Remarkable tubular atrophy (62.8±19.1%) and interstitial fibrosis (65.0±17.8%) were observed. PTC loss evaluated by CD34 staining was more significant in MHN patients (n=70), compared with benign hypertensive nephrosclerosis (n=17, P=0.025) and glomerular minimal lesion patients (n=17, P=0.001). PTC area correlated well with eGFR (r=0.496, P<0.001) and proteinuria (r=-0.351, P=0.006). Tubulointerstitial PDGFRβ expression (n=36) was higher than BHN (n=15, P=0.035) and GML patients (n=10, P=0.01). Immunofluorescence double staining of CD34 and PDGFRβ showed detachment of pericytes from PTC in tubulointerstitium. After 60.5±38.7 months' follow up of 92 eligible subjects, the cumulative renal survival rate at 1, 3, 5, and 10 years was 94.6%, 84.1%, and 69.2%, and 31.2%, respectively. Multivariate COX regression indicated PTC injury, inadequate blood pressure control and proteinuria>1g/d are associated with poor renal prognosis.

Conclusions: PTC injury predicted the long-term renal outcome in patients with MHN. Detachment of pericytes from endothelial cells might play a role of the PTC injury.

TH-PO474

Hypertensive Epidemiology and Potential Blood Pressure Goals in IgA Nephropathy

Ying Zheng, Yong Wang, Shuwei Duan, Guangyan Cai, Xiangmei Chen. *Chinese PLA General Hospital, Beijing, China.*

Background: IgA nephropathy is the most prevalent form of primary glomerulonephritis worldwide. Hypertension is one of the most important risk factors in the progression of kidney disease. Our aim was to identify the epidemiology of hypertension in IgA nephropathy.

Methods: This was a nationwide, multi-center, cross-sectional study. We analyzed 1055 patients with IgA nephropathy from 61 tertiary hospitals in China (except Hong Kong, Macao, and Taiwan). Hypertension was defined as blood pressure (BP) ≥ 140/90 mmHg. Three BP goals were used to assess BP control: < 140/90 mmHg, < 130/80 mmHg, and < 125/75 mmHg. The outcomes included factors associated with hypertension, decreased renal function, and potential BP range goals for IgA nephropathy, which were analyzed based on 24-hour proteinuria levels of <1 g/d or ≥ 1 g/d.

Results: We found that 63.3% of our participants with IgA nephropathy had hypertension. Blood pressures were controlled under 140/90 mmHg in 49.1% of participants, 34.3% of patients with proteinuria <1 g/d reached the goal of BP <130/80 mmHg, and only 12.9% of patients with proteinuria >1 g/d achieved BP <125/75 mmHg. With proteinuria <1 g/d, the odds ratios (95% confidence interval) [ORs (95% CI)] of decreased renal function with BPs < 140/90 mmHg, < 130/80 mmHg, and < 125/75 mmHg were 0.9 (0.5 - 1.6), 1.0 (0.5 - 1.8), and 1.0 (0.5 - 2.0), respectively (P > 0.05). With proteinuria ≥1 g/d, the ORs of target BPs < 140/90 mmHg, < 130/80 mmHg, and < 125/75 mmHg were 0.4 (0.2 - 0.6), 0.2 (0.1 - 0.4), and 0.3 (0.1 - 0.5), respectively (P < 0.05).

Conclusions: Hypertension was prevalent in IgA nephropathy and hypertensive control was suboptimal. It might be rational to keep BP < 140/90 mmHg in patients with proteinuria <1 g/d, and < 130/80 mmHg in patients with proteinuria ≥1 g/d, respectively. Randomized clinical trials in IgA nephropathy are needed to evaluate BP range goals.

TH-PO475

Anxious Adolescents and Diastolic Hypertension

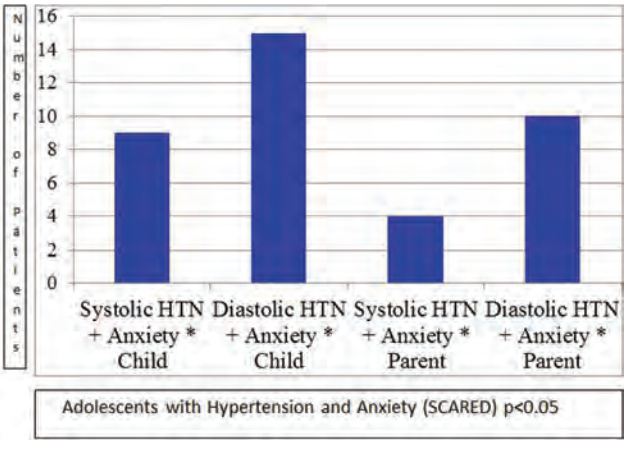
Sara G. Kibrom,[2] Tanya E. Pereira,[1] Dmitry V. Samsonov.[1] *[1]Pediatric Nephrology, New York Medical College, Valhalla, NY; [2]NYMC - Westchester medical center, Valhalla, NY.*

Background: Anxiety is prevalent in 15-20% of children, often negatively affecting health and quality of life. Pediatric hypertension (HTN) is on the rise, affecting 5% of all children. While anxiety correlates with elevated blood pressure (BP) in adults, this has not been studied in children. The primary objective of this study was to examine the relationship between anxiety and HTN in adolescents.

Methods: We screened Adolescents aged 12-18 years in a pediatric nephrology clinic for anxiety. Adolescents and their parents were asked to complete the generalized anxiety subset of the Screen for Child Anxiety Related Disorders (SCARED) questionnaire in regards to the adolescent. A score of ≥ 9 out of 18 was labeled as a positive screen for anxiety. BP was measured at the same visit. Hypertension was defined as systolic or diastolic BP > 95th percentile for age, height, and gender.

Results: Ninety-nine adolescents and their parents completed the questionnaire. The median age was 15 years with 54% of the responders being male. Sixty-two percent had either elevated blood pressures in the office or had diagnosis of hypertension. Nine percent had history of anxiety and 37% screened positive on the SCARED questionnaire. Adolescent's anxiety score correlated with parental rating of adolescent's anxiety (r = 0.4, p <0.01). Parents who perceive their children as anxious had a greater proportion of diastolic HTN compared to non-anxious children 53% vs 29% (p < 0.05) but not systolic hypertension 21% vs 26%, (p = 0.6). Anxious children had higher diastolic HTN (p < 0.05).

Conclusions: Parental perception of child's underlying anxiety level may predict higher diastolic BP measurement at office visit. Future studies should include larger cohort size, and use of ambulatory BP monitoring, and assessment of anxiety score in different subsets of HTN (primary vs secondary). Screening for anxiety may play an important role in the evaluation of patients with hypertension.



TH-PO476

High Prevalence of Significant Structural Heart Disease by Echocardiography in Patients Undergoing Evaluation for Kidney Transplantation

Idil Aktan, Laura Holsten, Sula Mazimba, Andrew D. Mihalek, Thu H. Le, Brendan T. Bowman, Alden M. Doyle, Jamie L. Kennedy. *University of Virginia, Charlottesville, VA.*

Background: Although the deleterious effect of structural heart disease in patients with advanced kidney disease is well known, the specific contribution of valvular abnormalities

has been less well characterized. Detailed echocardiographic criteria have been proposed by the Acute Dialysis Quality Initiative XI Workgroup to identify dialysis patients with underlying structural heart disease. We sought to determine the prevalence of structural heart disease, including valvular disease, in a single center cohort of dialysis patients referred for kidney transplant evaluation.

Methods: We performed a retrospective analysis of single center echocardiographic data obtained from patients undergoing kidney transplant evaluation from 2006 to 2018. Studies that took place at least six months after initiating dialysis were included. Analyses were performed with SAS using Chi square, ANOVA, or Fisher's exact test.

Results: Patients undergoing initial kidney transplant evaluation at the University of Virginia were evaluated by echocardiography, n = 461. They were 58.6% men, and median age was 58 years, interquartile range (IQR) 48 - 66. Median duration of dialysis was 29 months, IQR 17 - 50. Comorbidities included hypertension (89.6%), diabetes (55.8%), and coronary disease (21.7%). The table below shows the frequency of cardiac disease by transplant status at the time of data collection. There were no cases of significant mitral or tricuspid stenosis, and no significant pulmonic valve pathology.

Conclusions: Prevalence of structural heart disease in patients referred for kidney transplant evaluation is high. Patients who ultimately underwent kidney transplant had significantly lower prevalence of structural heart disease, including mitral regurgitation, aortic stenosis, and tricuspid regurgitation, compared to non-transplanted patients.

Echocardiographic Parameter	Overall Cohort (n=461)	Transplanted Patients (n=266)	Actively Listed (n=106)	Expired (n=62)	Inactive (n=27)	P value
Left ventricular dysfunction (EF ≤ 45%) (%)	17.57	6.02	15.09	56.45	51.85	< 0.0001
Right ventricular dysfunction (mild or worse) (%)	15.58	3.81	22.86	41.94	29.63	< 0.0001
Mitral regurgitation (moderate or worse) (%)	4.3	1.61	2.86	16.13	7.41	< 0.0001
Aortic stenosis (moderate or worse) (%)	3.09	0.55	4.12	11.32	0	0.0016
Aortic regurgitation (moderate or worse) (%)	0.51	0.48	0	0	3.7	0.2168
Tricuspid regurgitation (moderate or worse) (%)	7.05	2.04	6.6	27.42	7.41	< 0.0001
Pulmonary hypertension (estimated PASP ≥ 50 mm Hg) (%)	8.24	1.13	14.15	24.19	18.52	< 0.0001
Left ventricular hypertrophy (IVS or PWD ≥ 1.2 cm)	53.8	58.65	48.11	50	37.04	0.0628

TH-PO477

Association Between Post-Dialysis Blood Pressure and Extracellular Volume Status in Hemodialysis Patients

Hoon Young Choi,[1] Seok-hyung Kim,[1] Hyunwook Kim,[2] Jung eun Lee,[4] Hyung Jong Kim,[3] Hyeong cheon Park.[1] *[1]Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Yonsei University College of Medicine Gangnam Severance Hospital, Seoul, GYEONGGI-DO, Republic of Korea; [3]Bundang CHA Medical Center, CHA University, Seongnam, GYEONGGI-DO, Republic of Korea; [4]Yongin Severance Hospital, Yongin-si, Republic of Korea*.

Background: Volume status and hypertension are closely associated with cardiovascular outcome in receiving hemodialysis (HD) patients. New noninvasive bedside tools, such as bioimpedance analysis (BIA) has been reported to assess objective fluid status. Aim of the study was to ascertain the association between hydration status measured by BIA and postdialysis blood pressure in HD patients.

Methods: We conducted a cross-sectional multi-center study. All patients underwent a postdialysis BIA to assess hydration status which was calculated by the ratio of extracellular water (ECW) to total body water(TBW). Patients were divided into three groups, those in whom the blood pressure decreased during dialysis by≥20mm Hg (PDHYPO), those in whom the SBP increased by≥10mmHg (PDHYPER), and in whom the SBP did not meet the definitions of intradialytic hypotension or hypertension, termed as PDSTABLE group. DeltaSBP was calculated by SBP difference between before and after HD. Laboratory data including dialysate sodium as well as serum sodium level was collected and subjective global assessment (SGA) was used for assessing nutritional status.

Results: A total of 254 prevalent HD patients were included in this study. Fifty-four patients (21.3 %) had PDHYPO and seventy-four patients (39.2%) had PDHYPER. Age, SBP after dialysis (SBP_{post}), and deltaSBP were significantly higher, while hemoglobin, serum albumin and sodium and SGA were lower in the PDHYPER group than in PDHYPO and PDSTABLE group. The PDHYPER group showed higher ECW/TBW than in PDHYPO and PDSTABLE group. (0.414 ± 0.011 *vs.* 0.402 ± 0.012, 0.406 ± 0.02, $p<0.001$). In spearman correlation coefficient, deltaSBP ($r=+0.231$, $p<0.001$) and phase angle ($r=-0.804$, $p<0.001$) showed a significant correlation with ECW/TBW. In multiple logistic regression analysis, older age, lower SGA, lower albumin, and higher ECW/TBW were the independent risk factors affecting PDHYPER.

Conclusions: Our data support that increased ECW/TBW is significantly associated with postdialysis blood pressure in HD patients.

Normal Body Mass Index with Non-Alcoholic Fatty Liver Disease Is Associated with Coronary Calcification in Patients with CKD

Hoon Young Choi,[1] Seok-hyung Kim,[1] Tae hoon Kim,[1] Hyunwook Kim,[2] Hyeong cheon Park.[1] *[1]Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Republic of Korea; [2]Yonsei University College of Medicine Gangnam Severance Hospital, Seoul, GYEONGGI-DO, Republic of Korea*.

Background: Increased coronary artery calcification (CAC) for assessing the burden of coronary atherosclerosis has been reported in patients with chronic kidney disease (CKD). Although non-alcoholic fatty liver disease (NAFLD) is associated with obesity and metabolic syndrome, it may also present in lean individuals. This study aimed to investigate whether normal body mass index (BMI) with NAFLD is associated with coronary artery calcification (CAC) in the patients with CKD.

Methods: Data from a total of 1,479 patients with CKD with normal BMI were provided from 2005 through 2017. CAC score was measured with computed tomography. BMI was considered to be normal if it was less than 25 kg/m^2. To assess the central obesity, waist-to-hip ratio (WHR) was also obtained. NAFLD was diagnosed in patients with evidence of liver steatosis at ultrasonography.

Results: Six hundred ninety-nine (47.2%) patients had CAC in CKD with NAFLD. The CAC was significantly higher in the CKD patients with NAFLD than the CKD patients without NAFLD (66.2±238.9 vs. 39.8±158.2, $p<0.001$). After adjusting for age, gender, hypertension, diabetes, dyslipidemia, WHR, estimated glomerular filtration rate, fasting plasma glucose, total cholesterol, NAFLD was significantly associated with increased risk of CAC in CKD patients with normal BMI (OR=1.754, $P<0.001$).

Conclusions: Our study showed that NAFLD was significantly associated with CAC in the non-obese patients with CKD with normal BMI

TH-PO479

Obesity in Glomerular Disease

Paras P. Shah,[1] Kevin E. Meyers,[2] Tammy M. Brady,[3] Keisha L. Gibson,[4] Tarak Srivastava,[5] Christine B. Sethna.[6] NEPTUNE Cardiovascular Working Group *[1]Cohen Children's Medical Center, Fremont, CA; [2]The Children Hospital of Philadelphia and University of Pennsylvania, Philadelphia, PA; [3]Johns Hopkins University, Baltimore, MD; [4]University of North Carolina Kidney Center, Chapel Hill, NC; [5]Childrens's Mercy Hospital, Kansas City, MO; [6]Cohen Children's Medical Center of NY, New Hyde Park, NY*.

Background: Obesity is a risk factor for cardiovascular disease (CVD) and contributes to the development and progression of kidney disease. The impact of obesity on glomerular disease has not been well-described.

Methods: Longitudinal data were from 488 participants in the Nephrotic Syndrome Study Network (NEPTUNE). Obesity was defined as body mass index (BMI) ≥30 kg/m^2 for adults and ≥95% for children. Blood pressure (BP), lipids, complete remission ever (urine protein:creatinine [UPC] <0.3) and composite endpoint (ESRD or 40% decrease in eGFR) were compared in obese vs. non-obese. Generalized estimating equations examined obesity with outcomes, adjusted for age, sex, black race, glomerular diagnosis, follow-up, edema, UPC, eGFR, steroids, calcineurin inhibitors (CNI), renin angiotensin blockade (RAAS), SBP and obesityxedema.

Results: 322 adults (46.5±16 yr, 62% M, 21% black) and 166 children (9.6±5 yr, 57% M, 42% black) with baseline median eGFR 83 (IQR 53,105) ml/min/1.73m^2 and UPC 2(IQR 0.7,4.3) were evaluated. 43% of adults and 38% of children were obese (35% and 34% in non-edematous, respectively). The proportion with obesity did not change during mean 35±20 months of follow-up (Q=11.9, p=0.29). See Table 1. In adjusted models, obesity was associated with hypertension (HTN) (OR1.61 CI 1.14-2.28), greater SBP (β5.73 CI 0.15-11.3) and lower HDL (β-8.1 CI-12.17– -4.03) in adults. For children, obese had greater DBP index (0.03 CI 0.001– 0.07), greater triglycerides (β29.3 CI 1.91–56.7) and lower HDL (β-6.87 CI -12.07- -1.68), as well as increased odds of HTN (OR2.14 CI 1.26–3.65), dyslipidemia (OR1.61 CI 1.04–2.5) and high HDL (OR2.24 CI 1.31–3.81) compared with non-obese. Obesity was not associated with renal outcomes.

Conclusions: In NEPTUNE, obesity is common and associated with CVD risk when compared to non-obese participants.

Renal Transplantation Improves Cardiovascular Autonomic Efficiency and Decreases Stroke Volume Variability in Chronic Hemodialysis Patients

Dan Sapoznikov,[1] Michal Dranitzki Elhalel,[2] Dvora Rubinger.[1] [1]*Hadassah University Medical Center, Jerusalem, Israel;* [2]*Hadassah - Hebrew University Medical Center, Jerusalem, Israel.*

Background: Renal transplantation (TX) was shown to enhance autonomic function and its cardiovascular efficiency (CvE), but its effect on stroke volume (SV) variability (sdSV), a measure of myocardial responsiveness consistency and poor prognostic significance was not defined.

Methods: Beat-to-beat systolic blood pressure (SBP) and interbeat intervals (IBI) monitoring was performed in 72 non-diabetic chronic hemodialysis (HD) patients (pts.), in 41 pts. after TX and in 27 healthy controls (C). The power spectral densities of IBI and SBP in the low frequency (LF) range were calculated from Finometer recordings of SBP and IBI spontaneous variations. SV and total peripheral resistance (TPR) were assessed using the ModelFlow method. The standard deviations (sd) of the above indices were considered to represent their variabilities. Differences in variability indices between SBP periods, 10% above (high) or below (low) the mean SBP were considered representative of CvE.

Results: : Table 1 (see below) lists hemodynamic data and SBP and IBI variability indices during low-high SBP periods. These periods were associated with increased SV and TPR in all groups and decreased sdSV in HD. SBP and IBI variability changes between low-high periods were blunted in HD and restored in TX. Overall sdSV was significantly increased in HD (p=0.025 and 0.001 vs C and TX). Overall LFIBI was lower in HD (p=0.001 vs C). LF SBP decreased after TX (p=0.001 vs HD).

Conclusions: In HD, increased LF SBP, decreased LF IBI and the attenuated variation between low-high SBP episodes are consistent with sympatheric overactivity and suppressed overall autonomic function. Renal TX improves CvE and decreases sdSV,suggesting enhanced myocardial responsiveness.These effects may contribute to the improved survival after TX.

HIFs in the Renal Medulla Regulate Natriuresis and Blood Pressure Through COX2

Nan Guan. *Division of Nephrology,Huashan Hospital,Fudan University, Shanghai, Shanghai, China.*

Background: Hypoxia inducible factors (HIFs) are essential for the maintenance of cellular oxygen homeostasis. In response to hypoxia, stabilized HIFs initiate the expression of genes that alleviate hypoxic stress. HIFs are now important therapeutic targets for CKD anemia. In the phase 2 clinical trial of FG4592(a kind of HIFs stabilizers) in our center, we found that this drug not only corrected anemia but also downregulated blood pressure. Cyclooxygenase 2 (COX2) in the renal medulla was reported to promote natriuresis and decrease blood pressure. HIFs could induce COX2 in some tumors. In the present study we investigated the mechanism underlying the blood pressure lowering effect of HIFs.

Methods: We used mice metabolic cages to measure daily sodium balance. The mice were fed with the same amount of gel food. To capture transient changes in the urine Na+ excretion prior to attainment of a new steady state, daily 8-hour urine were collected after the administration of the drugs. The urinary volume and urinary sodium concentration were measured.

Results: In the clinical trial of FG4592 in our center, patients' mean blood pressure decreased about 5mmHg compared with basal condition(91.5±1.5mmHg vs. 96.5±1mmHg, $P < 0.05$,n=10) after 8-week treatment. The administration of FG4592 significantly increased the daily urinary volume and urinary sodium excretion of the mice on high salt diet (8%NaCl). The cumulative sodium excretion of consecutive 4 days was higher in the FG4592 group than the control group(3.77±0.36mmol vs. 2.82±0.25mmol, $P < 0.05$,n=8). The expression of COX2 in the medulla was increased in the FG4592 group. When we used COX2 inhibitor celecoxib together with FG4592, the natriuresis effect of the latter one was abolished.

Conclusions: HIFs in the renal medulla lower blood pressure through upregulating COX2 and promoting natriuresis.

Cilia Disruption May Regulate the Renal Inner Medulla NOS Pathway

Randee S. Sedaka, Bradley K. Yoder, Edward W. Inscho, Chunhua Jin, David M. Pollock, Jennifer S. Pollock. *University of Alabama at Birmingham, Birmingham, AL.*

Background: Primary cilia act as flow-mediated mechanosensors, signaling via intraflagellar transport (IFT). We previously reported that NO synthase 1 (NOS1) is the major isoform contributing to flow-induced nitric oxide (NO) production in the inner-medullary collecting duct (IMCD) and contributes to natriuretic responses. In this study, we hypothesized that functional ciliary IFT contributes to IMCD NOS1 abundance and activation.

Methods: Mouse IMCD cells were studied under static or flow (10 dynes/cm^2) conditions for 1-hr to assess NO production (HPLC) and ciliary marker expression (western blot). Inner medullary (IM) NOS isoform abundance and urinary NO excretion were measured in 2 models of cilia disruption, PCK rats and conditional IFT88 knockout mice.

Results: Exposure to flow significantly increased IMCD NO production (static: 168±18, flow: 312±26 pmol/mg pr/hr; n=6/group, p<0.05) and ciliary marker expression, IFT88 (static: 1.0±0.3, flow: 1.7±0.1 RDU/b-actin; n=6/group, p=0.02) and acetylated-α-tubulin (static: 1.0±0.2, flow: 1.9±0.2 RDU/b-actin; n=6/group, p=0.01) compared to static controls. IM NOS1α abundance was not elevated in PCK rats (SD: 1.00±0.1, PCK: 1.22±0.1 RDU/b-actin; n=4/group, p>0.05), but NOS1β abundance was increased compared Sprague Dawley (SD) control rats (SD: 1.0±0.2, PCK: 3.9±0.2 RDU/b-actin; n=4/group, p<0.01). NOS3 abundance was similar between SD and PCK rats (1.0±0.1 and 0.9±0.1 RDU/b-actin, respectively; n=4/group, p>0.05). However, pNOS3 Thr495 expression, a NOS3 inhibitory phosphorylation site, was significantly higher in PCK rats (SD: 1.0±0.3, PCK 3.1±0.5 RDU/total NOS3; n=4/group, p<0.01). Similarly, NOS1β expression in IFT88KO mice trended to be higher compared to controls (Cre-: 1.0±0.4,

Cre+ 3.0±0.6 RDU/b-actin; n=3/group, p=0.06). No significant changes in NOS3 abundance were observed (Cre-: 1.0±0.1, Cre+ 1.2±0.2 RDU/b-actin; n=3/group, p>0.05). Urinary NO excretion was similar in SD and PCK rats (SD: 6.1±2.2, PCK 10.0±0.4 umol/day; ßΔn=4-5/group, p>0.05) as well as Cre- and Cre+ IFT88KO mice (Cre-: 211±61, Cre+ 220±13 nmol/day; n=3/group, p>0.05) on normal salt diet. These data suggest that ciliary disruption influences NOS isoform abundance in the renal IM.

Conclusions: In conclusion, functional cilia may contribute to acute flow-induced NO production and NOS isoform abundance.

TH-PO483

Regulation of ABCG2 Transporter and Uric Acid Metabolism in a Model of Hyperuricemia

Chikayuki Morimoto,[1] Yoshifuru Tamura,[2] Emiko Kuribayashi-Okuma,[2] Takayo Murase,[4] Takashi Nakamura,[5] Yoshikazu Nemoto,[1] Shinichiro Asakawa,[1] Yoshihide Fujigaki,[3] Shunya Uchida,[1] Shigeru Shibata.[1] *[1]Teikyo University School of Medicine, Tokyo, Japan; [2]Teikyo University School of Medicine, Tokyo, Japan; [3]Teikyo University School of Medicine, Department of Internal Medicine, Tokyo, Japan; [4]Sanwa Kagaku Kenkyusyo Co., Ltd., Inabe-shi, Japan; [5]Sanwa Kagaku Kenkyusho, Inabe, Japan*.

Background: Hyperuricemia is one of the most frequent complications in chronic kidney disease (CKD). Previously, we showed that the gene expression of the urate transporter ATP-binding cassette subfamily G member 2 (ABCG2) is upregulated in the ileum in the rat remnant kidney model (Yano et al. Clin Exp Nephrol 2014), indicating that the intestine may participate in uric acid metabolism in CKD. However, the role of each part of the intestinal tract in uric acid metabolism in normal and hyperuricemic states have not been clarified. In this study, uric acid concentrations and ABCG2 expression in the different part of intestine were evaluated in normal and hyperuricemia model rats.

Methods: Using Sprague-Dawley rats, we evaluated ABCG2 expression in each part of the intestinal tract by immunofluorescent study. Uric acid concentrations in the serum and in the tissue homogenates were measured by LC/MS. We also evaluated the ABCG2 levels in the intestine of hyperuricemia rats. Hyperuricemia was induced by feeding a diet containing 5% oxonic acid, the uricase inhibitor.

Results: In the intestinal tract of normal rats, the concentration of tissue uric acid (in μg/g tissue) was 5-10 times higher in duodenum and jejunum than in ileum and transverse colon (duodenum 102 ± 16; jejunum 112 ± 16; ileum 17 ± 8.2; transverse colon 7 ± 4). Co-staining of ABCG2 and villin revealed that ABCG2 was highly present in the villus and crypt of the duodenum. Administration of oxonic acid increased serum uric acid levels by 2.1 fold ($P < 0.05$). Comparison of the ABCG2 staining between control and hyperuricemic rats indicated that ABCG2 was upregulated in the ileum by hyperuricemia.

Conclusions: ABCG2 is highly expressed in the duodenum and jejunum at basal condition. However, Hyperuricemia upregulates ABCG2 in the ileum. These data are consistent with our previous studies showing the upregulation of ABCG2 in the ileum in the rat remnant kidney model, and suggest a compensatory role of ileum in hyperuricemic states.

TH-PO484

Insulin: Genetic and Physiological Influences on Human Uric Acid Homeostasis

David B. Mount,[1,2] Tony Merriman,[3] Asim Mandal.[1] *[1]Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Renal Division, VA Boston Healthcare System, Boston, MA; [3]University of Otago, Dunedin, New Zealand*.

Background: Insulin plays a key role in hyperuricemia. In particular, hyperinsulinemia in metabolic syndrome is inversely correlated with urinary uric acid (UA) excretion and insulin infusion in humans reduces urinary fractional excretion of UA.

Methods: An existing GWAS cohort was analyzed, testing for association between genetic variants in the insulin and insulin receptor genes with serum UA (SUA). HEK 293T cells, human PTC5 proximal tubule cells, and *Xenopus* oocytes were probed with antibodies to UA transporters, the insulin receptor, downstream kinases, and the relevant phospho-kinases. ^{14}C-UA transport was assayed in these cell lines and in oocytes expressing individual transporters.

Results: Variants in the human insulin and insulin receptor genes demonstrated significance for association with variation in SUA, at $p<10^{-4}$ and $p<10^{-7}$, respectively. HEK293T and PTC5 proximal tubular cells express several endogenous UA transporter proteins, including GLUT9, OAT10, and URAT1. Insulin activates PI3 kinase/Akt and MEK/ERK signaling pathways through the insulin receptor in HEK 293T and PTC5 cells, as detected with phospho-kinase antibodies, with activation of endogenous ^{14}C-UA transport. The stimulatory effect of insulin on UA uptake is abrogated by uricosurics and by inhibition of protein tyrosine kinase (genistein), PI3 kinase (LY295002), and MEK/ERK (PD98059). UA transport mediated by GLUT9a, GLUT9b, OAT10, OAT3, OAT1, NPT1 and ABCG2, expressed separately in *Xenopus* oocytes, is also activated by insulin, with equivalent activation of signaling pathways and differential effects of signaling inhibitors on insulin-stimulated UA transport. Insulin has no effect on URAT1, OAT4, and the SMCT1/2 nicotinate transporters, when expressed in oocytes. GLUT9a is the basolateral exit pathway in reabsorption of filtered UA by the proximal tubule; given much greater absolute UA transport rates mediated by GLUT9 isoforms, much of the anti-uricosuric effect of *in vivo* insulin infusion is likely due to activation of GLUT9a.

Conclusions: Variation in the human insulin and insulin receptor genes affects SUA. Insulin and associated signaling pathways also activate multiple UA transporters, indicating a pivotal physiological role for insulin in UA homeostasis. We postulate that basolateral GLUT9a in the proximal tubule is the dominant post-translational target of insulin in the regulation of renal UA transport.

Claudin-10a Confers Chloride Permeability to the Tight Junctions of the Proximal Tubule

Nina Himmerkus,[1] Susanne Milatz,[1] Tilman Breiderhoff,[2] Merle Brinkhus,[1] Catarina Quintanova,[1] Dominik Müller,[2] Markus Bleich,[1] Dorothee Günzel.[3] *[1]Institute of Physiology, Christian-Albrechts-University Kiel, Kiel, Germany; [2]Department of Pediatric Nephrology, Charité - Universitätsmedizin Berlin, Berlin, Germany; [3]Institute of Clinical Physiology, Charité - Universitätsmedizin Berlin, Berlin, Germany*.

Background: In the renal proximal tubule (PT) part of the bulk reabsorption of water and electrolytes takes place via the paracellular pathway. This paracellular pathway is regulated by the tight junction (TJ) complex which consists of a belt like structure around the apical pole of the epithelial cells. In contrast to most other epithelia where this belt is composed of multiple strands forming a meshwork, the PT shows only between one and five strands reflecting its high paracellular permeability. The selectivity of the TJ is mainly determined by the claudin composition of the TJ.

Methods: Micro-dissected PTs of claudin-10a specific knock-out animals (KO) and of wild-type controls (WT) were investigated in a double-barreled perfusion system. Diffusion potentials (DPs) were generated by either replacing the basolateral solution by an isosmotic 30 mM NaCl solution or by replacing Cl^- with HCO_3^-. DP were used to calculate relative permeability (P) ratios for Na^+, Cl^- and HCO_3^-. Immunofluorescence against claudin-10, claudin-2 and claudin-3 was performed on single isolated tubules.

Results: In WT, the early convoluted part of the proximal tubule (early PCT) showed anion selectivity (P_{Cl}/P_{Na} = 1.52 ± 0.07), the last straight part (PST) showed cation selectivity (P_{Na}/P_{Cl} = 1.26 ± 0.06) and the convoluted segments in between showed intermediate selectivity. PT TJ showed higher permeability for Cl^- than for HCO_3^- with the highest P_{Cl}/P_{HCO3} (1.86 ± 0.25) in late PCT. In PCT, claudin-10a expression was dominant in the TJ, in PST claudin-2 expression predominated. In addition, in this last segment of the PT, the tightening claudin-3 was expressed and co-localized to the TJ. In KO early PCT, claudin-2 moved to the TJ. Consequently, the early PCT lost anion selectivity completely and displayed high cation selectivity (P_{Na}/P_{Cl} = 2.86 ± 0.45). In KO late PCT, P_{Cl} was lower than P_{HCO3} (P_{Cl}/P_{HCO3} = 0.88 ± 0.15). In KO PST differences were less pronounced but qualitatively similar (P_{Na}/P_{Cl} = 2.00 ± 0.14; P_{Cl}/P_{HCO3} = 1.05 ± 0.06).

Conclusions: In summary, PT TJ selectivity changes along its axis from anion to cation selectivity. The anion selectivity is further characterized by preference of Cl^- over HCO_3^- and is claudin-10a dependent.

Functional Proteomics of Isolated Perfused Cortical Collecting Ducts

Nina Himmerkus,[1] Markus Bleich,[1] Thomas Benzing,[2] Markus M. Rinschen.[2,3] *[1]Institute of Physiology, Christian-Albrechts-University Kiel, Kiel, Germany; [2]Department II of Internal Medicine, University Hospital Cologne, Köln, Germany; [3]Center of Metabolomics and Mass Spectrometry, The Scripps Research Institute, San Diego, CA.*

Background: In renal physiology and pathophysiology large-scale omic data sets are generally generated from bulk samples, e.g. the complete kidney or cortex vs. medulla. It is therefore difficult to predict implications for functional changes taking place in the individual, highly specialized and very distinct nephron segments. In the context of hypertension it is of high clinical relevance to understand regulation of salt transport in the collecting duct and the phenomenon of salt-sensitivity. The aim of this study was to establish a method to correlate measured electrophysiological properties of individual, isolated perfused cortical collecting ducts (CCD) with respective proteomic data.

Methods: For the electrophysiological properties, freshly isolated CCDs of 6-8 week old C57Bl6 mice were investigated in a double-barreled perfusion system. Transepithelial voltage (V_{te}) was recorded and transepithelial resistance as well as amiloride sensitive equivalent short-circuit current ($\Delta I'_{sc}$) were calculated. After these measurements every single tubule was recovered, processed and ultrasensitive mass spectrometry was performed.

Results: In manually collected CCD segments we were able to identify more than 4000 distinct proteins. In the perfusion experiments, protein expression patterns typical for intercalated cells or, principal cells, respectively, showed negative correlation in the proteome. V_{te} varied between -8.5 and -32.5 mV and correlated with the regulator protein NEDD4. $\Delta I'_{sc}$ as a measure of electrogenic sodium reabsorption was reflected by the expression level of the b-subunit of the epithelial sodium channel.

Conclusions: We could show that functional proteomics on a single nephron segment is possible and allows function-proteome correlations. This unique data acquisition approach will allow conclusions on physiological or pathophysiological outcomes based on omics data at the level of functional units rather than total organ samples.

TH-PO487

mTORC1 Regulates Renal Proximal Tubular Megalin Function

Madlen Kunke, Luis Zanon rodriguez, Gerburg Schwaerzer, Franziska Theilig. *Christian-Albrechts University zu Kiel, Kiel, Germany*.

Background: Renal proximal tubular cells constantly recycle nutrients to ensure minimal loss of essential substrates into the urine. Thus, endocytosis is a hallmark of the

proximal tubule. Protein uptake is mediated by the scavenger receptors megalin and cubilin, followed by internalization of the ligand-receptor complex via the clathrin-mediated pathway. The mTORC1 complex is a principle regulator of proximal tubular function, including endocytosis. However, the effect of mTORC1 on megalin function remains unknown.

Methods: Tubular deletion of mTORC1 was created by crossbreeding Raptor$^{fl/fl}$ with Pax8rt-TA and TetOCre mice. Phosphoproteomics were performed to analyze the phosphorylation of megalin in the renal cortex. Endocytosis was detected in proximal tubules using Alexa555-labelled lactoglobulin. *In vitro*, we induced mTORC1 activity through transient transfection with Rheb, used megalin minireceptor 2 (MMR2) to introduce mutations in the respective phosphosite S4577A, S4577D, S4577E, and followed endocytosis through Alexa555-labelled albumin.

Results: mTORC1-deficient mice showed normal megalin expression and distribution within proximal tubules compared to wildtype mice. Interestingly, receptor-mediated endocytosis of Alexa555-labelled lactoglobulin was blocked in mTORC1-deficient mice. Phosphoproteomics of mTORC1 deficient mice revealed a strongly reduced phosphorylation at S4577 of the C-terminus of megalin, which was confirmed by transient transfection of MDCKII cells with Rheb stimulating mTORC1 activity. Transfection of wildtype or mutated MMR2 in MDCKII cells caused no difference in megalin expression and its cellular distribution. However, endocytosis was increased in the presence of S4577D mutant compared to megalin wildtype

Conclusions: mTORC1 complex is an important regulator of proximal tubular function and phosphorylates megalin to influence megalin function.

Proximal Tubule-Specific Regulation of NPT2a by NHERF1

Kenneth Gagnon,[1] Michelle T. Barati,[1] Kathleen Kitterman,[1] Eleanor D. Lederer.[2]
[1]University of Louisville, Louisville, KY; [2]University of Louisville; Robley Rex VA Medical Center, Louisville, KY.

Background: NHERF1 (Na-H Exchanger Regulator Factor 1), a PDZ protein that expresses an Ezrin binding domain (EBD), regulates proximal tubule BBM expression of NPT2a (Na-phosphate cotransporter), a critical determinant of phosphate homeostasis, through interactions with NPT2a and Ezrin (an actin cytoskeleton linking protein). Knockout of NHERF1 or Ezrin results in aberrant trafficking and diminished BBM expression of NPT2a. Additionally, knockout of NHERF1 decreases association of NPT2a with Ezrin. We hypothesize that NHERF1 regulates NPT2a trafficking through PDZ interactions and NPT2a anchoring through EBD interactions.

Methods: To test our hypothesis, we generated cDNA constructs encoding: NPT2a full-length (FL); NPT2a PDZ1-deficient (TRL-); NPT2a/NHERF1 chimera wherein the EBD of NHERF1 replaces the TRL motif of NPT2a (Chimera); NHERF1 full-length (FL); and NHERF1 EBD deficient (EBD-). We transfected HEK293 cells, which express Ezrin but not NPT2a or NHERF1, with wild-type and mutant NPT2a and NHERF1 constructs and assessed their expression and function with ^{32}P-phosphate uptake, immunofluorescence microscopy, and differential centrifugation/western blot experiments.

Results: HEK293 cells expressing NPT2a FL, NPT2a TRL-, or NPT2 Chimera constructs all exhibited 2.5-fold greater phosphate uptake versus sham- or vector-only transfections. Co-transfection with NHERF1 FL or NHERF1 EBD- constructs did not enhance phosphate uptake. Contrary to the diminished NPT2a membrane expression observed in proximal tubule cells lacking NHERF1 or transfected with NPT2a TRL-, immunofluorescence of HEK293 cells transfected with wild type and mutant NPT2a constructs demonstrated plasma membrane localization in the absence or presence of NHERF1. Wild type and mutant NHERF1 constructs exhibited global expression throughout the cell, even at the lowest transfection level (75 ng/ul). Differential centrifugation/Western blotting of transfected cells revealed wild type and mutant NPT2a expression in only the organelle and plasma membrane compartments, while wild type and mutant NHERF1 construct expression was observed in organelle, plasma membrane, and cytosol compartments.

Conclusions: These studies suggest that 1) NHERF1 regulation of NPT2a is proximal tubule specific; and 2) unidentified accessory protein(s) are essential for the BBM trafficking, localization, and function of NPT2a in proximal tubule.

Dissecting the Na/K-ATPase Signaling Complex in Renal Proximal Tubule: A Cross-Linking Approach

Jiang Liu,[1] Fang Bai,[1] Rebecca Pratt,[1] Zi-jian Xie,[2] Joseph I. Shapiro.[1] *[1]Marshall University School of Medicine, Huntington, WV; [2]Marshall University, Huntington, WV.*

Background: The Na/K-ATPase α1 subunit and c-Src have been shown to form a signaling complex. Activation this signaling cascade regulates sodium handling in proximal tubule, systemic oxidative stress, and uremic cardiomyopathy. The present study is to investigate the formation of the Na/K-ATPase signaling complex, especially the binding of the α1 subunit and c-Src under native condition in live cells.

Methods: Crosslinking studies were performed in live LLC-PK1 cells with sulfhydryle-sulfhydryle crosslinkers BMH (non-cleavable) and DTME (cleavable). SDS-PAGE and WES system were used to determine the crosslinking efficiency and molecular weight shifts under denatured condition. Blue Native gel electrophoresis (BN-PAGE) was used to identify the molecular weight of the complex under native condition. A BN-PAGE/SDS-PAGE 2D system was used to separate and identify the components of the Na/K-ATPase complex by silver staining and Western blot.

Results: (1) Both BMH and DTMH effectively crosslink the α1 subunit and c-Src, demonstrated by Western blot analysis in both SDS-PAGE and WES system. (2) In BN-PAGE system, like in control, both BMH and DTME-treated samples showed protein bands closer to marker of 720 kDa (between 480 and 720 kDa markers). Western blot analysis showed co-existence of the α1 subunit, β1 subunit, c-Src, and caveolin-1. (3) In WES system, like seen in control, there is a clear crosslinking between the α1 subunit and c-Src, by comparing the data amongst BMH and DTME crosslinking treatments, combined with or without DTT/SDS cleavage. (4) In the BN-PAGE/SDS-PAGE 2D system, preliminary data showed that the complex contains the α1 subunit, c-Src, and caveolin-1. (5) Interestingly, pretreatment with pNaKtide (a peptide derived from the α1 subunit), an antagonist of the Na/K-ATPase signaling, increases ouabain-sensitive 86Rb+ uptake in LLC-PK1 cells. Moreover, pNaKtide also co-exists with the Na/K-ATPase complex.

Conclusions: Our data indicated that the Na/K-ATPase signaling complex contains the Na/K-ATPase α1 subunit, c-Src, and caveolin-1. Further studies with mass spectrometry need to be performed to confirm the findings, and might be able to find more component(s) of the complex.

TH-PO490

Osmotic Diuresis by SGLT2 Inhibition Is Associated with Increased Renal Solute-Free Water Reabsorption and AQP2 Expression in Diabetic Rats

Takahiro Masuda,[1] Shigeaki Muto,[1] Keiko Fukuda,[3] Minami Watanabe,[3] Yuko Watanabe,[1] Ken Ohara,[1] Hermann Koepsell,[4] Akito Maeshima,[1] Volker Vallon,[2] Daisuke Nagata.[1] *[1]Jichi Medical University, Shimotsuke, Japan; [2]University of California San Diego, San Diego, CA; [3]Jichi Medical Universtiy, Shimotsuke, Japan; [4]University of Würzburg, Germany, Würzburg, Germany.*

Background: Most of the filtered glucose is reabsorbed in the early proximal tubule by the sodium-glucose cotransporter SGLT2. The glycosuric effect of the SGLT2 inhibitor ipragliflozin is associated with a sustained diuretic and natriuretic tone that activates compensatory increases in fluid and food intake to stabilize body fluid volume (Am J Physiol Renal Physiol 2018, May 23. doi: 10.1152/ajprenal.00143.2018). However, the compensatory mechanisms that are activated on the level of renal tubules remain unclear.

Methods: Non-obese type 2 diabetic Goto-Kakizaki (GK) rats were treated with vehicle (Veh) or 0.01% (in diet) ipragliflozin (Ipra) (n= 4-5) with free access to food and water. After 8 weeks, GK rats were placed in metabolic cages for 24h urine collection. Blood was collected by cardiac puncture and whole kidneys for western blot were harvested under terminal isoflurane anesthesia.

Results: Body weight (365±10 vs. 353±5 g) and serum glucose (303±46 vs. 312±25 mg/dL) were similar between Veh and Ipra. Ipragliflozin increased food and fluid intake (food: 19.5±1.5 vs. 27.8±0.9 g/24h*, fluid: 37.0±7.0 vs. 87.0±5.9 mL/24h*, *P<0.05 vs Veh), urine volume (25.7±3.9 vs. 64.2±4.9 mL/24h*), urinary glucose excretion (1.0±0.6 vs. 5.9±0.4 g/24h*), urinary Na^+ excretion (2.2±0.2 vs. 3.2±0.3 mEq/24h*), renal osmolar clearance (128±17 vs. 265±13 mL/24h*) and solute-free water reabsorption (102±14 vs. 201±9 mL/24h*). The renal membrane protein expression of SGLT2 and AQP2 was increased, whereas NKCC2 expression was decreased in the Ipra vs Veh group. The expression of SGLT1, NHE3, phosphorylated NHE3 (S605 and S552), AQP1 and ENaC (aENaC, bENaC and gENaC) was similar between the groups.

Conclusions: The SGLT2 inhibitor ipragliflozin induced a sustained glycosuria, diuresis, and natriuresis, and increased solute-free water reabsorption in the kidneys of diabetic rats. The latter was associated with an increase in renal AQP2 expression. These results suggest that the osmotic diuresis induced by SGLT2 inhibition stimulates compensatory fluid reabsorption in the collecting duct.

Acidosis Stimulates SDF/CXCR4 Expression and Antimicrobial Responses via HIF-1α in Mouse Collecting Duct (M-1) Cells

Hu Peng,[3] George J. Schwartz,[1] Jeffrey M. Purkerson.[2] *[1]University of Rochester, Rochester, NY; [2]University of Rochester Medical Center, Rochester, NY; [3]Univeristy of Rochester medical center, Rochester, NY.*

Background: Intercalated cells (ICs) mediate H^+ and HCO_3 secretion in the kidney collecting duct (CD), We reported that IC adaptation to metabolic acidosis is mediated by SDF1 signaling via CXCR4 (JCI 125:4365, 2015), and that metabolic acidosis stimulates expression of the antimicrobial peptide (AMP) cathelicidin in rabbit urine (AJP 313: F1061, 2017).

Methods: We used M-1 cell line (ATCC CRL-2038), from mouse l (CD), as an *ex vivo* model. M-1 cells were cultured in normal (25mM $NaHCO_3$) and acidic (10mM $NaHCO_3$, 10uM EIPA) medium±HIF-1α stabilizer (IOX2,100uM), HIF-1α inhibitor PX-478 (60uM), LPS (200ng/ml), and Arginine (5mM) for 24hr. Total RNA was isolated and antimicrobial peptides, cathelicidin (Camp) and beta-defensin 2 (BD2)) and SDF1/CXCR4 mRNA abundance determined by real-time qRT-PCR and the ΔΔCt method. Uropathogenic *E. coli* (UPEC) were incubated (5 MOI) with M-1 cells for 90min; unbound bacteria removed by washing, intracellular infection of M-1 cells was determined by gentamicin (100ug/ml) treatment, prior to lysis. Dilutions of cell lysates were plated on agar to determine UPEC burden.

Results: Acidosis induced Camp (2.1 fold±0.20, n=3, p< 0.001), BD 2 (2.83 fold±0.26, n=3, p< 0.01), SDF1 (2.44 fold±0.28, n=3, p<0.01), and CXCR4 mRNA (3.1 fold±0.29, n=3, p<0.01); Prior exposure to acid media decreased by 35% the UPEC burden (mean CFU/ml: Normal=$1.12\pm0.07x10^6$; Acidosis= $7.37\pm0.03x10^5$, p<0.01). IOX2 increased Camp (2.81 fold±0.31, n=6, p< 0.05) and BD2 mRNA abundance (3.80 fold±0.36, n=6, p< 0.01),

and PX-478 reduced M-1 cell resistance to infection conferred by acid-medium by 12% (mean CFU/ml: Acidosis=4.5±0.45x10⁴; Acidosis+PX-478=5.3±0.6x10⁴, p<0.05). M-1 cells treated by combination of IOX2, LPS, and Arginine were substantially more resistant to infection (mean CFU/ml: Untreated=6.7±0.55x10⁴; IOX2, LPS,Arg=2.8±0.35x10⁴, p< 0.01), a 58.2% decrease in UPEC burden. LPS induced SDF1 and CXCR4 mRNA in normal (SDF1: 2.67±0.33, n=3, p< 0.01; CXCR4: 2.94±0.38, n=3, p<0.01) or acidic (SDF1: 4.68±0.61, n=3, p< 0.01; CXCR4: 6.47±0.29, n=3, p<0.01) medium.

Conclusions: Acidosis, via activation of HIF-1α, stimulates expression and function of innate immune defense peptides as well as SD1 and CXCR4 in kidney collecting duct cells.

TH-PO492

Metabolic Acidosis Increases Susceptibility of Mice to Uropathogenic E. coli (UPEC)-Induced Pyelonephritis (PN)

Jeffrey M. Purkerson,[2] Hu Peng,[3] George J. Schwartz.[1] *[1]Pediatrics, University of Rochester Med Ctr, Rochester, NY; [2]University of Rochester Med Ctr, Rochester, NY; [3]University of Rochester Med Ctr, Rochester, NY.*

Background: Carbonic anhydrase 2-deficient mice show metabolic acidosis with deficient urine acidification, and are more susceptible to UPEC-induced PN (Hains, AJP 307:F869, 2014). Whether the susceptibility to PN is due to H^+ transport abnormalities or acidosis is unclear. In this study we examined the impact of acidosis on susceptibility of refluxing C3H-HEouJ mice to PN.

Methods: Metabolic acidosis was induced in C3H-HEouJ mice via NH_4Cl (2% w/w) supplementation of food±I.P. administration of acetazolamide (ACZ 100 mg/kg). Acid-base state was assessed by blood gas using an iSTAT® G3+ and pH of urine collected under water-saturated mineral oil in metabolic cages housing 2-4 mice. Collecting duct (CD) fragments were enriched from collagenase-digested mouse kidney by DBA-lectin magnetic sorting. Relative abundance of SDF1 and antimicrobial peptide (AMP) mRNAs (cathelicidin [Camp]; beta defensin-2 [BD2]) in CDs was determined by qRT-PCR via ΔΔCt. Female C3H-HEouJ mice were infected with UPEC strain CFT073 @ 10^7 cfu/50 µl via transurethral inoculation. Bacterial burden (cfu/g) in bladder and kidney was determined by culture of tissue homogenates. Statistical significance utilized T-test or Mann-Whitney Test.

Results: NH_4Cl-fed mice were acidotic (s[HCO3] 18.2±0.65*, Ur pH 5.8±0.02*; N=8) compared to normal (NL) (s[HCO3] 22.2±0.68; Ur pH 6.8±0.01, *p<0.05, N=24); co-administration of ACZ resulted in severe acidosis and reduced urine acidification (s[HCO3] 12.8±0.7**; Ur pH 6.9±0.05, p<0.001 versus NL, N=5-9). UPEC infection alone did not induce SDF1 mRNA; however acidosis+UPEC infection induced SDF1 expression 3.5±0.4 fold over NL (p<0.01). Severe acidosis (NH_4Cl+ACZ) increased Camp (2.1±0.11) and BD2 (2.3±0.36) mRNA, whereas expression of SDF-1 mRNA was induced 10.5±1.0 compared to NL (p<0.01). Acidotic mice were more susceptible to PN than NL (kidney mean cfu/g: NL $4.1x10^3$; Acidosis $2.6x10^8$, p<0.001; N=7-8). UPEC burden was also higher in bladders from acidotic mice compared to normal (mean cfu/g: NL $6.8x10^5$; Acidosis $8.6x10^8$, p<0.001).

Conclusions: Metabolic acidosis increases the susceptibility of C3H-HEouJ mice to PN. Increases in AMP expression with acidosis do not compensate for an apparent loss of barrier function, manifested as increased production of SDF1, a key mediator of the kidney response to metabolic stress (e.g. hypoxia, acidosis).

TH-PO493

Monophosphoryl Lipid A (MPLA) Prevents LPS-Induced Inhibition of HCO3- Absorption in Medullary Thick Ascending Limb Through Negative Regulation of Interleukin-1 Receptor-Associated Kinase-1 (IRAK-1)

Bruns A. Watts,[1] Esther Tamayo,[1] Edward R. Sherwood,[2] David W. Good.[1] *[1]University of Texas Medical Branch, Galveston, TX; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: LPS inhibits HCO_3^- absorption in the MTAL through activation of a basolateral TLR4-MyD88-ERK pathway that is upregulated by sepsis. Recently we showed that pretreatment with the nontoxic immunomodulator MPLA prevents inhibition of HCO_3^- absorption by LPS through activation of a TLR4-TRIF-PI3K pathway that prevents LPS-induced ERK activation. Here, we examined molecular mechanisms that underlie the protective inhibitory interaction between the MPLA-PI3K and LPS-ERK signaling pathways.

Methods:

Results: We first examined IRAK-1, a critical mediator of LPS signaling downstream of TLR4 that is downregulated in LPS tolerant cells. Treatment of mouse MTALs with LPS for 15 min in vitro increased IRAK-1 phosphorylation 1.5-fold. The effect of LPS to activate ERK in the MTAL was prevented by a selective IRAK-1 inhibitor, establishing IRAK-1 as the upstream mediator of ERK activation in the LPS pathway. Pretreatment of MTALs with MPLA for 2 h in vitro prevented LPS-induced IRAK-1 activation. This effect of MPLA was eliminated by a PI3K inhibitor. Toll-interacting protein (Tollip) is an intracellular protein that is induced in LPS tolerant cells and negatively regulates LPS signaling by suppressing IRAK-1 activity. To assess whether Tollip may be involved in MPLA's actions in the MTAL, mice were pretreated with MPLA or vehicle 48 h prior to sham or cecal ligation and puncture (CLP) sepsis surgery. MPLA pretreatment increased Tollip expression in microdissected MTALs and inner stripe of outer medulla from sham and CLP mice. In addition, treatment with MPLA for 2-3 h in vitro increased Tollip expression in inner stripe of control mice.

Conclusions: We conclude that MPLA activates a PI3K-dependent pathway that inhibits LPS stimulation of IRAK-1 in the MTAL, thereby preventing LPS-induced ERK activation that inhibits HCO_3^- absorption. These protective effects of MPLA likely are mediated through the induction of Tollip, an immunomodulatory protein that negatively regulates IRAK-1. These results provide new evidence that renal tubule epithelial cells are capable of undergoing immune reprogramming that affords resistance to LPS and identify IRAK-1 as a key molecular target through which MPLA prevents LPS impairment of HCO_3^- absorption in the MTAL.

Secretin-Stimulated Urinary HCO3- Excretion: A Function of CFTR and Pendrin

Peder Berg,[1] Inês Cabrita,[3] Rainer Schreiber,[2] Karl Kunzelmann,[2] Jens G. Leipziger.[1] *[1]Aarhus University, Aarhus, Denmark; [2]University of Regensburg, Regensburg, Germany; [3]Physiology, University of Regensburg, Germany, Regensburg, Germany.*

Background: The gastro-intestinal hormone secretin (SCT), the first hormone ever discovered (Bayliss and Starling, ca. 1905), is able to acutely increase the amount of HCO_3^- in the urine, but the underlying mechanism remains enigmatic. The actions of secretin are well understood in gastro-intestinal physiology; among many functions it acts as an important activator of pancreatic HCO_3^- secretion. Intriguingly, the SCT receptor is also expressed in the collecting duct (CD) of the kidney.

Methods: Real time monitoring of urine flow and urinary pH was allowed by bladder catheterization and insertion of micro pH-electrodes in the outflow of the catheter in i.v. anaesthetized mice.

Results: Here, we show that SCT elicits acute urinary alkalisation, increases urinary [HCO_3^-] and urinary HCO_3^- excretion rate in anaesthetized mice. This effect is present in multiple mouse strains corroborating data from older studies in healthy humans. Importantly, we identified that the SCT effect is completely absent in mice lacking the apical Cl^-/HCO_3^- exchanger pendrin, which, in the kidney, is exclusively expressed in the apical membrane of β-IC of the CNT/CD. Moreover, we found that the SCT effect on urinary pH is dramatically diminished in mice with either global knock-out of CFTR or renal tubule-specific knock-out of CFTR. The effect on urinary [HCO_3^-] and urinary HCO_3^- excretion is completely abolished in both CF animal models, corroborating early data from children suffering from cystic fibrosis. Noteworthy, CFTR expression has been shown to be several folds higher in β-IC cells compared to α-IC and principal cells.

Conclusions: In conclusion, this study has defined the molecular mechanism of SCT-induced urinary HCO_3^- excretion as a function of the specific activation of the β-IC of the CD. Thus, in close similarity to the established mechanism of SCT-induced HCO_3^- excretion in the exocrine pancreas, an analogous mechanism was identified in the kidney.

TH-PO495

MAGE-D2 Promotes Expression and Stability of Pendrin Protein

Elie Seaayfan,[1] Aparna Renigunta,[1] Stefanie Weber,[1] Kamel Laghmani,[2] Martin Kömhoff.[1] *[1]University Children's Hospital Marburg, Marburg, Germany; [2]INSERM-CNRS, Paris, France.*

Background: We recently showed that mutations in *MAGE-D2* cause polyhydramnios with preterm delivery of the affected baby and a severe but transient form of antenatal Bartter's syndrome (tBS). Although reduced total and apical expression of the sodium–chloride transporters NKCC2 and NCC was shown in vivo and in vitro, which explains massive salt losing (Laghmani et al, N Engl J Med. 2016), additional transporters may also be impaired. One potential candidate is Pendrin, because its loss increases salt losing and because it is expressed in the distal tubule as MAGE-D2. Consequently, the aim of the present study was to investigate the potential role of MAGE-D2 in Pendrin biogenesis.

Methods: Pendrin protein expression was monitored in transiently transfected HEK293 cells by immunoblotting, which allows the detection of both the immature (core-glycosylated) and mature Pendrin protein. Stability of Pendrin protein was assessed by cycloheximide chase assay. We studied the effects of wild type MAGE-D2 and mutant R446CMAGE-D2 on Pendrin expression. In addition, the role of endogenously expressed MAGE-D2 role was investigated by small interfering RNA. To assess the specificity of our findings, we also analyzed the effects of MAGE-D2 overexpression on NHE3 biogenesis.

Results: MAGE-D2 co-expression robustly increased expression of immature and total cellular Pendrin protein in a dose dependent manner. Cycloheximide chase assays (CHX) showed that in cells over expressing MAGE-D2, stability of immature Pendrin is increased. In contrast to MAGE-D2 wild type, R446CMAGE-D2, a missense mutation identified in a tBS patient, co-expression significantly decreases Pendrin stability. Analogous to R446CMAGE-D2, knockdown of endogenous MAGE-D2 by small interfering RNA also decreases Pendrin stability. In contrast to Pendrin, our preliminary data did not reveal an effect of MAGED2 on the expression of total NHE3.

Conclusions: Our findings show that MAGED2 specifically promotes the expression of Pendrin. Importantly, our data indicate that MAGED2 affects multiple salt transporters in the distal tubule, thus explaining the severe phenotype.

TH-PO496

Transcriptome Profiling in Pendrin Deficient Mice Provides New Insight into the Role of Pendrin in Kidney Physiology

Jie Xu,[1] Sharon L. Barone,[1,2] Kamyar A. Zahedi,[1,2] Manoocher Soleimani.[1,2] *[1]Internal Medicine, University of Cincinnati, Cincinnati, OH; [2]Veterans Affairs Medical Center, Cincinnati, OH.*

Background: Slc26a4 (Pendrin) is a Cl^-/HCO_3^- exchanger that is primarily expressed on the apical membrane of B-intercalated cells in the kidney connecting tubules/cortical collecting ducts and plays a critical role in salt absorption and bicarbonate secretion.

Methods: To gain better insight into the role of pendrin in kidney function, RNA-Seq analysis was performed on kidney cortices of wild type and pendrin KO mice and results verified by Northern hybridization and/or immunofluorescence labeling.

Results: The most dramatic changes in the expression of solute transporters belonged to the families of organic anion and cation transporters and their collaborating partners, which are primarily expressed in the proximal tubule. The expression of the basolateral organic anion transporters, OAT1 and OAT3 (Slc22a6 and a8), along with their interacting partner NaDC-3 (Slc13a3), was significantly increased and paralleled a robust enhancement in the expression of the apical voltage driven urate efflux transporter Npt4 (Slc17a3). Likewise, the expression of the basolateral organic cation transporter, Oct2 (Slc22a2) increased and was matched by the enhanced expression of MATE1 (SLC47A1) and NHE-8 (Slc9a8) on the apical membrane. The activation of NHE-8 is likely to provide the necessary luminal proton for MATE1, an organic cation/H^+ exchanger on the apical membrane of the proximal tubule. In addition, the Na^+-Sulfate cotransporter (Slc13a1) which is expressed on the apical membrane of proximal tubules and mediates sulfate absorption showed significant up-regulation.

Conclusions: In conclusion, deletion of Slc26a4 is associated with enhanced expression of organic anion and cation transporters on the basolateral and apical membranes of the proximal tubule. We propose that the coordinated regulation of organic anion and cation transporters in the kidney proximal tubule of pendrin KO mice supports an important role for pendrin in the excretion of endogenous and exogenous organic cations (such as creatinine, guanidine, metformin, cisplatinum, etc), endogenous and exogenous organic anions (uric acid, prostaglandins, uremic toxins, penicillin, methotrexate, linezolid, etc), and inorganic anions such as sulfate.

NBCe1A Regulates Citrate Excretion During Hypokalemia Through NaDC1 Expression-Dependent and Independent Mechanisms

Kierstin L. Webster,[1] Hyun-Wook Lee,[1] Autumn N. Harris,[1] Michael F. Romero,[2] Jill W. Verlander,[1] I. D. Weiner.[1,3] *[1]University of Florida, Gainesville, FL; [2]Mayo Clinic College of Medicine, Rochester, MN; [3]Nephrology Section, NF/SGVHS, Gainesville, FL.*

Background: Urinary citrate is an alkali equivalent and chelates calcium, thus is critical to acid-base homeostasis and prevention of calcium nephrolithiasis. Hypokalemia causes hypocitraturia; proximal tubule NaDC1 mediates citrate reabsorption and is thought to be the major regulator of citrate excretion. However, whether NaDC1 protein expression changes in hypokalemia and the signaling pathways involved are unknown.

Methods: Mice were fed either a K-control diet for 2 days or K-control diet for 2 days then K-free diet for 4 days. Urinary citrate was measured using ^{1}H-NMR. We determined NaDC1 expression in the proximal convoluted tubule (PCT), proximal straight tubule in the medullary ray (PST-MR) and outer medulla (PST-OM) using quantitative immunohistochemistry. To determine the role of NBCe1-A in the signaling pathway regulating NaDC1 expression, we compared mice with NBCe1-A deletion (KO) with wild-type (WT) littermates.

Results: While on K-control diet, urinary citrate excretion did not differ between WT and NBCe1-A KO mice. However, KO mice had significantly less NaDC1 immunolabel than WT mice in the PCT and PST-MR. A K-free diet for 4 days decreased citrate excretion significantly in both genotypes, but the decrease was significantly blunted in KO mice compared to WT mice (WT, 95±3% decrease; KO, 83±6% decrease; $P<0.05$). In WT mice, K-free diet increased PCT and PST-MR NaDC1 immunolabel significantly compared to K-control. In contrast, in NBCe1-A KO mice NaDC1 expression did not differ significantly between K-control and K-free mice in any proximal tubule segment, PCT, PST-MR or PST-OM.

Conclusions: (1) K-free diet decreases citrate excretion by increasing NaDC1 expression in the PCT and PST-MR through a mechanism that involves signaling through the basolateral membrane protein NBCe1-A; (2) In NBCe1-A KO mice fed K-control diet, either alternative citrate transporters or NaDC1 regulation through a mechanism other than steady-state protein expression enables similar rates of citrate reabsorption despite less total NaDC1 expression than WT; and, (3) In the absence of NBCe1-A a K-free diet acts through NBCe1-A-independent signaling pathways to increase citrate reabsorption through a mechanism that does not involve altered NaDC1 protein expression.

TH-PO498

Proximal Tubule NBCe1-A-Dependent Regulation of Ammonia and Potassium Metabolism During Hypokalemia

Hyun-Wook Lee,[1] Autumn N. Harris,[1] Chao Chen,[1] Richard A. Coleman,[2] Paul A. Welling,[3] Michael F. Romero,[4] Jill W. Verlander,[1] I. D. Weiner.[1,5] *[1]University of Florida, Gainesville, FL; [2]Physiology Dept, U. of MD School of Medicine, Baltimore, MD; [3]University of Maryland School of Medicine, Baltimore, MD; [4]Mayo Clinic College of Medicine, Rochester, MN; [5]Nephrology Section, NF/SGVHS, Gainesville, FL.*

Background: Dietary potassium restriction is associated with increased ammonia excretion, but neither the specific proteins that signal this response nor the functional role of increased ammonia excretion are known. This study's purpose was to determine NBCe1-A's role in the effect of dietary potassium restriction on ammonia metabolism and potassium homeostasis.

Methods: Mice were fed either a K-control diet for 2 days or K-control diet for 2 days followed by K-free diet for 4 days. To determine NBCe1-A's role we compared mice with NBCe1-A deletion (KO) with wild-type (WT) littermates. All studies included both male and female mice and inclusion of sex in statistical analyses did not change any conclusions.

Results: Urinary ammonia excretion increased during each day of K restriction in WT mice. In KO mice the increase in ammonia excretion was significantly less on each day than in WT mice. Compared to WT, NBCe1-A KO had significantly lower cortical expression of key ammoniagenic proteins, phosphoenolpyruvate carboxykinase and phosphate-dependent glutaminase, and greater expression of the ammonia-recycling protein, glutamine synthetase. NBCe1-A deletion also altered renal K handling during K-free diet. After 4 days of K-free diet, hypokalemia was significantly more severe in KO mice than in WT (KO, 2.5±0.2; WT, 3.5±0.2 mM, $P<0.001$). Despite more severe hypokalemia, urinary K was significantly greater in KO than WT during dietary potassium restriction. Total NCC and phospho-NCC expression, which decrease renal K excretion, were significantly lower in hypokalemic KO than WT mice. Hypokalemia normally decreases ROMK expression; however, despite more severe hypokalemia in KO mice, ROMK expression did not differ significantly between WT and KO. This suggests abnormal ROMK regulation in NBCe1-A KO mice contributed to the more severe hypokalemia.

Conclusions: 1) NBCe1-A is essential to the signaling pathway that increases ammonia excretion in response to dietary potassium restriction; 2) Hypokalemia induced by a K-free diet appears to regulate distal K transport through a proximal tubule-dependent mechanism involving NBCe1-A, signaling through DCT NCC phosphorylation, and regulating ROMK expression.

Renal H+/K+ ATPases Mediate Benzamil-Inhibited Urinary H+ Excretion

Niklas Ayasse,[1] I. Jeanette Lynch,[2] Charles S. Wingo,[2] Jens G. Leipziger.[1] *[1]Aarhus University, Aarhus, Denmark; [2]University of Florida, Gainesville, FL.*

Background: Acute inhibition of ENaC causes a marked urinary alkalization. It was previously assumed that the so-called "voltage hypothesis" explains this urinary pH effect. The "voltage hypothesis" states that the lumen-negative ENaC-dependent transepithelial voltage provides the driving force for H^+ secretion via the vacuolar H^+ ATPase in neighbouring α-intercalated cells of the CD. In two preceding studies, we have contested the "voltage hypothesis". This, therefore, calls for an alternative explanation of the mechanism of ENaC blocker-mediated urinary alkalisation. Here we present data that strongly supports the involvement of renal H^+/K^+ ATPases, which are also located in the apical membrane of the α-IC.

Methods: In vivo studies in anesthetized mice were conducted to continuously measure urine output, urine electrolytes and urine pH.

Results: Application of benzamil acutely alkalized the urine (delta pH: 0.33±0.07). In parallel, the ambient luminal $[K^+]$ dropped markedly. In animals fed a low K^+ diet, the benzamil-induced urinary alkalisation was greatly enhanced (delta pH: 0.74±0.12) and a significantly lower urine $[K^+]$ nadir was reached. In double knock out mice lack both isoforms of the H^+/K^+ ATPases the benzamil effect was completely absent.

Conclusions: These data support the following explanation. ENaC inhibitors elicit their effect indirectly via their marked K^+ sparing property. They induced a strong drop of the ambient luminal $[K^+]$ concentration with impedes H^+/K^+ ATPases function and thus tubular H^+ secretion. Thus, we postulate that the lack of substrate (K^+) causes the luminal alkalisation by benzamil.

Muc1 Deficiency Causes Urinary Acidification Defects in Mice

Mohammad M. Al-bataineh,[1] Evan C. Ray,[2] Carol L. Kinlough,[4] Rebecca P. Hughey,[3] Thomas R. Kleyman.[1] *[1]University of Pittsburgh, Pittsburgh, PA; [2]UPMC, Pittsburgh, PA; [3]Dept Medicine-Renal Electrolyte Division, Pittsburgh, PA; [4]Department of Medicine University of Pittsburgh, Pittsburgh, PA.*

Background: Mucin 1 (human MUC1, mouse Muc1) is expressed on the apical surface of most epithelial cells, including the thick ascending limb (TAL) and distal nephron segments. Proximal tubular expression of Muc1 is induced in ischemia-reperfusion injury, where it stabilizes HIF-1a and b-catenin and plays a protective role. A frame-shift mutation in MUC1 causes autosomal dominant tubulointerstitial kidney disease. However, there is

limited information regarding its functional role in normal kidney. Muc1 knockout mice have no clear phenotype in the absence of stressors (e.g. bacterial infection). The TRPV5 Ca^{2+} channel was reported to be stabilized on the cell surface by galectin-dependent cross-linking to MUC1, providing a novel mechanism for regulation of this ion channel. We observed robust Muc1 apical and sub-apical staining in type A and type B intercalated cells (ICs). In Type A ICs, Muc1 co-localizes with the vacuolar H^+ ATPase (V-ATPase), a protein complex that mediates apical ATP-driven H^+ secretion. V-ATPase subcellular localization regulates H^+ secretion, while defects in V-ATPase function can cause renal tubular acidosis. As Muc1 and the V-ATPase are highly expressed in ICs, we tested the hypothesis that Muc1 regulates V-ATPase expression and function.

Methods: Muc1 KO ($Muc1^{-/-}$), Muc1 heterozygous ($Muc1^{+/-}$) and control mice were given 2.5% sucrose with or without 0.28 M NH_4Cl in drinking water for 7 days. Plasma electrolytes, urine pH and NH_4^+ were measured. Kidneys were processed for immunoblotting and confocal immunofluorescence (IF) microscopy.

Results: IF staining of fixed mouse kidney slices revealed that Muc1 co-localizes with luminal V-ATPase in ICs. Moreover, V-ATPase moved from the cytosol to the apical surface when WT mice were subjected to an acid load. In contrast, V-ATPase remained cytosolic in $Muc1^{-/-}$ mice. In response to acid-loading, both $Muc1^{-/-}$ and $Muc1^{+/-}$ mice exhibited impaired urinary acidification while only Muc1 KO mice exhibited greater metabolic acidosis. The IC-specific a4-subunit of V-ATPase co-immunoprecipitated with Muc1 in extracts of mouse kidney, suggesting that they are components of a protein complex.

Conclusions: These results suggest that Muc1 interacts with the V-ATPase and influences its cell surface localization in type A ICs, and is necessary for a normal renal response to an acid load.

AKAPs-PKA Disruptors Robustly Increase AQP2 Activity Independently of Vasopressin

Fumiaki Ando,[1] Naofumi Yui,[1] Naohiro Nomura,[1] Tatemitsu Rai,[2] Sei Sasaki,[1] Shinichi Uchida.[1] *[1]Tokyo Medical and Dental University, Tokyo, Japan; [2]Tokyo Medical & Dental Univ, Tokyo, Japan*.

Background: Congenital nephrogenic diabetes insipidus (NDI) is characterized by the inability of the kidney to concentrate urine. Congenital NDI is mainly caused by loss-of-function mutations in the vasopressin type 2 receptor (V2R), leading to impaired aquaporin-2 (AQP2) water channel activity. So far, treatment options of congenital NDI either by rescuing mutant V2R with chemical chaperones or by elevating cyclic adenosine monophosphate (cAMP) levels have failed to yield effective therapies. In this study, we focused on direct activators of PKA as novel therapeutic targets of congenital NDI. The intracellular distribution and activity of PKA are largely controlled by A-kinase anchoring proteins (AKAPs). We examined the effects of AKAPs-PKA disruptors, which dissociate the binding of AKAPs and PKA.

Methods: The effects of AKAPs-PKA disruptors, FMP-API-1 and its derivatives, were examined by mouse cortical collecting duct (mpkCCD) cell lines, isolated tubule microperfusion experiments, and V2R-inhibited NDI mouse model.

Results: FMP-API-1 increased PKA/AQP2 activity in mpkCCD cells. In microperfusion experiments, FMP-API-1 increased osmotic water permeability to the same extent as vasopressin. We then synthesized derivatives of FMP-API-1 to obtain greater pharmacological potency. *In vivo*, FMP-API-1/27 phosphorylated AQP2 at S256 and S269 more strongly than vasopressin and increased urine osmolality in V2R-inhibited NDI mouse model.

Conclusions: FMP-API-1 is a promising lead compound for the treatment of congenital NDI caused by V2R mutations.

TH-PO502

Empagliflozin Contributes to Polyuria via Transcriptional and Post-translational Control of Aquaporin-2 in Diabetic Rat Kidneys

Sungjin Chung, Seok Joon Shin, Cheol Whee Park, Yong-Soo Kim, Chul Woo Yang, Eun Sil Koh. *The Catholic University of Korea College of Medicine, Seoul, Republic of Korea*.

Background: It has been suggested that one of the most possible mechanisms for the positive cardiovascular and renal outcomes observed with empagliflozin, a selective sodium-glucose contransporter type 2 (SGLT2) inhibitor, would be related to effects on osmotic diuresis and natriuresis. However, the natriuretic effect of SGLT2 inhibitors has been reported to be transient, and long-term data related to diuretic change are sparse.

Methods: This study investigated the effect of a 12-week treatment with empagliflozin (3 mg/kg) on renal sodium transporters and water channels in diabetic OLETF rats by comparing it with other antihyperglycemic agents that included lixisenatide (10 μg/kg), a glucagon-like peptide receptor-1 agonist, and voglibose (0.6 mg/kg), an α-glucosidase inhibitor.

Results: At 12 weeks of treatment, the serum sodium level and fractional excretion of sodium were not significantly different between empagliflozin-treated and control diabetic rats. Empagliflozin-treated diabetic rats produced slightly decreased, but still high, urine volume and glycosuria, and showed significantly higher electrolyte-free water clearance than diabetic rats treated with other agents. In empagliflozin-treated rats, renal protein expressions of Na^+-K^+-$2Cl^-$ cotransporter and epithelial Na^+ channel were decreased, and Na^+-Cl^- cotransporter expression was unaltered compared with control diabetic rats. Empagliflozin increased the expression of aquaporin (AQP)7 but did not affect AQP1 and AQP3 protein expressions in diabetic kidneys. Despite the increased expression in vasopressin V2 receptor, protein and mRNA levels of AQP2 in kidneys of empagliflozin-treated diabetic rats were significantly decreased compared to control diabetic rats. In addition, empagliflozin increased the phosphorylation of AQP2 at S261 through the activation of p38- mitogen-activated protein kinase, protein phosphatase 2B and glycogen synthase kinase 3α, and cyclin-dependent kinases 1 and 5.

Conclusions: The collective results indicate that the long-term use of empagliflozin may promote diuresis associated with downregulation of AQP2 as well as its sustained natriuretic ability.

Epithelial Depolarization Induces AQP2 Up-regulation via Non-Canonical Ser-269 Phospho-Regulation Independently of Any Hormonal and Chemical Stimulation

Naofumi Yui, Fumiaki Ando, Sei Sasaki, Shinichi Uchida. *Tokyo Medical and Dental University, Sagamihara-shi, Kanagawa-ken, Japan*.

Background: Aquaporin-2 (AQP2) has multiple vasopressin-sensitive phosphorylation sites in its C-terminal region. We previously examined how pS256-positive AQP2 is catalyzed by vasopressin or forskolin stimulation using a phospho-specific AQP2 immuno-isolation technique, and identified a combined phospho-regulation: pS256-pS261-AQP2 changed to pS256-pS261-pS269-AQP2, and then transformed to pS256-pS269-AQP2 in both MDCK cells and mouse kidney. This cascade translocates pS256-positive AQP2 to the apical plasma membrane. We defined this phospho-regulation as canonical in this study. We next applied phospho-specific AQP2 immuno-isolation to quantify phospho-AQP2 in the total-AQP2 population. In the process of assay establishment, we hypothesized that cell polarization status affects AQP2 phosphorylation.

Methods: In this study, we divided MDCK cells stably expressing rat-AQP2 into two groups: cells were grown to confluence for 3 days and 1) their medium was just replaced with fresh normal DMEM without trypsinization (polarized group), or 2) they were trypsinized and re-plated with the same DMEM (depolarized group). Cells were lysed 24 h later without any hormonal or chemical stimulation and subjected to western blotting.

Results: Wild-type AQP2 significantly increased in the depolarized group. Ser-256 and Ser-261 phosphorylation was not changed, whereas Ser-269 phosphorylation significantly increased in the depolarized group. In S269A-AQP2 cells, depolarization-induced AQP2 upregulation did not occur. Interestingly, S256A-AQP2 was significantly upregulated in the depolarized group with a significant increase of Ser-269 phosphorylation.

Conclusions: These results demonstrate the existence of polarity-induced and hormone-independent AQP2 regulation, indicating a novel rationale for AQP2 function, i.e. in wound healing, tubular regeneration, cyst formation. In addition, we identified non-canonical AQP2 Ser-269 phospho-regulation, which is independent of prior Ser-256 phosphorylation and is not accompanied by subsequent Ser-261 dephosphorylation. These findings provide a basis for subsequent studies to investigate multi-functional roles of AQP2 beyond the categorical flame of apical water channel in polarized epithelial cells.

Funding: Government Support - Non-U.S.

TH-PO504

AQP11 Plays a Role in Water Homeostasis in Concert with AQP4 in the Brain

Kenichi Ishibashi,[1] Sei Sasaki,[2] Yasuko Tanaka.[1] *[1]Meiji Pharmceutical university, Kiyose, Japan; [2]Tokyo Medical and Dental University, Bunkyo-ku, Japan.*

Background: Water transport in the brain is tightly controlled by blood-brain-barrier (BBB) composed of endothelial cells (AQP1, 11) and glial foot processes (AQP4) where AQP4 regulates brain edema. Here we examined AQPs mRNA expression in acute hyponatremic or hypernatremic mice models of wild type and AQP11-null mice as AQP11-null mice suffer from renal failure which precludes chronic models.

Methods: By intraperitoneal injection, hypo- and hyper-natremic models were produced with water+desmopressin or 2M NaCl solution four or six hours before sacrifice, respectively. The expression of AQP1, 4 and 11 mRNA were quantified by RT-real-time PCR of whole brain RNA. Brain water content was calculated with 4-day-dried weight in 80 C oven and extravascular leakage by biotin permeability assay.

Results: In the control state, AQP11-null brain showed half AQP4 expression without AQP1 change as compared with wild mice (Na 153.3 vs. 150.7 mEq/L), whereas brain water content was similar (78.98 vs 78.61%). Acute hyponatremia (123.6 vs. 126.0 mEq/L) enhanced AQP4 expression in AQP11-null to the level of the wild mice with no change of AQP1, whereas it did not change AQP1, 4, nor 11 in wild mice. Brain water content was similar (79.93 vs. 79.8%) with expanded perivascular space, Virchow–Robin space. On the other hand, acute hypernatremia (199.5 vs. 208.0 mEq/L) increased AQP4 to the level of wild mice in AQP11-null with half AQP1 expression, whereas it decreased AQP1 and AQP11 by half without change in AQP4 in wild mice. Brain water content was significantly lower in AQP11-null than wild mice (75.34 vs. 76.65%) which was also documented histologically by cellular shrinkage in the brain cortex. Biotin permeability assay revealed no leakage in hypo- and hyper-natremic states. The results suggested that AQP4 expression was downregulated to match the decreased water transport at the endothelium in AQP11-null but may be enhanced to compensate for AQP11-null with osmotic changes although acute hypernatremia produced more water loss in AQP11-null brain.

Conclusions: We conclude that AQP11 may play a role in water homeostasis in concert with AQP4 at BBB with compensating enhanced AQP4 expression in AQP11-null with osmotic challenge. The results set a stage for examining the role of AQP11 in disease states such as brain edema. We are currently studying middle cerebral artery hemi-infarction model in AQP11 null mice.

TH-PO505

Lithium and Gsk3α Inhibition Reduces Aquaporin-2 Expression in Primary Cultured Inner Medullary Collecting Duct Cells Due to Independent Mechanisms

Bayram Edemir,[1] Marc Kaiser.[2] *[1]Martin Luther University Halle-Wittenberg, Halle (Saale), Germany; [2]Praxis am Markt, Froendenberg, Werl, Germany.*

Background: Lithium is a widely used drug for the treatment of bipolar disorders. However, it has severe side effects and up to 40 % of the treated patients develop a diabetes insipidus. Lithium affects also the activity of the glycogen synthase kinase 3 (Gsk3) and mice deficient for Gsk3β isoform in the renal collecting duct showed severe urine concentration abilities. The respective cellular and molecular mechanisms are still not fully understood.

Methods: We used primary cultured inner medullary collecting duct cells to analyze the underlying mechanisms. The cells were treated for different time points and with different concentrations of lithium, the pharmacological inhibitor of the Gsk3α/β (SB216763) or the Gsk3β specific Inhibitor TWS119. The cells were additionally incubated with inhibitors of the lysosomal (using bafilomycin) or proteasomal pathways (using MG132) alone or together with the above mentioned drugs. The expression of Aqp2 was analyzed on the mRNA level by qPCR and on the protein level by Western blot and immunofluorescence analysis.

Results: The qPCR experiments showed that only lithium induced a down regulation of Aqp2 mRNA expression while Gsk3 inhibition by SB216763 had no effect and surprisingly TWS119 led to increased expression. While inhibition of the proteasome with MG132 did not prevent the lithium or SB216763 mediated down regulation of Aqp2, the inhibition of the lysosomal activity with bafilomycin or chloroquine prevented lithium and SB216763 mediated down regulation of Aqp2 on the protein level. On the mRNA level lithium still induced down regulation of Aqp2. The treatment with bafilomycin and chloroquine induced accumulation of Aqp2 in lysosomal structures, which was prevented when the cells were treated with dbcAMP which led to phosphorylation and membrane localization of Aqp2. While down regulation of Aqp2 was also evident when lithium was applied together with dbcAMP, dbcAMP prevented the SB216763 induced down regulation of Aqp2. Interestingly the use of TWS119 induced the expression of Aqp2 on protein and mRNA level.

Conclusions: We showed that lithium and the Gsk3α/β inhibition by SB216763 induces down regulation of Aqp2 on different levels. The exclusive Gsk3β inhibitor TWS119 had the opposite effect indicating that Gsk3α inhibition is involved in Aqp2 down regulation.

Inhibition of Polo-Like Kinase 1 (PLK1), a Cell Cycle Regulator, Prevents the Dysregulation of AQP2, AQP3, and NKCC2 in Obstructive Nephropathy

Yue Zhang,[1] Yang Du,[2] Yun Qian,[2] Yan Guo,[2] Mingzhu Jiang,[2] Shuang Chen,[2] Guixia Ding,[3] Songming Huang,[2] Aihua Zhang,[2] Zhanjun Jia.[2] *[1]University of Utah/Nanjing Medical University, Nanjing, China; [2]Nanjing Medical University, Nanjing, China; [3]Nanjng Medical University, Nanjing, China.*

Background: Obstructive kidney disease is accompanied by the dysregulation of water channels and sodium transporters, which could account for the water/sodium disorders after obstruction release. PLK1 is known as a key modulator of cell cycle progression. Recently, cell cycle-associated mechanism was shown to contribute to the renal tubular injury. Here we proposed that the inhibition of PLK1 may preserve the water channels and sodium transporters of renal tubules in obstructive nephropathy.

Methods: Male C57BL/6 mice were subjected to unilateral ureteral obstruction (UUO) surgery or sham operation. On day 4 and day 6 after UUO surgery, mice received i.p injection of specific PLK1 inhibitor BI6727(15mg/kg). On day 7 after UUO surgery, animals were sacrificed and kidney samples were collected for analysis.

Results: qRT-PCR analysis detected that the marked reduction of AQP2, AQP3, and NKCC2 (40-60%) in obstructed kidneys were largely normalized by BI6727 treatment at mRNA levels. By immunohistochemistry and Western blotting, we further confirmed that post therapy (day 4 and day 6 after kidney obstruction) by BI6727 entirely restored the reduction of AQP2 and NKCC2 proteins to the normal levels. Due to the known role of PGE2 cascade in regulating water channels and sodium transporters in obstructed kidney, we measured COX-1, COX-2 and mPGES-1 and observed 3-8 folds increments of these components of PGE2-generating cascade. However, BI6727 therapy did not affect the upregulation of COXs and mPGES-1, suggesting that inihbition of PLK1 prevserved AQP2, AQP3, and NKCC2 possibly through a prostaglandin-independent mechanism.

Conclusions: Inhibition of PLK1 restored the downregulation of AQP2, AQP3, and NKCC2 in obstructed kidneys, suggesting a novel role of tubular cell cycle progression in dysregulating water channels and sodium transporters independently of prostaglandin-associated mechanism in obstructive nephropathy.

TH-PO507

Phosphorylation of Ser261 and Dephosphorylation of Ser269 Is Important for Urinary Excretion of AQP2

Sei Sasaki,[1,2] Masaki Sakai,[2] Hiroki Mizumura,[2] Tomoki Matsumoto,[2] Yumi Noda,[1] Naofumi Yui,[1] Kenichi Ishibashi.[2] *[1]Tokyo Medical and Dental University, Bunkyo-ku, Japan; [2]Meiji Pharmaceutical University, Tokyo, Japan.*

Background: AQP2 a key membrane protein which determines water permeability of collecting ducts. AQP2 is regulated by phosphorylation at S256, S261 and S269. As a short-term regulation of vasopressin, intracellular amount S261 phosphorylated-AQP2 (261-P) decreases whereas 269-P increases with relatively stable 256-P. The decrease in 261-P can be explained by dephosphorylation, degradation, or even extrusion out of the cell. In this sence, it is intriguing whether phoshorylation is involved in the urinary excretion of exosomal AQP2 and if so, which phosphorylation site is critical.

Methods: Human urine samples were obtained from a central diabetes insipidus patient (CDI, 45 years old, female). DDAVP 0.25ug was administered to the nasal mucosa after 24 h withdrawal. Urine samples were collected pre and after the administration until 3 h. Urine exosomes were obtained by the differential centrifugation, and analyzed by Western blot using a usual and 256-P, 261-P and 269-P-specific antibodies. Endogenously AQP2-expressing cells (mpkCCD) and stably rat AQP2-transfected MDCK cells (AQP2-MDCK) were cultured on the permeable support and the culture medium in the apical side were analyzed

Results: 1) In a CDI patient, DDAVP administration evoked a steady increase in urine osmolality until 3 h. Western blots of urine exosomal AQP2 excretion corrected for creatinine showed that total AQP2 rapidly increased until 1 h (8.5 times compared to the pre), then gradually increased until 3 h. 256-P progressively increased until 3 h. On the other hand, 261-P reached its peak increase at 0.5 h (2.4 times), and then, surprisingly decreased to the pre level at 2 h. 269-P was hardly visible throughout the study periods. 2) Western blots of apical culture medium of mpkCCD and AQP2-MDCK after vasopressin/forskolin stimulation, total, 256-P and 261-P were observed, but 269-P was minimally visible, although all these phosphorylated forms were observed in the cell lysates. 3) The LC-MS/MS phosphoproteomic analysis of human urine confirmed the presence of phosphorylation at S256 and S261, but not at S269.

Conclusions: These results indicate the importance of phoshorylation at S261 and dephoshphorylation at S269 in exosomal excretion of AQP2, highlighting the significant role of the endocytosis-exosome pathway in AQP2 metabolism in collecting ducts.

TH-PO508

Level of ENaC Activity Drives Hypertension from Chronic Activation of Vasopressin V2 Receptors

Alan C. Pao,[1,2] Hong Xiang,[1] Elena V. Mironova,[3] Susan B. Gurley,[4] Mohammed Z. Ferdaus,[4] James A. McCormick,[4] James D. Stockand.[3] *[1]Stanford University, Palo Alto, CA; [2]Veterans Affairs Palo Alto Health Care System, Palo Alto, CA; [3]University of Texas Health Science Center at San Antonio, San Antonio, TX; [4]Oregon Health & Science University, Portland, OR.*

Background: Vasopressin can contribute to sodium homeostasis and blood pressure regulation by stimulating the epithelial sodium channel (ENaC) through activation of vasopressin V2 receptors (V2R) in principal cells of the distal nephron. However, a direct link between chronic activation of V2R, high ENaC activity, and high blood pressure remains to be established *in vivo*.

Methods: We asked whether an isolated increase in V2R-mediated ENaC activity can lead to high blood pressure. We tested the blood pressure effects of chronic activation of V2R in mice with varying levels of ENaC activity. We infused dDAVP (100 ng/hr), a specific V2R agonist, for two weeks into Liddle (beta-ENaC-R566X), Pseudohypoaldosteronism Type 1 (PHA) mice, or wild type (WT) littermates and used radiotelemetry to compare blood pressure responses. We fed all mice normal sodium chow because they have similar blood pressures at this level of dietary sodium.

Results: We found that infusion of dDAVP into WT mice increased baseline blood pressure (systolic (SBP) by 4.3±0.47 mmHg and mean arterial pressure (MAP) by 3.7±0.45 mmHg, $P<0.05$); infusion of dDAVP into Liddle mice increased baseline blood pressure to a greater extent (SBP increase by 7.3±1.16 mmHg and MAP increase by 7.0 mmHg±1.57, $P<0.05$). Infusion of dDAVP into PHA1 mice induced no rise in baseline blood pressure. Blood pressure was highest in dDAVP-infused Liddle mice compared to dDAVP-infused WT or PHA mice (SBP 146±5.75 mmHg (Liddle) vs 135 or 137 mmHg; MAP 127±4.16 mmHg (Liddle) vs 119 or 120 mmHg). We also found that administration of benzamil, a specific ENaC inhibitor, only restored blood pressures of dDAVP-infused Liddle mice (SBP decrease by 4.86±1.31 mmHg and MAP decrease by 4.9±1.21 mmHg, $P<0.05$).

Conclusions: Our findings demonstrate that a specific increase in V2R-mediated ENaC activity in Liddle mice is sufficient to raise blood pressure. Since infusion of dDAVP can raise blood pressure in Liddle mice, our findings also suggest that the Liddle (beta-ENaC-R566X) mutation and V2R can stimulate ENaC through distinct pathways. Finally, since V2R-mediated increase in blood pressure in WT mice is not sensitive to benzamil inhibition, chronic activation of V2R is also sufficient to raise blood pressure through ENaC-independent pathways.

Loss-of-Function Mutation in the Epithelial Na+ Channel Alpha Subunit Reduces Salt/Aldosterone-Induced Hypertension in Mice

Shaohu Sheng,[1] Evan C. Ray,[2] Stephanie Mutchler,[1] Jingxin Chen,[1] Allison L. Marciszyn,[1] Xueqi Wang,[1] Thomas R. Kleyman.[1] *[1]Medicine, University of Pittsburgh, Pittsburgh, PA; [2]UPMC, Pittsburgh, PA.*

Background: Epithelial Na^+ channels (ENaC) have an important role in regulating blood pressure and extracellular [K^+]. We previously identified a point mutation in mouse ENaC alpha subunit (H283R) that significantly enhanced Na^+ self-inhibition, reflecting a reduced open probability specifically due to extracellular Na^+. Its homologous human variant

(H255R) has similar effects. In this study, we investigated whether the loss-of-function mutation H283R would protect mice from salt and aldosterone-induced hypertension.

Methods: H283R was introduced into the exon 2 of gene Scnn1a (encoding alpha ENaC) in C57/BL6J mice using CRISPR/Cas9-mediated gene editing method. Six homozygous H283R mice and six littermates were implanted with radio telemeters to record blood pressure, heart rate and activity level. Following seven days recording under normal salt (0.5% NaCl) diet, mice were fed with a high salt (4% NaCl) diet and implanted with minipumps for aldosterone infusion. Data recording continued for four additional weeks.

Results: There were no significant differences in pulse, systolic, diastolic and mean arterial pressures, heart rates, activity and blood electrolytes under normal Na^+ diet conditions, except for a modest difference in blood [Na^+]. Blood pressures displayed normal diurnal variation. Blood pressures gradually increased in all mice after switching to high salt diet plus aldosterone infusion. However, H283R mice displayed significantly lower systolic, diastolic and mean arterial pressures than wild type mice on multiple days ($p < 0.05$). Both day and night blood pressures showed significant differences between the two groups. Heart rate and activity were similar in the two groups. Plasma aldosterone levels measured at the end of the experiment were not significantly different. We did not observe significant differences in Na^+ and K^+ concentrations in blood and urine samples in these mice.

Conclusions: The Na^+ self-inhibition enhancing mutation H283R in ENaC alpha subunit protects mice from high salt and aldosterone-induced hypertension. Our observations suggest that certain loss-of-function human ENaC variants like H255R may protect individuals from the development of salt-sensitive hypertension.

Interleukin 6 plus High Salt Increases Functional Epithelial Sodium Channel Activity

Brandi M. Wynne,[1] Vadym Buncha,[2] Alena Cherezova,[2] Cameron G. McCarthy,[3] Gillian G. Hecht,[4] Camilla F. Wenceslau,[5] Robert S. Hoover,[4] Mykola Mamenko.[3]
[1]Emory University School of Medicine, Atlanta, GA; [2]Medical College of Georgia, Augusta University, Augusta, GA; [3]Augusta University, Augusta, GA; [4]Emory University, Atlanta, GA; [5]The University of Toledo, Toledo, OH.

Background: Hypertension (HTN) is characterized by increased sodium (Na^+) reabsorption, and increased cytokines such as interleukin 6 (IL6). Our data suggests that IL6 infusion increases blood pressure (BP) and distal nephron Na^+ transporter expression/activity, with an early reduction in urinary Na^+ excretion (U_{Na}). However, whether this reduction in U_{Na} is mediated by epithelial sodium channel (ENaC) activity is unknown. We hypothesize that IL6 increases ENaC activity.

Methods: Mice were treated with IL-6 (16ng/hr, 0.1%BSA) or vehicle via osmotic minipump, and fed high salt (HS, 4%) diet for 1 or 3 days (1D, 3D). ENaC open probability (P_o), functional expression (fN) and functional activity (fNP_o) were assessed in split open tubules (cortical collecting duct, CCD) from IL6-treated (IL6+HS) and vehicle (HS) mice. Data are expressed as mean±SEM, where SEM is patch number in at least 3 mice per group.

Results: We observed a trending increase in ENaC fN in CCD from IL6+HS after only 1D, reaching significance by 3D (0.94±0.14, n=44 *vs.*0.63±0.08, n=63, $p<0.05$), compared to HS only. Although open probability (P_o) was not increased, fNP_o was almost doubled in IL6+HS treated mice after 1D (0.24±0.08, n=51 *vs.* 0.12±0.04, n=62), and significantly increased after 3D (0.28±0.07, n=44 *vs.* 0.13±0.04, n=63, $p<0.05$).

Conclusions: Here, we show that increased IL6 causes trending increases in ENaC fN and fNP_o, after only 1D. These data correlate with our data showing U_{Na} is reduced in the first 24 hours. Continued IL6+HS treatment significantly increased both fN and fNP_o by day 3, also correlating with increases in ENaCα/γ expression and BP (by D3). We later see increased U_{Na}, indicating pressure natriuresis. These data suggest that, remarkably, IL6 may activate distal nephron Na^+reabsorption, even with increased dietary salt. These data reveal a novel role for IL6-mediated changes in U_{Na} excretion, leading to salt-sensitive HTN.

Role for Collecting-Duct ET-1 in the Response to High-Salt Diet plus Mineralocorticoid Treatment

Michelle L. Gumz,[1] Lauren G. Douma,[1] I. Jeanette Lynch,[1] Kit-yan Cheng,[1] Meaghan R. Holzworth,[1] Dominique H. Barral,[1] Sarah H. Masten,[1] Charles S. Wingo.[1,2] *[1]University of Florida, Gainesville, FL; [2]Research, NF/SG VHS, Gainesville, FL.*

Background: Mice lacking the circadian clock protein Per1 exhibit a reduced night:day ratio in urinary Na excretion during the acute response to a high salt (HS, 4% NaCl) diet plus mineralocorticoid (DOCP) treatment. New results indicate that 24 hr urinary Endothelin-1 (ET-1) peptide is increased in male kidney-specific Per1 KO mice compared to control mice under these conditions. ET-1 is a known circadian clock target gene. These data led us to hypothesize that ET-1 action is important for maintaining the normal night:day ratio in renal Na excretion in response to HS/DOCP.

Methods: We generated renal collecting duct-specific ET-1 KO mice using Aqp2-Cre. Male CD ET-1 KO (n=5) mice and age-matched littermate controls (WT)(n=6) were acclimated to metabolic cages. Urine collections (24 hr) were made over 3 days of control diet and 3 days of HS. Mice were then treated with 75 µg/g BW DOCP. Urine collections (12 hr) were made for 3 days of HS/DOCP. Cumulative Na balance was calculated. Genotype effects were assessed during the HS and HS/DOCP interval using linear regression. Genotype and treatment effects were assessed by 2-way repeated measured ANOVA. Night:day urine Na excretion ratios were compared by t-test.

Results: Contrary to our hypothesis, CD-specific KO of ET-1 did not alter the night:day ratio in urine Na excretion in response to HS/DOCP (KO 5.6±1.4, WT 3.8±0.7, $p=>0.05$). The rate of increase in cumulative Na balance was significantly greater in CD ET-1 KO mice vs. WT.

Conclusions: Under the conditions tested, CD ET-1 does not appear to be necessary to maintain night:day differences in urinary Na handling. However, consistent with the known natriuretic role for ET-1 in the CD, CD ET-1 mice do retain significantly more Na in response to HS/DOCP compared to WT. These data demonstrate that CD ET-1 is necessary for the natriuretic response to a high salt diet plus mineralocorticoid.

Detection of Na+ Stores in the Myocardium and Skeletal Muscle of DOCA Treated Mice Using 23Na-MRI

Anke Dahlmann,[1] Peter Linz,[2] Stojan Perisic,[4] Jonas Tschesche,[5] Armin M. Nagel,[7] Jens Titze,[3] Tobias Bäuerle,[6] Christoph Kopp.[1] *[1]Dept. of Nephrology and Hypertension, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany; [2]Institute of Radiology, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany; [3]Duke - National University of Singapore, Singapore, Singapore; [4]Max Planck Institute for medical research, Stuttgart, Germany; [5]Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany; [6]Institute of Radiology, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany; [7]Institute of Radiology, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany.*

Background: Disturbances in Na^+ homeostasis with accumulation of Na^+ in tissue are present in salt sensitive hypertension. Tissue Na^+ distribution could be recently visualized in vivo by ^{23}Na-MRI. If Na^+ accumulation occurs also in organs of the cardiovascular system is unknown. We hypothesized that the myocardium is able to absorb significant amounts of Na^+ that could be detected by ^{23}Na-MRI.

Methods: DOCA-pellets were implanted in 10 male FVB mice while a sham procedure was performed on 10 FVB mice. Subsequently, both groups received 1% NaCl water for 2 weeks. ^{23}Na-MRI at 7Tesla was used to quantify Na^+ in heart and skeletal muscle. Furthermore, electrolytes were determined chemically in both tissues. In a fraction of mice intracellular Na^+ of the myocardium was measured by electron beam microscopy. Echocardiography was performed and blood pressure determined.

Results: Compared to control mice DOCA treated mice showed a significantly higher Na^+ content in skeletal muscle (27.0 ± 5.7 vs. 46.6 ± 8.9 mmol/l, p<0.001) and in heart muscle (61.6 ± 9.1 vs. 73.7 ± 11.7, p<0.05, figure 1). The fraction of bound Na^+ was increased in DOCA skeletal muscle (6.4 ± 0.8 vs. 13.0 ± 4.3 a.u., p<0.05) suggesting intracellular Na^+ accumulation. Electron beam microscopy of heart muscle also detected a higher intracellular Na^+ amount in DOCA animals compared to controls (0.12 ± 0.03 (n=4) vs. 0.29 ± 0.01 a.u. (n=3), p<0.001). Chemical electrolyte analysis confirmed Na^+ accumulation in both tissues. A reduced ejection fraction (74 ± 4 vs. 46 ± 15%, p<0.05) and hypertension was found in DOCA animals.

Conclusions: Na^+ accumulation occurs intracellularly in skeletal muscle and in heart muscle in vivo upon DOCA salt treatment indicating Na^+ uptake rather than extracellular accumulation. Increased Na^+ content of the myocardium might directly contribute to cardiac dysfunction.

TH-PO513

Response of WNK-1 Intercalated Cell (IC) Knock-out Mice to a High K+ Diet

Evan C. Ray,[1] Rolando Carrisoza-Gaytan,[2] Allison L. Marciszyn,[3] Lubika J. Nkashama,[3] Jingxin Chen,[3] Aaliyah Winfrey,[3] Daniel Flores,[2] Peng Wu,[4] WenHui Wang,[4] Chou-Long Huang,[5] Donald E. Kohan,[6] Arohan R. Subramanya,[7] Lisa M. Satlin,[2] Thomas R. Kleyman.[3] *[1]Internal Medicine - Renal Electrolyte, University of Pittsburgh, Pittsburgh, PA; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]University of Pittsburgh, Pittsburgh, PA; [4]New York Medical College, Valhalla, NY; [5]University of Iowa Carver College of Medicine, Iowa City, IA; [6]University of Utah Health Sciences Center, Salt Lake City, UT; [7]University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: In the cortical collecting duct (CCD), IC BK channels mediate flow-induced K+ secretion (FIKS) and contribute to the renal adaptation to dietary K+ intake. IC BK channel apical expression and activity are enhanced by a high K+ diet. In HEK cells, L-WNK1 also stimulates BK channel expression and activity. The observation that L-WNK1 expression is enhanced in the CCD of rabbits on a high K+ (HK) diet suggests that L-WNK1 contributes to modulation of the BK channel by dietary K+. We asked whether IC L-WNK1 expression is necessary for enhanced BK activity and renal adaptation to a HK diet.

Methods: We generated mice with IC-specific deletion of L-WNK1 (IC-WNK1-KO) by crossing floxed L-WNK1 mice with V-ATPase Cre mice. KO and floxed control mice were placed on a HK diet for 10 days to maximally stimulate BK channel expression.

Results: Perforated whole-cell recordings of ICs in CCDs from IC-WNK1-KO mice revealed significant reduction in charybdotoxin (CbTX)-sensitive K+ currents vs. controls (440 +/- 64 pA vs. 703 +/- 92 pA, respectively; N = 4 and 4; p =0.003). IC-WNK1-KO mice also exhibited higher blood [K+] vs. controls (5.6 +/- 1.0 vs. 5.0 +/- 0.9 mEq/L; N = 21 and 19; p = 0.048). Despite the increased blood [K+] in the IC-WNK1-KO mice, urinary K+ excretion in response to an intra-peritoneal bolus of 10% vol/wt 0.9% saline was similar in KOs and controls (4.5 +/- 9.0 vs. 4.6 +/- 7.0 mcmol/hr/g; N = 9 and 7).

Conclusions: The observations that IC-WNK1-KO mice have higher blood [K+] and reduced CbTX-sensitive currents in CCD ICs indicate that these mice have a defect in urinary K+ secretion, highlighting the importance of L-WNK1 in ICs for adaptation to a HK diet. The retained capacity for K secretion in response to a saline load suggests upregulation of other K+ secretory processes.

Novel KLHL3-Binding Motif of WNK4 and Its Potential Role in Familiar Hyperkalemic Hypertension

Lingyun Wang, Ji-Bin Peng. *Divison of Nephrology, Department of Medicine, Nephrology Research and Training Center, University of Alabama at Birmingham, Birmingham, AL.*

Background: Gene mutations in with-no-lysine [K] kinase 4 (WNK4), and in kelch like 3 (KLHL3), have been found in patients with familiar hyperkalemic hypertension (FHHt, also known as pseudohypoaldosteronism type 2, PHAII). The level of WNK4 protein is controlled by KLHL3, which is the substrate adaptor in the cullin-RING ubiquitin E3 ligase complex for the degradation of WNK4. Mutations in either the acidic motif of WNK4 or the Kelch domain of KLHL3 impair their binding and raise the protein level of WNK4. The increased WNK4 protein abundance and total kinase activity stimulates the activity of sodium-chloride cotransporters (NCC) via SPAK/OSR1, and ultimately results in FHHt. Currently the acidic motif in WNK4 is recognized as the only binding motif for KLHL3. Our aim of this study is to determine whether additional KLHL3 binding site exists in WNK4, if so, whether it is relevant to FHHt.

Methods: WNK4 deletion constructs and KLHL3 FHHt mutants were made by PCR-based mutagenesis approaches. The constructs were expressed in *Xenopus laevis* oocytes. Western blotting and GST pull-down approaches were used to evaluate the interaction and degradation of WNK4 constructs.

Results: In addition to the region containing acidic motif, the WNK4 C-terminal region (amino-acids 1046-1243) was capable of pulling down KLHL3, indicating that there is a new KLHL3-binding motif in this region. Using deletion constructs, the new binding motif was narrowed down to a 30 amino-acid stretch (amino-acids 1051-1080). WNK4 lacking either the acidic motif or the novel motif was rapidly degraded in the presence of KLHL3; however, WNK4 protein was stable when both motifs were deleted. Similar to the acidic motif, the new motif is also rich in Asp/Glu residues. Since the Kelch domain of KLHL3 has a positive surface electrostatic potential, similar to the acidic motif, the negatively charged residues in the new motif are likely important for the electrostatic interactions. Indeed, FHHt mutations in the Kelch domain of KLHL3 impaired the degradation of WNK4 lacking the acidic motif, and this effect was more pronounced for the FHHt mutations at the surface of the Kelch domain.

Conclusions: A new KLHL3-binding motif was identified in the C-terminal region of WNK4. The new motif is likely involved in the pathogenesis of FHHt.

TH-PO515

WNK1 and WNK4 Form Heteromultimer to Regulate NCC In Vivo

Jian Xie,[1] Yih-sheng Yang,[2] Chou-Long Huang.[1] *[1]University of Iowa Carver College of Medicine, Iowa City, IA; [2]UT Southwestern Medical Center, Dallas, TX.*

Background: Sodium reabsorption via the sodium-chloride cotransporter (NCC) in distal convoluted tubule (DCT) plays an important role in total body sodium homeostasis. In vitro, with-no-lysine (WNK) kinases WNK1 and WNK4 both activate NCC through intermediate STE20/SPS1-related proline- and alanine-rich kinase (SPAK) and related oxidative stress-responsive 1 (OSR1). It has been reported that WNK1 and 4 interact in vitro. Yet, it is believed that in vivo WNK4 is the main regulator of NCC, in part based on findings that Wnk4-null mice have a nearly complete loss of NCC activity. In addition, WNK4 is essential for stimulation of NCC by low dietary potassium intake through lowering the intracellular chloride concentration. The role of WNK1 in the regulation of NCC in vivo remains poorly understood.

Methods: Global Wnk1-null mice are embryonic lethal, due to loss of WNK1-OSR1/SPAK signaling in the vascular endothelium. To study the role of WNK1 in kidney, we generated a mouse model that expresses constitutive-active SPAK in a variety of tissues including vascular endothelium, but with virtually no expression in the kidney. This approach creates a viable mouse model with functionally kidney Wnk1-null.

Results: Kidney Wnk1-null mice exhibit renal sodium wasting and little NCC activity compared to wildtype mice as assayed by thiazide-sensitive urinary Na excretion and phospho-NCC western blotting. Reciprocal co-immunoprecipitation experiments reveal that WNK1 and WNK4 form complexes in the kidney. Wnk4-null mice have minimal NCC activity and NCC activity is not stimulated by low dietary potassium intake. Unlike that in Wnk4-null mice, low dietary potassium intake stimulates NCC activity in kidney Wnk1-null mice.

Conclusions: Our results provide evidence supporting the notion that WNK1 and WNK4 form heteromultimers in vivo to regulate NCC. WNK4 is more sensitive than WNK1 to inhibition by intracellular chloride.

WNK1-SPAK-NCC Signaling Cascade Is Involved in Salt Sensitive Hypertension Induced by Aristolochic Acid Nephropathy

Taisuke Furusho, Eisei Sohara, Shintaro Mandai, Hiroaki Kikuchi, Fumiaki Ando, Moko Zeniya, Takayasu Mori, Naohiro Nomura, Tatemitsu Rai, Shinichi Uchida. *Department of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: Increased salt sensitivity is one of the major reasons for resistant hypertension in chronic kidney disease (CKD). Recent evidence suggests that not only reduced glomerular filtration but also aberrant sodium handling in renal tubules contribute to salt sensitivity. We previously demonstrated with-no-lysine kinase (WNK) - oxidative

stress-responsive gene 1 (OSR1)/Ste20-related proline-alanine-rich kinase (SPAK) - NaCl cotransporter (NCC) signaling cascade is essential for sodium handling in the distal nephron and its inappropriate activation leads to salt sensitive hypertension. However, WNK signaling in CKD has not been evaluated. In the present study, we investigated the role of WNK signaling in the development of salt sensitive hypertension induced by aristolochic acid nephropathy (AAN).

Methods: C57BL6/J or SPAK$^{-/-}$mice were administered aristolochic acid I (AA-I) intraperitoneally twice a week for 6 weeks followed by 6 week disease development time. After the treatment, sodium transporter protein expression was assessed and the effect of high salt diet (HSD) on blood pressure was examined.

Results: AAN mice showed salt sensitive hypertension (systolic blood pressure after HSD, mean±SE: 112.5±2.6 mmHg in AAN and 102±1.0 mmHg in control, $p<0.05$, unpaired t test). In the AAN model, protein levels of WNK1, phosphorylated SPAK and phosphorylated NCC were significantly increased. Immunofluorescent study revealed increased expression of WNK1 and phosphorylated SPAK at distal convoluted tubules. Even after mice were fed a HSD, expression level of WNK signal remained increased. Increased phosphorylation of NCC was not observed in AA-I treated SPAK$^{-/-}$mice, indicating NCC was activated through WNK1-SPAK phosphorylation cascade. As tumor necrosis factor α (TNFα) mRNA expression level was elevated in AAN mice kidney, we next evaluated the effect of TNFα on WNK signaling. We found that increased expression of WNK1, phosphorylated SPAK and phosphorylated NCC were attenuated in AAN mice treated with TNFα inhibitor etanercept.

Conclusions: NCC is activated through WNK1-SPAK signaling cascade in AAN mice and could contribute to salt sensitive hypertension. TNFα is involved in WNK signal activation induced by AAN.

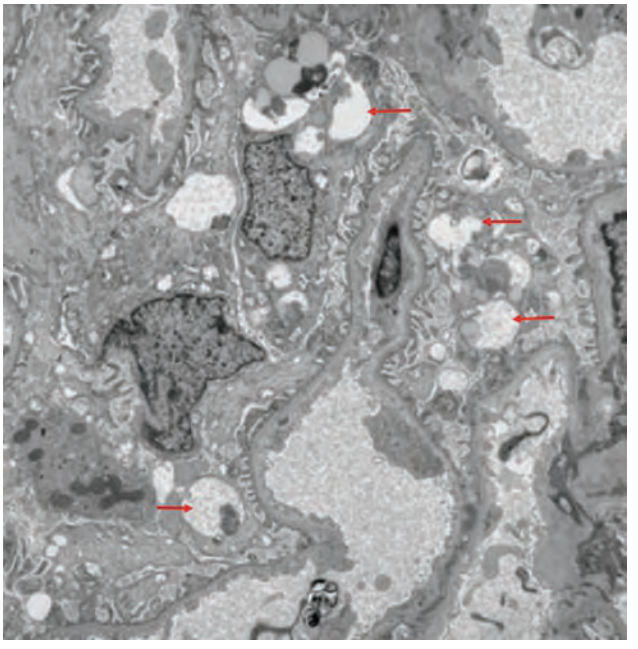
Vacuolated Podocytopathy: A Novel Injury with the Use of BRAF Inhibitors

Sarthak Virmani,[1] Anushree C. Shirali.[2] [1]*Yale School of Medicine, New Haven, CT;* [2]*Yale University, New Haven, CT.*

Introduction: With expanded use of BRAF inhibitors, nephrotoxicities including acute interstitial nephritis (AIN) and nephrotic syndrome (NS) have been described in recent literature. We present a novel case of vacuolated podocytopathy with sub-nephrotic range proteinuria associated with BRAF inhibition.

Case Description: A 64-year-old woman with non-small-cell lung cancer on dual BRAF/MEK inhibition with Vemurafenib and Trametinib, was referred for AKI evaluation. Her serum creatinine (SCr) was 2.1 mg/dL, increased from 1.0 mg/dL 2 months prior. Urine protein/creatinine ratio was between 0.4 – 0.7. Urinalysis was otherwise non-contributory. BRAF inhibition was held due to presumed AIN, but renal function only improved to 1.4 mg/dL. Treatment was restarted due to lack of therapy options with increase in SCr to 2.0 mg/dL. A renal biopsy was performed for definitive diagnosis. Pathology surprisingly showed a minimal interstitial infiltrate but extensive podocyte injury with cytoplasmic vacuolization and nearly global foot process effacement (FPE) was seen on electron microscopy. Given stable renal function, treatment was continued. Her SCr remained around 2.0-2.2 mg/dL and proteinuria remained < 1g until her death from septic shock few months later.

Discussion: BRAF inhibitors are linked with AIN and NS with diffuse FPE. We describe a novel finding of podocyte vacuolization and FPE with sub-nephrotic proteinuria. We recommend renal biopsy for patients on BRAF inhibitors with AKI of undetermined etiology to allow precise identification of the renal lesion. Our patient continued on BRAF inhibitors with stable CKD and proteinuria, suggesting that drug withdrawal is not necessary for all patients, particularly those with limited treatment options.



EM with podocyte vacuolization (arrow) and FPE

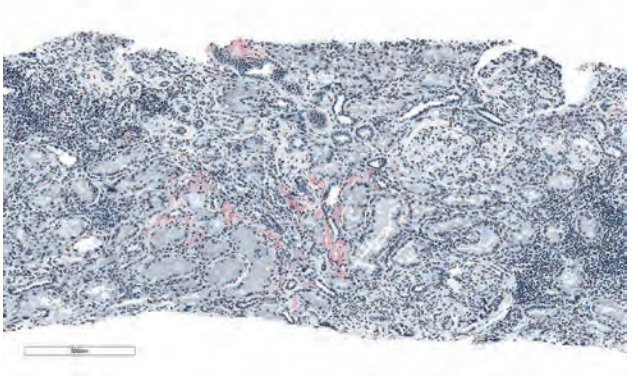
LECT2 Amyloidosis in a Pediatric Renal Allograft

Eliah Shamir, Marsha May Lee, Vighnesh Walavalkar. *UC San Francisco Medical Center, San Francisco, CA.*

Introduction: LECT2 amyloidosis is a common form of systemic amyloidosis. We present, to our knowledge, the first case of ALECT2 in a pediatric renal allograft.

Case Description: A 19 y/o Hispanic male with ESRD from posterior urethral valves, s/p living unrelated kidney transplant (2002, age 4), presented with a sCr of 2.4mg/dl (baseline 1.9mg/dl) and 3.6g/day proteinuria. He received daclizumab induction and was maintained on tacrolimus/MMF/sirolimus/prednisone. Past history was notable for episodes of ACR and C4d+AMR treated with thymoglobulin, IVIg, OKT3 and rituximab; de-novo C1q nephropathy; and ultimately transplant-glomerulopathy. Current biopsy showed Type1B ACR and chronic active AMR (C4d+). During low power ultrastructural analysis, unusual electron-lucent material was noticed in interstitial areas. Closer examination revealed disorganized fibrils measuring 8-12nm in diameter. Subsequent Congo Red staining confirmed scant interstitial amyloid deposits. Routine amyloid typing stains were negative, therefore mass spectrometry was performed, confirming ALECT2. Treatment with thymoglobulin, IVIg and rituximab stabilized the sCr at 1.9mg/dl. Follow-up biopsy showed resolution of the ACR. No further treatment changes were made. At last follow-up renal function was stable.

Discussion: ALECT2 is more common in elder Hispanic patients. ALECT2 can occur as a de-novo or recurrent process in renal transplants. Here we hypothesize that chronic inflammation from repeated episodes of rejection coupled with ethnic predilection resulted in ALECT2. Unexplained proteinuria in Hispanic patients and unusual patterns of amyloid distribution are clues to the diagnosis of ALECT. Detailed ultrastructural analysis could help to discover small amounts of amyloid not discernable by light microsopy. Mass spectrometry helps in cases that cannot be classified by stains. Awareness of ALECT2 in young patients is important due to prognostic implications and recurrence in subsequent allografts. There is no treatment for ALECT2.



Congo Red

TH-PO519

Leukocyte Chemotactic Factor 2 Amyloidosis with Concurrent Post-Infectious Glomerulonephritis and Diabetic Nephropathy

Jessica Cruz Whitley, Vishwa C. Sheth, Kuang-Yu Jen, Jose A. Morfin, Niti Madan. *University of California, Davis, Sacramento, CA.*

Introduction: Leukocyte chemotactic factor 2 amyloidosis (ALECT2) is a form of amyloidosis that manifests with progressive renal failure. Biopsies typically exhibit congophilic deposits that are most prominent in the interstitium. ALECT2 is the third most common form of amyloidosis with strong ethnic bias, affecting mainly Hispanics with chronic renal insufficiency. Significant proteinuria is rarely associated with ALECT2 unless a second concurrent glomerulopathy is present. We report a case of ALECT2 with nephrotic syndrome due to concurrent post-infectious glomerulonephritis and diabetic nephropathy.

Case Description: A 50-year-old Hispanic female with no significant medical history admitted for anasarca, was found to have bilateral pleural effusions and newly diagnosed type 2 diabetes mellitus. Laboratory values were significant for HgbA1c of 13.2%, normal renal function, albumin of 2.5 g/dL and 4.5 grams of proteinuria. Serological workup showed positive ANA with decreased C3 and C4. HIV, hepatitis, SPEP and serum free light chains were negative. Although diabetic nephropathy (DN) can cause nephrotic range proteinuria, it rarely presents with nephrotic syndrome. Thus, renal biopsy was performed which showed multiple glomerular abnormalities including glomerulonephritis (GN) with dominant C3 staining along with predominat mesangial deposits and nodular diabetic glomerulosclerosis. Congo red was performed which showed scattered positive staining in the interstitium, consistent with amyloid. Mass spectroscopy further characterized the amyloid type as ALECT2. The patient was discharged with insulin therapy and started on an ACE-inhibitor. The differential diagnosis for her C3-dominant GN included post-infectious GN and C3 GN. At 6 weeks clinic follow up, her C3 level normalized favoring the diagnosis of post-infectious GN.

Discussion: ALECT2 is one of the more recently recognized amyloid proteins to affect the kidney and fairly prevalent however it is still under recognized. Concurrent glomerular disease is not uncommon in patients with ALECT2, with DN being most frequent. Coexistence of three disease processes (post-infectious GN, DN and ALECT2) makes our case exceptional. This case also illustrates the significance of renal biopsy in patients with atypical presentations of common renal diseases.

TH-PO520

Fibrillary GN vs Amyloidosis on Renal Biopsy: Dilemma on How to Treat

Pulkit Gandhi,[1] Jie Tang.[2] *[1]Brown University, Providence, RI; [2]University Medicine; Brown University, West Roxbury, MA.*

Introduction: Glomerular disease may be associated with fibrillary deposits on glomerular basement membrane or mesangium. Frequently there is a clear distinction between Amyloidosis and non-amyloid fibrillary deposits based on the fibril size on electron microscopy and reaction to Congo red stain. But occasionally we see overlapping patterns. Here we present a unique case of glomerular deposition disease with an overlapping pattern, where the kidney biopsy showed Congo red positivity, but the fibril sizes were larger than as expected in amyloidosis. Patient presented with acute kidney injury (AKI) and clinical evidence of glomerulonephritis (GN).

Case Description: A 58 y/o male with medical history of hepatitis C status post treatment with Harvoni in 2015 with negative viral PCR (9/2016), well controlled type 2 DM (HbA1C 5.2), well controlled HTN, Chronic kidney disease stage III A presented as an outpatient consult for worsening serum creatinine. The serum creatinine rose from a baseline of 1.1 mg/dl to 3.2mg/dl in a period of 3 months. 24hr urine showed significant proteinuria measured at 2682 mg. His urine sediment showed microscopic hematuria, but no dysmorphic features. Serologic studies showed elevated kappa/lambda ratio at 2.52 but normal serum and urine protein electrophoresis, normal C3 and C4 complement levels, and negative anti neutrophil cytoplasmic antibody. Patient underwent renal biopsy, which showed glomerulopathy - mesangioproliferative pattern, with mesangial and subendothelial fibrillary deposits. The fibrils measured 14.8 nm in diameter, and these deposits were congo red positive, and were reactive for IgG (predominant IgG4) and C3. The stain for protein A was negative. In addition, there were advanced chronic changes noted in the parenchyma, including global and segmental glomerulosclerosis (52% of glomeruli) and significant tubulointerstital fibrosis (60% of the cortex). Considering atypical findings on renal biopsy and underlying significant tubulointerstital fibrosis, we decided to treat him with mycophenolate and prednisone instead of more aggressive chemotherapy for amyloidosis. He responded well as his serum creatinine trended down from 3.2 mg/dl to 1.5 mg /dl in 6 months.

Discussion: We believe this is the first case of glomerular deposition disease with overlapping features of amyloidosis and fibrillary GN, who responded well to a rather conservative regimen of MMF with steroid.

TH-PO521

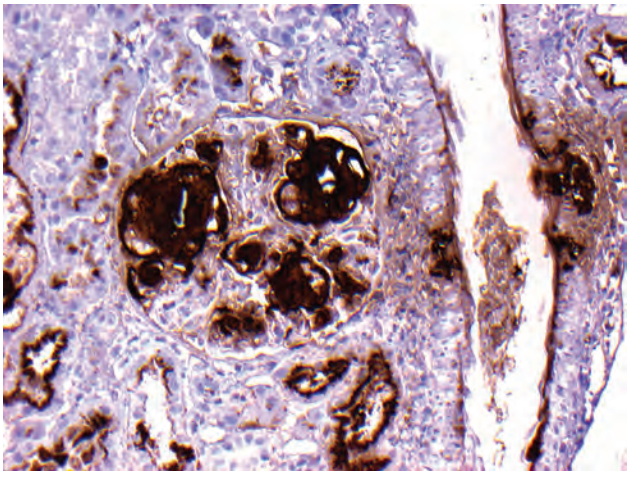
Unwanted Deposits: A Rare Cause of AA Amyloidosis

Romin Bonakdar, Srikar Kumar, Mona Shaban, Volker Nickeleit. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Introduction: Amyloidosis is a disorder resulting from pathologic deposition of protein subunits in multiple organ systems, often including the kidneys. It is divided into two major subgroups: AL amyloidosis due to overproliferation of light chains from a monoclonal plasma cell population, and AA amyloidosis resulting from chronic inflammatory states including a variety of autoimmune diseases, infections, and malignancies. Identification of the associated disorder can direct therapy to minimize further organ damage. We describe a case of AA amyloidosis secondary to Castleman's disease (CD).

Case Description: A 37 year old woman with a history of anemia was referred to clinic for nephrotic-range proteinuria. Laboratory evaluation showed a urine protein:creatinine of 10.3, a serum creatinine of 0.83 mg/dL and albumin of 2 g/dL. A kidney biopsy showed glomerular amyloid deposits. Serum protein electrophoresis and serum free immunoglobulins did not show evidence of a monoclonal gammopathy. Evaluation for secondary causes of AA amyloidosis was notable for a 5 cm pararenal mass and abnormal lymph nodes on PET scan. A biopsy of the mass revealed lymph node tissue with amyloid deposits and morphologic features consistent with CD. HHV-8 and HIV testing were negative. She was started on siltuximab, a monoclonal interleukin-6 (IL-6) antibody, with reduction in her urine protein:creatinine to 2.1, improvement in albumin to 3 g/dL and an increase in her hemoglobin from 6.2 g/dL to 15.6 g/dL.

Discussion: Amyloidosis carries tremendous morbidity to affected individuals with limited, non-curative therapy available. Identification of the patient's CD as the underlying trigger of her AA amyloidosis allowed for directed treatment that resulted in dramatic improvement in her proteinuria and resolution of her anemia. Excess IL-6 is hypothesized to play a role in CD, particularly HIV and HHV-8 negative cases. This case provides additional support for the role of IL-6 inhibitors in the treatment of idiopathic CD.



TH-PO522

Amyloid Nephropathy in the Setting of Rosai-Dorfman Disease

Maria Joana A. Thomas,[1] Kuang-Yu Jen,[2] Burl R. Don,[3] Brian Y. Young.[4] *[1]University of California Davis Medical Center, Sacramento, CA; [2]University of California, Davis, Sacramento, CA; [3]University of California Medical Center, Sacramento, CA; [4]UC Davis Medical Center, Sacramento, CA.*

Introduction: Rosai-Dorfman disease is a non-neoplastic histiocytic disorder characterized by massive lymphadenopathy secondary to infiltration and dilation of the lymph node sinuses by large histiocytes. Massive cervical lymphadenopathy is the hallmark, but extranodal involvement has been described in 43% of cases. It can affect most organs, with about 4% of cases affecting the kidneys.

Case Description: A 64-year-old Hispanic man with diabetes mellitus and hypertension was diagnosed with Rosai-Dorfman disease 9 years ago. He was treated initially with surgical debulking, rituximab, cyclophosphamide, vincristine and prednisone. Rituximab was used intermittently since, with the last dose given 4 years ago. On current presentation, he has dysphagia and progressive cervical, hilar, mediastinal and retroperitoneal lymphadenopathy. Creatinine was elevated at 2 mg/dL from a baseline of 1.17 mg/dL. Imaging and urological studies showed no evidence of obstruction. Diagnostic work-up revealed dysmorphic RBCs, proteinuria of 14 g/day, hypocomplementemia, and positive ANA and anti-RNP70. Hepatitis panel, HIV, PR3, and MPO were negative. There was an abnormal monoclonal protein in the gamma region but kappa/lambda ratio was normal. He was empirically treated with rituximab (375mg/m2 weekly for 4 doses) and dexamethasone 40 mg daily for disease recurrence. However, the kidney function continued to deteriorate, so a kidney biopsy was performed. Widespread amyloid was noted predominantly in the interstitium, with only focal glomerular and vascular involvement. Immunofluorescence showed weak IgG without light chain restriction and corresponded to scattered subepithelial immune deposits.

Discussion: There have been few reports of amyloidosis with Rosai-Dorfman Disease, one with generalized AA amyloidosis. We postulate that cytokine production by histiocytic cells, subsequently induced synthesis of precursor proteins facilitating amyloidogenesis in this patient. Amyloid can be found anywhere in the kidney, but glomerular deposition typically predominates in most forms. This report highlights a rare association of this histiocytic disorder and renal amyloidosis, predominantly with interstitial deposition.

TH-PO523

Apolipoprotein A-IV Amyloidosis: An Unusual Cause of Renal Amyloidosis and CKD

Sadaf N. Sheikh,[1] Tingting Li,[2] Ryan A. Kunjal.[3] WashU, Nephrology *[1]Washington university St Louis MO, Valley Park, MO; [2]Washington University in St. Louis, Saint Louis, MO; [3]Washington University, St Louis, MO.*

Introduction: Apolipoprotein A-IV associated amyloidosis (AApoAIV amyloidosis) is a rare cause of amyloidosis with only few reported cases in the literature. Renal AApoAIV amyloidosis histologically exhibits medullary involvement with sparing of the cortex. The diagnosis of renal AApoAIV amyloidosis requires a high degree of suspicion and examination of the renal medulla on renal biopsy. The definitive diagnosis is best established by mass spectrometry. Here we present two patients with renal AApoAIV amyloidosis.

Case Description: Case 1 Fifty-three-year-old white male with past medical history of well-controlled type 1 diabetes mellitus and hypertension presented with a 10-year history of slowly declining renal function (Serum creatinine 1.1 mg/dl 10 years ago and 1.7 mg/dl in 2018). Urinalysis was unremarkable and 24-hour urine collection showed 240 mg of protein. He was found to have a positive serum immunofixation with IgA kappa monoclonal protein and was diagnosed with IgA kappa smoldering myeloma by bone marrow biopsy. Subsequent renal biopsy showed multifocal, medullary deposition of amyloid of amyloid material. No similar deposits were seen within the renal cortex. Mass spectrometry surprisingly identified apolipoprotein A-IV amyloid deposition and no peptides were identified for any other types of amyloid. The smoldering myeloma was thought to be unrelated to the amyloid. Case2 Sixty-Eight-year-old white female has had stage 3 CKD since 2009, when her serum creatinine was 1.4. Creatinine increased to 1.6 in 2016 and she underwent renal biopsy which showed a focal area of amyloid deposits in the medulla. Mass spectrometry identified the amyloid as Apolipoprotein A-IV. The patient's renal function has remained stable over the last 2 years. Neither patient had extra-renal manifestations of amyloidosis or family history of amyloidosis.

Discussion: Apolipoprotein A-IV amyloidosis is a rare type of amyloidosis that seems to have a predilection for the kidney and is limited to the renal medulla. The limitations of the amyloid to the medulla correlates with the clinical findings of slow decline of renal function, unremarkable urinalysis, and no significant proteinuria. The pathogenesis of apolipoprotein A-IV amyloid formation is unknown. There are no known treatment options at this time and management is conservative.

TH-PO524

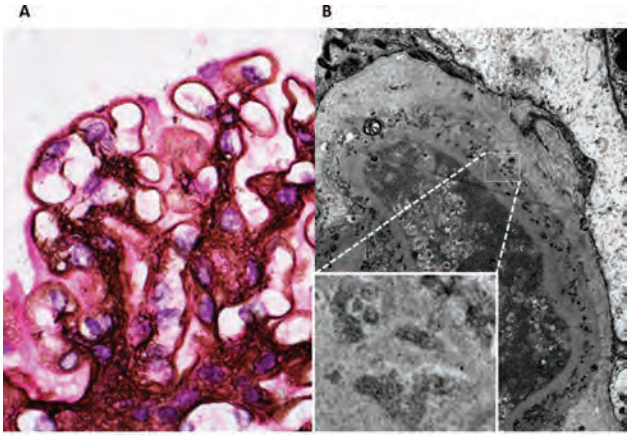
Podocytic Infolding Glomerulopathy in a Patient with Systemic Lupus Erythematous

Alice Chedid, Mohamad A. Hanouneh, Blaithin A. McMahon. *Johns Hopkins University School of Medicine, Division of Nehrology, Baltimore, MD.*

Introduction: Podocytic infolding glomerulopathy (PIG) has been proposed as a new disease entity. This is first case of PIG reported in a woman patient of African American ancestry. Five case reports of PIG complicated by focal segmental glomerulosclerosis (FSGS).

Case Description: A 35-year-old African American woman with a history of systemic lupus erythematous and autoimmune enteritic ganglionitis presents with new acute kidney injury with serum creatinine 1.6 mg/dL (baseline 0.8 mg/dL) and nephrotic range proteinuria. Urinalysis was positive for 3 red blood cells, 5 white blood cells per high power field and no red blood cell casts. Urine protein/creatinine ratio was 19 g/g. C3 and C4 levels were 90 and 30 mg/dL, respectively. Anti-DNA screen, anti-PLA2 receptor antibody, HIV and hepatitis panel was negative. Renal sonogram showed normal sized kidneys with minimally increased echogenicity and unchanged mild bilateral hydronephrosis. Kidney biopsy demonstrated significant FSGS with collapsing features. Under periodic acid methenamine silver (PAMS) staining, the glomeruli had a diffuse moth-eaten appearance along glomerular capillary loops (Figure A). On ultrastructural examination there were numerous electron dense intramembranous membrane bound structures and microspheres entrapped in the glomerular basement membrane (GBM) of capillary loops (Figure B and Inset) consistent with PIG. Despite treatment with various immunosuppressive therapies the patient still progressed to end stage renal disease.

Discussion: In PIG, microspheres or microtubular structures, or both, are associated with the infolding of cytoplasmic processes of podocytes into the GBM as a consequence of capillary wall remodeling. The mechanism of PIG is unknown and has been reported in predominantly in Asian and in the setting of connective tissue diseases.



TH-PO525

Collagen Glomerulopathy – A Rare Entity

Kothai divya Guruswamy sangameswaran, Krishna M. Baradhi. OU Tulsa *OU -Tulsa School of Community Medicine, Tulsa, OK.*

Introduction: Collagen glomerulopathy (CG) is a rare, non-immunoglobulin deposition disease of unknown etiology, first reported by Arakawa et al in 1979. CG is characterized by agglomeration of atypical type III collagen fibrils in mesangial matrix and subendothelial space. CG is a rare entity, with most of the cases reported from Japan. We describe one such rare case of CG seen in a pediatric patient and emphasize its clinical significance.

Case Description: A 7-year-old Hispanic girl presented with intermittent hematuria and foamy urine since few weeks. She had no family history of renal disease. Patient was normotensive with mild pedal edema and specifically no nail or patellar dysplasia. Labs revealed serum creatinine of 0.44 mg/dl, albumin of 3.3 g/dl, hyperlipidemia and normal complement levels. Urinalysis confirmed hematuria with 2.6 gm of proteinuria on quantification. Renal ultrasound was unremarkable. A diagnostic renal biopsy conducted revealed widespread foot process effacement and nodular mesangial deposits suggestive of collagen III glomerulopathy. She was managed conservatively with angiotensin converting enzyme inhibitors with partial remission of proteinuria.

Discussion: Type III collagen is a structural protein that is normally absent in the glomerulus. Abnormal accumulation of type III collagen in the mesangium and subendothelial space leads to proteinuria. Electron microscopy showing mesangial deposits of large (43-65 nm) whorled fibrils is essential for definitive diagnosis. This is distinguished from nail-patella syndrome by the absence of collagen III accumulation in lamina densa of basement membranes. CG typically presents with hypertension, edema, proteinuria and progressive kidney disease. Familial occurrence with autosomal recessive inheritance has been described. The etiopathogenesis remains elusive, but is associated with factor H deficiency and Hemolytic uremic syndrome. Supportive therapy with control of hypertension and edema is recommended. Role of corticosteroids is unclear. Among patients who received a transplant, none have shown disease recurrence. Our case represents only the second case of CG published from the US. Clinicians should be cognizant of this rare entity and differentiate it from other fibrillary disorders as treatment is supportive rather than the toxic immunosuppressive therapy.

TH-PO526

A Case of Sporadic Glomerulopathy with Fibronectin Deposits with a Mutation in FN1

Hideo Misawa,[1] Tetsuro Takeda,[1] Yoshihiko Ueda.[2] *[1]Dokkyo Medical University Saitama Medical Center, Koshigaya, Japan; [2]Saitama Medical Center, Koshigaya, Japan.*

Introduction: Glomerulopathy with fibronectin deposits (GFND) is a rare renal disease with massive mesangial, and subendothelial fibronectin deposits. It presents proteinuria, often in the nephrotic range in the third to fourth decade, and slow progression to end-stage renal disease. Here we describe a case with GFND from a genetic mutation.

Case Description: A 52-year-old lady presented with edema and 2-year-history of hypertension. Since 6 years ago, mild proteinuria and microscopic hematuria have been detected by regular health check-up. Family history was negative for any kidney diseases. She was diagnosed as having nephrotic syndrome (massive proteinuria, 7.7 g/gCr, hypoalbuminemia, 2.6 g/dl, normal level of creatinine of 0.42 mg/dl). A renal biopsy showed lobular appearance and membranoproliferative glomerulonephritis-like lesions on light microscopy. Electron microscopy revealed homogeneous granular fine fibers. In a case with micro-fibrillar deposits in glomeruli, it is necessary to rule out an amyloidosis and a glomerulopathy derived from immunoglobulins. In this case, Direct Fast Scarlet staining and immunofluorescence were all negative. Following the above results, we suspected her of GFND. Next, we carried out mass spectrometry to identify the origin of deposits in laser micro-dissected glomeruli. Majority of detected proteins was fibronectin. Furthermore, immunohistochemistry of the fibronectin showed intense staining in the mesangium and subendothelium. Thus, she was diagnosed as having GFND. We performed

genetic analysis to identify mutations of fibronectin 1 gene (FN1) and found heterozygous deletional mutation (p.Pro1472del).

Discussion: Clinically, it has been difficult to identify the origin of glomerular deposition especially in a case with micro-fibrillar deposits. However, laser micro-dissection and mass spectrometry could accurately identify the major protein of deposits, leading to a diagnosis with GFND. GFND is a rare inherited autosomal dominant disease and 60% of the cases have mutations in the FN1. Recently, 11 pathogenic variations (10 exonic and one intonic) in the FN1 have been reported. In exonic variants, only one is in the integrin-binding domain, the others are in the heparin-binding domain. In this case we detected deletional mutation in the integrin-binding domain (p.Pro1472del) which was consistent with those reported by others.

TH-PO527

A Unique Case of Lipoprotein Glomerulopathy

Kishore Patcha, Josephine Abraham, Mossab Aljuaid, Sarah Gilligan, Divya Raghavan, Laith Al-Rabadi. *University of Utah Hospital, Salt Lake, UT.*

Introduction: Lipoprotein Glomerulopathy has recently been recognized as a unique type of glomerular injury characterized by lipid accumulation in the glomerular capillaries. It has been mainly reported in Asian patients, and linked with rare APOE gene mutations resulting in a structurally abnormal Apolipoprotein E (ApoE).

Case Description: A 47-year-old Filipino male presented to the renal clinic with nephrotic-range proteinuria. Past Medical history was significant for hypertension treated with irbesartan and carvedilol. Physical exam was unremarkable. Labs showed serum creatinine of 1.47mg/dl (unclear baseline). Urine microscopy revealed several red blood cells. Urine protein to creatinine ratio was 5.1 g/g with a urine albumin to creatinine ratio of 3.7 g/g. Renal Ultrasound was unremarkable. Further workup, including ANA, ANCA, HIV, Anti-GBM antibody, serum and urine protein electrophoresis, was negative. Hemoglobin A1C was 5.1. Total cholesterol was 221mg/dL with triglycerides of 180 mg/dL, HDL cholesterol of 55mg/dL, VLDL cholesterol of 36mg/dL and LDL cholesterol of 142mg/dL. Patient underwent kidney biopsy for definitive diagnosis. Light microscopy showed 32 glomeruli, many with dilated capillary lumina filled with very pale, mesh-like lipoprotein "thrombi". Five glomeruli were globally sclerosed. Oil red O stain highlighted glomerular capillary lumina thrombi. There was evidence of focal areas of interstitial fibrosis and mononuclear inflammatory infiltration. Immunofluorescence did not reveal any immune-complex deposits. Electron microscopy showed remodeling of the glomerular basement membranes and capillary loops were distended and occluded by lipid-like material containing vacuoles of different sizes and with lamellation. His genetic testing showed both APOE alleles to be E3.

Discussion: Approximately 95% of individuals with type III hyperlipoproteinemia have the E2/E2 genotype. The remainder have rare mutations in one copy of the APOE gene some of which are not detectable by the APOE genotype test. Lipoprotein thrombi in the glomerulus should prompt consideration for Lipoprotein glomerulopathy. Based on clinical information and renal biopsy results, this patient has lipoprotein glomerulopathy in the absence of APOE E2/E2 genotype.

TH-PO528

A Case of Successful Treatment of Collapsing FSGS Secondary to Parvovirus B19

Fatima Sheikh,[1] Vanesa Bijol,[2] Daniel W. Ross.[2] *[1]Northwell, New Hyde Park, NY; [2]Northwell Health Hofstra University, Lake Success, NY.*

Introduction: Parvovirus B19 is a rare cause of collapsing glomerulopathy. The clinical course of collapsing glomerulopathy is characterized by proteinuria and progressive renal failure. This case discusses the first immunocompetent patient with biopsy proven collapsing glomerulopathy secondary to Parvovirus B19 successfully treated with Intravenous Immunoglobulin (IVIG).

Case Description: A 38 year old African American man presented to our ED with three days of fatigue, poor appetite, fever, chills, night sweats, and joint pain with swelling. At time of our evaluation his vital signs were within normal limits and physical exam was unremarkable. Laboratory data upon admission was notable for elevated creatinine (1.6mg/dL) and proteinuria (7.2 g/g). The patient's IgG, IgM and PCR for Parvovirus were positive. Kidney biopsy revealed collapsing glomerulopathy with acute tubular injury and minimal interstitial fibrosis. The patient's PCR titer was elevated to 542,000 IU/ml on hospital day 5. Intravenous immunoglobulin (IVIg) was started on day 6 at a dose of 400 mg/kg/day for a total dose of 150 grams over five days. On day 8, his repeat parvovirus PCR began to trend down. The patient's creatinine peaked at 2.29 mg/dL on hospital day 6 however then it began to trend down with treatment as well. The patient was discharged in stable condition on hospital day 11. Three weeks after discharge all his symptoms had abated and his serum creatinine improved to 1.38 mg/dL with proteinuria of 1.1g/g. Patient's parvovirus PCR titer notably decreased to 3,400 IU/ml with this treatment.

Discussion: Collapsing glomerulopathy is prevalaent in patients with human immunodeficiency virus (HIV) and more recently, there have been several cases showing an association with Parvovirus B19. Optimal treatment for Parvovirus associated collapsing glomerulopathy is unknown. We were able to diagnose Parvovirus B19 early by elevated viral PCR and initiated treatment for our patient quickly preventing further progressive renal damage. In addition to strict blood pressure control, the patient was treated with IVIG at a dose of 400mg/kg for five days. The patient was not placed on any corticosteriod therapy. The patient's Parvovirus viral PCR, serum creatinine and proteinuria trended downward. This is the first patient with successful corticosteriod-free treatment of parvovirus induced FSGS with intravenous immunoglobulin.

TH-PO529

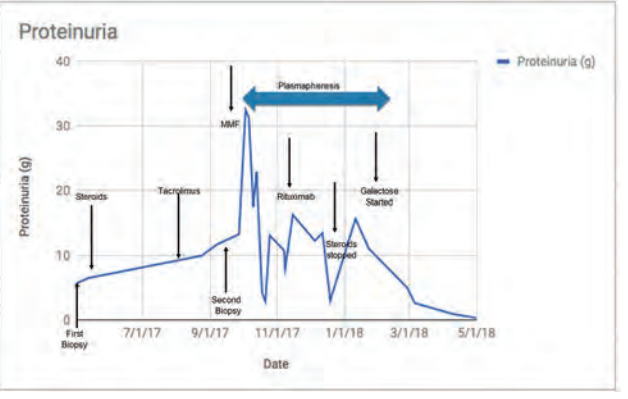
A Unique Treatment Strategy in Collapsing Glomerulopathy in a Native Kidney

Fatima Sheikh,[1] Sherry Shariatmadar,[2] Vanesa Bijol,[3] Kenar D. Jhaveri.[1] *[1]Nephrology, Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; [2]Blood Bank, Zucker School of Medicine at Hofstra Northwell, Manhasset, NY; [3]Pathology, Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Introduction: Collapsing glomerulopathy (CGP) is a fast progressive glomerular disease. We present a unique case of CGP in a native kidney that responded to multi-drug therapy, which included therapeutic plasma exchange (TPE) leading to complete remission.

Case Description: A 62 year old Indian male presented in June 2017 with AKI (2.65 mg/dl), and nephrotic syndrome (5.6g/24hours). His initial presentation prompted a kidney biopsy which revealed CGP with minimal fibrosis. The patient was started on steroid therapy and ARB therapy. The patient however continued to progress and tacrolimus was added to the regimen. His proteinuria worsened to 32.5g. The patient was subsequently re-biopsied. The biopsy revealed CGP with minimal IFTA. All of his secondary work-up for autoimmune, viral and cancer causes was negative. A combination therapy approach was used and the patient was then initiated on TPE, MMF and continued to tacrolimus (Figure). Steroids were tapered off. Interestingly, with only a few sessions of TPE, his proteinuria improved to <3gm. When TPE was halted, proteinuria returned. This prompted re-initiation of TPE. The patient subsequently had a progressive decrease in proteinuria down to <2gm over 2-3 months. He was maintained on MMF and tacrolimus. In an attempt to come off TPE, he was given a dose of rituximab 1gm and then started on supplemental powder of galactose 0.2 g/kg orally two times per day. After 2 months of therapy he is off TPE and his creatinine stable at 1.2mg/dl with 0.3g proteinuria.

Discussion: This case report suggests that administration of a multimodality approach as used in kidney transplant patients with recurrent CGP might be useful in native kidney idiopathic CGP. This novel case report findings support the performance of randomized clinical trials to assess the efficacy of the use of multi-modal approach to idiopathic CGP.



Proteinuria trend with reference to various treatments used

TH-PO530

Adrenocorticotropic Hormone (ACTH) in the Treatment of Refractory Childhood Nephrotic Syndrome (NS)

Amirtha Chinnadurai, Julie Goodwin. *Yale University School of Medicine, New Haven, CT.*

Introduction: Treatment resistance or failure to respond to conventional therapies in NS is associated with poor prognosis. ACTH is recognized as therapy for podocytopathies, though these data are based on small observational studies in adults. There are no published data on the use of ACTH therapy in the pediatric population. We report a case of steroid-resistant NS in a 10 year-old boy who failed multiple secondary therapies but showed a partial response to ACTH injection (ACTHAR) therapy.

Case Description: A 10-year-old Hispanic boy who was diagnosed with NS at the age of 2. He was initially steroid sensitive but frequently relapsing. Cyclosporine A (CsA) was initiated as a steroid-sparing agent and he achieved a 5-year period of stability. However, he eventually began to relapse while on CsA. Tacrolimus and mycophenolate mofetil (MMF) were also ineffective. During this time he became steroid resistant. Triple therapy with steroids, tacrolimus and MMF was unable to induce even a partial remission. A renal biopsy showed early focal segmental glomerulosclerosis (FSGS). Whole exome sequencing showed only a heterozygous variant in PLCE1. He became dependent on twice weekly albumin infusions due to anasarca and persistent hypoalbuminemia (less than 1.2g/dl). Urine protein/creatinine (UPC) ratios were persistently in the nephrotic range. Over 18 months he persisted in uncontrolled relapse, complicated with 5 episodes of acute kidney injury. His creatinine plateaued at 0.7-0.8 mg/dl, whereas in remission it had been 0.3-0.4 mg/dL. We initiated ACTHAR as a last resort given concerns for progressive renal impairment. Initial therapeutic response was minimal with dose of 40 units biweekly. After increment to 80 units biweekly, he demonstrated significant improvement. His serum creatinine improved to his baseline of 0.30 mg/dl and UPCs decreased by more than 50%. Serum albumin improved spontaneously to 1.9-2.0g/dl, resulting in discontinuation of scheduled albumin infusions.

Discussion: This case highlights that ACTHAR may be a viable therapeutic alternative for children who are resistant to other therapies for NS. Additionally, the role of his PLCE1 mutation is unclear but we suspect a compound heterozygous state for another unidentified pathogenic mutation and/or epigenetic modifications may be playing a role in his refractory NS.

TH-PO531

Treatment of Nephrotic-Range Proteinuria with Tacrolimus in Mitochondrial Trifunctional Protein Deficiency

Hostensia M. Beng, Asha Moudgil, Sun-Young Ahn. *Nephrology, Children's National Health System and The George Washington University, Washington, DC.*

Introduction: Mitochondrial trifunctional protein (MTP) deficiency is a rare autosomal recessive disorder of long-chain fatty acid oxidation that leads to lactic acidosis, recurrent rhabdomyolysis, cardiomyopathy, and hepatic dysfunction.

Case Description: A 7-month old girl, with known MTP deficiency, presented with poor oral intake and lethargy. Laboratory analysis revealed a low corrected serum calcium level of 6.6 mg/dl, elevated CK level of 14,080 U/L, and nephrotic range proteinuria with a urine protein to creatinine ratio (uPCR) of 7.6 mg/mg. Serum albumin was low at 2.8 g/dl and urine beta-2-microglobulin was mildly elevated at 556 mcg/g creatinine (nl <300 mcg/g). The patient was treated for primary hypoparathyroidism and rhabdomyolysis, known complications of MTP deficiency. Despite resolution of her rhabdomyolysis, she continued to have nephrotic range proteinuria and underwent a renal biopsy that demonstrated minimal change disease and foot process fusion. She was started on tacrolimus and her uPCR gradually normalized 8 months after treatment. She has continued to have normal renal function and uPCR values at the time of this report (2 years of age). The patient has an older sister with the same heterozygous deletion in the HADHB gene (c.1059delT), which is predicted to cause truncation and loss of long-chain-3-hydroxyacyl CoA dehydrogenase function, leading to MTP deficiency. This sister was diagnosed with nephrotic syndrome and focal segmental glomerulosclerosis at 18 months of age, and developed end stage renal disease at 20 months of age.

Discussion: Renal involvement has been reported in only 1 patient with MTP deficiency to date, the sister of our patient. The pathogenesis of proteinuria in the 2 siblings remains elusive. Given that other mitochondrial disorders, such as coenzyme Q10 deficiency, have been associated with nephrotic syndrome, the proteinuria may be related to their mitochondrial dysfunction. Calcineurin inhibitors have been reported to reduce proteinuria by stabilizing the podocyte actin cytoskeleton. Tacrolimus was an effective treatment for our patient, who has maintained normal renal function, unlike her sister. Further investigation will be needed to determine the role of calcineurin inhibitors in the treatment of nephrotic syndrome associated with mitochondrial disorders.

TH-PO532

Hepatitis B and C Dual Infection and Collapsing Glomerulopathy: Report of a Rare Association

Flor Espinoza, Marjan Afrouzian, Tunde O. Omitogun, Hania Kassem. *University of Texas Medical Branch, Galveston, TX.*

Introduction: Collapsing Glomerulopathy (CG) is marked by severe hypertension and proteinuria, poor response to corticosteroids, and a rapid progression to end-stage renal disease. Many viral illnesses, including HIV, have been implicated in the pathogenesis of this disease. However, the association between CG and Hepatitis C virus (HCV) or Hepatitis B virus (HBV) remains less clear.

Case Description: A 55 y/o man with a history of HTN, Hepatitis B and C, and liver cirrhosis presented with altered mental status. He was hemodynamically stable, however, had significant laboratory derangements including a Cr of 19 mg/dl (recent baseline was 0.9), K of 7.3, CO2 11, and pH of 7.14. His lactic acid, coagulation panel and bilirubin levels were within normal limits. Urine microscopy showed muddy brown casts and no hematuria. He was also found to have nephrotic range proteinuria. HIV and Parvovirus B19 IgM antibodies were negative. Dialysis had to be initiated for uremia, hyperkalemia and acidemia. By light microscopy, the renal biopsy showed segmental glomerulosclerosis in 10/17 viable glomeruli with 3 glomeruli showing a collapsing pattern and podocyte hyperplasia. Severe interstitial fibrosis and tubular atrophy (IFTA) was noted. Immunofluorescence and electron microscopy showed tubulo-reticular inclusions (TRIs) within the endothelial cytoplasm. Patient's mental status, electrolytes and acidemia improved with dialysis. However, he remained dialysis dependent and given the severity of his kidney disease on presentation and the degree of IFTA, renal injury was deemed unlikely to recover.

Discussion: The uncommon association of CG and HCV infection in HIV-negative patients has been reported, mainly in patients treated with interferon. There has been only one reported case of CG associated with HBV infection. As our patient was HIV-negative and was not treated with interferon, the occurrence of CG was attributed to his dual infection with HBV and HCV, especially since TRIs were found on electron microscopy. It is possible that a synergistic action during this dual infection led to the development of CG, a glomerular lesion that rarely occurs with either viral infection alone. This case highlights the need for further research to elucidate the pathogenetic role HBV and HCV may play in the development of CG.

TH-PO533

An Infantile Nephrotic Syndrome Case Caused by COQ6 Gene Defects Revealed by Pair Analysis and Custom Array CGH

Keita Nakanishi,[2] Kandai Nozu,[2] Takayuki Okamoto,[6] Asako Hayashi,[6] Toshiyuki Takahashi,[6] Nana Sakakibara,[2] China Nagano,[2] Junya Fujimura,[2] Tomoko Horinouchi,[2] Shogo Minamikawa,[1] Tomohiko Yamamura,[2] Hiroshi Kaito,[5] Yuko Shima,[3] Koichi Nakanishi,[4] Kazumoto Iijima.[2] *[1]Kobe University Graduate School of Medicine, Kobe, Japan; [2]Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan, Kobe, Japan; [3]Wakayama Medical University, Wakayama City, Japan; [4]Child Health and Welfare (Pediatrics), Graduate School of Medicine, University of the Ryukyus, Nishihara-cho, Japan; [5]Nephrology, Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan; [6]Hokkaido University Graduate School of Medicine, Sapporo, Japan.*

Introduction: Comprehensive genetic analysis using next-generation sequencer (NGS) of causative genes for steroid resistant nephrotic syndrome (SRNS) have been established all over the world currently. It enables us to treat some kinds of monogenic SRNS patients with specific therapies and improve the renal prognosis; Coenzyme Q10 (CoQ10) supplementation for patients with CoQ10 deficiency related gene variants, such as *COQ6*, *PDSS2*, *COQ2*, and *ADCK4*. In this study, we conducted NGS analysis for the infantile SRNS patient, and to detect a copy number variation (CNV), we performed NGS data-based pair analysis and custom array CGH.

Case Description: Patient was a 1-year-old boy. He was diagnosed with SRNS and performed a renal biopsy. Electron microscopic examination revealed abnormal mitochondria (dysmorphic mitochondria, lacking cristae or abnormal proliferation) in podocytes. We conducted targeted panel sequencing analysis using NGS and detected only one *COQ6* monoallelic reported variant on maternal allele (c.782C>T, p.Pro261Leu). Next, we conducted CNV analysis with pair analysis using the NGS analysis data and custom array CGH. Both analysis successfully detected the same copy number changes in exons 1–2 of the *COQ6* gene on paternal allele. He was thus started supplementation of CoQ10, and remission was achieved.

Discussion: Comprehensive gene screening system with NGS were effective method to detect causative gene variants in SRNS. In addition, conducting pair analysis and custom array CGH were remarkably useful to detect CNVs. Specific therapy of CoQ10 for the patient carrying *COQ6* mutations was very effective when it was started in the early stages, so try not to miss the opportunity for the cases with CoQ10 glomerulopathies starting supplementation.

TH-PO534

Identification of Novel Mutations and Phenotype in the Steroid Resistant Nephrotic Syndrome Gene NUP93

Ibrahim Sandokji,[1] Jonathan Marquez,[2] Weizhen Ji,[2] Monica Konstantino,[2] Saquib Lakhani,[2] Mustafa Khokha,[2] Jillian K. Warejko.[1] *[1]Department of Pediatrics, Section of Nephrology, Yale University School of Medicine, New Haven, CT; [2]Department of Pediatrics, Pediatric Genomics Discovery Program, Yale University School of Medicine, New Haven, CT.*

Introduction: In 11-30% of steroid-resistant nephrotic syndrome (SRNS), a known gene mutation can be detected. *NUP93* is a widely expressed gene that encodes a highly conserved nuclear pore protein that has been shown to cause non-syndromic autosomal recessive focal segmental glomerulosclerosis (FSGS). Here we describe a case of novel *NUP93* mutations in a child with a syndromic SRNS phenotype.

Case Description: We identified compound heterozygous mutations of *NUP93* gene using whole exome sequencing (WES) in a patient presented with syndromic SRNS and progressed to ESRD in her first decade of life. An African American and Hispanic 5-year-old girl presented with nephrotic syndrome, including nephrotic-range proteinuria (UPC of >29 mg/mg), edema, and hypoalbuminemia. She was clinically fluid overloaded, hypertensive, and quickly became anuric and required renal replacement therapy. She had signs of chronic kidney disease including hyperparathyroidism, anemia, and short stature. A urinalysis 1 year prior showed 3+ proteinuria that was not quantified. In addition to her kidney involvement, she had developmental delay with autistic features; including delays in expressive language, fine motor, social communication and repetitive hand movements. Additionally, she had two episodes of heart failure requiring inotropic support after having adequate dialysis for more than a month. Her echo showed systolic and diastolic dysfunction (ejection fraction as low as 35%) and dilated cardiomyopathy features of unclear etiology that did improve with aggressive nutritional support and blood pressure management.

Discussion: We detected compound heterozygous mutations in *NUP93* a maternal missense mutation (ch16:56855426 A>G) c.206A>G, p.Y69C and a paternal nonsense mutation (ch16:56868107 C>G) c.1236C>G, p.Y412X. The mutations were highly conserved through phylogeny and had high pathogenicity prediction scores. We describe in this case novel mutations in the SRNS gene *NUP93* resulting in a syndromic phenotype with neurologic and cardiac features. It remains unclear the degree to which *NUP93* contributed to her cardiomyopathy, as this gene has also been described as localizing to cilia as well as the nucleoporin. WES is the ideal test for patients with SRNS as a conclusive molecular diagnosis does influence therapeutic choices.

TH-PO535

A Patient with PLA2R Membranous Nephropathy and "Non-Depletion" After Rituximab

Wael A. Hanna,[1] Margaret Duffy,[2] Mohammad N. Saqib.[2] *[1]Lehigh Valley Hospital, Breinigsville, PA; [2]Valley Kidney specialists, Allentown, PA.*

Introduction: Rituximab failure in patients with membranous nephropathy with nephrotic syndrome has been described in the literature. We present a case of PLA2R membranous nephropathy who progressed immunologically and did not show evidence of B cell depletion despite use of rituximab.

Case Description: A 62 year-old man with history of hyperlipidemia and hypertension presented with sudden onset lower extremity edema. Labs revealed sCr 1.1 mg/dL, albumin 2.9 g/dL, total cholesterol 235 mg/dL, triglycerides 116 mg/dL, and LDL 132 mg/dL. He had 12.5 grams of protein/24 hour urine collection. ANA, C3, C4, hepatitis panel, serum and urine electrophoresis were all negative/ unremarkable. A renal biopsy was performed which revealed membranous nephropathy that stained positive for PLA2R. Proteinuria and renal function deteriorated despite maximal ARB therapy for >3 months. He was given rituximab infusion 1 g IV every 2 weeks x 2 doses in November 2017. PLA2R antibody titers, CD19 count, sAlb, and sCr were obtained after 2, 4, and 5 months from rituximab therapy as shown in Table 1. Unfortunately given the extent of immunologic progression, we considered treatment failure in this patient and decided against additional rituximab infusions.

Discussion: We present a case with a rare and relatively severe phenotype of PLA2R membranous nephropathy who did not show evidence of B cell depletion and had persistent PLA2R titer progression despite treatment with rituximab. In patients PLA2R membranous nephropathy with nephrotic phenotypes, the use of immunologic biomarkers to ascertain early response is critical in deciding whether to continue or to consider alternative treatments. Novel therapeutic targets such as newer generation anti-CD 20 agents (ie ofatumumab) and plasma cell targets may be helpful in patients with relapsing or rituximab resistant disease. Furthermore, additional biomarkers (eg long-lived plasma cell markers, CD38 and CD138) may be useful while assessing response.

Table 1

	1/2018	3/2018	4/2018
CD19 count (71-567/μL, 5-25 %)	8 (1%)	59 (3%)	49 (3%)
PLA2R Ab titer	1:320	1:640	1:5120
sAlb (g/dL)	1.9	1.2	1.7
sCr (mg/dL)	2.6	3.2	3.5

TH-PO536

A Case of Anti-PLA2R Antibody Positive Membranous Nephropathy Diagnosed in Pregnancy with Antibody Transfer to Infant

Kelly H. Beers, Niralee Patel, Amanda Dijanic, Shuchita Sharma. *Nephrology, Icahn School of Medicine at Mt. Sinai, New York, NY.*

Introduction: Phospholipase A2 receptor (PLA2R) antibody is a pathogenic agent found in 70-80% of patients with primary membranous nephropathy (MN). Whether anti-PLA2R Ab is transmitted from maternal to fetal circulation remains unknown. We report a case of nephrotic syndrome during pregnancy with elevated anti-PLA2R Ab level in maternal serum, and subsequent detection of high levels of antibody in the infant, suggesting that anti-PLA2R Ab likely crosses the placenta.

Case Description: A 33 year old woman was transferred to our medical center at 28 weeks of gestation for ongoing management of pregnancy complicated by nephrotic syndrome. The patient had been diagnosed with the nephrotic syndrome at approximately 16 weeks of gestation based on edema, hypoalbuminemia (0.9g/dL), and 6g of protein on 24 hour urine collection. She had no known history of kidney disease. On arrival to our institution, serum creatinine (Cr) was at her baseline of 0.6 mg/dL with albumin 0.4g/dL. Anti-PLA2R Ab levels were found to be elevated at 479.6 RU/mL. A presumptive diagnosis of primary MN was made and renal biopsy was deferred due to her advanced gestation. Pt remained in the hospital for the duration of her pregnancy and underwent successful diuresis documented by 80 pound weight loss and significant improvement in her edema. She had successful delivery of a male baby at 34 weeks 3 days of gestation. 24 hour urine collection from the patient immediately following delivery showed 12g proteinuria. Cr remained stable throughout the admission. Anti-PLA2R Ab was measured in both mother and baby immediately post-delivery with values of 405.1 and 43.1 RU/mL, respectively.

Discussion: This case suggests that anti-PLA2R Ab crosses the placenta to reach fetal circulation. Whether this results in renal disease in the baby is unclear, though there are case reports of fetal morbidity associated with maternal neutral endopeptidase deficiency leading to congenital membranous nephropathy. Children of mothers with primary MN during pregnancy should be monitored pre- and post-natally for signs of renal disease mediated by Anti-PLA2R Ab.

TH-PO537

PLA2R-AB Positive Malignancy-Associated Membranous Nephropathy: A Case Report

Amr Habbach,[1] Avi Z. Rosenberg,[2] Marco Delsante,[3] Blaithin A. McMahon.[1] *[1]Johns Hopkins Hospital, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD; [3]Universita' degli Studi di Parma, Baltimore, MD.*

Introduction: Membranous nephropathy (MN) is the most common cause of nephrotic syndrome in adults and the most frequent paraneoplastic glomerular disease associated with solid tumors. MN is either idiopathic (iMN) or secondary to malignancy (M-MN), infections, autoimmune diseases or drugs. Features such as the presence of the M-type Phospholipase A2 Receptor (PLA2R) antibodies and IgG subclass have been suggested to help distinguish idiopathic from secondary MN. However, 15-17% of cases of M-MN are anti PLA2R antibody positive, raising question about the specificity of these antibodies for the diagnosis of iMN. This is of importance as the treatment of this disease centers upon whether the disease is determined to be primary or secondary.

Case Description: We present here a case of a 78-year-old African female with pancreatic adenocarcinoma who was referred for lower extremity swelling and evaluation for proteinuria. A 24hr urine collection demonstrated 8.3 g of proteinuria and serum albumin of 1.3 g/dl. Her glomerular filtration rate was estimated to be 96 ml/min per 1.73/m2. Monoclonal gammopathy was not detected. Serum anti-PLA2R Antibodies were severely elevated, greater than 1500 RU/ml. A kidney biopsy revealed a prominent glomerular basement membrane and subepithelial deposits on electron microscopy. Anti-PLA2R AB was strongly positive on immunofluorescence. Features of paraneoplastic glomerulopathy were also present (near full-house pattern on IF, Kappa chain co-dominance, equivalent IgG4, IgG1 and IgG3 isotypes). The patient was empirically started on high dose corticosteroids given the preliminary result of proliferative glomerular disease and a near full-house pattern. She received capecitabine and radiotherapy with significant reduction in tumor size. Repeat Anti-PLA2R AB titers was 4 RU/ml

Discussion: This case highlights the complexity in trying to identify iMN from M-MN and the challenges facing the nephrologist in the treatment of this disease. The normalization of Anti-PLA2R AB in the setting of treating her malignancy suggests direct involvement of Anti-PLA2R AB in the mechanism of M-MN. Future studies are needed to evaluate the importance of anti PLA2R Antibodies in M-MN

TH-PO538

THSD7A Associated Membranous Glomerulonephritis Due to Antibody Produced by Lymph Node around Metastasis of the Thymoma

Wei Han,[1] Tomo Suzuki,[1] Shiika Watanabe,[1] Mayumi Nakata,[1] Daisuke Ichikawa,[1] Atsuko Ikemori,[2] Junki Koike,[3] Yugo Shibagaki.[1] *[1]Nephrology, St.Marianna university school of medicine, Kawasaki, Japan; [2]St. Marianna University School, Kawasaki, Kanagawa, Japan; [3]St.Marianna University, Kawasaki, Japan.*

Introduction: Membranous glomerulonephritis (MGN) are known to be associated with malignant tumor and tumor resection can lead to remission of MGN. MGN with thrombospondin type-1 domain-containing 7A (THSD7A), which is one of the transmembrane protein antigen to podocyte, have been recently reported to be also associated to malignancy. We present a first case of THSD7A-associated MGN with thymoma that was later diagnosed with lymphatic metastasis.

Case Description: A 61-year-old woman with past medical history of asthma was referred to our clinic for bilateral edema in lower extremities and proteinuria. Her labs showed nephrotic syndrome and kidney biopsy was done. Although there was no proliferative nor spike lesions in glomeruli on light microscopy, IgG and THSD7A were stained strongly positive along glomerular capillary on immunofluorescence and subepithelial deposits on electron microscopy. Thus, she was diagnosed as THSD7A-associated MGN and subsequently found to have thymoma. She underwent extended thymectomy and postoperative radiation since thymoma type B3 was confirmed pathologically. However, proteinuria persisted in spite of steroid administration for asthma. Three years later, positron emission tomography (PET) revealed a tumor of right subclavian space, in which biopsy specimen showed histology similar to that of thymoma, thus diagnosis of metastatic recurrence was made. She underwent another course of radiation, followed by a PET confirming the complete disappearance of the metastasis, and proteinuria decreasedto less than 1 g/gCr in a year. Additional investigation revealed that, although anti-THSD7A antibody was negative in thymoma itself and in metastatic lesion, it stained strongly positive in the cells of the lymphatic node around the metastatic lesion just as staining in the glomeruli.

Discussion: We report a first case as far as we know showing the THSD7A-associated MGN with metastatic thymoma. It is intriguing that thymectomy itself could not result in remission of her proteinuria presumably due to continued exposure to THSD7A antibody produced by the lymph node around the metastasis. We need to keep in mind of searching for metastasis or remnant tumor in cases which proteinuria does not respond well to tumor resection in THSD7A associated MGN complicated in malignancy.

TH-PO539

Secondary Membranous Nephropathy Was Induced by Gastrointestinal Stromal Tumor in Patient with Idiopathic Membranous Nephropathy

Maiko Nakayama,[1] Hitoshi Suzuki,[1] Yu Sasaki,[1] Shigeki Tomita,[2] Yusuke Suzuki.[1] *[1]Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Juntendo University Urayasu Hospital, Urayasu, Chiba, Japan.*

Introduction: The membranous nephropathy (MN) is a major cause of nephrotic syndrome. The major causes of secondary MN are malignancy, autoimmune disease, infection, and drug toxicity. However, gastrointenstinal stromal tumor (GIST) rarely induces secondary MN. We report here a biopsied case with onset of secondary MN accompanied by GIST on idiopathic MN successfully treated by the resection of GIST.

Case Description: A 77-year-old man was diagnosed as the idiopathic MN at 60-year-old, and treated by oral corticosteroid, resulted in incomplete remission. From age of 71, serum levels of CA19-9 had increased at 1278 U/mL, however, any malignancy was not detected. He was hospitalized because of exacerbation of urinary protein (5.1g/gCr) at 77-year-old. Although steroid pulse therapy was initiated, level of urinary protein was not improved. To rule out complication with other glomerular injuries, we performed renal biopsy. Light microscopic finding indicated MN, but not other glomerulonephritis. Immunofluorescence analysis of IgG subclass showed IgG1 and IgG2 dominant, despite IgG4 deposits were dominant in previous renal biopsy specimens. Furthermore, serum anti-PLA2R antibody was negative. We thus diagnosed as the secondary membranous changes on idiopathic MN. We further surveyed complication of malignant disease and could find GIST by PET-CT. After 1 month from resection of GIST, serum CA19-9 decreased within normal range, and the level of proteinuria also improved to 1.4 g/gCr.

Discussion: This is the novel case with onset of secondary MN on idiopathic MN. Moreover, GIST typically does not show increased levels of serum CA19-9 and rarely induced secondary MN.

TH-PO540

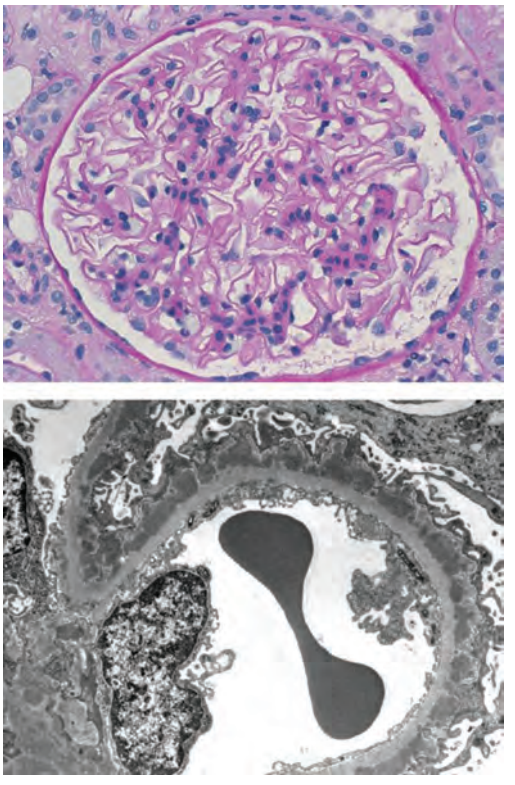
Diffuse Lymphadenopathy as Red Herring for Secondary Membranous Nephropathy

Priyanka Wani,[1] Jessica Cruz Whitley,[2] Kuang-Yu Jen,[3] Shubha Ananthakrishnan,[2] Brian Y. Young.[4] *[1]University of California Davis Medical Center, Sacramento, CA; [2]UC Davis, Sacramento, CA; [3]University of California, Davis, Sacramento, CA; [4]UC Davis Medical Center, Sacramento, CA.*

Introduction: Membranous nephropathy (MN) is associated with a high risk of thromboembolism. We describe a patient who presented with multiple thromboemboli with delayed diagnosis of secondary MN due to diffuse lymphadenopathy suspicious for malignancy.

Case Description: A 26-year-old African American female presented with dyspnea, pleuritic chest pain, and edema. CTA revealed multiple segmental PEs and a left renal vein thrombosis. Imaging also found diffuse mediastinal and axillary lymphadenopathy with a prominent hilar mass compressing the right lower lobe pulmonary artery, all of which were FDG avid on PET. Radiology findings was suspicious for lymphoma, however an axillary node biopsy was negative for cancer. Infectious workup was negative. Laboratories were significant for creatinine of 0.6mg/dl, albumin <1 gm/dl, and 7.3 grams proteinuria. Serologies were positive for ANA, anti-Smith, anti-dsDNA, and anti-U1RNP. Kidney biopsy showed widespread IgG-dominant subepithelial deposits consistent with MN. A secondary cause of MN was suggested by mesangial widening with deposits, tubuloreticular inclusions, and lack of PLA2R staining. Based on serologies, arthritis, and renal involvement, the patient was diagnosed with systemic lupus erythematosus (SLE). She was started on high dose prednisone, mycophenolate and anticoagulation. Resolution of proteinuria and edema was seen after six months. Followup physical exam and chest X-ray showed no lymphadenopathy.

Discussion: Diffuse lymphadenopathy, though less common nowadays, may be a prominent presenting feature of SLE and was highlighted in our case. Initial delays in kidney biopsy occurred due to malignancy evaluation and this atypical SLE presentation. Our case was ultimately diagnosed to be SLE with hypercoagulability due to nephrotic syndrome from MN.



TH-PO541

Biallelic CUBN Variants as a Cause of Isolated Proteinuria - Challenging the Investigative Paradigm

Kushani C. Jayasinghe,[1,2] Catherine Quinlan,[4] Ella J. Wilkins,[5] Susan M. White,[5] Cas Simons,[3] Andrew J. Mallett.[6] *[1]Monash Health, Clayton, NSW, Australia; [2]Kidney Development, Disease and Regeneration, Murdoch Children's Research Institute, Melbourne, VIC, Australia; [3]Murdoch Childrens Research Institute, Parkville, NSW, Australia; [4]The Royal Children's Hospital, Melbourne, VIC, Australia; [5]Victorian Clinical Genetics Services, Parkville, NSW, Australia; [6]Royal Brisbane and Women's Hospital, Stafford, QLD, Australia.*

Introduction: Proteinuria is a common kidney presentation. Historically, diagnostic workup of patients with isolated proteinuria involved thorough urinalysis, imaging and blood sampling before potentially proceeding to renal biopsy. However recent advances have resulted in reduced cost and increased availability of genomic sequencing for establishing clinical diagnoses.

Case Description: An 8year old boy was referred with an incidental finding of persistent proteinuria during investigation for nonspecific abdominal pain. He had no haematuria and had normal serum albumin. All other investigations including blood analysis for haematological, biochemical and immunological parameters, renal ultrasound, ophthalmology and audiology assessment were unremarkable. Further assessment revealed consanguineous family history and a brother also with isolated proteinuria. Renal biopsy demonstrated normal light microscopy and global uniform thinning of the glomerular basement membrane on electron microscopy. Chromosomal microarray revealed long continuous stretches of homozygosity (LCSH) representing ~4.5% of the genome. Shared regions of LCSH between the brothers were identified using the Genomic Oligoarray and single nucleotide polymorphism (SNP) Evaluation tool. Examination of these regions implicated *CUBN*, on chromosome 10p12.31. Research whole genome sequencing of both affected individuals was performed with informed consent (HREC/15/QRCH/126). This revealed a homozygous stop-gain variant in *CUBN* (NM_001081.3, c.4689_4690delTAinsAT, p.(CysIle1263*), ACMG Class 5).

Discussion: *CUBN* mutations have been implicated as a hereditary cause of megaloblastic anaemia and variable proteinuria. This is the second reported family with isolated proteinuria due to biallelic *CUBN* variants in the absence of megaloblastic anaemia, demonstrating the utility of genomics to identify single gene causes of nephropathy, and in doing so, to expand the associated phenotypic spectrum. Therefore, genomic sequencing, undertaken earlier in the diagnostic workup, has the potential to reduce the need for invasive investigations and to reduce the time to definitive diagnosis for patients and families.

TH-PO542

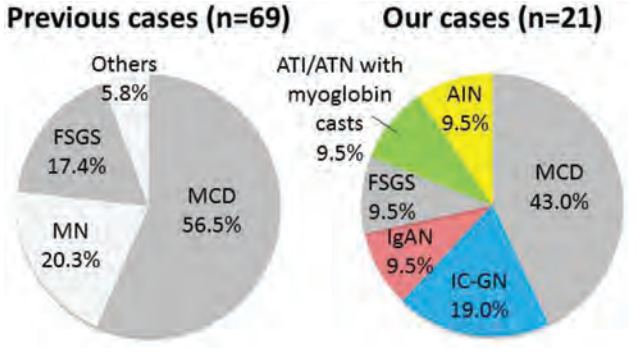
Thymic Disease-Associated Nephropathy: A Report of 21 Cases from a Single Institution

Takamasa Miyauchi, Narihito Tatsumoto, Michifumi Yamashita. *Pathology, Cedars-Sinai Medical Center, Los Angeles, CA.*

Introduction: Nephropathy in patients with thymic diseases such as thymoma and myasthenia gravis (MG) is rare. Previously, 69 cases have been reported from multiple institutions, and of these, common diseases are minimal change disease (MCD; 56.5%), membranous nephropathy (MN; 20.3%), and focal segmental glomerulosclerosis (FSGS; 17.4%). Here we characterize the spectrum of new 21 renal disease cases associated with thymic disease from a single hospital.

Case Description: Total 36,562 renal biopsy cases from 2005 through mid 2018 were reviewed at Cedars-Sinai Medical Center. 21 cases (0.057%) of patients have history of thymoma and/or MG. Pathological diagnoses are following: MCD (9 cases; 42.9%), Immune complex-mediated glomerulonephritis (IC-GN; 4 cases; 19.0%), FSGS (2 cases; 9.5%), IgA nephropathy (IgAN; 2 cases; 9.5%), acute tubular injury/necrosis (ATI/ATN) with myoglobin casts (2 cases; 9.5%), and acute interstitial nephritis (AIN; 2 cases; 9.5%).

Discussion: Consistent to the previous reports, MCD is the most common renal lesion in patients with thymic diseases. However, we did not observed MN, the second most common disease in the reports. We, instead, observed 4 cases of IC-GN that did not fit to MN: 2 showed mild IC-GN superimposing on MCD; 1 showed lupus nephritis-like GN (ISN/RPS CLASS II) without proliferative features; and 1 showed lupus nephritis-like GN (CLASS II) with segmental membranous change. We also experienced kidney diseases that haven't been reported before as an association with thymic disease: IgAN, ATI/ATN with myoglobin casts, and AIN. 2 cases of IgAN were low-grade without hypercellularity (endocapillary hypercellularity or crescents). 2 cases of ATI/ATN with myoglobin casts showed multiple myoglobin-positive tubular casts. Of AIN cases, one showed mild tubulitis with mild immune complex deposits both in mesangium and along tubular basement membranes. Another case showed granulomatous AIN. In conclusion, this is the largest and unique case series of nephropathy in patients with thymic disease from a single institution.



Summary

TH-PO543

Spontaneous Tumor Lysis Syndrome in Renal Solid Tumor: Case Report

Bruno N. Cesar,[1] Nilo E. Nunes,[4] Erica L. Reghine,[2] Cicero rodrigo M. Alves,[3] Renato D. Foresto,[2] Maria A. Hazin,[3] Marcelino S. Durao.[2] *[1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [2]Universidade Federal de Sao Paulo, São Paulo, Brazil; [3]Universidade Federal de Sao Paulo, São Paulo, Brazil; [4]Universidade Federal de Sao Paulo, São Paulo, Brazil.*

Introduction: Tumor Lysis Syndrome (TLS) results from a large release of intracellular material from malignant cells death, especially after chemotherapy. Spontaneous TLS (STLS) is commonly associated with aggressive hematological malignancies and rarely observed in solid tumors.

Case Description: A 67-year- old male presented to the hospital with progressive dyspnea, weakness and oliguria in the last two days. His medical records were hypertension, diabetes, coronary heart disease and a recently diagnosed renal mass. Blood tests showed creatinine: 8.8 mg/dL, urea: 272mg/dL; potassium: 6.4 mEq/L; serum uric acid: 15.9 mg/dL; phosphate: 7.6 mg/dL; ionic calcium: 1.07mmol/L. Two months before, creatinine level was 1.0 mg/dL. Abdominal and renal doppler ultrasound were performed and showed normal sized kidneys with a hypoechoic image on the left side, without signs of thrombosis. Abdominal CT scan showed a Bosniak-III left expansive kidney lesion. According to the clinical and laboratory findings, STLS diagnosis was performed. Due to a lack of response to conservative measures, hemodialysis was initiated and after three sessions kidney function improved and dialysis was discontinued. The patient underwent left nephrectomy. Histological analysis showed a clear cell renal cell carcinoma Fuhrman 3, stage T3a, with recent evidences of hemorrhage and tumor necrosis. The disease was restricted to kidney tissue. The patient was discharged from the hospital on the 5th post-operative day. At this time, blood tests showed creatinine was 1.6mg/dL, potassium 5 mEq/L, phosphate: 5.8 mg/dL, ionic calcium: 1.2 mmol/L and uric acid: 4 mg/dL.

Discussion: STLS is a serious event that affects patients with cancer. There are few reports of its association with solid tumors, especially in the case of renal cell carcinomas. In this report, the diagnosis of STLS was performed using the Cairo-Bishop criteria and was classified as grade 4. In most reported cases, larger masses with metastases prevailed and the patient died immediately after diagnosis. Physicians should be aware of the diagnosis since it requires prompt actions to improve outcomes.

TH-PO544

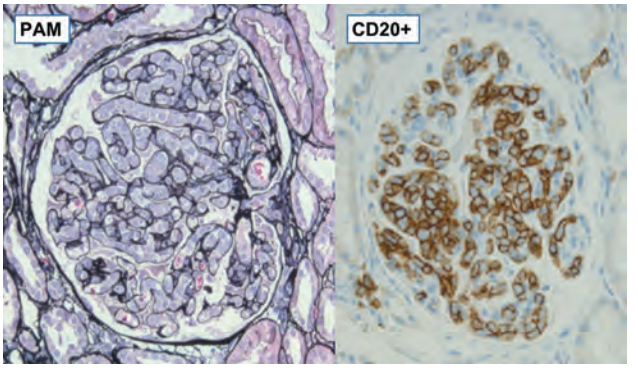
A Case of Intravascular Large B-Cell Lymphoma Diagnosed by Renal Biopsy

Rina Oba, Kentaro Koike, Naoko Nakaosa, Masahiro Okabe, Kei Matsumoto, Tetsuya Kawamura, Nobuo Tsuboi, Takashi Yokoo. The Jikei University School of Medicine, Division of Nephrology and Hypertension, Department of Internal Medicine. *The Jikei University School of Medicine, Minato-ku, Japan.*

Introduction: Intravascular large B-cell lymphoma (IVLBCL) is a rare subtype of large-cell lymphoma characterized by the proliferation of lymphoma cells within small vessels. In general, patients with IVLBCL exhibit aggressive clinical courses and most cases are diagnosed at autopsy. Although recent advancements in chemotherapy have markedly improved patient prognosis, an early diagnosis by biopsy remains critical. Therefore, random skin biopsy or bone marrow biopsy is performed in most cases. To date, some case reports have mentioned IVLBCL diagnosis by liver, lung, and brain biopsies. Here, we report a rare case of IVLBCL diagnosed by renal biopsy in a patient with the clinical phenotype of persistent proteinuria together with an elevated serum titer of proteinase-3-anti-neutrophil cytoplasmic antibody (PR3-ANCA).

Case Description: The patient was a 66-year-old woman with a history of bilateral leg edema, erythema, and pruritis. Laboratory data revealed high serum PR3-ANCA titer (92.6 U/ml), and chest computed tomography revealed lung nodules. Four months after the first presentation, the patient developed rapidly progressing dyspnea and persistent proteinuria (1.22 g/day) without hematuria. Renal biopsy revealed intraglomerular infiltration of enlarged atypical lymphocytes. Immunofluorescent staining showed that these cells were characterized as CD3-, CD5-, CD20+, CD79a+, CD10-, bcl-6+, and MUM1+. On the basis of these findings, the patient was eventually diagnosed with IVLBCL. After several cycles of chemotherapy, her proteinuria decreased (0.04 g/day) and PR3-ANCA titer declined (11.3 U/ml).

Discussion: We report a rare case of IVLBCL accompanied with persistent proteinuria and an elevated serum PR3-ANCA titer. In this case, identification of large lymphoma cells within the small vessels of the kidney was a key factor for early diagnosis and successful treatment.



TH-PO545

Primary Bilateral Renal T-Cell Lymphoma Presenting as Rapidly Progressive Glomerulonephritis

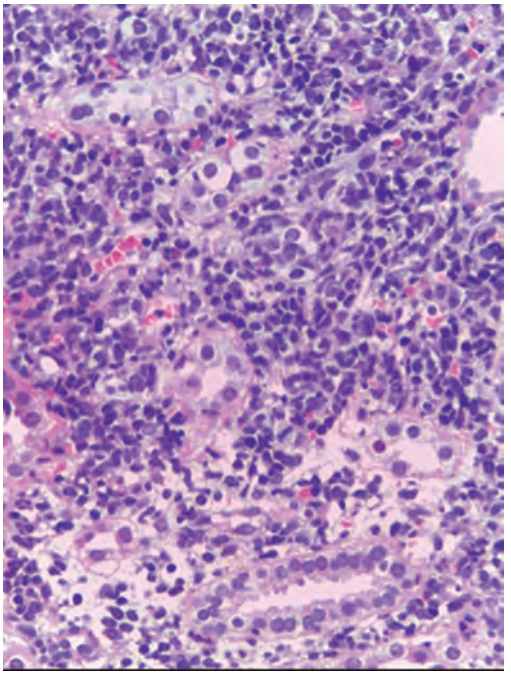
Maria Carolina R. Coêlho, Camila B. Oliveira, Denise M. Costa, Gisele Vajgel, Luis H. Sette, Marcelo Souto maior, Maria Alina G. Cavalcante, Lucila Maria Valente. *Hospital das Clínicas HC - UFPE, Recife, Brazil.*

Introduction: Primary renal lymphoma (PRL) is a extremely rare disease defined as a non-Hodgkin's lymphoma (NHL) involving the kidney in the absence of primarily extrarenal lymphatic disease. Acute kidney injury (AKI) as the initial presentation of lymphoma is even more uncommom.

Case Description: A 43 y/o man presented with edema, weight loss, asthenia and exertional dyspnea for 1 month. Urinalysis and renal function were normal (SCr 1.0mg/dL). After 2 weeks, SCr was 3.6mg/dl and he was hospitalized. He presented microscopic hematuria and mild proteinuria (486mg/24h) with progressive oliguric AKI (SCr 4.2) requiring dialysis. US showed discrete bilateral enlarged kidneys. He received methylprednisolone IV and oral prednisone 1mg/kg/day for the clinical diagnosis of rapidly progressive glomerulonephritis. Kidney biopsy showed diffuse lymphoid intersticial infiltration and immunohistochemistry was compatible with T-Cell lymphoma (CD 3 + / Bcl 2 + / CD 20 - / CD 10 - / CD 5 + / CD 23 - / Ki 67 90%). CT of the thorax, abdomen and pelvis confirmed enlarged kidneys and excluded infiltration in other organs. Before a specific treatment, the patient had a poor outcome, dying with septic shock days after.

Discussion: Despite its rarity, PRL should be kept in mind in the differential diagnosis of AKI with bilateral enlarged kidneys. Clinical manifestations are often nonspecific, with flank pain, hematuria, and weight loss predominating. Lymphomatous infiltration causing

AKI is a uncommon presenting finding and prognosis is poor. Although B-cell NHL are more commom, T-cell NHL have been described as a cause of PRL.



Intersticial lymphocytic infiltration (HE stain; magnification X 400)

TH-PO546

Renal Mucormycosis Presenting as Rapidly Progressive Renal Failure

Aileen Wang, Carrie L. Phillips, Asif A. Sharfuddin, Robert L. Bacallao. *Indiana University School of Medicine, Indianapolis, IN.*

Introduction: Mucormycosis is an invasive fungal infection with high mortality (~95% if disseminated). Caused by filamentous fungi in the Zygomycetes class, this infection has become increasingly frequent among immunosuppressed patients. The most common form of invasive mucormycosis is rhino-cerebral, with renal involvement being the rarest. Identification of mucormycosis as the cause of renal failure can be missed due to difficulty of successfully culturing mucorales. We describe a patient with chronic lymphocytic leukemia (CLL) and rapidly progressive renal failure (RPRF) with suspected Richter transformation who was diagnosed with angioinvasive mucormycosis based on renal biopsy specimen.

Case Description: 70-year-old Caucasian man with relapsed CLL presented with fevers up to 102°F daily and night sweats. Creatinine (Cr) increased from baseline 1.1 mg/dL to 3.65 on admission. He had been maintained on rituximab/revlimid for the past half-year. He was recently hospitalized for dyspnea and cough, for which he received voriconazole for suspicion of pulmonary aspergillus. PET scan revealed a new metabolically active retroperitoneal mass, while kidneys were unremarkable. Urine sediment showed RBCs, WBCs, and no casts. ANCA was negative. Despite IV fluids and suspension of nephrotoxic drugs, he progressed within one week to anuric renal failure necessitating hemodialysis. CT-guided renal biopsy was performed. Light microscopy showed necrotizing granulomas with multinucleated giant cells and pleomorphic, PAS-positive fungal forms that were interstitial and intra-arterial. Fungi were broad, non-septate, and thick-walled with irregularly spaced branching hyphae typical of mucor. He was immediately treated with liposomal amphotericin-B and IVIG, then isavuconazole for maintenance therapy. He defervesced after initiation of amphotericin-B but remains dialysis-dependent.

Discussion: This is a unique presentation of mucormycosis in a patient with underlying hematological malignancy and RPRF. This biopsy specimen drastically changed management. Manifestation of renal mucormycosis includes hematuria, pyuria and acute renal failure that can mimic RPRF. As mucorales are notoriously difficult to culture and radiologic imaging is nonspecific, histological diagnosis is required. This case speaks to the importance of early biopsy in renal failure of unclear etiology in immunocompromised patients.

TH-PO547

Mastocytosis of the Kidney: A Rare Manifestation of Systemic Mastocytosis

Regan M. Seipp, Mira T. Keddis, Margaret Ryan. *Mayo Clinic, Phoenix, AZ.*

Introduction: Systemic mastocytosis (SM), a rare, progressive myeloproliferative neoplasm, is characterized by clonal mast cell infiltration into tissues. Renal involvement of SM is unusual, with only three case reports currently described in the literature, and carries a grim prognosis.

Case Description: A 71 year old male with a history of hypertension, presented with a one year history of fatigue, 60 lb. weight loss, and increasing abdominal distention. Physical exam was notable for a frail, cachectic male with hepatosplenomegaly and peripheral edema. Laboratory analysis revealed acute kidney injury, decreased hepatic synthetic function, and pancytopenia. Urinalysis displayed grade 1 proteinuria and granular casts. Abdominal ultrasound showed increased echogenicity of the kidneys, ascites, and hepatic cirrhosis. The patient had no known risk factors for liver disease and underwent liver biopsy demonstrating diffuse mast cell infiltration with pericentral hepatocyte necrosis. Serum tryptase levels were elevated: 203 ng/ml (normal <11.5). Ensuing bone marrow biopsy showed 100% cellularity with 30-40% mast cells, confirming the diagnosis of SM. The kidney injury, initially managed as hepatorenal syndrome with albumin, midodrine, and octreotide, rapidly progressed requiring hemodialysis. Kidney biopsy revealed tubular injury and mast cell interstitial nephritis (Image 1). Midostaurin, a multikinase inhibitor, was initiated as disease directed therapy. The patient was eventually discharged but remained dialysis dependent.

Discussion: SM is associated with mutations in the receptor tyrosine kinase KIT (CD117). SM subtypes and median survival range from indolent (16 years) to mastocytoma (2 months). Renal involvement may occur even with indolent SM and has been reported as MPGN, interstitial nephritis, and light chain deposition disease. In each case, the kidney injury was progressive, requiring hemodialysis, and survival was worse than expected despite KIT directed therapy.

Image 2: Kidney biopsy CD117 stain highlighting increased interstitial mast cells

TH-PO548

Something Amiss with Cannabis: AKI Associated with Cannabidiol Ingestion

Timothy E. Yen,[1] Armando Aponte,[1] Lakshmi Chekuri,[3] Irina Lytvak,[3] Xin J. Zhou,[4] Hashim K. Mohmand.[2] *[1]Methodist Dallas Medical Center, Dallas, TX; [2]Dallas Nephrology Associates, Dallas, TX; [3]Methodist Richardson Medical Center, Plano, TX; [4]Renal Path Diagnostics, Lewisville, TX.*

Introduction: Cannabidiol (CBD) is a nonpsychoactive phytocannabinoid that is a popular dietary supplement with proposed medicinal properties. Although synthetic cannabinoids (SCs) such as K2/Spice have been implicated in kidney injury in over 20 case reports, CBD's renal effects are not as well documented.

Case Description: A 58 year old female with diabetes, hypertension and two weeks of abdominal pain and diarrhea presented with one day of emesis, anuria and CT imaging concerning for mild colitis. Medications were omeprazole, losartan, carvedilol, metformin and Insulin. She had started ingesting commercial, hemp-derived CBD Oil three months earlier but denied drug use, including Spice, K2 or marijuana. She had tachycardia and mild abdominal tenderness on physical examination. Initial lab tests showed renal failure, with a serum Cr 7.1 mg/dL (baseline 1.0), BUN 49 mg/dL, and potassium 7.1 mmol/L. The patient received emergent hemodialysis for refractory hyperkalemia. Urine output improved and gastrointestinal symptoms resolved in 24 hours. Urinalysis was negative for casts but urine protein/Cr and microalbumin/Cr ratios were 15 g/g and 4.4 g/g, respectively. Autoimmune and viral workups were unremarkable, as were SPEP, UPEP and free light chain assay. Renal biopsy showed extensive isometric cytoplasmic vacuolization of tubular cells. Under electron microscopy, these vacuoles were seen to be membrane-bound and corresponded to dilated endoplasmic reticulum. This disease pattern suggested toxic tubular injury and occurred on a background of diabetic glomerulosclerosis with mild TA/IF. Urine studies demonstrated evidence of a proximal tubulopathy with elevated 24h fractional excretion of phosphorous (68.4%) and Uric Acid (7.8%). The patient's renal function improved over the next week and she was discharged with a Cr of 3.1 mg/dL.

Five weeks after discharge, her serum Cr and proteinuria had improved to 1.4mg/dL and 215 mg/g, respectively.

Discussion: The mechanism for SC-associated kidney injury is unknown but tubular vacuolization has been documented in several cases. Although CBD differs from SCs in that it has little activity on the Cannabinoid 1 and 2 receptors, it has >65 molecular targets and could share a common mechanism for renal injury. This is the first reported case of renal injury associated with CBD use.

TH-PO549

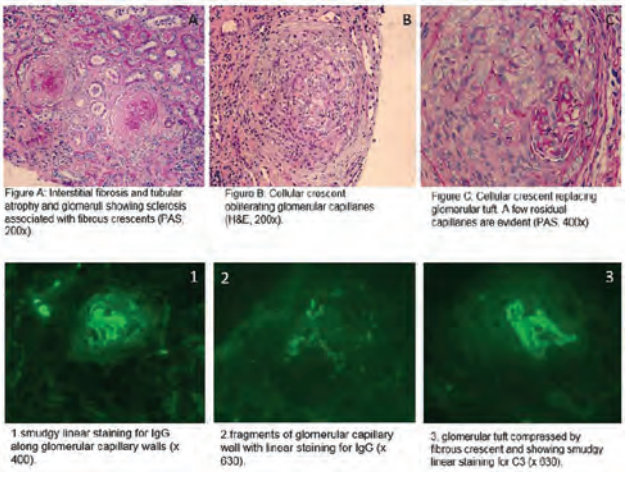
ESRD Secondary to Anti-Glomerular Basement Membrane Disease in a Child with Common Variable Immunodeficiency

Sai Sudha Mannemuddhu, Kiran K. Upadhyay. *Pediatric Nephrology, UF Shands, Gainesville, FL.*

Introduction: Anti- glomerular basement membrane (GBM) disease is an uncommon autoimmune disorder that is characterized by rapidly progressive glomerulonephritis (GN) caused by autoantibodies against the α3-chain of type IV collagen in the GBM. Commom variable immunodeficiency (CVID) is a primary immunodeficiency manifested by hypogammaglobulinemia, inability to make functional antibody, and recurrent infections. We report an interesting association of anti-GBM disease with CVID.

Case Description: A 15-year-old Caucasian female with prior normal renal function presented with 2 weeks of nephrotic proteinuria, oliguria, AKI, and was found to have serum anti-GBM antibody. She had been diagnosed with CVID and West Nile meningoencephalitis at 3 and 12 yrs of age respectively. Her renal biopsy showed crescentic GN with at least 50% global glomerulosclerosis and immunofluorescence showed linear staining for IgG along the glomerular capillary wall. There was no clinical or radiological evidence of pulmonary hemorrhage. She was treated with pulse IV steroids, Cyclophosphamide, Rituximab and several sessions of plasmapheresis. Her serum anti-GBM antibody level decreased from 194 U/mL at presentation to 0 U/mL post therapy. However, she progressed to ESRD within weeks and required dialysis. Her clinical course was complicated by hypertensive encephalopathy, CMV meningoencephalitis, CMV viremia, status epilepticus, and she passed away a few months later from lower respiratory infection related complications.

Discussion: Anti-GBM disease is a rare autoimmune condition, which has not been reported in association with a primary immunodeficiency syndrome. ESRD secondary to anti-GBM disease in a patient with CVID is an interesting association and supports role of immune dysregulation in systemic autoimmune disease.



Kidney Biopsy images- Anti GBM disease

TH-PO550

Renal Injuries Induced by Castleman's Disease

Takeo Koshida, Hitoshi Suzuki, Yuko Makita, Tomohito Gohda, Yusuke Suzuki. *Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Introduction: Castleman's disease is a benign lymphoproliferative disorder in which interleukin-6 (IL-6) is thought to play a pathogenetic role. Although renal involvement in Castleman's disease were reported, etiology of renal injuries is currently unknown, due to lack of data from renal biopsy. Here, we report two renal biopsied Castleman's disease in which successfully treated with the tocilizumab, a humanized anti-IL-6 receptor antibody.

Case Description: < *Case 1* > A 30-year-old man presented swelling of systemic lymph node. Pathological analysis of cervical lymph node biopsy showed plasmacyte infiltration, and ruled out malignant lymphoma and IgG4-related disease. Laboratory data indicated anemic state, hypoalbuminemia, polyclonal hypergammaglobulinemia, high levels of CRP (9.1 mg/dl), IL-6 (20.6 pg/ml) and VEGF (513 pg/mL). Taken together, he was diagnosed as multicentric Castleman's disease. The eGFR was 110.8 ml/min/1.73m^2, however, 0.6 g/day proteinuria and microscopic hematuria were detected. Then kidney biopsy was performed. The pathological findings of kidney biopsy specimen showed mild proliferation of mesangial cell. No immune deposits were detected by immunofluorescence analysis. < *Case 2* > A 49-year-old man was detected anemia and swelling of systemic lymph node. Cervical lymph node was biopsied, and laboratory investigation showed anemic state, hypoalbuminemia, polyclonal hypergammaglobulinemia and high level of CRP (8.7 mg/dl), IL-6 (43.0 pg/ml) and VEGF (1250 pg/ml). Taken together, he was diagnosed as multicentric Castleman's disease. The eGFR was 56.8 ml/min/1.73m^2, and 0.6g/day proteinuria and microscopic hematuria were detected at the time of renal biopsy. The pathological findings showed mild mesangial cell proliferation and global sclerosis in 10% of total glomerulus. Immunofluorescence analysis did not show any immune deposits.

Discussion: We present cases of kidney injury induced by Castleman's disease. In both cases, significant infiltration of plasmacyte and IL-6 positive cells were not detected in kidney biopsy specimens. Importantly, tocilizumab, but not corticosteroid successfully improved urinary abnormality. Although the mechanism and clinical course of renal involvement in Castleman's disease is unclear, these cases suggested that kidney injury in patients of Castleman's disease is induced by systemic overproduced IL-6 which proliferate mesangial cells.

TH-PO551

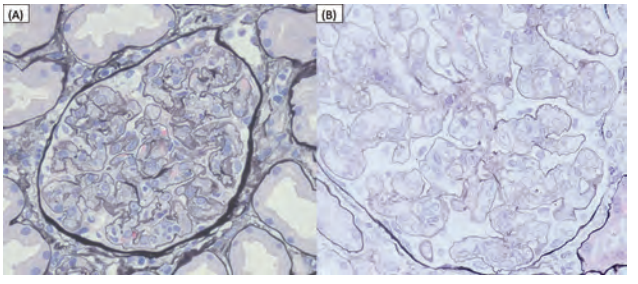
Prominent Swelling of Glomerular Endocapillary Cells in Two Cases of TAFRO Syndrome

Keiki Shimada,[1,2] Takaya Sasaki,[1,2] Kentaro Koike,[1] Yu Honda,[1,2] Masahiro Ishikawa,[1,2] Nobuo Tsuboi,[1] Takashi Yokoo.[1] *[1]The Jikei University School of Medicine, Minato-ku, Japan; [2]Kawaguchi Municipal Medical Center, Kawaguchi, Japan.*

Introduction: TAFRO syndrome, which is characterized by thrombocytopenia (T), anasarca (A), fevers (F), reticulin myelofibrosis/renal disorder (R), and organomegaly (O), is sometimes a fatal systemic inflammatory disease. The histopathological findings remain unclear because it is often difficult to perform renal biopsy due to severe thrombocytopenia. We herein report the histopathological findings of two cases of TAFRO syndrome in which renal biopsies were performed.

Case Description: Case 1: A 51-year-old male was admitted due to fever, fatigue, high CRP value, thrombocytopenia, and resistance to antibiotic drug treatment of two weeks' duration. He showed anasarca and multiple lymph node enlargement. He was diagnosed with TAFRO syndrome. Even though intensive care, including administration of corticosteroids, tocilizumab, and hemodialysis were continued, he died on the 24th day of hospitalization due to multiple organ dysfunction. Renal biopsy revealed marked swelling of glomerular endocapillary cells. Case 2: A 34-year-old man was referred due to fatigue, pretibial pitting edema, urinary protein, and urinary occult blood of one-month duration. He was admitted to the hospital for renal dysfunction and heightened inflammatory response. Hepatosplenomegaly, ascites, and thrombocytopenia was observed. He was diagnosed with TAFRO syndrome due to elevated VEGF and IL-6 levels. Prednisolone was administered and the heightened inflammatory response and proteinuria were ameliorated. Renal biopsy revealed endocapillary hypercellularity, endothelial cell enlargement, mesangiolysis, and duplication of basement membrane. These findings were compatible with thrombotic microangiopathy.

Discussion: The findings suggest that endothelial dysfunction is consistent with the characteristics of TAFRO syndrome, which was observed in this case as a membranous proliferative glomerulonephritis (MPGN)-like glomerular lesion. Renal impairment in TAFRO syndrome may be caused by secondary MPGN due to endothelial cell disorder.



TH-PO552

A Case of Multicentric Castleman Disease – TAFRO Variant, Presenting with Renal TMA

Fredrik Jenssen, Milos N. Budisavljevic, Andrew B. Elliott, Waleed Asfar. *Medical University of South Carolina, Charleston, SC.*

Introduction: Castleman's disease is a rare systemic lymphoproliferative disorder in which immune cells become activated to produce excess cytokines, particularly IL-6. A subset of cases are related to HIV or HHV-8. There is a wide heterogeneity of symptoms in the disease, ranging from asymptomatic to multisystem organ dysfunction. TAFRO syndrome is a unique clinicopathologic variant of multicentric Castleman's disease first described in 2010 in Japan by Takai et al. It includes thrombocytopenia, anasarca, microcytic anemia, fever, reticulin fibrosis, renal dysfunction, and organomegaly. To our knowledge, this syndrome has yet to be reported in the U.S.

Case Description: 20 y.o. male with previous normal kidney function, presented with AKI, lymphadenopathy, anasarca, and diarrhea after 2 month history of myalgia, malaise, back pain, diarrhea, vomiting, low grade fevers, and night sweats. He endorsed large amounts of NSAIDs use for myalgias. He presented with serum creatinine of 2.4 mg/dL which continued to rise despite conservative therapy with isotonic volume expansion and peaked at 4.7 mg/dL. The urinalysis was bland and urine protein-to-creatinine ratio was

0.1 g/g. Extensive workup including serologies for hepatitis and autoimmune disease were negative. Noncontrast CT was obtained which revealed prominent axillary, retroperitoneal, mesenteric, and inguinal lymphadenopathy. A renal biopsy revealed thrombotic microangiopathy (TMA) with mostly arterial changes, and evidence of mesangiolysis. Further workup for hemolytic-uremic syndrome and thrombotic thrombocytopenic purpura was negative. An excisional left axillary lymph node biopsy revealed classic findings of Castleman's disease. PCR for CMV, EBV, HIV, HHV-6, and HHV-8 were all negative. He was started on oral steroids, as well as IL-6 inhibitor (siltuximab) and developed hyperkalemia which was refractory to medical management, and required correction via conventional hemodialysis. He was continued on prednisone and received situximab infusion every 3 weeks with full recovery of renal function.

Discussion: Specific targeting of pathogenic mechanism of Castlaman's associated TMA with siltuximab in our case resulted in complete recovery of dialysis dependent renal TMA. To our knowledge, this is the first case of extremely favorable outcome of Castlaman's disease associated TMA treated with IL-6 inhibitor.

TH-PO553

Double Trouble or a Separate Entity: AKI Secondary to ANCA Vasculitis with IgG4 Nephropathy

Omar Mamlouk,[1] Hanan A. Khairalla,[1] William F. Glass,[2] Aisha Khattak.[1] *[1]Nephrology, The University of Texas Health Science Center at Houston, Houston, TX; [2]Pathology, The University of Texas Health Science Center at Houston, Houston, TX.*

Introduction: Antineutrophil Cytoplasmic Antibody-Associated (ANCA) vasculitis is reported to be associated with tissue infiltration by IgG4 cells and IgG4-related disease (IgG4-RD) is associated with elevated ANCA titers. IgG4-RD diagnosis is considered with caution in a patient with ANCA vasculitis as JSN criteria, one of widely used criteria for diagnosis, suggests that IgG4-RD is an unlikely diagnosis in patient with vasculitis. However, there is growing evidence of possible overlap between IgG4-RD and ANCA vasculitis, especially granulomatosis with polyangiitis, GPA. Few case reports showed histological evidence of both disease in the same organ. We present a case of GPA disease with concurrent histological evidence suggestive of IGg4 disease involving the kidney. These patients when treated with rituximab had good disease outcome

Case Description: A 61 year old woman with multiple co-morbidities including hypertension, chronic obstructive lung disease and chronic kidney disease was admitted for evaluation of shortness of breath and dysuria. she developed acute kidney injury during the first week of hospitalization along with purpuric rash on legs. no ocular, thyroid, salivary or oral manifestation by history or examination. urine analysis showed no dysmorphic RBCs. UPC was of 1.5. Serology for ANA, Anti-dsDNA, hepatitis panel and HIV was negative. PR3-ANCA was + and C3&4 were low. Renal biopsy was performed with finding of acute focal segmental necrotizing pauci-immune glomerulonephritis, active tubulointerstitial nephritis with interstitial and tubular basement membrane immune complex deposits, area of storiform fibrosis, and area of abundant IgG4 (20 cells/HPF). Serum IgG4 subclass level was elevated. These findings are suggestive of IgG4-RD. A CT of abdomen/pelvis did not reveal any other organ involvement. she was started on prednisone and rituximab with improvement of renal function back to baseline

Discussion: Clinical & histological evidence suggestive of IgG4-RD and ANCA vasculitis can co-exist in the same organ, including the kidney. Our findings support the growing evidence of possible association between IgG4-RD and GPA vasculitis. Understanding this association might help us have better understanding of underlying pathophysiology of both diseases. Rituximab was observed to be effective for treatment of IgG4-RD overlapping with ANCA vasculitis

TH-PO554

IgG4 Nephritis, When Rising Creatinine Is Not a Progression of CKD

Larissa Kruger gomes. *University of Connecticut Internal Medicine residency, Farmington, CT.*

Introduction: Immunoglobulin G4 (IgG4) is a rare disease with a diagnosis dependent on high clinical suspicion, specially when a single organ is affected. We present a case of IgG4 tubulointerstitial nephritis (TIN) and discuss when to suspect this disorder.

Case Description: A 64-year-old male with history of type 1 diabetes and chronic kidney disease with a creatinine (Cr) baseline of 1.2mg/dL, was referred to clinc after having an increase of Cr to 3.3mg/dL over 4 months. There were no recent changes in medications or sickness. Blood pressure and diabetes were under control with an HBA1C of 7.3% and microalbuminuria of 33mcg. Urinalysis (UA) showed 2-4 red blood cells and a protein/cr ratio of 800mg/g. Due to the unlikelihood of rapid progression of diabetic nephropathy, investigation for acute kidney injury with serology and renal ultrasound were pursued. Results were significant for low C3 and C4 and a rising Cr of 3.5mg/dL. Consequently, a kidney biopsy was done, revealling diffuse TIN with a dense plasma cell infiltrate with a high proportion of IgG4 cells and tubular basement membrane immunocomplex deposits. IgG4 levels were 683.5 mg/dL. With the diagnosis of IgG4 TIN, patient was started on prednisone 40 mg daily. After 1 month, the patient's Cr was 2.3mg/dL and after 4 months, 1.9mg/dL with IgG4 levels of 118 mg/dL. Patient is currently off prednisone and is being monitored for recurrence.

Discussion: IgG4-related kidney disease has higher prevalence among older men and it is usually related to extra renal disease, with sole renal impairment in 2-12% of cases. The pattern of intrinsic disease is most commonly TIN but can also be membranous. Patients can present with worsening of baseline CKD, making it important to add IgG4 disease in your differential. Igg4 disease should be suspected in patients with rising Cr and signs of tubular injury, but no white blood cells on UA neither obvious pharmacological or infectious etiology. Low complement levels and normal ESR/CRP are suggestive of IgG4 disease, however, to fit the diagnosis, biopsy findings of TIN with >10 igG4positive plasma cells/hpf in addition to one of the clinical criteria of elevated igG4 and igG levels, specific imaging findings or extra renal disease must be present. Steroids are first line treatment and remission is achieved in 82% of cases. Rituximab is indicated in refractory cases. Patients with higher GFRs tend to respond well to treatment.

TH-PO555

Rare Case of IgG4-Related Kidney Pseudotumor

Shengjie Cui,[1] Carrie L. Phillips,[1] Chandru Sundaram,[2] Omer A. Saeed.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN.*

Introduction: Immunoglobulin G4-related disease (IgG4-RD) is a chronic fibroinflammatory condition that can involve one or multiple organs in the body. It is characterized by tissue lymphoplasmacytic infiltration with IgG4+ plasma cells, storiform fibrosis, and possibly elevated serum IgG4 levels. Renal involvement by IgG4-RD is rare and can be confused with kidney neoplasms as it has the tendency to form pseudotumor.

Case Description: A 40-year-old woman complained of abdominal pain for three months. Abdominal CT and MRI scan revealed an enhancing lesion in the lower pole cortex of the left kidney measuring 2.7 x 2.4 x 2.2 cm. The lesion showed central necrosis with thick enhancing wall and it was minimally exophytic without violation of Gerota's fascia. There were also stable borderline and enlarged retroperitoneal lymph nodes. Kidney function tests including eGFR, BUN, and serum creatinine were normal. The patient's preliminary diagnosis was renal cell carcinoma and partial nephrectomy was performed. Gross examination showed a 2 X 2 X 1.3 cm white, firm poorly circumscribed irregular lesion with no evidence of necrosis or hemorrhage. Microscopic examination showed large areas of storiform fibrosis with intense lymphoplasmacytic infiltrate and vascular involvement. Immunohistochemical stains showed increased IgG4+ plasma cells (>25 cells/HPF). The IgG4+: IgG+ plasma cell ratio was 50%.

Discussion: IgG4-RKD is the term used to describe multiple kidney lesions including tubulointerstitial nephritis, renal pyelitis, or renal insufficiency as a result of retroperitoneal fibrosis. CT scan of patients with IgG4 tubulointerstitial nephritis usually reveals multiple low density parenchymal lesions. The presence of a solitary lesion with exophytic appearance is rare. In these circumstances, it is usually very difficult to rule out a neoplastic process based on imaging alone. Steroids are the first-line treatment in most patients. A high clinical suspicion, serum IgG4, and a representative biopsy are usually sufficient to make the diagnosis in most cases. Awareness about the unusual instances where imaging studies are worrisome for malignancy can help avoid unnecessary surgery.

TH-PO556

A Case of IgG4 Related Disease (IgG4-RD) Presented with Membranous Nephropathy (MGN) Several Years Before Other IgG4 Manifestations

Hisham Elsherbiny,[1] Mary E. Fidler,[3] Lynn D. Cornell,[3] Nelson Leung.[2] *[1]Mayo clinic, Rochester, MN; [2]Mayo Clinic, Rochester, MN; [3]Mayo Clinic, Rochester, MN.*

Introduction: IgG4-RD is a systemic immune mediated condition that is characterized by mass-forming inflammatory lesions and lymphoplasmacytic infiltration with increased IgG4 positive plasma cells in affected tissue. Tubulointerstitial nephritis is the most common form of renal involvement in IgG4-RD. MGN can be secondary to IgG4-RD ("IgG4-related MGN"), usually identifiable as such due to concurrent or previous other organ involvement by IgG4-RD.

Case Description: A 67 year old man initially presented with nephrotic syndrome with 7.8 g/day proteinuria. He underwent a renal biopsy which revealed by immunofluorescence global granular glomerular basement membrane staining with IgG, C3, and kappa and lambda light chains typical of MGN. The patient failed treatment with mycophenolate mofetil and subsequently was switched to oral cyclophosphamide which induced a remission. 3 Years later, at age 70, he developed chronic sinusitis that was resistant to medical treatment. At age 73, he developed bilateral large parotid glands. On further evaluation, serum IgG4 subclass was markedly elevated at 2180 mg/dL. A parotid fine needle aspiration was done which revealed a polytypic plasma cell infiltrate with increased numbers of IgG4-positive plasma cells consistent with IgG4-RD. He also underwent prostatic biopsy for enlarged prostate which revealed increased number of IgG4-positive plasma cells, consistent with involvement by IgG4-RD. The kidney disease remained in remission at the time of IgG4-RD diagnosis. Serum anti-PLA2R antibodies checked at the time of IgG4-RD diagnosis were negative.

Discussion: In this case a patient was diagnosed with IgG4-RD 7 years after initial diagnosis of MGN. PLA2R serum testing was not available at the time of initial presentation with proteinuria. The patient's MGN could have represented primary (PLA2R-associated) MGN that was treated and was in remission; alternatively, the MGN may have represented an early manifestation of IgG4-RD, which would provide a unifying diagnosis of the immune-mediated conditions. Teaching point: Clinicians should maintain high a suspicion for development of IgG4-RD years after initial diagnosis of MGN in the right

clinical setting. Serum PLA2R testing may be contributory, as reported IgG4-related MGN cases are negative for PLA2R.

TH-PO557

Tubulointerstitial Nephritis as the Initial Presentation of IgG4-Related Disease

Babajide Togonu-Bickersteth,[1] Nelson P. Kopyt.[2] *[1]Lehigh Valley Health Network, Easton, PA; [2]Lehigh Valley Hospital, Bethlehem, PA.*

Introduction: IgG4 related disease (IgG4-RD) is a systemic, autoimune fibrosing condition that was recently recognized, initially as autoimmune pancreatitis, less than 15 years ago. Since then, it has been shown to involve other organs, manifesting as cholangitis, retroperitoneal fibrosis, aortitis, pneumonitis and nephritis. While membraonus glomerulonephritis has been described, tubulointerstitial nephritis (TIN) is the most common for m of IgG-4 related kidney disease (IgG4-RKD). It is marked by IgG4 positive lymphoplasmocytic infiltrate.

Case Description: A 40 y/o caucasian male with a history of Asthma and Graves disease presented for evaluation of elevated creatinine, which was 1 mg/dl at baseline and on evaluation was 1.99 mg/dL. His creatinine increased over the next 6 months to a peak of 3.5. Urinalysis showed mild proteinuria and a bland sediment. He was referred for renal biopsy which showed significant plasma cell infiltrate with more than 50 IgG4 positive cells per HPF, as well as lymphocytic tubulitis. Intrestingly, eosinophils were seen on the biopsy. The clinical significance of this is as yet unclear. He was shown to have leveated total IgG as well as elevated IgG4. He subsequently developed respiratory symtoms and CT imging of his chest showed a nodule, with surrounding ground glass changes. Steroid therapy was initiated and he has had resolutionof the chest findings and improvement in creatinine.

Discussion: This case adds to our body of knowledge and supports proposed diagnostic criteria which combines histology, imaging and serology. It also supports the notion that renal involvement may precede systemic findings. Diagnosis of this condition warrants awareness and vigilance as specific immune staining is required and may need to be requested to make the diagnosis.

TH-PO558

Lysozyme-Induced Nephropathy as a Cause of Interstitial Nephritis in Sarcoidosis

Shohei Yoda,[1] Satoru Sanada,[1] Mitsuhiro Sato,[2] Toshinobu Sato,[1] Yoshio Taguma.[1] *[1]Japan Community Health Care Organization Sendai Hospital, Sendai, Japan; [2]Sendai Shakaihoken Hospital, Sendai, Japan.*

Introduction: Sarcoidosis manifests interstitial nephritis of an unknown etiology. We report a case series of interstitial nephritis in patients with sarcoidosis, that could be associated with lysozyme-induced tubular injury.

Case Description: Kidney biopsy specimens of four cases of sarcoidosis, four cases of other interstitial nephritis such as drug-induced, IgG4-related and Sjogren syndrome, and one case of chronic myelomonocytic leukemia induced interstitial nephritis were analyzed retrospectively by immunohistochemistry and electron microscopy. All four patients with sarcoidosis showed interstitial nephritis in the kidney. Specimens were stained with anti-lysozyme antibody and showed positive staining in proximal tubular cells, whereas negative immunostainings in the other three cases of interstitial nephritis. Strong lysozyme staining was also present in interstitial nephritis caused by chronic myelomonocytic leukemia, the mechanism of which is known as a lysozyme-induced tubular injury. The serum lysozyme level increased slightly in sarcoidosis and was markedly elevated in chronic myelomonocytic leukemia. Electron microscopy revealed increased number and size of lysosomes in proximal tubules of sarcoidosis and chronic myelomonocytic leukemia, those of which were associated with serum lysozyme levels.

Discussion: Underlying mechanisms of interstitial nephritis in sarcoidosis could be associated with proximal tubular absorption of lysozyme. We suggest that tubular injury of both sarcoidosis and chronic myelomonocytic leukemia could be categorized into lysosome-induced nephropathy. Chronic myelomonocytic leukemia induces acute kidney injury with overloaded lysozyme to the proximal tubules. On the other hand, chronic tubular injury of sarcoidosis may be associated with above average lysozyme stress on the tubules.

TH-PO559

ANCA Vasculitis Presenting with Chronic Active Interstitial Nephritis Without Glomerular Involvement

Callie Plafkin, Tripti Singh. *Department of Medicine, University of Wisconsin School of Medicine and Public Health, Madison, WI.*

Introduction: ANCA-associated vasculitis (AAV) with renal involvement typically causes pauci-immune glomerulonephritis. We present a rare case of chronic active interstitial nephritis as the sole renal lesion, without glomerulonephritis, in a patient with MPO AAV.

Case Description: A 45-year-old female with a history of Crohn's disease, GERD with Barrett's esophagus, endometriosis, and polyarthralgias was evaluated in nephrology clinic in 2018. Acute interstitial nephritis was initially diagnosed in 2011 on renal biopsy. There was no evidence of glomerulonephritis. p-ANCA was positive with MPO titer of >100 units/mL. She lacked systemic symptoms of AAV. Serum creatinine peaked at 2.1 mg/dL and improved to 0.9 mg/dL with prednisone and azathioprine. Repeat biopsy in 2013 for worsening renal function again showed acute interstitial nephritis and no vasculitic glomerular involvement. Prednisone and cyclosporine were started, with improvement in serum creatinine from 1.9 to 1.2-1.4 mg/dL. Crohn's disease was diagnosed in 2014 and adalimumab was started in 2016. Acute interstitial nephritis was attributed to Crohn's and cyclosporine was stopped in 2016. Her gastrointestinal symptoms improved with adalimumab, but renal function and abnormal urine sediment did not. Attempt was made to switch omeprazole to an H2-blocker but this was not tolerated. Repeat renal biopsy in 2/2018 showed chronic active interstitial nephritis with severe interstitial fibrosis and tubular atrophy and no active glomerular disease. MPO titers remained high at 132 units in 3/2018. She was started on mycophenolic acid and prednisone without significant response, followed by rituximab induction therapy for AAV-associated active interstitial nephritis. Serum creatinine continued to worsen to 5.5-5.7 mg/dL and preparations are being made to start peritoneal dialysis.

Discussion: AAV may present with isolated interstitial nephritis without glomerular involvement. The rarity of this presentation may contribute to delay in diagnosis and appropriate management. Alternate explanations for interstitial nephritis, such as Crohn's disease or PPI use, should be considered with caution in the setting of high-titer ANCA positivity.

TH-PO560

Anaplasmosis Induced Acute Interstitial Nephritis (AIN) Following Tick Bite: A Rare Association

Neelofar R. Khan,[1] Alia Hasan,[2] Vanesa Bijol,[3] Kenar D. Jhaveri,[4] Nupur N. Uppal.[1] *[1]Hofstra Northwell School of Medicine, Great Neck, NY; [2]Northwell Health, Briarwood, NY; [3]Northwell Health Hofstra University, Lake Success, NY; [4]Northwell Health Sys, Great Neck, NY.*

Introduction: AIN usually results from immune mediated tubulointerstitial injury initiated by medications and infections. We present a rare case of kidney biopsy proven AIN associated with Anaplasmosis following a tick bite.

Case Description: 82 year old Caucasian woman with HTN, HLD presented with fever, tremors, myalgia and fatigue following a camping trip in Catskills where had significant outdoor exposure to the woods. She was found to have AKI, thrombocytopenia and transaminitis. She had serum creatinine(Scr) of 6.62 on admission which peaked at 6.78 during hospitalization. Four months prior, her Scr was 0.9.She denied use of herbal supplements or antibiotics, however had used NSAIDs in the week before hospitalization. Urinalysis showed microscopic hematuria with 10-25 RBCs. Kidney ultrasound was negative for obstructive uropathy. Serological work up for glomerulonephritis was negative. Peripheral smear showed intracellular inclusions suggestive of morulae concerning for Anaplasmosis, and she was initiated on treatment with Doxycycline. Kidney biopsy was performed that revealed moderate AIN, along with 13% glomerulosclerosis, 10% interstitial fibrosis and tubular atrophy, and severe arterial and arteriolar sclerosis. AKI, transaminitis and thrombocytopenia started improving with initiation of Doxycycline. She did not require corticosteroid therapy. Although a tick was not noticed specifically, and work up including Anaplasma antibody, Ehrlicia PCR and Lyme's titres were negative, she was continued on treatment for Anaplasmosis due to high clinical suspicion of the disease. She completed 10 day course of Doxycycline. AKI resolved and Scr decreased to 1.16mg/dl 5 weeks after initial presentation.

Discussion: AIN mediated by various systemic bacterial, viral and parasitic infections is well known. However, association of AIN following anaplasmosis from a tick bite has not been well documented in the literature. To our knowledge, we report the first case of AIN in association with Anaplasmosis. Nephrologists, Infectious disease specialists and Internists should to be aware of this rare cause of AIN. Corticosteroids have no role in infection associated AIN as they are contraindicated in setting of active infection. AKI usually is reversible as infection is treated. Our patient regained baseline kidney function with antimicrobial therapy.

TH-PO561

AKI Associated with Suspected Yersinia Infection in Spring 2017

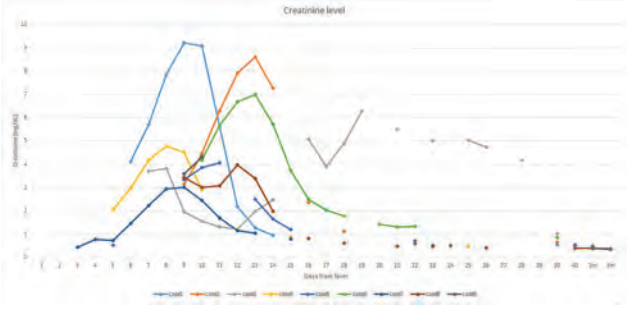
Yekyung Kim,[1] Myung hyun Cho,[1] Hyesun Hyun,[4] Eujin Park,[2] IL-Soo Ha,[3] Hae Il Cheong,[3] Hee Gyung Kang.[3] *[1]Seoul National university Children's hospital, Seoul, Republic of Korea; [2]Hallym University Kangnam Sacred Heart Hospital, Seoul, Republic of Korea; [3]Seoul National University Children's Hospital, Seoul, Republic of Korea; [4]St. Vincent's Hospital, The Catholic University College of Medicine, Soowon, Republic of Korea.*

Introduction: *Yersinia pseudotuberculosis*, a zoonotic pathogen is known to cause fever, acute gastroenteritis, mesenteric lymphadenitis, or acute kidney injury (AKI). There have been frequent *Yersinia* infection outbreaks associated with contaminated food and unsterile water ingestion in the past. While it was considered practically eradicated with improvement of public health including control of mountain water cleanness, we experienced several cases with suspected *Yersinia* infection in 2017.

Case Description: There were 9 cases suspected of *Yersinia* infection (Male:Female 6:3, mean age 7.57 years (range 3.01 - 12.18)). Six cases occurred in May and 8 resided in metropolitan Seoul area. Three cases had history of drinking mountain water. All the cases first presented with fever for median 13 days (range 6 - 20), and gastrointestinal symptoms and oliguria followed. Imaging studies revealed mesenteric lymphadenitis, terminal ileum wall thickening, and increased parenchymal echogenicity of kidney. Creatinine levels

increased to 3.03 - 9.22 mg/dL. Their urinalysis revealed sterile pyuria, proteinuria, and glycosuria, suggesting interstitial nephritis. Oliguria continued for 4-17 days and one patient required hemodialysis, however, all of them completely recovered from AKI. Rash developed later in four cases, and desquamation was noted in three. Mean disease duration from the onset of fever to discharge was 11.9 days (range 6 - 24). In the diagnostic work-up, *Yersinia pseudotubuerculosis* was isolated in stool culture in one patient. Anti-*Yersinia* IgA and IgG were found positivein six patients within three months after the onset of disease, suggesting recent *Yersinia* infection.

Discussion: *Yersinia pseudotubuerculosis* infection is a well-known cause of interstitial nephritis presenting with AKI. When a patient present fever, acute gastroenteritis, fever and AKI, clinician should suspect *Yersinia* infection. Furthermore, diagnosis of such a case warrants surveillance to identify the infection source and prevent an outbreak.



TH-PO562

A Unique Case of Tubulointerstitial Nephritis with Late-Onset Uveitis and Thrombotic Microangiopathy Induced AKI, Withdrawal from Hemodialysis, and Relapse

Youlu Zhao,[1,2] Jun-Wen Huang,[1,2] Zhikai Yang,[6] Tao Su,[5] Liu Yang,[4] Su X. Wang,[3] Li Yang.[1,2] *[1]Renal Division, Department of Medicine, Peking University First Hospital, Beijing, China; [2]Peking University Institute of Nephrology, Beijing, China; [3]Laboratory of Electron Microscopy, Peking University First Hospital, Bejing, China; [4]Department of Ophthalmology, Peking University First Hospital, Beijing, China; [5]Renal Division, Department of Medicine, Peking University First Hospital, Beijing, China; [6]Peking University First Hospital, Beijing, China.*

Introduction: Tubulointerstitial nephritis and uveitis syndrome (TINU) was first described in 1975 and there have been three hundred reported cases throughout the world since.

Case Description: A 37-year-old man presented with malignant hypertension (MHT) due to obstructive sleep apnea-hypopnea syndrome, acute kidney failure, and tubular dysfunction. Only hypertensive retinopathy was found. Renal biopsy showed TMA induced renal injury (possibly due to MHT)) with acute interstitial nephritis (AIN, Fig. 1-3). He had been taking pseudo-genseng lately. He was treated with hemodialysis, ACEI for MHT, oral prednisone for AIN (30mg/d for 6 weeks and then tapered to 5mg/d). His renal function improved 5 months post biopsy. Hemodialysis was withdrawn and steroid was stopped. Kidney injury recurred 3 months thereafter. Bilateral uveitis (Fig. 5-7) was found and TINU was confirmed. Prednisone of 15mg/d was reinitiated and renal and tubular recovery were observed within 6 weeks. He is under follow-up. Anti-mCRP antibody assay and Hazardous genotype were sent for tests.

Discussion: It is a unique case with severe AKI due to MHT induced TMA together with TINU. It is important to note that at the time of renal biopsy, with the history of pseudo-genseng use, and ocular tests, he was misdiagnosed as drug-induced AIN and therefore prescribed a relatively short course of prednisone. His recurrent kidney injury with concomitant uveitis after prednisone withdrawal strongly suggested the needs for long-term follow up and elongated prednisone therapy for TINU. Another issue is that routinely ocular examination is critical, as here uveitis can be completely asymptomatic. In this case both TMA and AIN contributed to AKI, which requires further investigation.

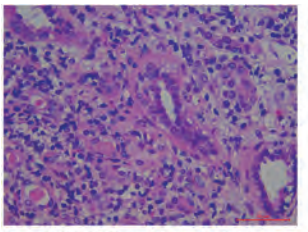


Figure 1. HE, tubulointerstitial infiltration of inflammatory cells

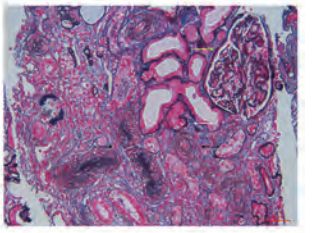
Figure 2. PASM+Masson, glomerular ischemia (yellow arrow), tubular atrophy with protein cast (white arrow), mucoid intimal thickening and onion peel like hyperplasia (black arrows).



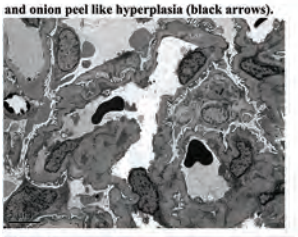


Figure 3. Electron microscope. Wrinkled glomerular basement membrane, atrophic tubules as well as interstitial infiltration of lymphocytes and monocytes were demonstrated, and there are no dense deposits.

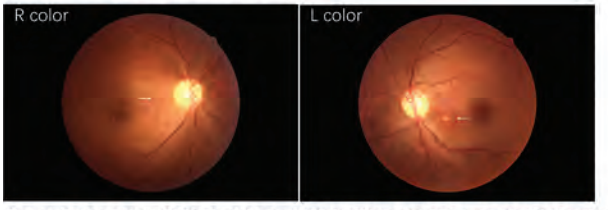

Figure 4. Fundus photograph Multifocal chorioretinal lesions (shown by white arrows, right side heavier)

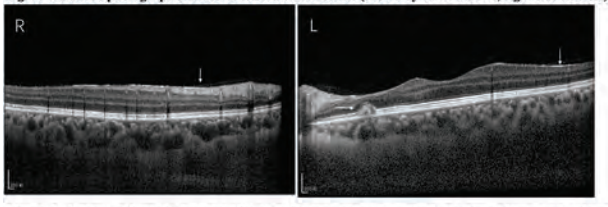

Figure 5. Optical coherence tomography of both eyes showed marked macular edema and epiretinal membrane, and focal lesion with high reflectivity (white arrows)

TH-PO563

Karyomegalic Interstitial Nephritis: A Genetic Form of Renal Disease

Ignacio A. Portales castillo,[1] Qiu J. Tong,[1] David Gerling,[2,1] Shubha Shastry.[1] *[1]Rochester General Hospital, Rochester, NY; [2]Rochester Regional Health, Rochester, NY.*

Introduction: Karyomegalic interstitial nephritis is a rare systemic disease mainly manifested as progressive renal disease

Case Description: A 34 years-old man from Burkina Faso presented to the nephrology clinic for evaluation of CKD. He moved to the USA 1 year before presentation. On the initial visit to our clinic he had no acute complaints. He was seen by a nephrologist 6 years ago at his home town and was told that he had an elevated serum creatinine of 1.62 mg/dL. His medical history included untreated hepatitis B, frequent upper tract respiratory infections and unilateral gynecomastia. Family and social history were non-contributory. His current laboratory exams revealed a normal cell count, creatinine of 1.6 mg/dL, BUN of 13 mg/dL, a protein/creatinine ratio of 0.45 mg/g and a ALT and AST of 53 and 42 U/L respectively with normal bilirubin and mild elevation of alkaline phosphatase, hepatitis b viral load was 15428 IU/mL. Urinalysis showed trace glucose, protein and blood with normal appearing RBC and few granular casts on the sediment. Further work up including ANA, ANCA, SPEP, RF, hemoglobin A1C, hepatitis C, complement levels and immunoglobulin levels, were all unremarkable. A renal biopsy was performed which showed a primary tubulointerstitial disease with enlarged tubular epithelial nuclei, suggestive of karyomegalic interstitial nephritis (KIN).

Discussion: KIN was first reported in 1974 on a 22 years-old woman who died from hepatic carcinoma and a fungal respiratory infection, autopsy showed extreme dysplasia in the renal tubular cells. There have been around 40 more case reports, most include young patients with CKD progressing to ESRD in early adulthood, recurrent respiratory infections and abnormal LFTs. Our patient had this classic features in addition to hepatitis B and gynecomastia, which are of unclear relevance. It was initially hypothesized that KIN was triggered by a virus or toxin causing transient LFT elevations, but recently mutations in FAN1, a gene coding for a nuclease involved in DNA repair, have been identified. There is no specific treatment, our patient is currently being evaluated for breast biopsy and treatment of hepatitis B, ACE inhibitor was started for renal protection. This case adds to

the short list of case reports and brings to clinicians an interesting differential diagnosis of chronic tubulointerstitial disease.

TH-PO564

HIV Infection Associated with Plasma Cell-Rich Acute Interstitial Nephritis: A Case Report

Hatem Elabd,[1,2] Tarek Rashid,[1] Mennallah Elkholi,[4] Michael B. Stokes.[3] *[1]Albert Einstein College of Medicine/Jacobi, New York, NY; [2]University of Cairo, Cairo, Egypt; [3]Columbia University Medical Center, New York, NY; [4]University of Alexandria, Alexandria, Egypt.*

Introduction: Acute interstitial nephritis (AIN) in HIV infected patients is usually attributable to drugs, opportunistic infections, and immune syndromes (e.g. immune reconstitution syndrome and diffuse infiltrative lymphocytosis syndrome). Whether HIV itself causes AIN is uncertain.

Case Description: A 59-year-old African female with a past history of hypertension was admitted with generalized weakness. Medications included lisinopril and nifedepine, and she denied NSAID, herbal, or illicit drugs. Physical exam disclosed no evidence of sicca syndrome. Laboratory evaluation was remarkable for serum creatinine of 12.9 mg/dl and blood urea nitrogen 149 mg/dl (baseline 3 months prior was 1.1mg/dl and 23 mg/dl respectively), hemoglobin 8.2g/dl, platelets 67 cells/mm^3, 2+ schistocytes in peripheral smear, and LDH of 365 U/L. Urine microscopy showed innumerable WBCs/hpf, but no RBCs or casts. Spot urine protein–to-creatinine ratio was 1.7g/g. Given the suspicion for microangiopathic hemolytic anemia, she received empirical plasma exchange for 8 sessions, with no improvement of hematological parameters. Subsequent HIV-1 antibody test was positive, with viral load of >715,000 copies/ml, and CD4+ count of 20 cells/mm^3. ADAMTS-13 activity was normal. Renal biopsy showed normal appearing glomeruli and tubulointerstitial nephritis with numerous CD138+ plasma cells. No granulomas or features of thrombotic microangiopathy were seen. Immunofluorescence exam was negative, and no electron dense deposits or endothelial cell tubuloreticular inclusions were seen. Extensive infectious disease work up was negative. Bone marrow biopsy revealed hypercellular marrow, polyclonal plasmacytosis with CD138+ plasma cells (20%), and no evidence for malignancy or infections. Antiretroviral therapy (ART) regimen was started, with subsequent improvement in hematological parameters. Serum creatinine improved to 2.5mg/dl and proteinuria resolved.

Discussion: To our knowledge, there are only 2 previous case reports where AIN was thought to be a direct complication of HIV infection, both of which also showed a plasma cell-rich tubulointerstitial infiltrate. The exclusion of common causes of AIN and response to ART therapy in our case suggest that HIV infection itself may occasionally present with acute kidney injury and AIN.

TH-PO565

Taming Nephrogenic Ascites by Living Kidney Transplant in a Developing Country

Raja M. Rashid,[1,2] Zahid Nabi,[3] Zahid Ul Zahideen.[4] *[1]CPSP, Islamabad, Pakistan; [2]Department of Nephrology, KRL hospital, Islamabad, Pakistan; [3]Nephrology, KRL hospital, Islamabad, Pakistan; [4]Department of Nephrology KRL islamabad, Islamabad, Pakistan.*

Introduction: Nephrogenic ascites is a diagnosis of exclusion and describes the refractory ascites in patients with renal failure before or after the initiation of dialysis. It's a rare and devastating condition with an inconsistently reported incidence that is as low as 0.7%. Renal transplant is considered the most effective management and has been described predominantly in deceased donor transplants from the high income countries. In low and middle income countries, nephrogenic ascites is still a visible problem but successful management with living kidney donation is not well reported.

Case Description: 45 years old male known case of ESRD was on twice weekly maintenance hemodialysis schedule since June 2010 via left brachiocephalic arterio-venous fistula, His Hypertension for the same time period was being managed by Losartan and Carvedilol. He presented with gradual abdominal swelling for last 6 months in the year 2016. There was no history of current or preceding fever, abdominal pain, altered bowel habits, jaundice, weight loss, body aches or missed dialysis sessions. He was being dialyzed twice weekly with blood flow of 300 ml/min and dialysate flow rate of 500-600 ml/min. His average Inter-dialytic weight gain had been around 2.5 kg. Examination and work up demonstrated a serum albumin of 3.7mg/dl, low SAAG and exudative lymphocytic ascites and a normal peritoneal biopsy in a well-nourished man. After exhaustive work up; cardiac, hepato-billiary, infective and other causes of ascites were appropriately excluded. Intensification of hemodialysis and ultrafiltration with intermittent paracentesis did not improve his ascites. He underwent renal transplantation by donation from his spouse with paracentesis prior to transplantation. Instant graft function and uneventful post-transplant period resulted in gradual resolution and disappearance of ascites over 2 months.

Discussion: Not all patients completely fit the usual profile for nephrogenic ascites. Our patient developed nephrogenic ascites despite adequate nutritional status, normal serum albumin, ACE inhibitors and strict compliance with the dialysis schedule. Meticulous work up is required to exclude the direct causative pathologies. Lliving kidney transplant is an effective management strategy and can be carried out with only a fractional increase in work up related cost even in low and middle income countries.

TH-PO566

A Unique Case of Oliguric Renal Failure in the Immediate Post-Transplant Period

Irene Chernova,[1] William S. Asch.[2] *[1]Yale New Haven Hospital, New Haven, CT; [2]Yale School of Medicine, New Haven, CT.*

Introduction: Vascular complications are a well-recognized cause of renal allograft failure in the immediate post-op period. Renal allograft torsion is a rare cause of vascular compromise leading to graft injury that is associated with significant morbidity. We present a case illustrating the unique challenges of recognizing and treating this condition.

Case Description: 69yo F with history of end-stage renal disease secondary to polycystic kidneys on hemodialysis presented for deceased donor kidney transplantation. She had excellent urine output (UOP) and a transplant ultrasound with normal flow dynamics in the immediate post-op period; however, on post-op day #1 there was a significant decline in UOP which did not improve with intravenous fluid administration. Ultrasound of the graft demonstrated "abnormal waveforms throughout the transplanted kidney with tardus parvus waveforms and reversed diastolic flow" concerning for either renal artery stenosis or main renal vein thrombosis. She was taken emergently to the operating room for exploration. It was revealed that the graft had rotated 180 degrees about the axis of the artery and vein with the lower pole pointing toward the right flank. It appeared that the inferior aspect of her native right polycystic kidney may have abutted the upper pole of the allograft causing it to rotate medially. Upon reversal of the rotation there was immediate restoration of normal color, turgor and palpable pulse to the renal parenchyma and Doppler ultrasound confirmed excellent venous and arterial flows; a nephropexy was performed prior to closure. The patient had excellent post-op UOP and creatinine began downtrending in the next week and had stabilized at 0.8mg/dL by 1 month post-transplant.

Discussion: Fewer than 20 cases of allograft torsion have been reported in the literature as a cause of graft failure; over 50% of these grafts were lost. Most cases (15/16 in one review) occurred in simultaneous pancreas kidney (SPK) transplant recipients (13/16) or pediatric recipients (2/16). We present a rare case of a non-SPK allograft recipient who experienced allograft torsion and the first reported implicating native polycystic kidneys as a risk factor. While a rare complication, allograft torsion is associated with a high rate of graft loss and non-specific ultrasound findings; a high index of suspicion and surgical exploration are needed to salvage the organ.

TH-PO567

An Atypical Cause of Autoimmune Hemolytic Anemia in a Post Kidney Transplant Patient

Aileen Wang, Asif A. Sharfuddin. *Indiana University School of Medicine, Indianapolis, IN.*

Introduction: Autoimmune hemolytic anemia (AIHA) is a rare but devastating consequence of solid organ transplantation. Commonly AIHA can be attributed to immunosuppression with calcineurin inhibitors or viral infection. Here we describe a unique cause of AIHA due to Coombs negative IgA associated AIHA that was refractory to both steroid therapy and adjustments in immunosuppression.

Case Description: 23-year-old Hispanic female with history of deceased donor kidney transplant in October 2016 (on tacrolimus, sirolimus, prednisone) presented with fatigue, sclera icterus, and jaundice. Recently she was given clindamycin for dental procedure. On lab Hgb low to 4 gm/dL (baseline 12). Work up revealed elevated LDH, low haptoglobin, elevated retic count, and indirect hyperbilirubinemia consistent with hemolytic anemia. Parvovirus B19 was negative. G6PD level was elevated. Peripheral blood smear revealed marked spherocytosis, anisocytosis, and schistocytes. High sensitivity Coombs test was negative. No splenomegaly on abdomen ultrasound. After transfusion Hgb improved to 8.6, and she was discharged on Prednisone 60mg daily. However she was readmitted a week later with Hgb low to 4.8. Cr uptrended to 1.48 mg/dL (baseline 1.2). Tacrolimus was discontinued. PNH flow cytometry and SPEP were unremarkable. Bone marrow biopsy revealed increased erythropoiesis, supportive of peripheral red blood cell destruction. After transfusion Hgb improved to 8. Pt was continued on 60mg Prednisone along with initiation of azathioprine. But one week later, Hgb again low to 4.9. Sirolimus was then stopped. Negative coombs hemolytic panel and a drug induced antibody panel were sent. Negative coombs hemolytic panel detected an IgA autoantibody against red blood cells. Rituximab was initiated (375mg/m^2 weekly). One month later, Hgb stabilized in range 13-14 with return of Cr to baseline. Sirolimus was restarted.

Discussion: This case illustrates an extremely rare autoimmune hemolytic process that is Coombs negative, non-drug induced, and steroid refractory in a kidney transplant patient. Splenectomy is usually considered as the first line therapeutic option for steroid refractory IgA associated AIHA, but in a post transplant patient there is the significant increase in infection risk that must be considered. Rituximab therapy though second line was the better choice in this patient who has achieved complete response to therapy.

TH-PO568

AKI from Orthostatic Renal Graft Compression Following Weight Gain

Sebastian O. Hultin,[1] Charles Fisher,[2] Linda Thebridge,[2] Carol A. Pollock.[3] *[1]Royal North Shore Hospital, Sydney, NSW, Australia; [2]Royal North Shore Hospital, St Leonards, NSW, Australia; [3]The University of Sydney, St. Leonards, NSW, Australia.*

Introduction: We present the first reported case of orthostatic renal graft compression from central adiposity resulting in acute kidney injury.

Case Description: A 61 year old man with a cadaveric transplant presented with hypertension and acute kidney injury with a creatinine rise from 80 to 210 μmol/L. His

past medical history included controlled diabetes, hypertension, ischaemic heart disease, and obesity requiring gastric sleeve with subsequent weight gain from 90 to 110kg. Renal biopsy was consistent with acute tubular necrosis without significant interstitial inflammation or signs of rejection. Serial renovascular duplex studies of the transplant graft were abnormal. Initial scanning showed severely reduced diastolic flow normalising towards the upper pole (RI0.78). The renal vein flow had normal phasicity and renal artery velocity was 336cm/s. Repeat scanning showed absence of diastolic flow and reduced perfusion despite a patent renal transplant artery and vein. Raising the fatty apron cephalad normalised renal blood flow with resistive indices between 0.76-0.79 throughout the kidney. Subsequent laparascopy ruled out adhesional obstruction and CO2 angiogram confirmed normal transplant vessels, anastomotic sites and intra-renal branches. Following initial empiric pre-biopsy pulsed steroids for presumed rejection, he was treated with bedrest and his creatinine was130µmol/L on discharge. Whilst advising weight loss, he was treated with an abdominal support belt.

Discussion: Our case highlights the potential growing problems of increasing obesity and inadequate assessment tools to assess abdominal weight gain in transplant patients. Transplant physicians and surgeons need to be aware of renal graft compression from an enlarged bulky omentum and fatty apron. Diagnosis requires positional prone doppler sonography. Aside from weight loss, optimal treatment is not known.

TH-PO569

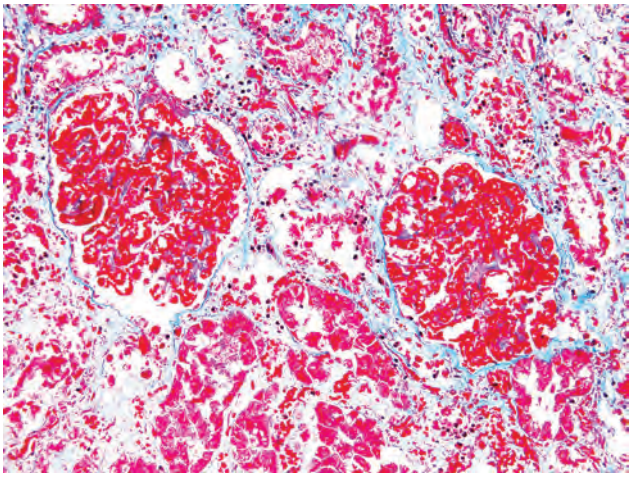
Transplant Renal Artery Thrombosis: Uncommon Complication of Acute Rejection

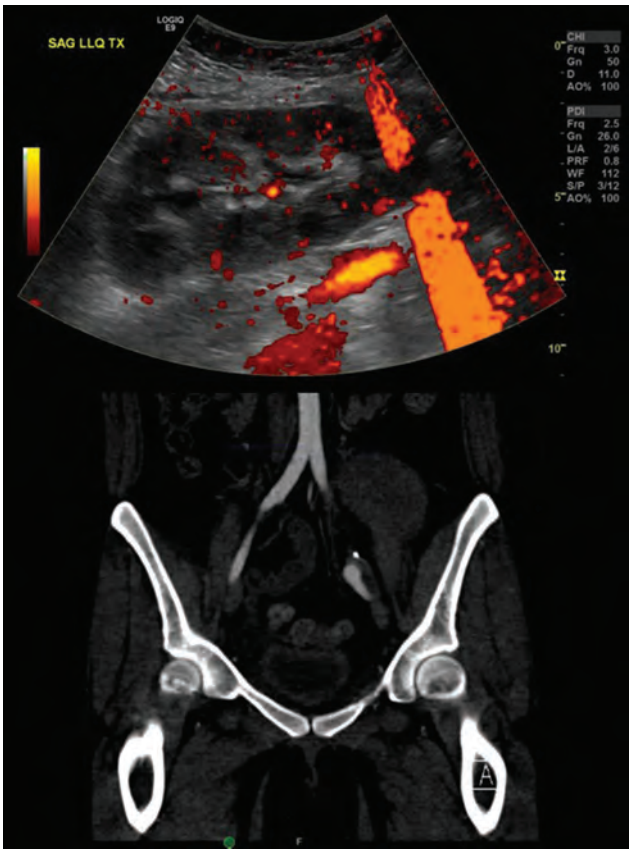
Jia Yi,[1] Abhijit V. Kshirsagar,[1] Randal K. Detwiler,[1] Harsharan K. Singh,[2] Charles Burke.[3] *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]University of North Carolina School of Medicine, Chapel Hill, NC; [3]University of North Carolina, Chapel Hill, NC.*

Introduction: Acute transplant renal artery thrombosis is rare, primarily seen in the immediate post-transplant setting related to surgical complication. We present a case of acute transplant renal artery thrombosis in a patient receiving treatment for acute cellular and antibody mediated rejection.

Case Description: 21 year old female with a stable renal transplant for 3 years (baseline creatinine 0.8 mg/dl) was admitted for acute kidney injury (creatinine 7.41) after not taking her immunosuppression due to gastroenteritis. She began empiric pulse dose methylprednisolone on presentation. Allograft biopsy on hospital day 3 showed acute cellular and antibody mediated rejection. She was started on thymoglobulin and plasma pheresis with initial improved renal function (creatinine 3.39). On hospital day 7, she began to have a progressive decline in urine output and kidney function. Doppler ultrasound revealed minimal perfusion to the transplant [Fig 1a]. Repeat kidney biopsy had near total renal infarction [Fig 2]. Confirmatory CT angiogram [Fig 1b] revealed no flow in the transplant renal artery. She re-initiated hemodialysis.

Discussion: Acute transplant renal artery thrombosis should be considered if anuria develops while being treated for allograft rejection. Prompt diagnosis and intervention is essential to prevent graft loss, unfortunately the most common outcome.





TH-PO570

Delayed Graft Failure Secondary to Renal Vein Thrombosis in a Patient with a Permanent IVC Filter

Kristyn L. Lewis, Payal P. Patel, Laura Gil, Gregory Frey, Hani Wadei, Pramod K. Guru. *Mayo Clinic, Jacksonville, FL.*

Introduction: Transplanted renal vein thrombosis (RVT) is a rare cause of delayed graft failure in renal transplant patients. The estimated prevalence of graft vein thrombosis is 0.1% to 4.2%, mostly occurring in the early transplant period. The associated morbidity is devastating, given the high risk of permanent graft failure. Patient and donor related factors, along with multiple perioperative events, and immunosuppressive agents are incriminated for venous thrombosis in the early transplant period. We describe herein, an unusual case of RVT leading to severe graft failure after ten years of transplantation.

Case Description: A 53-year-old male with a deceased donor renal transplant 10 years prior, for suspected glomerulonephritis, was admitted to the hospital with progressive bilateral lower extremity swelling, decreased urine output and weakness. One week prior, he was treated for suspected urinary tract infection at an outside facility. His graft function had been stable with a baseline creatinine 1.3-1.5 mg/dl on tacrolimus and mycophenolate. On evaluation, with help of ultrasonography and computed tomography, he was noted to have bilateral venous thromboses of iliac and popliteal veins with an extension into the transplanted renal vein. He was also noted to have a filter in his inferior vena cava, inserted in 2002. The patient was managed by catheter directed thrombolysis with help of tissue plasminogen activator (tPA), as well as systemic heparin therapy. His hospital course was complicated by acute severe graft dysfunction needing initiation of renal replacement therapy, and development of an anticoagulation related rectus sheath hematoma. His RVT showed partial resolution along with recovery of graft function in the ensuing two weeks. He was discharged on oral anticoagulation and off dialysis. Recent infection, obesity, a retained IVC filter, and possible undiagnosed hypercoagulable states were considered to have played roles in the thrombosis in this case.

Discussion: This case describes an atypically late presentation of transplanted renal vein thrombosis years after renal transplant. This case exemplifies both the risks associated with RVT, and the need for astute clinical vigilance for the early detection and timely initiation of appropriate therapy to salvage the precious graft in transplanted patients.

TH-PO571

Unusual Bilateral Renal Parenchymal Urine Leak After Pediatric En Bloc Kidney Transplantation

Rahul Nayak, Amit Sharma. *Virginia Commonwealth University, School of Medicine, Richmond, VA.*

Introduction: Use of en bloc kidney transplantation (EBKT) has not been universally accepted due to risk of technical difficulties and concerns related to inadequate nephron mass. We report an unusual case of renal parenchymal urine leak after EBKT that ultimately led to removal of both renal moieties.

Case Description: We transplanted pediatric en bloc deceased donor kidneys to a 49 year male with ESRD. Caudal ends of donor inferior vena cava and aorta were anastomosed to recipient's external iliac vein & artery. On POD 6, there was increased output of clear fluid in wound drain. CT-cystogram performed at this time showed mild caliectases of both transplant kidneys but no anastomotic bladder leak. Surgical re-exploration on POD 8 revealed necrotic area on infero-lateral pole of lateral kidney leaking urine. Parenchymal leakage was repaired, but drain output remained high. On POD 31, patient was readmitted for abdominal pain. Renal scan revealed tracer accumulation originating from lower pole of lateral kidney confirming persistence of urine leak. Exploration confirmed recurrent lateral kidney urine leak at site of previous repair but other kidney showed a necrotic area at lower pole. Both kidneys were removed. Patient was relisted for transplantation.

Discussion: Early onset of urine leak from a necrotic area points towards vascular injury. Interestingly, pediatric recipient of liver from same donor as en bloc kidneys developed portal vein thrombosis. Another possible mechanism of urine leak could be thermal injury if Argon beam coagulation is used for superficial hemostasis on the thin cortex of pediatric kidneys after reperfusion. It could be speculated that prolonged surgical drainage along with bladder decompression could have salvaged en bloc kidneys. However, this patient continued to have abdominal pain despite presence of surgical drain. The second kidney were removed due to concern for impending infection at vascular anastomosis.

Strategies to prevent complications after EBKT

Avoid very small pediatric donors with history of severe hypotension
Ensure good flushing of pediatric kidneys in donor
Preserve perinephric abd periureteric fat
Avoid vascular injuries during backbench preparation
Use pediatric ureteric stents
Avoid recipients with uncontrolled hypertension
Consider perioperative anti-coagulation

TH-PO572

Choriocarcinoma Related to Kidney Transplantation

Guilherme P. Santa Catharina,[1] Laura Onuchic,[1] Ivens S. L Leite,[1] Gabriel C. Barsotti,[1] Maria cristina R. Castro,[1] Leonardo A. Testagrossa,[2] Flavio De paula.[1] *[1]University of Sao Paulo, Sao Paulo, Brazil; [2]Hospital Sirio Libanes, São Paulo, Brazil.*

Introduction: Malignancy related to solid-organ transplantation (Tx) due to immunosuppression is widely discussed and appears as one of the most common causes of graft failure and death. Cancer in the donated organ is rare, however, and its prognosis uncertain.

Case Description: A 58 year-old (y/o) male, on hemodialysis for the past 5 years due to hypertensive nephrosclerosis, was admitted for kidney Tx. His serologies and Panel Reactive Antibodies were negative. The donor was a 41 y/o female whose cause of death was subarachnoid hemorrhage. Her creatinine was 0.6mg/dL and 2 previous spontaneous abortions were the only reported significant medical history. Tx proceeded with a 31-hour cold ischemia time, a 0.86 KDRI and 36% KDPI. We followed institutional protocols for surgery and immunossupression, with no apparent complications. The patient presented delayed graft function, assessed by kidney ultrasound, CT scan and biopsy. The diagnosis of acute BANFF IIB rejection was established and treatment with Thymoglobulin® initiated, however no graft function improvement was observed. He developed infectious complications thereafter, followed by transplantectomy due to the possibility of pyelonephritis. Anatomopathological analysis of the graft revealed metastatic choriocarcinoma to the kidney. Similar findings were reported in other recipients of organs from the same donor. The heart recipient presented normal graft function and no signs of metastasis despite abnormal levels of serum beta-HCG (45mUI/mL). The contralateral kidney recipient evolved with normal graft function in spite of ascending serum beta-HCG (48.450mUI/mL). Shortly after, she presented pulmonary metastasis and death after refusing transplantectomy and an unsuccessful attempt of chemotherapy. The liver transplant in another recipient was initially successful, however ascending beta-HCG and hepatic nodules were identified. This patient is currently under chemotherapy. Our patient has presented full recovery following transplantectomy, with no signs of metastasis on PET-CT scan and normal serum levels of beta-HCG (1mUI/mL).

Discussion: To our knowledge, this is the second report of kidney graft with choriocarcinoma metastasis, however the first to compare outcomes between kidney graft preservation and transplantectomy, and its metastatic implications to different grafts.

TH-PO573

PML-IRIS in a Patient with Kidney Transplant

Huiwen Chen,[1] Ghady Haidar.[2] *[1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]UPMC, Pittsburgh, PA.*

Introduction: Progressive multifocal leukoencephalopathy (PML) is a degenerative disease involving the central nervous system. It is caused by the John Cunningham virus (JCV) which commonly affects immunocompromised patients. We present the first case of PML complicated by immune reconstitution inflammatory syndrome (IRIS) described in a kidney transplanted patient.

Case Description: A 60 year old female with a history of kidney transplant in 2009 and native kidney failure due to IgA nephropathy who presented to the clinic with partial expressive aphasia and loss of executive function. Patient was on tacrolimus (FK) and mycophenolate (MMF) as maintenance therapy. Physical exam does not show any facial droops or motor weakness. MRI brain finding was concerning for PML. Lumbar puncture had positive PCR for JC virus in spinal fluid. Serum JCV viral load was positive. Remaining serology and metabolic panel were normal. MMF and subsequently FK were both removed from the regimen. Patient then developed aphasia and right sided weakness. MRI showed new mass effect. Brain biopsy was consistent with PML-IRIS. Patient was started on dexamethasone with a slow prednisone taper. She exhibited a good neurological improvement two weeks into the treatment.

Discussion: PML is a severe opportunistic infection commonly affecting patients with immunosuppressed state. Manifestations of PML include motor deficit, dysarthria, dysphasia but most commonly weakness. MRI shows hyperintense lesion on T2 at the subcortical white matter. IRIS occurs due to exaggerated T cell response in patient who was previously immunocompromised. Symptom can occur one week to few months after treatment of primary disease. PML-IRIS is well documented clinical entity in human immunodeficiency virus infection, however, there is scant data and little awareness about the presentation in transplant patients. In patient with kidney transplant, post-transplant lymphoproliferative disease is also highly on the differentials as it is common complication for all solid organ recipients. The re-activation of immune system in our patient was likely due to discontinuation of immunosuppressant in fear of progression of PML. Diagnosis would be challenging without biopsy. Take home points: This is the first case of PML-IRIS described in patients with kidney transplant. Patient had dramatic neurological recovery after prednisone taper, but patient is at high risk for chronic allograft rejection.

TH-PO574

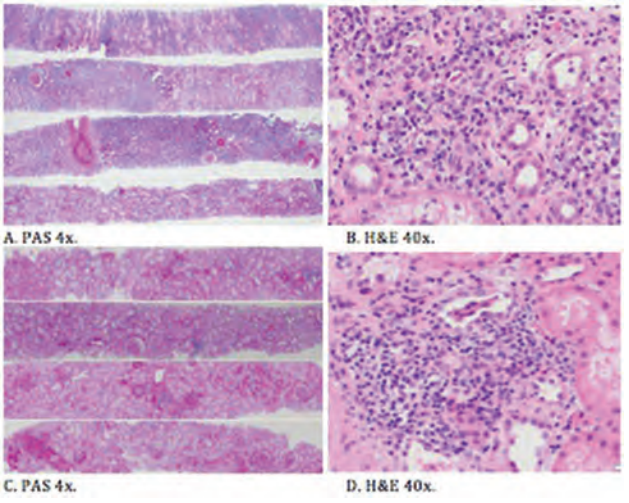
Breaking the Rules on PTLD

Brittaini D. Bunce,[2,3] Jeet Gandhi,[2] David N. Dado,[2,3] Yanli Ding,[1] Suverta Bhayana.[4] *[1]Pathology, University of Texas Health Science Center, San Antonio, TX; [2]Nephrology, University of Texas Health Science Center, San Antonio, TX; [3]Nephrology, San Antonio Military Medical Center, Fort Sam Houston, TX; [4]Transplant, University of Texas Health Science Center, San Antonio, TX.*

Introduction: Early post-transplant lymphoproliferative disorder (PTLD) is mostly, but not invariably, associated with Epstein-Barr virus (EBV) infection. Most EBV-negative PTLDs occur more than a year post-transplant (median 50 months versus 10 for EBV-positive) with the majority being monomorphic (67% versus 42% of EBV-positive). They are also more aggressive and more likely to require anti-neoplastic therapy along with reduced immunosuppression. Moreover, most PTLDs are B or T-cell clonal neoplasms and rarely plasma cell-rich entities.

Case Description: We present a unique case of a 53-year-old male with end-stage renal disease due to hypertensive nephrosclerosis who underwent deceased donor renal transplant with nadir serum creatinine (SCr) 1.6mg/dl. Perioperative course was uneventful. We used alemtuzumab induction with tacrolimus, mycophenolate mofetil, and corticosteroid maintenance therapy. Both donor and recipient were EBV seropositive. After the first month, patient underwent renal biopsy for suboptimal renal function, which showed nonspecific changes. At month two, he developed BK viremia, so immunosuppression was reduced. SCr then increased to 2.2mg/dl, prompting another biopsy, which showed a clonal plasma cell neoplasm (A, B) with lambda light chain predominance (kappa/lambda 1:10) and a negative EBV-encoded RNA in situ hybridization (EBER). Bone marrow biopsy showed no sign of plasma cell disorder. Patient was diagnosed with renal-limited polymorphic PTLD and treated with further immunosuppression reduction only. Biopsy six weeks later showed normal kappa/lambda and near complete resolution of PTLD (C, D).

Discussion: This is a very unusual case in that our patient was EBER-negative with a plasma cell-rich PTLD, yet presented early post-transplant with a polymorphic PTLD and an excellent response to reduced immunosuppression alone.



Diffuse interstitial inflammation (A) with many plasma cells (B). Focal interstitial inflammation (C) with few plasma cells (D).

TH-PO575

Recurrent Monoclonal Ig Associated C3GN Post Transplant

Narsimha R. Keetha,[1] Song C. Ong,[3] Vineeta Kumar.[2] *[1]Nephrology, university of alabama at birmingham, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL; [3]University of Alabama of Birmingham, Birmingham, AL.*

Introduction: C3 glomerulopathy (C3GN) is one type of renal injury characterized by the predominant staining for C3 with absent or minimal staining for other immunoglobulin (Ig). Although the optimal treatment is unknown, success has been reported with B cell targeted chemotherapy. We describe a case of monoclonal Ig-associated C3GN recurring soon after transplant.

Case Description: A young woman with ESRD attributed to hypertension on hemodialysis for 7 years underwent a deceased donor kidney transplant in 2017. Creatinine (Cr) was 1.1 mg/dL with proteinuria of 0.35g/g at 1 week post-transplant. Within several weeks of transplant, she developed clinical nephrotic syndrome with Cr 2.5 mg/dL and proteinuria 4.3g/g. Renal allograft biopsy demonstrated a membranoproliferative glomerulonephritis (MPGN) on light microscopy. Immunofluorescence (IF) showed 2+ staining for C3. There was weak staining for IgM and C1q. Electron microscopy showed rare subendothelial electron dense deposits. Serum and urine were positive for a monoclonal IgG kappa with M spike of 0.64 g/dL. Records retrieved included a kidney biopsy in 2009 which showed MPGN. IF showed IgG2+, C3 2+, C1q 2+, and kappa 1+. A monoclonal IgG kappa was detected, but a bone marrow biopsy was negative for a plasma cell dyscrasia. On reaching ESRD in 2010, she transferred care and records were not forwarded for transplant evaluation. Our patient underwent a second bone marrow biopsy that confirmed the presence of monoclonal plasma cells (0.2% of total). Workup for multiple myeloma was negative. She was commenced on cyclophosphamide, bortezomib, and dexamethasone. With treatment, proteinuria has improved to 2.2 g/g and renal function stabilized with a last follow-up Cr of 1.8.

Discussion: Our patient had a monoclonal gammopathy of renal significance (MGRS) which remained indolent for many years but caused recurrent disease rapidly after transplant. Successful treatment of monoclonal Ig associated C3GN in native kidney disease with chemotherapy has been described, but reports of treatment for recurrent disease post-transplant have been scant. In addition to chemotherapy, use of eculizumab has been reported to be successful. Following chemotherapy, our patient will be evaluated for an autologous stem cell transplant. Our case adds to the limited literature and awareness surrounding the diagnosis and treatment of this rare disease.

TH-PO576

New Pathogenic Mutations of Complement Factor H Causing Early Recurrence of C3 Glomerulonephritis After Kidney Transplantation

Juan P. Huidobro,[1] Rodrigo Sepúlveda,[1] Gonzalo P. Mendez,[2] Rodrigo Tagle,[1] Elena Bresin,[3] Aquiles Jara.[1] *[1]Nephrology, Pontificia Universidad Católica de Chile, Santiago, Chile; [2]Pathology, Pontificia Universidad Catolica de Chile., Santiago, Chile; [3]Mario Negri Institute for Pharmacological Research, Ranica, BG, Italy.*

Introduction: C3 glomerulonephritis (C3GN) is a rare group of kidney disorders caused by over-activation of the alternative complement pathway. C3GN usually recurs between 3 to 6 months post-transplant. Here we report two likely pathogenic heterozygous variants in complement factor H (CFH), not previously described, involved in early recurrence of C3GN.

Case Description: A 24 year old female with history of left nephrectomy (vesicoureteral reflux) and ESRD with a kidney biopsy showing C3GN (MPGN with C3 deposition and microangiopathy (TMA)) received a deceased donor kidney transplant (KDPI 54%). She was on hemodialysis for 3 years with 2 vascular access thrombotic events. Her cPRA was 0% and received steroids-basiliximab for induction. She developed early post-transplant renal vein thrombosis (day 1) with no urinary flow. A thrombectomy was performed and heparin was started. Thymoglobulin was initiated. The patient evolved with delayed graft function, with scintigraphy (MAG3) compatible with acute tubular necrosis (ATN), and was discharged on dialysis with tacrolimus, mycophenolate and prednisone. Three weeks later her creatinine clearance was 11 ml/min/1.73m^2. A kidney graft biopsy was performed showing signs of ATN but also arteriolar acute TMA and extensive C3 deposition, with negative C4d. Anti-HLA antibodies were negative. The patient developed recurrent allograft infections and loss of kidney function. Therefore, a transplant nephrectomy was performed 3 months after transplantation. A genetic study was performed by NGS for *CFH, CFI, CFB, C3, MCP, THBD, DGKE*, and MLPA for *CFH-CFHR1* hybrid gene and *CFHR1-CFHR3* deletion. Levels of CFH were slightly low 111.8 mg/L (NV 156-572). We found two variants in the N-terminal end of CFH: a new one in SCR1 domain (p.G60R) and a rare one in SCR4 domain (p.P260S) not previously reported.

Discussion: Several modeling software predicted that both mutations are probably pathogenic. In both cases the substitution induces the change of a hydrophobic amino-acid for an hydrophilic one, potentially affecting structure and function of CFH. We report these two new CFH mutations as a potential cause for both fluid phase and cell-surface complement activation, accounting for the original disease and the early recurrence after transplant.

TH-PO577

Short Eculizumab Administration in the Treatment of De Novo Thrombotic Microangiopathy (TMA) in Kidney Transplant: Case Series

Andrea Angeletti, Alessandra Spazzoli, Olga Baraldi, Vania Cuna, Valeria Corradetti, Giorgia Comai, Gaetano La Manna. *University of Bologna, Bologna, Italy.*

Introduction: De novo TMA adversely affects kidney transplant recipient and allograft survival. It remains unknown why only a relatively small percentage of the renal transplant recipients develop TMA. Complement activation is the common denominator in this condition. Eculizumab, a humanized monoclonal antibody targeted against complement C5, has been showed to be effective in the treatment of de novo TMA. How long the treatment have to be maintained is debated. We report the description of a prospective cohort of 10 patients primary treated with eculizumab (1 or 2 infusion) for de novo TMA after transplantation.

Case Description: All the recipients were transplanted with compatible ABO. The cohort were homogenous for age, sex, cold ischemic storage, inductive and mantainance imunosuppresive therapies. Diagnosis of de novo TMA was established by the founding of the triad: microangiopathic hemolytic anemia, thrombocytopenia and worsening of kidney function, excluding other potential secondary causes, as suggested in the literature. We performed kidney biopsies in 3 cases (**Figure 1**). All the subjects developed de novo TMA in the first week after transplantation. Eculizumab (600 mg) was administered once or twice based on lab findings at 1 week after infusion. TMA remission and impoved of kindey function were obtained in 9 patients (**Figure 2**).

Discussion: Eculizumab can be used to safely treat de novo TMA and also with efficacy, even if ceased in the short term.

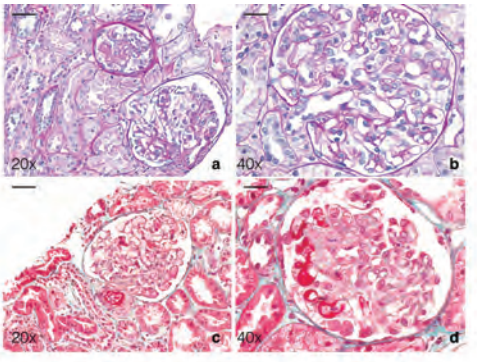


Figure 1. Representative images of a patients with acute thrombotic angiopathy; glomerular abnormalities; arterial and arteriolar lesions. (a), (b) Periodic acid-methenamine-silver stain; (c), (d) Masson trichrome stain.

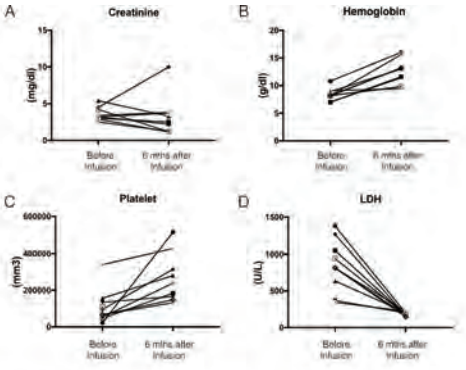

Figure 2. Individual outcome of the hematological and kidney parameters of the patients treated with aculizumab after the kidney transplantation at time points: Immediately before infusion and 6 months of follow up. A: creatinine; B: Hemoglobin; C: platelets; D: LDH (lactate dehydrogenase).

TH-PO578

Allograft Membranous Nephropathy of Donor Origin – Response to the Immunological Environment of the Recipient

Yan Zhong,[1] Philip M. Carpenter,[2] Annika Khine,[1] Neeraj Sharma,[2] Yasir A. Qazi,[2] Thin Thin Maw,[2] Miroslaw Smogorzewski.[2] *[1]LAC USC Medical Center, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA.*

Introduction: Primary membranous nephropathy (MN) is the common cause of nephrotic syndromes in adults. The exact mechanism of kidney injury remained elusive until discovery of the podocyte antigen PLA_2R and its IgG antibodies. We report a unique case of MN in the transplanted kidney.

Case Description: 59-year-old Caucasian female with history of HTN, DM and ESRD on hemodialysis for 6 years underwent the deceased donor renal transplant (DDRT) (HLA A24:68/B35:57/DR18:11 to A2:2/B35:39/DR4:14) with DGF. She required hemodialysis four times post DDRT. The kidney frozen section obtained before transplantation show 135 glomeruli, 4% glomerulosclerosis, mild fibrosis and acute tubular necrosis. Eighteen days post DDRT, urine protein/creatinine ratio 34.2gm/gm was noted and SCr was 1.73 mg/dL on standard therapy (tacrolimus, mycophenolate mofetil, prednisone). Allograft biopsy done 40 days post-transplant show thickened glomerular basement membranes with strong positivity for IgG, C3 and PLA_2R1. Electron microscopy show subepithelial deposits along the basement membranes with spikes in between them. The original allograft biopsy performed at the time of transplant was stained with Jones silver and positive for PLA_2R1, confirming that MN was of donor origin. The recipient's serum PLA_2R antibody was negative for 4 times over 8 months. Her serum albumin plummeted from 4.6g/dL to 2.4g/dL within 2 months after DDRT, but gradually improved to 4g/dL in 6 months. Proteinuria decreased to 1gm/24 hour and SCr remained 1.5-2.0mg/dL. Immunosuppression stays the same. We plan to repeat the allograft biopsy one year after DDRT to follow the expected histological recovery of the donor derived MN.

Discussion: This unique case of donor derived MN and subsequent clinical disease resolution after transplantation further supports the notion that PLA_2R antibody is critical for the pathogenesis of MN. It is possible that immune mediated GN may eventually clear from the transplanted kidney with no adverse effect on allograft function after kidney is removed from the donor auto-antigenicity environment. Thus, the future allograft biopsy should show disappearance of PLA_2R immune complex in the transplanted kidney.

TH-PO579

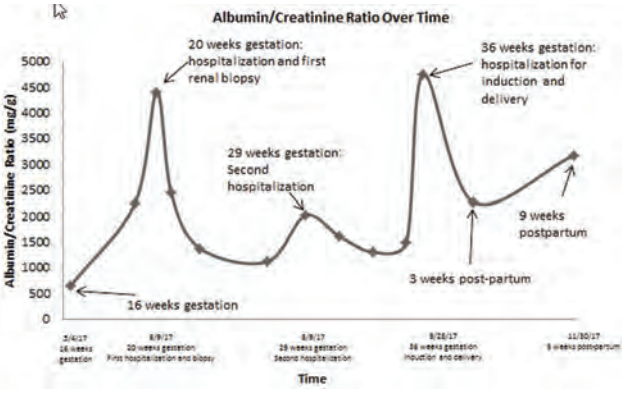
Secondary Focal Segmental Glomerulosclerosis in Pregnancy: A Risk for Renal Transplant Patients

Virginia Dines,[2] Matthew R. D'Costa,[1] Andrea G. Kattah.[1] *[1]Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Internal Medicine, Mayo Clinic, Rochester, MN.*

Introduction: Pre/eclampsia is usually the cause of worsening hypertension and proteinuria in pregnancy; however, these findings in a renal transplant patient lead to a wider differential. We present a case of focal segmental glomerulosclerosis (FSGS) in a pregnant patient 16 years post renal transplant.

Case Description: A 39 year old female with end stage renal disease secondary to lupus nephritis status/post living related kidney transplant, obesity, and hypertension presented with marked proteinuria and worsening hypertension at 14 weeks gestation. Her post-transplant course had been uncomplicated by proteinuria. At presentation, she developed worsening hypertension and 24h total protein was 3.2 g. With strict blood pressure control, urine albumin-to-creatinine ratio (ACR) decreased to 641 mg/g (figure). At 20 weeks, ACR increased to 4399 in the setting of worsening hypertension. She was admitted to the hospital, and urinalysis showed no hematuria and C3/C4, dsDNA and other serologic workup was negative. Kidney biopsy revealed cellular FSGS with glomerulomegaly and 70% foot process effacement, concerning for hyperfiltration injury vs *de novo* primary FSGS. Proteinuria initially improved with strict blood pressure control; however she developed worsening hypertension, proteinuria, and edema at 36 weeks gestation due to pre-eclampsia and underwent cesarean section. She continued to have nephrotic range proteinuria, and renal biopsy at 11 weeks post-partum demonstrated features of secondary FSGS.

Discussion: The differential for proteinuria and hypertension in pregnant renal transplant patients includes pre/eclampsia, rejection, transplant glomerulopathy, and recurrent or *de novo* glomerular disease. Pregnancy creates a physiologic state of hyperfiltration due to increased fluid retention and blood flow. While allografts generally adapt to these changes, patients with obesity and uncontrolled hypertension are at risk for hyperfiltration-induced renal injury and FSGS, which in this case, was unmasked by pregnancy.



TH-PO580

A Novel Approach to Successfully Prevent Membranoproliferative Glomerulonephritis Recurrence in a High-Risk Transplant Patient

Suresh Murthy,[1] Lachlan Mcmichael,[1] Georgina Irish,[1] Sean Haw Chang,[2,1] Stephen P. McDonald,[1,3] Patrick T. Coates.[1,3] *[1]Royal Adelaide Hospital, Seacombe Gardens, NSW, Australia; [2]SA Pathology, South Australia, Woodville South, SA, Australia; [3]University of Adelaide, Adelaide, SA, Australia.*

Introduction: Membranoproliferative glomerulonephritis (MPGN) is a particularly challenging primary pathology in kidney transplant patients due to its high rates of recurrence and graft loss. Aggressive or crescentic disease at presentation, low complement levels pre-transplantation, monoclonal gammopathy, live-related transplantation and certain HLA-associated risk factors are predictive of recurrence risk in the allograft. Various strategies have been used to manage such recurrence, but data is limited on pre-emptive management.

Case Description: We report the case of a 63-year-old woman with immune-complex-mediated idiopathic MPGN who had several risk factors for allograft recurrence, receiving a second renal transplant following early recurrence in her first transplant. Rising creatinine and new proteinuria led to biopsy confirmed recurrent disease in her first transplant at Day 76, with return to long term haemodialysis at day 86 despite maximal medical therapy to salvage the graft. 10 years later, she received a second, well matched transplant. Induction immunosuppression included anti-thymocyte globulin at day 0,1,2; plasma exchange at day 3 and rituximab at day 5 and 18. Protocol biopsy at day 79 demonstrated minimal tubulitis and no recurrent primary disease. Another biopsy performed at day 197 due to elevated creatinine following clostridium difficile infection, again demonstrated no recurrent disease. She remains on prednisolone, mycophenolate mofetil and tacrolimus with stable graft function at 7 months.

Discussion: The optimal management of patients with idiopathic MPGN at the time of transplantation is unknown. We demonstrate a new approach with rituximab and plasma exchange for pre-emptive management of a patient with idiopathic MPGN and multiple risk factors for early recurrence. This strategy has been successful in maintaining recurrence-free graft function at 7 months post transplantation

TH-PO581

Renal Replacement Lipomatosis in Transplanted Kidney

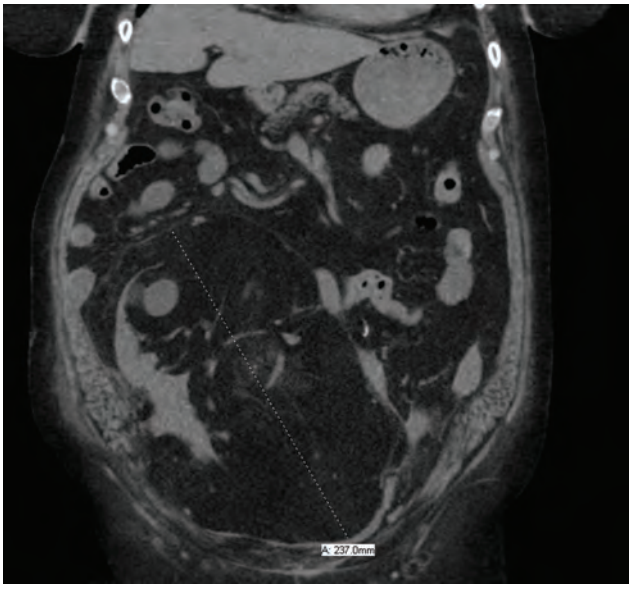
Wael A. Hanna,[1] Ravindra Bollu.[2] *[1]Lehigh Valley Hospital, Breinigsville, PA; [2]Valley Kidney Specialists, Allentown, PA.*

Introduction: Renal sinus lipomatosis (RSL) is a rare disorder where fatty tissue proliferate within the renal sinus and hilum. Renal replacement lipomatosis (RRL) is a severe form of RSL.

Case Description: A 63-year-old female with a history of end stage renal disease due to chronic glomerulonephritis underwent deceased donor renal transplant in February,1997. She has been diagnosed with chronic allograft dysfunction since 2002 with baseline S Cr 1.7-2 mg/dL. Immunosuppression has been maintained with Cyclosporine A, Mycophenolate mofetil and Prednisone. She experienced recurrent urinary tract infections since her kidney transplantation. She presented to emergency department with abdominal pain. On examination, a large right lower quadrant mass could be palpated. S Cr was at her baseline. CT scan of the abdomen and pelvis revealed a 24 cm large fatty mass centered in the hilum of the right lower quadrant renal transplant with splayed transplant parenchyma and collecting system. CT scan reading suggested the possibility of well differentiated liposarcoma. CT guided biopsy of the mass was performed. Pathology demonstrated mature adipose tissue with chronic inflammation.

Discussion: Renal replacement lipomatosis (RRL) is a rare condition, characterized by excessive fatty proliferation of the renal sinus with atrophy of the renal tissue. Aging, obesity and calculus disease are possible risk factors for RRL. Recurrent urinary tract infections has been described in most cases of RRL. The period between renal transplant

and RRL diagnosis has been variable in the literature, ranging from 6 months to 8 years. Our case was diagnosed after 21 years from her renal transplant. RRL is a very rare disease in kidney transplant. It should be differentiated from other fat containing tumors like liposarcoma and angiomyolipoma.



TH-PO582

A Case of a Kidney Transplant Recipient with Severe Throat Pain

Amin Khalifeh-Soltani,[1,3] Peter J. Kennel,[1,3] Jeffrey I. Silberzweig,[2] John R. Lee.[2]
[1]Weill Cornell Medicine, New York, NY; [2]The Rogosin Institute, New York, NY; [3]NewYork-Presbyterian Weill Cornell Medical Center, New York, NY.

Introduction: Deceased donor renal transplants have a 5-year graft survival rate around 90% at our center. However, combination immunosupressive therapy increases susceptibilty to infections. Here we report the case of a patient with a history of multiple bacterial, viral and fungal infections who presented with throat pain.

Case Description: This 50-year-old woman had chronic kidney disease secondary to lupus nephritis; she received a renal transplant from a deceased donor after a failed transplant from a live donor. She was managed with thymoglobulin-based induction and maintained on mycophenolate mofetil, prednisone, and belatacept, which was switched to tacrolimus four weeks after transplantation. Her course was complicated by ganciclovir-resistant CMV disease of the GI tract, recurrent ESBL E coli bacteremia, RSV bronchiolitis requiring prolonged intubation, Pneumocystic jiroveci pneumonia and probable pulmonary aspergillosis, requiring tracheostomy for ventilator weaning. Four months after being weaned from the ventilator, she presented with severe right neck pain, throat pain, and dysphagia. MRI revealed a rim enhancing collection in the left laryngeal tissue abutting the left lateral thyroid cartilage. Following percutaneous drainage, cultures grew no bacteria; she was treated with meropenem and vancomycin. Her throat pain and dysphagia worsened and she was started on voriconazole empirically. Left neck exploration revealed a severely remodeled, necrotic and fibrous sternothyroid muscle. Extensive debridement of the deep strap layer was performed and a subperichondrial abscess drained. Pathology revealed necrotic cartilage with septate fungal hyphae, compatible with a diagnosis of Aspergillus laryngeal abscess. Due to progression of the fungal infection on empiric voriconazole, the patient was switched to posaconazole. Her pain and dysphagia improved and she was discharged on day 23 with posaconazole. After 3 months of treatment, her throat pain resolved.

Discussion: We report a rare case of an Aspergillus abscess of the larynx causing neck and throat pain and dysphagia. Differential diagnosis for throat pain in immunosuppressed kidney transplant recipients needs to include bacterial, viral, and fungal pathogens.

TH-PO583

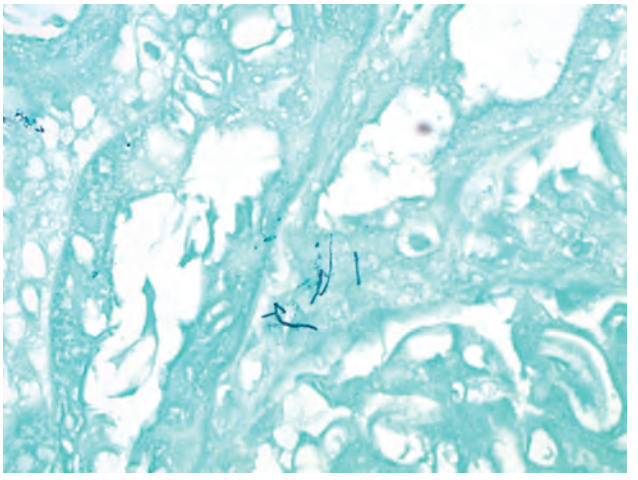
A Case of Biopsy Proven Histoplasmosis in a Renal Allograft

Anum Malik, Ziad S. Zaky, Ali Mehdi. *Cleveland Clinic, Beachwood, OH.*

Introduction: Fungal infections in immunocompromised hosts are well described. However, histoplasma capsulatum is not known to directly infect the allograft in kidney transplant (KT) patients. We report a case of disseminated histoplasmosis infecting the renal allograft.

Case Description: A 52 year old male with ESRD from IgA nephropathy, status post deceased donor KT in 2007, presented in 2017 with constitutional symptoms, dry cough and AKI for 3 weeks. His transplant course was complicated by an early Banff 1A rejection and was maintained on tacrolimus (FK), mycophenolate (MMF) & prednisone. Of note, he had recently been renovating a house in southern Ohio. CT chest & abdomen showed bilateral lung opacities, mediastinal/hilar lymphadenopathy & perinephric fat stranding around the allograft. Due to the unexplained AKI, a renal biopsy was done, showing focal granulomatous interstitial inflammation with silver positive organisms and glomerulitis with macrophages containing histoplasma. A transbronchial lung biopsy confirmed granulomatous pneumonia with histoplasma, meeting criteria for disseminated histoplasmosis. Histoplasma urinary antigen also resulted positive later. He was discharged on itraconazole and MMF was held. He was re-admitted a week later with diffuse morbiliform rash concerning for cutaneous histoplasmosis, but skin biopsy was consistent with drug reaction. Due to amphotericin B intolerance, he was switched to oral fluconazole, with a goal of 12 months treatment. At 3, 6 & 9 months follow up, he continued to do well with his creatinine stabilizing at baseline. His MMF was resumed after 6 months of antifungal treatment.

Discussion: We present a unique case of a biopsy proven disseminated histoplasmosis involving renal allograft in a KT patient who has done well with treatment. Our case underscores the importance of a broad differential and thorough history when evaluating immunocompromised patients.



GMS stain showing both yeast and hyphae in the interstitium, consistent with histoplasmosis.

TH-PO584

Isolated Intrarenal Mucormycosis Due to Rhizopus Species in a Pediatric Renal Transplant Recipient

Kiri W. Bagley, Keia Sanderson, William A. Primack. *University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Introduction: Mucormycosis (MM) is an unusual but well-known complication of solid organ transplant, which disseminates aggressively with a high mortality rate. Our patient may be the first reported child with isolated renal allograft MM.

Case Description: 3-y.o. female, with ESRD due to hypoplastic/dysplastic kidneys, received a cadaveric renal transplant after basiliximab induction, with subsequent pred, tac, and MMF. 4 weeks post Tx she developed fatigue, tachypnea, and increase in SCr to 1.7 from baseline of 0.4. UA revealed moderate LE, + nitrites, many WBCs and RBCs, and moderate bacteria. Renal US showed mildly distended ureter and renal pelvis with collecting system debris. She received broad-spectrum antibiotics. Renal biopsy showed tac toxicity. She stabilized and was discharged on reduced tac. Antibiotics discontinued as urine culture was negative. 5 weeks post-discharge, she redeveloped fever, pyuria, and rising SCr. US showed thickened ureter and renal pelvis. Parenteral antibiotics were resumed. Urine culture was negative. Repeat UA showed less but persistent pyuria. Antibiotics broadened on hospital day (HD) 2 due to unremitting fever. Steroid pulse on HD 3 for possible rejection. Fever abated on HD 4, and steroids tapered after no rejection on biopsy (HD 6). Tachycardia, new fever (HD 7) and tachypnea (HD 8) developed with progressive abdominal distention. US showed fluid collections within allograft. *Rhizopus* sp. was identified from intrarenal fluid aspirate, and amphotericin and posaconazole were begun. Transplant nephrectomy occurred the next day. CNS, chest, abdomen, and pelvis imaging were negative for disseminated MM. After nephrectomy, catheterized UA was benign. 10 days post-op, she developed new fever. Laparotomy showed no disease spread. Other organ recipients from same donor did not develop MM. She received a 3-month posaconazole course with clinical improvement. She was discharged after 2-month hospitalization. She has been off antifungal therapy for >1 month, and is doing well on outpatient hemodialysis.

Discussion: MM is a rare, usually disseminated complication of renal transplant with mortality reported as >50% when graft involvement occurs. MM isolated to the renal allograft is unusual. Clinicians should consider the possibility of intrarenal allograft MM with bacteriologic culture negative patients with pyuria.

TH-PO585

A Case Report of Pulmonary Alveolar Proteinosis in a Renal Transplant Recipient

Candice Khor,[1] Subramanian K. Kumar.[2] *[1]Gosford Hospital, Sydney, NSW, Australia; [2]Gosford Nephrology, TERRIGAL, NSW, Australia.*

Introduction: Pulmonary alveolar proteinosis (PAP) is a diffuse lung disease characterised by accumulation of surfactant. Clearance of surfactant by alveolar macrophages is regulated by granulocyte macrophage colony stimulating factor (GM-CSF). Autoimmune PAP due to GM-CSF antibodies is the most common cause of PAP

in adults. Secondary causes include dust exposure, haematological malignancy and immunosuppressive medications.

Case Description: A 52 year old man developed progressive shortness of breath, hypoxia and productive cough one year post living unrelated renal transplant for polycystic kidney disease. This is in the context of BK virus nephropathy at three months post-transplant requiring a change in immunosuppressants from tacrolimus and mycophenolate to cyclosporine and leflunomide. A high resolution computed tomography (HRCT) of the chest demonstrated bilateral peri-hilar ground glass opacities. Pneumocystis jiroveci pneumonia (PJP) treatment was commenced with no clinical improvement. Bronchoscopy with bronchoalveolar lavage was inconclusive. The patient underwent a transbronchial biopsy which was positive for periodic acid-Schiff (PAS) proteinaceous material confirming the diagnosis of pulmonary alveolar proteinosis. There was no evidence of haematological malignancy clinically and on bone marrow biopsy. Immunosuppression was changed to tacrolimus and mycophenolate with no improvement in respiratory symptoms. Serum GM-CSF antibodies subsequently returned positive with titres rising from 0.50 to 0.66 suggestive of autoimmune PAP. Rituximab, intravenous immunoglobulin and plasma exchange were considered however patient responded clinically and radiologically after a total lung lavage.

Discussion: Pulmonary alveolar proteinosis is a rare but important differential diagnosis to consider in patients with subacute onset of dyspnoea and hypoxia with the typical radiological changes of ground glass opacity and interlobular and intralobular septal thickening. Importantly PJP can mimic PAP and must be excluded in an immunosuppressed patient. Primary PAP due to GM-CSF antibodies accounts for the vast majority of adult PAP with whole lung lavage as the gold standard of treatment. Secondary PAP due to haematological malignancy, dust exposure and immunosuppressants must be considered and excluded.

TH-PO586

Belatacept Recovers Renal Allograft Function Despite Extensive Fibrosis

Arpita Basu,[1] Hatem Amer,[2] Mariam P. Alexander.[1] Mayo-Transplant Neph *[1]Mayo Clinic, Rochester, Rochester, MN; [2]Mayo Clinic, Rochester, MN.*

Introduction: Prolonging kidney allograft lifespan is a complex problem despite advances in the field. Histological findings of fibrosis indicate irreversible injury, that increases with severity, ultimately resulting in graft loss. Good renal function despite severe fibrosis is a goal of therapy. We present 2 patients whose renal function improved with Belatacept in presence of substantial chronic damage.

Case Description: Patient 1: 46 year old male recipient of a deceased donor kidney. Received thymoglobulin induction and maintained on Tacrolimus, Mycophenolate Mofetil and Prednisone. Biopsy 1 week post transplant for poor renal function, showed significant fibrosis(Table1). Belatacept was substituted for Tacrolimus.He was liberated from dialysis 4 months later. Renal function continued to slowly improve over the years. Patient 2: 35 year old lady received a living donor kidney. Immunosuppression similar to that of Patient 1. Three years post transplant, she was noted to have worsening renal function. Biopsy showed extensive chronic changes(Table1). Conversion to Belatacept led to gradual improvement in renal function.

Discussion: Belatcept's renal sparing abilities improve renal function and can extend allograft survival despite severe chronic injury. The improvement is gradual occurring over several months to years, indicating a mechanism beyond the initial mitigation of the vasoconstrictive effects of Tacrolimus.

Table 1

Time to Biopsy Post transplant(CrCl)	Banff Criteria
Patient 1:	
Time 0 (4ml/min)	g0, i0,t0, v0, cg0, ci1, ct1, cv3, mm0, ah2, ptc0, ti0

TCR NGS Based Evidence for Differential Diagnosis and Personalized Therapy in BKV Nephropathy

Ulrik Stervbo,[1] Mikalai Nienen,[1] Richard Viebahn,[2] Timm H. Westhoff,[1] Nina Babel.[1] *[1]University Hospital Marien Hospital Herne, Herne, Germany; [2]Ruhr University Bochum, Bochum, Germany.*

Introduction: BKV nephropathy (BKVAN) is a disease in 10% of renal transplant recipients which might lead loss of the graft in up to 80% of the cases. Current the diagnosis is based on assessment of BKV viral load in serum with assessment of inclusion bodies by kidney biopsy for definitive diagnosis. In case of identified BKVAN, the principle treatment is to decrease or alter the immunosuppressive regimen. However, the pathological features of BKVAN overlap with those of acute cellular rejection, where decrease of immunosuppression is detrimental.

Case Description: We were presented with a German male, transplanted with a kidney from a close living relative. The patient had a high BKV load (432500 copies/ml), but histological findings demonstrated borderline rejection according to BANFF, and SV40 negative findings. Faced with the vexing question of increasing or decreasing immunosuppression we obtained blood and a biopsy from the patient. By way of magnetic bead enrichment of activated T-cells we isolated T-cells reactive to BKV and donor cells in a direct and indirect fashion. Together with the fresh renal tissue, the activated T-cells were prepared for next-generation sequencing (NGS) of the T-cell receptor (TCR). We isolated T-cells in all three activation modi, which indicates an expansion of virus as well as donor specific T-cells in the patient, and underpins the complexity of diagnosis. When we compared the TCR repertoires of activated peripheral T-cells to those in the biopsy, we observed a distinct and strong presence of BKV specific T-cells in the transplant. This clearly excluded acute cellular rejection and allowed confident decrease of the immunosuppressive regimen. The graft function improved and the patient shows no signs of BKV infection nor graft rejection.

Discussion: TCR NGS profiling is a novel, but labor insensitive technique. The turnaround time is about 5 days and donor derived cells are required for optimal results. Identification of the specificity of tissue infiltrating T-cells by TCR NGS is nonetheless a valuable technique for differential diagnosis and personalized therapy.

TH-PO588

The Conundrum of a Peculiar Skin Lesion on the Face of a Renal Transplant Recipient

Muhammad O. Saleem, Sandeep Padala, Natalie Smith, Rajan Kapoor. Nephron@AU *Medical College of Georgia, Augusta University, Augusta, GA.*

Introduction: Parasitic infections may be challenging to diagnose especially in transplant population. We present a rare case of cutaneous larva migrans (CLM) at an unusual site in a renal transplant recipient.

Case Description: 64 year African American female with a medical history of Autosomal Dominant Polycystic Kidney Disease, who received a cadaveric transplant 3 months ago presented for routine follow up. She had no complaints except that of a disfiguring skin lesion on her forehead associated with itching. She denied fever, cough, other skin involvement, recent travel or exposure to sand beaches or contaminated soil. She does not have any pets. Physical exam revealed an expanding serpiginous papule on her forehead which was extremely pruritic. Home medications were not suggestive of any correlation. All routine labs were normal. She tried some over the counter topical and oral anti-allergic meds with no benefit. Although, a very unusual location but with telling clinical presentation a diagnosis of CLM was made and she was treated with oral Ivermectin. Patient reported complete resolution of her rash 5 days post treatment.

Discussion: Transplant population is prone to myriad of infections including parasitic infestations, incidence of which may be as high as 2.4%. The most common parasitic infection once reported was Strongyloids. Intestinal parasitic infestations are more common in Solid Organ Transplant recepients especially in developing countries. A parasitic infection should always be in the list of differential diagnosis, if clinically suggestive so as to avoid the diagnostic delay and further potential complications. CLM is rarely reported in transplant patients and the lesion on forehead is exceptionally rare. We present successful outpatient management of a rare clinical presentation of CLM.

Face lesion

Diffuse Alveolar Hemorrhage with Respiratory Failure: A Case of Strongyloides Hyperinfection Post Renal Transplantation

Imtiyaz H. Hakeem, Cristina E. Pinal, Faiza N. Khan. *Baylor Scott & White Health/Texas A&M COM-HSC, Temple, TX.*

Introduction: Strongyloides Stercoralis is an intestinal nematode which infects millions of people. It is endemic in South Asia, Latin America, Sub Saharan Africa and South Eastern United States. The infection usually is asymptomatic but can be serious in the immunocompromised Host.

Case Description: We present 60 y.o.African American Male an Army Veteran 2 months post Deceased Donor Renal Transplant on Immunosuppression. He presented with 10 days of severe fatigue, weight loss, cough, and multiple loose stools every day. He was born in Central Texas and lived most of his life in this area. He had no travel to Asia or the Middle East. Visited Mexico and Florida a few times in the remote past. Initial imaging was consistent with pulmonary infiltrates. Progressive Anemia with pulmonary infiltrates prompted Bronchoscopy with BAL which revealed Diffuse Alveolar Hemorrhage. Started on high dose pulse steroids, plasmapheresis. Intubated for Respiratory failure.. ANCA, APS, Anti-GBM, ANA profile was negative and kidney biopsy showed no evidence of vasculitis. Repeat BAL was positive for the larval forms of Strongyloides. Diffuse purpuric rash on abdomen, punch Biopsy revealed Strongyloides larvae. Stool O&P returned positive for the Strongyloides, but ELISA was negative.. He was started on subcutaneous Ivermectin and albendazole but showed no improvement. Irreversible septic shock ensued resulting in death. His pre transplant serum returned negative for Strongyloides antibody. Donor serum returned positive for Strongyloides. liver and lung tissues showed larval forms on autopsy.

Discussion: The global burden caused by Strongyloides stercoralis is not completely known. Humans become infected when filariform larva penetrates the skin or mucosa. Hyperinfection happens in immunocompromised hosts when reduced immunosurveillance leads to unrestricted proliferation of the worms. In hyperinfection, enteric bacteria can be carried by larvae which results in fatal septicemia. The American Society for Transplantation guidelines recommend screening for Strongyloides in recipients from endemic areas with no mention of donor screening Increased suspicion, surveillance, and screening of the donors and recipients from the endemic areas is needed to avoid any fatal effects of the superinfection in transplant recipients.

TH-PO590

APRT Deficiency Related Crystalline Nephropathy Causing Acute Renal Allograft Dysfunction: A Case Report

Sudip M. Patil, Sagar Gupta, Dinesh Khullar. *Max Super Speciality Hospital, New Delhi, India.*

Introduction: APRT(Adenine Phosphoribosyl Transferase) deficiency is an AR metabolic disorder that leads to accumulation of insoluble purine dihydroxyadenine (DHA) in the kidney. It results in crystalluria & urinary stones leading to renal colic, hematuria, UTI & renal failure. Age at presentation can range from 5 months to late adulthood. Upto 50% of patients may be asymptomatic. Prevalence is largely unknown. Lack of awareness, inadequate evaluation of stones & confusion of DHA crystals with uric acid or calcium oxalate contribute to diagnosis being missed. We report here a case of acute renal allograft dysfunction secondary to APRT deficiency related crystalline nephropathy, a relatively rare entity.

Case Description: A 51 year-old male was evaluated for acute allograft dysfunction. His past history was significant for ESRD secondary to nephrolithiasis. No stone biochemical analysis or genetic studies were performed. He underwent living unrelated kidney transplantation (donor wife) 3 months back. Post-operative period was uneventful with nadir S.Crt of 1.2mg/dl. Basiliximab for induction and tacrolimus, MMF& prednisolone were used for maintenance immunosuppression. On routine labs he was found to have S.Crt of 2.3mg/dL. USG allograft was unremarkable. Renal allograft biopsy was performed and showed 0/5 glomeruli being sclerosed. Tubulopathic changes in form of tubular epithelial simplification and intraluminal polarizable crystals were noted. No evidence of rejection was found. A histopathological diagnosis of acute tubular injury with tubular crystallization was made.24hUr oxalate level was 55.6mg/d(N<45) & Pl. Oxalate was 3.34µmol/L(N< 3.0). Genetic analysis revealed a previously unreported homozygous nonsense mutation in exon 3 of APRT gene. Hence a clinical diagnosis of APRT deficiency related renal disease was made. He was started on Allopurinol 100mgBID with low purine diet & increased fluid intake. S.Crt gradually improved to 1.2 and has remained stable for last 1 year.

Discussion: Initial presentation of APRT deficiency can be insidious onset of renal dysfunction due to crystalline tubulopathy or interstitial nephritis without urolithiasis. High index of suspicion, correct identification of DHA crystals, renal biopsy & genetic testing are needed to clinch the diagnosis. Treatment with allopurinol, low purine diet and increased fluid intake is simple & effective.

TH-PO591

Clinical Tolerance - A Rare but Highly Deserved State of the Post-Transplant Patient

Monzurul Chowdhury,[1] Kenneth A. Bodziak.[2] *[1]UMASS Memorial, Worcester, MA; [2]UMass Memorial Medical Center, Worcester, MA.*

Introduction: Graft tolerance is a clinical situation defined as stable graft function without clinical features of chronic rejection, and in the absence of any immunosuppressive drugs, usually for longer than 1 year's duration. This is observed more frequently in liver transplant patients but spontaneous graft tolerance has also been rarely reported in kidney allograft recipients. Many of these patients with presumed tolerance, in fact, are detected when they report to the treating physician with near normal graft function, but in the absence of immunosuppression. We present a case of immune tolerance following kidney transplant in an individual with normal graft function who had gone 10+ years without any immunosuppression.

Case Description: 62-year-old male with the history of DM II, hypertension, renal stone, past deceased donor kidney transplant (2002) presented with chief complaint of abdominal pain, fever, and diarrhea for one week. His CT of the abdomen and pelvis showed a perforated appendix and was treated with antibiotics and the abscess was drained. He recovered from his current illness and his discharge creatinine was 1.07 mg/dL with eGFR 75 ml/min. He received an HLA-matched deceased donor kidney transplant on 2002. His postoperative course was uncomplicated and creatinine improved from 5 mg/dL to 2 mg/dL at discharge. He was discharged on tacrolimus, mycophenolate, and prednisone. He gradually lost follow-up and stopped taking all of his medications, including his immunosuppressants, for more than 10 years on his own accord. He preserved his renal function for all these years without any immunosuppressive medications. His chimerism study from buccal mucosal cells was negative but could not exclude microchimerism. He was subsequently discharged and maintained off immunosuppressive medications.

Discussion: The evolution of tolerance to donor alloantigen in vivo is a dynamic process involving many mechanisms that contribute at different stages. The clinical characteristics of tolerance patients are limited due to its rare occurrence. Our patient gradually discontinued his immunosuppressive over the course of months by himself. The possible mechanisms for his immune tolerance could be central (intrathymic) deletion, peripheral deletion, anergy, ignorance and/or microchimerism, either alone or in combinations. He still maintains a good graft function without any immunosuppressant.

TH-PO592

Graft-versus-Host Disease After Kidney Transplant

Omar H. Sanchez vazquez, Renato Parra Michel, Marlene D. Cisneros-Carbajal, Antonio M. Murga, Francisco Fuentes Ramirez, Ana M. Molgado castillo. *Universidad de Guadalajara, Centro Universitario de Ciencias de la Salud, Hospital General Regional No.46, Instituto Mexicano del Seguro Social, Guadalajara, Mexico.*

Introduction: Graft-versus-host disease is an uncommon complication after solid organ transplantation. Few cases of graft-versus-host disease after kidney transplantation have been reported.

Case Description: A 32-year-old man was admitted to our hospital in August 2017 due to cellulitis of the right leg. He received ceftriaxone and clindamycin. His past medical history included end-stage renal failure at the age of 19 years old. It was necessary to start peritoneal dialysis until he received a renal transplant in 2007 from a related donor (his father, 41-years-old at the time), he had matching HLA (A, B and DR) antigens. The recipient received induction therapy with rabbit-antithymocyte globulin and a triple immunosuppressive regimen. In February 2018 he developed bullous lesions burning pain on the back of the left leg. Skin lesions then coalesced and became hemorrhagic, spreading to the rest of the leg and thigh. They eventually turned into crusts in a month. A Dermatology evaluation was requested, and a skin biopsy was performed. Biopsy reported: epidermal

acanthosis and mild spongiosis of the basal layer; upper dermis showed blood vessels with lymphocytic infiltrate (without vasculitis). There was proliferation, thickening and homogenization of collagen tissue fibers and deep perifollicular fibrosis with a suggestive diagnosis of sclerodermiform dermatosis chronic variant of graft-versus-host disease.

Discussion: The main risk factors include donor HLA homozygosity, peri-organ lymphoid tissue transfer and the relationship between recipient immunogenicity and the immunosuppressive drug regimen. Diagnosis is made by specific tests which detect macrochimerism, single-tandem repeat and DNA analysis which quantifies relative amounts of different DNA.

TH-PO593

Blood in a Urine Collection...Is It an Infection or Rejection? Adenovirus Is Our Selection!

Nashila AbdulRahim, Natalie E. Ellington, Allen Hendricks, Bekir Tanriover, Venkatesh Kumar Ariyamuthu. *UTSouthwestern, Dallas, TX.*

Introduction: Adenovirus-induced granulomatous interstitial nephritis (AGIN) is rare and has a high risk of graft loss in renal transplant patients. Diagnosis can be made with quantitative urine and blood PCRs and biopsy. We present a case of hemorrhagic cystitis, AGIN, admixed with rejection.

Case Description: 53 year old male with a history of ESRD secondary to ADPKD had a DDRT in 2010 with no notable post-transplant complications. His baseline SCr was 1.6 mg/dl, and he was maintained on tacrolimus, MPA, and prednisone, with goal tacrolimus troughs between 5-8 ng/ml. He had presented to an urgent care with dysuria, hematuria, and AKI (Scr to 1.9 mg/dl) and treated with ciprofloxacin for 10 days. He came to our facility one week later with diarrhea, fevers, and AKI (SCr of 2.9 mg/dl) that did not improve with IV fluids and antibiotics. In light of hematuria, urine and serum adenovirus PCR were sent which resulted as greater than 2,000,000 and 72,698 copies respectively. Transplant kidney biopsy showed ACR Banff IB, suspicious for chronic, active ABMR with severe glomerulitis, moderate pertitubular capillaritis, and mild transplant glomerulopathy. Light microscopy showed severe tubulointerstitial inflammation with lymphohistiocytic proliferation, numerous monocytes and lymphocytes with areas of interstitial hemorrhage, epithelial cell necrosis, rupture of basement membranes, and rare tubular epithelial cells with enlarged nuclei with a smudgy, glassy appearance. Occasional vague necrotizing granulomas were identified. Electron microscopy showed 30-40% foot process effacement with segmental duplication of capillary walls. SCr peaked at 3.2 mg/dl; he received IVIG for AGIN. Dose of prednisone was increased to 10 mg, and tacrolimus level ran between 5-8 ng/ml with MPA at 360 mg bid. He was unable to tolerate further IVIG secondary to headaches. Serum adenovirus PCR one week after IVIG dosing had detectable viral loads but less than 500 copies. Discussion with Transplant ID colleagues led to the decision to hold cidofovir secondary to potential nephrotoxicity. His renal function remains stable at SCr of 1.8 mg/dl.

Discussion: We identified and properly treated a rare cause of AKI due to AGIN admixed with ACR. Prompt diagnosis and treatment led to resolution of viremia as well as improvement in renal function with graft salvage.

TH-PO594

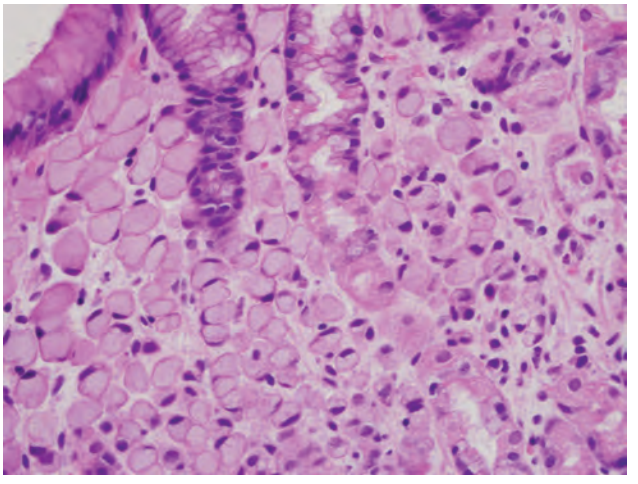
A Case of Hereditary Diffuse Gastric Cancer in a Renal Transplant Patient

Divya Raghavan,[1] Josephine Abraham,[1] Eric A. Swanson,[1] Monica P. Revelo Penafiel,[1] Faris A. Ahmed,[1] Isaac E. Hall,[1] Fuad S. Shihab.[2] Fellow *[1]University of Utah, Salt Lake City, UT; [2]University of Utah Health Science Center, Salt Lake City, UT.*

Introduction: Hereditary diffuse gastric cancer is a highly invasive malignancy which is usually advanced at the time of presentation and associated with a poor prognosis. We report a case diagnosed less than one year after kidney transplantation.

Case Description: A 33-year-old woman with end stage renal disease due to renal agenesis post kidney transplant 8 months ago was admitted with a 5-month history of post-prandial abdominal pain and a 20-pound weight loss. An abdominal CT scan and ultrasound prior to admission were unrevealing. An endoscopy 2 months ago showed gastritis, at which time she started pantoprazole and sucralfate, with no improvement. She was also on tacrolimus, mycophenolate sodium and prednisone. Her family history was significant for stomach cancer in her father who died at age 33 as a result. She had normal vital signs and exam except for a low blood pressure of 99/64. An upper endoscopy showed a localized area of gastritis in the posterior body of stomach which was biopsied. CT scan of the abdomen and pelvis showed mild ascites and a small bowel obstruction. Posterior wall biopsy result came back showing diffuse type adenocarcinoma with signet ring cells. Diagnostic paracentesis showed malignant cells. Genetic testing identified a mutation in CDH1. Patient's functional status was too poor for chemotherapy and she passed away 2 months from diagnosis.

Discussion: Hereditary diffuse gastric cancer is associated with mutations in a tumor suppressor gene (CDH1) which encodes E-cadherin. Affected individuals develop gastric cancer at a young age. Diffuse gastric cancer in first or second degree relatives under the age of 40 is an indication for genetic testing. Prophylactic gastrectomy is recommended between the age of 20 and 30 in mutation carriers because of the extremely high risk of cancer.



Pathology result showing signet cell adenocarcinoma

TH-PO595

Successful Treatment and Five Years Disease-Free Survival in a Donor Transmitted Metastatic Melanoma with Ipilimumab Therapy

Priyamvada Singh,[1] Bhavnish Bucktowarsing,[1] Todd E. Pesavento,[2] Thomas Olencki.[2] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Ohio State University, Columbus, OH.*

Introduction: Approximately 7% of deceased donors have unknown cancer at the time of organ procurement. More than 50% of these have no apparent contraindication to organ donation. The commonest transmitted malignancy is renal cell cancer (19%), followed by melanoma (17%). Donor transmission of melanoma is often fatal as it is commonly metastatic at the time of diagnosis. Cases with remission following transplant nephrectomy and withdrawal of immunosuppression are few. To our knowledge this is only the second case of donor-derived melanoma that was successfully treated with Ipilimumab. Our patient has the longest disease-free survival (five years) reported in the literature till date.

Case Description: 66-year-old female, status post deceased donor Kidney transplant in December 2012 for diabetic nephropathy received a 5/6 HLA-mismatched kidney, underwent induction with basiliximab and glucocorticoid followed by maintenance with tacrolimus and mycophenolate. In March 2013, she developed acute deterioration of allograft function. MRI abdomen/pelvis was suspicious for neoplastic involvement of the allograft with metastases to spleen and bone marrow. Biopsy of the posterior iliac spine and sacrum was positive for metastatic melanoma. Explantation of the allograft on 3/15/2013 showed metastatic involvement. Immunosuppressants were discontinued, and she was initiated on dialysis. Her melanoma was BRAF V600E mutation favorable. Staging studies confirmed widespread metastases involving the bone, liver, spleen, and lungs (TxNxM1c stage IV, allograft-associated). On 4/2013, she was started on vemurafenib (960 mg bid) but was discontinued in August 2013 due to several cutaneous lesions. She was then treated with four cycles of Ipilimumab (3 mg/kg, every three weeks, 8/13/13-10/15/13) without significant side-effects. Quality of life improved. No further progression of cancer was evident on serial imaging and she has been in remission for five years.

Discussion: Despite careful donor selection, cancer transmission to the recipient is inevitable. Early diagnosis, cessation of immunosuppression to allow rejection of the allograft and transplanted cancer cells, transplant nephrectomy, and treatment with chemotherapy/immunotherapy can improve survival. The role of HLA mismatch in prognosis is unclear and a topic for future research.

TH-PO596

A Rapid Onset of De-Novo Allograft Nephrolithiasis

Amita Maibam, Ana L. Castellanos. *University of Kentucky, Lexington, KY.*

Introduction: De-novo renal allograft nephrolithiasis is a rare condition with incidence of approximately 1 %. Persistent hyperparathyroidism (HPT) after kidney transplant occurs in 15-50% cases but rarely causes renal calculi. Mean duration to diagnosis is 28±22 months. Here we report a case of allograft nephrolithiasis soon after transplantation with underlying tertiary HPT on cinacalcet.

Case Description: A 47-year-old Caucasian male with history of biopsy proven IgA nephropathy, hypertension, ESRD on peritoneal dialysis for 4 years underwent a deceased donor kidney transplant. He received thymoglobulin induction and was started on mycophenolate, tacrolimus, and prednisone for maintenance immunosuppression. After 2 weeks of surgery, cinacalcet was started for hypercalcemia (11 mg/dl). At 6 weeks post transplantation, ureteral J stent was found to be severely encrusted. The stent was removed with subsequent passage of several small stones. Analysis showed 100% brushite stones. A CT stone protocol revealed transplanted kidney with multiple calculi within the collecting system with evidence of obstruction. It was treated with stenting, lithotripsy, and percutaneous nephrostomy placement. Intact parathyroid hormone (iPTH) was 455 pg/ml with serum ionized calcium 6.1 mg/dl and phosphorus of 2.2 mg/dl. Renal function remained stable with serum creatinine of 1.3 mg/dl to 1.4 mg/dl. Patient underwent near-total parathyroidectomy after a nuclear scan showed enlarged parathyroid glands. Histopathology reported hyperplastic glands. One year post parathyroidectomy, there has been no new stone formation with normalization of calcium and iPTH.

Discussion: The most striking aspect of our case was asymptomatic de-novo nephrolithiasis, which presented within 6 weeks after transplantation. It emphasizes the need to remain vigilant of this possible complication during the early post-transplant period in patients with persistent hypercalcemia and HPT. Close monitoring of calcium, phosphorus, and iPTH levels along with necessary imaging can lead to timely diagnosis of this potentially allograft threatening complication. Parathyroidectomy can be performed with excellent outcomes.

TH-PO597

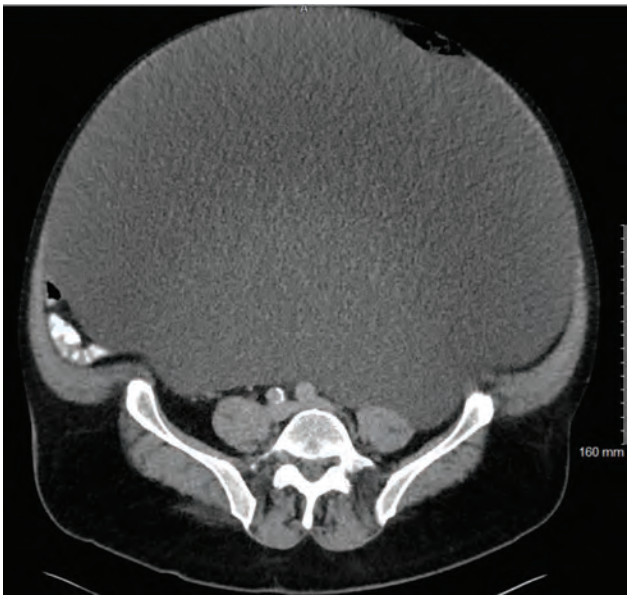
A Gigantic Renal Cyst Mimicking Ascites

Amita Maibam, Taha Ayach. *University of Kentucky, Lexington, KY.*

Introduction: The incidence of renal cyst increases with age above 50 years. Majority of the cyst are < 2cm and the reports of size >15cm are extremely rare. Here we present a peculiar case of a 75-year-old male with an exceptionally massive renal cyst, but unremarkable symptoms.

Case Description: A 74-year-old Caucasian male with history of type 2 diabetes mellitus and hypertension who was admitted to the hospital for evaluation of chest pain of cardiac origin. Incidentally on exam, he was found to have a protuberant abdomen with fluid wave concerning for ascites. He has no known history of liver disease and he reported gradual increase in abdominal girth for last 15 years. He was further evaluated with CT abdomen and pelvis which demonstrated numerous fairly simple appearing cysts noted to arise from both kidneys. The largest arises from the lower pole of the left kidney and measures 40 x 27 x 30 cm. He denies any family history of polycystic kidney disease. Patient underwent continuous percutaneous catheter placement in largest cyst with 20L of serous fluid removed over 2 days with negative microbiology, and with significant improvement in abdominal distention thereafter.

Discussion: Renal cyst should be considered as one of the differentials in patients with progressive distension of abdomen. To the best of our knowledge, this case represents the largest reported renal cyst. Our findings highlight the fact that benign renal cyst can grow over several years while remaining relatively asymptomatic, can mimic ascites and can pose diagnostic and therapeutic dilemma.



Computed tomography of abdomen showing bilateral renal cysts with the largest measuring 40 x 27 x 30 cm on the left kidney.

TH-PO598

CMV Nephritis with Glomerular Involvement

Mohammad Y. Alsawah. *Nephrology, St John Hospital & Medical Center, Detorit, MI.*

Introduction: Cytomegalovirus (CMV) infection is common in kidney transplant recipients, but infection related pathologic changes of the renal allograft are uncommon. Histologically, it presents with viral inclusions in tubular epithelial cells and interstitial inflammation. We describe a case of CMV nephritis with inclusions in glomerular endothelial cells without associated interstitial infiltrate or epithelial cell inclusions.

Case Description: A 17 year old African American male with history of ESRD from focal segmental glomerulosclerosis received a preemptive living kidney allograft from his mother. Both donor and recipient were CMV seropositive. Post-operatively, creatinine level plateaued at 2 mg/dL without significant proteinuria on serial monitoring. An allograft biopsy was performed for elevated creatinine level 5 weeks post-transplant showed no evidence of rejection or recurrence of the primary disease. Staining for both SV40 and CMV was negative. Three months postoperatively, the patient developed abdominal pain and weight loss. Abdominal CT scan showed no abnormalities. Gastric endoscopy showed mild gastritis. A peripheral blood quantitative CMV viral load by PCR was >3 million copies / ml. The patient's creatinine level increased to 2.5 mg/dL. A repeat allograft biopsy showed enlarged endothelial cells with cytoplasmic inclusion that stained positive for CMV. There was no evidence of capillary thrombosis, interstitial inflammation or tubular epithelial cell inclusions. Peripheral blood CMV viral load was elevated over 3 million IU/ml despite receiving maintenance valganciclovir post-transplant prophylaxis. CMV viral resistance pattern revealed a UL97 mutation. Viremia ultimately responded to increasing valganciclovir dose over a 5 months period of follow-up.

Discussion: CMV induced cell inclusions in kidney allograft recipients with CMV disease is uncommon and usually involves epithelial tubular cells. Bhadauria et al described CMV infection in 74 of 521 live donor kidney recipients (1). Only 4 cases developed histologically confirmed CMV allograft disease. In another review of 2900 kidney allograft indication biopsies only 4 cases of glomerular endothelial cells were described(2). Ganciclovir resistance occur in 2-4% of CMV infections (3), but there are no reports of association of this resistance with any specific pathologic findings on kidney biopsy.

TH-PO599

Everything Comes Down to Poo

Kapil Mahajan,[1,2] Shana M. Machado.[2] *[1]UT Health Houston, Stafford, TX; [2]UT-Houston Nephrology, Houston, TX.*

Introduction: Use of immunosuppressive agents can predispose transplant recipients to a variety of side effects like malignancies, infections, anemia. Anemia in post transplant period can be from several causes including delayed graft function, blood loss, infections. Here we present a case of anemia from Hemphophagocytic lymphocytosis (HLH) caused by Cytomegalovirus (CMV) colitis in a patient with negative CMV viremia

Case Description: A 54 yom was admitted for symptomatic anemia without active source of bleeding. He had a history of deceased donor renal transplant, CMV Donor negative/Recipient positive and EBV Donor positive/Recipient positive, complicated by delayed graft function. He had a history of chronic anemia, unresponsive to Epogen therapy. Bone marrow biopsy was done which demonstrated hemophagocytosis and atypical erythroblasts possibly related to viral infection. Immunostains for Parvovirus, EBV, CMV were negative. Due to RBC hypo-proliferation as well as development of diarrhea,

he was empirically started on IV ganciclovir for possible CMV colitis. He underwent colonoscopy with colon biopsy demonstrating distortion, increased chronic inflammatory cells, crypt atrophy, focal crypt abscess. Immunoperoxidase staining was positive for CMV. The etiology of patient's hemophagocytosis was from non-disseminated CMV. He was discharged home on oral valgancyclovir as well as outpatient clinic follow up

Discussion: Post transplant anemia can be due to medication side effects, frequent phlebotomy tests, slow graft function, viral infection. HLH is a syndrome of excessive inflammation and tissue destruction due to exaggerated immune response. Primary HLH is caused by a genetic mutation and secondary HLH occurs in autoinflammatory and autoimmune disease, lymphoma, viremia, iatrogenic immunosuppression. It is diagnosed if there is a mutation in a known causative gene or if at least 5 of 8 diagnostic criteria are met: fever, splenomegaly, cytopenia involving > 2 cell lines, hypertriglyceridemia or hypofibrinogenemia, biopsy proven hemophagocytosis, low or absent natural killer cell activity, elevated serum ferritin, elevated CD25 levels. The pathogenesis of HLH is not well understood. Impairment of Natural killer-cell (NK-cell) function caused by viral infections can lead to persistent activation of macrophages and production of cytokines. When HLH is triggered by a viral infection, treatment of the underlying viremia is recommended

TH-PO600

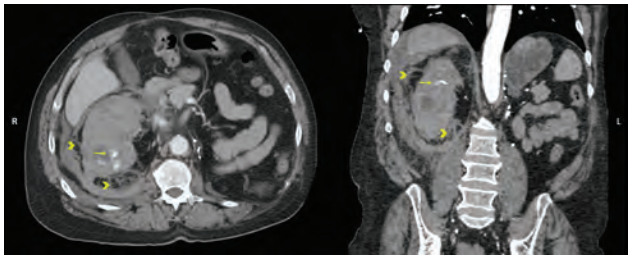
Spontaneous, Non-Traumatic Renal Hemorrhage: An Under-Recognized Entity

Gajapathiraju Chamarthi, Abhilash Koratala. *University of Flroida, Gainesville, FL.*

Introduction: We present a case of spontaneous, non-traumatic renal hemorrhage in a patient with end-stage renal disease (ESRD), also known as Wunderlich syndrome.

Case Description: A 61-year-old man with ESRD, on hemodialysis for two years, left renal cell carcinoma status post nephrectomy 20 years ago, hypertension and 40 pack-years smoking history presented to our institution for sudden-onset right flank pain radiating to the right leg. His blood pressure at presentation was 130/90 mmHg, pulse 98 bpm and physical examination was significant for tenderness over the right flank without signs of peritonitis. Laboratory testing was significant for a drop in hemoglobin to 7.9 g/dL from a baseline value of ~11 g/dL. Platelet count and international normalized ratio were within normal limits. A computed tomography (CT) scan of the abdomen demonstrated acute hemorrhage throughout the right kidney extending into the anterior and posterior pararenal spaces. In addition, there was extravasation of contrast at the upper pole, indicating active bleeding [Figure 1]. There was no obvious underlying renal mass or evidence for acquired cystic kidney disease. He underwent renal artery angiogram and embolization using lipiodol-ethanol mixture and gelfoam. His blood count subsequently stabilized and was discharged in stable condition.

Discussion: Wunderlich syndrome, first described in 1856 is a rare condition characterized by acute spontaneous, non-traumatic renal hemorrhage into the subcapsular and perirenal spaces. Patients may present with the classic 'Lenk's triad' of symptoms consisting of acute flank or abdominal pain, a palpable flank mass, and hypovolemia but the presentation is variable and non-specific in most cases. CT scan is the imaging modality of choice and treatment often includes renal artery embolization or nephrectomy, depending on the severity. It is important to note that ESRD patients are predisposed to bleeding diathesis in the setting of uremic platelet dysfunction, anemia, increases in nitric monoxide, irregularities in von Willebrand factor and impaired platelet-vessel wall interaction.



TH-PO601

Young African American Male with Mild Bilateral Hydronephrosis and Kidney Failure

Thuan V. Nguyen,[1] Caprice Cadacio,[1] Phuong-Thu T. Pham,[2] Phuong-Chi T. Pham.[1] *[1]Olive View-UCLA Medical Center, Los Angeles, CA; [2]UCLA Medical Center, Los Angeles, CA.*

Introduction: Retroperitoneal fibrosis (RPF) is a rare condition that requires high clinical suspicion for prompt diagnosis as routine imaging studies may be nondiagnostic.

Case Description: A 27-year old African American man presents with a 4-week history of constant aching pain of abdomen and back without associated consitutional symptoms. Past history: unprovoked deep venous thrombosis of right leg and a recent episode of scotal swelling/ejaculation difficulty Medication: apixaban Exam: ill-appearing, blood pressure 130/75 mmHg Unremarkable cardiopulmonary exam, minimally tender abdomen, bilateral costovertebral angle tenderness, trace bilateral lower leg edema Labs: Na 133, K 5.0, total CO_2 25 meq/l, blood urea nitrogen 57 mg/dl, creatinine 12.55 mg/dl Urinalysis bland Renal ultrasound: mild hydronephrosis Abdominal/pelvis CT without contrast: mild bilateral hydroureteronephrosis with inflammatory changes, no obvious mass/lymphadenopathy. At the insistence of the renal team to rule out RPF, a CT urogram was performed which revealed an infiltrative mass encasing aorta, inferior vena cava, and commmon iliac vessels. Evaluation for infectious, malignant, and vasculitic etiologies was negative. Laparoscopic biopsy revealed dense fibroadipose tissue, lymphocytic aggregates, focal scattered IgG4-positive plasma cells, and fibrin deposition. IgG4-related disease criteria not met. Patient underwent bilateral nephrostomy placement with resolution of kidney failure with plan to initiate corticosteroids for presumed idiopathic RPF.

Discussion: RPF is a relatively rare condition that involves chronic inflammatory and fibrotic changes in the retroperitoneum that can lead to encasement and compression of retroperitoneal structures. Implicated etiologic factors including drugs, malignancy, infections, radiation, and trauma may be present in 30% of cases and idiopathic in all others. Prompt diagnosis relies on recognition of a classic clinical presentation (Figure) as initial imaging studies (non-contrast CT or ultrasound) may be falsely negative for significant obstruction.

Figure 1. Renal ultrasound shows increased renal cortical echogenicity and mild hydronephrosis

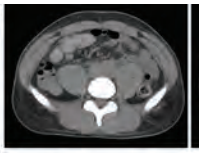


Figure 2. Abdomen/pelvis CT without contrast. Ill-defined, infiltrative soft tissue mass encasing both aorta and inferior vena cava. (Initially read as negative for mass or lymphadenopathy)

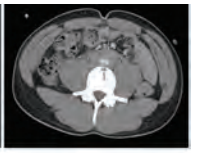

Figure 3. Abdomen/pelvis CT with contrast. 7.2cm mass encasing the aorta and inferior vena cava.

Clinical presentation of retroperitoneal fibrosis:
Typically affects patients between the ages of 40 and 60 years; Male predominance 2:1 to 3:1
Symptoms: generalized malaise, weight loss, nausea, oliguria, anuria; constant dull pain involving lower back and/or flank with radiation to groin or lower abdomen; testicular pain; deep venous thrombosis and lower extremity edema (compression of inferior vena cava); leg claudication (arterial compression); mesenteric ischemia (compression of mesenteric arteries)

TH-PO602

Rhabdomyosarcoma: A Frightening Differential for Bladder Outlet Obstruction (BOO) in Children

Elizabeth Wei,[2] Mohammed Khurram Faizan,[1,2] Robin A. Kremsdorf.[1,2] *[1]Pediatric Nephrology, Hasbro Children's Hospital, Providence, RI; [2]Pediatrics, Warren Alpert Medical School, Providence, RI.*

Introduction: Posterior urethral valves (PUV) are the most common cause of bladder outlet obstruction (BOO) in children. While many children are diagnosed prenatally on ultrasound, a few children may occasionally present outside of the neonatal period. In toddlers, bladder outlet obstruction can present with history of dribbling or weak urinary stream, and more often, following a febrile urinary tract infection. While PUV remains the most common cause of BOO in male children beyond the neonatal period, other etiologies for BOO must be considered, including urethral strictures, ureteroceles, bladder diverticula, and masses. We describe a case of rhabdomyosarcoma presenting with bladder outlet obstruction.

Case Description: 13month old previously healthy full term Caucasian male presented with two weeks of constipation, decreased appetite, decreased urine output, and concern for dehydration. On exam, he had hypertension, a distended, tender abdomen, and normal external genitalia. Labs were notable for CO2 of 10mEq/dL, BUN 83mg/dL, creatinine 1.4mg/dL, and WBC 17.6 $x10^9$/L. Abdominal Xray was unremarkable. Ultrasound revealed a distended bladder and bilateral hydronephrosis consistent with BOO. Pt experienced significant clinical improvement following urethral catheter placement; his creatinine improved to 0.2mg/dL. On voiding cystourethrogram (VCUG) for evaluation of posterior urethral valves, he was found to have a 2.9 x 2.8cm lobulated prostatic mass with invasion into the bladder. Biopsy revealed embryonal rhabdomyosarcoma. At this time, he continues on chemotherapy and radiation therapy.

Discussion: Rhabdomyosarcoma is the most common pediatric soft tissue sarcoma and accounts for 7-8% of all solid malignant tumors in children. It has a bimodal age distribution, affecting children less than two years old and adolescents. 15-20% arise from genitourinary sites. Bladder and prostate rhabdomyosarcoma can present with symptoms of bladder outlet obstruction, as in this patient. Prognosis and morbidity is dependent on staging, histology, age, and the extent of bladder sparing interventions. Rhabdomyosarcoma remains a rare, but important cause of bladder outlet obstruction in infants and toddlers. In children presenting with new onset obstructive uropathy, a broad differential including malignancy must be considered as prompt diagnosis allows for definitive therapy.

Rare Type of Pyelonephritis

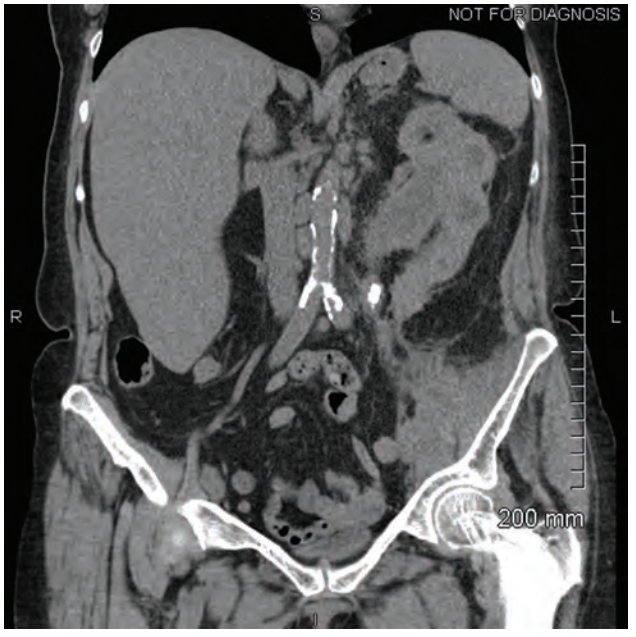
Mohammad Madani,[1] Joseph Schmidt.[2] *[1]Aurora St. Luke's Medical Center, Milwaukee, WI; [2]Aurora Medical Group, Wauwatosa, WI.*

Introduction: Xanthogranulomatous pyelonephritis (XGP) is a rare chronic destructive granulomatous inflammatory process of renal parenchyma accounting for 0.6% of histologic cases of chronic pyelonephritis. Exact etiology is unknown however this process is associated with long term obstruction and infection. The aim of this case report is to enhance awareness of this rare condition in an effort to prevent delayed treatment and adverse outcomes.

Case Description: A 69 year old woman presented with left hip and flank pain of 3 weeks duration. Vital signs were as follows: temp 98.5, 104 HR, 16 RR, BP 133/64. Physical exam revealed left costovertebral angle tenderness. Labs were notable for leukocytosis WBC 16.5, hemoglobin 8.4, hematocrit 26.9, MCV 83.5, creatinine 1.7, BUN 18 mg/dL. Urinalysis revealed >100 WBCs, positive nitrite, moderate leukocyte esterase. She

underwent CT scan of the abdomen pelvis which revealed severe cystic replacement of left renal parenchyma, perinephric inflammatory changes, left ureteral calculus distal to the left UPJ, and left psoas muscle fluid collection (figure). IV antibiotics and pain medication were given. A nephrostomy tube and drain was placed with cultures showing E coli. She remained afebrile and had satisfactory drain outputs. She underwent left radical open nephrectomy and adequate postoperative recovery. Specimens showed no distinct corticomedullary junctions, granulomatous inflammation and cholesterol clefts.

Discussion: Clinical presentation of XGP may be vague. Its diffuse or advanced stage typically requires nephrectomy. Antibiotics may be used for treatment of focal or bilateral XGP. In summary, this case highlights many features characteristic for a rare type of chronic pyelonephritis with associated psoas abscess complication. Maintaining a high index of suspicion for this condition leading to an accurate and earlier diagnosis may influence prognosis.



TH-PO604

Encrusted Pyelitis in a Patient with Solitary Functional Kidney

Meghana Chalasani, Bruce Horowitz, Josephine Abraham. *University of Utah, Salt Lake City, UT.*

Introduction: Encrusted pyelitis is a rare infectious disease affecting the urothelium and is usually caused by *Corynebacterium urealyticum*, a non-hemolytic gram-positive bacillus.

Case Description: A 79-year old woman with a history of urothelial carcinoma and atrophic left kidney was found on a surveillance abdominal CT scan to have linear calcifications within the collecting system of the right kidney with bilateral urothelial thickening concerning for encrusted pyelitis. Patient was diagnosed with urothelial carcinoma after a CT scan done for evaluation of painless hematuria showed severe left hydronephrosis with a focal enhancing mass at the left uretero-vesicular junction. She did not have evidence of metastases and underwent radical cystectomy with ileal conduit. Scan two months later showed resolution of left hydronephrosis, atrophic left kidney, and normal right kidney. CT scan three months later showed diffuse atrophy of the left kidney with minimal enhancement of the left renal artery, consistent with chronic ischemia and right-sided alkaline encrusted pyelitis. Patient reported urinary discoloration but no fever or dysuria. Serum creatinine remained unchanged. Urine culture was obtained and patient was started on ciprofloxacin. Urine culture was negative. Patient stopped taking the antibiotic due to shoulder pain. Urinalysis one month later showed a pH of 7.5, 5-10 red blood cells and 5-10 white blood cells per high power field, and a large leukocyte esterase. Culture was again negative. CT scan 2 months later showed progression of calcifications. A 24-hour urine stone risk profile is being considered.

Discussion: Encrusted pyelitis is a consequence of lithiasis due to urea-splitting organisms, particularly *Corynebacterium urealyticum*. Urea is hydrolyzed via urease to ammonium thereby alkalinizing the urine and promoting the formation of magnesium ammonium phosphate stones. Risk factors include endourological procedures, renal transplant, immunosuppression, and prolonged broad-spectrum antibiotics. Complications are ureteral stenosis, renal abscesses, and obstructive uropathy with resultant end-stage renal disease. Diagnosis is suggested by urine culture isolation of a culprit organism and unenhanced imaging which classically shows calcified encrustations in the wall of the urinary tract. Treatment involves antibiotic therapy for at least fourteen days and acidification of the urine.

Changes in Gene Expression of Hypothalamic Neuropeptides Controlling Feeding Regulation in Bilaterally Nephrectomized Rats

Hiromichi Ueno,[1] Tetsu Miyamoto,[2] Kenya Sanada,[4] Yoko Fujimoto,[1] Kenichiro Bando,[3] Yoichi Ueta,[1] Yutaka Otsuji,[1] Masahito Tamura.[5] *[1]University of Occupational and Environmental Health, Kitakyushu, Japan; [2]Second Department of Internal Medicine, Kitakyushu, Fukuoka, Japan; [3]University of occupational and environmental health, Kitakyushu, Japan; [4]University of Occupational and Environmental Health, Japan, Kitakyushu-shi, Japan; [5]University of Occupational & Environmental Health, Kitakyushu, Japan.*

Background: Anorexia is one of the most widespread eating disorders that appears to contribute to malnutrition in patients with advanced renal dysfunction. While several mechanisms underlying uremic anorexia have been proposed, the hypothalamic neuropeptides that regulate feeding in the hypothalamus of uremic patients are poorly understood. These neuropeptides act both on the hypothalamus and other appetite-regulating centers throughout the brain.

Methods: We evaluated the gene expression of hypothalamic feeding-regulating neuropeptides after bilateral nephrectomy, a model of acute renal dysfunction. Adult male rats received bilateral nephrectomy or a sham operation. The rats were decapitated at 6, 12, and 24 h after treatment. The brains were removed immediately, frozen on dry ice. The brains were then cut into 12-μm-thick sections using a cryostat and the locations of the hypothalamic areas, including the paraventricular nucleus (PVN), arcuate nucleus, and lateral hypothalamic area, were determined according to the coordinates of a mouse brain atlas. The gene expression of corticotrophin-releasing hormone (CRH) in the PVN; propiomelanocortin (POMC), cocaine- and amphetamine-regulated transcript, neuropeptide Y, agouti-related peptide in the ARC; and melanin-concentrating hormone and orexin in the LHA, were quantified by in situ hybridization histochemistry. After treatment, cumulative food intake, water intake, and body weight were measured.

Results: The mRNA levels of *POMC* and *CRH*, which suppress feeding behavior, were significantly increased after bilateral nephrectomy compared with sham-operated rats. The food intake of nephrectomized rats decreased compared with sham-operated rats, but there was no difference in body weight and water intake between both groups.

Conclusions: The results suggest that *POMC* and *CRH* in the hypothalamus may be involved in the development of anorexia in bilateral nephrectomized rats. This report may provide new insights into the physiological mechanism underlying anorexia in patients with renal dysfunction.

CD147/Basigin Is Involved in the Pathogenesis of Hepato-Renal Disease Under the Status of Satiation and Starvation

Akihiro Ryuge,[1] Tomoki Kosugi,[1] Yuka Sato,[2,1] Shoichi Maruyama.[1] *[1]Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]University of Colorado, Aurora, CO.*

Background: Gluconeogenesis from lactic acids and ketogenesis from fatty acids are critical for maintaining energy homeostasis and physiological activity during starvation in mammals. Besides ATP production necessary for substance transport by themselves, the kidneys are constantly complementing energy production of the liver which is a critical regulator in this setting. Therefore, excessive accumulation of glycogen and fat in metabolic syndrome causes chronic kidney disease and non-alcoholic fatty liver disease (NAFLD). CD147/Basigin (Bsg), a glycosylated transmembrane protein, is involved in glycolysis-lactate metabolism on carcinogenesis. We therefore investigated on physiologic functions of Bsg in energy metabolism under the status of satiation and starvation.

Methods: Two independent mice models were performed using wild-type ($Bsg^{+/+}$) or Bsg-deficient ($Bsg^{-/-}$) mice treated with high fat diet (HFD) or starvation (free drinking water), respectively.

Results: Levels of blood glucose (BS) and liver ATP in standard diet-fed $Bsg^{-/-}$ mice were lower than those of $Bsg^{+/+}$ mice. Alternatively, activation of β-oxidation and autophagy were observed in the kidneys and liver of $Bsg^{-/-}$ mice. AMPK activation was also found in $Bsg^{-/-}$ liver. BS suppression in tolerance tests for pyruvate or alanine was exhibited, indicating that $Bsg^{-/-}$ mice showed a reduction of gluconeogenesis. In accordance with these findings, HFD-fed $Bsg^{-/-}$ mice ameliorated tubulointerstitial injury showing vacuolar formation, disease activity of NAFLD, and insulin resistance. Of note, starved $Bsg^{-/-}$ mice became NAFLD as well. This phenomenon might be caused by autophagic activation leading to the accumulation of triglyceride. Regardless of lower ATP values in $Bsg^{-/-}$ mice, surprisingly, life survival of $Bsg^{-/-}$ mice was similar with that of $Bsg^{+/+}$ mice. The kidneys may compensate for energy shortage of $Bsg^{-/-}$ mice by activation of ketogenesis. Indeed, HMGCS2 that catalyzes the first reaction of ketogenesis was induced in $Bsg^{-/-}$ kidneys, but not liver.

Conclusions: CD147/Basigin is involved in the pathogenesis of hepato-renal disease through the regulation of autophagy, gluconeogenesis and ketogenesis under the status of satiation and starvation.

TH-PO607

Defining the Renoprotective Mechanism of Deiodinase 3 in Podocytes

Nicholas J. Tardi, Ranadheer Dande, Jochen Reiser. *Rush University Medical Center, Chicago, IL.*

Background: Deiodinase 3 (D3) is a membrane-bound enzyme that reduces local thyroid hormone signaling in most cell types. By preventing the bioavailability of tri-iodothyronine

(T3), the metabolically active thyroid hormone, D3 efficiently regulates thyroid signaling in tissues to modulate vital processes such as metabolism. While deiodinases have been studied in several endocrine tissues, the role of D3 in controlling T3 in renal tissue has not been addressed, despite emerging studies demonstrating overlapping complications of kidney disease and thyroid hormone dysfunction. As numerous glomerulopathies can stem from energetic dysfunction of podocytes, which have mechanisms that respond to both glomeruli derived and circulating changes in hormone levels, we aimed to determine the significance of D3 dysfunction in podocyte derived kidney disease.

Methods: D3 expression was measured via qRT-PCR, Western blot and confocal analysis. Regulatory capacity of D3 was analyzed via a T3 cleavage assay. The role of D3 in podocyte derived kidney disease was evaluated *in vitro* by inducing injury to cultured podocytes and *in vivo* using podocyte specific D3 KO mice challenged with LPS. Renal dysfunction was assessed by urine Albumin:Creatinine ratio and by quantifying effacement (processes/ GBM length). Cytoskeletal, metabolic and protein trafficking markers were measured in lentiviral-driven D3 knockdown podocytes to determine the renoprotective mechanism of D3. Glomerular D3 expression was measured in renal biopsies from kidney disease patients by immunofluorescence intensity.

Results: D3 is highly expressed in podocytes and downregulated in injury models, resulting in compartmentalization of D3 in the golgi and nuclear region where metabolically active T3 resides. Podocyte specific D3 KO mice responded poorly to LPS-induced kidney injury, resulting in heavy proteinuria and foot process effacement compared to control. Biomarkers of metabolic stress and impaired protein trafficking were upregulated in D3 deficient podocytes. D3 expression in glomeruli of kidney disease patients suffering from minimal change disease, diabetic nephropathy, or focal segmental glomerulosclerosis showed unique profiles amongst diseases.

Conclusions: D3 plays a renoprotective role against thyroid hormone associated kidney disease in podocytes. We propose D3 reduces energy expenditure to prevent podocyte exhaustion and death.

TH-PO608

Caloric Restriction Improves Established Proteinuria in Adriamycin-Induced Nephropathy

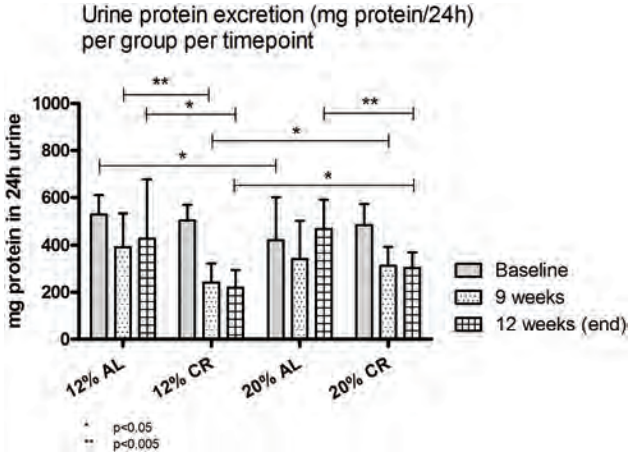
Jürgen Sijbesma, Aren V. Waarde, Stephan J. Bakker. 1Dept. of Nuclear Medicine and Molecular Imaging *University Medical Center Groningen, Roden, Netherlands*.

Background: Reduction of proteinuria is an important strategy to prevent loss of kidney function. Preclinical studies suggest that caloric restriction (CR), induced at young age, protects against age-related proteinuria. None of these studies investigated the effect of CR in established renal disease. We hypothesized that CR in established proteinuria reduces urinary protein excretion (UPE).

Methods: Male Wistar rats (n= 56; age 12± 2 wk) were intravenously injected with 2.1mg/kg Adriamycin. At 6 wks after injection, baseline UPE was measured. At 7 wks after injection rats were randomly assigned to 4 groups: An ad libitum (AL) and a CR group (60% of AL food intake) fed with a 12% protein diet (12%AL, 12%CR) and an AL and a CR group fed with a 20% protein diet (20%AL, 20%CR). All groups were treated for 12 wks. UPE was measured at wk 9 and 12 and mean arterial blood pressure (BP) at the end of the study.

Results: Baseline UPE was similar in all groups (p>0.20) with a median value of 495 and an interquartile range of 127mg/24h. After 12 wks of diet, all animals exposed to CR had a 20.3% lower UPE (p=0.003) compared to AL fed animals. At wk 9 this effect was only seen in the 12%CR group. BP in animals exposed to CR was -21.2% lower (p<0.0001) compared to AL fed animals.

Conclusions: Caloric restriction lowers UPE and BP in rats with established proteinuria. Protein restriction was effective if applied in combination with CR. These results may guide future intervention studies in patients with proteinuric and obesity-related nephropathy.



TH-PO609

Renal Adverse Effects of Long Term Whey Supplementation with Resistance Training in Rats

Atilla Kunt,[1] Omer faruk Ozer,[4] Ganime Coban,[3] Ali Toprak,[5] Rumeyza Kazancioglu.[2] *[1]School of Medicine, Bezmialem Vakif University, Istanbul, Turkey; [2]Nephrology, Bezmialem Vakif University, Istanbul, Turkey; [3]Pathology, Bezmialem Vakif University, Istanbul, Turkey; [4]Biochemistry, Bezmialem Vakif University, Istanbul, Turkey; [5]Biostatistics, Bezialem Vakif University, Istanbul, Turkey.*

Background: The usage of whey protein is already widespread; as resistance trainers and in-patients use whey protein alike. There is reliable evidence against other supplements, it is lacking for whey protein. The aim of the study was to identify the adverse effects of whey protein usage on kidneys.

Methods: 48 young male albino wistar rats are divided into 6 (n=8); Normal (20%) Protein(NP)-Sedentary(NPS), NP-Resistance training(NPRT), High(45%)Protein(HP) Sedentary(HPS), HP-Resistance Training(HPRT), Abuse(70% Protein)(A)-Sedentary(AS), and Abuse-Resistance Training(ART) groups. The rats were fed ad libitum. Training was maintained by resistance protocol in a motorised treadmill. On days 1 and 90 12 hour urine and blood samples were collected. Urea, microalbuminuria and pH were detected in the urine. Blood analysis included: Albumin, Blood Urea, Creatinine, CRP and NGAL. Rats were killed and histopathologically analyzed. Tissue samples were fixed with 10% formalin and stained with H&E, Kongo Red stains. Statistics were done by Kruskal Wallis test.

Results: Results are shown in Table 1. Histopathological examination shows congestion and tubular damage on HP-RT, A-RT, and HP-S groups. There was no sclerosis or glomerular damage present in any of the groups.

Conclusions: Whey protein intake created a dose-response in causing significant microalbuminuria and tubular destruction in our study. This supports the suggestion that long-term intakes of protein at the upper limits from whole protein sources may compromise renal health.

The Effects of Whey Protein Intake on Bone Mineral Metabolism in Rats

Atilla Kunt,[1] Omer faruk Ozer,[3] Ali Toprak,[2] Rumeyza Kazancioglu.[4] *[1]Faculty of Medicine, Bezmialem Vakif University, Istanbul, Turkey; [2]Biostatistics, Bezialem Vakif University, Istanbul, Turkey; [3]Biochemistry, Bezmialem Vakif University, Istanbul, Turkey; [4]Nephrology, Bezialem Vakif University, Istanbul, Turkey.*

Background: High protein intake affects the blood and urine phosphate levels. Phosphate is shown to be correlated with FGF-23. The aim of the study is to investigate the the effects of Whey Protein intake on the whole cascade of bone mineral metabolism.

Methods: 48 young male albino wistar rats are divided into 6 (n=8); Normal (20%) Protein(NP)-Sedentary(NPS), NP-Resistance training(NPRT), High(45%)Protein(HP) Sedentary(HPS), HP-Resistance Training(HPRT), Abuse(70% Protein)(A)-Sedentary(AS), and Abuse-Resistance Training(ART) groups. The rats were fed ad libitum. Training was maintained by resistance protocol in a motorised treadmill. On days 1,30, 60 and 90 a 12 hour urine sample and a blood samples were collected from each animal. Calcium, phospate were detected in the urine. The blood analysis included: LDH, Albumin, calcium, phosphate. FGF-23 and vit-D was analysed by ELISA.

Results: Results are shown in Table1.

Conclusions: Whey Protein intake negatively affected the the bone mineral metabolism and created a dose-response while training has an alleviating positive effect. Serum, urine phosphate and FGF-23 were shown to be significantly correlated and supports such studies.

Funding: Clinical Revenue Support

TH-PO611

Monounsaturated Fatty Acids Protect Proximal Tubules from Lipotoxicity

Albert Perez-Marti, Geraldine Mollet, Corinne Antignac, Matias Simons. *Institut Imagine, Paris, France*.

Background: A disrupted glomerular filtration barrier, such as in nephrotic syndrome, causes loss of serum albumin into the urine. As albumin is an important carrier of fatty acids (FAs), the increased exposure of the tubular nephron to FAs may contribute to disease progression. This is particularly the case for FAs such as palmitic acid (PA) as their saturated acyl chains are known to damage the endoplasmic reticulum (ER) and mitochondria. To cope with excess lipids, FAs can be esterified with glycerol and deposited as triglycerides in cytoplasmic lipid droplets (LD). Here, we addressed the question in how far lipid unsaturation promotes lipid storage and thereby prevents lipotoxicity in proximal tubular cells.

Methods: *in vitro* experiments with PA and oleic acid (OA) were performed on iREC (induced renal tubular epithelial cells) and HK-2 cells. The inducible conditional knockout mouse of *Nphs2* was used as an *in vivo* model of nephrotic syndrome. Mice were maintained on MUFA (monounsaturated fatty acids) or SFA (saturated fatty acids) diets two weeks before Cre induction until death.

Results: To mimic the overexposure of proximal tubules to albumin that takes place during nephrotic syndrome, iRECs were treated with different doses of albumin-FAs. While the treatment with PA-BSA resulted in the upregulation of ER stress markers and decreased cell survival, the additional treatment with OA-BSA completely rescued the phenotypes. To assess the capacity of OA to sequester saturated FAs into LDs, we analyzed lipid droplet formation. In contrast to PA, OA increased LD formation, which occurred in a DGAT1/2 dependent manner. Moreover, lipid trafficking studies with the fluorescent analog of a saturated fatty acid BODIPY-C12 showed that co-treatment with OA shifted BODIPY-C12 from the ER into LDs. Finally, our preliminary *in vivo* data suggest that Nphs2 KO mice live longer with MUFA diet compared to SFA diet.

Conclusions: Collectively, our work shows that OA protects renal tubular cells from lipotoxicity by channeling PA into LDs. Our findings suggest that promotion of unsaturation and, thereby, lipid storage can improve the homeostasis of PTs during nephrotic syndrome and, thus, ameliorate the progression of the disease.

GCN5-Like Protein 1 Controls Lipotoxicity in Proximal Tubule Cells by Regulating Fatty Acid Oxidation via Mitochondrial Enzyme Acetylation

Wei Xin,[1] Tingting Lv,[3] Yanyan Hu,[2] Hongjun Sun,[3] Qiang Wan.[3] *[1]Shandong Provincial Hospital affiliated to Shandong University, Jinan, China; [2]Tai'an City Central Hospital, Tai'an, China; [3]Shandong Provincial Qianfoshan Hospital affiliated to Shandong University, Jinan, China*.

Background: Lipotoxicity termed as the accumulation of satuarated nonesterified fatty acid (NEFA) and their metabolites playS a vital role during the progression of chronic kidney disease (CKD). NEFA catabolism is mainly through the b-oxidation in mitochondria. Due to a high energy demand and relatively little glycolytic capacity, fatty acid oxidation (FAO) is particularly important for the proximal tubule cells. However, the upstream mechanisms remain unclear. Lysine acetylation is a reversible post-translational modification, and is particularly important in the regulation of mitochondrial metabolic enzymes. However, the effects of acetylation status on the NEFA b-oxidation and lipotoxicity in the proximal tubule cells remains unclear. In this study, we aimed to investigate how FAO rate in the tubule cells is controlled by mitochondrial acetylation status and how these changes affect lipotoxicity.

Methods: Human proximal tubular epithelial cells (HK-2) were stimulated with palmitic acid (PA) and C57BL/6 mice were received a high-fat diet (HFD) for 18 weeks. The expression of acetylated-lysine and GCN5-like Protein 1 (GCN5L1) were detected by both immunohistochemistry and western blot. The immunoprecipitation assay was used to evaluate the acetylation levels of long-chain acyl-CoA dehydrogenases (LCAD) and 3-hydroxyacyl-CoA dehydrogenase (β-HAD). Fatty acid β-oxidation rate, triglyceride content, ac-CoA, and the activity of LCAD and β-HAD were assessed by appropriate kits.

Results: The expression of total lysine acetylation was increased in palmictic acid (PA) cultured HK-2 cells and high-fat feeding mice kidneys. PA induced LCAD and β-HAD hyperacetylation and reduced enzymatic activity along with decreased fatty acid oxidation rate and ac-CoA contents. Interestingly, GCN5L1 was upregulated in vivo and vitro high fat conditions. Finally, the silence of GCN5L1 in HK-2 cells led to the deacetylation of LCAD and β-HAD and accelerated FAO rate, which eventually attenuated lipid deposition.

Conclusions: The acetylation of mitochondrial proteins supressed FAO in renal proximal tubule cells. GCN5L1 suppression attenuates lipotoxicity by upregulating FAO via reversible mitochondrial enzyme LCAD and β-HAD acetylation. The manipulation of acetylation status might act as a promising therapeutic intervention for lipotoxicity in CKD.

Effect of Exogenous Supplementation with Alpha Lipoic Acid on Nuclear Reduced Glutathione Levels in Rat Kidney Cortex and Medulla

Marianna J. Zamlauski-Tucker, Bingwei Ye. *Ball State University, Muncie, IN*.

Background: Dietary supplementation with the antioxidant alpha lipoic acid has been found to increase reduced glutathione (GSH) levels in mitochondria from kidney and heart tissue in old rats. GSH is the major antioxidant inside cells and provides protection against damage by free radicals produced as a consequence of oxidative metabolism. The purpose of this study was to investigate the effect of dietary supplementation with alpha lipoic acid on GSH levels in the nucleus of rat kidney cells.

Methods: Old female Experimental Lewis rats (22 months of age; n = 4) received alpha lipoic acid (100 mg/Kg of body wt) via i.p. injection for one week. Age-matched Control rats (n = 4) did not receive any supplementation. The kidneys were harvested from anesthetized rats and the cortex and medulla were separated and homogenized. The nuclear fractions were isolated using differential centrifugation. The GSH and total glutathione (Tot GLUT; GSH plus oxidized GSH) were measured using a spectrophotometric assay. GSSG (oxidized GSH) levels were estimated from the difference between Tot GLUT and GSH levels and then divided by 2. Comparisons were done using a Student' s T Test.

Results: There were significant increases in GSH and Tot GLUT levels in both the kidney cortex and medulla with dietary supplementation.

Conclusions: These findings suggest that dietary supplementation with alpha lipoic acid may also be beneficial to cell nuclei in rat kidney by increasing the GSH levels and thus, providing protection against free radical damage.

Effect of Alpha Lipoic Acid on Nuclear GSH Levels in the Rat Kidney

Inhibiting Na/K-ATPase Oxidant Amplification Loop Regulates Aging in C57B16 Old Mice

Rebecca L. Klug,[1] Rebecca Pratt,[3] Jiang Liu,[1] Zi-jian Xie,[2] Komal Sodhi,[1] Joseph I. Shapiro.[3] *[1]Marshall University, Joan C. Edwards School of Medicine, Huntington, WV; [2]Marshall University, Huntington, WV; [3]Marshall University School of Medicine, Huntington, WV*.

Background: Aging is driven by accumulation of oxidative damage; Na/K-ATPase signaling amplifies oxidants and is linked to several oxidation-related diseases. The progressive decline of physiological integrity, manifests as: loss of cell division, oxidative stress, DNA damage and overexpression of senescence genes. Oxidant stress causes cellular and DNA damage contributing to impaired physiological function, disease development, and life span reduction. As we identified, the Na/K-ATPase amplifies oxidant signaling and we speculate that a peptide inhibiting this pathway, pNaKtide, may be effective to regulate cellular senescence, thus delaying and/or reversing aging by attenuating oxidative stress.

Methods: Using human fibroblasts we evaluated levels of senescence markers, cell injury, apoptosis, and Na/K-ATPase signaling activation, with and without pNaKtide. C57Bl6 male mice, young (4 months) and old (17 months) were fed normal chow diet or Western Diet (WD). They were randomly divided into 6 groups: (1) Young Control, (2) Young+pNaKtide (3) Old+Control, (4) Old+pNaKtide (5) Old+WD, (6) Old+WD+pNaKtide. After 8 weeks of control or WD diet, groups 2, 4 and 6 were injected with pNaKtide, (intraperitoneal dose of 25-mg/kg, every 7 days for 8 weeks). Tissues from liver, kidney, and heart were evaluated markers of aging and Na/K-ATPase signaling activation.

Results: Fibroblasts exposed to oxidative stress underwent oxidation-induced senescence and had increased levels of senescence markers, cell injury, apoptosis, and

Na/K-ATPase signaling activation. Treatment with pNaKtide significantly reversed those levels. Levels of aging markers and oxidant stress in old mice were higher than those of young mice. Among cardiac and adipose tissues, senescence, apoptosis and oxidant stress were exacerbated in old mice and even more so when fed WD. pNaKtide treatment significantly reversed levels of aging markers in old mice regardless of diet.

Conclusions: These data show that Na/K-ATPase signaling is intimately involved in the aging process and may serve as a target for anti-aging interventions. pNaKtide inhibited amplification of the oxidant signalling via blocking the Na/K-ATPase pump thus alleviating genetic and phenotypic attributes of aging. pNaKtide holds potential as a novel drug for treating cellular damage that contributes to manifestations of aging and WD.

TH-PO615

Effects of Gemfibrozil on Fatty Acid Induced Insulin Resistance in Adipocytes

Madhura Bose,[2] Sharma S. Prabhakar.[1] *[1]Texas Tech University Health Sciences Center, Lubbock, TX; [2]Texas Tech University, Lubbock, TX.*

Background: Hyperlipidemia, specifically hypertriglyceridemia has been incriminated in contributing to insulin resistance in diabetes. However it is unclear if correcting hypertriglyceriemia improves insulin sensitivity and prevent diabetes in the context of metabolic syndrome. We hypothesized that reduction of lipid uptake by adipocytes using gemfibrozil would improve insulin signaling and facilitate glucose transport.

Methods: Mouse 3T3-L1 preadipocytes were differentiated into adipocytes by commercial differentiation cocktail and were stimulated with fatty acids 1 mM of palmitate (C16:0), oleate (C18:1), and linoleate (C18:2) for 24 hrs on 8th day of differentiation. The fatty acid treated adipocytes were labeled as obese while the fatty acid untreated cells were labelled as lean. The obese cells were further treated with Gemfibrozil (10 μM, 25 μM, 50 μM and 100 μM) for 72 hrs. Triglyceride assay and Oil red O staining were performed to determine lipid droplet accumulation. Cell lysates were used to study expression of insulin signaling proteins by western blot analysis. For determining the expression of GLUT4, membrane fraction was separated from the cytosolic fraction.

Results: Upon incubation with fatty acid mixture, the lipid content in adipocytes significantly increased (obese cells) compared to untreated cells (lean cells). Gemfibrozil treatment decreased triglyceride content in the obese cells in a dose dependent manner with a significant change even at the lowest concentration of 25 μM. This data was further supported by reduction in lipid droplet accumulation in the obese cells as observed by Oil Red O staining. Western blot data revealed that gemfibrozil at 25 μM decreased IRS-1 phosphorylation at Ser 307 which is significantly increased in obesity and insulin resistance. Gemfibrozil also increased Akt phosphorylation which was decreased in the obese cells. GLUT 4 expression in whole cell lysate remain unchanged but increased in the membrane fraction of treated obese cells. Moreover investigation of upstream signaling showed that gemfibrozil reduced phosphorylation of IKK-β but not JNK.

Conclusions: We conclude that Gemfibrozil reversed insulin resistance in obese adipocytes by modulating phosphorylation of IRS-1, Akt and IKK-β and thereby facilitated insulin signaling.These observations may have implications for prevention and treatment of diabtetes in metabolic syndrome.

ATP-Citrate Lyase Is an Epigenetic Regulator to Promote Renal Injury in Metabolic Syndrome

Yinyin Chen,[1,2] Dilip K Deb,[1] Yanchun Li.[1] *[1]Dept. of Medicine, University of Chicago, Chicago, IL; [2]Dept. of Nephrology, Hunan Provincial People's Hospital, Changsha, China.*

Background: Metabolic syndrome, characterized by obesity and type 2 diabetes, is a leading cause of chronic kidney disease. Obesity-related renal injury, characterized by ectopic lipid accumulation in the kidney, has increased dramatically in recent years. Hyperglycemia and hyperlipidemia, key features of metabolic syndrome, drive excess nutrient flows into kidney cells; as a result, enhanced cell metabolism increases intracellular acetyl-CoA concentration, which provides the substrate for de novo lipid synthesis as well as for histone acetylation. Here we tested the hypothesis that ATP-citrate lyase (Acly), an enzyme that converts citrate to acetyl-CoA, functions as an epigenetic regulator of renal injury by promoting ectopic lipid synthesis and histone acetylation.

Methods: Acly, lipogenic and fibrogenic genes in the kidney of ob/ob BTBR mice and mesangial cells were quantified by qRT-PCR and Western blotting. Kidney sections were analyzed by H&E, PAS and oil red O staining. Histone acetylation in gene promoters was assessed by ChIP assays.

Results: Ob/ob BTBR mice developed glomerulomegaly, glomerulosclerosis and ectopic lipid accumulation in the kidney compared with ob/+ controls, accompanied by increases in total lipids, triglyceride and cholesterol contents in the renal cortex. Acly, lipogenic (ACC, FAS, HMGCR) and fibrogenic (TGF-β1, FN) genes were markedly up-regulated in the kidney of ob/ob BTBR mice, so was histone acetylation at the H3K9/14 and H3K27 sites. Inhibition of Acly activity by SB-204990 not only blocked histone acetylation but also suppressed the expression of the lipogenic and fibrogenic genes in the ob/ob BTBR kidneys. ChIP assays confirmed that these gene promoters were hyperacetylated at the H3K9/14 and H3K27 sites. Exposing mesangial cells to a combination of high glucose, sodium palmitate and TNF-α synergistically stimulated Acly expression and enzymatic activity, increased H3K4/19 and H3K27 acetylation, up-regulated the lipogenic and fibrogenic genes and promoted histone acetylation in these gene promoters. Blockage of Acly by SB-204990 or siRNA attenuated these regulatory processes, whereas Acly overexpression enhanced these regulations.

Conclusions: These observations strongly suggest that Acly is a critical epigenetic regulator to promote renal injury via epigenetic mechanisms in obesity

TH-PO617

Investigating the Sex-Specific Progression of CKD: Sex Hormones and Sex of the Cell in Human Kidney Metabolism

Sergi Clotet-Freixas,[1] Julie Anh Dung Van,[1] Aman Mehrotra,[1] Minna Woo,[1] Amy A. Caudy,[2] Ana Konvalinka.[1] *[1]University Health Network, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada.*

Background: Male sex predisposes to chronic kidney disease (CKD). We hypothesized that the effector androgen dihydrotestosterone (DHT) would induce key molecular alterations in human renal proximal tubular epithelial cells (PTECs). We quantified the proteome of DHT- vs. estradiol(EST)-treated PTECs, and uncovered androgen-induced perturbations in renal metabolism that may be directly responsible for the faster CKD progression in men. Our goal is to characterize sex- and sex hormone-specific alterations in the PTEC metabolic function, and relate them to hypertrophy, oxidative stress, and inflammation.

Methods: PTECs from 2 male vs. 2 female donors were stimulated with Control, DHT (100nM), or EST (100nM) for 16h or 24h. We employed a Seahorse analyzer to monitor glycolysis (as extracellular acidification rate, ECAR) and oxygen consumption rate (OCR). Changes in ECAR and OCR were related to the extracellular glucose levels, intracellular ATP, oxidative stress (O_2^-), apoptosis (phosphatidilserine, PS) and cell diameter (n=4-6/group). Secreted levels of 15 chemokines/cytokines were quantified through a Multiplex Bead-Based Assay.

Results: Male PTECs showed significantly increased ECAR and OCR, ATP-linked respiration, maximal glycolitic and respiratory capacity, O_2^- and PS levels than female PTECs. In male PTECs, ECAR was increased after DHT stimulation, whereas OCR was increased by DHT and EST at baseline and in response to mitochondrial stress. In male PTECs, glucose concentration in the media was reduced by DHT treatment and glucose reduction was prevented by androgen receptor inhibitors. In turn, ATP, O_2^-,PS levels, cell diameter and secretion of cytokines IL-6 and MCP1 were increased by DHT. DHT also augmented ATP levels in female PTECs. Interestingly, both DHT and EST increased ECAR and OCR in the PTECs from only one of the female donors.

Conclusions: DHT-induced proteome alterations are linked to a more glycolytic and oxidative phenotype in the human renal cell, and to higher glucose consumption, oxidative stress, apoptosis, IL-6/MCP1 secretion, and hypetrophy. Moreover, the metabolic function of PTECs and their susceptibility to sex hormones vary depending on the sex of the donor. Thus, not only hormonal but also (epi)genetic factors may contribute to a sex dimorphism in human renal metabolism.

TH-PO618

Renal Cortical Mitochondrial Dynamics and Elimination During the Normoalbuminuric Stage of Diabetes Mellitus

Naohito Ishii,[1] Pamela K. Carmines,[2] Akemi Imoto,[1] Yoshifumi Kurosaki,[1] Hideki Ikenaga,[3] Hajime Ojima,[1] Masanori Yokoba,[1] Tsuneo Takenaka,[4] Masato Katagiri.[1] *[1]Kitasato University, Sagamihara, Japan; [2]University of Nebraska College of Medicine, Omaha, NE; [3]Seiikai, Otawara, Japan; [4]International University of Health and Welfare, Sanno Hospital, Tokyo, Japan.*

Background: Oxidative stress during the normoalbuminuric stage of type 1 diabetes mellitus (DM) damages renal cortical mitochondria (Clin Sci 124:543-52, 2013). Because accumulation of damaged mitochondria can contribute to renal dysfunction, we aimed to determine if oxidative stress in DM triggers renal cortical mitochondrial fission, fusion and elimination through mitochondria-selective autophagy (mitophagy).

Methods: Rats receiving i.p. injection of streptozotocin (STZ, 65 mg/kg) or vehicle (Sham) were either left untreated or treated with telmisartan (TLM, an angiotensin receptor blocker; 10 mg/kg/d). Two weeks later, blood glucose concentration (BG), blood pressure (BP), glomerular filtration rate (GFR), and urinary excretion of albumin and *N*-acetyl-β-D-glucosaminidase (NAG) were measured. Renal cortical 3-nitrotyrosine (3-NT; an oxidative stress marker) was detected by HPLC. Fission-, fusion-, and mitophagy-related proteins were quantified in renal cortical homogenates by Western blot and localized by immunohistochemistry.

Results: STZ rats displayed hyperglycemia that was unaffected by TLM. BP, albumin excretion, and NAG excretion were similar in all groups. Compared with Sham rats, GFR and renal cortical 3-NT levels were increased in STZ rats, and both changes were prevented by TLM. Renal cortex from STZ rats displayed TLM-sensitive increases in the mitophagy-related proteins LC3-II and PINK1 (all $P<0.05$). Renal cortical Drp1 levels were 3-fold higher in STZ than in Sham rats, with STZ+TLM rats exhibiting intermediate levels of this fission marker. In contrast, levels of the fusion marker Mfn2, and mitophagy-related proteins BNIP3 (dimer) and p62 levels did not differ among groups. Immunohistochemical staining confirmed that the mitophagy-related proteins in STZ were located at renal tubular sites.

Conclusions: These data suggest that fission, but not fusion, of renal cortical damaged mitochondria is enhanced by in DM. TLM-sensitive accumulation of PINK 1 and LC3-II the tubular epithelium during DM suggests that oxidative stress activates the PINK1-parkin pathway, in which PINK1 binding to LC3-II (an established marker for autophagosome formation) results in mitochondrial elimination via autophagy.

Preliminary Analyses on Dietary Inflammatory Index Among Participants in the Palm Tocotrienols in Chronic Hemodialysis (PATCH, USA) Study

Dina A. Tallman, Eno Latifi, Deepinder Kaur, Pramod Khosla. *Wayne State University, Detroit, MI.*

Background: Inflammation is a predictor of mortality in hemodialysis (HD) patients. The dietary inflammatory index (DII) assesses the potential effect of diet on systemic inflammation. The aim of this preliminary analysis was to evaluate the use of DII and examine the associations between DII, diet composition and key anthropometry.

Methods: Dietary 24 hr recalls were collected at baseline from HD patients participating in the PATCH clinical trial (NCT02358967), an ongoing one year double-blind intervention (300 mg tocotrienols or placebo, daily) which includes quarterly anthropometric measures. Data was analyzed using Food Processor ESHA Research. After accounting for under reporters, the DII score was calculated from 85 patients (Age 62 ± 12 yrs., 67% men, 95% African American). Handgrip strength (HGS) was measured using a Jamar dynamometer for 48 of the subjects. A z-score transformation was applied to mean baseline HGS scores using normative grip strength data and these standard scores were compared with clinical and demographic characteristics collected from medical records.

Results: DII showed a significant positive correlation with percent calories from saturated fatty acids (r = 0.38) and significant negative correlations with dietary monounsaturated (r = -0.38) and polyunsaturated fatty acids (r = -0.37), vitamin E tocopherol (r = -0.69), the vitamin E to linoleic acid ratio (r = -0.23), and the phosphorus to protein ratio (r=-0.43). When subjects were divided into tertiles based on DII score, significant decreasing trends were observed for HGS and significant increasing trends for serum phosphorus. Weaker grip strengths were significantly and positively correlated with serum ferritin levels between 800 and 1200 ng/ml for a sub-set of the population (n = 18; r = -0.54).

Conclusions: Inflammation may be implicated in CKD induced muscle loss. The restrictive nature of the renal diet, though controlling serum phosphorus, was proinflammatory for this study group. Thus, DII may be a useful tool for exploring the role of specific dietary fatty acids and antioxidants to the contribution of inflammation in the African American HD population. (Supported by the Malaysian Palm Oil Board, Government of Malaysia)

TH-PO620

Impact of the Gene Encoding Canonical Transient Receptor Potential 1 Channel (TRPC1) on Glucose Intolerance and Liver Steatosis Is Condition-Specific: Role of Hyperphagia, Obesity, and High Fat Diet (HFD)

Bonnie Eby,[4] Lindsay J. Barron,[1] Alexander Lau,[4] Richard M. Atkins,[3] Chris Skaggs,[1] Usman A. Khan,[3,2] Leonidas Tsiokas,[5] Kai Lau.[1,2] *[1]University of Oklahoma Health Science Center, Oklahoma City, OK; [2]Medicine, VA Hospital & Medical Center, Oklahoma City, OK; [3]University of Oklahoma College of Medicine, Oklahoma City, OK; [4]University of Oklahoma Heath Sciences Center, Oklahoma City, OK; [5]University of Oklahoma Health Sciences Center, Oklahoma City, OK.*

Background: We recently noted spontaneous development of metabolic syndrome (MetS) in TRPC1 null mice vs wild type (wt). We now studied the impact of gene dosage, role of adipokines, & responses to a HFD (45%) vs. normal (N) (10-13%) FD x 4 m.

Methods: We did metabolic studies in ♂ littermates of all 3 genotypes, using standard chemical techniques & ELISA for insulin, leptin, & adiponectin

Results: On normal chow, from 4th-5th to 30th week, null mice ate & weighed more than +/- & wt. After 30 weeks, intake & weight gains in null became similar to +/- & wt. At 2 m, null mice had hyperglycemia & hypercholesterolemia. Their livers were 36% heavier & triglyceride content (TGC) 47% higher. Liver echogenicity was elevated by 50-150 % at 7, 11, & 22 m, corroborated by 140% higher liver TGC. At 12 m, only null mice had hyperlipidemia (30% higher blood total cholesterol, 60% higher LDL, & 200% higher TG). In +/- & wt, blood lipids, liver density at 12 & 19 m, & liver TGC at 19 m were all normal. Fasting glucose was elevated only in null (up 20% at 1 m, 23% at 3.5 m & 13% at 15.5 m). Thus on a normal diet, 1 TRPC1 gene allele could prevent hyperphagia, obesity, MetS & hepatic steatosis. As expected, HFD vs. NFD stimulated leptin & insulin, comparably in all 3 genotypes, without affecting adiponectin or weight gains. Contrary to a normal diet, HFD increased liver density in +/- & wt, but unexpectedly & inexplicably, not in null. On NFD, HOMA-IR was similar among all 3 genotypes, but HFD induced the highest HOMA-IR in wt (3.1 vs 1.3 in +/-) & the largest liver TGC hike in wt (3.3 x vs 2 x in +/- vs 1.6 x in null). During glucose tolerance test, the area under the curve for plasma glucose vs time was again paradoxically the highest in wt vs null.

Conclusions: We conclude: 1. Normally, TRPC1 helps maintain glucose & lipid homeostasis, presumably by preventing hyperphagia & obesity seen in diploid deficiency, which renders hypothalamic neurons relatively resistant to anorexigenic effects of lepin. 2. When stressed by a HFD, the wt TRPC1 gene dose-dependently predisposes the mice to glucose intolerance & steatosis. 3. Mechanisms for these diverse effects are unknown but unrelated to changes in insulin, leptin or adiponectin.

Daily Oscillation of the Plasma Inorganic Phosphate Concentration: Impact of Nampt Deficient Mice

Sawako Tatsumi,[1] Ichiro Kaneko,[3] Hiroko Segawa,[2] Ken-ichi Miyamoto.[4] *[1]The University of Shiga Prefecture, Hikone, Japan; [2]University of Tokushima Graduate School, Tokushima, Japan; [3]Tokushima University Graduate School of Biomedical Sciences, Tokushima, Japan; [4]Tokushima University, Tokushima City, Japan.*

Background: Circulating inorganic phosphate (Pi) exhibits a remarkable daily oscillation based on food intake. In humans and rodents, the daily oscillation in response to food intake may be coordinated to control the intestinal absorption, renal excretion, cellular shifts, and extracellular concentration of Pi. Hyperphosphatemia is linked to vascular calcification with chronic kidney disease (CKD) and is an independent risk factor for cardiovascular mortality in hemodialysis patients. Despite the circadian variations, it is the fasting morning serum Pi concentration that is linked to cardiovascular events and mortality in most epidemiologic studies. However, mechanisms regulating the resulting oscillation are unknown. Here we investigated the roles of the sodium Pi cotransporter SLC34 (Npt2) family and nicotinamide phosphoribosyltransferase (Nampt) in the daily oscillation of plasma Pi levels.

Methods: We used $Npt2^{-/-}$ mice, liver-specific $Nampt^{-/-}$ and $Nampt^{+/-}$ mice to reveal the mechanisms of daily oscillation of the plasma Pi concentration.

Results: The daily oscillation of the plasma Pi concentration is roughly linked to urinary Pi excretion. The expression of renal Npt2a and Npt2c, and intestinal Npt2b proteins also exhibit a dynamic daily oscillation. Analyses of $Npt2a^{-/-}$ and $Npt2c^{-/-}$ revealed the importance of renal Pi reabsorption and cellular Pi shifts in the daily oscillation. In $Npt2a^{+/+}$ and $Npt2a^{-/-}$, fasting significantly increases plasma Pi concentration and disappeared completely daily oscillation compared with the feeding group. The administration of nicotinamide (vitamin B3) and a specific Nampt inhibitor (FK866) in the active and rest phases revealed that the Nampt/NAD system is involved in renal Pi excretion. Additionally, for cellular shifts, liver-specific Nampt deletion disturbed the daily oscillation of plasma Pi during the rest but not the active phase. In systemic $Nampt^{+/-}$ mice, NAD levels were significantly reduced in the liver, kidney, and intestine, and the daily oscillation of the plasma Pi concentration was attenuated.

Conclusions: The findings of the present study suggest that the Nampt/NAD^+ system, together with the kidney and soft tissues, plays an important role in generating the daily oscillation of plasma Pi levels. It may enhance our understanding of the changes in plasma Pi levels in CKD patients.

Microbiota Dysbiosis Contributes to Liver Injury in Apolipoprotein Knockout Mice Through the Disruption of Cholesterol Homeostasis

Peipei Chen,[1] Kun ling Ma,[1] Yang Zhang,[1] Gui hua Wang,[1] Zebo Hu,[1] Jian Lu,[2] Chenchen Lu.[3] *[1]Institute of Nephrology,Zhongda Hospital,Southeast University, Nan Jing City, China; [2]Institute of Nephrology, Zhongda Hospital, Nanjing, China; [3]Institute of Nephrology, Zhong Da Hospital, Nan Jing City, China.*

Background: Our previous studies demonstrated that cholesterol accumulation in liver contributes to the progression of nonalcoholic fatty liver disease (NAFLD). The exact mechanisms of this process have not been completely explained. This study aimed to investigate the effects of gut microbiota on cholesterol homeostasis of liver in NAFLD.

Methods: Broad-spectrum antibiotics were used to eliminate gut microbiota in high-fat diet (HFD) induced apolipoprotein E knockout mice. Feces were collected and proportions of microbiota were analyzed by 16S rRNA gene sequencing. Serum lipids were examined by automatic analyzer. Cholesterol accumulation in liver was detected by Oil red O staining, Filipin staining, and intracellular free cholesterol quantitative assay. The expressions of molecules involved in cholesterol homeostasis were measured by immunohistochemical staining and Western blotting.

Results: As demonstrated by 16S rRNA gene sequencing,the abundance of *Desulfovibrio* was significantly increased in HFD mice while the abundance of *Bacteroidetes, Ruminococcaceae,* and *Lactobacillus* decreased when compared with the control. Antibiotics treatment effectively depleted gut microbiota in HFD mice. Interestingly, depletion of gut microbiota significantly decreased total cholesterol(TC) and low density lipoprotein(LDL) in the plasma and lipid accumulation in livers of HFD fed mice. Immunohistochemical staining and Western blotting further demonstrated that the expressions of LDL receptor (LDLR) and 3-hydroxy-3-methyl-glutaryl-CoA reductase(HMGR) were downregulated in antibiotics delpleted HFD fed mice.

Conclusions: Our findings demonstrated that gut microbiota dysbiosis may be responsible for the liver injury in NAFLD by disrupting cholesterol homeostasis. This study provides more evidence for that modification of gut microbita dysbiosis is suggested to be a potential target for NAFLD therapy.

TH-PO623

Arginine Bioavailability Correlates with Cardiac Remodeling in Mice with CKD

Loretta Reyes,[1,2] Mike Kelleman,[1] Frank Harris,[1] Lou ann S. Brown,[1,2] Claudia R. Morris,[1,2] Pamela D. Winterberg.[1,2] *[1]Pediatrics, Emory University School of Medicine, Atlanta, GA; [2]Children's Healthcare of Atlanta, Atlanta, GA.*

Background: Nitric oxide (NO) is critical for vascular homeostasis. Arginine (Arg), the sole nitrogen donor for NO synthesis, is the common substrate for NO synthase & arginase

enzymes (Fig 1). Global arginine bioavailability ratio (GABR) has been proposed to reflect substrate availability for NO synthesis by accounting for Arg concentration relative to its catabolic products ornithine (Orn) & citrulline (Cit). Low GABR has been associated with increased mortality in adults with heart failure & coronary artery disease. This study aimed to determine the relationship between GABR & measures of cardiac structure & function in mice with CKD.

Methods: CKD was established in male 129X1/SvJ mice via 2-stage partial nephrectomy. Plasma was collected at 8 & 16 wks post surgery & Arg, Orn & Cit were measured by LC/MS/MS. GABR was calculated as [Arg]/([Orn]+[Cit]). Echos were performed at 8 & 16 wks. Relative wall thickness (RWT) was calculated using M-mode parasternal long-axis measurements (IVS;d+LVPW;d)/LVID;d & myocardial performance index (MPI) as (IVCT+IVRT/ET) on trans-mitral Doppler. In a separate experiment, CKD mice received diet supplemented with Arg or alanine (nitrogen control) for 12 wks to determine effect on myocardial function.

Results: GABR was significantly reduced in mice with CKD compared to controls at both 8 wks [median (IQR) 0.56 (0.52-0.61) vs 0.74 (0.72-0.78); *p=0.01*] & 16 wks [0.41 (0.36-0.49) vs 0.64 (0.55-0.68); *p=0.03*]. There was a significant association between GABR & LVH (RWT; r=-0.39, p=0.02) & diastolic dysfunction (E/A ratio; r=0.37, p=0.04). At 12 wks, CKD mice on Arg supplementation compared to mice on control diet showed improved LVH (RWT 0.47±0.08 vs 0.58±0.06; *p=0.01*) & MPI (0.81±0.12 vs 1.05±0.11; *p<0.01*).

Conclusions: GABR is decreased in mice with CKD & correlates with worsening structural (RWT) & functional (E/A ratio) cardiac changes. Interestingly, Arg supplementation improved LVH & MPI at 12 wks. Additional studies are underway to determine underlying etiology of reduced GABR in CKD.

Eliminating SIRPα Prevents Elevations in Blood Pressure, Suppresses Aldosterone and Cardiac Fibrosis in CKD

Jiao Wu,[3] Zhaoyong Hu,[3] William E. Mitch,[3] Sandhya S. Thomas.[2,1] *[1]Michael E. Debakey Veterans Affairs Medical Center, Houston, TX; [2]Baylor College of Medicine, Houston, TX; [3]Baylor College of Medicine, Houston, TX.*

Background: A major consequence of chronic kidney disease (CKD) is uremic cardiomyopathy characterized by cardiac dysfunction and fibrosis. Potential mechanism for the development of CKD-induced cardiomyopathy is increased aldosterone and impairment of intracellular insulin signaling (i.e., dephosphorylation of IRS1 and the insulin receptor) mediated by SIRPα. We reported that SIRPα is activated by inflammation and found that SIRPα is increased in cardiac muscles of mice with CKD. Here we examine the influences of SIRPα on systolic blood pressure (BP), aldosterone and cardiac fibrosis.

Methods: We used a global KO of SIRPα (SIRPα Mt) mice and compared them with wild type (WT) mice ± CKD (subtotal nephrectomy). At 8 weeks following CKD, we examined mice for cardiac fibrosis by picrosirius red staining plus systolic BP. To determine if over-expression of SIRPα, affects fibrosis directly we transfected myotubes with a plasmid expressing SIRPα vs. GFP. Finally, we immunoblotted myotubes to evaluate levels of SIRPα, αSMA, pSMAD3, and GAPDH.

Results: Systolic BP levels in WT mice with CKD was higher compared to values in WT control mice. These results mirror increases in aldosterone (2.3-fold higher) vs. WT control mice. Interestingly, SIRPα Mt control mice had lower systolic blood pressures; aldosterone levels were also significantly lower vs. WT control. Additionally, WT mice with CKD displayed 5.2-fold higher levels of aldosterone vs. SIRPα Mt with CKD. Next, we stained for fibrosis markers in WT CKD and SIRPα Mt mice with CKD. Picrosirius red staining revealed a significant reduction in cardiac fibrosis found in SIRPα Mt with CKD compared to values in WT mice with CKD. Myoblasts that had been transfected to overexpress SIRPα vs. GFP plasmids. We determined that fibrosis markers (i.e. αSMA) were significantly increased in myotubes overexpressing SIRPα. Finally, intracellular signaling of TGFß, pSmad3 was significantly stimulated.

Conclusions: Since cardiac fibroblasts express high affinity corticoid receptors for aldosterone, our results suggest that SIRPα contributes to the accumulation of collagen within the myocardial interstitium, leading to cardiac fibrosis and failure in CKD. Thus, suppression of SIRPα undoubtedly plays a critical role in blocking aldosterone secretion and elevations in systolic blood pressure to prevent cardiac fibrosis in CKD.

Voluntary Physical Activity Improves Physical Function and Disease Outcomes in a Rat Model of CKD

Keith Avin,[1,2] Neal X. Chen,[2] Shruthi Srinivasan,[2] Kalisha O'Neill,[2] Matthew R. Allen,[2] Sharon M. Moe.[2] *[1]Indiana University-Indianapolis, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: Chronic kidney disease (CKD) progression is associated with reduced muscle size, strength and overall mobility. Previous studies using exercise as an intervention for CKD have been inconclusive. We hypothesized that physical activity would attenuate musculoskeletal dysfunction and CKD-related outcomes.

Methods: Four groups of rats were used: 1) CKD, 2) CKD + voluntary wheel running, 3) Normal littermates (NL) and 4) NL with voluntary wheel running (N=12/gr). Wheels were freely accessible in animal cages. Data collection began at 25 weeks (~CKD stage 2-3) and ended at 35 weeks of age (~stage 5 CKD). Muscle strength (i.e. maximal voluntary grip), maximal aerobic capacity (VO2 max), were tested at 25 and 35 weeks; serum biochemistries were assessed at 35 weeks. Data was analyzed via one-way ANOVA with post-hoc comparisons.

Results: CKD rats performed the same average wheel distance/day and speed as NL animals indicating exercise tolerability. Wheel running had negligible effects in NL animals. In contrast, wheel running significantly improved multiple outcomes in CKD rats: 1) significantly reduced phosphorous, PTH and FGF23 (Table 1); 2) reduced kidney weight and left ventricular mass index (-12%, p<0.05; -8.5%, p<0.01, respectively); 3) reduced serum oxidative stress marker 8-OHdG by (-45%, p<0.05); 4) improved grip strength by 16% compared to 10% reduction in CKD alone (p<0.05); and 5) Increased time to fatigue (min) during VO2 testing (12.6 min, 8.5 min, p<0.001) but did not change maximal oxygen capacity.

Conclusions: In a progressive rat model of CKD, voluntary wheel running had significant improvement of the biochemistry, tissue weights, oxidative stress and physical function. The results suggest that physical activity may have beneficial effects in CKD.

Funding: NIDDK Support

*p<0.05, CKD vs. CKD Wheel n=10-14 rats each group

TH-PO626

Chondroitin Sulfate Supplement Alleviates Nephrocalcinosis in Hyperoxaluric Rats

Thasinas Dissayabutra,[1] Nuttiya Kalpongnukul,[2] Kanokporn Chindaphan,[1] Wattanachai Ungjaroenwathana,[3] Maroot Kaewwongse,[4] Kroonpong Iampenkhae,[5] Piyaratana Tosukhowong.[1] *[1]Chulalongkorn University, Pathumwan, Bangkok, Thailand; [2]Biochemistry, Faculty Of Medicine, Chulalongkorn University, Pathumwan, Thailand; [3]Surgery, Sunpasitthiprasong Hospital, Meung, Thailand; [4]University of Phayao, Phayao, Thailand; [5]King Chulalongkorn Memorial Hospital, Bangkok, Thailand.*

Background: Nephrocalcinosis and nephrolithiasis are common features of primary hyperoxaluria that contributes to end stage renal disease. We observed low urinary chondroitin sulfate (CS) and high hyaluronic acid (HA) excretion in hyperoxaluric nephrolithiasis patients and considered these were risks of nephrocalcinosis. This study aimed to investigate the effect of CS and HA supplement in hyperoxaluric rats.

Methods: Hyperoxaluric Wistar rats induced by ethylene glycol and vitamin D intraperitoneal injection was supplemented with CS (40 mg/kg/day) and/or HA (10 mg/kg/day). Urinary CS and HA excretion were measured. Histopathology of kidney tissue was reported.

Results: All hyperoxaluric rats developed moderate to severe nephrocalcinosis in 15 days. CS supplement entirely inhibited calcium deposition in renal tissue in all rats (p < 0.05). HA supplement had no effect on nephrocalcinosis formation, however, combination of CS and HA supplement can lessen the degree of nephrocalcinosis, but not as effective as giving CS alone.

Conclusions: CS supplement in hyperoxaluric patients could be beneficial in prevention of nephrocalcinosis. Besides, HA supplement might have detrimental effect in interrupt the CS activity.

Severity score of nephrocalcinosis in hyperoxaluric rats

Group	Nephrocalcinosis grade (Median, IQR)	Tubular obstruction	Tubulo-interstitial fibrosis
Control	0 (0)	0	0
Hyperoxaluria	4 (2-4)	0	0
CS supplement	0 (0)*	0	0
HA supplement	2.5 (1-4)	0	0
CS & HA supplement	0.5 (0-2)*	0	0

Nephrocalcinosis grading score: 0, no deposit; 1, 1-2 deposits/section; 2, 3-5 deposit/section; 3, 5-10 deposits/section; 4, >10 deposits/section. Tubular obstruction score: 0, no obstruction; 1, tubular obstruction present. Tubulo-interstitial fibrosis: 0, no fibrosis; 1, fibrosis present. *p < 0.05 compared with Hyperoxaluria group.

TH-PO627

An Oral Absorbent, Surface-Deacetylated Chitin Nano-Fiber Ameliorates Renal Injury and Oxidative Stress in 5/6 Nephrectomized Rats

Makoto Anraku,[1] Daisuke Kadowaki,[1] Daisuke Iohara,[1] Toru Maruyama.[2] *[1]Faculty of Pharmaceutical Sciences, Sojo University, Kumamoto, Japan; [2]School of Pharmacy, Kumamoto University, Kumamoto, Japan.*

Background: We recently prepared surface-deacetylated chitin nanofibers (SDACNFs) by the mechanical treatment of the exoskeletons of crabs, followed by partial deacetylation of the amide groups on the surface of the resulting chitin nanofibers. SDACNFs have attracted considerable interest in medical fields, because of their various bioactivities. For example, SDACNFs were reported to suppress increases in body weight and serum leptin levels in a model of obesity that was induced by feeding a high fat diet. These results indicate that SDACNFs are work as potent functional foods that could be used in the treatment of various diseases.

Methods: The rats were divided into four groups as follows: (a) untreated nephrectomized group (N=5). The rats received only standard rat chow. (b), (c), and (d) deacetylated chitin powder (DAC), SDACNFs and AST-120 treated nephrectomized group, respectively. These rats received standard rat chow and the above samples at a daily dosage of 40 mg/kg of body wt for a period of 4 weeks, respectively (n=5). After 0 and 4 weeks of treatment, plasma samples obtained from each of the rats were immediately frozen and stored at -80 °C until used for analysis.

Results: An oral administration of low doses of SDACNFs (40 mg/kg/day) over a 4 week period resulted in a significant decrease in serum indoxyl sulfate (IS), creatinine and urea nitrogen levels, compared with a similar treatment with DAC or AST-120. The SDACNFs treatment also resulted in an increase in antioxidant potential, compared with that for DAC or AST-120. Immunohistochemical analyses also demonstrated that SDACNFs treated CRF rats showed a decrease in the amount of accumulated 8-OHdG compared with the CRF group.

Conclusions: The findings reported here indicate that a lower dose of SDACNFs than that of DAC has the potential to reduce the levels of uremic toxins (such as IS) that induce the production of free radicals in the intestinal tract, thereby inhibiting the subsequent occurrence of oxidative stress in the systemic circulation in CRF model rats. Thus, the removal of such substances from the systemic circulation could lead, not only to a reduction in oxidative stress, but also to the prevention of cardiovascular disease in CRF (Anraku et al., Carbohydrate Polymers, 2017).

Xenogeneic Kidney Generation with Human Nephron Progenitor Cells in Zebrafish

Wenqing Yin,[1,3] Navin R. Gupta,[2,3] Tomoya Miyoshi,[1] M. Todd Valerius,[1,3] Joseph V. Bonventre,[1,3] Ryuji Morizane.[1,3] *[1]Brigham and Women's Hospital, Boston, MA; [2]Brigham & Women's Hospital/Massachusetts General Hospital, Brighton, MA; [3]Harvard Medical School, Boston, MA.*

Background: Generating human stem cell-based tissue in animals may provide replacement human organs, establish novel disease models, and aid in drug development through toxicity screening and therapeutic testing. Human nephron progenitor cells (hNPCs) derived from human pluripotent stem cells (hPSCs) are attractive sources for human kidney generation in animals; however, techniques to replace host kidney tissue with hNPCs are yet to be developed. Here we employ transparent zebrafish (Casper) to enable real-time monitoring of xenotransplanted, fluorescent hNPCs and visualize human nephron formation.

Methods: hNPCs were differentiated from hPSCs by our previously established protocol. Cas9 mRNA and gRNAs targeting Lhx1a or Wt1b, essential transcriptional factors for kidney development in zebrafish, were injected into single cell stage embryos. Cell Tracker- or GFP-labeled hNPCs were transplanted to blastoderm stage embryos and nephrogenesis visualized overtime. Nephrons were evaluated by qPCR with human-specific primers and immunostaining for human solute transporters and segment-specific proteins.

Results: Zebrafish with targeted disruption of either Lhx1a or Wt1b died by 24 days post treatment (dpt), while transplantation of hNPCs rescued 14.5% of similarly treated zebrafish ($p<0.00001$). All zebrafish that underwent gRNA treatment exhibited renal insufficiency with evidence of edema at 3 dpt, however, hNPC transplantation resolved renal insufficiency by 20 dpt. Transplanted hNPCs migrated to the pronephric area, expressed human SIX2 in early nephrogenesis (9 dpt), and formed glomerular and tubular structures that connected to DBA^+ zebrafish collecting ducts at a later stage (26 dpt). Notably, hNPCs contributed to $Podocalyxin^+$ cells in membrane-enclosed structures that contained human $CD31^+$ capillary loops, indicating human glomerular development in zebrafish. qPCR using human-specific primers validated human nephron formation in zebrafish.

Conclusions: We developed novel methods for generating human kidney tissue in animals. After eliminating NPCs in early zebrafish embryos using CRISPR/Cas9 genome editing, xenotransplantation of hNPCs generated human nephron structures in zebrafish. Our results serve as a proof-of-concept that isogenic patient-specific kidney tissue may be generated in animals for translational applications.

Developmental Trajectories Inform the Derivation of Podocytes in-a-Dish

Trinh k (tracy) Tran,[1] Andrew P. McMahon.[2] The McMahon Laboratory *[1]University of Southern California, Los Angeles, CA; [2]Keck School of Medicine of the University of Southern California, Los Angeles, CA.*

Background: In the renal corpuscle, podocytes, mesangial cells and vascular endothelial cells form a highly organized filtration device that enables plasma fluid to pass from the circulatory system into the epithelail network of the nephron. The derivation of podocyte-like cells from differentiating pluripotent stem cells has been reported by a number of groups through a variety of approaches. Before moving to disease modeling and drug discovery, an evaluation of the properties of *in vitro* derived cells to their *in vivo* counterparts is important.

Methods: In this study, we used *in vivo* studies, single-cell RNA sequencing and bioinformatics to explore the developmental trajectory of the human podocyte. Employing a fluorescently labeled hESC line to visualize and isolate *in vitro* derived podocyte-like cells, we performed a comparative analysis of these cells with their human embryonic counterparts.

Results: Through high-resolution microscopy, chromatin structure profiling, single-cell and bulk transcriptional profiling, we identified transcriptional landmarks during *in vivo* and *in vitro* podocyte development.

Conclusions: We found that hESC-derived podocytes shared molecular signatures with normal human podocytes, including the ability to form intricate interactions with their neighbors and attract blood vessels. A substantial podocyte profile is generated without accompanying interactions with mesangial or endothelial cell types. Our analyses also identified distinct transcriptional signatures between *in vitro* and *in vivo*-derived cells that point to opportunities to improve podocyte production in culture.

TH-PO630

Brain Derived Neurotrophic Factor (BDNF) Inhibition Dramatically Reduces Off-Target Cells in Kidney Organoid

Kohei Uchimura,[1] Haojia Wu,[2] Erinn L. Donnelly,[3] Benjamin D. Humphreys.[3] *[1]Washington University in St. Louis, Saint Louis, MO; [2]Renal Division Washington University School of Medicine, Saint Louis, MO; [3]Washington University School of Medicine, Saint Louis, MO.*

Background: Kidney organoids differentiated from pluripotent stem cells hold great promise for disease modeling and ultimately as a source of replacement tissue, however we have shown that all protocols also generate substantial off-target cell types, primarily neurons. To eliminate off-target cells without altering kidney cell maturation, we performed single cell RNA-seq and analyzed ligand - receptor pairs expressed exclusively within the neuronal lineages. We identified 19 receptors with 24 cognate ligands, and determined that the neuron survival factor BDNF and its receptor NTRK2 was expressed exclusively in the neuronal lineage. We tested whethyer inhibition of BDNF-NTRK2 signaling during organoid differentiation would reduce neuronal populations without altering kidney differentiation.

Methods: A range of doses of the NTRK2 inhibitor K252a was screened as well as different time schedules during organoid differentiation from human induced pluripotent stem cells. We assessed marker expression by qPCR and immunofluorescence, as well as scRNA-seq on control and K252a-treated organoids. We sequenced 3,314 cells to a final read depth of 50K mapped reads/cell with 3,056 transcripts and 1,524 unique genes detected per cell.

Results: Out of 16 different dosing and timing protocols tested, we found that 250 nM, of K252a added at day 12 did not alter nephron formation according to marker expression by qPCR and immunofluorescence. By contrast, neuronal markers were reduced by almost ten-fold. scRNA-Seq of control vs. K252a-treated organoids showed that all major kidney cell types remained present with K252a treatment, but the neuronal lineage was reduced by over 90%, from 29.8% of total organoid cells before treatment to 2.1% after treatment.

Conclusions: We employed a rational approach based on organoid scRNA-seq to identify BDNF signaling as a potential neuronal survival pathway contributing to the growth of off-target cells in during kidney organoid differentiation. Inhibition of this pathway reduced off-target cells by more than an order of magnitude without affecting kidney differentiation, illustrating the power of scRNA-seq to improve organoid differentiation protocols.

Generation and Validation of a Novel Primary Renal Interstitial Cell Line

Sarah Mccarthy,[1,2] Leif Oxburgh.[1,2] [1]*Maine Medical Center Research Institute, Scarborough, ME;* [2]*Graduate School of Biomedical Sciences and Engineering, Orono, ME.*

Background: The renal interstitium is indispensable for proper nephrogenesis during mammalian kidney development. Interstitial cells also play a central role in the adult kidney fibrotic response. Despite the clinical significance, limited reagents are available to examine the signaling mechanisms that govern interstitial cell biology. To this end, we have generated an immortalized primary renal interstitial cell (PRIC) line. Canonical WNT signaling drives cellular proliferation in a number of developmental and disease contexts. Furthermore, *in vivo* deletion of Wnt7b from the collecting duct or β-catenin from interstitial cell precursors leads to medullary hypoplasia, suggesting a role for paracrine WNT signaling on interstitial cell maintenance. Biochemical analysis with our validated PRIC line confirmed that WNT drives renal interstitial cell proliferation.

Methods: A novel isolation method was utilized to purify PRICs from postnatal mice. Cells were then transduced with a mCherry-tagged SV40T temperature sensitive lentivirus construct to produce a heterogeneous population termed "bulk" SV40T PRICs. Clonal lines were isolated and expanded from single cells and screened for expression of postnatal interstitial zone markers. The transfection efficiency of isolated clones was evaluated with a GFP-expressing construct. The affects of treatment with the WNT agonist CHIR and the TCF/LEF1 inhibitor Fh535 on proliferation was measured by EdU labeling and ClickIt chemistry.

Results: As expected, "bulk" SV40T PRICs showed expression of SV40T at 33°C which was lost when cultured at 37°C. Clone 3-1 was selected for further characterization based on its transcriptional profile and expression of the common interstitial markers Pdgfrβ, α-SMA, Meis1, fibronectin and vimentin. The transfection efficiency of clone 3-1 was determined to be approximately 40%. Treatment of clone 3-1 with CHIR produced a time-dependent increase in the feedback pathway reporters *Axin2* and *Lef1*. In addition, clone 3-1 exhibited a dose-dependent increase in proliferation in response to CHIR. Finally, co-treatment with Fh535 abrogated the mitotic response observed with CHIR alone.

Conclusions: These experiments confirm that clone 3-1 is a viable *in vitro* model to study interstitial cell biology and that canonical WNT signaling through TCF/LEF1 drives renal interstitial cell proliferation.

TH-PO632

Directed Differentiation of Functional Kidney Cells from Human Induced Pluripotent Stem Cells

Samira Musah.[1,2] [1]*Harvard University, Boston, MA;* [2]*Wyss Instutute for Biologically Inspired Engineering at Harvard University, Boston, MA.*

Background: Many diseases and drugs affect kidney function by damaging the glomeruli, which serve as the functional units of the kidney and the center for blood filtration. An *in vitro* model of human glomerulus could facilitate therapeutic discovery and illuminate kidney disease mechanisms. Efforts to develop such models are hindered by the lack of functional human podocytes, the specialized epithelial cells that regulate selective permeability in the glomerulus. Human pluripotent stem (hPS) cells have a remarkable capacity to self-renew indefinitely and differentiate into almost any cell type under appropriate conditions. Thus, hPS cells could potentially serve as an unlimited source of podocytes; however, a method for directing their differentiation into glomerular podocytes remains elusive.

Methods: We hypothesized that a systematic investigation of multiple factors within the cellular microenvironment -- including cell-cell interactions, soluble signaling molecules, and mechanical properties of the extracellular matrix (ECM) -- could yield an effective method for podocyte differentiation.

Results: By following this principle, we developed a highly efficient method for differentiation of hPS cells into podocytes. The hPS-derived podocytes express markers consistent with mature phenotype and exhibit primary and secondary foot processes. By using Organ Chip microfluidic devices, we developed an *in vitro* model of the human glomerular capillary wall that supports podocyte differentiation and recapitulate the normal tissue-tissue interface and selective permeability of the glomerulus.

Conclusions: Our results demonstrate the feasibility of generating mature podocytes in a robust manner, providing an opportunity to engineer a functional human kidney model. These results could facilitate investigations to illuminate developmentally regulated events in kidney pathophysiology, and provide a low cost alternative to animal models for the development of therapeutics for human kidney disease. As podocytes are unable to undergo regenerative proliferation *in vivo*, these results also provide opportunities for cell therapy and regenerative medicine.

TH-PO633

A Simple Bioreactor-Based Method to Generate Kidney Organoids from Pluripotent Stem Cells

Alan J. Davidson. Davidson laboratory *Molecular medicine & pathology, The University of Auckland, Auckland, New Zealand.*

Background: Kidney organoids generated from human pluripotent stem cells have the potential to revolutionize how kidney development and injury are studied. Current protocols are technically complex and suffer from poor reproducibility and high reagent costs restricting scalability.

Methods: To overcome these issues, we have established a simple, inexpensive and robust method to grow kidney organoids in bulk from human induced pluripotent stem cells.

Results: Our organoids develop tubular structures by day (d) 8 and show optimal tissue morphology at d14. A comparison with fetal human kidney suggests that d14 organoid renal structures most closely resemble 'capillary loop' stage nephrons. We show that deletion of *HNF1B*, a transcription factor linked to congenital kidney defects, interferes with tubulogenesis, validating our experimental system for studying renal developmental biology.

Conclusions: Taken together, our protocol provides a fast, efficient and cost-effective method for generating large quantities of human fetal kidney tissue, enabling the study of normal and aberrant human renal development.

TH-PO634

Generation of Induced-Pluripotent Stem Cells and Kidney Organoids from Pediatric Urine Specimens

Jaap Mulder,[1] Sazia Sharmin,[2] Theresa Chow,[3] Deivid Rodrigues',[1] Robert D'Cruz,[4] Ian M. Rogers,[5] James Ellis,[1] Norman D. Rosenblum.[1] [1]*The Hospital for Sick Children, Toronto, ON, Canada;* [2]*University Of Queensland, Brisbane, NSW, Australia;* [3]*University of Toronto, Toronto, ON, Canada;* [4]*Sickkids Research Instituite, Toronto, ON, Canada;* [5]*Samuel Lunenfeld Research Institute, Toronto, ON, Canada.*

Background: Congenital Anomalies of the Kidney and Urinary Tract (CAKUT) are the leading cause of renal failure in children worldwide. Mouse models are widely used to explore underlying mechanisms in CAKUT, but important differences exist between human and murine renal development. Induced-pluripotent stem cells (iPSCs) and kidney organoids generated from actual CAKUT-patients, and closely related, healthy controls, can serve as complementary tools to study processes as nephrogenesis. **Objective:** Generate patient-specific iPSCs and kidney organoids in an efficient, non-invasive manner.

Methods: Previously published protocols (Zhou et al., *Nat Protoc*, 2012; Takasato et al., *Nat Protoc*, 2016) were adapted. Urine cells (UCs) were grown from remnant urine samples routinely obtained in a nephrology outpatient clinic (incl. bag-collected urine). UCs were reprogrammed to urinary iPSCs (UiPSCs) using non-integrating episomal reprogramming vectors (Oct4/Sox2/Lin28/L-Myc/Klf4). UiPSC pluripotency was confirmed by qRT-PCR, immunostaining and embryoid body assays, and euploidy by karyotyping. Kidney organoids were generated from UiPSCs and control blood-derived iPSCs (BiPSCs).

Results: Remnant urine specimens were obtained from 17 patients (1mo-17yr old). UC cultures were established in 71% (12/17) of single urine collections (urine bag: 4/7, 57%, p=0.59 vs. mid-stream specimens) with median urine volume 26ml (range 10-75ml). Sufficient UC numbers for reprogramming were obtained within 16-25 days. Bacterial contamination was not observed. Episome-free UiPSC clones were obtained within 2-3 passages after reprogramming three UC cultures. Differentiated UiPSCs showed mRNA expression patterns (HOXD11/GATA3) matching those of differentiated BiPSCs and published data of differentiated fibroblast iPSCs. Organoids generated from UiPSCs closely resembled BiPSC-kidney organoid morphology and mRNA/protein expression of glomerular, tubular and stromal markers.

Conclusions: A rapid and non-invasive protocol was established to generate iPSCs/kidney organoids from pediatric urine samples. These results provide a readily applicable new platform for CAKUT-research with a low threshold for participation of patients (including infants) and indispensable, patient-specific controls.

TH-PO635

Development and Characterization of Kidney Micro-Organoids from PSCs to Facilitate Kidney Cell Scale-Up

Santhosh V Kumar,[1,2] Pei Xuan Er,[1] Kynan T. Lawlor,[1] Alexander N. Combes,[1,3] Melissa H. Little.[1,2] Kidney development, disease and regeneration [1]*Murdoch Children's Research Institute, Parkville, NSW, Australia;* [2]*Department of Paediatrics, University of Melbourne, Melbourne, VIC, Australia;* [3]*Department of Anatomy and Neuroscience, University of Melbourne, Melbourne, VIC, Australia.*

Background: The directed differentiation of human pluripotent stem cells (hPSCs) has enabled the generation of kidney organoids with potential applications in disease modelling, drug screening and regenerative medicine. The approach is expensive and faces limitations to long-term culture. As a result, novel cost-effective techniques are needed to enable scale-up of kidney cells types *in vitro* and facilitate higher throughput screening approaches.

Methods: To generate kidney micro-organoids, hPSCs were differentiated to intermediate mesoderm using 7uM CHIR for 4 days and FGF9 until 7 days in 2D monolayer culture. On day 7 cells were dissociated using EDTA and allowed to form cell aggregates via low-speed swirling using an E6 media containing a cocktail of growth factors. Within 24hr, cell aggregates were transformed into cell aggregates which, after a further 12 to 18 days in suspension culture, formed complex kidney micro-organoids within a single culture flask.

Results: Mature kidney micro-organoids revealed the presence of intact nephron segments, including podocytes (NPHS1+), proximal (LTL+) and distal (ECAD+) nephron epithelium and collecting duct (ECAD+GATA3+) segments with distinct lumens. Each micro-organoid contains only 6-10 nephrons. As a result, imaging through an entire organoid is feasible. 10x Chromium single-cell RNA sequencing analysis identified the

presence of 11 distinct kidney cell types, both confirming the presence of anticipated renal cell types and revealing a reduced level of surrounding stroma compared to our previously described protocol (Takasato et al, 2015). With this novel method, a starting population of 4.5 million cells (D7+0) was expanded to 150-200 million kidney cells (40 fold) within 20 days, providing a platform for the economical production of kidney cells for various biological applications. Treatment of organoids with Adriamycin induced podocyte cell death and decreased podocyte specific gene expression.

Conclusions: This is a cost-effective method for the generation of large numbers of hPSC-derived kidney cells. As a result, this technique will improve the feasibility of drug toxicity screening and regenerative cell therapy.

TH-PO636

Fluorescent Reporters in Kidney Organoids Generated with Cheap Mini-Bioreactors for High-Throughput Modeling of Kidney Fibrosis

Zhao Sun, Kohei Uchimura, Haojia Wu, Erinn L. Donnelly, Benjamin D. Humphreys. *Renal Division Washington University School of Medicine, Saint Louis, MO*.

Background: Kidney organoids from human pluripotent stem cells (hPSCs) provide a unique opportunity to study human kidney development and kidney diseases. Current protocols are low throughput, generate immature and off-target cell types, and are costly. We tested the ability of spinning bioreactors to overcome these limitations.

Methods: We 3D-printed spinning mini-bioreactors that fit onto 12-well plates, as described (Qian et.al. Cell, 2016). We adapted the Takasato organoid differentiation protocol to the spinning mini-bioreactors by initially differentiating hPSC in a mono-layer for 7 days, followed by low-attachment plate culturing to generate spheroids for another 5 days, and then transferring the spheroids to a mini-bioreactor for maturation for 7- 42 days. We optimized the throughput and characterized resulting kidney organoids by qPCR, immunofluorescence and single cell RNA-seq (scRNA-seq). Finally, we generated and validated three novel fluorescent reporter hPSC lines relevant to the study of fibrosis in kidney organoids (Fibronectin1-GFP, Col1a1-GFP and Gli1-turboGFP).

Results: One 12-well plate could generate 200-600 kidney organoids, representing a more than 100 – fold increase compared to the original Takasato protocol. scRNA-seq analysis revealed that when compared to the standard organoid protocol using a transwell plate, the kidney organoids generated with the mini-bioreactor exhibit more mature nephron structures (including ureteric bud), and more closely resemble the adult human kidney by Pearson correlation. We validated that Fibronectin1-GFP, CollA1-GFP and Gli1-turboGFP all express in the correct stromal cell type in mini-bioreactor-derived organoids. Furthermore, kidney organoids generated by the mini-bioreactor method mount a fibrotic response when treated with 20 μM cisplatin for 2 days by using RPMI medium for organoid differentiation.

Conclusions: We used a 3D-printed spinning mini-bioreactor to increase kidney organoid throughput by at least 100-fold. The protocol is cheaper and results in better differentiation of nephron structures when compared to the standard protocol using a transwell plate. We have generated and validated novel fluorescent reporter hPSC lines relevant to studying fibrosis. This work will accelerate adoption of kidney organoid protocols for the research community.

Mesenchymal Stem Cells Derived from Induced Pluripotent Stem Cells and Bone Marrow Are Equally Effective in Ameliorating Lipotoxicity-Induced Kidney Injury

Bin Li, Joseph C K Leung, Loretta Y.Y. Chan, Wai Han Yiu, Kar Neng Lai, Sydney C. Tang. *Department of Medicine, The University of Hong Kong, Hong Kong, China*.

Background: Human induced pluripotent stem cell-derived mesenchymal stem cells (iPS-MSCs) are promising as an alternative to bone marrow-derived mesenchymal stem cells (BM-MSCs) for cell-based therapy. Lipotoxicity is an important pathogenetic factor leading to chronic kidney injury. This study aims to compare the therapeutic effects of iPS-MSCs and BM-MSCs in ameliorating lipotoxicity-induced kidney lesions.

Methods: Mice (C57BL/6J) fed normal diet (ND; 10 kcal%) or high-fat diet (HFD; 60 kcal%) for 12 weeks were randomly divided into vehicle control, iPS-MSC and BM-MSC subgroups (n=8 in each group), followed by infusion of saline or MSCs via tail vein and fed for further 8 weeks before sacrifice. Body weight, blood glucose and urine albumin were monitored throughout the experiment. Renal histological changes were assessed by Periodic acid-Schiff staining. Renal endoplasmic reticulum (ER) stress, inflammation and apoptosis were evaluated by real-time quantitative PCR, Western blot and TUNEL assay.

Results: Compared to ND group, mice fed HFD had significantly increased (1) body weight, blood glucose and urine albumin; (2) tubular injury score (tubular vacuolation and tubular glycogenated nuclei), glomerular size and mesangial expansion; (3) expression of markers for ER stress (BiP, p-eIF2α, ATF4, p-IRE1α, CHOP) and related phosphorylated signaling molecules (p-NF-κB, p-ERK, p-JNK); (4) expression of pro-inflammation mediators (IL-6, Cxcl1, Cxcl2) and (5) apoptosis (Bax/Bcl2 ratio and number of renal TUNEL-positive apoptotic cells). All these events were significantly attenuated by infusion with iPS-MSCs or BM-MSCs to the HFD-fed mice. Notably, iPS-MSCs and BM-MSCs infusion to HFD-fed mice have equivalent efficacy in ameliorating all the above-mentioned readouts in HFD-induced kidney injury.

Conclusions: Our study suggests comparable capability of iPS-MSCs and BM-MSCs in ameliorating lipotoxicity-induced kidney injury, supporting iPS-MSCs as a valuable alterative source to BM-MSCs for therapeutic application. Adipose-Derived Regenerative Cells: Therapeutic Potential

Rashida Lathan,[1] Ryan Ghita,[2] Patrick B. Mark,[1] Marc J. Clancy,[2] Rhian Touyz.[3] Marc Clancy and Patrick Mark Team *[1]University of Glasgow, Glasgow, United Kingdom; [2]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom; [3]Glasgow University, Glasgow, United Kingdom*.

Background: Studies in our hybrid rat model of transplantation/ischemic reperfusion injury (IRI) have demonstrated improvement in kidney function post injection of adipose-derived regenerative cells (ADRCs) into the renal artery. This technique has translational value in human transplant surgery as ADRCs provide a robust supply of cells from accessible tissue, do not require culturing, and can be generated/delivered at point of care during the time of transplant. The mechanism on how these cells establish regenerative conditions during IRI remains elusive.

Methods: Flow cytometric analysis was performed on rat ADRCs extracted from inguinal tissue (n=14). Cells were surveyed for markers that identify viability, immune cells, immune cell subsets, epithelial cells, pericytes, and mesenchymal stem cells. Rat ADRC RNA expression for angiogenic, anti-oxidant, and anti-/inflammatory markers were measured by real-time PCR. Whole body imaging and histology was performed to track DiR labelled ADRCs. Protein isolated from the kidney at 1 hour 24, and 48 hours post injection were surveyed with a proteome profile array and through western blotting.

Results: ADRCs appear to be a pleomorphic cell suspension with multiple potential active subsets including T-cells, macrophages and mesenchymal stem cells. RNA expression from whole rat ADRCs indicate production of growth and repair factors, and notably- angiogenin and matrix metallopeptidase-2; and chemokine, CXCL1. ADRCs accumulate in clustered regions of the corpuscle 1 and 24-hours post injection of ADRCs. Gene expression studies performed on the kidneys at 1, 24, and 48 hours post injection identified an upregulation of angiogenic factors VEGFa and angiogenin; anti-oxidant HO-1; and inflammatory factors IFN-gamma and IL-6 when compared to sham-injected control. Protein profiling indicated an upregulation of TIMP-1 and of ligands important in leukocyte trafficking.

Conclusions: Data in the context of our model, suggest they serve as a vehicle for discrete administration of angiogenic and anti-oxidant factors. Counterintuitively, data also suggests that concomitant to secreting repair factors, at early timepoints, factors are secreted which attract inflammatory-related immune cells. Collectively, changes in RNA and protein levels of leukocyte trafficking-related factors suggest a major role for leukocytes in early IRI repair.

Kidney Organoids for Improved Prediction of Human Nephrotoxicity

Akitoshi Tamura,[1] Koichiro Susa,[1,3] Pierre Galichon,[1] Navin R. Gupta,[1,2] Tomoya Miyoshi,[1] Venkata Sabbisetti,[1] Joseph V. Bonventre,[1,2] Ryuji Morizane.[1,2] *[1]Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Harvard Stem Cell Institute, Cambridge, MA; [3]Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan*.

Background: Nephrotoxicity accounts for only 2% of drug development failures in pre-clinical studies which rises to 19% of drug attrition during phase 3 clinical trials, highlighting the need for improved pre-clinical predictive tools. The poor predictability stems either from inter-species differences or from an inability to distinguish drug-specific versus generalized toxicity due to poor expression of drug transporters (TPs), such as Organic Cation Transporters (OCTs) and Organic Anion Transporters (OATs) in primary cells, and limited availability of co-culturing models recapitulating cell-cell interactions *in vitro*. Here we demonstrate the utility of human pluripotent stem cell-derived kidney organoids for pre-clinical nephrotoxic assessment.

Methods: Kidney organoids were generated following a 6-step directed differentiation protocol. Using qPCR and immunostaining, drug TP expression was characterized overtime from differentiation day 8 - 50. The following known nephrotoxicants were tested: cisplatin (an OCT-mediated tubular toxicant), aristolochic acid and tenofovir (OAT-mediated tubular toxicants), and puromycin aminonucleoside (a Plasma Monoamine Transporters [PMAT]-mediated podocyte toxicant). Injury responses were assessed by immunostaining, qPCR and biomarker assays. Cimetidine and probenecid, inhibitors of OCTs and OATs respectively, were employed to assess drug TP-mediated nephrotoxicity in tubules.

Results: Drug TPs, OAT1, OAT3, OCT2 and PMAT, were expressed in kidney organoids with maturity. Cisplatin 5 μM induced KIM-1 and γH2AX expression in LTL^+ tubules which was partially reversed by cimetidine, indicating TP-mediated injury. Cisplatin at 50 μM resulted in widespread injury to all nephron compartments with increased levels of MCP-1 and TNFR1 in culture media, representing generalized toxicity responses. Aristolochic acid and tenofovir also caused LTL^+ tubular injury at a low concentration, and probenecid suppressed injury responses. Puromycin aminonucleoside induced loss of foot processes and podocyte apoptosis without evidence of tubular injury.

Conclusions: Kidney organoids replicated drug TP-mediated nephrotoxicity in a segment-specific manner, serving as a novel pre-clinical tool to assess nephrotoxicity with the ability to distinguish between drug-specific and generalized toxicity responses.

Stem Cell-Derived Podocytes from Blacks with FSGS and High Risk ApoL1 Expressed More ApoL1 Protein and Reduced Viability in Response to Interferon γ

Opeyemi A. Olabisi,[1] Savannah Moore,[2] Rama Kataria.[3]
[1]Massachusetts General Hospital/Harvard Medical School, Boston, MA; [2]Massachusetts General Hospital, Brookline, MA; [3]Harvard Medical SChool, Boston, MA.

Background: Podocyte injury/loss is the cellular hallmark of ApoL1-nephropathies. Blacks with high risk (HR) ApoL1 alleles (G1G1, G2G2, or G1G2) have 7-10-fold increased risk of Focal segmental glomerulosclerosis (FSGS). HR ApoL1 is sensitive but not specific for FSGS. Estimated 20% of carriers of HR ApoL1 develop ApoL1-nephropathy. There is need for functional assay to identify truly at-risk blacks. Lack of disease-relevant podocyte model has stalled research progress. Our goal is to utilize stem-cell derived podocytes as tools for determining an individual's risk of ApoL1-nephropathy.

Methods: We recruited blacks with biopsy-proven FSGS (cases) and healthy controls with normal GFR and no proteinuria. ApoL1 was genotyped by sanger sequencing. Induced pluripotent stem cells (iPSCs) generated from PBMCs were differentiated into markers-confirmed podocytes based on published protocol. Podocytes were treated/not with interferon γ (IFNγ). Cell viability, comparative transcriptome, and protein expression were determined by cellular ATP content, RNA-seq and immunoblotting, respectively.

Results: 81.8% (9 of 11) cases have HR ApoL1 allele versus 16.7% (1 of 6) of controls. IFNγ induced higher ApoL1 protein expression in podocytes derived from cases despite similar intergroup ApoL1 mRNA levels. IFNγ reduced the viability of podocytes derived from cases with HR ApoL1 but not of controls, including control with HR ApoL1 genotype. Transcriptome analysis shows that IFNγ differentially upregulated genes involved in endocytic recycling, PI3K-mediated signaling, and actin filament-based movement in podocytes derived from cases.

Conclusions: iPSC- podocytes of blacks with ApoL1-nephropathies have a distinct cellular/molecular response to IFNγ which could be harnessed for Identification of blacks most at risk to develop ApoL1-nephropathy in future.

Modelling APOL1 Nephropathy Using Kidney Organoids

Justin Chun,[1,2] Martin R. Pollak,[3] Cristian Riella.[1] *[1]Beth Israel Deaconess Medical Center, Newton Center, MA; [2]Harvard Medical School, Boston, MA; [3]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA.*

Background: Apolipoprotein L1 (APOL1) is a gene expressed only in humans and some primates. Its genetic variants (G1 and G2) are strongly associated with kidney diseases including non-diabetic kidney disease, FSGS, and HIVAN. The mechanism leading to APOL1 nephropathy remains unclear partly due to inadequate animal models that can recapitulate the events leading to human disease.

Methods: We generated non-isogenic and isogenic iPSC lines for wild type APOL1 (G0) and risk variants (G1, G2) using dermal fibroblasts reprogrammed with Sendai virus. Kidney organoids were generated using the protocol established by Takasato et al. (Nat Protoc. 2016, 11:1681-92). RNA-sequencing was performed on differentiated kidney organoids day 28 with and without interferon (IFN)-gamma. After QC and adaptor trimming, reads were mapped to the reference genome with STAR aligner and then analyzed in EdgeR. Network analysis was performed with Metacore.

Results: As expected, iPSCs from different sources had variable characteristics in terms of rate of cell division, ability to differentiate and to form kidney organoids but we were able to select representative, comparable iPSC lines for the generation of kidney organoids. Our APOL1 kidney organoid model demonstrated expected localization of APOL1 to podocytes and proximal tubules and appropriately upregulate interferon stimulated genes when treated with IFN-gamma. APOL1 was equally expressed across the genotype groups. Gene enrichment analysis was notable for transcription changes in HIF1 targets in the risk variants compared with the wild type group.

Conclusions: Our human iPSC derived model for APOL1 nephropathy will be used to further characterize the APOL1 genetic variants. We now have a robust model that will serve as a platform for understanding the mechanisms that lead to disease, drug testing and potential cell therapies.

Identification of Nephron Progenitor Cell (NPC) Markers Derived from Human Embryonic Stem Cells (hESCs) by Single-Cell RNA Sequencing

Mien Nguyen, John F. Ouyang, Owen J. Rackham, Karl Tryggvason. *Duke-NUS Medical School, Singapore, Singapore.*

Background: The steady rise of chronic kidney diseases has caused a major burden for the healthcare systems worldwide. Yet, most of their molecular pathomechanisms are understudied due to the lack of functional model systems. In vitro modeling of kidney diseases and nephrotoxicity drug testing mainly employ immortalized kidney cell lines that do not truly represent their in vivo counterparts, or rely on limited sources of mouse and human primary kidney cells that de-differentiate in culture. hESC-derived NPCs, in contrast, may provide unlimited cell source for the generation of functional kidney disease models. Most current protocols differentiate pluripotent cells to various kidney cell types that aggregate into kidney organoids. These systems utilize undefined matrices and xenogenic products with high variability, making it difficult to study molecular disease mechanisms. The objective of this study was to generate a pure population of NPCs from hESCs in a chemically defined system through the identification of NPC markers.

Methods: hESCs were differentiated on human recombinant laminin toward mesoderm, metanephric mesenchyme and NPC lineage in the presence of relevant Wnt signaling molecule.

Results: By day 30, we observed 82% $WT1^+$ in total cell population via FACS analysis. Quantitative RT-PCR showed significant increases in mRNA expression of kidney lineage markers, in particular those of podocytes (OSR1, WT1, SYNPO, and NPHS1), and significant decreases in early metanephric mesenchymal markers from day 6 to day 30 (CD133 and CD24). We performed single-cell RNA sequencing on hESC-derived cells at different time points to establish signature surface markers that could allow us to purify and enrich for NPC population. From the analysis of the single-cell transcriptome, we have identified a set of genes whose gene expression profiles are highly correlated with those of podocyte lineage genes. Among those, we have selected potential surface markers for NPC enrichment, such as CD83, PLP2, and TM7SF2.

Conclusions: Our highly reproducible protocol allows efficient production of hESC-derived NPCs in monolayer in a chemically defined, xeno-free culture. These cells promise to provide an unlimited source to construct kidney disease models for analyzing drug clearance and toxicity, and for studying molecular disease mechanisms.

Identification of ROBO2 and Integrin B4 as Potential Surface Markers for the Isolation of Live Nephrogenic Cells from Human Fetal Kidneys

Astgik Petrosyan,[1] Julia Marcheque,[1] Matthew E. Thornton,[2] Brendan Grubbs,[2] Laura Perin,[1] Stefano Da Sacco.[1] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA.*

Background: In the developing kidney, the formation of new nephrons relies on a small population of self-renewing nephrogenic progenitors (NP) characterized by co-expression of SIX2 and CITED1. Despite their essential role in renal formation and maturation, identification of surface markers that can facilitate their isolation has not yet been successful. We report here the isolation of a live cell population with NP traits from human fetal kidneys (hFK) using a novel combination of surface markers.

Methods: We have previously reported the isolation of NP cells from hFK cells using RNA probes. Based on our RNA-seq performed on these cells we have identified ROBO2 and Integrin B4 as potential surface markers for direct isolation of NP of human origin. ROBO2+IntegrinB4+ cells were isolated using FACS and RNAseq analysis was immediately performed to characterize their gene expression and evaluate their genetic profile. Data were compared with the SIX2+CITED1+ cells isolated by RNA-probe. Dissociation/reaggregation assays were performed to confirm their nephrogenic traits. Potential for long term expansion was also explored.

Results: Expression of ROBO2 and IntegrinB4 was histologically confirmed within the cap mesenchyme during development in 17-week hFK. FACS of ROBO2+IntegrinB4+ cells from hFK confirmed enriched expression of SIX2 and CITED1 in more than 90% of the cells. RNASeq analysis confirmed expression of genes including SIX2, CITED1, SIX1, PHF19, OSR1 and EYA1 suggesting a nephrogenic signature. Expression of human NP markers was validated by flow cytometry. NP showed the ability to integrate in developing renal structures expressing nephrogenic markers when co-cultured with dissociated/re-aggregated hFK. Optimal culture conditions for long-term expansion without loss of NP traits were also successfully established.

Conclusions: Our preliminary results suggest that ROBO2 and IntegrinB4 are potential candidates as surface markers for the direct isolation of cells with nephrogenic characteristics, including the expression of SIX2 and CITED1, from hFK without the use of any genetic manipulation. This system represents a novel method of isolating a pool of NP that can be applied towards studies of renal cell specification, thus increasing our knowledge of human renal development

BMSCs Labeled with Sialyl Lewis X Had Higher Homing Rate to the Kidney of AKI Rats

Lin Yang,[1] Qi Wang,[2] Lihua Luo,[3] Fuli Luo,[4] Yun Li.[5] *[1]Nephrology, Jiangxi Provincial People's Hospital, Nanchang, China; [2]Nanchang University, Graduate School, Nanchang, China; [3]Ganzhou People's Hospital, Ganzhou, China; [4]Jiangxi University of Traditional Chinese Medicine?University Hospital, Nanchang, China; [5]Jiangxi Provincial Peoples' Hospital, Nanchang, China.*

Background: Bone marrow mesenchymal stem cells (BMSCs) were applied to treat various diseases. After transplantation, BMSCs could migrate to the injured organ which is called homing. To enhance homing, a new technology has been developed, in which biotin-streptavidin is used to attach sialyl LewisX, the ligand of adhesion molecule to BMSCs surface.

Methods: BMSCs from male SD rats were isolated, amplified, and labeled with sialyl LewisX by biotin-streptavidin system. The acute kidney injury(AKI) rat model was induced by cisplatin in female SD rats. Forty-eight AKI rats were divided into three groups: PBS, labeled BMSCs, and unlabeled BMSCs. After application of cisplatin, rats were transplanted with BMSCs or PBS.

Results: BMSCs significantly improved the renal function of AKI rats. Serum creatinine and blood urea nitrogen in BMSCs groups were statistically significantly lower than those of PBS group on 4-7 days after cisplatin injection (Fig. 1,2). Unfortunately the differences of renal function between the labeled and unlabeled groups were not statistically significant. There were more cells exuded in renal glomeruli and interstitium in the labeled group than in the unlabeled or PBS group, suggesting that the BMSCs labeling may increase BMSCs' homing to the kidney of AKI rats (Fig. 3-5). BMSCs reduced renal tubular and interstitial lesions to some extent, such as renal tubular dilatation, epithelial cell detachment, basement membrane exposure, intra-luminal cellular cast, interstitial edema and cell infiltration. The regeneration of renal tubular epithelium in transplanted groups were slightly higher (Fig. 6-8).

Conclusions: BMSCs labeled with sialyl LewisX had higher homing rate to the kidney of AKI rats. BMSCs transplantation significantly improved the renal function of AKI rats, and to some extent, reduced renal tubular and interstitial lesions.

Hypoxia-Preconditioned Mesenchymal Stem Cells Attenuate Renal Fibrosis by Upregulating Renal M2 Macrophage Polarization

Wei-Cheng Tseng,[1,3] Nien-Jung Chen,[4] Shih-Chieh Hung,[5,6] Der-Cherng Tarng.[2,3] *[1]Division of Nephrology, Department of Medicine, Taipei Veterans General Hospital; Institute of Clinical Medicine, National Yang-Ming University, Taipei, Taiwan; [2]Division of Nephrology, Department of Medicine, Taipei Veterans General Hospital; Institute of Clinical Medicine, Department and Institute of Physiology, National Yang-Ming University, Taipei, Taiwan; [3]Center for Intelligent Drug Systems and Smart Bio-devices (IDS2B), National Chiao-Tung University, Hsinchu, Taiwan; [4]Institute of Microbiology and Immunology, National Yang-Ming University, Taipei, Taiwan; [5]Integrative Stem Cell Center, Department of Orthopedics, and Graduate Institute of New Drug Development, Biomedical Sciences, China Medical University, Taichung, Taiwan; [6]Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan.*

Background: Tubulointerstitial fibrosis is the final common pathway of all kidney diseases and also represents the major determinant of renal function decline. Infiltrating renal macrophages critically govern the homeostasis of renal fibrogenesis and the extent of renal interstitial fibrosis. M1 macrophages release pro-inflammatory cytokines and result in tissue destruction; conversely, M2 macrophages secrete anti-inflammatory cytokines and promote tissue repair. Mesenchymal stem cells (MSCs) are promising cell-based therapy and previously we have shown hypoxia-preconditioned MSCs (HMSCs) exhibited better anti-inflammatory and anti-apoptotic effects. Nonetheless, whether HMSCs attenuate renal interstitial fibrosis through modulating the phenotype of infiltrating macrophages remains unclear.

Methods: Male C57BL/6J mice undergoing unilateral ureteral obstruction (UUO) were administered either phosphate-buffered saline, normoxic MSCs or HMSCs. Histology, fibrosis content, inflammation markers and macrophage phenotypes were analyzed in the obstructed kidney tissue. In vitro, we also determined the phenotypic change and inflammatory gene expression in M1 macrophages after coculture either with normoxic MSCs or HMSCs.

Results: The extent of fibrosis in UUO-injured kidney was significantly decreased by HMSCs treatment as compared with normoxic MSCs or phosphate-buffered saline. Interestingly, HMSCs significantly decreased the number of inducible nitric oxide synthase (iNOS)-positive M1 macrophages and contributed to early expression of arginase (Arg)-1-positive M2 macrophages in obstructed kidney than normoxic MSCs, suggesting that HMSCs facilitated an M1-to-M2 phenotypic transition in obstructed kidneys. Flow cytometry, immunoblotting and real-time polymerase chain reaction analysis also demonstrated that HMSCs downregulated STAT-1, iNOS expression and upregulating mannose receptor and Arg-1 expression. Furthermore, HMSCs treatment resulted in more anti-inflammatory M2c macrophages and less pro-fibrotic M2a macrophages infiltration in obstructive kidneys.

Conclusions: HMSCs treatment reduced renal fibrosis and facilitated an early M1-to-M2 phenotypic change of renal macrophages in mice UUO, predominantly upregulating M2c macrophages. HMSCs can be a promising therapeutic approach for the inflammatory fibrotic kidney diseases.

Adult Renal Stem/Progenitor Cells Exert Immunomodulatory Activity on T Regulatory Cells and Double Negative T Cells

Fabio Sallustio, Claudia Curci, Nada Chaoul, Angela Picerno, Rossana Franzin, Alessandra Stasi, Chiara Divella, Paola Pontrelli, Anna Gallone, Giovanni B. Pertosa, Giuseppe Castellano, Loreto Gesualdo. *University of Bari, Bari, Italy.*

Background: Several studies show the active role of Adult Renal Stem/Progenitor Cells (ARPCs) in kidney repair processes during acute or chronic injury. However, little is known about their immunomodulatory properties and their capacity to regulate specific T cell subpopulations. The aim of our study was to investigate the immunomodulatory properties of ARPCs on human T cells.

Methods: Human Peripheral Blood Mononuclear Cells (PBMCs) of healthy subjects were activated through incubation with Concanavalin A for 24h. ARPCs were activated by triggering TLR2 for 24h with Lipoteichoic acid (LTA) and co-cultured with T cells. Cell proliferation was measured by MTT cell viability assay. Phenotypic characterization of T cells was performed by flow cytometry. The relative expression levels of 36 cytokines of T cells and ARPCs, alone and in co-culture, were determined by Human Cytokine Proteome Array.

Results: TLR2-activated-ARPCs were able to decrease T cell proliferation after 24h of co-culture (p=0.017). In order to investigate changes in subset of T cell populations, we co-cultured PBMCs with activated ARPCs for short (5 days) and long period (15 days) of time. ARPCs did not affect CD3+CD8+ nor CD3+CD4+ T cells. Instead, we observed a significant decrease of Tregs (p<0.001) and CD3+CD4-CD8- DN T cell (p<0.0001) subpopulations after 5 and 15 days. Not significant effects were shown when T cells were co-cultured with renal proximal epithelial cells. Finally, by proteome array we identified cytokines secreted by ARPCs responsible for the immunomodulatory effect. SERPIN-E1, MIF, IL-8 and IL-6 were significantly up-regulated in the supernatant of T cells cocultured for 24h with TLR2-activated ARPCs, while were not present in supernatant of T cells alone.

Conclusions: Our data showed that ARPCs can regulate immune response by inducing T cell modulation through the TLR2 engagement. Interestingly, ARPCs lead to down-regulation of Tregs and DN T cells, which are involved in the balance between immune tolerance and autoimmunity. Moreover, we identified four cytokines with a key role in this system. These findings can help to clarify the role of ARPCs in immunomodulation and could be translated to potential clinical treatment.

Using the T30H Mouse to Investigate the Role of Myocardin in Obstructive Uropathy

Natalie J. Milmoe,[1] Daniel J. Stuckey,[2] Ahad A. Rahim,[3] Robert J. Harvey,[4] Paul Winyard.[1] *[1]UCL GOS Institute of Child Health, London, United Kingdom; [2]UCL, London, United Kingdom; [3]University College London, London, United Kingdom; [4]University of the Sunshine Coast, Sippy Downs, NSW, Australia*.

Background: Obstructive uropathies account for 20% of paediatric end stage renal failure. Irreparable damage often occurs to the kidneys before surgical correction of obstruction is possible. There are few in vivo models of this process. T30H mice were generated many years ago and have a balanced, heritable chromosomal translocation between chromosomes 2 and 11. The exact translocation point was previously unknown. They die soon after birth with large non-emptying bladders, hydronephrosis and reduced nephron numbers, despite there being no physical obstruction. Nevertheless, they are still a useful model for many features of obstructive uropathy.

Methods: We have utilised next generation sequencing, histology, RT-PCR and cell culture to examine gene expression and the bladder phenotype.

Results: We have investigated the T30H genome and discovered the exact translocation point, it does not span recognised genes, but is upstream of myocardin, a master regulator of smooth muscle. In the bladder, markers such as α SMA and Calponin are absent or expression is severely reduced. Urothelial markers such as Uroplakin 3a are unchanged. The translocation has no effect on all other systems involving smooth muscle, organs such as the heart and gut appear normal. The splice variants of myocardin present in wild type and T30H mice at birth are similar, suggesting expression levels of these splice variants are more important than whether or not they are expressed. Quantitative PCR will be required to confirm this hypothesis. We have isolated smooth muscle cells from wild type bladders at E14, then transfected them with lentivirus containing myocardin shRNA. This gene knockdown causes both reduced growth and expression of smooth muscle specific genes, including αSMA, consistent with the bladder phenotype *in vivo*. We are investigating the bladder phenotype in utero; the defect is identifiable using ultrasound from E16. In future we will uncover the developmental point when the defect is instigated, and whether the defect arises as a failure of muscle development, or whether the muscle grows and then is not maintained.

Conclusions: Understanding bladder smooth muscle regulation will better our knowledge of urinary tract development, and enable us to develop improved therapies for treating smooth muscle complications arising from urinary tract malformations.

Impact of Obesity on Mesenchymal Stem Cell Senescence

Sabena Conley,[1] Seo Rin Kim,[4] Hui Tang,[2] Xiang yang Zhu,[1] James L. Kirkland,[1] LaTonya J. Hickson,[1] Lilach O. Lerman.[3] *[1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic, Rochester, MN; [3]Mayo Clinic College of Medicine, Rochester, MN; [4]Mayo Clinic, Rochester, MN*.

Background: Obesity induces inflammation and contributes to the pathogenesis of kidney disease. Endogenous mesenchymal stem/stromal cells (MSC) mediate tissue repair, and show promise as exogenous therapy of kidney injury. However, chronic inflammation may impair the regenerative potential of MSC. We hypothesized that in human adipose tissue-derived MSC, obesity induces senescence, a growth-arrest program that transitions cells to a pro-inflammatory state.

Methods: MSC proliferation and migration were studied in MSC harvested from subcutaneous abdominal fat from obese (n=6, BMI ≥35 kg/m^2) and age-matched lean controls (n=6, BMI <30 kg/m^2) during bariatric or kidney donation surgeries. Cellular senescence was evaluated by senescence-associated β-galactosidase (SA-β-gal) activity (staining), and by expression of cell cycle arrest (p21) and senescent-associated secretory phenotype (SASP) (MCP-1, IL-1α, and PAI-1) markers (quantitative PCR).

Results: Among all subjects, mean age was 59±8 years, eGFR 64.8±15.3 mL/min/1.73m^2, and 66% were females. Obese-MSC exhibited similar proliferation capacity as Control-MSC, but their migratory potential was lower, suggesting MSC dysfunction (Fig A). Senescence burden as per SA-β-gal staining, p21 and SASP markers expression was elevated in Obese-MSC (Figs B-C).

Conclusions: Human obesity induces senescence in adipose tissue-derived MSC. This impairment in endogenous cellular repair systems may permit development of kidney lesions that are inadequately repaired in subjects with obesity, and limit delivery of autologous MSC to the subjects kidneys'.

The Metabolic Syndrome Alters the Transcriptome and Proteome of Swine Mesenchymal Stem Cells

Aditya S. Pawar, Alfonso Eirin, Xiang yang Zhu, Lilach O. Lerman. *Mayo Clinic, Rochester, MN*.

Background: Mesenchymal stem cells (MSCs) possess endogenous reparative properties & have been proposed as an exogenous therapeutic intervention in patients with chronic kidney disease (CKD). The metabolic syndrome (MetS) often coexists with and aggravates CKD, but whether MetS interferes with the reparative capacity of MSC remains unknown. We hypothesized that integrated comparison of the mRNA, microRNA, and protein content of MSCs isolated from Lean and MetS pigs would reveal pathways impacted in MSC by MetS.

Methods: Domestic pigs were fed a Lean or MetS diet (n=4 each) for 16 weeks. MSC were harvested from subcutaneous abdominal fat, and expression profiles of microRNAs, mRNAs, and proteins obtained by high throughput sequencing and LC-MS/MS proteomic analysis. TargetScan and ComiR were used to predict target genes of microRNAs (that often inhibit gene and protein expression) altered in MetS-MSCs. Functional annotation analysis was performed using DAVID 6.7 database.

Results: Differential expression analysis revealed 12 microRNAs upregulated in MetS-MSCs (fold change >1.4, p<0.05), which may target 7,728 genes, whereas 33 mRNAs and 78 proteins were downregulated (fold change <0.7, p<0.05). Integrated analysis showed that microRNAs upregulated in MetS-MSCs may target 33% of mRNAs and 45% of proteins downregulated in MetS-MSCs (Fig. 1A), and functional analysis showed that targeted proteins are mainly involved in apoptosis (e.g. CASP9, LAPTM5, LRG1) (Fig. 1B), angiogenesis (e.g. FGF1, AKT2) (Fig. 1C), and insulin signaling (e.g. AKT2, PP2CB) (Fig 1D).

Conclusions: MetS alters the transcriptome and proteome of swine adipose tissue-derived MSCs, via post-transcriptional regulation of genes and proteins involved in apoptosis, angiogenesis, and insulin signaling. MetS-induced changes in the MSC transcriptome and proteome may limit their use as an autologous cell-based regenerative therapy in CKD

Metabolic Syndrome and Renal Artery Stenosis Induce Mitochondrial Damage in Swine Scattered Tubular Cells

Arash Aghajani Nargesi, Xiang yang Zhu, Ishran M. Saadiq, Amir Lerman, Lilach O. Lerman, Alfonso Eirin. *Mayo Clinic Rochester MN, Rochester, MN.*

Background: Scattered tubular cells (STC) are considered to contribute to repair neighboring injured renal tubular epithelial cells. Mitochondria mediate STC biology and function, by producing energy and modulating redox status. We hypothesized that kidney injury due to coexisting metabolic syndrome (MetS) and renal artery stenosis (RAS) in swine impairs STC mitochondrial structure and function, which can be attenuated with mitoprotection.

Methods: CD24+/CD133+ STC (Fig. A) were isolated from pig kidneys after 16wks of MetS or Lean diet with or without RAS (n=7 each). Mitochondrial structure (electron microscopy), membrane potential (TMRE staining), and oxidative stress (Mito-SOX staining) were assessed in STC untreated or incubated with the mitoprotective drug elamipretide (ELAM, 1nM for 6hrs).

Results: Mitochondrial area increased and matrix density decreased in Lean+RAS- and MetS+RAS-STC compared to Lean- and MetS-STC, but both were restored in ELAM-treated pigs (Fig. B-C). Mitochondrial membrane potential diminished and mitochondrial production of reactive oxygen species increased in MetS-, Lean+RAS-, and MetS+RAS-STC, but reversed after treatment with ELAM (Fig. D-E).

Conclusions: Coexisting MetS and RAS induce structural and functional alterations in swine STC mitochondria, which might limit their regenerative potential. These observations suggest a potential role for mitoprotection in preserving the renal reparative capacity of STC.

Mechanisms Involved in the Disturbances in Renal Development in Pups from Vitamin D Deficient Dams

Lucas F. Almeida,[1] Heloisa D. Francescato,[1] Cleonice Silva,[2] Jose A. Rodrigues,[3] Terezila M. Coimbra.[1] *[1]University of Sao Paulo, Ribeirao Preto, Brazil; [2]Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto, Brazil; [3]FMRP-USP, Ribeirão Preto, Brazil.*

Background: Vitamin D_3 (Vit.D_3) has been related with cellular proliferation, differentiation and apoptose and with the regulation of renin gene, which are important events in renal development. Pups from dams submitted to a Vit.D_3 deficient diet during nephrogenesis (gestation and lactation), present changes in renal development that can persist in adult life. This study investigates the influence of Vit.D_3 deficiency on changes in renal development, the mechanisms involved and its consequences in adult life.

Methods: Offspring (Hannover rats) from mothers fed with normal (control group, CG) or vitamin D restricted (VitD-) diets were used in this study. Body weight (BW) was evaluated at birth, during lactation and at 3 months and 6 months of age. Systolic blood pressure (SBP) was measured monthly using a tail-cuff plethysmography. Blood and urine samples were collected to quantify Vit.D3, creatinine, Na^+, K^+, Ca^{+2}, angiotensin II (ANGII) and albuminuria levels. The kidneys were removed for histological, morphometric and immunohistochemical studies 3 and 6 months after birth.

Results: Vit.D deficient pups presented decreased BW at the end of lactation and increase in adult life compared to CG ($p< 0.05$). These animals showed higher SBP and plasma ANGII levels in the adult life compared to CG ($p< 0.05$). These pups also presented a significant decrease in urine osmolality, sodium and potassium fractional excretion and increase in water intake and urinary volume ($p< 0.05$). Decreased expressions of JG12 (a marker of endothelial cells) in renal cortex and glomerulus, and of synaptopodin (a marker of filtration barrier) in glomerulus were observed in VitD- compared to CG ($p< 0.05$). These animals also presented decreased glomerular area and increased fractional mesangial area compared to CG ($p< 0.05$). However, there was no difference in serum calcium levels, glomerular filtration rate, and albuminuria between the groups.

Conclusions: The current findings showed that the renal development is impaired in pups from dams VitD restricted with consequences in their adult life. These alterations can be at least in part provoked by the disturbances in the renal angiogenesis induced by the renin angiotensin system upregulation in pups with Vit.D deficiency

Autologous Mesenchymal Stromal Cell Paracrine Function in Diabetics with and Without Kidney Disease

LaTonya J. Hickson,[1] Alfonso Eirin,[1] Sabena Conley,[1] Ahmed Saad,[2] Ramila A. Mehta,[1] Hui Tang,[1] Ishran M. Saadiq,[1] John R. Woollard,[1] Sandra Herrmann,[1] Stephen C. Textor,[1] Lilach O. Lerman.[1] *[1]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [2]Mayo Clinic/ Loyola University Medical Center, Naperville, IL.*

Background: Cell-based therapy applying autologous mesenchymal stromal cells (MSCs) is a promising treatment option for diabetic kidney disease (DKD). MSC provide immunomodulatory, antioxidant, anti-fibrotic, and pro-angiogenic effects in the diseased kidney, but *the diabetic and/or uremic milieu may diminish their regenerative capacity in humans*. To test the relative contributions of these milieus, we studied MSC paracrine function in patients with diabetes with and without reduced kidney function.

Methods: MSCs were harvested from subcutaneous abdominal fat tissue of **DKD subjects** (**n=44**) and **Controls** (**n=6** kidney donors). Levels of secreted cytokines [VEGF, hepatocyte growth factor (HGF; angiogenesis), indoleamine 2,3-dioxygenase (IDO; immunomodulation)] were measured in conditioned media from 3rd passage MSC. MSC functional capacity was measured by migration and proliferation assays.

Results: DKD subjects were older (67±7 vs 47±22 years), had higher BMI (35±6 vs 30±4 kg/m^2), and lower eGFR (46±20 vs 92±24 mL/min/1.73m2; all p<0.05), while sex (females 41% vs 67%) and race (whites 84% vs 100%; all p>0.2) were similar to controls. eGFR was <60 in 36 (82%) DKD subjects. DKD-MSC **migration** and **proliferation** were reduced compared to Control-MSC (**Figure**) and their **IDO** secretion was lower. Yet, **VEGF** secretion was similar and **HGF** was increased in DKD-MSC. Most study differences between DKD-MSC and Control-MSC were independent of kidney function.

Conclusions: Diabetes blunts the migration and proliferation capacity of human MSC in vitro, with little further contribution by a fall in kidney function. Nonetheless, angiogenic cytokines important for kidney regeneration are relatively intact, supporting MSC suitability for autologous cell-based therapy in DKD patients.

Low Circulating CD34+ Cell Count Is a Significant Predictor of Cardiovascular Death Among Chronic Hemodialysis Patients

Ahmad B. Kaihan,[1] Yoshinari Yasuda,[2] Takahiro Imaizumi,[3] Masaki Okazaki,[3] Naotake Tsuboi,[3] Shoichi Maruyama.[3] *[1]Department of Nephrology/CKD, Nagoya University Graduate School of Medicine, Nagoya city, Japan; [2]Nagoya University Graduate School of Medicine, Nagoya, Aichi-ken, Japan, Nagoya, Japan; [3]Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Circulating CD34-positive (CD34+) cells play an essential role in neo-angiogenesis and in maintaining vascular endothelial function. A reduced CD34+ cell count was reported that associated with cardiovascular events and all-cause mortality. In this study, we aimed to validate association of low CD34+ cell count with cardiovascular death and all-cause mortality among chronic hemodialysis patients with longer follow up period.

Methods: In this prospective cohort study, 216 CKD patients on chronic hemodialysis enrolled from Mar 2005 to May 2005 and followed by the end of 2017 at Nagoya Kyoritsu Hospital. A cutoff number (0.41 cells/μl) for circulating CD34+ cells was determined by dividing all patients into two equal group of low CD34+ CPCs group (n=108) vs high CD34+ CPCs group (n=108) to predict cardiovascular death in the future, and the number of circulating CD34+ cells determined by flow cytometry at the time of enrollment. The primary outcome was cardiovascular death and all-cause mortality.

Results: During an average 59 months of follow-up, of 139 (64.7%) deaths, 38 (17.7%) cardiovascular deaths occurred. Cumulative cardiovascular death-free survival was significantly less in the low numbers of circulating CD34+ cells group. By multivariate analyses, age, DM, current smoking, history of CVD, and GNRI were significantly associated with all-cause mortalities, whereas, low numbers of circulating CD34+ cells (HR;1.98, p=0.037), GNRI (HR;0.95,p=0.042), and history of CVD (HR;2.92; p=0.031) were significant predictors for cardiovascular deaths.

Conclusions: This study revealed that a low number of circulating CD34$^+$ cells is significantly associated with risk of cardiovascular deaths, but not with all-cause mortalities in patients on chronic hemodialysis.

TH-PO654

Differentiation Efficiency of Human Induced Pluripotent Stem Cell (iPSC) to Endothelial Cells in Patients with ESRD

Do-hyun Na. Transplant research center, St. Mary's Hospital, College of Medicine *St. Mary's Hospital, College of Medicine, Seoul, Republic of Korea.*

Background: Human induced pluripotent stem cell-derived endothelial cells (hiPSC-ECs) could be promising for treatment of renal disease. However, it is unclear whether hiPSC could be differentiated to endothelial cell (EC) in ESRD patients. Therefore, we first sought to generate hiPSC from peripheral blood mononuclear cell (PBMC) of ESRD patient, then compared the efficiency of hiPSC lines differentiating into ECs with healthy control.

Methods: The hiPSC-ECs were generated from differentiation of hiPSCs using vascular endothelial growth factor (VEGF) and bone morphogenetic protein-4 (BMP-4). At first, the expression of iPSC markers (NANOG, SSEA-4, and TRA-1-81) were assessed with confocal laser scanning microscopy, then hiPSC-ECs were purified based on positive expression of CD31. Subsequently, expression of endothelial markers (CD31, CD 34, and CD 133) were assessed with flow cytometric analysis. After 6 days in cell culture, stain with pluripotency markers (NANOG, SSEA-4, and TRA-1-81) on confocal image revealed iPSC were successfully generated in both healthy control and ESRD patient.

Results: Upon magnetic purification based on CD31+ expression, the hiPSC-EC population was observed to display typical endothelial surface markers in both groups (CD31, CD34, CD133, vWF, and Flt). However, hiPSC-ECs from ESRD patient showed much lower colonies of co-expression of CD31/CD34, CD31/CD133, and CD34/CD133 in FACS, compared to normal control. This was consistent with that the percentage of CD31 expression cell or co-expression of CD31/CD34 cells to total cells were much lower in ESRD group compared to that of healthy control.

Conclusions: In conclusion, the efficiency of hiPSC differentiating into ECs in ESRD patient were diminished compared to healthy control.

TH-PO655

Prevalence Estimates of Polycystic Kidney and Liver Disease by Population Whole Genome Sequencing

Matthew B. Lanktree,[1] Amirreza Haghighi,[1] Elsa Guiard,[1] Ioan-Andrei Iliuta,[1] Xuewen Song,[1] Peter C. Harris,[2] Andrew Paterson,[3,4] York P. Pei.[1] *[1]Department of Medicine, Division of Nephrology, University Health Network, Toronto General Hospital, Toronto, ON, Canada; [2]Mayo Clinic, Rochester, MN; [3]Genetics & Genome Biology, The Hospital for Sick Children, Toronto, ON, Canada; [4]Epidemiology & Biostatistics, University of Toronto, Toronto, ON, Canada.*

Background: Estimating the prevalence of Autosomal Dominant Polycystic Kidney Disease (ADPKD) is challenging due to age-dependent penetrance and incomplete clinical ascertainment. ADPKD has an estimated lifetime risk of ~1 in 1000, while recent epidemiologic studies report a point prevalence of 3-5/10,000. Severe Autosomal Dominant Polycystic Liver Disease (ADPLD) is rare (<1 in 100,000), but milder forms may be clinically unrecognized. Quantity of functional polycystin-1 is a common genetic link between ADPKD and ADPLD. Using two large population sequencing databases, we estimated the lifetime prevalence of cystic kidney and liver diseases using stringent criteria for defining pathogenic variants.

Methods: Rare variants identified in genes involved in ADPKD (*PKD1, PKD2),* ADPLD (*SEC63, PRKCSH, GANAB, ALG8, SEC61B, LRP5*) and potential cystic disease

modifiers (*PKHD1, DZIP1L, UMOD, REN, MUC1, TSC1, TSC2, HNF1B, VHL, COL4A1, COL4A3, COL4A4, COL4A5)* were obtained from whole genome and exome sequencing from gnomAD ($n_{genomes}$=15,496, n_{exomes}=123,136) and BRAVO ($n_{genomes}$=62,784). Variants were evaluated for quality and annotation, compared with the Mayo PKD mutation database, and evaluated by bioinformatic prediction.

Results: High confidence pathogenic mutations in whole genome sequencing provides a lower bound lifetime ADPKD prevalence of 9.3/10,000 (95% confidence interval, 7.2 to 11.5). Estimates from whole genome and exome data were not statistically different. No significant differences in prevalence were observed between ethnicities. Protein truncating mutations in ADPLD genes and potential cyst modifier genes were found in 20.2/10,000 (95% confidence interval, 18.2 to 22.1) and 124.8/10,000 (95% CI, 119.4 to 129.1), respectively.

Conclusions: Population whole genome and exome sequencing supports a lower bound lifetime prevalence of ADPKD of about 1 in 1000. Truncation mutations in genes causative of ADPLD are surprisingly common, found in about 1 in 500. Individually rare variants in other cystic genes are cumulatively common and have the potential to modify the phenotype of ADPKD.

TH-PO656

Diverse Disease-Causing Genes in Clinical Diagnosed Autosomal Dominant Polycystic Kidney Disease in Taiwan

Daw-yang Hwang,[1] Chih-Chuan Yu,[2] Jer-Ming Chang,[1] Yi-Wen Chiu.[1] *[1]Kaohsiung Medical University, Kaohsiung, Taiwan; [2]Kaohsiung Medical University Chung-Ho Memorial Hospital, Kaohsiung, Taiwan.*

Background: To study the disease-causing mutations of autosomal dominant polycystic kidney disease (ADPKD) in Taiwan; we examined a total of 10 genes related to kidney and liver cysts. We collected a total of 153 ADPKD families and 40 cystic kidney disease individuals. The diagnosis of ADPKD were established by clinical and image studies from nephrology investigators. The study was approved by the institutional review board of the Kaohsiung Medical University Hospital.

Methods: We examined our cohort by study the disease-causing genes of ADPKD (*PKD1*, *PKD2*, *GANAB*, and *DNAJB11*), ARPKD (*PKHD1*), and ADPLD (*PRKCSH*, *ALG8*, *LRP5*, *SEC61B*, and *SEC63*). Long-range PCR primers were designed for *PKD1* exon1 to 33 and *PKD2* genes to avoid the amplification of *PKD1* pseudogenes. Primer pool 1 contained a total of 60 primer pairs for PKD1 exon 1 to 33 and the primer pool 2 contained 287 primer pairs for PKD1 exon 34-46 and other genes. Multiplex microfluidic PCR system (Fluidigm Access Array) was used, followed by barcoding PCR with next-generation sequencing on Illumina MiSeq or MiniSeq. Fastq files were loaded into CLCbio Genomic Workbench for bioinformatic analysis. Five microsatellites markers (D4S1534, D4S1542, D4S1563, D4S1544, D4S414) were used to analyze families with *PKD2* R803* mutation.

Results: We identified mutations in 74.5% (114/153) of the ADPKD families in Taiwan. PKD1 and PKD2 represented 65.8% and 34% of diagnosed families, respectively. More than half of PKD2 mutations (22/39) were *PKD2* R803* mutation. Marker D4S1563 differentiated those *PKD2* R803* families into two groups. Heterozygous mutations of *GANAB*, *ALG8*, *LRP5*, *SEC63*, and *PKHD1* were identified in our ADPKD cohort. Three missense PKD1 mutations were found in the non-ADPKD individuals.

Conclusions: Our study showed clinical diagnosed ADPKD is a genetic heterogeneous disease with different genes and variable clinical spectrum. De novo and compound heterozygous *PKD1* mutations were found in individuals presented with severe disease. Microsatellite analysis indicated two different but closely related founders leading to the high prevalence of *PKD2* R803* mutation in Taiwan. Furthermore, disease-causing ADPLD genes can be found in ADPKD families and *PKD1* mutations can be found in individuals diagnosed as simple kidney cysts.

TH-PO657

Development of Strategies for Genetic Diagnosis of Hereditary Glomerulopathies, Tubulopathies, and Cystic Kidney Diseases by the Sequencing Sets of Genes

M. Lara Besada-Cerecedo,[2] Noa Carrera cachaza,[3] Maria Garcia-Murias,[3] Ana Barcia de la Iglesia,[2] Jorge Amigo,[4] Beatriz Sobrino,[4] Angel Carracedo,[4] Candido Diaz-Rodriguez,[5] Miguel A. Garcia-Gonzalez.[1] *[1]Health Research Institute of Santiago de Compostela (IDIS)., Santiago de Compostela, Spain; [2]IDIS, Santiago de Compostela, Spain; [3]Fundación Instituto de Investigación Sanitaria de Santiago (FIDIS), Santiago de Compostela, Spain; [4]University of Santiago de Compostela, Santiago de Compostela, Spain; [5]University Clinical Hospital of Santiago de Compostela (CHUS), Santiago de Compostela, Spain.*

Background: Accurate clinical diagnosis in hereditary renal pathologies, especially glomerular and tubular disease, has proven to be difficult, as different pathologies may appear as clinical phenocopies. Genetic studies have the advantage of ensuring an accurate diagnosis and anticipate the disease. The implementation of NGS technology into routine genetic diagnostic practices allows the screening of large sets of genes in a single test.

Methods: Our group, based on the clinical classification, generated different panels for the sequence of renal disease genes in single tests: (1) panel for cystic kidney disease (up to 72 genes) (2) panel for glomerular disease (26 genes) and (3) panel for tubular disease (36 genes). Also, our group solved one of the limitations of conventional pre-designed NGS kits for target enrichment in regions with high homology pseudogenes (such as the *PKD1* gene) by developing particular primers to amplify specifically the replicated region of *PKD1* gene (exons 1-34).

Results: By analyzing a cohort of 291 families with PKD clinical diagnosis, we identified the causal mutation in 88% (n=255) of the families. In 94% (n=240) of these cases the clinical and genetic diagnosis were concordant. Of the 71 patients with a clinical diagnosis of glomerular disease and 31 with tubular disease subjected to genetic analysis, we identified the causal mutation in 62% (n=44) and 52% (n=16) of the cases, respectively. The concordance between genetic and clinical diagnosis was 66% (n=29) for the glomerular cohort and 69% (n=11) for tubular cohort. Most cases of misdiagnosis were associated with syndromic diseases with very similar phenotypes, such as Gitelman and Bartter syndromes.

Conclusions: The strategy of grouping genes by phenotype for genetic testing probed to be efficient in finding the causal mutation. Our results make clear the need of a genetic test to avoid misdiagnosis of certain renal pathologies.

TH-PO658

Whole Exome Sequencing Identifies Several Patients with Undiagnosed Autosomal Dominant Polycystic Kidney Disease in an Unselected Cohort

Yoosif Abdalla,[2] Jonathan Z. Luo,[2] Jamie A. Green,[2] Prince Mohan,[1,2] Tooraj Mirshahi,[2] Alex R. Chang.[2] *[1]Geisinger Medical Center, Danville, PA; [2]Geisinger, Danville, PA.*

Background: The utility of whole exome sequencing (WES) to identify genetic causes of end-stage renal disease (ESRD) such as autosomal dominant polycystic kidney disease (ADPKD) is uncertain.

Methods: We used WES data from the Geisinger-Regeneron DiscovEHR cohort, an ongoing health system-based genetics study, to identify patients with putative loss of function (pLOF) *PKD1* and *PKD2* mutations. Clinical evidence of ADPKD was ascertained using electronic health record data [diagnosis codes, estimated glomerular filtration rate (eGFR), family history], and confirmed by chart review. We considered ADPKD to be undiagnosed if there was no mention of the diagnosis in clinic notes.

Results: Out of 91,365 adults with WES data, we identified 87 (66 *PKD1*, 21 *PKD2*) patients with pLOF mutations. A total of 44 (29 *PKD1*, 15 *PKD2*) patients had previously been diagnosed with ADPKD, including 24 (21 *PKD1*, 3 *PKD2)* patients with ESRD **(Figure)**. Of the remaining 43 patients without existing ADPKD clinical diagnoses, 24 had imaging data available, and 5 had radiologic findings suggesting ADPKD (3 with multiple renal and liver cysts, 2 with multiple bilateral renal cysts). One of the 5 patients with undiagnosed ADPKD had *PKD2* pLOF mutation, ESRD at the age of 70 attributed to hypertension and diabetes and a brother with ESRD attributed to diabetes. The remaining 4 patients with radiologic findings suggesting ADPKD but no clinical diagnosis had eGFR ranging from 48 to 129 ml/min/1.73m^2). There were 19 patients with renal imaging (18 *PKD1*, 1 *PKD2*) who had no renal cysts.

Conclusions: Population-based WES may provide an opportunity to identify previously undiagnosed ADPKD patients who could benefit from targeted treatment and family counseling. Additional targeted sequencing will be needed to confirm WES results for PKD1 mutations.

TH-PO659

A Genotype-First Approach Identifies Atypical PKD in DNAJB11 Mutation Carriers

Jonathan Z. Luo,[1] Bryn S. Mooore,[1] Whitney E. Besse,[2] Stefan Somlo,[2] Alex R. Chang,[1] Tooraj Mirshahi,[1] Dustin N. Hartzel.[3] *[1]Geisinger, Danville, PA; [2]Yale University, New Haven, CT; [3]Geisinger Health System, Danville, PA.*

Background: Approximately 7-8% of autosomal dominant polycystic kidney disease (ADPKD) cases remain genetically unresolved. Mutations in *DNAJB11*, an ER co-chaperone molecule with a significant role in polycystin-1 maturation and trafficking, were recently identified in ADPKD patients with non-enlarged, cystic kidneys in the absence of PKD1/2 mutations. Little is known about the association between putative loss of function (pLOF) *DNAJB11* mutations with ADPKD in an unselected population.

Methods: We used whole exome sequencing (WES) from 91,365 patients in the Geisinger-Regeneron DiscovEHR cohort to identify patients with pLOF *DNAJB11* mutations (early-termination, frameshifts and start-loss mutations). Electronic health record data (diagnostic billing codes, eGFR, imaging) were examined to determine clinical phenotype. Evidence for the presence of renal and liver cysts was determined using natural language processing and manual review of imaging reports.

Results: We found 7 *DNAJB11* pLOF variants in 10 patients (median eGFR 60 mL/min/1.73m2) in our cohort, of whom 9 had renal imaging. Of the 2 younger patients (age 26 and 28) with renal imaging, 1 had a unilateral renal cyst, and 1 had bilateral hydronephrosis and right nephrolithiasis. Of the 7 older patients (age 49-72) with renal imaging, 3 had multiple, bilateral renal cysts, and 1 had multiple, unilateral renal cysts. One patient was diagnosed with ESRD at age 59. Two of the 7 patients were sisters carrying the same early termination mutation: a 61yo presenting with bilateral renal cysts, and a 55yo with multiple left renal cysts. Three patients carried rare *PKD1* missense variants (MAF 0.01%-0.15%), all of which are classified as *Likely Neutral* in the Mayo PKDB. Three patients presented with nephrolithiasis. Only one patient was hypertensive.

Conclusions: Using WES in an unselected population, our findings provide further evidence that loss of function mutations in *DNAJB11* could lead to normal-sized cystic kidneys and ESRD. Furthermore, we show the utility of a large-scale exome sequencing study combined with detailed EHR data in identifying rare genetic causes of kidney disease.

TH-PO660

PKD1 Duplicated Regions Limit Clinical Utility of Whole Exome Sequencing for Genetic Diagnosis of ADPKD

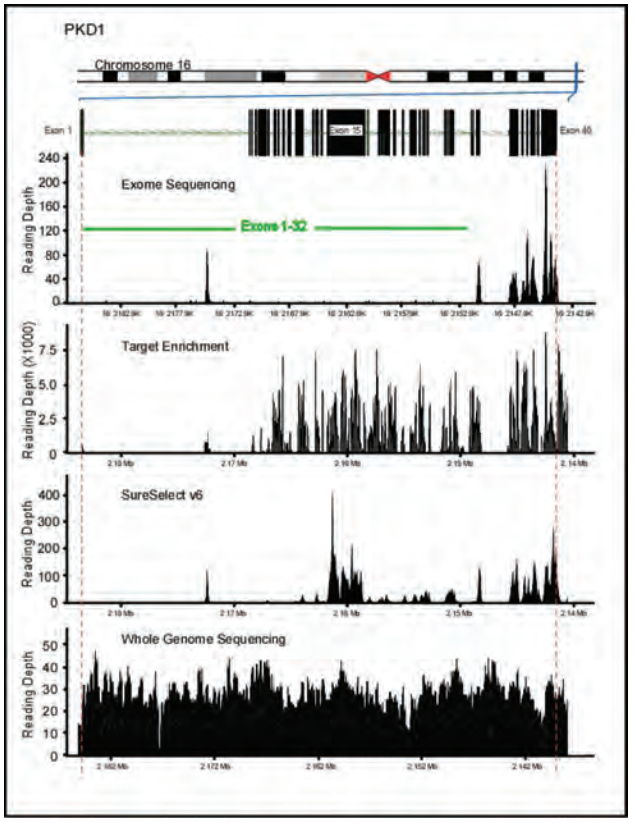
Hamad Ali,[1,2] Peter C. Harris.[3] PKD-KWI gorup *[1]Kuwait University, Jabriya, Kuwait; [2]Functional Genomic unit, Dasman Diabetes Institute, Dasman, Kuwait; [3]Mayo Clinic, Rochester, MN.*

Background: Genetic diagnosis of ADPKD is complicated by the existence of *PKD1* pseudogenes located proximal to the original gene. The ability of NGS platforms in identification of ADPKD mutations, especially in the duplicated regions of *PKD1*, is important for potential utilization of such technologies in diagnostic applications.

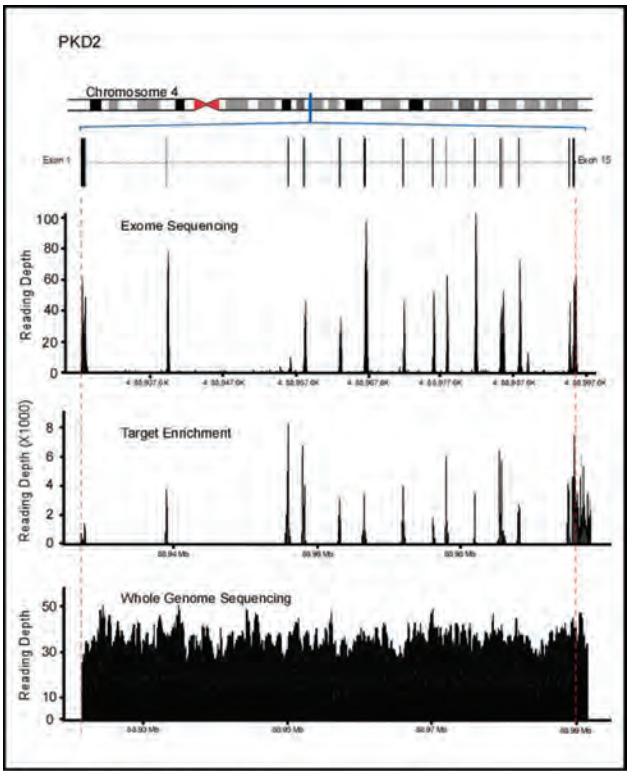
Methods: We evaluate the efficiency of WES, WGS & Targeted enrichment in sequencing *PKD1* and *PKD2* for the detection of ADPKD mutations in patients who were clinically evaluated by ultrasonography and RFT.

Results: WES had a 50% sensitivity in detection of *PKD1* mutations as the reading depth and sequencing quality were low over the duplicated regions of *PKD1*.

Conclusions: Our investigation highlights a major limitation of WES platform in ADPKD genetic diagnosis.



***WES and Target enrichment coverage map of* PKD1.** *WES of exons 1 to 32 of* PKD1 *showed low coverage while PKD2 coverage showed proper depth of all exons. Target Enrichment showed proper coverage for coding regions of PKD1 and PKD2. SureSelect v6 improved the coverage of* PKD1 *but in comparison to WES but exons 1 to 14 remained poorly covered. WGS showed proper covering of the entire* PKD1.



***WES, Target enrichment coverage map and WGS of* PKD2.** PKD2 *was covered properly using all methods.*

TH-PO661

The Genetic Complexity of ADPKD Is Illustrated in the HALT PKD Clinical Trial Cohort

Sarah R. Senum,[1] Emilie Cornec-Le Gall,[2] Godela M. Brosnahan,[7] Arlene B. Chapman,[3] Vicente E. Torres,[1] Ronald D. Perrone,[4] Alan S. Yu,[5] Theodore I. Steinman,[6] William E. Braun,[9] Kaleab Abebe,[8] Kyongtae T. Bae,[8] Peter C. Harris.[1] HALT PKD Consortium *[1]Mayo Clinic, Rochester, MN; [2]Centre Hospitalier Universitaire de Brest, BREST, France; [3]University of Chicago, Chicago, IL; [4]Tufts Medical Center, Boston, MA; [5]University of Kansas Medical Center, Kansas City, KS; [6]Beth Israel Deaconess Medical Center, Boston, MA; [7]University of Colorado Denver, Aurora, CO; [8]University of Pittsburgh, Pittsburgh, PA; [9]Cleveland Clinic, Cleveland, OH.*

Background: The HALT PKD clinical trials consisted of hypertensive ADPKD patients, 15-49y with an eGFR >60 ml/min/1.73m^2 (Study A; n=558) or 18-64y with an eGFR 25-60 ml/min/1.73m^2 (Study B; n=486), but without total kidney volume requirements for recruitment. Hence, this population represents the cross-section of ADPKD seen by nephrologists and so provides an opportunity to characterize the genetics of a "typical" renal clinic population.

Methods: DNA samples were available from 970 patients from Study A and B that were screened by Sanger sequencing and MLPA for the *PKD1* and *PKD2* genes. Genetically unresolved cases were screened on a next generation sequencing (NGS) panel containing 65 known or candidate PKD genes. In some cases, further family analysis was performed to test segregation.

Results: Likely pathogenic mutations were detected in 95.1% of cases, 506 (52.2%) and 266 (27.4%), *PKD1* truncating or *PKD1* non-truncating, respectively, with 166 (15.2%) *PKD2.* The NGS revealed 23 mutations missed by the Sanger screen (21 *PKD1*, 2 *PKD2*), some due to allele drop out, with two others still being evaluated. A GANAB and a DNAJB11 family were identified, plus one with *PKD2* and *COL4A1* mutations. Five patients were *PKD1* mosaics, detected due to family analysis (2x), MLPA (1x), or NGS (2x), with the mutant allele at ~20-40% of the wildtype level. One patient was digenic for a *PKD1* (2 codon, inframe deletion) and a *PKD2* (nonsense) mutation, with ESRD=43y. Two *PKD1* mutations were likely gene conversions with the *PKD1* pseudogenes, and in three other cases the pathogenic allele consisted of three weak *PKD1* variants in cis shown in vitro to have additive effects. Two PKD2 patients co-inheriting hypomorphic *PKD1* variants had move severe disease than expected.

Conclusions: While the majority of HALT PKD patients have ADPKD due to a monoallelic mutation to one of the two common genes, a total of five causative genes have now been identified. Mosaicism or complex inheritance were also characterized in >1% patients, likely an underestimate of the true complexity due to difficulty of detection and interpretation, in this "typical" ADPKD population.

Performance of Targeted Cystogene Next Generation Sequencing in an ADPKD Population with CKD

Sarah R. Senum,[1] Saurabh Baheti,[1] Emilie Cornec-Le Gall,[2] Vicente E. Torres,[1] Peter C. Harris.[1] *[1]Mayo Clinic, Rochester, MN; [2]Centre Hospitalier Universitaire de Brest, BREST, France.*

Background: Next generation sequencing (NGS) panels containing all genes in a disease category can provide high throughput, comprehensive coverage with a single screen, be cost effective, have high diagnostic efficiency, and provide information about possible disease modifiers. Mutation data in ADPKD is increasingly being recognized for its diagnostic and prognostic value. However, screening ADPKD populations is complicated by genic and extreme allelic heterogeneity, segmental duplication of *PKD1* with six pseudogenes sharing >97% sequence similarity with *PKD1*, and several GC rich regions.

Methods: The screened ADPKD patients had impaired renal function but without ESRD. Samples were screened using an NGS panel containing 136 known or candidate renal cystic or ciliopathy genes. Read alignment and variant calling were performed using the Genome Analysis Toolkit, and LOG2 ratio data was generated to assess for large deletions or duplications. Variant mining was performed with Golden Helix SNP & Variation Suite. Predicted pathogenic base pair variants were confirmed by Sanger sequencing with Multiplex Ligation-dependent Probe Amplification (MLPA) employed to confirm large rearrangements.

Results: A >40x read depth was obtained for 96.80 ± 0.14% (95% CI) of the 683kb target region, although lower coverage of particularly GC rich regions of *PKD1* was found. Of 384 cases with complete analysis, 187 (48.7%) were *PKD1* truncating, 98 (25.5%) *PKD1* non-truncating, and 63 (16.4%) *PKD2*. The pathogenic variants included 11 large deletions (8 in *PKD1* and 3 in *PKD2*) and 2 large duplications (*PKD1*) detected by CNV analysis. The 36 (9.4%) unresolved cases, including some with *PKD1* and *PKD2* variants of uncertain significance, are being rescreened by the conventional LR-PCR/Sanger approach to determine if specific mutations were missed. Genic and allelic complexity is also being assessed in these cases.

Conclusions: Targeted NGS identifies *PKD1* and *PKD2* pathogenic variants nearly as effectively as cumbersome LR-PCR/Sanger approaches. Detailed analysis of negative cases will detect screening deficiencies and highlight possible improvements to the panel design.

PKD1 Truncating Mutations with Mild Kidney Disease Is Underrecognized

Elsa Guiard,[2] Matthew B. Lanktree,[2] Ioan-Andrei Iliuta,[2] Beili Shi,[2] Marina Pourafkari,[2] Xuewen Song,[1] Korosh Khalili,[2] York P. Pei.[2] *[1]University of Toronto, Toronto, ON, Canada; [2]University Health Network and University of Toronto, Toronto, ON, Canada.*

Background: Renal disease is highly variable in autosomal dominant polycystic kidney disease (ADPKD). Multiple studies have shown that *PKD1* protein truncating (PT) mutations are associated with the most severe disease with larger TKV and earlier onset of renal failure among all mutation classes. In the Extended Toronto Genetic Epidemiology Study of Polycystic Kidney Disease (eTGESP), we sought to determine whether *PKD1* PT mutations were uniformly associated with severe kidney disease.

Methods: The study cohort comprised 1279 patients from 555 families recruited in Toronto between 2006 and 2017. All recruited families were comprehensively screened for *PKD1* and *PKD2* mutations; Mayo Clinic Imaging Classification (MCIC) was performed in 430 patients with TKV by MRI. Kidney function and MCIC were used to assess disease severity.

Results: We studied 430 patients with TKV and mutation results for their renal disease severity. Among 146 patients with *PKD1* PT mutations and TKV, 31 (21%) from 28 families were found to have mild renal disease (MCIC 1A or 1B; most with normal eGFR) which is comparaible to patients with PKD2 mutations (Table 1). Three families displayed concordance with mild renal disease among affected family members; 13 families displayed discordance with both mild and severe disease among affected family members. Their *PKD1* PT mutations were distributed across all exons and included 16 frameshift, 10 nonsense, and 2 canonical splice site mutations. No patients had atypical kidney imaging patterns.

Conclusions: We found mild kidney disease comparable to that associated with *PKD2* mutations in 21% of patients with *PKD1* PT mutations. The presence of a positive familiy history of ADPKD in many of these patients makes somatic mosaicism an unlikely explanation. Rather, our data suggest a favorable modifier effect due to as yet unidentified genetic and/or environmental factors. Future research to identify factors underpinning this modifier effect can provide insight into disease mechanism and improve patient care.

Molecular Genetic Analysis in Patients with Severe Polycystic Kidney Disease

Lena Obeidova,[1] Jitka Stekrova,[1] Jana Reiterová,[2] Vladimir Tesar.[2] *[1]Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czechia; [2]Department of Nephrology, Charles University and General Teaching Hospital, Prague, Czechia.*

Background: Autosomal recessive polycystic kidney disease (ARPKD) is a severe form of chronic kidney disease, frequently diagnosed prenatally. ARPKD is primaly caused by mutations in the PKHD1 gene, nevertheless, phenotype of polycystic kidneys with early onset is present as a part of several syndromes caused by mutations in number of other genes, such as HNF1β, PKD1, PKD2, NPHP etc. Thus, the molecular genetic analysis can be very useful in differential diagnosis of polycystic kidneys in young patients. The results of complex molecular genetic analysis of 42 patients with very early onset PKD are presented.

Methods: The molecular analysis was carried out using next-generation sequencing (NGS) method with capture-based library preparation. The panel of about 80 genes associated with the formation of polycystic kidneys was analyzed. Sequencing data were analyzed with an in-house bioinformatic pipeline designed for detection of single nucleotide variants, small indels and CNV (copy-number variation). Due to the existence of pseudogenes, the PKD1 gene was simultaneously analyzed by NGS with amplicon-based library using long-range PCR. The group of patients comprised 39 young patients with polycystic kidneys (16.6±13.4) and three prenatally diagnosed fetuses. All patients had phenotype compatible with ARPKD, early onset ADPKD or polycystic kidneys in combination with additional abnormities in various organs.

Results: The panel of 80 genes was analyzed in all 42 patients. Thirteen patients harbored mutations in genes PKHD1 or PKD1. In one child combination of one PKHD1 and one TMEM237 mutation was found (p.I2957T and p.A18X, respectively). Such a finding could explain phenotype of polycystic kidneys arising in a young age of this patient. But mutations in other genes were also found in 13 patients: TMEM67, NPHP4, OFD1, BBS1, BBS12, PEX6. These genes with detected mutations are associated with nephronophthisis and developmental abnormalities of kidneys. These heterogeneous findings mirror variable and unclear phenotype of young patients with polycystic kidneys.

Conclusions: Because of an etiologic heterogeneity of polycystic kidney disease phenotype, especially in patients with polycystic kidneys arising prenatally or in a very early age, the complex mutational analysis of several genes is needed for reliable diagnosis. TH-PO665

Rare Deleterious Collagen IV Gene Variants Are Overrepresented in "No Mutation Detected" ADPKD Patients

Ashima Gulati,[1] Jungmin Choi,[2] Stefan Somlo.[1] *[1]Yale University, New Haven, CT; [2]Genetics, Yale University, New Haven, CT.*

Background: Genetic investigation of autosomal dominant polycystic kidney disease (ADPKD) cohorts yields the underlying *PKD1* (77%) or *PKD2* mutation (15% cases); 8% cases have no mutation detected (NMD) in these genes. This NMD group may include ADPKD phenocopies. Type IV collagen, an integral component of the basement membrane exists mainly as α1α1α2 and α3α4α5 heterotrimers in the kidney. Mutations in genes encoding these α-chain isoforms are linked to Alport syndrome (*COL4A3*, *COL4A4*, *COL4A5*), Thin GBM disease (*COL4A3*, *COL4A4*) and HANAC (hereditary angiopathy, nephropathy, aneurysms, muscle cramps) (*COL4A1*). Bilateral kidney cysts are reported with heterozygous *COL4A1* mutations as part of HANAC syndrome and also sporadically in few patients with thin GBM disease.

Methods: A clinically and radiologically defined ADPKD cohort (N=178) constituting patients with *PKD1* or *PKD2* mutation (N=161) and those with NMD (N=17) in *PKD1, PKD2* or other genes known to associate with polycystic kidneys (*GANAB, DNAJB11* or Polycystic Liver Disease genes) was investigated using whole exome sequencing for rare (minor allele frequency $<5x10^{-5}$) variants meeting deleteriousness criteria using bioinformatics scores.

Results: Analysis of NMD patients (N=17) identified pathogenic heterozygous type IV collagen variants in four patients. These included HANAC causing *COL4A1* variants in 3 patients, of which 2 had missense variants each and one patient was compound heterozygous for a *COL4A1* truncating variant and a *COL4A3* missense variant. One patient had a splice site *COL4A4* variant that we confirmed to cause complete skipping of exon 28 by a minigene splice assay. Collagen IV variants of similar deleteriousness assessed in 161 patients with a *PKD1* or *PKD2* mutation revealed a significantly lower burden as compared to NMD patients (*COL4A1;* p-value 0.009); (*COL4A3* and *COL4A4*; p-value 0.029). Clinical and imaging review of NMD patients with collagen IV variants showed fewer or atypical appearing cysts.

Conclusions: Rare deleterious mutations in *COL4A1*, *COL4A3*, *COL4A4* are overrepresented in the 'no mutation detected' ADPKD cohort. Characterization of predicted deleteriousness of type IV collagen variants using bioinformatics scoring and splice assay is useful. The causation link, if any, between the type IV collagen genes and cystic kidneys is however elusive.

Correlation of Gene Mutation and Prognosis in Japanese ADPKD Patients

Keisuke Kawashima,[1] Saori Nishio,[1] Kanako Watanabe,[1] Toyokazu Seki,[2] Hiroki Shimada,[3] Naoki Nakagawa,[4] Daigo Nakazawa,[1] Yasunobu Ishikawa,[1] Tatsuya Atsumi.[1] *[1]Hokkaido University, Sapporo, Japan; [2]Otsuka Pharmaceutical Co.,Ltd, Tokushima, Japan; [3]Kitami Red-crossß Hospital, Kitami, Japan; [4]Asahikawa Medical University, Asahikawa, Japan.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the most prevalent hereditary renal disorder. PKD1 mutation is one of the risk factors of worse renal prognosis. Recently, the prognostic classification(Mayo classification), based on height-adjusted total kidney volume and age, has been proposed to predict renal outcomes. It is still unclear, however, whether PKD 1 mutation is definitive risk factor in Japanese patients due to the lack of relevant studies. The aim of this study is to examine whether known risk factors of ESRD are valid to predict renal prognosis in Japanese ADPKD patients.

Methods: Study design: retrospective cohort study. Primary outcome : Event-free survival rate; more than 30% decline in eGFR and initiation of renal replacement therapy were defined as event. We enrolled patients who visited our hospitals during 2006-2016. Gene analysis to detect PKD1 or PKD2 mutation was performed in all participants. Patients were classified into 1A~1E according to height-adjusted TKV (HtTKV) and age according to the Mayo classification. Cox proportional hazard model was used to estimate hazard ratios for renal event.

Results: We identified 255 patients with ADPKD. Among them, 191 patients (74.9%) had PKD1 mutation, 50 patients (19.6%) had PKD2 mutation, and in 14 patients (5.5%), we could not detect the mutations. In PKD1 group, larger proportion of patients were classified into 1C~1E of Mayo classification [1A: 6 (3.1%), 1B: 44 (23.0%), 1C: 76 (39.8%), 1D: 38 (19.9%), 1E: 27 (14.1%) vs 1A: 5(10%), 1B: 17(34.0%), 1C: 18 (36.0%), 1D: 9 (18.0%), 1E: 1 (2.0%)], which indicated worse prognosis in PKD1 group compared with PKD2 group at the baseline. The hazard ratio for renal event among PKD1 group, compared with PKD2 group was 2.45 (95% CI: 1.14-6.40; *P=0.0196*). The event free survival rates in patients with PKD1 truncating mutation and those with non-truncating mutation were 34.6% and 29.8%, respectively, but their difference was not statistically significant (Hazard ratio 1.1, 95% CI: 0.65-1.84; P=0.70).

Conclusions: This is the one of the largest cohort studies of ADPKD patients with gene analysis in JAPAN. In Japanese ADPKD, patients with PKD1 mutation had significantly worse renal prognosis than those with PKD2 mutation, as reported in American and European population.

TH-PO667

Quality Control of Polycystin 2 Missense Mutants in the Endoplasmic Reticulum

Christopher J. Guerriero, Jeffrey L. Brodsky. *University of Pittsburgh, Pittsburgh, PA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a common inherited disorder and is a leading cause of end-stage renal disease. ADPKD arises from mutations in the *PKD1* and *PKD2* genes, encoding the primary ciliary proteins polycystin 1 (PC1) and polycystin 2 (PC2), respectively. Myriad mutations have been documented throughout the *PKD* loci, ultimately resulting in aberrant signaling, cell proliferation, and fluid secretion. In addition to the primary cilium, PC2 also localizes to the endoplasmic reticulum (ER). Given PC2's large size, topological complexity, and localization, we hypothesize that PC2 missense mutants may misfold and be turned over by the endoplasmic reticulum-associated degradation (ERAD) pathway. ERAD triages newly synthesized aberrant proteins and directs misfolded or misassembled confomers for degradation via the ubiquitin proteasome system. Due to an incomplete understanding of the factors that influence early events during PC2 maturation, we investigated PC2 biogenesis in the genetically-tractable model system, *S. cerevisiae*.

Methods: We have established a yeast expression system for 3XHA-PC2 to study the early biosynthetic decisions that mediate the folding, maturation, and degradation of PC2 missense mutants. Disease-causing PC2 variants were generated by site-directed mutagenesis, expressed in *S. cerevisiae*, and their metabolism was examined using cycloheximide chase analysis. Results from the yeast model were further confirmed via transient transfection of GFP-PC2 into HEK293 cells.

Results: Our preliminary data indicate that select PC2 missense mutants are more rapidly degraded in both yeast and HEK293 cells relative to wild type PC2. Moreover, unstable PC2 mutants are more highly poly-ubiquitinated than wild type PC2. In addition, following treatment with the proteasome inhibitor MG132, the level of polyubiquitinated protein increases to a greater extent for PC2 missense variants, suggesting selective turnover by the proteasome.

Conclusions: The findings support our hypothesis that PC2 missense mutants are ERAD substrates. Given recent interest in the development of protein folding modulators for other ERAD-related diseases, our data provide a promising hint that the maturation of some PC2 missense mutants may be amenable to pharmacological correction. HDAC6 Controls Polycystin-2 Expression in Pkd1-Null Cells

Qin N. Yao,[1] Patricia Outeda,[1] Feng Qian,[1] Liudmila Cebotaru,[2] Terry J. Watnick,[1] Valeriu Cebotaru.[1] *[1]University of Maryland School of Medicine, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD.*

Background: ADPKD is a hereditary disorder that affects 1:1000 to 1:500 people and is characterized by fluid-filled cysts that arise from renal tubules. ADPKD results from mutations in either the PKD1 or PKD2 gene, which encode the gene products polycystin 1 (PC1) and polycystin 2 (PC2), respectively. Although PC1 and PC2 have been studied intensively, information on how they function is still emerging. It has been previously shown that PC2 is degraded via proteasome in MDCK cells. We have shown that overexpression of PC1 accelerates PC2 degradation via the autophagy in MDCK cells. It is unknown how PC2 is degraded in *Pkd1*-null cells. Here we proposed to determine degradation pattern of PC2 and whether HDAC6 alters PC2 expression in *Pkd1*-null cells.

Methods: To determine PC2 degradation pattern we have treated *Pkd1*-null and control cells with cycloheximide to block translation and then inhibited autophagy with bafilomycin and proteasome with MG132, and examined PC2 expression. Next, we inhibited HDAC6 activity with TSA and examined PC2 expression.

Results: Inhibition of proteasome with MG132 prevented degradation of PC2 in control cells, suggesting that PC2 is degraded via proteasome when PC1 is expressed. Inhibition of autophagy with bafilomycin prevented degradation of PC2 in *Pkd1*-null cells, suggesting that PC2 is degraded via autophagy when PC1 is absent. In immunoprecipitation assay PC2 had higher affinity for p97/VCP, a proteasome substrate, in control cells than in *Pkd1*-null cells, indicating that PC2 is degraded via proteasome when PC1 is expressed, but not in *Pkd1*-null cells. Inhibition of HDAC6 activity with TSA decreased PC2 expression in both *Pkd1*-null and control cells suggesting that HDAC6 regulates PC2 expression.

Conclusions: PC2 is mainly degraded via autophagy in *Pkd1*-null cells and via proteasome in control cells. HDAC6 regulates PC2 expression in both *Pkd1*-null and control cells. Further studies will have to determine whether HDAC6 controls PC2 trafficking in *Pkd1*-null cells.

TH-PO669

Human-Specific Abnormal Alternative Splicing of the Wild-Type PKD1 Gene Induces Premature Termination of Polycystin–1

Christopher J. Ward,[1] Wendy A. Lea.[2] *[1]KUMC, Kansas City, KS; [2]KUMC/ Kidney Institute, Kansas, KS.*

Background: Human *PKD1* is unusual in that it contains two long polypyrimidine tracts in introns 21 and 22 (2.5kb and 602bp, respectively, 97% C+T), whereas the mouse and other species lack these C+T rich regions. Western blot analysis of polycystin-1 (PC1), using a monoclonal antibody to the extreme N—terminus indicates that humans, but not mice, have a smaller EndoH sensitive product, termed Trunc_PC1. Here we show that Trunc_PC1 is the product of differential splicing across introns 21 and 22 and that 28.8-61.5% of human transcripts undergo splicing events that lead to premature translational termination. Thus, the presence of these polypyrimidine tracts leads to decreased levels of full length functional PC1 reducing the level of PC1 signaling from normal alleles and in the context of a mutant allele may force signaling below a critical 'cystogenic' threshold.

Methods: We used RT-PCR from exons 20-24 to quantify the number of splice forms terminating early using NanoPore sequencing. We also compared the number of copies PC1 mRNA per mg total RNA at the 5' and 3' end of the human transcript and compared this with the copy number from normal mouse kidneys. We also created a stable cell line that produces a C-terminally FLAG tagged PC1 cDNA that terminates after exon-20, the region where Trunc_PC1 is predicted to end.

Results: Assaying seven adult kidneys showed that 62.2±12.6% of PC1 transcripts read through and had the accepted sequence while the remainder mis-spliced and truncated. We measured the PC1 mRNA copy number in nine adult human kidneys. For the 5' probe (exon 15) and 3' (exon 34) probes, there were $7.38\pm3.47x10^5$ and $1.03\pm0.354x10^6$ copies/µg, respectively --- about 22--31 copies per cell. Mice had a similar number of total transcripts $9.59\pm2.30x10^5$ copies/mg. The synthetic cDNA had an identical mass to Trunc_PC1 showing that they are the same species.

Conclusions: About 40% of human *PKD1* transcripts terminate early producing Trunc_PC1 implying that humans are dosage hypomorphs when compared to mice. Furthermore, the presence of an ER resident truncated form of the PC1 protein may interfere with the assembly of the polycystin complex.

Species-Specific Differences in Pkhd1 Transcriptional Regulation: The Role of Cystin, the Cys1 Gene Product

Naoe Harafuji,[1] Santiago Cuevas,[1] Chaozhe Yang,[1] Maryanne Odinakachukwu,[1] Amar J. Majmundar,[2] Friedhelm Hildebrandt,[2] Lisa M. Guay-Woodford.[1] *[1]Children's National Health System, Washington, DC; [2]Boston Children's Hospital, Boston, MA.*

Background: ARPKD (MIM 263200) typically results from mutations in *PKHD1*, which encodes a set of secreted and membrane-bound isoforms, referred to as FPC (Onuchic, 2002). Our previous studies showed: 1) mouse *Pkhd1* is transcriptionally complex (Boddu, 2014); 2) cystin, the protein disrupted in the *Cys1*^{cpk} mouse, interacts with Srsf5, a pre-mRNA *splicing* factor (Watts, 2016); 3) *Pkhd1* exon 51 contains a functional Srsf5 binding site. In the current study, we compared *Pkhd1/PKHD1* and cystin

in mouse, rat and human; assessed whether cystin is a transcriptional regulator of *Pkhd1*; and examined consanguineous families with genetically unresolved hepato-renal fibrocystic disease (HRFD) for *CYS1* mutations.

Methods: We performed RT-PCR and comparative informatic analyses for mouse, rat and human *Pkhd1/PKHD1* and cystin, respectively. For minigene splicing assays, we transfected a mouse *Pkhd1* exon 6, 7, 51 construct into TERT-immortalized $Cys1^{wt}$ (wt) and $Cys1^{cpk}$ (*cpk*) stable cell lines, and wt and *cpk* primary collecting duct cells. Whole exome sequencing was performed in 258 consanguineous HRFD families.

Results: Comparative RT-PCR showed that mouse *Pkhd1* encodes multiple isoforms; rat *Pkhd1* and human *PKHD1* have minimal transcriptional complexity. There is limited inter-species *PKHD1/Pkhd1* homology (72%, human-mouse; 71%, human-rat; 86%, mouse-rat). In contrast, cystin is identical in mouse and rat, but rodent-human identities are limited (58%, human-mouse; 59%, human-rat). Quantitative minigene assays revealed differential splicing of the *Pkhd1* construct in wt and *cpk* cell lines. Preliminary Iso-Seq analyses of wt and *cpk* kidneys support differential *Pkhd1* splicing. Finally, we identified a 5 yo HRFD boy with a homozygous *CYS1* variant, c.318+5G>A, that is predicted to disrupt the exon 1 donor site.

Conclusions: Our data demonstrate that: 1) the transcriptional regulation of mouse *Pkhd1* is distinct from its rat and human orthologues; 2) cystin is highly conserved among rodents, but there is limited rodent-human homology; 3) cystin is a transcriptional regulator of mouse *Pkhd1*; and 4) *CYS1* mutations are a rare cause of human HRFD. Our data suggest that in $Cys1^{cpk/cpk}$ mice, loss of cystin function may contribute to renal cystogenesis due in part to alterations in *Pkhd1* transcriptional regulation.

TH-PO671

Identifying Genetic Modifiers in Severe Polycystic Liver Disease (PLD) by Whole Exome Sequencing

Amirreza Haghighi,[1] Xuewen Song,[1] Emilie Cornec-Le Gall,[2] Nathalie Demoulin,[3] Wybrich R. Cnossen,[4] Joost Hoenderop,[4] Olivier Devuyst,[5] Vicente E. Torres,[6] Peter C. Harris,[6] York P. Pei.[1] *[1]Division of Nephrology, University Health Network and University of Toronto, Toronto, ON, Canada; [2]Centre Hospitalier Universitaire de Brest, BREST, France; [3]Cliniques U St-Luc, Brussels, Belgium; [4]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [5]University of Zurich, Zurich, Switzerland; [6]Division of Nephrology, Mayo Clinic, Rochester, MN.*

Background: Severe PLD (sPLD) is a rare and poorly understood phenotype seen in both ADPKD and ADPLD. Mutations of *SEC61*, *SEC63*, *PRKCSH*, *GANAB*, and *ALG8* have been shown to cause PLD by impairing the maturation and transit of polycystin-1 (PC1) through the endoplasmic reticulum protein-processing (ER-PP) pathway. We hypothesize that rare mutations including ER-PP pathway genes that segregate in multiple families may modify PLD in patients with ADPKD and ADPLD.

Methods: We performed whole exome sequencing (WES) using Illumina HiSeq2000/2500 with SSV4/5 capture kit in 203 patients from Canada, U.S., Belgium, and the Netherlands, including 23 affected discordant sib-pairs and 16 affected concordant sib-pairs for sPLD from 39 families (matched by gender and age) and 125 sporadic cases. All patients with sPLD had a cystic liver of >4x normal volume. We performed a focused analysis on 168 genes involved in ER-PP pathway. Standard algorithms for sequence alignment, base calling, and QC filtering were applied to identify rare (MAF ≤1%) deleterious variants of high and moderate impact as predicted by PolyPhen-2, SIFT, PROVEN, Mutation Tester, Mutation Assessor, Mammalian and Vertebrate nucleotide-level conservation, and Combined Annotation Dependent Depletion.

Results: Overall, we achieved a mean target coverage of 99X with 90% of the targeted exomes having >30X read depth. We identified 123 ER genes with rare deleterious variants and among them, we found 9 ER genes (i.e. *UGGT1*, *UGGT2*, *SEC31B*, *SEC24D*, *SEC23B*, *ALG8*, *ALG6*, *PRKN* and *ATF6B*) with rare high and/or moderate impact variant(s) present in more than 6 subjects and each segregated with PLD disease severity in 1 to 4 families and 4-10 sporadic sPLD cases.

Conclusions: Our results suggest extensive genetic heterogeneity with no one single gene accounting for a large proportion of severe PLD cases. Future in-vitro and/or in-vivo functional studies will be needed to define the potential pathogenicity of the most promising candidate genes. Identification of genetic modifiers of severe PLD has the potential to improve risk prediction and treatment of this unusual complication.

Disruption of the EF-Hand Domain of Polycystin-2 Ameliorates Cystic Disease Caused by Polycystin-1 Deficiency

Matteus Krappitz,[2] Till A. Hollmann,[2] David R. Rümmele,[3] Tobias Staudner,[3] Ke Dong,[2] Sorin V. Fedeles,[4] Rachel Gallagher,[4] Yiqiang Cai,[4] Chao Zhang,[2] Stefan Somlo.[1,2] *[1]Yale University, New Haven, CT; [2]Yale School of Medicine, New Haven, CT; [3]Friedrich-Alexander-Universität Erlangen-Nürnberg, Detmold, Germany; [4]Yale University School of Medicine, New Haven, CT.*

Background: Polycystin-2 (PC2/TRPP2), the product of one of the genes mutated in ADPKD, is expressed in the endoplasmic reticulum (ER) and ciliary membranes. The COOH-terminal tail of PC2 contains a potential Ca^{2+} binding EF-hand motif. A mouse model termed $Pkd2^{TEAA}$, in which critical residues at the EF-hand were substituted with alanine (T769A, E772A) to inactivate the Ca^{2+}-binding properties of PC2-EF, was generated via CRISPR/Cas9 methodology [ASN2017, TH-PO597]. The $Pkd2^{TEAA}$ mutant does not result in loss of PC2 function as evidenced by the lack of cysts in $Pkd2^{TEAA/TEAA}$ animals. In this study we assessed the impact of the $Pkd2^{TEAA}$ allele on *Pkd1* derived cysts.

Methods: The $Pkd1^{R2220W}$ human REJ mutant ($Pkd1^{RW}$) is a representative candidate of a PC1 hypomorphic missense mutation as it leads to a clear yet partial defect in PC1 biogenesis and cleavage. Mutant alleles were further modified by insertion of a V5 epitope tag in-frame at the C-terminus to detect the mutant proteins ($Pkd1^{RW}$-*V5* and $Pkd2^{TEAA}$-V5). The $Pkd2^{TEAA}$ mouse was crossed onto a $Pkd1^{RW/flox}$ background under the control of *Pkhd1-Cre* (collecting duct-specific). The kidneys were examined by histological and morphological parameters.

Results: Compared to $Pkd1^{RW/flox}$*; Pkhd1-Cre* mice, the kidneys at P24 from $Pkd1^{RW/flox}$*;* $Pkd2^{TEAA/+}$*; Pkhd1-Cre* mice displayed a decreased KW/BW ratio (0.16 ± 0.02 vs 0.067 ± 0.04, ***p<0.001) and BUN (mg/dL: 93.6 ± 24.97 vs. 38.6 ± 19.54, **p<0.0013). We observed a marked increase in apoptosis specifically in cyst-lining epithelia expressing $Pkd2^{TEAA}$. No significant difference in the protein levels of PC1 or PC2 proteins could be detected between the different genotypes.

Conclusions: Inactivation of the Ca^{2+}-binding properties of PC2 EF-hand on a partially PC1 deficient background results in improved cystic phenotype possibly via specific apoptosis of PC1 mutant cyst-lining epithelial cells. Modulators of PC2 EF-hand function may alter PC2 function *in vivo* to slow cyst progression in the setting of some PC1 missense mutations.

Loss of the Master Regulator of Mitochondrial Fusion Opa1 in Renal Tubules Is Not Sufficient to Drive Polycystic Kidney Disease

Laura Cassina,[1] Marco Chiaravalli,[2] Martina Maserati,[1] Alessandra Boletta.[1] Molecular basis of Polycystic Kidney Disease Unit *[1]San Raffaele Scientific Institute, Milan, Italy; [2]San Raffaele Scientific Istitute, Milano, Italy.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a genetic disorder. The most commonly mutated gene, *PKD1*, encodes for polycystin-1 (PC1). We showed enhanced glycolysis and reduced mitochondrial-derived ATP in *Pkd1* mutant cells and kidneys (Rowe et al. 2013). A direct role of PC1 on mitochondrial regulation has been recently shown, either at the mitochondria-associated membranes, MAMs (Padovano et al. 2017), or by direct translocation of the PC1 C-terminal tail (CTT) in the mitochondrial matrix (Lin et al. 2018). We wondered whether mitochondrial dysfunction is a driver, or else a modifier, in PKD.

Methods: Transmission electron microscopy (TEM) on kidney sections, Seahorse XFe96 Analyzer for mitochondrial oxygen consumption rate (OCR) and extracellular acidification rate (ECAR), mitochondrial network morphology by mt-DsRFP live imaging, genetic ablation of *Opa1* using Ksp-Cre line.

Results: We detected alterations in mitochondrial network morphology, in OCR, and in ECAR in $Pkd1^{-/-}$ cells. We found decreased number of mitochondria, many with aberrant cristae, mitochondrial fragmentation, and decreased mitochondrial respiration in the cystic epithelia of $Pkd1^{fl/-}$*:Ksp-Cre* kidneys at P4. At the molecular level we identified decreased mitochondrial pro-fusion protein Opa1, and increased fission regulator Drp1 in the cystic kidneys. To determine the contribution of reduced Opa1 and the consequent mitochondrial alterations in renal epithelia, we generated $Opa1^{fl/fl}$*:Ksp-Cre* mice. Animals are born at the expected mendelian ratio and die within the first three months of life. At sacrifice gross kidney enlargement was observed, and this is mostly due to expansion of DBA positive tubules. Decreased mitochondrial respiration was observed, but cells maintained a cuboidal shape. Despite the increase in the kidney volume over time, we detected only mild tubule dilation at P60, and no overt cyst formation.

Conclusions: Our data indicate that deletion of PC1 in the kidney epithelium results in alteration in mitochondrial structure and fitness. Surprisingly, decreasing mitochondrial proficiency by means of Opa1 ablation is not sufficient *per se* to drive cystogenesis. We are currently verifying if crossing $Opa1^{fl/+}$ *with* $Pkd1^{fl/-}$*:Ksp-Cre* accelerates disease progression and/or other molecular players are involved in PKD.

TH-PO674

Rescue of Suppressed Autophagy in Polycystic Kidney Disease

Carolyn N. Brown,[2] Sara Holditch,[2] Natalie J. Serkova,[1] Charles L. Edelstein.[2] *[1]University of Colorado Denver, Aurora, CO; [2]UC Denver Anschutz Medical Campus, Aurora, CO.*

Background: Autophagy maintains proteostasis by sequestering damaged organelles and proteins into autophagosomes for delivery to the lysosome where cargo is degraded and recycled. Several treatments that have been shown to ameliorate PKD in mice are potent activators of autophagy. The aims of the study were to determine the effects of several autophagy inducers on autophagy, apoptosis, and proliferation markers in PKD kidneys and to determine whether kidney-specific autophagy knockout results in a cystic phenotype.

Methods: Mice were treated with 2-deoxyglucose (2DG), trehalose (TRE), or metformin (MET) followed by bafilomycin (BAF) to measure autophagic flux. p62 (autophagy-specific tag for degradation & marker of autophagy inhibition), LC3-II (marker of autophagosomes), Atg12-5 (marker of autophagosome elongation), cleaved caspase 3 (marker of apoptosis), and AMBRA1 (Activating molecule in Beclin1-regulated autophagy) that links autophagy to cell proliferation by promoting dephosphorylation and degradation of cMyc (transcription factor that activates pro-proliferative genes) were measured by immunoblot. Kidney-specific Atg7-/-mice received MRIs at 180D of age to precisely measure cyst volume and number.

Results: PKD kidneys had significantly reduced autophagic flux compared to WT, which was rescued by 2DG. Further, PKD kidneys had less Atg12-5 complex vs WT, an effect blocked by TRE. PKD kidneys had more cleaved caspase 3, a marker of apoptosis,

compared to WT, which was decreased by MET, 2DG, and TRE. cMyc phosphorylation was greater in PKD compared to WT, an effect blocked by 2DG. Trehalose increased AMBRA expression in PKD kidneys (Table 1, *p<0.05). On MRI scan, mean number of cysts (0.5mm) in 180 day old Atg7-/- mice was 5±2 vs. 1±0.5 in WT (p<0.05). One Atg7-/- kidney was massively cystic.

Conclusions: In summary, 2DG restored autophagic flux in PKD kidneys. Autophagy inducers increased expression of autophagy-related proteins and decreased apoptosis and proliferation markers. Kidney-specific knockout of autophagy in 180 day old mice resulted in a cystic phenotype.

TH-PO675

Head-to-Head Study of Sirolimus and an mTOR Kinase Inhibitor (TORK) in a Hypomorphic Model of Polycystic Kidney Disease

Carolyn N. Brown, Sara Holditch, Daniel Atwood, Charles L. Edelstein. *UC Denver Anschutz Medical Campus, Aurora, CO.*

Background: Sirolimus indirectly inhibits mTORC1 and reduces but does not completely inhibit cyst growth in rodent models of autosomal dominant polycystic kidney disease (ADPKD). Sirolimus was not effective in human PKD and was associated with side effects. The novel ATP competitive mTOR kinase inhibitors (TORKs) e.g. Torin2 directly inhibit mTOR kinase that results in inhibition of both mTORC1 and 2. TORKs, which increase liver enzymes, have a different side effect profile to sirolimus, which causes mucositis. We report a head-to-head comparison of Torin2 versus sirolimus in a hypomorphic mouse model of PKD.

Methods: C57Bl/6 *Pkd1* p.R3277C (PKD) mice were treated with 0.5mg/kg sirolimus (SIR) or 10mg/kg Torin2 (TORK) daily from 50 to 120 days of age. Serum BUN was analyzed using an enzymatic assay. Cyst area was quantified from H&E stained kidneys. Kidneys were immunoblotted for mTORC1 substrates, pS6 and p4E-BP1 (S65), mTORC2 substrate, pAkt (S473), LC3-II (autophagosome marker), and p62 (autophagy-specific ubiquitin-binding protein). Autophagic flux was defined as the difference between LC3-II before and after administration of the lysosomal inhibitor bafilomycin.

Results: Kidney weight and serum BUN were significantly decreased in TORK- and SIR-treated mice compared to vehicle (VEH). CVD showed a tendency to decrease with both TORK and SIR. pAKT was decreased in both TORK and SIR treatments. pS6 was significantly decreased in SIR-treated mice only. TORK significantly increased autophagic flux (FLUX). No side effects were noted on gross examination in either treatment group.

Conclusions: For the first time, we have shown in a head-to-head study that the TORK, Torin2, is as effective as sirolimus in decreasing kidney size and serum BUN in a hypomorphic ADPKD mouse model. Both drugs inhibited pAKT. SIR had a better effect on pS6 than TORK. Interestingly, TORK resulted in a significant increase in autophagic flux. As Torin2 has a short half-life (~1 hr), further studies are warranted to determine whether more frequent dosing of Torin2 will be more effective than sirolimus.

TH-PO676

The Role of LKB1-AMPK Signaling on Renal mTOR and Cyst Progression in ADPKD

Yan Zhang, Yuqiao Dai, Gail Reif, Emily A. Daniel, Aditi Khanna, Brenda S. Magenheimer, Darren P. Wallace. *Jared Grantham Kidney Institute, University of Kansas Medical Center, Kansas City, KS.*

Background: In ADPKD, the mTOR pathway is thought to contribute to cyst epithelial cell proliferation and cyst growth. Downstream components of the mTOR pathway, i.e. ribosomal protein S6, are aberrantly phosphorylated in cyst-lining cells. Fluid accumulation within the cyst cavity is driven by Cl^- secretion via apical CFTR Cl^- channels. AMP Kinase (AMPK) is an important negative regulator of both mTOR and CFTR. Liver Kinase B1 (LKB1), a well-known tumor suppressor, directly phosphorylates and activates AMPK. Previously, we showed that BIT-11, a novel small molecule LKB1 activator, increased P-AMPK and decreased P-S6 in human ADPKD cells. BIT-11 decreased ADPKD cell proliferation, Cl^- secretion and *in vitro* cyst growth and blocked cyst-like tubule dilations in *Pkd1*$^{-/-}$ mouse kidneys in metanephric organ culture. Our hypothesis is that the LKB1-AMPK pathway regulates mTOR-mediated cell proliferation and CFTR-dependent fluid secretion by cystic cells and modulates ADPKD progression.

Methods: An inducible LKB1 knockout cell line was generated from *Lkb1*$^{flox/flox}$*:ROSA26-Cre*^{ERT2} mouse kidneys. To determine if the loss of LKB1 is sufficient to induce cystic disease, we crossed *Lkb1*$^{flox/flox}$ and *Pkhd1-Cre* mice to knock out LKB1 selectively in collecting ducts (CDs). To test the effect of direct LKB1 activation, BIT-11 was delivered by daily gavage from 5 to 20 weeks to *Pkd1*$^{RC/RC}$*:Pkd2*$^{+/-}$ mice, an ADPKD model that develops a renal cystic disease by 5 weeks of age and a progressive decline in renal function.

Results: *Lkb1*$^{flox/flox}$*:ROSA26-Cre*^{ERT2} renal cells were treated with tamoxifen to delete LKB1 expression. The loss of LKB1 significantly decreased P-AMPK, but had no effect on mTOR signaling. CD-specific knockout of LKB1 in otherwise normal mice resulted in hydronephrosis; however, renal cyst formation was not observed. On the other hand, treatment with BIT-11 caused a significant decrease in kidney weight (percent body weight), blood urea nitrogen and interstitial fibrosis in *Pkd1*$^{RC/RC}$*:Pkd2*$^{+/-}$ mice.

Conclusions: The LKB1-AMPK pathway does not appear to regulate basal mTOR activity in the adult kidney; however, direct activation of this pathway using a novel LKB1 activator decreased mTOR-mediated cell proliferation and the decline in renal function in ADPKD mice, suggesting that this may be a potential therapeutic approach for the treatment of ADPKD.

Renal Stones in Mice Compound-Heterozygous for Hypomorphic Pkd1V and Pkd1RC Alleles

Stephen C. Parnell,[1,3] Heather A. Riddle,[1,3] Feng Qian,[2] Jason R. Stubbs,[1,3] Peter S. Rowe.[1,3] *[1]University of Kansas Medical Center, Kansas City, KS; [2]University of Maryland School of Medicine, Baltimore, MD; [3]Jared Grantham Kidney Institute, Kansas City, KS.*

Background: Disease severity in orthologous mouse models of ADPKD is determined in part by the nature of the *Pkd1* mutation. While null mutations cause *in utero* cyst formation and embryonic lethality, hypomorphic mutations *Pkd1*$^{V/V}$ and *Pkd1*$^{RC/RC}$ are sufficient for embryonic survival. *Pkd1*$^{V/V}$ mice express a mutant form of polycystin-1 that fails to undergo autocatalytic cleavage at its G-protein coupled receptor proteolysis site and develop renal cystic disease postnatally and die between 2-6 weeks of age. *Pkd1*$^{RC/RC}$ mice express a temperature-sensitive folding mutant with reduced levels of mature protein and can live over a year with mild, slowly progressive cystic disease. The phenotypic consequences of these two distinct hypomorphic *Pkd1* mutations together are not known.

Methods: *Pkd1*$^{V/+}$ and *Pkd1*$^{RC/+}$ mice on a C57 background were crossed to produce compound-heterozygous *Pkd1*$^{V/RC}$ mice. Mice were maintained on breeder diet from birth, and sacrificed at 3 or 26 weeks of age and kidneys analyzed. Presence of renal stones in 26 week old adult mice was determined by micro computed tomography (μCT) analysis of kidneys following euthanasia.

Results: Three week old *Pkd1*$^{V/RC}$ mice had elevated kidney weight to body weight ratios (15.3 ±0.87) and their kidneys were obviously cystic by visual inspection. To determine the long-term consequences of disease we maintained a cohort of mice to 26 weeks of age. The majority of the mice thrived throughout the duration of the study and had significantly lower kidney weight to body weight ratios compared to 3 week old mice. Visual inspection of kidneys from adult mice revealed the presence of numerous large, white masses immediately underneath the renal surface. Analysis of these kidneys by μCT determined that the masses were mineralized deposits of ~0.5mm diameter present throughout the renal cortex but absent from the medulla.

Conclusions: *Pkd1*$^{V/RC}$ mice are severely cystic by 3 weeks of age. However, these cystic kidneys retain sufficient function to maintain survival up to 26 weeks of age and presumably beyond. Kidneys from adult mice had mineralized deposits throughout the renal cortex. To our knowledge this is the first known instance of renal stones in a mouse model of ADPKD.

TH-PO678

The Role of Interferon Regulatory Factor-5 in Acceleration of Cystogenesis in Polycystic Kidney Disease

Kurt Zimmerman,[1] Jifeng Huang,[2] Lan He,[2] Molly Easter,[2] Bradley K. Yoder,[1] P. Darwin Bell,[2] Takamitsu Saigusa.[2] *[1]Cell Development and Integrative Biology, University of Alabama at Birmingham, Birmingham, AL; [2]Medicine/Nephrology, University of Alabama at Birmingham, Birmingham, AL.*

Background: In mouse models of polycystic kidney disease (PKD), unilateral nephrectomy (UNx: 1K) accelerates kidney cyst growth compared to non-nephrectomized (2K) mice. Analysis of RNA sequencing data revealed that 1K compared to 2K *Pkd1* deficient mice have enrichment of genes associated with inflammation, phagocytosis, and macrophages. Previous studies showed that macrophages promote cystogenesis in mouse models of PKD; however, transcription factors that control cytokine production by macrophages in cystic disease have not been identified. Herein, we study the role of interferon regulatory factor-5 (IRF5), a transcription factor involved in macrophage activation and cytokine release, during cyst progression in 2K vs 1K *Pkd1* deficient mice.

Methods: Adult *Pkd1*$^{flox/flox}$ mice with or without CAGG-cre were administered tamoxifen for global knockout of the *Pkd1* gene. Three weeks after cre induction, mice underwent sham surgery or UNx to accelerate cyst formation. Kidneys were harvested at 3 (early stage) or 6 (late stage) weeks after UNx and kidney immune cells were analyzed by flow cytometry. Some mice were treated with weekly injection of IRF5 antisense oligonucleotide (40mg/kg/wk: Ionis Pharma) or scrambled ASO for a total of 3 or 6 weeks after UNx and kidney was harvested for kidney immune cells/cytokine and histology.

Results: *Pkd1* deficient mice had increased kidney IRF5 mRNA levels compared to control mice. 1K *Pkd1* mice increased inflammatory cytokine production, cyst growth and infiltrating ($CD11b^{hi}$, $F4/80^{lo}$) and resident macrophage ($CD11b^{lo}$, $F4/80^{hi}$) numbers compared to 2K *Pkd1* deficient mice. Preliminary results indicate that treatment with IRF5 ASO (total 3 and 6 weeks) in 1K *Pkd1* mice had no effect on kidney macrophage numbers, but significantly decreased kidney T cell accumulation, inflammatory cytokine production and cyst growth. Further comparison of male and female mice shows that 1K female mice had higher kidney IRF5 levels compared to male mice and a better response to IRF5 ASO treatment.

Conclusions: UNx in *Pkd1* mice increases the number of kidney macrophages, inflammatory cytokine and cyst growth. IRF5 ASO treatment suppressed kidney IRF5 levels/reduced inflammation and attenuated the acceleration of cytogenesis in *Pkd1* mice.

TH-PO679

AMP-Activated Protein Kinase (AMPK) Drug Re-Purposing for Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Xuewen Song,[1] Wouter N. Leonhard,[3] Gregory R. Steinberg,[4] Dorien J. Peters,[3] York P. Pei.[2] *[1]Division of Nephrology, University of Toronto, Toronto, ON, Canada; [2]University Health Network and University of Toronto, Toronto, ON, Canada; [3]Leiden University Medical Center, Leiden, Netherlands; [4]McMaster University, Hamilton, ON, Canada.*

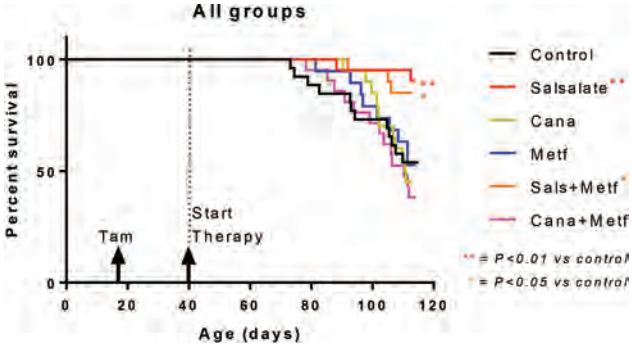
Background: ADPKD is an important cause of end stage renal disease (ESRD). Multiple studies have highlighted AMPK as a potential therapeutic target for ADPKD. Notably, metformin (MET) attenuated cystic kidney disease in an aggressive PKD model. MET and canagliflozin (CAN) are indirect AMPK inducers, while salsalate (SAL) is a direct AMPK activator; all have excellent safety profiles for clinical use.

Methods: We tested the efficacy of MET, CAN, SAL, MET+CAN or MET+SAL in a tamoxifen-inducible Pkd1(iKsp-Pkd1del) conditional knock-out mouse model. Tamoxifen was used on days p18 and p19 to induce adult onset PKD (n=20 male mice/group). AMPK drug treatments were then started from p40 using dosages expected to yield serum levels similar to those observed in the clinical settings. Blood Urea (BU) levels were monitored weekly and mice with ESRD (BU >20 mmol/L) were sacrificed. The experiment continued until 50% of the untreated mutant mice reached ESRD.

Results: Compared to the untreated mutant mice, SAL alone ($p<0.01$) or SAL+MET ($p<0.05$) improved kidney survival and reduced kidney weights (Figure). MET, CAN, or MET+CAN did not have any effect. At the end of the study, 91% and 85% of the SAL and SAL+MET groups were free of ESRD versus 38%-58% in the other groups. SAL+MET did not differ from SAL suggesting a lack of synergism. Molecular analyses (systems biology and protein analyses) are currently in process to understand the mechanisms of action.

Conclusions: SAL is a promising re-purposed drug which may be readily translated to the clinical setting for treatment of ADPKD. MET at the dosage used in the usual clinical setting had no therapeutic effect in our model. *Equal contribution of first two authors and last two authors.

Funding: Private Foundation Support



Improved survival free of ESRD in the Salsalate and Salsalate+Metformin groups compared to the untreated mutant mice and other treatment groups.

TH-PO680

Inhibition of Wnt/β-Catenin Signaling Slowed Cystogenesis in Postnatal Mouse Model of ADPKD

Yun Joon Jung,[1,2] Jordan A. Kreidberg.[1,2] *[1]Boston Children's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: The Wnt signaling pathway has an important role for nephron development and elevated expression of β-catenin, master regulator of the Wnt signaling pathway, is shown to correlate with cystogenesis in autosomal dominant polycystic kidney disease (ADPKD). Here we provide further evidence that inhibition of Wnt/β-catenin pathway slowed cystogenesis in a postnatal model of ADPKD using *Ksp-CreER^{T2}; Pkd1$^{flox/flox}$* mice.

Methods: To understand the pathological contribution of Wnt signaling in ADPKD, we measured expression of Wnt gene and β-catenin expression *in vivo* using two murine models of ADPKD where postnatal cystogenesis could be observed. We also tested the effect on cyst formation of small molecule inhibitors of β-catenin interaction with either CBP or p300.

Results: We observed increased expression of Wnt genes in and higher levels of β-catenin in cystic kidneys of both *Hoxb7-Cre-IRES-eGFP;Pkd1$^{flox/flox}$* mice and *Ksp-CreER^{T2};Pkd1$^{flox/flox}$* mice. Although the overall pattern differed between these models, Wnt7a was consistently over-expressed in both models of ADPKD. To test whether canonical Wnt signaling was required for cystogensis, we inactivated one copy of the *Ctnnb1* gene, encoding β-catenin, in *Ksp-CreER^{T2};Pkd1$^{flox/flox}$* mice. Reduced progression of cyst enlargement was observed in *Ksp-CreER^{T2};Pkd1$^{flox/flox}$:Ctnnb1$^{flox/+}$* mice. Furthermore, treatment of *Ksp-CreER^{T2};Pkd1$^{flox/flox}$* mice with a small molecule, ICG-001, that blocks the interaction of β-catenin with CBP slowed the progression of cyst formation and mice showed reduced kidney:weight to body weight ratio. In contrast, a small molecule, IQ-1, which blocked the interaction of β-catenin with p300 had no effect in cyst progression.

Conclusions: Our study demonstrates that the canonical Wnt signaling pathway has an important role in cystogenesis and inhibition of the β-catenin-CBP complex by ICG-001 may serve as a new therapeutic target to decrease cyst formation.

Funding: NIDDK Support

TH-PO681

COX2 Inhibition Slows Disease Progression and Improves the Altered Renal Lipid Mediator Profile in the Pkd2WS25/- Mouse Model of ADPKD

Md Monirujjaman,[1,2] Harold M. Aukema.[1,2] *[1]Food and Human Nutritional Sciences, University of Manitoba, Winnipeg, MB, Canada; [2]Canadian Centre for Agri-Food Research in Health and Medicine, St. Boniface Hospital Research Centre, Winnipeg, MB, Canada.*

Background: Oxylipins are bioactive lipid mediators formed by oxygenation of polyunsaturated fatty acids via cyclooxygenase (COX), lipoxygenase (LOX) and cytochrome P450 (CYP) monooxygenases. We have shown that the earliest and most consistent alteration in the oxylipin profile in diverse models of cystic kidney diseases is increased levels of COX derived prostanoids. Several of these, such as PGD_2 and PGE_2 have been shown to mediate renal cyst formation by increasing intracellular cAMP production, a known abnormality in various forms of cystic kidney diseases. Further, inhibition of COX oxylipin formation reduces disease progression in a model of nephronophthisis, as well as in some non-cystic renal diseases. The present study was carried out to determine whether a selective COX2 inhibitor would reduce disease progression and ameliorate the altered renal oxylipin profile in the Pkd2 orthologous mouse model of autosomal dominant polycystic kidney disease 2 (ADPKD2).

Methods: Weanling male $Pkd2^{WS25/-}$ mice were provided a standard laboratory rodent diet (AIN-93G) with or without 50 mg celecoxib per kg body weight per day, for 13 weeks. Renal cysts were analyzed histomorphometrically and serum BUN and creatinine levels were determined. Targeted lipidomic analysis of renal oxylipins was performed by HPLC-tandem mass spectrometry.

Results: Diseased animals had significant cyst involvement and reduced renal function as indicated by elevated BUN. Consistent with our previous studies, 8 of 11 COX derived prostanoids were higher in diseased kidneys. In addition, 24 of 33 LOX oxylipins and 7 of 16 CYP oxylipins were lower in diseased kidneys. Drug treatment reduced cyst area by 50%, cyst volume by 70%, and serum creatinine and BUN by 10-20%. With respect to lipid mediators, drug treatment reduced 5 of the 8 elevated COX derived prostanoids and increased 5 of the 24 LOX and 5 of the 7 CYP oxylipins that were reduced by disease.

Conclusions: Selective COX2 inhibition significantly ameliorates disease progression and improves renal function in Pkd2 mice. Further studies on dose, potential risks, and long-term effects of COX2 inhibition are needed to determine whether this is a viable therapeutic option to treat ADPKD. TH-PO682

A Strategy for Reducing Cysts in Autosomal Dominant Polycystic Kidney Disease with a CFTR Corrector

Liudmila Cebotaru,[1] Murali K. Yanda.[2] *[1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins School of Medicine, Baltimore, MD.*

Background: ADPKD is associated with progressive enlargement of cysts. Mutations in *pkd1 and pkd2* induce growth-related pathways, including heat shock proteins raising the prospect that pharmacological interventions that target these pathways might alleviate or prevent ADPKD. The purpose of our study was to demonstrate a role for VX-809, a corrector of cystic fibrosis transmembrane conductance regulator (CFTR), in reducing cyst growth.

Methods: We used the *Pkd1$^{fl/fl}$; Pax8^{rtTA}; TetO-cre* mouse model which, when treated with doxycycline, allows for the ablation of PC1. These mice, where injected IP with doxycycline (4 µg of doxycycline/g body weight) on postnatal days (PND)11, PND12, and PND13, to induce multiple large cysts and large polycystic kidneys at approximately 3 weeks of age. Kidneys were harvested, sectioned and analyzed.

Results: Mice injected daily with VX-809 (30 mg/kg) from PND10 to PND20 showed significantly less cyst growth (see Fig 1). VX-809 improved renal function, as evidenced by a lower blood urea nitrogen (BUN) and creatinine. In proximal tubule-derived, *Pkd1*-knockout cells and in cystic kidneys, VX-809 reduced both basal and forskolin-activated cAMP levels, inhibited cyst growth and reduced levels of the heat shock proteins Hsp27, 70, and 90 which are upregulated in cystic kidneys. In the cystic mice, VX-809 decreased an ER stress marker, the GADD153 protein, cell proliferation, and apoptosis. Importantly

in proximal tubule-derived, cultured *Pkd1*-knockout cells, VX-809 increased the activity of the sodium proton exchanger, NHE3 which is down regulated in these cells.

Conclusions: VX-809 reduces the ability of cysts to grow by reducing the levels of HSPs and restore the NHE3 activity in proximal tubule cells. VX-809 could potentially be a new way to treat patients with ADPKD.

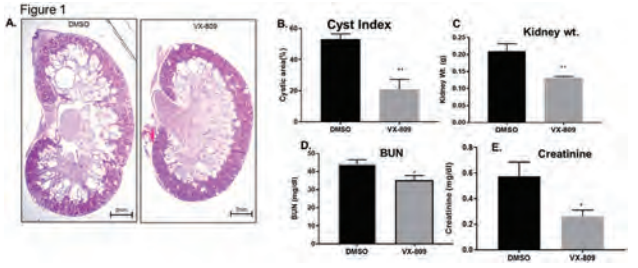

Fig. 1: Cystic mice kidneys before and after treatment with VX-809. See text for details.

TH-PO683

Ketogenic Dietary Interventions Ameliorate Disease Progression in a Rat Model of Polycystic Kidney Disease

Jacob A. Torres,[1] Samantha L. Kruger,[2] Tselmeg Amarlkhagva,[1] Caroline M. Broderick,[1] Alyssa Sahu,[2] Thomas Weimbs.[2] *[1]University of California Santa Barbara, Goleta, CA; [2]University of California Santa Barbara, Santa Barbara, CA.*

Background: PKD cells have recently been shown to have an altered metabolism favoring aerobic glycolysis similar to the Warburg effect in cancer. Possible glucose dependency may provide an opportunity for the treatment of PKD by dietary interventions. We and others recently showed that a mild reduction in food intake strongly inhibits disease progression in PKD mouse models. Here we tested the hypothesis that these beneficial effects are due to ketosis caused by intermittent starvation rather than caloric restriction per se.

Methods: The Han:SPRD rat model of PKD was utilized to test the effects of time restricted feeding and a ketogenic diet, respectively, and on the progression of PKD. For time-restricted feeding, animals were given access to normal chow *ad libitum* for 8 hours per day. A ketogenic diet consisting of ~80% dietary fat administered *ad libitum* without time-restriction.

Results: Animals treated with either a ketogenic diet or a time-restricted feeding regime consumed comparable calories to *ad libitum* controls and showed a significant decrease in markers of disease progression including a decrease in fibrosis, 2-kidney to bodyweight, cystic index, markers of proliferation, and mTOR activity.

Conclusions: Dietary interventions that lead to ketogenesis significantly attenuate disease progression in the Han:SPRD rat model of PKD. Mechanistically, this may be due to the lack of glucose availability in ketosis. Alternatively, or in addition, the ketone body beta-hydroxybutyrate (BHB) is known to regulate several signaling pathways involved in PKD, including mTOR, and may directly influence cell growth and proliferation of cystic cells. These data taken together suggest that safe and feasible dietary interventions may be effective PKD patients.

Glucose Metabolic Profiles in Renal Tissue of an Orthologous PCK Rat Model of Human PKD Using Metabolic and Proteomic Analyses

Shizuko Nagao,[1] Masanori Kugita,[1] Kanako Kumamoto,[1] Aya Yoshimura,[1] Tamio Yamaguchi,[4] Kazuki Nakajima,[3] Kazuo Takahashi,[2] Yukio Yuzawa.[2] *[1]Education and Research Facility of Animal Models for Human Diseases, Fujita Health University, Toyoake, Aichi, Japan; [2]Department of Nephrology, Fujita Health University School of Medicine, Toyoake, Japan; [3]Center for Research Promotion and Support, Fujita Health University, Toyoake, Japan; [4] Department of Clinical Nutrition, Suzuka University of Medical Science, Suzuka, Mie, Japan.*

Background: Polycystic kidney disease (PKD) is an inherited disorder characterized by excessive cellular proliferation and fluid secretion of the tubular epithelial cells due to genetic mutation. To detect altered renal metabolic and enzymatic activities, we performed metabolic and proteomic analyses in the PCK rat, an orthologous model of human autosomal recessive PKD.

Methods: In renal tissue of 20-week-old PCK and age-matched normal rats, metabolic products were analyzed by using capillary electrophoresis time-of-flight mass spectrometry and MasterHands metabolome analysis software; proteomic products were analyzed using Orbitrap mass spectrometry and Proteome Discoverer™ software.

Results: Metabolic analysis revealed a 1.8-fold increase in cAMP content in PCK cystic kidneys compared with normal kidneys, the same trend seen from our previous study using radioimmunoassay. Upstream glycolysis metabolites were decreased as follows: glucose 1-phosphate (0.5-fold), glucose 6-phosphate (0.5-fold) and fructose 6-phosphate (F6P, 0.6-fold); and downstream, 3-phosphoglyceric acid (3-PG, 4.2-fold) was increased in PCK samples. 2-Phosphoglyceric acid and phosphoenolpyruvate were detected in only PCK kidneys, not in normal kidneys. On proteomic analysis, increased fructose-bisphosphate aldolase A, an enzyme that converts F6P to 3-PG, was seen in PCK rats (3.6-fold). Tricarboxylic acid (TCA) cycle metabolites were increased as follows: citric acid (23-fold), *cis*-aconitic acid (8.5-fold), isocitric acid (32-fold), succinic acid (1.6-fold), fumaric acid (1.7-fold), and malic acid (2.1-fold) in PCK kidneys; 2-oxoglutarate was detected in only PCK kidneys. Citrate synthase, which converts acetyl CoA (2.0-fold) to citric acid, was increased (7.5-fold) in PCK kidneys. In the non-oxidative phase of the pentose phosphate pathway, increased ribose 5-phosphate (R5P) was detected in only PCK kidneys. Increased transaldolase (3.0-fold), which converts sedoheptulose 7-phosphate (S7P, 0.6-fold) to F6P, was found in PCK kidneys. Also, transketolase (2.4-fold), which converts S7P to R5P, was increased in PCK cystic kidneys.

Conclusions: These findings suggest that increased activity of pentose phosphate pathway as well as glycolysis and TCA cycle may play important roles in promoting PKD progression.

Discovery and Preclinical Characterization of RGLS4326 for the Treatment of Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Edmund Lee,[1] Tania M. Valencia,[1] Annelie E. Schairer,[1] Kara Kersjes,[1] Jian Li,[1] Andrea N. Flaten,[2] Vishal Patel.[2] *[1]Regulus Therapeutics, San Diego, CA; [2]University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Autosomal dominant polycystic kidney disease (ADPKD), caused by mutations in the *PKD1* or *PKD2* genes, is among the most common human monogenetic disorders and a leading genetic cause of end-stage renal disease (ESRD). MicroRNAs (miRs) are non-coding RNAs that play central roles in cell differentiation, proliferation and survival by binding to complementary target mRNAs, resulting in repression of translation and eventual degradation of the targeted mRNAs. We have previously demonstrated that miR-17 promotes ADPKD progression, and inhibiting miR-17 is a promising strategy for the treatment of ADPKD.

Methods: RGLS4326 was discovered through screening a chemically-diverse library of >100 oligonucleotides for their ability to inhibit miR-17 in a miR-17 luciferase sensor assay. RGLS4326 was extensively profiled in multiple safety assays, including biochemical, ex-vivo tissues slices and in vivo studies. Preclinical efficacy of RGLS4326 was studied in both Pkd2-KO and Pcy mouse models of PKD.

Results: In preclinical studies, RGLS4326 potently inhibited miR-17 activity, displaced miR-17 from the translationally active high molecular weight polysomes, and de-repressed multiple miR-17 target genes in different mouse kidney cell lines. RGLS4326 shows favorable pharmacokinetic profiles in both normal and PKD mouse models, where preferential distribution to kidney compare to other tissues was evident. Most importantly, we have demonstrated that RGLS4326 confers efficacy in two mouse models of PKD following subcutaneous administrations.

Conclusions: Our preclinical data support the clinical development of RGLS4326 for the treatment of ADPDK. RGLS4326 is currently being studied in Phase I clinical studies.

TH-PO686

Efficacy of RGLS4326 in Human Primary ADPKD 3D-Cyst Cultured Cells

Annelie E. Schairer,[1] Tania M. Valencia,[1] Steven Lockton,[1] Sole Gatto,[1] Michael Kim,[1] Darren P. Wallace,[2] Edmund Lee.[1] *[1]Regulus Therapeutics, San Diego, CA; [2]University of Kansas Medical Center, Kansas City, KS.*

Background: Autosomal dominant polycystic kidney disease (ADPKD), caused by mutations in the *PKD1* or *PKD2* gene, is among the most common monogenetic disorders and a leading genetic cause of end-stage renal disease. Kidney-specific overexpression of miR-17~92 produce kidney cysts in mice, whereas genetic knockdown of miR-17~92 attenuates disease progression in multiple mouse models of PKD. RGLS4326 is designed to specifically bind to miR-17 family of microRNAs, antagonize miR-17 activity and reduce disease progression in mouse models of PKD. In this study, we investigate the effect of RGLS4326 treatment on 3D growth of human primary ADPKD cyst cells derived from ADPKD donor nephrectomy samples.

Methods: Primary human ADPKD cyst cells (HuADPKD) were transfected with RGLS4326 or control oligo at 20nM, 100nM or 300nM for 24h. RNA samples were harvested for confirmation of miR-17 inhibition by measuring de-repression of a selected set of direct miR-17 target genes (PD-Sig) and RNA sequencing. Cells following 24h transfection were then seeded and further cultured in 3D cyst formation assay for 8 additional days.

Results: Functional inhibition of miR-17 in HuADPKD following RGLS4326 treatment was confirmed by PD-Sig. At the end of 8 additional days of 3D culturing, RGLS4326 consistently reduced growth of HuADPKD derived from multiple donors, decreasing cyst count and proliferation. Kolmogorov-Smironov test statistics on RNA sequencing data comparing log2FC cumulative distribution indicated significant upregulation (i.e. de-repression) of predicted miR-17 target genes after RGL4326 treatment. De-repression of selected direct miR-17 target genes were confirmed by qPCR and their implication on RGLS4326's mechanism of action in conferring efficacy were investigated.

Conclusions: RGLS4326 inhibits 3D cyst formation and growth of HuADPKD cells *in vitro* compared to oligo control. Our preclinical data supports the clinical development of RGLS4326 which is currently in Phase 1 for the treatment of ADPKD.

RGLS4326 Confers Efficacy and Modulate Aberrant Signaling and Metabolic Pathways in PKD Mouse Models

Tania M. Valencia,[1] Sole Gatto,[1] Annelie E. Schairer,[1] Steven Lockton,[1] Michael Kim,[1] Kara Kersjes,[1] Jian Li,[1] Andrea N. Flaten,[2] Vishal Patel.[2] *[1]Regulus Therapeutics Inc, San Diego, CA; [2]University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Autosomal dominant polycystic kidney disease (*ADPKD)* is caused by mutations in *PKD1* and *PKD2* genes, where expansion of fluid-filled cysts and renal fibrosis often leads to end-stage renal disease. MicroRNAs are short non-coding RNAs that modulate several biological processes. We have previously shown that aberrant expression of miR-17 family of microRNAs is involved in human ADPKD pathogenesis. RGLS4326 is a chemically-modified oligonucleotide designed to sterically inhibit miR-17 functions and has been shown to reduce cyst growth *in vitro* and *in vivo*. The goal of this study was to determine the signaling pathways modulated by RGLS4326 treatment in PKD mouse models

Methods: RGLS4326 is efficacious in the *Pkd2-KO* and Pcy mouse models of PKD. We performed RNA sequencing and metabolite profiling using kidney samples from both mouse models following RGLS4326 treatment. Ingenuity Pathway Analysis was used to provide novel insights into signaling pathways modulated by RGLS4326 treatment.

Results: Through RNA sequencing, we identified >10000 differentially expressed genes in the PKD kidney samples compared to their age- and strain-matched normal controls. Comparative pathway analysis identified several dysregulated signaling pathways in the two PKD mouse models, including the Pparα, WNT/ β-catenin and cell cycle signaling, that were in turn modulated following RGLS4326 treatment. Next, we performed global metabolite profiling comparing *Pkd2-KO* and normal kidneys, and identified several biochemical alterations in the *Pkd2-KO* model, including substantial changes in lipid metabolism. In particular, decrease in β-fatty acid oxidation pathway was observed in the *Pkd2-KO* kidneys, which corroborates with previously observed Pparα-dysregulation in PKD mouse models. Importantly, modulation in lipid metabolites were also observed following RGLS4326 treatment.

Conclusions: Our results indicate that RGLS4326 confers efficacy and modulate aberrant PKD signaling and metabolic pathways. RGLS4326 is currently in Phase I clinical studies for the treatment of ADPKD.

TH-PO688

Effects of Pharmacologic Galectin-3 Inhibition on the Cardiac Phenotype and Survival of Pkd1-Deficient Mice

Andressa G. Amaral, Jessica A. Freitas, Marcelo D. Melo, Vera M. Salemi, Luiz F. Onuchic. *University of São Paulo, São Paulo, Brazil.*

Background: Myocardial abnormalities are a significant phenotype in ADPKD. We have previously shown that *Pkd1*-deficient mice develop cardiac dysfunction, a phenotype significantly rescued by galectin-3 (Gal-3) knockout.

Methods: In this scenario, we investigated the effects of 2 Gal-3 inhibitors on the cardiac phenotype of a *Pkd1*$^{+/-}$ noncystic mouse (HT) and on survival of a severely cystic mouse homozygous for a *Pkd1*-knockin allele that prevents polycystin-1 cleavage (VV). GR-MD-02 (GR, 60mg/kg), a Gal-3 extracellular inhibitor, or FTS (10mg/kg), an intracellular inhibitor of Gal-3/Ras interaction, was administered intraperitoneally 3x/week, starting at P1. Echocardiographic and protein expression analyses were performed in HT and wild-type (WT) mice at 5-6 weeks while survival was assessed in VVs.

Results: Left ventricular (LV) ejection fraction and shortening fraction were decreased in HTs compared to WTs [43.1% (35.8-54.2) *vs* 59.2% (52.8-66.0), p<0.01; and 23.3% (22.9-25.1) *vs* 31.2% (25.2-39.4), p<0.01; respectively], parameters partially rescued by FTS [52.3% (48.8-57.1) and 27.0% (22.5-29.3) *vs* untreated WT, NS], but not by GR. Interventricular septum diameter, on the other hand, was increased by GR in HTs [0.75 (0.71-0.81) *vs* 0.63mm (0.55-0.68), p<0.01), with only a trend for FTS (p=0.09). GR was also followed by trends of increase in LV mass/BW (p=0.12) and LV posterior wall diameter (p=0.08) in HTs. GR increased P-ERK2 expression in HT and WT hearts [1.70 (1.19-2.46) *vs* 1.29 AU (0.82-1.32), p<0.05; and 1.65 (1.03-3.49) *vs* 1.01 AU (0.94-1.07), p<0.05; respectively], while FTS increased P-ERK2 only in WTs [1.98 AU (1.52-2.51), p<0.01]. GR and FTS did not modify expression of P-GSK3β and P-PKCα and δ in HT and WT hearts, and did not improve survival in VVs.

Conclusions: Our findings revealed that intracellular inhibition of Gal-3 partially rescued systolic function parameters in HTs while its extracellular inhibition induced cardiac hypertrophy without rescuing the systolic phenotype. Differences between effects of pharmacologic inhibition and genetic Gal-3 KO are likely based on their distinct timings of Gal-3 activity suppression, levels of suppression and action site profiles. Our data suggest that pharmacologic Gal-3 inhibition may lead to beneficial effects on the ADPKD cardiac phenotype under specific circumstances.

TH-PO689

PS-341 Attenuates the Progression of Autosomal Dominate Polycystic Kidney Disease

Meihan Chen. *Changzheng Hospital Second Military Medical University, Rochester, MN.*

Background: The proteasome, which is a key component of the ubiquitin-proteasome pathway, has emerged as an important cancer therapeutic target. PS-341 (also called Bortezomib or Velcade) is the first proteasome inhibitor approved for multiple myeloma and has been tested in many clinical trials against other types of cancers. One of the mechanisms by which PS-341 exerts its anticancer effect is inactivation of nuclear factor-kB (NF-kB) through prevention of IkBa degradation.

Methods: Pkd1 conditional knock out mice were injected intraperitonealy with ps-341 0.3mg/kg twice a week from postnatal 15th day. Then cacrificed at postnatal 32th day. Serum was collected to test the BUN and creatinine levels. We use IHC to measure protein levels of NF-kB pathways and PCNA, TUNEL and Flow cytometry to detect apoptosis, MTT to test proliferation.

Results: In this study, we showed that PS-341 can effectively inhibited cyst growth in Pkd1 conditional knock out mice. PS-341 attenuates the progression of PKD through alleviating the BUN and serum creatinine levels in Pkd1 conditional knock out mice as well as improving the survival rate. However we didn't found a decreased level of NF-kB which reveals that PS-341 may not retard disease progression through NF-kB pathway. However we found that PS-341 inhibits renal epithelial cells proliferation and promotes renal epithelial cells apoptosis in vivo and in vitro.

Conclusions: Collectively, these findings suggest that PS-341 inhibits renal epithelial cells proliferation and promotes apoptosis which provides a new strategy for treating and preventing the progression of ADPKD in the future.

Novel Screen to Identify Kinase Drug Targets for Autosomal Dominant Polycystic Kidney Disease

Irfana H. Soomro,[1] Aram Hong,[4] Zhai Li,[3] Edward Y. Skolnik.[2] *[1]Medicine-Nephrology, NYU Langone Medical Center, NY, NY; [2]New York University of Medicine, New York, NY; [3]NYUMC, New York, NY; [4]NYU, New York, NY.*

Background: Activation of kinases and the downstream signaling pathways they activate is central to the pathogenesis of cyst growth in ADPKD. However, while the human kinome consists of more than 500 kinases, only a fraction of these kinases have been tested to determine if they play a role in ADPKD pathogenesis. As a result, there are likely many kinases that are more active in ADPKD kidneys that play prominent roles in disease that are yet-to-be discovered and may be good therapeutic targets. We have now adapted a novel approach to broadly screen PKD kidneys in an unbiased manner for kinases that are more active in PKD kidneys compared with wild type kidneys.

Methods: Active kinases were affinity captured by passing wild type and PKD kidney lysates through columns containing multiplexed kinase inhibitor beads. Bound kinases were then identified by LC separation followed by tandem mass spectrometry. Increase in kinase expression and/or activity was validated by Western Blot and the specific kidney cells expressing the kinase was determined by Immunohistochemistry. The relevance of a kinase to cyst growth *in vivo* was assessed by treating PKD mutant mice with specific kinase inhibitors and/or genetically by generating kinase knockouts using CRISPR/Cas9.

Results: We identified a number of both known and unknown kinases specifically upregulated or downregulated in mouse PKD kidneys. Focal adhesion Kinase (FAK) is one of the promising kinase identified in the screen. We found that FAK and phospho-FAK expression was upregulated in cyst lining epithelium in PKD kidneys. Consistent with FAK playing an important role in cyst growth, treatment of *Pkhd1-Cre;Pkd1*$^{fl/fl}$ mice with the FAK inhibitor VS-4718 slowed cyst growth, preserved renal function, and prolonged survival. VS-4718 treatment led to the inhibition of multiple signaling pathways that could account for the therapeutic benefit including paxillin, p130cas, AKT and Stat3.

Conclusions: This is the first time PKD kidneys have been probed proteomically in an unbiased manner to identify the full range of kinases that are more active in PKD kidneys with the goal of identifying new therapeutic targets. So far we have identified FAK as a potential drug target that can slow cyst growth and preserve renal function and are currently in the process of working up several other promising kinases

TH-PO691

A Novel Zebrafish Drug-Screening Model for Cystic Kidney Disease

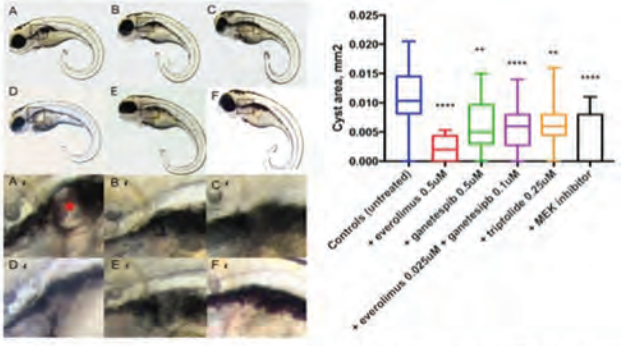
Maryam Khosravi,[1] Katia Nazmutdinova,[2] Tiago Martins,[2] Philip Beales,[2] Rachel H. Giles,[3] Stephen Wilson.[1] *[1]Cell and Developmental Biology, University College London, London, United Kingdom; [2]Institute of Child Health, Great Ormond Street Hospital, University College London, London, United Kingdom; [3]University Medical Center Utrecht, Utrecht, Netherlands.*

Background: Cystic kidney disease affects millions of people worldwide, and is most commonly associated with dysfunction of cilia. Ciliopathies are a highly heterogeneous disease group, continually expanding with the discovery of new genes and availability of genetic diagnostics. However, treatment options for ciliopathy lag far behind. We are using zebrafish to understand the genetic basis of ciliopathies and we have identified a new zebrafish model of ciliopathy that manifests cysts in the pronephric kidney of the zebrafish embryo and have developed this model for drug discovery.

Methods: In a forward genetic approach, mutagenesis of the zebrafish genome was carried out using an alkylating agent to cause random mutations, followed by screening over several generations to select for phenotypes of interest; which included body curvature and organ laterality defects. Further phenotypic characterisation of one mutant line revealed pronephric cysts. RNA sequencing was conducted to find a missense mutation in the highly conserved WD-40 domain of the Intraflagellar Transport protein - Ift144. This ciliopathy model was then used to screen selected drugs with known effect on kidney cysts. Zebrafish were dechorionated at 24 hours post fertilisation and exposed to treatment (drug in DMSO solvent, in E3 media) at 28°C until 4 days post fertilisation, and assessed under brightfield microscopy.

Results: The cyst area of *ift144* -/- embryos was measured repeatedly across three independent experiments to ensure both experimental and biological repeats. We observed significant reduction of cyst size compared to control, by Student's t-test for all treatment groups (see figure).

Conclusions: We present a novel zebrafish model for ciliopathy with a mutation in the ciliary gene *ift144*, which consistently presents with kidney cysts that can be rescued with drugs that are known to ameliorate cyst size. This model has significant advantages for use as a high throughput drug-screening system.



Drug effect on cyst size (black box and inset, cyst marked with asterisk) in ift144 -/- mutants according to treatment group. A: DMSO 'un-treated' control B: Everolimus (0.025μM) and ganetispib (0.1μM) C: Triptolide (0.25μM) D: Everolimus (0.5 μM) E: MEK inhibitor PD98059 (0.5μM) F: Ganetespib (0.5μM)

Results

succumb to disease within seven years of life. Thus, cats are a useful model to investigate genetic modifiers that influence disease progression and severity. Also, because of the consistent genetic background of the breed and the solitary causal mutation, drug trials can be more accurately interpreted as to success and failure, without complications of genetic heterogeneity of either the patient or the causal gene mutation.

Methods: Two normal and eleven Persian-derived cats heterozygous for the *PKD1* c.10063C>A variant were evaluated by ultrasound (US), computed tomography (CT) and magnetic resonance imaging (MRI). Glomerular filtration rate (GFR), complete blood count, serum chemistries, symmetric dimethylarginine (SDMA), and urine analyses were determined.

Results: Ten clinically normal cats had multiple bilateral cysts and classified as feline chronic kidney disease (CKD) stage 1. Most cysts were located in the cortex or at the corticomedullary junction, with far fewer in the medulla. The oldest cat, 8.1 yrs, had slightly elevated SDMA at 15 and creatinine at 16 and a slightly lowered urine specific gravity of 1.028, and tentatively classified as CKD stage 2. Three cats had GFRs below 2.5. CT-based fractional cyst volume (FCV in mls) ranged from 0.63 – 28.22% and increased with age (r = 0.94). One cat had fast progression when considering cystic development and age with 1.08 FCV/mo at 19 mo. The stage 2 cat had the highest FCV of 28.22% but its FCV/mo was 0.29 ml/mo.

Conclusions: CT and MRI modalities are sufficient in cats to determine TKV and FCV. TKV is not a prognostic indicator of disease in cats. FCV is highly correlated with age. Fast progressing cats can be identified and used for the analysis of genetic variants that modify disease progression. Whole genome sequencing of slow and fast progressing cats is underway to elucidate the modifying variants.

TH-PO692

Hearing Impairment, a Novel Functional Readout, in Pkd2 Mutant Zebrafish

Caroline R. Sussman, Elisabeth Pearson, Leah Andrews, Kaitlyn M. Johnson, Alaa Koleilat, Stephen C. Ekker, Lisa A. Schimmenti, Peter C. Harris, Vicente E. Torres. *Mayo Clinic, Rochester, MN.*

Background: Zebrafish have been a valuable model for studies of PKD, with conservation of phenotypes and signaling pathways. Phenotypic readouts have consisted mainly of pronephric cysts and body curvature. The only method for assessing kidney function in embryos is dye clearance, which is affected by many factors and, therefore, is not a reliable indicator. Hair cells of the ear and zebrafish lateral line share many features in common with renal epithelial cells and are responsible for hearing. We have identified hearing assays as a novel approach for assessing pkd2 function.

Methods: We assayed hearing using a standard acoustic startle response (ASR) in 6-7 day old zebrafish. 100 or 400 Hz stimuli were delivered using MATLAB, and responses were recorded using a video camera. Startle responses consisted of a sudden change in swimming velocity or direction in response to the tone and were scored as 1 or 0 for presence or absence, respectively.

Results: The ASR assay was validated using neomycin to ablate lateral line hair cells by established methods. After one hour in neomycin no hair cells were visible using yo-pro-1 or daspei vital dyes and the frequency of response to a 400 Hz tone was reduced 50% compared to untreated sibling controls (0.5±0.2 vs 0.24±0.2, $p<0.04$, n=24 fish/group from 3 clutches). The response of hi4166 pkd2$^{-/-}$ zebrafish to a 400 Hz tone was reduced 35% compared to wild-type sibling controls (0.50±0.2 vs. 0.17±0.2, $p<0.03$, n=56 fish/group from 7 clutches). This population of fish also responded 30% less frequently to a 100 Hz tone (0.83±0.1 vs 0.24±0.1, $p<0.0001$). Our ASR assay was additionally validated using a novel transposon mutant line, spinner. This line develops ventral body curvature, pronephric cysts, and fails to develop hair cell kinocilia analogous to the central cilium, as determined by acetylated alpha tubulin labeling. Spinner mutants show profound hearing loss at both 400 and 100 Hz (0.88±0 vs 0.04±0 and 0.93±0.1 vs 0.12±0.1, $p<0.001$, n=16-24 fish/group from 2-3 clutches).

Conclusions: These data show that the established hi4166 pkd2 mutant zebrafish line have hearing loss, suggesting hearing can be used as an alternative to dye clearing assays for pkd2 function in zebrafish. They further suggest the relevance of hair cells as a model for studies of PKD.

Feline Autosomal Dominant Polycystic Kidney Disease Model to Elucidate Genetic Modifiers of Cyst Progression

Leslie A. Lyons,[1] Yoshihiko Yu,[1,2] Kate Shumway,[1] Jodi S. Matheson,[1] Timothy L. Kline.[3] *[1]College of Veterinary Medicine, University of Missouri, Columbia, MO; [2]Nippon Veterinary and Life Science University, Musashinoshi, Tokyo, Japan; [3]Mayo Clinic, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited renal disease in domestic cats. The feline *PKD1* mutation (c.10063C>A) causes a stop codon in exon 29 (C3284X) and is the only known variant causing ADPKD in cats, specifically Persians and related-breeds. Many ADPKD cats remain subclinical though some show rapid disease progression, develop chronic kidney disease (CKD) and

TH-PO694

Early Imaging Biomarkers of ADPKD: Longitudinal Study of Quantitative MRI and Texture Analysis in a Murine Model

Timothy L. Kline, Megan M. Constans, Marie E. Edwards, Andrew J. Metzger, Kai Jiang, Lilach O. Lerman, Vicente E. Torres, Peter C. Harris, Slobodan Macura, Bradley J. Erickson. *Mayo Clinic, Rochester, MN.*

Background: Currently, only a fraction of the wealth of information that could be disclosed by radiological imaging is used to assess disease status and follow progression of ADPKD. Advanced MR imaging techniques can be used to measure renal structural and functional properties. We hypothesized that advanced MRI acquisitions and image analysis methods detect renal tissue alterations preceding changes in TKV in the *Pkd1*$^{RC/RC}$ mouse model in different backgrounds.

Methods: *Pkd1*$^{RC/RC}$ model mice (C57BL/6 and *C57Bl6 x 129s6Svev/Tac* 'F1' background, n=7 each), as well as wild-type (C57BL/6 and 'F1' background, n=5 each) were imaged at 3, 6, and 12-weeks of age. Mice imaging was performed under anesthesia with a 16.4T NMR spectrometer. TKV and texture were measured on T2-weighted images, and T1 relaxation maps were calculated and measured within the kidneys. Regions-of-interest were drawn to cover cortical and medullary regions.

Results: Figure 1 shows TKV progression for the four phenotypic groups, as well as the 3-week means of TKV, T1 relaxation, and entropy texture feature (a measure of tissue heterogeneity). The fast progressing group ('F1') exhibited a significant increase in TKV compared to wild-type, whereas the C57BL/6 model did not. In contrast, T1 relaxation and texture properties were found to clearly differentiate the model mice from corresponding wild-type.

Conclusions: Quantitative MR parameters and texture features can serve as early biomarkers of PKD. These parameters could be useful for pre-screening in trials as they inform on early disease. Moreover, they may afford more parameters to evaluate treatment benefits, which may be detectable over shorter study durations.

Funding: NIDDK Support

Deletion of miR-214 Skews Macrophage Polarization to Promote Cyst Growth in Autosomal Dominant Polycystic Kidney Disease

Ronak Lakhia,[1] Matanel Yheskel,[1] Andrea N. Flaten,[1] Karam S. Aboudehen,[2] Vishal Patel.[1] *[1]University of Texas Southwestern Medical Center, Dallas, TX; [2]University of Minnesota, Minneapolis, MN.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is characterized by fluid-filled cysts that arise from kidney tubules and compress functioning nephrons leading to kidney failure. MicroRNAs (miRs) are small non-coding RNAs that can regulate gene expression. Our understanding of the role microRNAs in ADPKD is limited. The goal of this study was to understand the role of miR-214 in ADPKD.

Methods: Q-PCR and in situ hybridization were performed to analyze the expression of miR-214 and its host lncRNA transcript, *Dnm3os* (Dynamin 3 opposite strand), in mouse and human ADPKD. Next, we genetically deleted miR-214 expression in *Pkhd1/Cre*; *Pkd2*$^{F/F}$ (*Pkd2*-KO) mice and *Pkd1*$^{RC/RC}$ mice, two genetic models of ADPKD. Kidney mRNA sequencing and pathway analysis was performed to elucidate the differential gene expression pattern between *Pkd2*-KO and *Pkd2*-miR-214$^{-/-}$ double KO mice. *In vitro*, mIMCD3 and RAW264.7 cells were treated with miR-214 mimics.

Results: Q-PCR showed that miR-214 and *Dnm3os* expression was upregulated in mouse and human ADPKD kidneys. In situ hybridization revealed that miR-214 and *Dnm3os* are expressed in both the cyst epithelium and interstitium. miR-214$^{-/-}$ mice displayed no phenotypic abnormalities. Deletion of miR-214 in *Pkd2*-KO mice increased kidney weight/body weight ratio, raised serum BUN and shortened survival. Pathway analysis of differentially expressed genes revealed that miR-214 deletion results in a shift in the type of inflammation present in *Pkd2*-KO kidneys. Accordingly, further molecular and histological analysis revealed an increase in M2-like macrophages in *Pkd2-miR-214*-KO kidneys. Conversely, miR-214 mimics reduced expression of M2 markers and cytokines in RAW264.7 and mIMCD3 cells. Deleting miR-214 in a second long-lived, slowly-progressing mouse model, the *Pkd1*$^{RC/RC}$ mouse, also led to increased total kidney volumes as measured by serial MRI and an increase in M2-like macrophages.

Conclusions: miR-214 expression is increased in mouse and human ADPKD kidneys. Deletion of miR-214 aggravates cyst growth and shortens survival. miR-214 may suppress cyst growth by inhibiting M2-like polarization of macrophages. Our studies suggest that augmenting miR-214 may be a potential novel therapeutic approach for ADPKD.

TH-PO696

miR-210-3p Inhibition Decreases Fibrosis and Improves Renal Function in Murine ADPKD

Ameya P. Patil,[1] William E. Sweeney,[1] Cynthia G. Pan,[2,1] Ellis D. Avner.[1] *[1]Medical College of Wisconsin, Wauwatosa, WI; [2]Children's Corporate Center, Milwaukee, WI.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by progressive cystic enlargement. In *mcwPkd1*$^{(nl/nl)}$ hypomorphic mice, peri-cystic areas are hypoxic early in the disease course. These hypoxic areas are markedly positive for hypoxia inducible factor-1α (HIF-1α). These areas develop fibrosis with disease progression. miR-210-3p is HIF-1α inducible and increases in response to hypoxia. We hypothesize that peri-cystic hypoxia initiates a repair response via HIF-1α and miR-210-3p which contributes to interstitial fibrosis.

Methods: Cystic kidneys at weekly intervals starting at postnatal (PN) day 21, were sectioned and stained with trichrome and PCNA. RNA extracted from laser capture micro-dissection (LCM) trichrome (TC) positive peri-cystic regions at PN28, & 42 was examined for expression of miRNA 210-3p. PN21 peri-cystic regions negative for trichrome stain was used as a control. Anti-miR-210-3p was injected IP starting at PN21 Q 4 days till PN42. Untreated cystic kidneys were used as control. RNA was extracted from both cystic treated and untreated kidneys at PN42. Serum obtained at harvest was used to assess renal function.

Results: 1. In LCM captured peri-cystic regions, miRNA-210-3p is upregulated 6-fold at PN28 and 5-fold at PN42 compared with PN21. 2. Anti-miR-210-3p treated cystic kidneys at PN42 compared with age-matched untreated cystic kidneys has: (a) 35% reduction in serum creatinine; (b) 75% decrease in trichrome positive/fibrotic areas; (c) proliferation (PCNA) is restricted to tubular epithelia vs both tubular epithelia and peri-cystic regions in untreated controls; (d) up-regulation of anti-fibrotic mRNA's Hgf (19.22-fold), IFNg (7.95-fold), Il10 (523.68-fold), Il13ra2 (31.99-fold) and down-regulation of pro-fibrotic mRNA's Ctgf (-10.79) and Il5 (-4.31) and ECM component Col1a2 (-94.86).

Conclusions: Conclusions- 1. We demonstrate that expression of miR-210-3p increases in hypoxic peri-cystic regions with disease progression at PN28 and PN42. 2. *In vivo* inhibition of miR-210-3p: improves kidney function; decreases interstitial fibrosis; reduces proliferation in peri-cystic regions; increases expression of anti-fibrotic mRNAs (Hgf, IFNg, Il10, Il13ra2) and decreases profibrotic (Ctgf, Il5) and ECM matrix component (Col1a2).

TH-PO697

Long Noncoding RNA Hoxb3os Is Dysregulated in Autosomal Dominant Polycystic Kidney Disease and Regulates mTOR Signaling In Vivo

Karam S. Aboudehen,[1] Shayan A. Farahani,[1] Mohammed S. Kanchwala,[2] Siu Chiu Chan,[1] Svetlana Avdulov,[1] Alan Mickelson,[1] Dayeon Lee,[1] Micah D. Gearhart,[1] Vishal Patel,[2] Chao Xing,[2] Peter Igarashi.[1] *[1]University of Minnesota, Minneapolis, MN; [2]University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is primarily caused by mutations in *PKD1* and *PKD2*. Mutations of *PKD1* and *PKD2* produce abnormalities in multiple intracellular signaling pathways, including activation of the mTOR pathway. Long noncoding RNAs (lncRNAs) are single-stranded RNA molecules over 200 nucleotides in length and lacking a long open-reading-frame. lncRNAs play important roles as epigenetic regulators of development and disease, but their involvement in PKD has not been previously described.

Methods: We have recently identified a kidney-specific lncRNA, called *Hoxb3os*, which is downregulated in kidney-specific *Pkd1* and *Pkd2* mutant mice and in cystic kidneys from ADPKD patients.

Results: Deletion of *Hoxb3os* in mIMCD3 mouse kidney epithelial cells resulted in activation of the mTOR pathway and increased oxidative phosphorylation (Aboudehen K, et al. J Biol Chem, 2018, in press). Consistent with activation of mTORC1 signaling, *Hoxb3os*-deficient cells displayed increased cell proliferation and defective autophagy. To identify the role of *Hoxb3os* in vivo, we used CRISPR-based gene editing to delete the genomic DNA encoding *Hoxb3os* in mouse zygotes. PCR analysis of genomic DNA and qRT-PCR analysis of kidney RNA demonstrated successful ablation of *Hoxb3os* in multiple independent founders. Mice lacking *Hoxb3os* were viable and had grossly normal kidney morphology up to age post-natal day P28. Immunoblot analysis of mutant kidney lysates showed increased phosphorylation of mTOR and downstream targets of mTORC1 but not mTORC2. *Hoxb3os* mutant kidneys also showed increased cell proliferation and defective autophagy. Co-immunoprecipitation experiments revealed that *Hoxb3os* was found in a complex with phosphorylated mTOR but not dephosphorylated mTOR in mouse kidney lysates.

Conclusions: Collectively, these findings identify *Hoxb3os* as a kidney-specific lncRNA that binds to mTORC1 and directly inhibits its downstream activity. Suppression of *Hoxb3os*may contribute to the activation of the mTOR pathway in ADPKD, and restoration of *Hoxb3os*may have therapeutic benefit.

TH-PO698

Actin and Intermediate Filament Protein LAD1 (Ladinin1) Is Dysregulated in ADPKD Mouse Model

Mahiro Kurashige,[1] Tsung-Jui Wu,[1,2] Chengchao Lin,[1] Fang Zhou,[1] Luis F. Menezes,[1] Gregory G. Germino.[1] *[1]NIDDK, National Institute of Health, Bethesda, MD; [2]Hualien Armed Forces General Hospital, National Defense Medical Center, Taipei, Taiwan.*

Background: There have been reports that Polycystin1 (PC1) co-localizes with actin/intermediate filament and could have functional roles in its organization, but much remains poorly understood. We have previously reported the transcriptomics of an orthologous ADPKD mouse model using 80 kidneys from *Pkd1*cko;Tg(Cre/Esr1) 102-210 days-old mice, in which *Pkd1* knockout was induced at P40. We found *Lad1* (Ladinin-1), a poorly characterized intermediate-filament protein, was one of the top differentially expressed genes. Here we focus on characterizing *Lad1* expression and function as a candidate regulator of cytoskeleton dynamics in ADPKD.

Methods: 16 kidneys (8 WT, 8 KO) were used for qPCR and 12 (6 WT, 6 KO) for immunoblotting. *Lad1* mRNA and protein expression levels were evaluated by qPCR and immunoblot in a pair of DBA and LTL cell lines derived from *Pkd1*$^{CKO/CKO}$ mouse, with corresponding mutant derived after Cre-expression. Mouse and humand Lad1 were cloned with various epitope tags to ease detection. A human keratinocyte cell line with high levels of endogenous LAD1, HaCat, and an MDCK cell line expressing recombinant, HA-tagged human PC1 were used for characterizing LAD1 and actin dynamics.

Results: *Lad1* mRNA and protein levels were 58.8% (exon1-2; 50.0% exon4-5) and 67% lower, respectively, in *Pkd1*mutant kidneys ($p<0.01$ for each analysis). In the cell lines, *Lad1* mRNA and protein levels were 46.0% (n=3, p=0.16) and 67.7% (n=3, $p<0.01$) lower in mutants compared to the paired WT cells. In characterizing Lad1 protein, we found that both endogenous and recombinant Lad1 migrates at ~72Kda, not at the size of 59kDa predicted by both its MW and companies that sell Lad1 antibodies. Using the HaCat cell line to better characterize LAD1 function, we found that LAD1 levels increased with cell confluency. Confocal studies determined that LAD1 generally co-localizes with actin in stress fibers and in a cortical "rim" pattern at the cell edge, which is decreased at cell-cell junctions. This pattern was also seen in the MDCK and DBA renal epithelial cell lines.

Conclusions: LAD1 is a poorly understood cytoskeletal protein whose expression increases with cell density but whose level is down-regulated in cystic kidney. Further study will be required to determine whether the downregulation observed in cystic kidney reflects altered cell-cell sensing.

Gene Expression Profile of Pkd1 Null Endothelial Cells During Embryonic Development

Patricia Outeda,[1] Hanwen Bai,[3] Joseph A. Mancini,[3] Luis F. Menezes,[2] Terry J. Watnick.[1] *[1]University of Maryland School of Medicine, Baltimore, MD; [2]National Institutes of Health, Bethesda, MD; [3]Vertex Pharmaceuticals, Inc., Boston, MA.*

Background: Polycystins (PCs) play a critical role in vascular development. *Pkd1/2* null embryos die in mid gestation with polyhydramnios, subcutaneous edema and focal hemorrhage. A subset of these phenotypes are recapitulated by deleting *Pkd1* or *Pkd2* in endothelial cells. At the cellular level, we have shown that *Pkd* deficient endothelial cells exhibit aberrant branching morphogenesis and altered directional migration. The specific signaling pathways regulated by polycystins in endothelial cells, however, are unknown. To understand the functional consequences of polycystin deficiency in endothelial cells we performed RNA sequencing (RNA-seq) in *Pkd1*$^{-/-}$ endothelial cells at two embryonic time points.

Methods: We harvested *Pkd1*$^{-/-}$ and littermate control embryos at E13.5 and E14.5 (N=36 total) and isolated endothelial cells using anti-CD31^{+} (specific marker for endothelial cells) coated magnetic beads. RNA was extracted and sequenced independently using 50bp single-end reads. Data was processed using Cutadapt and gene expression quantified using Salmon and R. Differential gene expression analysis was performed using DESeq2 package and enriched pathways were identified using clusterProfiler package.

Results: We identified more than 200 genes that were differentially expressed (Log2 (FC)≤ ± 0.25 and a corrected p-value of <0.05) at each time point. At E13.5 functional clustering revealed an enrichment of genes expressing extracellular matrix components and genes involved in the innate immune response among top ranked. At E14.5, we found upregulation of genes related to cell migration, cell proliferation and angiogenesis probably as a mechanism to compensate the aberrantly developed embryonic vasculature. We found that the *ATPase, H+ transporting, lysosomal V0 subunit C (Atp6v0c*, Gene ID11984) was the most highly downregulated gene at both developmental stages analyzed, (Log2 FC= -1.61 and -1.50 respectively, and q= 0.00E+00 for both). Silencing of this gene was shown to effectively suppress migration and invasion of prostate cancer cells (PC-3M-1E8), which is relevant in the context of the migration defects we observe in *Pkd* mutant endothelial cells.

Conclusions: Our study revealed extensive transcriptional changes in *Pkd1* mutant endothelial cells supporting the importance of polycystin signaling in endothelial cells and in vascular morphogenesis.

Exome-Wide Association Study Identifies Candidate Susceptibility Genes for Congenital Obstructive Uropathy

Dina Ahram,[1] Tze Yin Lim,[1] Rik Westland,[2] Priya Krithivasan,[1] Adele Mitrotti,[1] Monica Bodria,[3] Francesco Scolari,[4] Loreto Gesualdo,[5] Marijan Saraga,[6] Velibor Tasic,[7] Krzysztof Kiryluk,[1] Gian Marco Ghiggeri,[3] Ali G. Gharavi,[1] Simone Sanna-Cherchi.[1] *[1]Columbia University, New York, NY; [2]VU University Medical Center, Amsterdam, Netherlands; [3]Istituto G. Gaslini, Genoa, Italy; [4]University of Brescia, Montichiari (Brescia), Italy; [5]University of Bari, Altamura, Italy; [6]University Hospital in Split, Split, Croatia; [7]University Children's Hospital, Skopje, Macedonia (the former Yugoslav Republic of).*

Background: Congenital Obstructive Uropathy (COU) is a cause of kidney failure in children. Monogenic forms of disease account for a small portion of cases. Rare variant association tests are promising approaches to identify novel disease genes.

Methods: We conducted exome sequencing in 292 COU cases and 8541 controls. Following diagnostic variant annotation in genes implicated in congenital anomalies of the kidney and urinary tract (CAKUT) using ACMG criteria, we searched for novel susceptibility COU genes using case-control exome-wide collapsing analyses for rare functional variants. We tested gene-level dominant and recessive models via fisher-exact statistics. Qualifying variants were selected using computational scores based on conservation and location in intolerant exons or conserved domains. We analyzed gene-set enrichment using 299 OMIM genes implicated in CAKUT in comparison to a control set of 857 olfactory genes. Finally, we cross-annotated suggestive signals with results from a GWAS for common variants consisting 398 cases and 8197 controls.

Results: ACMG-based variant prioritization revealed pathogenic mutations in 11(3.7%) COU cases. Gene-level collapsing showed 20 genes with p<5x10-4 for dominant model (MAF<0.0005) and 2 genes for the recessive model (MAF<0.01), although no exome-wide significant signals (<2.5x10-6) were attained. Two candidate genes were particularly interesting: 1.*MAZ* (dominant missense model; p=3.58x10-5), a gene demonstrated to regulate urogenital development in a mouse model, and 2.*FLNA* (recessive model; p=4.25x10-5), a gene implicated in Otopalatodigital Spectrum Disorders, where hydronephrosis and megaureter were reported. Cross-annotation with GWAS signals revealed evidence for association of common variants to *MAZ* (p=7.06x10-3– 6.96x10-4). Gene set analysis for genes involved in kidney function showed enrichment for rare functional variant (χ2 = 9.12; p=2.5x10-3) compared to olfactory control genes (χ2=0.15; p=0.70) in cases versus controls.

Conclusions: This study addresses the contribution of rare and common variants under various genetic models to solve the etiology of COU. Preliminary results implicate both rare and common variants in *MAZ* as novel risk factors for COU.

TH-PO701

Analysis of De-Novo Coding Mutations Identifies New Candidate Genes for Kidney Malformations

Hila Milo Rasouly,[1] Maddalena Marasa,[1] Byum hee Kil,[1] Tze Yin Lim,[1] Thomas L. Ruan,[2] Jeremiah Martino,[2] Nicholas J. Steers,[1] Anna Materna-Kiryluk,[7] Giuseppe Masnata,[6] Velibor Tasic,[3] Marijan Saraga,[4] Gian Marco Ghiggeri,[5] Rosemary V. Sampogna,[1] Simone Sanna-Cherchi,[1] Ali G. Gharavi.[1] *[1]Columbia University, New York, NY; [2]Columbia University Medical Center, New York, NY; [3]University Children's Hospital, Skopje, Macedonia (the former Yugoslav Republic of); [4]University Hospital in Split, Split, Croatia; [5]U.O.C. Nefrologia, Dialisi e Trapianto, IRCCS Istituto G. Gaslini, GENOVA, Italy; [6]Azienda Ospedale G. Brotzu, Cagliari, Italy; [7]Department of Medical Genetics, Poznan University of Medical Sciences, Poznan, Poland.*

Background: Renal hypodysplasia (RHD) is one of the most common cause of pediatric kidney failure. Although multiple causative genes have been identified, they only account for 10-15% of cases. A search for de-novo "mutations" (DNMs), has led to the identification of numerous novel genes for congenital heart defects and neurodevelopmental disorders. We hypothesized that de-novo analysis can similarly identify new RHD-causing genes.

Methods: Whole-exome sequencing was performed on 88 RHD trios. The sequences were annotated using an in-house software, ATAV, and DNMs were identified. Potential enrichment for DNMs was analyzed with the denovolyzer package in R. Exploratory gene-set enrichment analysis was performed with the Molecular Signatures Database (MSigDB).

Results: We identified a significant 1.5-fold enrichment for DNMs in cases compared to expectations ($p= 1.7x10^{-4}$). The enrichment mostly originated from probands with renal agenesis or renal hypoplasia, and not from those with multicystic dysplastic kidneys. Globally, the DNM signal was mainly driven by genes that are highly expressed during murine kidney development. De-novo loss-of function mutations were detected only in two genes known to be associated with kidney disorders (*PAX2* and *TSC2*) but none of the missense DNMs occurred in known RHD genes. In pathway analysis, we observed a 11.8-fold enrichment for missenses in genes targeted by NF1 ($p= 7.9x10^{-5}$), a 4-fold enrichment for DNMs in the CHEK2 network ($p= 2.8x10^{-4}$) and a 6.4-fold enrichment for DNMs in genes potentially regulated by PAX4 ($p= 1.3x10^{-4}$). We did not find independent DNMs in the same gene, confirming heterogeneity of disease.

Conclusions: Despite limited sample size, we detected an excess of de-novo mutations in RHD, identifying an important mechanism of disease. Gene-set analysis may help to pinpoint which genes are driving this enrichment. Analysis of larger cohorts is likely to identify genes with recurrent de-novo variants, enabling identification of causal genes.

TH-PO702

Mutations in PIK3C2A Cause Syndromic Short Stature Associated with Eye, Skeletal, and Renal Involvement

Markus Schueler,[1] Anlu Chen,[2] Dov Tiosano,[11] Hagit N. Baris,[3] Marrit Hitzert,[8] Adi Mory,[5] Karl Knaup,[10] Ronald Roepman,[4] Rolph Pfundt,[9] Mariam Aslanyan,[12] David A. Buchner,[6] Michael S. Wiesener.[7] *[1]Department of Nephrology and Hypertension, University of Erlangen-Nuernberg, Erlangen, Germany; [2]Case Western Reserve Univ, Cleveland, OH; [3]Rambam Health Care Campus, Haifa, Israel; [4]Radboud University Medical Center, Nijmegen, Netherlands; [5]Rambam health care campus, Haifa, Israel; [6]Case Western Reserve University, Cleveland, OH; [7]University Hospital Erlangen, Erlangen, Germany; [8]University Medical Center Groningen, Groningen, Netherlands; [9]RadboudUMC, Nijmegen, Netherlands; [10]University of Erlangen-Nuremberg, Erlangen, Germany; [11]Divison of Pediatric Endocrinology, Mayer Children's Hospital, Haifa, Israel; [12]Department of Human Genetics, Radboud Institut for Molecular Life Science, Nijmegen, Netherlands.*

Background: PIK3C2A is a member of the phosphoinositide 3-kinase (PI3K) family that catalyzes the phosphorylation of phosphatidylinositol (PI). Class II PI3Ks has been attributed a wide-range of biological functions including, angiogenesis, cellular signaling, endosomal trafficking, exocytosis as well as ciliary formation and function. However, its function is still poorly understood. Identifying the genetic basis of Mendelian diseases provide insight into gene function, susceptibility to disease and can improve clinical care.

Methods: We performed whole exome sequencing in three independent consanguineous families to identify the underlying single-gene disease-causing mutation. We then obtained dermal fibroblasts from skin biopsies of the affected individual and healthy controls for molecular studies.

Results: We identified three homozygous protein-truncating mutations in the gene *PIK3C2A* in five children from independent consanguineous families. The affected individuals show a considerable overlapping phenotype including cataract, skeletal abnormalities, hearing loss and renal involvement among other features. Molecular data of patient-derived fibroblasts were consistent with loss of *PIK3C2A* function as evidenced by the lack of PIK3C2A protein. In addition we demonstrate that the PIK3C2A deficiency caused impaired cilia formation, decreased levels of PI in primary cilia, and altered the phosphorylation status of Akt, GSK3beta as well as the expression level of *AXIN2*.

Conclusions: We demonstrate that loss-of-function mutations in *PIK3C2A* resulting in a novel syndrome consisting of short stature, cataracts, hearing loss, skeletal abnormalities and renal involvement. This discovery, together with studies of other disorders of PI metabolism, will enable future studies to discover the pathophysiological mechanism basis of this syndrome to better understand the role of PIK3C2A.

TH-PO703

ZMYM2 Mutations Cause Congenital Anomalies of the Kidneys and Urinary Tract (CAKUT) with Syndromic Features

Dervla M. Connaughton,[1] Nina Mann,[1] Makiko Nakayama,[1] Rufeng Dai,[1] Caroline M. Kolvenbach,[2] Franziska Kause,[1] Dina Ahram,[4] Hila Milo Rasouly,[3] Simone Sanna-Cherchi,[3] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Columbia University, New York, NY; [4]Columbia University Medical Center, New York, NY.*

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) constitute the most common cause (45%) of chronic kidney disease in the first three decades of life. CAKUT can present as an isolated renal condition or as part of a clinical syndrome. First insights into the pathogenesis of CAKUT came from identification of ~40 single-gene causes of isolated CAKUT and ~179 single-gene causes of syndromic CAKUT.

Methods: We performed whole exome sequencing (WES) to identify novel monogenic causes in a worldwide cohort of 600 individuals with CAKUT.

Results: We identified 13 different dominant heterozygous mutations in *ZMYM2* (*MYM-type zinc fingers type 2*) in 15 unrelated families; p.Val61del, p.Glu126Ala, p.G257fs p.Ile387Val, p.Gln398*, p.Cys536Leufs*13, p.Arg540ins*, p.Lys649Arg, p.Tyr763His, p.Gly775Glu, p.Asp997del, p.Pro1002Ser, p.Glu1031Lys. *ZMYM2*, a transcriptional regulator, contains 10 tandem zinc fingers called myeloproliferative and mental retardation (MYM)-type zinc fingers. *ZMYM2* is expressed in the urothelial cells and renal tubules in human cells and in the bladder and genital tubercle of the developing mouse. The encoded protein acts as a transcriptional co-repressor as part of the BHC histone deacetylase complex and through interaction with SUMO-2. Affected individuals exhibited a broad spectrum of CAKUT phenotypes. In addition, there were genito-urinary tract pathologies including imperforate hymen and cryptorchidism. Interestingly, patients carrying missense alleles had an isolated CAKUT phenotype, whereas patients carrying truncating alleles exhibited syndromic features such as facial dysmorphsim, developmental delay, hypotonia, and autism spectrum disorder.

Conclusions: We here discovered *ZMYM2* mutations as a novel cause of autosomal dominant CAKUT. Furthermore, we found evidence of an allelic genotype-phenotype correlation, in which null mutations in *ZMYM2* (e.g., protein truncating) cause syndromic CAKUT phenotypes, whereas hypomorphic mutations (e.g., missense) cause isolated CAKUT phenotypes.

TH-PO704

COL4A1 Mutations as a Potential Novel Cause of Autosomal-Dominant CAKUT in Humans

Thomas Kitzler, Caroline M. Kolvenbach, Ronen Schneider, Dervla M. Connaughton, Amar J. Majmundar, Nina Mann, Makiko Nakayama, Shirlee Shril, Friedhelm Hildebrandt. *Boston Children's Hospital, Boston, MA.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) are the most common cause of chronic kidney disease <30 years of age. While the genetic locus containing *COL4A1* (13q33-34) has been implicated in vesicoureteral reflux (VUR), the role of *COL4A1* in isolated kidney disease is unclear (Vats *JASN* 17:1158, 2006). We hypothesized that mutations in *COL4A1* can cause abnormal kidney development in humans.

Methods: We performed whole exome sequencing in a cohort of 638 families (258 families with nephronophthisis (NPHP) and 380 families with CAKUT). Genetic variants were analyzed assessing evolutionary conservation, in-silico prediction programs, and minor allele frequency in public databases (gnomAD, EVS, 1000 Genomes), as previously described (Braun *Nat Genet* 49:1529, 2017).

Results: We identified eight different heterozygous mutations in *COL4A1* in eight unrelated families with CAKUT, while no *COL4A1* mutations were present in the NPHP negative control cohort. All eight individuals had heterozygous only missense variants in *COL4A1* (D928H, G1392S, G1450S L1235R, M838V, P603S, P816L, P1224L) with an isolated CAKUT phenotype. Affected individuals exhibited a spectrum of CAKUT phenotypes ranging from renal agenesis, small echogenic dysplastic kidneys, multicystic dysplastic kidney, left ectopic dysplastic kidney, hydronephrosis, to VUR. VUR was the predominant phenotype (5/8 families). Three patients had extra-renal features (facial dysmorphism, low set ears, hypotelorism, hearing loss, and uterus unicornis). *COL4A1* demonstrates extreme loss-of-function intolerance (pLI = 1), supporting autosomal dominant inheritance.

Conclusions: We identified heterozygous *COL4A1* mutations as a potential novel autosomal dominant cause of CAKUT. The observation that some patients exhibit an extra-renal phenotype, while others have isolated CAKUT, suggests the possibility of allelism.

Exome Sequencing in Human Bladder Exstrophy and Knockdown Studies in Zebrafish Implicate SLC20A1 as Candidate Gene and Major Regulator of Urinary Tract Development

Johanna Magdalena M. Schmidt,[2,1] Öznur Yilmaz,[1] Rong Zhang,[2] Anna S. Japp,[3] Heiko M. Reutter,[2,4] Benjamin Odermatt.[1] *[1]Institute of Anatomy, Faculty of Medicine, University of Bonn, Bonn, Germany; [2]Institute of Human Genetics, Faculty of Medicine, University of Bonn, Bonn, Germany; [3]Institute of Neuropathology, Faculty of Medicine, University of Bonn, Bonn, Germany; [4]Department of Neonatology and Pediatric Intensive Care, Faculty of Medicine, University of Bonn, Bonn, Germany.*

Background: Bladder exstrophy-epispadias complex (BEEC) represents the severe end of human congenital anomalies of the kidney and urinary tract (CAKUT). Exome and Sanger sequencing in BEEC patients identified two novel *de novo* variants (p.G237R; p.V298A) and one novel maternally transmitted variant (p.K441Q) from an affected mother in *SLC20A1*. All three variants were predicted to be disease causing. *SLC20A1* encodes for a Na^+/PO_4 cotransporter known to play a role in proliferation and TNF-induced apoptosis. We investigated the developmental function of *slc20a1a* in developing zebrafish larvae (zfl) performing Morpholino (MO) knockdown (KD) experiments. The urinary tract in zfl consists of two pronephric ducts, similar in segmentation to human nephrons, that fuse at the cloaca. *Slc20a1a* is frequently used as pronephric in situ hybridization (ISH) marker.

Methods: *Slc20a1a* KD was done by injecting ATG-binding MOs in 1-2 cell staged eggs, blocking the gene's translation. Specificity was shown by Western Blot and rescue experiments by co-injection of human mRNA transcripts of *SLC20A1*. For phenotype characterization different assays were used such as sulforhodamine 101 excretion, ISH, immunohistochemistry (IHC) on paraffin sections and the transgenic zf reporter line *Tg(wt1b:GFP)*.

Results: MO KD of *slc20a1a* in zfl results in a severe lethal phenotype affecting multiple organ systems. Focusing on urinary tract, we see formation of pronephric cysts and disorganization of the cloaca. Excretion assay uncovers severe opening defects of the cloaca for the intestine, similar to our index patient with cloacal exstrophy and an imperforate anus. Yolk endocytosis defects resemble abdominal wall fusion deficiencies. IHC shows defects in proliferation and apoptosis.

Conclusions: Our data suggests *slc20a1a* as major player in urinary tract development of zf. Mild MO phenotypes present with urinary tract abnormalities. Severe MO phenotypes present with a high lethality among zfl - underlining the overall importance of *slc20a1a* during embryonic development. In conclusion, exome sequencing in human bladder exstrophy and developmental biology studies in zfl implicate *SLC20A1 a*s disease gene for human BEEC and therefore CAKUT and as major regulator of urinary tract development.

TH-PO706

A Genome-Wide Association Study Provides Insight into the Etiology of Congenital Obstructive Uropathy

Tze Yin Lim,[1] Dina Ahram,[1] Rik Westland,[2] Miguel Verbitsky,[1] Priya Krithivasan,[1] Adele Mitrotti,[1] Francesco Scolari,[3] Marijan Saraga,[4] Gian Marco Ghiggeri,[5] Velibor Tasic,[6] Loreto Gesualdo,[7] Ali G. Gharavi,[1] Krzysztof Kiryluk,[1] Simone Sanna-Cherchi.[1] *[1]Columbia University, New York, NY; [2]VU University Medical Center, Amsterdam, Netherlands; [3]University of Brescia, Montichiari (Brescia), Italy; [4]University Hospital in Split, Split, Croatia; [5]Istituto Giannina Gaslini, Genoa, Italy; [6]University Children's Hospital, Skopje, Macedonia (the former Yugoslav Republic of); [7]University of Bari, Altamura, Italy.*

Background: Congenital Obstructive Uropathy (COU) is a frequent anomaly of the urinary tract. Human genetic and clinical data suggest that both rare and common genetic variants might be involved in the pathogenesis of COU.

Methods: We conducted SNP genotyping in 398 COU cases and 8197 controls on different Illumina platforms. Genome-wide association study (GWAS) was performed on two Caucasian cohorts of 280 cases (cohort 1) and 118 cases (cohort 2), divided based on platform. After standard QC we retained 444614 and 632574 markers in cohort 1 and cohort 2, respectively. We imputed these marker sets separately using the HRC1.1 panel. The results were meta-analyzed with METAL. Suggestive signals were cross-annotated with results from our exome-wide collapsing analysis for rare variants in 292 COU cases and 8541 controls.

Results: Meta-analysis of the two cohorts (398 cases, 8197 controls and 7503796 markers) revealed 3 suggestive associations. The 1st was on chr4q26 (rs4833590; p=3.01x10^{-7}) in *SEC24D*. A disruption of this gene causes embryonic lethality in mice, and mutations in humans are implicated in the Cole-Carpenter Syndrome-2 with no known urinary tract involvement. Other genes within 250Kb of this variant are *CEP170P1*, *LOC729218*, *METTL14* and *SYNPO2*. The 2nd was on chr12q21 (rs10777060; p=9.98x10^{-6}), 105.8kb upstream of *BBS10*, implicated in Bardet-Biedl syndrome, a ciliopathy with renal and urinary tract involvement. Neighboring genes are *OSBPL8* and *NAP1L1*. A 3rd suggestive signal was on chr4q32 (rs6536312;p=9.70x10^{-6}), 231.1kb upstream of *ETFDH*, a gene implicated in glutaric acidemia IIC, which features urogenital defects. Neighboring genes are *TMEM144*, *RXFP1*, *C4orf46* and *PPID*. Cross-annotation with exome-wide collapsing analysis in 292 COU cases and 8541 controls showed evidence for enrichment in rare variants in *BBS10* (p=3.2x10^{-3}) and *TMEM144* (p=1.2x10^{-2}).

Conclusions: We present preliminary GWAS findings based on a relatively small sample size of 398 COU cases and identified 3 candidate loci. Integration with rare variants from an exome-wide association study permitted locus refinement and identification of novel susceptibility genes for follow-up studies in larger cohorts.

A Mutation Identified in Patients with Congenital Anomalies of the Kidney and Urinary Tract Interrupts ROBO2-SLIT2 Association and Signaling Pathway

Xueping Fan,[1] Tou S. Thao,[2] Weining Lu.[3] *[1]Medicine, Boston University, Boston, MA; [2]Medicine, Boston University School of Medicine, Boston, MA; [3]Boston University Medical Center, Boston, MA.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) is a major cause of kidney failure in children and young adults. ROBO2 is a receptor for ligand SLIT2. ROBO2 and SLIT2 plays key roles in early ureteric bud outgrowth during kidney development and nervous system formation. There are approximately 30 *ROBO2* missense mutations identified in CAKUT patients. However, functional significances of these mutations are remained to be characterized. To elucidate if these mutations would structurally disrupt ROBO2-SLIT2 interaction and functionally compromise its signaling pathway, we have analyzed a missense mutation of *ROBO2*, p.G98W (c.292G>T), located in the ROBO2 first Ig domain that serves as the ligand binding site for SLIT2.

Methods: Site-directed mutagenesis was used to introduce c.292G>T point mutation into a human ROBO2 cDNA. Calcium phosphate transfection strategy was used to express ROBO2 in HEK cells. Protein expression was confirmed by Western blot analysis and ROBO2-SLIT2 interaction was analyzed using the ForteBio Bio-Layer Interferometry (BLI) system Octet RED96e. Postnatal anterior subventricular zone (SVZa) neuronal migration assay was performed to examine the functional impact of the mutation on ROBO2-SLIT2 signaling pathway.

Results: BLI binding assay showed a positive interaction between ROBO2 and SLIT2, however, the p.G98W mutation in ROBO2 first Ig domain hinders this binding compared with its wild type control. Functional assay indicates that the extracellular portion of ROBO2, a 153 residue peptide containing the binding domain for SLIT2, is able to block ROBO2-SLIT2 signaling pathway that repels neuronal migration. In contrast, after the p.G98W mutation was introduced, the mutated ROBO2 peptide reduces this functional blocking activity on neuronal migration.

Conclusions: Our results provide molecular mechanistic evidence that p.G98W in ROBO2 first Ig domain interrupts the ROBO2-SLIT2 receptor-ligand association, which may in turn disrupt their signaling pathway during early kidney development and result in CAKUT phenotypes in patients carrying this mutation.

Mutations in BNC2 Lead to Autosomal-Dominant Lower Urinary Tract Obstruction (LUTO)

Caroline M. Kolvenbach,[1,2] Gabriel C. Dworschak,[9] Sandra Frese,[15] Anna S. Japp,[5] Johanna Magdalena M. Schmidt,[6,7] Marcin Zaniew,[16] William G. Newman,[12] Glenda M. Beaman,[12] Helen M. Stuart,[12] Adrian S. Woolf,[12] Raimondo M. Cervellione,[13] Wolfgang H. Rösch,[11] Stefanie Weber,[8] Friedhelm Hildebrandt,[9] Bernd Hoppe,[10] Janine Altmüller,[17] Christoph Berg,[14] Heiko M. Reutter,[3] Benjamin Odermatt,[3] Alina Hilger.[2,4] *[1]Harvard Medical School, Boston, MA; [2]Department of Pediatric Nephrology, University Hospital Bonn, Bonn, Germany; [3]University of Bonn, Bonn, Germany; [4]Institute of Human Genetics, University of Bonn, Bonn, Germany; [5]University Bonn Medical Center, Bonn, Germany; [6]Faculty of Medicine, University of Bonn, Bonn, Germany; [7]Institute for Anatomy, University of Bonn, Bonn, Germany; [8]University Children's Hospital Marburg, Marburg, Germany; [9]Boston Children's Hospital, Boston, MA; [10]University Hospital Bonn, Bonn, Germany; [11]University Medical Center Regensburg, Regensburg, Germany; [12]University of Manchester, Manchester, United Kingdom; [13]Royal Manchester Children's Hospital, Manchester, United Kingdom; [14]University of Cologne, Cologne, Germany; [15]Universität Bonn, Bonn, Germany; [16]Children's Hospital, Pozna?, Poland; [17]Cologne Center for Genomics, Cologne, Germany.*

Background: Congenital "lower urinary tract obstruction" (LUTO) is defined by a decrease in the free passage of urine through the urethra. About three out of 10,000 pregnancies are affected; the etiology is so far unknown.

Methods: Whole exome sequencing (WES) in a family with 4 affected from 3 generations was performed. 258 LUTO patients were screened for further variants in the identified candidate gene *BNC2* using Sanger sequencing. Functional studies comprised in situ hybridization (ISH) studies in mouse embryos, translational knock-down (KD) in developing zebrafish larvae (zfl) using Morpholino oligonucleotides (MO) and 'rescue' experiments by co-injection of human *BNC2* mRNA with the *bnc2*-MO in zfl as well as overexpression of *BNC2* mRNA in zfl.

Results: Filtering of WES Data revealed a nonsense mutation (c.2554C>T; p.Arg852*) in *BNC2* (basonuclin 2). Out of 258 LUTO patients one additional family (affected father and son) carrying a novel missense mutation (c.2663A>G, p.H888R) in *BNC2* could be identified. Affected members in both families presented with anatomical obstruction of the urethra due to posterior urethral valves (PUV), requiring surgical removal, and urethral stenosis with fetal presentation, requiring surgical reconstruction. Functional characterization of *Bnc2* using ISH showed expression at E13.5 in developing mouse urethra. KD of bnc2 by injection MO in zfl caused cloacal obstruction with formation of a vesicle at the distal end of pronephric duct in 11% of zfl and cystic dilated deformed glomeruli and dilated pronephric ducts in 50%. Co-injection of human *BNC2* mRNA with *bnc2*-MO in zfl showed rescue of the phenotype only at an amount of 100pg of mRNA. Already slight overexpression of human *BNC2* mRNA in zfl lead to the same phenotype as KD, confirming the specificity of the *bnc2*-MO suggesting that the observed phenotypes in fish and human are the result of gene dosage imbalance of *BNC2*.

Conclusions: Human genetic and developmental biology models suggest BNC2 mutations as the first monogenic cause of LUTO.

TH-PO709

Tackling Undetermined ESRD by Whole Nephrome Sequencing in Adult Patients Waiting for Kidney Transplantation

Isabel Ottlewski,[1] Johannes Muench,[1] Timo Wagner,[2] Carsten Bergmann,[2] Anette Bachmann,[1] Tom H. Lindner,[1] Daniel Seehofer,[1] Jan Halbritter.[1] *[1]University Hospital Leipzig, Leipzig, Germany; [2]Bioscientia, Ingelheim, Germany.*

Background: End-stage renal disease (ERSD) of undetermined etiology constitutes a significant clinical challenge, notably in kidney transplantation (KT). In absence of renal histology, genetic analysis may further elucidate ESRD etiology. To date, hereditary kidney disease is thought to represent < 10% of ESRD patients, mainly attributed to ADPKD. In recent years, however, a multitude of additional rare genetic ESRD conditions have been discovered without being yet systematically considered in clinical routine. To tackle the issue of undetermined ESRD prior to KT, we aimed to broadly analyze for genetic causes in patients on the waitlist.

Methods: Patients on the local KT-waitlist (n=134) were stratified based on their presumed etiologies: i) non- hereditary (n=56); ii) hereditary, including clinically diagnosed ADPKD (n=29); iii) undetermined, including biopsy-proven FSGS (n=49). The latter patients were analyzed by whole "*nephrome*" sequencing, comprising more than 290 ESRD-associated OMIM-genes.

Results: An undetermined etiology was found in 36% of individuals (49/134) on the waitlist, 40% of whom reported a positive family history. We detected a robust genetic diagnosis in 24% (12/49). The genes COL4A3/5 were found most frequently mutated in undetermined ESRD. Taken together, hereditary nephropathies, including ADPKD, were identified in 31% (41/134) of the overall cohort. By significantly increasing the proportion of hereditary diagnoses (from n=29 to n=41, p<0,05), the rate of undetermined ESRD went down from n=49 to n=37 (p<0,05).

Conclusions: By this pilot study, we demonstrate the beneficial use of whole "nephrome" sequencing to significantly reduce the proportion of undetermined ESRD prior to KT. In absence of renal histology or unspecific histological conditions, such as FSGS or TMA, genetic analysis may not only provide a robust diagnosis but helps differentiating recurrent from non-recurrent etiologies, thereby contributing to personalized KT management and adequate evaluation of potential living donors.

TH-PO710

Outcomes of Patients with Genetic Renal Disease in Regional Australia

Matthew D. Jose,[1,2] Gabrielle E. Brailsford,[2] Ellie Cash,[2] Andrew J. Mallett,[3,4] Geoff Kirkland.[1] *[1]Renal Unit, Royal Hobart Hospital, Hobart, TAS, Australia; [2]School of Medicine, University of Tasmania, Hobart, TAS, Australia; [3]Royal Brisbane and Women's Hospital, Stafford, QLD, Australia; [4]KidGen Collaborative, Australian Genomics Health Alliance, Parkville, VIC, Australia.*

Background: Genetic aetiology comprises a significant proportion of adults with chronic kidney disease (CKD) who develop end-stage kidney disease (ESKD) and experience an excess of morbidity and mortality. Our aim was to evaluate the outcomes patients with genetic renal disease (GRD) in Tasmania, Australia.

Methods: Individuals with GRD in Tasmania were identified from AUDIT4 (renal unit clinical database, n=2407) and ANZDATA (Australia and New Zealand Dialysis and Transplantation Registry, n=361) from 1st January 2012 until 1st May 2018. After discarding duplicates, 2434 individuals referred to tertiary renal services were reviewed.

Results: In Tasmania, GRD comprised 8.5% of the CKD population (208/2434). GRD patients were younger than non-GRD patients (mean 52y vs. 64y, p <0.001). There was no significant difference in gender or mean eGFR (in non-dialysis patients) between cohorts. Since 2012, GRD patients have more commonly developed ESKD, commenced renal replacement therapy (RRT) or received transplants than non-GRD patients (40% vs. 17%, p<0.001; 39.4% vs. 12.3% p<0.001; 30.3% vs. 5% p<0.001). Furthermore, GRD patients commenced RRT at a younger age (mean 46y vs 55y, p<0.001). Of the GRD cohort, there was no significant difference in gender. Cystic kidney disease was the most common GRD (48%), followed by Congenital Abnormalities of the Kidneys and Urinary Tract (CAKUT) (37%). Patients with CAKUT started RRT younger than those with cystic disease (mean 39y vs. 55y, p<0.001). Those who received transplants did so earlier (mean 36y vs. 52y, p<0.001). Patients with glomerular, tubular/metabolic or other uncommon GRDs were more likely to be older males. Very few of the people with GRD were known to the Tasmanian Clinical Genetics Service, had received genetic testing or counselling.

Conclusions: Patients with GRD in Tasmania experience earlier morbidity, including the need for RRT and transplant. This data supports the development of a tailored genetic renal service to improve outcomes in affected individuals in Regional Australia.

TH-PO711

Yield of Atypical Hemolytic Uremic Syndrome (aHUS) Genetic Susceptibility Panel Testing

Chinmayee Bhimarao Nagaraj, James Denton, D. Brian Dawson. *Cincinnati Children's Hospital Medical C, Loveland, OH.*

Background: Hemolytic uremic syndrome (HUS) is characterized by hemolytic anemia, thrombocytopenia and renal failure secondary to thrombotic microangiopathy (TMA). 90% of HUS cases are associated with infection by Shiga toxin-producing E.coli. About 10% of HUS cases are associated with genetic or acquired defects in the regulation of the alternative complement pathway. In about 60% of individuals affected with aHUS, a specific genetic susceptibility variant may be identified. Clinical genetic testing in patients with aHUS not only informs their disease process but also provides therapeutic and prognostic insight for their management.

Methods: The Genetics and Genomics Laboratory at Cincinnati Children's Hospital has developed an aHUS genetic susceptibility panel which includes 10 aHUS associated genes. We reviewed the orders we received for this panel over the last two years (June 2016- May 2018) to assess the yield of this genetic test. We also assessed the proportion of pathogenic variants identified in each individual gene on this panel.

Results: Over the last two years, we have tested 338 patients suspected with genetic aHUS through our aHUS genetic susceptibility panel. 29.6% of the patients were heterozygous for the CFHR3-CFHR1 deletion, which is similar to its frequency in the general population. The CFHR3-CFHR1 deletion in the heterozygous state does not confer risk of developing aHUS. 8.3% of the patients were homozygous for the CFHR3-CFHR1 deletion, which is associated with increased risk of developing aHUS. 10.1% of the patients had pathogenic or likely pathogenic sequence variants in one or more of the ten genes on the panel. Two of the patients were homozygous for the CFHR3-CFHR1 deletion in addition to pathogenic sequence variants. Three of the patients had pathogenic sequence variants in two different genes. Overall, about 16.9% of the patients with suspected genetic aHUS were found to carry genetic variations that conferred them increased risk of developing aHUS. The proportion of pathogenic variants identified in each individual gene on this panel are *C3* (1.6%), *CFB* (1.6%), *CFH* (16.13%), *CFHR1* (4.8%), *CFHR3* (11.3%), *CFHR3- CFHR1* homozygous deletion (45.2%), *CFHR5* (3.2%), *CFI* (14.5%), *DGKE* (3.2%), *CD46* (6.5%) and *THBD* (1.6%).

Conclusions: This study emphasizes the significance of genetic analysis in patients with suspected aHUS.

TH-PO712

Whole-Exome Sequencings Reveal Additional Extracellular Matrix Gene Mutations in Atypical Hemolytic Uremic Syndrome

I-Ru Chen,[1,3] Hsin-Hung Lin,[1,2] Chin-An Yang,[4,2] Jan-Gowth Chang,[4,2] Gueijane Wang,[3] Hung chieh Yeh,[1] Ruey-Bing Yang,[5] Chiu-Ching Huang.[1,2] *[1]Kidney Institute and Division of Nephrology, Department of Internal Medicine, China Medical University Hospital, Taichung City, Taiwan; [2]School of Medicine, China Medical University, Taichung, Taiwan; [3]Graduate Institute of Clinical Medical Science, China Medical University, Taichung, Taiwan; [4]Department of laboratory Medicine, China Medical University Hospital, Taichung, Taiwan; [5]Academia Sinica, Taipei, Taiwan.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare disease caused by uncontrolled activation of the alternative pathway of complement and induces microangiopathic hemolytic anemia, thrombocytopenia, acute kidney failure and extrarenal manifestations. Most of studies revealed aHUS with pathogenic loss-of-function of complement or gain-of-function regulators of complement. Whether patients with aHUS may have additional extracellular matrix gene mutations is not known at present, we did this study to explore this possibility.

Methods: This study used whole-exome sequencing(WES) to screen our six adult patients, five of them responded to anti-C5 therapy while one patient did not receive anti-C5 treatment due to financial issue. After completing the whole-genome sequencing analyses, we used functional protein association network -STRING for correlation evaluation.

Results: The whole-exome sequencing analysis revealed all six patients were with loss-of-function of complement or gain-of-function regulators of complement (table 1). WES revealed a novel heterozygous mutation in AEBP1 in three aHUS patients, a novel heterozygous mutation in SCUBE1 in two aHUS patients, and a novel heterozygous mutation in WNT2B in two aHUS patients. In addition, one patient had both SCUBE1 and AEBP1 mutations. The STRING network revealed these mutation genes participated in extracellular matrix environment molecule pathways.

Conclusions: Our results demonstrate aHUS patients from Taiwan have additional mutations in extracellular matrix genes (e.g. AEBP1, SCUBE1, and WNT2B). The additional extracellular matrix gene mutations may play a role in the disease severity. We will further clarify the functional molecular interactions between alternative complement pathway and extracellular matrix genes.

Table 1

Patients	Complement related gene mutation	Extracellular Matrix Genes mutation
Case 1	CFH, CFHR1, CFHR3, CFI, C3, THBD	AEBP1
Case 2	CFH, CFHR1, CFHR3, CFI, C3, THBD, CFB	AEBP1
Case 3	CFH, CFHR1, CFHR3, CFI, C3, CD46, THBD, CFB	AEBP1, SCUBE1
Case 4	CFH, CFHR1, CFHR3, CFI, C3, CFB	SCUBE1
Case 5	CFH, CFHR1, CFHR3, CFI, C3	WNT2B
Case 6	CFH, CFHR1, CFHR3, CFI, C3, CD46, THBD, CFB	WNT2B

TH-PO713

Additional Genes Associated with Atypical Hemolytic Uremic Syndrome

James Kain,[1] Sujatha Venkataramani,[1] Joo E. Lim,[2] Gayatri Raghuraman,[1] Brad Lewis,[3] Michael Ero.[1] *[1]Machaon Diagnostics, Oakland, CA; [2]Machaon Diagnostics Inc., Oakland, CA; [3]Machaon Diagnostics, Inc, Oakland, CA.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a life-threatening, ultra-rare thrombotic microangiopathy. This partially penetrant genetic disease, featuring a characteristic triad of hemolytic anemia, thrombocytopenia and renal failure, is caused by complement overactivation. 50 to 80% of aHUS patients have a detectable genetic mutation in one of several genes that may lead to overactivation of complement. All aHUS sequencing assays cover a core group of complement genes: CFH, CFI, CFB, C3, MCP/CD46. Additionally, sequencing of CFHR5, THBD, DGKE, as well as copy number to detect the homozygous deletion of CFHR1-CFHR3 or CFHR1-CFHR4 (but not single nucleotide variants within CFHR1, CFHR3 or CFHR4 alone), are often included. More rarely, PLG is sequenced; its inclusion is based on findings from a single publication (Bu (2014) J Am Soc Nephrol 25, 1) where they found several aHUS patients harboring known, rare pathogenic PLG variants.

Methods: Genomic DNA was extracted from patient whole blood and sequenced using an aHUS genetic panel. This panel comprised twelve genes (CFH, CFI, CFB, C3, MCP/CD46, CFHR1, CFHR3, CFHR4, CFHR5, THBD, DGKE and PLG) and was sequenced using targeted next generation sequencing. Variants were confirmed by Sanger sequencing as needed.

Results: Here we describe multiple instances where we detected suspicious variants within PLG and CFHR3 in patients where the aHUS Genetic Panel was ordered by their physician. Some of the suspicious variants we found in PLG (eight cases with p.Lys38Glu and one case with p.Arg253His) were the same variants seen previously by Bu et al; both variants are also associated with plasminogen deficiency. The suspicious CFHR3 variants we observed were severe (splice site, nonsense, frameshift) and either exceedingly rare or novel.

Conclusions: These results 1) replicate the finding by Bu et al of PLG having a role in aHUS, and 2) suggest a potential novel contribution from CFHR3. CFHR3 has previously only been implicated in aHUS as part of a large homozygous deletion that also removes the neighboring gene CFHR1. Furthermore, it is thought that in the case of this large homozygous deletion, it is the absence of CFHR1 that is causitive while CFHR3 is incidental. These results hint at the possibility that rare, dominant negative variants in CFHR3 may also lead to aHUS.

TH-PO714

Safety and Effectiveness of Eculizumab for Adult Patients with Atypical Hemolytic-Uremic Syndrome in Japan: Interim Analysis of Post-Marketing Surveillance

Hirokazu Okada,[1] Hideki Kato,[2] Yoshitaka Miyakawa,[1] Yoshihiko Hidaka,[3] Norimitsu Inoue,[4] Shuichi Ito,[5] Shoji Kagami,[6] Shinya Kaname,[7] Masanori Matsumoto,[8] Masashi Mizuno,[9] Takahisa Matsuda,[12] Akihiko Shimono,[12] Shoichi Maruyama,[10] Yoshihiro Fujimura,[13] Masaomi Nangaku.[11] *[1]Saitama Medical University, Saitama, Japan; [2]The University of Tokyo Graduate School of Medicine, Bunkyo-ku, Japan; [3]Shinshu University School of Medicine, Matsumoto, Nagano, Japan; [4]Osaka International Cancer Institute, Osaka, Japan; [5]Department of Pediatrics, Graduate School of Medicine, Yokohama City University, Yokohama, Japan; [6]Tokushima Unversity, Tokushima, Japan; [7]Kyorin University School of Medicine, Mitaka, Tokyo, Japan; [8]Nara Medical University, Kashihara city, Japan; [9]Nagoya University, Nagoya, Japan; [10]Nagoya University Graduate School of Medicine, Nagoya, Japan; [11]the University of Tokyo School of Medicine, Tokyo, Japan; [12]Alexion Pharma GK, Tokyo, Japan; [13]Japanese Red Cross Kinki Block Blood center, Ibaraki, Japan.*

Background: Eculizumab has been available for the treatment of atypical hemolytic–uremic syndrome (aHUS) in Japan since 2013. To assess safety and effectiveness of eculizumab in adult aHUS patients in the real-life setting, we performed interim analysis of a post-marketing surveillance mandated by Japanese regulations.

Methods: This study enrolled any patient diagnosed with TMA excluding Shiga toxin-producing Escherichia coli-HUS or thrombotic thrombocytopenic purpura based on Japanese clinical guideline published in 2013 as inclusion criteria and treated with eculizumab. According to the guideline revised in 2016, the enrolled patients were with aHUS (complement-mediated HUS) and secondary TMA.

Results: Thirty-three patients with aHUS and 27 patients with secondary TMA were enrolled. Median treatment duration of aHUS was 24weeks. Complement genes variants were detected in 11 of 18 aHUS patients who underwent genetic analysis (61.1%). Among the 29 aHUS patients with available baseline data, platelet count (PLT), lactic dehydrogenase and serum creatinine (SCr) improved within 1-month after eculizumab initiation. TMA event–free status, complete TMA response, PLT normalization, and SCr decrease were achieved in 67.9% (19/28), 27.8% (5/18), 56.5% (13/23), and 57.1% (16/28) of patients, respectively. Thirty-three adverse reactions, i.e., hypertension, hyperuricemia, nasopharyngitis and edema, were observed in 13 of 33 aHUS patients.

Conclusions: This interim analysis confirmed the acceptable safety profile and effectiveness of eculizumab for Japanese adult aHUS patients in real-world settings.

Genetic Analysis and Genotype-Phenotype Studies of a Cystinuria Cohort

Andrea G. Cogal,[1] Sarah R. Senum,[1] Ramila A. Mehta,[1] Frank Modersitzki,[2] John C. Lieske,[1] David S. Goldfarb,[3] Peter C. Harris.[1] Rare Kidney Stone Consortium (RKSC) *[1]Mayo Clinic, Rochester, MN; [2]New York University School of Medicine, New York, NY; [3]NYU Langone, New York, NY.*

Background: Cystinuria is an inherited kidney stone disorder caused by mutations to the *SLC3A1* and *SLC7A9* genes. While most cases are due to biallelic mutations to either gene, monoallelic and digenic families have been described, with overall considerable disease variability. Nevertheless, clear genotype/phenotype correlations have not been described to date.

Methods: A next generation sequencing (NGS) panel consisting of 90 known and candidate kidney stone genes was developed and validated. A total of 49 unrelated, genetically unscreened individuals with a clinical diagnosis of cystinuria were analyzed using this panel. Preliminary correlations with phenotype were made with the genic groups.

Results: The baseline mean (SD) characteristics of the cohort were: age at diagnosis = 19.6y (12.5), number of stones = 5.8 (6.6), cystine excretion = 939.9mg (323.6), eGFR = 82.1ml/min/1.73m^2 (24.5), with age at last follow up = 43.8y (14). A total of 34 patients (69.4%) had biallelic *SLC3A1* and 11 (22.4%) biallelic *SLC7A9* mutations. One *SLC3A1* and two *SLC7A9* cases had a single detected mutation, and one case had no mutations detected. Large rearrangements, detected by LOG2 ratio analysis of the sequence data and confirmed by Multiplex Ligation-dependent Probe Amplification (MLPA), accounted for 31.9% of all *SLC3A1* mutations, mainly the common ex5-9 duplication. Other common mutations were the *SLC3A1* missense change p.Met467Thr (21.7% alleles) and the nonsense mutation p.Arg270* (18.8%), while for *SLC7A9* the missense mutation p.Gly105Arg accounted for 29.2% of pathogenic alleles. Ten novel mutations were identified for each gene. The only detected correlation with genotype was with baseline mean stone number, *SLC3A1* = 7.1 (7.1), *SLC7A9* = 2.0 (2.1; p=0.05) in this cohort.

Conclusions: This analysis shows the utility of a panel-based NGS approach in cystinuria populations and more broadly in patients with suspected monogenic stone disease. Other genetic and/or environmental factors likely also contribute to the observed phenotypic variability.

A Custom Next Generation Sequencing (NGS) Panel for Kidney Stone Disease Resolves Diagnosis in Mutation Negative Patients Clinically Diagnosed with Dent Disease

Andrea G. Cogal,[1] Sarah R. Senum,[1] Emilie Cornec-Le Gall,[2] Barbara M. Seide,[1] Carly Banks,[1] Julie B. Olson,[1] Tammy M. Greenwood,[1] David J. Sas,[1] Dawn S. Milliner,[1] Lada Beara Lasic,[3] John C. Lieske,[1] Peter C. Harris.[1] Rare Kidney Stone Consortium (RKSC) *[1]Mayo Clinic, Rochester, MN; [2]Centre Hospitalier Universitaire de Brest, BREST, France; [3]NYU Medical Center, Pelham, NY.*

Background: Dent disease is an X-linked disorder characterized by low molecular weight proteinuria, nephrolithiasis/nephrocalcinosis and CKD. We previously performed molecular screening of suspected Dent patients by Sanger sequencing of the known genes: *CLCN5* and *OCRL*. The majority of cases were genetically resolved, but there remained a cohort with no mutations detected (NMD), which we analyze here employing a NGS panel.

Methods: A NGS panel consisting of 90 known and candidate genes related to urinary stone risk was developed and 61 NMD suspected Dent families screened. The phenotype of resolved patients was compared to the implicated gene.

Results: Likely pathogenic mutations consistent, or in one case divergent, with the presenting phenotype were detected in 5 (8%) of the 61 NMD families (Table). Two cases with *SLC34A3* mutations were detected, one with a missense, an inframe deletion and a splicing mutation and a second homozygous for a novel frameshifting duplication. *SLC12A1* biallelic missense mutations were found in a patient with a typical Bartter phenotype. A patient with a *KCNJ1* frameshifting duplication and missense mutation had nephrocalcinosis, proteinuria, and CKD, but lacked the typical electrolyte abnormalities of Barrter. One subject was homozygous for a previously described *CLDN16* missense mutation. An additional patient was found to have two large chromosomal duplications, confirmed by MLPA and microarray analysis, which we have categorized as possibly pathogenic. Three additional patients with weaker biallelic variants in candidate genes are being further assessed.

Conclusions: This analysis demonstrates the utility of a panel-based NGS approach in unresolved patients with suspected monogenic causes of nephrocalcinosis or urinary stone disease and is valuable since the phenotypes of these disorders can demonstrate significant divergence and overlap.

SRNS-Associated MYO1E Mutations Have Differential Effects on Myo1e Activity and Stability

Pei-Ju Liu,[1] Diana Perez,[1] Jing Bi Karchin,[1] Christopher D. Pellenz,[1] Sharon E. Chase,[1] Maria Presti,[5] Eric L. Plante,[1] Claire E. Martin,[4] Svjetlana Lovric,[3] Friedhelm Hildebrandt,[2] Mira Krendel.[1] *[1]Cell and Developmental Biology, SUNY Upstate Medical University, Syracuse, NY; [2]Boston Children's Hospital, Boston, MA; [3]Hannover Medical School, Hannover, Germany; [4]University of Guelph, Guelph, ON, Canada; [5]SUNY Upstate Medical University, Syracuse, NY.*

Background: Mutations in the *MYO1E* gene, encoding myosin 1e (Myo1e), are associated with steroid resistant nephrotic syndrome (SRNS). We set out to characterize novel *MYO1E* mutations identified in SRNS patients (Sadowski et al., JASN, 2015, **26**(6): 1279-89).

Methods: Using adenoviral transduction of EGFP-Myo1e constructs into cultured podocytes, we compared steady-state expression levels, protein turnover rates, and localization of the wild type (wt) Myo1e and several Myo1e mutants, including mutants with point mutations in the motor domain and a frame shift mutant d3094-7 lacking the C-terminal SH3 domain.

Results: We found that two mutants, the T119I motor domain mutant and the d3094-7 frame shift mutant, had low expression levels and high turnover rates and did not localize to cell-cell junctions, where Myo1e is thought to aid in the assembly of the slit diaphragm complexes. In an attempt to restore Myo1e protein stability, we treated cells expressing these mutants with a proteasome inhibitor and observed accumulation of the mutant proteins. The restoration of protein expression in cells expressing the d3094-7 mutant resulted in a partial recovery of the junctional localization and dynamics of this protein. In contrast, an increase in the protein level of the T119I mutant achieved using proteasome inhibition was accompanied by formation of random, seemingly insoluble, aggregates (as determined using fluorescence recovery after photobleaching (FRAP)). Further investigating the properties of those Myo1e mutants that did not exhibit decreased protein stability, we found that the dynamics of one of the motor domain mutants at the junctions was decreased compared to the wt Myo1e. Using FRAP, we found that the mobile fraction of this mutant was lower than that of the wt Myo1e while the half time of fluorescence recovery was higher.

Conclusions: Overall, our findings indicate that while some SRNS-associated mutations affect Myo1e stability and folding, others may have more specific effects on motor domain activity. Furthermore, proteasome inhibition needs to be further examined as a potential therapeutic approach for alleviating the effects of those mutations that affect Myo1e stability without disrupting its motor function.

Quantification of Urinary 2,8-Dihydroxyadenine Excretion in Patients with APRT Deficiency

Hrafnhildur L. Runolfsdottir,[1,2] Runolfur Palsson,[1,2] Unnur A. Thorsteinsdottir,[2] Olafur S. Indridason,[1] Inger M. Agustsdottir,[1] Margret Thorsteinsdottir,[2] Vidar O. Edvardsson.[1,2] The Rare Kidney Stone Consortium *[1]Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland; [2]University of Iceland, Reykjavik, Iceland.*

Background: Adenine phosphoribosyltransferase deficiency (APRTd) is a rare disorder that results in renal excretion of 2,8-dihydroxyadenine (DHA) in large amounts, leading to kidney stones and chronic kidney disease. We have recently developed a high-throughput ultra-performance liquid chromatography-tandem mass spectrometry (UPLC-MS/MS) assay for quantification of urinary DHA. The purpose of this study was to assess 24-h urinary DHA excretion in APRTd patients, heterozygotes and healthy subjects, and the effect of varied purine intake in patients.

Methods: Nineteen patients in the APRT Deficiency Registry of the Rare Kidney Stone Consortium, 4 heterozygotes and 10 healthy volunteers not taking medications affecting the metabolism or excretion of purines, participated in the study. The effect of varied dietary purine intake was assessed in 4 patients not receiving drug treatment. Urinary DHA excretion was measured in 24-h urine specimens and single void urine samples, expressed as mg/24 h and DHA/Cr ratio (mg/mmol), respectively. Associations were examined using Spearman's correlation coefficient.

Results: The median (range) urinary DHA excretion in 28 samples from 19 patients with APRTd was 138.1 (63.8-291.5) mg/24 h. No DHA was detected in any 24-h urine samples from 4 heterozygotes and 10 healthy individuals. The DHA/Cr ratio in 42 random void urine samples from 19 patients was 13.1 (3.8-37.2) mg/mmol. No correlation was found between urinary DHA excretion and kidney function (r=0.04, p=0.816). The correlation between the first morning void urine DHA/Cr and the 24-h urinary DHA excretion in samples obtained in the same 24-h period was high (r=0.84, p<0.001). The urine DHA excretion was 128.6 (107.2-160.1), 135.8 (114.4-188.4) and 133.5 (102.6-159.6) mg/24 h on self-selected, purine enriched and purine restricted diets, respectively.

Conclusions: Patients with APRTd excrete large amounts of DHA in their urine, while DHA is undetectable in both heterozygotes and healthy subjects. Timed urine samples can be replaced with DHA/Cr ratio in first morning void urine specimens for monitoring of DHA excretion. Short-term changes in purine intake do not seem to affect DHA excretion.

TH-PO719

Diagnosis of Adenine Phosphoribosyltransferase Deficiency by ATR-FTIR Spectroscopy

Tzu-Ling Lin,[1] Robert J. Unwin,[1] Jill T. Norman,[1] Vidar O. Edvardsson,[2,5] Runolfur Palsson,[3,5] Peter R. Rich.[4] *[1]Centre for Nephrology, Division of Medicine, University College London, London, United Kingdom; [2]Division of Nephrology, Landspital - The National University Hospital of Iceland, Reykjavik, Iceland; [3]Children's Medical Centre, Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland; [4]Glynn Laboratory of Bioenergetics, Institute of Structural and Molecular Biology, University College London, London, United Kingdom; [5]University of Iceland, Reykjavik, Iceland.*

Background: Adenine phosphoribosyltransferase deficiency (APRTd) is a rare inherited disorder of purine metabolism characterized by renal excretion of large amounts of crystalline 2,8 dihydroxyadenine (DHA). Affected individuals develop kidney stones and progressive CKD, and eventual ESRD, secondary to renal parenchymal DHA crystal deposition; diagnosis is often missed and its true prevalence is uncertain. Currently, the primary method leading to diagnosis is the detection of DHA crystals by urine microscopy; however, several urinary crystalline species can easily be confused with DHA. Therefore, it is crucial to develop a rapid and sensitive point-of-care method for identification of DHA in human urine samples.

Methods: Fourier-transform infrared (FTIR) spectroscopy has been shown to be a straightforward and reliable technique for the diagnosis of a variety of kidney stones. We assessed attenuated total reflection (ATR) FTIR spectroscopy as a means of detecting DHA in urine.

Results: An optimal method for accurate detection and quantitation of DHA in a dried urine pellet was developed. Urine samples from untreated APRTd patients in whom the presence of DHA had been confirmed by ultra-performance liquid chromatography coupled to tandem mass spectrometry (UPLC-MS-MS) were assessed using ATR-FTIR. Insoluble DHA was detected in 17 of the 20 urine samples with concentrations ranging from 1.4 - 24.8 μM. In 3 samples, ATR-FTIR indicated the presence of a different insoluble component related to a form of uric acid or its salts, possibly in combination with other compounds. Hence, this method may be useful in routine clinical screening to identify cases of APRTd. In addition, IR analysis of pure DHA revealed a second physical form of DHA, probably an amorphous state, which has not been reported before. It is unclear whether amorphous DHA may be involved in disease pathogenesis and/or if the lack of recognition of amorphous DHA contributes to under-diagnosis of APRTd.

Conclusions: In conclusion, ATR-FTIR may be a useful and rapid 'point-of-care' screening tool for early diagnosis of APRTd. Both the method and instrumentation can be adapted easily and cheaply for clinical use. The clinical significance of the newly identified amorphous DHA remains to be established.

TH-PO720

Development of a 2D-UPLC-MS/MS Assay for Therapeutic Monitoring in Patients with APRT Deficiency

Vidar O. Edvardsson,[1,2] Unnur A. Thorsteinsdottir,[2,3] Hrafnhildur L. Runolfsdottir,[1,2] Thorsteinn H. Bjarnason,[2] Finnur F. Eiriksson,[3] Margret Thorsteinsdottir,[2,3] Runolfur Palsson.[1,2] The APRT Deficiency Program of the Rare Kidney Stone Consortium *[1]Landspital - The National University Hospital of Iceland, Reykjavik, Iceland; [2]University of Iceland, Reykjavik, Iceland; [3]ArcticMass, Reykjavik, Iceland.*

Background: Adenine phosphoribosyltransferase deficiency (APRTd) is a rare hereditary purine metabolism disorder resulting in accumulation and renal excretion of 2,8-dihydroxyadenine (DHA), causing kidney stones and chronic kidney disease (CKD). The drugs allopurinol and febuxostat reduce urinary DHA excretion and ameliorate the disease manifestations. We developed a two-dimensional ultra-performance liquid chromatography tandem mass spectrometry (2D-UPLC-MS/MS) assay for simultaneous measurement of DHA and the pharmacological agents allopurinol, its active metabolite oxypurinol, and febuxostat in human plasma for monitoring of pharmacotherapy.

Methods: A design of experiments was used to define the optimum 2D-UPLC-MS/MS conditions based on the minimum number of experiments. Experimental screening of the variables was performed by D-optimal design to identify factors influencing retention time, peak height and peak area for all compounds. Variables were optimized with central composite face design and related to sensitivity and retention time using partial least square regression. Protein precipitation was carried out with 1% formic acid in methanol as a crash solvent. Plasma samples from APRTd patients and control specimens from laboratory personnel were used for the study.

Results: The plasma concentration of DHA, allopurinol, oxypurinol, and febuxostat was reliably achieved with the 2D-UPLC-MS/MS assay. The DHA concentrations in plasma from 3 APRTd patients were 456, 459 and 741 ng/mL off drug treatment and 130, 61 and 27 ng/mL while on allopurinol or febuxostat therapy. By contrast, DHA was not detected in plasma from healthy controls. The plasma allopurinol and oxypurinol concentration during drug treatment in the 3 patients was 802, 2391, 5089 and 6810, 7076 and 12,510 ng/mL, respectively, and the febuxostat concentration was 1276 ng/mL in 1 patient.

Conclusions: Our data suggest that the 2D-UPLC-MS/MS assay may be used to monitor the efficacy of pharmacotherapy and treatment adherence among APRTd patients. This method may prove useful in determining the plasma DHA concentration that must be attained in order to prevent new kidney stone growth and CKD progression in these patients.

TH-PO721

Safety and Efficacy Study of Lumasiran (ALN-GO1), an Investigational RNA Interference (RNAi) Therapeutic, in Patients with Primary Hyperoxaluria Type 1

Sally Hulton,[1] Yaacov Frishberg,[8] Georges Deschênes,[3] Pierre Cochat,[2] Daniella Magen,[4] Jaap W. Groothoff,[11] Jerome Harambat,[5] William van't Hoff,[10] Bernd Hoppe,[6] John C. Lieske,[7] Tracy McGregor,[9] Patrick Haslett,[9] David V. Erbe,[9] Dawn S. Milliner.[7] *[1]Birmingham Childrens' Hospital, Birmingham, United Kingdom; [2]Université ClaudeBernard Lyon1-, Bron, France; [3]Hospital Robert Debre/Pediatric Nephrology, Paris, France; [4]Rambam Health Care Campus, Haifa, Israel; [5]Bordeaux University Hospital, Bordeaux, France; [6]University Hospital Bonn, Bonn, Germany; [7]Mayo Clinic, Rochester, MN; [8]Shaare Zedek Medical Center, Jerusalem, Israel; [9]Alnylam Pharmaceuticals, Cambridge, MA; [10]Great Ormond Street Hospital, Lond, United Kingdom; [11]Emma Children's Hospital AMC, Amsterdam, Netherlands.*

Background: In Primary Hyperoxaluria Type 1 (PH1), defective alanine:glyoxylate aminotransferase leads to excessive hepatic oxalate production, leading to progressive renal impairment and multi-organ damage from systemic oxalosis. Lumasiran, an investigational RNAi therapeutic suppresses hepatic glycolate oxidase, decreases the conversion of glycolate to glyoxylate, and results in reduced oxalate production.

Methods: ALN-GO1-001 is a randomized, placebo-controlled, single-blind, multicenter trial, evaluating lumasiran in patients with PH1 ≥6 years of age with urinary oxalate (UOx) ≥0.7 mmol/1.73m^2/day and eGFR >45 mL/min/1.73m^2. One of four patients in each dosing cohort was randomized to placebo prior to subcutaneous lumasiran. Cohorts 1 & 2 received 3 monthly doses of 1 mg/kg or 3 mg/kg, respectively; cohort 3 received 2 quarterly doses of 3 mg/kg lumasiran. An additional 4 patients received lumasiran in expansions of each of the first 2 cohorts. The primary endpoint is safety; secondary endpoints include change in 24-hour UOx from baseline. Eligible patients may continue dosing in the open-label extension (OLE) study.

Results: Patients in cohorts 1-3 had a mean age of 13.1 years (range 6-43), 7 (58%) female, and baseline UOx was 1.58 mmol/1.73m^2/day (range 0.63-2.37). Lumasiran has demonstrated acceptable preliminary safety and tolerability with no treatment related serious adverse events or discontinuations; majority of adverse events were mild/moderate and unrelated to study drug. All patients treated with lumasiran in cohorts 1-3 experienced UOx lowering below 0.7 mmol/1.73m^2/day, with a mean maximal decrease of 65%. Data available 85 days after initial dosing in the first 3 cohorts (n=9) showed a mean UOx reduction of 63% (range 49-73%). Data from patients in all cohorts (n=20), including quarterly dosing, expansions and OLE will be presented.

Conclusions: Preliminary results demonstrate acceptable safety data and lowering of UOx in patients with PH1 supporting the continued development of lumasiran as a potential therapeutic to alleviate pathologic overproduction and consequences of excess oxalate in this devastating disease.

TH-PO722

Endogenous Pentraxin 3 Inhibits Nephrocalcinosis and Protects from Hyperoxaluria-Induced CKD

Julian A. Marschner,[1] Shrikant R. Mulay,[1] Lidia Anguiano,[1] Stefanie Steiger,[1] Antonio Inforzato,[2] Hans J. Anders.[1] *[1]Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, LMU München, Munich, Germany; [2]Humanitas Clinical and Research Center, Pieve Emanuele, Italy.*

Background: Patients with primary hyperoxaluria type 1 have an elevated oxalate production leading to intrarenal calcium oxalate crystal deposition (nephrocalcinosis) and CKD progressing to ESRD. Pentraxin 3 (PTX3) exerts a variety of regulatory functions in acute and chronic tissue inflammation. Also, PTX3 acts as an opsonin for a variety of pathogens and endogenous particles. We hypothesized, that PTX3 would exhibit opsonin-like functions on calcium oxalate crystals and inhibiting crystal growth and nephrocalcinosis.

Methods: Direct effects of PTX3 on calcium oxalate crystals were investigated in chemico using standard imaging techniques. To study the role of PTX3 in vivo, we used a murine model of hyperoxaluria induced nephrocalcinosis where *Ptx3*-deficient B6;129-mice or their *PTX3*-competent littermates were fed with a high-oxalate diet for 21 days. PTX3 expression was assessed by Western blot and immunohistochemistry. Phenotype analysis included histochemistry, flow cytometry and GFR measurement.

Results: Adding PTX3 to supersaturated calcium and oxalate in-chemico dose-dependently inhibited crystal growth, while an isomolar albumin control did not (A). PTX3 protein was undetectable in the urine of healthy wildtype mice but increased within 3 weeks of oxalate feeding. Immunhistochemistry of kidney sections indicated that urinary PTX3 originated from tubular epithelial cells. Testing the role of PTX3 in vivo we induced hyperoxaluria in *Ptx3*-deficient mice and their wildtype littermates. In this particular background, lack of PTX3 induced profound nephrocalcinosis associated with interstitial inflammation and fibrosis as well as a linear decline in GFR, whereas *Ptx3*+/+ littermates where protected (B-D).

Conclusions: Thus, PTX3 is an endogenous inhibitor of calcium oxalate crystallization even in profound hyperoxaluria. It will be interesting to look into the precise mechanism

of action and to develop therapeutic strategies to exploit this novel found function of PTX3 to prevent nephrocalcinosis in primary hyperoxaluria, a disease with currently very few treatment options.

Cardiac Oxalosis in Primary Hyperoxaluria

Dawn S. Milliner,[1] Patricia A. Pellikka,[1] Ramila A. Mehta,[1] Jennifer Manggaard,[1] John C. Lieske,[1] David J. Sas,[1] Bastian Dehmel,[2] Felicity T. Enders.[1] Rare Kidney Stone Consortium *[1]Mayo Clinic, Rochester, MN; [2]OxThera AB, Thousand Oaks, CA.*

Background: Primary hyperoxaluria (PH) is an inherited disease characterized by increased hepatic production of oxalate (ox). Renal excretion of excess ox causes kidney stones, nephrocalcinosis, and renal damage. As GFR declines plasma ox (Pox) increases and can cause systemic calcium oxalate deposits (oxalosis). Cardiac involvement results in conduction abnormalities and infiltrative cardiomyopathy. However, epidemiology of cardiac oxalosis in PH is not well defined.

Methods: The PH registry of the Rare Kidney Stone Consortium was queried for information regarding cardiac function. Among 128 PH subjects with Pox available prior to transplant, 101 had type 1 (PH1), 14 PH2, and 13 PH3. ECG studies (n=433 from 52 subjects), echocardiograms (n= 92 from 40), Pox (nl < 1.6 umol/L), and urine ox (Uox, nl < 0.46 mmol/24 hrs) at initial evaluation and during follow-up were analyzed. E/e' was used for diastolic function (nl <13). LV strain nl < -18%.

Results: At diagnosis mean (median) age was 18.6 (11.5) yrs, eGFR 75 (65) ml/min/1.73m^2, urine oxalate (Uox) 1.9 (1.7) mmol/1.73m^2/day, and Pox 21.3 (6.1) umol/L. At diagnosis 1/52 ECGs were abnormal, with atrial fibrillation (afib) in a subject with eGFR 66. Subjects were followed for 14.1 (11.4) yrs. Pox increased as eGFR declined (p<0.0001) as expected. Overall 14/52 PH subjects had 48 abnormal ECGs showing 1st degree or variable AV block (n=6), bundle branch block (3), afib (5), and LVH (4). Abnormal ECG studies did not differ across eGFR groups (p=0.22). Table 1 shows clinical characteristics and echo at last followup.

Conclusions: Using standard clinical tests, most PH subjects demonstrate good cardiac function, even at eGFR < 30 when Pox increases significantly. Whether more sensitive monitoring tools will demonstrate earlier manifestions of cardiac oxalosis remains to be established.

Blood Pressure and Biological Phenotype in Healthy-Carrier Relatives of Patients with Gitelman Syndrome

Rosa Vargas-Poussou,[1] Laurence Dubourg,[3] Marion Vallet,[8] Julien Allard,[2] Jean-philippe Haymann,[6] Renaud De la faille,[10] Stephanie Baron,[9] Pascal Houillier,[7] Ivan A. Tack,[4] Anne Blanchard.[5] *[1]AP-HP Hôpital Européen Georges Pompidou, Paris, France; [2]University Hospital Limoges, LImoges, France; [3]hospices civils de Lyon -Université Claude Bernard Lyon 1-INSERM U 820, LYON, France; [4]Universite Paul SABATIER Toulouse III/Service Explorations Fonctionnelles Physiologiques, Toulouse Cedex 9, France; [5]APHP, HEGP, Paris, France; [6]Sorbonne Universit?, INSERM, UMR_S 1155, AP-HP, H?pital Tenon, Paris, France, Paris, France; [7]Paris Descartes University, Paris, France; [8]Hôpital Rangueil, Toulouse, France; [9]APHP Georges Pompidou european Hospital, PARIS, France; [10]Hopital Pellegrin, Bordeaux, France.*

Background: Gitelman syndrome (GS) is the most frequent salt-losing tubulopathy caused by loss of function mutations in the SLC12A3 gene, encoding for the thiazide-sensitive NaCl cotransporter. Depending on the country, 1 to 4 % of the population is heterozygous carrier of pathogenic variant. Consequence of this status remains debated. The aim of this study was to evaluate the impact of SLC12A3 heterozygous mutations on blood pressure (primary outcome) and on electrolyte and glucose homeostasis.

Methods: This cross-sectional study included 239 subjects, both sex, 18-75 years old: 81 heterozygous carriers (HC) of class 4-5 variants (ACMG 2015), 81 non-carrier normotensive subjects (NC) matched to HC on age, sex and BMI and 77 patients with genetically proven GS. Home blood pressure (HBP) measurements were done the 3 consecutive days before admission in hospital for blood and urine sampling and oral glucose tolerance test (OGTT).

Results: As compared to NC, HC had similar HBP, blood and urine concentrations of electrolytes (Na, K, Cl, tCO_2 Mg, Ca), and values of PTH, vitamin D, renin, aldosterone and markers of bone remodeling as well as response to OGTT (all p>0.05, paired t test NC vs HC). Systolic BP increased similarly with age in both groups. GS had renal hypokalemia, hypomagnesemia and low urinary calcium excretion. Ten patients had known hypertension. GS had however lower SBP than the other groups (mean difference 4.5 (CI95 1.18; 7.78), p 0.0087 and 4.1 mmHg (CI95 0.20; 8.07), p 0.0410; NN and HC vs GS) and higher cardiac frequency (mean difference 4.5 (CI95 -7.4; -1.5), p 0.0040 and -3.7 bpm (CI95 -7.0; -0.5), p 0.0271; NC and HC vs GS). The increase in SBP with age was blunted in GS patients. GS had significant higher basal glycaemia and insulin concentrations and HOMA-IR (homeostatic model assessment for insulin resistance) than the other groups independently of BMI. OGTT showed a prediabetes status in 14% of GS patients compared with 4 and 5% in HC and NC.

Conclusions: In conclusion, we found no difference between heterozygous carriers and age- and sex-paired healthy controls. GS patients have a risk to develop type 2 diabetes pointing out the importance of body weight control in GS patients.

TH-PO725

Markers of Potassium Homeostasis and Quality of Life in Salt Losing Tubulopathies

Zeljko Kikic, Roman Reindl-Schwaighofer, Marija Bojic, Elisabeth Darmann. *Medical University of Vienna, Vienna, Austria.*

Background: Gitelman and Barter Syndrome are the most frequent genetically inherited salt losing tubulopathies (SLT) with limited treatment options and quality of life (QOL) is reduced. Treatment options include supplementation of potassium (K+) and magnesium, potassium sparing diuretics. However evidence from randomized controlled trials indicate low efficacy of current treatments in terms of increasing K+. Morover K+ may not reflect the magnitude of the concommittant secondary hyperaldosteronism in those patients. Optimal endpoints for treatment trials should include QOL however little is known of optimal clinical cut-offs of laboratory values and their relation in SLT. The trans-tubular potassium gradient (TTKG) has been shown to be an accurate surrogate for hyperaldosteronism and of excellent use in other entities related to hyperaldosteronism like liver cirrhosis.

Methods: In this prospective cross-sectional study we included 11 patients with SLT. We measured laboratory parameters (K+, Mg++, Ca++, TTKG, Aldosteron) and their relation with QOL assessed by the RAND SF-36. The primary hypothesis was that TTKG may reflect QOL more accurately than K+ and serve as an end-point in future treatment trials. Secondary endpoints were the presence of cardiac arrhythmia in 24h ECG and cardiac abnormalities via ultrasound (US).

Results: The cohort consisted of mainly females with a median age of 29 years. The median K+ was 3.3 mmol/l and median TTKG 9.5. While there was a positive correlation of K+ and TTKG, we did not observe a significant correlation of TTKG with serum aldosterone. Comparing QOL domains we observed that TTKG showed a trend for better physical functioning while K+ was significantly related to emotional wellbeing and trend for energy and general health. Aldosterone was significantly related to role limitations emotional and physical. Urinary potassium with a threshold >20 mmol/l was inversely related with energy/fatigue and general health and a trend for emotional wellbeing while TTKG <10 or K+>3 mmol/l were not related to QOL. No relevant abnormalities were observed in either 24h ECG or cardiac US.

Conclusions: TTKG is not a suitable marker for hyperaldosteronism in SLT and K+ and TTKG are not sufficient endpoints for treatment trials for SLT in relation to QOL. Future treatment trials in SLT should include QOL assessment as well urinary parameters.

TH-PO726

MAP17 and SGLT2 Interaction in Cellular Models and Human Kidney Specimen

Joaquim T. Calado,[1,2] Ana Santos,[4] Ines Aires,[4] Jose S. Ramalho,[3] Fernando E. Nolasco.[4,1] ToxOmics *[1]NOVA Medical School; Faculdade de Ciencias Medicas, Lisbon, Portugal; [2]Nephrology, Centro Hospitalar Lisboa Central, Lisbon, Portugal; [3]NOVA Medical School, Lisbon, Portugal; [4]Hospital Curry Cabral, Lisbon, Portugal.*

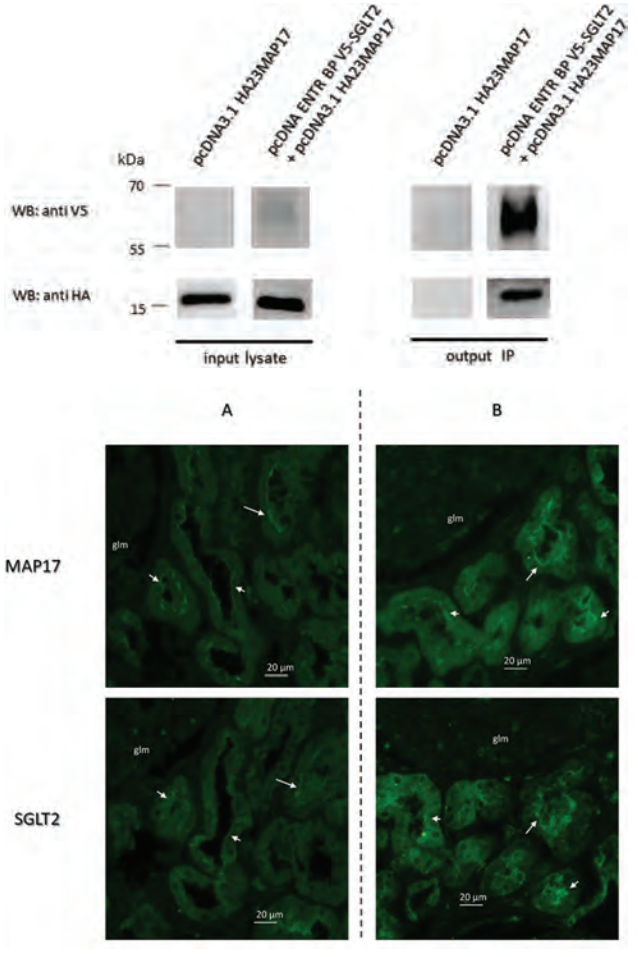
Background: Mutations in SGLT2, a Na/coupled glucose transporter of the early proximal tubule, are responsible for Familial Renal Glucosuria (FRG), and SGLT2 pharmacological inhibition has become a promising new therapy in type 2 Diabetes Mellitus. MAP17 was recently identified by means of expression cloning as an accessory protein for SGLT2 activity and mutations in MAP17 coding gene were found in a SGLT2 negative FRG individual. However, the way MAP17 promotes SGLT2 activity is unknown. In this work we investigated the hypothesis that MAP17 is a binding partner for SGLT2 and that both proteins interact and dimerize.

Methods: We engineered a N-terminal V5 tagged SGLT2 plasmid and coexpressed together with a HA tagged MAP17 construct in HEK293 cells. We assayed the interaction of both proteins in vitro by immunofluorescence and immunochemistry techniques. In

addition, we performed histological examination and immunofluorescence observations in human normal kidney sections to evaluate MAP17 and SGLT2 expression in the kidney.

Results: In HEK293 cells cotransfected with both constructs, MAP17 and SGLT2 were shown to colocalize in a perinuclear and cytoplasmic vesicular staining. In addition, MAP17 coimmunoprecipitated with anti V5 goat antibody only in the presence of V5-SGLT2 construct (fig.1). Finally, SGLT2 and MAP17 largely overlap in their abundance at the brush border of proximal tubule epithelial cells (fig. 2).

Conclusions: We have shown that SGLT2 and MAP17, when overexpressed, interact in vitro and, likewise, under constitutive expression in the kidney, they also overlap their abundance in the proximal tubule. This interaction provides the biochemical foundation for the physiological observation that MAP17 is a necessary activator of SGLT2.



TH-PO727

Renal Ablation of GLUT2 Leads to Intracellular Glycogen Accumulation and Recapitulates the Fanconi Bickel Syndrome

Anna Iervolino,[1] Luigi R. De la motte,[3] Federica Petrillo,[1] Federica Prosperi,[1] Vincenzo Costanzo,[2] Giovambattista Capasso,[3] Francesco Trepiccione.[3] *[1]Biogem, Ariano Irpino, Italy; [2]University of Bologna, Bologna, Italy; [3]University of Campania Luigi Vanvitelli, Napoli, Italy.*

Background: Fanconi-Bickel syndrome, also known as glycogenosis type XI, is characterized by hepatic glycogen accumulation and proximal renal tubular dysfunction. Patients mainly suffer for a typical renal Fanconi syndrome associated with fasting hypoglycaemia. Currently, there is no causative therapy beside fluid and electrolyte supplementation. Loss of function mutations of *SLC2A2,* encoding for GLUT2, causes FBS. Impairment of GLUT2 alters glucose metabolism in hepatocytes and increases glycogen accumulation. Since the cells of the proximal tubules share a similar glucose metabolism as hepatocytes, a similar mechanism could be hypothesized, but no evidences so far has been provided

Methods: In order to generate an experimental model of FBS, we selectively knock-out GLUT2 expression in PAX8 expressing cells by mean of a Cre-Lox recombination strategy. This approach results in an efficient ablation of GLUT2 in the renal cortex

Results: GLUT2 cKO mice recapitulate the renal phenotype of FBS patients. They present with normo-glycaemic glycosuria and no signs of altered glucose metabolism when challenged with a glucose load. Glycosuria decreases, but is still detectable after fasting. GLUT2 cKO mice present an osmotic driven polyuria that improves by reducing theosmotic load. cKO mice present low molecular weight proteinuria and phosphaturia. This latter is sustained by a downregulation of Napi2a abundance in the cortex of GLUT2 cKO mice. When challenged with a sodium bicarbonate load, at serum level of bicarbonate equal as control mice, they excrete a double amount of bicarbonate, showing that GLUT2 ablation lead to proximal renal tubular acidosis. At histology, the proximal tubule cells appear hypertrophic compared with littermate controls. Quantification of renal cortical glycogen content shows a three fold increase abundance in cKO mice, suggesting that GLUT2 ablation alters significantly the intracellular glucose metabolism

Conclusions: We generate a mouse model cKO for GLUT2 recapitulating FBS. We show that GLUT2 is crucial for intracellular glucose metabolism in the proximal tubule cells since its ablation leads to a severe glycogen accumulation and loos of function. This model is suitable for testing novel pharmacologic approach to rescue FBS

TH-PO728

A Unique Mutation in the MODY1 Gene HNF4A Causes Fanconi Syndrome by Shifting Lipid Catabolism to Anabolism

Valentina Marchesin,[1,2] Albert Perez-Marti,[1,2] Matias Simons.[1,2] *[1]Institut Imagine, Paris, France; [2]Université Paris-Descartes, Paris, France.*

Background: Renal proximal tubular cells (PTCs) have the task to reabsorb most of water, solutes and proteins filtered by the glomerulus. To cope with their high energy demand, PTCs exclusively rely on fatty acid oxidation. However, lipid metabolism needs to be finely regulated in this tissue as recent evidence has suggested that renal lipid accumulation and lipotoxicity may lead to kidney dysfunction. Here, we focus on the function of the nuclear hormone receptor HNF4A whose mutations cause MODY1, a monogenic type of diabetes in humans. Only one mutation (p.R85W) in the DNA binding domain leads to additional PTC dysfunction (also known as Fanconi syndrome), but the reason for this is unclear.

Methods: To address the role of HNF4A in lipid metabolism and to illuminate the pathogenetic mechanisms underlying the R85W mutation, we made use of the *Drosophila* model. In particular, we utilized fly nephrocytes as a simplified cell model for PTCs.

Results: We show that HNF4A controls a genetic program that regulates lipid metabolism in nephrocytes. Silencing HNF4A causes an increase in lipid droplet size and number, while the overexpression of HNF4A causes depletion of lipid stores through brummer/ATGL-mediated neutral lipolysis. Interestingly, very high expression levels of HNF4A or the expression of the R85W mutation behave in a dominant-negative fashion by triggering a shift from lipid catabolism to lipid anabolism. In addition to a lipolysis block, this involves the increased DGAT1-dependent formation of lipid droplets. In both conditions, the lack of lipolysis leads to mitochondrial depolarization, possibly due to the decreased availability of free fatty acids and lack of ATP production. The mitochondrial damage is accompanied by the accumulation of ER fragmentation, p62- and PDI-positive protein aggregates and a strong induction of autophagy. Collectively, these organellar injuries eventually lead to nephrocyte loss and shorten the life span of flies.

Conclusions: Altogether, our data describe a novel pathogenetic mechanism for Fanconi syndrome with important implications for the general understanding of lipid metabolism in PTCs. Moreover, targeting HNF4A or one of its downstream partners could represent a very useful therapeutic strategy in situations with lipid overload in the PTCs.

Congenital Renal Glycosuria Is Associated with Healthier Weight at Adolescence: Nationwide Cross Sectional Study of 2.38 Million Examinees

Adi Leiba.[1,2] *[1]Division of Nephrology and Hypertension, Assuta Ashdod Hospital, Ben Gurion University of the Negev, Ashdod, Israel; [2]Medicine and Medical Education, Mount Auburn Hospital, Harvard Medical School, Cambridge, MA.*

Background: Glucose filtered in the glomeruli is normally reabsorbed by the sodium coupled glucose transporters (SGLTs), mostly the SGLT2, located in the renal tubules. Mutations in the genes coding for these transporters were shown to cause renal glycosuria. It was shown recently in various studies that pharmacological inhibition of SGLT2 causing renal glycosuria is an effective treatment for diabetic patients. Among the desirable effects of these medications is weight lost and reduction of blood pressure. The aim of the current study is to investigate whether adolescents with renal glycosuria are less likely to be overweight or obese

Methods: Medical and socio-demographic data on 2,385,093 adolescents examined for medical fitness prior to military service from 1977 to 2016 were retrieved from the Israeli Defense Forces conscription center database. We conducted a cross sectional study to evaluate the association between renal glycosucria diagnosed in the conscription center and the overweight (85-95 BMI percentiles) and obesity (>95 bmi percentiles). Multinomial regression model were used.

Results: The final study cohort comprised of 2,388,163 conscripts of whom 1069 (0.045%) were assigned with numerical code meaning renal glycosuria not related to diabetes. The adjusted OR for overweight and obesity was 0.69 (95% CI, 0.54-0.89) and 0.60 (95% CI, 0.42-0.85), respectively.

Conclusions: Congenital Glycosuria may is associated with healthier metabolic profile, specifically less overweight and obesity, and this effect is already seen at adolescence

TH-PO730

Genetic and Functional Characterization of PHEX Gene Variants in 42 Children with X-Linked Hypophosphatemic Rickets

Aihua Zhang, Bixia Zheng, Chunli Wang, Yue Zhang, Guixia Ding, Songming Huang, Zhanjun Jia. *Children's Hospital of Nanjing Medical University, Nanjing, China.*

Background: X-linked hypophosphatemia, a disorder of renal phosphate wasting and the most common heritable form of rickets, is caused by loss-of-function mutations in the gene encoding phosphate-regulating endopeptidase homolog (PHEX). The aim of this study was to explore the molecular basis of 42 children with HR in the Chinese population.

Methods: All patients were analyzed for the PHEX gene by direct sequencing. When no mutations were detected in PHEX gene, multiplex ligation-dependent probe amplification (MLPA) analysis was performed. PHEX non-truncating mutation and two truncated mutations were characterized in vitro by assessing their effects on PHEX expression, subcellular localization and glycosylation pattern.

Results: Among 42 patients, 40 patients (95%) harbored mutations in the PHEX gene. In particular, we detected 35 different mutations, including eleven indel mutations including nine frameshift mutations resulting from small deletions or insertions and one 3bp deletion mutation (31.4%), seven missense (20%), seven splice sites mutations(20%), five nonsense (14.2%), and five exonic deletion (14.2%). Among these mutations, 21 mutations have not been previously described in the literature or entered in PHEXdb and HGMD. Clinical presentation and disease severity did not show an evident correlation between the truncating and non-truncating mutation type. Like the nonsense mutaion R567X and Q714X, five of the six non-truncating mutation detected in our cohort also led to retention of the PHEX protein in endoplasmic reticulum, in an immature form, as determined by glycosylation pattern and proteasomal degradation analysis and immunofluorescence.

Conclusions: Our findings expand the mutation spectrum of PHEX, confirm that mutations in PHEX are the most frequent cause of HR, and truncating mutations is the most often mutation type in Chinese patients. Our clinical and experimental evidence also showed no correlation between the degree of disease severity and the PHEX genotypes.

TH-PO731

Human Gout Risk Variant ABCG2 Q141K Results in Profound Hyperuricemia and Significant Changes to Kidney Function in a New Mouse Model

Owen M. Woodward, Mirajul H. Kazi, Eryn E. Dixon, Raychel M. Lewis. *University of Maryland School of Medicine, Baltimore, MD.*

Background: Gout is the most common inflammatory arthritic disease and is a consequence of having elevated circulating urate (UA) levels (hyperuricemia). GWAS studies have identified a number of key urate transporter genes that contribute to gout risk and are expressed in the kidney and the intestines. Yet recent work from others has shown individuals carrying the most common gout risk variant, Q141K ABCG2, have no measureable difference in their renal fractional excretion of urate (FEUA). These data beg the question of whether or not ABCG2 has a role in the renal urate excretion pathway.

Methods: We have made a new mouse knock-in model of the human gout risk variant, Q141K ABCG2 (in mice, Q140K) on a C57BL6J mouse background using CRISPR Cas9 gene editing techniques, and have used biochemical, Immunofluorescence, and renal physiological measurements to described the renal phenotypes of a human risk variant carried by 500 million individuals world-wide.

Results: We first confirmed and localized the ABCG2 protein in the mouse and human tubule, confirming unambiguously that ABCG2 expression in apical membrane of the human proximal tubule is robust. The Q140K ABCG2 mutant male mice proved to be profoundly hyperuricemic, and although the mutant mice displayed both a slight decrease in renal protein abundance and a decrease in FEUA, it was significantly less than observed in the intestines, with female mice showing no defect at all. In addition to the decrease in FEUA, the male mutant mice exhibited other hallmarks of declining renal function including, reduced eGFR, signs of metabolic acidosis, impaired ammonium secretion, and evidence of more wide spread metabolic alterations, including increased blood glucose and insulin levels.

Conclusions: Our new mouse model of the common human gout risk variant, Q141K ABCG2, shows that a single loss of function point mutation in a single urate transporter has significant phenotypic effects on mammalian physiology, and this work provides evidence that alterations in urate homeostasis alone can effect kidney function, consistent with the hypothesized causal role of urate in renal and metabolic diseases.

Urinary MicroRNAs in Fabry Disease Patients with Mild Nephropathy

Sebastian P. Jaurretche,[1,2] Graciela Venera,[4] Norberto Ricardo Antongiovanni,[3] Fernando J. Perretta,[5] German Perez.[6] *[1]Centro de Neurociencias Los Manantiales, Rosario, Argentina; [2]Biophysics and Human Physiology, Instituto Universitario Italiano de Rosario, Rosario, Argentina; [3]Nephrology, Clínica de Nefrología de Pergamino, Pergamino, Argentina; [4]Instituto universitario Italiano de Rosario, Rosario, Argentina; [5]Fresenius Medical Care, Escobar, Argentina; [6]Gammalab, Rosario, Argentina*.

Background: Analyze the urinary excretion profile of microRNAs (UEPmiR) regulated by TGF-β-SMAD. Fibrotic: miR-21;miR-192;miR-433. Anti Fibrotic: miR-29;miR-200)

Methods: microRNAs extraction from urinary cell pellet was achieved. RNAU6 was endogenous control. Relative miR expression levels were calculated with ΔΔCt method. Dependent variable: UEPmiR. Independent variables: age, gender, α-galA activity, genotype, CKD stage and proteinuria.

Results: Healthy subjets: 8p (4m/4f); age: 25.9±15.2ys; eGFR: 120.7±18.7 ml/min/1.73m^2. All nonalbuminuric patients. FD population: 24p (7m/17f); age: 23.7±17.3ys; decreased α-galA: 100% males/13.3% females; eGFR: 137.3±37.2 ml/min/1.73m^2; microalbuminuria: 16.7% (1/7) males/35.3% (6/17) females. There were no statistically significant differences in age (p=0.741), eGFR (p= 0.239) and ACR (p=0.204) between healthy subjects and FD patients. microRNA expression in FD patients according to age, gender, genotype, α-galA activity, eGFR, and ACR: significant differences were found between sexes and normal or decreased α-galA only in miR-29 (p=0.041;0.041) and miR-200 (p=0.048;0.048), respectively. FD patients with normal α-galA, without clinical criteria to start enzyme replacement therapy (ERT)(A1 group), did not present differences in UEPmiR compared to healthy subjects. FD patients with more severe phenotype and received ERT (A2 group) did not present differences in UEPmiR compared with healthy subjects neither A1 group. FD patients with normal α-galA and without clinical criteria to start ERT (B1 group), presented a UEPmiR indicative of renal fibrosis (decrease of miR-29 and miR-200). FD patients with decreased α-galA and clinical criteria to start ERT had a different UEPmiR than B1 group, finding that miR-29, in B2 group, behaves similar to healthy subjects.

Conclusions: FD males have a profibrotic UEPmiR. UEPmiR was similar between healthy subjects and two groups of FD patients, i) patients with mild FD phenotype and normal α-galA activity and ii) patients with normal α-galA but with a more severe phenotype receiving ERT. In FD patients with low α-galA activity without ERT, a profibrotic UEPmiR was found; compared with FD patients with low α-galA activity and severe phenotype with ERT, an increase of miR-29 was observed. A probable effect of ERT should be evaluated in longitudinal studies.

TH-PO733

The Prevalence of Fabry Disease in Patients Undergoing Hemodialysis in the Northernmost Region in Japan

Naoki Nakagawa. *Asahikawa Medical University, Asahikawa, Japan.*

Background: Fabry disease, an X-linked, progressive and life-threatening genetic disease, is caused by abnormalities in the α-galactosidase A (α-Gal A) gene. Several studies in Japan reported 2-3% of males suffering from left ventricular hypertrophy were affected with Fabry disease, however, the prevalence of Fabry disease in patients undergoing hemodialysis is still unknown.

Methods: In this prospective, multicenter study, we screened 1,476 patients receiving dialysis from multicenter of the northernmost prefecture in Japan. Patients with a low α-Gal A activity were assessed using dried blood spots on filter paper, and a genetic study of the α-Gal A gene was performed for these patients.

Results: A total of 1,476 patients (66% male, median age 67.0 years) underwent screening and 52 had low α-Gal A activity; of these, two males had α-Gal A mutations. A 64-year-old man had the genetic mutation of p.M187V in exon 4. Another 55-year-old man had the genetic mutation of c.908-928del21 in exon 7, which is a new mutation not described before in the literature, but potentially pathogenic. Both patients had severe left ventricular hypertrophy and had diagnosed as having chronic glomerulonephritis without renal biopsy. The prevalence of Fabry disease is 0.14% in patients undergoing hemodialysis in the northernmost region in Japan.

Conclusions: Dried blood spot screening was considered as a simple and effective method for detecting the underlying patients with Fabry disease. Clinicians should be aware of Fabry disease as a potential cause of hemodialysis, especially in hemodialysis patients with severe left ventricular hypertrophy without renal biopsy.

TH-PO734

Bedside Assessment of the Microcirculation in Patients with Fabry Disease

Anna Bertram,[1] Lisa K. Peede,[1] Natalia Goldenberg,[2] Jessica K. Kaufeld,[3] Hermann G. Haller.[1] *[1]Hannover Medical School, Hannover, Germany; [2]Medizinische Hochschule Hannover, Hannover, Germany; [3]Medical School of Hannover, Hannover, Germany*.

Background: Fabry disease is a hereditary lysosomal storage disease with a loss of α-galaktosidase A activity, in which accumulation of glycosphingolipids leads to cellular damage in endothelial cells and other cell types. The endothelial surface layer (ESL) with the glycocalyx is important for endothelial cell function. We, therefore, assessed the ESL as well as circulating components of the ESL in Fabry patients. Visualization of the microcirculation can lead to a better understanding of its contribution to the pathophysiological changes in Fabry disease.

Methods: 29 patients with Fabry disease and 33 healthy age- and gender-matched controls were analysed by intravital microscopy with the GlycoCheck™ technology (Micro Vascular Health Solutions) to measure ESL thickness (perfused boundary region), red blood cell filling velocity, and microvascular density. Circulating ESL components (syndecan-4, thrombomodulin), cytokines (MCP-1), and regulatory molecules (ADAM-17, VEGF-R1) were measured in plasma using ELISA. Patients were clinically characterized by organ involvement (heart, kidney, brain).

Results: Perfused boundary region was significantly decreased in patients with Fabry disease (1.96 ± 0.28, vs. 2.36 ± 0.27, p = 0.001). Circulating markers of the ESL were not different between groups. Microvascular density was significantly lower in Fabry patients compared to controls (median 284.50 vs. 580.83 μm/mm^2, p = 0.001). The alterations in microcirculation were independent of the degree of organ involvement. MCP-1 concentration was significantly increased in Fabry patients (346.19 ± 91.82 pg/ml

vs. 288.13 ± 95.22 pg/ml, p = 0.018) which was pronounced in patients with cardiac involvement.

Conclusions: Our data suggest an increase in ESL density, and no change in glycocalyx breakdown in patients with Fabry disease. In addition, a rarefication of microvessels was observed. Our findings suggest pathophysiological changes in the microvascular structure of patients with Fabry disease. The enhanced inflammation is not directly related to the microvascular changes.

TH-PO735

Fabry Nephropathy: Transcriptome Sequencing of Microdissected Renal Compartments from Archival Kidney Biopsies at Baseline, and After 5 and 10 Years of Enzyme Replacement Therapy

Oystein Eikrem,[1,2] Philipp Strauss,[1] Miroslav Sekulic,[3] Camilla Tøndel,[4] Arnar Flatberg,[6] Rannveig Skrunes,[4] Lea Landolt,[1] Janka Babickova,[1] Sabine Leh,[4,1] Andreas Scherer,[5] Einar Svarstad,[4,1] Hans-Peter Marti.[1,2]
[1]Department of Clinical Medicine, University of Bergen, Bergen, Norway; [2]Department of Medicine, Haukeland University Hospital, Bergen, Norway; [3]Brigham and Women's Hospital, Boston, MA; [4]Department of Pediatrics, Haukeland University Hospital, Bergen, Norway; [5]Spheromics, Kontiolahti, Finland; [6]Department of Clinical and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, Norway.

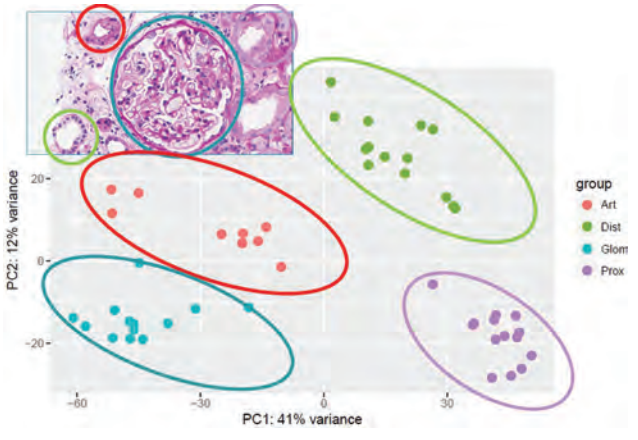
Background: The present study exploited next generation mRNA sequencing from kidney biopsies of Fabry patients with a classical phenotype

Methods: Kidney biopsies (n=15) were obtained with a 16G needle from Fabry patients (n=5) from 2003-2014. Median patient age at baseline biopsy was 18 years (7-30 y). Control biopsies from peri-tumorous tissue of renal cancer patients (n=32). Formalin-fixed, paraffin-embedded (FFPE) kidney biopsies were obtained: a) baseline prior to enzyme replacement therapy (ERT; n=5), b) after 5y of ERT (n=5), and c) 8-10y of ERT (n=5). Total RNA was extracted from laser-captured, microdissected glomerular, proximal tubular, distal tubular and arterial cross-sections (High Pure FFPET RNA extraction kit; Roche). cDNA libraries were prepared using the TruSeq RNA Access Library Prep Kit® (Illumina) and sequenced on an Illumina HiSeq 2500/HiSeq 4000 instrument

Results: We present the results of the first 42 samples of a larger ongoing series. Several hundred mRNAs were differentially expressed (p-value <0.05, abs. fold change >2) between normal controls and Fabry baseline samples, and between the baseline samples and the two different treatment time points. The samples segregated completely within their own compartment (Fig. 1) in principle component analysis. Gene Set Enrichment Analysis in the glomerular compartment demonstrated enriched gene sets of extracellular matrix, EMT, fibrosis, and immune response in the 10 year biopsies compared to baseline (p<0.05) despite ERT. Several key regulatory inflammatory genes were found to be upregulated in all compartments

Conclusions: NGS is feasible in archival Fabry disease kidney biopsies, expanding the potential utility of kidney biopsies to detect markers of Fabry nephropathy, chronic kidney disease and therapeutic targets

Funding: Commercial Support - Sanofi Genzyme, Shire, Government Support - Non-U.S.



TH-PO736

Implications of Renal Impairment on Dosing of Delayed-Release Cysteamine Bitartrate

Craig B. Langman,[1] Saba Sile,[3] Dennis M. Fisher.[2] *[1]Feinberg School of Medicine, Northwestern University, Chicago, IL; [2]P Less Than, San Francisco, CA; [3]Clinical Development, Horizon Pharma Inc, Lake Forest, IL.*

Background: Delayed Release Cysteamine Bitartrate(DRCys) is used to treat nephropathic cystinosis (NC) in order to prolong native kidney function and ameliorate other systemic effects of NC. A biomarker, WBC cystine levels (WBCCys) guides optimal cystine reduction. To date, there are no studies on the effects of impaired renal function, including hemodialysis (HD) on DRCys elimination, and Study RP103-16001 was designed to address these missing data.

Methods: Subjects (all without NC) with mild, moderate, or severe renal impairment, or ESRD requiring hemodialysis, (HD) (8 each; NKF classification based on eGFR) and 32 matched healthy controls were studied. HD subjects received a single 200 mg dose of DRCys twice: 3hr before or 2hr after HD on different days. All remaining subjects received one 200 mg DRCys dose. Blood was sampled for 24h after each dose to detemine cysteamine concentrations. Pharmacokinetic analysis was conducted using mixed-effects (population) methods with NONMEM software (ICON Development Solutions, Hanover MD).

Results: Table 1 reports drug clearance relative to healthy controls. For subjects with renal impairment except those on maintenance HD, the effect on DRCys clearance is small, within ±20% of the values in the controls. In HD subjects, clearance fluctuates between successive HD treatments, being maximal post HD and then decreasing.

Conclusions: Although increasing renal impairment is associated with a decrease in the apparent clearance of DRCys, the magnitude is relatively small, and unlikely to necessitate dose reduction However, the decrease in clearance between HD sessions may cause DRCys efficacy to vary over that time frame. Therefore, biomarker WBCCys results should be interpreted in the context of when patients had the WBCCys sampled relative to HD. Mechanisms for HD-associated clearance changes are unknown but may involve HD improving CYP function.

Funding: Commercial Support - Horizon Pharmaceuticals Inc.

Factors for apparent clearance of DRCys related to residual renal function (eGFR) compared to healthy controls

Degree of impairment	eGFR (ml/min/1.73m2)	Factor
Mild	>90	1.192
Moderate	60-89	0.849
Severe	30-69	0.801
ESRD	Maintenance HD	
Concurrent HD		0.602
Post-HD		0.803

TH-PO737

MAGED2 (Re)wires G-Protein Coupled Receptor Signaling in Renal Collecting Duct Cells

Malte P. Bartram,[1] Björn Reusch,[3] Bernhard Schermer,[1,2] Thomas Benzing,[1,2] Bodo B. Beck,[3] Markus M. Rinschen.[1,2] *[1]University Hospital Cologne, Cologne, Germany; [2]CECAD, Cologne, Germany; [3]University of Cologne Medical Center, Cologne, Germany.*

Background: Recently mutations in MAGED2 were identified as a genetic cause of very severe X-linked polyhydramnios and transient antenatal Bartter syndrome. Since MAGED2 does not code for a transmembrane protein, the molecular mechanisms that contribute to the antenatal Bartter syndrome remain elusive. First results suggest that MAGED2 acts indirectly on ion channels and transporter expression in the kidney tubule system.

Methods: The role of MAGED2 in renal cell culture systems was studied by analyzing the proteome and phospho-proteome after MAGED2 depletion and by analyzing the influence of MAGED2 on vasopressin induced signaling in mouse collecting duct cells using Western Blot, qPCR and proteomic analyses.

Results: We show that MAGED2 ablation in HEK293T cells induced large effects on the phosphoproteome, without affecting protein levels. Since MAGED2 is expressed during development in collecting duct cells of newborn mice, we analyzed the effects of MAGED2 knockdown on vasopressin-dependent signaling in renal collecting duct cells. We found that MAGED2 knockdown altered V2R-induced cAMP-generation kinetics, phosphoproteome rewiring, and blunted phosphorylation on downstream nodes such as phosphorylated CREB. V2R induced ERK inhibition and aquaporin-2 phosphorylation were not affected. Interestingly, these alterations resulted in a marked increase in aquaporin-2 abundance during long-term V2R activation, that was mediated transcriptionally, potentially through the mediator complex.

Conclusions: In conclusion, we show that MAGED2 is a novel modulator of G-protein coupled signaling, that might control important signaling events involved in ion transport and nephron plasticity in the distal nephron. The relevance of these findings needs to be recapitulated in vivo.

TH-PO738

Model of Megalin Trafficking in Differentiated Proximal Tubule Cells and Its Application in Dent Disease

Katherine Shipman, Kimberly R. Long, Youssef Rbaibi, Catherine J. Baty, Ora A. Weisz. *University of Pittsburgh, Pittsburgh, PA.*

Background: The polarized epithelial cells that comprise the proximal tubule (PT) have a specialized, high capacity apical endocytic pathway necessary to maintain a protein-free urine. The multiligand receptor megalin plays an essential role in the binding and uptake of proteins in the ultrafiltrate. The molecular identities of the compartments involved in sorting of ligands and recycling of receptors in PT cells and the kinetics of megalin trafficking through them are unknown. Dysfunctional PT endocytosis results in tubular proteinuria that can progress to renal failure, as is commonly observed in Dent disease, an X-linked disorder caused by mutations in the Cl^-/H^+ exchanger CLC-5. Reduced endocytic uptake in Dent disease is likely due to decreased expression of megalin receptors (without altered mRNA levels); however, the mechanism by which this occurs is unclear.

Methods: We previously discovered that OK cells cultured under continuous fluid shear stress develop morphological and functional features similar to that of the PT *in vivo*, including high apical endocytic capacity and increased megalin expression. Using

biochemical techniques, we have estimated endocytic and recycling rates and the half-life of surface megalin. These data were used to construct a model of megalin trafficking in differentiated PT cells. To study megalin trafficking in a Dent disease cell model, we knocked-down CLC-5 expression in these cells using siRNA. Typical knockdown efficiency was ~70%.

Results: We present an ordinary differential equation model of megalin trafficking describing surface and internalized pools of megalin with estimated kinetic parameters. The model is capable of achieving a steady-state with a much larger pool of internalized megalin compared to surface within a range of realistic parameters; this is consistent with observations made by our biochemical assays and by indirect immunofluorescence of endogenous megalin. In our Dent disease cell model, we observed decreased megalin expression as observed *in vivo*, and we are quantifying megalin trafficking kinetics in these cells to identify the affected step(s).

Conclusions: Our new PT cell culture model provides an ideal system in which to determine the organization of the apical endocytic pathway and to delineate the mechanistic basis of genetic diseases that cause tubular proteinuria.

Nephrogenic Syndrome of Inappropriate Antidiuresis (NSIAD) Associated with a Mutation in GNAS

Detlef Bockenhauer,[1,2] Heike Biebermann,[4] Gunnar Kleinau,[4] Mehul T. Dattani,[8] John W. Gregory,[5] Harald Jüppner,[3] Michael Mannstadt,[4] Sarah Paisdzior,[4] Patrick Scheerer,[4] Ian Tully,[5] Louise C. Wilson,[7] Annette Grueters.[6] GOSH *[1]University College London, London, United Kingdom; [2]Nephrology, Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom; [3]Massachusetts General Hospital, Boston, MA; [4]Charité Berlin, Berlin, Germany; [5]Cardiff University, Cardiff, United Kingdom; [6]university Hospital heidelberg, Berlin, Germany; [7]Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom; [8]UCL Institute of Child Health, London, United Kingdom.*

Background: NSIAD refers to a genetic form of urinary concentration independent of anti-diuretic hormone (ADH). So far, it has only been shown in association with gain-of-function mutations in AVPR2. Here, we present 2 unrelated boys with a novel syndrome including NSIAD.

Methods: Clinical and genetic investigations in 2 patients. The identified mutation was further studied *in vitro*.

Results: Both boys presented in the neonatal period with hyponatremia, initially treated with sodium supplementation and additional fludrocortisone, which was complicated by hypertension. Detailed investigations in one patient at the age of 3 years revealed clinical euvolemia, a persistently elevated urine osmolality (796-1006 mosm/kg) with suppressed copeptin (<3.6 pmol/l) and unresponsiveness to a tolvaptan challenge. Salt and mineralocorticoid supplementation was discontinued with normalization of blood pressure and maintenance of normonatremia with spontaneous reduction in fluid intake (30ml/kg/d). A subsequent transient episode of hyponatremia (128 mmol/l) was associated with increased weight and blood pressure, suppressed copeptin and a urine osmolality of 1038 mosm/kg. Both patients also had complex endocrine abnormalities, including elevated serum PTH concentrations (66-454 pg/l), hypocalciuria (0.06-0.09 mol/mol) and gonadotropin-independent precocious puberty. Molecular analysis revealed a de novo variant in *GNAS* c.1126T>G; p.(F376V) on the maternally inherited allele in both patients. In vitro studies of mutant Gαs-F376V revealed agonist-independent activation of AVPR2, LHCGR and PTH1R.

Conclusions: We show a novel form of NSIAD associated with an activating mutation in *GNAS*, encoding the stimulatory G protein Gαs. In the collecting duct, Gαs associates with AVPR2 and activates adenyl cyclase to initiate urinary concentration. Our data indicate that mutant Gαs-F376V can activate independent of ADH signalling. Different mutations in *GNAS* have been previously associated with disease, including McCune-Albright Syndrome and Pseudohypoparathyroidism. The unique phenotype associated with this mutation can be explained by the differential impact on signalling with the various associated receptors, as well as the effect of imprinting on tissue-specific expression.

TH-PO740

Whole Exome Sequencing Reveals Mutations in the Purinergic Receptors P2RX2 and P2RX7 as Novel Causes of Neurogenic Bladder and CKD

Nina Mann,[1] Franziska Kause,[1] Shirlee Shril,[1] Dervla M. Connaughton,[1] Rufeng Dai,[1] Caroline M. Kolvenbach,[2] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Neurogenic bladder is caused by disruption of the normal neural pathways that regulate bladder relaxation and contraction. In severe cases, neurogenic bladder can lead to vesicoureteral reflux, recurrent urinary tract infections, and even chronic kidney disease and renal failure. Animal models of bladder dysfunction suggest that neurogenic bladder can be caused by single gene mutations. However, to date, no mutations have been identified in humans.

Methods: To identify monogenic causes of neurogenic bladder, we applied homozygosity mapping with whole exome sequencing (WES) to our worldwide cohort of families with congenital anomalies of the kidneys and urinary tract (CAKUT).

Results: We identified a homozygous missense mutation (p.Gly322Arg) in the gene *P2RX2* and a compound heterozygous missense mutation (p.Leu320Pro, p.Pro582Leu) in the gene *P2RX7* in two families with neurogenic bladder. Both families also have secondary vesicoureteral reflux and chronic kidney disease. The mutations identified are well-conserved evolutionarily, rare in the general population, and have deleterious in silico prediction scores. P2RX2 and P2RX7 belong to the purinergic family of receptors, which are ATP-gated cation channels, and both are expressed in the urothelium and bladder smooth muscle. Additionally, *P2rx2* knockout mice have impaired bladder reflexes (Cockayne J Physiol 567:621, 2005), which mimics the phenotype of our patients.

Conclusions: We identified recessive missense mutations in two purinergic receptors, *P2RX2* and *P2RX7*, in families with neurogenic bladder. Purinergic signaling has been reported to play an important role in bladder contractility, and we therefore propose that mutations in these genes may be novel monogenic causes of neurogenic bladder in humans.

TH-PO741

Clinical Utility of Secondary Genetic Findings in CKD

Emily Groopman, Maddalena Marasa, Simone Sanna-Cherchi, Krzysztof Kiryluk, Ali G. Gharavi. *Columbia University, New York, NY.*

Background: Whole-exome sequencing (WES) is increasing utilized in nephrology. In addition to providing a specific etiology for nephropathy, genome-wide testing can detect other variants of potential clinical relevance. However, neither the prevalence of such secondary findings among patients with kidney disease nor their clinical implications, including for nephrologic care, has been assessed.

Methods: 2,187 patients with all-cause chronic kidney disease (CKD) underwent WES at the Columbia Institute of Genomic Medicine. 87% were adults (aged >21y) and 49% self-identified as non-European. We analyzed WES data for variants diagnostic for 850 medically actionable monogenic diseases, using American College of Medical Genetics clinical sequence interpretation criteria. The clinical implications of secondary genetic diagnoses were assessed via their capacity to initiate extra-nephrologic subspecialty referrals and to inform key aspects of nephrologic management, such as dialysis care and choice of therapy.

Results: 149 (7%) patients had a secondary genetic diagnosis. Yield did not differ significantly between pediatric and adult cases (OR=0.70 [0.37, 1.23], P=0.25) nor between self-identified Europeans and non-Europeans (OR=0.83 [0.59, 1.18], P=0.31). The secondary genetic diagnoses spanned 78 medically actionable monogenic disorders and would initiate extra-nephrologic referral involving 19 different specialties. Moreover, in 76 (51%) of the 149 cases, the disorders found could be mistaken as secondary CKD comorbidities and would require disease-specific treatment. Strikingly, in each case, the secondary genetic diagnosis had meaningful implications for nephrologic care. For example, the inherited cancers found in 79 patients would inform type and dose of immunosuppression for renal transplantation, and, in the 45 with glomerulopathy, therapy for their primary renal disease as well. Similarly, the hereditary cardiac conditions noted in 40 patients would impact dialysis and/or choice of anti-hypertensive agent.

Conclusions: WES of a large all-cause CKD cohort yielded secondary genetic diagnoses in 7%, with meaningful implications for nephrologic care. Our findings reveal a novel utility of genome-wide testing in nephrology and the associated need for multidisciplinary management.

TH-PO742

Enhance Utility of Family-Centered Diagnostic Exome Sequencing in Children with CKD: A Comparison of 497 Families in Trios and Singleton

Jia Rao, Qian Shen, Hong Xu. Chinese Children Genetic kidney Disease Database (CCGKDD) *Children's Hospital of Fudan university, Shanghai, China.*

Background: The utility of family centered whole exome sequencing (WES) for the diagnosis of children with chronic kidney disease (CKD) has not been adequately studied.

Methods: Patients with CKD identified according to KDIGO guidelines were grouped into five phenotype categories-nephrosis, nephritis, proteinuria(non-nephrotic), congenital abnormalities of the kidney and urinary(CAKUT), CKD2-5 stage of unknown cause and miscellaneous. WES data from Chinese Children Genetic kidney Disease Database (CCGKDD) including 10 different renal centers in CHINA were analyzed. Singleton WES was performed as a first-tier sequencing test. Family-based exome sequencing included trio whole exome sequencing followed by family inheritance–based model filtering, comprehensive medical review, familial segregation analysis, and analysis of novel genes.

Results: Of 497 enrolled children with CKD, 330 received genetic diagnosis through singleton WES compared with 167 who underwent trios-WES. A molecular diagnosis was reported for 171 families (34.4%) with 78.3% of the diagnostic mutations not previously reported. A positive or likely positive result in a known disease causing gene was identified in 29.0%(89/330) of patients in singleton vs. 49.1% (82/167) of families in trios. Genetic diagnosis rates for each phenotypic category were 33.3% for nephrosis group, 26.6% for nephritis group, 43.4% for proteinuria group, 349.3% for CAKUT group, 36.6% for CKD 2-5 stage of unknown cause group and 32.5% for miscellaneous group (Fig.1). Novel gene findings were identified in 4.2%(4/167) of patients in trios.

Conclusions: The multicenter cohort of WES cases demonstrate the utility of family-based exome sequencing and analysis to obtain the highest reported detection rate in children with CKD.

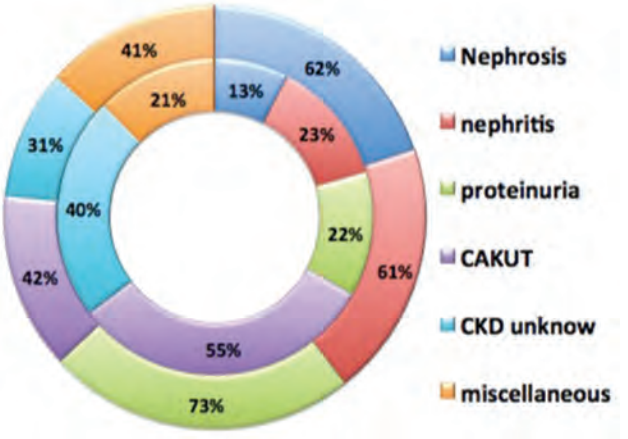

Fig.1 Genetic diagnosis rates for each phenotypic category in children with CKD comparing in singleton and trios-WES (Singleton: inner ring;Trios: outer ring)

TH-PO743

Novel Diagnostic and Therapeutic Approaches for Kidney Diseases: Potential Applications of Noncoding RNAs Associated with Regulation of NOTCH2 and TP53

Mohammed A. Al-Obaide, Tetyana L. Vasylyeva. *Texas Tech University Health Sciences Center, Amarillo, TX.*

Background: The NOTCH2 and TP53 genes are linked to many diseases including kidney diseases. In humans NOTCH2 associated with kidney developmental abnormalities and Alagille Syndrome. In addition to the known function of TP53 in limiting cell proliferation, TP53 involved in regulation of self-renewal and maintenance of the nephron progenitor pool. Previous studies showed excessive expression linkup NOTCH2 and TP53 to kidney diseases. We hypothesized that long noncoding RNA (lncRNA) which are tissue-specific regulators of gene expression are involved in cross-talk for tight control of expression of genes associated with kidney diseases, for example, the NOTCH2 and TP53. The genomic regions of the two genes host characterized and uncharacterized lncRNA. We aimed to investigate the potential interaction and cross-talk between the WRAP53 WD repeat containing antisense to TP53 and the uncharacterized lncRNA genes convergently or divergently configured to the protein-coding gene NOTCH2 in the regulation of both genes.

Methods: The search for unreported miRNA sequences in the WRAP53 WD repeat containing antisense to TP53 and predicted uncharacterized lncRNA LOC105378939, LOC111776218, LOC101929178 and LOC105378940 ncRNAs loci analyzed by the miRBase search tool. The microRNA recognition elements (MRE) in the NOTCH2 and TP53 mRNAs, identified by RNA22 v2 microRNA target detection tool. The miR binds to the target MRE.

Results: The lncRNAs loci are the source of various types of miRNAs. The analysis of the WRAP53 WD repeat containing antisense to TP53 and LOC105378939, LOC111776218, LOC101929178, and LOC105378940 detected several types of miRs. The discovered miRs bind to the target MRE of the mRNAs of the NOTCH2 and TP53. The miRs from WRAP53 WD repeat containing antisense to TP53 bind the MRE targets of NOTCH2. The miR sequences are comparable but not similar to the human (Homo sapiens) hsa-miR, for example, hsa-miR-6743-3p, hsa-miR-6510-5p, hsa-miR-1285-3p, and hsa-miR-519b-3p.

Conclusions: The detected miRNAs from the investigated lncRNAs may provide novel approaches to delineate the complex mechanisms associated with NOTCH2 and TP53 in kidney diseases. The lncRNAs can act as diagnostic biomarkers and suggest therapeutic opportunities for the treatment of kidney diseases.

TH-PO744

Kidney Disease Associated Variants of ApoL1 Show Gain-of-Function in the pH-regulated Cation Channel Activity

John C. Edwards. *St. Louis University, Saint Louis, MO.*

Background: Variants in the protein ApoL1 are largely responsible for the increased risk of progressive kidney disease in people of African ancestry. ApoL1 is an amphitropic membrane protein that inserts into membranes a low pH where it confers anion-selective permeability. After titration to neutral pH, the anion permeability is suppressed and a non-selective cation permeability is activated. We used vesicle based ion flux and membrane association assays to assess for functional difference among variants.

Methods: Recombinant ApoL1 isoforms were expressed in E. coli. KCl-loaded phospholipid vesicles were mixed with protein and assayed for efflux in presence of a large KCl gradient. Efflux was initiated by addition of selective ionophore (valinomycin to assess Cl permeability, or Cl ionophore 1 to assess K permeability), and detected with a chloride selective electrode. The initial rate of efflux after addition of ionophore minus the rate with control vesicles is taken as the ApoL1-dependent ion permeability. To assess membrane association, vesicles and protein were mixed at pH 6, then titrated to pH 7.5, stripped of peripherally bound protein, separated by flotation through a sucrose cushion and detected by western blotting.

Results: All variants show Cl-selective permease activity at low pH that is essentially identical. In contrast, the K-permeability of the disease-associated variants G_1 and G_2 is substantially higher than the WT (G_0). All three variants were purified simultaneously, with assays performed on the same day with the same reagents. Three independent sets of purified protein showed the same pattern of activity. Combining data from the three sets, G_1 and G_2 showed 2.08 ± 0.17 and 2.03 ± 0.28 fold greater activity than G_0 (mean ± SEM, P<0.001 for each). Membrane association experiments demonstrated consistently increased membrane binding by G_1 and G_2 compare to G_0 with 3.02 ± 0.49 and 3.30 ± 0.36 fold more binding than G_0, respectively (P<0.001 for each).

Conclusions: Kidney disease associated variants of ApoL1 show consistently greater cation channel activity and greater membrane insertion than the wild type protein. The data suggest increased membrane insertion and hence greater channel activity in kidney cells could be a mechanism contributing to disease progression.

TH-PO745

A Quantitative 23Na-MRI Protocol to Assess Muscle Na Concentrations: Protocol Reliability and Na Level Heterogeneity Between the Anterolateral and Superficial Posterior Compartments of the Lower Leg

Hsin-Yu Fang,[2] Luis M. Perez,[1] Brett Burrows,[2] Ryan J. Larsen,[2] Ken Wilund.[1] Renal and Cardiovascular Disease Research Laboratory UIUC *[1]University of Illinois, Urbana, IL; [2]University of Illinois at Urbana-Champaign, Urbana, IL.*

Background: Previous sodium magnetic resonance imaging (^{23}Na-MRI) studies demonstrated that sodium (Na) can be stored in muscle without thoroughly describing the image quantification methodology. ^{23}Na-MRI image region of interest (ROI) analysis is a subjective process that depends on user experience. We sought to develop a reliable protocol to quantify Na concentrations in two lower leg muscle compartments. The intra- and inter-rater reliability of our quantification protocol and the heterogeneity of Na level between two assessed muscle compartments were also examined.

Methods: Twenty-five ^{23}Na-MRI (3T system) images from 21 subjects (16 healthy subjects/5 hemodialysis patients) were quantified for muscle Na concentrations. We de-identified and randomized all images into two sets for ROI analysis by two trained researchers. Two ROIs were designated as the anterolateral (AL) and superficial posterior (SP) lower leg muscle compartments. We calculated Intraclass correlation coefficient (ICC) estimates based on 2-way mixed-effects models to determine the intra- and inter-rater reliability of our protocol on muscle Na concentrations of AL and SP compartments. Simple linear regression (SLR) analysis was used to investigate the relationship between the average muscle Na concentration of AL and SP (AL-SP mean) and the difference between AL and SP muscle Na concentrations (AL-SP difference).

Results: The ICCs of inter and intra-rater reliability for muscle Na concentrations of AL and SP compartments were all above 0.97, indicating excellent reliability. SP compartment muscle Na was higher than in the AL compartment (SP=20.32±8.69 mM, AL=15.57±5.92 mM, p=0.001). However, Na concentrations of the two compartments were strongly correlated (r=0.697, p<0.01). Linear regression of the AL-SP mean versus the AL-SP difference was significant (β1=-0.444, p=0.013; R2=0.232).

Conclusions: The reliability of our ^{23}Na-MRI image analysis protocol in the measurement of Na concentrations in lower leg muscular compartments was high. Muscle Na concentrations varied between muscle compartments, suggesting a heterogenous Na distribution among different muscle groups. The variance of muscle Na concentrations between compartments increased as the total muscle Na level elevated.

TH-PO746

Determination of Renal Blood Flow Based on PET/CT-Rubidium-82-Technology in Healthy Subjects

Stine Langaa,[1] Thomas G. Lauridsen,[1] Claire A. Fynbo,[2] Jorn Theil,[2] Jesper N. Bech.[1] *[1]University Clinic of Nephrology and Hypertension, Holstebro Hospital, Holstebro, Denmark; [2]Department of Nuclearmedicine, Herning Hospital, Herning, Denmark.*

Background: Changes in Renal Blood Flow (RBF) play an important patophysiological role in the widespread diseases hypertension and kidney disease. However present methods for RBF-determination in humans have several disadvantages. Myocardial blood flow is routinely assessed with PET/CT and the perfusion tracer rubidium-82 (Rb-82). Renal PET with Rb-82 has shown great promise regarding determination of RBF. The purpose of the study is to develop a new and reliable method for determination of RBF based on PET/CT and Rb-82 using a 1-tissue compartment model. To minimize radiation exposure, the input function in the model and the kidneys have to be in the same field of view. Therefore we examined whether the abdominal aorta (AA) is a valid alternative as input function instead of the left ventricular blood pool (LVBP) which is routinely used.

Methods: 10 healthy subjects underwent dynamic PET/CT-scans with Rb-82 as perfusion tracer in two different bed positions. Rb-82 was given as bolus injections. Volumes of interest were placed in the kidneys, LVBP and AA and time activity curves were generated. An input function was derived from both the LVBP and AA. A 1-tissue compartment model was used for estimation of RBF. The K1-parameter represents RBF. K1-values derived from the two different input functions were compared.

Results: The mean K1-value derived from LVBP was 2.14 ± 0.52 ml/min/g and 2.11 ± 0.57 ml/min/g for the right and left kidney respectively. The mean K1-value derived from AA was 2.69 ± 0.40 ml/min/g and 2.77 ± 0.77 ml/min/g for the right and left kidney respectively. For both input functions, the mean K1-value for the right kidney was not

significantly different from the mean K1-value for the left kidney. For LVBP the intra-assay variation coefficient was 14.7% for the right kidney and 12.2% for the left kidney. For AA the intra-assay variation coefficient was 12.7% and 13.2% for the right and left kidney respectively.

Conclusions: Our preliminary results show that the PET-Rb-82 method is feasible for determination of RBF. Use of AA-activity as input function seems to be physiologically most valid because of the direct input to the renal arteries and the derived K1-values are significantly higher than K1-values obtained using activity from LVBP.

Evaluation of Renal Fibrosis Using Elastic Scattering Spectrophotometry (ESS)

Mostafa Belghasem,[2] Ousama A'Amar,[1] Daniel M. Roth,[2] Nkiruka Arinze,[2] Sean Richards,[3] Joshua A. Walker,[2] Jean M. Francis,[3] David J. Salant,[3] Vipul C. Chitalia,[3] Irving J. Bigio.[1] *[1]Boston University, Dorchester, MA; [2]Boston University School of Medicine, Boston, MA; [3]Boston University Medical Center, Boston, MA.*

Background: Interstitial fibrosis and tubular atrophy (IFTA) are hallmarks of progressive CKD. The standard method of assessment requires one or more biopsy cores and semiquantitative measurement by histology using stains such as Masson's trichrome. The method is invasive, labor intensive and fraught with potential sampling error due to the patchy nature of IFTA. We propose an alternative, quantitative, minimally invasive method of fine-needle sampling at several sites using Elastic-Scattering Spectroscopy (ESS). ESS is a broadly applicable method that measures wavelength-dependence of optical scattering probability of tissue and is sensitive to the amount of fibrosis.

Methods: ESS was performed using three animal models (n=5 per model) of renal fibrosis (adenine-induced CKD, unilateral ureteral obstruction (UUO) and a remnant kidney model). The ESS spectrum was obtained using a fiberoptic probe with a 150 μm illumination fiber and a 100μm collection fiber, with measurements recorded from several points in the cortex and the medulla of the kidneys. The spectra were normalized at 650 nm to facilitate comparison of the spectral shapes to the ESS spectra obtained from time = 0 (untreated controls). The ESS spectra were correlated with the amount of fibrosis measured by trichrome staining.

Results: All three models were associated with a rise of BUN and an increase in IFTA. Adenine-induced fibrotic kidneys showed a distinct spectral trend of increased scattering intensity in the ultraviolet region (300-400 nm) compared to normal kidneys. Similar spectral changes were observed in the UUO model, with the degree of spectral change dependent on the time after ligation. A linear correlation was observed between fibrosis as assessed by Trichrome stain and the ESS spectral feature.

Conclusions: The linear correlation for even this small data set is encouraging and bodes well for ESS as a quantitative measure of IFTA. Collectively, these data support further studies to explore ESS as a viable point-of-care technique to detect renal fibrosis quickly, offering the potential for a rapid, quantitative and objective assessment of fibrotic status, overcoming some of the limitations of the current method.

TH-PO748

Stiffness Imaging in Native Kidneys by Magnetic Resonance Elastography: A Feasibility Study

Nayana Patel,[4] Berenice Y. Gitomer,[1] Diana George,[4] Kristen L. Nowak,[3] Michel Chonchol.[4] *[1]Div. Renal Diseases and Hypertension, Aurora, CO; [3]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO; [4]University of Colorado, Aurora, CO.*

Background: Development of kidney fibrosis results in loss of kidney function among patients with chronic kidney disease (CKD). Kidney biopsy is the standard method for fibrosis detection in native or transplanted kidneys and there is not currently a non-invasive technique to detect kidney fibrosis. We undertook a pilot study in healthy individuals of different ages to explore the feasibility of performing magnetic resonance elastography (MRE) to determine the range of stiffness in healthy kidneys.

Methods: Six healthy subjects with eGFR > 60 ml/min/1.73m^2 were included in the study. Kidney imaging was performed on a Siemens 3T MR scanner. Following acquisition of scout images for location of the kidneys, MRE was performed with patients in the prone position using 60Hz frequency with 2 different driver positions. In method 1 driver was placed in the midline overlying the spine just below the ribs and one image of both kidneys at the level of the hilum in the axial plane and one image through the long axis of each kidney obtained in the sagittal plane (3 images). In method 2 the driver was placed off midline on the flank to acquire images in the axial and sagittal planes a total of 4 images. MRE images were processed with multiple regions of interest in analysis for each kidney.

Results: Two male and 4 female subjects with age range 32 – 66 years were included. Kidney stiffness was heterogeneous across both kidneys and between individuals (Table 1). The overall mean stiffness measure for both kidneys together did not differ significantly between method 1 and method 2 (P = 0.4).

Conclusions: MRE of native kidneys was feasible and tolerated by all subjects. Kidney stiffness was heterogeneous across both kidneys. Stiffness measured by either method yielded similar results. However, method 1 requires acquisition of fewer images and does not require repositioning of the driver position thereby shortening scan time.

Understanding the Effects of Haemodialysis on Blood Flow: An Imaging-Mathematical Modeling Study

Sanjay R. Kharche,[2,1] Raanan Marants,[1] Elena Qirjazi,[2] Andrea D. Kassay,[2] Jermiah Joseph,[2] Kierra D. McDougall,[2] Ting Lee,[1] Christopher W. McIntyre.[2,1] *[1]University of Western Ontario, London, ON, Canada; [2]Medicine, Lawson Health Research Institute, London ON, ON, Canada.*

Background: Haemodialysis (HD) is a circulatory stress to organs. The clinical assessment of blood flow (BF) during HD is challenging. We are developing *in silico* tools to permit patient specific prediction of HD effects on BF, to accelerate translation. This study aimed to test the feasibility of creating imaging informed, patient specific simulations of multi-organ perfusion under the stress of HD.

Methods: We reconstructed 3D liver and kidney BF using CT images from a previous study, under both standard and cooled dialysate (DC). Ten patient data sets were analysed. Volumes of each organ were calculated. A binned histogram of blood flow distribution was computed for each case. Patient specific mathematical models of blood flow (Kharche *et al.* Front. Physiol. 2018) based on observed organ shape and BF distributions, known blood vessel morphometry, autoregulation mechanisms, and mathematically optimized spatial BF distribution were successfully generated for further study. Novel texture analysis based on fractal dimension was implemented to quantify BF heterogeneity in the images as well as models.

Results: One 3D reconstructed aorta-liver-kidney composite is shown in Figure 1,A. Histograms of BF (Figure 1, B) show that DC altered BF. In all cases, portal hepatic BF increased markedly due to DC. The volumes of organs were also affected by both dialysis and DC.

Conclusions: The development of patient specific *in silico* models of the multi-organ blood flow consequences of HD appears to be feasible and warrants further study to accurately predict individual treatment responses and optimize treatment parameters.

Funding: Private Foundation Support, Clinical Revenue Support

Quantification of the Effects of a Haemodialysis Patient's Cardiac Ejection Fraction: Towards Patient Specific Risk Prediction

Sanjay R. Kharche,[2,1] Wenyao Xia,[3] Andrea D. Kassay,[2] Jermiah Joseph,[2] Kierra D. McDougall,[2] Terry M. Peters,[3] Christopher W. McIntyre.[2]
[1]University of Western Ontario, London, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada; [3]Robarts Research Institute, London, ON, Canada.

Background: Hemodialysis (HD) patient hearts suffer chronic ischemia and uremia, leading to contractile dysfunction and arrhythmia risk. Although 2D echocardiography is advanced, image quality is a limiting factor. The black box nature of commercial software is a further challenge. To address these concerns, image analysis-computational tools were developed to produce patient specific structural and functional cardiac models to assist therapy individualisation.

Methods: Echo images from 7 patients were acquired from a previous study. The endocardial and epicardial borders were automatically segmented using our new computer codes. Using the endocardial border, 3D left ventricle chambers were reconstructed for each frame using the modified Simpson's rule. Normalised chamber volumes were computed from the 3D geometry. Patient specific geometries were encoded into low parameter oblate spheroid structures to permit future assessment of arrhythmia risk of the uremic hearts.

Results: 3D geometry reconstruction was successfully implemented in all data sets. A 3D endocardial surface encompassing the left ventricle chamber is shown in Fig. 1, A. The variation of left ventricle volume over one heart beat in one patient is shown in Fig. 1, B. HD reduced ejection fractions (avg. 50% to 44%).

Conclusions: Development of our own codes will permit us to customised analysis on a echocardiographic instrument vendor independent basis. The patient specific structural geometries will provide the essential basis for patient specific contractile and arrhythmia simulated assessment as a next generation tool for dialysis therapy optimisation.

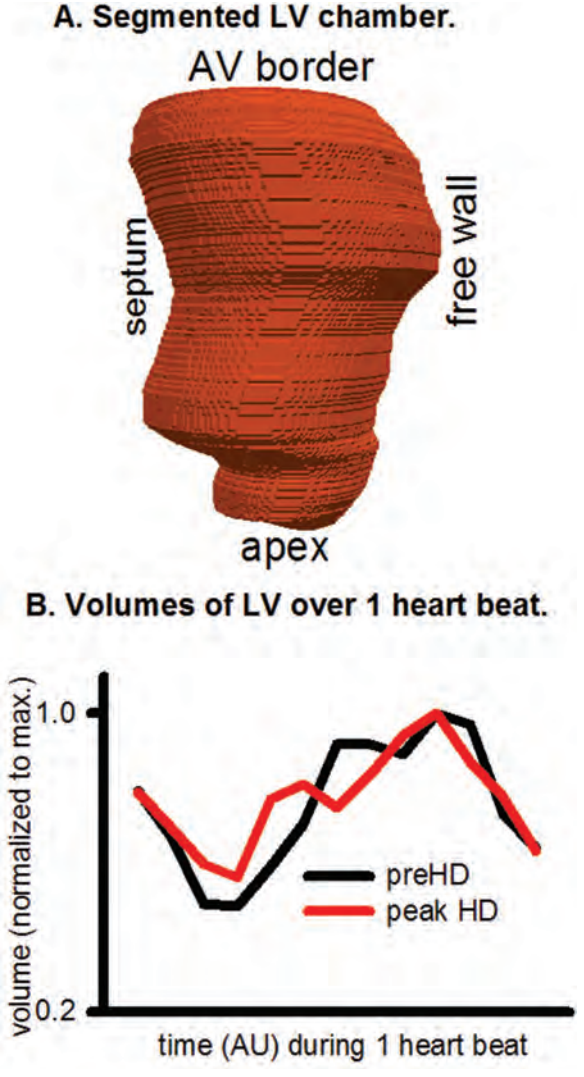

Figure 1. A. Reconstructed 3D LV chamber based on an echo frame. B. LV chamber volume during one heart beat.

Preliminary In Vitro Biocompatibility Test on a New Wearable/Portable Device for Extracorporeal Blood Ultrafiltration

Mauro Neri,[2] Diego Pomare' Montin,[4] Paolo Boscariol,[5] Giovanni Boschetti,[7] Massimo de Cal,[1] Anna Lorenzin,[4] Ilaria Palomba,[6] Dario Richiedei,[5] Alberto Trevisani,[5] Claudio Ronco.[3] *[1]San Bortolo Hospital, Vicenza, Italy;*
[2]University of Padova, Department of Management and Engineering, Vicenza,
Italy; [3]Ospedale "S. Bortolo" AZ. ULSS 6, Vicenza, Italy; [4]IRRIV, Vicenza, Italy; [5]Università degli Studi di Padova, Vicenza, Italy; [6]Free University of Bolzano-Bozen, Bolzano, Italy; [7]University of Padova, Vicenza, Italy.

Background: Development of a portable/wearable device for extracorporeal blood ultrafiltration (UF) would lead to impressive clinical, social and economic benefits for patients suffering of chronic kidney disease. This work presents a new prototype of a wearable device for blood UF, named RAP, able to remove excess fluids from fluid overload patients with chronic kidney disease, and a preliminary *in vitro* test of potential induced cytotoxicity by measuring apoptosis and necrosis in monocytes cell line due to indirect contact with the device.

Methods: The RAP has been developed as a backpack/trolley configuration. This original layout guarantees the best compromise between miniaturization and ergonomics, introducing an original positioning of many components in 3 independent panels:(a) disposable components,(b) non-disposable devices and (c) electronics. The device has been equipped with a power-bank able to last almost 6 hours and a device for remote monitoring. Cytotoxicity test was performed by circulating, through the RAP, complete RPMI medium. Monocytes were incubated for 24h in samples taken after 0', 30', 60'. 180' and 360'.

Results: RAP and its design are shown in Figure 1, where also the non-disposable panel and the disposable one, manufactured with addictive technology, are shown. As shown in Figure 2, no inductions of increased necrosis or apoptosis on monocytes with respect to control appeared during a 6h-treatment.

Conclusions: RAP is a new, innovative wearable device for blood ultrafiltration. Arrangement of components can simplify the preparation of the device. Cytotoxic tests demonstrate no induction of cells necrosis or apoptosis. RAP is now ready for human trial.

TH-PO752

Quantification of Internal Filtration in Hollow Fiber Hemodialyzers with Medium Cut-Off Membrane

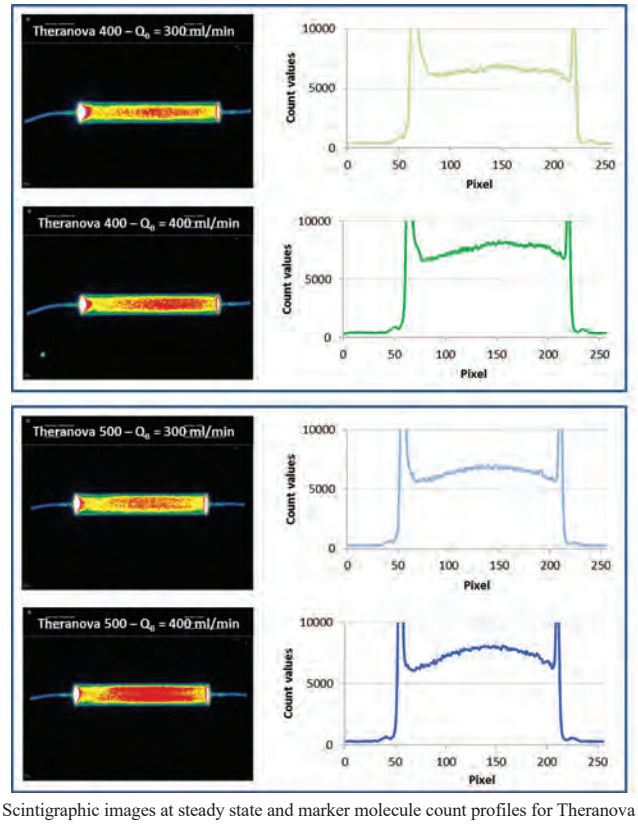
Anna Lorenzin,[1] Mauro Neri,[1] Alessandra Brendolan,[2] Claudio Ronco.[2] *[1]IRRIV, Vicenza, Italy; [2]Nephrology, St Bortolo Hospital, Vicenza, Italy.*

Background: Inadequate removal of molecules between 5 and 50KDa may cause long term complication in chronic hemodialysis. Medium Cut-off (MCO) is a new class of membranes with enhanced sieving properties and negligible albumin loss. MCO membrane allows to perform expanded hemodialysis (HDx), a technique based on high internal filtration (IF). The present study is designed to quantify IF in two MCO dialyzers (Theranova 400 and 500, Baxter, Deerfield, USA) using a nuclear imaging technique previously validated.

Methods: Blood and dialysate compartment pressure drop along with transmembrane pressure, were measured in a closed *in vitro* circuit with human blood (blood flow (Q_B)=300 and 400ml/min; dialysate flow 500ml/min; net ultrafiltration rate 0ml/min). A non-diffusible marker molecule (albumin macro-aggregates labelled with ^{99}Tc metastable) was injected in the blood compartment and nuclear emission was recorded by a gamma camera. Relative variations in concentration of the marker molecule along the length of the filter were used to calculate local cross filtration.

Results: Based on marker concentration profiles, IF was estimated (Figure 1). For Theranova 400, IF were 29.7 and 41.6ml/min for Q_B of 300 and 400ml/min. For Theranova 500, IF were 31.6 and 53.1ml/min for Q_B of 300 and 400ml/min respectively.

Conclusions: MCO membrane provides significant amounts of IF due to the particular combination between hydraulic permeability of the membrane and reduced inner diameter of the fibers. High IF combined with enhanced sieving profile of MCO membrane, leads to improved removal of a wider spectrum of uremia retention molecules in HDx, without requiring complex equipment.



Scintigraphic images at steady state and marker molecule count profiles for Theranova 400 and Theranova 500.

TH-PO753

Direct Hemoperfusion of Protein-Bound Uremic Toxins Using Activated Carbon

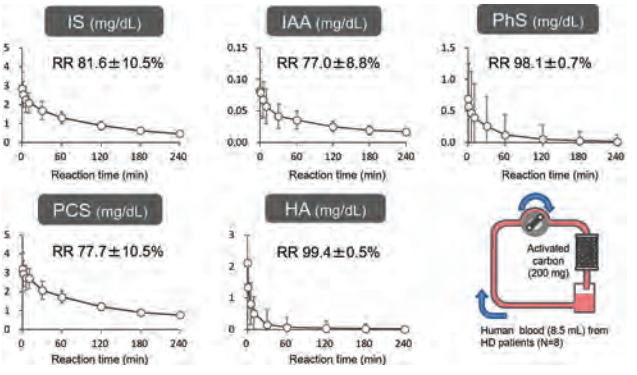
Suguru Yamamoto,[1] Yoshiharu Itoh,[2] Toru Ito,[1] Yoshikatsu Kaneko,[1] Shin Goto,[1] Fumitake Gejyo,[1] Ichiei Narita.[1] *[1]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Kureha Corp., Tokyo, Japan.*

Background: Accumulation of protein-bound uremic toxins (PBUTs) is associated with mortality due to various systemic disorders in patients with CKD, especially those undergoing dialysis. The clinical outcomes of such patients could be improved by removing sufficient quantities of PBUTs; however, conventional dialysis lacks this ability. We examined the efficacy of activated carbon in adsorbing circulating PBUTs via direct hemoperfusion *in vitro*.

Methods: An *in vitro* blood circulating system composed of 6.5-8.5 mL blood circulating around a column containing activated carbon (50, 100, or 200 mg) was constructed. Bovine blood containing PBUTs at the same concentration as that found in the blood of dialysis patients, as well as blood from hemodialysis patients (n = 8) were used. After circulation for the designated amount of time, sera were collected and the levels of PBUTs, such as indoxyl sulfate (IS), p-crecyl sulfate (PCS), indole acetic acid (IAA), phenyl sulfate (PhS), and hippuric acid (HA), were analyzed with mass spectrometry.

Results: Activated carbon decreased bovine blood PBUT level in a dose and time dependent manner (ex. reduction rate: IS 66.4%, 80.1%, and 93.8% following 60-minute circulation in columns containing 50, 100, and 200 mg of activated carbon, respectively). All tested PBUTs were dramatically adsorbed by activated carbon from the blood of patients undergoing hemodialysis [pre vs post 4-hour circulation: IS median 3.01 (IQR: 2.58-3.38) vs 0.43 (0.41-0.51) mg/dL, PCS 3.34 (0.38-5.15) vs. 0.96 (0.12-1.18) mg/dL, IAA 0.073 (0.057-0.080) vs. 0.018 (0.016-0.019) mg/dL, PhS 0.452 (0.240-0.651) vs. 0.008 (0.004-0.012) mg/dL and HA 1.368 (0.874-1.881) vs. 0.006 (0.004-0.013) mg/dL] (Figure).

Conclusions: Activated carbon effectively adsorbed blood PBUTs *in vitro*. Direct hemoperfusion with activated carbon could be a promising strategy to remove circulating PBUTs from the blood of patients with CKD.



TH-PO754

Evaluation of Biocompatibility and Cytotoxic Effects of New Sorbent Cartridges for Blood Hemoperfusion

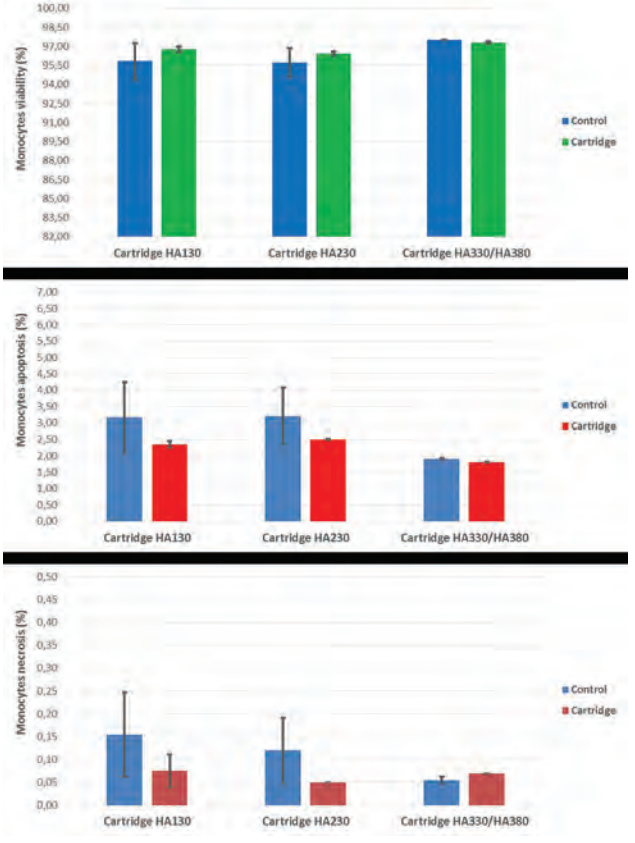
Diego Pomare' Montin,[1] Ghada A. Ankawi,[2,1] Anna Lorenzin,[1,3] Mauro Neri,[3,1] Carlotta Caprara,[1] Claudio Ronco.[4,1] *[1]IRRIV, Vicenza, Italy; [2]UWO, LONDON, ON, Canada; [3]San Bortolo Hospital, Vicenza, Italy; [4]Ospedale "S. Bortolo" AZ. ULSS 6, Vicenza, Italy.*

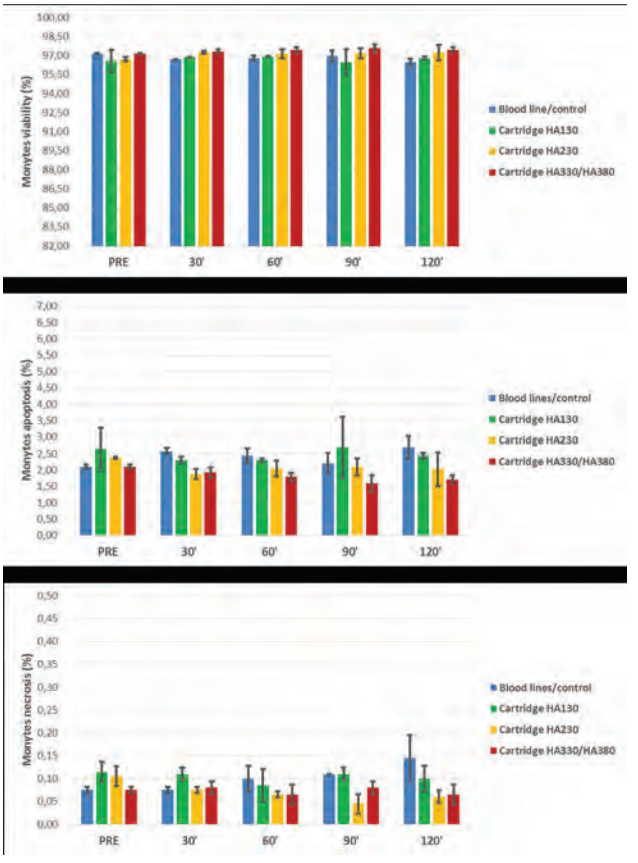
Background: Adsorption cartridges applied in extracorporeal purification therapies, involve direct contact of blood with the sorbent material. The potential induced cytotoxicity is an important issue. The aim of this study was to investigate potential *in vitro* cytotoxic effects of sorbent cartridges HA130, HA230, HA330/380 (Jafron, China) on U937 monocytes.

Methods: Monocytes were exposed to the sorbent material in static and dynamic manners. In static test, cell medium samples were collected after 24 hrs of incubation in the cartridges. In dynamic test, hemoperfusion modality has been carried out and samples at 30, 60, 90 and 120 min were collected.

Results: Compared to control samples, the viability remained the same and there was no evidence of increased necrosis or apoptosis in monocytes exposed to the cartridges in the static tests (fig.1). Similarly, there was no remarkable difference in the viability, apoptosis and necrosis of U937 between each sample and the controls during the dynamic test (fig.2).

Conclusions: Our in vitro testing suggests that HA130, HA230, HA330/380 cartridges possess an optimal level of biocompatibility and their use in HP is not associated with adverse reactions or signs of cytotoxicity.





TH-PO755

Immunomodulation Therapy Improves Cardiac Function in Chronic Heart Failure (CHF)

D. Buffington,[1] A. Westover,[1] L. Lou,[1] C. Pino,[1] K. Johnston,[1] Hani N. Sabbah,[2] H. David Humes.[1,3] *[1]Innovative BioTherapies, Inc., Ann Arbor, MI; [2]Henry Ford Health System, Detroit, MI; [3]University of Michigan Medical School, Ann Arbor, MI.*

Background: Cardiovascular disease is the leading cause of mortality in the US, accounting for 45% of all deaths. CHF and cardiorenal syndrome (CRS) are now understood to be multi-system disease processes involving not only the cardiovascular system but also the renal, neuroendocrine and immune systems. No effective therapy is currently available to treat the most severe subset of CHF patients that have progressed to acute decompensated HF. The **Selective Cytopheric Device (SCD)** is an immuno-regulating, extracorporeal, membrane device targeted to modulate the cardio-depressant effects that are associated with CHF. SCD is a platform technology focused on immunomodulation of the acute and chronic inflammation associated with acute and chronic organ dysfunction. SCD polysulfone fibers selectively sequester and immunomodulate activated systemic leukocytes as they flow through the fiber casing via an extracorporeal circuit and are subsequently released back to the systemic circulation.

Methods: 12 dogs with advanced CHF (ejection fraction (EF) <35%) were used: 5 dogs received sham therapy (No Rx) and 7 dogs received SCD Rx sessions. 6-hour Rx sessions were administered every 48-72 hours for a total of 3 times over a 1-week period. Cardiac parameters were measured at 48 hours, 2 and 4-weeks post. Samples were taken to evaluate of systemic cytokines, leukocyte immune state, spleen density, and macrophage distribution in heart tissue and peritoneal lavage.

Results: EF% significantly increased in SCD Rx animals from 34.0±0.8 to 38.7±1.2% ($p<0.01$) measured at 48 hours post Rx and sustained through 4 weeks at 39.3±1.5% ($p<0.005$). EF% correlated with significant increases in stroke volume, end systolic volume and overall cardiac output. Changes were not observed in control animals. Changes in cardiac parameters correlated to a decrease in systemic leukocyte activation as measured by CD11b, decrease in macrophage density in heart, less pro-inflammatory macrophages in peritoneal lavage, and normalization of spleen cell density.

Conclusions: Pre-clinical study results show SCD Rx for CHF to have clinically relevant therapeutic benefit that was sustained over the 4-week follow-up period. A pilot clinical study is planned to evaluate this approach in severe CRS.

Mussel-Inspired Approach Towards Heparin-Immobilized Cellulose Hydrogel for Selective Removal of Low Density Lipoprotein from Whole Blood

Yupei Li,[1] Baihai Su,[1] Weifeng Zhao,[2] Yuqin Xiong,[1] Ruoxi Liao,[1] Yilin Wang.[2] *[1]Department of Nephrology, West China Hospital, Sichuan University, Chengdu, China; [2]College of Polymer Science & Engineering, Sichuan University, Chengdu, China.*

Background: Cardiovascular disease is the leading cause of death in most countries and is responsible for a significant economic and health care burden. To date, it has been well established that the elevated low density lipoprotein (LDL) level in serum is associated with the development and progression of coronary artery disease, stroke, heart failure and peripheral arterial disease. Although statins exhibit excellent efficacy of lowering LDL in most occasions, they fail to improve the outcomes of patients with familial hypercholesterolemia without LDL apheresis. Dextran sulfate adsorption and heparin-induced extracorporeal LDL precipitation are commercially available at present in the US. However, both of them require initial separation of plasma, making it impossible to remove LDL from whole blood. Therefore, it is of great importance to develop a new LDL absorbent to overcome the drawbacks of the existing techniques.

Methods: Heparin-immobilized cellulose (HeTaCe) hydrogels were fabricated through a mussel-inspired approach. Fourier transform infrared spectroscopy, X-ray photoelectron spectroscopy, thermo-gravimetric analysis were used to characterize the chemical compositions of the hydrogels. The contact activation, complement activation, hemolysis ratio and clotting times of the hydrogels were performed to investigate the blood compatibility. Moreover, we conducted both statical adsorption test and dynamic simplified simulative column adsorption test to evaluate the adsorption clearance, capacity and selectivity of LDL from whole blood *in vitro*.

Results: Characterization of the hydrogels confirmed the successful synthesis of the new absorbent. HeTaCe hydrogels exhibited low hemolysis ratio (<1%), suppressed complement activation and contact activation, mild impact on whole blood and prolonged clotting times. *In vitro*, an ideal adsorption capacity of 79.1 mg/g with a significant clearance of 48.3% from 14.77 to 7.64mmol/L towards LDL was achieved and the dynamic adsorption test further demonstrated a selective adsorption of LDL without a significant reduction of HDL level in a simulative system.

Conclusions: HeTaCe hydrogels may have great potential application in safe and efficient LDL adsorption from whole blood, making it possible to improve the outcomes of patients with high cardiovasular risk.

Arteriovenous Mock Circulation Loop for Enhanced In Vitro Testing of an Implantable Bioartificial Kidney

Parsa Taheri-Tehrani,[1] Jarrett Moyer,[1] William H. Fissell,[2] Sukhveer S. Sandhu,[1] Shuvo Roy.[1] *[1]University of California San Francisco, San Francisco, CA; [2]Vanderbilt University, Nashville, TN.*

Background: Arterial mock circulation loops (MCL) are recognized as an appropriate *in vitro* alternative to cumbersome and cost-intensive animal studies for the development of blood-contacting mechanical circulatory assist devices. In contrast to an arterial pump, a silicon nanopore membrane (SNM)-based bioartificial kidney (BAK) is dependent upon arteriovenous (AV) implantation of a mechanically robust and biocompatible hemofilter. An MCL that mimics arteriovenous shunt physiology (pressure, flow rate and pressure-time curve) is an essential tool for *in vitro* refinement of the BAK. Here, we describe an AV-MCL and a corresponding bond graph mathematical model used to refine physiologic parameters of the physical setup.

Methods: An AV-MCL was prototyped using commercial off-the-shelf pneumatic and hydraulic components. Two check valves (mimicking heart valves), two vertical chambers (mimicking atrium and ventricle), and a pneumatic solenoid valve (mimicking the AV node) were used to reproduce cardiac function. Flow resistors, a compliance chamber, and venous reservoir were used to reproduce the circulatory system. BAK prototypes were mounted in the AV MCL, and surgically implanted in an adult Yucatan pig in separate experiments. The bond graph model was used to adjust the AV-MCL parameters to reproduce the AV physiologic parameters obtained experimentally in the animal.

Results: *In vivo* arterial, graft and venous pressures (mmHg) were 110/69 (mean 86), 78/60 (72), and 13/6 (9), respectively. The MCL yielded arterial, graft, and venous pressures of 110/67 (mean 81), 79/48 (58), and 13/10 (11). The BAK hemofilter blood flow *in vivo* was 1032 mL/min, compared to 940 mL/min in the MCL. The pressure waveforms measured from the AV-MCL were well predicted by the mathematical model.

Conclusions: An AV-MCL was developed with a corresponding bond graph mathematical model, and successfully replicated *in vivo* AV pressure and flow conditions through BAK prototypes. The bond graph model facilitates further refinement of AV-MCL physiologic parameters, such as pressure-time waveforms. Moreover, the MCL is portable, adjustable and reusable, allowing rapid iterative *in vitro* testing of BAK prototypes. This system offers device feedback and refinement of BAK design prior to animal trials.

Unveiling Protein-Protein Interaction of Maleic Acid-Induced AKI Using a Newly Developed Probe

Hugo Y. Lin,[1,2] Shih-Shin Liang.[3] *[1]University of California, Irvine, Irvine, AL; [2]Internal Medicine, Kaohsiung Municipal Ta-Tung Hospital, Kaohsiung, Taiwan; [3]Kaohsiung Medical University, Kaohsiung, Taiwan.*

Background: Protein-Protein Interactions (PPIs) are important regulators of cellular metabolism and functions in physiology and pathology. However, it is challenging to decipher this complex interaction network of proteins in cells. Maleic acid (MA), an industrial raw material, was found to be illegally added as an emulsifier to starch-based food products by manufacturers in Taiwan in 2013. MA has been associated with renal dysfunction in many animal experiments. The goal of this study was to create a chemical probe that could detect MA-associated proteins in human renal proximal tubular cells that might be used for future detection and therapeutic targeting purposes.

Methods: Chemical probes were developed to investigate protein–protein interactions between MA and renal proteins. In the fabrication of these MA probes, we used silicon dioxide (SiO_2) modified with a silanized linker (3-aminopropyl triethoxyslane, APTES) to generate MA with APTES–SiO_2 particles. The probes were then incubated with the cell lysates of normal human kidney cell lines (HK-2) and subjected to MS/MS to identify several MA-related proteins. STITCH database was utilized to create a schematic illustration of the relationship among proteins associated with MA.

Results: We found nucleophosmin, neutral alpha-glucosidase AB, translocon-associated protein subunit alpha, elongation factor 1-gamma, 60S acidic ribosomal protein P0-like, and heat shock protein (HSP 90-alpha and beta) to be MA-associated proteins. These findings suggest that MA-induced acute kidney injury may come about as a result of regulation of protein transportation, cell processing, endoplasmic reticulum stress, ribosomal modulation and protein folding and unfolding.

Conclusions: The probes developed for this study can potentially be used to identify and detect the target proteins and help characterize a network of MA PPIs.

TH-PO759

Glomerular Disease Augments Kidney Accumulation of Synthetic Polymers

Gary Liu,[1] Alexander Prossnitz,[1] Diana G. Eng,[2] Yilong Cheng,[1,3] Jeffrey W. Pippin,[2] Stuart J. Shankland,[2] Suzie Pun.[1] *[1]Bioengineering, University of Washington, Seattle, WA; [2]Medicine, University of Washington, Seattle, WA; [3]Applied Chemistry, Xi'an Jiaotong University, Xi'an, China.*

Background: Targeted polymeric drug carriers can significantly improve the solubility and therapeutic profiles of their drug cargoes, while minimizing side effects and toxicity. Physicochemical properties of the carriers drive organ accumulation and are therefore important in the design process. However, carrier properties such as polymer size and charge that are important for kidney targeting are not well understood or reported. To answer some of these questions, here we tested the effects of polymer charge and molecular weight (MW) on kidney distribution.

Methods: A panel of low-MW (LMW) polymers with fixed MW (~25 kDa) and increasing anionic content (0, 50, 80%) was intravenously injected into mice, and tissue accumulation was quantified after 7 days. A high-MW (HMW), highly anionic (47 kDa, 80% anionic) polymer as well as mice with experimental glomerular disease were used to test the effects of MW and loss of filtration selectivity on polymer distribution.

Results: LMW polymers exhibited increasing kidney accumulation with increasing anionic content, and this trend was statistically significant (p-value < 0.0001). Confocal imaging of kidney sections revealed that polymers accumulated mostly in proximal tubules. Glomerular disease significantly augmented kidney accumulation of LMW 80%, but not HMW 80%, polymers. *In vitro*, LMW 80% polymers did not cause significant changes in viability in cultured proximal tubule cells, and were shown to be uptaken by active endocytosis. Dextran sulfate, a competitor of scavenger receptors, significantly reduced polymer uptake (p-value < 0.0001).

Conclusions: This study revealed important features of polymers that drive kidney accumulation: highly anionic polymers with MW ~25 kDa preferentially accumulate in the kidneys and specifically in proximal tubules, and glomerular disease enhances accumulation. Importantly, these polymers were not cytotoxic *in vitro*, and were uptaken by endocytosis and/or anionic scavenger receptors. These findings establish an important foundation in developing targeted drug carriers for kidney disease applications.

Funding: Other U.S. Government Support

Small-Sized Cationic miRi-PCNPs Selectively Target the Kidney for High-Efficiency Anti-Fibrosis Treatment

Mengbi Zhang,[1] Xinran Geng,[2] Jianqiang Hu,[2] Aiqing Li.[1] *[1]Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Department of Chemistry, School of Chemistry and Chemical Engineering, South China University of Technology, Guangzhuo, China.*

Background: MicroRNA perhaps become an innovative and effective target in the clinical treatment of renal fibrosis. However, the poor stability *in vivo*, low transfection efficacy, inappropriate bio-distribution and rapid renal clearance of miRNA greatly limits its clinical applications. In this study, we produced small-sized cationic miRi-PCNPs with excellent biocompatibility, high cellular uptake efficiency, selectively kidney targeting capacity and high efficiency anti-fibrosis treatment.

Methods: The encapsulation efficiency and drug loading efficiency of miRi was evaluated through measuring UV-vis absorption peak intensity of the bottom solution. The conjugation and stability of the miRi in PCNPs were evaluated through agarose gel electrophoresis. Biocompatibility was assessed using cell counting kit-8, ELISA Kits and HE staining. Transfection efficiency of miRi-PCNPs *in vitro* was evaluated by fluorescence microscopy and flow cytometry. *In-* and *ex-vivo* fluorescence imaging software was used to assess the bio-distribution of PCNPs. Western blot, pathological staining and real-time PCR analyses showed that therapeutic efficiency of miRi-PCNPs on kidney fibrosis in unilateral ureteral obstruction mice.

Results: The image of agarose gel electrophoresis showed that easily degraded miRi was encapsulated in PCNPs and thus prevented from degradation by ribonuclease. Cytotoxicity, immunotoxicity and systemic toxicity assays suggested that PCNPs had excellent biocompatibility. Flow cytometric assessment revealed that high transfection efficacy of miRi-PCNPs. *Ex vivo* fluorescence imaging indicated that PCNPs had kidney-targeting ability. Western blot, pathological staining and real-time PCR analyses showed that therapeutic efficiency of miRi-PCNPs on kidney fibrosis was much higher than bare miRi.

Conclusions: The miRi-PCNPs possessed excellent biocompatibility, high gene transfection efficacy and specific kidney targeting capacity. Therefore, small-sized cationic PCNPs would be a promising drug deliver for RNA, which represents an innovative avenue of designing and developing targeting therapy system for renal fibrosis or other diseases.

TH-PO761

Substrate Elasticity Governs Differentiation of Renal Tubule Cells in Prolonged Culture

Harold D. Love,[2] Mingfang Ao,[2] Seiver K. Jorgensen,[1] Rachel C. Evans,[2] Lindsey Swearingen,[1] Nicholas J. Ferrell,[2] Raymond C. Harris,[2] Leslie S. Gewin,[2] Roy Zent,[4] Shuvo Roy,[3] William H. Fissell.[2] *[1]Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]UCSF, San Francisco, CA; [4]Vanderbilt Medical Center, Nashville, TN.*

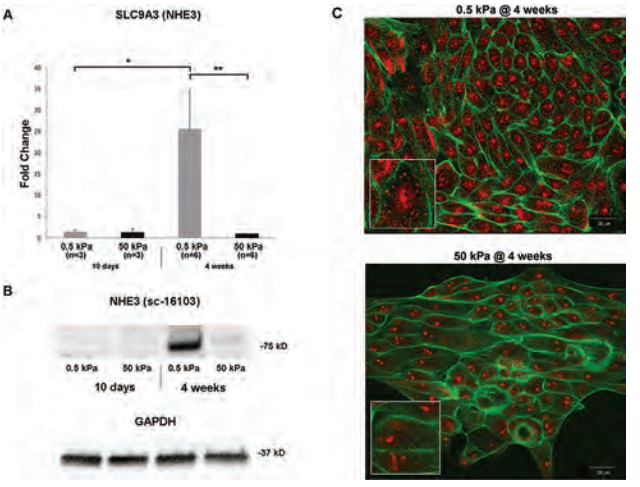
Background: Primary tubule epithelial cells rapidly dedifferentiate in culture and form a flattened epithelium lacking the brush border essential to apicobasal transport. This dedifferentiation undermines the use of cultured cells for drug screening and cell-based therapies. We hypothesized that substrate mechanical properties have a strong influence on differentiation in primary renal cell culture.

Methods: We cultured primary renal tubule cells on polyacrylamide hydrogels of varying elasticity for 2 and 4 weeks. We measured expression of key transporter proteins essential to renal tubule cell function at the transcript and protein level.

Results: Primary tubule cells cultured on soft substrates for two weeks did not show marked differences in transcript or protein levels for NHE3 or AQP1, but after 4 weeks in culture, NHE3 and AQP-1 were increased on 0.5kPa gels compared with 50 kPa gels. Smad2 phosphorylation increased with increasing substrate stiffness, suggesting a role for TGF-β signaling. Indeed, addition of TGF-β to cell culture media abolished the elasticity-dependent increase in NHE3.

Conclusions: These data support the hypothesis that scaffold elasticity is a critical factor in differentiation of renal tubule cells in culture.

Funding: Other NIH Support - NIBIB



NHE3 figure. (A): Expression levels of SLC9A3 (NHE3) were determined by qPCR in primary HREC cultured on soft (0.5 kPa), and stiff (50 kPa) hydrogels. Cells were harvested at short (10 days) and long (28 days) time points. (B): NHE3 protein levels were determined by Western Blot analysis. (C): NHE3 (Red) and F-actin (Green) staining of HREC cells cultured on soft (0.5 kPa) and stiff (50 kPa) hydrogels for 4 weeks. * p=0.003, ** p=0.00002.

TH-PO762

Gentamycin Induced Nephrotoxicity in an Artificial System of the Renal Proximal Tubule

Jan Sradnick,[1] Florian Schmieder,[2] Frank Sonntag,[2] Vladimir T. Todorov,[1] Bernd Hohenstein,[3,1] Christian Hugo.[1] *[1]University Hospital CGC, Technical University Dresden, Dresden, Germany; [2]Fraunhofer Institute for Material and Technology IWS, Dresden, Germany; [3]Nephrological Center Villingen-Schwenningen, Villingen-Schwenningen, Germany.*

Background: Mimicking proximal tubular physiology within cell-based artificial model systems might help to investigate pathophysiology of nephrotoxic drugs such as gentamycin commonly leading to acute kidney injury. We present a model system for transport processes along the proximal tubular barrier (TB).

Methods: Immortalized proximal tubule cells (RPTEC) and blood outgrowth endothelial cells (BOEC) were seeded on a transwell membrane (TW) to build a TB. Barrier function was measured by transepithelial electrical resistance (TEER) of the cellular layers on a daily basis. Gentamycin, moxifloxacin and vehicle control (CTRL) were added over the whole experiment (21 days) to investigate their nephrotoxic potential and disturb TB. The treatment influence on glucose transport through the TB was determined by adding fluorescent d-glucose analog (2-NBDG) to the medium above the RPTEC layer. Fluorescence intensity was measured after 90 min at the opposite TW side. Moreover the inhibition of SGLT2 by dapagliflocin (dapa) and canagliflocin (cana) and vehicle control (contr) during antibiotic treatment was studied.

Results: Moxifloxacin treatment increased TEER (median: 153 Ωcm² vs control 115 Ωcm²), while gentamycin lowered TEER (median: 73 Ωcm²). 2-NBDG concentration increased in the gentamycin treated group (0.79 µg/ml ±0.08 vs control 0.48 µg/ml ±0.07). No differences were found due to moxifloxacin. In CTRLs SGLT2 inhibition led to a reduction of 2-NBDG concentration in BOEC medium (CTRL: 0.5±0.07 µg/ml; ddapa: 0.3 ± 0.03 µg/ml; cana: 0.3 ± 0.06 µg/ml)). In cell systems treated with gentamycin 2-NDBG concentration was reduced following SGLT2 inhibition (contr: 0.8 ±0.09 µg/ml; dapa: 0.5 ±0.02 µg/ml; cana: 0,4 ±0.06 µg/ml). Moxifloxacin had no effect.

Conclusions: In the present study a functional renal proximal tubule cell culture model suitable for drug testing assays was established. TEER and direct 2-NDGB transport were suitable to identify nephrotoxic effects on the TB in vitro. In a next step, this system will be integrated in our established microfluidic system.

TH-PO763

Genome Engineering of Renal Epithelial Cells with Improved Function for an Implantable Artificial Kidney

Matthew H. Wilson,[2] Wentian Luo,[1] Ruth A. Veach,[1] Rick C. Welch,[4] Shuvo Roy,[3] William H. Fissell.[1] *[1]Vanderbilt University Medical center, Nashville, TN; [2]VA Medical Center, Nashville, TN; [3]UCSF, San Francisco, CA; [4]VUMC, Nashville, TN.*

Background: Development of an implantable artificial kidney (IAK) will require renal epithelial cells capable of reabsorption of salt and water. We used genome engineering to bioengineer cells for improved Na^+/H^+ exchange and H_20 reabsorption. The non-viral *piggyBac* transposon system enables genome engineering cells to stably overexpress one or more transgenes simultaneously. The CRISPR/Cas9 system (dCas9-VP64) enables selective endogenous gene upregulation in human cells.

Methods: We generated epitope tagged human sodium hydrogen exchanger 3 (NHE3) and aquaporin-1 (AQP1) cDNA expressing *piggyBac* transposon vectors. *piggyBac* transposase expression enabled stable transposon integration and overexpression of NHE3

or AQP1 in cultured renal epithelial cells. The transposon system was also used to integrate dCas9-VP64 into human kidney cells.

Results: As a proof-of-principle, we generated renal epithelial (MDCK) cells stably expressing a cumate inducible NHE3 and confirmed induced overexpression via Western blot and immunofluorescence analysis. We also generated MDCK cells stably overexpressing AQP1. Cell surface delivery of NHE3 and AQP1 was confirmed using cell surface biotinylation assays. Importantly, MDCK cells expressing AQP1 and cumate inducible NHE3 demonstrated increased cellular transport. We subsequently used a high-throughput flow cytometry analysis to generate a library of MDCK clones with varying expression of AQP1 and NHE3 to determine the best ratios for optimized transport function. We tested and validated various guide RNAs (gRNAs) for targeted upregulation of endogenous AQP1 and NHE3 in human kidney cells at both the mRNA and protein level.

Conclusions: Our results reveal that genome engineering can enable improved cellular transport via stable overexpression of AQP1 and NHE3 in polarized kidney epithelial cells. We are currently attempting to extend these studies to human renal proximal tubular epithelial (RPTEC) cells. Additionally, the dCas9-VP64 system enables upregulation of endogenous AQP1 and NHE3 in human kidney cells. These studies will allow us to determine the optimal genome engineering approach and renal epithelial cell type for maximal function in the IAK.

TH-PO764

Pathophysiology of Proteinuria: Human Serum Increases Proliferation and Markers of AKI in an Ex Vivo Model of the Human Proximal Tubule

Ranita S. Patel,[3] Kevin Lidberg,[4] Catherine K. Yeung,[5,2] Jonathan Himmelfarb,[2,1] Edward J. Kelly.[4,2] *[1]University of Washington, Seattle, WA; [2]Kidney Research Institute, Seattle, WA; [3]Nephrology, Seattle Children's Hospital, Seattle, WA; [4]Pharmaceutics, University of Washington, Seattle, WA; [5]School of Pharmacy, University of Washington, Seattle, WA.*

Background: Proteinuria is a pathological cause for progressive kidney damage. Prolonged exposure to excess glomerular filtered protein may create tubulointerstitial lesions via activation of proinflammatory, proapoptotic, and profibrotic pathways in renal proximal tubular cells[1]. Thus the proximal tubule likely plays an important role in propagating the decline of renal function in proteinuric kidney disease[2].

Methods: Here, we exposed a 3D microphysiological system (MPS) of the human kidney proximal tubule developed in our lab[3] to human serum to explore key functional and structural events that may eventually lead to progressive tubulointerstitial damage. This is a bioengineered platform containing a tubular collagen scaffold that houses human proximal tubule cells. Perfusion setup allows for the delivery of media and experimental solutions, as well as physiological shear stress applied to the cellular tubule.

Results: Treatment with 0.5%, 1%, and 2% human serum for 48 hours led to an increase in kidney injury molecule 1 (KIM-1) concentrations measured from MPS effluents, with an average 3.55 fold increase in the 2% human serum group. The percent of cells expressing the proliferation marker Ki67 dramatically increased with ascending concentrations of human serum (8% in control vs 38% in 2 percent human serum).

Conclusions: These data demonstrate that proximal tubule cells exposed to proteins contained in human serum shed KIM-1 (a urinary biomarker of acute kidney injury) and undergo a burst of proliferation, perhaps as a compensatory mechanism or as an initiative to begin tubular wound healing. Future efforts will include prolonging exposure times, quantifying injury-associated microRNAs, and performing transcriptomic profiling with RNA sequencing to reveal novel biomarkers or pathways involved in proteinuric pathophysiology.

TH-PO765

An In Vivo Vascularization Model for the Implantation of Embryonic Kidneys

Morgan Hamon,[1,3] Peter V. Hauser,[1,2] Lifu Zhao,[4,1] Masaki Nishikawa,[5,3] Hiroshi Kimura,[6] Naomi Yanagawa,[4,1] Norimoto Yanagawa.[1,3] *[1]Greater Los Angeles Veterans Administration, Los Angeles, CA; [2]Integrative Biology and Physiology, University of California Los Angeles, Los Angeles, CA; [3]Department of Medicine, University of California Los Angeles, Los Angeles, CA; [4]Sepulveda Research Corporation, North Hills, CA; [5]GLAVAHS at Sepulveda, North Hills, CA; [6]Tokai University, Hiratsuka, Japan.*

Background: A major obstacle to implantation of *ex vivo* engineered 3D tissues is the incorporation of a functional vascular supply in order to minimize the ischemic injury and support the growth of the new tissue. This may be overcome in an *in vivo* vascularization model where the engineered tissues can be implanted into a pre-vascularized chamber. The main goal of our present study is to design such a vascularization chamber and test its applicability for the implantation of embryonic kidneys.

Methods: The chamber was composed of three polydimethylsiloxane (PDMS) layers: a base layer holding the chamber, a center layer containing the vascularization chamber with an opening on one side to allow the in-growth of blood vessels, and a top layer that closes the chamber. Pre-vascularization of the chamber was achieved by first loading the chamber with collagen I (C), matrigel (M) or matrigel+VEGF (MV), followed by implantation of the chamber between the abdominal aorta and vena cava in a mouse. After the chamber was pre-vascularized, mouse embryonic kidneys were placed onto the chamber. The growth and development of the embryonic kidneys were monitored and analyzed.

Results: We found that endothelial cells and developing vascular networks were detected in the chamber as early as 48h after implantation. Filling the chamber with MV significantly shortened the time required for pre-vascularizaion: 7 days for C loaded chambers, 5 days for M loaded chambers, and 2 days for MV loaded chambers. As compared to non-vascularized chambers, implantation of E12.5 mouse embryonic kidneys to pre-vascularized chambers showed significant increase in size and ureteric branching after 7 days.

Conclusions: We demonstrate in our present study that the *in vivo* vascularization model by using pre-vascularized chamber could be useful for the implantation of embryonic kidneys. Further studies are going on to optimize our system and examine the development and vascularization of the implanted embryonic kidneys.

In Silico Pharmacological Assessment of Nifedipine and Mibefradil in Modulating Action Potential in Guinea Pig Ureter Smooth Muscle Cells

Chitaranjan Mahapatra. *Indian Institute of Technology Bombay, Mumbai, India.*

Background: Urinary stones with higher diameter are unlikely to pass in the ureter in most situations. Activation of muscarinic and adrenergic receptors increases the amplitude of ureter smooth muscle (USM) contractions. Understanding the drug effects with respect to various ion channels offers several possibilities for safety pharmacological assessment. Here our overarching objective is to utilize the computational model to simulate the effects of nifedipine and mibefradil on the USM cell action potential (AP).

Methods: The USM cell is described as an equivalent electrical circuit with a number of variable conductances representing two voltage-gated Ca^{2+} (T - type and L- type) channels, two voltage-gated potassium channels, three calcium-dependent potassium channels. A drug model for nifedipine and mibefradil were simulated by multiplying the maximal conductance of L-type and T-type Ca^{2+} channels with a scaling factor between 0 and 1 to mimic the drug concentration. The maximum conductance value of the L-type and T-type Ca^{2+} channels were set to 0.00006 and 0.00002 mho/cm^2 respectively.

Results: The resting membrane potential (RMP) was set at — 50mV. A current pulse of 2 nA for 50 ms was injected to evoke the AP. The peak amplitude of AP and total inward current were substantially reduced after adding nifedipine by 50% and 100 % of it's control value. Adding mibefradil by 50% of it's control value reduced the peak amplitude of AP and inward current. However, the addition of mibefradil by 100% resulted no AP and zero inward current. The results showed that both L-type and T-type Ca^{2+} channels play important roles in generating APs, although L-type calcium channel is the major contributor to the total inward current. This simulation showed that the activation of more T-type Ca^{2+} channels will cause higher excitability of the USM cell.

Conclusions: Our approach provides a "virtual workbench" for simulating USM cell AP with maximal objectivity and faithfulness with regard to recordings in experiments. This in silico assessment showed that while inhibition of L-type Ca^{2+} channel suppresses or eliminates APs, the RMP is left unaffected. Complete inhibition of T-type Ca^{2+} channel also reduced USM cell excitability. A compound of nifedipine and mibefradil may form a new pharmacological maneuver towards USM cell contraction of high amplitude.

TH-PO767

Extracellular Matrix Stiffening by Sugars: Implications for Diabetic Nephropathy

Snehal Sant, Nicholas J. Ferrell. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Stiffening of the extracellular matrix (ECM) contributes to a number of diseases including cancer and organ fibrosis. Diabetes leads to formation of advanced glycation end products (AGEs) that crosslink the ECM and may lead to increased matrix stiffness. The pathological consequences of ECM stiffening in diabetes are not fully understood and may be a mechanism by which AGEs contribute to disease progression is diabetic nephropathy. The goal of this work was to evaluate the effectiveness of AGE inhibitors in mitigating sugar-induced ECM stiffening of decellularized kidney ECM. AGEs are known to elicit receptor-mediated pathogenic effects that are independent of ECM stiffening. In order to evaluate the specific effects of ECM stiffening, we developed a novel ex vivo model to alter the mechanical properties of the ECM to evaluate effects on tubular epithelial cell function.

Methods: To evaluate the effects of sugar exposure on ECM stiffness, porcine kidney cortex was detergent decellularized and incubated in reducing sugars (glucose and ribose). The elastic modulus of sugar-modified ECM was measured by compression testing in the presence and absence of the AGE inhibitors pyridoxamine and DTPA. To evaluate cellular response to ECM stiffening, decellularized kidney cortical ECM was crosslinked with genipin. Tubular epithelial cells were cultured on genipin stiffened ECM and matrix and growth factor gene expression were analyzed by qRT-PCR.

Results: Sugar incubation resulted in a concentration-dependent increase in ECM stiffness in the presence of both glucose and ribose. Both PM and DTPA reduced ECM stiffening by glucose and ribose, but were most effective in the presence of glucose. Genipin modification of decellularized ECM resulted in a dose-dependent increase in stiffness that was similar to that induced by sugar modification. Tubular epithelial cells grown on genipin modified ECM showed upregulation of collagen IV and connective tissue growth factor gene expression.

Conclusions: These data show that inhibiting AGE formation mitigates sugar-induced ECM stiffening ex vivo. We introduce a method of evaluating cellular response to ECM stiffening by genipin modification of decellularized kidney ECM and show that kidney cells had increased expression of pro-fibrotic genes. These preliminary studies suggest that ECM stiffening may have pathological consequences in diabetic nephropathy.

Cyclosporine Induces Fenestral Injury in Bioengineered Human Kidney Microvessels

Ryan J. Nagao,[1] Shreeram Akilesh,[1] Jeffrey W. Pippin,[1] Edward J. Kelly,[1] Stuart J. Shankland,[1] Jonathan Himmelfarb,[2] Ying Zheng.[1] *[1]University of Washington, Seattle, WA; [2]Kidney Research Institute, Seattle, WA.*

Background: The use of cyclosporine A (CsA), a potent calcineurin inhibitor and immunosuppressant drug, has greatly improved the survival of patients receiving organ transplants, but also frequently results in significant nephrotoxicity. Transplant patients treated with CsA have developed acute kidney injury with arteriolopathy, thrombotic microangiopathy (TMA) and tubulopathy. However, the mechanisms underlying human kidney-specific toxicological sensitivity to CsA are still poorly understood. Thus, there is a need to build human kidney-specific biomimetic models capable of replicating clinical patterns of CsA-induced kidney injury.

Methods: Here, using 2-D culture and bioengineered 3-D microvessels containing human kidney peritubular microvascular endothelial cells (HKMECs), we show CsA exposure at as little as 1 h at 1 µg/mL leads to endothelial injury not observed using human umbilical vein microvascular endothelial cells (HUVECs). We then analyzed clinical biopsies of patients who recieived CsA and expressed TMA for the presence of peritubular capillary dysfunction.

Results: CsA induced dysfunction in HKMECs characterized by the loss of fenestrae, shear stress-related changes in cell morphology, signs of vascular inflammation, erythrocyte adhesion to the luminal surface of the endothelium and extravasation of erythrocytes into the interstitial space, whereas HUVECs were unaffected. CsA disrupted the formation of the fenestral diaphragm protein, PV-1. Vascular endothelial growth factor (VEGF) signaling, which is known to be integral to support fenestrae, was also blocked by CsA, whereas adding VEGF partially protected HKMECs from CsA-induced morphologic changes. Integrated genome regulatory analyses identified key distinctions in the landscapes of HKMECs compared to HUVECs, particularly around genes related to formation and maintenance of fenestrae. Kidney transplant biopsies from patients experiencing CsA toxicity showed a loss of PV-1 and evidence of erythrocyte extravasation which are consistent with changes in our bioengineered kidney 3-D microvessels.

Conclusions: These data demonstrate that CsA directly targets human kidney microvascular endothelial cells, disrupting their fenestral structure and function, and provides novel insights into kidney-specific organotypic mechanisms of CsA-induced microvascular injury.

Platelet Accumulated Stress Modeling Predicts Platelet Activation and Thrombosis

Emily Marsh,[2] Joseph J. Groszek,[7] Phillip E. Williams,[2] David C. Laneve,[6] Mark S. Goodin,[5] Steven G. Goebel,[5] Amanda Buck,[1] Nathan Wright,[3] Danny Bluestein,[4] Rachel C. Forbes,[2] Shuvo Roy,[3] William H. Fissell.[1] *[1]Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]UCSF, San Francisco, CA; [4]Stony Brook University, Stony Brook, NY; [5]SimuTech Group, Hudson, OH; [6]Vanderbilt Medical Center, Brentwood, TN; [7]STERIS, Lakewood, OH.*

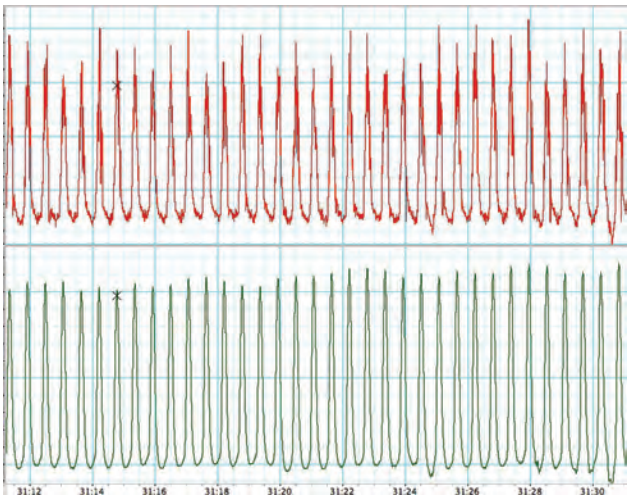
Background: Thrombosis is a dreaded complication in blood-contacting medical devices including implantable artificial kidneys (IAK). Fluid shear stress primes platelets to initiate thrombosis. We compared computational predictions of platelet accumulated stress (PAS), biochemichemical assays of platelet activation, and in vivo thrombosis between two different implanted hemofilter designs.

Methods: Platelet accumulated stress distributions under unsteady flow in two candidate blood conduit designs were predicted using computational fluid dynamics (CFD) tools. Hemofilter catrtridges were machined from polycarbonate and implanted in Class A dogs for 2-7 days without anticoagulation. Platelet activation was measured using a modified prothrombinase assay. Thrombosis was assessed by measuring cyclic variation in blood velocity downstream of a controlled femoral artery lesion.

Results: The two different hemofilter designs gave rise to two distinct histograms of PAS. In some animals, the hemofilter with the larger PAS (A) thombosed almost immediately while the other hemofilter (B) did not. In animals where both cartridges remained patent, platelet stress as measured by prothrombinase activity agreed with CFD predictions. Femoral artery flow was disrupted to a greater extent in animals implanted with hemofilter A than Hemofilter B.

Conclusions: We showed that CFD predicted biochemical measures of platelet activation and propensity to thrombosis in an animal model of an implanted hemofilter. Platelet stress is a useful tool to predict thromboembolic complications in blood contacting medical devices.

Funding: Other NIH Support - NIBIB



Pulsatile flow was comapred between a femoral artery with a standarized trauma (red) and a contralateral control artery (green). Cyclic variations in flow distinct from respiration arise from transient thrombosis at the arterial trauma.

Patient-Friendly Kidney Function Monitoring

Ragwa Elsayed. *San Jose State University, San Francisco, CA.*

Background: Chronic Kidney Disease was ranked the 13th leading cause of Death in 2013. Measuring the creatinine level in blood became an important biomarker to evaluate the kidney performance by filtering the wastes. The objective is to develop an easy low-cost monitoring method of the level of creatinine in blood without visiting a medical facility. It is an alert for individuals to check their kidney functions and communicate with a nephrologist when they suspect a kidney failure in the early stages.

Methods: The project is based on using paper microfluidics technology. A paper strip with alkaline picrate solution produces a colorimetric response upon applying a creatinine sample. 65 different creatinine concentrations were tested to detect the colorimetry change and images were captured using a smart-phone camera inside a light-box. The color intensity feature was extracted using different technqiues. The features extracted were used to train the several machine learning models for testing.

Results: The results show that the best machine learning models that gives the best accurate results and the lowest root mean square error is Nearest Neighbor regression model using the histogram of colors extraction technique.

Conclusions: We proved the feasibility and the reliability of our proposed technique. We are providing individuals with an affordable, reliable, and remote technology to allow rapid and frequent testing of kidney health. Individuals will be able to monitor their kidney functions without visiting a medical facility. So, we can imagine how this method would help patients to get early treatment, adjust medication dose, or monitor the performance of the transplanted kidney. Our approach is using a smart-phone for detection due to the accessibility of a smart-phone to any individual.

Root-mean square error for creatinine concentration prediction 0-4 (mg/dl)

	Linear Regression	Logistic Regression	Nearest Neighbor Regression	Support Vector Machine
REG pixels	0.51312543	0.8106177963	0.3936857306	0.4423723639
Histogram of Gradients	0.766976729	0.9150882978	0.7523593551	0.7856010536
Histogram of Colors	0.2710061214	0.380095781	0.2365255844	0.265266147

Exercise Games to Improve Balance and Mobility in Diabetic Patients Undergoing Hemodialysis: A Randomized Controlled Trial

Fadwa S. Al-Ali,[1] He Zhou,[2] Abdullah Hamad,[1] Rania A. Ibrahim,[1] Talal Talal,[3] Bijan Najafi.[2] *[1]Hamad Medical Corporation, Doha, Qatar; [2]Baylor College of Medicine, HOUSTON, TX; [3]hamad medical corp, Doha, Qatar.*

Background: Poor balance and mobility are serious problems for older adults undergoing hemodialysis (HD). Patients visit HD clinics multiple times a week which provides an optimal opportunity for intervention. We have developed an interactive foot and ankle exercise game (exergame) that can be played during HD to improve mobility and balance.

Methods: Sixty diabetic subjects receiving HD were recruited and randomized into an intervention group (IG: n=29, age=63.3±8years, BMI=31.2±6kg/m2, female=41%) or control group (CG: n=31, age=66.5±10years, BMI=32.3±8kg/m2, female=55%). Both groups underwent a 4-week ankle and foot exercise program (30-min per session, 2 sessions per week) during HD. The IG received exercise via the exergame program (Fig. 1). The CG received foot and ankle exercise without any technology. Balance and mobility were examined at baseline and conclusion of the program.

Results: All IG subjects achieved to complete all exercise tasks. No adverse event were reported. None of the subjects in the IG was dropped out. In balance exam under eyes-open condition, the IG had higher improvement in ankle stability, hip stability, and center of mass sway in response to exercise, when compared with the CG (58% vs. 3%, 47% vs -1%, and 59% vs. -8%, respectively, $p<0.05$). Similar between-group difference was also observed under eyes-closed condition. From mobility standpoint, results suggested 5% reduction in sedentary behavior ($p=0.049$, Cohen's effect size $d=0.70$) and 53% more vigorous activities in the IG compared to the CG in response to exercise.

Conclusions: This study demonstrated feasibility and effectiveness of an innovative game-therapy program to improve balance and mobility in HD patients. The key innovation of this intervention is its practicality to be done during HD, which could address the limitations of prior exercise interventions in HD patients.

TH-PO772

Augmented Foam Sclerotherapy with Laser Treatment for Cystic Disease from In Vitro Sclerosant Screening Platform

Soohyun Jeong, Min hee Park, Kangwon Lee. *Seoul National University, Seoul, Republic of Korea.*

Background: Sclerotherapy has been empirically used in cyst ablation as managemental treatment of polycystic kidney. However valid, clinical reports and research mostly rely on the ex-vivo platform and desultory treatment methods. To standardize the sclerotherapy and minimize the complication of usage of sclerotherapy treatment to cystic disease, in vitro platform from which the sclerosing solution be tested and enhanced sclerosing treatment methods for cyst ablation must be studied.

Methods: The transwell system and collagen embedded cells were used in this study as the in vitro platform. The cellular membrane-disrupting effect was quantitatively measured in vitro by LDH assays which have been not tried before to our knowledge. Screening of sclerosing solution was conducted by measuring LDH level on this system. Photochemical tissue bonding from foam-delivered rose Bengal stains was carried out using 532nm green laser and two-photon laser. Sclerosing effect and degree of inflammation from the augmented foam sclerosant was studied in vivo.

Results: We found that the suggested in vitro platform reflect differential sclerosing properties from different sclerosing material than conventional cell analysis. In this study, we obtained the improved sclerosing foam with greater sclerosing and retention properties. This sclerosant was optimized with polidocanol, glycerol and rose bengal sufficient for cyst ablation and laser-assisted photochemical tissue bonding of the cystic membrane.

Conclusions: To our knowledge, our study is the first in suggesting sclerotherapy with photochemical tissue bonding combined treatment methods, along with the suggested foam sclerosant screening platform. We believe our research would extend possible treatment option for cyst management in polycystic kidney, as well as the promoting the development of safer, better sclerosing materials.

TH-PO773

Prognosis of C1q Nephropathy Is Not Different According to the Presence of Segmental Sclerosis or Nephrotic Proteinuria

Ji Young Ryu,[1] Hyung Eun Son,[1] Ho Jun Chin.[1,2] *[1]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: C1q nephropathy is pathologically defined, however, clinical characteristics and prognosis of it remain poorly understood.

Methods: We collected the clinical and pathologic findings of 6413 adult patients with renal biopsy since 2000. We selected 29 patients followed more than 3 months after renal biopsy among 34 patients diagnosed as C1q nephropathy. We matched age and gender to the patients with FSGS and MCD and analyzed the incidence of ESRD.

Results: In patients with C1q nephropathy, estimated GFR was 83.2± 34.7 (20.1-126.9) ml/min/1.73 m^2 and UPCR was 3.30 ± 4.08 (0.05-18.53) g/g creatinine. Glomerular segmental sclerosis (SS) was present in 14 (48.3 %) patients. Patients with SS had higher level of systolic blood pressure and lower level of eGFR compared to patients without SS (127.0 ± 9.8 vs 114.5 ± 13.0 mmHg, p=0.010, and 67.4± 31.8 vs 98.0 ± 31.3 ml/min/1.73 m^2, p=0.016, respectively). Other findings such as UPCR and pathologic findings except amount of SS were not different between groups. The levels of eGFR and UPCR at 6 months after renal biopsy was not different in C1q patients according to the presence of SS. There were 17.2 % (5/29) incidence of ESRD during 94.2 ± 48.6 months. The most important prognostic factors were the amount of glomerular global sclerosis by Cox's hazard proportional model adjusted by age, gender, eGFR, and pathologic findings. The presence of SS or the level of UPCR at renal biopsy were not the independent risk factors to renal outcome. The renal outcome was worse in C1q nephropathy compared to MCD (0/28), but, similar between C1q nephropathy and FSGS (6/28) (p=0.008 by Log-rank test).

Conclusions: Glomerular global sclerosis is the most important risk factor to the renal outcome rather than glomerular segmental sclerosis or UPCR in C1q nephropathy. The prognosis of C1q nephropathy was similar to that of FSGS and worse than that of MCD.

TH-PO774

Histopathologic and Clinical Outcomes in Idiopathic and Diabetic Nodular Glomerulosclerosis

Mirza M. Baig,[1] Michael T. Eadon,[1] Carrie L. Phillips,[2] Sharon M. Moe,[1] Ranjani N. Moorthi.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Pathology, Indiana University Health, Indianapolis, IN.*

Background: Idiopathic nodular glomerulosclerosis (ING) is a rare form of glomerulopathy with an unclear pathogenesis. The hallmark of this entity is mesangial nodularity in the absence of diabetes mellitus or specific immune deposits on immunofluorescence. We hypothesized that ING and diabetic nephropathy (DN) have distinct histopathological features that explain their pathogenesis.

Methods: From Jan 2001 to Dec 2016, native renal biopsy interpretations were queried from Indiana University Health's electronic database. Natural language processing followed by manual adjudication confirmed 49 cases of ING. Histopathologic features were compared between individuals with ING(N=49) and DN (N=770). Clinical and histopathological features of ING cohort were studied in detail and compared with previous cohorts.

Results: The mean age of ING cohort was 68 y with a Caucasian (73%) and male (55%) predominance. Clinical findings at presentation included renal insufficiency (81%) and nephrotic range proteinuria (53%). 94% had hypertension while 68% had a smoking history. All 49 patients had prominent diffuse mesangial sclerosis with focal or global nodularity. Interstitial fibrosis, tubular atrophy, and arteriosclerosis were present in >90% of patients. Among cases with follow up (N=25, median 616 days), 60% progressed to ESRD, 67% had declining renal function (creatinine increase of 0.5 mg/dL), and 38% died. Between the ING and DN cohorts, the only significant differences in histological findings were the degree of arteriosclerosis and podocyte foot process effacement, which were more prevalent and severe in the diabetic cohort (P<0.001).

Conclusions: In our cohort of ING, we confirmed the close association of hypertension, hyperlipidemia, and smoking observed in prior studies. We found minimal histologic differences reported between patients diagnosed with ING and DN. The histologic similarity of ING and DN glomerular lesions suggests there may be a common pathogenic process that is distinct from the presence or absence of diabetes mellitus. Future longitudinal studies are required to determine the pathogenesis of nodule formation in ING.

TH-PO775

Glomerular Basement Membrane Composition Controls Podocyte Morphology and Downstream Signaling

Franziska Lausecker,[1] Michael J. Randles,[6] Hellyeh Hamidi,[3] Jon Humphries,[1] Adam Byron,[5] Jeffrey H. Miner,[2] Christoph Ballestrem,[1] Roy Zent,[4] Martin J. Humphries,[1] Rachel Lennon.[1] *[1]University of Manchester, Manchester, United Kingdom; [2]Washington University School of Medicine, St. Louis, MO; [3]University of Turku, Turku, Finland; [4]Vanderbilt Medical Center, Nashville, TN; [5]University of Edinburgh, Edinburgh, United Kingdom; [6]The University of Manchester, Chester, United Kingdom.*

Background: Type IV collagen α3,4,5 networks are specific to the basement membranes in the eye, ear and the kidney. Absence of the heterotrimer leads to Alport syndrome, characterized by basement membrane defects and in the glomerulus by podocyte foot process effacement and detachment. Previous studies have shown that podocytes in Alport syndrome are exposed to ectopic matrix ligands as type IV collagen α1,1,2. Here, we investigated how exposure of podocytes to distinct matrix ligands influences molecular signaling events.

Methods: Human podocytes were spread on type IV collagen or laminins (511 or 521), and cellular morphology was assayed using light microscopy. Podocyte adhesion complexes were isolated and we analysed global protein levels on the different ligands using mass spectrometry-based proteomics. We used laser-based micropatterning to restrict cellular morphology and dissect the links between cell geometry and matrix ligand signalling and to determine how these factors regulate intracellular signaling in time and space.

Results: Matrix ligands determined distinct podocyte morphologies: podocytes on type IV collagen were rounded, compared to podocytes on laminin isoforms, which were more elongated. Proteomic analysis revealed ligand-dependent adhesion complex composition, with upregulation of PKCa in laminin-spread podocytes. Ratiometric imaging revealed increased focal adhesion signaling in podocytes spread on type IV collagen, associated with increased Rac1 signaling. Interestingly, when podocytes were restricted to micropatterned laminin circles or collagen IV lines, there was a partial rescue of the focal adhesion-signaling phenotype.

Conclusions: We show that exposure to different basement membrane ligands results in altered downstream signaling and podocyte morphology. Furthermore, we suggest that podocyte morphology controls downstream signaling independently of the basement membrane ligand. Loss of the mature type IV collagen α3,4,5 network exposes podocytes to a range of different matrix ligands. Our data suggest that altered basement membrane composition may contribute to podocyte effacement in Alport syndrome through changes in podocyte morphology and signaling. Rescuing these defects in podocyte morphology could represent a new therapeutic strategy.

TH-PO776

Podocytic Infolding Glomerulopathy: An Indian Case Series

Sree bhushan Raju. *NIMS, Hydrabad, India.*

Background: Several cases of Podocytic infolding glomerulopathy (PIG) has been reported from Japan as a new disease entity since 2008. It is a rare glomerular abnormality seen predominantly among women in associaciation with membranous nephropathy and autoimmune diseases involving glomerular basement membrane (GBM) bubbling visualised by light microscopy (LM), invagination of the podocyte membrane, and the presence of microspheres viewable by electron microscopy (EM). The clinical features and pathogenesis of this condition are still unclear. We reviewed clinical, biochemical, and pathological features of cases of PIG at our institute.

Methods: We retrospectively analysed cases of PIG as per the diagnostic criteria during preceding two years

Results: Seven cases of PIG have been reported from our institute. The mean age of the patients was 48, (43-65) years, and all were men. Both hypertension and diabetes were seen in five, one each had hypertension and diabetes. Four patients had nephrotic range proteinuria and two had insignificant proteinuria. All had increased creatinine with a mean of 4.3mg%. Autoimmune workup and viral markers were negative in all. LM showed diabetic nephropathy (DN) in 5 cases and hypertensive changes in 1 case and secondary FSGS in 1 case. Microspheres were present in all but podocyte infolding was present in 1 and cluster formation of microspheres was found in 3 cases.

Conclusions: PIG in our case series differs from that of Japan in male preponderance and is associated with diabetic nephropathy. The clinical significance of PIG in south Indian population is yet to be elucidated

TH-PO777

Characterizing Renal Involvement in Hermansky-Pudlak Syndrome in a Zebrafish Model

Janina Müller-Deile,[1] Heiko J. Schenk,[1] Patricia A. Schroder,[2] Mario Schiffer.[3] *[1]MHH, Hanover, Germany; [2]Mount Desert Island Biological Laboratory, Salisbury Cove, ME; [3]Hannover Medical School, Hannover, Germany.*

Background: Hermansky-Pudlak Syndrome (HPS) is an autosomal recessive genetic disorder, which is characterized by oculo-cutaneous albinism, a platelet storage pool deficiency as well as a lysosomal accumulation of ceroid lipofuscin. Impaired renal function and proteinuric kidney disease has been reported in some studies but we hypothesize that renal involvement in HPS is underestimated.

Methods: To evaluate proteinuric kidney disease in HPS we used the transgenic zebrafish line Tg(l-fabp:eGFP-DBP). These zebrafish express a fabp-promoter regulated enhanced GFP-labeled vitamin-D-binding-protein that resembles the size of human albumin. The loss of eGFP-DBP from the circulation indicates a dysfunction of the glomerular filtration barrier and can easily be assessed in the eye of the fish. We performed morpholino injection of different HPS isoforms at one to four cell stage of the zebrafish.

Results: Pericardial effusion and yolk sac edema were seen after knockdown of HPS-1, -4 and -5. Knockdown HPS-1 and -5 induced significant of proteinuria at 96 hour post fertilization. To determine whether edema and proteinuria resulted from glomerular defects, we used transmission electron microscopy of the zebrafish pronephros. Intracellular inclusion bodies were mainly seen in podocytes indicating that podocytes are the dominant glomerular cell type effected in HPS. Moreover, podocyte effacement could be detected after knockdown of different HPS isoforms (figure 1).

Conclusions: We established the first animal model to investigate glomerular damage in HPS. Understanding the renal involvement in HPS may allow the use of already existing therapeutic options and could prolong the life expectancy of affected patients.

(figure 1)

TH-PO778

A High-Power View of Renal Pathology of Sickle Cell Disease In Vivo

Balint Der, Janos Peti-Peterdi. *Zilkha Neurogenetic Institute, Keck School of Medicine, University of Southern California, Los Angeles, CA.*

Background: Sickle cell disease (SCD) is commonly associated with chronic kidney disease. In SCD a mutation of the β-globin chain of hemoglobin (Hbb) causes the sickling of red blood cells (RBC). The complexity of renal histopathology in SCD is well recognized, however its pathogenesis is not fully understood. The purpose of this study was to improve the mechanistic understanding of the renal pathology development of SCD by establishing an intravital imaging model of the SCD kidney for the comprehensive, high-power quantitative visualization of renal morphology and function at the single cell and nephron level.

Methods: C57BL/6;129 female mice (5-8 weeks old) homozygous for both $Hbb^{tm2(HBG1,HBB)Tow}$ and $Hba^{tm1(HBA)Tow}$ mutations were used as a model of SCD. High resolution intravital multiphoton microscopy (MPM) of the intact living kidney was performed either in single-session or serial imaging.

Results: Compared to healthy control C57BL/6 mice, SCD mice displayed numerous enlarged superficial glomeruli with robust hyperdynamic vascular pathology and inflammation. Metabolites of hemoglobin degradation typical of the SCD environment (likely bilirubin) were readily detectable as green autofluorescence in the circulating plasma, and accumulated intracellularly in the glomerular mesangium and in tubular segments. Among the normally 'doughnut' shaped RBCs, sickled variants were also visible. Glomerular hyperfiltration was manifested by robustly increased glomerular diameter, and expanded Bowman's space and tubular lumen. However, RBC velocity was decreased in glomerular capillaries, likely due to sickling and the observed numerous microthrombi, and the glomerulus-specific homing of different immune cell populations ($CD3^+$ and $CD44^+$). Albumin-Alexa594 uptake was visible in endothelial cells, podocytes, and proximal tubule cells. Over time, glomerular filtration barrier permeability increased progressively as evidenced by the robust filtration of albumin and 500 kDa dextran to the Bowman's space by 8 weeks of age.

Conclusions: This study successfully performed in vivo MPM imaging of the SCD kidney, and directly visualized the impaired glomerular hemodynamics, endothelial and tubular injury, and chronic inflammation characteristic to SCD. MPM imaging of novel cellular and molecular mechanisms will help to improve our understanding of SCD kidney disease and to identify new targets for future therapeutic development.

Toll Like Receptor 4 Expression in Kidney Biopsies with Adaptive FSGS

Suman Krishna Kotla, Mythili Ghanta. *Internal Medicine / Nephrology, University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Adaptive focal segmental glomerulosclerosis (FSGS) is characterized histologically by glomerulosclerosis with progressive interstitial fibrosis and tubular atrophy (IFTA). This is an important cause of kidney failure in native as well as transplanted kidneys.

Any injury to the native or the transplanted kidney from factors such as chronic reflux, obesity, viral infections, rejection lead to progressive kidney failure which is histologically characterized by adaptive FSGS. Pathogenesis of progressive renal dysfunction in adaptive FSGS remains unclear and hence therapies remain ineffective at present. Toll like receptors are innate immune receptors that recognize molecular patterns of tissue injury termed as damage associated molecular proteins (DAMPs). The activation of this pathway leads to recruitment of inflammatory cells to the areas of injury leading to progressive fibrosis. Since adaptive FSGS is initiated by chronic injury we propose that DAMPs released from the injured kidneys lead to TLR activation and activate sterile inflammation and fibrosis leading to progressive disease.

Methods: Retrospective chart review was performed to identify patients with adaptive FSGS and clinical characteristics were obtained. Archived kidney biopsy slides of these cases were stained for TLR4 utilizing immunohistochemistry

Results: We analyzed expression of TLR4 in the native and transplant kidney biopsies of 8 patients with adaptive FSGS. 3 of the 8 biopsies showed tubular epithelial cell expression of TLR4. Mean Serum Creatinine at the time of biopsy and IFTA scores were higher in the group with TLR4 positive stain compared to the group with negative stain (Serum creatinine 3.7 mg/dl vs 1.16 mg/dl respectively) (IFTA 41% vs 21%).

Conclusions: This study identifies role of TLR4 activation in adaptive FSGS. Biopsies with advanced renal dysfunction expressed TLR4 and TLR4 expression was absent when the renal disease was not advanced. Findings of this study need to be verified in a large sample size.

TH-PO780

Identification of Disease-Relevant MicroRNA-Target Gene Interactions

Christopher L. O'Connor,[1] Jian Shi,[1] Huanqing Zhang,[2] David L. Turner,[2] Markus Bitzer.[1] *[1]Medicine, University of Michigan, Ann Arbor, MI; [2]Biological Chemistry, University of Michigan, Ann Arbor, MI.*

Background: We previously determined that deletion of the miR-21 gene accentuates TGF-β induced, diabetic and aging-associated glomerular disease in mice. Because miRNA-target gene interactions are cell-type and context specific, we used independent methods to identify relevant *in vivo* target gene interactions for miR-21.

Methods: Candidate microRNA target gene interactions for miR-21 were identified by Pearson correlation between mRNA and microRNA abundance in micro-dissected glomeruli from patients undergoing nephrectomy at Michigan Medicine using Affymetrix ST2.1 arrays and small-RNA Illumina-truseq (n=39). Genes differentially expressed in kidney cortex of miR-21 deficient and wildtype mice were determined using Affymetrix ST2.1 arrays (n=8). Presence of microRNA target genes in the RNA-induced silencing complex (RISC) were experimentally identified using PAR-CLIP (photoactivatable ribonucleoside-enhanced crosslinking and immunoprecipitation) and further validated using Bru-seq (bromouridine sequencing) in cultured human podocyte and HK2 cells. Retained candidate miR-21 target genes were further validated in kidney cortex of aged miR-21 deficient and wildtype mice (age 24-28 months; n=24) using qRT-PCR. The relevance of these genes for human pathology and phenotype was determined by association with clinical as well as glomerular and tubulointerstitial morphometric parameters as assessed through routine and immunohistochemical stains and quantitative image analysis in FFPE sections.

Results: 1761 and 1309 genes exhibited significant correlation with miR-21-5p or miR-21-3p ($p<0.05$; FDR<0.05: 10 and 1, respectively). 1728 genes were significantly different between miR-21 WT and KO mouse kidney cortex ($p<0.05$). PAR-CLIP identified 752 and 687 cross-linked binding sites for miR-21-5p and miR-21-3p in 517 and 367 unique genes, respectively. Some genes, including Smad7, exhibited differential targeting by miR-21 in podocytes and HK2-cells, and after exposure to TGF-β. Of these miR-21 target genes, 15 exhibited statistically significant correlation with clinical and morphometric parameters in nephrectomies and two exhibited significant differential expression in kidney cortex of aged miR-21 mutant mice ($p<0.05$).

Conclusions: MicroRNA-target gene interactions are cell-type and context specific and require careful further investigations.

Insertions and Deletions (InDels) in the Non-Translated Human Genome Upstream of ZHX2 Alter ZHX2 mRNA Expression in MCD and FSGS

Sumant S. Chugh,[1] Ranjan Das,[1] Maria Del Nogal Avila,[1] Joubert B. Kharlyngdoh,[1] Hector Donoro blazquez,[1] Eduardo Molina-Jijon,[1] Lionel C. Clement,[1] Camille E. Mace,[1] Carmen Avila-Casado.[2] Glomerular Disease Therapeutics Laboratory *[1]Rush University Medical Center, Chicago, IL; [2]University Health Network, University of Toronto, Toronto, ON, Canada.*

Background: ZHX proteins, especially ZHX2, play a critical role as transcriptional regulators of human and experimental podocyte disease. Multiple groups conducting whole exome sequencing were unable to find significant mutations in these genes in human glomerular disease. We sequenced the genome upstream of ZHX2 and the intronic sequence looking for insertions and deletions that may induce DNA conformational changes, resulting in altered ZHX2 expression.

Methods: The 1.3 million bp region between the beginning of the immediate upstream gene HAS2 and the end of ZHX2 was sequenced in 28 patients with nephrotic syndrome (8 MCD, 2 FSGS tip lesion, 8 FSGS with mutations in slit diaphragm genes, 4 recurrent FSGS,2 recurrent non-HIV collapsing glomerulopathy, and 4 Hodgkin disease with nephrotic syndrome) and 27 healthy controls using Agilent Custom capture and high throughput Illumina sequencing to obtain about 8 million sequences per sample. The Qiagen Biomedical Genomics Workbench software was used to identify InDels > 3 bp and > 20 sequences present exclusively in the patient population. One of the InDels identified was replicated in cultured podocytes using CRISPR Cas9 technology to study changes in ZHX2 expression.

Results: We identified 5 InDels (size range 6 to 67) shared by than one patient and 40 others (size range 4 to 133) present in a single patient. These InDels were absent in controls and the 1000 genomes project. Patients with MCD and FSGS tip lesion had a high percentage of deletions (approximately 80%), whereas those with other forms of FSGS had mostly insertions (approximately 66%). Significance of these indels was verified by inserting one of these indels upstream of ZHX2 in single cell derived immortalized human podocytes by CRISPR-Cas9 approach. Podocytes carrying this InDel developed reduced ZHX2 expression.

Conclusions: Insertions and deletions upstream of the ZHX2 gene are commonly present in patients with MCD and FSGS patients and alter ZHX2 mRNA expression.

TH-PO782

Proteoglycans Play a Major Role in the Charge Selectivity of the Glomerular Barrier

Alina Khramova,[1] Boerje Haraldsson,[2,1] Kerstin Ebefors,[1] Jenny C. Nystrom.[1] *[1]University of Gothenburg, Göteborg, Sweden; [2]Novartis, BASEL, Switzerland.*

Background: The loss of ability to retain macromolecules is a critical step during kidney disease progression. The luminal surface layer of the glomerular capillary endothelium (ESL) is an understudied part of the filtration barrier. The ESL consist of a glycocalyx and an endothelial cell coat, which together form a stagnant mucosal layer – an additional barrier to prevent a leakage of high molecular weight proteins such as albumin.

Methods: In this study, we were guided by basic principles of ion exchange chromatography. In order to elute highly negatively charged proteoglycans of the ESL, we used 1 M NaCl solution (HS). 1 M mannitol (HO) was included to evaluate osmotic effects. A control fraction was eluted with normal saline solution (0,15 M NaCl) (NS). Solutions were introduced intraarterially to rat kidneys under anesthesia *in vivo.* Venous effluent was collected and analyzed using proteomics and mass spectrometry. Immunohistochemistry was used to confirm the presence of identified PGs and the thickness of the glomerular ESL was evaluated using intralipid droplets.

Results: We identified 9 PGs in ESL, for their contribution to the glomerular barrier function (presented in the order of high to low abundance): lumican, glypican-1, syndecan-4, perlecan, podocan, decorin, serglycan, agrin and biglycan. In general, PGs were more abundant in HS samples compare to NS and HO. TEM demonstrated that the glomerular ESL thickness was significantly reduced in HS perfused rats – 28% ($p<0.05$) compared to rats perfused with NS.

Conclusions: ESL itself is formed by PGs, glycosaminoglycans, glycoproteins and soluble proteins and represents a dynamic structure with significant molecular turnover. As a part of molecular sieving system, PGs support the characteristic permselective properties in kidneys by balancing the level of mentioned molecules. Thus molecular composition of the ESL may have a significant impact on local charge alterations which can lead to severe interruptions of the filtration system and, as a result, macromolecular leakage. These findings might be essential for understanding kidney pathology development and protein leakage at a molecular level as well as result in new possible targets for treatment of proteinuria.

TH-PO783

The Role of DDR1 in Podocyte Lipotoxicity and Progression of Alport Syndrome

Jin Ju Kim,[1] Judith T. Molina David,[1] Javier T. Varona Santos,[1] Sandra M. Merscher,[1] Jeffrey H. Miner,[2] Alessia Fornoni.[1] *[1]University of Miami, Miami, FL; [2]Washington University School of Medicine, St. Louis, MO.*

Background: The glomerular basement membrane (GBM) is primarily composed of laminin and Collagen type IV. *De novo* production of the α1 chain of collagen type I (Col I) has been observed mouse models of Alport Syndrome (AS, Col4a3KO). Discoidin domain receptor 1 (DDR1) is a unique receptor tyrosine kinase that is activated by collagens. Deletion of the DDR1 in Col4a3KO mice was shown to improve survival and renal function. However, how DDR1 activation by aberrant collagen production contributes to podocyte injury and proteinuria is poorly understood. I test the hypothesis that aberrant Col I induced podocyte injury via DDR1-dependent lipotoxicity.

Methods: Differentiated human podocytes were serum starved, followed by 18hrs treatment with 50ug/mL Col I (Corning). Following collagen treatments, podocyte lipid content was determined by BODIPY 493/503 and Cell Mask Blue staining. Free Fatty acid (FFA) uptake assessed using a fluorometric free fatty acid uptake kit (abcam). Mice in which exon 5 of a3 chain of collagen type IV is deleted (Col4a3KO), a model for AS, were obtained from the Jackson Laboratory for the determination of kidney cortex DDR1 phosphorylation

Results: DDR1 phosphorylation was increased in kidney cortex from Col4a3KO mice and the degree of DDR1 phosphorylation correlated with blood urine nitrogen (BUN, $R^2=0.7$, $p<0.01$). *In vitro*, DDR1 was phosphorylated by collagen type I (50μg/mL, 18hr) in cultured human podocytes. Increased intracellular lipid accumulation ($p<0.05$), Free fatty acid (FFA) uptake ($p<0.01$) and intracellular triglyceride level ($p<0.01$) were also observed in Col I treated podocytes. DDR1 dominant active (DA) transfected HEK293 cells showed increased expression of CD36, a protein involved in FA uptake, and increased FFA uptake compared to cells transfected with DDR1 WT and dominant negative (DN, $p<0.05$). siRNA knock down of CD36 reduced FFA uptake when compared to scramble siRNA control ($p<0.05$). Col I induced DDR1 activation is associated with podocyte lipotoxicity, FFA

uptake and intracellular lipid droplet deposition. Glomeruli isolated from Col4a3KO mice showed increased lipid content and increased expression of CD36.

Conclusions: Our data suggest that Col I-induced/DDR1-mediated lipotoxicity may represent a novel mechanism leading to podocyte injury in AS.

Novel Parietal Epithelial Cell Subpopulations in FSGS and the Origin of the Glomerular Tip Lesion

Christoph Kuppe,[1] Turgay Saritas,[1] Victor G. Puelles,[2] Bart Smeets,[3] Peter Boor,[1] Mario Schiffer,[7] Agnes B. Fogo,[4] Hermann-Josef Groene,[5] Jürgen Floege,[6] Marcus J. Moeller.[1] Moeller group *[1]University Hospital of RWTH Aachen, Aachen, Germany; [2]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Radboud University Medical Center, Nijmegen, Netherlands; [4]Vanderbilt University Medical Center, Nashville, TN; [5]German Cancer Research Center, Heidelberg, Germany; [6]RWTH University of Aachen, Aachen, Germany; [7]Hannover Medical School, Hannover, Germany.*

Background: Beside the classical flat PECs, proximal tubular epithelial like cells extend onto Bowman's capsule (termed columnar PECs). In addition, a third intermediate PEC subgroup is identified at the junction between the flat and columnar PEC subgroups. Here, we have investigated the potential relevance of these PEC subgroups in focal segmental glomerulosclerosis (FSGS) for the first time.

Methods: The previously described transgenic mouse line PEC-rtTA labeled all three PEC subgroups. To allow lineage-tracing experiments, we identified the inducible Pax8-rtTA mouse line, which labeled specifically the two novel subgroups, columnar and intermediate PECs, but not flat PECs.

Results: In aging Pax8rtTA mice, cell fate mapping showed no evidence for significant transdifferentiation from flat PECs to columnar or intermediate PECs or vice versa. In glomerular disease (rapidly progressive glomerulonephritis, and FSGS), columnar PECs transitioned in part into the intermediate PEC phenotype. Intermediate PECs preferentially expressed activation markers CD44 and Ki-67, suggesting that this subgroup of PECs is activated more easily than the classical flat PECs. In murine FSGS, columnar and intermediate PECs formed sclerotic lesions contributing more than half of the cells. In FSGS patients, cells forming the tip lesions expressed markers of intermediate PECs.

Conclusions: In summary, columnar PECs acquire a transient phenotype termed intermediate PECs, which is more prone to cellular activation and proliferation compared to the classical flat PECs. Both novel PEC subgroups showed the capacity to form sclerotic lesions. We propose that in human FSGS patients tip lesions originate from this novel subgroup of PECs, which is located close to the tubular outlet.

Isolation of Functional Podocytes from Urine of Alport Patients and Establishment of a Kidney Glomerulus Chip

Benedetta Bussolati,[1] Corinne Iampietro,[2] Linda Bellucci,[2] Fanny O. Arcolino,[3] Elena N. Levtchenko.[4] *[1]University of Torino, Torino, Italy; [2]Universita' degli studi di Torino, Turin, Italy; [3]KU Leuven, Leuven, Belgium; [4]University Hospitals Leuven, Herent, Belgium.*

Background: Alport syndrome (AS) is a genetic disorder characterized by mutations in genes of collagen IV α3α4α5 network. In AS patients, podocyte loss starts at birth and results in progressive reduction in podocyte number per glomerulus with time, correlating with renal damage. However, data on the phenotypic characteristics of human AS podocytes are currently limited. Our goal was to set up a novel human *in vitro* model representing the functional and molecular alterations typical of human AS glomerulus.

Methods: We generated conditionally immortalized podocytes from urine of three different patients (aged 16.5 ± 5.5 years) with Alport syndrome (AS podocytes). Patient 1 showed mutation in Col4α3 gene, while Patient 2 and Patient 3 were mutated in Col4α5 gene in heterozygosity and in hemizygosity, respectively. AS podocytes were analyzed for specific podocyte markers by RT-PCR and Western Blot and release of collagen IV chains by ELISA. Podocyte motility was tested in a wound-healing assay. We generated a kidney glomerulus chip using primary human glomerular endothelial cells and control or AS podocytes using a millifluidic device for continuous perfusion of co-culture. Passage of FITC-labeled albumin and inulin was measured by fluorimeter.

Results: Podocytes were immortalized with temperature-sensitive SV40T and telomerase reverse transcriptase. Cell showed growth at 33°C (permissive condition) and differentiation at 37°C, with expression of typical podocyte markers. Levels of nephrin, but not of podocin or synaptopodin, were significantly reduced in respect to control podocytes. Significant reduction of specific collagen IV chains were detected, confirm specific functional alterations. AS podocytes had significantly reduced motility in respect to control podocytes. Moreover, when co-cultured with human glomerular endothelial cells in an organ-on-a-chip millifluidic device, AS podocytes presented increased permeability.

Conclusions: In conclusion, we generated Alport podocytes and identified specific molecular and functional alterations. Moreover, we developed a human Alport glomerulus-on-a-chip that replicates kidney disease phenotype in vitro. This will be pivotal to test pharmacological approaches for glomerular alterations in Alport disease.

β2-Adrenergic Receptor Stimulation Accelerates Podocyte Recovery from Injury Through Increased Mitochondrial Biogenesis

Ehtesham Arif,[1] Ashish K. Solanki,[1] Pankaj Srivastava,[1] Judit Megyesi,[3] Michael G. Janech,[1] Kenneth Kwon,[1] Justin B. Collier,[1] Rick G. Schnellmann,[4] Deepak Nihalani.[1] *[1]Medical University of South Carolina, Charleston, SC; [3]University of Arkansas for Medical Science, Little Rock, AR; [4]University of Arizona, Tucson, AZ.*

Background: Mitochondrial biogenesis (MB) is an adaptive response required to meet the metabolic and energy demand during acute injury to various organs, including kidney suggesting that MB plays a central role in cellular recovery from injury. In this report, we demonstrate that β2-AR mediated MB accelerates the recovery of podocytes from injury.

Methods: RNA-Sequencing of inured podocytes was performed to identify differential gene expression of mitochondrial genes. Oxygen consumption rate in response to β2-AR activation was measured using sea-horse approach. Effect of β2-AR agonist formoterol on restoring injury-induced loss of actin cytoskeleton organization and localization of slit-diaphragm protein Neph1 was analyzed using confocal microscopy. Additionally, formoterol was used to stimulate β2-AR in mice and determine its ability to restore the loss of glomerular filtration function. The histological, ultrastructural and immunostaining analysis of kidney sections was performed to assess structural and molecular changes in treated mice kidneys. MtDNA copy number was estimated through the qPCR analysis.

Results: Injury induced significant upregulation of β2-AR along with PGC-1α and several key components of the mitochondrial ETC. The activation of β2-AR by formoterol showed remarkable restoration of injury-induced changes in actin cytoskeleton organization and loss of Neph1 at the podocyte cell membrane. Importantly, in a mouse model of NTS-induced glomerulonephritis, post NTS-injury when glomerular dysfunction was established, treatment with β2-AR agonist formoterol accelerated the recovery of glomerular function by reducing proteinuria and restoring kidney pathology. Immunoblotting and qPCR analysis showed that multiple proteins of the ETC were elevated and glomerular expression of the MB marker PGC-1α was restored. mtDNA copy number was significantly higher in mice treated with β2-AR agonist formoterol. Additionally, β2-AR knockdown in cultured podocytes significantly reduced mtDNA copy number and increased podocytes susceptibility to glomerular injury.

Conclusions: Overall, these results reveal β2-AR stimulation as a critical event required for podocyte recovery and identifies β2-AR agonist as a novel therapeutic target for treating podocytopathies.

TH-PO787

MAD2B-Medicated Cell Cycle Re-Entry of Podocytes Is Involved in the Pathogenesis of FSGS

Dian Bao, Hua Su, Chun Zhang. *Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

Background: Mitotic spindle assembly checkpoint protein 2 (MAD2B), an APC/C inhibitor, plays a pivotal role in cell cycle control. Previously, we reported that upregulation of MAD2B is involved in several renal diseases. However, the role and mechanism of MAD2B in the pathogenesis of focal segmental glomerulosclerosis (FSGS) is not known. In this study, we aimed to explore the role and mechanism of MAD2B in regulation podocyte cell cycle re-entry during FSGS.

Methods: Mouse FSGS model and conditionally immortalized human podocytes (HPCs) under puromycin aminonucleoside (PAN) treatment was utilized. Expression of MAD2B, APC/C complex regulatory molecules Cdh1, as well as its substrates cyclinB1, skp2, p27 and cyclinE1 was detected by western blot and immunohistochemistry. The cell cycle was analyzed by flow cytometry. Ki-67 and p-H3 expression was assessed by western blot and immunofluorescence. Knockdown of MAD2B was carried out by lentiviral shRNA transfection. Ku55933, a specific inhibitor of ATM kinase, was utilized. And PYR-41 was applied to interfere ubiquitination. CoIP was performed to assess the interaction between ATM and MAD2B.

Results: Comparing to control mice, the level of MAD2B in the glomeruli of FSGS mice is elevated dramatically. In PAN-treated HPCs, MAD2B deficiency attenuated the upregulation of p-H3, cyclinB1 and reversed Cdh1 reduction, which was companied by less cells staying in S-stage. Furthermore, pharmacological interference of ATM kinase activity in vitro ameliorated the accumulation of MAD2B with the less expression of p-H3 and Ki67 and the preservation of podocyte function presenting as increased podocin and CD2AP abundance. Finally, by using inhibitor targeting ubiquitinaton abolished the ATM kinase-mediated MAD2B regulation and subsequent cell cycle re-entry of podocytes, both in vitro and in vivo.

Conclusions: Overexpression of MAD2B is involved in the cell cycle re-entry and podocyte injury during FSGS, while ATM kinase-mediated posttranslational modification, especially ubiquitination is the potential upstream mechanism for MAD2B regulation.

TH-PO788

Characterizing Podocyte Cell Cultures and Genetic Markers of Podocyte Maturity

Thomas Soare, Wei Zhang, Amy D. Westerling-Bui, Hien G. Hoang, Adam Tebbe, Liron Walsh, Peter H. Mundel, Thomas T. Tibbitts. *Goldfinch Bio, Cambridge, MA.*

Background: Podocytes are terminally differentiated cells that are vital to kidney function. Injury and loss of these cells leads to the presence of protein in the urine, scarring of the kidney, and ultimately renal failure. Conditionally-immortalized differentiated podocytes provide an in vitro model to test hypotheses regarding mechanisms of disease and responses to treatment. However, podocytes in culture lack slit diaphragms and may lack expression of certain podocyte-specific proteins, leading to doubts about maturation of cultured podocytes. Objective: To assess cultured podocytes for maturity, we characterized transcriptomic changes of podocyte differentiation at the single-cell resolution.

Methods: Undifferentiated and differentiated mouse podocytes were disassociated, prepped with a methanol fixation protocol (10X Genomics), and sequenced on an Illumina HiSeq machine (26x40). To assess transcriptomic changes associated with differentiation and passage number, cells were clustered with principal component analysis (PCA) and visualized with t-Distributed Stochastic Neighbor Embedding (tSNE). Cell clusters were labeled by visual inspection of expression of published cell-type specific markers. We leveraged publicly-available scRNAseq data of mouse kidney to identify differentially expressed genes associated with podocyte maturation and to infer the trajectory of differentiation along the podocyte lineage.

Results: We analyzed 1.8e9 reads in 17467 cells, identifying marker genes expressed in differentiated mouse podocytes. Differentiated podocytes in culture expressed markers of S-shaped bodies/early podocytes (Col4a1, Col4a2, Col4a5, Pax2) as well as markers of mature podocytes (Synpo, Podxl, Nupr1, Plce1, Foxd1). Other markers of mature podocytes were not expressed in cultured podocytes (Wt1, Nphs1, Nphs2, Col4a3, Col4a4).

Conclusions: Though differentiated podocytes in culture share transcriptomic signatures with mature podocytes in vivo, important differences remain. Future work will continue to differentiate mature mouse podocytes in culture as well as mature podocytes in human kidney organoids. Podocytes are critical to healthy kidney function. A robust in vitro model of mature podocytes is vital to assessing mechanisms of kidney disease and responses to treatment.

TH-PO789

Involvement of Alpha-Actinin-4 in Focal Adhesion Signaling in Podocytes

Hsiao-Hui Lee. *National Yang-Ming University, Taipei, Taiwan.*

Background: Podocytes are specialized epithelial cells that cover the outer surfaces of glomerular capillaries. They adhere tightly to the glomerular basement membrane and elaborate foot processes to form slit diaphragm for plasma ultrafiltration. Previously, we found that alpha-actinin-4 facilities the recruitment of Shp2 at focal adhesions (FA) that promotes RhoA/ROCK signaling for actomyosin contractility in cells response to matrix rigidity. In this study, we aim to investigate the role of alpha-actinin-4 in controlling cellular tension by focal adhesion signaling in podocytes.

Methods: A mouse temperature-inducible podocyte line was used as a cell model, and the alpha-actinin-4 gene, ACTN4, was knockout by CRISPR/Cas9 method to study its role in the regulation of Shp2 and ROCKII activation.

Results: Differentiated podocytes exhibited matured FAs and stress fibers accompany with hyperactivation of Shp2 and ROCKII that were sensitive to the puromycin aminonucleside-induced podocyte injury. We found that ACTN4 deficiency abolished adhesion-mediated Shp2 and ROCKII activation in podocytes. By Shp2 FRET biosensor, we also demonstrated that alpha-actinin-4 is important for Shp2 activation. Inhibition of Shp2 activity significantly reduced ROCKII activation, FA and stress fiber formation that resulted in protein leakage during filtration.

Conclusions: Our results suggest that alpha-actinin-4 is required for adhesion-mediated Shp2 activation. It facilitates ROCK-mediated actomyosin contractility for strengthening cell adhesion and cytoskeletal architecture those are crucial for podocyte filtration function.

Gut Microbial Metabolite Butyrate Protects Podocytes from Damage Through Epigenetic-Mediated Mechanisms

Raphael F. Felizardo,[1,2] Danilo C. Almeida,[1] Vinicius Andrade-Oliveira,[2] Rafael L. Pereira,[3] Ingrid K. Watanabe,[1] Niels O. Camara.[1,2] *[1]Federal University of São Paulo, São Paulo, Brazil; [2]University of São Paulo, São Paulo, Brazil; [3]Universidade Federal do Paraná, Curitiba, Brazil.*

Background: Chronic Kidney Disease (CKD) is characterized by gradual impairment of renal function over a period of months or years leading to permanent kidney failure. The damages or loss of podocytes, specialized cells involved on filtration process, stand as one of the most important causes that lead to a CKD. The literature comprises a large number of experimental attempts that focus on mitigating the damage to the podocytes. In recent years, many studies point to the gut microbiota as a modulator of intestinal and extraintestinal diseases through the generation of short chain fatty acids (SCFA). It is already known that chronic kidney patients have an imbalanced gut microbiota and lower production of SCFA. Thus, we have explored the protective role of butyrate, an AGCC able to regulate epigenetic processes during the progression of experimental glomerulopathy induced by doxorubicin.

Methods: Wild type mice were induced to develop glomerulopathy by a single dose of doxorubicin and treated with butyrate.

Results: Wild type mice treated with butyrate showed improvement of renal function, associated to a preserved podocyte layer in the glomerular basement membrane and reduction of pro-inflammatory and pro-fibrotic markers in the kidneys. Particularly, butyrate modulated the activity of enzymes involved on epigenetic modifications in the kidneys and changed the levels of histone markers (H3K9Ac, H3K4me3 and H3K9me3) in the promoter region of the genes encoding synaptopodin, podocin and NEPH-1 in podocytes. Concomitantly, treatment with butyrate was associated with the regulations of small GTPases activity Rac1 and Cdc42 and maintenance of the organization of actin filaments in the podocytes grown *in vitro*.

Conclusions: Our results demonstrate that butyrate exerts relevant effects on podocyte homeostasis during experimental nephropathy through epigenetic mediated mechanisms.

TH-PO791

Anti-PLA2R Modulation of Human Podocytes: An In Vitro Model to Investigate the Glomerular Basement Membrane (GBM) in Membranous Nephropathy (MN)

Maryline Fresquet,[1] Paul E. Brenchley,[2] Rachel Lennon.[1] *[1]University of Manchester, Manchester, United Kingdom; [2]Manchester Royal Infirmary, Manchester, United Kingdom.*

Background: 80% of MN patients have IgG autoantibodies to the phospholipase A2 receptor (PLA2R) expressed on podocytes. IgG-PLA2R immune complexes (IC) deposit in the GBM which over time shows expansion with associated proteinuria and consequent nephrotic syndrome. “Spikes” seen on silver stained sections represent formation of new GBM matrix between the deposits. How anti-PLA2R modulates podocyte, IC accumulation in the GBM and the molecular processes that control this GBM dysregulation remain unclear. **Hypothesis:** Anti-PLA2R treatment of podocytes *in vitro* will alter cell signaling and matrix composition/deposition.

Methods: In order to identify pathways involved in extracellular matrix (ECM) compositional changes in MN, we performed RNA sequencing and mass spectrometry (MS) analysis. Differentiated human podocytes over-expressing PLA2R were treated with protein G purified human anti-PLA2R from 10min up to 24h. Total RNA was sequenced and differential gene expression analysis was performed between the treated and control groups ($P<0.05$). For the MS experiment, podocytes were daily challenged with anti-PLA2R over 7 days. Cells were denuded and the deposited matrix analysed. Identified proteins were integrated with the human matrisome database and peptides quantified using Maxquant software.

Results: TGFβ and Hippo signaling pathways were upregulated in the treated podocytes. EGR1, a transcription regulator of target genes involved in inflammatory and tissue damage processes was significantly increased (11fold) 1 hour post treatment. CTGF and CYR61 genes were also upregulated (6 and 3fold) suggesting activation of the YAP/TAZ pathway, component of the Hippo cascade. This pathway maintains podocytes homeostasis, integrity of the GBM and increases expression of matrix genes. Preliminary MS data of the treated podocytes ECM revealed a decrease in laminin and collagen proteins and an increase in ECM regulators and proteoglycans.

Conclusions: Anti-PLA2R can modulate podocyte matrix production *in vitro*. Our study revealed an early activation of YAP/TAZ pathway in cultured podocytes when treated with anti-PLA2R and a decrease in the main proteins of the GBM at a later stage. Candidate pathways will need to be further validated in order to decipher the mechanism of GBM organisation and remodelling in MN.

TH-PO792

Single Glomerular Proteomes Connect Morphology and Function in Proteinuric Kidney Disease

Markus M. Rinschen. *CECAD, Cologne, Germany.*

Background: Kidney diseases are frequently heterogenous and affect different glomeruli to different extents.

Methods: We use ultrasensitive sample preparation combined with quantitative targeted and untargeted proteomics of single glomeruli to unravel functional co-expression modules in glomerular populations. We analyze microdissected glomeruli of three animal models

Results: In single glomeruli from three different rodent models of sclerotic glomerular disease, we identified a coherent protein expression module consisting of extracellular matrix protein deposition (reflecting glomerular sclerosis), glomerular albumin (reflecting proteinuria) and LAMP1, a lysosomal protein. This module was associated with a loss of podocyte marker proteins while genetic ablation of LAMP1-correlated lysosomal proteases could ameliorate glomerular damage in vivo. Furthermore, proteomic analyses of individual glomeruli from patients with genetic sclerotic and non-sclerotic proteinuric diseases revealed increased abundance of lysosomal proteins, in combination with a decreased abundance of mutated gene products.

Conclusions: Single glomerular proteomes connect morphology and function in proteinuric kidney disease. Altered protein homeostasis (proteostasis) is a conserved key mechanism in proteinuric kidney diseases. Moreover, our technology can capture intra-individual variability in diseases of the kidney and other tissues at a sub-biopsy scale.

Funding: Government Support - Non-U.S.

TH-PO793

A Multi-layered Quantitative In Vivo Expression Atlas of the Podocyte Unravels Kidney Disease Candidate Genes

Markus M. Rinschen,[1,2] Florian Grahammer,[3] Thomas Benzing,[4] Tobias B. Huber.[5] *[1]CECAD, Cologne, Germany; [2]The Scripps Research Institute, San Diego, CA; [3]University Hospital Hamburg-Eppendorf, Hamburg, Germany; [4]University of Cologne, Köln, Germany; [5]University Medical Center Hamburg, Hamburg, Germany.*

Background: Damage to and loss of glomerular podocytes has been identified as the culprit lesion in progressive kidney diseases. The molecular identity of podocytes is currently not known.

Methods: We combine deep mass spectrometry-based proteomics with mRNA sequencing, bioinformatics, and hypothesis-driven studies to provide a comprehensive and quantitative map of mammalian podocytes

Results: The analyses identified unanticipated signaling pathways in podocytes. Comparison of the in vivo datasets with proteomics data from podocyte cell cultures showed a limited value of available cell culture models. Moreover, in vivo stable isotope labeling by amino acids uncovered surprisingly rapid synthesis of mitochondrial proteins under steady-state conditions that was perturbed under autophagy-deficient, disease-susceptible conditions. Integration of acquired omics dimensions suggested FARP1 as a candidate essential for podocyte function, which could be substantiated by genetic analysis in humans and knockdown experiments in zebrafish. FARP1 is a potentially mechanosensitive proteins that links the actin cytoskeleton to the membrane.

Conclusions: This work exemplifies how the integration of multi-omics datasets can identify a framework of cell-type-specific features relevant for organ health and disease.

TH-PO794

Integrative Computational Characterization of Membranous Nephropathy from Genome-Wide Transcriptome Profiles

Rachel S. Sealfon,[1] Laura H. Mariani,[2] Viji Nair,[2] Julien Funk,[1] Aaron Wong,[1] Carmen Avila-Casado,[3] Olga Troyanskaya,[1,4] Matthias Kretzler,[2] Laurence H. Beck.[5] *[1]Flatiron Institute, New York, NY; [2]University of Michigan, Ann Arbor, MI; [3]University Health Network, University of Toronto, Toronto, ON, Canada; [4]Princeton University, Princeton, NJ; [5]Boston University Medical Center, Boston, MA.*

Background: Genome-wide expression data from kidney tissue of patients with nephrotic syndrome provide an opportunity to elucidate mechanisms of injury specific to membranous nephropathy (MN). NEPTUNE and ERCB are prospective, multicenter cohort studies of patients with kidney disease profiled for whole-genome transcriptomes from microdissected biopsy tissue. These datasets provide rich, complementary resources to study the molecular characteristics of MN.

Methods: We examine whole-genome expression profiles of patients with MN and with other causes of nephrotic syndrome (e.g. FSGS, MCD, IgAN) from the NEPTUNE and ERCB cohorts. We construct machine learning classifiers to distinguish patients with each disease based on gene expression and evaluate performance using five-fold crossvalidation. Using Significance Analysis of Microarrays, we identify genes differentially expressed in MN and common to both cohorts. To identify functional modules within the MN-specific gene set, we perform community clustering of these genes in a kidney functional network which integrates thousands of transcriptome-wide assays using tissue-specific regularized Bayesian integration (Greene et al. 2015; Krishnan et al. 2016).

Results: We find that glomerular gene expression can separate patients with MN from other nephrotic patients with high accuracy (AUC=0.9). The genes most predictive of MN diagnosis in NEPTUNE are also differentially expressed in MN patients in the independent ERCB cohort. We identify 220 genes differentially expressed in MN patients common to both cohorts. These genes are enriched in multiple Gene Ontology terms, including anatomical structure morphogenesis, biological adhesion, and basement membrane, and also significantly enriched in homologs of mouse podocyte markers (Park et al. 2018). Clustering the MN-specific genes in a kidney functional network uncovers multiple modules, including gene clusters enriched in ion transport and the extracellular matrix.

Conclusions: This work identifies an expression profile specific to MN patients, enriched in podocyte-specific genes, and shared across patients in two independent cohorts. Such work may facilitate transcriptome-based disease classification, insight into disease pathophysiology, and targeted therapeutics.

Urinary Lipidomics: A New Biomarker in FSGS

Elif Erkan,[1] Meredith P. Schuh,[2] Andrew Potter,[2] Steven Potter.[3] *[1]Children's Hospital of Cincinnati, CIncinnati, OH; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]Cincinnati Children's Hospital, Cincinnati, OH.*

Background: Primary focal segmental glomerulosclerosis (FSGS) is the most common glomerular pathology leading to end-stage renal disease in pediatric patient population. The refractory nature of FSGS and a more than 30% recurrence rate after kidney transplantation renders treatment of FSGS as one of the most difficult challenges in pediatric nephrology. A significant knowledge gap in understanding the mechanism of progression in FSGS hampers the development and implementation of successful treatment strategies. We reported an increase in urinary fatty acid (FA) and lysophosphatidylcholine (LPC) levels in patients with FSGS in comparison to patients with minimal change disease (MCD). **We hypothesize that phospholipase A2 (PLA2) metabolizes phosphotidylcholine (PC) leading to LPC and FA accumulation causing cellular toxicity in proximal tubule epithelial cells and podocytes contributes to progression in FSGS.**

Methods: Mouse model of FSGS was induced by mutation of Fyn and Cd2ap(Fyn$^{-/-}$ Cd2ap$^{+/-}$) in podocytes. Untrageted lipidomics of urine and kidney lysates of FSGS mice was analyzed by CSH-QTOF MS/MS. Cytosolic PLA2 expression in podocytes and proximal tubule epithelial cells was investigated by RNA sequencing. Western blotting and immunoflurescence staining was utilized to examine cPLA2 and PLA2 receptor expression in FSGS mice and human kidney biopsy sections with MCD and FSGS.

Results: Untargeted lipidomics of FSGS mice urine demonstrated increased FA and LPC levels reminiscent of human urine samples. Lipidomic analysis of kidney lysate of FSGS mice revealed increased LPC levels. Cytosolic PLA2 and PLA2 receptor expression was increased in the proximal tubule epithelial cells and podocytes by western blotting, immunofluorecence and RNA sequencing in FSGS mice. Human kidney biopsy sections with FSGS revealed increased cPLA2 and PLA2 receptor expression in proximal tubule epithelial cells and podocytes in comparison to MCD.

Conclusions: We concluded that PLA2 activity is increased in proximal tubule epithelial cells and podocytes in mouse and human FSGS. Moreover urinary detection of PLA2 by products, LPC and FA, renders urinary lipidomics a novel tool for predicting the diagnosis and prognosis of FSGS. We propose that increased levels of circulating PLA2 and cellular levels of cPLA2 leads to accumulation of toxic lipid metabolites and contributes to progression by inducing apoptosis and inflammation in FSGS.

Nebulette Is a Novel Actin-Associated Protein That Stabilizes Foot Process Architecture in Kidney Podocytes

Xuhua Ge, Xiaoxia Yu, Jordan M. Reid, Jenny Wong, Smiti Bhattacharya, Christina M. Cuttitta, Kirk N. Campbell, Evren U. Azeloglu. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Nebulette (*Nebl*) is a mechanosensitive actin-associated protein belonging to the nebulin family that stabilizes sarcomeric structures. It has been associated with dilated cardiomyopathy, and it is thought to be cardiac-specific. Its role in kidney function is unknown. Using isobaric tagged glomarular proteomics in the puromycin-induced rat nephropathy model, we identified nebulette as the most significant glomerular protein whose expression negatively correlated with proteinuria. We hypothesized that nebulette plays a critical role in cytoskeletal stability of kidney podocytes.

Methods: We used the NephroSeq database and immunohistochemistry to check for transcript and protein expression levels of nebulette in human kidneys. Primary podocytes isolated from global nebulette knockout mice (*Nebl*-KO) and their wild-type littermates (WT) were used to define the role of nebulette in podocyte physiology. We used high-content microscopy, live-cell imaging, and atomic force microscopy to quantify morphological characteristics, cell motility, calcium dynamics, and cytoskeletal integrity. We evaluated nebulette's functional role *in vivo* using the adriamycin-induced nephropathy model in WT and *Nebl*-KO mice.

Results: NephroSeq database revealed that nebulette expression was enriched in healthy glomeruli and decreased significantly in DN and FSGS patients. Immunohistochemistry and immunogold electron microscopy showed localization of nebulette in human podocytes, specifically in foot processes. Morphologically, *Nebl*-KO podocytes showed significantly smaller spreading area, nuclear size and lower number of focal adhesions. Further, *Nebl*-KO podocytes exhibited significantly altered cellular motility and calcium dynamics. *In vivo*, there was significantly higher albuminuria and foot process effacement in Nebl-KO mice treated with adriamycin at two weeks.

Conclusions: Nebulette is a novel actin-associated protein that localizes to the foot processes of kidney podocytes, and it is associated with glomerular disease in humans. It plays a key role in podocyte physiology by stabilizing the cytoskeletal integrity and regulating focal adhesion dynamics.

Gadolinium-Based Contrast Agents Are Metabolic Disruptors in the Kidney and Exacerbate Obesity- and Diabetes-Induced Kidney Injury

Brent Wagner,[1,3] Doug Y. Lee,[2] Chunyan Tan,[2] Catherine Do,[2] Yves C. Gorin.[2,1] *[1]Kidney Institute of New Mexico and the University of New Mexico Health Science Center, Albuquerque, NM; [2]University of Texas Health Science Center, San Antonio, TX; [3]Medicine Section, New Mexico Veterans Administration Health Care System, Albuquerque, NM.*

Background: Obesity-related renal injury and diabetic kidney disease are characterized by activation of glomerular mesangial cells and podocyte damage with alteration of lipid metabolism/lipid accumulation in both cell types resulting in matrix accumulation and eventual progression to glomerulosclerosis with loss of renal function. We examined the consequences of gadolinium-based contrast agent (GBCA) treatment in the kidney from mice with normal kidney function and the potential interplay between obese and diabetic states and GBCA exposure.

Methods: GBCA was administered for 4 weeks (as previously described); Metabolomics was by Metabolon. Obesity and diabetes (T1D) were induced by high fat diet (HFD, 60% kcal saturated fat) or streptozoticin, respectively (22 week durations of each condition). Obese and T1D mice in the GBCA groups were treated for 4 weeks prior to sacrifice.

Results: GBCA caused renal fibrotic lesions and podocyte injury that correlate with metabolic disorders as evidenced by increased serum triglyceride/cholesterol levels and insulin resistance. GBCA also induced expression of fatty acid translocase FAT/CD36—an indicator of fatty acid uptake—and lipogenic enzymes ATP citrate lyase (ACLY) and fatty acid synthase (FASN), indicators of *de novo* lipid synthesis. Metabolomic analysis indicated that renal lipid metabolism and metabolic markers of collagen turnover were significantly altered by GBCA. HFD- and T1D-induced fibrotic and podocyte injuries are worsened by GBCA. GBCA exacerbated 1) HFD-mediated hyperlipidemia, 2) CD36/ACLY/FASN upregulation, and 3) lipid metabolism as assessed by metabolomics.

Conclusions: Our work provides the first evidence that GBCA causes significant metabolic disorders and kidney injury in mice without renal insufficiency. These injurious actions of GBCA are amplified in obese and T1D. The understanding of the functional interplay between GBCA and diabetes/obesity will allow the development of therapeutic interventions or the establishment of effective preventive measures to reduce GBCA- and diabetes/obesity-mediated renal pathologies. This will help break the vicious cycle in which GBCA exposure in patients with normal kidney function or in obese or diabetic patients that may be more susceptible to GBCA-mediated renal pathologies.

KLF15 Suppress Mesangial Cell Proliferation via Increasing the Sumoylation of P53

Quan Hong, Ou Li, Guangyan Cai, Xiangmei Chen. *Chinese PLA Genaral Hospital, Beijing, China*.

Background: Mesangial cell proliferation is a key pathological feature in a number of common human renal diseases including IgA and diabetic nephropathies. Knowledge of MCs response to pathological stimuli is crucial to the understanding of these disease processes. Our previous study demonstrated Krüppel-like factor 15 (KLF15), a kidney-enriched zinc finger transcription factor, is required for inhibiting the proliferation of mesangial cell. This study aims to clarify the direct target gene and the downstream mechanism of KLF15 regulating mesangial proliferation.

Methods: DNA of primary human glomeruli mesangial cells (HMCs) was purified for sequencing after the chromatin immunoprecipitation with anti-KLF15 antibody. Differential expression protein of cells overexpressed KLF15 were assayed by SILAC/HPLC/MS-MS. We screened out small ubiquitin-related modifier 1 (SUMO1) as the direct transcriptional target of KLF15 and validated with ChIP-PCR or Luciferase assay. Finally, we interpreted whether SUMO1 was able to sumolyate p53 then block cell cycle and inhibit cell proliferation using co-IP and EDU assay in vitro. Also demonstrated these mechanisms on the anti-thy1 rat model.

Results: We showed that in vitro treatment with PDGF BB or high glucose induced a rapid decrease of KLF15 and SUMO1 expression in HMC with proliferation, also decreased in the renal cortex of anti-thy 1 model at the proliferated periods. SUMO1 was screened out and validated as one of the direct target proteins of KLF15. SUMOs are a group of post-translational modification proteins and participate in transcriptional regulation, protein stabilization, and the cell cycle. Furthermore we demonstrated overexpress KLF15 or SUMO1 enhanced the stability of P53 (Sumolyation-p53 expression increased) that functioned to block the cell cycle of HMCs, therefore obliterate the cell proliferation. Conversely, knockdown of SUMO1, even if cultured with PDGF BB, HMCs proliferation rates declined along with less sumolyation-P53. Finally, results showed the level of sumolyation-P53 in the kidney cortex from anti-thy 1 rat model decreased at proliferation periods.

Conclusions: These studies manipulate the critical mechanism of KLF15 targeting SUMO1 in mediating the proliferation of mesangial cells. It will be a potential target for IgAN or diabetic nephropahty's therapy.

TH-PO799

Gender Differences in the Development of Glomerulopathy in Mice with an EGFR Gain-of-Function Mutation

Ming-Zhi Zhang, Yan Li, Zhilian Li, Suwan Wang, Yinqiu Wang, Aolei Niu, Xiaofeng Fan, Raymond C. Harris. *Vanderbilt University Medical Center, Nashville, TN*.

Background: The epidermal growth factor receptor (EGFR) is widely expressed in the kidney in both glomeruli and tubules. Under pathological conditions, persistent and dysregulated EGFR activation mediates progressive glomerular and tubulointerstitial injury in progressive kidney diseases. Although gender differences mediating predisposition to kidney injury are well known, no previous studies have investigated the potential role of EGFR in these differences.

Methods: *Dsk5* mice have a Leu863Gln mutation within a region of the kinase domain that stabilizes the receptor activation loop, producing a gain-of-function allele that increases basal EGFR kinase activity. Both male and female heterozygous *Dsk5* mice on the 129 background were used. *Dsk5* mice were oopherectomized or castrated before puberty to investigate the effect of sex hormones on EGFR expression and glomerulopathy.

Results: In male *Dsk5* mice constitutive EGFR activation was confirmed by intense phospho-EGFR immunostaining not seen in wild type mice. At 15 weeks of age, male *Dsk5* mice exhibited glomerulopathy, with mesangial proliferation and segmental and global sclerosis. They also had increased albuminuria, loss of podocytes and increased tubulointerstitial fibrosis as indicated by Sirius red and Masson's trichrome staining. Kidneys had increased mRNA and protein levels of profibrotic and fibrotic components, including TGF-β, α-smooth muscle actin, connective tissue growth factor, fibronectin, collagens I, III, IV and increased immune cell infiltration and proinflammatory cytokines/chemokines, such as MCP-1, TNF-α, IL-6, and IL-1α. Unexpectedly, there was minimal kidney injury in female *Dsk5* mice at up to 30 weeks of age. Renal mRNA and protein EGFR levels were significantly lower in age-matched females than males. Oopherectomy had no effect on renal EGFR levels and injury in female *Dsk5* mice, while castration protected against the kidney injury seen in intact male *Dsk5* mice, in association with a reduction in EGFR expression to levels seen in female mice.

Conclusions: These studies indicate that constitutive EGFR activation promotes glomerular and tubulointerstitial injury in male mice, but not in female mice, and this gender difference may be at least in part due to androgen-dependent higher basal levels of EGFR expression.

Extracellular Vesicles Derived from Amniotic Fluid Stem Cells as Potential Therapy for CKD

Sargis Sedrakyan,[1] Valentina Villani,[1] Paola Aguiari,[1] Astgik Petrosyan,[1] Hasmik Soloyan,[1] Corinne Iampietro,[2] Benedetta Bussolati,[2] Laura Perin.[1] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]University of Torino, Torino, Italy*.

Background: The crosstalk between podocytes and glomerular endothelial cells (GEC) is vital for the maintenance of glomerular function. VEGF signaling plays a key role in the progression of chronic kidney disease (CKD). The discovery of safe therapeutics designed to specifically target the glomerular crosstalk, specifically VEGF signaling, is ground-breaking. We propose that extracellular vesicles derived from amniotic fluid stem cells (AFSC-EVs) can restore glomerular crosstalk and delay disease progression in Alport Syndrome, a model of CKD.

Methods: GEC were isolated from (Tek-Cre driven) tdT AS and WT mice along disease progression, characterized by WB and RNA-seq with specific focus on VEGF signaling and endothelial damage. EVs were isolated from AFSC, characterized and injected in vivo using our established protocols. Histology and kidney function were evaluated in injected and control mice.

Results: Glomeruli and GEC present with upregulated VEGF signaling before high level of proteinuria. RNA-seq data showed, for the first time, that AS-GEC present with modulation of genes involved in GBM deposition (collagen and laminin) and regulation (MMPs), glycocalyx component (syndecan, perlecan ect), and endothelial markers (VCAM1, ICAM), before the onset of proteinuria. Administration of EVs, at early stage, restore VEGF levels to normal by trapping excessive VEGF (EVs present VEGFR1 and VEGFR2 on the surface) and improve kidney function in AS mice. In light of clinical translation of EVs for CKD, we characterized EVs from human AFSC. We developed specific identity, purity and potency assays that generate EV lots with very similar characteristics between harvests. EVs of human origin present reno-protective activity in vivo in AS mice as well as capability of modulating glomerular VEGF signaling.

Conclusions: Our data suggest that VEGF-induced GEC damage might play a key role in the pathogenesis of AS and its progression and that administration of EVs can delay disease progression by preventing endothelial injury and by restoring to normal VEGF signaling. In sum, our work possibly will facilitate the discovery of new potential glomerulus-specific targeted intervention, thus possibly minimizing disease progression and ameliorating the life of patients affected by CKD.

ICOSL in Non-Immune Cells Functions as an Inducible Potent αvβ3 Integrin-Selective Antagonist to Prevent Early Kidney Disease

Kwi Hye Koh,[1] Yanxia Cao,[1] Steve Mangos,[1] Nicholas J. Tardi,[1] Ranadheer Dande,[1] Ha Won Lee,[1] Beata Samelko,[1] Mehmet M. Altintas,[1] Vincent P. Schmitz,[1] Hyun Lee,[2] Vasil Peev,[1] David J. Cimbaluk,[1] Jochen Reiser,[1] Eunsil Hahm.[1] *[1]Rush University Medical Center, Chicago, IL; [2]Univ. of Illinois at Chicago, Chicago, IL*.

Background: ICOSL, the ligand for the inducible co-stimulator (ICOS), was the third member of the B7 superfamily discovered, is mainly expressed by antigen presenting cells (APCs), and functions in regulating T cell mediated immune responses. ICOSL has traditionally been assigned the fundamental role as an exclusive ligand for ICOS and was thought to be restricted to the immune system. As such, its potential function in non-hematopoietic cells under disease conditions remains completely unexplored.

Methods: *In vitro* and *in vivo* approaches were used to conduct the following analyses: qPCR, immunohistochemistry, surface plasmon resonance, cellular adhesion assays, ACR and BUN level measurements, electron microscopy, and bone marrow transplantations. Available on-line databases were used for 3D-modeled homology structure analysis. Rescue experiments involved injection of recombinant ICOSL into ICOSL KO mice.

Results: We find that unlike other B7 co-stimulatory molecules, ICOSL contains a known integrin-binding motif: arginine-glycine-aspartic (RGD), and selectively binds to αvβ3 but not to α3β1 integrin. Indeed, this binding depends on the activation state of αvβ3 integrin and is largely inhibited by the presence of synthetic RGD peptide, a selective antagonist of αvβ3. We also find that the RGD motif present in ICOSL is functionally active and modulates the αvβ3 integrin-dependent adhesion of podocytes. Consistent with the rapid induction of podocyte ICOSL expression by inflammatory stimuli, glomerular ICOSL expression is greatly increased at early stages of human proteinuric kidney diseases such as focal segmental glomerulosclerosis (FSGS) and diabetic nephropathy (DN). Furthermore, ICOSL deficiency results in an increased susceptibility to kidney injury and severe proteinuria in mice, and can be rescued by recombinant ICOSL injection.

Conclusions: Here we report a novel, renoprotective role for ICOSL in early kidney disease through its selective binding to active αvβ3 integrin. Our work identifies a novel role for ICOSL: protecting the kidney filter from injury by serving as a potent αvβ3-selective antagonist, and provides new insights into various pathological diseases associated with aberrant αvβ3 activation.

TH-PO802

High Activity of Tissue Remodeling Cell Signaling Cascades in the Macula Densa

Urvi nikhil Shroff, Georgina Gyarmati, Janos Peti-Peterdi. *University of Southern California, Los Angeles, CA.*

Background: The macula densa (MD), a plaque of 15-20 specialized cells, sits at the vascular pole of the glomerulus and plays a traditional role in maintaining renal hemodynamics and the renin-angiotensin system. However, the new tissue remodeling function of MD cells is emerging. The present study aimed to examine the activity and role of major cell signaling pathways in MD cells, and to test if augmenting these pathways specifically in MD cells would alter renal tissue remodeling.

Methods: RNA seq and gene profiling was used to establish and analyze the gene profile of mouse MD cells under control and stimulating low dietary salt conditions. To confirm MD specificity of top gene candidates, immunohistochemistry (IHC) was performed on mouse and human kidney sections for Wnt/β-catenin, mTOR, PI3K, and MAPK signaling pathways that are known to regulate cell biology and tissue remodeling. To test for cell proliferation and rate of protein synthesis, EdU staining and a O-propargyl-puromycin incorporation-based assay were performed, respectively, in kidney sections of control WT mice and in a new genetic model of inducible MD-specific Wnt gain-of-function (*gof*).

Results: Combined gene profiling and IHC identified the highest activity of Wnt, mTOR, PI3K, and MAPK signaling in MD cells in the mouse and human kidney cortex. A TCF/Lef:H2B-GFP Wnt signaling reporter mouse model and activated β-catenin IHC showed the strongest labeling in MD cells. In MD-Wnt(*gof*) mice after 5 weeks of induction, a robust increase in MD cell proliferation, nucleus-to-cell volume ratio, and protein synthesis were found compared to WT control. MD-Wnt(*gof*) mice also featured enlarged glomeruli, increased PDGFRβ+ mesangial expansion and angiogenesis. Treatment with lithium (GSK3β inhibitor for Wnt stimulation) for 2 weeks had similar effects on MD cell morphology, cell biology, glomerular size and cell composition.

Conclusions: In summary, the renal cell type with the strongest Wnt, mTOR, PI3K, and MAPK activity is the MD, which is a chief sensor and effector of the local tissue environment. Wnt signaling is an important regulator of MD morphology, cell biology, and new function in tissue remodeling, which can be augmented in new developing regenerative therapeutic strategies.

TH-PO803

Investigating Basement Membrane Assembly

Nikki-Maria Koudis,[1] William Loewenhardt,[2] Michael J. Randles,[3] Rachel Lennon,[1] Brian Derby.[2] *[1]Wellcome Trust Centre for Cell-Matrix Research, University of Manchester, Manchester, United Kingdom; [2]School of Materials, University of Manchester, Manchester, United Kingdom; [3]Faculty of Health and Life Sciences, De Montfort University, Leicester, United Kingdom.*

Background: The glomerular basement membrane (GBM) is a specialised condensed network of extracellular matrix. Monocultures of podocytes and endothelial cells synthesise and organise a complex matrix *in vitro* and this has significant overlap with the components of the GBM *in vivo*. Whilst these cultures assemble type IV collagen this is predominantly the α1α1α2 network and not the mature α3α4α5 network, which is required for the long-term integrity of the GBM. We hypothesised that the combination of glomerular cell coculture and flow would alter the composition of matrix and lead to a more mature phenotype with greater similarity to the GBM *in vivo*.

Methods: To generate flow we utilised the QV600 bioreactor (Kirkstall) and a custom-designed bioreactor constructed with the silicone-based polymer PDMS. Detachable podocyte and endothelial cell sheets were engineered and assembled into the bioreactors to create cocultures without the need for an intervening material for support. Cells and matrix were examined in static and flow conditions using light and electron microscopy and mass spectrometry (MS)-based proteomics. The function of this coculture system as a semi-permeable filtration barrier was examined using fluorescently labelled dextrans.

Results: Endothelial cells and podocytes readily formed cell sheets and could be assembled as cocultures into bioreactors. Both cell types were viable in coculture and in static and flow conditions. Electron microscopy revealed the presence of basement membrane-like structures between cocultured cells and functional analysis confirmed intact barrier function. Proteomic analysis of cells under flow conditions demonstrated an upregulation of basement membrane proteins including altered laminin and collagen IV isoforms compared to static conditions.

Conclusions: Podocyte and endothelial cells are viable in direct contact and under flow conditions and flow influences both the composition and assembly of matrix in our system suggesting roles for both cell-cell cross-talk and fluid flow in the assembly of basement membranes. This system has utility for understanding the basic biology of GBM formation and glomerular cell interaction with the GBM in addition to testing compounds that could repair a damaged GBM in the context of glomerular disease.

Podocyte Development/Function Depends on Primary Cilia and the Exocyst

Ashish K. Solanki,[1] Ehtesham Arif,[1] Matt G. Sampson,[2] Deepak Nihalani,[1] Joshua H. Lipschutz.[1] *[1]Medical University of South Carolina, Charleston, SC; [2]University of Michigan, Ann Arbor, MI.*

Background: Diseases affecting podocytes are leading causes of ESRD. Until recently, podocytes were thought not to have primary cilia, as cilia are not seen on adult podocytes; however, primary cilia were reported on developing podocytes in 2010. In 2014, a mutation in ciliary protein IFT139 was found in patients with FSGS, suggesting cilia involvement in GN. Our mRNA profiling of injured podocytes showed downregulation of the highly-conserved 8 protein exocyst trafficking complex. We previously showed that the exocyst is necessary for ciliogenesis in kidney tubule cells, zebrafish, and mice. Exocyst members were also mutated in families with ciliopathies affecting the kidney. Thus, we hypothesized that the exocyst is critical for podocyte development/function.

Methods: We generated podocyte-specific Exoc5 knockout (KO) mice, by crossing Podocin-Cre and Exoc5 fl/fl mice, and studied patients in the Nephrotic Syndrome Study Network (NEPTUNE).

Results: Podocyte-specific Exoc5 KO mice showed massive proteinuria and died within 5 weeks of birth. Importantly, isolated glomeruli stained with acetylated alpha tubulin showed primary cilia in wild-type, but not Exoc5 KO, mouse glomeruli. Histological analysis showed severe defects with increased fibrosis, proteinaceous casts, effaced podocytes, and slit diaphragm loss in Exoc5 KO mice; while IF showed significant mislocalization of slit diaphragm proteins Neph1 and Nephrin. Podocyte-specific Exoc5 KO mice phenocopied Cdc42, an exocyst regulator, KO mice reported by others. Mapping and Western blot analyses showed upregulation of canonical and non-canonical arms of the TGFβ pathway, including ERK and SMAD3 activation, in Exoc5 knockdown podocytes, and Exoc5 KO glomeruli. We next examined copy number variation (CNV) data derived from genome-wide SNP arrays from 256 patients with nephrotic syndrome enrolled in NEPTUNE. This dataset identified CNV that were greater than 100kb, overlapped a gene, and were ultra-rare or absent in control populations. Within, we identified two patients with qualifying CNV affecting exocyst component, *EXOC4*: a male toddler of Asian ancestry with steroid resistant minimal change, and an African-American female in her third decade with collapsing FSGS.

Conclusions: Our data implicate exocyst-based ciliogenic mechanisms in podocyte development/function, and suggest a novel target for intervention.

TH-PO805

A Novel Interaction Between Synaptojanin-1 and ZO-1 Indicates Clathrin-Mediated Turnover at the Slit-Diaphragm

Marwin Groener,[1,2] Kazunori Inoue,[1] Xuefei Tian,[1] Christopher E. Pedigo,[1] Elizabeth Cross,[1] Ying Wang,[1] Shuta Ishibe.[1] *[1]Yale University School of Medicine, New Haven, CT; [2]FAU Erlangen-Nuremberg, Erlangen, Germany.*

Background: The importance of clathrin-mediated endocytosis (CME) for podocyte health has long been established. Deletion of Synaptojanin 1 (Synj1), which is involved in the uncoating of clathrin-coated vesicles (CCV), resulted in severe albuminuria and foot process effacement in mice. The aim of this study is to further understand the underlying mechanism and role of Synj1 at the slit-diaphragm (SD).

Methods: We created a mouse monoclonal antibody specific for the Synj1 isoform expressed in podocytes. Mass Spectrometry analysis following immunoprecipitation (IP) of podocyte lysate revealed tight junction protein, Zonula occludens 1 (ZO-1) as a binding partner. To further identify the binding domains, we transfected Cos7 cells with various tagged truncated ZO-1 and Synj1 plasmids and performed IP. We analyzed through live imaging, the temporal and spatial relationship between ZO-1 and clathrin in isolated control podocytes. Immunofluorescence (IF) staining with ZO-1 and clathrin light-chain antibodies on wild-type and *Synj1* KO mouse podocytes was performed to determine ZO-1 localization.

Results: The association of Synj1 with ZO-1 was confirmed by IP in Cos7 cells overexpressing Synj1 and ZO-1. Binding between the SH3 domain of ZO-1 and proline-rich domains of Synj1 was observed. IF staining of wild-type mouse podocytes demonstrated ZO-1 co-localized with clathrin-coated pits. Live cell imaging further revealed CME of ZO-1. However, Synj1 KO podocytes displayed ZO-1 mislocalization in the cytosol when compared to wild-type.

Conclusions: We identified a novel binding partner of Synj1, the slit-diaphragm protein ZO-1, which indicates clathrin-mediated turnover of ZO-1 similar to Nephrin likely occurs. IF images and live cell imaging further corroborated these findings. Furthermore, inhibiting uncoating of CCV in Synj1 KO podocytes resulted in mislocalization of ZO-1. These findings illustrate the importance of clathrin-mediated recycling of slit-diaphragm proteins during podocyte health and disease.

TH-PO806

Correlation Between Endocapillary Proliferative and Nephrotic-Range Proteinuria in Children with Henoch-Schönlein Purpura Nephritis

Yanjie Huang, Xiaoqing Yang. *The First Affiliated Hospital of Henan University of Traditional Chinese Medicine, Zhengzhou, China.*

Background: The endocapillary proliferative (EP) lesion is not included in ISKDC pathological classification of HSPN. The main objective of the study was to determine the

pathological importance of EP in the development of proteinuria in children with Henoch-Schönlein purpura nephritis (HSPN).

Methods: The pathological features of 148 HSPN children with nephrotic-range proteinuria were investigated retrospectively. 24-hour proteinuria was measured by pyrogallol red-molybdate. Urinary IgG, transferrin and albumin levels were measured by immunonephelometry. The correlations between EP lesion and 24-hour proteinuria, urinary IgG, urinary transferrin and urinary albumin were analyzed. Renal biopsy specimens were immunohistochemically stained for nephrin and podocalyxin.

Results: Of total 581 cases of children with HSPN who underwent renal biopsy, 148 cases (25.5%) presented with nephrotic-range proteinuria. The pathological types of HSPN with nephrotic-range proteinuria were categorized as IIb, IIIa, IIIb, IIIb with EP, IVb, and pure EP type. Among these types, pure EP type accounted for 7.4%. The levels of 24-hour proteinuria and urinary albumin were the highest in EP type among all pathological types, and the percentage of EP correlated with 24-hour proteinuria and urinary albumin levels. 24-hour proteinuria was significantly higher in pure EP type relative to HSPN IIb type, and significantly higher in IIIb with EP, compared with HSPN IIIb. Nephrin, but not podocalyxin, was downregulated in EP segment.

Conclusions: In addition to mesangial proliferation and crescent formation, EP is an independent pathogenic factor in HSPN with nephrotic-range proteinuria. Downregulation of nephrin in EP segment is a potential molecular mechanism of nephrotic-range proteinuria. Albumin is the major urinary protein component in HSPN with EP.

TH-PO807

Immune Response to Tonsillar Microbiome Are Perturbed in the Development of IgA Nephropathy

Hiroki Yamaguchi, Shin Goto, Hirofumi Watanabe, Masataka Yonezawa, Suguru Yamamoto, Yoshikatsu Kaneko, Ichiei Narita. *Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: The aberrant immune response in palatine tonsils against commensal bacteria has been estimated to be involved in the development of IgA nephropathy (IgAN). To elucidate these mechanisms, we focused on the relationship between the expression of TNFSF13 (APRIL) and galactose-deficient IgA1 (Gd-IgA1) and the composition of bacteria in tonsillar crypts.

Methods: We enrolled 57 patients with IgAN and 27 with recurrent tonsillitis (RT) who were undergone tonsillectomy. Genomic DNA were extracted from the excised tissues of tonsillar crypts in each patient and V4 regions of the 16S-ribosomal RNA gene sequence were applied to assess the relative abundance of bacteria. These tissues were also solubilized with a lysis buffer and the concentration of extracted proteins were quantified with BCA methods. The levels of APRIL and Gd-IgA1 in tonsils or serum were measured by ELISA, and the degree of Gd-IgA1 deposition in glomerulus were evaluated by immunohistochemical analysis. We analyzed the correlations between the levels of APRIL, Gd-IgA1 and bacterial abundance, as well as the grade of glomerular injury.

Results: Immunohistochemical analysis revealed that Gd-IgA1 was localized in germinal center of tonsils and the degree of its stained area was correlated with tonsillar Gd-IgA1 levels. The degree of Gd-IgA1 deposition in glomerulus was significantly correlated with tonsillar Gd-IgA1 levels. The levels of Gd-IgA1 in tonsil were significantly higher in IgAN patients with more extended glomerular damage, while tonsillar Gd-IgA1 levels in IgAN patients did not differ from those in RT patients. Tonsillar APRIL levels were significantly higher in IgAN patients than in RT patients ($P < 0.01$). The levels of tonsillar APRIL in RT were positively correlated with the relative abundance of *Prevotella* genus in tonsils, however, the upregulated levels of tonsillar APRIL in IgAN did not show any robust associations with 16S microbiota in tonsils.

Conclusions: Gd-IgA1 and increased APRIL expression in tonsils could be involved in the development of IgAN. Further analysis is needed to reveal the role of microbiome on the mucosal immunity in tonsils of patients with IgAN.

TH-PO808

Deposition of IgA and C3 on the Glomerular Loop Significantly Correlates with Urinary Protein in Immunoglobulin A Vasculitis with Nephritis (Henoch-Schonlein Purpura Nephritis)

Kazunori Karasawa, Takahito Moriyama, Kosaku Nitta. *Department medicine, Kidney Center, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Immunoglobulin A vasculitis with nephritis (IgAVN) is considered to be systemic form of IgA nephropathy (IgAN). Both IgAN and IgAVN are defined by the presence of IgA dominant glomerular deposits. However, the pathological significance of the difference in glomerular location of IgA and other immunogrobulin deposits is remain unclear. In this study, we investigated which clinical findings and renal prognosis correlate with immunostaining findings in IgAVN.

Methods: We conducted a retrospective study of 33 adult patients of biopsy-proven IgAVN and analyzed these cases in terms of clinicopathological feature and renal prognosis. Especially, we evaluated renal biopsy specimens of IgAV in detail by immunostaining.

Results: 33 adults IgAVN patients (male:21, female:12) were analyzed. Averege age was 41.12±14.7 years old at the renal biopsy. Localization of glomeruli of IgA, IgG, IgM as immunoglobulin, C3, C4d, C1q as complement factor, and fibrin, fibrinogen, kappa chain, lambda chain as others were examined by immunostaining. IgA deposition was observed on glomerular loop (capillary wall) of 10 patients (30%). The average proteinuria was 3.60±2.61 g/day in the IgA deposited on glomerular loop group and 1.53 ±1.63 g/day in the group with no IgA deposition on glomerular loop group. (P=0.0047) Furthermore, C3 deposition was also observed on glomerular loop of 10 patients (30%). The average urine protein was 4.04±2.64 g/day in the C3 deposited on glomerular loop group and 1.34±1.28 g/day in the group with no C3 deposition. (P<0.001) From these results, we revealed that the deposit of IgA and C3 on glomerular loop in immunostaining findings was positively correlated with the amount of the proteinuria. However, renal prognosis was no significant difference in both group in one year after treatment.

Conclusions: The deposition of IgA and C3 in the glomerular loop were significantly correlated with the amount of puroteinuria. These results suggested that these deposition may play a key role in the pathogenesis of IgAVN, and also suggested that the selection of therapy for IgAVN might be affected.

TH-PO809

GWAS-Follow-Up Study Identified Abnormal LIF Signaling Network Involving STAT1 and Src Family Protein-Tyrosine Kinases in IgA1-Secreting Cells from Patients with IgA Nephropathy

Koshi Yamada,[1,2] Zhi qiang Huang,[1] Milan Raska,[1] Colin Reily,[1] Joshua C. Anderson,[1] Hitoshi Suzuki,[1,2] Krzysztof Kiryluk,[3] Ali G. Gharavi,[3] Bruce A. Julian,[1] Christopher D. Willey,[1] Jan Novak.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Juntendo University Faculty of Medicine, Tokyo, Japan; [3]Columbia University, New York, NY.*

Background: Genome-wide association studies (GWAS) in IgA nephropathy (IgAN) provide insight into disease pathobiology by identifying genetic loci and mapping the associated molecular pathways. A GWAS locus on chr. 22q12 encompasses genes that include *LIF* that encodes leukemia inhibitory factor, an IL-6-related cytokine implicated in mucosal immunity and inflammation. In this study, we characterized LIF signaling pathways leading to overproduction of galactose-deficient IgA1 (Gd-IgA1), using IgA1-secreting cell lines derived from peripheral blood of patients with IgAN and healthy controls (HC).

Methods: IgA1 was determined by ELISA, Gd-IgA1 lectin ELISA with *Helix aspersa* lectin. To assess LIF signaling pathways, we used global protein-tyrosine kinases (PTKs) activity profiling, immunoblotting, siRNA knock-down, and a JAK2 inhibitor.

Results: LIF activated STAT1 phosphorylation (Y701) to a greater level in IgA1-secreting cells from patients with IgAN (n=5) compared with those from HC (n=5) ($p<0.01$). LIF-mediated increase in Gd-IgA1 production by IgA1-secreting cells from patients with IgAN were reduced by siRNA *STAT1* knock-down ($p<0.05$). Use of a JAK2 inhibitor revealed that this enhanced phosphorylation of STAT1 in IgA1-secreting cells from patients with IgAN was not mediated by JAK2. PTK activity profiling indicated that LIF signaling activated Src family of PTKs, based on highest kinase statistics (Kstat) and specificity.

Conclusions: LIF induced abnormal STAT1 signaling and enhanced production of Gd-IgA1 in IgA1-secreting cells from patients with IgAN, providing possible explanation for the phenotype associated with a GWAS locus encompassing *LIF*. Moreover, our exploratory data indicate involvement of Src family PTKs in LIF signaling that needs to be further explored.

TH-PO810

Nasal-Associated Lymphoid Tissue Is the Major Induction Site for Nephritogenic IgA in Murine IgA Nephropathy

Toshiki Kano, Hitoshi Suzuki, Yuko Makita, Yoshihito Nihei, Yusuke Fukao, Yusuke Suzuki. *Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: The pathogenesis of IgA nephropathy (IgAN) is closely associated with dysregulation of mucosal immune system, which manifests as mesangial IgA deposition leading renal impairment. Several papers reported that Toll-like receptor 9 (TLR9) activated by exogenous pathogens is suspected in aggravation of renal injury in IgAN. However, it is unclear which gut-associated lymphatic tissue (GALT) or nasal-associated lymphoid tissue (NALT) is more involved in the pathogenesis of IgAN. Although the origin of nephritogenic IgA has been obscure, several studies demonstrated the efficacy of tonsillectomy and corticosteroid therapy, whereas the novel targeted-release formulation of budesonide targeting intestinal mucosal immunity reduced proteinuria in IgAN patients. In present study, we focused on the role of NALT and GALT using IgAN-prone ddY mice.

Methods: Levels of aberrantly glycosylated IgA and IgG-IgA immune complexes (IC) in serum and supernatant from cultured cells from NALT, Mesenteric lymph node (MLN) and spleen were measured using IgAN onset and quiescent ddY mice (each n=16) with or without TLR9 ligand (CPG-ODN) stimulation. Level of aberrantly glycosylated IgA was measured by the binding of Sambucus nigra bark lectin (SNA) and Ricinus communis agglutinin I (RCA).

Results: In IgAN onset ddY mice, serum levels of aberrantly glycosylated IgA and IC were significantly higher than those in quiescent ddY mice. However, there were no significant differences in the levels of aberrantly glycosylated IgA and IC produced by MLN between IgAN onset and quiescent mice. Serum levels of aberrantly glycosylated IgA and IC correlated with those in culture supernatant of splenocytes, but SNA and RCA assay revealed that the sugar component of IgA from MLN was different from that in circulatory IgA in IgAN onset ddY mice. The levels of aberrantly glycosylated IgA and IC in NALT and splenocytes were significantly increased by CpG-ODN, however those in MLN were not increased.

Conclusions: Aberrant glycosylation of IgA leading to IC formation was found in cell supernatant from NALT but not in MLN/GALT. The present study suggest that the NALT has a key role in the pathogenesis of murine IgAN

TH-PO811

Patients with Immunoglobulin A Nephropathy Is Associated with Elevated Urinary Mitochondrial DNA Copy Number

Byung chul Yu,[3] Hyoungnae Kim,[2] Samel Park,[1] Moo Yong Park,[3] Soon hyo Kwon.[2] *[1]Soonchynhyang University Cheonan Hospital, Cheonan, Republic of Korea; [2]Soonchunhyang University Seoul Hospital, Seoul, Republic of Korea; [3]Soonchunhyang University Bucheon Hospital, Bucheon, Republic of Korea.*

Background: Urinary mitochondrial DNA (mtDNA) levels are considered to reflect mitochondrial injury in kidney. However, mitochondrial injury in IgA nephropathy (IgAN) remains unknown. We hypothesized that IgAN would be associated with increased urinary mtDNA copy numbers.

Methods: We prospectively enrolled age-sex matched healthy volunteers (HV) and biopsy-proven IgAN (n=30 each). Urinary copy number of the mtDNA genes cytochrome-c oxidase-3 (COX3) and nicotinamide adenine dinucleotide dehydrogenase subunit-1 (ND1) were measured by quantitative polymerase chain reaction. We measured also urinary ND-1 and COX3 3 months after medical treatment in IgAN (n=12).

Results: The mean estimated glomerular filtration rate (eGFR) was significantly lower in IgAN compared with HV (75.2±28.8 vs 107.2±12.1 mL/min/1.73m^2, respectively, p<0.001). $\log_{10}$ND1/nDNA and $\log_{10}$COX3/nDNA were significantly higher in IgAN compared with HV (5.70±0.36 vs 5.14±0.34, 5.68±0.37 vs 5.15±0.33 copies/μl of urine/nDNA, respectively, both p<0.001). There was no significant relation between urinary mtDNA copy numbers and tranditional prognostic markers at presentation in IgAN such as mean arterial pressure, eGFR, and the amount of proteinuria. In the M score of the Oxford classification, $\log_{10}$ND1/nDNA and $\log_{10}$COX3/nDNA were significantly lower in IgAN patients with mesangial hypercellularity (5.61±0.39 vs 5.89±0.20, p=0.014, 5.60±0.41 vs 5.85±0.16 copies/μl of urine/nDNA, p=0.022, respectively). Medical treatment did not reduced urinary mtDNA copy numbers.

Conclusions: Urinary mtDNA copy numbers were elevated in patients with IgAN. This suggests mitochondrial damage would be a pathogenesis in IgAN.

Relation between urinary mtDNA levels and clinical variables in patients with immunoglobulin A nephropathy

Variables	Mean arterial pressure	Estimated glomerular filtration rate	Proteinuria
log $_{10}$ND1/nDNA level	r = -0.072, P = 0.706	r = 0.147, P = 0.438	r = -0.073, P = 0.701
log $_{10}$COX3/nDNA level	r = -0.047, P = 0.805	r = 0.125, P = 0.511	r = -0.010, P = 0.957

Data were analyzed by Spearman's rank correlation coefficient.

COX3, cytochrome-c oxidase-3; mtDNA, mitochondrial DNA; ND1, nicotinamide adenine dinucleotide dehydrogenase subunit-1.

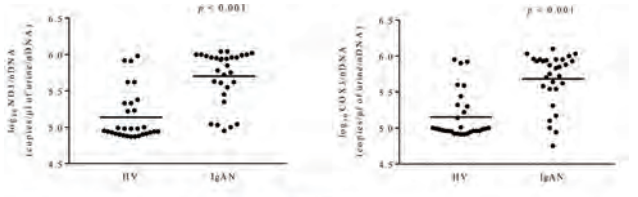

Figure. Urinary mtDNA copy number of patients with IgAN and HV.
COX3, cytochrome-c oxidase-3; HV, healthy volunteers; IgAN, immunoglobulin A nephropathy; mtDNA, mitochondrial DNA; ND1, nicotinamide adenine dinucleotide dehydrogenase subunit-1.

Plasma Galactose-Deficient IgA1/C3 Ratio Is Strongly Associated with Disease Progression in IgA Nephropathy

Pei Chen, Gui-zhen Yu, Xue Zhang, Sufang Shi, Jicheng Lv, Hong Zhang. *Peking University First Hospital, Beijing, China.*

Background: Galactose-deficient IgA1 (Gd-IgA1) and C3 mesangial codeposition is a hallmark of IgA nephropathy (IgAN). In this large cohort study, we aim to evaluate Gd-IgA1/C3 ratio in the progression of IgAN.

Methods: In this study, we included 1157 IgAN patients with a median follow-up period of 42 months. Plasma Gd-IgA1 was measured at the time of diagnosis using a lectin-based ELISA. The composite kidney failure event was defined by 50% decline in eGFR or ESRD and renal survival was modeled using the Cox proportional hazards method and restricted cubic splines.

Results: Although high plasma Gd-IgA1 levels were associated with the risk of kidney progression events, the association was not in a linear relationship. While the correlation between plasma Gd-IgA1/C3 ratio and risk of kidney failure was a linear relationship. After adjusted for traditional risk factors, higher levels of Gd-IgA1/C3 ratio was independently associated with a greater risk of deterioration in renal function with a HR of 2.15 (95% CI=1.21–3.81, P=0.008) per ln(Gd-IgA1/C3). In reference to the first quartile, the risk of kidney progression event increased such that the HR for the second quartile was 1.84 (95% CI=1.05–3.24, P=0.034), 1.79 (95% CI=1.02–3.12, P=0.041) for the third, and 2.08 (95% CI=1.22–3.54, P=0.007) for the fourth quartile of the Gd-IgA1/C3 ratio.

Conclusions: Plasma Gd-IgA1/C3 ratio was an independent risk factor for kidney progression events.

Cox regression model associations of baseline plasma Gd-IgA1/C3 levels with incidence of composite end point.

	HR (95% CI) and P value			
	Unadjusted	Model 1	Model 2	Model 3
Per ln(Gd-IgA1/C3)	3.00 (1.73-5.21)	3.02 (1.74-5.24)	2.68 (1.59-4.53)	2.15 (1.21-3.81)
P value	8.9×10^{-5}	8.1×10^{-5}	2.2×10^{-4}	0.008
Gd-IgA1/C3 quartiles				
1	Reference	Reference	Reference	Reference
2	1.68 (0.99-2.85)	1.61 (0.94-2.76)	1.63 (0.95-2.80)	1.84 (1.05-3.24)
P value	0.055	0.082	0.076	0.034
3	1.97 (1.17-3.31)	1.90 (1.13-3.22)	2.10 (1.24-3.55)	1.79 (1.02-3.12)

Collectin-11 Is a Recognition Molecule in Glomerular Activation of Lectin Pathway in IgA Nephropathy

Weiyi Guo, Li Zhu, Sufang Shi, Lijun Liu, Jicheng Lv, Hong Zhang. *Renal Division, Peking University First Hospital, Beijing, China.*

Background: Glomerular activation of lectin pathway (LP) was reported in IgA nephropathy (IgAN), and further associated with disease severity and therapy. Besides mannose-binding lectin (MBL) and ficolin, which could recognize glycans of IgA1 and lead to LP complement activation in IgAN, collectin-11 (CL-11) is a newly identified recognition molecule in LP. Here we explored the involvement of CL-11 in complement activation of IgAN.

Methods: We enrolled 60 IgAN patients for Immunofluorescence staining of CL-11, MBL, ficolin, MASP2, MASP1/3, C4d, C3c and C5b-9 in renal biopsy specimens. Additionally, plasma samples from 10 patients with IgAN were collected for IgA1 purification. Using jacalin affinity chromatography, Sephrcryl S300 and glycosyl hydrolysis treatment, monomeric IgA1 (mIgA1), polymeric IgA1 (pIgA1), as well as sialic acid deficient IgA1 (SAd-IgA1) and sialic acid/galactose deficient IgA1 molecules (Gd/SAd-IgA1) were prepared and their binding with CL-11 were detected by ELISA.

Results: In our IgAN patients, 36.7% (22/60) had mesangial CL11 deposition. Among them, 14 also had MBL and ficolin deposition, 1 had MBL without ficolin, 4 had ficolin without MBL, while 3 without MBL or ficolin. All of the 22 IgAN patients with mesangial CL-11 deposition, presented with MASP (MASP2 or MASP1/3), C4d, C3 and MAC deposition, which co-localized with CL-11. In vitro, pIgA1 showed a Ca^{2+}-independent binding with CL-11, and the binding was in a dose-dependent manner. Between concentrations of 0.625-2.5 ug/ml, pIgA1 showed significantly higher binding to CL-11 than mIgA1, while Gd/SAd-IgA1 had significantly higher binding to CL-11 than SAd-IgA1 and IgA1.

Conclusions: Our results suggested collectin-11 as a recognition molecule in LP in IgAN. Collectin-11 prone to bind with aberrant glycosylated polymeric IgA1, which might contribute to the glomerular complement activation of LP in IgAN.

VIS649 Reduces Serum IgA Levels in NHPs Dose Dependently: PK/PD Exposure-Response Modeling for Translation to Treatment of IgA Nephropathy

Susan E. Sloan,[1] Frank A. Engler,[2] Kristy J. Szretter,[1] James R. Myette,[1] Kristin Narayan,[1] Bharathi L. Sundaresh,[1] Brian J. Pereira.[1] *[1]Visterra, Inc., Waltham, MA; [2]Certara USA Inc., Parsippany, NJ.*

Background: VIS649 is a humanized IgG2 monoclonal antibody that targets A PRoliferation-Inducing Ligand (APRIL), a cytokine that is implicated in IgA nephropathy

(IgAN) pathogenesis. Targeting APRIL activity to reduce levels of aberrantly glycosylated circulating IgA_1 may alter IgAN disease progression.

Methods: Cynomolgus monkeys (NHP; n=4/grp) were IV administered vehicle or VIS649 (0.5, 2.5 and 10 mg/kg) once weekly for 4 weeks, and followed for 8 weeks without treatment. Study endpoints included serum VIS649 and immunoglobulin (Ig) levels and peripheral lymphocytes (flow cytometry). Temporal changes in IgA concentration after VIS649 administration were described with a population pharmacokinetic/pharmacodynamic (popPK/PD) model using an indirect response model.

Results: At the 0.5 and 2.5 mg/kg dose levels there was a ~50% reduction in serum IgA levels. VIS649 administration at 10 mg/kg levels resulted in a ~70% serum IgA reduction. This maximal effect of ~70% reduction was confirmed in parallel studies at doses of up to 100 mg/kg and indicates that additional mechanisms support basal levels of IgA production. The effect of VIS649 on reducing IgA levels was reversible and observed after discontinuation of VIS649 treatment during the no-dose period with dose-dependent time to recovery. There was a lesser effect on serum IgG/IgM levels and peripheral lymphocytes were not affected. In a parallel study, a reduction in IgA+ mononuclear cells in GALT and tonsil tissues was observed, consistent with APRILs effect on Ig class switching and plasma cell survival in the mucosal compartment. These data were used to develop a popPK/PD model. Model simulation of single dose VIS649 in humans, in the range of 1-3 mg/kg, predicts a maximal (~70%) reduction in IgA levels followed by a dose-dependent return to baseline. Model simulation of repeated monthly doses suggest dose levels in the 0.3 to 3 mg/kg range will maintain a reduction in IgA levels below 50% of baseline.

Conclusions: VIS649 treatment reduces serum IgA levels in NHPs in a dose proportional manner. These data point to a clear potential therapeutic use of VIS649 in humans with IgAN.

Comparison of IgA1 Hinge-Region O-Glycoforms Between Patients with IgA Nephropathy and Healthy Subjects

Yukako Ohyama,[1] Kazuo Takahashi,[1] Hisateru Yamaguchi,[2] Shoko Matsushita,[1] Kazuki Nakajima,[3] Daijo Inaguma,[1] Midori Hasegawa,[1] Jan Novak,[4] Yoshiyuki Hiki,[1] Yukio Yuzawa.[1] *[1]Fujita Health University School of Medicine, Toyoake, Japan; [2]Institute for Comprehensive Medical Science, Fujita Health University, Toyoake, Japan; [3]Fujita Academy, Fujita Health University, Toyoake, Japan; [4]University of Alabama at Birmingham, Birmingham, AL.*

Background: IgA1 with galactose (Gal)-deficient hinge-region (HR) *O*-glycans (Gd-IgA1) plays a key role in the pathogenesis of IgA nephropathy (IgAN). Monoclonal antibody (mAb) specific for Gd-IgA1 developed for detection of Gd-IgA1 was used in ELISA to confirm elevated serum Gd-IgA1 levels in IgAN patients. An earlier study found that IgAN glomerular immunodeposits were enriched for Gd-IgA1, supporting a key role of Gd-IgA1 in IgAN pathogenesis. To identify potentially disease-specific IgA1 HR *O*-glycoforms, we profiled serum IgA1 HR glycopeptides using specimens from Japanese IgAN patients and healthy controls (HC) of different races.

Methods: IgA1 from sera of 20 Japanese IgAN patients and 50 HC, recruited from Caucasian, Black, Hispanic, Asian, and Japanese populations, was purified by affinity chromatography. After neuraminidase treatment and trypsin digestion, IgA1 HR glycosylation heterogeneity was analyzed by liquid chromatography-high-resolution mass spectrometry (LC-MS). Area under the peaks of extracted ion chromatogram (XIC) of identified IgA1 HR *O*-glycopeptides was calculated and expressed as relative abundance (RA) for each glycopeptide as percentage of all HR glycopeptides. The amount of each glycopeptide was then calculated by multiplying serum IgA concentration (mg/dL) by RA for the specific glycopeptide.

Results: Approximately 60% of HR *O*-glycoforms contained one to three Gal-deficient *O*-glycans in IgA1 from IgAN patients as well as healthy subjects. The amount of Gal-deficient HR variants was increased in IgA1 from IgAN patients compared to that of HC (P =0.043, IgAN *vs.* all HC; P =0.011, IgAN *vs.* Japanese HC). IgA1 with single Gal-deficient *O*-glycan was notably increased in patients with IgAN compared to HC (P =0.043, IgAN *vs.* all HC; P =0.009, IgAN *vs.* Japanese HC).

Conclusions: Profiling of IgA1 HR *O*-glycoforms of IgAN patients and HC indicated that Gd-IgA1 glycoform with single Gal-deficient *O*-glycan was elevated in Japanese IgAN patients compared to HC. Future analysis of IgA1 HR *O*-glycoforms in the glomerular immunodeposits will allow comparison with nephritogenic Gd-IgA1 glycoforms in sera of IgAN patients.

Disease Specific Profile of Fecal Microbiome in IgA Nephropathy

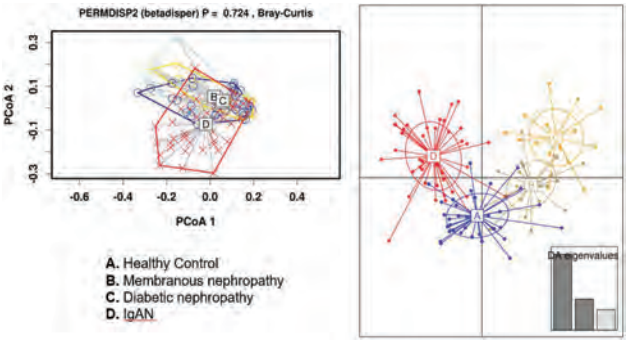
Ji In Park,[1] Hyunjeong Cho,[2] Ji Eun Kim,[3] Dong Ki Kim,[3] Seung Hee Yang,[4] Jung Pyo Lee,[5] Yon Su Kim,[6] Hajeong Lee.[6] *[1]Kangwon National University Hospital, Chuncheon-si, Republic of Korea; [2]Chungbuk National University Hospital, Cheongju-si, CHUNGCHEONGBUK-do, Republic of Korea; [3]Seoul National University Hospital, Seoul, Republic of Korea; [4]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [5]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [6]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: The mucosal immune system plays a role in the pathogenesis of Immunoglobulin A nephropathy (IgAN). Previously, the gut microbiota was proved to be essential to develop the IgAN in mice model. However, little has been known about the relationship between IgAN and the intestinal microbiome in human.

Methods: We enrolled 41 biopsy-proven IgAN patients at 3 centers and collected fecal specimens at the time of renal biopsy. Feces from 36 patients with biopsy-proven membranous nephropathy (MN) or diabetic nephropathy (DMN) were used as disease control (DC) and from 35 healthy volunteers as healthy control (HC). The composition of the microbiota was analyzed using extracted metagenomic DNA from the feces by Illumina MiSeq system.

Results: The estimated glomerular filtration rates (eGFR), which represents the renal function, were 106, 74 and 71 mL/min/1.73m^2 for HC, DC, and IgAN group, respectively. The Shannon diversity index did not differ among the 3 groups. Beta-diversity were plotted using principal coordinate analysis, which showed separation of IgAN from HC and DC groups. At phylum level, the relative abundances of Firmicutes and Acinetobacteria were higher, whereas those of Bacteroidetes and Proteobacteria were lower in IgAN patients than HC, DC groups. When we divided DC group into 21 patients with MN and 15 patients with DMN, the results from a comparison of 4 groups still showed IgAN specific character. At genus level, the number of the significantly different genus was 7 between HC and DC, 24 between HC and IgAN, and 28 between DC and IgAN. When IgAN patients were divided into two groups on the basis of eGFR 60 mL/min/1.73m^2 or 3g/day of proteinuria, the bacterial composition did not differ between groups.

Conclusions: The fecal microbiota of IgAN differed from those of healthy and disease control. We could tell the microbial difference of IgAN was not due to renal function but the IgAN-specific factor. For further investigation, shotgun metagenomic DNA sequencing is undergoing to characterize the functional genes of microbiota.



TH-PO817

The Differences in Podocyte Injury Between IgA Nephropathy and Membranous Nephropathy Based on Proteomics Analysis

Xizhao Chen,[1] Di Wu,[2] Guangyan Cai,[1] Xiangmei Chen.[1] *[1]Chinese PLA General Hospital, Beijing, China; [2]General hospital of PLA, Beijing, China.*

Background: IgA nephropathy (IgAN) is the most common primary glomerular nephritis worldwide. Currently, the diagnosis has to depend on renal biopsy which is an invasive practice. The developing proteomics can provide new ideas for exploring the potential biomarkers and pathogenesis of IgAN.

Methods: The renal tissue of 59 patients with IgAN was obtained and screened for differential protein expression (DEPs) profile by a high throughput method liquid chromatography-mass (LC-MS). The results in IgAN were compared to those in 9 patients with membranous nephropathy (MN) and 19 cases of adjacent normal tissues from renal cell carcinoma. Specific proteins in IgAN and MN were selected. Histochemical stain and double-labelling immunofluorescence stain were used to locate the proteins expressed in IgAN and MN. siRNA and stimulus were used to establish the gene expression cell models, and genes and proteins were detected by RT-PCR and western blot.

Results: (1) An overall sum of 6636 proteins were identified in IgAN, MN and normal tissue. There were 1086 DEPs in IgAN and 392 specific DEPs in IgAN when compared with MN. (2) Samples from patients with IgAN and MN were clearly distinguishable from normal controls. (3) Specific podocyte marker proteins such as nephrin and podocin were down-regulated both in IgAN and MN. Specific DEP CD151, which is a membrane protein of podocyte, was down-regulated in IgAN and has no expression change in MN. Histochemical stain and double-labing IF stain showed CD151 was located in IgAN and its expression was lower and weaker than that in MN and normal tissue. Specific DEP PLA2R1, which is a specific podocyte membrane protein, was significantly up-regulated in MN and has no expression change in IgAN. Histochemical stain showed PLA2R1 was higher and stronger expressed in the podocyte of MN. (4) TNFα could suppress CD151 expression and VEGFA could upregulate PLA2R1 expression in human primary podocyte, and down regulation of VEGFA in podocyte by siRNA could suppress the expression of PLA2R1.

Conclusions: Our study identified the differential expression of proteins in IgAN and MN tissues based on the proteomics analysis and detected the specific proteins CD151 and PLA2R1. TNFα-induced CD151 down-expression and VEGFA-induced PLA2R1 activation in podocyte might be one of the mechanisms in IgAN and MN that cause podocyte injury.

TH-PO818

Understanding the Nature of IgA Deposits in Secondary Glomerular Diseases

Anjali A. Satoskar,[1] Ana Malvar,[2] Valeria G. Alberton,[2] Cherri N. Bott,[1] Tibor Nadasdy,[1] Gyongyi Nadasdy,[1] Brad H. Rovin.[1] *[1]Ohio State University Wexner Medical Center, Columbus, OH; [2]HOSPITAL FERNANDEZ, Buenos Aires, Argentina.*

Background: Galactose-deficient IgA1 (Gd-IgA1) is important to the pathogenesis of primary IgA nephropathy (IgAN) and Gd-IgA1 is found in the glomeruli of IgAN. Other glomerular diseases mimic IgAN and feature significant glomerular IgA deposits, but it is not clear if the IgA in these kidneys is galactose-deficient. This study was done to qualitatively assess IgA in the glomerular deposits of patients with Staphylococcal infection-associated IgAN (IA-IgAN) and cirrhosis-associated IgAN (CA-IgAN).

Methods: Double immunofluorescence staining was done on paraffin-embedded kidney biopsies with anti-human IgA and with the monoclonal antibody KM55, which specifically recognizes Gd-IgA1. Kidney biopsies were from United State (US) and Argentine cohorts, and included patients with primary IgAN (n=9) as positive controls, lupus nephritis (LN, n=11) as negative controls, IA-IgAN (n=6) and CA-IgAN (n=5). The Argentine cohort also included 5 additional patients who had proliferative LN with dominant IgA deposits before and after treatment. IgA and Gd-IgA1 were graded semi-quantitatively based on an intensity scale of 0-3.

Results: Gd-IgA1 staining was robust in patients with primary IgAN as expected, and minimal in patients with LN (Table). In patients with CA-IgAN and IA-IgAN staining for Gd-IgA1 was positive but at about half the intensity of primary IgAN (Table). LN patients who had significant glomerular IgA deposits pre- and post-treatment did have detectable Gd-IgA1 at an intensity about half of Argentine primary IgAN. Gd-IgA1 intensity in primary IgAN was less in Argentine patients than US patients.

Conclusions: Galactose-deficient IgA is present in secondary glomerular diseases with IgA-dominant immune complexes. It is not clear if galactose-deficiency is acquired or if the systemic process unmasks intrinsic defects in IgA.

Funding: Clinical Revenue Support

Cohort	Gd-IgA1 Intensity
Primary IgAN-US	2.6±0.4
LN-US	0.4±0.4
CA-IgAN-US	1.3±0.9
IA-IgAN-US	1.7±1.2
Primary IgAN-Argentina	1.6±1.0
LN+dominant IgA-Argentina	0.7±0.3

TH-PO819

Activation of Toll Like Receptors 7/8 Altered IgA1 O-Glycosylation via Regulating Expression of O-Glycosyltransferases in IgA Nephropathy

Nuoyan Zheng,[1] Xueqing Yu.[2] *[1]The Translational Medical Center, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [2]Department of Nephrology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.*

Background: IgA nephropathy (IgAN) is featured with O-glycosylation deficiency of IgA1 antibody, but the underlying mechanism of production of Gd-IgA1 was unknown.

Methods: The expression levels of TLRs were analyzed by real-time PCR. The secretion of IgA1 molecules and their O-glycan after TLR activiation were meansured by ELISA. The expression of O-glycosyltransferases was analyzed by Western blot.

Results: We found that gene expression levels of TLR7 and TLR8 were significantly increased in peripheral blood mononuclear cells (PBMCs) of IgAN patients (Figure 1A). *Ex-vivo* activation of TLR7/8 in PBMCs led to more IgA1 antibody production and higher O-glycan deficiency of IgA1 antibody in IgAN patients as compared with healthy donors (Figure 1B). Meanwhile, activation of TLR7/8 resulted in decreased expression C1GalT1 and increased GalNAcT2 expression in B cells of IgAN patients (Figure 2).

Conclusions: Thus, activation of TLR7/8 play important role in pathogenesis of IgA nephropathy by regulating the expression of O-glycosyltransferase and later the galactose deficiency of IgA molecules.

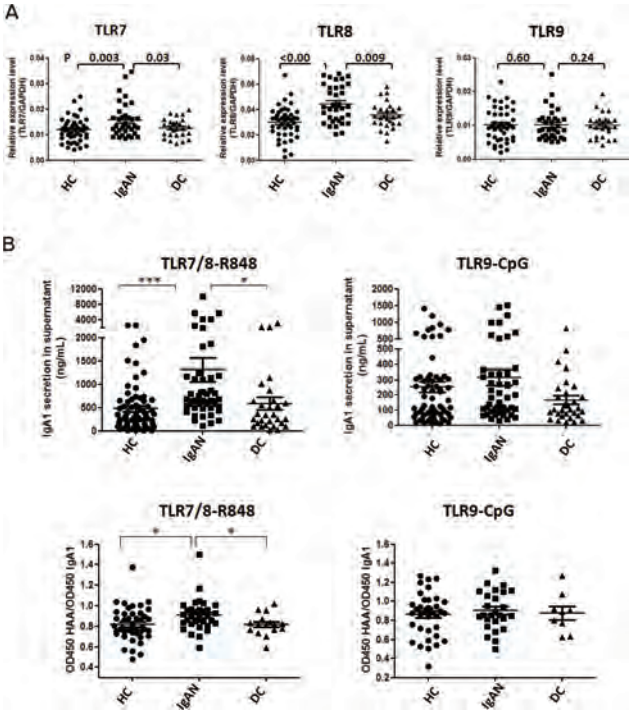


Figure 1-TLR7/8 activation led to augmented IgA1 secretion and galactose deficiency

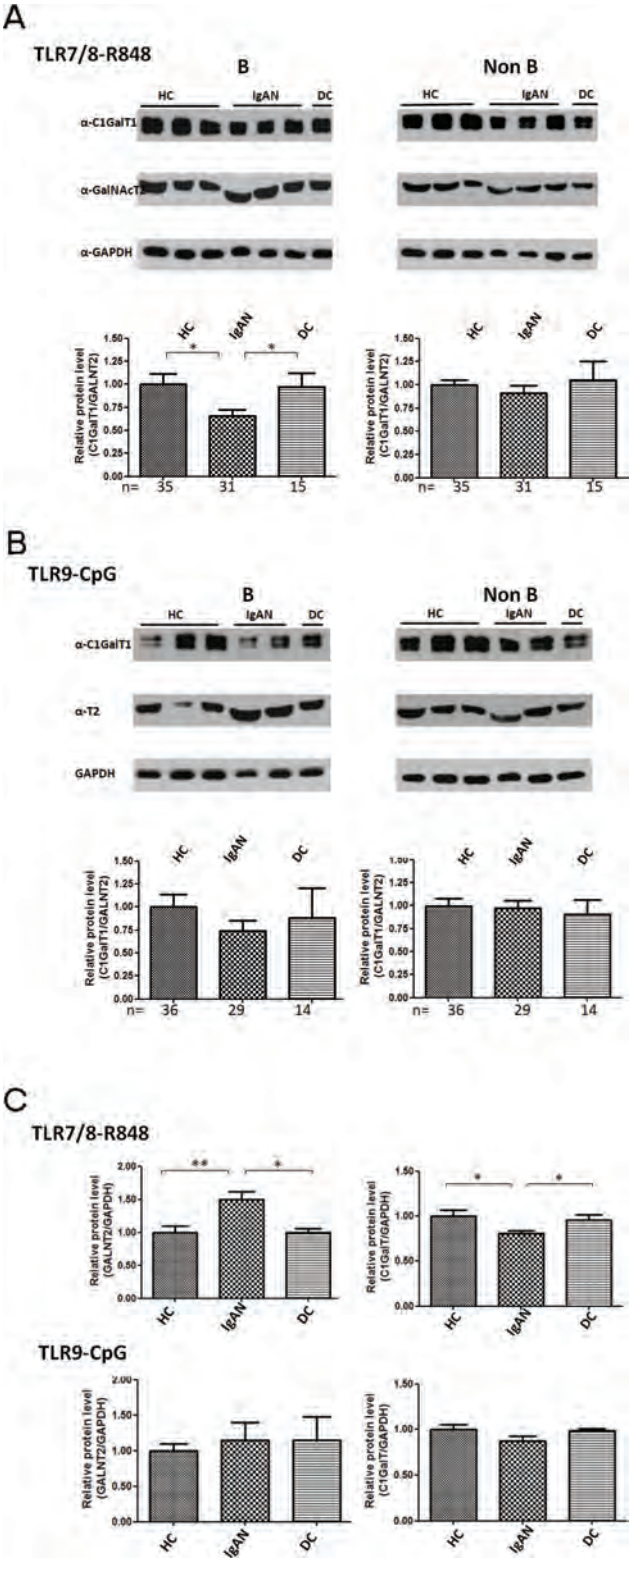

Figure 2-TLR7/8 activation regulates expression of O-glycosyltransferases.

TLR9 Activation Is Involved in Aberrant IgA Glycosylation via APRIL- and IL-6-Mediated Pathways in IgA Nephropathy

Yuko Makita,[1] Hitoshi Suzuki,[1] Toshiki Kano,[1] Bruce A. Julian,[2] Jan Novak,[2] Yusuke Suzuki.[1] *[1]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Department of Microbiology, University of Alabama at Birmingham, Birmingham, AL.*

Background: Toll-like receptors (TLRs) play a key role in the pathogenesis of IgA nephropathy (IgAN). Galactose-deficient IgA1 (Gd-IgA1) is involved in development of the disease. However, the mechanisms driving Gd-IgA1 production have not been fully elucidated. Although previous reports indicated a proliferation-inducing ligand (APRIL) and IL-6 may be involved in Gd-IgA1 synthesis in IgAN, the mechanisms leading to the overproduction of Gd-IgA1 and subsequent formation of Gd-IgA1 containing ICs are still unclear.

Methods: IgAN prone ddY mice were divided into two groups with CpG-ODN (TLR9 ligand) immunization (n=18) or without (n=18). CpG-ODN was injected intraperitoneally 3 times a week for 12 weeks. Renal pathology and serum levels of aberrantly glycosylated IgA, IgG-IgA ICs, APRIL and IL-6 were evaluated after 12 weeks. We also examined the mechanisms of production of Gd-IgA1 in human IgA1-secreting cells.

Results: Injection of ddY mice with CpG-ODN increased production of aberrantly glycosylated IgA and IgG-IgA ICs, resulting in exacerbated kidney injury ($P<0.05$). Serum levels of APRIL correlated with serum levels of aberrantly glycosylated IgA and IgG-IgA IC ($P<0.05$). CpG-ODN stimulation induced production of aberrantly glycosylated IgA in splenocytes of ddY mice through increase of APRIL and IL-6. In human IgA1-secreting cells, TLR9 activation enhanced Gd-IgA1 production *via* increase of APRIL and IL-6. Production of Gd-IgA1 was partly reduced by siRNA for *APRIL* and/or anti-IL-6.

Conclusions: TLR9 stimulation enhanced synthesis of nephritogenic IgA through overproduction of APRIL and IL-6 in IgAN. Moreover, the present study clarified the crosstalk between APRIL and IL-6, of note APRIL and IL-6 independently promote the production of aberrantly glycosylated IgA.

TH-PO821

T-Follicular Like Helper Cells Enhance IgA Secretion in IgA Nephropathy

Nicholas J. Steers,[1] Jaclyn L. Wold,[2] Maddalena Marasa,[1] Ali G. Gharavi.[1] *[1]Columbia University, New York, NY; [2]Columbia University Medical Center, New York, NY.*

Background: Dysregulated IgA1 response is a central defect in the development of IgA Nephropathy (IgAN), but is it not clear if the altered IgA1 response is attributed to excessive self-proliferation of IgA+ B-cells or an imbalance in the B-cell-T-cell interactions. We investigated the mechanism of IgA production, focusing on the function of T-follicular helper (Tfh) cells, which have recently been shown to play an essential role in antibody response.

Methods: We studied 15 IgAN patients and 20 healthy controls (HC). IgA antibody secreting cells (ASC) were measured by flow cytometry. Naive B-cells, Naïve CD4+ T-cells and T-follicular like helper cells were sorted from the PBMC of patients, and IgA was measured from the B-cell-T-cell co-cultures.

Results: We detected a 3.6 fold increase in IgA ASC numbers and 1.6-fold increase in Tfh like cells in the peripheral blood of IgAN patients compared to HC. Both IgA ASC and Tfh like cell numbers were strongly correlated with the increased IgA and IgA1 levels in the plasma. To distinguish whether enhanced IgA production is dependent on B-cells or Tfh like cells, we performed co-culture experiments. Autologous co-culture experiments of Tfh like cells with naïve B-cells resulted in significantly increased IgA production in cells derived from IgAN patients (172.9 ± 60.9 ng/ml), compared to HC (58.4 ± 13.3 ng/ml). Next, we performed co-culture experiments with cells derived from two pairs of monozygotic twins who are discordant for IgAN. Co-culture of Tfh like- and naïve B-cells from monozygotic twins with IgAN and one self-declared healthy control, and as expected yielded significantly higher IgA production compared to co-culture of cells from their corresponding healthy twins. In addition, Tfh like cells from the IgAN twins significantly increased IgA production from the naïve B-cells from the healthy twins (169.5 ± 31.9 ng/ml) but Tfh like cells from the one healthy twin only elicited baseline IgA production from naïve B-cells from the IgAN twins (59.3 ng/ml).

Conclusions: Our data demonstrate an independent role of T-follicular like helper cells in enhanced generation of IgA in IgAN, identifying a new important step in IgAN pathogenesis. Future studies will be directed towards identification of molecular programs leading to enhanced Tfh like cell count and activity in IgAN.

TH-PO822

Urinary Galactose-Deficient IgA1 Represent a Disease-Specific Marker of IgA Nephropathy

Hitoshi Suzuki, Toshiki Kano, Yuko Makita, Yusuke Fukao, Yusuke Suzuki. *Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: IgA nephropathy (IgAN) is an autoimmune disease characterized by IgA1-containing immune deposits in mesangium. Galactose-deficient IgA1 (Gd-IgA1) is recognized by anti-glycan autoantibodies, resulting in formation of pathogenic immune complexes. These immune complexes deposit in the kidney, activate mesangial cells, and induce glomerular injury. We recently elucidated that glomerular Gd-IgA1 was specifically detected in IgAN, but not in the other renal diseases by immunohistochemistry using Gd-IgA1 monoclonal antibody (KM55 mAb). We hypothesized that a fraction of Gd-IgA1 from

the glomerular deposits may be excreted into the urine and thus represent a disease-specific marker.

Methods: We recruited biopsy proven 129 patients with IgAN and 79 patients with other renal diseases (control) hospitalized from 2015 to 2017. Serum and urine samples collected at the time of renal biopsy were used to measure Gd-IgA1. Serum and urinary Gd-IgA1 were determined by KM55 mAb. Moreover, consecutive urinary Gd-IgA1 were measured during the course of therapy in 51 patients with IgAN.

Results: Urinary Gd-IgA1 levels were significantly higher in patients with IgAN compared with control (P<0.01). Even in patients with IgAN revealed trace proteinuria (less than 0.3g/gCr), urinary Gd-IgA1 were definitely detected. Moreover, urinary Gd-IgA1 decreased response to therapy (P<0.001). Urinary Gd-IgA1 levels were well correlated with proteinuria in patients with IgAN (P<0.001), but not in control.

Conclusions: Urinary Gd-IgA1 was elevated in patients with IgAN. The fraction of Gd-IgA1 from the glomerular deposits may be excreted into the urine, as serum levels of Gd-IgA1 did not correlate with urinary Gd-IgA1. Importantly, urinary Gd-IgA1 may be an early biomarker compared with proteinuria in patients with IgAN. U rinary Gd-IgA1 is also useful to determine disease activity. Urinary Gd-IgA1 may thus represent a disease-specific biomarker of IgAN.

Circulating Autoantibodies in Lupus Nephritis Patients Target the Cytoskeleton Linking Protein, Moesin, and Disrupt Podocyte Actin Cytoskeleton

Dawn J. Caster,[1] Erik Korte,[4] Michael Merchant,[2] Jon B. Klein,[3] Shweta Tandon,[4] Kenneth R. McLeish,[4] David W. Powell.[4] *[1]Medicine/Nephrology, University of Louisville, Louisville, KY; [2]University of Louisville Medicine, Louisville, KY; [3]University of Louisville Kidney Disease Program, Louisville, KY; [4]University of Louisville, Louisville, KY.*

Background: The pathogenesis of lupus nephritis (LN) is characterized by glomerular deposition of immune complexes (IC) containing nucleosomes and anti-nuclear autoantibodies. However, proteomic studies in LN and other glomerular diseases identified a number of autoantibodies against tissue proteins. We used a targeted proteomic approach combining immunoblot analysis of human podocyte membrane proteins using sera from LN patients with high performance MS to identify moesin as a candidate target protein. We showed that autoantibodies against moesin were present in the sera of patients with proliferative LN and glomeruli in renal biopsies from those patients showed increased expression of moesin. This study tested the hypothesis that autoantibodies to moesin participated in IC formation in LN.

Methods: Frozen remnant kidney biopsy samples from patients with proliferative LN were cut into 4-6 μm sections (n= 5) and incubated with anti-moesin antibody at 1:50 overnight followed by sequential incubation with: 1) fluorescent secondary antibody at 1:200 2) fluorescent conjugated anti-human IgG at 1:200. Images were obtained on confocal microscopy. A human-derived podocyte cell line was cultured on collagen-coated glass bottom dishes at 37°C for 8-10 days. Cells were serum starved with 0.5% FBS medium 24 h before anti-moesin antibody, IgG controls, or vehicle was added for 24 h. Actin organization was detected by staining with rhodamine-phalloidin for 30 minutes. Rhodamine staining on confocal microscopy images was analyzed visually and for actin anisotropy by FibrilTool.

Results: To determine if moesin was contained in IC, renal biopsies from patients with proliferative LN were examined for co-localization of moesin and IgG. Confocal images showed minimal co-localization, indicating anti-moesin autoantibodies were not participating in IC formation. As moesin is a cytoskeletal linking protein, the ability of anti-moesin to disrupt podocyte actin organization was tested. Podocytes cultivated with anti-moesin antibodies, but not control IgG or vehicle, showed loss of actin cytoskeletal organization and decreased anisotropy.

Conclusions: We conclude that autoantibodies against moesin may participate in glomerular injury in LN by disruption of podocyte cytoskeletal organization.

A Humanized Mouse Model of SLE and LN

Samia Q. Khan, Xiaobo Li, Huiting Wei, Eunsil Hahm, Meenakshi Jolly, Vineet Gupta. *Rush University Medical Center, Chicago, IL.*

Background: Lupus Nephritis (LN) is a common complication of systemic lupus erythematosus (SLE) with unclear etiology and limited treatment options. Single Nucleotide Polymorphisms (SNPs) in ITGAM (which codes for CD11b) strongly associate with disease pathogenesis. Yet, the role of these mutations in disease pathobiology is unclear, primarily because of a lack of experimental models. Additionally, while available spontaneous or induced mouse models of SLE have advanced our understanding of lupus, none of them replicate human disease very well. Here, we present a novel humanized mouse model of SLE and LN that better mimics the human disease and, we hope, will greatly improve our understanding of the cellular and genetic determinants driving lupus and aid in the development of novel therapeutics.

Methods: Peripheral blood mononuclear cells (PBMCs) were transferred from healthy donors or SLE patients into NSG mice (Healthy-NSG and SLE-NSG). Weekly blood and urine samples were collected and humanized mice were monitored for lupus symptoms until end-point at 6-weeks post engraftment when they were sacrificed and tissues, serum and blood were harvested for further analysis.

Results: Using our optimized protocol, the engraftment of healthy and SLE PBMCs was 100% successful in the NSG mice. We observed an average of 78% human CD45+ cells in the spleens at 6 weeks post engraftment. Interestingly, mouse CD11b+Gr1+ cells and human CD14+ cells were significantly elevated *in vivo* in SLE-NSG mice as compared to healthy-NSG mice. Within 1 week, SLE-NSG mice also lost whiskers and developed alopecia. Histopathological analysis of nasal dermis showed increased epidermal thickness and leukocyte density. Similar to human PBMC donors that displayed renal decline, SLE-NSG mice also showed significantly elevated levels of serum anti-dsDNA and suPAR, and significantly reduced kidney function, as indicated by elevated levels of proteinuria, renal leukocyte infiltration, renal fibrosis and glomerular damage.

Conclusions: This novel humanized SLE/LN model exhibits several clinical manifestations of human lupus and is an important tool to test therapies.

TH-PO825

Clinical Associations with Serum Syndecan-1 Level in Patients with Lupus Nephritis

Susan Yung, Kelvin Yu, Mel Chau, Kwok Fan Cheung, Daniel Tak Mao Chan. *The University of Hong Kong, Hong Kong, China.*

Background: Cardiovascular disease is an important long-term complication in patients with lupus nephritis. The endothelial glycocalyx regulates the adhesiveness of circulating cells to vascular endothelial cells and vascular permeability. Syndecan-1 is a component of the endothelial glycocalyx, and syndecan-1 shedding occurs in endothelial cell activation or injury.

Methods: Serial serum samples from patients with biopsy-proven Class III/IV lupus nephritis were obtained at intervals of 3-4 months over two years. In addition, paired samples with one obtained during flare and the other during remission were included. Sera from age- and sex-matched patients with IgA nephropathy (IgAN), SLE patients without nephritis, and healthy subjects were included as controls (n=25 for each group). Serum syndecan-1 level was determined by ELISA.

Results: Four hundred and sixty sera from 29 lupus nephritis patients (20 females and 9 males; age 39.0±10.2 years; disease duration 7.6±8.6 years) were studied. Serum syndecan-1 level was significantly higher during active lupus nephritis compared with remission, and also the IgAN, non-renal lupus, and healthy control groups (P<0.001, for all). Syndecan-1 level correlated with SLEDAI (r=0.535, P<0.001), anti-dsDNA antibody level (r=0.407, P=0.003), serum creatinine level (r=0.262, P=0.05), proteinuria (r=0.571, P<0.001), and inversely correlated with serum C3 (r=-0.443, P=0.001) and albumin levels (r=-0.568, P<0.001). Circulating syndecan-1 level showed a temporal relationship with disease activity and changes in anti-dsDNA antibody and C3 levels. ROC curve analysis showed that serum syndecan-1 level distinguished active lupus nephritis from healthy subjects with sensitivity and specificity rates of 96.3% and 96.0% respectively, from IgAN patients with respective rates of 85.2% and 91.3%, and from non-renal lupus patients with respective rates of 85.7% and 70.4% (P<0.0001, for all).

Conclusions: Active lupus nephritis is associated with increased circulating syndecan-1 level, and thus may contribute towards the pathogenesis of cardiovascular complications in patients with lupus nephritis.

Complement Activation in Renal Thrombotic Microangiopathy Associated to Systemic Lupus Erythematosus: An Exploratory Analysis

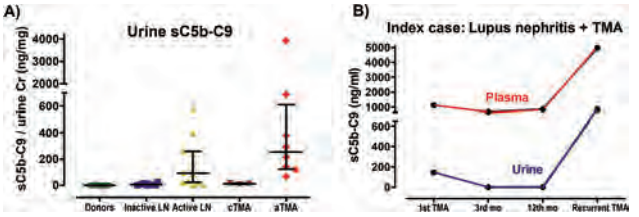
Ismael A. Gómez Ruiz, Carlos Nuñez alvarez, Cristinoc Cruz, Luis E. Morales-Buenrostro, Ricardo Correa-Rotter, Juan M. Mejia-Vilet. *Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico.*

Background: Renal thrombotic microangiopathy (TMA) in SLE is a rare and severe manifestation with dismal prognosis. While complement participation in lupus nephritis (LN) has been studied, its role in SLE renal TMA remains lesser explored.

Methods: To study complement proteins we included patients with SLE-renal TMA (n=12), active biopsy-proven LN (n=12), inactive SLE patients (n=9) and living kidney donors (n=5). Renal TMA patients were divided into acute TMA (aTMA) or chronic TMA (cTMA) according to histopathology. Terminal complement pathway activation was evaluated by a soluble C5b-C9 ELISA. Alternative pathway urine C3d fragment was evaluated with a specific monoclonal antibody. Groups were compared by Kruskal-Wallis test and correlations obtained by Spearman's rho.

Results: Of 12 patients with SLE renal TMA, 3 (25%) had positivity for aPL antibodies and 9 corresponded to aHUS. Renal TMA patients presented with higher arterial pressure, serum creatinine and dsDNA titers; while hemoglobin, platelets and haptoglobin levels were lower than in active LN. Notably, renal TMA patients had few systemic manifestations of microangiopathic hemolytic anemia. Renal TMA biopsies showed higher global sclerosis, interstitial fibrosis and tubular atrophy. Plasma and urine sC5b-C9 titers in both renal TMA and active LN groups were higher than in inactive LN and kidney donors. Urine sC5b-C9 titers were higher in renal aTMA compared to cTMA (Figure A). In the Figure B we present the case of a patient with SLE and 2 renal TMA episodes. As shown, urine and plasma sC5b-C9 titers rose during the acute event and diminished after treatment. There was a trend for higher urine C3d fragment in aTMA compared to cTMA and active LN. There was a correlation between urine sC5b-C9 titers and serum creatinine (r=0.308, p=0.017) and proteinuria (r=0.686, p<0.001).

Conclusions: There is activation of complement pathway in renal TMA evidenced by the elevation of complement protein's fragments. It should be further explored if these tests may be of use to follow-up the course of the disease.



TH-PO827

Hepcidin Modulates Macrophage Iron Metabolism to Attenuate Lupus Nephritis

Yogesh M. Scindia,[1] Ewa U. Mandziak,[1] Valentina Loi,[2] Joseph T. Leeds,[1] Sundararaman Swaminathan.[1] *[1]University of Virginia, Charlottesville, VA; [2]AO Brotzu Cagliari, Cagliari, Italy.*

Background: Lupus nephritis (LN) is an end-organ manifestation of systemic lupus erythematosus (SLE) mostly affecting the female population. Renal inflammation, macrophage recruitment and proliferation are associated with worse outcome in LN. Hepcidin is a primary regulatory of macrophage iron metabolism and phenotype. The role of Hepcidin or iron transport has not been investigated in lupus. We hypothesized that hepcidin would mitigate LN by targeting macrophage responses.

Methods: 8-week-old femaleMRL/*lpr* mice (a spontaneous model of SLE) were treated twice a week with saline or 50 µg of hepcidin (i.p) for 10 weeks, following which outcomes like microalbuminuria, histopathology, and other markers of macrophage inflammation and proliferation were examined. In-vitro, macrophages (J774A) were treated with Hepcidin and stimulated with Polyinosinic-polycytidylic acid (Poly (I:C)) or M-CSF1 to evaluate inflammatory and proliferative response.

Results: Saline-treated mice developed severe LN by 18 weeks of age as indicated by high microalbuminuria, fibrosis, renal Cox-2, IL-6, CXCL-1 and M-CSF transcripts, immune complex deposits, iron accumulation and an infiltration of F4/80+ve macrophages. Hepcidin treatment significantly reduced all these manifestations of LN. There was an increase in renal H-ferritin and a concomitant decrease Rrm-1 and Rrm-2, iron dependent enzymes required for DNA synthesis. This was associated with a reduction in Ki-67 positive macrophages and other cells within the kidney. In-vitro hepcidin induced H-ferritin in macrophages and reduced their labile iron (Fe^{2+}) content. H-ferritin^{hi}macrophages secreted less IL-1bfollowing Poly (I:C) stimulation and proliferated less in response to M-CSF1.

Conclusions: We demonstrate a novel protective effect of hepcidinagainst LN which could open new therapeutic approaches to treat LN. Hepcidin induces H-ferritin that lowers labile iron and reduces inflammatory response and macrophage proliferation, two cardinal features of LN. Renal iron accumulation and increased Cox-2 suggest involvement of Ferroptosis in the pathogenesis of SLE. Further studies are required to investigate whether hepcidin also targets renal parenchymal cells or other immune effectors.

TH-PO828

Urinary Galectin-3 Binding Protein as a Predictive Marker for Lupus Nephritis Flare

Samir V. Parikh,[1] Xiaolan Zhang,[1] Roberto Bassi,[2] Sneha Varghese,[2] Pramod P. Mehta,[3] Wen-Rong Lie,[3] Shinji L. Okitsu,[4] Brad H. Rovin.[1] *[1]Ohio State University Wexner Medical Center, Columbus, OH; [2]EMD Serono R&D Institute, Rockland, MA; [3]MilliporeSigma, St Louis, MO; [4]EMD Serono Research and Development Institute, Billerica, MA.*

Background: Identifying predictive markers of lupus nephritis (LN) flare has been elusive but is necessary to improve outcomes. Serum galectin-3 binding protein (G3BP) is correlated with interferon signature in active SLE. We aimed to define the specificity of urine G3BP (*u*G3BP) as marker of LN flare and determine its ability to predict flare and response to treatment.

Methods: *u*G3BP protein expression was measured from urine collected at the time of kidney biopsy and compared across multiple glomerular diseases including active LN (n=97), IgA nephropathy (n=27), diabetic nephropathy (n=10), primary membranous nephropathy (n=10), ANCA-associated vasculitis (n=4) and healthy controls (n=20). Additionally, active LN expression was compared to LN remission (n=52). *u*G3BP levels were normalized for urinary creatinine (Cr). To examine uG3BP expression longitudinally, urine from the Ohio SLE cohort study (OSS) of 27 LN patients (44 flares) was measured by ELISA at 5 different time points; -4, -2, flare, +2, and +4 months post flare. *u*G3BP expression was compared between each time point to understand if *u*G3BP is a sensitive marker to predict the development and resolution of inflammation in LN.

Results: *u*G3BP expression was significantly increased in all tested kidney diseases, except ANCA compared to healthy controls ($p<0.0001$). The highest concentration of *u*G3BP was found in active LN (423.79±32.06 ng G3BP/mg Cr). *u*G3BP expression was significantly greater at LN flare compared to controls (423.79±32.06 vs 44.8 ng G3BP/mg cr, $p<0.0001$), IgA nephropathy (423.79±32.06 vs 138 ng G3BP/mg Cr, $p<0.0001$) and remisison LN (423.79±32.06 vs127.5 ng G3BP/mg Cr, $p<0.0001$). *u*G3BP expression increased incrementally from 4 months pre-flare to flare, peaked 2 months post-flare ($p=0.02$ compared to flare levels) and significantly decreased 4 months post-flare ($p=0.01$).

Conclusions: *u*G3BP, while not specific, is highly expressed at LN flare reflecting interferon activation. *u*G3BP expression may predict LN flare but due to limited samples size data are currently inconclusive. Further investigation is warranted. *u*G3BP expression may be a predictive marker of treatment response.

TH-PO829

Molecular Profiling of the Kidney in Lupus Nephritis (LN) to Identify Heterogeneity in Different Races and Ethnicities

Isabelle Ayoub,[2] Ana Malvar,[1] Samir V. Parikh,[2] Huijuan Song,[3] John P. Shapiro,[5] Paolo Fadda,[5] Lianbo Yu,[3] Anjali A. Satoskar,[3] Brad H. Rovin.[4] *[1]HOSPITAL FERNANDEZ, Buenos Aires, Argentina; [2]Ohio State University Medical Center, Columbus, OH; [3]Ohio State University, Upper Urlington, OH; [4]Ohio State University Wexner Medical Center, Columbus, OH; [5]Ohio State University, Columbus, OH.*

Background: Black and Hispanic LN patients have worse kidney outcomes than white patients. Beyond socioeconomic status, we postulated that differential activation/inactivation of molecular pathways during LN flare may contribute to this racial and ethnic difference. To test this hypothesis we examined the intrarenal transcript profiles of African American (AA), Caucasian (Cau) and Caucasian Hispanic (H) patients at their first "induction naïve" LN flare

Methods: Kidney biopsies were done at the first episode of class III or IV LN in 13 AA, 11 Cau, and 8 H patients. Glomeruli were isolated by laser capture microdissection. RNA was analyzed using Nanostring technology. The expression of 579 genes was compared between groups. Transcripts with at least a 2-fold change and $p<0.01$ were considered differentially expressed

Results: Eight transcripts differentiated AA from Cau, one was upregulated. The expression of HLADRA was 2-fold higher and the immune-modulator HLADOB was 2-fold lower in AA compared to Cau. IL-4, a Th2 pathway gene was downregulated in AA compared to Cau. One hundred transcripts differentiated Cau from H. Thirty-three of these were upregulated in Cau compared to H. The top 3 upregulated transcripts were: fibronectin (FN1, fold change (FC) =34.82; p=1.8x10-12), osteopontin (SPP1, FC= 24.43; p=1.27x10-07) and FCER1G (FC 17.68; p=5.28x10-09). Pathway analysis revealed downregulation of INF (A1, A2 and B1) and Th2 signaling in Cau compared to H. Hundred and nine transcripts were downregulated in AA compared to H. The main pathways affected were T helper cell differentiation, Th1 and Th2 activation and T/B cell signaling.

Conclusions: Molecular signatures appear to be different for the same histologic class of LN in different races and ethnicities. The differences in HLA, IL4 and T/B cell signaling genes suggest a greater propensity toward immune activation and inflammation in AA compared to Cau. This may partly explain why AA LN patients have more severe kidney injury. The molecular signature of Cau compared to H suggests more inflammatory disease in Cau but more T cell-mediated immune activation in H

TH-PO830

Podocyte Autophagy Could Protect Renal Injury in Lupus and Might Be a Therapeutic Target

Xujie Zhou,[1] Yuan-yuan Qi,[2] Wang Yanna,[1] Hong Zhang.[1] *[1]Peking University First Hospital, Beijing, China; [2]1. Renal Division, Peking University First Hospital, 2. Peking University Institute of Nephrology, Beijing, China.*

Background: More recent studies suggested that defects in autophagy contribute to the pathogenesis of SLE, especially in adaptive immunity. Occurrence and progression of lupus nephritis (LN) is the end result of complex interactions between regulation of immune responses and pathological process by renal resident cells, but there is still a lot of missing information for an establishment on the role of autophagy in pathogenesis of LN and as a therapy target.

Methods: Systemic and organ specific etiologies of autophagy were firsly evaluated by autophagy protein quantification in tissue homogenates in MRL$^{lpr/lpr}$ lupus prone and female C57BL mice. Analysis of gene expression was also adopted in human blood and urine sediments. Then, some key mediators of the disease, including complement inactivated serum, IgG from patients with LN (IgG-LN) and IFN-α were chosen to induce podocyte autophagy. Podocyte injuries including apoptosis, podocin derangement, albumin filtration, and wound healing were monitered simultaneously with autophagy steady-state and flux.

Results: Elevated LC3B in kidney homogenates and increased autophagosomes in podocyte from MRL$^{lpr/lpr}$ were observed. In humans, mRNA levels of some key autophagy genes were increased in blood and urinary sediments, and podocyte autophagosomes were observed in renal biopsies from patients with LN. Complement inactivated serum, IgG-LN and IFN-α could induce podocyte autophagy in a time and dosage dependent manner, and by reactive oxygen species production and mTORC1 inhibition, respectively. Autophagy inhibition aggravated podocyte damage whereas its inducer relieved the injury.

Conclusions: Podocyte autophagy could protect renal injury in lupus and might be a therapeutic target.

TH-PO831

Urine IP-10 Increased Sensitivity in Lupus Nephritis Detection

Wonngarm Kittanamongkolchai,[1,2] Api Chewcharat,[1,2] Yingyos Avihingsanon.[1,2] Renal Immunology and Therapeutic Apheresis Research Unit *[1]Nephrology, Chulalongkorn University, Bangkok, Thailand; [2]Maha Chakri Sirindhorn Clinical Research Center, Chulalongkorn University, Bangkok, Thailand.*

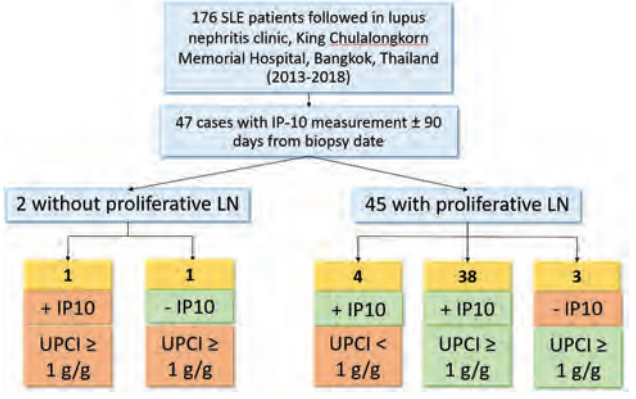
Background: Interferon γ-inducible protein(IP-10) is an important T-helper1 chemokine expressed locally in the kidney of lupus patients. Non-invasive test for urine IP-10 may improve the detection of active lupus nephritis(LN).

Methods: Since 2013, urine IP-10 has been measured in all SLE patients with clinical suspicion of LN at the specialized LN clinic in a tertiary care hospital in Thailand. We retrospectively reviewed the case records of those who underwent renal biopsy from October 2013 to February 2018 and had urine IP-10 measurement within 90 days from date of renal biopsy.

Results: Of 176 SLE patients followed at LN clinic, 47 had renal biopsy with urine IP-10 measurement within the certain period. Urine IP-10 was positive (> 2 log copies number) in 42 out of 45 patients(93%) with biopsy-proven proliferative LN, while proteinuria was found (UPCI > 1) in 41 patients (91%). Two patients who had only renal scarring on biopsy had proteinuria, while urine IP-10 was negative in 1 patient(Figure 1). Four patients with proliferative LN who had positive urine IP-10 without proteinuria were noted for focal podocyte foot process effacement (Table 1). All of them had stable renal function and normalization of C3 without proteinuric flare after 6-month of induction therapy. There were 8 patients who had serial urine IP-10 measurement prior to renal biopsy. In 6 patients, urine IP-10 was positive before proteinuric flare (median 6 months), whereas 2 patients were simultaneously positive for proteinuria and IP-10.

Conclusions: Urine IP-10 enhances sensitivity of LN detection, especially in those without proteinuria. Its levels even increased prior to proteinuric flare in most cases. Combined use of urine IP-10 and conventional markers may increase early detection of LN and ultimately improve renal outcomes

Funding: Government Support - Non-U.S.



Clinical and laboratory characteristics of patients with biopsy-proven proliferative lupus nephritis who had 1) positive urine IP-10 without proteinuria and 2) proteinuria with negative urine IP-10

Subject	ISN/RPS class	Foot process effacement	eGFR	Alb	UA WBC	UA RBC	UPCR	Anti-dsDNA	C3	C4	Indications for renal biopsy

Angiotensin-II Type 1 Receptor Agonist Antibodies Are Prevalent in Lupus Nephritis Patients But May Have Limited Clinical Impact

Juan M. Mejia-Vilet, Yesser J. López hernández, Mariedel Trujeque, Carlos alberto Carranza, Jesus I. Santander, Ricardo Espinosa-González, Norma O. Uribe-uribe, Luis E. Morales-Buenrostro. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico.*

Background: Angiotensin II type 1 receptor agonist antibodies (AT1R-AA) have been associated with hypertension, atherosclerosis and vascular inflamation in human diseases.

Methods: The aim of the study was to evaluate the prevalence of AT1R-AA in lupus nephritis (LN) and their association to hypertension and vascular damage. Eighty LN patients were evaluated by ambulatory blood pressure monitoring (ABPM), carotid Doppler ultrasound and renal biopsy vessel morphometry. AT1R-AA were evaluated in 112 kidney donors as a control group. AT1R-AA response to induction to remission therapy was followed for 6 months. Variables were compared by Fisher exact test or Kruskal-Wallis test. For correlations, serological titers were log-transformed and evaluated by Pearson test.

Results: Plasma AT1R-AA were positive in 45 (56.3%) and 23 (28.8%) had titers >250u/ml (Figure 1). AT1R-AA titers correlated with double-strand DNA antibodies' (dsDNA-Ab) titer (r=+0.651,p<0.001, Figure 1) and serum complement fragments C3 (r=-0.289,p=0.009) and C4 (r=-0.451,p<0.001). 77% of patients had an abnormal ABPM result, with 58% and 23% manifesting a diminished or absent dipping respectively. There was no association between AT1R-AA and ABPM blood pressure levels. Abnormal carotid intima-media thickness was found in 7.8%, with a trend for a greater CIMT in patients with the highest AT1R-AA titers. Subintimal fibrosis >10% was found in 46.3% of kidney biopsies. There was no association between AT1-AA titers and subintimal fibrosis. AT1R-AA response to treatment was evaluated in 40 patients. AT1R-AA titers course followed that of the dsDNA-Ab but was not associated with the response to treatment.

Conclusions: AT1R-AA are highly prevalent in lupus nephritis patients and closely correlate with serological activity but their pathogenic role is questionable. AT1R-AA cannot be recommended to be measured routinely.

Funding: Government Support - Non-U.S.

B Cell Subsets and Signatures in Lupus Nephritis Patients Receiving Mycophenolate or Azathioprine Maintenance

Desmond Y. Yap,[1] Paul Lee,[2] Cheryl Tam,[2] Irene Yam,[2] Susan Yung,[2] Daniel Tak Mao Chan.[1] *[1]Queen Mary Hospital, Hong Kong, China; [2]The University of Hong Kong, Hong Kong, China.*

Background: Mycophenolate mofetil (MMF) and azathioprine (AZA) are standard maintenance agents for lupus nephritis (LN), and recent data suggested that MMF confers lower long-term flare risk. Aberrant B cell profiles have been implicated in LN pathogenesis, but the effect of MMF and AZA on B cell subsets and related signatures has not been investigated.

Methods: We measured the B cell subsets and serum and intracellular levels of relevant B cell signatures (miRNA148a, BACH1, BACH2 and PAX5) in stable LN patients receiving MMF or AZA (n=10 in each group), combined with low-dose prednisolone, as maintenance immunosuppression.

Results: The MMF group showed higher % of circulating naïve B cells and lower % of plasma cells (4.8±5.2% and 0.2±0.3% respectively, compared with 0.9±1.5% and 0.8±0.9% in AZA group, p=0.029 and 0.043), but had no difference in circulating memory B cells (p=0.97). The MMF group also showed lower plasma cell/naïve B and memory B/naïve B ratios (0.1±0.2 and 1.3±2.1 respectively, compared with 1.7±1.4 and 1.7±1.1 in AZA group, p=0.003 and 0.023). The MMF group showed numerically higher intracellular BACH1, BACH2 and PAX5 in naïve B cells (relative expression (RQ): 1.2±0.5, 1.4±0.2 and 2.6±1.7 respectively compared with AZA group; p>0.05, for all) (Figure 1A) and in plasma cells (RQ: 1.3±0.1, 1.4±0.3 and 1.3±0.6 respectively compared with AZA group; p>0.05, for all) (Figure 1B), but showed no difference in serum and intracellular miRNA148a.

Conclusions: The alterations in B cell subsets and related signatures might contribute to the differential risk of relapse in patients receiving MMF or AZA maintenance.

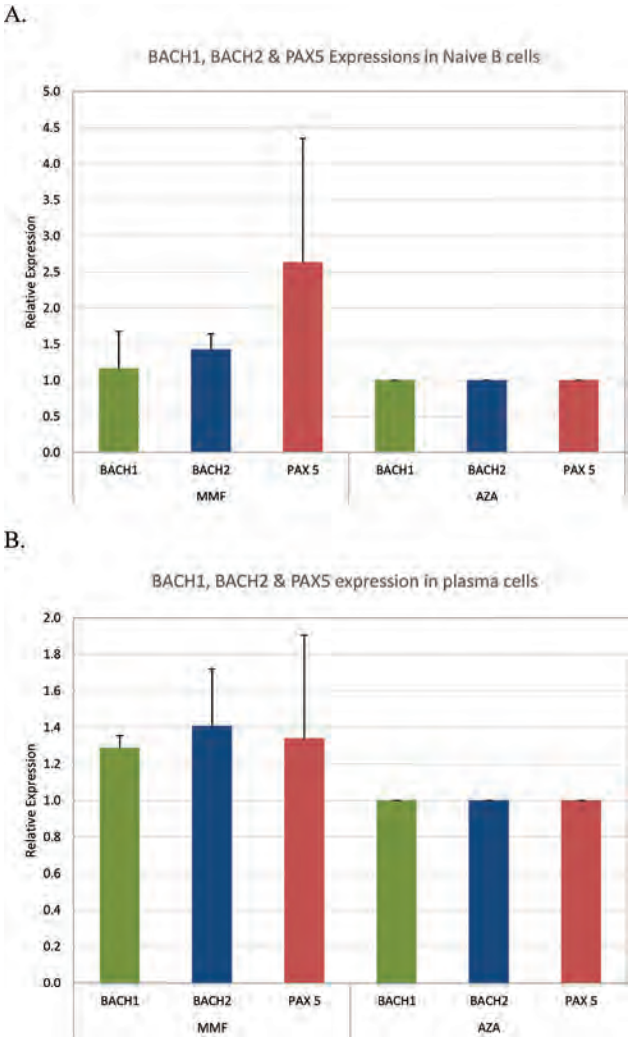

Figure 1. Intracellular BACH1, BACH2 and PAX5 expression in (A) naïve B cells and (B) plasma cells of patients receiving mycophenolate or azathioprine maintenance.

TH-PO834

Histologic vs Clinical Remission in Proliferative Lupus Nephritis at 6 Months - An Experience from a State Run Tertiary Care Centre in Southern India

Umesh L. *Institute of nephrourology, Bangalore, India.*

Background: Aim and objective of this study is to describe the renal histology of the second biopsy and correlate histopathological remission with clinical remission at 6 months.

Methods: The study conducted in Department of Nephrology, Institute of Nephro-Urology, Victoria Hospital Campus Bangalore, India between Oct 2015 and Nov 2017. A total of 50 consecutive patients with biopsy proven Proliferative Lupus Nephritis were included in the study. Clinical response was defined as complete (CRR), partial (PRR) or non-response (NRR) according to recent definitions. Histological response (HR) was defined as Class I, II or III/IV-C on repeat biopsies.

Results: 1/3 rd cases who were achieved complete remission clinically failed to achieve histological remission. Out of 19 patients 12(63%) had transformation to favorable class in CRR group. Out of 19 patients 12(63%) in PPR group and out of 12 patients 8(66%) in NRR group had unfavorable class at 6 months. Though Chronicity Index increased in all clinical subgroups, non responders had statistically significant increased CI.

Conclusions: The protocol renal biopsies performed at six months demonstrated an increase in chronicity, especially within the same histological class. 1/3rd patients with complete remission group had active lesions at the end of induction treatment, questioning the current induction therapy of 6 months which may not be sufficient. More RCTs are needed to test whether repeated biopsies should be considered as a part of the evaluation of treatment response in LN.

TH-PO835

The Composition of the Human Nasal Microbiome in Granulomatosis with Polyangiitis: A Pilot Study

Andreas Kronbichler,[1,2] Ewan M. Harrison,[5] Marcos Martinez del pero,[9] Beth Blane,[3] Gert J. Mayer,[1] Johannes Leierer,[4] Seerapani Gopaluni,[3] Mark A. Holmes,[3] Julian Parkhill,[6] Sharon J. Peacock,[7,3] David R. Jayne,[3] Josef Wagner.[8] *[1]Medical University Innsbruck, Innsbruck, Austria; [2]Vasculitis and Lupus Clinic, Cambridge, United Kingdom; [3]University of Cambridge, Cambridge, United Kingdom; [4]Medical University Innsbruck, Int. Medicine IV, Nephrology & Hypertension, Innsbruck, Austria; [5]Welcome Sanger Institue, Cambridge, United Kingdom; [6]The Sanger Institute, Cambridge, United Kingdom; [7]London School of Hyigene and Tropical Medicine, London, United Kingdom; [8]VIDRL, Melbourne, NSW, Australia; [9]West Suffolk Hospital / Cambridge University Hospitals, Bury St Edmunds, United Kingdom.*

Background: Granulomatosis with polyangiitis (GPA, formerly Wegener's granulomatosis) is a multi-system disease predominantly affecting the ear, nose and throat (ENT) tract, the lower respiratory tract and the kidneys. A role for *Staphylococcus aureus* nasal colonization in GPA has been proposed and thus we undertook a study to determine the role of the nasal microbiome in GPA.

Methods: We investigated the nasal microbiome by culture, bacterial 16S rRNA profiling, and shotgun metagenomic sequencing in patients with either active or inactive GPA, disease controls (microscopic polyangiitis or eosinophilic GPA), healthy healthcare professionals and healthy household controls.

Results: Presence of *S. aureus* as assessed by nasal culture could be detected in eight out of 12 active GPA patients (66.7%), which was more frequent compared to inactive patients (34.1%). Beta-diversity analysis revealed significant differences in the abundance of staphylococcal species between active GPA and healthy controls (p=0.0007) and disease controls (p=0.0023), while a correlation between *S. aureus* and active disease (p=0.0075) could be observed by Spearman correlation analysis. The presence of *Staphylococcus epidermidis* was associated with healthy controls (p=0.042). *Staphylococcus pseudintermedius*, generally assumed to be a dog- and cat-pathogen, showed an abundance of 13.01% among Staphylococci.

Conclusions: Our study offered new insights into the complex nasal microbiome of patients with GPA. We observed an association between active disease and *S. aureus*. Longitudinal studies are necessary to investigate the potential relationship of microbiome changes on the relapse rate of patients with GPA.

TH-PO836

Plasma Calprotectin Is a Marker of Stable Remission in ANCA Vasculitis

Elizabeth A. McInnis,[1] Yichun Hu,[1] Eve Wu,[2] Meghan E. Free,[1] Susan L. Hogan,[1] Donna O. Bunch,[1] Ronald J. Falk.[1] *[1]UNC Kidney Center, Chapel Hill, NC; [2]The University of North Carolina, Chapel Hill, NC.*

Background: In ANCA vasculitis, an increase in serum calprotectin (S100A8/9) was implicated as a marker of relapse and inflammation, but levels did not normalize during remission. Serum may not allow sensitive measurement of S100A8/9. We sought to determine if S100A8/9 is best measured in plasma or serum and if it is a marker of disease activity and remission in ANCA vasculitis.

Methods: S100A8/9 was measured by ELISA (BioLegend) in 16 paired serum and plasma samples. Plasma levels were also tested in 31 patients during active (BVAS>3, 15 MPO, 16 PR3) and remitting disease and in 14 age/gender matched healthy subjects. Additionally, 8 patients (4 MPO, 4 PR3) in long term remission off therapy (LTROT) for ≥5 years were evaluated and compared to healthy subjects.

Results: Serum measures of S100A8/9 averaged 2.90 μg/mL higher and had a higher standard deviation than plasma measures (4.29 vs 4.02 respectively). Thus, plasma measures were used for all analyses.

Conclusions: Plasma S100A8/9 levels were elevated during active disease. Levels decreased during remission, but remained higher than in healthy controls. Patients in LTROT, however, had plasma S100A8/9 levels similar to healthy subjects. These findings suggest S100A8/9 is elevated during active disease and decreases, but remains slightly elevated, during remission, possibly due to subclinical inflammation. Levels may continue to decrease and normalize in long term remission off therapy. Prior studies may have observed artificially elevated levels of S100A8/9 due to measurements obtained in serum rather than plasma.

Funding: NIDDK Support

Measurement of plasma S100A8/9 (ug/mL) in ANCA vasculitis patients and healthy subjects

Groups		Active Disease	Disease Remission	Healthy Subjects	P Value Paired Act vs Rem*	P Value Remission vs Healthy Subjects**
All paired patients	N Median (IQR)	31 2.56 (1.90, 5.31)	31 1.60 (1.13, 2.00)	14 0.86 (0.77, 1.26)	<.0001	0.009
MPO patients	N Median (IQR)	15 2.99 (1.99, 5.26)	15 1.60 (1.23,1.98)	14 0.86 (0.77, 1.26)	0.002	0.005

Myeloperoxidase-ANCA-Positive Granulomatosis with Polyangiitis Is a Distinct Subset of ANCA-Associated Vasculitis: A Retrospective Analysis Of 455 Patients from a Single Center in China

Dongyuan Chang, Zhi-Ying Li, Min Chen, Minghui Zhao. *Renal Division, Peking University First Hospital, Beijing, China*.

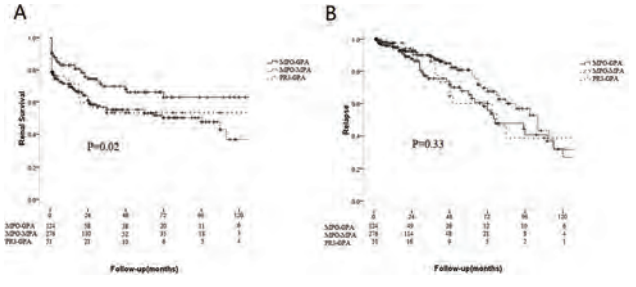
Background: Antineutrophil cytoplasmic antibody (ANCA) directed to proteinase 3 (PR3) used to be considered the serologic marker for granulomatosis with polyangiitis (GPA). However, patients with myeloperoxidase (MPO)-ANCA positive GPA have been increasingly reported. The aim of this study was to analyze the clinical and pathological characteristics and outcome of Chinese patients with MPO-ANCA positive GPA.

Methods: The clinical and renal histology data, renal outcomes, response to treatment, relapse and mortality were compared between patients with MPO-ANCA positive GPA and MPO-ANCA positive microscopic polyangiitis (MPA) as well as proteinase 3 (PR3)-ANCA positive GPA.

Results: 455 patients with ANCA-associated vasculitis (AAV) were recruited in this study. 276/455 patients were classified as MPO-ANCA positive MPA, 4/455 patients were classified as PR3-ANCA positive MPA,124/455 were MPO-ANCA positive GPA and 51/455 were PR3-ANCA positive GPA. Compared with MPO-ANCA positive MPA patients, MPO-ANCA positive GPA patients had significantly higher BVAS score and milder renal lesion at diagnosis. The probability of developing ESRD was significantly higher in patients with MPO-ANCA positive MPA than MPO-ANCA positive GPA. MPO-ANCA positive GPA patients were likely to have relapse than MPO-ANCA positive MPA patients. Compared with PR3-ANCA positive GPA patients, MPO-ANCA positive GPA patients had significantly higher proportion of female, less constitutional symptoms and milder renal lesion at diagnosis.

Conclusions: Patients with MPO-ANCA positive GPA should be regarded as a unique subset of AAV. This subset of AAV patients had relatively milder renal injury. Although ANCA specificities play an important role in differentiating AAV, taking the disease type together to classify AAV may be more rational.

Funding: Government Support - Non-U.S.



(A) Renal survival of the three subsets of patients. (B) Relapse of the three subsets of patients.

A Staphylococcal Plasmid Encoded Peptide Induces Anti-Myeloperoxidase Nephritogenic Autoimmunity

A. Richard Kitching,[1,2] Joshua D. Ooi,[1] Jhih-Hang Jiang,[3] Anton Y. Peleg,[3,4] Stephen R. Holdsworth.[1,2] Autoimmune Kidney Disease and Vasculitis Research Group *[1]Centre for Inflammatory Diseases, Monash University, Clayton, VIC, Australia; [2]Nephrology, Monash Health, Clayton, VIC, Australia; [3]Microbiology, Monash University, Clayton, VIC, Australia; [4]Infectious Diseases, The Alfred Hospital, Melbourne, VIC, Australia*.

Background: Loss of tolerance to MPO in ANCA-associated glomerulonephritis (GN) is poorly understood. It is unknown whether molecular mimicry plays any role in this process. We tested whether microbial peptides homologous to a dominant pathogenic MPO CD4+ T cell epitope ($MPO_{409-428}$), relevant to several MHCII and lying within an MPO epitope hot spot, would induce anti-MPO autoimmunity.

Methods: Immunity to MPO and $MPO_{409-428}$ was studied in microbial peptide immunized C57BL/6 (B/6, I-A^b), BALB/c (I-A^d/E^d) and HLA-DR15 transgenic mice (proliferation, IFN-γ and IL-17A ELISPOT). Anti-MPO GN and anti-MPO immunity in response to peptides, proteins (MPO/ovalbumin as positive/negative controls) and *S.aureus* strains with/without plasmids carrying the relevant 6-phosphogluconate dehydrogenase (6PGD) sequence were studied in B/6 mice (I-A^b/$MPO_{415-428}$ tetramers, cytokines, MPO-ANCA IIF/ELISA, neutrophil ROS production, MPO-ANCA transfer). Anti-6PGD antibodies (Ab) were measured in sera of healthy humans and patients.

Results: The 4 most homologous microbial peptides were immunogenic but did not induce anti-MPO autoreactivity. However, a plasmid-derived peptide from 6PGD (6PGDp) with similar critical binding residues for $MPO_{409-428}$ in B/6, BALB/c and DR15+ mice, found in some *S.aureus* strains, induced expansion of $MPO_{415-428}$ tetramer+CD4+ cells, anti-MPO T cell autoimmunity (to $MPO_{408-428}$ and whole MPO) and bioactive MPO-ANCA in B/6 mice. 6PGDp induced anti-MPO autoreactivity in mice with different MHCII (I-A^d/E^d and DR15). Related 6PGD sequences from other *S.aureus* strains did not induce anti-MPO responses. Healthy human and vasculitis patient sera contained anti-6PGD Ab, demonstrating its immunogenicity in humans. 6PGDp-immunized mice developed GN when MPO was deposited in glomeruli by anti-basement membrane globulin. Immunization with *S.aureus* containing a plasmid with the mimic 6PGD sequence, or another *S.aureus* strain transformed with a different plasmid expressing the 6PGD mimotope, also induced anti-MPO GN with anti-MPO cellular and humoral autoimmunity, showing that plasmids with this sequence induce nephritogenic anti-MPO autoimmunity.

Conclusions: A microbial plasmid encoded peptide induces anti-MPO autoimmunity via molecular mimicry implicating plasmids, as bacterial replicons capable of horizontal gene transfer, in autoimmune disease.

Integrated Proteomics and DNA Analysis of Pathogenic IgG from Patients with Anti-GBM Nephritis

Mary H. Foster,[1,2] Vadim Pedchenko,[3] Amy G. Clark.[1] *[1]Duke University Medical Center, Durham, NC; [2]Medicine/Research, DVAMC, Durham, NC; [3]Vanderbilt University Medical Center, Nashville, TN*.

Background: Anti-glomerular basement membrane (anti-GBM) nephritis (Goodpasture's disease) is marked by immune destruction of kidneys and lungs triggered by IgG autoantibodies that bind the NC1 domain of the α3 chain of collagen IV. Current therapy consists of toxic immunosuppression. Selective therapeutic targeting of pathogenic IgG and B cells is highly desirable, but precluded by the lack of information about their structural basis.

Methods: To address this problem, we used an innovative approach validated in vaccine biology. $F(ab')_2$ fragments were isolated by pepsin digestion from circulating IgG of two patients with active anti-GBM nephritis and purified on α3(IV)NC1 affinity columns. Antigen-binding (Ag+) and non-binding (NB) flow-through $F(ab')_2$ were trypsin digested and evaluated by liquid chromatography-tandem mass spectrometry. Peptide spectra were analyzed using a reference library generated from productively rearranged Ig heavy chains (n=11903) in the International ImMunoGeneTics database and formatted for use by the Mascot search engine.

Results: 826 unique spectral matches were identified. 41 peptides were identified in both patients' Ag+ $F(ab')_2$ and absent in NB flow-through $F(ab')_2$. All Ag+ matches aligned to Ig heavy chain variable region (VH) genes, primarily in conserved framework regions. Notably, 32% aligned to alleles of a VH gene with an unusual highly hydrophobic heavy chain complementarity determining region 2 (HCDR2) that was previously associated with autoreactivity and reported to encode a human anti-α3(IV)NC1 collagen monoclonal Ig derived from a humanized immune system mouse.

Conclusions: We find evidence of shared and biased gene use among pathogenic IgG that bind α3(IV)NC1 collagen in patients with anti-GBM nephritis. This suggests that patients' GBM-binding IgG contain unusual targetable motifs in their Ag binding sites. Future interrogation of the spectra using patient-specific Ig DNA reference libraries, generated from patients' lymphocytes, will permit identification of non-genomic-DNA-templated peptide sequences that are found within HCDR3, a unique region of the Ag binding site created in B cells during VH-DH-JH gene recombination and for which sequences are not present in public databases. Rare motifs will provide additional therapeutic targets for personalized disease management.

Modulation of Immune Response in Kidney Lymph Node During Crescentic Glomerulonephritis

Vivek Kasinath,[1] Osman A. Yilmam,[2] Mayuko Uehara,[1] Liwei Jiang,[2] Farideh Ordikhani,[2] David J. Salant,[3] Reza Abdi.[1] *[1]Transplantation Research Center and Division of Renal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Transplantation Research Center, Brigham and Women's Hospital, Boston, MA; [3]Renal Section, Boston University Medical Center, Boston, MA.*

Background: Crescentic glomerulonephritis (GN) is an inflammatory condition characterized by a rapid deterioration of renal function. Previous studies of crescentic GN have focused on immune activation in the kidney. However, the role of fibroblastic reticular cells (FRCs), the prominent cells comprising the stromal compartment of the kidney lymph node (KLN), has not been studied in this condition.

Methods: We induced nephrotoxic serum nephritis (NTN), a classic experimental model of crescentic GN, in mice. We investigated the contribution of FRCs in the KLN to the activation of the immune response in crescentic GN using flow cytometry, RT-PCR, hematoxylin and eosin (H&E) staining, and immunofluorescence staining.

Results: Investigation of the microarchitecture of the KLN during NTN revealed an increase in the deposition of extracellular matrix fibers by FRCs, associated with the propagation of specialized blood vessels known as high endothelial venules, through which lymphocytes traffic into the lymph node, as well as the expansion of the lymphatic vasculature. The KLN contained an expanding population of pro-inflammatory $CD4^+$ effector memory T cells and Th17 cells. Removal of the KLN, depletion of FRCs, and treatment with anti-podoplanin antibody each resulted in a reduction of renal injury.

Conclusions: The pro-inflammatory activity of FRCs in the KLN is crucial to the propagation of the immune response in crescentic GN. Our findings can serve as a basis for the development of immunosuppressive therapy for crescentic GN directed towards modulating the activity of FRCs.

TH-PO841

Targeting Neutrophil Serine Proteases in ANCA-Associated Vasculitis

Uwe Jerke,[1] Claudia Eulenberg-Gustavus,[1] Anthony Rousselle,[1] Adrian Schreiber,[1,2] Brice Korkmaz,[3] Ralph Kettritz.[1,2] *[1]Experimental and Clinical Research Center (ECRC) Campus Buch, Berlin, Germany; [2]Charite Berlin, Berlin, Germany; [3]INSERM U-1100, Tours, France.*

Background: ANCA-activated neutrophils and monocytes cause necrotizing vasculitis. Enzymatically active neutrophil serine proteases (NSPs) contribute to the injury. NSPs include neutrophil elastase (NE), cathepsin G (CatG), and proteinase 3 (PR3) that also provides a major ANCA antigen. NSPs are generated from inactive zymogens by cathepsin C (CatC) during neutrophil maturation in the bone marrow. CatC loss-of-function mutations prevent NSP maturation leading to zymogen degradation. We characterized NSPs in humans and mice and tested the hypothesis that pharmacological CatC inhibition eliminates NSPs in a neutrophil differentiation model and reduces PR3-ANCA induced respiratory burst as well as neutrophil-mediated endothelial injury.

Methods: We prepared highly purified human and murine neutrophils and monocytes. We assessed NSP proteins by immunoblotting and flow cytometry, and proteolytic activity using specific FRET substrates. We employed a reversible cyclopropyl nitrile CatC inhibitor (IcatC) to reduce NSPs in neutrophils differentiated from $CD34^+$ HSC *in vitro*. We assessed superoxide production by ferricytochrome C reduction and endothelial injury by phalloidin staining.

Results: Human and murine neutrophils and monocytes expressed PR3, NE, and CG by immunoblotting and flow cytometry. All three NSPs were enzymatically active by FRET assays. Protein amounts and proteolytic activity were significantly higher in neutrophils compared to monocytes. *In vitro* differentiated human neutrophils progressively expressed active NSPs during maturation. IcatC significantly reduced NSP proteins and enzymatic activity. PR3 surface protein decreased by 79%±10% ($p<0.01$), cellular protein by 82%±4% ($p<0.001$) and PR3 enzymatic activity by 98%±1% ($p<0.001$). Anti-PR3 antibodies provoked less superoxide release (46%±6% of control, $p<0.01$) in neutrophils differentiated in the presence of IcatC compared to buffer control (n=4). In addition, supernatants from neutrophils that were differentiated in the presence of IcatC caused less cytoskeletal damage in HUVECs.

Conclusions: Pharmacological CatC inhibition down-regulates NSPs, abrogates PR3-ANCA induced respiratory burst in an *in vitro* neutrophil differentiation model, and reduced neutrophil-mediated endothelial damage. CatC inhibition may provide a future treatment strategy in ANCA vasculitis.

TH-PO842

Spleen Tyrosine Kinase Expression and Function in Human Neutrophils in ANCA-Associated Vasculitis

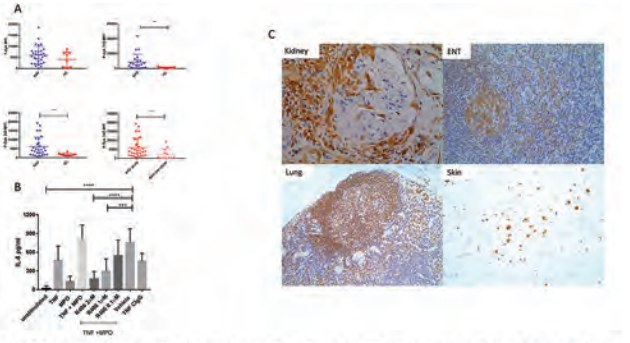
Maria Prendecki, Fayaz Dudhiya, Kavita Gulati, Frederick W. Tam, Charles D. Pusey, Stephen P. McAdoo. *Imperial College London, London, United Kingdom.*

Background: Syk is a cytoplasmic tyrosine kinase which plays an important role in immunoreceptor signalling. Syk is phosphorylated following ANCA-induced neutrophil activation, and we have previously shown that a Syk inhibitor is an effective treatment in experimental autoimmune vasculitis. This study aimed to investigate neutrophil SYK function in patients with AAV.

Methods: Neutrophils were isolated from healthy donors (n=10) and patients with AAV (acute presentation n=21; relapse n=10; remission n=12). Intracellular staining for total (T-Syk) and phosphorylated (P-Syk) was analysed using flow cytometry. Neutrophils were primed with TNFα 2ng/ml and stimulated with 100 μg/ml MPO-ANCA IgG (or control IgG). R406, a small molecule Syk inhibitor, or vehicle was added prior to addition of IgG. RNAscope for Syk mRNA was performed on kidney sections, and IHC for T-Syk on extra-renal AAV tissues including ENT, lung and skin.

Results: There were similar levels of T-Syk present in neutrophils from HC and those with AAV. There was increased Syk phosphorylation at both the 319 and 348 residues in patients with active AAV compared to HC or patients in remission (Figure 1A). When TNFα primed neutrophils were stimulated with MPO-ANCA IgG there was significant IL-8 release, that was inhibited by R406 in a dose dependent manner (Figure 1B). There was evidence of T-Syk in infiltrating inflammatory cells in non-renal sites of AAV (Figure 1C). There was also evidence of Syk mRNA in infiltrating leucocytes in glomeruli from patients with crescentic AAV but not in patients with sclerotic lesions.

Conclusions: Syk is phosphorylated to a greater degree in patients with than in healthy controls indicating greater neutrophil Syk activity in patients with AAV. Syk plays a role in cytokine production from neutrophils which may be pathogenic, and Syk mRNA and protein can be identified at sites of tissue inflammation. These results suggest there may be a role for Syk inhibition in decreasing neutrophil mediated damage in patients with AAV.



A. T-Syk and P-Syk expression in neutrophils from healthy controls (HC) and patients with AAV. Statistical analysis carried out using Mann-Whitney U test: **p<0.01 **B.** IL-8 production by human neutrophils following stimulation with TNFα and MPO-ANCA IgG. Statistical analysis carried out using one way ANOVA with Dunnetts post hoc correction for multiple comparisons. ****p<0.0001, ***p<0.001 **C.** T-Syk expression in vasculitis.

TH-PO843

P2X7 Knockout Does Not Protect from Experimental Glomerulonephritis and Vasculitis

Maria Prendecki,[1] Stephen P. McAdoo,[1] Tabitha Turner-Stokes,[1] Kevin Woollard,[1] Robert J. Unwin,[2] H. Terence Cook,[1] Jacques Behmoaras,[1] Tim Aitman,[3] Charles D. Pusey,[1] Frederick W. Tam.[1] *[1]Imperial College London, London, United Kingdom; [2]University College London Medical School, London, United Kingdom; [3]University of Edinburgh, Edinburgh, United Kingdom.*

Background: P2X7 is an ionotropic receptor for extracellular ATP previously shown to be important in inflammation and fibrosis. It may also play a role in autoimmunity. Both strains of P2X7 deficient mice are incomplete knockouts and have generated conflicting results. Therefore we have assessed the importance of P2X7 in autoimmunity and glomerulonephritis (GN) using a novel P2X7 knockout (KO) rat & a small molecule P2X7 inhibitor.

Methods: Three in vivo models, nephrotoxic nephritis (NTN), experimental autoimmune GN (EAG) and experimental autoimmune vasculitis (EAV) were used to induce disease in P2X7 KO and WKY wild type (WT) rats. P2X7 antagonist (A438079) or vehicle (sterile water) was administered twice daily for 6 days after induction of NTN. Disease severity and development of autoimmunity were assessed in each model (NTN- day 7 and 28, EAG- day 28, EAV- day 42).

Results: P2X7 KO rats were not protected from disease in NTN, EAG or EAV models. P2X7 KO and WKY WT rats had similar renal function, urinary abnormalities, histological disease severity, lung injury and circulating and deposited antibody. Figure 1 shows a representative EAG experiment. However, when P2X7 antagonist (A438079) was administered to rats with NTN from day 0-6 both WT and P2X7 KO rats were protected from disease with marked improvement in urinary abnormalities, renal function and histological disease severity (Figure 2).

Conclusions: P2X7 KO rats are not protected from 3 distinct models of glomerular disease. However, the P2X7 antagonist had a marked protective effect from renal injury in both P2X7 KO and WKY WT rats, suggesting that its effect is unrelated to P2X7 and is off-target.

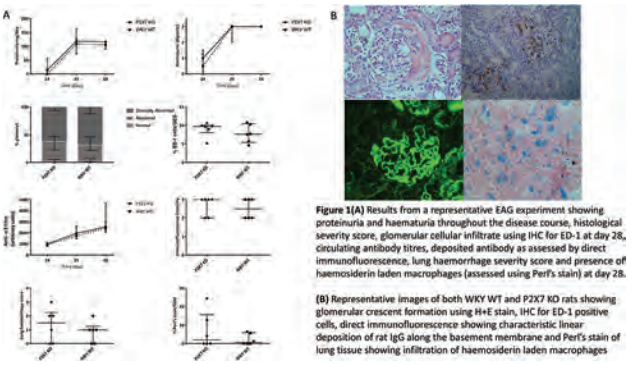


Figure 1(A) Results from a representative EAG experiment showing proteinuria and haematuria throughout the disease course, histological severity score, glomerular cellular infiltrate using IHC for ED-1 at day 28, circulating antibody titres, deposited antibody as assessed by direct immunofluorescence, lung haemorrhage severity score and presence of haemosiderin laden macrophages (assessed using Perl's stain) at day 28.

(B) Representative images of both WKY WT and P2X7 KO rats showing glomerular crescent formation using H+E stain, IHC for ED-1 positive cells, direct immunofluorescence showing characteristic linear deposition of rat IgG along the basement membrane and Perl's stain of lung tissue showing infiltration of haemosiderin laden macrophages

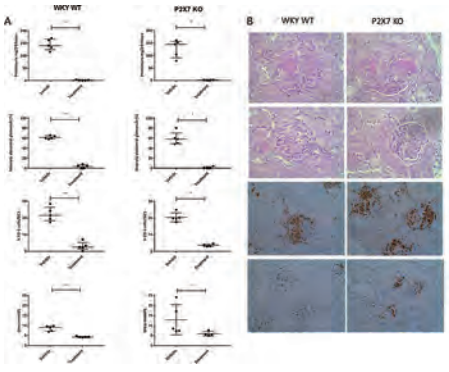

Figure 2(A) Day 7 NTN in P2X7 KO and WKY WT rats treated with P2X7 antagonist or vehicle. Antagonist treated rats in both the P2X7 KO and WKY WT groups have decreased proteinuria, markedly decreased severity of glomerular injury, decreased infiltrating ED-1 positive cells and improved renal function when compared to vehicle treated rats. Statistical analysis performed using Mann-Whitney U test. **p<0.01, *p<0.05

(B) Representative histology showing severe glomerular injury in vehicle treated rats on row 1 and near normal glomeruli in antagonist treated rats on row 2. IHC for ED-1 positive cells with profound cellular infiltrate in vehicle treated rats on row 3 and minimal infiltrate in antagonist treated rats on row 4.

TH-PO844

Critical MPO Epitopes Drive the Adaptive Immune Response in MPO-ANCA Vasculitis

Meghan E. Free,[1,3] Katherine G. Stember,[3] Jacob J. Hess,[1,4] Olivier Lardinois,[5] Carmen E. Mendoza,[3] Andrew K. Le,[1] Susan L. Hogan,[3] Yichun Hu,[1] Mark A. Pilkinton,[7] Eddie A. James,[6] William W. Kwok,[6] Benjamin Vincent,[3] Simon Mallal,[7] J. Charles Jennette,[3] Dominic J. Ciavatta,[3] Ronald J. Falk.[1,2] *[1]UNC Kidney Center, Chapel Hill, NC; [2]University of North Carolina, Chapel Hill, Chapel Hill, NC; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Columbia University, New York, NY; [5]National Institute of Environmental Health Sciences, Research Triangle Park, NC; [6]Benaroya Research Institute, Seattle, WA; [7]Vanderbilt University Medical Center, Nashville, TN.*

Background: Autoimmune diseases, including ANCA vasculitis, rely on broad immunosuppression to treat disease. However, research to understand the interactions between human leukocyte antigen (HLA), autoantigen, and effector immune cells, would permit the development of targeted therapies to revolutionize treatment.

Methods: HLA was determined by sequence typing and peptide-HLA interactions were predicted and confirmed by *in silico* and *in vitro* binding studies. Class II tetramers were utilized to identify circulating autoreactive T cells. The clonality of anti-myeloperoxidase (MPO) T cells was determined by TCR sequencing. ELISA studies examined the temporal B cell response to MPO peptides.

Results: Patients with HLA-DPB1*04:01 and/or HLA-DRB4*01:01 exhibit CD4+ T cell reactivity to specific epitopes of MPO contained in tetramers. Autoreactive T cells are enriched for memory T cells as indicated by expression of CD25, CD45RO and CCR7. Additionally, autoreactive cells produce IL-17A upon stimulation. Tetramer positive cells are clonally restricted as evidenced by loss of TCR diversity when compared to naïve and memory T cell populations. Furthermore, this region of MPO is targeted by patient ANCA, and specific antibody reactivity is most detectable at onset of disease. These T and B cell epitopes are contained in a region of MPO that is buried and immune system recognition is dependent on secondary structure.

Conclusions: These data define the specific interactions between the autoantigen, MPO, and the adaptive immune system within ANCA vasculitis. Collectively, this study informs the development of new antigen-specific therapies in ANCA vasculitis and autoimmune disease.

TH-PO845

Identification of PR3-ANCA MPA and MPO-ANCA GPA as Different Subsets of ANCA Disease

Marco A. Alba,[1] Yichun Hu,[2] Caroline J. Poulton,[2] Lauren N. Blazek,[2] J. Charles Jennette,[1] Ronald J. Falk,[2] Susan L. Hogan.[2] *[1]University of North Carolina at Chapel Hill, Chapel hill, NC; [2]UNC Kidney Center, Chapel Hill, NC.*

Background: Granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) are two major clinicopathologic variants of ANCA vasculitis. Typically, MPA and GPA have been associated with MPO-ANCA and PR3-ANCA, respectively. In this study, we detailed the characteristics of the less common subsets PR3-ANCA MPA and MPO-ANCA GPA.

Methods: Patients from the Glomerular Disease Collaborative Network (GDCN) inception cohort were analyzed. Clinicopathologic phenotype was established according to the Chapel Hill Consensus Conference nomenclature. Baseline manifestations, relapses, ESRD, and survival were studied. Fisher's exact test and Wilcoxon rank sum test were used for comparisons. Proportional hazards models were used to evaluate multivariable time to relapse, ESRD, and death for specificity controlling for age, sex, lung and ear, nose, and throat (ENT) involvement, creatinine at diagnosis and induction with cyclophosphamide. Because the GDCN is primarily composed of nephrologist thus resulting in a cohort where biopsy-proven renal involvement was present in almost all patients, prevalence of kidney disease was not compared between groups.

Results: See Table 1. *MPO-ANCA MPA vs PR3-ANCA MPA*: MPA patients with MPO-positivity were older and had lower prevalence of ENT and musculoskeletal manifestations. *MPO-ANCA GPA vs PR3-ANCA GPA*: Patients with MPO-ANCA were older, more likely female, and had lower prevalence of ENT and nervous system involvement. In the proportional hazards models, ANCA serotype was not predictive of relapse, ESRD, or death neither in MPA nor in GPA (Table 1).

Conclusions: PR3-ANCA MPA and MPO-ANCA GPA represent particular subsets of ANCA disease with distinct organ involvement. The impact of these differences on the clinical management warrants further evaluation.

Funding: Other NIH Support - *

The Role of MPO, Plasma Cell, and CD20 in the Pathogenesis of Human MPO-ANCA-Associated Glomerulonephritis

Soko Kawashima, Shinya Kaname. First Department of Internal Medicine, Kyorin University School of Medicine *Kyorin University School of Medicine, Mitaka, Japan.*

Background: Myeloperoxidase anti-neutrophil cytoplasmic antibody (MPO-ANCA)-associated glomerulonephritis (GN) is characterized by pauci-immune necrotizing glomerulonephritis. We reported that MPO and immune complexes composed of MPO-anti MPO antibody may play some direct roles in the pathogenesis of glomerular capillary injuries in the early phase of the disease. Previous studies have suggested involvement of infiltrated macrophages and lymphocytes. Here we investigated a possible role of MPO-positive cells, plasma cells, CD20-positive B-lymphocytes in the development of MPO-ANCA- associated GN.

Methods: Patients with ANCA-associated vasculitis (AAV) were diagnosed according to the definition of the 2012 Chapel Hill Consensus Conference and the 1990 American College of Rheumatology classification criteria. Using renal biopsy specimen including more than 10 glomeruli that were obtained from 20 patients with MPO-ANCA-associated GN, we analyzed the extent of glomerular infiltration of CD20-positive cells and plasma cells as well as extracellular and cellular deposition of MPO by immunohistochemistry. The colocalization of MPO and plasma cells / CD20 cells was also examined by double staining for MPO and CD20 using immunofluorescence.

Results: CD20-positive cells were found only in 5 of the 151 glomeruli (0.67%) and mainly located in the peritubular capillaries around the glomeruli with active lesions. In contrast, plasma cells were frequently observed in 124/151 glomeruli (82.1%) of the early phase and located mainly in the endocapillary proliferative lesions and extra-capillary crescentic lesions. MPO exists along the glomerular capillary walls near the infiltrated MPO-positive neutrophils in the early phase. No colocalization of CD20-positive cells with MPO-positive cells / MPO deposition was observed, but MPO was occasionally stained in plasma cells.

Conclusions: These results suggest that plasma cells, rather than CD-20 positive cells, may play some roles possibly through MPO in the pathogenesis of human MPO-ANCA-associated glomerulonephritis.

TH-PO847

Chemokine Receptor 8 in Peripheral Blood Mononuclear Cells Can Be a Novel Diagnostic Biomarker for ANCA-Negative ANCA-Associated Vasculitis

Shigeto Mashiko, Satoru Sanada, Mitsuhiro Sato, Toshinobu Sato, Yoshio Taguma. *Japan Community Health Care Organization Sendai Hospital, Sendai, Japan.*

Background: Diagnosis of antineutrophil cytoplasmic autoantibodies associated vasculitis (ANCA-associated vasculitis; AAV) is based on clinical and histologic features with elevated serum ANCA levels, however, not all cases show ANCA positive. In such cases, diagnosis of AAV without histological examination is quite difficult. We have found that the chemokine receptor 8 (CCR8) level in peripheral blood mononuclear cells correlates with activity of MPO-ANCA positive AAV; CCR8 is upregulated both in mRNA

and protein levels, which was reported in the previous meeting. In this study, we extended our research of CCR8 levels in ANCA-negative AAV.

Methods: Peripheral blood mononuclear cells were collected from 81 patients representing rapidly progressive glomerulonephritis on their initial visit. Participants were categorized as ANCA-positive AAV, immune complex small vessel vasculitis, vasculitis associated with systemic disease, and ANCA-negative AAV according to Chapel Hill consensus conference criteria. CCR8 gene expression levels in each group were assessed retrospectively.

Results: CCR8 gene expression levels were significantly higher in patients with ANCA-negative AAV compared to those in healthy controls. The area under the ROC curve was 0.92 (95% CI: 0.76-1.00) with a sensitivity of 91.7% and a specificity of 100%. CCR8 levels in patients with ANCA-positive AAV also showed a higher value with statistical significance. The area under the ROC curve was 0.83 (95% CI: 0.79-0.96) with a sensitivity of 75.6% and a specificity of 100%. Immune complex small vessel vasculitis and vasculitis associated with systemic disease did not show the CCR8 elevation. These data indicate that CCR8 is upregulated in pauci-immune glomerulonephritis regardless of serum ANCA levels.

Conclusions: CCR8 could be a useful biomarker in diagnosis of ANCA-negative AAV representing rapidly progressive glomerulonephritis.

TH-PO848

The Emergence of Goodpasture's Disease Following Hematopoietic Stem Cell Transplant: Clues to Disease Etiology?

Vadim Pedchenko,[4] Paul E. Gray,[1] Hugh J. Mccarthy,[5] Moin Saleem,[2] A. Richard Kitching,[3] Agnes B. Fogo,[4] Billy G. Hudson.[4] *[1]Immunology and Infectious Diseases, Sydney Children's Hospital, Sydney, NSW, Australia; [2]University of Bristol, Bristol, United Kingdom; [3]Monash University, Monash Health, Clayton, VIC, Australia; [4]Nephrology and Hypertension, Vanderbilt University Medical Center, Nashville, TN; [5]Syndey Children's Hospital Network, Westmead, NSW, Australia.*

Introduction: Goodpasture's disease is an autoimmune disorder caused by autoantibodies against collagen IV in the glomerular and alveolar basement membranes. It has been postulated that a conformational change of the native autoantigen, the α345NC1 hexamer of collagen IV, is imperative for the development of disease. Perturbation of the quaternary structure causes dissociation of the hexamer, which elicits autoantibodies against subunits, but not the native hexamer. This contrasts with Alport's post-transplant nephritis, where the pathogenic alloantibody binds directly to native NC1 hexamer.

Case Description: We studied a patient who developed anti-GBM disease following allogeneic haematopoietic stem cell transplant. Autoantibody specificity was analysed by ELISA including binding to individual NC1 monomers of collagen IV (α1-α6), immunodominant epitopes of α3 chain, and native versus dissociated NC1 hexamers from glomerular basement membrane. Binding of autoantibody from patient serum to normal kidney GBM was also assessed. Anti-GBM antibodies were directed against the α3 NC1 domain of collagen IV and developed rapidly reaching peak level in patient serum within 5 weeks. They targeted predominantly the E_A epitope of α3 NC1. Antibody binding to native α345NC1 hexamer was minimal; however, binding was greatly increased upon hexamer dissociation. None of the polymorphic genetic differences between donor and recipient collagen IV genes would be predicted to cause a significant NC1 conformational change or to provide a target for antibody binding. Both patient and donor possessed the Goodpasture's susceptibility HLA-allele *DRB1*1501*.

Discussion: This is the first report of Goodpasture's disease occurring post-HSCT where the pathogenesis has been studied from onset to recovery. The specificity and binding properties of the antibodies along with sequencing results indicate that this is a post-transplant autoimmune rather than alloimmune phenomenon. This case also demonstrated the rapidity, in a matter of weeks, of high titres of pathogenic antibody production highlighting the nature of emergent Goodpasture's disease. Our findings demonstrate the importance for early diagnosis of Goodpasture's disease and timely treatment for preserving kidney function.

High Glucose Promotes Macrophage Switching to M1 Phenotype via Down-regulating STAT-3-Mediated Autophagy

Yu Zhao,[1] Xiaodong Zhu,[1] Yuteng Jiang,[1] Yuqiu Liu,[1] Xiaoliang Zhang.[2] *[1]Institute of Nephrology, Zhong Da Hospital, Southeast University, School of Medicine, Nanjing, China; [2]Zhong Da Hospital, Southeast University, School of Medicine, Nanjing, China.*

Background: Imbalance of M1/M2 macrophages phenotype activation is a key point in diabetic nephropathy (DN). Macrophages mainly exhibit M1 phenotype, whcih contribute to the inflammation and fibrosis in DN. Studies indicate that autophage plays an important role in M1/M2 activation. However, the mechanism of autophage regulating macrophage M1/M2 phenotype in DN is unknown. Thus, the aim of this study is to explore whether high glucose induced macrophage switch to M1 phenotype via down-regulating STAT-3-mediated autophagy.

Methods: In vivo, DN model rats were established by intraperitoneal injection with streptozocin (STZ). Rats were sacrificed respectively at 18w for histological and molecular analysis. In vitro, RAW264.7 cells were cultured with 30mM glucose with or without autophagy regulator and STAT-3 regulator intervention. Meanwhile, the classical activation models of M1 and M2 macrophages were established as control group. The expressions of autophagy-related proteins (LC3, Beclin-1, p62), M1 markers (iNOS, TNF-α) and M2 markers (MR, Arg-1) were detected by immunofluorescence and Western Blot.

Results: In vivo, macrophages were exhibited to M1 phenotype in DN and displayed a lower level of autophagy. Additionally, iNOS expression was negative correlated with LC3 (r=-0.619, P<0.05) and pSTAT-3 (r=-0.951, P<0.05). In vitro, electronic microscope analysis showed intact autophagy (Fig.1). RAW264.7 macrophages switched to M1 phenotype under high glucose conditions. Autophagy was downregulated in such high glucose induced M1 macrophages. The expression of LC3 (autophagy maker) increased by STAT-3 activator. Meanwhile, both the STAT-3 activator and autophagy activator (rapamycin) promoted glucose-induced M1 macrophage translating to M2 macrophage. However, after inhibition of STAT-3 expression with STAT-3 siRNA, autophagy activator contributes to the reduction of the conversion of macrophages from M1 into M2 phenotype in high glucose-induced macrophage.

Conclusions: High glucose promotes macrophage switching to M1 phenotype via down-regulating STAT-3-mediated autophagy.

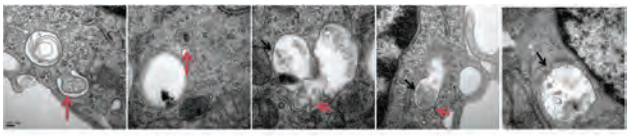

Fig.1 The intact autophagy is observed in vitro.

Active Vitamin D Regulates Macrophage M1/M2 Phenotypes via the STAT-1-TREM-1 Pathway in Diabetic Nephropathy

Yu Zhao,[1] Yuteng Jiang,[1] Xiaodong Zhu,[1] Xiaoliang Zhang.[2] *[1]Institute of Nephrology, Zhong Da Hospital, Southeast University, School of Medicine, Nanjing, China; [2]Zhong Da Hospital, Southeast University, School of Medicine, Nanjing, China.*

Background: Imbalance of M1/M2 macrophages phenotype activation is a key point in diabetic nephropathy (DN). TREM-1(Triggering Receptor Expressed On Myeloid Cells 1) is essential for macrophage function regulation. Signal transducer and activator of transcription (STAT) is a key factor that regulates the activation of macrophage M1/M2 phenotypes. Our previous studies indicated that active vitamin D (VD) has renoprotective role. This study aimed to investigate whether VD suppresses macrophage transition to the M1 phenotype via inhibiting the high glucose-induced STAT-1 phosphorylation to reduce TREM-1 expression.

Methods: Pathological changes in kidney tissue were detected and the expression of CD68 TREM-1, STAT-1, M1 makers and M2 makers were acquired in renal tissue of DN patients and 18w DN rats. In vitro, RAW 264.7 cells were treated by high glucose with or without VD. TREM-1 siRNA, STAT-1 siRNA and high expression plasmid of TREM-1 and STAT-1 were explored to elucidate the underlying mechanism. The expression of TREM-1 and STAT-1 and the changes of macrophage phenotype were examined separately by Western Blot, immunofluorescence stain.

Results: (1) In DN patients, the expression of M1 markers (iNOS, TNF-α) and TREM-1, pSTAT-1 were increased in comparation with NC group(P<0.05). Additionally, iNOS expression was positive correlated with the TREM-1 expression (r=0.757, P<0.05), pSTAT-1 (r=0.808, P<0.05). (2) In DN rats, the enlargement of glomerular surface area, expansion of glomerular mesangial matrix, the expression of CD68, TREM-1, pSTAT-1 and M1 markers (iNOS) were significantly increased compared with NC group (P<0.05), while above changes were markedly decreased in DN+VD group (P<0.05). (3) In vitro, VD significantly decreased high glucose induced CD68, TREM-1, pSTAT-1 and M1 markers (iNOS) expression. However, above effects from VD were abolished when TREM-1 or STAT-1 expression was overexpressed by TREM-1 or STAT-1 plasmid. Inhibition of STAT-1 expression with STAT-1 siRNA decreased TREM-1 expression, while, TREM-1 regulation by TREM-1 siRNA or TREM-1 overexpression techniques did not affect STAT-1 expression.

Conclusions: VD can inhibit macrophage transition to the M1 phenotype through the STAT-1/TREM-1 pathway under high glucose condition.

TH-PO851

Serum Amyloid A and Clinical Outcomes in Early Diabetic Kidney Disease

Brad Dieter,[1] Sterling McPherson,[2] Radica Z. Alicic,[3] Pierre Jean Saulnier,[4] Robert G. Nelson,[5] Matthias Kretzler,[6] Katherine R. Tuttle.[7] *[1]Providence Health Care, Spokane, WA; [2]Washington State University College of Medicine, Spokane, WA; [3]Providence Medical Research Center, Spokane, WA; [4]CHU poitiers, Poitiers, France; [5]National Institutes of Health, Phoenix, AZ; [6]U. Michigan, Ann Arbor, MI; [7]University of Washington School of Medicine, Spokane, WA.*

Background: Risk of end-stage renal disease (ESRD) and death is increased by higher systemic levels of serum amyloid A (SAA) in patients with advanced diabetic kidney disease (DKD), but not among those with early or no DKD. The study aim was to determine relationships between indicators of locally-produced SAA and clinical outcomes in these patients.

Methods: In Pima Indians with type 2 diabetes, SAA protein was measured in urine (enzyme-linked immunosorbent assay, n=159) and SAA mRNA was quantified (microarray, n=46) in kidney tissue from research biopsies. Cox-proportional hazard models tested

whether urinary SAA forecasted future ESRD and all-cause death. Linear regression models tested for cross-sectional associations of SAA mRNA in kidney tissue with urine albumin-to-creatinine ratio (UACR) or estimated glomerular filtration rate (eGFR; CKD-EPI-creatinine). Urine and blood samples for these analyses were collected within 6 months of the biopsies.

Results: Baseline characteristics included: age 47±11 (mean±SD) years, women (117/159; 74%), hemoglobin A1c 9.1±2.3%, diabetes duration 17±7 years, body mass index 36±8 kg/m^2, renin angiotensin system inhibitor use (64/159; 40%), systolic blood pressure 124±16 mm Hg, UACR 39,14-209 mg/g (median, interquartile range), eGFR 103, 91-114 mL/min/1.73m^2. During a median of 12.5 years, 25 participants developed ESRD and 53 died. SAA-positive urine forecasted ESRD (hazards ratio [HR] 3.73, 95% confidence interval [CI] 1.11–12.53, p=0.022), but not death (HR 1.71, 95% CI 0.53– 5.50). In kidney tissue, tubulointersitial SAA mRNA was associated with a 6.3 mL/min/1.73m^2 lower eGFR (p<0.001) and a 0.80 log-fold increase in UACR per log-fold change in SAA mRNA (p<0.001). Glomerular SAA mRNA was associated with a 4.5 mL/min/1.73m^2 lower eGFR (p<0.001) and a 0.58 log-fold increase in UACR per log-fold change in SAA mRNA (p<0.001).

Conclusions: Urinary SAA forecasted ESRD and higher levels of SAA mRNA in kidney tissue correlated with lower eGFR and higher UACR. Associations between indicators of locally-produced SAA and clinical outcomes point to a candidate mechanism for DKD onset and progression in diabetic patients with early or no DKD.

TH-PO852

Sodium Glucose Cotransporter 2 Inhibition with Dapagliflozin Confers Renoprotection by Downregulating Megalin in Proximal Convoluted Tubules

Tomomichi Iida,[2,3] Shoji Kuwahara,[2] Michihiro Hosojima,[4] Tomomi Ishikawa,[2,3] Eri Wada,[2,1] Hideyuki Kabasawa,[4] Sawako Goto,[2,3] Daisuke Ugamura,[2,3] Yuta Yoshizawa,[2,3] Ryohei Kaseda,[3] Yoshiki Suzuki,[5] Ichiei Narita,[3] Akihiko Saito.[2] *[1]Gunma University Institute for Molecular and Cellular Regulation, Maebashi, Japan; [2]Applied Molecular Medicine, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [3]Clinical Nephrology and Rheumatology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [4]Clinical Nutrition Sciences, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [5]Health Administration Center, Niigata University, Niigata, Japan.*

Background: Megalin is an endocytic receptor expressed in the proximal tubules. We found that megalin mediates the endocytosis of glomerular-filtered nephrotoxic proteins, causing high-fat diet (HFD)-induced kidney disease in mice (JASN 2016). Thus, we speculate that appropriate suppression of renal megalin function may delay the development and progression of DKD. Sodium glucose transporter 2 (SGLT2) inhibitors are known to exert renoprotective actions and increase β_2-microglobulin, an endocytic ligand of megalin, in urine of patients with type 2 diabetes. Therefore, we studied the effect of dapagliflozin, a widely used SGLT2 inhibitor, on megalin expression in proximal tubular epithelial cells (PTECs).

Methods: Eleven-week-old male C57BL/6J mice, fed a normal fat diet (NFD), were administered 1mg/kg dapagliflozin or vehicle via oral gavage for 7 days; or eight-week-old mice were fed an HFD and administered 1mg/kg dapagliflozin or vehicle for 4 weeks. The effect of dapagliflozin on renal megalin expression was investigated by immunoblotting, quantitative PCR, and immunohistochemistry. Cultured immortalized rat PTECs (IRPTCs) transfected with human SGLT2 cDNA (S-IRPTCs) were treated with 20 μM dapagliflozin or vehicle and evaluated for 2-deoxy-D-glucose uptake and megalin expression.

Results: Dapagliflozin suppressed megalin expression transcriptionally in mice fed either an NFD or HFD. Megalin expression was decreased in the proximal convoluted tubules, but not in the proximal straight tubules. In HFD-fed mice, no difference was noted in blood glucose levels between dapagliflozin and vehicle treatments. Urinary albumin and α_1-microglobulin, endocytic ligands of megalin, were increased in dapagliflozin administered mice. In S-IRPTCs treated with dapagliflozin, the expression of both megalin protein and mRNA was decreased in association with decreased glucose uptake.

Conclusions: The renoprotective effect of SGLT2 inhibitors may be at least partly due to megalin downregulation, which would have impacts on the therapeutic strategies with SGLT2 inhibitors including the interpretation of megalin-associated urinary biomarkers in diabetes.

TH-PO853

SGLT2 Inhibition Relieves High Glucose-Induced Metabolic Disorders in Tubular Epithelial Cells Through Regulation of HIF-1α Pathway

Ting Cai,[2] Yang Zhou,[1] Junwei Yang.[1] *[1]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China; [2]Nanjing Medical University, Nanjing, China.*

Background: SGLT2 inhibitor (SGLT2i) has been proved to be renoprotective by reducing hyperperfusion, hyperfiltration and hypertension in glomeruli of diabetic kidney. However, high concentration of glucose reabsorbed into proximal tubular cells induced consequence abnormalities in glucose and lipid metabolism seems to be detrimental in diabetic kidney disease (DKD). In this study, we examined whether SGLT2i dapagliflozin may rectify metabolic disorders and explore the possible mechanism.

Methods: Diabetic model was induced by streptozotocin injection. Losartan was used as hemodynamic control. Dapagliflozin and losartan were given by oral gavage for 12 weeks. Mice were randomly assigned into six groups as follows: control + vehicle, control + dapagliflozin (5mg/kg), control + losartan (10mg/kg), diabetes + vehicle, diabetes + dapagliflozin (5mg/kg), diabetes + losartan (10mg/kg). High glucose-incubated primary tubular cells (PTCs) were treated with or without dapagliflozin for indicated time periods.

Results: In both diabetic kidney and glucose-treated PTCs, metabolic abnormalities were notable as demonstrated by increased lactate level and lipid accumulation accompanied with increased expression of enzymes for glycolysis and decreased expression of enzymes for fatty acid oxidation. Dapagliflozin treatment decreased blood glucose level, attenuated the increase of kidney/body weight ratio, albuminuria excretion rate, urinary NGAL level and tubulointerstitial fibrosis. Furthermore, dapagliflozin treatment relieved the increase of lactate level and accumulation of lipid droplet in tubular cells. The increased expression of glycolytic enzymes and decreased expression of fatty acid enzymes were rectified by dapagliflozin. These metabolic benefits were not observed in losartan-treated group. Moreover, expression of HIF-1α, the regulator of metabolism was increased, which suggested the stabilization of HIF-1α in diabetic kidney. Nevertheless, dapapagliflozin treatment inhibited HIF-1α stabilization. HIF-1α stabilizer BAY85-3934 blocked the protective role of dapagliflozin on metabolism in high glucose-treated PTCs.

Conclusions: We suggested that SGLT2 inhibitor protects against metabolic abnormalities and relieves tubular damage in diabetes through HIF-1α pathway.

TH-PO854

Renal SGLT2 mRNA Expression in Diabetic and Non-Diabetic Kidney Disease in Humans

Vikas Sridhar,[1] Jaya P. Ambinathan,[1] Matthias Kretzler,[3] Petter Bjornstad,[4] Sean Eddy,[3] David Cherney,[1,2] Heather N. Reich.[1,2] ERCB and NEPTUNE groups *[1]Nephrology, University of Toronto, Toronto, ON, Canada; [2]Toronto General Hospital, Toronto, ON, Canada; [3]University of Michigan, Ann Arbor, MI; [4]Children's Hospital Colorado, Aurora, CO.*

Background: In the setting of diabetes, intraglomerular hypertension is associated with chronic kidney disease (CKD) progression, in part through sodium-glucose cotransporter 2 (SGLT2)-mediated suppression of tubuloglomerular feedback (TGF). Pharmacological inhibition of SGLT2 activates TGF and reduces CKD progression in the setting of diabetes, and is being examined as a renal protection strategy in non-diabetic CKD trials. Despite interest in this field and ongoing trials, levels of renal SGLT2 mRNA expression in human health and disease have not yet been fully examined. Our aim was to quantify human renal SGLT2 mRNA expression in healthy controls (HC), in glomerulonephritis subtypes (GN) and in patients with diabetic kidney disease (DKD).

Methods: SGLT2 mRNA expression was quantified and compared in HC vs. GN vs. DKD in the European Renal cDNA Bank (ERCB). Second, renal SGLT2 mRNA expression from the Nephrotic Syndrome Study Network (NEPTUNE) was analyzed using biopsies from patients with membranous nephropathy (MN), minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS) and IgA nephropathy (IgAN). mRNA was obtained by microdissection of tubulointerstitial compartments from adult renal biopsies and processed using a microarray platform.

Results: In ERCB (n=166), SGLT2 mRNA expression was 9.42±0.50, 9.19±0.50 and 8.85±0.64 in HC, GN and DKD respectively (p=0.0044). SGLT2 mRNA expression was higher in HC vs. DKD and GN vs. DKD (p<0.05 for both). In NEPTUNE (n=121), there were no mRNA expression differences across GN subtypes (MN vs. MCD vs. FSGS vs. IgAN). In NEPTUNE patients with GN, eGFR (r= 0.32, p<0.001) was positively correlated with SGLT2 mRNA expression and interstitial fibrosis was negatively correlated with SGLT2 expression (r=-0.23, p<0.01). No relationships were seen with proteinuria.

Conclusions: SGLT2 mRNA expression is lower in patients with DKD compared to HC or GN, and is related to the degree of interstitial fibrosis in GN patients. In light of protective effects on DKD outcomes in clinical trials despite apparently having the lowest SGLT2 mRNA expression, further studies are required to better understand the relationship between SGLT2 protein levels and/or activity and CKD outcomes in humans.

TH-PO855

Early B Cell Factor 1 Plays a Role in the Maintenance of Glomerular Filtration Barrier Integrity

Darrell C. Andrews,[1] Eoin P. Brennan,[1] Laura L. Beverly-Staggs,[6] Patricia A. Schroder,[4] Peter J. Conlon,[5] Mario Schiffer,[3] Catherine Godson.[2] The GENIE Consortium *[1]University College Dublin, Dublin, Ireland; [2]The Conway Institute of Biomolecular and Biomedical, Belfield, Dublin, Ireland; [3]Hannover Medical School, Hannover, Germany; [4]Mount Desert Island Biological Laboratory, Salisbury Cove, ME; [5]Beaumont Hospital, Dublin 9, Co Dublin, Ireland; [6]Mount Desert Island Biological Lab, Salisbury Harbor, ME.*

Background: Diabetic kidney disease (DKD) is the leading cause of end-stage renal disease (ESRD) and organ failure worldwide. Current therapies are inadequate and at best slow progression but do not arrest or reverse it. Proteinuria is associated with DKD progression and reflects loss of integrity of the glomerular filtration barrier (GFB). Defining the mechanisms underlying a compromised GFB during the progression of DKD is key to developing effective therapeutic strategies. We identified *EBF1* as associated with macroalbuminuria and ESRD by our GWAS analysis in a case (n=2,861 individuals with T1DM) vs control (n=12,418 individuals with T1DM and no evidence of renal disease 15 years post-diagnosis) approach. Here we investigate the contribution of EBF1 to proteinuria associated with DKD using a zebrafish model of GFB integrity and elaborate on its role in maintaining a functional GFB.

Methods: To investigate a possible causative role for EBF1 in loss of GFB integrity with resulting proteinuria Tg(l-fabp:DBP:EGFP) zebrafish embryos were injected with

control or EBF1 morpholinos. Morpholinos targeting the podocyte gene *CD2AP* were used as a positive control. Tg(l-fabp:DBP:EGFP) transgenic zebrafish express a fluorescent plasma protein with a molecular weight equivalent to human albumin. Compromised GFB integrity leading to loss of the fusion protein from the circulation can be quantified by fluorescence imaging of the retinal plexus. The ultrastructure of GFB was visualised using electron microscopy. While RNA sequencing analysis was used to map the transcriptome of EBF1 knockdown fish vs control.

Results: EBF1 knockdown led to a significant loss of retinal fluorescence compared to control and equivalent to that of CD2AP at 96hpf. Knockdown also caused generalised edema compared to control, further supporting a role for this gene in kidney function. EM analysis revealed loss of EBF1 caused pronounced podocyte foot process effacement and screening of a cohort of cell lines confirmed high levels of expression of EBF1 in podocytes. RNA sequencing analysis combined with Ingenuity Pathway Analysis revealed desregulated transcripts and key pathways affected by EBF1 knockdown which were validated by real time PCR.

Conclusions: These findings suggest that EBF1 plays a key role in maintaining GFB integrity.

Microangiography Reveals the Protective Role of Liraglutide on Renal Microvascular Impairment in Rats with Metabolic Syndrome

Vijayakumar Sukumaran,[1] Hirotsugu Tsuchimochi,[1] Takashi Sonobe,[1] Mikiyasu Shirai,[2] James T. Pearson.[1,3] *[1]Department of Cardiac Physiology, National Cerebral and Cardiovascular Centre, Suita, Japan; [2]Center for Advanced Medical Research for on Pulmonary Hypertension, National Cerebral and Cardiovascular Center, Suita, Japan; [3]Department of Physiology, Monash Biomedicine Discovery Institute, Monash University, Clayton 3800, VIC, Australia.*

Background: Progressive renal impairment associated with metabolic syndrome remains a significant cause of morbidity and mortality. We investigated whether chronic high dose liraglutide (LIRA, GLP-1 agonist) treatment affects the metabolic profile and extent of renal inflammation and renal endothelial function in lean fa/+ and obese fa/fa (ZFDM) rats.

Methods: 8-week old lean fa/+ and obese fa/fa ZFDM rats were treated with vehicle or LIRA (1mg/kg/day, subcutaneous) for 8 weeks. Systolic blood pressure (SBP) was monitored in ZFDM rats at 0, 4 and 8 weeks using tail-cuff method. Glomerular filtration rate (GFR) was measured in conscious rats at 0, 4 and 8 weeks using the fluorescein isothiocyanate sinistrin method. X-ray microangiography was then used to investigate renal vascular function (vessels 70-350 μm diameter). Further, renal function parameters including urinary albumin, creatinine and albumin creatinine ratio were measured.

Results: We found that in comparison to the saline treated obese fa/fa rats, LIRA treated rats had significantly lower SBP, and restored GFR (Fig. 1A-B) due in part to an increase in nitric oxide-mediated vasodilation in small renal arteries and arterioles (<200 μm diameter) (Fig. 1C-F). Further, vessel internal diameter, visible vessel number and caliber (%) increased after LIRA treatment compared to vehicle-treated rats (Fig. 1G-I). Moreover, the high dose LIRA treatment largely prevented the decline in renal function seen in vehicle treated obese fa/fa rats (elevated urinary albumin and depressed creatinine).

Conclusions: These results strongly suggest that high dose LIRA treatment significantly improved the endothelial function of microvessels in the renal circulation, and greatly improved renal function.

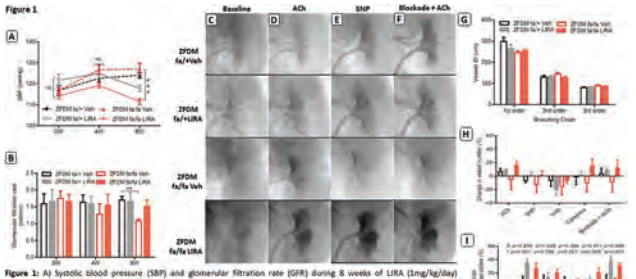

Figure 1: A) Systolic blood pressure (SBP) and glomerular filtration rate (GFR) during 8 weeks of LIRA (1mg/kg/day) treatment in lean fa/+ and obese fa/fa ZFDM rats. **Representative X-ray micro angiograms of the renal vasculature in ZFDM rats after 8 weeks of LIRA treatment.** (C-F) Images during baseline, and infusions of acetylcholine (ACh), sodium nitroprusside (SNP) and ACh following blockade of gap junctions (carbenoxelone), prostaglandins (indomethacin) and endothelium derived hyperpolarization factors (charabydotoxin, apamin). Calibration wire = 50 μm. (G) Vessel internal diameter categorized by branching order during baseline lactate infusions. (H) LIRA treatment shown greater vessel number recruitment after blockade compared to vehicle treated rats. (I) Mean change in 2nd order vessel diameter from baseline ± SEM. The significance of group differences was determined by ANOVA for factors of strain (S) and drug treatment (T).

Possible Role of Ketone Body Metabolism in SGLT2 Inhibitor-Mediated Renoprotection in High Fat Diet-Fed ApoE-Knockout Mice

Tomita Issei,[1] Shinji Kume,[1] Norihisa Osawa,[1] Kosuke Yamahara,[1] Mako Yamahara,[1] Naoko Takeda,[1] Masami Kanasaki,[1] Eric Mayoux,[2] Tatsuroh Kaneko,[3] Shin-ichi Araki,[1] Hiroshi Maegawa.[1] *[1]Shiga University of Medical Science, Otsu, Japan; [2]Boehringer-Ingelheim, Biberach an der Riss, Germany; [3]Nippon Boehringer Ingelheim, Tokyo, Japan.*

Background: A recent study showed that empagliflozin, a SGLT2 inhibitor, slowed renal function decline rate in diabetic patients regardless of proteinuria stage, suggesting that the treatment has a renoprotective property in diabetes. This animal study was aimed at revealing the renoprotective action of empagliflozin on atherosclerosis-related renal injury in diabetes, and a possible role of ketone body production in its renoprotective mechanism.

Methods: Study 1 examined the effect of oral administration of empagliflozin (30mg/kg) for 8 weeks on atherosclerosis and renoprotection in high fat diet (HFD)-fed ApoE knockout (ApoE$^{-/-}$) mice, an animal model for atherosclerosis. Study 2 examined the effect of oral administration of 1,3-butanediol, a ketone body precursor, for 8 weeks on atherosclerosis and renoprotection in HFD-ApoE$^{-/-}$ mice.

Results: In Study 1, empagliflozin treatment significantly improved atherosclerosis in HFD-fed ApoE$^{-/-}$ mice. HFD-ApoE$^{-/-}$ mice showed significant increases in serum cystatin C levels without albuminuria, and F4/80-positive macrophage infiltration and fibronectin deposition in renal interstitium. These renal alterations were all significantly improved by the empagliflozin treatment, which was accompanied by significant increases in serum β-hydroxybutyric acid (β-OHB) levels. In study 2, although the 1,3-BD treatment did not improved atherosclerosis in HFD-fed apoE$^{-/-}$ mice, similarly to the results from the empagliflozin study, the 1,3-BD treatment significantly improved serum cystatin C, and renal F4/80-positive macrophage infiltration and fibronectin deposition along with maintaining renal ATP contents in HFD-ApoE$^{-/-}$ mice. Finally, we confirmed that β-OHB supplementation inhibited apoptosis in the cultured proximal tubular cells stimulated with high glucose, saturated fatty acids and hypoxia.

Conclusions: Ketone body-derived energy supply to the hypoxic kidney could be a promising therapy for preventing renal dysfunction in diabetic kidney disease.

TH-PO858

Association Between MYH9 and APOL1 Gene Polymorphisms and the Risk of Diabetic Kidney Disease in Patients with Type 2 Diabetes in a Chinese Han Population

Hailing Zhao, Ping Li. *China-Japan Friendship Hospital, Beijing, China.*

Background: Single nucleotide polymorphisms (SNPs) in MYH9-APOL1 gene regions have been reported to be associated with diabetic kidney disease (DKD) in the American population. The susceptibility of MYH9 and APOL1 polymorphisms with DKD in Chinese populations has not been well studied. In this study, we examined the association of MYH9 rs3752462 (T>C) and APOL1 rs136161 (C>G) with DKD in a Chinese Han population.

Methods: MYH9 rs3752462 (T>C) and APOL1 rs136161 (C>G) were genotyped in 303 DKD patients and 364 type 2 diabetes mellitus (T2DM) patients without kidney disease using the TaqMan SNP genotyping assay. Chi-squared test and multivariate logistic regression were used to evaluate the association.

Results: We observed that only MYH9 rs3752462 was associated with DKD (genotype, P= 0.004; allele, P= 0.002). Genetic model analysis revealed that rs3752462 was associated with increased risk of DKD under a dominant model adjusted by age and sex (adjusted Odds ratio [aOR], 1.675; 95% CI 1.225-2.289; P= 0.001) and an additive model (TC vs TT: aOR, 1.649; 95% CI 1.187-2.290; CC vs TT: aOR, 1.817; 95% CI 0.980-3.367; P= 0.005). The combined effect of rs3752462 TC + rs136161 CC genotype showed a association of DKD adjusted by age and sex (aOR, 1.732; 95% CI 1.128-2.660; P= 0.012). After a Holm-Bonferonni correction for multiple tests, the C allele frequencies of the rs3752462 and the TC + CC genotype in dominant model were considered statistically significant with a markedly increased risk of DKD (P<0.00208; P<0.002).

Conclusions: Our results suggest that MYH9 rs3752462 is significantly associated with an increased risk of DKD in Chinese Han individuals.

Genome-Wide Association Study of Urinary and Plasma KIM-1 Levels in Type 1 Diabetic Subjects with Diabetic Kidney Disease

Marcus G. Pezzolesi,[1] Eiichiro Satake,[2] Adam Smiles,[2] Christopher Simeone,[2] Julio C. Fierro,[1] Bozena Krolewski,[2] Stephen Rich,[3] Andrzej S. Krolewski.[2] *[1]University of Utah, Salt Lake City, UT; [2]Joslin Diabetes Center, Boston, MA; [3]University of Virginia, Charlottesville, VA.*

Background: Kidney injury molecule 1 (KIM-1) is a transmembrane protein primarily expressed at the apical membrane of proximal tubular cells following kidney damage. Urinary and plasma levels of this biomarker are increased in patients with non-diabetic chronic kidney disease and diabetic kidney disease. Here, we performed a genome-wide association study (GWAS) to investigate whether genetic factors influence urinary and plasma KIM-1 levels in type 1 diabetes.

Methods: KIM-1 levels were measured in 688 baseline urine specimens and 826 plasma specimens from participants with type 1 diabetes enrolled in the Joslin Kidney Study. Genotyping was performed using Illumina's HumanCoreExome BeadArray. Imputation of additional variants across the KIM-1 locus was performed using IMPUTE2 and 1000 Genomes Phase 3 data. Association analyses between KIM-1 levels and single nucleotide polymorphism (SNP) data were calculated using linear regression implemented in Plink.

Results: The strongest GWAS SNP associated with urinary KIM-1 levels was a missense variant (rs12522248; Thr207Ala; P=6.3x10^{-6}) located in exon 3 of the *KIM1* gene. The most strongly associated GWAS SNP with plasma KIM-1 levels was rs2436424 (P=5.0x10^{-6}), located 230kb downstream of *KIM1*. Using imputed SNPs to fine-map this locus, we identified 45 SNPs with P<1.0x10^{-5}, including 2 variants approximately 50kb downstream of *KIM1* with P<1x10^{-7}.

Conclusions: Using a GWAS and imputation analysis of urinary and plasma KIM-1 levels, we identified strong associations in the KIM1 gene that suggests that genetic variants at this locus impact KIM-1 levels in response to kidney injury. Further investigation is needed to fully understand the role of genetic variation on KIM-1 levels and how these

potentially impact the utility of this biomarker in patients with or at risk of diabetic kidney disease.

TH-PO860

Prevalence of Angiotensin Type II Receptor (ATTR) Gene Polymorphism in Patients with Type 2 Diabetes with Nephropathy in India and Its Effect on the Antiproteinuric Efficacy of ACE Inhibitor Therapy

Om P. Kalra,[1] Neerja Aggarwal,[2] Parul Varshney,[2] Anil K. Yadav,[2] Alpana Raizada,[2] Basu D. Banerjee,[2] Ashok K. Tripathi,[2] Madhu V. S.[2] *[1]Pt. B.D. Sharma University of Health Sciences, Rohtak, Haryana, India; [2]University College of Medical Sciences and GTB Hospital, Delhi, India*.

Background: Involvement of renin angiotensin system has been implicated in the etiopathogenesis of diabetic nephropathy (DN). Angiotensin converting enzyme inhibitor (ACEI) drugs are commonly prescribed for reno-protection in patients with DN; however, response to ACEI therapy is not uniform in all patients. Aim of this study was to investigate the prevalence of ATTR A1166C gene polymorphism in North Indian patients with DN and its role on the anti-proteinuric efficacy of ACEI therapy.

Methods: In the present study, 270 patients having Type 2 diabetes mellitus for ≥ 5 years with nephropathy aged between 30 to 65 (mean 52.23±6.01) years were enrolled and treated with ACE inhibitor (ramipril) and subsequently followed at regular intervals for 2 years for assessment of urinary albumin/creatinine ratio (ACR) and estimated GFR. Patients were classified as responders if they had a decrease in urinary ACR by ≥50% at the end of 2 years follow up. Genotyping of ATTR A1166C gene polymorphism was performed by primer specific polymerase chain reaction and RFLP technique.

Results: Out of 270 patients, 231 completed the follow up of 24 months. 151(65%) patients with DN were found to be responders following ACE inhibitor therapy. Median urinary ACR values declined from the baseline value of 109.9 mg/g creatinine to 47.3 mg/g creatinine ($p<0.001$). At the end of 24 months, increase in serum creatinine above the baseline (0.28±0.3 v/s 0.61±0.2) ($p=0.269$) and decline in eGFR-MDRD (8.40±16.0 v/s 12.84±15.0 mL/min/1.73m^2) ($p=0.058$) between responders and non-responders respectively were not significantly different. All subjects displayed wild type allele (A) of this polymorphism and showed no genotypic variation; hence polymorphism of ATTR A1166C gene does not appear to have any role on the variability of anti-proteinuric effect following ACEI therapy.

Conclusions: In patients with Type 2 diabetes mellitus with nephropathy, approximately two third patients were found to have significant anti-proteinuric response following ACEI therapy. ATTR A1166C gene polymorphism is extremely rare in Northern India and does not appear to play any role in influencing the variation in anti-proteinuric effect following ACEI therapy.

XORs in the Genetic Susceptibility of Diabetic Kidney Disease in Mice

Haiying Qi,[2] Liping Yu,[1] Qin Wang,[3] Ilse S. Daehn.[1] *[1]Mount Sinai School of Medicine, New York, NY; [2]Mount Sinai school of medicine, Chatham, NJ; [3]Icahn School of Medicine at Mount Sinai, New York, NY*.

Background: Diabetic kidney disease (DKD) is the leading single cause of ESRD in the United States. Approximately 30% of diabetic patients develop DKD even with comparable blood glucose levels, indicating a significant genetic component for disease susceptibility. Differential susceptibilities to DKD have also been observed in well-defined strains of inbred mice. The underlying mechanisms that contribute to differential susceptibility to DKD are still poorly understood in both patients and rodent models. The glomerulus is the primary site of injury with glomerular hypertrophy and podocyte depletion being the hallmarks for progressive DKD. Our work has demonstrated that ROS and mitochondrial oxidative stress damage accumulation, particularly in glomerular endothelial cells (GECs), leads to podocyte loss via endothelial-to-podocyte crosstalk in experimental mouse models of DKD and focal segmental glomerulosclerosis.

Methods: We used the BXD recombinant inbred panel to map genetic loci (QTL) associated with number of podocytes after long-term diabetes (6 months). We used parent strains inbred DBA/2J (D2) mice as susceptible, and C57BL/6J (B6) mice as resistant to diabetes-induced podocyte depletion associated with DKD susceptibility. Genetic mapping identified a cis-acting regulatory of the Xdh gene encoding xanthine dehydrogenase XDH/XO (xanthine oxidoreductase (XOR)). XORs catalyze the oxidation of purine substrates, xanthine and hypoxanthine, producing uric acid (UA) and are a major enzymatic source of cellular ROS. Both products have been demonstrated to be risk factors for cardiovascular diseases and DKD.

Results: Xdh expression in glomeruli and XO activity in serum were significantly increased in diabetic D2 mice, but not B6 resistant mice. XOR inhibition resulted in significantly reduced albuminuria, prevention of podocyte loss, as well as a reduction in DNA oxidation damage in the glomeruli of diabetic D2 mice. Using a luciferase reporter assay we examined if the two nucleotide variant could influence XOR activity. Our results show increased XOR activity of 293T cells when treated with high glucose (30mM) compared to controls. We have now generated mice with knock-in variants using CRISPR/Cas9 to determine their functional role in DKD susceptibility.

Conclusions: These data suggest that the identified promoter variant regulates XOR activity potentially linked to genetic susceptibility to DKD.

Tubular and Injury Marker Expression Across Nephron Subsegments in Diabetic Nephropathy

Daria Barwinska,[2] Yinghua Cheng,[2] Michael J. Ferkowicz,[2] Seth Winfree,[2] Kimberly S. Collins,[2] Ken Dunn,[1] Katherine J. Kelly,[1] Timothy A. Sutton,[2] Brad H. Rovin,[5] Samir V. Parikh,[3] Pierre C. Dagher,[1] Tarek M. El-Achkar,[1] Michael T. Eadon.[4] *[1]Indiana University, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Ohio State University Medical Center, Columbus, OH; [4]Indiana University Division of Nephrology, Indianapolis, IN; [5]Ohio State University Wexner Medical Center, Columbus, OH*.

Background: Laser Microdissection (LMD) allows precise separation of nephron structures under immunofluorescence (IF). Several markers have been identified in the literature that are associated with specific subsegments of a nephron. Here, we examine the expression of known tubular and injury markers in kidney tissue of diabetic nephropathy (DN) biopsies and healthy nephrectomies.

Methods: Kidney biopsies from subjects with DN as well as a wedge biopsy from a healthy donor kidney were obtained. Tissue was preserved in OCT for 4 years at -80° C and sectioned into 12 µm thick sections on LMD PPS-membrane slides. Each slide was subjected to a rapid staining protocol, using DAPI, FITC-Phalloidin and Na/K channel antibody. Each slide underwent identical antibody staining and LMD, followed by RNA isolation, and sequencing. Transcriptomics data were obtained using RNAseq methodology on Illumina platform, and analyzed using R Studio.

Results: This study revealed that LMD methodology successfully allows for accurate identification of specific sub segments of a nephron, as shown by presence of markers associated with those structures and the absence of markers associated with other regions: NPHS1 and NPHS2 for the glomerulus, CUBN and SLC34A1 for the S1 and S2 proximal tubule, LRP2 for the S3 proximal tubule, and AQP2 and SCCN1G for the collecting duct. In addition, the transcriptomic analysis revealed differential expression of tubular injury markers like LCN2 (NGAL) expressed in the S1 and S2 subsegment. In contrast, HAVCR1 (KIM1) and TIMP2 expression was increased in the S3 subsegment.

Conclusions: LMD is an important tool that allows for accurate identification and isolation of tubular subsegments within renal tissue and subsequent RNA analysis. An increased expression of injury markers associated with different tubules was observed in the diseased kidney tissue samples. This suggests that specific regions of the nephron may respond to injury in different ways, which may further contribute to the pathogenesis and progression of DN.

Intraglomerular Cross-Talk Between Mesangial Cells and Podocytes Inhibits Normal ER-Associated Degradation Processes and Induces Podocyte Injury in Diabetic Nephropathy

Daisuke Fujimoto,[1] Takashige Kuwabara,[2] Yusuke Hata,[2] Shuro Umemoto,[4] Tomoko Kanki,[5] Yoshihiko Nishiguchi,[3] Teruhiko Mizumoto,[6] Manabu Hayata,[5] Yuichiro Izumi,[5] Yutaka Kakizoe,[2] Masashi Mukoyama.[2] *[1]Department of Nephrology, Kumamoto University, Kumamoto, Japan; [2]Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan; [3]Kumamoto University Hospital, Kumamoto, Japan; [4]Kumamoto University Graduate School of Medicine, Kumamoto, Japan; [5]Kumamoto University, Kumamoto, Japan; [6]Department of Nephrology Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan*.

Background: We previously reported that endoplasmic reticulum (ER) stress induced by glucolipotoxicity and homeostatic inflammation through intraglomerular cellular crosstalk may play an important role in the progression of diabetic nephropathy. However, involvement with these consequences in podocyte injury still remains unclear.

Methods: Cluster analyses were performed using cDNA microarray data set of isolated glomeruli from two distinct diabetic mouse models. ER stress and apoptotic responses were evaluated in cultured mouse podocytes MPC5 stimulated with mesangial cell-cultured medium (MC-sup) under high- and low-glucose conditions (HG, LG). The effects of an ER-associated degradation (ERAD) inhibitor Eeyarestatin I (EerI) in MPC5 and db/db mice were also examined.

Results: Commonly increased or decreased genes in both DM models were associated with apoptosis (enrichment score 3.03), inflammation (3.03), and energy metabolism (1.24), suggesting ER stress as a potential factor. Pathway-focused PCR array analysis revealed that ERAD pathway was suppressed, but apoptotic pathway was enhanced in podocytes stimulated with HG MC-sup. Besides, these responses were also observed in isolated diabetic glomeruli. In vitro, IRE1α and spliced XBP1 were suppressed in podocytes by HG MC-sup, although apoptosis evaluated by TUNEL-staining, Bax, ATF6 and CHOP was markedly increased. These results were augmented by HG MC-sup compared to LG MC-sup. Other types of cells, such as proximal tubular cells or macrophages, did not show any similar responses. Of note, treatment with EerI recapitulated these results in podocytes, and exacerbated albuminuria in db/db mice.

Conclusions: It is recently reported that ERAD pathway may play important roles in the maintenance of podocytes to avoid ER stress in several glomerular diseases including diabetic nephropathy. In the present study, we firstly reveal that intraglomerular crosstalk between mesangial cells and podocytes inhibits normal ERAD processes, potentially causing podocyte injury in diabetic conditions.

TH-PO864

Irisin, a Myokine, Ameliorates Diabetic Nephropathy by Restoring Autophagy in Podocytes

Dan Luo, Wenbo Zhao, Yin Li, Yang C. Lun, Hongchun Lin, Tan-qi Lou, Hui Peng. *The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, Guangdong, China*.

Background: Moderate exercises have been demonstrated to ameliorate diabetic nephropathy in some clinical studies. However, the mechanism remains unknown. Skeletal muscle could excrete many myokines while exercises. Irisin is one of the myokines which could mediate the communication between muscle and other organs. Therefore, we hypothesis that exercised muscle-excreted irisin protects kidneys from diabetes mellitus.

Methods: We crossbred muscle-specific PGC-1α overexpression of mice (an animal model mimicking exercise) with db/m mice to get mPGC-1α-db/db mice. The urine albumin creatinine ratio (uACR) and pathologic change of kidneys were examined. Besides, recombinant irisin had been administrated to twelve-week-old db/db mice and their db/m littermates. The renal function and pathologic change were accessed to evaluate the protection effect of Irisin. Conditionally immortalized human podocyte cells were used for in vitro study to investigate how irisin protect podocytes from injury of high glucose (30mmol/l).

Results: There were significant accumulation of mesangial matrix, fusion of podocytes foot processes, widen of GBM as well as decrease of autophagy in the kidney of db/db mice. However, these kidney pathological injuries were remarkably improved in mPGC-1α-db/db mice. Meanwhile, the mice also showed significant alleviation of the excretion of uACR than db/db mice without mPGC-1α. These results indicate that mPGC-1α could alleviate kidney injury induced by diabetes. Irisin was found as one of the significantly increased myokines in the skeletal muscles of mPGC-1α mice, then we treated db/db mice with irisin for eight weeks. After peritoneal injection of irisin, the kidney pathologic change and microalbuminuria of db/db mice were all alleviated when compared to those db/db mice without irisin injection. Furthermore, Irisin treatment significantly restored autophagy in podocytes of db/db mice. Meanwhile, in vitro study, irisin improved the expression of autophagy related proteins and autophagy flux in high glucose cultured podocytes.

Conclusions: Our results indicate that the myokine, irisin, prevents the progression of diabetic nephropathy by restoring autophagy in podocytes. Irisin is one of the myokines that mediate the effect of exercised-muscle prevents diabetic nephropathy, which may become a new strategy to protect the kidney from diabetes.

TH-PO865

Astaxanthin Attenuates Diabetic Kidney Injury Through Up-Regulation of Autophagy

Chen Zhengyue. *Ningbo Urology and Nephrology Hospital, Ningbo, China*.

Background: The aim of this study was to investigate effects of astaxanthin (ATX) on renal injury in diabetic mice and its underlined renal protective mechanism.

Methods: Rats were randomly divided into five groups: normal, high fat diet, high fat + DM, high fat + ATX treatment, high fat + DM + ATX treatment. Fasting blood glucose, Urinary protein / Crea were measured. Renal pathological changes were evaluated with HE and PAS staining. In vitro, HTECs, HMCs and Podocytes were treated with ATX in the presence or absence of 30 mmol/L D-glucose or autophagy inducer.

Results: Diabetic rats treated with ATX had reduced 24h urinary protein excretion, blood glucose and lipids level as compared with those in vehicle-treated rats. The same as Glomerulus mesangial matrix expansion and renal tubular epithelial cell injury(Fig1,2). Moreover, ATX treatment markedly reduced protein levels of p62, α-SMA, FN and collagen IV in the kidney of diabetic rats(Fig3). In vitro, high glucose was shown to inhibit expression LC3-II and increase expression of p62 as compared with normal glucose while these changes were reversed with ATX treatment. ATX treatment also inhibited expression of α-SMA, collagen IV and FN in cultured kidney cells(Fig4,5).

Conclusions: The current study shows that ATX attenuates diabetes-induced kidney injury probably through upregulation of autophagic activity in kidney cells and anti-fibrosis effects.

Funding: Government Support - Non-U.S.

Apelinergic System in the Kidney: Implications for Diabetic Kidney Disease

Tilman Müller,[1] Anastasia Z. Kalea,[3] Syed K. Haque[2] Minghao Ye,[1] Jan Wysocki,[1] Daniel Batlle.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]American Laboratory Consultant LLC, Park Ridge, IL; [3]University College London, London, United Kingdom.*

Background: The bioactive peptides of the apelinergic system and its receptor APJ may play a protective role in cardiovascular and diabetic kidney disease (DKD). We examined the glomerular localization of APJ in the db/db mice and the effect of hyperglycemia and Angiotensin II on APJ mRNA in cultured podocytes. The impact of AT1R blockade on APJ expression was also studied in db/db mice.

Methods: Obese db/db mice of 8wk of age were used as a model of type 2 diabetes and their littermates db/m served as non diabetic controls. mRNA for APJ and propreapelin was measured by real time PCR; protein expression for APJ was studied by western blot on kidney lysates. Immunohistochemistry and immunofluorescence microscopy was used to localize APJ in the kidney.

Results: APJ co-localized with podocyte but not endothelial cell markers. In podocytes stimulated with *Pyr*[1]Apelin-13 a change in the phosphorylation status of the signaling proteins, AKT, ERK and p70S6K, was observed with an increase 15 min after stimulation. Apelin-13 decreased activity of Caspase-3 in podocytes after high glucose exposure reflecting an anti-apoptotic effect of APJ stimulation. In podocytes, APJ mRNA was down regulated in high glucose, and exposure to angiotensin II led to a further significant decrease in APJ mRNA. APJ and propreapelin mRNA in kidneys from *db/db* mice were decreased when compared to *db/m* controls; treatment with the specific AT1R blocker Telmisartan significantly increased APJ mRNA and propreapelin levels.

Conclusions: APJ is mainly localized in podocytes and in this cell type its activation by Apelin-13 abolishes the proapoptic effect of high glucose, suggesting a potential therapeutic role of apelin and emerging agonists with extended half- life in DKD. In addition, AT1 blockade with Telmisartan resulted in an increase in APJ mRNA and propreapelin levels in db/db mice suggesting a link of the apelinergic system and the AT1 receptor

TH-PO867

Effects of Ang-(1-7) and Its Receptor Regulating Bradykinin System on Podocyte Injury Induced by High Glucose

Guixiang Chen,[2] Guanghui Shen,[1] Jianxin Lu,[2] Feng Ding.[2] *[1]Department of Clinical Laboratory, Shanghai Ninth People's Hospital, Affiliated to Shanghai JiaoTong University, School of Medicine, Shanghai, 200011, P.R.China., Shanghai, China; [2]Division of Nephrology, Shanghai Ninth People's Hospital, Affiliated to Shanghai JiaoTong University, School of Medicine, Shanghai, 200011, P.R.China., Shanghai, China.*

Background: The mechanisms of diabetic nephropathy are still enigmatic. We hypothesized that RAS component Ang-(1-7) and its Mas receptor (MasR) and bradykinin (BK) system may play a protective role in podocyte injury induced by high glucose.

Methods: The Podocytes cultured in vitro were respectively interfered with low glucose (5mM, LG), high glucose (30mM, HG), HG+Ang-(1-7), HG+HOE140 (BKB2R antagonist), HG+ des[Arg(9)]BK (BKB1R agonist), HG+Ang-(1-7)+A779 [Ang-(1-7) antagonist], HG+ Ang-(1-7)+HOE140 and HG+ Ang-(1-7)+des[Arg(9)]BK. The CCK8 method detected the activity of podocytes and the flow cytometry detected the apoptosis of podocytes. The mRNA and proteinic expression of AT1R, MasR, BKB1R, BKB2R and podocyte-specific proteins (nephrin, podocin, WT-1) was examined by q-PCR and Western blot. The podocytes were also interfered with inhibitor of ERK and JNK, the expression of pERK/ERK, pJNK/JNK in podocytes was semi-quantificated by Western blot to investigate the signaling passway involved in the regulation.

Results: The CCK8 and flow cytometry results showed that the descent of podocyte activity and podocyte apoptosis induced by HG was rescued by Ang-(1-7) and HOE140. The effect presented concentration dependency. des[Arg(9)]BK and A779 displayed antagonistic action against Ang-(1-7), which aggrated the podocyte apoptosis and the descent of cell activity, moreover, the effect was most obviously at 10uM concentration. The results of q-PCR and Western blot indicated that HG stimulation up-regulated the expression of AT1R, BKB1R, BKB2R and down-regulated MasR, Nephrin, Podocin and WT-1. Ang-(1-7) and HOE140 could relieve the action of HG but A779 and des[Arg(9)]BK was the converse of Ang-(1-7) in some extent. The synergetic protective effect of HOE140 and Ang-(1-7) was more significantly. HG and des[Arg (9)]BK activated the MAPKs signaling passway yet Ang-(1-7) and HOE140 inhibited it. The inhibitor of MAPKs further decreased the podocyte apoptosis induced by HG.

Conclusions: Ang-(1-7)/MasR may decrease the up-regulation of BKB1R and BKB2R induced by HG, antagonist Ang II- ACE-AT1R axis, and then inhibit the activation of MAPKs and podocyte apoptosis. The synergistic reaction of Ang-(1-7)/MasR and BK system could protect podocyte from injury induced by HG.

Diabetic Conditions Enhance the Phosphorylation of PACSIN2/Syndapin II in Podocytes

Sanna H. Lehtonen,[1] Vincent Dumont,[1] Sonja Lindfors,[1] Carol Forsblom,[2] Hiroshi Kawachi,[3] Per-Henrik Groop,[4] Shiro Suetsugu.[5] *[1]University of Helsinki, Helsinki, Finland; [2]Folkhalsan Research Center, Helsinki, Finland; [3]Department of Cell Biology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [4]University of Helsinki and Helsinki University Hospital, Helsinki, Finland; [5]Nara Institute of Science and Technology, Nara, Japan.*

Background: We previously found that PACSIN2/syndapin II, which regulates endocytosis and intracellular trafficking, is elevated in glomeruli of Zucker Diabetic Fatty (ZDF) rats showing aberrant localization of nephrin and severe albuminuria. We also showed *in vitro* that PACSIN2 overexpression reduces nephrin insertion at the plasma membrane. PACSIN2 can be phosphorylated at serine 313 (pS313-PACSIN2) by Protein Kinase C alpha (PKCα), which in turn regulates the endocytic activity of PACSIN2. Importantly, PKCα is elevated in diabetes and associated with loss of nephrin expression. The aim of this study was to evaluate the phosphorylation status of PACSIN2 in glomeruli in diabetes. We also assessed the regulation of pS313-PACSIN2 and the presence of nephrin at the plasma membrane after treating cultured podocytes with palmitate, elevated in patients with diabetes.

Methods: PKCα, total PACSIN2 and pS313-PACSIN2 levels were assessed by Western blotting. On-Cell Western, a 96-well plate -based surface labeling assay, was used to determine the insertion of nephrin at the plasma membrane. Glomeruli were isolated from lean and obese ZDF rats by graded sieving. Cultured podocytes were incubated with palmitic acid or with sera from patients with T2D having normo- or microalbuminuria.

Results: PKCα, total PACSIN2 and pS313-PACSIN2 were elevated in glomeruli of obese and diabetic ZDF rats compared to lean controls. Also, the level of free fatty acids was increased in the sera of obese ZDF rats. Increased pS313-PACSIN2 and a trend for an increase of total PACSIN2 were observed when human podocytes were incubated with sera from patients with T2D with microalbuminuria compared to normoalbuminuric patients. Treating podocytes with palmitic acid resulted in the time-dependent phosphorylation of PACSIN2 on S313. Palmitic acid treatment also resulted in the reduction of nephrin inserted at the plasma membrane.

Conclusions: Our results indicate that PACSIN2 and its phosphorylation at serine 313 are elevated in glomeruli in a rat model of diabetes and diabetic kidney disease. This could be a consequence of elevated circulating palmitate and result in the reduction of nephrin at the plasma membrane, causing the destabilization of the slit diaphragm and albuminuria.

Knockout of Heterogeneous Nuclear Ribonucleoprotein F (hnRNP F) in Podocytes Aggravates Podocyte Loss in Streptozotocin-Induced Diabetic Mice Through Alternative Splicing of Insulin Receptor Gene

Chao-Sheng Lo,[1] Isabelle Chenier,[1] Janos G. Filep,[2] Julie R. Ingelfinger,[3] Shao-Ling Zhang,[1] John S. Chan.[1] *[1]CRCHUM, Universite de Montreal, Montreal, QC, Canada; [2]Maisonneuve-Rosemont Hosp., Montreal, QC, Canada; [3]The New England Journal of Medicine, Boston, MA.*

Background: Insulin receptor (INSR) signaling is important for podocyte integrity. The INSR gene encodes two isoforms via alternative splicing: INSR-A (excluding exon 11) and INSR-B (including exon 11). In pancreatic beta cells, INSR-A renders beta cells vulnerable to programmed cell death, whereas INSR-B is protective. In the present study, we investigated whether deletion of heterogeneous nuclear ribonuclear protein F (hnRNP F) in podocytes would aggravate podocyte injury in streptozotocin (STZ)-induced diabetic mice through modulating the alternative splicing of INSR isoforms.

Methods: Podocyte-specific hnRNP F knockout (KO) mice were generated by crossbreeding podocin (Pod)-Cre mice with floxed hnRNP F mice. Diabetes was induced in male 12-week old Pod-hnRNP F KO mice and control littermates with streptozotocin (STZ) (i.p., 50 mg/kg/day) for five consecutive days. Mice were euthanized 8 weeks after the STZ injections. Urinary ACR was assessed at 4 and 8 weeks after STZ-administration. Kidneys were processed for histology. Podocyte numbers were counted by p57 staining. Mouse renal cortex, isolated glomeruli and primary cultured podocytes were subjected to RT-PCR to assess INSR-A and INSR-B mRNA expression. Podocytes from control littermates and Pod-hnRNP F KO mice cultured in normal and high glucose media were also studied.

Results: INSR-A and INSR-B mRNA were equally expressed in the glomeruli of non-diabetic WT mice. STZ-induced diabetes aggravated kidney injury and podocyte loss in Pod-hnRNP F KO mice as compared with diabetic control littermates. Diabetic Pod-hnRNP F KO mice exhibited lower INSR-B/A mRNA ratio in isolated glomeruli and primary cultured podocytes as compared to diabetic control mice. *In vitro*, in high glucose media, more cultured podocytes from Pod-hnRNP F KO were detached as compared to those from control littermates.

Conclusions: Deficiency of hnRNP F in podocytes aggravates podocyte loss and kidney injury in STZ-diabetic mice through modulation of the alternative splicing of INSR mRNA resulting in lower INSR-B/A mRNA ratio.

ABCA1 Mediated Mitochondrial Dysfunction Contributes to Podocyte Injury in Diabetic Kidney Disease

Gloria Michelle Ducasa,[1] Alla Mitrofanova,[1] Christopher E. Pedigo,[2] Alexis J. Sloan,[1] Matthias Kretzler,[3] Yu Ishimoto,[4] Reiko Inagi,[5] Armando Mendez,[7] Robert G. Nelson,[6] George W. Burke,[8] Flavia Fontanesi,[7] Sandra M. Merscher,[1] Alessia Fornoni.[1] *[1]University of Miami School of Medicine/Katz Division of Nephrology, Miami, FL; [2]Yale University, New Haven, CT; [3]U.Michigan, Ann Arbor, MI; [4]Tokyo University, Hongo, Japan; [5]The University of Tokyo Graduate School of Medicine, Bunkyo-ku, Japan; [6]National Institutes of Health, Phoenix, AZ; [7]University of Miami, Miami, FL; [8]University of Miami Miller School of Medicine, Miami, FL.*

Background: Diabetic kidney disease (DKD) is characterized by podocyte loss, altered mitochondrial oxidative phosphorylation complexes (OXPHOS), and glomerular lipid accumulation. We have shown that ATP Binding Cassette A1 (ABCA1)-mediated cholesterol efflux is impaired in clinical and experimental DKD. Here, we test the hypothesis that ABCA1 deficiency causes mitochondrial dysfunction in podocytes and contributes to injury in DKD.

Methods: Sera were obtained from Pima Indian patients with diabetes and progressive DKD (P, n=15) and non-progressive DKD (NP, n=16) as assessed by changes in measured GFR over a 10 year period. Scrambled control (siCO) and siRNA *ABCA1* podocytes (siABCA1p) were treated with patient sera. ABCA1 expression, cholesterol efflux, mitochondrial OXPHOS complexes, cardiolipin (mitochondrial specific phospholipid) content and cytotoxicity were measured. Elamipretide (cardiolipin peroxidase inhibitor) was utilized for selected *in vitro* and *in vivo* experiments. $BTBR^{ob/ob}$ (ob/ob) mice with podocyte specific ABCA1 deficiency (DKO) were generated and analyzed.

Results: P sera treated podocytes show reduced ABCA1 mRNA expression, and cholesterol efflux and increased cytotoxicity compared to NP. siABCA1p are more susceptible to NP and P sera induced cytotoxicity when compared to siCO. siABCA1p show decreased basal OCR, cardiolipin accumulation, and alterations in OXPHOS complexes. Elamipretide treated siABCA1p are protected from NP and P sera mediated cytotoxicity compared to siCO. DKO mice have increased albuminuria, mesangial expansion, podocyte loss, FPE and mitochondrial damage as compared to ob/ob mice. Treatment with Elamipretide of db/db mice is sufficient to reduce albuminuria, mesangial expansion, BUN and podocyte loss.

Conclusions: Our data indicate that a reduction of *ABCA1* expression in podocytes is a susceptibility factor for DKD progression. These data also indicate that ABCA1 deficiency results in cardiolipin accumulation and mitochondrial dysfunction. Inhibition of cardiolipin oxidation prevents podocyte loss and DKD in diabetic mice. Treatment strategies to restore ABCA1 function may be beneficial in DKD.

DESI-MSI Based Spatial Metabolomics and METASPACE Indicates RNA and Mitochondrial Dysfunction in Renal Proximal Tubules of Mice with Diabetes

Guanshi Zhang, Manjula Darshi, Kumar Sharma. *University of Texas Health San Antonio, San Antonio, TX.*

Background: Diabetic kidney disease (DKD) remains the largest contributor to end stage renal disease and insightful biomarkers are required for identifying pathways to target for prognosis and therapeutics. Knowledge about the spatial distribution of metabolites in kidney tissues of DKD patients/animals will enhance the cellular contribution of biomarkers.

Methods: In the current study, we employed an ambient desorption electrospray ionization - mass spectrometry imaging (DESI-MSI) approach to characterize the metabolome in kidney tissue sections in a model of DKD. The data output was coupled to a novel bioinformatics platform (METASPACE). DESI-MSI was performed for spatial

untargeted metabolomics analysis in kidneys of mouse models (F1 C57BL/6J-Ins2Akita male mice at 17 weeks of age) of type 1 diabetes (T1D, n = 5) and heathy controls (n = 6). MetaboAnalyst 3.0 was employed for statistical analysis, metabolic pathway analysis, and biomarker analysis.

Results: Mice with DKD had increased relative abundances of pseudouridine, accumulation of free polyunsaturated fatty acids (PUFAs), and decreased relative abundances of phospholipids in cortical proximal tubules when compared with healthy controls. In the biomarker analysis, a five-metabolite biomarker set (i.e., phosphatidylglycerol (PG) 32:0, pseudouridine, hexose, phosphatidylserine (PS) 34:1, and diphenyl disulfide) was developed for diagnosing DKD. The AUC for the ROC curve is 0.994 (95% CI, 0.981-1; Empirical $P < 0.001$), which indicates that the biomarker set has excellent diagnostic ability for DKD in mice.

Conclusions: In summary, this new study demonstrates that DESI-MSI can be successfully used to distinguish cortical proximal tubules in healthy and diabetic tissues based on altered relative abundance of lipid profiles. DESI-MSI technology coupled with the METASPACE will serve as a powerful tool to shed new light on fundamental pathways in DKD.

Carrier Specific miRNA Distribution and Function in Diabetic Nephropathy: A Novel Concept for Monitoring Microvascular Injury

Barend W. Florijn,[1] Wendy Stam,[1] Johannes H. Levels,[2] Rienk Nieuwland,[2] Ton J. Rabelink,[1] Marlies Reinders,[1] Anton J. Van Zonneveld,[1] Roel Bijkerk.[1] *[1]Leiden University Medical Center, Leiden, Netherlands; [2]Academic Medical Center, Amsterdam, Netherlands.*

Background: We previously demonstrated an association between total plasma levels of specific microRNAs (miRs) and microvascular injury in patients with diabetic nephropathy (DN). However, circulating miRs are carried in exosomes, the RNA-binding protein Argonaute2 (AGO-2) or high-density lipoprotein (HDL). Therefore, identification of the carrier specificity of selected miRs could improve their biomarker potential while carrier-specific transfer of miRs to vascular cells could affect vascular integrity.

Methods: We assessed the plasma carrier distribution of miRs in DN (n=21), diabetes mellitus (DM; n=15; eGFR of ≥ 30 mL/min) patients and healthy controls (n=15). Exosomes, HDL and AGO-2 were isolated using size exclusion chromatography, KBr density gradient ultracentrifugation and immunoprecipitation, respectively. MiR expression was determined and validated using TaqMan® miRNA Arrays and correlated to markers of vascular injury, including angiopoietin-2 (Ang2), soluble thrombomodulin (sTM) and capillary tortuosity. *In vitro* studies were performed to assess transfer and function of specific miRNA-carrier complexes.

Results: Specific miR-carrier complexes associated with DN and vascular injury. Most notably, we found exosome-miR-21 and AGO-2-miR-660 levels to display a significant increase in both DM and DN groups compared to healthy controls and correlated with capillary tortuosity and Ang2, respectively. Furthermore, exosome-miR-126 levels increased while HDL-miR-132 levels decreased in DN and correlated with levels of Ang2. Mechanistically, *in vitro* studies demonstrated that HDL-miR-132 and exosome-miR-21 and -126 transferred to endothelial cells, repress validated target genes and ultimately affect angiogenic capacity and barrier function.

Conclusions: Our data suggest that carrier specific miRs have improved sensitivity as biomarkers for vascular injury in DN and are not just by-products of disease progression but can play an active, and modifiable role in the regulation of vascular integrity.

TH-PO873

Transcriptome of Extracellular Vesicles Derived from In-Vitro Podocytes, Proximal Tubule, and Mesangial Cells

Harry B. Holthofer,[1] Karina A. Barreiro,[4] Abigail C. Lay,[5] Wei Liang,[6] Xu Xiaomeng,[1] Sihui Luo,[8] Tillmann Bork,[2] Richard Coward,[5] Denis Delic,[7] Tobias B. Huber.[3] *[1]University of Helsinki, Finnish Institute of Molecular Medicine, Helsinki, Finland; [2]University Hospital Freiburg, Freiburg, Germany; [3]University Medical Center Hamburg, Hamburg, Germany; [4]Institute for Molecular Medicine Finland FIMM, University of Helsinki, Helsinki, Finland; [5]University of Bristol, Bristol, United Kingdom; [6]Renmin Hospital of Wuhan University, Wuhan, China; [7]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany; [8]The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: Extracellular vesicles (EVs) are lipid-bilayer structures of variable sizes (30-1000nm) secreted by all cell types. They show a characteristic vesicle surface consisting of a variety of proteins and lipids while the intracellular content is a rich array of proteins and distinct RNA species. These reflect accurately the physiological state of their cells of origin. In diabetes, development of renal insulin resistance has a major role in end-organ complications like Diabetic Kidney Disease (DKD). Little is still known of the secreted EV repertoire of especially podocytes. Here our objective was to characterize EVs secreted by DKD target cells, podocytes, proximal tubular cells and mesangial cells using the Hydrostatic Filtration Dialysis (HFD) for EV harvesting.

Methods: We used cell culture media from podocytes, proximal tubule and mesangial cells in four conditions; 1) Basal 2) Insulin resistant 3) Insulin receptor transfected 4) Insulin receptor transfected and insulin resistant. EVs were isolated from 50ml of cell culture media, respectively using the recently described HFD. Quality of EV yield was analyzed by negative-staining EM and by Western blotting. Vesicle concentration was determined by Nanoparticle Tracking Analysis (NTA). Isolated RNAs were profiled with Bioanalyzer Pico kit and subjected to RNAseq after cDNA library preparation using QIAseq miRNA Library Kit. RNAseq was performed using HiSeq 3000 (Illumina) Paired-end (2X150) protocol.

Results: The isolated EVs appeared typical at EM and were positive for the EV-marker TSG101 in Western blotting. RNA yield was of high quantity and quality and thus suitable for RNAseq. Different treatments had distinct effect on vesiculation of the investigated cells. Ninety-six EV miRNAs could clearly discriminate between cell types and engineered cells. There were distinct EV miRNAs to reflect treatment effect within each of the individual cell types studied.

Conclusions: EV analysis provides a novel approach to reveal valuable pathophysiology, pathway and signaling information of cultured target cells. Changes in EV miRNAs may give insight into insulin resistance on DKD target cells and on diabetic nephropathy.

TH-PO874

Long Noncoding RNA DLX6-AS1: A Novel Biomarker of Diabetic Kidney Disease

Jia Guo,[1,2] Yifang Hu,[2] Rujun Gong,[1] Zhangsuo Liu.[2] *[1]University of Toledo Medical Center, Toledo, OH; [2]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China.*

Background: A growing body of evidence suggests that lncRNAs act as competing endogenous RNAs or natural microRNA sponges and are involved in diverse human diseases including diabetic kidney disease (DKD). Our previous study showed that LncRNA DLX6-AS1 expression was increased in kidney biopsy specimens from DKD patients. However, whether LncRNA DLX6-AS1 expression is associated with albuminuria in DKD remains unknown and was explored in this study.

Methods: A total of 22 type II diabetic patients without albuminuria (diabetes mellitus group), 43 patients with DKD (microalbuminuria group=20,macroalbuminuria group=23) and 32 healthy controls were enrolled in this study. Blood samples were collected. The levels of LncRNA DLX6-AS1 was estimated by RT-qPCR. The correlation between LncRNA DLX6-AS1 levels and clinical variables was assessed by Spearman correlation analysis. Linear regression was applied to model the relationship between urine albumin/creatinine ratio as the dependent variable and other parameters. ROC analysis was performed and the area under the curve (AUC) was estimated to evaluate the power of LncRNA DLX6-AS1 for predicting DKD.

Results: The four groups were comparable in sex, age and triglyceride levels. No significant difference was noted in duration of diabetes and incidence of diabetic retinopathy among subgroups of diabetes. Compared with healthy controls, the serum levels of lncRNA DLX6-AS1 was decreased in diabetic mellitus group ($P<0.05$), but was increased in DKD patients ($P<0.05$). This difference remained statistically different after adjustment for eGFR or HDL-C, as shown by linear regression analysis. In addition, serum LncRNA DLX6-AS1 levels were found to positively correlate with urine albumin/creatinine ratios(rs=0.626,$P<0.001$), but negatively correlate with eGFR(rs=-0.289,$P=0.020$). Receiver operating characteristic (ROC) curve analysis was conducted to determine the ability of serum LncRNA DLX6-AS1 levels to serve as biomarkers for predicting DKD. The area under the ROC curve (AUC) was estimated to be 0.879 (95% CI = 0.798 to 0.961), suggestive of an excellent sensitivity and specificity of serum LncRNA DLX6-AS1 levels in predicting DKD.

Conclusions: Serum levels of LncRNA DLX6-AS1 correlate with albuminuria in patients with diabetic kidney disease and may serve as a biomarker for predicting DKD.

TH-PO875

The Leptin Receptor in Mouse Kidney: Gene Expression of Splice Variants and a Potential Anti-Albuminuric Role in Podocytes

Hadi Fattah, Winnie Huang, Rohit Patel, Yiling Fu, Josselin Nespoux, Brent Freeman, Volker Vallon. *Department of Medicine, University of California, San Diego & VA San Diego Healthcare System, San Diego, CA.*

Background: Leptin regulates food intake and metabolism primarily through leptin receptor splice variant B (LEPRB) in brain and liver. Little is known about LEPR splice variants in the kidney or their function.

Methods: A) Urinary albumin to creatinine ratios (UACR) and mRNA expression of renal LEPR splice variants LEPRA, LEPRB & LEPRC (by RT-qPCR, norm. to b-actin) were determined in non-diabetic mice (nd) and in obese/hyperglycemic mice lacking endogenous leptin (ob/ob) ± leptin substitution for 6 days (osmotic minipump: 4.7 μg/day s.c.) (all mice ~4 months of age & BTBR background)(n=5-8/group). B) C57BL6 mice with knockdown of LEPRs in podocytes (podocin-Cre) were generated to determine GFR (by plasma elimination kinetics of FITC-sinistrin in conscious mice) and UACR (n=8/group).

Results: A) Leptin substitution restored plasma leptin levels in ob/ob (4.3±0.3 vs 4.6±0.7 ng/ml in nd mice) and reduced hyperglycemia (275±29 vs 573±17 mg/dl in vehicle-treated ob/ob; $P<0.05$). In all 3 groups, the renal mRNA expression was higher for LEPRA vs LEPRB or LEPRC, and the expression of all 3 variants was higher in medulla vs cortex. The cortical expression of all 3 variants was lower in ob/ob vs nd, and not significantly affected by leptin substitution. Medullary expression was more variable. The transcription factor Atf3 is a newly discovered mediator of brain LEPRB. Atf3 mRNA was increased in kidney cortex & medulla in ob/ob vs nd and not altered by leptin substitution. The latter, however, reduced UACR in ob/ob (pre to post: 650±145 to 167±45 μg/mg; $P<0.05$) whereas vehicle was ineffective (632±283 to 819±217 μg/mg). B) Ten week old male mice with LEPR knockdown in podocytes had similar blood glucose

(129±5 vs 117±3 mg/dl) and GFR (436±16 vs 443±18 μl/min) but enhanced UACR vs wild-type littermates (20.5±7.4 vs 8.8±1.5 μg/mg; P<0.05).

Conclusions: On mRNA level, LEPRA is the dominant renal splice variant of the LEPR, and LEPR splice variants are higher expressed in medulla vs cortex. Absence of leptin did not upregulate mRNA expression of LEPR splice variants in cortex or medulla, but enhanced mRNA of the LEPRB target gene Atf3. Functional studies were consistent with an anti-albuminuric effect of leptin, potentially via LEPR in podocytes.

TH-PO876

Photoacoustic Ultrasound Can Non-Invasively Detect Kidney Fibrosis

Xiaolin He,[2] Jiayin Dong,[1] Elizabeth S. Berndl,[1] Tianzhou Zhang,[2] Michael C. Kolios,[1] Darren A. Yuen.[2] *[1]Ryerson University, Toronto, ON, Canada; [2]St. Michael's Hospital, Toronto, ON, Canada*.

Background: Fibrosis is a key manifestation and driver of chronic kidney injury. Despite its importance, the options for measuring fibrosis are limited. The only available test is a needle biopsy, a time-consuming, invasive procedure that at best samples < 1% of one kidney, leading to the potential for sampling bias. Unlike biopsy, ultrasound can quickly and non-invasively image the entire kidney. While historically limited to the imaging of gross abnormalities, the recent combination of laser technology with ultrasound ("photoacoustic (PA) ultrasound") has dramatically expanded its capabilities. Based on the principle that each molecule has its own unique light absorption spectrum, PA ultrasound can be used to non-invasively image specific molecules. We have previously demonstrated that PA ultrasound can specifically detect extracellular matrix in a model of ischemia-reperfusion injury (doi: 10.1117/12.2291199). Our goal was to test whether PA ultrasound could detect milder degrees of fibrosis in a clinically relevant model of diabetic nephropathy.

Methods: Diabetes was induced in renin-overexpressing, hypertensive TTRhRen mice using a low dose STZ injection protocol (Ren-STZ mice, n=7). Ren-STZ mice develop hypertension, hyperglycemia, albuminuria, and renal fibrosis (Thibodeau et al, PLoS ONE 2014). Kidneys were imaged in vivo using a VevoLAZR system at 21 MHz by Photoacoustic (PA) spectral sweep from 680 to 970 nm at 0 and 20 wks post-STZ, and compared with wild-type littermates injected with citrate (WT-citrate, n=9). 20 wks post-injection, kidneys were assessed by picrosirius red (PSR) staining to quantify fibrosis.

Results: Ren-STZ mice developed hypertension (138±7vs. 98±5 mmHg) and hyperglycemia (28.0±2.6 vs. 9.7±0.3 mmol/L) compared to WT-citrate mice 20 wks post-STZ injection. As expected, Ren-STZ kidneys were more fibrotic than WT-citrate controls (PSR intensity: 5.4±0.1 vs. 2.8±0.1). Prior to STZ injection, the photoacoustic spectra of Ren-STZ and WT-citrate kidneys were similar. However, 20 wks post-STZ, Ren-STZ kidneys demonstrated significantly different photoacoustic spectra compared to their WT-citrate counterparts, in line with the fibrosis observed histologically.

Conclusions: Our data suggest that photoacoustic ultrasound may enable the non-invasive, whole organ imaging of kidney fibrosis.

ROCK2 Inhibitors for the Treatment of CKD

Emily P. Offer,[1] Nicolas E. Guisot,[1] Stuart A. Best,[1] Thomas Pesnot,[3] Philip MacFaul,[1] Sara Ceccarelli,[1] Kay Eckersley,[1] Gary R. Pitt,[2] Peter R. Bunyard,[1] Clifford D. Jones,[1] Richard Armer.[1] *[1]Redx Pharma Plc, Macclesfield, United Kingdom; [2]Walter and Eliza Hall Institute, Melbourne, NSW, Australia; [3]Concept life sciences, Macclesfield, United Kingdom*.

Background: The Rho Associated Coiled-Coil Containing Protein Kinase (ROCK) serine/threonine kinases, ROCK1 and ROCK2, are central signalling proteins that regulate a range of cellular responses such as cell migration, contraction, proliferation, cytokine and growth factor expression, and integrin-mediated cell-to-cell adhesions. These processes are central to the aberrant wound healing response that can progress to chronic injury and organ fibrosis. Small molecule pan-ROCK inhibitors have been shown to be anti-fibrotic in a range of animal models including: bleomycin induced lung fibrosis, high fat diet induced liver fibrosis and models of kidney fibrosis. However, ROCK signalling is also involved in regulating vascular tone and pan-ROCK inhibitors have been shown to cause hyperaemia and hypotension, limiting their use in patients. There is significant homology between the ROCK1 and ROCK2 isoforms however there is evidence that ROCK2 has additional roles distinct from ROCK1 in both inflammation and wound healing. For example, ROCK2 is upregulated in diabetic kidney disease and in the diseased vascular network of patients at risk of chronic kidney disease (CKD).

Methods: Redx have developed a series of potent ROCK2 inhibitors, that are highly selective against ROCK1 and a panel of 468 kinases.

Results: Redx ROCK2 selective compounds potently suppress the release of pro-fibrotic factors from kidney mesangial cells, cultured in high glucose. In a model of acute kidney injury, our selective ROCK2 tool compound reduced podocyte damage, and the expression of inflammatory and profibrotic genes in the kidney. In addition, in a telemetered rat study, no significant reduction in blood pressure or increase in heart rate was recorded, indicating that a selective ROCK2 inhibitor could avoid these side-effects typically observed with pan-ROCK inhibitors and increase the safety window at efficacious doses.

Conclusions: Highly selective ROCK2 inhibitors, therefore, could provide a novel and effective therapy for patients with progressive kidney fibrosis who currently have few and largely ineffective therapy options.

TH-PO878

Hyperoside Alleviates the Early Glomerular Pathological Changes in Diabetic Kidney Disease by Inhibiting Akt/mTOR/p70S6K Signaling Activity

Wei Wu, Yigang Wan. *Department of Traditional Chinese Medicine, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, China*.

Background: Hyperoside (HYP), a bioactive component of *Abelmoschus manihot*, has been widely applied to clinical therapy in the early diabetic kidney disease (DKD) patients. However, it remains elusive whether HYP can ameliorate inchoate glomerular injuries in hyperglycemia. Recently the activation of phosphatidylinositol-3-kinase (PI3K)/serine-threonine kinase (Akt)/mammalian target of rapamycin (mTOR) signaling and its downstream regulator, 70-kDa ribosomal protein S6 kinase (p70S6K), play important roles in the early glomerular pathological changes of DKD including glomerular hypertrophy, glomerular basement membrane (GBM) thickening and mild mesangial expansion. This study aimed to clarify therapeutic effects of HYP during the initial phase of DKD and its underlying mechanisms.

Methods: Fifteen rats were randomly divided into 3 groups: the normal, the model and the HYP groups. The early DKD model rats were induced by unilateral nephrectomy combined with intraperitoneal injection of streptozotocin, and administered with either HYP suspension or vehicle after modeling and for a period of 4 weeks. Changes in incipient glomerular lesions-related parameters in urine and blood were analyzed. Kidneys were isolated for histomorphometry, immunohistochemistry, immunofluorescence and Western blotting (WB) at sacrifice. In vitro, murine mesangial cells (MCs) were used to investigate inhibitory actions of HYP, on cellular hypertrophy-associated signaling pathway by WB, compared with rapamycin (RAP).

Results: For the early DKD model rats, HYP ameliorated micro-urinary albumin, body weight and serum albumin, but had no significant effects on renal function and liver enzymes; HYP improved renal shape, kidney weight and kidney hypertrophy index; HYP attenuated glomerular hypertrophy, GBM thickening and mild mesangial expansion; HYP inhibited phosphorylation of Akt, mTOR and p70S6K, and protein over-expression of transforming growth factor-β1 in kidneys. *In vitro*, phosphorylation of PI3K, Akt, mTOR and p70S6K in MCs induced by high-glucose was abrogated by treatment of HYP or RAP.

Conclusions: This study demonstrated HYP alleviates the early glomerular pathological changes of DKD, likely by inhibiting Akt/mTOR/p70S6K signaling activity *in vivo* and *in vitro*, and provided the first evidence that HYP directly contributes to the prevention of the early DKD.

Funding: Government Support - Non-U.S.

Identification and Validation of Differentially Expressed Urinary Exosomal MicroRNAs in Type 2 Diabetic Kidney Disease

Jinnan Zang,[1] David A. Simpson,[2] Alexander P. Maxwell,[1] Gareth J. McKay.[1] *[1]Centre for Public Health, Queen's University Belfast, Belfast, United Kingdom; [2]Centre for Experimental Medicine, Queen's University Belfast, Belfast, United Kingdom*.

Background: There is a need for improved biomarkers for the early detection of diabetic kidney disease (DKD). MicroRNAs (miRNAs) are short, non-coding regulatory RNA molecules commonly found in urinary exosomes that may be differentially expressed during renal dysfunction. We evaluated urinary exosomal miRNA expression in type 2 DKD (T2DKD).

Methods: 87 previously reported human urinary exosomal miRNAs were profiled (Qiagen Human Urine Exosome Focus miRNA Panel) to identify differentially expressed miRNAs in a discovery cohort of patients with T2DKD (n= 14) and individuals with T2D and normal renal function, matched by age and gender (n= 15). Differentially expressed target miRNAs were validated in a second cohort of patients with T2DKD (n= 22) or no diabetes and poor renal function (n=18), and control subjects with T2D and normal renal function (n= 22).

Results: Quantitative expression profiles were normalised according to the NormFinder algorithm. Urinary miR-21-5p, let-7e-5p and miR-23b-3p were significantly upregulated in T2DKD cases compared to T2D controls with good renal function (P<0.05). Conversely, miR-30b-5p and miR-125b-5p expression were significantly lower in T2DKD cases compared to T2D controls (P<0.05). In a logistic regression analysis adjusted for age, sex and mean arterial blood pressure, only miR-21-5p remained significantly associated with T2DKD (odds ratio=3.28, confidence intervals: 1.14 – 9.43; P=0.03). Independent validation in the replication cohort confirmed up-regulation of miR-21-5p expression in T2DKD (2.13-fold, p<0.01) and also in patients without diabetes and poor renal function (1.73-fold, p<0.05). In contrast, miR-30b-5p was downregulated in T2DKD (1.22-fold, p<0.01) and in patients without diabetes and poor renal function (1.52-fold, p<0.005).

Conclusions: Our data identified differential expression of miR-21-5p and miR-30b-5p in individuals with poor renal function, although further clarification to determine if these are associated with general mechanisms of renal dysfunction is required.

Soluble cMet Levels in Urine Are a Significant Prognostic Biomarker for Diabetic Nephropathy

Yong Chul Kim,[1] Jung Nam An,[2] Chun Soo Lim,[2] Yon Su Kim,[3] Seung Hee Yang,[4] Jung Pyo Lee.[2] *[1]SNUH, Seoul, Republic of Korea; [2]Seoul National University Boramae Medical Center, Seoul, SEOUL, Republic of Korea; [3]Seoul National University College of Medicine, Seoul, Republic of Korea; [4]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea.*

Background: Hepatocyte growth factor (HGF) and its receptor, cMet, activate biological pathways necessary for repair and regeneration following kidney injury. Here, we evaluated the clinical role of urinary cMet as prognostic biomarker in diabetic nephropathy (DN).

Methods: A total of 218 patients with DN were enrolled in this study. We examined the association of urine cMet levels and long-term outcomes in patients with DN.

Results: The levels of urinary cMet were higher in patients with decreased renal function than in patients with relatively preserved renal function (5.17 ± 9.56 ng/ml versus 1.86 ± 4.85 ng/ml, P = 0.001). A fully adjusted model revealed that a urinary cMet cutoff of 2.9 ng/mL was associated with a hazard ratio for end-stage renal disease of 2.50 (95% confidence interval 1.18–4.53, P = 0.007). The addition of urinary cMet to serum creatinine and proteinuria provided the highest net reclassification improvement. We found that in primary cultured human glomerular endothelial cells, TGFβ treatment induced fibrosis, and the protein expression levels of collagen IV, fibronectin, and αSMA were decreased after administration of an agonistic cMet antibody.

Conclusions: In conclusion, elevated levels of urinary cMet at the time of initial diagnosis could predict renal outcomes in patients with DN.

Urinary Peptidomic Analysis Reveals Bioactive Uromodulin Peptides Associated with Early Type 1 Diabetes

Julie Anh Dung Van,[1] Sergi Clotet-Freixas,[2] Ihor Batruch,[3] Xiaohua Zhou,[1] Farid H. Mahmud,[4] Eleftherios P. Diamandis,[5] James W. Scholey,[1] Ana Konvalinka.[1] *[1]University of Toronto, Toronto, ON, Canada; [2]University Health Network, Toronto, ON, Canada; [3]Mount Sinai Hospital, Toronto, ON, Canada; [4]Hospital for Sick Children, Toronto, ON, Canada; [5]Mount Sinai Hospital and University Health Network, Toronto, ON, Canada.*

Background: Diabetic nephropathy is the leading cause of kidney disease worldwide. Yet, current treatments cannot prevent the progressive nature of the disease, exposing our limited understanding of the early kidney response to chronic hyperglycemia. In this study, we compared the urinary peptidomes of youths with type 1 diabetes without evidence of nephropathy and age/sex-matched healthy controls, in order to determine early changes in protein processing in the hyperglycemic kidney.

Methods: The study population comprises two separate cohorts: a discovery cohort (N = 30) and an internal validation cohort (N = 30). Urines were normalized to creatinine and underwent 10kDa-filter centrifugation to isolate naturally occurring peptides. In the discovery phase, filtered peptides were then fractionated and then injected on a Q-Exactive mass spectrometer. For the validation phase, parallel reaction monitoring (PRM) assays were developed on a Q-Exactive HFX instrument. MaxQuant and Skyline were used for peptide identification and quantification. Proteasix was used to predict proteases responsible for generating differentially excreted peptides.

Results: A total of 6349 urinary peptides from 750 proteins were quantified. Of the 15 differentially excreted peptides (P < 0.05), five remained significant after Benjamini-Hochberg adjustment (q < 0.05). Seven of these top 15 peptides derive from the C-terminal region of uromodulin, which regulates uromodulin polymerization. Out of the twelve predicted proteases, hepsin, granzyme A, kallikrein-6, and plasminogen were shortlisted because they were detected in healthy kidney tissues (Human Protein Atlas) and were altered at the level of gene expression in diabetic nephropathy (Nephroseq v5 database). Differential excretion of six uromodulin peptides was validated by PRM. Two of the validated uromodulin peptides induced NF-κB signaling in HK-2 cells, suggesting a potential role in mediating inflammation in kidney cells.

Conclusions: Differences between youths with type 1 diabetes and healthy controls are reflected in the urinary peptidome before the development of microalbuminuria. Uromodulin peptides we discovered may play a significant role in the early injury in a diabetic kidney and may represent a therapeutic target.

TH-PO882

Pirfenidone May Protect Against Diabetic Kidney Disease by Reducing Fumarate

Jiwan J. Kim,[1] Manoj Bhattarai,[1] Satoshi Miyamoto,[2] Daniel Montemayor,[1] Manjula Darshi,[1] Kumar Sharma.[1] *[1]University of Texas Health San Antonio, San Antonio, TX; [2]Okayama University Hospital, Okayama, Japan.*

Background: Recent studies suggest that Pirfenidone (PFD) has anti-fibrotic effect in various diseases including diabetic kidney disease (DKD). We previously demonstrated that in type 2 diabetic animal models PFD significantly reduces the expansion of mesangial matrix. Furthermore, in a placebo-cotrolled clinical study we found that PFD treatment for 54 weeks significantly improved eGFR with a low dose. In the current study we aim

to identify predictive metabolite biomarkers and potential mechanisms associated with renoprotective effects of PFD and also tested a longer acting and better tolerated version.

Methods: 1) Two types of PFD (short acting and long acting) were administered to 16 week db/db and db/m control mice (n=8 each). After 4 weeks, 24 hr urine was collected and 70 urinary metabolites were quantified using GC-MS/MS. 2) Urine and plasma from our prior clincal trial was assessed for metabolite markers from samples collected every 3 months. Fumarate in human urines was also assessed with a specific fumarate assay kit.

Results: Significant changes in metabolites were observed between the db/mand db/db, and PCA plot clustered the two groups into well-defined spaces. The db/db mice treated with PFD were in closer proximity to the db/db cluster with a slight trend toward the db/m cluster. Untreated Db/db mice had lower levels of succinate, citrate, 3-methyl crotonyl glycine, 2 hydroxyglutarate, and uracil, but PFD treated db/db mice had the levels restored either partially or completely back to the levels of db/m. Interestingly, the db/db mice had three fold increase in fumarate as compared to the db/m mice ($p<0.0001$), while long acting PFD treatment significantly reduced the fumarate levels below that of db/m mice ($p<0.0001$). In the human study, the baseline urine fumarate level of placebo treated patients showed negative correlation with the rate of change in GFR at 12 months ($r=-0.89$, $p<=0.05$). The correlation was not observed in subjects treated with PFD.

Conclusions: The anti-fibrotic effects of PFD in kidney has effects on several urinay metabolites identified to be regulated in human diabetic kidney disease. Fumarate may be a useful biomarker in the mouse model of diabetic kidney disease and may be a potential marker for anti-fibrotic therapies.

Urinary Baseline AQP5 Is Independently Associated with eGFR Decline in Patients with Type 2 Diabetes and Nephropathy

Chao Gao,[1] Michelle Pena,[2] Hiddo J. Lambers Heerspink,[2] Wenzheng Zhang.[1] *[1]Albany Medical College, Albany, NY; [2]University Medical Center Groningen, Groningen, Netherlands.*

Background: Water channel AQP5 has been shown to be upregulated in kidney biopsies from patients with diabetic nephropathy, and may serve as a biomarker for tubular damage. Here we investigate whether urinary baseline water channel AQP5 is independently associated with eGFR decline in patients with type 2 diabetes and nephropathy.

Methods: Baseline urine samples (n=997) were used from the SUN-Macro randomized placebo controlled double blind clinical trial, which evaluated the renoprotective effects of sulodexide in patients with type 2 diabetes and nephropathy. Human AQP5-specific enzyme-linked immunosorbent assay was measured in baseline urine. Pearson correlation and multiple linear regression between baseline AQP5 with eGFR slope (calculated by ≥3 serum creatinine during follow-up) was performed, and association with fast renal function decline, defined as eGFR slope less than 3.0 mL/min/1.73m^2/year, was determined by logistic regression.

Results: Follow-up eGFR data over 1.4 years from n=700 were available for analysis. AQP5 was undetectable in 138 patients. Tertiles of baseline AQP5 were 0.4 [0 – 2.2], 7.3 [5.9 – 9.1], and 16.0 [13.0 – 21.6] (ng/mL), respectively (p-value <0.01). Patients in the highest tertile of AQP5 had significantly higher total cholesterol, lower baseline eGFR, and higher levels of albuminuria compared to the lowest tertile. Baseline AQP5 was inversely correlated with eGFR slope (Pearson's r = -0.12, p-value = 0.001), and independent of clinical risk factors age, sex, race, and baseline: SBP, DBP, HbA1c, Tot. Cholesterol, eGFR, and UACR (β = -0.05, p-value = 0.004). Furthermore, baseline AQP5 was significantly associated with fast eGFR decline (OR = 1.03 (95%CI 1.003 – 1.06), p-value = 0.03).

Conclusions: Our data suggest that baseline AQP5, a possible marker of tubular dysfunction, is independently associated with the progression of eGFR decline in patients with type 2 diabetes and nephropathy. Validation of these findings in an external cohort is necessary.

PI3 Kinase/Akt Node Acts as a Driver for High Glucose-Induced miR-214 Expression to Induce a Positive Feedback Loop via PTEN for Matrix Protein Expression in Proximal Tubular Epithelial Cells (PTECs)

Soumya Maity, Falguni Das, Nandini Ghosh-choudhury, Balakuntalam S. Kasinath, Goutam Ghosh-Choudhury. *UTHSCSA, San Antonio, TX.*

Background: We have recently shown that high glucose (HG) increased the expression of miR-214 to regulate renal fibrosis by directly targeting the 3' UTR of PTEN tumor suppressor protein (Am J Physio Cell Physiol 313: C430, 2017). The mechanism by which HG regulates miR-214 expression is not known. We hypothesized involvement of PI 3 kinase (PI 3 K)/Akt cascade in this process.

Methods: Human PTECs, activation-specific phospho-antibodies, shRNA, dominant negative kinases, real time qRT-PCR and immunoblotting were employed.

Results: In human PTECs, HG increased the expression of miR-214. To address the role of PI 3 K, we used its inhibitor Ly294002 (Ly). Ly significantly inhibited the HG-stimulated expression of miR-214. Similarly, expression of dominant negative PI 3 K markedly blocked the miR-214 expression in response to HG. Inhibition of Akt, the downstream kinase of PI 3 K, by MK2206 significantly suppressed the HG-induced miR-214 expression. In diabetic renal pathology a significant role of mechanistic target of rapamycin complex 1 (mTORC1) has been established. Rapamycin significantly attenuated the miR-214 expression by HG. Furthermore, shRNA against raptor, required for mTORC1 activation, blocked the HG stimulated miR-214 expression, similar to rapamycin. Since miR-214 downregulates PTEN to drive tubular matrix protein expression, we examined the role of PI 3 K/Akt in PTEN protein expression. Downregulation of PTEN by HG was reversed by dominant negative PI 3 K or Akt, which led to inhibition of mTORC1 activity as judged by phosphorylation of its substrate S6 kinase at Thr-389. Consequently, the HG-induced fibronectin expression was blocked by the dominant negative PI 3 K and Akt. Interestingly, plasmid-derived expression of miR-214 attenuated the increment of PTEN by the dominant negative PI 3 K or Akt in the presence of HG, resulting in increase in mTORC1 activity and expression of fibronectin.

Conclusions: These results are the first demonstration for a key role of PI 3 K/Akt signaling in HG-induced miR-214 expression. Furthermore, our data give evidence for a positive feedback loop involving the PI 3 K/Akt/mTORC1/miR-214 and PTEN for driving tubular fibrosis.

Inhibition of MicroRNA-451 Increases Metabolic Acidosis in a Mouse Model of Insulin Resistance and Early Diabetic Nephropathy

Maurice B. Fluitt, Narayan Shivapurkar, Carolyn M. Ecelbarger. *Georgetown University, Washington, DC.*

Background: Metabolic acidosis (MA) is a common complication of diabetic nephropathy (DN) and is associated with an increased risk of end-stage renal failure. MA has major systemic consequences which include protein wasting, inflammation, insulin resistance, worsened hypertension and bone disease. Several studies suggest a renal protective role of microRNA-451 (miR-451) in ameliorating progression of DN. The current study aimed to elucidate the role of miR-451 in the development of MA in a mouse model of insulin resistance.

Methods: Male TALLYHO/Jng mice (insulin resistant and obese) were placed on a high-fat diet (60% kCal) and divided into two treatment groups. Mice received 8 consecutive weekly intraperitoneal injections of locked nucleic acid (LNA) miR-451-inhibitor or LNA-scramble (2 mg/kg bw; n =8/treatment). 24-hr urine was collected at 2-week intervals. Mice were humanely euthanized after 12 weeks and kidneys harvested.

Results: LNA-miR-451-inhibitor reduced renal expression of miR-451 6-fold in inhibitor treated mice ($p=0.0002$). Masson's Trichrome revealed inhibition of miR-451 increased collagen deposition by 68% ($p=0.007$). Blood chemistry revealed higher blood Na+ concentrations (2.4%; $p=0.007$) and anion gap (165%; $p=0.01$) in the mice treated with inhibitor versus vehicle control. There was also a strong trend for lower blood TCO_2 (12.6%; $p=0.06$) and HCO_3 (13.6%; $p=0.06$) in inhibitor-treated mice. There were no significant differences in serum K+ and Cl-. Western blotting analysis of cortex homogenates revealed significant increases in aquaporin-2 (52.8%, $p=0.03$), the sodium bicarbonate cotransporter (NBCe1) (28.3%, $p=0.02$) and SNAT3 (80.7%, $p=0.0008$) in inhibitor-treated mice. Additionally, there was a strong trend for an increase in the a-subunit of the epithelial sodium channel (ENaC) (35.5%, $p= 0.05$) in inhibitor-treated mice.

Conclusions: These findings suggest miR-451 may protect against the development of acidosis in the setting of insulin resistance and early diabetic nephropathy, further supporting its potential use as a therapuetic target for DN. Upregulation of transporters involved in proximal-tubule ammoniagenesis are likely a response to the acidosis.

Diabetes Potentiates the Differentiation of Bone Marrow-Derived Cells into Glomerular Endothelium

Hiroshi Nobuta,[1,2] Takahiko Nakagawa,[3] Miwako Katagi,[2] Shinji Kume,[1] Tomoya Terashima,[2] Hideto Kojima,[2] Shin-ichi Araki,[1] Hiroshi Maegawa.[1] *[1]Department of Medicine, Shiga University Of Medical Science, Otsu, Japan; [2]Department of Stem Cell Biology and Regenerative Medicine, Shiga University of Medical Science, Otsu, Japan; [3]Department of Future Basic Medicine, Nara Medical University, Kashihara, Japan.*

Background: Diabetes causes its complication including neuropathy and nephropathy, and these disorders could share a common mechanism. Recently, it has been shown that bone marrow-derived cells (BMDCs) play a role in the development of diabetic neuropathy. In particular, BMDCs expressing TNF-α reach peripheral neuronal systems to cause functional disorders. However, it remains unclear if BMDCs are involved in the kidney injury of diabetes. We thus hypothesized that BMDCs cause diabetic nephropathy (DN). To test our hypothesis, we examined the role of BMDCs in mice with DN.

Methods: We transplanted the total bone marrow of GFP-Tg mice into wild type mice and then induced diabetes by intraperitoneal injection of 55mg/kg streptozotocin (STZ) for five consecutive days. At 6 and 20 weeks after STZ injection, mice were sacrificed for analyses. Non-diabetic control mice were injected citrate buffer only.

Results: We first confirmed using FACS analysis that over 98% of BMDCs of recipient mice were GFP positive. Immunofluorescence study demonstrated that the number of GFP-positive BMDCs in diabetic glomerulus was significantly higher than that in non-diabetic glomerulus. Most GFP-positive cells were also positive for CD31 and isolectin B4, but negative for podocin, α8 integrin and F4/80, suggesting BMDCs could differentiate into glomerular endothelial cells. Interestingly, the number of residential endothelial cells (GFP-negative endothelial cells) were identical between diabetic and non-diabetic glomerulus. These data suggest that BMDCs could contribute to the development of neovascularization in DN.

Conclusions: BMDCs arrive at glomerulus and they may be involved in neovascularization in diabetic mice. BMDCs could play a potential role in the development of DN.

TH-PO887

Myo-Inositol Oxygenase Modulates the Progression of Renal Fibrosis in Diabetes via Oxidant and ER Stress

Isha Sharma,[2] Fei Deng,[2] Lin Sun,[3] Yashpal S. Kanwar.[1] *[1]Northwestern University Medical School, Chicago, IL; [2]Northwestern University, Chicago, IL; [3]Second Xiangya Hospital Central South University, Changsha, China.*

Background: Myo-inositol oxygenase (MIOX) is a renal tubular specific enzyme and its overexpression is associated with increased oxidant stress and renal fibrosis. Excessive ROS generation leads to accumulation of misfolded proteins in endoplasmic reticulum (ER) causing ER stress. How MIOX serves as a nodal molecule for regulating the progression of diabetic tubulopathy via oxidant and ER stress in hyperglycemia remains unexplored.

Methods: A diabetic state was induced with the administration of STZ in wild type (WT), MIOX transgenic (TG) and MIOX$^{-/-}$ (KO) mice. In addition, *MIOX*$^{-/-}$ (KO) mice were cross bred with *Ins2* ^{Akita} mice to generate mice with double mutation (*Ins2* ^{Akita}*/MIOX-KO*) to assess if genetic deletion of MIOX ameliorates the progression of tubulo-interstitial injury in *Ins2* ^{Akita} mice.

Results: The expression of GRP78/Bip, a marker of ER stress, and another ER stress regulator, i.e., transcription factor X-BOX binding protein-1 (XBP-1), were increased in kidneys of WT and MIOX-TG mice with STZ-induced diabetes and *Ins2* ^{Akita} mice. Interestingly, by EMSA and ChiP assays MIOX expression was noted to be regulated by XBP-1. MIOX-KO and *Ins2* ^{Akita}*/MIOX-KO* had reduced expression of XBP1 and GRP78/Bip in diabetic state, and the kidneys of these mice had reduced tubulo-interstitial injury and fibrosis. Concomitantly, the extent of renal cellular redox was reduced in MIOX-KO and *Ins2* ^{Akita}*/MIOX-KO* mice, while markedly accentuated in WT, MIOX-TG and *Ins2* ^{Akita} mice, as indicated by perturbed NADPH:NADP ratios and increased DHE, and DCF staining in renal tissues. The assessment of relevant signaling molecules revealed an increase in the expression of p-PDK1, p-PKC in kidneys of MIOX-TG mice. Likewise, expression of TGF-β and Smad 3, 4 were relatively high in diabetic WT and MIOX-TG, and *Ins2* ^{Akita} mice. The expression of the signaling molecules were marginally affected in KO mice. Similar results were observed in *in vitro* HK-2 cells studies with MIOX over-expression and gene disruption of MIOX as well as the XBP1, a hallmark of ER stress.

Conclusions: These findings identify a link between the biology of MIOX and oxidant and ER stress and delineate the role of MIOX as a nodal molecule in the pathogenesis of tubulo-interstitial fibrosing injury in diabetic state.

Allogeneic "Neo-Islets," Composed of Mesenchymal Stem and Islet Cells, Are Immune Protected and Control, After i.p. Administration, Auto-Immune Type 1 Diabetes Mellitus in Pet Dogs

Christof Westenfelder, Anna Gooch, Zhuma Hu, Ping Zhang. *SymbioCellTech, SLC, UT.*

Background: Curative T1DM therapies are needed that do not depend on potentially toxic anti-rejection drugs, encapsulation devices or the requirement for up to 5 pancreas donors per islet transplant. We demonstrated that allogeneic, ip administered "Neo-Islets" (NIs), aggregates of cultured islet cells (ICs) and immune- and cyto-protective Adipose Derived Stem Cells (ASCs), reestablished durable normoglycemia through omental engraftment and splenic and omental upregulation of Tregs, in autoimmune T1DM NOD mice without immunosuppressive agents. Comparable euglycemia was achieved with dog-derived NIs in STZ-diabetic NOD/SCID mice (*SCTM* 2017;6:1631). Here we report on an FDA supervised pilot study (*INAD 012-776*) using this NI therapy in 2 insulin-dependent pet dogs.

Methods: Insulin dependent (≥ 6 months), diabetic pet dogs, ≤12 kg, were included, 6 enrolled; 3 treated, and 2 (Dogs 1 and 2, male) followed for 6 months. Pre-treatment serum from Dog 1 and Dog 2 was tested for the presence of islet autoantibodies, and comorbidities and blood glucose levels were treated. 2x10e5 allogeneic NIs per kg b.wt. were then given i.p. Blood glucose levels, insulin requirements and formation of antibodies to allogeneic NIs were closely monitored.

Results: Prior to treatment Dog 1 had no islet autoantibodies, suggesting insulin resistance, while Dog 2 had islet autoantibodies, indicating autoimmunity. Both dogs have improved glycemic control. Dog 2's insulin requirements have decreased by 50% after 6 months. Neither dog developed antibodies to the administered NIs, and no adverse events related to treatment were observed.

Conclusions: This ongoing pilot study in diabetic dogs demonstrates that NI therapy progressively reduces insulin requirements. This was achieved, without anti-rejection drugs. NIs, as engineered here, provide a novel therapy that, we posit, has significant translational relevance to clinical T1DM. We thank site PIs Drs. Rance Sellon, WSU, Pullman, WA, Natasha Loy Son and Julie Fisher, Veterinary Specialty Hospital, San Diego, CA, for their excellent collaboration.

TH-PO889

Effect of DsbA-L on Renal Ectopic Fat Deposition and Lipid-Related Kidney Damage in Diabetic Nephropathy

Xianghui Chen,[1] Yachun Han,[1] Ming Yang,[1] Peng Gao,[1] Yashpal S. Kanwar,[2] Lin Sun.[1] *[1]Second Xiangya Hospital Central South University, Changsha, China; [2]Northwestern University Medical School, Chicago, IL.*

Background: Emerging evidence suggests that ectopic fat deposition (EFD) in the kidney is related to the progression of diabetic nephropathy (DN), but the mechanism remains elusive. Disulfide-bond A oxidoreductase-like protein (DsbA-L) also known as Glutathione S-transferase kappa 1 (GSTK1), which has been demonstrated to regulate adiponectin multimerization, alleviate endoplasmic reticulum stress and prevent obesity-induced inflammation and insulin resistance. But the role of DsbA-L in renal EFD and lipid-related kidney damage is unknown.

Methods: In this study, patients with DN, DsbA-L deficiency mice (DsbA-L$^{-/-}$ mice), DsbA-L overexpression mice and HK-2 cells, a human proximal tubular cells line were used. Differentially expressed genes were identified by transcriptome in the kidney tissues of mice. Oil red o staining, electron microscope and immunostaining of adipocyte differentiation-related protein (ADRP) were used to observe or detect the lipid depostion in the kidney tissues of DN patients or mice.

Results: Here, we identified decreased expression of disulfide - bond A oxidoreductase-like protein (DsbA-L) and increased expression of adipocyte differentiation-related protein (ADRP) in the kidney of diabetic mice. Further, obvious lipid droplets (LDs) deposition and decreased DsbA-L expression were observed in the kidney of diabetic mice, accompanied by abnormal levels of phosphorylation of 5'AMP-activated kinase (p-AMPK), p-adipose triglyceride lipase (p-ATGL), p-3-hydroxy-3-methylglutaryl- CoA reductase (p-HMGCR), collagen I and fibronectin (FN). The above alterations were further increased in diabetic DsbA-L$^{-/-}$ mice. Overexpression of DsbA-L ameliorated high glucose (HG)-induced intracellular LDs deposition, whereas DsbA-L siRNA treatment aggravated it and was accompanied by reduced levels of p-AMPK, p-ATGL and p-HMGCR in HK-2 cells, a human proximal tubular cells line. Additionally, HG plus palmitic acid (PA) enhanced the expression of interleukin-1β and interleukin-18, which was further increased after DsbA-L siRNA treatment, but was alleviated by cotreatment with an AMPK activator. In the kidneys of DN patients, LDs deposition was negatively associated with DsbA-L expression but positively correlated with kidney damage.

Conclusions: Collectively, DsbA-L protects against renal EFD and lipid-related kidney damage via AMPK pathway.

Attenuated Lymphatic Proliferation Ameliorates Diabetic Nephropathy and High-Fat Diet-Induced Renal Lipotoxicity

Yaeni Kim,[1] Ji Hee Lim,[2] Min Young Kim,[2] Eun Nim Kim,[2] Seon Deok Hwang,[3] Bumsoon Choi,[4] Yong-Soo Kim,[5] Cheol Whee Park.[2] *[1]Incheon St. Mary's Hosp, Catholic Univ of Korea, Incheon, SEoul, Republic of Korea; [2]The Catholic University of Korea, SEOUL, Republic of Korea; [3]inha university, Incheon, Republic of Korea; [4]Division of Nephrology, Department of Internal Medicine, Seoul, Republic of Korea; [5]The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.*

Background: Lymphangiogenesis occurs in response to renal injury in renal proximal tubular epithelial cells (PTECs) and infiltrating macrophages and is correlated with the degree of renal interstitial fibrosis. Diabetes and high-fat diet-induced renal lipotoxicity causes glomerular sclerosis and tubulointersitial fibrosis, but its possible involvement with regard to lymphangiogenesis has not been elucidated. Peroxisome proliferative-activated receptor (PPAR)a plays an important role against lipotoxicity under the control of AMP-activated protein kinase (AMPK). We evaluated whether fenofibrate has a renoprotective effect by ameliorating lipotoxicity-induced lymphangiogenesis.

Methods: Eight-week-old male C57BLKS/J *db/db* mice and spontaneously hypertensive rats (SHRs) were fed either a normal chow or a high-fat diet (HFD) and fenofibrate for 12 weeks and were evaluated for biochemical parameters and renal phenotypes.

Results: In *db/db* mice, fenofibrate inhibited the accumulation of intra-renal lipids by increasing the expression of PPARa and phosphorylation of AMPK. It decreased lymphatic growth, as represented by decreases in the expression of lymphatic endothelial hyaluronan receptor-1 (LYVE-1) and podoplanin, along with decreases in vascular endothelial growth factor-C (VEGF-C) and vascular endothelial growth factor receptor-3 (VEGFR-3). Consequently, fenofibrate reversed mesangial expansion, tubulointerstitial fibrosis and chemokine-induced inflammatory cell infiltration by improving apoptosis and oxidative stress. In HFD SHRs, fenofibrate attenuated renal lymphatic proliferation and inflammation by decreasing lipotoxicity-induced oxidative stress and apoptosis through PPARa-AMPK phosphorylation. In cultured HK2 cells and RAW 267 cells, fenofibrate prevented palmitate- and high glucose-induced expression of VEGF-C, VEGFR-3, and LYVE-1 via activation of PPARa-AMPK-pACC signaling and enhanced expression of M1 phenotype macrophage.

Conclusions: A causal relationship between lipotoxicity and lymphatic proliferation with a cellular link to macrophage activation can be speculated; pro-inflammatory M1 type macrophages may be primarily involved in the development of intrarenal lymphangiogenesis through stimulation of VEGF-C and by its transdifferentiation into lymphatic endothelial cells.

TH-PO891

Basigin/CD147 Exacerbates Diabetic Kidney Disease Dependent of Proteinuria

Tomoharu Watanabe,[2] Tomoki Kosugi,[1] Akihiro Ryuge,[1] Tomohiro Masuda,[1] Kayaho Maeda,[1] Sawako Kato,[1] Shoichi Maruyama.[1] *[1]Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Nagoya University, Nagoya, Japan.*

Background: CD147/Basigin (Bsg), a glycosylated transmembrane protein, contributes to cell survival, migration, cancer invasion and inflammation. We have so far demonstrated its pathophysiological roles in the kidney diseases, ranging from the occurrence of acute kidney injury accompanied by ischemia to progression of renal fibrosis and lupus nephritis. However, the mechanism of diabetic kidney disease (DKD) involving Bsg remains unknown. We therefore focused on Bsg function in the development of DKD with proteinuria.

Methods: Two independent mice models were performed using wild-type (*Bsg*$^{+/+}$) or Bsg-deficient (*Bsg*$^{-/-}$) *mice treated with streptozotocin or overloaded by bovine serum albumin, respectively. Primary proximal tubular epithelial cells (PTECs) derived from Bsg*$^{+/+}$ or *Bsg*$^{-/-}$ *mice and human PTECs were exposed to high glucose (30mM) or albumin. In clinical study, DKD patients (N=52) registered with UMIN Clinical Trials Registry (8016) were treated with spironolactone 25 mg once daily for 8 weeks. The relationships between urinary Bsg values and clinical indicators were examined.*

Results: While *Bsg*$^{-/-}$ *mice induced by protein overload ameliorate the development of tubulointerstitial injury, no obvious difference in the two genotypes representing DKD was found. In clinical study, DKD patients showed higher plasma and urinary Bsg values and marked Bsg inductions in injured tubulointerstitium. Plasma and urinary Bsg levels showed close correlations with eGFR and proteinuria, but not HbA1c, respectively.* DKD patients treated with spironolactone showed a striking reduction of urinary Bsg values as well as albuminuria. A close association between reduction rates of urinary Bsg values and albuminuria was observed. In *in vitro* study, Bsg inductions in primary PTECs after exposure of albumin, but not high glucose, were found in a concentration-dependent fashion. *Bsg silencing and gene deficiency in PTECs limited inflammation-related chemotactic activation such as MMPs and MCP-1.*

Conclusions: *Bsg plays an indispensable role in the development of DKD evoked by proteinuria through the activation of inflammatory signaling.*

TH-PO892

Different Renoprotective Mechanism of TMX-049, a Novel Xanthine Oxidoreductase Inhibitor, from Losartan: The Importance of Renal Tubule for Diabetic Kidney Disease Treatment

Takashi Shirakura,[1] Yoshiki Tsubosaka,[1] Yohei Sakamoto,[2] Tsunefumi Kobayashi,[1] Reiko Aizawa,[1] Shunsuke Tsujimoto,[1] Johji Nomura,[1] Chieko Matsui.[1] *[1]Pharmacology Research Department, Teijin Pharma Limited, Hino, Japan; [2]Toxicology Research Department, Teijin Pharma Limited, Hino, Japan.*

Background: Diabetic kidney disease (DKD) is a major renal complication of diabetes. Although the glomerulus has been considered as the primary site of injury, recent studies have suggested that renal tubule is also the prominent site. Current medications such as losartan (Los) exert the renoprotective effects by reducing intraglomerular pressure. However, there is no drug which targets tubular injury. Xanthine oxidoreductase (XOR) is an enzyme producing uric acid and its inhibitors have been reported to improve albuminuria in DKD patients. To date we found that XOR is mainly expressed in renal tubule in rats, suggesting the target site of XOR inhibitor may be renal tubule. To determine the renoprotective effect of TMX-049, a novel XOR inhibitor, and the importance of renal tubule as a target site for DKD treatment, we examined them using animal models of DKD and albumin-induced tubular injury.

Methods: 1. Male ZDF rats were orally administrated TMX-049 or Los for 13 weeks. 2. Male unilateral nephrectomized rats were intraperitoneally injected with bovine serum albumin and orally administrated with TMX-049 or Los for 3 weeks. Urinary albumin, and KIM-1 as a tubular injury marker, were measured. XOR activity in the renal cortex was measured and histological and immunohistochemical analyses were performed.

Results: XOR, mainly expressed in renal tubule, was increased in ZDF rats, consistent with the increased XOR activity in renal cortex. TMX-049 but not Los inhibited XOR activity. In addition, TMX-049 as well as Los decreased urinary albumin and KIM-1 excretions, and ameliorated histological damage in both glomerular and tubular region in ZDF rats. Albumin induced the damage in tubular region and urinary KIM-1 excretion, indicating tubular injury by albumin, while there were no changes in glomerular region. Consistent with ZDF rats, XOR activity in renal cortex was increased in albumin-treated rats. Importantly, TMX-049 attenuated albumin-induced tubular damages whereas Los failed.

Conclusions: TMX-049 attenuated renal tubular damage by inhibiting tubular XOR, leading to suppress renal injury. These results suggest the therapeutic potential of TMX-049 and the importance of renal tubule as a target site for DKD treatment.

TH-PO893

Metabolic Differences in Diabetic Kidney Disease Patients with and Without Albuminuria

Stein I. Hallan,[2,3] Manjula Darshi,[1] Marius A. Øvrehus,[2] Knut Asbjørn R. Langlo,[2,3] Kumar Sharma.[1] *[1]University of Texas Health San Antonio, San Antonio, TX; [2]Norwegian University of Science and Technology, Trondheim, Norway; [3]St. Olavs Hospital HF, Trondheim, Norway.*

Background: The classical paradigm describing diabetic kidney disease (DKD) as a linear progression with stages of glomerular hyperfiltration, progressive albuminuria, and subsequent declining GFR is being recently challenged. 25-50% of DKD with eGFR <60ml/min/1.73m^2 do not have albuminuria, and the underlying pathology in this group is not well studied. We studied the metabolic differences in unselected well-matched DKD patients with (DKD A1+) and without (DKD A0) albuminuria.

Methods: 41 patients with DKD, defined as diabetes mellitus with eGFR <60mL/min/1.73m^2, and 60 healthy age- and sex-matched controls were randomly chosen from the general population (HUNT-3 study, 2006-08, Norway). Urine samples were analyzed and 75 organic acids quantified using gas chromatography-mass spectrometry (GC-MS, 4-6 calibration points, CV 10-20%). Kidney function was followed over 10 years.

Results: 15 of 41 DKD patients (37%) had ACR <3.0mg/mmol. Age and sex were similar in the healthy control, DKD A0 and DKD A1+ groups (~ 71 years, p=0.3; and 40% males, p=0.6). Baseline eGFR was identical in DKD A0 and A1+ (51 vs 51 ml/min/1.73m^2). They also had similar BMI, BP, BP medication, physical activity and education (p>0.4 for all), while DKD A0 had more never-smokers (p=0.002). PLS-DA analysis of the organic acid metabolites showed that the three groups separated moderately, with DKD A0 positioned between controls and DKD A1+ patients (Figure 1). When comparing the two DKD groups, we found 22 metabolites with VIP scores ≥1.0, i.e. considered to contribute significantly to separation. Top metabolites were hexanol glycine, lactic acid and keto-glucatic acid. Enrichment analysis based on these metabolites showed that citric acid cycle, Warburg effect, glucose-alanine, keton body metabolism, and fatty acid biosynthesis were the most affected pathways (p<0.05 and ~ 5-fold enriched for all).

Conclusions: DKD patients with and without albuminuria differ substantially in their metabolic disturbances and could represent different clinical phenotypes

Haploid Deletion of TRPC1 Gene Produces Hypercalcemia, Anemia, Diabetes, and Renal Failure, as Diploid Deletion Causes Obesity, Metabolic Syndrome, Hyperparathyroidism, Liver Steatosis, and Larger Bone Mass

Bonnie Eby,[1] Meghan M. Pantalia,[2] Lindsay J. Barron,[1] Alexander Lau,[1] Richard M. Atkins,[3] Usman A. Khan,[3] Leonidas Tsiokas,[1] Kai Lau.[1,4] *[1]University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]Columbia University, New York, NY; [3]University of Oklahoma College of Medicine, Oklahoma City, OK; [4]Medicine, VA Hospital & Medical Center, Oklahoma City, OK.*

Background: The gene encoding the canonical transient recpetor potential 1 channel (TRPC1) is ubiquitously expressed. It is known to be involved in signal transduction by changing intracellular Ca, cytokine & hormone secretion, cell proliferation & differentiation. Gene deletion is now known to produce a myriad of abnromal but nonlethal phenotypes, including hypercalcemia, anemia, diabetes, renal failure, obesity, metabolic syndrome, hyperparathyroidism, hepatic steatosis & increased bone mass. We tested the hypothesis of relative gene dosge in these phenotypes by studying ♂ littermates of all 3 genotypea born to only +/- breeders.

Methods: Standard metabolic studies, glucose tolerance tests, & routine lab chemistry were done from age 1 to 22 m. Mouse ELISA were used to measure insulin, PTH, adipokines & FGF-23. Creatinine (Cr) was measured by HPLC & glomerular filtration rate (GFR) by inulin or Cr clearance.

Results: In +/- mice, like the null, we found fasting hyperglycemia at 3 m, diabetes at 6 m, hypercalcemia at 7-12 m, anemia at 11 m, & reduced GFR of 40% at 16 m. However, only in null mice could we document the following phenotypes: hyperphagia, excessive

weight gain, obesity, hypertriglyceridemia (all at 2-4 m), reduced serum FGF 23 at 3-5 m, metabolic syndrome at 6 m, increased serum leptin & reduced adiponectin at 7 m, hepatic steatosis at 12 mon, hyperparathyroidism despite hypercalcemia & hypocalciuria [like the human familial hypocalciuric hypercalcemia (FHH)] at 12 m, & increased bone mass at 19-22 m. Liver triglyceride content was elevated only in null mice. If haploid deletion replicates the phenotypes of diploid deletion, the degree of abnormalities was uniformly ccomparable.

Conclusions: We conclude: 1. Since haploid deficiency of TRPC1 gene produces anemia, diabetes, hypercalcemia & renal failure, the usual normal phenotypes would require both wild type alleles. 2. Since diplid deficiency is needed to produce hyperphagia, obesity, metabolic syndrome, FHH, hepatic steatosis & increased bone mass, the corresponding normal phenotypes can be maintained by 1 wild type allele. 3. Additional insights on the pathobiology will depend on studies in tissue-specific TRPC1 gene deletion.

In Vivo Evidence of Role of Diabetes in Accelerating Kidney Tumorigenesis

Samy L. Habib.[1,2] [1]*UTHSCSA, San Antonio, TX;* [2]*Geriatric Research, Education and Clinical CTR, South Texas Veterans Health System, San Antonio, TX.*

Background: Our published clinical data show a strong risk of diabetes in increasing of renal cell carcinoma in a cohort study of kidney cancer patients whereas 25.4 % of kidney cancer patients have history of diabetes and our recent clinical data showed that RCC patients with history of diabetes increased by 33.3%. The increasing incidence of diabetes in our population will increase the risk of solid tumors including renal cell carcinoma (RCC). The mechanism by which diabetes enhances certain pathways to develop kidney tumor is largely unknown.

Methods: The inherited renal tumor was identified in TSC2+/- animal model, which is naturally heterozygous for mutation in tumor suppressor genes, Tuberous Sclerosis Complex (TSC). The majority of tumors observed in the kidney of TSC2+/- mice originate from renal proximal tubules develop around age of 12 months. We have generated a new mouse model of TSC2+/-/dbdb-/- by cross breed TSC2+/- and dbdb mice to investigate whether diabetes accelerates tumors in new mouse model at early ages.

Results: At the day of sacrificing, WT and TSC2+/- mice showed normal blood glucose levels (80-109 mg/dL), while db/db and TSC2+/-/dbdb mice showed ranges of hyperglycemia between 405-510mg/dL measured by Glucometer in overnight fasting animals. Our novel in vivo data showed for the first time that diabetes accelerates kidney tumor size to 4-fold and number to 2-fold in TSC2+/-/dbdb new mouse model compared to TSC2+/- mice at 10 months old. Data show that no significant difference in tumor size and number between TSC2+/-/dbdb and TSC2+/- mice at age of 8 months. We didn't recognize any tumor in WT and db/db mice at this age. Next, we performed RNA sequencing in RNA isolated from kidney cortex of WT, db/db, TSC2+/- and TSC2+/-/dbdb mice at age of 10 months. The sequencing data show different patterns of downregulation and upregulation of several genes between TSC2+/-/dbdb, TSC2+/- and dbdb compared to WT mice that have significant interest in regulation of tumorigenesis.

Conclusions: Our data provided in vivo evidence of role of diabetes in accelarting kidney tumorigeneis. These data suggest that short term of diabetes is not effective to enhance tumorigenesis in TSC2+/-/dbdb mice and longer exposure to hyperglycemia is required to initiate tumorigenesis. These data confirmed for the first time that diabetes is a major risk factor for increasing kidney cancer.

Relationship Between Endothelial Damage and Expression of Tropomyosin on Peritubular Capillary During the Progression of Experimental Obstructive Nephropathy

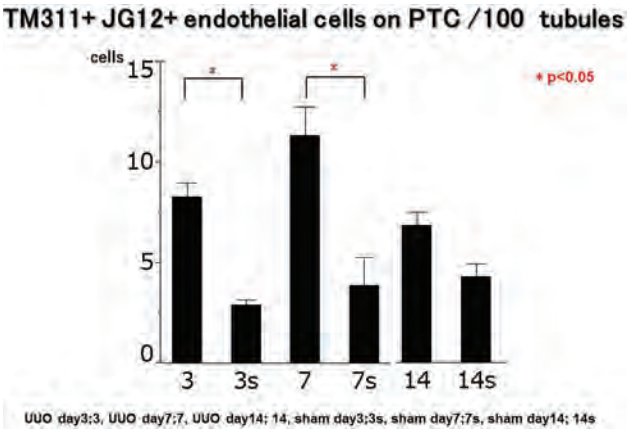
Ken Kitamura,[1,2] Kentaro Nakai,[3,2] Hideki Fujii,[2] Shinichi Nishi.[2] [1]*Kita-Harima Medical Center, Ono, Japan;* [2]*Kobe University Graduate School of Medicine, Kobe, Japan;* [3]*Fukuoka Red Cross Hospital, Fukuoka, Japan.*

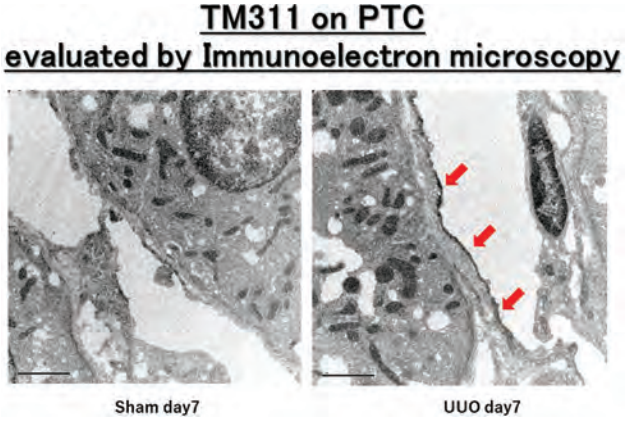
Background: Tubulointerstitial injury(TI) is a major determinant factor in progressive renal diseases. Although the injuries to peritubular capillary (PTC) network is crucial for the progression of TI, it has been few reported about marker for detecting endothelial damage on PTC. We investigated expression of Tropomyosin (TM), one of the actin-associated proteins on PTC during the progression of experimental obstructive nephropathy.

Methods: Male Wister rats (7 week old) were subjected to UUO or sham-operation, and kidneys were harvested on days 3, 7 and 14 post-surgery after pimonidazole infusion for evaluation of low oxygen area. We evaluated the expression of TM on PTC by immunostaining and immunoelectron microscopy. And real-time polymerase chain reaction, and western blot were performed. To clarify the mechanism, we assessed the expression of TM in human umbilical vein endothelial cells (HUVEC) exposed to hypoxia condition.

Results: The expression of TM on PTC significantly increased on day 3, reached a peak at day 7, and decreased on day14 by immunostaining. Also, TM was identified at cytoplasm of PTC by immunoelectron microscopy 7 days after operation, not identified in sham rats. In UUO, TM significantly expressed at low oxygen area, tended to co-express with Ki67. We confirmed the increased expression of TM in the whole kidney. In HUVEC, 12 hours hypoxia condition induced the expression of TM in immunofluorescent staining.

Conclusions: TM is a protein related to angiogenesis and increased the expression on PTC at the early stage of TI. This fact suggested TM might be a marker of endothelial damage on PTC to play a work for the protection against hypoxia damage.





TH-PO897

Oral Administration of Paramylon, a β-1,3-D-Glucan Isolated from Euglena gracilis Z Protects Against Renal Damage in CKD Rats

Yoshikuni Nagayama,[1] Mizuki Yamano,[1] Ayaka Nakashima,[2] Kengo Suzuki,[2] Katsuyuki Matsui.[1] [1]*Teikyo University Mizonokuchi Hospital, Kawasaki, Japan;* [2]*euglena Co.,Ltd., Tokyo, Japan.*

Background: Paramylon is a β-1,3-D-Glucan that is stored by *Euglena gracilis Z* and a large porous molecule and plays various roles in chemical storage, ion exchange, and as a molecular sieve. It has been demonstrated to have anti-allergy effects and enhance immunological functions. Now available treatments are limited in the progression of chronic kidney disease (CKD). The aim of this study is to investigate the effect of Paramylon in CKD rats.

Methods: CKD was induced in 8-week-old male Wistar rat by 5/6 nephrectomy (Nx). A normal diet was given for 8 weeks in Sham control or in Nx rats. A diet containing 5% paramylon (PAR) obtained from euglena Co., Ltd was given for 8 weeks in Nx + PAR rats.

Results: There were no significant differences of the body weight, diet intake, and water intake between Nx and Nx + PAR groups. Increases in serum urea nitrogen and urinary protein excretion in Nx were significantly suppressed in Nx + PAR. Nx + PAR also showed histologically milder disease when compared to Nx (glomerular sclerotic score 1.8±0.4 vs. 0.9±0.2, means±SEM, $p<0.05$; tubular injury score 2.8±0.3 vs. 1.0±0.2, $p<0.05$; fibrosis area (%) 4.0±0.7 vs. 2.7±0.5, $p=0.15$; the number of interstitial PCNA-positive cells per high-power field 72±10 vs. 36±6.5, $p<0.05$).

Conclusions: Our data suggest that Paramylon may be a novel compound against the progression of renal damage in CKD rats.

TH-PO898

Altered Expression of the Renal Prostaglandin E2 Signaling System in Kidney Tissue from Patients with Hydronephrosis and Renal Fibrosis

Kirsten Madsen,[1] Signe S. Tofteng,[1] Amalie Kamstrup mogensen,[2] Boye Jensen.[1] [1]*University of Southern Denmark, Odense C, Denmark;* [2]*Department of Cardiovascular and Renal Research, Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark.*

Background: Renal fibrosis is the final common pathway in chronic kidney diseases (CKD). Increased prostaglandin E_2-EP_4 receptor signaling through increased EP_4 receptor expression has been suggested to attenuate renal fibrosis in mice using the unilateral ureteral obstruction (UUO) model. It is unknown if patients with hydronephrosis and renal fibrosis show similar regulation of the renal prostaglandin E_2 signaling system. We tested the hypothesis that hydronephrosis and renal fibrosis is associated with increased renal COX-2 and EP_4 receptor expression in humans.

Methods: Kidney tissue was collected from patients diagnosed with hydronephrosis undergoing unilateral nephrectomy (n=12) at the Dept. of Urology, Odense University Hospital. Normal appearing kidney tissue from age- and gender matched subjects undergoing nephrectomy due to renal cell carcinoma (n=12) was used as control. The percentage of the cortical region affected by interstitial fibrosis was scored and expression of the prostaglandin E_2 signaling system was determined by qPCR.

Results: Mean age was 54 years [range 26-78 years] in the hydronephrosis group and 55 years [range 28-78 years] in the control group. All patients in the control group showed minimal or no signs of renal fibrosis (0-10%). In the hydronephrosis group, 4 patients showed mild (10-25%), 3 patients moderate (26-50%) and 2 patients severe fibrosis (50-100%). 3 patients showed minimal or no signs of renal fibrosis. No significant changes in COX-2, COX-1 or PTGES mRNA was detected. In kidney cortex, a significant upregulation of EP_2 receptor mRNA was detected in the hydronephrosis group compared to controls and a concomitant downregulation of the EP_3 receptor mRNA level. No significant changes in EP_1 or EP_4 receptor mRNAs were seen. In outer medulla, a significantly reduced expression of the EP_3 receptor was seen in the hydronephrosis group. No changes in EP receptor expression were seen in the inner medulla.

Conclusions: In conclusion, hydronephrosis and renal fibrosis in humans is associated with altered renal EP_2 and EP_3 receptor expression. No changes were detected in COX-2 and EP_4 receptor expression as has been described in mice. Results suggest the EP_2 and not the EP_4 receptor to be dominant in PGE_2 receptor signaling during renal fibrogenesis in humans.

Mechanisms of High Salt Intake-Increased (Pro)renin Receptor Expression in the Nephron of Dahl Salt-Sensitive Rats

Seiko Yamakoshi,[1,2] Osamu Ito.[3,2] *[1]Nikko Medical Center, Dokkyo Medical University, Nikko, Japan; [2]Tohoku University Graduate School of Medicine, Sendai, Japan; [3]Tohoku Medical Pharmacetical University Faculty of Medicine, Sendai, Japan.*

Background: We recently reported that high-salt (HS) intake increased the (P)RR expression by 3-5 fold in several nephron segments of Sprague-Dawley rats (Peptides 63: 156-162, 2015). The present study examined the mechanisms of the HS-intake increased (P)RR expression in Dahl-Salt sensitive (DS) rats.

Methods: Male DS rats were fed a normal salt (NS) diet (0.6%NaCl) and a HS diet (8%NaCl) for 4weeks. A part of the rats fed the HS diet were treated orally with xanthine oxidase (XO) inhibitor, febuxostat (Feb, 10mg/kg/day) or mineralocorticoid receptor (MR) antagonist, spironolactone (Spi, 100mg/kg/day). Additionally, deoxycorticosterone acetate (DOCA, 50mg/kg/week) administered to DS rats fed the NS diet for 4weeks. The (P)RR expression in the kidney sections and proximal tubules (PT) was examined by immunoblot and immunohistochemical analyses. XO activity in the CO was measured.

Results: HS intake increased the blood pressure, and Feb and Spi decreased the HS intake-increased blood pressure ($p<0.01$). HS intake increased the XO activity by 1.7 fold ($p<0.01$), and febuxostat blocked completely the activity. HS intake increased the (P)RR expression in the cortex by 22.6 fold ($p<0.001$) and the PT by 4.9 fold ($p<0.01$). Feb and Spi inhibited the HS intake-increased (P)RR expression in the cortex by 55% and 89%, respectively ($p<0.001$). Feb inhibited the HS intake-increased (P)RR expression in the PT by 69% ($p<0.001$), but Spi did not change the expression. Immunohistochemical analysis revealed that HS intake increased the (P)RR expression in the PT and distal tubules (DT) and that Feb inhibited the expression in the PT, and Spi inhibited the expression in the DT. In addition, DOCA increased the (P)RR expression in the cortex by 80% ($p<0.001$) and the DT, but not in the PT.

Conclusions: HS intake-increased (P)RR expression is enhanced in the PT and distal tubules of DS rats. The mechanisms of HS intake-increased (P)RR expression may be MR-dependent manner in the DT and XO-dependent manner in the PT.

TH-PO900

Olmesartan Attenuates Kidney Injury in Experimental Alport Syndrome

Eun Hui Bae,[2] Injin Kim,[2] Jihong Song,[2] Seong Kwon Ma,[2] James W. Scholey,[1] Soo Wan Kim.[2] *[1]University of Toronto, Toronto, ON, Canada; [2]Chonnam National University Medical School, Gwangju, Republic of Korea.*

Background: As angiotensin-converting enzyme 2 (ACE2) was identified as a negative regulator of the renin-angiotensin-aldosterone system, there have been many reports concerning its role in several tissues, including kidney. We have reported that ACE2 expression and activity in the kidney are reduced in experimental Alport syndrome (AS) and olmesartan has known as increased ACE2 activity.

Methods: To examine the effects of olmesartan treatment in AS, we used the Col4a3$^{-/-}$ mice. Mice were divided into three groups: saline-treated wild type mice group, saline-treated Col4a3$^{-/-}$ mice, and Ang-(1-7) treated Col4a3$^{-/-}$ mice group. Olmesartan medoxomil (5 mg/kg/day) was administered from 4 to 7 weeks of age via drinking water.

Results: Treatment with olmesartan led to decreased urinary NGAL excretion in 7-week-old *Col4a3*$^{-/-}$ mice. Pathological changes were attenuated by olmesartan treatment. Olmesartan ameliorated kidney fibrosis as shown by decreased expression of profibrotic genes, less accumulation of extracellular matrix proteins, and inhibition of TGF-β signaling. Further, increases in proinflammatory cytokine expression, macrophage infiltration, inflammatory signaling pathway activation, and heme oxygenase-1 (HO-1) levels in *Col4a3*$^{-/-}$ mice were also reduced by olmesartan treatment. Lastly, olmesartan influenced the turnover of renal ACE2, as it suppressed expression of TNFα-converting enzyme (TACE), a negative regulator of ACE2.

Conclusions: In summary, treatment with olmesartan alters angiotensin peptide metabolism in kidneys of *Col4a3*$^{-/-}$ mice and attenuates the progression of AS nephropathy.

TH-PO901

Therapeutic Targeting of GSK3β Rectifies Profibrogenic Plasticity of Renal Tubular Epithelial Cells in Progressive CKD

Bohan Chen,[1,2] Pei Wang,[1] Lance D. Dworkin,[2] Zhangsuo Liu,[1] Rujun Gong.[2] *[1]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [2]University of Toledo Medical Center, Toledo, OH.*

Background: Renal tubular cells play a key role in chronic kidney injury. After a prolonged persistent injury beyond self-healing capacity, renal tubular cells will resort to maladaptive plasticity and undergo dedifferentiation, growth arrest and convertion to profibrogenic phenotypes that ultimately lead to renal fibrosis. Evidence suggests that glycogen synthase kinase (GSK) 3β is centrally implicated in kidney injury. However, its role in maladaptive renal tubular cell plasticity is unknown and was explored here.

Methods: In cultured renal tubular cells expressing diverse GSK3β mutants or treated with GSK3β inhibitors, TGFβ1-induced phenotypic changes were evaluated. In mice with tubular specific knockout of GSK3β or in mice treated with microdose lithium folic acid-induced chronic kidney injury was examined.

Results: TGFβ1 treatment triggered renal tubular cell dedifferentiation, marked by conversion from cuboidal to dispersed spindle shape, loss of cell tight junction molecules like E-cadherin and ZO-1, and *de novo* expression of vimentin. In addition, growth inhibition was noted as shown by cell cycle arrest at G2/M phase. Moreover, increased extracellular matrix proteins like collagen I and fibronectin, as well as overproduction of profibrotic cytokines, such as PAI-1 and CTGF, was evident after TGFβ1 exposure. All these profibrogenic phenotypes were reinforced in cells expressing the constitutively active mutant of GSK3β, but largely abolished by ectopic expression of a dominant negative mutant or by GSK3β inhibitors. Mechanistically, GSK3β blockade potentiated CREB activity and subsequently antagonized the TGFβ1/Smad signaling, which drives tubular cell profibrogenic plasticity. Moreover, structural rather than transcriptional β-catenin was up-regulated after GSK3β inhibition, denoting a strengthened cell tight junction. So did cyclin D1, an essential element for cell cycle progression. *In vivo*, in folic acid-injured mice, tubular cell dedifferentiation, G2/M arrestrenal and PAI-1 and CTGF expression were all mitigated by GSK3β gene ablation or by microdose lithium, a standard GSK3b inhibitor, concomitant with attenuated tubular atrophy and renal fibrosis.

Conclusions: GSK3β is likely a pragmatic therapeutic target for correcting profibrogenic plasticity of renal tubular cells in CKD to improve renal fibrosis.

TH-PO902

Proximal Tubule ATR in Humans and Mice Is a Key Regulator of the DNA Repair Response Protecting the Kidney Against Maladaptive Repair and Fibrosis After Tubular Injury

Seiji Kishi,[2,1] Craig R. Brooks,[3] Takaharu Ichimura,[1] Kenji Nishimura,[2] Ryuji Morizane,[1] Joseph V. Bonventre.[1] *[1]Brigham & Women's Hospital/Harvard Medical School, Boston, MA; [2]Nephrology, Tokushima University Hospital, Tokushima, Japan; [3]Vanderbilt University Medical Center/Division of Nephrology & Hpertension, Nashville, TN.*

Background: Renal proximal tubular epithelial cells (RPTECs) comprise the bulk of the renal parenchyma and are the primary target of a variety of insults to the kidney. Maladaptive repair of RPTECs has been implicated in kidney fibrosis through induction of cell cycle arrest at G2/M. The DNA damage response (DDR) is a mechanism of DNA repair that is responsible for maintaining genome integrity. We hypothesize that inhibition of DDR, through deletion of the DNA damage sensor ataxia telangiectasia and Rad3 related (ATR), would worsen the fibrotic response in RPTECs.

Methods: Human kidney biopsy tissue was analyzed from 11 patients with interstitial fibrosis and elevated serum creatinine and 9 cases with minor glomerular abnormalities and good preservation of tubules. Kidney organoids were generated from human pluripotent stem cells. An active form of ATR and the marker of DNA damage (γH2AX) were studied by immunocytochemistry along with KIM-1 to evaluate whether DDR correlates with eGFR or fibrosis. We generated RPTC-specific conditional ATR knockout ($ATR^{RPTC-/-}$) mice by crossing ATR floxed ($ATR^{fl/fl}$) with $ATR^{+/-}$ and tamoxifen-inducible RPTC-CRE driver (SLC34a1-CreERT2) mice and evaluated kidney injury, fibrosis and cell cycle arrest following ischemia/reperfusion, cisplatin and ureteral obstruction-induced injury in these mice.

Results: Humans with chronic fibrotic kidney disease and human kidney organoids treated with cisplatin have activation of ATR and extensive DNA damage in proximal tubules with an inverse correlation between p-ATR and DNA damage marked by γH2AX in human biopsies. $ATR^{RPTC-/-}$mice exhibited greater kidney functional impairment, DNA damage, and fibrosis in response to kidney injury induced by either bilateral ischemia reperfusion, cisplatin or unilateral ureteral obstruction. $ATR^{RPTC-/-}$mice had increased G2/M arrested cells after these kidney injuries.

Conclusions: DDR is activated in human kidney disease and ATR plays a protective role against tubular cell injury, death and fibrotic response. Proximal tubule ATR activation is a key component of the DDR which confers a protective effect by mitigating maladaptive repair and consequent fibrosis that follows kidney injury.

Proximal Tubule Angiotensin II Type 1 Receptor-Associated Protein Regulates Kidney Aging and Lifespan Through Sirtuin1-Mediated Pathway

Takahiro Yamaji,[1] Kazushi Uneda,[1] Sho Kinguchi,[1] Kohji Ohki,[1] Ryu Kobayashi,[2] Kengo Azushima,[1] Hiromichi Wakui,[1] Yoshiyuki Toya,[1] Kouichi Tamura.[2] *[1]Yokohama City University, Yokohama, Japan; [2]Yokohama City University Graduate School of Medicine, Kanazawa-Ku, Japan.*

Background: The kidney is easily affected by aging-associated changes including tubulointerstitial fibrosis and tubular atrophy. Angiotensin II type 1 receptor (AT1R)-associated protein (ATRAP), which was originally identified as a molecule that binds to AT1R, is highly expressed in the kidney. Previously, we have shown that ATRAP suppresses hyper-activation of AT1R signaling, but does not affect the physiological AT1R signaling pathway. This time, we hypothesized that proximal tubule ATRAP suppresses aging-related kidney fibrosis through Sirtuin1-mediated pathway independent of angiotensin signaling.

Methods: ATRAP-knockout mice (KO mice) and their wild-type control mice (WT mice) were fed the standard diet and maintained until death to estimate their life spans. Their growth, physiological parameters and aging-related organ damages in the hearts, aortas and kidneys were analyzed in both groups. To further investigate the mechanism exacerbating aging-related kidney fibrosis in KO mice, the expression of the pro-survival genes was examined using human tubular epithelial cells.

Results: KO mice exhibit a normal age-associated appearance without any evident alterations in physiological parameters, including blood pressure and cardiovascular and metabolic phenotypes. However, in KO mice compared with wild-type mice, the following takes place: (1) age-associated renal function decline and tubulointerstitial fibrosis are more enhanced; (2) renal tubular mitochondrial abnormalities and subsequent increases in the production of reactive oxygen species are more advanced; and (3) lifespan is 18.4% shorter (median lifespan: 100.4 vs. 123.1 week). As a key mechanism, age-related pathological changes in the kidney of KO mice correlated with decreased expression of the pro-survival gene Sirtuin1. Furthermore, in cultured human proximal tubular epithelial cells, deletion of ATRAP also downregulated mRNA expression levels of Sirtuin1 under serum starvation condition.

Conclusions: These results indicate that proximal tubule ATRAP regulates renal Sirtuin1 expression and plays an important role in inhibiting aging-related kidney changes and protecting the normal lifespan.

TH-PO904

Dicer Deficiency in Proximal Tubules Exacerbates Renal Injury and Tubulointerstitial Fibrosis in Diabetes and UUO Models by Upregulating Smad2/3 Expression

Zhengwei Ma,[1] Qingqing Wei,[1] Zheng Dong.[2] Augusta University *[1]Medical College of Georgia, Augusta University, Augusta, GA; [2]Medical College of Georgia, Augusta, GA.*

Background: Renal fibrosis is a common pathological feature in chronic kidney disease, including diabetic kidney disease (DKD) and obstructive nephropathy. Multiple microRNA species have been implicated in the pathogenesis of both DKD and obstructive nephropathy. Dicer is a key RNase III enzyme for microRNA biogenesis, which has been shown to play an important role in kidney development and renal ischemia-reperfusion injury. However, the role of Dicer in diabetic and obstructive kidney diseases remain unclear.

Methods: Dicer was specifically ablated from Kidney proximal tubules in mice by breeding Dicer-floxed mice with PEPCK-Cre mice. Proximal tubule Dicer knockout (PT-Dicer-KO) mice and wild-type (WT) mice were subjected to STZ treatment to induce DKD or unilateral urethral obstruction (UUO) to examine renal hypertrophy, renal injury and fibrosis.

Results: We found that Dicer-KO in proximal tubules deteriorated renal interstitial inflammation, tubular injury, and tubulointerstitial fibrosis without significantly affecing renal hypertrophy following STZ treatment. Dicer-KO exacerbated renal injury and tubulointerstitial fibrosis in the UUO model as well. At the molecular level, Dicer deficiency induced Smad2/3 expression in proximal tubules, which may contribute to the enhanced tubulointerstitial fibrosis in both STZ-diabetes and UUO models.

Conclusions: Our results provide further support for the regulatory role of Dicer and associated microRNA production in the development of chronic renal pathologies in DKD and obstructive nephropathy. Dicer deficiency may up-regulate Smad2/3 and increase renal apoptosis to enhance the progression of chronic kidney disease.

Lactate Induced Interstitial Fibroblasts Activation and Extracellular Matrix Accumulation in Folic Acid Induced AKI

Lei Jiang,[2] Yan Shen,[1] Junwei Yang.[2] *[1]Nanjing Medical University, Nanjing, China; [2]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: Recent studies have indicated a substantial proportion of acute kidney injury (AKI) patients may undergo chronic kidney disease (CKD) in long term follow-up. However, the mechanisms are still unclear. Previous evidences affirmed that interstitial myofibroblasts play a key role in AKI-CKD transition. In previous tests, we observed folic acid (FA) injection could induce extracellular matrix (ECM) deposition. Further researches revealed tubular epithelial and interstitial cells proliferate after FA-AKI and the later was significantly delayed than the former. Meanwhile, we confirmed there was active glycolysis in proliferative tubular epithelial cells and secreted abundant lactate after FA-AKI injury. Thus, we speculated the glycolysis metabolic end-product lactate secreted by injured renal tubular epithelial cells induced the activation of interstitial fibroblasts and led to ECM accumulation in folic acid AKI models.

Methods: We checked whether lactate itself could induce fibroblasts activation and express fibrotic proteins. In vivo, rat kidney fibroblast (NRK-49F) were exposed to lactate at different concentration and time interval, harvested and subjected to different detection methods. Secondly, different glycolytic inhibitors 2-deoxyglucose (2-DG) and oxamate were explored in FA treatment mice. Lactate production at acute injured phase was measured. We further verified whether ECM deposition was alleviated after suppressing lactate production. Finally, we preliminary explored the possible molecular mechanisms of lactate in the activation of interstitial fibroblasts.

Results: Lactate could induced NRK-49F cells activation and expressed abundant fibrotic proteins such as alpha-smooth muscle actin (α-SMA), fibronectin (FN). Both 2-DG and oxamate could inhibit the production of lactate by renal tubular epithelial cells and alleviated FA-AKI associated ECM deposition. The protective effects improved with the dose increased and 2-DG seemly more excellent. Lactate may stimulate fibroblasts via altering fibroblasts energy metabolism or affecting proliferative associated cells growth factors expression in fibroblasts.

Conclusions: Lactate secreted by injured renal tubular epithelial cells may play a key role in the activation of fibroblasts and ultimately led to abundant ECM accumulation in folic acid induced acute kidney injury.

Hepatic Alkaline Phosphatase Activity Is Increased in CKD and Is Regulated by the Intestinal Microbiota

Cassandra R. Johnson, Ogorchukwu F. Omede, Jason R. Stubbs. *University of Kansas Medical Center, Kansas City, KS.*

Background: Patients with chronic kidney disease (CKD) exhibit a pro-inflammatory phenotype that may partially result from intestinal dysbiosis and gut barrier dysfunction. A major function of liver alkaline phosphatase (ALP) is the neutralization of microbial toxins that enter the portal circulation from the intestine. The purpose of this study was to characterize expression and activity levels of liver ALP in both mice and humans with CKD, and explore the role of the intestinal microbiota in regulating ALP activity.

Methods: We first assessed liver ALP expression (Western blot) and function (ALP activity assay) in two CKD mouse models (*Col4a3*$^{-/-}$ and adenine diet) and non-CKD controls. Next, we confirmed the generalizability of our findings to humans by assessing ALP expression and function in liver samples from deceased tissue donors with advanced CKD or normal kidney function (n=10/group). Lastly, we performed fecal transplant studies to examine how repopulating the intestine of wild-type mice with microbiota from either CKD or control mice impacted liver ALP expression and function.

Results: CKD mice (*Col4a3*$^{-/-}$ model) exhibited a 50% higher liver ALP protein expression ($P<0.05$), that was accompanied by a 10-fold greater liver ALP activity (CKD 3,140 vs. non-CKD 294 mU/mg protein; $P<0.001$). Similar findings were observed in mice with CKD induced by chronic adenine ingestion. Despite markedly higher liver ALP activity in CKD mice, serum ALP activity was equal between CKD and non-CKD mice. Next, we observed 3-fold higher liver ALP activity in human CKD livers (CKD 6,624,488 vs. non-CKD 2,459,531 mU/mg protein; $P=0.09$), but no obvious difference in total protein expression. Lastly, transplantation of CKD stool into wild-type mice resulted in substantially higher liver ALP protein expression and ALP activity compared to wild-type mice transplanted with non-CKD stool (ALP activity: CKD stool 5,104 vs. non-CKD stool 863.4 mU/mg protein; $P<0.05$).

Conclusions: Both mice and humans with CKD exhibit higher liver ALP activity that may be partially stimulated by factors derived from the CKD microbiome. We speculate that enhanced liver ALP activity is important for neutralizing microbial toxins that enter the portal circulation as a result of gut dysbiosis and barrier dysfunction in CKD.

PI3K/Akt/NFκB Signaling Pathway Might Be the Potential Injury Pathway in IgG4-Related Urinary Disease

Fei Teng, Ke Zheng, Xuemei Li. *Peking Union Medical College Hospital, Beijing, China.*

Background: Diffuse lymphocytes infiltration and diverse inflammatory factors activation represent the inflammation status of IgG4-related disease(IgG4-RD), while its specific pathogenesis remains confusing, especially in IgG4-related urinary disease (IgG4-RUD). This study aims to preliminarily investigate the potential inflammatory and injury pathway of IgG4-RUD via urinary exosomes.

Methods: Four untreated biopsy proven IgG4-RUD inpatients, two IgG4-RD patients without urinary system involvement(disease control, DC) and two healthy controls(HC) were enrolled from Feb to May, 2018 in Peking Union Medical College Hospital. Disease activity was assessed using IgG4-RD Responder Index(RI). Urinary exosomes were isolated from fresh morning urine via ultracentrifugation method. Two-color Western blot was conducted to semi-quantify the expression of mTOR, PI3K, Akt, NFκB, Fas and caspase3 in urinary exosomes. Image data were analyzed using Image Studio Ver.5.2.

Results: Among the IgG4-RUD inpatients, two were diagnosed of retroperitoneal fibrosis, one of IgG4-related kidney disease and the other of IgG4-related ureteral lesion. All patients denied diabetes mellitus, other autoimmune disease and cancer history. Mean

disease duration was 67.5 months(6-120). For clinical parameters, mean serum IgG4 was 12307.5mg/L(3030-17900), IgG 27.76g/L(22.02-38.06), SCr 419.1μmol/L(146-690), and 24hUP 0.93g(0.43-1.23). Serological inflammatory markers as ESR 59.75mm/h(8-109), hsCRP 3.18mg/L(2.12-7.16). All patients were disease active with mean RI of 8(6-10). Compared with DC or HC group, the mean expression of PI3K(5300 vs 22.55 vs 437), Akt(22200 vs 1935 vs 2008), NF-κB(5455 vs -22.5 vs 259) and Fas(11517.5 vs 67.35 vs 176) were all obviously higher in urinary exosomes of IgG4-RUD, and caspase3 was expressed only in the ureteral lesion patient. mTOR was not detected.

Conclusions: Urinary exosomes could be a noninvasive injury indicator for IgG4-RUD, and PI3K/Akt/NFκB signaling pathway might play a part in tissue injury.

Multiparametric MRI for Assessment of CKD: Correlation with Histology and Progression

Charlotte E. Buchanan,[1] Huda Mahmoud,[3,2] Eleanor Cox,[1] Benjamin L. Prestwich,[1] Nicholas M. Selby,[3,2] Maarten W. Taal,[3,2] Susan Francis.[1]
[1]Sir Peter Mansfield Imaging Centre, University Park, University of Nottingham, Nottingham, United Kingdom; [2]University of Nottingham, Derby, United Kingdom; [3]Royal Derby Hospital Renal Unit, Derby, United Kingdom.

Background: Multiparametric Magnetic Resonance Imaging (MRI) allows non-invasive assessment of renal structure and function in CKD. Here, MR results are correlated with biopsy and clinical measures at baseline, with repeat scanning after 1 year to assess progression.

Methods: 26 CKD patients (Stage 3-4, eGFR 20–59ml/min/1.73m^2, 19M, 56±15yrs) were scanned within a median 53 days from renal biopsy, data were also collected on age-matched healthy volunteers (HVs). At baseline, patients were scanned twice, two weeks apart, to assess reproducibility. Histological fibrosis quantification was performed on renal biopsies with sirius red staining to measure % interstitial fibrosis (IF). GFR was determined using Iohexol clearance and urine PCR was measured. Clinical and MRI assessments were repeated at 1 year. Scanning was performed on a 3T Philips Ingenia scanner and included T1 mapping and diffusion weighted imaging as markers of fibrosis and inflammation, arterial spin labelling to assess perfusion, T2* mapping as a marker of oxygenation, and measures of kidney volume and renal artery flow. Analysis was performed using in-house software to create multiparametric maps. Baseline MR data were assessed against clinical measures and biopsy results, year 1 data was analysed to assess progression.

Results: Cortex T1 was significantly increased in CKD patients compared to HVs (CKD:1559±18,HV:1435±19ms, p<0.001). Cortex diffusion was reduced in CKD patients, but not significantly. There was no significant difference in kidney volume or T2* between CKD patients and HVs. Cortex perfusion (CKD:86.8±10,HV:199.5±12ml/100g/min) and renal artery flow (CKD:156.9±10,HV:227.4±10ml/100g/min) were significantly lower in CKD (p<0.001). GFR was correlated with cortex perfusion, diffusion, T1 and renal artery flow. The strongest MRI measure to correlate with IF score was perfusion, whilst glomerular sclerosis correlated with cortex T1. The mean GFR did not vary significantly across 1 year, however patients fell into 2 groups; those with improved (n=8) and declined (n=12) renal function. There was a trend for change in T1 to be associated with progression of disease severity.

Conclusions: This work demonstrates MRI can differentiate pathophysiological changes in CKD and can be used as a method to assess progression of CKD.

TH-PO909

SerpinA3K Is Abnormally Found in Urine of Patients with CKD from Different Etiologies

Andrea Sanchez-Navarro,[1,2] Rosalba Pérez-villalva,[1,2] Juan M. Mejia-Vilet,[2] Diego L. Carrillo Perez,[2] Gerardo Gamba,[1,2] Norma Bobadilla.[1,2] *[1]Molecular Physiology Unit, México, Mexico; [2]IIB UNAM/INCMNSZ, Mexico, Mexico.*

Background: We previously identified serpinA3K by high-resolution mass spectrometry as an early biomarker of acute kidney injury to CKD transition in rats. This study was designed to determine whether serpinA3K could be abnormally detected in urine from CKD patients and to evaluate its specificity in kidney diseases, compared with urines from patients with other pathologies without renal dysfunction.

Methods: We included 74 patients with CKD of different etiologies such as: FSGS, class III, IV or V lupus nephritis (LN), ANCA associated vasculitis (AAV), and diabetic nephropathy (DN) that were compared with 10 healthy volunteers. In addition, we included 17 patients with other pathologies and normal renal function: hepatic cirrhosis (HC), pancreatitis (Pan), and rheumatoid arthritis (RA). SerpinA3K was evaluated in urine (Western blot) and in renal biopsies (immunohistochemistry).

Results: In HC, Pan and RA patients without renal dysfunction urine serpinA3K was not detected. In Table 1 are the main results of the CKD patients. In addition, immunohistochemistry analysis showed that serpinA3K was expressed in tubular epithelial cells, and translocated from the cytoplasmic region to the luminal membrane in CKD patients.

Conclusions: Urinary serpinA3K was detected in all patients with CKD. Urine serpinA3K titers closely correlated with the renal fibrosis observed by histopathological analysis (p<0.0001). Moreover, this biomarker was able to differentiate between class III/IV and class V LN, in spite of severe proteinuria in these patients. These results suggest that urine serpinA3K comes from damaged kidney cells and could be used as a specific biomarker of ongoing renal inflammation, fibrosis and therefore CKD. SerpinA3K is found in the urine of CKD patients from different etiologies and correlates with renal fibrosis. SerpinA3K constitutes a specific promising CKD biomarker.

Levels of Biomarkers of Extracellular Matrix Turnover in Serum and Urine Reflect the Burden of Fibrosis in Kidney Biopsies from IgA Nephropathy and ANCA-Associated Vasculitis Patients

Federica Genovese,[1] Nadja Sparding,[1] Morten A. Karsdal,[1] Doubravka Frausova,[2] Eva Honsova,[3] Vladimir Tesar,[4] Zdenka Hruskova.[5] *[1]Nordic Bioscience, Herlev, Denmark; [2]Department of Nephrology, First Faculty of Medicine, Charles University and General University Hospital in Prague, Czech Republic, Prague, Czechia; [3]IKEM, Prague, Czechia; [4]General University Hospital in Prague, Prague, Czechia; [5]Department of Nephrology, General University Hospital and First Faculty of Medicine, Charles University, Prague 2, Czechia.*

Background: Renal fibrosis is a common feature of chronic kidney disease (CKD) and is characterized by an imbalanced turnover of extracellular matrix (ECM) components. It is associated with progression to end-stage renal disease, the need for dialysis or renal transplantation and with mortality. ECM biomarkers describing the morphological changes in the kidney tissue are potentially detectable in serum and urine before markers of loss of kidney function, such as serum creatinine, due to the fact that changes in the tissue precede and are the cause of changes in function.

Methods: The cohort consisted of 49 and 47 patients with IgA nephropathy (IgAN) and anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), respectively. We measured a fragment of collagen type III degradation generated by MMP-9 (C3M) and a fragment of type VI collagen formation, the C5 domain of the α3 chain (PRO-C6), in paired serum and urine samples using novel ELISAs. Renal biopsies were taken at the time of sample collection. Interstitial fibrosis was quantified according to the Banff classification, and in addition, scored according to the MEST-C classification (IgAN) or classified based on AAV morphology (AAV).

Results: Urinary C3M inversely correlated (r=-0.43, p<0.0001) and PRO-C6 (in urine and serum) correlated (r=0.51, p<0.0001 and r=0.35, p=0.0009, respectively) with the level of histological fibrosis in the kidney. Whereas urinary C3M decreased, PRO-C6 increased with CKD stages and Banff scores in both patients with IgAN and AAV. In IgAN patients, urinary C3M and PRO-C6 (in urine and serum) gradually decreased and increased, respectively, with interstitial fibrosis/tubular atrophy according to MEST-C. In addition, all three ECM markers were able to separate the AAV patients with biopsies classified as sclerotic from patients with biopsies classified as focal.

Conclusions: In this study, we demonstrated that C3M and PRO-C6, novel biomarkers of ECM turnover, not only correlated with decline in kidney function, but actually reflect the burden of fibrosis in the kidneys, as confirmed by the association with the extent of kidney fibrosis in biopsies.

Sequential Changes of Gut Microbiota According to the Stages of CKD

Ji Eun Kim,[1] Ji In Park,[2] Hyunjeong Cho,[3] Dong Ki Kim,[1] Seung Hee Yang,[4] Jung Pyo Lee,[5] Yon Su Kim,[1] Hajeong Lee.[1] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Kangwon National University Hospital, Chuncheon-si, Republic of Korea; [3]Chungbuk National University Hospital, Cheongju-si, chungcheongbuk-Do, Republic of Korea; [4]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [5]Seoul National University Boramae Medical Center, Seoul, Republic of Korea.*

Background: Recent evidences suggest that the microbiome profile is altered in patients with end-stage renal disease (ESRD) compared to healthy population. However,

sequential changes of gut microbiota according to the stages of chronic kidney disease (CKD) have been explored rarely.

Methods: We prospectively enrolled 139 patients including CKD patients underwent kidney biopsy, ESRD patients waiting for kidney transplantation, and 35 kidney donors from three tertiary hospitals. The composition of microbiota was analyzed using extracted metagenomic DNA from the feces by Illumina MiSeq system. Estimated glomerular filtration rate (eGFR) was calculated using CKD-EPI equation.

Results: Total of 194 subjects were enrolled and divided into 4 groups according to their renal function as follows; 55 healthy control, 47 CKD stage 1-2, 42 stage 3-5 without receiving dialysis, and 50 stage 5 with maintenance dialysis. The mean eGFR of each groups were 103.4±15.2, 93.3±17.4, 29.6±20.4, and 7.1±2.5 mL/min/1.73 m^2, respectively. The bacterial operational taxonomic units, diversity and richness were significantly different among 4 groups. Next, we compared 35 genera, which account for more than 1% of the sample composition in at least 1/10 of the total samples, among groups. Fourteen of the 35 genus groups showed significant differences among groups. Among those genera, *Alistipes, Pseudoflavonifractor, Ruminococcus_g4* and *Hungatella* showed statistically significant increasing trend according to CKD groups and *Lachnospira*, *Dialister* and *Haemophilus* showed statistically significant decreasing trend according to the CKD groups with or without CKD 5D. *Blautia* showed an increasing trend according to the CKD group, but when the CKD 5D was included, the trend disappeared. Compared with CKD3-5ND and CKD 5D, *Prevotella, Bifidobacterium* and *Agathobacter* decreased after dialysis, and *Clostridium* and *Pseudoflavonifractor* increased after dialysis. The genera showing a change by dialysis and the genera showing a trend according to CKD stage showed different patterns except for *Pseudoflavonifractor*.

Conclusions: We found specific fecal microbiotas that changed according to the CKD stage, and they differed from the microbiota which was altered by dialysis. Further studies on the association of these microbiotas with CKD progression are needed.

TH-PO912

Glycolysis Inhibitors Suppress Renal Interstitial Fibrosis via Divergent Effects on Fibroblasts and Tubular Cells in Kidneys

Qingqing Wei,[1] Jennifer J. Su,[3] Zheng Dong.[2] *[1]Medical College of Georgia, Augusta University, Augusta, GA; [2]Medical College of Georgia, Augusta, GA; [3]Augusta University, Martinez, GA.*

Background: Renal interstitial fibrosis is a common pathological feature of chronic kidney disease that may involve changes of the metabolism in kidney cells.

Methods: In this study, we first showed that blockade of glycolysis with two inhibitors [Dichloroacetate-DCA and shikonin] reduced renal fibrosis in the mouse model of unilateral ureteral obstruction (UUO).

Results: Both inhibitors evidently suppressed the induction of fibronectin and collagen 1 in obstructed kidneys, while DCA also showed inhibitory effect on collagen IV and a-SMA. Histological examination also confirmed less collagen deposition in DCA treated kidneys. We also examined renal apoptosis by TUNEL assay and identified significant suppression of apoptosis after glycolysis blockage by both DCA and shikonin. We further examined their effects on fibrotic changes in cultured renal proximal tubular BUMPT cells and renal NRK-49F fibroblasts (cells). While glycolysis inhibitors reduced fibronectin and a-SMA production in NRK-49F cells, no obvious effect or even induction of fibronectin or a-SMA was detected in BUMPT cells during TGF-b1 or hypoxia stimulation.

Conclusions: Altogether, these results suggest that inhibition of glycolysis may reduce renal interstitial fibrosis by suppressing renal apoptosis and fibrotic alterations in fibroblasts.

Uremic Toxin Decreases Intestinal Defense Peptides and Barrier Functions in Chronic Renal Failure Mice

Minoru Satoh,[1] Seiji Itano,[1] Megumi Kondo,[2] Yoshihisa Wada,[2] Hiroyuki Kadoya,[1] Tamaki Sasaki,[1] Naoki Kashihara.[1] *[1]Kawasaki Medical School, Kurashiki, Japan; [2]Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Japan.*

Background: Alterations of intestinal bacterial flora and intestinal barrier function in chronic kidney disease (CKD) have been reported to affect on uremic toxin influx. However, alteration mechanisms of microbiota and intestinal barrier have not been elucidated. Antimicrobial peptide contributes to maintenance of microbiota. We examined whether uremic toxin decreases intestinal antimicrobial peptide and barrier function in chronic renal failure model mice.

Methods: We used male ICR-derived glomerulonephritis (ICGN) mice for renal failure group. Gene expression in ascending colon was analyzed by microarray analysis and quantitative real-time PCR (qPCR). Gene expression patterns of a whole bacterial flora in the intestine were analyzed by terminal restriction fragment length polymorphism analysis method. Fecal and serum bacteria products (phenol, para-cresol, indole/indole sulfateand skatole) were examined by quantitative chemical analysis. In vitro experiment, Caco-2 cells were exposed to indoxyl sulphate at clinically relevant concentrations (0.1-0.5 mM). Expressions of defensins and tight junction molecules were analyzed by qPCR and ELISA.

Results: Microarray analysis showed antimicrobial peptide, defensin, significantly decreased in ICGN mice. Defensin alfa1 and beta1 mRNA expressions in ascending colon were reduced in ICGN mice compared with control mice. The ratio of pathogenic bacteria clostridia was increased, and the ratio of opportunistic pathogen bacteroides was decreased in intestinal bacterial flora of ICGN mice. Fecal bacteria products phenol and para-cresol were increased in feces of ICGN mouse. Barrier function associated molecules, such as C-type lectin and tight junction, were significantly decreased in ICGN. Intestinal permeability in ICGN was increased compared to ICR mice. Indoxyl sulphate significantly decreased the expressions of C-type lectin and tight junction in Caco2 cells. Indoxyl sulphate also significantly decreased defensin mRNA and protein expression in Caco2 cells.

Conclusions: Uremic toxin decreases intestinal antimicrobial peptides which induce gut microbiome alteration in CKD. Uremic toxin also decreases intestinal barrier function molecules which increase Intestinal permeability in CKD. Both are combined and contribute to the loss of intestinal barrier function in CKD.

Hyperoside Diminishes Tubulointerstitial Fibrosis in Obstructive Nephropathy via Targeting Pericyte-Myofibroblast Transition

Yigang Wan, Wei Wu. *Department of Traditional Chinese Medicine, Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Nanjing, China.*

Background: Pericyte-myofibroblast transition (PMT) plays an important role during the progression of tubulointerstitial fibrosis (TIF) in chronic kidney disease (CKD). Blocking PMT has been recognized as a potential target for anti-fibrotic therapy. In China, hyperoside (HYP), a bioactive component of *Abelmoschus manihot*, has been frequently used to treat TIF in CKD patients. However, the therapeutic mechanisms *in vivo* of the dose-effects of HYP on TIF by targeting PMT and its signaling activation remained unclear.

Methods: Twenty-five rats were divided into 5 groups, the sham, the vehicle, the high dose of HYP, the low dose of HYP and the imatinib groups. The different doses of HYP, imatinib and distilled water were administrated with intraperitoneal injections or oral for 2 weeks before and after the induction of TIF by unilateral ureteral obstruction (UUO), respectively. Rat's general status, 24 h urinary protein, urinary *N*-acetyl-beta-*D*-glucosaminidase, blood biochemical parameters, tubulointerstitial morphological changes, the markers of PMT such as platelet-derived growth factor receptor (PDGFR)β, α-smooth muscle actin (αSMA) and vimentin, as well as the key signaling molecular expressions in PDGFR pathway and vascular endothelial growth factor receptor (VEGFR) pathway in the kidney were observed, respectively.

Results: TIF was induced in the obstructed kidneys of the UUO model rats. PMT was triggered, marked by the increased expressions of PMT markers in peritubular pericytes. In addition, TIF was aggravated by PMT and could be significantly improved by the high dose of HYP and imatinib *in vivo*, reflected by inhibiting PMT markers' expressions in peritubular pericytes and attenuating ECM accumulation and collagen deposition in renal interstitium. HYP and imatinib could block PMT through inhibiting PDGFR and VEGFR signalings activation. Furthermore, the effects of HYP at the high dose were partially superior to those of imatinib.

Conclusions: In this study, we clarified that the high dose of HYP, superior to imatinib, can attenuate TIF through blocking PMT and inhibiting the key signaling molecular expressions in PDGFR and VEGFR pathways. These findings may partly explain the therapeutic mechanisms of HYP in treating CKD, and further suggest that targeting PMT and its signaling activation may provide new strategies for TIF treatment in CKD.

Honokiol decreases TGF-β1 Induced Renal Fibroblast Activation by Regulation of TGF-β1/Smad Signaling Pathway

Woong Park, Won Kim, Kyung Pyo Kang. *Chonbuk National University Medical School, Jeonju, Republic of Korea.*

Background: In progressive renal disease, tubulointerstitial fibrosis is a final common feature. These fibrotic process is characterized by inflammation, excessive extracellular matrix deposition and organ dysfunction. Modulation of renal fibrogenesis may be one of the promising therapeutic targets for attenuating the progression of chronic kidney diseases. Honokiol is a natural biphenolic compound derived from the bark of magnolia trees and has anti-inflammatory, anti-oxidative, anti-tumor and neuroprotective effects. In this study, we investigate the effect of honokiol on TGF-β1-induced real fibroblast activation and unilateral ureteral obstruction (UUO)-induced renal fibrosis.

Methods: Renal fibrosis was induced by UUO in the six-week-old C57BL/6 mice for 10 days. Honokiol (5 mg/kg) was treated by intraperitoneal injection for 7 days before induction of renal fibrosis and continued for 10 days. Histologic examination and Western blot analysis for α-smooth muscle actin (α-SMA), type I collagen and intercellular adhesion molecule (ICAM)-1 were performed. *In vitro* experiments were performed using rat renal fibroblast cell line (NRK-49F cells). Cell proliferation and migration were evaluated by XTT assay and wound healing assay. TGF-β1-induced renal fibroblast activation was evaluated by Western blot analysis.

Results: Treatment of TGF-β1 increased significantly proliferation and cell migration of NRK-49F cells compared to that of vehicle treated cells. Honokiol treatment decreased TGF-β1-induced renal fibroblast proliferation and activation in a dose dependent manner. TGF-β1 treatment increased the levels of phospho-Smad2 and 3 in NRK-49F cells, and honokiol significantly decreased the levels of phosphorylation of Smad2 and 3. In in vivo experiment, honokiol decreased UUO-induced renal tubular injury and renal fibrosis. Honokiol also decreased UUO-induced renal inflammation by regulation of phosphorylation of NFκB p65.

Conclusions: These results suggest that honokiol has a beneficial effect on UUO-induced tubulointersitial inflammation and fibrosis by regulation of TGF-β1/Smad signaling pathway.

Funding: Government Support - Non-U.S.

TH-PO916

6-BIO Attenuates TGFβ-Induced Fibrosis by Suppression of Transcription Factor AP-1 and SP-1 of Plasminogen Activator Inhibitor Type-1 in the Human Renal Proximal Tubular Epithelial Cells

Jung Sun Park,[1] Hoon In Choi,[2] Donghyun Kim,[3] Eun Hui Bae,[3] Seong Kwon Ma,[2] Soo Wan Kim.[2] *[1]Chonnam National University, Gwangju, Republic of Korea; [2]Chonnam National University Medical School, Gwangju, Republic of Korea; [3]Chonnam National University Hospital, Gwangju, Republic of Korea.*

Background: PAI-1 is expressed at high levels in several both acute and chronic kidney diseases, and leading to activation of lung, liver, kidney fibrosis. We investigated whether 6-BIO, a glycogen synthase kinase-3β inhibitor, attenuates fibrosis by PAI-1 inhibition in TGFβ-induced proximal tubular (HK2) cells injury.

Methods: The effects of 6-BIO in TGFβ-induced cell fibrosis were determined using human renal proximal tubular epithelial (HK-2) cells. The effects of TGFβ and 6-BIO on cell viability were determined using EZ-CyTox assays. The protein and mRNA expression of PAI-1, Collagen I, Collagen IV, CTGF, SMAD, PI3K/AKT, MAPK, and NF-κB was determined by semiquantitative immunoblotting and RT-PCR. To study the factors that regulation of PAI-1 expression, we analyzed the promoter activities of transcription factors AP-1 and Sp-1 were determined by luciferase assays.

Results: Treatment of TGFβ increase expression of PAI-1, Collagen I, Collagen IV, and CTGF in HK-2 cells. Furthermore, TGFβ-treatment induces the activation of p-SMAD2/3, SMAD4, p-AKT, p-ERK1/2, p-p38, and p-JNK MAPK signal pathway as well as NF-κB nuclear transactivation. AP-1 and SP-1 promoter luciferase activity is increase by TGFβ treatment. 6-BIO pretreatment decreases PAI-1, Collagen I, Collagen IV, CTGF fibrotic protein expression in TGFβ-induced HK-2 cells. 6-BIO decreases the increased NF-κB nuclear transactivation, p-SMAD2/3, SMAD4, p-AKT, p-ERK1/2, p-p38, and p-JNK MAPK pathway in HK-2 cells. Additionally, pretreatment of 6-BIO attenuates AP-1 and SP-1 promoter activity.

Conclusions: Treatment of 6-BIO may exert anti-fibrotic effect by controlling SMAD, PI3K/AKT, MAPK, and NF-κB signal pathways via inhibition of the transcription factor AP-1 and SP-1 of PAI-1 in TGFβ-treated HK-2 cells.

Lymphangiogenesis Within Kidney and Its Draining Lymph Nodes Mediates Renal Inflammation and Fibrosis

Pei Guangchang,[2] Rui Zeng,[1] Gang Xu.[2] *[1]Tongji Hospital, Huazhong Univ of Science and Technology, Wuhan, China; [2]Tongji Hospital, Tongji Medical College, Huazhong 9 University of Science and Technology, Wuhan, China.*

Background: Lymphangiogenesis has been reported in kidney transplant and chronic kidney diseases (CKD). Here, we demonstrate a crucial role for the newborn lymphatic vessels (LVs) within kidney and its draining lymph nodes (RDLNs) in driving intrarenal inflammation and fibrosis.

Methods: In the present study, we examined the lymphangiogenesis within kidney and RDLNs in different renal interstitial fibrosis models. Conditional knockdown of LVs in LYVE-1-Cre/iDTR mice and knockdown of lymphangiogenesis by sVEGFR3-FC or sLYVE-1-FC were adopted to observe the relationship between LVs with renal inflammation and fibrosis. CCR7 neutralizing antibody were used to blocking CCR7/CCL21, to further explore the role of CCR7/CCL21 in immunocytes recruitment.

Results: Lymphangiogenesis occurs in kidney and its DLNs after renal injury, which mainly results from the local proliferation of pre-existing lymphatic endothelium. The newborn LVs like the inherent LVs essentially express C-C chemokine ligand 21 (CCL21). The expansive LVs system play an important role in the recruitment of more CCR7+ dendritic cells(DCs) and lymphocytes into RDLNs and spleen, and finally inducing systemic lymphocyte expansion. Blocking CCR7+ cell recruitment into RDLNs and spleen by genetically or biologically knockdown of LVs, or inhibiting CCR7+ cell expansion using CCR7 neutralizing antibody, attenuated intrarenal inflammation and fibrosis.

Conclusions: We show a previously unidentified role for lymphangiogenesis in regulating intrarenal inflammation and fibrosis, which uncovered novel strategies for preventing CKD progression.

Inhibition of Fibronectin Polymerization Attenuates Ischemia-Induced Kidney Fibrosis

Stephanie L. Bowers, Stephanie Davis, Valeriia Rudomanova, Qing Ma, Prasad Devarajan, Burns C. Blaxall. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Fibrosis is a hallmark of chronic kidney disease (CKD), regardless of pathophysiologic origin. After injury, activation of tissue fibroblasts leads to increased extracellular matrix (ECM) deposition and adverse tissue remodeling. Fibronectin (FN) is a vital component of the ECM that orchestrates the composition and organization of numerous matrix and cell surface proteins. The current study tested the hypothesis that treatment with the peptide pUR4, which inhibits cell-mediated FN polymerization, would mitigate ischemia-induced tissue remodeling and preserve renal morphology.

Methods: A mouse model of unilateral ischemia/reperfusion (UIR) injury was created by placement of an atraumatic clamp on the left renal artery for 30 minutes, followed by 14 days of reperfusion. Daily IP injections of pUR4 (25mg/kg), control inactive peptide (III-11C; 25mg/kg) or PBS were started on the same day (concomitant), or 7-days post-UIR (delayed). After 14 days, mice were sacrificed and both the left (injured) and right (uninjured) kidneys were collected; animals were assessed for evidence of injury by histology and immunofluorescence.

Results: Inhibition of FN polymerization with delayed (but not with concomitant) pUR4 treatment decreased renal FN expression and deposition following UIR (1.0 (III-11C) vs. 0.56 (pUR4), p=0.01, n=4 each). Delayed pUR4 administration alleviated the characteristic UIR-induced decrease in kidney weight (5.4 vs. 6.5mg/kg body weight, p=0.009; n=12 for III-11C, n=14 for pUR4). Moreover, delayed pUR4 decreased cortical fibrosis (by picrosirius Red staining) compared to III-11C (12.1 vs. 6.0%, p=0.0009, n=12 or 14, respectively) but not medullary fibrosis (20.2 vs. 14.4%, p=0.18). Histologic evaluation also revealed preserved tubule morphology with delayed pUR4 treatment.

Conclusions: Collectively, these experiments provide evidence that decreasing FN polymerization may attenuate the progression of CKD following renal ischemic injury.

Inhibition of Fibronectin Fibrillogenesis Attenuates Progression of Fibrosis in Animal and Kidney Organoid Models

Cuiyan Xin,[2] Navin R. Gupta,[3] Amrendra K. Ajay,[1] Akinwande A. Akinfolarin,[1] Edgar Garcia,[1] Ryuji Morizane,[1] Joseph V. Bonventre,[1] Venkata Sabbisetti.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [3]Brigham & Women's Hospital/ Massachusetts General Hospital, Brighton, MA.*

Background: Renal fibrosis is the principal pathological process underlying the progression of chronic kidney disease (CKD) to end-stage renal disease (ESRD). Fibronectin (FN) assembly is required for collagen matrix deposition and localized activation of TGF-ß. We hypothesize that interfering with FN polymerization would attenuate fibrosis in *in vitro* and *in vivo* kidney fibrosis models.

Methods: Mice were subjected to unilateral ureteral obstruction (UUO) and treated with fibronectin polymerization blocking peptide (pUR4) and control peptide (CIII-11C) to evaluate the therapeutic benefit of blocking FN assembly in attenuating or reversing fibrosis progression. We evaluated the efficacy of pUR4 peptide in attenuating kidney fibrosis in two different treatment modalities. In parallel treatment model, we evaluated the therapeutic efficacy in halting or slowing the progression of fibrosis by injecting pUR4 (i.p, 100 mg/kg) & CIII-11C (i.p, 100 mg/kg) from day 5 - day 10 post-UUO every day. In successive treatment model, we evaluated the efficacy of the pUR4 in halting or reversing the established fibrosis by giving pUR4 from day 10 – day 15 post-UUO. Mice were sacrificed at the end of the study and urine, blood and tissues were collected. Efficacy of pUR4 peptide was also evaluated in cisplatin induced kidney organoid models of fibrosis.

Results: *In vivo*, pUR4-treatment reduced fibrosis in both parallel and successive model of UUO induced fibrosis. pUR4 treated mice display reduced picrosirius red staining as compared to & CIII-11C treated mice in both treatment modalities. There was a corresponding decrease in urinary markers including KIM-1, MCP-1, IL-6, NGAL and microalbumin in pUR4 treated mice in both the models. Levels of collagen 1, α-SMA and CTGF were significantly reduced in pUR4 treated mice in both the models. In kidney organoids, pUR4 treatment diminished fibrilogenesis and accumulation of fibronectin and collagen after repetitive cisplatin injury induced fibrosis.

Conclusions: In the current study, we demonstrated that blocking fibronectin fibrillogenesis halts progression of kidney disease in experimental models of kidney fibrosis. Thus, interfering with the FN polymerization may offer a new therapeutic strategy for treating kidney fibrosis

SMOC2 Mediates Renal Fibrosis by Activation of Inflammation and Fibroblast to Myofibroblast Differentiation

Cuiyan Xin. Vaidya Lab *Brigham and Women's Hospital, Harvard Medical School, Boston, MA.*

Background: Fibrosis is a common end stage of nearly all chronic inflammatory organ diseases including chronic kidney diseases (CKD). Secreted modular calcium-binding protein 2 (SMOC2) belongs to the secreted protein acidic and rich in cysteine (SPARC) family of matricellular proteins whose members are known to modulate cell-matrix interactions. SMOC2 has been shown to contribute to CKD by regulating

initiation and progression of kidney fibrosis. We therefore investigated the mechanisms responsible for signaling activation pathways by SMOC2 resulting in its fibrogenic effect.

Methods: To determine SMOC2 expression in CKD, three mice CKD models were employed: ***Alport nephropathy mice model (caused by a null mutation of the a3*** chain of collagen type IV), RNA-Seq was performed to determine extracellular matrix genes in this model; ***Parabiotic aging model*** generated by parabiosis sugery for 4 weeks and unilateral ureter obstruction (UUO) surgery in 5 and 10 days, separately; ***Sequential ischemia-nephrectomy CKD model*** was generated by bilateral ischemia reperfusion (Bi-IRI) and unilateral nephrectomy surgeries time-dependently. RT-PCR and western-blot were employed to determine fibrotic gene mRNA and protein expression in these three models. To investigate the mechanism of SMOC2 triggered fibrogenesis and activation of fibrogenic signaling pathways, SMOC2 protein was used to stimulate interstitial fibroblasts and human primary proximal tubular epithelial cells.

Results: We found that SMOC2 is in the top 10 DEGs of extracellular matrix genes in Alport mice. SMOC2 gene and protein were highly expressed in Col4a3 knockout (KO) mice tissue compared to wildtype (WT) mice. Furthermore, SMOC2 over expression in fibrosis was also confirmed in parabiotic-UUO kidney disease model and in-house developed CKD model. Mechanistically, SMOC2 activates Smad and MAPK signaling in fibroblast and proximal tubular epithelial cells, which are both inhibited by TGFbRI inhibitor (SB431542) and MAPK p42/44 inhibitor (U0126). SMOC2 also promotes inflammatory gene expression such as IL-6 and TNFa.

Conclusions: SMOC2 is a key signaling molecule mediating fibrogenesis, and modulating of SMOC2 may provide a new potential therapeutic target for chronic kidney diseases.

K-Cadherin Expression Regulates Activation State of Transcription Factors in the Presence and Absence of TGF-β1

Kameljit K. Kalsi,[1] Seema Jain,[1,2] Mysore K. Phanish,[1,2] Mark E. Dockrell.[1]
[1]South West Thames Institute for Renal Research, Carshalton, United Kingdom; [2]Epsom and St Helier University Hospitals NHS Trust, Carshalton, London, United Kingdom.

Background: K-cadherin (Cadherin 6) is an atypical type I cadherin with high expression in the kidney where it is exclusively expressed in the proximal tubule. Unlike other cadherins in the tubule K-cadherin is expressed basally directly adjacent to the basement membrane. Disruption and loss of renal K-cadherin expression is associated with progressive diabetic nephropathy. Disruption of the precise cellular localisation has been reported in Renal Cell Carcinoma. Recently we have reported a similar disruption in biopsies from renal transplants. The alteration of K-cadherin expression in cancer and fibrosis suggests a potential role in regulating gene expression.

Methods: HKC clone 8 cells, a transformed human PTEC line which do not have detectable K-cadherin protein, were transfected with human K-cadherin pcDNA3.1 expression vector (1µg). Cells were fixed and stained for K-cadherin and visualized by using a 3D deconvolution microscope. Primary human PTECs (K-cadherin positive), control HKC8 (HKC8 K-) and transfected HKC8 cells (HKC8 K+) were grown on non-coated plastic and collagen IV coated dishes and exposed to 2.5 ng/ml TGF-β1 for 5 min before cells were lysed and analysed by western blot.

Results: HKC8 K+ cells showed K-cadherin expression similar to that expected in primary cells, localised in vesicular Golgi-type structures as well as at the cell periphery and was predominantly found in the basal layer. Regulation of important transcription factors Elk1, Erk5a & Erk5b were investigated. TGF-β1 induced an increase of phospho-Elk1 in HKC8 K- cells grown on collagen IV but a reduction in phospho-Elk1 in HKC8 K+ cells. The expression of K-cadherin had no effect on TGFβ-induced phospho-Elk1 in cells grown on plastic. In primary PTECs grown on collagen IV TGFβ1 reduced phospho-Elk1 levels. Although TGFβ1 induces phosphorylation of Erk5a it has no effect on the levels of activated (phosphorylated) Erk5b. However, the expression of K-cadherin alone significantly increased phospho-Erk5b.

Conclusions: The basal expression of K-cadherin appears to be critical in regulating transcription factor activation in human primary proximal tubule cells due, at least in part, to its interaction with collagen IV. Disrupted expression seen in cancer and during renal injury will result in alteration of gene activation and cellular responses.

TH-PO922

Latent Transforming Growth Factor Beta Binding Protein 4 (LTBP4) Deficiency Attenuates the Severity of Renal Fibrosis

Chi-Ting Su,[1,2] Jenq-wen Huang.[1] *[1]Renal Division, National Taiwan University Hospital, Taipei, Taiwan; [2]Human Genetics, University of Pittsburgh, Pittsburgh, PA.*

Background: Transforming growth factor beta (TGFβ) has been proved to be related to fibrosis including renal fibrosis that is characterized by the accumulation of extra-cellular matrix (ECM). LTBPs are recognized to direct and facilitate TGFβ action through several mechanisms. Moreover, the complexity of progression of renal injury remains vague. The intensive investigation of the mechanism will lead us understand the potential therapy for patients. We propose that ltbp4 can be an essential regulatory factor in renal injury because of its variety.

Methods: To create renal fibrosis model, we did unilateral ureteral ligation (UUO) in mice and check echocardiography to exam the cardiac contractility every other weeks. *Ltbp4S-/-* mice were used to investigate the potential regulatory role of ltbp4 in renal fibrosis related to TGFβ signaling. Protein and RNA extraction were collected for real-time PCR, RNA-Seq, and down-stream signaling, protein-protein interaction, and proteomics analysis.

Results: Up-regulation of ltbp4 had been noted 14 days after UUO at gene and protein levels. The major area of ltbp4 expression in the renal tissue was around proximal tubules areas and glomerular area was absent of expression. In addition, α-smooth muscle actin (SMA), kidney Injury Molecule-1 (KIM-1) and monocyte chemoattractant protein-1 (MCP-1) expression at mRNA level increased significantly following the UUO surgery but in ltbp4S-/- mice, the expression had been drastically reduced. KIM-1, pSMAD2, pEKR and platelet-derived growth factor receptors beta (Pdgfrb) were increasing at protein levels after renal injury. Immunofluorescence staining studies revealed less expression of Pdgfrb, F4/80 and collagen I in ltbp4S-/- mice. TGFB receptors are speculated to be interacted with ltbp4, leading to abnormal down-stream signaling in ltbp4-deficient environments.

Conclusions: Reduced macrophage infiltration had been noted in renal injury tissue among post-UUO surgery *ltbp4S-/-* mice. Moreover, renal myofibroblasts expressed less Pdgfrb. In ltbp4-deficient environment, the severity of inflammation and renal injury induced by UUO can be reduced.

Cleavage of the Matricellular Regulators of Fibrosis, CCN2, and 3 at the Third Intermodular Junction

Abigail Dear,[1] Mysore K. Phanish,[3] Frederick W. Tam,[2] Mark E. Dockrell.[1]
[1]South West Thames Institute for Renal Research, Surrey, United Kingdom; [2]Imperial College Kidney and Transplant Institute, London, United Kingdom; [3]Epsom and St helier University Hospitals NHS Trust, Carshalton, London, United Kingdom.

Background: CCN proteins are modular matricellular factors with roles in cancer and fibrosis. Members of the family consists of 4 modules encoded by 4 exons. The strucuture contributes to their role regulating interactions between cells and matrix. CCN2/CTGF is a fibrogenic factor with actions in the lung, liver, skin and kidney. CCN3 is reported to counterbalance the actions of CCN2. We have previsouly described the expression and anti-fibrotic effects of CCN3 on proximal tubule cells when we also identified a truncated form consisiting of just the first 3 modules. Here we investigate the enzymatic truncation of both CCN2 & 3 and the resultant effects.

Methods: Human primary proximal tubules were cultured on collagen IV. Protein expression was determined by western blotting and immunofluorescent microscopy. Bioinformatic analysis to identify potential cleavage sites was performed using expasy peptide cutter.. Mass spectrometry was carried out using 2D nano ES-MS/MS analysis after trypsin digestion.

Results: Enzymatic cleavage sites were identified between modules 3 & 4 of CCN2; two for glutamyl peptidase, and one each for HIV-1 retropepsin and MMP9. Accumualtion of secreted full-length CCN2 following TGFβ1 treatment dropped by 72 h following MMP9 induction. We hypotheised MMP9 was cleaving the protein. Co-incubation with the MMP9 specific inhibitor prevented the fall in full length molecule. Full length hrCCN2 potentiated TGFβ-induced fibronectin expression while the 4th module of CCN2 reduced TGF β-induced fibronectin in primary PTEC in culture. Enzymatic cleavage sites were identified between modules 3 & 4 of CCN3 including two for cathepsin K and one for MMP9. Inhibition of MMP9 did not alter the amount of CCN3. Mass Spec analysis of the 39KDa CCN3 isoform also suggrested cathepsin K.Cathepsin K is known to be induced by members of the TGFβ family.

Conclusions: The enxymatic cleavage of CCN2 & 3 acts a postranslational modiification altering the nature of the proteins..Although the potentially opposing factors share a putative MMP9 cleavage site the actually cleavage is performed by different enzymes. The induction of cleavage appears to be part of an endogenous regulatory process by TGFβ. Targeting the enzymatic cleavage of CCN proteins may be an alternative therapeutic approach in fibrosis and cancer.

Fibroblast-Specific p90RSK Promotes Epithelial Transdifferentiation and Kidney Fibrosis

Ling Lin, Chaowen Shi, Kebin Hu. *Penn State University College of Medicine, Hershey, PA.*

Background: Epithelial integrity and interactions between epithelial cells and other kidney cells play important roles in maintaining normal kidney structure and environment. p90RSK, a serine/threonine kinase, is recently shown to promote diabetic endothelial dysfunction and atherosclerosis, however, the role of p90RSK in chronic kidney disease remains largely unknown.

Methods: We generated a novel fibroblast-specific p90RSK transgenic mouse (RSK-Tg) and established a fibroblast-epitheial coculture system using primary kidney fibroblasts from RSK-Tg and RSK-wt mice and human proximal tubular epithelial cells (HKC-8) to investigate the role of p90RSK in fibroblast-epitheial interactions and kidney fibrosis.

Results: First, we examined the expression of phospho-specific and total p90RSK during the course of chronic kidney injury in the classic unilateral ureter obstruction (UUO) model. It's found that p90RSK is dramatically activated, largely in the interstitial FSP-1-positive fibroblasts. We generated fibroblast-specific p90RSK transgenic mouse, RSK-Tg, and found that this mouse has normal phenotype as the littermate control (RSK-wt). However, after UUO injury, RSK-Tg mice display significantly worse tubular damage, decreased E-cadherin expression, and *de novo* activation of alpha-SMA, as well as increased fibrosis, in comparison with their littermates. We further found, in our *in vitro* fibroblast-epithelial coculture system, that RSK-Tg fibroblasts dramatically induced epithelial activation of β-catenin and its transdifferentiation into myofibroblasts, as indicated by

reduced E-cadherin and *de novo* expression of alpha-SMA. Intriguingly, blocking epithelial β-catenin using siRNA reversed epithelial transdifferentiation.

Conclusions: Thus, it is clear that fibroblast-specific p90RSK activation promotes the epithelial-to-mesenchymal transition (EMT) through activating epithelial β-catenin pathway.

The Role of miR-21/Wnt in the Development of Renal Tubulointerstitial Fibrosis Secondary to Aristolochic Acid Induced AKI

Yi Fang,[1,2] Qing Kuang,[1] Sheng Wu,[1] Ning Xue.[1] [1]*Zhongshan Hospital, Fudan University, Shanghai, China;* [2]*Shanghai Medical Center of Kidney, Shanghai, China*.

Background: AKI is increasingly recognized as a cumulative risk factor for developing advanced CKD. However, the factors governing the underlying mechanisms remain unclear. Previously we have found that the development of tubulointerstitial fibrosis after AKI was accompanied with an overwhelmed activation of miR-21 and canonical Wnt signaling, while inhibiting miR-21 or silencing Wnt ligands could partially attenuate AKI to CKD transition.

Methods: To explore the interaction between miR-21 and Wnt/β-catenin signaling, we exam the effects of genetic absence or pharmacologic inhibition of miR-21 on the expression of Wnt/β-catenin signaling pathway.

Results: In miR-21$^{-/-}$ mice, or in wild type mice treated with anti-miR-21 oligos, a significant reduction of Wnt1 and Wnt4 canonical signaling was found in the renal tissue, with partially reversal of renal interstitial fibrosis. Although renal abundance of miR-21 remains unchanged either after inhibition or activation of Wnt/β-catenin signaling, down-regulation of β-catenin with early intervention of ICG-001, a typical β-catenin inhibitor was associated with significant attenuation in renal interstitial fibrosis, protein expression of genes coding extracellular matrix as well as the downstream genes of β-catenin. Moreover, inhibiting β-catenin within 24h after aristolochic acid administration, not at a late stage, also attenuated aristolochic acid induced apoptosis and inflammation.

Conclusions: In conclusion, these results suggest that inhibiting miR-21 and β--catenin signaling may be effective approaches to preventing AKI to CKD progression.

TH-PO926

miR-214-3p Is Activated in Fibroblasts in Progressive Renal Fibrosis

James O'Sullivan, Carolynn Cairns, Bryan Conway, Laura Denby. Denby *University of Edinburgh, Edinburgh, United Kingdom*.

Background: Renal fibrosis is referred to as the final common pathway of progressive kidney disease (Humphreys 2013). miR-214-3p has been demonstrated to be an important promoter of fibrosis in experimental renal fibrosis (Denby 2014) and may function as a therapeutic target. More in-depth study of miR-214's renal cell-type specificity is needed in order to identify its deleterious mechanism in renal fibrosis. Gli1+ myofibroblasts in the kidney have recently been implicated as one of the main contributors to renal fibrosis (Humphreys 2015). The aim of this study was to identify which renal cell types express and upregulate miR-214 in response to renal injury.

Methods: Unilateral ureteral obstruction (UUO) or subtotal nephrectomy (STNx) was performed on mice (C57blk, SV129 or Gli1 reporter mice) and mice culled at 7 days (UUO), 6 or 10 weeks (STNx). During STNx model, metabolic cages were used to obtain urine. At cull, tissue was collected for RNA extraction, histology & FACS, and serum for biochemical analysis. Gene and miRNA expression was determined via qRT-PCR by specific primers and normalised to Ppia (gene) and U6 (miRNA).

Results: miR-214-3p expression significantly increased compared to sham in STNx and UUO models of renal fibrosis. This correlated with increased fibrosis histologically, pro-fibrotic gene expression (via qPCR) and biochemical markers of renal dysfunction (in STNx). Interestingly, miR-214-3p was significantly increased 6-weeks post STNx. LTL+ proximal tubular cells and Pdgfrb+ fibroblasts were found to be the source of miR-214 in UUO animals. STNx was performed on Gli1 reporter mice which revealed a significant increase in renal Gli1 (via FACS & qPCR). Here, miR-214 was upregulated with STNx in Gli1 +ve Pdgfrb -ve, Pdgfrb +ve Gli1 -ve, and dual +ve cells vs sham.

Conclusions: miR-214-3p is upregulated in proximal tubular cells, Pdgfrb+ve cells and Gli1+ve cells following renal injury. STNx kidneys had significantly increased miR-214 expression, correlating with a significant increase in Gli1+ cells within the kidney. This expands on previous work which showed Gli1+ cells to be critical in the development of renal fibrosis in UUO and IRI models, demonstrating the expansion of these cells in a progressive model of renal fibrosis. These data will facilitate the investigation of miR-214-3p's mechanism and as a therapeutic target in renal fibrosis.

TH-PO927

The Regulation of MicroRNAs on Galactose-Deficient IgA1 and Its Pathogenic Mechanism in IgA Nephropathy

Ludan Liang,[1,2] Chunhua Weng.[1,2] [1]*Zhejiang University, Hangzhou, China;* [2]*Kidney Disease Center, The First Affiliated Hospital of Zhejiang University, Hangzhou, China*.

Background: Abnormal increase of Gd-IgA1 is a recognized pathogenic factor of IgAN. Glycosylation of IgA1 is dependent on 3 key enzymes (C1GALT1, COSMC, ST6GALNAC2). Deposition of Gd-IgA1 in kidney mesangium causes IgAN, whereas the mechanism is not elucidated yet. This study focuses on how microRNA interfere IgA1 glycosylation by targeting C1GALT1, and futher leading to mesangial cell malfunction, thereby shedding light on the mechanism of IgAN.

Methods: Part 1. 1) Screen candidate miRNAs targeting C1GALT1, verification of targeted regulation by Luciferase Reporter System, RT-PCR and Western Blot; 2) Change expression level of miRNA in DAKIKI cell, detect Gd-IgA1/IgA1 in the culture medium by ELISA; 3) Stimulate Human Mesangial Cells with Gd-IgA1 in vitro, analyse cell cycle by Flow cytometry. Part 2. 1) Analyse miRNA expression in PBMC, serum Gd-IgA1 level in IgAN and HC; 2) Conduct RNA-seq of glomerulus, analyse DEGs in different kidney cell types, especially in mesangial cells. Calculate DEGs expression change in HMC stimulated by Gd-IgA1.

Results: In Part 1, We screened out 6 candidate miRNAs possibly targeting C1GALT1. miR-152 most effecienty binds to C1GALT1 3'UTR region, inhibits C1GALT1 at both transcriptional and translational level. Overexpression of miR-152 mimics in DAKIKI obviously increases the Gd-IgA1/IgA1 in the culture medium. Stimulation of HMC by Gd-IgA1 drives the cell cycle towards S phase and G2/M phase, which possibly indicates cell proliferation. In Part 2, expression level of miR-152 was much higher in PBMC of IgAN than of HC. Gd-IgA1 serum concentration was obviously higher in IgAN than in HC. Subgroup analysis revealed that IgA1/IgA ratio is related to S-score in MEST-C Oxford classification system of IgAN. RNA-seq of glomerulus revealed 4 DEGs (SERPINE1, USP2, SOX9, KLF6) closely related to mesangial cells. Stimualting HMC with Gd-IgA1 significantly increased the expression level of those 4 markers, among whom, increasement of SERPINE1 mRNA is the most remarkable, in a dose- and time-dependent manner.

Conclusions: miR-152, which is highly expressed in PBMC of IgAN patients, obstructs the glycosylation process of IgA1 by targeting C1GALT1, resulting in elevation of Gd-IgA1, which will further stimulate kidney mesangial cells, increase the expression level of mesangial cell markers, especially SERPINE1, promote cell proliferation, finally leads to IgAN.

TH-PO928

Regulation of Renal Fibroblast Migration, Contraction, and Myofibroblast Differentiation by LPA-LPA1 Signaling via Specific G Proteins

Norihiko Sakai, Koichi Sato, Taito Miyake, Akihiro Sagara, Shinji Kitajima, Tadashi Toyama, Akinori Hara, Yasunori Iwata, Miho Shimizu, Kengo Furuichi, Takashi Wada. *Department of Nephrology, Kanazawa University, Kanazawa, Japan*.

Background: Renal fibrosis is a common pathway leading to end-stage renal disease regardless of etiologies. Pathologically, tissue fibrosis is characterized by the accumulation of fibroblasts/myofibroblasts and the excessive deposition and contraction of extracellular matrix. We have previously found the lipid mediator lysophosphatidic acid (LPA) and one of its receptors, LPA_1, contributes to the development of renal fibrosis. However, the precise mechanisms by which LPA-LPA_1 signaling activates renal fibroblasts (RFBs) remain to be determined.

Methods: In this study, we focused on the direct effects of LPA-LPA_1 signaling on RFBs biologies, especially migration, contraction and myofibroblast differentiation. Cultured RFBs were used to examine cell migration, cell contraction and the expression of alpha smooth muscle actin (aSMA), a marker for myofibroblast differentiation, in response to LPA. RFBs were transfected with either LPA_1 siRNA or control siRNA to determine the impact of LPA_1 on RFBs biologies. In addition, we also investigated the involvement of G proteins in the LPA-LPA_1 signaling-associated biologies of RFBs.

Results: RFBs treated with control siRNA were attracted by LPA in a dose-dependent manner, whereas LPA did not stimulate LPA_1 siRNA-treated RFBs migration. In addition to RFBs migration, we also found that LPA directly induced cell contraction and aSMA gene expression by RFBs dependent on LPA_1. To determine the involvement of G proteins in the LPA-LPA_1 signaling, RFBs were transfected with siRNAs targeting G proteins. The chemotactic activity of LPA was significantly inhibited by siRNA treatment against Ga_i class of G proteins. In addition to that, pertussis toxin (an inhibitor of Ga_i) also blocked LPA-induced migration of RFBs. We also found that LPA-LPA_1 signaling enhanced cell contraction and aSMA expression through $Ga_{12/13}$ class of G proteins.

Conclusions: Our results suggest that LPA-LPA_1 signaling directly modulates RFBs biologies dependent on specific G proteins in the pathogenesis of renal fibrosis.

TH-PO929

CCN2 Module-IV Promotes Renal Fibrosis Through Activation of the FAK Pathway in the Tubular Epithelium

Hiroaki Amano, Tsutomu Inoue, Hirokazu Okada. *Saitama Medical University, Saitama, Japan*.

Background: CCN2 is known to mediate the profibrogenic actions of TGF-beta in the kidney. We previously demonstrated that CCN2 promotes renal fibrosis via its module-IV by using mutated-CCN2 knocked-in mice (CCN2m/m) expressing mutated CCN2 lacking module-IV. CCN2 was reported to use FAK, Smad2/3 and LRP6 to promote renal fibrosis. Among these, a significant decrease in p-FAK was found in primary skin fibroblasts derived from CCN2m/m compared with the wild-type cells. In this study, therefore, we examined possible downstream pathways through which CCN2 module-IV promotes fibrosis in the kidney.

Methods: Expression of candidate proteins involved in the early downstream pathways of CCN2 were measured by immunoblotting using kidney samples from CCN2m/m and wild-type mice with or without ureter obstruction (UUO). Additionally, the expression

and localization of other downstream proteins of the FAK pathway in those samples were examined by immunoblotting and immunohistochemistry.

Results: Expression levels of p-FAK, p-Smad2/3 and p-LRP6 were significantly higher in the fibrotic wild-type UUO kidney on day 7 in comparison with the sham-operated control. However, p-FAK, but not p-Smad2/3 or p-LRP6, was significantly lower in the CCN2m/m UUO kidney compared with the wild-type UUO kidney (p-FAK/FAK: 1.1+/-0.1 vs. 2.6+/-0.4, p<0.01). Furthermore, mutant CCN2 showed significantly lower expression levels of p-Akt and total beta-catenin, which are considered downstream pathway proteins of pFAK, in the UUO kidney in comparison with the wild type (p-Akt/Akt: 0.1+/-0.1 vs. 0.6+/-0.2, p<0.03; beta catenin/GAPDH: 1.6+/-0.1 vs. 2.8+/-0.5, p<0.03). Immunohistochemistry revealed that FAK was activated in the tubular epithelium of the fibrotic wild-type UUO kidney, whereas these were significantly suppressed in the CCN2m/m UUO kidney.

Conclusions: CCN2 module-IV activates the FAK pathways in the tubular epithelium and, as a result, fibrosis is promoted in the UUO kidney. To prove this, primary tubular epithelial cells derived from CCN2m/m are being generated to examine the role of CCN2 module-IV *in vitro*.

Insulin-Like Growth Factor Binding Protein 3 Specific Binding DNA Aptamer Attenuated Renal Tubular Fibrosis

Mi Jung Lee,[1] Yubum Choi,[1] Jung Tak Park,[2] Tae-Hyun Yoo,[3] Seung Hyeok Han,[3] Hyung Jong Kim.[1] *[1]CHA Bundang Medical Center, CHA University College of Medicine, Seongnam, SEOUL, Republic of Korea; [2]Yonsei University Health System, Seodaemun-Gu, Seoul, Republic of Korea; [3]Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Insulin-like growth factor binding protein 3 (IGFBP3) is a predominant IGFBP family member of six IGFBPs. Emerging evidence has indicated that IGFBP3 has cell- and tissue-specific effects, and it is an important mediator of fibrosis in various cell types and the organs. However, to date, the effect of IGFBP3 on renal fibrosis has not been fully evaluated. This study was to investigate whether IGFBP3 is involved in renal tubular fibrosis and IGFBP3 inhibition by aptamer treatment is effective for attenuating renal tubular fibrosis.

Methods: IGFBP3 and fibrosis-related protein expression were evaluated in unilateral ureteral obstruction (UUO) rats. In vitro, the proximal tubular cells (NRK-52E) were treated with TGF-β1 (10 ng/ml). IGFBP3 inhibition was performed by IGFBP3 small interfering RNA (siRNA, 100 pmol/ml) and IGFBP3-binding DNA aptamer (200 pmol/ml) for 48 hours, respectively. Changes of fibrosis related protein expression were examined by real-time PCR and Western blot.

Results: IGFBP-3 and fibrosis-related protein expressions were up-regulated in the kidney of UUO rats. In TGF-β1-stimulated NRK-52E cells, IGFBP3 protein expression was increased in dose- and time-dependent manners. TGF-β1 treatment induced IGFBP3 and fibrosis-related protein expression, including fibronectin and type I collage, in renal proximal tubule cell. IGFBP3 siRNA treatment significantly abrogated the increase in fibrosis-related protein expression induced by TGF-β1. Furthermore, the IGFBP3-binding DNA aptamer also significantly attenuated fibrosis-related protein expression up-regulated by TGF-β1 treatment.

Conclusions: This study suggests that IGFBP3 is significantly associated with pathogenesis of renal tubulointerstitial fibrosis. Furthermore, IGFBP3 aptamer treatment can be a potential therapeutic option for renal tubulointerstitial fibrosis in chronic kidney disease patients.

TH-PO931

Differences in Proximal Tubular Secretion Across Categories of CKD

Ke Wang,[1] Leila R. Zelnick,[2] Yan Chen,[1] Andrew N. Hoofnagle,[1] Bryan R. Kestenbaum.[1] *[1]University of Washington, Seattle, WA; [2]Kidney Research Institute, Seattle, WA.*

Background: Absent a kidney biopsy, the cause of chronic kidney disease (CKD) is determined by clinical assessment, which includes measures of glomerular function (estimated glomerular filtration rate (GFR) and urinary albumin excretion). However, the underlying causes of CKD may also differentially impact non-glomerular tissue, including the proximal tubule. We quantified a set of proximal tubular secretory solutes and compared their clearances among varying causes of CKD.

Methods: We evaluated timed overnight urine specimens from 223 participants in the Seattle Kidney Study, a prospective study of CKD. We used liquid chromatography-mass spectrometry to quantify serum and urine concentrations of ten secretory solutes and calculated clearance of each solute (mL/min). We abstracted CKD causes from review of nephrology clinic notes and categorized these causes as vascular, diabetic, glomerular, and tubulointerstitial kidney diseases. We used one-way analysis of variance to compare differences in solute clearances among the CKD causes and we advanced three solutes for further analyses based on meeting a 5% false discovery threshold. For each significant solute we used linear regression to compare the relative difference in secretory clearance among disease group after adjustment for age, race, gender, body mass index, estimated GFR, and urine albumin to creatinine ratio.

Results: Three secretory solutes met the threshold for significance across the suspected etiologies of CKD: isovalerylglycine, kynurenic acid, and tiglylglycine. Glomerular disease was associated with greater clearances of all three secretory solutes. Diabetic kidney disease was associated with greater isovalerylglycine clearance compared with vascular disease after adjustment (Table).

Conclusions: Secretory solute clearance relative to GFR is higher in CKD patients with glomerular disease compared to vascular disease.

Inactivation of KLHL3 Kelch Like Family Member 3 Ameliorates Renal Fibrosis in Unilateral Ureteral Obstructive Mice

Dae Eun Choi,[1] Yoon-Kyung Chang,[2] Hyunsu Choi,[3] Jin young Jeong,[1] Jae wan Jeon,[4] Ki Ryang Na,[5] Youngrok Ham,[5] Jiwon M. Lee,[1] Kang Wook Lee.[5] *[1]Chungnam National University, Daejeon, Republic of Korea; [2]The Catholic University of Korea, Daejeon, Republic of Korea; [3]Daejeon St. Mary's Hospital, Daejeon, Republic of Korea; [4]Asan Medical Center, Seoul, Republic of Korea; [5]Chungnam National University Hospital, Daejeon, Republic of Korea.*

Background: KLHL3 kelch like family member 3 (KLHL3) regulate some electrolyte in kidney tubules. In human, the mutation of KLHL3 induce hypertension, characterized by pseudoaldosteronism (decreasing aldosterone). We evaluated whether the KLHL3 could be fair target of RAAS inhibition, resulting in inhibition of renal fibrosis in unilateral ureteral obstructed (UUO) mice.

Methods: 10-week-old male B6 mice background KLHL3 KO mice and wild type mice were divided into 4 groups; wild, KLHL3 KO, wild with UUO, and KLHL3 KO with UUO. Mice were sacrificed at 7 days after surgery and kidney tissue were collected. Real time RT-PCR, western blot and immunohistochemistry for molecular study and H&E stain and PAS stain for histologic examination were performed.

Results: KLHL3 KO with UUO mice showed improvement of renal cell survival, renal function, and pathologic damage compared to wild type UUO mice. Wild type with UUO kidney showed decrease of renal expression of KLHL3 and WNK4, and increase of renin and angiotensin I receptor, compared to sham mice. However, KLHL3 KO with UUO reduced the renal expression of renin, angiotensin I receptor, alpha-SMA, collagen IV, and TGF-β in UUO kidney, compared to wild type with UUO mice.

Conclusions: KLHL3 KO ameliorate renal fibrosis in UUO kidney via inhibition or renin angiotensin system.

Mouse Model of Progression to Chronic Kidney Injury from AKI

Jie Zhang,[1] Jin Wei,[1] Lei Wang,[1] Ruisheng Liu.[2] *[1]USF, Tampa, FL; [2]University of South Florida College of Medicine, Tampa, FL.*

Background: There is no animal model displaying the typical characteristics of CKD following an episode of AKI. Thus, the aim of the present study was to develop an AKI to CKD animal model.

Methods: We first tested whether current AKI models can induce CKD. Bilateral renal ischemia reperfusion (IR) and unilateral renal IR plus uninephrectomy with stepwise lengths of ischemic time were performed in C57BL/6 mice. Then we developed a two-stage AKI to CKD model in C57BL/6 mice. In stage I, IR induced AKI was performed in the left kidney with stepwise lengths of ischemic time, while the right kidney was kept intact. In stage II, after 2 week recovery for the injured left kidney, the intact right kidney was removed. Kidney function and renal injury were evaluated afterwards.

Results: In current IR induced AKI models, the animals either fully recovered if the renal injury was moderate with <18 min bilateral or <15 min unilateral ischemic time, or died if the renal injury was life-threatening with >21 min bilateral or >18 min unilateral ischemic time. No typical CKD feature was observed in these models. In two-stage AKI to CKD models, after removal of the intact right kidneys, the mice with 21 min or 24 min left renal ischemia exhibited the characteristics of CKD, including continuous decline in GFR (from 206.6±9.5 μl/min to 76.3±8.1 μl/min in 21 min group, from 199.2±6.7 μl/min to 49.5±11.3 μl/min in 24 min group), gradual increase in PCr (from 0.13±0.03 mg/dl to 0.43±0.05 mg/dl in 21 min group, from 0.09±0.03 mg/dl to 0.65±0.09 mg/dl in 24 min group), exacerbation in urine albumin-to-creatinine-ratio (from 13±6 μg/mg to 3457±342 μg/mg in 21 min group, from 9±5 μg/mg to 4841±375 μg/mg in 24 min group), histopathological changes including tubular atrophy, interstitial fibrosis, glomerular sclerosis, collapse of glomerular tufts and dilated Bowman's capsule, and transmission electron microscopy ultrastructural alterations including peritubular interstitium expansion, collagen deposition, cellular debris within Bowman's space, GBM thickening, and podocyte foot process effacement. The mice

with 15 min or 18 min left renal ischemia had a full recovery. All mice with 27 min or 30 min left renal ischemia died within 7 days after right kidney removal.

Conclusions: In conclusion, we successfully developed a novel mouse model with a direct transition from renal IRI induced AKI to subsequent progression of CKD.

The Sulfate Moiety in Indoxyl Sulfate Is Critical for Activation of Aryl Hydrocarbon Receptor–Tissue Factor Axis and 3-Indole Methanol Is a Competitive Antagonist of Indoxyl Sulfate

Sean Richards,[1] Joshua A. Walker,[2] Daniel M. Roth,[3] Mostafa Belghasem,[2] Norman Lee,[2] Stephen A. Whelan,[2] Nkiruka Arinze,[4] Sung bok Yoo,[2] Jean M. Francis,[1] Vipul C. Chitalia.[3] *[1]Boston University Medical Center, Boston, MA; [2]Boston University, Boston, MA; [3]Boston University School of Medicine, Boston, MA; [4]Boston Medical Center, Boston, MA.*

Background: Indolic solutes (indoxyl sulfate –IS, Indoxyl acetate -IA) are bonafide uremic solutes with protean systemic manifestations, including prothrombotic effect through activation of the Aryl hydrocarbon receptor (AHR) and tissue factor (TF). Despite its well-established pathogenicity, molecular determinants of IS that regulate its prothrombotic propensities remain unknown.

Methods: A structure activity relationship analysis was performed using a set of commercially available analogs. Activity was compared biochemically using validated AHR and TF activity assays, and visually in a transgenic zebrafish model containing a CYPA1 promoter tethered to a GFP reporter. A newly identified antagonist, indole-3-methanol (3-IM) was confirmed by using an carotid thrombosis model in mice treated with IS, as well as by ability to reduce TF in vascular smooth muscle cells treated with sera obtained from CKD patients with known concentration of IS levels.

Results: Modifying the sulfate moiety of IS altered its ability to increase AHR and TF activities. IA exhibited 100-fold higher AHR activation in cells and zebrafish models than IS. Of a total of thirteen analogs analyzed, five showed an agonistic activity in the presence of IS while one showed no effect. Of seven analogs with antagonistic activity towards IS, 3-IM significantly inhibited IS-induced AHR activation and TF with an IC50 of 50uM. 3-IM showed a potent anti-thrombotic activity in an IS-specific mouse model of thrombosis. Importantly, the downregulation of TF with 3-IM was significantly higher in vascular smooth muscle cells treated with uremic sera compared to cells treated with control sera. The ability of 3IM to suppress TF inversely correlated with the levels of IS in sera of end stagre renal disease patients.

Conclusions: The sulfate moiety is an important determinant of activity of IS in the AHR-TF axis. A non-sulfated analog, 3-IM suppresses TF and thrombosis in an IS-specific manner. These results point to the potential of 3-IM as a new therapeutic in counteracting IS-mediated systemic manifestations.

Silence of Central (Pro)renin Receptor Ameliorates Salt-Induced Renal Injury and Oxidative Stress in CKD

Jiawen Li, Mengbi Zhang, Lishan Tan, Minzi Qiu, Aiqing Li. *Nanfang Hospital, Southern Medical University, Guangzhou, China.*

Background: High salt diet promotes renal injury and oxidative stress via the brain and renal RAS axis in CKD rats. (Pro)renin receptor(PRR) can mediate oxidative stress. However, central PRR regulates salt-induced renal oxidative stress in CKD remains undefined. Here we hypothesized that the reduction of central PRR expression could ameliorate oxidative stress and thereby prevent renal injury in high-salt-load CKD rats.

Methods: We used the lentivirus as a vector to screen out the sequences that inhibit the central PRR expression in mature rat hippocampal neural stem cells in vitro. Moreover, we investigated renal oxidative stress, renin-angiotensin system, sympathetic nerve activity and tissue injury in 5/6 nephrectomy CKD model rats fed high dietary salt after silence of central PRR expression by intracerebroventricular (ICV) lentivirus RNAi.

Results: We found that high salt diet contributes to progression of renal injury, fibrosis and oxidative stress in CKD; The expression of PRR in the subfornical organ was decreased after ICV administration of lentivirus RNAi, indicating that shRNA successfully inhibited the expression of PRR in the brain. The expression of tyrosine hydroxylase in neurons of the rostral ventrolateral medulla of the brain, and the serum, renal norepinephrine levels were decreased, indicating that activation of the sympathetic nerve system was prevented by silence of central PRR expression; while kidney H&E staining and Sirius Red staining, as well as Fibronectin, α-SMA, and Collagen I were down-regulated, indicating that inhibition of central PRR can improve renal injury and reduce renal fibrosis. In addition, renal RAS components such as PRR, Angiotensinogen, and Angiotensin II, and kidney NADPH oxidase (Nox2, Nox4) were down-regulated, while renal antioxidant enzymes (CAT, GP1, and SOD1) were up-regulated. These experimental data suggest that silencing PRR expression in the CNS may down-regulate renal RAS expression and reduce renal damage and oxidative stress levels.

Conclusions: Silence of central PRR expression ameliorates renal fibrosis, injury, and oxidative stress in CKD model fed high salt.

TH-PO936

Scavenging Reactive Dicarbonyls Improves Renal Injury: Role of Urinary Isolevuglandin-Modified Lipoproteins and Renal Lymphangiogenesis

Jianyong Zhong,[1] Haichun Yang,[1] Taiji Matsusaka,[2] Agnes B. Fogo,[1] Macrae F. Linton,[3] Valentina Kon,[4] Sean S. Davies.[4] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Tokai University School of Medicine, Isehara, Japan; [3]Vanderbilt University School of Medicine, Nashville, TN; [4]Vanderbilt University, Nashville, TN.*

Background: The kidney has a well-developed lymphatic system and lymphangiogenesis occurs in diseased kidney. Our previous studies revealed that proteinuric injury increases urinary lipoproteins which were recently shown to regulate lymphangiogenesis. Isolevuglandins (IsoLG) and related reactive dicarbonyls are lipoxidation products that can modify lipoproteins and degrade their functions. We determined if scavenging dicarbonyls, including IsoLG that block protein modification, can modulate renal lymphangiogenesis and lessen renal injury.

Methods: Nphs1-hCD25 mice (Nep25) expressing podocyte-specific human CD25 become proteinuric after injection of immunotoxin (LMB2). Nep25 mice were treated with the dicarbonyl scavenger, PPM (1g/L) or vehicle from onset of proteinuria until sacrifice (2 weeks). We assessed proteinuria [measured as albumin:creatinine ratio (ACR)], urinary apoAI, IsoLG, KIM-1 (marker of tubular injury), and the renal expression of lymphatic markers (LYVE-1 and podoplanin). *In vitro*, we assessed the effects of apoAI or modified apoAI (IsoLG-apoAI) ± PPM in lymphatic endothelial cells (LEC).

Results: After LMB2 injection, Nep25 mice had significantly higher urinary ACR (32-fold), KIM-1 (35-fold), urinary apoAI (7.3-fold), and IsoLG-protein adduct excretion (1.3-fold). Proteinuric kidneys showed greater immunostaining for apoAI and a denser lymphatic vessel network (podoplanin staining: 2.1-fold). *In vitro*, IsoLG-apoAI increased LEC viability (1.6-fold) and migration (1.1-fold) vs unmodified apoAI. These effects were significantly abrogated by exposure to PPM. *In vivo*, proteinuric Nep25 mice treated with PPM showed reduced lymphangiogenesis (podoplanin: 0.7-fold and LYVE-1: 0.5-fold). PPM treatment also significantly reduced ACR (0.8-fold), urinary KIM-1 (0.7-fold) together with significant reduction in IsoLG excretion (0.4-fold).

Conclusions: We conclude that dicarbonyl scavenger PPM lessens proteinuric renal damage through mechanisms that include preserving lymphatic endothelial cell functionality and diminishing urinary lipoprotein-stimulated renal lymphangiogenesis.

Identification of C/EBPβ-TMIGD1 as a Novel Renoprotective Pathway

Mostafa Belghasem,[1] Joseph Y. Tashjian,[3] Daniel M. Roth,[1] Joshua A. Walker,[1] Sean Richards,[1] Jean M. Francis,[2] Nader Rahimi,[1] Vipul C. Chitalia.[1] *[1]Boston University School of Medicine, Boston, MA; [2]Boston University Medical Center, Boston, MA; [3]Boston University, Boston, MA.*

Background: The management of chronic kidney disease (CKD) patients lacks agents that protects functional renal mass, which predominantly consists of tubules. We recently identified transmembrane and immunoglobulin domain-containing 1 (**TMIGD1**) as a novel receptor expressed predominantly in the proximal tubular epithelial cells. TMIGD1 regulates epithelial cell adhesion and protects kidney epithelial cells from oxidative stress-induced cell injury in cell culture. While, TMIGD1 expression changes in acute kidney injury and chronic CKD mouse models, depending to the stage of disease the in vivo renoprotective function of TMIGD1 remains unknown.

Methods: TMIGD1 transcriptional regulation and promoter were characterized using electrophoretic mobility shift assay (EMSA). Expression of TMIGD1 and C/EBPb were examined in three discrete CKD models – unilateral ureteral obstruction (UUO), Adenine-induced CKD and remnant kidney model (RKM) model through immunofluorescence staining. CRSIPR/Cas9 TMIGD1 $^{+}$/- mice were subjected to adenine-induced CKD model. Targetability of TMIGD1 was demonstrated using TMIGD1 blocking antibody.

Results: C/EBPβ strong interacts with TMIGD1 promoter and stimulates promoter activity of TMIGD1 in HEK-293 cells. C/EBPβ showed nuclear localization in normal renal tubular cells, however, it was lost with the induction of CKD and correlated with the downregulation of TMIGD1 in renal tubules. CRSIPR/Cas9 TMIGD1 $^{+}$/-CKD mice showed a significantly lower kidney weight/body weight ratio suggesting a greater extent of renal atrophy compared to the wild type littermates. Pre-treatment of mice with a TMIGD1 blocking antibody augmented renal tubular damage.

Conclusions: We present C/EBPβ-TMIGD1 axis as a novel renoprotective pathway, which can be explored further to preserve the functional renal mass in CKD.

TH-PO938

Use of Population Management Tools to Identify Patients at High-Risk of ESRD Progression

Sijie Zheng,[1] Rushdy M. Al-Moomen,[1] Yiann E. Chen,[2] Joanna Mroz,[1] Leonid Pravoverov.[3] The Permanente Medical Group *[1]The Permanente Medical Group, Oakland, CA; [2]Kaiser Permanente Medical Center, Richmond, CA; [3]Kaiser Permanente, Oakland, CA.*

Background: The current health care system focuses on treatment rather than prevention of illness. There is inadequate support for patients who are unable to adhere to complex medical therapies. Transition from CKD to ESRD is a perfect example: many patients are not engaged in renal care due to psycho-social issues such as denial, lack of understanding of disease, or lack of financial resources for travel and/or medications. Kaiser

Permanente Northern California (KPNC) is an integrated health care system providing care for 4.3 million members. In 2016, KPNC East Bay Nephrology department started a pilot to identify patients with moderate to advanced CKD who had not received Nephrology care.

Methods: We used our Electronic Medical Record (EMR) system to identify late stage CKD patients (eGFR less than 30 ml/min) who have not been seen by a Nephrologist. The patient list was monitored daily by a nurse and reviewed weekly with a Nephrologist. Nephrologists screened patients to determine if they were appropriate for referral to nephrology specialty care. Primary care providers were contacted with recommendation to review chart and determine if those patients may benefit from referral to nephrology care.

Results: After the implementation of the pilot, many patients who would likely have been "lost to follow up" were captured by this program. The Nephrology team educated patients about the presence of advanced CKD and developed a comprehensive plan of care (Figure).

Conclusions: Establishing a "safety net" by developing an automated process of identifying patients with elevated risk characteristics and enrolling them in a structured CKD care program can potentially lead to a smoother transition to ESRD in our integrated health care system. In addition, this program supports the development of individualized care pathways depending on patient-identified goals of care.

Population Management of CKD Patients by Building a Safety Net to Identify High Risk Patients

TH-PO939

Treatment of Anemia with Oral and Parenteral Iron Leads to Bone Loss in Juvenile Mice with CKD

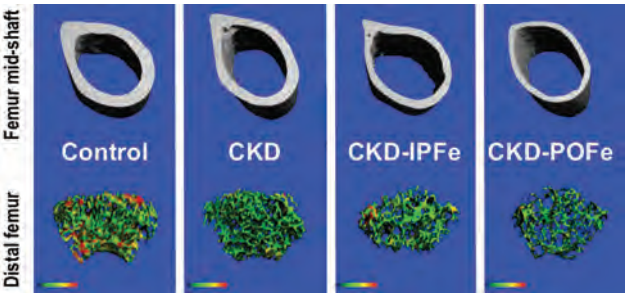
Oleh M. Akchurin,[1] Edwin Patino,[1] Sureshbabu Angara,[1] Divya Bhatia,[1] Vidhi Dalal,[1] Kelly Meza,[1] Stefano Rivella,[2] Mary E. Choi.[1] *[1]Weill Cornell Medicine, New York, NY; [2]Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Anemia is common in children with CKD and is associated with altered iron metabolism. Thus, many children with CKD are receiving iron therapy. Iron sequestration due to elevated hepcidin is a concern in CKD. Iron supplementation induces bone loss in mice without CKD. The effects of iron on bone health in juvenile CKD remain poorly understood.

Methods: CKD in juvenile mice was induced by 8 weeks of a 0.2% adenine diet, post-weaning. Bone histology and micro-CT was compared between four groups of mice: 1. Control (no CKD). 2. CKD without iron supplementation. 3. CKD + weekly 0.5g/kg of iron dextran intraperitoneally (CKD-IPFe). 4. CKD + 0.5% carbonyl iron diet (CKD-POFe). ANOVA was used for statistical analysis. For all reported data, pairwise comparisons between groups 1/2, 2/3, and 2/4 were significant ($p<0.05$).

Results: Renal function was reduced in all CKD groups (serum creatinine 0.22, 0.55, 0.32, and 0.79 mg/dL in groups 1-4 respectively). As expected, mice with untreated CKD were anemic. Treatment with oral and IP iron resulted in improvement of Hgb (13.9, 11.5, 13.1, and 13.3 g/dL in groups 1-4), Hct, MCV, MCH, and RDW. Mice with CKD had thinner and more porous cortical bone, and lower trabecular bone mass compared to controls. Iron treatment resulted in further cortical thinning (Ct.Th 0.18, 0.15, 0.12, 0.10 mm in groups 1-4), and decrease in cortical tissue mineral / apparent density, compared to untreated mice with CKD. Iron treatment also led to further reduction of trabecular bone volume (BV/TV 17.6, 12.2, 8.8, 8.6% in groups 1-4), trabecular number and increase in trabecular separation (Fig), compared to untreated mice with CKD.

Conclusions: Iron therapy improved anemia but was complicated by the loss of cortical and trabecular bone in this model of juvenile CKD. In our ongoing studies we aim to elucidate the underlying mechanisms. Our findings suggest a need to consider potential bone-related effects of iron in optimizing CKD management in children with CKD.



Cortical and trabecular bone micro-CT in four groups of mice

TH-PO940

Translational Medicine in CKD: Therapeutic Targeting of p-Cresyl Sulfate Triggered Nonspecific ROS in Uremic Lung Injury

Jia-Feng Chang. *En Chu Kong Hospital, New Taipei City, Taiwan.*

Background: p-Cresyl sulfate (PCS) exerts pro-inflammatory, pro-oxidant, and pro-apoptotic effects on multi-cell systems. Nonetheless, mechanisms and therapies of PCS induced uremic lung injury (ULI) in chronic kidney disease (CKD) remain unclear.

Methods: We analyzed pleural effusions from CKD and non-CKD patients with respiratory distress for uremic toxins, hydroxyl radicals, and chemotactic cytokines. From bedside to bench, cell viability and inflammatory signaling pathways with reactive oxygen species (ROS) were investigated in PCS-treated human alveolar cell model. To mimic human diseases, CKD-ULI mouse model was developed with quantitative comparison of immunostaining and morphometric approach.

Results: Pleural effusions exhibit higher expressions of PCS/ indoxyl sulphate/ hydroxyl radicals/ IL-5/ IL-6/ IL-8/ IL-10/ ENA-78/ MDC/ THPO/ VEGF and leukocyte recruitment with proteinaceous leak in CKD patients. In vitro, PCS promotes alveolar cell death, cPLA2/COX-2 expression, and NADPH oxidase/mitochondria activation-related ROS burst. Intracellular ROS burst is abrogated by non-specific antioxidant (N-acetyl cysteine, NAC), inhibitors of NADPH oxidase and mitochondria-targeted superoxide scavenger. However, only NAC protects against PCS-induced cell death. In vivo, expressions of cPLA2/ COX2/ 8-OHdG, dust cells, recruited leukocytes, alveolar space, plasmatic leakages and interstitial edema increase in lung tissues of CKD-ULI mice, and NAC pretreatment ameliorates ULI and alveolar cell death.

Conclusions: PCS impairs alveolar-capillary integrity through triggering intracellular ROS burst, activating downstream PG pathways, cell death, and recruiting leukocytes to release ROS and multiplex chemoattractants. Our translational research resolves puzzling mechanisms of CKD-ULI, proving that PCS and nonspecific ROS serve as potential therapeutic targets.

Mechanisms of CKD-ULI

TH-PO941

Sucroferric Oxyhydroxide Ameliorates Glomerular Podocyte and Tubulointerstitial Injury in the Rat Remnant Kidney Model

Yoshikazu Nemoto,[1] Takanori Kumagai,[1] Takeshi Shiraishi,[1] Kenichi Ishizawa,[1] Osamu Yamazaki,[1] Yoshifuru Tamura,[1] Makoto Kuro-o,[2] Shunya Uchida,[1] Shigeru Shibata.[1] *[1]Teikyo University School of Medicine, Tokyo, Japan; [2]Jichi Medical University, Shimotsuke, Japan.*

Background: Previously, we reported that the elevation of serum phosphate can accelerate CKD progression in the retrospective cohort study (Plos One 2016). In this study, we evaluated the protective effects of sucroferric oxyhydroxide (SF), a phosphate binder, in a rat model of CKD.

Methods: SD rats received 5/6 nephrectomy (RK) and had a normal diet containing 0.3% phosphate. Control rats without 5/6 nephrectomy received the same diet. A subgroup of RK rats received SF (50 mg/g chow; RK+SF). Renal histology was evaluated at 8 weeks.

Results: RK rats showed increased FGF23 levels compared with control rats. Serum phosphate levels were also moderately but significantly increased. SF administration significantly decreased serum FGF23 and phosphate levels in RK rats. Urinary phosphate excretion was also significantly lower in RK+SF rats than RK rats. Of note, albuminuria in RK rats was significantly ameliorated by SF administration at 8 weeks (RK, 8.42 ± 1.49 mg/day versus RK+SF, 2.71 ± 1.15 mg/day; $P < 0.01$). In the PAS-stained kidney sections, SF administration attenuated glomerulosclerosis and tubulointerstitial injury in RK rats. Consistently, gene expression of inflammatory and profibrotic cytokines were significantly lower in the kidney in RK+SF rats than in RK rats. In the glomeruli, we found that the increased expression of desmin, a marker for podocyte injury, was attenuated by SF. Consistently, nephrin protein expression was preserved in RK+SF rats compared with RK rats. The protective effects on podocytes were confirmed by morphological analysis under transmission electron microscope. In von Kossa staining, calcium phosphate was detected neither in RK nor RK+SF rats, indicating that renal injury in this model is independent of ectopic calcification at this stage. Plasma levels of calciprotein particles were significantly lower in RK+SF than RK rats, indicating the reduced mineral stress by SF.

Conclusions: These data indicate that phosphate loading to the kidney causes glomerular and tubulointerstitial injury in the absence of calcium phosphate deposition, and support the pathological role of phosphate loading in CKD progression.

TH-PO942

Adiponectin and Its Receptors in Peripheral Muscle and Fat Tissues of CKD Patients

Samantha Milanesi,[1,2] Daniela Verzola,[1,2] Michela Saio,[1,2] Daniela Picciotto,[1,2] Giuliano Brunori,[3] Chiara Venturelli,[4] Giacomo Garibotto.[1,2] *[1]University of Genoa, Genoa, Italy; [2]Policlinico S.Martino, Genoa, Italy; [3]Ospedale S. Chiara, Trento - Italy, Trento TN, Italy; [4]APSS TRENTO, Trento, Italy.*

Background: Inflammation contributes to protein-energy wasting (PEW) in CKD, but the role of adiponectin (APN), which has anti-inflammatory properties, is not known. APN is secreted preferentially by adipocytes, but also by skeletal muscle. APN binds two receptor isoforms, adiponectin receptor 1 (AR1) and adiponectin receptor 2 (AR2). The aim of this study was to examine the expression of APN and its receptors in skeletal muscle and adipose tissue in CKD patients.

Methods: Muscle biopsies were obtained from 29 CKD (eGFR 8±3 ml/min per 1.73m^2, 15M/14F, age 69 yrs) patients and 14 controls (C) rectus abdominis muscle samples. In this cohort, visceral fat samples were also obtained in 16 CKD and 10 C subjects. The expressions of APN, AR1 and R2 were tested by rtPCR and immunohistochemistry.

Results: *Skeletal Muscle*: APN gene expression and protein were up-regulated, (by 6-3.5 folds with respect to C, $p< 0.001$), AR1 and R2 mRNAs were markedly downregulated (-90 %, $p<0,001$), while protein expression was unchanged in CKD vs. C. *Adipose tissue*: APN, AR1 and R2 mRNAs were upregulate (by 2-7 folds, $p<0.05$) in CKD vs. C. Muscle APN mRNA was directly related to TLR4 protein expression ($r^2=0.33$, $p=0.023$); moreover, APN and IL-6 protein were directly related ($r^2=0.28$, $p<0.01$). Only as a trend, APN protein was related to NF-kB pp65 ($r^2=0.179$, $p=0.056$). Visceral Fat APN was directly related to plasma CRP ($r=0.62$, $p=0.028$).

Conclusions: In conclusion, muscle and visceral fat APN and APN receptors expression pattern is markedly modified in CKD. The APN system appears to respond to chronic inflammation as a compensatory mechanism which helps to maintain body homeostasis.

TH-PO943

NLRP3 Inflammasome Is Activated in Skeletal Muscle of Patients with CKD

Daniela Verzola,[1,2] Samantha Milanesi,[1,2] Chiara Barisione,[3,1] Silvano Garibaldi,[1,2] Michela Saio,[1,2] Daniela Picciotto,[1,2] Abitha Murugavel,[1,2] Francesca Costigliolo,[1,2] Giuliano Brunori,[4] Chiara Venturelli,[5] Giacomo Garibotto.[1,2] *[1]DiMI University of Genoa, Genoa, Italy; [2]Policlinico S.Martino, Genoa, Italy; [3]University of Genova, Genova, Italy; [4]Ospedale S. Chiara, Trento - Italy, Trento TN, Italy; [5]APSS TRENTO, Trento, Italy.*

Background: Inflammation in skeletal muscle is implicated in the pathogenesis of insulin resistance and cachexia but why uremia upregulates muscle pro inflammatory cytokines is not completely understood.The NOD-like receptors (NLRs) are a group of pattern recognition receptors which activate the inflammasome platform. Aim of this study was to investigate the NLP3 role in skeletal muscle of CKD patients and the effects of uremic milieu on the NLRP3 pathway and mitochondria homeostasis.

Methods: Rectus abdominis muscle biopsies were collected from CKD5 patients (n= 25, 18M/7F, age 69±10 yrs, eGFR 8±1mL/min 1,73m^2) and from 10 controls (C) (age 68±11 7M/3F, eGFR 100±4mL/min 1,73m^2). NLRP3, IL1β expression was studied by immunohistochemistry, mRNA (NLRP3,IL1β,PGC1α,MFN2, NRF2) by rt-PCR. To assess the effects of uremic milieu, C2C12 myotubes were exposed to 10% normal serum (NS) or Uremic (US) Serum for 5-48 hours (h). NLRP3,IL1β,PGC1α,MFN2,NRF2 were studied by rtPCR, caspase1 by western blot and mitochondria damage by JC1 staining.

Results: In CKD, NLRP3 mRNA and protein were overexpressed (by 16-2 folds, $p<0.05$-0.025). IL1β mRNA was upregulated ($p=0.02$). In vitro, 5 hour US treatment upregulated NLRP3 and IL1β mRNAs (by 71-12 folds $p<0.01$) and caspase1 (+30% $p<0.05$). TAK 242 (1μM) a TLR4 antagonist prevented these effects. In CKD muscle, PGC1α (a mitochondrial biogenesis regulator), MFN2 (involved in mitochondrial fusion and in the mitochondrial network maintenance) and Nrf2 (a player in supporting the mitochondria structural and functional integrity) were significantly elevated (0.05-0.01) respect to C. Moreover, US upregulated PGC1α, MFN2 and Nrf2 (by 2-26 folds $p<0.05$-0.001) and altered mitochondrial membrane potential ($p<0.05$). These effects were partially blocked by TAK 242.

Conclusions: Our data show that NLRP3 inflammasome is activated and mitochondria dysregulated in CKD 5 skeletal muscle. These effects are rescued by TLR4 block, showing a link between TLR4 and inflammasome. TLR4/NLRP3/IL-1β blockade offers a novel method for reducing inflammation in muscle of CKD patients.

TH-PO944

Towards a Standardized Histological Identification of CINAC Patients: Methods and Pitfalls in Microscopic Diagnosis

Gerd Schreurs,[1] Cynthia C. Nast,[2] Channa Jayasumana,[3] Frank Roels,[5] Chulani A. Herath,[4] Swarnalata Gowrishankar,[7] Christiane I. Mousson,[8] Rajeewa T. Dassanayake,[6] Carlos M. Orantes,[9] Patrick C. D'Haese,[1] Marc E. De Broe,[1] Benjamin A. Vervaet.[1] *[1]University of Antwerp, Antwerp, Belgium; [2]Cedars-Sinai Medical Center, Los Angeles, CA; [3]Faculty of Medicine, Anuradhapura, Sri Lanka; [4]Sri Jayawardenepura General Hospital, Colombo 5, Sri Lanka; [5]Ghent University, Gent, Belgium; [6]General hospital Polonnaruwa Sri Lanka, Polonnaruwa, Sri Lanka; [7]Apollo Hospitals, HYDERABAD, India; [8]University Hospital Dijon, Dijon, France; [9]National Direction of Non-communicable diseases of Ministry of Health of El Salvador, San Salvador, El Salvador.*

Background: Patients with Chronic Interstitial Nephritis in Agricultural Communities (CINAC) demonstrate previously unidentified enlarged granules in the proximal tubular (PT) epithelium, first discovered and easily recognizable on Jones' methenamine silver stained renal biopsies and by autofluorescence. The aim is to 1) identify the nature of the granules, 2) provide a standardized Jones staining protocol for granule identification, 3) evaluate autofluorescence as a rapid diagnostic method and 4) assess EM analysis.

Methods: Formalin fixed deparaffinized renal tissue sections (4μm) of Sri Lanka and El Salvador CINAC patients and patients with proteinuric pathologies were subjected to Jones staining protocols with varying silver solution incubation times. Autofluorescence of 4μm sections was imaged (2-7 secs shutter time), followed by standardized Jones staining of the same tissue section. Immunofluorescence microscopy was performed for the mitochondrial marker COX6c and for lysosomal markers LAMP1 and Cathepsin B. EM of CINAC and proteinuric renal biopsies was performed.

Results: Jones stain invariably revealed the specific PT granules only when the incubation in silver-solution was ≥90 min, surpassing the time (60 min) needed to visualize basement membranes. CINAC biopsies showed PT autofluorescent granules in a pattern similar to the argyrophylic granules, with nearly all autofluorescent granules also being argyrophylic. Most autofluorescent granules were identified as lysosomes with LAMP1 and Cathepsin B. In proteinuric patients, PT argyrophylic and autofluorescent granules may occur. However, on EM, proteinuric lysosomes were round, and did not contain dispersed electron dense aggregates as obseved in CINAC patients.

Conclusions: PT CINAC granules are lysosomes, identifiable by Jones staining with prolonged silver incubation and more rapidly by autofluorescence. EM of PT lysosomes can identify suspected CINAC patients, with or without proteinuria.

TH-PO945

Stanniocalcin-1 Inhibits ER Stress-Induced Apoptosis and Renal Fibrosis via Restoration of ER-Mitochondrial Calcium Communication

Eun mi Yang,[1] Soo Wan Kim,[1] Eun Hui Bae,[2] Seong Kwon Ma,[1] Jung Sun Park.[3] *[1]Chonnam National University Medical School, Gwangju, Republic of Korea; [2]Chonnam National University Hospital, Gwangju, Republic of Korea; [3]chonnam national university, Gwang Ju, Republic of Korea.*

Background: Endoplasmic reticulum (ER) stress is a common feature of several physiological and pathological conditions. ER stress-associated apoptosis plays a role in organ remodeling after insult, and overwhelming ER stress lead to renal cell apoptosis and subsequent fibrosis. Stanniocalcin-1 (STC-1) is a multifunctional glycoprotein which is targeted to the mitochondria to exert putative anti-apoptotic effects. The present study aimed to investigate the effects of STC-1 in ER stress-induced apoptosis and renal fibrosis in human renal proximal tubular (HK-2) cells.

Methods: HK2 cells pretreated with STC-1 (200 ng/ml) for 1 hours followed by treatment with TGF-β (10 ng/ml) for 24 hours. The protein expression of ER stress, apoptosis, and fibrosis markers was determined by semiquantitative immunoblotting.

The level of reactive oxygen species (ROS) was determined by fluorescent microscopy immunofluorescence. Using microscopy and immunocytochemistry, immunolabelling of Ca^{2+}, calcium sensing receptor and inositol 1,4,5-trisphosphate receptor (IP3R) was detected.

Results: TGF-β treatment induced ER stress via upregulation of PERK-eIF2-ATF signaling, and suppressed cytosolic calcium concentration via downregulation of IP3R. Pretreatment of STC-1 attenuated the TGF-β induced up-regulation of PERK-eIF2-ATF4 signaling and restored the cytosolic Ca concentration, thus reducing apoptosis. TGF-β treatment induced mitochondrial ROS generation and cytosolic cytochrome c release. STC-1 pretreatment significantly blocked mitochondrial ROS generation and cytosolic cytochrome C release. TGF-β treatment also induced upregulation of E-cadherin, collagen IV and fibronectin and downregulation of N-cadherin, which was counteracted by STC-1 pretreatment.

Conclusions: Restoration of ER-mitochondrial calcium signal by STC-1 attenuated ER stress induced apoptosis and fibrosis in HK2 cells. The present study suggested that the STC-1 may serve as a potential treatment for renal fibrotic disease.

TH-PO946

Sex-Specific Renal Pathology Following 5/6 Nephrectomy Is Modulated by miR-146b

Mark Paterson, Alison J. Kriegel. *Medical College of Wisconsin, Milwaukee, WI.*

Background: Chronic kidney disease (CKD) presents a complex pathological landscape in both men and women. Many studies have shown miRNAs can be powerful mediators of pathology at the molecular level. Our work focuses on the role of miRNAs in CKD, utilizing the 5/6 nephrectomy (5/6Nx) rat model. We have reported a significant increase in the expression of miR-146b in kidney tissue following 5/6Nx. The present study investigates the contribution miR-146b to CKD, and the relative contribution of sex hormones in modulating the pathology of CKD.

Methods: Male and female Sprague Dawley (SD) rats underwent 5/6Nx or sham surgeries at 10 weeks of age. The 5/6Nx consists of surgical resection of 2/3 of the left kidney and the entire right kidney. Seven weeks later, urine and blood were collected, the rats were euthanized, and the kidneys harvested for downstream application. To study the contribution of miR-146b, wild-type SD rats (WT) were compared to miR-146b null mutants (KO). To study the contribution of sex hormones, intact rats were compared to gonadectomized rats. Histological examination of kidney tissue was performed to assess renal fibrosis. Metabolite and electrolyte levels were measured in blood and urine using a blood gas analyzer. Creatinine clearance (CrCl) and fractional excretion of sodium (FE_{Na}) were derived from plasma and urine concentrations and urine flow rate.

Results: Following 5/6Nx, male WT and KO rats exhibit impaired renal function without significant renal fibrosis; diminished CrCl (WT: 2.09 vs. 0.85 ml/min, KO: 3.28 vs. 0.82 ml/min; sham vs. 5/6Nx) and increased FE_{Na} (WT: 0.12 vs. 0.40%; KO: 0.09 vs. 0.40%). Female WT rats exhibited similar renal dysfunction without fibrosis; reduced CrCl (0.99 vs. 0.28 ml/min) and elevated FE_{Na} (0.17 vs. 0.72%). However, female KO rats exhibited an exacerbation of renal dysfunction and injury compared to WT after 5/6Nx; sharply reduced CrCl (0.28 vs. 0.08 ml/min, WT vs. KO 5/6Nx), elevated FE_{Na} (0.72 vs. 4.43%), and significant fibrosis in the renal cortex (3.30 vs. 13.1% fibrotic area). Ovariectomy ameliorated nearly all structural and functional pathologies.

Conclusions: Our study suggests an important protective role for miR-146b in CKD which may be, in part, via modulation of estrogen signaling in the kidney. Future studies will address specific pathways targeted by miR-146b to elucidate its mechanism of action in CKD.

TH-PO947

Altering Body Temperatures Response to Heat Modulates Kidney Injury

Yuka Sato, Carlos A. Roncal-jimenez, Ana Andres-hernando, Gabriela E. Garcia, Miguel A. Lanaspa, Richard J. Johnson. *Kidney Disease and Hypertension, University of Colorado Denver, Aurora, CO.*

Background: Hispanic Americans may be at more risk than African Americans for kidney damage from heat stress due to greater mitochondrial uncoupling because of genetic polymorphisms. Indeed, mitochondrial uncoupling proteins (UCP) dissipate the proton gradient in the mitochondria, resulting in more heat generation instead of ATP synthesis. We therefore hypothesized that the administration of a drug that could induce a mitochondrial uncoupling might result in a greater increase in body temperature following heat exposure, and that this might lead to greater renal damage.

Methods: To test this hypothesis C57BL/6 mice were exposed to 39.5°C for 30 minutes with subcutaneous injection of the chemical uncoupler; 2,4-dinitrophenol (DNP). After heat exposure, mice were returned to room temperature, and received access to water and food freely for one hour to avoid dehydration. The heat exposure was repeated twice per day for 10 days. Body temperature was evaluated with rectal probes.

Results: Body temperature immediately after the heat exposure was increased by heat and DNP (Table1). Albuminuria (uAlb) and BUN were increased in DNP+Heat group (Table1). uAlb correlated with body temperature (R=0.6, p<0.038). CPK was not increased in any groups, indicating an absence of rhabdomyolysis. Renal pathology showed greater tubular cell proliferation (proliferating cell nuclear antigen (PCNA) positive), tubular injury and interstitial macrophage infiltration (F4/80 positive) in the DNP+Heat group (Table1). HSP 70 expression was increased in Heat group and much more in Heat+DNP group.

Conclusions: Increasing body temperature for the same level of heat stress is associated with greater renal injury. Studies should evaluate whether individual temperature responses can predict renal injury in high risk subjects such as sugarcane workers.

A Novel Conditionally Immortalized Kidney Pericyte Cell Line to Model Myofibroblast Transition

Benjamin D. Humphreys,[1] Erinn L. Donnelly,[1] Monica Chang Panesso,[2] Eoghainín O hAinmhire,[3] Flavia G. Machado.[4] *[1]Washington University School of Medicine, Clayton, MO; [2]Washington University in St. Louis, St Louis, MO; [3]Washington University, Lake St. Louis, MO; [4]Washington University in St Louis, School of Medicine, St Louis, MO.*

Background: Gli1-positive resident pericytes and perivascular fibroblasts are the predominant source of kidney myofibroblasts in kidney fibrosis but the study of pericyte to myofibroblast transition is hampered by the absence of appropriate cell culture models.

Methods: We crossed bigenic Gli1-CreER^{t2}; R26tdTomato mice with the 'immorto-mouse,' which expresses a temperature sensitive SV40 gene, and with the 'terminator' mouse, which expresses the diphtheria toxin receptor except after Cre-mediated recombination. After tamoxifen administration, we isolated tdTomato-positive Gli1 cells from kidney, and elimated all non-recombined cells by administration of diphtheria toxin. We characterized these cells ability to differentiate into myofibroblasts using a variety of methods, including scRNA-seq.

Results: Kidney Pericyte-Gli1 (KPG) cells maintain expression of appropriate pericyte cell markers, respond to hedgehog pathway activation and display robust myofibroblast differentiation upon treatment with TGFb. In support of their pericyte identity, co-culture of KPG with endothelium stabilizes capillary formation. Single cell RNA-sequencing analysis (5,000 cells) during the myofibroblast differentiation timecourse identified autocrine ligand-receptor upregulation including the connective tissue growth factor, platelet-derived growth factor and transforming growth factor beta-3 pathways. Strong upregulation of genes in the focal adhesion pathway led us to test the serum response factor inhibitor CCG-203971 which potently inhibited TGFb-induced pericyte to myofibroblast transition. Finally, our single cell analysis identified the unexpected upregulation of nerve growth factor (NGF) in KPG cells treated with TGFb. We confirmed strong NGF upregulation in two mouse kidney fibrosis models, and identified expression of the NGF receptor TrkA in VSMC cells in vivo, suggesting a novel role for perivascular fibroblast-derived NGF signaling to VSMC during kidney fibrosis.

Conclusions: KPG cells accurately model pericyte to myofibroblast transition, and we used them to identify a novel inhibitor of this process and the unexpected upregulation of the NGF pathway during renal fibrosis.

Three Dimensional Super-Resolution Microscopy and Automatic Quantification of Podocyte Foot Processes in Humans, Rats, and Mice

Nadine Artelt,[1] Florian Siegerist,[1] Alina M. Ritter,[1] Olaf Grisk,[3] Rabea Schlueter,[2] Karlhans Endlich,[1] Nicole Endlich.[1] *[1]Anatomy and Cell Biology, University Medicine Greifswald, Greifswald, Germany; [2]Biology, University of Greifswald, Greifswald, Germany; [3]Physiology, University Medicine Greifswald, Karlsburg, Germany.*

Background: Until today, laborious and time-consuming transmission electron microscopy has been used to assess podocyte effacement in human and rodents. Recently, our group has shown that super-resolution 3D-structured illumination microscopy (3D-SIM) can be applied to visualize individual foot processes in human kidney biopsies. Furthermore, we have developed a software-based approach to quantify the structure of podocyte foot processes named podocyte exact morphology measurement procedure (PEMP). PEMP allows to quantify podocyte injury using filtration slit density (FSD), i.e. filtration slit length per capillary surface area, as the surrogate parameter for podocyte effacement in patients suffering from minimal change disease. As in basic science rodent models are widely distributed, we applied PEMP to mice and rats, the most used rodent models.

Methods: We co-stained 4 µm formalin-fixed and paraffin-embedded sections of healthy human, rat and mouse kidney tissue with antibodies targeted against the slit diaphragm protein nephrin and the actin-associated protein synaptopodin detected by Cy3 and Alexa 488-labeled secondary antibodies, respectively. Subsequently, we imaged these sections by wide-field microscopy, confocal laser scanning microscopy and 3D-SIM. PEMP was performed by FIJI utilizing a custom-built macro that semi-automatically detects the filtration slit and calculates FSD.

Results: In a comparative analysis, we show that only 3D-SIM is able to clearly visualize the nephrin-stained slit diaphragm between synaptopodin-stained foot processes in all three species. Using PEMP, we determined values for FSD in healthy individuals from all three species. The FSD in humans was 3.106 ± 0.024 μm^{-1} (mean ± SEM). The FSD was

significantly higher in rats and mice with a mean value of 3.364 ± 0.049 μm^{-1} and 3.829 ± 0.032 μm^{-1}, respectively. Since foot process width is inversely related to FSD, the width of foot processes continuously increases from mice to rats and humans.

Conclusions: Taken together, we present a method for basic research which allows fast evaluation and quantification of podocyte foot process morphology in rodents by using 3D-SIM on standardized histological material and tissue processing.

Funding: Government Support - Non-U.S.

TH-PO950

Lack of P2X7 Receptors Protects Against Pyelonephritis Associated Renal Fibrosis

Jacob R. Therkildsen, Mette G. Christensen, Stine Julie T. Pedersen, Rikke Norregaard, Helle A. Praetorius. *Aarhus University, Aarhus C, Denmark.*

Background: Severe urinary tract infections are regularly caused by sub-strains of *E. coli* secreting the pore-forming virulence factor α-haemolysin (HlyA). Repeated cases of pyelonephritis can cause marked renal scarring that subsequently leads to progressive failure. We have previously demonstrated that HlyA releases cellular ATP directly through its membrane pore and that acute HlyA-induced cell damage is completely prevented by blocking ATP-signalling. Moreover, there is substantial evidence that local ATP signalling and $P2X_7$ receptor activation plays a key role in the development of tissue fibrosis. This study investigates the effect of $P2X_7$ receptors in infection-induced renal scarring in a murine model of pyelonephritis.

Methods: Pyelonephritis was induced by injecting 100 mill HlyA-producing, uropathogenic *E. coli* into the urinary bladder of balb/c mice. Pyelonephritis was confirmed by culture of the right kidney at day 5 post infection with concomitant high levels of proinflammatory cytokines (IL-6 and IL-1b) a response similar in both $P2X_7^{+/+}$ and $P2X_7^{-/-}$ mice.

Results: Lack of $P2X_7$ receptor did not influence on the mortality in the mice exposed to bacteria (n_{total} = 131). Fibrosis was first observed 2 weeks post infection. Our data clearly demonstrate that $P2X_7^{-/-}$ mice showed markedly less renal fibrosis following a similar degree of infection compared to $P2X_7^{+/+}$ controls ($p<0.001$), reducing the renal scarring from 1.153 ± 0.0755 mm^{-2} to 0.296 ± 0.036 mm^{-2} (fibrotic areas/mm^2 in the cortex). Similarly, a $P2X_7$ antagonist BBG reduced the formation of fibrosis ($p<0.001$) to 0.3810 ± 0.03532 mm^{-2} in the cortex. Immunohistochemistry revealed comparable degree of neutrophil infiltration in kidneys from $P2X_7^{+/+}$ and $P2X_7^{-/-}$ mice, with diminished macrophage infiltration and reduced neutrophil clearance in $P2X_7^{-/-}$ mice or mice treated with BBG compared to controls.

Conclusions: Hence this study suggests the $P2X_7$ receptor to be an appealing antifibrotic target following renal infections.

TH-PO951

Genetic Ablation of Spermidine Oxidase Leads to Blunted Production of the Uremic Toxin Acrolein but Does Not Prevent CKD

Krister Bamberg,[1] Charlotte Ericson,[1] Lars Löfgren,[1] Barbro Basta,[1] Katja Madeyski-Bengtson,[1] Marcello Maresca,[1] Yosuke Inui,[2] Hideki Mochida,[2] Ola Fjellström.[1] *[1]AstraZeneca, Gothenburg, Sweden; [2]Mitsubishi Tanabe Pharma Corporation, Toda, Saitama, Japan.*

Background: The uremic toxin acrolein, a highly reactive aldehyde, is associated with cardiovascular disease and has been linked to chronic kidney disease (CKD). Sources of acrolein include e.g. smoking, lipid peroxidation and spermine metabolism. Spermine oxidase (SMOX) converts spermine to spermidine and generates acrolein.

Methods: Spermine oxidase germline deficient mice (SMOX-/-) were generated by CRISPR mediated gene deletion. Mice were subjected to an LPS challenge to study acute effects on polyamine and acrolein production. To study more chronic effects, renal ischemia reperfusion injury (IRI) or adenine diet induced kidney injury were elicited. 3HPMA, a stable metabolite of glutathione adducted acrolein, was measured in plasma and organs to assess acrolein production.

Results: SMOX deletion resulted in reduced circulating spermidine and acrolein levels. Following an LPS challenge, the acutely elevated acrolein levels, but also plasma creatinine levels particularly in males, were blunted in SMOX-/- animals. Both renal IRI and adenine diet induced chronic kidney injury led to increased circulating levels of acrolein in wild type but not in SMOX-/- animals. However, SMOX-/- did not prevent progression of kidney injury.

Conclusions: SMOX-/- animals responded with a blunted elevation of circulating acrolein levels after acute and chronic reduced kidney function. Reduction of this uremic toxin did not correlate to improved chronic kidney function in the models assessed here. It remains to be established whether reduction of SMOX activity and acrolein levels have a protective role in other cardiovascular diseases.

Near-Infrared Autofluorescence Is Useful for Non-Invasive Imaging of Injured Kidneys

Ayumi Matsumoto, Isao Matsui, Karin Shimada, Nobuhiro Hashimoto, Yohei Doi, Satoshi Yamaguchi, Keiichi Kubota, Tatsufumi Oka, Yusuke Sakaguchi, Takayuki Hamano, Yoshitsugu Takabatake, Yoshitaka Isaka. *Osaka University Graduate School of Medicine, Suita, Japan.*

Background: Tubulointerstitial injury (TI) is the final common pathway leading to end-stage renal disease. Because TI is an important therapeutic target in kidney diseases, it is indispensable to establish non-invasive strategies that enable us to evaluate the progression of TI.

Methods: Near-infrared autofluorescence (AF) of injured kidney was non-invasively evaluated by IVIS imaging system. A combination of excitation 710 nm and emission 810-875 nm was used. Two animal models, unilateral ureteral obstruction and folic acid induced nephropathy, in BALB/c mice were analyzed. The origin of the renal AF was analyzed by confocal microscopy. Normal portions of human kidney tissues obtained from surgically resected kidneys owing to malignant tumors were also analyzed (35 patients (male 20, female 15), median age 69 (interquartile range (IQR) 62-74), median estimated glomerular filtration rate (eGFR) 57.25 mL/min/1.73m^2 (IQR 38.9-73.45)).

Results: The AF levels were positively correlated with the progression of TI in both animal models. Microscopic analysis of the kidney sections revealed that the AF was originated from the injured tubular cells. Because porphyrins are intrinsic fluorescent substrates that have near-infrared emission peak, we analyzed renal expression levels of enzymes that participate in the metabolism of porphyrin. Among 10 enzymes, only coproporphyrinogen oxidase (CPOX) was suppressed in the injured kidneys in both animal models, suggesting that coproporphrinogen III, a substrate for CPOX, and its spontaneously oxidized product, coproporphyrin III, were accumulated in the injured kidneys. We found that coproporphyrin III had identical fluorescent properties observed in the injured kidneys. Intraperitoneal injection of δ-aminolevulinic acid, a substrate of porphyrin synthesis, enhanced the AF of injured kidneys. The AF was also enhanced in BALB/c-nct/nct mice, a mice strain that retains only 15% of the wild type CPOX activity. Furthermore, AF levels of human kidney samples were inversely associated with eGFR.

Conclusions: Near-infrared AF derived from coproporphyrin III is useful for non-invasive imaging of TI.

TH-PO953

Tissue-Resident Mucosal-Associated Invariant T (MAIT) Cells in Human Renal Fibrosis and CKD

Helen G. Healy,[1,2] Becker Meng-Po Law,[1,2] Xiangju Wang,[1,2] Katrina Kildey,[1,2] Kurt T. Giuliani,[1,2] Ray Wilkinson,[1,2] Andrew J. Kassianos.[1,2] *[1]Kidney Health Service, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [2]Conjoint Kidney Research Laboratory, Pathology Queensland, Brisbane, QLD, Australia.*

Background: MAIT cells are a specialised lymphocyte population associated with chronic inflammatory disorders in peripheral tissues. To date, MAIT cell research has focused primarily on mucosal tissue, with limited studies on non-mucosal organs such as kidneys. In this study, we evaluated MAIT cells in human native kidneys with tubulointerstitial fibrosis, the pathological hallmark of CKD.

Methods: MAIT cells were identified, enumerated and phenotyped from human kidney tissue by multi-colour flow cytometry. Localisation of MAIT cells was performed by immunofluorescence microscopy. MAIT cells and human primary proximal tubular epithelial cells (PTEC) were co-cultured under hypoxic (1% O_2) conditions to examine mechanistic tubulointerstitial interactions.

Results: We detected significantly elevated numbers of MAIT cells (TCR-Vα7.2+ CD161++) in diseased biopsies with interstitial fibrosis compared with diseased biopsies without fibrosis and healthy kidney tissue. The increased numbers of MAIT cells also correlated significantly with loss of kidney function (eGFR). MAIT cells in fibrotic biopsies expressed cytokine receptors (IL-7Rα, IL-18Rα), activation receptor (NKG2D), extravasation marker (CD44) and tissue-resident markers (CD69, CD103). Immunofluorescent staining of fibrotic kidney tissue localised the accumulation of MAIT cells within the tubulointerstitial compartment, adjacent to PTEC. Notably, under *in vitro* pro-fibrotic/hypoxic conditions, PTEC induced the up-regulated expression of tissue-resident markers on MAIT cells.

Conclusions: We provide the first characterisation of MAIT cells in human kidney tissue. Collectively, our data suggest that human MAIT cells are retained as tissue-resident lymphocytes and are positioned to contribute to the fibrotic process via complex interactions with PTEC. Further dissection of kidney MAIT cells is now required for the development of novel CKD therapeutics.

TH-PO954

RNA Seq Interrogation of a Clinical Kidney Biopsy Biobank Identifies Axl Kinase as an Anti-Fibrotic Target

Monica F. Tolosa,[1] Lauren V. Caldwell,[3] Yanling Zhang,[1] Kerri Thai,[1] Anish Kirpalani,[1] Adriana Krizova,[1] Richard E. Gilbert,[1,2] Darren A. Yuen.[1,2] *[1]St. Michael's Hospital, Toronto, ON, Canada; [2]Fibrocor Therapeutics, Toronto, ON, Canada; [3]Lunenfeld Tanenbaum Research Institute, Ajax, ON, Canada.*

Background: Fibrosis is a key manifestation and driver of chronic kidney injury. No safe and effective renal anti-fibrotic agents exist, in part because of the lack of human kidney tissue for study. Well annotated human kidney tissue biobanks are rare given their maintenance costs and the resources required to collect follow-up data. The few biobanks that exist have been primarily interrogated using microarrays, which while enabling multi-gene assessment, is limited to the probes on the array, and usually requires an extra, specially stored biopsy core. Here we describe the interrogation of archived remnants of clinical kidney biopsy tissue using a comprehensive RNA seq-based platform, enabling the study of clinical samples and linking to routinely obtained follow-up data.

Methods: RNA extracted from remnants of 14 frozen clinically indicated kidney transplant biopsies at St. Michael's Hospital (SMH) was subjected to RNA sequencing. Clinical data (age, gender, Banff histologic scores, eGFR values) was collected from the SMH Kidney Transplant Database. Preliminary findings were confirmed in the murine unilateral ureteral obstruction (UUO) model of kidney fibrosis.

Results: The mean slope of eGFR change post-biopsy was -4.8 +/- 8.6 mL/min/yr. 7 biopsies were scored as ci 1 (5 – 25% fibrosis), 6 biopsies as ci 2 (25 – 50% fibrosis), and 1 biopsy as ci 3 (> 50% fibrosis). In addition to known fibrosis-associated transcripts (collagens, TGF-beta, CTGF), we found that mRNA levels of the tyrosine kinase Axl were positively associated with fibrosis score (rho = 0.48, p = 0.03) and negatively with slope of eGFR change post-biopsy (rho = -0.52, p = 0.02). We found a similar increase in Axl mRNA levels in fibrotic UUO kidneys. As Axl mRNA expression was localized primarily to fibroblasts, we next treated NRK49F fibroblasts with an Axl inhibitor (BGB324), finding that Axl inhibition blocked TGF-beta-induced collagen production.

Conclusions: We describe a novel RNA seq-based platform that can interrogate routinely stored remnants of clinically obtained kidney biopsy tissue, enabling the use of archived clinical samples and their associated follow-up data. Our initial studies identified known fibrosis-associated transcripts, and also potential druggable targets that may lead to new anti-fibrotic strategies.

TH-PO955

The Effect of Complement 3 in Chymase Promoting Renal Interstitial Fibrosis

Jian-xin Wan. *The First Affiliated Hospital of Fujian Medical University, Fuzhou, China.*

Background: To investigate the effect of complement 3 (C3) on chymase promoting renal interstitial fibrosis.

Methods: To establish UUO model with wild type C57BL/6 mice (WT) and C3 gene knockout mice (C3KO). WT mice were intraperitoneally injected with 10mg/Kg chymostatin in the first to fourteenth day after operation. All mice were sacrificed at fourteenth days and ipsilateral renal tissue. Masson staining was used to observe the renal interstitial fibrosis. The expression of C3, tryptase, chymase, rennin, AngII, TGF-β1, MMP9 in renal interstitium were detected by immunohistochemistry or immunofluorescence or real time quantitative PCR or western blot. Chymase activity of renal tissue was detected by kit. ELISA kit was used to detect AngII, C3a, MMP9.

Results: Compared with WTcontrol group, C3, C3a, mast cells, chymase, renin, AngII, TGF-β1, MMP9 significantly increased in WTuuo group (P<0.001). Compared with WTuuo group, renal tubular injury and interstitial fibrosis were attenuated in C3KOuuo group (P<0.001), C3, C3a, mast cells, chymase, renin, AngII, TGF-β1, MMP9 significantly decreased in WTuuo group (P<0.001). Compared with WTuuo group, enal tubular injury and interstitial fibrosis were attenuated in WTuuo+chymostatin group (P<0.001), chymase activity was significantly decreased (P<0.001), the expression of AngII, TGF-β1 and MMP9 reduced significantly in WTuuo+chymostatin group (P<0.01).

Conclusions: Complement 3 may promote renal interstitial fibrosis by participating in recruitment and activation of mast cells.

TH-PO956

Complement 3 Mediated Macrophage Polarization Contributes to Renal Interstitial Fibrosis

Jian-xin Wan. *The First Affiliated Hospital of Fujian Medical University, Fuzhou, China.*

Background: To explore regulation of complement 3 (C3) on polarization of interstitial macrophages and related outcomes in renal fibrosis.

Methods: C57 BL/6 wild type and C3-deficient mice were created for UUO and sacrificed at days 3, 7, 14 after the operation. Obstructed kidneys were collected and assessed. Expression of C3 in kidneys was detected by immunohistochemical staining. Phenotypes of interstitially infiltrated macrophages, interstitial fibrosis, peritubular capillary density, expression of VEGF and inflammatory cytokines were compared between wild type and C3-deficient UUO mice. Propotion of macrophage phenotypes were identified by double immunofluorescence for F4/80 and iNOS or CD206, western blot for iNOS, Arg-1 and CD206. Paraffin sections were stained with HE and Masson's trichrome. Score of tubulointerstitial injury and percent of renal interstitial fiobrotic area were obtained. Peritubular capillary density was detected by CD31 immunohistochemical staining. VEGF164, sVEGFR1, TNF-α, IL-10 were examined by real time quantitative PCR and western blot. Wild type and C3-deficient UUO mice were treated by liposome clodronate in early or late stage respectively then interstitially infiltrated macrophages and interstitial fibrosis were analysed.

Results: C3-deficient UUO mice had milder degree of tubulointerstitial fibrosis and fewer M1 but more M2 interstitial infiltration in early stage compared with wild type mice. This macrophage polarization shift was accompanied with decreased expression of TNF-α and sVEGFR1, increased expression of IL-10 and VEGF164 in kidney, as well as increased peritubular capillary density. Depletion of macrophages ameliorated renal fibrosis in wild type UUO mice but had no effect on C3-deficient UUO mice.

Conclusions: Complement 3 activation has a close relationship with renal interstitium infiltrating macrophages and fibrosis, and contributes to renal interstitial fibrosis by promotion of macrophage polarization, increasement of inflammatory cytokines, reduction of peritubular capillary density in kidney.

TH-PO957

Effect of Long-Term Tubular Overexpression of Hypoxia-Inducible Factor-2a on the Progressive Renal Fibrosis in a CKD Model

Kyoung Hye Kong, Hyung Jung Oh, Dong-Ryeol Ryu. *Ewha Womans University, Seoul, Republic of Korea.*

Background: Although hypoxia-inducible factor (HIF) is a key transcriptional factor in the response to hypoxia, and the effect of selective tubular activation of HIF-2α on renal fibrosis was demonstrated recently, there is no study for the effect of long-term tubular activation of HIF-2α on the progressive renal fibrosis.

Methods: We are mainly performed using PAX8-rtTA/tetO-Cre/HIF2dPA-HA transgenic mice(Tg). For the induction of renal fibrosis and CKD, the mice were fed a 0.2% adenine-containing diet for 2, 4, and 6 weeks with doxycycline (DOX, 2mg/ml) administration at day 0. Moreover, isolated primary renal tubular epithelial cells (TECs) from Tg mice were divided into one of four groups: the control, DOX (5ug/ml), TGF-β1(10ng/ml), and DOX+TGF-β1 groups (for 24, 48 and 72 h), *in vitro*. For renal function, Cr and BUN were measured, and real-time PCR, western blotting and immunohistochemical staining were performed.

Results: Serum Cr and BUN levels were significantly higher in WT and Tg CKD mice compared with the control mice at 2, 4 and 6 weeks. However, those levels of only 6-week HIF-2α activated CKD mice were significantly decreased compared to those in 6-week WT CKD model. The WB (fibronectin, E-cad/α-SMA, type I collagen) and IHC also showed the increased renal fibrosis in WT CKD mice at 2, 4 and 6 weeks compared with control mice. However, in only 6-week Tg CKD mice, the increased fibrosis was significantly attenuated compared to that in the same week WT CKD mice. In vitro, the increased fibronectin and type I collagen protein expressions after TGF-β1 stimulation were significantly decreased in the 72 h HIF-2α continuous activation except for 24 and 48 h groups.

Conclusions: These findings showed that long-term HIF-2α activation in CKD might inhibit the progression of renal fibrosis and improve renal function, which suggests that long-term renal HIF-2α activation could represent a new therapeutic way in CKD.

Nrf2 Activator, RTAdh404, Attenuates Tubular Injury via Eliminating Mitochondrial ROS in Proteinuria Induced Renal Failure Mice

Yuji Sogawa,[1] Hajime Nagasu,[1] Minoru Satoh,[1] Tamaki Sasaki,[1] Christian Wigley,[2] Colin J. Meyer,[2] Naoki Kashihara.[1] *[1]Kawasaki Medical School, Kurashiki, Japan; [2]Reata Pharmaceuticals, Irving, TX.*

Background: Severe proteinuria, including that associated with diabetic kidney diseases (DKD), leads to renal failure. Abundant proteinuria produces excessive reactive oxidative species (ROS), which trigger inflammation via mitochondrial dysfunction. Regulation of ROS is one of the potential therapeutic strategyies for DKD with proteinuria. We focused on NF-E2-related factor 2 (Nrf2), which is a master regulator for the cellular defense against oxidative stress. Nrf2 activator has a renoprotective effect by eliminating excessive ROS in ischemic-reperfusion injury. However, the mechanisms of the renoprotective effect of Nrf2 activator are not fully understood, especially in DKD. We thus investigated whether RTAdh404 attenuates proteinuria-induced renal tubular damage via mitochondrial protection.

Methods: Male ICR-derived glomerulonephritis mice (ICGN) were used. The mice were divided into three groups: ICR as a control, ICGN+Vehicle (Vehi), and ICGN+RTA dh404 (dh404). dh404 was administered orally for three weeks (dh404;10 mg/kg/day)). Serum creatinine was evaluated as a marker of a renal function. Mitochondrial function was assessed by COX staining and transmission electron microscope. Next, in vitro study, human proximal tubular epithelial cells (hPTECs) were used to determine the mechanism of renal protective effect by dh404. hPTEC were stimulated with bovine serum albumin (BSA) binding bound to free fatty acid (FFA) and treated with or without dh404 for six hours.

Results: In ICGN+Vehi groups, renal dysfunction, based on the serum creatinine was significantly exacerbated. dH404 was able to treatment attenuated renal dysfunction in ICGN mice. Then Tubulointerstitial injury and fibrotic changes were also significantly worsened in ICGN+Vehi mice. Mitochondrial respiratory enzyme and the mitochondrial formation were injured. These damages were improved in ICGN+dh404 groups. These data suggest that RTA dh404 has a renoprotective effect via mitochondrial protection. In vitro study, hPTECs stimulated with FFA+BSA increased mitochondrial ROS and decreased mitochondrial membrane potential. These changes were improved with treatment of dh404.

Conclusions: RTA dh404 attenuates proteinuria induced tubular cell injury through improvement mitochondrial function via eliminating mitochondrial ROS.

Endothelial Dysfunction Exacerbates Renal Tubular Cell Injury Through Inflammasome Activation in a Hypertensive Mouse Model

Yuji Sogawa, Hajime Nagasu, Megumi Kondo, Yoshihisa Wada, Hiroyuki Kadoya, Kengo Kidokoro, Minoru Satoh, Tamaki Sasaki, Naoki Kashihara. *Kawasaki Medical School, Kurashiki, Japan.*

Background: Chronic inflammation is a common pathway of progressive kidney diseases. One of the mechanism in forming chronic inflammation is NLRP3 inflammasome activation. We reported that aldosterone induced hypertension progress tubular interstitium injury via NLRP3 inflammasome activation. However, it is unclear how NLRP3 inflammasome is regulated in the kidney. On the other hand, it is reported that nitric oxide(NO) derived from iNOS suppress inflammasome activation in macrophage. So, we investigated whether or not NO derived from eNOS suppress inflammasome activation in hypertensive kidney disease because it is well known that endothelial dysfunction promotes progressive kidney disease.

Methods: Six weeks male C57BL/6 mice (WT) and eNOS deficient mice (eNOSKO) were used. These mice were divided into four groups (WT, WT-Ald, eNOS, and eNOS-Ald). Aldosterone (Ald) was continuously administered for four weeks by infusion pump. Next, eNOS/ASC double deficient mice (eNOS/ASC DKO) were generated to investigated whether inhibition of inflammasome activation can reduce kidney injury caused by endothelial dysfunction. Finally, we explored the molecular mechanisms underlying the regulation of inflammasome activation by endothelial dysfunction. Bone marrow-derived macrophages (BMDMs) were stimulated with ATP after priming LPS and simultaneously primed with S-nitrosoglutathione (GSNO) as an NO donor or Bay41-2272 as a sGC stimulator.

Results: NLRP3 inflammasome activation was increased in the kidneys of the eNOS-deficient mice, and tubulointerstitial fibrosis was accelerated. Suppression of inflammasome activation by knocking out ASC prevented tubulointerstitial injury in the eNOS knockout mice, indicating that the eNOS-NO pathway is involved in the development of kidney dysfunction through acceleration of NLRP3 inflammasome in macrophages. ATP stimulation with LPS priming caused NLRP3 inflammasome-dependent cell death and IL1beta secretion. While GSNO inhibited this activation, it did not affect the sGC stimulator. This data suggests that NO can suppress NLRP3 inflammasome activation directly in macrophages.

Conclusions: eNOS-NO pathway could be a therapeutic target for the treatment of chronic kidney disease associated with endothelial dysfunction.

Tenascin-C-Rich Extracellular Microenvironment Impairs Renal Tubular Integrity and Promotes Renal Fibrosis

Haili Zhu,[1] Jinlin Liao,[1] Xue Hong,[1] Haiyan Fu,[1] Youhua Liu.[2] *[1]Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Department of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Background: Tenascin-C (TNC), an extracellular matrix glycoprotein, is the major component of fibrogenic niche that facilitates renal fibrosis through multiple mechanisms. We previously reported that focal expression of TNC after injury sets up a favorable microenvironment for fibroblast activation and proliferation. However, whether such a TNC-rich niche also affects tubular cell integrity and phenotype remains unclear.

Methods: Serum and biopsy specimens from CKD patients as well as various CKD animal models were used. TNC and its downstream signaling was manipulated or therapeutically inhibited *in vivo*. The 2-Dimensional and 3-Dimensional culture of human kidney proximal tubular cells (HKC-8) and mouse primary proximal tubular epithelial cells were applied.

Results: ELISA results demonstrated that TNC level significantly elevated in the serum of CKD patients, and consistently its expression was also induced in kidney biopsy specimens from CKD patients with different etiologies. *In vitro*, TNC significantly promoted HKC-8 cell migration and induced them to undergo epithelial-mesenchymal transition (EMT). Similarly, TNC also impaired the integrity of mouse primary proximal tubular epithelial cells by triggering EMT. Using de-cellularized kidney tissue scaffold (KTS) isolated from fibrotic kidneys, we found that TNC-enriched KTS facilitated tubular epithelial cell EMT, whereas TNC-deprived KTS inhibited it. Mechanistically, TNC induced integrin αvβ6, activated focal adhesion kinase (FAK), leading to the activation of ERK signaling. Blockade of FAK signaling abolished TNC's ability to induce tubular cell EMT in vitro. In mouse models of CKD induced by unilateral ureteral obstruction or ischemia/reperfusion injury, knockdown TNC or specific inhibition of FAK signaling with small molecule inhibitor repressed partial EMT and ameliorated fibrotic lesions.

Conclusions: These studies unveil that TNC-rich extracellular niche plays a critical role in impairing tubular cell integrity by inducing partial EMT. Our data also indicate that blockade of TNC/FAK signaling is a novel strategy for therapeutic intervention of renal fibrosis.

rAAV6-Mediated miR-29b Delivery Suppresses Renal Fibrosis

Suguru Saito,[1] Shinichiro Ohno,[2] Masahiko Kuroda,[2] Yoshihiko Kanno.[1] *[1]Deparatment of Nephrology, Tokyo Medical University, Tokyo, Japan; [2]Deparatment of Molecular Pathology, Tokyo Medical University, Tokyo, Japan.*

Background: Renal fibrosis is a common feature of CKD, which has no available specific treatment. Micro RNAs (miRNAs) are short endogenous non-coding RNAs that regulate various cellular processes. Previous studies showed that miR-29b inhibits renal fibrosis in mice models. Therefore, miR-29b replacement therapy represents a promising approach for treating renal fibrosis. However, an efficient method of kidney-targeted miRNA delivery has yet to be established. Recombinant adeno-associated virus (rAAV) vectors have great potential for clinical application. The distinct AAV serotypes exhibit different tissue tropisms. For kidney-targeted gene delivery, the most suitable AAV serotype has yet to be established. Here, we identified the most suitable AAV serotype for kidney-targeted gene delivery, and determined that AAV-mediated miR-29b delivery can suppress renal fibrosis *in vivo*.

Methods: We used the normal rat kidney fibroblast cell line (NRK-49F), rat TEC line (NRK-52E), and human kidney proximal TECs to determine which AAV serotype is suitable for kidney-targeted gene delivery *in vitro*. To determine transduction efficiency, GFP-positive cells were identified by flow cytometry after the infection of rAAV serotype 1–9 vectors containing the *EGFP* gene. Next, we went on to investigate the transduction efficiency of mouse kidney by using rAAV serotype 1–9 vectors *in vivo*. We injected rAAV vectors into the renal pelvis. To determine transduction efficiency, GFP expression was measured seven days after injecting rAAV vectors carrying the *EGFP* gene Finally, we investigated whether rAAV6-mediated miR-29b delivery can suppress renal fibrosis in a unilateral ureteral obstruction (UUO) mouse model.

Results: We found that rAAV6 vector is the most suitable for targeting kidney cells regardless of animal species *in vitro* and rAAV6 is the most suitable vector for kidney-targeted *in vivo* gene delivery in mice. Intra-renal pelvic injection of rAAV vectors can transduce genes into kidney TECs. Furthermore, rAAV6-mediated miR-29b delivery attenuated renal fibrosis in UUO model by suppressing *Snail1* expression.

Conclusions: In summary, our study has revealed that rAAV6 is the most suitable serotype for kidney-targeted gene delivery and rAAV6-mediated miR-29b delivery into kidney TECs can suppress established renal fibrosis. Our findings may provide novel information for facilitating kidney gene therapy.

DNM3OS Non-Coding RNA as a New Therapeutic Target in the Context of Renal Fibrosis

Christelle Cauffiez,[1] Grégoire Savary,[1] Edmone Dewaeles,[1] Julie Lemaire,[1] Francois Glowacki,[2,1] Nicolas Pottier.[1] *[1]University of Lille EA4483, Lille, France; [2]CHRU de Lille, Lille, France.*

Background: The study of miRNAs in fibroproliferative diseases, and in particular in kidney fibrosis, has underscored their involvement in the key mechanisms of fibrogenesis. In the context of pulmonary fibrosis, the polycistronic RNA DNM3OS, producing the three fibromiRs, miR-199a-5p, miR-199a-3p and miR-214-3p, has recently been described as a regulator of the process fibrosis. Indeed, these three miRNAs participate in TGF-β pathway regulation and in the differentiation of fibroblasts into myofibroblasts. The aim of this study was to evaluate in kidney the anti-fibrotic potential of targeting the non-coding DNM3OS RNA by different oligonucleotide approaches directed against DNM3OS or miR- 199a-5p.

Methods: In a first step, the oligonucleotides were selected according to their anti-fibrotic efficacy in the 3T3 fibroblast cell line. The study then relies mainly on the use of a murine model of renal fibrosis induced by unilateral ureteral obstruction. After evaluating their safety (acute or chronic administration), oligonucleotides formulated for in vivo administration and directed against either miR-199a-5p or DNM3OS (Gapmer) were systemically injected before and after the induction of renal fibrosis. Fibrotic lesions was evaluated by studying the renal expression of fibronectin 1 (FN1) and Collagen 1a1 (COL1A1) genes as well as by the histological analysis of kidney sections by immunohistochemistry and Sirius Red staining.

Results: Our results showed that the administration of oligonucleotides directed against miR-199a-5p or DNM3OS allows a significant reduction in renal fibrosis lesions induced by ureteral obstruction. In particular, we observed a decrease in the expression of extracellular matrix compounds such as FN1 and COL1A1. In addition, tolerance studies (single or chronic) of anti-miR-199a-5p did not reveal any renal or hepatic toxicity of the oligonucleotide in mice.

Conclusions: Overall, in the context of fibroproliferative pathologies, our results underline the interest of the therapeutic targeting of polycistronic RNA DNM3OS based on the modulation of the expression of this non-coding RNA or of one of the miRNAs that it produces using synthetic oligonucleotides. The clinical development of such molecules could eventually limit the progression of fibrosis.

Therapeutic Effect of siRNA-CD40 on AKI Caused by Reversible Obstructive Nephropathy in Mice

Roser Guiteras,[1] Alonso N. Barros,[1] Anna Sola,[1] Anna Manonelles,[2] Joan Torras,[2] Josep M. Cruzado.[2] *[1]IDIBELL, Hospitalet de Llobregat, Spain; [2]Hospital Universitari de Bellvitge, Barcelona, Spain.*

Background: The costimulatory CD40-CD40L pathway plays a role in kidney inflammation. We have previously reported that renal CD40 upregulation precedes cellular interstitial infiltrate and fibrosis in the unilateral ureteral obstruction (UUO) model. Here we sought to evaluate whether the administration of siRNA anti-CD40 has a therapeutic effect in a reversible UUO mice model (rUUO).

Methods: Eight week-old C57BL6J male mice were divided into four groups: **wild type** (n=6); **rUUO-Sham** (n=8); **rUUO+siRNA Scrambled**, a non-specific siRNA (n=6), and **rUUO+siRNA anti-CD40**, specific siRNA anti-CD40 (n=8). Ureteral clamping was performed on 8 week-old C57BL6J male mice. At day 3 after surgery, the ureteral clamp was removed and nephrectomy of the contralateral kidney was performed. Immediately, PBS, siRNA SC (50μg) or anti-CD40 (50μg) was administrated via the tail vein. Mice were killed 48h hours after. Blood samples at days 0, 3, 4 and 5 were collected for creatinine analysis. Histology and kidney mRNA expression were performed.

Results: The administration of siRNA anti-CD40 was associated with a significant reduction of renal CD40 mRNA expression (Table 1). siRNA anti-CD40 reduced significantly the severity of acute renal failure associated with UUO (Figure 1). Pathologic analysis showed reduction of tubular dilation, F4/80 macrophage infiltration and interstitial fibrosis in animals treated with CD40-siRNA (Table 1). Furthermore, kidney mRNA gene expression analysis showed significantly lower levels of pro-inflammatory cytokines such IL-2 and CCL-2 and pro-fibrotic TGFβ-1 in CD40-siRNA mice.

Conclusions: The administration of siRNA-CD40 therapy at the time of ureter clamp removal in the UUO model reduces the severity of the acute kidney injury and promotes kidney repair.

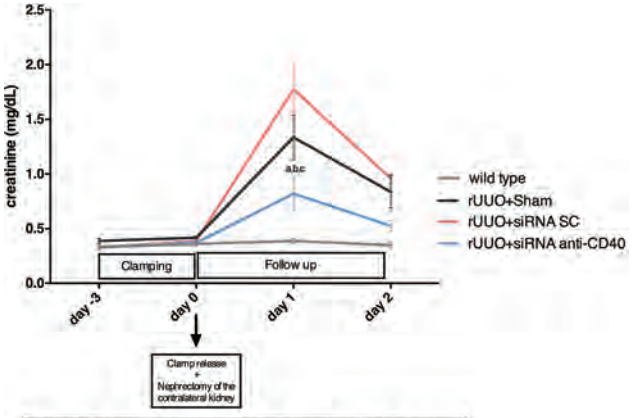

Figure 1. Serum creatinine analysis. Creatinine levels increased showing maximum values at day 1 post clamp release and nephrectomy of the contralateral kidney. siRNA anti-CD40 treated group was the only group displaying significant fewer values compared to rUUO+Sham and rUUO +siRNA SC. a. siRNA anti-CD40 vs wild type; b. siRNA anti-CD40 vs Sham; c. siRNA anti-CD40 vs siRNA SC.

TH-PO964

Pericyte-Myofibroblast Transition Induced Tubulo-Interstitial Injury in a Novel Renal Venous Congestion Rat Model

Takuo Hirose,[1,2] Satoshi Shimada,[2] Chika Takahashi,[1] Emiko Sato,[2] Satoshi Kinugasa,[1,2] Sadayoshi Ito,[2] Takefumi Mori.[1,2] *[1]Division of Nephrology and Endocrinology, Tohoku Medical and Pharmaceutical University, Sendai, Japan; [2]Division of Nephrology, Endocrinology and Vascular Medicine, Tohoku University Graduate School of Medicine, Sendai, Japan.*

Background: Increased central venous pressure in congestive heart failure is responsible for renal dysfunction. However, the knowledge of the underlying mechanisms is limited. We hypothesized that renal interstitial hydrostatic pressure (RIHP) and expansion pressures of the vasa recta are responsible for pericyte detachment resulting renal congestion-mediated fibrosis. We created a novel rat renal congestion model to investigate the effect of renal congestion on hemodynamics and its molecular mechanisms.

Methods: The inferior vena cava (IVC) between the renal veins was ligated by suture in male Sprague-Dawley rats to increase upstream IVC pressure and induce congestion in the left kidney only.

Results: Left kidney congestion reduced renal blood flow in cortex (33.6%, 28.3 to 16.0 mL/min) and in medulla (41.8%, 11.9 to 6.9 mL/min) and glomerular filtration rate (17.2%, 1.16 to 0.20 mL/min/kg BW), and increased RIHP (1.4 fold, 12.6 to 17.6 mm Hg). In the congestive kidneys, hypoxia was observed in the medullary thick ascending limb of Henle. Tubulointerstitial injury, podocyte injury, albuminuria, and reduced creatinine clearance were observed in the congestive kidneys. Molecules related to extracellular matrix expansion, tubular injury, and focal adhesion were upregulated in microarray analysis. Renal decapsulation ameliorated the tubulointerstitial injury (mRNA expression of *Kim1* 15.3 to 4.3 A.U., *αSma* 5.3 to 2.8 A.U.). Electron microscopy captured pericyte detachment in the congestive kidneys. Transgelin and platelet-derived growth factor receptors (PDGFRs), as indicators of pericyte-myofibroblast transition, were upregulated in the pericytes and the adjacent interstitium. Imatinib, a PDGFR inhibitor, ameliorated the interstitial injury.

Conclusions: Our results reveal a novel mechanism of worsening renal function associated with congestive heart failure, and provide a new therapeutic candidate based on a better understanding of the pericyte-myofibroblast transition.

TH-PO965

Varying AKI Types Affect Parietal Epithelial Cell Function with Different Impact on Tubuloglomerular Cross-Talk

Jiayi Wang,[1] Xin Li,[3] Ming-Zhi Zhang,[1] Raymond C. Harris,[1] Taiji Matsusaka,[2] Haichun Yang,[1] Agnes B. Fogo.[1] *[1]Vanderbilt University Medical School, Nashville, TN; [2]Tokai University School of Medicine, Isehara, Japan; [3]The Medicine College of Shanghai JiaoTong University, Shanghai, China.*

Background: Previously we found that mild tubulointerstitial fibrosis sensitizes the kidney to subsequent glomerular injury. The transition of acute kidney injury (AKI) to chronic kidney disease depends on the severity of AKI. In this study, we explored whether the type of initial proximal tubular (PT) injury impacts the glomerular response to a subsequent injury, and the role of parietal epithelial cells (PECs) in this response.

Methods: We induced AKI by injecting diphtheria toxin (DT) in DTR transgenic mice that express human DT receptor in S2 and S3 PT, or by injecting aristolochic acid (AA) which targets all PT and part of PECs. All mice were mated with NEP25 mice, which express human CD25 on podocytes, and podocyte injury can be induced by immunotoxin (LMB2). Mice underwent LMB2 injection at 6 wks after DT or AA injury, with control mice (PODO) only receiving LMB2 without preceding tubular injury, followed by uninephrectomy 1 wk later and sacrifice 4 wks later. In vitro, PECs were exposed to vehicle or AA for 24h, followed by exposure to supernatant from injured podocytes for 48 hours.

Results: Urinary KIM-1/NGAL recovered to baseline in DT while they remained high in AA mice at wk 6 after injury. AA+LMB2 mice had significantly higher albuminuria than PODO, while DT+LMB2 had no significant increase vs PODO, at 1 wk after LMB2. Columnar PECs may have more stem cell potential vs flat PECs, and columnar/flat PECs ratios were higher in PODO mice and DT+LMB2 than AA+LMB2. Expression of β–catenin and ILK in PECs increased in AA+LMB2, but not in DT+PODO, compared to PODO. WT1+ cell density was decreased in both AA+LMB2 and DT+LMB2 vs PODO. At 4 wks after LMB2, 0/16 PODO and 1/23 DT+LMB2 vs 8/16 AA+LMB2 mice had died. GFR, ACR and glomerulosclerosis were similar among groups in surviving mice. Both DT+LMB2 and AA+LMB2 showed more CD44+/α-SMA+ cells on the glomerular tuft than PODO, suggesting mesenchymal transition of activated PECs. In vitro, AA-treated PECs expressed more ILK and CTGF vs vehicle after cells were exposed to injured podocyte medium.

Conclusions: Tubular injury that involves specific PT segments and PECs, which may serve as stem cells and participate in glomerular rescue after injury, may result in less recovery and increased sensitization of glomeruli to a second hit.

TH-PO966

IL-6 Signaling Triggers Expulsion of Uropathogenic Bacteria from Host Epithelial Cells to Limit UTI Chronicity

Sudipti Gupta, Christina B. Ching, Brian Becknell. *Nationwide Children's Hospital, Columbus, OH.*

Background: Treatment of urinary tract infections (UTIs) has historically relied on the use of antibiotics which are limited by patient intolerance and rising bacterial resistance. Innate immunity represents an attractive alternative in UTI treatment and prevention; however, its influence on bacterial virulence is not well known. Specifically, IL-6 is induced during UTI, but our understanding of its role in UTI pathogenesis is limited. We sought to determine how IL-6 expression alters urothelial susceptibility to infection and impacts bacterial clearance.

Methods: 6-8 week old female wild type (WT) C57BL/6J and IL-6 knock out (KO) mice were transurethrally infected with uropathogenic Escherichia coli (UPEC). Bacterial burden was assessed by dilution plating; and intracellular bacterial communities (IBC) were enumerated by beta-galactosidase staining. Gentamicin protection assay quantified intracellular bladder bacterial burden. The impact of IL-6 neutralization and IL-6 rescue on IBC formation was studied in WT and IL-6 KO mice, respectively. Neutralization of serum IL-6 was confirmed by ELISA. *In vitro* gentamicin protection assay was used to study the impact of recombinant IL-6 on bacterial attachment, invasion, and expulsion in bladder epithelial cells (BECs). Results were evaluated by Mann-Whitney U test with $p < 0.05$ being significant.

Results: A significant increase in IBCs was observed in IL-6 KO mice vs. WT controls early during infection but resolved 24 hours post infection (hpi). These findings were recapitulated by antibody neutralization of IL-6 in WT mice. The increase in IBCs in IL-6 KO animals was reversed with recombinant IL-6. We confirmed an increase in bladder bacterial burden in IL-6 KO mice by *ex vivo* gentamicin protection assay, which accounts for increased bacteriuria in IL-6 KO compared to WT mice beginning after 24 hpi. *In vitro* experiments in BEC demonstrated that IL-6 treatment significantly increased UPEC expulsion but did not impact invasion or attachment.

Conclusions: IL-6 reduces UTI susceptibility by promoting UPEC expulsion from host epithelial cells, thereby limiting the ability of UPEC to persist intracellularly and form IBCs. Given that IBC formation represents a significant bottleneck event in UPEC survival, these findings suggest a mechanism whereby IL-6 reduces UTI chronicity.

Mitigation of Radiation Injury by Epoxyeicosatrienoic Acid Mimetic Assessed by Urinary Proteomics

Ann M. Kolbach-Mandel,[2] Eric P. Cohen,[1,3] Neil S. Mandel,[2] John D. Imig,[2] Abdul Hye Khan,[2] Brian L. Fish,[2] Maureen A. Kane,[1] Weiliang Huang.[1] *[1]University of Maryland, Baltimore, MD; [2]Medical College of Wisconsin, Milwaukee, WI; [3]Medicine, Baltimore VAMC, Baltimore, MD.*

Background: Radiation exposure due to radionuclide cancer therapy, accident, or radio-nuclear attack could cause radiation induced nephropathy. Non-biased urinary proteomic analysis can identify novel urine biomarkers that precede tissue injury and may be mechanistically relevant.

Methods: 20 male WAG/RijCmcr rats underwent partial body irradiation (PBI) with one leg shielded to allow bone marrow reconstitution. 24 hour urine was collected four weeks after PBI from control (0 Gy) or irradiated (11 Gy) without or with epoxyeicosatrienoic acid (EET) mimetic therapy. Renal injury was assessed by urine protein and urine creatinine. Proteomic analysis was performed on urine (ultrafiltered > 3kDa) using standardized methods. Protein abundance determinations (% Extracted Ion Chromatograph, % XIC) were normalized to total urine protein, urine creatinine, and rat weight. Final protein concentrations are reported as protein/creatinine/weight (mg/g/kg).

Results: Baseline rat weights did not differ according to experimental group. At 4 weeks after PBI the 11 Gy rats weighed significantly less than controls. The radiated rats did not differ in total urine protein, urine creatinine, urine protein/creatinine, or urine volume. Proteinuria occurs starting at six weeks in this model. Mass spectrometry-based proteomics yielded 781 proteins with 99.9% overlap in all experimental groups. The increased abundance of proteins in irradiated rats were largely of extracellular origin and part of biological networks related to nucleic acid, carbohydrate, and collagen metabolism. The EET mimetic significantly changed select proteins related to these networks. Notable changes in mg/creat/body weight were: Malate dehydrogenase 0.06/0.18/0.11, Glyceraldehyde 3 phosphate dehydrogenase 0.05/0.20/0.12, and Lysyl Oxidase 0.01/0.25/0.01.

Conclusions: Radiation exposure results in significant increases in urinary proteins, largely extracellular in origin, related to nucleic acid, carbohydrate, and collagen metabolism. The largest effect was on lysyl oxidase, an enzyme that increases collagen crosslinking which may presage tissue fibrosis in this model. This offers some insight into the known therapeutic benefits of the EET mimetic.

TH-PO968

Urinary Extracellular Vesicles (uEVs) Have Unique Characteristics as Demonstrated by Imaging and Spectral Cytometry

Luca Musante,[1] Sabrina La salvia,[1] Joanne Lannigan,[1] Uta Erdbruegger.[2] *[1]University of Virginia, Charlottesville, VA; [2]University of Virginia Health System, Charlottesville, VA.*

Background: Urinary extracellular vesicles (uEVs) provide a source of valuable biomarkers for kidney and urogenital diseases. Analysis of uEVs is challenging due to its intrinsic complexity. Imaging flow cytometry (iFC) allows detection of particles that are < 200 nm in size and has a high level of sensitivity for small particle fluorescence. In addition, spectral flow cytometry (sFC), which is based on whole spectrum analysis, can be used to further characterize the findings of the iFC analysis.

Methods: First morning void urine, blood and saliva (internal auto fluorescent control) were centrifuged at relative centrifugation force RCF of 4.600g for 30 minutes. The supernatants was further centrifuged at 20,000g to collect EVs. uEVS were stained with different annexin V conjugates: FITC, PE, PerCPCy5.5, Pacific Blue™, Brilliant Violet 421, Brilliant Violet 510, APC, Alexa Fluor® 647 respectively. Gating strategy was based on the low scatter of the unstained uEVs and the negative control was all fluorescent probes alone in buffer. Stained and unstained EVs from urine, plasma and saliva were evaluated

Results: Acquisition of uEVs alone in iFC showed an interesting auto-fluorescence emission in channel 5 (λ_{ex} 660 nm; λ_{em} 740 nm) for camera 1 and channel 11 (λ_{ex} 660 nm; λ_{em} 740 nm) for camera 2. Auto fluorescence emission in channel 11 was caused by excitation from the violet laser (λ_{ex} 405 nm) and red laser (λ_{ex} 642 nm). Auto-fluorescence in Channel 5 was caused by excitation of both blue (λ_{ex} 488 nm) and yellow laser (λ_{ex} 561 nm). Spectral analysis of unlabelled uEVS, plasma EVs (pEVs), and saliva EVs (sEVs) showed that this auto-fluorescence was unique and specific for uEVs. Spectrum plots showed a distinct signature

Conclusions: While imaging flow cytometry represents a major advancement in the identification of uEVs, our results suggest that unexpected additional complication of the analysis originated from the auto-fluorescence with a peculiar spectral emission that needs to be taken into account when multicolor antibodies panels are planned. Likewise, choice of AV fluorochrome conjugate should be carefully considered.

TH-PO969

Enrichment and Identification of Ubiquitinated Proteins in Urinary Extracellular Vesicles

Yongqiang Li, Hequn Zou. *Third Affiliated Hospital of Southern Medical University, Guangzhou, China.*

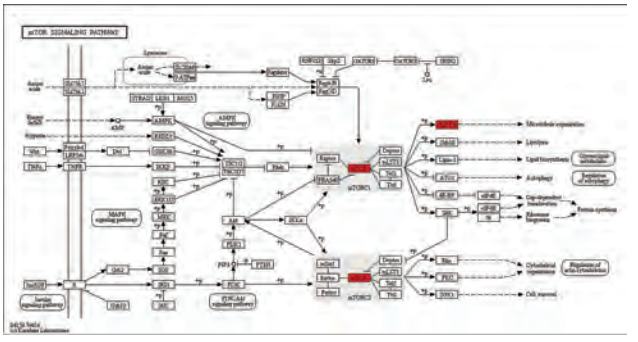
Background: Urinary extracellular vesicles(uEVs) is widely considered to represent pathological events in the kidneys and the urogenital epithelium. Ubiquitin mediates proteolysis through the enzymatic conjugation of UB to proteins that contain primary degradation signals. The aim of our current study was to establish a method to enrich and identify ubiquitinated protein in uEVs.

Methods: After 2000g centrifugation, supernatant 2000g was obtained from 1st morning urine. Then supernatant 2000g was processed by Hydrostatic dialysis filter using dialysis membrane with a molecular weight cutoff (MWCO) of 1,000 kDa. Protein-A Sepharose® IgG was used to concentrate ubiquitinated proteins, which is based on the binding of antibodies to Sepharose beads and subsequent cross-linked by Dimethyl pimelimidate(DMP). Coomassie staining, western blot and mass spectrographic analysis were used to characterize the ubiquitinated protein in uEVs.

Results: Ubiquitinated proteins in uEVs are enriched successfully. We detected 60 specific sites of 37 ubiquitinated proteins. These ubiquitinated proteins were mainly enriched in the biological process categories of cellular process. Most of the ubiquitinated proteins in the cellular component category occurred in the nucleus. The KEGG enrichment pathway analysis of these ubiquitinated proteins suggested that ubiquitination maybe play an indispensable role in the regulation of the mTor signaling pathway.

Conclusions: We provides a simplified method to enrich and identify ubiquitinated proteins in uEVs. 60 specific sites of 37 ubiquitinated proteins were discovered. Till now, all screening ubiquitinated proteins in urinary EVs of this study have not been previously reported. These method and findings allows the possibility to further chronic kidney disease studies in uEVs related to ubiquitinated proteins.

Funding: Government Support - Non-U.S.



The proteins in red were identified in mTOR of this project

Circulating Exosomes Mediate Inter-Organ Communication in Type 2 Cardiorenal Syndrome

Cong Wang,[1] Lili Zhou,[1] Youhua Liu.[2] *[1]Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Department of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Background: Inter-organ crosstalk plays an essential role in regulating tissue homeostasis, injury repair and the pathogenesis of multi-organ dysfunction. Cardiorenal syndrome type 2 (CRS2) is characterized by chronic abnormalities in cardiac function causing progressive chronic kidney disease (CKD). However, the mediators connecting heart and kidney are poorly characterized. In this study, we report that exosomes produced by injured heart plays a vital role in mediating cardiorenal connection in mouse model of transverse aortic constriction (TAC).

Methods: Four weeks after TAC, mice were randomized into three groups: 1) sham control; 2) TAC mice; 3) TAC mice injected daily with cyclopamine (CPN), a specific small molecule inhibitor of hedgehog signaling. At 8 weeks after TAC, all animals were sacrificed. Urine, blood, heart and kidney tissues were collected for analysis. Exosomes were isolated from mouse serum, and incubated with normal rat kidney interstitial fibroblast (NRK-49F) cells.

Results: At 8 weeks after TAC, cardiac hypertrophy and fibrosis were prominent, as evidenced by increased expression of β-myosin heavy chain, α-actin and fibronectin. Echocardiography also revealed an impaired cardiac function in TAC mice. These cardiac lesions were accompanied by an upregulation of sonic hedgehog (Shh) and increased production of exosomes in cardiac tissue. Blockade of Shh signaling by CPN ameliorated cardiac injury and restored heart function. Notably, TAC mice also developed kidney lesions secondary to chronic heart failure, manifested by proteinuria, kidney fibrosis and renal upregulation of Shh. CPN mitigated all these lesions in the kidneys. Serum derived from TAC mice was able to induce renal interstitial fibroblast activation in vitro, indicating the circulating factors as mediators of cardiorenal connection. Furthermore, exosomes isolated from TAC serum was sufficient to cause fibroblast activation and matrix production. Western blot demonstrated the presence of Shh and Smo in the isolated exosomes from TAC serum, but not in the exosomes from the control serum.

Conclusions: These studies demonstrate that heart-derived, circulating exosomes are a unique and effective vehicle to deliver Shh to the kidney after TAC. Targeted inhibition of Shh signaling could be a promising therapeutic strategy for protecting both heart and kidney in cardiorenal syndrome.

Renal NMDA Receptor Mediates the Amino Acid Induced Vasodilation Through Connecting Tubule-Glomerular Feedback (CTGF)

Cesar A. Romero,[1] Hong Wang,[1] Yilin Ren,[2] Oscar A. Carretero.[2] *[1]Hypertension and Vascular Research, Internal Medicine, Henry Ford Hospital, Detroit, MI; [2]Henry Ford Hospital, Detroit, MI.*

Background: The intravenous infusion of amino acids increase the renal blood flow and glomerular filtration rate, and it used to quantify the renal functional reserve. Similarly, high protein diet promotes the progression of chronic kidney diseases in part due to an increase in the renal blood flow, and glomerular pressure. Those glomerular effects are thought to be related to a vasodilation mediated by the amino acids that are released from the diet. However the vasodilator mechanism related to the amino acids in kidney is unknown. Kidney expresses the amino acid receptor N-methyl-D-aspartate (NMDA) that is activated by glutamate and glycine. Our lab described an intrinsic kidney feedback mechanism called CTGF that by sensing sodium in the connecting tubule (CNT) induces the dilation of the afferent arteriole (Af-Art). We hypothesize that in the kidney through the NMDA receptors the amino acids induce Af-Art dilation by activating CTGF.

Methods: By using double-perfusion of Af-Art and CNT technique *in vitro* (rabbit) and Stop-Flow Pressure (SFP) technique *in vivo* (Sprague Dawley Rat), we test the Af-Art dilation induced by CTGF when the CNT perfuse with glycine plus glutamate 10^{-3}M with or without the NMDA blocker MK-801.

Results: *In vitro,* in pre-constricted Af-Arts, addition of glycine plus glutamine to the CNT increases the Af-Art dilation (EC_{50} 10.7) vs. control (EC_{50} 24.5; $p<0.001$), and that dilation is blocked by CTGF blocker benzamil, suggesting that glycine plus glutamine enhanced CTGF. When we add the NMDA receptor blocker MK-801 to the CNT, the increased CTGF response is blunted. *In vivo,* the intratubular infusion of the amino acid induces vasodilation (SFP mmHg 37.9±2.6 vs. 28.6±1.9 control; $P<0.01$) and that vasodilation is blocked by benzamil.

Conclusions: Renal vasodilation induced by amino acid is mediated by the CTGF through the NMDA receptor in the connecting tubule. The activation of the CTGF by amino acids explain the basis of the renal functional reserve test and provide potential mechanism to prevent the renal damage associated with high protein diet.

Autophagy Protects Kidney Proximal Tubules from Phosphate-Mediated Mitochondrial Dysfunction

Ryuta Fujimura,[1] Takeshi Yamamoto,[1] Yoshitsugu Takabatake,[1] Satoshi Minami,[1] Atsushi Takahashi,[1] Tomoko Namba,[1] Jun Matsuda,[1] Shinsuke Sakai,[1] Isao Matsui,[1] Fumio Niimura,[2] Taiji Matsusaka,[2] Yoshitaka Isaka.[1] *[1]Nephrology, Osaka University Graduate School of Medicine, Osaka, Japan; [2]Tokai University School of Medicine, Isehara, Japan.*

Background: Autophagy is one of the major degradation pathways in the cell and maintains cellular homeostasis in various settings. Hyperphosphatemia is associated with a faster progression of chronic kidney disease (CKD), as well as an increased risk of cardiovascular mortality. However, molecular mechanisms of phosphate-mediated kidney injury are largely unknown.

Methods: We investigated the pathogenesis of phosphate-mediated kidney injuries in the proximal tubular epithelial cells(PTECs) with a focus on autophagy and mitophagy, and the effects of autophagy deficiency and enhancement on kidney morphology and function during phosphate overload.

Results: In GFP-MAP1LC3 transgenic mice, high phosphate(HP) diet continuously stimulated autophagy in the PTECs. In novel mitophagy-reporter mice (mito-QC), HP diet also increased the number of mitolysosomes (mitochondria-containing autolysosomes) exclusively in the PTECs. High concentration of inorganic phosphate (Pi) in the medium increased PINK1/Parkin expression as well as autophagic activity in cultured PTECs. High Pi not only induced mitochondrial ROS production and mitochondrial permeability transition pore (mPTP) opening, but also reduced mitochondrial membrane potential, ATP production and oxygen consumption rate, all of which were significantly exaggerated by autophagy deficiency. A ROS scavenger, *N*-acetylcysteine (NAC), blocked mPTP opening, reduced PINK1/Parkin-dependent mitophagy, and successfully alleviated phosphate-mediated cellular damages. HP diet-fed mice showed mitochondrial dysfunction, reactive oxygen species (ROS) production, apoptosis, and inflammasome activation in the kidney, which were significantly exaggerated by autophagy deficiency. Finally, HP diet-fed proximal tubule-specific Rubicon knockout mice, in which autophagic flux is genetically enhanced, ameliorated HP-mediated kidney injuries.

Conclusions: Phosphate overload induces mitophagy in PTECs, which is indispensable for maintaining proper mitochondrial functions. Enhancing autophagic activity could be a promising way to suppress CKD progression.

TH-PO973

A Circadian Pattern in Urine Exosome Excretion Is Not Influenced by Sex or Food-Water Deprivation: Implications for Biomarker Normalization

Erik H. Koritzinsky, Jonathan Street, Robert A. Star, Peter S. Yuen. *National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Urine exosomes are extracellular vesicles released by all cells along the nephron and represent a promising source of non-invasive biomarkers. Many candidate urine exosomal biomarkers have been described, yet none have reached clinical use, in part because how to normalize them is unknown, as urine flow rate or concentration can vary by over an order of magnitude. We previously showed that urine exosome excretion displays a circadian pattern in male rats (peak at 21:00), but little is known about what factors modulate urine exosome release.

Methods: Timed urine samples from healthy rats (n=6M, 6F) were collected over 24 hr in six 4-hr fractions. A subset of these rats (n=4) underwent a second matched 24 hr collection with 13 hr of food and water deprivation spanning the full dark (active) period. Urine exosomes were isolated by ultracentrifugation and counted by Nanoparticle Tracking Analysis.

Results: 24 hr urine exosome excretion varied widely between animals (CV=71%). To study the circadian pattern, variability was reduced by normalizing exosome excretion for each fraction to the peak excretion rate for each animal. Normalized urine exosome excretion displayed a similar circadian pattern in both male and female rats. There was no correlation between urine exosome excretion and urine flow rate (Male: $r^2=0.004$, Female: $r^2=0.04$). Food-water deprivation had no detectable impact on exosome excretion but significantly increased exosome concentration 13-17 hr after removal of food and water ($p=0.03$), likely due to decreased urine output.

Conclusions: Urine exosome excretion displays a distinct circadian pattern that complicates the measurement of urine exosomal biomarkers. The observed pattern in urine exosome excretion was neither sex specific nor affected by food-water deprivation. Spot urine concentration of exosomal biomarkers can be normalized by exosome concentration. This adjusted measure of biomarker content per exosome appears to be independent of time of collection, sex or food-water intake. Proper exosomal biomarker normalization will be essential in advancing promising candidates to clinical use and can uncover patterns otherwise obscured by natural biological variation, increasing their clinical utility and enabling the reliable use of spot urine measurements instead of timed collections.

Tertiary Lymphoid Tissue Is a Novel Histological Marker Reflecting Local Injury and Inflammation in Murine and Human Kidneys

Yuki Sato,[1] Peter Boor,[2] Jürgen Floege,[2] Motoko Yanagita.[3] *[1]Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]RWTH University of Aachen, Aachen, Germany; [3]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: Tertiary lymphoid tissues (TLTs) are ectopic lymphoid tissues that are formed under various pathologic conditions such as autoimmunity and infection, and support priming of immune responses. We previously demonstrated that aged but not young mice exhibited multiple TLTs after AKI, which underlie maladaptive repair. TLTs were also detected in human aged and diseased kidneys, yet the comprehensive understanding is lacking and the clinical relevance remains controversial.

Methods: We analyzed human renal TLTs utilizing surgically resected kidneys from aged patients (N=69) and pyelonephritis patients (N=16) and proposed a novel staging scheme of TLTs. To validate this, we utilized murine TLT model utilizing aged mice subject to IRI. In this model, TLTs develop and expand as ischemic time or the time after IRI increase.

Results: TLTs in both human groups shared a perivascular, periglomerular and subcapsular location as well as similar components such as a homeostatic chemokine CXCL13, but exhibited heterogeneity in phenotype. We classified TLTs into three developmental stages based on the presence of follicular dendritic cells and germinal centers, and demonstrated in mice that the TLT stages advanced with the extent of kidney injury. Dexamethasone treatment after TLT formation decreased the size of TLTs, accompanied with improvement of renal inflammation and fibrosis, indicating the reversibility of TLTs. Consistently, the kidneys of aged patients with CKD exhibited more frequent and more advanced stages of TLTs than those without CKD, and pyelonephritis kidneys exhibited more frequent TLTs with more advanced stages than aged CKD kidneys.

Conclusions: Spatial and developmental similarities of TLTs in both groups indicated that TLT formation might not be disease-specific but rather a common pathological process. On the other hand, the phenotypic heterogeneity of TLTs reflected severity of kidney injuries, which explained the high frequency and advanced stages of TLTs in the kidneys with severe pyelonephritis. The reversibility of TLTs also indicated the potential of TLT-associated molecules as a novel candidate of biomarkers reflecting renal injury. Taken together, our data provide a mechanistic framework for studying TLT formation as a previously unappreciated pathological pathway in kidney disease progression in mouse and human.

p90RSK Modulates Fibroblast-Epithelial Communication

Chaowen Shi, Ling Lin, Kebin Hu. *Penn State University College of Medicine, Hershey, PA.*

Background: Tubular epithelial damage is one of the prominent hallmarks of both acute and chronic kidney injury. Emerging evidence illuminates the fundamental role of intercellular communication in maintaining the integrity of kidney structure and environment. P90RSK is a serine/threonine kinase induced in the fibrotic kidneys. However, its role in kidney fibrosis remains unknown.

Methods: We examined p90RSK activation in human kidney samples. We generated a novel fibroblast-specific p90RSK transgenic mouse (RSK-Tg) and established a fibroblast-epitheial coculture system using primary kidney fibroblasts from RSK-Tg and RSK-wt mice and human proximal tubular epithelial cells (HKC-8) to investigate the role of p90RSK in fibroblast-epitheial interactions

Results: We discoved that p90RSK phosphorylation was increased in the kidney samples from patients with chronic kidney disease. We also found that RSK-Tg mice displayed enhanced renal fibrosis and increased tubular epithelial cell death after obstructive injury than their littermates (RSK-wt), indicating a role of p90RSK in fibroblast-epithelial communication. We established an *in vitro* fibroblast-epithelial coculture system using primary kidney fibroblasts from RSK-Tg and RSK-wt mice and human proximal tubular epithelial cells (HKC-8), and found that RSK-Tg fibroblasts dramatically aggregated staurosporine or H_2O_2-induced epithelial apoptosis. We further discovered that RSK-Tg fibroblasts constantly produced and released higher level of H_2O_2 into the coculture medium causing epithelial oxidative stress and nuclear translocation of β-catenin. Intriguingly, blockade of reactive oxygen species (ROS) reduced RSK-Tg fibroblasts-induced β-catenin and epithelial apoptosis. Moreover, knockdown of β-catenin by RNA silencing eliminated RSK-Tg fibroblast-induced epithelial cell death.

Conclusions: Thus, it is clear that fibroblast-p90RSK mediates epithelial cell death through ROS-activated β-catenin pathway.

TH-PO976

CMV Modifies Disease Progression in a Mouse Model of Sepsis

William Nash, Michael G. Brown, Sundararaman Swaminathan. *University of Virginia, Charlottesville, VA.*

Background: Sepsis is the leading cause of death in hospitals and accounts for around 250,000 deaths in the U.S. anually. Despite its prominence as a global health concern, relatively little is understood about the mechanisms associated with survival or mortality. This is, in part, due to the failure of promising data from animal models to translate into measurable benefits during clinical trials. Hence, improving trial and animal model design are two main focuses in the field. We are approaching this issue by considering the effect of a history of infection on sepsis progression. A major difference between mice and human patients is their exposure to pathogens. Nearly all patients will have a latent infection of some kind and understanding how this may influence the septic syndrome is an important healthcare priority.

Methods: Cecal contents were collected from B6-background mice and processed into a working-stock slurry. Sepsis was induced in experimental mice via i.p. injection of slurry stock induce to life-threatening sepsis. Prior to sepsis, some experimental mice were injected with MCMV and allowed to progress to latency (60+ days). Septic mice were monitored frequently and survival, body weight, and clinical score were recorded. Upon reaching an endpoint, serum and tissue were collected for further analysis.

Results: When CMV-naive and CMV-latent male mice were given body weight-adjusted doses of cecal slurry, all CMV-naive mice succumbed within 2 days while all CMV-latent mice survived out to 13 days (experimental endpoint). Upon further investigation, CMV-latent mice were found to have greater preservation of MHC class II on splenic dendritic cells which correlated with a greater representation of splenic CD3+ cells while CD19+ cell representation was unchanged. Analysis of mice treated with an LD50 dose of slurry for 48 hours revealed that CMV-latent mice also trended toward lesser clinical scores, controlled body weight loss, and higher serum levels of IFNγ, IL-12p70, and IL-1β. BUN levels were elevated in the serum of all mice at 48 hours, but we did not detect any CMV-specific alterations.

Conclusions: The data suggest that CMV is modifying the early progression of sepsis and favoring less severe disease. These effects appear to stem from experience of the immune system leading to a better regulated inflammatory response and preservation of specific lymphocyte populations.

TH-PO977

Realization and Future Applications of LCM from Renal Formalin-Fixed Paraffin-Embedded Slices

Carlo M. Alfieri,[1] Deborah Mattinzoli,[2] Masami Ikehata,[1] Donata Cresseri,[1] Gabriella Moroni,[1] Valentina Vaira,[3] Francesco Pallotti,[1] Piergiorgio Messa.[1,4] *[1]Fondazione IRCCS Ca' Granda Ospedale Policlinico Milan, Milan, Italy; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy; [3]University of Milan, Milan, Italy; [4]Università degli Studi di Milano, Milan, Italy.*

Background: Kidney transplantation(KTx) damage surveillance is relevant in clinical practice. Renal biopsy(RBx) is essential to guide a specific treatment. Laser capture microdissection(LCM) combining molecular biology and histology is a novel approach. Using LCM, we aim to test the expression of some pathologic markers in different renal compartments starting from formalin-fixed paraffin-embedded(FFPE) samples.

Methods: The principal difficulties present in LCM realization were the poor quantity and quality of the FFPE samples related to not RNA suitable sample procession. The late housekeeping Ct coupled with the uncertain RNA amount, caused by infiltrating inflammatory cells and by the fibrosis presence, lead us to opt for a cDNA pre-amp. Since RNA quality has a significant impact on reference gene stability, samples quality was evaluated by means of the housekeeping stability. Among the housekeeping examined, RPL4 had the best Ct and stability.

Results: After verifying the reliability of the selected SsoAdvanced PreAmp Supermix Bio-Rad kit, the method was first used in two different RBx (RBx-A: biopsy without histological alteration; RBx-B: biopsy from a KTx patient with initial transplant glomerulopathy). Then, the most promising biomarkers evidenced were validated in two RBx from the same KTx patient in distinct CKD progression phase (RBx-C1: no injuries;RBx-C2: initial chronic allograft nephropathy, associated to severe interstitial fibrosis) Renal fibrosis: our result suggested a DDR1-TGFβ-COLIII-COLI- chronological formation of the fibrotic matrix in all RBx-B compartments. The same gene expression trend was observed in the RBx-C1 with a later collagens protein formation in the RBx-C2. Predictive biomarkers: Among the biomarkers, Klotho resulted the earliest with a downregulation in RBx-B and RBx-C1. Periostin, although later than Klotho, showed a great damaged compartment discrimination capacity resulting higher in both RBx-B and RBx-C2 glomeruli.

Conclusions: The method presented permits to obtain reliable results in LCM from FPPE samples. Furthermore, it is reproducible, easy and fast. In the future, a study in KTx-RBx of the relationship between RNA-expression at different renal sites and clinical and biochemical parameters and of its predictive role of KTx outcome will be possible.

TH-PO978

Pathological Characteristics of USAG-1 and BMP-7 Expression in Rats with CsA nephrotoxicity

Keisuke Sugimoto,[2] Kohei Miyazaki,[2] Takuji Enya,[2] Tomoki Miyazawa,[2] Mitsuru Okada,[2] Tsukasa Takemura.[1] *[1]Kushimoto municipality hospital, Wakayama, Japan; [2]kindai University Faculty of Medicine, Izumi, Japan.*

Background: CsA-nephrotoxicity is associated with decreased renal bone morphogenetic protein-7 (BMP-7) expression. Uterine sensitization-associated gene-1 (USAG-1), a kidney-specific BMPs antagonist, plays an important role in processing renal damage. The study aimed to evaluate the renal expression of USAG-1 and BMP-7 induced by CsA in a rat model.

Methods: Eight BrlHan:WIST@Jcl (GALAS) rats were assigned to two groups: control (untreated) and CsA (orally received CsA 10 mg/kg body weight). After 28 days, the renal tissues were examined for CsA toxicity, specifically, tubulointerstitial damage and arteriolopathy, by light microscopy. Furthermore, the area of USAG-1 and BMP-7 expression was scored by immunohistochemical staining.

Results: The CsA group showed mild interstitial fibrosis, but no arteriolohyalization and tubular atrophy. Two of the 4 rats in the CsA group presented findings similar to those observed during the early stage of focal segmental glomerulosclerosis (FSGS) development, such as enlargement of glomeruli and foam cells. In these 2 rats, high focal USAG expression and significantly decreased BMP-7 expression were also noted. In contrast, a broad area with BMP-7 expression was observed in the kidney of the 2 rats from the CsA group that presented fewer FSGS-like findings and in the control rats (no CsA nephrotoxicity).

Conclusions: In this study, the characteristic histologic changes of CsA-nephrotoxicity were not observed, but FSGS-like findings were noted. USAG expression may contribute to BMP-7 suppression, resulting in FSGS-like pathology that leads to CsA-nephrotoxicity. Furthermore, an imbalance in USAG-1 and BMP-7 expression may also be involved in CsA-induced nephrotoxicity.

TH-PO979

Ionizing Radiation Could Cause Cellular Senescence in Kidney and Late-Onset Kidney Dysfunction - Experiment Using Radiation Nephropathy Rat Model

Sae Aratani,[1] Masako Tagawa,[2] Shinya Nagasaka,[2] Yukinao Sakai,[1] Akira Shimizu,[2] Shuichi Tsuruoka.[2] *[1]Nippon Medical School Hospital, Tokyo, Japan; [2]Nippon Medical School, Tokyo, Japan.*

Background: Cellular senescence is one of the major risk factors for chronic kidney disease. Cellular senescence is caused by a variety of stressors, such as ionizing radiation (IR). The kidney is known as radiosensitive organ, however the association between cellular senescence and kidney dysfunction is still unclear.

Methods: 7-8-week-old male rats received unilateral IR of 18 Gy on the left or right kidney (irradiated kidney) whereas normal rats received sham IR (normal kidney). We compared the presence of cellular senescence, kidney dysfunction, and pathological changes at 9 months after the IR. Cellular senescence was defined by positive staining for SA-β-gal and p21, increased mRNA expression level of p21, and senescence associated secretory phenotype (IL-6). Pathological evaluation was performed focusing on glomerular findings, which were evaluated in 50 glomeruli. Endothelial cell was detected by CD31 staining. We also confirmed the endothelial senescence by vitro fashion with rat cultured endothelial cells received IR of 20 Gy with 25 days culturing.

Results: As shown in Table, markers of cellular senescence were elevated only in irradiated kidney. Regarding kidney dysfunction, irradiated rats showed higher proteinuria, and greater serum level of BUN. Pathological findings suggested strong endothelial cell injury in irradiated kidney with greater TMA and collapsing glomeruli, and reduced endothelial cell numbers. We confirmed endothelial cell senescence in vitro model, showing increased positive staining for SA-β-gal, expression level of p21 and IL-6.

Conclusions: Taken together, these data suggested IR could cause cellular senescence in the kidney and lead to resultant kidney dysfunction. The cellular senescence of glomerular endothelial cells may be associated with TMA and glomerular collapse, that lead to kidney dysfunction.

Marker of Cellular Senescence		Irradiated kidney	Normal kidney	p value

TH-PO980

Serotonin Receptor Expression in the Normal Adult Human Kidney and in Glomerular Diseases

Claudia R. van Roeyen,[1] Jenny Vu,[1] Bart Smeets,[2] Marcus J. Moeller,[1] Luc Maroteaux,[3] Hermann-Josef Groene,[4] Jürgen Floege,[1] Tammo Ostendorf,[1] Gerald S. Braun.[1] *[1]RWTH University of Aachen, Aachen, Germany; [2]Radboud University Medical Center, Nijmegen, Netherlands; [3]INSERM U839, Paris, France; [4]German Cancer Research Center, Heidelberg, Germany.*

Background: Serotonin (5-HT) is the phylogenetically oldest neurotransmitter and acts *via* specific receptors. Serotonin receptors 5-HT_{2A} and 5-HT_{2B} are G-protein-coupled and mediate vasoconstriction and hypertension. The 5-HT_{2A} receptor is also engaged in blood coagulation and wound healing. Little is known about the function of 5-HT and its receptors 5-HT_{2A} and 5-HT_{2B} in the normal kidney or during renal disease.

Methods: Localization of 5-HT_{2A} and 5-HT_{2B} receptors was analysed by immunohistochemistry in the human healthy kidney and during renal disease. Serum 5-HT and urine 5-HT metabolite 5-HIAA concentrations were measured by HPLC. *In vitro* studies were performed to identify the role of 5-HT_{2A} and 5-HT_{2B} receptors in primary murine glomerular parietal epithelial cells (PECs). Mice with 5-HT_{2A} and 5-HT_{2B} deletions are available.

Results: In the normal human kidney (living donor biopsies), 5-HT_{2A} and 5-HT_{2B} receptors localized to PECs, proximal tubuli and the loop of Henle. In all renal diseases investigated, 5-HT_{2A} and 5-HT_{2B}-expression in tubuli was maintained. In glomeruli, the number of 5-HT_{2B}-positive cells increased significantly with disease. Serum 5-HT concentrations were significantly reduced in patients with rapidly progressive glomerulonephritis (RPGN), whereas 5-HT metabolite concentrations in tendency increased in the urine of these patients. By immunofluorescence, glomerular 5-HT_{2B}-positive cells could be identified as PECs. In biopsies of patients with IgA nephropathy or RPGN, the cell diameter of 5-HT_{2B}-positive PECs was significantly increased in comparison to receptor-negative PECs. In primary PECs *in vitro*, removal of serotonin from culture medium reduced the expression of activation markers. *Vice versa,* activation of 5-HT_{2A} and 5-HT_{2B} receptors induced an overexpression of CXCR4 and VCAM.

Conclusions: In summary, we demonstrate for the first time the constitutive expression of 5-HT_{2A} and 5-HT_{2B} receptors in the adult human kidney with glomerular upregulation in different renal diseases. Our studies identify PECs as the primarily cell type involved in serotonin receptor upregulation in glomerular disease. Further *in vivo* studies in murine models of glomerular disease are currently under way in order to elucidate the potential pathophysiological role of these receptors.

What Is the Sufficient Minimum Number of Glomeruli in a Kidney Biopsy to Detect Nephrosclerosis?

Robert S. Niznik, Camden Lopez, Walter K. Kremers, Aleksandar Denic, Fernando G. Cosio, Andrew D. Rule. *Mayo Clinic, Rochester, MN.*

Background: The number of glomeruli present is often used to determine the sufficiency of a kidney biopsy sample (e.g., at least 10 glomeruli). The assumption is that with fewer glomeruli, the biopsy findings are too imprecise to draw inferences regarding the underlying pathology in the kidney. The true amount of nephrosclerosis (global glomerulosclerosis, fibrosis, and arteriosclerosis) is expected to not depend on the number of glomeruli of the biopsy.

Methods: We studied 2,915 implantation needle core kidney biopsies from living kidney donors at three transplant centers. The number of glomeruli, the % globally sclerotic glomeruli (%GSG), the amount of interstitial fibrosis (number of fibrosis foci), and the severity of arteriosclerosis (% intimal narrowing) were quantified on digital images of a single PAS-stained section. A beta-binomial model was used to estimate the mean whole-kidney %GSG and the biological (between-kidney) variability in %GSG, number of fibrosis foci, and %intimal narrowing for the number of glomeruli on the biopsy section.

Results: Fewer glomeruli on biopsy correlated with both a higher mean %GSG (16% increase per 10 fewer glomeruli) and more between-patient variability in %GSG in the kidney (See figure). Because of this, the probability of the whole kidney having %GSG >10% with the biopsy %GSG>10% was 45% with 1-9 glomeruli and 31% with 10 or more glomeruli. Similar findings were seen for interstitial fibrosis and arteriosclerosis.

Conclusions: A lower number of total glomeruli correlated with increasing nephrosclerosis and is consistent with the concept of nephron dropout/decreased cortical volume. The presence of fewer glomeruli on a kidney biopsy is itself informative of pathology and is not always indicative of an inadequate sample. It also may represent cortical scarring and volume loss. Thus, requiring a minimum acceptable number of glomeruli should be applied cautiously when interpreting renal biopsies.

TH-PO982

The Clinical Features and the Expression of suPAR and ApoA-1 in Focal Segmental Glomerulosclerosis

Jia Lv,[1] Wanwan Gao,[2] Liyi Xie,[1] Ping Lan.[1] *[1]Nephrology Department, First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [2]Huaihe Hospital of Henan University, Kai Feng, China.*

Background: Our purpose is to explore whether serum and urine suPAR and ApoA-1 can be used as markers in patients with FSGS and to evaluate the value of serum and urine suPAR and ApoA-1 in predicting FSGS.

Methods: Subjects were selected by inclusion and exclusion criterias, divided into four groups: FSGS group, MN group, IgAN group and healthy group. Serum and urine samples were collected. Serum and urine suPAR levels and urine ApoA-1 levels were detected in each group by ELISA and analyzed. Their correlations with gender, age, urea nitrogen, creatinine, 24h urinary protein, eGFR, serum albumin, total cholesterol, and triglyceride were also analyzed.

Results: Serum suPAR levels of FSGS group were higher than the MN group, IgAN group and healthy control group ($P < 0.05$); in FSGS group, serum suPAR was positively correlated with serum creatinine ($P < 0.05$), negatively correlated with eGFR ($P > 0.05$). There was no significant correlation with gender, age, urea nitrogen, 24h urinary protein, serum albumin, total cholesterol and triglyceride ($P > 0.05$). Urine suPAR levels of FSGS group were higher than the MN group, IgAN group and healthy group ($P < 0.05$); in FSGS group, Urine suPAR was positively correlated with 24h urinary protein ($P < 0.05$), but no significant correlation with gender, age, Urea nitrogen, serum creatinine, eGFR,serum albumin, total cholesterol and triglyceride ($P > 0.05$). Urine ApoA-1 levels of FSGS group, MN group and IgAN group were higher than healthy group($P < 0.05$). There was no significant difference among FSGS group, MN group and IgAN group ($P > 0.05$). There was no significant correlation with dender, age, serum albumin, urea niteogen, serum creatinine, eGFR, total cholesterol and triglyceride ($P > 0.05$). The best predictive value of serum suPAR for FSGS was 3280.28 pg/ml; the area under the curve of AUC was 0.831 (95%CI, 0.736-0.926), with sensitivity of 74.2% and specificity of 81%. The area under the curve of AUC for urine suPAR levels in predicting FSGS was 0.781 (95%CI, 0.673-0.890), with sensitivity of 71% and specificity of 77.8%. AUC for urinary APoA-1 in predicting FSGS was 0.483 (95%CI, 0.356-0.610) with sensitivity of 45.2% and specificity of 48.1%.

Conclusions: The value of serum suPAR level in predicting primary FSGS is higher than that of urine suPAR and ApoA-1. Serum suPAR is expected to be a serological marker for auxiliary diagnosis of FSGS.

The Effect of Sertraline on Reduction of Albuminuria Due to the Inhibition of Caveolae Pathway Through Glomerular Endothelial and Epithelial Cells

Takahito Moriyama, Kosaku Nitta. *Tokyo Women's Medical University, Tokyo, Japan.*

Background: Previously, we have reported the caveolae mediated endocytosis, transcytosis, and exocytosis of albumin through glomerular endothelial cells as a new etiology of urinary albumin excretion (J Cell Biochem 116; 1065-9: 2015, J Cell Physiol 232; 3565-73: 2017). The selective serotonin reuptake inhibitor, sertraline, inhibited the

dynamin which played a pivotal role for fission of caveolae from cell membrane in caveolae endocytosis. We hypothesized that sertraline might reduce the albuminuria by interfere the caveolae mediated intracellular trafficking pathway.

Methods: In this study, we analyzed whether the dynamin inhibitor sertraline interfered the albumin internalization through caveolae in glomerular epithelial and endothelial cells, and sertraline reduced the amount of albuminuria in puromycin aminonucleoside induced nephrotic syndrome modeled mice (PAN mice) as a novel treatment of glomerulonephritis.

Results: In vitro studies, western blotting analysis and immunofluorescence (IF) study showed that dose dependent (5 and 10 μM) treatment of sertraline significantly reduced the expression of albumin in glomerular endothelial and epithelial cells ($P<0.01$), though the Caveolin-1 (Cav-1) expression was not reduced. In vivo analysis, the electron microscopic findings showed that the foot process fusion and swelling of endothelial cells in dimethyl sulfoxide (DMSO) treated PAN mice as vehicle and also sertraline treated PAN mice, and the IF analysis showed the stronger Cav-1 expression on capillaries in both mice in comparison to normal control mice ($P<0.0001$). However, the amount of proteinuria was not increased in sertraline treated PAN mice in comparison to normal control mice (0.05 vs. 0.02 mg/mgCre, $p=0.17$), though it was significantly increased in DMSO treated PAN mice (0.12 vs. 0.02 mg/mgCre, $P=0.0027$).

Conclusions: Though the foot process fusion, endothelial swelling, and caveolin-1 expressions were occurred, albumin internalization into glomerular endothelial and epithelial cells and albuminuria in PAN mice were reduced by sertraline. These results indicated that sertraline interfered albumin internalization thorough caveolae by inhibition of dynamin and resulted in reduction of albuminuria. Sertraline might become the novel therapeutic option to reduce albuminuria in glomerulonephritis.

TH-PO984

Identification of Cytoplasmic Proteins Associated with Ephrin-B1 at the Slit Diaphragm of Podocyte: PDZ Proteins, Par6, Par3 and NHERF2 Are Associated with Ephrin-B1

Yoshiyasu Fukusumi, Sayuri Takamura, Ying Zhang, Hidenori Yasuda, Hiroshi Kawachi. *Department of Cell Biology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: We have recently reported ephrin-B1 interacts with nephrin via their extracellular domains in cis form and plays an essential role at the slit diaphragm. We also reported the phosphorylated ephrin-B1 activates the JNK signaling independently of nephrin phosphorylation (JASN 2018). Because ephrin-B1 has a PDZ binding motif in its C-terminus, it is estimated that PDZ proteins interact with ephrin-B1. However, the cytoplasmic proteins interacted with ephrin-B1 in podocyte and the precise signaling pathways activated by the phosphorylated ephrin-B1 remain unclear.

Methods: To identify the proteins associated with ephrin-B1, we performed the gene expression profiling of glomerular sample of the podocyte-specific ephrin-B1 knockout (KO) mice. We found PDZ proteins, Par6, Par3 and NHERF2 were evidently downregulated, but the expressions of other PDZ proteins, ZO-1, MAGI1, CASK, which are already reported to be expressed at the slit diaphragm, were not changed. In this study the expression of Par6, Par3 and NHERF2 and their interaction with ephrin-B1 were analyzed.

Results: The decrease in mRNA expressions of Par6, Par3 and NHERF2 were confirmed with real-time RT-PCR (Par6, 20 ± 11%, $p<0.01$, Par3, 14 ± 9% to control, $p<0.05$, NHERF2, 17 ± 6%, $p<0.001$). The immuno-staining intensity of these proteins in glomeruli was decreased and their staining pattern evidently changed in the KO mice. Dual labeling analyses showed Par6, Par3 and NHERF2 were colocalized with ephrin-B1 in normal glomeruli. The immunostaining of these molecules as well as ephrin-B1 were clearly decreased in the nephrotic state caused by PAN injection. The remaining Par3 and Par6 in this proteinuric state were dissociated from ephrin-B1. By contrast, the remaining NHERF2 was still colocalized with the remaining ephrin-B1. Immunoprecipitation assay showed Par3 interacted with both ephrin-B1 and nephrin, and Par6 interacted with ephrin-B1 but not with nephrin. It is also observed that the phosphorylation of ephrin-B1 inhibited its interaction with Par6 and Par3.

Conclusions: Par6, Par3 and NHERF2 interact with ephrin-B1 and may contribute to the maintenance of the structure and the function of slit diaphragm cooperated with ephrin-B1.

Chronic High-Dose Candesartan Therapy Promotes Podocyte Recruitment from Glomerular Parietal Epithelial Cells Involving Suppression of GSK3β Signaling

Minglei Lu,[1,2] Lance D. Dworkin,[2] Zhangsuo Liu,[1] Rujun Gong.[2] *[1]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [2]University of Toledo Medical Center, Toledo, OH.*

Background: Evidence suggests that non-podocyte cells like glomerular parietal epithelial cells(PEC) contribute to podocyte repopulation and glomerular filtration barrier(GFB) repair in chronic kidney disease(CKD). Angiotensin blockades, as the standard of care for CKD, however, only exhibit a marginal effect on podocyte regeneration. At doses higher than recommended, angiotensin blockades are known to exert an extra anti-proteinuric and renoprotective effect. This study aims to explore if this additional benefit is associated with podocyte regeneration.

Methods: After unilateral nephrectomy, spontaneously hypertensive rats received variable doses (standard, 5 mg/kg/d; high, 25 mg/kg/d; and ultrahigh, 75 mg/kg/d) of candesartan for 14 months. Renal expression of podocyte and PEC markers was evaluated.

Results: Despite a comparable effect attained by all doses on normalizing systemic hypertension, high and ultrahigh dose candesartan exhibited a more potent proteinuria-reducing effect that is independent of blood pressure control. Accordingly, glomerulosclerosis was improved by candesartan in a dose dependent mode. The variable outcomes in proteinuria is suggestive of disparity in GFB integrity. Indeed, increasing doses of candesartan progressively augmented the number of podocytes, marked by WT-1 staining. This effect seems to be attributable to new podocyte recruitment from PEC, because the number of cells in glomerular tufts positive for both synaptopodin and Pax2, a PEC marker, was increased. This coincided with a potentiated transdifferentiation of PEC to podocyte phenotypes in parietal epithelia. In contrast, PEC activation, probed by CD44 expression in glomeruli, was diminished by candesartan in a dose dependent fashion. Glycogen synthase kinase (GSK)3β, a multitasking serine/threonine protein kinase, has been recently implicated in impaired podocyte regeneration. In the diseased kidney, glomerular expression of GSK3β was amplified, predominantly located to PEC and podocytes. Increasing dose of candesartan progressively obliterated glomerular overexpression of GSK3β, concomitant with an improved glomerular histology and podocyte integrity.

Conclusions: Chronic high-dosage candesartan therapy is able to potentiate podocyte derivation from PEC *via* inhibition of GSK3β signaling and attenuate glomerular injury.

DGKE Gene Variants in C3 Glomerulopathy

Ashwani Kumar,[1] Raja Ramachandran,[3] Ritambhra N. Duseja.[2] PGIMER *[1]Histopathology, PGIMER, Chandigarh, India; [2]Post Graduate Institute of Medical Education and Research, Chandigarh, India; [3]Nehru Hospital, Chandigarh, India.*

Background: DGKE is intra-cellular lipid kinases that phosphorylate the diacylglycerol (DAG) to phosphatidic acid (PA). Normal expression of DGKE is found in podocytes, endothelium, and platelets. Evidence of some variants of DGKE is reported in association with glomerular microangiopathies and found to have some overlapping feature with membranoproliferative glomerulonephritis (MPGN). As a pilot study, we screened patients of C3G in addition to alternative complement pathway related gene with focus on DGKE gene which confirmed its involvement in aHUS.

Methods: DNA from blood (EDTA) was isolated. Whole exome sequencing, clinical exome sequencing and targeted sequencing (15 genes; CFH, CFHR1, CFHR2, CFHR3, CFHR4, CFHR5, CD46, CFI, CFB, DGKE, C3, THBD, CFD, and properdin) were performed in 5 cases of C3GP. Test findings were analyzed and correlated with clinical outcome of these five patients.

Results: In addition to CFH and CFHR5 gene variants, whole exome sequencing in two cases revealed two variants in DGKE gene i.e. c.1583G>A (missense variants) and c.183G>A (synonymous variant) in case 1 whereas in case 2, only one variant c.579A>C (synonymous variant) was documented. Clinical exome sequencing was performed in case 3 which showed a variant in exon 6 of DGKE gene (c.998C>G). This variant is of undetermined significance that results in the amino acid substitution of Glycine for Alanine at codon 333 (p.Ala333Gly; ENTST00000284061). Targeted sequencing in other two patients showed c.579A>C (case 4) and c183G>A (case 5) variants in DGKE gene. Of 5 cases, case 1 and 2 are from the same family with the history of renal disease in the family. Case 1 expired and other receive a renal transplant. Case 3 had a history of UTI in childhood followed by MPGN on renal biopsy, which rapidly progressed to end-stage renal disease (ESRD)/underwent transplant and had graft failure in 16 months followed by graft nephrectomy. Patient 4 and 5 also had rapid progression to ESRD.

Conclusions: In present pilot study, the mutation/variants found in DGKE gene showed that genetic defects in C3G is not only limited to alternative complement pathway-related genes. Hence, we strongly recommend the screening of DGKE in all C3G patients. More data is needed to validate our findings.

Transcription Factor Dach1 in Podocytes

Masahiro Okabe,[2,1] Yoichi Miyazaki,[1] Takashi Yokoo,[1] Taiji Matsusaka.[2] *[1]Jikei University School of Medicine, Tokyo, Japan; [2]Tokai University School of Medicine, Isehara, Japan.*

Background: Podocyte injury is crucial for the progression of chronic kidney diseases (CKD). Transcriptional factors, *Wt1*, *Mafb*, and *Foxc2*, are highly expressed in normal podocytes and rapidly decreased upon injury. These play important roles in maintaining normal podocyte function. We aim to find transcriptional factors with similar expression patterns, and study the function in podocytes.

Methods: We combined NEP25 mice, an immunotoxin-inducible podocyte injury model, with RiboTag mice, in which podocyte-specific polysome mRNAs can be yielded by immunoprecipitation in glomerular homogenate. We analyzed gene expression changes of normal and injured podocytes by microarray.

Results: We found the following 8 transcription factor mRNAs were highly expressed in normal podocytes and rapidly decreased after injury; *Wt1*, *Mafb*, *Foxc2*, *Tcf21*, *Foxd2*, *Banp*, *Hoxc6*, and *Dach1*. We focused on *Dach1* because SNPs of *DACH1* gene were associated with the progression of CKD by genome-wide association studies. RT-PCR analysis confirmed that *Dach1* mRNA was concentrated in normal podocytes (7.33±0.68-fold vs glomerulus) and decreased in podocytes injured by immunotoxin (0.371±0.0053-fold vs normal podocytes). Immunostaining showed that Dach1 protein was intensely expressed in the nucleus of normal podocytes and decreased upon injury not only in NEP25 model but also in adriamycin nephropathy and HIV-associated nephropathy models.

DACH1 protein was also expressed in human normal podocytes and the expression was decreased in diabetic nephropathy, lupus nephritis, and IgA nephropathy but not in minimal change disease. Kockdown of *Dach1* by siRNA in murine primary cultured podocytes suppressed the proliferation and DNA synthesis of podocytes, contrasting to the growth inhibitory effect of DACH1 previously reported in cancer cells. The DNA binding sites of DACH1 are reported to co-localize with those of FOX family members. Suppression of *Dach1* gene by siRNA in murine primary cultured podocytes decreased the expression of Foxc2-target genes, *Podxl* and *Dpp4* (0.624±0.12 and 0.626±0.29-fold, respectively), suggesting that Dach1 may modulate or collaborate with Foxc2 in podocytes.

Conclusions: Dach1 is highly expressed in normal podocytes and downregulated upon injury. This transcription factor may play a role in maintaining normal podocyte function.

miR-466o-3p Promotes Podocyte Injury Through Targeting WT1

Qiyan Chen,[1] Lili Zhou,[1] Youhua Liu.[2] *[1]Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Department of Pathology, University of Pittsburgh, Pittsburgh, PA.*

Background: Podocytes are highly specialized cells that maintain normal function of the glomerular filtration barrier. Dysregulation of Wnt/β-catenin signaling has been linked to podocyte injury; however, the underlying mechanism remains incompletely understood. In this study, we explored the roles of microRNA in mediating Wnt/β-catenin-triggered podocyte dysfunction and proteinuria.

Methods: Mouse podocytes were transiently transfected with expression vector encoding constitutively activated β-catenin (pDel-β-cat) or empty vector (pcDNA3). The differential expression of microRNA between these two groups was analyzed microarray assay and bioinformatics analysis. The role of miR-466o-3p in podocyte biology was investigated in vitro and in vivo. The BALB/c mice were randomly divided into 3 different groups: i) sham control; ii) ADR mice injected with empty vector pcDNA3; iii)ADR mice injected with miR-466o-3p plasmid. Urine, blood and kidneys were collected at 1 week after ADR injection.

Results: We identified multiple miRNAs whose expression was modulated by β-catenin activation in podocytes. Real-time RT-PCR validated that miRNA-466o-3p was upregulated in cultured podocytes after β-catenin activation and in kidney tissues after adriamycin (ADR) injection. *In situ* hybridization demonstrated that miR-466o-3p was up-regulated in glomerular podocytes. Bioinformatics analysis and luciferase reporter assay confirmed that miR-466o-3p directly targeted WT1 mRNA. Furthermore, overexpression of miR-466o-3p downregulated WT1 protein *in vitro* and promoted podocyte injury, although it did not affect WT1 mRNA level. Conversely, inhibition of miR-466o-3p alleviated β-catenin induced podocyte injury. In ADR model, Overexpression of miR-466o-3p inhibited WT1, aggravated podocytes injury and increased proteinuria in mice.

Conclusions: These studies demonstrate that miR-466o-3p plays a critical role in mediating Wnt/β-catenin-triggered podocyte injury. Our findings uncover a new pathogenic mechanism by which Wnt/β-catenin promotes podocyte injury and proteinuria.

TH-PO989

Podocyte-Specific Knockdown of PAI-1 Protects Against Podocyte Injury

Jianyong Zhong,[1] Taiji Matsusaka,[2] Haichun Yang,[1] Agnes B. Fogo.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Tokai University School of Medicine, Isehara, Japan.*

Background: Plasminogen activator inhibitor-1 (PAI-1) is upregulated in a variety of fibrotic kidney diseases. Our previous study showed systemic knockout of PAI-1 protects against development of glomerulosclerosis (GS) and podocyte injury in both models of primary podocyte injury and secondary FSGS in the 5/6 nephrectomy model. In this study, we investigated whether knockdown (KD) of PAI-1 only in podocytes can protect against podocyte and glomerular injury.

Methods: We generated inducible podocyte PAI-1 knockdown mice (PAI-1 KD, PAI-1^{floxed}/ rtTA/podocin Cre^{+}) and wild type control (WT, PAI-1^{floxed}/ rtTA/podocin Cre^{-}). A model of secondary mild hypertensive podocyte injury was induced by high salt+uninephrectomy (uNX)+AngII. We also mated PAI-1 KD mice with Nphs1-hCD25 mice (Nep25), which express human CD25 just in podocytes, and develop primary podocyte injury when injected with immunotoxin (LMB2). Podocyte injury and GS were compared in these two models. In vitro, we cultured primary podocytes from these WT and PAI-1 KD mice and exposed cells to AngII or LMB2, respectively.

Results: In vitro primary cultured podocytes showed reduced PAI-1 after doxycycline induction. In vivo, double staining confirmed reduced PAI-1 in podocytes in both models, but increased PAI-1 expression in endothelial cells and mesangial cells. In the Nep25 model, PAI-1 KD in podocytes resulted in less albuminuria (ACR) and GS with more differentiated podocytes than WT (WT-1^{+} cell density, PAI-KD 27.4±1.8 vs. WT 21.8±1.9x10^{-4}/μm^2). In the high salt+uNX+AngII model, although podocytes expressed less desmin (PAI-KD 0.027±0.008 vs. WT 0.051±0.008), a marker of podocyte injury, ACR and mesangial expansion were similar in PAI-1 KD and WT. In vitro, knockdown of PAI-1 induced more podocyte proliferation, adhesion and migration in both LMB2 and AngII injury models, with less CTGF and desmin expression vs WT. ILK was reduced in PAI-1 KD vs WT only in the AngII model.

Conclusions: Knockdown of PAI-1 only in podocytes protected against primary podocyte injury and GS, while there was less effect on GS if the injury involved multiple cells, as seen in the AngII model. Our data further suggest that PAI-1 upregulation of ILK may be one mechanism related to podocyte injury.

Deletion of Ste20-Like Kinase SLK Induces Cytoskeletal Changes in Podocytes

Boyan Woychyshyn, Joan Papillon, Julie Guillemette, Andrey V. Cybulsky. *Medicine and Physiology, McGill University, Montreal, QC, Canada.*

Background: Glomerular epithelial cells (GECs; podocytes) are essential in maintaining glomerular permselectivity. Their function is dependent on an intact actin cytoskeleton. Regulation of the actin cytoskeleton, in part, relies on the assembly of a phospho-ezrin-NHERF2-podocalyxin complex at the apical surface of the podocyte. SLK is a serine/threonine kinase ubiquitously expressed in mammalian tissues, including GECs. SLK was reported to be involved in the arrangement of the actin cytoskeleton and in mediating cell cycle progression. Deletion of SLK in podocytes in mice leads to proteinuria and disruption of podocyte architecture as mice age. The aim of this study was to determine if SLK phosphorylates ezrin in podocytes and is critical in maintaining cytoskeletal integrity.

Methods: We generated a SLK knockout (KO) GEC line by transducing immortalized GECs isolated from mice carrying a floxed SLK allele with tamoxifen-inducible Cre recombinase. We also depleted SLK in GECs using siRNAs. We studied the effect of SLK deletion on phosphorylated ezrin, podocalyxin and F-actin using immunoblotting and immunofluorescence microscopy.

Results: In GECs, both KO of SLK using Cre recombinase and depletion of SLK with siRNAs reduced SLK protein expression and pT183 phosphorylation, which reflects catalytic activity (KO being more effective than siRNA). SLK KO did not affect the rate of proliferation of GECs. Both SLK KO and depletion markedly reduced activation-specific phosphorylation of ezrin, while total ezrin protein levels remained unchanged. Expression of podocalyxin, a protein essential to foot process integrity, was significantly reduced in the SLK KO cells. Levels of F-actin were markedly reduced in SLK KO cells and stress fiber arrangements were altered; however, total actin was unaffected. Treatment of GECs with erlotinib, a chemical inhibitor of SLK, showed effects on F-actin similar to KO of SLK.

Conclusions: SLK is not essential for cell cycle progression in GECs. SLK phosphorylates ezrin, and decreased ezrin phosphorylation due to deletion of SLK leads to reduction in podocalyxin and disruption of the actin cytoskeleton. The result suggests that SLK is important in the maintenance of the ezrin-NHERF2-podocalyxin complex and foot process integrity.

TH-PO991

FK506 Binding Protein 12 (FKBP12) Is Highly Expressed in Glomerular Podocyte in Kidney: FKBP12 in Podocyte Is Co-Localized with Actin Cytoskeleton and Is Re-Distributed in Injured Podocytes

Hidenori Yasuda, Yoshiyasu Fukusumi, Ying Zhang, Hiroshi Kawachi. *Department of Cell Biology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: FKBP12, a 12 kDa cytoplasmic immunophilin, was identified as a binding protein of FK506 (tacrolimus). Tacrolimus and rapamycin bind to FKBP12 and exhibit immunosuppressant effect through inhibition of calcineurin and mTOR, respectively in T cells. FKBP12 is reported to be expressed in various organs, and the distribution is associated with side effects of these drugs. It is also known that FKBP12 functions independently of these immunosuppressants; for example, FKBP12 binds to TGF-b type 1 receptor and inhibits its signaling. However, the localization and the physiological function of FKBP12 in kidney are not well elucidated.

Methods: mRNA expression of FKBP12 in several tissues and cultured podocytes was analyzed with RT-PCR and its precise localization was investigated with the immuno-histochemical analyses with a specific antibody produced in a rabbit immunized with specific peptide. The FKBP12 expression in injured podocytes was also analyzed.

Results: FKBP12 mRNA expression in whole kidney was lower than in other organ materials such as cerebrum, liver, heart and lung, but the high expression was detected in glomeruli. The histochemical analysis with rat kidney section showed FKBP12 was highly expressed in glomeruli. Dual labeling staining with glomerular cell markers showed the FKBP12 expression in glomeruli was restricted in podocyte and the staining in podocyte was mainly detected at the cytoplasm close to cell membrane. FKBP12 staining in cultured pocoytes was colocalized with cytoskeletal actin. mRNA expression of FKBP12 in glomeruli was downregulated at the initiation phase of nephrotic models, anti-nephrin antibody-induced nephropathy (20.0% to normal, P<0.001) and in PAN nephropathy, a mimic of MCNS (26.0% P <0.001). Immuno-staining of FKBP12 was clearly lowered when proteinuria peaked in PAN nephropathy (staining score, 2.7 vs 3.5 of normal, P<0.05), and in ADR nephropathy, a mimic of FSGS (score 2.9, P<0.05). FKBP12 staining was clearly decreased in the human cultured podocytes treated with ADR (67% to normal; P<0.05) and with serum free medium (61% P<0.05).

Conclusions: FKBP12 is mainly expressed along cytoskeletal actin in podocyte and its altered expression might be associated with cytoskeletal remodeling in podocyte injury.

TH-PO992

Transcription Factor MAFB is a New Key Regulator of Podocyte Autophagy

Kosuke Yamahara,[1] Tillmann Bork,[3] Wei Liang,[4] Christoph Schell,[3] Shinji Kume,[1] Mamoru Yoshibayashi,[1] Shin-ichi Araki,[1] Hiroshi Maegawa,[1] Tobias B. Huber.[2] *[1]Shiga University of Medical Science, Otsu, Shiga, Japan; [2]University Medical Center Hamburg, Hamburg, Germany; [3]University Hospital Freiburg, Freiburg, Germany; [4]Renmin Hospital of Wuhan University, Wuhan, China*.

Background: Autophagy is an intracellular catabolic system with protective roles against fasting and cellular damage. Podocytes have high autophagy activity in basal condition; however, their autophagy regulating mechanisms are unclear. To reveal the regulating mechanism of podocyte autophagy, we focused on transcriptional regulation of autophagy related genes.

Methods: We searched the candidate transcription factors which regulate autophagy related genes with the potential to bind to transcription regulatory sites from the web database Motifmap. Next, we sorted the transcription factors which are strongly expressed in podocytes from RNA sequence data of primary culture podocytes. MAFB was extracted as a candidate from the results of these two analyses. To investigate the location of MAFB in the cell, we stained MAFB protein in mouse kidney sections and human podocyte cell lines. To exhibit the transcriptional role of MAFB on autophagy activation, we modified MAFB expression levels in human podocyte cell lines using either overexpression vector or siRNA, and evaluated autophagy activity by LC3-II protein expression. In addition, to reveal the role of MAFB for cell damage, we induced cell damage by incubation with palmitate and evaluated apoptosis and autophagy-related proteins using the cell line of tetracycline-induced overexpression/shRNA of MAFB.

Results: MAFB was localized at nuclear areas in podocytes of mouse kidney sections and human podocyte cell lines. LC3-II protein abundance was significantly increased in the MAFB overexpression group and decreased in siRNA of MAFB group. In cell damage experiments with palmitate, we observed suppression of apoptosis accompanied by high LC3-II protein abundance in the MAFB overexpression group. Phosphorylation of ULK1 proteins, which are well known as a key autophagy regulator, was not significantly changed in any experiment.

Conclusions: We identified the transcription factor MAFB as a novel autophagy regulator independent of phosphorylation of ULK1 in podocytes. The activation of MAFB can be a potential therapeutic target against podocyte damages via autophagy activation.

TH-PO993

Soluble Form of VCAM-1 Ameliorates Podocyte Injury by Plasma Membrane PTEN Recruitment

Shun Manabe,[1,2] Kazuo Sakamoto,[1] Naoko Ito,[1] Nobuyuki Saga,[1] Kosaku Nitta,[2] Michio Nagata.[1] *[1]Kidney and Vascular Pathology, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan; [2]Department of Medicine, Kidney Center, Tokyo Women's Medical University, Shinjuku, Japan*.

Background: Various types of stresses cause epithelial-mesenchymal transitions (EMTs) and detachments of podocyte that result in glomerular sclerosis. Podocyte has self-defense mechanisms to resist against the stresses by expressing aberrant proteins. Vascular cell adhesion molecule-1 (VCAM-1) is a well-known protein induced by stresses that serve functions in membrane-bound and soluble form (sVCAM-1). However, in podocyte, the link between VCAM-1 and stress resistance remains unknown.

Methods: NEP25 transgenic mouse that develop podocyte-specific injury by immunotoxin injection were used. We assessed podocyte VCAM-1 and its ligand expressions by immunostaining, PCR, and western blot (WB). *In vivo* functions of sVCAM-1 were assessed by inhibiting ADAM17, the shedding enzyme of VCAM-1, by BB94. Immortalized podocyte were used for *in vitro* studies. The podocyte treated with H_2O_2, TGF-β1, sVCAM-1, and bpV were analyzed by immunostaining, real-time PCR, WB, and migration assay.

Results: Podocyte-specific injury of NEP25 mouse induced aberrant podocyte VCAM-1 and ADAM17 expression, which suggests the generation of sVCAM-1. Human focal segmental glomerular sclerosis also expressed podocyte VCAM-1. *In vivo*and *in vitro*podocyte expressed α9β1 integrin, which is the ligand of sVCAM-1.*In vitro*, sVCAM-1 ameliorated TGF-β1 induced podocyte EMT; amelioration of enhanced motility, maintenance of podocyte specific proteins, and inhibition of Akt phosphorylation. Mechanistically, sVCAM-1 recruited PTEN against plasma membrane, which was shown by immunostaining and WB analysis of plasma membrane fraction protein. Blockage of PTEN by bpV diminished the efficacy of sVCAM-1 to ameliorate podocyte EMT. Finally, we treated immunotoxin-injected NEP25 mouse by BB94 to inhibit sVCAM-1 generation that resulted in exacerbation of renal disfunction, urinary protein and glomerular sclerosis.

Conclusions: Aberrant sVCAM-1 generation recruited PTEN against plasma membrane to ameliorate podocyte injury by inhibiting Akt phosphorylation. VCAM-1 expression might be one of the intrinsic self-defense mechanisms to resist against stresses in podocyte.

Advanced Optical Clearing Protocols Enable Fine Analysis of Glomerulus Three-Dimensionally with Confocal Microscopy

Hiroyuki Yamada,[1,2] Shinichi Makino,[1,2] Takafumi Miyake,[2,3] Motoko Yanagita,[2,3] Katsuhiko Asanuma.[1,2] *[1]Department of Nephrology, Chiba University Graduate School of Medicine, Chiba, Japan; [2]The Laboratory for Kidney Research (TMK Project), Kyoto University Graduate School of Medicine, Kyoto, Japan; [3]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan*.

Background: In order to visualize slit diaphragm of podocyte, it is necessary to use an electron microscopy or super-resolution microscopy. However, there are some disadvantages to these approaches in terms of economics and viewable dimensions. We hypothesized that advanced optical clearing methods with confocal microscopy could enable the three-dimensional (3D) analysis of the fine structure of glomerulus and podocyte.

Methods: From among several advanced optical clearing methods, the following protocols were selected based on the simplicity of the technique and the number of citations: CUBIC, PACT, ScaleS, BABB, iDISCO and SeeDB2. Each protocol with immunostaining against Nephrin were applied to a 1-mm-thick slice of adult rat kidney. We investigated which method was most suitable for observing the fine structure of podocyte with confocal microscopy three-dimensionally. Next, the optimal method among them was applied to anti-glomerular basement membrane (anti-GBM) nephritis rats.

Results: All of these protocols could turn the rat kidney sample transparent. Although each protocol made it possible to visualize the 3D image of the whole glomerulus, a few protocols were capable of visualizing their fine structure of podocytes with confocal microscopy. When analyzing anti-GBM nephritis rat with 3D image, the ratio of the glomeruli with crescent formation in 3D analysis was significantly higher than that in the conventional two-dimensional histological analysis (34.1% versus 14.6%, $p<0.01$). High magnification of the 3D images showed that the meandering pattern of the slit diaphragm was sustained in the vehicle group while it was partially effaced in the anti-GBM nephritis group.

Conclusions: Advanced optical clearing methods enables a pathological 3D diagnosis of glomeruli and has a high sensitivity for pathological lesions. Moreover, using even confocal microscopy, it could visualize the fine structure of podocyte three-dimensionally. Optical clearing methods could make an outstanding contribution to our clinical practices in many aspects.

A Deep Learning Approach for Detection of Normal and Globally Sclerotic Glomeruli on Whole Slide Images from Renal Biopsy Sections Stained with H&E

Yijiang Chen,[1] Andrew Janowczyk,[1] Matthew Palmer,[2] John R. Sedor,[3] John F. O'Toole,[3] L. Barisoni,[4] Anant Madabhushi.[1] *[1]Case Western Reserve University, Cleveland, OH; [2]University of Pennsylvania, Philadelphia, PA; [3]Cleveland Clinic, Cleveland, OH; [4]U. Miami, Miller School of Medicine, Miami Beach, FL*.

Background: Clinically useful quantitative assessment of renal biopsies requires robust methodologies. We demonstrated that accurate estimates of glomerular global sclerosis (GS) adjusted for age can predict outcomes across proteinuric diseases. However, visual assessment is poorly reproducible and time consuming. To increase efficiency, we present a deep learning-based approach for detection and segmentation (object extraction) of normal and globally sclerotic glomeruli (histologic primitives) digital renal biopsies.

Methods: A convolutional neural network (CNN) architecture based on Alexnext was trained using transfer learning to produce 3 classifiers: (i) normal glomerular tuft, (ii) normal glomerulus (tuft + Bowman's capsule), and (iii) GS. We used 74 cropped images from whole slide images of NEPTUNE renal biopsies sections stained with H&E, divided into training and testing sets.

Results: The detection and pixel level segmentation results for all 3 classifiers was graded via the F-score (A measure of classification accuracy that considers both precision and recall; 1 = perfect, 0 = worst).

Conclusions: The development of these 3 CNNs represents the first step in evaluating renal biopsies using novel machine-human interactive protocols. The classifier "normal glomerulus" is a better denominator compared to "normal glomerular tuft" to estimate percentage of GS. Improvement in F-score for the classifier GS, however, is necessary before automatic assessment of GS adjusted for age can be applied in clinical research and practice. Future steps to implement extended machine-human interactive protocols will include generation of other classifiers for the annotation of additional glomerular, tubulointerstitial and vascular normal and abnormal histologic primitives.

Activation of Non-MC1R-Mediated Melanocortinergic Signaling Ameliorates Podocytopathy and Proteinuria in Experimental Focal Segmental Glomerulosclerosis (FSGS)

Yingjin Qiao,[1,2] Pei Wang,[1] Yan Ge,[3] Lance D. Dworkin,[2] Zhangsuo Liu,[1] Rujun Gong.[2] *[1]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [2]University of Toledo Medical Center, Toledo, OH; [3]Brown university, Providence, RI.*

Background: The clinical effectiveness of melanocortin therapy with adrenocorticotropin in inducing remission of steroid-resistant nephrotic syndrome points to a steroidogenic-independent anti-proteinuric activity of melanocortins. However, which melanocortin receptor(MCR) conveys this beneficial effect is controversial. Moreover, it remains uncertain if a systemic or podocyte specific mechanism is involved. By harnessing the naturally occurring MC1R-null mice and using NDP-MSH, a potent nonsteroidogenic pan-MCR agonist, this study aims to validate if a podocyte-specific MC1R-mediated melanocortinergic signaling mediates the beneficial effect in glomerulopathy, as proposed recently.

Methods: FSGS was induced in wild-type (WT) and MC1R-null mice by Adriamycin, treated with NDP-MSH and was evaluated. Primary podocytes were injured with Adriamycin and cytopathy assessed.

Results: WT mice developed heavy proteinuria after Adriamycin insult, associated with progressive glomerulosclerosis and podocytopathy, marked by loss of podocin and synaptopodin, podocytopenia and extensive foot process effacement on electron microscopy. All these injurious effects were prominently attenuated by NDP-MSH. Surprisingly, MC1R deficiency in MC1R-null mice barely affected the severity of Adriamycin-elicited injury. Moreover, the beneficial effect of NDP-MSH was equally observed in MC1R-null mice to an magnitude comparable to that in WT mice, suggesting that MC1R is likely nonessential for the protective action. A direct podocyte effect seems to contribute, at least in part, to the beneficial effect of NDP-MSH, because Adriamycin-inflicted cytopathic signs in primary podocytes prepared from WT mice were all diminished by NDP-MSH, including loss of podocyte markers, apoptosis, *de novo* expression of podocytopathic B7-1, actin cytoskeleton disruption and podocyte hypermotility. Consistent with *in vivo* findings, NDP-MSH protected the MC1R-null podocytes against Adriamycin injury to a degree equal to that observed in WT podocytes, again suggesting that non-MC1R-transmitted melanocortinergic signaling is responsible for this direct podocyte protection.

Conclusions: Melanocortin therapy protects against podocyte injury and ameliorates proteinuria and glomerulopathy via a non-MC1R-mediated melanocortinergic signaling.

Phospholipase A2 Receptor 1 Antibody Levels at the Time of Diagnosis Determine Renal Outcome in Patients with Membranous Nephropathy

Maida Mahmud,[1] Hans O. Pinnschmidt,[2] Linda Reinhard,[1] Sigrid Harendza,[1] Thorsten Wiech,[3] Rolf A. Stahl,[1] Elion Hoxha.[1] *[1]III. Department of Internal Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Institute of Medical Biometry and Epidemiology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Department of Nephropathology, Institute of Pathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: Membranous nephropathy (MN) is an autoimmune disease caused by circulating antibodies against the podocyte protein phospholipase A_2 receptor 1 (PLA_2R1-ab) in 80% of cases. PLA_2R1-ab levels correlate with disease activity and treatment response. However, their significance on long-term renal outcome is not clear.

Methods: In this prospective observational multicenter study we investigated the predictive role of PLA_2R1-ab levels for long-term renal outcome in 243 patients with newly diagnosed, biopsy-proven PLA_2R1-associated MN, who had received no immunosuppressive treatment prior to study enrollment. The median follow-up time was 48 months. The primary endpoint was defined as doubling of serum creatinine or development of end-stage renal disease. PLA_2R1-ab levels, proteinuria and serum creatinine were prospectively measured every three months.

Results: 243 patients (171, 70% males; median age 55 years, IQR: 43–66 years) were included in the study. Thirty-six (15%) of the 243 patients reached the study endpoint. Multivariate Cox regression analyses adjusting for all clinical relevant parameters revealed that the following independent predictors significantly increased the risk for reaching the study endpoint: PLA_2R1-ab levels (HR=1.36, 95%CI 1.11–1.66, p=0.003), percentage of tubular atrophy and interstitial fibrosis in the biopsy (HR=1.32, 95%CI 1.03–1.68, p=0.030), relapse of PLA_2R1-ab during follow-up (HR=3.22, 95%CI 1.36–7.60, p=0.008), and relapse of proteinuria (HR=2.60, 95%CI 1.17–5.79, p=0.019). Fifty-four (22%) patients received no immunosuppressive treatment during the study. In 41 (76%) of these patients PLA_2R1-ab spontaneously disappeared during the follow-up, 29 (54%) of them had a complete remission of proteinuria, and 19 (35%) a partial remission. Patients who were not treated with immunosuppressives were more often female and had lower PLA_2R1-ab levels, proteinuria, and serum creatinine at baseline compared to patients receiving immunosuppression.

Conclusions: PLA_2R1-ab levels are, in addition to pre-existing renal damage, a predictive factor for long-term outcome in patients with MN and should be considered when deciding on treatment of these patients.

Anti-PLA2R Antibodies and Outcome in Patients with Membranous Nephropathy

Anne-Els van de Logt,[1] Joana Justino,[3] Coralien Vink- van Setten,[1] Jan A. van den Brand,[1] Gerard J. Lambeau,[2] Jack F. Wetzels.[1] *[1]Radboud University Medical Center, Nijmegen, Netherlands; [2]Institute of Molecular and Cellular Pharmacology, CNRS and University of Nice, Valbonne, France; [3]Institut de Pharmacologie Moleculaire et Celluleire, Sophia Abtipolis, France.*

Background: Personalized treatment for patients with membranous nephropathy (MN) requires accurate prediction of disease course at an early stage. We evaluated the added value of including level of anti-PLA2R antibodies (PLA2Rab) and epitope spreading at baseline in prediction models.

Methods: We included untreated patients with PLA2R-related MN who were referred to our clinic between 1995 and 2016. Patients with nephrotic range proteinuria (UPCR ≥ 3 gram/10 mmol in 24-hours urine) and a creatinine level of ≤ 135 umol/l were included. Outcomes were progression, defined as the need for immunosuppressive therapy because of an increase of serum creatinine level of >30 % from baseline or severe persistent nephrotic syndrome, and spontaneous remission as a competing event. We fitted a Fine and Gray survival model to simultaneously predict the probabilities of progression and spontaneous remission. We included serum creatinine, UPCR and the urinary excretion of $\alpha_1$microglobulin as known prognostic markers, and added sequentially baseline PLA2Rab titers (ELISA) and epitope spreading. We estimated bootstrapped C-statistics and obtained calibration plots at twelve-month intervals during follow-up.

Results: We included 142 patients. Univariate comparison of progressors vs non-progressors is presented in Table 1. Neither PLA2Rab titer nor epitope spreading improved prognostic predictions when combined with known prognostic markers. The C-statistics for respectively progression and remission were between 0.71 and 0.70 at 12 and 60 months follow-up, respectively. The model was well calibrated for both progression and remission.

Conclusions: Whereas baseline PLA2Rab titer and epitope spreading predicted response to treatment in patients with MN, our data from this cohort suggest that their added value over and beyond traditional risk biomarkers for predicting spontaneous remission may be limited.

	Progressors n=92	Non-progressors n=30	P value
Age (years)	53 ± 13	52 ± 13	0.67

Differences in Outcome in Patients with Membranous Nephropathy with and Without Anti-PLA2R Antibodies

Anne-Els van de Logt,[1] Joana Justino,[2] Coralien Vink- van Setten,[1] Jan A. van den Brand,[1] Gerard J. Lambeau,[3] Jack F. Wetzels.[1] *[1]Radboud University Medical Center, Nijmegen, Netherlands; [2]Institut de Pharmacologie Moleculaire et Celluleire, Sophia Abtipolis, France; [3]Institute of Molecular and Cellular Pharmacology, CNRS and University of Nice, Valbonne, France.*

Background: The identification of autoantibodies against PLA2R1 (PLA2Rab) defined membranous nephropathy as an auto-immune disease. There is debate if outcome is different in PLA2Rab-positive and PLA2Rab-negative patients. We evaluated differences in the natural course of primary MN between PLA2Rab-positive and PLA2Rab-negative patients.

Methods: We included untreated patients with MN who were referred to our clinic between 1995 and 2016. Inclusion criteria were nephrotic range proteinuria (Upcr ≥ 3 gram/10 mmol) and a serum creatinine level of ≤ 135 µmol/l. Primary outcome was spontaneous remission, both partial and complete, or progression, defined as the need for immunosuppressive therapy because of an increase of serum creatinine level > 30% or severe persistent nephrotic syndrome. In stored samples PLA2Rab were measured with ELISA (Euroimmun®). A cut-off value of < 14 RU/ml was used to define seronegativity.

Results: In total 182 patients were included. PLA2Rab were detected in 75 % of patients. Clinical characteristics were similar between both groups (table 1). During follow-up, 65% of PLA2Rab-positive patients needed immunosuppressive therapy versus 48% of seronegative patients. At 60 months of follow-up, cumulative incidence of spontaneous remission was 52% vs 34% (p = 0.008) and progression was 43% vs 65% (p=0.02) for PLA2Rab-negative compared to positive patients.

Conclusions: The natural course of MN is more favorable in PLA2Rab-negative patients.

Levels of Anti-PLA2R Antibodies Predictive of Renal Prognosis in Japanese Patients with PLA2R-Associated Primary Membranous Nephropathy

Asaka Hachiya, Shin'ichi Akiyama, Shoichi Maruyama. *Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Measurement of circulating levels of autoantibody against phospholipase A2 receptor (PLA2R) antibody at diagnosis is important for not only differentiation but also for prediction of renal prognosis. Recent studies suggest that a poor renal outcome mainly occurs in patients with PLA2R-associated primary membranous nephropathy (pMN) who have a high level of anti-PLA2R antibody (aPLA2R-Abs) at diagnosis. This study investigated the association between aPLA2R-Abs levels and renal prognosis in Japanese patients with PLA2R-associated pMN.

Methods: We retrospectively enrolled 53 consecutive Japanese patients with biopsy-proven PLA2R-associated pMN (males, 38; median age, 64 [IQR 53-69] years old; observation period, 62 [43-91] months, urinary protein levels, 5 [4-9] g/day) admitted to our hospitals between January 2003 and December 2012. The primary outcome was the cumulative rate of 1.5-fold increase in serum creatinine and all-cause death. Sera were collected at the time of renal biopsy. We identified the levels of aPLA2R-Abs predictive of renal prognosis on the basis of C-index calculated with Cox proportional hazards models.

Results: Median levels of aPLA2R-Abs at diagnosis were 62 [IQR 32-165] RU/ml. Patients with ≥50 RU/ml (35 of 53) showed lower renal survival rates and more reached the outcomes compared to those with <50 RU/ml (17 of 35 vs. 1 of 18, p=0.01). Patients with ≥50 RU/ml also showed significantly lower serum albumin at baseline and received more frequent remission-induction immunosuppressive therapies (p<0.01, p=0.01, respectively). Cox proportional hazards models indicated that a level of ≥50 RU/ml at diagnosis predicted poor renal prognosis (adjusted hazard ratio by age, sex, urinary protein levels and use of immunosuppressive agents within 1 year, 8.3 [95% confidence interval 1.1–62.5, p=0.01]).

Conclusions: APLA2R-Abs levels of ≥50 RU/ml at diagnosis could help predict poor renal prognosis in Japanese patients with PLA2R-associated pMN.

TH-PO1001

Determination of Anti-PLA2R and Anti-THSD7A Antibodies in Brazilian Patients with Idiopathic and Lupus Membranous Nephropathy

Ligia C. Battaini,[1] Pamela B. Larrea,[1] Lia J. Marçal,[2] Lectícia Jorge,[3] Leila Antonangelo,[2] Denise M. Malheiros,[4] Luis Yu.[5] *[1]University of Sao Paulo Brazil, Quito, Ecuador; [2]Universidade de Sao Paulo, Sao Paulo - SP, Brazil; [3]University of São Paulo, São Paulo, Brazil; [4]Univ of Sao Paulo, Sao Paulo, Brazil; [5]University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: Membranous Nephropathy (MN) is a common cause of nephrotic syndrome in adults. In Brazil, it is the second most frequent cause of glomerulopathies. Incidence variations in between the various studies may reflect patterns of biopsy indication in different countries however, it may also be related to socioeconomical, ethnical or environmental characteristics. In the past years, the role of anti-phospholipase A2 (anti-PLA2R) receptor autoantibodies and the antibody against THSD7A (thrombospondin type 1 domain containing protein 7A) in the pathogenesis of idiopathic MN were described. The determination of these serum and renal tissue antibodies have not yet been performed in the Brazilian population.

Methods: Blood samples were collected from 26 patients diagnosed with MN and 13 patients with Lupus Membranous Nephropathy (LMN), confirmed by renal tissue biopsy (OM and IF). The anti-PLA2R antibody was measured by the ELISA and IIFT techniques and antibodies against THSD7A by IIFT. In addition, routine tests of renal function and proteinuria were also collected. Patients will be followed and evaluated after 6 months and 1 year of the initial consultation.

Results: All 13 patients with LMN were negative for anti - PLA2R and anti - THSD7. A total of 26 patients with MN tested negative for anti - THSD7A. Out of 26 patients, 13 (50%) were anti-PLA2R negative by both ELISA and IIFT. On the other hand, 10 patients (38.4%) were positive by both methods and 3 patients were positive only by IIFT and had intermediate titers by ELISA method, resulting in 13 positive patients (50%). Proteinuria levels in ELISA and IIFT negative patients were 1.98g / vol, 6.7g / vol for ELISA and IIFT positive patients and 2.96g / vol for intermediate ELISA and IIFT positive patients, respectively. In this sample, there was a positive correlation between the anti - PLA2R titers and the levels of proteinuria.

Conclusions: In this Brazilian population of MN patients, there was a 50% positivity for anti - PLA2R. The IIFT technique was more sensitive than the ELISA test. No patient was positive for anti-THSD7A. All patients with LMN were negative for both antibodies. There was a positive correlation between the anti - PLA2R antibodies serum levels and the degree of proteinuria.

Combined Assessment of Serum Anti-PLA2Rabs and Glomerular PLA2Rags Deposition in Patients with Membranous Nephropathy (MN)

Pinelopi Kouki,[1] Aikaterini A. Damianaki,[1] Evgenia Ventouri,[2] Athanasia Kapota,[1] Kostas Stylianou,[3] Harikleia Gakiopoulou,[2] Dimitrios I. Petras.[1] *[1]Hippokration Hospital of Arhens, Athens, Greece; [2]1st Department of Pathology School of Medicine University of Athens, Athens, Greece; [3]University Hospital of Heraklion, Heraklion, Greece.*

Background: MN is the most common cause of nephrotic syndrome in adults. The involvement of PLA2R (Ags and Abs) in the pathogenesis of the disease (idiopathic MN) is investigated. The purpose of the study was to correlate the glomerular deposition of PLA2R-antigens (Ags) and circulating serum anti-PA2R-antibodies (Abs) to renal function (eGFR), proteinuria and clinical outcome in patients with idiopathic MN.

Methods: Twenty patients with idiopathic MN met the study criteria. Initial eGFR and proteinuria were recorded at months 0 and 6 as well as the clinical outcome after treatment. Glomerular PLA2R-Ags deposition intensities (mild, moderate, strong) were evaluated with immunohistochemistry. Serum anti-PLA2R-Abs (detectable / undetectable) were also evaluated.

Results: Positive PLA2R-Ags was detected at 81.25%, while detectable anti-PLA2R-Abs in 62.5% of patients. Mean proteinuria values at months 0 and 6 were 9.1 grams and 1.8 grams / 24 hours, respectively. Mean eGFR at months 0 and 6 was 73.1 ml / min / 1.73 m^2 and 75.83 ml / min / 1.73 m^2. Strong glomerular PLA2R-Ags deposition was positively correlated with renal function at time 0 ($p < 0.05$) and reduction in proteinuria at 6 months ($p < 0.01$). Serum anti-PLA2R-Abs levels were not correlated with eGFR and proteinuria at 0 and 6 months. Our results are not in accordance with the literature, probably due to early refferal of the patients.

Conclusions: In conclusion glomerular PLA2R-Ags deposition appears to be more closely correlated with renal function and the rate of proteinuria reduction than serum anti-PLA2R-Abs in patients with idiopathic MN. More studies are needed to prove this predictive role.

TH-PO1003

Optimization of the Cutoff Value for a Commercial Anti-PLA2R ELISA to Diagnose PLA2R-Associated Membranous Nephropathy in Japanese Patients

Shin'ichi Akiyama,[1] Asaka Hachiya,[2] Shoichi Maruyama.[1] *[1]Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Nagoya University, Nagoya, Japan.*

Background: Anti-PLA2R antibodies (aPLA2R-Ab) is a potentially useful diagnostic and therapeutic biomarkers for PLA2R-associated primary membranous nephropathy (PLA2R-pMN). aPLA2R-Ab titer is easily quantified by a commercial ELISA kit. However, we observed more false-negative results in our experiments in Japan, when considering the manufacturer's cutoff value (14 RU/ml) for ELISA than with western blot (WB) analysis and a commercial IIFT-CBA, indicating that the manufacture's cutoff value is too high for the diagnosis of aPLA2R-Ab in Japanese PLA2R-pMN patients. Hence, it is important to optimize the cutoff value for ELISA in each region. This study aimed to investigate the optimal index cutoff value of the commercial aPLA2R-Ab ELISA kit for Japanese patients with PLA2R-pMN.

Methods: The aPLA2R-AB in serum samples from 117 patients with biopsy-proven primary membranous nephropathy (MN) were measured by WB and commercial ELISA (EUROIMMUN AG). WB analysis was performed under non-reducing condition and with diluted sera at x1/101. The ELISA was used in accordance with the manufacturer's instructions. Primary MN patients were divided into an aPLA2R-Ab-positive group and a -negative group per the results of WB. Receiver operating characteristic (ROC) curves were plotted to generate the cutoff value for screening aPLA2R-Ab positive patients diagnosed via WB analysis from among all patients with pMN. Furthermore, to confirm the absence of changes in specificity, disease control sera from 30 each patients with secondary MN and other glomerulonephritis were measured by the ELISA.

Results: WB revealed that of 117 patients with pMN, 59 were aPLA2R-Ab-positive; 58, -negative. ROC curve analysis revealed a cutoff value of 5 RU/ml with a sensitivity and specificity of 50% and 93%, respectively. With a cutoff value of 5 RU/ml, none of the aPLA2R-Ab-positive serum samples were screened from disease control groups. The index cutoff value decreased from 14 to 5 RU/ml, thereby improving the sensitivity of the aPLA2R-Ab ELISA from 39% to 48%.

Conclusions: The optimal cutoff value of the aPLA2R-Ab ELISA for Japanese patients with PLA2R-pMN is 5 RU/ml. The cutoff value, thus optimized, of the ELISA enhanced the interpretation and confidence levels in the screening of PLA2R-pMN and eliminated the need for confirmation via WB analysis.

An Indian Experience with M-Type Phospholipase A2 Receptor (PLA2R) Antibody in Membranous Nephropathy

Ashwani Gupta, Aakash Shingada, Anil Bhalla, Anurag Gupta, Vinant Bhargava, Lovy Gaur, Devinder S. Rana. *Nephrology, Sir Ganga Ram Hospital, New Delhi, India.*

Background: Membranous Nephropathy(MN) is one of the common cause of nephrotic syndrome in adults. We present our data, one of the first studies from India, on sensitivity of tissue and serum PLA2R in Membranous nephropathy and its association with disease activity.

Methods: Treatment-naïve biopsy-proven MN patients were included. Anti-PLA2R antibody in serum and PLA2R antigen in tissue was tested at the time of first diagnosis. Disease activity was assessed by measurement of proteinuria, serum albumin and renal function. Detailed history, examination and investigations were performed to rule out a secondary cause of MN.

Results: We included 38 patients in the study. Mean age was 45.09 +/- 14.29 yrs (27 males & 11 females). A secondary cause of MN was found in 4/38(10.5%). PLA2R (either serum or tissue) was positive in 25/38(65.8%) patients; 24/34(70.5%) in iMN and 1/4(25%) in secondary MN. Pattern of PLA2R positivity in iMN has been described in the image. PLA2R was associated with heavier proteinuria (11.27 ± 5.74gm/d) vs (4.08 ± 2.61gm) in patients negative for PLA2R($p<0.001$) and significant hypoalbuminemia with serum albumin 2.11g/dl ± 0.7g/dl in PLA2R positive patients vs 2.93 ± 0.3g/dl in patients negative for PLA2R($p<0.001$). No difference was found in serum creatinine between the groups (PLA2R positive - 1.03 ± 0.35 mg/dl vs PLA2R negative – 0.91 ± 0.29mg/dl, p - 0.3).

Conclusions: Though PLA2R is an important diagnostic tool in patients with Membranous nephropathy, yet it cannot replace biopsy, in view of moderate sensitivity as seen in our study. PLA2R is associated with heavy proteinuria and hypoalbuminemia.

Pattern of PLA2R positivity in Idiopathic MN (n=34)

Tissue PLA2R	Serum PLA2R reactivity: Positive	Negative	Total
Positive	17	2	19
Negative	5	10	15
Total	22	12	34

Total PLA2R reactivity – 17+5+2 = 24(out of 34 patients) – 70.5%
Tissue reactivity – 19/34(55.9%)
Serum reactivity – 22/34 (64.7%)

Transplacental Passage of Phospholipase A2 Receptor Antibodies from Maternal to Fetal Circulation and Secretion into Breastmilk

Mala Sachdeva,[1,3] Fatima Sheikh,[3] Laurence H. Beck,[2] Steven Fishbane,[3] Llene J. Miller.[4] *[1]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; [2]Boston University Medical Center, Boston, MA; [3]Northwell Health, Great Neck, NY; [4]North Shore University Hospital, Great Neck, NY.*

Introduction: Phospholipase A_2 receptor (PLA_2R) was described as the major target antigen in idiopathic membranous nephropathy (IMN). During pregnancy, certain maternal antibodies transport across the placenta. Whether PLA2R-Ab crosses over from maternal to fetal circulation is still unknown. We report a case of biopsy proven maternal membranous nephropathy where there was transfer of PLA2R-Ab from maternal to fetal circulation. We further report the first case where PLA2R-Ab is secreted into mother's breast milk.

Case Description: A 33 year old female presented at 30 weeks gestation with nephrotic syndrome. Her initial PLA_2R Ab was 57 RU/mL. At 33 weeks, her pregnancy was complicated by oligohydramnios and worsening of her nephrotic syndrome. Her PLA_2R-Ab titer was noted to progressively increase from 75RU/mL at 34 weeks to 111RU/mL at 36 weeks to 161RU/mL at the time of delivery to 506 RU/mL one month post-partum. At 37 weeks, a 2.29kg male was delivered. Cord blood for PLA_2R-Ab was 59 RU/mL and infant's serum showed PLA_2R-Ab of 57 RU/mL. At 18 days, the infant's urine spot protein:creatinine ratio (P:C) was 0.8 g/g, albumin was 3.5g/dL, with the PLA_2R Ab 3RU/mL (nl). At one month, the infant's P:C normalized with serum albumin of 3.8g/dL, however his PLA_2R-Ab rose to 25RU/mL. Mother's breast milk was assessed by Western blot and IgG4 PLA_2R-Abs against full-length PLA2R were detected.

Discussion: This is the first case of biopsy proven-IMN with rising PLA_2R-Ab confirming transplacental passage of the PLA_2R Ab to the fetus. PLA_2R-Ab was detected in the cord blood and the peripheral circulation at the time of delivery which then decreased to normal by 18 days post-partum. Clinically, the infant had a low albumin level and proteinuria at 2.5 weeks post-delivery which then normalized by his one month follow up visit. Whether this reflects a mild case of neonatal membranous nephropathy is still unknown but possible. Furthermore, we have demonstrated the ability of PLA_2R-Ab to be secreted into breastmilk, likely accounting for the rise in the infant's one month titer. These findings potentially affect the future care of pregnant women with IMN as well as their newborns.

108 Cases of Idiopathic Membranous Nephropathy Patients with Clinical and Pathological Analysis

Xin Li. *Nephropathy Department, Tongji Hospital, Shanghai, China.*

Background: Idiopathic membranous nephropathy is the most common cause of adult nephrotic syndrome. Its onset is hidden and its progress is slow. The prognosis is different. Analyze the clinical and pathological characteristics of the patients with IMN will help us to get a better understanding of the disease process. The objective was to retrospectively analyze the clinical and pathological features of idiopathic membranous nephropathy in our single center.

Methods: The clinicopathological data of 108 patients with biopsy-proven IMN from January 2013 to December 2017 were analyzed retrospectively. IMN patients were divided into NS and non-NS groups. Analyse the clinical and pathological characteristics of these two groups.

Results: The average age was 57 years and 59.3% were male patients. Compared with patients without NS,IMN patients with NS were older,lower eGFR, higher total cholesterol, low density cholesterol and serum creatinine (P<0.05). The effective rate of conservative treatment in IMN patients without NS was 61.7%.The effective rate of immunosuppressive therapy in IMN patients with NS was 70.8%, and low serum albumin was an independent risk factor for the poor efficacy(p=0.021 OR 1.329). The effective rate of conservative treatment in IMN patients with NS was 47.3%,and low serum albumin was an independent risk factor for the poor efficacy(p=0.042 OR 1.201).

Conclusions: The remission rate of conservative treatment non-NS patients was not low. Hypoproteinemia may be a predictor of poor efficacy with NS patients.

Associations of HLA Class II Alleles with Clinical Phenotype and Outcome in Patients with Primary Membranous Nephropathy: A Single Amino Acid Makes the Difference

Huaiyu Wang, Zhao Cui, Minghui Zhao. *Peking University First Hospital, Peking University, Beijing, China.*

Background: GWAS and HLA genotyping have revealed associations between HLA alleles and susceptibility to primary membranous nephropathy(pMN), but the associations with clinical phenotypes and kidney outcome are underinvestigated.

Methods: Patients with pMN were included. Associations between HLA alleles and clinical variants were analyzed by Logistic regression. Risk factors for kidney outcome were analyzed by Kaplan-Meier curve and COX regression. Structure of HLA molecules were modelled.

Results: DRB1*0301 was associated with higher level of PLA2R-Ab (OR=1.58, 95%CI 1.13-2.22, *P*=0.008). Although DRB1*1502 differs from DRB1*1501 by a single amino acid and was not risk allele for pMN, it was associated with lower eGFR both at baseline (OR=1.79, 95%CI 1.18-2.72, *P*=0.006) and last follow-up (OR=1.72, 95%CI 1.17-2.53, *P*=0.006), worse renal outcome (*P*=0.013) and higher risk of ESRD (HR=4.52, 95%CI 1.22-16.74, *P*=0.024). DRB1*1502 correlated to higher PLA2R-Ab level [161.4 (28.1, 268.0) vs. 36.3 (2.8, 130.5) U/mL, P=0.013] and showed interaction with DRB1*0301 for the variable(*P*=0.049). Homologous modelling showed the amino acid on position 86 is a valine in DRB1*1501, but a glycine in DRB1*1502, the latter facilitating the formation of a larger pocket 1 in the binding groove.

Conclusions: Our findings show that HLA genes control PLA2R antibody production and pMN severity and outcome. They additionally suggest that DRB1*1502 behaves like a modifier gene with a strong predictor value when associated with HLA risk alleles.

The Role of Fumarate on the Outcomes of Membranous Nephropathy: Urine Metabolomics Analysis and Its Experimental Validation

Hyung Ah Jo,[1] Jin Seong Hyeon,[2] Youngae Jung,[2] Minkyoung Park,[3] Seung Hee Yang,[3] Dong Ki Kim,[4] Geum-Sook Hwang.[2] *[1]Department of Internal Medicine, Inje University Ilsan Paik Hospital, Goyang, Republic of Korea; [2]Korea Basic Science Intsitute, Seoul, Republic of Korea; [3]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [4]Seoul National University Hospital, Jong ro Gu, SEOUL, Republic of Korea.*

Background: Anti-PLA_2R antibody (PLA2R Ab) is a useful biomarker in membranous nephropathy (MN), however, the levels of PLA_2R Ab do not always predict the prognosis or treatment response. There are need to seek additional biomarker to predict both of immunosuppressive agent response and renal prognosis. Also, it is not yet known how PLA_2R Ab-antigen reaction causes the changes in podocytes and become a pathogenicity of MN. We aimed to figure out biomarkers predicting the prognosis and treatment response using metabolomics analysis of urine samples.

Methods: The nuclear magnetic resonance-based method was used to examine the urine samples at the time of kidney biopsy from patients with PLA_2R-associated MN and minimal change disease (MCD). The negative control was urine samples from healthy controls.

Results: Metabolites significantly higher in PLA_2R-associated MN than healthy controls were fumarate, choline, mannitol, isoleucine, glucose, valine, leucine, tyrosine, and betaine. Fumarate was the only differential metabolite in PLA_2R-associated MN compared with MCD. PLA_2R-associated MN patients with high urine fumarate levels had a greater risk of composite renal outcome and lower likelihood of having treatment response and achieving remission. The *in-vitro* validation study was performed using primary cultured human podocytes treated with IgG purified from a patient with PLA_2R-associated MN (MN IgG). PLA_2R Ab-antigen interaction in MN IgG stimulated podocytes was confirmed and further identified increased the expression of both fibronectin and Snail, despite decreased fumarate hydratase, WT-1, and ZO-1 expression. Lentivirus-mediated fumarate hydratase activation showed improvement of fumarate hydratase, WT-1 and ZO-1, and attenuation of expression in fibronectin and Snail. Albumin permeability test confirmed that absorbance of albumin was increased in podocytes after activation of MN IgG. The fluorescence intensity of ZO-1 was decreased in podocytes by stimulation of MN IgG. Albumin absorbance and fluorescence intensity of ZO-1 in podocytes were reversed by activation of fumarate hydratase.

Conclusions: These findings suggest that fumarate might play an important role in the progression and disease activity of PLA_2R-associated MN via the regulation of podocyte integrity and renal fibrosis.

Serum GDH-15 Predicts the Outcome of Idiopathic Membranous Nephropathy

Youngrok Ham,[2] Dae Eun Choi,[1] Jae wan Jeon,[2] Jiwon M. Lee,[1] Yoon-Kyung Chang,[3] Ki Ryang Na,[2] Kang Wook Lee.[2] *[1]Chungnam National University, Daejeon, Republic of Korea; [2]Chungnam National University Hospital, Daejeon, Republic of Korea; [3]The Catholic University of Korea, Daejeon, Republic of Korea.*

Background: Idiopathic membranous nephropathy (IMN) is a major cause of nephrotic syndrome. Growth differentiation factor-15 (GDF-15) is a member of the transforming growth factor-β superfamily and has been associated with chronic inflammatory disease. It has the potential to be a useful prognostic marker in patients with renal diseases, such as diabetic nephropathy and IgA nephropathy. This study examined whether GDF-15 is associated with the clinical parameters in IMN and showed that GDF-15 can predict IMN disease progression.

Methods: A total of 35 patients with biopsy-proven IMN, treated at Chungnam National University Hospital from January 2010 to December 2015, were included. Patients younger than 18 years, those with secondary membranous nephropathy, and those lost to follow-up before 12 months were excluded. Levels of GDF-15 at the time of biopsy were measured using enzymelinked immunosorbent assays. Disease progression was defined as a ≥30% decline in estimated glomerular filtration rate (eGFR) or the development of end-stage renal disease.

Results: The mean follow-up was 44.1 months (range: 16–72 months). Using receiver operating curve analysis, the best serum GDF-15 cut-off value for predicting disease progression was 2.15 ng/ml (sensitivity: 75.0%, specificity: 82.1%, p = 0 007). GDF-15 was significantly related to age and initial renal function. In the Kaplan-Meier analysis, the risk of disease progression increased in patients with GDF-15 ≥ 2.15 ng/ml when compared with those with GDF-15 < 2.15 ng/ml (50.0% versus 9.7%) (p = 0 012). In the multivariate Cox regression analysis adjusted for potential confounders, only GDF-15 was significantly associated with disease progression in IMN (p = 0 032).

Conclusions: The GDF-15 level at the time of diagnosis has a significant negative correlation with initial renal function and is associated with a poor prognosis in IMN. Our results suggest that GDF-15 provides useful prognostic information in patients with IMN.

Novel ELISA for THSD7A Autoantibodies in Membranous Nephropathy

Christelle Zaghrini,[1] Barbara Seitz-Polski,[2] Joana Justino,[1] Guillaume Dolla,[1] Christine Payre,[1] Noemie Jourde-Chiche,[3] Anne-Els van de Logt,[6] Jennie Lonnbro-Widgren,[4] Jenny C. Nystrom,[5] Zhao Cui,[10] Jack F. Wetzels,[6] Gian Marco Ghiggeri,[9] Laurence H. Beck,[7] Pierre M. Ronco,[8] Hanna Debiec,[8] Gerard J. Lambeau.[1] *[1]Institut de Pharmacologie Moleculaire et Cellulaire, University Cote d'Azur, Sophia Antipolis, France; [2]Pasteur University Hospital, Nice, France; [3]Aix-Marseille University, Marseille, France; [4]Sahlgrenska University Hospital, Gothenburg, Sweden; [5]University of Gothenburg, Goteborg, Sweden; [6]Radboud University Medical Center, Nijmegen, Netherlands; [7]Boston University Medical Center, Boston, MA; [8]Hospital Tenon, Sorbonne University, Paris, France; [9]G. Gaslini Children Hospital, Genoa, Italy; [10]Peking University First Hospital, Peking, China.*

Background: In 2014, THSD7A was identified as a second autoantigen for 2-5% of membranous nephropathy (MN) patients whereas PLA2R1 is the major autoantigen for 70% of patients. Detection and accurate measurement of anti-PLA2R1 and anti-THSD7A titers provide key biomarkers to diagnose MN, monitor disease activity and predict clinical outcome. To date, antibodies in THSD7A-associated MN patients are only evaluated semi-quantitatively by WB and IIFT. We aimed to develop a robust and rapid assay for the quantitative measurement of antibody levels in THSD7A-associated MN patients.

Methods: Screening of 1012 biopsy-proven MN patients led to the identification of 28 THSD7A-positive patients by ELISA. Screening of additional MN patients, mostly PLA2R1-negative, identified 21 more cases, establishing the largest cohort of 49 THSD7A-positive patients to date. We validated the positivity of the 49 patients by ELISA, WB, IIFT and biopsy staining. We analyzed the clinical parameters of this population for age, gender, disease activity and possible links to etiology including malignancy. We described eight patients double positive for THSD7A and PLA2R1 antibodies.

Results: The novel ELISA and commercial IIFT titers correlated significantly (p<0.0001). Among the 49 patients with anti-THSD7A antibodies, 57% were males. Females were younger than males (49 versus 67 years, p=0.003). Levels of anti-THSD7A antibodies were similar between male and female patients and correlated with disease activity and treatment efficacy. The double positive patients had varying antibody titers for both antigens and displayed no clinical difference compared to the rest of the population. Patients with a history of malignancy (16%) were older than others (76 versus 54 years old, p=0.002) and only 3 were diagnosed for malignancy within 2 years of MN diagnosis.

Conclusions: This novel ELISA assay can be used to identify patients with THSD7A-associated MN and monitor antibodies during follow-up. Our data suggest a weak association between MN and malignancy in our population of THSD7A-positive patients.

Membranous Nephropathy at Diagnosis and Follow-Up: Comparison Between Elderly and Young Patients

Renata P. Brandão, Cristiane B. Dias, Lectícia Jorge, Denise M. Malheiros, Viktoria Woronik. *University of São Paulo, São Paulo, Brazil.*

Background: This study aims to evaluate the epidemiological profile between elderly and young patients with Membranous Nephropathy (MN) diagnosed in a single center.

Methods: This was a retrospective cohort study from 1999 to 2017, where clinical, epidemiological, laboratory and histological data of patients with MN accompanied by the Nephrology Department of the Hospital das Clinicas de São Paulo were evaluated. The only exclusion criterion was to have a diagnosis of Systemic Lupus Erythematosus at the time of the renal biopsy.

Results: In these period 219 patients had renal biopsy proving MN, presenting a mean age of 45.3 ± 15.7 years and 53.8% of women. Laboratory data at diagnosis were: serum creatinine median of 1.0 (0.8-1.7) mg/dl; median proteinuria of 6.0 (3.0-8.8) g/day and serum albumin median of 1.8 (1.2-2.5) g/dL. There were 48.4% of patients with hypertension and 35.6% with hematuria at diagnosis. A total of 44 (20%) patients were elderly at diagnosis and comparation with the young patients are in table 1.. Forty patients (18.2%) presented secondary causes, being infectious causes in 18, with hepatitis B in 4 patients; autoimmune causes in 11, with rheumatoid arthritis in 3; and cancer in 11.

Conclusions: MN showed a different epidemiological profile among young and elderly patients, with a predominance of men, hypertension, and increased serum initial creatinine in the latter group. The secondary forms corresponded to less than 20% in these cases, predominating the infectious and autoimmune etiologies.

Comparison between elderly and young patients with MN

	Elderly (≥ 60 years) n=44	Young (<60 years) n=175	p
Male (n/%)	28/63.6	73/41.7	<.05
Hematuria (n/%)	19/43.1	59/33.7	ns
Proteinuria (g/day) -median (quartiles)	5.3 (3.2-8.0)	6.0 (2.9-9.2)	ns
Initial Serum creatinine (mg/dL) - median (quartiles)	1.3 (1.0-2.3)	1.0 (0.7-1.4)	<.05
Arterial hypertension (n/%)	31/70.4	75/42.8	<.05

Polymorphisms in the Exon 1 of the MBL2 Gene Are Not Associated with a Poor Prognosis in Membranous Nephropathy

Maria Carolina R. Coêlho,[1] Camila B. Oliveira,[1] Carolina A. Vasconcelos,[2] Denise M. Costa,[1] Gisele Vajgel,[1] Maria Alina G. Cavalcante,[1] Lucila Maria Valente.[1] *[1]Hospital das Clínicas HC - UFPE, Recife, Brazil; [2]IMIP, Recife, Brazil.*

Background: MBL2 polymorphisms may be associated with the activation of lectin pathway by IgG4 subclass antibodies in membranous nephropathy (MN). Studies involving systemic lupus erythematosus (SLE) have conflicting results, with some data sugesting the association between MBL2 polymorphisms with more severe forms of disease. We investigated whether the prognosis among patients with MN differ according to the presence or absence of these polymorphisms.

Methods: Polymorphisms in the exon 1 of the *MBL2* gene (codons 52, 54 and 57) were evaluated in 59 patients with the two main etiologies of MN in our setting: idiopathic (35 patients) and secondary to SLE (24 patients). We divided the patients into two groups according to the presence or absence of the polymorphisms and analyzed proteinuria as a response parameter after 6 months, 1 and 5 years.

Results: The 59 patients were analysed as their baseline clinical characteristics (Table 1). In both genders, as in both MN etiologies, the presence of polymorphism was predominant. There was no distinction between groups with and without polymorphism with respect to age, initial LDL, serum creatinine (SCr), proteinuria, serum Albumin (SAlb) and blood pressure. After 6 months, 1 year and 5 years, there was no difference in relation to SCr and SAlb among the groups evaluated. No differences in mean and median levels of proteinuria were observed when we compared the patientes with and without *MBL2* polymorphisms after 6 months (4.1 x 3.8, p = 0.838), 1 year (2.1 x 1.7, p = 0.876) and 5 years (0.2 x 1.0, p = 0.110),.

Conclusions: Our data did not support the hypothesis that *MBL2* polymorphisms may be associated with a poor prognosis in patients with MN. Because of the small number of subjects studied, a larger study of MN patients would seem necessary to confirm these findings.

Elevated Level of Urinary Angiotensinogen Is Correlated with Severity of Idiopathic Membranous Nephropathy (IMN)

Ziyong Tang, Yue Wang, Danxia Zheng. *Department of Nephrology, Peking University Third Hospital, Beijing, China.*

Background: The severity of IMN is a main concern for making a decision whether a patient should be treated with immunosuppressive agents as the treatment will predispose the patient to opportunistic infections. Urinary angiotensinogen (UAGT) has been shown highly correlated with the severity of chronic kidney disease and its relationship with severity of IMN was explored.

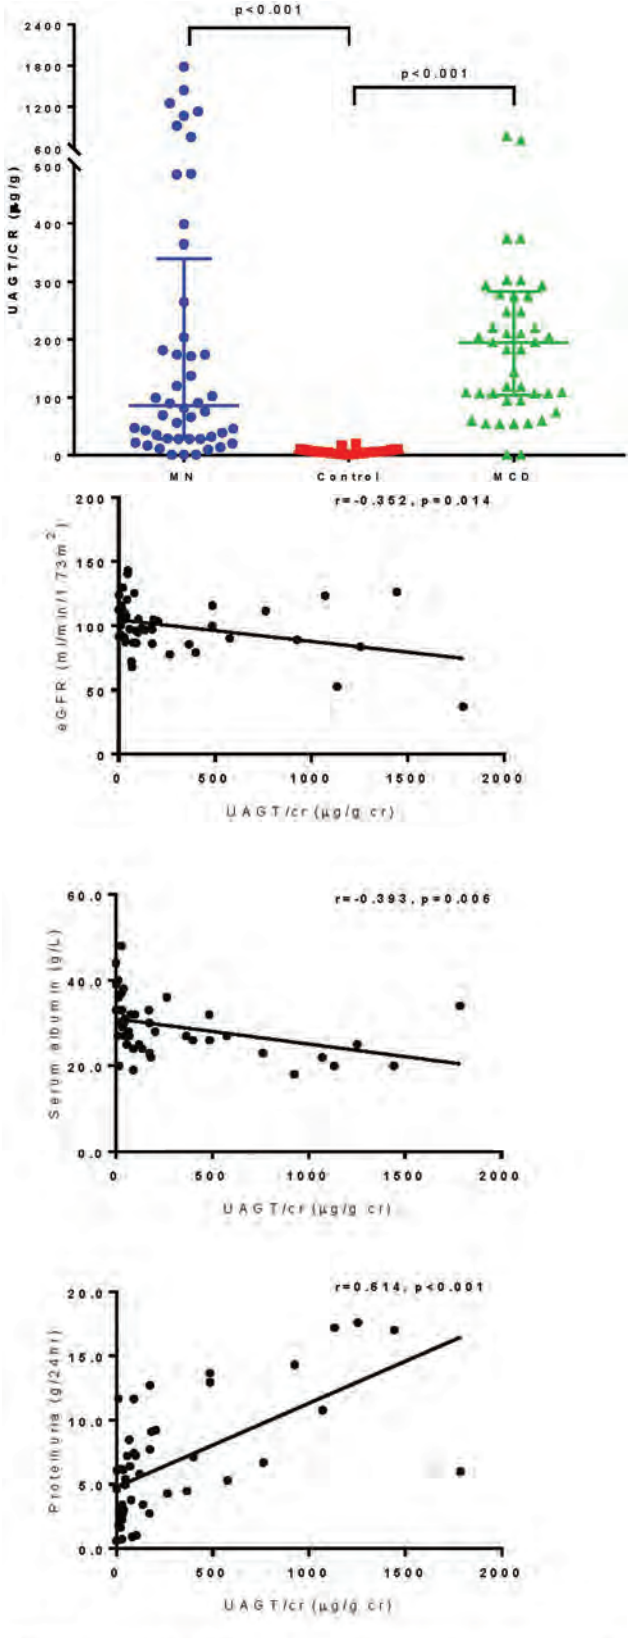
Methods: Data were collected from 48 biopsy-proven IMN, 46 minimal change disease (MCD), and 44 healthy controls. Urine samples were collected before the use of RAS inhibitors. UAGT levels were determined with a method of ELISA.

Results: UAGT levels were not different between IMN and MCD patients, but both of them were higher than those of normal subjects. In IMN patients, UAGT was correlated with serum albumin, estimated glomerular filtration rate and proteinuria. These associations

were not found in MCD patients. Multivariate regression showed that only proteinuria independently determinate the value of UAGT (β=0.649, p<0.001) in IMN patients. ROC curve analysis showed that proteinuria >7.8g/d was associated with higher UAGT level (sensitivity=55.00% specificity=89.29%, p=0.001).

Conclusions: UAGT level is one of severity markers of IMN and may serve as a cofactor in making a treatment decision.

Funding: Government Support - Non-U.S.



UAGT was correlated with eGFR, serum albumin, and proteinuria.

TH-PO1014

Clinical Implications of Pathological Features of Primary Membranous Nephropathy

Xiao-dan Zhang,[1] Zhao Cui,[2] Minghui Zhao.[3] *[1]Renal Division, Peking University First Hospital, Beijing, China; [2]Peking University First Hospital, Beijing, China; [3]Peking University First Hospital, Peking University, Beijing, China.*

Background: The clinical outcome varies considerably in primary membranous nephropathy (pMN). It was controversial whether the histopathological features of pMN could predict treatment response and kidney outcome.

Methods: A retrospective study was conducted in 371 patients with biopsy-proven pMN. Pathological parameters included immunofluorescence staining, membranous Churg's stages, sclerosis, crescent, focal segmental sclerosis lesion, chronic and acute tubulointerstitial injury.

Results: We found that patients with higher intensity of C3 staining, advanced membranous stage, and more severe chronic tubulointerstitial injury presented with higher positivity rate of anti-PLA2R antibodies, higher levels of urinary protein excretion and serum creatinine, and lower level of serum albumin. Univariate Cox regression analysis showed that severe (grade=3) chronic tubulointerstitial injury was a risk factor to the kidney outcome of ESKD and over 50% reduction of eGFR. Multivariate analysis demonstrated it as an independent risk factor to ESKD.

Conclusions: We found the prognostic role of chronic tubulointerstitial injury to the kidney outcome of pMN. This study highlighted the value of kidney biopsy under the widespread usage of anti-PLA2R antibodies for diagnosis and prognosis.

Table. The risk factors of ESKD in patients with pMN

Treatment Patterns Among Adults with Membranous Nephropathy in the Cure Glomerulopathy Network (CureGN)

Louis-Philippe Laurin,[1] Andrew S. Bomback,[2] Michelle A. Hladunewich,[3] Jonathan P. Troost,[4] Brenda W. Gillespie,[4] Amy Kogon,[8] Debbie S. Gipson,[5] Kevin C. Abbott,[6] Michelle M. O'Shaughnessy.[7] CureGN Membranous Epi Treated vs. Not Treated Work Group *[1]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [2]Columbia University, New York, NY; [3]University of Toronto, Toronto, ON, Canada; [4]University of Michigan, Ann Arbor, MI; [5]University of Michigan Mott Children's Hospital, Ann Arbor, MI; [6]The National Institutes of Health, NIDDK, Bethesda, MD; [7]Stanford University, Palo Alto, CA; [8]Children's Hospital of Philadelphia, Wynnewood, PA.*

Background: Patients with membranous nephropathy (MN) and risk factors for progressive disease may benefit from immunosuppressive therapy (IST). Most guidelines and expert opinion recommend a 6-12 mo observation period before initiating IST. Current practice patterns regarding choice and timing of IST in MN remain largely unknown.

Methods: CureGN is an ongoing 70-center prospective cohort study of children and adults with biopsy-proven MCD, FSGS, MN, or IgAN/IgAV. Biopsies were performed between 2010 and 2017. Descriptive statistics were used to assess choice and timing of IST after kidney biopsy. Categorical data are presented as frequencies and % and compared using χ^2 tests; continuous data as median(IQR) and compared using the Kruskal-Wallis test.

Results: As of May 2018, 303 adult MN patients were enrolled in CureGN. Of those, 274 were considered unexposed to IST prior to biopsy, including 267 who received no prior IST and 7 who received steroids alone for a maximum of 6 wks before biopsy. Characteristics at biopsy: age 53 yrs (42-63), 36% Female, 71% White, UP:C 5.7 g/g (3.6-8.5), serum albumin 2.7 g/dl (2.1-3.6), eGFR 81 ml/min/1.73m^2 (57-103). 212/274 (77%) received IST (Table 1) for a median follow-up time of 31 mo (16-50), with 74% of IST treatments started in the first 6 mo after biopsy. 140/274 (51%) received RAAS blockers by 6 mo. Patients treated with IST (vs. untreated) within the first 6 mo after biopsy had higher UP:C (7.1 vs. 4.0 g/g; p<0.01), lower serum albumin (2.4 vs. 3.3 g/dl; p<0.01) and lower eGFR (77 vs. 89; p=0.03) at time of biopsy.

Conclusions: Seventy four percent of treated patients with biopsy proven MN were started on IST within the first 6 mo after kidney biopsy. IST choices were heterogeneous and many patients were treated with steroids alone. Reasons for poor alignment with KDIGO guidelines regarding timing and choice of IST in MN require further exploration.

Immunosuppressive Therapy for Children with Membranous Nephropathy: A Report from the Cure Glomerulopathy Network (CureGN)

Louis-Philippe Laurin,[1,8] Isa Ashoor,[10] Tarak Srivastava,[2] Amira Al-Uzri,[9] Jonathan P. Troost,[3] Michelle N. Rheault,[4] Raed Bou Matar,[5] Keisha L. Gibson,[6] David T. Selewski,[3] Debbie S. Gipson,[7] Chia- Shi Wang.[11] CureGN Membranous Epi Treated vs. Not Treated Work Group *[1]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [2]Childrens's Mercy Hospital, Kansas City, MO; [3]University of Michigan, Ann Arbor, MI; [4]University of Minnesota, Minneapolis, MN; [5]Cleveland Clinic, Cleveland, OH; [6]University of North Carolina Kidney Center, Chapel Hill, NC; [7]University of Michigan Mott Children's Hospital, Ann Arbor, MI; [8]University of Montreal, Montreal, QC, Canada; [9]Oregon Health & Science University, Portland, OR; [10]Children's Hospital of New Orleans, New Orleans, LA; [11]Emory University School of Medicine, Atlanta, GA.*

Background: Membranous nephropathy (MN) is a rare cause of nephrotic syndrome in children. Current practice patterns regarding choice and timing of immunosuppressive therapy (IST) remain largely undescribed.

Methods: CureGN is an ongoing multi-center prospective, observational cohort of children and adults with biopsy-proven MCD, FSGS, MN, or IgAN/IgAV. Biopsies were performed between 2010 and 2017. Descriptive statistics were used to assess choice and timing of IST after incident kidney biopsy. Categorical data are presented as frequencies and percentages and compared using chi-square tests; continuous data as median(IQR) and compared using the Kruskal-Wallis test.

Results: Forty-one children with MN were enrolled. Thirty participants without pre-biopsy IST exposure (N=29) or exposed to steroids only within 6 weeks before biopsy (N=1) were treated as IST naïve and included in the analysis. Median age at time of biopsy was 14 yrs (12-16). 57% were female. Median urine protein to creatinine ratio (UP:C) was 3.8 (1.3-7.4), serum albumin was 2.2 g/dl (1.7-3.1), and estimated GFR was 107 mL/min/1.73m2 (84-137). 21/30 (70%) of patient received IST (Table 1), with 81% of IST treatments started in the first 6 months after biopsy. 15/30 (50%) were treated with RAAS blockers by 6 months. Treated patients with IST (vs. untreated) by 6 months after biopsy had similar UP:C (3.8 vs. 3.4 g/g; p=0.60), serum albumin (2.4 vs. 2.1 g/dl; p=0.81) and eGFR (119 vs. 100; p=0.56) at time of biopsy.

Conclusions: Corticosteroids and calcineurin inhibitors were the main agents used in children with biopsy-proven MN. Therapies were started early within the first 6 months after biopsy in 81% of patients, deviating from current KDIGO practice guidelines.

Response to Therapy Is Poor in Anti-PLA2R Positive Idiopathic Membranous Nephropathy Patients as Compared to Anti-PLA2R Negative Patients

Narayan Prasad, Akhilesh Jaiswal, Harshit Singh, Vikas Agarwal. *Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India*.

Background: Idiopathic membranous nephropathy (IMN) is associated with Anti-PLA2R antibody expression on podocytes. We aimed to decipher the efficacy of tacrolimus (Tac) plus prednisolone, changes in anti-PLA2R level and differences in response to therapy in anti-PLA2R+ve and -ve patients.

Methods: In the study, total 101 (77 IMN and 24 seconday MN) patients were included. All secondary MN (15 diabetic, 7 lupus, 1 HBV and 1 collagen disease) were excluded. All IMN(n=77) patients were treated with combination of prednisolone (1mg/kg alternate day) and Tac 0.1mg/kg/day (target trough 6-10 ng/ml first 6 months(M) and 4-6 ng/ml for next 3M and then tapering by 1/3 each months to stop at 12M. Anti-PLA2R level was estimated at baseline, 3M, 6M,12M and end of follow-up (13 to 55, median 36 months). Total remission, complete(CR) and partial (PR), relapse and side-effects were recorded and compared between Anti-PLA2R +ve and -ve groups.

Results: Of the 77 patients, at 3M 60(77.92%) CR-37, PR-23 ; 6M 61(79.22%) CR-53, PR-8; at12M 53(68.86%) CR-47, PR-6 achieved remission. Eight (10.38%) relapsed during tapering and 16(20.77%) showed no response at 12M. At the end, 68.51% remained in remission and 31.48% relapsed. Out of 77 patients, 51 (66.3%) were anti-PLA2R +ve. Remission rate was lower in anti-PLA2R+ve than -ve (36/51 vs 24/26; p=0.03) at 3M; (36/51 vs 25/26; p=0.009) at 6M; and (31/51 vs 22/26; p=0.03) at 12M. PLA2R level was decreased by 60.38% and 77.56% at 3M and 6M respectively. Relapse rate was higher in anti-PlA2R +ve than–ve patients(P=0.02). There was significant correlations between PLA2R level and 24h proteinuria at baseline (r=0.72), 3M(r=0.81) and 6M(r=0.76). During therapy 4 patients develop new diabetes, 4 cutaneous tinea, 1 osteonecrosis of femur head, 1 carpal tunnel syndrome, 3 tremor and 10 upper GI symptoms. eGFR decreased significantly (p=0.003) by 26.5% at end, which normalized after stopping Tac. Five non-responsive patients had doubled of serum creatinine and progressively deteriorated eGFR. To note, 4 females had succesful pregnancy and delivery, of them one had relapse after delivery.

Conclusions: Anti-PLA2R+ve IMN patients had poor response and more relapses as compared to PLA2R-ve patients. Remission with Tac and pred therapy is comparable to historical Ponticelli regimen with lesser side effects.

TH-PO1018

Treatment of Moderate and High-Risk Idiopathic Membranous Nephropathy with Intravenous Cyclophosphamide Pulses and Oral Steroid

Angel C. Ortiz Bello, Luis E. Álvarez Rangel, Ida jayna I. Ruiz serrano. *Instituto Mexicano del Seguro Social, Mexico City, Mexico*.

Background: Idiopathic membranous nephropathy (IMN) is one of the most frequent causes of nephrotic syndrome in adults with risk of progression to end-stage renal disease. Proteinuria portend worse renal outcomes and is a risk factor for cardiovascular morbidity. The standard treatment includes oral cyclophosphamide and prednisone. Little is known about the efficacy of the treatment with pulse intravenous cyclophosphamide and oral steroid in moderate and high-risk patients and the factors associated with non-response.

Methods: A retrospective cohort study was performed on the data of patients with idiopathic membranous nephropathy. We included patients with biopsy-proven IMN treated with pulses of intravenous cyclophosphamide (750 mg/m2) and oral steroid between June 2012 to December 2017. Continuous variables were expressed as mean ± SD. Categorical variables were expressed as frequencies or proportions. Comparisons of continuous and categorical variables were performed using Student's t-test and the Chi.square test, respectively. A *p value* of <0.05 was considered statistically significant. The odds ratios (OR) with their corresponding 95% confidence intervals (CI) were estimated.

Results: Sixty-one biopsy-proven IMN patients were included. The patients were predominantly male (72.1%), with mean age of the sample of 47.75 ± 12.49 years. The average eGFR was 88.85 ± 29.92 ml/min/1.73 m2 and mean baseline proteinuria was 12.13 ± 5.4 g/day. During the median follow-up duration of 26.52 ± 21.14 months, overall remission was achieved in 82% (50 cases), partial remission in 45.9% (28 cases) and complete remission in 36.1% (22 cases). The treatment failure was observed in 18% (11 cases). Adverse events related to treatment were reported in 18%. Peak proteinuria greater than 8 g/day (OR:1429, 95% CI:1192-1713) and non-reduction of proteinuria greater than 50% at month 3 (OR:3333, 95% CI:2183-5.090) were associated with the treatment failure.

Conclusions: Pulse intravenous cyclophosphamide and oral steroid is a therapeutic alternative in the treatment of idiopathic membranous nephropathy with a low incidence of adverse events. Peak proteinuria high-risk greater than 8 g/day and non-reduction of proteinuria greater than 50% at month 3 of treatment are factors associated with treatment failure.

TH-PO1019

Rituximab in Primary Membranous Nephropathy Systematic Review and Meta Analysis

Laila Alharbi, Michael Walsh. Mike Walsh *McMaster University, Hamilton, ON, Canada*.

Background: Primary membranous nephropathy is a kidney limited, autoimmune disease caused by circulating antibodies directed against phospholipase A2 receptor (PLA2R), a cell surface trans membrane receptor expressed on the surface of podocytes of the renal glomeruli. As our understanding of PMN has evolved and B cell played a major role in PMN, there has been paradigm shift in the treatment of PMN and Rituximab has emerged as a potential treatment. **Objectives**: to assess the effects of Rituximab in primary membranous nephropathy

Methods: Search methods: we searched the following databases up to January 26, 2018: MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials, Conferences organized by the following organizations: The American Society of Nephrology, Canadian Society of Nephrology, and International Society of Nephrology. We also search trial registries. **Selection criteria**: We included randomized controlled trials and non-randomized studies with a minimum follow-up duration of 12 month that have investigated the effect of Rituximab compared to standard of care in patients diagnosed with PMN. We assessed the following outcomes: proteinuria remission, AntiPLAR2 depletion and adverse events. **Data collection and analysis:** two reviewers independently extracted data from the **included studies**: The treatment effect (dichotomous variable) was assessed using risk ratio with 95% confidence intervals (CIs). We performed meta-analyses for 6 month and 12 month follow-ups.

Results: Main results: two randomized trials (202 participants) were included in the final analysis. At six month, RR 1.01(95% CI0.42 to 2.42) of proteinuria remission with rituximab compared to standard of care in PMN, and at twelve months RR 1.40, (95% CI 0.89 to 2.29). Additional data from three cohort studies showed RR 1.11(95% CI 0.70 to 1.76) of proteinuria remission with rituximab compared to standard of care in PMN at 12 months

Conclusions: conclusions: there is insufficient evidence to draw conclusions that rituximab is more effective with less adverse events than standard of care in primary membranous nephropathy. There is a need for further research in this area with larger sample size and longer term follow up.

TH-PO1020

Five-Year Outcomes of Idiopathic Membranous Nephropathy and Nephrotic Syndrome After a Combination Treatment with Mizoribine and Low-Dose Prednisone

Yoshihiro Matsumoto,[1] Yasushi Shimada,[1] Youichi Nojima,[1] Koichiro Iguchi,[1] Yasuo Mori.[2] *[1]Shizuoka City Hospital, Shizuoka, Japan; [2]Shibukawa Clinic, Shizuoka, Japan*.

Background: Patients with idiopathic membranous nephropathy (IMN) showing persistent high-grade proteinuria have the highest risk for developing end-stage renal failure. We previously reported the favorable short-term outcomes of treatment with mizoribine followed by low-dose prednisone. The purpose of the present study was to assess the long-term efficiency of this combined treatment in a larger number of patients.

Methods: Between 2004 and 2014, 22 patients with IMN and nephrotic-range proteinuria were administered the combined treatment. Mizoribine was initiated at a dose of 150 mg/day; after 1–3 months, 20 mg/day prednisone was added. The dosage of prednisone or mizoribine was tapered according to the urinary protein-to-creatinine ratio (P/C). For some of the patients who experienced side effects, relapse, or no response (NR), other immunosuppressive regimens were substituted. We evaluated patient outcomes for up to 5 years after initiating the combination therapy. The statuses of patients who were not followed up after the achievement of complete remission (CR), defined as a decrease in urinary P/C to <0.5, were assessed through a follow-up interview

Results: Before treatment, patient urinary P/C ranged from 3.7 to 15.9 g/g. At 1, 2, and 3 years after combination therapy, 68%, 77%, and 77% of patients attained CR, respectively. The 5-year actual rates for CR, partial remission, NR, two-fold Cr increase, and death were 82%, 14%, 5%, 5%, and 0%, respectively. Sixteen patients (73%) stopped treatment after 9–53 months of combination therapy. In patients who achieved at least one CR, the 3-year actual risk of relapse was 11%. Side effects, including fracture, were observed in four patients.

Conclusions: The addition of prednisone after mizoribine monotherapy resulted in fast and safe remission in a high proportion of patients with IMN and nephrotic syndrome. The risks associated with immunotherapy might be decreased by the initial prescription of mizoribine alone, which may act as a base for establishing therapy, followed by low-dose prednisone treatment.

TH-PO1021

Mycophenolate Mofetil and Tacrolimus versus Tacrolimus Alone for the Treatment of Idiopathic Membranous Glomerulonephritis: A Randomised Controlled Trial

Aikaterini K. Nikolopoulou,[1] Marie B. Condon,[3] H. Terence Cook,[1] Neill D. Duncan,[2] Jack W. Galliford,[2] Jeremy B. Levy,[2] Liz Lightstone,[1] Charles D. Pusey,[1] Candice A. Roufosse,[2] Tom Cairns,[2] Megan Griffith.[2] *[1]Imperial College London, London, United Kingdom; [2]Imperial College Healthcare NHS Trust, London, United Kingdom; [3]St. Helier Hospital, Surrey, United Kingdom.*

Background: Membranous nephropathy (MN) is a common cause of nephrotic syndrome in adults. Tacrolimus (TAC) is effective in inducing remission of proteinuria; however relapses after TAC withdrawal are common. We aimed to investigate if the addition of mycophenolate mofetil (MMF) to TAC reduces the relapse rate of nephrotic syndrome in patients with MN after treatment withdrawal.

Methods: A single centre randomised controlled trial was undertaken from 2008 to 2014; patients with biopsy proven idiopathic MN were recruited and randomly assigned to receive MMF and TAC or TAC alone. Treatment was for 1 year initially; once patients were in remission for 12 months the MMF was stopped and TAC tapered over 6 months in both groups. The primary outcome was the efficacy of MMF in preventing relapse of nephrotic syndrome on withdrawal of TAC.

Results: We randomly assigned 40 patients, 20 of whom received MMF and TAC and 20 received TAC alone. Both groups had similar baseline characteristics. Retrospective anti phospholipase A2 receptor (PLA2R) biopsy staining showed similar PLA2R positivity in both groups. Follow up was until primary endpoint or for a minimum of 3 years. The time to relapse after treatment withdrawal was similar in the two groups. 40% of patients (n=8) in the TAC/MMF group relapsed after treatment withdrawal compared to 35% (n=7) in the TAC group; there was no statistically significant difference in the relapse rate between the two groups (p=0.77). Both treatments were equivalent in achieving remission; 85% of patients in the TAC/MMF group and 75% in the TAC group reached complete remission (p=0.7). There was a trend to earlier remission in the TAC/MMF group; median time to remission 40 weeks compared to 54 weeks with TAC alone, but this was not statistically significant (p=0.46). Both treatments were well tolerated with similar adverse events.

Conclusions: The addition of MMF to TAC did not protect from relapse of nephrotic syndrome due to idiopathic MN compared to treatment with TAC alone; both groups showed similar remission rates and adverse events. The treatment was well tolerated and further studies are needed to investigate if high risk subgroups may benefit from combination therapy.

TH-PO1022

Symptoms and Health-Related Quality of Life (HRQOL) in Primary Membranous Nephropathy

Shannon L. Murphy,[1] Jill Powell,[4] Adeline Dorough,[4] Amy K. Mottl,[1] Bryce B. Reeve,[3] Patrick H. Nachman.[2] *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]University of Minnesota, Minneapolis, MN; [3]Duke University, Durham, NC; [4]UNC Kidney Center, Chapel Hill, NC.*

Background: Primary membranous nephropathy (MN) can affect patients' HRQOL in profound and differing ways. Better understanding patient perspectives on disease experience may identify important outcomes to consider in clinical trials and facilitate more patient-centered care. To our knowledge, symptoms and HRQOL have not been richly characterized among individuals with MN. We sought to address this gap by exploring patient experiences with MN with a focus on symptoms and HRQOL.

Methods: We conducted 45-60 minute semi-structured interviews with 13 adults with primary MN. Inclusion criteria included active disease in the last 5 years and non-dialysis dependence. We used purposive sampling to achieve heterogeneity on relevant demographic and clinical characteristics. Interviews were recorded and professionally transcribed. Transcripts were coded independently by two team members and analyzed for concepts and themes.

Results: Participants ranged 40-68 years old, with 46% male and 85% Caucasian. Each had lived with MN for 1-14 years (5.3 ± 4.4), had peak proteinuria ranging from subnephrotic to 23 g, and serum albumin ranging from normal to 1.5 g/dL. Treatment regimens included steroids (N=6), cyclophosphamide (N=6), calcineurin inhibitors (N=7), rituximab (N=9), and conservative management (N=2). The most common symptoms were 1) lower extremity edema (92%), 2) fatigue (77%), 3) pain or discomfort due to swelling (62%), 4) weight gain (46%), and 5) sleep changes (38%). Other reported symptoms included cramping, itching, and irritability. We identified 5 major themes: 1) experiencing sacrifice and loss, 2) feeling powerless in the face of disease, 3) navigating uncertainty, 4) living with constant worry, and 5) developing strategies and evolving perspective to cope. Overall, participants frequently struggled with the substantial physical, emotional, social, and/or financial effects of MN; yet, with time, many developed adaptive coping skills and often changed their outlook on life for the better.

Conclusions: These data shed light on the substantial burdens born by individuals with primary MN. Development of a MN-specific patient-reported outcomes instrument that captures symptoms and HRQOL is an important next step to facilitate focus on patient-centered outcomes in research and clinical care.

TH-PO1023

Prevalence of Renal Dysfunction Among Rheumatoid Arthritis Patients in Jordan

Ashraf O. Oweis,[1] Sameeha A. Alshelleh.[2] *[1]Jordan University Of Science and Technology, Amman, Jordan; [2]Medicine, University of Jordan, Amman, Jordan.*

Background: Rheumatoid Arthritis (RA) is an autoimmune disorder characterized by inflammation of multiple synovial joints, it can affect other organs such as kidneys. RA can affect the kidneys by direct effect of the disease itself, or secondary to the drugs used to treat the disease; both biological agents as well as simple analgesics like non-steroidal anti-inflammatory drugs(NSAIDs). Clinico-pathological correlations showed that the most common pathological findings on renal biopsy were secondary amyloidosis, membranous nephropathy, less commonly RA can cause rapidly progressive glomerulonephritis

Methods: Using our electronic records, we retrospectively evaluated RA patients in our tertiary referral hospital between 2010 – 2016 with at least one year follow up, renal dysfunction was defined as the presence of hematuria and/or at least +1 proteinuria on dipstick urine analysis on at least 2 occasions, and/or abnormal serum creatinine values. Glomerular filtration rate was calculated using CKD-EPI equation

Results: We evaluated 233 patients with a diagnosis of RA, mean age was 54.5 years, females were 84.9% vs. 15.1% for males, for baseline characteristics see Table 1. 44 patients (18.8%) presented with microscopic hematuria, 16 (6.9%) with proteinuria, only 5 (2.1%) presented with both microscopic hematuria and proteinuria. At presentation 48.2% were on NSAIDs, 16 (6.9%) patients treated with methotrexate, 52(22.3%) were treated with anti-TNF, 26 (11.1%) continued on NSAID's. At last follow up: 32 (13.7%)patients had microscopic hematuria, 22 (9.4%) with proteinuria, and 7 (3%) with both microscopic hematuria and proteinuria. eGFR at last follow up was 93.2 ml/mi (±22.3) compared to 97.1ml/min at presentation only 2 patients underwent renal biopsy, both had concomitant IgA nephropathy in their biopsies.

Conclusions: Renal dysfunction is not uncommon in RA patients, though more careful evaluation and attention to urine analysis and microscopy for renal dysfunction is required

Baseline characteristics

Age	54.5 (±47.2)
Male	40(15.1%)
Female	225(84.9%)
DM	24(9.1%)
HTN	41(15.5%)
ACEi/ARB	24(9.1%)
eGFR	97.1ml/min(±22.5)

TH-PO1024

Small Kidney Size Relative to Body Mass Is a Risk Factor for Renal Function Deterioration in IgA Nephropathy Patients

Yooju Nam,[1] Seon yeong Lee,[1] Joohwan Kim,[1] Ki Heon Nam,[1] Jung Tak Park,[2] Seung Hyeok Han,[1] Tae-Hyun Yoo.[1] *[1]Yonsei University College of Medicine, SEOUL, Republic of Korea; [2]Yonsei University Health System, Seodaemun-Gu, seoul, Republic of Korea.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis worldwide. However, identifying IgAN patients at higher risks for renal function decline is still a challenge. Recent investigations have proposed kidney size to be a risk factor for renal function decline in kidney transplantation recipients. Therefore, this study aimed to investigate whether kidney size has an effect on renal function deterioration rate in patients with IgAN.

Methods: Retrospective analysis was preformed from electronic medical records of 516 biopsy-proven IgAN patients. Kidney length was considered as the longest longitudinal diameter from sonographic measurements obtained at the time of biopsy. The average length of both kidneys was divided by body mass index for each individual to make adjustments for subject size (BMI-adjusted kidney size). Renal outcome was defined as a composite of a ≥ 50% decline in estimated glomerular filtration rate (eGFR) from baseline or the onset of end-stage renal disease.

Results: The mean age of the patients was 40.4 ± 12.1 years and 211 patients (40.9%) were male. The mean eGFR was 79.6 ± 28.3 mL/min/1.73 m^2 and the average kidney length was 102.8 ± 8.8 mm at baseline. The median follow-up duration was 51 months. When the patients were grouped into tertiles based on BMI-adjusted kidney size, renal outcome occurred in 30 (17.0%), 25 (14.0%), and 12 (7.4%) patients in the 1st, 2nd, and 3rd tertile groups, respectively. The amount of proteinuria was lowest and eGFR was highest in the 3rd tertile of BMI-adjusted kidney size group. Multivariate Cox proportional analysis revealed that the risk of renal outcome significantly lower in the 3rd tertile group as compared to the 1st tertile group (hazard ratio [HR], 0.44; 95% confidence interval [CI], 0.21-0.93; P = 0.031). Additionally, the risk of renal outcome significantly decreased as the BMI-adjusted kidney size increased (HR, 0.55; 95% CI, 0.36-0.86; P = 0.008). These results remained robust even after adjustments were made for confounding factors including baseline eGFR and proteinuria.

Conclusions: Small kidney size could be a risk factor for renal function decline in IgA nephropathy patients. Simple sonographic kidney size measurements may help stratifying progression risk in patients with IgA nephropathy.

TH-PO1025

External Validation of the Kidney Failure Risk Equation in Biopsy Proven IgA Nephropathy

Rupert Major,[1,2] Jorge Jesus Silva,[1,4] James F. Medcalf,[1] Nigel J. Brunskill,[1,3] Jonathan Barratt.[1,3] The Mayer Leicester IgA Nephropathy Group *[1]University Hospitals of Leicester, Leicester, United Kingdom; [2]Health Sciences, University of Leicester, Leicester, United Kingdom; [3]Infection, Immunity and Inflammation, University of Leicester, Leicester, United Kingdom; [4]Facultad de Medicina, Universidad Nacional Autonoma de Mexico, Mexico City, Mexico*.

Background: The Kidney Failure Risk Equation (KFRE) has been externally validated in over 30 multi-national multiple aetiology chronic kidney disease (CKD) cohorts. It has high discrimination and good calibration for endstage renal disease (ESRD) events. However, KFRE has not been validated in IgA nephropathy (IgAN). Risk factors for IgAN progression to ESRD may be different to those used in KFRE. Therefore, our aim was to perform an independent, external validation of the 2 and 5-year 4-variable KFRE in adults with biopsy proven IgAN.

Methods: Using electronic records for the Leicester Renal Network, UK, we assessed model performance of the 2 and 5-year 4-variable KFRE. The C-statistic was used to assess discrimination. Calibration of the KFRE was assessed using the linear predictor's calibration slope and observed versus predicted event rates plots with risk categories of 0 to <5%, ≥5% to <25% and ≥25%.

Results: The cohort consisted of 353 individuals with biopsy proven IgAN, of whom 166 had CKD stages 3-5 at their biopsy date. In CKD stages 3-5, mean age was 49.2 (SD 14.4) years, 30.1% were female, mean EPI eGFR was 37.6 l/min/1.73m^2 (SD 13.5) and median ACR was 52.2 (IQR 2.2 to 124.6) mg/mmol. 59 (35.5%) ESRD events occurred over median follow-up of 3.6 (IQR 1.5 to 7.7) years. For eGFR and ACR nearest to the date of biopsy, discrimination by KFRE was good (Harrell's C-statistic 0.71, 95% CI 0.62 to 0.81), although possibly inferior to the published model (Harrell's C-statistic 0.90, 95% CI 0.87 to 0.93). The linear predictor for calibration was 0.29 (95% CI 0.14 to 0.44). Calibration plots suggested that risk was over estimated at 2 and 5 years for low (<5%) KFRE predicted risk groups. For higher risk groups, the model was well calibrated. Results were similar when earliest available, instead of biopsy, eGFR and ACR were used in KFRE.

Conclusions: In an independent, external validation of KFRE in biopsy proven IgAN, discrimination was good but calibration was poor in lower predicted risk individuals. For patients with biopsy proven IgAN, the KFRE may need model adjustment, particularly for lower predicted risk individuals. Adjustments may be required to existing variables and/or inclusion of other variables, such as Oxford Classification histology findings, before KFRE can be used for prognostic purposes in IgAN.

TH-PO1026

Combinatory Approach of Oxford Classification Allows a Tailored Prediction of Renal Death in IgA Nephropathy

Chazot Robin,[2] Perrine Jullien,[2] Blandine Laurent,[2] Miriana Dinic,[2] Damien Thibaudin,[2] Eric Alamartine,[1] Christopher R. Mariat,[2] Nicolas Maillard.[2] *[1]Chu St Etienne Hospital Nord, Saint Priest En Jarez Cedex, France; [2]CHU Saint Etienne, Saint Etienne, France*.

Background: The prognostic of IgA nephropathy (IgAN) is highly heterogeneous, ranging from isolated hematuria to End-Stage Renal Disease (ESRD). The Oxford classification has been developed and recently updated to stratify patients according to the risk of progression considering histological elementary lesions. From a clinical standpoint, each patient has a proper combination of Oxford classification lesions, but the knowledge about the distribution and the prognostic impact of such combinations is lacking. Our study describes the distribution of those combinations in our population and evaluate their particular association with renal death.

Methods: This retrospective, monocentric cohort study included all Caucasian patients with biopsy-proven IgAN since 1979. Renal biopsies were scored by one pathologist blinded to the clinical data and according to the Oxford classification. We analyzed the distribution and grouped the patients according to the combination of histological MESTC score components to assess their risk to progress to ESRD (cox model, non adjusted and adjusted on proteinuria, hypertension, eGFR).

Results: A total of 695 patients were retained for analysis (mean age and proteinuria respectively 38.6 years and 1.04 g/day). The distribution of combinations was heterogenous: Most frequent lesions were M0S0E0T0C0, S1 alone, combined S1 and T1 alone, as shown in Figure 1. M0S0E0T0 was set as the reference (Hazard Ratio (HR) for progression =1). The higher and significant unadjusted risk for progression was found for the association S1E1T1 (HR 38.14 [14.9;97.7]), S1T1 (HR 24.87 [12 ; 51.7]), S1E1C1 (HR 8.02[3.38;19.01]), M1S1E1 (HR 7.69[2.36;25.0]), S1E1 (HR 3.88 [1.22;12.39]) as shown in Figure 2. Isolated S1 (HR 1.35 [0.52;3.5]), isolated M1 (HR 1,43 [0,18;11,3]), were not significantly associated with renal death contrary to isolated T1 (HR 14.7 [4.39;43.5]) and isolated E1 (HR 5.34 [1.46;19.5]).

Conclusions: This combinatory approach of Oxford classification lesions allows to identifying the unbalanced histological combinations with better homogeneity in renal outcomes prediction. Isolated M1 and S1 lesions did not seem to associate with ESRD.

TH-PO1027

Genome-Wide Study Investigating Potential Loci Associated with Risk of ESRD in IgA Nephropathy Patients

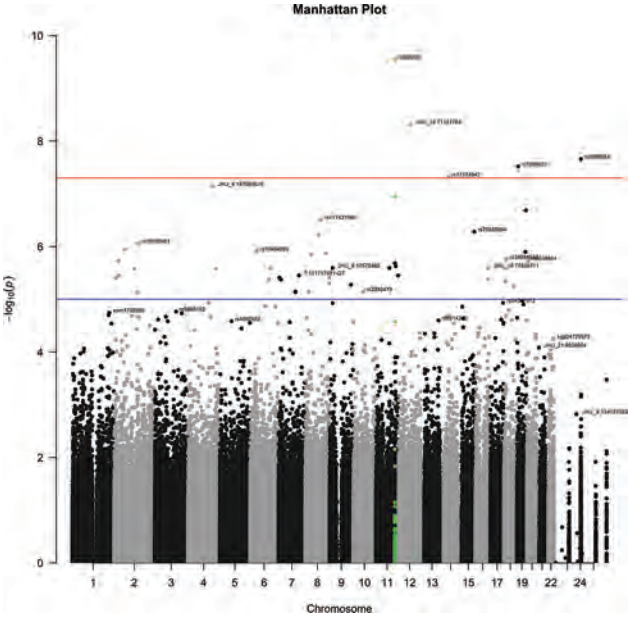
Sehoon Park,[1] Seung Hee Yang,[2] Krzysztof Kiryluk,[3] Dong Ki Kim,[1] Yon Su Kim,[4] Hajeong Lee.[4] *[1]Seoul National University Hospital, Jongno-gu, SEOUL, Republic of Korea; [2]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [3]Columbia University, New York, NY; [4]Seoul National University College of Medicine, Seoul, Republic of Korea*.

Background: End-stage renal disease (ESRD) is one of the most critical outcomes of IgA nephropathy (IgAN). Although genetic factor might have some effect on this outcome within IgAN patients, a genome-wise study regarding ESRD outcome was scarce, particularly in Korea which is known to have high incidence and worse prognosis of IgAN.

Methods: We performed genome-wide association and survival analyses including native kidney IgAN patients in Korea. Retrospectively collected 695 native IgAN patients were screened for inclusion. Genome-wide associations were calculated with logistic regression and cox regression analyses.

Results: After quality control, 691 patients and 603,128 single nucleotide polymorphisms (SNPs) were included in the analysis. Although an association analysis dealing ESRD as a binomial outcome did not show any significantly associated SNPs after Bonferroni correction, survival analysis including renal survival from birth revealed that following SNPs were significantly associated with risk of ESRD; rs655250, rs17574942, rs7259423, and rs5989654. When we applied less stringent threshold value, there was suspicious association of clusters of SNPs on chromosome 11, including rs655250 which showed the most significant p value, on gene coding NCAM1 (CD56). When time from IgAN diagnosis to ESRD was included as the survival duration, adjusted for age and sex at the time of IgAn diagnosis, following SNPs showed significant association with ESRD outcome; JHU_1.247982701, rs13095453, JHU_7.26585574, exm813062, rs2151745.

Conclusions: Potential gene loci identified in our analysis may be associated with risk of renal failure in IgAN patients. Further validation and expansion of our results may reveal association between genetic factors and IgAN prognosis.



TH-PO1028

Association of the CMIP Gene Single Nucleotide Polymorphism with Serum Lipids Parameter of IgA Nephropathy

Ling Pan, Yunhua Liao, Xiaohua Li, Manqiu Mo. *The First Affiliated Hospital of Guangxi Medical University, Nanning, China*.

Background: The effect of dyslipidemia on cardiovascular complications and renal progression in IgAN has been confirmed. The CMIP gene was recently found to be closely related to TC, LDL-C and HDL-C levels. The relationship between dyslipidemia of IgAN and CMIP gene polymorphism has not been reported so far.

Methods: Study subjects were selected in the First Affiliated Hospital of Guangxi Medical University from August 2010 to December 2017. TC, TG, HDL-C, LDL-C, ApoA1 and ApoB levels were tested. Blood samples were extracted for DNA, PCR amplification, electrophoresis imaging. PCR products were sent to measure genotypes. The genotypic and allelic frequencies were measured. We explored the relationship between CMIP gene SNPs and serum lipid levels, and analyzed the risk factors of dyslipidemia.

Results: The study included 543 patients, 51.7%were dyslipidemia. The genotype and allele frequency of *CMIP* rs16955379 were statistically different between the two groups ($P < 0.05$). TG, HDL, BP, tubular atrophy and interstitial fibrosis(TA/IF) were significantly different between *CMIP* rs16955379 C allele carriers and non-carriers. TC, BP, Scr, UA, urine protein, renal dysfunction, and TA/IF were significantly different between *CMIP* rs2925979 A allele carriers and non-carriers. TC level was associated with rs16955379

C allele carrier, hypertension, alcohol and UA. TG level was associated with renal dysfunction, rs16955379 C alleles carrier, alcohol, smoking, BMI, UA, and TA/IF. HDL was associated with rs16955379 C allele carrier, UA, renal dysfunction, and mesangial cell proliferation. LDL was associated with rs16955379 C allele carrier, hypertension, and UA($P < 0.05$, respectively). There was a linkage disequilibra(LD) between rs16955379 and rs2925979, and rs2925979G-rs16955379T was the most common haplotype. The haplotype frequencies of *CMIP* SNPs were significantly different between dyslipidemia and normal group ($P < 0.05$).

Conclusions: About half of IgAN patients had dyslipidemia. The genotypic and allelic frequencies of rs16955379 were significant different between dyslipidemia group and normal group. There were significant differences in several lipid levels between *CMIP* SNPs different allele carriers. There was a LD between rs292597 and rs16955379. The most common haplotype was rs2925979G-rs16955379T. The related haplotypes increased the risk of dyslipidemia in IgAN.

TH-PO1029

Pathologic Tonsillar Findings Similar to Immunoglobulin A Nephropathy in Patients with Frequently Relapsing Nephrotic Syndrome

Keisuke Sugimoto,[1] Kohei Miyazaki,[2] Takuji Enya,[5] Tomoki Miyazawa,[3] Mitsuru Okada,[1] Tsukasa Takemura.[4] *[1]Kindai University Faculty of Medicine, Osaka, Japan; [2]Department of Pediatrics, Kinki University School of medicine, Osaka, Japan; [3]kindai University Faculty of Medicine, Izumi, Japan; [4]Pediatrics, Kushimoto Municipality Hospital, Higashimurogun, Japan; [5]kinki university school of medicine, Osakasayama, Japan.*

Background: Several studies have reported that regulatory T (Treg) cells are of critical importance for maintenance of tolerance in not only immunoglobulin A nephropathy (IgAN) but also nephrotic syndrome (NS). The pathologic tonsillar findings in IgAN differ significantly from those in chronic tonsillitis. However, the pathologic tonsillar features in patients with NS are unclear.

Methods: Immunohistochemical staining for tonsillar CD4, CD8, HLA-DR and cytokeratin was performed in 8 patients with frequently relapsing nephrotic syndrome (FRNS) who underwent tonsillectomy for chronic tonsillitis,. The patients were in complete remission, and were followed on low-dose prednisolone for FRNS.

Results: In 6 of 8 patients, T-cell nodules were enlarged by infiltration of HLA-DR-positive cells. Infiltration with both CD4-positive and CD8-positive cells was prominent in interfollicular areas. Cytokeratin staining showed that the layer of crypt epithelium was replaced by squamous epithelium.

Conclusions: The efficacy of tonsillectomy for IgAN is thought to be due to regulation of tolerance abnormalities. Replacement from the layer of crypt epithelium implies involution of lymphoepithelial symbiosis. The distribution of CD4 and CD8 is characteristic in the tonsils of those with IgAN. These pathologic findings in FRNS patients suggest the existence of a similar tolerance abnormality in the tonsils of those with NS. Our results may help to clarify intolerance in NS. Further studies are necessary to clarify the clinical efficacy of tonsillectomy for NS patients.

TH-PO1030

The Predictive Value of Crescents in Adult Henoch-Schölein Purpura Nephritis

Fei Han. *First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China.*

Background: To study the predictive value of crescents in adult Henoch-Schölein purpura nephritis(HSPN).

Methods: We retrospectively analyzed 275 adult patients with biopsy proven HSPN in the First Affiliated Hospital of Zhejiang University, and divided the patients into 4 groups: 99 patients in none crescent croup(NC), 34 patients in segmental crescents group(SC), 109 patients with circumferential crescents ≤25% were categorized into group C1, and 33 patients with crescents >25% were categorized into group C2. Data including serum creatinine(Scr), evaluated glomerular filtration rate(eGFR), 24h urine protein and mean arterial pressure were compared, and primary outcome was defined as ≥50% reduction of eGFR from baseline in 2 years, doubling of serum creatinine (Scr), or end stage renal disease (ESRD). ESRD was defined by reaching an eGFR of <15ml/min/1.72m^2 or requiring maintaining renal replacement therapy for more than 3 months. Univariate analysis and multivariate analysis were used to compare the outcome.

Results: There were no significant difference in gender or age($p>0.05$). Differences in Scr($p=0.002$), eGFR($p=0.007$), 24h urine protein ($p<0.001$)were found significant. The median Scr level of NC, C1,C2, SC group were 59.0(51.0, 75.0)μmol/L,66.0(52.5, 77.0)μmol/L, 72.0 (55.0, 94.0) μmol/L, 68.0(56.5,118.0) μmol/L, respectively. Further analysis showed that patients with crescents (including segmental crescents) have a higher Scr level than those without crescents. The urine protein level of each group were 0.75(0.42,1.53),1.17(0.63,2.02)g, 1.60(0.86,3.00)g, 2.48(1.12,4.63) g, respectively. The median follow-up duration was 56(33,85) months, and 18 patients reached renal endpoint. Kaplan Meier analysis suggested that the renal outcomes were significantly different($p=0.002$), the renal survival rates of NC, C1, C2, SC group were 96%, 88.1%, 78.8%, 100%, respectively. And Cox model suggested that a crescent ratio of more than 25% is an independent predictor of poor renal outcome.

Conclusions: A crescent ratio of more than 25% is an independent predictor of poor renal outcome in adult patients with Henoch-Schölein purpura nephritis.

TH-PO1031

Crescentic Lesions in IgA Nephropathy: Impact on Outcome

Sofia Correia,[1] Filipa S. Silva,[4] Sofia Santos,[1] Ana Castro,[1] Joana M. Tavares,[1] Andreia Campos,[1] Carla L. Moreira,[1] Jorge Malheiro,[2] Josefina Lascasas.[3] *[1]Centro Hospitalar do Porto, Porto, Portugal; [2]Nephrology Department - Centro Hospitalar Porto, Porto, Portugal; [3]CHP- Hospital Santo Antonio, Porto, Portugal; [4]Centro Hospitalar e Universitário do Porto, Porto, Portugal.*

Background: Recently, IgAN Classification Working Group has published an update to the Oxford Classification that recommends changing the MEST to a MEST-C score, defending that the fraction of crescents are associated with outcome. Nevertheless, the role of crescentic lesions is still controversial and needs better characterization. The aim was to study the impact of the crescents in the outcome in our population.

Methods: A total of 88patients with biopsy-proven IgAN between January'07 and December'17 were re-assessed using the MEST-C, in this retrospective analysis. The composite outcome was defined as 50%decline in eGFR or ESRD. We compare two groups:with crescents(N=24,27%)and with no crescents.

Results: The baseline characteristics were similar between the groups. The patients with C had more proteinuria and hypoalbuminemia at presentation but had similar eGFR. Endocapillary hypercellularity and segmental glomerulosclerosis lesions were higher in patients with crescents($P<0.02$). During a mean follow-up of 55.4months, 50% of the patients with crescents reached the composite outcome compared with27%of patients without($P<0.05$). Survival curves are presented. ESRD were more likely in the first group($P<0.02$) and50% decline in eGFR was more frequent but was not statistically significant. The independent predictors of composite outcome were eGFR at presentation, proteinuria, presence of crescents and moderate to severe interstitial fibrosis and tubular atrophy. In a multivariable Cox analysis, crescents(HR3.33, CI95%1.24-8.90, $p<0.02$), eGFR(HR0.16,$p<0.001$) and no immunosuppressive therapy(IST) (HR3.23,$p<0.05$)were associated with an increased risk of developing the composite outcome. IST was based on corticosteroid therapy, in 4cases prednisolone and cyclophosphamide were administrated. The survival at 96months in patients without IST was71%if they had no crescents and 42% if had any crescent($P=0.022$). The survival among those that were treated with IST was 80% if had no crescents (vs51%,$P=0.124$).

Conclusions: Crescents, along with higher eGFR at presentation, were an independent prognostic factor in our population. The main histologic alterations associated with the outcome were severe interstitial fibrosis, tubular atrophy and crescents. Our study suggests that crescent have value in predicting renal outcomes in our population with IgAN.

TH-PO1032

Urinary Soluble CD163 Level Predicts Renal Prognosis of IgA Nephropathy

Jiong Tian. *Kidney Disease Center, the First Affiliated Hospital, College of Medicine, Zhejiang University, HANGZHOU, China.*

Background: In IgA nephropathy (IgAN), crescent percentage was added to the make the new Oxford MESTC scores system recently. Macrophage is the most important inflammatory cell type in crescent and CD163 is a specific marker for M2c macrophage. Its soluble form (sCD163) is present in the bio-fluid in inflammation.sCD163 may serve as a biomarker for macrophage activation but its role in renal prognosis is unknown.

Methods: 115 patients of IgAN were studied. Clinical parameters including blood pressure, urinary protein, creatinine and eGFR at renal biopsy and the last follow-up were recorded. The renal end point was defined as ESRD or the eGFR declined >50% or serum creatinine doubled during the follow up. The serum and urinary level of sCD163 were determined by ELISA.

Results: The cohort were divided into three groups according to the crescent percentage. Urinary sCD163 in group C2 (crescents in>25% of glomeruli) were significantly elevated compared to that in group C1 (crescents in <25% of glomeruli) and group C0 (no crescent). Urinary sCD163 level was negatively correlated with eGFR and positively correlated with serum creatinean and proteinuria. Urinary sCD163 level was associated with M,E,S and C scores. There was a significantly positive correlation between urine urinary sCD163 level and the percentage of crescents. Renal end points developed in 12 patients during the 42.6±7.4 months of follow-up. Most importantly, our results showed that increased urinary sCD163 level was significantly associated with poor renal outcome.

Conclusions: The level of urinary sCD163 was closely related to clinical and pathological features in IgAN and it can serve as a non-invasive biomarker to reflect the severity of IgAN. An increased urinary sCD163 level was related with poor renal outcome in patients with IgA nephropathy.

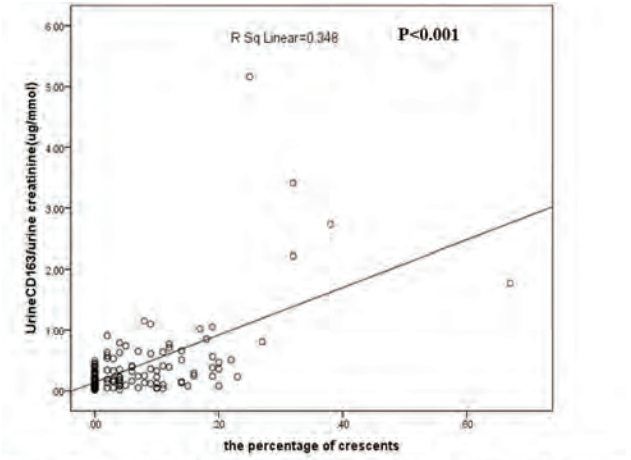

Figure1 The correlation between urinary sCD163 and the percentage of crescents

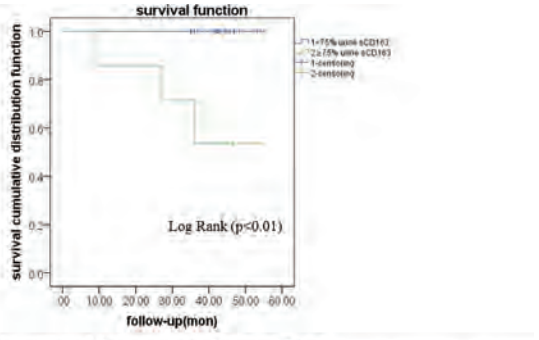

Figure 2 The survival function of urinary sCD163

The 75% urinary sCD163 =0.69(ug/mmol); A low concentration corresponded to those cases were below the 75% of all cases, and a high concentration corresponded to those cases were above the 75% value.

TH-PO1033

Prognostic Value of Mesangial C3 and C4d Deposition in IgA Nephropathy

Ki Heon Nam, Yooju Nam, Seon yeong Lee, Joohwan Kim, Tae-Hyun Yoo, Dae-Suk Han, Seung Hyeok Han. *Yonsei University College of Medicine, Seoul, Republic of Korea*.

Background: Activation of complement system can play an important role in the pathogenesis of IgA nephropathy (IgAN). C3 and C4d can be representative markers of alternative and lectin pathway, respectively. We studied whether mesangial C3 or C4d deposits can predict adverse renal outcome better than conventional risk factors and determined relative contribution of each pathway to disease progression.

Methods: A total of 265 patients with biopsy-proven IgAN between 2000 and 2013 were enrolled. The degree of C3 was evaluated by immunoflurorescence staining and graded as 0, 1+, 2+, and 3+. We also determined C4d deposition by immunohistochemistry. The study endpoint was a composite of a ≥ 30% decline in estimated glomerular filtration rate or the onset of end-stage renal disease.

Results: During a mean follow-up of 6.8 years, 82 (30.9%) patients reached the composite end point. In the fully adjusted multivariable model, risk of reaching renal outcome was significantly higher in patients with mesangial C3 deposition of 2+ to 3+ (HR, 1.89; 95% CI, 1.11-3.20; P = 0.019) than in those with the deposition of 0 to 1+. In addition, patients with positive C4d deposition had a 1.9-fold increased risk of adverse outcome compared with those without deposition (HR, 1.90; 95% CI, 1.07-3.40; P = 0.03). The risk was highest in patients with both C3 and C4d deposition (HR, 2.61; 95% CI, 1.08-6.27; P = 0.03). Adding mesangial C3 deposition to risk prediction model significantly increased the integrated discrimination improvement and the net reclassification improvement, whereas C4d-added model did not. However, adding both mesangial C3 and C4d deposition together significantly improved risk prediction over C3-added model.

Conclusions: This study showed that mesangial C3 and C4d deposition were independent risk factors for renal progression. In addition, predictability of C3 was superior to that of C4d. C4d may play an additive role in increasing predictive power.

TH-PO1034

The Role of Expression of Toll-Like Receptors 4 and 9 in Stratification of Severity of IgA Nephropathy

Hana Ciferska,[1] Eva Honsova,[2] Zdenka Hruskova,[3] Michaela Neprasova,[9] Miloslav Suchanek,[4] Tomas Zima,[5] Rosanna Coppo,[10] Vladimir Tesar,[6] Jan Novak,[7] Dita Maixnerova.[8] *[1]Institute of Rheumatology, Praha, Czechia; [2]IKEM, Prague, Czechia; [3]Department of Nephrology, General University Hospital and First Faculty of Medicine, Charles University, Prague 2, Czechia; [4]University of Chemical Technology Prague, Prague, Czechia; [5]Firts Faculty of Medicine, Charles University, Prague 2, Czechia; [6]General University Hospital in Prague, Prague, Czechia; [7]University of Alabama at Birmingham, Birmingham, AL; [8]Dept. of Nephrology, Prague, Prague, Czechia; [9]General Teaching Hospital in Prague, Dobris, Czechia; [10]Fondazione Ricerca Molinette, Regina Margherita Hospital, Turin, Italy*.

Background: The onset of IgA nephropathy (IgAN), characterized by glomerular deposition of IgA immune complexes, is often associated with synpharyngitic hematuria. Innate immune responses mediated by toll-like receptors (TLR) may play a role in IgAN onset and/or progression. Here, we assessed the expression of TLR 4, 7, 8, and 9 in renal-biopsy specimens from patients with IgAN, with different degree of proteinuria and eGFR, compared with normal kidney specimens from cadavers and a disease controls (ANCA vasculitis).

Methods: Expression of TLR 4, 7, 8, and 9 was assessed using immunohistochemical staining of paraffin-embedded renal-biopsy tissue specimens with specific antibodies and evaluated semiquantitatively by light microscopy. Linear discriminant analysis (LDA) was used to test whether intrarenal staining of TLR 4, 7, 8, and 9 distinguished patients with IgAN (n=34) from controls. Moreover, patient with IgAN represented four subgroups based on eGFR and proteinuria. All biopsies of patients with IgAN were scored according to the Oxford Classification.

Results: LDA showed that TLR 4, 7, 8, and 9 staining was more intense in specimens from IgAN patients than in normal kidney tissues. LDA also distinguished four subgroups of patients with IgAN based on MEST scoring. The intensity of intrarenal staining of TLRs discriminated four groups of IgAN divided according severity of renal impairment and proteinuria.

Conclusions: Intrarenal staining of TLRs together with clinical parameters (serum creatinine, eGFR, and proteinuria) analyzed by LDA may be helpful in assessment of disease prognosis. **References:** Supported by the project (Ministry of Health, Czech Republic) for conceptual development of research organization 00023728 (Institute of Rheumatology) and by PROGRES Q25/LF1. TH-PO1035

Clinical and Pathological Characteristics of Patients with HBV-Associated IgA Nephropathy: A Case Series

Bogdan Obrisca, Roxana A. Jurubita, Bogdan M. Sorohan, Oana C. Ion, Andreea Andronesi, Gener Ismail. *Fundeni Clinical Institute, Bucharest, Romania*.

Background: A higher prevalence of hepatitis B surface antigen (HBsAg) is reported in patients with IgA nephropathy (IgAN) from endemic areas. However, little is known about the clinicopathological characteristics and outcome of these patients. We sought to characterize a cohort of patients with IgAN and HBsAg (HBsAg-IgAN).

Methods: Medical records of 110 patients with biopsy-proven IgAN, between 1999 and 2017, were retrospectively reviewed. Of these, 10 patients had HBsAg. Clinical and pathological characteristics (MEST-C score) at baseline, and outcomes were compared between HbsAg positive and negative IgAN patients.

Results: 10 patients (9.1%) with HBsAg-IgAN (mean age: 47 ± 20 years) were identified in our cohort. Mean eGFR, hematuria, and 24-hour proteinuria were 47 ± 20 ml/min, 50 ± 60 RBC/µl and 2.3 ± 2.8 g/day, respectively. The percentage of patients that showed M1, E1, S1, T1 and C1 were 80%, 10%, 70%, 50% and 20%, respectively. By comparison to patients with HBsAg negative IgAN, there was a tendency towards a worse renal function at baseline with more severe features on kidney biopsy (fewer patients showing E lesions and more with crescents, segmental sclerosis and interstitial fibrosis). 30% of patients had a halving of eGFR (within 27 ± 20 months), versus 14% (within 45 ± 42 months) of patients with HBsAg negative IgAN. All patients received antiviral therapy, 40% having undetectable viral load at biopsy, 40% having a HBV-DNA below 1000 IU/l (mean 264 ± 357 IU/l) and 20% having over 1000 IU/l (mean 11000 ± 8680 IU/l). 40% of patients received additional immunosuppressive treatment (IS). There were no significant differences in terms of renal survival between those with high versus low viral replication and between those receiving antiviral therapy alone and combined antiviral/IS therapy. Additionally, patients receiving combined antiviral/IS therapy didn't show any sign of HBV reactivation.

Conclusions: HBV-associated IgAN patients had a worse renal function at baseline, with more severe activity and chronicity features, both clinically and pathologically, as compared to HBsAg-negative IgAN patients. These characteristics determined a more rapid decline of renal function in our cohort of HBV-associated IgAN.

TH-PO1036

Using the Oxford Classification in Assessing the Therapeutic Effects in IgA Nephropathy: A Secondary Analysis from a Randomized Clinical Trial

Shuwei Duan,[1] Guangyan Cai,[2] Xiangmei Chen.[3] *[1]Department of Nephrology, State Key Laboratory of Kidney Disease, Beijing, China; [2]Chinese PLA Genaral Hospital, Beijing, China; [3]Chinese PLA General Hospital, Beijing, China.*

Background: The Oxford Classification established a consensus on pathologic features that could predict the risks of progression of IgA nephropathy(IgAN). Clinically, histopathology is essential for both evaluating the severity of the lesions and guiding therapeutic strategies for IgAN. It remains a challenge whether or not Oxford Classification can guide therapeutic strategies. The aim of the analysis was to evaluate if the oxford classification can predict the therapeutic effects for patients receiving telmisartan and/or clopidogrel with/without leflunomide.

Methods: The multicentre, prospective, double-blind, double-dummy RCT was conducted between July 2010 and June 2012 in Beijing, China. The results were published in Chinese Medical Journal in 2016. There were 162 cases, who were diagnosed in Chinese PLA General hospital, included in this secondary analysis. The complete or partial remission was defined as 24 hour proteinuria <0.3g or ≥30% reduction and stable kidney function. Stable kidney function was defined as increase in serum creatinine less than 26.4umol/L at week 24. The other was defined as ineffectiveness. The logistical regression was used to analyse the relationship between the character of Oxford classification and the effect.

Results: Multiple logistic regression analysis showed that both of 24 hour proteinuria≥1g (Odds Ratio(OR)=2.13, 95%CI 1.04-4.36) and taking leflunomide(OR=5.70, 95%CI 2.66-12.24) were the advantage factors. Only tubular atrophy/interstitial fibrosis >50% were the risk factor(OR=18%, 95%CI 8%-40%). Especially, we found that there were interaction between mesangial hypercellularity >0.5 and leflunomide.

Conclusions: This secondary analysis supports the oxford classification for IgAN has capacity to predict the therapeutic effects for patients receiving telmisartan with leflunomide. Mesangial hypercellularity >0.5 maybe the potential character of taking leflunomide.

TH-PO1037

Clinical Impact of Endocapillary Proliferation with Modified Cutoff Point in IgA Nephropathy Patients

Ahmad B. Kaihan,[2,3] Yoshinari Yasuda,[4] Takahiro Imaizumi,[4] Manabu Hishida,[1] Naotake Tsuboi,[5] Shoichi Maruyama.[5] *[1]Nagoya University, Nagoya city, Japan; [2]Department of Nephrology/CKD, Nagoya University Graduate School of Medicine, Nagoya, Japan; [3]Internal medicine, Balkh university/Faculty of medicine, Mazar-e-Sharif, Afghanistan; [4]Nagoya University Graduate School of Medicine, Nagoya, Aichi-ken, Japan, Nagoya, Japan; [5]Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Predictive values of mesangial proliferation (M), endocapillary proliferation (E), segmental glomerulosclerosis (S), and crescents (C) among 19-validation studies of Oxford Classification were discrepant, in particular among Asian IgA nephropathy (IgAN) patients. These validation studies indicate that cutoff points of MESC score in the Oxford Classification may not be generalizable. Thus, we aimed to improve clinical value of MESC scores by modifying cutoff points.

Methods: A total of 104 IgAN diagnosed from 2001 to 2012 by renal biopsy, and retrospectively evaluated at Nagoya University Hospital. Cutoff point for modified (M′E′S′C′) was determined by receiver operating characteristic curve in association with renal outcome in the training cohort. Clinical value of the Oxford MESTC vs M′E′S′C′ cutoff points were analyzed by Kaplan-Meier and Cox regression for renal outcome in the validation and all cohort.

Results: Of 104 participants 12.5% of them reached renal outcome over 6.25 [4.16-9.61] years of follow-up. The modified cutoffs were defined ≥40%, ≥10%, ≥20%, and ≥5% in glomeruli for M′E′S′C′ respectively. In univariate analysis, E′, S′, and T were significantly associated with renal outcome. Whereas, the Oxford MESC, M′, and C′ in the training and validation cohort demonstrated no significant association with renal outcome. By multivariate analysis in the presence of eGFR, only E′ was a significant predictive factor for renal outcome.

Conclusions: The E′ with modified cutoff point of 10% significantly improved predictive value for renal outcome in IgAN. Clinical value of modified cutoff points for M′E′S′C′ scores should be validated with various cohort studies in different regions.

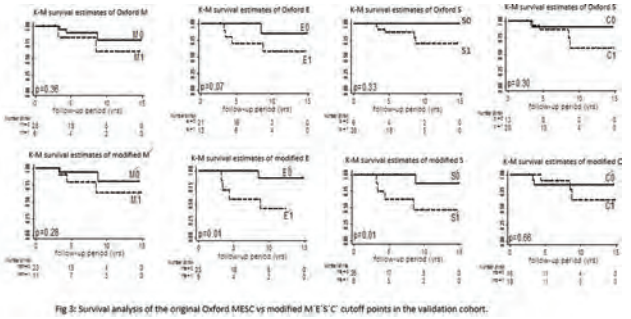

Fig.3: Survival analysis of the original Oxford MESC vs modified M′E′S′C′ cutoff points in the validation cohort.

Steroid Responsiveness on Remission of Urinary Abnormalities According to the Pathological Lesions in IgA nephropathy: A Japanese Multicenter Prospective Cohort Study

Ritsuko Katafuchi,[1] Tetsuya Kawamura,[2] Akinori Hashiguchi,[3] Satoshi Hisano,[4] Akira Shimizu,[5] Kensuke Joh.[6] The IgA nephropathy Study Group in Japan *[1]National Fukuoka-Higashi Medical Center, Koga, Fukuoka, Japan; [2]Jikei University School of Medicine, Tokyo, Japan; [3]Keio University School of Medicine, Tokyo, Japan; [4]University of Occupational and Environment Health, Kitakyushu, Japan; [5]Nippion Medical School, Tokyo, Japan; [6]Tohoku University Graduate School of Medicine, Sendai-city, Japan.*

Background: The effectiveness of steroids on clinical course and its indication in IgA nephropathy (IgAN) are controversial.

Methods: 797 patients with IgAN were included. Treatment groups were defined by steroid (ST) and tonsillectomy (TX): group 1; ST-TX-, groups 2; TX only, group 3; ST only, group 4; TX+ST+. Acute lesions (AL) such as cellular or fibrocellular crescent, or tuft necrosis, chronic lesions (CL) such as fibrous crescent, segmental or global glomerulosclerosis, Japanese histological grade (HG) and Oxford classification (MEST-C) were evaluated. The endpoint was the remission of urinary abnormality within 24 months. The remission of proteinuria (UPR) was defined less than 0.3/day. The remission of hematuria (OBR) was defined less than 5 RBC/HPF. Clinical remission (CLR) was defined UPR and OBR. The effect of treatment groups, and pathological parameters on UPR, OBR, and CLR was analyzed by logistic model.

Results: The mean age was 38, the median of UP was 0.58, mean eGFR was 76.9. The median AL, CL was 3.8, and 20%. AL and CL were tertile categorized with 0 and 7.7 % for AL and 13.3 and 30.8% for CL as cutting values. HG1 to 4 was 61, 26, 10, and 2.8 %. M1, E1, S1, T1-2 and C1-2 were 24, 36, 81, 27, 62 %. The treatment group 1 to 4 was 35, 5, 25 and 40 %. Group 3 and 4 showed significant positive effect on UPR, OBR and CLR with reference (ref) group 1. The effect of group 4 with ref group 3 was significant on OBR. AL3 showed significant positive effect with ref AL1 on UPR and CLR. CL2 and CL3 showed significant negative effect with ref CL1 on UPR. CL3 showed significant negative effect on CLR. HG2 and HG3-4 showed significant negative effect on UPR with ref HG1. HG3-4 showed significant negative effect on CLR. E1 showed significant positive effect on UPR. M1, S1, T1-2 showed significant negative effect on UPR with ref M0, S0, and T0. On CLR, C1-2 showed significant positive effect with ref C0, and T12 showed significant negative effect with ref T0.

Conclusions: Steroid was significantly effective on proteinuria and hematuria. Higher percentage of acute lesions showed significant effect of steroid on proteinuria. The additional effect of tonsillectomy to steroid was found on hematuria.

Primary Efficacy Analyses from a Phase 2 Trial of the Safety and Efficacy of Bardoxolone Methyl in Patients with IgA Nephropathy

Geoffrey A. Block,[1] Gerald B. Appel,[2] Ahmed M. Awad,[9] Judith A. Betts,[10] Melanie Chin,[3] Colin J. Meyer,[3] Pablo E. Pergola,[4] Anjay Rastogi,[5] Dana Rizk,[6] Kevin Schroeder,[7] Arnold L. Silva.[8] *[1]Colorado Kidney Care, Denver, CO; [2]Columbia University College of Physicians and Surgeons, Scarsdale, NY; [3]Reata Pharmaceuticals, Irving, TX; [4]Renal Associates, PA, San Antonio, TX; [5]Division of Nephrology, University of California at Los Angeles Medical Center, Los Angeles, CA; [6]University of Alabama, Birmingham, AL; [7]Ohio Kidney Consultants, Columbus, OH; [8]Boise Kidney & Hypertension Institute, Meridian, ID; [9]Clinical Research Consultants, LLC, Kansas City, MO; [10]Austin Kidney Associates, Austin, TX.*

Background: Bardoxolone methyl (BARD) has been shown to significantly increase eGFR in patients with CKD and type 2 diabetes and Alport syndrome suggesting that the anti-inflammatory and anti-fibrotic effects of BARD may target the common pathways contributing to GFR loss in multiple forms of CKD. As a result, a Phase 2 trial (PHOENIX, NCT03366337) was initiated to test the hypothesis that BARD will improve kidney function in patients with IgA nephropathy (IgAN) as well as other forms of CKD.

Methods: The Phase 2 open-label, multicenter study enrolled a cohort of 26 patients with biopsy-confirmed IgAN. Eligible patients were 18 to 65 years of age with eGFR values between 30 to 90 mL/min/1.73 m^2 and urine albumin to creatinine ratio (UACR) ≤ 2500 mg/g. Patients received BARD at an initial dose of 5 mg, dose-escalated to 20 mg (for patients with baseline UACR ≤ 300 mg/g) or to 30 mg (for patients with baseline UACR > 300 mg/g) and were treated for 12 weeks. The primary efficacy endpoint was the change from baseline eGFR after 12 weeks of treatment. Interim results for the cohort enrolling patients with IgAN are described herein.

Results: At data cutoff on May 15th, 2018, 5/26 (19%) of the enrolled patients with IgAN had completed the study. From a mean (± SE) baseline eGFR of 46.2 ± 2.5 mL/min/1.73 m^2, BARD treatment resulted in a significant increase from baseline in eGFR of 7.8 ± 1.8 mL/min/1.73 m^2 ($p<0.0001$) at Week 12. The improvements were consistent, and 4 of the 5 (80%) patients had increases from baseline in eGFR > 5 mL/min/1.73 m^2 at Week 12. No patients have discontinued from the study and no serious AEs considered related to BARD have been reported in this ongoing trial.

Conclusions: BARD was generally well tolerated and significantly increased eGFR in patients with IgAN. In patients with other forms of CKD, short term eGFR increases with BARD are predictive of durable eGFR improvements and additional studies are needed to study the longer-term effects of BARD on eGFR in IgAN.

Corticosteroid Therapy in IgA Nephropathy

Soumita Bagchi, Adarsh Barwad, Raj K. Yadav, Sandeep Mahajan, Dipankar M. Bhowmik, Sanjay K. Agarwal. *All India Institute of Medical Sciences, New Delhi, India.*

Background: Corticosteroid therapy is used in patients with IgA nephropathy(IgAN) with persistent proteinuria, but there is a lack of cosensus about its overall benefits. There is a paucity of data about steroid use in Indian patients who have an aggressive clinical course. This study aims to look at the response to steroid therapy in Indian patients with IgAN.

Methods: Patients with biopsy proven primary IgAN treated with oral corticosteroids from 2012 to 2017 with minimum 12 months follow up were included in the study. MEST-C score was assigned as per the Oxford classification to all biopsies. All patients received oral prednisolone 1mg/Kg/day for 8-12weeks followed by gradual tapering over 6-12 months. Complete remission(CR) was defined as 24-hour urine protein of <500 mg/d with stable eGFR and partial remission(PR) was defined as atleast 50% reduction in proteinuria with stable eGFR with a decline of proteinuria to <3.5g/day.

Results: Of the 94 patients included in study, 64.9% were males with mean age of 30.4±11.9 years. Mean proteinuria was 5.2±2.6 g/day and 53.2% had gross or microscopic hematuria. Mean serum creatinine was 1.4±0.6 mg/dl and mean eGFR was 75. 4± 48.1 ml/min/1.73m^2. 77.7% patients had received ACEi/ARB before starting steroid therapy. The distribution of MEST lesions were: M1-70(74.5%), E1-7(7.5%), S1-56(59.6%), T1-26(27.7%) lesions and T2-7(7.5%). 9(9.6%) patients had crescents[C1-7(7.5%), C2-2(2.1%)]. 42(44.7%) patients responded to steroid therapy (CR-22, PR-20), of whom 7 patients had one steroid responsive relapse during the follow up and three were steroid dependent. On univariate analysis,S1 lesions on biopsy (p=0.011) and eGFR<30ml/min/1.73m^2(p=0.056) predicted steroid resistance. Serious adverse effects were seen in 16 (17.0%) patients mainly comprising of infections (13) with 4 patients developing Tuberculosis. One patient died due to pulmonary nocardiosis.

Conclusions: Steroid therapy reduces proteinuria in 44.7% patients with IgAN. However it is associated with serious infectious complications. The presence of S1 lesion and renal dysfunction at baseline predict poor response.

The Global, Regional, and National State of CKD Epidemiology from 1990 to 2016: An analysis of the Global Burden of Disease Study

Yan Xie,[1] Benjamin C. Bowe,[2] Hong Xian,[4] Yan Yan,[3] Tingting Li,[5] Geetha S. Maddukuri,[1] Cheng-You Tsai,[4] Tasheia A. Floyd,[1] Ziyad Al-Aly.[1] *[1]VA Saint Louis Health Care System, Saint Louis, MO; [2]Research and Development Service, Veterans Affairs St Louis Health Care System, St. Louis, MO; [3]Washington University Medical School, Saint Louis, MO; [4]Saint Louis University College for Public Health & Social Justice, St. Louis, MO; [5]Washington University in St. Louis, Saint Louis, MO.*

Background: The last quarter century witnessed significant population growth, aging, and major changes in epidemiologic trends which may have shaped the state of chronic kidney disease (CKD) epidemiology. The GBD study provides a detailed epidemiologic assessment of 333 diseases and injuries and 84 risk factors by age and sex on a global scale and for 195 countries and territories.

Methods: Data collected from the GBD study will be used to describe the change in burden of CKD from 1990 to 2016. In this work, we used the Global Burden of Disease (GBD) study methodologies to describe the change in burden of CKD including decomposition analysis to understand factors that drove change and frontier analysis that evaluate the relationship between burden of CKD and socio-demographic development.

Results: Globally, incidence of CKD increased by 88.76%, prevalence increased by 86.95%, death due to CKD increased by 98.02%, and DALYs increased by 62.21%. Measures of burden varied substantially by level of development and by geography. Decomposition analyses showed that the increase in CKD DALYs was driven by population growth and aging; globally and in most GBD regions, age-standardized DALYs rates decreased. More of the CKD burden (62.96%) was in low and lower-middle-income countries; there was an inverse relationship between age-standardized CKD DALYs rate and healthcare access and quality (r=-0.52). Frontier analyses showed significant opportunities for improvement at all levels of the development spectrum.

Conclusions: Our results demonstrate that the global toll of CKD is significant, rising, and unevenly distributed; it is primarily driven by demographic expansion and in some regions significant tide of diabetes epidemic. Opportunities exist to reduce CKD burden at all levels of development.

Generalizability of SPRINT-CKD Cohort to CKD Patients Referred to Renal Clinics

Roberto Minutolo, Luca De Nicola. *Nephrology, University of Campania, Naples, Italy.*

Background: It is unknown whether the SPRINT-CKD sub-cohort is representative of CKD patients under nephrology care. We compared risk profile and outcomes of SPRINT-CKD versus a pooled cohort of four prospective studies enrolling consecutive patients with CKD stage I-V under nephrology care from >6 months in 40 Italian outpatient renal clinics.

Methods: In referred cohorts, we implemented the same inclusion/exclusion criteria adopted in SPRINT and the same endpoints: (1) a composite of myocardial infarction, acute coronary syndrome, stroke, heart failure and CV death (2) all-cause mortality and (3) end-stage renal disease (ESRD) as a composite of chronic dialysis, transplantation or 50% eGFR decline. Referred CKD patients were compared with those in SPRINT-CKD randomized to standard BP arm because management in this group is comparable to that performed in clinical practice where SBP target <140 mmHg is usually pursued. To compare outcomes, we only considered for analysis the events occurring no later than 4.8 years after enrolment, i.e. the maximum follow up available in SPRINT.

Results: From the initial pooled cohorts (n=3225), we deleted 338 duplicate patients, 27 patients without data on SPRINT selection criteria and 13 subjects lost to follow-up. Out of the evaluable 2847 patients, only 20.1% (n=571) of the patients of the referred cohorts could have been potentially eligible for SPRINT trial. These patients had a worse risk profile at baseline (Table). At a median follow-up of 4.0 years (IQR 2.8-4.8), we registered 85 CV events (50 fatal), 78 all-cause death with annual incidence rates higher than those observed in the SPRINT standard group (Table).

Conclusions: In conclusion, we suggest that the SPRINT-CKD cohort is poorly representative of "real-world" CKD population. Ad hoc trials are needed in referred CKD population.

	SPRINT Standard group (n=1316)	Referred CKD cohort (n=571)
Age (years)	71.9±9.5	72.1±9.4
Women (%)	39.6	42.2
Body mass index (kg/m^2)	29.5±5.8	27.4±4.8
Current smoker (%)	8.1	11.2
Clinical CVD (%)	19.5	25.7
Framingham risk score (%)	27.2±24.7	31.9±14.6
Framingham risk score >15% (%)	78.2	87.5
Systolic/Diastolic BP (mmHg)	139±16/75±12	142±10/80±10
eGFR$_{MDRD}$ (mL/min/1.73m^2)	47.9±9.5	38.1±10.6
Proteinuria (mg/day)	NA	190 [70-430]
Urinary ACR (mg/g)	14 [6-44]	NA
Antihypertensive medications (n)	2.11±1.01	2.14±1.00
Statin use (%)	53.4	29.2
Aspirin use (%)	55.5	21.4
Incidence rate of adverse events		
CV outcome (%/year)	3.19	4.13
All cause death (%/year)	2.21	3.64
ESRD (%/year)	0.41	2.80

Demographics and clinical characteristics at baseline, and incidence rates of endpoints in the two groups

TH-PO1043

Explaining Racial Inequality in Albuminuria Through Multiple Mediators

Marcelo Lopes,[1] Hal Morgenstern,[1] Jennifer L. Bragg-Gresham,[1] Deidra C. Crews,[2] Neil R. Powe,[3] Nilka Rios Burrows,[4] Rajiv Saran.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Johns Hopkins University School of Medicine, Baltimore, MD; [3]Priscilla Chan and Mark Zuckerberg San Francisco Gen Hosp & UCSF, San Francisco, CA; [4]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: Previous studies have shown that blacks have a higher prevalence of albuminuria than whites and that certain risk factors may account for that racial inequality. No research, however, has assessed the role of multiple risk factors collectively as mediators of the race effect.

Methods: Using cross-sectional data from the 2007-2010 National Health And Nutrition Examination Surveys for 6700 non-Hispanic black and white adults, ages 20+, we applied flexible mediation analysis (medflex, R package) to decompose the total effect of black race on albuminuria prevalence (albumin/creatinine ratio ≥30 mg/g) into direct and indirect (mediated) effects for combinations of 4 potential mediators: diabetes; hypertension; obesity (body mass index ≥30 kg/m^2), and low vitamin D level (25[OH]D3 <50 nmol/L). For each set of mediators, we estimated odds ratios (OR; 95% CI) for the direct, indirect and total effects and the percentage of the total effect that was mediated; ORs were adjusted for age, sex and non-mediating confounders.

Results: The weighted mean albuminuria level was 32 mg/g in blacks and 23 mg/g in whites; the adjusted OR for the total effect of black race on albuminuria was 1.61 (1.23, 2.11). The % mediated by each risk factor treated separately was 50% for low vitamin D, 44% for diabetes, 27% for hypertension, and 12% for obesity. When all 4 mediators were analyzed jointly, the direct-effect OR was 1.10 (0.65, 1.86), the indirect-effect OR was 1.46 (1.23, 1.74), and 84% of the total effect was mediated by these 4 risk factors. Excluding low vitamin D reduced the percentage mediated to 46%; doing the same with the other 3 mediators reduced the percentage mediated to no less than 70%.

Conclusions: The 4 risk factors treated as mediators in this study—especially low vitamin D and diabetes—appear to explain most of the racial difference in albuminuria prevalence in the United States. Although causal inference is limited by the cross-sectional design and possible residual confounding, the findings suggest that much of the racial inequality may be preventable through improvement of the risk-factor profile in blacks. As we learn more about how to control vitamin D level, the long-term impact on the incidence of chronic and end-stage renal disease could be appreciable.

TH-PO1044

Disparities in CKD Progression Across Racial Groups in Two Large Health Systems

Susanne B. Nicholas,[1] Kenn B. Daratha,[5] Jenny I. Shen,[4] Cami R. Jones,[6] Obidiugwu Duru,[1] Sterling McPherson,[7] Radica Z. Alicic,[6,3] Katherine R. Tuttle,[2,6] Keith C. Norris.[1] CURE CKD *[1]Medicine, David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]University of Washington School of Medicine, Spokane, WA; [3]Providence Medical Research Center, Spokane, WA; [4]LaBiomed at Harbor-UCLA, Torrance, CA; [5]Washington State University, Colbert, WA; [6]Providence St. Joseph Health, Spokane, WA; [7]Washington State University College of Medicine, Spokane, WA.*

Background: Disparities exist in progression of chronic kidney disease (CKD) across racially diverse groups. The University of California, Los Angeles Health (UCLA) and Providence St. Joseph Health (PSJH) systems formed a CKD and At-risk CKD Data Registry to inform advances in population health, individual behaviors, social and physical environment, and precision medicine.

Methods: CKD progression was determined across self-reported racial/ethnic groups in the database (>3.1 million patients) that was populated from electronic health records of adults treated at UCLA and PSJH from 2006 to 2016. Eligibility in the Registry was based on identification of CKD, and at-risk for CKD defined by hypertension, diabetes, or pre-diabetes. Linear regression coefficients for individual trajectories were calculated for patients having at least 3 eGFRs (CKD-EPI-creatinine). Individuals were classified by change in eGFR over time. Linear mixed models were used to assess racial differences in eGFR trajectories, controlling for age, gender, and time-varying measurements of systolic blood pressure, hemoglobin A1C, and renin angiotensin system inhibitor use.

Results: Patients with statistically significant eGFR decline (≥2-3 mL/min/1.73m^2/year; n=182,959, 16%) had a baseline of 79±26 mL/min/1.73m^2 (mean±SD) versus 81±23 mL/min/1.73m^2 in non-decliners (n=980,022, 84%). Non-White were more likely than White patients to experience eGFR decline after adjustment for relevant covariates in multi-variable models. Mortality rate for patients with significant eGFR decline was >3 times higher than in patients without eGFR decline.

Conclusions: In this large data registry from electronic health records at UCLA and PSJH, after multi-variable adjustment Non-White patients with CKD or at-risk for CKD are more likely to experience eGFR decline, which was associated with higher risk of mortality. Future directions include assessing eGFR decline by race/ethnicity and mortality risk in our unique cohort.

TH-PO1045

The Impact of Gender on Inpatient Mortality of Hypertensive Latino Patients Across CKD Stage 3 to ESRD in the United States

Mark A. Nader,[1,2] Rodrigo Aguilar Campos,[2] Oussama Hassan,[3] Carmen E. Cervantes,[4] Ricardo Correa,[6] Prabin Sharma,[5] Rehan Shafique,[1] Omar Hamze,[8] Hieu Q. Vo,[9] Judit Gordon,[7] Ping Li.[7] *[1]Kidney Care Consults, Memphis, TN; [2]Georgetown University Hospital, Washington, DC; [3]Royal London Hospital, Austin, TX; [4]Aventura Hospital and Medical Center, Aventura, FL; [5]Yale University Bridgeport Hospital, Bridgeport, CT; [6]University of Arizona, Phoenix, AZ; [7]Medstar Georgeotown University Hospital, Washington, DC; [8]Kidney Care Consultants, Memphis, TN; [9]University of Tennessee, Memphis, TN.*

Background: HTN and CKD are two of the most important risk factors for CVD, a major cause of death in the US population. The impact of gender or menopausal age in this equation remains unclear on how it affects the Hispanic population. Studies comparing the difference in inpatient mortality between male and female with hypertension and CKD are sparse. Our aim was to determine if gender in Latino population affect the inpatient survival rate among hypertensive patients across different CKD stages.

Methods: Data was extracted from the 2005 to 2012 Nationwide Inpatient Sample (NIS). Using propensity score matching, female hypertensive with chronic kidney disease (stage 3, 4, 5 or ESRD) patients were matched with hypertensive males at a 1:1 ratio. We compared inpatient mortality, per CKD stage, length of stay and total hospital charges between male and females. Analyses were performed using SAS version 9.3.

Results: Among 227,923 hospitalized hypertensive patients, 118,132 (51.83%) were males and 109,791 (48.17%) females. There was 18.76% females with CKD3, 10.31% with CKD4, 3.85% with CKD 5 not on dialysis and 67.17% with ESRD. Similarly there was 19.47% men with CKD 3, 9.54% with CKD4, 3.63% with CKD5 not on dialysis and 67.43% with ESRD on dialysis. In-hospital mortality was higher for males compared to females before match, (3.89 vs 3.74 p= 0.05), but non significant after matching the groups (3.85 vs 3.79 p= 0.48). Studying the effect of menopausal age, we find Latino women <50y to have less mortality risk compared to matched group of men irrespective of CKD stage while it is not different when comparing Men and women >50y with CKD stages 3 to 5. Post menopausal women with ESRD have a significantly higher mortality compared to men (5.15% vs 4.24%; p<0.0001). Hospitalized hispanic men had higher hospital charges (63,686 vs 61,667 dollars,p=0.001) even though hispanic women had a significantly longer mean length of stay (6.74 vs 6.70 days,p=0.001).

Conclusions: Mortality in Hispanic women with CKD 3 to 5 compared to men, is reduced when < 50y, comparable after >50y and increased when on dialysis. Further studies are needed to elucidate the possible links of menopause and sex hormones with in-hospital mortality of hypertensive hispanic patients.

TH-PO1046

Impact of Kidney Function on Quality of Anticoagulation in Adults with Atrial Fibrillation: The CVRN WAVE Study

Alan S. Go,[1] Dongjie Fan,[2] Sue hee Sung,[1] Marc S. Williams,[4] Thida C. Tan,[1] Jerry H. Gurwitz.[3] *[1]Kaiser Permanente Northern California, Oakland, CA; [2]Kaiser permanente, Oakland, CA; [3]Meyers Primary Care Institute, Worcester, MA; [4]Geisinger, Danville, PA.*

Background: Despite the development of direct oral anticoagulants, warfarin remains an important anticoagulation option for stroke prevention in adults with CKD. However, the impact of kidney function on the quality of anticoagulation for atrial fibrillation (AF) has not been well-defined.

Methods: Across 5 participating healthcare systems in the Cardiovascular Research Network (CVRN), we identified all adults with diagnosed AF who initiated warfarin and had ≥1 follow up international normalized ratio (INR) measurement. We used multivariable logistic regression, Cox regression and Kaplan-Meier curves to assess the relationship between estimated glomerular filtration rate (eGFR) by CKD-EPI with three metrics of quality of anticoagulation: patient-level %TTR, time to achieve a stable INR [between 2.0-3.0], and early warfarin termination. Stroke and bleeding risk factors were ascertained from health system electronic health records.

Results: Among 24,634 eligible patients, mean age was 73 years and 44% were women. Baseline eGFR (ml/min/1.73 m^2) was 64% for eGFR ≥60, 22% for eGFR 45-59, 11% for eGFR 30-44, 2.5% for eGFR 15-29 and 2% for eGFR <15 or receiving dialysis. Patient-level %TTR ranged from 43% for eGFR <15 or dialysis to 66% for eGFR ≥60, with a graded increased adjusted odds of poorer anticoagulation control with lower eGFR. Overall, 77% reached a stable INR within the first 90 days of therapy, with only eGFR <15 or dialysis significantly associated with a longer time to reach stable INR. There was no significant association of kidney function with early warfarin termination.

Conclusions: In adults with AF starting warfarin, we found graded increased odds of suboptimal %TTR with lower eGFR. While only eGFR <15 or dialysis was associated with a lower chance of reaching a stable INR within 90 days, eGFR did not appear to influence the likelihood of stopping warfarin within the first 12 months of treatment.

TH-PO1047

Trends in Statin Use Among Those with CKD in the United States, 1999 to 2014

Daniel P. Murphy, Robert N. Foley. *University of Minnesota, Minneapolis, MN.*

Background: Chronic kidney disease (CKD) has been recognized as a risk factor for cardiovascular disease (CVD). Statins have been shown to reduce CVD events in those with CKD not on dialysis, and CKD has been suggested as a candidate for determining statin therapy in cholesterol-focused guidelines. Statins have been shown to be used by a minority of those with CKD. Descriptions of temporal tends and disparities in statin use among those with CKD, identifying those who may benefit most from inclusion of CKD in such guidelines, are needed.

Methods: We studied trends in statin use among adult participants of the National Health and Nutrition Examination Survey, years 1999-2014, with creatinine-based estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73m^2 or albumin-creatinine ratio ≥ 30 mg/g. Differences among racial/ethnic, other demographic, and comorbid characteristics were also examined.

Results: 28.9% of those with CKD used a statin. Encouragingly, statin use rose across the four eras studied (P < 0.001), though they may have begun to plateau after 2010: 1999-2002, 17.1%; 2003-2006, 27.0%; 2007-2010, 33.4%, and 2011-2014, 35.6%. While albuminuria increased the likelihood of statin use (23.6% vs 12.2%, P < 0.001), a greater effect was seen among those with reduced eGFR < 60 ml/min/1.73m^2 compared to those with preserved eGFR (41.4% vs 11.4%, P < 0.001). Those of Hispanic race/ethnicity with CKD received fewer statins: 15.4% compared to 32.0% for white, 26.2% for black, and 24.6% for other race/ethnicity (P < 0.001). Statin use was more prevalent among males with CKD than females (32.4% vs. 26.3%, P < 0.001). In age, sex, and race/ethnicity adjusted models, statins were associated with: era (adjusted odds ratio (AOR) 1.77 [95% CI: 1.44-2.17] for 2003-2006, 2.51 [95% CI: 2.04-3.08] for 2007-2010, and 2.94 [95% CI: 2.34-3.70] for 2011-2014, vs. 1999-2002) and Hispanic race/ethnicity (AOR 0.62 [95% CI: 0.50-0.78] vs. white). Other multivariate associations (P < 0.05) were older age, male sex, BMI ≥ 30 kg/m^2, diabetes mellitus, hypertension, myocardial infarction, heart failure, and stroke.

Conclusions: Statin use has increased over time but remains the case for the minority in community-based CKD. Those of Hispanic race/ethnicity with CKD receive the fewest statins while males with CKD receive statins more often than females. Further research into such disparities is needed.

TH-PO1048

Statin Use Remains Suboptimal Among US Veterans with Stage 3-5 Non-Dialysis Dependent CKD

Talar Markossian,[3,2] Kevin Stroupe,[2,3] Nick Burge,[2] David J. Leehey,[2,1] Ivan M. Pacold,[2,1] Holly J. Kramer.[3,2] *[1]Loyola University Medical Center, Maywood, IL; [2]Hines VA Medical Center, Hines, IL; [3]Loyola University Chicago, Maywood, IL.*

Background: Statin use is one of the few interventions demonstrated in clinical trials to reduce cardiovascular disease (CVD) in adults with non-dialysis dependent chronic kidney disease (CKD-ND). KDIGO guidelines published in 2013 recommend statin use for adults age ≧50 years with CKD-ND. We previously reported suboptimal statin use during calendar year 2012 in U.S. Veterans with stage 3-5 CKD-ND with only 62.1% using statins overall and only 21.8% of Veterans with CKD-ND in absence of diabetes, clinical CVD or hyperlipidemia using statins. In this study, we reexamined statin use during calendar year 2015 among U.S. Veterans age ≧50 years with stage 3-5 CKD-ND.

Methods: We used data from the VA Corporate Data Warehouse which includes demographics, inpatient and outpatient encounter diagnosis and procedure codes [International Classification of Diseases, Ninth/Tenth Revision, Clinical Modification (ICD9/10-CM) and Current Procedural Terminology codes], outpatient pharmacy prescriptions reported by Veterans, and patient labs. Information on medications dispensed within the VA system was obtained from the Managerial Cost Accounting National Data Extracts which contains medications names and supply durations. Data were linked with the Medicare files to capture health care use and medications dispensed from non-VA pharmacies. CKD status was based on presence of at least two estimated glomerular filtration rate (eGFR) values < 60 ml/min/1.73 m^2 in outpatient laboratory data spaced 90+ days apart. Co-morbidities were defined by ICD9/10 codes.

Results: There were 242,865 Veterans age ≧50 years with at least two eGFR values <60 ml/min/1.73 m^2 spaced 90+ days apart during calendar year 2014 with no history of dialysis or transplantation. Mean age was 76.4 years (standard deviation 9.6) and 96.7% were male and most were white with 14.9% reporting black race. During calendar year 2015, 68.7% of these Veterans with stage 3-5 CKD-ND were using statins. Among Veterans with CKD-ND accompanied by diabetes or CVD, statin use was 75.1%. In contrast, only 36.6% of Veterans with CKD-ND in absence of diabetes, CVD or hyperlipidemia were using statins.

Conclusions: Statin use appears to have increased among Veterans with stage 3-5 CKD-ND but use still remains suboptimal, especially among those CKD-ND in the absence of diabetes or clinical CVD.

TH-PO1049

US Veterans with Stage 3-5 Non-Dialysis Dependent CKD Are More Likely to See a Cardiologist Than a Nephrologist

Talar Markossian,[2,3] Holly J. Kramer,[2,3] David J. Leehey,[3,1] Ivan M. Pacold,[3,1] Nick Burge,[3] Kevin Stroupe.[3] *[1]Loyola University Medical Center, Maywood, IL; [2]Loyola University Chicago, Maywood, IL; [3]Hines VA Medical Center, Maywood, IL.*

Background: Nephrology care has been shown to improve outcomes and delay or even prevent end-stage renal disease (ESRD) in adults with established chronic kidney disease (CKD) but many never see a nephrologist. We examined the percentage of U.S. Veterans with -5 non-dialysis dependent CKD (CKD-ND) with at least one nephrology clinic encounter during calendar year 2015. We also examined the percentage of adults with CKD-ND with at least one cardiology clinic encounter during calendar year 2015 and examined whether referal patterns for nephrology or cardiology differed by race.

Methods: We used data from the VA Corporate Data Warehouse which includes demographics, inpatient and outpatient encounter diagnosis and procedure codes [International Classification of Diseases, Ninth/Tenth Revision, Clinical Modification (ICD9/10-CM) and Current Procedural Terminology (CPT) codes], and patient labs. Since a percentage of Veterans receive their care from non-VA sources, we linked data from the Center for Medicare & Medicaid Services administrative databases to capture non-VA health care use. CKD status was based on presence of at least two estimated glomerular filtration rate (eGFR) values < 60 ml/min/1.73 m^2 in outpatient laboratory data spaced 90+ days apart.

Results: There were 242,865 Veterans age ≧50 with at least two eGFR<60 ml/min/1.73 m^2 spaced 90+ days apart during calendar year 2014 with no history of dialysis or transplantation. Mean age was 76.4 years (standard deviation 9.6) and 96.7% were male and most were white with 14.9% reporting black race. In this group with stage 3-5 CKD-ND, 16.6% saw a VA nephrologist and 6.1% saw a Medicare reimbursed nephrologist while 21.4% saw a VA cardiologist and 19.5% saw a Medicare reimbursed cardiologist. Compared to whites with stage 3-5 CKD-ND, black Veterans with stage 3-5 CKD-ND were more likely to see a VA or Medicare reimbursed nephrologist (31.8% vs. 20.1%, p<0.001) but less likely to see a VA or Medicare reimbursed cardiologist (32.3% vs. 38.7%; P < 0.001).

Conclusions: Veterans with stage 3-5 CKD-ND are almost twice as likely to receive cardiology care than nephrology care although this differs somewhat by race. Increasing nephrology referral rates for patients with CKD-ND should be a priority for health systems in order to delay or prevent ESRD.

TH-PO1050

Environmental Chemical Exposures in African Children with CKD: H3 Africa Cohort Experience

Howard Trachtman,[1] Leonardo Trasande,[1] Akinlolu O. Ojo,[4] Dwomoa Adu,[2] Kurunthachalam Kannan,[3] Suzanne M. Vento,[1] Laura Jane Pehrson,[1] Joseph F. Gilbert,[1] Tony T. Koshy.[1] *[1]NYU Langone Health, New York, NY; [2]University of Ghana, Accra, Ghana; [3]Wadsworth Center, New York State Department of Health, Albany, NY; [4]University of Arizona Health Sciences, Tucson, AZ.*

Background: Environmental chemical exposures are linked to oxidative stress and kidney injury in children and adults. This applies to short-lived organic compounds such as bisphenol A and phthalates and persistent synthetic chemicals such as perfluoroalkyl acids (PFAAs). Most investigations to date have been conducted in developed countries with few data about environmental chemical exposures in children living in Africa.

Methods: Clinical and laboratory data about pediatric patients enrolled in the H3 Africa observational cohort study including age, gender, BMI, serum creatinine, eGFR, proteinuria were collected. Serum samples that had been collected at enrollment were retrieved from the Biorepository and analyzed for PFAAs and polybrominated diphenyl ethers (PBDEs) and DDE presticides using established methods. Proteinuria was assessed in a first morning urine sample. Results are presented as mean±SD.

Results: 86 patients with CKD (41 M:45 F), age 12.6±2.6 yr old, were included in this nested case control study. The eGFR was 75±4 and the albumin:creatinine ratio was 65±186. The chemical exposures are summarized in the Table. There was no association between exposure (log of serum concentration) to PFAAs and proteinuria. However, controlling for age, gender, and BMI, there was an inverse relationship between eGFR and exposure to PFNA, -21.2 [95% CI:-41.6 - 0.8] and PFDA -18.3 [95% CI:-35.3 - -1.3] ml/min/log unit increase in exposure and a trend towards a similar effect for PFOS. PBDE/DDEs were detected in a small fraction of children and because of small sample size associations with effect markers were not made

Conclusions: PFAA exposure is substantially lower in H3 Africa participants than in healthy US children, age 12-19 enrolled in NHANES 2003-2010. However, even at these lower levels of exposure there was an adverse association between select PFAAs and GFR. These studies indicate the feasibility of measuring environmental chemical exposure in developing countries. The impact of these chemical exposures on kidney function will require larger cohorts of children followed for more extended periods of time.

Funding: NIDDK Support

TH-PO1051

Risk Factors for Albuminuria and Reduced eGFR in Sub-Saharan Africans: Findings from the H3Africa Kidney Disease Research Network Project

Yemi R. Raji,[1,2] Charlotte Osafo,[7] Manmak Mamven,[13] Timothy O. Olanrewaju,[8] Titilayo O. Ilori,[10] Shikhar Kumar,[12] Adebowale A. Adeyemo,[11] Rasheed A. Gbadegesin,[5] Rulan S. Parekh,[6] Babatunde L. Salako,[9] Dwomoa Adu,[4] Akinlolu O. Ojo.[3] H3Africa Kidney Disease Research Project *[1]University of Ibadan and University College Hospital, Ibadan, Oyo State, Nigeria, Ibadan, Nigeria; [2]Medicine, University of Ibadan, Ibadan, Nigeria; [3]University of Arizona Health Sciences, Tucson, AZ; [4]University of Ghana, Accra, Ghana; [5]Duke University Medical Center, Durham, NC; [6]The Hospital For Sick Children, Toronto, ON, Canada; [7]University of Ghana Medical School, ACCRA, Ghana; [8]University of Ilorin and University of Ilorin Teaching Hospital, Ilorin, Kwara State, Nigeria; [9]College of Medicine, University of Ibadan, Ibadan, Nigeria; [10]Emory University School of Medicine, Chandler, AZ; [11]National Institutes of Health, Bethesda, MD; [12]The university of arizona, Tucson, AZ; [13]Medicine, University of Abuja Teaching Hospital, Abuja, Nigeria.*

Background: Chronic kidney disease (CKD) in sub-Saharan Africa (SSA) is among the most common non–communicable diseases ravaging the sub-continent. Data on comprehensive epidemiology of CKD phenotypes and genotypes are lacking from the region. The H3Africa Kidney Disease Research Network (H3Africa KDRN) was established to develop the first Pan-African study in CKD and to rapidly build capacity for genomic studies of kidney disease in Africa. The objective of this analysis was to characterize risk factors associated with albuminuria and low eGFR among the participants in the study.

Methods: Participants were enrolled from 8 clinical sites from 4 participating countries. We determined prevalent risk factors by collecting biometric that includes albuminuria and eGFR, the later was calculated using CKD - EPI equation. Crude and adjusted odds were determined for the risk factors for albuminuria of > 30mg/g and eGFR < 60 ml/min/1.73m^2.

Results: Among the 3,323 participants with a median age of 45.73±15.5yrs, 57.3% were female. We observed that hypertension, Diabetes mellitus (DM), smoking and occurrence of CVD were significantly associated with albuminuria and reduced eGFR while gender was significantly associated with albuminuria (Table 1 and 2).

Conclusions: Hypertension, diabetes mellitus and cigarette smoking are the most prevalent risk factors for CKD in this study and are independently associated with albuminuria and low eGFR in SSA.

Funding: NIDDK Support

TH-PO1052

CKD Epidemiology in Rural East Africa: The SEARCH-CKD Study

Anthony N. Muiru,[1] Assurah W. Elly,[2] Jane Kabami,[4] Mucunguzi Atukunda,[4] Edwin Charlebois,[1] Diane Havlir,[1] Michelle M. Estrella,[3] Chi-yuan Hsu.[1] Sustainable East Africa Research on Community Health (SEARCH) Collaboration *[1]University of California San Francisco, San Francisco, CA; [2]KEMRI-SEARCH Study, MBITA, Kenya; [3]University of California, San Francisco and San Francisco VA Medical Center, San Francisco, CA; [4]Infectious Diseases Research Collaboration, Kampala, Uganda.*

Background: Little is known about CKD epidemiology among individuals living in Sub Saharan Africa (SSA) who may have heightened burden of kidney disease similar to African Americans due to shared genetic susceptibility. Non-infectious diseases and ongoing HIV epidemic can lead to significant CKD burden in SSA. Assessment of CKD burden in this region thus far has been limited by small studies or focus in urban areas. We sought to comprehensively ascertain the burden of CKD and its risk factors in rural areas, where most of the population resides.

Methods: We conducted a home-based assessment of CKD and its risk factors among a stratified random sub-sample of a large ongoing, population-based HIV test-and-treat trial in rural Uganda and Kenya (SEARCH study, NCT01864603). Prevalent CKD was defined as an eGFR <60 mL/min/1.73m2 or dipstick proteinuria ≥1+. Exposures of interest including traditional risk factors for CKD (hypertension, diabetes and HIV), were measured at mobile community health campaigns according to the SEARCH study protocol. We used household census population and sampling weights to estimate the community-based prevalence of CKD. To assess the association of potential risk factors with CKD, we used multivariable log-link Poisson models.

Results: We enrolled 5,035 participants from 30 communities (median age 41 [IQR 31-53], 64% female). The overall CKD prevalence was 8.0% (95% CI 7.2-9.0%), and varied by region: Eastern Uganda, 13.0% (11.1-15.2%), Kenya, 7.1% (5.8-8.6%) and Western Uganda, 3.7% (2.7-5.1%). Over half (52%) of persons with CKD did not have hypertension, diabetes, or HIV. Independent risk factors associated with higher CKD prevalence included being from Eastern Uganda (prevalence ratio [PR] 1.97; 95% CI 1.50-2.60), increasing age (PR 1.03; 95% CI 1.02-1.04) and HIV infection (PR 1.58; 95% CI 1.28-1.97).

Conclusions: In rural East African communities, the prevalence of CKD is high and varies by region considerably. While HIV was associated with greater CKD prevalence, over half of the CKD cases could not be attributed to HIV, hypertension or diabetes. Further research and interventions are needed to address the burden of CKD in this vulnerable population where chronic dialysis and transplant are often unavailable.

TH-PO1053

Prevalence of Proteinuria, Glycosuria, and Hypertension in a Walk-In Clinic in Rural Tanzania

David W. Ploth,[1] Virginia Fonner,[1] Michael D. Sweat,[1] Jessie K. Mbwambo.[2] *[1]Medical University of South Carolina, Charleston, SC; [2]Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of.*

Background: Non-communicable diseases (NCD) including chronic kidney disease (CKD) and the typically comorbid conditions of diabetes mellitus (DM), hypertension (HTN), and cardiovascular disease represent increasing public health challenges in low- and middle-income countries. The present studies were conducted to explore the hypothesis that there are previously underappreciated and interrelated epidemics of CKD, DM, and HTN in rural Tanzania.

Methods: We recently reported prevalence estimates for CKD(Stages III-V) of 12.4%; Stage I or II HTN of 19.9% and DM(HbA_{1c}>6.5%) of 14.8% for a random sample of 712 residents in rural Tanzania. To assess HTN, DM, and CKD further, we obtained a single BP measurement and obtained random urine samples for dipstick measurement of glycosuria and proteinuria for individuals that voluntarily appeared at a walk-in clinic that was part of the overall study

Results: Table: Normal BP was reported for 33% (296/897) and prehypertension was reported for 35 % (317/897). Glycosuria and proteinuria were highly correlated (p≤0.001, Chi-Square). Glycosuria but no proteinuria was observed in 1.5%(13/833) of the samples; proteinuria but no glycosuria was present in 4.6%(38/833); and both proteinuria and glycosuria were present in 1.6%(14/833). Increasing age but was associated with HTN or DM but gender not. HTN was associated with overweight/obese but DM was not. DM and HTN were associated with each other(p≤ 0.002, Chi-square).

Conclusions: In summary, although the data are undoubtedly biased by the methodology available to us, we observed high prevalence of HTN, glycosuria and proteinuria in a community walk-in clinic that are consistent with the high rates of CKD, HTN, and DM observed in our earlier study. It is imperative that additional studies be performed to carefully asses the prevalence of these non-communicative diseases and their causes so that effective prevention and treatment strategies can be directed at reducing of the risk of kidney disease, DM, HTN and the expected cardiovascular complications that will follow in rural Tanzania

Trends in CKD Prevalence in the KEEP Mexico from 2008 to 2017

Gregorio T. Obrador,[2] Alejandro Raña,[2] Daniela Contreras Estrada,[2] Diego J. Aguilar,[2] Ximena D. Rubilar,[2] Nadia Olvera,[1] Alma Sotelo,[1] Mariana Lopez,[2] Montserrat M. Cuadra,[2] Stefany Jacob Kuttothara,[2] Marselle Urquiza,[2] Antonio Villa.[2] *[1]Sociedad de Asistencia Panamericana, MEXICO, Mexico; [2]School of Medicine, Universidad Panamericana, Mexico City, Mexico.*

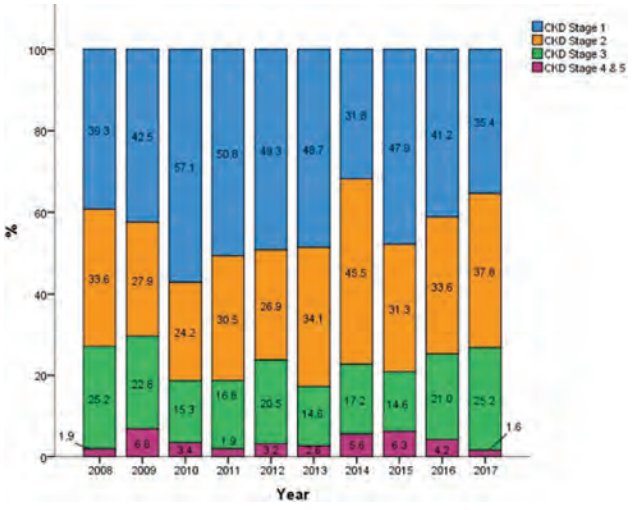
Background: The Kidney Early Evaluation Program (KEEP) is a screening and educational program aimed at detecting CKD among adults with risk factors, such as DM, HTN, family history of these conditions or CKD. In 2008 the Mexican Kidney Foundation adapted KEEP; since then, 67 screening campaigns have been performed

Methods: Adults with DM, HTN, family history of DM, HTN, or CKD participated from 2008 to 2017. All completed a questionnaire and BP, weight, and height were measured. Albuminuria and serum creatinine were obtained, and GFR was estimated

(CKD-EPI). Age-adjusted analyses were done to describe trends in CKD prevalence for almost a decade

Results: 6,885 patients with risk factors for CKD participated in a single KEEP Mexico program from 2008 to 2017. Mean age of participants was 49.7 ± 14.5 years, 69% were women. Prevalence of DM and HTN were 36.9%, and 39.5% respectively. Mean duration of DM and HTN were 10.1 and 8.5 years respectively. CKD prevalence was 30.2%, with CKD 1-2 being the most frequent stages. CKD prevalence increased over the study period, particularly at the expense of stage 2. Prevalence of stage 1 decreased and of stages 3, 4 & 5 remained virtually unchanged. CKD prevalence among patients with DM, HTN, or both was 25.3%, 21%, and 33.2% respectively, and increased over time

Conclusions: CKD prevalence in the KEEP Mexico has increased over a decade, with the most significant increase in stage 2. CKD prevalence is higher in patients with both DM and HTN compared with those with either risk factor. Further analyses are being conducted to determine the factors associated with these trends. A longitudinal analysis of KEEP participants previously reported showed that a high proportion of patients who initially tested positive for CKD were eventually confirmed to have the disease



TH-PO1055

Risk Factors for CKD Progression in the Mexican Chronic Renal Insufficiency Cohort (MCRIC) Study

Magdalena Madero,[2] Jinsong Chen,[1] Ana C. Ricardo,[1] Eunice Carmona,[1] Ana P. Hernández martínez,[2] Ana K. Fernández yepez,[2] Esteban A. Cedillo-Couvert,[1] Mayank Kansal,[1] Bernardo Moguel,[2] Carlos A. Linares-Koloffon,[1] James P. Lash.[1] *[1]University of Illinois at Chicago, Chicago, IL; [2]Instituto Nacional de Cardiología, Ciudad de México, Mexico.*

Background: Chronic kidney disease (CKD) is a major public health problem in Mexico. However, little is known about the risk factors for progression of kidney disease among individuals with CKD living in Mexico.

Methods: MCRIC is an ongoing, prospective observational cohort study of adults with CKD recruited from a referral center in Mexico City, with entry estimated glomerular filtration rate (eGFR) 20-60 ml/min/1.73 m^2. Using data from 257 participants who completed at least two study visits, we conducted Cox proportional hazards regression analysis to evaluate risk factors for CKD progression defined as 30% decline in eGFR from baseline.

Results: At study entry, mean age was 56.6 ± 0.8 years, 72.2% were male, 23% reported current cigarette smoking, and 53% had a diagnosis of diabetes. Mean body mass index (BMI) and systolic blood pressure (SBP) were 28.2 ± 4.5 Kg/m^2 and 123.4 ± 19.6 mmHg, respectively. The mean baseline eGFR was 41.1 ± 15.4 ml/min/1.73m^2, and the median (IQR) urine protein excretion 633 (124-2460) mg/24 hours. During a median follow-up of 1.9 years, there were 57 CKD progression events (event rate 11.3 per 100 person-years). In unadjusted analysis, significant predictors of CKD progression included diabetes (HR, 95% CI, 2.00, 1.15-3.50) and higher log-transformed urine protein (1.62, 1.34-1.95). After adjusting for age, sex, SBP, baseline eGFR and diabetes, only proteinuria remained a significant predictor (1.64, 1.33-2.04).

Conclusions: This cohort of adults with CKD in Mexico experienced a high rate of CKD progression which was significantly associated with baseline proteinuria. Long-term follow-up is needed to better understand risk factors for CKD progression in this population.

TH-PO1056

Survey of Migrant Dialysis Patients Discloses a Majority with Paraquat or Other Agrochemical Exposure: A Potential Etiology for CKDu

Michael Holliday,[1] Jose R. Dominguez,[1] Edlyn G. Bustamante,[2] Ilse M. Espina,[1] Maulin Shah,[1] Samaya J. Anumudu,[1] Ahmed A. Awan,[1] David Sheikh-Hamad.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Harris Health System, Houston, TX.*

Background: Chronic kidney disease of unknown etiology (CKDu) is a global epidemic of renal disease. Prior studies have reported associations of CKDu with Leptospira, heat and heavy metal exposures, and agricultural chemical use. From a screen of migrant workers with ESRD at a Houston safety net hospital, we identified Gramoxone (paraquat herbicide) exposure as a possible etiologic factor. Further, we found that repetitive administration of low dose paraquat to mice resulted in renal pathology similar to that of CKDu. We expanded our survey to an outpatient safety net dialysis unit that primarily serves migrants with ESRD.

Methods: 155 patients were screened at our outpatient dialysis unit. Of these, 38 met inclusion criteria and were surveyed. Exclusion criteria included known causes of primary or secondary renal disease (e.g. diabetes, hypertension, SLE, IgA, etc.). Included patients were also negative for viral hepatitis, HIV, ANA, ANCA, or monoclonal gammopathies.

Results: Average patient age at presentation was 40 (range 24-60) and 36 of 38 surveyed patients were male. 58% (22) were from Mexico, 37% (14) from El Salvador, and one each from Guatemala and Honduras. Before immigration, 27 (71%) lived in a farm/village and 11 (29%) lived in urban area. 76% (29) reported living in hot climate and 74% (28 patients) had worked in agriculture for an average of 10+/-6 years prior to immigration. 16% (6) of patients had rare use of NSAID. 29% (11 patients) reported use of Gramoxone (paraquat-based herbicide) by name, while 22 (58%) patients reported prior herbicide and/or pesticide exposure but could not identify agents; the average duration of exposure was 10+/-5 years. 58% (22) consumed well water, and of patients with herbicide/pesticide exposure, 18 (82%) consumed well water.

Conclusions: Patients with CKDu encountered at a Houston safety net hospital consist of migrant workers, predominantly male and young. Before immigrating to the US, most of the patients lived in hot mountainous climate, in a farm/village. They did not consume sweetened drinks and their main hydration solution consisted of well water. We found no clear identifiable risk factors for uCKD, except for chronic exposure to paraquat/Gramaxone in farm workers and consumption of well water.

TH-PO1057

Chronic Interstitial Nephritis in Agricultural Communities (CINAC) Is Strongly Associated with Pesticides

Channa Jayasumana,[2] Chulani A. Herath,[3] Marc E. De Broe.[1] *[1]University of Antwerp, Lokeren, Belgium; [2]Faculty of Medicine, Anuradhapura, Sri Lanka; [3]Sri Jayawardenepura General Hospital, Colombo 5, Sri Lanka.*

Background: Pesticides are hypothesized as a main etiological factor behind CINAC. Our aim was to see whether pesticides are associated with CINAC.

Methods: A case control study was carried out in a CINAC endemic region in Sri Lanka. Confirmed cases with CINAC (N=125) and controls (N=180) were recruited to the study. Socio-demographic and data related to usage of applying pesticides were studied. Participant's urine samples were analyzed using ELISA to determine the levels glyphosate and paraquat.

Results: In the epidemiological study, we found CINAC is strongly associated with overall pesticide application (OR 2.34, 95% CI; 0.97-5.57), use of glyphosate (OR 5.12, 95% CI; 2.33-11.26) and use of paraquat (OR 4.53, 95% CI; 1.23-10.03) adjusted for age, sex, education, family history of CINAC and exposure modifiers. In the analytical study it has been shown that creatinine adjusted values of urinary glyphosate in CINAC cases (12.7 µg/g creatinine) was significantly higher when compared to non-endemic controls (2.4µg/g creatinine). Further, we found paraquat residues are still present in urine samples (Mean 1.08, Min-0, Max-11.42 µg/g creatinine) obtained from people living in CINAC endemic regions despite parquet had been banned in 2010 in Sri Lanka. Similar association between CKD and pesticide usage is previously reported. In 2015 Lebov and colleagues have shown herbicides alachlor, atrazine, metolachlor, paraquat, and pendimethalin, and the insecticide permethrin are associated with end stage renal disease (ESRD) in USA among licensed pesticide applicators.

Conclusions: Epidemiological and toxicological findings suggest CINAC is a toxic nephropathy associated with paraquat and glyphosate.

TH-PO1058

Far from the "Hot Coast": Prevalence of Mesoamerican Nephropathy (MeN) in a Cooler Mountain Community of Nicaragua

Stefano Bianchi, Filippo Cellai, Francesca Nistri, Andrea Grillo, Roberto Bigazzi. *Medicine, ASLNordovest, UOC di Nefrologia e Dialisi, Livorno, Italy.*

Background: MeN is an "epidemic" of chronic kidney disease (CKD) of unknown etiology, affecting populations of Nicaragua (N) and other pacifical coast regions wich are all caracterized by high temperature. Dehydration, volume depletion and heat stress are all risk factors for MeN commonly linked to strenuous work conditions during seasonal harvest. In a previous study, we have found an high prevalence of MeN (26,4%) in a general population (GP) sample of a costal city (Leon, N). The pecularity of our results has been a census based general population analysis, and not a selected group of subjects as reported in the majority of the previous studies published on this issue, mainly involving sugar cane agricoltural workers. The aim of the present study was to investigate MeN prevalence in the

general population of a city (Condega, N), which is located at 560 feet above sea level, very far from the pacific coast, with different mean temperatures (daily mean 22C° vs 30 C°of Leon) and farmer activities (mainly coffee).

Methods: Out of a GP population of 28.481 inhabitants, we ramdomly selected 1024 subjects aged ≥ 18 years. The final sample of population we have studied counted 976 subjects, mean age 41.84 ± 16.73; 457 males and 519 females. Blood and urine samples were collected to estimate glomerular filtration rate (eGFR-CDK-EPI, mL/min/1.73 m2) and urine albumin excretion (UAE, albumin mg/creatinine g).

Results: Among 976 participants to the study, 725 (74.28%; mean age 39.7; 358 males and 385 females) had normal eGFR; 251 (25.7 %; mean age 46.53; 106 males and 145 females) manifested CKD (14.3 % stage 1, 16.7 % stage 2, 35.1% stage 3a, 12.4% stage 3b, 10.8% stage 4, 10.4% stage 5). Out of 173 participants in stage 3-5 of CKD, 143 (82,7%) had UAE<30 mg/g, 23 (13,3%) had UAE>30 mg/g <300 mg/g and only 7 (4%) had UAE> 300 mg/g

Conclusions: In Nicaragua, even far from the high temperatures of the pacific cost, the prevalence of MeN seems to be very high. The cause(s) of MeN remains still unknown. However, there is more than dehydration, volume depletion and heat stress.

Funding: Other NIH Support - Prevenzione, diagnosi precoce e cura dell'insufficienza Renale Cronica nel dipartimento di Leon. Fase 2. DGR 697 del 19/07/2016, PIR Decreto 7722 del 05/06/2017

TH-PO1059

eGFR, CKD Epidemiology in a Nicaraguan High Risk Area for Mesoamerican Nephropathy (MeN)

Antonino Sidoti,[1,2] Martha Vargas,[2] Maria José Sequeira Reyes,[2] Paolo Mazzacani.[2] Consulta Nefrologica, Fundación Coen, Chinandega, Nicaragua *[1]Nephrology Unit Poggibonsi (Si) Italy, Pisa, Italy; [2]Fundacion Coen, Chinandega, Nicaragua*.

Background: MeN is linked with field working at sea level (mainly sugarcane) CKD and death in young age. Chinandega department has the two biggest sugarcane country plantations in El Viejo and Chichigalpa, CKD prevalence figures and etiology are unknown. On 2017 we enrolled age 12-22 people for a three years study to detect CKD precociously, assess CKD prevalence and risk factors, facilitate nephrological medical consult.

Methods: Population is 51746, by double randomization sampling 1202 record were completed. Plasma creatinine, blood pressure (BP), weight, height were measured; a questionnaire on occupation, water source, medical history, use of nSAID was administered. eGFR<60ml/min' was diagnostic for CKD with Schwartz bedside for children and CKD-EPI for adults (Schw_CKD_EPI). eGFR via combined full age spectrum formula (FAS) for children and CKD-EPI for adults (FAS_CKD_EPI) was calculated to choose the best suited formula for longitudinal eGFR follow-up and to compare different communities (Pearson bivariate). Schw_CKD_EPI eGFR was used for continuous and quartiles variable analyses by Anova and χ squared testing respectively. CI by Jeffreys method.

Results: Schw_CKD_EPI was 101±21, CKD-EPI 121±14, FAS_CKD_EPI 118±18. Schwartz vs FAS r=-790, p<.001. CKD prevalence was 0.75% (CI 0.31-1.36). Three municipalities had cases: Corinto 0,67% (CI 0.12-3.6),Chichigalpa 0.78%(CI 0.22-2.8), El Viejo 0.73% (CI 0.28-1.5). There was no relationship between eGFR and previous and actual occupation, medical antecedent i.e.dengue n=133, leptospirosis n=6, recurrent urinary tract infections n=209, previous episodes of dehydration n=119, frequent tonsillitis n=542, chikungunya n=293, malaria n=36, water source, fluid intake, frequent use of nSAID n=408, BP. Three communities (LM, KI, MA) were at extremes for eGFR. Differences in eGFR were better discriminated (p<.05) with FAS_CKD_EPI than Schw_CKD_EPI (pNS): LM 127±20 vs 88±18, KI 110±19vs 105±18, MA 129±12 vs. 93±17 respectively.

Conclusions: CKD prevalence is very high, well above NHANES 2011-14 age 20-39 (0.3%). No clues about causality come from our baseline data. In the subsequent years of study FAS_CKD_EPI use is advisable to focus geographical areas of investigation and health interventions, moreover its closeness with CKD-EPI values would help eGFR follow up from pediatric to adult age.

Identifying CKD of Unknown Etiology in Sri Lanka

Shuchi Anand,[1] Maria E. Montez-Rath,[2] Dinuka M. Adasooriya,[3] Neelakanthi V. Ratnatunga,[4] Neeraja Kambham,[1] Zeid Badurdeen,[5] Stephen L. Schensul,[6] Penny Vlahos,[7] Lali (Lalarukh) Haider,[8] Vivek Bhalla,[1] Adeera Levin,[9] Glenn M. Chertow,[2] Nishantha Nanayakkara.[3] *[1]Stanford University, Palo Alto, CA; [2]Stanford University School of Medicine, Palo Alto, CA; [3]Teaching Hospital, Kandy, Bamunakotuwa, Sri Lanka; [4]Faculty of Medicine university of Peradeniya Sri Lanka, Kandy, Sri Lanka; [5]University of Peradeniya, Sri Lanka, Kandy, Sri Lanka; [6]University of Connecticut School of Medicine, Farmington, CT; [7]University of Connecticut, Groton, CT; [8]University of CT Health Center, West Hartford, CT; [9]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada*.

Background: A kidney disease of unknown cause is common in Sri Lanka's lowland region. No evidence exists to inform an approach to a non-invasive clinical diagnosis.

Methods: In a prospective study to determine whether non-invasive measures can identify CKDu, we surveyed 600 new patients coming to nephrology clinic in a hospital servicing endemic regions over one year. 87 underwent kidney biopsy; 43 (49%) had a pathology diagnosis of tubulointerstitial disease. Using logistic regression, we tested the association of nine pre-selected factors with likelihood of tubulointerstitial nephritis on biopsy. We used bootstrap validation to calculate the model validated AUC. We tested a Full model and five parsimonious models.

Results: AUC for the Full model to predict CKDu was 0.82. A parsimonious model with age, serum albumin, and urine dipstick for protein had an AUC of 0.84 and bootstrap calibration slope of 0.84 (Table 1); with PPV 82.9% and NPV 80.4%. Patients with diabetes or hypertension recommended for kidney biopsy did not experience lower odds of a CKDu diagnosis.

Conclusions: We developed a standardized approach relying on non-invasive measures to identify probable cases of CKDu in Sri Lanka. Such an approach can strengthen CKDu surveillance, geographic mapping and rigorous investigations into cause via case-control studies.

TH-PO1061

KIM-1 as an Early Biomarker of Kidney Injury in Agricultural Communities in Sri Lanka

Mariana Cardenas-Gonzalez,[3,1] P. mangala C. De silva,[5,7] Dilini V. Ekanayake,[6] Gayani T. Wanniarachchi,[6] Nandita Srayoshi,[10] Sudheera Jayasinghe,[8] Ediriweera patabandi S. Chandana,[7] Channa Jayasumana,[2] Sisira Siribaddana,[9] Venkata Sabbisetti,[3] Joseph V. Bonventre.[4] *[1]Laboratory of Systems Pharmacology, Harvard Medical School, Boston, MA; [2]Faculty of Medicine, Anuradhapura, Sri Lanka; [3]Brigham and Women's Hospital, Boston, MA; [4]Brigham and Women's Hospital, Boston, MA; [5]Harvard Medical School, Malden, MA; [6]University of Ruhuna, Sri Lanka, Matara, Sri Lanka; [7]Zoology, University of Ruhuna, Matara, Sri Lanka; [8]University of Ruhuna, Galle, Sri Lanka; [9]Faculty of Medicine, Rajarata University of Sri Lanka, Nugegoda, Sri Lanka; [10]Harvard Institute of Medicine, Boston, MA.*

Background: Chronic kidney disease of unknown etiology (CKDu) is common among agricultural communities in Sri Lanka (SL), with prevalence between 10–15%. No definitive causes for CKDu has been identified. Early detection through community screening is essential for estimating true prevalence and guiding preventive management.

Methods: Inhabitants of selected villages in SL who worked in rice, sugarcane or vegetables farming, and a village of fishermen were recruited (647, male 61%, mean age 44.7 y). Estimated GFR, urine albumin, and KIM-1, were measured. Logistic regression analysis was used to determine the odds ratios for underlying kidney proximal tubule (PT) injury (urinary KIM>250 pg/mg creat).

Results: Kidney disease, defined by GFR<60 ml/min and/or albuminuria >300 mg/mg, was present in 9% of the population. KIM-1 negatively correlated with eGFR, positively correlated with urine albumin (r~0.2; p<0.01, for both). KIM-1 levels were elevated in 27% of the population who had no defined kidney disease, indicating that these subjects have underlying PT injury and may be more prone to developing CKD. KIM-1 levels were higher in farmers than in fishermen (151±75 vs 36±21 pg/mg; p=0.01). Among farmers, vegetable farmers had the highest levels (310±54 pg/mg; p<0.01). Wasgamuwa, an endemic CKDu rice farmer community, had the highest percentage of kidney disease (24%) and higher levels of KIM-1 when compared to Agunukolapallassa, a non-endemic CKDu rice farmer community (454±93 vs 50±20 pg/mg; p<0.01). Importantly, 62% of Wasgamuwa farmers had KIM-1 levels >250 pg/mg, indicating that a significant fraction of this population may have subclinical kidney injury. Farmers have ~5 times higher risk of having underlying PT injury than fishermen, independent of age, sex, diabetes and hypertension (OR 4.8, 95%CI: 2.6 to 8.9; p<0.01). Among farmers, vegetable farmers were twice at risk of having underlying PT injury than sugarcane farmers, after adjusting for age, sex, diabetes, hypertension and farming duration (OR 2, 95%CI, 1.2 to 3.9; p=0.04).

Conclusions: KIM-1 is a potential biomarker for screening populations at risk for underlying kidney injury in endemic and non-endemic areas of CKDu in SL.

TH-PO1062

Prevalence and Prognosis of CKD in Italy: The Role of Demographic Shift Towards Older Age Groups

Fiammetta Ravaglia,[1] Giuseppe L. Spatoliatore,[1] Alberto Rosati,[1] Paolo Francesconi.[2] *[1]USL Toscana Centro, Florence, Italy; [2]Agenzia Regionale di Sanità Toscana, Florence, Italy.*

Background: Prevalence of chronic kidney disease(CKD) stages 3-5 in Europe is variable(1.0-5.9%), but lower than in United States(US)(13%). In Italy, real-world data is uncertain as previous studies were limited by methodological sampling and lack of prognostic data. To address this issue, we designed a population study based on administrative data, including the elderly typically under-represented. Objectives:to estimate CKD 3-5 stages prevalence in the resident population of a Tuscan city health unit(Empoli ASL), with sub-analysis in diabetic and hypertensive patients;to calculate the relative risk(RR) of myocardial infarction, stroke, heart failure, peripheral artery disease and death;to standardize data on the whole regional population.

Methods: All individuals referring to Empoli ASL were reviewed through the Tuscany Regional Agency for Health database. Patients>45yrs with a serum creatinine determination(SCr) in 2011-2013 by isotopic dilution mass spectrometry to estimate GFR by CKD-EPI equation were included and stratified in CKD 3a, 3b, 4-5(Renal Replacement Therapy patients excluded). Crude and standardised prevalence by sex, age and comorbidity were recorded. RR of death and cardiovascular events was assessed by Multivariate Cox analysis(controls=GFR>60ml/min).

Results: Of the 238,873 Empoli residents, 79,277(78%) were>45yrs and performed at least one SCr. 9082(11.4%) had GFR<60ml/min and 686(0.87%) had GFR<30ml/min. Age and sex distribution of CKD 3-5 showed higher prevalence in females and older age(p <0.0001)(Tab1). eGFR<60ml/min prevalence in the standardized general population>45yrs was 10.5%: stage 3a=7.1%, 3b=2.6%, 4-5=0.8%. Prevalence increased with age, in 45-74yrs group was 4.4%, in the group>85yrs: stage 3=36.5%, 4-5=4.1%(Fig1). RR of death and cardiovascular events in Tab2.

Conclusions: This is the first Italian study to evaluate CKD prevalence with a large sample (238,000 inhabitants, 6.2% Tuscany population). CKD prevalence in 45-74yrs in Tuscany resulted 4.4% (lower than US and among the lowest in Europe), however including age>45yrs it reached 10.5%, highlighting the higher prevalence in the elderly, associated with more age-related comorbidities. The comparison of CKD prevalence between Europe and US, usually based on age group 45-74yrs, underestimates the real prevalence in European countries.

Determinants of Intraregional Differences in Renal Function in the Northern Netherlands: The Lifelines Cohort Study

Qingqing Cai, Louise H. Dekker, Stephan J. Bakker, Martin H. De Borst, Gerjan Navis. *University Medical Center Groningen, Groningen, Netherlands.*

Background: Although interregional disparity in CKD prevalence has been reported globally, it is unclear which factors drive renal function clustering within regions. We studied the intraregional distribution of renal function in the Northern Netherlands and identified factors associated with its geographic variability.

Methods: We included 130,545 participants in LifeLines, a prospective population-based cohort in the Northern Netherlands. Spatial analysis was performed to identify spatial clusters of eGFR (CKD-EPI), and multivariable logistic regression was used to identify demographic, clinical and environmental factors associated with 99% confidence hot *vs* cold spot clusters.

Results: Significant spatial clustering of high (hot spot) and low (cold spot) eGFR was found independent of age, sex and BSA (Figure). Participants in cold spot area had lower eGFR (95.47±15.50 *vs.* 98.47±14.61 ml/min/1.73 m^2) and lower 24h creatinine clearance (126.75±35.48 *vs.* 130.94±33.72 ml/min) compared to those in hot spot area (p<0.05). In multivariable logistic regression, blood pressure (OR for being in cold spot: 1.01 [95% CI 1.00-1.01]), BMI (1.03[1.03-1.04]), serum potassium (0.38[0.34-0.43]), diuretics use (0.73[0.60-0.90]), education level (1.10[1.05-1.15]) and urbanity (2.77[2.66-2.88]) were all independently associated with spatial distribution of renal function (model R^2=0.301). Subanalysis in 6,535 individuals showed that PM10 (3.67[3.07-4.39]), PM2.5 (5.02[3.90-6.47]), NO_2 (1.11[1.07-1.15]) were independently associated with renal function distribution, respectively.

Conclusions: Intraregional clustering of renal function was observed in the Northern Netherlands; determinants included blood pressure, BMI, serum potassium, diuretics use, education level, urbanity, and air pollution.

TH-PO1064

Incidence of CKD Stages 1-5 in Iceland

Arnar J. Jonsson,[2,3] Sigrun H. Lund,[1] Runolfur Palsson,[2,1] Olafur S. Indridason.[2] *[1]University of Iceland, Reykjavík, Iceland; [2]Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland; [3]University of Iceland, Reykjavik, Iceland.*

Background: Chronic kidney disease (CKD) is a major public health problem with a prevalence in the range of 5-10%, but its incidence is less clear due to lack of longitudinal data. The aim of this study was to estimate the incidence of CKD stages 1-5 based on serum creatinine (SCr) measurements, albuminuria and other markers of kidney damage.

Methods: In this retrospective study from 2008 to 2016, we obtained all standardized SCr and urine protein measurements from every clinical laboratory in Iceland. Information on age, sex, kidney-specific diagnoses and co-morbid conditions were also retrieved from nationwide electronic medical records. eGFR was calculated from SCr using the CKD-EPI equation. Incidence of CKD was defined as presence of kidney damage or eGFR <60 mL/min/1.73m^2 for more than 3 months, in individuals without CKD at study entry. Kidney damage was defined as albuminuria or presence of kidney-specific diagnoses including glomerular diseases and structural kidney abnormalities. CKD was staged according to the KDOQI guidelines. Incidence rates were standardized to the EU27 population.

Results: We obtained 2,049,482 SCr values for 213,011 individuals. The median (range) age was 63 (18–109) years; 47% were men. A total of 205,484 did not have evidence of CKD upon study entry, of whom 21,160 developed CKD during the study period. The annual age-standardized incidence of CKD 1–5 per 100,000 was 1,023 in men and 1,323 in women. The annual age-standardized incidence of CKD per 100,000 in men was 117 for stage 1, 153 for stage 2, 514 for stage 3A, 184 for stage 3B, 58 for stage 4 and 16 for stage 5 CKD. In women, the age-standardized incidence of CKD per 100,000 was 198 for stage 1, 141 for stage 2, 678 for stage 3A, 247 for stage 3B, 63 for stage 4 and 12 for stage 5 CKD.

Conclusions: This nationwide Icelandic study comprising SCr values and other markers of kidney damage from the majority of the Icelandic population indicates a CKD incidence of approximately 1% per year, although slightly higher in women than men.

Funding: Government Support - Non-U.S.

TH-PO1065

Association Between CKD and Socioeconomic Status: The Korea National Health and Nutrition Examination Survey 2010-2015

Subin Hwang,[1] Kyung Don Yoo,[2] Hyo Jin Kim,[2] Ji In Park,[3] Ho seok Koo.[1] *[1]Department of Internal medicine, Inje University Seoul Paik Hospital, Inje University School of Medicine, Seoul, Republic of Korea; [2]Division of Nephrology, Department of Internal Medicine, Dongguk University College of Medicine, Gyeongju, Republic of Korea; [3]Department of Internal Medicine, Kangwon National University Hospital, Chuncheon, Republic of Korea.*

Background: The prevalence of chronic kidney disease (CKD) has been increasing. CKD affects in the patients' aspects regarding economic, social and emotional status. However, few recent studies dissecting the socioeconomic characteristics focused on CKD patients. We examined associations of CKD with annual income levels, education, smoking and alcohol consumption status, and emotional status independent of age and sex.

Methods: We performed a cross-sectional study of 23,701 participants with CKD, using data from the Korea National Health and Nutrition Examination Survey (KNHANES), obtained from 2010 to 2015. CKD was defined as dipstick positive proteinuria or estimated glomerular filtration rate<60mL/min/1.73m^2. The same number of participants was propensity score matched by age and sex (each group n=1,952). Clinical and socioeconomic characteristics of two groups were analyzed.

Results: For participants with CKD versus without CKD, the estimated prevalence of hypertension and diabetes was 41.8% versus 32.4% and 24.3% versus 13.6%, respectively (each P<0.001); from the lowest to the highest, the income quartiles were 26.1%, 24.7%, 25.2%, 24.0% versus 22.6% 24.4% 26.0%, 27.0%, respectively (P=0.038). The Education level was lower in patients with CKD than in normal subjects. There were more irregular workers in the CKD group. In CKD group, current smoker was higher than non CKD group (26.8% versus 21.8%, P<0.001) but case with no history of alcohol drinking in the past year was also higher (28.3% versus 20.6%, P<0.001). Depressive symptoms for two consecutive weeks and suicidal ideation were higher in CKD group (12.2% versus 8.8%, P<0.001; 9.8% versus 7.2%, P<0.001, respectively). In logistic regression, the risk of CKD was 1.21 (95% CI 1.00-1.46, P=0.393) in lowest quartile of income group, 1.25 (95% CI 1.00-1.56, P=0.049) and 1.11 (95% CI 0.84-1.46, P=0.453), respectively, in the order of the quartiles based on the highest group. After adjusting, the risk of CKD was 1.17 (95% CI 0.97-1.42, P=0.085), 1.24 (95% CI 0.99-1.57, P=0.059) and 1.19 (95% CI 0.89-1.57, P=0.226), respectively.

Conclusions: Patients with CKD are associated with other chronic disease, low annual income, low education level, irregular workers, high smoking rate, and depressive mood contributing substantially to the burden for CKD.

TH-PO1066

Recent Prevalence and Characteristic of CKD Including Diabetic Kidney Disease Among Participants of Nationwide Health Check Program in Japan

Koichi Asahi,[1] Kei Nagai,[2] Ryouya Tsunoda,[2] Kazuhiko Tsuruya,[3] Kunitoshi Iseki,[4] Kunihiro Yamagata.[2] *[1]Department of Chronic Kidney Disease Initiatives, Fukushima Medical University, Fukushima, Japan; [2]Department of Nephrology, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan; [3]Department of Nephrology, Nara Medical University, Kashihara, Japan; [4]Nakamura Clinic, Urasoe, Japan.*

Background: Diabetic kidney disease (DKD) is most important target of intervention for improvement of outcome of chronic kidney disease (CKD). Recent prevalence and characteristic of CKD including DKD among a Japanese general population are not fully elucidated.

Methods: Subjects were residents from 27 of the 47 prefectures in Japan who enrolled in national health insurance and participated in annual health check program including a CKD screening in 2015 (n=1,059,888; age, 40-74 years; male, 42.8%; diabetics [HbA1c≥6.5% or undergoing pharmacotherapy for diabetes], 12.3%). CKD was defined as estimated glomerular filtration rate (eGFR) <60 mL/min/1.73 m^2 or dipstick albuminuria ≥1+. CKD comorbid with diabetics was regarded as DKD. Cross-sectional analysis of the distribution of GFR (G) and albuminuria (A) categories by sex/age group among participants were performed. (A1: <1+, A2: 1+, A3: ≥2+ by dipstick)

Results: The distribution of each G and A categories are summarized in **Table**. Thus, in this screened population, the crude prevalence of CKD was 19.7%, and those with reduced renal function classified between G3-5 accounted for 16.6%. Among diabetics, the crude prevalence of CKD was 27.7% and was higher than in non-diabetics across all age groups with tendency that became noteworthy in younger population. (**Figure 1**) As for the distribution of G and A category among DKD, G3a and A1 were most prevalent in the age groups ≥65 years. (**Figure 2**)

Conclusions: Recent prevalence of G3-5 might slightly increase compared with similar cross-sectional analysis in 2008 (Iseki K, et al. Clin Exp Nephrol 16: 244-249, 2012). The overwhelming majority of aged DKD remain mild to moderate renal dysfunction without albuminuria. Therefore, it is important for screened DKD that strategic allocation of health resources according to age and individual risk would be established.

Funding: Government Support - Non-U.S.

Table Distribution (%) of each GFR-albuminuria (G-A) categories among screened population

	A1	A2	A3
G1	12.1	0.4	0.1

TH-PO1067

Prevalence of CKD in the Punjab, Northern India: A Comparison with the United States

Jennifer L. Bragg-Gresham,[1] Jarnail S. Thakur,[2] Sanjay Jain,[3] Subramaniam Pennathur,[1] Rajiv Saran.[1] *[1]University of Michigan, Ann Arbor, MI; [2]PGIMER, Chandigarh, Chadigarh, India; [3]PGIMER, Chandigarh, India.*

Background: India is witnessing a disturbing growth in non-communicable diseases (NCDs), including CKD. Recently, a WHO STEPS survey was conducted in the state of Punjab in northern India to collect data from the adult population on NCD risk factors (2014-2015). We sought to compare the prevalence of CKD and its risk factors between this large state in northern India and the US.

Methods: Data from 1,928 participants in the Punjab survey and 5,588 in the US (National Health and Nutrition Examination Survey- NHANES, 2013-2014) with complete information on estimated glomerular filtration rate and albuminuria were examined. Both regions used multi-stage stratified sampling designs to collect data representative of the general population. All analyses used sampling weights.

Results: The average age in the Punjab sample of adults (age 20 years+) was significantly lower than the US (39.2 vs. 47.5 years, p<0.0001) and had a higher proportion of males (57.8% vs. 48.1%, p<0.0001). The US had a much higher percentage of high school or higher education and private health insurance coverage (p<0.0001). In the US body size was much larger in terms of height, weight, BMI, and waist circumference. While smoking and obesity were higher in the US, diabetes and hypertension were much more common in Punjab (39.6% vs. 10.7% and 49.5% vs. 39.8%, respectively, p<0.0001). No differences were seen in the prevalence of cardiovascular disease or triglyceride levels, although the US had higher total cholesterol. Significant differences were seen in the prevalence of CKD markers, with lower prevalence of eGFR < 60 ml/min/1.73m^2, but markedly higher albuminuria (see Table).

Conclusions: We report a strikingly high prevalence of albuminuria in the Punjab (with well over a third of the adult population being affected!), and much higher prevalence of both DM and HT compared with the US. In contrast, the prevalence of eGFR <60 was relatively low. These findings need to be further confirmed, and if true have enormous public health and resource implications for a low-middle income country such as India, specifically in the realm of CKD, cardiovascular disease and other NCDs.

Measure	Punjab (2014-2015) Mean (SE) or %	US (2013-2014) Mean (SE) or %	P value
Creatinine (μmol/L)	0.70 (0.01)	0.91 (0.01)	<0.0001
eGFR (mL/min/1.73m^2)	113.9 (1.1)	93.0 (0.6)	<0.0001
eGFR < 60 mL/min/1.73m^2	2.0 %	7.5 %	<0.0001
Albumin: Creatinine ratio [ACR (mg/g; median)]	25.5 (2.5)	7.0 (2.9)	<0.0001
Albuminuria (ACR > 30 mg/g)	47.3 %	10.1 %	<0.0001

TH-PO1068

Targeted Screening for Albuminuria in Diabetes Mellitus: A Strategy Worth Revisiting?

Jennifer L. Bragg-Gresham,[1] Brenda W. Gillespie,[1] William H. Herman,[1] Neil R. Powe,[2] Tanushree Banerjee,[3] Jessica L. Harding,[4] Sharon Saydah,[4] Rajiv Saran.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Priscilla Chan and Mark Zuckerberg San Francisco Gen Hosp & UCSF, San Francisco, CA; [3]San Francisco General Hospital, San Francisco, CA; [4]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: Albuminuria is a risk factor for cardiovascular disease (CVD), kidney disease and their progression. Current guidelines recommend screening all people with diabetes (DM) for albuminuria to identify those at greatest risk. However, only 40% of DM patients currently receive albuminuria screening. We assessed patient characteristics associated with albuminuria in people with DM.

Methods: Associations between individual characteristics (self-reported and biometric) and albuminuria (albumin-to-creatinine ratio of ≥30 mg/g) were assessed among 4,222 individuals with DM (self-reported, or HbA1c > 7%), aged 20+ years, from the National Health and Nutrition Examination Survey (1999-2014), using multivariable survey-weighted logistic regression. We assessed model predictive ability using Harrell's c-statistic.

Results: Mean age was 59 (range 20-85+) years and the prevalence of albuminuria was 30.3% (95% CI: 28.7-31.8%). Significant predictors of albuminuria are shown in the Table below (c-statistic = 0.67, indicating moderate prediction of albuminuria).

Conclusions: In this study several self-reported and biometric characteristics were independently associated with albuminuria and collectively, moderately predictive of albuminuria. Targeted screening of people with DM at high risk for albuminuria may improve albuminuria detection and in turn, may help with prevention or management of CVD and kidney disease.

Population Estimates of Predicted Risk of Kidney Failure Among Individuals with Hypertension in Rural Bangladesh, Pakistan, and Sri Lanka - Health Systems Perspective

Liang Feng, Tazeen H. Jafar. *Duke-NUS Medical School, Singapore, Singapore*.

Background: South Asia is suffering an increasing burden of hypertension, chronic kidney disease (CKD) and end-stage kidney disease (ESKD). We estimated the proportion and number of individuals aged≥40 years with hypertension and CKD carrying a high risk for ESKD in rural Bangladesh, Pakistan, and Sri Lanka.

Methods: We analyzed baseline data from ongoing Control of Blood Pressure and Risk Attenuation (COBRA) study on 2643 hypertensives aged≥40 years recruited via door-to-door sampling in 30 rural communities in Bangladesh, Pakistan, and Sri Lanka. Serum creatinine was measured, and CKD-EPI eGFR was computed. Predicted risk of kidney failure at five years was computed using 4-variable (age, sex, albuminuria, eGFR) Kidney Failure Risk Equation (KFRE) in hypertensives with CKD Stage 3 or worse (eGFR <60 ml/min/1.73 m^2). Country-level population statistics from 2016 World Bank Data were used to project population estimates of these conditions.

Results: See attached table

Conclusions: There is a high burden of CKD progressive to ESKD in hypertensive individuals in rural South Asia. There is noticeable cross-country heterogeneity in the proportion and number of hypertensive individuals with CKD Stage 3 or worse (highest in Sri Lanka), proportion at high risk of ESKD (highest in Pakistan), and the absolute number at high risk of ESKD (highest in Bangladesh). Countries in South Asia, need immediate public health measures to prevent onset and progression of CKD including establishing timely referrals to nephrologists, and accessible renal replacement therapy programs. **Limitations:** KFRE has not been validated for use in South Asian rural health systems. Our population estimates of CKD are limited to individuals with hypertension.

CKD and At-Risk of CKD Registry: CURE-CKD

Radica Z. Alicic. *Providence Medical Research Center, Spokane, WA.*

Background: Most healthcare systems have not been proactively prepared to identify patients with or at-risk of chronic kidney disease (CKD) to improve care and clinical outcomes. The aim of this study was to classify and describe these patients in two large healthcare systems.

Methods: PSJH and UCLA healthcare systems collaboratively formed a registry (CURE-CKD) from their respective electronic health records (EHR). Participants were identified by a diagnosis of CKD or at-risk of CKD (diabetes, hypertension, pre-diabetes) by ICD-9/10 codes, guideline-based clinical criteria, and medication specific to a particular condition from the years 2006-2016.

Results: CURE-CKD includes 2,401,403 individuals. The table shows baseline characteristics by CKD (N=554,051) and at-risk of CKD (N=1,847,352) groups.

Conclusions: Real world, practice-based evidence can be used to classify patients as a platform for strategies to prevent CKD progression and complications as well as incident CKD.

Baclofen Usage in Patients with Diminished Kidney Function

Alia Hasan,[1] Kenar D. Jhaveri,[1] Matthew A. Sparks,[2] John K. Roberts,[2] Niraj R. Kothari,[2] Jamil Ibrahim,[1] Melissa Makar,[2] Syed M. Zaidi,[3] Joel Boggan,[4] Jamie S. Hirsch.[1] *[1]Nephrology, Zucker School of Medicine at Hofstra/Northwell, GREAT NECK, NY; [2]Duke University and Durham VA Medical Centers, Durham, NC; [3]Medical University of the Americas, Briarwood, NY; [4]Durham VA Medical Center, Durham, NC.*

Background: Baclofen, a muscle relaxant, is primarily excreted via the kidneys. As per pharmacy dosing guidelines, it is contraindicated in paients with eGFR <30cc/min and on dialysis.

Methods: We examined all orders in 2017 for baclofen across 15 hospitals in two large health systems. For each order, we determined the dose and frequency ordered and whether a dose was actually administered. Renal function was determined using the CKD-EPI equation based upon the most proximate serum creatinine at the time of the baclofen order. Presence of dialysis was based upon any order for HD or PD placed during the same visit within 7 days prior to baclofen order. The physician notes were then reviewed from the start date of baclofen administration- 2 days after it was discontinued to see if any new neurological symptoms arose (headache, dizziness, weakness, nausea, vomiting, seizures, lethargy, hallucinations, agitation)

Results: Over 2652 unique orders were placed for baclofen in one health system informatics records. 131 orders were in patients with eGFR <30cc/min (4.9%), 93 (71%) resulted in at least one dose administered to the patient. Similar baclofen usage was seen at second institution with 1182 inpatient unique orders with 95 occurring in patients with eGFR <30cc/min (8%). 86% of the orders were NOT PRN orders, while remaining were PRN orders. Muscle spasms and hiccups were the indications for PRN orders. 46% of the patients- females; 58% -white vs 18% AA; 20% patients were ESKD on dialysis; 8% were incident dialysis patients (required initiation of HD this admission). Most baclofen orders were written by internal medicine (84%) services followed by surgical (7%) and others (4%). 80% of the orders were written by either attendings (50%) or residents (50%), and the remaining 20% by NP/PAs. 42% of the orders led to neurological symptoms findings.

Conclusions: Baclofen was ordered in 5-8% of patients with significantly impaired kidney function. Most baclofen orders were standing medications rather than PRN, and were ordered at high doses, increasing the toxicity risk. A significant percentage of the orders were written by internal medicine physicians. This study highlights the need for an urgent education of renal clearance of several medications such as baclofen to prescribing staff & pharmacists.

The Burden of Polypharmacy in Patients with CKD: The GCKD Study

Insa M. Schmidt,[2] Silvia Huebner,[6] Jennifer Nadal,[10] Stephanie I. Titze,[13] Matthias Schmid,[11] Barbara Bärthlein,[8] Georg Schlieper,[12] Thomas Dienemann,[11] Ulla T. Schultheiss,[1] Heike Meiselbach,[7] Anna Kottgen,[1] Jürgen Floege,[3] Martin Busch,[5] Reinhold Kreutz,[9] Jan T. Kielstein,[4] Kai-Uwe Eckardt.[2] *[1]Medical Center - University of Freiburg, Freiburg, Germany; [2]University Medicine-Charite, Berlin, Germany; [3]RWTH University of Aachen, Aachen, Germany; [4]Academic Teaching Hospital Braunschweig, Braunschweig, Germany; [5]University Hospital Jena, Jena, Germany; [6]University Erlangen, Nuremberg, Germany; [7]Nephrology and Hypertension, Erlangen, Germany; [8]Medical Centre for Information and Communication Technology (MIK), University Hospital Erlangen, Erlangen, Germany; [9]Charite-University Medicine Berlin, Berlin, Germany; [10]IMBIE, Bonn, Germany; [11]University of Erlangen-Nuremberg, Erlangen, Germany; [12]MVZ DaVita Karlstraße, Duesseldorf, Germany; [13]KBV, Berlin, Germany*.

Background: Patients with chronic kidney disease (CKD) bear a substantial burden of comorbidities leading to the prescription of multiple medications. However, data on medication use patterns in this population is scarce. This study uses data of a longitudinal, multicentre study in CKD patients to evaluate drug use trajectories as well as the prevalence of polypharmacy and its associated risk factors over 4 years of observation.

Methods: We analyzed data of 5217 patients aged 18– 74 years with an estimated glomerular filtration rate (eGFR) between 30–60 ml/min/1.73m^2 or an eGFR ≥60 and overt proteinuria (>500 mg/d) who participated in the German Chronic Kidney Disease (GCKD) study. Self-reported data on current medication use assessed at baseline (2010-2012) and after 4 years of follow-up were used for this analysis. Prevalence and risk factors associated with polypharmacy (defined as the use of ≥5 drugs/d) as well as initiation or termination of polypharmacy were evaluated using multivariable logistic regression.

Results: The prevalence of polypharmacy at baseline and follow-up was almost 80 % and ranged from 62 % in patients with eGFR >90 ml/min/1.73m^2 to 86 % in those with eGFR 30–45 ml/min/1.73m^2. Patients took on average 7 medications per day (range 0-20), most frequently beta blockers, ACE-inhibitors and statins. In multivariate analysis, female sex and a lower educational level were independently associated with polypharmacy. Increasing CKD stage, age and BMI as well as diabetes mellitus, cardiovascular disease and a history of smoking were significantly associated with both, the prevalence of polypharmacy and the maintenance of polypharmacy over time. Comorbid diabetes mellitus was a significant risk factor for the initiation of polypharmacy in CKD patients (OR 2.46, p=0.003).

Conclusions: This study highlights the medication burden in CKD patients and strongly suggests that further research is needed to address the risks of polypharmacy in this vulnerable population.

TH-PO1073

Opiate and Non-Opiate Analgesic Use and Mortality Among CKD Patients Transitioning to Dialysis

Amy S. You,[1] Elani Streja,[2] Vanessa A. Ravel,[3] John J. Sim,[7] Yoshitsugu Obi,[1] Danh V. Nguyen,[1] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh,[5] Connie Rhee.[6] *[1]University of California, Irvine, Orange, CA; [2]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [3]Harold Simmons Center, University of California at Irvine, Orange, CA; [4]University of Tennessee Health Science Center, Memphis, TN; [5]University of California Irvine, School of Medicine, Orange, CA; [6]University of California Irvine, Huntington Beach, CA; [7]Kaiser Permanente Southern California, Los Angeles, CA*.

Background: Population based studies show there is a high prevalence of chronic kidney disease (CKD) patients suffering from chronic pain. While opiates are frequently prescribed as analgesics, there may be toxic accumulation of metabolites, particularly among those with non-dialysis dependent CKD (NDD-CKD) progressing to end-stage renal disease (ESRD). We thus sought to examine the association of opiate vs. non-opiate analgesic use during the pre-ESRD (prelude) period with post-ESRD mortality risk among NDD-CKD patients transitioning to dialysis.

Methods: We examined a national cohort of US veterans with NDD-CKD who transitioned to dialysis over 2007-14. Among patients who had receipt of prescriptions in the Veterans Affairs (VA) Healthcare System within one year of transitioning to dialysis, we examined the association of pre-ESRD analgesic use (opiate analgesic, non-opiate analgesic, vs. no analgesic use) with post-ESRD all-cause mortality risk using adjusted Cox models.

Results: Among 57,764 patients who met eligibility criteria, pre-ESRD opiate use was associated with higher post-ESRD mortality risk (ref: no analgesic use), whereas non-opiate analgesic use was not associated with higher death risk in expanded case-mix adjusted analyses: HRs (95%CIs) 1.11 (1.08-1.13) and 1.01 (0.98-1.04), respectively. In sensitivity analyses, increasing frequency of opiate prescription in the one-year prelude period was associated with higher post-ESRD mortality risk: (ref: no analgesic use): HRs (95%CIs) 0.99 (0.95-1.02), 1.12 (1.06-1.18), 1.15 (1.07-1.23), 1.20 (1.10-1.31), and 1.31 (1.25-1.37) for 1, 2, 3, 4, and ≥5 prescriptions, respectively.

Conclusions: In NDD-CKD patients transitioning to dialysis, more frequent pre-ESRD opiate use was associated with higher post-ESRD death risk, whereas non-opiate analgesic use was not associated with higher mortality. Further studies are needed to identify non-opiate based interventions for pain management in this population.

Polypharmacy in Older Patients Developing Advanced CKD in 6 European Countries: Results from the EQUAL Study

Samantha J. Hayward,[1] Barnaby D. Hole,[3,1] Rachel Denholm,[3] Polly R. Duncan,[3] Simon D. Fraser,[2] James E. Morris,[2] Rupert A. Payne,[3] Paul J. Roderick,[2] Marie Evans,[7] Maurizio Postorino,[8] Christoph Wanner,[4] Friedo W. Dekker,[6] Kitty J. Jager,[5] Fergus J. Caskey.[1,3] On behalf of the EQUAL Study investigators *[1]North Bristol NHS Trust, Bristol, United Kingdom; [2]University of Southampton, UK, Southampton, United Kingdom; [3]University of Bristol, Bristol, United Kingdom; [4]University Hospital, Wuerzburg, Germany; [5]Academic Medical Center, Amsterdam, Netherlands; [6]Leiden University Medical Center, Leiden, Netherlands; [7]Karolinska Institutet, Stockholm, Sweden; [8]G.O.M Bianchi-Melacrino-Morelli, Reggio Calabria, Italy*.

Background: Polypharmacy is increasing in the general population. We aimed to describe associations with the number of prescribed medications to identify patients who are most likely to experience polypharmacy.

Methods: The EQUAL Study follows patients aged 65+ years from 6 European countries whose eGFR dropped to ≤20 ml/min/1.73m^2 for the first time. Demographic, clinical and medication data were collected at baseline. Univariable and multivariable linear regression were used to determine the association between baseline factors (age, sex, education, eGFR, comorbidity and country) and number of medications.

Results: Recruited patients (n=1647) had a mean age of 76.4 years (SD 6.7) and 65.2% were male. Multimorbidity was common; the mean Charlson Comorbidity Index (CCI) was 7 (SD 1.9). The mean number of medications was 8 (SD 3.6, range 0-21) and 75% of patients were on >5 medications. In the univariable analysis, all age groups except >85 years were on more medications than the reference group (65-70 years). Each additional CCI point was associated with 0.48 additional medication (p<0.001). As education attainment increased, people were on fewer medications. German patients were on 1.72 additional medications and Swedish patients were on 3.68 fewer medications when compared to the UK (both p<0.001). Sex and eGFR had no association with number of medications. After adjusting for country, education and CCI, the number of medications was only associated with age in the most elderly group. Those >85 years were on 1.41 fewer medications compared to those aged 65-70, table 1.

Conclusions: Polypharmacy was common amongst EQUAL recruits, but the relationship with age is complex. Unlike the general population where polypharmacy increases even to the oldest age groups, the oldest EQUAL recruits were on fewer medications. This contrast may reflect de-prescribing.

Table 1. Linear regression of number of medications by age group

Age group (years)	Univariable			Multivariable (country, education)			Multivariable (country, education, CCI)		
	Regression coefficient	P value	95% CI	Regression coefficient	P value	95% CI	Regression coefficient	P value	95% CI

TH-PO1075

Assessing Baseline Medication Use in CKD: An Analysis of the SHARP-ER Study

Min Jun,[1] Louisa Sukkar,[2] Meg J. Jardine,[3] Ben Talbot,[4] Alan Cass,[7] Martin J. Landray,[6] Christina A. Reith,[8] Robert J. Walker,[5] Martin P. Gallagher.[1] SHARP-ER Study Collaborators *[1]The George Institute for Global Health, UNSW Sydney, Newtown, NSW, Australia; [2]The George Institute for Global Health, Sydney, NSW, Australia; [3]The George Institute for Global Health, UNSW, Newtown, NSW, Australia; [4]George Institute, Erskineville, NSW, Australia; [5]University of Otago, Dunedin, New Zealand; [6]University of Oxford, Oxford, United Kingdom; [7]Menzies School of Health Research, Darwin, NT, Australia; [8]CTSU, Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom.*

Background: Medication use of patients with CKD in Australia is accepted as high, but systematic, national data has not been available. The Pharmaceutical Benefits Scheme (PBS), a national program providing medication subsidies in Australia, offers a novel means of medication use pattern assessment in CKD based on routinely collected data. We assessed baseline medication use in CKD patients of the SHARP-ER study using PBS data.

Methods: Australian participants from the SHARP-ER study, a 5-year post-trial (2010-2015) extended follow-up of SHARP participants known to be alive at the end of the trial (study of cholesterol-lowering in CKD) in Australia, New Zealand and Malaysia, were linked to the PBS. Prescription medication dispensation in the year prior to SHARP-ER baseline, defined as the first study visit which occurred 1.5-2 years following the final SHARP visit, were obtained. We examined medication use (receipt of ≥1 prescription) from any of the following medication groups: cardioprotective (blood pressure-lowering, lipid-lowering, glucose-lowering, anticoagulant, antiplatelet, anaemia treatment), anti-infective, immunosuppressant, proton pump inhibitor (PPI) treatment and others.

Results: Of 304 participants, 86 (28.3%) were on maintenance dialysis at baseline. Overall, there were 11,272 unique prescriptions dispensed in the year prior to baseline which included those for cardioprotective (58.4%), anti-infective (9.6%), immunosuppressive (7.6%), PPI (12.6%) treatment and others (11.6%). On average, patients were prescribed 6 different medications (IQR:4-8). The distributions of medication use across the medication groups in the 304 participants were: 92.8%, 68.4%. 25.3%, 53.3% and 54.3%, respectively. The proportion of patients receiving ≥3 medication groups was significantly higher among those on dialysis (76.7% vs. 64.7%;p=0.04) compared with non-dialysis CKD patients.

Conclusions: PBS data in patients with moderate-to-severe CKD suggests a high medication burden primarily directed at cardiovascular risk mitigation. Further longitudinal assessments of cardioprotective and anti-infective medication use according to patient characteristics are needed.

Funding: Government Support - Non-U.S.

Sleeping Pills and Risk of CKD? A Nationwide Population-Based Retrospective Cohort Study

Chen-Yi Liao,[2] Chia-chao Wu.[1] *[1]Tri-Service General Hospital, Taipei, Taiwan; [2]Tri-service general hospital, Taipei city, Taiwan.*

Background: Sleeping disorder has long been connected with chronic kidney disease (CKD). But the correlation between sleeping pills and CKD has not been in-depth exploration. This study aimed to evaluate the potential harm of sleeping pills on the risk for CKD and CKD progression to dialysis-requiring end-stage renal disease (ESRD).

Methods: In a population-based cohort study of 204,176 sleeping pill users within 989,753 individuals, after exclusion criteria (those with sleeping pills use less than 3 months, with acute kidney injury, CKD and ESRD diagnosis before sleeping pills use, with obstructive sleep apnea and non-apnea sleep disorder, with age less than 18 years and gender unkown), a total of 183,321 sleeping pills users were compared to 366,642 individuals without sleeping pills use followed up for 13 years after been diagnosed as CKD (ICD-9-CM). Using propensity score matching, we analyzed the type of sleeping pills related to risk of CKD and CKD progression to ESRD by Cox proportional hazards regression with adjustment for sex, age, and comorbidities.

Results: Sleeping pills use was associated with increased risk for CKD after adjusting underlying comorbidities (aHR 2.002, 95% CI 1.790-2.333, p <0.001). Despite high social economic status (insured premium more than 35,000 Taiwanese dollars) and those with hyperlipidemia, those with sleeping pills use among most comorbidities are correlated with risk of CKD. Persistent use of sleeping pills after CKD also increased the risk of concurrent ESRD (aHR 7.981, 95% CI 5.117-10.986, p <0.001). After subgroup analyzing for sleeping pill use, flurazepam (p=0.198), lorazepam (p=0.051) and triazolam (p=0.125) are the drugs with no significance in correlation to CKD risk increasing.

Conclusions: Sleeping pills use was associated with increased risk of CKD and ESRD. Further studies are warranted to confirm these findings.

TH-PO1077

The Economic Burden of CKD Progression Among Patients with and Without Major Adverse Cardiac Events (MACE) in the US

Tony Okoro,[1] Yong Chen,[1] Linda Casillas,[1] Shan Zheng,[1] Daniel C. Parks,[1] Csaba P. Kovesdy.[2] *[1]GlaxoSmithKline, Collegeville, PA; [2]University of Tennessee Health Science Center, Memphis, TN.*

Background: Little is known about the costs of CKD progression among patients with cardiovascular disease. The objective of this study was to assess the economic burden of CKD progression among CKD patients with and without MACE.

Methods: Optum claims data were used to identify patients with baseline non-dialysis dependent CKD (stages 3a, 3b, 4 and 5) in 2013 using estimated glomerular filtration rate (eGFR) based on the Kidney Disease Outcomes Quality Initiative (KDOQI) diagnosis criteria. Patients were followed through 6/30/2017 to assess CKD progression defined as worsening CKD stage from baseline. Annualized all-cause costs were assessed between patients with and without defined CKD stage progression and then stratified by the presence or absence of follow-up MACE.

Results: 57,597 CKD patients were identified in 2013, among which 35,975, 16,982, 4,340 and 299 had CKD stages 3a, 3b, 4 and 5, respectively. Among those without MACE (n=47,004), mean annualized all-cause costs increased from stage 3a ($8,398) to 5 ($12,711) in those without stage progression and from stage3a ($12,062) to 5 ($79,093) in those with stage progression. Mean annualized all-cause costs among patients with ≥1 MACE (n=10,593) were from $35,924 for stage3a to $42,479 for stage5 without stage progression and from $40,687 (stage 3a) to $97,013 (stage 5) with stage progression. Overall, CKD progression costs for the entire cohort increased from stage3a ($6,010) to stage5 ($66,737) (P for trend < 0.001). The trends were consistent among those with and without MACE.

Conclusions: Progression of CKD increases the economic burden in patients regardless of MACE status but healthcare costs are higher in those with MACE compared to those without MACE. Preventing renal function decline could reduce economic burden seen in patients with advanced CKD stages and MACE.

Prior Military Service Associated with CKD: Analysis of the Behavioral Risk Factor Surveillance System

Ian J. Stewart,[1,2] Eduard Poltavskiy,[1] Jeffrey T. Howard,[3] Lauren Walker,[1] Jud C. Janak.[3] *[1]Clinical Investigation Facility, David Grant USAF Medical Center, Travis AFB, CA; [2]Medicine, Uniformed Services University of the Health Sciences, Bethesda, MD; [3]Department of Defense Joint Trauma System, Fort Sam Houston, TX.*

Background: While military service is associated with health promoting and compromising factors, prior work shows that veterans report poorer overall health and higher prevalence of many health compromising behaviors compared to the civilian population. Although some evidence suggests that veterans may be at higher risk for cardiovascular disease, there is a paucity of evidence regarding other medical conditions, such as chronic kidney disease (CKD). We sought to determine if CKD is more common among veterans by analyzing data from the Centers for Disease Control and Prevention Behavioral Risk Factor Surveillance System (BRFSS).

Methods: We performed a cross-sectional study of BRFSS from 2011 to 2016. The presence of CKD and prior military service were determined by self-report. Standard statistics were used to compare demographic data and health behaviors between groups with and without prior military service. Weighted univariate and multivariable logistic regression analyses were performed to compare the odds of CKD development based on military status. *A priori* subgroup analyses stratified by race were also examined.

Results: Our search yielded a total of 2,861,628 subjects for analysis, 14.8% (n=369,844) of whom had prior military service. Individuals with prior service were more likely to have CKD (3.9% vs 2.6%; p<0.001). On univariate analysis, military service was associated with CKD development [odds ratio (OR) 1.55, 95% confidence interval (CI) 1.50-1.61; p<0.001). While attenuated, this difference remained significant in the multivariable model (OR 1.12, 95% CI 1.07-1.17; p<0.001). On analysis of racial subgroups, white subjects with prior military service were more likely to report CKD compared to those without prior military service (OR 1.15, 95% CI 1.09-1.21; p<0.001) in the multivariable model. No significant difference was observed in black (OR 1.07, 95% CI 0.92-1.25; p=0.40) or Hispanic (OR 1.15, 95% CI 0.93-1.41; p=0.20) subjects.

Conclusions: While differences seem to exist across racial strata, these results from a nationally representative sample support an association between prior military service and CKD. Further research is needed to determine why veterans are at a higher risk for CKD to guide treatment and prevention efforts.

Housing Insecurity and Risk of Kidney Disease in an Urban Population

Tessa K. Novick,[3] Dingfen Han,[3] Alan B. Zonderman,[1] Michele K. Evans,[2] Deidra C. Crews.[3] *[1]Intramural Research Program, NIA, NIH, Baltimore, MD; [2]National Institutes of Health/National Institute on Aging, Baltimore, MD; [3]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Housing insecurity is characterized by high housing costs or unsafe living conditions that prevent general self-care and threaten independence. It is associated with decreased healthcare access, and increased risk for chronic diseases and medical complications. The objective of this study was to examine the association between housing insecurity, incident chronic kidney disease (CKD) and rapid kidney function decline.

Methods: Data from the Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study (Baltimore, MD) was used for this longitudinal analysis. Housing insecurity was defined as answering yes to the question, "Can you afford a suitable home?" at the HANDLS wave 3 visit. We used multivariable logistic regression to compare risk of rapid kidney function decline (loss of > 5ml/min/1.73m^2 eGFR per year over a median of 3.5 years), incident reduced eGFR (< 60 ml/min/1.73m^2) and incident albuminuria (albumin-creatinine ratio [ACR] > 30mg/g), between participants with and without housing insecurity.

Results: Of the 1354 HANDLS participants included, mean age was 48 years, 40% were male and 57% were African American. A total of 443 (32.7%) were housing insecure. After a median of 3.5 years follow up, rapid kidney function decline, incident reduced eGFR and incident albuminuria occurred in 213 (15.7%), 68 (5.2%) and 80 (6.6%) participants respectively. After multivariable adjustment, housing insecurity was associated with increased odds of incident albuminuria but there were no statistically significant associations between housing insecurity and rapid kidney function decline or incident reduced kidney function (**Table**).

Conclusions: Housing insecurity was associated with increased risk for incident albuminuria in an urban population. The prevalence of housing insecurity among persons with CKD and its impact on kidney outcomes is worthy of further study.

Funding: Other NIH Support - National Institute on Aging

Table. Logistic regression results. Odds ratios (OR) for rapid eGFR decline, incident eGFR < 60 ml/min/1.73m^2, and incident ACR >30mg/g for those with versus without housing insecurity.

	Rapid eGFR Decline			Incident Reduced eGFR			Incident Albuminuria		
Model	N	OR	95% CI	N*	OR	95% CI	N**	OR	95% CI
Model 1	1354	1.23	0.91, 1.67	1308	0.67	0.38, 1.18	1206	1.99	1.26, 3.14
Model 2	1324	1.25	0.90, 1.72	1280	0.86	0.44, 1.67	1178	1.83	1.08, 3.09

Model 1: unadjusted.

Model 2: adjusted for age at enrollment, sex, race, poverty level, baseline eGFR, albumin-creatinine-ratio, systolic blood pressure and diabetes.

*Excluded individuals with eGFR < 60ml/min/1.73m^2 at baseline..

**Excluded individuals with ACR >30mg/g at baseline.

Association Between Religiosity and Risk of End-Stage Kidney Disease (ESKD) Among Blacks and Whites in the Southeastern United States

Devika Nair,[1] Kerri L. Cavanaugh,[1] Ken Wallston,[1] Aihua Bian,[2] Thomas G. Stewart,[1] William J. Blot,[1] Talat Alp Ikizler,[1] Loren Lipworth.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University, Nashville, TN.*

Background: Religiosity is associated with improved outcomes in chronic illnesses via healthy behaviors and is prevalent among blacks as a means to cope with health-related stress. No study of religiosity in kidney disease has examined its association with objective measures of physical health such as progression to ESKD.

Methods: The Southern Community Cohort Study is a large prospective cohort of low socioeconomic status blacks and whites in the southeastern U.S. Using a case-cohort design, we examined the association between religiosity and ESKD among 737 incident ESKD cases ascertained by USRDS linkage and a probability sampled subcohort (n=4,238). Religiosity was recorded at enrollment via three self-reported items: frequency of church service attendance; degree of spirituality; and degree of comfort from religion. We constructed Cox regression models, accounting for sampling weights, of time to ESKD in relation to each religiosity item, and adjusted for demographic, psychosocial (social support, depressive symptoms), and clinical variables (including diabetes, hypertension, estimated glomerular filtration rate). Interaction between each religiosity item and race was statistically significant (p<0.01).

Results: Overall, 24% of blacks, compared to 18% of whites, reported the highest frequency of service attendance (>once/week); 57% and 72% of blacks reported very high spirituality and high degree of comfort from religion, respectively, compared to 51% and 56% of whites. Among blacks, hazard ratios (HR) and 95% confidence intervals (CI) for ESKD associated with the highest vs. lowest categories of service attendance, spirituality, and comfort from religion were 0.74 (0.57-0.97), 0.66 (0.54 to 0.80), and 0.23 (0.15-0.36), respectively. Among whites, the corresponding estimates were 0.28 (0.16-0.50), 1.08 (0.66-1.77), and 1.11 (0.44-2.78).

Conclusions: Frequent attendance at religious services is associated with a decreased risk for ESKD among socioeconomically-disadvantaged black and white adults. Among blacks, spirituality and comfort from religion are also associated with decreased ESKD risk. Engaging blacks in faith-based community settings may be a culturally-relevant way to facilitate healthy behaviors to decrease kidney disease progression.

CKD Self-Management in Older Adults

Sarah J. Schrauben,[1] Julie A. Wright Nunes,[9] Michael J. Fischer,[2] Anand Srivastava,[3] Thida C. Tan,[4] Ana C. Ricardo,[5] James P. Lash,[5] Myles Wolf,[6] Amanda H. Anderson,[7] Jing Chen,[8] Harold I. Feldman.[7] *[1]Department of Medicine, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]University of Illinois Hospital and Health Sciences Center, Chicago, IL; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]Kaiser Permanente Northern California, Oakland, CA; [5]University of Illinois at Chicago, Chicago, IL; [6]Duke University, Durham, NC; [7]University of Pennsylvania, Philadelphia, PA; [8]Tulane School of Medicine, New Orleans, LA; [9]UM Health System, Ann Arbor, MI.*

Background: Chronic kidney disease (CKD) patients are asked to engage in self-management behaviors in order to manage the disease and mitigate its sequelae. However, an examination of self-management behaviors and their association with clinical outcomes in older adults has not been well characterized.

Methods: Data from the Chronic Renal Insufficiency Cohort were analyzed using latent class analysis (LCA) to identify behavior patterns among those <65 and ≥65 years of age. LCA was based on body mass index, diet, physical activity, blood pressure, smoking, and hemoglobin A1c. Logistic regression assessed association of select factors to behavior patterns. Cox proportional hazards models were used to examine association of behavior patterns with cardiovascular events, CKD progression, and death. Results stratified by diabetes.

Results: Three behavior patterns (healthy, obese/sedentary, non-obese/smoking) were identified separately among age groups. Less healthy patterns included those with more depression, lower education, and self-efficacy. In older adults, less healthy patterns were associated with inadequate health literacy, less social support, and physical functioning. Among <65 years, the obese/sedentary pattern had increased hazard of death, CKD progression (diabetics), and cardiovascular events (non-diabetics), and the non-obese/sedentary pattern had an increased hazard of death (diabetics), and cardiovascular events (non-diabetics). Among 65+ years, the obese/sedentary and non-obese/smoking patterns were associated with increased death and CKD progression (non-diabetics), see Table.

Conclusions: Self-management behavior engagement patterns are associated with risk of important outcomes among CKD patients. These patterns may be able to identify high-risk groups and be targeted for aggressive management.

Markers of Modifiable Health Behaviors, Cardiovascular Events, Death, and CKD

Sarah J. Schrauben,[1] Sandra Amaral,[4] Amanda H. Anderson,[3] Harold I. Feldman,[3] Laura M. Dember.[2] *[1]Department of Medicine, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]University of Pennsylvania School of Medicine, Philadelphia, PA; [3]University of Pennsylvania, Philadelphia, PA; [4]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Chronic kidney disease (CKD) guidelines focus on modifiable health behaviors in the effort to decrease the risk of death and atherosclerotic events, both of which are increased in CKD. However, the effectiveness of these recommendations is relatively unknown since they were based largely on general population research. We examined the relationship of markers of modifiable health behaviors and clinical outcomes among those with and without CKD.

Methods: Data pooled from Atherosclerotic Risk in Communities Study, Multi-Ethnic Study of Atherosclerosis, and Cardiovascular Health Study. CKD defined as estimated glomerular filtration rate (eGFR) <60 ml/min/1.73^2. Markers of modifiable behaviors: physical activity, blood pressure, smoking, diet, body mass index, and fasting blood glucose. Multivariable adjusted Cox proportional hazards models estimated risk of death and a composite of atherosclerotic events. Effect modification was explored for age.

Results: Those with CKD (n = 8,542): mean 59.7 yrs, eGFR 54.7; without CKD (n=19,188): mean 60.2 yrs, eGFR 77.3. There was evidence of an interaction by age with behaviors for both outcomes. Results reported by <65 and 65+ yrs (see Table). Overall,

recommended markers of health behaviors were associated with decreased death and atherosclerotic events. Particularly, controlled BP had a stronger association in CKD.

Conclusions: Markers of modifiable behaviors were associated with reduced risk of death and atherosclerotic events in CKD and without CKD. Blood pressure control had a stronger association among those with CKD.

Health Literacy and Rapid Kidney Function Decline

Rekha Kambhampati,[5] Marie Kuczmarski,[1] Mara McAdams-DeMarco,[5] Dingfen Han,[2] Alan B. Zonderman,[3] Michele K. Evans,[4] Deidra C. Crews.[5] *[1]University of Delaware, Newark, DE; [2]Johns Hopkins, Baltimore, MD; [3]Intramural Research Program, NIA, NIH, Baltimore, MD; [4]National Institutes of Health/National Institute on Aging, Baltimore, MD; [5]Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Health literacy is the ability to understand basic health information. Cross-sectional studies have revealed an association between limited health literacy and lower eGFR in those with CKD. The association of health literacy and kidney function over time has not been described, therefore, we conducted a prospective analysis of this question.

Methods: We studied 1,603 Healthy Aging in Neighborhoods of Diversity across the Life Span study participants with preserved kidney function (eGFR ≥ 60 mL/min/1.73 m^2). A Rapid Estimate of Adult Literacy in Medicine test score of ≤ 60 indicated limited health literacy. We used multivariable logistic regression to assess the association of health literacy with rapid kidney function decline (eGFR loss ≥ 3 mL/min/1.73 m^2 per year over median of 5 years).

Results: Participants' mean age was 48 years. The prevalence of limited health literacy was 29.7% (n=476). Participants with limited health literacy were more likely to be male (50.4% vs 37.1%), African American (74.8% vs 52.4%), living in poverty (51.9% vs 31.2%), have less educational attainment (mean 11.3 vs 13.3 years of schooling), and be current smokers (53.1% vs 41.5%) than persons with adequate health literacy (p<0.05 for all). Both literacy groups had similar baseline levels of eGFR, systolic BP, self-reported hypertension, and diabetes. A total of 218 (13.6%) participants had rapid kidney function decline at follow-up. The unadjusted odds of rapid kidney function decline among those with limited health literacy compared to adequate health literacy was 1.20 (95% CI: 0.81-1.77). After adjusting for age, sex, race, poverty status, education, smoking status, BP, and diabetes, there was still no association (OR 0.99, 95% CI: 0.67-1.47). A series of alternate outcomes (rapid eGFR decline of ≥3% decrease per year, eGFR decrease of ≥25% over a median of 5 years, incident eGFR<60, and incident albuminuria) revealed results consistent with the primary outcome.

Conclusions: There was no association between health literacy and various measures of kidney function decline in this cohort. Although previous cross-sectional analyses have shown an association between health literacy and kidney function, this finding was not present in this prospective analysis. Factors other than health literacy may have more influence over early loss of kidney function.

Family Relationships and Self-Reported Outcomes in Patients with Moderate or Advanced CKD: Findings from the French CKD-Renal Epidemiology and Information Network (CKD-REIN) Study
