Case Description: This is a 52-year-old male with a history of bioprosthetic aortic valve replacement (AVR) who presents to the ED with 6 days of bilateral flank pain and hematuria. Physical exam was largely unremarkable including no rashes. Creatinine was 7 mg/dl. Urinalysis was remarkable for gross blood, 100 RBCs, proteinuria and RBCs casts. Imaging of abdomen and pelvis were unremarkable. Autoimmune workup was negative. Urgent hemodialysis (HD) and corticosteroids were started. Kidney biopsy was inconclusive due to inadequate tissue. He was discharged on outpatient HD and a steroid taper. One month later, repeat kidney biopsy showed crescentic segmental necrotizing GN and focal deposits of IgM, C19 and C3. He was readmitted for plasmapheresis and a steroid course and then discharged with maintenance HD. Over the next 2 months, the patient had multiple episodes of fever, but blood cultures were persistently negative. After four months from initial presentation, he presented to the ED with chest pain and fever. He was diagnosed with NSTEMI. Trans-esophageal echocardiogram showed a small mildly calcified echodensity on the bioprosthetic AVR indicating endocarditis and a small echolucent area in the perivalvular region suggestive of an aortic root abscess. The patient subsequently underwent a sternotomy and aortic valve replacement. PCR performed on the vegetation was positive for Bartonella, as well as Bartonella henselae serology was positive for IgG (1/1024) and IgM (> 1/20).

Discussion: The interval development of endocarditis on echocardiogram, positive Bartonella antibodies and PCR suggest the patient developed GN associated with Bartonella endocarditis. Bartonella is a frequent cause of culture negative endocarditis. Immune deposits showing C3 dominance with IgM staining are consistent with chronic infection related GN. This case highlights the importance of ruling out infectious etiologies of GN before starting immunosuppressants. As treating an active infection with immunosuppressive agents can be life threatening.

SA-PO253

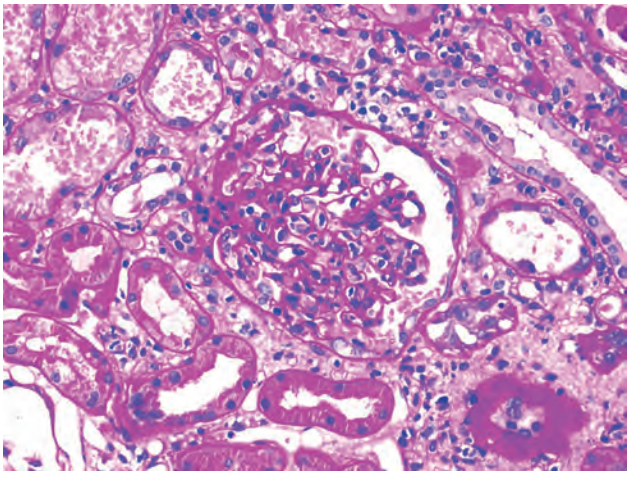
Bartonella Endocarditis Causing Immune Complex Mediated Glomerulonephritis

Hamid Mukhtar,[1] Anubha Mutneja.[2] *[1]Iowa Methodist Medical Center, Des Moines, IA; [2]Iowa Kidney Physicians, PC, Des Moines, IA.*

Introduction: Bartonella is associated with subacute bacterial endocarditis. While vegetations are commonly seen, rarely there are cases of subacute endocarditis showing only valvular thickening. We describe one such case of bartonella endocarditis with immune complex mediated glomerulonephritis.

Case Description: A 63-year-old male with history of aortic bioprosthetic valve presented with fevers, chills and myalgias. On presentation, labs showed pancyctopenia- Hb 6.6 g/dL, ANC 1500 per mm^3 and platelet 39 k/mm^3. Creatinine was 3.8 mg/dL, urinalysis showed proteinuria 2+ along with hematuria. LDH was 293 U/L, haptoglobin 25 mg/dL, peripheral smear did not show any schistocytes. Serological work-up showed low C3 at 71 mg/dL, normal C4, negative ANA, positive c-ANCA (1:256) and positive PR-3 Ab. Bone marrow biopsy showed myeloid hyperplasia, reactive-appearing along with polyclonal expansion of plasma cells 10-20%. Renal biopsy showed endocapillary proliferation with no fibrinoid necrosis or cellular crescents. IF showed near full house immune complex deposition with granular, mesangial staining for IgG (2+), IgM (1+), C3 (2+), C1q (trace), kappa (2-3+) and lambda (1+). Infectious work-up showed positive titers for Bartonella Henselae, both IgG (>1:1024) and IgM (1:512), serum PCR was negative. TEE showed severe stenosis of the prosthetic aortic valve and patient was started on doxycycline for Bartonella endocarditis. Four weeks later, he was noted to have partial recovery in renal function but continued to be dialysis dependent given high fluid gains.

Discussion: Bartonella endocarditis can lead to immune complex mediated glomerulonephritis. Even with absence of characteristic vegetations, presence of positive antibody titers along with hypocomplementemia and immune -complex mediated GN, support the diagnosis of endocarditis. Bartonella PCR even though has high specificity, its sensitivity is only about 40-70%. Timely initiation of appropriate antibiotic therapy may improve renal outcome.



SA-PO254

Triple Hit – Case of IgA nephropathy with Thin Glomerular Basement Disease and Nutcracker Syndrome

Solomiia Savedchuk,[1] Saima Mansuri.[2] *[1]Beaumont Health, Royal Oak, MI; [2]Beaumont Hospital, Royal oak, MI.*

Introduction: Included in the differential of hematuria are IgA nephropathy (IgAN) and thin glomerular basement membrane disease (TGBM). IgAN is the most common cause of idiopathic glomerulonephritis with slow progression to End Stage Renal Disease in up to 50% of patients. IgAN has been reported to be associated with TGBM. Recurrent gross hematuria could also be seen in nutcracker syndrome, the incidence of which is increasing with the use of CT/MR-angiography. We report a patient diagnosed concomitantly with nutcracker syndrome, IgAN, and TGBM

Case Description: We present a case of 33-year-old Caucasian female with hematuria. She reported microscopic hematuria since the age of 7 and strong family history of microscopic hematuria. Five years prior to presentation she started developing intermittent gross hematuria with periods of stress and URTIs. Her past medical history is significant for long-standing abdominal and pelvic pain. She also reported episodes of orthostatic hypotension. She was diagnosed with median arcuate ligament syndrome and underwent MAL release in 2015 without resolution of symptoms. Physical exam was unremarkable. Laboratory and other work up was unremarkable except for 3+ blood with numerous RBC/hpf without evidence of infection on urinalysis. Urine protein:creatinine ratio ranged from 0.62-2.04. She had orthostatic proteinuria. Her renal function was stable. Her prior MRA from 2015 revealed a focal narrowing of left renal vein (LRV) between aorta and SMA. Given this constellation of symptoms, not completely explained by one pathology, possibility of nutcracker syndrome was entertained and CTA was repeated which confirmed the LRV narrowing. However, due to her family history of hematuria, intermittent episodes of gross hematuria and proteinuria, a renal biopsy was performed with findings suggestive of IgAN and TGBM.

Discussion: There are published case reports about the association between IgAN and TGBM as well as IgAN and nutcracker syndrome. However, coexistence of all three diseases has not been reported. There are no distinguishing clinical or laboratory features. The causal relationship and prognosis remains unclear. The presence of multiple glomerular pathology poses a unique diagnostic and management challenge. This, combined with anatomic vascular abnormality, further complicates management.

SA-PO255

A Terrible Triad: A Case of Anti-GBM, Membranous, and Waldenstrom's

Niranjan Gunasekaran,[2] Yashpal S. Kanwar,[1] Eudora Eng.[2] *[1]Northwestern University Medical School, Chicago, IL; [2]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: Anti-GBM disease is a rare disease with a very rapid and destructive course. Much of the knowledge gained has been through case reports and case series. Here, we describe a case of anti-GBM complicated by many factors and the treatment regimen used.

Case Description: A 52y/o man with cryoglobulinemia manifested only by pruritus presented with 12 days of fever, malaise, night sweats and anorexia. Admission creatinine was 1.7, from a baseline 3 days prior of 0.9. Creatinine rapidly worsened and he became oliguric by the 3rd hospital day. Renal biopsy was done on day 4. A dialysis catheter was placed on day 5, anti-GBM resulted at 7.6 and light and IF of renal biopsy showed membranous nephropathy, anti-GBM with necrotizing crescentic GN and severe tubulointerstitial disease. He was pulsed with steroids, started on plasmapheresis,

dialysis, and IV cyclophosphamide. Because of the membranous nephropathy, history of paraproteinemia, increased IgM lambda and lymphadenopathy, bone marrow biopsy was done, showing Waldenstrom's macroglobulinemia. However, due to prior reports that Waldenstrom's is linked to a number of autoimmune diseases including cases of RPGN, he was switched to rituximab, with increasing urine volume up to 2L/day, and decreasing pre-dialysis BUN and creatinine. However, after 6 of 8 cycles of ritumab, anti-GBM titer rebounded to 144. He was re-pulsed with steroids, restarted on cyclophosphamide and underwent daily plasmapheresis for 3 weeks until the GBM titer was zero. Despite preserved urine volume, he remains on hemodialysis.

Discussion: Although there are reports of simultaneous membranous and anti-GBM, or Waldenstrom's and membranous, we could find only one case report of anti-GBM disese and Waldenstrom's, and none with all three. Rituximab, an accepted treatment for Waldenstrom's and membranous nephropathy has been used in a few patients with anti-GBM, mostly those who failed cyclophosphamide. Despite an initial response to therapy, he relapsed after completion of plasmapheresis, while still receiving rituximab. We suspect membranous nephropathy secondary to Waldenstrom's. PLA2R was negative but obtained after plasmapheresis/dialysis. We speculate uncovering of the Goodpasture's epitope, secondary to another underlying process.

SA-PO256

A Case of Concurrent IgA Nephropathy and Microscopic Polyangiitis

Kristine Soltanpour,[1] Tiffany N. Caza,[2] Apurv Khanna.[1] *[1]Nephrology, Upstate University Hospital, Syracuse, NY; [2]SUNY Upstate Medical University, Clay, NY.*

Introduction: IgA nephropathy is the most common cause of glomerulonephritis worldwide. It is rarely seen to concur with anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis. This is a case of a elderly female patient with an overlap of microscopic polyangiitis and IgA nephropathy responsible for acute kidney injury which responded to immunotherapy.

Case Description: An 82 year old lady with a history of hypertension and diabetes mellitus presented to the hospital for evaluation of AKI detected on routine blood work. Her creatinine was 5.3 mg/dL from a baseline of 1.2 mg/dL and she had hematuria for over 1 year. She has a past medical history of multiple autoimmune diseases, including thyroid disease, vitiligo, keratoconjunctivitis sicca, arthritis, and myopathy, and remote pancreatic adenocarcinoma status-post Whipple procedure. Review of systems was positive for fatigue, chills, arthralgias, myalgias, back pain, and dysuria. Physical exam was unremarkable. UA was significant for glycosuria (50 mg/dL), hemoglobinuria (3+), hematuria (34 RBC/hpf), and proteinuria (3.0 grams). Serology shown a positive ANA, positive ANCA with anti-MPO specificity, and hypocomplementemia (C3 48 mg/dL, C4 9 mg/dL). A renal biopsy revealed crescentic glomerulonephritis, glomerular IgA-dominant immune complex deposition, and peritubular capillaritis in the setting of advanced arterio-nephrosclerosis. A severe, active glomerulonephritis with fibrous and fibrocellular crescents was present, concurrent with low grade immune complex deposition, which was IgA-dominant and was restricted to the mesangium. This suggested that the ANCA-associated process was predominant, with concurrent IgA nephropathy. The patient was treated with Cytoxan and pulse steroid therapy. The patient had an acute drop in hemoglobin to 6.5 mg/dL with respiratory distress with increased oxygen requirements, and was found to have an alveolar hemorrhage. The patient was given oxygen, red cell transfusions, and plasmapheresis. There were no additional complications and the patient had improved respiratory and renal function at follow up.

Discussion: Although IgA nephropathy and ANCA-associated vasculitis do not frequently overlap clinically, recognition of concurrence is critical, as these cases are associated with aggressive disease with rapidly progressive glomerulonephritis, yet have good outcomes with immunosuppressive therapy.

SA-PO257

Concomitant Atypical Hemolytic Uremic Syndrome and Lupus Nephritis in a Pregnant Woman

Mohan krishna Bangaru,[1,3] Sulaiman J. Barkho,[1,2] Noreen F. Rossi,[4] Yeohan Song.[5,2] *[1]Nephrology, Wayne State University School of Medicine, Detroit, MI; [2]Detroit Medical Center, St Clair Shores, MI; [3]Detroit Medical Center, Detroit, MI; [4]Wayne State University School of Medicine, Detroit, MI; [5]Wayne State University/Detroit Medical Center, Detroit, MI.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is a rare but devastating condition. It involves uncontrolled activation of alternative complement pathway either due to genetic mutation or autoantibodies leading to dysfunction of regulatory proteins. Various triggering factors have been associated with aHUS including infections, pregnancy, drugs, and systemic lupus erythematosus (SLE). In pregnancy with known SLE, diagnosing aHUS can be delayed as the presentation may mimic a flare of lupus nephritis.

Case Description: A 20-year female diagnosed with lupus nephritis (Class III) diagnosed at the age of 13 was on maintenance therapy with prednisone and mycophenolate mofetil with preserved renal function for 6 years, creatinine 0.6 mg/ml. She stopped taking immunosuppressive medications on her own initiative. Two months later she became pregnant. At 10 weeks gestation, creatinine had increased to 3.3 mg/dl accompanied by severe anemia, thrombocytopenia, high anti-ds DNA titers, and severe hypocomplementemia. Her pregnancy was terminated, and she was placed on hemodialysis and was discharged after being treated as a lupus nephritis flare with prednisone and cyclophosphamide. She was readmitted 2 weeks later with shortness of breath worsening anemia and thrombocytopenia with numerous schistocytes. ADAMTS13 activity level was 100% prompting initiation of plasmapheresis, but without improvement. aHUS panel showed low complement factor H levels with normal complement factors I and B. Renal biopsy showed class V lupus nephritis and thrombotic microangiopathy with focal interstitial fibrosis consistent with aHUS. She was initiated on eculizumab as well as prednisone and mycophenolate mofetil and continues on hemodialysis and this pharmacologic regimen.

Discussion: Diagnosis of aHUS can be difficult and is often delayed in patients as the clinical presentation may mimic lupus nephritis particularly in pregnancy or may be present together with lupus nephritis. Assessment of the alternative complement pathway, early diagnosis and treatment with eculizumab is important in these setting.

SA-PO258

Vancomycin Associated AKI: Think of Thrombotic Microangiopathy

Anshul Bhalla, Matthias Wacker, Nitender Goyal. *Tufts Medical Center, BOSTON, MA.*

Introduction: Vancomycin-induced renal toxicity is common and thought to be due to interstitial nephritis or direct tubular toxicity. Vancomycin can also induce an immunological response, leading to production of drug-dependent anti-platelet antibodies and cause immune-mediated thrombocytopenia. A similar antibody mediated process can be associated with drug-induced thrombotic microangiopathy (TMA) and AKI.

Case Description: A 51 year old woman, who recently completed a 2 week course of Levofloxacin for pneumonia, was diagnosed with a lung abscess and empyema and initiated on Vancomycin, Cefepime and Metronidazole along with a chest tube placement. She remained hemodynamically stable with kidney function at baseline. On hospital day 5, she developed oliguric AKI with supratherapeutic vancomycin levels. She was also noted to be thrombocytopenic. Hemolysis labs were abnormal with LDH 730 and haptoglobin <10. Peripheral smear showed 10-12 schistocytes/hpf. Liver function tests, disseminated intravascular coagulation workup, complement levels, auto-immune and vasculitis serologies were within normal limits. ADAMTS13 activity was markedly low (<5%) and ADAMTS13 inhibitor presence was confirmed with Bethesda assay. Vancomycin-dependent anti-platelet antibody (tested at Blood Center of Wisconsin) was positive. Diagnosis of acquired TTP was made and managed with discontinuation of vancomycin and initiation of plasma exchange for a total of 4 exchanges and prednisone with improvement in platelet count, hemolysis parameters and kidney function. (Table 1).

Discussion: We report a case of acquired TTP with ADAMTS13 inhibitor and vancomycin-dependent antiplatelet antibody. A previous study reported one patient with suspected vancomycin-induced TMA with presence of anti-platelet antibodies but ADAMTS13 activity was not tested. In our case, timing of TMA and AKI after 5 days of vancomycin exposure along with presence of the antibody point towards a vancomycin associated immune mediated process. It is difficult to ascertain if the antiplatelet antibody was detected as the ADAMTS13 inhibitor or if both antibodies co-existed. TMA should be identified as a cause of vancomycin associated AKI.

TABLE 1. LABORATORY PARAMETERS

	Day 1	Day 4	Day 5	Day 6	Day 10 (After PLEX started)	Discharge
Serum Creatinine (mg/dL)	0.6	0.6	3.1	5.2	2.2	0.9
Hemoglobin (g/dL)	10.6	9.8	9.4	7.2	7.9	8.5
Platelet Count X10^3/μL	273	132	23	27	55	286
Vancomycin level μg/mL	15	22.5	60.9	47.2	10.2	2.3

SA-PO259

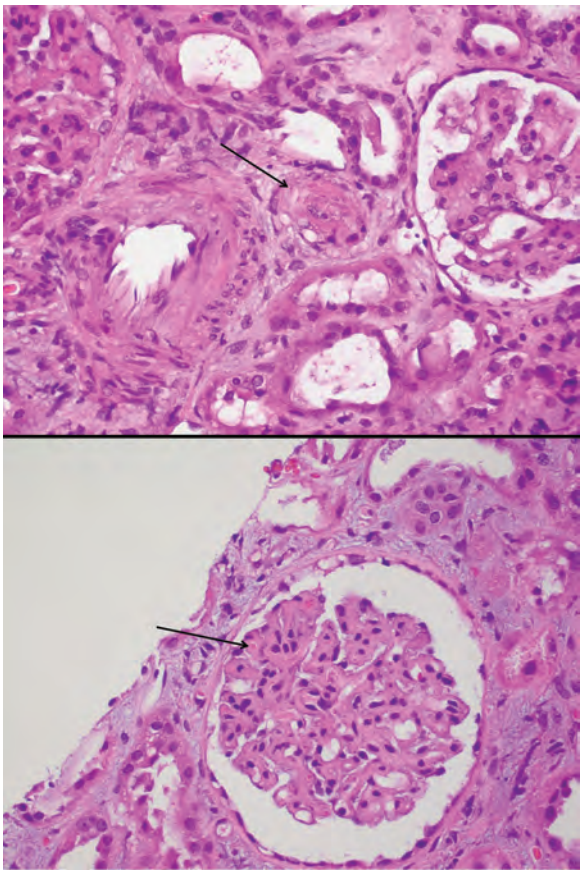
Eculizumab in the Setting of Gemcitabine Induced Thrombotic Microangiopathy

Adam Klein, Renuka Chowdhury. *Methodist Health Systems of Dallas, Dallas, TX.*

Introduction: Thrombotic Microangiopathy (TMA) is a rarely encountered side effect in gemcitabine use. Previous studies have suggested that eculizumab might be an effective treatment in gemcitabine induced TMA. We present a case of gemcitabine induced TMA in a patient who did not improve with supportive care and withdrawal of the offending agent, who was successfully treated with eculizumab.

Case Description: A 68-year-old female with history of hypertension and metastatic breast cancer, previously treated with carboplatin and gemcitabine presented with anemia and fever. The patient was noted to have hemoglobin 4.6g/dL, reticulocyte percentage 4.79, elevated total bilirubin 2.5 mg/dL, evidence of hemolysis (haptoglobin < 20 mg/dL, elevated LDH 2810.0 U/L, and schistocytes on the peripheral smear), and thrombocytopenia (platelet count 83 x 10^3/uL). The patient had initiated treatment with gemcitabine two days before presenting to the Emergency Department. The patient's creatinine on admission was 2.7 mg/dL, previously 0.80 mg/dL. Despite discontinuation of gemcitabine and institution of supportive care, the patient's creatinine continued to rise throughout her hospitalization and she became anuric requiring dialysis. Needle core kidney biopsy demonstrated thrombotic microangiopathy. The patient underwent treatment with eculizumab and had recovery of her kidney function with improvement in her creatinine and urine output.

Discussion: Treatment with eculizumab in gemcitabine induced TMA has shown good results in previous case studies as well as an observational, retrospective, multicentric study previously performed in four French centers. In this report, the use of eculizumab supports the benefit of C5 inhibition for the treatment of gemcitabine induced TMA refractory to supportive care.



SA-PO260

Successful Treatment of Refractory Gemcitabine-Associated Thrombotic Microangiopathy with Eculizumab

Daniil Shimonov,[1] Naomi Friedman,[3] Minesh Khatri.[2] *[1]Internal Medicine, NYU-Winthrop Hospital, Mineola, NY; [2]Nephrology, NYU-Winthrop Hospital, Mineola, NY; [3]Stony Brook School of Medicine, Bronx, NY.*

Introduction: Gemcitabine can lead to thrombotic microangiopathy (TMA) which is characterized by microangiopathic hemolytic anemia (MAHA), thrombocytopenia and AKI. We report a novel treatment approach for a man with pancreatic carcinoma with refractory gemcitabine associated TMA successfully treated with eculizumab, a monoclonal antibody against C5 complement.

Case Description: A 69-year-old man with a history of pancreatic adenocarcinoma treated with gemcitabine and normal baseline renal function (Cr 1.0mg/dl) presented with thrombocytopenia (platelets 31 K/uL), MAHA (schistocytes and LDH 582 IU/L), and AKI (Cr 2.1mg/dl) concerning for Gemcitabine-associated Thrombotic Microangiopathy (GA-TMA), subsequently diagnosed by renal biopsy. Initially, chemotherapy was held and patient was started on high dose glucocorticoids and 20 PLEX treatments, with rituximab added the next month due to ongoing TMA. There was mild improvement in renal function, but hemolysis and thrombocytopenia persisted, prompting implementation of eculizumab a month later. Patient's hematologic parameters improved and kidney function stabilized. In the meantime, chemotherapy was delayed for 5 months, his cancer progressed, and he passed away 7 months after presentation.

Discussion: This case report demonstrated that eculizumab could successfully treat refractory GA-TMA. GA-TMA is a rare condition that carries mortality rates from 50-70%. Discontinuing gemcitabine, initiating steroids, PLEX, dialysis, and rituximab have been standard therapy. Eculizumab has been shown in a few case reports to normalize some or all the parameters of the disorder, indicating that dysregulation of the complement pathway may play a significant role. Our patient did not respond well to steroids, PLEX and rituximab prompting a novel approach with eculizumab, with subsequent significant improvement in the hemolytic parameters and stabilization of renal function. Further research should focus on randomized controlled trials comparing eculizumab with standard therapy for GA-TMA, and potentially as first line therapy to possibly allow for earlier initiation of non-Gemcitabine chemotherapeutic agents. We need an improved understanding of the mechanisms by which certain chemotherapeutic agents induce TMA, and be able to better identify patients that would be most likely to benefit from eculizumab.

SA-PO261

Ideal Clinical Outcome and Potential Cost Savings with Individualized Eculizumab Dosing using Bayesian Modeling in Atypical Hemolytic Uremic Syndrome

Stefanie W. Benoit,[1] Keri A. Drake,[2] Tsuyoshi Fukuda,[3] Bradley P. Dixon.[4] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]UT Southwestern Medical Center, Dallas, TX; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]Children's Hospital of Colorado, Aurora, CO.*

Introduction: Ecullizumab (Ecu) acquisition cost is approximately $7,000 per 300mg vial. There is limited literature regarding individualized Ecu dosing in atypical hemolytic uremic syndrome (aHUS), particularly in pediatric patients and as disease activity varies.

Case Description: A previously healthy 4 year old male presented with acute onset muscle weakness, elevated creatine kinase, and elevated liver enzymes. He subsequently developed anemia, thrombocytopenia, hypertension, and anuric acute kidney injury requiring dialysis. A muscle biopsy revealed microthrombi in skeletal muscle vessels, and a renal biopsy confirmed thrombotic microangiopathy. He showed clinical improvement with Ecu, although he required an increase in dose amount and frequency to maintain clinical stability and Ecu level >100mcg/mL. With increased dosing, he achieved remission with eventually normalized kidney function. Dosing was adjusted based on Ecu levels to maintenance on standard Ecu dosing. Pharmacokinetic (PK) analysis using Bayesian fitting with population PK parameters (Fig.1) now indicates a sufficient Ecu level could be maintained with every 3 week dosing. The cost of the Ecu doses required to suppress his early, severe disease was $84,000. Standard dosing costs $14,000 every 2 weeks; $364,000 per year. Spacing to every 3 weeks would cost $242,200, a savings of $121,800 per year.

Discussion: This report describes an unusual presentation of aHUS with severe multisystem involvement and highlights the potential for improved clinical outcomes and cost savings by individualizing Ecu dosing in aHUS patients.

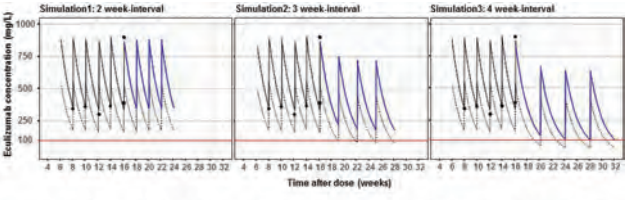


Figure 1: Bayesian Modeling of Ecu Dosing in an aHUS Patient. Dashed lines show the population PK curve in aHUS patients based on mean PK parameters in FDA approval document. Solid lines show this patient's PK profile based on 5 Ecu levels (black circles). Red lines show the recommended concentration of Ecu to control aHUS. Blue lines are simulated PK profiles of this patient with 2, 3 and 4 week-interval dosing.

SA-PO262

Therapeutic Plasma Exchange in Carfilzomib Associated Thrombotic Microangiopathy

Jonida Krate, Ibrahim Qaqish. *Internal Medicine, St. Joseph's Hospital and Medical Center Phoenix, Arizona, Phoenix, AZ.*

Introduction: Thrombotic microangiopathy (TMA) was reported to be associated with second generation proteasome inhibitors. The role of therapeutic plasma exchange(TPE) in management of carfilzomib induced TMA is not clear. Here we present our experience on TPE use in management of carfilzomib induced TMA.

Case Description: 61 year old man with past medical history of congestive heart failure, type 2 diabetes mellitus, hypertension, chronic kidney disease, diagnosed with kappa light chain multiple myeloma in February 2016. He was started on Cybor-D chemotherapy in March 2016. His chemotherapy was interrupted several times due to acute kidney injury (AKI). Subsequently, he progressed and he was transitioned to carfilzomib, revlimid, and dexamethasone combination of chemotherapy in May 2017. Two months after initiation of carfilzomib therapy patient developed markedly elevated BUN and serum creatinine. Patient underwent kidney biopsy, which revealed abundant glomerulosclerosis (8/10 globally sclerotic) and ~ 70% of interstitial fibrosis and tubular atrophy. Some non-sclerotic glomeruli showed global capillary thrombosis and necrosis. Patient underwent eight sessions of TPE. Lactate dehydrogenase improved after termination of carfilzomib and continued to improve after TPE. Haptoglobin improved after TPE. Platelet count did improve despite termination of chemotherapy and TPE. Unfortunately, because of severity of AKI patient never regained kidney function and required chronic hemodialysis.

Discussion: We presented case of TMA after initiation of carfilzomib for the treatment of multiple myeloma. Patient did not have ADAMTS 31 deficiency. TPE was held to assess for platelet response, which remained stable then increased and therefore TPE was not resumed. In our patient platelete transfusion given prior to renal biopsy confounded interpretation of total TPE. Given the pattern of minimal hematological and clinical response in our patient to TPE compared to the response in patients with idiopathic TTP, we speculate the optimum role of TPE is minimal or not established in Carfilzomib associated TMA. Discontinuation of the drug remains an important management strategy and the role of TPE is still not categorized by ASFA. Clinicians should be aware of rare association between carfilzomib underlying TMA. Discontinuation of the drug, future drug avoidance and supportive care is the corner stone of management.

SA-PO263

Reversible Dialysis Dependent AKI Due to Carfilzomib Induced Thrombotic Microangiopathy (TMA)

Abhishek J. Patel,[2] Aravind Dasari,[2] Hieu Q. Vo,[2] Barry M. Wall.[1,2] University of Tennessee Health Science Center, Memphis, TN, United States [1]*Veterans Affairs Medical Center, Memphis, TN;* [2]*Nephrology, University of Tennessee Health Science Center, Memphis, TN.*

Introduction: Renal complications of carfilzomib, a second-generation proteasome inhibitor used in treatment of relapsed or refractory multiple myeloma, are typically mild and reversible. However, severe acute kidney injury (AKI) related to TMA and tumor lysis have also been reported. We report an additional patient with kidney biopsy confirmed TMA leading to dialysis dependent AKI that fully resolved after discontinuing caflizomib without the use of immunosuppressive medications or plasmapheresis.

Case Description: 56 year old male with stage 1 IgG kappa light chain restricted multiple myeloma with 50-60% of bone marrow replacement with CD138+ plasma cells with t(11;14) translocation received intial treatment with bortezomib, lenalidomide and dexamethasone with minimal response. He was then treated with one cycle of carfilzomib (20 mg/m^2 on 2 consecutive days), lenalidomide, and dexamethasone. He subsequently presented two weeks later with non-oliguric AKI with a serum creatinine of 10.3 mg/dL (pre-treatment creatinine, 0.9 mg/dl). He was euvolemic by clinical examination and no kidney abnormalities were noted on kidney ultrasound. Additional laboratory included: uric acid 11.7mg/dL, serum calcium 7.5mg/dL, phosphorus 4.8mg/dL and potassium 3.6mg/dL. Hemoglobin had decreased from 13.8 to 9.8 g/dl, platelet count decreased from 384 to 72 K/ul, and schistocytes were noted on the peripheral blood smear. AKI worsened despite discontinuing carfilzomib and the administration of intravenous fluids and rasburicase. Temporary hemodialysis support was required for one week. Renal biopsy revealed thrombotic microangiopathy, acute tubular injury, moderate arteriosclerosis and arteriolar hyalinosis. AKI rapidly resolved with follow up serum creatinine of 1.1 mg/dL. Similarly, hemoglobin and plateltet count gradually returned to pre- treatment values. He is currently being evaluated for autologous stem cell transplantation and has not been rechallenged with carfilzomib..

Discussion: Our patient had renal biopsy proven TMA following a single cycle of carfilzomib treatment that resulted in dialysis dependent non-oliguric AKI with associated microangiopathic anemia and thrombocytopenia. AKI was reversible after discontinuing carflizomab without concomitant use of plasmapheresis or immunosuppressive medications, consistent with direct drug induced toxicity.

SA-PO264

A Rare Case of Methamphetamine Induced Thrombotic Microangiopathy and End Stage Renal Failure

Kothai divya Guruswamy sangameswaran, Krishna M. Baradhi. OU Tulsa *OU -Tulsa School of Community Medicine, Tulsa, OK.*

Introduction: Recreational drug abuse is not only a major public health problem with significant morbidity and mortality, but also one of the frequently neglected risk factors for End Stage Renal Disease (ESRD). Amongst these inconsiderate risk factors, methamphetamine induced Thrombotic Microangiopathy (TMA) and ESRD is indeed a rare entity. We report a rare case of ESRD from methamphetamine induced TMA and stress the importance of recognizing methamphetamine as a cause of ESRD.

Case Description: A 26 year-old-man with history of drug abuse presented with fatigue, dyspnea and epistaxis for two weeks. Exam revealed a pale young man with tachycardia, pedal edema and a BP of 210/124 mm of Hg. Labs showed hemoglobin of 5gm/dl with mild thrombocytopenia and renal failure with BUN of 171mg/dl and creatinine of 20mg/dl. Peripheral smear revealed schistocytes, consistent with microangiopathic hemolysis, yet did not favor hemolytic uremic syndrome-thrombotic thrombocytopenic purpura due to minimally elevated LDH, normal haptoglobin, bilirubin and ADAMTS13 activity. Serological work up for vasculitis was unrevealing and a renal biopsy was done which showed thrombotic microangiopathic injury and advanced glomerulosclerosis. He was declared ESRD based on biopsy and remained dialysis-dependent. TMA induced ESRD is doubtlessly from methamphetamine abuse, as the patient admitted to using crystal methamphetamine on a weekly basis for many years with several episodes of hypertensive surges as evident by severe left ventricular hypertrophy on echocardiogram.

Discussion: Methamphetamine is a psycho-stimulant, sympathomimetic drug, well known to cause systemic hypertension and cardiomyopathy. A recent study from South Africa showed malignant hypertension in 44.7% and chronic kidney disease in 95.7% of methamphetamine users. Our case report illustrates the need for detailed drug history and considering methamphetamine as a potential cause of TMA and ESRD, as early identification and cessation of drug abuse could prevent irreversible renal damage.

SA-PO265

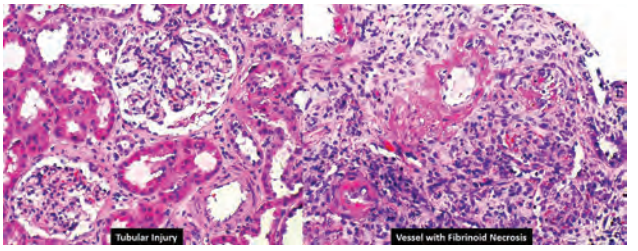
A Curious Case of Methamphetamine Induced Renal Pseudo-Vasculitis

Gajapathiraju Chamarthi, Justin Lee Loy, Abhilash Koratala. *University of Flroida, Gainesville, FL.*

Introduction: Methamphetamine is a synthetic-drug that is widely abused by young adults and can have deleterious effects on many organ systems including the kidney. Hyponatremia and AKI from non-traumatic rhabdomyolysis are the most common manifestations pertinent to renal system. Herein, we present a case of methamphetamine ingestion mimicking systemic vasculitis in a patient with multiorgan failure.

Case Description: A 38-year-old man who was otherwise healthy except for chronic back pain presented to the local hospital with weakness and epigastric pain. Examination revealed several skin pustules on his legs, which he attributed to insect bites. His urine toxicology screen was positive for amphetamines and serum creatinine (Scr) was 1.4mg/dL. He soon developed sepsis with respiratory failure requiring mechanical ventilation and AKI requiring dialysis and transferred to our facility for further management. On exam, petechial and purpuric lesions were noted on legs and laboratory data including serum CPK, liver enzymes, IgG4 were within normal limits. Viral Hepatitis and HIV testing, vasculitic work up including ANA, ANCA, cryoglobulin was negative. Skin biopsy was not suggestive of vasculitis but could not yield specific etiology. Renal biopsy was consistent with ATN but also showed medium vessel vasculitis (Figure) which can be associated with illicit drug use such as cocaine and methamphetamine. Patient had renal recovery and was dialysis independent at discharge.

Discussion: Amphetamine derivatives are widely abused drugs for their euphoric, stimulant and hallucinogen properties. Hyponatremia and AKI are frequent complications of their use. AKI typically results from rhabdomyolysis. Other rare manifestations such as isolated proximal tubular dysfunction, obstructive nephropathy from bladder neck dysfunction and seronegative necrotizing vasculitis as in our patient have been reported and Nephrologists have to be familiar with these for appropriate management.



SA-PO266

Resistant Hypertension in Dialysis Patients: Pitfalls of Biochemical Testing

Gajapathiraju Chamarthi,[1] Justin Lee Loy,[2] A. A. Ejaz,[2] Rajesh Mohandas.[2] [1]*University of Flroida, Gainesville, FL;* [2]*University of Florida Gainesville, Gainesville, FL.*

Introduction: Hypertension is common in patents with End Stage Renal Disease (ESRD). Fluid retention and excess sympathetic activity are thought to be responsible for high blood pressures in majority of these patients. Rarely, pheochromocytomas have been reported in patients with ESRD. Non-specific elevation of catecholamine levels in renal failure, inability to check urinary catecholamine levels and interference from medications can make diagnosis challenging. We present a patient with ESRD with severely elevated catecholamine levels.

Case Description: 68-year-old female with ESRD on hemodialysis presented with a BP of 260/80 mm Hg and pulmonary edema. She was started on a Nicardipine infusion and underwent dialysis with aggressive ultrafiltration. She was restarted on her usual antihypertensive medications (Amlodipine 10 mg daily, Clonidine 0.3mg TID, Hydralazine 100mg TID, Labetalol 300mg TID, Losartan 100 mg daily and Prazosin 2mg bid). A work up for secondary causes of hypertension revealed markedly elevated norepinephrine levels of 7332 pg/ml (ref range 80- 520) and plasma normetanephrine at 3.26 nmol/L (ref range 0-0.89). Epinephrine and metanephrine levels were within normal limits. Patient underwent an extensive imaging for occult pheochromocytoma including CT scan of abdomen and pelvis, 123 MIBG scan, Octreotide scan and whole body PET scan, all of which failed to reveal any evidence of a catecholamine secreting tumor.

Discussion: Catecholamine levels are often elevated in patients with ESRD and normal levels in chronic kidney disease or ESRD have not been established. Our patient had levels of norepinephrine that were 14 fold higher than upper limit of the reference range. She was on Mirtazapine, Prazosin and Labetalol, all of which can specifically increase norepinephrine levels. Normal metanephrine levels, absence of tumors on imaging, improvement in blood pressures with ultrafiltration and a downward trend in norepinephrine levels suggested the elevated norepinephrine levels were due to a combination of medications and ESRD. We conclude that one should be cautious in interpreting biochemical tests for pheochromocytoma in patients with kidney disease, particularly those on dialysis. Elevations in metanephrines might be more specific for pheochromocytoma. More studies are necessary to establish cut offs for catecholamine levels in dialysis patients.

SA-PO267

Holy "Molly!" An Intriguing Case of AKI

Gajapathiraju Chamarthi, Justin Lee Loy, Abhilash Koratala. *University of Flroida, Gainesville, FL.*

Introduction: Molly is the slang for 'molecular', which refers to the powder or crystal form of the synthetic psychoactive drug MDMA (3,4-methylenedioxymethamphetamine). Molly is often mixed with other drugs and substances such as bath salts (e.g. 4-methyl-apyrrolidinohexanophenone) and is not safe. While urine toxicology can detect amphetamines, current drug screens do not typically detect bath salts and other contaminants. MDMA can lead to severe hyperthermia, hyponatremia, liver, kidney and cardiovascular failure. Herein, we present a case of severe AKI in a Molly abuser.

Case Description: A 41-year-old man with a history of polysubstance abuse including alcohol, cocaine and molly presented to our institution with abdominal pain and vomiting. He has been taking molly prior to presentation and urine drug screen was positive for amphetamine. Labs showed AKI with a serum creatinine of 9 mg/dL (baseline 0.9), hyperkalemia (K 7 mmol/L) and hyperphosphatemia (P 18 mg/dL). Serum sodium

was relatively normal (134 mmol/L). Serum creatine kinase (CPK) was elevated at 6814 U/L (Ref: 5-180). UA showed large blood on dipstick with 5 RBC/hpf consistent with myoglobinuria. Imaging excluded obstructive nephropathy and he was treated with intravenous hydration and supportive care. His renal function improved gradually over next several days.

Discussion: AKI associated with MDMA is primarily attributable to rhabdomyolysis, which could result from direct myocyte toxicity or seizures from symptomatic hyponatremia. Excessive physical exertion in the setting of inadequate water intake and impaired thermoregulation often complicates the picture. Direct tubulotoxicity, necrotizing vasculitis and malignant hypertension are other mechanisms of AKI. Rarely, it can cause bladder neck dysfunction leading to obstructive nephropathy. In addition, bath salts that contaminate molly can cause ATN and rhabdomyolysis. In addition to tubular toxicity, our patient could have had more severe rhabdomyolysis prior to presentation leading to pigment-induced AKI though the presentation CPK was not very high. It is also not certain whether his kidney injury is a result of MDMA alone or related to bath salts/other contaminants as well. Clinicians need to consider all these possibilities while evaluating patients with AKI and suspected drug abuse. History may not be always clear, especially in obtunded patients.

SA-PO268

Spontaneous Renal Artery Dissection: A Diagnostic and Therapeutic Challenge

Gajapathiraju Chamarthi, Abhilash Koratala, Justin Lee Loy, Rupam Ruchi. *University of Florida Gainesville, Gainesville, FL.*

Introduction: Spontaneous renal artery dissection (SRD) is a rare and under-recognized entity and is distinct from traumatic or iatrogenic causes of renal artery dissection. Herein, we present a case of SRD that mimicked a urinary tract infection (UTI).

Case Description: A 44-year-old woman presented to our institution for worsening right flank pain associated with fever and chills. 5 days prior to presentation, she was empirically treated at a local facility for UTI with an oral antibiotic, which failed to relieve her symptoms. Laboratory data was significant for neutrophil-predominant leukocytosis and elevated lactate dehydrogenase. Because of the persistent flank pain, a CTA of the abdomen was obtained which showed right renal infarct and irregularity of the lumen of the renal artery, concerning for focal dissection. Vasculitis work up was negative. Angiogram demonstrated proximal dissection with distal aneurysmal dilatation affecting the superior segmental branch of the right renal artery. Several branches arising from the abnormal vessel appeared to perfuse viable renal parenchyma, mostly within the superior pole and embolization was not performed due to the risk of infarcting such a large volume of tissue, possibly leading to abscess formation. The patient was treated conservatively with medical management for pain and hypertension and was discharged in a stable condition.

Discussion: SRD is most commonly encountered in middle aged men and has been associated with malignant hypertension, fibromuscular dysplasia, collagen vascular diseases, cocaine use and extracorporeal shock wave lithotripsy in the literature. The symptoms can be nonspecific and often mimic other conditions such as pyelonephritis and nephrolithiasis. Conservative management includes hypertension and pain control with or without systemic anticoagulation. Endovascular interventions and surgical revascularization are reserved for patients with hemodynamically significant occlusions of the arteries, uncontrolled renovascular hypertension and worsening renal function or progression of dissection.

SA-PO269

Methimazole-Induced Severe Anti-Neutrophil Cytoplasmic Antibody Associated Vasculitis with Rapidly Progressing Glomerulonephritis

Neelofar R. Khan,[4] Rimda Wanchoo,[4] Vanesa Bijol,[1] Kenar D. Jhaveri,[2] Nupur N. Uppal.[3] *[1]Northwell Health Hofstra University, Lake Success, NY; [2]Northwell Health Sys, Great Neck, NY; [3]Hofstra Northwell School of Medicine, Great Neck, NY; [4]Zucker School of Medicine at Hofstra Northwell, GREAT NECK, NY.*

Introduction: Vasculitis associated with anti-neutrophil cytoplasmic antibodies (ANCA) is a rare complication of treatment with antithyroid medications. It has been mainly described in patients treated with Propylthiouracil(PTU), and rarely with use of Methimazole(MMI). While most reported cases of MMI induced ANCA associated vasculitis(AAV) were diagnosed on skin or lung pathology, we report a unique case of severe, systemic, kidney biopsy proven drug induced AAV with MMI.

Case Description: A 64-year-old Guyanese woman with primary hyperthyroidism presented with abdominal pain and diarrhea. On admission, herserum creatinine(Scr) was 2.8mg/dl (baseline 1.2mg/dl). She denied use of NSAIDs, PPIs or herbal medications however reported to have completed course of clarithromycin for a respiratory infection 2 weeks ago. Her only home medication at the time of presentation was methimazole. During the course of her hospitalization, she developed gross hematuria with worsening AKI. UA showed 173 RBCs, 13 WBCs and spot urine protein to creatinine ratio of 1.2. Serological work up was positive for Anti-Nuclear Antibody (ANA 1;640), p(perinuclar)-ANCA (1:320) and Myeloperoxidase antibody (MPO 109.4). C(cytoplasmic)-ANCA, proteinase 3(PR3) and double stranded DNA antibodies were negative. She was initiated on pulse dose corticosteroids and underwent kidney biopsy which showed 25 glomeruli, of which 2 were globally sclerosed, 4 had cellular crescents with all arteries revealing extensive necrosis and signs of small vessel vasculitis with minimal chronic changes and no tubular changes; Pathology findings were consistent with pauci immune vasculitis/ AAV, thought to be drug induced. Methimazole was held. Few days later, she developed hemoptysis and was initiated on plasmapheresis for concern of pulmonary alveolar hemorrhage. She eventually became oliguric requiring hemodialysis. Worsening of her vasculitis lead to her demise despite aggressive medical management.

Discussion: The reported incidence of MPO ANCA Vasculitis for PTU is 39.2 times higher compared to that with MMI. Although uncommon, MMI can lead to AAV. Nephrologists, rheumatologists and endocrinologists should all be aware of this rare, life threatening complication of MMI.

SA-PO270

A Case of Golimumab-Associated Pauci-Immune Glomerulonephritis

Sandhira Wijayaratne,[2] Nikhil Agrawal,[1] Philip S. Kemp,[1] Joseph Kupferman.[1] *[1]Beth Israel Deaconess Medical Center, Brookline, MA; [2]Harvard Medical School, Boston, MA.*

Introduction: Golimumab is a monoclonal TNF-alpha inhibitor approved for rheumatoid arthritis (RA), ulcerative colitis (UC), psoriatic arthritis, and ankylosing spondylitis. It may be preferred in some patients due to easier dosing (monthly subQ injections) and ability to control symptoms in UC. Clinical trials studying golimumab have not reported glomerulonephritis as an adverse event, though there is at least one report of golimumab accelerating preexisting lupus nephritis. To our knowledge, there have been no reports of golimumab-associated, new-onset glomerulonephritis. Here, we present a patient with RA on golimumab who developed a pauci-immune crescentic glomerulonephritis with no signs of systemic vasculitis.

Case Description: 87-year-old male with hypertension and rheumatoid arthritis referred by his rheumatologist with a creatinine of 2.6 mg/dL. He had a baseline creatinine of 1.29 mg/dL and 0.9 mg/dL, four months and nine months prior to his presentation, respectively. His RA was previously managed by steroids but was switched four years ago to monthly golimumab, last dose was 2 months ago. Urinalysis showed 3+ protein, negative leukocytes, 80-100 RBC/hpf, and 5-7 acanthocytes/hpf. Labs including C3, C4, ANA, ANCA, dsDNA, anti-histone antibody, cryoglobulin, Hepatitis B and C serologies, SPEP, UPEP were ordered; all eventually came back negative. Renal biopsy showed 18 of the 36 glomeruli had extracapillary proliferation, 14 of which had evidence of fibrinoid necrosis or cellular crescents. Findings were consistent with a diagnosis of pauci-immune crescentic glomerulonephritis. Over the course of the patient's 5-day hospital stay, his creatinine was stable with a range of 2.5-2.8 mg/dL. He was discharged on 60 mg prednisone daily, golimumab was not restarted.

Discussion: This case represents the first report of crescentic pauci-immune glomerulonephritis associated with golimumab. With increasing use of TNF-alpha inhibitors, there lies a risk of increased episodes of glomerulonephritis associated with these medications. As with this patient, renal limited vasculitis may not appear until years into treatment, and could present with aggressive features. Patients should be monitored for glomerulonephritis and screening protocols with serial urinalysis and serum creatinine may be necessary. Long term data may help define relative risk with individual medications.

SA-PO271

PR3 Positive Crescentic Glomerulonephritis in Pembrolizumab Treated Metastatic Melanoma

Maria Joana A. Thomas,[1] Andrew I. Chin.[2] *[1]University of California Davis Medical Center, Sacramento, CA; [2]University of California Davis, Sacramento, CA.*

Introduction: Immune checkpoint blockade has demonstrated to be effective for treating various cancers including melanomas. Pembrolizumab, a monoclonal antibody that targets the programmed cell death (PD-1) receptor of lymphocytes, enhances immunologic destruction of cancer cells. The PD-1 pathway plays an important role in immunologic homeostasis, enabling the body to defend against pathogens while protecting against self-reactivity. Use of these medications may lead to dysregulation of T cell activation, causing a pathologic immune response, including inciting autoimmunity.

Case Description: A 73 year old woman with metastatic melanoma with normal renal function was treated with 4 doses of Pembrolizumab. Creatinine rose to 1.7 mg/dL. Biopsy revealed acute and chronic interstitial nephritis. After the drug was held, Prednisone 60 mg daily was started. Creatinine remained at 1.6 - 1.9 mg/dL. Twelve months later, she developed arthralgias and targetoid lesions on her fingers. A skin punch biopsy showed vasculitis. Creatinine was 5.2 mg/dL. UPC was 2.9 g/g. Complements were normal. Cryoglobulin, MPO, HIV, hepatitis panel and renal ultrasound were negative. She tested positive for PR3-ANCA at 1675 U/mL (normal 0-19 U/mL). Biopsy revealed pauci-immune crescentic glomerulonephritis (GN). She received 6 sessions of plasmapheresis, weekly Rituximab with Methylprednisolone, and later switched to Prednisone 60 mg daily. Creatinine improved with a decrease in PR3 titers. Rituximab maintenance infusions were terminated due to progression of melanoma.

Discussion: There are a few cases of Minimal Change Disease and IgA Nephropathy reported with PD-1 inhibitor, and a case of Granulomatous Polyangiitis after a single dose of Pembrolizumab. Immune-related adverse events have been cited to start within a few weeks to months after treatment, but can occur anytime after treatment discontinuation, with skin events usually the first to appear. Our patient presented with skin findings and

had severe renal injury from PR3-positive GN. T-cell activation has been implicated in the development of crescentic GN. We postulate that Pembrolizumab set the scene for a dysregulation of T cell function, with development of a pathogenic autoantibody such as PR3-ANCA, as well as possibly unmasking an underlying autoimmunity. This report highlights an important potential renal effect from this drug.

SA-PO272

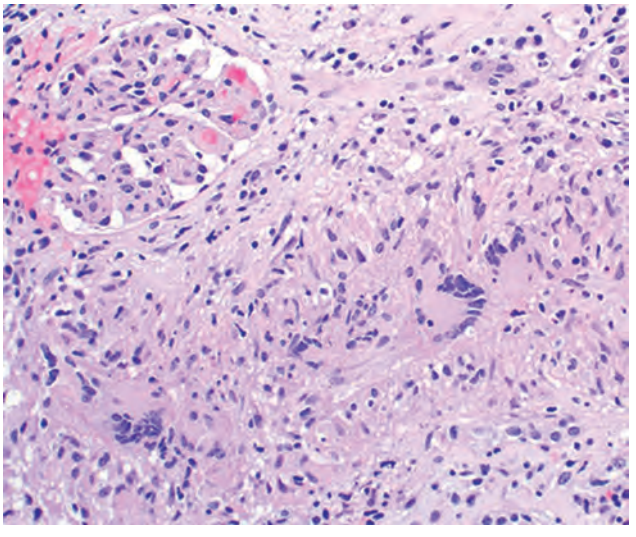
Immune Checkpoint Inhibitor (ICI) Induced Necrotizing Granulomatous Arteritis, Interstitial Nephritis, and Dermatitis

Sneha Mohan,[1] Gunjan Garg,[2] Evan A. Farkash,[2] Rachel Perlman.[2] *[1]All India Institute of Medical Sciences (AIIMS), New Delhi, India; [2]University of Michigan, Ann Arbor, MI.*

Introduction: With emergence of ICIs as potent agents against melanoma, there has been a rapid surge in use of drugs like ipilimumab, targeted against cytotoxic T lymphocyte associated antigen 4(CTLA-4), and nivolumab, targeted against programmed death 1(PD-1) protein. Immune related adverse events (IRAE), including skin lesions and AKI, have been reported with use of ICIs. Nivolumab has been associated with sarcoidal pattern of granulomatous dermatitis while both drugs have been associated with acute interstitial nephritis (AIN). We present a case of skin and renal complications following concomitant nivolumab and ipilimumab therapy.

Case Description: A 67 yo man diagnosed with melanoma 9mos ago, on 3rd cycle of ipilimumab and nivolumab presented with fever, skin rash and AKI. Serum creatinine (Cr) was 2.65 mg/dL (baseline 0.8 mg/dL). Skin biopsy (B_x) showed granulomatous dermatitis compatible with granuloma annulare. Renal B_x showed necrotizing granulomatous arteritis with interstitial fibrosis and tubular atrophy (Fig). ANA and ANCA were negative. Mycobacterial and fungal causes were excluded. Given the suspicion of ICIs related cutaneous and renal side effects, both drugs were stopped and 80mg daily oral prednisone was initiated for 1mo followed by slow taper. Rash improved rapidly and Cr returned to baseline.

Discussion: These findings describe another pathological manifestation of ICIs. We suspect that synergistic effects of anti-CTLA-4 and anti-PD1 therapy triggered the granulomatous arteritis. With increasing use of ICIs for melanoma and other cancers, it is important to be vigilant of their side effects. Steroid therapy, initiated early, appears to have utility in reversing IRAEs.



Renal B_x showing obliteration of an intralobular artery by granulomatous inflammation with multinucleated giant cells, accompanied by interstitial hemorrhage and AIN. H&E, 200x

SA-PO273

Lupus Nephritis Due to Anti-TNF Alpha Therapy

Kamal Nayyar,[1] Dominick Santoriello,[2] James Drakakis,[1] Naveed N. Masani.[1] *[1]NYU Winthrop Hospital, Mineola, NY; [2]Columbia University Medical Center, New York, NY.*

Introduction: Drug induced lupus erythematosus is a lupus-like syndrome temporally related to continuous drug exposure which resolves upon drug discontinuation. Findings include skin manifestations, arthritis, serositis, and ANA/anti-DS DNA seropositivity. It can be divided into systemic, subacute cutaneous, and chronic cutaneous forms. Drugs most frequently associated are hydralazine, procainamide, and quinidine. In rare cases, anti-TNF alpha therapies have also been implicated. It is estimated that up to 10% of SLE cases are drug-induced. Such autoimmunity is idiosyncratic and unpredictable.

Case Description: An 80 year old male with a past medical history significant for DM II, hypertension, resolved hepatitis B infection, seropositive Rheumatoid Arthritis (RA), and CKD stage III with a baseline creatinine of 1.5 mg/dl was started on Etanercept (anti-TNF alpha therapy) due to severe erosive RA. After 6 months of treatment he presented with joint pains and swelling of the extremities, was noted to have acute renal failure with a creatinine of 2.0 mg/dl, proteinuria of 1.2 gm, new onset microscopic hematuria, hypocomplementemia, and anti -DsDNA/ANA seropositivity. Renal biopsy revealed diffuse endocapillary glomerulonephritis with immunofluorescence staining for IgG, IgA, C3, c1q, kappa and lambda; electron microscopy was devoid of tubuloreticular inclusion bodies. Given the lack of extra-renal SLE findings and the timing of etanercept, the biopsy findings were attributed to TNF-alpha inhibitor therapy, which was subsequently discontinued. The patient was treated with corticosteroids, with stabilization of renal parameters and resolution of anti-DsDNA and ANA positivity. Of note, the patient exhibited no other SLE type symptoms prior to or since TNF-alpha inhibitor therapy. Therapy for RA was switched to Rituximab.

Discussion: Anti-TNF alpha induced lupus represents a major therapeutic challenge. Most cases are caused by infliximab, followed by etanercept and adalimumab. Symptoms range from mild cutaneous lesions, to more systemic involvement including pericardial effusions, deep venous thrombosis, pneumonitis, and lupus nephritis. Most of the reported clinical features of anti-TNF-alpha -induced SLE present as cutaneous lesions, which are similar to those present in idiopathic SLE. This case exhibits the silent menace of the exceedingly rare anti-TNF-alpha induced lupus nephritis.

SA-PO274

An Unusual Case of Hydronephrosis Caused by Iliac Artery Aneurysm

Kamal Nayyar, James Drakakis, Louis J. Imbriano. *NYU Winthrop Hospital, Mineola, NY.*

Introduction: Isolated internal iliac artery aneurysm is a rare but serious condition of which nephrologist should be aware. The natural history is one of continued expansion and rupture with high mortality rate. These can result in hydronephrosis and hydroureter with displacement of the ureter by a mass lesion. With proper treatment survival can be improved. Here we discuss a case of patient with acute renal failure in the setting of a pelvic kidney and symptomatic iliac artery aneurysm.

Case Description: A 66 year old male with a history of hypertension, hyperlipidemia, and smoking was admitted with angina. Serum creatinine was 1.7 mg/dl, and urinalysis showed trace proteinuria with no blood. Cardiac catheterization revealed 2 vessel disease. Within 12 hours of admission the patient developed vomiting, diarrhea, hypotension and new onset paresis of the left upper extremity. Creatinine rose in a saw-tooth pattern to 4.0 mg/dl over 5 days. MRI of the brain without contrast revealed a small right posterior frontal cortical infarct as well as multiple lacunes in the right basal ganglia, and 60% stenosis of the origin of the right internal carotid with an ulcerated plaque. During the angiogram, films of the aorta revealed mild right renal artery stenosis and an ectopic left pelvic kidney with hydronephrosis due to a 3.3 cm left common iliac artery aneurysm impinging on the ureter. Surgery was performed to repair the common iliac artery aneurysm and relieve the obstructed ureter of the pelvic kidney. Hydronephrosis of the left pelvic kidney was partially relieved, and subsequent renal scans showed no significant hydronephrosis.

Discussion: This patient demonstrates an obstructed pelvic kidney by an asymptomatic common iliac artery aneurysm. Isolated iliac artery aneurysms are exceedingly rare, account for <7% of all intra-abdominal aneurysms and are found in only 0.03% of the population in autopsy studies. They are most often due to atherosclerotic vascular disease occurring in males in the 7th or 8th decade. Symptoms vary and are related to pressure by the aneurysm on the ureter, the internal iliac vein, the lumbosacral nerve trunk, the external iliac vein, obturator nerve, and the colon. The risk of hydronephrosis may be increased in the pelvic kidney due to malrotation of the kidney and an anteriorly placed renal pelvis. This case exhibits the silent menace of an iliac artery aneurysm.

SA-PO275

Drug Induced Lupus Nephritis in Psoriasis Secondary to Adalimumab Use

Gurleen Kaur,[1] James L. Bailey.[2] *[1]Emory, Decatur, GA; [2]Emory University School of Medicine, Atlanta, GA.*

Introduction: Adalimumab, an anti-Tumor necrotic factor α agent (anti-TNF α), is approved by the FDA for treatment of moderate to severe chronic plaque psoriasis. The drug is generally well-tolerated, however auto immunity with the development of systemic lupus erythematosus (SLE) is a rarely reported. We describe a case of Adalimumab being used for chronic plaque psoriasis in which the patient developed lupus nephritis.

Case Description: A 32 year-old-lady with refractory chronic plaque psoriasis had been on Adalimumab for 3 months and presented with a 3-day history of bilateral lower extremity swelling. On evaluation, she was found to have a malar rash and alopecia, hemoglobin 6.7g/dL, creatinine 0.6 mg/dL, albumin 1.5g/dL, UA 3+ protein and 50 RBCs. A spot urinary protein: creatinine ratio was 4.8g/g with microalbumin of >1g. Further work up for proteinuria revealed a positive ANA, SSA, Anti Ro, Anti La, RNP, Anti Smith (519 AU/mL), ds DNA (1257 IU/mL), anti-histone (>999 AU/mL) while other serological work up was negative. A renal biopsy was performed on day 3: focal proliferative glomerulonephritis with 1 focally sclerosed glomerulus and full house staining on immunofluorescence consistent with class III lupus nephritis was found. The adalimumab was stopped and she was started on Prednisone and Hydroxychloroquine. On follow up, she was started on cyclophosphamide. Subsequently, her proteinuria and other symptoms improved.

Discussion: "Anti-TNF α-induced lupus (ATIL)" is characterized by high prevalence of anti-dsDNA antibodies (>90%) and low prevalence of ant histone (57%) with respect to the classic form of SLE. The presence of SLE meeting the American college of rheumatology guidelines and concomitant exposure to lupus-inducing drug are widely accepted criteria for ATIL. There have been no cases reported in the literature of adalimumab induced lupus nephritis. In our case, the lupus nephritis improved after discontinuation of the drug, supporting the diagnosis of ATIL. Symptoms resolve within 3 weeks to 6 months after

stopping the drug. Additional immunosuppressant medications may be required to achieve full remission.

SA-PO276

Glomerular Injury Related to Immune Related Adverse Events: IgA Nephropathy After Nivolumab Therapy for Postoperative Recurrence of Lung Cancer

Maho Iwaki, Seiji Kishi, Masanori Minato, Masanori Tamaki, Fumi Kishi, Taichi Murakami, Hideharu Abe, Kojiro Nagai. *Department of Nephrology, Tokushima University, Tokushima, Japan.*

Introduction: Immune checkpoint inhibitors (ICIs; anti-PD-1 or anti-CTLA-4) are becoming a common and an important therapeutic option for cancer patients. ICIs are associated with a unique category of side effects calld immune-related adverse events (irAE) and physicians should be aware of its clinical importance. According to previous reports, renal irAEs are less frequent than other organ involvement and glomerulonephritis is not typical. In this report, we present a case of nivolumab associated mesangial proliferative glomerulonephritis (IgA nephropathy), previously not reported.

Case Description: A 72-year-old man with postoperative recurrence of lung squamous cell carcinoma treated with nivolumab (anti-PD-1 antibody) who developed proteinuria and worsening kidney function was referred to our department. Ten months previously, he had been started on intravenous nivolumab therapy because of the postoperative recurrence of lung squamous cell carcinoma (cT3N2M0 stage IIIA). Six months after the first nivolumab treatment, the patient's creatinine began to increase and proteinuria was noted. Kidney biopsy showed mesangial proliferative glomerulonephritis with C3 and IgA deposition. Electron-microscopy demonstrated a small amount of high electron-dense deposits in the subepithelial and mesangial regions. After drug withdrawal, the proteinuria improved and the deterioration of the renal function was halted.

Discussion: To our knowledge, this is the very rare case of biopsy-proven immune complex glomerulonephritis following treatment with ICI. Although it may be difficult to prove a causal relationship of ICI and IgA nephropathy, we suspect nivolumab played a role in the pathogenetis of IgA nephropathy. The patient did not have disease-precipitating events such as upper respiratoty infection prior to the disease onset and we observed the decrease in proteinuria and improvement in serum creatinine after drug withdrawal. The previous study showed PD-1 knockout mice develop immune complex glomerulonephritis. These findings suggested that PD-1 signaling pathway is important to minimize T-cell-mediated renal inflammation. Glomerular lesions have been exacerbated from subacute to chronic course in our case, which suggests the possibility of another type of disease progression.

SA-PO277

IgM Nephropathy, M-Spike, and Chronic EBV Infection with Certolizumab Use

Arun Rajasekaran,[1] Mario A. Mendoza.[2] *[1]University of Central Florida College of Medicine, Kissimmee, FL; [2]Orlando VA Medical Center, Orlando, FL.*

Introduction: IgM Nephropathy is a rare cause of nephrotic syndrome seen in children and young adults. We describe IgM nephropathy causing nephrotic syndrome in an elderly male with normal serum IgM levels and having Rheumatoid Arthritis (RA); who also had tubuloreticular inclusions in his kidney likely caused by chronic EBV infection.

Case Description: A 60 year old male with known RA and ulcerative colitis, on Certolizumab and prednisone therapy, presented with nephrotic range proteinuria. Erosive hand joints and pedal edema were seen. He has known high-titer Rheumatoid factor positive RA with negative anti-CCP antibodies. Labs revealed a normal electrolyte panel, total protein, albumin and renal function. UA showed 3(+) protein. 24-hour-urine specimen revealed 3360 mg of protein. ANA titers were 1:160 (homogenous pattern). Anti-dsDNA, anti-MPO and Proteinase-3 antibodies; and ANCA panel were negative. Complements were low (C3 – 67, C4 – 14). Hepatitis B, C, HIV and CMV serologies were negative. EBV IgM titers were negative, but EBV IgG (728 U/ml) titers were markedly elevated. Serum IgM was normal (178 mg/dl), with a mild increase in IgA (657 mg/dl) and IgG (1858 mg/dl) levels. No monoclonal proteins were seen on UPEP. SPEP revealed an IgG Kappa monoclonal band. Renal biopsy was performed and LM showed mild mesangial hypercellularity, mild to moderate interstitial fibrosis with tubular atrophy. IF showed mesangial regions staining for IgM (3+), IgG (1+), IgA (1+), C3 (1+), and trace kappa and lambda light chains. EM demonstrated patchy podocyte foot processes effacement, several electron dense deposits in an expanded mesangial matrix. Few subepithelial and subendothelial deposits were noted, and many tubuloreticular inclusions were seen. Oncology opined that the IgG Kappa monoclonal band in the SPEP was likely secondary to Certolizumab use, and his Certolizumab was held and a repeat SPEP is pending. Oral diuretics and Lisinopril were started given his edema and proteinuria.

Discussion: Renal IgM deposits can be seen in RA. RA patients' have impaired control of EBV infection and have high antibody titers against EBV antigens. Our patient had IgM nephropathy with a normal serum IgM level, and our case highlights the need to test for EBV in the setting of RA and IgM nephropathy.

SA-PO278

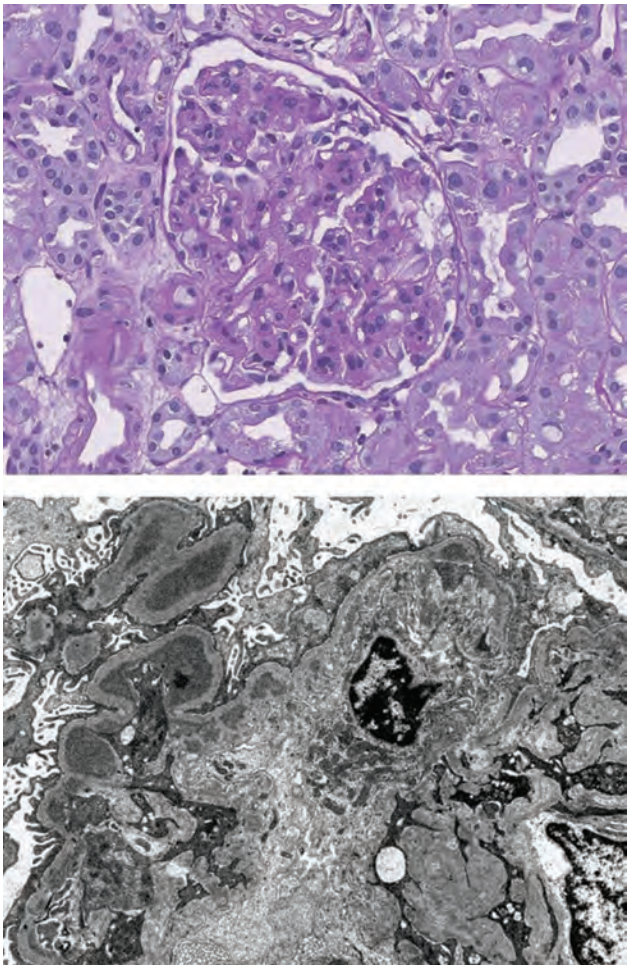
Membranoproliferative Glomerulonephritis (MPGN) Associated with Nivolumab Therapy

Jessica Cruz Whitley, Priyanka Wani, Brian Y. Young. *University of California Davis Medical Center, Sacramento, CA.*

Introduction: Nivolumab is a chemotherapeutic checkpoint inhibitor targeting PD-1 receptors on T cells. Nivolumab has classically been associated with acute interstitial nephritis (AIN). We present a case of Nivolumab associated nephrotic syndrome due to MPGN.

Case Description: 75-year-old female with a history of non-Hodgkin's lymphoma s/p allogenic bone marrow transplant 10 years prior was diagnosed with metastatic anal cancer. She was unresponsive to surgery and chemoradiation, and thus Nivolumab was initiated. Two months into Nivolumab therapy, her creatinine rose from 1.07 to 1.63mg/dl. Nivolumab was held and she was started on prednisone for presumed AIN. Atypically, she had edema and new onset proteinuria with 12.5 g/g on spot UPCR. Urinalysis was otherwise negative. Workup showed C3 and C4 were low at 76 and 10. Paraproteins, ANA, ASO, HBsAg, HCV ab, ANCA, and cryoglobulin were negative. After four weeks of prednisone, her proteinuria persisted. Kidney biopsy showed subendothelial deposits of C3 and IgM consistent with MPGN and mild interstitial inflammation. No features of TMA were found. Findings were felt due to persistent Nivolumab injury. Nivolumab was held for 3 months while prednisone continued. Her creatinine and proteinuria improved but unfortunately her cancer progressed, and she chose to pass away on hospice. Spot UPCR at that time was 1.1 g/g.

Discussion: This case demonstrates an atypical association of Nivolumab with MPGN. Nephrotic syndrome has been rarely reported with checkpoint inhibitors, though prior cases were minimal change disease and membranous nephropathy. We believe this to be the first case of checkpoint inhibitor associated MPGN, suggesting these agents can lead to a broad spectrum of immune-related kidney disorders



PAS / EM with MPGN and subendothelial deposits of C3 and IgM

SA-PO279

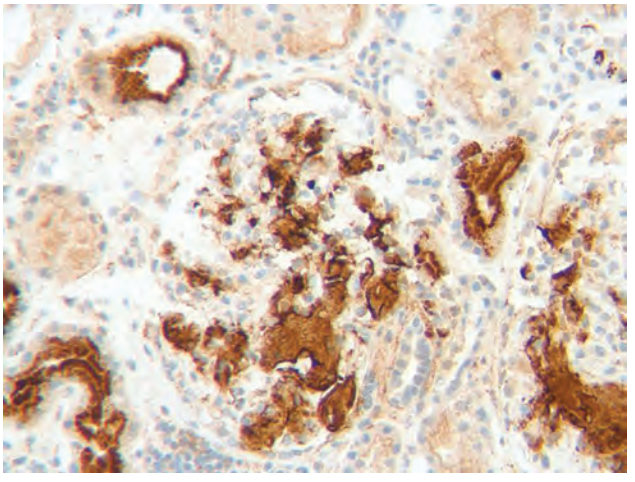
Secondary (AA) Amyloidosis Associated with Checkpoint Inhibition

Anne D. Sebastian,[1] William L. Whittier,[2] David J. Cimbaluk.[2] [1]*Rush University Medical Center, Chicago, IL;* [2]*Rush University Medical Center, Chicago, IL.*

Introduction: Nivolumab (Nb) is an immune checkpoint inhibitor (CPI) which targets solid tumors but can cause nephrotoxicity by accelerating systemic inflammation. We report a case of a patient who achieved partial remission of squamous cell lung cancer (SCLC) with Nb but later developed nephrotic syndrome from secondary (AA) amyloidosis.

Case Description: A 75 y.o. white man presented with anasarca. He was diagnosed with metastatic SCLC 2 years ago and received 4 cycles of Nb. His last dose was 10 months ago. It was stopped due to failure to thrive as he had acheived partial remission. Exam notable for diffuse anasarca. Alb 1.1 g/dL, Cr 0.76 mg/dL. ANA (-). C3 77, C4 25 mg/dL, RF 67 IU, CRP 86.8 mg/L, ESR >140 mm/hr. SIEP and UIEP (-) for monoclonal protein. A year ago, Alb 2.6 g/dL, UA trace protein. Renal biopsy demonstrated apple green birefringent deposits in the glomeruli and arterioles on Congo red (Figure 1). Amyloid A immunostain was (+). IF was (+) for full house mesangial staining of IgG (3+), IgA (3+), IgM (2+), C3 (3+), C1q (3+) and C4 (1+) and equal for κ & λ stain (3+). EM with randomly arranged fibrils 8-12 nm in the GBM & mesangium. He was started on prednisone, bactrim, and colchicine and his U P/C improved to 5.1 g/g in 3 months. His inflammatory markers improved and his SCLC remained in partial remission.

Discussion: We present a patient with secondary (AA) amyloidosis with diffusely positive mesangial IF 10 months after receiving Nb. Although progressive cancers can be associated with AA amyloidosis, his SCLC was in partial remission, making it an unlikely etiology. In addition, his elevated ESR, CRP, RF, and full house IF are signs of active inflammation. CPIs exert their antineoplastic action by accelerating inflammation, causing interstitial nephritis. In contrast, our case illustrates the possibility that the immune checkpoint inhibitor created an uncontrolled inflammatory response leading to secondary (AA) amyloidosis.



SA-PO280

Dasatinib-Associated FSGS: A Case Report

Valentina Loi,[1] Nicola Lepori,[1] Matteo Floris,[1] Anna Maria Asunis,[2] Andrea Angioi,[1] Riccardo Cao,[1] Alice Atzeni,[1] Doloretta Piras,[1] Gianfranca Cabiddu,[1] Antonello Pani.[1] [1]*Nephrology, Ospedale Brotzu, Cagliari, Italy;* [2]*Anatomic Pathology, Ospedale Brotzu, Cagliari, Italy.*

Introduction: Renal adverse effects associated with the use of TKI include arterial hypertension, proteinuria, acute kidney injury (AKI), and thrombotic microangiopathy (TMA); however there are only a few reports of TKI-associated nephrotic syndrome

Case Description: A 69 y/o woman was diagnosed in June 2016 with Philadelphia chromosome-positive chronic myeloid leukaemia for which she was initially treated with hydroxyurea 1.5 g/day for 2 weeks and then with Dasatinib100 mg/day achieving complete remission. Her past medical history included arterial hypertension, type 2 diabetes mellitus and dyslipidaemia. Her previous kidney function was normal and she had no proteinuria. After 8 months on Dasatinib, the patient developed a progressive and rapid worsening of her kidney function (sCr from 0.76 to 2.2mg/dL) associated with the onset of a nephrotic syndrome with proteinuria up to 6g/24h, hypoalbuminemia (serum albumin 2.4g/dL), lower extremity pitting oedema and mild pleural and pericardial effusion. Blood cell count showed a mild anaemia; ANA, ANCA, HBV and HCV markers, complement were normal. In consideration of this clinical picture, the drug dose was reduced to 100mg every other day. Over the next few months her kidney function remained stable with sCr of 1.7mg/dL, proteinuria of 3.5g/24h, serum albumin of 2.9g/dL, total cholesterol level of 297mg/dL. In October 2017 the patient underwent a kidney biopsy. Light microscopy showed glomeruli with segmental collapse of the tuft with concomitant pseudo-crescents. A mild mesangial expansion with a limited cellular proliferation was diffusely observed. Of interest, endothelial cells showed swollen cytoplasm with evident nuclei, suggestive of a diffuse endothelial injury. Tubuli, interstitium and vessels were unremarkable. IF was unremarkable. The patient was started on prednisone (0,5 mg/Kg/die) and Dasatinib was discontinued. After 6 months of treatment, proteinuria improved to 2,2g/24 hours, albuminemia raised to 3.5 g/dl and sCr improved to 1.5 mg/dl

Discussion: The improvement in proteinuria and albuminemia after cessation of Dasatinib and steroid treatment strongly imply this association between the nephritic syndrome and the treatment. This is, to our knowledge, the first case of focal segmental glomerulosclerosis secondary to Dasatinib treatment in an adult patient

SA-PO281

A Case of Lenalidomide-Induced Tubulointerstitial Nephritis

Alex Dinh,[1] Matthew Palmer,[2] Jonathan J. Hogan.[3] [1]*Internal Medicine, University of Pennsylvania, Philadelphia, PA;* [2]*Pathology, University of Pennsylvania, Philadelphia, PA;* [3]*Nephrology, University of Pennsylvania, Philadelphia, PA.*

Introduction: Lenalidomide is a thalidomide-derivate immunomodulatory drug that has shown efficacy in multiple myeloma and relapsed Hodgkin Lymphoma (HL). Renal insufficiency with lenalinomide is commonly-observed but poorly characterized. We describe a patient with relapsed HL who developed AKI and lower extremity rash while taking lenalidomide, with kidney biopsy showing tubulointerstitial nephritis.

Case Description: A 24-year-old male had refractory HL previously treated with autologous stem cell transplant four years prior to presentation, and nivolumab, pembrolizumab, and chimeric antigen receptor T cell therapy two years prior to presentation. During this time his SCr increased from 0.5-0.8 mg/dL to 1.1-1.6 mg/dL. Lenalidomide was started and over four months his SCr elevated to 2.3 mg/dL. Urinalysis was negative for protein, blood and leukocyte esterase, and microscopy showed no red blood cells or white blood cells. Peripheral blood eosinophils were elevated with a peak of 14%. Imaging revealed no evidence of obstruction. Lenalidomide was discontinued without improvement of his SCr. During the same month of discontinuing lenalidomide, he developed a rash on his lower extremity, and skin biopsy showed psoriasiform epidermal hyperplasia and chronic inflammation. A kidney biopsy showed patchy tubulointerstitial inflammation accompanied by tubulitis with mild chronicity, and approximately 10% interstitial fibrosis consistent with a diagnosis of tubulointerstitial nephritis. Mononuclear infiltrative cells were negative for lymphoma. He received three days of intravenous methylprednisolone 125 mg and oral prednisone with a subsequent steroid taper. His SCr returned to his prior baseline of 1.1 to 1.6 mg/dL at one month follow-up and his lower extremity rash resolved. Peripheral blood eosinophils returned to normal.

Discussion: Renal insufficiency associated with lenalidomide is commonly reported in plasma cell dyscrasias, but very few patients undergo kidney biopsies to establish the mechanism of kidney injury. The patient's treatment exposures prior to receiving lenalidomide included multiple T cell modulating therapies. Three case reports to date have been published describing lenalidominde-associated interstitial nephritis in patients with multiple myeloma. This is the first case to describe lenalidomide-induced interstitial nephritis in a patient undergoing treatment for HL.

SA-PO282

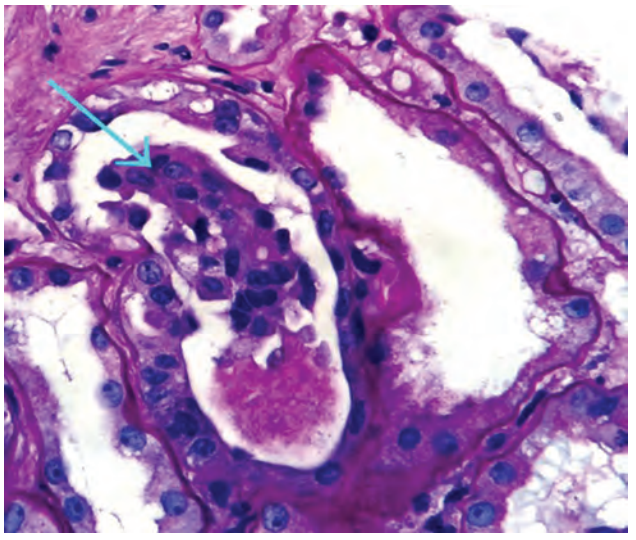
Varenicline Associated Acute Interstitial Nephritis

Hamza Salam, Areeba Jawed. *Wayne State University, Detroit, MI.*

Introduction: Varenicline is a nicotinic receptor partial agonist with proven benefits in smoking cessation. It is not known to cause renal toxicity. 2 case reports describe acute insterstitial nephritis (AIN) due to varenciline with pre-existing renal impairment. We describe a case with normal renal function who presented with acute renal failure soon after starting varenicline.

Case Description: 59-year-old male with history of HIV, hepatitis C, hyperthyroidism, hypertension and diabetes mellitus. Patient presented with worsening lower extremity edema. He was on HAART therapy with darunavir, etravirine and raltegravir. Other medications included amlodipine, lisinopril, metformin, glipizide, terazosin and varenicline. Varenicline was started 1 month prior to presentation and was the only new medication. Patient had normal kidney function at baseline serum creatinine (sCr) 1.1 as per labs drawn 2 months prior. Physical exam showed a middle-aged man with normal vitals, bilateral pitting edema up to the ankles, mild abdominal distension. Initial labs showed sCr 6.5, BUN 60, albumin 3, normal CBC, LFTs, lipase and CPK. On Urinalysis, blood 2+, protein 300, WBC 20-50, WBC esterase 1+,. Spot urine protein to creatinine ratio was 6.5. Ultrasound showed subtle hypoechoic bilateral renal pyramids with increased echogenicity in the renal parenchyma possibly related to underlying renal disease or inflammation. Patient was started on intermittent hemodialysis due to declining urine output and uremia. A renal biopsy was performed during admission that confirmed acute interstitial nephritis. Varenciline was held, patient was started on steroids. Renal function began improving and dialysis was stopped. sCr returned to baseline at clinic follow up.

Discussion: This is only the third case describing Varenciline associated AIN. A careful medication history with biopsy was essential in diagnosing cause for kidney injury in this patient with multiple comorbidities.



SA-PO283

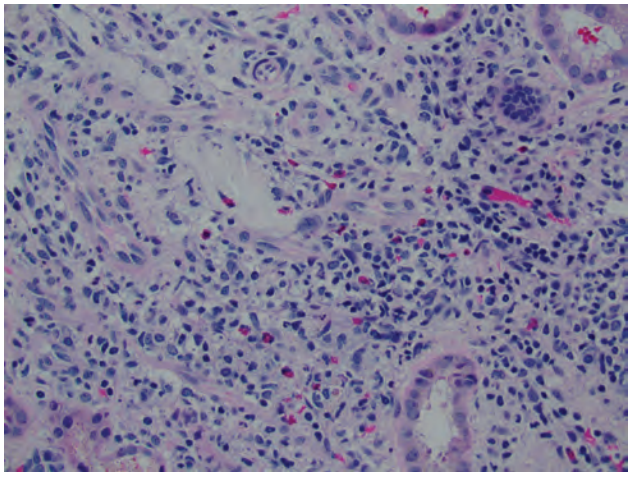
Novel Oral Anticoagulant and AKI: Apixaban Induced Acute Interstitial Nephritis

Christina Dimaria,[1] Wael A. Hanna,[2] Damon J. Mcenroe,[4] James P. Reichart.[3]
[1]Einstein Medical Center, Cherry Hill, NJ; [2]Lehigh Valley Hospital, Breinigsville, PA; [3]Valley Kidney Specialists, Macungie, PA; [4]Lehigh Valley Health Network, Allentown, PA.

Introduction: Novel Oral AntiCoagulants (NOACs) are changing the landscape of clinical practice for patients requiring short and long term anticoagulation. This case presentation of Apixaban-induced acute interstitial nephritis (AIN) shows a side effect of an increasingly common medication.

Case Description: A 70 year-old male with PMH of HTN, CHF, Atrial Fibrillation presented with a 2-month history of fatigue and intermittent hematuria. Home medications were Apixaban, Amlodipine, Epleronone, Cholecaliferol, Dofetilide, Metoprolol, and Rosuvastatin. He denied NSAID or PPI use. Physical exam showed normal vitals with trace edema and no rash. Laboratory studies showed S Cr of 2.6 mg/dL (baseline 0.90 mg/dL). Renal US showed no hydronephrosis or stones. Urinalysis showed 11-20 WBC, 100 RBC/hpf with urine protein:creatinine ratio of 0.57 g/g. ANA, ANCA, C3, C4 and SPEP were negative. While holding Apixaban for a renal biopsy, S Cr trended down to 2.2 mg/dL. Renal biopsy showed acute tubulointerstitial nephritis with eosinophilic component. The immunofluorescence microscopy displayed weak mesangial granular staining with IgA and glomerular tuft staining with C3 suggestive of IgA nephropathy. He received Prednisone 60 mg daily for two weeks with a taper. Apixaban was restarted and the patient's S Cr increased to 3.8 mg/dL. Apixaban was discontinued and Warfarin was started. S Cr improved slowly to 1.3 mg/dL and his hematuria improved to microscopic hematuria over a 4-month period.

Discussion: Oral anticoagulant can cause AKI by inducing glomerular hematuria or rarely AIN. Our patient had IgA nephropathy which can explain his persistent microhematuria while on the anticoagulants. The biopsy results and the patient's clinical improvement substantiate the diagnosis. Given the increasing use of Apixaban, it is worth recognizing that it can cause AIN at any time. To the best of our knowledge, there are only two reported biopsy proven cases of Apixaban induced AIN.



SA-PO284

A Case of Rivaroxaban Associated Nephropathy

Adrian Krukowski,[1] Sai prasad Gadapa,[2] Alexander J. Gallan,[3] Anthony Chang,[4] Patrick Cunningham.[2] *[1]Weiss Hospital, Chicago, IL; [2]University of Chicago, Chicago, IL; [3]The University of Chicago, Chicago, IL; [4]UChicago Medicine, Chicago, IL.*

Introduction: The adverse effects of oral anticoagulants (ACs) are commonly related to bleeding, however, a less common complication described with warfarin is the development of AC nephropathy. Novel ACs are quickly replacing warfarin, as they do not require monitoring of INR. Because they have not been used as long, the scope of their adverse effects are still coming to light.

Case Description: A 55-year-old Caucasian man was referred to the Nephrology clinic for worsening renal function. His PMHx includes a nerve sheath sarcoma in his right arm treated with surgery, radiation, and ifosfamide 15 years prior, stable CKD-II, and a large unprovoked pulmonary embolism 3 years prior. There was no history of hypertension or diabetes. He was placed on rivaroxaban with the intention of lifelong anticoagulation. He had otherwise been active and well. He denied hematuria, cloudy/frothy urine, nephrolithiasis, dysuria, edema, or dyspnea. Medications were rivaroxaban 20 mg daily, famotidine, and tramadol PRN. Social and family history was unremarkable. Physical exam revealed clear breath sounds and absent lower extremity edema. On presentation, creatinine (Cr) was 1.6 mg/dL and GFR was 45 mL/min. Other lab testing was unremarkable. His previous baseline serum Cr was stable at 1.2-1.4 mg/dL until two months before referral. UA revealed 1+ blood, 1+ protein, 3-5 RBCs/HPF, and no casts. Spot protein/Cr ratio revealed a value of 0.18, compared to a single measurement of 1.2 a year prior. Renal US was normal. Renal biopsy revealed eosinophilic granular intratubular casts with occasional RBCs, and mild acute tubular injury. Glomeruli showed congestion with RBCs and focal duplication of the glomerular basement membrane. Electron microscopy revealed multilayering of the peritubular capillary basement membranes but no other abnormalities. No immune complex-mediated disease was identified. Two months after biopsy serum creatinine is unchanged.

Discussion: There have been few published reports of nephropathy associated with novel ACs. As these drugs become more popular, it is possible that the incidence of associated nephropathy will increase. Extrapolating his decline in GFR suggests the patient could need renal replacement therapy in the next 10 years. Therefore, it is important to raise awareness that novel oral ACs such as rivaroxaban may be a cause of worsening kidney function.

SA-PO285

Aminocaproic Acid Induced Anuria

Salah-ud-din Amjad,[1] Jason M. Kidd.[2] *[1]Virginia Commonwealth University, Richmond, VA; [2]VCU Medical Center, Richmond, VA.*

Introduction: 59 year old woman with leukemia and severe thrombocytopenia developed acute kidney injury following treatment with Aminocaproic acid.

Case Description: A 59 year old female with leukemia and severe thrombocytopenia developed the acute onset of bilateral lower back pain. Prior to this, she had been receiving Aminocaproic acid (Amicar) for epistaxis and easy bruising related to her thrombocytopenia (platelets < 2000 repeatedly). Subsequently, she became anuric and serum creatinine increased from 0.55 mg/dl to 1.98 mg/dl. Potassium was 6 mEq/L. A renal sonogram showed bilateral hydronephrosis. A foley catheter was placed with minimal output. Contrast tomography was performed with IV contrast and showed no masses or hematoma. Urology was consulted and was initially hesitant to perform invasive testing due to her thrombocytopenia and immune suppressed state. She was started on dialysis for management of hyperkalemia. She ultimately underwent cystourethroscopy and was found to have clots bilaterally obstructing the ureteral openings in the bladder without any other filling defects. In the following 2-3 days, urine output began to increase with improved clearance and intermittent dialysis was stopped. Patient had full renal recovery.

Discussion: We believe this case has important clinical relevance due to the use of aminocaproic acid leading to obstruction and need for short term dialysis. Recognizing the clinical presentation of Amicar related renal failure can help direct the care and provide resolution such as in our case. It is known that in patients with upper urinary tract bleeding, the use of Amicar has resulted in intrarenal obstruction in the form of glomerular capillary thrombosis or clots within the renal pelvis and ureters. Keeping this in mind, benefits should outweigh the risks if Amicar is to be used. A question to be asked is the adverse effect of renal failure dose related or is it merely due to exposure of the drug. An important point to remember is that Amicar is renally excreted which would change dosing in a patient with pre-existing renal dysfunction or would need dynamic dose regulation in someone who suffers new kidney injury while on the drug. Contrast Induced injury was less likely in our patient due to acute kidney injury occurring earlier than expected in CIN. Also, renal recovery occurring after obstruction was corrected is more of a reason that renal injury was due to Amicar related obstructive uropathy.

SA-PO286

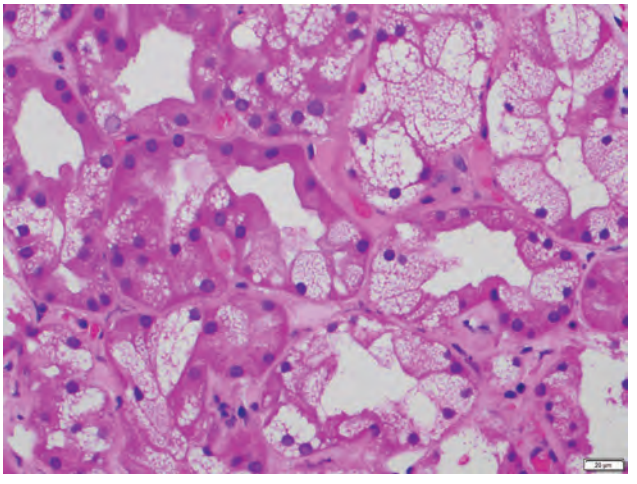
Osmotic Nephrosis: SGLT2 Inhibitor (SGLT2-i) Leaves a Footprint Behind

Amit Kaushal,[1] Gautam M. Phadke,[1,4] Richard J. Johnson,[2] Aleksandra Kukla,[3] Mariam P. Alexander,[3] Weimin Hao,[1,4] Miguel A. Lanaspa,[2] Adit S. Mahale.[1,4] *[1]University of North Dakota School of Medicine, Fargo, ND; [2]University of Colorado Denver, Aurora, CO; [3]Mayo Clinic, Rochester, MN; [4]Sanford Heath, Fargo, ND.*

Introduction: SGLT2-i causing acute kidney injury has been reported. Our case, defines the pathogenesis of severe AKI due to SGLT2-i. This class of medications cause functional reduction in GFR by activating tubuloglomerular feedback from enhanced distal sodium delivery. Osmotic nephropathy due to use of Canagliflozin has not been reported.

Case Description: A sixty eight year old diabetic, hypertensive Caucasian male, recovering from left septic knee due to group B streptococcus infection at a swing bed, got admitted with oliguric renal failure. His baseline creatinine was 1.2 mg/dL, with eGFR 62 ml.min and no baseline proteinuria, last A1c of 7.2% one month prior. One week prior to admission, he was started on Canagliflozin 300 mg daily. No history of volume depletion, and no evidence of hypotension, contrast exposure, or NSAID use noted. He was on furosemide 80 mg daily, Enalapril 5 mg daily. Complements were normal, urine revealed active sediment and 2.3 grams proteinuria. Hemodialysis was initiated due to oliguric AKI. Canagliflozin was stopped. Week after admission, creatinine improved to 1.7 mg/dL and the patient is off dialysis. Biopsy revealed features of osmotic nephrosis (Fig. 1).

Discussion: Enhanced **glucose** delivery to S3 segment of proximal tubule (PT) due to it's blocked uptake at S1 segment of PT by SGLT2-i, activates osmosensitive aldose reductase. Glucose is converted to sorbitol and to fructose. Fructose-uric acid axis is postulated in pathogenesis of **chronic kidney injury** related to diabetic nephropathy. In our case, although the exact etiology of osmotic nephrosis is not known, we hypothesize that higher concentrations of intracellular fructose may have caused local toxicity leading to the described pathological changes and severe **acute renal failure.**



Osmotic Nephrosis : Proximal tubule cell with severe vacuolization, loss of brush border, and cell death

SA-PO287

Euglycemic Diabetic Ketoacidosis Caused by a Sodium Glucose Cotransporter-2 Inhibitor

Jacob A. Hettenbaugh,[1] Faizan Syed,[1] Scott G. Westphal.[2] *[1]University of Nebraska Medical Center, Omaha, NE; [2]University of Nebraska Medical Center-Nebraska Medicine, Omaha, NE.*

Introduction: The use of Sodium Glucose Cotransporter-2 (SGLT-2) Inhibitors in the treatment of diabetes mellitus has continued to grow in the last several years, owing to their ability to reduce cardiovascular morbidity and mortality, and prevent incident or progressive diabetic nephropathy. With their increasing use, providers must understand the side effect profile of this new drug class. Here, we present a case of euglycemic diabetic ketoacidosis secondary to empaglliflozin, which is a rare, but potentially life threatening complication of SGLT-2 inhibitors.

Case Description: A 53-year-old man with type 2 diabetes mellitus managed with metformin and empagliflozin, presented with progressive nausea and vomiting, and was found to have a severe anion gap metabolic acidosis. On presentation, his pH was 7.11, serum bicarbonate 5 mmol/L, and anion gap was severely elevated. His blood glucose was 184 mg/dl. Beta-hydroxybutryate was markedly elevated, serum lactate was normal at 0.8 mmol/L, and serum creatinine was 1.0 mg/dl. He was diagnosed with non-hyperglycemic diabetic ketoacidosis based on strong clinical suspicion. Although glucose was < 200 mg/dl, he was treated with IV insulin and withdrawal of his empagliflozin. Within two days his acidemia had resolved with serum pH improving to 7.37, serum bicarbonate increasing to 24 mmol/L, and resolution of his anion gap.

Discussion: Ketoacidosis is a rare complication of SGLT-2 inhibitors. Unlike diabetic ketoacidosis in patients with type 1 diabetes mellitus, patients taking SGLT-2 inhibitors do not present with overt hyperglycemia. Due to this, ketoacidosis may go unrecognized leading to a delay in diagnosis and therapy. The cause of this complication is assumed to be due to decreased insulin production and loss of regulation of glucagon leading to increased glucagon secretion. As many nephrologists are now using SGLT-2 inhibitors regularly in patients with type 2 diabetes mellitus, providers need to be aware of this rare, but potentially serious complication in order to make a prompt diagnosis and institute timely treatment.

SA-PO288

ARF Caused by Tacrolimus Nephrotoxicity Due to Enhanced Absorption Mediated by Ledipasvir Inhibition of Gut Permeability-Glycoprotein

Usman A. Khan,[1] Kai Lau,[2] Taseen A. Syed,[2] Aemen S. Khakwani.[3] *[1]University of Oklahoma Health Science Center, Oklahoma City, OK; [2]University of Oklahoma Health Sciences Center, Oklahoma cty, OK; [3]University of Oklahoma Health Sciences Center, Oklahoma city, OK.*

Introduction: Recently discovered Novel Direct-acting antivirals (DAA's) have completely changed the spectrum of Hep.C treatment with multiple studies showing sustained virological response of over 90% in many genotypes. Treatment of hepatitis C with DAA's in renal transplant has been associated with nephrotoxicity at the pharmacodynamic level due to indirect interaction with immunosuppressive medications especially tacrolimus. We report a case of acute renal failure from increased tacrolimus plasma levels secondary to Harvoni mediated inhibition of gut permeability- glycoprotein.

Case Description: 65-yo M with a h/o renal transplant for ESRD due to DM and HTN and hep.C being treated with Harvoni (ledipasvir/sofosbuvir) was admitted for incidental ARF when presented initially for lesions on his AVF.His immunosuppression was tacrolimus 5 mg q 12 h and MMF 1 g bid. Physical exam was within normal limits. Lab was remarkable for an acute bump in Cr from his baseline of 1.5 to 2.1 mg%, along with blood tacrolimus level of 14 ng/ml. There were no identifiable nephrotoxic insults or medications. The clinical diagnosis of tacrolimus nephrotoxicty was made and was attributed to excessive gut tacrolimus absorption because ledipasvir is known to inhibit the gut p-Glycoprotein which normally limits the absorption of tacrolimus. His dose was gradually reduced from the home regimen of 5 mg bid to 2 mg bid, with a subsequent drop in his tacrolimus levels and recovery of serum creatinine to baseline of 1.5 mg% at a tacrolimus level of 7.8 ng/ml. After resolution of his ARF, he was discharged on 2 mg bid with the target tacrolimus level 6-8 ng/ml while he was still getting Harvoni. After the completion of his 12-week course of Harvoni, he was put back on a higher dose of tacrolimus, to avoid allograft rejection due to inadequate tacrolimus level secondary to the sudden drop in gut absorption without ledipasvir.

Discussion: Emerging DAAs seem to have a reduced potential for drug interactions, which will facilitate their use in the treatment of HCV in renal transplant patient. Close monitoring and dose titration of immunosuppressive medication especially Tacrolimus in renal transplant HCV infected patients being treated with DAA's is important to prevent Nephrotoxicity from higher plasma levels and renal rejection from lower plasma levels of tacrolimus.

SA-PO289

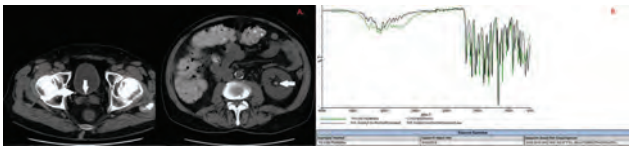
Severe Drug-Induced Bilateral Obstructive Nephropathy in a Lung Transplant Recipient: A Case Report and Literature Review

Vidhit Puri,[1] Pridvi Kandagatla,[1] Nishant K. Puri,[1] Gunjan Garg,[1] Tina Nigam,[2] Sowmya Goranta,[3] Raviprasenna K. Parasuraman.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Michigan State University, Lansing, MI; [3]Hurley Medical Center, Flint, MI.*

Introduction: Drug induced nephrolithiasis is rare and accounts for 1-2 % of all renal stone disease. Sulfamethoxazole mediated renal injury is mostly from interstitial nephritis and crystalluria with occasional renal stone formation. We present a rare case of Sulfamethoxazole induced acute bilateral ureteral stones causing hydronephrosis and severe AKI in a lung transplant recipient.

Case Description: A 59-year-old lung transplant recipient presented with a 3-day history of bilateral flank pain, weakness, anorexia, and decreased urine output after 4 weeks of high dose sulfamethoxazole-trimethoprim (Bactrim DS 2 TID) for cavitating Nocardia pneumonia. Examination was significant for moderate volume depletion, bilateral flank tenderness and oligo-anuria. Serum chemistry was significant for creatinine of 5.08 mg/dL (baseline 0.9), hyponatremia (130meq/L), and hyperkalemia (5.2meq/L) with a normal uric acid level. UA showed aciduria (pH=5.0). US and CT showed bilateral ureteral stones, hydronephrosis and bladder sediment layering (Fig.1a). Patient underwent bilateral ureteral stent placement and the urine (frank hematuria, unable to appreciate crystals) was strained and subjected for stone analysis. The infrared spectroscopy (IS) showed > 95% of absorbance pattern consistent with N4-acetylsulfamethoxazole, confirming the diagnosis of sulfamethoxazole stone (Fig.1b). Cessation of Bactrim therapy, urine alkalization, and volume replacement resulted in resolution of hydronephrosis and complete recovery of renal function.

Discussion: Bactrim induced interstitial nephritis, hyperkalemia and crystalluria is frequently seen. However, acute bilateral ureteral stone causing obstructive nephropathy is rare and to our knowledge not reported. The major risk factors include higher dose of medication, low urinary pH (poor solubility), and volume depletion. Our case exemplifies the importance of monitoring patient's urine pH, crystalluria, renal function, and volume status when using high doses of Bactrim.



A. CT showing Distal Rt & Proximal Lt ureteral calculus with stone layering in bladder. B. IS showing stone composition matching metabolite of sulfamethoxazole.

Stones and Woes: A Case of Tiopronin Associated Proteinuria

Sehrish Ali, Ahmed A. Awan, Prejith P. Rajendran, Natasha N. Dave, Jingyin Yan. *Nephrology, Baylor College of Medicine, Houston, TX.*

Introduction: Cystinuria is a rare genetic disorder characterized by impaired renal cystine transport causing increased cystine excretion and cystine nephrolithiasis. Treatment aims at maintaining urine cystine concentration below solubility level by hydration and alkalization. Patients resistant to conservative measures or who have a high cystine excretion rates are treated with Tiopronin or D-penicillamine. Tiopronin is usually well tolerated. Here we report a rare side effect of Tiopronin induced nephrotic range proteinuria.

Case Description: A 41 year-old woman with kidney stones for six years, presented to our stone clinic with complaints of recurrent stone passage. Her past medical history is significant for multiple urological procedures for stone removal. Her stone analysis showed 100% cystine calculi. She was managed with increased hydration and potassium citrate (60meq/daily) for stone prevention and she reported good compliance to treatment. However, CT of abdomen showed recurrent bilateral staghorn renal calculi. She underwent bilateral complicated procedures, and eventually the stone burden was cleared. Given the resistance to conservative treatment, she was started on Tiopronin at 800mg per day, which was gradually increased to 1000mg per day. At six months followup, 24 hour urine test showed decreased supersaturation and increased capacity of cystine. Repeat imaging of kidneys showed no new stone formation. However, she developed proteinuria from a baseline of 0.11mg/dL to 3.8mg/dL. Initially, a lower dose of Tiopronin was attempted with no improvement in the proteinuria. Subsequently, Tiopronin was withdrawn, and a resolution of the proteinuria was noted after that.

Discussion: Tiopronin is effective in reducing cystine stones in up to 70% of patients. With a better side effect profile compared to D-penicillamine, Tiopronin is first line for patients resistant to conservative therapy. Proteinuria due to Tiopronin is a rare, dose dependent side effect that resolves with cessation of therapy. Optimal monitoring for adverse effects is still not well defined; nonetheless, clinicians remain vigilant by monitoring urine protein to creatinine ratios every three to six months while patients are on Tiopronin.

SA-PO291

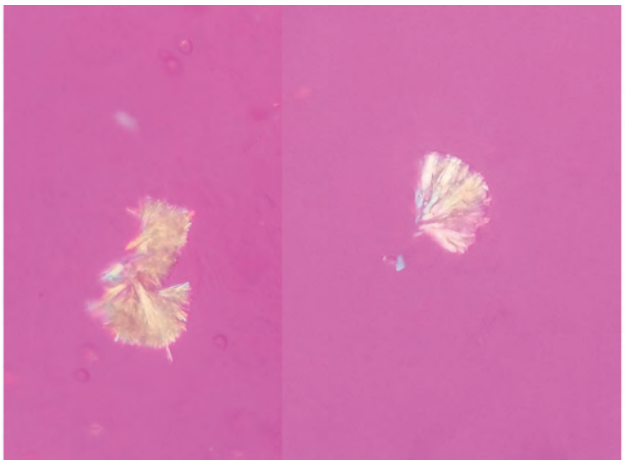
Sulfadiazine Induced Crystalluria

Alice Chedid, Mohamad A. Hanouneh, Keiko I. Greenberg. *Johns Hopkins University School of Medicine, Division of Nephrology, Baltimore, MD.*

Introduction: Crystal-induced acute kidney injury (AKI) is caused by the intratubular precipitation of crystals, which results in obstruction. Crystal-induced AKI mostly occurs as a result of acute uric acid nephropathy and following the administration of drugs or toxins that are poorly soluble.

Case Description: A 23 year-old man with history of untreated HIV presented with 1 week history of right sided weakness. HIV viral load was 274,000 copies/mL and absolute CD4 count was 2 /cu mm. Brain MRI showed bilateral ring enhancing lesions. Patient was started empirically on pyrimethamine 75 mg daily, sulfadiazine 1.5 g q6 hours and leucovorin 25 mg daily. Brain biopsy confirmed the diagnosis of toxoplasmosis. Hospital course was complicated by AKI 8 days after starting this regimen. Labs revealed BUN 12 mg/dL and serum creatinine 2.0 mg/dL (baseline 0.8 mg/dL). Urinalysis showed no hematuria or pyuria; pH was 6. Urine protein/creatinine ratio was 0.42 g/g. Kidney ultrasound showed non-obstructing bilateral ureteral stones. Examination of urine sediment under polarized light revealed multiple yellow brown asymmetric rosette shaped crystals (sulfonamide crystals) (figure 1). Sulfadiazine was discontinued and patient was switched to clindamycin. Patient was treated with IV fluids (sodium bicarbonate) to alkalinize the urine (urine pH goal was > 7 with urine output goal was 2 L/day). The patient's serum creatinine returned to baseline within 8 days.

Discussion: Sulfadiazine induced crystalluria is a serious complication in patients with AIDS who are treated for toxoplasmosis. Predisposing factors include high dose of sulfadiazine and volume depletion. It usually presents with AKI within 3 weeks of starting the medication. Treatment requires stopping the offending agent, aggressive IV hydration (UOP at least 1.5 L/day) and bicarbonate infusion to alkaline the urine (goal pH > 7).



SA-PO292

Two Cases of Lurasidone-Associated AKI

Nimesh K. Shah,[1] Valerie S. Barta,[2] Fatima Sheikh,[3] Hitesh H. Shah.[4] *[1]Nephrology and Hypertension Division, Lenox Hill Hospital, New York, NY; [2]Hofstra Northwell School of Medicine Lenox Hill Hospital, New York, NY; [3]Zucker School of Medicine at Hofstra/Northwell, New Hyde Park, NY; [4]Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY.*

Introduction: Lurasidone (Latuda) is a novel atypical antipsychotic used for schizophrenia and bipolar disorder. AKI has rarely been reported with lurasidone in trials. We report the first two clinical cases of AKI with lurasidone, including the first case of biopsy proven chronic interstitial nephritis (CIN).

Case Description: Case 1: 70-year old bipolar female was sent to ER for serum creatinine (Scr) of 8.4mg/dL. Scr was 1mg/dL six months prior. Medications included lurasidone, escitalopram, lamotrigine, lithium (Li), alprazolam, amphetamine, anastrazole, propranolol, and metformin. Lurasidone was the only new medication, started 6 months prior. Vitals and physical exam were unremarkable. Serum potassium was 6mmol/L, CO2 13mmol/L and Li 0.6mmol/L. 24-hr urine protein was 0.7g. Serologic work-up was negative. Metformin and Li stopped and patient discharged with Scr of 6.2mg/dL. Patient re-hospitalized one month later for Scr 9.8mg/dL requiring 3 sessions of hemodialysis for uremia. Kidney biopsy showed ATN and severe chronic interstitial nephritis (CIN). The lack of micro-cysts or granulomatous CIN was inconsistent with Li or lamotrigine induced AKI respectively. Oral corticosteroids initiated and lurasidone was held. Scr decreased to 2.6mg/dL four weeks later. Case 2: 50-year old male with schizophrenia was seen in clinic for elevated Scr of 1.6mg/dL. Scr was 1.3, 6 months prior to presentation. Medications included lurasidone, clozapine, clozaril, klonopin, lamictal, tamsulosin and metoprolol. Physical exam was unremarkable. Spot urine total protein-to-creatinine was 0.1. Serological work-up was negative. Lurasidone dose was reduced from 160mg to 80mg daily and Scr subsequently decreased to 1.3mg/dL.

Discussion: A review of FDA Adverse Event Reporting System (FAERS) revealed AKI in 18/3076 users of lurasidone. All cases were female ≥60years with AKI seen within 1yr of drug initiation. CrCl <50mL/min raises serum levels of lurasidone thereby increasing risk of AKI, as does adjunctive therapy with Lithium. AKI improved in our cases after discontinuation and steroids, or reduction of lurasidone therapy alone. It is important for clinicians to be aware of the potential AKI and CIN risk associated with lurasidone so renal function can be closely monitored in these patients.

SA-PO293

Rapid Loss of Kidney Function Associated with the Use of Capreomycin

Rafaela M. Gouveia,[1] Moacir C. Netto,[1] Ana Paula Gueiros,[1] Mirna D. Meira,[1] Cidcley N. Cabral,[1] Heliana M. Mello.[2] *[1]Instituto de Medicina Integral Professor Fernando Figueira, Recife, Brazil; [2]IMIP, Recife, Brazil.*

Introduction: Capreomycin (CPM) is used in the treatment of resistant forms of tuberculosis (TB), resulting in the adverse effect of nephrotoxicity. In the acute forms, tubular necrosis or glomerular alteration occurs, which is reversible if the use of the drug is suspended. Chronic impairment is characterized by interstitial nephritis. We report the case of a patient who developed severe renal dysfunction associated with the use of CPM.

Case Description: Male (aged 65), diabetes mellitus (DM) for 4 years, diagnosed with pulmonary TB (positive smear microscopy), initiated treatment with Rifampicin (RFP), Isoniazid, Pyrazinamide (PZA) and Etambutol (ETB). After 9 months, he remained symptomatic and GeneXpert detected resistance to RFP. In June 2017, he initiated treatment with CPM, ETB, Levofloxacin, Terizidone and PZA. At this time, he presented with creatinine (Cr mg/dL) 0.58 and hemoglobin (Hb g/dL) 13. After 6 months on the new treatment, he presented with Cr 2.5. In the ninth month, with negative sputum culture and undetectable GeneXpert, CPM and PZA were suspended, as recommended by the Brazilian Ministry of Health. In the tenth month, Cr was 2.64 and Hb 8.2, and the dosage of the other medications was adjusted according to the glomerular filtration rate (GFR). Although CPM was suspended, the patient evolved with no improvement in the GFR, with Cr 2.46, an

absence of proteinuria, hematuria or leukocyturia and proteinuria/24h 162mg. He presented a normal kidney ultrasound and a fundoscopy with non-proliferative diabetic retinopathy. Renal biopsy: normal glomeruli, no mesangial, endo or extracapillary proliferation, necrosis, sclerosis or thickening of the basement membrane; mild atrophy and interstitial fibrosis, with interstitial mononuclear infiltrate and arterial segment with mild fibro-intimal hyperplasia. Immunofluorescence did not demonstrate immunocomplexes.

Discussion: This case demonstrates a rapid, severe alteration of the GFR in a diabetic, normotensive patient with no evident proteinuria. The biopsy did not reveal kidney impairment from the DM. The literature reports few cases on nephrotoxicity from CPM. This study emphasizes the importance of strict controlling the GFR in patients on CPM, especially the elderly and those with comorbidities.

SA-PO294

Effectiveness of Hemodialysis and L-Carnitine in Severe Valproate Overdose

Mubasshar Rehman,[1] Ambreen Azhar,[2] Martine Pollack-Zollman.[3] *[1]Mount Sinai Saint Luke's and mount Sinai West, Bronx, NY; [2]mount sinai st lukes, New York, NY; [3]Mount Sinai Hospital, NY, NY.*

Introduction: Valproic acid (VPA) is used to treat seizure disorders and psychiatric illnesses. Acute VPA intoxication usually results in mild, self-limited CNS depression. VPA and its metabolites are low molecular weight, osmotically active acids and anions that may cause elevated osmolar and anion gap metabolic acidosis, hypocalcemia, hypernatremia, hyperammonemia with or without hepatic failure, cerebral edema leading to death if ingested in large doses. Prospective studies are lacking with regard to the management of VPA overdose, and the available data is mainly from case reports or retrospective studies. We present a case of sodium valproate overdose where hemodialysis was used due to rapid clinical deterioration

Case Description: A 24 year old female with seizure disorder on VPA and prior suicide attempts was brought to the ED with incoherent speech and encephalopathy after ingesting 100 tabs (100mg each) of VPA Shortly after arrival, she became agitated and required mechanical ventilation and pressor support. VPA level was >1200μg/ml along with AGMA, osmolar gap, hypernatremia, hypocalcemia and hyperammonemia (see table). CT head was negative for cerebral edema. She was admitted for acute VPA Toxicity. Charcoal suspension via NGT and L-carnitine infusion were initiated. Due to rapid clinical deterioration, she required a single 6 hour session of emergent hemodialysis with an Optiflux F160 dialyzer, Qb 400cc/min. Following dialysis, she clinically improved and VPA level was 439μg/ml at 24hrs

Discussion: Our patient presented with classic symptoms and lab abnormalities seen in acute VPA toxicity. Due to its low molecular weight and high free serum levels at supratherapeutic doses, hemodialysis seems an effective treatment. Mitochondial dysfunction and carnitine depletion occurs with VPA toxicity which leads to hyperammonemia. Retrospective studies suggest the use of L-carnitine to reverse these defects and hemodialysis can also be used for further ammonia clearance

Labs	Initial Labs	Subsequent Labs (24 hours)	Subsequent Labs(48 hours)

SA-PO295

A Case of Phenobarbital Overdose - Managed by High Flux Hemodialysis

Huiwen Chen. *University of Pittsburgh Medical Center, Pittsburgh, PA.*

Introduction: Intentional and accidental drug overdose result in approximately 10, 000 death per year. While some overdose can be managed with antidote, others might require more invasive care. Although techniques such as charcoal hemoperfusion have gone obsolete, hemodialysis (HD) has become the new standard to remove drugs that are moderately protein bound but small in size. We present a case of phenobarbital (PB) overdose corrected by HD.

Case Description: A 52 year old female with a history of seizure on PB who was brought to the hospital because of unresponsiveness secondary to an apparent suicide attempt via medication overdose. Ingestions occurred more than 24 hours prior to arrival. Vitals:T 36.8C, BP 106/82, HR 113, RR 40, Sat: 96% on non-rebreather. GCS< 8 She was breathing spontaneously and pupils were small but reactive to light. She was intubated for airway protection. Serum chemistry was within normal limits. Urine drug screening was positive for PB, benzodiazepine, and opioids. The rest of the toxicology workup was negative. Urine PB level was 147.9 ug/ml and therapeutic range is between 30 to 40 ug/ml. CT brain did not show cerebral pathology. EEG was consistent with cortical irritability and potential for seizure. Given that there was a national shortage of bicarbonate solution, serum and urine alkalization were not performed. One session of four-hour hemodialysis (HD) was initiated. Initial post-HD PB level was 54.2 ug/ml. Two hour post-HD PB level was 35.6 ug/ml. Patient was able to open her eyes the following day with drug level 43 ug/ml. No further dialysis was required.

Discussion: The therapeutic level of PB for seizure disorder is 30-40 ug/ml. A concentration above 60 ug/ml is considered toxic. The half life of PB in adults is between 50 to 140 hours depends on patients' age. Although PB is 20-45 percent protein bound, its plasma volume of distribution is large, between 0.6-1.0 L/kg, and the molecular size is only 232 daltons, making elimination of the drug easily with HD. The calculated time for this patient to reach non-toxic level of drug concentration with native renal clearance would be at least 100 hours. However, it took less than 24 hours to reach similar level with the help of HD. Take home message: While PB overdose can be treated with supportive care, in patients who are intubated, implementation of HD can effectively reduce the serum drug level and potentially reduce ventilator time.

SA-PO296

Outpatient Drug Dosing for Patients with CKD: Is It Time to Include Pharmacists?

Talar Kharadjian, Marie Pietruszka, Tripti Singh. *University of Wisconsin Health & Clinics, Madison, WI.*

Introduction: Neurotoxicity due to inappropriate valacyclovir dosing in patients with chronic kidney disease (CKD) is a recognized adverse effect. Electronic databases such as Lexicomp provide pharmacists and physicians with standard dose reductions for renal clearance. Our cases demonstrate the inadequacy of our current systems, which unfortunately failed to avert these preventable outcomes.

Case Description: Case 1 51-year-old male with end-stage renal disease (ESRD) on hemodialysis (HD) was seen in primary care clinic for shingles. Due to ongoing renal transplant workup, he was given valacyclovir 1g three times daily (immunocompromised dosing). Two days later, he presented to the emergency department (ED) with confusion and visual hallucinations. A pharmacist reviewed the dose and recommended switching to acyclovir 800mg five times daily based on clinical indication rather than renal dosing. He later returned to the ED with worsening symptoms. His pre-dialysis acyclovir level was 12mg/L, improved to 3.5mg/L after 3 hours of HD. He had daily HD for 3 days and discharged on valacyclovir 500mg daily for 7 days. **Case 2** 53-year-old male with HIV and ESRD on HD developed shingles treated with valacyclovir 1g three times daily (HIV dosing). He became somnolent, agitated and confused. He was admitted for neurotoxicity due to inappropriate valacyclovir dosing, treated with urgent HD for 3 hours. Symptoms improved over 24 hours and he discharged on valacyclovir 500mg daily for 7 days.

Discussion: Our cases demonstrate the limitations of our current electronic medical record, which does not alert prescribers to data present in the chart at the time of medication order entry, namely glomerular filtration rate (GFR) and diagnosis of CKD. Such alerts can reduce the risk of inappropriate renal dosing. We also propose that community pharmacists be granted access to the medical record to properly verify dosing in the outpatient context as it occurs on inpatient wards. This would provide added safety to a currently disjointed prescriber-pharmacist interface in the outpatient setting. Another solution would be an identifying bracelet for patients with GFR<30 mL/min per 1.73m^2, similar to community Do Not Resuscitate (DNR) bracelets, which would also foster greater public and provider awareness regarding the vulnerability of this patient population to such medical errors.

SA-PO297

Fibromuscular Dysplasia in a Patient with Vascular Type Ehlers-Danlos Syndrome Who Presented with Spontaneous Renal Artery Perforation

Junaid Nasir, Anum Bilal, Rafia I. Chaudhry, Loay H. Salman. *Nephrology, Albany Medical Center, Albany, NY.*

Introduction: Fibromuscular Dysplasia (FMD) is a rare segmental disease of small and medium sized arterial wall musculature. FMD is noninflammtory and nonatherosclerotic in nature and affects renal and internal carotid arteries in 75% of cases. Renovascular hypertension in young females is the most common presentation, while spontaneous dissection, bleeding and renal infarction is rare; however these are seen more often in males affected by FMD. We present a rare case of coexistent FMD and Ehers-Danlos Syndrome presenting as spontaneous renal artery dissection.

Case Description: A 44-year-old male presented to the ED with severe left flank pain. Patient was hypotensive (S.B.P 80 mmHg), in hemorrhagic shock and had AKI, Hb 9.8 gm/dL, Cr 1.69 mg/dL). CT angiogram abdomen revealed massive retroperitoneal bleed from left renal artery. Emergent laparotomy confirmed pseudoaneurysm from dissected left renal artery extending to sub-segmental arteries. Revascularization attempt was futile due to friability of the vessels and left nephrectomy was performed. Histologic evaluation of the kidney demonstrated marked fibrointimal thickening with hypocellular intimal sclerosis and focal cellular fibroplasia, medial hypertrophy, and abrupt broad regions deficient in internal elastic lamina. The severe fibro-obliterative renovascular disease findings were consistent with fibromuscular dysplasia, with features of both the medial fibroplasia and intimal type. Genetic testing was performed confirming pathogenic mutation in COL3A1 gene (c.1106G>T) diagnostic of Vascular Ehlers-Danlos Syndrome (vEDS).

Discussion: Spontaneous renal artery dissection is rare, and has been associated with FMD (especially in males), malignant hypertension, severe atherosclerosis, severe trauma, Marfan syndrome, or Ehlers-Danlos syndrome. vEDS has an Autosomal Dominant

inheritance, and is the most severe form of EDS, increasing the risk of arterial aneurysm rupture. Co-existing FMD and vEDS of renal artery has not been described before. This case highlights the need for genetic testing of patients diagnosed with FMD, to rule out additional connective tissue disorders, as co-existence of both conditions can potentially increase the risk of life threatening complications.

SA-PO298

Takayasu's Arteritis Induced Bilateral Renal Artery Stenosis Refractory to Medical Therapy

Rahul Kumar, Georges Nakhoul, Jonathan J. Taliercio. Cleveland Clinic Foundation *Glickman Urological and Kidney Institute, Cleveland, OH.*

Introduction: Takayasu's arteritis (TAK) is a granulomatous large-vessel vasculitis. It primarily affects women of age 10 to 40 years. In patients with TAK, the prevalence of hypertension varies from 23% to 76% across the world and about half of the case are secondary to renal artery involvement. In this study, we present a patient with difficult to control hypertension and worsening renal function secondary to TAK induced renal artery stenosis in spite of adequate medical management.

Case Description: A 39-year-old Caucasian female presented with sudden onset chest pain, left arm pain, muscle ache, and 50-pound weight loss over the past one year. Patient has a past medical history of multiple sclerosis, ulcerative colitis, and cigarette smoking. On exam, blood pressure was 110/72 mmHg in the right arm and 88/70 mmHg in the left arm. A left subclavian bruit was present with a feeble left radial pulse. EKG showed an anterior STEMI. A coronary angiogram revealed 99% LAD ostial stenosis and incidentally showed high-grade stenosis of the proximal left subclavian and bilateral renal arteries. The patient underwent an urgent coronary artery bypass graft. On further workup, a CT angiogram showed severe stenosis of the proximal left subclavian artery, superior and inferior mesenteric artery, celiac artery and bilateral renal artery (80% RRA and 90% LRA stenosis). A clinical diagnosis of Takayasu's arteritis was made and the patient was started on prednisone and methotrexate. At a six-month follow-up, the patient was found to have BP of 160/90 mmHg in spite of being on four antihypertensives including an ACE-I and a decreased eGFR of 40 ml/min/1.73m^2. MRA abdomen showed a completely occluded right renal artery with an atrophied right kidney. Renal Duplex US showed LRA proximal stenosis with a significantly increased PSV of 760 cm/sec and RRI of 60%. An aortogram confirmed the RRA occlusion. The patient underwent left aorto-renal bypass grafting of her solitary kidney. A six-month follow-up showed improved eGFR to 76 ml/min/1.73m^2 and a decrease in antihypertensive medicines to carvedilol and enalapril.

Discussion: In TAK with advanced renal artery stenosis refractory to medical therapy, endovascular or surgical revascularization is the treatment of choice. The patient was prevented from becoming dialysis dependent by the timely recognition, close monitoring, and intervention.

SA-PO299

Baroreceptor Failure – A Rare Form of Secondary Hypertension

Kai Chin,[2,1] Jesse M. Wickham.[2,1] *[1]UT Health San Antonio, San Antonio, TX; [2]Nephrology, San Antonio Military Medical Center, San Antonio, TX.*

Introduction: Baroreceptors in the neck play a large role in blood pressure (BP) regulation. They sense distension of the vessel wall and help stabilize blood pressures during changes in volume and/or posture. Injury to the baroreceptors can cause extremely labile blood pressure with BP surges. We present a case of baroreceptor failure, a rare form of secondary hypertension.

Case Description: A 65-year-old male with hypertension (HTN), anxiety and soft palate cancer s/p radiation therapy was admitted for planned carotid endarterectomy. Patient's BP rose to 290/102mmHg when he was placed supine in the operating room. Surgery was aborted and nephrology was consulted to assist with BP therapy and secondary workup. Patient stated these BP surges had been occurring for years. However, they only began after he received radiation therapy to his neck at age 55. His current medications were Felodipine 10mg daily and Carvedilol 12.5mg twice daily. Patient kept detailed BP logs 6 times a day with average BP 210s/100s mmHg, with surges to 260 mmHg systolic. Patient stated he used to be on many BP medications to treat his surges, but it would cause severe hypotension if he didn't have surges. Patient had a secondary HTN workup which was negative for pheochromocytoma, hyperaldosteronism, and renal artery stenosis. He also had Positron Emission Tomography and Computerized Tomography scans done for surveillance of his cancer, which were negative for new masses. As a result, we concluded the patient likely had baroreceptor failure caused by radiation therapy to his neck. Review of the literature showed that Clonidine and benzodiazepines are beneficial in limiting BP surges. He was started on Clonidine 0.1mg/24hr patch and discharged with follow-up to titrate his Clonidine and wean his other BP medications. His Alprazolam for anxiety was switched to Diazepam as well. After 3 months, patient was on Clonidine 0.4mg/24hr patch, Valium 10mg BID and no longer on Felodipine or Carvedilol. His peak surge BPs are now 180 mmHg systolic, and average BP is now 160-180/70-90 mmHg.

Discussion: Baroreceptor failure is a rare form of secondary hypertension, but it can be suspected if a patient presents with very labile blood pressure and high BP surges. Very commonly, there is a history of neck trauma (i.e. radiation therapy, neck surgery). Clonidine (central alpha-2 agonists) and benzodiazepines are effective in reducing blood pressure surges.

SA-PO300

Hypertension Associated with Herbal Supplements: "Diosmin Complex," "Raphacholin C," and "Herbatka Fix Na Cholesterol": A Case Report

Jaibir Bhullar,[1] Ravleen K. Saini,[1] Shaheen Jadidi,[2] Rayaan A. Rauf,[3] Suneel M. Udani.[4] *[1]Avalon University School of Medicine, Youngstown, OH; [2]Midwestern University, Downers Grove, IL; [3]Advocate Good Samaritan Hospital, Downers Grove, IL; [4]Nephrology Associates of Northern Illinois and Indiana, Oakbrook, IL.*

Introduction: We report a case of hypertension associated with the ingestion of several Herbal Supplements (Diosmin Complex, Raphacholin C, and Herbatka Fix Na Cholestrol).

Case Description: A 60-year-old female patient, who had been ingesting these supplements sporadically for years, had increased her intake to twice a day for a month. Over the course of that month the patient developed palpitations, weight gain, trace edema, and mild jugular venous distention. Laboratory findings were notable for hypokalemia, hypocalcemia and hypomagnesemia with normal renal function. Urine chemistries confirmed mineralocorticoid excess with the presence of renal potassium wasting. The nutritional substance was subsequently ceased and supportive treatment was begun with low-dose carvedilol 6.25mg BID, and oral and IV potassium supplement. Further investigation was done of the renin aldosterone axis which confirmed the absence of primary hyperaldosteronism or high plasma renin activity. The patient's condition improved rapidly with supportive treatment and ceasing of the supplements.

Discussion: Current information regarding the adverse effects of these herbal supplements is very scarce, therefore potential damage should be kept in mind before ingesting these nutritional supplements or anything similar. This report serves as an important reminder to the public, as well as healthcare providers, of the potential of hypertensive urgency related to such nutritional supplements.

SA-PO301

Application of a Central Iliac Arteriovenous Coupler Device in Severe Resistant Hypertension: A 3.5-Year Follow-Up

Susanne Jung,[1] Christian Ott,[2] Marina V. Karg,[3] Agnes Bosch,[3] Michael Schmid,[4] Stephan Achenbach,[5] Roland E. Schmieder.[4] *[1]Departments of Cardiology, Nephrology and Hypertension, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany; [2]Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany; [3]University Hospital of Erlangen, Erlangen, Germany; [4]University Hospital Erlangen, Erlangen, Germany; [5]Friedrich-Alexander-Universität Erlangen-Nürnberg, 91054 Erlangen, Germany.*

Introduction: In patients with resistant hypertension (RH), iliac arteriovenous (AV) coupler implantation leads to blood pressure (BP) reduction via decreased total vascular resistance and improved arterial compliance. However, long-term efficacy and safety need to be further explored. We report on the first case of 3.5-year follow-up (FU) in a patient treated by coupler implantation, who underwent repeated right heart catheterization (RHC).

Case Description: A patient with RH was admitted to hospital. Despite treatment with 6 anti-hypertensives his BP was poorly controlled. Previously, he had undergone renal denervation, not leading to significant BP decrease. Therefore an AV coupler was implanted in our catheterization laboratory, causing a periinterventional BP decrease from 198/90 to 163/69mmHg. The patient was discharged with a BP of 122/71mmHg. After 3 months there was a sustained BP decrease, whereas later it was fluctuant (office BP: 147-173/85-95mmHg, ABPM: 153-166/81-94mmHg) probably due to medication non-adherence, confirmed by a urinary screening test. One year later the patient was hospitalized with iliac venous stenosis, which was treated by venoplasty and stenting. After 3.5 years he complained about progressive dyspnea and weight gain. FU RHC showed an increased pulmonary artery-, right atrial- and wedge-pressure as well as cardiac index and a decreased pulmonary vascular resistance. Central aortic pressure had decreased indicating device effectiveness. An invasive closure maneuver led to an immediate BP increase (+30mmHg) and a similar decrease after re-opening of the coupler, verifying its functionality. To unload the right ventricle, an intensive diuretic therapy was introduced leading to clinical improvement.

Discussion: This is the first case of 3.5-year FU after arteriovenous coupler implantation, leading to significant BP decrease. We verified a proper long-term function of the device and demonstrated changes in hemodynamic parameters related to volume congestion, which were resolved by an intensified diuretic therapy.

Hemodynamic changes obtained by RHC

Date of RHC	Right atrial pressure [mmHg] (s/d/m)	Pulmonary artery pressure [mmHg] (s/d/m)	Cardiac index (Fick) [l/min/m^2]	Pulmonary vascular resistance [dyn x sec/cm^5]	Central aortic BP [mmHg] (s/d/m)
Baseline	11/10/7	36/13/21	2.6	160	214/105/141
0.5-year follow-up	13/9/7	39/13/23	3.0	129	214/92/133
3.5-year follow-up	14/13/12	56/20/35	4.1	114	165/70/105

Post-Implantation Syndrome Following Abdominal Aortic Aneurysm Repair Causing Podocytopathy

Corey J. Cavanaugh, Randy L. Luciano. *Yale University School of Medicine, New Haven, CT.*

Introduction: A systemic inflammatory response of fever, leukocytosis, and pleural effusion following various vascular interventions including endovascular aortic repair (EVAR) is well recognized phenomena known as post-implantation syndrome. We describe a case of podocytopathy following EVAR.

Case Description: A 69-year-old man with no significant previous medical history presented with fevers progressive generalized edema and shortness of air after undergoing EVAR for ruptured abdominal aortic aneurysm (AAA) one month prior. He underwent repeat CT of the chest abdomen and pelvis, revealing bilateral pleural effusions that were proven exudative, with intact endovascular repair. His serum albumin fell to 2.0g/dl from a previous baseline of 3.8g/dl, with 2+ proteinuria on urinalysis. Urine microscopy was notable for Maltese crosses reflecting lipid droplets. The serum creatinine (SCr) remained at baseline of 1.4 mg/dl. A renal biopsy showed 4 glomeruli, 1 with global sclerosis, focal interstitial infiltrate of lymphocytes and plasma cells, global foot process effacement on electron microscopy without immune complex deposition. Immunofluorescence was not completed. A final diagnosis of MCD or unsampled primary focal segmental glomerulosclerosis (FSGS) was given by the renal pathologist and given scarring with interstitial infiltrate a clinical diagnosis of FSGS was more likely. A unifying diagnosis of post-implantation syndrome was made after an extensive infectious, vasculitis, and rheumatologic work up were negative. Prednisone 60mg daily with loop diuretics was started. Upon follow up his serum albumin rose to 3.6g/dl, his edema and pleural effusions had resolved.

Discussion: Post-implantation syndrome describes the clinical entity of systemic inflammatory response after repair of AAA. The incidence of the syndrome has been reported to vary widely between 3% and 60% for AAAs. We describe the first case of podocytopathy following EVAR in a patient with post-implantation syndrome, that responded to corticosteroids.

SA-PO303

A Tough Nut to Crack

Danielle Janosevic,[1] Michael T. Eadon.[2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University Division of Nephrology, Indianapolis, IN.*

Introduction: "Nutcracker Kidney" is a puzzling diagnosis which conventional imaging can miss. We present a case with a high degree of clinical suspicion wherein positional Doppler imaging was required to confirm the diagnosis.

Case Description: A 37 year old African American male with no past medical history presented with several months of intermittent gross hematuria associated with left sided flank pain radiating to his bladder, which was exacerbated with vigorous physical activity and would resolve completely with rest. He had been self-medicating for the pain with NSAIDs on a daily basis (200-400 mg/d). Physical exam revealed a male of thin, tall stature, with a mild tenderness over the suprapubic region and left CVA. Labs: serum creatinine of 1.21 mg/dl (GFR MDRD 82 ml/min/1.73 m2), and urine microscopy with non-dysmorphic red blood cells (>250 on UA, no WBC), 24 hour urine protein of 338 mg/day. Negative urine culture and urine fungal culture. C3 was 91 mg/dl, C4 was 10 mg/dl and ANA was negative. He had a normal hemoglobin electrophoresis, 24 h urine calcium 128 mg/d. CT scan of abdomen/pelvis was significant for absence of renal calculi, cysts, or hydroureteronephrosis. CT also noted an unremarkable bladder, no papillary necrosis, no AVM, and widely patent bilateral renal veins. A cystoscopy revealed negative cytology without bladder masses. A renal doppler study in the supine and standing position was obtained due to a high suspicion for dynamic renal vein compression. The study revealed a normal right renal vein in the supine, seated, and standing positions. Two left renal veins were noted. While one left renal vein was non-pathologic, the second left renal vein doppler showed intact flow in the supine and seated positions, but continuous flow suggestive of compression in the standing position. The patient was offered intravascular intervention, but elected conservative therapy by limiting provocative physical activity.

Discussion: "Nutcracker kidney" is a challenging clinical diagnosis. The mechanism of "nutcracker kidney" is venous hypertension from compression of the left renal vein between the aorta and superior mesenteric artery. Clinicians must maintain a high index of suspicion to diagnose it with targeted dynamic imaging. In this case, all standard imaging failed to reveal the etiology and only the use of positional (standing) Doppler interrogation confirmed the diagnosis.

SA-PO304

A Diagnostic Challenge: Acute Nutcracker Abdomen

Sandheep Venkataraman,[1] John S. Kang,[2] Lin N. Lwin.[1] *[1]Montefiore Medical Center, Bronx, NY; [2]Metropolitan Hospital Center, New York, NY.*

Introduction: Nutcracker syndrome or left renal vein entrapment syndrome is a rare condition caused by the compression of left renal vein between the abdominal aorta and superior mesenteric artery (SMA). We describe the case of a young female presenting with intractable pain.

Case Description: 26-year old woman with history of recently diagnosed untreated H. pylori gastritis presented with sudden onset severe abdominal pain which lasted three weeks. The pain was sharp and worsened with food intake. She denied fever, nausea, vomiting, blood in urine, or recent NSAID use. She was tender to palpation over right and left upper quadrants of abdomen. Labs were normal. CT scan with IV contrast revealed left renal vein compressed between the aorta and the SMA, congested left kidney, medullary edema, and numerous retroperitoneal venous collaterals. This was thought to be incidental. She was diagnosed as gastritis and discharged on H. pylori treatment. However, she returned one month later with persistent abdominal pain. Renal doppler ultrasound showed significant narrowing of left renal vein with significant velocity gradient, consistent with Nutcracker syndrome. Contrast venography revealed proximal left renal vein narrowing, with elevated distal left renal vein pressure, which resolved with stent placement. She became pain-free after the procedure.

Discussion: Nutcracker syndrome was first described in 1937. It occurs due to an idiopathic decrease in the angle between the aorta and the SMA (to less than 35 degrees), with consequent compression of the left renal vein. It is most often asymptomatic, painless, and requires a high index of suspicion to diagnose. Serum biochemistry and urinalysis are often unremarkable. Our patient presented atypically with only acute abdominal pain, which can have a broad differential, making this diagnosis easy to miss. In some cases of nutcracker syndrome, severely increased pressure can lead to abnormal thin-walled collaterals which rupture leading to gross or microscopic hematuria, which was not seen in our patient. The diagnosis is usually made based on degree of stenosis and increased flow velocity as seen on doppler ultrasound. Venography is confirmatory. Treatment can be conservative or surgical. Given the rarity of the condition and limited evidence, the long-term prognosis remains to be elucidated.

SA-PO305

Deletion of Matrix Metalloproteinase-10 Ameliorates Aldosterone-Induced Glomerular Injury in Guanylyl Cyclase-A Knockout Mice

Keisuke Osaki,[1] Yukiko Kato,[1] Naohiro Toda,[2] Akira Ishii,[1] Keita P. Mori,[1] Shoko Ohno,[1] Kiyoshi Mori,[5] Masato Kasahara,[3] Masashi Mukoyama,[6] Motoko Yanagita,[4] Hideki Yokoi.[1] *[1]Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Kansai Electric Power Hospital, Osaka, Japan; [3]Institute for Clinical and Translational Science Nara Medical University Hospital, Kashihara, Japan; [4]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [5]School of Pharmaceut Sci, University of Shizuoka, Shizuoka, Japan; [6]Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan.*

Background: Recently, we and others have unveiled the novel renal function of natriuretic peptide receptor/guanylyl cyclase-A (GC-A) system on antagonizing aldosterone-induced podocyte injury as well as the conventional effects on natriuresis and reducing blood pressure. We previously investigated uninephrectomized, aldosterone-infused, and high salt diet-fed (ALDO) systemic GC-A knockout (KO) mice, resulting in hypertension, massive albuminuria, mesangial expansion and podocyte injury. However, genes involved in glomerular injury are elusive.

Methods: To identify responsible genes for podocyte injury, we compared glomerular mRNAs from ALDO control mice with ALDO systemic GC-A KO mice using microarray. Furthermore, we examined the role of the identified gene using its KO mice. We performed immunofluorescence study for an identified protein.

Results: Microarray analysis revealed that matrix metalloproteinase-10 (MMP-10) was upregulated more than 40 times in glomeruli of ALDO GC-A KO mice. To investigate the role of MMP-10, we generated double KO (DKO) mice for systemic GC-A and systemic MMP-10. ALDO systemic GC-A and MMP-10 DKO mice showed 80% reduction of albuminuria (4657μg/mgCr vs 24516μg/mgCr, $p<0.05$), and amelioration of podocyte injury demonstrated by improvement of foot process effacement and preservation of podocyte number, compared with ALDO systemic GC-A KO mice. Glomerular mRNA expression of extracellular matrix-related genes such as Tgfb1, Ctgf, and Col4a3 was upregulated in ALDO GC-A KO mice, and the upregulation was canceled by deletion of MMP-10. Immunofluorescence study revealed that MMP-10 expression was pronounced mainly in glomerular cells in ALDO GC-A KO mice. MMP-10 expression was also increased in proliferative lesions of human glomerular diseases such as Lupus nephritis, ANCA related nephritis, and IgA nephritis. *In vitro*, mRNA expression of MMP-10 was increased in human podocytes with TNF-α or TGF-β stimulation.

Conclusions: These results suggest that MMP-10 plays a crucial role in aldosterone-induced podocyte injury in GC-A KO mice, and can be a potential new target for treating kidney diseases.

SA-PO306

Par3A and Par3B Orchestrate Podocyte Polarity

Sybille Köhler,[1] Sandra Iden,[2] Carien M. Niessen,[4] Bernhard Schermer,[1] Thomas Benzing,[2] Barry Denholm,[3] Paul T. Brinkkoetter.[1] *[1]University Hospital Cologne, Cologne, Germany; [2]University of Cologne, Cologne, Germany; [3]Edinburgh University, Edinburgh, United Kingdom; [4]CECAD University clinic of Cologne, Cologne, Germany.*

Background: Polarity signaling through the aPKC-Par polarity complex is essential for the development and maintenance of the podocyte architecture and the function of the glomerular filtration barrier of the kidney. Despite its well-established role in aPKC-mediated signaling, Par3A appears to be dispensable for the function of the glomerular filtration barrier. Interestingly, loss of Par3B also did not result in albuminuria and glomerulosclerosis.

Methods: To study potential compensatory mechanisms between Par3A and Par3B, we employed conditional *in vivo* targeting strategies specifically in podocytes and generated podocyte-specific Par3A/B double knockout mice.

Results: Within 8 weeks Par3A/B DKO mice developed severe proteinuria and renal failure. We utilized *Drosophila* nephrocytes to further study the interplay between the

different Par3 proteins. Here, we show co-localization of the Par3A/B homolog bazooka and the nephrocyte diaphragm proteins Sns (nephrin) and Duf (NEPH1) at different developmental stages. Silencing bazooka expression resulted in disturbed nephrocyte diaphragm morphology, severe filtration defects and delayed larval development. To investigate the functional role of Par3A and Par3B, we re-expressed different murine Par3 variants in a *bazooka* knockdown background using the UAS-GAL4 system. Here, we performed several morphological and functional studies and observed different degrees of rescue potential. We utilized high resolution microscopy to resolve the nephrocyte diaphragm pattern and observed a decreased coverage and severely changed localization of Duf (dNeph) and Pyd (dZO-1) after nephrocyte-specific depletion of bazooka. This phenotype can be partially rescued by re-expression of aPKCiota-binding Par3 variants, while the 100kDa Par3A variant and Par3B present with almost no rescue. As none of the Par3 variants is able to provide a full rescue and to study the potential compensatory phenotype between Par3A and Par3B we generated Par3A/B double rescue flies and could show an almost complete rescue in Duf (dNeph) and Pyd (dZO-1) localization, confirming the compensatory potential of the two Par3 variants.

Conclusions: Taken together, these findings support the hypothesis of a potential compensatory mechanism between Par3A and Par3B to maintain polarity signaling at the slit diaphragm which are - at least partially – independent of aPKC.

SA-PO307

Complete Lack of Synaptopodin Causes No Overt Podocyte Defects

Liang Ning,[2] Hani Suleiman,[2] Jeffrey H. Miner.[1] *[1]Washington University School of Medicine, St. Louis, MO; [2]Washington University, St. Louis, MO.*

Background: Synaptopodin (Synpo) is an actin-associated protein found in podocyte foot processes and in dendritic spines. Many functions in regulating the actin cytoskeleton via RhoA and other pathways have been ascribed to Synpo, yet no pathogenic mutations in *SYNPO* have been discovered in patients. Several naturally occurring Synpo isoforms have been described (e.g., Synpo-short and -long), and a novel truncated protein (Synpo-T) was detected in the podocytes of *Synpo*mutant mice. Synpo-T was reported to maintain some Synpo functions, thus preventing a major podocyte phenotype from emerging. To further investigate the functions of Synpo in podocytes, we attempted to knockout the majority of the *Synpo*gene and prevent production of a protein.

Methods: We used CRISPR/Cas9 in embryos with two guide RNAs targeting near the 5' and 3' ends of the Synpo gene to attempt to either delete most of the gene or mutate each end to prevent protein production. DNA sequencing was used to identify specific mutations. Immunofluorescence and western blotting using antibodies to amino-terminal, internal, and carboxyl-terminal epitopes were used to assay for Synpo protein. Mutant mice were observed for up to 12 months. Urine, blood, and tissue were taken at select time points to evaluate albuminuria, BUN, histopathology, and glomerular capillary wall ultrastructure. Super-resolution imaging was used to characterize the cytoskeleton. Adriamycin injections were performed.

Results: Many mutations were discovered in 80 founder mice: small deletions and insertions that shifted the reading frame; two deletions of 8 kb between the gRNA target sites; a 6 kb inversion; and a 3' deletion of 7 bp that produced a truncated protein. Several of these were made homozygous or compound heterozygous. There were no significant differences in body weight between the mutants and controls. Urinary protein levels were normal up to 12 months regardless of the Synpo mutation(s) present. There were no obvious histological or ultrastructural abnormalities in 36-week-old mutant mice, and the actin cytoskeleton showed no obvious defects other than the absence of Synpo. However, Synpo mutant podocytes had worse injury from ADR.

Conclusions: Synaptopodin is dispensable for the development and maintenance of podocytes and for function of the glomerular filtration barrier. This is consistent with the lack of *SYNPO* mutations found in proteinuric patients.

SA-PO308

Protecting Glomerular Disease Progression in Mice Lacking Podocyte Associated Talin1 by Tangshen Formula

Tingting Zhao,[3,1] Xuefei Tian,[2] Ping Li,[3] Shuta Ishibe.[4] *[1]Yale School of Medicine, New Haven, CT; [2]Yale University, New Haven, CT; [3]China-Japan Friendship Hospital, Beijing, China; [4]Yale University School of Medicine, New Haven, CT.*

Background: Loss of podocyte associated talin1 in mice results in severe proteinuria and kidney failure. Tangshen Formula (TSF), a traditional Chinese Medicine, has been confirmed to play a renal protective effect in rats with diabetic kidney disease and in patients with type 2 diabetic kidney disease. In this study, we further investigate the effect of TSF in genetic mouse model of disease where robust proteinuria is evident.

Methods: Twelve 8 weeks old *Tln1*$^{fl/fl}$ Pod-rtTA TetO-Cre mice (i*Tln1* KO) were induced with doxycycline for three weeks to specifically delete talin1 expression in the podocytes. After 2 weeks of doxycycline induction, the mice were separated into two groups +/- TSF treatment (6 *vs* 6). TSF were delivered by oral gavage at a dosage of 2.4g/Kg body weight/day for total of 5 weeks.

Results: Two weeks of doxycycline induction in the i*Tln1* KO mice, resulted in robust albuminuria prior to treatment (TSF treatment group: 817.35 ± 69.99 vs 53.02 ±10.34 μg/mg creatinine; Placebo treatment group: 781.97 ±72.70 vs 63.49 ±15.52 μg/mg creatinine) measured by ELISA. Following TSF or Placebo treatment for 5 weeks, TSF treatment in the i*Tln1* KO mice significantly reduced albuminuria compared to the placebo group (2136.88 ±270.32 vs 4028.4±516.67 μg/mg creatinine, P<0.05). TSF treatment in the i*Tln1* KO mice improved renal function measured by plasma creatinine (0.46±004 mg/dl to 0.33±0.03 mg/dl. P<0.05). TSF treatment in i*Tln1* KO mice ameliorated glomerulosclerosis and inhibited tubulointerstitial injury including interstitial fibrosis, tubular dilatation, and proteinaceous casts. Ultrastructural examination by transmission electron micrographs also showed improvement in foot process effacement and thickness of the basement membrane in i*Tln1* KO mice treated with TSF.

Conclusions: These results suggest a potential therapeutic role of TSF mice with proteinuric kidney disease and may have a protective role in human glomerulonephropathies.

SA-PO309

Deletion of NuRD Component MTA2 in Nephron Progenitors Results in Renal Hypoplasia and Focal Segmental Glomerulosclerosis

Jeannine M. Basta,[1,2] Lynn Robbins,[1,2] Lisa Stout,[1] Darcy R. Denner,[3] Michael I. Rauchman.[1,2] *[1]Internal Medicine- Nephrology, Washington University in St. Louis, St. Louis, MO; [2]VA St. Louis Healthcare System, St. Louis, MO; [3]Washington University in St. Louis, St. Louis, MO.*

Background: The Nucleosome Remodeling and Deacetylase Complex (NuRD) is a large multi-protein, evolutionarily conserved chromatin remodeling complex that harnesses the power of ATP via the ATPase Chd4 (Mi2β) to mediate nucleosome sliding and remodeling. It also has histone deacetylase activity via Hdac 1/2. We showed that the NuRD component Mi2β and the association between Sall1-NuRD is required for the regulation of nephron progenitor cells (NPCs).

Methods: In this study we deleted the NuRD specific component *Mta2* in Six2+ NPCs.

Results: Mutant mice were viable, although mild renal hypoplasia was evident at embryonic day (E)14-16 (kidney area/body weight 41.2±2.6 vs 53.6±1.7 mm^2/gm). Immunostaining for nephron segment specific markers showed that the nephrogenic zone was not reduced and all differentiating nephron structures appeared normal in the mutant. RNA-seq analysis at E17 showed a number of downregulated genes important for metabolic pathways (23 genes, $p=9.78X10^{-4}$), indicating reduced metabolic fitness of NPCs may account for renal hypoplasia. By 2 months of age *Mta2* mutant mice developed proteinuria (1614±469 vs 53±15 ug albumin/mg creatinine, n= 20 mut, 13 control). Analysis of mutant kidneys revealed findings consistent with focal segmental glomerulosclerosis (FSGS), including mesangial hypercellularity, segmental glomerular scarring, and tip lesions. At 6 months of age albuminuria progressed in the mutant (7110±3739 vs 25±4, n=8 mut 8 control); histopathology showed an increase in globally sclerotic glomeruli, proliferation of parietal epithelial cells with formation of pseudo-crescents, and trichrome staining revealed tubulo-interstitial fibrosis. Mitochondrial dysfunction in podocytes has been shown to contribute to development of FSGS. Transcriptional profiling at 2 months of age revealed significant enrichment in the oxidative phosphorylation pathway for downregulated genes in the mutant (35 genes, $p=1.18 \times 10^{-18}$). Mutant mice frequently die after 6 months of age, however survivors at 1 year of age have significantly elevated sCr (0.16±0.013 vs 0.122±0.009 mg/dL, p=0.035, n= 5 mut, 10 control).

Conclusions: Our results suggest that regulation of metabolic homeostasis by NuRD is required for proper kidney development and for maintenance of normal glomerular function after birth.

SA-PO310

Intervention with the Novel Fibrokinase Inhibitor ANG3070 Mitigates Glomerular Scarring and Attenuates Proteinuria in a Model of Focal Segmental Glomerulosclerosis

Prakash Narayan,[1] Quaisar Ali,[2] Latha Paka,[1] Jingsong Li,[2] Dibyendu Dana,[2] Satishkumar V. Gadhiya,[2] An-Hu Li,[2] Michael A. Yamin,[2] Itzhak D. Goldberg.[2] *[1]Angion Biomedica Corp, Uniondale, NY; [2]Angion Biomedica Corp., Uniondale, NY.*

Background: Steroid-resistant (SR) primary Focal Segmental Glomerulosclerosis (FSGS) is accompanied by nephrotic-range proteinuria and necessitates renal replacement therapy. We investigated the effects of a novel small molecule platelet-derived growth factor (PDGF) receptor + vascular endothelial growth factor (VEGF) receptor inhibitor, ANG3070, in a clinically relevant model of FSGS.

Methods: Adult male rats were administered puromycin ((puro), 100 mg/kg, intraperitoneal) or saline (sham). On day 3, after onset of proteinuria, the puro cohort was randomized to vehicle or ANG3070. Twenty-four hour urine was collected on days 7 and 14 at which kidneys were retrieved for analysis.

Results: Puro administration was associated with accumulation of PDGF in the glomerulus, increased glomerular dimension and scarring, and proteinuria. Intervention with ANG3070 attenuated proteinuria on days 7 and 14. Puro-induced glomerular hypertrophy and scarring were both reduced with ANG3070 intervention. Proteinuria-induced tubular toxicity was also reduced with drug.

Conclusions: In a clinically relevant model of FSGS, intervention with ANG3070 is beneficial. These data, form, in part, the basis for using a Precision Medicine approach to evaluate safety and efficacy of this drug in SR primary FSGS.

SA-PO311

Differences in Podocyte Regeneration Between Cortical and Juxtamedullary Nephrons Defined by 3D Analysis and STED Imaging

Maria Lucia Angelotti,[1] Giulia Antonelli,[2] Carolina Conte,[2] Maria elena Melica,[3] Hans J. Anders,[4] Paola Romagnani.[2] *[1]Excellence Center for Research, Transfer and High Education Denothe, University of Florence, Florence, Italy; [2]University of Florence, Florence, Italy; [3]Università di Firenze, Florence, Italy; [4]Klinikum der Universitat Munchen, Munchen, Germany.*

Background: Podocyte injury is a central pathomechanism of glomerulosclerosis. Regeneration of lost podocytes from podocyte progenitors along Bowman's capsule can occur but the number of new podocytes seemed to be rather low. We hypothesized that traditional 2D tissue analysis underestimates podocyte regeneration and that injury and regeneration are not equally distributed between cortical and juxtamedullary nephrons.

Methods: To test this concept we employed *Nphs2.rtTA;TetO.Cre;mT/mG* and *Pax2.rtTA;TetO.Cre;mT/mG* mice to quantify adriamycin (ADR)-related podocyte loss and de novo podocyte formation from Pax2+ podocyte progenitors by lineage tracing, using Z-stack confocal microscopy for 3D quantitative analysis and STED microscopy to assure integration of new podocytes into the glomerular filtration barrier. CXCL12 inhibition was used to assess drug-related enhancement of podocyte regeneration.

Results: 2D analysis underestimated the percentage of glomeruli showing podocyte regeneration in comparison to 3D (8.05% *vs* 25.23% $p<0.05$). Doxycyclin-induced podocyte labeling in *Nphs2.iCreER;mT/mG* mice revealed a higher number of podocytes in juxtamedullary glomeruli vs. cortical glomeruli (52.56±1.5 *vs* 81.96±2.85, $p<0.001$). In contrast, doxycyclin-induced Pax2+ progenitor labeling in *Pax2.rtTA;TetO.Cre;mT/mG* mice revealed that less juxtamedullary glomeruli had progenitors along Bowman's capsule vs. cortical glomeruli (79.03±0.15% *vs* 46.15±2.2%, $p<0.05$). Upon ADR exposure, *Nphs2.iCreER;mT/mG* mice juxtamedullary glomeruli lost a higher percentage of podocytes as compared to cortical glomeruli (13.79±3.18% vs 34.11±1.65%, $p<0.05$). *Pax2.rtTA;TetO.Cre;mT/mG* mice revealed that podocyte regeneration was limited in juxtamedullary glomeruli, while cortical glomeruli revealed new progenitor-derived podocytes, a difference that increased with CXCL12 inhibition (24.03±4.8 *vs* 75.96±4.8, $p<0.05$). STED microscopy revealed the ultrastructure of new podocytes, including secondary and tertiary foot processes. CXCL12 blockade also resulted in proteinuria improvement ($p<0.05$ at 28 days).

Conclusions: These results show that juxtamedullary and cortical nephrons differ in their capacity to regenerate podocytes upon injury and explain the clinical observation that FSGS starts and is more severe in juxtamedullary nephrons.

Funding: Government Support - Non-U.S.

SA-PO312

Mechano-Growth Factor (MGF) Mediation of Glomerulosclerosis (GS) Involves Activation of PKC

Yongxin Gao,[2] Emma P. Bueno,[1] Nanjoo Shin,[2] Leighton R. James,[1] Charles W. Heilig.[1] *[1]UF COM- Jacksonville, Jacksonville, FL; [2]University of Florida, Jacksonville, FL.*

Background: We previously reported PKC ß1 and PKC a activation in our non-diabetic GS mouse model Fvb Os/+, with reduced glomerular numbers, glomerular hypertension, and increased SNGFR. GS develops rapidly after birth leading to renal failure and premature demise. MGF is expressed in the glomeruli and is responsive to stretch in other tissues. Here we investigate MGF expression in Fvb Os/+ glomeruli, in cultured Fvb Os/+ mesangial cells(MC), and potential MGF-regulation of PKC activation. We hypothesize that MGF activation of PKC may explain the GS in Fvb Os/+ mice and excess extracellular matrix (ECM) in cultured Fvb Os/+ mesangial cells (MC).

Methods: 1. Fvb Os/+ and Fvb +/+ mouse kidneys were harvested and fixed at age 4 weeks for PAS staining and immunolabelling (0 - 4+) for MGF, active PKC ß1 and active PKC a; Total glomerular or MC proteins were also isolated for Western analyses of selected proteins then semiquantitated. 2. Primary culture MC's from mice of both genotypes were grown to 80-100 % confluence in DMEM medium 8mM glucose,10% FBS at 37 C and 5% CO_2. 3. Normal mouse MC's transduced (pWZLneo MoMuLV expression vector) to overexpress (MGF-S), or suppress (MGF-AS) MGF were examined with Western analyses to investigate potential PKC regulation by MGF. 4. Mean ± SEM was determined and statistical analyses performed with one way ANOVA, & Students T-test where indicated.

Results: 1. Fvb Os/+ glomeruli exhibited > 2-fold ($P < .005$) increase in glomerular MGF vs. control. 2. Fvb Os/+ MC's had 1.6-fold elevated MGF ($P < 0.05$), with increased active PKC ß1 (3.5-fold, $P < 0.005$) and active PKC a (2.9-fold, $P < 0.005$). This correlated with increased fibronectin (FN) and Type IV collagen (Col-IV) in the cells. 3. MGF-S had 4.5-fold overexpression of MGF protein, ($P < 0.02$), with increased active PKC ß1 (4-fold, $P < 0.05$) and PKC a (4-fold $P < 0.05$). MGF-AS had 50% suppression of basal PKCß1.

Conclusions: 1. Increased MGF was observed in FvbOs/+ glomeruli and cultured Fvb Os/+ MC, correlating with PKC B1 and PKC a activation in both. High MGF and PKC activation were maintained with passage of Fvb Os/+ MC in vitro, associated with high FN and Col-IV. 2. MGF-S also exhibited activation of PKC ß1 and PKC a, which may mediate the increased ECM in these cells as well.

SA-PO313

The Molecular Mechanism of Action of AT2R Agonist Compound 21 (C21) on Ameliorating Murine FSGS

Min-Chun Liao,[1] Shiao-Ying Chang,[1] Chao-Sheng Lo,[1] Isabelle Chenier,[1] Julie R. Ingelfinger,[2] John S. Chan,[1] Shao-Ling Zhang.[1] *[1]CRCHUM, Universite de Montreal, Montreal, QC, Canada; [2]The New England Journal of Medicine, Boston, MA.*

Background: We previously reported (*J Pathology 2017*) that angiotensin II type 2 receptor (AT_2R) deficiency is associated with podocyte loss and podocyte transition from normal morphology to apoptotic and/or fibrotic-like phenotype via hedgehog interacting protein (Hhip) gene expression. Here, we examined whether the administration of AT_2R agonist Compound 21 (C21) would ameliorate murine FSGS and investigated the underlying mechanisms both *in vivo* and *in vitro*.

Methods: FSGS was induced by a single intravenous injection of doxorubicin (18 mg/kg, body weight, in saline) in both male wild type (WT) and AT_2R knockout (KO) mice at 8 weeks of age. Mice were euthanized 4 weeks after doxorubicin injection. Five subgroups of mice including WT [Control (WT-Con), WT-FSGS, FSGS treated with C21 (0.3 mg/kg/day, intraperitoneal (i.p.) (WT-FSGS-C21] and AT_2R KO mice [Control (KO-Con) and KO-FSGS] were studied. Physiological parameters, renal morphology/function analysis and molecular analysis in glomeruli were carried out; *in vitro* studies were done in a mouse podocyte cell line (mPODs).

Results: FSGS was far more severe in AT_2RKO mice as compared to WT-FSGS mice, evidences by profound glomerulosclerosis on Periodic Acid Schiff and Masson trichrome staining, increased podocyte loss (synaptopodin- and p57-immunofluorescence (IF) staining) and more proteinuria (urinary albumin/creatinine ratio measurement and urinary Coomassie blue staining), together underscoring the key role of AT_2R in FSGS-related podocyte-glomerulopathy. As compared with WT-Con, WT animals with FSGS had high numbers of parietal epithelial cells (PECs), which are paired homeobox 2 (Pax2) positive cells, but fewer podocytes (IF-p57 positive and IF-Pax2 negative cells). Intriguingly, C21 administration (WT-FSGS-C21) ameliorated the features of FSGS (proteinuria, renal morphology/function) via inhibition of glomerular Hhip expression. *In vitro*, increased Hhip and Pax2 gene expression with transient transfection of respective cDNAs promoted apoptotic and/or fibrotic-like phenotype shift in podocytes.

Conclusions: The glomerular AT_2R-Pax2-Hhip axis appears to be involved in the transition of podocytes to PECs; we speculate such transition occurs through AT_2R-Pax2-Hhip modulation of PEC-related profibrotic effects and subsequent podocyte loss/sclerosis in FSGS

Klotho Ameliorates Diabetic Glomerulonephritis by Suppressing TRPC6 in Podocytes

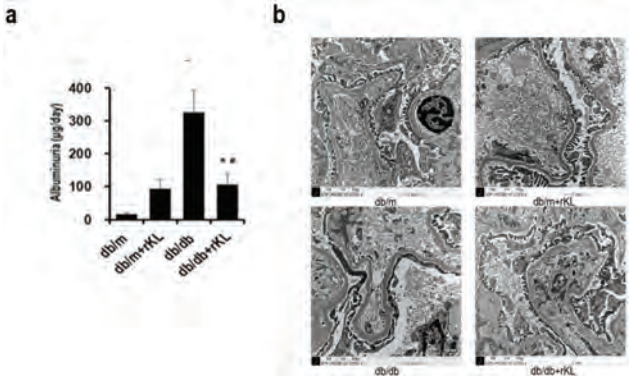
Jinho Lee, Tsogbadrakh B. Bodokhsuren, Sohyun Yun, Hyunjin Ryu, Eunjeong Kang, Minjung Kang, Curie Ahn, Kook-Hwan Oh. *Seoul National University Hospital, Seoul, Republic of Korea.*

Background: Glomerular podocyte injury is the hallmark of diabetic nephropathy (DN). This damage is related with increase of transient receptor potential channel 6 (TRPC6) calcium channel in podocytes, mediating calcium influx, thus causing foot process effacement. Since klotho is reported as a TRPC6-suppressing factor in nephrectomized mice, we hypothesized that klotho may also inhibit diabetes-induced TRPC6 up-regulation in podocytes, thereby reduce albuminuria.

Methods: We injected recombinant klotho protein (rKL) into db/db and db/m mice for 8 weeks, and collected the urine and the kidney. We treated rKL to cultured podocytes, with or without high glucose (HG, 30mM) exposed.

Results: rKL treated db/db mice showed dramatic glomerular recovery, including amelioration of basement membrane thickening and foot process effacement, as well as remarkably reduced albuminuria. We also confirmed increased renal expression of TRPC6 and its downstream molecules, PI3K and calcineurin in diabetic mice, were normalized by rKL. Next, we analyzed TRPC6, PI3K and calcineurin in podocytes. HG-mediated increase of TRPC6 in podocytes is normalized by rKL treatment, showing improved cell survival and reduced intracellular calcium in HG environment.

Conclusions: Our data reveals that klotho protects the podocytes in diabetic condition by suppression of TRPC6.



rKL treat to db/db mice induced: a) reduced albuminuria, and b) glomerular recovery.

SA-PO315

A TRPC5 Inhibitor Protects Podocytes from Injury in a Minimal Change Disease Rat Model

Yiming Zhou,[1,2] Fan Zhang,[1,2] Andrew J. Watts,[1,2] Katherine A. Vernon,[1,2] Anna Greka.[1,2] *[1]Brigham and Women's Hospital/Harvard Medical School, Boston, MA; [2]Broad Institute of MIT and Harvard, Cambridge, MA.*

Background: Inhibition of the Rac1-TRPC5 disease pathway in podocytes using specific TRPC5 ion channel inhibitors has been shown to protect from podocyte injury and loss in two pre-clinical animal models: a transgenic rat model of FSGS and a spontaneous hypertensive rat model of FSGS. Since the Rac1-TRPC5 disease pathway has been implicated in the earliest cytoskeletal podocyte changes leading to the development of nephrotic range proteinuria, we asked whether TRPC5 inhibition can confer benefit in a rat model of minimal change disease (MCD).

Methods: We investigated the effect of the specific TRPC5 inhibitor AC1903 in a puromycin aminonucleoside (PAN)-induced rat model. PAN treatment has been shown to induced podocyte injury, foot process effacement and proteinuria with no glomerular histological changes in rats, which most closely resembles human MCD.

Results: We found that a single injection of 50 mg/kg PAN caused podocyte injury and led to a significant increase in proteinuria 7 days after a single injection of PAN. Treatment with AC1903 administered intraperitoneally (i.p.) twice daily significantly reduced the amount of proteinuria induced by PAN injection as measured in 24 hour urine collected in metabolic cages on day 7 post-PAN injection. In histologic analysis of rat kidney tissue, no glomuerular lesions or other obvious changes were found, whereas electron microscopy revealed severe foot process effacement (FPE) induced by single PAN injection. This was significantly ameliorated after treatment with AC1903. Western blotting from rat kidney lysates showed that treatment with AC1903 preserved synaptopodin and podocin abundance in PAN rats.

Conclusions: Taken together, these results show that inhibition of TRPC5 ion channels by AC1903 protects podocytes from injury in a rat model of MCD. Our data thus highlight the potential of this therapeutic strategy for the full spectrum of nephrotic syndrome from MCD to FSGS.

Differential Effects of TRPC5 and TRPC6 Channels in Angiotensin II Induced Glomerular Hyperpermeability

Carl M. Öberg,[1,2] Julia Dolinina,[1,2] Anna Rippe.[1] Renal Physiology & Peritoneal Dialysis Group *[1]Department of Clinical Sciences Lund, Lund University, Lund, Sweden; [2]Department of Nephrology, Skane University Hospital, Lund, Sweden.*

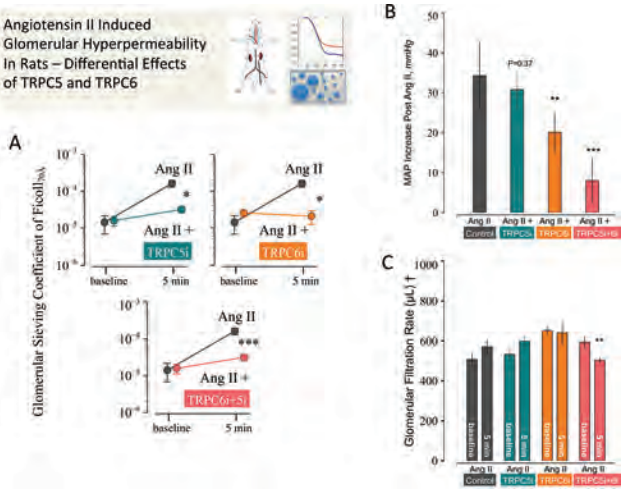
Background: Angiotensin II (Ang II) rapidly induces marked, dynamic increases in the permeability of the glomerular filtration barrier (GFB) in rats. After binding to its receptor(s), Ang II elicits Ca^{2+} influx into cells mediated by TRPC5 and TRPC6 (transient receptor potential canonical type 5 and 6). We here identifed TRPC5 and TRPC6 as regulators of Ang II induced glomerular hyperpermeability while the latter also appears to be involved in the hemodynamic effects induced by Ang II.

Methods: In anesthetized Sprague-Dawley rats, the left ureter was cannulated for urine collection and blood access was achieved. Rats were infused with Ang II (80 ng kg^{-1} min^{-1}) alone, or together with the TRPC5 blocker clemizole or low dose La^{3+} (activates TRPC5, blocks TRPC6) or high dose La^{3+} (blocks both TRPC5 and TRPC6). Plasma and urine samples were taken during baseline and at 5 min after the start of the infusions and analyzed by high-performance size-exclusion chromatography for determination of glomerular sieving coefficients (θ) for Ficoll 10-80Å (1-8 nm).

Results: Ang II infusion into rats caused marked increases in glomerular permeability to large Ficoll molecules (Ficoll 50–80Å), which were abrogated by the TRPC5 blocker clemizole, having no effect on glomerular filtration rate (GFR) or Ang II mediated increase in MAP (ΔMAP). In contrast, agents blocking TRPC6 (high and low dose La^{3+}) significantly lowered ΔMAP and nearly completely abrogated Ang II induced hyperpermeability effects. The higher dose of La^{3+}, blocking both TRPC5 and TRPC6, significantly lowered left-kidney GFR.

Conclusions: Our data unveil differential effects of Ca^{2+} signaling via TRPC5 and TRPC6 following Ang II stimulation. Especially, it appears that inhibition of TRPC5 in rats can abrogate AngII-induced glomerular hyperpermeability without affecting GFR or Ang II induced increases in MAP. Inhibition of TRPC5 may thus be a potential target for a novel antiproteinuric agent.

Funding: Government Support - Non-U.S.



SA-PO317

Small Molecule Inhibition of TRPC5 Protects Against Podocyte Injury and Proteinuria in FSGS

Amy D. Westerling-Bui,[1] Maria Beconi,[1] Hien G. Hoang,[1] Maolin Yu,[2] Matthew Daniels,[1] Goran Malojcic,[1] Mark Ledeboer,[1] Liron Walsh,[1] Thomas T. Tibbitts,[1] Jean-Christophe P. Harmange,[1] Peter H. Mundel.[1] *[1]Goldfinch Bio, Cambridge, MA; [2]Goldfinch Bio, Cambridge, MA.*

Background: FSGS is a rare kidney disorder of the podocyte with a high likelihood of progression to kidney failure. The activation of the TRPC5-RAC1 pathway in podocytes is a critical driver of proteinuria in many forms of familial and sporadic FSGS. The Ca^{2+}permeable TRPC5 channel is a critical mediator of proteinuria in FSGS. Inhibition of TRPC5 channel activity protects against proteinuria and podocyte loss in AT1R transgenic and Dahl salt sensitive rats (Zhou et al. Science, 2017).

Methods: We performed high throughput screening of a structurally diverse compound collection followed by lead optimization for the development of several potent TRPC5 inhibitors. We then analyzed the TRPC5 inhibitors in several in vitro models of podocyte injury (protamine sulfate induced cytoskeletal disruption, restoration of stress fibers in synaptopodin-depleted podocytes, inhibition of pathogenic podocyte migration) and in the DOCA-salt rat model of FSGS in vivo.

Results: Here we report the identification of potent and selective small molecule inhibitors of TRPC5. activity against TRPC5 and selectivity across other TRP channels were determined using FLIPR based assays and electrophysiology. We show that TRPC5 inhibition protects against protamine sulfate induced loss of stress fibers. TRPC5 inhibition also restores stress fibers in podocytes after knockdown of synaptopodin. We further show that inhibition of TRPC5 suppresses pathogenic podocyte motility in a scratch assay. Finally, we demonstrate that inhibition of TRPC5 suppresses proteinuria in hypertension-induced FSGS in uninephrectomized DOCA salt rats without altering blood pressure.

Conclusions: In summary, we have identified new selective small molecule inhibitors of TRPC5 for the treatment of proteinuria in FSGS.

Aldosterone Causes Albuminuria by Inducing MMP-Mediated Glomerular Endothelial Glycocalyx Dysfunction

Matthew J. Butler,[1] Raina D. Ramnath,[1] Hiroyuki Kadoya,[2] Rebecca R. Foster,[1] Janos Peti-Peterdi,[2] Simon C. Satchell.[1] *[1]University of Bristol, Bristol, United Kingdom; [2]University of Southern California, Los Angeles, CA.*

Background: Aldosterone contributes to renal disease. Mineralocorticoid receptor (MR) inhibitors slow disease progression but side effects limit their use. Damage to the endothelial glycocalyx (glx), a luminal biopolymer layer, has been implicated in pathogenesis of endothelial dysfunction and albuminuria. We investigated if glx damage contributes to aldosterone-induced renal disease.

Methods: *In vitro human* glomerular endothelial cells (GEnC) *were exposed to 0.1nM aldosterone for 5 days* +/- 1µm spironolactone. *In vivo* mice received aldosterone (0.6µg/g/day via osmotic minipump) and 1.0% NaCl drinking water +/- 5mg/kg MMP2/9 inhibitor I.P. daily. Tail cuff blood pressure (BP) measurements were conducted after 5 days training. MMP2 activity was studied using a specific activity assay. Multiphoton microscopy was used to measure the glomerular sieving coefficient for albumin (GSC_{alb}) and a novel peak-to-peak method was developed to assess changes in GEnC glx thickness

over time. ELISAs were used to measure syndecan-4 ectodomain concentrations and urine albumin levels.

Results: *In vitro* aldosterone reduced GEnC syndecan-4 ectodomain expression 0.76 fold (p=0.02) and increased MMP2 mRNA 4.5 fold (p=0.0003). Spironolactone blocked these effects. *In vivo* aldosterone resulted in significant albuminuria by day 10. Aldosterone increased glomerular MMP2 mRNA expression 5.3 fold (p=0.003) and plasma active MMP2 (22 vs 27ng/ml, p=0.045) without altering the systolic BP. The GSC_{alb} increased 7.6 fold by day 10 (p=0.0079) and the GEnC glx thickness fell from 1.1μm to 0.59μm (p=0.0013). No significant changes were detected in controls. Daily IP MMP2/9 inhibitor prevented glx loss, maintained the GSC_{alb} and prevented albuminuria without affecting the BP. Changes in glx depth predicted changes GSC_{alb} within the same glomeruli (R^2=0.8185, p=0.0028), highlighting the importance of the glx in limiting albumin filtration.

Conclusions: Syndecan-4 (a key glx component and known substrate for MMP2) is shed in response to aldosterone via an MR-MMP dependent pathway. *In vivo* aldosterone results in significant thinning of the GEnC glx and albuminuria. MMP inhibition preserved the glx and prevented albuminuria and could represent a novel potential therapeutic strategy.

Ezetimibe Protects from Renal Dysfunction in a Mouse Model of Alport Syndrome

Judith T. Molina David,[1,2] Jin Ju Kim,[1,2] Javier T. Varona Santos,[1,2] Sandra M. Merscher,[1,2] Alessia Fornoni.[1,2] *[1]1Katz Family Division of Nephrology and Hypertension, Department of Medicine, University of Miami Miller School of Medicine, Miami, Florida., Miami, FL; [2]2Peggy and Harold Katz Family Drug Discovery Center, University of Miami Miller School of Medicine, Miami, FL.*

Background: Alport Syndrome (AS) is characterized by renal disease inevitably progressing to end-stage kidney disease (ESKD), and no treatment strategies are currently available. We have recently discovered an important contribution of renal parenchyma lipid accumulation to ESKD in mice affected by AS. We hypothesized that treatment with the lipid-lowering compound ezetimibe (EZ), which targets the cholesterol transport protein Nieman Pick C1-like 1 protein and has been shown to modulate fatty acid uptake in other organs, can prevent renal lipid accumulation and podocyte injury in an experimental mouse model of AS thus improving renal function.

Methods: EZ was administered for 4 weeks by oral gavage at 5 mg/kg to 4-week-old knockout (KO) and wildtype (WT) mice. All mice were sacrificed at 8 weeks of age. The following four groups of mice were analyzed: WT, WT + EZ, KO and KO + EZ.

Results: We detected a significant decrease in the albumin-to-creatinine ratio (ACR) in KO mice treated with EZ when compared to untreated KO mice (p<0.01). Additionally, a decrease of BUN and serum creatinine levels was observed (p<0.05). EZ treatment of KO mice also resulted in a significant reduction in the body weight loss observed during disease progression (p<0.05). Furthermore, EZ normalized renal lipid metabolism as indicated by decreased total kidney cortex triglyceride content in EZ treated KO mice compared to untreated mice (p<0.05).

Conclusions: Based on these results, we conclude that EZ improves renal function in experimental AS and could represent a new repurposing strategy for the treatment of affected patients.

Differential Pathogenic Roles of Notch4 and Notch3 in the Progression of HIV Associated Nephropathy

Jessica Y. Idowu,[2] Trisha Home,[1] Pravin C. Singhal,[3] Timothy A. Fields,[2] Madhulika Sharma.[2] *[1]University of Kansas Medical Centre, Kansas City, KS; [2]University of Kansas Medical Center, Kansas, KS; [3]North Shore LIJ Health System, Great Neck, NY.*

Background: Notch pathway activation plays a central role in pathogenesis of many glomerular diseases. We have previously shown that Notch 4 and Notch 3 were up-regulated in various renal cells in HIV associated Nephropathy (HIVAN) patients and rodent models of HIVAN. Notch inhibition by gamma secretase inhibitors ameliorated disease progression in the Tg26 mouse model of HIVAN. Since gamma secretase inhibitors are associated with toxicity in clinics, here we explore individual effects of genetic inhibition of Notch4 and Notch3 on HIVAN pathogenesis.

Methods: Tg26 mice were bred with mice deleted for the intracellular domain of Notch 4 and Notch 3 separately to generate Tg26 mice with homozygous Notch4 deletion and homozygous Notch3 deletion, respectively. The effect of Notch4 and Notch3 deletion in Tg26 mice was determined by analyzing renal function, histology, cell proliferation/ podocyte differentiation and inflammatory markers.

Results: Deletion of either Notch 4 or Notch 3 in Tg26 mice significantly decreased the mortality rate and reduced kidney injury in Tg26 mice. While, Notch 4 deletion in male Tg26 mice reduced kidney injury, controlled cell proliferation, cell differentiation and inflammatory response of NF kappa B positive cells in Tg26 mice, it was not enough to significantly reduce proteinuria and blood urea nitrogen (BUN) levels. In contrast, genetic depletion of Notch3 appeared to be effective in a broader way, controlling proteinuria and BUN in Tg26 mice. In addition, histological studies indicated a significant improvement in kidney injury as evident by the reduction in glomerulosclerosis, tubule-interstitial fibrosis and interstitial inflammation in Notch3 deleted Tg26 mice. More studies are underway to reveal subtle roles of Notch4 and Notch3 activation in HIVAN.

Conclusions: Our study supports a non-redundant role of Notch 4 and Notch 3 in HIVAN pathogenesis and suggests therapeutic implications of Notch3 and Notch 4 inhibition in HIV associated nephropathy.

Targeted Inhibition of Calpain-1 and -2 Activities Improves the Progression of Proteinuric Kidney Disease in Mice Following Podocyte Injury

Xuefei Tian, Kazunori Inoue, Christopher E. Pedigo, Shuta Ishibe. *Yale University School of Medicine, New Haven, CT.*

Background: We have previously shown that calpain activation occurs in mice glomerular injury models and in urine samples of proteinuric patients with FSGS. However, calpain's function in podocyte biology has not been fully elucidated. This study examines whether the decrease in calpain-1/-2 activities, by calpain inhibitor or deletion of podocyte-associated *CAPN4* improves the progression of mice podocyte injury.

Methods: Using the proteinuric models *Tln1$^{fl/fl}$* Podcin-Cre mice (Germline Talin1 podocyte knockout mice, *Tln1* KO) and Doxycycline inducible *Tln1$^{fl/fl}$* Pod-rtTA TetO-Cre mice (i*Tln1* KO), inhibiting calpain-1/-2 activities with calpain inhibitor III (CI) was examined for albuminuria, histological changes, and kidney function. Furthermore, a mouse model with podocyte-specific deletion of *CAPN4* was generated abrogating both calpain-1/-2 activities. We investigated the above changes on the *Tln1$^{fl/fl}$ CAPN4$^{fl/fl}$* Podcin-Cre mice (*Tln1+CAPN4* DKO) and *Tln1$^{fl/fl}$* Pod-rtTA TetO-Cre mice (i*Tln1+CAPN4* DKO).

Results: Treatment of *Tln1* KO mice with CI (30mg/kg B.W/day, i.p) was started at 2 weeks of age when robust albuminuria was already present. At 8 weeks, significantly reduced albuminuria was observed in the CI treated mice (18229.61±1537.80 vs 12963.55 ±1182.49 μg/mg creatinine). Furthermore, treatment with CI prolonged the survival of the *Tln1* KO mice (median survival: 9 weeks vs 4 weeks). Treatment with CI for 4 weeks in the i*Tln1* KO mice also reduced the degree of albuminuria (4949.55±320.46 vs 3327.87 ±217.28 μg/mg creatinine), improved renal histological lesions, and kidney function. Mice with genetic ablation of *CAPN4* in podocytes on the background of *Tln1* KO or *iTln1* KO reduced the degree of albuminuria (18574.82±1703.31 vs 13398.37 ±1457.07 μg/mg creatinine in *Tln1* KO vs *Tln1+ CAPN4* DKO at 8 weeks of age; 4335.27±438.42 vs 2445.92 ±367.28 μg/mg creatinine in i*Tln1* KO vs i*Tln1+CAPN4* DKO), while also improving the renal histological lesions and kidney function, and leading to the prolonged survival (median survival: 9 weeks vs 4.5 weeks in *Tln1+CAPN4* DKO vs *Tln1 KO*).

Conclusions: Proteinuric kidney disease in both germline *Tln1* KO or i*Tln1* KO mice are attenuated by reduction of calpain-1/-2 activities, thus representing a potential novel therapeutic strategy for the progression of proteinuric kidney disease.

SA-PO322

Elucidating the Pathogenesis of Focal Segmental Glomerulosclerosis Using CRISPR/Cas9 Mediated Genome Engineering

Linus Butt,[2] David Unnersjö-Jess,[1] Markus M. Rinschen,[2] Dervla Reilly,[2] Lioba Ester,[2] Hjalmar Brismar,[1] Paul T. Brinkkoetter,[2] Bernhard Schermer,[2] Thomas Benzing.[3] *[1]Royal Institute of Technology, Solna, Sweden; [2]University Hospital Cologne, Cologne, Germany; [3]University of Cologne, Köln, Germany.*

Background: *NPHS2* encodes for the PHB-domain protein podocin and is one of the most frequently mutated genes in patients with Focal Segmental Glomerulosclerosis (FSGS). Currently, loss of podocytes is regarded as the hallmark of the pathogenesis of FSGS. Investigating the initial molecular events causing podocyte injury and depletion is of utmost importance for future preventive and therapeutic strategies.

Methods: Here, we present a mouse model for a late-onset FSGS phenotype. Using CRISPR/Cas9 mediated genome engineering, we separately integrated two point mutations in the *Nphs2* gene which, in compound-heterozygosity, represent a commonly found genotype in patients with a late-onset.

Results: *In vivo* data of compound-heterozygous animals reveal an early onset of mild proteinuria long before the manifestation of FSGS lesions. The proteinuria increases gradually and reaches nephrotic range in young adult mice (> 8 weeks). Histologically, FSGS lesions are found between 8 and 20 weeks. By using STED microscopy at different time points (P0, 2, 4, 8, 20 weeks) we show a shortening and widening of the foot processes and a decreasing containment of the capillary surface by the secondary processes in compound-heterozygous in comparison to control mice. Quantification of podocyte numbers in kidney sections revealed a progressive decline in mutant mice. The glomerular proteome at 3 weeks shows a general decrease in podocyte specific proteins, in particular of polarity related proteins.

Conclusions: In this study, we have generated a late-onset FSGS disease model resembling human genetic disease by using CRISPR/Cas9 mediated genome engineering. Mutant mice develop progressive proteinuria accompanied by a full blown morphological manifestation of FSGS. Delineation of the foot process microarchitecture by STED microscopy shows a loss of the distinct microarchitecture of the podocyte and a decreased containment of the capillary surface as an early pathological sign that precedes the onset of massive proteinuria. Interestingly, the containment is relatively steady throughout the first phase of podocyte depletion, possibly by expansion of individual foot processes. The shift in the glomerular proteome is consistent with a podocyte dedifferentitation and/or loss of polarity.

SA-PO323

Podocyte-Specific Deletion of Hypoxia-Inducible Factor 1α (Hif-1α) Identifies Downstream Mediators That Are Targets to Prevent Proteinuria and Subsequent Glomerulosclerosis

Xiaoyan Liang, H. William Schnaper, Tomoko Hayashida. *Northwestern University, Chicago, IL.*

Background: While augmentation of signals mediated by HIFs preserves organs in ischemia, the role of HIFs in more chronic glomerulopathies following podocyte injury is rather controversial. We recently reported that mice in which systemic knockout of HIF-1α is induced at the age of 6 weeks demonstrate significantly less fibrosis in Adriamycin (ADR)-induced glomerulopathy. Others previously reported that podocyte-specific deletion of von Hippel Lindau protein, that targets HIFs for degradation, resulted in increased expression of HIFs and severe glomerulopathy in mice. These results suggest that HIFs aggravate glomerular injury. Here, we further evaluated the roles of HIF specifically in podocytes, using mice that lack podocyte HIF-1α.

Methods: HIF-1$\alpha^{f/f}$ mice were crossed with NPHS2-Cre mice. Adriamycin (ADR, 10mg/kgBW) was administered intravenously to the HIF-1$\alpha^{-/-Podo}$ or their wild-type (WT) littermates to induce glomerulopathy, and urine and kidneys were obtained on day14. RNA was isolated from cryosectioned glomerular samples using laser-capture microdissection, and HIF-1α-target gene were evaluated by qPCR. HIF-1α knockdown podocytes were generated using lenti-viral shRNAs.

Results: HIF-1$\alpha^{-/-Podo}$ mice were viable and no proteinuria was detected basally. ADR caused severe proteinuria, glomerular fibrosis and podocyte effacement in WT mice, whereas in HIF-1$\alpha^{-/-Podo}$ mice, proteinuria and glomerular sclerosis were minimally observed and podocyte structures were preserved. Among known HIF-1α-target genes tested, *Irg2* and *Mif* were increased in glomeruli of WT mice treated with ADR but not in HIF-1$\alpha^{-/-Podo}$ mice, whereas *ApoE* expression was elevated in both WT and HIF-1$\alpha^{-/-Podo}$ glomeruli. *PGK* expression was not changed in either group of mice. In cultured mouse podocytes, *Mix1, Eef1a1* and *ApoE* were differentially expressed in the presence or absence of HIF-1α after TGF-β1 treatment, whereas *Irf7, Mt2* and *Plod2* were regulated independent of HIF-1α.

Conclusions: We have identified several HIF-1α target genes that could play a role in in proteinuria and glomerulosclerosis. These could be novel therapeutic targets for glomerulopathy.

Inhibiting Podocyte Endoplasmic Reticulum Stress-Mediated Apoptosis to Treat Genetic Nephrotic Syndrome

Sun-Ji Park, Ying M. Chen. *Division of Nephrology, Washington university in St. Louis, St. Louis, MO.*

Background: Pierson syndrome (OMIM 609049) characterized by congenital nephrotic syndrome (NS) and diffuse mesangial sclerosis, is caused by mutations in *LAMB2* encoding laminin β2. The major laminin heterotrimer in the mature glomerular basement membrane is laminin α5β2γ1, and laminin trimerization occurs in the endoplasmic reticulum (ER). There is no effective treatment for Pierson syndrome and most cases of genetic forms of NS. Here for the first time, we have shown that targeting podocyte ER stress-specific apoptosis may provide a new therapeutic approach to treat Pierson syndrome and other genetic nephrotic syndromes.

Methods: To recapitulate human Pierson syndrome, *Lamb2* null mice were generated. We isolated mouse glomeruli and cultured primary podocytes before the onset of significant proteinuria to investigate ER stress signaling cascades. Western blot was utilized to determine ER stress-induced pro-apoptotic pathway. Furthermore, *Lamb2*$^{-/-}$ mice were crossed with *Chop*$^{-/-}$ mice to investigate the functional consequence of CHOP (C/EBP homologous protein) deletion in the disease development.

Results: At the early stage of NS, LAMB2 deficiency induced podocyte ER stress and selectively activated ATF6 (activating transcription factor 6) pathway without involvement of IRE1α and PERK pathways. Moreover, LAMB2 depletion differentially triggered ER stress-specific CHOP pro-apoptotic pathway, but not caspase 12 and JNK pathways, in mutant podocytes. Most importantly, CHOP ablation in *Lamb2*$^{-/-}$ mice significantly prolonged the lifespan of *Lamb2* null mice.

Conclusions: Despite the importance of podocyte ER dysfunction in the pathogenesis of NS, there is no treatment that targets the podocyte ER. Our promising results indicate that antagonizing the pro-apoptotic CHOP pathway in ER-stressed podocytes may lead to paradigm-shifting innovative therapeutic strategies to combat genetic or acquired NS.

SA-PO325

GLEPP1 Deficiency Alters GBM Composition and Extracellular Matrix (ECM) Deposition in Aging Mice

Eva Koenigshausen,[1] Ernest Kaufmann,[1] Christian Weigel,[1] Philip Schüppler,[1] Catherine Meyer-Schwesinger,[2] Magdalena Woznowski,[1] Lars C. Rump,[1] Lorenz Sellin.[1] *[1]Medical Faculty Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany; [2]University of Hamburg, Hamburg, Germany.*

Background: Proteinuria results from a defect in the glomerular filter which is composed of the fenestrated endothelium, the glomerular basement membrane (GBM) and the podocytes. Major components of the GBM are collagen IV (col IV), agrin, nidogen and laminin. Col IV of the mature GBM is composed of alpha 3, 4, 5 chains while the immature GBM is built of col IV alpha 1, 2, 1 chains. Mutations in the GLEPP1 gene lead to nephrotic syndrome in humans. GLEPP1 is a receptor tyrosine phosphatase within podocytes and its deficiency leads to morphologic GBM alterations and proteinuria in aging mice. Its molecular function is still unknown.

Methods: GLEPP1 WT and KO mice were analyzed at 4, 6 and 10 months of age. Glomeruli were isolated. For col IV analysis, glomeruli were digested with collagenase to release col IV NC1 domains. Immunofluorescence of mouse kidneys was performed for col IV chains. Primary podocytes were isolated and analyzed for purity by WT1 immunofluorescence staining. Podocytes were lysed, ECM digested with collagenase and subjected to western blot analysis. Col IV chain specific antibodies against NC1 domains of col IV alpha 1, 2, 3 and 5 were used. In addition, antibodies against laminin alpha 1, agrin and nidogen 1 were used.

Results: Glomerular col IV alpha 1 and 2 protein chain expression is significantly enhanced in 6 and 10 month old GLEPP1 KO mice, while col IV alpha 1 and 2 protein expression levels are reduced in GLEPP1 KO mice at 4 months of age. Glomerular laminin alpha 1 protein expression is significantly elevated in GLEPP1 KO mice compared to controls at 10 months of age. Immunofluorescence of col IV chains in kidney sections of GLEPP1 WT and KO mice localized enhanced expression of immature col IV chains within the GBM. Purity of primary podocytes of GLEPP1 WT and KO mice was confirmed by WT1 staining. Col IV deposition by GLEPP1 KO primary podocytes in cell culture resembles the col IV expression pattern with increased expression of col IV alpha 1 and 2 and decreased expression of col IV alpha 5 in GLEPP1 KO mice. These data confirm our previous results from rt-PCR and immunofluorescence.

Conclusions: GLEPP1 deficiency leads to an immature GBM composition which is responsible for less mechanical stability of the GBM and proteinuria in aging mice and humans.

SA-PO326

Development of a Glomerular Specific Targeting System with Perfluorocarbon Nanoparticles

Jin Wei,[1] Ryan Grabau,[1] Jie Zhang,[1] Lei Wang,[1] Samuel Wickline,[1] Hua Pan,[1] Ruisheng Liu.[2] *[1]USF, Tampa, FL; [2]University of South Florida College of Medicine, Tampa, FL.*

Background: Perfluorocarbon (PFC) nanoparticles (NPs) are primarily limited to intravascular space. Glomerular basement membrane (GBM) is the only site where collagen IV (Col4) has direct contact with blood via fenestrated capillary endothelium. Our goal is to develop a novel Col4-targeted PFC NP that selectively targets kidney glomeruli as a local therapeutic vehicle.

Methods: Col4 -targeted PFC NPs were formulated by coupling PFC NPs to a Col4-targeting ligand. The binding specificity and efficiency of the Col4 -targeted NPs were evaluated on Col4 coated plate surfaces, *in vitro* with primary glomerular endothelial cells and mesangial cells, and *in vivo* in C57BL/6 mice.

Results: Rhodamine labeled Col4 targeted or non-targeted PFC NPs were applied in Col4 pre-coated 96 wells plate at stepwise doses (1, 2, 5, 10 and 20 ul/ml). The binding affinity was determined by fluorescence intensity with IVIS. The wells incubated with Col4 targeted PFC NPs showed a dose dependent increase in fluorescence as radiant efficiency e^{10} (0.37 ± 0.03, 0.51 ± 0.05, 1.33 ± 0.07, 2.38 ± 0.19, 2.71 ± 0.28). Minimal non-specific binding appeared. To evaluate the targeting properties *in vitro*, 1ul/ml rhodamine labeled Col4 targeted or non-targeted PFC NPs were applied on glomerular endothelial cells and mesangial cells. Significant cellular uptake of the Col4 targeted PFC NPs was observed, while it was not detectable in the cells incubated with non-targeted NPs. To evaluate the targeting properties in vivo, C57BL/6 mice were treated i.v. with 100ul rhodamine labeled Col4 targeted or non-targeted PFC NPs. Col4 targeted PFC NPs localized to glomeruli in the kidney sections, whereas non-targeted PFC NPs were undetectable, as shown in Figure.

Conclusions: We have designed PFC nanoparticles that selectively target glomeruli by binding to Col4 of GBM.

The Hippo Effector Tead1 Interacts with Wt1 on a Gene-Regulatory Level by Co-Binding at Podocyte Enhancers

Mahdieh Rahmatollahi,[1] Tsimafei Padvitski,[2] Bernhard Schermer,[1] Thomas Benzing,[1] Andreas Beyer,[2] Martin Kann.[1] *[1]Department II of Internal Medicine, University of Cologne, Cologne, Germany; [2]University of Cologne, Köln, Germany.*

Background: In a genome-wide analysis of gene-regulatory functions of the transcription factor (TF) Wt1 in podocytes we identified an interaction of Wt1 with hippo signaling, which has since emerged as a key pathway relevant to podocyte health and disease. However, gene regulatory effects of hippo signaling in podocytes have not been examined in detail. Here we investigate Wt1 and Tead1 co-regulation in wildtype podocytes in vivo by ChIPseq.

Methods: ChIP-seq for Tead1 and Wt1 was carried out on wildtype mouse glomeruli. Bioinformatic analyses were conducted using standard software and algorithms.

Results: ChIP-seq for Tead1 on mouse glomeruli identified more than 19,000 high confidence and reproducible Tead1 peaks. Tead1 binding occurred at both, promoters and enhancers as indicated by histone modification signatures obtained from ENCODE ChIPseq data. Functional analysis of Tead1 binding events by GO enrichment algorithms revealed differential functions of enhancer vs promoter binding. Promoter binding sites were predominantly located at genes involved in pathways canonically linked to hippo signaling such as regulation of apoptosis and cell cycle. In contrast, enhancer binding occurred at genes of signaling pathways highly relevant to podocytes, such as integrin signaling, the actin cytoskeleton, and Tgf-beta/Smad signaling. Tead1 also bound enhancers relevant to Vegf-, and PDGF-signaling genes suggesting novel links between hippo signaling and further signaling pathways in podocytes as well as novel contexts of hippo signaling in general. Integrative analysis of Wt1 and Tead1 ChIPseq data showed co-binding of the two TFs in ~7,000 instances with predominance of enhancer binding events. Enhancer co-binding of Wt1 and Tead1 showed speicifc overrepresentation of genes relevant to adherens junctions and focal adhesions when compared to datasets obtained from one TF only. Furthermore, many of the cis-regulatory regions co-bound by Wt1 and Tead1 were associated with genes relevant to glomerular disease and FSGS in particular.

Conclusions: In summary, integrative analysis of Tead1 and Wt1 ChIPseq data in podocytes in vivo reveals novel candidate pathways interacting with hippo signaling. We identify a functional interaction of the TFs to control cell-adhesion signaling bearing high relevance to glomerular disease.

SA-PO328

APOL1 G1 Risk Variant Contributes to Podocyte Injury in a Mouse Model of FSGS

Mengyuan Ge,[1] Gloria Michelle Ducasa,[1] Maarten Hoek,[2] Jeffrey B. Kopp,[3] Sandra M. Merscher,[1] Alessia Fornoni.[1] *[1]University of Miami School of Medicine, Miami, FL; [2]Merck & Co., Inc, Kenilworth, NJ; [3]NIDDK, NIH, Bethesda, MD.*

Background: Focal segmental glomerulosclerosis (FSGS) is the most common primary glomerular disorder causing chronic kidney disease. Susceptibility to FSGS in African Americans is associated with the presence of genetic variants of the Apolipoprotein L 1 gene (APOL1) named G1 and G2. We recently published that mice with podocyte-specific, doxycycline (Dox)-inducible expression of constitutively active NFATc1nuc (NFAT) represent a valuable new model for FSGS.

Methods: Human BAC transgenic mice that express the different APOL1 genetic variants (G0, G1, G2) under the endogenous promoter were used in this study. Podocyte specific Dox-inducible constitutively active NFATc1 mice (NFAT;Podocin-rtTA, DT) were expanded for consecutive breeding to G0, G1 or G2 BAC transgenic mice to generate triple transgenic mice (APOL1;NFAT;Podocin-rtTA, TT). NFATc1nuc transgene expression was induced by feeding of doxycycline chow (200 ppm) for 4 months. Urinary albumin-to-creatinine ratios were determined using mouse specific albumin ELISA and creatinine companion kits. Blood samples collected from mice at sacrifice were analyzed for BUN. Perfused kidneys were fixed and paraffin embedded for H&E, PAS staining.

Results: We tested the relative contribution of APOL1 risk variant expression to podocyte injury in mice expressing each of the APOL1 genetic variants under the control of the endogenous promoter region at baseline as well as in a mouse model of FSGS-like injury. Glomerular expression of APOL1 mRNA was similar among BAC transgenic mice carrying APOL1 G0 and G1, but significantly lower in G2 carrying mice ($p<0.01$) and these mice did not develop proteinuria for at least up to 7 months of age. Histological analysis among APOL1 transgenic mice carrying each of the APOL1 genetic variants and wildtype mice revealed no differences. However, Dox-induced TT mice carrying the G1 allele showed increased proteinuria, higher serum BUN levels and a more severe form of glomerulosclerosis when compared with induced TT mice carrying G0 or G2. Induced G1 TT mice were also characterized by an earlier onset of proteinuria which remained sustained over time.

Conclusions: Our data reveal that transgenic APOL1 risk variant expression in mice does not impair kidney function at baseline whereas APOL1 G1 expression may contribute to APOL1 mediated susceptibility in NFAT-mediated FSGS.

SA-PO329

ApoL1 G0, G1, and G2 Are Expressed on the Podocyte Cell Membrane with Similar Overall Topologies

Nidhi Gupta, Suzie J. Scales. *Genentech, South San Francisco, CA.*

Background: Human Apolipoprotein L1 (ApoL1) is responsible for innate immunity against trypanosome infections. Two variants of ApoL1, G1 and G2, are responsible for the high rate of kidney disease in African diaspora and cause kidney podocyte damage by unclear mechanisms. ApoL1 can form pH-gated cation (K^+ and Na^+) channels in lipid bilayers, as well as pH-independent chloride channels in liposomes. Two papers showed overexpressed ApoL1 in HEK-293 cells forms potassium efflux channels at the cell surface, which leads to stress-activated protein kinase stimulation and cell death. However, contradictory results were obtained regarding ApoL1 G0 toxicity thereby questioning if G1 and G2 toxicity is variant specific or expression level dependent. Total expression levels (by Western Blot) may not be indicative of cell surface ApoL1 levels. It is actually unclear if endogenous ApoL1 and its variants are found at the cell surface and whether differences in trafficking, expression level or topology could account for the differential toxicity. Also, not much is known regarding toxicity in podocytes.

Methods: Using a panel of in house generated ApoL1-specific monoclonal antibodies to various domains, we performed flow cytometry on wild type podocytes. We also generated several clones of ApoL1 knockout podocytes stably re-expressing doxycycline-inducible ApoL1 G0, G1 or G2 to avoid any interactions (potential heterozygosity) with endogenous ApoL1. Cells were also tested for variant specific cell toxicity at comparable surface expression levels.

Results: By flow cytometry, endogenous ApoL1 was found at the cell surface of wild type podocytes, with most of the pore forming domain and end of the SRA-interacting domain exposed, but not the membrane-addressing domain. Surface ApoL1 was increased up to 500x in the inducible podocytes in a dose-dependent manner, but G0/G1/G2 maintained similar topology to endogenous ApoL1. We aim to clarify if cytotoxicity correlates with cell surface expression or variant genotype.

Conclusions: Endogenous ApoL1 and stably transfected G0/G1/G2 are all expressed on the podocyte plasma membrane with similar gross topology and are therefore correctly located to form potential surface ion channels. Thus, any differential ionic conductance is likely not due to gross topology differences at the plasma membrane.

ApoL1 Is Not Normally Internalized by Podocytes

Suzie J. Scales, Nidhi Gupta, Andrew S. Peterson. *Genentech, South San Francisco, CA.*

Background: Human Apolipoprotein L1 (ApoL1) is secreted by the liver and circulates on HDL particles, where it protects from human African trypanosomiasis (sleeping sickness). This innate immunity is achieved by internalization of HDL particles to the trypanosome lysosomes, where ApoL1 forms pores leading to trypanolysis. ApoL1 G1 and G2 variants evolved in Africans to kill additional species of trypanosome, but greatly increase the risk of chronic kidney disease (ApoL1-nephropathies) by unclear mechanisms involving loss of kidney podocytes. The "internalization model" posits that circulating ApoL1 is internalized into podocytes to cause damage akin to trypanolysis, while the "intrinsic model" supposes that endogenous ApoL1 variants in podocytes are cytotoxic. Recombinant ApoL1 was reportedly internalized into podocytes, potentially supporting the internalization model, but the destination compartment was unclear. Most other studies support the intrinsic model, but have yet to agree on a cellular mechanism, ranging from ER stress, mitochondrial or lysosomal permeability, endocytic or autophagy disruption to cell surface cation channel activity. Clarification on whether intrinsic ApoL1 or ApoL1 in HDL particles is really internalized in podocytes might help to pinpoint the correct mechanism.

Methods: We evaluated internalization of recombinant ApoL1, ApoL1 in HDL particles, endogenous ApoL1 and stably expressed ApoL1 variants in cultured podocytes by immunofluorescence microscopy with ApoL1-specific monoclonal antibodies.

Results: Recombinant ApoL1 was internalized by podocytes, but only by virtue of being sticky, as it bound to other proteins in the media. Non-sticky ApoL1 in native HDL particles up to 1mg/ml or in amphipol was not visibly internalized by podocytes. Monoclonal antibodies detected endogenous ApoL1 in podocytes at the cell surface, but were not endocytosed. Overexpressed ApoL1 in podocytes likewise remained at the cell surface, unless the antibodies were aggregated.

Conclusions: Neither intrinsic ApoL1 nor HDL-bound ApoL1 is detectably internalized by podocytes *in vitro*, suggesting ApoL1 is not actively trafficked to endosomes or lysosomes. These data do not support the circulating model of ApoL1 activity and further suggest that intrinsic secreted ApoL1 might exert its effect at the plasma membrane rather than in the endolysosomal system.

Semaphorin3A-Inhibitor Ameliorates Podocytopathy and Tubular Fibrosis in Adriamycin-Induced Renal Injury

Yizhen Sang,[2] Kenji Tsuji,[2] Akiko Inoue-Torii,[1] Kazuhiko Fukushima,[2] Shinji Kitamura,[2] Jun Wada.[2] *[1]Eiju General Hospital, Tokyo, Japan; [2]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Scineces, Okayama, Japan.*

Background: Semaphorin3A (SEMA3A) is a guidance protein that regulates angiogenesis, cell motility, immune cell regulation and cancer progression. In the

mammalian adult kidneys, SEMA3A and its receptor, neuropilin-1 (NRP1) are expressed in podocytes, tubular cells and collecting ducts. However, the pathophysiological roles of the SEMA3A in renal diseases are still unclear. Here we analyzed the role of the SEMA3A-NRP1 signaling using the adriamycin (ADR)-induced podocytopathy mouse model and examined the therapeutic effect of SEMA3A-inhibitor.

Methods: Wild-type male Balb/c mice (10-week old) were assigned into three groups (n=5): ADR group (single injection of 10 mg/kg ADR by tail vein), ADR+SEMA3A-I group (ADR injection + daily intraperitoneal injection of 20 μg SEMA3A-inhibitor) and control group (saline injection by tail vein). All the mice were sacrificed 2 weeks after the ADR injection, and the expression of SEMA3A and NRP1, proteinuria, tubular injury and renal fibrosis were analyzed. We also examined the effect of recombinant SEMA3A and SEMA3A-inhibitor on immortalized mouse podocytes and proximal tubular cells (mProx24 cells) in vitro.

Results: The expression of SEMA3A in podocyte and NRP1 in proximal tubular cells were dramatically increased in ADR group compared to control group. SEMA3A-inhibitor significantly attenuated ADR-induced albuminuria (urinary albumin / creatinine ratio (mg/gCr): ADR group vs. ADR+SEMA3A-I group; 626.5±102.9 vs. 66.0±7.4, $p<0.05$), tubular injury and tubular fibrosis as well as the cell apoptosis in both podocytes and tubular cells. In vitro, SEMA3A caused the cell apoptosis in cultured podocytes and proximal tubular cells as well as the increase of TGF-β1 expression. In addition, the treatment with TGF-β1 increased NRP1 mRNA expression in the podocytes (5.2-fold) and proximal tubular cells (1.7-fold) compared to the control, implying SEMA3A-NRP1 signaling is associated with tubular fibrosis. Taken together, increased SEMA3A expression in podocytes induced by ADR might cause podocytopathy and proximal tubular injury by accelerating cell apoptosis and renal fibrosis.

Conclusions: SEMA3A-inhibitor ameliorates podocytopathy and tubular fibrosis in ADR-induced renal injury. It would be the therapeutic target for preventing the progression of the renal injury.

ARHGEF7 Promotes Stress Fiber Loss in Podocytes by Activation of Rac1

Lovisa Bergwall,[2] Hanna I. Wallentin,[1] Roberto Boi,[2] Anna Granqvist,[1] Jenny C. Nystrom,[2] Lisa Buvall.[1,2] *[1]CVRM, IMED Biotech Unit, AstraZeneca, Gothenburg, Sweden; [2]University of Gothenburg, Goteborg, Sweden.*

Background: Today it's known that most kidney diseases are caused by damages to the glomerular filtration barrier, partially by disruption of the actin cytoskeleton in the podocyte. Mutations in several actin regulatory proteins have been identified in patients with renal disease with several of them found to be present in proteins regulating actin cytoskeleton formation. The small RhoGTPase proteins are central in actin cytoskeleton regulation and lately several studies support the detrimental role of activation of the small RhoGTPase Rac1 and its role in stress fiber loss in podocytes.

Methods: In this study we aimed at identifying RhoGTPase regulatory proteins important in actin cytoskeleton loss in podocytes by using phosphoproteomics, lentiviral shRNA knockdown and stressfiber analysis on cultured podocytes, in combination with RNA sequencing of glomeruli from diabetic nephropathy animal models.

Results: By using protamine sulfate, known to cause actin cytoskeleton injury, on cultured podocytes followed by phosphoproteomics and pathway analysis we identified actin cytoskeleton to be the top ranked activated pathway. The guanine nucleotide exchange factor ARHGEF7 was identified to be phosphorylated at Ser 340, a site when phosphorylated known to cause Rac1 activation. Podocytes depleted of ARHGEF7 was protected from stress fiber loss when exposed to protamine sulfate, further confirming the involvement of ARHGEF7 in actin cytoskeleton rearrangement. In combination, RNA sequencing data from two diabetic nephropathy models, BTBR ob/ob and eNOS db/db mice, showed increased levels of ARHGEF7 in isolated glomeruli, indicating increased ARHGEF7 activity in nephrotic syndrome.

Conclusions: These data reviles upregulation of ARHGEF7 in diabetic nephropathy mice models and that ARHGEF7 plays a central role in podocyte actin cytoskeleton regulation, promoting loss of actin cytoskeleton in podocytes by the activation of Rac1.

Extracellular Vesicles as Local Messengers in Glomerular Cross-Talk

Sargis Sedrakyan,[1] Hasmik Soloyan,[3] Paola Aguiari,[2] Laura Perin.[1] GOFARR laboratory for organ regenerative research and cell therapeutics *[1]Childrens Hospital Los Angeles, Los Angeles, CA; [2]Children's Hospital, Los Angeles, Los Angeles, CA; [3]Children's Hospital Los Angeles, Los Angeles, CA.*

Background: The crosstalk between the podocyte and glomerular endothelial cells (GEC) is vital for the maintenance of glomerular function. Any slight alteration of their communication propagates injury and disruption of glomerular function, commonly observed during CKD. Extracellular vesicles (EV) have key paracrine functions in physiological and pathological processes. Thus, we hypothesize that EVs play important role in glomerular crosstalk through horizontal transfer of their cargo to the target cells, especially during CKD when the glomerular filtration barrier is damaged. In particular, this study focuses on the transfer and paracrine signaling of GEC-EV to podocytes.

Methods: We isolated EV from GEC and characterized them by Nanosight analyzer, PCR, WB and flow cytometry for size distribution, RNA and protein content, and for surface marker expression. We used a no-cell-contact co-culture model to establish the transfer and intake of GEC-EV by podocytes, which was further confirmed in isolated glomeruli by the Cre-lox method. Podocytes exposed to GEC-EV were analyzed by PCR. To study EV transfer *in vivo* we used a transgenic model of CKD, Alport syndrome - characterized by a deficiency in the type IVα5 collagen and expression of *td*Tomato in endothelial cells, including GEC. TEM studies using immunogold co-labeling for *td*Tomato and CD63 were used to identify EV origin and uptake.

Results: GEC-EVs expressed exosomal CD9, C63, cell-adhesion and angiogenic markers, especially the VEGF receptors type I and II. In vitro, transfer of normal GEC-EV to podocytes was confirmed by the Cre-lox activation of the *td*Tomato in podocytes by the Cre protein delivered via the GEC-EV. Transfer of GEC-EVs maintained podocyte morphology, WT1, podocin, nephrin and VEGF expression, while podocytes exposed to EVs isolated from Alport GEC showed alteration of these markers, thus possibly indicating that Alport GEC-EVs present a different cargo than normal GEC-EVs. *In vivo*, TEM data showed a presence of GEC-EV in podocytes, confirming EV transfer across the glomerular filtration barrier.

Conclusions: Our data suggest that EV transfer across the glomerular filtration barrier is an essential physiological event that regulates cellular function in podocytes. Identification of novel mediators of endothelial-podocyte crosstalk may lead to the development of more effective treatments for glomerular kidney disease.

Association of uTWEAK Levels with Histological Findings, Endothelial and Tubulointerstitial Markers (VEGF/VCAM-1, TGFβ) in Patients with Lupus Nephritis (LN)

Fabiola Reyes,[4] Germain Toledo,[4] Virgilia Soto,[3] L. M. Perez-Navarro,[2] Rafael Valdez-Ortiz.[1] *[1]Hospital General de Mexico, Mexico City, Mexico; [2]Hospital General de México Dr. Eduardo Liceaga, México, Mexico; [3]INC Ignacio Chavez, Mexico City, Mexico; [4]IMSS, México, Mexico.*

Background: Urinary TWEAK levels (uTWEAK) are a sensitive and specific biomarker in the evaluation of LN in patients with SLE, however, its association with histological findings and expression of endothelial and tubulointerstitial lesion marker is unknown.

Methods: Cross-sectional study. We determinate the degree of association between uTWEAK with histological findings and markers of endothelial lesion (VEFG and VCAM-1) and tubulointerstitial (TFGβ) in patients with LN that have not been received immunosuppressive treatment. Non parametric statistics, logistic regression model, 95%CI, and $p<0.05$ were performed as statistically significant.

Results: Thirty-six patients were evaluated, 83.3% (30) were female. With predominance of histological class IV+V (41.6%). In the histological findings, 63.8% had a low chronicity index (<6 points), the activity index (AI) was 50% >12 points. The uTWEAK according to the histological class did not show statistically significant differences. In 72.2% of the patients, VEGF at glomerular was ≥50% and at the arteriolar level, 77.8% of the patients presented deposits of ≥50%. In Figure 1, the correlation between the histological findings and the endothelial and tubolointerstitial biomarkers is observed. Although, uTWEAK was not associated significantly with AI and arteriolar VEGF deposits (OR 4.18, p= 0.223 and 11.298, p= 0.120), effect size (d-Cohen) was of 0.78 and 1.33 respectively.

Conclusions: The uTWEAK represents a sensitive and specific biomarker in the evaluation of LN in patients with SLE, however, his expression does not seem to distinguish between the different classes of LN; an association was found with AI and VEGF. It is relevant to evaluate the outcome of the patients and to establish if the markers evaluated have an impact on the prognosis of the patients.

Antigen-Specific IgG Subclasses in Primary and Malignancy-Associated Membranous Nephropathy

Franziska Von haxthausen, Linda Reinhard, Elion Hoxha, Rolf A. Stahl. *III. Department of Internal Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: The immunologic mechanisms leading to initiation of primary MN are assumed to be different from those in cancer-associated MN, however, the evidence for this proposal has not been systematically evaluated. For decades primary MN was considered to have an IgG4-driven autoimmune genesis, while secondary MN associated with other diseases, most notably cancer, was not linked to IgG4. The identification of the phospholipase A_2 receptor 1 (PLA_2R1) and thrombospondin type-1 domain-containing 7A (THSD7A) as target antigens of autoimmunity in MN now allows a pathogenesis-driven differential diagnosis and may help to better understand the differences between the pathomechanisms of primary and secondary MN. Recent data showing a molecular link between THSD7A expression in tumors and THSD7A-antibody positive MN suggest a similar pathogenesis of malignancy-associated and primary MN.

Methods: In this study we systematically analyzed circulating antigen-specific IgG subclasses in the serum of 76 patients with PLA_2R1-associated MN and 41 patients with THSD7A-associated MN in relationship to concurrent malignancy and disease outcome. All IgG subclasses were analyzed by Western blot. Twenty-three patients in the study had a malignancy-associated MN. Human lung and glomerular protein extracts were analyzed under non-reducing conditions for expression of both PLA_2R1 and THSD7A.

Results: At baseline all 117 patients were positive for IgG4-antibodies against either PLA_2R1 or THSD7A, while IgG3, IgG1 and IgG2-antibodies were found in 87%, 72% and 26% of patients, respectively. There were no differences in the IgG subclass distribution between patients with primary versus cancer-associated MN and no association with disease outcome. Both podocytes and lung bronchioles showed expression of both PLA_2R1 and THSD7A when analyzed by immunofluorescence and Western blot. Every antigen-specific IgG subclass showed identical antigen-binding in both organs and autoantibodies bound the respective antigen only under non-reducing conditions.

Conclusions: We conclude that antigen-specific IgG subclasses do not differentiate between primary and malignancy-associated MN or predict disease prognosis. The data support the view that one common pathway may lead to primary and cancer-associated MN induced by PLA_2R1- or THSD7A-antibodies.

The Conformational Anti-Phospholipase A2 Receptor Autoantibodies in Primary Membranous Nephropathy

Quansheng Zhu,[1] Meryl A. Waldman,[3] Liyo Kao,[2] Hong Tang.[1] *[1]ImmunoWork, Monrovia, CA; [2]Division of Nephrology, UCLA, Los Angeles, CA; [3]NIDDK, NIH, Bethesda, MD.*

Background: Primary membranous nephropathy (PMN) is a leading cause of nephrotic syndrome in adults. The dominant antigen, phospholipase A2 receptor (PLA2R) is detected in the subepithelial immune deposits in over 80% of the PMN patients. Anti-PLA2R autoantibodies (PLA2R-Ab) bind to PLA2Rs on the basal surface of the podocytes triggering immune complex formation *in situ* that impairs the glomerular filtration barrier function causing massive leakage of the plasma proteins into the urine. We and others determined that the dominant epitope for autoantibody binding is located at the N-terminus of PLA2R. Additional studies also reported that 3 independent epitopes are present in PLA2R and that epitope spreading occurs in the patients and is associated with disease progression. Here we further characterized the autoantibody-PLA2R epitope interaction using 48 patient samples.

Methods: 48 PLA2R-Ab positive sera from patients with biopsy-proven MN were collected and assessed for their reactivities to PLA2R using Western-blot, immunoprecipitation under the native condition and immunodiffusion assays.

Results: 6 serum samples were identified to react strongly to the region of CysR-FnII-CTLD1-3, but weakly to the region of CysR-FnII-CTLD1 when diluted at 1:5000 on the Western-blot. 42 samples collected from patients who had relapsed disease all reacted strongly to the CysR-FnII-CTLD1 region at the same dilution. Follow-up studies in 3 patients who did not receive immunosuppressive treatment demonstrated that the autoantibodies initially reacted to the large CysR-FnII-CTLD1-3 region but later switched to the small CysR-FnII-CTLD1 region, coinciding with the worsening of proteinuria. Further analysis of autoantibody interaction with the purified PLA2R extracellular region in the immunodiffusion assay indicated that no insoluble lattice could be formed with any of the collected sera, suggesting that PLA2R is unlikely to have independent, separated epitopes in the extracellular region.

Conclusions: Our results indicated that two overlapping PLA2R epitope regions are present in the PMN patients with the autoantibody reaction to CysR-FnII-CTLD1-3 is likely to occur before the reaction to CysR-FnII-CTLD1. This data suggest that the overall conformation of PLA2R plays an important role in autoantibody formation and that autoantibody maturation is associated with PMN progression.

SA-PO337

Proteomic Analysis of Complement Factors in PLA2R-Positive Membranous Nephropathy

Sanjeev Sethi,[1] Benjamin J. Madden,[1] Cristine Charlesworth,[1] Daniel C. Cattran,[2] Fernando C. Fervenza.[1] *[1]Mayo Clinic, Rochester, MN; [2]Toronto General Hospital, Toronto, ON, Canada.*

Background: Membranous nephropathy (MN) is characterized by deposition of immune-complexes and complement factors along the glomerular basement membrane. Phospholipase A2 receptor (PLA2R) is the target antigen in approximately 70% of MN. Although complement deposition is seen PLA2R-associated MN, a comprehensive and detailed analysis of complement factors in PLA2R-associated MN has not been done.

Methods: We used laser microdissection and mass spectrometry (MS) to dissect glomeruli and identify the glomerular and complement proteins in 7 cases of PLA2R-associated MN. For control cases, we used 6 cases of time 0 transplant protocol biopsies.

Results: MS identified very high total spectral counts (TSC) for PLA2R in all cases of PLA2R-associated MN with average TSC of 87 (range 45-135). In comparison, the avarage TSC in control cases was only 5 (range 0-7) which is similar to many house-keeping proteins. With regards to complement factors, C3 was the most abundant complement protein with average TSC of 413 (range 324-708), followed by C4 (C4-B avg 176, C4-A avg 174). Moderately high TSC of C9 (avg 79,) and C5 (avg 54) were also detected. Lesser amounts of C6 (avg 31), C7 (avg 20) and C8 (avg 21) were also present. C1 was absent or present in very low spectral counts. In addition, complement regulating facors- complement factor H (avg 57), complement factor H-related protein 5 (avg 65.5) and complement factor H-related protein 1 (avg 30) were also detected. The average TSC of complement factors in control cases for C3, C4-B, C4-A and C5 was 107, 40, 39, and 5, respectively. With regards to immunoglobulins (Ig) in PLA2R-associated MN, IgG4 was the most abundant Ig (avg 91), followed by IgG1 (avg 68), IgG3 (avg 64) and IgG2 (avg 49). The avgerage Ig total TSC in control cases for IgG4, IgG1, IgG3 and IgG2 was 22, 56, 45 and 45, respectively.

Conclusions: Using MS analysis, we show accumulation of large amounts of C3 and C4, followed by C9 and C5, and lesser amounts of C6, C7 and C8 indicating a role of complement in the pathogenesis of PLA2R-associated MN. The TSC of C3 and C4 was much higher than the TSC of PLA2R or Ig indicating amplification and accumulation of complement factors in greater amounts than the PLA2R antigen or Ig. The large amounts of C3 and C4 and absence of C1 suggests involvement of the lectin pathway.

SA-PO338

Exostosin 1/Exostosin 2-Associated Membranous Nephropathy

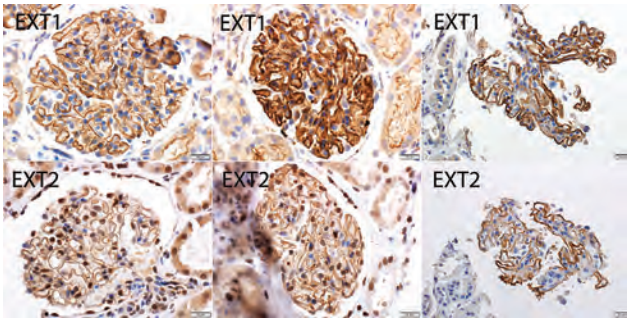
Sanjeev Sethi, Benjamin J. Madden, Cristine Charlesworth, Fernando C. Fervenza. *Mayo Clinic, Rochester, MN.*

Background: Membranous nephropathy (MN) is is characterized by deposition of immune-complexes and complement along the glomerular basement membrane (GBM). Phospholipase A2 receptor (PLA2R) and thrombospondin type-1 domain containing 7A are target antigens in ~70% and 5% cases, respectively. In the remaining cases, the target antigen is unknown.

Methods: We studied 22 cases of MN: 7 PLA2R-positive and 15 PLA2R-negative; and 6 control time 0 transplant protocol biopsies. Glomeruli were laser microdissected and mass spectrometry (MS) was performed to detect the proteomic profile. This was followed by immunohistochemical studies (IHC) to identify and localize the overexpressed proteins.

Results: MS identified high total spectral counts (TSC) for PLA2R in cases of PLA2R-positive MN. In 5 of the 15 PLA2R-negative MN, high TSC for both exostosin 1 (EXT1) and exostosin 2 (EXT2) were present. The TSC of EXT1 and EXT2 were comparable to the TSC of PLA2R in PLA2R-positive cases. EXT I and II are glycosyltransferases that exist as heterodimers and are responsible for the synthesis of the heparin sulfate backbone in the GBM. Of the remaining 10 PLA2R-negative cases, 2 cases of negative PLA2R by IF were positive for PLA2R, 3 cases had suboptimal tissue, and in 5 cases comparable high TSC of a single protein was not present. EXT1 and EXT2 were absent in PLA2R-positive and control cases. None of the PLA2R negative cases showed THS7DA. In all MN cases, high TSC for complement factors and Ig were also present. To confirm the findings we performed IHC that showed bright granular EXT1 and EXT2 GBM staining in EXT1/EXT2-positive MN cases, in a distribution similar to Ig (Figure 1). Furthermore, EXT1/EXT2 staining was specfic as staining for Exostosin-like 2 (EXTL2) was negative in the EXT1/EXT2-positive cases. All control and PLA2R-positive cases were negative for EXT1/EXT2/EXTL2.

Conclusions: A subset of PLA2R-negative MN is associated with accumulation of EXT1 and EXT2 in GBM, representing a distinct subtype of MN.



EXT1 and EXT2 staining in 3 cases of PLA2R-negative MN. Each column is 1 case.

SA-PO339

Generating a Mouse Model of Membranous Nephropathy (MN)

Samuel J. Rhoden,[1] Franziska Lausecker,[1] Maryline Fresquet,[1] Antony Adamson,[1] Thomas A. Jowitt,[1] Paul E. Brenchley,[2] Rachel Lennon.[1] *[1]University of Manchester, Manchester, United Kingdom; [2]Manchester Royal Infirmary, Manchester, United Kingdom.*

Background: 75% of patients with MN develop autoantibodies against PLA2R, which is expressed on podocytes. Autoantibody binding causes immune complex deposition in the glomerular basement membrane (GBM), podocyte effacement and the clinical phenotypes of proteinuria and nephrotic syndrome. The lack of an *in vivo* model for MN, due to rodents expressing minimal PLA2R on podocytes, has impeded the investigation of disease mechanisms and novel therapeutics. The aims of this study were to 1) develop a podocyte-specific PLA2R knock-in mouse and 2) induce MN through passive transfer of anti-PLA2R antibodies.

Methods: A transgene was created for insertion of a flag-tagged PLA2R fragment (NC3) containing the transmembrane and the first 5 extracellular domains, including the immunodominant epitope of PLA2R. Podocyte restricted expression of NC3 is driven by the *NPHS2* promoter. Transgene positive pups were bred with BL6/J mice to spawn heterozygous knock-in mice. Kidneys, glomeruli and podocytes were isolated from subsequent offspring for analysis by reverse transcription PCR (RT-PCR), targeted locus amplification (TLA) sequencing, western blotting (WB), and immunohistochemistry (IHC). Induction of MN in PLA2R knock-in mice will be achieved by intravenous injection of human anti-PLA2R and analysed for glomerular deposition, proteinuria and complement activation.

Results: TLA sequencing confirmed successful in-frame insertion of the transgene in PLA2R knock-in mice. RT-PCR and WB analysis of kidneys and glomeruli demonstrated the expression of NC3 mRNA and protein in PLA2R knock-in mice. IHC of kidney sections using human anti-PLA2R antibodies indicated strong podocyte staining of NC3 in the glomerulus of PLA2R knock-in mice. PLA2R knock-in mice demonstrated no differences to wild type mice in regards to proteinuria, weight and histology under basal conditions. We anticipate that injection of MN patient IgG will induce the MN phenotype in PLA2R knock-in mice.

Conclusions: We have successfully developed a PLA2R knock-in mouse. Expression of NC3 did not induce a phenotype under basal conditions. Current work focusses on the induction of MN using patient IgG. This mouse model gives exciting prospects for validating the pathogenicity of anti-PLA2R antibodies and the role of immune complex formation, complement activation and GBM thickening in causing proteinuria.

SA-PO340

T-Regulatory and B-Regulatory Cells in Primary Membranous Nephropathy

Raja Ramachandran,[2] Urvashi Kaundal,[2] Aruna Rakha,[2] Krishan Lal L. Gupta,[1] Vivekanand Jha.[3] *[1]Postgraduate Institute of Medical Education & Research, Chandigarh, India; [2]PGIMER, Chandigarh, India; [3]George Institute for Global Health, New Delhi, India.*

Background: Primary membranous nephropathy (PMN) is an antibody-mediated disease. Both T-regulatory (TREGs) and B-regulatory (BREGs) cells are decreased in patients with autoimmune disease. The data on TREGs and BREGs in PMN is very scanty. We evaluated the TREG and BREG population in patients of PMN treated with cyclical cyclophosphamide and steroid therapy (cCTX/GC).

Methods: Twenty-four patients of PMN and 10 healthy controls were enrolled in the study at Nehru Hospital, PGIMER, Chandigarh. All the patients were resistant to restrictive strategy and were treated with cCTX/GC therapy. The proteinuria, serum creatinine and serum albumin were tested at monthly intervals and blood samples were collected prior to starting cCTX/GC and at 6 and 8 (2 months wash out) months of therapy. The peripheral blood mononuclear cells (PBMCs) were isolated from the collected blood samples using density gradient centrifugation. PBMCs after staining with fluorochrome-conjugated antibodies were then subjected to flow cytometric analysis for detection of TREGs ($CD3^+CD4^+CD25^{hi}CD127^{lo}FoxP3^+$) and BREGs ($CD19^+CD5^+CD1d^{hi}IL10^+$) at all time-points. TREGs and BREGs are presented as the percentage of CD3+CD4+ and CD19+ cells, respectively.

Results: The mean proteinuria, serum albumin and creatinine at baseline was 8.74±4.85 g, 2.33±0.80 g/dL and 1.06± 0.53 mg/dL, respectively. Patients with PMN had a lower percentage of TREGs and BREGs compared to healthy controls ($p<0.05$). There was a significant increase in both BREGs and TREGs with the treatment at 6 and 8 months (Table). The rise in both BREGs and TREGs were apparent after stopping (8 months) immunosuppressive therapy (Table).

Conclusions: As compared to the healthy controls, patients with PMN displayed a lower percentage of TREGs and BREGs. Both TREGs and BREGs significantly improved with disease-specific therapy. The increase in both the regulatory cells is apparent after two months of stopping cCTX/GC.

Pre-Diagnostic Evaluation of Anti-Phospholipase A2 Receptor Antibodies in Primary Membranous Nephropathy

Megha R. Joshi,[1] Peter D. Burbelo,[3] Meryl A. Waldman,[4] Sarah M. Gordon,[2] John S. Thurlow,[1] Stephen W. Olson.[1] *[1]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]TAMC, Kaneohe, HI; [3]NIDCR, NIH, Bethesda, MD; [4]Nephrology, NIH, Bethesda, MD.*

Background: M-type phospholipase A_2 receptor antibodies (PLA_2R –Ab) are present in 60-80% of primary membranous nephropathy (pMN) cases at diagnosis. PLA_2R-Ab is assumed to directly contribute to pMN pathophysiology, but there has not been confirmatory animal models or evaluation of PLA_2R –Ab before pMN diagnosis. We sought to describe PLA_2R-Ab levels before both biopsy diagnosis and documented proteinuria before biopsy diagnosis to better understand pMN pathophysiology.

Methods: We performed a retrospective case-control Department of Defense Serum Repository (DoDSR) study comparing PLA_2R-Ab in patients with pMN, presumed secondary MN, and healthy controls. MN cases were first identified and confirmed by review of the military electronic medical record. Background data was collected to include the earliest date of abnormal proteinuria and the most recent date of negative proteinuria before biopsy diagnosis. Based on background and biopsy data, MN patients were divided into pMN and secondary MN cases. The DoDSR then provided up to 4 prediagnostic specimens for each MN case and age, race, sex and age of serum matched healthy controls. PLA_2R-Ab was measured at the NIH using a luciferase assay.

Results: More pMN cases had elevated PLA_2R-Ab than secondary membranous disease controls before biopsy diagnosis [44% (59/134) vs. 2.8% (1/35), $p<0.001$]. No matching healthy controls had detectable PLA_2R-Ab at any time point. PLA_2R-Ab became elevated a median of 274 days prior to biopsy diagnosis (IQR: 63days, 811 days). 15 cases demonstrated significantly elevated prediagnostic PLA_2R-Ab at or up to 5 years prior to the earliest documentation of non-nephrotic range proteinuria before biopsy diagnosis. Two unique cases demonstrated elevated PLA_2R-Ab with confirmed negative proteinuria over a year before biopsy diagnosis.

Conclusions: PLA_2R-Ab is detectable not only before biopsy proven pMN, but also prior to the earliest subclinical presence of non-nephrotic range proteinuria which supports a direct contribution to the pathogenesis of pMN. Early serum testing of PLA_2R-Ab in patients with unexplained non-nephrotic range proteinuria may allow for early diagnosis and monitoring of pMN.

PLA2R1 Epitope Recognition Patterns and Clinical Outcome in Patients with Membranous Nephropathy

Elion Hoxha,[1] Gunther Zahner,[3] Linda Reinhard,[1] Rolf A. Stahl.[2] *[1]III. Department of Internal Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]University of Hamburg, Hamburg, Germany; [3]University hospital hamburg, Hamburg, Germany.*

Background: Phospholipase A_2 receptor 1 antibodies (PLA_2R1-ab) are found in 80% of patients with membranous nephropathy (MN). While PLA_2R1-ab levels are closely associated with treatment response and disease prognosis, the clinical role of epitope regions targeted by autoantibodies is less clear.

Methods: The epitope recognition patterns of PLA_2R1-ab from 150 patients with newly diagnosed PLA_2R1-associated MN were analyzed by Western blot and correlated with disease activity, clinical characteristics and outcome.

Results: In addition to the three known epitope regions in the CysR, CTLD1 and CTLD7 domains, we identified a fourth epitope region in the CTLD8 domain of PLA_2R1. While PLA_2R1-ab from all patients recognized an epitope in the N-terminal region (defined as CysR – CTLD1 domains), 82.7% of patients also recognized a C-terminal epitope in PLA_2R1, namely in the CTLD7 and/or CTLD8 domain. Patients with C-terminal epitope recognition had almost 10-fold higher PLA_2R1-ab levels, higher proteinuria and needed immunosuppressive treatment twice as often as patients with epitope recognition confined at the N-terminal region of PLA_2R1. After adjusting for these factors in multivariate analyses, C-terminal epitope recognition was not predictive for any of the clinical study endpoints, defined as depletion of PLA_2R1-ab, remission of proteinuria, and doubling of serum creatinine during follow-up. Additional dilution of sera recognizing C-terminal epitopes of PLA_2R1 led to abolishment of C-terminal epitope recognition, while N-terminal epitopes remained detectable. Therefore, one can speculate, that some of the 17.3% of patients in our cohort, who only showed reactivity to the N-terminal region of PLA_2R1, may also have had autoantibodies targeting the C-terminal region, however, the sensitivity of the method was not sufficient to detect them.

Conclusions: There are at least four target epitope regions in the PLA_2R1 and a clear association between epitope recognition patterns and PLA_2R1-ab levels. C-terminal epitope recognition is not associated with disease outcome if all other clinical variables are adjusted for, therefore considering PLA_2R1-ab levels is fundamental for the interpretation of the clinical relevance of PLA_2R1 epitope recognition patterns.

SA-PO343

Relation Between Anti-PLA2R Titer and the Likelihood of Spontaneous Remission in Membranous Nephropathy

Elias A. Jatem,[1] Luisa Martin-conde,[2] Maria Molina,[1] María P. Marco,[1] Alfonso Segarra.[1] *[1]Hospital Universitari Arnau de Vilanova, Lleida, Spain; [2]University Hospital Arnau de Vilanova, Lleida, Spain.*

Background: In idiopathic membranous nephropathy (iMN), the antibody titer of anti-PLA2R correlates with the activity of the disease and the likelihood of spontaneous remission (SR). Based on measurements of the basal anti-PLA2R titer, some authors have proposed algorithms, for guiding the decision making process regarding the timing for initiation of immunosuppresive treatment in patients with iMN. Objectives: 1.- To analyze the probability of SR based on the initial titer of anti-PLA2R antibodies. 2.- Analyze if the dynamic of the antibody titer during the observation period, allows for a better estimation of the likelihood of SR.

Methods: 94 patients with iMN with anti-PLA2R antibody titers> 20 U / mL at the time of diagnosis. The patients were followed for at least 6 months before initiation immunosuppressive therapy. Blood samples were obtained prospectively at the time of diagnosis, at 8 weeks, at 12, and at 24 weeks after diagnosis. The measurement of the anti-PLA2R titer, and the predictive capacity of these titers on the likelihood of SR was analyzed with ROC curves, univariate and multivariate analysis.

Results: 28 of 94 patients (29.8%) entered immunological remission followed by clinical remission, which was total in 5 patients (5.31%) and partial in 23 (24.4%). The mean interval between diagnosis and immunological and clinical remission was 5.9 ± 1.6 months and 6.5 ± 2.3 months, respectively. Patients with SR presented lower proteinuria, lower anti-PLA2R titers at diagnosis, and a significant decrease thereof over time. The probability of SR was associated linearly with ranges of values, but not with a single value. The logistic model with greater predictive capacity included the basal titers and the change at 12 weeks.

Conclusions: In patients with iMN, the probability of SR can be estimated with adequate predictive power from the baseline anti-PLA2R antibodies, but a best estimation model is obtained when adding the antibody titer at 12 weeks.

SA-PO344

PLA2R Expression in Pediatric Membranous Nephropathy: A Multi-Institution Retrospective Study

Marco Delsante,[1] Marco Allinovi,[2] Donghyang Kwon,[5] Miriam Conces,[4] Benedetta Mazzinghi,[2] Bakri Alzarka,[3] Bhaskar Kallakury,[5] Avi Z. Rosenberg.[1] *[1]Renal Pathology, Johns Hopkins Hospital, Baltimore, MD; [2]Meyer Children's Hospital, Firenze, Italy; [3]Children's National Medical Center, Washington, DC; [4]Nationwide Children's Hospital, Columbus, OH; [5]Georgetown University Hospital, Washington, DC.*

Background: Membranous nephropathy (MN) is a rare cause of nephrotic syndrome in children and can be idiopathic (IMN) or secondary to systemic diseases (i.e. SLE, chronic infections and malignancy). In adults with IMN, antibodies against phospholipase A2 receptor (PLA2R) are present in 57-82% of patients and expression of PLA2R is increased in glomeruli by histochemical staining. The latter is a useful diagnostic tool allowing the pathologist to suggest an idiopathic versus secondary process. However, PLA2R expression in children with MN has not been studied in large cohorts, and small case series have shown lower sensitivity (6-45%) compared to adults.

Methods: We retrospectively collected 82 cases of IMN and secondary MN (lupus-related (SLEMN) and non-SLEMN) from 4 Institutions. Formalin fixed paraffin embedded sections were stained for PLA2R and scored blindly as positive or negative and results were correlated with clinical, histomorphologic, IF and electron microscopy (EM) findings.

Results: Of 37 IMN, PLA2R-positivity was observed in 62% of cases, was variable in non-SLEMN (54%) and mostly negative in SLEMN (91%). Thus, PLA2R staining alone was not sufficient to parse IMN from non-SLEMN (p=0.61). SLEMN were more likely to show mesangial expansion compared to IMN and non-SLEMN (p<0.0001 and p=0.0016 respectively), subendothelial deposits (p<0.0001) and more mesangial deposits compared to IMN (p=0.0004) but not non-SLEMN (p=0.1228). Tubuloreticular inclusions were more frequent in SLEMN and non-SLEMN compared to IMN (p<0.0001 and 0.0004 respectively) with no difference between SLEMN and non-SLEMN. IF patterns were similar in IMN and non-SLEMN with more "full-house" patterns in SLEMN. PLA2R-negative cases were more likely to have mesangial expansion, full house staining, subendothelial and mesangial deposits (p=0.0381, 0.0341, 0.0008 and 0.0351 respectively). Glomerular basement membrane alterations, global/segmental glomerulosclerosis (%) and tubulointerstitial scarring (%) did not differ significantly between groups.

Conclusions: We show a higher prevalence (62%) of PLA2R positive IMN compared to previous reports. However, PLA2R positivity was observed in a 54% of secondary MN (non-SLEMN). PLA2R-positivity did not correlate with any specific histological characteristics but was uncommon in SLEMN.

SA-PO345

Hypocomplementemia and Membranous Nephropathy Among the Patients with Anti-U1 Ribonucleoprotein (RNP) Antibody

Natsuki Shima,[1,2] Keiichi Sumida,[1] Masayuki Yamanouchi,[1] Junichi Hoshino,[1,3] Yoshifumi Ubara.[1,3] *[1]Nephrology Center, Toranomon Hospital, Kawasaki, Japan; [2]Division of Rheumatology and Clinical Immunology, Department of Medicine, Jichi Medical University, Shimotsuke, Japan; [3]Okinaka Memorial Institute for Medical Research, Tokyo, Japan.*

Background: The significance of anti-ribonucleoprotein (RNP) antibody and anti-Sm antibody remains still unclear on patients with systemic lupus erythematosus (SLE) or mix connective tissue disease (MCTD).

Methods: Thirty patients showing the positivity for antinuclear antibodies (ANA) and anti-RNP antibody, who were diagnosed with SLE or MCTD and received renal biopsy in our hospital between January 1980 and December 2014, were retrospectively enrolled into this study. These 30 patients were classified into 4 groups based upon anti-dsDNA (+)/(-) and anti-Sm (+)/(-); group A (n = 10): anti-dsDNA(-) plus anti-Sm(-), group B (n = 7): anti-dsDNA(-) plus anti-Sm (+), group C (n = 6): anti-dsDNA(+) plus anti-Sm(-), and group D (n = 7): anti-dsDNA(+) plus anti-Sm(+). Among these 4 groups, clinical marker and renal histology were compared. Renal histology showed 3 types including pure subepithelial membranous nephropathy(MN), mesangial proliferative nephropathy(MES), and MN plus MES.

Results: Thirty patients with anti-RNP antibody included SLE (n = 25) and MCTD (n = 5). The mean age (SE) was 38.6 (2.5) years, and 26 out of 30 patients (87%) were women. Fourteen patients (47%) showed the positivity for anti-Sm antibody and thirteen patients (43%) showed the positivity for anti-dsDNA antibody. Anti-Sm (-) groups showed normocomplementemia, and anti-Sm (+) groups showed hypocomplementemia. Pure MN was noted in anti-dsDNA (-) group or anti-Sm (-) group. The comparison between group A and group B showed that anti-Sm (-) has a close relation with normo-complementemia and MN lesion, and anti-Sm (+) has close relation with hypo-complementemia and MES lesion on patients with RNP(+) and ds-DNA(-). The comparison between group C and group D showed that anti-Sm (+) has close relation with hypo-complementemia, but does not have any relation with renal histology on patients with RNP(+) and ds-DNA(+).

Conclusions: Our study indicates that the single positivity of anti-RNP antibody contributes to MN formation with normocomplementemia, while additional positivity of anti-Sm antibody results in hypocomplementemia-related MES formation.

SA-PO346

Patients with Membranous Nephropathy Display Unexpectedly Decreased Circulating T Follicular Helper (TFH) and TH17 Cells and Increased Regulatory B Cells (Breg)

Chiara Cantarelli,[1] Clara Fischman,[2] Andrea Angeletti,[2] Joaquin Manrique,[3] Ilaria Gandolfini,[4] Emilie Chan,[5] Chiara Donadei,[2] Ioannis Tassiulas,[5] Gaetano La Manna,[3] Paolo Cravedi.[2] *[1]Az. Osp. Univ. Parma, Gattatico (Reggio Emilia), Italy; [2]Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Complejo Hospital de Navarra, Pamplona, Spain; [4]university hospital parma, Parma, Italy; [5]Mount Sinai Hospital, New York, NY.*

Background: Primary membranous nephropathy (PMN) is characterized by the presence of antibodies to the podocyte, but little is known on circulating T and B cell populations, especially the percentages of T_{FH} and Breg.

Methods: We performed a comprehensive follow-cytometric analysis of 38 T and B lymphocyte subpopulations, including intracellular staining for IFN-g, IL-4, and IL-17 production in 16 patients with severe PMN and compared them with 12 age-matched healthy individuals.

Results: Within the T cell compartment, we found that patients with PMN had significantly fewer $CD4^+CD25^+CD127^{lo}$ Tregs (Treg; p=0.04), IL-17^+CD4^+ T_H17 cells (p=0.01), and $CD4^+CXCR5^+PD1^+$ T_{FH} cells (p=0.02) than healthy controls (**Figure 1A**). While $CD4^+CD45RO^+CD27^-$ effector T cells were not differentially increased in PMN patients compared to healthy controls, they positively correlated with proteinuria in the PMN patients at baseline (r^2=0.33; p=0.02). Within the B cell compartment, PMN patients had significantly fewer $CD19^+CD27^+IgD^+$ unswitched B cells (p=0.01) and $CD19^+IgD^+CD27^-CD24^{lo}CD38^{lo}$ naïve transitional B cells (p<0.0001) and significantly more $CD19^+CD25^+CD71^+$ Bregs (p=0.046) than healthy controls (**Figure 1B**). Within PMN patients, we did not find a relationship between anti-PLA_2R antibodies and any of the T or B cell subsets investigated.

Conclusions: Consistent with previous reports, patients with PMN display a unique immune phenotype characterized by reduced Treg and naïve B cell percentages. Unexpectedly, we newly found that PMN patients also display increased Breg, fewer T_{FH}, and a positive correlation between $CD4^+$ effector T cells and proteinuria, suggesting a pathogenic link.

Funding: NIDDK Support

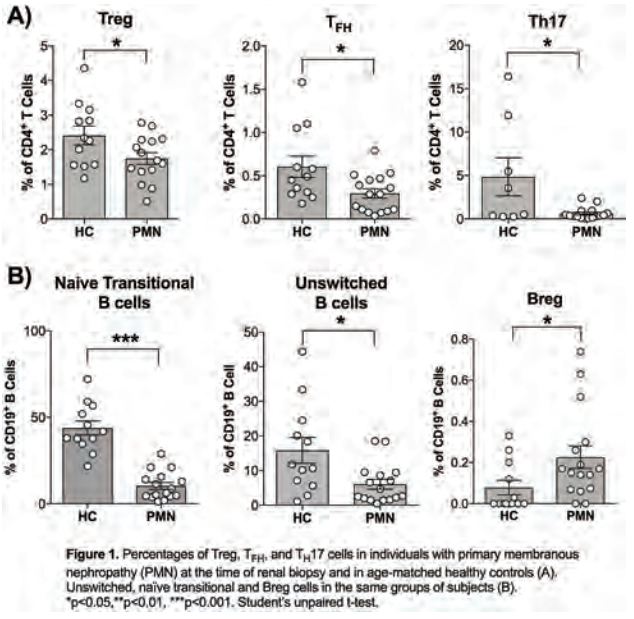

Figure 1. Percentages of Treg, T_{FH}, and T_H17 cells in individuals with primary membranous nephropathy (PMN) at the time of renal biopsy and in age-matched healthy controls (A). SA-PO347

Clinical Characteristics and Renal Outcomes in Patients Developing Membranous Nephropathy After Allogeneic Stem Cell Transplantation

Roman A. Shingarev,[2] Ann A. Jakubowski,[2] Surya V. Seshan,[1] Insara Jaffer Sathick,[2] Edgar A. Jaimes,[2] Ilya Glezerman.[2] *[1]Weill Cornell Medical Center, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Introduction: The overall probability of developing nephrotic syndrome (NS) in allogeneic stem cell transplant (allo-SCT) patients with graft-versus-host disease (GVHD) is estimated to be 8%. Membranous nephropathy (MN) accounts for the majority of these cases and has been ascribed to renal-specific manifestation of GVHD based on MN association with GVHD in other organs, immunosuppression (IS) reduction at the time of MN diagnosis and negative tissue PLA2R staining. Treatment regimens range from corticosteroids (CS) to rituximab with variable clinical response.

Case Description: Chart review identified 8 cases of clinically diagnosed NS at our institution that developed after allo-SCT from 2010 through 2017 and was evaluated with kidney biopsy. No transplants had antigen mismatch. All had a history of, but no concurrent GVHD in the settings of IS reduction. Minimal change disease was responsible for 3 and MN for 5 cases. Stain for PLA2R was present in the glomerular capillary loops in 4 of 5 MN cases. Plasma PLA2R titers were negative when checked. Partial or complete remission of proteinuria (PTN) was achieved in 4 MN cases with the utilization of single agent Tacrolimus or its combination with CS, without complications arising from the treatment (Table).

Discussion: We report a series of MN cases diagnosed after allo-SCT and characterized by PLA2R-positive tissue staining. Although the presence of PLA2R in the glomerular tissue is thought to be specific for idiopathic MN, our findings raise the possibility of PLA2R being an epi-phenomenon occurring in both idiopathic and GVHD-related MN. Tacrolimus alone appears to be effective in inducing at least partial remission of PTN. Additional CS may confer a faster and more durable response; however, this benefit must be weighed against the side effects associated with their long-term use.

Patient	Age	Hematological Diagnosis	Post-transplant time (d)	GVHD status	PLA2R tissue	PLA2R Plasma	Initial Treatment	Treatment duration (d)	Treatment response (UPC)	Subsequent treatment
1	55	AML	839	prior	+	-	Tacrolimus + CS	160	partial (1.0)	none
2	66	MDS	864	prior	+	Indeterminate	Tacrolimus + CS	294	complete (0.1)	none
3	35	TCL	937	prior	+	not checked	Tacrolimus	394	complete (0.1)	Tacrolimus
4	73	AML	1248	prior	+	-	Tacrolimus	90	none (17)	Tacrolimus + CS
5	56	AML	1065	prior	-	not checked	Tacrolimus	747	partial (1.5)	Mycophenolate Mofetil

Complement Activation Products in the Circulation and Urine of Primary Membranous Nephropathy

Mufan Zhang,[1] Jing Huang,[1] Zhao Cui,[1] Minghui Zhao.[2] *[1]Peking University First Hospital, Beijing, China; [2]Peking University First Hospital, Peking University, Beijing, China.*

Background: Complement activation plays a substantial role in the pathogenesis of primary membranous nephropathy (pMN). C5b-9, C3c, MBL, and factor B have been documented in the subepithelial immune deposits. However, the changing of complement activation products in circulation and urine is not clear.

Methods: We measured the circulating and urinary levels of C1q, MBL, C4d, Bb, properdin, C3a, C5a, and sC5b-9, in 134 patients with biopsy-proven pMN, by enzyme-linked immunosorbent assay. All the plasma values were corrected by eGFR and all the urinary values were corrected by urinary creatinine and urinary protein excretion. Anti-PLA2R antibodies were measured in all patients.

Results: The plasma complement activation products were elevated both in the patients with and without anti-PLA2R antibodies. C3a levels were remarkably increased in the circulation and urine, much higher than the elevated levels of C5a. C5b-9 was in normal range in plasma, but significantly higher in urine. The urinary C5a had a positive correlation with anti-PLA2R antibody levels and urinary protein. The plasma level of C4d was elevated, but C1q and MBL were comparable to healthy controls. Positive correlations were observed between plasma C4d/MBL and urinary protein, only in the patients with positive anti-PLA2R antibodies but not in those without. The plasma level of Bb was elevated and had positive correlation with urinary protein only in the patients without anti-PLA2R antibodies.

Conclusions: Complement activation products were remarkable increased in pMN and may serve as sensitive biomarkers of disease activity. The complement may be activated through lectin pathway with the existence of anti-PLA2R antibodies, while through alternative pathway in the absence of antibody.

SA-PO349

Identification of Novel Target Antigens in Sera of Membranous Nephropathy Patients Using Whole Proteome Peptide Array Technology

Marco Prunotto,[1] Maurizio Bruschi,[2] Andrea Cavalli,[5] John C. Tan,[3] Giovanni Candiano,[4] Dana Mcclintock,[6] Jigar Patel,[8] Gian Marco Ghiggeri.[7] *[1]F. Hoffmann-La Roche Ltd., Basel, Switzerland; [2]Laboratory of Molecular Nephrology, Istituto Giannina Gaslini, Genoa, Italy; [3]Roche Diagnostics, Madison, WI; [4]Laboratory of Molecular Nephrology, Istituto Giannina Gaslini, Genova, Italy, Genoa, Italy; [5]Universita della Svizzera Italiana, Bellinzona, Switzerland; [6]Genentech, Inc, South San Francisco, CA; [7]Istituto Giannina Gaslini, Genoa, Italy; [8]Pharmaceutical, Madison, WI.*

Background: Membranous nephropathy (MN) autoantigens have been discovered using the established laboratory technique of Western blotting, in which human sera from patients with MN were utilized to screen for specific reactivity with proteins extracted from human glomerular fractions. The objective of the present study was to investigate a highly characterized group of patients using a technology routinely adopted in antibody epitope mapping.

Methods: Sera from patients with membranous nephropathy, selected to have good (n=5) or bad prognosis (n=5) at hospitalization (T0) or twelve months after (T12) were hybridized with a whole proteome peptide array chip. The intensity of the signal retrieved by whole proteome peptide array chip was used to feed a weight gene co-expression network analysis (WGCNA) algorithm to identify a network of relationships between the signals and renal outcome in search of established and novel antigens of MN.

Results: Whole proteome peptide array technology allowed retrieving known antigens (*e.g.*, PLA2R1 or THSPD7A) and identified specific peptide sequences on those proteins recognized by autoantibodies predictive of renal outcome. Peptides belonging to previously unknown target antigens in MN were also retrieved.

Conclusions: Whole proteome peptide array and extracellular protein microarray technologies can be profitably applied to the study of autoimmune diseases. The technologies identify known antigens of MN and novel unknown ones. Those preliminary findings need extensive validation in a large patient set.

SA-PO350

Deletion of the Mitochondrial Complex-IV Co-Factor Heme A: Farnesyltransferase Causes FSGS and Interferon Response

Jea-Hyun Baek,[1] Ivan G. Gomez,[1] Yukihiro Wada,[3] Allie M. Roach,[1] Don J. Mahad,[4] Jeremy S. Duffield.[1,2] *[1]Biogen Inc., Cambridge, MA; [2]University of Washington, Seattle, WA; [3]Division of Nephrology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan; [4]University of Edinburgh, Edinburgh, United Kingdom.*

Background: Mutations in mitochondrial DNA as well as in nuclear-encoded mitochondrial proteins have been reported to cause tubulointerstitial kidney diseases and focal segmental glomerulosclerosis (FSGS). More recently, genes and pathways affecting mitochondrial turnover and permeability have been implicated in adult onset FSGS. Furthermore, dysfunctioning mitochondria may be capable of engaging intracellular innate immune sensing pathways.

Methods: To determine the impact of mitochondrial dysfunction in FSGS and secondary innate immune responses, we generated Cre/*loxP* transgenic mice to create loss-of-function deletion mutation of the Complex IV assembly co-factor heme A:farnesyltransferase (COX10) restricted to cells of the developing nephrons.

Results: These mice develop severe, early onset FSGS with innate immune activation, and die prematurely with kidney failure. Mutant kidneys showed loss of glomerular and tubular epithelial function, epithelial apoptosis and in addition a marked interferon response. *In vitro* modeling of *Cox10* deletion in primary kidney epithelium compromises oxygen consumption, ATP generation, and induces oxidative stress. In addition, loss of *Cox10* triggers a selective interferon response, which may be caused by the leak of mitochondrial DNA into the cytosol activating the intracellular DNA sensor, STING.

Conclusions: This new animal model provides a mechanism to study mitochondrial dysfunction *in vivo* and demonstrates a direct link between mitochondrial dysfunction and intracellular innate immune response.

B-Cell Profiles in FSGS Rituximab Responders with T-Cell Hyporesponsiveness

Chang-Yien Chan,[1,2] Isaac Liu,[1,2] Kong Peng Lam,[3] Kar Hui Ng,[1,2] Hui Kim Yap.[1,2] *[1]National University of Singapore, Singapore, Singapore; [2]Khoo Teck Puat-National University Children's Medical Institute, National University Health System, Singapore, Singapore; [3]Bioprocessing Technology Institute, A*STAR, SINGAPORE, Singapore.*

Background: We recently reported a subgroup of focal segmental glomerulosclerosis (FSGS) patients bearing an immunological signature of T-cell hyporesponsiveness who responded to rituximab treatment, suggesting a possible role of B-T cell interactions in modulating podocyte injury. This study aimed to investigate the B-cell profiles in this subgroup of immune-mediated FSGS.

Methods: At baseline before rituximab treatment, FSGS patients were stratified into the hyporesponsive T-cell activation (HT) and non-HT groups. HT group is defined by activated IFN-γ+CD3+ expression <2.5% following PMA and ionomycin stimulation. Blood samples were washed thrice before staining of B-cell subsets using lysed whole blood method. B-cells were isolated using CD19 microbeads and stimulated with lipopolysaccharide (LPS) for 4 hours. Cytokine levels in culture supernatants were quantified using multiplex suspension bead array system.

Results: 19 FSGS patients receiving rituximab were recruited of which 11 patients were in the HT group. At baseline, the FSGS HT group showed significantly higher percentage of double negative (DN) memory B cells (CD19+CD27-IgD-) (7.8±1.1%) compared to FSGS non-HT patients (3.8±0.6%) (P=0.009), although this did not reach statistical significance compared to 14 controls (4.8±0.6%) (P=0.08) and 12 patients with minimal change disease (MCD) (5.8±0.9%) (P=0.2). Following stimulation, of the 27 cytokines analysed, B-cell production of IL-4, IL-9 and IL-10 levels were also significantly higher in FSGS HT group compared to non-HT group (Table 1). Among these cytokines, only IL-4 and IL-10 levels in FSGS HT group were significantly higher than MCD.

Conclusions: FSGS rituximab responders with HT phenotype demonstrated elevated DN memory B cells, IL-4 producing Be-2 cells and IL-10 producing regulatory B-cells, possibly explaining the T-cell hyporesponsiveness.

Mann-Whitney U test with P<0.05 comparison between: a) HT vs non-HT FSGS; b) HT vs healthy controls; c) non-HT FSGS vs healthy controls; d) HT FSGS vs MCD; e) non-HT FSGS vs MCD; and F) healthy controls vs MCD

SA-PO352

Complement Components Activation in Subjects with Primary FSGS Associates with Reduced Glomerular Expression of Decay Accelerating Factor (DAF)

Clara Fischman,[1] Andrea Angeletti,[2] Chiara Donadei,[3] Deborah Malvi,[4] Chiara Cantarelli,[5] Gaetano La Manna,[4] Paolo Cravedi.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Mount Sinai Nephrology, Pianoro, Italy; [3]Nephrology, Dialysis and Kidney Transplantation, Bologna, Italy; [4]DIMES - University of Bologna, Bologna, Italy; [5]University Hospital, Parma, Parma, Italy.*

Background: Split products of complement system activation (Ba, Bb, C4a and C5b9) have been identified in plasma and urine of subjects with primary FSGS at the time of diagnosis. We hypothesized that complement system activation in FSGS results from a downregulation of DAF (CD55), a cell surface expressed complement regulator.

Methods: We measured urine C3a and C5a in 23 subjects with primary FSGS at the time of diagnosis and serially thereafter and in 10 healthy controls by ELISA. We stained for C3d and DAF in renal sections of 10 subjects with primary FSGS and of 10 healthy controls (healthy sections obtained from nephrectomies for neoplasm).

Results: At the time of diagnosis, patients with primary FSGS have detectable urinary C3a and C5a, whose values are positively correlated with proteinuria (**Figure 1A-B**). Urine of healthy subjects was undetectable for both C3a and C5a. After therapy, proteinuria decline was paralleled by a reduction in both C3a and C5a in the urine (**Figure 1C**). In patients with primary FSGS, glomerular C3 deposits were associated with reduced expression of CD55 (**Figure 1D**).

Conclusions: Reduced glomerular expression of DAF is associated with glomerular C3 deposits and higher levels of complement components in the urine, suggesting a possible effect of DAF in complement activation during FSGS, and, possibly, in mediating renal injury.

Funding: NIDDK Support

Representative C3d deposit (IF) and DAF expression (IHC) in the glomeruli from FSGS patients and control kidneys (**D**).

SA-PO353

Complement Activation Mediates Accelerated Tubular and Glomerular Inflammaging in Adriamycin (Adr)-Induced FSGS

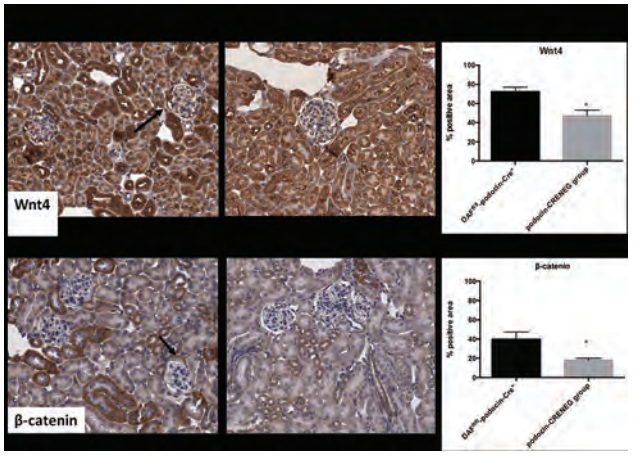
Giuseppe Castellano,[1] Alessandra Stasi,[1] Chiara Divella,[1] Rossana Franzin,[1] Fabio Sallustio,[1,3] Claudia Curci,[1] Paola Pontrelli,[4] Loreto Gesualdo,[1] Paolo Cravedi.[2] *[1]University of Bari, BARI, Italy; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Department of Basic Medical Sciences, Neuroscience and Sense Organs, University of Bari, Bari, Italy; [4]University of Bari-Dept. of Emergency and Organ Transplantation, Bari, Italy.*

Background: Complement activation and chronic low-grade inflammation (inflammaging) have been implicated in renal disease progression. Whether complement activation on podocytes promotes inflammaging and mediates progression of FSGS is unknown.

Methods: We stimulated human primary podocytes with C5a (10-7M) and H_2O_2 (300μM; positive control) for 24h and then we measured *p21* gene expression by qPCR to assess senescence. Then, we injected newly developed DAF$^{fl/fl}$ podocin-Cre^{POS} and DAF$^{fl/fl}$ podocin-Cre^{NEG} controls (on a B6 background) with Adr (20mg/kg, i.v.). We serially measured urine albumin/creatinine (A/C) and at 6 weeks we quantified histological injury and stained sections for complement activation products and for senescence markers (WNT4, β-catenin, and p16^{INK4a}).

Results: C5a stimulation induced cellular senescence in podocytes as demonstrated by an increase in p21 marker *in vitro* ($p<0.05$). While podocin-CRE^{NEG} mice were resistant to Adr, $DAF^{fl/fl}$-podocin-Cre^{POS} had glomerular deposition of C3b and severe proteinuria (albumin/creatinine: 788.9±342.7 vs. 52.8±59.1mg/g; $P<0.05$). Immunohistochemistry analyses showed that $DAF^{fl/fl}$-podocin-Cre^{POS} had a significant increase in tubular WNT4, β-catenin and $p16^{INK4a}$ expression in the nuclei compared to podocin-CRE^{NEG} mice ($p<0.05$). Podocytes and epithelial cells of Bowman's capsule also showed significantly increased WNT4 and β-catenin expression in $DAF^{fl/fl}$-podocin-Cre^{POS} compared to podocin-CRE^{NEG} animals ($p<0.05$) (**Figure**).

Conclusions: We demonstrated that DAF deficiency and complement activation induce accelerated senescence in podocytes and tubular epithelium. These data provide a rationale for testing inhibition of cell senesce as a strategy to retard complement-mediated renal disease progression.



SA-PO354

A Composite Diagnostic Assay for FSGS

Kamalika Mukherjee,[1] Nada Alachkar,[2] Changkyu Gu,[4] Garrett Garborcauskas,[5] Monica H. Stevens,[4] Jochen Reiser,[3] Sanja Sever.[4] *[1]Massachusetts General Hospital/Harvard Medical School, Charlestown, MA; [2]Johns Hopkins Hospital, Baltimore, MD; [3]Rush University Medical Center, Chicago, IL; [4]Massachusetts General Hospital, Charlestown, MA; [5]The Massachusetts General Hospital, Charlestown, MA.*

Background: Proteolytic cleavage of the membrane bound urokinase-type plasminogen activator receptor (uPAR) leads to the release of its soluble form suPAR, which has been identified in body fluids. The full-length suPAR undergoes further cleavage and exists in two additional forms: $suPAR_{II-III}$ (fragment consists of domain 2 and 3) and $suPAR_I$ (fragment consists of domain 1). Elevated levels of plasma suPAR and suPAR mediated β3 integrin activation on podocytes have been associated with renal dysfunction and the onset of chronic kidney disease (CKD). However, an increase in suPAR level has also been reported in other disease conditions such as cancer. Therefore, only suPAR level may not be sufficient as a diagnostic parameter for CKD. Here, we sought to develop a composite scoring system, which considers multiple biomarkers, to generate an efficient diagnostic platform for focal segmental glomerulosclerosis (FSGS), a type of CKD.

Methods: Serum samples obtained from healthy individuals and patients with FSGS were analyzed. The levels of full-length suPAR, $\alpha_v\beta_3$ integrin activation and the presence of $suPAR_{II-III}$ fragment were determined. The data were statistically analyzed to develop a biomarker based predictive assay for FSGS.

Results: The majority of FSGS patients exhibited high levels of suPAR and $\alpha_v\beta_3$ integrin activation on human podocytes in culture. A subset of patients' serum was positive for the presence of $suPAR_{II-III}$ fragment.

Conclusions: The composite diagnostic assay suggests suPAR fragment driven $\alpha_v\beta_3$ integrin activation in FSGS.

Complement Deposits Are Not Just Non-Specifically Entrapped in FSGS: C4d Can Precede the Development of Recurrent FSGS in Allograft Biopsies

Nina A. Van de Lest, Malu Zandbergen, Ron Wolterbeek, Jan A. Bruijn, Ingeborg M. Bajema, Marion Scharpfenecker, Jamie S. Chua. *Leiden University Medical Center, Leiden, Netherlands.*

Background: Complement deposition in focal segmental glomerulosclerosis (FSGS) is often considered aspecific entrapment in sclerotic lesions. However, recent studies showed that complement activation may be involved in the development of FSGS. We previously found that C4d deposition precedes the development of segmental glomerulosclerosis in an animal model of FSGS, and that C4d is present in non-sclerotic glomeruli of patients with FSGS. Here, we investigated if complement activation can precede the development of recurrent FSGS after transplantation. To this end, we studied C4d deposition in transplantation biopsies prior to the development of recurrent FSGS lesions.

Methods: We stained allograft biopsies without FSGS lesions from 34 patients with native primary FSGS for C4d: 18 patients developed recurrent proteinuria or recurrent FSGS in follow-up biopsies and 16 patients did not. As controls, we included allograft biopsies from 34 patients with a native kidney disease other than FSGS. Patients with confounding factors for C4d deposition were excluded.

Results: In allograft biopsies of patients with recurrent proteinuria or recurrent FSGS, glomerular C4d preceded the recurrence of FSGS lesions in 72% of patients (n=18). This was significantly more prevalent than in transplantation controls (27%; p=0.001). In 16 patients who did not develop recurrent proteinuria or FSGS, the prevalence of glomerular C4d was similar compared to transplantation controls (50% and 27%, respectively; $p<0.10$).

Conclusions: Our data show that C4d deposition precedes the recurrence of segmental lesions in patients with native FSGS, specifically at the onset of proteinuria. As the FSGS lesions had not yet developed, our data refute the hypothesis of non-specific entrapment as sole etiology for observed complement deposition. As C4d is a stable biomarker of complement activation, our data provide further evidence for complement activation in the development of FSGS. We suggest that a subgroup of patients with FSGS may have increased susceptibility to complement-mediated injury. Complement-inhibiting therapies could be promising in these cases.

SA-PO356

Apolipoprotein L1 Dynamics in Human Parietal Epithelial Cell (PEC) Molecular Phenotype Kinetics

Vinod Kumar,[1] Nitpriya Paliwal,[5] Xiqian Lan,[5] Kamesh R. Ayasolla,[5] Seyedeh Shadafarin Marashi Shoshtari,[2] Sheetal Chowdhary,[3] Ashwani Malhotra,[8] Catherine Meyer-Schwesinger,[4] Karl Skorecki,[6] Pravin C. Singhal.[7] *[1]Fienstine Institute for Medical Research, New York, NY; [2]The Feinstein Institute for Medical Research, Manhasset, NY; [3]Feinstein Institute of Medical Research, New Hyde Park, NY; [4]University of Hamburg, Hamburg, Germany; [5]Feinstein Institute for Medical Research, Manhasset, NY; [6]Rambam Health Care Campus, Haifa, Israel; [7]North Shore LIJ Health System, Great Neck, NY; [8]Feinstein Institute Medical Research and NSLIJ, MANHASSET, NY.*

Background: PECs do not express APOL1. We hypothesize that APOL1 expression emerges in PECs for podocytes' (PDs) renewal (PECs' transition) in adverse milieus. We further hypothesize that the absence of APOL1 favors the PEC phenotype and that the induction of APOL1 transitions to PD renewal.

Methods: Immortalized human PECs, which proliferate at 33°C and differentiate (transition) after 14 days after incubation in special media were characterized and used. PECs' expression of APOL1 was evaluated at different time intervals (0, 4, 8, 14 days) during their transition (Tr). Effects of a miR193a inhibitor/ overexpression of miR193a as well as APOL1-silencing/APOL1-overexpression was evaluated on PECs' expression APOL1 and miR193a. Effects of vitamin D receptor agonist (VDA), IFN-γ, and HIV were examined on the induction of APOL1 and associated expression of PD markers in HEKs and PECs. Luciferase assay was used to establish a putative interaction between miR193a and APOL1 in PECs. To confirm the PEC induction of APOL1 *in vivo*, renal biopsy specimens of HIVAN patients were co-labeled for APOL1 and synaptopodin.

Results: PECs at 33°C did not exhibit APOL1 expression. During PECs' transition, APOL1 expression coincided with the expression of PD markers (PEC transition) along with down-regulation of miR193a. The induction of APOL1 down-regulated miR193a and induced PD markers in PECs; whereas, the APOL1-silencing in Tr-PECs up- regulated miR193a expression suggesting a reciprocally linked feedback loop relationship between APOL1 and miR193a. HIV, IFN-γ, and VDA down-regulated miR193a expression as well as induced the expression of APOL1 and PD markers both in PECs. Since silencing of APOL1 attenuated HIV-, VDA-, and IFN-γ-induced expression of PD makers, it appears that APOL1 is an important functional constituent of miR193a-APOL1 axis. This notion was further confirmed by enhanced expression of PEC markers in APOL1 silenced Tr-PECs despite down-regulation of miR193a. Luciferase assay suggested a putative interaction between miR-193a and APOL1. Renal biopsy specimens from HIVAN patients revealed PECs' expression of APOL1 and synaptopodin.

Conclusions: APOL1 absence favors PECs' phenotype but its expression facilitates PECs transition

SA-PO357

Modulation of APOL1-miR193a Axis Protects Against Apoptosis in Adverse Milieus

Vinod Kumar,[4] Nitpriya Paliwal,[2] Xiqian Lan,[2] Kamesh R. Ayasolla,[2] Sheetal Chowdhary,[6] Seyedeh Shadafarin Marashi Shoshtari,[7] Ashwani Malhotra,[5] Karl Skorecki,[1] Pravin C. Singhal.[3] *[1]Rambam Health Care Campus, Haifa, Israel; [2]Feinstein Institute for Medical Research, Manhasset, NY; [3]Medicine, Feinstein Institute for Medical Research, Manhasset, NY; [4]Fienstine Institute for Medical Research, NEW YORK, NY; [5]Feinstein Institute Medical Research and NSLIJ, MANHASSET, NY; [6]Feinstein Institute of Medical Research, New Hyde Park, NY; [7]The Feinstein Institute for Medical Research, Manhasset, NY.*

Background: Both Puromycin aminonucleoside (PAN) and adriamycin are known to promote podocyte (PD) apoptosis in both *in vitro* and *in vivo* studies. We have recently reported that APOL1 wild-type (G0) has a potential to preserve podocyte molecular

phenotype in high glucose milieu. APOL1 inversely regulates PD expression of miR193a and forms reciprocally linked feedback relationship. We now hypothesize that upregulation of APOL1-miR193a axis has a potential to prevent PD apoptosis in PAN and adriamycin milieus.

Methods: To aim differentiation, immortalized human podocytes (PDs) stably expressing vector (PDV) or APOL1G0 (wild- type, PDG0) were incubated in media for 10 days. Differentiated (D) PDVs and PDG0 were treated with different concentrations of Adriamycin (0,5, 15, 30, 50, and 100 nM) or PAN (0, 5, 10, 25, 50, and 100 nM) for 48 hours (n=4); in other sets, DPDVs were incubated in media containing Adriamycin (30 mM), PAN (50 nM), with/without miR193a inhibitor (25 nM) for 48 hours (n=4). Cells were evaluated for reactive oxygen species (ROS) generation (DCF detection assay), caspase-3 cleavage, and apoptosis (TUNEL assay). Proteins and RNAs were extracted from cells treated under similar conditions (n=4). Protein blots were probed for APOL1 and caspase-3; RNAs were assayed for miR193a. DPDs were transduced with either empty vector and miR193a plasmid and evaluated for APOL1 and caspase-3 expressions.

Results: PDVs displayed higher (P<0.01 vs. respective controls) generation of ROS and a greater (P<0.01 vs. respective controls) percentage of apoptosis when compared to PDG0, both in adriamycin and PAN milieus. PDG0 displayed enhanced (two-fold) expression of APOL1, but decreased (2.8-fold) miR193a levels when compared to PDVs. Both Adriamycin and PAN exhibited enhanced PD expression of miR193a and caspase-3. MicroRNA193a inhibitor decreased (3-fold) miR193a levels, increased APOL1 (1.8-fold) expression, and attenuated (P<0.5 vs. adriamycin and PAN) apoptosis in both adriamycin and PAN milieus. DPDs overexpressing miR193a displayed decreased expression of APOL1 and enhanced cleavage of caspase-3.

Conclusions: APOL1Go provides protection against apoptosis in adverse milieus through down-regulation of miR193a and attenuated generation of ROS.

A Cross-Talk Between HIV-Injured Podocytes and Parietal Epithelial Cells (PECs) Results in Proliferation of PECs

Vinod Kumar,[2] Xiqian Lan,[1] Kamesh R. Ayasolla,[1] Sheetal Chowdhary,[8] Seyedeh Shadafarin Marashi Shoshtari,[7] Ashwani Malhotra,[3] Catherine Meyer-Schwesinger,[4] Karl Skorecki,[5] Pravin C. Singhal.[6] *[1]Feinstein Institute for Medical Research, Manhasset, NY; [2]Fienstine Institute for Medical Research, NEW YORK, NY; [3]Feinstein Institute Medical Research and NSLIJ, MANHASSET, NY; [4]University of Hamburg, Hamburg, Germany; [5]Rambam Health Care Campus, Haifa, Israel; [6]North Shore LIJ Health System, Great Neck, NY; [7]The Feinstein Institute for Medical Research, Manhasset, NY; [8]Feinstein Institute of Medical Research, New Hyde Park, NY.*

Background: HIV-associated nephropathy is characterized by an abundance of proliferating PECs in Bowman's space. The involved mechanism of PECs proliferation in HIV milieu is not clear. Interleukin (IL)-1 β has been reported to stimulate PECs proliferation. We have recently reported that HIV infection stimulates generation of IL-1β by PDs. We now hypothesize that a cross-talk between HIV-infected PDs and PECs would promote PECs proliferation.

Methods: Immortalized differentiated human PDs (DPDs) were transduced with either vector (DPDV) or HIV (NL4-3, DPDHIV) and assayed for pyroptosis (morphologic assay). Control DPDs and DPDHIV were incubated in serum-free media for 24 hours. Incubation (conditioned, C) media was collected and stored at -80°C. PECs were incubated in serum-free media containing 10% of control (DPDV) and experimental (DPDHIV) conditioned media for 48 hours. In another set of experiments, PECs were incubated in serum-free media containing 10% control and experimental media with or without IL-1β (neutralizing) antibodies for 48 hours. Cells were evaluated for proliferation by MTT cellular growth assay. To confirm the role of cross-talk, PECs were grown in outer wells and DPDV/DPDHIVs were seeded into inner wells (Trans-well plates). After 48 hours, cells in outer wells were assayed for proliferation. Cellular lysates/incubation media of DPDVs and DPDHIVs were assayed for IL-1β by ELISA. Additionally, PECs grown on coverslips were treated with 10% control and experimental media for 48 hours followed by immunolabeling for either PCNA or Ki67.

Results: DPDHIV displayed a higher percentage of cells with pyroptosis (P<0.01 vs respective controls). Cellular lysates and incubation media of DPDHIV showed increased (P<0.05 vs. DPDV) content of IL-1β. Conditioned media of DPDHIV promoted PECs proliferation; however, anti-IL-1β antibody partially inhibited DPDHIV-conditioned media-mediated proliferation. PECs growing in outer wells of trans-well plates containing DPDHIV also displayed enhanced proliferation. PECs treated with DPDHIV conditioned media exhibited a higher percentage (P<0.01 vs. DPDV) of PCNA/Ki67 +ve cells.

Conclusions: A cross-talk between PDs to PECs promotes PECs proliferation in HIV milieu.

HIV-Induced Parietal Epithelial Cell Proliferation: Role of miR193a

Vinod Kumar,[1] Nitpriya Paliwal,[2] Xiqian Lan,[2] Kamesh R. Ayasolla,[2] Sheetal Chowdhary,[8] Seyedeh Shadafarin Marashi Shoshtari,[3] Ashwani Malhotra,[4] Catherine Meyer-Schwesinger,[5] Karl Skorecki,[6] Pravin C. Singhal.[7] *[1]Fienstine Institute for Medical Research, NEW YORK, NY; [2]Feinstein Institute for Medical Research, Manhasset, NY; [3]The Feinstein Institute for Medical Research, Manhasset, NY; [4]Feinstein Institute Medical Research and NSLIJ, MANHASSET, NY; [5]University of Hamburg, Hamburg, Germany; [6]Rambam Health Care Campus, Haifa, Israel; [7]North Shore LIJ Health System, Great Neck, NY; [8]Feinstein Institute of Medical Research, New Hyde Park, NY.*

Background: miR193a has been reported to play an important role in the determination of glomerular epithelial cells' phenotype. miR193a is a tumor suppressor gene and its downregulation has been associated with enhanced cellular proliferation. HIV-associated nephropathy (HIVAN) is characterized by an accumulation of proliferating parietal epithelial cells (PECs) in the Bowman's space; however, the involved mechanism is not clear. Since HIV down-regulates the expression of miR193a, we asked whether HIV is stimulating PECs proliferation through down-regulation of miR193a.

Methods: Immortalized PECs were transduced with vector (PECV) or different concentrations of HIV (10^4, 10^3, 10^2, and 10^1 GEU/ml; PECHIV) followed by growth arrest (24 hours), followed by incubation in media containing 1% serum for 48 hours (n=4). Cell growth was assayed by cell count and MTT assay. To determine the role of miR193a, PECVs and PECHIV were transduced with empty vector (25 nM), miR193a (25 nM), an inhibitor of miR193a (25 nM) plasmids (n=4). After 48 hours, proteins and RNAs were extracted. Protein blots were probed for molecular markers of mTOR (p-mTOR, p-70S6K, p-4EBP, and p-eEF) and epithelial-mesenchymal transition (α-SMA, SNAIL, and fibronectin; EMT) pathways and reprobed for β-actin. RNAs were assayed for miR193a. *In vivo* studies, renal tissues of 4-week old control and HIV transgenic (Tg26) mice (n=6) were evaluated for the activation of mTOR and EMT pathways (Western blotting analysis and immuno-labeling of renal cortical sections). Renal tissues from control and Tg26 mice were also examined for miR193a expression (Fluorescent in situ hybridization, FISH).

Results: PECHIV stimulated PEC proliferation at lower concentrations (10^3 and 10^2 GEU/ml). PECHIVs-overexpressing miR193a exhibited a decrease in proliferation when compared to PECHIVs. PECHIVs and renal tissues from Tg26 mice showed the activation of the mTOR as well as EMT pathways. Renal cortical sections of Tg26 mice showed a decrease in miR193a expression when compared to control mice; additionally, renal cortical sections of Tg26 mice displayed enhanced proliferation of PECs as indicated by an increased number PCNA +ve cells in Bowman's space.

Conclusions: HIV induces PEC proliferation through down-regulation of miR193a.

Disrupted APOL1-miRNA Axis Induces an Imbalance Between Autophagic Load and Handling in Podocytes Expressing APOL1 Risk Alleles

Abheepsa Mishra,[1] Kamesh R. Ayasolla,[2] Nitpriya Paliwal,[2] Seyedeh Shadafarin Marashi Shoshtari,[3] Vinod Kumar,[8] Ashwani Malhotra,[4] Catherine Meyer-Schwesinger,[5] Karl Skorecki,[6] Pravin C. Singhal.[7] *[1]The Feinstein Institute for Medical Research, Northwell Health, MANHASSET, NY; [2]Feinstein Institute for Medical Research, Manhasset, NY; [3]The Feinstein Institute for Medical Research, Manhasset, NY; [4]Feinstein Institute Medical Research and NSLIJ, MANHASSET, NY; [5]University of Hamburg, Hamburg, Germany; [6]Rambam Health Care Campus, Haifa, Israel; [7]North Shore LIJ Health System, Great Neck, NY; [8]Fienstine Institute for Medical Research, NEW YORK, NY.*

Background: MicroRNA193a has been reported to enhance autophagy in several cell types. A recent report suggests that human podocytes (PDs) expressing APOL1 risk alleles (G1 and G2) have an altered autophagic reflux. We hypothesize that disruption of APOL1-miR193a axis would contribute to an imbalance between autophagic load and handling in PDs expressing APOL1 risk alleles.

Methods: Immortalized human podocytes (PDs) stably expressing vector, APOL1G0/G1/G2 were differentiated and evaluated for APOL1 (protein and mRNA) and miR193a expressions. To determine the effect of miR193a on autophagy, PDs were transfected with empty vector or different concentrations of miR193a plasmid (0, 50, 100 nM), or an inhibitor of miR193a (0, 25, 50, and 100 nM), followed by an evaluation for autophagy markers (P62, LC3II, and beclin 1). To determine the role of the mTOR pathway, PDs were transfected with either empty vector, miR193a, or a miR193a inhibitor (plasmids) followed by analysis for phos-mTOR and GAPDH by Western blotting. To examine the role of miR193a-APOL1 axis, PDs were transfected with either scrambled or APOL1 siRNA and then evaluated for miR193a expression and autophagy markers. To examine autophagic flux, PDs expressing vector (PDV), APOL1G0/G1/G2 were transfected with GFP-tagged LC3II plasmid and treated with Bafilomycin (100 nm) and examined at 0, 2, and 4 hours under a confocal microscope.

Results: APOL1G0 down-regulated but APOL1G1 and APOL1G2 upregulated miR193a expression in PDs. Overexpression of miR193a down-regulated but a miR193a inhibitor enhanced the expression of phos-mTOR. APOL1-silenced PDs showed enhanced expression of miR193a as well as of autophagy markers. PDs expressing APOL1G1 and G2 displayed a higher expression of LC3II in a time course manner in Bafilomycin blockade experiments, suggesting an increased load or sluggish autophagic flux. Since APOL1 risk alleles displayed 2.5- fold higher expression of miR193a when compared to PDs expressing

APOL1G0, it appears that they carried an enhanced autophagic load, in addition to sluggish autophagic flux.

Conclusions: Disrupted APOL1-miR193a axis induces an imbalance between autophagic load and handing in podocytes expressing APOL1 risk alleles.

SA-PO361

What's the RUSH? The Role of Calcium in APOL1 Toxicity

Joseph A. Giovinazzo,[1] Russell P. Thomson,[1] Nailya Khalizova,[1] Nirav Malani,[3] Ryan Schreiner,[2] Jayne Raper.[1] *[1]CUNY Hunter College, Brooklyn, NY; [2]Weill CornellMedical College, New York, NY; [3]Independent, Flemington, NJ.*

Background: APOL1 is an innate immunity protein that forms toxic ion channels in trypanosomes. Variants of APOL1, G1 and G2 but not G0, are linked to kidney disease, however the mechanism responsible remains controversial. Here we propose that the key upstream event is APOL1 localization to the plasma membrane (PM), where it forms channels that lead to the passage of ions across the membrane, with Ca^{2+} influx being a driver of cell death.

Methods: APOL1 was expressed in FlpIn TREX 293 cells or HEK and CHO cells via the Retention Using Selective Hooks (RUSH) system. RUSH is a streptavidin-binding method that retains tagged APOL1 in the ER until biotin addition. Toxicity was measured via LDH release. rAPOL1 was purified from *E. coli* and reconstituted in planar lipid bilayers to measure channel selectivity. High throughput widefield microscopy was performed to quantify cytosolic and ER Ca^{2+} in cells expressing indicators GCaMP6f and ER-LAR-GECO, along with viability dye DRAQ7. IF with confocal microscopy was performed to quantify APOL1 localization.

Results: When retained in the ER, G1 and G2 are not toxic, and only release from the ER leads to cell death. The toxicity of G1 is delayed relative to G2, and G0 is not toxic. A previous study in *Xenopus* oocytes reported that APOL1 leads to Ca^{2+} influx. We tested rAPOL1 selectivity and found that all variants form channels that are permeable to Ca^{2+}. Furthermore, G1 and G2 toxicity is dependent on extracellular Ca^{2+}, as increasing [Ca^{2+}] led to more cell death, while chelation with EGTA rescued. Measurement of cytosolic Ca^{2+} revealed that G1 and G2, only after ER release, led to a significant Ca^{2+} influx over 2-4h that preceded cell swelling and death. IF indicated that APOL1 localizes to the PM prior to Ca^{2+} influx, and that G1 traffics slower than G2. Simultaneous measurement of cytosolic and ER Ca^{2+} demonstrated that there is no ER Ca^{2+} release.

Conclusions: These data demonstrate that the toxicity of G1 and G2 requires PM localization and an influx of Ca^{2+}. We also report a novel difference between the trafficking and toxicity kinetics of G1 and G2. The ion channel at the plasma membrane is likely the key event that leads to cell death, and the sustained influx of Ca^{2+} may unify the disparate theories of APOL1 toxicity, from mitochondrial damage to inflammatory pathways, which can all be triggered by Ca^{2+}.

SA-PO362

Characterization of Novel APOL1 G0, G1S342G and APOL1-/- Podocyte Cell Lines and Their Response to HIV Infection

Heidi Karttunen,[2] Alan Rosales,[2] Xiaobo Gao,[2] Michael J. Ross.[1] *[1]Albert Einstein College of Medicine/ Montefiore Medical Center, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY.*

Background: Persons with APOL1 high risk genotypes are at increased risk of several forms of progressive CKD and remarkably, have a 29 to 89-fold increased risk of HIV-associated nephropathy (HIVAN). HIV gene expression in renal epithelial cells, including podocytes, is a critical mediator of HIVAN pathogenesis but previous studies have failed to detect an increase in APOL1 expression in HIVAN biopsy specimens, suggesting that changes in APOL1 function, and not expression levels, may drive pathogenesis. The APOL1 G1 risk allele consists of 2 nonsynonymous SNPs (S342G and I384M) and S342G is likely sufficient to drive the risk attributed to G1. Since overexpression models may not accurately model APOL1 function, we used CRISPR-Cas9 to generate isogenic human podocyte lines with APOL1 G0, $G1^{S342G}$, and $APOL1^{-/-}$ and determine the effects of APOL1 genotype upon response to HIV infection.

Methods: We used CRISPR-Cas9 to modify conditionally immortalized $APOL1^{G0/G0}$ podocytes. Guide RNAs and single stranded oligonucleotides were designed to target the APOL1 locus to generate the $G1^{S342G}$ allele or delete exons 4 and 5 ($APOL1^{-/-}$). In lentiviral transduction studies, podocytes were transduced with VSV-pseudotyped NL4-3DG/P-EGFP (HIV), or HR-IRES-EGFP (control). Endogenous APOL1 was immunprecipitated after HIV or control infection and APOL1-binding proteins were identified by mass spectrometry.

Results: Clonal homozygous $G1^{S342G}$ and $APOL1^{-/-}$ podocytes lines were generated. All podocyte lines expressed normal podocyte markers, including podocin. APOL1 expression was lower in $G1^{S342G}$ than G0 podocytes and APOL1 expression increased as podocytes were differentiated at 37C. Proteasome inhibition increased APOL1 protein abundance, suggesting that it is degraded by the ubiquitin-proteasome system. HIV infection did not increase APOL1 expression in any podocyte cell lines. Immunoprecipitation of endogenous APOL1 after HIV or control infection and identification of APOL1 binding proteins by mass spectrometry identified numerous cellular proteins that differentially bind $G1^{S342G}$ in the presence of HIV infection with known roles in kidney injury.

Conclusions: We developed novel podocyte cell lines with alterations in the APOL1 coding sequence that will allow for studies to determine changes in function of the APOL1 alleles when expressed at physiologic levels.

APOL1 RNA Is Differentially Spliced in Nephrotic Syndrome and in Response to Therapy

Jiro Kino,[1] Amy Webb,[2] Melinda A. Chanley,[3] William E. Smoyer,[3,2] Shipra Agrawal.[1,2] *[1]The Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Ohio State University, Dublin, OH; [3]Nationwide Children's Hospital, Columbus, OH.*

Background: *APOL1* has been a subject of intense research since the discovery of the association of its risk alleles with heightened risk for end stage kidney disease in African Americans. However, the potential role of alternate splicing of *APOL1* in podocyte biology and in the regulation of kidney disease is unknown. Recent evidence suggests that the presence and/or absence of exons 2 and 4 distinguish known splice variants of *APOL1*, and that exon 4 contributes to cytotoxicity. We hypothesized that *APOL1 RNA is differentially spliced in nephrotic syndrome (NS) and in response to glucocorticoid (GC) therapy, thus playing a potential pathophysiological role in both disease and health, regardless of APOL1 haplotype.*

Methods: *APOL1* RNA and splice variant expression was analyzed in podocytes injured with puromycin aminonucleoside (PAN), and treated with dexamethasone (Dex) by RT-PCR using splice variant specific primers. Splice variant analyses were also performed in circulating leukocytes of children with steroid sensitive (SSNS) and steroid resistant NS (SRNS), before and following initial GC therapy (N =8 SSNS and 8 SRNS paired samples). T-test and 2 way ANOVA statistical analyses were performed to measure relative variant expression.

Results: Podocytes expressed all 5 known splice variants of *APOL1* [v.A, variant3 v.A, v.B1,v.B3 and v.C]. Higher relative expressions of exon 4 (+) [v.A, v.B1] and exon 2 (-) [v.A, v.C] forms were observed, with variant 1 [v.A] the most predominantly expressed form. Dex increased the relative expression of splice variants exon 4 (+) and exon2 (-), which in contrast was decreased with PAN-induced injury. Although RNASeq data analysis was unable to detect these variants, in-depth RT-PCR analyses revealed that both exon 4 (+) and (-) variants were expressed in the circulating leukocytes of SSNS and SRNS patients, while exon 2 (+) forms were only minimally expressed. SRNS patients had increased levels of almost all *APOL1* variants [except exon 2 (+)] compared to SSNS patient prior to GC treatment. GC treatment induced expression of most of the recognized splice variants increased in SSNS, but decreased them to varying degrees in SRNS.

Conclusions: Cultured podocytes and circulating human leukocytes express distinct *APOL1* splice variant patterns and differential splicing of *APOL1* is associated with NS and in response to GC therapy.

SA-PO364

CD80 and CD163 as Biomarkers of Nephrotic Syndrome

Marie C. Hogan,[1] Anatilde M. Gonzalez guerrico,[1] Jonathan P. Troost,[2,3] Adam M. Wright,[1] Fernando C. Fervenza,[1] George G. Klee,[1] John C. Lieske.[1] NEPTUNE Consortium *[1]Mayo Clinic, Rochester, MN; [2]University of Michigan, Ann Arbor, MI; [3]NEPTUNE Consortium, Ann Arbor, MI.*

Background: Cellular expression of CD80 and CD163 may play a role in the pathogenesis of certain glomerulopathies. Urinary or blood concentrations may predict and/or track response to specific immunosuppressive therapies and long term renal function.

Methods: Urine was obtained from Mayo Clinic patients (286) and NEPTUNE cohort participants (104) with biopsy-proven minimal change disease (MCD, 103), focal segmental glomerulosclerosis (FSGS, 97), lupus nephritis (LN, 31), IgA nephropathy (IgAN, 28), and membranous nephropathy (MN, 54), as well as non glomerular disease patients with autosomal dominant polycystic kidney disease (ADPKD, 9), pyuria (19), and controls (34). Data expressed as (mean, median (IQR)) was analyzed by Kruskal-Wallis test, generalized estimating equation models (GEE) or receiver operating characteristic (AUC) curve analysis.

Results: CD80/Creatinine and CD163/Creatinine were higher in relapse vs remission in paired urine samples of MCD and FSGS cases (GEE: Active vs. remission $p<0.0001$); MCD vs. FSGS $p<0.0001$). Urinary CD80/Creatinine ratios were higher in active MCD, LN, DN and CD163/Creatinine was higher in active LN compared to active cases of other glomerular diseases or controls (**Table 1**). Differences remained significant after adjusting for proteinuria ($p \leq 0.01$; GEE).

Conclusions: Urinary CD80 and CD163 excretions varied between disease groups and by disease activity. These results suggest a pathogenic role for these molecules in certain glomerular diseases, including diabetic nephropathy.

Funding: Commercial Support - Bristol-Myers Squibb, Private Foundation Support

Urinary CD80/creat and CD163/Creat discriminate by proteinuric kidney disease type.

	# samples	CD80 (ng/g Creat) Median (IQR)	p vs. Control	p vs. MCD	CD163 (µg/g Creat Median (IGR)	p vs. Control
Control	32	46 (21, 76)	REF	<.01	0.3 (0.2, 0.9)	REF
MCD	47	139 (79, 221)	<.01	REF	5.3 (2.2, 18.3)	<.01
FSGS	58	82 (40, 114)	0.03	<.01	5.6 (3.1, 8.6)	<.01
IgAN	9	19 (7, 52)	0.09	<.01	3.9 (2.9, 6.7)	<.01
Lupus	10	165 (76, 395)	0.02	0.86	51.1 (13.4, 156.1)	<.01
MN	27	64 (28, 96)	0.18	<.01	7.3 (4.7, 11.4)	<.01

Identifying the Role of Soluble Circulating Permeability Factors in Proteinuria in a Zebrafish Parabiosis Model

Heiko J. Schenk,[2] Janina Müller-Deile,[2] Patricia A. Schroder,[1] Mario Schiffer.[2,1]
[1]Mount Desert Island Biological Laboratory, Salisbury Cove, ME; [2]Hannover Medical School, Hannover, Germany.

Background: Proteinuria may be induced by an impairment in any component of the glomerular filtration barrier. To determine the role of circulating permeability factors to cause proteinuria through glomerular damage as a result from reduced specific podocyte protein expression, we developed a parabiosis-based zebrafish model to generate a common circulation between two zebrafish larvae.

Methods: Zebrafish eggs were dechorionated at the 128-cell blastula stage and moved to the desired orientation for fusion that was achieved by a micro cell transfer from one embryo to the other with a glass micropipette. We injected npnt-morpholino (MO) into the yolk of a 1-4 cell embryo of *Tg(flk1-mCherry)* zebrafish and performed the fusion at a 256-cell stage with control *Tg(l-fabp:eGFP-DBP)* zebrafish embryos. By using a FITC-labelled MO, we ruled out a MO-transfer between both parabionts. Common circulation and loss of plasma proteins were investigated and the glomeruli of both zebrafish pairs were analyzed using electron microscopy.

Results: We fused blastulae from *Tg(l-fabp:eGFP-DBP)* zebrafish that express a green fluorescent vitamin D binding protein in their blood plasma with blastulae of *Tg(flk1-mCherry)* zebrafish that express a red fluorescent endothelium. Confocal imaging of parabiotic zebrafish with these backgrounds showed a detectable green fluorescent plasma protein from the *Tg(l-fabp:eGFP-DBP)* zebrafish in the red fluorescent blood vessels of the *Tg(flk1-mCherry)* parabiotic partner at 72 hpf, indicative of a common circulation system. Fluorescence analysis of the parabiotic zebrafish larvae after npnt knockdown revealed a reduction of the eGFP-labelled protein from the common circulatory system suggestive of proteinuria. Knockdown of npnt in the injected parabiont showed podocyte effacement and altered glomerular basement membrane. Remarkably, also the control parabiotic partner developed podocyte effacement and glomerular endothelial swelling as well but had a regular glomerular basement membrane. We could not only detect proteinuria and glomerular damage caused by the knockdown of the podocyte gene npnt in injected fish, but also in the fused partner.

Conclusions: These data suggest that circulating permeability factors may be induced by proteinuria even when an induced dysregulation of a podocyte gene is the initiating cause.

Podocyte-Specific Crb2 Knockout Mice Cause Proteinuria

Kan Katayama,[1,2] Yugo Ito,[3] Masaaki Ito.[1] *[1]Department of Cardiology and Nephrology, Mie university graduate school of medicine, Tsu, Japan; [2]Department of Medical Biochemistry and Biophysics, Karolinska Institute, Stockholm, Sweden; [3]Department of Medical Biochemistry and Biophysics, Karolinska Institute, Stockholm, Sweden.*

Background: Crumbs 2, Crb2 is known to be expressed in the podocytes. Knockdown of crb2 caused cardiac edema in zebrafish and full knockout of Crb2 resulted in embryonic lethality. Moreover, there have been reports of steroid-resistant nephrotic syndrome by CRB2 mutations. However, its precise mechanism is still elusive.

Methods: We generated conditional Crb2 floxed mice that possessed loxP sites flanking exon 7 and 8. Podocyte-specific Crb2 knockout mice were generated by breeding Crb2 conditional knockout mice with NPHS2-Cre mice. Urine, blood, and renal histology were examined in NPHS2-Cre or Crb2 flox/flox or NPHS2-Cre & Crb2 flox/flox mice.

Results: NPHS2-Cre & Crb2 flox/flox mice showed massive proteinuria at two or six months of age compared to NPHS2-Cre mice or Crb2 flox/flox mice. Blood urea nitrogen or serum creatinine at two months of age was comparable among the three groups. Although renal histology at two months of age was also comparable among the three groups, glomerular sclerotic indices of NPHS2-Cre & Crb2 flox/flox mice at six months of age were significantly higher than those of NPHS2-Cre mice or Crb2 flox/flox mice.

Conclusions: Knockout of Crb2 in the podocytes might play an important role in developing proteinuria.

Podocyte-Expressed STAT5 Confers Protection During Experimental Glomerulonephritis and Adriamycin Nephropathy in Mice

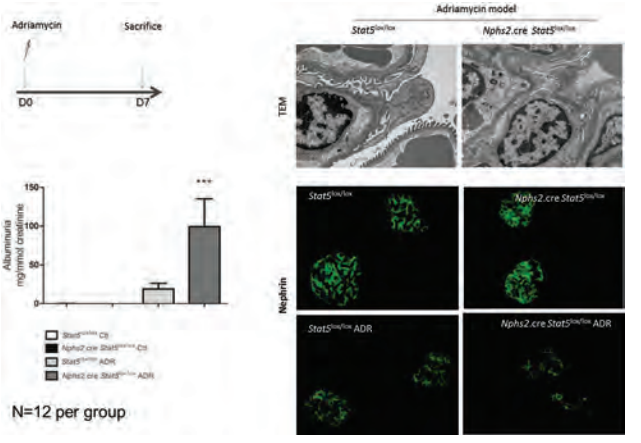
Kevin Louis,[2] Aïssata Niasse,[2] Anthony Corchia,[2] Hélène Dobosziewicz,[2] Placier Sandrine,[2] Yi-chun Xu-dubois,[2] Sophie Vandermeersch,[2] Eric Rondeau,[3] Laurent Mesnard,[3] Yosu Luque.[1] *[1]Assistance Publique Hopitaux de Paris, Paris, France; [2]Inserm U1155, Hôpital Tenon, Paris, France; [3]APHP; University Paris 6, PARIS, France.*

Background: Glomerular diseases are a leading cause of chronic kidney failure and the podocyte is one of the main target of these diseases. We previously evidenced a protective role for a podocyte-expressed immune receptor such as the common gamma chain (γC) during glomerulonephritis. We also found that STAT5, a transcriptional factor classically described and activated downstream γC in T cells is upregulated in podocytes during glomerulonephritis. Hitherto, STAT5 role in podocyte remains to be determined.

Methods: Using mice with a podocyte-specific deletion of *Stat5*, we analyzed the role of STAT5 in two experimental models of glomerular diseases.

Results: First, during crescentic glomerulonephritis, podocytic-STAT5 deficient mice developed increased proteinuria compared to their wild-type littermates. Second, during adriamycin induced-nephropathy, the absence of podocyte STAT5 led to increased albuminuria and severe podocytic injuries in comparison to controls (**Figure 1**). Moreover podocytic lesions were associated with loss of podocyte differentiation markers such as WT1 especially in podocytic-STAT5 deficient animals. Renal T-cells and macrophages infiltration were not affected by the deletion of podocytic Stat5.

Conclusions: Taken together, our results suggest an yet unsuspected protective role of podocytic γC /STAT5 signaling during glomerular diseases.



SA-PO368

Expression of Chemokine Receptor 2 (CCR2) on Renal Podocyte Progenitor Stem Cells

Bin N. Zhao,[1] Zhenhua Miao,[2] Linda Ertl,[2] Xiaoping Zang,[3] Israel Charo,[2] Thomas J. Schall,[2] Rajinder Singh.[2] *[1]Chemocentryx Inc., Mountain View, CA; [2]ChemoCentryx, Mt View, CA; [3]ChemoCentryx, Inc., Mountain View, CA.*

Background: Several lines of evidence support a role for chemokine receptor 2 (CCR2) through interaction with its ligand CCL2 in the pathogenesis of kidney diseases. We have shown recently that inhibition of CCR2 by small molecule inhibitors markedly reduce proteinuria, improve renal function and preserve or restore podocyte density in murine models of Focal Segmental Glomerulosclerosis (FSGS). To understand the mechanism of this protection, we have examined the expression of CCR2 on human and murine kidneys.

Methods: CCR2 expression on the kidneys was assessed by immunohitochemistry (IHC) on formalin fixed, paraffin-embedded human and mouse kidney sections, and by flow cytometry with freshly isolated murine renal cells.

Results: IHC with a human CCR2 antibody revealed CCR2 expression on glomerular cells in human CCR2 knock-in, but not CCR2 knockout mouse kidneys. Flow cytometry of freshly isolated murine kidney cells confirmed CCR2 expression on CD45 negative-cells, indicating that the positive IHC signal was not due to mature blood cells. CD133 and CD24 are cell surface markers of a heterogeneous population of renal progenitor cells, and approximately 5% of these cells also express the podocyte marker podocalyxin (PDX), marking them as podocyte precursors. By flow cytometry we found that ~8% of the murine renal CD133+CD24+ PDX+ cells, were also positive for CCR2, indicating that CCR2 was present on a subset of cells destined to become mature podocytes. Finally we used IHC to examine CCR2 expression on human renal biopsies of FSGS patients and non FSGS patients and found out that increased staining for CCR2 in the FSGS kidneys in the glomerulus and Bowman's capsule areas. These data provide clear evidence that CCR2, the target of the small molecule that we have shown reduces proteinuria and improves renal function in murine models of FSGS is present on non-hematopoietic cells in the kidney.

Conclusions: This is the first demonstration of the presence of CCR2 on renal progenitor cells that are destined to become podocytes, and reveals a potential new role for this chemokine receptor whose function as been heretofore mainly connected to monocyte/macrophage biology. Taken together, these data provide the foundation for a mechanistic understanding of the therapeutic benefit of CCR2 antagonists in FSGS, and possibly other renal diseases.

Anti-Proteinuria Effect of Antibody Against ANGPTL3 Coiled-Coil Domain on Adriamycin-Induced Nephropathy in Mice

Hong Xu,[1,2] Jia Rao,[1,2] Qian Shen.[1,2] *[1]Children's Hospital of Fudan university, Shanghai, China; [2]Shanghai Kidney Development & Pediatric Kidney Disease Research Center, Shanghai, China.*

Background: We firstly found that Angiopoietin-like-3 (Angptl3) expression is increased in glomerular podocytes of nephrotic syndrome. Our previous research showed Angptl3 plays an important role in podocyte injury and proteinuria. This study aims to confirm whether proteinuria in Adriamycin-induced nephropathy mice can be alleviated though neutralizing Angptl3 by antibody.

Methods: The polyantibody against Angptl3-CCD was prepared (namely Anti-angptl3-antibody). Nephropathy was established by Adriamycin injection in 8-12 wk-old female mice. The blockade of Angptl3 by Anti-angptl3-antibody (20mg/kg) was performed every three days for nine times after Adriamycin injection. All mice were sacrificed on day 28. Proteinuria was measured weekly. Albumin, TG and T-CHO in serum were measured on day 28, Histological changes were observed by light microscopy and transmission electron microscope. The distribution of antibody was confirmed by IF analysis.

Results: The Anti-angptl3-antibody can recognize angptl3 specifically. On the 14th day after modeling, proteinuria in the ADR group was significantly increased, but not in ADR plus Anti-angptl3-antibody group until 28th day. The proteinuria of the ADR plus Anti-angptl3-antibody group was significantly lower than that of the ADR group both on the 21th day and 28th(4.46±0.88 vs 11.36±1.00,P=0.010, 21th day; 6.11±1.33 vs 18.97±4.33,P=0.008, 28th day). Compared to the ADR group, serum ALB was higher (p=0.05, n=5), serum CHO (p<0.01, n=5) and TG (p=0.026, n=5) were lower in the ADR plus Anti-angptl3-antibody group. The levels of serum creatinine did not show significantly difference in each group. Focal sclerotic glomeruli were found in the renal tissue of the ADR group, but not found in the ADR plus Anti-angptl3-antibody group. Podocyte injury in the ADR plus Anti-angptl3-antibody group was markedly relieved compared with the ADR group, in which Podocyte foot processes were widely fused. The Anti-angptl3-antibody was detected in the liver and kidney where Angptl3 is expressed in higher amount.

Conclusions: This study demonstrated that Anti-angptl3-antibody can delayed the appearance of proteinuria and decreased the level of proteinuria in Adriamycin-induced nephropathy in mice.

A Novel Mouse Model Embodying Minimal-Change Nephrotic Syndrome Through Crumbs 2-Mediated Signaling to the Cytoskeleton in Podocytes

Ichiro Hada,[1] Naoaki Mikami,[1] Satoka Mori,[5] Yoshiaki Hirayama,[4] Akira Shimizu,[2] Kunimasa Yan.[3] *[1]Kyorin University, Mitaka, Japan; [2]Nippion Medical School, Tokyo, Japan; [3]Kyorin University School of Medicine, Mitaka, Japan; [4]Denka-seiken co., ltd., Gosen-shi, Japan; [5]Denka Co., Ltd., Tokyo, Japan*.

Background: The cellular events in podocyte injury causing minimal-change nephrotic syndrome (MCNS) remain largely obscure. Recent reports implicated genetic mutation of crumbs homolog 2 (CRB2), a type-1 transmembrane protein, as a cause of congenital nephrotic syndrome. However, an involvement of CRB2 dysfunction in the selective permeability barrier of mature glomerulus has not been demonstrated. The aim of the present study is to determine whether MCNS is caused by alteration of CRB2-mediated signaling in podocytes.

Methods: A partial recombinant protein including the extracellular part of mouse CRB2 was produced in an *Escherichia coli* system. An Enzyme-Linked Immunosorbent Assay was established to measure anti-CRB2 antibody in the serum. C3H/HeNmice and A/Jmice (complement C5 deficient mice) were injected with CRB2 recombinant protein. Urinary protein was analyzed, and kidney tissue was subjected to immunofluorescence microscopy, light microscopy, electron microscopy and immuno-electron microscopy of actin. Isolated glomeruli were subjected to Western blot analysis of phosphorylated moesin.

Results: Both C3H/HeNmice and A/J mice developed massive proteinuria at 4-6 weeks after immunization with CRB recombinant protein, which was associated with elevation of anti-CRB2 antibody. Light microscopy revealed minimal glomerular lesions even at a heavily proteinuric stage. Electron microscopy revealed prominent foot process effacement where broad dense areas were seen. Immuno-electron microscopy showed that these areas were positively immunostained for actin. Immunofluorescence microscopy revealed positive IgG staining in podocyte foot processes, but not complement C3. Finally, Western blot analysis showed phosphorylation of moesin in glomerular samples at the proteinuric stage.

Conclusions: The present study reveals a novel pathway involved in the pathophysiology of MCNS through an interaction between CRB2-mediated signaling and the actin cytoskeleton network. CRB2 may be an important scaffold molecule that mediates outside-in signaling in podocytes, thereby leading to actin cytoskeleton reorganization and resulting in MCNS.

SA-PO371

Knockout of the Neonatal Fc Receptor (FcRn) Abrogates IL6 Mediated Signaling in Podocytes

Pantipa Tonsawan,[2] James F. Dylewski,[3] Judith Blaine.[1] *[1]University of Colorado Denver, AURORA, CO; [2]Khon Kaen University, Khon Kaen, Thailand; [3]University of Colorado Hospital, Aurora, CO*.

Background: FcRn has been shown to be required for antigen presentation in dendritic cells and global knockout of FcRn attenuates immune mediated kidney disease. FcRn is expressed in podocytes but the role of podocyte FcRn in immune mediated renal disease is unknown. Previous work has shown that podocytes express the IL6 receptor and produce IL6 under proinflammatory conditions. Here we examine the role of FcRn in the IL6-mediated inflammatory response in podocytes.

Methods: We examined IL6 production by ELISA and expression by qPCR in WT and FcRn knockout (KO) podocytes after treatment with proinflammatory stimuli including albumin, IgG, interferon gamma (IFNγ) and immune complexes. We performed western blot analysis of the IL6-mediated Jak/STAT signaling pathway after treatment of WT and FcRn KO podocytes with IFNγ and immune complexes. We also examined podocyte motility in WT and FcRn KO podocytes in vitro after a proinflammatory challenge. In vivo, we examined synaptopodin expression in WT and podocyte-specific FcRn KO mice as inhibition of IL6 has been shown to decrease synaptopodin expression.

Results: We found that FcRn KO podocytes produced minimal amounts of IL6 after treatment with albumin, IgG or immune complexes whereas WT podocytes had a robust response. FcRn KO podocytes also had minimal expression of IL6 as measured by qPCR compared to WT after an immune challenge. By western blot analysis, FcRn KO podocytes expressed significantly less phosphorylated STAT3, a key component in the IL6 signaling pathway, than WT after treatment with IFNγ or immune complexes. In a scratch assay to assess mobility, FcRn KO podocytes showed increased mobility compared to WT, suggesting defects in actin dynamics. Expression of synaptopodin in the glomerulus was also significantly reduced in podocyte-specific FcRn KO mice compared to controls at 6 and 12 months of age, suggesting FcRn mediated defects in synaptopodin regulation.

Conclusions: This study shows that in podocytes, FcRn modulates the IL6-mediated response to proinflammatory stimuli and regulates podocyte motility and synaptopodin expression.

Impact of Toxic Loss of Function of Ubiquitin C-Terminal Hydrolase L1 (UCH-L1) on Podocyte Integrity

Julia Reichelt,[1] Gunther Zahner,[1] Elion Hoxha,[2] Rolf A. Stahl,[3] Catherine Meyer-Schwesinger.[3] *[1]University hospital hamburg, Hamburg, Germany; [2]III. Department of Internal Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]University of Hamburg, Hamburg, Germany*.

Background: The deubiquitinating enzyme ubiquitin C-terminal hydrolase L1 (UCH-L1) is highly *de novo* expressed in affected podocytes in human membranous nephropathy (MN), its role in podocyte injury remains elusive. We could previously demonstrate that UCH-L1 induces podocyte hypertrophy in MN. Furthermore, chemical inhibition of UCH-L1 hydrolysis function was shown to ameliorate experimental MN, suggesting a disease-perpetuating effect of UCH-L1 activity in podocytes. It is known that oxidative modification of UCH-L1 in the brain secondary to oxidative stress could lead to a dysfunctional mutant protein, which could affect neuronal proteostasis by aberrant protein interactions. We therefore investigated the differential contribution of intact and oxidative modified UCH-L1 for the development of podocyte injury in MN. Furthermore, we searched for the existence and binding affinity of reported UCH-L1 autoantibodies to intact and modified UCH-L1 in sera of patients with MN.

Methods: To assess the effects of altered enzymatic and biochemical properties of UCH-L1, mice with a podocyte-specific overexpression of UCH-L1 wildtype or with an enzymatic-deficient UCH-L1 I93M protein were generated and investigated by Western blot, enzyme activity assays and immunohistochemistry. Sera from patients with MN were investigated for the occurrence of UCH-L1 autoantibodies by Western blot. For this purpose flag-tagged human wildtype UCH-L1 or human mutant I93M protein were cloned and transiently overexpressed in HEK-293T cells.

Results: UCH-L1 I93M induced a significant accumulation of polyubiquitinated proteins in isolated glomeruli of transgenic mice resulting from proteasomal impairment. Expression of intact UCH-L1 on the other hand eventuated in increased proteasomal capacity accompanied by a dedifferentiated podocyte phenotype and mild proteinuria. A subset of sera (30 %) from MN patients contained anti-UCH-L1 autoantibodies. The quantification of UCH-L1 autoantibody reactivity showed a higher binding capacity to the defect I93M UCH-L1 protein than to the wildtype UCH-L1 protein.

Conclusions: Expression of UCH-L1 I93M results in a protein accumulative phenotype in podocytes similar to the one observed in human MN. Anti-UCH-L1 antibodies with an enhanced binding capacity to the defect I93M UCH-L1 protein are present in a subset of MN patients.

SA-PO373

Malignant Hypertension Induced Vicious Circle Culminating in Podocyte Detachment

Ramzia Abu hamad,[3] Ilia Beberashvili,[2] Shai Efrati.[1] *[1]Nephrology and Reseach Unit, Assaf Harofeh Medical Center, Zerifin, Israel; [2]Nephrology Division, Assaf Harofeh Medical Center, Zerifin, Israel; [3]Nephrology Division, Assaf Harofeh Medical Center, Zerifin, Israel*.

Background: . Renal injuries induced by increased intra-glomerular pressure coincide with podocyte damage and proteinuria. In a previous study we have demonstrated that in a direct response to pressure, podocytes increase Angiotensin-II levels and via AT1 receptors to structural changes in adhesion proteins, culminating in viable podocyte detachment. The aim of this study was to further investigate the pathophysiologic effect of malignant hypertension on podocyte mitochondrial functions, NOX4, SOD2 and inflammatory mediators.

Methods: Human Podocyte cells were exposed to high hydrostatic pressure for 1h, to mimic the incidence of malignant hypertension. Podocytes were placed in mesangial cell media pre-exposed to pressure to simulate the paracrine effect. Mitochondrial function, NOX4, SOD2, Angiotensin-II, inflammatory mediators, integrinβ1 expression and Podocyte detachment were evaluated.

Results: Pressure enforcement decreased mitochondrial membrane potential accompanied by a reduction of SOD2. Moreover, augmented detachment of viable/apoptotic podocytes with decrease expression of integrins β1, mediated via AT1/AT2, was induced by the high pressure. Mesangial pre-exposed to pressure release exaggerated amounts of Angiotensin-II and TGFβ1. Podocytes placed in this mesangial media induced an inflammatory flare-up increase via TGFβ1 and Il-6. In addition, an increase of NOX4

and decline of SOD2 resulted in mitochondrial membrane potential decrease mediated via AT1/AT2 leading to apoptosis.

Conclusions: Malignant hypertension, induced mitochondrial dysfunction combined with structural changes and detachment of Podocyte mediated by increase Angiotensin-II. The paracrine effect, mediated by increasing production of Angiotensin-II by the mesangial cells, increase apoptosis and enhance mitochondrial dysfunction via decrease SOD2, activation of NOX4 and flare-up of inflammatory mediators.

SA-PO374

Sorting Nexin 9 Facilitates Podocin Endocytosis in the Injured Podocyte

Yu Sasaki. *Juntendo University, Tokyo, Japan.*

Background: The irreversibility of glomerulosclerotic changes depends on the degree of podocyte injury. We have previously demonstrated the endocytic translocation of podocin to the subcellular area in severely injured podocytes and found that this process is the primary disease trigger. We identified the protein sorting nexin 9 (SNX9) as a novel facilitator of podocin endocytosis in a yeast two-hybrid analysis. SNX9 is involved in clathrin-mediated endocytosis, actin rearrangement and vesicle transport regulation.

Methods: We conducted co-immunoprecipitation assays to confirm the interaction between podocin and SNX9 using lysates of FLAG-podocinand GFP-SNX9-overexpressing cells. To map the podocin binding site(s) in SNX9, we tested the abilities of various truncated GFP-SNX9 constructs to co-precipitate with FLAG-podocin. To further demonstrate that podocin can directly bind to SNX9, we performed GST pull-down assays with purified recombinant proteins. To detect SNX9 expression in kidney samples, we subjected normal and adriamycin (ADR)-injected mice to immunofluorescence staining. To evaluate SNX9 expression *in vitro*, we performed immunofluorescence staining on non-treated and ADR-treated cultured human podocytes. To assess SNX9 expression in human kidney glomeruli, we subjected human kidney biopsy specimens to immunofluorescence staining.

Results: Our results revealed and confirmed that SNX9 interacts with podocin exclusively through the Bin–Amphiphysin–Rvs (BAR) domain of SNX9. Immunofluorescence staining revealed the expression of SNX9 in response to podocyte adriamycin-induced injury both *in vitro* and *in vivo*. Finally, an analysis of human glomerular disease biopsy samples demonstrated strong SNX9 expression and co-localization with podocin in samples representative of severe podocyte injury, such as IgA nephropathy with poor prognosis, membranous nephropathy and focal segmental glomerulosclerosis.

Conclusions: We identified SNX9 as a facilitator of podocin endocytosis in severe podocyte injury and demonstrated the expression of SNX9 in the podocytes of both nephropathy model mice and human patients with irreversible glomerular disease.

SA-PO375

Novel Role for Albumin and Its Modifications in Podocyte and Glomerular Injury

Shipra Agrawal,[1] Jiro Kino,[1] Tetsuya Kitao,[2] Melinda A. Chanley,[2] William E. Smoyer.[2] *[1]The Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Nationwide Children's Hospital, Columbus, OH.*

Background: Albuminuria is both a characteristic hallmark and a known risk factor for progressive glomerular disease. We previously identified that both albumin deficiency and albumin overload resulted in enhanced glomerular injury. We thus hypothesized that glomerular and podocyte injury can be regulated by modifications of albumin levels, binding to free fatty acid (FFA) and associated factors, and molecular charge.

Methods: *In vitro* podocyte injury was studied following exposure to native albumin (anionic), delipidated albumin, FFA, and cationic albumin. The ability of plasmapheresis effluents (PE) from nephrotic patients to induce podocyte injury *in vivo* and *in vitro* was also analyzed. Additional analyses included testing the ability of various clinically applicable matrices to ameliorate albumin- and PE-induced podocyte injury.

Results: While exposure of podocytes to albumin or FFA (lauric acid, oleic acid and arachidonic acid) alone reduced podocyte viability, supplementation of FFA with delipidated albumin restored podocyte viability. Albumin exposure also activated the kinases p38 MAPK, JNK/SAPK and AKT. While arachidonic acid and delipidated albumin alone did not activate these kinases, activation was moderately increased when podocytes were exposed to their combination. Additionally, cationic albumin induced greater podocyte toxicity vs. albumin, even at 1000x lower concentration. Translational studies in nephrotic PE revealed diverse signs of direct podocyte injury, including reduced viability, actin cytoskeletal disruption, lipid accumulation, activation of Erk1/2 and JNK/SAPK, and induction of COX-2. Importantly, some of these responses were attenuated by pretreatment of PE with selected matrices (charcoal, blue sepharose, liposorber gel and dextran sulfate). Finally, compared to the albumin alone-treated rats, we found significantly greater albuminuria at 48 hr in rats also injected with nephrotic PE.

Conclusions: Albumin modifications, including altered levels, binding to FFA and associated factors, and altered ionic charge can regulate albumin-induced podocyte and glomerular injury. Moreover, treatment with clinically applicable matrices appears to be able reduce this injury, thus representing a potential novel mechanistic approach to reduce glomerular injury and disease progression.

Predicting and Defining Steroid Resistance in Pediatric Nephrotic Syndrome by Cytokine Profiling

Shipra Agrawal,[1] Manuela Colucci,[2] Jyotsna Nateri,[3] Mark W. Hall,[4] Marina Vivarelli,[5] William E. Smoyer.[6] *[1]The Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]Bambino Gesù Children's Hospital - IRCCS, Rome, Italy; [3]Nationwide Childrens Hospital, Columbus, OH; [4]Nationwide Children's Hospital, Columbus, OH; [5]Bambino Gesu Children Hospital and Research Center IRCCS, Rome, Italy; [6]Nationwide Children's Hospital, Columbus, OH.*

Background: Steroids (glucocorticoids, GC) are the cornerstone of therapy for nephrotic syndrome (NS). However, they only induce remission of NS in ~50% of adults and ~80% of children. Unfortunately, there are no validated biomarkers able to predict steroid response in NS. Several clinical and experimental observations suggest that reversible immune dysregulation is a key feature of idiopathic NS. This study aims to identify early prognostic immunological biomarkers and molecular pathways associated with steroid resistance in NS pediatric patients.

Methods: Paired plasma samples were collected from 26 steroid-sensitive NS (SSNS) and 13 steroid-resistant NS (SRNS) patients, obtained both at initial disease presentation and after ~7 weeks of GC therapy, when SSNS *vs* SRNS was clinically determined. The cytokine profiling was performed using a 27 cytokine panel on a Luminex® Technology platform using a bead-based fluorescence assay. Data were compared using the nonparametric Wilcoxon signed-rank test and the Mann Whitney U test (statistically significant differences at $p<0.05$).

Results: In comparison to SSNS, SRNS patients at presentation showed higher plasma levels of IL-1β, IL-6, IL-8, TNF-α, IFN-γ, IL-7, and MIP-1α, and reduced levels of IL-1Ra, IL-2, IL-9, MIP-1β. GC treatment of SSNS patients induced significant reductions in all of the elevated cytokine levels above (IL-6 undetectable at presentation in most SSNS patients). Of note, circulating cytokine levels appear not be influenced by differences in proteinuria, as we found reduced levels in SSNS patients in remission. In contrast, GC therapy in SRNS patients failed to induce remission or to significantly reduce the above plasma cytokine levels (except for TNF-α).

Conclusions: These studies suggest that an increase in a panel of plasma pro-inflammatory cytokines, produced primarily by monocytes/macrophages and Th1 cells, may be able to predict steroid resistance in NS prior to GC treatment. In addition, steroid-resistance is also associated with persistence elevated levels of pro-inflammatory cytokines, suggesting a potential pathogenic role for these circulating factors in SRNS.

SA-PO377

The Proteasomal Degradation System Plays a Prominent Role in Podocyte Protein Homeostasis

Wiebke Sachs,[1] Marlies Sachs,[3] Catherine Meyer-Schwesinger.[2] AG Meyer-Schwesinger *[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]University of Hamburg, Hamburg, Germany; [3]UKE, Hamburg, Germany.*

Background: Protein degradation plays a major role in protein quality control and therefore in cell homeostasis. Two different degradation systems are responsible for clearance of disused or defective proteins, the ubiquitin-proteasome system (UPS) and the autophagy-lysosome system (ALS). During membranous nephropathy the UPS is upregulated. The aim of the project is to understand the significance and interplay of the proteasomal and lysosomal degradation system for podocyte proteostasis under naïve conditions and during THSD7A-associated membranous nephropathy.

Methods: For proteasomal inhibition, Balb/C mice were treated with epoxomicin over 4 days. As models of lysosomal impairment Balb/C mice were treated with the lysosomal inhibitor leupeptin A over 4 days or mice with general lysosomal dysfunction (Mucolipidosis (ML) type II) were analyzed. To investigate the effect of the degradation systems on disease progression, THSD7A-associated MN was induced and mice were treated in a preventive and a therapeutic regimen with proteasomal inhibitors and leupeptin A. Renal function was assessed by BUN and creatinine measurements, podocyte injury by proteinuria. The glomerular and tubulointerstitial integrity was assessed by PAS, confocal and electron microscopy. The effects of proteasomal or lysosomal inhibition on glomerular cell proteostasis were analyzed by Western blotting and enzyme activity assays.

Results: Mice treated with epoxomicin developed proteinuria with abnormal glomerular protein accumulations in the subepithelial space and in podocytes. Leupeptin A treatment did not affect proteasomal activity in glomeruli and the tubulointerstitium. Morphological analyses were significant for abnormal accumulations in tubular cells and the glomerular mesangium. MLII mice showed severe lysosomal dysfunction in glomeruli and tubulointerstitial cells without the development of proteinuria. Morphologically, MLII mice exhibited accumulations of large lysosomes in all resident glomerular cells. Therapeutic and preventive inhibition of both degradation systems during THSD7A-associated MN led to increased proteinuria compared to the controls.

Conclusions: Failure of the proteasomal degradation system has a great impact on podocyte cell proteostasis. Inhibition of either the proteasomal or the lysosomal degradation system enhances the progression of THSD7A-associated MN.

P2X7-ATP May Mediate Propagation of Podocyte Damage

Kazuyoshi Yamamoto,[2] Masahiro Okabe,[2] Taiji Matsusaka,[1] Takashi Yokoo.[2] *[1]Tokai University School of Medicine, Isehara, Japan; [2]The Jikei University School of Medicine, Tokyo, Japan.*

Background: We previously generated a mosaic mouse model in which a fraction of podocytes express hCD25 and can be injured by hCD25-directed immunotoxin, LMB2. After injection with LMB2, not only hCD25(+) podocytes but also hCD25(-) podocytes were injured. A possible mechanism is that damage-associated molecular patterns (DAMPs) released from the damaged podocytes may secondarily injure the hCD25(-) podocytes. In the present study, we aim to find a candidate molecule that mediates spreading of podocyte damage.

Methods: Mosaic mice (n=4, each time point) were injected with 25 ng/g BW of LMB2, hCD25(+) and (-) podocytes were harvested by FACS sorting, and RNAs were analyzed with Agilent's 8X66K microarray. Functional assay was performed in primary cultured mouse podocytes by transiently transfecting expression plasmid.

Results: Among DAMPs and their receptors, we found that P2X7 mRNA was markedly increased both in hCD25(+) podocytes (>3000 folds) and in hCD25(-) cells (59 folds) 4 days after LMB2, which were confirmed by qRT-PCR analysis (>40,000 folds, 53 folds). P2X7 is a receptor for extracellular ATP and triggers signaling pathways leading to inflammation and cell death in immune cells. To test the role of P2X7-ATP in podocytes, we transfected primary cultured podocytes with P2X7 expressing plasmid. By 2 hours after administration of ATP (1 mM), cell number decreased by 53.4%, with 18.6% of cells incorporating propidium iodide. This is contrasting to P2X7 expressing cells without ATP, or mock-transfected cells with or without ATP, in which cell number decrease was <5% and propidium iodide incorporation was <2%. 6.7% of P2X7 expressing podocytes were stained with Annexin V one hour after ATP, whereas 2.6% of mock + ATP cells and 0% of P2X7 without ATP were Annexin V +.

Conclusions: These suggest that podocytes in damaged glomeruli express P2X7, respond to ATP released from adjacent dying podocytes, and are secondarily damaged. Thus, P2X7-ATP may mediate propagation of podocyte damage.

SA-PO379

Angiotensin II-Induced Podocyte Apoptosis Is Ameliorated by AMPK Activation and the Improvement of CD2AP

Tae-Sun Ha. *Chungbuk National University College of Medicine, Cheongju-si, Republic of Korea.*

Background: Angiotensin II (Ang II) promotes the development and progression of proteinuria and renal diseases and induces podocyte apoptosis. CD2-associated protein (CD2AP) in podocytes, anchoring slit diaphragm proteins to actin filaments of podocyte cytoskeleton, facilitates the nephrin-induced PI3-K/AKT signaling, which protects podocytes from apoptosis. AMP-activated protein kinase (AMPK), as a sensor of cellular energy status, has been known to play an important role in the pathophysiology of metabolic diseases, including diabetes, and its renal complications. We investigated the role of AMPK on the changes of CD2AP and podocyte apoptosis induced by Ang II.

Methods: Mouse podocytes were incubated in media containing various concentrations of Ang II and AMPK-related agents. The changes of CD2AP and podocyte apoptosis were observed by confocal imaging, western blotting, TUNEL assay and FACS assay according to the presence of Ang II.

Results: CD2AP and AMPKα were located diffusely but predominantly in peripheral cytoplasm and co-localized with nephrin. Ang II reduced AMPKa in time and dose-sensitive manners and also decreased CD2AP stainings diffusely and induced spatial separation from concentrated nephrin, similar to those of compound C-treated condition. AICAR and metformin, AMPK activators, ameliorated the abnormal distributional changes of AMPKα and CD2AP. Ang II also reduced (Thr172) phosphorylation of AMPKα and CD2AP in time- and concentration-dependent manners, which were significantly recovered by metformin and AICAR. Ang II type 1 receptor antagonist, losartan also recovered CD2AP suppressed by Ang II. LY294002, a PI3-K inhibitor, reduced CD2AP suppressed by Ang II. Ang II increased apoptosis in time- and concentration-dependent manners, which were ameliorated by AMPK activators, however, aggravated by siCD2AP.

Conclusions: Our findings suggest that Ang II induces the relocation and suppression of podocyte CD2AP and AMPKα via Ang II type 1 receptor and through the inhibition of PI3-K signaling, which trigger podocyte apoptosis induced by Ang II.

IL-9 Ameliorates Progressive Glomerulosclerosis

Tingting Xiong,[2] Madena Attar,[3] Martina Becker,[4] Jan-Eric Turner.[1] Turner Lab *[1]University Medical Center Hamburg, Hamburg, Germany; [2]University Medical Center Hamburg, Hamburg, Germany; [3]University Medical Center Hamburg, Hamburg, Germany; [4]University Medical Center Hamburg, Hamburg, Germany.*

Background: It has been established that IL-9 expression enhances tissue regeneration after lung injury, but data about the involvement of IL-9 in renal tissue protection are still very limited. Especially, the potential role of IL-9 in immune-mediated kidney disease is largely unknown. In this study, we focus on the role of IL-9 in Adriamycin-induced nephropathy (AN), a mouse model of focal and segmental glomerulosclerosis.

Methods: Progressive glomerulosclerosis in wild-type and *Il9*$^{-/-}$ mice was induced by injection of Adriamycin and analyses of histopathology, renal function parameters, albuminuria and renal immune cell infiltration were performed. The role of selective IL-9 deficiency of either the innate or the adaptive immune system for the outcome of AN was examined in *Il9*$^{-/-}$*Rag2*$^{-/-}$ mice and IL-9^{deltaT,B} mixed bone marrow chimeras, respectively. *Il9*^{Cre} x *R26r*^{eYFP} fate reporter mice were used to assess the cellular source of IL-9 in AN.

Results: *Il9*$^{-/-}$ mice with AN displayed accelerated development of proteinuria, aggravated glomerulosclerosis and deterioration of kidney function, as compared to wild type (WT) mice. In line, electron microscopy revealed early aggravation of podocyte damage in *Il9*$^{-/-}$ mice. First experiments with IL-9 fate reporter mice suggested that T cells might be a major source of IL-9 in the injured kidney. Accordingly, innate IL-9 deficiency in *Il9*$^{-/-}$ *Rag2*$^{-/-}$ mice did not alter the outcome of AN, whereas selective deficiency of adaptive IL-9 in IL-9^{deltaT,B} mixed bone marrow chimeras resulted in aggravation of glomerulosclerosis and kidney impairment, comparable to the phenotype observed in the completely IL-9-deficient mice. Possible mechanisms of the protective IL-9 effect, such as a direct pro-survival effect on glomerular epithelial or endothelial cells, are under active investigation.

Conclusions: In summary, we demonstrate here that IL-9 deficiency aggravates kidney failure in Adriamycin-induced nephropathy. As a cellular source of IL-9, T cells seem to play an important role in this model. The tissue-protective mechanisms of IL-9 need to be further elucidated and may offer a therapeutic approach in immune-mediated kidney diseases in the future.

Beneficial Effect of Low-Density Lipoprotein Apheresis via Modifying Immune System in Patients with Refractory Nephrotic Syndrome

Hiroko Kakita,[1] Hiroyuki Suzuki,[1] Tatsuo Tsukamoto,[1] Eri Muso.[1,2] *[1]Nephrology & Dialysis, Tazuke Kofukai Foundation, Medical Research Institute, Kitano Hospital, Osaka, Japan; [2]Food and Nutrition, Faculty of Contemporary home Economics, Kyoto Kacho University, Kyoto, Japan.*

Background: In refractory nephrotic syndrome (rNS), in addition to direct injury of heavy proteinuria, longstanding hypercholesterolemia is known to provide poor renal outcome. The amelioration of dyslipidemia by low-density lipoprotein apheresis (LDL-A) in combination with conventional therapy was reported to induce rapid remission of NS primarily in focal segmental glomerulosclerosis (FSGS) and evidence of these beneficial effect has additionally accumulated in minimal change nephrotic syndrome (MCNS) and membranous nephropathy (MN). As the mechanism of action, in addition to the renal protection by rapid removal of low-density lipoprotein cholesterol (LDL-C), LDL-A has been proved to provide amelioration of macrophage dysfunction, restore steroid and cyclosporine susceptibility and adsorption of circulating permeability factors. To investigate immune-modulatory effect, we measured serum cytokines and chemokines level before and after LDL-A in a patient of FSGS and compared with familial hypercholesterolemia (FH) and reported significant and specific increase of Interleukin-10 (IL-10) after LDL-A in rNS, but not in FH. In the present study, in order to obtain more precise elucidation of immunological effect and disease specificity of LDL-A, the changes of not only serum but peripheral blood mononuclear cell (PBMC) cytoplasmic cytokines in patients with FSGS, MCNS and MN were evaluated.

Methods: Serum cytokines level before and after LDL-A sessions was assessed in three cases of rNS due to FSGS (6 sessions), MCNS (12) and MN (4), and compared with a non-NS, arteriosclerosis obliterans (ASO) patient treated by LDL-A (5 sessions). 27 types of cytokines were measured by Bio-Plex Pro human 27-plex kit (Bio-Rad). Cytoplasmic cytokines among PBMC were evaluated by flow cytometry.

Results: IL-10 was significantly elevated after LDL-A in all NS patients ($p=7.2x10^{-5}$). In ASO, IL-10 was not detected in sera before nor after LDL-A. Cytoplasmic IL-10 was positive in $CD19^{+}CD5^{+}$ cells, $CD19^{-}CD5^{-}$cells and $CD19^{-}CD5^{+}$cells. In addition, another anti-inflammatory cytokine, IL-1 receptor antagonist (IL-1Ra) was significantly elevated after LDL-A ($p<0.002$) in both NS and ASO.

Conclusions: LDL-A may induce rapid remission in rNS patients, via immunomodulation by session synchronized elevation of IL-1Ra and IL-10 regardless of causative disease.

Proteasome Inhibitors (PIs) Reduce PAN Induced Proteinuria by Enhancing FOXO3a/β-Catenin Complex in Minimal Change Disease (MCD)

Himanshu Vashistha,[1] Frank C. Abbruscato,[1] Radhakrishna Baliga.[2] *[1]Ochsner Health System, New Orleans, LA; [2]LSU Health Sciences Center, Shreveport, LA.*

Background: Proteasomes play a major role in the pathophysiology of several disease processes in part through its action on a crucial transcription factor, nuclear factor-kappa B (NF-κB). NF-κB regulates the expression of a variety of inflammatory genes and plays a major role in MCD. The role of PIs in ongoing glomerular injury and the potential beneficial effects of PIs have not been previously examined. We show here that administration of PIs resulted in marked protection against puromycin aminonucleoside (PAN) -induced proteinuria by enhancing nuclear FOXO3a/β-Catenin complex, increasing expression of antioxidant enzymes and attenuates reactive oxygen species (ROS).

Methods: MCD was induced in rats by injecting PAN IV as a single dose and proteinuria measured as albumin to creatinine ratio (ACR) (μg/mg) until day 10. MG-132 was administered by osmotic pumps and Carfilzomib (CAR) was administered IV. Proteins were analyzed by Western Blot and immunocytochemistry. Immunohistochemical analysis was also performed on the kidney cortical sections.

Results: Administration of MG-132 and CAR prevented PAN induced proteinuria (PAN 147±29, MG132+PAN 98±32*, CAR+PAN 75+18*; P<0.05* compared to PAN

alone). This was accompanied by marked decrease in lipid peroxidation in PIs-treated rats compared to PAN alone. MG-132 significantly decreased the nuclear translocation of NF-KB, activation of IL-6, up regulation of CYP, significantly reduced H2O2 release and 8-Oxo-dG expression in cultured human podocytes. Electron Microscopy data showed that MG-132 and CAR treatment prevented foot process effacement of podocytes. Immunohistochemical analysis of cortical sections of PIs treated rats and immunocytochemical analysis of cultured human podocytes treated with PIs revealed increased β-Catenin and FOXO3a colocalization. Human podocytes treated with PIs showed upregulated PAN induced HO-1 and SOD with significant decrease in cell death.

Conclusions: These in vitro and in vivo data imply the crucial role of proteasome in progressive glomerular injury. CAR, which is currently used in humans should be considered as a potential therapeutic alternative in MCD.

SA-PO383

Nephrotic Range of Proteinuria with Cholesterol Crystal Embolization

Eri Ataka,[1] Kenji Harada,[2] Akihiro Tsuchimoto,[3] Hidetoshi Kanai.[4] *[1]Kokura memorial Hospital, Kitakyushu, Japan; [2]Kokura memorial hospital, Kitakyusyu city, Japan; [3]Kyushu University, Fukuoka, Japan; [4]Kokura Memorial Hospital, Kita Kyushu, Japan.*

Introduction: Cholesterol crystal embolism(CCE) is often caused by transcatheter therapy, vascular surgery or anticoagulant therapy, clinically characterized by vessel obstruction from cholesterol crystals and the subsequently provoked immune response. Once it developed in kidney, renal function may gradually decline. Moreover, renal prognosis is poor with the majority of patients having progressive kidney failure. Generally, proteinuria is rare with CCE patients.

Case Description: Here, we report a case of nephrotic range of proteinuria caused by CCE. A 72-years-old man with atherosclerotic disease such as hypertension, diabetes mellitus and an abdominal aortic aneurysm, underwent percutaneous coronary intervention(PCI) on February 1, 2017. Acute kidney injury and nephrotic range of proteinuria occurred after four months of PCI. Kidney biopsy was performed to determine the etiology of renal dysfunction and massive proteinuria. Renal pathological diagnosis revealed CCE and focal segmental glomerulosclerosis(FSGS), severe endocapillary proliferation with foam cells. Steroid pulse therapy and oral prednisolone at a dose of 30 mg/day were administered. After those therapy serum-creatinine level and protein to creatinine ratio improved from 2.5 mg/dL to 1.3 mg/dL and 8 g/gCr to 0.5 g/gCr, respectively.

Discussion: Renal cholesterol crystal embolization with massive proteinuria is rare. In this case, endocapillary proliferation with foam cells thought to be caused by CCE. These suggests that steroid therapy might be effective treatment for CCE with FSGS lesions accompanied by proteinuria.

SA-PO384

(STEC-HUS) in Adults: An Underrecognized Cause of Thrombotic Microangiopathy

Caroline Duineveld,[1] Kioa L. Wijnsma,[2] Jack F. Wetzels,[1] Nicole Van De Kar.[2] the Dutch aHUS working group *[1]Department of Nephrology, Radboudumc, Nijmegen, Netherlands; [2]Department of Pediatric Nephrology, Amalia Children's Hospital, Nijmegen, Netherlands.*

Background: In children, most cases of hemolytic uremic syndrome (HUS) are caused by an infection with a Shiga toxin-producing *Escherichia coli* (STEC). In contrast, in adults most cases of HUS are considered to be atypical HUS (aHUS), attributed to dysregulation of the alternative complement system. However, during major outbreaks of STEC infection, hemolytic uremic syndrome in adults is not uncommon and morbidity and mortality, especially in elderly patients, may be considerable. Only few sporadic cases of STEC-HUS in adults have been described. Typically, STEC HUS is preceded by diarrhea, which is reported to be bloody in 60% of the patients. In the Netherlands routine screening for STEC is not recommended in adults with TMA, unless diarrhea is present.

Methods: Since 2015/2016, patients presenting with TMA in the Netherlands, in which aHUS is suspected, are discussed by the Dutch aHUS working group. Diagnostic options are carefully evaluated. This has increased awareness for STEC-HUS testing.

Results: Of 44 TMA patients who were discussed in the Dutch aHUS Working Group in the time period 2015/2016-2018, aHUS was diagnosed in 24 patients. STEC-HUS was found as the cause of TMA in 10 adult patients. Detailed clinical information could be obtained from seven STEC-HUS patients. The age of the patients ranged between 17 and 74 years. Of note, in three patients no diarrhea was reported. All presented with TMA (median thrombocytes 30 x 10^9/L (range 8-33), LDH 1409 g/L (range 946-3265) and an undetectable haptoglobin (<0.10 g/L)). Fecal or rectal swab PCR for Shiga toxin (Stx) was positive in all patients. In five patients PCR *Stx2* was positive; two of them also had a positive PCR for *STx1*. Serotype could be identified in four patients: O157, O27:H6, O-:H34 and O183:H18. Acute renal injury was seen in six patients, and four were treated with hemodialysis. Renal function recovered in five patients, however one patient remaining dependent on dialysis. Median eGFR was 83 ml/min/1.73 m^2 (range <5-133) after a follow-up of 1 to 15 months after presentation.

Conclusions: STEC HUS among adults is not uncommon and may not be preceded by diarrhea. We advocate routine screening for STEC infection in adults patients presenting with TMA.

SA-PO385

Systemic Sclerosis Medications and the Prevention of Scleroderma Renal Crisis

Sarah M. Gordon,[3] Robert Nee,[2] Stephen W. Olson.[1] *[1]Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; [2]Walter Reed National Military Medical Center, Vienna, VA; [3]TAMC, Kaneohe, HI.*

Background: Scleroderma Renal Crisis (SRC) develops abruptly in systemic sclerosis (SSc) and is associated with significant morbidity and mortality. High risk SSc subjects may benefit from treatment to prevent SRC. Though angiotensin converting enzyme inhibitors (ACEi) are the standard of care for SRC at diagnosis, previous case series found no benefit for initiation at SSc diagnosis to prevent SRC and a potential paradoxical association with development of SRC. There are no previous cohort studies of the potential prophylactic benefit for calcium channel blockers (CCB), angiotensin receptor blockers (ARB), endothelin receptor blockers (ERB), non-steroidal anti-inflammatory drugs (NSAID), or mycophenolate mofetil (MMF) to prevent SRC.

Methods: : In this retrospective cohort study of the entire military electronic medical record between 2005 and 2016, we compared the use of ACEi, ARB, CCB, NSAID, ERB and MMF after SSc diagnosis for 31 cases who subsequently developed SRC to 322 SSc without SRC disease controls. We conducted logistic regression analyses to evaluate for medications independently associated with SRC.

Results: Baseline ACEi use was more common in SSc patients that subsequently developed SRC [77% (24/31) vs. 33% (108/322), p<0.001]. ACEi was associated with an increased risk for SRC adjusted for age, race, gender, and prednisone use [odds ratio (OR) 4.0, 95% confidence interval (CI) 1.6-10.3, P=0.003]. On stratified analyses, there was no association between ACEi and SRC in the absence of proteinuria, while in the presence of proteinuria, ACEi was significantly associated with SRC [OR 5.28, 95% CI 1.1-29.2, p=0.03]. In addition, a doubling of ACEi dose [61% (19/31) vs. 12% (38/322), p<0.001) and achieving maximum ACEi dose [45% (14/31) vs. 4% (14/322), p<0.001] after SSc diagnosis was associated with future SRC. CCB, ARB, NSAIDs, ERB, and MMF use were not significantly associated with SRC.

Conclusions: Medications commonly used in SSC were not associated with a reduced risk of SRC. Paradoxically, ACEi use at SSC diagnosis was associated with an increased risk of SRC. This relationship was observed only in those with a heightened risk for SRC from proteinuria, suggesting that it may be a passive marker of evolving subclinical disease. SSC patients that require ACEi should be more closely monitored for SRC.

N-Acetylmannosamine (ManNAc) Therapy Mitigates Glomerular Hyposialylation and Proteinuria

Marjan Huizing,[2] Jonathan P. Troost,[1] Petcharat Leoyklang,[2] Steven P. Bodine,[2] Matthias Kretzler,[1] William Gahl,[2] Jeffrey B. Kopp,[3] May christine Malicdan.[2] *[1]University of Michigan, Ann Arbor, MI; [2]Medical Genetics Branch, NHGRI, NIH, Bethesda, MD; [3]Kidney Disease Branch, NIDDK, NIH, Bethesda, MD.*

Background: Glomerular hyposialylation of glycoproteins and glycolipids has been implicated in human and experimental nephrotic syndromes. In this study we assessed the prevalence of glomerular hyposialylation in human nephrotic syndromes and explored therapeutic potential of the sialic acid precursor *N*-acetylmannosamine (ManNAc) in three different nephrotic mouse models.

Methods: We created neuraminidase-induced and adriamycin-induced nephrotic mice and a nephrotic knock-in mouse model deficient in *Gne*, a central enzyme in sialic acid biosynthesis. ManNAc was administered in drinking water (~1 g/kg/d) to all three mouse models and clinical/biochemical parameters were assessed at different timepoints. Human glomerular sialylation was assessed by lectin histochemistry and confocal imaging in kidney biopsies of 91 well-phenotyped subjects with minimal change disease (MCD; 29 subjects), focal segmental glomerulosclerosis (FSGS; 37 subjects) or membranous nephropathy (MN; 25 subjects) supplied by the Nephrotic Syndrome Study Network (NEPTUNE).

Results: In all three mouse models, ManNAc administration increased glomerular sialylation and markedly reduced proteinuria and podocyte injury within a week of treatment. Hyposialylation was detected in an unexpectedly high percentage (~72%) of human kidney biopsies across all three disease entities, indicating that this condition may occur frequently, remains greatly unexplored and, importantly, may be treatable. Correlating sialylation status to clinical, pathological or other documented subject data, showed a trend of correlation of severe glomerular hyposialylation with decreased eGFR, increased interstitial fibrosis and increased tubular atrophy, in particular in FSGS subjects.

Conclusions: These encouraging preclinical data, together with minimal toxicity of oral ManNAc therapy in humans (demonstrated in Phase 1 and 2 clinical trials for the rare hyposialylation disorder GNE myopathy) led to obtaining an Investigational New Drug approval to start a Phase 1 clinical trial to evaluate the safety, tolerability and pharmacokinetics of ManNAc in subects with primary podocyte diseases (ClinicalTrials.gov NCT02639260). Preliminary results of this ongoing study are promising regarding safety and tolerability in subjects with glomerular disease.

Two Cases of Multicentric Castleman Disease with Nephrotic Syndrome Treated with Tocilizumab

Naoya Fukunaga,[1] Kohei Aoki,[1] Akihiro Fukuda,[1] Takeshi Nakata,[1] Noriko Uesugi,[3] Satoshi Hisano,[4] Hirotaka Shibata.[2] *[1]Oita University, Yuhu, Japan; [2]Oita University Faculty of Medicine, Yufu city, Japan; [3]Fukuoka university, Fukuoka-city, Japan; [4]University of Occupational and Environment Health, Kitakyushu, Japan.*

Introduction: Multicentric Castleman disease (CD) is a systemic lymphoproliferative disease with an incompletely understood etiology. Renal complications of this disease have been reported in a few cases. We herein report two cases of multicentric CD with nephrotic syndrome treated with tocilizumab.

Case Description: ***Case 1*** A 58-year-old man was diagnosed with multicentric CD by lymph node biopsy 7 years previously. He was followed closely without therapy because of his asymptomatic condition. He was admitted to our hospital with acute onset of nephrotic syndrome [albumin, 2.0 g/dl; urine protein:creatinine ratio (UP/UCr), 4 g/g creatinine). Light microscopic examination of kidney biopsy specimens revealed membranous nephropathy with cellular and fibrocellular crescents. Based on these findings, we diagnosed the patient with secondary membranous nephropathy due to CD. Steroid and tocilizumab therapy was started. After 3 months, the proteinuria had improved (UP/UCr < 1 g/g creatinine). ***Case 2*** A 49-year-old woman was diagnosed with multicentric CD by lymph node biopsy 9 years previously. She was followed closely without therapy because of her asymptomatic condition. She was admitted to our hospital with acute onset of nephrotic syndrome (albumin, 2.0 g/dl; UP/UCr, 5 g/g creatinine). Light microscopic examination of kidney biopsy specimens revealed Congo red stain-positive amyloid deposition. Based on these findings, we diagnosed the patient with secondary amyloidosis due to CD. Steroid and tocilizumab therapy was started.

Discussion: Few reports have described the various renal complications of CD, such as minimal change disease, mesangial proliferative glomerulonephritis, membranous glomerulonephritis, and amyloidosis. We have herein described two rare cases of multicentric CD with nephrotic syndrome and effective treatment with tocilizumab. Tocilizumab may be another therapeutic choice for multicentric CD with nephrotic syndrome.

Serum Cystatin C Is a Significant Marker of Early Glomerular and Tubular Interstitial Lesions in Patients with Primary Glomerulonephritis: Results from Single Center Cross-Sectional Single-Blind Study

Elena Saganova, Olga Galkina, Vasiliy Sipovskii, Alexey Smirnov. *Pavlov First Saint-Petersburg State Medical University, Saint-Petersburg, Russian Federation.*

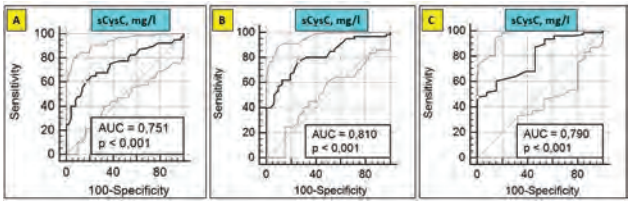
Background: Serum Cystatin C (sCysC) is well known endogenous alternative marker of GFR in research and clinical practice. sCysC can be used as a predictor of adverse outcomes in patients with CKD. However, the role of sCysC is not still obvious in patients with glomerulonephritis (GN) especially as a predictor of morphological lesions. Our aim was to assess sCysC as a predictor of various morphological lesions in patients with GN

Methods: 91 patients [50 male,41 female; age Me(min 18;max 83) – 42(28; 55) years] with biopsy proven GN and without AKI, infectious diseases, severe heart failure, respiratory insufficiency, cancer, abnormal thyroid status and treatment with prednisolone more than 10 mg/per day were enrolled in the study. Based on the results of kidney biopsy in 31% of cases a focal segmental glomerulosclerosis was diagnosed, in 28,5% – membranous nephropathy, in 40,5% – IgA-nephropathy. sCysC was measured in the morning on the day of biopsy by immunoturbidimetric method. The extent of glomerulosclerosis (GS) was assessed quantitatively. Tubulo-interstitial fibrosis (TIF) and tubular atrophy (TA) – semi-quantitatively. According to the degree of each morphological lesions all patients consistently were separated into 2 groups: *"light"* (GS less than 25% or TIF/TA grade 0 or 1) and *"severe"* (GS ≥ than 25% or TIF/TA grade 2-3). We evaluated specificity, sensitivity, diagnostic accuracy of sCysC regarding to the extent of each morphological lesion (GS/TIF/TA) by ROC-analysis

Results: sCysC was positively associated with GS (p<0,001;r=0,53), TIF (p<0,001;r=0,68) and TA (p<0,001;r=0,68). sCysC was significantly higher in patients with "light" GS (p<0,001), TIF (p<0,001) and TA (p<0,001). All patients were separated in 2 groups using sCysC according to the degree of morphological lesions ("light" or "severe") (Figure 1)

Conclusions: sCysC is a significant marker of various morphological lesions in patient with GN. sCysC can be used as a predictor of mild degree of glomerular and interstitial sclerosis, tubular atrophy with high diagnostic value

Funding: Government Support - Non-U.S.



SA-PO389

First-in-Man Cross-Sectional Single Center Study of Multimarker Panel Validation for Early Prediction of Morphological Lesions in Patients with Primary Glomerulonephritis

Elena Saganova, Olga Galkina, Vasiliy Sipovskii, Alexey Smirnov. *Pavlov First Saint-Petersburg State Medical University, Saint-Petersburg, Russian Federation.*

Background: Measurement of various biomarkers (BM) as a predictors of morphological lesions can improve detection and risk stratification for CKD progression. Our aim was to evaluate combination of serum und urinary BM as a predictor of various morphological lesions in patients with glomerulonephritis (GN)

Methods: 100 patients[52 male; age Me(min 18;max 83) – 39(27; 54) years] with biopsy proven GN, without AKI, infectious diseases, severe heart failure, respiratory insufficiency, cancer, abnormal thyroid status, prednisolone treatment more than 10 mg/per day were included in the study. Based on the results of kidney biopsy in 9% of cases minimal change disease was diagnosed, in 28% – focal segmental glomerulosclerosis, in 26% – membranous nephropathy and in 37% – IgA-nephropathy. Serum/urine (24-hour collection) creatinine (sCr/uCr), cystatin C (sCysC/uCysC), EFMg, urinary transferrin (uTr), IgG (uIgG), α1-microglobulin, β2-microglobulin were measured in the morning on the day of biopsy. The extent of glomerulosclerosis (GS) was assessed quantitatively, tubulo-interstitial fibrosis(TIF), tubular atrophy(TA) - semi-quantitatively. According to the degree of each morphological lesions (GS/TIF/TA) all patients consistently were separated into 2 groups: *"light"*(GS less than 25% or TIF/TA grade 0 or 1) and *"severe"*(GS ≥ than 25% or TIF/TA grade 2-3). We evaluated specificity, sensitivity diagnostic accuracy of BM panel regarding to the extent of GS/TIF/TA by multivariate and ROC-analysis

Results: Discriminant linear function analysis followed by ROC analysis showed that from included to the panel BM (Figure 1): GS (Biomarker Panel 1 (BP1); p<0.001; Fig1A), TIF (BP2; p<0.001; Fig1B), TA (BP3; p<0.001; Fig1C) were associated with sCr, sCysC, uTr, uIgG

Conclusions: Combination of sCr, sCysC, uTr, uIgG is a significant biomarker panel of various morphological lesions in patient with GN and can be used as a strong predictor of mild degree of GS, TIF and TA with high sensitivity, specificity and accuracy.

Geospatial Clustering of Incident Glomerulonephritis Suggests Disease-Specific Risk Factors

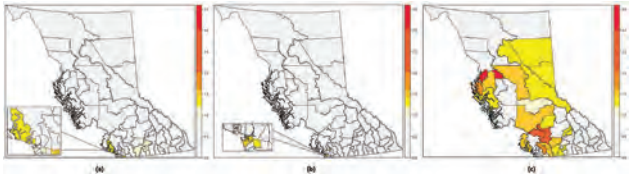
Mark Canney,[1,2] Dilshani Induruwage,[2] Heather N. Reich,[3] Sean Barbour.[1,2] *[1]University of British Columbia, Vancouver, BC, Canada; [2]BC Provincial Renal Agency, Vancouver, BC, Canada; [3]Toronto General Hospital, Toronto, ON, Canada.*

Background: Few studies have rigorously evaluated regional differences in the incidence of glomerulonephritis (GN) subtypes, thus limiting our understanding of potential sociodemographic or environmental risk factors. As such, we used population-level data from British Columbia (BC), Canada, to investigate geospatial differences in the incidence of biopsy-proven membranous nephropathy (MN), IgA nephropathy (IgAN) and ANCA-associated vasculitis (AAV).

Methods: All native kidney biopsies in BC from 1/1/2000 to 12/31/2012 were analyzed from a central registry to identify all cases of GN. Patient-level data were captured via linkage with provincial administrative databases. We used local health authorities (n=75) to define discrete geographical regions in BC (population 4.6 million) with region-level age, sex and race distributions from census data. For each GN we employed a hierarchial Bayesian model to estimate the incidence rate ratio (IRR) for each region accounting for adjacent spatial correlation. Contiguous regions with high probability of IRR>1.0 were combined into super-regions to estimate the IRR adjusted for age, sex and race.

Results: A total of 1624 patients were included: 401 MN (mean age 56, 57% male); 824 IgAN (mean age 44, 61% male); 399 AAV (mean age 61, 45% male). For each GN we identified several regions with high probability of being a cluster (Figure). The number of clusters and magnitude of increased risk were greatest for AAV (IRR 1.1-3.5), intermediate for IgAN (IRR 1.2-2.2) and lowest for MN (IRR 1.1-1.9). Results were similar for aggregated super-regions after multivariable adjustment.

Conclusions: Using a novel and robust approach, we describe geospatial clustering of biopsy-proven GN which varied by GN subtype and was not explained by inter-regional differences in age, sex and race. Our findings suggest that health services delivery for each type of GN needs to be tailored to individual regions at higher risk, and that there are likely disease-specific environmental and/or genetic risk factors that require further study.



Areas with high probability of being a cluster for MN (a), IgAN (b) and AAV (c). The color gradient represents the magnitude of IRR.

The Impact of a Diagnostic Support System on Rare Disease Cases

Simon Ronicke,[1,2] Dr. martin C. Hirsch,[2] Ewelina Türk,[2] Annette D. Wagner.[1]
[1]Medizinische Hochschule Hannover, Hannover, Germany; [2]Ada Health GmbH, Berlin, Germany.

Background: Diagnostic support systems (DSS) can be used to enhance clinical diagnosis. We report about the use of Ada/DX, a DSS in development, in an outpatient clinic for rare inflammatory systemic diseases with kidney involvement. Presenting preliminary results, we evaluate the system's diagnostic accuracy and potential impact on the time to diagnosis.

Methods: This retrospective study is being conducted at the outpatient clinic for rare inflammatory systemic diseases with kidney involvement at the Hannover Medical School, Germany. To date, 67 (of a total 120) patient cases with confirmed diagnosis were included. The time of the visit of first documented symptoms and the time of diagnosis was identified. Time to diagnosis (TD) was calculated. Information from the medical record was transferred to the DSS and the disease suggestions in the DSS were evaluated. Primary endpoint was the correctness of top disease suggestions for the visit of diagnosis. In these cases, secondary endpoints were the time to first correct top rare disease suggestion (TR) and the time to first correct top 5 rare disease suggestion (T5R). The difference between TD and TR and the difference between TD and T5R was calculated. Wilcoxon signed-rank test was conducted.

Results: On preliminary evaluation, primary accuracy of top suggestions of the DSS at the time of diagnosis was 80.6% (71.1% to 90,3%, 95% CI). The table shows a comparison of time to diagnosis with and without the aid of the DSS. The Wilcoxon signed-rank test shows a significant difference for TD - TR (z-score -4.78, α=0.05, p<0.001) and TD - T5R (z-score -5.44, α=0.05, p<0.001).

Conclusions: The DSS suggested the correct diseases based on information from the medical record in most of the analysed rare disease cases. The DSS often suggested the correct diseases at times prior to the visit of diagnosis. DSS might help to reduce time to diagnosis and improve patient outcomes. Prospective research is needed to verify the results.

Comparison of the original time to diagnosis and the time to correct DDS disease suggestions

	Mean	Std Dev	PCTL 25	PCTL 50	PCTL 75
TD	56.53	87.2	3.0	17.0	55.5
TR	23.0	47.4	0.0	2.0	19.0
T5R	11.3	31.5	0.0	0.0	4.0
TD - TR	32.4	74.5	0.0	1.0	20.5
TD - T5R	44.2	82.7	0.8	8.0	39.4

Studying Rare Disease Using an Electronic Health Record (EHR) and Machine Learning Based Approach: The Kaiser Permanente Southern California (KPSC) Membranous Nephropathy (MN) Cohort

Amy Z. Sun,[1] Yu-Hsiang Shu,[4] Teresa N. Harrison,[4] Michelle M. O'Shaughnessy,[2] John J. Sim.[3] *[1]Department of Internal Medicine, Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA; [2]Division of Nephrology, Stanford University, Palo Alto, CA; [3]Division of Nephrology and Hypertension, Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA; [4]Kaiser Permanente, Pasadena, CA.*

Background: Large scale epidemiology studies on glomerular disease such as MN are needed. Identifying MN patients using EHR is limited by the need to manually review kidney biopsy pathology reports (gold standard diagnostic test) to confirm cases. An ability to accurately identify patients with MN using only structured EHR data (e.g. diagnosis codes) would enhance the efficiency and scale of observational and comparative effectiveness studies within this population.

Methods: A retrospective cohort study was performed among KPSC patients who underwent a kidney biopsy 6/28/1999-6/25/2015 (n=5542). Biopsies were manually reviewed and designated as MN or non-MN. The sensitivity (SN), specificity (SP), and positive predictive value (PPV) of ICD9 diagnosis codes appearing w/in 1 yr after biopsy were determined using 2 approaches: 1) Clinical (581.1, 582.1, or 583.1, MN specific codes) AND 2) Machine learning (ICD9 codes, kidney-related or not, with highest predictive performance).

Results: Among biopsy proven MN cases, 59% and 86% received a MN diagnosis w/ in 30 days and 1 yr after biopsy, respectively. The SN and SP of this clinical approach were 86% and 76% respectively, but the PPV was 26%. If >2 codes were required, SP increased and PPV improved, but SN declined. Machine learning approach detected that using just 2 ICD9 codes (581.1 or 583.1) improved SP to 94% and PPV to 58% with a decrease in SN to 83%. SP was 98%, PPV 78%, and SN 64% if ≥3 codes was required.

Conclusions: Our study is the one of the first to leverage the EHR (ICD codes) to identify patients with biopsy-proven MN. Data-driven approaches showed better overall performance than a solely clinical-based approach. Expanding machine learning approaches to include demographics, additional clinical data, or free text from pathology reports might further increase diagnostic performance.

Conceptualizing the Future of Personalized Precision Medicine for Glomerular Disease

Debbie S. Gipson,[1] Howard Trachtman,[2] L. Barisoni,[3] Jeffrey B. Hodgin,[4] Habib Hamidi,[5] Sean Eddy,[5] Laura H. Mariani,[5] Matt G. Sampson,[5] Lawrence B. Holzman,[6] Jonathan P. Troost,[5] John R. Sedor,[7] Matthias Kretzler.[8] Nephrotic Syndrome Study Network *[1]University of Michigan Mott Children's Hospital, Ann Arbor, MI; [2]NYU Langone Health, New York, NY; [3]U. Miami, Miller School of Medicine, Miami Beach, FL; [4]The University of Michigan, Ann Arbor, MI; [5]University of Michigan, Ann Arbor, MI; [6]University of Pennsylvania, Philadelphia, PA; [7]Cleveland Clinic, Cleveland, OH; [8]U.Michigan, Ann Arbor, MI.*

Background: Glomerular disease therapy selection and outcomes have been hampered by imprecise disease characterization. Scientific advances have been generated in research contexts but few have crossed the research - patient care divide.

Methods: We hypothesized that comprehensive clinical, demographic and molecular phenotypes could be integrated into a personalized, comprehensive disease profile that could be used to understand the disease within nephrotic syndrome subjects. Physician- scientists and project managers from NEPTUNE were invited to participate in the model development. A multicenter, interdisciplinary NEPTUNE Kidney Review Board (KRB) model was created. Testing of this model used archived cases from the NEPTUNE study cohort. Return of results to caregivers or subjects was prohibited during this model testing phase.

Results: Data domains including, clinical phenotype, pathology, genetics, renal gene expression, and proteomics, were evaluated for each case. KRB participants were educated about data domain content, analytic methods, results display and supporting evidence from published literature. Multicenter web-enabled conferences were used to a) present case-specific information, b) review subject-specific data for each domain and c) integrate the multi-scalar data to develop theoretical management and treatment strategies for the subject. The multicenter, NEPTUNE KRB pilot was launched in February 2018. This pilot phase allowed the team to practice baseline evaluation of each case using a systems biology approach in a blinded manner, assemble the information into a case specific knowledge environment. Following discussion, the outcome of the case based on longitudinal observation was disclosed.

Conclusions: Integration of clinical, pathologic and molecular data will enable personalized disease profiling and will be essential in matching the right therapies for the right patients. In order to accomplish this, a prepared community of clinicians and scientists are needed to effectively interpret the strengths and limitations of the evidence. Furthermore, addition of patient advisors and ethicists will strengthen this initiative. KRBs provide a rational and effective strategy to bring precision health to the glomerular disease community.

Changes of Epidemiology, Renal and Patient Outcomes over Time in Glomerular Disease of Korea

Minjung Kang,[1] Sehoon Park,[2] Dong Ki Kim,[2] Kook-Hwan Oh,[2] Kwon Wook Joo,[2] Yon Su Kim,[3] Ho Jun Chin,[4] Hajeong Lee.[3] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, SEOUL, Republic of Korea; [3]Seoul National University College of Medicine, Seoul, Republic of Korea; [4]Seoul National University Bundang Hospital, Seong nam, Republic of Korea.*

Background: Epidemiology of glomerular disease has been revealed temporal changes according to the population sanitation standard, socioeconomic status, and improvement of medical care. We aimed to explore changes of epidemiology, renal and patient outcome over time in glomerular disease (GD) in Korea, which is one of countries experienced rapid socioeconomic changes during short time.

Methods: After excluding 98 with more than the second times biopsy, 7,402 biopsy-proven primary and secondary GD patients from 1979 to 2018 are included from 2 tertiary hospitals. The outcome is CKD progression and all-cause mortality. CKD progression is defined as either incident ESRD or halving eGFR.

Results: During median 59 (18 - 138) months of follow-up period, patients who were taken kidney biopsy tended to be significantly older and more women over time. In overall, the most common primary GD was IgA nephropathy (IgAN), followed by membranous nephropathy (MN), minimal change disease (MCD), and focal segmental glomerulosclerosis (FSGS) with similar proportions. The most common secondary GD was lupus nephritis (LN), diabetic nephropathy (DN), and hepatitis-B-associated GN (HBGN). Proportion of IgAN had continuously increased over time, however it showed plateau since 2009, then it decreased to a certain degree. Proportion of MCD had decreased, whereas that of crescentic GD had increased as times go by. Diagnosis of MN or FSGS was not affected by the time change. Among secondary GDs, LN remained most common, however, it has decreased recently. DN has increased dramatically, whereas HBGN has decreased continuously. Patients presenting nephrotic syndrome has been decreased recently. 10-year renal survival was the lowest in DN (45.0%), followed by crescentic GD (62.0%), FSGS (78.4%), and IgAN (83.7%). Patient survival was the lowest in crescentic GD (76.6%), followed by DN (88.6%). Other GN showed similar patient survival with more than 90% of rate.

Conclusions: From our large cohort with long term follow-up, we identified significant changes in demographic or epidemiologic characteristics as well as outcomes of overall GDs. Improvement of socioeconomic and medical care may contribute to these changes.

SA-PO395

A Review of Therapies over 17 Years for Glomerular Disease in a Single Center

Sara Syeda, Sairah Sharif. *Brown University, Cranston, RI.*

Background: Glomerular disease is the third leading cause of end stage renal disease in adults in the United States. There is lack of consensus on treating glomerular disease due to general lack of randomized control trials in this field. There is a lot of variability in therapy both due to physician and patient factors.

Methods: We undertook this study to evaluate the trends in therapies of the most common glomerular diagnosis over the years in our center. This is a retrospective chart review of medical therapies of 322 patients who underwent a kidney biopsy between year august 2000 to october 2017. We also reviewed pregnancy outcomes of patients who were diagnosed with glomerular disease. Patients who did not have a renal biopsy at our center were excluded.

Results: Results: Our study population is ethnically diverse with 68% white, 16% black, 3% asian and 2% hispanic patients. The 3 most common clinical presentation that lead to renal biopsy were acute kidney injury, nephrotic syndrome and a combination of both. Amongst nephrotic syndrome FSGS was treated with steroids 80%, cyclosporine 20%, tacrolimus 14%, MCD was treated with steroids 99%, and membranous nephropathy was treated with steroids 90%, cyclophosphamide 30% of the cases. Patients with IgANP got renin angiotensin inhibitors 72%, steroids 22% of the time. Patients with ANCA vasculitis got steroids 95% of the time, cyclophosphamide 64% and rituximab 30% of the time. The therapy changed over time and rituximab use was more after 2012. Out of females between ages 18 to 50 years, 20 got pregnant any time after renal biopsy. Out of these pregnancies the live birth was 30%. The most common immunosuppressive drug to be used during pregnancy was mycophenolate and most common anti-hypertensive methyldopa. Pregnancy induced hypertension and preeclampsia was frequent 72%.

Conclusions: In our ethnically diverse population we found that LN, FSGS, MGN and IgANP were the most common glomerular disease. We found a great variability in treatment of glomerular disease including more rituximab after 2012.

Changes in Patient-Reported Outcomes and Glomerular Disease Activity: CureGN

Shannon L. Murphy,[1] John D. Mahan,[2] Jonathan P. Troost,[3] Tarak Srivastava,[4] Amy Kogon,[5] Yi Cai,[6] T. Keefe Davis,[15] Hilda E. Fernandez,[7] Alessia Fornoni,[8] Rasheed A. Gbadegesin,[9] Emily G. Herreshoff,[3] Pietro A. Canetta,[7] Patrick H. Nachman,[10] Bryce B. Reeve,[1] David T. Selewski,[3] Christine B. Sethna,[11] Chia- Shi Wang,[14] Sharon M. Bartosh,[16] Debbie S. Gipson,[12] Katherine R. Tuttle.[13] On Behalf of the CureGN Consortium *[1]University of North Carolina, Chapel Hill, NC; [2]Nationwide Children's Hospital, Columbus, OH; [3]University of Michigan, Ann Arbor, MI; [4]Childrens's Mercy Hospital, Kansas City, MO; [5]Children's Hospital of Philadelphia, Wynnewood, PA; [6]Helen DeVos Children's Hospital, Grand Rapids, MI; [7]NYP-CUMC, New York, NY; [8]University of Miami, Miami, FL; [9]Duke University Medical Center, Durham, NC; [10]University of Minnesota, Minneapolis, MN; [11]Cohen Children's Medical Center of NY, New Hyde Park, NY; [12]University of Michigan Mott Children's Hospital, Ann Arbor, MI; [13]University of Washington School of Medicine, Spokane, WA; [14]Emory University, Atlanta, GA; [15]Washington University, St. Louis, MO; [16]University of Wisconsin Children's Hospital, Madison, WI.*

Background: Prior cross sectional studies suggest that health-related quality of life (HRQOL) is worse in patients with active glomerular disease compared with inactive patients. This analysis was conducted to assess changes in longitudinal HRQOL with changing disease status.

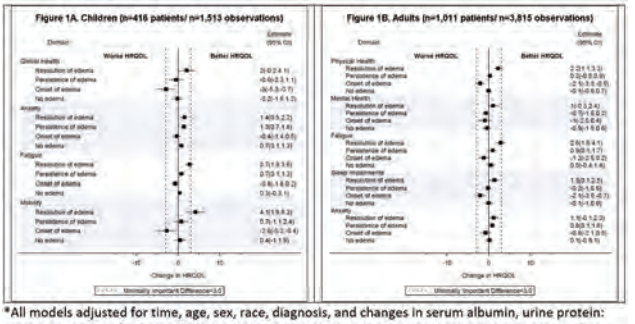
Methods: Longitudinal data were collected in CureGN, a cohort of patients with minimal change disease, focal segmental glomerulosclerosis, membranous nephropathy, IgA vasculitis or IgA nephropathy. HRQOL was assessed at enrollment and at visits ranging from 1 - 3 times annually for up to 5 years with the Patient Reported Outcomes Measurement Information System (PROMIS). Global Health, Anxiety, and Fatigue domains were measured in all; Mobility was measured in children; and Sleep was measured in adults. Linear mixed effects models were used to evaluate HRQOL responsiveness to changes in disease activity.

Results: 416 Children and 1,011 Adults with PROMIS scores were included in the analysis. Edema was associated with all PROMIS domains other than Adult Mental Health (Figure). For example, children with edema resolution had improved Mobility (change +4.1; 95% CI +1.9 to +6.3), while those with edema onset had worse Mobility (change= -2.8 CI=-5.2 to -0.4). Serum albumin also associated with HRQOL for Child Global Health, Child Mobility, and all Adult Domains (effect sizes of +0.8 to +2.1 points per g/dL, $p<0.05$).

Conclusions: HRQOL, as measured by PROMIS, was responsive to changes in glomerular disease patient edema and serum albumin levels with score changes ranging from 0.3 - 1.3 times the PROMIS minimally important difference of 3. Future studies may reveal a glomerular disease specific PRO instrument to be more sensitive to within patient changes in disease status.

Funding: NIDDK Support

Figure. The impact of within-patient changes in edema status on changes in PROMIS domain scores: results of adjusted* mixed-effects models.



*All models adjusted for time, age, sex, race, diagnosis, and changes in serum albumin, urine protein: creatinine ratio, eGFR, hemoglobin and immunosuppressive therapy were tested as covariates. After backwards selection, final models for Child Global Health, Child Mobility, and all Adult Domains adjusted for changes in serum albumin. Adult Physical Health and Adult Fatigue final models also adjusted for changes in eGFR.

Disease Activity in Longstanding Glomerular Diseases: The Columbia University-CureGN Experience

Elisa Delbarba,[1] Maddalena Marasa,[3] Stacy E. Piva,[2] Debanjana Chatterjee,[3] Byum hee Kil,[3] Xueru Mu,[3] Ali G. Gharavi,[3] Andrew S. Bomback.[3] On Behalf of the CureGN Consortium *[1]Spedali Civili di Brescia, Cologne, Italy; [2]Columbia University Medical Center, New York, NY; [3]Columbia University, New York, NY.*

Background: Glomerular diseases are characterized by variable disease activity over many years. The CureGN study enrolls patients (pts) with minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS), membranous nephropathy (MN), and IgA nephropathy (IgAN) whose 1st biopsy falls within 5 years of enrollment. We aimed to determine whether pts with more longstanding disease would show similar disease activity as CureGN pts.

Methods: Using CureGN's definitions of disease activity, we compared activity in pts followed at Columbia & excluded from CureGN due to their 1st biopsy done prior than 5 years from screening (Out of Window, OW) to both enrolled Columbia pts (CUMC) & to the entire CureGN cohort. For the OW, we assessed disease activity at the 1st clinical encounter from Nov 2014 (when CureGN enrollment opened). For the CureGN pts, we used disease activity at enrollment.

Results: OW and CUMC pts were similar in age, sex, and race; the CureGN cohort had a greater representation of African-Americans compared to the CUMC and OW. OW pts had, on average, lower eGFR than both CUMC and CureGN ones. For each disease subtype, disease activity in the OW cohort was equal or higher than disease activity in both the entire CureGN and the CUMC cohort (Fig1). When limiting our comparisons to disease activity in "incident" CUMC pts (1st diagnostic biopsy within 6 months of enrollment), OW pts demonstrated similar activity rates as incident pts (91% MCD, 60% FSGS, 73% MN, 80% IgA). Disease activity also did not differ by comparison for treatment thresholds.

Conclusions: Disease activity did not differ among pts with shorter vs longer duration of disease. Our OW cohort may include pts with more severe disease variants who still require a careful follow-up >5 years after initial diagnosis. Such pts are potentially highly informative for understanding the clinical course and pathogenesis of glomerulopathies and can help identify risk factors mediating more chronic subtypes of disease.

Factors Associated with Incident Diabetes in Patients with Glomerular Disease: The CureGN Study

Amy K. Mottl,[1] Sarah Mansfield,[11] Matthew Palmer,[2] Andrew S. Bomback,[3] Carla M. Nester,[4] Virginie Royal,[5] L. Barisoni,[6] Michael B. Stokes,[7] J. Charles Jennette,[1] Matthias Kretzler,[8] Katherine R. Tuttle,[9] Cynthia C. Nast.[10]
[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]University of Pennsylvania, Philadelphia, PA; [3]Columbia University, New York, NY; [4]University of Iowa Hospitals and Clinics, Iowa City, IA; [5]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [6]U. Miami, Miller School of Medicine, Miami Beach, FL; [7]Columbia University Medical Center, New York, NY; [8]U. Michigan, Ann Arbor, MI; [9]University of Washington School of Medicine, Spokane, WA; [10]Cedars-Sinai Medical Center, Los Angeles, CA; [11]Arbor Research, Ann Arbor, MI.

Background: Glomerular disease is often complicated by incident diabetes which may raise the long-term risk:benefit ratio of immunosuppressive treatment. There is a paucity of information regarding descriptive characteristics of individuals with glomerular disease and incident diabetes.

Methods: We studied 2009 individuals from the CureGN Cohort Study, an observational cohort study of people with IgA Nephropathy/Vasculitis (IgAN/IgAV), Membranous Nephropathy (MN), Focal Segmental Glomerulosclerosis (FSGS) and Minimal Change Disease (MCD), followed prospectively starting less than 5 years after kidney biopsy. We compared sociodemographic and clinical characteristics of individuals with versus without incident diabetes diagnosed after kidney biopsy. Statistical significance was calculated using Chi-square or Fisher's exact test for categorical or Kruskal-Wallis test for continuous variables.

Results: There were 71 individuals with incident diabetes diagnosed a median of 4 (IQR 0-22) months after kidney biopsy. Diabetes was considered medication induced in 44 (62%) and 75% were treated with insulin. Characteristics of individuals with and without incident diabetes are shown in the table. Incident diabetes was more frequent in MN than in other glomerular diseases. Patients with versus without incident diabetes were older, more likely to have a family history of diabetes, and had a greater prevalence of obesity, smoking, hypertension and cardiovascular disease at enrollment. There was no difference in cumulative exposure to steroids between those with versus without incident diabetes.

Conclusions: Incident diabetes was more common in MN than other glomerular diseases, possibly due to older age at presentation of this disease. The absence of a difference in steroid exposure between those with versus without incident diabetes was unexpected and will be the focus of future analyses.

Funding: NIDDK Support

Table 1. Sociodemographic and clinical characteristics of CureGN participants with versus without incident diabetes from the time of kidney biopsy.

	Incident diabetes (N=71)	Without diabetes (N=1948)	P-value[a]
Age at biopsy (years), median (IQR)[1]	54 (40, 63)	25 (11, 46)	<0.001

Predictors of Non-Linearity in eGFR Trajectories in the Nephrotic Syndrome Study Network (NEPTUNE)

Abigail R. Smith,[1] Nan Ji,[1] Jarcy Zee,[1] Viji Nair,[2] Laura H. Mariani.[1,2] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.*

Background: Surrogate outcomes for end-stage kidney disease (e.g. eGFR slope or 40% decline) often assume linear changes, which may not always reflect true eGFR trajectories. The objective of this study was to identify patient characteristics associated with non-linear eGFR trajectories in a cohort of patients with nephrotic syndrome.

Methods: Data were obtained from the NEPTUNE study, a multicenter observational cohort study of adult and pediatric patients with >500mg/day of proteinuria enrolled at the time of clinically indicated biopsy or initial presentation of disease without biopsy (pediatric patients). eGFR was calculated using the CKD-Epi formula for patients ≥18 years old and modified CKiD-Schwartz formula for patients <18. Probability of non-linearity (PNL) was calculated using Bayesian smoothing of individual eGFR trajectories, and patient demographic and clinical variables and follow-up time were used to predict PNL in multivariable linear regression.

Results: 385 patients with ≥3 eGFR measurements and ≥1 year of follow-up were included (median follow up time 39 months). Median PNL was 0.047, with 15.6% and 6.5% having a PNL >50% and >75%, respectively. Higher baseline eGFR and UPCR, black race and steroid use at baseline were associated with higher PNL (9% increase per 10 unit increase in eGFR, p=0.001; 4% increase per unit increase in UPCR, p=0.011; 40% higher in black patients, p=0.038; 56% higher with steroid use at baseline, p=0.008, Table). Age and maximum follow-up time were associated with lower PNL (16% decrease per 10 year increase in age, p<0.001; 34% decrease per year increase in follow-up time, p<0.001).

Conclusions: While non-linear eGFR trajectories were common in this cohort, increasing follow-up time resulted in more linear trajectories. Higher baseline eGFR, younger age, black race, and steroid use were associated with higher probability of non-linear eGFR trajectories. Surrogate outcomes that assume linearity may be valid with sufficient follow-up.

Table: Factors associated with probability of non-linearity (PNL) of eGFR trajectories

	PNL Ratio (95% CI)	p-value
Baseline eGFR (per 10 mL/min/1.73m²)	1.09 (1.09,1.10)	0.001
UPCR (per 1 mg/mg)	1.04 (1.01,1.07)	0.011
Age (per 10 years)	0.84 (0.83,0.85)	<0.001

Infectious Complications in Patients with Glomerular Disease: An Analysis of the Cure Glomerulonephropathy (CureGN) Study

Dorey A. Glenn,[1] Candace D. Henderson,[1] Yichun Hu,[1] Dawn Zinsser,[6] Michelle M. O'Shaughnessy,[2] Larry A. Greenbaum,[3] Jarcy Zee,[6] Andrew S. Bomback,[4] Keisha L. Gibson,[1] Amy K. Mottl,[1] Susan L. Hogan,[1] Patrick H. Nachman,[5] Ronald J. Falk.[1] CureGN Consortium *[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Stanford University, Palo Alto, CA; [3]Emory University, Atlanta, GA; [4]Columbia University, New York, NY; [5]University of Minnesota, Minneapolis, MN; [6]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Infections are an important contributor to patient morbidity and mortality in glomerular disease (GD). We sought to understand the epidemiology of infections and infection-related healthcare utilization among patients with GD.

Methods: CureGN is a prospective multi-center cohort study of patients with minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS), membranous nephropathy (MN), or IgA Nephropathy/Vasculitis (IgAN/IgAV). We describe the rate of infections requiring hospitalization or emergency department (ED) visit, primary infection sites, hospital lengths of stay, and ICU use within this cohort, stratified by age and GD type.

Results: Overall, 202 confirmed infections occurred in 158 (8%) of 1965 participants over a mean follow up time of 1.3 years (SD 0.9), a rate of 0.08 infections per person year. Ten percent of all hospitalizations or ED visits were due to infection. The rate of infection-related hospitalizations or ED visits was significantly higher in children (p<0.001), and in patients with MCD relative to MN (p=0.02) or IgAN/IgAV (p=0.004). Admission to the ICU was required in 9% of infection-related hospitalizations. The most frequent sites of infection were the lower (23%) and upper (23%) respiratory tract, and gastrointestinal system (13%).

Conclusions: Infection-related ED visits and hospitalizations are an important contributor to healthcare utilization among patients with GD. Further study is needed to analyze risk factors for infection and develop strategies to mitigate these events. Attention should focus on children and those with MCD, who have the highest rates of infection-related healthcare utilization.

Patient Experience in ANCA-Associated Vasculitis - Challenges from Diagnosis and Need for New Approaches

Peter A. Rutherford,[1] Dieter K. Goette,[1] James E. O'Donoghue,[2] Xierong Liu.[2] *[1]Vifor Pharma, Zurich, Switzerland; [2]Elma Research, London, United Kingdom.*

Background: ANCA-associated vasculitis (AAV) brings challenges to patients in terms of acute illness and then a long term remitting relapsing condition. Therapy is complex and associated with significant acute toxicity as well as cumulative damage. Relatively little is known about the patient experience and how it evolves over time.

Methods: Qualitative research was performed using 1 on 1 interviews with 33 AAV patients (11 male) from 4 EU countries. 20 patients had granulomatosis with polyangiitis, 12 microscopic polyangiitis, and 1 had eosinophilic granulomatosis with polyangiitis. AAV duration (median 3.5 years, range 1-32) and patient age (3 < 40 years, 25 aged 40-80 years and 25 > 70 years) allowed rich insight from diagnosis through follow up.

Results: Thematic analysis of the interviews identified issues along the patient journey. Key findings were: (1) Suboptimal referral – long delays in diagnosis lead to long lasting psychological damage, worsened with treatment; (2) Recognition - sudden onset and misdiagnosis impairs patient experience. Patients are concerned over low empathy and understanding of their needs by healthcare professionals; (3) Knowledge gaps – patients want to know when they will return to normal and the duration of therapy and its impact; (4) Measuring response – patients have a low awareness of how their response is assessed clinically with scales/scores; instead they refer to the importance of "feeling better" and going home; (5) Decision making – patients report a low involvement in treatment decisions particularly over glucocorticoids (GCs) and immunosuppression; and (6) Unmet needs – patients have high regard for the efficiency of GCs in the acute phase but report major side effects which impair quality of life and functional status as GC dose changes. Findings were consistent across the 4 countries; differences reflected variations in healthcare system and organization.

Conclusions: Patients are challenged before and after diagnosis and once treatment begins with evolving experience over time. Physicians need to be aware of AAV patients concerns and needs from first interaction, when assessing response, and if treatment changes are needed. GCs pose a particular problem for patients and new therapies which reduce the significant treatment burden of AAV would be beneficial.

Patients with Relapsing ANCA-Associated Vasculitis (AAV) Experience Unmet Needs around Remission Induction and Therapy Related Adverse Events

Peter A. Rutherford,[1] Dieter K. Goette,[1] Melinda Stamm,[2] Xierong Liu.[2] *[1]Vifor Pharma, Glattbrugg, Switzerland; [2]Elma Research, London, United Kingdom.*

Background: Relapse in AAV remains a clinical challenge, with 5-10% of patients experiencing relapses of varying severity each year. Such patients are at risk from both acute vasculitis damage but also drug toxicity and cumulative organ damage related to AAV and glucocorticoid (GC) adverse events. This study aimed to measure outcomes and adverse events in relapsing AAV patients in real clinical practice.

Methods: 268 relapsing AAV patients from 4 European countries received remission induction therapy between 2014-17 and data collected at baseline, 1, 3, 6 and 12 months following commencement of induction therapy was reviewed retrospectively.

Results: Patient mean age was 58.3 years with 60% male; 54% of patients had granulomatosis with polyangiitis, and 46% had microscopic polyangiitis. At the time of relapse, 7.1% of patients had experienced a past GC adverse event and only 16.0% were free from comorbidity. Birmingham vasculitis activity score (BVAS) was used in 17% at relapse diagnosis and 21% at time of relapse. Vasculitis was reported as mild/localized in 9.7 % of patients 64.6% as moderate systemic, and 25.7% as severe, life threatening. 44.0% of patients received rituximab and 35.1% received cyclophosphamide, whilst 76.5% received GCs. As BVAS was not used routinely, clinical response was assessed as full (no vasculitis activity and GC taper on track), partial (reduction in vasculitis activity), or no response (no improvement in vasculitis). Response to therapy varied, and adverse events and infections were common. Full response at 1 month was associated with good 12-month outcomes (81% full response), whereas a partial response at 1 month (53%) was associated with less favourable 12-month outcomes (49% full response).

Conclusions: Relapsing AAV patients frequently have comorbidities and their response to remission induction therapy is variable. An early positive response associates with a good response rate at 12 months. Many patients experience adverse events, and infections are common especially early in treatment. Relapsing patients still face unmet medical needs.

Real World Experience in ANCA-Associated Vasculitis (AAV) – A Complex Pathway of Patient Referral, Diagnosis, and Management

Peter A. Rutherford,[1] Dieter K. Goette,[1] Melinda Stamm,[2] Xierong Liu.[2] *[1]Vifor Pharma, Glattbrugg, Switzerland; [2]Elma Research, London, United Kingdom.*

Background: AAV is a severe systemic small vessel vasculitis with frequent renal involvement. Diagnosis can be difficult and referral pathways complicated with potentially several different specialists involved. Patient comorbidity is important but poorly reported. This retrospective study aimed to examine referral, diagnosis, and therapy outcomes in AAV patients managed in routine clinical practice.

Methods: A retrospective study was performed on 1197 patients receiving care from 399 physicians in 4 EU countries and 929 incident AAV patients are reported here. Patients were referred between 2014-17 and data collected at baseline and 1, 3, 6 and 12 months following commencement of therapy.

Results: Mean patient age was 56.8 years and 54% were male. 75% of patients were referred by other physicians, 25% direct acute presentations with only 16% referred with ANCA diagnosis. Referral symptoms were general in most cases – fatigue (58%), fever (54%), weight loss (53%), joint pain (47%) – 64% had renal disease. Physicians reported that 16% of patients had had symptoms for over 3 months. Comorbidities were common

(hypertension 45%, diabetes 18%, COPD/asthma 15%, coronary arterial disease 10%, arthritis 9%, osteoporosis 7% and cardiac failure 6%) with only 32% having none. At diagnosis, the median eGFR 35 ml/min, protein excretion median 595 mg/24 hours and 62% had microscopic haematuria; a renal biopsy was performed in 64%. Granulomatosis with polyangiitis was diagnosed in 54% of patients. In only 12% of patients was a formal scale (Birmingham Vasculitis Activity Scale, BVAS) used to assess activity. Clinically, 12% had mild disease, 54% had moderate/systemic disease and 34% had severe/rapidly progressive disease. Resource use at diagnosis and treatment was significant with a mean length of stay of 17 days including 3 intensive care unit days. 83% of patients were managed in collaboration with other specialties (Nephrologist 51%, Rheumatologist 27%, Internal Medicine 18%, Respiratory 16%, ENT 11%).

Conclusions: AAV patients have complex pathways to diagnosis and many have features of renal disease at presentation. Most patients have comorbidities which need to be considered during AAV therapy. BVAS is used rarely in clinical practice and resource utilization at presentation is significant.

SA-PO404

Response to Induction Therapy and Treatment Adverse Events in Incident ANCA-Associated Vasculitis (AAV) Patients

Peter A. Rutherford,[1] Dieter K. Goette,[1] Melinda Stamm,[2] Xierong Liu.[2] *[1]Vifor Pharma, Glattbrugg, Switzerland; [2]Elma Research, London, United Kingdom.*

Background: AAV is a severe systemic vasculitis with a variable clinical presentation and frequent renal involvement. Rapid induction of remission is desirable and therapy is typically a combination of high dose glucocorticoids (GC) with rituximab (RTX) or cyclophosphamide (CYC). Treatment-related adverse events (AEs) are common and contribute to long term organ damage as well as acute morbidity. This retrospective study aimed to document clinical outcomes and AEs in incident AAV patients managed in routine clinical practice.

Methods: 929 incident AAV patients from 4 European countries (399 physicians) were diagnosed between 2014-17 and data collected at baseline, 1, 3, 6 and 12 months following commencement of induction therapy was reviewed.

Results: 54% of patients had granulomatosis with polyangiitis, and 46% had microscopic polyangiitis; mean age was 56.82 years (SD 14.2) with 53.7% male. Birmingham vasculitis activity score (BVAS) was used in only 12% of cases. Physicians reported 12% patients as mild/localized, 54% as moderate systemic and 34% as severe life threatening AAV. Induction therapy varied with 59% receiving CYC, 24% RTX and 3% a combination of CYC+RTX+GC, whilst 83% received GCs. As BVAS was not used routinely, clinical response was assessed as full (no vasculitis activity and GC taper on track), partial (reduction in vasculitis activity), or no response (no improvement in vasculitis). Response rate varied and AEs were common. Full response at 1 month was associated with good 12-month outcomes (81% full response) whereas partial response at 1 month (56%) was associated with less favorable outcomes (58% full response at 12 months). 6% of incident patients relapsed within the first 12 months.

Conclusions: Response rate to remission induction therapy in AAV is still variable. Early response is associated with a better response rate at 12 months. Infections and treatment-related AEs are common, especially in the first 3 months. New targeted therapy options are needed to improve response rates and reduce burden of therapy.

Funding: Commercial Support - Vifor Pharma

SA-PO405

Adverse Events Due to Glucocorticoids in ANCA-Associated Vasculitis Are Frequent but Reporting Should Improve

Peter A. Rutherford,[1] Dieter K. Goette,[1] Tanvi Patil,[2] Priyanga N. Aerian,[2] Kumari Priyanka.[2] *[1]Vifor Pharma, Glattbrugg, Switzerland; [2]Indegene, Bengaluru, India.*

Background: High dose glucocorticoids (GCs) are an integral part of therapy in ANCA-associated vasculitis (AAV). The adverse event (AE) profile of GC is well known and can lead to acute and chronic toxicity, resulting in an unmet need in clinical practice to reduce GC exposure in AAV. This systematic literature review aimed to examine AEs related to GC use in AAV clinical studies.

Methods: A systematic literature review was performed of studies published between 1 Jan 2007 and 30 January 2018. Data on GC-related AEs (any untoward medical occurrence) and serious AEs (defined in European Medicines Agency CPMP/ICH/377/95) which threaten life or function were extracted from studies.

Results: Thirty-three studies were identified in which GC-related AEs were published. Of the 25,745 patients enrolled in the 33 studies, 24,566 were exposed to GCs. Seventeen studies reported AEs only, with 23 reporting serious AEs. Overall AE rate in AAV studies appears low possibly due to under-reporting, as GC effects are so well known. The most common serious AEs were infection and mortality. Infection was the leading cause of mortality, occurring more frequently in the first 6 months of treatment. Generally, infections are commonly reported but site and microbiological cause of infection were presented rarely. Metabolic and infection are the most common AEs, and 83% of metabolic events are due to diabetes mellitus. Musculoskeletal AEs and serious AEs are also relatively common.

Conclusions: GC related AE reporting in AAV studies can be improved and follow published guidelines (EULAR Ann Rheum Dis 2010; 69: 1913-19). Serious AEs such as mortality and infection remain a major clinical problem. Metabolic and musculoskeletal events are also a patient burden. New therapeutic options for AAV should aim to reduce this AE profile.

Funding: Commercial Support - Vifor Pharma

	Serious AE	AE
Patients exposed to GCs in studies reporting GC-related events (n)	3543	22278
Events (n)	1102	4284
Most common events reported	Mortality 33%	Metabolic 37%
	Infection 20%	Infection 15%
	Musculoskeletal 17%	Neuropsychiatric 8%
	Renal 15%	Musculoskeletal 8%

Clinical and Therapy Related Risk Factors for Survival in ANCA-Associated Glomerulonephritis

Silke R. Brix,[1] Verena Wunsch,[2] Silay Arici,[2] Martin Busch,[3] Martin Nitschke,[4] Wolfram J. Jabs,[5] Tobias B. Huber,[1] Ulf Panzer,[1] Rolf A. Stahl.[1] *[1]University Hospital Hamburg-Eppendorf, Hamburg, Germany; [2]University of Hamburg, Hamburg, Germany; [3]University Hospital Jena, Jena, Germany; [4]University of Lübeck, Lübeck, Germany; [5]Vivantes, Berlin, Germany.*

Background: Renal involvement and infectious complications have great impact on mortality in patients with anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis.

Methods: We retrospectively investigated a multicenter ANCA-associated glomerulonephritis (GN) cohort for clinical and therapy related factors associated with relapse, end stage renal disease (ESRD) and survival in these patients.

Results: In 270 patients with a newly diagnosed, biopsy proven ANCA-associated necrotizing crescentic GN, the most sensitive markers for mortality were age and development of ESRD ($p<0.0001$, respectively). Gender, antibody and disease subtype did not influence patient survival. Patients with renal limited disease had the same renal and overall survival compared to patients with multi-organ involvement, e.g. patients with pulmorenal syndrome. Patients who were dialysis dependent at the time of diagnosis had a higher mortality during follow up ($p<0.05$). There was no difference in mortality between cyclophosphamide and rituximab treated patients. In the elderly population (age ≥ 70 years; n=84), a sub-cohort was given a reduced induction immunosuppression (4-6 cycles of 500mg; n=29). These patients had a higher rate of survival ($p<0.05$) compared to elderly patients with a regular cyclophosphamide induction while no differences in dialysis dependence or relapses were detected.

Conclusions: Our data suggest that a reduced induction immunosuppression in elderly patients may be appropriate, as this population seems not to benefit from a higher cyclophosphamide induction dosage.

SA-PO407

The Cyclophosphamide-Sparing Role of an Intensified B-Cells Depletion Protocol in ANCA-Associated Vasculitis: A Case-Control Study

Roberta Fenoglio,[1] Savino Sciascia,[2] Dario Roccatello.[3] *[1]Nephrology and Dialysis Unit and Center of Research of Immunopathology and Rare Diseases, Hospital Hub San Giovanni, Turin, Italy; [2]Nephrology and Dialysis Unit and Center of Research of Immunopathology and Rare Diseases (CMID), Giovanni Bosco Hospital and University of Turin, Italy, Center of Research of Immunopathology and Rare Diseases (CMID), Division of Clinical Immunology, Giovanni Bosco Hospital and University of Turin, Ita, Turin, Italy; [3]Ospedale San GIovanni Bosco, Torino, Italy.*

Background: ANCA-associated vasculitis (AAV) are systemic diseases with relapsing chronic course. The management of AAV requires the use of immunosuppressive drugs whose use is associated with potential toxicity. This case-control study aims to evaluate the immunosuppressive-sparing effect of rituximab (RTX) used with cyclophosphamide (CYC), compared to a traditional regimen based on high-dose CYC.

Methods: 26 patients (pts) with AAV with a necrotising extracapillary glomerulonephritis were prospectively enrolled. 13 pts received the intensified protocol of B-lymphocyte depletion therapy (IBCDT) "4+2" with RTX and CYC (4 weekly infusions of RTX followed by 2 monthly followed by prednisone tapered to 5 mg/day in 3 months). 13 pts treated with the high-dose CYC treatment protocol followed by azathioprine as maintenance therapy were enrolled as controls.

Results: In the 13 cases treated with the IBCDT we observed a significant reduction in mean values of parameter of disease activity. After administration of RTX, a significant reduction of the mean s-creatinine values and BVAS was observed. All pts had full B-cell depletion on peripheral blood after the first IBCDT protocol after 1 year. No further maintenance therapy was given. In the cases, a response was observed in 8/13 cases. 4 pts did not respond and a death was observed for cardiovascular causes. No significant difference was observed in terms of response to therapy between the two groups. The IBCDT allows a significant reduction in the cumulative dose of CYC to which each patient was exposed during follow-up, reaching statistical significance levels ($p<0.001$). Calculated on a monthly basis, the "4+2" protocol allowed an average reduction in the CYC cumulative dose equivalent to 827 mg/month.

Conclusions: in a selected sample of patients with AAV with renal involvement, the IBCT regimen appeared to be non inferior in terms of the efficacy when compared to CYC-based standard regimens. Moreover, the IBCDT regimen allowed a net reduction in the cumulative average dose of CYC to which pts are exposed, quantifiable in approximately 1g/month.

SA-PO408

B Cell Suppression and Relapse of Vasculitis in Maintenance Therapy of Rituximab for Granulomatosis with Polyangiitis

Miho Karube, Soko Kawashima, Shinya Kaname. *Kyorin University School of Medicine, Tokyo, Japan.*

Background: The protocol of rituximab (RTX) use during the maintenance treatment for ANCA-associated vasculitis has not been established. Thus, we retrospectively investigated the efficacy of RTX between the regular and "on-demand" use in patients with granulomatosis with polyangiitis (GPA).

Methods: The subjects were 8 GPA patients in our hospital, and RTX was introduced by refractory active vasculitis with cyclophosphamide (CY) treatment difficulties or CY contraindications. The Japanese 8 patients with GPA refractory to or contraindicated for cyclophosphamide (CY) were investigated. The patients were 6 males and 2 females, with the median ages of 68 years old, and we compared B cell counts, relapse rates between 6 regular-use cases with every 6 months and 2 on-demand-use cases when RTX were administered after the reconstitution of B cells. We also examined glucocorticoid doses and safety profiles.

Results: The RTX were used as a single dose of 375 mg/m^2 in all patients. The periods from remission to the initial maintenance therapy were 7 to 12 months. The two "on-demand" patients showed eGFR less than 45 ml/min /1.73 m^2. In the regular-use group, no relapses of vasculitis or reappearance of B cells were observed. In the on-demand-use cases, the reappearance of B cells was seen after 8.5 months on average, and one of the two cases showed relapse of vasculitis with worsening renal function, proteinuria and CRP positivity after an interval of 20 months. Both groups showed comparable glucocorticoid doses and no serious infection was observed in both groups.

Conclusions: It is suggested that the regular use of RTX was well tolerated and may show persistent remission induction, rather than on-demand use, in the maintenance treatment for patients with GPA, although further study in the large cohort is required.

SA-PO409

10 Year, Age-Stratified Outcomes of ANCA Associated Vasculitis Treated with IV Cyclophosphamide

Hugh Leonard,[1,2] Bhrigu Raj Sood,[4] Marie B. Condon,[3] David Makanjuola,[3] Fiona E. Harris.[5] *[1]St Helier Hospital, London, United Kingdom; [2]Department of Transplantation, Immunology and Mucosal Biology, King's College London, London, United Kingdom; [3]St. Helier Hospital, Surrey, United Kingdom; [4]South West Thames Renal Unit, Carshalton, United Kingdom; [5]Epsom and St Helier NHS Trust, Surrey, United Kingdom.*

Background: ANCA associated vasculitis (AAV) is a multisystem disease with morbidity and mortality associated with disease and treatment. The aim is to induce and maintain remission, and minimise side effects. Studies suggest high mortality among treated elderly patients and concerns have been raised about under-treatment in younger patients. We use IV cyclophosphamide (CyP) for induction (dose adjusted for age, weight and eGFR). We present mortality and renal outcomes in patients treated with IV CyP for AAV followed by maintenance therapy with Azathioprine or Mycophenolate.

Methods: Data was collected from medical records of patients treated with IV CyP from Jan 2007 to Jan 2017 with follow up until May 2018.

Results: 197 patients met the inclusion criteria: 54% men, 89% Caucasian, median age of 70(18-89) and 45% had PR3 antibodies. 41% were dialysis-dependent at diagnosis. IV steroids were used in 58% and Plasma Exchange in 32%. Induction with CyP was not completed in 4 patients due to intolerance/infection. Rituximab was given to 3 who failed to achieve remission. Median follow up was 60 months(10-133). 44(22%) patients died due to: infection(9), vasculitis(3), malignancy(6) and other(26). 5 died during induction: 2 of vasculitis and 3 of unknown causes. 42 had at least one relapse. Of the 80 who were dialysis-dependent at diagnosis, 52 recovered renal function. Age($p<0.01$) and end-stage renal failure(adjusted OR 8.1, $p<0.01$) were associated with mortality. 27 new cancers were detected during follow up.

Conclusions: We report on a single-centre cohort followed up for up to 10 years with a large number of elderly patients. The oldest age group had longest time to relapse, but also the highest unadjusted mortality and highest frequency of advanced CKD. There was a trend towards more relapses among younger patients. Although the dose of CyP is stratified according to age and renal function, this study highlights the possibility of under-treatment in younger patients.

Table 1 (Outcomes according to age)

Age Group	<50 years	50-65 years	65-80 years	>80 years
Number (% male)	22 (59% male)	51 (58% male)	97 (55% male)	27 (37% male)
Relapse (%)	9 (41%)	11 (22%)	17 (18%)	5 (19%)
Median time to relapse in months	21	31	30	33
Died during follow up (%), p<0.01	0	7 (14%)	28 (29%)	9 (33%)
Median time to death in months	NA	36	36	23
CKD stages 4-5 (%), p<0.01	3 (14%)	19 (37%)	47 (48%)	17 (63%)

SA-PO410

Pregnancy Outcomes in ANCA-Associated Vasculitis: A Retrospective Review

Melissa L. Swee,[1] Jennifer Strouse,[1] Mandeep S. Gill,[1] Manish Suneja,[2] Bharat Kumar.[3] *[1]University of Iowa, North Liberty, IA; [2]The University of Iowa, Iowa City, IA; [3]University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: ANCA-Associated Vasculitis (AAV) is a small-vessel vasculitis that predominantly affects the kidneys and respiratory tract, among other organ systems. It has been traditionally associated with elderly males, but its occurrence in young, potentially childbearing, females is increasingly being recognized. In this study, we characterize the outcomes of pregnancy in ANCA-associated vasculitis.

Methods: We performed a retrospective chart review of all patients at the University of Iowa Hospitals and Clinics with a positive PR3 or MPO and a documented diagnosis of vasculitis between 2000 and 2017. Inclusion criteria included female sex and age younger than 45. Charts were reviewed to identify disease activity, clinical manifestations, medication regimens, and pregnancy outcomes.

Results: 24 patients met the inclusion criteria, of which 11 were pregnant at some point, accounting for 29 total pregnancies. Among these, 8 had at least one pregnancy after the diagnosis of AAV and 5 before the diagnosis. Those who were pregnant after diagnosis all had single pregnancies and accounted for 16 pregnancies in total. Seven pregnancies were viable, 2 are currently gravid, and 7 resulted in spontaneous abortions. Six (75%) were MPO positive while 2 (25%) were PR3 positive. Two patients were on moderate doses of prednisone (15mg – 20mg daily); the others were not on any immunosuppressive therapy. For induction therapy, 5 had cyclophosphamide, 1 had rituximab, and 2 had limited disease not requiring induction therapy. In vitro fertilization was documented in only 1 patient. Four were delivered by Caesarean section. All 6 who have completed pregnancy experienced complications, including premature birth (4), preeclampsia (2), preterm premature rupture of membranes (1), and cholestasis of pregnancy (1). One required tracheostomy for subglottic stenosis at 11 weeks.

Conclusions: Women with AAV should be considered at high risk for pregnancy complications due to the underlying disease and chronic immunosuppressive treatment regimens. With very close clinical monitoring, women with AAV may be able to conceive and give birth.

SA-PO411

The Endothelial Glycocalyx Is Damaged in Acute ANCA-Associated Vasculitis and Is Improved After Treatment

Hui Liew,[1,2] Matthew A. Roberts,[1,2] Lawrence P. McMahon.[1,2] *[1]Renal Medicine, Eastern Health, Melbourne, VIC, Australia; [2]Monash University, Melbourne, VIC, Australia.*

Background: The endothelial glycocalyx (EG) lines and protects the luminal surface of the endothelium. Damage to this layer can be detected by increased serum levels of EG constituents as well as an increase in the perfused boundary region (PBR) of sublingual capillaries using the novel Glycocheck™ device. ANCA-associated vasculitis (AAV) is a widespread inflammatory process affecting blood vessels, causing endothelial dysfunction (ED). The effects of AAV on the EG are unknown.

Methods: We aimed to examine the effects of acute AAV and its treatment on the EG compared to healthy controls by collecting blood for EG markers (syndecan-1 and hyaluronan), markers of ED (vascular cell adhesion molecule: VCAM-1), urine for albumin:creatinine ratio (uACR), and performing a PBR measurement. Investigations for controls were performed once, whereas vasculitis patients were studied at the time of admission, after 2 weeks of plasma exchange (PEX) if indicated, and after 3 months of immunosuppressive therapy.

Results: Patients with acute AAV (n=8) and healthy controls (n=28) were recruited. Mean ages were 63 ± 13 years and 40 ± 13 years ($p<0.001$), respectively. AAV patients demonstrated EG damage at baseline compared to controls, with higher syndecan-1 and hyaluronan levels and a greater PBR. Three patients required dialysis, and one remained on dialysis at 3 months. After treatment, the median eGFR of AAV patients increased from 12 (3-40) mL/min at baseline to 19 (6-60) after plasma exchange ($p=0.031$, n=5), but not at 3 months. Median syndecan-1 levels decreased significantly from baseline to 3 months with a corresponding decrease in PBR values. However, no differences were detected in hyaluronan, VCAM-1 or uACR at any point.

Conclusions: Markers of EG damage were higher in the AAV patients at baseline compared to controls. The PBR and syndecan-1 levels of these patients improved at 3 months, reflecting an improvement in the EG layer due either to treatment or better renal function. The lack of change in hyaluronan and VCAM-1 levels warrants further investigation.

	Controls	Patients with acute AAV				
		Baseline	Post PEX	3 months	Paired t-test Controls vs. Baseline	Paired t-test Baseline vs. 3 months
PBR (μm)	2.04 ± 0.31	2.39 ± 0.23	2.43 ± 0.31	2.09 ± 0.16	0.0014	0.045
Syndecan (ng/mL)	26 (10-146)	100 (58-205)	76 (20-131)	44 (27-99)	<.0001	0.034
Hyaluronan (ng/mL)	32 ± 25	92 (16-134)	92 (24-175)	95 (24-240)	0.0002	0.562
VCAM-1 (ng/mL)	613 (379-1189)	1208 (27-1511)	465 (16-1372)	1091 (52-1597)	0.59	0.844
uACR (mg/mmol)	0.5 (0-2)	121 ± 87	431 ± 173	303 ± 270	<.001	0.625

SA-PO412

Urinary Cell mRNA Profiling Distinguishes Disease Activity in ANCA GN

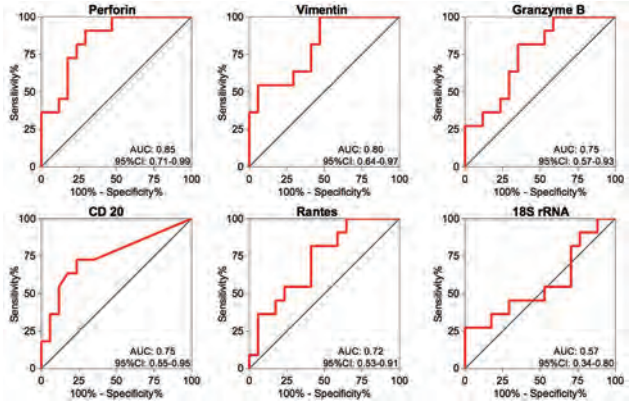
Sam Kant,[1,4] Carol Y. Li,[3] Thangamani Muthukumar,[3] Duvuru Geetha.[2] *[1]University of Maryland Medical Center, Baltimore, MD; [2]John Hopkins Bayview Medical Center, Baltimore, MD; [3]Weill Cornell Medical College, New York, NY; [4]Johns Hopkins Hospital, Baltimore, MD.*

Background: Hematuria, proteinuria and increase in serum creatinine are noninvasive but inaccurate indicators of active GN. Renal biopsy is the gold standard for diagnosis of active GN but recurrent biopsies can be laden with risk. We aimed to ascertain if urinary cell mRNA profiling could be used to differentiate active versus remission phase in ANCA GN

Methods: Patients with biopsy proven ANCA GN were enrolled and activity was scored using BVAS. Patients in active phase had urine sample collected at the time of diagnostic biopsy and remission samples were collected during remission phase with a BVAS of zero. Total RNA was isolated from the urinary cells and mRNA expression of specific genes was examined by reverse transcription and PCR. We measured urinary cell levels of 19 mRNA's encoding proteins implicated in innate and adaptive autoimmunity. The levels of mRNA in the urinary cells for each sample were normalized by the levels of 18S rRNA in the same sample. Mann-Whitney U test and AUC were used to evaluate the ability of mRNA's to discriminate between groups

Results: Eleven patients with active disease and 17 in remission were enrolled. There were no significant differences between the groups with respect to age and ANCA subtype. Urinary expression of mRNA's for the cytotoxic attack molecules Perforin (p=0.001) and Granzyme B (p=0.02), B cell CD20 (p=0.012), Vimentin (p=0.0068), and RANTES (p=0.5) was significantly higher in active disease group compared to remission group. There were no significant differences between the groups for mRNA's encoding TGFβ1, FOX-3,CD25 ,Tbet,CD3GB,MCP1,MIG,C3,CXCR3,E-cad,NKCC2,VEGF,CD46 and IP10. ROC curve analysis demonstrates these markers can discriminate vasculitic activity (Image1)

Conclusions: This study demonstrates that urine mRNA profiling may be a non-invasive method of monitoring disease activity in ANCA GN. Elevated levels of perforin, granzyme B and CD20 are consistent with the role of cytotoxic T cells and B cells in ANCA GN



SA-PO413

Characterization of Lymphocytic Interstitial Infiltrate in ANCA GN

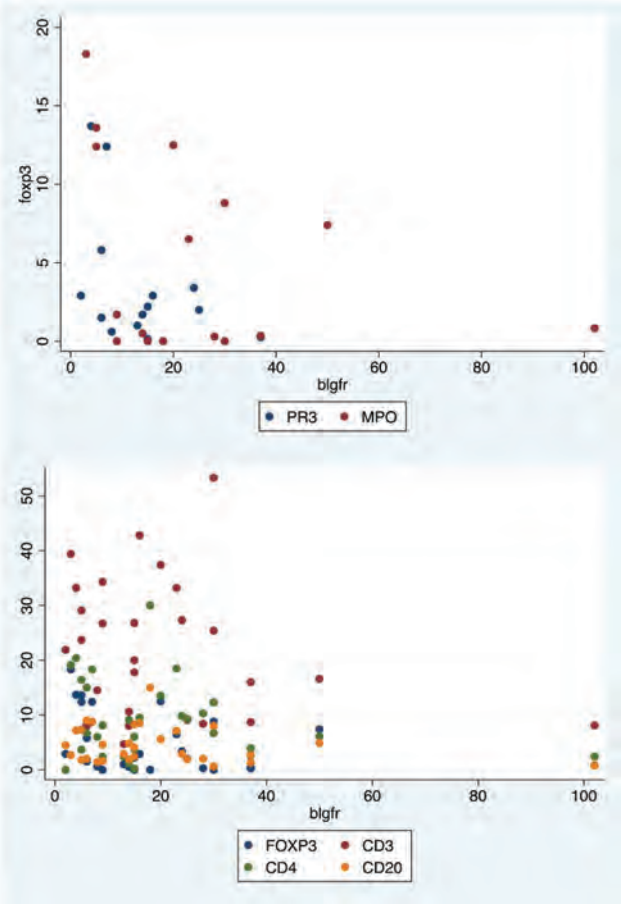
Sam Kant,[1,3] Lois J. Arend,[3] Eric J. Gapud,[4] Duvuru Geetha.[2] *[1]University of Maryland, Baltimore, MD; [2]John Hopkins Bayview Medical Center, Baltimore, MD; [3]Johns Hopkins Hospital, Baltimore, MD; [4]Johns Hopkins School of Medicine, Baltimore, MD.*

Background: B %T cells have a pathogenic role in ANCA associated vasculitis. There are differences in renal outcome based on ANCA type, therefore, we sought to characterize the interstitial lymphocytic infiltrate in ANCA GN to determine differences in relation to ANCA type and entry GFR.

Methods: Renal biopsies of patients with ANCA GN were stained for CD3, CD4, CD20, C4d and FOXP3. The percentage of cortical interstitium containing positive cells was determined by light microscopy. Demographics, ANCA type and entry eGFR were recorded. The level of staining was compared between ANCA type and entry eGFR using Wilcoxon rank sum test.

Results: Renal biopsies of 16 patients with MPO and 14 with PR3 ANCA GN were studied. CD3 cells were the predominant cells, with CD4 and FOXP3 staining positive in all biopsies. C4d staining was negative in all biopsies. There was no significant difference in staining between MPO and PR3 groups. However, regardless of ANCA type, FOXP3 staining was significantly higher in patients with baseline GFR<10 compared with GFR>10 (mean 7.54, SD 6.6 versus mean 2.67, SD 3.6; p=0.04). Image 1 demonstrates scatter plots of mean percentage of interstitial staining for markers and entry GFR(blgfr) in MPO and PR3 subsets.

Conclusions: These data confirm the role of CD4 cells in ANCA GN and demonstrate no differences in interstitial T and B cell infiltrates between PR3 and MPO ANCA GN. A higher FOXP3 signal suggests a role for regulatory T cells and merits further characterization of CD4 T cell subset.



SA-PO414

Urinary CD11b and CD163 Reflect Clinical and Histological Disease Activity in Renal Involvement of Anti-Neutrophil Cytoplasmic Antibody-Associated Vasculitides

Yuki Yokoe, Naotake Tsuboi, Shoichi Maruyama. *Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Glomerular leukocyte infiltration on histology reflects the renal inflammation in various forms of glomerulonephritis. Especially glomerular crescent formation, evidenced with robust extracapillary leukocyte and epithelial cell proliferation at the active stage, often present on glomerulonephritis complicated with anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV), has been proposed as a significant indicator of the disease activity and prognosis. Both cell surface molecules of CD11b, an α subunit of leukocyte integrin Mac-1 expressed on neutrophils and monocytes/macrophages, and of CD163, a scavenger receptor expressed on macrophages, have been demonstrated their cleavage from leukocyte upon inflammation-related cell activation. In the present study, we investigated the clinical significance of urinary CD11b (U-CD11b) and CD163 (U-CD163) as potential biomarkers for AAV.

Methods: We measured U-CD11b and U-CD163 by ELISA in AAV patient samples from the institutional (N-KDR; 61 patients at the diagnosis) and Japanese nation-wide (RemIT-JAV-RPGN; 138 at the diagnosis and 56 patients after 6 months treatment) cohorts, and evaluated those associations with clinical and histological parameters.

Results: Both U-CD11b and U-CD163 significantly correlated with renal score of Birmingham Vasculitis Activity Score (BVAS), and were particularly elevated in AAV patients classified in crescentic category by European Vasculitis Study Group (EUVAS) evaluation. Histological analysis for leukocyte profiles demonstrated significant association of U-CD11b levels with glomerular $CD11b^+$ cell numbers both in endo- and extra-capillary. On the other hand, U-CD163 reflected glomerular $CD163^+$ cells in extra-capillary. Significant reduction of U-CD163 (U-CD163; p<0.001, U-CD11b; p=0.26) was observed in identical AAV patients at 6 months following by the remission induction therapy.

Conclusions: U-CD11b and U-CD163 reflect clinical and histological disease activity of AAV renal manifestations, in particular glomerular crescentic formation. Moreover, these two biomarkers can respectively associate with the glomerular infiltrates of different leukocyte subsets in endo- and extra- capillary. U-CD163 may superior to U-CD11b for the evaluation of therapeutic efficacy in clinical settings.

Molecular Risk Prediction in ANCA-Associated Crescentic Glomerulonephritis: Added Value over Clinical and Histologic Parameters

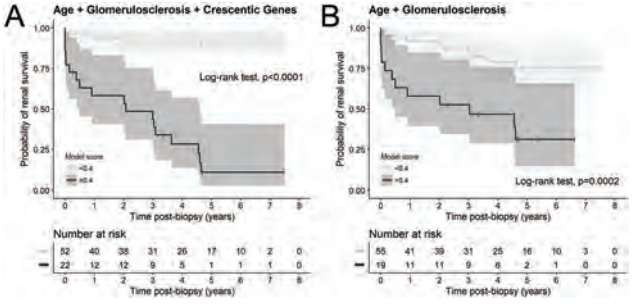
Benjamin A. Adam, Kristalee Watson, Peter Dromparis, Ainslie M. Hildebrand, Michael Mengel. *University of Alberta, Edmonton, AB, Canada.*

Background: Novel molecular tools have the potential to improve current clinical and histology-based risk classification systems for ANCA-associated crescentic glomerulonephritis (GN). We aimed to assess the utility of gene expression for improving biopsy-based risk prediction in these patients.

Methods: NanoString was used to measure the expression of 54 previously-described inflammation, nephron injury and crescent-related genes in 74 archival, formalin-fixed paraffin-embedded (FFPE) native kidney biopsies with ANCA-associated crescentic GN. Corresponding clinical and histologic data were retrieved. Multivariate Cox proportional hazards regression was used to identify the clinical, histologic and gene expression variables independently predictive of end-stage renal disease (ESRD). Receiver operating characteristic (ROC) curve, net reclassification index (NRI) and integrated discrimination improvement (IDI) analyses were used to compare full and reduced logistic regression models composed of the independently predictive variables. Kaplan-Meier renal survival curves were used to further assess differences in model performance. Data analysis was performed using nSolver and R.

Results: Multivariate Cox analysis demonstrated lower patient age (p=0.002), higher percentage global glomerulosclerosis (p=0.003) and higher expression of crescent-related genes (p<0.001) to be independently predictive of ESRD. Comparison of logistic regression models demonstrated that adding crescentic gene expression to age and global glomerulosclerosis significantly improved the prediction of ESRD versus age and global glomerulosclerosis alone (AUC 85.1 vs. 71.9, respectively, p=0.023; continuous NRI 94.1%, p<0.001; IDI 17.3%, p=0.001). Kaplan-Meier renal survival curves further demonstrated improved model performance with the addition of crescentic gene expression (Figure 1).

Conclusions: Adding FFPE-derived gene expression to existing clinical and histologic parameters improves the prediction of ESRD in ANCA-associated crescentic GN.



SA-PO416

Soluble CD163 Differentiates Active Vasculitis and Lupus Nephritis from Inactive Disease

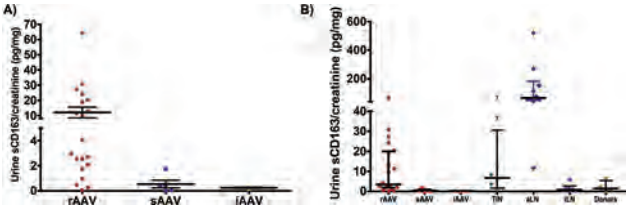
Daniel A. Amador, Juan M. Mejia-Vilet, Cristinoc Cruz, Ricardo Correa-Rotter, Jose A. Nino-Cruz. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico.*

Background: Urine soluble CD163 (sCD163) is an enzymatically cleaved form of CD163 that has been described to discriminate active from inactive renal ANCA-associated vasculitis (rAAV) with 71-87% sensitivity and >97% specificity. sCD163 has also been reported to be elevated in active lupus nephritis (aLN).

Methods: The aim of the study was to evaluate urine sCD163 in patients with rAAV (n=20), systemically-active AAV without renal vasculitis (sAAV, n=5), inactive AAV (iAAV, n=4), aLN (n=10), clinically-inactive LN (iLN,n=5), and living-kidney donors (KD,n=5). To explore other diseases that may increase urine sCD163 we also evaluated patients with tubulointerstitial nephritis including tuberculous TIN (n=3) and IgG4 TIN (n=2).

Results: Median BVAS score was 19 (14-23), 7 (5-18) and 0(0-0) in rAAV, sAAV and iAAV respectively. Renal BVAS was 12 (10-12) in rAAV and 0 in both sAAV and iAAV. aLN patients had a median NIH activity score of 11 (10-12) and chronicity score of 4 (3-5). M edian urine sCD163 titers were 3.5ng/mg (1.8-20.0) in rAAV, 0.4ng/mg (0.03-1.1) in sAAV, and 0.2ng/mg (0.1-0.3) in iAAV (Figure 1A). The AUC was 0.919 to differentiate rAAV from non-renal AAV (p<0.001). With a cutoff>1.75ng/mg the sensitivity was 80% and specificity 100%. Median urine sCD163 was 66.3ng/mg (52.0-182.0) in aLN compared to 1.0ng/mg (0.3-3.8) in iLN with 100% sensitivity and specificity to differentiate between both groups (Figure 1B). Tuberculous TIN and IgG4 TIN had urine sCD163 values >3.0ng/mg.

Conclusions: Urine sCD163 is a good biomarker to differentiate both active renal AAV and active LN from inactive disease. Nevertheless, urine sCD163 titers were highest in aLN. This molecule can be also elevated in other diseases such as granulomatous and IgG4 TIN. Its use as biomarker should be further explored in longitudinal cohorts.



SA-PO417

The Association Between Lymphocyte Counts and Risk of Relapse and Risk of Serious Infection in Patients with ANCA-Associated Vasculitis

Lonnie Pyne,[1] Michael Walsh,[1] Kathleen Quinn,[2] Nader A. Khalidi,[1] Laila Alharbi.[3] *[1]McMaster University, Hamilton, ON, Canada; [2]Western University, London, ON, Canada; [3]macmaster university, Hamilton, ON, Canada.*

Background: Patients with anti-neutrophil cytoplasm antibody (ANCA) associated vasculitis (AAV) commonly have relapses of their disease and/or infections. Lymphocyte counts may represent both a biomarker of adequate immunosuppressive treatment and an increased risk of infection. We assessed the association between lymphocytes counts and both infection and relapse in patients with AAV.

Methods: We conducted a single centre, retrospective review of patients with known AAV and abstracted patient characteristics at the time of relapse requiring immunosuppressive treatment up to 24 months after relapse. We assessed the relationship between lymphocyte counts and the outcomes of relapse and infection using multi-level logistic regression in which laboratory data including lymphocyte counts were treated as time-varying. All models were adjusted for age, neutropenia, need for dialysis and type of ANCA.

Results: We identified 158 patients of which 149 had useable data. During the follow-up period there were 87 relapses in 59 patients and 39 infections requiring antibiotics in 26 patients. Lymphocyte counts $<0.05 \times 10^9$ were not significantly associated with relapse (odds ratio 1.02, 95% confidence interval 0.26 to 3.98). Lymphocyte counts $<0.5 \times 10^9$ were independently associated with infection (odds ratio 7.00, 95% confidence interval 2.77 to 17.7).

Conclusions: Lymphopenia appeared more strongly associated with infection than it was protective of relapse. These data suggest inducing lymphopenia may cause more harm than benefit in patients with AAV.

SA-PO418

ANCA-Associated Vasculitis Through the Continuum of Age: A Retrospective Chart Review

Mandeep S. Gill,[1] Bharat Kumar,[2] Jennifer Strouse,[1] Melissa L. Swee,[1] Manish Suneja.[3] *[1]University of Iowa, Iowa City, IA; [2]University of Iowa Hospitals and Clinics, Iowa City, IA; [3]The University of Iowa, Iowa City, IA.*

Background: ANCA-associated vasculitis (AAV) is a heterogenous group of small-vessel vasculitides that typically affects the kidneys, respiratory tract, and other organ systems. The onset of AAV may occur at any age, although literature suggests that this is more common in the elderly. We aim to characterize the clinical and laboratory manifestations of AAV based on age of onset in pediatric and adult patients younger than 35 years, compared to other age groups.

Methods: We performed a retrospective chart review of all patients with positive MPO or PR3 lab results by ELISA and a diagnosis of vasculitis from 2000 to 2017. Patients were classified into four groups according to age and divided into two groups each depending on MPO or PR3 serotypes. These features were compared to one another through descriptive statistics, as noted in table 1.

Results: 141 patients were identified based on the inclusion criteria, of which 31 were below the age of 35. The majority of patients were white females. Upper respiratory tract involvement and arthritis were much more common in the pediatric and adults younger than 35. PR3 was also more frequent in this group as well. Renal and lower respiratory involvement were comparable between the age groups.

Conclusions: Onset of AAV in young adulthood has distinct characteristics that more closely resemble pediatric AAV than compared to their older counterparts. Prior literature demonstrates a much higher percentage of extra-renal, extra-respiratory involvement in the pediatric population, which is consistent in our sample as well. Further analysis on clinical presentation, prognosis and treatment outcomes are forthcoming.

	Age < 18		18 < Age <35		35≤Age<65		Age≥65	
	MPO	PR3	MPO	PR3	MPO	PR3	MPO	PR3
Total Number	7	6	4	14	36	31	26	17
Female	6	4	3	6	20	14	18	7

SA-PO419

ANCA-Associated Vasculitis in a Predominantly Hispanic Population in the Western United States

Yan Zhong,[1] Nina Petrosyan,[2] Philip M. Carpenter,[3] Li Ding,[3] Becky M. O'Neal, C-TAGME,[4] Hui Yi Shan.[4] *[1]LAC USC Medical Center, Los Angeles, CA; [2]Keck School of Medicine, Los Angeles, CA; [3]University of Southern California, Los Angeles, CA; [4]University of Southern California/LAC+USC Medical Center, Los Angeles, CA.*

Background: ANCA-associated vasculitis (AAV) is a group of rare systemic autoimmune diseases with significant geographic and ethnic differences in disease prevalence and severity. Both environmental factors and genetic susceptibility are thought to contribute to such differences. Most published data thus far have been collected from Caucasian and Asian patients. The aim of this study is to characterize the features of AAV in a specific cohort of patients, predominately of Mexican descent, who reside in the Western United States.

Methods: A retrospective review of all native kidney biopsies for patients above age of 18 years old that were performed at the Los Angeles County University of Southern California Hospital from 2008-2018 was done. 43 patients with AAV were identified. Based on pathology results, we classified these patients into focal, crescentic, mixed and sclerotic subtypes.

Results: Among the 43 patients, 38 were Hispanic and 20 of which were from Mexico. The mean age at diagnosis was 49.8 years old. Patients' median serum creatinine on presentation was 2.4 mg/dl. 17 patients (39.5%) had kidney involvement alone, 5 patients (11.6%) with kidney and nasopharyngeal, 13 (30.2%) with kidney and lung, and 8 (18.6%) with kidney, lung and nasopharyngeal involvement. 30 patients (73.2%) were myeloperoxidase (MPO) positive and 10 (24.4%) were proteinase (PR3) positive. One patient was both MPO and PR3 positive. Pathological classification revealed 15 focal, 11 crescentic, 8 mixed, and 9 sclerotic subtypes. The majority (83%) of the patients received steroids with rituximab or steroids with cyclophosphamide. At 1 year of follow up, 7 (16.3%) patients relapsed, 12 (27.9%) patients had ESRD, and 4 (9.3%) patients died.

Conclusions: Our study showed that this predominately Mexican-American cohort residing in the Western United States from 2008-2018 presented with AAV at younger age and had worse 1-year renal survival as compared to data published on Asian and Caucasian populations. In addition, kidney involvement and MPO positivity dominated this cohort.

SA-PO420

Risk Factors for Progression to ESRD in Patients with ANCA Associated Vasculitis - Experiences from a Chinese Single Center

Ying Xu,[1] Fei Han,[2] Jianghua Chen.[3] *[1]The kidney disease center, The first affiliated hospital, College of Medicine, Zhejiang University, Hangzhou, China; [2]First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China; [3]The Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China.*

Background: Although ANCA associated vasculitis (AAV) is not a common disease, AAV renal damage is the leading rapidly progressive glomerulonephritis leading to end-stage renal disease (ESRD). If we can screen out the risk factors for progression to ESRD, it will be valuable for the treatment.

Methods: 498 AAV patients diagnosed from October 23, 1999 to February 15, 2017 were enrolled, the latest follow up date was February 21, 2018. The general conditions, clinical manifestations, laboratory investigations, renal biopsy results, treatment regimens and prognosis (renal/patient survival) were analyzed.

Results: Among the 498 cases, there were 283 females and 215 males. The average onset age was 60.9±14.5 years old (10-90). MPO-AAV was more than PR3-AAV (91% vs 9%). 486 patients (97.6%) had renal impairment. 216 patients (44.4%) received renal biopsy. 54 patients (11.1%) received dialysis at the onset and 11 of them get rid of dialysis. Apart from 56 patients (11.2%) lost to follow up and 53 patients (10.6%) died, we divided patients to ESRD group (n=145) and Stable group (n=302). We compared the baseline data of the two groups (age, sex, onset to diagnosis time, clinical presentation, BVAS score and lab investigation) and treatment regimen (whether plasma replacement, whether or not glucocorticoid pulse therapy). The results showed that the parameters associated with the progression of the patients to ESRD included the type of vasculitis (P=0.016), the combination of hypertension (P<0.001), the combination of fever (P=0.048), hemoglobin level, platelet level, 24-hour proteinuria, serum creatinine level, eGFR level and the need for dialysis (P<0.001). Multiple factor Cox regression analysis showed that daily urine protein (3.21±2.46 vs 1.71±1.61g, 95% CI 0.67-0.99, P=0.041) and eGFR level (9.25±6.10 vs 44.37±40.76ml/min, 95% CI 1.018-1.159, P=0.013) were independent risk factors for the patient's progression to ESRD.

Conclusions: The prognosis of renal function was poor in patients with heavier proteinuria or lower eGFR level. Due to the low rate of renal biopsy, we found that the segmental crescentic ratio and fibrinous necrosis were associated with deterioration of renal function, but not independent risk factors.

SA-PO421

The Antineutrophil Cytoplasmic Antibody–Associated Vasculitides Concomitant with IgG4-Related Disease: A Case Series

Fei Han. *First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China.*

Background: Antineutrophil cytoplasmic antibodies (ANCA)-associated vasculitides (AAV) and IgG4-related disease (IgG4-RD) have similarities in clinical characteristics and histopathological features. Concomitance of these two diseases have been reported previously.

Methods: We compared the characteristics of AAV patients, IgG4-RD patients and concomitant AAV and IgG4-RD patients in our center. One hundred and sixty-nine AAV patients, 58 IgG4-related disease patients and 8 concomitant patients were included. The serum IgG subclasses of MPO-ANCA were measured.

Results: The patients in concomitant group had both elevated serum IgG4 level and positive ANCA. They had lower levels of hemoglobin, serum albumin, glomerular filtration rate and higher levels of platelet, serum creatinine, erythrocyte sedimentation rate and C-reactive protein compared with IgG4-RD group. Their involved organs were mainly kidney (100%), lung (62.5%) and lacrimal glands (62.5%). They had higher serum globulin level and even lower serum albumin level than patients with AAV. Six renal biopsies were performed in concomitant group. They achieved remission with improved renal function, one patient was on maintained dialysis and one patient died of acute gastric perforation. The IgG4 subclass of MPO-ANCA was higher in concomitant group than in AAV group (OD450 value 12.42±6.63 vs 3.03±3.67, P=0.017), whereas the other three subclasses (IgG1, IgG2 and IgG3) of MPO-ANCA were parallel between these groups.

Conclusions: We showed a new overlap syndrome of AAV and IgG4-RD, and the IgG4 subclass of ANCA may be a pathogenic factor in this concomitant disease. Besides, we suggested the concomitant patients be treated as AAV, as they were more likely to show the clinical features of AAV.

A Cohort Study to Assess the Role of Sensitivity C-Reactive Protein Level in the Evaluation of Activity and Prognosis of Microscopic Polyangiitis

Bin Zhu. *Hangzhou Hospital of Chinese Medicine, Hangzhou, China.*

Background: To investigate the role of high-sensitive C-reactive protein(hs-CRP) level for the evaluation of activity and prognosis of microscopic polyangiitis(MPA).

Methods: A total of 149 patients with MPA were enrolled from June 23rd, 2008 to January 20th, 2017. We collected demographic characteristics, biochemical parameters and pathological changes. These patients were divided into high hs-CRP group and low hs-CRP group at the cutpoint of 7.05 of the median of hs-CRP of these patients to compare the clinical features and prognosis between these two groups. A Kaplan–Meier survival analysis was performed to compare the survival rate using a log-rank test. Cox proportional hazards models were used to evaluate the association between hs-CRP levels and outcomes.

Results: The patients with crescentic type in the high hs-CRP group was significantly higher than that in the low hs-CRP group. The patients with sclerotic type was lower than that in the low hs-CRP group. The cases to reach the primary outcome (death, renal replacement therapy) in the hs-CRP group were significantly higher than that in the low hs-CRP group(Figure 1). A high level of hs-CRP(HR: 3.11, 95% CI: 1.10 to 8.80) and renal interstitial infiltrates(HR: 2.94, 95% CI: 1.14 to 7.58) were independent risk factors for the progression of microscopic polyangiitis by a multivariable COX regression analysis.

Conclusions: Baseline serum hs-CRP level was a risk factor for the progression of microscopic polyangiitis, indicating that serum hs-CRP could be adopted as a clinical parameter for the evaluation of microscopic polyangiitis.

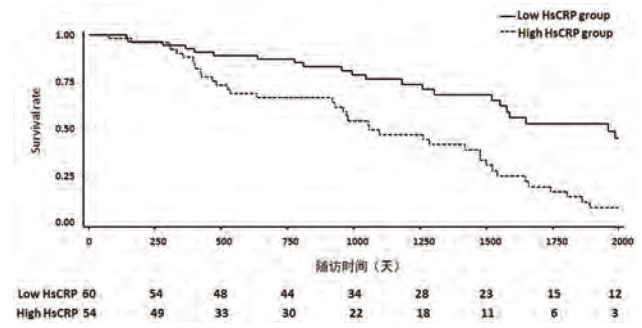

Figure 1. The patients survival rate in the high hs-CRP group was worse than that in the low hs-CRP group.

Biomarkers of Complement Activity in C3 Glomerulopathy Patients

Andrew S. Bomback,[1] Byum hee Kil,[1] Amanda Luu,[3] Yongsen Zhao,[4] Manuel D. Galvan,[3] Jane A. Thanassi,[3] Hetal S. Kocinsky,[3] Steven D. Podos,[5] Wengang Yang,[3] Mingjun Huang,[6] Gerald B. Appel.[2] *[1]Columbia University, New York, NY; [2]Columbia University College of Physicians and Surgeons, Scarsdale, NY; [3]Achillion Pharmaceuticals, New Haven, CT; [4]Achillion Pharmaceuticals, Inc., New Haven, CT; [5]Achillion Pharmaceutical, Inc., New Haven, CT; [6]Achillion Pharmacueticals, New Haven, CT.*

Background: C3 glomerulopathies (C3G) are characterized by isolated or dominant glomerular C3 staining on immunofluorescence that implies an etiology rooted in dysregulation of the alternative complement pathway. To date, no biomarkers for disease activity have reliably predicted outcomes in C3G.

Methods: We measured circulating factor D, factor B, Ba, Bb, plasma and serum C3, and C3a as potential biomarkers of complement activity in a group of C3G patients with longitudinal outcome data. The primary outcome combined doubling of creatinine, progression to CKD stage 5, ESRD, transplantation, or death. The secondary outcome was remission, defined as stable creatinine with >50% reduction in proteinuria to subnephrotic range.

Results: We compiled a biomarker profile on 38 C3G patients (25 with C3 glomerulonephritis and 13 with dense deposit disease) with a mean follow-up of 62 months from diagnosis to last encounter. Factor D levels were low in 50% of patients, factor B levels were low in 21% of patients, plasma C3 levels were low in 53% of patients, and serum C3 levels were low in 42%. Factor B split products, Ba and Bb, were elevated in 66% and 55% of patients, respectively, while C3a was elevated in 61% of patients. Seven patients reached late or end stage kidney disease. In univariate analyses, Ba (p=0.002) and Bb (p=0.03) levels, but not C3a levels (p=0.2), emerged as predictors for the primary outcome. Plasma (p=0.04) but not serum (p=0.2) levels of C3 were also predictive of progression. Seventeen patients achieved disease remission, but no biomarker was predictive of this outcome.

Conclusions: Elevated levels of the factor B split products (Ba and Bb), which denote newly formed C3 convertase of the alternative pathway, are associated with progression of C3G to advanced and end stage kidney disease. These biomarkers may help risk-stratify newly diagnosed C3G patients and present a treatment target for disease.

Evaluation of Urine Complement Biomarker in C3G Following ΔΔComplement Alternative Pathway Inhibition with ACH-4471

Manuel D. Galvan,[1] Jane A. Thanassi,[1] Dharaben Patel,[1] Steven D. Podos,[1] Amanda Luu,[1] Guangwei Yang,[1] Yongsen Zhao,[1] Hetal S. Kocinsky,[2] Catherine L. Kelleher,[2] Michael Geffner,[2] Thomas D. Barbour,[3] Wengang Yang,[1] Mingjun Huang.[1] *[1]Complement Biology, Achillion Pharmaceuticals, Inc., New Haven, CT; [2]Clinical Development, Achillion Pharmaceuticals, Inc., New Haven, CT; [3]Medicine, Royal Melbourne Hospital, Parkville, VIC, Australia.*

Background: C3 glomerulopathy (C3G) is a rare disease of complement alternative pathway (AP) dysregulation that is characterized by glomerular C3 fragment accumulation, progressive kidney damage, and proteinuria. Preliminary data from an ongoing 14-day proof-of mechanism clinical trial provided evidence that ACH-4471, an oral AP-specific inhibitor that blocks complement factor D (CFD) function, can reverse the systemic AP hyperactivation and reduce the proteinuria in C3G patients. Although complement biomarkers in blood are valuable for assessing systemic AP activation, their levels in urine may provide additional information about AP activation in the kidney. Here, we report a comparative evaluation of systemic and urinary AP biomarkers in C3G patients enrolled in the aforementioned clinical study of ACH-4471.

Methods: Urine and blood samples were collected from patients at protocol-specified timepoints prior to, during, and after dosing with ACH-4471. Complement biomarkers including the proximal and terminal complement activation products, Ba and sC5b-9, were measured in serum or plasma and in urine samples. Serum, plasma, and urine from non-study healthy volunteers served as control samples. Urinary levels of complement products were normalized to urinary creatinine levels and are denoted as "/Cr".

Results: Urinary Ba/Cr and/or sC5b-9/Cr levels at baseline were significantly higher in patients than in healthy controls, even though plasma Ba and sC5b-9 levels were not always above normal. Following dosing with ACH-4471, urinary Ba/Cr and/or sC5b-9/Cr levels were significantly decreased, often to a greater extent than the levels of plasma Ba and sC5b-9. Lastly, the reductions in urinary Ba/Cr and sC5b-9/Cr levels during treatment were independent of the accompanying reduction in proteinuria, as indicated by the comparable reductions observed when urinary Ba and sC5b-9 levels were normalized to urinary albumin.

Conclusions: Our findings suggest that complement proteins in urine may serve as additional biomarkers for understanding C3G pathology and predicting responsiveness to ACH-4471.

C3 Glomerulopathy: Clinical Determinants of Prognosis and Response to Immunosuppression

Fernando Caravaca-Fontan,[1] Teresa Cavero escribano,[2] Elena Goicoechea de jorge,[3] Manuel Praga.[2] on behalf of GLOSEN group *[1]Nephrology, Hospital Universitario 12 de Octubre, Madrid, Spain; [2]Nephrology, Hospital Universitario 12 de Octubre, Madrid, Spain; [3]Complutense University Madrid, Madrid, Spain.*

Background: C3 glomerulopathy (C3G) is a clinicopathological entity secondary to a dysregulation of the alternative complement pathway. Despite significant advances in our understanding of the pathophysiology of this disease, less is known about its prognostic determinants.

Methods: Retrospective, observational study in 28 hospitals belonging to GLOSEN group. All patients fulfilling diagnostic criteria of C3G were included. Clinical, biochemical and histologic parameters of prognostic interest were recorded to analyze the main determinants of disease progression and response to different therapeutic regimens.

Results: The study group consisted of 104 patients: 90 C3 glomerulonephritis (C3GN) and 14 dense deposit disease (DDD). 17% were diagnosed during pediatric age, 49% between 18-50 years, and 34% above 50 years. A monoclonal gammopathy of unknown significance was observed in 16% of patients. The most common presentation in pediatric age was nephrotic syndrome, whereas acute kidney injury and isolated urinary abnormalities were the most frequent clinical findings in adults. Membranoproliferative glomerulonephritis was the most predominant pattern of injury, with C3 only deposition in 49% of cases. In a median follow-up of 48 months [IQR:18–100], 45 patients (43%) achieved remission (partial or complete). Treatment with steroids and mycophenolate mofetil was associated with significant improvement in renal survival compared to other treatments or conservative management. During the follow-up period, 45 patients (43%) developed end-stage renal disease (ESRD). By Cox regression analysis, the main determinants of ESRD were: age (HR: 1.026;C.I.95%: 1.008–1.044; p=0.004), serum creatinine at diagnosis (HR: 1.213;C.I.95%: 1.115–1.318;p<0.0001), and degree of interstitial fibrosis and tubular atrophy (HR: 1.891;C.I.95%: 1.384–2.582;p<0.0001). No differences were found between C3GN and DDD. Twenty-five patients (24%) underwent kidney transplantation, 14 of which (56%) had disease recurrence after a median follow-up of 12 months [3–107].

Conclusions: C3G is associated with poor renal outcome in a substantial percentage of patients. Steroids and mycophenolate were shown to be the most effective regimen to achieve remission. Older age, elevated serum creatinine and tubular atrophy/interstitial fibrosis were the main determinants of renal survival.

SA-PO426

Expression and Role of TET Proteins in Fetal Kidneys of Control and Nutrient-Restricted Rat Dams

Mariko Hida, Midori Awazu. *Keio University School of Medicine, Tokyo, Japan.*

Background: The ten-eleven translocation (TET) proteins are enzymes that oxidize 5-methylcytosine to 5-hydroxymethylcytosine and regulate DNA methylation and hydroxymethylation, which are important epigenetic modifications in fetal programming. We previously reported that inhibition of DNA methylation reduces ureteric branching and kidney growth in organ culture (ASN 2015). We also showed that kidneys of offspring of nutrient-restricted rat dams were characterized by reduction in global DNA methylation, ureteric branching, and kidney size. In the present study, we examined global DNA hydroxymethylation and the expression of TET proteins in fetal kidneys of control (CON) and nutrient-restricted (NR) rat dams. The role of TET proteins was further examined in organ culture.

Methods: NR rats were subjected to 50% food restriction throughout pregnancy. Expression of TET1, 2, and 3 was analyzed by immunoblot in the kidney of embryonic day 18 (E18). Global DNA hydroxymethylation was quantified by ELISA. In organ culture, E13 to E14 metanephroi were cultured for 2 to 3 days in the presence or absence of ascorbic acid that facilitates TET enzyme activity, or dimethyloxallyl glycine (DMOG), a small-molecule inhibitor of TET.

Results: TET1, 2, and 3 were expressed in the E18 kidney and their expression was increased in NR compared with CON. Global DNA hydroxymethylation was also increased in NR compared with CON by 1.5-fold. Metanephroi cultured with ascorbic acid 0.1 mg/mL had significantly fewer ureteric bud tips (6.5±0.3 vs 9.0±0.3 per kidney) with no difference in kidney size (6.1±0.4 vs 6.1±0.5 arbitrary units) compared with those cultured with vehicle. DMOG 1 mM, on the other hand, significantly decreased both ureteric bud tip number (3.0±0.6 vs 9.7±1.7 per kidney) and kidney size (1.1±0.1 vs 1.9±0.2 arbitrary units). The effect of DMOG was similar in metanephroi cultured from nutrient-restricted dams. Thus ureteric tip number (2.7±0.3 vs 8.0±1.2 per kidney) and kidney size (1.2±0.1 vs 1.9±0.2 arbitrary units) were significantly decreased by DMOG.

Conclusions: TET proteins are expressed in fetal kidney with increased levels in NR, which is characterized by higher global DNA hydroxymethylation. Both stimulation and inhibition of TET disturb normal kidney development. Whether TET proteins regulate kidney development through DNA methylation and or hydroxymethylation needs to be investigated.

Spatiotemporal Patterning of Intrarenal Urothelium During Embryogenesis

Monica L. Hoff,[1,2] Claudia F. Mosley,[2] Kirk M. McHugh,[1,2] Brian Becknell,[1] Ashley R. Jackson.[1] *[1]Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University, Columbus, OH.*

Background: Congenital urinary tract obstruction (UTO) is a leading cause of chronic kidney disease in children. Intrarenal urothelial remodeling occurs prior to parenchymal injury, and formation of a protective uroplakin (Upk) plaque is a key feature of UTO remodeling. Little is known about progenitor-progeny relationships within the renal urothelium during development, precluding efforts to promote adaptive urothelial remodeling during UTO.

Methods: Krt5$^+$, Krt7$^+$, Krt14$^+$, p63$^+$, and Upk$^+$ renal urothelial cells (RUCs) were localized at embryonic days (E)15-E18. EdU (thymidine analogue) was used to identify stage-specific proliferation indices. Krt7$^+$ was used to establish total RUC counts. Renal urothelial thickness was measured at each stage. *Krt5^{CreERT2}* and *Upk2^{CreERT2}* lines were used to indelibly label Krt5$^+$ or Upk2$^+$ cells and their daughters at E16.

Results: Renal urothelial thickness decreased from E15-E18, and demonstrated heterogeneous expression patterns in renal papilla, fornix and pelvis. Rare, discrete Upk$^+$ RUCs were first observed at E16 and formed a nearly contiguous apical lining by E18. Basal Krt5$^+$ RUCs were first identified at E17. Krt14$^+$ RUCs were robustly expressed at E17-E18. p63$^+$ RUCs were observed in basal renal urothelium beginning at E16, commonly localized to Krt5$^+$ RUCs at E17. Proliferation peaked at E15 and EdU co-localized more commonly to Krt5$^+$ rather than Upk$^+$ RUCs.

Conclusions: Renal urothelium thinned as RUC specification occurred. The identification of Upk$^+$ RUCs at E16 coincides with the initiation of urine production. The appearance of Upk$^+$ prior to Krt5$^+$ RUCs indicates an earlier need for terminally differentiated characteristics, while co-localization of EdU to Krt5$^+$ RUCs suggests a developmental progenitor role. Lineage assays will determine progenitor-progeny relationships and establish model systems to evaluate candidate pathways utilized during UTO remodeling.

Transient Hydronephrosis in the Developing Kidney Leads to Long-Term Epigenetic Changes and Increased Susceptibility to Acute Renal Failure in Adulthood

Scott R. Manson,[1,2] Carlos AF Molina,[1,2] Paul Austin.[1,2] *[1]Pediatric Urology, Texas Children's Hospital, Houston, TX; [2]Urology, Baylor College of Medicine, Houston, TX.*

Background: The criteria for surgical intervention in patients with congenital urinary obstruction are poorly defined and little is known about the long-term effects of hydronephrosis in the developing kidney. In this study, we evaluated the impact of developmental context on disease progression, the need for intervention, and long-term susceptibility to kidney disease.

Methods: Disease progression was compared in murine models of unilateral ureteral obstruction (UUO) at P1 during nephrogenesis, P14 during the proliferative growth phase, and P60 at maturity. A reversible UUO model (rUUO) was used in neonates to assess the impact of intervention and its timing on long-term outcomes at maturity including growth and maturation, kidney function, and susceptibility to acute renal failure after unilateral ischemic injury (IR/Nx). Disease progression was evaluated by histological methods, functional assessment (serum BUN/Cre), and whole transcriptome analysis (RNA-seq).

Results: While UUO at P60 leads to inflammation and fibrosis, disease progression in neonates is instead characterized by profound developmental deficits. UUO at P1 triggers a 43.8% decrease in nephrogenesis and 35.2% decrease in kidney growth. UUO at P14 results in a 61.6% decrease in proliferation and 26.3% decrease in kidney growth. Impaired renal maturation is prevented by early intervention following rUUO at P14 but not P1 (Recovery/ P1 – 27.1%, P14 – 67.1%). Although mice subjected to rUUO at P14 had only minimal differences in kidney weight and function after 12 weeks of recovery, whole transcriptome analysis showed significant changes in the expression of 30.4% of all genes. Furthermore, when these mice were challenged with an IR/Nx protocol that typically has only moderate effects, they strikingly exhibited acute renal failure (SrCre: CON – 1.8, rUUO – 3.1) and low rates of survival (CON – 100.0%, rUUO – 12.5%). [All results are $p<0.05$]

Conclusions: This study reveals that developmental context has a significant impact on disease mechanisms, long-term outcomes, and treatment strategies. While deficits in nephrogenesis are irreversible, early intervention restores proliferative growth and kidney function. Continued monitoring is required even after recovery as the epigenetic signature remains altered and there is an elevated risk for kidney disease.

Terminal Differentiation of the Intrarenal Urothelium Attenuates Kidney Injury During Congenital and Acquired Urinary Tract Obstruction

Ashley R. Jackson,[1] Birong Li,[1] Shira H. Cohen,[2] Sudipti Gupta,[4] Christina B. Ching,[3] Kirk M. McHugh,[1] Brian Becknell.[1] *[1]Nationwide Children's Hospital, Columbus, OH; [2]The Research Institute at Nationwide Children's Hospital, Columbus, OH; [3]Nationwide Children's Hospital, Columbus, OH; [4]Nationwide Childrens Hospital, Columbus, OH.*

Background: Congenital urinary tract obstruction (UTO) is the leading cause of chronic kidney disease and end stage renal disease in children. Despite timely detection and surgical correction of the primary obstructive lesion, outcomes vary widely with regard to CKD progression. We hypothesized that remodeling of the intrarenal urothelium confers a protective adaptation during congenital and acquired UTO, by terminal differentiation and elaboration of a highly compliant uroplakin (Upk) plaque.

Methods: The Upk plaque was destabilized in a congenital model of functional lower UTO by generating *Mgb$^{-/-}$;Upk1b$^{-/-}$* mice. As an acute UTO model, unilateral ureteral obstruction (UUO) was induced in young adult *Upk1b$^{-/-}$* and wild type (WT) mice. Alternatively, diphtheria toxin (DT)-mediated depletion of Upk(+) cells was induced following UUO. Urine UPK2 and UPK3A levels were measured by ELISA in children undergoing pyeloplasty for ureteropelvic junction obstruction (UPJO) versus nonobstructed controls.

Results: During congenital and acquired UTO, progressive hydronephrosis triggers reorganization of the intrarenal urothelium, which elaborates a continuous Upk plaque. *Upk1b$^{-/-}$;Mgb$^{-/-}$* mice experience accelerated onset of bilateral hydronephrosis with severe (>67%) parenchymal loss, leading to renal failure and mortality in adolescence. *Upk1b* deletion or depletion of Upk$^+$ cells accelerate renal parenchymal loss following ureteral ligation, attesting to a conserved, stabilizing role for Upk plaque deposition in the acutely obstructed kidney. Lineage analysis demonstrates that UUO triggers a sequence of Upk plaque loss, proliferation, and reacquisition of the Upk plaque by Upk+ cells. Children with UPJO manifest higher urinary UPK protein levels than unobstructed controls.

Conclusions: These complementary experiments provide the first evidence that the Upk plaque confers an essential, protective adaptation to preserve renal parenchymal integrity during congenital and acquired urinary tract obstruction.

SA-PO430

Urinary NGAL as a Risk Factor for Recurrence of Febrile Urinary Tract Infection in Children

Sohsaku Yamanouchi, Takahisa Kimata, Yuko Akagawa, Shohei Akagawa, Shoji Tsuji, Kazunari Kaneko. Department of Pediatrics, Kansai Medical University *Kansai Medical University, Hirakata-shi, Japan.*

Background: Urinary neutrophil gelatinase-associated lipocalin (NGAL) has received attention recently as a sensitive biomarker of acute kidney injury. However, its ability to protect endogenously against urinary tract infection (UTI) is lesser known. That is, NGAL, which is expressed and secreted from activated neutrophils, acts as an iron chelator and antibacterial peptide that suppresses the growth of *Escherichia coli* and other bacteria. Purpose: To prove the hypothesis that reduced NGAL expression causes recurrence of febrile UTI (fUTI) in children.

Methods: The subjects were 45 children who were diagnosed as having fUTI and treated at our institution from 2012 to 2016 (median age, 1.5 years; 34 boys). We measured their urinary NGAL levels in the non-infected stage (at least 4 months since fUTI recovery). To examine risk factors for recurrence of fUTI, the subjects were divided into a non-recurrent group (24 cases) and a recurrent group (21 cases) according to the presence or absence of fUTI over 1 year. The following items were examined as risk factors: age, sex, presence or absence of grade III or higher vesicoureteral reflux (VUR; all cases received preventive antibiotics), presence or absence of renal scarring, and urinary biomarkers (NGAL and β2-microglobulin). The urinary biomarkers were corrected for creatinine (Cr) level.

Results: In a multiple logistic regression analysis, significant differences between the groups were not observed for age, sex, renal scarring, or β2-microglobulin/Cr level, while the recurrent group had significantly more cases with grade III or higher VUR ($p < 0.01$). Furthermore, the urinary NGAL/Cr in the recurrent group (median, 3.2 μg/gCr; interquartile range, 2.0–4.0 μg/gCr) was significantly lower than that in the non-recurrent

group (median, 16 μg/gCr; interquartile range, 11–20 μg/gCr; p = 0.016). We then created the ROC curve to examine the cut off value of NGAL for predicting recurrence of fUTI. In the area under the ROC curve, which was calculated for NAGL/Cr, was 0.86. Cut off value of 7.6 μg/gCr appeared to have the best predicting accuracy yielding a specificity of 81% and a sensitivity of 88%.

Conclusions: Reduced level of urinary NGAL, which functions to protect endogenously against UTI, is a risk factor of recurrence of fUTI and thus could serve as a biomarker.

SA-PO431

The Ribonuclease Inhibitor Regulates the Host Immune Response to Uropathogenic Escherichia coli

Hanna H. Cortado,[1] Sudipti Gupta,[2] Birong Li,[1] Ashley R. Jackson,[1] Christina B. Ching,[3] Brian Becknell.[1] *[1]Nationwide Children's Hospital, Columbus, OH; [2]Nationwide Childrens Hospital, Columbus, OH; [3]Nationwide Children's Hospital, Columbus, OH.*

Background: The Ribonuclease (RNase) A Superfamily encodes cationic antimicrobial peptides with bactericidal activity toward uropathogens. The endogenous RNase Inhibitor (RI) binds to RNases with femtomolar affinity and inhibits their antimicrobial activity. Here, we tested the hypothesis that RI serves a critical role in regulating the host innate immune response during experimental urinary tract infection (UTI).

Methods: We investigated RI expression in the urinary tract by immunofluorescence microscopy and evaluation of beta-galactosidase activity in RI^{LacZ} reporter mice. Using Cre/LoxP recombination, we deleted RI ubiquitously ($RI^{\Delta UBI}$) or selectively in urothelial cells ($RI^{\Delta URO}$) or leukocytes ($RI^{\Delta WBC}$) of adult mice. We transurethrally inoculated control and RI conditional knockout mice with uropathogenic *Escherichia coli* (UPEC) and enumerated bacterial burden in urinary tract tissues by homogenization and serial plating.

Results: We identified RI expression by bladder umbrella cells, renal collecting ducts, and phagocytes, all distinct sources of antimicrobial RNase secretion during UTI. Ubiquitous RI deletion led to rapid onset of erosive esophagitis and gastritis, resulting in profound weight loss and failure to thrive, precluding investigation of UTI susceptibility. $RI^{\Delta URO}$ mice were healthy and deletion of RI within umbrella cells did not lead to alterations in UPEC burden during experimental UTI. In contrast, $RI^{\Delta WBC}$ animals were protected from experimental UTI, with significantly reduced bladder UPEC burden, compared to controls.

Conclusions: RI is a negative regulator of the host leukocyte response to UPEC. Interfering with RI-RNase interactions represents a novel, rational approach to augment innate immunity during UTI.

SA-PO432

Ribonuclease 6 Protects the Kidney from Ascending Infection by Uropathogenic Escherichia coli

Hanna H. Cortado,[1] Sudipti Gupta,[2] Birong Li,[1] Ashley R. Jackson,[1] Christina B. Ching,[3] Brian Becknell.[1] *[1]Nationwide Children's Hospital, Columbus, OH; [2]Nationwide Childrens Hospital, Columbus, OH; [3]Nationwide Children's Hospital, Columbus, OH.*

Background: Ribonuclease 6 (RNase 6) is an evolutionarily-conserved antimicrobial peptide with potent bactericidal activity that is induced during urinary tract infection (UTI). Previously, we demonstrated that human and mouse RNase 6 kills uropathogenic *Escherichia coli* (UPEC) *in vitro* at low micromolar concentrations. Here, we investigated the hypothesis that RNase 6 serves an essential protective role in limiting ascending infection by UPEC *in vivo*.

Methods: We generated a $Rnase6^{EGFP}$ knock-in allele to (1) identify the cellular sources of RNase 6 in $Rnase6^{EGFP/+}$ mice; and (2) to determine the consequence of biallelic *Rnase6* deletion ($Rnase6^{EGFP/EGFP}$) on host susceptibility to experimental UTI. We evaluated EGFP fluorescence by flow cytometry and epifluorescence microscopy. We evaluated bactericidal activity and nitric oxide production by bone marrow-derived macrophages using gentamicin protection and fluorometric assays, respectively. We transurethrally inoculated $Rnase6^{EGFP/EGFP}$, $Rnase6^{EGFP/+}$, and control female mice with UPEC. We enumerated bacterial burden in urinary tract tissues by homogenization and serial plating.

Results: Flow cytometry in $Rnase6^{EGFP/+}$ mice reveals EGFP expression by circulating $Ly6C^{hi}$ monocytes which undergo maximal recruitment to the infected bladder by 6 hours post infection. In addition, we identified EGFP expression within resident macrophages of the bladder and kidney. In contrast, the *Rnase6* promoter is not active in renal or bladder epithelial cells. We confirmed *Rnase6* deletion in $Rnase6^{EGFP/EGFP}$ mice, which displayed normal urinary tract development, fertility, and hematopoiesis. *Rnase6* deficiency did not inhibit nitric oxide production or UPEC killing by bone marrow-derived macrophages. In contrast, *Rnase6* deficiency resulted in increased susceptibility to experimental UTI, with significantly higher UPEC burden throughout the urinary tract, compared to control mice.

Conclusions: Use of $Rnase6^{EGFP/+}$ mice offers a powerful approach to track cellular sources of RNase 6, as well as a means to screen compounds that regulate *Rnase6* promoter activity in the future. Use of $Rnase6^{EGFP/EGFP}$ mice confirms a critical role for RNase 6 in UPEC clearance *in vivo*.

SA-PO433

Dual Role for the Uroplakin Plaque in Establishment and Maintenance Phases of Urinary Tract Infection

Birong Li, Ashley R. Jackson, Brian Becknell. *Nationwide Children's Hospital, Columbus, OH.*

Background: Uropathogenic *Escherichia coli* (UPEC) account for up to 90% of human urinary tract infections (UTI). Specialized epithelial cells of the bladder produce glycosylated uroplakin (Upk) plaques, which bind to type I fimbriae of UPEC in a mannose-dependent manner. Here we evaluated the role and regulation of the Upk plaque during experimental UTI.

Methods: We established acute experimental UTI in 6-8 week old female $Upk1b^{-/-}$ and FVB/N mice by transurethral inoculation of UPEC or *Enterococcus faecalis*. Intracellular bacterial communities were detected based on β-galactosidase activity. Upk proteins were localized by immunohistochemistry, and plaque ultrastructure was visualized by transmission electron microscopy. Urothelial barrier function was evaluated on the basis of permeability to FITC-Dextran. We modeled chronic UTI by UPEC inoculation of 6-8 week old female C3H/HeOuJ mice.

Results: *Upk1b* deletion results in absent uroplakin plaque on the apical surface of bladder epithelial cells and increased permeability to FITC-Dextran. While intracellular bacterial communities were easily detectable in control urothelium, $Upk1b^{-/-}$ bladders lacked these intracellular reservoirs of UPEC entirely. Moreover, *Upk1b* loss led to reduced neutrophil infiltration of the bladder urothelium. Consistent with the failure of UPEC to invade the epithelium in the absence of the Upk plaque, $Upk1b^{-/-}$ mice exhibited reduced UPEC urinary tract colonization compared to controls ($p < 0.05$, Mann-Whitney U test). In contrast, Upk plaque loss did not impact the ability of *Enterococcus faecalis* to establish experimental UTI. When UTI were established in the chronic C3H/HeOuJ model, *Upk* mRNA and Upk protein levels decreased rapidly and remained suppressed for up to 4 weeks following infection.

Conclusions: Upk1b is critically required for Upk plaque assembly in superficial bladder epithelial cells. The Upk plaque initially facilitates UPEC invasion of the bladder, but this structure is dispensable for maintenance of infection, as chronic UTI results in downregulation of Upk plaque assembly at the mRNA and protein levels.

RNase 7 Shields the Kidney and Bladder from Uropathogens

Kristin Bender,[5] Tad Eichler,[2] Matthew J. Murtha,[3] Birong Li,[4] Brian Becknell,[4] John D. Spencer.[1] *[1]The Research Institute at Nationwide Children's, Columbus, OH; [2]The Research Institute at Nationwide Childrens Hospital, COLUMBUS, OH; [3]Ohio State University Hospital, Columbus, OH; [4]Nationwide Children's Hospital, Columbus, OH; [5]The Research Institute at Nationwide Children's Hospital, Columbus, OH.*

Background: In an era of multi-drug resistant pathogens, new therapies are needed to prevent urinary tract infections (UTI). Our laboratory identified Ribonuclease 7 (R7) as a human antimicrobial peptide that is secreted by the bladder urothelium and kidney's intercalated cells into the urine. Neutralization of R7's urinary antibacterial activity facilitates uropathogenic *Escherichia coli* (UPEC) replication. While R7 has potent bactericidal activity against UPEC, our understanding of its contributions to urothelial defenses is limited *in vivo* because its expression is absent in the laboratory mouse and restricted to humans/upper primates. Thus, we generated humanized transgenic R7 mice and assess R7's *in vivo* antimicrobial activity.

Methods: Using BAC-based recombineering, we integrated the human *RNASE7* gene into the mouse genome. BAC-R7 transcript and peptide expression was characterized in kidneys and bladders from R7 transgenic mice and littermate controls in states of health and after mice were transurethrally infected with UPEC. R7 cytotoxicity and its impact on murine immunity was evaluated with cytokine arrays, complete blood counts, serum chemistry, and histology. R7's antibacterial activity was evaluated by subjecting mice to experimental UTI. After infection, kidneys, bladders, and urine were collected and UPEC burden was quantitated.

Results: R7 transgenic mice had normal development, phenotypes, and urinary tract histology. R7 mRNA and peptide expression were detected in bladder and kidneys of transgenic mice. Immunostaining localized R7 production to the kidney's intercalated cells and the bladder urothelium, which mirrors human expression. R7 mice had normal renal function, cytokine profiles, and complete blood counts. After UTI, R7 transgenic mice had 2-3 fold lower urine, bladder, and kidney UPEC burden compared to littermate controls. Following UPEC inoculation, R7 mRNA and peptide expression increased in bladders and kidneys.

Conclusions: R7 expression in our transgenic humanized mice is similar to humans. R7 has limited cellular toxicity and does not impact basal murine immune function. Following experimental UTI, R7-expressing mice are significantly protected from UPEC. These studies provide the needed evidence that R7 has a key role in urothelial defense against UPEC and suggest that R7 may be an ideal candidate to develop as a new UTI therapy.

Fibroblast Growth Factor 23 Is Associated with Impaired Cognition in Children with CKD

Jennifer S. Yokoyama,[7] Mina Matsuda-Abedini,[2] Bradley A. Warady,[3] Susan L. Furth,[4] Stephen R. Hooper,[5] Anthony A. Portale,[6] Farzana Perwad.[1] *[1]Pediatrics, University of California San Francisco, San Francisco, CA; [2]The Hospital for Sick Children, Toronto, Toronto, ON, Canada; [3]Children's Mercy Kansas City, Kansas City, MO; [4]The Children's Hospital of Philadelphia, Philadelphia, PA; [5]University of North Carolina School of Medicine, Chapel Hill, NC; [6]University of California San Francisco, San Francisco, CA; [7]University of California, San Francisco, San Francisco, CA.*

Background: Plasma FGF23 concentrations increase early in the course of chronic kidney disease (CKD) in children and are a strong predictor of disease progression and left ventricular hypertrophy. High plasma FGF23 has been linked to cognitive dysfunction and cerebrovascular disease in adults with CKD. Whether FGF23 associates with impaired cognition in children is unknown.

Methods: In 538 children with CKD stages 2-4 enrolled in the Chronic Kidney Disease in Children (CKiD) study, we measured plasma C-terminal FGF23 and phosphorus and performed cognitive function tests of intelligence, academic achievement, and targeted executive functions. We used multivariate linear regression to analyze cross-sectional associations of baseline FGF23 and phosphorus concentrations with standardized cognitive test scores and cognitive risk (defined as a score ≥1 standard deviation (SD) below mean performance for age in healthy children), adjusting for age, sex, race, estimated GFR, proteinuria, blood pressure, and anemia.

Results: At baseline, median age was 12 [95% CI: 8.3, 15.2] years, eGFR was 54 [40.5, 67.8] ml/min/1.73 m^2, plasma FGF23 and phosphorus were 168 [78, 175] RU/ml and 4.2 [4, 4.9] mg/dl, respectively. In univariate analyses, higher tertiles of FGF23 were associated significantly with impaired test scores for errors of omission, a measure of attention regulation (p=0.002, 2-tailed Kruskal-Wallis rank test), and academic achievement (p=0.06). In fully adjusted analyses, we observed that each 50% increase in plasma FGF23 was associated with a 1 SD worsening of omission scores (β=2.07 [0.7-3.4], p=0.003). The percentage of children at risk for one or more cognitive deficits ranged from 18 to 32%. Furthermore, the cognitive risk for errors of omission was 14% higher in children in the highest compared to the lowest FGF23 tertile (p=0.01, 2-tailed chi-squared test). Plasma phosphorus, normalized for age, did not associate with cognitive test scores or cognitive risk.

Conclusions: In children with pre-dialysis CKD, higher baseline plasma FGF23 is associated with lower performance in targeted tests of executive function, specifically attention regulation, independent of GFR. These data suggest that high plasma FGF23 contributes to a greater risk for disorders of attention regulation as GFR declines.

SA-PO436

FGF23, Blood Pressure, and Urinary Sodium Handling in Young CKD Patients

Michael Freundlich,[1] Carlos Cuervo,[2,1] Carolyn L. Abitbol.[3] *[1]Pediatric Nephrology, University of Miami, Miami, FL; [2]university of miami/jackson memorial hospital, Miami, FL; [3]University of Miami/ Pediatric Nephrology, Miami, FL.*

Background: FGF23 has been associated with hypertension, partly attributed, to experimental observations describing FGF23-mediated enhanced Na reabsorption in the distal tubule, ↓natriuresis, volume expansion and hypertension. We examined whether FGF23 levels and urinary Na excretion are associated with blood pressure (BP) measurements in patients with incipient chronic kidney disease (CKD).

Methods: Systolic (S) and Diastolic (D) Blood pressure (BP) height- and age-adjusted percentiles (%ti), and C-terminal FGF23, 24-hour natriuresis (UNa), and fractional excetion of Na (FENa) were analyzed in young patients with CKD stages 1,2 and 3. Estimated GFR (eGFR) were calculated by cystatin (cys) and creatinine (cr) equations.

Results: 57 patients (age± SD, 14.5 ±2.1 years; 41 males), 17 African Americans, 26 Whites and 14 of other ethnicities, were defined CKD stages 1,2 and 3 by eGFRcys (94±29; 37-188) and eGFRcr (97±33; 34-71) ml/min/1.73 m_2. Serum Na, P, 1,25$(OH)_2$D and plasma renin were normal. UNa (162±73 mEq/24 hours), FENa (0.6±0.46; 0.03-1.8 %) or FGF23 levels (113±83; 13-606 RU/ml, normal< 200 RU/ml) did not correlate with SBP %ti (69±32; >95 in 30%) or DBP %ti (66±24; >95 in 10%). Although FGF23 levels were higher in CKD stages 2 and 3 vs Stage1, natriuresis and FENa values did not differ among groups (Table). Patients with FENa < 1st quartile (0.24%) had FGF23 levels (103 ± 55 RU/ml) comparable to those in higher quartiles (119±94 RU/ml), and SBP %ti were similar in both groups (57±32 vs 71±31, respectively).

Conclusions: Despite higher levels of FGF23 in CKD stages 2-3 vs. Stage 1, FENa values were comparable, and neither FGF23 nor FENa correlated with BP. These observations do not support a role of FGF23-mediated increased tubular reabsorption of Na as a mediator of elevated BP in the earlier stages of CKD.

SA-PO437

Persistent Asymptomatic Isolated Hematuria in Children in IgA Nephropathy: Histopathological Features and Prognosis

Cambier Alexandra,[1] Marion Rabant,[2] Michel Peuchmaur,[3] Alexandre Hertig,[4] Georges Deschênes,[5] Remi Salomon,[6] Julien Hogan,[7] Thomas Robert.[8] *[1]Robert Debré hospital, PARIS, France; [2]NECKER Hospital, PARIS, France; [3]APHP Université Diderot Paris7, Paris, France; [4]Sorbonne University, Paris, France; [5]Hospital Robert Debre/Pediatric Nephrology, Paris, France; [6]hopital Necker, PARIS, France; [7]Emory University, Atlanta, GA; [8]Assistance Publique des Hôpitaux de Marseille, Marseille, France.*

Background: Patients with recurrent episodes of macroscopic hematuria and persistent isolated microscopic hematuria (proteinuria<0.03g/mmol creatinuria and EGFR> 90ml/min/1.73m2) in IgA nephropathy (IgAN) does not correlate with prognosis. Early studies suggest that gross hematuria was associated with better outcome and with normal or minor abnormalities tissue on biopsy. We studied clincial and histological findings and prognosis in children with biopsy-proven with persistent isolated microscopic hematuria.

Methods: Data on 82 consecutive children were reviewed. 14 children with persistent isolated microscopic hematuria (median 11.7 years old; median of clinical follow-up 4.3 years) were reviewed. Renal biopsies were scored for Oxford classification.

Results: 13 out 14 patients were male. Analysis of renal biopsies finds: Mesangial proliferation in 9 patients (64,3%), endocapillary proliferation in 7 (50%) patients and no patient have extracapillary proliferation. Focal glomerulosclerosis/adhesion was found in 8 (57.1%) patients, podocytopathic features in 1 (8.3%) patient and no patient have tubular atrophy/interstitial fibrosis. 2 (14.3%) patients received steroid therapy and 5 (35.7%) patients were treated with supportive care treatment alone (renin angiotensin system blockade (RASb)). At the last clinical follow up, no patients reach end-stage of renal disease, median eGFR was 100.9 ml/min/1.73m^2 and median proteinuria 0.15 g/g.

Conclusions: In western countries, recurrent isolated microscopic hematuria is not a common indication for kidney biopsy. In our study, we show that children with recurrent episodes of macroscopic hematuria and persistent isolated microscopic hematuria does not preclude normal or minor abnormalities tissue. Renal biopsy should be proposed in children with recurrent episodes of macroscopic hematuria and persistent isolated microscopic hematuria. Mesangial and endocapillary proliferation is significantly associated with a poor long-term renal outcome and should open discussion about treatment (steroid therapy and/or RASb) even in absence of proteinuria and renal dysfunction.

SA-PO438

Immunosuppressive Treatment in Children with IgA Nephropathy and Evidence to Support the Clinical Value of Podocytopathic Features

Cambier Alexandra,[1] Marion Rabant,[2] Michel Peuchmaur,[3] Alexandre Hertig,[4] Georges Deschênes,[5] Remi Salomon,[6] Julien Hogan,[7] Thomas Robert.[8] *[1]Robert Debré hospital, Paris, France; [2]NECKER Hospital, PARIS, France; [3]APHP Université Diderot Paris7, Paris, France; [4]Sorbonne University, Paris, France; [5]Hospital Robert Debre/Pediatric Nephrology, Paris, France; [6]hopital Necker, PARIS, France; [7]Emory University, Atlanta, GA; [8]Assistance Publique des Hôpitaux de Marseille, Marseille, France.*

Background: There is a need for treatment guidelines and prognostic factor identification in children with primary IgA nephropathy (IgAN). We analyzed the causative effect of steroids and the applicability of the Oxford classification

Methods: Data on 82 consecutive children (mean 10.6 years; median follow-up 3.3 years) were reviewed. 21 patients (25.6%) presented with acute kidney injury, and 6 (7.3%) with nephrotic syndrome. Renal biopsies were scored for Oxford classification, podocytopathic features, and extracapillary proliferation in two groups: a groupG1, treated with steroid therapy (later in association with cyclophosphamide) and supportive care (renin angiotensin system blockade) and a group treated by supportive care alone.

Results: The two groups were not comparable, since baseline clinical data were different. eGFR in immunosupressive group significantly improved between M0 and M6 from 89.9 (61.2–114.5) to 111.7 (101.7–120)ml/min/1.73m^2, p=0.001). Proteinuria also significantly decreased from (1.6 (1–4.3) to 0.3 (0.2–0.7)g/g creat, p<0.001). In the supportive care group group, eGFR and proteinuria remained stable. Podocytopathic features were predictive of renal function decline by univariable (-4.9±14.9ml/min/1.73m^2, p=0.0079) and multivariable analysis and of poor renal prognosis to a combined event (renal function impairment more than 10% of the eGFR baseline or chronic kidney disease stage 3 at 6 months) in univariable and multivariable analysis. MEST-C score failed to prove its prognostic value.

Conclusions: Immunosuppressive treatment, especially steroid therapy, seems beneficial in children with glomerular inflammation and proliferation. The Oxford classification does not appear to be entirely appropriate in predicting long-term renal prognosis for children, whereas the characteristics of podocytopathy are strongly predictive of renal prognosis.

SA-PO439

Clinical and Histological Differences Between Adults and Children in New Onset IgA Nephropathy

Cambier Alexandra,[1] Marion Rabant,[2] Michel Peuchmaur,[3] Alexandre Hertig,[4] Georges Deschênes,[5] Remi Salomon,[2] Julien Hogan,[6] Thomas Robert.[7] *[1]Robert Debré hospital, Paris, France; [2]NECKER Hospital, PARIS, France; [3]APHP Université Diderot Paris7, Paris, France; [4]Sorbonne University, Paris, France; [5]Hospital Robert Debre/Pediatric Nephrology, Paris, France; [6]Emory University, Atlanta, GA; [7]Assistance Publique des Hôpitaux de Marseille, Marseille, France.*

Background: Recent studies showed that prognosis of children IgAN could be as severe as adults but would manifest differently. We addressed this question comparing clinical and histological characteristics at diagnostic of IgAN between children and adult.

Methods: Data on 211 consecutive patients, including 82 children and 129 adults were reviewed. Renal biopsies were scored for Oxford classification and podocytopathic features.

Results: Estimated glomerular filtration (eGFR) and serum albumin at diagnostic was lower in adults compared to children (64 vs 89.5 ml/min/1,73m^2; p=0.0001) and (3.4 vs 3.8g/dl, p=0.0001). Serum albumin was lower in children compared to adults (3.4 vs 3.8g/dl, p=0.0001) while proteinuria was not different. Histological analysis of kidney biopsy finds higher proportion of mesangial (M1) and endocapillary (E1) proliferation in children compared to adult (M1 (80.7% vs 27.9% p=0.0001); E1 (71.3% vs 30% p=0.0001). Focal glomerulosclerosis (S1), tubular atrophy/interstitial fibrosis ≥ 25% (T1) and podocytopathic features (P1) were higher in adult, (S1 (81.5% vs 61.3% p=0.0012), T1 (49.5% vs 1.35% p=0.0001), P1 (33.8% vs 16.4% p=0.007)). Proteinuria was associated with M1, E1 and C1 in children (M1, p=0.001; E1, p=0.0005; C1, p=0.0014) whereas proteinuria was associated with S1, P1 and T1 in adult (S1, p=0.0001; P1, p=0.0001; T1, p=0.001). After steroid treatment, proteinuria decreased in children (1.54 (0.9–3.6) to 0.03 (0.2–0.7)g/g, p<0.001) and in adult group (1.31 (0.77–2.2) to 0.4 (0.2–1)g/g, p<0.001). eGFR remain stable in adult (41.4 to 36.9 ml/min/1.73m2) and increase significantly in children (98.6 to 109,3 ml/min/1.73m2) between M0 and last follow-up.

Conclusions: In children IgAN, proteinuria is related to glomerular proliferative lesions whereas in adult proteinuria is related to chronic lesions. Steroid would be more effectiveness on eGFR and proteinuria in children due to the steroid sensitivity of glomerular lesion.

SA-PO440

Does MEST-C Score Predict Outcomes in Pediatric Henoch Schönlein Purpura Nephritis?

Adam Jimenez,[1] Ashton Chen,[2] Jen-Jar Lin,[2] Andrew M. South.[2] *[1]Wake Forest School of Medicine, Winston-Salem, NC; [2]Wake Forest Baptist Health, Winston Salem, NC.*

Background: Children with Henoch-Schönlein purpura nephritis (HSPN) are at risk for long-term negative renal outcomes. HSPN renal biopsies have been graded using the International Study of Kidney Disease in Children criteria, which is limited by a lack of correlation with outcomes. The MEST-C scoring system by 2016 Oxford Classification has been shown to predict poor outcomes in IgA nephropathy (IgAN) but its utility in predicting outcomes in HSPN is incompletely described. Our hypothesis is that MEST-C score predicts outcomes in US children with HSPN.

Methods: Data of 32 children with HSPN referred to pediatric nephrology who underwent renal biopsy between April 1, 2004 and March 1, 2018 were reviewed. Logistic regression analysis was used to compare MEST-C scores to a composite outcome at the last known follow-up visit: hypertension (systolic or diastolic blood pressure ≥95% for age/sex/height), chronic kidney disease (glomerular filtration rate <90 mL/min/1.73 m^2), or proteinuria (urine protein-to-creatinine ratio >0.2 mg/mg).

Results: Their median baseline age was 7.9 years (IQR 5.9); 56% were male, 16% were Hispanic, 12.5% African-Americans, and 71.5% Caucasians. 31% of patients had a S1 score. After a median follow up of 2.7 years (IQR 4.3), 34% of patients reached the outcome. Of the MEST-C components, only S1 was significantly associated with the outcome (OR 10.5, 95% CI 1.9 to 59.4). ROC analysis revealed that an S1 score predicted the outcome (AUC 0.75, 95% CI 0.58 to 0.91) with 63.6% sensitivity (95% CI 30.8 to 89.1%) and 85.7% specificity (63.7 to 97.0%), indicating a positive predictive value of 70.0% (34.8 to 93.3%) and a negative predictive value of 81.8% (59.7 to 94.8%).

Conclusions: Our study demonstrated that MEST-C score, specifically S1, strongly predicted the development of hypertension, proteinuria, and chronic kidney disease in HSPN children in the US. Further investigation in larger, multi-center studies are warranted to validate our findings.

SA-PO441

Clinical Relevance of C4d Deposition in Pediatric IgA Nephropathy

Min Hyun Cho,[2] Jaehun Jung,[2] Yong-Jin Kim,[1] Man-hoon Han,[1] Hee Sun Baek.[2] *[1]Pathology, Kyungpook National University Hospital, Daegu, Republic of Korea; [2]Pediatrics, Kyungpook National University Hospital, Daegu, Republic of Korea.*

Background: Immunoglobulin A nephropathy (IgAN) is one of the most common causes of primary glomerulonephritis and is characterized by predominant IgA deposition in the glomerulus mesangium. Recently, it has been well-known that the activation of complement system plays an important role in the development and progression of IgAN. The aim of this study is to investigate the association between the evidence of C4d staining and clinical or histopathologic features of pediatric IgAN patients.

Methods: Fifty-six pediatric patients diagnosed with IgA nephropathy through renal biopsy from 2006 to 2017 were reviewed retrospectively. Immunohistochemical C4d staining was performed in all biopsy tissues. Clinical/histopathological features were statistically analyzed according to C4d staining positivity.

Results: A total of 56 patients (male 58.9%, female 41.1%) were included in the study and the mean age at diagnosis was 12.1 ± 4.7 years. Among the 56 patients, 31 (55.4%) showed positive glomerular C4d staining; a mesangial (n=16), a peripheral capillary (n=11), or a mixed (n=4) distribution pattern. Urine protein-to-creatinine ratio was significantly higher in C4d-positive patients (p = 0.001). The severity of mesangial proliferation according to the Haas and Oxford classification were significantly associated with positive C4d staining (p < 0.001). In the Haas classification, the positive rate of C4d in patients with subclass I was 12.9% (n=4), but in them with subclass III and IV were 45.2% (n=14) and 38.7% (n=12), respectively. In addition, as for the Oxford classification of IgAN, positive C4d staining turned out to be significantly associated with the evidence of mesangial proliferation (M1) (p<0.001). The positive rate of C4d in patients with M1 was 67.7% (n=21), but in them with M0, 32.3% (n=10). However, there was no significant association of the evidence of endocapillary hypercellularity, segmental sclerosis, and tubulointerstitial fibrosis/atrophy between the patients with positive C4d and them with negative C4d. Additionally, as for C4d staining patterns such as mesangial, peripheral capillary or mixed patterns, there was no significant correlation between these patterns and histologic severity of the Haas or Oxford classification.

Conclusions: Positive C4d staining was found to be significantly associated with clinical/histopathological progression of pediatric IgAN.

SA-PO442

Renal Involvement of Inflammatory Bowel Diseases in Children and Adolescents: From Korean Pediatric IBD Cohort

Min Hyun Cho,[1] Jaehun Jung,[1] Hee Sun Baek,[1] Heeyeon Cho,[2] Yeonhee Lee.[2] *[1]Pediatrics, Kyungpook National University Hospital, Daegu, Republic of Korea; [2]Samsung Medical Center, Seoul, Republic of Korea.*

Background: Recently, the incidence of inflammatory bowel disease (IBD) has been rising rapidly, and several reports have described renal complications of IBD. We evaluated the clinical manifestations of renal complications in children with IBD to enable early detection and prompt treatment of renal complications.

Methods: We retrospectively reviewed the medical records of 456 children and adolescents aged <20 years who had been diagnosed with IBD since 2000. We analyzed age, sex, medication use, IBD disease activity, and clinical manifestations of renal symptoms.

Results: Our study comprised 456 children with IBD including 299 boys (65.6%) and 157 girls (34.4%) with a mean age±SD of 14±3 years. The mean follow-up period was 4.61±2.93 years. The study included 346 children with Crohn's disease (CD, 75.9%) and 110 with ulcerative colitis (UC, 24.1%), and the incidence of CD was >UC. Among the 456 children studied, 67 (14.7%) showed confirmed renal manifestations, and 59 were identified as children with CD and 8 as children with UC. We observed 26 children (38.8%) with isolated hematuria, 30 (44.8%) with isolated proteinuria, and 11 (16.4%) with hematuria and concomitant proteinuria. A renal biopsy was performed in 7 children with CD. Of them, 5 children showed both microscopic hematuria and proteinuria. Persistent microscopic hematuria and recurrent gross hematuria was observed in 2 children. Histopathological examination revealed IgA nephropathy in 5 children (71.4%) and Henoch-Schönlein purpura (HSP) nephritis in 1 child (14.2%), whereas 1 child (14.2%) showed no histopathological abnormalities. IBD disease activity was evaluated in 102 children, of which 81 showed CD and 21 showed UC. No significant correlation was observed between the IBD disease activity and the presence of renal manifestations in 102 children in whom we were able to assess disease activity. In all 102 children, disease activity was mild, and the disease was well controlled.

Conclusions: Children with IBD are more likely to show kidney-related symptoms than healthy children and adolescents. Therefore, regular screening of urine and evaluation of renal function are necessary for early detection of renal complications.

SA-PO443

Long-Term Outcome of 62 Pediatric Henoch-Schönlein Nephritis Patients Treated with Methylprednisolone Pulses or Cyclosporine A

Antti Koskela,[1] Timo Jahnukainen,[5] Kira Endén,[7] Pekka M. Arikoski,[3] Janne T. Kataja,[2] Matti Nuutinen,[4] Elisa Ylinen.[6] *[1]University of Helsinki and Helsinki University Hospital, Finland, Helsinki, Finland; [2]Turku University Hospital, Turku, Finland; [3]Kuopio University Hospital, Kuopio, Finland; [4]Oulu University Hospital, Oulu, Finland; [5]Children?s Hospital, Helsinki University Hospital, Helsinki, Finland; [6]Children's Hospital, University of Helsinki, Helsinki University Hospital, Helsinki, Finland; [7]Tampere University hospital, Tampere, Finland.*

Background: The optimal treatment of Henoch-Schönlein purpura nephritis (HSN) has remained unclear. We evaluated the outcome of pediatric HSN patients treated initially with methylprednisolone (MP) or cyclosporine A (CyA) in the five university hospitals in Finland between 1996 and 2011.

Methods: The medical charts were reviewed until the last follow-up visit and 47 (76 %) patients attended also additional urine and blood sample screening. MP-treated patients (n=42) received three 30 mg/kg pulses followed by oral prednisone for a median of 4.3 (IQR 3.8 – 5.9) months. Median treatment time for CyA-treated patients (n=20) was 1.2

(IQR 1.0 – 1.7) years with an initial target blood concentration of 150-200 μmol/l. Fifty-nine (95 %) patients had received ACE-Is and/or ARBs.

Results: Baseline characteristics at the time of renal biopsy and outcome after a mean follow-up of 10.8 years are shown in Table 1. Eighteen (90 %) CyA-treated and 26 (62 %) MP-treated patients achieved favorable treatment response with initial treatment and needed no additional immunosuppressive therapy (RR 1.45, 95 % CI 1.07 – 1.96, p=0.035; for favorable treatment response). One patient developed ESRD and another patient had decreased renal function (eGFR <60 ml/min/1.73m^2), both initially treated with MP. Six patients (5 MP, 1 CyA) had mildly decreased renal function (eGFR 60 – 89 ml/min/1.73m^2), one of them having non-nephrotic proteinuria.

Conclusions: Renal outcome was good in both treatment groups. However, CyA-treated patients needed less additional immunosuppressive treatment and none of the initially CyA-treated patients had decreased renal function (eGFR <60 ml/min/1.73m^2) after 10.8 years of follow-up. Urinary abnormalities may persist or develop and therefore long-term follow-up of HSN patients is mandatory.

Funding: Private Foundation Support

Table 1

Baseline characteristics at renal biopsy	Initial MP treatment (n=42)	Initial CyA Treatment (n=20)	p-value
Age (years)	9.5 ± 3.3	10.7 ± 3.4	0.16
Patients with nephrotic-range proteinuria (>40mg/m2/h)	36 (86 %)	14 (74 %)	0.29
ISKDC grade ≥ III (%)	29 (71 %)	18 (90 %)	0.12
Outcome at the end of follow-up			
Patients with proteinuria (%)	9 (22 %)	2 (11 %)	0.48
Patients with hematuria (%)	5 (13 %)	3 (17 %)	0.70
Patients with blood pressure medication (%)	8 (20 %)	7 (35 %)	0.22
eGFR (ml/min/1.73m2)	110 ± 21	109 ± 12	0.95

Clinicopathological Significance in Juvenile-Onset Silent Lupus Nephritis

Yuko Shima,[1] Koichi Nakanishi,[2] Taketsugu Hama,[1] Masashi Sato,[1] Hironobu Mukaiyama,[1] Yu Tanaka,[1] Hiroshi Kaito,[3] Kandai Nozu,[4] Ryojiro Tanaka,[3] Hiroyuki Suzuki,[1] Kazumoto Iijima,[4] Norishige Yoshikawa.[1] *[1]Wakayama Medical University, Wakayama City, Japan; [2]Graduate School of Medicine, University of the Ryukyus, Nishihara-cho, Japan; [3]Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan; [4]Dept. of Pediatrics, Kobe Univ. Graduate School of Medicine, Kobe, Japan.*

Background: In patients with juvenile-onset systemic lupus erythematosus (SLE), there have been reports of silent lupus nephritis (SLN) patients without abnormal urinalysis and renal impairment. Currently, renal biopsies are the gold standard for diagnosis and monitoring of LN. The purpose of this study is to clarify the clinicopathological significance of juvenile-onset SLN.

Methods: Retrospective analysis of 57 patients who underwent renal biopsy among 59 patients diagnosed as juvenile-onset SLE who met the American College of Rheumatology criteria for the classification of SLE between December 2000 and March 2017 to compare clinical and pathological findings between SLN and others.

Results: There were 27 patients (47.4%) with SLN. Clinical findings showed significant differences (SLN vs. non-SLN) in eGFR (174.9 vs 147.5 ml/min/1.73m^2, p=.02) and serum C3 level (76.0 vs 46.5 mg/dl, p=.04). The distribution of ISN/RPS classes of LN was as follows: class I: II: III: IV: V (12: 11: 3: 1: 0 vs 2: 7: 6: 14: 1; p=.003). Though SLN group showed milder pathological presentation, 4 cases with SLN showed severe pathological findings such as class III or IV. The 4 patients with class III and IV had significantly higher dsDNA antibody titer (159.2 vs 42.1 IU/ml, p =.02) and lower serum C3 level (37 vs 77 mg/dl, p =.03) than the other SLN cases. As to immunofluorescence, all patients showed the deposition of immunoglobulins and the degree of deposition of IgG and C3 in SLN was significantly weaker than in non-SLN. In electron microscopy, the degree of subendothelial and subepithelial EDD was significantly weaker in SLN.

Conclusions: Most of the patients with SLN showed milder pathological presentation, but some cases showed severe pathological presentation regardless of minor clinical presentations. We confirmed an importance of renal biopsies for juvenile-onset SLE. Serum C3 level might be an important marker of the severity of SLN.

SA-PO445

Altered Expression of CD46 Mediated Tr1 Cytoplasmic Isoforms Associated with IL-10 Secretion Can Induce Remission of Active Lupus Nephritis

Ching-Yuang Lin. *Children's Hospital, China Medical University, Taichung, Taiwan.*

Background: CD46-costimulated T cells in the presence of IL-2 acquire a Tr1 type Treg phenotype, secreting high amount IL-10 and granzyme B. There was two forms of CD46 cytoplasmic isoforms. Cyt1 inhibits and Cyt2 augments inflammation. To elucidate whether CD46 mediated Cr1 cells can induce remission in active lupus nephritis (LN) by intravenous methylprednisolone (IVMP) therapy, we evaluate IL-10 secreting Tr1 cells in peripheral blood mononuclear cells (PBMCs) and renal biopsy specimens, the capacity of CD46$^+$ Tr1 cells to induce IL-10 production, altered expression of CD46 cytoplasmic ioforms before and after IVMP therapy.

Methods: PBMCs were isolated from fourty pediatric class III or IV LN active LN patients and from ten healthy controls before and after three days of IVMP. Purified CD4$^+$ T cells from patients before and after IVMP as well as healthy controls were stimulated with anti-CD3 and CD46 mAbs in the presence of IL-2 to generated Tr1 cells.

Results: Decreased CD46 expression on CD4$^+$ T cell in PBMCs and renal biopsy specimens from active LN patients versus controls, correlating with higher anti-dsDNA Ab level and lower serum C3, C4 levels. IL-10, granzyme B, CCR4, CCR7 expression and CD4$^+$ T cell proliferation were diminished by CD3/CD46-activated Tr1 cells in active LN. CD4$^+$ T cell from active LN patients showed a statistically increase in IFN-r$^+$ T cells when compared to healthy control T cells following CD3 activation but failed to switch efficiently from IFN-r to IL-10 production following CD3$^+$/CD46 stimulation. After IVMP altered expression of CD46$^+$ Tr1 cell cytoplasmic isoform with increasing CD46-Cyt1/ -Cyt2 ratio. IVMP also increased AKT phosphorylation and enhanced adhesion, migration of CD3/CD46 activated Tr1 cells and IFN-r switch to IL-10 production in active LN patients.

Conclusions: Switching efficiency from IFN-r to IL-10 production of CD3$^+$/CD46 stimulated Tr1 cells was failed in active LN patients. IVMP rescue INF-r switching IL-10 production associated with induction of remission in active LN also increasing adhesion and migratory capacity to suppress inflammation by CD46-mediated Tr1 cells. Thus, pharmacologic intervention to alter pattern of CD46-Cyt1, -Cyt2 expression with inducing IL-10 secretion by CD46 medicated Tr1 cells are viable approach in active LN patients.

SA-PO446

Association of APOL1 Risk Variants with Subclinical Renal Disease in HIV Infected Children and Apparently Healthy Children from Central Africa (Democratic Republic of Congo)

Pepe M. Ekulu,[1,2] Michel N. Aloni,[2] François Lepira,[3] Elena N. Levtchenko.[1] *[1]Department of Paediatric Nephrology & Growth and Regeneration, KU Leuven, Leuven, Belgium; [2]Division of Nephrology, Department of Pediatrics, University of Kinshasa, Kinshasa, Congo (the Democratic Republic of the); [3]Division of Nephrology, Department of Internal Medicine, University of Kinshasa, Kinshasa, Congo.*

Background: Apolipoprotein-L1 (*APOL1*) risk variants G1 and G2 increase the risk of progressive chronic kidney disease (CKD), including HIV-related CKD, among sub-Saharan African descents. HIV infection, a substantial healthcare problem in sub-Saharan Africa, is an extremely potent trigger factor for *APOL1* kidney disease. However, data on *APOL1* risk genotypes from Central Africa still remain limited and the association with HIV-related CKD is not yet well documented. We aimed to describe the prevalence of *APOL1* risk variants in the Democratic Republic of Congo (DRC) and to assess the association between these variants and the subclinical renal disease in both HIV infected children and apparently healthy children.

Methods: A total of 813 participants, of whom 401 HIV infected children treated with antiretroviral therapy (ART) and 412 apparently healthy children, were enrolled from four large districts in Kinshasa, the capital of the DRC. *APOL1* high-risk genotype (HRG) was defined by the presence of 2 risk variants (G1/G1, G2/G2, and G1/G2) and low risk genotype (LRG) if 0 or 1 risk variants were present. As the main outcomes, reduced kidney function was defined as eGFR <60 ml/min per 1.73 m^2 and elevated urine albumin-to-creatinine ratio (ACR) ≥ 30mg/g.

Results: From 813 participants, *APOL1* sequence analysis revealed 52 (6.4%) carrying HRG. Regarding LRG, 168 (20.6%) participants carried G1/G0 while 116 (14%) carried G2/G0. Of 401 HIV infected children, 72 (18%) had elevated albuminuria versus 40 (9.7%) out of 412 apparently healthy children (p<0.001) and reduced kidney function was detected in 26 (6.5%) against 13 (3.1%) (p=0.019). Considering the association between *APOL1* HRG and renal disease, 18/23 (78.3%) HIV infected children carrying HRG had elevated albuminuria (0R 21.6, 95%CI 7.3-76.6; p<0.001) against 5/29 (17.2%) apparently healthy children (0R 2.1, 95%CI 0.6-6.0; p=0.137). No significant difference was found concerning the reduced renal function.

Conclusions: The *APOL1* risk variants are highly prevalent in the DRC. The HIV infection is strongly associated with the presence of subclinical renal disease, especially in those carrying the *APOL1* HRG.

SA-PO447

Novel Truncating Mutations in Autosomal Dominant FSGS Genes Cause Childhood Onset Steroid-Resistant Nephrotic Syndrome

Jennifer D. Varner,[1,2] Megan Chryst-Stangl,[2] Tracy E. Hunley,[3] Brandon M. Lane,[2] Guanghong Wu,[2] Gentzon Hall,[4] Rasheed A. Gbadegesin.[5] *[1]Duke University School of Medicine, Durham, NC; [2]Duke Molecular Physiology Institute, Durham, NC; [3]Vanderbilt University Medical Center, Nashville, TN; [4]Division of Nephrology, Duke University Medical Center, Durham, NC; [5]Department of Pediatrics, Duke University Medical Center, Durham, NC.*

Background: Steroid-resistant nephrotic syndrome (SRNS) is a leading cause of end stage kidney disease in children. Most autosomal dominant genes are presumed to be due to gain-of-function mutations. Mutations in transient receptor potential canonical 6 (*TRPC6*) and inverted formin 2 (*INF2*) have been described in familial focal segmental glomerulosclerosis (FSGS). Most of the mutations described are missense mutations. Truncating (loss of function) mutations in these genes have not been well described.

Methods: We identified 181 families with SRNS in our worldwide cohort. Families were screened for variants in ten known autosomal dominant FSGS genes (*INF2, TRPC6, COL4A3, COL4A4, WT1, ACTN4, ANLN, CD2AP, ARHGAP24,* and *LMX1B*) using targeted sequencing of custom amplicons (TSCA). Causative mutations were defined as non-synonymous variants, obligatory splice site variants, or truncating variants that had a minor allele frequency <1% in the normal population. Non-synonymous variants were considered pathogenic if they were also reported to be deleterious by at least 2 *in silico* software models. Variants were confirmed using Sanger sequencing.

Results: We identified two novel truncating mutations in *TRPC6* and *INF2*, respectively, in two families with onset of disease at age <10 years. Family DUK34462 consists of three affected members with an autosomal dominant pattern of inheritance. We identified a novel stop codon change in *INF2* (p.E249X) in a child who presented with disease at the age of eight years. The second family is DUK40015 with one affected individual with onset of disease at the age of ten years. We identified a frameshift mutation in *TRPC6* (p.G39fsX41) in this child. Apart from early onset of disease, the phenotype in these two families was not different from individuals with missense mutations in the two genes, in that they both have therapy resistant disease.

Conclusions: In conclusion, truncating mutations in autosomal dominant SRNS/FSGS genes may cause early onset childhood SRNS, likely by haploinsufficiency effect on pathways that are critical for normal development of the glomerular filtration barrier.

SA-PO448

Evidence Against Routine Genetic Testing for SRNS in an Outbred Population

Jennifer D. Varner,[1,2] Megan Chryst-Stangl,[3] Chris Esezobor,[4] Brandon M. Lane,[3] Guanghong Wu,[2] Gentzon Hall,[5] Rasheed A. Gbadegesin.[6] *[1]Duke University School of Medicine, Durham, NC; [2]Duke Molecular Physiology Institute, Durham, NC; [3]Duke Molecular Physiology Institute, Durham, NC; [4]College of Medicine, University of Lagos, Akoka, Nigeria; [5]Division of Nephrology, Duke University Medical Center, Durham, NC; [6]Department of Pediatrics, Duke University Medical Center, Durham, NC.*

Background: Steroid-resistant nephrotic syndrome (SRNS) is a leading cause of end stage kidney disease in children. Recent advances in genomic technology have led to the identification of more than 50 genetic causes of SRNS, most of which code for proteins located within the glomerular filtration barrier. Despite these advances, there are no clear clinical guidelines for genetic screening in patients with SRNS.

Methods: Our worldwide multi-ethnic cohort consisted of 492 individuals from 181 families with SRNS, of whom 86 families had familial disease and 95 individuals had sporadic disease. Initial genetic screening was performed by direct sequencing of candidate genes and whole exome sequencing. Analysis in recent years was performed using targeted high-throughput sequencing of 42 known SRNS genes and risk loci. Causative mutations were defined as missense variants, truncating variants, and obligatory splice site variants with a minor allele frequency <1% in the normal population. Non-synonymous variants were considered pathogenic if determined to be deleterious by at least two *in silico* software models. In order to provide clinical guidelines, we evaluated for differences in age at disease onset, sex, race, family history of SRNS or chronic kidney disease (CKD), extra-renal manifestations, and renal biopsy findings.

Results: We identified disease causing variants in 34/81 (39.5%) families with familial SRNS and 6/95 (6.3%) individuals with sporadic disease. Amongst families with hereditary disease, causative variants were identified in 44.6% of families with presumed autosomal dominant inheritance and 23.8% of families with presumed autosomal recessive inheritance. Variants in *INF2*, *COL4A3*, and *WT1* accounted for over half of all causative mutations. Family history of SRNS or CKD was the only significant clinical factor predictive of identifying a causative mutation (χ^2 p<0.00001).

Conclusions: In this worldwide cohort, we identified causative mutations in almost 40% of all families with hereditary SRNS, compared to only 6% of individuals with sporadic disease, making family history the single most important clinical predictor of monogenic causes of disease. These data support the use of genetic testing in patients with a positive family history of SRNS, and selective testing in those with sporadic disease.

SA-PO449

Adrenal Suppression After Prednisolone Treatment in Children with Idiopathic Nephrotic Syndrome: A Multicenter Prospective Study

Ryoko Harada,[1] Kaori Kikunaga,[1] Koichi Kamei,[2] Riku Hamada,[1] Hiroko Nagata,[3] Takashi Ando,[4] Kenji Ishikura.[2] *[1]Tokyo Metropolitan Children's Medical Center, Tokyo, Japan; [2]National Center for Child Health and Development, Tokyo, Japan; [3]Kumamoto University, Kumamoto, Japan; [4]Tsukuba Gakuen hospital, Tsukuba, Japan.*

Background: Severe iatrogenic adrenal insufficiency can occur after steroid treatment. However, there have been a limited number of studies in adrenal insufficiency after prednisolone (PSL) treatment in children with idiopathic nephrotic syndrome (NS), despite much repeated use of PSL.

Methods: We prospectively obtained data of patients with NS aged 2 to 19 years who underwent PSL treatment using International Study of Kidney Disease in Children (ISKDC) regimen from September 2016 to August 2017 at two children's hospitals in Tokyo. In the present study, adrenal insufficiency was defined as cortisol values less than 5 mcg/dL at 9 AM, based on our previous study in Kawasaki disease showing that single serum cortisol values less than 5 mcg/dL obtained at 9 AM from children treated with PSL were significantly correlated with peak serum cortisol value less than 15 mcg/dL in the corticotropin-releasing hormone stimulation test. Patients were divided into two groups and compared: an adrenal insufficient group (I) and a sufficient group (S) based on the serum cortisol values.

Results: Ninety-eight children (70 boys) were enrolled and analyzed in this study: 12 (12.2%, 10 boys) were in the I group and 86 children (87.8%, 60 boys) were in the S group. The median serum cortisol value was 7.7 mcg/dL [IQR 6.9-15.1]. There was no statistically significant difference in age, period from final PSL administration to the cortisol measurement, or number of relapses between the two groups. The median dosage of PSL over one year up to the cortisol measurement day in the I group was significantly higher than that in the S group (3000 mg [778-5359] vs 0 mg [0-1395], p=0.004), and the number of children who experienced relapses during PSL treatment in the I group was also more than those of the S group (4/12 (33.3%) vs 8/86 (9.3%), p=0.038).

Conclusions: Adrenal suppression can occur in a significant proportion of children with NS treated with PSL. Care must be taken to avoid adrenal insufficiency in these children. A measurement of serum cortisol values after PSL treatment is necessary, particularly in those receiving high-dose steroid within a year.

SA-PO450

Vitamin D Receptor Gene Polymorphisms in Childhood Idiopathic Nephrotic Syndrome

Yee-Hsuan Chiou,[1,2] Shiao-Ping Huang,[3] Nai-Wen Fang.[1] *[1]Kaohsiung Veterans General Hospital, Kaohsiung, Taiwan; [2]School of Medicine, National Yang-Ming University, Taipei, Taiwan; [3]Fooyin University, Kaohsiung, Taiwan.*

Background: Idiopathic nephrotic syndrome (INS) is the most frequent type of nephrotic syndrome in children. The pathogenesis of remains controversial and may be mediated by the immune system and the imbalance between T-helper cell subtype 1 (Th1) and subtype 2 (Th2) cytokines, which are regulated by the vitamin D. Vitamin D exerts its effects through its receptor (VDR). Its response to steroids treatment are also varied. The aim of this study was to analyze the correlation between the VDR gene polymorphisms and the response to steroids treatment in INS children.

Methods: Thirty four patients with INS were enrolled and divided into 2 groups: 18 steroid-sensitive (SS) and 16 steroid-resistance (SR). To analyze the VDR gene polymorphisms, the SNP genotyping for Fok1, Apa1, Cdx2, Taq1, Bsm1 were performed using TaqMan Genotyping Assays. The genotypic and allele frequency were analyzed.

Results: The Apa1 C allele was associated with steroid resistance then A allele [OR 8.75, p=0.009]. The frequency of the C allele was significantly higher in SR than in SS subjects (0.84 vs. 0.47, respectively). The Bsm1 G allele was associated with steroid resistance then A allele [OR 7.00, p=0.017]. The frequency of the G allele was significantly higher in SR than in SS subjects (0.88 vs. 0.50, respectively). The Fok1 C allele was associated with steroid resistance then T allele [odds ratio (OR) 6.00, p=0.015]. The frequency of the C allele was significantly higher in SR than in SS subjects (0.66 vs. 0.33, respectively). There was no significant correlation in Cdx2 and Taq1 polymorphisms in VDR gene between treatment response.

Conclusions: Our results indicate that among our pediatric patients with INS, the VDR gene polymorphism: Fok1, Apa1, and Bsm1 were associated with steroid resistance; while the Cdx2 and Taq1 gene polymorphisms showed no statistical significance between these 2 groups.

Urine Biomarker Potential for Assessment of Disease Activity in Pediatric Nephrotic Syndrome

Taketsugu Hama,[1] Yu Tanaka,[1] Masashi Sato,[1] Hironobu Mukaiyama,[1] Yuko Shima,[1] Koichi Nakanishi,[3] Norishige Yoshikawa,[2] Hiroyuki Suzuki.[1] *[1]Pediatrics, Wakayama Medical University, Wakayama, Japan; [2]Clinical Study Support Center, Wakayama Medical University, Wakayama, Japan; [3]Department of Child Health and Welfare (Pediatrics), Graduate School of Medicine, University of the Ryukyus, Okinawa, Japan.*

Background: Biomarkers are considered to be a powerful tool of diagnosis and assessment of disease activity. Currently, proteinuria is the standard means of diagnosis of nephrotic syndrome (NS). Other non-invasive biomarkers are desired, especially those that may provide better understanding of NS activity than proteinuria.

Methods: We extracted urine RNA and using real-time PCR, examined the expression levels of various biomarkers. Expression levels were then compared between NS and other diseases. We also investigated the correlation between biomarkers and the conditions of disease across four stages; pre-treatment proteinuria (stage 1), proteinuria during treatment (stage 2), remission during treatment (stage 3) and post-treatment remission (stage 4). At our hospital, 117 RNA samples were taken from 104 consecutive patients with various kidney diseases (30 nephrotic syndrome, 27 IgAN, 15 isolated hematuria, 7 isolated proteinuria, 25 others). Across the four stages, the 30 NS patients provided 46 RNA samples (stage 1 = 7, stage 2 = 8, stage 3 = 12, stage 4 = 19).

Results: Using biomarkers, we could diagnose NS and observe its activity across the four stages. Pediatric NS samples showed significantly higher levels of liver fatty acid-binding protein (FABP-1) (p<0.01), megalin (p<0.01), cubilin (p<0.01) and lower level of podocin (p<0.01) compared to the other diseases. In NS samples only, FABP-1, cubilin and kidney injury molecule-1 (KIM-1) expression levels correlated positively with urine protein volume, whereas podocin correlated negatively. FABP-1 expression was around double and podocin expression was approximately 75% lower in relapse than in remission (Table 1). In stage 2, cubilin expression doubled. In stage 3, KIM-1 expression increased 170%.

Conclusions: Urine RNA expressions reveal clues to the pathophysiology of NS. Urine biomarkers other than proteinuria can be considered an effective non-invasive tool to understand disease activity in pediatric NS.

Funding: Government Support - Non-U.S.

Table 1. Urine RNA relative expression

	FABP-1	KIM-1	cubilin	IL-18	NGAL	megalin	podocin	Thy1	HSPG2
Pre-treatment proteinuria [stage 1, n=7]	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0
Proteinuria during treatment [stage 2, n=8]	1.3	0.9	1.8	1.5	1.6	1.7	1.0	1.5	3.5
Remission during treatment [stage 3, n=12]	0.4	1.7	0.9	2.3	2.0	1.4	3.7	1.8	3.6
Post-treatment remission [stage 4, n=19]	0.5	0.5	0.9	2.8	3.6	0.8	6.3	1.5	2.7

SA-PO452

Urinary CD80 as a Novel Biomarker of Podocyte Injury

Shoji Tsuji, Yuko Akagawa, Takahisa Kimata, Sohsaku Yamanouchi, Shohei Akagawa, Kazunari Kaneko. *Kansai Medical University, Hirakata-shi, Japan.*

Background: CD80, which is expressed by antigen-presenting cells, was recently reported to also be expressed in podocytes in pathological conditions such as idiopathic nephrotic syndrome (INS); moreover, CD80 over-expression could be detected in urine (Reiser J, et al. 2004; Garin, EH, et al. 2009). However, as there are many skeptical reports, a conclusion has yet to be drawn. The purpose of this study was to clarify whether podocyte-derived CD80 appears in urine, where it may serve as a biomarker for podocyte disorder.

Methods: Patients with INS (median age 7.9 years, n=10) were grouped into initial attack and relapse (group A), and remission (group B), and compared with patients with other renal diseases (e.g., IgA vasculitis nephritis; median age 8.2 years, n=7; group C). Single voided urine and serum samples were collected at the same time. Urine and serum CD80 levels were measured by ELISA and compared among the three groups to examine potential correlations. The correlation between urine CD80 and urinary protein excretion was also investigated. In addition, puromycin was added to a human podocyte cell line to prepare an *in vitro* INS model, and expression of CD80 after 72 hours was confirmed using western blotting.

Results: (1) Urinary CD80 was significantly increased in group A compared with group B (group A:group B=465.94:0.00; ng/gCre, numerical value is median, p=0.0072). Group A was also higher than group C, however there was no significant difference (group A:group C=465.94:422.04, p=0.65). (2) Although there was no significant correlation between urinary CD80 and serum CD80 values, there was a correlation between urinary CD80 and urinary protein excretion (r=0.24, p=0.17; r=0.35, p=0.0031, respectively). (3) As a result of administration of puromycin to the human podocyte cell line, CD80 expression was increased almost two-fold compared with control (untreated podocytes: puromycin-treated poocytes=8201.26:16309.43, p=0.015).

Conclusions: A significant amount of CD80 was excreted in the urine of INS and other renal disease patients, and its concentration did not correlate with serum concentration. In addition, CD80 expression was also confirmed in an INS human cell line model. Furthermore, urinary CD80 was significantly correlated with amount of urinary protein reflecting podocyte injury, suggesting that it could be a biomarker of podocyte disorder.

SA-PO453

All-Trans Retinoic Acid Directly Acts on Podocytes by Regulating CD80 Expression

Yuko Akagawa, Shoji Tsuji, Shohei Akagawa, Sohsaku Yamanouchi, Takahisa Kimata, Kazunari Kaneko. *Kansai Medical University, Osaka, Japan.*

Background: Pathogenesis of minimal change nephrotic syndrome (MCNS) remains unclear, though recent studies suggest a role for malfunction of regulatory T cells (Tregs) and abnormal expression of several podocyte-related molecules, such as CD80 (Garin E, et al. Pediatric Nephrology, 2016). All-trans retinoic acid (ATRA) has the potential to regulate the immune system, including induction and differentiation of Tregs, in addition to its vitamin function. Therefore, we aimed to investigate the potential of ATRA as a protective therapy for MCNS through suppression of CD80 *in vitro*.

Methods: Human-derived immortalized podocytes were treated with puromycin aminonucleoside (PAN) as an *in vitro* model of MCNS. Cells were treated with ATRA (10 μM) or DMSO in starvation medium on day 1 followed by PAN (50 μg/ml), or PBS on day 0. Samples were collected after 72 h for analysis. Protein expression levels of CD80 and retinoic acid receptor (RAR) were measured by western blotting.

Results: PAN induced increased protein expression of CD80 and RAR both of which were restored by ATRA treatment (Figure1). These results suggested that the overexpression of CD80 after PAN stimulation can be restored by ATRA through RAR.

Conclusions: ATRA suppresses CD80 overexpression caused by PAN stimulation through RAR in podocytes. ATRA might have an antiproteinuric effect on MCNS through its direct effect on podocytes.

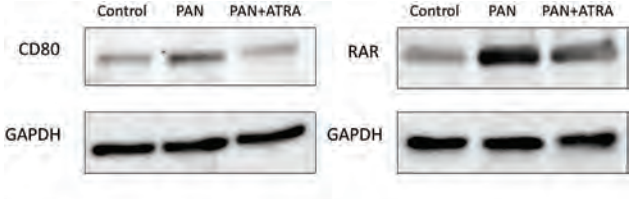

Figure1. Effect of ATRA on the expression of CD80 and RAR in podocytes

SA-PO454

Expression and Functional Activity of Multidrug Resistance-Associated Protein-1 and P-Glycoprotein on T-Cells Is Associated with Steroid Resistance Nephrotic Syndrome in Children

Narayan Prasad,[1] Harshit Singh,[2] Saurabh Chaturvedi,[2] Akhilesh Jaiswal,[3] Vikas Agarwal.[2] *[1]SGPGIMS CAMPUS, Lucknow, India; [2]SGPGIMS, Lucknow, India; [3]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.*

Background: Steroid remains as mainstay of therapy for Idiopathic Nephrotic Syndrome (NS). Other than histological factors like changes from minimal change to FSGS, pharmacogenomic factors may affect steroid response, however not well studied. Overexpression of P-glycoprotein (P-gp) and Multidrug resistance associated protein 1 (MRP-1) modulate pharmacokinetics of steroid and contribute in steroid resistance.

Methods: P-gp, MRP-1 expression were evaluated on whole blood and functional activity on peripheral blood mononuclear cells (PBMCs) by Flow Cytometry in steroid sensitive NS (SSNS) (n=80,male 43, age=8.54±4.3 yrs);and steroid resistant NS (SRNS) (n=50, male 29, age=7.72±3.6yrs). Multi resistance activity factor (MAF) was calculated using formula (MAFMDR1=100× (FMDR1-F0)/FMDR1).

Results: Percentage of P-gp (10.35±2.15 vs 4.19±1.07, p<0.001);and MRP-1(17.03±3.45 vs 8.71±2.97, p<0.001) were significantly higher in SRNS than SSNS. Absolute P-gp (64.96±12.78 vs 32.63±12.07, p<0.001) and MRP-1 (64.72±10.27 vs 40.28±11.24, p<0.001) expression were also significantly high in SRNS. P-gp expression on CD4+ (6.08±1.06 vs 4.34±1.47, p<0.001); and CD8+cells (8.65±2.19 vs 3.99±1.72, p<0.001) was significantly higher in SRNS than SSNS. MRP-1 expression on CD4+ cells (12.06±2.91 vs 3.35±0.83, p=0.001); and CD8+cells (5.11±0.68 vs 1.59±0.39, p<0.001) was significantly high in SRNS.Functional activity of P-gp (66.12±12.71 v/s 28.22±7.35, p<0.001);and MRP-1 (72.30±8.38 v/s 32.38±8.89,p<0.001) was significantly increased in SRNS.

Conclusions: Overexpression of P-gp and MRP-1 on T cells contribute in steroid resistance and may be biomarker of steroid resistance. Use of P-gp and MRP-1 inhibitors may prevent SRNS status.

SA-PO455

Metabolite Predictors of CKD Progression in Children

Michelle Denburg,[1] Alison G. Abraham,[5] Josef Coresh,[3] Jingsha Chen,[5] Morgan Grams,[10] Harold I. Feldman,[7] Paul L. Kimmel,[6] Casey Rebholz,[5] Eugene P. Rhee,[8] Vasan S. Ramachandran,[9] Bradley A. Warady,[4] Susan L. Furth.[2] for the CKD Biomarkers Consortium *[1]The Children's Hospital of Philadelphia, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [4]Children's Mercy Kansas City, Kansas City, MO; [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [6]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [7]University of Pennsylvania, Philadelphia, PA; [8]Massachusetts General Hospital, Newton, MA; [9]Boston University School of Medicine, Framingham, MA; [10]Johns Hopkins University, Baltimore, MD.*

Background: We sought to perform the first large-scale discovery of novel metabolite biomarkers of CKD progression in children.

Methods: We evaluated an untargeted GC/MS2 and LC/MS2-based metabolomics quantification (Metabolon) of baseline plasma samples from 587 Chronic Kidney Disease in Children (CKiD) participants. Cox proportional hazards and lognormal regression were used to examine the association between standardized, log transformed metabolites and progression to end stage kidney disease (ESKD: dialysis/transplant), adjusting for age, sex, race, body mass index, hypertension, anemia, glomerular (G) vs. non-glomerular (NG) diagnosis, serum albumin, proteinuria, and estimated glomerular filtration rate (eGFR). Stratified analyses were performed within G and NG subgroups.

Results: Cohort characteristics were: 354 male (60%); median age 12.3 years; median eGFR 53.2 mL/min/1.73m^2; 409 (70%) NG diagnosis. 171 (29%) developed ESKD over a median observation time of 5.0 years (inter-quartile range 3.1-7.5). Of 949 known non-drug metabolites identified, 16 were associated with time to ESKD in both the fully adjusted Cox and lognormal models by the pathway specific false discovery rate threshold <0.05 (Figure). 13 were lipids and 6 were in the hexosylceramide pathway. 10 of the 16 metabolites remained associated in stratified analyses, mostly within the G subgroup, and the magnitude of the HR was generally greater than that for the full cohort. An additional 9 metabolites (4 in the lysoplasmalogen pathway) were identified in stratified analyses, predominantly within the G group.

Conclusions: Untargeted metabolomic profiling identified several novel metabolite biomarkers associated with CKD progression in children independent of established predictors, including hypertension, proteinuria and eGFR, and distinct from metabolites identified in adult studies. Further studies are needed to replicate these findings and delineate mechanism.

Funding: NIDDK Support

Evaluation of Urinary C5b-9 as a Biomarker of Hematopoietic Stem Cell Transplant-Associated Thrombotic Microangiopathy

Stefanie W. Benoit,[1] Stella M. Davies,[1] Thelma Kathman,[1] Jay Patel,[1] Melinda Tepe,[1] Adam Lane,[1] Bradley P. Dixon.[2] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Children's Hospital of Colorado, Aurora, CO.*

Background: Thrombotic microangiopathy (TMA) affects 39% of pediatric hematopoietic stem cell transplant (HSCT) patients. Renal involvement, characterized by hypertension, proteinuria, and kidney injury, may be confounded by the side effects of corticosteroids and calcineurin inhibitors, and highly sensitive and specific biomarkers for HSCT TMA are currently lacking. Urinary C5b-9 (uMAC) is associated with disease activity in other forms of TMA such as preeclampsia. However, complement activation has been demonstrated in vitro when plasma is acidified by mixing with urine. We hypothesized that uMAC would be associated with the diagnosis of HSCT TMA, but potentially confounded by BK cystitis.

Methods: uMAC was measured prospectively in 80 consecutive pediatric allogeneic HSCT patients weekly from Days 0 – 35, and Days 48, 60, and 100 using a commercial ELISA clinically validated for use with urine. Association of uMAC with patient, primary disease, and HSCT characteristics was assessed. We then analyzed the association between the clinical outcomes of measurable uMAC, hematuria, BK viremia, and BK cystitis with the diagnosis of TMA.

Results: 48 patients had at least one uMAC >0ng/mL. There were no patient, primary disease, and HSCT characteristics associated with having measurable uMAC. In univariate analysis, TMA was associated with uMAC (p=0.04), hematuria (p<0.001), BK viremia (p<0.01), and BK cystitis (p<0.01). In multivariate analysis, uMAC was no longer associated with TMA (p=0.94), whereas BK viremia (p<0.01) and hematuria (p<0.05) maintained their association with TMA.

Conclusions: uMAC is not associated with HSCT TMA. uMAC is confounded by hematuria, which may have implications for its use and interpretation in other disease processes. Unexpectedly, hematuria demonstrated a strong association with TMA diagnosis in HSCT patients, perhaps suggesting its utility as an additional diagnostic criterion in establishing the diagnosis of TMA.

SA-PO457

Coexisting Variations in Complement Regulatory Genes Increase Risk of Relapse in Anti-Factor H (FH) Antibodies Associated Atypical Hemolytic Uremic Syndrome (aHUS)

Priyanka Khandelwal,[1] Mohammed Faruq,[2] Mamta Puraswani,[1] Aditi Sinha,[1] Arvind Bagga.[1] Indian HUS database *[1]All India Institute of Medical Sciences, New Delhi, India; [2]Institute of Genomics and Integrative Biology, New Delhi, India.*

Background: Patients with anti-FH antibodies, comprising one-half of children with aHUS in India, are managed by PEX and immunosuppression (IS). While deficiency of FH related protein-1 (*CFHR1*) is strongly associated, prevalence of additional variations and their impact on outcomes is unclear.

Methods: Of 435 children with anti-FH aHUS in the nationwide database, 93 (21%) were screened by targeted sequencing of 27 genes, comprising full length *CFH, CFI, CFB, C3, CD46, THBD, DGKE,* coding regions of *CFHR1-5, PLG, ADAMTS13* and lectin & terminal pathway. Genotype-phenotype correlation and risk-factors for relapse & adverse outcomes (eGFR <30 mL/min/1.73 m^2 or death) were evaluated.

Results: Patients aged 9±3 yr had high anti-FH titers (median 4684 AU/ml) that persisted >1000 AU/ml during remission in one-third. At 44-mo follow up, adverse outcome was seen in 20% and relapses in 30% (17% and 30% in database, respectively; P=0.02 and <0.001). Sequencing at mean depth of 123X (96% coverage) showed variants of unknown significance (VUS) in 6.5% (Table). MLPA showed homozygous deletion (90%) or duplication (N=1) of *CFHR1*. Severity of renal and extrarenal manifestations were independent of genetic variations. Prompt PEX (Hazard ratio, HR=1.03; P=0.009), lower anti-FH titers (HR=1.00; P=0.06) and lower peak creatinine (HR=1.2; P=0.008) were associated with improved outcomes. *MASP1* (c.*822C>T) polymorphism protected against relapses (allele frequency relapsers 0.015; non- relapsers 0.11; *P*=0.02). Maintenance IS (odds ratio, OR=10; *P*=0.02), no coexisting variations (OR=13; *P*=0.03); low C3 at onset (OR=5; *P*=0.03) and *MASP1* polymorphism (OR=8; *P*=0.06) independently reduced the risk of relapses.

Conclusions: Prompt PEX & IS improves long-term outcomes and prevents relapses in patients with anti-FH aHUS. Coexisting variations in regulatory genes might predispose to relapses.

CH50 Result Variability by Methodology in Eculizumab-Treated Patients with Atypical Hemolytic Uremic Syndrome

Ellen Cody,[1] Ashley Frazer-Abel,[2,3] Bradley P. Dixon.[1,2] *[1]Department of Pediatrics, University of Colorado School of Medicine, Aurora, CO; [2]Department of Medicine, University of Colorado School of Medicine, Aurora, CO; [3]Exsera BioLab, University of Colorado School of Medicine, Aurora, CO.*

Background: The advent of complement-targeted therapy for the treatment of atypical hemolytic uremic syndrome (aHUS) has led to an increasing use of pharmacodynamic monitoring in patients to ensure adequate complement blockade to suppress disease activity. Measurement of terminal pathway activity and functionality with plasma sC5b-9 and CH50, respectively, have gained wide acceptance as means to assess the adequacy of complement blockade in such patients. However, methodologies for the CH50 assay may vary widely among institutions, and some methodologies may be insufficiently sensitive to determine such adequacy of blockade.

Methods: In patients treated with eculizumab for aHUS and other forms of thrombotic microangiopathy, CH50 was clinically measured at regular intervals during the induction phase of treatment by a laboratory-developed standard hemolytic assay. We compared

these results to results obtained by two additional methods, the Wieslab CP assay and an instrument-based liposomal assay for CH50. Adequate complement blockade was defined as a CH50 value less than 10% of the lower limit of normal for each assay.

Results: We identified that in a number of patients treated with eculizumab, breakthrough of complement blockade prior to the next scheduled dose of eculizumab was noted by an upward trend of CH50 results obtained by hemolytic methodology, whereas values obtained by both Wieslab CP and instrument-based methodologies suggested ongoing suppression and did not detect this breakthrough in blockade. Breakthrough of complement blockade in several instances influenced therapeutic decision making, in which supplemental doses were administered to ensure sufficiency of suppression of disease activity.

Conclusions: These findings suggest that the sensitivity of CH50 to detect small but clinically meaningful changes in complement suppression may differ by assay methodology, and that care must be taken in the interpretation of the results of these assays for pharmacodynamic monitoring of patients on eculizumab.

Pediatric CKD Is Associated with Lower Cortical and Cerebellar Brain Volumes

Lyndsay Harshman,[1] Marci Novak,[2] Vincent Magnotta,[3] Susan L. Furth,[4] Patrick D. Brophy,[6] Peggy C. Nopoulos.[5] *[1]Pediatric Nephrology, University of Iowa Stead Family Children's Hospital, Iowa City, IA; [2]University of Iowa Stead Family Children's Hospital, Iowa City, IA; [3]University of Iowa, Iowa City, IA; [4]The Children's Hospital of Philadelphia, Philadelphia, PA; [5]University of iowa, Iowa City, IA; [6]University of Rochester, Rochester, NY.*

Background: Children with chronic kidney disease (CKD) are at risk for neurocognitive deficit. Neuroimaging studies provide the opportunity to accurately assess the brain and provide clues to the underlying mechanisms of observed neurocognitive abnormalities. To date, only a few published studies exist evaluating brain structure in pediatric CKD and often involve heterogenous samples with late CKD/end-stage populations of varying etiologies.

Methods: The purpose of this study is to quantitatively characterize brain structure in relationship to neurocognitive function in pediatric CKD patients with mild to moderate, non-glomerular CKD compared to age- and gender-matched, healthy controls using magnetic resonance imaging (MRI). Patients age 6-16 with congenital, non-glomerular causes of CKD (eGFR 30-90 ml/min/1.73m2) were invited to participate. Participants completed a neurocognitive evaluation, laboratory evaluation and MRI scan. The MRI scan included structural and functional sequences.

Results: Neurocognitive and structural MRI data were available for 26 participants (11 cases, 15 controls). Cases showed ***significantly lower cortical brain volume ($p = 0.046$) and notable volumetric decreases within the cerebellum*** ($p = 0.016$). There is specifically lower cerebellar gray matter in cases compared to controls ($p = 0.009$). Data suggest potential for a direct relationship between structural abnormality of the cerebellum and lower eGFR ($R^2 = 0.267$, see Figure 1).

Conclusions: Our data link volumetric differences noted most prominently in the cerebellums of CKD participants with lower eGFR. It is possible that the decline in renal function associated with CKD may perpetuate these findings. Understanding the influence of pediatric CKD progression and severity on the developing brain may allow enhanced awareness of the role of disease progression on neurodevelopmental outcomes in childhood and inform new approaches to treatment and patient education across the CKD lifespan.

Genomic Disorders, CKD, and Neurocognitive Status in Youth

Hilda E. Fernandez,[1] Emma Kirschner,[1] Emily Groopman,[1] Rachel E. Reingold,[1] Pooja Vekaria,[1] Susan L. Furth,[2] Ali G. Gharavi.[1] *[1]Columbia University, New York, NY; [2]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: A subset of youth w/ chronic kidney disease (CKD) harbor genomic disorders that impair both kidney and neurobehavioral function. The resultant neurocognitive (NC) deficits may impact patient outcomes, e.g. suboptimal medication adherence or poor school/work performance.

Methods: We are conducting genomic and NC testing in youth aged 8-25y w/ CKD (CKD Stage 2-5, on dialysis, or transplanted). Analyses integrate assessment of microarray and exome sequence to identify pathogenic variants associated w/ CKD and neurodevelopmental disorders. Enrollment goal is 200 subjects.

Results: Thus far, 30 subjects have completed NC testing (**Table**) and 24 underwent genomic analysis. On NC testing (**Figure**), we noted impaired NC outcomes, including lower IQ, weaknesses in global executive functioning, worse attention, and higher anxiety. In 3 of 24 cases who completed exome sequencing, we detected putatively pathogenic variants for monogenic forms of CKD: 2 w/ COL4A5 variants, associated w/ X-linked Alport syndrome; 1 w/ a ROBO2 variant, associated w/ Vesicoureteral Reflux 2. None had known pathogenic variants associated w/ neurodevelopmental disorders.

Conclusions: Our preliminary results support the need for genomic and NC assessment in youth w/ CKD to enable specific diagnosis and support early interventions. Further study incorporating genomic and NC performance data will help to elucidate genetic factors underlying CKD and NC deficits.

Renal Complications in Congenital Anomaly Syndrome Patients with Genetic Variants

Tomoko Uehara,[1] Hisato Suzuki,[1] Toshiki Takenouchi,[2] Kenjiro Kosaki.[2] *[1]Keio University School of Medicine, Shinjuku-ku, Japan; [2]Keio University, Tokyo, Japan.*

Background: Early detection and early treatment of renal complications of patients with intellectual disabilities are critical for predicting their prognosis. However, phenotypes of kidney diseases are usually silent and, therefore, it is difficult to make early diagnosis. We assessed the renal complications among patients with intellectual disabilities.

Methods: 1211 patients who showed intellectual disabilities and congenital anomalies and their parents were recruited through the Japanese nation-wide undiagnosed disease program, Initiative on Rare and Undiagnosed Diseases (IRUD). Whole blood was collected from them after informed consent. Comprehensive genetic diagnosis was performed by medical exome sequencing (MES; Illumina TruSightOne, Illumina MiSeq) or whole exome sequencing (WES; Agilent SureSelect, Illumina HiSeq2000). Variants detected by the sequencer were filtered on quality, frequency, segregation pattern, previous reports, and genetic function and were confirmed by Sanger sequencing.

Results: Diagnoses were made in 417 patients (34.4 %) and renal complications were presented in 41(9.8 %) of these 417 patients. Among these 41 patients, kidney hypoplasia was present in seven patients, vesicoureteral reflux was present in one patients, hydronephrosis was present in seven patients, and multiple cystic kidney disease was present in one patient. Sequence analyses identified constitutional variants including *AUTS2*, *CHD7*, *CREBBP*, *EFTUD2*, *GNB1*, *KAT6A*, *KAT6B*, *KMT2A*, *KMT2D*, *MAGEL2*, *PBX1*, *PURA*, and *UBE3B*.

Conclusions: Renal phenotypes were not rare but critical complications of patients with congenital anomaly syndromes. Various types of kidney diseases were present in them and most of these diseases were able to be detected by urinary test or kidney echogram. However, it is difficult to make early diagnosis and early treatment of kidney complications if they were not taken into doctor's considerations. Furthermore, there were not only disease with high incidence of kidney phenotypes like CHARGE syndrome, or Rubinstein-Taybe syndrome, but also diseases with low incidence of kidney diseases, such as Kabuki

syndrome or Cornelia de Lange syndrome. Taken together, to perform both urinary test and kidney echogram at least once may be need for patients with congenital anomaly syndromes to be made early detection and treatment of kidney diseases.

Primary Cause of Kidney Disease and Mortality in Children on Dialysis

Yusuke Okuda, Melissa Soohoo, Yoshitsugu Obi, Elani Streja, Ying Tang, Connie Rhee, Kamyar Kalantar-Zadeh. *Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, Orange, CA.*

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) has been associated with slower progression of chronic kidney disease in children. However, little is known about the association of CAKUT vs. other primary causes of kidney disease with mortality risk after dialysis initiation.

Methods: We used the United States Renal Data System to identify 25,761 incident dialysis patients who were ≤21 years old between 1995–2016. We examined the risk of the primary cause of kidney disease with mortality using adjusted Cox models. Sensitivity analyses included stratification on age and individual non-CAKUT causes, and propensity score (PS)-matched analyses. The PS was calculated based on case mix variables.

Results: The median (IQR) age was 17 (11–19) years and 4,780 (19%) had CAKUT. The case mix-adjusted hazard ratio (HR) for CAKUT patients was 0.72 (95%CI, 0.64–0.81) (ref: non-CAKUT). In age stratified analysis, the case mix-adjusted HRs (95%CIs) for CAKUT patients were 0.66 (0.54–0.80), 0.56 (0.39–0.80), 0.66 (0.50–0.86), 0.97 (0.80–1.18) in <6 years, 6–<13 years, 13–<18 years, and ≥18 years, respectively (ref: non-CAKUT) [Figure]. Among the non-CAKUT causes, mortality associated with primary glomerulonephritis (HR, 0.93; 95%CI, 0.80–1.10) and focal segmental glomerulosclerosis (HR, 0.89; 95%CI, 0.75–1.04) was comparable or slightly lower compared to CAKUT, whereas most other causes were associated with higher mortality risk. The lower mortality risk in CAKUT patients was consistent in the PS-matched cohort.

Conclusions: CAKUT was associated with lower mortality in children on dialysis, especially in those younger than 18 years old. Additional studies are needed to investigate the mortality risk for rare non-CAKUT causes.

SA-PO463

Estimated Glomerular Filtration Rate at Dialysis Initiation and Mortality in Children

Yusuke Okuda, Melissa Soohoo, Yoshitsugu Obi, Elani Streja, Ying Tang, Connie Rhee, Kamyar Kalantar-Zadeh. *Harold Simmons Center for Kidney Disease Research and Epidemiology, Division of Nephrology and Hypertension, University of California, Irvine, Orange, CA.*

Background: The timing of dialysis initiation and estimated glomerular filtration rate (eGFR) has been hotly debated for adult dialysis patients. However, there are scarce data on the association between eGFR at dialysis initiation and mortality in children.

Methods: In a cohort of incident dialysis patients from 1995-2016 identified from the United States Renal Data System and aged 1–17 years old, we examined the association of eGFR at dialysis initiation with mortality. Mortality risk was estimated using Cox model with three levels of adjustment, i.e., unadjusted, case mix-adjusted, and fully adjusted model including height, body mass index, hemoglobin, and albumin. eGFR was calculated using the pediatric specific bedside Schwartz equation.

Results: Among 10,251 included patients, median age was 13 (IQR: 10–16) years and median eGFR was 7.8 (IQR: 5.7–10.5) mL/min/1.73 m^2. There appeared a trend toward higher mortality risk across higher eGFR. In particular, eGFR <5 mL/min/1.73 m^2 was associated with low mortality (fully adjusted hazard ratio [HR], 0.64; 95%CI, 0.50–0.84) (reference: eGFR 5 to <7 mL/min/1.73 m^2). This association was consistent in children ≥6 years old, whereas HR was 1.25 (95%CI: 0.67–2.31) for eGFR<5 mL/min/1.73 m^2 among those <6 years old (reference: eGFR 5 to <7 mL/min/1.73 m^2) [Figure].

Conclusions: Low eGFR at dialysis initiation was associated with lower mortality, especially for eGFR levels less than 5 mL/min/1.73 m^2 in incident dialysis children. The result does not suggest an independent indication of dialysis initiation based on eGFR. If the clinical status allows it, eGFR at dialysis initiation should be considered. Further considerations are needed in children younger than 6 years old.

SA-PO464

Cause of Death in Children and Young Adults Treated with Dialysis: 1990-2015

Elaine Ku,[1] Patrick Ahearn,[3] Charles E. McCulloch,[1] Barbara A. Grimes,[3] Mark Mitsnefes.[2] *[1]University of California San Francisco, San Francisco, CA; [2]Cincinnati Children's Hospital, Cincinnati, OH; [3]UCSF, San Francisco, CA.*

Background: Survival of children on dialysis has improved over the last two decades. However, few studies have examined whether there have been differences in attributed causes of death (cardiovascular, infectious, or malignancy-related) over time in children or young adults treated with dialysis.

Methods: We included patients ages 0-25 years who started dialysis between 1990-2010 followed through December 31, 2015 in the United States Renal Data System. We examined overall mortality and cause-specific mortality (categorized as cardiovascular (CV), infectious, or malignancy-related) by calendar year. We used Cox models to examine differences in the risk of all-cause and cause-specific mortality over time (using 1995 as a reference), accounting for age at dialysis initiation, sex, race, median neighborhood income, cause of ESRD, and insurance type. Follow-up was censored at receipt of a first kidney transplant.

Results: We included a total of 41,339 individuals who started dialysis between 1990-2010, of whom 6344 died during 3.5 years of follow-up. Mean age was 16 yrs, 56% were male. 54% of deaths were secondary to CV causes, 14% infectious causes, and 2% were secondary to malignancy. In adjusted analysis, risk of overall death appeared to increase initially up to 2006, then decreased thereafter (Figure, p<0.001 for non-linearity). Risk of CV-related death also increased initially, but then declined after 2006 (p<0.001 for non-linearity). Risk of infectious-related death steadily decreased over time by 4%/yr (p<0.001, Figure). In contrast, risk of malignancy-related death increased over time by 4%/yr, although this trend did not achieve statistical significance (p=0.08).

Conclusions: Survival in a prevalent cohort of children and young adults receiving dialysis appears to be relatively stable over the last two decades, but differed by cause of death. Risk of infectious-related death has steadily improved, whereas risk of malignancy-related death has steadily increased over time. Further studies are needed to understand the reasons for these findings.

SA-PO465

Impact of Fluid Overload on Growth of Low-Weight Children (<15 kg) Undergoing Chronic Hemodialysis

Cristina Henriques,[1] Simone Vieira,[1] Shirlei Komi,[1] Maria fernanda C. Carvalho,[1] Paulo C. Koch nogueira.[2] *[1]Hospital Samaritano, Sao Paulo, Brazil; [2]UNIFESP, Sao Paulo, Brazil.*

Background: To assess whether fluid overload estimated by interdialytic weight gain (IWG) in low-weight children on hemodialysis (HD) impacts patient growth.

Methods: Prospective cohort study of 43 patients (11F and 32M) with weight <15 kg. 91% of patients underwent daily HD. IWG was defined as the difference between pre-HD weight and estimated dry weight of the patient, expressed as percentage of weight. IWG was estimated at each HD session and the median of all values during follow-up was then calculated for each individual. The following procedures were adopted to estimate possible effect of IWG on patient growth: a) Growth during the 6-month follow-up period was calculated, defined as the delta between the repeated measures of the Z-score of height for age parameter (first measure minus second measure).

Results: Median follow-up time was 151 days (IQR = 141 to 153 days). At study baseline, median patient age was 2.0 years (IQR = 0.8 to 2.9) and median Z-score for weight/age was -3.0 (IQR= -4.5 to -2.4). Median Z-score for height/age was -3.8 (IQR = -5.2 to -2.6) at study baseline and -3.5 (IQR=-4.8 to -2.8) at end of follow-up, a difference that was not statistically significant for the overall sample (p=0.365). The assessment of IWG of all patients at 6 months revealed a median of 2.8% (IQR 0.0% – 6.2%). Patients were classified according to IWG into: a) High IWG, where 20 patients had IWG exceeding the median (>2.8%); and b) Low IWG, where 23 patients had IWG lower than the median (<2.8%). Comparison of height delta revealed 0.22 (-0.02 to 0.53) in the Low IWG group versus -0.12 (-0.31 to 0.24) in the High IWG group, a statistically significant difference (p=0.030) indicating impaired growth in the children with High IWG. On the repeated measures model using the GEE, a significant difference (p=0.026) in slope of Z-score of height for age curves was evident between groups with Low IWG=0.3 (SE=0.1) and High IWG=-0.1 (SE=0.1).

Conclusions: Besides the specific factors of CKD that lead to growth deficit, High IWG can negatively impact growth, representing a further factor impairing height in these patients. Hypervolemia promotes greater energy expenditure and contributes to systemic inflammation, leading directly or indirectly to greater protein-calorie depletion.

SA-PO466

AKI Biomarkers Associate with Risk for Diabetic Nephropathy

Robin A. Kremsdorf,[2,1] Lisa S. Topor.[2,1] *[1]Pediatrics, Hasbro Children's Hospsital, Providence, RI; [2]Brown University, Providence, RI.*

Background: Children with diabetes mellitus (DM) are at significant risk to develop diabetic nephropathy. While conventional therapies (glycemic control, treating microalbuminuria with ACE inhibition) can reduce this risk, other determinants of renal outcomes in children with DM are poorly understood. We measured urine biomarkers of acute renal tubular injury in children and young adults with DM to identify if these biomarkers correlate with traditional renal risk factors.

Methods: Subjects between the ages of 10-21 years were recruited from DM clinics. Inclusion criteria included Type 1 DM for 3 years or longer or Type 2 DM for any duration. Clinical data, blood samples, and urine samples were obtained. The urine biomarkers neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule 1 (KIM1), and liver fatty-acid binding protein (L-FABP) were measured. Linear regression was used to analyze the relationship between each biomarker and clinical parameters (age, duration of diabetes, gender, hemoglobin A1c, presence of microalbuminuria > 30 mg/g).

Results: Of 155 subjects, 64 (41%) were female, 109 (70%) where white, and 129 (83%) had Type 1 DM. Mean (standard deviation, SD) age was 15.5 (2.7) years. Mean (SD) hemoglobin A1c was 9.1% (1.7) in those with Type 1 DM and 7.9% (2.6) among those with Type 2 DM. NGAL was associated with female gender (43 ng/mL higher in females), higher KIM-1 associated with microalbuminuria (6047 pg/mL higher in the presence of microalbuminuria), and L-FABP associated with hemoglobin A1c (0.23 pg/mL lower for each 1% increase of HgbA1c). These associations persisted when the analysis was restricted to subjects with Type 1 DM.

Conclusions: Amongst children and young adults with DM, acute kidney injury biomarkers have baseline associations with known risk factors for diabetic nephropathy. It will be important to determine if these biomarkers are associated with clinically relevant endpoints in the future.

Predictors of AKI in Pediatric Rhabdomyolysis

Rebecca Levy,[1] Frederick J. Kaskel,[2] Michal L. Melamed,[3] Kimberly J. Reidy.[1] *[1]Children's Hospital at Montefiore/ Albert Einstein College of Medicine, Bronxville, NY; [2]Children's Hospital at Montefiore, Bronx, NY; [3]Albert Einstein College of Medicine, Bronx, NY.*

Background: Rhabdomyolysis is an uncommon but serious disease in children. The most serious complication of rhabdomyolysis is acute kidney injury (AKI). Risk factors for AKI include greater hematuria, faster fluid administration, and higher initial creatine kinase (CK). Here, we describe the baseline characteristics of children with rhabdomyolysis and identify predictors of AKI in a large, urban tertiary care children's hospital.

Methods: This study was a retrospective cohort. Participants included children (aged less than 18 years) evaluated in the Children's Hospital at Montefiore (CHAM) 1/1/2006-12/31/2015 with CK >1000. The outcome is AKI defined as increase in sCr ≥0.3mg/dL. Potential covariates were identified from biologically plausible variables and include age, sex, race, and biochemical markers at presentation. Bivariate associations were explored using X^2 tests, *t* test or Mann-Whitney U test fas appropriate. All analysis was conducted using STATA v15.0. Protocols were approved by the AECOM IRB.

Results: A total of 447 participants were identified, of whom 124 had AKI. Participants with rhabdomyolysis and AKI were younger and more often female than those without; they did not differ by race. Participants with AKI had higher initial CK, were more acidotic, and had higher baseline phosphorus levels than participants without AKI but did not differ in baseline potassium or calcium (Table 1).

Conclusions: Demographic characteristics and baseline biochemistry are associated with increased risk of AKI in pediatric rhabdomyolysis. Strengths of this study include large sample size. Limitations include missing data and inability to confirm etiology; detailed chart review is ongoing. Next steps include regression analysis and validation of adult risk prediction equations.

Novel Cardiac Biomarkers for AKI Risk Stratification After Pediatric Cardiac Surgery

Jason H. Greenberg,[1] Michael R. Parsons,[6] Michael Zappitelli,[2] Yaqi Jia,[3] Heather Thiessen Philbrook,[3] Prasad Devarajan,[4] Allen D. Everett,[7] Chirag R. Parikh.[5] TRIBE-AKI *[1]Yale University, New Haven, CT; [2]Toronto Hospital for Sick Children, University of Toronto, Toronto, ON, Canada; [3]Yale University, New Haven, CT; [4]Cincinnati Children's Hospital, Cincinnati, OH; [5]Yale University and VAMC, New Haven, CT; [6]Johns Hopkins, Baltimore, MD; [7]Johns Hopkins School of Medicine, Baltimore, MD.*

Background: Children undergoing cardiac surgery are at high risk for postoperative AKI. Novel biomarkers are needed to improve risk stratification of AKI with consideration given to changes in physiology and biomarker distribution throughout childhood.

Methods: We enrolled children from 1 month to 18 years old, undergoing cardiopulmonary bypass. Plasma ST2, galectin-3, and NTproBNP, three FDA approved biomarkers of cardiac stretch or fibrosis, were measured preoperatively and postoperatively on day 1, within 6 hours of cardiac surgery.

Results: Postoperatively, AKI, defined by a doubling of baseline serum creatinine or dialysis, was diagnosed in 79/395 (29%) children. NTproBNP was the only biomarker in the preoperative period that was significantly different between patients with *vs* without AKI (median 0.7 [0.3, 2.9] vs. median 0.4 [0.2, 1.1]). First post-operative ST2, galectin-3, and NTproBNP were significantly higher in patients with vs. without AKI (ST2: median 21.2 [9.7, 74.0] vs 7.7 [3.8, 24.2] ($p<0.001$), galectin-3: median 16.4 [10.6, 21.0] vs 13.3 [9.4, 17.9], NTproBNP: median 1.3 [0.7, 6.5] vs. 0.6 [0.2, 2.2). A significant interaction between biomarker and age was present for both galectin-3 and NTproBNP ($p<0.05$). In children ≥2 years old, after multivariable adjustment, the highest tertile of preoperative galectin-3 and NTproBNP as well as day 1 ST2, galectin-3, and NTproBNP were associated with AKI (Table 1).

Conclusions: Novel cardiac biomarkers, particularly ST2 measured within 6 hours of cardiac surgery, can be used for risk stratification of AKI. The performance of biomarkers after cardiac surgery is affected by age and additional research is required to develop novel cardiac biomarkers for children less than 2 years old.

Open-Label, Single-Dose Study to Evaluate the Safety, Tolerability, Pharmacokinetics, and Pharmacodynamics of Etelcalcetide in Subjects Aged 2-<18 Years with sHPT Receiving Maintenance Dialysis

Lucy Yan,[1] Ogo I. Egbuna,[4] Claus Peter Schmitt,[6] Christina Taylan,[3] Johan Vande walle,[5] Jude Ngang,[4] Bradley A. Warady.[2] *[1]Amgen, San Mateo, CA; [2]Children's Mercy Kansas City, Kansas City, MO; [3]University Hospital of Cologne, Cologne, Germany; [4]Amgen Inc, Thousand Oaks, CA; [5]UZGent, Gent, Belgium; [6]Center for Pediatric and Adolescent Medicine, Heidelberg, Germany.*

Background: Approximately 60% to 80% of the paediatric dialysis population receives treatment for secondary HPT with vitamin D. The burden of complications of secondary HPT in the paediatric dialysis population and limitations of current therapy underscore the need for better treatments for secondary HPT in these patients. Etelcalcetide is the only calcimimetic formulated for IV administration and is administered TIW (three times a week) as a bolus dose at the end of the haemodialysis treatment.

Methods: This phase 1 study was conducted to investigate the safety, tolerability, PK and PD characteristics of etelcalcetide after the administration of a single dose that may represent a safe starting dose for this titratable drug to paediatric hemodialysis patients. Subjects (2 to < 18 yrs old) received a single IV dose of 0.035 mg/kg etelcalcetide at the end of a hemodialysis session. Intensive PK and PD samples were collected on Day 1 at 10 min and 4 hours after etelcalcetide administration and for 10 days post dose with a safety follow-up period of up to 30 days post dose.

Results: Six subjects (3M, 3F, 6-15 yrs old) have completed the study. In general, the single dose of etelcalcetide was well tolerated. Adverse events reported during this study were consistent with the known safety profile of etelcalcetide. All corrected calcium levels reported were above 2.25 mmol/L. No clinical symptoms possibly related to hypocalcemia were observed. PK exposure was within the predicted range at this dose level (see Figure below- the dipping point on Day 3 was related to hemodialysis).

Conclusions: Single dose of 0.035 mg/kg etelcalcetide is well tolerated in paediatric patients on hemodialysis. The preliminary PK and safety data collected so far are within the predicted range at this dose level.

Burosumab Improved Rickets and Clinical Outcomes Compared to Conventional Therapy in Children with XLH

Anthony A. Portale,[1] Erik Imel,[2] Craig Munns,[4] Leanne M. Ward,[3] Michael Whyte,[5] Jill Simmons,[6] Raja Padidela,[7] Meng Mao,[8] Alison Skrinar,[8] Javier San martin,[8] Francis H. Glorieux.[9] *[1]University of California San Francisco, San Francisco, CA; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Children's Hospital of Eastern Ontario, University of Ottawa, Ottawa, ON, Canada; [4]The Children's Hospital at Westmead, Westmead, NSW, Australia; [5]Washington University School of Medicine, St. Louis, MO; [6]Vanderbilt University Medical Center, Nashville, TN; [7]Manchester University NHS Foundation Trust, Manchester, United Kingdom; [8]Ultragenyx Pharmaceutical Inc., Novato, CA; [9]Shriners Hospital for Children-Canada, Montreal, QC, Canada.*

Background: In children with X-linked hypophosphatemia (XLH), high circulating levels of FGF23 cause hypophosphatemia with consequent rickets, skeletal deformities, and growth impairment. Burosumab is an FDA-approved fully human monoclonal antibody against FGF23 for patients ≥1 year of age with XLH. Conventional therapy consists of multiple daily doses of oral phosphate and active vitamin D (Pi/D).

Methods: In the study CL301 (NCT02915705), 61 children with XLH (1-12 years old) were randomized (1:1) to receive subcutaneous burosumab starting at 0.8 mg/kg every 2 weeks (wk) or Pi/D as prescribed by the investigator. Eligibility criteria included a Total Rickets Severity Score (RSS) ≥2.0.

Results: Burosumab showed significantly greater improvement than Pi/D in rickets as assessed by radiologists blinded to treatment using the radiographic global impression of change (RGI-C) at Wk 40 (primary endpoint). More subjects in the burosumab group had substantial healing (RGI-C ≥+2.0) at Wk 40, compared with the Pi/D group (21/29, 72% vs 2/32, 6%; odds ratio of healing 39.1, p<0.0001). Decreases in rickets severity assessed by RSS and alkaline phosphatase also were greater with burosumab. Increases in serum phosphorus were greater with burosumab than with Pi/D. Standing height Z-score increased from a baseline mean (SD) of -2.32 (1.17) to -2.12 (1.22) at Wk 40 for burosumab; and from -2.05 (0.87) to -1.97 (0.87) for Pi/D. Percent predicted distance walked increased with burosumab (Baseline to Wk 40: 62% to 72%) and was unchanged with Pi/D (76% to 75%). Adverse events of interest were higher in the burosumab group, but were mild to moderate in severity overall, with no discontinuations.

Conclusions: Burosumab resulted in significantly greater improvement in rickets and serum phosphorus than conventional therapy in 1-12 year-old children with XLH.

Funding: Commercial Support - Ultragenyx Pharmaceutical Inc.

Summary of Efficacy in UX023-CL301

Assessment	Pi/D (N = 32)	Burosumab (N = 29)	Difference, p-value
RGI-C Global Score at Week 40, LS Mean ± SE	+0.77 ± 0.11	+1.92 ± 0.11	1.14, p<0.0001
Total RSS, LS mean ± SE Change from Baseline to Week 40	-0.71 ± 0.138	-2.04 ± 0.145	-1.34, p<0.0001
Alkaline Phosphatase, U/L, LS Mean ± SE Change from Baseline to Week 40	-35 ± 19	-131 ± 13	-97, p<0.0001
Serum Phosphorus, mg/dL, LS Mean ± SE Change from Baseline to Week 40	+0.20 ± 0.06	+0.92 ± 0.08	0.71; p<0.0001
TmP/GFR, mg/dL, LS Mean ± SE Change from Baseline to Week 40	-0.17 ± 0.08	+1.16 ± 0.12	1.33, p<0.0001

Higher RGI-C and lower RSS = improvement; p-values from ANCOVA (Rickets) & GEE (ALP, TmP/GFR, and Pi).

Bone and Circulating Sclerostin and Histomorphometry in Pediatric Patients with CKD

Marciana Laster,[1] Renata C. Pereira,[2] Barbara Gales,[1] Isidro B. Salusky.[3] *[1]University of California Los Angeles, Los Angeles, CA; [2]University of California, Los Angeles, CA; [3]Mattel Children's Hospital, Los Angeles, CA.*

Background: Serum sclerostin, a bone formation inhibitor, increases in CKD but little is known of its role in predicting turnover and mineralization states in pediatric renal osteodystrophy.

Methods: Serum sclerostin was measured in a group of 58 dialysis and 35 pre-dialysis CKD patients at the time of iliac crest bone biopsy. Sclerostin expression in bone biopsy specimens was quantified using immunohistochemistry (IHC). Spearman correlations and multivariable linear regression analyses were performed to determine the relationship between serum and bone sclerostin levels and parameters of the TMV bone classification system. Models were controlled for gender and PTH-two well-known confounders of serum sclerostin.

Results: Cohort characteristics are presented in Table 1. Median serum sclerostin levels were higher in the dialysis vs. CKD patients; although IHC expression was no different (Table 2). In dialysis patients, significant correlations ($p<0.05$) included sclerostin with osteoid thickness (OTH, r=-0.27), osteoid volume (OV/BV, r=-0.26) and osteoid surface (OS/BS, r=-0.26). These relationships were lost after adjustment for gender and PTH. In CKD patients, significant correlations included serum sclerostin with bone formation rate (BFR/BS, r=-0.37) and eroded surface (ES/BS, r=-0.48). Both relationships persisted after adjustment resulting in sclerostin predicting 3% lower BFR/BS and 2% lower ES/BS for every unit increase in sclerostin ($p=0.03$ and $p=0.01$, respectively). Bone expression of sclerostin predominated in cortical areas and likely for this reason failed to correlate with trabecular TMV parameters.

Conclusions: The association of serum sclerostin with bone histomorphometry varies across the spectrum of GFR. The association of sclerostin with bone turnover in CKD patients is consistent with descriptions of Wnt antagonism as an early determinant of bone turnover in CKD. Such findings may have potential therapeutic implications in CKD-MBD.

Real-World Utilization of Prescription Medications to Manage Pain in Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Myrlene Sanon,[1] Efstathios N. Michalopoulos,[2] Robert A. Stellhorn,[1] Dorothee Oberdhan,[2] Christina Pao,[1] Linda Mccormick.[1] *[1]Otsuka Pharmaceutical Development & Commercialization, Inc., Princeton, NJ; [2]Otsuka Pharmaceutical Development & Commercialization, Inc., Rockville, MD.*

Background: ADPKD is a rare inherited disease characterized by progressive kidney enlargement and leads to end stage renal disease. Symptoms of ADPKD include chronic and transient types of pain in more than 80% of patients which can range in severity from mild to disabling. Understanding utilization of pain medications is important given pain has been linked to lower quality of life. Study aims to characterize management of pain through use of prescription medications.

Methods: Patients diagnosed with ADPKD (ICD-9/10 codes 753.12, 753.13, Q61.2, or Q61.3) were selected from Optum Clinformatics 2007-2017 US research database which is comprised of 7 million commercial and Medicare Advantage beneficiaries. Patients were aged 18 years or older, with continuous medical and pharmacy benefits for 6 months pre-index date (baseline period) and at least 6 months post-index date. The index date was the date of ADPKD diagnosis. Descriptive analyses described baseline patient characteristics, comorbidities, and utilization of pain medications by drug class during one-year post index-date. Included pain medications were selected per literature assessment of common pharmacologic treatments for the management of non-neuropathic and neuropathic pain syndromes.

Results: 8,984 ADPKD patients met study inclusion criteria. Mean age was 57 years (SD=17) and 50% male. Mean follow-up time was 36 months (SD=27). At baseline, the mean Charlson comorbidity score was 1.86 and common medical comorbidities included hypertension (65%), diabetes (25%), chronic pulmonary disorder (14%), depression (9%), and anxiety (8%). Seventy percent (N=6,285) received at least one prescription for a medication commonly used to treat pain during one-year post index. Opioids were used by 50% of patients, followed by corticosteroids (31%), hypnotics including benzodiazepines (28%), antidepressants (20%), NSAIDS (18%), and anticonvulsants (11%).

Conclusions: Results show pharmacologic treatment of pain is common in patients with ADPKD with high use of opioids, corticosteroids, hypnotics, antidepressants, and NSAIDS. Use of NSAIDs in this population is relatively contraindicated suggesting higher severity of pain in this population and warrants further investigation.

AD(H)PKD – A Prospective Cohort Study on the Use of Tolvaptan in ADPKD

Roman-Ulrich Mueller, Polina Todorova, Victor Suárez, Bernhard Schermer, Thomas Benzing, Volker R. Burst, Franziska Grundmann. *Dept. 2 of Internal Medicine, University of Cologne, Koeln, Germany.*

Background: The approval of tolvaptan as the first targeted therapy of autosomal-dominant polycystic kidney disease is a significant progress in the treatment of this disease. But how is this therapy managed in the real-life setting? How is it accepted by patients taking into account the consecutive polyuria?

Methods: To answer these questions, we initiated the AD(H)PKD registry which enrolls ADPKD patients that have not reached ESRD yet and present with the question whether tolvaptan would be a treatment option. We collect data on a yearly basis including lab values, kidney volume, quality of life, adherence, genotype, extrarenal manifestations, comorbidity, side effects and complications.

Results: Since the start of the study at the end of 2015 until May 2018 more than 450 patients could be enrolled. Here, we present - apart from the general characterization of the cohort – first data regarding the use of tolvaptan in the real-life setting. The urine volume increases to 5-7.5 liters in the majority of patients on tolvaptan. The largest increase occurs when starting the first dose step (45/15 mg), whilst the further uptitration (60/30 and 90/30 mg) only shows a minor additional effect on urine output. The same holds true for urine osmolality. Adherence to the therapy is currently about 80%; most patients that discontinue tolvaptan do so early after initation with polyuria-related events being the most common reason. More than 75% of patients report little to no problems with the therapy in everyday life. Patients skip a dose 1-2x per month on average and do so mainly due to professional and leisure-time activities.

Conclusions: The AD(H)PKD study continues successful enrolment and allows for a first insight into patient-reported outcomes like quality of life and feasibility of the therapy. The adherence of about 80% confirms the data obtained in TEMPO 3:4. Furthermore, AD(H)PKD provides the first systematic data on urine volume and osmolality in the real-life setting. These results will be very helpful for guiding management of ADPKD patients and patient counselling in the future.

SA-PO474

An Analysis of Novel Quantitative MRI Parameters to Evaluate Cystic Burden in Autosomal-Dominant Polycystic Kidney Disease

Roman-Ulrich Mueller,[1] Florian Siedek,[2] Daniel Pinto dos santos,[2] Stefan Haneder,[2] Thomas Benzing,[1] Thorsten Persigehl,[2] Bettina Baessler,[2] Franziska Grundmann.[1] *[1]Dept. 2 of Internal Medicine, University of Cologne, Koeln, Germany; [2]Institute of Diagnostic and Interventional Radiology, University of Cologne, Cologne, Germany.*

Background: In ADPKD, parameters that correlate with severity of disease are of crucial importance in guiding the management. To date, these rely primarily on genetics, clinical evaluation and kidney volumetry (TKV). Whilst TKV has been shown to be a very useful tool to predict future outcome, measuring the cyst fraction would be favorable. However, this is currently not feasible in the everyday clinical setting. Here, we present a novel approach employing MRI T2 mapping.

Methods: 141 ADPKD patients from the AD(H)PKD-cohort and 10 healthy controls underwent MRI (1.5T system). HtTKV was calculated on coronary T2-weighted images using semi-automatic segmentation. Renal T2 relaxation times [ms] were generated using a Gradient-Spin-Echo (GraSE) T2 mapping sequence. Cyst fractions and mean T2 relaxation times (kidney-T2) were calculated using a plugin in Osirix. For analysis of T2-times of the remaining renal parenchyma (parenchyma-T2) a single ROI was chosen manually in 3 slices of each kidney and the results were averaged. Based on the cyst fraction patients were separated into three groups (<35%, 36-70%,> 70%).

Results: Obtaining parenchyma-T2 required 6-10fold less time than kidney-T2 or htTKV by semiautomatic segmentation (0,78±0,14 vs. 4,78±1,17 min, $p<0,001$, 0,78 ±0,14 vs. 7,59±1,57 min, $p<.001$). Importantly, parenchyma-T2 showed a similarly strong correlation to the cyst fraction ($r=0,77$, $p<0,001$) as kidney-T2 ($r=0,77$, $p<0,001$) and resulted in the clearest separation of patient groups. HtTKV showed only a moderate correlation to cyst fraction ($r= 0,48$, $p<0,001$) and did not allow for a clear group separation. Limiting the analysis to CKD stage 1 ($n = 47$) increased this discriminatory power whilst maintaining a similar correlation to the cyst fraction (parenchyma-T2: r=0,81; kidney-T2: r=0,79; htTKV: $r = 0,48$, $p<0,001$ for all).

Conclusions: Renal T2-mapping allows the determination of novel imaging parameters which show a high correlation to the cyst fraction. Whilst currently used methods for measuring TKV and cyst fraction are time-consuming, parenchyma-T2 can be measured within one minute. The high correlation with cyst fraction makes this parameter a promising biomarker, the power of which regarding disease progression will now be examined.

Acute Tolvaptan Treatment Has No Immediate Effect on Renal Plasma Flow or Glomerular Filtration Rate in Polycystic Kidney Disease

My E. Malmberg,[1,4] Rikke L. Sønderbæk,[1,4] Frank H. Mose,[1] Jens jorgen Jensen,[2] June A. Ejlersen,[2] Erling B. Pedersen,[3] Jesper N. Bech.[1] *[1]University Clinic in Nephrology and Hypertension, Regional Hospital Unit West Jutland, Holstebro, Denmark; [2]Department of Nuclear Medicine, Regional Hospital Unit West Jutland, Herning, Denmark; [3]University Clinic in Nephrology and Hypertension, Hospital Jutland West, Risskov, Denmark; [4]University of Aarhus, Aarhus, Denmark.*

Background: Autosomal dominant polycystic kidney disease ADPKD is a common genetic disorder, characterized by formation of cysts in the kidneys, causing gradual renal failure. Tolvaptan is a vasopressin 2 antagonist that seems to reduce the decline in glomerular filtration rate (GFR) in ADPKD. The mechanisms are not fully understood and could, at least partly, be related to changes in renal plasma flow (RPF). The purpose of this randomized, cross-over, double-blind, placebo-controlled study was to investigate if acute tolvaptan treatment increases RPF and/or GFR in patients with ADPKD.

Methods: We studied 18 ADPKD patients (chronic kidney disease stages 1-3) on two separate occasions after a single dose of tolvaptan 60 mg or placebo. Two hours after treatment, RPF and GFR were measured by 99-mTc-DTPA renography. Blood pressure was measured every fifteen minutes throughout the day by Mobil-O-Graph®. Renal vascular resistance (RVR) was estimated by the equation mean arterial pressure/RPF.

Results: 99-mTc-DTPA renography showed a similar RPF after tolvaptan treatment and placebo treatment (673 ±262 ml/min vs. 650 ±209 ml/min p = 0.571). GFR estimated by 99-mTc-DTPA renography was also unchanged after tolvaptan (78 ±26 ml/min after tolvaptan vs. 79 ±21 ml/min after placebo p = 0.774). During renography, after tolvaptan intake, the brachial systolic blood pressures dropped significantly (135 ±13 mmHg after tolvaptan vs. 141 ±19 mmHg after placebo p = 0.043). We found no significant change in brachial diastolic, central systolic or central diastolic blood pressure. Estimated RVR during renography was unchanged after tolvaptan treatment (0.20 ±0.12 mmHg/ml/min after tolvaptan vs. 0.20 ±0.08 mmHg/ml/min after placebo p = 0.908).

Conclusions: Our results suggest that acute tolvaptan treatment has no immediate effect on RPF and GFR. Our results do not support the hypothesis that the effect of tolvaptan on ADPKD progression is mediated by changes in renal hemodynamics.

SA-PO476

The Impact of Tolvaptan on Glomerular Filtration Rate in Patients with Autosomal Dominant Polycystic Kidney Disease

Gabrielle Côté, Lori Asselin-Thompstone, Paul Rene De Cotret, Fabrice Mac-Way, Mohsen Agharazii. *CHU de Quebec, Hotel-Dieu de Quebec Hospital, Quebec, QC, Canada.*

Background: Tolvaptan, a V2 receptor antagonist that induces aquaresis, has been shown through placebo-controlled studies to slow the decline in kidney function of patients with autosomal dominant polycystic kidney disease (ADPKD). Polyuria is a significant side-effect that can be attenuated by reducing daily sodium intake. In a cohort of ADPKD on tolvaptan, we aimed to identify the determinants of polyuria, to evaluate the impact of dietary counselling on the natriuresis and to compare the decline of estimated glomerular filtration rate (eGFR) before and after tolvaptan.

Methods: Retrospective study of 29 patients with ADPKD on tolvaptan. Serum creatinine level and 24-hour urine collection with volume and natriuresis were obtained before tolvaptan initiation. Patients had individual nutrition counselling to reduce their sodium intake. Tolvaptan was introduced after the nutrition counselling with serum creatinine level and 24-hour urine collection obtained on treatment. Polyuria was arbitrary defined as a urine volume of >5L/d. We used linear regression model and generalized estimation equations to analyse the data.

Results: The average of age and eGFR were respectively 44±11 years and 60±25 mL/min/1.73m^2. The urinary volume increased from 2.5 to 5.2L/d (95%CI: 4.6 to 5.8) on tolvaptan. Dietetic counselling resulted in a reduction of natriuresis (147 mmol/d (95%CI: 129 to165) to 131mmol/d (95%CI: 114 to 184)) (p=0.028). For each baseline increment of 10 mmol of daily sodium intake the odds ratio of polyuria was 3.4 (95%CI: 2.7-4.5). After adjusting for tolvaptan dose, an increase in 100 mmol of sodium intake was associated with an additional urinary volume of 1.1 L/d (95%CI: 0.6 to 1.6). The annual rate of eGFR loss was -5.5 ml/min/1.73m^2/year (95%CI: -8.2 to -2.7) before tolvaptan and -1.6 ml/min/1.73m^2/year (95%CI: -3.5 to 0.2) on tolvaptan. This slower rate of decline was statistically significant (p=0.033).

Conclusions: Natriuresis before tolvaptan is the major determinant of the polyuria on tolvaptan, but natriuresis can be significantly reduced by dietetic counselling. In this small cohort, we observed a slower decline in renal function after tolvaptan, as compared to the annual rate of decline before treatment with tolvaptan.

SA-PO477

Association Between Initial Dose of Tolvaptan and Reduction of Total Kidney Volume in Autosomal Dominant Polycystic Kidney Disease

Kenjiro Honda,[1] Ryo Matsuura,[4] Yu Ishimoto,[2] Masaomi Nangaku.[3] *[1]The University of Tokyo, Tokyo, Japan; [2]Tokyo University, Hongo, Japan; [3]the University of Tokyo School of Medicine, Tokyo, Japan; [4]The University of Tokyo Hospital, Tokyo, Japan.*

Background: It is occasionally difficult to increase dosage of tolvaptan in autosomal dominant polycystic kidney disease (ADPKD) treatment. The reason of difficulty in increase of tolvaptan dosage is mainly limitation of water intake. Therefore, the effect of lower tolvaptan dose is one of major concerns in ADPKD treatment. Despite that TEMPO3:4 trial and REPRISE trial revealed efficacy of high dose tolvaptan among ADPKD patients, dose-dependent efficacy of tolvaptan remains unclear.

Methods: We selected ADPKD patients who underwent tolvaptan treatment from 2014 to 2017 in our department. The association between averaged dose of tolvaptan during the first six months after the initiation of tolvaptan treatment and change rate of total kidney volume after the treatment. Total kidney volume was estimated by abdominal MRI.

Results: The median age of 10 male and 14 female patients was 50 years (IQR, 45 to 65 years). The total kidney volume, height-adjusted total kidney volume, and annual change rate were 1024mL (918 to 1819mL), 673mL/m (606 to 1137mL/m), +10.7% (+7.7 to +26.6%), respectively. Serum creatinine level was 0.9mg/dL (0.74 to1.42mg/dL), and eGFR was 52mL/min/1.73m^2 (37.7 to 71.8 mL/min/1.73m^2). CKD G2, G3a, G3b and G4 were 11 (44%), 4 (16%), 6 (24%), and 4 (16%) while Mayo classification 1A, 1B, 1C, 1D, and 1E were 0 (0%), 14 (58%), 3 (13%), 4 (17%), and 3 (13%). The annual rate of total kidney volume after tolvaptan treatment for six months was significantly lower than that of pretreatment level by -9.6% (-29.1 to +3.2%) ($P<1x10^{-5}$). When all the patients were divided into two groups according to median of difference between annual total kidney volume change before and six months after tolvaptan treatment, averaged tolvaptan dose during the first six months of tolvaptan treatment was higher in a group with stronger inhibition of kidney enlargement than a group with weaker inhibition of kidney enlargement (P=0.05). Mayo classification and CKD GFR stage were similar between the stronger and weaker inhibition groups.

Conclusions: Early effect on inhibition of total kidney volume growth may be associated with initial tolvaptan dose during the first six months after the initiation of tolvaptan treatment.

SA-PO478

Clinical Features Expecting High Efficacy of Tolvaptan in ADPKD Patients

Yuta Kogure,[1] Kaori Takayanagi,[1] Mariko Sato,[1] Yu Shimozato,[1] Kento Hirose,[1] Kunihiko Yasuda,[2] Yuya Shioda,[2] Minoru Hatano,[1] Tomonari Ogawa,[1] Koichi Kanozawa,[1] Hajime Hasegawa.[1] *[1]Saitama Medical Center, Saitama Medical University, Saitama, Japan; [2]Saitama Medical center, Saitama Medical University, Kawagoe, Japan.*

Background: Clinical efficacy of tolvaptan is variable in individual ADPKD patient. In our facility, we manage 120 ADPKD patients at present, and adapt 49 patients to the tolvaptan therapy. Among the cases, 40 patients have been proceeded more than one year after induction to the therapy, they are enabled to be examined the efficacy of tolvaptan. When the effectiveness would be defined as the reduction of total kidney volume (TKV) or the annual expansion rate of kidney volume (kidney growth rate: KGR) being less than 5%, tolvaptan showed approximately 70% of effectiveness in our facility. In this study, we retrospectively studied common clinical features in ADPKD patients who showed higher efficacy to tolvaptan by primarily focusing on KGR.

Methods: Forty ADPKD patients who had been treated with tolvaptan for at least one year were included in this study. KGR was calculated by CT-based total kidney volume (TKV) at one-year prior, just before, and one-year passed to the therapy. Response to tolvaptan was determined by ΔKGR (subtraction of pre-KGR from post-KGR), and negative value of ΔKGR indicates that the increase in TKV was inhibited by tolvaptan. Enrolled patients were stratified into 3 groups by ΔKGR value, and multiple clinical parameters were compared between 1st tertile group (1TG, lowest ΔKGR indicating highly effective) and 3rd tertile group (3TG, highest ΔKGR indicating poorly effective).

Results: ΔKGR values in 1TG and 3TG were -16.9% and 13.3%, respectively. Baseline values of TKV, KGR, systolic blood pressure (SBP), body mass index (BMI) and eGFR were significantly different between 1TG and 3TG (median TKV: 2005 mL vs 2534 mL, median KGR: 18.4% vs 3.0%, SBP: 123.1±16.5 mmHg vs 133.9±17.7 mmHg, BMI: 22.5±4.0 vs 26.3±7.4, eGFR: 57.1±23.7 mL/min vs 40.5±14.1 mL/min).

Conclusions: Present study may indicate that ADPKD patients who show less TKV, higher KGR, lower blood pressure, not-obese and renal function is not severely damaged would be expected higher efficacy of tolvaptan.

SA-PO479

Tolvaptan (TLV) in Children and Adolescents with Autosomal Dominant Polycystic Kidney Disease (ADPKD): Design of a Two-Part, Randomized, Double-Blind, Placebo (PBO)-Controlled Trial

Franz S. Schaefer,[1] Djalila Mekahli,[2] Francesco Emma,[3] Rodney D. Gilbert,[4] Detlef Bockenhauer,[5] Melissa A. Cadnapaphornchai,[6] Lily Shi,[7] Ann Dandurand,[7] Suzanne Watkin,[7] Susan E. Shoaf.[7] *[1]University of Heidelberg, Heidelberg, Germany; [2]KULeuven, Leuven, Belgium; [3]Bambino Gesu Children's Hospital, Rome, Italy; [4]Southampton Children's Hospital, Southampton, United Kingdom; [5]University College London, London, United Kingdom; [6]Rocky Mountain Pediatric Kidney Center, Rocky Mountain Hospital for Children at Presbyterian St. Luke's Medical Center, Denver, CO; [7]Otsuka Pharmaceutical Development & Commercialization, Rockville, MD.*

Background: TLV slows ADPKD progression in adults; its value in affected children and adolescents remains unknown. The first trial to assess TLV in pediatric ADPKD is currently ongoing (NCT02964273). We present the unique features of the trial population and its design.

Methods: This multicenter trial comprises two phases: Phase A is one year, randomized, double-blind, and PBO-controlled, Phase B is a two year open-label extension for subjects who completed Phase A. As formal diagnostic criteria for pediatric ADPKD are not developed, an advisory panel agreed eligibility would be based on family history/genetic criteria and would require ≥ 10 renal cysts measuring ≥ 0.5 cm on MRI to warrant treatment. Subjects (n=60) are allocated into 4 groups by gender and age (12–14y;15–17y). Subjects aged 4–11y may enroll. TLV is initiated at a weight-adjusted split dose ≤ 67% of the adult starting dose to allow for acclimation to excess diuresis; TLV is up-titrated after 1 wk to approximate the weight-adjusted starting dose for adults. Down-titration is permitted per tolerance. Assessments include spot urine osmolality and specific gravity (co-primary endpoints), total kidney volume, eGFR, PD parameters (urine volume, fluid intake and fluid balance, serum sodium, serum creatinine, and free water clearance), PK parameters, and generic pediatric QoL assessments. Safety parameters include AEs, changes in creatinine, vital signs, and lab values. Subjects are tested for ALT/AST, alkaline phosphatase and total bilirubin during screening and for ALT/AST monthly during treatment. Liver function tests are reviewed by investigators, and by independent hepatic adjudication and independent data monitoring committees. Stringent monitoring and intervention rules ensure rapid response to any potential hepatic signals.

Results: Pending

Conclusions: Kidney enlargement is continuous in ADPKD; cysts expand years before a reduction in GFR is apparent. This trial assesses the tolerability of TLV and begins to test the hypothesis that early treatment with a disease-modifying agent might be beneficial. Available interim data will be presented.

SA-PO480

Canadian Real-Life Assessment of Tolvaptan in Autosomal Dominant Polycystic Kidney Disease (ADPKD): C-MAJOR Study and Hepatic Safety Monitoring Program

Philip McFarlane,[1] Daniel G. Bichet,[4] Luc Bergeron,[2] Annick Laplante.[3] *[1]St. Michael's Hospital, Toronto, ON, Canada; [2]Otsuka Canada Pharmaceutical Inc., Saint-Laurent, QC, Canada; [3]Otsuka Canada, Saint-Sauveur, QC, Canada; [4]University of Montreal, Montreal, QC, Canada.*

Background: Tolvaptan is the only treatment slowing renal function decline, kidney enlargement and progression to end-stage renal disease in ADPKD. Health Canada mandated a patient registry of long-term clinical outcomes and a hepatic safety monitoring and distribution program (HSMDP) to mitigate the risk of liver injury. The objectives were to describe the baseline characteristics, quality of life (QoL), adherence, liver profile elevation rates and overall safety profile of patients enrolled in the real life setting of these two programs.

Methods: This is the 3rd interim analysis of C-MAJOR, the Canadian, non-interventional registry of ADPKD patients treated with tolvaptan and the 1st analysis of the HSMDP documenting the appropriate laboratory monitoring of hepatic function.

Results: 1143 and 250 patients were included in the HSMDP and C-MAJOR, respectively. At tolvaptan initiation, hypertension (77%), hepatic cysts (63%), and renal pain (21%) were the most common ADPKD manifestations. Patients presented with chronic kidney disease (CKD) Stage 1 (16%), 2 (28%), 3a (24%), 3b (20%) and 4 (8%) and with family history of ADPKD (77%) and family history of early ESRD (36%). At treatment initiation, 87 % of patients were considered at high risk of disease progression as per the Mayo classification (1C, D or E). QoL was assessed in newly initiated tolvaptan patients. Although not significantly different, progressively severe ADPKD-Pain and Discomfort Scale and Impact Scale scores in all domains were observed for increasing CKD stage. Over a mean (SD) follow-up of 64.1 (43.0) weeks, 3.1% of the 941 patients on tolvaptan experienced an elevation of LFT >3 X ULN. No cases of drug-induced liver injury were reported. The 6, 12 and 24-month treatment persistence rates on tolvaptan were 89.2%, 83.9% and 77.9% respectively. 47% of patients experienced an adverse event, most commonly nocturia (12%), polydipsia (9%), hypertension (8%), dizziness (7%), polyuria (6%) and fatigue (5%).

Conclusions: This interim report on real-life utilization of tolvaptan in Canada provides evidence of advanced disease at treatment initiation. The safety profile and persistence rate are similar to that reported in clinical trials. The liver safety evidence demonstrates that the HSMDP is effective in mitigating the risks to the patients.

SA-PO481

Gender-Specific Differences in Baseline Fluid and Solute Intake in the PREVENT-ADPKD Study

Carly Mannix,[1,2] Annette Wong,[1,2] Jennifer Zhang,[1,2] Sunil V. Badve,[4] Neil Boudville,[3] David C. Harris,[1,2] Vincent W. Lee,[1,2] Kamal Sud,[1,5] Bradley J. Erickson,[7] Vicente E. Torres,[7] Anna M. Rangan,[6] Margaret Allman-Farinelli,[6] Gopi Rangan.[1,2] PREVENT-ADPKD *[1]Centre for Transplant and Renal Research, The Westmead Institute for Medical Research, The University of Sydney, Sydney, NSW, Australia; [2]Department of Renal Medicine, Westmead Hospital, Sydney, NSW, Australia; [3]Sir Charles Gairdner Hospital, Nedlands, WA, Australia; [4]Department of Nephrology, St George Hospital, Kogarah, NSW, Australia; [5]Department of Renal Medicine, Nepean Hospital, Sydney, NSW, Australia; [6]School of Life and Environmental Sciences, The University of Sydney, Sydney, NSW, Australia; [7]Translational Polycystic Kidney Disease Center, Mayo Clinic, Rochester, MN.*

Background: Adequate hydration may slow the postnatal growth of renal cysts in autosomal dominant polycystic kidney disease (ADPKD) by attenuating the release of arginine vasopressin (AVP). However, the efficacy, safety and feasibility of this approach, and whether baseline fluid and dietary solute intakes vary by gender are not known.

Methods: PREVENT-ADPKD is a 3-yr multi-centre randomized controlled trial determining the effect of Prescribed Fluid Intake (sufficient to reduce urine osmolality to ≤270 mOsmol coupled with reduced dietary solute intake) on the progression of height-corrected total kidney volume (Ht-TKV) compared to Usual Fluid Intake in ADPKD patients (eGFR≥30ml/min/1.73m^2; Mayo Class 1B-1E). Recruitment was completed in May 2018.

Results: Of 1571 patients assessed for eligibility at 13 sites in Australia, 1295 were excluded due to ineligibility (n=1144) or declined to participate (n=151). The remaining 276 patients consented to the study, of whom 89 failed run-in (Mayo Subclass 1A, n=37; atypical kidneys, n=3; cannot do MRI, n=5; eGFR<30, n=7; pregnancy, n=2; non-compliance, n=31; and other exclusion criteria met, n=4) and 187 were randomised into Usual Fluid Intake (n=93) or Prescribed Fluid Intake (n=94). The median age of the randomised cohort was 43 yrs (range: 19-67; 94 women; 72% caucasian). At baseline, men had worse clinical characteristics of ADPKD (higher blood pressure, Ht-TKV and serum creatinine; P<0.001) but reported less kidney pain (P=0.03). Baseline 24hr urine volume did not differ by gender (P=0.85), whereas men had higher 24hr urine osmolality (26.6%), 24hr urine sodium excretion (31.0%), serum osmolality (1.7%) and serum copeptin (biomarker of AVP release) (116.1%) compared to women (P<0.001). Ninety percent of the cohort consumed caffeinated drinks but this did not differ by gender.

Conclusions: Baseline fluid intake is not affected by gender, but dietary sodium intake and AVP release are higher in men compared to women with ADPKD. These data support the importance of targeting both fluid and dietary solute intake to synergise the possible benefits of the intervention in PREVENT-ADPKD.

SA-PO482

Random Daytime Spot Urine Correlates with Twenty-Four Hour Urine Osmolality in Patients with Autosomal Dominant Polycystic Kidney Disease

Carly Mannix,[1,2] Annette Wong,[1,2] Jennifer Zhang,[1,2] Vincent W. Lee,[1,2] David C. Harris,[1,2] Kamal Sud,[1,3] Gopi Rangan.[1,2] PREVENT-ADPKD *[1]Centre for Transplant and Renal Research, The Westmead Institute for Medical Research, The University of Sydney, Sydney, NSW, Australia; [2]Department of Renal Medicine, Westmead Hospital, Western Sydney Local Health District, Sydney, NSW, Australia; [3]Department of Renal Medicine, Nepean Hospital, Nepean Blue Mountains Local Health District, Sydney, NSW, Australia.*

Background: Urine osmolality (UOsm) is a surrogate measure of hydration and dietary solute intake, regulated by levels of circulating arginine vasopressin (AVP). Monitoring UOsm may be useful to gauge adherence to fluid and diet prescriptions in autosomal dominant polycystic kidney disease (ADPKD). Traditionally, UOsm has been determined by 24hr urine collection but patients find this method cumbersome, and hence we investigated if spot urine could serve as an alternative method. The aim of this study was to determine the relationship between random daytime spot UOsm and 24hr UOsm in patients with ADPKD.

Methods: Random spot urine was collected prospectively from ADPKD patients (18-65 years, eGFR≥30 mL/min/1.73m^2) during the Screening Visit of the PREVENT-ADPKD study (a randomised controlled trial investigating the efficacy of prescribed fluid intake on kidney cyst growth). Urine specific gravity (USG) and serum copeptin (a biomarker of AVP release) were also analysed at the study visit, and patients then performed two 24hr urine collections over the subsequent 12 weeks.

Results: Seventy-nine participants were included (age:43±11 ys; 54% male). The mean spot UOsm was 491±196 mOsmol/L and correlated moderately with the mean 24hr UOsm (424±173 mOsmol/L; r=0.56; P<0.001). In contrast, the association between spot UOsm to urine creatinine ratio and the mean 24hr UOsm was weak (r=0.16, P=0.03). As expected, spot UOsm predicted the USG (P<0.001), and the latter was also positively correlated with the mean 24hr UOsm (r=049, P<0.001). Spot UOsm had a weak association with serum copeptin (median 4.2, range 0.9-28.1 pmol/L; r=0.26; P<0.001).

Conclusions: These data suggest that spot urine collected randomly during the day (either at a clinic visit for measurement of UOsm or by patient self-monitoring for USG)

may be an alternative method to estimate 24hr UOsm in patients with ADPKD. Further prospective studies and the outcome of the PREVENT-ADPKD trial are required to validate these findings.

SA-PO483

A Randomised Feasibility Trial of High vs Ad Libitum Water Intake in Autosomal Polycystic Kidney Disease

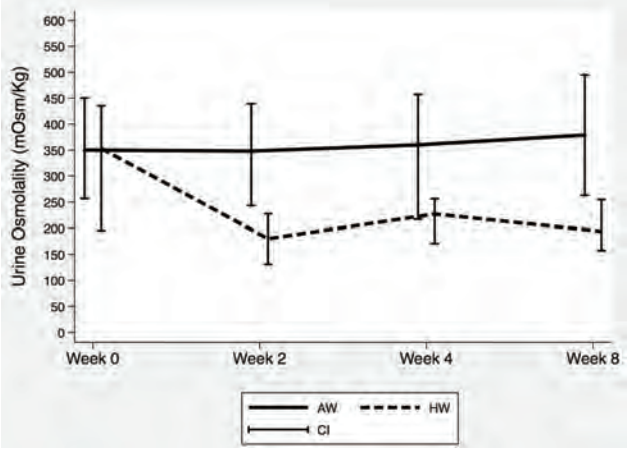
Ragada El- Damanawi,[1,2] Michael C. Lee,[3] Tess M. Harris,[4] Laura B. Mader,[5] Holly Pavey,[2] Ian Wilkinson,[1,2] Alison Burrows,[6] Przemyslaw R. Woznowski,[6] Yoav Ben-shlomo,[6] Fiona E. Karet,[7] Thomas F. Hiemstra.[1,2] *[1]Department of Medicine, Division of Experimental Medicine and Immunotherapeutics, Cambridge, United Kingdom; [2]Cambridge Clinical Trials Unit, Cambridge, United Kingdom; [3]Division of Anaesthesia, University of Cambridge, Cambridge, United Kingdom; [4]Polycystic Kidney Disease Charity, London, United Kingdom; [5]Patient Led Research Hub, Cambridge, United Kingdom; [6]University of Bristol, Bristol, United Kingdom; [7]Department of Medical Genetics, University of Cambridge, Cambridge, United Kingdom.*

Background: High water intake is a rational therapeutic approach in Autosomal Dominant Polycystic Kidney Disease (ADPKD) and may have similar benefits to tolvaptan, but the efficacy of high water intake in slowing ADPKD progression has not been assessed. It is not known whether a randomised trial of high water intake in ADPKD would be feasible.

Methods: In a single-centre, open label randomised controlled feasibility trial, we assigned adult ADPKD patients with an eGFR≥20ml/min/1.73m2 to either 1) individualised daily fluid prescription with target urine osmolality ≤270mOsm/kg (HW), or 2) drinking to thirst (AW), over 8 weeks. Co-primary feasibility endpoints were the recruitment rate and separation between treatment arms in urine osmolality.

Results: 42 participants (57% female, age 46±13 years) were randomised (1:1) to HW (n=21) and AW (n=21) at a recruitment rate of 1 patient every 10 days. Baseline characteristics did not differ between trial arms (eGFR 68.4 (35.9-107.2) vs 75.8 (35.9-107.2) ml/min respectively). Significantly more HW patients achieved the target uOsm (14/21, 67%) compared to the AW group (5/21, 24%) during the 8 week treatment period ($p<0.001$), with uOsm significantly lower throughout follow-up in the in the HW group (Figure, $p=0.02$). There were no significant differences in CKD-EPI eGFR between arms, and no acute effects on ^{51}Cr-EDTA GFR.

Conclusions: Rapid recruitment to the trial, compliance with prescribed fluid intake, and separation between trial arms in uOsm suggest that a large-scale trial of high water intake in ADPKD is feasible.



Change in urine osmolality over time by treatment group

SA-PO484

Smart Water Bottle Technology and Adherence to Fluid Prescription in ADPKD Patients

Kendall I. Elue,[1] Michael Gwede,[1] Amina Madhwala,[2] Diboro L. Kanabolo,[1] Rita L. McGill,[1] Anna L. Zisman,[1] Arlene B. Chapman.[1] *[1]University of Chicago, Chicago, IL; [2]Touro College Of Osteopathic Medicine, Naperville, IL.*

Background: The Vasopressin (V) V2 receptor antagonist, Tolvaptan, slows cyst growth and loss of kidney function in autosomal dominant polycystic kidney disease (ADPKD). Water intake inhibits V secretion and may have similar benefits. Using smartphone technology, the water bottle (HidrateSpark© (SB)) reminds individuals to drink at specific times and documents volume and time of fluid intake. We sought to determine if SB and dietary recommendations (DR) improved fluid prescription adherence versus DR alone.

Methods: SB was tested to known volumes for accuracy and 24-hour urine volume (24UV) (mean % error= -3.69%, p=NS), precision (relative uncertainty=0.0035), limit of detection (15 mL), between bottle reproducibility (p=0.94), and inter and intra-operator reliability (0.005% variability, p=0.97; p=0.216) were calculated. Subjects were randomized to receive DR or DR/SB and prescribed a 20% increase in fluid intake from their most recent 24UV or 3 liters/day, whichever was greater. All subjects received DR at 6 weeks and completed 24UV at 6 and 12 weeks. DR and DR/SB groups were analyzed for significance utilizing chi-square analysis methods comparing the proportion that met fluid goals and a t-test comparing mean fluid intake.

Results: With 36 subjects enrolled, 15 DR and 15 DR/SB completed the study. Target fluid intake in DR and DR/SB were 3460.88±416.3 and 3661.5±752.5 mL (p=NS). At 6 weeks, 40 and 67% of DR and DR/SB subjects met fluid goals (p=0.143). At week 12, 40 and 80% of DR and DR/SB subjects met fluid goals ($p<0.03$). At 6 and 12 weeks, DR/SB fluid intake was greater than DR (p=0.026; p=0.006). DR/SB subjects used SB 88.25% and 80.5% of days between 0-6 and 6-12 wks. DR/SB patients met or exceeded their fluid prescription on 41% of days.

Conclusions: DR/SB subjects attained their fluid prescriptions more often than DR subjects. Additionally, DR/SB patients displayed greater adherence and fluid intake with longer use of the bottle. However, day-to-day adherence was less than ideal. This indicates that use of a smart water bottle increases hydration, provides the potential for ongoing feedback, and can potentially lead to sustained behavioral change in ADPKD patients.

SA-PO485

Effect of Somatostatin Analogues on the Vasopressin Pathway in Patients with ADPKD

A. L. Messchendorp,[1] Bart J. Kramers,[1] Katrin Stade,[2] Esther Meijer,[1] Ron T. Gansevoort.[1] DIPAK consortium *[1]UMCG, Groningen, Netherlands; [2]Brahms GmbH, Hennigsdorf, Germany.*

Background: The vasopressin V2 receptor antagonist tolvaptan slows the rates of total kidney volume growth and GFR decline in ADPKD, but its effect is limited and aquaretic side effects hamper wide spread clinical use. Therefore somatostatin analogues are of interest, which also interfere with cyst formation. Interestingly, several studies have suggested that somatostatin is involved in renal water handling, indicating that there may be an interaction between the somatostatin and vasopressin pathways. We therefore investigated if the somatostatin analogue lanreotide has an effect on vasopressin levels and aquaresis in patients with ADPKD.

Methods: Patients were included who participated in the DIPAK-1 study, a randomized, open-label controlled clinical trial to test the efficacy and safety of the somatostatin analogue lanreotide in later stage ADPKD. Patients were invited for a baseline visit, and randomized to receive either lanreotide or standard care in a 1:1 ratio. Blood and 24 hour urine samples were collected at baseline and after 12 weeks. Free water clearance (FWC) was calculated as 24 hour urine volume-((Urine osmolality*24 hour urine volume)/plasma osmolality) and fractional free water clearance (FFWC) as (FWC/eGFR)*100%.

Results: Overall, 305 ADPKD patients were included, 53% female, 48±7 years of age, with an eGFR of 50±11 ml/min/1.73m^2. At baseline, there were no differences in plasma copeptin levels (a surrogate for vasopressin), 24 hour urine volume, FWC and FFWC between patients randomized to lanreotide (n=153) or standard care (n=152). From baseline to week 12, we observed no differences in change in plasma copeptin, 24 hour volume, FWC and FFWC between patients receiving lanreotide or standard care (-0.93±13.5 vs. -0.07±5.58 pmol/L, p=0.48; -0.02±0.6 vs. 0.07±0.7 L/24hr, p=0.25; 0.09±0.6 vs. 0.2±0.8 L/24hr, p=0.39 and 0.2±1.3 vs. 0.3±1.7 %, p=0.79 respectively).

Conclusions: The somatostatin analogue lanreotide does not affect vasopressin levels or aquaresis in patients with ADPKD. Our data therefore do not support an effect of somatostatin on the vasopressin pathway. An effect of lanreotide on vasopressin V2 receptor antagonist induced renoprotection and polyuria is therefore not to be expected.

Two Year Open Label Extension Study of Pasireotide LAR in Polycystic Liver and Kidney Disease

Marie C. Hogan,[1] Lisa E. Vaughan,[2] Walter K. Kremers,[2] Kathleen Leistikow,[2] Andrew J. Metzger,[1] Marie E. Edwards,[2] Vicente E. Torres,[1] Tetyana V. Masyuk.[1] *[1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic, Rochester, MN.*

Background: Mass symptoms from liver (LV) & kidney (KV) volumes negatively impact quality of life in ADPKD & ADPLD patients. The SST analog Pasireotide LAR (Pas LAR) has a broader binding profile & higher affinity to SST receptors with potential for greater efficacy than octreotide or lanreotide. In our one year randomized controlled trial Pas LAR signifiantly reduced LVs and KVs but not GFR decline.

Methods: Pas LAR was offered to all participants every 28d for an additional 2 yrs. Changes beyond yr 1 in all subjects on continued or beginning (placebo in year 1) PasLAR for another 2 yrs were assessed. Using MRI, % changes in LV in placebo group before (yr 1) & after (yrs 2-3) cross-over to active treatment were assessed and effects of Pas LAR for 3 years. Annualized % changes in LV in treatment arm at yr 3 compared to the placebo arm during yr 1 & changes in KV from baseline at 12 & 36 mo in ADPKD cases were also assessed.

Results: Of 41 participants who completed LV measurements at 12 mo, 24 had LV and 15 had KV data at end of yr 3. Among 6 given placebo at baseline, the difference in the rate of change in LV baseline to yr 1 (5.4%) vs in the OLE_{on} period from yr 1 to OLE_{end} (-2.4%) was significantly decreased (P=0.037). Among the 4 patients given placebo at baseline with KV available, the difference in the rate of change in KV baseline to yr 1 (6.0%) vs. in the OLE_{on} period from yr 1 to OLE_{end} (-1.2%) decreased (P=0.043). Similarly, differences in the rate of change in LV of patients on placebo baseline to yr 1 (n=6, 5.4%) vs those from the Pas LAR group baseline to OLE_{end} (n=18, -0.3%) were lower (P=0.046). Differences

in the rate of change in KV of patients on placebo baseline to yr 1 (n=4, 6.0%) vs those from the treatment group baseline to OLE_{end} (n=11, 0.2%), (P=0.068). Of 17 who discontinued the study during OLE_{on} reasons included 6 hepatectomies (2 later returned to OLE_{on}), 2 had liver transplants, 7 with hyperglycemia.

Conclusions: Over three years Pas LAR continued to significantly slow the progressive increase in LV & TKV growth rates to a lesser extent, but participants experienced a higher frequency of AEs (hyperglycemia and diabetes).

Pancreatic Cysts and Intraductal Papillary Mucinous Neoplasm in Autosomal Dominant Polycystic Kidney Disease

Bairbre A. McNicholas,[2] William P. Martin,[3] Marie E. Edwards,[1] Patrick S. Kamath,[4] Vicente E. Torres,[1] Peter C. Harris,[1] Marie C. Hogan.[1] *[1]Mayo Clinic, Rochester, MN; [2]Division of Intensive Care, Galway University Hospitals, Galway, Ireland; [3]Galway University Hospital, Health Service Executive West, Galway, Ireland; [4]Mayo Clinic, Rochester, MN*.

Background: Pancreatic Cyst lesions in ADPKD are primarily cysts. They are recognized increasingly, with isolated reports of intraductal papillary mucinous neoplasia (IPMN).

Methods: Tertiary care center retrospective study to determine prevalence, number, size, and location of pancreatic abnormalities (pancreatic cyst lesions [PCLs], IPMN, and not-otherwise-specified abnormalities) with abdominal magnetic resonance imaging (MRI) of genotyped ADPKD patients (1998 - 2013) and compared with age- and sex-matched non-ADPKD controls. We evaluated presentation, investigation, and management of all IPMNs among individuals with ADPKD (1997- 2016), for natural history and management of pancreatic abnormalities.

Results: Abdominal MRIs (104 with and 167 without gadolinium) were examined for 271 genotyped ADPKD patients. At least 1 PCL was noted in 19% of ADPKD patients (n=52) compared with 10.2% of controls (n=28) (*P*=.03). Mean (SD) age at diagnosis was 42(12) years for ADPKD vs 50(9) years (controls) (*P*<.001). Thirty-seven (71%) had a solitary PCL; 15 (28%) had multiple. PCL prevalence did not differ by genotype. IPMNs were detected in 1% of ADPKD cases. Among 12 IPMN patients (7 branch duct; 5 main duct or mixed type) monitored for ~140 months, 2 with main duct IPMN required Whipple resection, and 1 patient died of complications from small-bowel obstruction after declining surgical intervention.

Conclusions: With MRI, PCLs were detected in 19% and IPMNs in 1% of 271 ADPKD patients with proven mutations, without difference across genotypes. PCLs were asymptomatic and remained stable in size. No malignant transformation occurred among 12 IPMN patients.

SA-PO488

Epidemiology of Autosomal Dominant Polycystic Kidney Disease (ADPKD) in Olmsted County

Tatsuya Suwabe,[1] Alanna Chamberlain,[1] Emilie Cornec-Le Gall,[2,1] Jill M. Killian,[1] Peter C. Harris,[1] Vicente E. Torres.[1] *[1]Mayo Clinic, Rochester, MN; [2]Centre Hospitalier Universitaire de Brest, BREST, France*.

Background: ADPKD is the most common inherited kidney disease. A prior study in Olmsted County estimated an incidence of ADPKD of 1.38 per 100,000 during 1935–1980; however, contemporary data on the incidence of ADPKD are scarce. We aimed to determine the incidence of ADPKD in Olmsted County, MN during 1980-2016.

Methods: Mayo Clinic and Olmsted Medical Center (OMC) deliver most health care to Olmsted County residents. We searched diagnostic codes and the Mayo Clinic and OMC radiology databases to identify subjects and all medical records were reviewed to validate ADPKD diagnoses using the following criteria. Diagnosis of definite ADPKD was based on radiographic findings plus family history of ADPKD or genetic testing; likely ADPKD, on >10 cysts in each kidney without advanced CKD or different renal cystic diseases; possible ADPKD, on cyst number exceeding the 97.5 percentile in kidney donors of the same sex and age. Incidence of ADPKD during 1980-2016 and point prevalences for the year 2010 were calculated.

Results: We reviewed medical charts and abdominal images and/or radiology reports of 1,231 subjects with diagnostic codes of cystic disease during 1980-2016, and the medical charts and abdominal CT or MR scans of 2,765 subjects with multiple cysts from radiology databases during 1997-2016. 364 patients with incident ADPKD (85 definite, 45 likely, 234 possible) were identified. Overall age and sex adjusted annual incidence rates of definite ADPKD were 1.79 (95% CI: 1.40, 2.17) and those of definite or likely ADPKD 3.06 (2.52, 3.60) per 100,000 person-years. The peak incidence rate of definite and likely cases was 5.27 (3.07, 8.44) in the 60-69 year age group. Incidence rates of possible ADPKD increased markedly after 1997 when CT and MRI became available electronically. On January 1, 2010, the overall age and sex adjusted prevalence of definite ADPKD was 47.0 (35.4, 58.5), definite or likely ADPKD was 68.0 (53.9, 82.1) and definite, likely or possible ADPKD was 123.9 (104.6, 143.2) per 100,000 population.

Conclusions: The incidence of definite or likely ADPKD was 2.22 times higher than in the 1935-1980 study likely due to more comprehensive ascertainment of the population. Genetic testing will be necessary to determine how many of the patients classified as possible cases have ADPKD or another genetic renal cystic disease.

SA-PO489

Prediction of Autosomal Dominant Polycystic Kidney Disease (ADPKD) Outcomes at Birth

Michal Mrug,[1] Tiange Shi,[2] Vicente E. Torres,[3] Frederic F. Rahbari-Oskoui,[4] Kyongtae T. Bae,[2] Peter C. Harris,[3] Lisa M. Guay-Woodford,[5] William M. Bennett,[6] Alan S. Yu,[7] Arlene B. Chapman.[8] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]University of Pittsburgh, Pittsburgh, PA; [3]Mayo Clinic, Rochester, MN; [4]Emory University School of Medicine, Atlanta, GA; [5]Children's National Health System, Washington, DC; [6]Legacy Good Samaritan Medical Center, Portland, OR; [7]University of Kansas Medical Center, Kansas City, KS; [8]University of Chicago, Chicago, IL*.

Background: The identification of high-risk ADPKD patients at birth may help them to receive appropriate medical attention.

Methods: We developed logistic, tree and random forests models for reaching CKD stage 3b progression endpoint (GFR<45 ml/min/1.73m^2) based on data collected by the Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease study (CRISP; 241 ADPKD adults). We validated these models using data collected by the HALT-A study (558 ADPKD adults). In addition to the GFR endpoint and age, analyzed variables included race, gender, birth weight, gene type and mutation strength-based indices (data available at birth).

Results: The logistic regression model yielded area under an ROC curve (AUC) 0.786 (95% CI: 0.7231, 0.8491; p<0.001). The tree model pruned to the optimal complexity parameter of 0.038 had a similar prognostic ability as the logistic model (their 95% CI of AUC overlapped). Random forests grown by 1000 bootstrap replicate samples of a size of 196 samples with replacement improved the prognostic ability of the factors available at birth and reached AUC 0.91 (95% CI:0.8689, 0.9467; p<0.001). Validation of these models in HALT-A cohort revealed much lower AUC for the logistic regression model (AUC 0.537), the tree model (AUC 0.552), as well as random forests (AUC 0.612). This likely occurred in part due to overfitting during analyses of CRISP data.

Conclusions: The data available at birth have modest value in prediction of advanced CKD outcomes based on information collected in the CRISP and HALT-A studies. Our analyses also demonstrate an essential role of predictive model validation using independent cohort datasets.

SA-PO490

Defining the Prevalence and Clinical Characteristics of Atypical Polycystic Kidney Disease (PKD)

Ioan-Andrei Iliuta,[1] Aung Z. Win,[2] Beili Shi,[1] Marina Pourafkari,[2] Elsa Guiard,[1] Korosh Khalili,[2] York P. Pei.[1] *[1]Nephrology, University Health Network, Toronto, Toronto, ON, Canada; [2]Medical Imaging, University Health Network, Toronto, Toronto, ON, Canada*.

Background: The Mayo Clinic Imaging Classification is now widely used for risk assessment of autosomal dominant polycystic kidney disease, but requires exclusion of cases with atypical kidney imaging. Here, we report the first systematic study to define the prevalence and clinical correlates of atypical PKD.

Methods: We reviewed all patients seen at the Toronto General Hospital PKD Clinic between 5/2007 to 10/2017 for their clinical, genetic, and MRI/CT results. Atypical PKD was classified as: (i) unilateral, (ii) segmental, (iii) asymmetric, (iv) lopsided, (v) mild lopsided, (vi) unilateral or bilateral atrophy, or (vii) segmental sparing.

Results: 7.6% (n=36) of 472 patients reviewed displayed imaging patterns consistent with atypical PKD. Compared to patients with a typical imaging pattern, they were older with normal renal function and displayed a high rate of no mutation detected (see Table).

Conclusions: Atypical PKD is generally associated with mild kidney disease and needs to be vigorously excluded from kidney volume-based risk assessment. The etiologies of these cases are likely heterogeneous, but many may be underpinned by somatic mosaicism which can be unravelled by Next Generation Sequencing.

Characteristics of cohort

	Total (n=472)	Typical (n=436)	Atypical (n=36)
Age, mean [range]	43 [16-78]	43 [16-78]	54 [20-74]
Male:Female	213:259	191:245	22:14
Positive family history, n (%)	331 (70.1)	320 (73.4)	11 (30.6)
Mutation class, n (%)			
PKD1 PT	167 (35.4)	165 (37.8)	2 (5.6)
PKD1 in-frame indel	16 (3.4)	16 (3.7)	0 (0)
PKD1 NT	100 (21.2)*	98 (22.5)	2 (5.6)

SA-PO491

PROPKD Score Predicts Kidney Decline in Australian Patients with Autosomal Dominant Polycystic Kidney Disease in Clinical Practice

Andrew J. Mallett,[1,2] Samuel S. Chan,[1,2] Chirag Patel.[3] *[1]Kidney Health Service, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [2]Faculty of Medicine, The University of Queensland, Brisbane, QLD, Australia; [3]Genetic Health Queensland, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia.*

Background: The PROPKD score was recently developed from a single-country cohort study to enable risk stratification of progression to end-stage kidney disease in patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD). The aim of this study was to validate whether the PROPKD score predicts kidney function decline in clinical practice amongst Australian ADPKD patients.

Methods: A cross-sectional study was conducted of 39 unrelated individuals with genetically confirmed ADPKD encountered by the Queensland Conjoint Renal Genetics Clinic Service between 1st January 1994 to 31st May, 2018. Clinical and genetic factors were examined using the PROPKD score, to assess its relationship with kidney function decline prediction over a three year period.

Results: Of the 39 individuals in this study, 15 patients were low risk, 17 were intermediate risk and 7 were high risk. The median age for the low risk group commencing renal replacement therapy (RRT) was 60 years, 54.5 years for the intermediate risk group, and 55.3 years for the high risk group. Of those who commenced RRT, 1 was high risk, 6 were intermediate risk and 1 was low risk. One high risk patient underwent pre-empt live transplant at 48 years. The median change in estimated glomerular filtration rate (CKD-EPI) in the low risk group was 1.5ml/min/1.73m^2/yr, 12.5 ml/min/1.73m^2/yr in the intermediate risk group and 15 ml/min/1.73m^2/yr in the high risk group ($p<0.001$). There were no deaths from this cohort.

Conclusions: The PROPKD score accurately predicts kidney function decline in patients with ADPKD in this Australian cohort in clinical practice. This prediction tool may enable future personalised clinical prognostication and therapeutic management of ADPKD, as well as for potential participants to be identified for clinical trials.

SA-PO492

Disease Symptoms and Poor Quality of Life (QoL) in Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD) and Preserved Kidney Function

Aaron Yarlas,[2] Dorothee Oberdhan,[1] Holly Krasa,[1] Stephen M. Maher,[2] Jakob B. Bjorner.[2] *[1]Otsuka, Rockville, MD; [2]Optum Patient Insights, Johnston, RI.*

Background: ADPKD is a hereditary progressive disease in which enlarging kidney cysts impair function and lead to kidney failure. In general, patients in early-stage chronic kidney disease [CKD] (eg, stages 1 and 2) tend to have normal QoL, but there is variability in disease burden with early-stage ADPKD. A subgroup of patients within an observational study had significant disease burden prior to renal function decline. We examine the characteristics of this subgroup.

Methods: Data were from a multi-center, longitudinal, observational study of 3,409 adult ADPKD patients (NCT01430494) with 990 and 956 patients in CKD stages 1 and 2, respectively. A subgroup of patients in stages 1 or 2 (n=42) was identified based on poor scores (≥3 points) on 2 of 3 ADPKD-Impact scale (ADPKD-IS) subscales (physical, emotional, fatigue). We examined associations of poor ADPKD-IS scores with clinical outcomes (eg, albuminuria, kidney stones, urinary tract infection [UTI]), biomarkers (eg, height-adjusted total kidney volume, estimated glomerular filtration rate, abdominal girth), and patient-reported outcome (PRO) measures (ADPKD-Urinary Impact Scale, SF-12v2® Health Survey, Brief Pain Inventory). Analyses used χ^2 tests, receiver operating characteristic (ROC) curves, and Cohen's *d* effect sizes for mean differences.

Results: Patients in the poor ADPKD-IS subsample were more likely than other early-stage CKD patients to have albuminuria, hematuria, kidney pain, kidney stones, and UTI (all p <.05). ROC analyses found that biomarkers did not distinguish between the poor ADPKD-IS subgroup and other early-stage patients: all areas under the curve (AUC) ≤.60, all p >.05. All PRO scores accurately differentiated the poor ADPKD-IS subgroup from the remaining early stage sample: AUCs from .83 to .95 (all p <.0001), with large mean sample differences (all $d \geq 1.6$).

Conclusions: A subgroup of ADPKD patients in early-stage CKD experience poor symptomatology and QOL. These patients are more likely to have albuminuria, hematuria, kidney pain, kidney stones, or UTI.

SA-PO493

Patient-Reported Outcomes (PROs) as Predictors of Healthcare Utilization (HCU) and Work Outcomes in Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Aaron Yarlas,[2] Dorothee Oberdhan,[1] Holly Krasa,[1] Asia Sikora Kessler,[2] Stephen M. Maher,[2] Jakob B. Bjorner.[2] *[1]Otsuka, Rockville, MD; [2]Optum Patient Insights, Johnston, RI.*

Background: ADPKD is a rare progressive hereditary disease where cysts in the kidneys reduce renal function, often leading to kidney failure. ADPKD is associated with deficits in patients' quality of life (QoL) and functioning. We examine if PROs predict HCU and work outcomes in ADPKD patients.

Methods: In a global, multi-center, longitudinal, observational study of 3,409 ADPKD patients (NCT01430494) data collection at baseline and every 6 months (up to 30 months) included measures of ADPKD-associated symptoms and health burden (ADPKD-Impact Scale [ADPKD-IS], ADPKD-Urinary Impact Scale [ADPKD-UIS]), generic QoL (SF-12v2® Health Survey [SF-12v2]), and pain (Brief Pain Inventory-Short Form [BPI-SF]) as well as HCU and work outcomes. Separate logistic regression models examined each PRO as a predictor of dichotomous HCU (0, ≥1 hospitalization) and work outcomes (0, ≥1 sick days). Ordinary least squares regression examined each PRO as a predictor of continuous work outcomes (sick days, work effectiveness). Baseline to month 18 data were used for this analysis.

Results: The likelihood of ≥1 hospitalization in the previous 6 months was significantly predicted by worse baseline scores on ADPKD-IS fatigue, emotional, and physical scales (Odds ratios [ORs] from 1.55 to 1.77), ADPKD-UIS frequency, nocturia, and urgency scales (ORs from 1.32 to 1.43), SF-12v2 physical and mental component summaries (ORs: 0.97, 0.96), and BPI-SF pain severity and pain interference scales (ORs: 1.11, 1.16), all P <.05. The likelihood of ≥1 sick day in the previous 6 months was significantly predicted by worse scores on ADPKD-IS and ADPKD-UIS scales (ORs from 1.24 to 1.76), SF-12v2 summaries (ORs: 0.95, 0.96), and BPI-SF scales (ORs: 1.25, 1.26), all P <.001. Worse scores on PROs predicted a higher number of work days missed (all P <.001), while worse scores on ADPKD-IS and ADPKD-UIS scales, SF-12v2 summaries, and the BPI-SF pain interference scale predicted lower work effectiveness (all P <.05).

Conclusions: ADPKD-associated symptoms, QoL, and pain PROs were predictive of ADPKD patients' HCU and work outcomes. These findings support the inclusion of PROs in clinical studies and practice with ADPKD patients.

Patient and Caregiver Beliefs, Attitudes, and Perspectives on Genetic Screening and Testing for Autosomal Polycystic Kidney Disease

Charlotte Logeman,[1,2] Yeoung Jee Cho,[16] Gopi Rangan,[6] Talia M. Gutman,[1,2] Jonathan C. Craig,[3] Albert C. Ong,[7] Arlene B. Chapman,[8] Curie Ahn,[9] Ron T. Gansevoort,[11] Ronald D. Perrone,[12] Tess M. Harris,[13] Vicente E. Torres,[14] York P. Pei,[15] Jessica Ryan,[10] Andrea K. Viecelli,[16] Claire Geneste,[17] Yaerim Kim,[9] Martin Howell,[18] Karine E. Manera,[4] Armando Teixeira-Pinto,[5] Allison Tong.[4] SONG-PKD Steering Group *[1]Centre for Kidney Research, Camperdown, NSW, Australia; [2]School of Public Health, University of Sydney, Sydney, NSW, Australia; [3]University of Sydney/Children's Hospital, Sydney, NSW, Australia; [4]The University of Sydney, Westmead, NSW, Australia; [5]University of Sydney, Camperdown, NSW, Australia; [6]Westmead Institute for Medical Research, The University of Sydney, Sydney, NSW, Australia; [7]University of Sheffield, Sheffield, United Kingdom; [8]University of Chicago, Chicago, IL; [9]Seoul National University Hospital, Seoul, Republic of Korea; [10]Monash Health, Clayton, NSW, Australia; [11]University Medical Center Groningen, Groningen, Netherlands; [12]Tufts Medical Center, Boston, MA; [13]Polycystic Kidney Disease Charity, London, United Kingdom; [14]Mayo Clinic, Rochester, MN; [15]University Health Network and University of Toronto, Toronto, ON, Canada; [16]Princess Alexandra Hospital, Brisbane, QLD, Australia; [17]University Francois Rabelais, Tours, France; [18]University of Sydney, School of Public Health, Sydney, NSW, Australia.*

Background: Predictive genetic screening and testing is available for accurate and early diagnosis of hereditary autosomal polycystic kidney disease. However, the complex ethical and psychosocial implications can make decision-making challenging and data on patients' perspectives are limited. We aimed to describe patient and caregiver perspectives on the value and risks of genetic screening and testing for autosomal polycystic kidney disease (ADPKD).

Methods: 154 participants (120 patients and 34 caregivers) from 8 centres in Australia, France and Korea participated in 17 focus groups. Transcripts were analysed thematically.

Results: We identified five themes: *financial constraints* (insecurity in the inability to obtain life insurance, self-doubt in limited work opportunities, financial barrier of test); *futility in unpredictability* (accepting erratic and diverse manifestation of disease, inevitable disease progression, daunted by perplexity of results); *lacking autonomy and support in decisions* (overwhelmed by ambiguous information, medicalising family planning, appeasing the family, financial barrier); *seizing control of wellbeing* (gaining confidence through disease management, reassurance in family resilience, hope for health innovations to benefit the next generation, minimalising regret with preparation); and anticipating impact on quality of life (comforted by lack of symptoms, decisional uncertainty in risk of inheriting PKD, judging the value of life with PKD in family planning, guilt in foetal testing or abortion).

Conclusions: For patients with ADPKD, genetic screening or testing provides an opportunity for them to take ownership of their health through family planning and preventive measures. However, they are also concerned and uncertain about the accessibility of these services, psychological sequelae of testing, and potential financial consequences. Patient-centred genetic counselling and education that addresses patients' concerns may support informed decision-making about genetic testing and screening in ADPKD.

SA-PO495

Patient-Reported Disease Burden and Urinary Impact in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Dorothee Oberdhan,[1] Myrlene Sanon,[1] Indra Agarwal,[1] Frank S. Czerwiec,[1] Ronald D. Perrone.[2] *[1]Otsuka, Rockville, MD; [2]Tufts Medical Center, Boston, MA.*

Background: ADPKD is an inherited disease leading to kidney enlargement, worsening of kidney function, and quality of life impacts. ADPKD patients experience symptoms consistent with urine concentration deficits, such as polyuria, nocturia, urinary frequency and urgency. Combined with tolvaptan (TLV) therapy those symptoms may be accentuated.

Methods: In a randomized, placebo-controlled, double-blind clinical trial (NCT01451827) urinary burden, and health-related quality of life (HRQoL) were assessed over 8 weeks. Urinary burden was measured by number of voids and 24h urine volume. HRQoL measures included the ADPKD Impact Scale (ADPKD-IS), ADPKD Urinary Impact Scale (ADPKD-UIS), and SF-12v2 Physical and Mental Component Summary (PCS and MCS).

Results: A total of 177 subjects enrolled in the clinical trial. 134 subjects were randomized to various doses of TLV in several formulations (50-120mg/day, pooled) and 42 subjects to placebo (PLC). Mean number of voids were similar for TLV and PLC subjects at baseline (daytime: 6.4 vs 6.2; nighttime: 1.5 vs 1.6) but increased in the TLV group by Week 8 (daytime: 10.1 vs 6.9, p=0.0002; nighttime: 2.4 vs 1.5, p≤0.00001). Mean 24h urine volume at baseline was similar between TLV and PLC subjects (2.3L vs 2.4L) but increased in the TLV group through Week 8 (6.1L vs 2.9L, p<0.0001). Compliance was 98% for TLV vs 97% for PLC.

Conclusions: Baseline urinary burden is low with subjects reporting only minimal bother/impact during daytime and slightly higher burden associated with nocturia. With tolvaptan treatment, the urine volume doubled and number of voids increased by over 50% with intermediate increases in patient-reported urinary burden during daytime and nighttime. Overall HRQoL showed no noticeable change during the study duration even with increased urinary burden.

Funding: Commercial Support - Otsuka Pharmaceutical Development & Commercialization, Inc.

Patients Values and Preferences About Renal Cysts: A Survey

Reem Mustafa. *University of Kansas, Kansas City, KS.*

Background: Renal cysts are a common incidental finding on radiographic imaging. While most cysts are indolent, individuals with such cysts are frequently monitored for interval growth and potential malignant transformation, which is ultimately rare.

Methods: We are deploying a cross-sectional survey to patients who have billing code for renal cysts and those who do not in the Greater Plain Collaborative (GPC) de-identified dataset. We developed and prepiloted a survey that assesses patients values and preferences about renal cysts. Here we present preliminary results from the University of Kansas Medical Center.

Results: To date, there have been 71 respondents. The mean age was 61 (range 30-82) years. 4% were Asian, 3% were black, 91% were white and 56% were female. The majority of respondents were college graduates (33%) or possessed post graduate degrees (37%). 72% of people reported no family history of kidney disease, and 66% of respondents (47 people) reported being told by a doctor that they have a kidney cyst. Of those with a renal cyst, 24 reported having one cyst. 39 people reported having no treatment plan for their cyst(s), and of those who reported having a treatment plan (n=15), all reported follow-up visits providing a sense of security and reassurance. 12 of these 15 reported that they would worry more about the cyst(s) if there were no follow-up. 15 people with renal cyst(s) reported seeing their primary care physician for their cyst, and 30 people reported seeing a nephrologist for their cyst(s). Of those with a renal cyst, 34 felt their doctor considered their values and opinions regarding follow-up imaging for renal cyst(s). 29/71 respondents wanted to know more about their cyst(s), and 23/29 specified wanting to know more about how often it should be imaged, if there are treatments, and the risk of progression to cancer. 20/71 people reported feeling anxious or would feel anxious about their renal cyst(s)

Conclusions: There is wide variability in patient values and preferences regarding renal cysts and their follow-up. While some expressed concerns about the risk of progression to cancer, others were not worried at all. It is unclear if this correlates to knowledge about prognosis of renal cysts or perceived risk. Guidance on this topic is needed and could help physicians and patients with shared decision making regarding renal cyst management.

Composite End Points in ADPKD Studies: A Guide for Best Practices

Reem Mustafa,[1] David Baron,[4] Frank S. Czerwiec,[5] Alan S. Yu,[2] Ronald D. Perrone.[3] for the Polycystic Kidney Disease Outcome Consortium (PKDOC) composite outcomes subcommittee *[1]University of Kansas, Kansas City, KS; [2]University of Kansas Medical Center, Kansas City, KS; [3]Tufts Medical Center, Boston, MA; [4]PKD Foundation, Kansas City, MO; [5]Otsuka Pharma. Devel. & Comm., Inc., Rockville, MD.*

Background: There is considerable inconsistency in the outcomes reported in Autosomal Dominate Polycystic Kidney Disease (ADPKD) and how they are measured. In this article, we aim to highlight the appropriateness of different outcomes to be included as a component in composite outcomes

Methods: We developed guidance including a summary table for components of the composite end points in ADPKD. We utilized the results of a systematic review and discussions among the Polycystic Kidney Disease Outcome Consortium (PKDOC) composite endpoint subcommittee. The subcommittee consists of Scientists, clinicians, methodologists, manufacturers, patients, advocacy groups representatives, and critical path institute representatives, all with experience in ADPKD. The investigators assessed the face validity of the suggested guidance and used an iterative approach of feedback, revision, and testing.

Results: Table 1 summarizes outcomes that are reported in ADPKD studies and the different ways they can be measured. It also explores pros and cons for including them as part of a composite outcome for ADPKD studies.

Conclusions: Composite end points will continue to be used in ADPKD studies and may be more utilized in-light of new approved treatments. Understanding the unique considerations about the different components and their use in ADPKD studies is essential in developing high quality evidence that will appropriately assess the short and long term effects of different interventions.

Table 1

Endpoint	Feasibility of collecting data	Event frequency	Acceptability to regulators	Previous body of evidence in a clinical area	Comments
Death	Yes	Rare	Yes	Commonly reported as a component of a composite	- Likely more appropriate to use overall mortality -Disease specific mortality requires clear definitions. - Death rate will depend on baseline risk of mortality in the population of interest, which is low in ADPKD -Should be considered but may not apply in all cases (e.g. children).
ESRD including preemptive transplant	Yes	Varies depending on genotype, rate of progression and comorbidities	Yes	Commonly reported as a component of a composite	Enrichment strategies are useful to increase the event rate of the outcome. -Clear definitions of ESRD are necessary.
Hospitalization	Yes	Varies; Can be affected by patients' history	Yes	Reported as an outcome but not often part of a composite	Hospitalization due to disease specific interventions or complications should be very clearly defined and adjudicated
Worsening kidney function	Yes	Varies/Frequent	Yes	Commonly reported as a component of a composite	-Reported using different measures (e.g. doubling of serum Cr, 50% reduction in eGFR, reduction of eGFR beyond a certain threshold) -Important to note that the pattern of treatment effects on GFR must be examined, specifically acute effects on eGFR -Need to be aware of hyperfiltration as a potential confounder to the results of kidney function
Hypertension	Complicated if agent affects BP and by concomitant anti-hypertensive use	Frequent	Accepted surrogate	Reported as an outcome but not often part of a composite	-could be unreliable unless very clearly defined. -Reported using different measures (e.g. SBP, DBP, worsening hypertension as defined by "intensified therapy") - It is important to include the actual BP value
Chronic or acute pain / Medication	? lack of reliable and responsive tools to assess pain and identify cause	Varies/Frequent	Yes when using validated tools	Reported as an outcome but not part of a composite	-Reported using different measures (e.g. significant kidney pain necessitating medical leave, pharmacologic treatment or invasive intervention) -Challenging to distinguish Kidney pain

SA-PO498

Identifying Patient-Important Outcomes in Polycystic Kidney Disease: An International Nominal Group Technique Study

Yeoung Jee Cho,[1] Talia M. Gutman,[2] Gopi Rangan,[3] Jonathan C. Craig,[4] Andrea K. Viecelli,[5] Claire Geneste,[8] Yaerim Kim,[6] Curie Ahn,[6] Hyunsuk Kim,[9] David W. Johnson,[5] Allison Tong.[7] on behalf of SONG-PKD Steering Committee
[1]Nephrology, Princess Alexandra Hospital, Brisbane, QLD, Australia; [2]Centre for Kidney Research, Bondi Junction, NSW, Australia; [3]Westmead Institute for Medical Research, The University of Sydney, Sydney, NSW, Australia; [4]University of Sydney/Children's Hospital, Sydney, NSW, Australia; [5]Princess Alexandra Hospital, Brisbane, QLD, Australia; [6]Seoul National University Hospital, Seoul, Republic of Korea; [7]The University of Sydney, Seven Hills, NSW, Australia; [8]University Francois Rabelais, Tours, France; [9]Chuncheon Sacred Heart Hospital, Chuncheon, Gangwon-Do, Republic of Korea.

Background: Patients with autosomal dominant polycystic kidney disease (ADPKD) are at increased risk of premature mortality, morbidities, and complications, which severely impair quality of life. However, patient-centered outcomes are not consistently reported intrials in ADPKD, which can limit shared decision-making. We aimed to identify outcomes important to patients and caregivers and the reasons for their priorities.

Methods: Patients with ADPKD and their caregivers were purposively selected from eight centers across Australia, France and Republic of Korea. Participants identified ranked and discussed outcomes for trials in ADPKD. We calculated an importance score (0-1) for each outcome and conducted thematic analyses.

Results: Across 17 groups, 154 participants (121 patients, 33 caregivers) aged 19 to 78 (mean 54.5 years) identified 55 oucomes. The 10 highest ranked outcomes were: kidney function (mean importance score 0.36), end stage kidney disease (0.32), survival (0.21), cyst size/growth (0.20), cyst pain/bleeding (0.18), blood pressure (0.17), ability to work (0.16), cerebral aneurysm/stroke (0.14), mobility/physical function (0.12), and fatigue (0.12). Three themes were identified: threatening sembalance of normality, inability to control, and making sense of the diverse risks.

Conclusions: For patients with ADPKD and their caregivers, kidney function, delayed progression to end stage kidney disease and survival were the highest priorities, and were focused on achieving normality, and maintaining control over health and lifestyle. Implementing these patient-important outcomes may improve the meaning and relevance of trials to inform clinical care in ADPKD.

Description and Variability of Dietary Intake of Patients with Autosomal Dominant Polycystic Kidney Disease

Melanie Betz,[1] Arlene B. Chapman.[2] *[1]University of Chicago Medicine, Chicago, IL; [2]University of Chicago, Chicago, IL.*

Background: Nutrition counseling is imperative for Autosomal Dominant Polycystic Kidney Disease (ADPKD) patients; proper intake of protein and sodium can delay cyst growth and reducing diet acid load may delay progression of disease. Little has been published describing the diet of ADPKD patients. Food records collected over 3 days are standard practice to account for daily variations in intake. However, it is unknown how much nutrient intakes vary and if three days of food records are necessary. The objective of this project was to describe the diet of ADPKD patients and to understand how much nutrient intake varies daily.

Methods: Three-day food records were collected in a genetic disorder nephrology clinic at University of Chicago Medicine. A Registered Dietitian provided food record instructions and analyzed the record with National Data Research System, 2017. Potential Renal Acid Load (PRAL) and the variability of nutrient intake between three days of food record for a single patient were calculated.

Results: A total of 22 patients were included in analysis with a mean age of 48.18years, BMI of 26.6kg/m^2 and GFR of 58.29ml/min (n=15); 91% were Caucasian. See table for dietary analysis results and day-to-day variability.

Conclusions: ADPKD patients are consuming excess protein, sodium, saturated fat and cholesterol; whereas potassium, calcium and fiber intake is inadequate. These results showcase the importance of nutrition counseling for ADPKD patients. Nutrient intake varies greatly from day to day, highlighting the importance of capturing more than a single day when assessing diet.

Average Nutrient Intake and Daily Variability

	Average Intake	Variability
Calories	1929	29%
Protein	81g	42%
Fat	85g	41%
Carbohydrate	209g	37%
Sodium	2770mg	42%
Potassium	2663mg	35%
Phosphorus	1257mg	38%
Magnesium	332mg	33%
Calcium	930mg	47%
Cholesterol	334mg	56%
Fiber	22g	36%
% Calories from Saturated Fat	13%	42%
% Calories from Added Sugar	2%	63%
Potential Renal Acid Load (PRAL)	9.09 mEq/day	126%

SA-PO500

Survey of Contemporary Management of ADPKD Highlights Need for Improved Knowledge Translation

Tae won Yi,[1] Mark Canney,[1] Adeera Levin,[2] Micheli U. Bevilacqua.[1] *[1]Department of Nephrology, University of British Columbia, Vancouver, BC, Canada; [2]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada.*

Background: Recent years have witnessed a paradigm shift in the management of ADPKD, including novel biomarkers of disease progression such as total kidney volume (TKV), refined blood pressure (BP) targets, and repurposed drugs such as Tolvaptan. We sought to identify clinician's familiarity with and usage of these new management tools in contemporary-real world practice.

Methods: An online survey of 20 questions was disseminated to 71 nephrologists across British Columbia. The survey consisted of multiple choice questions regarding: clinician demographics, sources of information regarding ADPKD care, self-identified needs for optimal management of ADPKD, types of renal prognostication tools used, imaging tests and frequency of follow up imaging, blood pressure targets, and understanding of Tolvaptan utility.

Results: A total of 22 nephrologists (28%) completed the questionnaire. 89% of respondents are assessing risk of renal progression before GFR decline in their ADPKD patients, with a variety of tools being used. 90% of respondents obtain additional imaging after diagnosis in some or all of their ADPKD patients, but only 40% report use of imaging to assess risk of renal progression. 1 in 5 respondents are confident in their ability to interpret metrics of kidney size in ADPKD. 60% of nephrologists have been approached by patients about Tolvaptan, but 55% of respondents were not confident or only somewhat confident in their ability to identify which patients would benefit from treatment with Tolvaptan. Only 30% of respondents use the HALT-PKD BP target of <110/75 with the remainder using higher BP targets. The necessity for clear treatment guidelines and algorithms was identified by 25% of clinicians as the greatest unmet need.

Conclusions: The results of this survey indicate that there is variability in practice patterns, usage and familiarity with evidence-based ADPKD management tools among clinical nephrologists. Although only a minority of clinicians are confident in their ability to use these new tools and treatments appropriately, the vast majority show interest in further education. This emphasizes a need for ongoing efforts to translate these developments in ADPKD care into routine clinical practice.

SA-PO501

Standardized Image Acquisition and Measurement Methods Yield Accurate Total Kidney Volume Assessment in Polycystic Kidneys via CT or MRI

Micheli U. Bevilacqua,[1,2] Cameron Hague,[1] Alexandra Romann,[2] Hana Sheitt,[1] Dragos M. Vasilescu,[1] Tae won Yi,[1] Adeera Levin.[1,2] *[1]University of British Columbia, Vancouver, BC, Canada; [2]BC Provincial Renal Agency, Vancouver, BC, Canada.*

Background: Total Kidney Volume (TKV) assessment is a robust tool for predicting renal prognosis in autosomal dominant polycystic kidney disease (ADPKD) but is difficult to obtain outside of research settings or large academic centers. Bringing TKV measurement into routine clinical practice requires imaging protocols that are widely available and interpretation methods that are feasible for clinical radiologists.

Methods: 30 participants >18 years of age with a diagnosis of ADPKD were recruited. Participants underwent 3 scans; an MRI, a low-dose CT (LD) scan and an ultra-low dose CT scan (ULD). The ULD was also reconstructed via model based iterative reconstruction (MBIR) yielding a 4th image set. The images from the 4 modalities were analyzed with three standardized TKV measurement equations and compared to the gold standard method of MRI manual planimetry. Images were interpreted by radiologists using detailed measurement instructions, but without any formal training in TKV. Accuracy, variation and reproducibility of the different imaging modalities and measurement techniques was assessed.

Results: All imaging modalities (LD, ULD and MBIR) as well as all measurement equations ('Traditional ellipsoid', 'Mayo ellipsoid' and the 'mid-slice method') had excellent correlation with the gold standard with r^2 values for all being over 0.97. Variation was within ranges reported in previous analyses of TKV measurement, although un-reconstructed ULD and the mid-slice method showed higher variability. Intraclass Correlation Coefficients were >0.98 for all methods, demonstrating high reproducibility. The standardized measurement methods had interpretation times of 5 minutes compared to 45 minutes for the gold standard. The ULD CT scan had a mean effective radiation dose of 0.88 mSv, a value approaching average exposure for an abdominal x-ray series.

Conclusions: Accurate and reproducible TKV measurements can be obtained using time saving interpretation methods and readily available image acquisition methods including abbreviated CT protocols with minimal radiation exposure. These results confirm the accuracy of a variety of standardized TKV measurement methods which may facilitate the implementation of TKV assessment in routine clinical use across diverse practice settings.

SA-PO502

Using Segmental Bioelectrical Impedance Analysis to Predict Abdominal Cystic Organ Volumes in Autosomal Dominant Polycystic Kidney Disease

Hyunjin Ryu,[1] Hyunsuk Kim,[3] Hayne C. Park,[4] Kook-Hwan Oh,[1] Curie Ahn,[1] Yun Kyu Oh.[2] *[1]Seoul National University Hospital, JongNo-Gu, SEOUL, Republic of Korea; [2]Department of Internal Medicine, Boramae Medical Center, Seoul, Republic of Korea; [3]Chuncheon Sacred Heart Hospital, Chuncheon, Gangwon-Do, Republic of Korea; [4]Kangnam Sacred Heart Hospital, Seoul, Republic of Korea.*

Background: Increased abdominal cystic organ volume are risk factor for pressure-related complications and malnutrition in autosomal dominant polycystic kidney disease (ADPKD). However measuring actual abdominal cystic organ volume can be difficult in routine practice. Bioelectrical impedance analysis (BIA) are non-invasive, easy-to-use tool which can be applied in outpatient clinic. In this study, we evaluated the association of segmental BIA parameters with abdominal cystic organ volume in ADPKD patients.

Methods: In this single center, cross-sectional study, segmental BIA (Inbody S10) were measured and height-adjusted total kidney and liver volume (htTKLV) were calculated using recent CT scan in all patients.

Results: A total of 288 patients were included in the study and 47.9% were female. The mean age was 48.3±12.2 years and the mean estimated glomerular filtration rate (eGFR) was 65.3±25.3 mL/min/1.73m^2. The median values of htTKLV were 1,776 mL/m (IQR 1,361–2,381 mL/m). The highest correlation between BIA parameters and nature log value of htTKLV (ln htTKLV) was observed for the ratio of extracellular water to total body water (ECW/TBW) of trunk (ECW/TBW_{TR}) (r=0.466), followed by whole-body (ECW/TBW_{WB}) (r=0.407), lower extremity (ECW/TBW_{LE}) (r=0.385), and phase angle of trunk (PhA_{TR}) (r=0.215). The phase angle of lower extremity (PhA_{LE}) correlated negatively with ln htTKLV (r=-0.279). To exclude the effect of renal function on BIA, the subgroup analysis of patients with eGFR ≥45 mL/min/1.73 m^2 were conducted and correlations were similar. In the Receiver-operating characteristics analysis to predict the significant htTKLV (defined as ≥2,400 mL/m, the value known to increase 8.7 fold of malnutrition risk from previous study), ECW/TBW_{TR} showed the largest area under curve (0.726) with the following order; ECW/TBW_{WB} (0.697), ECW/TBW_{LE} (0.683), PhA_{LE} (0.637) and PhA_{TR} (0.601). The cut off value of ECW/TBW_{TR} to predict significant htTKLV was ≥0.387 with sensitivity of 57.7% and specificity of 76%.

Conclusions: Among segmental BIA parameters, ECW/TBW_{TR} showed highest correlation with htTKLV. Using the cut off value of ECW/TBW_{TR} ≥0.387, significant htTKLV values of ≥ 2,400 mL/m can be detected with sensitivity of 57.7% and specificity of 76%.

SA-PO503

Alteration of Tubular Secretion in Polycystic Kidney Disease

Ke Wang,[1] Leila R. Zelnick,[2] Yan Chen,[1] Andrew N. Hoofnagle,[1] Terry J. Watnick,[3] Stephen L. Seliger,[3] Bryan R. Kestenbaum.[1] *[1]University of Washington, Seattle, WA; [2]Kidney Research Institute, Seattle, WA; [3]University of Maryland School of Medicine, Baltimore, MD.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common genetic cause of kidney disease. Glomerular filtration rate (GFR) typically remains normal during early stages of disease; however the impact of ADPKD on other kidney functions is less certain. We compared proximal tubular solute clearance in 124 ADPKD patients from the Baltimore PKD Center to that of healthy controls and individuals with non-ADPKD chronic kidney disease (CKD).

Methods: We used liquid chromatography-mass spectrometry to quantify serum and urine concentrations of ten secretory solutes and calculated solute fractional excretions relative to creatinine. For 31 ADPKD patients with normal estimated GFR (eGFR), we compared fractional excretions with 25 healthy individuals. For 93 ADPKD patients with impaired eGFR, we compared fractional excretions with 91 general CKD patients from the Seattle Kidney Study matched by age, race, gender, and eGFR stage. We used linear regression to compare relative differences in fractional excretions adjusted for eGFR, age, gender, and body mass index. Among ADPKD patients we used linear regression to assess associations of fractional excretion with height adjusted kidney volume, determined by magnetic resonance imaging.

Results: The fractional excretions of most secretory solutes were lower in PKD patients compared with healthy controls and general CKD patients. Associations for six solutes were significant after accounting for multiple comparisons (Table). None of the secretory solutes were associated with kidney volume.

Conclusions: Secretory solute excretion is lower in ADPKD patients compared with healthy controls and general CKD patients independent of eGFR.

Funding: NIDDK Support

SA-PO504

Arterial stiffness Is Independently Associated with Total Kidney Volume in Children and Young Adults with ADPKD

Kristen L. Nowak, Mikaela R. Malaczewski, Berenice Y. Gitomer, Diana George, Michel Chonchol. *University of Colorado Denver: Anschutz Medical Campus, Aurora, CO.*

Background: Large-elastic artery stiffness is independently associated with both impaired kidney function and future decline in estimated glomerular filtration rate (eGFR) in chronic kidney disease. In patients with autosomal dominant polycystic kidney disease (ADPKD), an increase in total kidney volume (TKV) precedes the decline in kidney function and is a prognostic marker of future kidney function decline. We hypothesized that large-elastic artery stiffness, measured as carotid-femoral pulse-wave velocity (CFPWV), would be independently associated with height-adjusted TKV (htTKV) in children and young adults with ADPKD and preserved kidney function.

Methods: 51 non-diabetic children and young adults (6-25 years) with ADPKD and eGFR >90 ml/min/1.73m^2 with baseline data from an ongoing clinical trial underwent measurement of CFPWV and htTKV (by magnetic resonance imaging). The cross-sectional association of CFPWV with htTKV was evaluated using multiple linear regression models.

Results: Mean±s.d. age was 19±5 years, median htTKV was 371 (274, 509) ml/mm, and median CFPWV was 515 (455, 569) cm/sec. htTKV was greater in participants with CFPWV above the median (455 [308, 969] ml/m) compared to below the median (309 [267, 397] ml/m; p<0.0001). After adjustment for age, sex, race/ethnicity, systolic blood pressure, eGFR, and overweight/obesity, greater CFPWV was associated with larger htTKV (β-estimate: 11.27; 95% Confidence Interval: 1.0, 21.6, per 10 unit increase in CFPWV; p<0.05).

Conclusions: In children and young adults with ADPKD, CFPWV is independently associated with increased htTKV, an important predictor of progression in early-stage disease. Targeting arterial stiffness may be a novel strategy to slow kidney growth in children and young adults with ADPKD.

SA-PO505

Overweight and Obesity Are Independently Associated with Total Kidney Volume in Children and Young Adults with ADPKD

Kristen L. Nowak, Mikaela R. Malaczewski, Berenice Y. Gitomer, Diana George, Michel Chonchol. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Similar to the general population, body-mass index (BMI) in individuals with autosomal dominant polycystic kidney disease (ADPKD) has been increasing over recent decades. We recently reported that overweight and obesity are predictors of progression in adults with early-stage ADPKD who participated in the HALT-PKD study. We hypothesized that overweight and obesity would be also be independently associated with height-adjusted total kidney volume (htTKV) even earlier in the course of the disease (children and young adults).

Methods: 51 non-diabetic children and young adults (6-25 years) with ADPKD and estimated glomerular filtration rate (eGFR) >90 ml/min/1.73m^2 with baseline data from an ongoing clinical trial were classified as normal weight (<85th BMI percentile for age, sex, and height in children; BMI of 18.5-24.9 kg/m^2 in adults; ref; n=37), or overweight/obese (≥85th BMI percentile in children; BMI ≥25.0 in adults; n=14), using body weights adjusted to remove the contribution of kidneys. The cross-sectional association of overweight/obesity with htTKV by magnetic resonance imaging was evaluated using multiple logistic regression models.

Results: Mean±s.d. age was 19±5 years and median htTKV was 371 (274, 509) ml/m. htTKV was greater in the overweight/obese group (532 [421, 969] ml/m) compared to the normal weight group (316 [258, 428] ml/m; p=0.01). After adjustment for age, sex, race/ethnicity, systolic blood pressure, eGFR, and glucose, overweight/obesity was associated with increased odds of htTKV above the median compared to normal weight (Odds Ratio: 25.6; 95% Confidence Interval: 2.1, 333.3).

Conclusions: In children and young adults with ADPKD, overweight and obesity are independently associated with increased height-adjusted total kidney volume, an important predictor of progression in early-stage disease. Maintaining ideal body weight may be an important strategy to slow kidney growth in children and young adults with ADPKD.

SA-PO506

Nephrolithiasis as a Risk Factor for Kidney Disease Progression in ADPKD

Berenice Y. Gitomer,[1] Zhiying You,[2] Wei Wang,[3] Godela M. Brosnahan,[4] Kristen L. Nowak,[5] Katharina Hopp,[13] Peter C. Harris,[6] Vicente E. Torres,[6] Arlene B. Chapman,[7] Ronald D. Perrone,[8] Theodore I. Steinman,[9] Alan S. Yu,[10] Kyongtae T. Bae,[11] Kaleab Abebe,[11] Michel Chonchol.[12] *[1]Div. Renal Diseases and Hypertension, Aurora, CO; [2]UC Denver, Aurora, CO; [3]University of Colorado Anschutz Medical Campus, Aurora, CO; [4]University of Colorado Denver, Aurora, CO; [5]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO; [6]Mayo Clinic, Rochester, MN; [7]University of Chicago, Chicago, IL; [8]Tufts Medical Center, Boston, MA; [9]Beth Israel Deaconess Medical Center, Boston, MA; [10]University of Kansas Medical Center, Kansas City, KS; [11]University of Pittsburgh, Pittsburgh, PA; [12]University of Colorado, Aurora, CO; [13]University of Colorado Denver, AMC, Aurora, CO.*

Background: Kidney stones are a frequent complication among patients with autosomal dominant polycystic kidney disease (ADPKD). Previous studies have shown a higher risk of incident chronic kidney disease in persons with a history of kidney stones, but these studies did not examine patients with ADPKD. Thus, we hypothesized that a history of kidney stones may affect the rate of kidney function decline or increase in height corrected total kidney volume (HtTKV) in patients with ADPKD.

Methods: We assessed the association between a history of nephrolithiasis and annual rate of eGFR decline or % increase HtTKV using linear regression in 898 HALT-PKD study participants. To better ensure the temporal relation between nephrolithiasis and kidney function decline, we required that eGFR measurements were at least 180 days after the date of the kidney stone ascertainment. Analyses were adjusted for age, sex, body mass index, randomization group, baseline eGFR, systolic blood pressure, albumin excretion and genotype.

Results: A total of 898 subjects (mean age 43±10 years), comprising 789 non-stone forming (NKS) subjects and 109 subjects (46 with eGFR > 60 and 63 with eGFR 25-60 ml/min/1.73m^2 at baseline) with kidney stones (KS) and complete data were included in the analysis of eGFR decline. Baseline eGFR was 70±26 ml/min/1.73m^2 in the NKS group and 70±28 ml/min/1.73m^2 in the KS group (p= 0.9). Stone forming patients had a significantly faster yearly rate of kidney function decline of -5.3 ±8.3 ml/min/1.73m^2 vs. NKS -3.6±4.1 ml/min/1.73m^2 after adjustment for all variables (p<0.001). A total of 435 subjects (mean age 37±8.3 years), comprising 389 NKS (HtTKV 710±413 ml) and 46 KS (HtTKV 727±449ml) were included in the analysis of kidney volume progression. There was no significant difference in the rate of increase in HtTKV between the NKS and KS groups.

Conclusions: The presence of kidney stones was associated with more rapid loss of kidney function, thus may be a risk factor for more rapid kidney disease progression in ADPKD. As there were fewer subjects and imaging measures over the course of the HALT-PKD study this may confound ability to detect an effect of kidney stones on the rate of increase in HtTKV.

Serum Micro RNA Levels and Disease Progression in ADPKD

Berenice Y. Gitomer,[1] Wei Wang,[2] Aik choon Tan,[2] Zhiying You,[4] Kristen L. Nowak,[5] Katharina Hopp,[13] Godela M. Brosnahan,[6] Peter C. Harris,[7] Vicente E. Torres,[7] Arlene B. Chapman,[8] Ronald D. Perrone,[9] Theodore I. Steinman,[10] Alan S. Yu,[11] Kyongtae T. Bae,[12] Kaleab Abebe,[12] Michel Chonchol.[3] *[1]Div. Renal Diseases and Hypertension, Aurora, CO; [2]University of Colorado Anschutz Medical Campus, Aurora, CO; [3]University of Colorado, Aurora, CO; [4]UC Denver, Aurora, CO; [5]University of Colorado Denver: Anschutz Medical Campus, Aurora, CO; [6]University of Colorado Denver, Aurora, CO; [7]Mayo Clinic, Rochester, MN; [8]University of Chicago, Chicago, IL; [9]Tufts Medical Center, Boston, MA; [10]Beth Israel Deaconess Medical Center, Boston, MA; [11]University of Kansas Medical Center, Kansas City, KS; [12]University of Pittsburgh, Pittsburgh, PA; [13]University of Colorado Denver, AMC, Aurora, CO.*

Background: The rate of kidney disease progression is highly variable among patients with autosomal dominant polycystic kidney disease (ADPKD). Unfortunately, there is currently no biomarker that accurately predicts disease progression especially in the early stages of disease while kidney function is normal. Changes in circulating micro RNA (miR) levels occur in patients with chronic kidney disease and also in patients with acute kidney injury. We hypothesized that a signature of miRs may distinguish ADPKD patients at increased risk for faster kidney disease progression.

Methods: Forty-six serum samples from HALT ADPKD study participants were analyzed, 23 from fast progressors (eGFR decline > 3.4 ml/min/1.73m^2/year) and 23 from slow/normal progressors (eGFR decline ≤ 3.4 ml/min/1.73m^2/year). Subjects were matched by sex, gene mutation, mutation type and age (± 5 years). Serum miRs were analyzed by RNASeq and human mature miRNA sequences were mapped to miRBase 21.

Results: The baseline characteristics and eGFR decline rate for both groups are shown in Table 1. The differentially expressed miRs in the fast compared to slow progressors included miR 1246, miR 6785-5p and miR 323a-3p which were significantly up-regulated in the fast progressors while miR 93, miR 451a and miR 106-5p were down regulated. Pathways associated with up-regulated miRs included adherens junction, renal cell carcinoma and AMP kinase signaling and those associated with down-regulated miRs included TGF-β and mTOR signaling, focal adhesion and extracellular matrix interaction.

Conclusions: The results indicate that aberrant expression of serum miRs occurs in ADPKD patients with fast disease progression. These may indicate further disruption of key pathways in patients with faster kidney disease progression. Future validation in a large cohort will be necessary to fully chracterize the key signature of discriminatory miRs.

Urinary Epidermal Growth Factor/Monocyte Chemotactic Peptide 1 Ratio Predicts Outcome in Patients with Autosomal Dominant Polycystic Kidney Disease

Silvia Matino,[1] Maria T. Rocchetti,[6] Francesco Pesce,[1] Giovanni Piscopo,[2] Maddalena Gigante,[5] Francesco Trepiccione,[3] Giovanna Capolongo,[4] Marco A. Moschetta,[8] Giovambattista Capasso,[7] Loreto Gesualdo.[1] *[1]University of Bari, Porto Cesareo, Italy; [2]Ospedale della Murgia, Altamura, Italy; [3]University of Campania "Luigi Vanvitelli", Napoli, Italy; [4]Second University of Naples, Naples, Italy; [5]University of Foggia, Foggia, Italy; [6]University of Foggia-Faculty of Medicine-Biomedical Sciences Department, Fogga, Italy; [7]University of Campania Luigi Vanvitelli, Napoli, Italy; [8]University of Bari Medical School, BARI, Italy*.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a common inherited condition leading to end stage renal disease, but it is difficult to predict the rate of disease progression. Total kidney volume (TKV) is an independent prognostic marker of renal function decline and is used to define the Mayo classification. Urinary Epidermal Growth Factor/Monocyte Chemotactic Peptide 1 ratio (uEGF/MCP1) has been shown to be a prognostic biomarker in IgA nephropathy. In this study, we tested the role of uEGF/MCP1 in predicting outcome of ADPKD patients according to the Mayo classification.

Methods: A cohort of 46 (32 F, 14 M) patients with ADPKD consecutively enrolled was evaluated. Urinary EGF and MCP1 levels were measured by ELISA. TKV calculation and Mayo classification were based on MRI measurements. The Mayo classification was used for the prediction of the eGFR at 10 years to calculate the ΔT0-T10. The outcome was defined as follows: Mayo Classes 1A-1B patients were classified as "non-progressors", whereas 1C-1E patients were classified as rapid disease "progressors" (corresponding to a predicted eGFR decrease ≥2.5 mL/min/1.73 m2 per year).

Results: Clinical data at baseline (T0) were the following: age 44±13 years, eGFR 71±32 ml/min/1.73 m^2, TKV 1239 (731–2287) ml, uEGF/MCP1 58.5 (16.8–127.1), Mayo Class (no.) 1A (3), 1B (10), 1C (13), 1D (16), 1E (4), progressors/non-progressors (no.) 33/13. uEGF/MCP1 at T0 was significantly different across Mayo Classes (p=2.14e-05) showing a trend towards a reduction in Class 1E and correlated with the predicted variation of eGFR at 10 years (ΔT0-T10, r =-0.405, p=0.004). In addition, both urinary EGF (r=-0.313, p=0.027) and MCP1 (r=0.404, p=0.004) correlated with the ΔT0-T10. In a multivariate analysis including adjustment for age and sex we found that uEGF/MCP1 at T0 is an independent predictor of outcome (OR 0.98; 95% CI: 0.97-0.99, p=0.005) and this model showed an area under the ROC curve of 0.90 (95% CI: 0.81-0.98), achieving a specificity of 0.92 and a sensitivity of 0.82.

Conclusions: These findings show that uEGF/MCP1 can be used as a reliable and non-invasive biomarker for the estimation of disease progression in patients with ADPKD.

SA-PO509

Identifying Urine Biomarkers of Disease Progression in Pediatric Autosomal Dominant Polycystic Kidney Disease Patients

Madhurima Baliga,[1] Jost Klawitter,[2] Uwe Christians,[6] Michel Chonchol,[2] Berenice Y. Gitomer,[4] Melissa A. Cadnapaphornchai,[3] Jelena Klawitter.[5] *[1]University of Colorado School of Medicine, Aurora, CO; [2]University of Colorado, Aurora, CO; [3]Rocky Mountain Pediatric Kidney Center, Rocky Mountain Hospital for Children at Presbyterian St. Luke's Medical Center, Denver, CO; [4]Div. Renal Diseases and Hypertension, Aurora, CO; [5]University of Colorado Denver, Aurora, CO; [6]Department of Anesthesiology, University of Colorado Denver, Aurora, CO*.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most commonly inherited kidney disease. Though children with ADPKD show normal renal function, rapid cyst development is already occurring. In this study, we aimed to identify urine biomarkers of disease progression in the pediatric ADPKD population.

Methods: Urine samples from 70 ADPKD patients aged 8-26 years were collected at baseline. Following collection at baseline, 37 patients were randomized to a pravastatin treatment group and 33 to a placebo group. Metabolomic analysis of urine was performed using targeted liquid chromatography-mass spectrometry. Within the treatment and placebo groups, differences between biomarkers at baseline and 36 months were evaluated. Metabolites with a P value < 0.05 were identified as significant. Pathway analysis was conducted on significant metabolites.

Results: Within the pravastatin treatment group, 27 metabolites were uniquely and significantly changed. Metabolites involved in glutamine metabolism (glutamic acid, α-ketoglutarate) and pyruvate metabolism (dihydroxyacetone phosphate, acetylphosphate) were all decreased at 36 months. Interestingly, ascorbic acid, a metabolite with antioxidant properties, was increased by 59% at 36 months in the treatment group. Within the placebo group, 37 metabolites were uniquely and significantly changed. Metabolites of the citric acid cycle (oxaloacetic acid, malic acid, cis-aconitic acid, citric acid, pyruvic acid) were decreased, and literature confirms that citric acid cycle activity is decreased in patients with CKD. Trimethylamine N-oxide (TMAO) is a marker of atherosclerotic risk and it has been shown to be elevated in the plasma of patients with CKD, in part due to decreased renal clearance. Our results were consistent with this finding as we found metabolites involved in the TMAO pathway (betaine, choline, and TMAO) to be decreased in the placebo group at 36 months.

Conclusions: Progression of ADPKD was associated with a decline in the renal clearance of citric acid cycle and betaine metabolism intermediates, preceding any loss of renal function. Future work involves correlating urine metabolites to plasma metabolites in order to identify biomarkers that may be able to risk stratify patients over the course of the disease.

SA-PO510

Plasma Metabolomics to Identify Biomarkers and Altered Pathways in ADPKD

Madhurima Baliga,[1] Jost Klawitter,[3] Uwe Christians,[6] Michel Chonchol,[3] Berenice Y. Gitomer,[2] Melissa A. Cadnapaphornchai,[4] Jelena Klawitter.[5] *[1]University of Colorado School of Medicine, Aurora, CO; [2]Div. Renal Diseases and Hypertension, Aurora, CO; [3]University of Colorado, Aurora, CO; [4]Rocky Mountain Pediatric Kidney Center, Rocky Mountain Hospital for Children at Presbyterian St. Luke's Medical Center, Denver, CO; [5]University of Colorado Denver, Aurora, CO; [6]Department of Anesthesiology, University of Colorado Denver, Aurora, CO*.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most commonly inherited kidney disease. Though children with ADPKD show normal renal function prior to adulthood, rapid cyst development is already occurring. In this study, we aimed to identify plasma biomarkers of disease progression in the pediatric ADPKD population.

Methods: Plasma samples from 81 ADPKD patients aged 8-22 years were collected. Samples from healthy children (60 subjects, aged 1-3 years) served as a control. Metabolomic analysis was performed using liquid chromatography-mass spectrometry and differences in biomarkers between healthy subjects and ADPKD patients were evaluated. Additionally, longitudinal analysis of the ADPKD patients was completed over 36 months. Metabolites with a P value < 0.05 and a fold change of 50% or greater were identified as significant. Pathway analysis was conducted on significant metabolites.

Results: Cardiovascular risk markers and intermediates of the methionine cycle (uric acid, allantoin, cysteine, S-adenosyl-homocysteine, methionine sulfoxide), intermediates of the Krebs cycle and glycolysis (pyruvate, α-ketoglutarate, D-glyceraldehyde-3-phosphate), and bile acids (deoxycholic and cholic acids) were increased in plasma in ADPKD patients. An increase in intermediates of tryptophan metabolism (kynurenine, 3-hydroxykunurenine, xanthurenic acid and anthranilic acid) was accompanied by a decrease in nicotinamide in patients with ADPKD. The concentration of pipecolic acid, a diagnostic marker for peroxisome biogenesis disorders such as the renal cystic disorder Zellweger syndrome, was also significantly higher in ADPKD patients. Longitudinal analysis of ADPKD patients showed the above metabolites remained changed at 36 months. For the tryptophan pathway, changes became more pronounced.

Conclusions: Kynurenine metabolism is elevated in children with ADPKD suggesting that its direct targeting via, for example inhibition of the pathway's regulating enzyme indolamine-2,3-dioxygenase (IDO1), could prevent progression of the disease. Markers of cardiovascular risk were increased in pediatric ADPKD patients compared to healthy subjects. Qualification of these as markers for disease progression could help to risk stratify patients and help identify molecular targets for further therapeutic developments.

Proteomic Differential Study Associated to Autosomal Dominant Polycystic Kidney Disease in Mouse Embryonic Models

Vanesa Calviño,[2] Adrian Cordido,[3] Marta Vizoso,[2] Susana Bravo,[4] Candido Diaz-Rodriguez,[5] Miguel A. Garcia-Gonzalez.[1] *[1]Health Research Institute of Santiago de Compostela (IDIS)., Santiago de Compostela, Spain; [2]Health Research Institute of Santiago de Compostela (IDIS), Santiago de Compostela, Spain; [3]Instituto de Investigacion Sanitaria (IDIS) de Santiago de Compostela, Santiago de Compostela, Spain; [4]Instituto de Investigación Sanitaria (IDIS) de Santiago de Compostela, Santiago de Compostela, Spain; [5]University Clinical Hospital of Santiago de Compostela (CHUS), Santiago de Compostela, Spain.*

Background: The autosomal dominant polycystic kidney disease (ADPKD) is a genetic disease characterized by the formation of cysts along the nephrons that can lead to renal failure. It is associated with other extrarenal manifestations such as the formation of hepatic or pancreatic cysts, aneurysms, etc. ADPKD is caused by mutations in the PKD1, PKD2 and GANAβ genes. Mouse models of ADPKD with homozygous variants in PKD1 or PKD2 genes present cystogenesis from day 15.5 of gestation and die during embryonic development typically around day 17. The study of these models at embryonic ages could be useful to investigate the molecular mechanisms involved in the onset of cyst formation.

Methods: In order to identify proteins and pathways involved in cystogenesis, we compared the proteome of double mutants vs. healthy mouse embryos kidney. Embryo kidneys were removed at day 15.5 and 16.5 from two animal models of ADPKD with germline mutations in the PKD1 ($PKD1^{del2\text{-}4}$) and PKD2 ($PKD2^{\Delta 11\text{-}13}$) genes as well as wild type animals. A combined study of two mass spectrometry technologies was carried out: LC-MALDI using a MALDI TOF-TOF 4800 and LC-MS / MS using a MALDI-TripleTOF 6600. The differential proteome of double mutants and healthy mice was identified and their involved pathways were analyzed with Reactome.

Results: We identified 1 protein in E15.5 PKD1 double mutant model not detected in healthy embryo, 6 in E16.5 PKD1, 2 in E15.5 PKD2 and 19 in E16.5 PKD2. We also identified 37 proteins in E15.5 PKD1 models only detected in healthy individuals; 20 in E16.5 PKD1; 20 in E15.5 PKD2 and 5 in E16.5 PKD2. These proteins are involved in different pathways such as metabolism, signal transduction, transcription and immune system as well as development biology, vesicle-mediated transport, hemostasis or cell cycle among others.

Conclusions: Our results would contribute to improve the knowledge on the molecular mechanisms underlying the processes of cystogenesis, as well as to identify possible therapeutic targets.

Proteomic Analysis for the Identification of the PKD1 Related Signaling Pathways and Direct Targeting of Polycystic Kidney and Liver Disease: Few Cysts Remain Uncontrolled

Adrian Cordido,[1] Miguel A. Garcia-Gonzalez,[1] Marta Vizoso,[1] Vanesa Calviño,[2] Candido Diaz-Rodriguez,[3] Susana Bravo.[1] *[1]Health Research Institute of Santiago de Compostela (IDIS)., Santiago de Compostela, Spain; [2]Health Research Institute of Santiago de Compostela (IDIS), Santiago de Compostela, Spain; [3]University Clinical Hospital of Santiago de Compostela (CHUS), Santiago de Compostela, Spain.*

Background: Different mechanisms have been related to the pathogenesis of renal and hepatic cystogenesis but the identification of **the proteome signature for the identification of the cystogenic fingerprint and consequent treatment approaches has never been develop up to date.**

Methods: We inactivated Pkd1 (*$Pkd1^{cond/cond}$TamCre)* gene at postnatal day 10/11 (cystic window) and postnatal day 15/16 (non-cystic window) and recollected organs at day 30 for kidney (cystic kidney proteome or CKP) and liver (cystic liver proteome or CLP) proteome analysis by **mass spectrometry MALDI-TOF. We refined the renal and hepatic cystogenic proteome** (Reactome, KEGG, FunRich, String) by the identification of 34 specific proteins related to the liver phenotype (26 up and 8 down) and 22 to the kidney phenotype (16 up and 6 down).

Results: As expected, the major **pathways related to CKP and CLP are** signal transduction, immune system, metabolism and metabolism of proteins. Interestingly, vesicle-mediated transport and cell cycle pathways are specifically related to CLP and, in contrast, extracellular matrix organization and developmental biology pathways are specific of CKP. Based on this and previous results, approach treatment of PKD animals allowing us to inhibition of liver cystogenesis and significantly reduction of kidney cystic index and volume, recovering physiological parameters of kidney and liver function. In addition, we combined our molecules with known therapies for ADPKD (Tolvaptan) showing recovery of kidney and liver physiological parameters, although THP-positive nephron segment and a low portion of DBA positive remain cystic. This indicates the need of continuing puzzling out the remaining cysts for further treatments.

Conclusions: We described a list of **new signaling pathways and possible targets** for the development of specific therapeutic approaches **for renal and hepatic phenotypes related to ADPKD**. This data opens a new understanding of the molecular basis of the disease based on an organ specific protein profile of cystogenesis.

SA-PO513

Exploring KIM-1 as a Marker for Kidney Disease in ADPKD: Analysis from the HALT-PKD Studies

Lama A. Noureddine,[1] Berenice Y. Gitomer,[2] Zhiying You,[3] Wei Wang,[4] Michel Chonchol,[5] Diana I. Jalal.[6] HALT Investigators *[1]Universty of Iowa Carver College of Medicine, Iowa City, IA; [2]Div. Renal Diseases and Hypertension, Aurora, CO; [3]UC Denver, Aurora, CO; [4]University of Colorado Anschutz Medical Campus, Aurora, CO; [5]University of Colorado, Aurora, CO; [6]University of Iowa, Iowa City, IA.*

Background: Cyst compression of renal tubules and intrarenal microvasculature play a vital role in progression of autosomal dominant polycystic kidney disease (ADPKD) and may induce kidney injury molecule-1 (KIM-1). We hypothesized that urinary KIM-1 is a marker of disease progression in ADPKD.

Methods: We measured baseline and 48-month urinary KIM-1/urinary creatinine (UKIM-1/Cr) of participants in the HALT-PKD studies. We evaluated whether UKIM-1/Cr predicted decline in eGFR in studies A and B (n=738) or increase in height-adjusted TKV (TKV) in study A (n=283) and whether intensive, compared to standard, blood pressure (BP) control lowered UKIM-1/Cr over 48 months in study A (n=101).

Results: Higher baseline UKIM-1/Cr was associated with decline in eGFR in unadjusted analysis (β-estimate for eGFR slope=-0.04, 95% C.I. -0.06- -0.01, P=0.0006). After adjusting for demographics, PKD1 genotype, SBP, DBP, BMI, baseline eGFR, urinary albumin/Cr ratio (UACR), and TKV, baseline UKIM-1/Cr was associated with slightly greater kidney function decline (β-estimate = -0.03, 95% C.I. -0.05- -0.003, P= 0.03). In linear mixed model regression analysis, baseline UKIM-1/Cr was associated with increased TKV over time in the multivariate model (β-estimate= 0.10, 95% C.I. 0.002-0.20, P=0.05). Intensive, compared to standard, BP control was not associated with lower UKIM-1/Cr levels. However, after adjusting for interaction with baseline UACR, intensive BP control was associated with lower KIM-1 in the multivariate model (β-estimate= -0.27, 95% C.I. -0.52- -0.011, P= 0.04). This persisted after adjustment for renal blood flow and inflammatory markers (Table).

Conclusions: UKIM-1/Cr was associated with slightly greater decline in kidney function in ADPKD and intensive BP control was associated with lower UKIM-1/Cr over 48 months. Further studies are needed to determine what role KIM-1 plays in ADPKD progression.

Effect of intensive vs standard BP control on UKIM-1/Cr in study A:

Odds ratio (CI)	P value
-0.32 (-0.58 to -0.06) *	0.02
-0.33 (-0.59 to -0.06) #	0.02

*adjusted for demographics age, male gender, PKD1 genotype, SBP, DBP, BMI, baseline eGFR, baseline UACR, baseline TKV, and baseline renal blood flow

#: Variables in * + high sensitivity CRP (hs-CRP), interleukin-6 (IL-6)

SA-PO514

Assessment of Endocannabinoid System as a Biomarker for Progression of ADPKD

Cristina Sempio,[1] Jost Klawitter,[1] Uwe Christians,[2] Michel Chonchol,[1] Melissa A. Cadnapaphornchai,[3] Berenice Y. Gitomer,[4] Jelena Klawitter.[5] *[1]Department of Anesthesiology, University of Colorado Denver, Aurora, CO; [2]Department of Anesthesiology, University of Colorado Denver, Aurora, CO; [3]Rocky Mountain Pediatric Kidney Center, Rocky Mountain Hospital for Children at Presbyterian St. Luke's Medical Center, Denver, CO; [4]Div. Renal Diseases and Hypertension, Aurora, CO; [5]Department of Anesthesiology, University of Colorado Denver, Aurora, CO.*

Background: Endocannabinoids (eCBs) are endogenous lipid ligands of the cannabinoid-1 receptor (CB1). In the renal vasculature, CB1 is involved in the regulation of renal blood flow and hemodynamics via NO release. Expression of CB1 and main eCBs are significantly increased in the fibrotic kidney where they modulate inflammation and fibrosis, another pathophysiological mechanism of autosomal dominant polycystic kidney disease (ADPKD).

Methods: Plasma from children and young adults with ADPKD and normal renal function were collected during an interventional trial at 0, 18 and 36 months. A single serum sample from adult ADPKD patients was collected at baseline of a cross-sectional trial (n=71, eGFR >60 mL/min per 1.73m^2). All patients had available measures of total kidney volume (normalized to height (HtTKV) in pediatric patients or to body surface area (TKV/BSA) in adult patients) and left ventricular mass index (LVMI). Analysis of fourteen eCBs was performed using a liquid chromatography tandem mass spectrometry with online extraction. Statistical analysis was performed using SPSS v. 24.

Results: In children and young adults, plasma AEA (n=118, cross-sectional) correlated with HtTKV. The association was independent of the treatment group but highly dependent on child's age. After control for age and sex, linoeyl ethanolamide was positively correlated with HtTKV and cardiovascular LVMI. In 11 placebo treated pediatric patients with available samples at 0 and 36 months, the change in concentration of O-arachidonoyl ethanolamide positively correlated with ΔHtTKV (r=0.659) adjusted for age and sex. In adult ADPKD patients, plasma palmitoyl- (r=0.379) and stearoyl-ethanolamide (r=0.426) positively correlated with TKV/BSA, after control for age and sex. AEA also increased with disease progression; significant negative correlation between the renal function as measured by eGFR and AEA (r=-0.395) was observed.

Conclusions: Our results showed that an overall increase of the circulating endocannabinoids is present in patients with ADPKD, with manifestations already present early in the disease, in children with ADPKD and normal kidney function. Thus, eCBs should be evaluated for their potential as biomarkers of ADPKD severity and progression and in mechanistic studies evaluating CB1's role in mediating renal fibrosis.

NADPH Oxidase (NOX4) and Mitochondrial Injury Contribute to Oxidative Stress and Endothelial Dysfunction in Young Normotensive Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Suleyman Y. Goksu, Gizem Yilmaz, Fouad T. Chebib, Alfonso Eirin, Amir Lerman, Lilach O. Lerman, Peter C. Harris, Vicente E. Torres, Maria V. Irazabal. *Mayo Clinic, Rochester, MN.*

Background: Endothelial dysfunction (ED) is an independent predictor of cardiovascular (CV) events. In ADPKD, ED and oxidative stress (OS) develop early on, preceding hypertension (HTN) and renal function decline. However, the mechanisms responsible remain unknown. We hypothesized that NOX4 and mitochondrial injury contribute to OS and ED preceding HTN in young normotensive ADPKD patients.

Methods: We prospectively measured plasma levels of homocysteine (Hcy), 8-isoprostane, NOX4 and the mtDNA genes cytochrome-c oxidase-3 (COX3) and nicotinamide adenine dinucleotide (NADH) dehydrogenase subunit-1 (ND1), in young, normotensive (without BP medication) ADPKD patients, and age/gender-matched healthy volunteers (HV) (n=10, each). Total kidney volume (TKV) and Renal Blood Flow (RBF) were evaluated by MRI.

Results: BP levels were higher in ADPKD, and HtTKV was twofold higher in ADPKD vs. controls. Yet, eGFR and RBF were similar between the groups (Table). Plasma Hcy, 8-isoprostanes and NOX4 were higher in ADPKD (Figure), and correlated directly with HtTKV ($p<0.05$, figure), but the correlation with RBF was not significant. Plasma mtDNA levels were lower in ADPKD vs controls, and correlated inversely with HtTKV (R^2 0.397 and 0.392 respectively).

Conclusions: Early ADPKD is associated with elevated Hcy, 8-isoprostane, and NOX4, and decreased mtDNA levels, which precede the reduction in RBF and the development of HTN, and are associated with disease severity. These findings suggest that NOX4 and mitochondrial abnormalities contribute to oxidative stress, endothelial dysfunction, and possibly the development of HTN and disease progression in ADPKD

Funding: Private Foundation Support

Table

	HV	ADPKD	*p value*
Number of patients	10	10	N/A
Gender (Female/Male)	6/4	6/4	N/A
Age (years)	23.2 ± 3.2	22.5 ± 3.2	N/A
Systolic blood pressure (mmHg)	114.6 ± 9.0	123.6 ± 11.0	**0.008**
Diastolic blood pressure (mmHg)	70.2 ± 8.4	77.3 ± 8.3	0.063
Serum creatinine (mg/dL)	0.9 ± 0.1	0.8 ± 0.2	0.494
eGFR-CDK-EPI (ml/min/1.73m²)	104.9 ± 19.3	110.6 ± 12.4	0.411
HtTKV (mL/m)	179 (160 - 189)	347 (270 - 460)	**<0.001**
RBF (cc/min/1.73m²)	624 ± 100	619 ± 79	0.903

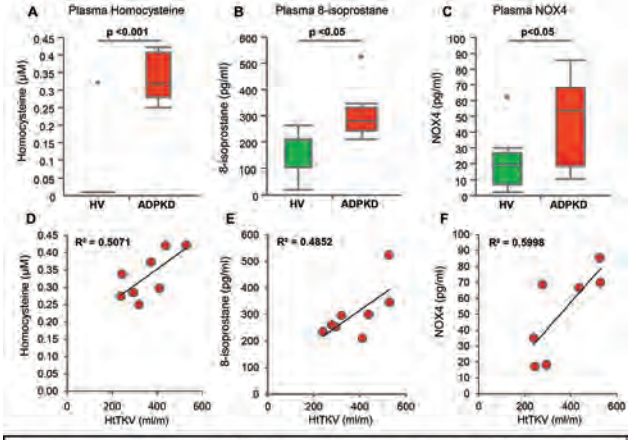

Figure. Top: Plasma levels of Hcy (A), 8-isoprostane (B) and NOX4 (C) in ADPKD patients and HV. Top and bottom boxes are estimated 75th and 25th percentiles, respectively. Vertical lines extend from the 75th percentile to the highest and from the 25th percentile to the lowest data points. Bottom: HtTKV correlated directly with plasma Hcy (D), 8-isoprostane (E), and NOX4 (F).

ELiSA, a Phase 2 Clinical Study with the Novel Vasopressin V2 Receptor Antagonist Lixivaptan in Patients with Autosomal Dominant Polycystic Kidney Disease

Lorenzo Pellegrini,[1] Linda C. Hogan,[1] Ruth Ann Subach.[2] *[1]Palladio Biosciences, Newtown, PA; [2]DS InPharmatics, LLC, Harleysville, PA.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is one of the most prevalent inherited genetic diseases of the kidney in humans. Recent advances established vasopressin V2 receptor inhibition as a clinically validated mechanism of action for the treatment of ADPKD; however, safe and effective disease-modifying therapies for ADPKD are still lacking. Here we describe a first-in-patients clinical study with lixivaptan, a potent, selective vasopressin V2 antagonist, in patients with ADPKD.

Methods: ELiSA (Evaluation of Lixivaptan in Subjects with ADPKD) is a phase 2, open-label, multicenter clinical study of lixivaptan in patients with ADPKD to be conducted at up to 15 clinical sites in the United States. Eligible patients will include adults aged 18–60 years with relatively preserved kidney function (chronic kidney disease CKD1 and CKD2; n = 16) or moderately impaired renal function (CKD3; n = 16). Two doses of lixivaptan, administered for 7 days, will be tested in eight patients within each patient group.

Results: The primary objectives of the ELiSA study are to characterize the safety, tolerability and pharmacokinetic profile of lixivaptan and its major metabolites following multiple doses in ADPKD patients with various degrees of kidney function impairment. The secondary objectives are to characterize the effect of lixivaptan on pharmacodynamic markers that have been shown to correlate with the clinical activity of vasopressin antagonists in the treatment of ADPKD, including urine osmolality, urine output, serum creatinine, plasma copeptin and total kidney volume.

Conclusions: The ELiSA clinical study is an important milestone toward the potential approval of lixivaptan as a safe and effective therapy for the treatment of ADPKD in a broad patient population. Study results will inform the design and execution of an upcoming pivotal registration study with lixivaptan for the treatment of ADPKD.

SA-PO517

Soluble Urokinase Plasminogen Activator Receptor Levels Predict Renal Function Decline in Autosomal Dominant Polycystic Kidney Disease

Salim Hayek,[2] Sharin Roth,[3] Christina Pao,[3] Martin G. Zeier,[4] David C. Wei,[1] Jochen Reiser.[1] *[1]Rush University Medical Center, Chicago, IL; [2]Emory University School of Medicine, Atlanta, GA; [3]Otsuka Pharmaceutical Development and Commercialization, Princeton, NJ; [4]Heidelberg University, Heidelberg, Germany.*

Background: Levels of soluble urokinase-type plasminogen activator receptor (suPAR), a signaling molecule and marker of immune activation, have been shown to predict incident kidney disease. Patients with autosomal dominant polycystic kidney disease (ADPKD) experience progressive but highly variables rates of decline in renal function, with highly heterogenous outcomes. Whether suPAR levels are predictive of decreasing kidney function in patients with ADPKD independently of known prognostic factors such as proteinuria and kidney volume, is unknown.

Methods: SuPAR levels were measured in a subset of 479 patients with ADPKD (mean age 39, 52% male, 80% Caucasians) enrolled in the TEMPO 3:4 trial and randomized to the placebo arm. All subjects randomized into the placebo arm with plasma samples that were available were included. Patients underwent scheduled follow-up for 3 years, with repeated measurements of height-adjusted kidney volume (htTKV), urine albumin-creatinine ratio (UACR), and Cockcroft-Gault calculated estimated glomerular filtration rate (eGFR). Linear mixed models for repeated measures were used adjusting for age, gender, baseline eGFR, UACR and htTKV to examine the association between baseline suPAR levels stratified by tertiles and follow-up eGFR measures.

Results: At baseline, the median suPAR level was 2544 pg/mL [IQR 2125-3221], with 32% of subjects having suPAR levels≥3000 pg/mL, while median eGFR was 78 [IQR 62;96] and htTKV 853 mL/m [IQR 623-1151]. Baseline suPAR levels were weakly associated with htTKV (β 0.15 95%CI[0.00;0.29] independently of eGFR, UACR, gender, age and hypertension. Patients in the first, second and third tertiles of suPAR had a 10%, 15% and 23% decrease in eGFR (P<0.001), and a 18%, 18% and 17% increase in htTKV at 3-years follow-up (P=0.6). The associations did not differ according to gender and was independent of age, baseline UACR and eGFR.

Conclusions: SuPAR levels were associated with decline in renal function in patients with ADPKD. Whether suPAR can be used as a prognostic marker to identify patients at high risk of decline in renal function that would benefit from early therapeutic intervention remains to be determined.

SA-PO518

Preeclampsia an Under Recognised Cause of AKI in Pregnancy

Raja Ramachandran,[1] Krishan Lal L. Gupta,[3] Vivekanand Jha.[2] *[1]Nehru Hospital, Chandigarh, India; [2]George Institute for Global Health, New Delhi, India; [3]Postgraduate Institute of Medical Education & Research, Chandigarh, India.*

Background: Obstetric acute kidney injury (AKI) constitutes about 8-12% of all AKI in developing countries, with blood loss and sepsis as the main causes. Reliance on clinical parameters alone may lead to underestimation of the prevalence of preeclampsia (PE) in those with AKI, and use of biomarkers may help identify more cases.

Methods: All patients with obstetric AKI referred to the nephrology unit from September 2015 to August 2017 were evaluated. PE was diagnosed as clinical (cPE) in the presence of new onset of hypertension and proteinuria (≥ 1+ on dipstick) or hypertension and end-organ dysfunction with or without proteinuria after 20 weeks of gestation in a previously normotensive woman; and serological (sPE) on the basis of soluble fms-like tyrosine kinase(FLT1)/placental growth factor (PIGF) ratio of > 85 (<34 weeks of gestation) and > 110 (≥34 weeks of gestation) when clinical findings were indeterminate. Patients with pre-existing CKD or known systemic illnesses were excluded. We evaluated 6-month maternal and fetal outcomes in all patients.

Results: Out of a total of 73 patients seen during the study, 64 (87.7%) were seen in third trimester/postpartum period. The mean age was 26.38±3.92 (range 19-38) years. Thirty-six (49%), 34 (47%), and 57 (78%) patients had evidence of blood loss, sepsis and HUS respectively. cPE was diagnosed in 19 (30%) cases, and an additional 11 (17%) showed evidence of sPE. Fourteen (47%), 11 (37%) and 27 (90%) patients with PE had haemorrhage, sepsis and of HUS respectively. A total of 5 (17%) patients died, and 10 (33%) failed to recover from AKI. Only 6 (20%) had a successful fetal outcome.

Conclusions: Use of clinical criteria alone leads to under-diagnosis of PE in patients with obstetric AKI in developing countries. Sepsis, blood loss and AKI mask the clinical manifestations.

Effect of Spironolactone in Ischemic AKI in Critically Ill Cancer Patients: A Pilot Study

Bertha M. Cordova-Sanchez,[1] Silvio A. Ñamendys- Silva,[1] Rosalba Pérez-villalva,[2] Juan A. Ortega-Trejo,[2] Luis E. Morales-Buenrostro,[2] Norma Bobadilla.[2,3] *[1]Instituto Nacional de Cancerologia, Mexico City, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; [3]Instituto de Investigaciones Biomedicas, Mexico City, Mexico.*

Background: Acute kidney injury (AKI) is a common complication in critically ill patients, about 30% of cases occur after major surgery caused by hypoperfusion. Cancer

patients who undergo major surgery have a greater AKI risk, due to factors associated with cancer or its treatment. Previous animal studies from our laboratory showed that mineralocorticoid receptor blockade with spironolactone, after renal ischemia/reperfusion prevents AKI. In this pilot study, we explored the tolerance and effectiveness of spironolactone for AKI prevention in critically ill cancer patients after major surgery.

Methods: We included 24 patients in a randomized, double-blinded, placebo-control trial. Patients received either spironolactone 25 mg or placebo, at 0, 24, and 48 h after surgery and were followed for five days. Our outcomes were AKI defined by KDIGO criteria, urinary biomarkers, hyperkalemia, lactate clearance, and days with vasopressor use.

Results: There were no differences between groups at inclusion. In spironolactone group, 6/12 patients developed AKI compared to 7/12 patients in placebo group (p=0.682). Spironolactone did not alter potassium, lactate clearance, or days with vasopressor. We analyzed the percentage change in biomarkers obtained at 48 h compared to the baseline level. We found that NGAL decrease and KIM1 increase significantly in spironolactone group.

Conclusions: In this exploratory study, we observed that spironolactone was well tolerated, although it did not reduce the incidence of clinical AKI in relation with the sample size, the significant decrease in urinary NGAL in the group treated with spironolactone suggests a decrease in tubular damage. These data can be useful in the design of larger controlled studies.

Variable	Spironolactone (n=12)	Placebo (n=12)	p value
Male gender	6	5	1.00
Age	58±13	55±17	0.61
Baseline creatinine(mg/dl)	0.75±0.2	0.78±0.3	0.80
NGAL % change	-68(-84 to 75)	+57(-32 to 130)	0.03
Hsp72 % change	-26(-88 to +340)	-44(-77 to +44)	0.76
KIM1 % change	+159(+48 to +315)	-33(-49 to +21)	0.00
Maximum potassium level	4.3 ±0.5	4.4±0.1	0.50
Decrease in lactate	-3 (-2 to-4)	-2 (-2 to-5)	0.84

SA-PO520

Rate of AKI with Epithelial Growth Factor Tyrosine Kinase Inhibitors

Sheron Latcha,[1] Michaela Scott.[2] *[1]Medicine, Memorial Sloan Kettering Cancer Center, New York, NY; [2]Medicine, New York Medical College, New York, NY.*

Background: Epithelial growth factor receptor (EGFR) mutations are found in several tumors, especially non-small cell lung cancer (NSCLC), occurring in 10-15% of NSCLC in Europe and 30-40% in Asia. Renal dysfunction is rare with EGFR TKIs. In phase III clinical trials, one patient on erlotinib had any grade renal failure and 1.5% of patients treated with gefitinib had an elevated creatinine (Cr). EGFR is expressed throughout the mammalian kidney and EGF and EGFR ligands are involved in renal development. In animal models, EGFR activation, and reductions in EGFR or EGFR TKI activity are associated with both benefit and harm to renal function, depending on the model of renal injury. The purpose of this this study is to determine the rate of acute kidney injury (AKI) with the use of EGFR TKIs at a single center.

Methods: Retrospective data was collected on all adult patients at our institution who received any EGFR TKI from 1/1/2014-12/31/2016. Demographic data, baseline Cr (Cr within 30 days prior to treatment) and peak Cr after each treatment cycle were collected. AKI was defined as an increase in Cr ≥1.5x baseline. Incomplete recovery of renal function was defined as a last Cr ≥25% of baseline. All statistical analyses was conducted using R version 3.4.4. A p-value of <0.05 was considered statistically significant.

Results: Analyses was performed on 1831 observations in 503 patients. Of 503 patients, AKI occurred in 121 (24%). Of these, 103(85%) had incomplete recovery of renal function. The average time from baseline to last Cr was 314.8 days. Overall, 85% of patients were treated for lung cancer. AKI occured in 26% of lung cancer patients and 92% of all patients with AKI had underlying lung cancer (p=0.001). Overall, 385 (77%) patients were treated with erlotinib. AKI occured in 28% of patients treated with erlotinib and 89% of all patients with AKI had received erlotinib (p=0.002). Overall, the group was largely white (67%), non-Hispanic (91%) and female (70%), with no significant differences between those with and without AKI.

Conclusions: The rate of AKI with any EGFR TKI was 24%. On follow up, 85% of patients never returned to within 25% of their baseline Cr. AKI rates were significantly higher in lung cancer patients and with erlotinib use. Retrospective data with it attendant limitations cannot assign causality or define mechanisms. This relationship needs further examination.

Immune Interstitial Nephritis Complicating Treatment of Lung Cancer

Krishna M. Baradhi,[1] Kothai divya Guruswamy sangameswaran.[2] *[1]Nephrology, University of Oklahoma, Tulsa, OK; [2]OU -Tulsa School of Community Medicine, Tulsa, OK.*

Introduction: Immune check point inhibitors (ICPIs) have revolutionized the treatment of cancer therapy in the modern era. Amongst these, Nivolumab targeting programmed-death-1 (PD-1) and its ligand (PD-L1) is increasingly being used for treatment of metastatic melanoma, non-small cell lung cancer, and renal carcinomas. The advent of these novel biologics, also brought with them the unique spectrum of immune mediated adverse effects. We describe a case of nivolumab induced immune nephritis and stress the importance of renal surveillance, as early recognition and treatment can prevent irreversible renal damage.

Case Description: An 82-yr-old female with metastatic squamous cell carcinoma of lung was admitted to the hospital due to Acute kidney injury (AKI) (creatinine 3.3 mg/dl), found on routine labs. Her chemotherapy was recently changed from paclitaxel to nivolumab due to non-response to paclitaxel as well as positive PD-1 mutation. Urinalysis showed persistent pyuria with 1% eosinophils and renal ultrasound was unremarkable. Renal biopsy done to further evaluate, revealed diffuse mononuclear infiltrate, predominantly plasma cells in the tubulointerstitial compartment with severe tubulitis. Patient was diagnosed with nivolumab induced immune tubulointerstitial nephritis. Her kidney function gradually improved to creatinine of 1 mg/dl, with withdrawal of nivolumab and short course of steroids. Our case spotlights the immune mediated injury and warrants renal monitoring while on ICPIs.

Discussion: Nivolumab is an IgG4 fully humanized monoclonal antibody, precisely a PD-1 inhibitor. Nivolumab is highly effective in treating melanoma, lung and renal cancers. As the use of these ICPIs is widening, prevalence of immune adverse effects is also spiraling. The incidence of AKI associated with these ICPIs was found to be 2.2 % per Cortazar et al, however recent studies showed higher incidence of 9.9 – 29 %. Clinical awareness regarding these unfamiliar immune side effects of ICPIs should be raised, as timely diagnosis and early intervention plays a crucial role in the management of these complications. Renal surveillance every two weeks is recommended while on ICPIs and withdrawal of offending agent is based on the severity of AKI and cancer prognostic risk. Multidisciplinary approach and close alliance between oncologists and nephrologists is advocated for optimal clinical outcomes.

SA-PO522

Outcome and Possible Mechanism of Acute Tubulointerstitial Nephritis

Dong hwan Yun,[1] Min woo Kang,[1] Minjung Kang,[1] Soie Kwon,[1] Jung Nam An,[3] Dong Ki Kim,[2] Yon Su Kim,[1] Jung Pyo Lee,[3] Ho Jun Chin,[4] Seung Seok Han.[1] *[1]Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, SEOUL, Republic of Korea; [4]Seoul National University Bundang Hospital, Seong nam, Republic of Korea.*

Background: Acute tubulointerstitial nephritis (ATIN) is an important cause of acute kidney injury (AKI) and often described as a potentially reversible disease. Some previous guidelines or studies recommended corticosteroid usage, but the role of steroids remains controversial and underlying mechanisms remain unresolved. The study purpose was to evaluate the steroid effect and the possible mechanism of ATIN.

Methods: A total of 82 adult patients with biopsy-proven ATIN except combined glomerulonephritis, pyelonephritis, and vasculopathy from three tertiary referral centers were recruited between 2001 and 2017. Renal recovery was defined as improvement in Cr level to 1.3 mg/dL or ≥ 50% decrease of the peak Cr. The effect of corticosteroid therapy was determined using multivariate logistic model.. Plasma and urine inflammatory cytokines at the time of biopsy were analyzed using a multi-analyte flow assay kit (n=33).

Results: Causes of ATIN included unknown (74.4%), drugs (17.1%), autoimmune (6.1%), and obstructive disease (2.4%). In drug-induced ATIN, herbal medication was the most common cause (35.7%), and followed by NSAID (28.6%), antibiotics (28.6%). Overall, 76.8% of ATIN patients experienced renal recovery once or more. 59.8% of patients encountered renal recovery status at 6 months post-biopsy. 23.2% of the patients were dependent on dialysis at final follow-up. Among a total of 82 patients with unknown and drug-induced ATIN, 24 patients (82.9%) were treated with corticosteroid. There were no significant difference in renal recovery, ESRD progression, and mortality between steroid-treated and non-treated groups. In both Cox regression for renal recovery and logistic regression for renal recovery at 6 months post-biopsy, steroid use was not significant factor. Among several inflammatory cytokines, monocyte chemotactic protein 1 and interleukin-8 levels were markedly elevated in both plasma and urine; and interleukin-18 levels were high in plasma alone

Conclusions: Steroid use may not determine the overall outcome of ATIN. Therefore, targeting therapy based on the pathophysiology of ATIN should be investigated to improve overall outcomes. The present cytokine results will be helpful to develop a novel targeting therapy for ATIN.

SA-PO523

AKI Due to Methotrexate-Induced Crystal Nephropathy with Electron Microscopy

Gabriel Contreras,[2] Aza Abdalla,[1] Pooja D. Amarapurkar,[1] David B. Thomas.[3] *[1]Jackson Memorial Hospital/University of Miami, Miami, FL; [2]University of Miami, Miami, FL; [3]University of Miami, Miller School of Medicine, Miami, FL.*

Introduction: High dose methotrexate (MTX) (infusion of 1.5 to 8.0 gm/m2) is a key component of regimens for treatment of primary central nervous system lymphoma (PCNSL). 90% of MTX and its metabolites are excreted via the kidney. They are poorly soluble in acid pH and need intense hydration and alkalization of the urine (pH > 7) to reduce the risk of acute kidney injury (AKI) to less than 5%. Here, we present a case of AKI due to MTX-induced crystal nephropathy with by electron microscopy.

Case Description: A 53 years old male presented with frontal headaches. Imaging study followed by brain biopsy confirmed the diagnosis of PCNSL. Patient had normal baseline serum creatinine of 0.91 mg/dL prior to two infusions of high dose MTX 3.5 gm/m2 on 3/7/18 and 3/21/18. MTX and serum creatinine levels peaked at 12.3 mmol/L on 3/24/18 and 5.82 mg/dl on 3/28/18 respectively. Patient developed AKI in spite of maintaining intensive hydration, urine pH between 8 and 9 with the use of crystalloid solution of sodium bicarbonate and an adequate urine output of approximately 100 mL/hour. The urine sediment showed brownish crystals. Kidney biopsy done on 4/3/18, revealed light

microscopy diffuse severe acute tubular epithelial cell injury (acute tubular necrosis, ATN) with tubular lumen MTX crystals also present by electron microscopy (image 1). After discontinuing MTX, the serum creatinine gradually improved to a level of 2.1 mg/dL on the day of discharge on 4/21/18.

Discussion: supersaturation is the initial step in crystallization of MTX in the renal tubular lumens, may occur despite maintaining adequate urine output and urine alkalization and leads to MTX-induced crystal nephropathy. We report a case of MTX-induced crystal nephropat, renal biopsy morphologic features of nephrotoxic ATN and MTX crystals both by light microscopy and electron microscopy.

SA-PO524

Severe AKI Due to Minocycline-Associated Heme Pigment Nephropathy

Abdallah Sassine Geara,[1] Matthew Palmer,[3] Afshin K. Hannani,[4] Jonathan J. Hogan.[2] *[1]Nephrology, University of Pennsylvania, Philadelphia, PA; [2]Hospital of the University of Pennsylvania, Haddonfield, NJ; [3]University of Pennsylvania, Philadelphia, PA; [4]Mercer Renal Associates, PA, Hamilton, NJ.*

Introduction: Minocycline-associated acute kidney injury (AKI) is rarely reported in the literature. We present a patient with two separate episodes of minocycline-induced hemolytic anemia with severe AKI due to heme pigment nephropathy.

Case Description: A 45-year-old woman with a history of recurrent acne resumed minocycline after a six-month hiatus from taking the drug. She developed acute nausea, vomiting and dark urine within hours of drug administration, and presented to the hospital. She was noted to have AKI (SCr peaked at 5.8 mg/dL) and acute hemolytic anemia (Hemoglobin decreased from 14 to 10 g/dL; LDH 2335 U/L; haptoglobin < 15 mg/dL). A UA was positive for 1+ protein and gross blood with RBC 2-5/HPF. A kidney biopsy showed acute tubular injury with multifocal pigmented casts with negative immunostaining for myoglobin. There was no evidence of thrombotic microangiopathy. Her minocycline was held and her AKI and anemia resolved without additional therapy. One year after this episode, she was restarted on minocycline for recurrent acne, and again experienced nausea, vomiting, diarrhea and back pain within few hours of the first minocycline dose. She presented to the hospital where she developed anuric AKI (peak SCr 8.0 mg/dL), hemolytic anemia (Hgb of 11.0 g/dL; LDH 3000 U/L; haptoglobin < 15 mg/dL) and thrombocytopenia (Plts 40,000/μL). She was started on plasma exchange therapy due to an initial concern for TTP. A repeat kidney biopsy was not performed. She again had rapid and full recovery of AKI, hemolytic anemia and thrombocytopenia with holding minocycline. .

Discussion: Minocycline-induced hemolytic anemia is rare, with only 1 published case of hemolytic anemia and hemoglobulinuria. An FDA Adverse Events reporting system search revealed 5 cases of anemia and 1 case of anuria attributed to minocycline. AKI was more frequently recorded (48 cases). This is the first report of biopsy-proven heme pigment nephropathy associated with minocycline.

SA-PO525

Effectiveness of Inactivated Hantavirus Vaccine on the Disease Severity of Hemorrhagic Fever with Renal Syndrome

Yongjin Yi,[1] Hayne C. Park.[2] *[1]Armed Forces Capital Hospital, Seongnam-si, GYEONGGI-DO, Republic of Korea; [2]Kangnam Sacred Heart Hospital, Seoul, Republic of Korea.*

Background: An inactive Hantaan virus vaccine (iHV) has been broadly used as a preventive strategy in the South Korean army. After the vaccination program, the overall incidence of Hantavirus cases was reduced. However, hundreds of new HFRS cases occur annually. Furthermore, few studies have demonstrated the efficacy of the iHV's in field settings. This study aimed to evaluate the vaccine efficacy on HFRS severity.

Methods: From 2009 to 2017, we registered all reported Hantavirus cases in the South Korean army hospitals along with the patients' vaccination history. We retrospectively classified HFRS patients into both groups according to their vaccination records: no history of iHV vaccination and valid vaccination. To evaluate the vaccine efficacy on the severity of renal injury, acute kidney injury (AKI) ≧ stage 3 and event of dialysis were investigated.

Results: We assessed the effect of the vaccine on severity in 18 and 110 HFRS patients with and without valid vaccination history, respectively. In the valid-vaccination group, six of 18 patients (33.3%) had stage 3 AKI, compared to 60 of 110 (54.5%) HFRS patients in the non-vaccination group. The vaccine efficacy against HFRS progression (VE_p) was 58.1% (95% confidence interval [CI]: -31.3–88.0%).

Conclusions: The vaccine efficacy against the progression of HFRS in this case-control study failed to show a statistically significant result. However, different severity profiles were observed between the vaccinated and none-vaccinated groups. More studies with large vaccinated populations are needed to demonstrate the effectiveness of the vaccine in patients with HFRS.

Funding: Government Support - Non-U.S.

	No Vaccination Group (n = 110)	Valid Vaccination Group (n = 18)	Vaccination Effectiveness on Progression (VE_p)
HFRS with KDIGO-AKI stage 3, n (%)	60 (54.5%)	6 (33.3%)	58.1% (-31.3%, 88.0%)
HFRS with renal replacement therapy, n (%)	25 (22.7%)	2 (11.1%)	57.3% (-102.1%, 95.5%)

SA-PO526

Eculizumab Safety: 5-Year Experience from the Global aHUS Registry

Eric Rondeau,[1] Daniel Landau,[2] Spero R. Cataland,[3] Christoph Gasteyger,[5] Nicholas J. Webb.[4] *[1]Urgences Néphrologiques et Transplantation Rénale, Hôpital Tenon and Université Paris VI, Paris, France; [2]Schneider Children's Medical Center, Sackler School of Medicine, Petach Tikva, Israel; [3]Division of Hematology, The Ohio State University, Wexner Medical Center, Columbus, OH; [4]Department of Paediatric Nephrology, University of Manchester, Royal Manchester Children's Hospital, Manchester, United Kingdom; [5]Alexion Pharma GmbH, Zürich, Switzerland.*

Background: Eculizumab (ECU) is approved for treatment of atypical hemolytic uremic syndrome (aHUS), a rare and life-threatening disease. The Global aHUS Registry was initiated in 2012 and has recruited both ECU- and non-ECU-treated adult and pediatric patients (pts).

Methods: This observational, multinational Registry (NCT01522183) evaluates safety and effectiveness of ECU in pts with aHUS, while also assessing clinical characteristics at enrollment and follow-up visits every 6 months thereafter, irrespective of disease management. Herein, we report baseline characteristics and targeted safety events from adult and pediatric pts who were "ever treated" (ET) vs "never treated" (NT) with ECU in the first 5 years of the Registry through the study cut-off date of January 26, 2017.

Results: Overall, N=1321 pts (ET, n=865; NT, n=456) have been enrolled. In ET patients, mean (SD) ECU exposure was 2.17 (1.56) years in adults and 2.72 (1.74) years in children. At baseline, ET pts had greater rates of organ involvement (renal: 79.2% vs 23.7%; gastrointestinal: 35.0% vs 9.9%; cardiovascular: 28.3% vs 8.6%; CNS: 25.9% vs 7.9%; and pulmonary: 15.0% vs 6.4%), and poorer quality of life (lower median Functional Assessment of Chronic Illness Therapy–Fatigue scores: 30 vs 41), compared with NT pts, respectively. Prespecified targeted safety events reported for 801 adult and 464 pediatric pts are presented in the Table. No differences in event rates between ET and NT pts were observed, except for serious infections in pediatric pts, which were more common in ET vs NT.

Conclusions: Five-year data from the Global aHUS Registry reveal no new safety signals with ECU treatment in either adult or pediatric ET pts, confirming ECU's safety profile and, therefore, its positive benefit:risk ratio in a real-world setting.

Funding: Commercial Support - Alexion Pharmaceuticals, Inc.

Deaths, n (%)†	25 (4.7)	27 (9.9)	6 (1.8)	0

*In adults, reported as probably related to ECU; the patient recovered without treatment interruption. In pediatric patients, one case was possibly related and one case was unlikely related to ECU. Both recovered, one without and one with ECU treatment interruption.
†One adult patient death occurred after a meningococcal meningitis event. Meningitis was reported as probably related to ECU treatment, but the cause of death was reported as unknown and no further details are available for this patient; 2 pediatric deaths (viral pneumonia followed by respiratory arrest; suspected sepsis) were deemed possibly related to ECU.

SA-PO527

Differences in Cardiovascular and Renal Complication Rates in Thrombotic Microangiopathies with and Without Hemolytic Uremic Syndromes

Sanjeev Gupta,[1] Srikanth Yandrapalli,[2] Savneek S. Chugh.[3] *[1]Westchester county medical center, White Plains, NY; [2]Westchester Medical Center, Valhala, NY; [3]New York Medical College, Hartsdale, NY.*

Background: Pathophysiologic differences between different thrombotic microangiopathies (TMAs) might predispose to varying complications. We sought to study if there is a difference in the incidence of cardiovascular and renal complications between hemolytic uremic syndrome (HUS)-TMA and non-HUS TMAs.

Methods: We queried the United States National Inpatient Sample years 2005 to 2014 to identify hospitalizations in adult patients (age≥18 years) complicated by either HUS-TMA or non-HUS TMA using ICD-9 codes 283.11 (HUS) and 446.6 (TMA). In this cohort, we analyzed differences in the rates of acute myocardial infarction (AMI), heart failure (HF), stroke or transient ischemic attack (TIA), acute kidney injury (AKI), plasmapheresis and hemodialysis requirement, and in-hospital mortality.

Results: Out the weighted 59,166 cases in our study (mean patient age 50 years, 64% women), HUS-TMA was present in 24.5% (N=14,508) and non-HUS TMA in 75.5% (N=44,658). Patients with non-HUS TMA were older than those with HUS-TMA (mean age 50 years vs 48 years, p<0.001) but had similar gender distribution (women: 64.5% vs 62.9%, p=0.171). Compared to HUS-TMA, non-HUS TMA had higher rates of AMI (5.3% vs 4.2%, p=0.017), stroke/TIA (8.2% vs 3.0%, p<0.001), and plasmapheresis use (39.2% vs 30.9%, p<0.001). Compared to non-HUS TMA, HUS-TMA had higher rates of AKI (58.2% vs 36.4%, p<0.001), CHF (15.7% vs 12.5%, p<0.001), and HD requirement (41.6% vs 16.7%, p<0.001). In-hospital mortality was higher with non-HUS TMA (10.2%) than with HUS-TMA (8.5%, p=0.011).

Conclusions: In this large study of TMAs, HUS-TMAs were associated with more renal complications and non-HUS TMAs with more cardiovascular complications. The microvascular derangements in non-HUS TMA might be responsible for the higher incidence of AMI and stroke/TIA, whereas fluid balance disturbances from renal failure might contribute to increased heart failure with HUS-TMA. The high complication rates and mortality associated with these conditions necessitate further research into identifying underlying mechanisms and developing appropriate therapeutic strategies.

SA-PO528

The Risk Factors Analysis of Idiopathic Membranous Nephropathy Complicated with AKI

Yi-yi Xie,[2] Li-jun Xie,[1] Yunhua Liao.[1] *[1]Renal Division, Department of Medicine, First Affiliated Hospital of Guangxi Medical University, Nanning, China; [2]The second people's hospital of nanning, Nanning, China.*

Background: Idiopathic membranous nephropathy (IMN) is the most conmon pathological types for nephrotic syndrome. In Chinese population, the proportion of IMN in primary glomerular disease increased obviously in recent years. Acute kidney injury(AKI) is a common complication of IMN. The risk factors of IMN complicate with AKI were unknown.

Methods: We collected the clinical data of 129 IMN patients diagnosed by renal biopsy from March 2011 to October 2015 in the First Affiliated Hospital of Guangxi Medical University, including 35 IMN patients complicated with AKI (AKI group) and 94 IMN patients without AKI (Non-AKI group). The age, blood pressure, BMI, blood homocysteine, blood 25(OH) vit-D3, 24h urinary protein, many other laboratory parameters and pathological parameters were compared between these two group. Single factor analysis and multivariate analysis were conducted to explore the independent risk factors of AKI.

Results: The age, systolic blood pressure(SBP), blood homocysteine, blood 25(OH) vit-D3, 24h urinary protein, blood IgG and blood IgG/C3 showed significant statistically differences between these two group (P <0.05). In AKI group, age, SBP, 24h urinary protein, blood homocysteine was higher than those in non-AKI group, but blood 25(OH) vit-D3, blood IgG, blood IgG/C3 was lower than those in non-AKI group. The SBP, level of blood homocyhsteine, level of low-density lipoprotein cholesterol, and level of 24 urinary protein was positively correlated with the occurrence of AKI (P<0.05). However, the level of 25(OH) vit-D3, blood IgG and blood IgG/C3 was negatively correlated with the occurrence of AKI (P <0.05). In multivariate analysis, high blood homocysteine, high 24h urinary protein, hypertension, high pathological stage was the risk factors of AKI.

Conclusions: The IMN patients, with advancing age, higher SBP, higher serum homocysteine, lower serum 25(OH) vit-D3, lower IgG/C3 and higher pathological stage were more prone to complicate with AKI.

Randomized Controlled Trial of Omega 3 Fatty Acids to Reduce Contrast-Induced Nephropathy in CKD Patients Undergoing Coronary Angiography

Fadel A. Al-Rowaie, Khalid I. Almatham. *King Fahad Medical City, Riyadh, Saudi Arabia.*

Background: Contrast-induced nephropathy (CIN) is a leading cause of acquired acute kidney injury and has been associated with prolonged hospitalization and adverse clinical outcomes. The results of studies investigating the effects of antioxidants on the prevention of CIN remain inconsistent. Omega 3 fatty acids have been shown to reduce inflammatory markers and oxidative stress, improve endothelial function, and reduce kidney dysfunction following reperfusion injury and chronic renal insufficiency in animal models. This pilot study aimed to determine the effects of omega 3 fatty acids on CIN prevention in patients with chronic kidney disease (CKD) undergoing coronary angiography

Methods: 67 patients were assigned to the N-acetylcysteine (NAC) and 63 patients were assigned to the omega 3 fatty acids (omacor ®). Both drugs were administered orally twice per day on the day prior to and on the day of contrast administration, for a total of 2 days. The primary endpoint was the occurrence of CIN, defined as an increase in baseline serum creatinine levels of > 0.5 mg/dl (44 μmol/l) or > 25% increase in serum creatinine levels from baseline levels 48–72 h following contrast administration. The secondary endpoints were: the need for renal replacement therapy, death, and length of hospitalization after contrast administration

Results: Of the 130 CKD patients enrolled in this study, 10 (7.7%) experienced an increase of at least 0.5 mg/dl (44 μmol/l) in serum creatinine levels 48 h after administration of the contrast agent, including 5 of the 67 patients in the NAC group (7.5%) and 5 of the 63 patients in the omega 3 fatty acids group (7.9%; P = 0.919). There were no significant differences in the need for renal replacement therapy or in the mortality rate between both groups

Conclusions: Short-term prophylactic omega 3 fatty acid treatment with hydration does not reduce CIN in CKD patients undergoing coronary angiography

Funding: Government Support - Non-U.S.

Primary and secondary endpoints

Outcome	NAC (N=67)	Omega 3 fatty acid (N=63)	P-value
Primary endpoint			
Increase in creatinine > 44 μmol/l	5 (7.5%)	5 (7.9%)	0.919
Increase in creatinine > 25%	6 (9.1%)	9 (14.3%)	0.358
Secondary endpoints			
renal replacement therapy	2 (3.0%)	6 (9.5%)	0.121
death	2 (3.0%)	4 (6.3%)	0.361
hospitalization(days)	6.70 ± 8.73	6.16 ± 7.82	0.714

Are the Iodinated Contrast Media Dangerous? Influence of Iodinated Contrast Media on Renal and Thyroid Gland in Patients with CKD

Dorota Brodowska-Kania,[1] Stanislaw Niemczyk.[2] *[1]MIlitary Intitiute of Medicine, Warsaw, Poland; [2]Military Medical Institute of Warsaw, Warsaw, Poland.*

Background: The aim of our study was to assess the risk and incidence of CIN in patients with CKD, the impact of iodine CM on the endocrine function of the thyroid gland and the impact of renal impairment on the risk of contrast-induced hypothyroidism or hyperthyroidism.

Methods: We included 75 patients(pts). The first CKD-Group: 36pts with eGFR<60ml/min. (mean age 69.4±11, male-72.2%). The second RRT-Group: 20pts chronically dialysed (mean age 63.7±12.2, male-50%). The control group: 19pts with eGFR>60 ml/min, (mean age 48.2±18.0, male-57.9%). CIN prevention were conducted among all patients: hydration and N-acetylocysteine. All patients received iomeprol or iohexol. Patients were monitored for 6 months after the administration of CM (48 hours, 14 days and 6 months

after contrast administration). Creatinine, urea, eGFR, cystatin C, TSH, free-T3(fT3), free-T4(fT4), reverse-T3(rT3), were monitored. The results were statistically analyzed. Study was approved by the Ethics Committee.

Results: AKI was found in 2.7% in test group (3 pts). In the CKD group, the mean creatinine was 1.65mg / dl (1.33-2.28), eGFR 39.91 ± 12.89, cystatin C 2.17mg / dl ± 0.83, urea 67.7mg / dl ± 27.55. Increase in creatinine value was not statistically significant (ΔCREA 0.2 p = 0.8, Δcystatin C-0.04, p = 0.891, and ΔeGFR = 0.62, p = 0.912 within 48 hours after administration of CM. In the CKD group two weeks after administration of CM a decrease fT3, ΔfT31CKD -0.39 ± 0.77 p1CKD = 0.004. changes fT3 persisted during the 6 months follow-up (ΔfT32CKD = -0.36 ± 0.91 p2CKD = 0.023). The changes of ΔfT3 were no correlation with dose of CM and eGFR. In the group of RRT a change of ΔfT41RRT 1.58 ± 2.56 p1RRT = 0.013 was observed after 2 weeks, which maintained for 6 months (ΔfT42RRT 2.0 ± 3.38 p2RRT = 0.016). In the control group the changes were minimal and not statistically significant. No thyroid dysfunction was observed.

Conclusions: Adverse effects of intravenous administration of iodine contrast are rare. CIN in the group with CKD is 2.7%. CM have no adverse effect on kidney and thyroid function among patients with good function of these organs. CKD is not a risk factor for contrast-induced hyperthyroidism or hypothyroidism. Changes in thyroid hormones were statistically significant but asymptomatic. CM are not so dangerous. Further research is needed.

SA-PO531

New Perspectives on Bothrops-Induced AKI: Novel Biomarkers and Coagulation Disturbances

Polianna Lemos m.m. albuquerque,[2] Geraldo B. Silva Junior,[1] Gdayllon Cavalcante meneses,[2] Alice maria Costa martins,[2] Jacques Raubenheimer,[3] Fathima Shihana,[3] Nicholas Buckley,[4] Elizabeth De francesco daher.[2] *[1]University of Fortaleza, Fortaleza, Brazil; [2]Federal University of Ceara, Fortaleza, Brazil; [3]University of Sydney, Sydney, NSW, Australia; [4]The University of Sydney, Sydney, NSW, Australia.*

Background: *Bothrops sp* is the most common snake genus associated with acute kidney injury (AKI) in Latin America. We evaluated novel biomarkers and coagulation disturbances among patients with *Bothrops* venom-induced AKI.

Methods: This is a prospective study of patients with snakebite (*Bothrops*)-induced AKI admitted to a referral emergency hospital in Fortaleza city, Brazil, from December 2015 to December 2016. Biomarkers were measured in blood (sNGAL) and urine (uNGAL, uMCP-1, uKIM-1, VCAM-1 and IL-6) using ELISA.

Results: 63 patients were included, and 22 (34.9%) developed AKI. The age, time elapsed between snakebite and administration of antivenom, number of administered antivenom vials, gender distribution and severity of the envenomation were similar in the groups. The biomarkers uMCP-1 and uNGAL were significantly higher in the AKI group: uMCP-1 (471.2 ± 60.40 vs. 288.8 ± 41.42pg/ml; p=0.014) and uNGAL (15.27 ± 1.28 vs. 10.29 ± 1.06ng/ml; p=0.006). The activated partial thromboplastin time (APTT) on admission, was significantly longer in the AKI group (p=0.011). Urinary proteinuria correlated highly with two specific urine biomarkers: uMCP-1 (r=0.5242, p=0.0003) and uNGAL (r=0.4938, p=0.0008). The fractional excretion of sodium (FE_{Na}) also strongly correlated with uMCP-1 (r=0.8696, p<0.0001) and uNGAL (r=0.6833, p<0.0001). The correlation between FE_{Na} and uMCP-1was largely confined to the AKI-group (Figure 1). The FE_K also positively correlated with uMCP-1 (r=0.5775, p<0.0001) and uNGAL (r=0.5647, p=0.0001).

Conclusions: Coagulation abnormalities seem to be a pivotal factor in AKI development in *Bothrops*-induced AKI. The higher levels of uMCP-1 and uNGAL could represent early tubular and glomerular dysfunction caused by snakebite venom, and the abnormalities in fractional excretion of electrolytes point to tubular transport dysfunction.

Ex Vivo MSC Therapy for Subjects with AKI

Rita N. Barcia. *Sentien Biotechnologies, Lexington, MA.*

Background: Mesenchymal stromal cells (MSCs) are known to secrete potent molecules and extracellular vesicles contributing to immunomodulation and wound healing. There is a good deal of interest in MSC based approaches for the treatment of human kidney injury driven by evidence that MSCs repair the kidney by paracrine and endocrine mechanisms (Humphreys & Bonventre, 2008). Though clinical trials using MSCs as infusion therapeutics have been successful in demonstrating safety, clear clinical benefit has not consistently been realized. Lack of clinical effectiveness may be due to ineffective dosing of MSCs and short exposure times of the infused cells. Sentien Biotechnologies has pioneered a new way to control the delivery of MSC secreted factors by using an ex vivo cell therapy approach as a novel route of extracorporeal administration. Sentien's lead product consists of a continuous flow bioreactor with MSCs immobilized on the extraluminal side of a hollow fiber membrane. Patient's blood flows through the lumen of the hollow fibers and are conditioned by MSC secreted factors, allowing for the blood cells and MSCs to sense their environment and react to it.

Methods: In vitro studies were performed to assess MSC function within Sentien's reactors. The technology was also tested as a continuous ex vivo therapy in an ischemia/reperfusion dog model of Acute Kidney Injury (AKI). Toxicological studies were performed in healthy dogs. A multi-center, randomized, placebo-controlled double-blind study of extracorporeal MSC therapy has begun in human subjects with AKI receiving continuous renal replacement therapy.

Results: In vitro studies showed that MSCs are viable and responsive in the biorector. In a dog model of AKI, an increase in survival was observed in the treated animals. Additionally, toxicological studies verified a pharmacokinetic and pharmacodynamic response to MSCs that was consistent with a potent immunomodulatory mechanism of action. Preliminary results from the ongoing clinical trial will be presented.

Conclusions: Ex vivo MSC therapy using this reactor technology has promise for other clinical applications requiring systemic immunotherapy for tissue repair and regeneration.

The Effect of Fluid Resuscitation with Normal Saline versus Ringer's Acetate on Renal Function and Host Defense in Severe Sepsis/Septic Shock Patients: A Randomized Controlled Trial

Sasithorn Kunupakan,[1] Sadudee Peerapornratana,[2] Nuttha Lumlertgul,[3] Nicha Thamrongsat,[4] Kearkiat Praditpornsilpa,[2] Kriang Tungsanga,[5] Somchai Eiam-Ong,[2] Nattachai Srisawat.[1] *[1]Chulalongkorn university, Bangkok, Thailand; [2]Chulalongkorn University, Bangkok, Thailand; [3]Renal Division, Chulalongkorn University, Bangkok, Thailand; [4]Chulalongkorn university, Bangkok, Thailand; [5]King Chulalong Memorial lHospital, Bangkok, Thailand.*

Background: Recent large observational studies in severe sepsis showed that Normal Saline (NSS) might worsen acute kidney injury (AKI) determined by serum creatinine. In animal model with sepsis, NSS could impair monocyte/neutrophil functions, the main host defense mechanism during sepsis, and this impairment might cause renal dysfunction.

Methods: NSS or RA was utilized for volume expansion during fluid resuscitation phase for 72 hours. The treatment followed the recommendations for fluid therapy provided by the Surviving Sepsis Campaign. Blood and urine samples were collected at 72 hrs. Primary outcome was median difference of uNGAL levels on day 3. Secondary outcomes were difference of monocyte HLA-DR (mHLA-DR)expression, neutrophil chemotaxis activity, and CD11b expression on day 3, and maximum AKI state on day 7.

Results: Fifty-nine patients were recruited, 29 and 30 for NSS and RA, respectively. The volume of resuscitation during the first 6 hours were comparable (NSS=1000 (1000,2000) mL, RA=1000 (700,1500) mL, p=0.38). Patients receiving NSS became more acidic than RA. There was no significant difference in renal function between both groups at baseline. The median uNGAL levels were not different between groups (NSS=111 (36.4, 262.2) ng/mL, RA= 32.7 (8.85, 178.1) ng/mL, p=0.59), mHLA-DR expression, neutrophil chemotaxis, and CD11b expression on day 3 were no improvement in NSS groups. But there were significant improvement in chemotaxis (p=0.024) and mHLA-DR expression (p=0.036) in RA group. The maximal AKI state determined by serum creatinine on day 7 were not different (NSS=24.1%, RA=26.7%, p=0.82).

Conclusions: Our study showed that there was significant improvement of immunoparalysis status (increased HLA-DR and chemotaxis activity) in RA group. No significant difference in tubular dysfunction between groups. (But lower trends of uNGAL and L-FABP in RA group.)

SA-PO534

Balanced Crystalloids vs Normal Saline and Risk of AKI in Critically Ill Patients: A Systematic Review and Meta-Analysis

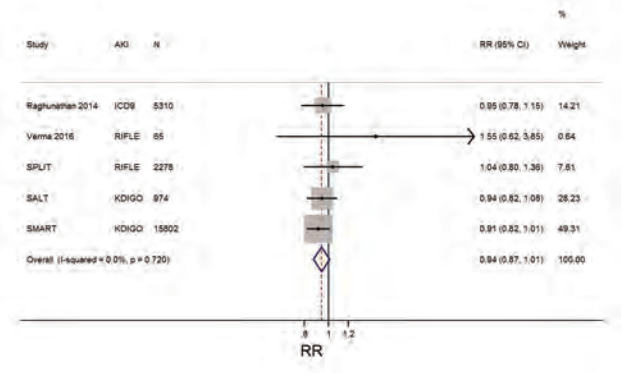
Mengyao Tang,[1] Jerald Cherian,[1] Sahir Kalim.[2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Massachusetts General Hospital/ Harvard Medical School, Cambridge, MA.*

Background: In both animals and in vitro human studies, the high chloride content of normal saline (NS) has been linked with adverse pathophysiological effects. Emerging evidence, including a recent large clinical trial, suggests that balanced fluids (e.g. lactated Ringer or Plasma-Lyte A) may result in fewer adverse renal outcomes. However, whether NS is associated with a higher incidence of AKI when compared to balanced crystalloids in critically ill adults remains controversial.

Methods: A meta-analysis of RCTs and observational studies that enrolled critically ill patients receiving balanced crystalloids or NS in an ICU setting was conducted. Electronic databases (PubMed, EMBASE, Cochrane) were searched from inception until April 2018. Relative risks (RR) and 95% CIs were pooled using the random effects model in STATA. The primary outcome was AKI, as defined by the individual study. The secondary outcome was the requirement for renal replacement therapy (RRT).

Results: Five studies with a total of 24,429 patients met the eligibility criteria and were included. The definition of AKI was based on KIDGO criteria, RIFLE criteria or ICD-9 code. The risk of AKI with balanced crystalloids was not significantly different when compared to NS (RR 0.94; 95% CI, 0.87, 1.01, p=0.08) (Figure 1), but there was a trend toward a more favorable outcome. There was also no difference between the two groups in new RRT requirements (RR 0.98; 95% CI, 0.87, 1.09, p=0.65).

Conclusions: Although there is a trend toward less detriment to renal function with balanced crystalloids, the current evidence insufficiently supports their use over NS for fluid resuscitation to decrease the risk of AKI or RRT requirement in critically ill patients in the ICUs. Current studies are limited by the inconsistent definition of AKI. Therefore, additional clinical trials adopting a standardized AKI definition are needed to further clarify the ideal resuscitation fluid for critically ill patients.



SA-PO535

AKI Evaluation and Mortality Risk on Mexican Patients

Priscila B. Villalvazo,[2] Milagros M. Flores Fonseca,[1] Viridiana Rodriguez,[3] Benjamin Gomez-Navarro,[4] Jorge Andrade-Sierra.[5] *[1]Centro Medico Nacional de Occidente, Guadalajara, Mexico; [2]IMSS, Zapopan, Jaliscco, Mexico; [3]Instituto Mexicano Del Seguro Social, Guadalajara, Mexico; [4]IMSS, HECMNO, Zapopan, Jalisco, Mexico; [5]Universidad de Guadalajara, Cucs, Guadalajara, Jalisco Mexico, Mexico.*

Background: AKI prevalence in Mexico is unknown and mortality rates are estimated 16 – 18%, its presence increases the risk of death in critically ill patients and is associated with high morbidity and mortality. In Mexico, limited data including early RRT, AKI biomarkers, furosemide response and risks factors of AKI progression, remains AKI treatment controversial. This study aimed to evaluate characteristics and risk factors of AKI and predict RRT and renal function recovery.

Methods: We analyze a single center AKI cohort of 112 Mexican patients. Serum creatinine assay was done to diagnose AKI. Demographics, clinical and biochemical profiles, risk factors for AKI and RRT prescription was assessed and reported during diagnosis and discharge. Outcome measures were renal recovery, mortality and causes of death.

Results: Mean age was 56.81 ± 18.38 years, 73% on AKI stage 3, mixed causes (60%) and pre-renal AKI (26%) were the most frequent forms. Main etiologies were cardiovascular disease (30%) and sepsis (24%). Of 112 patients, 49% initiate RRT and 55% had renal recovery. Global mortality rate was 48% mainly due to cardiovascular disease. We observed significant differences between (p=0.05) in serum creatinine admission OR=01.65 (1.47-1.83) and fluid balance OR=1.56 (1.45-1.69) as risk factors for RRT and furosemide response OR 9.16 (4.03-39.96) as renal recovery factor.

Conclusions: This was the first study that evaluate AKI risk factors, allowing RRT therapy and enhance renal recovery. Our findings support the furosemide stress test response strongly allows the adequate risk stratification, and can be used for early RRT initiation and might prolong time to renal recovery. Further studies are needed to determine if at the time of admission measurement of AKI biomarkers, may significantly improve the ability to predict hard outcomes (RRT, renal recovery and death).

Funding: Government Support - Non-U.S.

SA-PO536

AKI in a Developing Country: Clinical Course, Renal Recovery and Patient Outcome

Arunkumar Subbiah, Sanjay K. Agarwal, Dipankar M. Bhowmik, Sandeep Mahajan, Soumita Bagchi, Raj K. Yadav. *All India Institute of Medical Sciences, New Delhi, India.*

Background: Acute Kidney Injury (AKI) is an important determinant of outcome in hospitalized patients. Moreover, there is a risk for future development of Chronic Kidney Disease (CKD). Though the long-term impact of AKI has been studied in developed countries, there is a paucity of data in this area from the Indian subcontinent. This single-centre study aimed to assess the pattern, clinical spectrum and long-term outcome of AKI.

Methods: In this prospective observational cohort study, detailed demographic and clinical data at presentation, during hospital stay and follow-up at 1, 3, 6 and 12 months after discharge were obtained prospectively for a cohort of patients with AKI. Both community (CAAKI) and hospital acquired AKI (HAAKI) were included. Patient with preexisting CKD were excluded. Outcome variables were in-hospital mortality, renal function at discharge and on long-term follow-up.

Results: Of the 476 patients, majority of the cases, 395 (83%) were CAAKI. The mean age was 44.8 ± 18.7 years. Etiology groups included medical (84%), surgical (10%) and obstetric (6%) with sepsis (176/476; 36.9%) being the most common cause of AKI. The in-hospital mortality rate was 38%. Age >60 yrs (HR = 1.51; 95% CI, 1.11 – 2.07), oliguria (HR = 1.48; 95% CI, 1.05 – 2.10) and need for ventilator (HR = 2.45; 95% CI, 1.36 – 4.41) and/or inotropes (HR = 14.4; 95% CI, 6.28 – 33.05) were predictors of mortality. At discharge, 146 (30.7%) patients had complete renal recovery, while 149 (31.3%) had partial renal recovery. Oliguria ($p < 0.001$), hypoalbuminaemia ($p = 0.001$) and need for renal replacement therapy (RRT) ($p = 0.01$) were significantly associated with partial recovery. Of the 295 patients on follow-up, 211 (71.5%) patients had normal renal function, 4 (1.4%) died and 33 (11.2%) lost to follow up; 41(14%) patients developed CKD while 6 (2%) were dialysis dependent. The need for RRT during hospital stay was the single most important factor predicting the risk of CKD (OR 1.77, 95% CI, 1.12-2.78).

Conclusions: In conclusion, our data shows that AKI in hospitalized patients still has high mortality. Though a fairly good percentage of cases recovered, there is a definite risk of CKD development, especially in patients who required RRT during hospitalization.

SA-PO537

Recovery from AKI-Requiring Dialysis in Hospital Survivors Discharged to a Rehabilitation Facility

Meredith McAdams,[1] Melissa R. Jordan,[3] Victor M. Ortiz-Soriano,[3] George Vasquez-Rios,[4] Brian S. Armentrout, MS, PA-C,[1] Florence Lima,[3] Javier A. Neyra.[2] *[1]University of Kentucky, Lexington, KY; [2]University of Kentucky Medical Center, Lexington, KY; [3]University of Kentucky, Lexington, KY; [4]Saint Louis University School of Medicine, Saint Louis, MO.*

Background: Acute kidney injury-requiring dialysis (AKI-D) occurs in about 5% of hospitalized patients and is associated with poor outcome. Little is known about the incidence of AKI-D recovery following hospital discharge. We aim to examine AKI-D recovery in hospital survivors transferred to an affiliated rehabilitation facility (Select) with need of hemodialysis (HD) for AKI.

Methods: Single-center, retrospective cohort study of 42 patients who were admitted to the University of Kentucky Hospital (8/2015 to 3/2018), suffered from AKI-D and were transferred to Select with ongoing need for HD. Kidney recovery was defined as the patient being alive and no longer requiring HD support. Kidney recovery was assessed at the time of discharge from Select and from Select discharge until the end of the observation period (5/2018). Multivariable logistic regression models were performed to assess clinical characteristics associated with kidney recovery.

Results: Mean (SD) age was 61.4 (9.6) years; 61.9% were males and 90.5% whites. A total of 29 out of 42 patients (69%) recovered kidney function by the time of discharge from Select. Of these, 5 (17%) died after Select discharge (median follow-up 9.1 months). A total of 5 (12%) patients died during their stay at Select. Of the 8 (19%) patients that were discharged from Select with HD-dependent status, 3 (38%) died and only 1 recovered kidney function (median follow-up 16.5 months). The total number of hospital dialysis days was independently associated with kidney recovery at Select discharge (OR 0.81, 95% CI 0.68–0.98, p=0.027) and the number of intradialytic hypotension events during the stay at Select was associated with death or HD-dependent status at follow-up (OR 1.24, 95% CI 1.02–1.51, p=0.034).

Conclusions: At least 2 out of 3 patients transferred to a rehabilitation facility with AKI-D diagnosis recovered kidney function no longer requiring HD by the time of discharge. Dialysis-specific characteristics such as total days and intradialytic hypotension events may play a key role in the development of risk prediction models and 'best clinical practices' to promote kidney recovery in this susceptible population.

SA-PO538

Long Term Outcomes of Acute Tubular Necrosis and Acute Tubulointerstitial Nephritis

Sewon Oh,[1] Junyong Lee,[2] Jihyun Yang,[3] Myung-Gyu Kim,[4] Sang-Kyung Jo.[5] *[1]Korea University Anam Hospital, Korea University College of Medicine, Seoul, Republic of Korea; [2]Korea University Anam Hospital, Seongbuk-Gu, Seoul, Republic of Korea; [3]Korea universtiy Anam hospital, Seoul, Republic of Korea; [4]National Institutes of Health, Bethesda, MD; [5]Korea University Hospital, Seoul, Republic of Korea.*

Background: Renal damage of acute tubular necrosis (ATN) and acute tubulointerstitial nephritis (ATIN) are considered reversible. However, the prevalence and long-term outcome of ATN and ATIN were unknown.

Methods: We included 4690 adult patients who had underwent kidney biopsy in two tertiary hospital in Korea during 1979-2017. We excluded patients with biopsy confirmed end stage renal disease (ESRD), previous kidney transplantation, malignancy, and inadequate biopsy specimen.

Results: Mean age was 39.0±15.5 years and 55% was male. Primary glomerulonephritis (PGN) was 3466 (65.4%), secondary glomerulonephritis (SGN) was 1088 (20.5%), and ATN or ATIN was 136 (2.6%). Patients with ATN or ATIN were significantly older compared than PGN or SGN (P<0.001) and had lower eGFR (P<0.001; 31.9±28.0, 74.5±36.6, and 70.9±38.5ml/min/1.73m^2, respectively). Mortality was the highest in patients with SGN (18.0%). Mortality in patients with PGN was 8.7%, and ATN or ATIN was 7.4% (P<0.001). The incidence of ESRD was much lower in patients with ATN or ATIN (2.9%) compared than PGN (14.4%) or SGN (15.0%) (P=0.001). During 156.8 ± 101.8 months follow up period, the adjusted risk of mortality was higher in patients with SGN compared than PGN (RR 2.156; 95% CI, 1.795-2.590). However, risk of mortality was not significantly different between PGN and ATN or ATIN. The adjusted risk of ESRD was significantly lower in patients with ATN or ATIN (RR 0.100; 95% CI, 0.037-0.268) compared than PGN, and the risks of ESRD was not different between PGN and SGN during 155.3±105.8 months.

Conclusions: The risk of long-term mortality was not different between PGN and ATN or ATIN. Although the risk of ESRD was significantly lower in patients with ATN or ATIN compared than GN, 2.9% of ATN or ATIN patients progressed to ESRD.

SA-PO539

AKI in Patients with Hip Fracture: A Single Centre Experience

Anna K. Forbes, Nivi Singh, Bhrigu Raj Sood. *Epsom and St Helier NHS Trust, Carshalton, United Kingdom.*

Background: Hip fracture is the most common serious injury in the elderly associated with high morbidity and mortality. These patients are high risk of developing acute kidney injury (AKI). We evaluated the incidence of AKI occurring anytime during admission and impact on length of stay (LoS) and mortality in patients admitted with hip fracture. St Helier Hospital Hip Fracture Unit is the best performing and second busiest in London according to the Department of Health's Best Practice Tariff. We sought to establish if this good practice translated to reduced AKI incidence and improved outcomes.

Methods: This is a retrospective observational study of patients presenting to St Helier Hospital Hip Fracture Unit between January 2015 and December 2016. Patients were identified from the National Hip Fracture Database. AKI was identified from electronic pathology alerts and defined according to Kidney Disease Improving Global Outcomes criteria.

Results: 861 patients presented with hip fracture; 246 males (28.6%) and 615 females (71.4%). Mean age was 83.4 years (60-104 years) and median LoS was 23 days (IQR 11-27 days). 16.4% (141) patients developed AKI; 11.1% (96) with AKI stage 1, 3% (26) with AK1 stage 2 and 2.6% (19) with AKI stage 3. AKI was associated with increased LoS. Death was adjusted for by assigning median LoS to those who died. Median LoS was 31 days (IQR 16-36 days) in patients with AKI compared to 22 days (IQR 11-25 days) without AKI. Patients who developed AKI were less likely to be discharged home. 31.9% patients with AKI were discharged to their own home compared with 41.7% of patients without AKI. AKI was associated with increased unadjusted mortality. Patients with AKI had a 30 day mortality of 16.3% compared with 4.4% in patients without AKI. 30 day mortality was 15.6%, 19.2% and 15.8% in patients with AKI stage 1, 2 and 3, respectively. Patients with AKI had an inpatient mortality of 16.3% compared with 3.75% in patients without AKI. Inpatient mortality was 13.5%, 19.2% and 26.3% in patients with AKI stage 1, 2 and 3, respectively.

Conclusions: The incidence of AKI at our unit (16.4%) is significantly lower than previously published data (24%) but despite this, it is associated with increased LoS and mortality. This suggests early and intensive ortho-geriatrician and multi-disciplinary team input can improve AKI incidence and also outcomes in these patients.

SA-PO540

Temporal Trend of Utilization of Palliative Care Encounters in Hospitalized Patients with Dialysis Requiring AKI - A Nationwide Analysis

Yumeng Wen,[1,2] Marcelo X. Hernandez Cuchillas,[1,2] Changchuan Jiang,[1,2] David Mariuma,[1,2] Di Pan.[1,2] *[1]Mount Sinai St Luke's and Mount Sinai West, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Dialysis requiring AKI (AKID) is major cause of in-hospital morbidity and carries high rate of mortality. We sought to investigate the temporal trend of the utilization of palliative care (PC) in hospitalized patients with AKID in United States.

Methods: We conducted a retrospective study using the national inpatient sample from 2005 to 2014, to identify hospitalized patients complicated by AKID. The outcomes were the temporal trend and factors associated with utilization of PC in hospital. Multivariate logistic analysis was conducted to calculate odds ratios, adjusting for demographics, hospital characteristics, comorbidities and code status. Analysis was performed using Stata 14.0.

Results: A cohort of 808,159 patients was identified from 2005 to 2014, of whom 5.88% had palliative care consult referral. The incidence of palliative care contact increased from 0.41% in 2005 to 12.38% in 2014 (aOR 1.18, p<0.01). Patients who received palliative care contact, compared to who did not, were older (65.37 vs 62.50, p<0.01) and more likely to die in hospital (75.00% vs. 25.62%, p<0.01). Factors associated with more frequent PC referral included more cormobidities, Caucasian race (compared to other minorities), teaching hospitals, larger hospitals, hospitals region other than Northeastern area, Medicaid insurance and do not resuscitate status (shown in Table 1).

Conclusions: The use of palliative care consultation for patients with AKID who are admitted to hospitals, based on the NIS, is approximately 5.88%. Race, insurance status, hospital size, location and teaching status all were associated with differential rates of referral. There was a significant increase in palliative care use observed from 2005 to 2014.

Prognostic Tool in Dialysis Treated AKI

Tatiana Tanasiychuk, Alon Antebi, Daniel Kushnir, Jerom Marcuson, Amnon Gil, Tatyana Gorlachev, Victoria Svistunov, Muhammad Abd Elhalim, Oleg Sura, Victor Frajewicki. *Department of Nephrology and Hypertension, Carmel Medical Center, Haifa, Israel.*

Background: AKI is a common condition in hospitalized patients, having a mortality which may exceed 50%. Although dialysis may extend life in some subjects with AKI, elderly patients, with multiple comorbidities have a significantly shortened life expectancy. Attempts to identify prognostic models for a more accurate estimation of survival for AKI which was treated by dialysis were not successful. Utility of the "surprise" question to identify chronic dialysis patients with high mortality was reported, but studies on general population of seriously ill patients this question performs poor to modest predictive tool. The aim of our study was to identify the sensitivity of the "surprise" question in patients with unscheduled in-hospital started dialysis.

Methods: Prospective cohort study of all AKI patients who were treated by hemodialysis between January 1st, 2013 and December 31, 2017 in our center. During this period nephrologists had to answer the "surprise" question (Would I be surprised if this patient died in the next 6 months?) regarding every patient with AKI at the day of the first dialysis.

Results: The cohort included 475 patients**,** 60% males, 60% diabetics, aged 72.8 ± 12.2 (Range 20.6-98.7). In 31% of cases patients suffered from AKI and in 69% from Acute on Chronic Kidney Disease. In 41%, patients started dialysis in an ICU. The 30- days-all- cause mortality was 37% and the 6-months mortality rate 53%. The 7-days mortality was 20%. The Positive Predictive Value of the "surprise" question was 65%, the Negative Predictive Value 58% with a Sensitivity 58% and Specificity 65%.

Conclusions: The "surprise" question showed a weak predictive value for death in AKI patients treated by dialysis. Since patients requiring dialysis have a poor general prognosis, we need more sensitive instruments to choose the right patient for the right treatment avoiding unnecessary and futile treatments.

SA-PO542

AKI Outcomes as a Quality Paradigm: A Health Systems Approach

Prakash S. Gudsoorkar,[1] Jwalant R. Modi,[1] Karthikeyan Meganathan,[1] Anthony C. Leonard,[1] Charuhas V. Thakar.[1,2] *[1]University of Cincinnati, Cincinnati, OH; [2]Renal Section, Cincinnati VAMC, Cincinnati, OH.*

Background: Acute kidney injury (AKI) affects 1-in-3 hospitalized patients; survivors face long-term consequences including high risk of re-admissions, end-stage renal disease (ESRD), or mortality. Retrospective studies estimate that only 15-20% of patients receive follow-up renal care within one year of discharge. At a large tertiary care health system, we operationalized and implemented a quality improvement program (QIP) to track discharge disposition and post-discharge follow-up renal care of all AKI consults.

Methods: By combining billing data and health-system wide informatics, we considered all non-ESRD, non-transplant hospitalizations receiving renal consults for each calendar quarter. The first hospitalization with an AKI renal consult in each quarter was considered as the index event. Discharge dispositions included expired/hospice, inter-facility transfers (long-term acute care/acute care), home with self-care or home-health, nursing home, and others. All survivors except inter-facility transfers were considered eligible for renal follow-up metric defined as any renal contact within 90-days of discharge (office visits, chronic dialysis visits, or renal follow-up during readmission). We also tracked all-cause 90-day re-admissions. Chi-square and Kruskal-Wallis test was used for comparison across quarters.

Results: Between 10/2015 and 12/2017 (9 quarters) we identified 2,383 AKI consults (60% male, 64% White). Overall, 22% expired/discharged to hospice (18% to 25% across quarters; p = 0.70); 12% inter-facility transfers; and 66% were eligible for renal follow-up metric (23% home with self-care; 18% home with home-care; 23% rehab-nursing home; 2% others). Of the eligible patients, 42% met the metric (range from 39% to 49% across quarters p=0.09); renal office visits occurred in 29% (range across quarters 22% to 37%), with a median time to renal visit of 31 days (q1, q3, 18, 49). Overall 90-day re-admission rate was 40% (range 35 to 46% across quarters; p=0.29), with median time to re-admission of 17 days (q1, q3, 7, 42).

Conclusions: This is the first report of operationalizing system-wide AKI metrics in real-time and can inform optimal strategies to improve post-discharge care in AKI. Such informatics-based QIP have the potential to plan and implement targeted resource allocation and improve patient and process outcomes.

SA-PO543

Integrating Electronic Alerts and Clinical Decision Support Systems to Improve Diagnosis and Management of AKI

Shina Menon,[1,2] Hong Wu,[1] Rod Tarrago,[1,2] Karyn Yonekawa.[1,2] *[1]Seattle Children's Hospital, Seattle, WA; [2]Pediatrics, University of Washington, Seattle, WA.*

Background: Acute kidney injury(AKI) is a common clinical event with severe consequences. It is associated with prolonged hospital stay, increased risk of mortality and progression to chronic kidney disease. It is often underrecognized and underdiagnosed as seen in studies with significant discrepancy in incidence based on methods (administrative data vs chart review). Early, accurate diagnosis and correct management can improve the standard of care and patient outcomes

Methods: This is preliminary data from an ongoing prospective intervention study across all non-nephrology, non-intensive care patients (6 mo-18yrs) at Seattle Children's Hospital. Our aim was to see if an electronic-alert (e-alert) combined with a clinical decision support system (CDSS) can improve detection and outcome of AKI. We developed an automated real-time e-alert using Kidney Disease Improving Global Outcomes (KDIGO) criteria. E-Alert with stage of AKI was sent as a text page to the contact provider in a patient's electronic health record. It was linked to a CDSS providing basic guidelines on AKI management. The CDSS did not place orders or consults automatically.

Results: 83 AKI alerts were recorded across both phases(Table). Both groups had similar baseline characteristics including age, admitting service, history of transplant or past AKI. There was significant difference in the recognition and documentation of AKI (41%, pre-alert phase vs 80%, alert phase, p<0.005). More renal consults were obtained for severe AKI (≥KDIGO Stage 2) in the alert phase (86.6% vs 36.3%, p<0.005). A higher proportion of patients in alert phase showed return to a baseline kidney function by discharge. Data on follow up and long term outcome is awaited.

Conclusions: Our study shows that AKI remains under diagnosed. E-alerts improve the recognition of AKI, enabling providers to intervene early. They encourage nephrology consultation for severe AKI. This may improve outcomes of children with AKI

Key differences between the study phases

	Pre-alert phase (43 episodes in 41 admissions)	E-alert phase (40 episodes in 38 admissions)
History of transplant, n	BMT = 6 Heart = 5 Liver = 0	BMT = 7 Heart = 5 Liver = 1
Previous AKI, n (%)	20 (48%)	21 (58%)
AKI severity, n (%)	Stage 1= 31 (72%) Stage 2/3= 12 (28%)	Stage 1= 25 (62.5%) Stage 2/3= 15 (37.5%)
AKI documented, n (%)	18 (41.8%)	32 (80%)*
Renal consult for AKI Stage 2 or 3, n(%)	4 (33.3%)	13 (86.6%)*
Return of kidney function to baseline at discharge, n(%)	20 (48.7%)	23(63.8%)

SA-PO544

Real Time Utilization of TIMP2*IGFBP7 in ICU Patients: A Quality Initiative

Jay L. Koyner,[1] Samantha Gunning,[1] Alissa Kunczt,[1] Sharon A. Trevino,[1] Siaw li Chan,[2] Sarah E. Groboske,[1] Edward K. Leung,[3] Kiang-Teck J. Yeo.[1] *[1]University of Chicago, Chicago, IL; [2]Rochester Regional Health, Rochester, NY; [3]The University of Chicago, Chicago, IL.*

Background: Little is known about the real-time clinical use of urinary [tissue inhibitor of metalloproteinase-2]*[insulin-like growth factor binding protein 7] (Nephrocheck, Astute Medical) (NC) in mixed ICU patients at risk for acute kidney injury (AKI).

Methods: We conducted a single center before and after quality initiative assessing outcomes in ICU patients at risk for severe AKI (defined as elevated cardiovascular or pulmonary SOFA score or having KDIGO Stage 1 AKI). We compared 70 retrospective patients who had NC measured but never clinically reported with 60 prospective patients who had NC reported with clinical guidance about their severe AKI risk. We assessed patient outcomes including maximal AKI stage, need for RRT, nephrotoxin exposure and need for nephrology consult.

Results: There was no difference in age, race, gender, baseline hypertension, diabetes, CKD, baseline serum creatinine (SCr) between the retrospective and prospective cohorts. Compared to prospective patients, retrospective patients had higher APACHE II scores(p<0.001), but there was no difference in the need for vasoactive medications(p=0.87). On the day the biomarker was measured both SCr and NC were higher in the prospective cohort.(Table) Despite higher NC values in the prospective cohort there was no difference in the development of Stage 2/3 AKI (p=0.72) or the need for RRT (p=0.68). There was a trend toward decreased mortality in the prospective group (p=0.08). The prospective cohort was more likely to have a nephrology consult in the 24 hours following NC measurement. Prospective patients with a NC>2.0 (n=19) were less likely to be exposed to a nephrotoxins (NSAIDs, Aminoglycosides, amphotericin, r adiocontrast and diuretics) over the first 48 hours compared to retrospective patients with NC>2.0 (n=12)(p<0.01).

Conclusions: Real-time NC measurement decreases nephrotoxin exposure in at risk patients, increases nephrology-based care and improves ICU patient outcomes.

TIMP2*IGFBP7 Outcomes

Variable (either median(IQR) or n(%))	Retrospective Cohort (n=70)	Prospective Cohort (n=60)	p-value
Baseline Serum Creatinine (mg/dl)	1.0 (0.7 - 1.4)	1.0 (0.7 - 1.3)	0.93
Serum Creatinine on Day of NC Measurement	1.1 (0.7 - 1.7)	1.4 (1.0 - 2.1)	0.012
Nephrocheck value	0.33 (0.1 - 1.6)	0.74 (0.24 - 2.3)	0.06
Reached Stage 2 or 3 AKI	18 (24%)	17 (28%)	0.72
Inpatient Mortality	16 (23%)	7 (11%)	0.08
Nephrology Consult within 24 hour of NC measurement	4 (5.7%)	11 (18%)	0.03

SA-PO545

AKI Awareness Among Hospitalized Survivors of AKI

Joseph Lunyera, Aviel N. Alkon, Jennie Riley, Cassandra Bowman, Dinushika Mohottige, Jennifer St. Clair Russell, Clarissa J. Diamantidis. *Duke University School of Medicine, Durham, NC.*

Background: Low health literacy (HL) has been linked to poor patient awareness of health conditions, particularly chronic kidney disease (CKD). Little is known about patients' awareness of AKI, and the role of HL. Using data from the Change AKI study, we examined the association of patient and clinical factors with AKI awareness among hospitalized survivors.

Methods: The Change AKI Study is an ongoing pilot study of an AKI educational intervention for hospitalized survivors of AKI at Duke University Hospital, seen in consultation by an inpatient nephrology service, and enrolled beginning in 2017. All participants completed baseline and 1-month surveys of AKI-related risk factors and awareness. We defined adequate HL at baseline as a Rapid Estimation of Health Literacy Measure (REALM-SF) score ≥7. The primary outcome was baseline AKI awareness, defined as a "yes" response to the question "Before right now, did anyone in the hospital tell you that you had acute kidney injury?" We used multivariate logistic regression to examine the association of HL with baseline AKI awareness, adjusted for patient demographic (age, sex, race, education) and clinical (severity of AKI, need for dialysis, baseline CKD) factors. In a *post hoc* analysis, we examined the association of discharge-related factors (AKI in discharge summary, instructions, or schedule follow-up care) with AKI awareness at follow-up among those previously unaware at baseline.

Results: Among 61 AKI survivors, 46% were aware of their AKI diagnosis at baseline and 78% had adequate HL. HL was not associated with AKI awareness (odds ratio 2.25, 95% confidence interval 0.61-8.31), even after accounting for demographic or clinical

factors. Of 45 participants at follow-up, 20% and 68% had AKI mentioned in their discharge instructions and summaries, respectively. Only 37% had scheduled follow-up care for AKI. Of 30 participants who were unaware at baseline, 43% were aware at follow-up; discharge-related factors were not associated with new AKI awareness.

Conclusions: AKI awareness in hospitalized patients seems unrelated to HL, demographic or clinical factors. Discharge-related educational and follow-up processes are suboptimal and need improvement. Multifactorial interventions targeting AKI awareness need further investigation.

SA-PO546

Nephrology Consultation After AKI Can Improve Patients' In-Hospital Survival

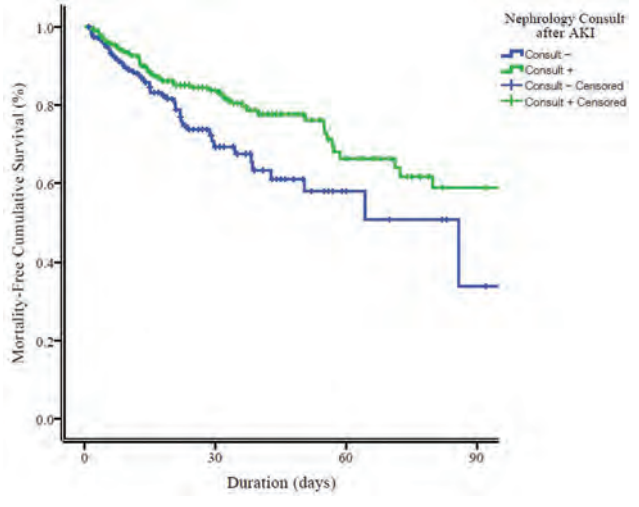
Jeonghwan Lee,[1] Ji Young Ryu,[2] Hyung Eun Son,[2] Ho Jun Chin,[3] Ki Young Na,[3] Sejoong Kim.[3] *[1]Internal Medicine, SMG-SNU Boramae Medical Center, Seoul, Republic of Korea; [2]Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [3]Seoul National University Bundang Hospital, Seong nam, Republic of Korea.*

Background: The significance of nephrology consultation in patients with acute kidney injury (AKI) is not well established.

Methods: We enrolled a total of 20,914 patients who were admitted to the Seoul National University Bundang Hospital from January 1, 2013 to December 31, 2013. All clinical and laboratory data were retrieved retrospectively from the electronic medical record database.

Results: In total, 2,603 (12.4%) patients had AKI during admission (8.7% AKI stage 1, 2.1% AKI stage 2, 1.6% AKI stage 3). Among the 2603 patients with AKI, 446 (17.1%) patients were referred to nephrologists for consultation. Patients who were referred to nephrologists showed characteristics of older age (68.7 ± 14.6 vs. 66.3 ± 15.7 years old, P = 0.0002), male preponderance (60.8% vs. 55.6 %, P = 0.045), more surgical operation (39.7% vs. 29.6%, P < 0.001), more ICU care (51.8% vs 24.1%, P < 0.001), increased baseline creatinine level (1.51 ± 1.58 vs. 1.05 ± 1.28, P < 0.001), high comorbidity score (0.89 ± 1.00 vs. 0.67 ± 0.75), and more advanced AKI stage (eg. AKI stage 3, 33.6% vs. 9.0%, P < 0.001). Overall, patients who were referred to nephrologists for consultation showed similar survival rate compared with patients who were not consulted to nephrologist (log-rank P = 0.223, HR 1.190 (0.899-1.575). After propensity score matching (1:1, n= 359 in both group), both group showed comparable clinical characteristics, and nephrology consulted patients showed better survival outcomes (log-rank P = 0.07, HR 0.614 (0.428-0.881). The time from AKI to nephrology consultation and time to answer after consultation did not significantly affect patient survival.

Conclusions: Patients with AKI who were consulted to nephrologists have a better survival prognosis than those who were not. AKI patients should be encouraged to be consulted to nephrologists for appropriate management and improvement of clinical outcomes.



Propensity Score Matched Patients Survival after AKI according to the Nephrology Consultation.

SA-PO547

Provider-Level Exposure to AKI Alerts in an Ongoing Randomized Trial

Francis P. Wilson,[1] Melissa Martin,[1] Yu Yamamoto,[6] Erica Moreira,[6] Chirag R. Parikh,[2] Harold I. Feldman,[3] Amit X. Garg,[4] Paul M. Palevsky,[5] Ugochukwu C. Ugwuowo,[6] Aditya Biswas.[6] *[1]Yale School of Medicine, New Haven, CT; [2]Yale University and VAMC, New Haven, CT; [3]University of Pennsylvania, Philadelphia, PA; [4]London Health Sciences Centre, London, ON, Canada; [5]University of Pittsburgh/VA Pittsburgh Healthcare System, Pittsburgh, PA; [6]Yale University, New Haven, CT.*

Background: Electronic alerts for acute kidney injury (AKI) are increasingly considered in clinical care because of the potential harms that may come from missed diagnoses of AKI. Alert fatigue, however, may reduce the effectiveness of AKI alerts.

Methods: The Electronic Alerts for AKI Amelioration (ELAIA-1) trial began in March 2018 and will randomize 6,030 patients to real-time, electronic health record-based AKI alerts or usual care across 6 hospitals. Alerts fire when the electronic health record is opened by an MD, NP, or PA while AKI diagnostic criteria are met. In this preliminary analysis, we describe the differential exposure to AKI alerts at the provider level.

Results: Two months into the study, 10,665 alerts had fired for 217 patients with AKI over a six-week period, at a median of 30 (IQR 13-72) alerts per patient. At the patient level, the median alert duration was 1.1 (0.5-2.9) days. A total of 996 unique providers were exposed to alerts with a median of 0.09 (.05-0.31) alerts per day per provider. Fellows received the most alerts per day while attending physicians and PAs received the fewest. Alert burden was highest in the ICU (Figure) and substantially lower in the hospital wards and emergency department.

Conclusions: Despite the large total number of alerts, provider alert burden was generally low. Fellows experienced the highest median number of alerts per day, a potential signal for higher risk of alert fatigue. Providers caring for patients in the ICU may also be at higher risk of alert fatigue.

Funding: NIDDK Support

Exposure to AKI Alerts by Provider Type

Provider	Unique Providers	Alerts Per Day, Median (IQR)	Alerts Per Day (Max)
Attending	450	0.08 (0.04 - 0.16)	3.77
Fellow	119	0.21 (0.08 - 0.49)	2.35
Resident	416	0.12 (0.04 - 0.40)	4.59
Physician Assistant	93	0.10 (0.02 - 0.29)	3.64
Nurse Practitioner	58	0.14 (0.06 - 0.33)	3.29

Focused Ultrasound in Nephrology: A Nephrology Fellow's Perspective

Muhammad O. Saleem,[1] Colleen S. Boyle,[1] Azeem Mohammed,[1] John J. White,[1,2] Laura L. Mulloy,[1,2] N. Stanley Nahman.[1,2] Nephrons@AU *[1]Medical College of Georgia, Augusta University, Augusta, GA; [2]Norwood VAMC, Augusta, GA.*

Background: The portable bedside ultrasound has recently been widely used in clinical practice. The time efficient bedside evaluation is invaluable in managing a patient. Focused Assessment with Sonography for Trauma (FAST) exam is a standard now in Emergency Medicine. Renal fellows are also being encouraged by training programs to use this evolving tool to improve patient care. So we performed a series of case studies to assess usefulness of portable bedside sonography on acute renal consults, termed Focused Ultrasound in Nephrology (FUN)

Methods: 14 patients were studied by a renal fellow and subjected to FUN. All patients had Acute Kidney Injury with an initial impression of pre, post or intra-renal etiology. Volume status was defined by physical exam. Bedside FUN was performed on the same day to see if it changed management. FUN is a quick 4 point bedside ultrasound on initial assessment of patients using a Philips Lumify portable ultrasound. 4 points chosen were bilateral lung scans at mid-axillary lines to look for lung B-lines, IVC for >50% collapsibility on inspiration and bladder scan for distension. Extra 2 point kidney ultrasound to look for kidney size and hydronephrosis was excluded because of lack of training.

Results: 5 out of 14 patients' management was changed on the basis of FUN: 6 scan findings validated the physical exam and 3 did not benefit from the study. 3 patients who were initially rendered euvolemic on physical exam, received IV diuretics when found to have significant lung B-lines (>3) with non-collapsing IVC by FUN. 2 patients who were initially rendered euvolemic had a change in diagnosis to pre-renal and received volume expansion when found more than 50% IVC collapsibility without significant lung B lines. In 3 cases bladder distension was picked up earlier at bedside and later confirmed by a sonogram performed by radiology.

Conclusions: We propose a 4-6 point FUN exam by fellows on acute renal consults. It is a real time assessment of intravascular volume status (pre-renal), pulmonary congestion, bladder obstruction (post-renal) and renal anatomy. Minor training is needed but potential benefits far outweigh the limitations of bedside FUN.

SA-PO549

Comparison of Effectiveness of Renal Ultrasonography in the Work-up of AKI Before and After the Introduction of a Risk Stratification Model

Anna S. Gutman,[1,2] Shimshon Wiesel,[3] Naureen Narula,[3] Nicholas Fuca,[3] Lazer Leifer,[4] Suzanne E. El Sayegh.[3] *[1]Northwell Health, Brooklyn, NY; [2]Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY; [3]Staten Island University Hospital, Staten Island, NY; [4]SIUH, Brooklyn, NY.*

Background: In 2010, Licurse et al, created the Licurse Model for risk stratification of patients according to the probability of having an obstructive cause of acute kidney injury (AKI). The researchers suggested that renal ultrasonography (RUS) findings do not change the management of patients with AKI in most cases. They found that performing RUS only in patients with a higher pre-test probability of urinary tract obstruction conserves resources. They constructed a model consisting of seven variables, which stratified patients with AKI into low, medium, and high risk of obstructive cause of AKI.

Methods: We conducted a retrospective chart review project looking at a total of 482 patient charts, who had RUS performed in the work up of AKI from Jan. 2012 to Mar. 2018 at Staten Island University Hospital. In the months of Oct. 2017 through Dec. 2017 we performed an intervention, which consisted of educating the house staff regarding the appropriate use of a RUS in the work up of AKI. We compared the percentage of patients who met the criteria of the Licurse Model for ordering RUS, had positive findings on RUS, and had a change in clinical management based on the RUS findings before and after our intervention.

Results: We found that the percentage of patients who had RUS in the work up of AKI was 49.9% before the intervention, compared to 49.3% after the intervention, P-value 0.936. The percentage of patients who had a change in clinical management based on RUS findings was 7.23% before the intervention, and 6.17% after the intervention, P-value 0.734.

Conclusions: Our results show that there was no improvement in the effectiveness of RUS for the work up of AKI after the intervention at our facility. Our intervention consisted of educating the resident physicians, and a small number of the attending physicians about the proper use of RUS for the work up of AKI.

SA-PO550

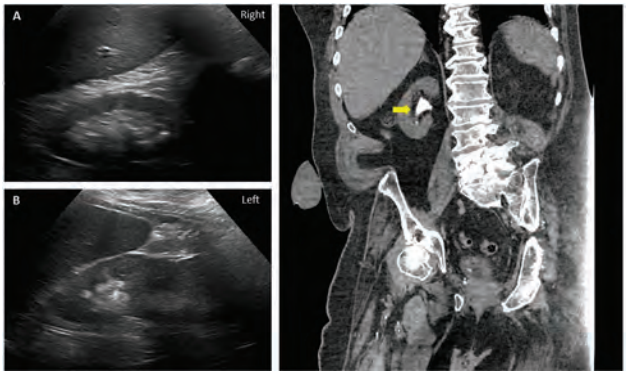
Absence of Hydronephrosis Does Not Exclude Obstructive Nephropathy

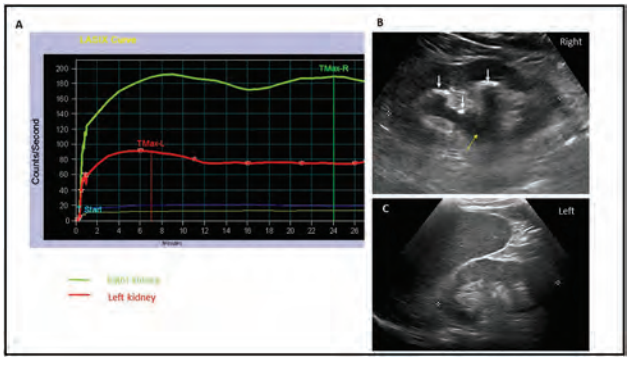
Abhilash Koratala,[1] Olanrewaju A. Olaoye.[2] *[1]University of Florida, Gainesville, FL; [2]University of Florida, Division of Nephrology, Gainesville, FL.*

Introduction: Clinicians should be aware of the pitfalls associated with diagnostic renal imaging.

Case Description: A 63-year-old man with a history of nephrolithiasis and neurogenic bladder requiring chronic indwelling urinary catheter was admitted for urinary tract infection and acute kidney injury (AKI) with a serum creatinine of 3.6 mg/dL (baseline ~1.9-2.2). Bedside renal sonogram did not demonstrate hydronephrosis or nephrolithiasis [Figure-1A,B]. Non-contrast CT scan of the abdomen also was negative for hydronephrosis but showed a 2.6 cm staghorn-appearing calculus in the right kidney [Figure-1C]. As the patient appeared dehydrated, he was treated with intravenous hydration along with antibiotics. However, renal function continued to worsen. Because of high index of suspicion for obstructive nephropathy, a radioisotope-lasix renogram was performed, which demonstrated complete obstruction on the right [Figure-2A]. Moreover, right kidney had a differential function of ~70%, which explains AKI with unilateral obstruction. Interestingly, a repeat renal sonogram demonstrated mild hydronephrosis and calculus in the right kidney [Figure-2B,C]. Serum creatinine improved significantly after nephrostomy tube placement, reaching baseline in a few days.

Discussion: Renal imaging can be negative for hydronephrosis in the setting of volume depletion. It should be repeated after volume repletion if the index of suspicion for obstructive nephropathy is high. Radioisotope renography is beneficial in selected cases. Early diagnosis is crucial for timely intervention and prevention of irreversible renal injury.





SA-PO551

Association of Body Mass Index with Outcomes in a Critically Ill Population on Renal Replacement Therapy

Sophia L. Ambruso,[1] Sarah Faubel,[1] Benjamin Griffin,[2] Anna J. Jovanovich,[3] Jessica B. Kendrick,[4] Zhiying You,[5] Paul M. Palevsky.[6] *[1]University of Colorado Denver, Denver, CO; [2]University of Colorado, Aurora, CO; [3]Denver VA / University of Colorado, Denver, CO; [4]University of Colorado School of Medicine, Aurora, CO; [5]UC Denver, Aurora, CO; [6]University of Pittsburgh/VA Pittsburgh Healthcare System, Pittsburgh, PA.*

Background: The prevalence of obesity is rising in the critically ill population. Acute kidney injury (AKI) is a common complication seen in the intensive care unit (ICU) with 5% requiring renal replacement therapy (RRT). Limited data exists on the association of body mass index (BMI) and outcomes in patients on RRT in the ICU. In our study, we investigated the impact of very high and very low BMI on mortality rates.

Methods: We conducted a secondary analysis of the Acute Renal Failure Trial Network (ATN) database, which compared less-intensive to more-intensive RRT dosing in the ICU population with AKI. Weights >128.5kg, which exceeded the max dosing capabilities of the Prisma machine at the time, were excluded. In this analysis, patients were categorized into BMI quintiles; Q1 (<23.5kg/m^2, n=173), Q2 (23.5-26.2kg/m^2, n=174), Q3 (26.21-28.39kg/m^2, n=173), Q4 (28.4-32.77kg/m^2, n=174) and Q5 (≥32.78kg/m^2, n=174). Q3 was the comparison value. Our primary endpoint was 60-day mortality. Logistic regression was used to adjust for demographics, SOFA score, Charlson score and treatment strategy.

Results: Participants were mainly white (79%) males (70%) with a mean age of 60 ± 15.3 and overall mortality rate of 52%. Those in the highest quintile of BMI had a lower mortality rate (mortality rate 44% vs. 53%, 59%, 51% and 56% in quintiles 1,2,3 and 4, respectively). However, compared to quintile 3, those in the highest quintile did not have significantly lower odds of mortality in unadjusted or adjusted models. Compared to quintile 3, lower quintiles of BMI did not have a significant association with mortality.

Conclusions: Very high and very low BMI was not associated with an increased risk of mortality in critically ill patients requiring RRT. The small number of patients per quintile limited the power of this study. Larger studies analyzing the impact of BMI on mortality in critically ill patients with AKI is needed.

Multivariate analysis for 60-day ICU mortality

	Odds Ratio (95% CI)		
	Unadjusted Model 1	Model 2	
Q1	1.0 (0.69-1.6)	1.1 (0.7-1.7)	1.2 (0.7-1.9)
Q2	1.3 (0.88-2.0)	1.3 (0.9-2)	1.3 (0.8-2.1)
Q3	REF	REF	REF
Q4	1.2 (0.78-1.8)	1.2 (0.8-1.9)	1.3 (0.9-2.1)
Q5	0.7 (0.5-1.11)	0.8 (0.5-1.2)	0.8 (0.5-1.0)

Model 1: Age, race, gender

Model 2: SOFA score, Charlson score, Treatment strategy + Model 1

SA-PO552

Analysis of Survival After Initiation of Continuous Renal Replacement Therapy in Patients with Extracorporeal Membrane Oxygenation

George Kuo. *Nephrology, Chang Gung Memorial Hospital, Linkou, Taoyuan, Taiwan.*

Background: No study has specifically investigated the duration of continuous renal replacement therapy (CRRT) in patients who suffered acute kidney injury during extracorporeal membrane oxygenation (ECMO) support. However, there are concerns that prolonged CRRT may be futile.

Methods: A retrospective population-based cohort study using Taiwan National Health Insurance Research Database data collected between January 1, 2007 and December 31, 2013. Patients who received ECMO and CRRT during the study period were included. We divided the patients into three groups based on the duration of CRRT received: ≤ 3 days, 4–6 days, and ≥ 7 days.

Results: The overall survival after discharge did differ significantly among the three CRRT groups. The patients who received CRRT ≥ 7 days had a higher risk of ESRD than did those who received CRRT ≤ 3 days (adjusted hazard ratio [aHR] 3.46, 95% confidence interval [CI] 1.47–8.14) and between 4 and 6 days (aHR 3.10, 95% CI 1.03–9.29). The incidence of ventilator dependent was higher in the patients with CRRT ≥ 7 days than in those with ≤ 3 days (aHR 2.45, 95% CI 1.32–4.54). The CRRT ≥ 7 days group also exhibited a higher readmission rate than did the 4–6 days and ≤ 3 days groups (aHR 1.43, 95% CI 1.04–1.96 and aHR 1.67, 95% CI 1.13–2.47, respectively).

Conclusions: Our study found similar long-term survival but increased long-term ESRD and ventilator dependency among the ECMO patients who underwent CRRT for 7 days or more. These results offer reason to be concerned that this aggressive form of life support may maintain patient survival but do so at the cost of long-term disabilities and, consequently, a lower quality of life

Platelet Decrease Following Continuous Renal Replacement Therapy (CRRT) Initiation Predicts Mortality in Patients with Severe AKI

Benjamin Griffin,[1] Nigel Arruda,[1] Anna J. Jovanovich,[2] Katja M. Gist,[3] Muhammad Aftab,[4] Diana I. Jalal,[5] Sarah Faubel.[6] *[1]University of Colorado, Aurora, CO; [2]Denver VA / University of Colorado, Denver, CO; [3]University of Colorado, Children's Hospital Colorado, Aurora, CO; [4]University of Colorado, Anschutz Medical Center, Aurora, CO; [5]University of Iowa, Iowa City, IA; [6]University of Colorado Denver, Denver, CO.*

Background: Thrombocytopenia is common in critically ill patients and is associated with increased mortality. Recent data suggest that CRRT is associated with decreased circulating platelet levels, possibly due to consumptive platelet-filter interactions. The impact of this platelet decrease on mortality is unclear. The purpose of this study was to examine the impact of platelet decrease following CRRT initiation on in-hospital mortality.

Methods: We conducted a retrospective analysis of adult patients initiated on CRRT at the University of Colorado Hospital between July 2015 and September 2016. Patients who died < 24 hours after CRRT initiation were excluded. Patients were categorized based on the percentage decrease from pre-CRRT levels to nadir following CRRT initiation: (1) no decrease (platelet increase from baseline), (2) mild decrease (0-50% decrease), and (3) severe decrease (>50% decrease). The primary outcome was in-hospital mortality. Logistic regression was used to adjust for SOFA score (excluding platelet component), body mass index (BMI), gender, and baseline platelets.

Results: A total of 154 cases met inclusion criteria. Platelet counts decreased in 101 (65.6%) patients and 38 (24.7%) had a decrease of >50%. In-hospital mortality occurred in 72 (46.7%) patients. Patients with a severe decrease in platelets were 3.16 times more likely to die in the hospital compared to patients with an increase in platelets after adjusting for confounders (Table 1). In this study, <50% platelet decrease was not associated with mortality.

Conclusions: Platelet consumption following CRRT initiation is common, and a severe decrease is independently associated with mortality after adjusting for confounders. The mechanism of platelet decrease and its impact on mortality in patients requiring CRRT merits further study.

Funding: Other NIH Support - T32 DK 007135

Table 1. Effect of platelet decrease in final multivariate model for in-hospital mortality

Variable	OR (95% CI)	p value
Platelet Decrease > 50%*	3.16 (1.11 - 8.99)	0.003
Platelet Decrease 0-50%*	1.59 (0.64 - 3.95)	0.3

*Platelet decreases are in comparison to patients with an increase in platelets following CRRT initiation. The model was also adjusted for SOFA score (minus platelet component), Gender, BMI, and baseline platelets.

SA-PO554

Continuous Renal Replacement Therapy Is Associated with Acute Myocardial Injury in Critically Ill Patients

Marat Slessarev,[1] Fabio R. Salerno,[2] Christopher W. McIntyre.[3] *[1]University of Western Ontario, London, ON, Canada; [2]Clinica Nefrologica H San Gerardo, Monza, Italy; [3]London Health Sciences Centre, London, ON, Canada.*

Background: Intermittent renal replacement therapy induces cardiac stunning in chronic hemodialysis (HD) and acute kidney injury (AKI) patients. In chronic HD, recurrent stunning contributes to heart failure and cardiac death, with ultrafiltration and intra-dialytic hypotension being the principal determinants of this injury. Continuous renal replacement therapy (CRRT), with its lower ultrafiltration rates and improved hemodynamic profile, should protect against cardiac stunning in AKI. We assessed whether CRRT is associated with cardiac stunning in critically ill patients with AKI.

Methods: We prospectively measured cardiac function using global and segmental longitudinal left ventricular (LV) strain derived from transthoracic echocardiography in 11 critically ill patients who were started on CRRT for AKI. We compared measurements at 4, 8 and 24 hours to baseline immediately prior to initiation of CRRT, with each patient serving as their own control. We also recorded blood pressure, heart rate, dose of vasoactive medications and ICU mortality.

Results: 10/11 patients developed new regional cardiac stunning, with 8/11 within 4 hours of starting CRRT, despite stable hemodynamics. The number of affected LV segments varied from 1 to 11 (out of 12). The stunning occurred both in patients with preserved and impaired baseline cardiac function, and 7/11 patients died in the ICU.

Conclusions: Initiation of CRRT in critically ill patients with AKI is associated with cardiac stunning despite stable hemodynamics. This mechanism may explain lack of clinical benefit of CRRT over intermittent modalities and warrants further investigation to improve cardiovascular outcomes in critically ill patients with AKI.

SA-PO555

The Impact of Early Initiation of Continuous Renal Replacement Therapy in Critically Ill Patients with AKI

Junyong Lee, Jihyun Yang, Sang-Kyung Jo, Sewon Oh, Myung-Gyu Kim. *Korea University Anam Hospital, Seongbuk-Gu, SEOUL, Republic of Korea.*

Background: The acute kidney injury (AKI) in ICU patients is one of a risk factor for mortality ICU patients. Continuous renal replacement therapy (CRRT) widely used in various situation, but the optimal timing for initiation of CRRT in critically ill patients with AKI remains controversial. The purpose of this study is to investigate the impact of early, preemptive initiation on outcomes of AKI patients in ICU compare to classic, delayed initiation.

Methods: This is two center retrospective review from 2014 to 2017. Any type of stage IV cancer patients, CRRT duration less than 24 hours, end-stage renal disease with hemodialysis or peritoneal dialysis or kidney transplanted patients were excluded. The primary clinical outcome variables were 90-day Mortality and Renal recovery. Renal recovery was defined by creatinine clearance (≥15 mL/minute) with no need for renal replacement therapy at 90 days.

Results: Total 1152 patients are included, 583 patients were analyzed. Compare to delayed initiation group, early initiation group had lower eGFR(80 vs 52 mL/min/1.73m^2, p<0.001), more chronic kidney disease patients which is defined eGFR lower than 60 mL/min/1.73m^2 (59 vs 19%, p<0.001), more extra-corporeal membrane oxygenation application (1 vs 8%, p=0.005), longer survival period (42.2 vs 58.01 days, p=0.03), severe inflammatory/infectious condition (leukocytosis and higher C-reactive protein level). Ventilator care and higher APACHE-II score, classic initiation of CRRT were risk factors for non-real recovery at 90day. Elderly, CKD, underlying liver disease, higher APACHE-II score, ECMO, and delayed initiation were risk factors for 90-day mortality.

Conclusions: Delayed initiation of CRRT was independently associated with 90-day mortality. They showed lower renal recovery than the non-classic group. Delayed initiation of CRRT was independently associated with greater odds of non-renal recovery. Initiating CRRT in critically ill patients with AKI should not be delayed until fulfillment of classic indications.

SA-PO556

Modified APACHE II and SOFA Scores in Patients Requiring Continuous Renal Replacement Therapy

Yaerim Kim,[1] Dong Ki Kim,[1] Ho Jun Chin,[2] Ki Young Na,[2] Kwon Wook Joo,[1] Yon Su Kim,[1] Sejoong Kim,[2] Seung Seok Han.[1] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Seoul National University Bundang Hospital, Seong nam, Republic of Korea.*

Background: Based on the worse outcomes of intensive care unit patients, acute physiology and chronic health evaluation II (APACHE II) and sepsis-related organ failure assessment (SOFA) scores have been frequently used to predict mortality. Nevertheless, these prediction models have not been optimized to the patients receiving continuous renal replacement therapy (CRRT) because of acute kidney injury.

Methods: A total of 828 patients who underwent CRRT from June 2010 to December 2015 were retrospectively reviewed. All the components of APACHE II and SOFA were collected at the time of starting CRRT. End-points were 7-day and 30-day mortality. Based on the restricted cubic spline results, modified scores were assigned to each variable. Additionally, abbreviated model including the best predictable variables alone was developed after stepwise selection analysis.

Results: The prediction powers indicated by c-statistics were 0.683 and 0.668 for 7- and 30-day mortality by APACHE II; and 0.683 and 0.660 for 7- and 30-day mortality by SOFA. After modification of these models, the prediction powers increased up to 0.765 for APACHE II and 0.775 for SOFA. Using multivariate stepwise analysis, the respiratory rate, FiO2, bilirubin, pH, and inotropics used were selected in the abbreviated 7-day mortality model (c-statistics = 0.765). For a 30-day mortality model, AaDO2, respiratory rate, Glasgow coma scale, hematocrit, whole blood cells, bilirubin, potassium, and inotropics used were selected (c-statistics = 0.771).

Conclusions: Modified APACHE II and SOFA models are better than the originals in predicting mortality of patients receiving CRRT, which may ultimately be helpful in clinical practice.

SA-PO557

Hypotension within One-Hour from Starting CRRT Is an Independent Predictor for In-Hospital Mortality

Khaled Shawwa,[1] Panagiotis Kompotiatis,[1] Brandon M. Wiley,[2] Jacob Jentzer,[1] Kianoush Kashani.[2] *[1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic, Rochester, MN.*

Background: In-hospital mortality in critically ill patients who require renal replacement therapy is high. Patients who receive CRRT may be at higher risk for hemodynamic instability that can have implications in terms of renal recovery and mortality.

Methods: This is a retrospective analysis of a cohort of patients admitted to the ICUs at a tertiary care hospital from December 2006 through November 2015 who underwent CRRT. The primary outcome was in-hospital mortality. Multivariate logistic regression was performed to identify independent predictors of in-hospital mortality. Hypotension within the first hour of CRRT initiation was defined as: MAP <60 mm Hg, SBP <90 mm Hg or a decline in SBP >40 mm Hg from baseline, a positive fluid balance more than 500 ml or increased vasopressor requirement.

Results: The analysis included 1,743 patients, 345 (19.8%) with ESRD and 1,398 (80.2%) with AKI. The median age was 63 (IQR 53-73) years with 699 (40%) female, median Charlson comorbidity index 5 (IQR 3-7) and median SOFA on the day of CRRT initiation was 12 (IQR 9-14). Overall in-hospital mortality occurred was 50%. Hypotension within one hour of CRRT initiation occurred in 64% of the patients. Predictors of in-hospital mortality in univariate analysis included: SOFA score (OR 1.13 per 1 unit increase, 95% CI:1.10-1.16), mechanical ventilation (OR 1.6, 95% CI:1.2-2.1), hypotension within 1 hour (OR 1.6, 95% CI:1.3-1.9), AKI compared to ESRD (OR 1.9, 95% CI:1.5-2.5) and modified shock index (OR 2.1 per 1 unit increase, 95% CI:1.7-2.7). Hypotension within one hour of CRRT initiation remained an independent predictor of in-hospital mortality (OR 1.45, 95% CI:1.15- 1.82, p=0.001), after adjusting for age, gender, SOFA score, mechanical ventilation, fluid balance between ICU admission and CRRT initiation, modified shock index, Charlson comorbidity index, AKI vs ESRD, ICU type, creatinine closest to CRRT initiation and ICU day number when CRRT was initiated.

Conclusions: Hypotension occurs frequently in patients receiving CRRT despite being chosen as a modality with better hemodynamic tolerance. Hypotension during the first hour after initiating CRRT is a significant independent risk factor for in-hospital mortality. Further studies are required to help understand this phenomenon given its implications for in-hospital mortality.

SA-PO558

Predictive Factors for Successful Discontinuation of Continuous Renal Replacement Therapy in AKI

Song in Baeg, Hyo jin Boo, Minjung Kim, Eun jeong Lee, Jung eun Lee, Wooseong Huh, Dae Joong Kim, Yoon-Goo Kim, Ha Young Oh, Hye Ryoun Jang. *Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Although continuous renal replacement therapy (CRRT) is the standard treatment for severe acute kidney injury (AKI) in critically ill patients, there is no practical consensus for discontinuing CRRT. In this retrospective study, predictive factors for successful discontinuation of CRRT was investigated.

Methods: Adult patients (≥18 years) who received CRRT at Samsung Medical Center from June 2007 to June 2017 were included (n=4166). Patients with preexisting end stage renal disease (ESRD), patients who progressed to ESRD within 1 year after CRRT discontinuation or died within 7 days were excluded. Successful discontinuation of CRRT was defined as no requirement of RRT for 7 days after discontinuing CRRT. Patients were divided into the failure group and the success group. Clinical information and laboratory results were collected via electronic medical records.

Results: A total of 1158 patients were analyzed. There were no differences in comorbidities. The duration of CRRT was longer in the failure group. Mean arterial pressure (MAP) on discontinuation day (D0) was lower in the success group (failure vs. success, 80.86±12.56 vs. 78.95±12.51 mmHg, p=0.010). Urine output on the day before discontinuation (D-1) (140 vs. 648 mL/day, p<0.001) and D0 (253 vs. 1298 mL/day, p<0.001) and the proportion of patients who received vasopressors on D-1 (26.6% vs. 43.1%, p<0.001) and D0 (19.1% vs. 34.8%, p<0.001) were higher in the success group. Serum potassium on D0 was lower in the success group (4.02±0.45 vs. 3.88±0.46 mmol/L, p<0.001). Multivariable analysis showed that urine output on D0 (odds ratio [OR], 1.621; 95% confidence interval [CI], 1.468 to 1.789; p<0.0001), difference in HCO_3 between D0 and D-1 (OR, 1.070; CI, 1.009 to 1.135; p=0.0231) and vasopressor use on D0 (OR, 2.306; CI, 1.348 to 3.946; P=0.0023) were significant predictive factors for successful discontinuation of CRRT. MAP on D0 (OR, 0.980; CI, 0.969 to 0.992; p=0.0007) and serum potassium on D0 (OR, 0.592; CI, 0.732 to 0.809; p=0.001) were also significant predictive factors.

Conclusions: Our study showed that greater urine output, maintenance of adequate blood pressure with vasopressors, and lower normal range of serum potassium on discontinuation day were associated with successful discontinuation of CRRT.

SA-PO559

CVVH Yields Better Renal Outcomes Than Intermittent Hemodialysis Among Traumatic Intracranial Hemorrhage Patients with AKI: A Nationwide Population-Based Retrospective Study in Taiwan

Min-Feng Tseng,[2] Chia-chao Wu.[1] *[1]Tri-Service General Hospital, Taipei, Taiwan; [2]1. Division of Nephrology, Department of Internal Medicine, Zuoying Branch of Kaohsiung Armed Forces General Hospital, Kaohsiung, Taiwan, Taipei City, Taiwan.*

Background: Traumatic intracranial hemorrhage (TICH) patients with acute kidney injury (AKI) were reported to have a high mortality rate. Renal replacement therapy (RRT) is indicated for patients with severe kidney injury. This study aimed to compare the effects of different RRT modalities in terms of chronic dialysis rate among adult TICH patients with AKI.

Methods: A retrospective search of computerized hospital records from 2000 to 2010 for patients with a discharge diagnosis of TICH was conducted to identify the index cases. We collected the data of TICH patients with increased intracranial pressure combined with severe AKI who received intermittent hemodialysis (IHD) or continuous veno-venous hemofiltration (CVVH) as RRT. The outcome was dialysis dependence between 2000 and 2010.

Results: From a total of 310 patients who were enrolled in the study, 134 (43%) received CVVH and 176 (57%) received IHD. The risk of dialysis dependency was significantly lower in the CVVH group than in the IHD group (adjusted hazard ratio: 0.368, 95% CI, 0.158–0.858, P = 0.034). Diabetes mellitus and coronary artery disease were risk factors for dialysis dependency. CVVH compared with IHD modality was associated with lower dialysis dependency rate in TICH patients combined with AKI and diabetes mellitus and those with an injury severity score (ISS) ≥16.

Conclusions: CVVH may yield better renal outcomes than IHD among TICH patients with AKI, especially those with diabetes mellitus and an ISS ≥16. Therefore, the beneficial impact of CVVH on TICH patients needs to be clarified in a large cohort study in future.

SA-PO560

AKI in Patients Requiring Extracorporeal Membrane Oxygenation

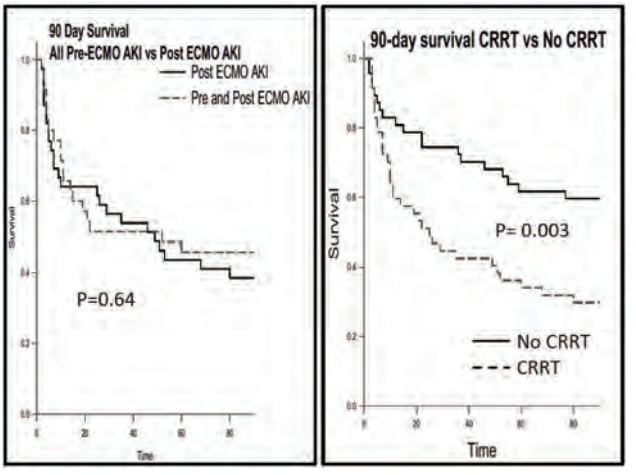
Fouad Kutuby,[1] Jay L. Koyner,[1] Rebecca Rose,[2] Tae H. Song.[1] *[1]University of Chicago, Chicago, IL; [2]University of Chicago Medicine, Chicago, IL.*

Background: There is limited published data on the outcomes in those with AKI after extracorporeal membrane oxygenation (ECMO) cannulation.

Methods: We performed a single center retrospective study of patients who underwent ECMO cannulation between 1/2015 and 7/2017. We excluded patients with pre-existing End Stage Renal Disease (ESRD) and those who died within 24 hours of ECMO initiation. AKI was defined by the KDIGO criteria within 7 days of ECMO cannulation. Survival analyses were performed using the log-rank test.

Results: We found 117 patients but excluded 23(18 of whom died within 24 hours of ECMO). Of the remaining 94 patients 76(81%) received veno-arterial (VA-ECMO) and 18 received Veno-venous (VV-ECMO). Of the 94 patients, 13(13.8%) did not experience AKI during their entire hospital stay. AKI prior to ECMO cannulation occurred in 42(44%) patients and 39(41%) patients only developed AKI after ECMO. Of those with AKI(n=81), 16 developed Stage 2 AKI, 51 developed Stage 3 AKI of which 47(50%) received renal replacement therapy (RRT). AKI rates were not different across VA and VV ECMO(p=0.15). Patients with any AKI were more likely to die at 30 and 90 days compared to those without any AKI(p<0.01 for both). Figure A demonstrates no difference in 90 day mortality between those with pre-ECMO AKI compared to those with post-ECMO AKI (p=0.64). Those who did receive RRT(n=47) did not have significantly different pHs, hemoglobin or other pre-ECMO co-morbidities (CKD, CHF, Diabetes) compared to those without RRT(n=47). In a multivariate model the presence of pre-ECMO vasopressors was an independent predictor for the need for RRT(OR(95%CI) 4.59(1.10-19.2)p=0.037). Patients requiring RRT had increased 90-day mortality compared to those without RRT(p<0.003) Figure B.

Conclusions: AKI is common in the setting of ECMO. While there was no difference in mortality in those with pre versus post ECMO AKI, AKI requiring RRT significantly decreases patient survival at 90 days.



SA-PO561

Inhibition of PARP1 Attenuates Rat Renal Ischemia Reperfusion Injury

Christina Bracken,[1] Katelyn Pulito,[1] Jeff H. Stanwix,[1] Robert W. Shine,[1] Mahati Krishna,[2] Nan Ji,[1] Effie Tozzo,[1] Dominique Stickens.[1] *[1]Mitobridge, an Astellas company, Cambridge, MA; [2]Syngene International Pvt. Ltd., Bangalore, India*.

Background: Renal ischemia reperfusion injury (IRI) generates superoxide and other reactive species and induces PARP1 activation to repair ROS-mediated DNA strand breaks. However, PARP1 activation depletes NAD^+ and ATP, and promotes pro-inflammatory signal transduction, all of which can exacerbate IRI. We hypothesized that inhibiting PARP1 would decrease/prevent NAD^+ depletion and reduce IR-induced acute kidney injury (AKI).

Methods: We evaluated the ability of a novel and selective PARP1 inhibitor, Cmpd A to boost NAD^+ and mitochondrial respiration in control and cisplatin challenged human proximal tubule cells (PTC). Sprague-Dawley rats underwent a 50 minute bilateral IR and were administered Cmpd A (or vehicle), twice daily at 0.1, 0.3, 1, 5, or 15 mg/kg by intravenous injection for 2 days, beginning at 4 hours post reperfusion. Cmpd A activity was assessed by measuring renal PAR levels, NAD^+ and its breakdown products, by ELISA or mass spectrometry. Renal injury biomarkers were measured in plasma at 24 and 48 hr post reperfusion and tubular injury was evaluated by histopathology. Gene expression analysis for inflammatory mediators and *Vegfa* were assessed using Nanostring technology.

Results: Cmpd A treatment increases NAD^+ levels by 35% and enhances mitochondrial respiration under normal PTC culture conditions while preventing nephrotoxin-induced NAD^+ depletion when PTC are treated with cisplatin. In the rat model of IR-AKI, Cmpd A lowers plasma creatinine and BUN dose dependently at 24 and 48 hr post injury. This translates to improved renal function via increased creatinine clearance and normalization of fractional excretion of Na^+ (FENa). Assessment of kidney histopathology at 48 hr post reperfusion revealed that Cmpd A normalizes renal tubular architecture. In addition, Cmpd A treatment reduces IR-induced upregulation of inflammatory mediators and restores the downregulation of *Vegfa* gene expression.

Conclusions: Dosing of a selective PARP1 inhibitor after an ischemic AKI event in rats recovers renal and tubular function. Mechanistically, our data suggest that this effect is mediated by a reduction of pro-inflammatory signaling, preservation of *Vegfa* and increase of NAD^+ levels.

SA-PO562

The Protective Effect of Klotho Against Contrast-Associated AKI via the Anti-Oxidative Effect

Kyoung Hye Kong, Hyung Jung Oh, Dong-Ryeol Ryu. *Ewha Womans University, Seoul, Republic of Korea*.

Background: Contrast-associated acute kidney injury (CA-AKI) is defined as AKI caused by the supplementation of iodinated contrast agents, and oxidative stress is one of its main factors. Klotho, an anti-aging gene, shows anti-oxidative activity and is expressed in renal tubular cells. We investigated the protective effect of klotho against CA-AKI via the anti-oxidative effect.

Methods: We used NRK-52E cell lines and iopamidol as the contrast agent. Experiments were performed after cell cultures were divided into one of three groups: the control, iopamidol, and iopamidol+recombinant klotho (rKL) groups. Moreover, the siRNA-mediated knockdown of *klotho (siklotho)* was also done to reveal the endogenous klotho effect. Cell viability and oxidative stress were measured, and real-time PCR and western blotting were performed. We also designed a CA-AKI mouse model with ketorolac, L-NAME and iopamidol, and performed experiments similar to our *in vitro* experiments.

Results: The viability of the NRK-52E cells significantly decreased, but oxidative stress significantly increased after 200 mgI iopamidol was supplemented for 1h compared to the controls. Protein and mRNA expressions of klotho also significantly decreased, while apoptotic markers (Bax/Bcl_2, cleaved caspase3) increased significantly after iopamidol injection. However, the decrease in cell viability after iopamidol supplementation was significantly attenuated after the cells were exposed to rKL, and rKL mitigated the elevated apoptotic markers and oxidative stress under iopamidol injection. Additionally, the apoptotic markers and oxidative stress were significantly upregulated in the group of iopamidol-treated *siklotho* compared to the iopamidol-treated NTC group. Our *in vivo* study results showed similar trends to our *in vitro* experiments.

Conclusions: This study showed that klotho can protect against CA-AKI via the anti-oxidative effect. These findings provide new insight into the mechanisms behind the protective effect of klotho in CA-AKI.

Funding: Government Support - Non-U.S.

SA-PO563

Increased Soluble Guanylyl Cyclase Activity in Ischemia/Reperfusion Induced AKI Suppresses PGC-1a and Mitochondrial Biogenesis

Pallavi Bhargava,[1,2] Rick G. Schnellmann.[1] *[1]Pharmacology and Toxicology, University of Arizona, Tucson, AZ; [2]Drug Discovery and Biomedical Sciences, Medical University of South Carolina, Charleston, SC.*

Background: Acute Kidney Injury (AKI) can result from numerous causes such as ischemia/reperfusion (I/R) injury. We have shown that mitochondrial biogenesis (MB) is persistently suppressed following diverse injuries and that stimulation of MB, by targeting PGC-1a, the master regulator of MB, promotes recovery of renal function. Soluble guanylyl cyclase (sGC) is a heterodimer that catalyzes the production of cGMP from guanosine triphosphate (GTP). cGMP can be increased by sGC activity or by pharmacological inhibition of phosphodiesterases (PDE) 3 and 5, enzymes that degrade cGMP. Although inhibition of PDE3 and 5 induces MB and promotes renal recovery in AKI models, the role of sGC in AKI has received minimal attention.

Methods: Mice underwent bilateral I/R and were euthanized 24 h later. Kidney function was determined by serum creatinine (SCr). Cell signaling was measured using RT-qPCR and immunoblot analysis. sGC enzyme activity was determined by measuring cGMP in renal cortical homogenates.

Results: SCr increased 10-fold to 1.8 mg/dL 24 h after I/R injury. While renal cortical protein expression of the sGC subunits was not altered, sGC activity increased 1.6-fold in I/R mice compared to sham mice. Increased cGMP activated protein kinase G (PKG). In turn, phosphorylated p38, a target of PKG, increased in I/R mice. Phosphorylated FOXO1, a target of activated p38, also increased, inhibiting FOXO1 translocation into the nucleus. PGC-1a mRNA, a transcriptional target of FOXO1, decreased 24 h after I/R.

Conclusions: I/R injury initiates a signaling pathway comprised of sGC-cGMP-PKG-p38-FOXO1-PGC-1a and resulted in decreased PGC-1a transcription. These results are consistent with previous findings demonstrating decreased PGC-1a in various forms of AKI and the suppression of MB.

Adipose Stem Cell-Derived Exosomes Afford Effective Survival Benefits and Functional Rescue from Severe, Progressive IRI-Induced AKI in Rats

Anna Gooch,[2] Ping Zhang,[2] Zhuma Hu,[2] Christof Westenfelder.[1] *[1]University of Utah and VA Medical Centers, Salt Lake City, UT; [2]SCT, Salt Lake City, UT.*

Background: Bone marrow and Adipose-derived Mesenchymal Stem Cells (M/ASCs) are effective for prevention of Acute Kidney Injury (AKI). Yet when MSCs are given 48 hrs post-insult, a time at which severe clinical AKI is diagnosed and when no rescue therapy is currently available, they are ineffective or potentially damaging because the introduction of large cells (~50μm) into the compromised microvasculature may impair renal function. M/ASCs' renoprotection is mediated by their paracrine release of anti-inflammatory and trophic cytokines and their exosomes. Exosomes signal, post uptake by target cells, through the lateral transfer of mRNAs, miRNAs, DNA, proteins, and lipids. Since ASC-derived exosomes can prevent AKI we tested whether their small size and ability to move through the compromised renal microvasculature might allow them to provide effective rescue therapy for late stage AKI.

Methods: Exosomes from Sprague Dawley (SD) rat ASCs were isolated post 24 hr culture in SFM, purified using the ExoQuick-TC kit, and characterized for size, protein and gene expression of relevant markers. I/R AKI (52 min bilateral renal pedicle clamp) was induced in female SD rats. If the SCr value on D2 was greater than that on D1, then rats were administered via left carotid artery either 1 ml of Vehicle (PBS; n=8), Exosomes (200 μg protein-equivalent; ~4x10e10 exosomes; n=6), or ASCs (2x10e6 ASCs; n=6) on D3.

Results: 1e6 ASCs secrete ~ 4.9x10e10 exosomes and other microvesicles (mode 136.7 nm) and >95% express CD44 and CD29, and carry mRNAs of renoprotective genes expressed in ASCs. While both ASC and exosome administration improved survival over PBS, renal function only showed significant and sustained improvement in exosome-treated rats.

Conclusions: ASC-derived exosome therapy 3 days post progressive AKI, when renal blood flow is significantly impaired and when most clinical AKI is diagnosed, is superior to ASC therapy, likely due to their ability to deliver their renoproetective cargo into the compromised renal microcirculation. These data have, we posit, significant translational promise for the development of an effective rescue therapy for advanced AKI.

Transfer of Healthy Isolated Mitochondria in Established Injury Reduces Progression to Fibrosis

Kyle J. Alexander, Kailo H. Schlegel, Amandeep Bajwa. *University of Virginia, Charlottesville, VA.*

Background: Ischemia induces altered bioenergetics with increased mitochondrial swelling and reactive oxygen species (ROS) and ultimately degradation of cellular function. Therapeutic interventions that target to improve mitochondrial health to repair, reprogram or replace mitochondria to restore respiratory functions are beneficial for prevention and/or treatment of established disease.

Methods: Renal injury was assessed by plasma creatinine (PCr; mg/dl). 8-wk old C57BL/6 mice were i.v. injected with isolated mitochondria (50mcg, from healthy non-ischemic mouse liver). 1d, 3d or 5d after unilateral IRI. Nephrectomy of contra-lateral control kidney was done on day 13. Change in fibrosis genes were measured by RTPCR and histology changes with Masson trichrome and picrosirius red were done on day 14. For *in vitro* studies, PT cells (TKPTS) were treated with 10 or 20 mcg of isolated mitochondria 1d prior to analysis that included measurement of ATP levels, mitochondrial functions (Seahorse analyzer), cytokines (RTPCR), immunofluorescence microscopy (uptake efficiency) and flow cytometry (mitotracker dyes).

Results: *In vivo* studies demonstrated treatment of mice with 50 mcg of mitochondria at 1d, 3d or 5d after IRI significantly protected compared to vehicle treated mice after IRI [Day 14 PCr (0.6±0.04 (+1d) vs 0.68±0.18 (+3d) vs 0.57±0.18 (+5d) vs 1.54±0.16), $p<0.05$]. Transfer of labeled isolated mitochondria (mitotracker dye) signal was found in spleen (in macrophages) and kidney (in PT, identified with anti-CD13 antibody [labels brush border]). The +3d mitochondria treated kidneys had significantly lower levels of Acta and Col3a1 and significantly higher PGC1α gene expression compared to vehicle treated mice at day 14. *In vitro* studies demonstrate that treatment of TKPTS with mitochondria had significantly higher levels of ATP, higher basal oxygen consumption rate and spare respiratory capacity measured by Seahorse analyzer.

Conclusions: Our current study demonstrates that up take of healthy mitochondria by PT helps maintain bioenergetics through upregulation of mitochondria biogenesis gene, PGC1α. Treatment to mice with established AKI with mitochondria attenuates progression to fibrosis compared to vehicle treated mice. Mitochondria could be used as a therapeutic modality to lessen progression of AKI to CKD.

Kidney Injury Under Oxidative Stress Release CD36 and CD47 Microparticles

Begoña Campos,[1] Samuel P. Bockhorst,[1] Keith L. Saum,[1] Charuhas V. Thakar.[1,2] Kidney Injury Translational Research Group *[1]University of Cincinnati, Cincinnati, OH; [2]Renal Section, Cincinnatin VAMC, Cincinnati, OH.*

Background: Kidney epithelial cell damage is the major cause of acute kidney injury (AKI). Thrombospondin 1 (TSP-1) is released by renal epithelial cells and mediates kidney damage in murine ischemia reperfusion injury (IRI). TSP-1 exerts its inflammatory modulating effects through signaling of CD36 (pro-inflammatory) and CD47 (anti-inflammatory) ligands. Given that CD36 reduces angiogenesis, and stimulates VEGF induced migration and apoptosis, whereas CD47 stimulate angiogenesis, these ligands may play a role in epithelial to endothelial cross-talk. We hypothesized that in both *in vivo* murine models of IRI and *in vitro* models of oxidative stress to human renal epithelial cells (h-RPTEC), CD36 and CD47 proteins will be released as MP significantly when compared to control.

Methods: h-RPTEC line was used and oxidative stress (induced by adding 0.03 mM of H_2O_2 for 1hr) was evaluated for MP release and apoptosis compared to controls. IRI was performed in C57BL/6 mice by renal pedicle clamp for 30 minutes followed by reperfusion compared to sham. Animals were euthanized at 48 hrs. Histology was performed by standard techniques to evaluate kidney damage. Citrate poor plasma was collected at 0, 12, 48 hrs to measure urea (BUN). MP were measured with flow cytometry and were reported at 10^5 /ml and analyzed by flow jo software. Unpaired t test Welch's correction were used for comparisons.

Results: h-RPTEC contained CD36 and CD47 receptors in the cellular membrane, confirmed by immunohistochemistry. Upon exposure to H_2O_2, cell viability study showed 25% apoptotic, 15% in necrotic and 60% viable. A a significant increase of release of MP was observed for CD36 vs control (2.7 $X10^5$ MP/ml vs. 0.73 $X10^5$ MP/ml; p=0.001); and for CD47 vs control (31.84 10^5 MP/ml vs 2.51 10^5 MP/ml; p=0.001). For *in vivo* studies, compared to sham, IRI mice showed that MP containing CD36 were released at 12 hr and remained elevated at 48 hr. In contrast, CD47 showed an increase at 12 hrs and returned towards baseline by 48 hr. Analysis of percent expression showed that CD36 expression increased with time compared with CD47.

Conclusions: In murine and in vitro models of oxidative stress CD36 and CD47 are released as MP. Given the role of TSP-1 and other thrombomodulins in AKI, MP may serve as ligands to both potentiate epithelial cell injury as well as mediate cross-talk between epithelium and endothelium.

SA-PO567

Microparticles Can Phenotype Ischemic and Nephrotoxic AKI

Begoña Campos,[1] Samuel P. Bockhorst,[1] Keith L. Saum,[1] Charuhas V. Thakar.[1,2] Kidney Injury Translational Research Group *[1]University of Cincinnati, Cincinnati, OH; [2]Renal Section, Cincinnati VAMC, Cincinnati, OH.*

Background: Acute tubular necrosis is the major cause of acute kidney injury (AKI), occuring due to ischemia reperfusion injury (IRI) or nephrotoxicity (NT); however, it cannot be differentiated by biochemical or histological parameters. Although biomarkers allow earlier identification of AKI, they cannot discriminate cause-specificity, leading to impediment in translating novel therapies. Our prior work confirmed that CD10, CD13 and CD146 proteins on renal epithelial cells are released as microparticles (MP) upon exposure to oxidative or inflammatory stress. We evaluated whether these MP can discriminate IRI or NT in murine models.

Methods: In C57BL/6 mice, IRI was performed by clamping both renal pedicles for 30 minutes followed by reperfusion and NT was induced by injecting intraperitoneal (IP) Cisplatin at 20 mg/kg. Sham mice underwent surgery without clamp in IRI and IP normal saline in NT. Mice were euthanized at 48 hrs and examined by standard techniques for renal histology. Citrate poor plasma was collected at 0, 12, 48 hrs. Blood urea nitrogen (BUN), neutrophil gelatinase associated lipocalin (NGAL); and MP containing CD10, CD13 and CD146 were measured using flow cytometry and analyzed by flow jo software. MP were expressed as 10^5/ml, and compared within each model over time, and across models by Chi-square tests.

Results: AKI was confirmed in IRI and NT samples by histology, BUN and NGAL levels at 48 hrs. In IRI (48 hrs), CD10 and CD13 MP increased by 1.77 and 1.5 fold respectively, but CD146 declined by 1.7 fold from baseline. In contrast, NT model showed decline of MP quantity at 48 hrs relative to baseline in CD10, CD13 and CD146 by 1.5, 1.5 and 3.6 fold respectively. When examined across the models, then proportion of MP released at 48 hrs in IRI were 64% CD10, 6% CD13 and 30% CD146. Interestingly NT model showed distinctly different proportions: 6% CD10, 18% CD13 and 76% CD146 quantitatively. ($p<0.0001$ for comparison across models)

Conclusions: Despite similar biochemical, histological and biomarker parameters, MP quantity changed over time differently in each model. More importantly, the pattern of MP proportions almost switched across IRI and NT models, allowing discrimnation of ischemic and toxic cell injury. MP measured in plasma can phenotype AKI based on cause-specificity and can lead to development of novel diagnostic or therapeutic strategies.

β-Hydroxybutyrate Attenuates Renal Ischemia-Reperfusion Injury Through Its Anti-Pyroptotic Effects via Epigenetic Mechanism

Takaya Tajima,[1] Ayumi Matsui,[1] Tomoaki Ito,[1] Kiyotaka Uchiyama,[3] Shu Wakino,[2] Hiroshi Itoh.[4] *[1]Keio medical university, TOKYO, Japan; [2]Keio University, Tokyo-to, Japan; [3]Keio University, School of Medicine, Tokyo, Japan; [4]Keio University School of Medicine, Tokyo, Japan.*

Background: An endogenous ketone, β-hydroxybutyrate(β-OHB) is used as an energy source in various organs including kidney and has therapeutic benefits against stress conditions. In this study, we evaluated its protective effects and potential mechanisms in renal ischemia/reperfusion injury(IR).

Methods: Male C57BL/6J mice undetook heminephrectomy and separated into 4 groups: saline-treated sham-operated mice (Sham: n=6), β-OHB-treated sham mice (Sham+β-OHB ; n=6), saline-treated mice with IR (IR; n=8), β-OHB-treated mice with IR (IR+β-OHB; n=8). In IR injury mice were subject to clamping of both renal arteries and veins for 45 min and to reperfusion. β-OHB was administered continuously by osmotic mini-pump at the dose of 8 mg/h. Kidneys were harvested 24 h after IR injury, and functional and molecular parameters were evaluated. In vitro studies, HK-2 cells were incubated for 1 h with mineral oil to induce hypoxic injury, and incubated for 24 h after medium replacement. These HK-2 cells were treated with various doses of β-OHB and molecular parameters were evaluated.

Results: In IR mice, blood urea nitrogen, serum creatinine levels, and renal tissue injury scores were significantly higher than those in control mice. These values were significantly lowered in IR+β-OHB group. β-OHB treatment significantly reduced the TUNEL-positive cell number and increased FOXO3 and its downstream target molecule, apoptosis repressor with caspase recruitment domain (ARC) expressions. Although β-OHB unchanged the apoptotic markers, it decreased the expressions of caspase-1, the proinflammatory cytokines interleukin (IL)-1β and IL-18 in IR-injured kidneys, indicating that β-OHB blocked pyroptotic cell death rather than apoptotic cell death. In HK-2 cell subject to hypoxic insult, β-OHB reduced the number of cell death through the inhibition of pyroptosis pathway in FOXO3-dependent fashion. Histone acetylation deceased in IR mice and in hypoxic HK-2 cells through the inactivation of histone acetyltransferase activity. This reduction was ameliorated by β-OHB through the inactivation of histone deacetylase.

Conclusions: β-OHB attenuates renal IR injury by its anti-pyroptotic effect through its epigenetic effects on FOXO3 expression.

Regulation of Fibronectin Splicing with Antisense Oligonucleotides in an Aristolochic Acid Model of AKI to CKD

Pritpal S. Virdee,[1] Mark E. Dockrell,[3] Mysore K. Phanish.[2] *[1]South West Thames Institute For Renal Research, London, United Kingdom; [2]Epsom and St helier University Hospitals NHS Trust, Carshalton, London, United Kingdom; [3]South West Thames Institute for Renal Research, Surrey, United Kingdom.*

Background: Extra Domain A Fibronectin (EDA+FN) is an active glycoprotein present at sites of fibrosis and is produced through post transcriptional alternative splicing of mRNA. Bonventre et al have previously described an early peak at 3 hours with significant fall in EDA+FN at 6 weeks post ischaemia reperfusion injury. We developed a murine model of aristolochic acid nephropathy (AAN) exhibiting acute to chronic progression and investigated the effects of RNAse H-Independent ASO on EDA+FN expression and subsequent impact on markers and mediators of tubulointerstitial fibrosis.

Methods: In a short model of AAN, CD1 mice aged 10 weeks received subcutaneous (SC) PBS (n=6), RNAse H-independent negative control (NC-ASO, n=6) or target antisense (T-ASO, n=6) at 50mg/kg at day -1 followed by one dose of intraperitoneal (IP) AA 3.5mg/kg on day 1 for each arm, mice culled at day 3. In the long model they were injected with IP AA 3.5mg/kg on days 1 and 5 followed by SC PBS (n=6) or 50mg/kg NC-ASO (n=12) or T-ASO (n=12) at day -1 and 3 and then weekly injections until day 96. Whole kidney tissue was extracted and RNA analysis undertaken using RT PCR.

Results: In the short model KIM1, CD68 and EDA + FN mRNA expression was significantly increased at 48 hr post AA compared to Day 0 ($p<0.05$). T-ASO reduced EDA+FN mRNA significantly compared to NC-ASO ($p<0.0001$) with no effect on CD68 or KIM1. TGFβ1 expression was downregulated by T-ASO ($p<0.05$). In PBS arm of the long model at day 96, compared to day 0 there was statistically significant increase in mRNA expression of EDA+FN, EDA-FN, TGFβ1, LTBP1, MMP2, MMP9, αSMA, KIM1 and Coll1a1. At day 96, T-ASO resulted in significant knock down of mRNA expression of EDA+FN, TGFβ1and LTBP1 compared against NC-ASO with no effect on expression of αSMA, Coll1a1, MMP2 or KIM1.

Conclusions: In this model of AAN we have demonstrated increased mRNA expression of EDA+FN in the early phase but also sustained at day 96. We have demonstrated the ability to knockdown EDA+FN mRNA at both time points and also noted knockdown of TGFβ1 and LTBP1 mRNA with our target antisense suggesting a functional interaction. Antisense did not have an effect on markers of AKI or other mediators of fibrosis. Further analysis of samples with immunohistochemistry will help determine whether T-ASO has an impact on attenuation of fibrosis in this model.

SA-PO570

Inhibition of CXCR3 Expression Through Blockade of STAT3 Alpha Signaling Down-Regulates Inflammation of Renal Ischemia-Reperfusion Injury

Jae Yoon Park,[1] Kyung Don Yoo,[4] Sung joon Shin,[1] Kyung Soo Kim,[1] Yon Su Kim,[3] Seung Hee Yang.[2,3] *[1]Dongguk University Ilsan Hospital, Gyeonggido, Republic of Korea; [2]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [3]Seoul National University College of Medicine, Seoul, Republic of Korea; [4]Dongguk University Gyeongju Hospital, Gyeongju-si, SEOUL, Republic of Korea.*

Background: Signal transducer and activator of transcription 3 (STAT3) is the main mediator of interleukin 6 (IL-6)–type cytokine signaling. Although it exists in two isoforms: the full-length STAT3α and the truncated STAT3β, their role in acute kidney injury is not clarified. We investigated their relative function through inhibiting STAT3α in ischemia-reperfusion (IR)-induced renal inflammation.

Methods: IR injury was induced in B6 wild type mice. Stattic (a nonpeptide small molecular inhibitor of STAT3 activation and dimerization) was treated 3 hours prior to IR injury. We quantified intrarenal cytokine expression using real-time PCR and performed FACS analysis. We cultured human tubular epithelial cells (TECs) in hypoxic condition and evaluated the effect of Stattic treatment. We detected the isoforms of phosphorylated STAT3 using western blot analaysis.

Results: IR injury produced more severe tubular damage in control group than in Stattic-treated mice (serum creatinine, 2.2±0.1 versus 1.6±0.1 mg/dL, $p<0.05$). Although inflammatory cytokines/chemokines, such as IL-6, total STAT3, STAT3α, CXCR3, IL-10 and TGF-β were increased by IR injury in control group, they were attenuated in Stattic-treated mice. Apoptosis of TECs and infiltration of mononuclear cells and macrophages were decreased and the expression of STAT3α as well as total STAT3 was reduced in Stattic-treated mice. These findings were supported by in-vitro study with human TECs. Whereas the level of pSTAT3α was elevated in the hypoxia-conditioned TECs and it was decreased in Stattic-treated cells, the level of pSTAT3β was not changed in both cell groups. The expression of CXCR3 was decreased in accordance to the STAT3α decrease and the supernatant levels of IL-6 and IL-8 were decreased in Stattic-treated cells.

Conclusions: We demonstrated that the activation of STAT3 is associated with progression of IR injury and the α-isoform may contribute as major player. These mechanisms of STAT3/CXCR3 signaling according to each isoforms suggest a novel strategy for management of AKI with STAT3 inhibitor.

SA-PO571

PHD Inhibition Reduces Reactive Oxidative Stress in In Vitro Ischemia Model

Marie Ito,[1] Tetsuhiro Tanaka,[2] Takeshi Wakashima,[3,1] Masaomi Nangaku,[2] Kenji Fukui.[3] *[1]the University of Tokyo graduate school of medicine, Tokyo, Japan; [2]the University of Tokyo School of Medicine, Tokyo, Japan; [3]Biological and Pharmacological Research Laboratories, Central Pharmaceutical Research Institute, Japan Tobacco Inc., Osaka, Japan.*

Background: Hypoxia-inducible factor (HIF) is widely accepted to mediate the protection by hypoxic preconditioning in both *in vitro* and *in vivo* ischemia models but the underlying mechanism remains unknown. Prolyl hydroxylase domain proteins (PHDs) serve as main HIF regulator via hydroxylation of HIF-α leading to its degradation. Several PHD inhibitors, including enarodustat are now under clinical trials as treatment for renal anemia and the beneficial effect might go far beyond.

Methods: We investigated the role of PHD inhibition in oxygen-glucose deprived (OGD) model of human renal tubular cells (HK2) as an *in vitro* model of renal ischemia. Enarodustat or siRNA knockdown of PHD isoforms was used to study the impact of PHD inhibition on cytoprotection and ROS. Cell viability and ROS were measured using the Muse™ Count & Viability Assay Kit and Oxidative Stress Kit according to the manufacturer's instructions. mRNAs for antioxidative genes (GPX1, catalase, SOD1, SOD2, HO-1 and NQO1) were quantified by real-time PCR. Specific effects of HIF isoforms and respective antioxidative genes were studied using siRNA knockdown series. The role of autophagy was evaluated with Atg7-KO cells.

Results: Enarodustat treatment and siRNA knockdown of PHD2, but not of PHD1 or PHD3, significantly increased cell viability and reduced reactive oxygen species (ROS) levels by HIF stabilization. These effects were offset by simultaneous knockdown of HIF-α isoforms. HIF-1α alone could confer protection in both viability and ROS levels, while the contribution of HIF2 was only evident in combination with HIF1, with a larger role in viability. As candidate mechanisms for ROS elimination, we examined the role of autophagy and antioxidants. Autophagy reduces ROS by degrading damaged mitochondria in several models. However, in our OGD model cell death and ROS were not increased in Atg7-KO cells. Next we measured the mRNA levels of antioxidants and among them superoxide dismutase 2 (SOD2) and heme oxygenase-1 (HO-1) are significantly increased in enarodustat-treated cells. While SOD2 knockdown had little effect, HO-1 knockdown partially abrogated the cytoprotection and ROS reduction by PHD inhibition.

Conclusions: HIF stabilization by PHD inhibition increased cell viability and decreased ROS levels, and HO-1 partially mediated the effect.

SA-PO572

Hypoproteic Diet During Pregnancy and/or Lactation Differentially Affects the Response of the Offspring to an Episode of AKI

Luis E. García-Ortuño,[1,2] Jonatan Barrera-Chimal,[1] Rosalba Pérez-villalva,[1,2] Juan A. Ortega-Trejo,[1,2] Ixchel Q. Lima Posada,[1,2] Luis A. Reyes castro,[3] Norma Bobadilla.[1,2] *[1]Molecular Physology Unit, Mexico City, Mexico; [2]INCMNZS-UNAM, Mexico City, Mexico; [3]INCMNSZ, MEXICO, Mexico.*

Background: Protein restriction during pregnancy induces morpho-functional alterations related to deficient nephrogenesis. We studied the renal functional and morphological significance of protein restriction during pregnancy (Preg), lactation (Lact) or both, in the adult stage of the offspring and their repercussion on the AKI severity.

Methods: Female rats were randomly assigned to the following groups: C = standard diet, (SD) during Preg and Lact; CR = SD during Preg and protein restriction diet (PR) during Lact; RC = PR during Preg and SD during Lact and RR = PR during Preg and Lact. Three months after birth, at least twelve male offspring of each group underwent randomly to bilateral renal ischemia for 45 min (IR) or sham surgery. Thus, eight groups were studied 24 h after reperfusion: C, C+IR, CR, CR+IR, RC, RC+IR, RR and RR+IR.

Results: The CR, RC, and RR groups exhibited a significant reduction by ≈ 15% in the nephron number that was associated with a reduction in renal blood flow (RBF). In spite of this, glomerular hypertrophy was observed together with a significant reduction in endothelin, angiotensinogen and their receptors, as well as catalase and GPx mRNA levels. In the next table appears the % change in renal function and vasoactive factors mRNA levels after the IR injury compared to their respective control group.

Conclusions: During basal conditions, the lesser nephrons observed in the offspring of protein-restricted mothers was associated with glomerular hypertrophy and reduced expression in vasoconstrictor factors. The ischemic insult in these groups induced a differential vasoconstrictor response that allowed a faster recovery in RBF, as compared to control group. These results suggest that CR, RC and RR groups respond better to an ischemic insult and most likely to the long-term consequences of AKI.

Hypoxia Induces Ligand-Receptor Interactions to Mediate Exosome Targeting to Endothelial Cells in AKI

Jose L. Vinas,[2] Matthew Spence,[2] Alex Gutsol,[5] Dylan Burger,[2] Joe A. Zimpelmann,[4] David Allan,[3] Kevin D. Burns.[1] *[1]Medicine, Kidney Research Centre, Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada; [2]Medicine, Kidney Research Centre, Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada; [3]Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada; [4]Kidney Research Centre, Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada; [5]Kidney Research Centre, Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada.*

Background: Intravenous (i.v.) injection of exosomes derived from human endothelial colony forming cells (ECFCs) leads to selective targeting of the kidneys after ischemic injury in mice, along with increased miR-486-5p levels. Mechanisms mediating recruitment of exosomes are unclear. We previously showed that exosomes express CXC chemokine receptor type 4 (CXCR4), and a neutralizing antibody to stromal cell-derived factor (SDF)-1α prevented exosome uptake into normoxic endothelial cells. Here, we determined if exosomes transfer miR-486-5p to endothelial cells and nephron segments after kidney ischemic injury, and further explored the role of the CXCR4/SDF-1α interaction.

Methods: Ischemia-reperfusion kidney injury was induced in mice by renal vascular clamp, with or without i.v. infusion of ECFC exosomes. Kidneys were removed 30 min after reperfusion, and endothelial cells were isolated by enzymatic digestion and sorting using CD31-labeled magnetic beads, followed by PCR for miR-486-5p. Proximal tubules and glomeruli were microdissected. Human umbilical vein endothelial cells (HUVECs) were exposed to hypoxia to study the role of CXCR4/SDF-1α interaction.

Results: Infusion of ECFC exosomes increased kidney cortical levels of miR-486-5p at 30 min after reperfusion ($P<0.05$; n=4). Exosomes significantly increased miR-486-5p levels in endothelial cells, proximal tubules, and glomeruli ($P<0.05$ vs ischemia-reperfusion alone; n=4). PKH26-labeled exosomes were detected mainly in the tubulointerstitial compartment of the kidney 30 min after infusion. In HUVECs, hypoxia increased secreted levels of SDF-1α and enhanced exosome uptake. Incubation with neutralizing antibody to SDF-1α or the CXCR4 inhibitor Plerixafor blocked exosome uptake into hypoxic HUVECs (n=4). Hypoxia also increased uptake of exosomal-derived Cy3-labeled miR-486-5p, which was inhibited by either neutralizing antibody to SDF-1α or Plerixafor (n=4).

Conclusions: ECFC exosomes target endothelial cells, proximal tubules, and glomeruli in ischemic kidneys, with transfer of miR-486-5p. Selective targeting of ischemic kidneys by exosomes may involve an interaction of exosomal CXCR4 with hypoxia-induced SDF-1α in endothelial cells. These data provide further support for the promising therapeutic potential of ECFC exosomes in human acute kidney injury.

Fibroblast mTORC2/PPARγ-Dependent HGF Production Protects Against Tubular Cell Death and AKI

Gui Yuan, Chunsun Dai. *Nanjing medical university, Nanjing, China.*

Background: Kidney interstitial fibroblasts play a crucial role in dictating tubular cell fate and the outcome of acute kidney injury (AKI). However, the underlying mechanisms remain to be further determined.

Methods: Mouse model with inducible Rictor gene deletion in fibroblast was generated. Kidney ischemia/reperfusion injury was employed to induce acute kidney injury in mice.

Results: Here, we found that Rictor/mTORC2 signaling was activated in mouse kidney interstitial fibroblasts after ischemia/reperfusion injury (IRI). Ablation of Rictor in fibroblasts led to more severe kidney dysfunction and morphological damage in mice after IRI compared to their littermate controls. More tubular cell apoptosis and inflammatory cell accumulation were detected in the knockout kidneys after IRI. In *in vitro*, a co-culture system between fibroblasts and tubular cells was generated. Blockade of Rictor/mTORC2 signaling in fibroblasts with Rictor gene ablation or pharmacological inhibition facilitated staurosporine-induced tubular cell death. In addition, blocking fibroblast mTORC2 signaling could downregulate its peroxisome proliferator-activated receptor gamma (PPARγ) and hepatocyte growth factor (HGF) expression, as well as attenuate c-met signaling activation in tubular cells. Moreover, activation of fibroblast PPARγ could augment HGF expression and attenuate tubular cell death. Notably, in mouse kidneys, ablation of fibroblast Rictor reduced the PPARg and HGF expression. The tyrosine phosphorylation of HGF receptor c-met was also diminished in the knockout kidneys after IRI.

Conclusions: Together, these data suggests that Rictor/mTORC2 signaling activation in kidney interstitial fibroblasts may protect against tubular cell death and dictate the outcome of acute kidney injury through PPARγ-stimulated HGF production.

Funding: Government Support - Non-U.S.

Cultured Renal Tubular Epithelia in Migration Develop 3 Forms of Filopodia Having an Inherent Short Diameter: A Scanning Electron Microscope (SEM) Study

Kiyoko Inui,[1] Hiroyuki Morita,[2] Yoshihiko Inoue,[1] Yoshinori Sato,[1] Eri Kawashima,[1] Ashio Yoshimura,[3] Fumihiko Koiwa.[1] *[1]Showa University Fujigaoka Hospital, Yokohama, kanagawa, Japan; [2]Aichi Medical University School of Medicine, Nagakute, Japan; [3]Shinyokohama Daiichi Clinic, Yokohama, Japan.*

Background: Renal tubular epithelial regenerate themselves after severe injuries as exemplified in acute kidney injury (AKI), when cell migration plays a crucial role. Studies have demonstrated that formations of filopodia are pivotal in cell migration. However, ultrastructure of cells with filopodia in migration largely remains to be seen. In this study, we use scanning electron microscope (SEM), and report fine ultrastructural images of filopodia that tubular epithelia form in cell migration.

Methods: Rat renal epthelialia, NRK-52E, were grown to confluence, and then, scratched or subcultured. At various time points until the next 100% confluence, they were fixed and subjected to SEM analysis. Filopodia were found in the specimens almost without exceptions. 20 different areas were randomly picked up to measure the short and long diameters of filopodia.

Results: Major findings of this study were 1) Filopodia were classified into 3 groups: having A(32±9)nm, B(108±16) nm, and C(155±21) nm short diameters. 2) Typically, the ratio of the short diameter to the long diameter in A, B, and C were 1:70, 1:150, and 1:400, respectively. 3) Group C filopodia were the major one when the cells were directionally migrating at >70% confluence. Interestingly, Group C filopodia was seen after the cells were grown to confluence (Figure). Appearances of Group A filopodia were rare.

Conclusions: Our ultrastructural study identified 3 forms of filopodia, although reciprocal relationship among them remained to be elucidated. Each one was associated with cell migration. We propose a hypothesis that group C filopodia play a role in learning the position of a cell in relation to adjacent ones.

3D Organellar Morphological Dynamics in Kidney Tissue Using SIM Super-Resolution Microscopy

Kensei Taguchi,[1] Craig R. Brooks.[2] *[1]Vanderbilt University Medical Center/Division of Nephrology & Hpertension, Nashville, TN; [2]Vanderbilt University Medical Center/Division of Nephrology & Hpertension, Nashville, TN.*

Background: Organellar dynamics, mitochondrial morphology, endoplasmic reticulum (ER) morphology and autophagosome formation, are key components in the pathology of kidney disease. Imaging organellar dynamics in isolated cells has been a cornerstone to our understanding of cellular biology. Visualizing changes in these organelles in kidney tissue, however, remains difficult and largely limited to electron microscopy (EM), which provides a very narrow two dimensional image of the cellular/organellar structure. Thus, our understanding of organelle structure *in vivo*, and how this structure changes with disease, remains limited. Here, we investigate whether structured illumination microscopy (SIM) could be used to visualize three dimensional organellar dynamics in kidney tissue.

Methods: Human biopsies or kidneys from sham, aristolochic acid- or ischemic reperfusion-injured C57BL/6 mice were fixed and paraffin embedded following standard protocols. Sections of the kidneys were mounted on silane-treated coverslips and stained for intracellular organelles markers, and then imaged by Nikon N-SIM microscope. Kidney tissue was co-stained for markers of kidney injury, such as kidney injury molecule 1 (KIM-1)

and markers of the cell cycle. Changes in organelle structure were quantified with Imaris software.

Results: SIM reveals a dramatic increase in the number and size of autophagosomes in injured tubular cells marked with KIM-1. Likewise, the ER morphology is significantly altered in injured kidneys. Mitochondrial morphology was found to be far more complex than suggested by EM. 3D rendering of the mitochondria demonstrates that within one cell in uninjured kidneys the mitochondrial network is nearly continuous. After injury, this network breaks down into many smaller mitochondria. Importantly, SIM analysis of human kidney tissue exhibits dramatic changes in mitochondrial and other organelle structures.

Conclusions: SIM imaging provides a novel approach to analyze organellar dynamics and interfaces of organelles in kidney tissue and enables a 3D morphological analysis. KIM-1 staining is associated with increased autophagy and mitochondrial fragmentation. When combined with Injury or other markers SIM imaging can help delineate the pathways involved in organelle dynamics *in vivo* in human disease or animal models.

SA-PO577

A Novel 3D Cell Model That Mimics Renal Tubular Injury and Repair

Shuan Zhao,[1] Jiachang Hu,[2] Xialian Xu.[3] *[1]Zhongshan hospital, Fudan University, Shanghai, China; [2]Zhongshan hospital of Fudan University, Shanghai, China; [3]Zhongshan Hospital, Fudan University, Shanghai, China.*

Background: Acute kidney injury (AKI) is a major health problem with high morbidity and mortality. Despite decades of research, there is still no specific therapy for AKI. To develop targeted therapies to prevent or treat AKI, a basic prerequisite is a clear understanding of how cells repair injured kidney. When epithelial cells in the proximal portion of the nephron are damaged they rapidly proliferate to repair the damage to the kidney. Here, we developed a novel 3D culture model of AKI and, in a key insight, looked for genes that were involved in injury and repair.

Methods: A mosaic MDCK cysts were cultured in Matrigel and damaged at Day 7. During cysts repairing, total RNA of MDCK cells at indicated stages were extracted, purified and concentrated. After microarray analysis, genes that significantly expressed were selected, and verified in mouse ischemic reperfusion injury model at multiple time points by qRT-PCR.

Results: In our 3D culture system, cysts with monolayer of highly polarized cells were formed at Day6. Sectional cells in mosaic cyst could be induce apoptosis by oligomerization of a membrane localized, truncated form of caspase 8 and thereby cause damage to the cysts. Intriguingly, the remaining cells in the damaged cysts were able to re-enter the cell cycle, and restore the cysts to their pre-apoptotic state. Microarray analysis highlights a cascade of temporal-specific gene expression patterns related to tubular injury/repair. Seven genes that involved in cell junction and adhesion were selected and verified in animal AKI model. Three of those genes were significantly upregulated at 24h after IRI, two of those genes were dramatically reduced after IRI, and one gene's expression has no change before 48h.

Conclusions: Using this 3D cell model of AKI, we have generated a list of gene candidates. Seven genes that related to cell junction and adhesion were identified, and expression patterns were similar between cell and mouse AKI model at multiple time points.

Mitigation of AKI in Mice Using DNase I Inhibitor

Todd Fite,[1] Alena Savenka,[1] Alexei G. Basnakian.[1,2] *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]Central Arkansas Veterans Healthcare System, Little Rock, AR.*

Background: Our previous studies showed that genetic inactivation of the most active kidney apoptotic endonuclease, DNase I, was partially protective against tubular epithelial cell death induced by hypoxia-reoxygenation or cisplatin. Our recent discovery of the first pharmaceutically meaningful DNase I inhibitor, IG-17, provides an opportunity for the development of first anti-DNase drug mitigating acute kidney injury (AKI).

Methods: *In vitro* experiments using kidney tubular epithelial NRK-52E cells showed that IG-17 was able to suppress DNase activity inside the cells, and provided partial protection against hypoxia-reoxygenation, cisplatin or hemin toxicity measured using LDH release assay and TUNEL.

Results: The absence of IG-17 toxicity in mice at 1, 5 or 25 mg/kg was shown by 14 blood plasma assays for organ function. AKI experiments were done in male and female mice subjected to bilateral kidney 50-min ischemia followed by 24-h reoxygenation, or injected with cisplatin (20 mg/kg, IP), or glycerol (50% solution, 8 ml/kg, IM). Kidney failure was measured by serum creatinine and BUN. Structural kidney damage was assessed by acute tubular necrosis and TUNEL. In all three *in vivo* models, SC or IP injections of IG-17 (5 mg/kg) were either partially (ischemia-reperfusion, cisplatin) or fully protective (glycerol).

Conclusions: The results of this study suggest that IG-17 has a promise as the first non-toxic anti-DNase agent for mitigation of AKI.

SA-PO579

Inhibition of BRD4 with MS417 Lessens the Inflammatory Response Following Ischemia Reperfusion Injury

Shelby Reid,[1] Xiaohua Zhou,[2] Rohan John,[3] James W. Scholey.[2] *[1]Institute of Medical Science, University of Toronto, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]University Health Network, Toronto, ON, Canada.*

Background: A key regulator of the immune and inflammatory response is the NFκB// Rel protein family. A variety of stimuli, including ischemia reperfusion injury (IRI), activate the NFκB signalling cascade which stimulates the transcription of genes primarily involved in immune and inflammatory response. A key regulator of NFκB transcription is BRD4 which binds to acetylated RelA leading to the recruitment and activation of CDK9, subsequently resulting in the phosphorylation of RNA polymerase II and the transcriptional activation of NFκB target genes. The key role of BRD4 in transcription has led to the development of small molecule inhibitors that competitively bind to the acetylated RelA. One inhibitor, MS417, has shown promise in attenuating injury in different models of kidney injury, but has yet to be analyzed in a model of ischemia reperfusion injury.

Methods: Male C57BL/6 mice were treated with 1 μM of MS417 or vehicle via oral gavage daily for 7 days before unilateral IR was performed by clamping off the renal artery for 45 minutes followed by reperfusion. Daily treatment was continued until the time of sacrifice when tissue was collected for immunohistochemistry (IHC) and PCR analysis. Fixed kidney tissue was paraffin-embedded, sectioned, stained with periodic acid–Schiff (PAS) and scored for glomerular injury as well as for infiltrating neutrophils in a blinded manner. RNA was extracted from snap-frozen kidney tissue and was reverse transcribed into cDNA which was subsequently used in quantitative polymerase chain reaction.

Results: IHC staining for tubular injury and neutrophil infiltration showed a marked increase in the control group (treatment with saline) when compared to shams (no IRI). Treatment with MS417 prior to IR resulted in a lower trend in both injury and neutrophil infiltration. Administration of MS417 further suppressed the increase of the transcript levels of the proinflammatory markers C-C Motif Chemokine Ligand 2, Interleukin-1β, and Interleukin-6 by approximately 50%.

Conclusions: Treatment with the BRD4 inhibitor, MS414, prior to IR resulted in reduced tubular injury and neutrophil recruitment as well as reduced expression of proinflammatory genes. Further analysis of MS417's specificity and role in lessening the inflammatory response following IR is required.

PMMA-Based Continuous-Adsorbitive-Hemofiltration Abrogated Complement Activation and Tubular Senescence-Associated Secretory Phenotype (SASP) in LPS-Induced AKI

Giuseppe Castellano,[1] Alessandra Stasi,[1] Chiara Divella,[1] Rossana Franzin,[1] Fabio Sallustio,[1] Claudia Curci,[1] Angela Picerno,[2] Claudio Ronco,[3] Vincenzo Cantaluppi,[6] Massimo de Cal,[4] Mauro Neri,[4] Anna Lorenzin,[5] Giovanni B. Pertosa,[1] Loreto Gesualdo.[1] *[1]University of Bari, BARI, Italy; [2]University of Bari "Aldo Moro", Bari, Italy; [3]Ospedale "S. Bortolo" AZ. ULSS 6, Vicenza, Italy; [4]San Bortolo Hospital, Vicenza, Italy; [5]IRRIV, Vicenza, Italy; [6]University of Piemonte Orientale (UPO), Novara, Italy.*

Background: During sepsis-induced AKI, inflammatory mediators could induce a maladaptive response in tubular epithelial cells (TEC). Hemofeel (TORAY, Japan) is a PMMA membrane based hemofilter indicated for blood purification therapies in continuous modality (CRRT), combining filtration and adsorption.

Methods: After 3h from LPS infusion, 8 pigs (female, 40-50 Kg) were treated with PMMA-CVVH (CH-1.8 W series), working in post-dilution modality (time =7 hours; Qb= 150 ml/min; Effluent rate =2000 ml/h; Substitution Rate = 2000 ml/h; UF rate = 0 ml/h). 8 control pigs received no treatment and developed endotoxemia-induced oliguric AKI. Renal biopsies were collected at 24h and analyzed by IHC and IF. Systemic Complement activation was evaluated by Wieslab kit. In vitro, tubular epithelial cells (TEC) were stimulated with LPS (4μg/ml) for 24h and then analyzed for SASP markers (p53, p21, cyp1b1, Klotho) by qPCR.

Results: A significant activation of Complement classical and alternative pathways was observed at 3h and 24h after LPS infusion. Histological and Confocal analysis revealed extensive Pentraxin-3 and collagen deposits at the interstitial level, along capillaries with diffuse glomerular thrombi compared to healthy pigs (T24LPS vs T24CTR, $p < 0.05$). Interestingly, we found significant TEC senescence with increased $p16^{INK4a}$ expression (IHC T24LPS vs T24CTR $p < 0.05$). PMMA-CVVH treatment significantly reduced Complement activation and antagonized SASP by restoring $p16^{INK4a}$ basal expression (T24LPS vs T24PMMA $p < 0.05$). In accordance, LPS stimulation of TEC (24h) in vitro induced accelerated senescence by up-regulating p53, p21, cyp1b1 (2-DDCT: LPS: 4.3 ± 0.63 vs Basal: 1 ± 0.00, $p < 0.05$) and reducing Klotho expression ($p < 0.05$).

Conclusions: Endotoxemia can induce AKI with systemic Complement activation leading to the development of SASP phenotype in TEC. PMMA treatment might be a new therapeutic approach to prevent Complement activation in LPS-induced AKI.

SA-PO581

The Stabilizing Effect of Dipeptidyl Peptidase-4 Inhibitors on the Epithelial Barrier in the Colistin-Induced Tubular Injury

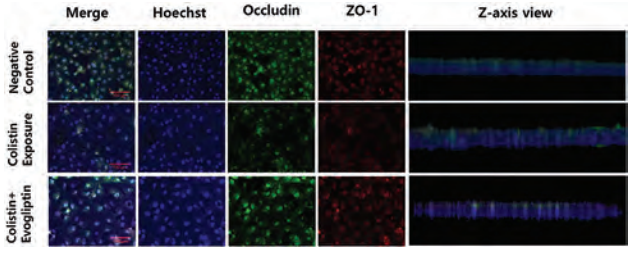
Ji Young Ryu,[1] Kipyo Kim,[1] Hyung Eun Son,[1] Ho Jun Chin,[1,2] Sejoong Kim.[1,2] *[1]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [2]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Recently, dipeptidyl peptidase-4 inhibitors (DPP4i) have been identified to have some pleiotropic effects in different kidney diseases including diabetic kidney disease, ischemic acute kidney injury. In terms of pathophysiology, few studies have examined the effects of DPP4i on the epithelial barrier in drug-induced acute kidney injury. The increased tubular epithelial cell permeability and barrier dysfunction have been shown in previous studies regarding colistin-induced nephrotoxicity. This study was performed to evaluate the renoprotective effect of DDP4i in colistin-induced tubular injury using a two-layered kidney-on-a-chip device.

Methods: The kidney-on-a-chip device consists of upper and lower channels mimicking intraluminal space and interstitial space. Kidney tubular epithelial cells were seeded into upper channel and exposed to colistin at a concentration of 400 μg/ml for 48 hours under physiological shear stress condition (1 dyn/cm^2). Evogliptin (Suganon®, Dong Ah Pharm., Korea) was administered to the lower channel at a concentration of 50 nM for 48 hours. Transmembrane permeability, tight junction protein expression, cell viability, and tubular injury marker, kidney injury molecule-1 (KIM-1), in outlet-collected media were evaluated in evogliptin-treated and control groups.

Results: After colistin treatment, transmembrane permeability increased from 6.75% to 51.5%, but evogliptin decreased transmembrane permeability to 34.6%. In addition, the fluorescence intensity of tight junction proteins, occludin and ZO-1, which were reduced by 56.2% and 44.5% after colistin exposure, were maintained during the treatment with evogliptin. The dead cell percentage and KIM-1 level were slightly decreased in evogliptin-treated groups.

Conclusions: We identified some renoprotective effects of the DPP4i on the epithelial barriers in short-term colistin-induced tubular injury. Further studies are required for the cytoprotective effect in long-term colistin injury models.



SA-PO582

Exercise Attenuates Ischemia–Reperfusion-Induced AKI

Joao Paulo M. Telles, Isabella P. Zanfra, Leticia U. De Castro, Amaro N. Duarte-Neto, Jose Manuel Condor Capcha, Mirela Santinho, Lucia Andrade. *University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: Aerobic (endurance) and strength (resistance) exercise have both been proven to be beneficial for patients with chronic kidney disease. Acute kidney injury continues to be the leading cause of death among critical care patients. We hypothesized that there is cross-talk between muscles and the kidneys and that exercise could attenuate the renal damage caused by ischemia–reperfusion. In this study, we assess the impact of exercise in rats submitted to renal ischemia–reperfusion injury (IRI).

Methods: Wistar rats were divided into two groups: Exer+IRI (n = 7), in which rats were submitted to a standardized protocol consisting in a treadmill run at up to 60% of the maximum calculated speed and climbing of a standardized ladder (30 min of running+10 climbs with tail weights, 5 times a week for 8 weeks), followed by bilateral clamping of the kidney hila (30 min) and subsequent reperfusion; and control+IRI (n = 6) in which the protocol consisted in a treadmill run at the lowest speed (30 min, 5 times a week for 8 weeks: control condition), bilateral clamping of the kidney hila (30 min), and subsequent reperfusion. All studies were performed 48 h after reperfusion. Data are mean ± SEM.

Results: Serum levels of urea were higher in control+IRI rats than in Exer+IRI rats (143 ± 43 vs. 92 ± 12 mg/dl), as were urinary levels of NGAL (46 ± 10.6 vs. 24 ± 5.6 μg/mg urinary creatinine, $p < 0.05$). In kidney tissue, protein expression of Toll-like receptor 4 (TLR4) was higher in control+IRI rats than in Exer+IRI rats (105 ± 2.4 vs. 67 ± 1.9%; $p < 0.01$). Renal protein expression of Klotho was lower in control+IRI rats than in Exer+IRI rats (99.5 ± 1.6 vs. 134 ± 6.7%; $p < 0.01$) as was protein expression of manganese superoxide dismutase (98.8 ± 2.2 vs. 122 ± 5.7%, $p <0.01$). Renal apoptosis (determined by TUNEL) was lower in Exer+IRI rats than in control+IRI rats (3.7 ± 0.8 vs. 11.5 ± 5.0 positive cells/0.087 mm^2; $p < 0.05$). Acute tubular necrosis was more extensive in control+IRI rats than in Exer+IRI rats (5.3 ± 0.6 vs. 3.8 ± 0.4, $p < 0.05$), most control+IRI rats presenting damage in >50% of the tubular area, compared with <50% for the Exer+IRI rats.

Conclusions: Exercise attenuates renal IRI by decreasing TLR4 expression and is renoprotective in a Klotho-dependent manner. (FAPESP)

SA-PO583

Renal Hypercoagulability Is Front and Center in Ischemic Injury

Jesus H. Dominguez,[1] James M. Dominguez,[2] Danhui Xie,[3] Katherine J. Kelly.[2] *[1]VAMC, Indianapolis, IN; [2]Indiana University, Indianapolis, IN; [3]IUPUI, Indianapolis, IN.*

Background: The transition of acute kidney injury (AKI) to chronic kidney disease (CKD) is common and misunderstood. We hypothesize that widespread renal clotting impairs reperfusion following renal ischemia in rats. This renal response is manifested as no-reflow in the microcirculation, causing swaths of renal micro ischemia, inflammation, apoptosis and fibrosis.

Methods: SD rats (n = 5/group) were subjected to 50 minutes of renal ischemia and then to 6 days of reperfusion. We used RNAseq comprehensive transcriptome analysis and measured 12,159 renal transcripts in sham and ischemic rats. The data were analyzed with established informatics tools.

Results: Renal ischemia activated the intrinsic renal clotting system and clotted renal microvessels. This response to injury included prothrombotic stimulation manifested by renal tubular activation of tissue factor (up 1.9 fold; $p<0.002$), and inhibition of tissue factor pathway inhibitor (down 1.44 fold, $p = 0.008$). Moreover, all three chains of renal fibrinogen were upregulated (up to 33 fold; 2.2E-10) and circulating fibrinogen also surged: 140±30 to 719±29 mg/dl, $p<0.0024$. Renal plasminogen was not expressed. There was major inhibition of fibrinolysis represented by activation of plasminogen activator inhibitor (up 5.6 fold; p = 1.7E-7), lack of response in renal urokinase and tisue plasminogen activator, and inhibition of plasminogen activator kallikrein (down 10 fold, p = 1.85E-6). In addition the thrombin receptor F2rl1 was activated 2 fold ($p<0.0001$). Complement component C1qa,b,c increased 3 fold ($p <0.0001$), C3 (up 5 fold p= 1.2E-5), and C4 a,b (up 12.56 and 20 fold respectively, p = 1.9E-13). These renal mRNA changes were associated with similar responses in renal cognate proteins and fibrin deposition. Kegg pathway analysis confirmed differential expression in ischemia of coagulation and complement pathways P=2.68 x 10-3.

Conclusions: We suggest the renal pro-thrombotic and fibrinolytic balance is essential to protect and assure competent blood flow. In renal injury, this balance is disrupted in favor of hypercoagulability. The risk to renal microthrombosis is further enhanced by complement activation and inhibition of a robust renal fibrinolytic system. We propose that in ischemic AKI the most optimal option is to re-activate fibrinolysis, anticipating that anti-coagulant agents are unlikely to be effective.

SA-PO584

High Throughput Metabolic Flux Analysis of Intact Kidney Tissue Reveals Abnormal Mitochondrial Respiration During AKI to CKD Transition

Aqeela Afzal, Andres A. Urrutia, Volker H. Haase. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Mitochondrial dysfunction has been implicated in the pathogenesis of multiple renal diseases, including acute kidney injury (AKI) and chronic kidney disease (CKD). However, knowledge about mitochondrial function during AKI to CKD transition is limited. The assessment of basal oxygen consumption rates (OCR) and the responses to electron transport chain inhibitors and uncoupling agents represent the first steps in evaluating cellular mitochondrial function. In order to avoid artifacts associated with tissue disruption or primary cell culture, we developed a novel method that permits the measurement of OCR in intact kidney tissue slices and investigated mitochondrial function during AKI to CKD transition.

Methods: 9-12 week-old C57/BL6 male mice were subjected to unilateral ischemia reperfusion injury (IRI) induced by 30 minutes of renal pedicle clamping. Kidneys were analyzed immediately after clamp removal (no-reperfusion) and at 24 hours, day 3, day 7 and day 21 post IRI. After removal of the kidney capsule, a portion of the kidney was used for DNA, RNA and histologic analysis. The remainder of the kidney was submerged in oxygenated modified Ringers solution. 1mm punch-biopsies were obtained from 100 μm vibratome sections of kidney pole tissue and loaded into an islet capture plate. OCR and extracellular acidification rates (ECAR) were analyzed with a Seahorse XF^{e}24 metabolic flux analyzer.

Results: Basal OCR and ECAR rates were significantly reduced immediately following IRI and recovered incompletely by day 3 post IRI. Day 7 and day 21 were characterized by a further reduction in OCR and ECAR below day 3 levels. The reduction in OCR correlated with significantly diminished mitochondrial DNA and gene expression levels and the development of fibrosis at day 7 an day 21. Similarly reduced ECAR values were associated with reduced glycolytic gene expression.

Conclusions: Here we present a novel approach for high throughput monitoring and analysis of mitochondrial respiration in intact kidney tissue sections. Our data indicate that AKI to CKD transition is associated with reduced mitochondrial respiration and glycolysis rates. A detailed protocol of this method will be presented at the meeting.

SA-PO585

Lipopolysaccharide Causes Renal Biotin Uptake Inhibition via a Transcriptional Mechanism

Ashwinkumar subramenium S. Ganapathy,[3] Hamid Moradi,[1,4] Veedamali Subramanian,[1] Hamid M. Said.[2] *[1]University of California, Irvine, Orange, CA; [2]UCI/VA, Long Beach, CA; [3]Penn State Hershey Medical Center, Hershey, PA; [4]Long Beach VA Healthcare System, Long Beach, CA.*

Background: Biotin (vitamin B7), a water-soluble vitamin, is indispensable for normal human health and its deficiency is associated with various severe clinical conditions. Renal proximal tubule epithelial cells are critical to maintaining normal body biotin homeostasis by mediating its reabsorption via a specific carrier mediated process (sodium-dependent multivitamin transporter [SMVT]). Although it has also been shown that lipopolysaccharides (LPS) can cause intestinal biotin deficiency by inhibiting its absorption, very little is known about the effect of inflammation and LPS on the kidney biotin uptake process.

Methods: Given the major role of inflammation in kidney disease and injury we sought to assess the effect of LPS exposure on renal biotin transport. We evaluated the impact of LPS on renal biotin uptake, expression, promoter activity and transcriptional regulation using *in vitro* (human proximal tubule kidney epithelial HK2 cells) and *in vivo* (mice) models subjected to LPS for 72 hours.

Results: The HK2 cells treated with LPS from gram negative E. coli (10 μg/ml) exhibited a significant inhibition in carrier-mediated biotin uptake, compared to controls. This inhibition was associated with a significant reduction in SMVT protein, mRNA and hnRNA expression levels. Similar inhibition of SMVT protein, mRNA and hnRNA expression levels were also observed in mice injected with LPS (2 mg/kg body weight). Additionally, we found that *SLC5A6* (biotin) promoter activity was attenuated following LPS treatment of HK2 cells. This was associated with a significant reduction in the mRNA expression levels of activator protein-2 (AP-2), a transcription factor which drives the *SLC5A6* promoter activity, in both of our *in vitro* and *in vivo* models.

Conclusions: This study shows for the first time that LPS inhibits renal biotin uptake via a transcriptionally-mediated mechanism. The potential clinical impact of these findings and possible role of biotin therapy in kidney injury caused by LPS remains to be determined.

Funding: NIDDK Support, Veterans Affairs Support

Lack of DJ-1 Amplifies Sepsis-Associated AKI and Increases Daxx-Mediated Parenchymal Apoptosis

Joseph T. Leeds,[1] Yogesh M. Scindia,[2] Valentina Loi,[3] Ewa U. Mandziak,[1] Saleh Mohammad,[1] Sundararaman Swaminathan.[1] *[1]University of Virginia, Charlottesville, VA; [2]Univerisity of Virginia, Charlottesville, VA; [3]AO Brotzu Cagliari, Cagliari, Italy.*

Background: Sepsis is frequently complicated by acute kidney injury (AKI). AKI in sepsis is associated with increased morbidity and mortality. Studies of sepsis-induced AKI suggest that uncontrolled inflammatory responses to tubular injury can further worsen renal damage. DJ-1 is a known anti-oxidant protein that is expressed in the brain, kidney, and immune cells. The role of DJ-1 in sepsis is not clear. AKI is one of the common sepsis-associated pathologies, and there is no data on the role of DJ-1 in sepsis-associated AKI.

Methods: Wildtype and DJ-1 knockout mice both on B6 background were administered 6.5 mg/kg LPS (i.p.) and tissues were harvested 24 hours later. Renal function and injury, as well as markers for inflammation were studied. Inner Medullary Collecting Duct cells (iMCD3) were used to study activation as well as cytotoxic serum responses.

Results: Compared to WT mice, DJ-1$^{(-/-)}$ mice were more susceptible to LPS-induced AKI as indicated by higher plasma creatinine (WT LPS 0.61 ± 0.11 Vs DJ-1$^{(-/-)}$ LPS 0.87 ± 0.23; p= 0.0006) and Kidney Injury Marker-1 (KIM-1). Markers of renal inflammation (s100A8 and s100A9) and Reactive Oxidant/Nitrogen Stress (ROS/RNS) were increased in renal tissue of DJ-1 deficient mice. The increased oxidative stress was associated with induction of Daxx-mediated apoptosis in the kidney. We demonstrate a protective effect of DJ-1 against LPS serum toxicity with *in vitro* studies on IMCD3 cells.

Conclusions: Our data suggests DJ-1 plays an important protective role in against sepsis-associated renal inflammation and injury, through ROS/RNS control, and by preventing Daxx-dependent apoptosis.

SA-PO587

Severity and Frequency of Tubule Injury Induced by Ischemia-Reperfusion Determines Prognosis of AKI

Yang Dong, Ying Fan, Qunzi Zhang, Jiejun Wen, Yiyun Wang, Niansong Wang. *Shanghai 6th People's Hospital affiliated to Shanghai Jiaotong University, Shanghai, China.*

Background: Ischemia is a common etiology in human acute kidney injury (AKI), which is an underestimated, yet significant predisposing factor for development of chronic kidney disease (CKD). However, a systematic and explicit reference standard is lacking for researchers when IRI models with divergent outcomes are to establish. Also, the biomarkers reflecting AKI to CKD progression are particularly lacking. The purpose of the current study was to establish suitable mice models simulating different clinical situations of renal ischemia patients, investigating the time and frequency effect of ischemia on AKI and subsequent AKI to CKD progression and exploring the potential function of noninvasive biomarkers KIM-1 and NGAL in predicting the renal outcome and prognosis.

Methods: Male C57BL/6J mice were subjected to different durations and episodes of ischemia attack for the UIRI (Unilateral Ischemia-Reperfusion Injury). We collected and analyzed the kidney samples at different time point post-ischemia. The concomitant changes of tubular injury biomarkers KIM-1 and NGAL in blood and urine along with different disease progression pattern were also investigated.

Results: We found that short-term duration of ischemia induced mild and reversible AKI in mice, while long-term duration of ischemia led to severe and progressive AKI. Repeated attack of moderate ischemia reperfusion injury could be applied to establish a model of AKI on CKD in mice. Furthermore, levels of KIM-1 and NGAL restored completely in reversible AKI, while they remained increased in progressive AKI. To be specific, levels of NGAL presented an increasing tendency till the chronic phase of the disease, while levels of KIM-1 merely peaked at the acute phase then suffered a subsequent decrease although still significantly higher than basal values.

Conclusions: In conclusion, different severity and frequency of ischemia injury dictate the divergent outcomes of ischemia-induced AKI. Both KIM-1 and NGAL enable noninvasive and early detection of AKI, also NGAL may better reflecting and predicting the process of AKI to CKD progression.

PBI-4050 Reduces Systemic Inflammation, Electrolyte Disturbances, and Renal Injury in Mice with Sepsis-Induced AKI: Role of GPR84

Jean-Francois Thibodeau,[1,3] Chet E. Holterman,[3] Marie-Pier Cloutier,[1] Jean-Christophe Simard,[1] Lyne Gagnon,[1] Pierre Laurin,[1] Richard L. Hébert,[2,3] Francois A. Leblond,[1] Chris R. Kennedy.[2,3] *[1]Prometic Biosciences Inc., Laval, QC, Canada; [2]Department of Cellular and Molecular Medicine, Faculty of Medicine, University of Ottawa, Ottawa, ON, Canada; [3]Kidney Research Centre, Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

Background: PBI-4050, Prometic Biosciences Inc.'s lead drug candidate, exerts anti-inflammatory and anti-fibrotic effects in several diabetic and non-diabetic models of kidney injury through modulation of GPR40 and GPR84 fatty acid receptors. Primarily in macrophages and fibroblasts, we have shown that the pro-inflammatory GPR84 receptor is induced in cultured human renal cells including proximal tubule epithelial cells (hPTEC) and podocytes (hPod) stimulated with bacterial lipopolysaccharides (LPS). We therefore queried the impact of PBI-4050 in a model of endotoxemia-induced AKI and evaluated the role of GPR84 in this regard.

Methods: Eight-week old male C57BL/6 mice were treated with PBI-4050 (200 mg/kg BW, p.o.) for 14 days followed by LPS (10 mg/kg, i.p.)-challenge and sacrificed 24 hours later.

Results: AKI was confirmed as LPS led to a rapid rise in plasma creatinine and urea, which were significantly decreased in PBI-4050-treated mice. LPS-induced hyperphosphatemia, hyperkalemia, hypocalcaemia and hypoglycemia, were also significantly improved by PBI-4050. Circulating levels of several major pro-inflammatory cytokines, including IL-1β, IL-6, MCP-1, TNFα, CXCL-1 and Rantes (CCL5) correlated with creatinine levels, and were significantly decreased by PBI-4050 in LPS mice. Moreover, PBI-4050 reduced LPS-induced albuminuria and albuminemia. Histological assessment revealed tubular cell injury was reduced and PT-megalin expression improved with PBI-4050, as was peri-glomerular and tubulointerstitial α-SMA expression. In a pilot study, GPR84$^{-/-}$ mice challenged with 24 hours LPS showed modest yet significant improvements in renal function. LPS caused GPR84 induction in cultured hPTECs and hPODs. PBI-4050 treatment in LPS-stimulated hPTEC and hPods decreased pro-inflammatory gene expression including MCP-1, IL-6 and IL-8.

Conclusions: Taken together, PBI-4050 improves systemic inflammation and indicators of glomerular and tubular injury in a model of LPS-induced AKI partly through GPR84 and may directly target specific renal cell types including PTEC's and podocytes.

Ceria-Zirconia Nanoparticles as an Enhanced Multi-Antioxidant Attenuates Apoptosis of Human Kidney Proximal Tubular Epithelial Cells in Hypoxia

Se-Hee Yoon,[1] Jang-Hee Cho,[2] Won Min Hwang,[1] Sung-Ro Yun,[1] Kuk-Ro Yoon.[3] *[1]Konyang University Hospital, Daejeon, Republic of Korea; [2]Kyungpook National University Hospital, Daegu, Republic of Korea; [3]Hannam University, Daejeon, Republic of Korea.*

Background: Hypoxia is an important cause of acute kidney injury (AKI) in various conditions because kidneys are one of the most susceptible organ to hypoxia. Various mechanisms have been introduced as mediators of the AKI caused by hypoxia, including calcium overload, endoplasmic reticulum stress, complement system activation, and reactive oxygen species (ROS). ROS play an important role in hypoxia induced AKI by affecting the function of cellular DNA, proteins, and lipids. The use of antioxidants can benefit the control and prevention of hypoxia induced AKI. Ceria-Zirconia nanoparticles (CZ NPs) exhibit superoxide dismutase and catalase mimetic activities. We investigated the effect of CZ NPs in cultures of hypoxia exposed human proximal tubular epithelial cells.

Methods: CZ NPs with size 2-3nm were synthesized using non-hydrolytic sol-gel reaction. To investigate the catalytic effect of CZ NPs, reactive oxygen species (ROS) production was measured using DHE, DCF-DA and amplex red assay. Cellular survival rate and cytotoxicity were measured with 3-(4,5-dimethyl-2-thiazolyl)-2,5-diphenyl tetrazolium bromide (MTT) assay. Cellular signaling pathway were studied by real time polymerase chain reaction and Western blot analysis.

Results: Cell survival was reduced in a dose-dependent manner for 24h after hypoxia exposure. Hypoxia caused a significant increase in ROS production 24 h after hypoxia. The extent of the effect of hypoxia on ROS levels was significantly reduced by CZ NPs treatment. CZ NPs downregulated proinflammatory markers and reduced caspase 3/7 activity in hypoxic HK-2 cells. CZ NPs also improved the survival of HK-2 cells in response to hypoxia.

Conclusions: CZ NPs have the potential as a therapeutic medicine for preventing ROS-related hypoxia induced AKI

NADPH Oxidase 4 Mediates TGF-β1/Smad Signaling Pathway Induced AKI in Hypoxia

Se-Hee Yoon,[1] Jang-Hee Cho,[2] Won Min Hwang,[1] Sung-Ro Yun.[1] *[1]Konyang University Hospital, Daejeon, Republic of Korea; [2]Kyungpook National University Hospital, Daegu, Republic of Korea.*

Background: Hypoxia is an important cause of acute kidney injury (AKI) in various conditions because kidneys are one of the most susceptible organ to hypoxia. Reactive oxygen species (ROS) plays an important role in hypoxia induced AKI. Among various sources of ROS, nicotinamide adenine dinucleotide 3-phosphate (NADPH) oxidase (Nox) is the major intracellular non- mitochondrial ROS source. Because among seven Nox families, Nox4 is the most abundant in the human kidney, changes of Nox4 expression in hypoxia are predicted to affect the progression of AKI by altering the intracellular ROS level in the kidney. Based on these observations, we investigated the role of Nox4 and the benefits of Nox4 inhibition in hypoxia induced AKI.

Methods: The hypoxic injury induced in HK-2 cells by hypoxia chamber and $CoCl_2$. Reverse transcription polymerase chain reaction for Nox4 and TGF-β1 was performed. Western blotting for Nox4 and Smad pathway were done. ROS production was detected using a DHE stain and Amplex red assay. HK-2 cells were transfected with siNox4 and pretreated with GKT137831(most specific Nox1/4 inhibitor). ELISA has been used to measure TGF-β1 levels. The effect of treatment with TGF-β1 type 1 tyrosine kinase inhibitor SB431542 on Nox4 expression was observed.

Results: Expression of Nox4 in cultured human renal proximal tubular epithelial cells (HK-2) was significantly increased by hypoxic stimulation. TGF-β1 was endogenously secreted by hypoxic HK-2 cells. SB4315432 (a TGF-β1 receptor I inhibitor) significantly inhibited Nox4 expression in HK-2 cells through the Smad-dependent cell signaling pathway. Silencing of Nox4 using *Nox4* siRNA and pharmacologic inhibition with GKT137831 reduced the production of ROS and attenuated the apoptotic pathway. In addition, knockdown of Nox4 increased cell survival in hypoxic HK-2 cells and pretreatment with GKT137831 reproduce these results.

Conclusions: This study demonstrates that hypoxia induces HK-2 cell apoptosis through a signaling pathway involving TGF-β1 via Smad pathway induction of Nox4-dependent ROS generation. Therapies targeting Nox4 may be effective against hypoxia-induced AKI.

SA-PO591

Ischemia Time Effects Long-Term Kidney Function in a Murine Model of Unilateral Ischemic AKI

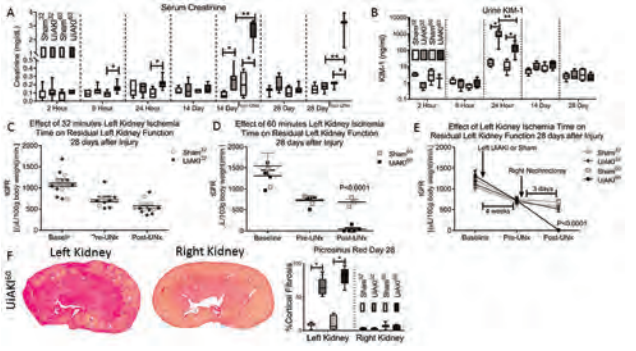
Danielle Soranno,[1] Lara A. Kirkbride-Romeo,[2] Sarah Faubel.[1] *[1]University of Colorado Denver, Denver, CO; [2]University of Colorado, School of Medicine, Aurora, CO.*

Background: The duration of ischemia that allows for complete recovery remains undetermined. Parekh performed a prospective study in patients undergoing unilateral ischemia-reperfusion acute kidney injury (UiAKI) for partial nephrectomy, and evaluated histological, serum and urine biomarker changes. Their findings suggested that while there was evidence of acute biomarker and histological injury, the injury was short-lived and did not correlate with ischemia times. This study has been utilized clinically to reassure against long-term renal damage following prolonged ischemia, but did not include outcomes beyond the immediate post-operative period.

Methods: Adult male C57BL/6 mice underwent UiAKI or sham procedure on the left kidney for 32 or 60 minutes. Serum and urine biomarkers were evaluated at 2, 6, and 24 hours, and 14 and 28 days. Transcutaneous glomerular filtration rate (tGFR) was measured serially. Additional 14 and 28 day groups underwent healthy unilateral nephrectomy 3 days prior to sacrifice in order to unmask any compensatory hyperfiltration.

Results: tGFR and histological outcomes demonstrated significant functional impairment and fibrosis despite reassuring serum biomarkers at the 14 and 28 day time-points.

Conclusions: Ischemia time correlates with functional impairment and fibrosis despite reassuring urine and serum biomarkers. Efforts to limit ischemia time in renal-sparing surgery remain warranted.



(A) Serum creatinine and (B) Urine KIM-1 were reassuring at the day 14 and 28 time-points (without nephrectomy), while functional assessment of glomerular filtration rate and histological outcomes demonstrated higher degrees of injury proportional to the ischedmia time. Specifically, 32 minutes of ischemia did not impair GFR 28 days later (C) and (E) while 60 minutes of ischemia resulted in nil function of the injured kidney (D) and (E). Picrosirius Red staining demonstrated increased fibrosis in the left injured kidney for both the 32 and 60 minute ischemia times (F). n = 5-7, $p < 0.05$.

SA-PO592

Metabolomic Alterations in a Mouse Model of Cisplatin-Induced AKI

Yong Jin (James) Lim,[1] Emily D. Hartjes,[1] Brad Urquhart.[1,2] *[1]Physiology and Pharmacology, Western University, London, ON, Canada; [2]Medicine, Division of Nephrology, Western University, London, ON, Canada.*

Background: Cisplatin-induced acute kidney injury (AKI) occurs in approximately 1/3 of patients receiving cisplatin therapy, but the reason why only certain patients develop AKI is unknown. AKI is currently diagnosed by increases in serum creatinine (SCr), but nephrotoxicity develops prior to detectable rises in SCr. Discovery of novel predictive/diagnostic markers of AKI is necessary and may help explain the differential susceptibility of cisplatin patients to AKI. FVB mice have shown greater susceptibility to cisplatin AKI than C57BL/6 mice. These two strains were used to model the variability of cisplatin nephrotoxicity observed in humans. We aim to: 1) Determine the differences in expression of renal transporters and enzymes involved in cisplatin disposition these mouse strains; 2) Investigate metabolic differences between FVB and C57BL/6 mice using metabolomics, with the aim of biomarker discovery.

Methods: FVB and C57BL/6 strains were treated with 15 mg/kg cisplatin or saline by intraperitoneal injection. Mice were sacrificed 1 and 3 days following treatment, and blood, urine, and kidneys were collected. Gene expression was assessed using RT-PCR. Liquid chromatography-mass spectrometry was used for untargeted metabolomics.

Results: Renal expression of transporters Oct2 and Oat1, and metabolizing enzyme Ggt1 were higher (+20%, $p<0.05$; +38%, $p<0.01$; +45%, $p<0.05$) in untreated FVB mice compared to C57BL/6. Principle component analysis (PCA) of plasma and kidney samples from untreated FVB and C57BL/6 showed visual separation based on mouse strain. PCA of day 3 plasma and kidney samples separated cisplatin and saline groups for both strains. Multivariate analysis revealed uremic toxins indoxyl sulfate, phenyl sulfate and p-cresyl sulfate to be altered in cisplatin AKI.

Conclusions: FVB mice exhibited increased expression of various renal transporters and enzymes involved in cisplatin disposition, as compared to C57BL/6. PCA clustering of plasma and kidney samples from untreated mice indicates baseline metabolic differences between the strains, while separation by treatment (saline vs. cisplatin) suggests that cisplatin administration alters the metabolic profile of the mice. Future work will further characterize metabolic changes associated with cisplatin AKI. Our data suggests possible mechanisms why FVB mice are more susceptible to cisplatin AKI compared to C57BL/6 mice.

Coenzyme Q-10 Protects Against Radiocontrast-Induced AKI by Regulating Heme Oxygenase-1 (HO-1) and Inducible Nitric Oxide Synthase (iNOS)

Sheila M. Fernandes,[2,1] Maria De Fatima Vattimo,[2,1] Cassiane D. da Fonseca,[2,1] Mirian Watanabe,[2,1] Karina B. Peres,[2,1] Carolina F. Vasco.[3] *[1]EEUSP, São Paulo, Brazil; [2]Universidade de São Paulo (USP), São Paulo, Brazil; [3]Universidade de São Paulo, São Paulo, Brazil*.

Background: Radiocontrast agents are thought to induce acute kidney injury in part through increased production of reactive oxygen species. Recently, we reported that IC reduced inulin clearance and increased urinary peroxides, nitric oxide and TBARS with consumption of antioxidant reserve, that were significantly attenuated by COQ-10 (Vattimo MFF, JASN 2016). The aim of this study is to examine if the renoprotective effect of COQ-10 is mediated by heme oxygenase-1 (HO-1) and inducible nitric oxide synthase (iNOS) in diabetic rats.

Methods: Adult male Wistar rats, randomized into 4 groups: Citrate - citrate buffer (streptozotocin vehicle); DM (streptozotocin, 65 mg/kg, iv).; DM+IC - DM animals that after 4 weeks received iodinated contrast (IC, 6 ml/kg, ip); DM+IC+CO-Q10 - DM preconditioned animals (COQ-10, (10 mg/kg, ip). Were evaluated gene expression and protein syntesis of heme oxygenase-1 (HO-1) and inducible nitric oxide synthase (iNOS) in CI-AKI in diabetic rats treated with COQ-10.

Results: Treatment with IC significantly incresed gene expression and reduced protein syntesis of HO-1 in diabetic rats compared the DM group. COQ-10 induced an elevation in gene expression and in the protein syntesis of HO-1. IC led to a increasing the levels of gene expression and protein syntesis of iNOS in the kidney rats diabetic. Treatment with COQ-10 was able to attenuate the increase in iNOS protein levels observed in DM+CI group.

Conclusions: The data highlighted that the regulation of HO-1 and iNOS can be point out as the mechanism involved in the renal protective effect of the COQ10 in the CI-AKI in diabetic rats, probably due to its anti-oxidative and anti-nitrosative effective.

Heme Oxigenase-1 (HO-1) and Inducible Nitric Oxide Synthase (iNOS) Modulate by Resveratrol in Contrast-Induced AKI in CKD Rats

Sheila M. Fernandes,[5,4] Maria De Fatima Vattimo,[5,4] Mirian Watanabe,[2,4] Karina B. Peres,[3,4] Daniel M. Martins,[1] Carolina F. Vasco.[6] Experimental lab on animal models *[1]University of São Paulo, Carapicuíba, Brazil; [2]University of Sao Paulo, Sao Paulo, Brazil; [3]EEUSP, São Paulo, Brazil; [4]Escola de Enfermagem da USP (EEUSP), Universidade de São Paulo (USP), São Paulo, Brazil; [5]Universidade de São Paulo (USP), São Paulo, Brazil; [6]Universidade de São Paulo, São Paulo, Brazil*.

Background: Iodinated contrast (IC)-induced acute kidney injury (AKI) is an important complication in patients with chronic kidney disease (CKD). In previous studies, we demonstrated a protective effect of Resveratrol (R) treatment demonstrated improvement of renal function in IC-AKI by renal hemodynamic modulation in CKD rats (VATTIMO MFF, JASN 2016). The aim of this study was to evaluate the potential renoprotective effect of resveratrol as anti-oxidate and anti-nitrosative by modulation of heme oxygenase-1 (HO-1) and nitric oxide induced synostosis (iNOS) in rats with CKD treated with IC.

Methods: Wistar, adult, male rats were randomized in four groups. Sham (control group), 5/6 (CKD model: 5/6 nefrectomy), 5/6+IC (CKD model + IC, 6ml/Kg, intraperitoneal- i.p., single dose), 5/6+IC+R (CKD model + R, 25 mg/Kg, intraperitoneal, single dose + IC, i.p, single dose, 30 minutes after R). Gene expression and protein syntesis of HO-1 and iNOS in renal tissue were evaluated.

Results: Treatment with IC significantly incresed gene expression and protein synthesis of HO-1 in 5/6 + IC rats compared to the 5/6 (DRC model) group and treatment with Resveratrol induced an additional elevation in gene expression and in the protein synthesis of HO-1 in 5/6 + IC + R rats. The levels of gene expression and protein synthesis of iNOS also to increase in the kidney of 5/6+IC group. 5/6 + IC + R reduced iNOS protein levels compared to 5/6 + IC rats.

Conclusions: These results demonstrate that Resveratrol influence renal HO-1 and iNOS expression after IC-induced AKI in CKD rats and may contribute to better outcomes in this setting by involvement in the modulation of oxidative and nitrosative stress.

Renal Epithelial Cells Reprogram Metabolism to Adapt to Sepsis

Carlos L. Manrique-Caballero, David R. Emlet, Alicia Frank, Abigail E. Marrow, John A. Kellum, Hernando Gomez Danies. *Center for Critical Care Nephrology, University of Pittsburgh, Pittsburgh, PA.*

Background: Adaptive metabolic reprogramming may play a key role in the development of sepsis induced acute kidney injury (AKI). Like monocytes, renal tissue shifts metabolism toward glycolysis early after cecal ligation and puncture. In monocytes, this shift is driven by the hypoxia inducible factor (HIF-1a) though expression of pyruvate kinase M2 (PKM2) and pyruvate dehydrogenase kinase (PDHK), whereas return to oxidative phosphorylation (OXPHOS) is driven by the activation of Sirtuin 1 (Sirt1). We hypothesized that human kidney 2 cells (HK2) follow the same biphasic reprogramming as an adaptive mechanism to sepsis.

Methods: HK2 were cultured in serum containing media and plated in XF24 microplates and 6-well plates for Seahorse and immunoblotting (WB) respectively at 21% O_2. Cells were treated with vehicle or sepsis mix (SM=LPS+HMGB1). We measured oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) as surrogates of glycolysis and OXPHOS, respectively at 3 and 24 hours after treatment. HIF-1a, PDHK, Sirt1 and b-Actin were identified by WB at 3, 6, and 24h.

Results: SM induced a decline in ECAR and an increase in OCR at 24h (Fig 1), suggesting that utilization of glycolysis decreases, and utilization of OXPHOS increases by 24h of SM. SM induced an increase in HIF-1α levels at 3h, with a late decrease by 24h. Protein levels of the downstream HIF-1α target, PDHK also increased from 3 to 6h, followed by a similar decline by 24h. SM induced a delayed increase in Sirt1 by 24h, with an early suppression at 3h (Fig 2).

Conclusions: Our study shows that in response to SM, HK2 cells shift metabolism by decreasing the use of glycolysis and increasing the use of OXPHOS by 24h. Increased expression of drivers and mediators of glycolysis early (3h) after SM, followed by a late (24h) decline in glycolysis concomitant with increased expression of drivers of OXPHOS, suggests a biphasic HK2 response to inflammation, reminiscent of that of monocytes.

Funding: Other NIH Support - 1K08GM117310-01A1

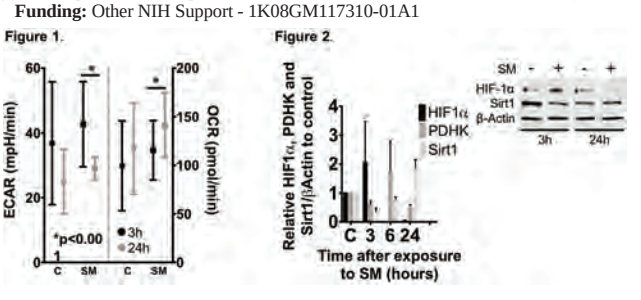

Fig 1. Change in glycolysis and OXPHOS from 3 to 24h after exposure to SM **Fig 2.** Protein expression of drivers of glycolysis and OXPHOS in HK2 cells after SM

SA-PO596

Cyclophilin A Promotes AKI and Inflammation Following Renal Ischaemia/Reperfusion Injury

Khai Gene Leong,[1,2] Elyce Ozols,[1,2] John Kanellis,[1,2] David J. Nikolic-Paterson,[1,2] Frank Y. Ma.[1,2] *[1]Department of Nephrology, Monash Health, Clayton, VIC, Australia; [2]Centre for Inflammatory Diseases, Monash University, Clayton, VIC, Australia*.

Background: Cyclophilins are enzymes that regulate protein folding. During various pathological conditions, cyclophilin A (CypA) has been shown to promote leukocyte recruitment and inflammation. However, the contribution of CypA in acute kidney injury (AKI) and renal fibrosis is poorly understood. The aim of this study was to determine the role of CypA in renal tubular damage, inflammation, and fibrosis using the: (1) renal ischaemia/reperfusion injury (IRI), and (2) unilateral ureteric obstruction (UUO) models.

Methods: Groups (n=10) of wild type (WT) and CypA-/- mice on the 129 background were subjected to either: (1) bilateral renal IRI (19min at 37°C) and killed 24 hours post reperfusion, or (2) UUO surgery and killed on day 7. Controls were sham operated.

Results: Renal IRI induced AKI with a >6-fold rise in serum creatinine (sCr) in WT mice (41±13.8 vs 6.3±1.7umol/L in sham; P<0.0001) and marked tubular damage based on the tubular injury score, increased KIM-1 mRNA levels, and tubular cell death (TUNEL+ cells; all P<0.0001 vs sham). CypA-/- mice were protected from renal dysfunction with a 50% improvement of sCr (20.7±3.5umol/L; P<0.0001), less histologic tubular damage (P<0.01), lower KIM-1 mRNA levels (P<0.01), and less tubular cell death (P<0.001). Renal IRI caused upregulated mRNA levels of inflammatory molecules (TNF-α and IL-36-α; P<0.05), and neutrophil infiltration (Ly6G+ cells; P<0.0001). CypA-/- mice had a clear reduction in inflammatory molecules (P<0.05) and less infiltrating neutrophils (P<0.001). UUO in WT mice resulted in significant renal fibrosis (3-fold increase in collagen IV deposition by immunostaining; P<0.001 vs sham), with significant infiltrates of macrophages (F4/80+ cells), T cells (CD3+ cells) and neutrophils (Ly6G+ cells) (all P<0.0001 vs sham). CypA-/- mice were not protected from renal fibrosis or leukocyte infiltration in the UUO model.

Conclusions: CypA contributes to leukocyte infiltration and inflammation leading to AKI following IRI. In comparison, the leukocyte infiltration and renal fibrosis seen following the less severe tubular injury in UUO does not require CypA. This contrast may relate to differences in CypA release/secretion by tubular cells in the two models.

SA-PO597

Preexisting CKD Impairs Recovery from AKI in Female Rats

Jacqui Potter, Aaron J. Polichnowski. *East Tennessee State University, Johnson City, TN*.

Background: We previously demonstrated that male rats with preexisting CKD exhibit impaired recovery from AKI and the subsequent development of *de novo* mechanisms of CKD progression. The goal of this study was to determine if impaired recovery from AKI is also observed in female rats with preexisting CKD.

Methods: We induced two levels of CKD in 10-12 week old male and female Sprague-Dawley rats by performing either 50% renal mass reduction via a right uninephrectomy (UNX, n=14, 6 females) or 75% renal mass reduction via a right UNX + surgical excision of 1/2 of the left kidney (3/4 NX, n=12, 6 females). Two weeks later, rats were subjected to 35 minute ischemia-reperfusion (IR)-induced AKI. Blood samples were obtained prior to IR and at 48 hours and 7, 14 and 28 days post IR to assess plasma creatinine (P_{Cr}). A 24-hour urine collection was performed in a subset of rats prior to IR and at 28 days post IR to assess proteinuria. At the end of the study, renal pathology and tubular vimentin expression were assessed.

Results: The severity of AKI, based on P_{Cr} levels 48 hours post AKI, was similar between UNX vs. 3/4 NX groups. The severity of AKI was lower (P<0.05) in females vs. males with 3/4 NX (1.9±0.3 vs. 3.3±0.3 mg/dl) but not significantly different between females vs. males with UNX (1.7±0.6 vs. 2.7±0.4 mg/dl). While minimal injury and vimentin expression (0.7±0.2) was observed in females with UNX, females with 3/4 NX exhibited greater (P<0.05) tubular vimentin staining (1.3±0.3), tubular injury and fibrosis 28 days post IR. Moreover, recovery of P_{Cr} over 28 days post IR was delayed in females with 3/4 NX vs. UNX. Finally, female rats with 3/4 NX developed substantial (P<0.05) increases in proteinuria 28 days post IR as compared to pre-IR levels (195±57 vs. 62±20 mg/day) while proteinuria was similar at 28 days post IR vs. pre-IR in female rats with UNX (21±4 vs. 23±5 mg/day). Males with 3/4 NX exhibited impaired recovery from AKI and the development of proteinuria 28 days post AKI as compared to males with UNX.

Conclusions: These data support previous studies documenting resistance to IR-induced AKI in female vs. male rats. However, our data indicate that preexisting CKD of greater than 50% renal mass reduction predisposes female rats to impaired recovery from AKI and the subsequent development of mechanisms of CKD progression, similar to male rats.

SA-PO598

Double-Negative T-Cells That Express PD-1 Are Early Responders During Ischemic AKI

Mohanraj Sadasivam,[1] Sanjeev Noel,[1] Sul A Lee,[2] Abdel Hamad,[1] Hamid Rabb.[2] *[1]Johns Hopkins University, Baltimore, MD; [2]Johns Hopkins University School of Medicine, Baltimore, MD*.

Background: Unconventional T cells (e.g. Tregs and γδT cells) are increasingly recognized for their roles in maintaining homeostasis and protecting non-lymphoid tissues against injury/stress. CD4-CD8- double negative (DN) αβT cells are abundant in mouse and human kidneys, actively dividing in steady state and involved in protecting against ischemic AKI. However, there is less knowledge about DN T cells residing in kidney are known.

Methods: C57BL/6J (WT), B6.129P2-B2mtm1Unc/J (β2m KO), B6.129S2-H2dlAb1-Ea/J (MHC II KO), B6.129P2-H2-K1tm1Bpe H2-D1tm1Bpe/DcrJ (KD KO) and Nu/J mice were used for this study, n=3-7/group. Human kidney samples were from nephrectomies for renal cancers. Kidney lymphocytes were isolated and analyzed by flow cytometry.

Results: Our data demonstrates that kidney DN T cells are thymus-derived as lack of thymus significantly reduced the absolute count of DN T cells in kidney (WT, $2.2x10^4$ vs. Nu/J, $0.24x10^4$, P<0.05) and also comprised of two (PD-1^+ and NK1.1^+) subsets whose development and homeostasis are dependent on non-classical MHC class I molecules. Development of the NK1.1^+ subset is restricted by β2m-dependent non-classical MHC molecules as the frequency of NK1.1^+ DN T cells was significantly reduced in β2m KO (10.3±2) but not in KD-deficient mice (21.5±2) then WT mice (23.1±3, P<0.001). In contrast, homeostasis but not development of the PD-1 subset is regulated by β2m-dependent non-classical MHC molecules as the frequency of PD-1^+ DN T cells was significantly higher in β2m KO (70.2±5) then WT mice (44.2±3 P<0.001). DN T-cells are present in kidney of β2m KO mice, but lose their phenotypic activation (>60%, P<0.001), spontaneous steady proliferation (>40%, P<0.05) and undergo apoptosis. DN T cells retained in kidneys of β2m KO mice are mostly PD-1^+ and remain functionally responsive to external stimuli as indicated by their rapid activation and expansion in response to ischemic AKI. Both normal human kidney and cancer samples express the PD-1^+ (% normal, 39.5±8 vs. tumor, 47.9±7.8) and NK1.1^+ subsets (% normal, 26.2±8.4 vs. tumor, 23.0±8.3).

Conclusions: These findings demonstrate that kidney DN T cells, particularly PD-1^+ DN T cells, are early responders of the renal immune surveillance system utilizing recognition/activation/regulation mechanisms that differ from conventional T cells.

Targeting Enhancer of Zeste Homolog 2 Protects Against AKI

Xiaoxu Zhou,[2] Shougang Zhuang.[1] *[1]Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI; [2]Rhode Island Hospital, Brown University, Providence, RI*.

Background: Despite the established oncogenic and profibrotic functions of enhancer of zeste homolog 2 (EZH2), a methyltransferase that induces histone H3 lysine 27 trimethylation (H3K27me3), its role in acute kidney injury (AKI) remains unclear.

Methods: In this study, we examined the effect of EZH2 inhibition on acute kidney injury in murine models induced by induced by either ischemia-reperfusion (IR) or folic acid (FA).

Results: We demonstrated that EZH2 and H3K27me3 were upregulated in the murine kidney with AKI in both models. Pharmacologic inhibition of EZH2 with 3-deazaneplanocin A (3-DZNeP) inhibited tubular injury in both models as demonstrated by a decrease in renal dysfunction, reduced neutrophil gelatinase-associated lipocalin expression and a lower rate of renal tubule cell death. Injury to the kidney resulted in reduced expression of E-cadherin and ZO-1, whereas EZH2 inhibition largely preserved their expression. Moreover, 3-DZNep was effective in counteracting the increased expression of matrix metalloproteinase (MMP) -2 and -9 as well as the phosphorylation of Raf-1 and ERK1/2 in the injured kidney. Conversely, blocking EZH2 reversed the decrease of tissue inhibitor of metalloproteinase (TIMP)-2 and -3 and Raf kinase inhibitor protein (RKIP) in the kidney after acute injury. Similarly, oxidant injury to cultured kidney proximal tubular epithelial cells caused a decrease in the expression of E-cadherin, ZO-1, TIMP-2/-3, and RKIP as well as an increase in the expression of MMP-2/9 and phosphorylation of Raf-1 ERK1/2. Blocking EZH2 with 3-DZNep or SiRNA hindered these responses.

Conclusions: These results suggest that targeting EZH2 protects against AKI through a mechanism associated with the preservation of adhesion/junctions, reduction of matrix metalloproteinases and attenuation of the Raf-1/ERK1/2 pathway.

SA-PO600

Deciphering the Role of Angpt4-Tie2 Signaling in the Kidney

Antoine Tarjus,[1,2] Rizaldy P. Scott,[1,2] Tuncer Onay,[1,2] Susan E. Quaggin.[1,2] Quaggin lab *[1]Northwestern University, Feinberg School of Medicine, Chicago, IL; [2]Department of Medecine, Division of Nephrology and Hypertension, Northwestern Medecine, Chicago, IL*.

Background: The angiopoietin-Tie2 signaling pathway is fundamental for vascular development and has been linked to numerous kidney diseases including diabetic nephropathy and sepsis-related AKI. The pathway is composed of two receptors, Tie1 and Tie2, and three ligands, Angiopoiein-1, Angiopoietin-2 and Angiopoietin-4 (Angpt-4). Among the ligands, Angpt-4 has been poorly characterized. While Angpt4 has been suggested to act as a Tie2 agonist and seems to be highly regulated by hypoxia, its physiological role remains elusive. Moreover, the study of Angpt-4 function is currently challenging due to the lack of knockout transgenic model. In order to decipher its physiological role, we have developed a new Angpt4 mouse model.

Methods: We generated a new reporter and conditional allele for Angpt4 in mice. Using the X-gal chromogenic substrate of the β-galactosidase, this model allows us to characterize high-resolution expression pattern of Angpt-4. To identify the cell type expressing Angpt-4, we performed immunohistochemical staining on tissue sections using antibody coupled with the alkaline phosphatase enzyme. Global and timed deletion of Angpt4 was accomplished using ubiquitous and tetON inducible Cre-deletor lines.

Results: X-gal staining reveals strong expression restricted to the vasculature of organs including the kidney, adrenal glands, gonads, and mesentery. In the kidney, X-gal staining is found in the renal and interlobular arteries. Using an antibody against Transgelin (SM22), a marker of smooth muscle cells, we show Angpt-4 co-localizes with vascular smooth muscle cells in the kidney. Global KO mice survive to birth and renal function testing is underway.

Conclusions: Our data demonstrate a highly specific vascular pattern of expression for Angpt-4 in smooth muscle cells of the vascular wall. These observations suggest that Angpt-4 may have a role in arterial function with potential impact in the pathology of renal ischemia as Angpt-4 has been shown to be regulated by hypoxia.

SA-PO601

Targeting IL-17 Activity Protects from Salt Sensitive Progression of CKD Following AKI

Purvi Mehrotra,[1] Riley P. O'Shaughnessy,[2] David P. Basile.[3] *[1]Indiana School of Medicine, Indianapolis, IN; [2]IUSM, Indianapolis, IN; [3]Indiana University School of Medicine, Indianapolis, IN.*

Background: Patients surviving AKI have a higher risk for chronic kidney disease (CKD). Previous studies in rats demonstrate that inhibition of T-cell activity (e.g., using mycophenolate or losartan) following recovery from AKI attenuates the subsequent development ofproteinuria, inflammation and fibrosis. Th17 cells, characterized by IL-17 secretion, are the predominant T helper subset associated with the AKI-to-CKD transition. Blockade of IL-17 activity using IL-17Rc receptor antagonist significantly decreased fibrosis and neutrophil recruitment in post ischemic rats compared to vehicle treated controls but other parameters of AKI-CKD transition have not been evaluated.

Methods: Male Sprague Dawley rats were subjected to unilateral I/R (40min) and allowed to recover for 5 weeks on low salt diet (0.4%). Rats were subjected contralateral nephrectomy UNx and elevated dietary NaCl (4%) for 4 additional weeks to hasten CKD. The rats were injected anti-IL-17 (5 mg/kg) or IgG control during the exposure to high salt diet and blood pressure measured by telemetry.

Results: Renal hypertrophy was evident in post-AKI IgG-treated rats relative to sham (~14%), which was significantly attenuated by IL-17 neutralizing antibody ($p<0.05$). There was a significant increase in the levels CD4+IL17+ cells and CD4+IFNγ+ cells in kidney of post AKI rats which was significantly reduced by IL-17 neutralizing antibody (IL17: IgG 17847±3787 and IL-17 7360±1680; p£0.05; IFNγ+: IgG 2703±495 and IL-17 1083±314; cells/g tissue p£0.05). Histological examination demonstrated that anti-IL17 antibody treatment reduced the level of renal fibrosis as indicated by picrosirius red staining. In addition, m-RNA expression of Kim-1 and Tgf-bwas reduced by 25% and 42% respectively. Mean arterial blood pressure was significantly attenuated by ~ 12 mm Hg in post-ischemic rats treated with anti-IL17 relative to vehicle treated post-AKI rats.

Conclusions: These data suggest that enhanced expression of CD4+IL-17 cells contribute to renal inflammation, fibrosis and hypertension in CKD following AKI.

Hypoxic Preconditioning Suppresses Renal Inflammation in Ischemic and Septic AKI

Rafael Torosyan, Ganeshkumar Rajendran, Michael P. Schonfeld, Pinelopi P. Kapitsinou. *University of Kansas Medical Center, Kansas City, KS.*

Background: Prolyl-hydroxylases (PHDs) have emerged as safeguards of cellular metabolism through their oxygen sensing function, which enables them to regulate the activity of hypoxia-inducible factors (HIF). We previously reported that activation of HIF signaling via pharmacologic inhibition of PHDs (PHI) protects against kidney ischemia reperfusion injury (IRI). Here, we investigated whether HIF activation through exposure to normobaric hypoxia mimics the renoprotection induced by PHI. Using an unbiased metabolomic approach, we identified conserved metabolic responses between these interventions.

Methods: C57BL/6 male mice aged 8-10 weeks were subjected to normobaric hypoxia (8% O_2) for 48 hours prior to induction of AKI via unilateral renal artery clamping (IRI) or LPS administration. Untargeted metabolomic screening by a GC/MS and LC/MS based platform was performed in sera from mice treated with PHI or exposed to acute hypoxia.

Results: Pre-ischemic exposure to normobaric hypoxia attenuated kidney injury at day 3 post IRI as indicated by improved kidney histogical scores and a 2.3-fold reduction of *Kim1* mRNA levels in kidney homogenates compared to normoxic controls (n=7-8, P=0.0002). Furthermore, hypoxic preconditioning suppressed the expression of pro-inflammatory genes *Vcam1* and *Tnf*α by 2.6-fold (n=7-8, P<0.0001) and diminished the infiltration of $Ly6B.2^{+ve}$ cells in injured kidneys by 85% (P<0.0001) compared to controls. In a septic model of AKI induced by LPS, hypoxic preconditioning suppressed the transcripts of *Tnf*α and *Il-6* by 2.3- and 5-fold respectively (Day 1 post LPS, n= 11-14; p < 0.009). Comparative untargeted metabolomic analysis revealed that exposure to hypoxia and pharmacologic PHD inhibition led to significantly overlapping alterations in serum metabolome. For instance, serum levels of α-ketoglutarate, a TCA cycle metabolite, were reduced by 60% in the setting of hypoxic preconditioning (n=8, P <0.0001) and by 36% with PHD inhibition (n=8, P = 0.004) compared to their corresponding controls.

Conclusions: Our data demonstrate that exposure to normobaric hypoxia attenuates kidney inflammation in both IRI-and sepsis-induced AKI. Furthermore, PHD inhibition induced by exposure to hypoxia or pharmacologic means lead to metabolic reprogramming, which may play a critical role in regulating inflammatory responses in the context of AKI.

Conditional Histone Deacetylase-2 Knockout Within Renal Tubular Cells Is Protective in Renal Ischemia-Reperfusion Injury

David D. Aufhauser,[1] Seth Concors,[1] Zhonglin Wang,[1] Douglas R. Murken,[1] Paul T. Hernandez,[1] Guanghui Ge,[1] Wayne W. Hancock,[2] Matthew H. Levine.[2] *[1]University of Pennsylvania, Philadelphia, PA; [2]Children's Hospital of Philadelphia and University of Pennsylvania, Philadelphia, PA.*

Background: Ischemia/reperfusion injury (IRI) is a major source of morbidity in renal transplantation and other surgical scenarios. In renal transplantation, IRI contributes to poor outcomes and early graft loss. Histone deacetylases (HDACs) regulate diverse cellular processes. We have previously shown that the class I HDACs 1 and 2 have reciprocal effects on renal ischemia-reperfusion injury (IRI) with HDAC1 deletion increasing vulnerability and HDAC2 protection providing profound protection. A more thorough understanding of the mechanism of this protection, including the site of action, is critical to develop specific targeting in IRI.

Methods: Renal tubule-specific tamoxifen-inducible HDAC-2 knockout (HDAC2-pax8), and tamoxifen-treated WT female (WT) control mice were used. Mice were subjected to warm renal IRI through unilateral clamping of the renal pedicle and contralateral nephrectomy under strict temperature control. Creatinine and BUN were examined at 24-, 48-, 72-, and 96-hours post-IRI.

Results: HDAC2-pax8 mice had significant protection from renal injury after renal IRI versus WT mice, as shown by decreased elevations in BUN and Cr post-injury (Figure 1, $p<0.005$).

Conclusions: Renal tubule-specific HDAC2 deletion is protective in a standardized model of renal warm IRI. We have now moved from showing efficacy with pan-HDAC inhibition to kidney-specific inhibition and now to proximal tubule-specific inhibition. This finding has important translational potential and provides guidance for identifying renal-specific targets for clinical use.

Renal Tubular Epithelial Cell Proliferation Inhibition by C-Reactive Protein and Myeloid Derived Suppressor Cells

Rachel Jimenez,[1] Alexander J. Szalai.[2] [1]*University of Alabama at Birmingham, Birmingham, AL;* [2]*The University of Alabama at Birmingham, Birmingham, AL.*

Background: Re-establishment of renal function after acute kidney injury (AKI) largely depends on the recovery of injured renal tubular epithelial cells (RTEC). However, the inflammatory response that accompanies AKI complicates RTEC recuperation. In a series of studies, we showed that C-reactive protein (CRP), a well-known biomarker of inflammation, plays a causal role in AKI *i.e.* human CRP transgenic mice (CRPtg) subjected to renal ischemia-reperfusion have more severe AKI compared to CRP knockout mice. Notably, for CRPtg the exacerbation of AKI is accompanied by increased renal infiltration by myeloid derived suppressor cells (MDSC), and depletion of human CRP blunts both MDSC infiltration and renal injury. In the present study we explored the CRP → MDSC → RTEC axis.

Methods: To determine the direct impact of human CRP on MDSC functions and RTEC health, and to establish whether MDSCs can suppress RTEC proliferation, primary mouse RTECs were isolated and mouse MDSCs were generated from bone marrow (BM-MDSC) and studied *in vitro* using microscopy, flow cytometry, and co-culture assays.

Results: We first confirmed that BM-MDSCs ($CD11b^+CD11c^-F4/80^-Ly6C^+Ly6G^+$ cells with an immature nuclear morphology) effectively suppressed the proliferation of CD3ε/CD28-stimulated $CD4^+$ T cells and that this BM-MDSC suppressive action is enhanced by human CRP. When human CRP was added to freshly isolated bone marrow, human CRP increased the proportion of BM-MDSCs ultimately generated and also increased the proportion of BM-MDSCs entering S phase. Co-cultures with BM-MDSCs in transwells inhibited the cell cycling of primary RTEC monolayers.

Conclusions: Our results show that human CRP promotes the generation of MDSCs from bone marrow precursors and enhances their ability to suppress target-cells. Our initial evidence suggests BM-MDSCs suppress primary RTEC cell cycling in a contact-independent manner. These new *in vitro* data align with our earlier observation that AKI is worsened in CRPtg. We hypothesize that in CRPtg with AKI, human CRP enhances the noxious effects of renal infiltrating MDSCs, thereby promoting inhibition of RTEC and delaying their recovery. Ongoing work investigates whether human CRP enhances the MDSC-mediated suppression of RTEC proliferation and whether this effect requires MDSC expression of CRP receptor(s).

Impact of Ciprofloxacin on Renal Tubular Epithelial Injury Through the Interaction of Autophagy and Apoptosis

Woo Yeong Park,[1,2] Hayeon Park,[1] Kyubok Jin,[1,2] Sung Bae Park,[1,2] Seungyeup Han.[1,2] [1]*Internal Medicine, Keimyung University School of Medicine, Daegu, Republic of Korea;* [2]*Keimyung University Kidney Institute, Daegu, Republic of Korea.*

Background: Autophagy and apoptosis play an important role in renal tubular epithelial injury by hypoxia, nutrient deprivation, and oxidative stress. Recent research reported that antibiotics might contribute to ischemic renal injury characterized by both apoptosis and inflammation, but the mechanism remains unclear. Therefore, we investigated the impact of ciprofloxacin on renal tubular epithelial injury through the interaction of autophagy and apoptosis.

Methods: We used MDCK cells, a model for renal distal tubular epithelial cells. We performed TUNEL assay to identify the effect of ciprofloxacin for cell viability under nutrient deprivation for 48 hours (hrs). We assessed apoptosis and autophagy markers to investigate the effect of ciprofloxacin through the interaction between apoptosis and autophagy.

Results: In the TUNEL assay, the ratio of apoptotic cells/total cells was significantly lower in the ciprofloxacin group (100 ug/mL) than in the control group (0 ug/mL) (7.17 ± 1.25 vs. 20.41 ± 1.04, $P < 0.001$). Among apoptosis markers, the ratio of pBax/Bax was reduced at 6 hr, and pBcl-2/Bcl-2 was increased at 12 hr in the ciprofloxacin group compared with the control group. In the MAPK pathway, located further upstream of Bax and Bcl-2, the ratio of pJNK/JNK, pp38/p38, and pERK/ERK was decreased at 12 hr in the ciprofloxacin group compared to the control group. The ratio of cleaved caspase 3/caspase 3, the final effector caspase, was decreased at 36 hr in the ciprofloxacin group compared with the control group. Among autophagy markers, the level of Beclin-1 was increased at 6 hr in the ciprofloxacin group compared with control group, and the level of LC3B was increased after 12 hr. Finally, activation of autophagy by ciprofloxacin during apoptosis by nutrient deprivation might cause recovery of renal tubular epithelial injury.

Conclusions: Ciprofloxacin can help to restore cell viability against renal tubular epithelial injury under nutrient deprivation condition, and the cell viability by ciprofloxacin might be associated with the crosstalk of autophagy and apoptosis. Therefore, ciprofloxacin is helpful to increase cell viability through activation of autophagy under ischemic renal injury.

SA-PO606

5-HT1F Receptor Mediates Renal Vascular Homeostasis and Mitochondrial Biogenesis

Tess Dupre, Rick G. Schnellmann. *Pharmacology/Toxicology, University of Arizona, Tucson, AZ.*

Background: Acute kidney injury (AKI) is a devastating disease with no treatment options. After AKI, there is a marked reduction in renal vasculature. Thus, promoting vascular recovery following AKI could facilitate renal repair as the vasculature is responsible for carrying oxygen and nutrients to extravascular tissues. Our laboratory has shown that stimulating mitochondrial biogenesis (MB) through the $5\text{-}HT_{1F}$ receptor stimulates recovery from AKI. In contrast, $5HT_{1F}$ receptor knockout mice have decreased MB and poor renal recovery. Importantly, induction of MB has been linked to increased angiogenesis. Thus, we hypothesized that the $5HT_{1F}$ receptor plays a role in vascular homeostasis and mediates MB in renal endothelial cells.

Methods: Primary human glomerular endothelial cells (HEC) and mouse glomerular endothelial cells (MEC) were treated with the $5\text{-}HT_{1F}$ receptor agonists LY344864 or lasmiditan (0-500 nM) for 24 or 72h. Mitochondrial respiration using Seahorse analysis, mitochondrial proteins using immunoblot analysis and mitochondrial copy number using qPCR analysis was determined. Immunohistochemical analysis for CD31 was performed on paraffin embedded kidney sections.

Results: We determined that HEC and MEC express the $5\text{-}HT_{1F}$ receptor. Treatment of HEC and MEC with LY344864 or lasmiditan induced MB, as evidenced by maximal mitochondrial respiration, a marker of MB. HEC that were treated with lasmiditan or LY344864 had increased expression of nuclear- and mitochondrial-encoded proteins (PGC1α, TFAM, NDUFS1, COX-1, and VDAC) and mitochondrial DNA copy number, confirming MB and increased mitochondrial content. Lastly, $5\text{-}HT_{1F}$ receptor knockout mice had decreased renal vascular content, as immunohistochemical analysis revealed decreased $CD31^+$ renal endothelial cells.

Conclusions: Stimulation of $5\text{-}HT_{1F}$ receptor with LY344864 and lasmiditan induces MB in HEC and MEC, *in vitro*, and $5\text{-}HT_{1F}$ receptor mediates vascular homeostasis, *in vivo*. We propose that inducing MB in endothelial cells after AKI could restore vascular function and stimulate renal repair and recovery.

Abnormal Uromodulin Glycosylation in AKI and Its Interaction with Protein in Lectin Pathway of Complement

Kunjing Gong,[1] Min Xia,[2] Yaqin Wang,[3] Nan Hu,[1] Yuqing Chen.[1] [1]*Peking University First Hospital, Beijing, China;* [2]*Renal Division, Peking University First Hospital, Beijing, China;* [3]*Renal division, Peking University First Hospital, Beijing, China.*

Background: Uromodulin (UMOD) is a glycoprotein with a carbohydrate content, nearly 30%. It might protect against urinary tract infection and kidney stones, have roles in kidney injury and innate immunity. Many functions were glycosylation dependent. Mannose binding lectin (MBL) and collectin 11 (CL-11) were the initiated protein of lectin pathway (LP) with a carbohydrate-recognition domain (CRD). In the present study, we measured the glycosylation of acute kidney injury (AKI) patients and the binding affinity of UMOD to lectin pathway protein in modified glycosylation of uromodulin

Methods: 10 AKI patients and 10 healthy control recruited for this study after matched their age and gender. After purified the UMOD with diatomaceous earth, structure of the protein glycosylation chains was analyzed using matrix assisted laser desorption/ionization-time of flight mass spectrometry (MALDI-TOF MS). Different kinds of glycosidase digested UMOD to make glycan-deficient protein. Binding affinity of uromodulin to MBL and CL-11 were probed by ELISA

Results: The profile of MALDI-TOF-MS N-glycans released from uromodulin healthy control showed more complex N-glycan structures. The amount of high mannose and core fucosylation were increase in the AKI patients compare with those healthy control ($P<0.05$). Native uromodulin could bind to CL-11 (Ca^{2+} independent) and MBL(Ca^{2+} dependent). The binding activity of UMOD to CL-11 was significantly decreased by digesting the protein with fucosidase and neuraminidase. Digested by EndoH could decrease the binding activity as well, while the decrease was slightly.

Conclusions: Abnormal glycosylation of UMOD could be observed in AKI patients. UMOD bind to lectin pathway protein, and this interaction was dependent on glycan structure of UMOD.

SA-PO608

Hes1, a Newly Identified Downstream Mediator of α7nAChR on Macrophages in the Cholinergic Anti-Inflammatory Pathway, Plays a Protective Role in AKI

Tsuyoshi Inoue,[1,2] Chikara Abe,[3] Shinji Tanaka,[1] Diane L. Rosin,[1] Masaomi Nangaku,[2] Youichiro Wada,[2] Mark D. Okusa.[1] *[1]University of Virginia, Charlottesville, VA; [2]The University of Tokyo, Tokyo, Japan; [3]Gifu University, Gifu, Japan.*

Background: The cholinergic anti-inflammatory pathway (CAP) links the nervous and immune systems and modulates innate and adaptive immunity. Activation of the CAP by vagus nerve stimulation (VNS) exerts protective effects in a wide variety of clinical disorders including rheumatoid arthritis and Crohn's disease. The CAP involves splenic alpha7-nicotinic acetylcholine receptor (α7nAChR)-positive macrophages although their detailed role *in vivo* has yet to be established.

Methods: RNA-seq using peritoneal macrphages from WT and α7nAChRKO mice was performed after nicotine and/or LPS treatment. Kidney IRI (bilateral, 26 mins) was used as an acute kidney injury model and was performed 24 hr after VNS (left side, 5 Hz, 50 μA for 10 min) treatment or adoptive transfer of treated-macrophages. Kidney injury was evaluated 24 hr later using plasma creatinine, kidney Kim-1 mRNA expression and histology (H&E). TNF level in the media was measured by ELISA and RAW 264.7 cells were used as macrophages for the experiments requiring modifications of gene expression.

Results: Adoptive transfer of $1x10^5$ nicotine-treated peritoneal macrophages from $\alpha7nAChR^{+/+}$ (α7WT; progeny control) but not from $\alpha7nAChR^{-/-}$ (α7KO) mice protected kidneys of recipient mice from IRI, showing the importance of α7nAChR on macrophages. Nicotine-induced genes whose expressions were lower (<1/2 compared to $\alpha7nAChR^{+/+}$-derived cells) in $\alpha7nAChR^{-/-}$-derived peritoneal macrophages were extracted by RNA-seq. We focused on hairy and enhancer of split-1 (Hes1), a basic helix-loop-helix (bHLH) transcription factor that acts as a transcriptional repressor of genes that require a bHLH protein for their transcription. VNS induced Hes1 expression in peritoneal macrophags. siRNA against Hes1 inhibited nicotine-induced TNF suppression, and Hes1 overexpression suppressed LPS-stimulated TNF induction in RAW 264.7 cells. Hes1 overexpression in RAW 264.7 cells mainly induced macrophage M2 markers (anti-inflammatory). Lastly we found that adoptive transfer of Hes1-overexpressing RAW 264.7 cells protected the kidney from IRI.

Conclusions: These data demonstrate that Hes1 is a new downstream signaling molecule of α7nAChR in the CAP.

Influence of Renal Ischemia-Reperfusion Injury on Renal Neutrophil Gelatinase-Associated Lipocalin Receptor (24p3R) in Rats

Yusuke Arakawa,[1,2] Kentarou Ushijima,[3] Akiko Mii,[4] Shuichi Tsuruoka,[4] Akio Fujimura.[5] *[1]Nephrology, Nippon Medical School, Tokyo, Japan; [2]Pharmacology, Jichi Medical University, Tochigi, Japan; [3]Jichi Medical University, Shimotsuke, Japan; [4]Nippon Medical School, Tokyo, Japan; [5]Jichi Medical Univ., Simotsuke, Japan.*

Background: The neutrophil gelatinase-associated lipocalin (NGAL) receptor (24p3R) is expressed in distal nephron, and contributes to the endocytosis of NGAL in urine. This study was undertaken to evaluate an influence of renal ischemia-reperfusion injury on 24p3R.

Methods: Unilateral renal pedicle was clamped for 0, 10, 20, 30, or 45 min in male Wistar rats. Urine was collected for 24hours after reperfusion, and ischemic kidney was obtained.

Results: Renal NGAL mRNA expression and urinary NGAL excretion elevated in rats with renal ischemia for more than 20min. On the other hand, renal mRNA expressions of 24p3R, and megalin and cubilin which are expressed in proximal nephron and uptake NGAL in urine, decreased in animals with renal ischemia for more than 20min. Renal protein expressions of 24p3R and megalin decreased in rats with renal ischemia for 30 and 45min.

Conclusions: This study showed for the first time that renal 24p3R decreased in response to renal ischemia. As NGAL in urine is reabsorbed by the megalin-cubilin complex at the proximal nephron and by the 24p3R at the distal nephron, the down-regulations of these proteins might contribute to the elevated urinary NGAL excretion in rats with renal ischemia-reperfusion injury.

SA-PO610

Lipopolysaccharide Induces Filtrate Leakage from Tubular Lumen to Interstitial Space via Proximal Tubular TLR4-Dependent Pathway in Mice

Daisuke Nakano,[1] Helge Wiig,[4] Motoko Yanagita,[5] Jens Titze,[2] Akira Nishiyama.[3] *[1]Kagawa University, Kagawa, Japan; [2]Duke - National University of Singapore, Singapore, Singapore; [3]Kagawa University Medical School, Kita-Gun, Japan; [4]University of Bergen, Bergen, Norway; [5]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: We previously reported by using intravital imaging technique that lipopolysaccharide (LPS) slowed proximal tubular flow rate in an early phase of endotoxemia. However, the mechanism by which LPS reduced tubular flow rate was unclear. Hereby, we hypothesized that LPS might disrupt tight junction in proximal tubular cells and induce leakage of filtrate through a Toll-like receptor 4 (TLR4)-dependent mechanism.

Methods: Tubular flow rate was determined by the timing of the appearance and disappearance of intravenously injected dyes in the early segments of proximal tubules in mice under 2-photon laser microscopy observation.

Results: LPS at 5 mg/kg did not change the inflow rate of filtrate into the proximal tubules, which reflect unchanged GFR, and significantly reduced the outflow rate from the proximal tubules at 6h. LPS at 15 mg/kg reduced both inflow and outflow rate. Both dosages of LPS induced oliguria. LPS (5 mg/kg) induced paracellular leakage of FITC-inulin and reduced tight junction mRNA expression (occludin and cldn2). LPS also increased water content, interstitial hydrostatic pressure and Na^+/K^+ ratio in the kidney, indicating the accumulation of extracellular fluid in the interstitium. These changes were diminished by the conditional knock out of TLR4 in proximal tubules. Furthermore, denuding renal capsule further slowed tubular flow down, suggesting that increasing interstitial pressure might counteract the leakage.

Conclusions: Our results suggest that LPS disrupted tight junction of proximal tubular cells via a TLR4-dependent mechanism, resulting in paracellular leakage of filtrate to interstitium in an early phase of endotoxemia in mice.

Clinician Attitudes Toward Implementation of Precision Medicine

Purnima R. Tripathy,[2] Karthik Kannegolla,[1] Ranjani N. Moorthi,[3] Michael T. Eadon.[4] *[1]Indiana University, Bloomington, IN; [2]Nephrology, indiana university, Indianapolis, IN; [3]Indiana University School of Medicine, Indianapolis, IN; [4]Indiana University Division of Nephrology, Indianapolis, IN.*

Background: Advancements in understanding the genetic basis of CKD & pharmacogenomic drug dosing are facilitated by the discovery of genetic predictors. We implemented precision medicine testing in our renal clinics to assess CKD progression risk and hypertension drug dosing.

Methods: Physicians on nephrology services (N=42) were surveyed about their knowledge, attitude & willingness to act on genetic testing results. A 26 question survey was graded on a LIKERT scale from "strongly agree" to "strongly disagree." Respondents were stratified according to knowledge & attitude. Statistics were calculated with a Fisher's exact test. We hypothesized clinicians who agreed sufficient evidence was available to support implementation would have more positive attitudes & greater willingness to act on genetic data.

Results: Respondents were grouped as those who agreed there is sufficient evidence to implement genetic testing (supporters N=14) & those who disagreed (nonsupporters N=28). Compared to nonsupporters, supporters agreed that: 1) genetic testing helps them better identify etiology of CKD (p=0.05), 2) the presence of 2 *APOL1* risk alleles impacts their management of focal segmental glomerulosclerosis (p=0.05), 3) testing could change their choice of antihypertensives (p=0.01) and 4) testing will help to delay the progression of CKD (p=0.006). Most respondents agreed (98%) that a patient's genetic profile can influence their response to antihypertensives. We assessed the attitude of clinicians toward genetic testing by asking "whether a discussion of genetic test results is too time-consuming for an encounter". Clinicians who agreed (negative attitude N=19) & those who disagreed (positive attitude N=23) showed differences in their willingness to act on genetic data. Those who felt there is sufficient time to discuss results also agreed that genetic testing of CKD patients provides information that changes their dialysis preparation strategies (p=0.02).

Conclusions: Physicians with greater awareness of the evidence supporting implementation of genomic testing appear to be more likely to act on the genomic results.

SA-PO612

A Novel Nomogram to Predict the Reliability of Estimated Glomerular Filtration Rate Formula in Oncology Patients

Yichun Cheng,[1] Liu Huang,[2] Yunfeng Han,[3] Gang Xu,[5] Shuwang Ge.[4] *[1]Department of Nephrology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China; [2]Oncology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China; [3]Nuclear Medicine, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China; [4]Nephrology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China; [5]Nephrology, Tongji hospital affiliated to Tongji medical college, Huazhong University of Science and Technology, Wuhan, China.*

Background: Formulae of estimated glomerular filtration rate (eGFR) based on serum creatinine (Scr) are routinely used for drug dosage in oncology patients, however, they are inaccurate in some populations. Our aim was to identify population characteristics where eGFR formulae performed poorly and thereby build a nomogram to predict the reliability of estimates.

Methods: Measured GFR (mGFR) using isotope from 444 oncology patients were compared with eGFR from four formulae (Cockcroft-Gault, de-indexed MDRD, de-indexed CKD-EPI and Wright). Multivariate logistic regression was applied to identify characteristics associated with inaccurate eGFR and construct a predictive nomogram.

Results: The Cockcroft–Gault formula exhibited estimates with lowest bias and highest precision. Nonetheless, it was still unreliable in a relevant proportion of patients. The percentage of patients within 30%, 20%, and 10% of the accurate percentage error (APE) was seen in only 62.8%, 47.7% and 24.8% of patients respectively. Inaccuracy was

found in overweight patients or in patients with BUN/Scr ratio greater than 20 or with eGFR greater than 60 ml/min/1.73m^2. A novel nomogram was constructed to help oncologists to predict the risk of inaccuracy of eGFR. The calibration curve showed good agreement.

Conclusions: Our results suggest that all eGFR formulae tend to overestimate the eGFR in oncology patients. Our nomogram may assist oncologists in decision-making when mGFR is needed.

SA-PO613

Mechanism of Difference in Plasma and Urinary Clearance Glomerular Filtration Rate (GFR) Determinations

Ruben M. Sandoval,[1] Silvia B. Campos-bilderback,[2] Mark C. Wagner,[3] Jered Myslinski,[1] Bruce A. Molitoris.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University, Indianapolis, IN; [3]Indiana University Medical Center, Indianapolis, IN.*

Background: It is well established, but not understood, that plasma clearance GFRs exceed urinary clearance GFRs for the same filtered marker, often by 5-10%. Therefore, the present studies were undertaken to determine the role of proximal tubule endocytosis in reducing urinary excretion of filtration markers.

Methods: To visualize and quantify the effect of PTC uptake on reducing urinary GFR determinations freely filterable fluorescently labeled dextrans, inulin and small molecular weight proteins were investigated. All had a glomerular sieving coefficient of 1.0, and given by bolus intravenous administration. Ratiometric analysis of 2-photon images and urinary quantification of neutral (TRITC) and negatively charged (FITC) markers was used to quantify PTC uptake and the effect of charge on PTC uptake.

Results: Intravital 2-photon imaging revealed PTC endocytic uptake of freely filtered GFR markers was rapid, dose and time dependent. pH mediated quenching of FITC fluorescence resulted in a pseudo-reduction in apparent PTC uptake of FITC labeled markers. Neutrally charged fluorescent markers were internalized by PTC $S_2 > S_1$. Negatively charged FITC dextrans and inulins were preferentially taken up versus a neutral TRITC inulin, particularly in S_1 PTC. Two-photon imaging demonstrated that a negative charge increased PTC uptake, as the injected ratio of FITC /TRITC inulin was increased from 0.504 to 0.729 +/- 0.056 for a 45% increase in negatively charge inulin uptake. On the other hand, the urine FITC/TIRTC ratio decreased 38.7% +/-0.1%, consistent with increased PTC endocytosis of negatively charged inulin.

Conclusions: PTC reabsorbed filtration markers, including inulin, in a dose and time dependent fashion via endocytosis. PTC uptake explains in part the reduction in urinary compared to plasma GFR clearance. Finally, a negative charge on these molecules increases uptake by PTC, especially in the S1 segment.

SA-PO614

Renal and Dialytic Clearances of Uremic Solutes

Jerome Lowenstein,[1] Aleksey Etinger,[1] James Slater,[2] Bjorn Meijers,[3] Robert Holzman.[4] *[1]New York University Medical Center, New York, NY; [2]NYU Langone Health, New York, NY; [3]University Hospitals Leuven, Leuven, Belgium; [4]NYU School of Medicine, New York, NY.*

Background: Many uremic solutes are protein bound and removed by proximal tubular organic anion transporters (OATs) rather than filtration.

Methods: In 4 subjects undergoing right heart catheterization, samples were obtained from the right renal vein and the inferior vena cava below the renal veins.Total and ultrafiltrate concentrations of uremic solutes were measured utilizing MS-HPLC.

Results: Renal extraction ratio (removal across the renal vascular bed) and renal excretion fraction (renal clearance of solute relative to creatinine) varied greatly. HA and PAG exhibited the highest renal extraction ratios and excretion fractions approximating values reported for para-amino-hippurate (PAH). The dialytic clearance of these solutes exhibited the same pattern but never exceeded estimated creatinine clearance. Highly bound solutes (IS, PCS) exhibited low renal extraction and low renal excretion fractions. KA was an anomaly. Though highly bound, renal extraction and excretion were higher than expected, possibly related to pKa or other unique properties of this solute.

Conclusions: The findings suggest that endogenous hippurate clearance might provide a measure of effective renal plasma flow. The finding that uremic retention solutes such as IS, PCS, and KA, known to bind to OAT receptors on vascular endothelium where they act as transcription factors, are also tightly bound to albumin suggests that protein binding serves to deliver solutes to receptors in a manner analogous to the delivery of hormones, bound to carrier proteins, from an endocrine source to distant receptors.

The Pathophysiology of Augmented Renal Clearance Similarly Affects Hepatic Clearance in Critically Ill Trauma Patients

George N. Coritsidis, Sean Yaphe, Jayaramakrishna Depa, Scott Lee. *Elmhurst Hospital Center, Forest Hills, NY.*

Background: In trauma, the systemic inflammatory response and intensive care therapy leads to a hypermetabolic state described as Augmented Renal Clearance (ARC). Literature has shown an association between ARC and sub-therapeutic antibiotic concentrations and suggests worst clinical outcomes. We examined whether hepatic clearance is also augmented in trauma by measuring Dilantin levels (DL), a drug primarily metabolized by the liver.

Methods: A retrospective review of the trauma registry at our level 1 trauma center was conducted from 2009 to 2014 for adults admitted for traumatic brain injury receiving Dilantin. Patients with acute kidney injury were excluded. GFR was estimated using CKD-Epi formula. DL were corrected for hypoalbuminemia (<3 g/dL) and compared between ARC patients (eGFR ≥ 130) and those without (nARC) at 24, 48 hours, and 72 hours.

Results: There were a total of 98 nARC (eGFR= 97.4) and 20 ARC patients (eGFR=133.3) all of which dosed similarly. ARC patients were younger, had lower creatinine and DL at 72 hours. At 48 and 72 hours the correlation comparing eGFR to DL is negative ($p<.05$). At 48 hours ALT levels were significantly higher ($p<0.05$).

Conclusions: ARC patients had lower DL at 24 and 48 hours, and DL correlated negatively with GFR augmentation. ALT and AST levels were higher in the ARC patients possibly due to increased hepatic function. In ARC, hepatic clearance may also be augmented raising issues of drug dosing regardless of renal or hepatic metabolism.

Descriptive statistics comparing ARC vs non-ARC patients

	non-ARC (n=a98)	ARC (n=20)	
	mean	mean	P-value
Age	53.45	30.2	<.001
Creatinine at 48 hours	0.86	0.63	<.001
Dilantin level at 72 hours	12.24	9.32	0.007
GFR on admission	89.93	125.40	<.001
GFR at 24 hours	94.54	134.10	<.001
GFR at 48 hours	97.94	133.30	<.001
Average GFR	94.01	130.94	<.001
ALT at 48 hours	23.35	38.92	<.05

Probability of Target Attainment Estimated by Residual Blood Sampling Agrees with Intensive Sampling Predictions

Christin M. Giordano McAuliffe,[2] Katherine Akers,[3] Megha Salani,[4] Sylvia M. Verhoven,[2] Pratish C. Patel,[2] Jennifer M. Colby,[2] Matthew S. Shotwell,[1] William H. Fissell.[2] *[1]Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Western Nephrology, Denver, CO; [4]Nephrology Associates of Mobile, PA, Mobile, AL.*

Background: Patients with critical illness and multiple organ failure have altered pharmacokinetics and are at risk of over- or under- dosing. Patient-specific estimates of target attainment require timed and repeated phlebotomy. This additional loss of blood is undesirable and, in a research setting, requires individual informed consent. Blood tests ordered for clinical purposes rarely consume the entire sample volume. We hypothesized that residual blood samples could be used to estimate target attainment in critically ill patients.

Methods: We adapted Bayesian population-pharmacokinetic statistical tools to accommodate the sparse sampling and irregular timing of clinical samples. This method incorporates dosing history, a priori estimates of population heterogeneity, other available clinical information, and patient-specific measurements of piperacillin concentration in residual blood samples to estimate patient-specific probability of target attainment. We compared these estimates to a gold-standard estimate of target attainment using intensive repeated sampling in ten patients.

Results: There was excellent agreement between the two methods. Just one of ten subjects was misclassified as having failed to meet target exposure, and that was in a subject whose residual sample was obtained 72 hours prior to intensive sampling for the gold-standard estimate. Excluding this subject, the correlation between the residual and gold-standard estimate of drug exposure was 0.91 (95% CI: 0.62, 0.98). No subjects were misclassified as having attained target exposures when they had not.

Conclusions: Although this was a small sample, consistent results in this subtype of patient demonstrates that residual blood sampling may be useful for the estimation of antibiotic target attainment. As a result, residual blood sampling may be an efficient use of patient blood, a scarce resource, for pharmacokinetic measurements and therapeutic drug monitoring. Overall, residual blood sampling would reduce blood loss and potentially lower requirements for blood transfusion during a prolonged hospital stay. In addition, use of residual blood sampling may increase research participation, as it would allow for the avoidance of additional venipuncture which is often a common barrier to consent.

SA-PO617

Prevalence and Adverse Outcomes Associated with Opioid Prescriptions Across the Range of eGFR

Tessa K. Novick,[1] Aditya L. Surapaneni,[1] Jung-Im Shin,[1] G caleb Alexander,[1] Lesley Inker,[3] Alex R. Chang,[2] Morgan Grams.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Geisinger Medical Center, Danville, PA; [3]Tufts Medical Center, Boston, MA.*

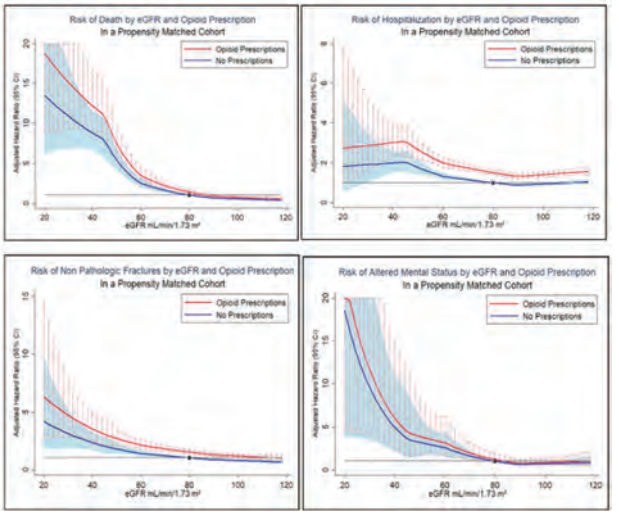
Background: Kidney disease limits therapeutic options for pain control given the relative contraindication to non-steroidal antiflammatory drugs. The goal of this study was to assess the prevalence and safety of prescription opioid use across the range of eGFR in a U.S. outpatient population.

Methods: Using electronic medical records from the Geisinger Health System, we described trends in opioid prescriptions by CKD stage between 2011 and 2016. In a cohort matched on propensity for ≥2 opioid prescriptions during a 2-year baseline period (2011-2013) we used Cox proportional hazards regression to evaluate the association between opiate prescription compared to no opiate prescription and death, total hospitalizations, non-pathologic fracture, and presentations for altered mental status, as well as whether associations differed by eGFR level.

Results: Opioid prescriptions increased over time, particularly among patients with eGFR < 30 ml/min/1.73m². For example, 43.5% patients with eGFR < 30 ml/min were prescribed opioids in 2011 compared to 46.4% in 2016 (p for trend < 0.001). Among 22,261 patients receiving at least two opiate prescriptions during the baseline period, a suitable match was found for 5,337 based on 23 clinical and demographic covariates. Patients with opioid prescriptions had significantly increased risk for death (HR 1.39, 95% CI 1.16-1.67), hospitalization (HR 1.51, 95% CI 1.39-1.63), and non-pathologic fracture (HR 1.51, 95% CI 1.33-1.72) compared to their counterparts for all levels of eGFR (p >0.05), but differences in altered mental status were not statistically significant (HR 1.22, 95% CI 0.79-1.88) (**Figure**).

Conclusions: Opioid prescriptions are common in patients with CKD and are associated with higher risk for death, hospital admissions and non-pathologic fracture.

Figure. Adjusted hazard ratios for (A) death, (B) hospitalization, (C) non-pathologic fracture and (D) altered mental status comparing those with and without opioid prescriptions in the baseline period across different levels of eGFR.



SA-PO618

G-Protein Signaling and Kappa Opioid Mediated Aquaresis

Kevin Ebert, Daniel R. Kapusta. *Louisiana State University Health Sciences Center, New Orleans, LA.*

Background: Kappa opioid agonists act centrally to inhibit antidiuretic hormone (ADH) secretion and increase renal sympathetic nerve activity. Together, these effects lead to a water diuresis. However, the signaling pathway by which kappa opioid receptor (KOR) activation produces these effects remains unknown. In prior studies, we have shown that activation of opioid receptor like one (ORL1) by the ligand nociceptin produces a marked diuresis in rats by a downstream G-alpha z protein pathway that inhibits ADH secretion. These studies investigated whether central G-alpha protein signaling pathways also contribute in producing the diuretic and/or antinatriuretic response to central administration of the kappa opioid agonist, U-50488H.

Methods: Sprague Dawley rats were implanted with an intracerebroventricular (i.c.v.) cannulae and pretreated with vehicle or pertussis toxin (PT), which inhibits the Gi/o family of proteins except for Gz. After 48-hrs pretreatment, rats were instrumented with cannula in the femoral artery, vein, and bladder and infused i.v. with isotonic saline (55 µl/min). After stabilization, blood pressure (BP), heart rate (HR), and urine output (V) was collected in conscious rats before (control) and for 90-min after (10-min collections) i.c.v. U-50488H (n=6).

Results: In vehicle pretreated rats, i.c.v. U-50488H produced a marked increase in V (max Δ, 101±8 ul/min) and decrease in urinary sodium excretion (UNaV; max Δ, 5±0.5 ueq/min). The diuretic response produced by U-50488H was significantly ($p<0.05$) blunted by pretreatment with PT (max Δ, 57±3 ul/min). In contrast, PT did not alter the decrease in UNaV. U-50488H did not alter BP or HR in either group. To explore which G-alpha proteins may participate in mediating the kappa diuresis, separate rats were pretreated i.c.v. (24-hrs) with an oligodeoxynucleotide (ODN), which selectively targeted a specific G-alpha protein. In these studies, pretreatment of groups of rats (n=6/group) with a single ODN for either Gi1, Gi2, Gi3, Go, or Gz, failed to blunt the maximal diuresis as compared to the increase in V produced by i.c.v. U-50488H in scrambled ODN treated rats.

Conclusions: These results demonstrate that central kappa opioids produce a pertussis toxin sensitive diuresis, but not antinatriuresis. This suggests that a combination of Gi/o proteins may be required to produce the aquaretic effects of kappa opioid agonists.

Ouabain Regulated Phosphoproteome Reveals Molecular Mechanisms Behind Na,K-ATPase Control of Cell Adhesion, Proliferation, and Survival of Renal Cells

Lena Scott,[1] Liang Zhang,[1] Jacopo M. Fontana,[1] Daniel Svensson,[1] Hjalmar Brismar,[2,1] Anita Aperia.[1] *[1]Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden; [2]Royal Institute of Technology, Stockholm, Sweden.*

Background: Ouabain, a Na,K-ATPase ligand, triggers calcium release and Erk phosphorylation. Ouabain protects from apoptosis and stimulates proliferation and cell contact in primary and immortalized kidney epithelial cells. However, the mechanisms that connect the calcium and Erk signaling with the downstream effects are unknown.

Methods: We have performed a proteomic and phosphoproteomic study on COS cells, derived from embryonic monkey kidney. Cells were treated with ouabain for 10 and 20 min in concentrations that do not increase $[Na^+]_i$. Hierarchical clustering was applied to describe the temporal pattern of phosphorylation events. Gene ontology analysis was then used to examine whether phosphorylation events with different temporal patterns regulate distinct cellular processes. To verify the significance of identified proteins, siRNA studies were performed on primary rat proximal tubule cells.

Results: We identified 1941 ouabain-regulated sites that were either phosphorylated or dephosphorylated in a transient or sustained manner. The state of phosphorylation for proteins associated with cell adhesion and proliferation was prominently altered by ouabain. Analysis of protein-protein interaction networks showed a high connectivity of phosphoproteins that regulate cell adhesion and cell proliferation. Protein kinases and calcium dependent protein kinases were enriched among the proteins where the phosphorylation state is regulated by ouabain. Downregulation of protein expression by siRNA showed that CaMKK1 and CaMK2γ are essential for ouabain protection from apoptosis caused by serum deprivation or exposure to high glucose

Conclusions: This study represents a major advancement in the understanding of the dual function of Na,K-ATPase as an ion pump and as a signal transducer. It offers an insight into the role of ouabain for kidney growth and development and for protection against apoptosis.

Prescribing and Safety of Direct-Acting Oral Anticoagulants Compared to Warfarin in Atrial Fibrillation Patients on Chronic Hemodialysis

Estella Davis,[1,3] Dallin Darais,[3] Khalid Bashir,[2,4] Kevin T. Fuji.[1] *[1]Pharmacy Practice, Creighton University School of Pharmacy, Omaha, NE; [2]CHI Clinic, Nephrology, Omaha, NE; [3]Pharmacy, CHI Health-Creighton University Medical Center- Bergan Mercy, Omaha, NE; [4]Medicine, Creighton University School of Medicine, Omaha, NE.*

Background: ESRD patients on hemodialysis (HD) were excluded from safety and efficacy studies of direct-acting oral anticoagulants (DOACs) in atrial fibrillation (AF). The objective of this study was to evaluate prescribing, dose selection, and safety outcomes of DOACs compared to warfarin in AF patients on chronic HD. Secondary objectives were to evaluate major ISTH bleeding and clinically relevant non-major bleeding (CRNMB).

Methods: This was a retrospective study of AF patients on outpatient HD and oral anticoagulation (OAC) with warfarin or DOAC from April 2010-April 2016. Records were obtained from metro area CHI Health System and Dialysis Clinics Inc. Data was analyzed using descriptive statistics, ANOVA and chi-square.

Results: 91 patients were included (52% male, 79% white, mean age 69). Average CHA_2DS_2Vasc was 4.6 and HASBLED was 3.8. Warfarin was the initial OAC in most patients (n=76), mean dose 29mg/week. 15 patients were initially on DOACs: apixaban 2.5mg (n=7), apixaban 5mg (n=5), dabigatran 75mg (n=2), and dabigatran 150mg (n=1). Of 14 patients whose initial OAC was switched, 12 switched to apixaban 5mg or 2.5mg. Initial apixaban was dosed appropriately in most patients (83%) compared to apixaban switches (42%) where 9 on low dose did not meet dose reduction criteria. HASBLED scores were higher in switched patients not dosed appropriately (4 vs. 3.2, p=0.156). 26 patients experienced a bleed, with significantly more bleeding in warfarin compared to DOAC (31% vs 28%, p=0.022) patients. Most major bleeds (n=7), CRNMB (n=12), and major plus CRNMB (n=1) occurred with warfarin alone. Bleeding in DOAC patients: 1 on warfarin to dabigatran 75mg (major), 1 on warfarin to apixaban 2.5mg (major), 2 on apixaban 2.5mg (CRNMB), 1 on warfarin to dabigatran 150mg (major and CRNMB), and 1 on dabigatran 150mg to apixaban 5mg (major and CRNMB).

Conclusions: More HD patients were prescribed warfarin initially and more of these patients experienced a bleed. More prescribers selected appropriate dose apixaban as the initial DOAC or switched to it as low dose when dose reduction criteria were not met.

Bleeding occurred in DOAC patients with prior warfarin therapy, switching between DOACs, and maintained on the initial DOAC. Larger studies evaluating DOAC prescribing and impact on safety in AF patients on chronic HD are warranted.

SA-PO621

Increasing Use of Direct Oral Anticoagulants Among Hemodialysis Patients with Medicare Prescription Drug Coverage

Eric D. Weinhandl,[1,2] Debabrata Ray,[1] Kristine Kubisiak,[1] Allan J. Collins.[1,2] *[1]NxStage Medical, Inc., Victoria, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: For decades, warfarin was the only agent to be used for long-term anticoagulation. Since 2010, a series of direct oral anticoagulants (DOACs) have been approved by the United States Food and Drug Administration, including dabigatran, rivaroxaban, apixaban, edoxaban, and betrixaban. The efficacy and safety of DOACs in hemodialysis (HD) patients is poorly understood. We assessed trends in utilization of warfarin and DOACs among HD patients in 2011-2015.

Methods: We analyzed data from the United States Renal Data System. For each calendar month from January 2011 to December 2015, we identified patients who underwent HD and were enrolled in Medicare Part C or D; we also assessed whether HD was delivered in a facility or at home. From pharmacy claims, we identified whether each patient possessed a supply of warfarin, rivaroxaban, apixaban, or edoxaban. We estimated percentages of patients with a supply of any anticoagulant, any DOAC, and individual DOACs. We fit logistic generalized estimating equations of DOAC use, with adjustment for age, race, sex, primary cause of end-stage renal disease (ESRD), and dialytic setting.

Results: Monthly sample sizes increased from roughly 249,000 in January 2011 to 311,000 in December 2015. During this era, the percentage of patients using any anticoagulant steadily increased from 9.2% to 10.2%. However, the percentage of patients using warfarin reached an apex of 9.4% in December 2013 and subsequently fell to less than 9.0% in late 2015. Concurrently, the percentage of patients using any DOAC increased from 0.1% to 1.3%. By December 2015, 11.6% of patients using an anticoagulant were DOAC users and 93.0% of patients using a DOAC were apixaban users. Among patient-months with anticoagulant use in 2015, positive predictors of DOAC use were older age and Asian (versus white) race; negative predictors were black (versus white) race and glomerulonephritis and polycystic kidney disease (versus diabetes) as the primary cause of ESRD. Relative to in-center hemodialysis, home hemodialysis was associated with 18% lower odds of DOAC use, but the association was not statistically significant ($P = 0.09$).

Conclusions: Among hemodialysis patients, warfarin use is decreasing, DOAC use is increasing, and apixaban dominates DOAC utilization. Direct comparisons of warfarin and apixaban are urgently needed.

Funding: Commercial Support - NxStage Medical, Inc.

SA-PO622

Prevalence and Outcomes Associated with NSAID Use in Patients with CKD

Samantha L. Chan,[2] Etienne Macedo,[2] Danuta Trzebinska,[2] Linda Awdishu.[1] *[1]UCSD Skaggs School of Pharmacy and Pharmaceutical Sciences, La Jolla, CA; [2]University of California San Diego, San Diego, CA.*

Background: Nonsteroidal anti-inflammatory drugs (NSAIDs) have been associated with an increased risk of incident acute kidney injury and chronic kidney disease (CKD). The effect of NSAIDs on the rate of CKD progression is still uncertain. The purpose of this study is to measure the prevalence of NSAID use in CKD patients under the care of a nephrologist compared to a primary care physican (PCP) and evaluate the impact of NSAID use on CKD progression.

Methods: This is a single center, retrospective study of patients with CKD stage 3 to 5 over a 1 year period. Patients 18 years or older with GFR < 60 mL/min (2 occasions), an office visit with nephrologist or PCP and an active NSAID prescription were included. We excluded hospitalized patients, transplant recipients, AKI episodes or dialysis dependency. We evaluated the change in GFR pre and post NSAID prescription over 1 year compared to non-NSAID users and compared nephrology to PCP care. Multivariate logistic regression identified potential co-variates of GFR change.

Results: Of the 2,157 patients included in the study, 12.2% had an NSAID prescription; 9.6% vs. 15% for patients receiving care from a nephrologist or PCP (p<0.001). Table 1 describes baseline demographics. GFR change was -3.9 vs. -3.7 mL/min/1.73 m^2 (p=NS) for NSAID users and non-users, respectively. In patients managed by a nephrologist, GFR change was -4.94 vs. -4.21 mL/min/1.73m^2 (p=NS) in users and non-users, while GFR change for patients managed by a PCP was -3.18 vs. -3.05 mL/min/1.73m^2 (p=NS) in users and non-users, respectively. Age (p<0.001), diabetes (p=0.02) and hepatitis C (p=0.001) were significantly associated with GFR change.

Conclusions: NSAIDs are prescribed to more than one out of every ten patients with CKD; more often by PCPs than nephrologists. Over 1 year, there was no statistically significant GFR change for NSAID users compared to non-users. Further long term studies are warranted to confirm safety of this medication class.

Baseline Demographics

Variable	Nephrology (n = 1,123)	Primary Care (n = 1,034)
Age, mean (IQR)	64 (56-75)	73 (65-82)

SA-PO623

Cause Specific Mortality Attributable to Proton Pump Inhibitor

Yan Xie,[1] Benjamin C. Bowe,[2] Tingting Li,[3] Yan Yan,[4] Hong Xian,[5] Ziyad Al-Aly.[1] *[1]VA Saint Louis Health Care System, Saint Louis, MO; [2]Research and Development Service, Veterans Affairs St Louis Health Care System, St. Louis, MO; [3]Washington University in St. Louis, Saint Louis, MO; [4]Washington University Medical School, Saint Louis, MO; [5]Saint Louis University College for Public Health & Social Justice, St. Louis, MO.*

Background: Proton pump inhibitors (PPI) are widely used; and their use is associated with increased risk of adverse events and death. However, a detailed analysis of the cause of the death distribution among users of PPI is not available. In this work, we aimed to characterize the cause of death among users of PPI.

Methods: A cohort of 325,307 new users of PPI or H2 blockers was built. Cause of death data from National Death Index was used to examine the association between PPI and cause specific morality. Multiple survival models including proportional hazards models, accelerated failure time models, and additive hazard models were used. we used an instrumental variable approach based on clinicians' prescribing behavior and high-dimensional propensity score in domains including diagnoses, procedures, medications and laboratory results to account for measured and unmeasured confounders, respectively. For each outcome, model-covariate combination with smallest Brier score was selected and the survival possibility for the cohort was calculated.

Results: During 10 years of follow up, PPI use was significantly associated with all-cause mortality, and mortality from circulatory, and genitourinary causes. Compared to users of H2 blockers, event rate per 1000 persons attributable to PPI use was 5.44 (17.57, 33.43), 9.91 (3.94, 15.79) and 5.17 (2.83, 7.51) for all-cause, circulatory and genitourinary mortality, respectively. The excess death accounted for 6.94% (4.85, 9.03), 7.15% (2.90, 11.17) and 32.58% (19.34, 43.56) of all the all-cause, circulatory, and genitourinary mortality in PPI users. Further analyses within the circulatory and genitourinary causes showed PPI use was associated with 8.07 (3.29, 12.77) and 3.66 (1.95, 5.46) excess death per 1000 persons from coronary artery disease and chronic kidney disease, which accounted for 10.22% (4.27, 15.72) and 35.97% (21.07, 48.23) of the related deaths. Death from acute kidney injury was not associated with PPI use (excess death 0.61 (-0.27, 1.51) and population attributable fraction 29.32% (-15.42, 56.11)).

Conclusions: In this work, we used advanced statistical methodologies to map the cause of death distribution among users of PPI. Our findings suggest that PPI use is associated with increased mortality from circulatory and genitourinary causes, but not other causes of death. PPI should only be used when medically indicated.

SA-PO624

Retrospective Population Scale Analysis Reveals Associations of Proton-Pump Inhibitor Use with Kidney Related Disorders

Tigran Makunts, Isaac V. Cohen, Ruben Abagyan, Linda Awdishu. *UCSD Skaggs School of Pharmacy and Pharmaceutical Sciences, La Jolla, CA.*

Background: Proton pump inhibitors (PPIs) are one of the most widely prescribed and sold drugs globally. Recent studies have revealed associations between PPI use and acute kidney injury (AKI), chronic kidney disease (CKD), and end stage renal disease (ESRD). The growing concern over potentially serious adverse events (AE) associated with their use warrants an evaluation of post marketing surveillance.

Methods: This is a retrospective study of 9.5 million voluntary adverse event (AE) reports to the FDA Adverse Event Reporting System (FAERS) from January 2004 to August 2017. Two cohorts were constructed from these reports: (1) PPI (n=665,735) and (2) histamine receptor antagonists (H2RA) (n=124,251) cohorts. Any report of patients taking concurrent nephrotoxins or where age was not reported was excluded resulting in 150,361 PPI and 29,115 H2RA AE reports. Outcomes were CKD, AKI, ESRD, nephrolithiasis and electrolyte disorders (hypomagnesemia, hypocalcemia and hypokalemia) defined by coding data. Frequencies of all reported AEs and corresponding odds ratios (OR) were calculated in each cohort.

Results: Patients who received PPIs had a significant increase in the number of reports for CKD OR 1.87 95% CI [1.3, 2.7], AKI 1.23 [1.1, 1.4], nephrolithiasis 2.16 [1.6, 2.9], hypomagnesemia 2.62 [2, 3.4], and hypocalcemia 1.95 [1.5, 2.5]. There was no significant difference in the frequency of hypokalemia 1.15 [0.91, 1.5] and ESRD 7.17 [0.99, 52]. Significant increases in CKD reports were identified for omeprazole 1.89 [1.3, 2.8], esomeprazole 1.95 [1.3, 2.9], dexlansoprazole 10.65 [3.3, 35]. Omeprazole and pantoprazole were significantly associated with increased AKI reports, 1.54 [1.4, 1.7] and 1.64 [1.4, 1.9], respectively whereas esomeprazole had a decrease in AKI reports 0.85 [0.75, 0.96].

Conclusions: In this study, we replicated the association between PPI exposure and the increased risk of AKI, CKD and electrolyte abnormalities from the AE reports in the FAERS database. To our knowledge this is the first large scale study showing a significant association of PPI use with nephrolithiasis. We found differences in AE reporting risk for individual PPIs. Further studies evaluating individual drug effects are warranted to confirm these findings.

SA-PO625

Does Desmopressin Decrease Kidney Biopsy Bleeding Risk in Patients with CKD?

Cagil D. Arslan, Ambarish Athavale, Edwin Okyne, Peter D. Hart. *John H Stroger Hospital of Cook county, Chicago, IL.*

Background: Kidney biopsy, the gold standard for diagnosing kidney disease, is associated with bleeding risk. Desmopressin is routinely prescribed to improve platelet function and decrease bleeding risk of kidney biopsy. It is not known if desmopressin decreases the risk of clinically significant bleeding (defined as post-biopsy hematoma, decrease in hemoglobin or need for RBC transfusion) in patients with CKD.

Methods: Retrospective review of consecutive percutaneous kidney biopsies performed at Stroger hospital between January 2014 and March 2018. CKD was defined as eGFR < 60ml/min/1.73 m^2. All biopsies were performed under real-time ultrasound guidance. Patients with bleeding time > 10 minutes were excluded from the study.

Results: 323 kidney biopsies were performed during the study period of which 217 had CKD. As compared to patients who did not receive desmopressin, administration of desmopressin did not decrease the risk of post-biopsy hematoma (18.94% in desmopressin group vs 19.44% in non-desmopressin group; p = 0.90) or need for blood transfusion (p=0.08). The mean decrease in hemoglobin was statistically significant in the desmopressin group than the non-desmopressin group (0.79 g/dl vs 0.46 g/dl; p = 0.0001) but not clinically significant. Both groups had adequate number of glomeruli on biopsy.

Conclusions: Routine administration of desmopressin in patients with CKD did not reduce the risk of clinically significant post-biopsy bleeding.

Clinical features and outcomes of kidney biopsy in patients with CKD

	Desmopressin (n=88)	No Desmopressin (n=129)	P value
Age	50.66 (13.42)	48.85 (13.83)	0.32
BMI	28.82 (6.2)	30.72 (6.32)	0.02
Serum creatinine	4.02 (2.51)	2.80 (1.46)	0.0001
Baseline hemoglobin	10.07 (1.45)	11.32 (1.81)	0.0001
Systolic BP	135 (15)	136 (16)	0.6
Platelet count	213.12 (71.91)	239.89 (85.28)	0.01
Bleeding time	7.10 (2.88)	4.61 (1.87)	0.0001
Number of passes	2.52 (0.79)	2.69 (1.11)	0.22
Number of glomeruli	21.40 (9.66)	17.92 (8.78)	0.005
Mean hemoglobin decrease	0.79 (0.63)	0.46 (0.54)	0.0001
Gross hematuria	9 (11.39%)	4 (3.10 %)	0.0001
Post-biopsy hematoma	14 (18.91%)	21 (19.44%)	0.90
RBC transfusion	5 (6.03%)	1 (0.007%)	0.08

SA-PO626

Use of Urinary Exosomes to Confirm Pharmacological Activity of CXA-10 on Nrf2 and Heat Shock Response Gene Expression in the Kidney of Patients with CKD

Rachel Garner,[1] Anna-Liisa Levonen,[5] Carla Chieffo,[2] Christine M. Debouck,[3] Francisco J. Schopfer,[4] Diane K. Jorkasky.[1] *[1]Complexa, Inc., Berwyn, PA; [2]Complexa, Inc. Consultant, Berwyn, PA; [3]Ardennes Biosciences LLC, Wayne, PA; [4]University of Pittsburgh, Pittsburgh, PA; [5]University of Eastern Finland, Kuopio, Finland.*

Background: CXA-10 is an electrophilic nitrated fatty acid being developed for focal segmental glomerular sclerosis. In animal studies, CXA-10 modulated several pathways including activation of nuclear factor E2-related factor 2 (Nrf2) and heat shock response (HSR). Urinary exosomes are small cell-derived vesicles shed from kidney cells that carry mRNA and proteins. Genetic material in urinary exosomes reflects gene activation in the kidney. The purpose of this study was to examine the ability of CXA-10 to induce Nrf2- and HSR-dependent gene expression in blood and kidney of subjects with chronic kidney disease (CKD).

Methods: This was a multicenter, open-label, single-dose study of CXA-10 in subjects with moderate and severe CKD. Four subjects received a 1-hour infusion of 0.34 mg/kg and 8 subjects received a 1-hour infusion of 0.68 mg/kg CXA-10. Gene expression assessments were conducted from predose to 96 hours postdose as the time course of responses was unknown. Whole blood and urine samples were collected for analysis of target genes by qRT-PCR in isolated PBMCs and exosomes, respectively. Target genes were from the Nrf2 pathway, NAD(P)H quinone dehydrogenase 1 (NQO1) and Heme Oxygenase 1 (HMOX-1) and the heat shock pathway, Heat Shock Protein Family A and 1B (HSPA1A/B).

Results: Gene expression increased after CXA-10 dosing for all target genes. Maximum gene expression per subject showed a dose-response relationship for NQO1 and HSP1A/B in both PBMCs and urinary exosomes. Gene expression response, defined as ≥3-fold increase from baseline, was exhibited in 10 subjects (83.3%) for ≥1 target gene. PBMC gene expression response was observed in 8 subjects (66.7%) and urinary exosome gene expression in 6 subjects (50%). HSPA1A/B showed the highest level of induction in both PBMCs and urinary exosomes.

Conclusions: A single IV dose of CXA-10 increases cellular protective Nrf2- and HSR-related genes in subjects with CKD. This study demonstrates the first human translation of the pharmacological actions of CXA-10 that have been previously characterized in vitro and in animal models. To our knowledge, this is the first use of urinary exosomes to demonstrate the pharmacological action in the target organ of a novel drug in clinical development.

Tumor Lysis Syndrome Linked to Anticancer Agents: An Analysis Using the FDA Adverse Event Reporting System

Akimasa Sanagawa,[1,2] Yuji Hotta,[2] Masahiro Kondo,[1,3] Nishikawa Ryohei,[4] Masahiro Tohkin,[4] Kazunori Kimura.[2,3] *[1]Department of Pharmacy, Nagoya City University Hospital, Nagoya, Japan; [2]Department of Hospital Pharmacy, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; [3]Department of Clinical Pharmacy, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan; [4]Department of Regulatory Science, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan.*

Background: Tumor lysis syndrome (TLS) is an oncologic emergency that can lead to severe renal impairment, cardiac arrhythmias, seizures, and death. We used the Food and Drug Administration Adverse Reporting System (FAERS) database to identify associations between anticancer agents and TLS.

Methods: Reports of TLS were retrieved from the FAERS database. Reporting odds ratios (RORs) were used to estimate associations between TLS and old and new anticancer agents or their combinations.

Results: We identified 1,615 TLS cases from among 4,330,807 case reports from the first quarter of 2004 through the first quarter of 2014. Statistically significant risk signals were detected for 56 of 64 anticancer agents. Bortezomib (BOR), a drug used for multiple myeloma (MM), had a high ROR and large number of TLS events relative to that of molecular-targeted drugs (161 TLS events, ROR = 28.89, 95% CI: 24.53–34.02). However, MM is a disease considered low-risk for TLS. We analyzed regimens containing novel MM drugs (e.g., BOR, lenalidomide, and thalidomide). Of those drugs, TLS was more frequently reported for BOR-containing treatments than for other MM treatments (Fig. 1).

Conclusions: Although the risk of TLS is generally considered low for MM patients, careful evaluation of TLS risk is recommended for those receiving BOR-containing therapy.

Funding: Government Support - Non-U.S.

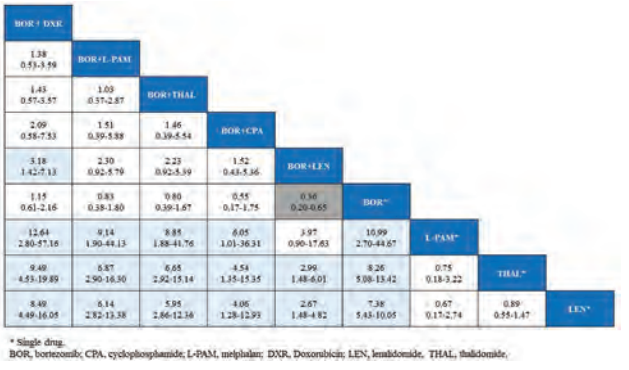

Fig. 1 Estimates of TLS risk in MM chemotherapy regimens. Chemotherapy drug combinations are in blue cells. Values listed are for the TLS risk of column-defined combinations relative to that of row-defined combinations. For RORs in the opposing direction, reciprocals of the listed values must be used. ROR values > 1 favor the column-defined combinations. Light blue and gray cells indicate statistical significance. Ranges represent 95% confidence intervals.

SA-PO628

The Pharmacokinetics of Meropenem and Piperacillin/Tazobactam in Haemodiafiltration

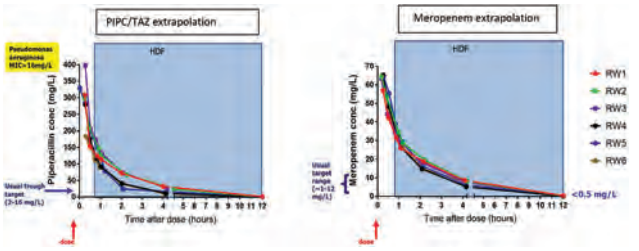
Sine Donnellan,[2] Dan Wright,[1] Stephen Duffull,[1] Tracey L. Putt,[2] John B. Schollum,[2] Robert J. Walker.[1] *[1]University of Otago, Dunedin, New Zealand; [2]Dunedin Hospital, Dunedin, New Zealand.*

Background: Meropenem and piperacillin/tazoobactam (PIPC/TAZ) are commonly used in the treatment of sepsis. Their effectiveness is dependent upon time above minimium inhibitory concentration (MIC). Dosing practices in haemodiafiltration (HDF) rely on extrapolation from intermittent haemodialysis (IHD) or continuous renal replacement therapies and may lead to subtherapeutic concentration due to fundamental differences in membrane characteristics, duration of therapy and blood flow rates.

Methods: We performed an open label pilot study on 6 stable haemodialysis patients. HDF prescription was based upon our local intensive care practice. Patient characteristics, bioimpendance and any deviation from prescription were documented. Meropenem (1g) was administered 1 hour prior to commencement of HDF. 12 blood samples were taken (baseline, pre, post membrane during HDF and 1 hour post cessation). This was repeated with PIPC/TAZ (4.5g) 1 week later. Samples were analysed by validated chromatography. Pharmacokinetic modelling analysis was performed on each of the samples using non-compartmental methods. Extrapolation of plasma concentrations to 12 hrs was approximated assuming an exponential decline, given by; $C_{p(t)} = C_{p0} \times e^{-kt}$ were Cp(t) is the plasma concentration at time (12 hrs post=dose in this case),C_{p0} is the plasma concentration at time 0, and *k* is the terminal phase rate constant.

Results: Participants were mostly male with a mean age of 63.8±14 yrs. Haemodiafiltration clearance (HDCL) ranged from 8.9-10.8 L/h for meropenem and 9.6-19.1 L/h for PIPC/TAZ with an area under the plasma concentration-time curve during HDF (AUC_{HDF}) of 83-99 and 195-351 mg/L*h respectively. Fig 1 shows approximation of the PIPC/TAZ and meropenem data assuming the HDF continued for 12 hours without repeated dosing.

Conclusions: Meropenem and PIPC/TAZ removal during HDF is substantial with potential subtherapeutic concentration after a relatively short period.



SA-PO629

Meropenem Renal Kinetics in Human Kidney Biopsies

Rodrigo Sepúlveda, Patricio Downey, Juan P. Huidobro, Dagoberto Soto, Max Andresen. *Pontificia Universidad Católica de Chile, Santiago, Chile.*

Background: Urinary tract infection is the most common bacterial infection. Usually it has good prognosis even though some cases can have serious complications. Last decades multi-resistant bacterial strains are arising but development of antibiotics has declined. Meropenem is a broad-spectrum antibiotic with activity against many bacteria including multi-resistant strains; however, its renal tissue kinetics is unknown.

Methods: We conducted a descriptive study in humans with indication of kidney biopsy. Meropenem was infused over 30 minutes one hour before biopsy performed and was evaluated the plasmatic concentration after meropenem infusion (T1), 60 minutes (T2) and 120 minutes (T3). Also meropenem concentration in the kidney sample was measured. It was used a fluorescent biosensor for B-Lactams antibiotics to measure levels of meropenem.

Results: In 14 patients, 64% women, body mass index was 26.3 ±2.9, eGFR was 57.5 ±44.1 ml/min/1.73m^2 and plasma albumin 3.8 ±0.9 g/dL. Kidney biopsy was done at 68.9 ±20.3 minutes after meropenem infusion; the second plasma sample was obtained at 82.1 ±21.2 minutes and the third at 149.6 ±31.5 minutes. Meropenem concentrations at T1, T2 and T3 were 45.9 ±10, 20.7 ±13, 16.6 ±13 μg/mL respectively. Mean kidney sample weight was 5.9 ±3.0 mg and meropenem concentration was 3.1 ±1.9 μg/mL. For each patient a decay curve was constructed and meropenem plasma concentration was estimated at the biopsy time. The ratio of meropenem concentration between plasma and renal tissue (mP/mK) was 14 ±10% with a range of 3.8% – 34.8%. Meropenem excretion occurs predominantly by glomerular filtration, thus plasma concentration and glomerular filtration rate determine the filtered load, modifying the urinary concentration and keeping the (mP/mK) ratio constant over time. The absence of linear correlation between (mP/mK) ratio and eGFR supports this idea. With the standard meropenem doses and normal renal function, we estimate that is possible treating with bactericide effect to bacteria with MIC90 <0.76 μg/mL.

Conclusions: With standard meropenem doses is possible achieve adequate concentration in renal parenchyma to treat, with bactericide effect, most frequent uropathogens. Nevertheless, for resistant bacteria is necessary increase the dose or consider another antibiotic. Renal failure does not avoid achieving adequate meropenem renal tissue concentrations.

SA-PO630

Pharmacokinetics of Intraperitoneal Cefazolin and Ceftazidime in Automated Peritoneal Dialysis Patients with Peritonitis

Pinpongsarn Triyawatanyu,[1] Pisut Katavetin,[3] Pajaree Chariyavilaskul,[2] Weeraya Phaisal,[4] Sadudee Peerapornratana,[2] Talerngsak Kanjanabuch,[2] Kearkiat Praditpornsilpa,[2] Somchai Eiam-Ong.[2] *[1]Chulalongkorn university, Nongkhai, Thailand; [2]Chulalongkorn University, Bangkok, Thailand; [3]King Chulalongkorn Memorial Hospital, Thai Red Cross Society and Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [4]chulalongkorn university, Bangkok, Thailand.*

Background: The current peritoneal dialysis (PD) guideline suggested that intraperitoneal (IP) antibiotics should be administered only in a long dwell (≥6 hours). We previously showed that IP cefazolin and ceftazidime during short-dwell cycling PD (<2-hour) could provide adequate plasma concentration for up to 24 hours in non-peritonitis patients. This study was aimed to evaluate bioavailability, as well as plasma and dialysate concentration of IP cefazolin and ceftazidime during short-dwell cycling PD in patients with peritonitis.

Methods: PD patients with peritonitis were enrolled. Cefazolin and ceftazidime (2,500 mg each) were added in a 5-liter bag containing 2.5% dextrose PD fluid, placed on the warmer of PD cycling machine. Another 5-liter bag of PD fluid was connected to the machine, off the warmer. Patients underwent 5 exchanges of 2-liter PD fluid over 10 hours by the PD cycling machine without last fill or additional dwell. Antibiotics concentrations were determined by high-performance liquid chromatography.

Results: Six PD patients with peritonitis participated in this study. The IP bioavailability of cefazolin and ceftazidime were 50.3±16.4% and 56.6±18.4%, respectively. Plasma cefazolin and ceftazidime levels exceeded the minimum inhibitory concentration (MIC) of 8 mg/L within the first hour (cefazolin 37.0±6.5 and ceftazidime 21.4±5.7 mg/L), peak at 10 hours (100.1±4.0 and 54.0±14.5 mg/L) and then sustained well above the MIC at 24 hours after the infusion (82.3±3.2 and 40.2±10.5 mg/L). Dialysate cefazolin and ceftazidime levels were also sustained above the MIC throughout the PD session in all patients.

Conclusions: The IP cefazolin and ceftazidime during short dwells in peritonitis patients provided sufficient bioavailability as well as adequate plasma and dialysate concentrations. This regimen should be one of the standard regimens for treatment of peritonitis in PD patients.

The Distribution Profile of Anti-Sense Oligonucleotides Indicates That Proximal Tubular Targets Should Be Prioritized in Renal Disease

Anna Granqvist,[1] Lena William-Olsson,[1] Barbro Basta,[2] Charlotte Ericson,[1] Pernilla Tonelius,[1] Åsa Wåhlander,[1] Thomas Bell,[4] Patrik Andersson,[1] Magnus Soderberg,[1] Robert J. Unwin,[3] Mark J. Anderton,[1] Christine Ahlström.[1] *[1]AstraZeneca, Molndal, Sweden; [2]Astrazeneca, Mondal, Sweden; [3]University College London Medical School, London, United Kingdom; [4]Ionis Pharmaceuticals, Carlsbad, CA.*

Background: Antisense oligonucleotides (ASOs) are predominantly taken up by the liver and kidneys, which makes them a potentially attractive modality for the treatment of renal disease. However, it is not clear to what extent ASOs reach the different compartments of the kidney. The biodistribution of ASOs is dependent on plasma protein binding, which delays urinary excretion, but may also facilitate uptake into proximal tubular cells (PTCs).

Methods: We investigated the tissue exposure and distribution of a phosphorothioate cEt gapmer ASO in three different renal disease models: the diabetic BTBR*ob/ob*, the 5/6 nephrectomy and the adenine diet mouse models. Mice were subcutaneously administered weekly doses of 3, 10 or 30 mg/kg ASO and followed for between 2 and 12 weeks.

Results: In all treated animals, renal tissue ASO exposure and significant knockdown of the target gene were achieved. Detailed analysis of the ASO distribution and knockdown revealed that the primary site of action is the PTCs, whereas knockdown in the glomerular compartment required higher doses. Uptake of ASOs in distal tubules was only detected in the adenine model in which PTCs were severely injured.

Conclusions: These results indicate that ASOs can primarily be used for treatment targets in PTCs, while targets in the distal tubule will require facilitated delivery for efficient knockdown.

Identification of Patients with High Probability of Not or Poorly Responding to Mycophenolic Acid Prodrugs

Wolfgang Winnicki, Gurkan Sengoelge. *Medical University of Vienna, Vienna, Austria.*

Background: The antiproliferative agent mycophenolic acid (MPA) exerts its immunosuppressive effect by a selective inhibition of inosine 5'-monophosphate dehydrogenase (IMPDH), the rate-limiting enzyme of purine metabolism. The isoenzyme IMPDH2 predominates in activated lymphocytes, and its inhibition by MPA is part of standard immunosuppressive therapy in transplant medicine. Previously, factors which might explain differences in MPA efficacy and tolerability among patients have been studied: polymorphism rs11706052 in the IMPDH2 gene has been identified to reduce the antiproliferative effect of MPA on lymphocytes; data on therapeutic drug monitoring using MPA trough levels and IMPDH activity were not conclusive. Yet, whether a combination of

pharmacogenomic, pharmacokinetic and pharmacodynamic factors explain the differences in response to MPA therapy and drug tolerance remains to be elucidated.

Methods: This was designed as a prospective study of kidney transplant patients with and without biopsy-proven rejection (BPR). Both groups were tested for the presence of SNP rs11706052. In addition, MPA trough levels in plasma were measured by high performance liquid chromatography and IMPDH enzyme activity in peripheral blood mononuclear cells was tested by liquid chromatography–mass spectrometry. Correlations between BPR and the presence of rs11706052, MPA trough levels, IMPDH activity as well as the IMPDH/MPA ratio (assuming that a higher IMPDH activity requires higher MPA trough levels for an adequate immunosuppressive effect) were examined.

Results: Preliminary results from 50 kidney transplant recipients with biopsy-proven rejection and 100 controls without rejection suggest 1.) IMPDH activity was significantly higher in patients with BPR compared to patients with a stable graft function over 12 months with no immunological complications, 2.) no correlation between IMPDH activity and MPA levels, BPR and the IMPDH/MPA ratio, 3.) no influence of rs11706052.

Conclusions: This is the clinical extension of our previous in vitro study, which has shown that the polymorphism rs11706052 reduces the immunosuppressive effect of MPA. This prospective study investigates the susceptibility to reject kidney allografts using a combined pharmacogenomic, pharmacokinetic and pharmacodynamic approach.

SA-PO633

Tacrolimus Troughs and Doses in African American, Asian, Caucasian, and Hispanic/Native American Kidney Transplant (tx) Recipients

Pamala A. Jacobson,[1] David P. Schladt,[2] William S. Oetting,[1] Baolin Wu,[1] Weihua Guan,[1] Casey R. Dorr,[2] Rory P. Remmel,[1] Roslyn B. Mannon,[3] David N. Ikle,[4] Arthur J. Matas,[1] Ajay K. Israni.[5,1] DeKAF Genomics *[1]University of Minnesota, Minneapolis, MN; [2]Minneapolis Medical Research Foundation, Minneapolis, MN; [3]University of Alabama at Birmingham, Birmingham, AL; [4]Rho Federal Systems Division, Chapel Hill, NC; [5]Hennepin County Medical Center, Minneapolis, MN.*

Background: TAC is an immune suppressant with a narrow therapeutic index and high inter-individual pharmacokinetic (PK) variability. African Americans (AA) have lower troughs and higher dose requirements primarily due to the *CYP3A5*1* allele that results in CYP3A expression. Caucasians have higher troughs and lower dose requirements due to the loss of function variants *CYP3A5*3* and *CYP3A4*22.* TAC trough and genotype relationships for Asian and Hispanic/Native Americans are not well described.

Methods: 2739 adult kidney tx recipients enrolled in the multicenter DeKAF Genomics and the GEN03 genome wide association studies (GWAS) who received TAC maintenance and had TAC troughs available in the first 6 mo posttx were studied. Race was identified and confirmed through principal component analysis using the GWAS. We tested the association between genetic variants (CYP3A5*3, *6 and *7, CYP3A4*22) and dose-normalized TAC troughs in each population adjusting for center, age and gender

Results: The allele frequency of CYP3A5*3 differed between the groups; 0.30, 0.72, 0.92, 0.84 in AA, Asian, Caucasian and Hispanic/Native Americans, respectively. The median (IQR) TAC dose-normalized trough, dose and trough by population are in the table. CYP3A5*3 was highly significant in all groups (p = 3.3E-09 to 4.9E-127). CYP3A5*6 and *7 were associated with troughs in the AA group (p=2.0E-12 and 1.3E-24) and CYP3A4*22 in the Caucasian group (2.2xE-22).

Conclusions: The Hispanic/Native American group had the highest dose-normalized TAC trough and the AA the lowest. The most rapid TAC metabolism occurs in AA followed by Asians, Caucasians and Hispanic/Native Americans. Genetic variants that influence TAC metabolism are highly significant and vary by race. This data suggest that additional variants may be present in the Asian and Hispanic/Native American groups which impact CYP3A4 and 5 substrate metabolism.

Race	TAC dose-normalized trough	TAC Daily Dose	TAC trough
African American (n=516)	0.77 (90.52-1.19)	8.0 (6.0-12.0)	6.8 (4.9-8.9)
Asian (n=91)	1.50 (0.98-2.53)	6.0 (3.5-8.0)	6.7 (6.7-10.6)
Caucasian (n=2055)	1.55 (1.02-2.40)	5.0 (4.0-8.0)	8.4 (6.5-10.3)
Hispanic/Native American (n=77)	1.73 (1.06-2.67)	5.0 (3.0-8.0)	8.3 (6.3-10.3)

SA-PO634

Safety and Single Ascending Dose Pharmacokinetic Study of DUR-928 in Patients with CKD versus Matched Control Subjects

Jaymin C. Shah, David J. Ellis, Andrew R. Miksztal, Wei Qi Lin. *DURECT Corporation, Cupertino, CA.*

Background: DUR-928 ((5-cholesten-3β,25-diol 3-sulfate (25HC3S)) is an endogenous intracellular sulfated oxysterol that has been shown to regulate lipid metabolism, inflammatory response, and cell survival. This first-in-class investigational product is being developed for the treatment of various liver and kidney diseases. Animal ADME studies have shown that ≈ 17% of DUR-928 is eliminated through the urine. This study was to evaluate the impact of renal impairment in chronic kidney disease (CKD), on the safety and pharmacokinetics (PK) of DUR-928.

Methods: The study was a Phase 1b, open label, single ascending dose study to evaluate the safety and PK of IM injected DUR-928 in patients with moderate and severe kidney function impairment (Stage 3 and Stage 4 CKD) and matched control subjects (MCS), matched by age, BMI, and gender, with normal kidney function. The two doses of DUR-928 in the study were 30 mg and 120 mg. Biomarkers were also examined. All study subjects were followed through 7 days post dosing.

Results: Eleven CKD patients (Stage 3 (N=8), Stage 4 (N=3)) and six MCS completed the study. A total of 13 TEAEs were reported by 8 participants, mostly mild and none were severe. A clinically non-significant decrease (≈ 10%) in exposure was observed in CKD patients as compared to MCS at both dose levels of DUR-928. The AUC values for 30 and 120 mg doses in CKD patients were 1061 and 4304 ng*hr/mL vs. 1138 and 4766 ng*hr/mL in MCS. Similarly, the C_{max} values for 30 and 120 mg doses in CKD patients were 281 and 890 ng/mL vs. 345 and 997 ng/mL in MCS. The plasma half-life ($T_{½}$) was in the range of 1.5 to 2 hours. Participants with elevated levels of CK-18 (markers of cell death) or bilirubin at baseline showed considerable reduction of these markers at 12 or 24 - 48 hours after a single IM injection of DUR-928.

Conclusions: Single IM doses of DUR-928 in CKD patients were found to be well tolerated. Kidney function impairment did not impact the PK of DUR-928. These data support further evaluation of DUR-928 in patients with kidney disease.

SA-PO635

Evaluation of the Antioxidant Effects of Benzbromarone in Angiotensin II Induced Hypertension Model

Daisuke Kadowaki,[1] Yuki Narita,[2] Shigeyuki Miyamura,[1] Kohei Uchimura,[3,4] Kenichiro Kitamura,[4] Toru Maruyama,[2] Sumio Hirata,[2] Hakaru Seo.[1] *[1]School of Pharmacy, Sojo University, Kumamoto, Japan; [2]School of Pharmacy, Kumamoto University, Kumamoto, Japan; [3]Washington University in St. Louis, Saint Louis, MO; [4]University of Yamanashi School of Medicine, Chuo, Japan.*

Background: Uric acid exerts an important antioxidant effect against external oxidative stress under physiological conditions. However, oxidative stress induced by hyperuricemia is closely associated with the renin-angiotensin system, as well as the onset and progression of cardiovascular disease (CVD) and chronic kidney disease (CKD). Furthermore, uric acid locally activates the renin-angiotensin system, thus producing angiotensin II and subsequently increasing intracellular oxidative stress. Benzbromarone has been reported to suppress uric acid reabsorption via uric acid transporter 1 inhibition in renal tubular cells. In this study, we evaluated the antioxidant effect of benzbromarone from several perspectives *in vitro* and *in vivo*.

Methods: First, the direct radical-trapping capacity of benzbromarone was measured by chemiluminescence assay and electron paramagnetic resonance spectroscopy *in vitro*. Second, the intracellular antioxidant activity of benzbromarone was evaluated using endothelial cells. Finally, the antioxidant effects of benzbromarone were evaluated *in vivo* via oral administration of benzbromarone for 4 weeks to model rats with angiotensin II– and salt-induced hypertension.

Results: benzbromarone showed direct radical scavenging capacity against the superoxide anion radical *in vitro*. In addition, benzbromarone inhibited reactive oxygen species production that was induced by angiotensin II or uric acid in endothelial cells. In *in vivo* study, benzbromarone did not alter plasma uric acid levels or blood pressure, but significantly reduced the levels of advanced oxidation protein products, which are oxidative stress markers. Furthermore, dihydroethidium staining of the kidney revealed a reduction in oxidative stress after benzbromarone administration.

Conclusions: These findings suggest that benzbromarone possesses the ability directly to scavenge radicals and may act as an antioxidant against uric acid and angiotensin II-induced oxidative stresses in endothelial cells or angiotensin II induced hypertension.

SA-PO636

C-PAM, a Novel Iron Oxide-based Oral Drug, Efficiently Lowers Serum PI

Susanne E. Wagner,[2] Jörg Schnorr,[1] Monika Ebert,[1] Nicola Stolzenburg,[1] Matthias Taupitz.[1] *[1]Charité - Universitätsmedizin Berlin, Berlin, Germany; [2]Wagner MSL Management, Mahlow, Germany.*

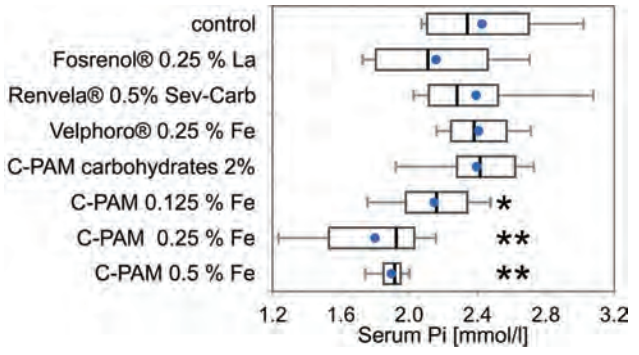
Background: C-PAM is a novel compound designed for use as a serum Pi-lowering oral drug. It is composed of iron (Fe) oxide nanoparticles with a maghemite structure, mannitol, inulin, and Arabic gum. In previous analytical tests, C-PAM had a superior Pi-binding capacity compared to major approved Pi-binders. The hypothesis of this experimental in vivo study is that C-PAM more efficiently lowers serum Pi compared to those Pi-binders.

Methods: Healthy male Sprague-Dawley rats with a starting weight of 250 g were treated with drug co-feeding for 4 weeks (n=8 rats per group). C-PAM was added to Altromin standard 1320 diet (containing 0.6 wt% free adsorbable Pi) at 0.125, 0.25, and 0.5 wt% Fe. For comparison, three groups received Fosrenol® at 0.25 wt% La, Renvela® at 0.5 wt% sevelamer carbonate, and Velphoro® at 0.25 wt% Fe. As controls, one group received standard diet only and one group the carbohydrate components of C-PAM (mannitol, inulin, Arabic gum) at 2.0 wt%. Blood was sampled at the end of the 4-week study period and analyzed for serum Pi and standard parameters of hematology and clinical chemistry. For histopathology, HE and iron stains of liver, spleen, heart, lung, kidney, stomach, duodenum, jejunum, ileum, colon, and intestinal lymph nodes were assessed. Student's t-test was used for statistical analysis.

Results: At all doses investigated, C-PAM reduced serum Pi significantly (0.125 wt%: $p < .05$, 0.25 and 0.5 wt%: $p < .01$). None of the other products tested or the carbohydrate components of C-PAM had a significant serum Pi lowering effect (figure). For C-PAM, except serum Pi, there was no effect on hematology and clinical chemistry parameters. No histopathologic changes were observed.

Conclusions: Even at a low dose, C-PAM effectively reduces serum Pi in healthy rats and thus is superior to three major approved products.

Funding: Government Support - Non-U.S.



In vivo efficacy of C-PAM in lowering serum Pi at three different doses compared with three approved products, the carbohydrate components of C-PAM only, and with a control group (*p<.05; **p<.01).

SA-PO637

C-PAM, a Novel Serum Phosphate-Lowering Oral Drug with Dual Mode of Action, Prevents Serum Phosphate Rise After Drug Skip

Matthias Taupitz,[1] Jörg Schnorr,[1] Nicola Stolzenburg,[1] Franziska Rausch,[1] Monika Ebert,[1] Susanne E. Wagner.[3] *[1]Charité - Universitätsmedizin Berlin, Berlin, Germany; [3]Wagner MSL Management, Mahlow, Germany.*

Background: In ESRD patients, medications based on Pi-binders to control serum Pi require regular oral drug intake with each meal. Such a regimen is not conducive to adequate compliance, and occasional drug skipping is one reason why <20% of patients have serum Pi levels within the KDOQI® recommended target range. C-PAM is a novel compound consisting of iron oxide nanoparticles with a maghemite structure, mannitol, inulin, and Arabic gum. C-PAM showed superior Pi-binding in earlier analytical tests and better serum Pi-lowering in experimental in vivo studies, both compared to major approved drugs. The hypothesis for this experimental study was that, for C-PAM, a 1-day drug skip does not significantly increase serum Pi.

Methods: Healthy male Sprague-Dawley rats (CD Charles River) with an initial weight > 320 g were treated with drug co-feeding for 4 weeks (n=8 rats per group). Group A: C-PAM added to Altromin standard 1320 diet (0.47% digestable Pi) at 0.75 wt% total drug substance. Group B: Renvela® at 1.5 wt% total drug substance. Blood was sampled at the end of each week (W1 to W4) for analysis of serum Pi. During one day before W3 blood sampling, rats received the standard diet only. After W4 sampling, rats were sacrificed and the intestine was analyzed for NaPi2b expression using PCR. For statistical analysis student's t-test was used.

Results: Serum Pi was as follows [mmol/l]: C-PAM: BL 2.31±.21; W1 2.13±.21; W2 2.15±.27; W3 (after drug skip) 2.29±.20; W4 1.92±.20. Renvela®: BL 2.60±.25; W1 1.89±.24; W2 1.93±.44; W3 (after drug skip) 2.56±.27; W4 1.87±.13. After drug skip the rise was 7% (n.s.) and 33% (p<.01) resp. After drug skip the values were -10% and +1% resp. compared to age matched controls (n.s.). PCR analysis showed less expression of NaPi2b (ΔΔCt) in the proximal jejunum in the C-PAM group (3.08±.05) compared to the Renvela group (5.30±2.56, p<.05).

Conclusions: C-PAM effectively reduces serum Pi at a low dose and is robust against a 1-d drug skip, which is because of its dual mode of action combining highly effective Pi binding with an effect on NaPi2b transporters. If C-PAM is equally effective in the clinical setting, treatment of ESRD patients may be impoved by a significantly lower pill burden with better maintainance of serum Pi within the KDOQI® recommended target range.

Effect of Serum Parathyroid Hormone on Tacrolimus Therapy in Kidney Transplant Patients: A Possible Biomarker for a Tacrolimus Dosage Schedule

Rui Fujimura,[1,2] Hiroshi Watanabe,[3] Kenshiro Hirata,[4] Toru Maruyama.[3] *[1]Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kumamoto University, Kumamoto, Japan; [2]Program for Leading Graduate Schools "HIGO (Health life science: Interdisciplinary and Glocal Oriented) Program, Kumamoto University, Kumamoto, Japan; [3]Biopharmaceutics, School of Pharmacy, Kumamoto University, Kumamoto, Japan; [4]Pharmacy, Japanese Red Cross Kumamoto Hospital, Kumamoto, Japan, Kumamoto, Japan.*

Background: The mechanism responsible for the decreased extra-renal CYP3A activity in chronic kidney disease (CKD) patients remains unknown. Using an animal model, we previously found that elevated levels of serum intact parathyroid hormone (iPTH) caused a reduced CYP3A activity. The purpose of this study is to investigate whether serum iPTH levels affects the pharmacokinetics of tacrolimus, a CYP3A substrate, and its dosage schedule in kidney transplant recipients.

Methods: Thirty-four patients who were recipients of kidney transplantation between April 2014 and March 2016 and were administrated prolonged-release tacrolimus (Graceptor®, Astellas Pharm Inc.) once daily were the subjects of this study. Among the 34 patients, 22 patients had received the concomitant CYP3A substrate drug. To clarify the role of iPTH on the pharmacokinetics of tacrolimus, we performed the analysis using 12 patients who had not been administered concomitant CYP3A substrate drug.

Results: To investigate the relationship between serum iPTH levels and tacrolimus trough levels, we monitored the serum iPTH levels in patients before kidney transplantation. At this time point, serum iPTH levels in these subjects were increased, but with large deviations due to the difference in the patients' background such as the causes of and the progression of renal failure and complications. Therefore, we examined the correlation between serum iPTH levels and trough levels after the first oral administration of tacrolimus at 4 days before kidney transplantation. A significant positive correlation between serum iPTH level and the initial trough level for tacrolimus was found. This indicates that the tacrolimus trough level before transplantation was higher in patients with high serum iPTH levels as compared to patients with low iPTH values. These data suggest that CYP3A activity might be lower in patients with high serum iPTH levels, as was observed in the previous animal study, and that the initial trough level of tacrolimus could be predicted from serum iPTH levels before kidney transplantation.

Conclusions: Monitoring serum iPTH levels could predict the trough level for the initial administration of tacrolimus, and may serve as an index for the initial dose of tacrolimus in kidney transplantation patients.

Rhein Attenuates D-Galactose Induced Renal Aging via Regulation of mTOR-Mediated Autophagy

Yue Tu, Diping Chen, Yihuang Gu. *Department of TCM Health Preservation, Nanjing University of Chinese Medicine, Nanjing, China.*

Background: In recent years, traditional Chinese herbal medications (TCHMs) are found to possess potent anti-aging activities. Rhubarb, derived from the root of *Rheum palmatum*, has been found to have anti-aging pharmacological effect. Rhein, a bioactive constituent of rhubarb, plays a vital role in its pharmacological effect. However, the potential mechanism of rhein in anti-aging remains unclear. Autophagy and its related signaling pathway mTOR play the important roles in aging.

Methods: *In vitro*, D-galactose (D-gal) was used to induce renal cellular aging in NRK-52E cells, following treating with or without rhein or vitamin E (VE). To measure renal cellular aging, the klotho protein expression was detected, and the senescence-associated-β-galactosidase (SA-β-gal) staining were observed. To study the changes of autophagy in the aging effects, several key autophagic markers protein expressions, including LC3 I/II, beclin1, SQSTM1/p62 and phospho-p62 (p-p62), were detected. Further, the changes of key protein expressions in mTOR signaling, including mTOR, and phospho-mTOR (Ser2448 and Ser2481), were detected in the same condition. The changes of the key protein expressions in mTOR-mediated autophagy were detected in NRK-52E cells exposed to D-gal and rhein or VE with or without mTOR inhibitor rapamycin (RAP) and mTOR activator MHY1485. *In vivo*, SD rats were divided into Normal, D-gal, Rhein-low dose, Rhein-high dose, VE, RAP and MHY1485 groups. The renal aging and mTOR-mediated autophagy related protein expressions and SA-β-gal staining were detected.

Results: Results showed that, renal tubular cellular aging *in vitro* and renal aging *in vivo* both induced by D-gal could be ameliorated by rhein and VE by inducing klotho protein expression, and attenuating the positive area of SA-β-gal staining. Rhein and VE could regulate mTOR-mediated autophagy by reducing autophagic related protein expressions and increasing mTOR signaling related protein expressions both *in vitro* and *in vivo*.

Conclusions: In this study, we demonstrated that rhein, similar to VE, could alleviate renal aging via regulating mTOR-mediated autophagy. These findings suggest that targeting autophagy and related signaling pathways may provide new strategies in the age-associated renal damage of the elderly patients.

Effect of CKD on Fexofenadine Disposition in Humanized OATP1B1/1B3 Mice

Nicholas Tonial,[1] Yong Jin (James) Lim,[1] Brad Urquhart.[1,2] *[1]Physiology and Pharmacology, Western University, London, ON, Canada; [2]Medicine, Division of Nephrology, Western University, London, ON, Canada.*

Background: Patients with chronic kidney disease (CKD) often experience variable responses to drug therapies evidenced by their elevated incidence of adverse drug reactions. Cytochrome P450s (CYPs) and drug transporters are major contributors to drug disposition, as they mediate drug metabolism and removal from blood, respectively, to facilitate non-renal excretion. Rodent models of CKD exhibit reduced CYP expression and activity. However, the impact of CKD on drug transporters, namely organic anion transporting polypeptides (OATPs), is not well elucidated. Fexofenadine is a commonly used transporter probe ideal to study non-renal clearance since it is not metabolized and not eliminated in the urine. Multiple studies have documented significantly increased fexofenadine exposure in CKD patients, although the mechanism is unclear. This study investigated the effects of CKD on hepatic drug transporter activity in a humanized hepatic OATP1B1/1B3 mouse model by evaluating the liver distribution fexofenadine. It was hypothesized that CKD would decrease the activity of these transporters, as shown by a reduction in hepatic fexofenadine distribution.

Methods: CKD was induced in humanized OATP1B1 and OATP1B3 FVB/N mice by feeding chow supplemented with 0.2% adenine (n=6) for a total of 28 days while controls (n=6) received standard chow. Blood and organs were collected at sacrifice and plasma creatinine concentrations and the liver to plasma ratio of fexofenadine ($L:P_{FEX}$) were measured using ultra performance liquid chromatography coupled to mass spectrometry.

Results: Plasma creatinine was two-fold higher in adenine-fed mice compared to controls (p=0.0011). L:P_{FEX} was reduced by 15%, indicating a modest decrease in hepatic fexofenadine liver distribution (p=0.1870).

Conclusions: Induction of CKD did not significantly alter the liver distribution of fexofenadine in the humanized hepatic OATP1B1/1B3 mouse model. Further analysis into expression levels of these transporters, and other hepatic transporters such as P-glycoprotein, will provide further insight into the impact of CKD on drug transporters and distribution of fexofenadine in the liver.

Activity of Brincidofovir (BCV) Against Murine Polyoma Virus (MuPyV) in a Mouse Infection Model

Odin Naderer,[1] Heidi Colton,[1] Ge Jin,[2] Matthew D. Lauver,[2] Aron Lukacher.[2]
[1]Chimerix, Durham, NC; [2]Pennsylvania State University, Hershey, PA.

Background: BK virus (BKV) is a ubiquitous polyomavirus which can result in up to 10% of kidney transplant recipients to develop BKV-associated nephropathy and organ loss. As no antivirals are available, the current treatment paradigm is reduction of immunosuppression which can risk organ rejection. An active antiviral capable of reducing BK viral burden while maintaining optimal immunosuppression could have a substantial impact on the survival of existing kidney grafts and avoid re-transplantation. BCV is a lipid conjugated nucleotide analog of cidofovir (CDV) with potent antiviral activity against BKV in vitro (EC_{50}= 0.02 uM) without CDV-associated nephrotoxicity. In this study, we assessed the in vivo antiviral activity of BCV against a murine polyomavirus (MuPyV) which infects the kidney in a mouse model.

Methods: Fifteen C57BL/6 mice (8–12 weeks old) were randomized 1:1:1 to placebo, BCV 20mg/kg or BCV 40mg/kg IP twice weekly. Treatment was given on Day -7, Day -3, Day 1, and Day 4. Mice were inoculated in hind footpads with 1.0×10^6 PFU of MuPyV on Day 1. qPCR of kidney and spleen were performed at Day 5 (Termination).

Results: All mice tolerated all BCV IP doses to termination. BCV 20 mg/kg or higher delivered IP decreased viral load in the kidney by ~1 log.

Conclusions: BCV demonstrated antiviral activity in mice infected with MuPyV in this prophylaxis model. Evaluation of BCV activity in a post -infection treatment model of MuPyV is warranted to support BCV as a potential treatment for BKV.

Brincidofovir (BCV) Demonstrates Antiviral Activity Against Murine Polyoma Virus (MuPyV) in a Mouse Model of Acute Infection

Odin Naderer,[1] Heidi Colton,[1] Ge Jin,[2] Matthew D. Lauver,[2] Aron Lukacher.[2]
[1]Chimerix, Durham, NC; [2]Pennsylvania State University, Hershey, PA.

Background: BK virus (BKV) is a ubiquitous polyomavirus which can result in up to 10% of kidney transplant recipients to develop BKV-associated nephropathy and organ loss. As no antivirals are available, the current treatment is reduction of immunosuppression which can risk organ rejection. An active antiviral capable of reducing viral burden while maintaining immunosuppression could have a substantial impact on the survival of existing kidney grafts and avoid re-transplantation. BCV is a lipid conjugated nucleotide analog of cidofovir (CDV) with potent antiviral activity against BKV in vitro (EC_{50}= 0.02 uM) without CDV-associated nephrotoxicity. In this acute infection-treatment model study, we assessed the antiviral activity of BCV against MuPyV which infects the kidney.

Methods: Twenty-seven C57BL/6 mice (8–12 weeks old) were assigned to one of three treatment groups (n=6/group) or three corresponding placebo groups (n=3/group). For the treatment groups, BCV 80 mg/kg was delivered over a one-week period as a single dose or through divided doses: BCV 80mg/kg IP on Day 1; BCV 40mg/kg IP on Days 1 and 4; or BCV ~13 mg/kg IP on Days 1-6. Mice were inoculated in hind footpads with 1.0×10^6 PFU of MuPyV on Day 1. qPCR of kidney and spleen were performed at Day 7. Placebo groups were pooled for analysis.

Results: All mice tolerated all BCV IP doses to termination. All animals that received BCV had kidney viral loads 2-logs lower than animals that received placebo.

Conclusions: BCV reduced the viral load in the kidneys of mice acutely infected with MuPyV in this model. Further evaluation of BCV activity in immunocompromised mice with chronic MuPyV is planned to further explore BCV as a potential treatment for BKV.

Characterization of GFB-8438, a Potent and Selective TRPC5 Inhibitor Under Evaluation for the Treatment of FSGS

Maria Beconi, Mark Ledeboer, Maolin Yu, Matthew Daniels, Goran Malojcic, Marie F. Coeffet-LeGal, Xin-Ru Pan-Zhou, Peter H. Mundel, Jean-Christophe P. Harmange. *Goldfinch Bio, Cambridge, MA.*

Background: The predominant role of podocyte in the development of FSGS is well established. One of the central mechanisms leading to FSGS is the disruption of the podocyte actin cytoskeleton via Rac1 activation. TRPC5 has been identified as a key regulator of Rac1 activation in podocytes and its role was reinforced by the antiproteinuric effect of two TRPC5 small molecule inhibitors in two models of FSGS (Zhou et al, 2017). Here we present the preclinical characterization of GFB-8438, a potent and selective inhibitor of TRPC5. Metabolism, pharmacokinetic and the pharmacology of GFB-8438 will be discussed.

Methods: High throughput screening of a structurally diverse compound collection followed by lead optimization yielded several potent TRPC5 inhibitors. GFB-8438 inhibitory activity against TRPC5 and selectivity across other TRP channels were determined using FLIPR based assays and electrophysiology. Additional profiling was conducted using standard receptor and kinase panels. In vitro routes and clearance mechanisms across species and drug-drug interaction (DDI) potential were evaluated using standard ADME assays. The pharmacokinetic profile was characterized in rats and dogs at 1 mg/kg iv (solution) and at 3, 10, 30 and 100 mg/kg po (suspension). The in vivo efficacy was evaluated in a uni-nephrectomized DOCA-salt rat model of FSGS. PK/PD relationships were derived.

Results: GFB-8438 is a potent TRPC5 inhibitor with high selectivity against TRPC6. Further profiling in standard receptor and kinase panels did not reveal any off-target activities. GFB-8438 is metabolized primarily by oxidation and renal clearance is predicted to be low. Oral bioavailability in rats and dogs is acceptable, with favorable human PK projections given the low rate of hepatic metabolism. When dosed to DOCA-salt rats (single daily dose for 21 consecutive days), GFB-8438 reduced the rate of albuminuria progression without affecting the blood pressure. Rate of albuminuria reduction correlated well with exposure.

Conclusions: GFB-8438 is a potent and selective TPRC5 inhibitor with favorable DMPK and pharmacology characteristics under evaluation for the treatment of FSGS. Characterization in toxicology models is ongoing.

SA-PO644

Preclinical Safety and Scalability of VIS649 Production for Clinical Trials for the Treatment of IgA Nephropathy

Veronica M. Miller, Susan E. Sloan, Emily A. Helger, James R. Myette, Pat Vollmer, Kristy J. Szretter, Ketan Deotale, Brian J. Pereira. *Visterra, Inc., Waltham, MA.*

Background: IgA Nephropathy (IgAN) is the most common cause of glomerulonephritis worldwide, with no disease-specific therapies currently available. VIS649 is a humanized IgG2 monoclonal antibody targeting the cytokine named A Proliferation Inducing Ligand (APRIL) that is implicated in the pathophysiology of IgAN. To demonstrate the feasibility of generating a commercially available VIS649 treatment, the preclinical effects, potency and safety attributes of VIS649 materials that were produced using a range of scaled down bench-top and scaled up manufacturing processes were compared.

Methods: VIS649 was first produced in-house using a CHO cell line – Batch 1, followed by small scale production at a CRO using a pool of CHO clones (Batch 2) and finally at a larger-scale manufacturing plant using CHO cells from a research cell bank (Batch 3). Each batch of VIS649 was then assessed for preclinical safety and efficacy in

non-human primates (NHPs). In addition, *in vitro* analytical assays were used to compare the batches including APRIL binding (ELISA), and engagement with immune factors and receptors (complement, FcRI, FcRII and FcRIII binding by Octet). Finally, because glycans can influence the half-life and metabolism of immunoglobulins the glycan profile of each batch was assessed using MS, HPLC and CE methods.

Results: VIS649 synthesized at each scale was found to produce equivalent maximal reductions in circulating IgA levels (~70%) in the NHP studies. Furthermore, *in vitro* assessments confirmed that the three batches of VIS649 had similar binding to APRIL, as well as minimal FcRI, II, III and complement binding. Observed minor changes in glycans were not found to impact *in vivo* or *in vitro* VIS649 activity.

Conclusions: These data confirm that VIS649 production can be consistently scaled from small to larger scale manufacturing, while retaining important potency, purity and safety characteristics. These results support that large-scale production of VIS649 will be suitable for use in clinical trials to assess both safety and efficacy in IgAN patients.

Crotamine, a Cell Penetrating Peptide, Targeting Renal Proximal Tubular Epithelial Cells: A Potential Future for Kidney Gene Therapy

Joana D. Campeiro,[1,2] Wendy Dam,[1] Sunamita C. Lima,[2] Gabriela G. Monte,[2] Lilian Caroline G. Oliveira,[2] Marcela B. Nering,[2] Gustavo M. Viana,[2] Eduardo B. Oliveira,[3] Jacob van den Born,[1] Mirian A. Hayashi.[2] *[1]University Medical Center Groningen, São Paulo, Brazil; [2]Federal University of São Paulo, São Paulo, Brazil; [3]University of São Paulo, Ribeirão Preto, Brazil.*

Background: Activated proximal tubular epithelial cells (PTECs) play a crucial role in progressive tubulointerstitial fibrosis in native and transplanted kidneys. Active targeting of PTECs by non-viral gene delivery vectors such as cell penetrating peptides (CPPs) might be useful to influence the expression of genes in these cells, however most CPPs are not very cell type specific. Crotamine, isolated from the venom of rattlesnake, is characterized as CPP due to its ability to cross lipid cell membranes. Crotamine is also able to form complexes with DNA molecules and contains a nuclear retention motif, which helps to deliver DNA cargo into the nucleus enabling its use as a cell transfection agent. The ability of crotamine to internalize and carry molecules into cells is dependent on proteoglycans present on the cell membrane.

Methods: Crotamine was administered intraperitoneally to 14 week-old mice for 21 consecutive days. Main organs and body weight, food and water intake and renal function biomarkers were assessed. Fluorescently-labeled Cy3-crotamine was injected to track its localization throughout the kidney. Kidney was collected for immunohistochemistry assays. Crotamine binding, uptake and reporter gene expression was assessed in PTEC cell line.

Results: We demonstrated the safety of long-term crotamine administration and after injection into mice, crotamine passes the glomerular filter, is selectively taken up by PTECs, and subsequently localized into the nuclei of these cells. *In vitro* we could show that the binding and uptake of crotamine into PTEC cell line is mediated via the heparan sulfate side chains of syndecan-1, a major proteoglycan on these cells. *In vitro* we also showed efficient gene-delivery and reporter gene expression in this cell line.

Conclusions: This study shows the in vivo applicability of using crotamine as PTEC specific gene delivery nanocarrier and might be a prototypic example of the next generation kidney specific non-viral gene delivery vectors to modulate aberrant gene expression in PTECs in kidneys in order to slow down progressive tubulointerstitial fibrosis. Support: FAPESP/Capes.

Unbiased Interrogation of Clinically-Indicated Biopsies Identifies Discoidin Domain Receptor Inhibition as Target for Anti-Fibrotic Therapy: Cell, Animal, and Pharmacological Intervention Studies

Richard E. Gilbert,[1,2] Kerri Thai,[1] Yanling Zhang,[3] Lauren V. Caldwell,[4] Darren A. Yuen.[1,2] *[1]St. Michael's Hospital, Toronto, ON, Canada; [2]Fibrocor Therapeutics, Toronto, ON, Canada; [3]St. Michael Hospital, University of Toronto, Toronto, ON, Canada; [4]Lunenfeld Tanenbaum Research Institute, Ajax, ON, Canada.*

Background: Regardless of etiology, most forms of kidney disease are characterized by advancing fibrosis, the extent of which correlates closely with declining kidney function. As such, fibrogenesis may be a final common pathway in kidney disease progression so that strategies to temper it may attenuate the loss of function in a broad range of kidney diseases. While most efforts at developing anti-fibrotic drugs have focused on inhibiting transforming growth factor-beta (TGF-beta) or connective tissue growth factor (CTGF), other yet unidentified mediators may also be importamt targets for therapeutic development.

Methods: RNA was extracted from 14, -80C degrees frozen, clinically-indicated kidney transplant biopsies and subjected to RNASeq analysis. Clinical data including sequential eGFR values were also collected.

Results: In addition to TGF-ß and CTGF we also found that the abundance of discoidin domain receptor (DDR) mRNA correlated closely with both the extent of fibrosis (rho=0.6, p=0.01) and rate of eGFR decline (rho=0.6, p=0.01). Since DDR is a receptor tyrosine kinase that is activated by binding to fibrillary collagen, we exposed NRK-49F renal fibroblasts ($p<0.05$) to type I collagen and noted that this not only led to DDR phosphorylation but also induced the de novo synthesis of collagen, identified by the incorporation of 3H-proline. We next synthesized a DDR inhibitor, 6j (Wang et al., J. Med. Chem. 2016, 59, 5911–5916), showing that it dose-dependently reduced DDR phosphorylation and 3H-proline incorporation in renal fibroblasts ($p<0.05$) in response to collagen I. We then conducted in vivo proof-of-concept studies in the unilateral ureteric obstruction (UUO) model of kidney fibrosis showing robust reduction in collagen III deposition at 50 mg/kg/day ($p<0.05$) at 7 days.

Conclusions: Merging unbiased transcriptomic analysis of clinically-indicated kidney biopsies with histopathological and clinical data can identify novel mediators of fibrogenesis. The pathophysiological relevance of the so-derived targets can then be assessed by in vitro and in vivo models as a prelude to the development of new therapies for human use that aim to slow, arrest or potentially even reverse the progression of CKD.

Dexamethasone-Loaded Macrophage-Derived Microvesicles: A Novel Approach for Enhanced Anti-Inflammatory Efficacy for Renal Disease

Tao-Tao Tang, Linli Lv, Cao Jingyuan, Ye Feng, Zuolin Li, Bi-Cheng Liu. *Zhong Da Hospital, Southeast University, Nanjing, China.*

Background: Although glucocorticoids are the mainstays in the treatment of renal disease, the dose dependent side effects have largely restricted their clinical use. Microvesicles (MVs) are nano-sized extracellular vesicles with a membrane lipid bilayer that are shed by cells and efficiently entering other cells. Here, we investigated whether macrophage-derived MVs can function as efficient carriers of dexamethasone (DEX), and the anti-inflammatory efficacy of the novel DEX delivery system was assessed in both in vitro and in vivo models of renal disease.

Methods: MVs were prepared from the supernatants of RAW 264.7 cells treated with DEX by centrifugation. In vivo, the therapeutic potential of DEX-packaging MVs (MV-DEX) was assessed in LPS and Adriamycin (ADR) induced nephropathy model. In vitro, the therapeutic efficacy was assessed in glomerular endothelial cells (GECs).

Results: The mean diameter of MV-DEX was 140.7±4.8 nm and the average drug content was $6.2\mu g/1\times10^{10}$ MVs. Compared with GECs without LPS stimulation, more MVs were accumulated in the inflamed GECs. Consistently, the higher renal radiance signal of DID-labelled MVs was observed in LPS and ADR model. The extent of average radiance was positively correlated with renal TNF-α or IL-6 protein levels. In vitro, we found that the mRNA levels of proinflammatory cytokines, protein expression of NF-κB p65 and p-p65, and levels of TNF-α and IL-6 in the supernatants were significantly inhibited by MV-DEX treatment. Inflammation was blunted with free DEX, however, to a much lesser extent than with MV-DEX therapy. In LPS model, treatment with MV-DEX increased the animal survival rate. In ADR model, albuminuria, glomerulosclerosis and foot process effacement were remarkedly ameliorated with MV-DEX threatment. In both models, the mRNA levels of proinflammatory cytokines, protein expression of p65 and p-p65, and infiltration of inflammatory cells were inhibited after MV-DEX treatment. Interestingly, MV-DEX treatment showed better therapeutic efficacy than free DEX both in vivo and in vitro.

Conclusions: Our studies firstly demonstrated that macrophage-derived MVs could efficiently deliver DEX into inflamed kidney and exhibit a superior ability to suppress renal inflammation compared to routine DEX therapy.

SA-PO648

Safety and Efficacy of a New Biomimetic Sorbent Hemoperfusion Device in Removing Bacteria from Hemodialysis Patients with Blood Stream Infections - Results of a Multicenter First-in-Human Study

Gabriele C. Eden,[1] Julius Schmidt,[2] Stefan Büttner,[5] Alexandros Rovas,[4] Philipp Kümpers,[3] Bernhard M. Schmidt,[2] Jan T. Kielstein.[1] *[1]Academic Teaching Hospital Braunschweig, Braunschweig, Germany; [2]Hannover Medical School, Hannover, Germany; [3]University Clinics Münster, Münster, Germany; [4]University Hospital Münster, Münster, Germany; [5]University hospital Frankfurt, Frankfurt am Main, Germany.*

Background: Prompt reduction of bacterial load improves survial of bacteremic patients, so strategies above and beyound antibiotics are invesitagted. Binding of bacteria to heparan sulfate can be used to remove bacteria from the circulating blood by mimicking heparan sulfate grafting heparin to beads packed in a column. This device, the Seraph® 100 Blood Filter (Seraph), also removes toxins, and cytokines. Aim of this multicenter first in human study was to asses safety and efficacy of the Seraph in hemodialysis patients with bacteremia.

Methods: Fifteen (3F/12M, median age 75 [66-79] years) patients were included (www.clinicaltrials.gov. NCT02914132). The Seraph was placed in series, upstream from a dialyzer during a single four hour dialysis session. Vital signs as well as coordinates of the hemodialysis and a detailed laboratory analysis were performed. Efficacy was evaluated by measuring time to positivity in the blood cultures taken before and after the Seraph at several time points. Patient follow up was 14 days.

Results: As the last patient was enrolled before the abstract deadline complete data are only available in 14 patients. Vital signs remained stable and peripheral oxygen saturation improved during treatment unrelated to fluid removal. In patients with bacteremia at the time of treatment despite an adequate dose on antibiotics (4 out of 15), Seraph lead to a decrease in bacterial count.

Conclusions: Seraph treatment is well tolerated by hemodialysis patients, and can quickly remove bacteria from blood. It's rapid, broad-spectrum binding and inherent blood compatibility suggest future use as a prophylactic, or at the first sign of bloodstream infection, even before pathogen identification. Improvement of oxygen saturation during treatment deserves further investigation.

Urinary Exosomes Identify Inflammatory Pathways in Vancomycin Induced AKI

Amy Le,[1] Jordan Amato,[1] Vidhyut G. Jani,[1] Robert Mills,[1] David J. Gonzalez,[1] Ashita J. Tolwani,[3] Anjali Acharya,[2] Jorge Cerda,[4] Melanie S. Joy,[5] Sucheta M. Vaingankar,[6] Satish P. Ramachandrarao,[6] Ravindra L. Mehta,[6] Linda Awdishu.[1,6] *[1]UCSD Skaggs School of Pharmacy and Pharmaceutical Sciences, La Jolla, CA; [2]Jacobi Medical Center, Albert Einstein College of Medicine, Bronx, NY; [3]University of Alabama at Birmingham, Birmingham, AL; [4]Capital District Renal Physicians, Albany, NY; [5]University of Colorado Anschutz Medical Campus, Aurora, CO; [6]University of California San Diego School of Medicine, San Diego, CA.*

Background: Vancomycin is used as a first line empiric therapy for gram positive organisms such as resistant Staphylococcus species. Vancomycin-induced acute kidney injury (VAN-AKI) has been reported in up to 43% of patients, especially in those targeting higher trough concentrations. The mechanism of injury in humans remains not well understood with recent evidence pointing to cast nephropathy. In this study, we investigate the protein contents of urinary exosomes in patients with VAN-AKI to further elucidate mechanisms of injury.

Methods: Urine samples from 10 patients with VAN-AKI who were enrolled in the DIRECT study and 12 healthy control urine samples from the UAB-UCSD O'Brien Center Biorepository were included in the analysis. Exosomes were extracted using solvent exclusion principle and polyethylene glycol induced precipitation. Protein quantification was analyzed by high throughput liquid chromatography/mass spectrometry. Significant proteins were determined by Pi score >1, which accounts for both fold change and t-test significance. Western blotting is currently being conducted as validation of proteomic findings.

Results: Subjects were male with a mean age of 40.8±18.3 years, BMI of 26.6±7.0, and a distribution of comorbidities. The mean peak serum creatinine was 3.7±1.4 mg/dL and time to kidney injury was 4.0±3.0 days. At discharge, 90% of patients demonstrated none or partial recovery; 33% experienced full recovery by day 28. Twelve samples were included in the final proteomic analysis and revealed 2009 proteins in all samples and 251 proteins significantly associated with VAN-AKI (Pi score >1). The top discriminatory proteins were fibrinogen, complement C3, complement C4, galectin-3-binding protein, alpha-2 macroglobulin, immunoglobulin heavy constant mu and serotransferrin. Galectin-3 binding protein binds glycoproteins such as serotransferrin and alpha 2 macroglobulin and up-regulation has been previously correlated with inflammation, fibrosis and rapid kidney function decline. Fibrinogen upregulation and complement activation have been demonstrated after ischemia reperfusion injury.

Conclusions: Urinary exosomes reveal up-regulation of inflammatory proteins after nephrotoxic injury in VAN-AKI.

Attenuation of Renal Ischemic Reperfusion Injury in Rats with DUR-928, a Novel, First-in-Class Therapeutic in Development for Renal Disease

Mee J. Kim, Hongwei Wu, Wei Qi Lin. *DURECT Corporation, Cupertino, CA.*

Background: DUR-928 (5-cholesten-3β,25-diol 3-sulfate) is a first-in-class, endogenous sulfated oxysterol that regulates lipid metabolism, inflammatory response, and cell survival. It has been reported that this molecule protects against acute organ injury, including the kidney, and improved survival, from LPS-induced endotoxin shock and acetaminophen overdose/toxicity mouse models when administered at doses of 25-50 mg/kg by intraperitoneal (IP) injection.

Methods: In this study, the potential therapeutic effect of DUR-928 was investigated in a rodent model of acute kidney injury (AKI) induced by renal ischemia/reperfusion (I/R) injury. Renal ischemia was achieved by transient occlusion of the left kidney in adult male Lewis rats (9-11 weeks of age) for 50 minutes. At reperfusion, the right kidney was removed. Rats were randomized into three treatment groups (N=6 rats/vehicle control; N=11-12 rats/DUR-928) for IP administration of DUR-928 (25 mg/kg/day) or vehicle control. Three or four daily IP injections of DUR-928 or vehicle control were administered and rats were followed through 7 days of observation after I/R injury.

Results: On Days -2 (Baseline), 3 and 7 after surgery, serum creatinine (sCr) and blood urea nitrogen (BUN) were measured to evaluate renal function. Induction of I/R injury in rats was successfully achieved. sCr and BUN levels peaked significantly on Day 3 compared to Baseline. Improvement of these measures was observed on Day 7 due to spontaneous self-recovery that is characteristic of this I/R injury model. IP administration of 4 daily doses of 25 mg/kg DUR-928 resulted in significant reductions in sCr and BUN compared to vehicle-treated rats on Day 3, suggesting improved renal function. DUR-928 treatment resulted in a 63% reduction in sCr (118.4±85.9 mg/dL versus 317.3±296.6 mg/dL; $p<0.05$) and a 57% reduction in BUN (23.4±14.8 mg/dL versus 54.0±27.7 mg/dL; $p<0.05$) compared to vehicle. Similar results were found with 3 daily doses of DUR-928, with a 43% reduction in sCr ($p=0.05$) and 45% reduction in BUN ($p<0.05$), compared to vehicle.

Conclusions: The current study highlights the potential of DUR-928 to attenuate kidney injury in an acute setting and supports the continued evaluation of DUR-928 in renal disease.

Multipronged Systems Approach to Enhance Medication Safety in Patients with CKD

Sijie Zheng,[1] Dennis Y. Wu,[2] Lin Duong,[3] Tracy Y. Jonelis.[4] KPNC Renal Pharmacy Group *[1]The Permanente Medical Group, Oakland, CA; [2]Kaiser Permanente, Modesto, CA; [3]HMO, Vacaville, CA; [4]The Permanente Medical Group, Inc, San Francisco, CA.*

Background: In the United States, 1 in 7 people have chronic kidney disease (CKD), over 650,000 people have end stage renal disease (ESRD). Patients with CKD experience polypharmacy with ESRD patients taking average 10-12 prescriptions. Pharmacokinetic differences in CKD/ESRD patients require increased awareness and dose adjustment to minimize adverse events from prescription and OTC medications or herbal supplements. Kaiser Permanente Northern California (KPNC) is an integrated health care system that provides care to 4.3 million members with over 300,000 CKD patients through 21 medical centers.

Methods: In 2016, a workgroup was formed to improve medication safety for patients with CKD. The workgroup comprises of nephrologists, pharmacists and pharmacy informatics across the region. The work group met monthly via web conferencing. The workgroup outreached to relevant stakeholders and decision-makers between meetings. Leveraging Electronic Medical Record (EMR) and the expertise of the members, the workgroup used a multipronged systems approach to identify gaps and developed standardized protocols. The work group also optimized processes to enhance medication safety in CKD and to reduce acute kidney injury (AKI).

Results: In the inpatient setting, the work group standardized protocols for antibiotic dosing, created order sets to minimize use of nephrotoxic agents including elimination of sodium phosphate enema use, and implemented calcineurin inhibitor drug interaction alerts. Additionally, EMR alerts are being placed for outpatient prescriptions that require dose adjustment or are contraindicated in CKD. In the home setting, herbal supplements and OTC medications tip sheet was produced for patient education and kidney protection.

Conclusions: In an integrated healthcare system such as KPNC, creation of an integrated nephrology pharmacy workgroup may help develop objectives and provide implementation strategies to reduce potential adverse medication events in patients with CKD.

Efficacy of Teriparatide and Denosumab on Bone Mineral Density in Dialysis Patients: A Meta-Analysis

Anawin Sanguankeo,[1,3] Sikarin Upala.[2,3] *[1]Johns Hopkins University, Baltimore, MD; [2]University of Chicago, Cooperstown, NY; [3]Preventive and Social Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand.*

Background: Teriparatide and denosumab are therapeutic agents proven to increase bone density and prevent fracture in patients with osteoporosis. Evidence of efficacy of these agents in end-stage renal disease (ESRD) is still lacking. This meta-analysis evaluated the effect of Teriparatide and denosumab on bone mineral density (BMD) and biochemical testing in ESRD patients on dialysis.

Methods: We comprehensively searched the databases of MEDLINE, EMBASE, and Cochrane Databases. The inclusion criteria were published studies using denosumab or teriparatide in dialysis patients with low bone mass for at least six months. The primary outcome was BMD at the femoral neck, lumbar spine, and radius. The secondary outcome was parathyroid hormone (PTH), calcium, phosphorus, and bone-specific alkaline phosphatase (BSAP). A random-effects meta-analysis was performed to compare the change in outcome at baseline and after denosumab or teriparatide was given.

Results: Four studies using teriparatide were included in the meta-analysis of BMD. Overall, there was no significant change in BMD at the femoral neck ($p=0.59$), lumbar spine ($p=0.05$), or radius ($p=0.23$). There was also no significant change in calcium ($p=0.33$), phosphorus ($p=0.23$), PTH ($p=0.46$), and BSAP ($p=0.86$). Four studies using denosumab were included in the meta-analysis. There was a significant decrease in PTH with a standardized mean difference of 2.22 (95% CI: 0.13 to 4.31). No significant change in calcium ($p=0.37$), phosphorus ($p=0.43$), and BSAP ($p=0.15$) was found. There was not enough study to assess the effect on BMD.

Conclusions: Current evidence does not support the use of denosumab or teriparatide in dialysis patients with low bone mass. More studies are needed to evaluate efficacy and safety of these therapeutic agents for osteoporosis in this population.

Bone Mineral Density and Handgrip Strength in Early CKD: Cross-Sectional Analysis of CARTaGENE

Louis-Charles Desbiens,[1] Remi Goupil,[2] Francois Madore,[2] Fabrice Mac-Way.[1]
[1]CHU de Québec - Université Laval, Québec, QC, Canada; [2]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada.

Background: Bone mineral density (BMD) and handgrip strength (HGS) are associated with adverse outcomes in general and advanced CKD populations. However, how early CKD impacts these two parameters has not been well studied.

Methods: Cross-sectional analysis of CARTaGENE, a population-based health survey of 40 to 69 years old individuals from Quebec. Individuals with data on estimated glomerular filtration rate (eGFR) over 30 ml/min/1,73m^2, BMD and HGS were included. BMD was measured by quantitative ultrasound at the calcaneus and HGS by a hand dynamometer. Early CKD was expressed continuously (eGFR) and categorically (KDIGO stages). Association between CKD, BMD and HGS was assessed with linear regression in univariate and multivariate models adjusted for demographics, comorbidities and medication. BMD results were stratified for sex because of an interaction between CKD and sex.

Results: We included 15,721 individuals (51% male with a mean age of 54 years and a mean eGFR of 88 ml/min/1.73m^2). 47% of individuals had G2 CKD and 4% G3 CKD. Mean BMD t-score was 0.19 in non-CKD individuals, 0.22 in G2 CKD and 0.08 in G3 CKD (G3 vs G1-G2 p=0.01). Mean HGS was 68kg in non-CKD individuals, 69kg in G2 CKD and 64kg in G3 CKD (G3 vs G1-G2 p<0.001). In univariate analysis, eGFR was not associated with HGS, but was positively associated with BMD in men and negatively in women. In adjusted models, eGFR was negatively associated with both HGS and BMD (Table). G2 and G3 CKD were associated with higher HGS compared to non-CKD. G2 CKD was associated with increased BMD in both men and women while G3 CKD was associated with increased BMD in men only.

Conclusions: In a large population of 40 to 69 years old individuals and in contrast to advanced CKD, early CKD is not associated with a decrease in BMD and HGS.

Effect of Denosumab on Trabecular Bone Score (TBS) in De Novo Kidney Transplant Recipients (KTR)

Rudolf P. Wuthrich,[1] Nicole Graf,[2] Marco Bonani.[3] *[1]University Hospital, Zurich, Switzerland; [2]graf biostatistics, Winterthur, Switzerland; [3]University Hospital Zurich, Zurich, Switzerland.*

Background: Kidney transplant recipients (KTR) are at high risk to lose bone mass in the first year after transplantation. The trabecular bone score (TBS) represents a recently developed parameter of lumbar spine bone texture that correlates with the occurrence of fractures. The utility of the TBS and its response to anti-resorptive treatment with denosumab in the first year after kidney transplantation is not known.

Methods: Post-hoc analysis of 1-year changes in TBS in 44 de novo KTR (mean age 50.6±12.6 years; 28 [64%] were male; mean baseline eGFR 54.1±16.5 ml/min/1.73 m^2) which were randomized 1:1 to denosumab or no treatment, and correlation with 1-year areal bone mineral density (aBMD) changes at the lumbar spine and total hip as assessed by dual energy X-ray absorptiometry (DXA), and peripheral bone microarchitecture as assessed by high-resolution peripheral quantitative computed tomography (HRpQCT).

Results: The baseline TBS in KTR amounted to 1.312±0.101 which was reduced compared to an age-matched normal control population (1.464±0.071). There was a significant correlation between TBS and aBMD at the lumbar spine (Spearman's ρ=0.56; p<0.001) and total hip (ρ=0.33; p<0.05). The TBS also correlated with HRpQCT-derived total (ρ=0.49; p<0.05) and trabecular volumetric BMD at the tibia (ρ=0.57; p<0.01), whereas no such correlation was found at the radius. Denosumab treatment led to an increase in TBS, paralleling the BMD changes at the lumbar spine. More denosumab-treated than control KTR showed an increase in TBS at 6 months (91% vs. 55%; p<0.01) and 12 months (87% vs 71%; p=ns). TBS increased more in denosumab-treated than control KTR (+4.0% vs +1.5%) in the first 6 months, but changed little (-0.4% vs +0.6%) in the subsequent 6 months.

Conclusions: The TBS represents a valuable parameter which provides additional data on bone health in KTR. The increase in TBS in denosumab-treated de novo KTR suggests that denosumab may improve bone microarchitecture in KTR.

SA-PO655

AKI Followed by Complete Recovery Is Associated with Increased Bone Fracture Risk

Sophia L. Ambruso,[2] Zhiying You,[3] Benjamin Griffin,[2] John R. Holmen,[4] Titte Srinivas,[5] Michel Chonchol,[2] Sarah Faubel,[6] Anna J. Jovanovich.[1,7] *[1]Denver VA, Denver, CO; [2]University of Colorado, Denver, CO; [3]UC Denver, Aurora, CO; [4]Intermountain Healthcare, Murray, UT; [5]Intermountain Medical Center, Murray, UT; [6]University of Colorado Denver, Denver, CO; [7]University of Colorado, Aurora, CO.*

Background: Acute kidney injury (AKI) affects multiple organ systems, including bone mineral metabolism. Fracture risk is increased among dialysis-requiring AKI patients. The relationship between fracture risk and AKI with complete recovery has not been characterized. We investigated fracture risk following an admission complicated by non-dialysis requiring AKI with complete recovery in a propensity score-matched cohort of cases and controls.

Methods: We identified 1139 AKI cases (AKI Network definition) with complete recovery at discharge, defined by creatinine <1.10 times the pre-admit baseline value, during a hospitalization between January 1, 1999 and December 31, 2009 from an integrated health care delivery system. We matched 1139 controls (no AKI during index admission) based on a propensity score including age, sex, race, prior inpatient visits, baseline creatinine, all comorbidities in the Charlson index, and season of admission. The primary outcome was incident bone fracture following discharge. Cox proportional hazards models were adjusted for prior fracture and body mass index (BMI) and censored for death.

Results: Baseline characteristics among cases and controls were similar: age 62 ± 17 years, 45% female, 92% white, creatinine 0.9 ± 0.2 mg/dL. During a median [IQR] follow-up of 63 [10-87] months, 294 (26%) AKI cases and 169 (15%) controls had a bone fracture. Those with AKI followed by complete recovery had a two-fold increased hazard of bone fracture (HR 2.13 [95% CI, 1.76-2.58]; p=<0.0001). After adjusting for prior fracture and BMI the association persisted but was somewhat attenuated (HR 1.49 [95% CI, 1.23-1.80]; p<0.0001).

Conclusions: Hospitalized patients whose course was complicated by non-dialysis requiring AKI with complete kidney function recovery had an increased risk of fracture following discharge compared to propensity score-matched controls. These data suggest alterations in bone mineral metabolism during AKI may be associated with long-term risk of fracture even if serum creatinine returns to baseline. Further studies investigating bone and mineral metabolism pathophysiology and AKI are warranted.

SA-PO656

The Relationship Between Density Measurements and Histomorphometric Parameters of Cortical Bone of Patients in the Early Stages of CKD

Amandha Bittencourt,[1] Maria Eugenia F. Canziani,[1] Larissa Rodrigues,[1] Carlos E. Rochitte,[2] Aluizio B. Carvalho.[1] *[1]Federal University of Sao Paulo, Sao Paulo, Brazil; [2]Heart Institute (InCor) University of São Paulo Medical School, São Paulo, Brazil.*

Background: Cortical bone comprises a compact tissue, which is denser, less porous and metabolically active than trabecular bone. These differences give to the cortical bone a mechanical function while the mineral homeostasis is the main role of the trabecular bone. In order to evaluate these tissues, bone biopsy is the gold standard tool, but it is an invasive and expensive method. In this context, the possibility of using a non-invasive technique is clinically relevant. Quantitative computed tomography of the vertebrae (QCT) is effective for evaluating trabecular bone when compared to structural histomorphometric parameters of patients with chronic kidney disease (CKD). This relationship has not yet been fully evaluated in cortical bone. We investigated the relationship between vertebrae density measured by QCT and structural histomorphometric parameters of cortical bone of patients in the early stages of chronic kidney disease.

Methods: A post-hoc analysis of a cross-sectional study with 50 CKD stage 2-5ND patients undergone QCT and bone biopsy. Undecalcified bone samples from iliac crest was submitted to histomorphometric analysis using the Osteomeasure software (Osteometrics Inc., Atlanta, GA, USA). The histomorphometric parameters analyzed were: Ct.Po (cortical porosity) and Ct.Th (cortical thickness). The cortical bone density, expressed in Hounsfield Units (HU), was obtained by QCT from the thoracic vertebrae at the aorta root.

Results: Patients were 52±10years, 68%male and 30%diabetes mellitus. Laboratorial data included eGFR34±16 mL/min/1.73m^2, ionized calcium 1.30±0.06mmol/L, phosphorus 3.8±0.7mg/dL, alkaline phosphatase 116(71.5;160.5)U/L; iPTH 83(53.5;167.5)pg/mL, 25OHD30.8±10.1ng/dL and 1,25OH$_2$D 35.8(30;47.5)pg/mL. Regarding cortical histomorphometric parameters, cortical porosity was 4.6%(2.6;6.6) and cortical thickness was 578.4±151.8µm. The cortical bone density was 379.0 HU(344.7;411.4). There was no correlation between cortical porosity and cortical density(p=0.67) or cortical thickness and cortical density(p=0.41).

Conclusions: Cortical bone density measured by quantitative computed tomography is not associated to structural histomorphometric parameters of cortical bone of patients in the early stages of chronic kidney disease.

Etelcalcetide in the Treatment of Secondary Hyperparathyroidism in Patients Uncontrolled with Cinacalcet – Results from a Prospective Study

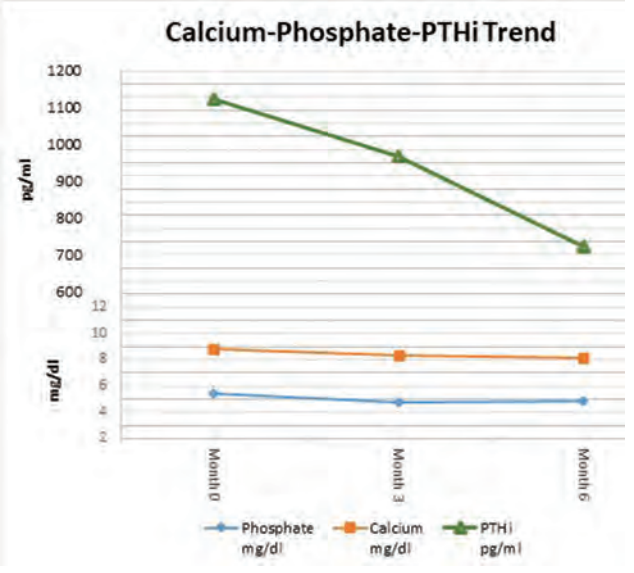
Andre L. Weigert,[1,3] Manuel A. Amoedo,[1,4] Teresa Mendes,[5] Marco A. Marques,[6] Catarina Meng,[2] Luciano Pereira,[1,2] Joao M. Frazao.[1,2] *[1]DaVita, Portugal, Portugal; [2]Nephrology, São João Hospital Center and School of Medicine, Porto, Portugal; [3]Hospital Santa Cruz, School of Medicine, Lisbon, Portugal; [4]Nephrology, Hospital Divino Espírito Santo, Évora, Portugal; [5]Nephrology, CHUC, Coimbra, Portugal; [6]Affidea Laboratories, Lisbon, Portugal.*

Background: Secondary hyperparathyroidism (sHPT) is associated with increased risk of fractures, vascular calcifications and all-cause mortality. Etelcalcetide is a new calcimimetic with a pharmacokinetic profile that allows thrice weekly intravenous(IV) dosing after hemodialysis(HD), recently approved for sHPT treatment. There is scarce clinical experience with this agent with respect to its efficacy in patients with sHPT that is uncontrolled with cinacalcet.

Methods: We conducted a prospective cohort study in prevalent HD patients in DaVita clinics in Portugal who had uncontrolled sHPT under cinacalcet treatment for at least 3 months. Inclusion criteria included mean intact PTH(iPTH) levels above 800 pg/mL and total calcium(Ca) above 8.3 mg/dL in the previous 3 months. After 1 week of cinacalcet washout, etelcalcetide 5mg IV/HD was initiated. iPTH, Ca and phosphorus were followed; FGF-23 and sclerostin levels were analyzed before the start of etelcalcetide and after 6 months.

Results: Thirty-four patients participated in the study; mean age was 60.7(SD ± 12.3) years; median time on HD was 82.5(7-296) months and median cinacalcet dose was 180(90-840) mg/week. Median etelcalcetide dose remained at 5mg/HD at 3 and 6 months. Evolution of biochemical parameters is represented in the figure. Over 6 months of etelcalcetide treatment, serum FGF-23 decreased from 39.3(23.0-43.3) pmol/L to 29.1(11.5 -115.6) pmol/L and sclerostin increased from 37.2(5.8 – 200.7) pmol/L to 71.7(28.2- 185.5) pmolL (p<0.0001).

Conclusions: Etelcalcetide was efficacious in improving sHPT control in this group of patients and significantly increased plasma sclerostin concentration. This is the first study describing the impact of etelcalcetide treatment on plasma sclerostin levels.



SA-PO658

Superior Effects of Etelcalcetide Compared to Cinacalcet on Increasing Bone Mineral Density in Patients Receiving Hemodialysis with Secondary Hyperparathyroidism

Satoshi Funakoshi,[3] Jyunichiro Hashiguchi,[3] Tayo Kawazu,[3] Kenji Sawase,[3] Yuko Maruyama,[3] Yoko Obata,[1] Tomoya Nishino,[2] Takashi Harada.[3] *[1]Nagasaki University Hospital, Nagasaki, Japan; [2]Nagasaki University School of Medicine, Nagasaki, Japan; [3]Nagasaki Kidney Hospital, Nagasaki, Japan.*

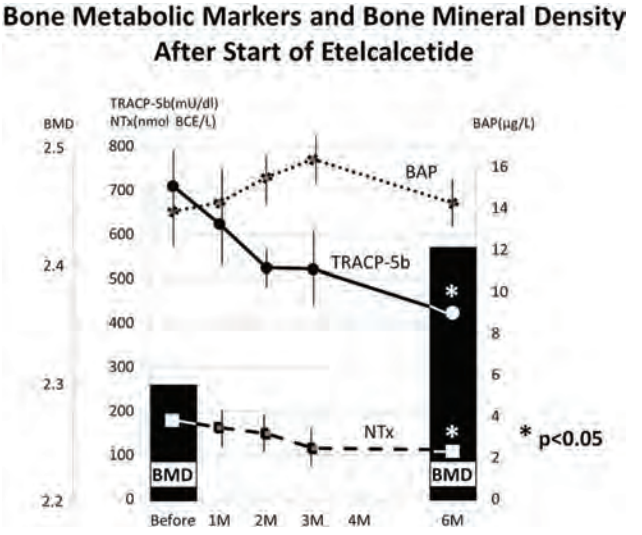
Background: Etelcalcetide hydrochloride (ET) is a novel peptide calcimimetic agent that has a similar mechanism of action as cinacalcet hydrochloride (CT). Clinical trials have demonstrated the safety and efficacy of ET in hemodialysis (HD) patients. In this study we evaluated the efficacy of ET on increasing bone mineral density (BMD) in HD patients with secondary hyperparathyroidism (SHPT).

Methods: Ten HD patients with SHPT (M/F: 6/4, mean age: 61.9 years, mean HD duration: 10.3 months) who received oral CT were enrolled in this study after their informed consent was obtained. Various doses of oral CT were converted to 5mg of intravenous ET, and bone resorption markers; TRCP-5b, NTx and bone formation marker; BAP were compared in each patient. BMD was assessed 6 months after conversion to ET treatment by digital image processing (DIP).

Results: As shown in figure, significant declines (p<0.05) were observed in serum levels of TRCP-5b and NTx (from 710.0 ± 289.0 to 420.9 ± 221.1 mU/dL, from 179.6 ± 35.5 to 112.1 ± 26.1 nmol BCE/L, respectively). On the other hand, there was no significant change in serum BAP level. Notably, BMD was significantly increased 6 months after ET treatment was started (p<0.05).

Conclusions: In our study, significant decrease of bone resorption markers, TRCP-5b and NTx, along with no alteration of BAP as a bone formation marker may explain the significant increase in BMD in HD patients with SHPT.

Funding: Private Foundation Support



SA-PO659

Denosumab: Is It Safe to Use in CKD?

Eimear Mckenna. *Altnagelvin Area Hospital, Derry, United Kingdom.*

Background: Denosumab is a monoclonal antibody directed against receptor activator of RANK ligand used to treat osteoporosis. It has been promoted as safe to use in Chronic Kidney Disease (CKD) as it does not appear to accumulate in kidney failure and because of the experience in a small number of patients with CKD 3-4 enrolled in RCTs. There is no evidence for use in CKD 5. Case reports show patients with severe CKD are at higher risk of developing hypocalcemia following Denosumab. This may be due to hyperparathyroidism and vitamin D deficiency. In this case series we have examined the incidence of hypocalcemia following Denosumab treatment and tried to identify any risk factors.

Methods: Patients with CKD stages 3-5 attending our service treated with Denosumab in the last 5 years were included. Retrospective data was collected using an electronic patient database. Data collected included Corrected calcium levels prior to and after dosing, vitamin D and Parathormone (PTH) levels prior to dosing.

Results: 14 patients were identified; 9 had a functioning renal transplant and 1 patient was on hemodialysis. 4 patients were male and 10 female. Mean duration of treatment was 2.2 years. Average eGFR was 27 ml/min/1.73m2. Mean patient age was 60 years (range 44-84). Mean BMI was 25 (range 19-36). 11 patients were on oral steroids. The average calcium prior to dosing was 2.35 mmol/l (2.12 to 2.54) falling to 1.98mmol/l (1.58-2.22) after dosing. 9 patients achieved their lowest calcium at 1 week, 2 at 4 weeks and 3 at 8 weeks. Average PTH level prior to dosing was 153ng/l (42-371) and after was 888ng/l (155-1990). 5 patients developed severe hypocalcemia (corrected calcium less than1.9mmol/l), average prior calcium in this group was 2.39mmol/l (2.22 – 2.54) falling to 1.77mmol/l (range 1.58 – 1.86). The average prior PTH was 206ng/l, rising to 1171ng/l after denosumab. Four patients did not have Vitamin D checked before dosing.

Conclusions: Denosumab will cause a small but not clinically significant reduction in serum Calcium in most patients with CKD. Severe hypocalcaemia can result if Vitamin D levels are unknown or in higher PTH levels. eGFR does not seem to correlate with the risk of hypocalcaemia. The biochemical abnormalities associated with CKD should be corrected, specifically, calcium, phosphate, PTH and vitamin D. Densoumab is the preferred treatment in CKD 4/5 however its use should be avoided in severe hyperparathyroidism and vitamin D deficiency.

SA-PO660

Proton Pump Inhibitors, But Not Histamine-2 Receptor Antagonists, Associate with Hip Fracture Risk Among Patients on Hemodialysis

Chandan Vangala,[1,2] Jingbo Niu,[1] William E. Mitch,[1] Sankar D. Navaneethan,[1] Wolfgang C. Winkelmayer.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Division of Nephrology, Michael E. DeBakey VA Medical Center, Houston, TX.*

Background: An association between proton pump inhibitor (PPI) use and hip fracture risk has been described in the general population, where the primary causative hypothesis focuses on impaired gastrointestinal calcium absorption. The impact of acid suppressor use on hip fracture risk in a high-risk subset, patients with end-stage kidney disease requiring hemodialysis, is unknown and could help further distinguish the reason for increased susceptibility among PPI users.

Methods: Using the U.S. Renal Data System (USRDS), we identified all hip fracture events recorded between 2009 and 2014 among hemodialysis-dependent patients. Eligible cases were matched on index date with 10 controls. We identified PPI and histamine-2 receptor antagonist use from Medicare Part D claims covering 3 years prior to index date and stratified according to proportion of days covered by filled prescriptions. Using logistic regression with multiple imputation for missing data, we estimated unadjusted and multivariable-adjusted odds ratios (OR) and 95% confidence intervals (CI).

Results: We studied 4,551 cases and 45,510 controls. Cases were older, more likely to be female and Caucasian, and had shorter dialysis vintage; fewer were obese. A larger proportion of cases had any prior PPI (70% *vs.* 63%) or histamine-2 receptor antagonist (25% *vs.* 23%) use. Use of PPI was associated with higher risk of hip fracture (adjusted OR 1.19, 95% CI 1.11-1.28). This association remained within subgroups of low, moderate, and high PPI use, yielding adjusted ORs of 1.16 (1.06-1.27), 1.21 (1.11-1.31), and 1.20 (1.09-1.32), respectively.

Conclusions: Conclusion: Among patients with end-stage kidney disease on hemodialysis, PPIs, and not histamine-2 receptor antagonists, were associated with hip fracture events.

Funding: Private Foundation Support

SA-PO661

Selective Serotonin Reuptake Inhibitors Associate with Hip Fracture Risk Among Patients on Hemodialysis

Chandan Vangala,[1,2] Jingbo Niu,[1] Sankar D. Navaneethan,[1] Wolfgang C. Winkelmayer.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Division of Nephrology, Michael E. DeBakey VA Medical Center, Houston, TX.*

Background: Selective serotonin reuptake inhibitor (SSRI) use has been associated with hip fracture risk in the general population. Patients with end-stage renal disease on hemodialysis (HD) are a unique, high-risk subset with distinct metabolism and bone pathology, and the impact of SSRI use on hip fracture risk in this subset remains unexplored.

Methods: Using the U.S. Renal Data System, we identified all hip fracture events recorded between 2006 and 2014 among HD-dependent patients. Eligible cases were matched on index date with 10 controls; all were required to have >1 year of Medicare Parts A & B coverage. To study cumulative long-term exposure, we further required >3 years of part D coverage. We defined and stratified SSRI use by the proportion of days covered by filled prescriptions in the 3 years prior to index. In a separate study of short-term exposure, we selected subjects with >18 months of Part D coverage and required no prior antidepressant use for 1 year (months 7-18). We defined SSRI use by filled claims in the 6 months prior to index. Using conditional logistic regression, we estimated unadjusted and multivariable-adjusted odds ratios (OR) and 95% confidence intervals (CI).

Results: In the long-term study, we identified 4,551 cases and 45,510 controls. Compared to controls, a larger proportion of cases had any prior SSRI (37.2% *vs.* 27.6%) use. Use of SSRIs was associated with increased hip fracture risk (adjusted OR 1.30, 95% CI 1.20-1.40). The subgroups of low, moderate, and high SSRI use yielded adjusted ORs of 1.27 (1.15-1.41), 1.32 (1.19-1.45), and 1.31 (1.16-1.47), respectively. In the short-term study, we examined 4,354 cases and 43,540 controls. Increased hip fracture risk was also associated with short-term use of SSRIs (adjusted OR 1.51, 95% CI 1.29-1.76).

Conclusions: Compared to long-term SSRI use, the stronger association of short-term use with increased hip fracture risk in HD-dependent patients may suggest an acute mechanism potentially related to falls.

Association Between Malnutrition-Inflammation Complex Syndrome (MICS) and the Risk for Bone-Vascular Events in Patients Receiving Maintenance Hemodialysis: The Q-Cohort Study

Shunsuke Yamada,[1] Hokuto Arase,[1] Masanori Tokumoto,[5] Masatomo Taniguchi,[4] Hisako Yoshida,[3] Kazuhiko Tsuruya,[2] Toshiaki Nakano,[1] Takanari Kitazono.[1] *[1]Department of Medicine and Clinical Science, Kyushu University, Fukuoka, Japan; [2]Nara Medical University, Kashihara, Japan; [3]Osaka City University Graduate School of Medicine, Osaka, Japan; [4]Fukuoka Renal Clinic, Fukuoka, Japan; [5]Department of Internal Medicine, Fukuoka Dental College, Sawara-ku, Japan.*

Background: Malnutrition-inflammation complex syndrome (MICS) is highly prevalent in hemodialysis patients and increases the risk for morbidity and mortality. MICS is supposed to affect bone-vascular system. However, it is unknown whether MICS increases the risk for both bone fracture and cardiovascular events in maintenance hemodialysis patients. To determine the association between MICS and those risks, we analyzed the data of the Q-Cohort Study, a multicenter, prospective, observational study.

Methods: A total of 2887 hemodialysis patients were included in the analysis. As a simple indicator for MICS, we newly developed a score (0-12) reflecting MICS by semi-quantitatively scaling the following five baseline parameters and adding up the scores of each parameters; age (0-3), serum levels of albumin (0-3), creatinine (0-3), and C-reactive protein (0-2), and body mass index (0-1). The main outcomes were the incidence of bone fracture, cardiovascular events, and all-cause death. The main exposure was MICS score. Patients were divided into four groups based on the MICS score; 0-3, 4-5, 6-8, and 9-12). Risk estimates for each outcome were calculated by Cox proportional hazards model with multivariable adjustments.

Results: During the median follow-up period of four years, 134 patients developed bone fracture, 519 patients developed cardiovascular events, and 482 patients died of any cause. The average MICS score was 5.16. Patients in the highest MICS score group (9-12) showed an increased risk for bone fracture, cardiovascular events, and all-cause mortality (HR [95%CI]; 2.14 [1.08–4.02], 2.17 [1.52–2.96], and 5.07 [3.37–7.63], respectively) compared with the lowest MICS score group (0-3). We also confirmed the internal validity of our MICS score by applying bootstrap resampling. A principal analysis also confirmed that the five parameters of the MICS score increased the risk for the three outcomes examined in our patients.

Conclusions: A higher MICS score was associated with the increased risk for bone fracture and cardiovascular events in patients receiving hemodialysis.

SA-PO663

Effectiveness of Elcatonin in Osteoporosis Patients Undergoing Hemodialysis

Jin ho Lee,[1] Seon Deok Hwang,[2] Seoung Woo Lee,[3] Woo Yeong Park,[7] Jeong Ho Kim,[8] Hee yeoun Kim,[4] Seong min Kim,[5] Joon Seok Oh,[6] Dongyeol Lee,[1] Yong hun Sin,[9] Joong Kyung Kim.[1] *[1]Bong Seng Memorial Hospital, Busan, Republic of Korea; [2]Inha University College of Medicine, Incheon, Republic of Korea; [3]Inha University Hospital, Inchon City, Republic of Korea; [4]Bongseng hospital, Busan, Republic of Korea; [5]Dongrae Bongseng Hospital, Busan, Republic of Korea; [6]Bong Seng Hospital, Korea, Dong-gu, Busan, Republic of Korea; [7]Dongsan Medical Center, Daegu, Republic of Korea; [8]Daejeon St. Mary's Hospital, Daejeon, Republic of Korea; [9]Bong Seng Hospital, Busan, Republic of Korea.*

Background: Osteoporosis is a very serious risk factor for fractures that are related to patient mortality, Quality of Life worsening, and hospitalization in hemodialysis(HD) patients. In particular, treatment methods are very limited in HD patients compared with normal population. Therefore, most dialysis patients will not be able to treat osteoporosis, which can lead to bone fractures. On the other hand, elcatonin inhibits bone resorption and causes bone bone mineral density(BMD) elevation, but it is difficult to maintain bone mass and strengh. Although this medication reduces osteoporosis-induced pain, it is known to increase bone mass in some studies, and it can also be used in dialysis patients

Methods: We retrospectively studied 32 elecatonin-treated HD patients and 178 untreated HD patients. The follow up period was from 2005 to 2017, and the study was conducted at a single center. Osteoporosis was defined by WHO criteria (T score <-2.5). Elcatonin treatment group was diagnosed with osteoporosis, and 20 units were injected intramuscularly once a week after the patient 's consent was obtained. The primary outcome were Incidence of bone fracture, changes in BMD. Secondary outcomes was reduction of bone pain

Results: Fractures were observed in 7 patients (21%) in the Elcatonin group and 9 (11%) in the control group, but there was no statistical significance(p-value = 0.088). In 2013, the BMD in the Elcatonin group was 0.689 ± 0.039 which was statistically significantly lower than that of the control group of 0.937 ± 0.181(p-value <0.001). Also, in 2018, the BMD of the elcitonin group was 0.724 ± 0.08, which was statistically significantly lower than that of the control group of 0.9672 ± 0.186(p-value <0.001). There was no significant difference in reduction of bone pain between the two groups

Conclusions: Elcatonin was not effective in reducing the frequency of fractures or reducing bone pain in hemodialysis patients. Rather, the Elcatonin group had a further decrease in BMD compared with the control group. It is possible that the results have been observed to be worse because the Elcatonin group has been used on existing osteoporosis patients. However, Elcatonin seems to be ineffective in HD patients because it causes pain, increases drug costs and is not effective in treating osteoporosis.

SA-PO664

Bone Mineral Density in Patients with CKD: Hip Is More Affected Than Spine

Kalyanna S. Bezerra de carvalho,[1] Melani Custodio,[4] Rosa M. Moyses,[3] Raquel F. Vasco,[1] Vanda Jorgetti,[2] Rosilene M. Elias.[2] *[1]Hospital das Clinicas HCFMUSP, Universidade de Sao Paulo, Sao Paulo, Brazil;, São Paulo, Brazil; [2]Universidade de Sao Paulo, Sao Paulo, Brazil; [3]Universidade Nove de Julho, São Paulo, Brazil; [4]Universidade de São Paulo, São Paulo, Brazil.*

Background: Patients with chronic kidney disease (CKD) have a higher risk of fracture than the general population. Osteoporosis is a co-prevalent disease, twice as common in this population, and dual-energy X-ray absorptiometry (DXA) has been recognized to predict fracture in CKD. We hypothesized that low bone mineral density (BMD) will be more

prevalent as kidney function decreases and will be associated with biomarkers of mineral and bone disease.

Methods: We investigated the features of BMD in patients with CKD stages 1-5, in a decade observation. DXA obtained from January 1st 2007 to Dec 31st 2017, clinical, demographic and biochemical data at the time of image acquisition were recorded. A total of 1,172 patients were enrolled into this study (81.3% women, 79.9 % white, and 8.6% diabetic).

Results: Osteopenia and osteoporosis in at least one site (total hip or spine) were found in 32.7% and 20.0% of patients, respectively. As CKD progresses, the percentage of patients with normal BMD decreases whereas the percentage of osteopenia and osteoporosis increases, which was mostly due to the total hip involvement. Older age and hyperparathyroidism (PTH>65pg/ml) were independently risk factors for osteopenia/osteoporosis at total hip. Regarding spine, female gender, older age and higher iCa were independently associated with the risk of osteopenia/osteoporosis in the entire population. The odds ratios for osteoporosis/osteopenia at the hip were 1.14 (95% CI: 2.10-3.85) and 1.05 (95% CI: 1.87-3.35) for patients with eGFR <15 and 15-30 ml/min/1.73m^2, respectively. None eGFR category was significantly associated with the risk of osteoporosis/osteopenia at the spine.

Conclusions: We confirmed the risk factors for low BMD already described for the general population, and demonstrated the association with impaired renal function and the more expressive hip involvement than spine. In addition, hyperparathyroidism seems to be an additional, and sizable risk factor in this population.

SA-PO665

Bone Loss in Kidney Transplant Recipients and Patients on Dialysis Treated with Nocturnal Hemodialysis, Conventional Hemodialysis, and Peritoneal Dialysis

Thijs T. Jansz,[1] Hanna C. Willems,[5] Pim A. De jong,[2] Marianne C. Verhaar,[1] Brigit C. van Jaarsveld.[3,4] *[1]Nephrology and Hypertension, University Medical Center Utrecht, Utrecht, Netherlands; [2]Radiology, University Medical Center Utrecht, Utrecht, Netherlands; [3]Nephrology, VU University Medical Center, Amsterdam, Netherlands; [4]Dianet Dialysis Centers, Utrecht, Netherlands; [5]Internal Medicine and Geriatrics, Academic Medical Center Amsterdam, Amsterdam, Netherlands.*

Background: Patients on dialysis have an increased risk of fractures due to mineral bone disorder. This disturbed mineral metabolism is improved by nocturnal hemodialysis, an intensified hemodialysis regimen, and completely normalized by kidney transplantation. This study therefore had two aims: to compare bone loss and its determinants in kidney transplant recipients and patients on dialysis, and to compare bone loss between patients on nocturnal hemodialysis, conventional hemodialysis, and peritoneal dialysis.

Methods: In this prospective observational study, we measured trabecular bone mineral density at the thoracic spine with computed tomography annually for up to 3 years in 45 incident kidney transplant recipients and 78 patients on dialysis (30 on nocturnal hemodialysis, 28 on conventional hemodialysis, and 20 on peritoneal dialysis), who were all transplantation candidates. We used mixed models to compare bone loss between treatment groups and used logistic regression to assess determinants of significant bone loss.

Results: Overall, mean age was 51 ±13 years, and 80 (65%) were male. Bone mineral density remained stable in kidney transplant recipients (change 1.9, 95% confidence interval -1.4; 5.2 mg/cm^3 per year), while it decreased in patients on dialysis at a rate of -6.4, 95% confidence interval -9.2; -3.7 mg/cm^3 per year (P<0.001 for difference). In kidney transplant recipients, determinants of significant bone loss were female sex and over 50 years old (P=0.01), higher baseline bone mineral density (P=0.01), and no calcium supplementation (P=0.03). In patients on dialysis, determinants were female sex (P=0.01) and low parathyroid hormone levels (P=0.03). In patients on dialysis, bone loss was similar in patients on nocturnal hemodialysis, conventional hemodialysis, and peritoneal dialysis (P=0.92 for differences).

Conclusions: After kidney transplantation patients have stable trabecular bone mineral density, while patients who remain on dialysis lose substantial amounts of trabecular bone. This loss is similar in treatment with nocturnal hemodialysis, conventional hemodialysis, and peritoneal dialysis. Whether this is due to oversuppression of parathyroid hormone needs further study.

Variability and Facility Predictors of Cinacalcet Prescription Among US Hemodialysis Facilities

Douglas S. Fuller,[1] Shan Xing,[2] Vasily Belozeroff,[2] Alon Yehoshua,[2] Hal Morgenstern,[3] Bruce M. Robinson,[1] Robert J. Rubin,[4] Nisha Bhatt,[2] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Amgen Inc, Thousand Oaks, CA; [3]University of Michigan, Ann Arbor, MI; [4]Georgetown University, Bethesda, MD.*

Background: Calcimimetic drugs used to treat secondary hyperparathyroidism (SHPT) are being considered for inclusion in the ESRD bundled payment system. Understanding of utilization patterns of calcimimetics across dialysis facilities may help align financial incentives with clinical goals. The objective of our study was to describe the distribution of cinacalcet prescription across dialysis facilities and to explore factors that may influence utilization of cinacalcet.

Methods: We used monthly cross-sectional data from the Dialysis Outcomes and Practice Patterns Study in 2014 to characterize the distribution of cinacalcet prescription across 203 US hemodialysis facilities (10,521 patients). Based on associations with PTH levels from patient-level analyses, we used linear mixed-effects regression to estimate the association between three facility-level exposures – % black, % <65 years old, % having a dialysis vintage ≥3 years – and the prevalence of cinacalcet prescription, adjusting for facility- and patient-level potential confounders.

Results: The average unadjusted mean percentage of patients in each facility prescribed cinacalcet was 23.0% in June 2014 (median, 21.9%; IQR, 12.8-30.5%). The percentage of patients in each facility prescribed cinacalcet in June 2014 was strongly and positively associated with the percentage of patients in the facility who were black, <65 years old, and had a dialysis vintage ≥3 years, adjusting for patient case-mix and dialysis chain affiliation (Figure).

Conclusions: Given these systematic differences of cinacalcet use across dialysis facilities, facilities treating proportionally more patients who are black, under age 65, and having ≥3 years on dialysis may bear disproportionally greater financial burden for treating patients with SHPT after calcimimetics are added to the ESRD bundle. Additional studies evaluating the differential financial impact on facilities of adding calcimimetics to the bundle are warranted.

SA-PO667

The Effects of Lanthanum Carbonate on Bone Metabolic Markers and Bone Mineral Density in Incident Hemodialysis Patients

Kimihiko Goto, Shunsuke Goto, Hideki Fujii, Keiji Kono, Shinichi Nishi. *Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Abnormal bone turnover is a risk factor for cardiovascular disease in hemodialysis (HD) patients. Lanthanum carbonate (LC) is widely used as one of calcium-free phosphate binders and some clinical trials reported the effect of LC on vascular calcification in HD patients. We previously conducted a randomized controlled trial which focused on the effect of LC on coronary artery calcification compared with calcium carbonate (CC) in patients after initiating HD. The aim of the present study was to investigate the effect of LC on bone metabolic markers and bone mineral density (BMD) compared with CC in subjects new to HD.

Methods: We conducted a post hoc analysis from our previous randomized controlled trial. We measured osteocalcin (OC), bone alkaline phosphatase (BAP), tartrate-resistant acid phosphatase 5b (TRACP-5b), and sclerostin in serum at baseline, 12, and 18 months. The measurement of BMD at lumbar spine and femoral neck was performed at the same time. The patients who did not have the data of bone metabolic markers were excluded from this study. Finally, 65 subjects were included in the present study.

Results: Serum OC, BAP, TRACP-5b, and sclerostin levels were comparable between the two groups at baseline. Serum OC levels in the LC group were significantly higher than those in the CC group at 18 months [LC vs CC, 30.0 (18.9-53.2) pg/mL vs 21.7 (15.3-28.3) pg/mL, p = 0.015]. Serum BAP and TRACP-5b levels tended to be higher in the LC group than in the CC group at 18 months [LC vs CC; BAP, 11.9 (8.1-18.5) vs 9.5 (8-12.9) μg/L, P = 0.174; TRACP-5b, 456.0 (228.0-644.0) vs 326.5 (183.3-487.5) mU/dL, P = 0.158, respectively]. Serum sclerostin levels were not different between the two groups. Although serum phosphate levels were comparable between the two groups, serum calcium levels tended to be lower and intact parathyroid hormone levels tended to be higher in the LC group than those in the CC group at 18 months. BMD at both lumbar spine and femoral neck were comparable between the two groups.

Conclusions: In the present study, bone formation and resorption markers were higher in the LC group than in the CC group. Our findings suggested that the treatment of LC was able to maintain proper bone turnover compared with calcium-containing phosphate binders in incident HD patients.

SA-PO668

Etelcalcetide Utilization Pattern in a Mid-Size Dialysis Organization

Virginia (Ginger) S. Arnott,[2] Tzu-Chieh Lin,[1] David C. Hallett,[3] Nisha Bhatt,[1] Ayodele Erinle.[4,2] *[1]Amgen, THOUSAND OAKS, CA; [2]U.S. Renal Care, Midlothian, TX; [3]Amgen Inc., Glendale, CA; [4]High Desert Nephrology Associates, Gallup, NM.*

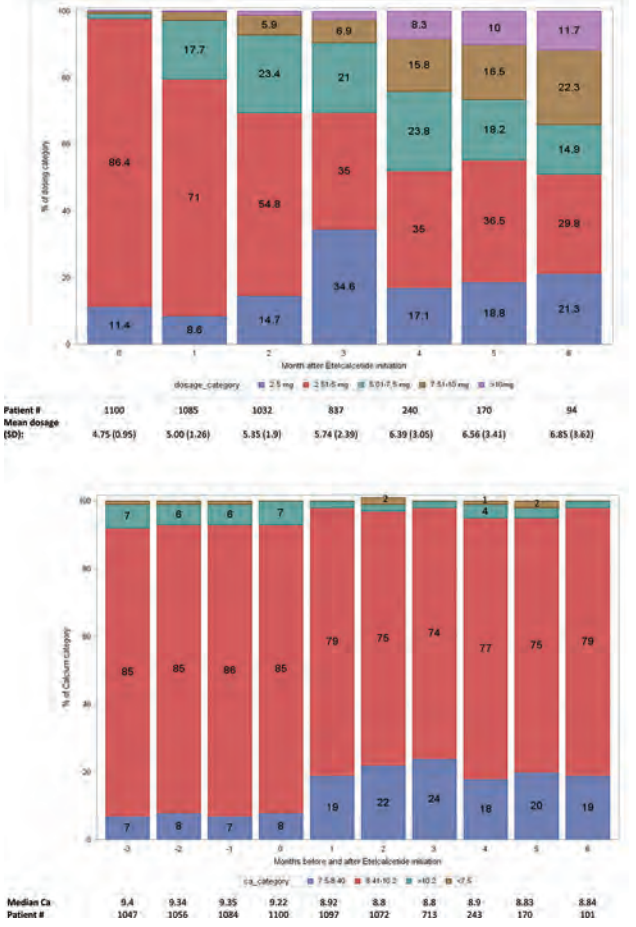
Background: Etelcalcetide is a new calcimimetic agent just entered into clinical practice. The aims of this study are to describe the initial etelcalcetide doses, titration and changes of three key laboratory indices for secondary hyperparathyroidism (SHPT) management.

Methods: This retrospective cohort study included all US ESRD patients ≥18 years, who had received in-center hemodialysis at US Renal Care centers and initiated etelcalcetide between 2/2017 and 2/2018. Every patient was followed from etelcalcetide initiation date until the earliest date of 6 months, death, transplantation, parathyroidectomy, termination of follow-up. Descriptive analyses (mean, median and %) for etelcalcetide dosage, 3 key laboratory indices for SHPT management (parathyroid hormone (PTH), corrected calcium (cCa) and phosphorus (P)) were presented at baseline period and during follow-up.

Results: A total of 1,100 patients initiated etelcalcetide, and the mean (SD) age was 58.7±13.8 years. A total of 86.4% of patients initiated etelcalcetide at 5mg, and 11.4% at 2.5mg three times a week (TIW). The mean (SD) monthly dosage increased from 5.0±1.3 mg at the first month to 6.9±3.6 mg at the 6th month (**Figure 1A**). After etelcalcetide initiation, the proportion of patients achieved a PTH goal of <600 increased from 19% to 51%. During follow-up, 19-24% of patients had at least one cCa level <8.4mg/dL, with <2% (of 1,100) had cCa <7.5 mg/dL (**Figure 1B**). The median P level remained between 5.5-5.7 mg/dL during follow-up.

Conclusions: We found the vast majority of patients were initiated on etelcalcetide at a dose of 5 mg TIW consistent with approved prescribing information. The prevalence of serious hypocalcemia was low, with less than 2% of patients ever having cCa levels <7.5 mg/dL.

Funding: Commercial Support - Amgen, Thousand Oaks



SA-PO669

Etelcalcetide from Controlled Trial to Bedside

Domenico Russo,[1] Daniela Di giuseppe,[3] Salvatore Coppola,[7] Biagio Di iorio,[2] Pasquale Guastaferro,[4] Yuri Battaglia,[5] Luca Di Lullo,[6] Bernadette Scognamiglio,[1] Vincenzo Panuccio.[8] *[1]Public Health, University Federico Ii, Naples, Italy; [2]Landolfi Hospital Solofra, Avellino, Italy, Solofra, Italy; [3]VENODIAL, Cava dei tirreni, Italy; [4]Sant'Angelo dei lombardi hospital, Avellino, Italy; [5]Hospital-University St. Anna, Ferrara, Italy; [6]U.O.C. Nefrologia e Dialisi, Grottaferrata, Italy; [7]P.O. Piedimonte matese, Caserta, Italy; [8]UO Nefrologia, Dialisi, Trapianto, Reggio Calabria, Italy.*

Background: Cinacalcet reduces high PTH levels (SHPT) in dialysis patients. Relevant complaints associate cinacalcet: nausea, vomiting, hypocalcemia. Therefore, clinicians are forced to reduce dose or discontinue cinacalcet with consequent poor PTH control. Etelcalcetide in randomized trials resulted non inferior to cinacalcet at lowering PTH. Common adverse events are hypocalcemia and gastrointestinal symptoms. This pilot observational multicenter study was conducted to evaluate efficacy and occurrence of side effects of etelcalcetide in a "real world" setting that is different from randomized controlled trials.

Methods: Patients on thrice weekly maintenance hemodialysis, stable doses of phosphate binders, calcitriol or active vitamin D were evaluated. Investigator were free in prescriving starting dose and etelcalcetide increments. Biochemistry and side effects were recorded after etelcalcetide. Clinician's satisfaction was evaluated by questionnaire.

Results: n.73 patients (mean age:61±13 years; males:62 %; diabetics:25 %;dialysis vintage:78±52months) received etelcalcetide. Many patients (83%) were treated with cinacalcet (median daily dose:30 mg). Cinacalcet-dependent gastrointestinal side effect were 49%; episodes of hypocalcemia were 4. No changes were observed in phosphate binder, vitamin D sterols and ESA doses, and serum hemoglobin concentration. Further results are reported in table.

Conclusions: The study shows that in high-risk dialysis patients, lower doses of etelcalcetide than that reported before reduce PTH with minimal gastrointestinal discomfort and low occurrence of hypocalcemia requiring drug discontinuation. The effect on PTH seems dose dependent. Almost all participating clinicians regarded etelcalcetide as very handy medication. Larger study and longer follow-up in "real world" setting are mandatory.

Daily versus Post-Dialysis Administration of Calcimimetics for the Treatment of Secondary Hyperparathyroidism in Hemodialysis Patients: An Interventional, Multi-center Study

Tarek M. Demerdash,[1,2] Mostafa A. Abdelkhalek,[1,3] Mohammed M. Assem,[1,2] Mahmoud M. Shaheen,[1,2] Farida Elsafty,[1] Ibrahim A. Jubran,[1] Saad S. Alobaili,[1] Abdullah Kashgary,[1,4] Wisam H. Al-Badr,[1] Abdulkareem Alsuwaida.[1] *[1]DaVita-Saudi Arabia, Riyadh, Saudi Arabia; [2]Cairo University, Cairo, Egypt; [3]Mansoura Faculty of Medicine - Mansoura University, Mansoura, Egypt; [4]King Abdulaziz University, Jeddah, Saudi Arabia.*

Background: Treatment of secondary hyperparathyroidism (SHPT) in patients on hemodialysis (HD) may be hampered by poor medication adherence. The aim of this study was to assess the effectiveness of supervised, post-HD administration of calcimimetics in controlling mineral bone disorder (MBD) in patients on maintenance HD.

Methods: This was a multi-center prospective study that included adults treated at DaVita HD facilities in Saudi Arabia with HD vintage ≥6 months and proven SHPT. Patients with previous parathyroidectomy, baseline corrected calcium <8.4 mg/dL, tertiary HPT, and patients having other causes of hyper- or hypo-calcemia were excluded. As of Nov 1, 2017, study patients were shifted from daily dosing of calcimimetics to three weekly doses taken at the end of each HD session. Intact parathyroid hormone (iPTH), serum calcium, phosphorus, alkaline phosphatase levels, dosage of phosphate binders (calcium carbonate/sevelamer), and vitamin D analog were compared at baseline and 6 months after initiation of thrice-weekly calcimimetic dosing.

Results: A total of 73 HD patients switched to receive calcimimetics after dialysis. After 6 months, there was a significant reduction in both calcimimetic dose (p=0.005) and iPTH (p=0.013). Despite the absence of any significant change in serum calcium, phosphorus, or alkaline phosphatase, there was an increase in calcium carbonate dose (p<0.009) and a reduction in sevelamer dose (p<0.011)

Conclusions: Compared to daily dosing, supervised calcimimetic dosing after HD was more effective in controlling SHPT. Evaluation in large-scale randomized controlled studies is recommended.

Funding: Commercial Support - DaVita

Effects of alternate dose of cinacalcet on laboratory values and dosage of medications

	Baseline	After 6 months	P value
Serum phosphate, mean ± SD	5.5±1.52	5.83±1.3	0.135
Serum calcium, mean ± SD	9.2±0.8	9.3±0.74	0.62
Alkaline phosphatase, median (IQR)	133 (138)	125 (125)	0.314
iPTH, median (IQR)	1213 (784)	849 (1028)	0.013

Conversion from Cinacalcet to Etelcalcetide in a Mid-Size Dialysis Organization: Real-World Therapeutic Conversion

Dongyang Shang,[1] Shaun S. Collard,[1] Graham E. Abra,[1,2] Brigitte Schiller.[1,2] *[1]Satellite Healthcare, San Jose, CA; [2]Stanford University, Palo Alto, CA.*

Background: There are two FDA approved calcimimetics available in the United States, intravenous etelcalcetide and oral cinacalcet. There is limited data to guide therapeutic conversion from cinacalcet to etelcalcetide in a real-world hemodialysis (HD) setting. Here we describe our experience with conversion from cinacalcet to etelcalcetide HD patients in a mid-size dialysis provider organization.

Methods: Data from 1264 in-center hemodialysis patients treated with cinacalcet from 60 dialysis centers from December 2017 to April 2018 are reported. Conversion from cinacalcet to etelcalcetide occurred in February 2018. All patients started etelcalcetide at 2.5 mg IV three times a week regardless of previous cinacalcet dose after a 7 day wash out period. Etelcalcetide doses were subsequently adjusted monthly to achieve a target iPTH of 150-700 pg/mL and an adjusted calcium of 8.0-10.2 mg/dL.

Results: The percentage of patients with an adjusted calcium reaching the target iPTH declined temporarily, but increased in month 1 and 2 after conversion. Monitoring in all patients treated with etelcalcetide, recorded the following adverse events (AEs) profiles: 4% of patients experienced nausea/vomiting and 24% hypotension. No severe AEs were reported.

Conclusions: In this real-world dosing conversion from cinacalcet to etelcalcetide aggregated biochemical targets after converting all patients to etelcalcetide 2.5 mg IV three times a week regardless of previous cinacalcet dose showed a decrease in percentage of patients reaching iPTH targets during conversion month with improving iPTH results in the subsequent two months post conversion. Side effect profile was unchanged compared to commonly reported AEs.

Uremic Periodontitis: Bacterial Dysbiosis and Immune Dysfunction

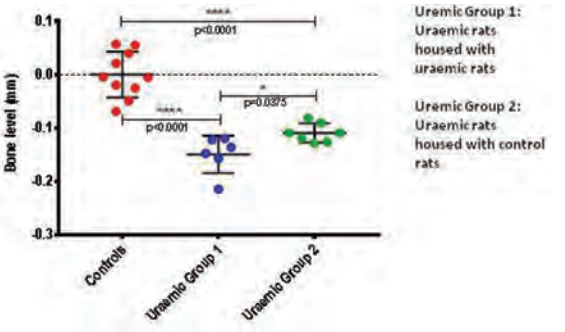
David Randall,[1] Asil Alsam,[2] Julius E. Kieswich,[1] Susan Joseph,[2] Kieran Mccafferty,[1] Michael A. Curtis,[2] Muhammad M. Yaqoob.[1] *[1]William Harvey Research Institute, Queen Mary University of London, London, United Kingdom; [2]Dental Institute, Kings College London, London, United Kingdom.*

Background: Patients with CKD have a high incidence of periodontitis, which acts as a marker for increased mortality in these individuals. We sought to establish whether this represents a causal association, and to understand the mechanisms responsible.

Methods: Two models of CKD were used in wild-type Wistar rats: feeding with 0.75% adenine and subtotal nephrectomy. Of the uremic animals, half were housed with other uremics whilst half were housed with controls. The oral microbiome was assessed using next-generation sequencing and culture-based methods. Periodontal bone loss was measured as the distance between the cemento-enamel junction and the alveolar bone ridge, supplemented by immunohistochemistry, micro-CT imaging and scanning electron microscopy.

Results: In both models of CKD, uremic rats displayed significantly more periodontal bone loss than controls (alveolar bone level > 0.1mm lower in uremics, p<0.0001). These animals displayed substantial oral dysbiosis compared to controls, including a reduction in cultured bacterial counts (log 5.95 vs log 6.21, p=0.05), increased alpha diversity (Inv Simpson index 10.3 vs 6.46, p=0.03), a decline in health-associated phylum Firmicutes (55.2% vs 66%, p=0.05) and genus Streptococcus (29.8% vs 45.8%, p=0.004), and an increase in disease-associated Gammaproteobacteria (29.6% vs 19.4%, p=0.038). Histology and imaging confirmed bone disease associated with IL-17 driven inflammation. Significantly, uremic rats housed with healthy controls demonstrated milder bone loss than those housed with other uremics (p=0.037).

Conclusions: This work proves for the first time that periodontitis can be caused by uremia. A key role for bacterial dysbiosis is suggested from the fact that periodontal disease was partially reversed in uremic animals housed with controls. We propose that oral bacterial dysbiosis induces Th17-driven inflammatory periodontal bone loss.



The mean of the bone levels of the control rats has been used as a baseline. Negative values of alveolar bone level indicate bone loss relative to this baseline. Each circle represents the mean bone level for an individual rat with horizontal lines representing the mean bone levels per group +/- SD.

SA-PO673

The Ability of Intact Parathyroid Hormone and Total Alkaline Phosphatase to Predict Bone Turnover in Patients with Renal Osteodystrophy

Jose E. Gueiros, Ana Paula Gueiros, Luiz A. Coutinho, Julia B. Vaz. *UFPE, Recife, Brazil.*

Background: Bone turnover (BT) markers reflect bone cell activity and are useful in the diagnosis and management of chronic kidney disease-mineral and bone disorders. Bone biopsy (BB) is considered gold standard for diagnosing renal osteodystrophy, although it should be reserved just for certain patients. The objective of this study was to evaluate the predictive value of intact parathyroid hormone (iPTH) and total alkaline phosphatase (tALP) as BT markers.

Methods: This was a cross-sectional retrospective diagnostic test study. Two hundred and eleven patients were assessed through BB and serum levels of iPTH and tALP. iPTH assays were performed using the same methodology (chemiluminescence: NR: 15-65 pg/mL). For the tALP analysis, an index representing the ratio between tALP and the maximum reference value for the method was used, since there are tests with different methodologies. According to histological diagnosis, the patients were divided into high turnover (HT), those with fibrous osteitis and mixed disease, and low turnover (LT), those with adynamic bone disease and osteomalacia. An analysis was conducted in order to derive the area under the receiver operating characteristic (ROC) curve (AUROC) to determine the diagnostic ability of BT as a biomarker.

Results: Patients (48.9 years) had been on hemodialysis for 9.5 years, of whom 84% and 16% were classified as HT and LT, respectively. The median serum level of iPTH was 1296 in the HT patients, and 116 in LT patients. The median tALP index was 1.82 for the HT and 0.9 for the LT patients. To predict HT, the iPTH presented an AUROC of 0.908, with a cutoff value of 363 with a sensitivity of 82.5% and a specificity of 88%; while the tALP index demonstrated an AUROC of 0.747, with a cutoff value of 1.01, with a sensitivity of 72.3% and a specificity of 65%. To predict LT, the iPTH and tALP index were not good markers, with an AUROC of 0.092 and 0.253, respectively. Limitations**:** Histomorphometry and bone alkaline phosphatase were not performed; Predominance of severe secondary hyperparathyroidism.

Conclusions: Our results have demonstrated that the iPTH and tALP were excellent predictors for HT, but it was evident that iPTH was far superior.

SA-PO674

Twenty-Four Hour Urine Testing in Kidney Stone Formers: A Veterans Health Administration Study

Calyani Ganesan,[1] I-Chun Thomas,[5] Andrew J. Sun,[2] Simon Conti,[4] Christopher S. Elliott,[4] Joseph C. Liao,[2] Manjula Kurella Tamura,[2] Glenn M. Chertow,[3] John Leppert,[2] Alan C. Pao.[2] *[1]Stanford Nephrology, Redwood City, CA; [2]Stanford University, Palo Alto, CA; [3]Stanford University School of Medicine, Palo Alto, CA; [4]Stanford, San Jose, CA; [5]VA Palo Alto, PALO ALTO, CA.*

Background: The American Urological Association recommends 24-hour urine testing in stone formers to prevent recurrent stones. However national practice patterns of

metabolic evaluation which utilize urine testing remain uncharacterized. To address this, we identified stone formers in the national Veterans Health Administration (VHA) database and assessed the characteristics of those who received 24-hour urine testing and the timing and frequency of testing.

Methods: We defined stone formers as those with one or more inpatient ICD-9 codes for stones, two or more outpatient ICD-9 codes for stones, or one or more CPT codes for stone procedures in 2007-13 using the national VHA database. We defined a 24-hour urine test as having a 24-hour urine calcium, oxalate, citrate or sulfate measurement. We compared demographics and clinical characteristics among Veterans who received testing and those who did not. We determined the timing and frequency of 24-hour urine testing and evaluated whether urine testing varied geographically. We assessed factors associated with 24-hour testing using multivariable regression.

Results: We identified 130,489 individuals with a stone encounter between 2007-2013. Within this stone cohort, 13.3% (19,288 individuals) underwent 24-hour urine testing. These individuals were younger, had fewer comorbidities, and were more likely to be seen on an outpatient basis. In addition, those with 24-hour urine testing had more stone procedures than those who did not (3.0 ± 2.8 vs. 2.3 ± 2.1, p <.001). The majority of testing occurred within 1 year of a stone encounter. There was considerable geographic variation in the utilization of 24-hour urine tests, ranging between 1% and 40% across VA facilities, with the most frequent testing in the western United States.

Conclusions: We found high facility level variation in 24-hour urine testing among stone formers. Our results suggest that in addition to patient risk, physician practice patterns influence the use of 24-hour testing in urinary stone disease. Comparative effectiveness research could help to define the role of 24-hour urine testing in the evaluation and management of kidney stones.

Prevalence of Kidney Stones in Cystic Fibrosis

Jeremy F. Wright,[1,2] David S. Goldfarb,[3,4] Eric N. Taylor,[1,2] Jonathan Zuckerman.[1,2]
[1]Maine Medical Center, Portland, ME; [2]Tufts University School of Medicine, Boston, MA; [3]NYU Medical School, New York, NY; [4]New York Harbor VAMC, New York, NY.

Background: Cystic fibrosis (CF) may predispose patients to urinary stone disease (USD) via several proposed mechanisms including antibiotic exposure and intestinal malabsorption. Prevalence of USD in patients with CF was estimated at 2-6% in studies with mean age 16-27 years. These data are limited by small sample sizes and single-center settings. The CF Foundation Patient Registry (CFFPR) began collecting prevalence data on USD in 2006.

Methods: We studied 29,396 patients in the CFFPR living in 2016 to calculate age-stratified prevalence of USD.USD was assessed by trained CF clinic staff at each encounter. For 15,531 patients age 18 or older we examined associations between age, BMI, demographics, CFTR mutation class, other clinical parameters, and prevalent USD using multivariate logistic regression.

Results: Overall prevalence of USD was 3.1% (95% CI 2.9-3.3%). Prevalence under age 18 years was 0.4% (0.3-0.5%), 18 to 24 years, 3.1% (2.7-3.6%), 25 to 34 years, 6.4% (5.8 -7.1%), 35 to 44 years, 7.5% (6.5-8.5%), and 45 years and older, 6.7% (5.8-7.8%). Mean age of all patients was 21.3 years. We also calculated prevalence for age ranges 20-29, and 30-39 years to compare with published NHANES data for the general population. Stone prevalence was 4.8% and 7.1% in in CF patients within these two age cohorts, respectively, compared to 3.4 and 6.4% in NHANES. Multivariate adjusted odds ratios for stone prevalence were significant for female sex, OR 1.4 (95% CI 1.2-1.7), severe CFTR mutations, OR 1.8 (1.2-2.5), diabetes, OR 1.2 (1.0-1.5), hypertension, OR 1.4 (1.0 -1.9), and chronic macrolide therapy, OR 1.3 (1.1-1.6). BMI was not associated with USD.

Conclusions: USD prevalence in CFFPR may be higher than in the general population and increased with age. Some risk factors for stone disease in the general population appear significant for adult patients with CF, including hypertension and diabetes. However, BMI did not show the same relationship. Several novel associations with USD in CF patients also were identified, including a greater prevalence in women. This study is limited by the method of USD assessment; it is possible patients with more severe CF had higher rates of reported asymptomatic stones incidentally diagnosed due to more frequent imaging. As life expectancy of people with CF increases, the prevalence of USD may also increase.

SA-PO676

Correlation of Papillary Grading and Metabolic Parameters in Calcium Stone Formers

Anna L. Zisman, Fredric L. Coe, Elaine M. Worcester. *University of Chicago, Chicago, IL.*

Background: Papillary grading has emerged as a novel technique to standardize ureteroscopic findings, but its relationship to stone pathogenesis is poorly understood. As 24-hour urine metabolic risk parameters predict stone type and likelihood of recurrence, we sought to determine whether papillary grading correlates with these parameters.

Methods: Patients' endoscopic findings during stone procedures were graded by two urologists at a single academic institution using a previously described renal papillary grading system. This system quantifies the degree of Randall's plaque (RP), pitting, plugging, and loss of contour, yielding a summary score for each papillum. Composite scores were generated by averaging all papillary scores from a single kidney. Patients were included if they had calcium based stones and completed two 24-hour urine collections with paired serum studies prior to treatment. Pearson correlations were used to determine relationships between individual components of the score, total score, and average across the categories as related to urinary metabolic risk factors.

Results: 41 patients (43% Male, 63% Caucasian) were included. The mean age was 52.1 yrs (±7.5) and mean BMI was 30.8 (±4.0) kg/m2. Contour was inversely related to 24 hr urine calcium (P<0.05) and calcium phosphate supersaturation (SSCaP) (p<0.05). Pitting is directly related to 24-hr urine oxalate (p<0.05) and inversely related to urine volume (p<0.05) (Figure). No significant correlations were found for urine pH or 24 hr urine citrate. Significant differences in RP scores (AA 0.53, C 1.35, p<0.003), but not the other grading components, were noted across racial groups.

Conclusions: Papillary grading correlates with 24 hr urine volume, calcium, oxalate, and SSCaP. Racial differences in RP burden suggest differing mechanisms of calcium lithogenesis by race which warrants further study.

SA-PO677

Prevention of Recurrent Stones and CKD in Kidney Stone Formers: What Are the Goals for Biochemical Parameters in Urine Collections?

Juan Carlos Ramirez-Sandoval,[1] Cynthia Garcia-Sanchez,[3] Ricardo Correa-Rotter.[2] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, México city, Mexico; [2]Institutor Nacional de la Nutricion, Mexico City, Mexico; [3]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico, Mexico.*

Background: The evidence of effective prevention of recurrent stone formation and CKD in kidney stone formers (KSF) through the treatment of biochemical abnormalities present in repeated 24h urine collections (24UC) is scarce. Our aim was to analyze the association between metabolic control (assessed by yearly 24UC) and kidney stone recurrence rates and decline in eGFR in KSF attending a nephrolithiasis clinic.

Methods: Single-center cohort study of KSF with at least three 24UC and ≥2 years of follow-up. Exclusions: primary hyperparathyroidism, eGFR >30 mL/min/1.73m^2. Medical data, including chemistry of 24UC, were compared using analysis of variance and general linear modelling.

Results: Of 220 KSF, 63% had absorptive hypercalciuria and 64% hipocitraturia (median follow-up of 4 yrs [IQR 4-5.2 yrs]). All KSF with hypercalciuria received chlortalidone. 24UC abnormalities display a trend to improve along time in all the cohort. Stone recurrence (≥2 episodes, 35% of KSF) was associated with higher urinary Ca/Cr index compared with KSF free of stone recurrence at follow up with treatment (yearly mean 24UC Ca/Cr 0.15±0.08 Vs. 0.12±0.05 respectively, p=0.02). Inappropriate eGFR decline (>2 mL/min/year) not related to obstruction or AKI episodes was observe in 13% of KSF and was associated with lower citraturia (yearly median citrate 192 mg/24UC [IQR 153-290] Vs 354 mg/24UC [IQR 237-541], p=0.003). Other parameters of the 24UC (volume recollected, Na, oxaluria, or uricosuria) were not associated with recurrence or eGFR decline.

Conclusions: Among 24UC yearly measurement; a very low Ca/Cr index was effective preventing stone recurrence in KSF. Low citrate excretion predicted an inappropriate eGFR decline, even before treatment.

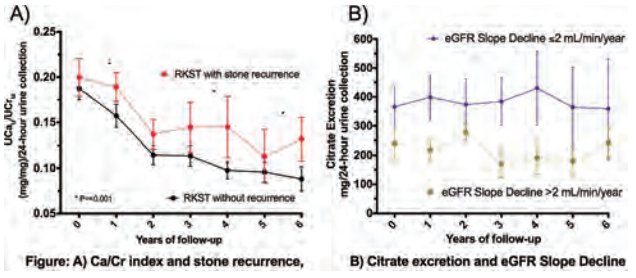

Figure. Association between repeated urinary chemistry of yearly 24-hour collections and renal outcomes. A) Calciuria/creatinuria index and stone recurrence. B) Citrate excretion and eGFR Slope Decline.

SA-PO678

Manifestations of Kidney Stone Recurrence and Their Prediction by Risk Factors

Matthew R. D'Costa, Kristin C. Mara, William E. Haley, Felicity T. Enders, Terri J. Vrtiska, Cynthia H. Mccollough, John C. Lieske, Andrew D. Rule. *Mayo Clinic, Rochester, MN.*

Background: The relationship between symptomatic and radiographic kidney stone recurrence is unclear. Risk factors may also differ in their association with symptomatic and radiographic recurrence.

Methods: First-time symptomatic stone formers were recruited from 2009 to 2013 in MN and FL. Baseline and 5-year follow-up visits included CT scans, surveys, and medical record review. At 5 years, symptomatic recurrence was identified by clinical care (medical record) and self-report (survey); radiographic recurrence was identified by new stone, stone growth, or stone disappearance between CT's. A Recurrence of Kidney Stone (ROKS) score summed risk factors for recurrence (young age, male gender, high BMI, family history of stones, pregnancy, asymptomatic or suspected stone prior to first episode, history of a brushite/struvite/uric acid stone, no history of COM stone, pelvic/lower pole stone, no uterovesical junction stone, number of stones in kidney, and diameter of largest kidney stone). The 5-year incidence of recurrence and its association with ROKS score was compared.

Results: There were 175 stone formers studied (55% had an asymptomatic kidney stone at baseline). By year 5, 19% had symptomatic recurrence (clinical care), 25% had symptomatic recurrence (self-report), 35% had a new stone, 24% had stone growth, and 26% had stone disappearance. Of those with an asymptomatic stone, 47% had stone disappearance, and 50% of those had a concurrent symptomatic recurrence. Symptomatic recurrence by clinical care versus self-report was more strongly associated with new stone (OR=4.8 95% CI [2.2-10.6] versus 1.9 [1.0-3.9]) or stone disappearance (OR=3.9 [1.8-8.5] versus 2.0 [1.0-4.2]). The ROKS score associated more strongly with radiographic recurrence than only symptomatic recurrence (Table).

Conclusions: Clinical care is more strongly associated with recurrence than self-report. Half of first-time stone formers have an asymptomatic stone. By 5 years, half of these stones will have passed with symptoms occurring half the time (Rule of Halves). While symptomatic recurrence is more clinically relevant, asymptomatic radiographic recurrence is better predicted by risk factors.

	Symptomatic recurrence: clinical care only	Symptomatic recurrence: clinical care or self-report	Radiographic recurrence: new stone, stone growth or stone disappearance	Symptomatic or radiographic recurrence
5-year rate	19%	30%	59%	67%
OR (95% CI) per standard deviation of ROKS score	1.7 (1.1, 2.5)	2.1 (1.5, 3.1)	3.7 (2.4, 5.8)	3.6 (2.3, 5.5)

SA-PO679

Rotating Shift Work and Kidney Stones

Megan Prochaska,[1] Eric N. Taylor,[3] Gary C. Curhan.[2] *[1]Renal, Brigham and Women's Hospital, Boston, MA; [2]Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA; [3]Maine Medical Center and Tufts University School of Medicine, Portland, ME.*

Background: Related to circadian rhythm, which is the 24-hour periodicity of physiologic processes, there is diurnal variation in excretion of urinary factors, including factors associated with kidney stone risk. Rotating shift work disrupts circadian rhythm but has not been evaluated as a risk factor for kidney stones. We examined rotating shift work with risk of incident kidney stones and 24-hour urine composition in the Nurses' Health Study II.

Methods: We conducted a prospective analysis of 101,983 Nurses' Health Study II participants who provided information on rotating shift work and kidney stones. We used multivariate adjusted Cox proportional hazards models to compare current (1 to 9 months, or 10 or greater months) and past rotating shift work to no rotating shift work. In a separate analysis, we used multivariate adjusted Cox proportional hazards models to compare cumulative shift work exposure to no shift work. We also analyzed rotating shift work in 24-hour urine collections from 3811 participants. We used ANOVA to compare urinary factors by rotating shift work duration.

Results: In 22 years of follow-up, there were 3,281 incident kidney stones. Compared with no rotating shift work, the multivariate adjusted relative risks for incident kidney stone were 1.16 (95% CI 0.92 to 1.46) for 1 to 9 months current rotating shift work, 1.12 (95% CI 0.92 to 1.34) for 10 months or greater current rotating shift work, and 1.12 (95% CI 1.04 to 1.20) for past rotating shift work. Compared with no rotating shift work, participants with the highest exposure of cumulative rotating shift work, 10 years or greater, the multivariate adjusted risk for incident kidney stone was 1.19 (95% CI 1.06 to 1.34). There were no substantial differences or trends in the urine composition profiles when comparing 24-hour urine collections for participants who had no rotating shift work, 1 to 4 months, 5 to 14 months, and 15 months or greater of rotating shift work during the collection period.

Conclusions: Rotating shift work was associated with a slightly higher risk of incident kidney stone compared with no rotating shift work. There were no differences in urine composition based on rotating shift work.

Stone Frequency Determines Health-Related Quality of Life (HRQoL) in Cystine Stone Formers (CSF)

Frank Modersitzki,[1,2] David S. Goldfarb.[1,2] Rare Kidney Stone Consortium *[1]New York University School of Medicine, New York, NY; [2]New York Harbor VAMC, New York, NY.*

Background: CSF have lower HRQoL compared to US Standard Population. We have shown previously that HRQoL results need to be controlled for the last stone event and comorbidities. We now show the first longitudinal HRQoL domain profiles for baseline and two yearly follow-ups.

Methods: CSF were enrolled from the RKSC registry. HRQoL was measured with the generic non-disease specific SF-36v2. Results were calculated as norm-based scores (NBS) based on US Standard Population (Domain score mean = 50). We selected 3 stone frequency groups (SFG): low (stone-free during observation period), medium (minimum of one stone event between 31 - 365 days) and high (stone event always present within 30 days of the survey), and compared the groups' HRQoL at baseline and second follow-up.

Results: We scored 386 surveys. 78 participants (32 males and 46 females) were compared at baseline and 2 follow-up assessments. Mean age was 45 years (male 44/ female 46). Repeated measure ANOVA showed no difference within each SFG over time (Fig 1). However, domain scores were significantly different between SFG's ($p<0.05$) at each time point, with low>medium>high stone frequency. Whether surgical intervention was required, and type, were not predictors of HRQoL outcomes. Better HRQoL tracked with lower cystine excretion per liter on 24h urine collections; lower cystine capacity and higher citrate doses were underpowered (NS).

Conclusions: CSF with high stone event rates experience worse HRQoL over time, while CSF with no stone events achieved better HRQoL than US standard. Clinnical data suggest that the high SFG is undertreated.

Funding: NIDDK Support

Vascular Calcifications in Patients with Calcium and Uric Acid Kidney Stone Composition

Pietro Manuel Ferraro,[1] Riccardo Marano,[2] Aniello Primiano,[3] Jacopo Gervasoni,[4] Giovanni Gambaro.[1] *[1]Fondazione Policlinico Universitario A. Gemelli, Rome, Italy; [2]Polyclinic Foundation A. Gemelli IRCCS - Catholic University, Rome, Italy; [3]Istituto di Biochimica e Biochimica Clinica Università Cattolica del Sacro Cuore, Rome, Italy; [4]Area Diagnostica di Laboratorio IRCCS Fondazione Policlinico Universitario A. Gemelli, Rome, Italy.*

Background: Kidney stone disease has been associated with incident cardiovascular events, as well as with vascular calcifications. It is not known whether the likelihood and extent of vascular calcifications differ in patients with different types of stone composition.

Methods: We retrospectively evaluated CT scan images of patients who underwent at least one kidney stone composition analysis during the 2015-2018 period. Kidney stones were analyzed by Fourier-transform infrared spectroscopy and categorized as follows: calcium stones (≥50% calcium oxalate or calcium phosphate), uric acid stones (any uric acid). A calcification score was calculated from the CT scan images at the abdominal aorta and expressed as calcium volume. The radiologist who performed the calcification score evaluation was not aware of the stone composition group of the patients. For patients who underwent multiple kidney stone composition analyses and/or CT scans, information on vascular calcification was obtained from the CT scan closest in time to a kidney stone composition analysis.

Results: We enrolled 30 patients with at least one kidney stone composition analysis in the observation period who had undergone at least one CT scan examination at our Institution. Average age was 56±16 years, 16 (53%) were males. Patients with uric acid stones had significantly higher values of calcification at abdominal aorta (975 mm^3, 95% CI –3, 1,953 mm^3; p=0.05). However, such differences attenuated after adjustment for age (370 mm^3, 95% CI –598, 1,337 mm^3; p=0.44).

Conclusions: Patients who form uric acid stones seem to have worse calcifications at abdominal aorta compared with those who form calcium stones; however, this association could be at least in part mediated by differences in age between groups.

SA-PO682

Nephrolithiasis in HIV+ Patients with CKD: A Case Series

Ryan Spiardi, Maliha Ahmed, Robert Fleyshman, Abbas Raza, Suzanne Boyle. *Drexel University College of Medicine, Philadelphia, PA.*

Background: Nephrolithiasis and CKD are highly prevalent in the HIV+ population, independent of each other. The association between some anti-retroviral therapy (ART) and both nephrolithiasis and CKD, respectively, has been demonstrated. However, amongst HIV+ patients, there are limited data on the relationship between nephrolithiasis and CKD progression. It is unknown if HIV+ patients have risk factors for nephrolithiasis beyond ART. We describe a series of HIV+ patients with a history of nephrolithiasis in a CKD clinic.

Methods: In a CKD clinic of HIV+ patients (n = 55), we identified those with history of nephrolithiasis by radiology or self-report. Data was collected on demographics; co-morbidities; HIV control; age at first stone; urologic interventions; ART; creatinine trends; urine chemistries; and stone composition.

Results: The prevalence of nephrolithiasis was 21.8% (n = 12). Sixty-seven percent were black; 92% male; 75% had HTN; 8%, DM. At the initial CKD appointment, median age was 53; baseline creatinine, 1.5 mg/dl (IQR, 1.2-1.8); eGFR, 49 ml/min/1.73m^2; UPCR, 1.02 (IQR, 0.37-1.89). Ninety-two percent had an undetectable viral load (VL). Eighty-three percent had taken tenofovir disoproxil fumarate (TDF); 50%, atazanavir; 17%, indinavir. The majority had their first stone after HIV diagnosis (58%) and 42% of first episodes were between ages 51-60. After the first stone, there was a generalized upward creatinine slope in 75% of patients (n = 9). Only one patient had data on stone composition, and two, urine chemistry.

Conclusions: There was a high prevalence of nephrolithiasis among HIV+ patients in a CKD clinic. Most patients had their first stone after HIV diagnosis and experienced an upward slope in creatinine after this. Nearly all had early CKD with sub-nephrotic proteinuria and undetectable VL. While most patients had exposure to ART that might increase stone risk, we cannot infer that this entirely accounts for the high prevalence. Studies show that proximal tubule cells are a reservoir for HIV. This could be a potential risk factor for stones by altering urine chemistry. Controlled studies are needed to describe urine chemistries in HIV+ patients with nephrolithiasis as well as the association between nephrolithiasis and CKD progression.

SA-PO683

Independent Effects of Age and Kidney Function on Urine pH in Stone Forming Patients

Cameron J. Menezes,[1] John R. Asplin,[2] Elaine M. Worcester,[1] Fredric L. Coe.[1] *[1]University of Chicago, Chicago, IL; [2]Litholink Corp, Chicago, IL.*

Background: We have found that normal women (W) have higher urine pH (UpH) than men (M) fed identical diets in a clinical research center. Prevalence of high UpH-dependent phosphate stones decreases with age while that of uric acid stones – signifying low UpH - increases. We sought to determine if UpH falls with age in a large population of stone formers (SF), and if so to quantify the independent effects of sex, falling renal function, and age itself.

Methods: From a large dataset of 12839 SF patients with pretreatment 24 hour urine collections and matching serum collections (Litholink) we selected 7891 (3605 F) SF without markers of systemic disease, infections, or missing lab values. The final dataset was used to model UpH using continuous generalized linear models with urine potential renal acid load (uPRAL) calculated from urine charge balance, age, creatinine clearance (CCr) and their appropriate cross products. To directly compare the effect sizes of CCr and age, we treated both as categorical variables in a separate analysis.

Results: UpH in W was higher than M at all ages and UpH declines with age and CCr via separable effects. uPRAL, age, and CCr are all significant ($p<.01$) predictors of UpH (Table), and the effect of uPRAL is conditioned by both CCr and age. The observed sex difference is fully accounted for after adjustment in both the continuous and categorical models of UpH.

Conclusions: Age and CCr exert separate effects on UpH in SF patients. Of the two, age is the more important predictor with an effect size approximately twice that of CCr. UpH is most strongly conditioned by uPRAL with effects that are mediated by age and kidney function.

Funding: NIDDK Support

Correlation of Vitamin D and Insulin Resistance Among Calcium Kidney Stone Formers

Pulkit Gandhi,[1] Roopali G. Gandhi,[2] Jie Tang.[3] *[1]Brown University, Providence, RI; [2]Rhode island hospital, Providence, RI; [3]University Medicine; Brown University, West Roxbury, MA.*

Background: Existing evidence suggest that vitamin D could play a role in the pathogenesis of type 2 diabetes, by affecting insulin sensitivity. However, the interaction of 25(OH)-vitamin D (25D) with insulin sensitivity has not been examined in calcium kidney stone formers, a unique population whose 1,25(OH) vitamin D (1,25-D) action seems to be hyperactive.

Methods: Prevalent non-diabetic calcium kidney stone formers from 2015 to 2018 were enrolled in this study. We assessed the association between serum 25D and insulin resistance measured by Homeostatic model assessment insulin resistance {HOMA IR = (fasting glucose (mg/dl) × fasting insulin (mU/L)/(405)} using univariate analysis and multivariate regression model adjusting for demographics and important clinical covariates. P values less than 0.05 were considered significant.

Results: A total of 94 non-diabetic calcium kidney stone formers were enrolled in this study. Among them, 51% were male, 86% were Caucasian, 38% had history of hypertension, and 29% had history of dyslipidemia. Mean age was 54 years, mean creatinine clearance (CrCl) was 131 ml/min, mean body mass index was 31.3 kg/m^2, mean serum 25D was 28 ng/ml, mean serum 1,25D was 52 pg/ml and mean serum parathyroid hormone level was 66 pg/ml. The mean HOMA IR was calculated at 8.1. In univariate analysis, 25D had no significant association with HOMA-IR (p=0.68), however, hypertension, dyslipidemia, CrCl and BMI associated significantly with HOMA-IR ($p<0.05$). After adjusting for demographics, 25D again did not associate significantly with HOMA-IR (p=0.33), but the associations between HOMA-IR and hypertension, dyslipidemia, CrCl and BMI remained significant ($p<0.05$). Finally, after adjusting for demographics, hypertension, dyslipidemia, CrCl, BMI and serum uric acid, the association between 25D and HOMA-IR remained insignificant (p=0.14). Like 25D, serum 1,25D levels had no association with HOMA-IR in univariate and multivariate analyses.

Conclusions: Unlike the general population, low serum 25D levels, had no significant association with insulin-resistance measured by HOMA IR in calcium kidney stone formers.

Unmet Need in Enteric Hyperoxaluria: Clinical Characteristics and Stone Burden in Patients from ALLN-177 Studies

Sagar U. Nigwekar,[1] James E. Lingeman,[2] Linda H. Easter,[3] Danica Grujic,[4] Zhiqun Zhang,[4] Annamaria T. Kausz.[4] *[1]Massachusetts General Hospital, Cambridge, MA; [2]IU Health Physicians Urology, Indianapolis, IN; [3]Wake Forest School of Medicine, Kernersville, NC; [4]Allena Pharmaceuticals, Inc, Newton, MA.*

Background: Hyperoxaluria (HOx) is a serious metabolic disorder and a key risk factor for progression of kidney stone (KS) disease and other renal complications. Patients with malabsorptive gastrointestinal (GI) conditions (e.g., bariatric surgery, Crohn's disease) can develop what is called enteric HOx (EH) due to over-absorption of oxalate (Ox). Standard

of care interventions are non-specific, and many have persistently high urine Ox (UOx) levels. The existing KS burden in patients with EH has not been described.

Methods: Baseline data on33 patients with EH enrolled in 3 Phase II studies of ALLN-177 (an oral, non-absorbed, Ox-specific enzyme therapy) were analyzed. Medications, 24-hr urine parameters, KS history, and dietary Ox were assessed in all 3 studies; computed tomograms (CT) were obtained in 2 studies to define silent KS burden (active renal colic was exclusionary).

Results: Mean age was 64 (range 41-82) and 57.6% were female. The enteric condition was bariatric surgery in 24 (73%), Crohn's in 5 (15%), pancreatic insufficiency in 2 (6%) and 'other' disease in 2 (6%). Mean (SD) dietary Ox was 185±138 mg/d, urine volume 1.9± 0.8 L/d and UOx 102±55 mg/d. Twenty-one (64%) subjects overall were on calcium and/or citrate supplements, thiazides, allopurinol and/or pyridoxine. Among the 28 participants who provided KS medical history, 93% had at least one KS episode in past 5 years. Among the 20 participants who had a CT scan, 16 (80%) had at least one KS and 8 (40%) had KS in both kidneys; on average participants had 3 KS. Notably, 4 (20%) had KS >10 mm and 8 (40%) had KS 5-10 mm in size.

Conclusions: Despite standard interventions, patients with EH had persistently high UOx. In addition, a substantial KS burden was found on CT; many patients had multiple KS, including some with larger KS that could require urological intervention. Both HOx and KS burden are risk factors for progressive loss of kidney function. Our analysis highlights a significant unmet need in the EH population, and the current ALLN-177 development program is focused on addressing this.

Analysis of Gut Microbiome Alterations in Hyperoxaluric Patients

Lama Nazzal,[1] Menghan Liu,[1] Barbara M. Seide,[3] Mary Mcintosh,[5] Ignacio Granja,[4] John R. Asplin,[4] Melody Ho,[1] Dawn S. Milliner,[3] David S. Goldfarb,[1,2] Martin J. Blaser.[1] The Rare Kidney Stone Consortium *[1]New York University School of Medicine, New York, NY; [2]New York Harbor VAMC, Hastings on Hudson, NY; [3]Mayo Clinic, Rochester, MN; [4]Litholink Corp, Chicago, IL; [5]University of Arizona College of Medicine, Tucson, AZ.*

Background: About 60–80% of kidney stones are composed of calcium oxalate (CaOx); idiopathic CaOx kidney stones (CaOPx), primary hyperoxaluria (PH) and enteric hyperoxaluria (EH) are diseases predisposing to stones. *Oxalobacter formigenes (Oxf)* is a human gut commensal that depends on oxalate for its carbon and energy, and may be protective against CaOx stones. We hypothesize that the microbiome community structure differs between patients with CaOx, PH, EH and normal subjects (NS). We also expect that *Oxf* isolates from PH patients will result in further reduction in urinary oxalate when compared to *Oxf* reference strain CC13, in a germ-free (GF) mouse model.

Methods: We collected fecal specimens from 34 subjects (mean age: 39.1 ± 11.9 years) with PH (n=6), CaOPx (n=10), EH (n= 5) and NS (n=13) in a cross-sectional observational study, and tested fecal samples from the groups by: 1)16S rRNA sequencing to determine the microbiome community structure, 2)PCR and qPCR for *Oxf* colonization and, 3) culturing in high oxalate selective media for indication of *Oxf* presence and subsequent isolation. We isolated *Oxf* from 4 PH (*Oxf* PH) subjects. We gavaged a growing culture of PH *Oxf* (n=6), *Oxf* reference strain CC13 (*Oxf* CC13) (n=5), and sham (n=6) into adult C5B6 GF mice, observing them for 4 weeks. We collected urine from mice for 48 hours before sacrifice to be tested for oxalate and creatinine (Uox/cr).

Results: *Oxf* was detected in 6 (46%) of 13 NS, 1 (10%) of 10 CaOPx, 0 (0%)of 4 EH, and 5 (83%) of 6 PH. Microbiome analysis revealed that the 4 groups differed in beta diversity, based on Bray-Curtis dissimilarity (p=0.08). Alpha diversity analysis trended toward lower Shannon and phylogenetic diversity index in the CaOPx and EH subjects compared to PH and NS. Introducing the PH *Oxf* to GF mice led to lower Uox/cr than in uninoculated controls (0.68 ± 0.14, and 2.26 ±0.49, respectively, p=0.04 by Mann-Whitney U test), but not significantly different from the *Oxf* CC13-innoculated mice (0.68 ± 0.14, and 0.91 ±0.24, respectively, p=0.26 by Mann-Whitney U test).

Conclusions: These studies provide evidence of differences in *Oxf* colonization rates and in microbiome composition in patients with CaOx stones and show the functional capacity of a PH *Oxf* strain to ameliorate hyperoxaluria. Studies to expand these patient groups are on-going.

SA-PO687

Pharmacokinetics and Pharmacodynamics of SNF472 in Calciphylaxis Patients: Results from a Phase 2 Clinical Trial (SNFCT2015_04)

Carolina Salcedo,[2] Miquel D. Ferrer,[2,1] Maria del mar Perez,[2] Ana-Zeralda Canals,[2] Joan Perelló.[2,1] *[1]University of the Balearic Islands, Palma, Spain; [2]Laboratoris Sanifit, Palma de Mallorca, Illes Balears, Spain*.

Background: SNF472 is a selective calcification inhibitor that interferes in the formation and growth of hydroxyapatite crystals. It is being developed for the treatment of calciphylaxis (CUA), a severe form of vascular calcification that affects the small vessels under the skin in patients with end-stage renal disease on hemodialysis (HD).

Methods: This was an open label, single arm trial investigating the effect of SNF472 on top of standard of care in the treatment of CUA in HD patients. Patients were treated for 12 weeks with intravenous 6-9 mg/kg of SNF472 three times per week during each dialysis session. The dose (400, 450, 700 or 900 mg) was adjusted by body weight categories. SNF472 levels were measured in plasma samples obtained pre-HD (baseline) and at the end of SNF472 infusion on the first and the last treatment sessions. Another aliquot of plasma was used to measure ex-vivo the propensity of plasma to induce calcium phosphate (CaP) crystallization as a pharmacodynamic (PD) measurement.

Results: The study enrolled 14 patients with 11 completing the treatment. The maximum SNF472 concentration in plasma was 29.1 ± 19.1 μM in week 1 and 26.3 ± 21.3 μM in week 12. There was no accumulation of SNF472 or any effect of repeated administration for up to 12 weeks in the exposure to the compound, confirming the results of a previous phase 1b trial in HD patients. The ex-vivo induction of CaP crystallization was inhibited up to 65 ± 14% after treatment with SNF472 (week 1) and up to 60 ± 29% at week 12. No differences attributable to the doses tested were observed concerning the PD effect, as all doses were on the plateau of the effect. These results were in accordance with the previous data seen in the Phase 1b trial. No inhibition of crystallization was evidenced in one patient that did not present detectable SNF472 levels (<0.76 μM) after treatment at week 12, showing a relationship between SNF472 circulating levels and PD.

Conclusions: These results suggest that the administration of SNF472 to CUA patients on HD allows to attain potentially therapeutic levels, as evidenced by both its circulating levels and the inhibition of ex-vivo calcification induction.

The Novel Bone Alkaline Phosphatase Isoform B1x in Serum Identifies Patients with Calciphylaxis on Vitamin K Antagonist Treatment

Mathias Haarhaus,[1,2] Vincent Brandenburg,[3] Markus Ketteler,[4] Rafael Kramann,[5] Per Magnusson.[2] *[1]Dep. of Renal Medicine, CLINTEC, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden; [2]Department of Clinical Chemistry, Linköping University, Linköping, Sweden; [3]Department of Cardiology, Nephrology and Intensive Care Medicine, Rhein-Maas Klinikum, Würselen, Germany; [4]Klinikum Coburg GmbH, Coburg, Germany; [5]RWTH Aachen University, Aachen, Germany*.

Background: The novel bone alkaline phosphatase (BALP) isoform B1x is only detectable in serum from patients with advanced chronic kidney disease (CKD) or end-stage renal disease. B1x has been proposed as a marker for low bone turnover, furthermore, B1x activity increases in calcifying vascular smooth muscle cells. Vitamin K antagonists (VKA) prevent activation of the potent vascular calcification inhibitor matrix Gla protein. VKA is associated with an increased risk for calciphylaxis (calcific uremic arteriolopathy, CUA), a rare and often fatal complication associated with severe calcification of arterioles. The objective was to study the appearance of B1x in serum from CKD patients with CUA.

Methods: Seventeen CKD patients with CUA (15 on hemodialysis, 1 transplanted, 1 pre-dialysis) were recruited from the European Calciphylaxis Network. Serum total ALP was determined by a kinetic assay and the BALP isoforms (B/I, B1, B1x and B2) by high-performance liquid chromatography. Fetuin A, intact parathyroid hormone (iPTH), total BALP (ELISA), C-reactive protein, sclerostin, C-terminal fibroblast growth factor 23, tartrate-resistant acid phosphatase type 5b (TRAP5b), osteoprotegerin, 25-OH vitamin D, total calcium (Ca) and phosphate were also assessed.

Results: B1x was detected in 10 patients (56%). These patients were more often treated with VKA (7 VKA patients B1x positive, vs 1 VKA patient B1x negative), had a more frequent history of myocardial infarction, lower total ALP (P=0.025), lower BALP (P=0.025), lower BALP isoform B1 (P<0.001) and lower total Ca (P=0.014) in serum. There was a tendency towards lower iPTH and lower TRAP5b (P=0.055 for both).

Conclusions: Patients with B1x were more often treated with VKA. Circulating bone markers indicate an association of B1x with low bone turnover. We hypothesize that VKA induce a specific subtype of vascular calcification, which is different from non-VKA-users. Based on the BALP isoform analysis, subgroups of CUA could be identified, which might also reveal differences in terms of bone metabolism.

Improvements in Calcific Uremic Arteriolopathy Wound Healing During SNF472 Treatment Assessed with the BWAT-CUA

Smeeta Sinha,[1] Lisa Gould,[2,3] Vincent Brandenburg,[4] Glenn M. Chertow,[5] Stephan Miller,[6] Rekha Garg,[6] Alex Gold,[6] Joan Perelló.[7] *[1]Salford Royal NHS Foundation Trust, Salford, United Kingdom; [2]South Shore Hospital Center for Wound Healing, Weymouth, MA; [3]Department of Medicine, Brown University, Providence, RI; [4]University Hospital, Aachen, Germany; [5]Nephrology Division, Stanford University School of Medicine, Palo Alto, CA; [6]Sanifit, San Diego, CA; [7]Laboratoris Sanifit, Palma de Mallorca, Spain*.

Background: Calcific uremic arteriolopathy (CUA/calciphylaxis) in patients with end-stage renal disease is a severe form of vascular calcification characterized by painful necrotic skin ulcers and very high mortality. No approved therapies are available. The investigational drug SNF472 is an intravenous formulation of myo-inositol hexaphosphate that inhibits formation and growth of hydroxyapatite crystals, the final common step in the pathophysiology of vascular calcification. A recent open-label, single-arm, 12-week Phase 2 trial of SNF472 in patients with CUA receiving hemodialysis demonstrated statistically and clinically significant improvements from baseline to end-of-study in wound healing, pain, and wound-related quality of life (NCT02790073).

Methods: 14 patients with CUA were treated with SNF472 thrice weekly during each hemodialysis session for up to 12 weeks. We assessed effect on wound healing with the Bates-Jensen Wound Assessment Tool (BWAT), a 13-item, objective, quantitative tool originally developed and validated for the assessment of pressure ulcers. Based on the expert opinion of specialists in plastic surgery, wound care, and nephrology (all experienced in the care of patients with CUA) we derived a targeted modification of the BWAT using 8

items focused on prototypical features of CUA lesions: necrotic tissue type, necrotic tissue amount, exudate type, exudate amount, skin color surrounding wound, peripheral tissue edema, peripheral tissue induration, and granulation tissue.

Results: Mean (SE) BWAT-CUA improved from 21.2 ± 2.0 at baseline to 14.9 ± 1.4 at Week 12 ($p<0.002$). Among the individual BWAT items, the largest improvements were observed for peripheral tissue induration, skin color surrounding wound, and granulation tissue.

Conclusions: BWAT-CUA is an objective and quantitative tool targeted for evaluation of CUA lesions and will be used in the upcoming Phase 3 randomized controlled trial of SNF472 for CUA.

SA-PO690

National Trends in Hospitalization in the US Calciphylaxis Population from 2007 to 2014

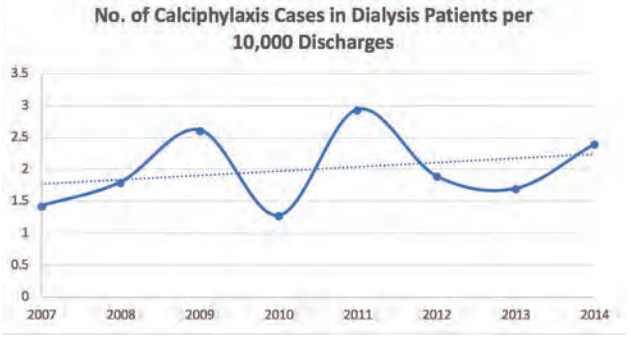
Pablo Garcia,[2,1] Paris Charilaou,[1] Xavier F. Parada,[3] Mario R. Funes-Hernandez,[4] Sagar U. Nigwekar.[3] *[1]Saint Peter's University Hospital, New Brunswick, NJ; [2]Nephrology, Stanford University, Palo Alto, CA; [3]Massachusetts General Hospital, Boston, MA; [4]Saint Peter's University Hospital, Somerset, NJ.*

Background: Calciphylaxis is a rare syndrome of vascular calcification characterized by occlusion of microvessels in the subcutaneous adipose tissue and dermis, resulting in painful, ischemic skin lesions. The definitive diagnosis is made by confirming the presence of calcified dermal arterioles on a skin biopsy in a patient with clinical suspicion for calciphylaxis. In this study we describe the trends and patient distribution and characteristics of calciphylaxis in the US inpatient population from 2007-2014.

Methods: We included all adult discharges from the National Inpatient Sample (NIS) from 2007-2014, from large (>=325 beds) teaching hospitals, excluding cases with missing data on age, gender, or inpatient mortality. We used a previously published algorithm to identify patients with calciphylaxis from the NIS. This algorithm applies the ICD-9-CM diagnosis code 275.49 "Other Disorders of Calcium Metabolism" in combination with the ICD-9 code 86.1.

Results: We identified 1576 probable calciphylaxis discharges from 2007 to 2014, with 69% patients on dialysis of which 90% where patients on HD, 54.8% were white and 70.5% were females. Mean age was 59 years (95% CI: 57 to 61 years). 35% belonged in the lowest income quartile and 17% belonged to the upper quartile in the US. Most patients were located in the Southern (39.8%) and Midwest (29%) Region of the US. 49% of the patients had DM, 19% were obese, 78% had HTN and 26% had A-Fib. Overall inpatient mortality was 7.9%. The median length of stay was 11 days (range 0-98) and mean hospitalization cost was $31467 ±$2127. We found that 63% patients were discharged to rehab, skilled nursing facility or home with nurse care and 37% went home.

Conclusions: Calciphylaxis was more prevalent in females. One third of the patients belonged to the lowest income quartile. Most of the patients with calciphylaxis were located in the Southern and Midwest Region. Most of the patients were discharged to rehab, skilled nursing facility or home with nurse.



SA-PO691

Modeling Decision Making for IV Vitamin D Titration in Patients on Hemodialysis (HD)

Rasheeda K. Hall,[1] Jonathan A. Wilson,[1] Alyssa C. Platt,[1] Patti Ephraim,[3] Daniel E. Weiner,[2] L. Ebony Boulware,[1] Jane F. Pendergast,[1] Julia J. Scialla.[1] *[1]Duke University, Durham, NC; [2]Tufts Medical Center, Boston, MA; [3]Johns Hopkins University, Baltimore, MD.*

Background: Studies in HD often focus exclusively on parathyroid hormone (PTH) as the driver of intravenous (IV) vitamin D titration. We hypothesized that a constellation of mineral metabolism (MM) laboratories (labs), including calcium (Ca), phosphorus (Pi) and PTH, influence titration.

Methods: We retrospectively studied 62,284 decisions in 5442 patients initiating in-center HD between 2006-2008 in Dialysis Clinic, Inc. facilities with non-missing data. We used multinomial transition mixed models to predict increase, decrease or no change in IV vitamin D based on monthly albumin-corrected Ca, Pi, and PTH using piecewise linear functions with knots at 8.0 and 10.2 mg/dl for Ca, 3.5 and 5.5 mg/dl for Pi, and 150 and 300 pg/ml for PTH, 3 sets of lagged monthly lab values, and interactions between current labs to capture a fully integrated lab phenotype. Adding piecewise functions and lab interactions improved fit as reflected in AIC (66,282 vs. 80,084).

Results: Participants contributed a mean ± SD of 9.3 ± 8.5 treatment months. The PTH threshold at which IV vitamin D is more likely to be increased than decreased is the intersection of solid (probability of increase) and dashed (probability of decrease) lines (Figure). This threshold PTH is higher when Ca and Pi were higher, demonstrating that Ca and Pi influence providers' effective PTH titration goal. Titration or addition of alternative therapies, such as cinacalcet, are not depicted here, but are also impacted by integrated lab phenotypes (data not shown).

Conclusions: Prescribers consider multiple lab dimensions when titrating IV vitamin D. Comparative effectiveness studies and trials in MM may be improved by appropriately capturing complex lab phenotypes that contribute to decision-making.

Funding: NIDDK Support

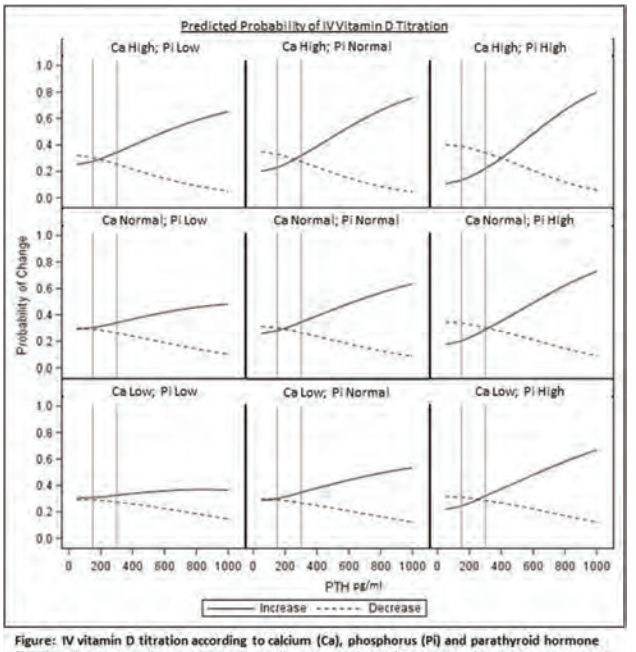


Figure: IV vitamin D titration according to calcium (Ca), phosphorus (Pi) and parathyroid hormone (PTH) levels. Presented probabilities depict decisions at 12 months post HD initiation among users of IV vitamin D sterols alone when Ca is 8.0 (low), 9.0 (normal) or 10.7 mg/dl (high), Pi is 3.0 (low), 4.5 (normal) or 6.5 mg/dl (high), PTH is 100-1000 pg/ml and lagged lab values are the same as current labs. Increase is depicted by solid lines, decrease by dashed lines. No change is not depicted.

SA-PO692

Free 25(OH) Vitamin D and Mortality Among Hemodialysis Patients

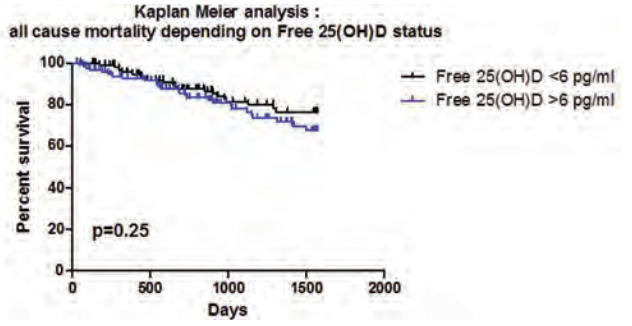
Etienne Novel-Catin,[1] Laetitia Koppe,[1,4] Anaïs Bouchara,[1] Marie-christine Carlier,[1] Myriam Pastural,[3] Granjon Samuel,[2] Jean-christophe Szelag,[3] Maurice Laville,[1] Denis Fouque,[1,4] Solenne Pelletier.[1] *[1]University Center Hospital - Lyon Sud, Saint Priest, France; [2]Cerballiance laboratory, Lyon, France; [3]AURAL, LYON, France; [4]CarMeN laboratory INSERM U1060, F-69621 Villeurbane, France.*

Background: Most of the circulating 25-(OH) vitamin D (abbreviated 25(OH)D) is bound to proteins. Free vitamin D represents only 1% of the circulating vitamin D. There is abundant evidence that this free faction is the bioactive form of vitamin D. Total 25(OH) D deficiency has been associated with early mortality and cardiovascular events (CV) in chronic kidney disease (CKD) patients. The aim of the present study was to investigate a potential association between serum free 25(OH)D levels and i) other biochemical parameters of mineral metabolism, (ii) CV events and (iii) mortality.

Methods: 253 patients undergoing maintenance hemodialysis (HD) were included. Serum free 25(OH)D measurement by ELISA (Diasource® Leuven, Belgium) as well as routine biochemistry tests were performed. Enrolled patients were prospectively monitored for cardiovascular (CV) events and mortality.

Results: During a mean study period of 2.5 years, 48 patients died and 60 suffered from a CV event. Median serum free 25(OH)D was 6.01 pg/ml [4.67 – 7.39] and median total 25(OH)D was 32.2µg/l [24.8-39.9]. Free 25(OH)D was strongly associated with total 25(OH)D ($r= 0.77$, $p < 0.01$). Free 25(OH)D was positively associated with serum calcium levels ($r= 0.29$, $p<0.01$) and negatively with serum PTH ($r= - 0.19$, $p<0.01$). Kaplan-Meier analysis showed no significant association between below median free 25(OH) and all-cause mortality (log rank, $p=0.25$, see figure 1) nor CV events (log rank, $p=0.91$).

Conclusions: This is the first study reporting survival depending on free 25(OH)D status in maintenance dialysis patients. It shows that free 25(OH)D levels are not associated with mortality nor cardiovascular events among maintenance HD patients. Our data concur with precedent results showing that bioavailable vitamin D is positively associated with calcium levels and negatively associated with serum PTH.



SA-PO693

Relationship Between Bioelectrical Impedance Body Composition and CKD-MBD in Dialysis Patients

Eduardo J. de Sa Carneiro Filho,[2] Shirley F. Crispilho,[1] Lilian Cordeiro,[2] Maria Dalboni,[1] Rosilene M. Elias,[2,1] Rosa M. Moyses.[2,1] *[1]Universidade Nove de Julho, São Paulo, Brazil; [2]Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: Recent studies have assessed body composition through multifrequency bioelectrical impedance analysis (MF-BIA). However, none has employed this technique to test the associations of CKD-MBD with body composition. As recent experimental studies have linked hyperparathyroidism with an increase in energy expenditure, it is important to validate this hypothesis in a clinical scenario.

Methods: In a transversal study, we evaluated 160 prevalent dialysis patients (hemodialysis, HD = 99; peritoneal dialysis, PD = 61) through whole-body and segmental composition and correlated MF-BIA with CKD-MBD parameters.

Results: Patients were 49 years old (range 18-90), with BMI = 24.6 kg/m^2 (13.3-49.3), fat mass (FAT) = 17.8 kg (1.1-61.5), muscular mass (MUSC) = 25.6 kg (10.1-45.4), bone mineral content (BMC) = 2.78 kg (2.43-3.30). In PD patients, serum 25 vitamin D correlated with MUSC (r= 0.41 p = 0.002) and BMC (r = 0.42 p =0.002). Alkaline phosphatase correlated negatively with FAT (r = - 0.30. p 0.02). No significant correlations were found for parathormone, calcium, phosphate or albumin. In HD patients, we did not find any significant correlation between MF-BIA and CKD-MBD parameters.

Conclusions: Assuming the accuracy of MF-BIA, in PD patients, higher serum vitamin D levels were associated with lower risk of sarcopenia and low bone mineral density, whereas higher alkaline phosphatase was linked with lower fat mass. Future prospective studies should evaluate whether cholecalciferol supplementation and hyperparathyroidism control could improve muscle, bone and fat masses in these patients.

Funding: Government Support - Non-U.S.

SA-PO694

Efficacy of High versus Conventional Dose of Ergocalciferol Supplementation on Serum 25-Hydroxyvitamin D and Interleukin-6 Levels in Hemodialysis Patients with Vitamin D Deficiency

Wittaya Siricheepchaiyan, Pamila Tasanavipas, Theerasak Tangwonglert, Naowanit Nata, Amnart Chaiprasert, Ouppatham Supasyndh, Bancha Satirapoj. *Phramongkutklao Hospital, Bangkok, Thailand.*

Background: Vitamin D deficiency alters innate and adaptive immune function, which will increase inflammatory cytokines production. Long-term dialysis is chronic inflammatory state and it has high prevalence of vitamin D deficiency. Trials examining the efficacy, and dosage of ergocalciferol supplementation in end stage renal disease (ESRD) on hemodialysis have been limited.

Methods: A multicenter, randomized, controlled trial was conducted in ESRD on hemodialysis with serum 25-hydroxyvitamin D (25[OH]D) level < 30 ng/mL. The conventional-group (N=35) and the high-dose group (N=35) were treated with ergocalciferol according to the K/DOQI guidelines and double dosage of ergocalciferol from the recommendation for 8 weeks, respectively. The main outcomes were measured by serum 25[OH]D, IL-6, calcium, and phosphorus levels.

Results: At the end of 8-week, there was a statistically significantly greater increase of mean serum 25[OH]D levels in the high-dose group compared with the conventional-dose group (17.8 ng/mL [95%CI 15.8 to 19.7] vs. 9.2 ng/mL [95%CI 7.4 to 11.1], P<0.001) and the high-dose group had also higher achievement of vitamin D sufficiency (25[OH]D level >30 ng/mL) than the conventional-dose group (97.4% vs. 76.4%, P=0.012). A trend toward lower serum IL-6 levels in the high-dose group (-0.45 pg/mL [95%CI -3.57 to 2.68], P=0.772) and there was a statistically significance lower serum IL-6 levels in the subgroup who had baseline serum 25[OH]D levels < 20 ng/mL (-2.67 pg/mL [IQR -6.56 to -0.17], P=0.039). There were no differences between the two groups in changes in serum calcium, phosphorus levels, and adverse events.

Conclusions: Oral high-dose ergocalciferol supplementation has achieved higher vitamin D sufficiency than standard recommendation dose in ESRD patients on dialysis with vitamin D deficiency. It might also be benefit on reduction of the inflammatory cytokine in group of patients with baseline serum 25[OH]D levels < 20 ng/mL.

SA-PO695

Evaluation of Long Term Supplementation with Cholecalciferol on the Levels of 25-Hydroxyvitamin D (25[OH]D) and on Bone Turnover Biomarkers of Chronic Hemodialysis Patients

Andreas Bozikas,[1] Iliana Kiriakoutzik,[1] Eleni Kitoukidi,[1] Pinelopi Pisanidou,[1] Styliani Vakiani,[1] Antigoni Martika,[1] Nikolaos Georgilas,[1] Panagiotis Pangidis,[1] Konstantinos Tsitouridis,[3] Asimoula Koteli,[2] Sofia Spaia.[1] *[1]Nephrology, General Hospital of Thessaloniki "Agios Pavlos", Thessaloniki, Greece; [2]Microbiology, General Hospital of Thessaloniki "Agios Pavlos", Thessaloniki, Greece; [3]Radiology, General Hospital of Thessaloniki "Agios Pavlos", Thessaloniki, Greece.*

Background: We addressed the safety of long term supplementation with cholecalciferol in maintenance hemodialysis patients along with its effect on markers of bone and mineral metabolism.

Methods: Sixty stable hemodialysis patients, initially, received a dose of 1200 IU of cholecalciferol orally, once daily, every 48 hours, for 18 months. This dose was, subsequently, increased to 1200 IU, once daily for another 6 months. 25[OH]D levels were measured at 0, 4, 12, 18, and 24 months along with Ca, P, ALP, iPTH, HbA1c levels and BMI. Additionally, all patients had a T – score evaluation by dual – energy x – ray absorptiometry (DXA) at the beginning of the study and after 12 and 24 months.

Results: All patients proved to be 25[OH]D deficient, regardless that measurements were done during the summer period (increasd sunlight). There was no correlation of the low 25[OH]D levels with age, sex, time on hemodialysis and HbA1c levels, but they did correlate to BMI, implicating diet as a source of 25[OH]D. Likewise, we observed no correlation with the administration of phosphate binders, statins or vitamin D receptor activators. Alternate day supplementation improved 25[OH]D levels, which evolved from the deficient level to stage of insufficiency (p<0.01). Daily administration – after 18 months – was achieved by 46 patients (76%). Annual screening of bone density revealed gradual amelioration of T – score (p<0.01). No significant changes of the other markers were observed.

Conclusions: In conclusion, the very low levels of calcidiol in dialysis patients should draw considerable attention. A "safe" threshold of 20 ng/ml was achieved by choosing the alternate day supplementation of 1200 IU of cholecalciferol, with no particular financial burden and succeeding compliance. The positive effect on bone density which was shown in this long term study regards more extended research. Although supplementation with calcidiol is not considered to be an essential treatment, yet, we consider that there are sufficient data to support long term supplementation of 25[OH]D for maintenance dialysis patients.

SA-PO696

Paricalcitol and Renal Anemia: A Novel Association Beyond Inflammation

Miguel Uriol Rivera,[1] Angel Garcia-Alvarez,[2] Manuel Luque-Ramírez.[3] *[1]Hospital Universitario Son Espases, Palma de Mallorca, Spain; [2]Hospital Comarcal de Inca, Inca, Spain; [3]Hospital Universitario Ramón y Cajal, Madrid, Spain.*

Background: The utilization of the paricalcitol (a selective vitamin d receptor activator) for the control of the secondary hyperthyroidisms (SHPT) and its antinflammatory properties have been associated with a better response to the erythropoietic stimulating agents(ESA). Whether the effect of the paricalcitol is directly associated with the erythropoiteic process and its influence on endogenous erythropoietin production is unknow. **Objective:** To evaluate the influence of the paricalcitol on the novel parameters associated with the erythropoiesis in anemic hemodialysis patients.

Methods: These are the results of the secondary objective of the MIR-EPO trial (EudraCT: 2009-015511-40). Study subjects were allocated to those treated with paricalcitol (group A: N=23) and those without it (group B, N=8). Plasma factors associated with inflammatory anemia (interleuquin-6 and hepcidin) and accelerated red blood cells death (eryptosis: soluble alpha-Klotho levels) were evaluated. Plasma erythropoietin and its main transcriptional factor: hypoxia inducible factor 2-alpha (HIF-2a)) were also evaluated during the evaluation period (from month 3 to 6).

Results: Five patients (22%) under paricalcitol stopped ESA by protocol (*P*=0.06). Lower IL-6 and higher s-klotho levels were observed in those under paricalcitol. Erythropoietin levels (median) increased significantly from 10 to 20 mUI/ml in patients under paricalcitol. The percentage of patients who increased HIF-2a at M6 with respect to M3 (35%) was also significantly only in the group A (*P*=0.01). After adjusting by IL-6 levels, HIF-2a increased in the group A (0.40 pg/ml,$_{log}$ *P*=0.030), but did not change in the group B (-0.31 pg/ml,$_{log}$ *P*=0.340). Free serum iron and transferrin saturation index changes correlate negatively with changes on IL-6 and positively with s-Klotho changes.

Conclusions: The use of the paricalcitol may improves the erythropoiesis process through direct effect on erythropoietin/HIF-2a axes stimulation. Our results suggest an important influence of the vitamin D selective activation on iron metabolism, erythropoietin synthesis and could be on eryptosis process. Larger controlled studies are needed to confirm these findings for potential benefit of the paricalcitol for renal anemia control.

Renal Complication and Mineral Ion Abnormalities in Patients with Jansen Metaphyseal Chondrodysplasia

Hiroshi Saito,[1,2] Harald Jüppner.[1,2] *[1]Massachusetts General Hospital, Boston, MA; [2]Pediatric Nephrology Unit, Harvard Medical School, Boston, MA.*

Background: Jansen metaphyseal chondrodysplasia (JMC) is a rare disease that is caused by heterozygous, activating mutations in the PTH/PTHrP receptor (PTHR1). Expression of PTHR1 mutants in growth plate chondrocyte impairs their maturation leading to marked skeletal abnormalities. Because the PTHR1 is also expressed in kidney and bone, JMC patients can develop PTH-independent hypercalcemia, hypophosphatemia, and high bone turnover, and thus nephrocalcinosis and impaired renal function. Long-term outcome of multiple JMC patients was recently reported (Saito et al., JCEM, 2018). We now emphasize the renal abnormalities associated with JMC.

Methods: Clinical and laboratory findings in 24 patients with JMC due to five different PTHR1 mutations (H223R, T410P, T410R, I458R, and I458K).

Results: During the first 2 weeks of life, calcium levels were normal in most patients. During childhood hypercalcemia was severe (11.8±1.4 mg/dL), but improved by adulthood (10.0±1.0 mg/dl). Phosphate and PTH levels were at the lower end of normal ranges. Urinary Ca/Cr (mg/mg) were consistently elevated (children, 0.8±0.4; adults, 0.3±0.2; normal:<0.2). Growth was severely impaired resulting in adult heights well below the 3rd percentile; furthermore, scoliosis and other skeletal deformities were noted. Most young JMC patients had nephrocalcinosis, but normal renal function. Two middle-aged patients revealed continuously worsening renal function, probably secondary to stag horn renal calculi, recurrent UTIs, and urinary tract obstructions.

Conclusions: Activating PTHR1 mutations are associated with persistently increased urinary calcium excretion, which is caused by the PTH-independent hypercalcemia. Hypercalciuria contributes early in life to nephrocalcinosis, which leads in adults to a decline in renal function. Treatment with bisphosphonates to reduce bone resorption may limit calcium excretion to slow the progression of chronic kidney disease. Although an inverse PTH agonist, namely [L11,dW12,W23,Y36]PTHrP(7–36), reduced basal cAMP signaling of the mutant PTHR1s in vitro, it remains to be determined whether such peptides have therapeutic potential.

SA-PO698

Risk Factors Associated with Hyperparathyroidism in Maintenance Hemodialysis Patients

Sinee Disthabanchong. *Division of Nephrology, Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand.*

Background: The severity and progression of hyperparathyroidism (HPT) are different among individuals with end-stage-renal disease. Factors other than decreased 1,25-OH-D level and phosphate retention likely participate in the severity and progression of HPT. The present study identified risk factors associated with the progression of HPT as well as factors associated with parathyroid hormone (PTH) levels above the KDIGO's recommended range in maintenance hemodialysis patients.

Methods: Five hundred and one patients were included. Exclusion criteria were previous parathyroidectomy or taking calcimimetic. Changes in PTH levels over 24 months were categorized into 4 patterns as follows, "progression" (increase in PTH levels >= 50%), "reduction" (decrease in PTH levels > 50%), "fluctuation" (changes in PTH levels >= 50% in BOTH directions) and "stable" (changes in PTH levels < 50% in either directions).

Results: 29% of PTH values were > 9 times, 22% were < 2 times and 49% were between 2-9 times of the upper normal limit (UNL). Progression of HPT occurs in 32%, reduction in 19%, fluctuation in 21% and stable in 28% of the patients. The progression group was more likely to have PTH levels > 300 pg/mL, whereas the fluctuation and reduction groups were more likely to have PTH levels <= 300 pg/mL. Factors associated with the progression of HPT were younger age, non-diabetics, suboptimal insurance program (limited access to non-calcium binders and newer drugs), higher PTH levels and higher serum phosphate. Factors associated with PTH levels > 9 times the UNL were younger age, not having DM, CVD and DLP, prolonged dialysis vintage, suboptimal insurance program, higher active vitamin D dose, higher serum phosphate, albumin and creatinine.

Conclusions: Young healthy patients (not having CVD risks including DM and DLP) with better overall health status (higher serum albumin, phosphate and creatinine) are likely to experience the progression of HPT overtime. Prolonged dialysis vintage and suboptimal insurance program also play substantial roles in the increase in PTH level above the KDIGO's recommended range.

Association of Secondary Hyperparathyroidism with Thymic Atrophy in Patients with CKD

Kenichiro Iio,[1] Rei Iio,[3] Takayuki Hamano,[2] Yoshitaka Isaka,[2] Yutaka Ando.[1] *[1]National Hospital Organization, Osaka Minami Medical Center, Kawachinagano, Japan; [2]Osaka University Graduate School of Medicine, Suita, Japan; [3]Osaka General Medical Center, Osaka, Japan.*

Background: Immune aging, including thymic atrophy, is accelerated in patients with chronic kidney disease (CKD) and can lead to cardiovascular and infectious diseases. However, the mechanism of thymic atrophy is not well understood. Mineral and bone disorders (MBD) affect mortality through bone-related factors and blood vessel calcification; parathyroid hormone (PTH) and fibroblast growth factor 23 (FGF23) also affect immune cells and possibly thymic atrophy.

Methods: We examined the cross-sectional association between thymic atrophy, evaluated as the number of $CD3^+CD4^+CD45RA^+CD31^+$ cells [recent thymic emigrants (RTE)/μL], and MBD-related factors (PTH, FGF23, and alkaline phosphatase) in patients with non-dialysis-dependent CKD.

Results: This study enrolled 125 patients with CKD (median eGFR, 17 mL/min/1.73 m^2). Age (r = –0.46) and male sex (r = –0.34) correlated negatively and eGFR (r = 0.27) correlated positively with RTE. In terms of MBD-related factors, corrected calcium (r = 0.27) correlated positively whereas PTH (r = –0.36) and alkaline phosphatase (r = –0.20) correlated negatively with RTE. In contrast, FGF23 and phosphorus were not correlated with RTE. Multivariate non-linear regression analysis adjusted for age, sex, eGFR, diabetes, corrected calcium, phosphorus, vitamin D supplementation, and use of phosphate binder indicated a negative association between PTH and log-transformed RTE (P = 0.030, P for non-linearity = 0.124). However, FGF23 and alkaline phosphatase were not associated with RTE.

Conclusions: Secondary hyperparathyroidism appears to be related to thymic atrophy, contributing to immune abnormalities in patients with CKD. Our findings may partially explain the mechanism through which PTH is associated with mortality.

SA-PO700

Serum 1,25-Dihydroxyvitamin D Concentrations in Maintenance Hemodialysis Patients: In the Era of CKD-MBD Guideline

Eiji Ishimura,[1,2] Shinya Nakatani,[3] Senji Okuno,[4] Shuko Ueda,[1] Nobuyuki Kuwamura,[1] Yukihiro Nin,[1] Tetsuya Makino,[1] Ryusuke Kakiya,[1] Masaaki Inaba.[3] *[1]Meijibashi Hospital, Matsubara, Osaka 580-0045, Japan; [2]Osaka City University Graduate school of Medicine, Abeno-ku, Japan; [3]Osaka City University Graduate School of Medicine, Osaka, Japan; [4]Shirasagi Hospital, Osaka, Japan.*

Background: In hemodialysis (HD) patients, serum levels of 1,25-dihydroxyvitamin D (1,25D), an active form of vitamin D, are low; however, 1,25D, even in low, was reported to play an important role in HD patients (Ando R et al, J Jap Soc Dial Ther 1996). Currently, little is known about serum 1,25D concentrations in HD patients, particularly in the era of CKD-MBD guideline. We measured serum 1,25D concentrations in stable HD patients, and examined their association with clinical factors.

Methods: A total of 89 HD patients (71±11 year-old, 48 males, HD duration 9.4±7.4 years, 36 with type 2 diabetes) were examined. Serum 1,25D was measured by a 1,25D RIA kit (Ishimura E et al. Kidney Int 1999), and intact PTH by a Elecsys PTH IRMA assay (Kurajoh M et al. Osteoporos Int 2008).

Results: Serum 1,25D concentrations were 14.4±8.0 pg/ml, being lower compared to those of healthy subjects. Serum 1,25D concentrations were significantly higher in males than in females (p=0.045). They were tended to be negatively correlated with age (r=-0.034, p=0.083) and HD duration (r=-0.042, p=0.055). Serum 1,25D concentrations were significantly, negatively associated with intact PTH (r=-0.085,p⟨0.001), although they were not with serum calcium or phosphate. There were no significant differences in serum 1,25D between patients with (n=65) and without vitamin D treatment, and between those with (n=12) and without calcimimetics. However, serum 1,25D concentrations in patients with intravenous treatment of maxiacalcitol, an active form of vitamin D, (n=12) were significantly higher than those without (p=0.045). In a multiple regression analysis after adjustment of age, gender, HD duration, and vitamin D treatment, serum 1,25D concentrations were significantly, independently associated with serum intact PTH (β=-0.310, p=0.003) (R^2=0.200, p=0.002).

Conclusions: These results indicate that serum 1,25D, even in low, is significantly associated with intact PHT. The results also suggest that, even in the era of CKD-MBD guidelines, a clinical importance of serum 1,25D concentrations may be re-considered for the assessment of CKD-MBD, particularly in regards to prevention of secondary hyperparathyroidism. Intravenous, rather than oral, vitamin D treatment may be useful for treatment of secondary hyperparathyroidism.

SA-PO701

Secondary Hyperparathyroidism: Are KDIGO Guidelines for PTH Testing Being Followed?

Nicholas S. Roetker,[1] James B. Wetmore,[2] Yi Peng,[1] Akhtar Ashfaq,[3] David T. Gilbertson.[1] *[1]Chronic Disease Research Group, Minneapolis, MN; [2]Hennepin County Medical Center, Minneapolis, MN; [3]OPKO Health, Miami, FL.*

Background: KDIGO recommends that patients with chronic kidney disease (CKD) undergo parathyroid hormone (PTH) testing beginning in CKD stage 3 followed by testing in stage 4 (every 6-12 months) and in stage 5 (every 3-6 months). KDIGO also suggests a role for 25-hydroxyvitamin D [25(OH)D] testing, although frequency is not specified. Adherence to these guidelines is unknown.

Methods: Using the 2007-2015 20% Medicare sample, we identified a cohort of patients with stage 3, 4, or 5 CKD. CKD stage was determined by presence of two or more claims with ICD-9-CM codes for CKD. Only patients with 30 or more days of follow-up were included. Frequency of 25(OH)D and PTH testing was identified using laboratory procedure codes. Factors associated with PTH testing by each CKD stage were then determined using separate logistic regression models.

Results: A total of 381,332 (stage 3), 86,875 (stage 4), and 14,401 (stage 5) CKD patients were identified. Over mean follow-up of 2.3 ± 1.8 (stage 3), 1.3 ± 1.3 (stage 4), and 0.7 ± 0.9 (stage 5) years, 54% of stage 3, 61% of stage 4, and 70% of stage 5 patients were not tested for 25(OH)D deficiency; corresponding percentages for PTH were 66%, 56%,

and 52%, respectively (**Table**). Factors inversely associated with PTH testing were older age and presence of most comorbid conditions.

Conclusions: Testing for 25(OH)D deficiency was relatively infrequent. PTH testing was undertaken less than half as often as is recommend by KDIGO guidelines. This is potentially concerning, especially since recent data indicate it can be challenging to achieve PTH targets even with routine testing. How the uncertainty over optimal PTH targets in CKD, as discussed in the current KDIGO guidelines, will affect future testing patterns, should be studied.

Diagnosis of Renal Osteodystrophy by Bone Histomorphometry in Chronic Hemodialysis (HD) Patients

Suthanit Laowalert,[1] Tanatorn Khotavivattana,[1] Lalita Wattanachanya,[2] Pobe Luangjarmekorn,[3] Suwasin Udomkarnjananun,[4] Pisut Katavetin,[5] Paweena Susantitaphong,[4] Somchai Eiam-Ong,[4] Kearkiat Praditpornsilpa.[4] *[1]Division of Nephrology, Bangkok, Thailand; [2]endocrinology, King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [3]orthopedics, Chulalongkorn university, Bangkok, Thailand; [4]Chulalongkorn University, Bangkok, Thailand; [5]King Chulalongkorn Memorial Hospital, Thai Red Cross Society and Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand*.

Background: Management of secondary hyperparathyroidism has been evolving and requires more investigations. Currently, the relatively "wide" recommended target for intact parathyroid hormone (iPTH) level has proved to be reasonable only in limited circumstances. This study was conducted to determine the prevalence of various types of renal osteodystrophy in Thailand and to investigate the correlation between bone markers and bone histomorphometry to suggest an optimal iPTH level.

Methods: 22 chronic HD patients participated in this cross-sectional study. iPTH, serum calcium, phosphate and 25-hydroxyvitamin D and bone turnover markers including tartrate-resistant acid phosphatase-5b (TRAP-5b) and bone specific alkaline phosphatase (B-ALP) were measured. Double tetracycline-labeled iliac crest bone specimens were evaluated for static and dynamic parameters by using specialized program (Osteomeasure®). The types of bone histomorphometry were classified based on turnover (T), mineralization (M), and volume (V) classification.

Results: Mean age and iPTH were 48±10 years and 523±238 pg/mL, respectively. Median dialysis vintage was 64 months. Adynamic bone disease was the most common bone abnormalities (50%), followed by osteitis fibrosa (40.9%) and mixed uremic osteodystrophy (9.1%). No evidences of osteomalacia and aluminum bone disease were detected. iPTH at the cutoff of 484.5 pg/mL predicted high bone turnover with an area under the receiver operating characteristic curve (AUROC) of 0.86 (95 % CI 0.70-1.0) with the sensitivity and specificity of 0.82 and 0.82 respectively.

Conclusions: Adynamic bone disease remains the most common bone disease among chronic HD patients in Thai population, albeit iPTH levels were close to the upper limit target of KDIGO guideline. Our study suggested that bone biopsy is required as an accurate diagnostic tool and providing guide for the treatment of chronic HD patients with renal osteodystrophy.

Funding: Government Support - Non-U.S.

Bone Biomarker	AUROC	95%CI	P-value	Best cutoff	Sensitivity	Specificity
iPTH	0.86	0.704-1.0	0.004	484.5	0.818	0.818

SA-PO703

Parathyroidectomy (PTX) and Anemia in a Cohort of Italian Dialysis Patients

Sandro Mazzaferro.[1,2] *[1]Dept. Cardiovascular, Respiratory, Nephrology, Anesthetic and Geriatric Sciences, Sapienza University of Rome, Roma, Italy; [2]On behalf of the Italian Study Group of Mineral Metabolism, IT, Italy*.

Background: Secondary hyperparathyroidism (SHP) negatively affects endogenous erythropoietin (EPO) synthesis, bone marrow erythroid progenitors, and red cell survival, thus contributing to anemia. PTX is generally thought to be followed by improved anemia control. However, low turnover bone disease (LTBD), a common finding after PTX, could negatively affect anemia. We compared anemic status and EPO therapy in two prevalent populations of dialysis patientswho received or not PTX

Methods: We enrolled both hemo- and peritoneal dialysis patients, aged ≥18 y, from 149 Italian dialysis units. The control group (C) was selected to be comparable to the prevalent population of PTX patients for age, sex and dialysis duration. Local EC approved the protocol (N° 888/09).

Results: We obtained data of 527 PTX patients (age: 57.90±12.52 yo; M/F = 44/56%; D time: 14.5±8.4 y) and 432 C patients (age 58.9±16.5 y.o.; M/F = 45/55 %; D time 11.7±2.6 y). PTH levels were lower in PTX (181.9±292.5 vs 333.7±293.7 pg/ml; p<.01), with 17 % and 35% respectively at KDOQI target (p<.001). In particular, cases with values <150pg/ml were 60% and 20% in the PTX and C groups respectively (p<.001). PTX patients were similarly less at target for Ca (50.9 vs 57.6, p<.001) and P (55.3 vs 58.8%; p<.05). Hemoglobin levels (PTX=11.3±1.1vs C=11.3±1.1 mg/dl), hsCRP (PTX 2.82±4.93 vs C=2.59±5.39 mg/dl) and ESR (PTX=32.29±23.98 vs C=36.46±24.49 mm/hr) were similar in the two groups. Ferritin values were higher in the C group (443.1±363.39 vs 339.84±336.9mg/dl; p<.0001). Patients receiving ESA (either epoietin or darbepoietin) were significantly higher in the PTX group (80.9% vs 70%, X^2=15.2; p<.001) while average doses of EPO (expressed as mean darbepoietin considering 1 mcg darbepoietin = 200 IU epoietin), were not different (PTX 0.34±0.25 vs C 0.33±0.25mcg/Kg/weekly).

Conclusions: Our data suggest that, in the long term, PTX does not associate with improved anemia. This is possibly due, in our population, to worse biochemical control of SHP, most frequently showing low PTH (indicative of LTBD). In conclusion, it seems thatit is more important the biochemical control of SHP than neck surgery to improve anemia in dialysis.

SA-PO704

Clinical Outcomes and Costs of Parathyroidectomy in CKD Patients

Andrew J. Mallett,[1,2] Scott Jones,[1] Katharine Hegerty,[1] Carla E. Scuderi,[1] Jesseca Eglington,[1] Huan Zhang,[1] Toni Broadbent,[1] Ben Green.[1] *[1]Kidney Health Service, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [2]Faculty of Medicine, The University of Queensland, Brisbane, QLD, Australia*.

Background: Cinacalcet (CT) for treatment of secondary hyperparathyroidism (SHPT) in chronic kidney disease (CKD) was withdrawn in August 2016 from the Australian Pharmaceutical Benefits Scheme. We aimed to audit parathyroidectomy (PT) for SHPT in CKD, and, to compare PT costs to those of CT therapyin one tertiary Australian centre.

Methods: A retrospective audit of CKD patients with SHPT at a tertiary Australian centre who underwent PT between 1/1/11 and 31/6/17 (n=44) (HREC/17/QRBW/231). Median wait time to renal transplant in Australia is 2.4yrs (range 1.3-4.1yrs) thus centre-specific total cost of 2.4yrs of CT therapy 60mg/day was calculated and compared to the total cost of PT based on hospital records, length of stay (LOS) and peri-operative complications (Cx).

Results: 34 and 11 PT were performed respectively in the 67months pre & 11months post August 2016. Median age and body mass index of patients undergoing PT were 51.5yrs (range 24-79yrs) and 29 (range 22-55). 30/34 patients were on dialysis. 5/34 patients were treated according to centre-specific pre-operative protocol. 18/34 patients were treated as per protocol post-operatively. 23/34 patients experienced post-operative Cx/s; ≥2 Cx in 52%. The median LOS post-PT was 6.5days (range 2-35days) with 32% of patients admitted to the intensive care unit. There was a 23.5% re-admission rate within 28 days of PT. All-cause mortality was 5% at 12months post-PT. A median of 5 outpatient reviews (range 0-37) were required before patients had two consecutive post-operative serum calcium results in normal range whilst on oral therapy. The median follow-up of patients post-PT was 25.5 months. The mean cost of CT ($13,149/patient) was less than the mean total cost of PT ($23,062/patient; range $11,375-53,279/patient). The median postoperative LOS was 7.51days (range 3.47-35.74days).

Conclusions: PT for SHPT in CKD patients is associated with a significant Cx, protocol non-adherence, re-admission rate and cost. There has been an overall increased annual rate of PT for SHPT in CKD patients. Further, we identified CT to be more cost-

effective than PT as a treatment approach in CKD patients with SHPT. Optimised patient selection, protocol review and clinician engagement is indicated to guide best treatment for patients.

SA-PO705

An Examination of Multiple Explanations for Secondary Hyperparathyroidism

Kenneth R. Phelps,[1,2] Darius Mason.[3] *[1]Research, Stratton VAMC, Albany, NY; [2]Medicine, Albany Medical College, Albany, NY; [3]Pharmacy, Methodist South Hospital, Memphis, TN.*

Background: We have advanced the tradeoff-in-the-nephron hypothesis to explain the evolution of secondary hyperparathyroidism (SHPT) in CKD (*Nutrients* 2017;9:pii:E427). The hypothesis states that a high phosphate (P) concentration in the cortical distal nephron ($[P]_{CDN}$) limits availability of calcium (Ca) for reabsorption and necessitates high [PTH] for maintenance of normocalcemia. With assumptions, P excreted per volume of filtrate (E_p/C_{cr}) is a surrogate for $[P]_{CDN}$ to which [PTH] can be compared. In the present study, we used contemporaneous data to assess our hypothesis and others.

Methods: Fasting specimens of serum (s), plasma, and urine (u) were obtained from 30 patients with stages 3 or 4 CKD (mean eGFR 29.5 mL/min/1.73m^2). Concentrations of creatinine ([cr]), P, Ca, and ionized calcium ($[Ca]_i$) were measured with standard methods. [PTH]1-84 and intact [FGF23] were measured with ELISAs (Scantibodies and Immutopics), [25OHD] with an enzyme immunoassay (immunodiagnosticsystems), and $[1,25(OH)_2D]$ with a radioimmunoassay (Labcorp). E_p/C_{cr} and E_{Ca}/C_{cr} were calculated as $[P]_u[cr]_s/[cr]_u$ and $[Ca]_u[cr]_s/[cr]_u$. Simple linear regressions were performed to examine theories of SHPT (see table).

Results: [PTH] varied directly with 100/eGFR, E_{Ca}/C_{cr}, [FGF23], and E_p/C_{cr}. Other regressions were not significant.

Conclusions: The *direct* relationship of [PTH] to E_{Ca}/C_{cr} undermines the theory of skeletal resistance to PTH. The relationship to [FGF23] probably reflects dependence of FGF23 synthesis on PTH (*Kidney Int* 2017;92:165). The regression of [PTH] on E_p/C_{cr} supports the tradeoff-in-the-nephron hypothesis. The regression also explains the inverse relationship of [PTH] to eGFR and the historic observation that influx of P determines [PTH] in CKD. Our data do not support other explanations for SHPT.

Funding: Veterans Affairs Support, Commercial Support - Sanofi-Genzyme

EXPLANATION FOR INCREASED PTH SECRETION	REGRESSION(S) EXAMINED	R2	p
CKD causes SHPT	[PTH] on 100/eGFR	0.33	≤ 0.001

Cost Effective Model for Bone Mineral Disease Management in Hemodialysis Population in Qatar

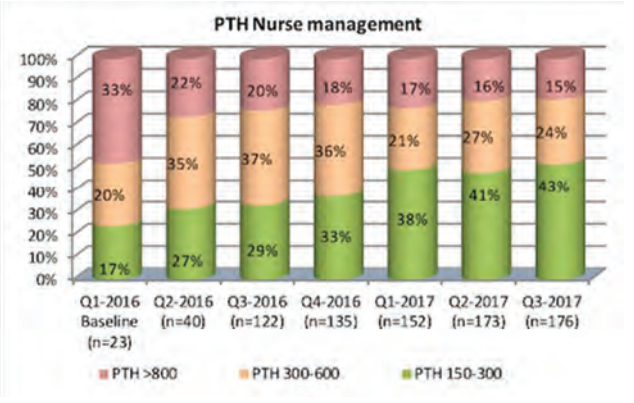
Mohamed Y. Mohamed, Fadwa S. Al-Ali, Abdullah Hamad. *Hamad Medical Corporation, Doha, Qatar.*

Background: Hemodialysis population have multiple comorbidities with high morbidity and mortality. High calcium level contributes to vascular calcification and increased cardiovascular mortality in the dialysis population. Hypercalcemia, hyperphosphataemia and high parathyroid hormone level are related to vascular calcification and increased cardiovascular mortality. On our annual report we found suboptimal MBD results in 2015. That is why a change was needed.

Methods: BMD team consisted of 2 part-time nurses and a nephrologist who provided extensive training for 2 months to work almost independently. We started April 2016 and followed theses target for calcium. We followed this available target for calcium (<2.37 mmol/L), phosphorus (<1.75 mmol.) And PTH (150-600 pg/mL) or >800 pg/mL (negative outcome). Nurse review the results within 4 days after blood extraction with the nephrologist and prescription were written simultaneously (physician prescription is mandatory), Data collection was done under IRB approval.

Results: all first-floor patient's (176/380) were included. Over a short period, we were able to achieve our targets. There was statistically significant difference in the number of patients in target range for PTH in interventional group compared with standard care group in the ground floor (43% versus 17%), (P value <0.005), and PTH less than 800(15% versus 83%),(P Value 0.0006). Through proper accounting for medicine dispensing, we were able to reduce number of prescription and pill burden. Reduced number of sevelamer tablets estimated at 4.5 tablets/Week/Patient (average of 30 tablets/week/patient in the new model versus 34.5 in the standard of care) with annual course surfing estimated at 60,000 $. Cinacalcet consumption dropped from 430 mg/week/patient to 370mg/week/patient with an annual cost saving of 125000 US dollars.

Conclusions: MBD nurse manager model in dialysis was successful to achieve, exceed and maintain patients within benchmark for calcium, phosphorus, and PTH.



SA-PO707

Determinants of Secondary Hyperparathyroidism Progression in CKD Patients

Raquel F. Vasco,[1] Flávia L. Carvalho Goncalves,[1] Rosilene M. Elias,[1,2] Rosa M. Moyses.[1,2] *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Universidade Nove de Julho, São Paulo, Brazil.*

Background: Secondary hyperparathyroidism (SHPT) is a common complication in patients with CKD and should be early identified and managed. However, it is still unknown which factors are associated with SHPT progression.

Methods: Electronic charts of all nephrology outpatients clinic (n=1,170) in the period between Jan-2017 and Dec-2017 with CKD stages 3 and 4 were included. Estimated glomerular filtration rate (eGFR) based on CKD-EPI equation and biochemical parameters were assessed. Patients were divided in two groups: those who exhibited SHPT (final PTH > 150 pg/ml; n= 279) and those who did not (n = 891).

Results: Patients who developed SHPT had lower basal calcium (9.45 ± 0.6 vs. 9.57 ± 0.5 mg/dl), eGFR (24±7 vs. 34±11 ml/min, p=0.002) and 25 vitD (25±10 vs. 27±10 ng/dl, p=0.002), despite a trend for a higher prevalence of cholecalciferol supplementation (77 vs. 72%, p=0.07). They also had higher phosphate (3.68 ± 0.7 vs. 3.52 ± 0.7 mg/dl, p=0.001) and eGFR loss (3.3±6 vs. 1.0±7.6 ml/mi, p=0.0001). No association was found for age or gender. Multivariate analysis disclosed that SHPT progression was associated with more rapid progression of CKD, as well as lower vit D and higher phosphate at baseline.

Conclusions: Our data suggest that patients with faster progression of SHPT present lower eGFR and 25 vitD and higher phosphate, even within the reference range. These patients should be closely monitored and future prospective studies might show whether interventions such as phosphate restriction and more vigorous cholecalciferol supplementation could change the SHPT natural history.

SA-PO708

A Qualitative Analysis of the Medical Record of a National Cohort of Patients with Advanced Kidney Disease Not Treated with Maintenance Dialysis in the US Department of Veterans Affairs

Susan P. Wong,[1,2] Lynne V. Mcfarland,[3,1] Chuan-fen Liu,[5] Ann M. O'Hare.[4,2] *[1]VA Health Services Research and Development Center, Seattle, WA; [2]University of Washington, Seattle, WA; [3]Puget Sound VA, Seattle, WA; [4]VA Puget Sound Health Care System, Seattle, WA; [5]VA Puget Sound Health Care System, HSR&D, Seattle, WA.*

Background: Although it is widely recognized that not all patients with advanced chronic kidney disease (CKD) will choose to receive maintenance dialysis, little is known about the clinical context in which these decisions occur.

Methods: We performed an in-depth qualitative analysis of the electronic medical records of a national cohort of 851 patients with advanced CKD and in whom there had been a decision not to initiate maintenance dialysis in the Veterans Affairs (VA) healthcare system between 2000-2011. We used inductive content analysis to identify clinical events, care processes, healthcare interactions and documented concerns of patients and providers relevant to the decision not to pursue dialysis

Results: Overall, 66.6% of cohort members were white and 61.3% were aged ≥75 years. We identified three major dynamics relevant to understanding the context in which decisions not to pursue dialysis unfolded: 1) *Perseveration about dialysis*, which reflected circumstances in which some patients had refused dialysis but providers did not readily accept this decision and seemed rooted to the possibility of starting dialysis. Providers repeatedly questioned patients' preferences, questioned patients' competency to make this decision, increased opportunities for patients to initiate dialysis, and proceeded as if patients would change their minds about dialysis; 2) *Not candidates for dialysis*, which reflected circumstances in which providers deemed some patients not to be candidates or appropriate for dialysis on the basis of patients' characteristics and expected prognosis rather than on patients' values and preferences; and, 3) *Nothing left to offer*, which reflected providers' tendency to view that they had little else to offer when patients did not receive dialysis and pressed patients to enter hospice care, often before patients were ready.

Conclusions: Our findings reveal the all-or-nothing approach to caring for patients with advanced CKD who did not pursue maintenance dialysis. Greater efforts are needed

to develop patient-centered models of care for advanced CKD capable of supporting those who do not to start dialysis.

SA-PO709

Association Between eGFR and Cognitive Performance

Suzanne Dominique Genest,[1] Remi Goupil,[2] Josee Bouchard,[2] Stephan Troyanov,[2] Francois Madore.[2] *[1]Université de Montréal, Montreal, QC, Canada; [2]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada.*

Background: Moderate to severe chronic renal failure is known to be associated with cognitive impairment; however, few studies have looked at the impact of subclinical kidney dysfunction on cognition. This study aimed at investigating the association between cognition and eGFR in a population-based cohort.

Methods: We evaluated cardiovascular, renal and cognitive profiles in randomly selected individuals from the general population between the ages of 40 and 69 years. Cognitive function was quantified by computer-based testing of reaction time, paired associates learning (memory), and verbal-numerical reasoning. eGFR was estimated using the CKD-EPI equation. We used multivariate analysis to study the association between eGFR and cognition, while adjusting for confounders, including age, gender, income, education, smoking, hypertension, dyslipidemia, diabetes, body mass index, cardiovascular diseases, alcohol intake and psychoactive medication use.

Results: A total of 15 897 patients had cognitive testing and eGFR measurements performed during the same clinic visit. Mean eGFR was 88.0± 14.6 ml/min/1.73m^2. After adjusting for age, gender, income, education, alcohol intake and known cardiovascular risk factors, lower eGFR was significantly associated with poorer performance on reaction time testing, paired associates learning (memory), and verbal-numerical reasoning. These associations remained significant after further adjustment for use of psychoactive medications (cf. table).

Conclusions: Subclinical renal dysfunction may be associated with impaired cognitive performance, independently of known risk factors for cognitive decline.

Funding: Government Support - Non-U.S.

Table - Association between eGFR and cognitive function.

	Quartile	Adj. eGFR* (SD) ml/min/1.73m^2	Adj. p-value*
Reaction time	Q1	90.4 (5.2)	< 0.001
	Q2	88.5 (5.6)	
	Q3	87.0 (6.0)	
	Q4	85.6 (6.1)	
Memory	Q1	89.2 (5.7)	< 0.001
	Q2	88.2 (5.9)	
	Q3	87.3 (6.0)	
	Q4	86.3 (6.1)	
Reasoning	Q1	88.4 (5.7)	< 0.001
	Q2	88.2 (5.8)	
	Q3	88.0 (5.9)	
	Q4	87.5 (6.2)	

*Adjusted for age, gender, income, education, smoking, alcohol intake, hypertension, dyslipidemia, body mass index, diabetes, history of cardiovascular disease, including stroke, and psychoactive medication use. The first quartile (Q1) corresponds to best cognitive performances while that of the fourth quartile (Q4) relates to worst cognitive performances.

SA-PO710

Trajectories of Distress in Older Patients at Initiation of Haemodialysis

Helen Alston,[1] Aine Burns.[2] *[1]Royal Free Hospital, London, United Kingdom; [2]Centre for Nephrology Royal Free NHS Trust, London, United Kingdom.*

Background: Previous studies examined trajectories of functional status (Kurella Tamura et al, 2010; Murtagh et al, 2011) and trajectories of quality of life (da Silva Gane et al, 2012) at dialysis initiation. We compared trajectories of functional status and distress in older patients before and after dialysis initiation.

Methods: We obtained records for 316 CKD4/5 patients aged <70 with ≥3 DTs and KPSs in their patient record. 23 started haemodialysis during the study period. Linear regression analysed distress, KPS and other factors of interest at baseline. Multi-level regression analysed changes in DT and KPS score over time. Visual Graphical Analysis (VGA) assessed the trajectories of patients who started dialysis in the study period.

Results: For each 10% loss of functional performance on the KPS, DT score fell by 0.47 (p<0.001). The relationship between DT scores and factors such as gender, eGFR and age, was not statistically significant. We identified 5 categories of DT trajectory: 1: increase in distress around the time of starting dialysis, returning to baseline levels of distress (psychological adaptation) after a couple of months 2: increase in distress around the time of starting dialysis, but with no return to baseline 3: unaffected by the start of dialysis – reported no distress at all 4: unaffected by start of dialysis because they were so distressed all the time that dialysis made no difference to their DT scores 5: unaffected by start of dialysis but experienced a rise in distress at other times.

Conclusions: A majority of participants experienced a rise in DT score around start of dialysis, and for some this did not return to baseline even after six months. However low eGFR was not associated with higher levels of distress. How do we reconcile this? We found an association between functional status and distress, suggesting that the distressing aspects of dialysis initiation may be unrelated to declining kidney function, instead due to the impact of haemodialysis on their previous life.

SA-PO711

Impact of Effective Treatment of Hyponatremia in Geriatric Patients

Volker R. Burst,[2] Franziska Grundmann,[3] Victor Suárez,[4] Polina Todorova,[1] Paul T. Brinkkoetter.[1] *[1]University Hospital Cologne, Cologne, Germany; [2]Department 2 of Internal Medicine, Renal Division; University of Cologne, Cologne, Germany; [3]University of Cologne, Cologne, Germany; [4]University Hospital of Cologne, Koeln, Germany.*

Background: Hyponatremia is highly prevalent in old age and associated with increased morbidity and mortality. Until now it is not known whether effective treatment of frequently perceived asymptomatic hyponatremia in the geriatric population has an impact on patient outcome. Here, we investigate the effect of inpatient treatment of patients with hypotonic hyponatremia on neurocognitive and motor performance using a comprehensive geriatric assessment (CGA).

Methods: 150 geriatric patients with serum [Na^+] <130 mEq/L on admission and complete diagnostic datasets were enrolled. The results of the CGA on admission as well as the change of individual CGA tests until discharge were compared to a matched (sex, age, Barthel index of activities of daily living [ADL]) control group.

Results: Both groups were similar with respect to comorbidities and clinical characteristics. There were no differences in the individual assessments (ADL, Tinetti's Mobility Assessment, Timed Up and Go-Test, Mini-Mental State Examination [MMSE], handgrip strength, Geriatric Depression Scale, Clock-drawing Test, and Esslinger Transfer Scale) at baseline (i.e. upon admission). A small but highly significant improvement as compared to the control group between baseline and time of discharge was observed with regard to ADL (mean(SD): 14.3(17.12)] vs. 9.84(14.67); P=0.002) and MMSE (mean(SD): 1.43(3.71) vs. 0.72(2.17); P=0.002) in the primary analysis group and this improvement was attributable to those patients in which serum [Na+] was increased by >5 mEq/L whereas no improvement was seen in those in which serum [Na+] was increased by only ≤5 mEq/L. However, regression analyses were not able to confirm a statistically significant association between effective [Na+] increase and CGA outcome within the primary analysis group. With respect to the subgroup of euvolemic hyponatremia, only changes of MMSE results were significantly different.

Conclusions: With the most robust changes observed with ADL and MMSE, the results of this prospective observational study suggest a true impact of treating hyponatremia on quality of life and neurocognitive function. However, the detected differences are small and further investigations are needed to prove their clinical relevance.

SA-PO712

Patiromer and Maintenance of RAASI Therapy in Hyperkalemic Medicare Patients

Nihar Desai,[1] Christopher G. Rowan,[2] Paula J. Alvarez,[3] Jeanene Fogli,[3] Robert D. Toto.[4] *[1]Yale School of Medicine, New Haven, CT; [2]COHRDATA, LLC, Santa Monica, CA; [3]Relypsa, Inc., a Vifor Pharma Group Company, Redwood City, CA; [4]University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Continuing RAASI is critical for patients (pts) with high cardiovascular risk. Patiromer (PAT) is a Na-free non-absorbed K^+-binder approved for hyperkalemia (HK) treatment in Oct 2015. PAT has been shown to reduce recurrent HK and allow pts to maintain RAASI. This retrospective cohort study evaluated RAASI utilization among Medicare Advantage pts with HK.

Methods: RAASI utilization was evaluated from a large, de-identified national health insurance claims database from 1/1/16 to 3/31/17. Three HK cohorts were identified based on: dispensed a K^+-binder, either 1) patiromer [PAT cohort] or 2) SPS [SPS cohort], or 3) HK diagnosis code without a K^+-binder dispensed (HK cohort). Pts were included who had a pre-index serum K^+ ≥5.0 mEq/L and were continuously exposed to RAASI for ≥6 months pre-index (ie, date of first K^+-binder dispensing or HK diagnosis). We evaluated RAASI continuation and down-titration (the latter assessed for lisinopril, losartan, and valsartan) within 1, 3, and 6 months post-index.

Results: Pre-index pt characteristics and sample sizes are listed in the **Table**. At 6 months post-index RAASI continuation rates were 87%, 72%, and 57% (**Figure**) and down-titration rates were 11%, 11%, and 9% in the PAT, SPS, and HK cohorts, respectively.

Conclusions: The highest RAASI continuation rate was observed in the PAT cohort across all time intervals, and down-titration rates in all 3 cohorts were low (~10%). Further study is warranted to fully elucidate these findings in early patiromer users.

Funding: Commercial Support - Supported by Relypsa, Inc., a Vifor Pharma Group Company

Discharge Destination and Disparities in Dialysis Patients' Post-Acute Care

Nancy G. Kutner,[1] Rebecca H. Zhang,[2] C. Barrett Bowling.[3] *[1]Emory University School of Medicine, Atlanta, GA; [2]Emory University, Atlanta, GA; [3]Durham VA Medical Center, Durham, NC.*

Background: Post-acute care (PAC) goals emphasize functional recovery and reduced re-hospitalization, and PAC use has increased markedly since 2000. However, a recent concern is that lack of evidence-based guidelines for PAC decision-making creates opportunities for disparities in care, as in black/white disparities in PAC post-arthroplasty (JAMA 2018) and in PAC services among older community residents (JAGS 2017). Home health (HH) and skilled nursing facility (SNF) are most used but include substantially different levels of patient support (HH higher) and cost (HH lower). The inpatient rehabilitation facility (IRF) emphasizes physician involvement and care coordination, and IRF cost is higher. Outcomes following IRF may be superior to those following SNF for comparable patients with hip fracture and stroke diagnoses. Using Medicare claims data in USRDS files, we examined dialysis patient PAC patterns after lower-extremity amputation (LEA), fracture, and stroke, conditions for which kidney patients and blacks are at increased risk.

Methods: Prevalent dialysis patients with Medical Evidence data and Medicare Part A/B coverage, who were hospitalized at least once 11/2011-12/2012 followed by one or more PAC provider claims in 2012, were the study cohort (n=85,242). We identified IRF providers by matching CMS Certification Numbers with USRDS facility IDs in a provider crosswalk file. USRDS maintains HH and SNF analysis files. Dialysis patients' receipt of HH, SNF and IRF following LEA (n=10,290), fracture (n=10,119), and stroke (n=5,537) was observed in claims data.

Results: Median (IQR) age was 66 (58, 75) for HH users, 72 (63, 80) for SNF users, and 69 (60, 77) for IRF users. Women were 50% of HH and SNF users and 45% of IRF users; blacks were 32% (HH), 29% (SNF), and 30% (IRF). The percentage of dialysis patients with LEA, fracture and stroke was larger among IRF users than among SNF users, but SNF use far exceeded IRF use. Among those who received IRF services, blacks accounted for 39% of those with LEA and 31% of those with stroke, but only 17% of all IRF patients with fracture.

Conclusions: Equity is needed in PAC choices, and the challenge of "who belongs where" when multiple PAC options are available calls for well-designed studies of patients' rehabilitation needs and outcomes during an extended window of patient experience.

SA-PO714

Health Outcome Priorities of Older Adults with Advanced CKD and Concordance with Their Nephrology Providers' Perceptions

Sarah Ramer,[3] Cassianne Robinson-Cohen,[1] Aihua Bian,[2] Thomas G. Stewart,[1] Loren Lipworth,[1] Khaled Abdel-Kader.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University, Nashville, TN; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

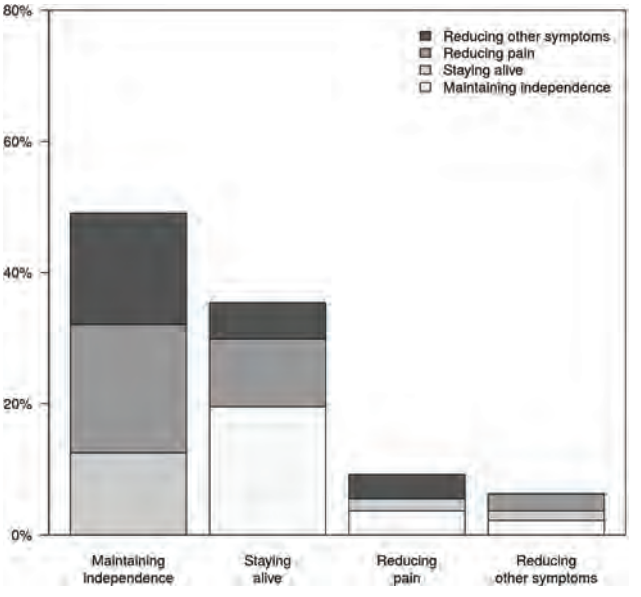
Background: Nephrology providers must understand their patients' priorities before recommending treatments, especially in older adults, for whom the tradeoffs in risks and benefits become more salient. We therefore elicited the health outcome priorities (HOPs) of older adults with advanced non-dialysis-dependent CKD; examined the association between priorities, self-reported health, and acceptance of common end-of-life scenarios; and measured concordance between patients' priorities and providers' perceptions of these priorities.

Methods: Patients ≥ 60 years old with non-dialysis-dependent CKD stages 4-5 recruited from a US nephrology clinic completed a validated HOP tool, self-rated health question, and end-of-life scenarios tool. For each enrolled patient, the nephrology provider completed the same HOP tool.

Results: Among 271 patients, 46% women, with median age 71, 49% chose maintaining independence as their top HOP, followed by staying alive (35%), reducing pain (9%), and reducing other symptoms (6%) (Figure). 49% ranked staying alive as their 3rd or 4th priority. There was no association between patients' self-rated health and top priority ranking (P=0.33), but for 6 of 13 common end-of-life scenarios (e.g., "are an emotional or financial burden to family"), reported acceptance significantly differed by top HOP. Patient-provider concordance on HOPs was overall poor (weighted kappa <0.1 for all 4 choices at any rank).

Conclusions: Nearly half of a group of older adults with advanced CKD ranked maintaining independence as their top HOP. Almost as many ranked staying alive as their last or second-to-last HOP. Nephrology providers demonstrated limited knowledge of their patients' priorities.

Funding: Private Foundation Support



Patients' 1st (main bars) and 2nd (sub-bars) HOP choices

SA-PO715

Factors Associated with Fractures in Octogenarian Patients with CKD

Flávia L. Carvalho Goncalves,[1] Venceslau A. Coelho,[1] Mariana P. Veloso,[1] Raquel F. Vasco,[1] Rosa M. Moyses,[1,2] Rosilene M. Elias.[1] *[1]HCFMUSP - SP - BRASIL, BRASILIA, Brazil; [2]Universidade Nove de Julho, São Paulo, Brazil.*

Background: Fracture risk is increased in chronic kidney disease (CKD), and is associated with a higher mortality rate, mainly in the elderly patients. However, little is known regarding the factors associated with fracture risk in octogenarian patients with CKD

Methods: This study investigates the associations among bone turnover markers, cognition, comorbidities and prevalent fractures in a cohort of octogenarian CKD patients. The comprehensive geriatric assessment was applied by a geriatric and nephrologist team, and data obtained in two occasions were extracted from electronic charts including estimated glomerular filtration rate (eGFR) based on CKD-EPI equation, biochemical and demographic data, modified mini-mental state examination (MMSE), and Charlson Comorbidity Index (CCI). The median time between assessments was 174 days.

Results: The fracture prevalence was 26.5% in a sample of 49 patients (67% men, age 83±7 years). We did not find differences regarding age, gender, eGFR, proteinuria, calcium, phosphate PTH, serum vitamin D, supplementation of cholecalciferol, use of omeprazole, diuretic and calcitriol between those with and without fractures (p>0.05). However, patients

who had fracture had higher comorbidity - CCI >7 (92% *vs.* 8%; p=0.031) and lower MMSE scores (15±9 *vs.* 23±5; p=0.018). During the follow-up, we observed that patients with fracture had a rapid loss of renal function (eGFR -0.016 ± 0.040 *vs.* 0.019 ± 0.052 ml/min/1.73m^2/month, p=0.017).

Conclusions: Elderly patients with CKD who experience fractures are usually marked by more comorbidities, more cognitive deficits, and greater loss of renal function. A closing monitoring of falls and a multidisciplinary care is warranted to minimize fractures and understand the mechanisms of deteriorating renal function.

SA-PO716

Quantitative Gait Abnormalities and Risk of Falls in CKD

Jeannie Tran,[3] Emmeline Ayers,[1] Joe Verghese,[2] Matthew K. Abramowitz.[1]
[1]Albert Einstein College of Medicine, New York, NY; [2]AECOM, Bronx, NY; [3]UCLA, Culver City, CA.

Background: Physical function is impaired in people with chronic kidney disease (CKD), leading to a high risk of falls and the development of disability. It is not known whether gait abnormalities are present which may explain their risk of falling.

Methods: Quantitative and clinical gait assessments and kidney function measurement were performed in 330 community dwelling adults aged 65 years and older. Fall history was obtained every two months by standardized telephone questionnaire. CKD was defined as an estimated glomerular filtration rate (eGFR) <60 mL/min/1.73m^2. Cox proportional hazards models adjusted for demographics, comorbidities, and history of falls were created to examine the risk of falls.

Results: Participants with CKD had slower gait speed, as well as gait cycle abnormalities including shorter stride length and greater time in the stance and double-support phases. Cadence and stride length variability did not differ between CKD and non-CKD. Among people with CKD, lower eGFR was significantly associated with the severity of gait cycle abnormalities (per 10 mL/min/1.73m^2 lower eGFR: 3.6 cm (95% CI 1.4-5.8) shorter stride length; 0.7% (95% CI 0.3-1.0) greater time in stance phase; 1.1% (95% CI 0.5-1.7) greater time in double-support phase) after adjustment for demographics and comorbidities, and these abnormalities mediated the association of lower eGFR with slower gait speed. The associations with eGFR remained significant after adjustment for measures of cognitive function, muscle strength, and sensory neuropathy. On clinical gait exam, consistent with the quantitative abnormalities, short steps and marked sway or loss of balance with straight or tandem walking were more common among participants with CKD, yet the majority had no identifiable gait phenotype. A gait phenotype defined by these abnormal gait signs was associated with the risk of incident falls among participants with CKD (compared with non-CKD without gait phenotype: HR 1.8 (95% CI 1.2-2.9, p=0.01) for CKD with phenotype, HR 0.9 (95% CI 0.6-1.5, p=0.72) for CKD without phenotype).

Conclusions: The association of CKD with slow gait speed is explained by more proximal changes in gait. A newly identified gait phenotype predicts fall risk among older adults with CKD.

SA-PO717

Is Healthy Aging Associated with Preserved Kidney Function?

Bjorn O. Eriksen,[1] Natalie Ebert,[2] Olafur S. Indridason,[5] Toralf Melsom,[4] Runolfur Palsson,[5] Elke Schaeffner.[3] *[1]Metabolic and Renal Research Group, UiT The Arctic University of Norway, Tromsø, Norway; [2]Charite University Hospital, Belgrade, Serbia; [3]Charite, Berlin, Germany; [4]University Hospital of North Norway, Tromso, Norway; [5]Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland.*

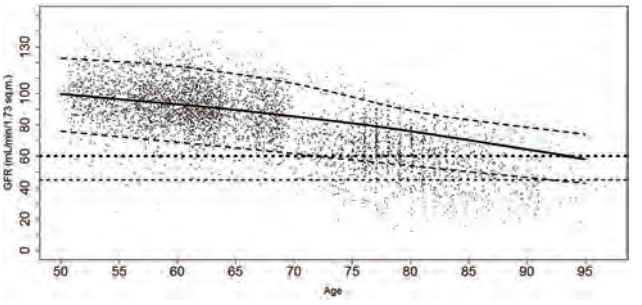
Background: Studies of kidney function based on creatinine in older adults have indicated a wide variation in age-related GFR decline and that healthy persons age with a well-preserved GFR. However, estimated GFR from creatinine is problematic in this age group because of confounding by sarcopenia. We investigated variation of measured GFR in the general population to study whether healthy ageing is associated with a stable GFR.

Methods: We measured iohexol clearance in three European cohorts (AGES-II-Reykjavik Study, Berlin Initiative Study and Renal Iohexol Clearance Survey (RENIS)) representative of the general population aged 50 to 97 years. The iohexol assays were calibrated across cohorts. We also registered the most important prevalent diseases representing risk factors for chronic kidney disease (diabetes, hypertension, cardiovascular disease and cancer). We predicted the median, 2.5th and 97.5th percentiles of cross-sectional GFR by age for persons without these risk factors using generalized additive quantile mixed models.

Results: We included 3002 persons. For persons > 90 years, the maximum observed GFR was 78 mL/min/1.73 m^2. For a person free from diabetes, hypertension, cardiovascular disease and cancer, the predicted 2.5th, 50thand 97.5th percentiles of GFR uniformly declined across the investigated age range. At 90 years, the predicted GFR values at these percentiles were 47, 64 and 78 mL/min/1.73 m^2, respectively. The 2.5th percentile crossed the 60 mL/min/1.73 m^2 level at 71.5 years and the 45 mL/min/1.73 m^2 level at 91.6 years (Figure).

Conclusions: Persons without the most important risk factors for chronic kidney disease are not exempt from age-related GFR decline. This indicates that GFR decline in these persons is caused by general ageing rather than by kidney disease.

Funding: Government Support - Non-U.S.



Points are individual measurements of GFR. Line (dashed lines) are predicted median (2.5th and 95th percentiles) under the statistical model for a person without diabetes, hypertension, CVD or cancer. Dotted horizontal lines indicate 45 and 60 ml/min/1.73 m^2.

SA-PO718

Differential Impact of Self-Reported and eGFR-Based CKD on the Outcomes of Community-Dwelling Elderly

Chia-Ter Chao.[1,2] COhort of GEriatric Nephrology in NTUH (COGENT study group) *[1]National Taiwan University Hospital BeiHu branch, Taipei City, Taiwan; [2]National Taiwan University Hospital, Taipei, Taiwan.*

Background: Awareness of CKD has been low among affected patients, particularly elderly. However, whether such awareness is synonymous with the presence of laboratory-diagnosed CKD is currently unclear.

Methods: We retrospectively enrolled 2932 community-dwelling old adults (≥65 years) who received health examinations between 2013 and 2016 from a regional hospital. Clinical information and geriatric syndromes including depression, cognitive impairment, fall, quality of life, and visual disturbance were evaluated during medical interview. We compared differences in clinical features between those with and without self-reported or estimated glomerular filtration rate (eGFR)-based CKD and investigated their influences and interactions on the risk of CKD complications and geriatric syndromes.

Results: Among 2932 elderly (mean 73.4 years), 93 (3%) reported having CKD by history, while 585 (20%) had an eGFR <60 mL/min/1.73m2 persisted over 3 months. The prevalence of body mass index, waist circumference, and the incidence of fall differed only between those with and without eGFR-based CKD, but not self-reported CKD. A synergistic effect was found between self-reported and eGFR-based CKD regarding the CKD complication severity, including malnutrition (albumin), anemia (hemoglobin), dyslipidemia (serum cholesterol), and geriatric syndromes (cognitive and quality of life impairment) (Fig 1). Those with self-reported without eGFR-based CKD had specific features differing from others (Fig 2). Multivariate regression analyses showed that self-reported CKD exhibited better predictive efficacy for lower serum albumin and hemoglobin than eGFR-based CKD, while the latter outperformed the former for predicting lower serum cholesterol and a higher risk of cognitive impairment.

Conclusions: Among older adults, self-reported CKD may not be a surrogate for laboratory-diagnosed CKD and has an independent effect on CKD-related complications.

A Census of Skilled Nursing Facility Utilization in Medicare Dialysis Patients

Kristine Kubisiak,[1] Debabrata Ray,[1] Allan J. Collins,[1,2] Eric D. Weinhandl.[1,2]
[1]NxStage Medical, Inc., Victoria, MN; [2]University of Minnesota, Minneapolis, MN.

Background: The size of the dialysis patient population that resides in a skilled nursing facility (SNF), either for short-term rehabilitation or long-term custodial care, is unclear. Medicare Part A covers SNF care only in specific circumstances, thus complicating interpretation of Medicare claims analysis. However, Yun *et al* (*Health Serv Outcomes Res Methodol*, 2010) proposed an algorithm that collects data from Part A claims for SNF care and Part B claims for physician visits in a SNF to identify Medicare beneficiaries who reside in a SNF. We implemented this algorithm in Medicare dialysis patients to identify an ongoing census of SNF utilization.

Methods: We analyzed data from the United States Renal Data System. For each calendar month from January 2013 to September 2015, we identified patients who underwent outpatient dialysis and carried Medicare Parts A and B as primary payer. According to the algorithm proposed by Yun *et al*, we ascertained 3 classes of claims among these patients: (1) Medicare Parts A claims submitted by a SNF; (2) Medicare Part B claims submitted by physicians, with place of service code 31 (SNF), 32 (nursing facility), or 33 (custodial care facility); (3) Medicare Part B claims submitted by physicians, with a *Current Procedural Terminology* code indicating evaluation or management of a nursing facility patient. In each calendar month, we estimated the percentage of patients residing in a SNF, and further classified patients as short-term or long-term residents.

Results: Monthly counts of Medicare dialysis patients increased from approximately 306,600 patients during the first quarter of 2013 to approximately 315,600 patients during the third quarter of 2015. The mean percentage of Medicare dialysis patients residing in a SNF during a month was 8.57%, with a range from 8.24% to 8.90%. Concurrently, the mean percentage of patients residing in a SNF for short-term care was 4.91%, whereas the mean percentage of patients residing in a SNF for long-term care was 3.66%. In the subset of patients with age ≥75 years, the mean percentage of patients residing in a SNF during a month was 14.85%, with 8.70% in a SNF for short-term care and 6.16% in a SNF for long-term care.

Conclusions: During any month, slightly more than 85 of every 1000 Medicare dialysis patients reside in a SNF, with a ratio of approximately 4 to 3 for short-term versus long-term care.

Proteinuria Selectivity Index as a Predictor for Response to Therapy in Nephrotic Syndrome

Maiko Nakayama, Hitoshi Suzuki, Yusuke Suzuki. *Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: The nephrotic syndrome (NS) is defined by heavy proteinuria due to abnormal increase of glomerular permeability and following hypoalbuminemia, hyperlipidemia and edema. Clinical manifestation of NS is highly variable due to the response to therapy. Selectivity index (S.I.) that commonly used for initial examination to differentiate minimal change disease (MCD). However, clinical application of S.I. is controversial for reliability. In present study, we evaluated clinical examinations including S.I. and prognosis of NS.

Methods: We retrospectively analysed 66 cases with NS who underwent renal biopsy in our hospital from 2013 to 2017. The clinical features at the time of renal biopsy, remission rate of initial therapy, and relapse rate of during the course of medication were evaluated in each primary glomerulonephritis.

Results: Of the 66 cases of NS, 47 cases were caused by primary glomerulonephritis. The incidence of MCD, idiopathic membranous nephropathy (MN), focal segmental glomerulosclerosis (FSGS) and membranoproliferative glomerulonephritis (MPGN) were 55%, 32%, 9%, and 4%, respectively. Prevalence of each causal disease of NS was similar to data of Japanese renal biopsy registry. At the time of renal biopsy, levels of proteinuria (6.9g/day), degree of hypoalbuminemia (1.6 g/dL) and dyslipidemia in MCD were most severe as compared with other primary glomerulonephritis (P=0.02). Complete remission rate of initial therapy in each primary glomerular disease were 96% for MCD, 57% for MN, 50% for FSGS and 50% for MPGN, respectively. However, 42.3% patients with MCD recurred during the course of immunosuppression therapy, despite high frequency of remission. Of note, patients with 67% of MN and 75% of FSGS indicated high S.I. (less than 0.2). There was the trend that in cases with high S.I. patients with MN and FSGS indicated high remission rate by initial therapy.

Conclusions: Although levels of proteinuria and degree of hypoalbuminemia were most severe in MCD, remission rate of MCD was high by initial therapy. The recurrence rate is also high in patients with MCD. The high S.I. may be useful to expect response to initial therapy in patients with MN and FSGS.

SA-PO721

Clinical Outcomes and Effects of Treatment in Older Patients with Idiopathic Membranous Nephropathy

Yaeni Kim,[1] Hye Eun Yoon,[2] Yu Ah Hong,[5] Bumsoon Choi,[6] Cheol Whee Park,[2] Chul Woo Yang,[4] Yong-Soo Kim,[7] Hyeon Seok Hwang.[3] *[1]Incheon St. Mary's Hosp, Catholic Univ of Korea, Incheon, seoul, Republic of Korea; [2]The Catholic University of Korea, Incheon, INCHEON, Republic of Korea; [3]Division of Nephrology, Department of Internal Medicine, College of Medicine, Kyung Hee University, Seoul, Republic of Korea; [4]Seoul St. Mary's Hospital, Seoul, Republic of Korea; [5]College of Medicine, The Catholic University of Korea, Daejeon, Republic of Korea; [6]Division of Nephrology, Department of Internal Medicine, Seoul, Republic of Korea; [7]The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.*

Background: Membranous nephropathy (MN) is the most common primary glomerular disease diagnosed in older patients. However, few reports describe the clinical outcomes in older patients with idiopathic MN.

Methods: The outcomes of 135 patients with histologically proven MN were analyzed. 'Older' was defined as 60 years of age or older at the time of the renal biopsy. The rates of complete remission (CR), progression to end-stage renal disease (ESRD) and infection were compared between older and younger patients.

Results: The cumulative event rate for achieving CR was inferior (P = 0.012) and that for requiring renal replacement therapy was higher (P = 0.015) in older patients, and they had a greater risk of infection (P = 0.005). Older age was a significant predictor of a lower rate of CR from proteinuria (adjusted odds ratio [OR] = 0.51, 95% confidence interval [CI] 0.26–0.98), and was a robust predictor of infection (adjusted OR = 5.27, 95% CI 1.31–21.20). Conservative treatment was associated with a lower remission rate (P = 0.036) and corticosteroid treatment was less effective in achieving CR (P = 0.014),

in preventing progression to ESRD (P = 0.013) and in reducing infection (P = 0.033) in older patients. Cyclosporine treatment had comparable clinical outcomes with regard to CR, ESRD progression, and infection.

Conclusions: Older age was independently associated with inferior rates of CR and greater risk of infection. Treatment modalities affected the outcomes of older patients differently in that cyclosporine treatment is predicted to be more useful than corticosteroids in this population.

SA-PO722

Histological and Clinical Patterns in Glomerular Diseases of the Elderly: A Monocentric Study

Andrea Angioi,[1] Nicola Lepori,[1] Matteo Floris,[1] Riccardo Cao,[1] Anna Maria Asunis,[2] Gianfranca Cabiddu,[1] Antonello Pani.[1] *[1]Nephrology, Ospedale Brotzu, Cagliari, Italy; [2]Anatomic Pathology, Ospedale Brotzu, Cagliari, Italy.*

Background: Renal biopsy is an essential instrument for diagnosis of glomerular disease: according to data described in literature, this tool is overlooked in the elderly patients, which represent 15% of renal biopsies

Methods: Our Division is the regional hub of renal diseases in Sardinia, covering around 1.6 million of inhabitants, of whom 217.000 are eldery. We retrospectively reviewed histological and clinical data of all biopsy proven glomerular disease performed on ≥65 y/o patients from 2000 to 2016.

Results: 227 patients, with a mean age of 73.62 ± 6.41 years, were included in our analysis. 61.2% of them were younger than 75 y/o and 3.5% were older than 85 y/o (with 3 patients > 99 y/o). The annual incidence of biopsy proven glomerular diseases in the elderly population increased progressively in the considered period, from 4 cases/100.000 exposed in 2000 to 11.5 cases/100.000 in 2016. Membranous Nephropathy was the most recurrent histological diagnosis (23.8%), followed by Minimal Change Disease (13.2%), AL amyloidosis (9.3%) and MPO-ANCA vasculitis (9.3%). Our analysis showed few significative differences when patients were classified according their age (65-74, 75-84 and ≥85 years old): diabetic nephropathy was more frequent in the third group (p 0.001) and MPO-ANCA vasculitis were more frequently diagnosed in group 1 and 2 than in group 3 (p 0.05). Interestingly, incidence of MGRS and malignant clones with renal involvement rose from no cases in 2000-2003, to a peak of 33% in 2013

Conclusions: Incidence of glomerular diseases is increasing, likely due to more comprehensive indications to renal biopsy from 2000 to 2016. Histological patterns revealed a substantial homogeneity in among the three subgroups analyzed. Coherently, most of patients benefited of a specific treatment. Renal biopsy is, therefore, an irreplaceable tool even in a selected elderly population

Annual number of new biopsy proven diagnosis of glomerular disease in elderly patients at Ospedale Brotzu Nephrology Department (2000-2016)

SA-PO723

Functional Decline and Associated Risk Factors in a Survivor Cohort of Older Dialysis Patients

Rasheeda K. Hall, Alison Luciano, Jane F. Pendergast, Cathleen Colon-emeric. *Duke University, Durham, NC.*

Background: At least 50% of older adults undergo functional decline or die within the first 6 months of dialysis. Little is known about functional decline in older adults who survive the first 6 months of dialysis. We sought to identify risk factors for functional decline, as measured by Short Form-12 physical component score (SF-12 PCS) change, in a survivor cohort of older dialysis patients.

Methods: We conducted a retrospective study of 3,284 adults aged ≥ 65 years with ≥ 6 months of hemodialysis and complete SF-12s in 2012 and 2013. We calculated PCS change as second minus first PCS for individuals with PCSs ≥ 300 days apart. Using a multivariable linear regression, we modeled PCS change and adjusted for baseline age, gender, race, Medicaid status, access type, Kt/V, albumin, hemoglobin, time on dialysis, Charlson index, hospitalization rate, and days between PCSs. In post hoc analysis, we compared individuals in categories: clinically relevant (CR) PCS decline or increase (PCS change > 3) and no CR change.

Results: Of 3,284, 801 (24.4%) died and an additional 1,112 (33.9%) did not have 2 PCSs ≥ 300 days apart. Our analytic cohort included the remaining 1,371 (41.7%) who had 2 PCSs ≥ 300 days apart (mean 399 ± 74 days), mean time on dialysis 6.1 ± 3.1 years, and mean PCS change -0.9 ± 9.6. Cohort members with time on dialysis < 5 years had significant but modestly smaller decline in PCS compared to those with ≥ 5 years (p=0.03) (Table), but the regression did not reveal any significant associations between patient characteristics and PCS change. The proportion with CR PCS decline, increase, or no CR change were 39.3% (n=539), 32.2% (n=442), and 28.4% (n=390), respectively. Mean hospitalization rate was highest among those with CR PCS decline (2.0 ± 3.7) compared to those with CR increase (1.7± 3.5) or no CR change (1.4 ± 2.6) (p<0.05).

Conclusions: In this survivor cohort, nearly 25% died and 40% of those who did not die had CR PCS decline within 2 years. Although age, race, time on dialysis, and access type were not associated with SF-12 PCS change, one potential risk factor for CR PCS decline is recurrent hospitalizations.

Preliminary Satisfaction and Acceptability Ratings of a Supportive Care Video Decision Aid for Elderly Patients with Advanced CKD

Nwamaka D. Eneanya,[1] Shananssa Percy,[1] Michael J. Germain,[2] Ravi I. Thadhani,[5] Jennifer S. Temel,[4] Michael Paasche-Orlow,[3] Angelo Volandes.[4] *[1]Massachusetts General Hospital, Boston, MA; [2]Renal and Transplant Assoc of New England, Hampden, MA; [3]Boston University, Boston, MA; [4]MGH, Waban, MA; [5]Cedars-Sinai, Los Angeles, CA.*

Background: The benefits of dialysis remain uncertain for elderly and frail patients with advanced chronic kidney disease (CKD). Recent studies have not shown an improvement in survival or quality of life for many such patients on dialysis, thus making supportive kidney care a viable option. Furthermore, decision aids to promote informed decision making about supportive care are lacking. As part of a randomized controlled trial (RCT) to test preliminary efficacy of a video decision aid on knowledge of supportive care among elderly patients with advanced CKD, we explored satisfaction and acceptability ratings among participants who received video education.

Methods: Eligible patients are age ≥ 65 years, English-speaking, and receive primary nephrology care at a large medical center in Boston, MA. The video was developed in an iterative process by a national panel of nephrologists with an expertise in shared decision making in this patient population. The video includes images of patients undergoing hemodialysis, peritoneal dialysis or no dialysis.

Results: A total of 64 out of eligible 100 patients have enrolled in the RCT and 43.8% (n=28) have been randomized to video education. Satisfaction and acceptability ratings of the video decision aid are displayed in Table 1.

Conclusions: Most patients who have received the video decision aid thus far in the RCT report high satisfaction and acceptability ratings. These findings contradict historical beliefs that patients are fearful or averse to learning about supportive care. Future research will determine whether a supportive care video decision aid improves supportive care knowledge for elderly patients with CKD.

Funding: NIDDK Support

Table 1. Satisfaction and acceptability ratings of a supportive care video decision aid

Question	Very N (%)	Somewhat N (%)	A little N (%)	Not N (%)
How satisfied were you with this video?	17 (60.71%)	9 (32.14%)	1 (3.57%)	1 (3.57%)
How helpful was the video in forming your preferences for end-stage renal disease care?	17 (60.71%)	7 (25.00%)	2 (7.14%)	2 (7.14%)
How comfortable were you when you watched this video?	21 (75.00%)	6 (21.43%)	0	1 (3.57%)
	Definitely N (%)	Probably N (%)	Probably not N (%)	Definitely not N (%)
Would you recommend this video to other people who are thinking of making similar decisions?	18 (64.29%)	8 (28.57%)	2 (7.14%)	0

SA-PO725

Effect of Pentoxifylline on Pericyte in Aging Mice Kidney

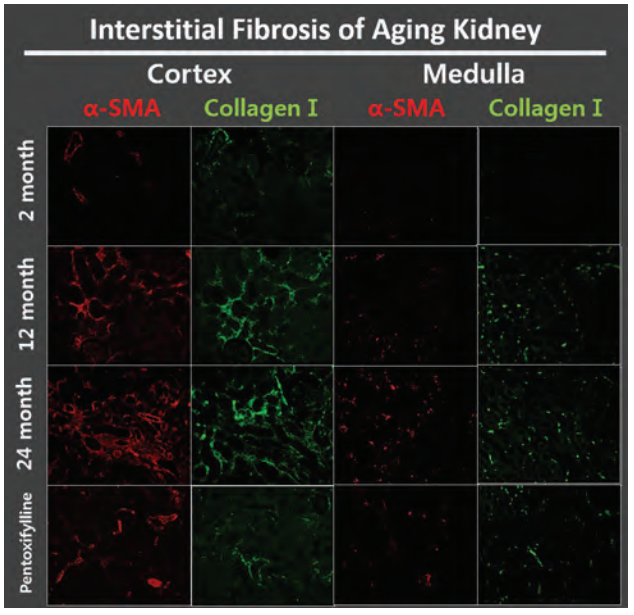
Hyung Duk Kim,[2,3] Eun Nim Kim,[1,3] Ji Hee Lim,[1,3] Min Young Kim,[1,3] Hye Eun Yoon,[4,3] Eun jeong Ko,[2,3] Tae Hyun Ban,[2,3] Byung ha Chung,[2,3] Cheol Whee Park,[2,3] Chul Woo Yang,[2,3] Yong-Soo Kim,[2,3] Bumsoon Choi.[2,3] *[1]Division of Nephrology, Department of Internal Medicine, Seoul, Republic of Korea; [2]Division of Nephrology, Department of Internal Medicine, Seoul St. Mary's hospital, Seoul, Republic of Korea; [3]The Catholic University of Korea College of Medicine, Seoul, Republic of Korea; [4]Incheon St. Mary's Hospital, Incheon, Republic of Korea.*

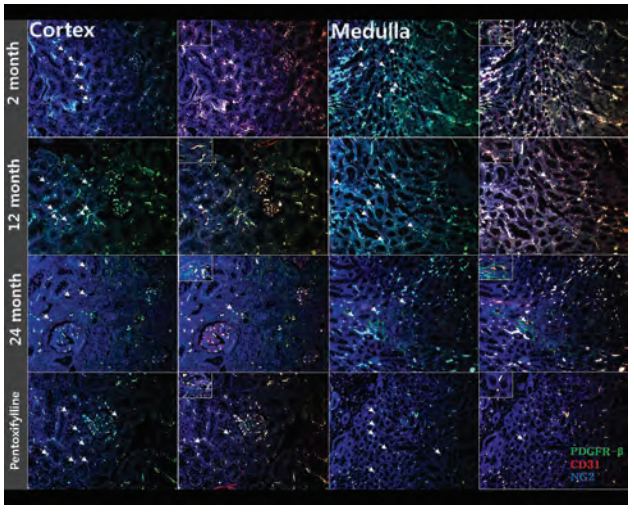
Background: In aging kidney, oxidative stress and inflammation lead to a decrease in renal function. Recent studies related to the aging process of the kidneys have shown that pericyte is a progenitor cell of myofibroblast, and the relationship between renal fibrosis and pericyte has been reported. In this study, we investigated the effect of pentoxifylline on pericyte.

Methods: 2, 12, and 24-months-old mice were assigned to control group. (Each group consisted of 7 mice) Seven 18-month-old mice were treated with pentoxifylline for 6 months. Pericyte was confirmed by PDGFR-beta and NG2 double stain.

Results: Abundant microvascular density was detected in kidney of 2 and 12-months-old young mice. In 24-months-old mice kidney, CD31 stain decreased and collagen I stain increased which means progression of renal fibrosis. In the Pentoxifylline group, the collagen I stain was significantly decreased and the microvascular density was increased compared to the 24 months group. In the 24-months group, the pericyte marker was significantly decreased and the endothelial contact was disappeared. However, the pericyte was not decreased in the pentoxifylline group and maintained their perivascular location.

Conclusions: Pentoxifylline attenuates tubulointerstitial fibrosis in aging mice kidney via pericyte.





SA-PO726

Serum Stem Cell Factor Level Predicts Declined Kidney Function in Healthy Adults

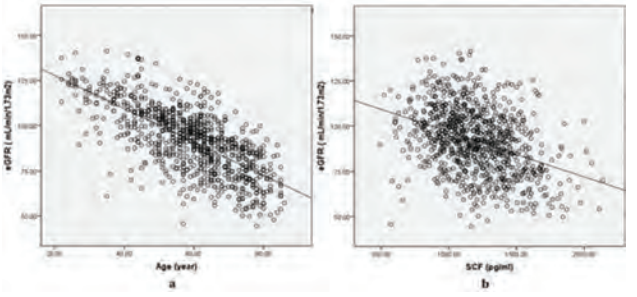
Weiguang Zhang, Linpei Jia, Xiaomin Liu, Qian Wang, Xiangmei Chen. *Department of Nephrology, Chinese PLA General Hospital, Chinese PLA Institute of Nephrology, State Key Laboratory of Kidney Diseases, BeiJing, China.*

Background: Stem cell factor (SCF), the ligand of mast cells' c-kit receptor, actively participates in the organ reconstruction and fibrosis in various diseases. Recent studies also revealed that SCF plays an important role in kidney diseases, including nephrotoxic nephritis and crescentic glomerulonephritis. However, it remains unclear whether SCF play a role in the ageing of kidney. This study was designed to investigate the relationship between serum SCF level and the function of kidney aging.

Methods: In this study, we collected the data of serum SCF, estimated glomerular filtration rate (eGFR) calculated by CKD-EPI equation and other biological indicators in a Chinese Han and investigated the relationship of SCF and the renal function in the aging process, so as to search new biomarkers of kidney aging. The levels of serum SCF (R&D Systems, Min., U.S.A) were tested by enzyme-linked immunosorbent assay (ELISA). Then correlation analysis, redundancy analysis and multiple linear regression were done to select potential indicators to estimate renal function decline. We divide subjects into youth (age<45), middle-aged (45≤age<60), young elderly (60≤age<75) and elderly (age≥75) groups. SCF levels were compared among different age groups and genders using one-way ANOVA (P<0.05) and student t test (P<0.05) respectively.

Results: 1. Demographic features Initially, 1,368 volunteers were enrolled. After the screening, 892 healthy participants of mean age 59.0 ± 13.4 years were finally enrolled. 2. **Age and SCF level are predictors of eGFR**. The final relationship between eGFR and SCF level was expressed as: eGFR = 154.486 – (0.846 × age) – (0.011 × SCF level). Fig. 1. Associations of predictive variables with the estimated glomerular filtration rate (eGFR).

Conclusions: In conclusion, we investigated the relationship between SCF and eGFR in the ageing process of kidney, and revealed that SCF is closely related with eGFR. Finally, we constructed an eGFR estimated equation for kidney aging.



SA-PO727

Impact of Aging on Kidney and Gut Cross-Talk in AKI

Myung-Gyu Kim, Ko Yoon Sook, Lee Hee Young, Junyong Lee, Jihyun Yang, Sewon Oh, Sang-Kyung Jo. *Korea University Anam Hospital, Korea University College of Medicine, Seoul, Republic of Korea.*

Background: Recently, the high incidence of acute kidney damage (AKI) and the mortality rate in elderly population are important healthcare burdens. Although, experimental studies showed that interaction between the kidney and the remote organ (lung, heart, bowel, etc.) could significantly affect the outcome of AKI, the impact of aging on the remote organ effects of AKI are still unknown. Here, we investigated the effects of aging on AKI outcomes, especially kidney and gut crosstalk in animal models.

Methods: In old (10mo) and young (2mo) C57BL/6 mice, 25min bilateral ischemia reperfusion injury (IRI) was applied, and then expression of inflammatory cytokines as well as functional and histological changes of kidney and colon were examined on day 1 and 3 after IRI. Intestinal barrier integrity was assessed by permeability to FITC-dextran.

Results: There was no significant difference in renal function between old and young mice on day1 post IRI, but the mRNA expression of IL-6, TNF-α, IL-12 and IFN-r was significantly higher in the kidneys of old mice than in young mice on day 1, and the expressions of TNF-α and IL-12 were also increased in old mice on day3. The balance of the M1/M2 markers (iNOS/mannose receptor) skewed towards M2 phenotype on day3 post IRI in young mice, however it was significantly blunted in old mice. Interestingly, this intrarenal inflammatory milieu in old mice was similarly observed in the colon. In the aged colon, TNF-α and IL-12 mRNA expression was significantly higher and mannose receptor and arginase-1 expression was lower than in young mice on day3 post IRI. Increased inflammatory cytokines in the colon were accompanied by an increase in TUNEL-positive apoptotic colon epithelial cells and increased permeability of the colon in old mice. The AKI-induced "leaky gut" showed a strong positive correlation with high TNF-α expression in mesenteric lymph nodes, suggesting that persistent inflammation of the kidney after IRI in old mice contributes to increased colon inflammation and permeability.

Conclusions: We conclude that AKI in old mice results in a more M1-related inflammation in the kidney and colon, and worsens AKI-induced "leaky gut". These results suggest that strategies for targeting intestine might provide novel therapeutic opportunities for reducing poor outcomes in elderly patients with AKI.

SA-PO728

Cystatin C and Cystatin C-Based GFR Markers for Prediction of Mortality in Elderly Patients with CKD

Sebastjan Bevc,[1,2] Nina Hojs,[1,2] Masa Knehtl,[1,2] Nejc Piko,[1] Robert Ekart,[1,2] Radovan Hojs.[1,2] *[1]University Clinical Centre Maribor, Maribor, Slovenia; [2]Faculty of Medicine, University of Maribor, Maribor, Slovenia.*

Background: The prevalence of chronic kidney disease (CKD) in the elderly is high. Serum cystatin C is an accurate marker of kidney function and also has prognostic utility in CKD patients. The aim of our study was to determine the prediction of cystatin C and cystatin-C based markers of kidney function (eGFR) on long-term survival in elderly CKD patients.

Methods: In our study 58 adult Caucasian patients, older than 65 years (50% women; mean age 73 years; range from 65 to 85 years), were included. Patients with known malignancy, thyroid disease and/or on steroid therapy were not enrolled in the study. In each patient ^{51}CrEDTA clearance, serum cystatin C (immunonephelometric method) and eGFR using two cystatin C-based formulas (CKD-EPI cystatin and FAS cystatin) were determined on the same day and patients were then followed for 12 years or until their death.

Results: The mean values: ^{51}CrEDTA clearance 53.3±17.4 ml/min/1.73m^2, serum cystatin C 1.79±0.5 mg/l, CKD-EPI cystatin 36.1±13.6 ml/min/1.73m^2, FAS cystatin 40.1±11.7 ml/min/1.73m^2. In the follow up period of 12 years 48 (83%; 24 women and

24 men) of our elderly CKD patients died. Cox regression analysis showed different hazard ratios (HR) for death: for ^{51}CrEDTA clearance HR was 1.024 (95% CI 1.001-1.042; P=0.009), for serum cystatin C HR was 2.021 (95% CI 1.264-3.229; P=0.003), for CKD-EPI cystatin HR was 1.034 (95% CI 1.008-1.062; P=0.01), for FAS cystatin HR was 1.041 (95% CI 1.010-1.071; P=0.008).

Conclusions: Our results show that in elderly CKD patients the highest hazard ratio for all-cause mortality has serum cystatin C compared to the cystatin C-based markers of kidney function (eGFR).

SA-PO729

Chloride Channel Accessory 1 Protein Could Be a Novel Regulatory Factor in Aging-Related Changes in the Kidney

Andrew Donati,[1] Hak Joo Lee,[2] Adam Salmon,[1,5] Goutam Ghosh-Choudhury,[2,5] Corinna Ross,[4] Suzette D. Tardif,[3] Balakuntalam S. Kasinath.[1,5] *[1]Univeristy of Texas Health, San Antonio, TX; [2]University of Texas Health, San Antonio, TX; [3]Texas Biomedical Research Institute, San Antonio, TX; [4]Texas A&M San Antonio, San Antonio, TX; [5]South Texas Veterans Health Care System, San Antonio, TX*.

Background: We have reported that aging induces kidney fibrosis, albuminuria and impairs clearance function in mice (Sataranatarajan K, Aging Cell, 2012). The underlying mechanisms are not well understood. In the current study, we took an unbiased discovery approach to identify potentially novel mechanisms.

Methods: We performed RNA Seq on renal cortical samples from C57BL6 male young mice (5 months old, n=4) and old mice (30 months old, n=3). Next, we directly verified changes in mRNAs that showed the maximum increase by performing qRT-PCR. We studied changes in renal cortical chloride channel accessory protein 1 (CLCA1) protein expression by immunoblotting (male and female young and old mice, n=6 to 10 per group). To study if changes found in mice were evolutionarily conserved, we studied kidney tissue from non-human primate marmosets (young 3 yrs of age, old 16 yrs of age, male and female, n=8-10 per group).

Results: On RNA Seq, we found CLCA1 as one of the mRNAs that showed most significant increase in old vs. young mice (p=7.6E-27). We performed qRT-PCR to directly test the status of CLCA1 mRNA; we confirmed a 10-fold increase in renal cortex of old male mice compared to young mice. Immunoblotting showed a 2-fold increase in CLCA1 protein in renal cortex of old male mice but not old female mice. We have reported that renal hydrogen sulfide (H2S) generation is reduced in aging mice; administration of sodium hydrosulfide (NaHS, a source of H2S) to 19 month-old mice for 5 months ameliorates aging-related kidney changes in mice (Lee HJ, GeroScience, 2018). NaHS administration decreased renal cortical CLCA1 expression by 40% compared to untreated Control old mice. On immunohistochemistry CLCA1 was expressed mostly in the tubules in young marmosets. Renal cortical CLCA1 expression was increased 2-fold in old male and female marmosets.

Conclusions: Increase in renal cortical CLCA1 expression correlates with aging-related kidney dysfunction in male mice; it appears to be evolutionarily conserved from mice to marmosets. CLCA1 activates Ca^{++}-dependent chloride channel TMEM16A that is expressed in kidney proximal tubules and podocytes. Mechanisms by which CLCA1 contributes to renal aging need to be explored.

Loss of Asparaginyl Endopeptidase Accelerates Cellular Senescence and Boosts Age-Related Renal Interstitial Fibrosis

Xiaoyue Tan, Dekun Wang, Chuanai Chen, Lichun Kang. *the School of Medicine, NanKai university, Tianjin, China*.

Background: Asparaginyl endopeptidase (AEP) is highly expressed in the renal tubuli while significantly declined in the elderly ones. AEP exhibits anti-fibrotic effect in the mouse model of unilateral ureteral obstruction. The role of AEP in the age-related fibrosis is obscure.

Methods: We compared the level of renal interstitial fibrosis and renal tubular senescence in the wild-type (wt) and AEP knockout (*AEP$^{-/-}$*) mice at different ages. We established stable AEP-knockdown HK2 cell line (HK2-shAEP) and analyzed the cellular senescence. Then, we co-cultured HK2-shAEP with fibroblasts and assessed the activated indexes of fibroblasts. We also evaluated the lysosomal pH and change of autophagy upon AEP downregulation.

Results: Renal tubular senescence was obvious from the 3rd months in *AEP$^{-/-}$* mice with significant accumulation of Fibronectin and Collagen I/III in the renal interstitial area. Levels of serum creatinine and urea nitrogen were 2 times higher than that in wt mice at the 6th months. *In vitro*, AEP knockdown induced the cell cycle arrested at G1/S with increased expression of β-Gal, p21^{cip1} and p16^{ink4a}. HK2-shAEP cells expressed and secreted more pro-fibrotic cytokines, including TGF-β1, CTGF and PAI-1. Co-culture with HK2-shAEP promoted the differentiation, migration and proliferation of fibroblasts. Blocking the senescent signaling via downregulating p21^{cip1} or p16^{ink4a} could reverse the accelerated senescence and pro-fibrotic effects of HK2-shAEP cells. Assessment of autophagy and lysosomal PH showed that knockdown of AEP led to impaired autophagy flux and disturbance of lysosomal homeostasis, accompanying with accumulation of ROS. Autophagy inducer rapamycin or anti-senescence agent spermidine could reverse the senescent state of HK2-shAEP cells. *in vivo*, both spermidine and genetical mutant of p53 alleviated renal interstitial fibrosis of *AEP$^{-/-}$* mice.

Conclusions: The study defines the role of AEP in regulation of autophagy via maintainance of lysosomal hemostasis in renal tubuli. Loss of AEP accelerates tubular senescence and boosts aged-related interstitial fibrosis. Therefore, our finding highlights AEP as a potential biomarker of age-related kidney diseases and therapeutic target.

Marmoset - A Non-Human Primate Model to Study Aging Associated Changes in the Kidney

Hak Joo Lee,[1] Olga D. Gonzalez,[6] Edward J. Dick,[3] Andrew Donati,[1] Denis Feliers,[1] Goutam Ghosh-Choudhury,[1,4] Corinna Ross,[2] Manjeri A. Venkatachalam,[5] Suzette D. Tardif,[3] Balakuntalam S. Kasinath.[1,4] *[1]University of Texas Health Science Center, San Antonio, TX; [2]Texas A&M San Antonio, San Antonio, TX; [3]Texas Biomedical Research Institute, San Antonio, TX; [4]South Texas Veterans Health Care System, San Antonio, TX; [5]University of Texas Health San Antonio, Shavano Park, TX; [6]Texas Biomed, San Antonio, TX*.

Background: Because of the genetic distance between rodents and humans an appropriate primate model to study kidney aging is needed. We evaluated whether the marmoset can fill this need by studying kidney parameters in healthy young and aged marmosets of both sexes.

Methods: We studied 4 young male (average age 3 years) and 4 young female (average age 2.8 years) marmosets, and, 5 aged male (average age 16.1 years) and 5 aged female (average age 15.9 years) marmosets. We examined structural changes in the kidney by H and E and PAS stains. Immunoblotting was employed to study changes in the expression of proteins. Measurement of urinary albumin and protein was by ELISA and Bio-Rad assay, respectively.

Results: Aging was associated with glomerulosclerosis, tubulointerstitial fibrosis and arteriolosclerosis constituting nephrosclerosis in both sexes; patchy areas of interstitial nephritis were seen. The renal cortical content of matrix proteins laminin, type III collagen, and fibronectin was increased on immunoblotting. Functionally, aging resulted in an increase in urinary albumin to creatinine ratio and protein to creatinine ratio in association with reduction in kidney expression of nephrin. There was a robust correlation between histologic markers of fibrosis and albuminuria and proteinuria. We explored signaling pathways as potential mechanistic events. Aging in males, but not in females, was associated with reduced renal cortical activity of AMP-activated protein kinase (AMPK) and a trend toward activation of mechanistic target of rapamycin complex 1 (mTORC1); upstream of AMPK and mTORC1, Akt and insulin–like growth factor 1 receptor were activated. In both sexes, aging promoted renal cortical expression transforming growth factor β-1 and phospho-Smad3. Since kidney fibrosis is associated with deficiency of hydrogen sulfide synthesis in renal disease, we examined its status in aging marmosets. While the expression of cysthathionine β-synthase, an enzyme involved H_2S synthesis, was reduced in both aged males and females, decreased H_2S generation was seen only in the males.

Conclusions: Our studies show that the marmoset is a valid model to study kidney aging; some of the signaling pathways involved in renal senescence differ between male and female marmosets.

Sirt1-Induced Hypoxia-Inducible Factor-1α Deacetylation Attenuates Tubulointerstitial Damage in Aged Kidney

Hyunjin Noh,[1,2] Mi ra Yu,[2] Dong-Ryeol Ryu,[3] Soon hyo Kwon.[1,2] *[1]Soon Chun Hyang Univ., Seoul, Republic of Korea; [2]Hyonam Kidney Laboratory, Seoul, Republic of Korea; [3]Ewha Womans University, Seoul, Republic of Korea*.

Background: Although it is well known that the expression and activity of Sirt-1 are decreased in the aged kidney, the role of interaction between Sirt-1 and hypoxia-inducible factor (HIF)-1 is largely unknown. Here, we investigated whether HIF-1α could be a deacetylation target of Sirt-1 and the effect of their interaction on age-associated renal injury.

Methods: Five-week-old (young) and 24-month-old (old) male C57Bl/6J mice were assessed for their age-associated changes. To clarify the underlying mechanisms, HK-2 cells were exposed to hypoxia. The effect of chronic activation of HIF-1α was investigated using tubular cell-specific HIF-1α transgenic mice.

Results: Kidneys from aged mice showed increased infiltration of CD68 positive macrophages, higher expression of extracellular matrix (ECM) proteins, and apoptosis than young controls. They also showed decreased expression of Sirt-1 along with increased acetylated HIF-1α. Bcl-2/adenovirus E1B 19 kDa-interacting protein 3 level, which is regulated by HIF-1α, was significantly higher in aged mice suggesting that HIF-1α activity is increased. In HK-2 cells, Sirt-1 inhibitor sirtinol or siRNA-mediated knock-down of Sirt1 enhanced apoptosis and ECM accumulation whereas Sirt1 over-expression induced the opposite changes. During hypoxia, Sirt-1 was down-regulated, which allowed the acetylation and activation of HIF-1α. Resveratrol, a Sirt1 activator, effectively prevented hypoxia-induced production of ECM proteins, mitochondrial damage, reactive oxygen species generation, and apoptosis. The findings that Sirt1-induced deacetylation of HIF-1α inhibits HIF-1α activity were also confirmed by Sirt1 over-expression under hypoxic condition and by resveratrol treatment or Sirt1 over-expression in HIF-1α transfected HK-2 cells. Finally, we confirmed chronic activation of HIF-1α promoted apoptosis and fibrosis using tubular cell-specific HIF-1α transgenic mice.

Conclusions: Taken together, our data suggest that Sirt-1-induced deacetylation of HIF-1α may have protective effects against tubulointerstitial damage in aged kidney.

Podocyte-Specific Knockout of the Transcriptional Factor C/EBPα Aggravates Podocyte Senescence and Kidney Injury in Aging Mice

Liwen Zhang,[1] Fangfang Zhou,[1] Liu Jian,[2] Xialian Yu,[3] Yunzi Liu,[1] Weiming Wang.[1] *[1]Department of Nephrology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]Ruijin Hospital, Shanghai, China; [3]Ruijin Hospital Institute of kidney research, Shanghai, China.*

Background: CCAAT/enhancer binding protein α (C/EBPα) is a widely expressed transcriptional factor, participating in regulation of metabolism, inflammation and differentiation. We have previously showed that C/EBPα expression was suppressed in glomerular cells, particularly in podocytes, in focal segmental glomerulosclerosis (FSGS), and have demonstrated its anti-inflammatory effects in FSGS in *vivo* and in *vitro*. And as terminally differentiated cells, podocytes are vulnerable to stress and play a central role in kidney aging. However, the specific role of C/EBPα in kidney aging remains undefined.

Methods: By crossing floxed C/EBPα mice with Pod-Cre mice, we generated podocyte-specific C/EBPα knockout mice. Both the homozygous transgenic mice (KO) and their wild-type littermates (WT) were sacrificed at 3 and 20 months of age as young and aging groups, respectively. Immortalized mouse podocyte line with transient C/EBPα overexpression and induced senescence by adriamycin (ADR) were used for in vitro experiments.

Results: KO-Young kidneys showed little morphological or gene expression change except reduced C/EBPα compared to WT-Young kidneys. In WT-Aging mice, foot process effacement, positive senescence-associated β-galactosidase (SA-β-Gal) staining accumulation in podocytes, glomerulosclerosis and tubular basement membrane thickening occurred, accompanied by epithelial-mesenchymal transdifferentiation and AMPK-SIRT1-PGC1α-mitochondria axis inhibition in tubular cells. These were aggravated in KO-Aging mice, as well as significant albuminuria and decreased podocyte markers occurred. In ADR induced senescent model in cultured podocytes, C/EBPα was down-regulated, and vimentin, CTGF, VEGFA and IL-6 increased. These phenotypes was rescued by C/EBPα overexpression.

Conclusions: These findings suggest that loss of C/EBPα accelerates podocyte senescence, aggravating glomerulosclerosis and tubular injury in aging mice. Targeting C/EBPα in podocytes may be a novel strategy for improving kidney aging.

SA-PO734

Hospitalizations within the First Year and Survival in Patients Aged Above 80 Who Start Dialysis in Emergency

Patrick Saudan,[1] Cyrielle Alves,[1] Amalie Frandsen,[2] Thomas Ernandez,[1] Pierre-Yves F. Martin.[1] *[1]Division of Nephrology, Geneva University Hospitals, Geneva, Switzerland; [2]SZO Visp, Zeneggen, Switzerland.*

Background: Implementation of dialysis in octogenarians is a debated question on account of an unfavourable short-term prognosis. We therefore analyzed what is the impact of planned implementation versus emergency dialysis on first year hospitalizations and survival in this population.

Methods: During the past 16 years, all patients who started maintenance dialysis in our unit were reviewed. Patient's demographic and clinical characteristics were collected. Emergency implementation of maintenance dialysis was defined as no prior referral to a nephrologist one month before starting dialysis.

Results: From 2000 to the end of 2016, 684 patients started maintenance dialysis in our unit, of whom 96 were aged 80 and above. Mean age was 83 ± 2.4 years. Hemodialysis and peritoneal dialysis were implemented in 78 and 18 patients respectively. There were 66% male, 33 % diabetic and median eGFR at start of dialysis was 8± 3 ml/min. Emergency dialysis was implemented in 44% of the patients. Overall mean survival was 33 ± 3 months. One-year mortality was 36.4% in referred patients who had emergency dialysis and 11.5% patients with planned dialysis. One-year mean survival was 334±12 days in patients with planned dialysis implementation versus 274± 21days in those who had emergency dialysis ($p< 0.004$). In a multivariate analysis including prior referral, age, gender, comorbidity score and dialysis modality, one-year survival was only associated with prior referral (HR: 0.36; 95% CI. 013-0.98). In patients with planned dialysis implementation, one -year hospitalization-free days were 269±108 versus 212± 136 days in those who had emergency dialysis ($p< 0.03$).

Conclusions: Prior referral to nephrologists substantially increase one-year hospitalization-free days and survival after dialysis implementation in ESKD patients aged above 80.

SA-PO735

Risk of the Dialysis Disequilibrium Syndrome in Japanese Elderly

Saeko Kagaya-Takeuchi,[1] Hiroyuki Sato,[1] Gen Yamada,[1] Yoichi Takeuchi,[2] Tasuku Nagasawa,[2] Mariko Miyazaki.[2] *[1]Japanese Red Cross Ishinomaki Hospital, Ishinomaki, Japan; [2]Tohoku University Hospital, Sendai, Japan.*

Background: In Japan, there is an increased number of elderly patients with end-stage renal disease (ESRD). Elderly patients are more likely to develop a dialysis disequilibrium syndrome (DDS). To improve their quality of life, recognizing the mild symptoms of DDS is necessary. High level of blood urea nitrogen and severe metabolic acidosis are regarded as risk factors of DDS, but the accurate incidence of them remains unclear in Japan. Here, we aim to evaluate the incidence and risk of mild to severe DDS for the well-managed ESRD patients in a single facility.

Methods: A total of 75 ESRD patients aged over 65 years were included, who had undergone scheduled hemodialysis after arteriovenous fistula creation at our hospital from 2015 through 2017. The DDS, or primary outcome, is defined as the mild to severe symptoms developing at the first dialysis treatment like headache, nausea and/or vomiting, appetite loss, muscle cramp, psychomotor agitation, and convulsions. Demographics and clinical data obtained before first dialysis were assessed as covariates to calculate the adjusted odds ratio in the multivariate analysis.

Results: The DDS was observed in 23 of 75 patients of interest. Headache was the most common symptom of them. Logistic regression model revealed that low level of eGFR, excessive fluid removal, and non-medication of sodium bicarbonate were independently associated with DDS in the ESRD elderly. Oral sodium bicarbonate was administered to 36 patients. Significant difference was found in serum [HCO_3^-] between two groups with and without oral sodium bicarbonate (median 19.7 mEq/L [IQR: 13.1 - 29.1] vs. median 17.0 mEq/L [IQR: 6.70 - 27.7], $P = 0.015$) using Mann-Whitney U test. These suggested that efficient dose of bicarbonate were taken in the ESRD patients. After adjustment for covariates, oral sodium bicarbonate for preventing metabolic acidosis significantly reduced the incidence of primary outcome (adjusted odds ratio 0.21 [95%CI: 0.06 - 0.77], $P = 0.019$).

Conclusions: At the first dialysis treatment for the ESRD elderly, we should pay attention to metabolic acidosis as a risk developing DDS. The effectiveness of oral sodium bicarbonate is necessary to be examined by prospective studies.

SA-PO736

Outcomes Among Those Receiving Veterans Affairs (VA) Insurance in the United States

Scott Reule,[1,4] Donal J. Sexton,[3] Robert N. Foley.[2] *[1]Medicine, University of Minnesota, Minneapolis, MN; [2]University of Minnesota, Minneapolis, MN; [3]The Irish Longitudinal Study on Ageing (TILDA), Trinity College Dublin., Dublin, Ireland; [4]Medicine, Department of Veterans Affairs, Minneapolis, MN.*

Background: Recent policy initiatives seek to address barriers to subspecialty care for veterans based on clinic wait times and geographic distance through a mechanism of outsourcing to community providers. Due to limited Veterans Health Care Service (VAHCS) capacity to provide care to those with end-stage kidney disease (ESKD), we set out to describe characteristics, trends and important healthcare outcomes among Veterans Affairs (VA) insured patients from 1995-2012.

Methods: United States Renal Data System (USRDS) combined with United States (US) census data was used to compare baseline characteristics and adjusted outcomes for mortality and transplantation among those initiating maintenance renal replacement therapy receiving VA insurance.

Results: A total of 32,035 VA insured patients initiated maintenance RRT over the time period of 1995-2012 with follow up extending to June 30th, 2014. Compared to 1995-1996, overall incidence of RRT initiation increased in a linear fashion (IR 1.94, 2011-2012). Subgroups experiencing the greatest increase included those > 65 years of age (IR 2.16), female (IR 2.54), and white patients (IR 2.35). Compared to 1995 - 2004, VA insured patients initiating between 2005 – 2012 were more likely to be 40-64 years of age (51.3% vs. 50%), > 65 years of age (47.3% vs. 46.4%), and less likely to be female (8.4% vs. 9.4%) or Hispanic (8.7% vs. 10.9%). No difference in mortality hazard was observed in demography adjusted models (AHR 1.03; CI 0.99 – 1.08), however, VA insured patients were more likely to be listed for (AHR 1.23; CI 1.10 – 1.37) and to receive kidney transplantation (AHR 1.19; CI 1.03 – 1.38).

Conclusions: In conclusion, VA insured patients initiating RRT has increased significantly in recent years. While older patients are increasingly likely to have initiated RRT in recent years, the finding of no mortality difference in adjusted models is reassuring.

SA-PO737

Impact of Hemodialysis Hours on Outcomes in Elderly Hemodialysis Patients

Emily K. Yeung,[3] Kevan Polkinghorne,[1] Matthew A. Roberts.[2] *[1]Monash Medical Centre and Monash University, Melbourne, VIC, Australia; [2]Eastern Health and Monash University, Melbourne, VIC, Australia; [3]Monash Health, Melbourne, VIC, Australia.*

Background: Longer treatment time is associated with improved outcomes in hemodialysis (HD) patients. Longer treatment times pose additional challenges in the elderly, who are more likely to suffer from conditions like arthritis which make sitting for long periods uncomfortable. The aim of this study is to determine whether or not a mortality benefit exists with longer treatment time in elderly (age ≥ 65 years) HD patients.

Methods: Data was obtained from the Australia and New Zealand Dialysis & Transplant Registry. Incident patient on thrice weekly HD were included if they were ≥65 years of age at HD commencement. Subjects entered the analysis at 90 days after start of HD. The exposure of interest was treatment time (hours per HD session) at HD commencement categorised into 5 groups. The primary outcome was all-cause mortality. Censoring events were transplantation, switch to another dialysis modality, recovery of kidney function, or loss to follow up. Cox regression models adjusting for age and treatment time and age interaction were assessed.

Results: 8992 subjects were included in the analysis with 30541 person-years of data. The incidence rate of death was 16 per 100 person-years. The risk of death decreased with increasing duration of dialysis. However, inclusion of age in the model attenuated this association. The interaction of age and hours was not significant (p=0.895). Inclusion of gender in the model did not alter associations.

Conclusions: Longer treatment times are associated with reduced risk of mortality in a dose-response relationship. However, once adjusted for age, there is no longer a significant mortality benefit to longer hours. This suggests that in the elderly, longer dialysis hours may not reduce mortality risk, and other factors such as quality of life should be considered in a dialysis prescription.

	Unadjusted HR (95% CI)	p-value	Adjusted HR (95% CI)	p-value
Age	1.03 (1.02-1.04)	<.001	1.05 (1.04-1.06)	<.001

SA-PO738

Associations of Cognitive Function and Education Level with All-Cause Mortality in Adults on Hemodialysis: The COGNITIVE-HD Cohort Study

Anita van Zwieten,[1,2] Germaine Wong,[1,2] Marinella Ruospo,[3,4] Armando Teixeira-Pinto,[1,2] Clement Loy,[1,6] Jonathan C. Craig,[1,2] Giovanni F. Strippoli.[3,5] The COGNITIVE-HD Study Investigators *[1]Sydney School of Public Health, University of Sydney, Sydney, NSW, Australia; [2]Centre for Kidney Research, Kids Research Institute, Children's Hospital at Westmead, Westmead, NSW, Australia; [3]Diaverum Medical Scientific Office, Lund, Sweden; [4]Division of Nephrology and Transplantation, Amedeo Avogadro University of Eastern Piedmont, Novara, Italy; [5]Department of Emergency and Organ Transplantation, University of Bari, Bari, Italy; [6]Huntingdon Disease Service, Westmead Hospital, Westmead, NSW, Australia*.

Background: Cognitive impairment is common in dialysis patients and is associated with lower education levels. Associations of cognitive impairment and education with mortality in dialysis patients are understudied. We aimed to assess the association between cognitive function and all-cause mortality in adults on hemodialysis, and the independent and interactive effects of education.

Methods: We recruited adult hemodialysis patients from 20 centers in Italy, assessing their cognitive function on 5 domains (memory, attention, executive function, language, perceptual-motor function) with 10 neuropsychological tests, and their self-reported education. We examined associations of cognition (any domain impaired, number of domains impaired, global score from principal components analysis of all tests) and education with all-cause mortality in multivariable Cox models.

Results: Of 958 patients, 676 participated (70.6%). Patients' median age was 70.9 years (IQR: 59.9-78.1) and 262 (38.8%) were female. Education levels were 338 (50.0%) primary/less, 163 (24.1%) lower secondary, 175 (25.9%) upper secondary/higher. Of 664 with data, 527 (79.4%) were impaired on at least 1 domain. Median follow-up was 3.3 years (IQR: 1.9-3.6) and there were 206 deaths in 1874.2 person-years. Adjusted HR (95% CI) for cognition were: 1.77 (1.07-2.93) for any impairment (referent: none, N=630); 1.48 (0.82-2.68) for 1 domain impaired, 1.88 (1.01-3.53) for 2 domains, 2.01 (1.14-3.55) for 3 or more (referent: none, N=564); 0.68 (0.51-0.92) per standard deviation increase in global cognitive score (N=429). Adjusted education HR (95% CI) were 0.94 (0.61-1.45) for lower secondary and 1.49 (1.02-2.18) for upper secondary/higher (referent: primary/less, N=630). The cognition-by-education interaction was not significant (p=.691).

Conclusions: Cognitive impairment appears to predict mortality in hemodialysis patients.

SA-PO739

Validation of Indices Predicting 6 Month Mortality for Incident Dialysis Patients Over 75

Bjoerg Thorsteinsdottir,[1] LaTonya J. Hickson,[1] Rachel Giblon,[1] Natalie B. Connell,[1] Ladan Zand,[1] Navdeep Tangri,[2] Robert C. Albright.[1] *[1]Mayo Clinic, Rochester, MN; [2]Nephrology, Seven Oaks General Hospital, Winnipeg, MB, Canada*.

Background: Prognosis is one of the pinnacles of shared decision making. Much research has been done in the development of valid prognostic tools for mortality in patients on dialysis, however the performance and clinical applications of these tools in elderly incident dialysis patients remains to be determined. We aimed to find the best performing prognostic tool for short term mortality in elderly incident dialysis patients.

Methods: Six validated indices (Foley, NCI, REIN, newREIN, Thamer, and Wick) were identified in a systematic review for short term mortality prediction in incident dialysis patients. We applied these indices to an established cohort of 349 incident dialysis patients who were >75y old and used each to predict 6 month mortality. Variables were extracted from the medical record, and missing variables were imputed. Models were compared using the c-statistic, i.e. area under the receiver operating characteristic curve (ROC). Sensitivity and specificity were also calculated.

Results: The average age of our population was 81.5 years, 65.9% male, median survival was 351 days. The ROC ranged from 0.57 to 0.73, with the Foley and Wick indices performing the best, see Figure 1. The following cutoff scores yielded a specificity of >50% and >90% respectively in predicting mortality: Foley 7 and 10, NCI 4 and 10, REIN 4.2 and 8.2, REIN_new 12.1 and 16.4, Thamer 4.2 and 6.5, Wick 6 and 10. Sensitivity ranged from 45.8-76.4 for 50% mortality prediction with Wick having highest sensitivity and 9.0-22.0 for 90% mortality with Foley having highest sensitivity.

Conclusions: Most of the indices can predict which patients are more likely than not to die within 6 months of dialysis start with acceptable sensitivity and specificity. Higher cutoff scores can be used to predict death with high specificity (>90%) but at the considerable loss of sensitivity. The Wick and Foley indices performed best.

SA-PO740

Prognosis in Shared Decision Making for Advanced CKD: A Qualitative Study

Bjoerg Thorsteinsdottir,[1] LaTonya J. Hickson,[1] Susan H. Curtis,[2] Annika Beck,[3] Brigid M. Amberg,[3] Nataly R. Espinoza,[3] Cristina Wirtz,[3] Ladan Zand,[1] Erin Dahlen,[3] Kevin Shaw,[3] Ian G. Hargraves,[3] Robert C. Albright.[1] *[1]Mayo Clinic, Rochester, MN; [2]Mayo clinic, Rochester, MN; [3]Mayo Clinic, Rochester, MN*.

Background: Prognostic information is key to shared decision making. Efforts are underway to enhance and implement prognostic tools for prediction of CKD progression and mortality. Whether patients are receptive and value such individualized risk predictions is unclear.

Methods: Semi-structured telephone or in-person interviews were conducted following routine visits to a multidisciplinary CKD clinic. Each patient was asked about his or her perspectives and experiences related to sharing dialysis risk prediction and prognosis with patients. Interviews were audiotaped, transcribed verbatim, and analyzed. Our team engaged in line-by-line, open, axial, and selective coding followed by content analysis.

Results: We enrolled 19 patients stage 3b-5, age 67-89 (avg. 78.57), 74% men. Often patients dreaded the possibility of starting dialysis, considering it a "last resort." Most patients understood that dialysis would impose significant limitations on their freedom. Almost all patients reported that they wanted to receive (or would not object to) a prediction of their risk of progressing to dialysis, even if it would be "kinda scary." Patients reported this could help them "plan for the future" and motivate them to adhere to preventive measures, but noted that the prediction might be upsetting to some. There was less agreement about the value of receiving a life expectancy prediction. Patients suggested that it should be offered only when a patient requests it or agrees to it. A life expectancy prediction would help patients "make an informed decision" about how to treat their CKD, and help them make preparations for the end of life if needed. We identified that several patients conflated the risk of progression to dialysis with the risk of death, equating refusing dialysis with rapid death.

Conclusions: This prospective patient-centered qualitative study confirms previous survey results suggesting that CKD patients are interested in prognostic information. Furthermore our findings add context and depth to the value of risk prediction in the clinical encounter and suggest ways in which to address individualized prognosis with patients. This can help further the development of intuitive shared decision making tools to relay this information to the patients who want it.

SA-PO741

Factors Affecting Mortality in the Very Elderly on Haemodialysis – A Single Centre Study

Tayeba Roper,[1] Thomas G. De'Ath,[2] Maggi Steele,[1] Joe Wang,[3] David Makanjuola.[4] *[1]Epsom & St Helier NHS Trust, Surrey, United Kingdom; [2]Epsom and St Helier NHS Trust, London, United Kingdom; [3]Epsom & St Helier Hospital NHS Trust, London, United Kingdom; [4]St. Helier Hospital, Carshalton, United Kingdom*.

Background: The number of elderly patients currently managed on haemodialysis (HD) is increasing. We aimed to determine the outcome of very elderly patients (over the age of 85 years) on HD and to identify any factors associated with mortality in this group.

Methods: Data were retrospectively collected from a single UK centre over 11 years (2003-2014). HD dependence was defined as those requiring HD for more than 90 days. All patients starting HD at the age of 85 years or over were included. Demographics, reasons for starting HD, access at initiation and co-morbidities were recorded. The Davies Co-morbidity Score (DCS) was used to quantify co-morbidities in patients. Outcomes were of death, recovery of function and continued HD. Chi-square tests were used for categorical analysis of DCS.

Results: Of 149 patients, 144 were included (5 excluded due to lack of data). Age ranged from 85 to 98 years (modal age 85.04). 73.6% were male. Time on HD ranged from 95 - 2598 days (median 546 days). Overall mortality at 1-year was 18.8% (18.2% for 85-90 years and 25% for over 90 years). 74.3% started HD with a line and 25.7% with an arterio-venous fistula (AVF): A higher 1-year mortality (16.7%) was seen in the former group compared to the latter (2.1%). Overall 72.2% were non-diabetic (ND) with mortality at 1-year being 16.0% compared to 2.8% in diabetic patients. Mortality according to DCS is shown in Table 1. There was no significant difference in 1-year mortality between DCS groups (p >0.05).

Conclusions: Our HD cohort demonstrates better overall 1-year survival than that of the UK Renal Registry 2015 (71% in 85+ years). Type of HD access was the most important factor affecting mortality. Though the reasons for this are varied, HD via a line may reflect a more acute decline in renal function. DCS and diabetes were not independent predictors of mortality in this cohort. It may be that, in this age group, traditional markers of renal progression are no longer relevant. Further work is needed to look at other markers of survival and HD benefit in this age group, such as frailty and quality of life scores, to aid decision making with regards to HD in the very elderly.

Table 1

Davies Co-morbidity Score	1-year Mortality (%)

SA-PO742

Prognostic Value of a Geriatric Assessment in Older Patients Starting Dialysis

Ismay N. Van Loon,[1,2] Namiko A. Goto,[3] Frans T. Boereboom,[1,4] Marianne C. Verhaar,[3] Marije Hamaker.[4] *[1]Dianet Dialysis Center, Utrecht, Netherlands; [2]Department of Nephrology and Hypertension, University Medical Center Utrecht, Utrecht, Netherlands; [3]University Medical Center Utrecht, Utrecht, Netherlands; [4]Diakonessenhuis, Utrecht, Netherlands.*

Background: A geriatric assessment (GA) is a structural method for identifying frail patients. The prognostic value of a GA in end-stage kidney disease (ESKD) is not known. The subject of the GOLD (Geriatric assessment in OLder patients starting Dialysis) Study was to assess the relation of GA at dialysis initiation with poor outcome.

Methods: Patients ≥65 years old were included just prior to dialysis initiation. All underwent a GA, including assessment of ADL, instrumental (i)ADL, mobility, cognition, mood, nutrition, comorbidity, and a frailty screening (Fried Frailty Index, FFI). Quality of life (QoL) was scored with the visual analogue scale of the EuroQol-D5 (ranging from 0 [poor] to 10 [good]). Outcome measures were 6-and 12-months mortality, and 6-month hospitalization and change in QoL. Mortality was assessed with cox-regression and hospitalization with logistic regression, adjusting for age, sex and comorbidity.

Results: 192 patients were included, mean age 75±7 years, of whom 48% had ≥ 3 geriatric impairments and were considered frail. Mortality rate was 8% and 15% for 6-and 12-months. ADL, depressive symptoms and malnutrition were significantly related to 1-year mortality. Compared to non-frail patients, 1-year mortality risk was higher in patients with ≥ 3 impairments (HR 2.61 [95%CI 1.14-5.98]). Frailty was associated with lower baseline QoL (6.0±1.4 vs. 6.6±1.4, p=0.01), but not with 6-month change (overall improvement +0.3±1.4, p<0.01). Depressive symptoms, ADL and iADL were associated with hospitalization, but overall GA was not. Screening for frailty with the FFI resulted in 44% frail patients and FFI was related to mortality (HR 4.5 [95%CI 1.44-14.36) and hospitalization (OR 1.93 [95%CI 1.00-3.72]).

Conclusions: Geriatric impairment at dialysis initiation is related to mortality, hospitalization and QoL. A GA offers the advantage of both risk assessment and identification of potential targets for intervention and improving QoL. Whether these results contribute to decision-making in the pre-dialysis population should be the subject of further research.

Quality of Life After Initiation of Dialysis or Maximal Conservative Management

Ismay N. Van Loon,[2,1] Namiko A. Goto,[3] Frans T. Boereboom,[2,4] Marianne C. Verhaar,[3] Marije Hamaker.[4] *[1]Nephrology%Hypertenstion, University Medical Center Utrecht, Utrecht, Netherlands; [2]Dianet Dialysis Center, Utrecht, Netherlands; [3]University Medical Center Utrecht, Utrecht, Netherlands; [4]Diakonessenhuis, Utrecht, Netherlands.*

Background: Maximal conservative management (MCM) may be an appropriate option for dialysis in some elderly patients with end stage kidney disease (ESKD). Whether MCM offers a better quality of life (QoL) compared to dialysis is not known. In the GOLD (Geriatric assessment in OLder patients starting Dialysis) Study the trajectory of QoL was assessed in patients starting dialysis or MCM.

Methods: Patients ≥65 years old were included just prior to dialysis initiation or after decision for MCM. Baseline data included demographics, QoL (EuroQol-D5 visual analogue scale [VAS], 0[poor]-10[good]) and geriatric impairment: mobility, (instrumental) ADL, mood, cognition, nutrition and comorbidity. Six-months follow-up data included QoL, mortality and hospitalizations. In both groups, logistic regression was used to assess the relation between impairment and deterioration of QoL (≥1 point), adjusting for age, sex, comorbidity and baseline QoL.

Results: The cohort comprised 192 dialysis (23% PD) and 88 MCM patients. The MCM patients were older (mean age 82±6 vs. 75±7 years, p< 0.01) and mean kidney function was better (eGFR 11.5±4.0 vs. 8.0±2.9 ml/min/1.73m^2, p<0.01). In both groups, poorer QoL was significantly associated with impairment in (i)ADL, mobility and mood; in dialysis patients also with comorbidity. Baseline QoL did not differ between dialysis and MCM (6.3±1.3 vs.6.3±1.4 respectively; p=0.91) and change in QoL was +0.3±1.4 (p< 0.01) and -0.4±1.4 (p<0.01) respectively. At 6 months follow-up, 8% of patients starting dialysis had died and Qol in 23% deteriorated, while 40% showed improved QoL. This was 18%, 31% and 15% respectively in MCM. Impairments were not associated with deterioration in QoL in both groups. Hospitalization differed relevantly (24% in MCM vs. 51% in dialysis; p< 0.01).

Conclusions: QoL was comparable for patients starting dialysis and MCM. Small improvement of QoL after dialysis start was seen. For MCM, QoL slightly decreased after six months. Geriatric impairment is associated with baseline QoL, but not with deterioration after start of dialysis or MCM.

Identification and Prioritization of Quality Indicators for Conservative Kidney Management

Tyrone Harrison,[1] Helen Tam-Tham,[2] Brenda Hemmelgarn,[2] Matthew T. James,[2] Aynharan Sinnarajah,[2] Chandra M. Thomas.[2] *[1]Medicine, University of Calgary, Calgary, AB, Canada; [2]University of Calgary, Calgary, AB, Canada.*

Background: Conservative kidney management (CKM) is comprehensive patient-centred care for individuals with end-stage renal disease (ESRD) without renal replacement therapy. CKM focuses on delaying progression of kidney disease, symptom management, and frequent communication and support. Currently there is no consensus as to what constitutes high quality CKM. We aimed to develop a consensus-based set of quality indicators (QIs) for the conservative management of ESRD.

Methods: A nominal group technique study of patients and caregivers was used to identify and prioritize QIs for CKM, guided by QIs reported in the literature. A Delphi process with healthcare providers was used to rate the QIs using a 9-point Likert scale, in a series of four rounds, until consensus was reached based on pre-specified criteria. Consensus for the QIs in the Delphi process was met if the mean rating on the Likert scale was ≥7.0 and percent agreement was >75%.

Results: Sixteen patients and caregivers from Calgary, Canada participated in two nominal group meetings. Ninety-one multidisciplinary healthcare providers from 10 countries took part in the Delphi process. Patients and caregivers prioritized QIs focused on quality of dying and access to CKM personnel. Healthcare providers prioritized 99 QIs (out of a total 160) that met consensus criteria for inclusion. Nearly all (98.7%) participating healthcare providers indicated that quality of CKM delivery was important to measure, though less than a third (32.1%) measured quality in their provision of CKM. The most highly rated QI in the Delphi process was the "percentage of patients that die in the place they desire." There were several limitations as participants were largely from high-income, English-speaking countries, and most had structured CKM programs in place.

Conclusions: Quality of CKM care is important to patients, caregivers, and healthcare providers, though differences in priorities were noted. CKM programs and healthcare providers can use this international consensus-based QI list to evaluate and modify their CKM program delivery.

SA-PO745

Patient-Reported Experiences of a Shared Decision-Making Process on Dialysis or Conservative Care

Wouter Verberne,[1] Willem Jan W. Bos.[1,2] *[1]St Antonius Hospital, Nieuwegein, Netherlands; [2]Leiden University Medical Center, Leiden, Netherlands.*

Background: Older patients approaching end-stage renal disease face the decision whether to start dialysis, or conservative care (CC)—which is argued to be a reasonable treatment option, particularly in the oldest old and those with severe comorbidity. Shared decision-making has been recommended to align treatment plans with the patient's values and preferences. Little is known regarding experiences of patients with such decision-making process.

Methods: We developed a questionnaire in collaboration with the Dutch Kidney Patients Association to assess older patients' experiences of their decision-making process on choosing dialysis or CC. We included 99 patients with stage 4/5 CKD and aged ≥70 years, who had chosen dialysis (n=75) or CC (n=24). A shared decision-making process had been initiated by a multidisciplinary team when the estimated glomerular filtration rate fell below 20 mL/min/1.73m^2, and included in-depth discussions in which oral and/or written information was given about dialysis and CC.

Results: Overall, patients stated to be satisfied with the decision-making process (median score on a 11-point Likert scale; dialysis group: 8.0 vs. CC group: 9.0; p = 0.06), as well as with their treatment decision (8.0 vs. 9.0; p = 0.07). Most felt they had enough time (79% vs. 87%) and information (80% vs. 73%) to make a decision, although factors as more time, information, and deliberation were mentioned as potential improvements. Patients choosing dialysis reported life prolongation and feeling of lack of choice as important

reasons for their decision, whereas quality of life and treatment burden were important reasons in choosing CC. 53% of the patients in the dialysis group considered their own opinion as most important in their treatment choice compared to 95% in the CC group (p = 0.003). More patients in the dialysis group felt forced by the situation to make a decision (32% vs. 4%; p = 0.01), or still doubted their treatment decision (17% vs. 0%; p = 0.03).

Conclusions: In this small Dutch sample, older kidney patients reported to be overall satisfied with a shared decision-making process on choosing dialysis or CC, although some had important recommendations for improvement. Patients had contrasting reasons for their treatment choice. Patients choosing CC experienced more autonomy and ownership in their decision-making.

Shared-Decision Making and Renal Supportive Care: A Patient-Centered Clinical Trial

Mark L. Unruh,[1] Sarah L. Goff,[2] Jamie Klingensmith,[2] Nwamaka D. Eneanya,[4] Kelly Chong,[1] Michael J. Germain,[5] Lewis Cohen.[3] *[1]University of New Mexico, Los Ranchos, NM; [2]University of Massachusetts Medical School - Baystate, Springfield, MA; [3]Baystate Medical Center, Springfield, MA; [4]Massachusetts General Hospital, Boston, MA; [5]Renal and Transplant Assoc of New England, Hampden, MA.*

Background: End-of-life (EOL) care planning in ESRD patients occurs infrequently, contributing to decreased quality of care and patient suffering. ESRD patients are much more likely to receive intensive care and less likely to receive hospice than other chronic conditions. The SDM-RSC study sought to create an easily replicable patient-centered model for EOL care planning discussions in dialysis units and to determine impacts on hospice use, EOL advanced planning, and to assess effect on patient quality of life.

Methods: We selected participants who were receiving maintenance hemodialysis and had poor prognoses using a validated prognostic instrument. Social workers and nephrologists received separate ACP training prior to inception of the intervention. Nephrologists participated in a one-hour training session that included reviews of mortality rates and ACP for hemodialysis patients. The social worker received a one-day training session and four additional telephonic "booster" sessions over two years. The intervention visit consisted of an initial patient and family meeting involving a dialysis social worker, and nephrologist; followed by ongoing contacts by the social worker and hospice contacts to dialysis units. We examined clinic-level data using an interrupted time-series design to assess changes in hospice usage over time.

Results: We recruited 125 participants from 18 dialysis units in 3 states. Our sample was 51% male, median age=70, 12% African-American, 14% American Indian, 46% White; and 37% Hispanic ethnicity. Overall clinic-level hospice usage did not vary significantly between pre- and post-intervention periods (observed average rate=25%). In participants that died during the study period, 48% stopped dialysis prior to death and 43% received hospice services. Of enrolled participants with follow-up, 75% had completed a healthcare proxy; 63% completed Medical (or Physician) Orders for Life-sustaining Treatment (MOLST/POLST). Quality of life indicators did not change significantly within 6 months of the initial meeting.

Conclusions: Clinic level effects of the intervention were not observed. There were important changes in EOL care planning for individuals, including completion of advanced care planning documents. The SDM-RSC intervention used existing staff at clinics making it practical to replicate.

Palliative Care Use and Patterns of End-of-Life Care in Hospitalized Patients with Calciphylaxis

Kabir O. Olaniran, Shananssa Percy, Sagar U. Nigwekar, Nwamaka D. Eneanya. *Division of Nephrology, Massachusetts General Hospital, Boston, MA.*

Background: Calciphylaxis (CUA) is a rare debilitating condition that is associated with poor quality of life and significant morbidity and mortality. Given that palliative care referrals are scarce in this population, we investigated the frequency of palliative care referrals and patterns of end-of-life (EOL) care in hospitalized CUA patients.

Methods: We included patients with CUA (confirmed by skin biopsy or clinical diagnosis via chart review) who were admitted to a large health care system in Boston, MA and died between 1/2014-4/2018. Terminal admissions were identified by chart review and outcomes included palliative care consultation, opiate use, receipt of cardiopulmonary resuscitation, mechanical ventilation, tube feeds, and vasopressor therapy, hospice referral, and place of death.

Results: Thirty CUA patients were identified. Seven percent had chronic kidney disease and 87% received dialysis. The median age at diagnosis was 60(15) years, 53% were female and 80% were White. The median Charlson Comorbidity Index score was 6(3) and median follow-up time was 63(104) days. Outcomes are displayed in Table 1.

Conclusions: Among CUA patients that died during the study period, less than half received palliative care consults and many patients received intense care prior to death. Furthermore, a minority of patients were referred for hospice care prior to death. Our data highlights the need for improved integration of palliative care to decrease care intensity and improve quality of EOL care for this seriously ill patient population.

Outcomes in Terminal Admissions

Outcomes	Terminal (N = 30)
Palliative care consultation	14 (47%)
Opiate use	25 (83%)
Cardiopulmonary resuscitation	5 (17%)
Mechanical ventilation	11 (37%)
Tube feeds	5 (17%)
Vasopressor therapy	10 (33%)
Hospice referral	8 (27%)
Place of death	
Inpatient ward	7 (23%)
Intensive care unit	13 (43%)
Inpatient hospice	4 (13%)
Unknown	6 (20%)

SA-PO748

In-Center Extended-Hour Hemodialysis Can Be Effective in Improving the Mortality of Elderly Dialysis Patients

Masaki Okazaki,[1] Daijo Inaguma,[2] Takahiro Imaizumi,[1] Manabu Hishida,[1] Takaya Ozeki,[1] Yoko Kubo,[1] Yoshinari Yasuda,[1] Sawako Kato,[1] Naotake Tsuboi,[1,2] Hiroshi Kaneda,[3] Shoichi Maruyama.[1] *[1]Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Fujita Health University School of Medicine, Toyoake, Japan; [3]Kamome Clinic, Yokohama, Japan.*

Background: Amid the global problem of aging among dialysis patients, it has become more difficult to improve prognosis among dialysis patients. Despite previous reports that the extended-hour hemodialysis (HD) can reduce the risk of death, the impact of this treatment on elderly patients remains unclear. The aim of this study is to investigate the effect of extended-hour HD on elderly patients, using largest cohort of incident extended-hour HD in Japan.

Methods: Multicenter retrospective cohort study; we included 205 consecutive patients who had received in-center extended-hour HD since the initiation of HD in 4 facilities during Oct. 2008 to Sept. 2017 (extended-HD). We also included 1382 consecutive patients who initiated conventional HD in 17 facilities during Oct. 2011 to Sept. 2013 as the control group (conventional). Each treatment group was divided into two age subgroups (over or less than 70 years old). We compared the risk for mortality during the first 5 years of follow-up among the treatment groups and age subgroups.

Results: The mean age was 63.3±14 years in extended-HD and 68.1±13 years in conventional. The crude mortality in the extended-HD group was 3.9 deaths per 100 patient-years compared with 7.9 deaths per 100 patient-years in the conventional group. Extended-HD was associated with a 37% reduction in mortality after adjustment for age, sex, body mass index, diabetes, and cardiovascular disease (95% confidence interval (CI): 5-58%). In the subgroup analyses, elderly dialysis patients (>70 years old) treated with extended-HD had a 48% lower adjusted mortality than that of conventional (95% CI: 10-71%).

Conclusions: Especially for the elderly, treatment with extended-hour HD was associated with a lower risk of mortality compared to conventional HD.

Single Measurements of Fibroblast Growth Factor 23 and Clinical Risk Prediction in CKD

Daniel Edmonston,[1] Rupal Mehta,[2] Daniel Wojdyla,[9] Xuan Cai,[8] Claudia M. Lora,[3] Matthew R. Weir,[4] John W. Kusek,[10] Raymond R. Townsend,[5] Debbie L. Cohen,[5] Jiang He,[11] Alan S. Go,[6] Tamara Isakova,[7] Myles Wolf.[1] for the CRIC Study Investigators *[1]Duke University, Durham, NC; [2]Northwestern Univesrsity, Feinberg School of Medicine, Chicago, IL; [3]University of Illinois at Chicago, Chicago, IL; [4]University of Maryland School of Medicine, Baltimore, MD; [5]University of Pennsylvania School of Medicine, Villanova, PA; [6]Kaiser Permanente Northern California, Oakland, CA; [7]Feinberg School of Medicine, Northwestern University, Chicago, IL; [8]Northwestern University, Chicago, IL; [9]Duke Clinical Research Institute, Durham, NC; [10]NIDDK, Bethesda, MD; [11]Tulane School of Public Health and Tropical Medicine, New Orleans, LA.*

Background: Elevated fibroblast growth factor 23 (FGF23) levels are independently associated with a number of adverse outcomes in patients with chronic kidney disease (CKD) at the population level, but it is unknown if FGF23 testing can improve individual clinical risk prediction.

Methods: In 3879 participants in the Chronic Renal Insufficiency Cohort Study, we tested whether addition of a single baseline measurement of FGF23 testing to standard clinical risk predictors (Figure) significantly improves prediction of all-cause mortality, incident end-stage renal disease (ESRD), heart failure (HF) admission, and atherosclerotic events over periods of 3 (primary analysis), 5, and 8 years of follow-up. We assessed changes in C index, integrated discrimination improvement (IDI), relative IDI, and category-based net reclassification index (NRI). We also compared the incremental utility of FGF23 versus an analogous model using serum phosphate concentration.

Results: The base model best predicted incident ESRD and HF (Figure). The addition of FGF23 improved prediction of all-cause mortality and HF admissions by change in C index, IDI, and relative IDI (NRI trended towards significance), but not incident ESRD or atherosclerotic events (Figure). The years 5 and 8 results were qualitatively similar to the 3-year results. FGF23 outperformed phosphate for all outcomes.

Conclusions: In CKD, single measurements of FGF23 improves prediction of risks of all-cause mortality and HF admissions but not ESRD or atherosclerotic events. Future studies are needed to evaluate the predictive utility of repeated FGF23 testing.

Funding: NIDDK Support

Candidate variables included in base model

Candidate Variables			
Demographics	**Medical History**	**HTN Burden**	**Lab Values**
Age	Diabetes	Number of antihypertensive medications	Estimated GFR
Sex (male vs female)	Coronary artery disease	Systolic blood pressure	Albumin-to-creatinine ratio
Race (Black vs non-Black)	Heart failure		Serum albumin
Ethnicity (Hispanic vs non-Hispanic)	Stroke		Total cholesterol
	Smoking history		

FGF23 Model Discrimination Summary

Outcome	C Index		ΔAUC (95% CI)	IDI (95% CI)	Relative IDI (95% CI)	NRI (95% CI)

Even Low-Grade Proteinuria Increases Progression to Renal End-Points in Non-Diabetic Hypertensive Veterans

Olurinde Oni,[3] Virginia J. Savin,[2,1] Mukut Sharma,[2,1] Ram Sharma,[3] Thomas Wiegmann,[3] Rajat S. Barua,[3] Rishi Sharma.[4,2] *[1]Kidney Institute, Univ. of Kansas Medical Center, KANSAS CITY, KS; [2]KCVA Medical Center, Kansas City, MO; [3]KCVA Medical Center, Kansas City, MO; [4]Univ. of Missouri Kansas City, Kansas City, MO.*

Background: Proteinuria is an indicator of renal injury but there is little quantitative information about the predictive value of low concentrations of urine protein in patients without diabetes. We hypothesized that incremental risk would accrue with increasing proteinuria in hypertensive, non-diabetic patients.

Methods: A cohort of 153,848 hypertensive non-diabetic patients in the VA national database (VINCI) and recorded urinalysis was categorized as 'no proteinuria' or by first recorded urine protein (dip-stick: ≤30, 31-100, and >100 mg/dl) and by CKD stage. Endpoints included ESRD and all-cause mortality. Baseline characteristics were compared using ANOVA, Chi square tests and non-parametric tests. Adjusted Cox regression, and Kaplan Meier analyses were conducted to compare risks.

Results: Proteinuric groups had accelerated progression to ESRD and combined renal endpoint, and had increased all-cause mortality (Logrank P<0.01). Proteinuria < 30 mg/dl was associated with renal endpoint and had a relatively smaller effect than higher grades proteinuria. Younger age, higher CKD stage, prior diagnosis of AKI, or use of ACEI, ARB or β-blocker at first proteinuria were associated with higher risk of progression and all-cause mortality.

Conclusions: We conclude that, in non-diabetic Veterans with hypertension, even low concentrations of proteinuria predict renal failure and mortality and should not be ignored. Early identification of proteinuria as a risk will permit research regarding novel mechanisms of progression and may define interventions to delay progression and lower mortality.

Funding: Veterans Affairs Support

Adjusted Hazard ratios for Renal Endpoints

The Kidney Failure Risk Equation Predicts Progression to Hemodialysis in Cancer Patients with CKD

Luiz F. Souza,[1] Ivens S. L Leite,[1] Renato A. Caires,[2] Fernanda O. Coelho,[2] Francisco Z. Mattedi,[2] Veronica Torres,[2] Elerson Costalonga.[2,1] *[1]University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [2]Sao Paulo State Cancer Institute - USP, Sao Paulo, Brazil.*

Background: Cancer patients have a high prevalence of chronic kidney disease (CKD). The aim of this study was to assess prognostic factors for progression to hemodialysis (HD) in a cohort of cancer patients with CKD.

Methods: Among 397 outpatients with cancer referred to nephrology evaluation (2009-12), 202 had CKD according KDIGO definitions and at least 3 months of follow up. Clinical and biochemical data were retrieved from patient medical records. The primary endpoint was defined as progression to HD during follow up. The Cox regression was used to examine the association between the baseline features and progression to HD.

Results: Throughout a mean follow up period of 3.7±2.3 years, 10% of patients progressed to HD. Patients baseline features data are shown in Table 1. In the Cox regression analyses, the risk of HD estimated by the 4-variable Kidney Failure Risk Equation (aHR=1.05; 95% CI 1.03-1.06, p<0.001) was the strongest predictor of HD in our population after adjusments for CKD etiology.

Conclusions: In this cohort, traditional risk factors as hypertension, diabetes and albuminuria were associated with a greather risk of hemodialysis in univariated analysis. Beyond, the Kidney Failure Risk Equation was a good instrument for identifying a high risk of progression to HD among cancer patients with CKD.

Table 1. Baseline Features

	Hemodialysis (n=19)	No Hemodialysis (n=183)

Validation of the Kidney Failure Risk Equation in Primary Care Clinics in Southeast Asia

Yeli Wang,[1] Francis Nguyen,[2] John C. Allen,[3] Ngiap chuan Tan,[4] Tazeen H. Jafar.[1,2] [1]*Program in Health Services and Systems Research, Duke-NUS Medical School, Singapore, Singapore;* [2]*Health Services Research Centre, SingHealth, Singapore, Singapore;* [3]*Centre for Quantitative Medicine, Duke-NUS Medical School, Singapore, Singapore;* [4]*SingHealth Polyclinics, Singapore, Singapore.*

Background: Patients with chronic kidney disease (CKD) are at high risk of progression to end stage kidney disease (ESKD). The Kidney Failure Risk Equation (KRFE) was developed to accurately predict the progression of CKD to kidney failure. However, it has not been validated in primary care clinic settings in Asia. The objective of this study was to validate the predictive utility of KFRE for ESRD risk, and compare it with that of eGFR alone in polyclinics in Singapore.

Methods: Electronic health records were extracted from 9 government clinics on 117,528 patients aged 40 years or older visiting clinics during 1st Jan 2010 to 31st Dec 2012 with at least one measurement of serum creatinine or proteinuria. All patients with CKD-EPI estimated glomerular filtration rate (eGFR) <60 ml/min/1.73m^2 and proteinuria had KFRE evaluated using the 4-variable equation (age, sex, eGFR, ACR). ESRD was determined by linkage with Singapore Renal Registry. Area under the operating characteristics curves (AUC) was used to calculate the predictive utility for 5-year risk of ESRD with KFRE versus eGFR alone.

Results: A total of 17271 participants had eGFR <60 ml/min/1.73m^2 of whom 49% were men, 80% were Chinese, 12% were Indian and 4% were Malays. After a mean follow-up of 5 years, a total of 491 (2.8%) patients developed ESRD. The AUC (95% confidence interval) for KFRE and eGFR alone was 0.93 (0.92-0.94) and 0.89 (0.88-0.91), respectively.

Conclusions: The KFRE showed excellent predictive utility, which was better than eGFR alone for ESRD risk in this multi-ethnic population. We provided several thresholds below for the clinical decision making and implementation in primary care clinics in Singapore and possibly other Asian countries.

Funding: Government Support - Non-U.S.

Table. Summary statistics of different thresholds to assess discrimination for ESKD.

	KFRE AUC (95% CI): 0.93 (0.92-0.94)				CKD-EPI eGFR ml/min/1.73m^2 AUC (95% CI): 0.89 (0.88-0.91)

SA-PO753

Validation and Assessment of Kidney Failure Risk Equations in Korean Population

Min woo Kang,[1] Yong Chul Kim,[1] Jung Nam An,[2] Navdeep Tangri,[3] Kwon Wook Joo,[1] Yon Su Kim,[1] Jung Pyo Lee.[2] [1]*Seoul National University Hospital, Seoul, Republic of Korea;* [2]*Seoul National University Boramae Medical Center, Seoul, Seoul, Republic of Korea;* [3]*University of Manitoba, Winnipeg, MB, Canada.*

Background: Predicting the risk of chronic kidney disease (CKD) may facilitate early and appropriate nephrology care of CKD patients. Previously, kidney failure risk equations were developed in Canadian population and validated in more than 30 countries spanning 4 continents. However, there is no validation data in Korean population. Thus, we attmped to evaluate the accuracy of the risk equations in Korean population and to adjust the equation.

Methods: SNU cohort, including 1315 patients with CKD in Seoul National University Hospital (SNUH) and Seoul National University Boramae Medical Center (SNUBMC), were studied. These cohorts collected data from 2001 through 2016. With the risk factors from the original risk equations, hazard ratios were estimated in SNU cohort and used to adjust the equation. The time horizon for risk prediction was 5 years. We used three risk prediction equations, 4-variable, 6-variable and 8-variable equations. Then, these three equations were evaluated using AUROC for the goodness of a predictor, integrated discrimination improvement (IDI) for discrimination, and net reclassification improvement (NRI) at 5 years.

Results: The mean age of the study population was 58 years, and the mean baseline eGFR was 73 mL/min/1.73m2. The three risk prediction equations showed great performance of prediction (AUROC, 0.91; 95% CI, 0.88-0.94 at 4-variable equation, 0.91; 95% CI, 0.88-0.94 at 6-variable equation, 0.91; 95% CI, 0.89-0.94 at 8-variable equation). Using DeLong test, 4-variable equation and 6-variable equation were compared with at 8-variable equation. There was no improvement in performance with 8-variable equation (4-variable equation vs 8-variable equation, p=0.068 and 6-variable equation vs 8-variable equation, p=0.080)

Conclusions: Adjusted Kidney failure risk equation showed high performance of prediction in Korean population. However, further verification in a larger cohort may be necessary in the future.

Validation of Predictive Model for Progression of CKD to ESRF in Singapore

Jolyn H. Pang,[1] Jia Liang Kwek,[2] Huihua Li,[2] Lydia Lim wei wei,[2] Jason Choo Chon Jun,[2] Lina Choong,[2] Choong Meng Chan,[2] Marjorie W. Foo.[2] [1]*National University of Singapore, Singapore, Singapore;* [2]*Singapore General Hospital, Singapore, Singapore.*

Background: Risk stratification of chronic kidney disease (CKD) patients allows clinicians to individualize treatment and improves resource allocation on the national level. Tangri et al *(JAMA. 2011 Apr 20;305(15):1553-1559)* proposed and validated a predictive model for progression of chronic kidney disease to kidney failure in a Canadian population and subsequently in a meta-analysis of multinational cohorts. As accuracy of the prediction model may vary among different populations, we aim to validate this prediction model in a Singapore CKD cohort and to determine if a calibration factor is required.

Methods: The study population was derived from newly referred patients to Department of Renal Medicine at Singapore General Hospital (SGH), Singapore in 2009. Eight variables based on the most accurate model in the Tangri et al study were obtained within 90 days of the initial visit. Primary outcome measure is kidney failure in 5 years and time to kidney failure was defined from initial renal medicine visit to kidney failure.

Results: Out of 2216 patients reviewed, 795 were included in the analysis. The mean age is 65.8 years old, mean eGFR is 34.5ml/min/1.73m^2. Majority are Chinese (74.6%) with 15.5% Malay, 6.2% Indian, 1.1% Eurasian and 0.6% others (2 Thais, 1 Filipino, 1 Indonesian and 1 Arab). Six hundred and forty (80.4%) are on angiotensin converting enzyme inhibitor (ACEi) or angiotensin receptor blocker (ARB). Four hundred and ninety-seven (62.4%) have diabetes mellitus. Two hundred and twelve (26.7%) reached kidney failure. Mean time to renal failure is 1288 days (3.5 years). Both the 8-factor (age, gender, estimated glomerular filtration rate (CKD-EPI) (eGFR), albuminuria (ACR), serum albumin, serum phosphate, serum bicarbonate and serum calcium) and 4-factor (age, gender, eGFR and ACR) model are accurate (C-index 0.863 and 0.865 respectively) in predicting risk of kidney failure with the 8-factor model outperforming the 4-factor model (adequacy index of 98.8% vs 97.2%)

Conclusions: The predictive model developed by Tangri et al is accurate in predicting the progression of CKD to ESRF in 5 years in the Singapore CKD population.

SA-PO755

Underperformance of ESRD Prediction Equations in a Contemporary Diverse Adult Population with Advanced CKD

Sijie Zheng,[1] Leonid Pravoverov,[2] Victor Shiau,[3] Rishi V. Parikh,[2] Nhi Tan,[5] Joanna Mroz,[1] Thida C. Tan,[3] Tracy Y. Jonelis,[4] Alan S. Go.[3] [1]*The Permanente Medical Group, Oakland, CA;* [2]*Kaiser Permanente, Walnut Creek, CA;* [3]*Kaiser Permanente Northern California, Oakland, CA;* [4]*The Permanente Medical Group, Inc, San Francisco, CA;* [5]*Kaiser Oakland Medical Center, OAKLAND, CA.*

Background: Two risk prediction models (Tangri, KPNW) have been proposed for risk stratification for transition to ESRD in adults with CKD 3-5. We evaluated the performance of these models in an ethnically diverse advanced CKD population.

Methods: We identified all adult members of Kaiser Permanente Northern California (KPNC) with Stage 4-5 CKD between Jan. 2008-Sep. 2015. Receipt of RRT through Sep. 2016 was ascertained from an internal ESRD registry. Data on patient characteristics and lab results were obtained from electronic health records. We examined model discrimination (c statistic) and calibration (observed vs. predicted risk) for initiating RRT at 1, 2 and 5 years for the Tangri equation and at 2 years for the KPNW equation.

Results: In 17,586 adults with CKD 4-5, mean age was 73.7 years, 53% were women, and 49% were persons of color. The 1-, 2- and 5-year crude risks for RRT were 8.8% (95%CI:8.3-9.2%), 20.1% (19.5-20.8%) and 37.9% (36.9-38.8%), respectively. For Tangri, we found lower discrimination at 1 year (c=0.80 KPNC, c=0.86 Tangri), and 5 years (c=0.76 KPNC, c=0.84 Tangri), with substantial underestimation of actual absolute risk (Figure 1A). Similarly, for the KPNW model, we observed lower discrimination (c=0.79 KPNC, c=0.96 KPNW) and underestimation of actual risk (Figure 1B).

Conclusions: In a large, ethnically diverse CKD 4-5 population, Tangri and KPNW prediction models exhibited both lower discrimination and significant underestimation of absolute RRT risk. Given that most ESRD cases are derived from CKD 4-5 patients, more accurate prediction models are needed to help tailor management.

Clinical Utility of the Kidney Failure Risk Equation in Determining Timing of Predialysis Education

Marina Wainstein,[1] Saiyini Pirabhahar,[1] Hendrick E. Van deventer,[3] Kylie M. Turner,[1] Su San Lim,[1] Ivor J. Katz.[1,2] *[1]St George Hospital, Sydney, Elizabeth Bay, NSW, Australia; [2]University of New South Wales, Sydney, NSW, Australia; [3]Lancet Laboratories, Johannesburg, South Africa.*

Background: The Kidney Failure Risk Equation (KFRE) has been validated to predict decline in chronic kidney disease (CKD) and proposed as a tool for dialysis planning. Timing of predialysis education is known to impact short- and long-term outcomes on dialysis. Current guidelines recommend it occurs within 12 months before initiation but little evidence exists to guide the timing of this referral. Our aim was to assess and validate the efficacy of the KFRE in predicting optimal timing for dialysis education.

Methods: A 2 year risk of end stage kidney disease (ESKD) was calculated using the 4-variable KFRE in a cohort of patients with CKD stages 3-5 and compared to eGFR with respect to predictive efficacy. The sensitivity and specificity of the test using KFRE thresholds of 10 and 20% as well as eGFR of 15 and 20 ml/min/1.73 m^2 were examined, reflecting KFRE risk suggestions and eGFR cut-offs currently used for referral to predialysis education. In patients who developed ESKD and commenced dialysis we searched retrospectively for an association between KFRE and time from predialysis education to initiation (dependent variable) using linear regression.

Results: Of 294 patients included in the analysis, 106 progressed to ESKD over the 2 year follow-up period. The area under the receiver operating curve for KFRE was 0.97 [95% confidence interval (CI) 0.96-0.99]) and 0.93 for eGFR (95% CI, 0.90-0.97). Using a KFRE threshold of 10% the sensitivity was 82% and specificity 97% and at 20% the sensitivity decreased to 57% but specificity was maintained (98%). Use of eGFR cut-offs of 20 and 15 ml/min/1.73 m^2 resulted in lower sensitivity (56% and 18% respectively) but equivalent specificity (97 and 99% respectively). There was a weak, positive association between KFRE risk and longer time from dialysis education to initiation (r^2 = 0.072, p = 0.016).

Conclusions: The KFRE can be considered validated in our population as a good predictor of ESKD and modestly superior to eGFR. A threshold KFRE risk of 10% over 2 years appears to be a more useful guide than eGFR for timely referral to predialysis education. However, this was not observed at a higher threshold, suggesting that other factors may impact on the rate of progression to dialysis. KFRE requires ongoing evaluation for decision-making nearing ESKD.

SA-PO757

Predicting Incidence of CKD G3+ (eGFR <60 mL/min/1.73 m2) in the General Population

Robert G. Nelson. CKD Prognosis Consortium *CKD Prognosis Consortium (CKD-PC), Baltimore, MD.*

Background: Risk-based treatment strategies are one method of delivering personalized medicine. Valid risk scores are needed for the prediction of CKD G3+, which may prompt albuminuria testing in those who are not already advised to undergo screening because of diabetes, hypertension, or history of cardiovascular disease (CVD).

Methods: Among 26 general population and high-risk population cohorts (N=2.1 million participants) with eGFR ≥60 ml/min/1.73 m^2, we estimated risk factors of incident eGFR <60 ml/min/1.73 m^2 (CKD G3+) and eGFR <30 ml/min/1.73 m^2 (CKD G4+). We derived a risk score using random-effects meta-analyzed sub-hazard ratios from all cohorts, and random-effects meta-analyzed re-fit subhazards from the six cohorts with frequent creatinine measurements. Risk factors evaluated included age, sex, race, baseline eGFR, history of CVD, diabetes, smoking status, hypertension, and body-mass index. Albuminuria was modeled in people with and without diabetes separately due to differences in data availability.

Results: Mean age of participants was 54 years, 53% were female, and mean baseline eGFR was 91 ml/min/1.73 m^2. Over a mean follow-up of 4.5 years, there were 152,968 events of incident eGFR <60 ml/min/1.73 m^2 and 31,631 events of incident eGFR <30 ml/min/1.73 m^2. All risk factors listed in the methods were statistically significant. Applying the risk score to NHANES 2011-2016, the 10th and 90th percentiles of 5-year risk of incident eGFR <60 ml/min/1.73 m^2 were 0.04% and 3.7% for those aged 18-39 years, 0.6% and 21.9% for 40-59 years, 6.9% and 64.4% for 60-79 years, and 29.3% and 84.6% for ≥80 years. Corresponding estimates of incident eGFR <30 ml/min/1.73 m^2 were 0.01% and 0.02%, 0.09% and 1.3%, 0.6% and 5.1%, and 1.4% and 7.8%, respectively. Specific equations for patients with diabetes as well as incorporating albuminuria, when measured, provide better personalization.

Conclusions: A risk score for CKD incidence developed from risk factors available in electronic health records had a 10-100 fold risk gradient and could help guide screening and prevention.

Random Survival Forest Identifies Key Factors Predicting CKD Progression: The CRIC Study

Zihe Zheng,[1] Dawei Xie,[2] Shoshana Weiner,[9] Jing Chen,[3] Debbie L. Cohen,[4] Paul E. Drawz,[5] Dominic S. Raj,[6] James H. Sondheimer,[7] Harold I. Feldman,[1] James P. Lash,[8] Amanda H. Anderson.[1] CRIC (Chronic Renal Insufficiency Cohort) *[1]University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania School of Medicine Center for Clinical Epidemiology and Biostatistics, Philadelphia, PA; [3]Tulane School of Medicine, New Orleans, LA; [4]University of Pennsylvania School of Medicine, Philadelphia, PA; [5]University of Minnesota, Minneapolis, MN; [6]GWU Medical Faculty Associates, Washington, DC; [7]Wayne State University School of Medicine, Detroit, MI; [8]University of Illinois at Chicago, Chicago, IL; [9]University Of Maryland School Of Medicine, Baltimore, MD.*

Background: Increasing numbers of clinically-available and novel factors bring opportunities to improve CKD risk prediction, as well as statistical challenges of multiple comparison, nonlinearity, variable interactions, and missing data. We applied the machine learning technique of random survival forest (RSF) to identify factors associated with CKD progression.

Methods: We studied 3,939 subjects in the Chronic Renal Insufficiency Cohort and followed them for the composite survival outcome of eGFR halving or incident ESRD for 12 years. We used 73 clinically-available and 25 novel baseline variables as exposures, which covered a broad spectrum of socio-demographics, comorbidities, physical and laboratory measurements and medications. We applied the RSF approach with 1000 bootstrap iterations and log-rank splitting rule. We calculated statistics of variable importance and minimal depth to rank predictors according to their impact on prediction accuracy. We also graphed the adjusted relationships of CKD progression and the top 10 strongest predictors.

Results: After setting the outliers to missing, we included 3,921 individuals in the analysis. Missing data were imputed and variable interactions were incorporated in the RSF algorithm. The 98-predictor RSF model yielded a low prediction error of 14.2% (1 minus Harrell's C-index). The top 10 predictors identified with highest variable importance values and smallest minimal depths are urine protein/creatine ratio, urine albumin/creatinine ratio, eGFR, serum urea nitrogen, parathyroid hormone, serum albumin, high sensitivity troponin T, systolic blood pressure, NT-proBNP, and FGF-23. The relationships of the predicted survival at 1-, 2-, and 5-years and the 10 factors are shown in the partial dependence plots.

Conclusions: We identified and ranked variables that are most important to CKD progression from among 98 clinically-available and novel factors using the RSF method. Utilizing high-dimensional data enabled us to predict outcomes with a low error rate.

Mediation of the Association Between Particulate Matter Air Pollution and Renal Disease by Diabetes

Benjamin C. Bowe,[1,3] Yan Xie,[1] Ziyad Al-Aly,[1,2] Tingting Li,[1,2] Yan Yan,[1,2] Hong Xian.[1,3] Clinical Epidemiology Center *[1]Clinical Epidemiology Center, VA Saint Louis Health Care System, Saint Louis, MO; [2]Washington University in St. Louis, Saint Louis, MO; [3]Saint Louis University College for Public Health & Social Justice, St. Louis, MO.*

Background: Evidence suggests that elevated levels of fine particulate matter of <2.5 µm in aerodynamic diameter ($PM_{2.5}$) are associated with increased risk of kidney disease. However, $PM_{2.5}$ is also associated with risk of diabetes, which is a major driver of CKD. Whether and to what extent the association of $PM_{2.5}$ and CKD is mediated by diabetes is unknown.

Methods: Databases from the Environmental Protection Agency (EPA) and National Aeronautics and Space Administration (NASA) were linked with those from Department of Veterans Affairs. Inverse odds ratio-weighted estimations for mediation analyses were undertaken to quantitate the proportion of the association between $PM_{2.5}$ and risk of CKD outcomes that is mediated by diabetes. CKD outcomes included incident eGFR < 60 mL/min/1.73m^2, incident CKD, incident eGFR decline ≥ 30%, and time until end stage renal disease (ESRD) or eGFR decline ≥ 50%.

Results: In a cohort of 2,444,157 United States Veterans followed for a median of 8.5 years, using EPA data, the proportion of the association (between $PM_{2.5}$ and risk of CKD outcomes) mediated by diabetes was 4.7%, 4.8%, 5.8%, and 16.5% for risk of incident eGFR less than 60 mL/min/1.73m^2, risk of incident CKD, risk of eGFR decline of 30% or more, and risk of ESRD or eGFR decline ≥50%, respectively. Results were consistent when exposure was defined according to NASA data.

Conclusions: Our findings demonstrate that a small proportion of the association between $PM_{2.5}$ and CKD was mediated by diabetes, suggesting that the presence of other mediators or a direct effect between $PM_{2.5}$ and CKD may drive the association between $PM_{2.5}$ and CKD.

SA-PO760

Improvement in Glomerular Filtration Rate Among CKD Patients: Findings from the CRIC Study

Paula F. Orlandi,[1] Dawei Xie,[2] Amanda H. Anderson,[1] Harold I. Feldman.[1] CRIC Study Investigators *[1]University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania School of Medicine Center for Clinical Epidemiology and Biostatistics, Philadelphia, PA.*

Background: Improvement of eGFR has been observed in approximately 10% of participants in numerous CKD cohorts. Among those with improving eGFR, a counterintuitive association with increased risk of coronary heart disease and death compared to those with stable or slightly declining eGFR has been reported. Sarcopenia, edema, and other indicators of clinical deterioration may be responsible for the increased risk of poor outcomes among subjects with improving eGFR. We aimed to assess the association between slopes of eGFR and time to cardiovascular events and all-cause mortality accounting for many factors potentially confounding this relationship.

Methods: We studied 3024 participants of the CRIC Study, a multi-center cohort of adults with CKD. We performed Cox Proportional Hazards models with time-varying covariates to investigate the association between slopes of eGFR and cardiovascular events and all-cause mortality. Slopes were estimated using linear mixed effects models and were updated whenever a new eGFR was assessed over a median of 9 years. Individuals were characterized according to three groups based on their slope at year 2: decliner (slope<=-2); stable (slope>-2 and <2); improver (slope>=2ml/min/1.73m2).

Results: In the CRIC Study, 327(11%) presented improvement of eGFR, 1045 (34%) were stable, and 1652 (55%) were decliners. Improvers were predominantly male (60%), had lower systolic blood pressure (mean: 118 mmHg), and lower proteinuria (median: 0.09 g/day). In models adjusted for demographics, diabetes, eGFR, proteinuria, systolic blood pressure, fat-free mass, ejection fraction, antihypertensive drugs and other laboratory markers, time-updated improvement of eGFR was associated with increased risk of death compared to stable slopes: HR 1.89 (95%CI: 1.63 -3.22). The risk of death for steep decliners was also significantly higher: HR 1.63 (95%CI: 1.25 - 2.14).

Conclusions: Slopes of eGFR higher than 2ml/min/1.73m2/year were associated with increased risk of death compared to subjects presenting stable slopes of eGFR. This association was not explained by markers of cardiovascular function, body composition, or by a time-updated approach.

First-Year Estimated Glomerular Filtration Rate Variability After Pre-ESRD Program Enrollment and Adverse Outcomes of CKD

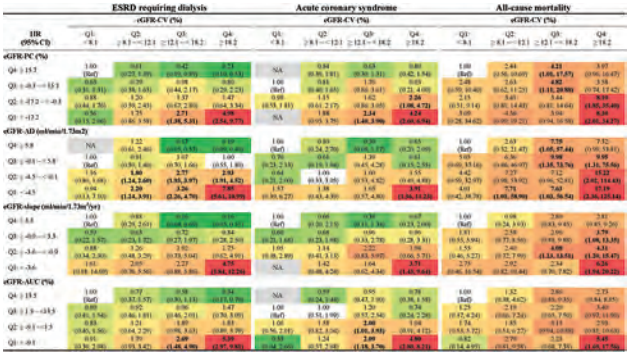
Chin-Chi Kuo,[1] Ching-Wei Tsai.[2] *[1]Big Data Center and Kidney Institute, China Medical University Hospital, Taichung City, Taiwan; [2]Kidney Institute and Big Data Center, China Medical University Hospital, Taichung City, Taiwan.*

Background: Scarce evidence associates the first-year estimated glomerular filtration rate (eGFR) variability and longitudinal change scales concomitantly to the risk of developing end stage renal disease(ESRD), acute coronary syndrome(ACS), and death following pre-ESRD program enrollment in chronic kidney disease(CKD).

Methods: We conducted a prospective cohort study of 5,092 CKD patients receiving multidisciplinary care between 2003 and 2015 with careful ascertainment of ESRD, ACS, and death during the follow-up. First-year eGFR dynamics included coefficient of variation (eGFR-CV), percent change (eGFR-PC), absolute difference (eGFR-AD), slope (eGFR-slope), and area under curve (AUC).

Results: A total of 786 incident ESRD, 292 ACS, and 410 death events occurred during the follow-up. In the multiple Cox regression, the fully adjusted HRs for incident ESRD comparing the extreme with the reference quartiles of eGFR-CV, eGFR-PC, eGFR-AD, eGFR-slope, and eGFR-AUC were 2.67(95% CI, 2.11, 3.38), 8.34(6.33, 10.98), 19.08(11.89, 30.62), 13.08(8.32, 20.55), and 6.35(4.96, 8.13), respectively. Similar effects on the risk of developing ACS and mortality was observed. In the 2x2 risk matrices, patients with the highest quartile of eGFR-CV and concomitantly with the most severely declining quartiles of any other longitudinal eGFR change scale had the highest risk of all outcomes.

Conclusions: The dynamics of eGFR changes, both overall variability and longitudinal changes, over the first year following pre-ESRD program enrollment are crucial prognostic factors for the risk of progression to ESRD, ACS and deaths among patients with CKD. A risk matrix combining the first-year eGFR variability and longitudinal change scales following pre-ESRD enrollment is a novel approach for risk characterization in CKD care.



Risk matrices demonstrating the adjusted hazard ratios (aHRs) for ESRD requiring dialysis, ACS, and all-cause mortality by using eGFR-CV (in quartiles) and other scales of eGFR longitudinal change scales, namely eGFR-PC, AD, slope, and AUC.

Estimating Short-Term Risk of Disease-Related Outcomes in ADPKD: A Prediction Model Based on Longitudinal Data from the OVERTURE Study

Ronald D. Perrone,[2] Jogarao Gobburu,[6] Frank S. Czerwiec,[7] Christina Pao,[1] John Ouyang,[4] Olga Sergeyeva,[5] Vijay Ivaturi.[3] *[1]Otsuka Pharmaceutical Development and Commercialization, Princeton, NJ; [2]Tufts Medical Center, Boston, MA; [3]University of Maryland, Baltimore, Baltimore, MD; [4]Otsuka Pharm. Dev. & Comm., Rockville, MD; [5]Otsuka Pharmaceuticals, Princeton, NJ; [6]Dr., Baltimore, MD; [7]Otsuka Pharma. Devel. & Comm., Inc., Rockville, MD.*

Background: Models are available for predicting rapid decline in kidney function in autosomal dominant polycystic kidney disease (ADPKD), but there is a need for a clinical tool that estimates the short-term risk of other ADPKD-related complications. We analyzed observational data to identify patient baseline variables most useful for estimating risk of complications and to construct a patient risk calculator.

Methods: OVERTURE was a prospective study with follow-up at 6-month intervals to assess for 17 types of ADPKD-related manifestations that included hematuria, kidney pain, albuminuria, urinary tract infection (UTI) and nephrolithiasis. In our analysis, occurrence of each type of manifestations in a patient was assigned a score of 1, yielding a maximum ADPKD severity score of 17. Item response analysis[1] was used to determine the complications that contributed most to overall disease severity across the population, and multivariate logistic regression was performed to ascertain which patient baseline risk factors best predicted experiencing ≥1 of the identified complications in the follow-up 6–18 months.

Results: Among 1880 subjects with follow-up data over the analysis period, the manifestations that contributed most to overall ADPKD severity were hematuria, kidney pain, albuminuria, UTI, and nephrolithiasis. In the regression model, baseline risk factors most predictive of occurrence of ≥1 of these manifestations over 6–18 months were: age ≤35, male sex, non-Hispanic ethnicity, higher baseline total kidney volume growth rate, and higher risk class in the Mayo ADPKD classification system.[2] These predictive variables were incorporated into a simple nomogram for patient risk scoring.

Conclusions: Patient baseline risk factors can be used to estimate the risk of experiencing ≥1 of 5 important ADPKD-related manifestations over 6–18 months. A prediction nomogram that assigns point scores for each predictive variable enables rapid risk estimation in the clinic.

Predicting CKD in the CARRS Study: Strategies for Screening in the Indian Population

Christina L. Bradshaw,[1,2] Yuanchao Zheng,[1] Maria E. Montez-Rath,[1] Dorairaj Prabhakaran,[3] Shuchi Anand.[1] *[1]Nephrology, Stanford University School of Medicine, Palo Alto, CA; [2]Centre for Chronic Disease Control, Gurgaon, India; [3]Public Health Foundation of India, Gurgaon, India.*

Background: Chronic kidney disease (CKD) is a significant global health issue. Much of the rise in CKD-attributable deaths has occurred in low- and middle-income countries (LMICs). Population-wide screening for CKD is not cost-effective and likely untenable in resource-limited settings. Development of a tool that identifies at-risk persons and allows targeted screening is paramount to manage this growing problem.

Methods: Using data from the Centre for Cardiometabolic Risk Reduction in South Asia (CARRS) study, we fit a logistic regression model based on 30 variables easily measured during a home visit. Final predictors were selected through a step-down procedure. We defined presence of CKD as eGFR <60 ml/min/1.73m^2 by the CKD-EPI equation or urine albumin-to-creatinine ratio (UACR) ≥30 mg/g. Discrimination was assessed with the c-statistic and calibration with the calibration slope. Model predictive ability was compared across different probability cut-offs. We used bootstrap for internal validation.

Results: In our sample of 8,698 participants from Delhi and Chennai, CKD prevalence was 10.9%. Our final model consisted of 19 variables (**Figure 1**). Development and validated c-statistics were 0.79 and 0.78, respectively. Calibration slope was 0.97 after validation. Using a probability cut-off of 0.075, the model identified 3,489 people (40% of original sample) as needing confirmatory testing for CKD with serum creatinine or UACR, giving a sensitivity of 78% and specificity of 65%.

Conclusions: Our prediction model exhibited good sensitivity and discrimination for CKD, while narrowing the pool of people who necessitate confirmatory testing. We are the first to use large-scale population data to develop a tool that facilitates targeted screening for CKD in urban India. Future efforts include external validation on a separate Indian cohort.

SA-PO764

CKD Without Significant Proteinuria—Is It Possible to Predict Faster Decline in eGFR?

Hiroshi Tanaka. *Internal Medicine/Nephrology, Mihara Red Cross Hospital, Mihara, Japan.*

Background: CKD patients without significant proteinuria have been recognized that they tend to have slower eGFR decline than proteinuric CKD patients have. However substantial population of those patients eventually reach ESRF. The aim of this study is to elucidate risk factors for progressive decline in eGFR in patients without significant proteinuria.

Methods: A hospital-wide survey included a whole set of laboratory tests over 24 months. Patients with at least 3 measurements of eGFR over 365 days or more, with an averaged eGFR of less than 50mL/min/1.73m^2 were collected. An eGFR slope was calculated for each patient. For the assessment of proteinuria, a dipstick urine protein determination was considered to better represent the real-world clinics for all the subspecialities in the Hospital; numbers of 0, 0.5, 1, 2, 3 or 4 were applied to (-), (+-), (1+), (2+), (3+) or (4+) respectively, then the numbers were averaged during the study period (avUprot); an excellent relation between avUprot and averaged U-protein/U-creatinine ratio has been previously confirmed in a different cohort (Up/Ucr = -0.346 + 1.185*avUprot, n=1,379; p<0.0001). Patients with avUprot less than 1.0 comprised the final cohort for this study. All the laboratory values such as serum albumin were equally averaged during the study period for each patient.

Results: Among the total 40,797 patients with laboratory examination, the final cohort included 1,174 patients (M:F 581:593, age 32-95 (median 77)), with eGFR 5.8-49.9 (41.3) mL/min/1.73m^2 and avUprot 0.00-0.96 (0.14) g/g Cr. In a univariate analysis, the eGFR slope was associated with age, plasma ALT (alanine aminotransferase), serum Na and serum albumin. In a multivariate stepwise analysis, the eGFR slope was correlated with ALT, serum Na and serum albumin. In a 3x3 table where the cohort was divided into tertiles for ALT and serum albumin, patients with the lowest tertile of serum albumin (1.70-3.87 g/dL) combined with the highest tertile of ALT (22.0-265.4 IU/L) had the fastest eGFR decline (-4.07+-9.11 (median -2.44) mL/min/1.73m^2/yr) among the 9 divisions, with an OR 2.13 for the fastest-eGFR-slope tertile (-2.47 mL/min/1.73m^2/yr or below) against the sum of the remaining 8 divisions as a reference.

Conclusions: Combination of serum albumin and ALT might serve as a simple measure to predict progressive decline in eGFR in the CKD patients with minimal or no proteinuria.

SA-PO765

Can Rapidly Progressing CKD Patients Be Identified Using Billing Codes?

Kabir Jalal,[1] Rocco C. Venuto,[2] Edwin J. Anand,[2,1] Pradeep Arora.[3,1] *[1]University at Buffalo, Amherst, NY; [2]Erie County Medical Center, Buffalo, NY; [3]Nephrology, Veterans Affairs Medical Center, Buffalo, NY.*

Background: The International Classification of Diseases (ICD) coding system is the industry standard diagnostic coding tool. However, ICD codes often do not reflect the clinical diagnosis, particularly among Chronic Kidney disease (CKD) patients. This study evaluates the diagnostic accuracy in identifying rapidly progressing CKD patients using CKD-related ICD codes in a large insurer database.

Methods: Serial observations from 2007 through 2014 were examined. 216,529 individuals had valid serum creatinine measurements. The progression of CKD using a longitudinal mixed-model was contrasted with that documented by ICD codes. Rapid progressors (yearly eGFR loss greater than 4 ml/min/1.73m^2) were identified. Clinical diagnosis according to the Kidney Disease Outcomes Quality Initiative (KDOQI) was compared to diagnosis using ICD codes.

Results: 323 rapid progressors were identified among the 10,927 CKD patients qualifying for inclusion in the clinical progression analysis. ICD codes identified 83 of these, for a sensitivity of 25.7% and specificity 95.09%. Of 28,762 laboratory-confirmed CKD patients, 9,249 had a qualifying ICD code, for a sensitivity of 16%. Of 187767 patients without laboratory-confirmed CKD, 182,359 did not have a qualifying ICD code, for a specificity of 97.12%.

Conclusions: This study leverages 7 years of serial observations, facilitating identification of disease progression, and depicts the novel finding that ICD-codes display poor capacity to identify rapidly progressing CKD patients when compared to gold standard KDOQI guidelines, and further demonstrates the limitations of coding in CKD diagnosis management. This study further defines the limitations of ICD codes in addressing diagnosis of disease severity or disease progression for clinical or epidemiological purposes.

Comparisons of Different Equations for Estimated Glomerular Filtration Rate in Chinese Han Patients with CKD in Real World

Huijuan Mao. *First Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: The currently recognized and most accurate estimate of glomerular filtration rate(eGFR) formula is the creatinine- cystatin C joint formula(EPI_Cr_CysC) developed by the Chronic Kidney Disease Epidemiology Research Group. However,

cystatin C (CysC) can not be determined in many cases, so that the wide application of EPI_Cr_CysC formula is limited. The purpose of this study is to study the agreement, precision and accuracy between other eGFR formulas and EPI_Cr_CysC formulas, and to find the best alternative formula for EPI_Cr_CysC.

Methods: We conducted a cross-sectional study research of 1913 CKD patients. The eGFRs were calculated separately by creatinine clearance rate and Cockcroft-Gault equation corrected for standard body surface area (Ccr_BSA and eCcr_BSA), CKD-EPI_creatinine equation (EPI_Cr), CKD-EPI_cystatin C equation (EPI_CysC), EPI_Cr_CysC equation, Modification of Diet in Renal Disease equation with standardized serum creatinine (MDRD) and full-age-spectrum creatinine equation (FAS). And EPI_Cr_CysC equation was used as the reference.

Results: When compared with EPI_Cr_CysC equation, EPI_Cr equation achieved the highest agreement in eGFR estimates [Lin's concordance correlation coefficient (95%CI), 0.936(0.930, 0.941)]. And eCcr_BSA and EPI_Cr equation achieved the first and second highest percent agreement in accurate classification of the CKD stage [percent agreement, 72.55% VS 71.25%]. MDRD equation got the minimal bias and was closely followed by EPI_Cr equation [median difference (95% CI), -1.3(-2.0, -0.8) VS 2.5(1.7,3.3) mL/min/1.73m2]. EPI_CysC and EPI_Cr equations achieved the first and second highest precision [IQR of the difference (95% CI), 12.2(11.6,12.9) VS. 15.5(14.7,16.3) mL/min/1.73m2]. EPI_Cr and MDRD equations performed similarly and tied for first place in 30% accuracy [1-P30 (95% CI),18.6(16.9,20.4) % VS 18.6 (16.8, 20.3) %].

Conclusions: For assessment of renal function, EPI_Cr equation performed the best and remained an acceptable alternative to EPI_Cr_CysC equation in the absence of cystatin C.

Estimation of Glomerular Filtration Rate in Multi-centre Chinese Individuals: Comparison of 2017 New FAS (Full Age Spectrum) and 2012 CKD-EPI (CKD Epidemiology Collaboration) Equations

Zhenzhu Yong. *The First Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: The recent guidelines recommend using the estimated glomerular filtration rate (eGFR) to evaluate renal function. There are two reported full-age-spectrum (FAS) equations in 2017, which based on serum cystatin C (Cys) concentrations with or without accompanying serum creatinine (Cr) level (FAS_{Combi} or FAS_{Cys}). We compared the performance and assessed the applicability of the new FAS formulae with the 2012 CKD-EPI ($CKD\text{-}EPI_{Cys}$ and $CKD\text{-}EPI_{Cr\text{-}Cys}$) equations in Chinese subjects.

Methods: A total of 1184 technetium-99m diethylene-triamine-penta-acetic acid (99mTc-DTPA) renal dynamic images from four different hospitals in China to measure GFR (mGFR) regarded as the referenced method. The bias, precision and accuracy of eGFR and mGFR calculated by four formulae were compared.

Results: The two CKD-EPI equations performed poor in elderly with moderately-severely injured GFR (the proportion of estimated GFR within 30% of referenced GFR, P30, <70%). FAS_{Combi} formula had less bias (median bias, -2.87), more precision (the inter-quartile range of difference, IQR, 19.01), and more accuracy (P30, 74.16%) in whole cohort, and the difference compared with other three equations was statistically significant. In the rGFR <60 ml/min/1.73m^2 subgroup, the FAS_{Combi} formula showed the best performance and the differences were statistically significant. In older subjects, compared with FAS_{Cys}, $CKD\text{-}EPI_{Cr\text{-}Cys}$ and $CKD\text{-}EPI_{Cys}$, the FAS_{Combi} formula had relatively less bias (median bias, -8.09 vs. -9.63, -7.52, -11.04, p<0.05), most precise (IQR, 15.18 vs. 16.32, 15.22, 16.63), and most accuracy, P30 was statistically different from the other equations, and achieved a ideal value >70%.

Conclusions: The performance of the FAS_{Combi} formula is better than that of the $CKD\text{-}EPI_{SCr\text{-}Cys}$ formula in the Chinese population, particularly in the elderly. Yet, further modification of FAS equations from a large-scale study could be more suitable for the Chinese population, particularly in older subjects.

SA-PO768

GFR Slopes – The Statistical Method Matters

Marieke van Rijn,[1] Jack F. Wetzels,[2] Peter J. Blankestijn,[4] Jan A. van den Brand.[3] *[1]Radboud Univ Medical Centre, Nijmegen, Netherlands; [2]Radboud University Medical Center, Nijmegen, Netherlands; [3]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [4]University Medical Center----, Utrecht, Netherlands.*

Background: The FDA is considering the use of eGFR decline and eGFR slope as surrogate endpoints in CKD research. Several statistical methods can be used to estimate GFR decline (Coresh 2014, Leffondre 2015, Asar 2015). We questioned if these methods differed with respect to the estimates of GFR slopes.

Methods: We used the MASTERPLAN (Multifactorial Approach and Superior Treatment Efficacy in Renal Patients with the Aid of Nurse practitioners) dataset, which included 762 patients with an eGFR between 20 to 70 ml/min, a median follow-up of 4.8 yr (IQR 4.3-5.3) and 103 ESRD events. We estimated percentage and annual change in MDRD eGFR over a period of 2 years using 3 methods. For annual change: 1) last estimated GFR – first estimated GFR, 2) linear mixed model (LMM) using the first and last measured GFR, 3) LMM using all GFR measures in 2 years' time. For percentage change: 4) (last estimated GFR – first estimated GFR) / (first estimated GFR) * 100 and 5) LMM with log-transformed GFR using the first and last measured GFR, 6) LMM with log-transformed GFR using all GFR measures in 2 years' time.

Results: Overall data were available of 6275 visits and 91% of patients had at least 4 visits within 2 years. Both the distribution for annual and percentage change in eGFR varied greatly between the different statistical methods (Figure 1). Using the first-last eGFR method to estimate GFR slope resulted in a 5 fold wider distribution on the annual scale and 10 fold on the relative scale compared to using a LMM.

Conclusions: The statistical method that is used to estimate change in GFR has a great impact on the estimated GFR slopes. The current debate about the use of eGFR declines and eGFR slope as surrogate endpoints in CKD should also consider the statistical method how to estimate GFR decline.

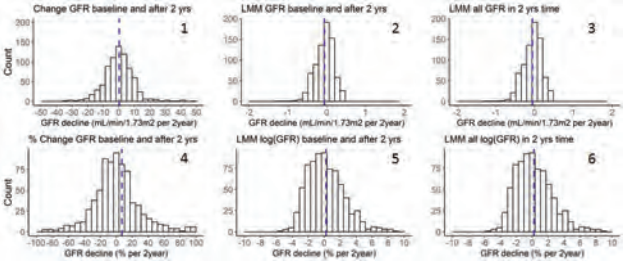

Figure1: Distribution of GFR slopes. The number in the figure corresponds to the statistical method described in the methods. The blue line is the average GFR slope.

SA-PO769

Optimal Follow-Up Intervals for Different Stages of CKD

Keita Hirano,[1] Yasuo Ohashi,[2] Yasuhiro Komatsu,[3] Motoko Yanagita,[1] Akira Hishida.[4] *[1]Department of Nephrology, Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]University of Tokyo, Tokyo, Japan; [3]Gunma University, Graduate School of Medicine, Maebashi, Gunma, Japan; [4]Yaizu City Hospital, Yaizu, Japan.*

Background: Chronic kidney disease is a public health challenge. However, no evidence-based, optimal, follow-up intervals for patients with chronic kidney disease have been suggested. This study aimed to clarify appropriate follow-up intervals for different chronic kidney disease stages.

Methods: We studied 2682 patients with chronic kidney disease. Both of the numbers of patients experiencing a 50% increase in creatinine and those reaching end-stage renal failure were tabulated by their chronic kidney disease stage. The renal function-testing interval was defined as the estimated time for 0.1% of the patients with chronic kidney disease to have a composite renal outcome, when adjusted for clinical risk factors. Transitions from chronic kidney disease stage-based subgroups were analyzed using parametric cumulative incidence models. Other sensitivity analyses involved the estimation of the time to renal event occurrence for 1% of patients.

Results: Of the 913 patients (34%) who had a composite renal event, 29 patients had stage 3A (10.5%), 151 had stage 3B (16.3%), 429 had stage 4 (41.0%), and 304 had stage 5 chronic kidney disease (70.9%). The estimated renal function testing intervals were 6.0 months for chronic kidney disease stage 3A, 3.4 months for stage 3B, 2.0 months for stage 4, and 1.2 months for stage 5.

Conclusions: The optimal follow-up intervals were longer for patients with lower chronic kidney disease stages. These estimates are longer than those recommended by the relevant guidelines, and may serve as a reference to inform nephrologists in selecting follow-up intervals for their individual patients.

Methods to Identify Novel, Repeatedly Measured Biomarkers of CKD Outcomes

Qian Liu,[1] Abigail R. Smith,[1] Laura H. Mariani,[2,1] Viji Nair,[2] Jarcy Zee.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.*

Background: Identifying novel biomarkers is critical to advancing diagnosis and treatment of CKD, but relies heavily on the statistical methods used. Inappropriate methods can lead to both false positive and false negative associations between biomarkers and outcomes. This study assessed accuracy of methods using computer simulations and compared biomarker effect estimates in NEPTUNE, a prospective cohort study of patients with glomerular disease.

Methods: We compared four methods for analyzing repeatedly measured biomarkers in Cox models: 1) baseline, that only uses the single baseline biomarker value, 2) time-dependent with last observation carried forward (LOCF), that assumes the biomarker is unchanged until the next value, 3) time-averaged, that averages the biomarker values over all follow up and uses that average as a baseline covariate, and 4) time-dependent cumulative average, that updates the average using biomarker values at or before each time point.

Results: Simulation results showed the time-averaged method often gave extremely biased, inaccurate results. In NEPTUNE, all assessed urinary biomarkers were positively associated with 40% reduction in eGFR. Compared to the LOCF method, the baseline method had 6-21% lower hazard ratios (HRs), and the time-averaged method had 3-32% higher HRs [figure]. For complete remission, Eotaxin and TIMP1 were negatively associated with the outcome, and PDGF-BB had little association. HRs from the time-averaged method were always higher (1-13%) than the LOCF method.

Conclusions: Different analytic methods resulted in markedly different results. Using inappropriate methods such as time-averaging can bias effect estimates, while other methods provide prognostic (baseline), additive (cumulative average), or instantaneous (LOCF) effects depending on the hypothesized underlying mechanism.

GFR Decline Based on Albuminuria Status in Patients with DM, Hypertension, and eGFR≥60

Adrian Liew,[1] Yee Ang,[2] Chun wei Yap,[2] Chee Kong Lim,[3] Wanting Weng.[1] *[1]Renal Medicine, Tan Tock Seng Hospital, Singapore, Singapore; [2]National Healthcare Group, SIngapore, Singapore; [3]National Healthcare Group Polyclinics, Singapore, Singapore.*

Background: In patients with GFR≥60, CKD is defined by presence of 2 albuminuria (UACR), obtained 3 months apart. Often, due to the clinical stability of these patients and limited clinic resources, most patients ended up with 1 UACR done annually with a potential delay in CKD diagnosis and treatment. We postulate that a single UACR reading in DM and hypertensive patients at high risk for the development of CKD, could have a significant impact in the progression of CKD. Our study aims to determine the eGFR decline in patients with only 1 UACR reading at baseline compared to those who meets the traditional criteria for CKD of 2 readings.

Methods: In this retrospective cohort study, we included patients with DM or hypertension, GFR≥60, from 9 primary care clinics between 2010 to 2014. UACR results were obtained for up to 2 years prior to study period, and patients were stratified into 3 groups (Gp) – Gp 1: normal UACR; Gp 2: 1 abnormal ACR; Gp 3: 2 abnormal UACR at least 90 days apart. The patients were followed up for 2 years and GFR decline were compared, and adjusted for age, ethnicity, HbA1c, blood pressure and ACEi use.

Results: Of 11,783 patients in the study, 85.4% have DM. Baseline parameters between groups were similar. Malay patients with DM was found to have a greater GFR decline (-1.0 [-1.6, -0.4], p<0.001), consistent with previous reports. Unadjusted GFR decline, when stratified by DM status, was greater for those with positive UACR (See table). GFR decline was similar between Gp 2 and 3, especially in DM patients. In the multivariate analysis with Gp 1 as reference, GFR decline was similar between Gp 2 and 3 in diabetic patients, but higher in Gp 3 in hypertensive patients.

Conclusions: In diabetic and hypertensive patients, albuminuria was associated with greater GFR decline. GFR decline was similar regardless of 1 or 2 UACR results, especially in patients with DM. This suggests that treatment should be considered with a single albuminuria result before a second reading is needed to meet the CKD definition.

	Unadjusted GFR Decline (DM)		Unadjusted GFR Decline (Non-DM)	
	GFR≥90	GFR 60-89	GFR≥90	GFR 60-89
Gp 1	-2.0±4.6	-0.9±5.7	-1.7±4.2	-1.1±5.5
Gp 2	-3.8±6.4	-3.0±7.1	-2.7±5.0	-2.2±6.2
Gp 3	-3.2±5.5	-3.0±7.0	-3.9±5.8	-3.5±5.7
	GFR Decline after Multivariate Analysis			
Gp 1	Reference			
Gp 2	-1.5 (-1.8 to -1.1) p<0.001	-1.8 (-2.2 to -1.5) p<0.001	-1.0 (-1.7 to -0.4) p=0.003	-1.1 (-1.8 to -0.3) p=0.008
Gp 3	-1.0 (-1.6 to -0.4) p<0.001	-1.8 (-2.4 to -1.3) p<0.001	-2.1 (-3.5 to -0.7) p=0.003	-2.8 (-4.2 to -0.7) p=0.006

SA-PO772

High Instead of Lower CKD-EPI-Based eGFR Values in Dutch Ethnic Minorities at Risk for CKD

Brechje Huisman, Charles Agyemang, Bram Hafkamp, Bert-jan Van den born, Ron Peters, Marieke Snijder, Liffert Vogt. *Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands.*

Background: According to the widely adopted KDIGO guidelines, classification of chronic kidney disease (CKD) and evaluation of prognosis is based on two components: estimated glomerular filtration rate (eGFR) and urinary albumin-to-creatinine ratio (ACR). This approach has, however, never been validated for various ethnic groups living in the Netherlands and might lead to uncertainty in CKD staging. We investigated to what extent ethnic differences in eGFR and ACR can be explained by differences in demographics and traditional cardiovascular risk factors.

Methods: Baseline data from the HELIUS study, a multi-ethnic cohort study conducted in the city of Amsterdam, were used. Analyses were conducted among 18,534 participants (aged 18-70 years) of Dutch, South-Asian Surinamese, African Surinamese, Ghanaian, Moroccan and Turkish ethnic origin. We used multiple regression analyses to determine ethnic differences in eGFR (CKD-EPI formula) and ACR, with additional adjustments for age, sex, traditional cardiovascular and kidney risk factors, and educational level.

Results: Mean (SE) eGFR was higher in all ethnic minority groups as compared to those of Dutch origin (eGFR 94.9±0.3 mL/min/1.73m^2), ranging from 1.9±4.1 in subjects from South-Asian Surinamese origin to 15.0±0.39 in subjects from Moroccan origin. Also, ACR was higher among all ethnic minorities as compared to those of Dutch origin (ACR 0.6±0.2 mg/mmol), ranging from 0.5±0.2 in subjects from African Surinamese origin to 1.7±0.2 in subjects from South-Asian Surinamese origin. Adjustment for age, sex, traditional cardiovascular and kidney risk factors diminished the differences in both eGFR and ACR for most ethnic groups but these differences were still highly significant.

Conclusions: Our results show that eGFR is higher among ethnic minority groups as compared to those from Dutch origin. Regarding previously found higher CKD prevalence in ethnic minority groups of HELIUS, these findings underscore the need for ethnicity specific GFR estimations, as the currently recommended use of the CKD-EPI-based eGFR, which only distinguishes 2 ethnic groups, might lead to an underestimation of risk in multi-ethnic populations. Given the observed higher ACR values among minority groups, ACR might represent a more useful risk factor in multi-ethnic populations.

SA-PO773

Mortality Risk for Low Density Lipoprotein Cholesterol Across CKD Stages in 1.95 Million US Veterans

Melissa Soohoo,[1,2] Hamid Moradi,[1,2] Carola-Ellen Kleine,[1,2] Maria V. Marroquin,[1,2] Taryn B. Benson-Hernandez,[2] Csaba P. Kovesdy,[3] Kamyar Kalantar-Zadeh,[4] Elani Streja.[1,2] *[1]Tibor Rubin Long Beach VA Medical Center, Long Beach, CA; [2]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [3]University of Tennessee Health Science Center, Memphis, TN; [4]University of California Irvine, School of Medicine, Orange, CA.*

Background: Prior studies have shown that higher low-density lipoprotein cholesterol (LDL) levels are associated with worse survival in the general population, yet this

association is attenuated in chronic kidney disease (CKD) patients. However, the graded impact of kidney disease on the association of LDL with mortality is unclear.

Methods: We investigated a cohort of 1.95 million US veterans with baseline LDL and creatinine data from 2004-2006. Over a median[IQR] follow-up of 10.5[7,11] years, we examined the relationship of baseline LDL with all-cause and cardiovascular (CV) death risk across CKD stage in Cox proportional hazard models adjusted for demographics, comorbid conditions, smoking status, other lipids and prescription of statins and non-statins. CKD stage was determined according to estimated glomerular filtration rate (eGFR) at the time of LDL measurement.

Results: The cohort had a mean±SD age of 65±14 years, and included 5% females, 15% African-Americans, 22% diabetics, 32% statin-users and 44% current smokers. The median[IQR] of baseline LDL was 103[82,128] mg/dL and eGFR was 76[61,91] mL/min/1.73m^2. Patients with higher LDL were more likely to be younger, African-American, a current smoker, not on a statin, and have a higher eGFR. Patients with lower LDL (<60mg/dL) had a higher risk of all-cause and CV mortality across all stages of CKD, compared to LDL 80-<100 mg/dL. Higher LDL(≥140 mg/dL) was associated with higher all-cause and CV mortality risk in CKD3A and 3B, but these associations were attenuated for CKD4 and 5. Of note, in non-CKD veterans, higher LDL was protective for both CV and all-cause death risk. [Figure]

Conclusions: Elevated LDL ≥140 mg/dL is associated with higher all-cause and CV mortality risk among CKD 3A and 3B, but not among more advanced CKD stages. Future studies are needed to evaluate the impact of lipid lowering therapies and effect of time-updated LDL with mortality risk across CKD stages.

SA-PO774

Associations of Cholesterol and Mortality Across eGFR Strata in the NHANES Cohort

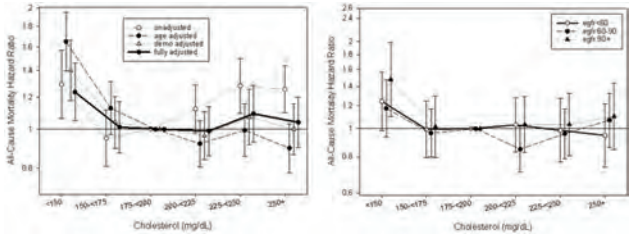
Taryn B. Benson-Hernandez,[3] Melissa Soohoo,[1] Hamid Moradi,[2] Carola-Ellen Kleine,[1] Csaba P. Kovesdy,[4] Kamyar Kalantar-Zadeh,[5] Elani Streja.[1]
[1]Harold Simmons Center for Kidney Disease Research and Epidemiology, Orange, CA; [2]University of California, Irvine, Orange, CA; [3]UC Irvine Medical Center, Bishop, CA; [4]University of Tennessee Health Science Center, Memphis, TN; [5]University of California Irvine, School of Medicine, Orange, CA.

Background: Prior studies in chronic kidney disease (CKD) patients have shown a paradoxical association where CKD patients with higher cholesterol did not have the higher risk of mortality, as observed in the general population. However, the cholesterol-mortality relationship has not been thoroughly examined in a single nationally representative cohort with the ability to assess the impact of CKD stage on this relationship.

Methods: Using data from the National Health and Nutrition Examination Surveys (NHANES), we identified 31,270 adults with available measurements on serum cholesterol and creatinine between 1999-2006. We examined the association of cholesterol with mortality in 6 groups of cholesterol, and stratified by 3 levels of estimated glomerular filtration rate (eGFR). Associations were examined with Cox models with multivariable adjustment for demographics, comorbidities, medication use, body mass index and albumin.

Results: The cohort mean age was 47±20 years and comprised of 52% females and 20% non-Hispanic black patients. Patients with higher cholesterol tended to be older, female, non-Hispanic white, but less likely to be diabetic, or take medications for high cholesterol. Over a median follow-up of 6[3, 9] years, 2,802 deaths occurred. Compared to cholesterol 175-<200 mg/dL, both low and high cholesterol was associated with higher death risk in unadjusted models, but associations for higher cholesterol was attenuated after age adjustment. In fully adjusted models, patients with lower cholesterol (<150 mg/dL) had or trended towards a higher risk of mortality across all strata of eGFR. Yet, higher cholesterol was not associated with higher mortality risk in any strata of eGFR. [Figure]

Conclusions: Among the nationally representative NHANES cohort, higher cholesterol is not associated higher mortality risk. Future studies evaluating the impact of kidney disease on the cholesterol-mortality association are needed.



SA-PO775

Patterns of Troponin Elevation in Patients with CKD and Long-Term Mortality Risk After Progression to ESRD

Lekha K. George,[1] Santhosh K. Koshy,[2,1] Miklos Z. Molnar,[1] Praveen Kumar Potukuchi,[1] Manyoo Agarwal,[3] Koshy K. George,[4] Kamyar Kalantar-Zadeh,[5] Csaba P. Kovesdy.[6,1]
[1]University of Tennessee Health Science Center, Memphis, TN; [2]Regional One Health - University of TN Health Sciences Ctr, Memphis, TN; [3]University of Tennessee Health Science Center, Memphis, TN; [4]University of Queensland, Memphis, TN; [5]University of California Irvine, School of Medicine, Orange, CA; [6]Memphis VA Medical Center, Memphis, TN.

Background: Elevated troponin as a marker of myocardial infarction is associated with poor short and long term mortality. Chronic kidney disease is commonly associated with higher and sustained levels of troponin due to reduced clearance. It is not known if the pattern of troponin elevation in patients with advanced CKD confers higher mortality risk after starting dialysis.

Methods: We examined 16,563 US veterans who had troponin levels measured during the 3 years prior to start of dialysis. We examined associations of 24-hour slope of troponin elevation, maximum troponin level, and the absolute value and percentage of the difference between the maximum and minimum troponin levels with all-cause mortality in Cox models adjusted for demographics, comorbidities, smoking status, blood pressure, BMI and baseline eGFR.

Results: Patients were 66±10 years old, 97% male, 37% African-American, 77% diabetic, and 67%, 69% and 41% had histories of ischemic heart disease, congestive heart failure and cerebrovascular disease, respectively. 11,196 patients died (mortality rate: 243/1000 patient-years, 95%CI: 238-248) over a median follow-up of 2.43 years after starting dialysis. Steeper rise in troponin level over 24 hours was not associated with higher mortality (Figure). Higher levels of maximum troponin level were associated with significantly higher mortality, whereas a higher absolute and percentage difference between maximum and minimum troponin levels was less consistently associated with increased mortality (Figure).

Conclusions: Elevated troponin in patients with advanced stage CKD is associated with higher risk of mortality after initiation of dialysis. Higher levels of maximum troponin values show the most consistent association with higher mortality, whereas the rate of troponin rise over a 24-hour period is not associated with long term mortality.

SA-PO776

Longitudinal Relationship of Left Ventricular Hypertrophy with Cardiovascular Events in CKD

Jinwei Wang,[1] Luxia Zhang,[2,3] Kevin He,[5] Minghui Zhao.[4] the Chinese Cohort Study of Chronic Kidney Disease
[1]Renal Division, Department of Medicine, Peking University First Hospital; Peking University Institute of Nephrology, Beijing, China; [2]Peking University Institute of Nephrology, Beijing, China; [3]Center for Data Science in Health and Medicine, Peking University, Beijing, China; [4]Reanl division, Peking University First Hospital, Beijing, China; [5]Kidney Epidemiology and Cost Center, University of Michgian, Ann Arbor, MI.

Background: We aimed to evaluate the relationship between left ventricular (LV) hypertrophy and adverse cardiovascular (CV) events among patients with chronic kidney disease (CKD).

Methods: Based on the Chinese Cohort Study of CKD (n=3499), 2000 participants with interpretable echocardiograms, complete relevant clinical data and without a baseline CV disease history were enrolled in the study. LV mass was calculated using the area-length method and indexed to height$^{2.7}$. CV events included incident acute myocardial infarction, unstable angina, hospitalization for congestive heart failure, cerebrovascular events and peripheral vascular diseases. The population was followed-up until occurrence of CV events or by June 30, 2017. Cox proportional hazards regression model was used to estimate the relationship between the exposure and outcomes.

Results: The mean age of the population was 47.2±13.7 years, with 56.4% of males. The mean level of estimated glomerular filtration rate (eGFR) was 52.9±31.3ml/min/1.73m^2. The proportions of CKD stages 1, 2, 3a, 3b and 4 were 16.8%, 17.5%, 14.9%, 23.3% and 27.7%, respectively. Mean level of LV mass/ height$^{2.7}$ was 39.7±12.7g/m$^{2.7}$, with

the proportion of LV hypertrophy (LV mass/height$^{2.7}$≥47g/m$^{2.7}$ in women and ≥50 g/m$^{2.7}$ in men) being 17.9%. After a median follow-up of 4.45(inter-quartile range: 3.76-5.05) years, 89 CV events occurred, with an incidence rate of 1.03 per 100 person-years among total patients with CKD, 2.23 per 100 person-years among those with LV hypertrophy and 0.78 per 100 person-years among those without LV hypertrophy (log-rank p-value<0.001). LV hypertrophy or a standard deviation increase in LV mass/ height$^{2.7}$ was significantly associated with increased risk of CV events after adjustment for traditional CV risk factors, albuminuria and eGFR. The hazard ratios and 95% confidence interval were 1.78(1.12-2.81) and 1.40(1.19-1.66), respectively. Sensitivity analysis among those with chronic glomerular nephritis or excluding congestive heart failure from the CV events showed consistent results.

Conclusions: LV hypertrophy is independently associated with increased risk of CV events among patients with CKD. Further studies are needed to evaluate the clinical effectiveness of screening high risk population among patients with CKD by using LV hypertrophy.

Funding: Government Support - Non-U.S.

SA-PO777

Association Between Polymorphism of rs11864909 and Serum Uromodulin Among CKD Was Modified by Kidney Function

Jinwei Wang,[1] Luxia Zhang,[2] Kevin He,[3] Minghui Zhao.[4] the Chinese Cohort Study of Chronic Kidney Disease *[1]Renal Division, Department of Medicine, Peking University First Hospital; Peking University Institute of Nephrology, Beijing, China; [2]Peking University Institute of Nephrology, Beijing, China; [3]Kidney Epidemiology and Cost Center, University of Michgian, Ann Arbor, MI; [4]Reanl division, Peking University First Hospital, Beijing, China*.

Background: The single nucleotide polymorphism (SNP) of rs11864909 is located close to uromodulin gene of *UMOD*. A genome-wide association study in east Asian populations detected a genome-wide significant association between the SNP and estimated glomerular filtration rate (eGFR). We aimed to test the association of the SNP with serum uromodulin among patients with chronic kidney disease (CKD) and test if the association was modified by eGFR.

Methods: Altogether, 1812 participants with complete relevant clinical and genotyping data in the Chinese Cohort Study of CKD (n=3499) was enrolled in the study. Genotyping for rs11864909 was conducted by TaqMan genotyping assay. Serum uromodulin was measured by a commercially available ELISA kit. Linear regression analysis was used to test the association between rs11864909 and serum uromodulin.

Results: The mean age of the population was 48.4±13.7 years, with 56.9% of males. The mean level of eGFR was 52.5±30.5ml/min/1.73m^2. The proportions of patients with CKD stage 1, 2, 3 and 4 were 15.3%, 16.8%, 41.2% and 26.7%, respectively. The mean level of serum uromodulin was 90.9±61.2 ng/mL. The CC, CT and TT genotype of the rs11864909 polymorphism accounted for 72.7%, 24.7% and 2.6% of the population (*P* for Hardy-Weinberg equilibrium>0.05). People with the CT&TT genotype had a significantly lower level of serum uromodulin than those with CC genotype (79.7 ng/mL vs. 95.1 ng/mL, *P*<0.001). After inclusion of the interaction term between rs11864909 and eGFR (*P* for interaction<0.001) in the multi-variable adjusted linear regression model, the regression coefficient (standard error) per 1 ml/min/1.73m^2 increase in eGFR increased from 1.4(0.039) to 1.5(0.045), while the effect of rs11864909 (CT&TT vs. CC) lost statistical significance (regression coefficient increased from -20.6[2.3] to -2.1[4.6]). Sensitivity analysis among those with CKD stages 3 and 4 and those from large central study sites got consistent results.

Conclusions: The common polymorphism of rs11864909 in the *UMOD* gene associated with the level of serum uromodulin among patients with CKD, but the relationship was influenced by kidney function. The results add further insights into the effect of *UMOD* gene among CKD.

Early Impairment of Kidney Function Is Associated with Changes in Cardiac Structure and Function – Findings from a Large Population-Based Cohort of Elderly Subjects

Anders Christensson. *Skane University Hospital, Malmo, Sweden*.

Background: The pathophysiological association between heart and kidney diseases is often referred to as the cardiorenal syndrome. There are only few previous community-based studies reporting on the association between renal function and left ventricular (LV) function. In recent years also a minor reduction of glomerular filtration rate (GFR) has emerged as a risk marker for changes in cardiac structure. However, there is little knowledge about this in early renal impairment and echocardiographic functional parameters indicating diastolic dysfunction in community-based cohorts.

Methods: The study population consisted of 1504 individuals with no prior history of congestive heart failure or asymptomatic left ventricular ejection fraction ≥40% and an estimated glomerular filtration rate (eGFR) based on cystatinC >15 mL/min/1.73m^2. Participants were categorized according to eGFR; ≥90; 75-89; 60-74; 45-59; 30-44; and 15-29 mL/min/1.73m^2. We evaluated associations between eGFR and echocardiographic findings. Transmitral pulsed Doppler flow and tissue Doppler imaging (TDI) in the four-chamber view were used to measure LV diastolic function. Peak myocardial velocity of the basal LV wall in early (É) and late (Á) diastole in the lateral (lat) and septal (sept) walls and Doppler measurement of peak velocity of blood flow through the mitral valve in early (E) and late (A) diastole were measured.

Results: Associations between reduced eGFR and echocardiographic findings indicating early structural changes were found for; left atrium area/body surface area (p=0.013) and diastolic function; peak early mitral valve velocity (A) (p=0.003), peak late atrial mitral valve velocity/ peak systolic myocardial velocity at mitral annulus in lateral wall; (E/Élat) (p=0.002), mean of É mean of lateral and septal wall/ Á mean of lateral and septal wall (mean Ém/Ám) (p=0.027). Associations between E/Élat and meanÉm/Ám and eGFR were present already in mild-moderate kidney dysfunction (eGFR 45-60 mL/min/1,73m^2). These associations were only significant among men.

Conclusions: A significant association between early impairment of renal function and echocardiographic markers of cardiac structure and diastolic function was observed supporting the hypothesis that interaction between the kidney and heart exists even in the early stages of renal impairment.

The Association of Markers of Mineral Bone Disease with CVEs in Early CKD

Natasha J. McIntyre,[1] Adam Shardlow,[2] Nitin V. Kolhe,[2] Richard J. Fluck,[2] Christopher W. McIntyre,[3] Maarten W. Taal.[1,2] *[1]Faculty of Medicine and Health Sciences, University of Nottingham, London, ON, Canada; [2]Royal Derby Hospital, Derby, United Kingdom; [3]London Health Sciences Centre, London, ON, Canada*.

Background: Markers of mineral bone disease (MBD), particularly FGF23 and serum phosphate, are associated with a higher risk of cardiovascular events (CVEs) in Chronic Kidney Disease (CKD). However, it is not clear if these associations exist in early CKD, when phosphate is normal and FGF23 only mildly elevated. We investigated biomarkers of MBD as risk factors for CVE in people with CKD stage 3 in primary care.

Methods: 1741 people with estimated GFR 59-30mL/min/1.73m^2 (eGFR) were recruited to the Renal Risk in Derby (RRID) study and assessed at baseline, year 1 and 5. Data on all hospital admissions with CVE (using ICD-10 coding) and cardiovascular deaths between 2008 to 2015 were obtained from NHS Digital. Cox regression analysis was performed on the whole cohort, those with heart failure (HF) or atherosclerotic events to identify risk factors for CVEs.

Results: 608 CVEs occurred during a mean period of 5.1±2.2 years, a rate of 6.8/100 participant years. The most frequent CVE was HF (345/608=57%). In the whole cohort age, male sex, HDL cholesterol, smoking, eGFR and urinary albumin to creatinine ratio were confirmed as independent risk factors for CVEs. Among the MBD biomarkers, phosphate and PTH predicted CVEs but FGF23 and vitamin D did not. There were differences in risk factors for HF versus atherosclerotic events (Table).

Conclusions: We identified HF as the commonest CVE in those with early CKD. In addition we identified phosphate and PTH as independent risk factors for CVEs even at early stages of CKD, when there is only minor perturbation of these variables. Our findings suggest trials of interventions to lower serum phosphate in early CKD are warranted.

Worsening of Renal Function Predicts Mortality in Patients with Cancer and CKD

Ivens S. L Leite,[1] Luiz F. Souza,[1] Renato A. Caires,[2] Francisco Z. Mattedi,[2] Fernanda O. Coelho,[2] Veronica Torres,[2] Elerson Costalonga.[2] *[1]University of Sao Paulo School of Medicine, Sao Paulo, Brazil; [2]Sao Paulo State Cancer Institute - USP, Sao Paulo, Brazil*.

Background: Cancer patients have a high prevalence of chronic kidney disease (CKD). The aim of this study was to assess prognostic factors for death in cancer patients with CKD.

Methods: Among 397 outpatients with cancer referred to nephrology evaluation (2009-12), 202 had CKD according KDIGO definitions and at least 3 months of follow up. Clinical and biochemical data were retrieved from patient medical records. The Cox regression was used to examine the predictors of mortality.

Results: After a follow-up of 3.9±2 years, the mortality rate observed was 57%. The patients features are shown in Table1. In the Cox regression analyses, serum albumin (aHR=0.38; CI 0.28-0.54, p<0.001), ongoing chemotherapy [aHR=0.61; CI 0.38-0.97, p=0.038], and CKD progression [aHR: 2.54; CI 2.54-4.18, p<0.001), defined as a sustained decline in eGFR of more than 5ml/min/1.73m^2/yr, were the independent predictors of mortality in our population. Of note, worsening of renal function remained a independet risk factor for mortality even after adjustments for important cancer related factors (presence of metastasis) and Karnofsky index.

Conclusions: Patients with cancer and CKD have a poor prognosis. Serum albumin, ongoing chemotherapy, and CKD progression were independent factors associated to mortality.

Table 1. Baseline Features

	Death (n=116)	Surviving (n=86)
Age (yr)	67±12	65±12

Association of eGFR and ACR with Cardiovascular Outcomes in the Elderly

Andreas Kuehn,[1] Natalie Ebert,[1] Jens Gaedeke,[3] Markus van der Giet,[1] Martin K. Kuhlmann,[2] Nina Mielke,[1] Elke Schaeffner.[1] *[1]Charite - Universitaetsmedizin Berlin, Berlin, Germany; [2]Vivantes Klinikum im Friedrichshain, Berlin, Germany; [3]Dept. of Nephrology, Charité, Berlin, Germany*.

Background: Data on the effect of kidney function (eGFR) / kidney damage (ACR) on cardiovascular (CV) outcomes in the elderly remain scarce. We investigated the effect of eGFR on cardiovascular outcomes using data of the Berlin Initiative Study (BIS).

Methods: The BIS has followed 2069 older adults ≥70 yrs since 2009. eGFR/kidney damage were assessed by eGFR-BIS2(crea/cysC) and ACR, respectively. ICD-10-based outcomes were stroke or myocardial infarction (MI), combined or single, ischemic stroke, and death to all-cause. A Competing Risk Model was set up for CV events, a Cox proportional hazards model for all-cause mortality for hazard ratios(HR) and 95% confidence intervals (CI). Individuals with CV event before baseline were excluded. Models adjusted for age, sex, diabetes, smoking, waist-to-hip-ratio, antihypert. treatment, systolic BP, pulse pressure, c-reactive protein, total and high density cholesterol.

Results: Within a median f/up of 7.1 yrs, 276 CV events and 680 deaths occured. For eGFR<60mL/min/1.73m^2 highest HRs were seen for (ischemic) stroke (Table 2). Highest HR of 2.11 (1.36-3.29) was observed for ischemic stroke if eGFR was 45-59mL/min/1.73m^2. HRs were highest for the combination of eGFR <60mL/min/1.73m^2 and ACR >30mg/g for all outcomes. For stroke, isolated reduced eGFR revealed a similar HR of 1.85 (1.19-2.90) as reduced eGFR and increased ACR combined. For death, isolated increased ACR had a HR of 2.04 (1.43-2.90).

Conclusions: After adjusting, reduced eGFR was highly associated with hazard of stroke in older adults. As for the combination of eGFR and ACR, the distribution of HRs for the cardiovascular outcomes suggests an association of ischemic stroke risk only with eGFR and a strong independent association of ACR with all-cause mortality.

Trends in Mortality Among Medicare Beneficiaries with and Without CKD

Monica Shieu,[1] Kevin He,[2] Diane Steffick,[1] Hal Morgenstern,[1] Bruce M. Robinson,[3] Rajiv Saran.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Kidney Epidemiology and Cost Center, University of Michgian, Ann Arbor, MI; [3]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Decreasing mortality rates have been observed for Medicare beneficiaries with claims-based diagnosis of CKD. It is unclear whether this is a true decline in CKD mortality or an artifact of increasing recognition of earlier stages of CKD. We sought to examine trends in mortality rate by stage of CKD.

Methods: Persons from 2008-16 Medicare 5% samples were required to be alive, aged >65 on Jan 1, without ESRD, and covered by Medicare Parts A and B but not C for all of the year. Years at risk were calculated from Jan 1 each year and censored at the start of ESRD, Dec 31, or disenrollment from Medicare. CKD claims-based diagnoses were searched from the year before, using ICD-9-CM and ICD-10-CM codes used to define CKD and its stages. The crude mortality rate each year was calculated as the number of deaths divided by the patient-years at risk. Cox regression, stratified by CKD stage, was used to estimate annual (hazard) rates standardized to the age-sex-race distribution of the Medicare 2011 population.

Results: Between 2008 and 2016, the percentage of people with diagnosed CKD stages 1-3 decreased. Persons without CKD had the lowest mortality rate each year, with unadjusted rate decreasing by 49.6 since 2008 to 41.9 in 2016. While the crude mortality rate decreased in CKD stages 1-2 and stage unknown by 17.6% and 27.5% respectively, the rates for stages 3-5 remained relatively unchanged. With standardization for age, sex, and race, we observed less change in mortality rates between 2008 and 2014, but sudden increases in 2015 and sudden decreases in 2016, especially in more advanced CKD stages. (See Figure)

Conclusions: The decline observed in the crude mortality rate among all CKD patients may be due to the changing distributions of age/sex/race/CKD stage, improved care of underlying risk factors, but not to greater recognition of early stage CKD. We acknowledge the limitations of claims-based diagnosis of CKD in this study. Furthermore, the sudden changes in standardized mortality rates between 2014 and 2016 remain unexplained and require further study.

Albuminuria, Reduced Kidney Function, and the Risk of ST and Non-ST Elevation Myocardial Infarction

Sonali N. De Chickera,[5] Ngan Lam,[2] Samuel A. Silver,[3] Amber O. Molnar,[4] Edward G. Clark,[5] Manish M. Sood.[1] *[1]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]University of Alberta, Edmonton, AB, Canada; [3]Queen's University, Kingston, ON, Canada; [4]McMaster University, Hamilton, ON, Canada; [5]The Ottawa Hospital and Kidney Research Centre - Ottawa Hospital Research Institute, University of Ottawa, Ottawa, ON, Canada.*

Background: Myocardial infarctions (MIs) in patients with chronic kidney disease (CKD) are associated with high rates of mortality and complications. CKD is a recognized risk factor for cardiovascular disease, but whether the risk of ST-elevation MI (STEMI) and non-ST-elevation MI (NSTEMI) differs in the CKD population is unknown. We examined the association of CKD (defined by reduced estimated glomerular filtration rate (eGFR) or albuminuria) with risks of STEMI and NSTEMI.

Methods: Using administrative data from Ontario, Canada, we examined older individuals (≥66 years of age) with an outpatient eGFR and albuminuria measure for incident MI from 2002 to 2015. Multivariate Fine & Gray sub-distribution hazards (sHR), adjusted for demographics, comorbidities, health resource utilization and medications, accounting for the competing risk of death were used.

Results: In 248,438 patients with over 1.2 million person-years of follow-up, STEMI, NSTEMI and death occurred in 1,436 (0.58%), 4,431 (1.78%) and 30,015 (12.08%) patients, respectively. In adjusted models, both eGFR and urine albumin to creatinine ration (ACR) were associated with STEMI and NSTEMI (P<0.0001). The highest level of ACR (>30 mg/mmol) was associated with a two-fold higher adjusted risk of both STEMI and NSTEMI among patients with eGFR ≥60 ml/min/1.73m^2 compared to ACR <3 mg/mmol. The lowest level of eGFR (<30 ml/min/1.73m^2) with ACR < 3 mg/mmol was not associated with higher STEMI risk but a four-fold higher risk of NSTEMI compared to eGFR ≥60ml/min/1.73m^2. The lowest eGFR (<30 ml/min/1.73m^2) and highest ACR (>30 mg/mmol) was associated with a greater than four-fold higher risk of both STEMI and NSTEMI (sHR (95% CI) 4.53 (3.30-6.21) and 4.42 (3.67-5.32), respectively) compared to ACR <3 mg/mmol and eGFR ≥60 ml/min/1.73m^2.

Conclusions: Elevations in albuminuria are associated with a higher risk of both NSTEMI and STEMI, regardless of kidney function, whereas reduced kidney function with minimal albuminuria is associated with only a heightened NSTEMI risk.

SA-PO784

The Bidirectional Nature of the Cardio-Renal Link in Stable CKD Patients

Evangelia Dounousi,[1] Xanthi Zikou,[2] Konstantinos Pappas,[3] Francesca Mallamaci,[4] Carmine Zoccali.[4] *[1]University of Ioannina, Ioannina, Greece; [2]Nephrology, University Hospital Ioannina, Ioannina, Greece; [3]University Hospital of Ioannina, Ioannina, Greece; [4]CNR IFC, Clinical Epidemiology of Renal Diseases and Hypertension, Reggio Calabria, Italy.*

Background: In patients with heart disease, left ventricular (LV) dysfunction and heart failure are associated with reduced GFR and vice-versa, in CKD patients, LV hypertrophy and dysfunction go along with the CKD severity. Experimental models support the causal nature of these cardio-renal links. However, there is no clinical study investigating the bi-directionality of these links in stable non-dialysis CKD patients.

Methods: We tested the longitudinal relationship between the estimated GFR (eGFR) and the LV mass index (LVMI) and vice versa in a cohort of 206 stage G1-5 (non-dialysis) CKD patients. Overall, 498 simultaneous eGFR and LVMI measurements in 206 patients were available over a 3 year follow-up. Data analysis was performed by the mixed linear model. In this analysis each predictor (either the eGFR or LVMI) was paired with the subsequent measurement of the pertinent outcome measure (i.e. LVMI when the predictor was the eGFR and the eGFR when the predictor was the LVMI) and adjusting for both, the eGFR and the LVMI of the preceding visit.

Results: At baseline the eGFR (MDRD) was 54±29 ml/min/1.72 m^2 and LVMI was 70±24 $gr/m^{2.71}$. In the analysis testing the LVMI as a predictor of the evolution of the eGFR over time, an increase in LVMI of 10 $gr/m^{2.71}$ predicted a eGFR loss of 0.41±0.25 ml/min/1.72 m^2over follow up but such an effect failed to attain statistical significance (P=0.10). Vice versa, in the analysis testing the eGFR as a predictor of the evolution of the LVMI over time, a decrease in eGFR of 10 ml/min/1.73m^2predicted an increase in LVMI of 1.1±0.4 $g/m^{2.71}$ over follow up and this change was highly significant (P=0.001).

Conclusions: This longitudinal analysis in stable non-dialysis CKD patients shows that eGFR loss predicts a rise in LVMI over time. A similar trend exists for the opposite relationship, i.e. LVMI worsening predicts a subsequent eGFR loss but this relationship is much weaker than the previous one and does not achieve formal statistical significance. Overall, these observations suggest that the kidney disease-driven risk for cardiomyopathy progression is more consistent than the simultaneous heart-disease driven risk for CKD progression.

SA-PO785

Inflammatory Markers and Incidence of Hospitalization with Infection in CKD: The Chronic Renal Insufficiency Cohort Study

Junichi Ishigami,[1] Jonathan J. Taliercio,[2] Harold I. Feldman,[3] Anand Srivastava,[4] Raymond R. Townsend,[5] Debbie L. Cohen,[5] Panduranga S. Rao,[6] Jeffrey C. Fink,[7] Ana C. Ricardo,[8] Teresa K. Chen,[9] Myles Wolf,[10] Tamara Isakova,[11] Jeanne Charleston,[15] James H. Sondheimer,[12] Edward J. Horwitz,[16] Lawrence J. Appel,[13] Kunihiro Matsushita.[14] *[1]Johns Hopkins School of Public Health, Baltimore, MD; [2]Glickman Urological and Kidney Institute, Cleveland, OH; [3]University of Pennsylvania, Philadelphia, PA; [4]Northwestern University Feinberg School of Medicine, Chicago, IL; [5]University of Pennsylvania School of Medicine, Villanova, PA; [6]University of Michigan Health System, Ann Arbor, MI; [7]University of Maryland, Baltimore, MD; [8]University of Illinois at Chicago, Chicago, IL; [9]Johns Hopkins University School of Medicine, Baltimore, MD; [10]Duke University, Durham, NC; [11]Feinberg School of Medicine, Northwestern University, Chicago, IL; [12]Wayne State University School of Medicine, Detroit, MI; [13]Johns Hopkins Medical Institutions, Baltimore, MD; [14]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [15]Johns Hopkins University, Baltimore, MD; [16]MetroHealth, Cleveland, OH.*

Background: Low grade inflammation may be linked to the impaired immune response in CKD. Whether inflammatory markers are associated with risk of hospitalization with infection is unknown.

Methods: In 3,622 participants of the CRIC Study, we assessed the association between the baseline levels of four inflammatory markers (interleukin-6 [IL-6], tumor necrosis factor-α [TNF-α], interleukin-1 receptor antagonist [IL-1RA], and transforming growth factor-β [TGF-β]) and incidence of hospitalization with major infections (pneumonia, urinary tract infections, cellulitis and osteomyelitis, and bloodstream infections) using Cox models adjusted for potential confounders including eGFR and uACR to estimate hazard ratio (HR). The inflammatory markers were log-transformed and modeled as restricted cubic spline with the knots at 5th, 50th, and 95th percentile.

Results: During a median follow-up of 7.5 years, 36% (n=1,294) had a hospitalization with major infections. Higher levels of IL-6 and TNF-α, but not IL-1RA or TGF-β, were each monotonically associated with increased risk of hospitalization with infection (**Figure**) (HR at 95th vs. 5th percentile, 2.27 [95%CI, 1.81-2.85] for IL-6 and 1.96 [1.59-2.42] for TNF-α). The associations of IL-6 and TNF-α were independent of each other and consistent across types of infection or in demographic and clinical subgroups.

Conclusions: Higher levels of IL-6 and TNF-α, but not IL1RA or TGF-β, were independently associated with increased risk of hospitalization with infection. Future studies are needed to explore the underlying mechanisms of the discrepant patterns in the association with risk of infection across inflammatory markers.

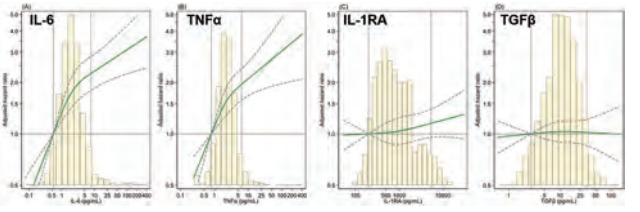

Figure: Histogram and HRs of hospitalization with infection for (A) IL-6, (B) TNF-α, (C) IL-1RA, and (D) TGF-β. Vertical lines indicate 5th (reference) and 95th percentiles.

Infection-Related Hospitalizations Across Different Levels of Kidney Function: Data from the EXTEND45 Study

Brendon L. Neuen,[1] Meg J. Jardine,[1] Louisa Sukkar,[1,2] Amy Kang,[1] Celine Foote,[4,1] Kris Rogers,[1] Anish Scaria,[1] Alan Cass,[3] Martin P. Gallagher,[1] Min Jun.[1] EXTEND45 Study Steering Committee *[1]The George Institute for Global Health, UNSW Sydney, Newtown, NSW, Australia; [2]School of Public Health, University of Sydney, Sydney, NSW, Australia; [3]Menzies School of Health Research, Darwin, NT, Australia; [4]Concord Repatriation General Hospital, Sydney, NSW, Australia.*

Background: The risk of infection associated with differing levels of kidney function is unclear. We sought to determine the risk of infection-related hospitalization and mean hospital length of stay across different levels of kidney function in a community-based cohort study.

Methods: Based on data from the EXTEND45 Study (the 45 and Up Study linked to hospital and community pathology datasets by the Centre for Health Record Linkage [CHeReL]), we identified a population-based cohort (2006-2014) of 41,099 people aged ≥45 years who had a measure of kidney function (estimated glomerular filtration rate [eGFR]). The risk of infection-related hospitalization and mean hospital length of stay were assessed by eGFR categories (≥90, 60-89, 45-59, 30-44 and <30ml/min/1.73m^2) using multivariable Cox regression.

Results: Of 41,099 participants, 18.6% had an eGFR <60 ml/min/1.73m^2. Overall, 2,598 (6.3%) participants experienced ≥1 infection-related hospitalization over a mean follow-up of 5.8 years. After adjusting for age and sex, risk of infection increased with declining eGFR in a graded and linear fashion (HR 0.91 [95% CI: 0.79-1.04], 1.16 [0.99-1.37], 1.48 [1.22-1.78], and 1.83 [1.44-2.31] for eGFR ≥90, 60-89, 45-59, 30-44, and <30 ml/min/1.73 respectively). Pneumonia, urinary tract infections, and cellulitis were the most common infections across all eGFR categories. Mean hospital length of stay similarly increased with declining eGFR categories (4.9, 6.5, 7.5, 7.8 and 7.9 days, respectively).

Conclusions: The risk of serious infection increases as kidney function declines, independent of age and sex, suggesting that susceptibility is likely related to other factors (e.g. alterations in immune function) and begins in mild-moderate renal impairment.

SA-PO787

Predictors of CKD in the EXTEND45 Study: An Australian Population-Based Study

Amy Kang,[2] Louisa Sukkar,[1] Min Jun,[2] Celine Foote,[1,6] Roberto Pecoits-Filho,[3] Brendon L. Neuen,[1] Anish Scaria,[1] Jannah F. Baker,[1] Kris Rogers,[1] Alan Cass,[4] Carol A. Pollock,[5,7] Germaine Wong,[5] John Knight,[1] David Peiris,[1] Martin P. Gallagher,[2] Meg J. Jardine.[2] *[1]The George Institute for Global Health, Camperdown, NSW, Australia; [2]The George Institute for Global Health, UNSW Sydney, Newtown, NSW, Australia; [3]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [4]Menzies School of Health Research, Darwin, NT, Australia; [5]The University of Sydney, St. Leonards, NSW, Australia; [6]Department of Renal Medicine, Concord Repatriation General Hospital, Sydney, NSW, Australia; [7]Kolling Institute for Medical Research, Sydney, NSW, Australia.*

Background: The AUSDIAB study found an incidence rate of CKD (eGFR<60ml/min/1.73m^2) of 0.4 per 100 person-years in the adult Australian community aged ≥25 years. We aimed to assess: 1) the incidence and prevalence of chronic kidney disease (CKD), 2) risk factors for incident CKD in a contemporary Australian population-based cohort of adults aged 45 and older.

Methods: Based on data from the EXTEND45 study (the 45 and Up Study linked to [1]hospital and community pathology datasets by the Centre for Health Record Linkage[CHeReL] and [2]the Medicare Benefits Schedule[MBS] and Pharmaceutical Benefits Scheme[PBS] datasets provided by the Department of Human Services), we identified a population-based cohort (2006-2014) of 41,099 people aged ≥45 years who had ≥2 measures of kidney function. Prevalent CKD (defined as eGFR <60 ml/min/1.73m^2) was determined at study recruitment. The CKD incidence rate over the study period was determined using Poisson regression. Cox regression was used to determine associations between baseline sociodemographic factors, comorbidities and future incident CKD.

Results: Of 41,099 participants, 7,641(18.6%) had prevalent CKD and 5,481 developed incident CKD over a mean follow-up of 5.6 years. The incidence rate of CKD was 3.2(95% CI:3.1-3.3) per 100 person-years. Baseline characteristics: age (per year increase; HR: 1.08[1.07-1.08]), regional residence (inner regional vs city: 1.26[1.18-1.36]), diabetes (1.28[1.19-1.38]), hypertension (1.58[1.48-1.70]), heart disease (1.22[1.14-1.31]), stroke (1.16[1.03-1.29]), depression (1.25[1.15-1.35]) and higher BMI (obese vs normal: 1.38[1.27-1.49]) were predictive of incident CKD. Alcohol consumption (7-13 vs 0-6 drinks/week 0.89[0.82-0.97]) was associated with a lower risk of incident CKD.

Conclusions: Baseline depression and regional residence predicted future incident CKD in conjunction with established risk factors of age, diabetes, hypertension, high BMI and vascular disease.

SA-PO788

Burden of Metabolic Complications with Advancing CKD in the Irish Health System

Leonard Browne,[1] Paul O'Hara,[1,2] Edward P. Mc Monagle,[2] Austin G. Stack.[1,2] *[1]Graduate Entry Medical School, University of Limerick, Limerick, Ireland; [2]University Hospital Limerick, Limerick, Ireland.*

Background: The prevalence of Chronic Kidney Disease (CKD) exceeds 15% in the Irish health system and is associated with adverse clinical outcomes. The goal of this study was to describe the burden of common metabolic complications in CKD and assess the impact of deteriorating kidney function.

Methods: Utilising data from the National Kidney Disease Surveillance System, we conducted a cross sectional study of adult patients, age > 18 years, from the Midwest region in 2014 with data on serum creatinine measurements and metabolic indicators of anaemia, nutrition, metabolic bone disease and acidosis. Dialysis patients were excluded. The following definitions were used: anaemia: haemoglobin <13 g/dL in men and <12 g/dL in women; hyperkalaemia: K+ > 5.5 mmol/L; hypoalbuminaemia; serum albumin <35g/L, metabolic acidosis: bicarbonate < 22 mmol/L, and hyperphosphatemia: phosphate >1.5 mmol/L. Logistic regression models explored associations of estimated glomerular filtration rate (eGFR) with each metabolic complication expressed as adjusted odds ratio (OR) and 95% Confidence intervals.

Results: There were 133,558 adults with average age 54.3 (±17.7) years and eGFR 87.9(±21.1) ml/min/1.73m^2. The prevalence of metabolic complications were as follows: acidosis (28.9%), anaemia (13.6%), hyperkalaemic (13.1%), hypoalbuminaemia (9.9%), and hyperphosphatemia (2.3%). In multivariate models adjusting for age and sex only, each 5mL/min/1.73m^2 fall in eGFR was associated with higher odds of anaemia, [OR 1.08 (95% CI; 1.07-1.09)]; hyperkalaemia [OR 1.09 (95% CI; 1.08-1.10], hypoalbuminaemia, [OR 1.02 (1.01-1.03)], metabolic acidosis [OR 1.03 (95% CI; 1.02-1.04)], and hyperphosphatemia [OR 1.23 (95% CI; 1.21-1.26)].These findings were accentuated in the elderly (Table 1).

Conclusions: The burden of CKD-related metabolic complications is substantial within the Irish health system and increases with advancing CKD. Patients with low eGFR, especially the elderly, are at increased risk for several serious but treatable metabolic complications. Early identification and treatment of these disorders may lead to improved patient outcomes

Funding: Government Support - Non-U.S.

Table 1. AOR of metabolic complications for a 5mL/min/1.73m^2 decrease in eGFR stratified by Age group

Variable	<40	40-59	60-80	>80
Anaemia	0.86 (0.84-0.87)	1.00 (0.99-1.01)	1.18 (1.18-1.19)	1.13 (1.11-1.14)
Hyperkalaemia	1.10 (1.08-1.12)	1.09 (1.07-1.10)	1.09 (1.08-1.10)	1.12 (1.10-1.15)
Hyperphosphatemia	1.07 (1.02-1.12)	1.23 (1.19-1.26)	1.29 (1.25-1.33)	1.40 (1.28-1.53)
Metabolic Acidosis	0.94 (0.92-0.95)	1.00 (0.99-1.02)	1.08 (1.07-1.10)	1.14 (1.11-1.16)
Hypoalbuminemia	0.76 (0.74-0.77)	1.03 (1.01-1.05)	1.12 (1.11-1.13)	1.05 (1.03-1.06)

Model: Sex & eGFR adjusted. The likelihood of these complications were far greater in older patients with declining eGFR. (p values for the age X GFR interaction term: <0.001 for anaemia, acidosis, hyperphosphatemia, hypoalbuminaemia and p=0.016 for hyperkalaemia)

SA-PO789

Assessing the Risk and Severity of Hospitalisations According to Level of Kidney Function: An EXTEND45 Analysis

Min Jun,[1] Louisa Sukkar,[2] Brendon L. Neuen,[2] Celine Foote,[2] Kris Rogers,[2] Amy Kang,[2] Anish Scaria,[2] Alan Cass,[5] Carol A. Pollock,[3] John Knight,[2] Martin P. Gallagher,[1] Meg J. Jardine.[4] EXTEND45 Study Steering Committee *[1]The George Institute for Global Health, UNSW Sydney, Newtown, NSW, Australia; [2]The George Institute for Global Health, Sydney, NSW, Australia; [3]The University of Sydney, St. Leonards, NSW, Australia; [4]The George Institute for Global Health, UNSW, Newtown, NSW, Australia; [5]Menzies School of Health Research, Darwin, NT, Australia.*

Background: Contemporary assessments of the relationship between chronic kidney disease (CKD) and health services use in Australia by level of eGFR have been limited. Prior studies typically used diagnosis codes to identify CKD which have relatively low sensitivity for ascertaining earlier stages of CKD. We determined the risk and severity of all-cause and cardiovascular hospitalisations by eGFR in a community-based cohort study of adults aged ≥45 years in New South Wales, Australia.

Methods: Based on data from the EXTEND45 study (the 45 and Up Study linked to hospital and community pathology datasets by the Centre for Health Record and Linkage [CHeReL]), we identified a population-based cohort (2006-2014) of 41,099 people aged ≥45 who had a measure of kidney function (eGFR). The risk and severity of hospitalisations (defined by the hospitalisation length of stay [HLOS]) were assessed by eGFR category (≥90 [reference], 60-89, 45-59, 30-44 and <30ml/min/1.73m^2) using multivariable Cox regression.

Results: Of 41,099 participants, 80.2% experienced ≥1 hospitalisation event over a mean follow-up of 5.8 years. All-cause hospitalisation risk increased as eGFR declined (HR 0.99 [95% CI:0.97-1.03]; 1.05 [1.00-1.09]; 1.17 [1.10-1.24] and 1.57 [1.43-1.72] for eGFR 60-89, 45-59, 30-44, and <30ml/min/1.73m^2, respectively; p-trend<0.001) even after adjustment for age and sex. Cardiovascular events rose even more steeply than all-cause hospitalisations (HR 1.23 [1.08-1.39]; 1.49 [1.28-1.73]; 1.73 [1.45-2.07] and 2.24 [1.80-2.79], respectively). Mean HLOS also increased as eGFR declined (all-cause hospitalisation [2.3, 2.8, 3.9, 5.1 and 5.7 days, respectively]; cardiovascular hospitalisations [3.7, 3.8, 5.7, 5.9 and 8.3 days, respectively).

Conclusions: In contemporary NSW, declining kidney function is associated with higher illness burden, particularly cardiovascular burden. The increased mean HLOS suggests that discrete medical events are more severe as kidney function declines.

SA-PO790

Genome Wide Association Study Identifies Novel SNPs Associated with Albuminuria in Japanese General Population

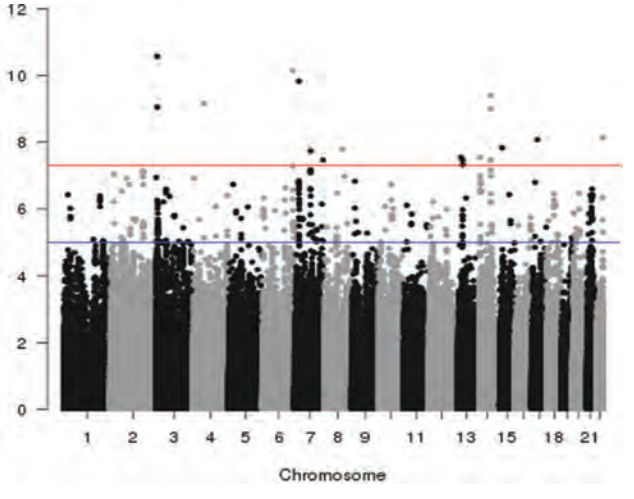
Hiroshi Okuda. *Tohoku University, Sendai, Japan.*

Background: Urinary albumin excretion (UAE) is a good biomarker for chronic kidney disease, cardiovascular disease, diabetes mellitus or obesity. We usually expect the individual amounts of UAE show large variations among similar conditioned patients. The variations could be contributed with many genetic factors. However, a few Genome-wide association analysis studies (GWAS) of UAE based in European population were reported and there was not in Japanese general population. Here we conducted GWAS using health-survey data collected by Tohoku Medical Megabank Organization (ToMMo) and listed up several candidates of single nucleotide polymorphisms (SNPs) on UAE.

Methods: GWAS of continuous variables of UAE as an outcome was performed using about 1 million SNPs genotypes (Illmina HumanOmniExpressExome) from 9966 participants (Miyagi; 4974, Iwate; 4992) collected by ToMMo in 2013. As quality control, SNPs with low call rates (<0.98), low Hardy–Weinberg equilibrium exact test P-values (<1×10^{-4}) or low minor allele frequencies (MAF; <0.01) were filtered out. As a covariate, age, sex, BMI, blood pressure, renal function (eGFR calculated by plasma cystatin C), HbA1c was used. Genotypic imputation was performed using a haplotype panel consisting of 2000 samples NGS data, further analysis was performed on the data, and each MAF and INFO value after imputing were adjusted.

Results: Analysis results were examined with p <5 × 10 - 8 as the significance level, and 18 candidates of novel SNPs related to UAE were identified. SNPs with particularly strong associations were observed on chromosome 14.

Conclusions: The 18 SNPs were identified associated with UAE and we are considering the mechanisms and the further verification necessarily.



SA-PO791

Downregulation of Renoprotective Factors Is Associated with Outcome in CKD

Paul Perco, Michael Rudnicki, Julia Kerschbaum, Johannes Leierer, Gert J. Mayer. *Medical University Innsbruck, Innsbruck, Austria.*

Background: An imbalance of nephroprotective factors and renal damaging molecules contributes to development and progression of chronic kidney diseases. Molecules with renoprotective properties and capacity to induce renal repair might serve as biomarkers, drug targets as well as therapeutic options themselves. In this study we determined the

potential of renoprotective factors to predict disease progression in a set of chronic kidney disease (CKD) patients.

Methods: Gene expression profiles were determined for 197 previously published proteins with renoprotective properties in renal biopsies of 63 CKD patients with different disease diagnoses. The statistical analysis of microarray method was used to identify downregulated factors in the group of progressive patients as compared to those showing a stable course of disease with a false discovery rate < 5%. Progression was defined as reaching end-stage renal disease or doubling of serum creatinine. Significance of renoprotective factors to predict course of disease was in addition analysed in time-to-event analysis using Kaplan Meier curves and log-rank statistics. Cox regression models were used to adjust for the clinical parameters estimated glomerular filtration rate (eGFR) and diagnosis type.

Results: The six renoprotective factors dicarbonyl and L-xylulose reductase (DCXR), epidermal growth factor (EGF), glutathione S-transferase mu 1 (GSTM1), kininogen 1 (KNG1), nitric oxide synthase 3 (NOS3), and uromodulin (UMOD) were significantly downregulated in the group of progressive patients and were also significantly associated with outcome in time to event analysis. DCXR (p-val = 0.0277), EGF (p-val = 0.0264), GSTM1 (p-val = 0.0039), and KNG1 (p-val = 0.0372) remained significant after adjustment for eGFR and diagnosis in Cox regression analysis thus being independently associated with outcome. This is to our knowledge the first study describing the prognostic potential for DCXR in human CKD samples with literature evidence already being available for the other three markers showing significance in our cohort.

Conclusions: We identified a set of four renoprotective factors being downregulated in progressive CKD patients on the mRNA level and independently associated with disease outcome.

SA-PO792

Association of Polygenic Risk Scores and CKD in the UK Biobank

Thi ha my Vy, Lili Chan, Kumardeep Chaudhary, Steven G. Coca, Ron Do, Girish N. Nadkarni. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Genome wide association studies (GWAS) have tested for associations between single nucleotide polymorphisms (SNPs) and chronic kidney disease (CKD). Polygenic risk scores (PRS) have shown significant promise for risk discrimination in complex disease but there are no studies on PRS in CKD.

Methods: We generated per-individual genome-wide additive polygenic risk scores (PRS) using published GWAS statistics and tested them for association with CKD in 8,432 cases and 400,529 controls of self-identified white British ancestry in the UK Biobank. We derived PRS using GWAS summary statistics from four different sets of SNP's; (1) 33 loci significantly associated with $eGFR_{creatinine}$; (2) 53 loci significantly associated with CKD; (3) >38,000 independent SNVs using a linkage disequilibrium (LD) pruning approach; and (4)~1,800,000 SNVs with re-assigned coefficients adjusted for linkage disequilibrium (LD) by LDpred.

Results: Among the four PRS, the area under the curve (AUC) was slightly higher for PRS score 4 using ~1,800,000 SNPs (AUC=0.703) compared to PRS score 1 (0.7); 2 (0.700) or 3 (0.701). The odds ratios (OR) for CKD prevalence increased significantly at higher quintiles of genome wide PRS score 4 compared to bottom quintile (Table 1). Individuals with highest decile of PRS score had two-fold odds of CKD vs. lowest decile (OR=2.0; 97.5% Confidence Interval 1.7-2.3; $p=2.28x10^{-24}$).

Conclusions: PRS incorporating higher number of SNPs had slightly higher discrimination compared to those incorporating only GWAS significant SNPs, indicating polygenic architecture of CKD. PRS may provide modest improvements in risk prediction, especially in the extremes of genetic risk distribution.

Prevalence of CKD in higher polygenic score bins in comparison with the bottom 20% of polygenic score distribution

PRS Quintile	Odds Ratio	2.5% CI	97.5% CI	P value
20-40%	1.3	1.1	1.4	2.12x10-4
40-60%	1.3	1.1	1.5	2.48x10-5
60-80%	1.5	1.3	1.6	4.06x10-10
>80%	1.8	1.6	2.0	8.70x10-22

SA-PO793

Using an IgA Genetic Risk Score to Estimate the Prevalence and Improve Diagnosis of IgA Nephropathy

Kittiya Sukcharoen,[1,2] Seth A. Sharp,[2] Robert A. Kimmitt,[3] Jamie W. Harrison,[8] Coralie Bingham,[5] Monika Mozere,[9] Michael Weedon,[2] Jonathan Barratt,[4] Daniel P. Gale,[6] Richard A. Oram.[7] *[1]Royal Devon and Exeter Foundation Trust, Exeter, United Kingdom; [2]University of Exeter, Exeter, United Kingdom; [3]Royal Devon and Exeter NHS Foundation Trust, Exeter, United Kingdom; [4]University of Leicester, Leicester, United Kingdom; [5]Royal Devon and Exeter Hospital, Exeter, United Kingdom; [6]University College London, London, United Kingdom; [7]University of Exeter Medical School, Exeter, United Kingdom; [8]University of exeter medical school, Tiverton, United Kingdom; [9]UCL, London, United Kingdom.*

Background: IgA nephropathy(IgAN) is the commonest glomerulonephritis worldwide. It is difficult to assess true prevalence of IgAN, people with mild disease do not commonly receive a biopsy. Multiple single-nucleotide polymorphisms(SNPs) are associated with IgAN. We aimed to generate and validate an IgAN genetic risk score(GRS) and assess the excess IgAN genetic risk in people with haematuria, hypertension and microalbuminuria in UK Biobank(UKBB) to estimate the proportion of these phenotypes.

Methods: We calculated the IgAN GRS using 14 SNPs associated with IgAN in Caucasians using established methods. We generated the GRS in 464 biopsy proven IgAN from the UK Glomerulonephritis (UK GN) DNA Bank, and in 344,244 Caucasians from UKBB, using SNP array data. We accessed diagnostic codes from electronically linked healthcare records, questionnaire data and baseline albumin creatinine ratio from UKBB. We compared the IgAN GRS in UK GN cases with healthy individuals in UKBB. We assessed the proportion of hypertension and microalbuminuria by comparing IgA GRS using this formula: *Proportion=(phenotype - control)/(IgAN - control)*

Results: The IgA GRS was discriminative of IgAN v non-IgAN (Mean[95% confidence interval]) GRS 4.35 (4.26,4.41) v 3.98 (3.96,3.99); P <0.0001. UKBB participants with an ICD10 diagnosis of IgAN (N=116) GRS 4.19(4.01, 4.36) had a similar GRS to the IgA GN cohort; P=0.1 and combined score of 4.307 (4.24,4.38). The GRS was higher in phenotypes with possible undiagnosed IgAN compared to healthy subjects, haematuria (N=13,119) GRS 4.04(4.03, 4.06); P<0.0001, haematuria and proteinuria (N=1827) GRS 4.06(4.01,4.1); P=0.002, and haematuria, hypertension and microalbuminuria (N=1431) GRS 4.07(4.02,4.11); P=0.002. We calculated that IgA accounted for 19% (15-25) of haematuria, 22% (10-37) haematuria and microalbuminuria and 27% (13-40) haematuria, hypertension and microalbuminuria in UKBB.

Conclusions: We used a novel GRS approach to estimate the prevalence of IgAN contributing to common phenotypes that would not normally be biopsied. These data may allow a UK population estimate for the prevalence of undiagnosed IgAN. Further work is needed to assess if an IgAN GRS may be useful for individual diagnosis.

SA-PO794

Significant Urinary Metabolites in the Progression of CKD

Yaerim Kim,[1] Jueun Lee,[2] Geum-Sook Hwang,[2] Dong Ki Kim.[1] *[1]Seoul National University Hospital, Seoul, Republic of Korea; [2]Korea Basic Science Intsitute, Seoul, Republic of Korea.*

Background: Despite the development of diagnostic techniques, methods for predicting changes in renal function or outcomes are still insufficient. Metabolomics is considered to be a breakthrough method to address the shortage of tools by analyzing the end metabolites, reflecting genetic and environmental factors. Herein, we would like to propose the metabolites which significantly associated with development and progression of chronic kidney disease (CKD).

Methods: We measured urinary metabolites from 1,274 urine samples at the time of renal biopsy and 147 urine samples from healthy subjects using nuclear magnetic resonance. The clinical outcome was defined as a decrease in estimated glomerular filtration ≥ 30%, doubling of serum creatinine, or development of end-stage renal disease.

Results: Initial partial components analysis and partial least squares-discriminant analysis score plots showed discriminated cluster between CKD and control, and according to the stage of CKD. A total of 41 metabolites confirmed to candidate marker associated with CKD. Six of metabolites (betaine, glycine, glycerol, trimethylamine-N-oxide, taurine, choline) showed increasing pattern, and 6 of metabolites (1-methylnicotinamide, formate, hypoxanthine, ethanolamine, citrate, 3-hydroxyisovalerate) showed decreasing trend to the stage of CKD. A total of 14 metabolites (phenylalanine, fumarate, betaine, glycine, glycerol, taurine, trimethylamine-N-oxide, betaine, choline, acetoacetate, acetone, acetate, isoleucine, leucine) had significantly increased hazard ratio to composite outcomes, and four metabolites (fumarate, betaine, taurine, choline) showed higher hazard ratio to outcome of creatinine doubling. In survival analysis using the median value of each metabolite, the cumulative incidence of clinical outcomes was significantly increased in 19 metabolites and decreased in 4 metabolites.

Conclusions: Metabolites which inform the disease progression or development can be a noble biomarker. In our study, betaine, choline, taurine, trimethylamine-N-oxide, glycine, and glycerol were shown to be a significant predictor in the progression of CKD. Although additional study for validation should be performed, we could find significant metabolites associate with CKD. And these results could be an instrumental keynote to moving ahead.

SA-PO795

Urinary Metabolites Associated with Non-Diabetic CKD Progression

Sohyun Yun,[1] Miyeun Han,[2] Hyunjin Ryu,[1] Eunjeong Kang,[1] Minjung Kang,[1] Tsogbadrakh B. Bodokhsuren,[1] Jinho Lee,[3] Curie Ahn,[1] Kook-Hwan Oh.[1] *[1]Seoul National University, Seoul, Republic of Korea; [2]Pusan National University, Pusan, Republic of Korea; [3]Seoul National University, Seoul, Republic of Korea.*

Background: Metabolome analyses have been on the rise recently for the discovery of biomarkers for chronic kidney disease. Urinary metabolome can be appropriate prognostic markers to predict CKD progression.

Methods: We conducted a case-control study comparing progressor (case) with non-progressor (control) in non-diabetic chronic kidney disease patients (polycystic kidney disease excluded). Urine samples and clinical data were taken from the KoreaN Cohort Study for Outcome in Patients With Chronic Kidney Disease (KNOW-CKD). These random urine samples were harvested at enrollment. Participants were followed-up for eGFR at 6- or 12-month interval for > 2 years. Subjects of the study were 100 individuals that are comprised of 50 progressors and 50 non-progressors with their age, gender and initial eGFR values matched. Progressor and non-progressor group were divided on the basis of estimated GFR slope, which revealed -0.91±0.75 and 1.43±1.23 ml/min/1.73m^2/yr, respectively. The urinary metabolite profiling was performed with an untargeted metabolomics approach using ultra-performance liquid chromatography time-of-flight mass spectrometry in conjugation with multivariate statistical analysis.

Results: A total of 9,345 compound ions were detected in positive ion mode, and 27 endogenous ions satisfied the false discovery rate adjusted p-value (Q-value). Among them, three candidate markers were discovered; X, Y and Z. These three metabolites showed statistically significant difference between CKD progressor and non-progressor group. X and Y had higher concentration in non-progressors unlike Z which were lower in concentration from non-progressors.

Conclusions: We identified three urinary metabolic markers associated with renal progression of non-diabetic chronic kidney disease. They can provide information to predict CKD progression as prognostic markers.

Concordance of Metabolite Correlations with Measured GFR in Children and Adults

Josef Coresh,[1,2] Alison G. Abraham,[2] Michelle Denburg,[3] Susan L. Furth,[4] Jingsha Chen,[2] Casey Rebholz,[2] Eugene P. Rhee,[5] Harold I. Feldman,[6] Paul L. Kimmel,[7] Vasan S. Ramachandran,[11] Bradley A. Warady,[8] Morgan Grams,[9] Lesley Inker,[10] Andrew S. Levey.[10] CKD Biomarkers Consortium *[1]Welch Center for Prevention, Epidemiology & Clinical Research, Baltimore, MD; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [3]The Children's Hospital of Philadelphia, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; [4]The Children's Hospital of Philadelphia, Philadelphia, PA; [5]Massachusetts General Hospital, Newton, MA; [6]University of Pennsylvania, Philadelphia, PA; [7]National Institute of Diabetes and Digestive Kidney Diseases (NIDDK), Bethesda, MD; [8]Children's Mercy Kansas City, Kansas City, MO; [9]Johns Hopkins University, Baltimore, MD; [10]Tufts Medical Center, Boston, MA; [11]Boston University School of Medicine, Framingham, MA.*

Background: Metabolites are strongly influenced by reduced GFR but it is unknown whether the associations are similar in adults and children.

Methods: We evaluated an untargeted GC/MS2 and LC/MS2-based metabolomics quantification (Metabolon) of frozen serum from 962 African-American Study of Kidney Disease and Hypertension (AASK) and frozen plasma in 702 Chronic Kidney Disease in Children (CKiD) participants. Metabolites were standardized, log transformed and then correlated to measured GFR (mGFR). GFR was measured using urinary Iothalamate clearance in AASK and plasma Iohexol clearance in CKiD (median (5^{th}-95^{th} %ile) GFR of 48 (24-64) in AASK and 57 (23-114) in CKiD).

Results: There very high agreement between the correlation of the 871 metabolites with mGFR in AASK and the corresponding correlation in CKiD (Figure; correlation of the correlations 0.896). Both studies had an excess of negatively correlated metabolites with mGFR, 311 of them at p<0.001 (denoted with red pluses on the lower left quadrant). Creatinine is shown for reference and pseudouridine for being the most negatively correlated. Among these, the negative correlation with mGFR was stronger in CKiD than AASK (mean difference -0.10, p<0.001), likely due to the wider GFR range in CKiD. The first principal component explained 10% and 13% of the variance and had a correlation with mGFR of -0.71 and -0.86 in AASK and CKiD respectively.

Conclusions: GFR is strongly associated with a large proportion of the metabolome concordantly in children and adults with CKD. These findings hold promise for improvements in adjusting for confounding by GFR and developing equations to better estimate GFR that incorporate metabolite data.

Funding: NIDDK Support, Commercial Support - Metabolon funded assays in AASK as part of a collaboration agreement

SA-PO797

A Metabolomics Approach to CKD Prediction After RCC Nephrectomy

Edgar A. Jaimes,[1,2] Irina Ostrovnaya,[3] Axel S. Martin,[4] Robert H. Weiss.[5] *[1]Memorial Sloan-Kettering Cancer Center, New York, NY; [2]Weill Cornell Medical College, New York, NY; [3]Memorial Sloan Kettering Cancer Center, New York, NY; [4]Memorial Sloan Kettering, New York, NY; [5]UC Davis, Nephrology, Davis, CA.*

Background: Patients with RCC who undergo nephrectomy can develop CKD as result of reduction in renal mass and given common risk factors between CKD and RCC it is likely that RCC patients already have parenchymal kidney disease. Thus it is imperative to obtain additional information in order to identify those at higher risk for CKD and/or its progression.

Methods: We hypothesized that there is a metabolomics signature for future renal functional decline in tumor-adjacent "normal" kidney tissue. We utilized a non-targeted metabolomics approach coupled with longitudinal patient data from post-operative visits to identify metabolites in non-malignant renal tissue linked to future eGFR decline. We used two statistical approaches: (1) univariate analysis adjusting for age, BMI, and nephrectomy type, and (2) cross-validated penalized regression (elastic net) methodology. Metabolomic analysis was performed by Metabolon (Durham, NC) using non-targeted metabolomic gas and liquid chromatography coupled to a mass spectrometry approach.

Results: We studied 138 samples from nephrectomies performed at MSKCC. 79 were radical (57.2 %), 100 subjects were male (72.5%), 122 were white (88.4%), average age was 61.9 years and 23 were diabetic (16.7 %). 476 metabolites were included in our analysis. Using univariate linear regression, we found that the most significant associations with eGFR slope were by the metabolites N6-trimethyl-lysine, guanosine and tyrosyl-leucine, as well as two unidentified metabolites, X13871 and X15168, with p<=0.012, although none reached significance when adjusted for multiple comparisons using FDR. We also created composite metabolite score utilizing all of the metabolites using elastic net modelling fitted on cross-validation samples. This score was univariately associated with the eGFR slope with p<0.001 and remained significant after adjusting for clinical variables. A similarly developed score based on tumor tissue metabolites was not significantly associated with the slope (p=0.18).

Conclusions: In this study we identified metabolites found in the adjacent non-malignant kidney tissue that are associated with eGFR decline post-nephrectomy. Prospective evaluation of surgical specimens using a targeted metabolomics approach to validate our findings will lead to a new paradigm by which RCC patients can be evaluated, and potentially treated, for unrecognized and incipient CKD.

Blood Microbiome Profile Characteristics in Patients with CKD

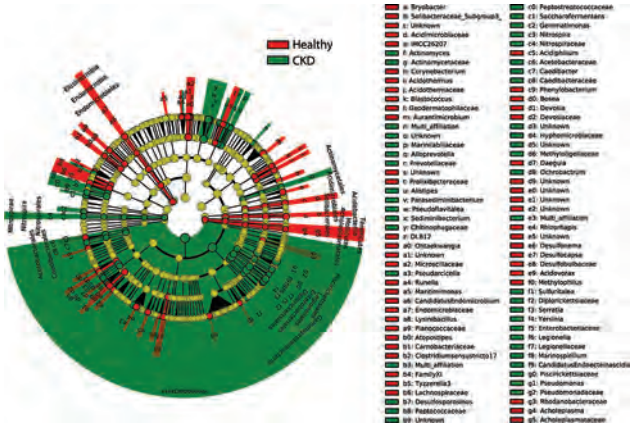
Neal B. Shah,[1] Benjamin Lelouvier,[3] Andrew S. Allegretti,[2] Ravi I. Thadhani,[4] Alessio Fasano.[5] *[1]Nephrology, Massachusetts General Hospital, Boston, MA; [2]Nephrology, Massachusetts General Hospital, Boston, MA; [3]Vaiomer, LABEGE, France; [4]Cedars-Sinai, Los Angeles, CA; [5]Massachusetts General Hospital, Boston, MA.*

Background: Association between gut dysbiosis, increased intestinal permeability and endotoxemia mediated inflammation has been well established in Chronic Kidney Disease (CKD). Microbiome data in circulating blood is lacking. Our pilot study's aim was to compare blood microbiome 16S ribosomal DNA (rDNA) levels and metagenomic profiles between CKD patients and healthy controls.

Methods: A case control study of 20 non-diabetic CKD and age and sex matched 20 healthy controls was done. Blood bacterial DNA was studied in buffy coat samples both quantitatively by 16S PCR and qualitatively by 16S targeted metagenomic sequencing using a molecular pipeline specifically optimized for blood samples. Patients with inflammatory bowel disease, WBC>$11x10^9$/L or taking antibiotics at enrollment were excluded.

Results: Median 16S rDNA levels did not significantly differ between CKD and healthy groups (117 vs 122 copies/ng DNA, p=0.38). 16S Metagenomic sequencing revealed a significant decrease in alpha diversity (Chao1 index) in CKD group compared to healthy (p=0.0483). Linear discriminant analysis effect size (LEfSe, Fig 1) displays numerous bacterial taxa with proportions significantly modified in CKD group. There was significant increase in proteobacteria phylum, gammaproteobacterial class and enterobacteriacea, pseudomonadaceae and legionellaceae families in the CKD group compared to healthy group. At deeper taxonomic levels, there were other striking differences between bacterial profiles. No significant correlation was found between glomerular filtration rate and 16S rDNA levels (r= -0.002, p=0.98).

Conclusions: Our study demonstrates reduced alpha diversity and significant variations in blood microbial profile in CKD patients with numerous bacterial taxa impacted. Studying larger populations of CKD from various etiologies may help identify microbiome patterns as predictive and diagnostic biomarkers.



Taxonomic Cladogram using LEfSe analysis

Bariatric Surgery Reduces Elevated Urinary Mitochondrial DNA Copy Number in Non-Diabetic Obese Patients

Haekyung Lee, Hyoungnae Kim, Moo Yong Park, Hyunjin Noh, Soon hyo Kwon. *Soonchunhyang University Hospital, Seoul, Republic of Korea.*

Background: Obesity is an independent risk factor for chronic kidney disease (CKD). However, the mechanisms responsible for renal injury have not been totally elucidated. Mitochondrial damage is considered to have implications for renal injury, and urinary mitochondrial DNA (mtDNA) is a marker of mitochondrial damage. We hypothesized that urinary mtDNA copy number in non-diabetic obese patients would be higher than in healthy volunteers, and bariatric surgery could reverse elevated urinary mtDNA copy number.

Methods: We prospectively recruited age-sex matched healthy controls and non-diabetic obese patients who were going to undergo bariatric surgery (n = 22 each; male=8, female=14) at a single center in Korea. We quantified the urinary absolute copy number of the mitochondrial nicotinamide adenine dinucleotide dehydrogenase subunit-1 (mtND-1) gene in healthy volunteers by quantitative polymerase chain reaction. In obese patients, mtND-1 copy number was measured before bariatric surgery and six months after bariatric surgery.

Results: Age (35.2 ± 9.6 years vs 32.2 ± 10.0 years) and eGFR (108.1 ± 11.7 mL/min vs 109.7 ± 24.0 mL/min) in both groups were not significantly different. 24 hour urinary albumin was higher in the obese group (2.7 ± 3.0 mg/day vs 52.9± 163.6 mg/day, *P*<0.001). In the obese group, BMI decreased from 41.0 ± 5.7 to 36.0 ± 7.2 *(P*=0.002) six months after bariatric surgery. Urinary mtND-1 copy number in the obese group was higher in healthy controls (*P*=0.001) (fig 1). In obese patients with high urinary mtND-1 copy number, bariatric surgery reduced urinary mtND-1 copy number (*P*=0.006).

Conclusions: Obesity is associated with elevated urinary mtND-1 copy number. Bariatric surgery reduces urinary mtDNA in obese patients with especially high mtDNA copy number. This suggests bariatric surgery would improve mitochondrial damage in kidney cells.

Kidney Ly6c- Macrophages Directly Promote Ischemia Induced Renal Fibrosis

Qian Yang, Rui Zeng, Gang Xu. *Tongji Hospital, Huazhong Univ of Science and Technology, Wuhan, China.*

Background: Macrophages are a plastic and heterogeneous cell type in renal injury, repair and fibrosis in acute kidney injury (AKI) to chronic kidney disease (CKD) progression, but the function of different macrophage population is still elusive.

Methods: In our study, we focused on exploring the function of Ly6c- macrophages in AKI induced renal fibrosis, which are widely considered to be derived from derived from sac yolk. The AKI to CKD transition was induced by severe (30 min) ischemia reperfusion (I/R).

Results: We found CCR2 deficience alleviated acute kidney injury after I/R, which is consistent with previous reports, however, deteriorates renal fibrosis in CKD phase. Furthermore, we identified the cell type in $CCR2^{-/-}$ mice with I/R induced CKD, and it showed $Ly6C^-$ macrophages were predominantly infiltrated in $CCR2^{-/-}$ kidney during CKD phase after I/R, which suggested that $Ly6C^-$ macrophages play a critical role in AKI induced renal fibrosis. To further confirm the hypothesis, we used chlodronate liposome to deplete the renal $Ly6c^-$ macrophages in $CCR2^{-/-}$ mice during I/R induced CKD, and we found renal injury and fibrosis were both alleviated compared to $CCR2^{-/-}$ with PBS intervention. Similar results were identified in wild type mice by depletion of $Ly6C^-$ macrophages with chlodronate liposome. Furthermore, $Ly6C^-$ macrophages were extracted and adoptive transferred to severe immune deficient mice, which showed that renal injury and fibrosis were directly induced by $Ly6C^-$ macrophages. In vitro, we further confirmed that $Ly6C^-$ macrophages exerted their profibrotic function by promoting fibroblasts transdifferentiation into myofibroblasts.

Conclusions: In conclusion, kidney Ly6C- macrophages play an important role in directly promoting ischemia induced renal fibrosis, and this function is related to affecting fibroblast transdifferentiation.

iTRAQ-Based Renal Proteomic Analysis Exploring the Influence of Bone Marrow Derived MSCs on CKD Rats

Chen Bo,[1,2] Jianchun Li,[5] Hui Diao,[3] Yuan Liao,[4] Dan Wen,[3] Li Wang.[2] Innovative team of integrated traditional Chinese and western medicine for prophylaxis and treatment of chronic kidney disease *[1]Department of Human Anatomy, Southwest Medical Univeristy, Luzhou, China; [2]Research Center of Integrated Chinese and Western Medicine, Affiliated Traditional Medicine Hospital of Southwest Medical University, Luzhou, China; [3]Department of Nephrology, Affiliated First Hospital of Southwest Medical University, Luzhou, China; [4]Department of Nephrology, Affiliated Traditional Medicine Hospital of Southwest Medical University, Luzhou, China; [5]Research Center of Integrated Chinese and Western Medicine, Affiliated Traditional Medicine Hospital of Southwest Medical University, Luzhou, China.*

Background: The antifibrosis still represents the final target to treat chronic kidney disease (CKD). Mesenchymal stromal cells (MSCs) have been verified with significant improvement in the therapy of anti-fibrosis in the lastest 10 years. We attempted to clarify iTRAQ-based renal proteomic analysis exploring the new mechanism of MSCs on renal fibrosis.

Methods: Chronic kidney disease (CKD) models were established through combined with adriamycin and adenine in rats. A single intravenous MSCs injection was performed in the early period. Renal fibrosis was evaluated by sirius red staining and extracellular matrix components labeled by immunohistochemistry, respectively. Renal proteomic analysis was analyzed using iTRAQ-based mass spectrometry, and primarily differentially expressed proteins were further assessed by quantitative PCR and Western Blot.

Results: MSCs delivery decreased myofibroblast marker (α-SMA), extracellular matrix expression, and ameliorated the renal function in MSCs group compared to model group. 6,213 proteins were identified, and 40 proteins exhibited significant differences (30 up-regulated, 10 down-regulated) compared to model group. Bioinformatics analysis revealed that these proteins play important roles in biological process, cellular process, biological regulation, response to stimulus, metabolic process, organic substance metabolic process, single-organism process. Lgals3, Ifi47, Armc1 and Mgat3 may play important roles in the improvement of CKD fibrosis by MSCs. Lgals3 protein was down-regulated in MSCs group which has recently been deemed as a new biomarker of renal fibrosis.

Conclusions: We depicted the differently expressed proteins in the early period of MSCs delivery in adriamycin and adenine-induced CKD rat kidney by iTRAQ-based proteomic analysis which may provide valuable information to understand the molecular mechanisms involved in MSCs-based therapy for CKD fibrosis.

Macrophage-Derived miR-155-Containing Exosomes Promotes Angiotensin-II Induced Senescence and Oxidative Stress in Proximal Tubular Cells

Bin Wang,[1] Jialing Ji,[2] Bi-Cheng Liu.[1] *[1]Zhong Da Hospital, Southeast University, Nanjing, China; [2]Department of Pediatric Nephrology, Nanjing Medical University, Nanjing, China.*

Background: The activation of the renin-angiotensin (Ang)-aldosterone system (RAAS) is a major hallmark in the development and progression of organ damage in chronic kidney disease (CKD). Here, we examined the role of macrophage-derived miR-155-containing exosomes in regulating oxidative stress and senescence in Ang-II induced PTCs both in vivo and in vitro.

Methods: CKD mice model: An osmotic minipump was implanted subcutaneously to infuse Ang-II for 4 weeks after a right uninephrectomy or sham operation in wild type or miR-155-deficient mice. Macrophage-derived miR-155-containing exosomes were infused in miR-155-deficient mice through tail injection. In vitro, primary cultured PTCs were treated with Ang-II (10^{-7}M) in the presence or absence of macrophage-derived miR-155-containing exosomes or miR-155 inhibitor. Finally, kidney samples and cultured PTCs in various groups as indicated above were analyzed for markers of senescence and oxidative stress.

Results: Our study revealed that miR-155 expression, the number of infiltrated macrophages, and oxidative stress and senescence were substantially increased in PTCs in Ang-II infused mice relative to the control group. Ang-II infused miR-155-deficient mice display attenuated senescence and mild oxidative stress compared that in wild type mice. Conversely, macrophage-derived miR-155-containing exosomes enhanced oxidative stress and senescence in Ang-II infused miR-155-deficient mice. Interestedly, pri-miR-155 was only expressed in macrophages, but not in PTCs, and macrophage-derived miR-155-containing exosomes can be transferred into PTCs. Hence, it is not strange that blocking exosome secretion with GW6849 attenuated oxidative stress and senescence in Ang-II infused wild type mice. Additionally, we found that miR-155 inhibitor abrogated oxidative stress and senescence in PTCs by directly down-regulating FoxO3a expression.

Conclusions: Taken together, our results demonstrated that infiltrated macrophages secreted miR-155-enriched exosomes and promoted oxidative stress and senescence by directly targeting FoxO3a in Ang-II infused PTCs injury.

Macrophage Chemoattractant Protein-1 (MCP-1) Promotes Renal Fibrosis in AKI-to-CKD Transition

Leyuan Xu, Lloyd G. Cantley. *Section of Nephrology, Yale University School of Medicine, New Haven, CT.*

Background: Acute kidney injury (AKI) significantly increases the risk of developing progressive kidney fibrosis and chronic kidney disease (CKD). Macrophages play complex roles in AKI, with proinflammatory macrophages initially serving for clearance of apoptotic cells/debris after injury, followed by reparative macrophages promoting tubule repair. Using a CKD model of unilateral ischemia-reperfusion (U-IRI) in which the injured kidney undergoes fibrosis and atrophy rather than effective repair, we recently showed that macrophages downregulate reparative activation and transition to a profibrotic phenotype by day 14 after injury. In this study, we investigated the mechanism by which macrophages become profibrotic during the AKI-to-CKD transition.

Methods: Male wild-type or Ccr2-/- mice were subjected to warm U-IRI (27 min). Serum KIM1 level on day 1 after U-IRI was used to define the degree of initial injury. The injured kidney was removed on day 14 or 30 after U-IRI. Renal cells were flow sorted on day 14 to define the macrophage homing signals. Renal fibrosis was assessed on day 30 by Sirius red staining, qPCR and Western blotting for Col1a1, Col3a1 and Fn1. Macrophage accumulation was assessed by IHC for F4/80 and qPCR for Cd68. Interstitial inflammation was assessed by qPCR for Tnfa.

Results: Failure of kidney repair by day 14 after U-IRI led to sustained high expression of macrophage chemoattractant protein-1 (Mcp1) in the injured kidney compared to the contralateral control kidney (53-fold increase, n=10, $p<0.001$). CD45+F4/80+ macrophages and CD45+CD11c+F4/80- dendritic cells were the major cellular sources of this late, persistent Mcp1 expression (34- and 5-fold increase compared to renal cells and CD45+CD11c-F4/80- T cells/PMNs), while all bone marrow derived CD45+ cells expressed high levels of the Mcp1 receptor Ccr2. Injured kidneys from Ccr2-/- mice showed ~30% less profibrotic macrophage accumulation, interstitial fibrosis and inflammation in comparison to the wild-type control mice (n=5, $p<0.01$). Furthermore, administration of a CCR2 inhibitor (RS102895, 5 mg/kg, every 12 h) to wild-type mice for 7 days beginning 7 days after U-IRI replicated these results (n=8, $p<0.05$).

Conclusions: Our data showed that MCP-1 may serve as an autocrine and/or paracrine factor for profibrotic macrophage accumulation, leading to increased interstitial fibrosis during the AKI-to-CKD transition.

SA-PO804

"Nephrogenic" Systemic Fibrosis Is Driven by C-C Chemokine Receptor 2-Dependent Myeloid- and Resident Tissue-Derived Fibrocyte Activation

Brent Wagner,[1,2] Catherine Do,[4,3] Chunyan Tan,[3] Viktor Drel,[3] Doug Y. Lee,[3] Yves C. Gorin.[3,1] *[1]Kidney Institute of New Mexico and the University of New Mexico Health Science Center, Albuquerque, NM; [2]Medicine Service, New Mexico Veterans Administration Health Care System, Albuquerque, NM; [3]University of Texas Health Science Center, San Antonio, TX; [4]Medicine Service, South Texas Veterans Health Care System, San Antonio, TX.*

Background: Gadolinium-based contrast agents are now associated with multiple conditions, including 'nephrogenic' systemic fibrosis/gadolinium-associated systemic fibrosis (NSF) and symptoms attributed to gadolinium retention. Bone marrow-derived fibrocytes and the monocyte chemoattractant protein 1 (MCP1) inflammatory pathway have been implicated as mediators. *Mechanistic studies are scant.* We established a mouse model of NSF.

Methods: Marrow was transplanted to lethally-irradiated mice: 1) recipients with 5/6 nephrectomies received green fluorescent protein- (GFP-) expressing marrow, 2) C-C chemokine receptor 2- (CCR2-) deficient mice received GFP-expressing marrow, and 3) wild-type mice received CCR2-deficient marrow. After engraftment periods, recipients were randomized to untreated or gadolinium-based contrast agent treatment (Omniscan—96% gadodiamide—2.5 mmol/kg, 20 doses intraperitoneally over 4 weeks).

Results: Dermal cellularity was increased in contrast-treated GFP chimeric mice. Compared to control, skin GFP, fibronectin, and type I collagen were increased in the contrast-treated chimeric animals. Importantly, CD45RO—a fibrocyte marker—was abundant in the dermis of contrast-treated animals and expressed by the myeloid cells. Many of these cells expressed cytoplasmic α-smooth muscle cell actin, a marker of myofibroblast activation. Activated myofibroblasts and fibrosis colocalized with the myeloid marker in contrast-treated animals. MCP-1 and CCR-2 were increased in the tissues from contrast-treated mice. CCR2-deficient recipients of GFP-expressing marrow had a partial abrogation of gadolinium-induced pathology and displayed less GFP positivity in the skin. Wild-type animals that received CCR2-deficient marrow had a complete abrogation of dermal pathology.

Conclusions: Systemic fibrosis is induced by gadolinium contrast in mice. The abundance of myeloid cells in an involved organ, the skin, in tandem with a fibrocyte marker—CD45RO—supports the blood-borne circulating fibrocyte hypothesis of the disease. This is the first demonstration of fibrocyte trafficking ever demonstrated in mice. Similar to what is observed in a rat model, our data demonstrate that the monocyte chemoattractant protein 1/CCR2 axis plays a critical role in the pathogenesis of gadolinium-induced systemic fibrosis.

Bone Marrow Mesenchymal Stem Cells (BMSCs) Ameliorate Experimental Renal Interstitial Fibrosis via Promoting Tertiary Lymphoid Organ Neogenesis

Fengge Zhu, Xiangmei Chen, Shuwei Duan, Ying Zheng, Jiuxu Bai. *Department of Nephrology, Chinese PLA General Hospital, State Key Laboratory of Kidney Diseases, National Clinical Study Center for Kidney Diseases, Beijing, China.*

Background: Earlier studies indicate that bone marrow mesenchymal stem cells (BMSCs) is effective in protecting experimental renal interstitial fibrosis. However, the exact mechanism is not clear. We purpose that BMSCs may ameliorate renal interstitial fibrosis via promoting renal tertiary lymphoid organ (TLO) neogenesis.

Methods: We establish unilateral ureteral obstruction model using C57/BL6 male mice. BMSCs is given to animals 4 hours after surgery via tail vein, single time, 10^6 cells per mouse. Animals are sacrificed at the seventh day after surgery and kidney

tissues are harvested for histopathological assessment, immunoflurescence staining, immunohistochemistry staining and Western Blotting protein assay.

Results: BMSCs treatment significantly ameliorates renal tubulointerstitial fibrosis and reduce kidney injury score at the 7th day after UUO surgery. BMSCs treatment also reduces PDGFRβ+ fibroblast and α-SMA+ myofibroblast infiltration within the kidney, as well as suppresses the renal expression of extracellular matrix proteins collagen I, vimentin and fibronectin. BMSCs treatment also promotes the formation and neogenesis of tertiary lymphoid organ within the kidney, identified with markers PNAd, LYVE-1, and GL-7. Further more, BMSCs treatment significantly inhibits the renal infiltration of CD3e+ T lymphocytes, CD11b+ monocytes and Ly6C/Ly6G+ neutrophils. Our results indicate a possible role of tertiary lymphoid organ formation and leukocyte trafficking in BMSCs' ability to ameliorate kidney injury and interstitial fibrosis.

Conclusions: BMSCs protection from experimental renal tubulointerstitial fibrosis could at least partly be attributed to their promotion of tertiary lymphid organ neogenesis and leukocyte trafficking within the obstructed kidney.

Funding: Government Support - Non-U.S.

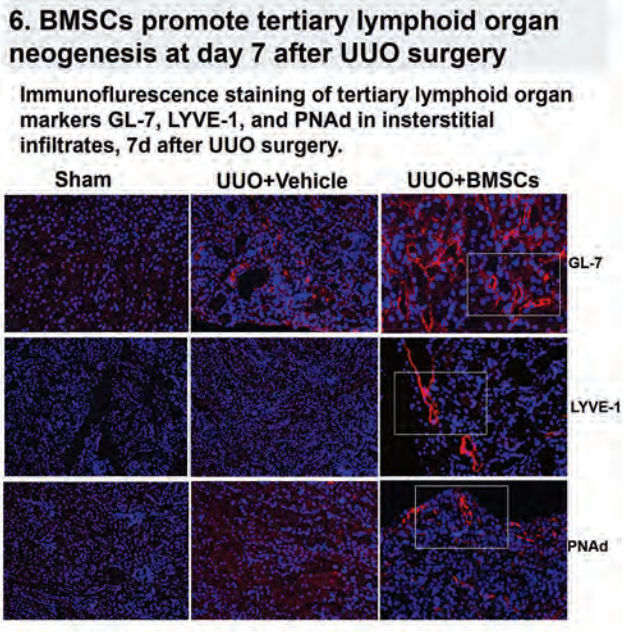

Figure 6. BMSCs promote neogenesis of tertiary lymphoid organ in UUO model, day 7.

Twist1 in Kidney Epithelium but Not Macrophages Propagates Aristolochic Acid Nephropathy

Jiafa Ren,[2] Yi Wen,[3] Xiaohan Lu,[1] Jamie Privratsky,[2] Steven D. Crowley.[2] *[1]Duke University, Durham, NC; [2]Duke University Medical Center, Durham, NC; [3]Southeast University, Nanjing, China.*

Background: Aristolochic acid, the causative agent in Chinese herbal and Balkan nephropathies, triggers persistent tubular injury and interstitial inflammation culminating in renal fibrosis. The transcription factor Twist1 induces pro-fibrotic gene expression programs in renal tubular cells (RTCs) but suppresses pro-fibrotic cytokines in macrophages. To discriminate these opposing, cell-specific actions of Twist1 in CKD, we subjected mice with RTC- or macrophage-specific Twist1 deficiency to chronic aristolochic acid nephropathy (AAN).

Methods: Mice with a floxed allele for the gene encoding Twist1 were backcrossed to the injury prone 129/SvEv strain and bred with 129/SvEv Ksp-Cre or LysM-Cre mice to yield Twist1 "KKO" or "MKO" mice with RTC- or macrophage-specific Twist1 deletion, respectively. AA (5mg/kg IP) was injected into Twist1 KKO, Twist1 MKO, and wild-type (WT) littermate control mice every other day for 12 days.

Results: 5 weeks after the last AA injection, Twist1 KKO mice compared to WTs had attenuated CKD as measured by BUN (41 ± 4 vs 52 ± 3 mg/dl; p = 0.035), blinded injury scores of PAS stains (2.0 ± 0.3 vs 2.9 ± 0.2; p = 0.038), and renal NGAL mRNA levels (0.6 ± 0.1 vs 1.0 ± 0.1; p = 0.036). Twist1 deletion in RTCs ameliorated kidney fibrosis as exhibited by reduced mRNA for Col-I (0.69 ± 0.05 vs 1.00 ± 0.09; p = 0.022) and TGF-β1 (0.81 ± 0.05 vs 1.00 ± 0.05; p = 0.019) and decreased protein levels of fibronectin (0.60 ± 0.03 vs 1.00 ± 0.07; p< 0.001) and α-SMA (0.55 ± 0.06 vs 1.00 ± 0.06; p<0.001). Twist1 in RTCs also secondarily regulated innate immune responses in the kidney as Twist1 KKO kidneys showed reduced mRNA expression for the macrophage chemokine CCL2 (0.72 ± 0.07 vs 1.00 ± 0.10; p = 0.046) and cytokine TNF-a (0.73 ± 0.08 vs 1.00 ± 0.08; p = 0.038). Accordingly, flow cytometric analysis after 5 weeks of AAN revealed reduced numbers of CD64+ (45906 ± 5279 vs 62986 ± 4822; p = 0.03) and F4/80+ (49949 ± 4441 vs 65581 ± 5005; p = 0.033) CD11b+Ly6G- macrophages in the Twist1 KKO kidneys versus WT controls. By contrast, robust deletion of Twist1 directly from myeloid cells in the Twist1 MKO cohort (>80%, p < 0.0001) had no impact at 5 weeks on renal tubular injury, interstitial fibrosis, or local inflammation.

Conclusions: Twist1 in RTCs rather than in myeloid cells regulates chronic inflammation and injury in the kidney during AAN.

SA-PO807

Genetic Depletion of Adenosine Kinase in Macrophage Aggravates Renal Fibrosis by Modulating M1/M2 Macrophage Polarization

Chang Ying Xing,[1] Xi Liu,[2] Yanggang Yuan,[2] Xiaofei An,[3] Huijuan Mao,[1] Bo Zhang.[4] *[1]First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [2]the First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [3]Jiangsu Province Hospital of Chinese Medicine, Nanjing, China; [4]The first affiliated hosptial of Nanjing Medical University, Nanjing, China.*

Background: Renal fibrosis is a common pathological manifestation of chronic renal diseases to end-stage renal failure, regardless of the cause. Accumulating evidence suggests a key role of macrophages in the pathogenesis of renal fibrosis. Adenosine (ADO) is an endogenous nucleotide involved in the energy metabolism and adenosine can be metabolized by adenosine kinase (ADK) or adenosine deaminase in cells. Adenosine can regulate the function of multiple immune cells. Therefore, we assume that the specific knockout of adenosine kinase gene can affect the function of macrophages and play a role in renal fibrosis.

Methods: 12 wild-type adult male mice and 12 ADK-deficient adult male mice undergo a sham operation or a unilateral ureteral occlusion operation.14 days after surgery, the kidney cortex was preserved to investigate renal pathological changes and renal fibrosis extent. F4/80 immunofluorescence staining and immunohistochemical staining was used to detect the degree of macrophage infiltration and M1 and M2 macrophages respectively. in vitro, we investigate the effrct of ADKI to RAW264.7 macrophages.

Results: ADK-/- UUO group had more severe interstitial fibrosis than that in WT UUO group. Infiltrated macrophages in the ADK-/- UUO group were increased than the WT UUO group (P<0.05) and M2 macrophages were predominate. ADKI promoted the RAW264.7 macrophages migration (P<0.05) and increased M2 macrophages biomarker expression along with inhibiting pron of -inflammatory cytokines release. ADKI increased the basic oxygen demand and maximal oxygen consumption of macrophages and reduced the extracellular acidification rate compared with Contol group (P<0.05). The numbers of M2 macrophages were negatively correlated with eGFR. The numbers of macrophages infiltrated in patients of Class III and IV DN was significantly higher than Class IIa or IIb stage(P < 0.05). patients with more severe renal tubular injury and interstitial fibrosis had more M2 macrophage.

Conclusions: Genetic depletion of adenosine kinase of macrophage exacerbates UUO-induced fibrotic lesions by mediating macrophage migration and promoting M2 macrophages transformation. Inhibition of ADK promote the conversion of macrophages to M2 type by inhibiting the glycolytic pathway. the more severe renal damage in patients with DKD, the more macrophages infiltrate.

Glycolytic Reprogramming and Development of Renal Fibrosis

Jessica M. Overstreet,[1] Sungjin Chung,[3] Ming-Zhi Zhang,[1] Raymond C. Harris.[2] *[1]Vanderbilt University Medical School, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]The Catholic University of Korea College of Medicine, Seoul, Republic of Korea.*

Background: Tubule dysfunction, myofibroblast differentiation and macrophage polarization are important in the development of renal fibrosis, which accompanies chronic kidney disease (CKD). Glycolytic reprogramming is critical for myofibroblast differentiation and fibrosis in the lung and the polarization of macrophages to an M1 phenotype. Although, dysregulation of cellular metabolism plays a role in the pathogenesis of several diseases, the role of glycolytic reprogramming in kidney fibrosis is unclear.

Methods: Glycolytic flux was measured by determination of extracellular acidification rates (ECAR) using Seahorse respirometry. An acute kidney injury (AKI)-CKD fibrotic model was performed by 31 min unilateral I/R, followed by uninephrectomy at day 8 and initiation of administration of the glycolysis inhibitor, PFK15 every 3 days until day 28. Human renal proximal tubule epithelial cells, mouse renal fibroblasts, and freshly isolated renal macrophages were used for in vitro studies.

Results: Transforming growth factor-β (TGF-β) is a master regulator of glycolytic reprogramming. TGF-β treatment led to increased glycolytic flux in both cultured renal epithelial cells and fibroblasts, as indicated by increased ECAR and ATP production. Glycolysis was reduced to basal levels with glycolytic inhibitors, PFK15 or 3-PO. TGF-β-induced glycolysis in fibroblasts was also confirmed by increased production of lactate. TGF-β-induced proliferation, differentiation (α-SMA), and matrix production (fibronectin) of renal fibroblasts was inhibited by PFK15. I/R injury for 2 days led to increased glycolysis in isolated CD11b+ renal macrophages, which was inhibited by PFK15. In the AKI/CKD fibrotic model, PFK15 markedly decreased renal interstitial fibrosis, indicated by less Sirius red and Masson's Trichrome staining. PFK15 also inhibited matrix and collagen deposition, α-SMA+ myofibroblasts, epithelial injury (e.g., KIM-1), and immune cell infiltration, including macrophages, CD3+ lymphocytes, and neutrophils.

Conclusions: These results suggest that glycolytic reprogramming is involved in renal tubular epithelial cell dysfunction, myofibroblast differentiation, and macrophage polarization in AKI, and inhibition of glycolytic flux may provide a new therapeutic target to prevent renal fibrosis when recovery from AKI is incomplete.

The FDA-Approved MEK Inhibitor Trametinib Ameliorates Kidney Fibrosis by Suppressing ERK1/2 and mTORC1 Signalling

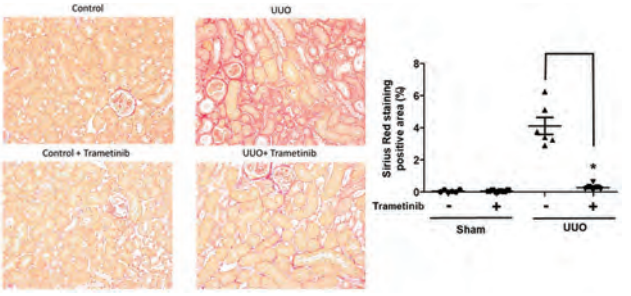
Petros Andrikopoulos,[2,1] Julius E. Kieswich,[2] Sabrina C. Pacheco,[2] Luxme Nadarajah,[2,3] Steven M. Harwood,[2] Muhammad M. Yaqoob.[2,1] *[1]Diabetic Kidney Disease Centre, Renal Unit, The Royal London Hospital, London, United Kingdom; [2]Queen Mary, University of London, London, United Kingdom; [3]Barts and the London Hospital, London, United Kingdom.*

Background: The incidence of Chronic Kidney Disease (CKD) is reaching epidemic proportions with rising associated morbidity and mortality. Consequently, there is an urgent need for novel treatments. The ERK1/2 pathway is activated during kidney fibrosis, a hallmark and promoter of CKD irrespective of the underlying cause, and has been detrimentally implicated in the differentiation and expansion of kidney fibroblasts. Trametinib, an ERK1/2-pathway inhibitor has been recently approved for the treatment of melanoma. However, the efficacy of trametinib in the setting of renal fibrosis has not been explored.

Methods: Unilateral Ureteral Obstruction (UUO) was established in male C57BL/6J mice. Trametinib (3mg/Kg) was admisnistered, once daily, by oral gavage for 6 days. or. in a parallel study, 4 days after UUO once daily for six days. Human kidney fibroblasts were from Cambridge Bioscience. Immunoblot was conducted using the NuPAGE system (Invitrogen). Immunostaining was performed with the DISCOVERY XT (Ventana) instrument.

Results: Trametinib significantly attenuated collagen deposition and myofibroblast differentiation and expansion in the UUO model of kidney fibrosis. In addition to the ERK1/2 pathway trametinib also ameliorated mTORC1 activation, another key pro-fibrotic signalling pathway, in injured kidneys. Trametinib also supressed ERK1/2 and mTORC1 pathways activation in cultured primary human renal fibroblasts in response to TGF-β1. Additionally, trametinib reduced the expression of the myofibroblast marker αSMA and the proliferation of these cells.. Crucially, trametinib also significantly ameliorated renal fibrosis progression when administered to animals with established fibrotic injury.

Conclusions: Our work shows that trametinib could be beneficial for the treatment of chronic renal fibrotic diseases of diverse aetiologies.



Sirius red staining of kidney sections from UUO or contralateral control kidneys 7days afer surgery. Animals received trametinib (3mg/kg for 6days) or vehicle as indicated. N=6

ATF6α and PPARα Cross-Talk Provides New Insights into Lipotoxicity-Induced Tubulointerstitial Fibrosis

Tzu-Ming Jao, Tsuyoshi Inoue, Mai Sugahara, Hiroshi Maekawa, Yu Ishimoto, Tetsuhiro Tanaka, Masaomi Nangaku, Reiko Inagi. *The University of Tokyo, Tokyo, Japan.*

Background: Lipid accumulation in renal tubules is frequently observed in CKD patients with tubulointerstitial fibrosis (TIF). However, the molecular mechanisms modulating lipotoxicity-induced TIF remain obscure. ATF6α, a transcription factor of the unfolded protein response, is reported to be an upstream regulator of fatty acid metabolism. Fatty acids are the main energy source of proximal tubular cells (PTCs), resulting from their high energy demand. We therefore hypothesized that ATF6α regulates tubular fatty acid metabolism, and is thereby linked to lipotoxicity-induced TIF.

Methods: Human proximal tubular cells, HK-2, were transduced with Mock, dominant active ATF6α or dominant negative ATF6α lentivirus for various experiments. Kidney unilateral ischemia-reperfusion (uIRI) (27 mins) was used as a chronic kidney injury model and kidney injury was assessed on day 14 post-uIRI using WT and Atf6α-/- mice. Mitochondrial fatty acid β-oxidation, glycolysis and function were measured using a Seahorse flux analyzer.

Results: Overexpression of activated ATF6α transcriptionally downregulates PPARα, the master regulator of lipid metabolism, leading to reduced activity of fatty acid β-oxidation and cytosolic accumulation of lipid droplets in HK-2. Such ATF6α-induced lipotoxicity causes mitochondrial dysfunction, enhanced apoptosis and connective tissue growth factor (CTGF) expression, as well as reduced cell viability, suggesting the promotive effects of ATF6α in TIF. Atf6α-/- mice showed less tubular lipid accumulation in association with sustained PPARα expression after uIRI, resulting in the amelioration of apoptosis; reduced expression of CTGF, α-SMA and collagen I; and subsequent TIF. These findings indicate the pivotal role of ATF6α in lipotoxicity-mediated TIF. Administration of fenofibrate, a PPARα agonist, in uIRI-operated mice alleviated the tendency to lipid accumulation and TIF.

Conclusions: These findings indicate that under the pathogenic condition, maladaptive ATF6α activation deranges fatty acid metabolism in PTCs, which leads to lipotoxicity-mediated apoptosis and CTGF upregulation, both of which may accelerate TIF.

STAT3 Deletion from Stromal Cells Protects Mice from Folic Acid or Aristolochic Acid-Induced Kidney Fibrosis by Limiting Differentiation and Migration of Pericytes

Amrendra K. Ajay,[1,2] Shruti Vig,[5] Akinwande A. Akinfolarin,[3] Venkata Sabbisetti,[4,2] Joseph V. Bonventre.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Brigham And Womens Hospital, Mckinney, TX; [4]Brigham and Women's Hospital, Boston, MA; [5]Brigham and women's hospital, Boston, MA.*

Background: STAT3 is a key transcription factor, which is phosphorylated in response to growth factors and cytokines. Upon phosphorylation, STAT3 regulates cell proliferation and migration. Here, we investigated the function of STAT3 signaling in the development of kidney fibrosis.

Methods: STAT3 activation was measured in 5 patient biopsy samples. Stromal cell-specific STAT3 deletion was performed by breeding STAT3 floxed mice with FoxD1 Cre mice. Kidney fibrosis was induced by administering 300 mg/kg folic acid (FA) or 5 mg/kg body weight aristolochic acid (AA). We developed STAT3 activated pericytes like 10T1/2 cells using two CRISPR based methods: i) Synergistic Activation Mediators (SAM) sgRNA, and ii) mutation of alanine 662 and asparagine 664 residues to cysteines. Additionally, using CRISPR, we mutated serine 727 to alanine of STAT3 in pericyte cell line. Cell migration was evaluated with wound scratch assays. RT-PCR, immunostaining and western blotting were performed to measure changes in STAT3-dependent genes and to quantitate pro-fibrotic cytokines.

Results: STAT3 phosphorylation was increased in tubular epithelial cells and interstitial cells of 5 human subjects with chronic kidney disease. Deletion of STAT3 from pericytes protects mice from FA or AA-induced kidney fibrosis at 7 and 14 days post-treatment. Fibrotic markers, including fibronectin, collagen1a1, and α-SMA, were reduced in STAT3 KO mice. STAT3 KO mice show similar acute injury and have less KIM-1 expression at 7 and 14 days. CRISPR-Cas9 mediated activation and inhibition studies *in vitro* confirmed that STAT3 is directly regulating profibrogenic signaling in pericytes. STAT3 phosphorylation increased migration and differentiation of pericytes. STAT3 is phosphorylated after treatment with TGF-β. Inhibition of TGF-β induced STAT3 phosphorylation significantly decreased the proliferation, production of profibrotic cytokines and differentiation of pericytes.

Conclusions: STAT3 leads to fibrosis by increasing proliferation, migration and differentiation of pericytes into myofibroblasts. STAT3 is a potential therapeutic target for kidney fibrosis.

Renalase (RNLS) Attenuates Cisplatin (CP)-Induced CKD by diminishing Stress Kinases and Regulated Necrosis

Robert L. Safirstein,[2] Xiaojia Guo,[1] Tian-Min Chen,[3] Heino Velazquez,[2] Gary V. Desir.[2] *[1]Yale Univ, Woodbridge, CT; [2]Yale and VAMC, West Haven, CT; [3]Yale University, New Haven, CT.*

Background: CP is widely used as an effective chemotherapeutic agent for cancer yet it causes CKD upon repeated doses, which limits its use. We have induced CKD in mice using 2 doses of CP 2 weeks apart and have shown that CKD developes 2 weeks after the second dose. Previously we have shown that RNLS attenuates acute ischemic and cisplatin-induced AKI. We now report on the role of RNLS to prevent CP-induced CKD.

Methods: CKD was induced by 2 doses of CP 15 mg/kg ip 2 weeks apart in C57BL/6J mice. Mouse PT cells (TKPTS) were incubated with 25 ug/ml CP and studied 24 hours after treatment. A non-enzymatic peptide of RNLS (p81), 4mg/kg sc, that signals via a surface receptor was given to a separate group of mice 3 times a week beginning with the first dose of CP. Immunoblotting, immunoflourescence, cell viability, and serum creatinine was applied to evaluate the effect of RNLS on cell viability, expression of stress kinases and regulated necrosis mediators, and renal function.

Results: RNLS expression was reduced in CP-induced CKD by 60% at 4 weeks and almost completely at 9 weeks in the proximal tubules of CKD mice. CP reduced renalase expression in TKPTS cells treated with CP as well. RNLS peptide p81 reduced CP-induced CKD signifcantly(n=4, p<.05) and reduced Kim-1, RIPK1, and MAPK activation. Viability of TKPTS cells was increased and activation of caspase 3 (apoptosis), TLR2, RIPK 1 and 3, and MLKL (necroptosis) was supressed. RNLS knockout animals had a heightened stress kinase and necroptotic response to CP.

Conclusions: We conclude that RNLS attenuates CP-induced CKD by intervening in cell death pathways activated by CP. RNLS acts as a survival factor for proximal tubule cells as RNLS knockout provokes cell death by similar pathways. These data suggest that RNLS may be an effective therapeutic agent to prevent CKD in patients treated with repeated doses of cisplatin.

Failed Repair, Not Fibrosis, Determines the Conversion of AKI to CKD in Cisplatin (CP)-Induced CKD

Robert L. Safirstein,[1,2] Sarah Landau,[4] Xiaojia Guo,[5] Heino Velazquez,[3] Richard Torres,[4] Gilbert W. Moeckel,[4] John J. Chang,[1] Gary V. Desir.[4] *[1]Connecticutt VAMC, West Haven, CT; [2]Nephrology, Yale School of Medicine, New Haven, CT; [3]Yale and VAMC, West Haven, CT; [4]Yale University School of Medicine, New Haven, CT; [5]Yale Univ, Woodbridge, CT.*

Background: Repeated doses of CP leads to CKD in humans but its mechanism is unknown. Previously we reported on a model of CP-induced CKD in mice that fully recapitulates the human disease.

Methods: Mice received CP 15mg/kg (ip) 2 weeks apart and multiphoton microscopy, cDNA microarray, PCR, western blotting, and immunocytochemistry were applied 4 weeks after the first dose in the two-dose model, when CKD is fully developed, and compared in mice 2 and 4 weeks after a single dose, when recovery is completed. Statistically significant differences ($p<.05$) were determined after correction for multiple comparisons.

Results: A fixed decline in GFR occured at 4 weeks in the 2 dose group and was associated with a loss of the glomerular parietal epithelial cells, a lesion that develops in CP-CKD. No increase in collagen deposition, the invasion of macrophages, or the loss of endothelial cells accompanied these changes. The onset of CKD showed expression of genes underlying regulated necrosis including Toll-Like Receptors 2 and 4, the Receptor-Interacting Protein Kinases 1 and 3, the Mixed Lineage Kinase-Like, and Cyclophilin D, while apoptosis played a minor role in cell death. Expression of the damage molecules Kim-1 and Ngal persisted after the second dose as did the reactivation of the stress kinases JNK and ERK, indicating continued injury. Cell cycle activity was markedly reduced after the second dose of CP. Although levels of CXCL1, CCL2, and CCR2 that play a critical role in CP AKI were elevated,. knockout of these genes did not prevent the development of CKD. Prominent and prolonged expression of the p21 gene was observed, which underlies the progression of CKD after 5/6 nephrectomy, but p21 knockout animals still progressed to CKD in the model.

Conclusions: Epithelial cell loss and regulated necrosis is a primary event in the development of CKD induced by two doses of CP. Progression of CKD is independent of the accumulation of fibrous tissue, macrophages, the loss of endothelial cells, or the production of key cytokines activated in AKI. Rather, deficient repair and continued loss of proximal tubule cells is the primary event in the conversion of AKI to CKD after repeated doses of cisplatin. A focus on interceding in the mechanisms of regulated necrosis could be successful in preventing CKD

SA-PO814

DNA Methylation Suppresses HoxA5 for Jag1-Notch1 Signaling in Renal Interstitial Fibrosis

Xiao Xiao.[1,2] *[1]Augusta University, Augusta, GA; [2]Wuhan University Zhongnan Hospital, Wuhan, China.*

Background: DNA methylation has been implicated in the regulation of renal interstitial fibrosis in kidney diseases, but the mechanism remains incompletely understood.

Methods: In this study, we analyzed genome-wide changes in DNA methylation during renal fibrosis in the mouse model of unilateral ureteral obstruction (UUO) by using the reduced representative bisulfite sequencing.

Results: UUO induced renal interstitial fibrosis, which was accompanied by an overall increase in DNA methylation in kidney tissues. 5-aza-2'-deoxycytidine (5-aza, DNA methylation inhibitor) blocked DNA methylation in UUO and suppressed renal fibrosis. Among the genes with altered DNA methylation in UUO, HoxA5 had seven hypermethylated CpG sites on its promoter that were further verified by pyrosequencing. Hypermethylation of HoxA5 was associated with decreased HoxA5 expression in UUO. 5-aza could partially prevent HoxA5 decrease in UUO, further confirming the regulation of HoxA5 by DNA methylation. Overexpression of HoxA5 suppressed renal fibrosis in UUO and attenuated TGF-β-induced fibrotic changes in renal tubular cells. Mechanistically, HoxA5 was shown to repress Jag1 via gene promoter binding, resulting in the suppression of the Jag1-Notch signaling pathway of renal fibrosis.

Conclusions: Together, these results suggest that DNA methylation may promote renal interstitial fibrosis by suppressing HoxA5 for the activation of Jag1-Notch1 signaling.

SA-PO815

Genetic Nrf2 Enhancement Increases Proteinuric Renal Injury

Brittney M. Rush,[2] Corry D. Bondi,[2] Kacie Barry,[2] Sean D. Stocker,[2] Soma Jobbagy,[2] Donna B. Stolz,[2] Dionysios Chartoumpekis,[2] Thomas W. Kensler,[2] Roderick J. Tan.[1] *[1]Medicine, University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA.*

Background: Proteinuric chronic kidney disease (CKD) is a major cause of progressive renal failure and has limited therapies. Nrf2 (nuclear factor erythroid 2 like 2) is a transcription factor that upregulates cytoprotective mechanisms including antioxidants and detoxifying genes. Keap1 (kelch-like ECH-associated protein 1) binds and inhibits Nrf2 under normal conditions to prevent activity. Under conditions of oxidative stress or chemical exposure, the Keap1 repressor releases Nrf2 which then initiates target gene transcription. While this might be expected to prevent disease, both preclinical and clinical data have suggested that Nrf2 could paradoxically aggravate proteinuria. We therefore hypothesized that Nrf2 activity accelerates progression of proteinuric CKD.

Methods: Keap1 hypomorphic mutant mice have reduced Keap1 expression and enhanced Nrf2 activity. Wild-type mice and Keap1 hypomorphs were subjected to a variety of proteinuric injuries including continuous angiotensin II infusion, adriamycin, and albumin overload models. Urinary albumin excretion was measured with ELISA, and glomerular damage assessed via assessment of foot process effacement, nephrin, and Wilms Tumor 1 (WT1). Systemic blood pressure was measured with radiotelemetry, and glomerular filtration rate (GFR) was determined with FITC-sinistrin. The synthetic triterpenoid, CDDO-Im, was used in the adriamycin model to upregulate Nrf2 activity.

Results: Compared to wild-type mice, Keap1 hypomorphs had significantly increased proteinuria in all disease models. This was associated with worsened podocyte foot process effacement and decreased nephrin and WT1, indicating increased glomerular injury. We did not detect any increase in GFR in the mutants to explain this difference. While there were mild elevations in the systolic, diastolic, and mean blood pressures in the Keap1 hypomorphs before and after angiotensin II infusion, the proteinuria was out of proportion to these differences. Treatment of wild-type mice with CDDO-Im enhanced Nrf2 activity but also increased mortality after adriamcyin exposure.

Conclusions: Genetic Nrf2 upregulation significantly promotes glomerular injury and lethality in proteinuric kidney injury models. This phenomenon is partly explained by higher blood pressure in hypomorphic mice but other mechanisms likely play a role.

SA-PO816

Involvement of Endoplasmic Reticulum Stress and Autophagy on Homocysteine Induced Apoptosis of Human Glomerular Mesangial Cells

Shanshan Liang,[1] Hongli Jiang.[2] *[1]Dialysis Department of Nephrology Hospital, First Affiliated Hospital of Medicine School, Xi?an Jiaotong University, Xi?an, China; [2]First Affiliated Hospital of Medicine School, Xi?an Jiaotong University, Xi?an, China.*

Background: Homocysteine (Hcy) levels significantly increased in chronic renal failure (CRF). It has been reported that Hcy can induce proliferation and apoptosis of glomerular Mesangial cells. The purpose of this study was to investigate whether autophagy and endoplasmic reticulum stress were involved in the induction of glomerular Mesangial cells apoptosis by Hcy, and to provide evidence for further elucidation of the toxicity of Hcy on Mesangial cells.

Methods: Human Glomerular Mesangial cells (HMC) were incubated with different concentrations of Hcy (50~1000 μ mol/L) for 24h and Hcy 250 μmol/L for different hours (0~48h). Flow cytometry was used to detect the changes of apoptosis after different concentrations and times of Hcy treatment. Western blotting was used to detect the changes of related proteins after exposure to Hcy 250 μmol/L for 24h. Apoptosis as well as protein changes were separately detected by flow cytometry and Western blotting after treatment with endoplasmic reticulum inhibitor 4-PBA and Atg 5 siRNA respectively.

Results: The proliferation ability and cell viability of HMC gradually decreased. The proportion of Mesangial cell apoptosis increased with the increase of the concentration of Hcy and the prolongation of the incubation times in a time-and concentration-dependent manner. The expression of apoptosis-related protein Bax and cleavage caspase-3 were significantly increased, with the autophagy related proteins LC3-II/LC3-I, beclin1 and Atg5 were significantly increased and p62 decreased. The expression of ER stress-related proteins ATF4, CHOP, GRP78 and p-eIF2α all increased significantly. After the intervention of 4-PBA, the ER stress-related proteins and the proportion of apoptosis decreased with the expression of apoptosis-related protein improved. The expression of p62 increased and LC3-II/LC3-I, beclin1 and Atg5 decreased. At the same time, after intervened with Atg5 siRNA, the expression of Atg5 decreased, and the ratio of LC3-II/LC3-I decreased and the p62 degraded with cleavage caspase-3 and CHOP increased, but p-eIF2α did not change significantly.

Conclusions: Hcy induced glomerular mesangial cell apoptosis in a concentration- and time- dependent manner and may via an ER stress-triggered signaling pathway. Atg5-dependent autophagy plays a protective role in the process.

SA-PO817

Regulation of Klotho by Proteinuria in CKD

Vasiliki Delitsikou,[1,2] Frederique Ino,[1,2] George Jarad,[3] Jeffrey H. Miner,[3] Sophie M. De Seigneux.[1,2] *[1]Cell Physiology and Metabolism, Faculty of Medicine, University of Geneva, Geneva, Switzerland; [2]Department of Internal Medicine Specialties, Division of Nephrology, HUG, Geneva, Switzerland; [3]Washington University School of Medicine, St. Louis, MO.*

Background: Albuminuria, caused by lesions in the glomerular filtration barrier, promotes tubular inflammation, apoptosis and fibrosis in Chronic Kidney Disease (CKD). Previously, it was shown that albuminuria is associated with lower Klotho levels. Our aim is to further investigate how albuminuria regulates Klotho expression.

Methods: Transgenic mice with inducible podocyte apoptosis (POD-ATTAC) were used, as well as Alport mice, either wild type or deficient in albumin. For the *in vitro* experiments, HEK cells overexpressing the human transmembrane form of Klotho and HK-2 cells were used.

Results: *In vivo* in POD-ATTAC mice, 3 and 7 days after podocyte loss, both Klotho mRNA and protein levels were downregulated without modifications of ADAMs activities and expression. *In vitro*, upon BSA treatment, the total and membrane fractions of the Klotho protein were decreased while Klotho protein half-life was also significantly reduced. Cleaved Klotho as measured in the supernatant was decreased proportionally, arguing against enhanced cleavage. Likewise, a reduction of Klotho mRNA and protein levels was

observed in HK-2 cells. In the Alport mice, Klotho expression was decreased as measured by qPCR and Western blot. However, this was not the case in the Alport albumin deficient mice, implying some specificity of the regulation by albuminuria itself and not only by the primary renal disease. Similarly, there was no Klotho downregulation upon exposure to immunoglobulins *in vitro*. *In vivo* and *in vitro*, albuminuria induced some features of ER stress. Inhibition of ER stress increased Klotho protein levels *in vitro and in vivo*, suggesting that this mechanism may participate to the enhanced Klotho degradation by albuminuria.

Conclusions: In conclusion, albuminuria has a specific role on Klotho downregulation *in vitro* and *in vivo* that seems to depend on ER stress induction.

SA-PO818

Calcitriol Ameliorates Kidney Injury and Fibrosis by Activating Klotho and Inhibition of TGFβ1 Signaling Pathway

Ao Cheng. *Department of Neprology, The Fist Affiliated Hospital of Xiamen University, Xiamen, China.*

Background: Active vitamin D3 (Calcitriol) can effectively remit the progression of chronic kidney disease, but its mechanism is not clear. Klotho as an anti-aging protein played a variety of physiologic roles in the kidney. The main purpose of this experiment is to explore whether Calcitriol could up-regulated expression of the Klotho in vitro and in vivo, and ameliorates kidney injury and fibrosis by targeted inhibition of TGFβ1 activation.

Methods: (1) Animal Experiment: The rats were divided into three groups: sham group, 5/6 nephrectomy group, 5/6 nephrectomy + calcitriol group. 1) Through serum biochemical tests, to detect the levels of BUN, Creatine in various groups and determine expression of Klotho, TGFβ1 in serum. 2) By HE, Masson staining of renal tussues, Observation of renal fibrosis and collagen deposition; 3) Detection expression of Klotho, TGFβ1, E-cadherin and α-SMA in renal tussues by Immunohistochemical staining. 4) Using PCR and Western-Bloting detect expression of Klotho, TGFβ1, E-cadherin and α-SMA in renal tussues; (2) In Vitro: Calcitriol, Klotho siRNA and TGFβ1 ware prepared and mouse renal tubular epithelial cells were cultured in vitro. Mouse renal tubular epithelial cells was treatment with various concentrations and time period of Calcitriol before TGFβ1 stimulation, and pretreatment or not with Klotho siRNA. Klotho, Snail1, PAI-1, E-cadherin and α-SMA were measured by real-time PCR and Western-blot.

Results: (1) Animal Experiment: 1) Calcitriol could effectively reduce the elevated creatinine, BUN in the 5/6 nephrectomy rats; 2) Calcitriol might ameliorate kidney injury and fibrosis by light microscopy; 3) In renal tissue, calcitriol may induce Klotho and E-cadherin expression and reduce TGFβ1 and α-SMA expression; (2) In Vitrio: Calcitriol in a dose and time dependent manner induce Klotho and E-cadherin expression and reduce Snail1, PAI-1 α-SMA expression by TGFβ1 stimulation. Klotho siRNA could mitigate effective role of Calcitriol.

Conclusions: Calcitriol could ameliorate kidney injury and mitigate TGFβ1 induced fibrosis by activating Klotho in vivo and in vitro.

SA-PO819

PBI-4050 Signals via GPR40 to Decrease Adenine-Induced Tubulointerstitial Injury and ER Stress

Jean-Francois Thibodeau,[1,3] Chet E. Holterman,[3] Jean-Christophe Simard,[1] Francois A. Leblond,[1] Brigitte Grouix,[1] Rania Nasrallah,[3] Pierre Laurin,[1] Richard L. Hébert,[2,3] Chris R. Kennedy,[2,3] Lyne Gagnon.[1] *[1]Prometic Biosciences Inc., Laval, QC, Canada; [2]Department of Cellular and Molecular Medicine, Faculty of Medicine, University of Ottawa, Ottawa, ON, Canada; [3]Kidney Research Centre, Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

Background: PBI-4050, a novel first-in-class orally active compound currently in clinical phase III in IPF patients, exerts antifibrotic effects in several organs via a novel mechanism of action. In the kidney, PBI-4050 exerts its antifibrotic effects primarily through GPR40 activation. The aim of this study was to further examine the effects of PBI-4050 in both WT and GPR40$^{-/-}$ mice on adenine-induced tubulointerstitial fibrosis, inflammation and the unfolded protein response pathway, all of which contribute to CKD progression.

Methods: Adenine-induced CKD was achieved in eight-week old male C57BL/6 mice fed a diet supplemented with 0.25% adenine. After one week, PBI-4050 (50, 100, 200 mg.kg^{-1}day) or vehicle was administered daily by oral-gavage for three weeks. In parallel, eight-week old wild-type and GPR40$^{-/-}$ mice were also subjected to adenine-CKD, with or without a PBI-4050 (200 mg.kg^{-1} day) treatment.

Results: PBI-4050 treatment reduced adenine-induced polyuria and maintained urine osmolality. Plasma urea and creatinine were significantly increased four and two-fold respectively in vehicle treated mice, while PBI-4050 decreased these values. PBI-4050 treatment decreased adenine-mediated renal fibrotic lesions in a dose dependent manner. Accordingly, α-SMA and fibronectin expression were also reduced by PBI-4050 as well as several pro-inflammatory genes. Moreover, renal ER-stress and pro-apoptotic markers were significantly reduced by PBI-4050 in adenine fed mice. In parallel, GPR40$^{-/-}$ mice given adenine had increased tubulointerstitial injury, exacerbated renal function and ER-stress associated protein expression compared to WT mice. PBI-4050 treatment in adenine-fed GPR40$^{-/-}$ mice failed to reduce anemia, tubulointerstitial injury and ER-stress.

Conclusions: PBI-4050 treatment decreased the severity of several adenine-induced sequelae including tubular injury, tubulointerstitial fibrosis, anemia, apoptosis and ER-stress. The GPR40 receptor mediates PBI-4050's beneficial effects in this model. Taken together, these data reinforce PBI-4050's use as a renoprotective therapy and identify important pathways involved.

Peroxiredoxin V (PrdxV) Negatively Regulates EGFR/Stat3-Mediated Fibrogenesis via Cys48-Dependent Interaction Between PrdxV and Stat3

Hoon In Choi,[1] Jung Sun Park,[1] Donghyun Kim,[2] Injin Kim,[2] Eun Hui Bae,[2] Seong Kwon Ma,[1] Soo Wan Kim.[1] *[1]Chonnam National University Medical School, Gwangju, Republic of Korea; [2]Chonnam National University Hospital, Gwangju, Republic of Korea.*

Background: Activation of epidermal growth factor receptor (EGFR)/signal transducer and activator of transcription 3 (Stat3) signaling pathway has been reported to be associated with renal fibrosis. In addition to the anti-inflammatory effect and the anti-oxidative effect of Peroxiredoxin V (PrdxV), recently it has been shown that PrdxV acts as an anti-fibrotic effector by inhibiting the activity of Stat3 in TGF-β-treated NRK49F cells. However, the relevance and the underlying mechanism of Prdx V to renal pathobiology remains poorly understood.

Methods: To investigate the role of PrdxV in renal fibrosis, we used a transgenic mouse model with PrdxV siRNA expression controlled by U6 promoter (C57BL/6J-Tg(U6-PrdxVsi)1Thlee/Krb; PrdxVsi mice). Both PrdxV^{wt} and PrdxV^{si} mice were subjected to unilateral ureteral obstruction (UUO) for 7 days (Control vs. UUO group, n = 8 per each group). To understand the molecular mechanism for anti-fibrotic effect of PrdxV, HA-tagged WT PrdxV and C48S PrdxV were transiently transfected into 209/MDCT cells and treated with TGF-β.

Results: We confirmed that the protein level of PrdxV was inversely related to the progression of UUO-induced renal fibrosis. Transgenic PrdxV^{si} mice exacerbated epithelial-to-mesenchymal transition as well as the increase of oxidative stress by UUO. In the fibrotic kidney of PrdxV^{si} mouse, knock-down of PrdxV increased Y1068-specific EGFR and Stat3 phosphorylation, whereas overexpression of WT PrdxV in 209/MDCT cells showed the opposite results. Immunoprecipitation revealed the specific interaction between WT PrdxV and Stat3 in the absence or presence of TGF-β stimulation, whereas no PrdxV-EGFR or C48S PrdxV-Stat3 interaction were detected under any conditions.

Conclusions: PrdxV is an anti-fibrotic effector that sustains renal physiology. Direction interaction through Cys48 between PrdxV and Stat3 is a major molecular mechanism.

Funding: Government Support - Non-U.S.

cMet Agonistic Antibody Attenuates Renal Fibrosis in Obstructive Nephropathy

Yong Chul Kim,[1] Jung Nam An,[2] Chun Soo Lim,[2] Yon Su Kim,[3] Seung Hee Yang,[4] Jung Pyo Lee.[2] *[1]SNUH, Seoul, Republic of Korea; [2]Seoul National University Boramae Medical Center, Seoul, SEOUL, Republic of Korea; [3]Seoul National University College of Medicine, Seoul, Republic of Korea; [4]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea.*

Background: Hepatocyte growth factor (HGF) and its receptor, cMet, activate biological pathways necessary for repair and regeneration following kidney injury. The Met receptor is expressed in multiple cell types within the kidney, each of which is capable of regulating fibrotic responses. Since HGF is a quite unstable molecule in its biologically active form, we asked whether a monoclonal antibody (Ab) that displays receptor full agonist activity could protect kidney from fibrosis.

Methods: We tried to determine whether cMet agonistic Ab might reduce fibrosis, the final common pathway for chronic kidney diseases. We primary cultured human proximal tubular epithelial cells (PTECs) for in vitro study and a mouse model of renal fibrosis disease induced by unilateral ureteral obstruction (UUO) was introduced.

Results: In kidney biopsy specimens of CKD patients, cMet immunohistochemistry staining showed remarkable increase than patients with normal renal functions. cMet Ab treatment significantly increased phospho-cMet expression and abrogated protein expressions of fibrosis markers such as fibronectin, collagen IV, αSMA and also Bax2 which is a marker of apoptosis triggered by recombinant TGF-β1 in PTECs. In a wound healing scratch assay, PTECs treated with cMet Ab progressed into the wound area more rapidly inducing wound healing than untreated cells. Remarkably, injections of cMet Ab significantly prevented renal fibrosis in the obstructed kidneys quantified by Masson Trichrome staining. Consistently, cMet Ab decreased the expression of fibrosis markers such as, collagen 1 and αSMA, and E-cadherin which is a cell-to-cell adhesion molecule was recovered.

Conclusions: cMet-mediated signaling may have a considerable role in the renal fibrosis. And cMet agonistic Ab may thus be a valuable substitute for HGF, being more easily available in a biologically active, stabilized, and purified form.

The Histone Demethylase Jumonji Domain-Containing Protein 3 Acts as an Epigenetic Suppressor of Renal Fibrosis

Chongxiang Xiong,[2] Hequn Zou,[3] Shougang Zhuang.[1] *[1]Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI; [2]Rhode Island Hospital, Providence, RI; [3]The 3rd Affiliated Hospital of Southern Medical University, Guangzhou, China.*

Background: The histone demethylase Jumonji domain-containing protein 3 (JMJD3) is the enzyme that induces demethylation of histone H3 lysine 27 (H3K27) and its activation is involved in the tumor genesis. Although activation of H3K27 methyltransferase has been shown to be required for renal interstitial fibroblast activation and renal fibrogenesis, the role of JMJD3 in these processes remains elusive.

Methods: In this study, we examined the effect of pharmacological inhibition of JMJD3 on renal fibroblast activation and renal fibrosis development in a murine model of unilateral ureteral obstruction.

Results: Following unilateral ureteral obstruction, expression levels of JMJD3 and methylated H3K27 were increased in the kidney. Administration of GSKJ4, a specific inhibitor of JMJD3, aggravated renal fibrosis and increased expression of alpha-smooth muscle actin (alpha-SMA), a hallmark of myofibroblasts (active fibroblasts) and promoted deposition of collagen I, one of major extracellular matrix proteins. GSKJ4 inhibition also increased expression of transforming growth factor β1 (TGF-b1) and enhanced the phosphorylation of Smad3, a key molecule of TGF-β signaling. Moreover, GSKJ4 potentiated expression of Notch1 and Notch3 as well as phosphorylation of NF-κB and Stat3. Finally, treatment with GSKJ4 increased expression of alpha-SMA, collagen I and fibronectin in cultured renal epithelial cells.

Conclusions: Collectively, these data suggest that JMJD3 functions as a suppressor of renal fibroblasts and renal fibrosis in the kidney after ureteral obstruction.

A Pilot Study to Explore Relationships of Mitochondrial DNA Copy Number in Blood and Kidney Tissue and Their Associations with Kidney Health

Vasantha Jotwani,[1] Gregory J. Tranah,[2] Ronit Katz,[3] Mark J. Sarnak,[4] Chirag R. Parikh,[5] Steven Cummings,[6] Joachim H. Ix,[7] Samir M. Parikh,[8] Adrienne Tin,[9] Dan Arking,[9] Michael Shlipak,[10] Sushrut S. Waikar.[11] *[1]UCSF, San Francisco, CA; [2]Sutter Health, San Francisco, CA; [3]University of Washington, Seattle, WA; [4]Tufts Medical Center, Boston, MA; [5]Yale University and VAMC, New Haven, CT; [6]San Francisco Coordinating Center, Mill Valley, CA; [7]UCSD, San Diego, CA; [8]Beth Israel Deaconess Medical Center, Boston, MA; [9]Johns Hopkins University School of Medicine, Baltimore, MD; [10]San Francisco VA Medical Center, San Francisco, CA; [11]Harvard Medical School, Boston, MA.*

Background: Despite several animal studies linking mitochondrial damage to the development of acute and chronic kidney injury, human studies have been sparse due to our limited methods for assessment of mitochondrial health by stored specimens. A key question is whether peripheral mitochondrial measures adequately reflect mitochondrial health in kidney tissue. We conducted a pilot study to compare mitochondrial DNA (mtDNA) copy number in blood and kidney tissue and to evaluate their associations with renal function and pathology.

Methods: We measured mtDNA copy number in blood buffy coat and kidney specimens of 9 participants of the Brigham and Women's Hospital Nephrectomy Cohort who were selected to represent a broad range of age and kidney function. MtDNA copy number was determined by a real-time quantitative PCR assay that measures the ratio of the mtDNA-encoded *ND1* gene to the single-copy nuclear β2-Microglobulin gene. Kidney specimens were assessed by a pathologist using a standardized scoring protocol.

Results: The mean age was 64 ± 12 years and mean eGFR was 46 ± 21 ml/min/1.73m^2. Blood mtDNA copy number (r=0.739, p=0.023) and kidney mtDNA copy number (r=0.883, p=0.002; **Figure**) correlated strongly with eGFR and with each other (r=0.756, p=0.019). Compared to participants with severe tubulointerstitial fibrosis, participants with mild fibrosis had higher blood and kidney mtDNA copy numbers (p=0.03).

Conclusions: Higher mtDNA copy number, measured in blood or kidney, correlated positively with eGFR and negatively with tubulointerstitial fibrosis, suggesting that mitochondrial abundance is important for kidney health. Strong correlations between mtDNA copy number in blood and kidney tissue support the use of peripheral mitochondrial measures in future studies.

Activation of FXR Regulates Kidney Autophagy for Suppressing Renal Fibrosis

Donghyun Kim,[1] Hoon In Choi,[2] Jung Sun Park,[3] Eun Hui Bae,[1] Seong Kwon Ma,[2] Soo Wan Kim.[2] *[1]Chonnam National University Hospital, Gwangju, Republic of Korea; [2]Chonnam National University Medical School, Gwangju, Republic of Korea; [3]chonnam national university, Gwang Ju, Republic of Korea.*

Background: Autophagy is an evolutionarily conserved catabolic process that removes damaged organelles and maintains cellular energy homeostasis. Acute regulation by nutrient-sensing of autophagy and long-term transcriptional regulation by nuclear hormone receptor farnesoid X receptor (FXR) is well known. Also, kidney autophagy regulates TGFβ expression and suppresses kidney fibrosis. However, the functional role of FXR on TGFβ-induced kidney autophagy is relatively unknown.

Methods: Expression levels of LC3 protein and autophagy related genes were measured on treatment with TGFβ and FXR agonists, GW4064, CDCA, and INT-747, in human proximal tubule cells (HK2 cells). Also, we tested expression levels of autophagy related proteins and genes in unilateral ureteral obstruction mice model. The LC3 Puncta formation was monitored by fluorescence microscopy. Expression levels of protein and autophagy related genes were measured on down-regulation of FXR by siRNA in HK2 cells or FXR knock-out mice.

Results: Treatment with TGFβ (5 ng/ml) in HK2 cells resulted in an increase in the level of LC3 protein and autophagy related genes, along with an increase in fibrosis markers. Activation of FXR by agonists in TGFβ-induced HK2 cells regulates LC3 I and II expression levels. Autophagy related genes were decreased in FXR agonists treated HK2 cells. Also, autophagic flux was further increased on co-treatment with GW4064 and TGFβ in HK2 cells. Autophagy related genes has no GW4064 effects on down-regulation of FXR by siRNA in HK2 cells. Protein levels of LC3 and fibrosis markers were increased in FXR-KO UUO mice model compared to those of WT UUO mice model.

Conclusions: These data reveal a functional role of FXR for kidney autophagy regulator in TGFβ-induced HK2 cells and suggest that FXR may play an important role in the suppression of renal fibrosis through kidney autophagy.

Rab27a Dependent Exosome Secretion from Tubular Epithelial Cell Promotes Albumin-Induced Tubulointerstitial Inflammation

Ye Feng, Linli Lv, Xin Zhong, Zuolin Li, Bi-Cheng Liu. *Zhong Da Hospital, Southeast University Medical School, Nanjing, China.*

Background: Tubular epithelial cells (TECs) secrete increasing exosomes under with proteinuria toxicity. However, the mechanism through which exosomes are produced and the effect on tubular cell hemostasis and tubulointerstitial inflammation are unknown.

Methods: Proteinuric renal disease model was induced by adriamycin (ADR) administration through tail vein. Urinary albumin was determined at 0, 7, 14, 21 and 23 days after ADR injection. Histological changes were examined by PAS staining. For *in vitro* studies, TECs were treated with albumin. We found that the release of exosomes may result in TECs inflammation. Exosomes were isolated from isolated tubules of kidney and cell culture supernatant for characterization and functional study.

Results: Chronic kidney injury was induced by administration with ADR. Urinary albumin was significantly increased in ADR-treated mice 2 weeks after injection compared with controls. Histologically, the TEC injury and protein cast were observed in ADR-injected mice. Electron microscopy and western blotting analysis of exosome markers, CD9, CD81, Alix confirmed the typical characteristics of isolated exosomes from kidney. Exosome production was increased significantly in kidney of ADR mice and in TECs with albumin exposure. Interestingly, we showed increasing levels of Rab27a mRNA and protein both in the tubule of ADR-injected mice and in BSA-treated TECs in a dose dependent manner. And the increased exosome production was dependent on Rab27a up-regulation since silencing of Rab27a reversed the exosomes secretion. Importantly, the mRNA expression of inflammatory cytokines in TECs treated with BSA was reduced after inhibition of exosome secretion by Rab27a knocking down. To explore the effect of TEC exosome production under albumin exposure, TEC-exosomes were purified and added to naïve TEC. Up-regulation of inflammatory cytokines were found in receipt TECs.

Conclusions: These results provide a novel finding that TECs exosomes were produced increasingly through Rab27a dependent mechanism. And TEC exosome production exacerbated TECs injury by enhancing inflammatory response and may consequently lead to tubulointerstitial inflammation.

Amelioration of Renal Fibrosis and Tubulointerstitial Damage in Fat-1 Transgenic CKD Mice by Compensation of Decreased Omega-3 Fatty Acids in the Kidney

Naohiro Takahashi,[1] Hiroaki Kikuchi,[1] Tomoaki Ishihara,[2] Makoto Arita,[2] Taisuke Furusho,[1] Fumiaki Ando,[1] Takayasu Mori,[1] Kiyoshi Isobe,[1] Koichiro Susa,[1] Naohiro Nomura,[1] Tatemitsu Rai,[1] Shinichi Uchida,[1] Eisei Sohara.[1] *[1]Tokyo Medical and Dental University, Tokyo, Japan; [2]RIKEN-IMS, Yokohama, Japan.*

Background: Although recent advances have led to better understanding of the linkage between inflammatory diseases and lipid mediators, little has been reported on the changes of lipid profile of kidney tissue in chronic kidney disease (CKD). Lipidomics is a powerful

tool for the identification and the quantification of the lipid metabolites. In this study, we applied lipidomics to the kidney from the mice performed with subtotal nephrectomy, to identify specific lipid mediators as novel therapeutic targets in CKD.

Methods: Subtotal nephrectomy or oral administration of adenine was performed to C57BL/6J mice to establish CKD models. Kidney tissue samples from subtotal nephrectomy mice were analyzed with lipidomics to reveal lipid profile of CKD kidneys. We also analyzed the CKD models of *fat-1* transgenic mice expressing the *C. elegans fat-1* gene encoding an omega-3 fatty acid desaturase, leading to abundant omega-3 fatty acids in kidneys. To evaluate effects of lipid metabolites on fibrosis, we used cultured NRK-49F cells.

Results: Lipidomics analysis revealed that omega-3 fatty acids (EPA and DHA) and their downstream lipid metabolites were significantly decreased in CKD kidneys in comparison with sham control kidneys. Therefore, to investigate the effects of decreased omega-3 fatty acids on CKD kidneys, we examined two CKD models of *fat-1* transgenic mice, subtotal nephrectomy and adenine-induced nephropathy. Alpha-SMA (a marker of renal fibrosis) and NGAL (a marker of tubulointerstitial damage) were suppressed in *fat-1* transgenic CKD mice, suggesting that increased omega-3 fatty acids in kidney have beneficial effects on CKD. Some specific omega-3 fatty acid metabolites which were decreased in CKD kidneys attenuated fibroblast activation *in vitro*, indicating that they could be novel therapeutic lipid mediators for CKD treatment.

Conclusions: Lipidomics of the kidneys from subtotal-nephrectomy mice revealed reduction of omega-3 fatty acids and their down-stream lipid metabolites. Supplementation of omega-3 fatty acids and their downstream metabolites to kidneys might ameliorate tubulointerstitial damage and renal fibrosis in CKD.

Renal Hemodynamic Effects of a sGC Stimulator vs Activator in Conscious Sprague-Dawley and Obese Diabetic ZSF1 Rats

Karen A. Griffin,[4] Geoffrey A. Williamson,[2] Perriannan Sethupathi,[3] Agnes M. Benardeau,[5] Anil K. Bidani.[1] *[1]Loyola University Med Ctr and Hines VA Hospital, Maywood, IL; [2]Illinois Institute of Technology, Chicago, IL; [3]Loyola University Medical Center, Maywood, IL; [4]Loyola University Medical Center Hines VA Hospital, Maywood, IL; [5]Bayer Pharma AG, Wuppertal, Germany.*

Background: Endothelial dysfunction and/or NO loss accelerate the progression of diabetic and non-diabetic chronic kidney disease (CKD). Therefore, soluble guanylate cyclase (sGC) stimulators and activators are being developed as potential novel therapeutic interventions in CKD. Stimulators sensitize sGC to low levels of bioavailable NO in the presence of reduced (ferrous) prosthetic heme, while sGC activators preferentially activate sGC when it is in an oxidized or heme free state. But their comparative renal hemodynamic effects have not been examined in conscious rat models.

Methods: Conscious chronically instrumented conscious Sprague-Dawley rats (body weight ~300g) and obese diabetic ZSF1 rats (body wt ~500g) underwent repeated simultaneous 1-2 hr BP (radiotelemetry) and RBF (Transonic) recordings over 3 wks (2-4 x wk) while they were sequentially receiving: vehicle only by gavage (5 ml/kg), a low and a high dose of either the sGC activator (BAY-543) or the stimulator (BAY-747) (3-4 days/wk with a ~3 day washout period). Effects on mean arterial pressure (MAP), RBF, renal vascular resistance (RVR) and the autoregulatory (AR) ability to buffer spontaneous BP fluctuations were assessed using a methodology recently developed in our lab.

Results: Table (mean ± SEM) While both the sGC stimulator and the sGC activator in the dosages used had similar BP effects in both SD and ZSF1 rats, the sGC activator tended to produce greater renal vasodilation with both doses in both strains but which was significant only in the ZSF1 rats. Despite the renal vasodilation, AR buffering of spontaneous BP fluctuations was not impaired by either agent in either strain.

Conclusions: The significantly greater renal vasodilatory effects of sGC activator in a renal disease model, the ZSF1 rat, may have relevance when considering therapy with sGC modulators in CKD states.

High Salt Enhances ROS and Ang II Contractions of Glomerular Afferent Arterioles from Mice with Reduced Renal Mass

Christopher S. Wilcox,[1] Lingli Li,[4,2] En yin Lai,[3,2] Glenn Solis,[1] Anton Wellstein,[2] William J. Welch.[2] *[1]Georgetown University Medical Center, Washington, DC; [2]Georgetown University, Washington, DC; [3]Zhejiang University School of Medicine, Hangzhou, China; [4]NIH, Clarksburg, MD.*

Background: High salt intake, angiotensin II (Ang II), and reactive oxygen species (ROS) enhance progression of chronic kidney disease (CKD). We reported that myogenic contractions of renal afferent arterioles (RAAs) were enhanced by superoxide generated from $p47^{phox}$/NOX2 but inhibited by H_2O_2 generated from POLDIP2/NOX4. We tested the hypothesis that feeding a high salt diet to mice with the reduced renal mass (RRM) model of CKD generates specific ROS in their RAAs that enhances Ang II contractions.

Methods: C57BL/6 mice received surgical RRM or sham operations and 6% or 0.4% NaCl salt for 3 months. Ang II contractions were measured in RAAs perfused at 45 mmHg and superoxide and H_2O_2 by fluorescence microscopy.

Results: RRM enhanced the gene expression in RAAs for $p47^{phox}$ and NOX2 and high salt intake in mice with RRM enhanced the gene expression for AT1Rs, POLDIP2 and NOX4 and reduced the gene expression for catalase. Mice with RRM fed a normal salt diet had contractions to 10^{-6} M Ang II similar to sham (-56 ± 5 vs -52 ± 5 %; NS). However, RRM mice fed a high salt diet had an enhanced superoxide and H_2O_2 generation ($P<0.005$) with Ang II in RAAs and enhanced Ang II maximal contractions (-72 ± 2 vs -45 ± 2%; $P<0.005$) that were dependent on superoxide from NOX2 since they were prevented in $p47^{phox}$ -/- mice and on H_2O_2 from NOX4 since they were prevented in mice with transgenic smooth muscle cell expression of catalase ($tg^{CAT\text{-}SMC}$), and in POLDIP2 +/- mice. However, RAA contractions to lower concentrations of Ang II (10^{-8} to 10^{-11} M) were paradoxically enhanced in $tg^{CAT\text{-}SMC}$ vs Wt mice (-17 ± 2 vs -1 ± 1%; $P<0.01$) and in POLDIP2 +/- vs +/+ mice (-22 ± 3 vs -5 ± 3; $P<0.01$). Tempol normalized the ROS and Ang II contractions in RAAs from mice with RRM.

Conclusions: Both superoxide from $p47^{phox}$/NOX2 and H_2O_2 from NOX4/POLDIP2 enhance maximal Ang II contractions of RAAs from mice with RRM fed a high salt diet but H_2O_2 from NOX4/POLDIP2 reduces the sensitivity to lower concentrations of Ang II by >100-fold and tempol prevents all of these changes Thus, although a high salt intake reduces circulating Ang II, blockade of angiotensin receptors or ROS may prove beneficial for patients with CKD unable to restrict salt.

SA-PO829

Targeting Pathologic Gβγ-GRK2 Signaling in CKD

Valeriia Rudomanova,[1] Iñigo Valiente-Alandi,[1] Qing Ma,[3] Prasad Devarajan,[3] Burns C. Blaxall.[2] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]Cincinnati Children's Hospital, Cincinnati, OH.*

Background: Chronic kidney disease (CKD) is a progressive deterioration of renal function characterized by replacement of functional renal parenchyma with fibrotic tissue. Our group recently reported the beneficial effects of attenuating Gβγ-G-protein coupled receptor kinase 2 (GRK2) signaling in the ischemia/reperfusion murine model of acute kidney injury (AKI). In this study, we tested the hypothesis that inhibiting Gβγ-GRK2 signaling might bestow a renoprotective effect in animal models of chronic kidney injury.

Methods: Research animals (C57Bl/6 10 week old male mice) were subjected to unilateral ischemia-reperfusion (UIR, 30min) or sham surgery followed by 14 days of reperfusion. The Gβγ-GRK2 small molecule inhibitor, Gallein, or Vehicle (PBS) were given once daily i.p. beginning 7 days after the injury and continued until sacrifice. GRK2 expression was also evaluated in human kidney biopsies and whole murine kidney lysates by RT-qPCR and Western blot.

Results: We first identified a significant elevation of GRK2 mRNA (8 normal vs 10 dialysis, 1.9 fold increase, P=0.01) and protein (9 normal vs 10 dialysis, 20.6 fold increase, P=0.02) expression in biopsies obtained from dialysis patients vs normal human kidney biopsies. In the UIR model of CKD, GRK2 transcript expression positively correlated with Lipocalin 2 (NGAL) transcript, a clinically used renal injury marker (R squared=0.7488, P<0.0001). Small molecule inhibition of Gβγ-GRK2 significantly alleviated renal fibrosis as assessed by Picrosirius red staining (Sham, UIR+Vehicle, UIR+Gallein, n=8 per group, % fibrosis mean 1.422, 10.08, 4.665, respectively, P<0.0001), accompanied by a decline in NGAL gene expression.

Conclusions: Our results identify Gβγ-GRK2 signaling as a potential mediator of renal tubular injury and fibrosis and a promising target in CKD.

Funding: Other NIH Support - NIH 1R01HL133695-01 (BCB)

WNK1 Regulates Skeletal Muscle Hypertrophy by Modulating Phosphorylation, Nuclear Localization, and Transcriptional Activity of FoxO4

Shintaro Mandai,[1,2] Takayasu Mori,[1] Naohiro Nomura,[1] Taisuke Furusho,[1] Yohei Arai,[1] Hiroaki Kikuchi,[1] Emi Sasaki,[1] Eisei Sohara,[1] Tatemitsu Rai,[1] Shinichi Uchida.[1] *[1]Nephrology, Tokyo Medical and Dental University, Tokyo, Japan; [2]Nephrology, Nitobe Memorial Nakano General Hospital, Tokyo, Japan.*

Background: With-no-lysine (K) (WNK) kinases, mutated in the inherited form of hypertension pseudohypoaldosteronism type II, are essential regulators of ion transporters. WNK kinases phosphorylate and activate SLC12A cation-chloride cotransporters via the intermediate kinases SPAK/OSR1. We previously showed that Na^+-K^+-$2Cl^-$ cotransporter 1, a member of SLC12A family, promotes mouse skeletal myogenesis and its inhibitor loop diuretics are associated with risk for sarcopenia in patients with chronic kidney disease (CKD). We further aimed to investigate the physiological role of WNK1 that is the major WNK isoform in mammalian skeletal muscle.

Methods: In C2C12 mouse skeletal muscle cells, differentiation was induced after transfection of *Wnk1*-targeted siRNA, and the diameter of differentiated myotubes was evaluated. In C57BL/6J mice, WNK1 protein abundance was evaluated after six weeks of voluntary wheel running or four weeks of 0.25% adenine-containing diet feeding (CKD model).

Results: In C2C12 cells, silencing of WNK1, but unexpectedly not SPAK/OSR1, induced myotube atrophy and remarkable increases in the mRNA expression of the muscle atrophy ubiquitin ligases MAFbx and MuRF1 called 'atrogenes'. These atrogenes are predominantly upregulated by transcription factors forkhead box protein O (FoxO)1/3/4 in CKD or other diseases causing sarcopenia. WNK1 silencing selectively increased FoxO4 nuclear localization, and co-transfection of *FoxO4*-targeted siRNA completely reversed the myotube atrophy and upregulation of atrogene transcription. Phos-tag SDS-PAGE revealed that WNK1 silencing decreased FoxO4 phosphorylation, which might be associated with nuclear localization and transcriptional activity of this protein. We further showed that WNK1 abundance in mouse skeletal muscle was increased by chronic exercise and decreased in adenine-induced CKD and sarcopenia. Moreover, to validate the role of WNK1 in muscle hypertrophy *in vivo*, a WNK kinase inhibitor WNK463 was administered by oral gavage (10 mg/kg), resulting in marked increase of atrogene expression in mouse skeletal muscle.

Conclusions: WNK1 physiologically regulates mammalian skeletal muscle hypertrophy via interactions with FoxO4. The WNK1-FoxO4 axis may be a novel therapeutic target in sarcopenia.

SA-PO831

Taurine Protects Against Urea-Induced Protein Carbamylation and Renal Fibrosis in an Oxalate Model of Kidney Injury

Mahtab Tavasoli,[1,3] S. Ananth Karumanchi,[1] Zsuzsanna K. Zsengeller,[1] Isaac E. Stillman,[1] Tim Bergmann,[1,2] Sahir Kalim,[4] Anders H. Berg.[1] *[1]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA; [2]Internal Medicine, University Hospital Wuerzburg, Wuerzburg, Germany; [3]Pharmacology, Dalhousie University, Halifax, NS, Canada; [4]Massachusetts General Hospital/ Harvard Medical School, Cambridge, MA.*

Background: It has been long argued that the increased levels of urea in patients with chronic kidney disease (CKD) have negligible toxicity; However, there is growing evidence for the hypothesis that protein carbamylation modifications caused by high urea contributes to disease pathogenesis, vascular complications, uremic cardiomyopathy and mortality. Furthermore, it appears that amino acids can compete with proteins for carbamylation and effectively protect proteins from harmful carbamylation. Here we tested the hypothesis that concentrations of urea associated with chronic renal failure, exacerbate pre-existing renal disease and cardiomyopathy and that dietary taurine supplementation protects against this.

Methods: Mice were fed diets supplemented with sodium oxalate for 3 weeks to induce crystal nephropathy. Mice with mild/moderate oxalate crystal-induced nephropathy were then maintained on western-type diet and 50g/L urea with or without taurine 10g/L (as carbamylation scavenger) in their drinking water for 8 weeks. Control animals were similarly treated with oxalate but only fed western-type diet.

Results: Dietary urea induced hypercarbamylation of proteins in plasma, heart and kidneys in the CKD mice compared to the CKD control animals. Dietary urea exacerbated renal fibrosis and increased ROS levels in renal vessels as well as ANP expression in heart. The carbamylated albumin (C-Alb) and kidney homocitrulline/lysine were strongly correlated with the extent of interstitial fibrosis with a correlation coefficient of 0.84 and 0.86 respectively; (n=12, *P<0.001). Protein carbamylation and its associated pathologies were rescued with taurine supplements (Table below).

Conclusions: Urea-induced protein carbamylation contributes to renal fibrosis in the oxalate model of kidney injury and taurine may mitigate oxalate-induced renal injury, at least in part, by preventing excessive protein carbamylation.

Funding: Other NIH Support - NIH/NHLBI

Treatment Group	C-Alb (mmol/mol)	Heart homocitrulline/lysine (umol/mol)	Kidney homocitrulline/lysine (umol/mol)	Fibrosis Area (%)

The Long Noncoding RNA Meg3 Mediates TLR4–Induced Renal Inflammation in Experimental Obstructive Nephropathy

Wai Han Yiu,[1] Dickson W. Wong,[1] Wing yan Lok,[1] Wing han Liu,[1] Ye Li,[1] Loretta Y.Y. Chan,[1] Joseph C K Leung,[1] Kar Neng Lai,[1] Hui Y. Lan,[2] Sydney C. Tang.[1] *[1]The University of Hong Kong, Hong Kong, China; [2]The Chinese University of Hong Kong, Shatin, China.*

Background: Renal inflammation has been implicated in many types of kidney injury and is a potential therapeutic target for most chronic kidney diseases. Accumulating evidence shows that long noncoding RNAs function as critical regulators of inflammatory responses. This study aims at investigating the role of Toll-like receptor 4 (TLR4)-driven lncRNAs in regulating renal inflammation.

Methods: Tubule-specific TLR4 knockout mice were generated by crossing *TLR4* $^{flox/flox}$ and *Ksp-Cre* mice. Both *Ksp-Cre.TLR4* $^{flox/flox}$ (KO) and *TLR4* $^{flox/flox}$ (WT) mice were subjected to unilateral ureteral obstruction (UUO). Deep RNA sequencing was performed to identify dysregulated lncRNAs that are associated with tubular TLR4 expression. Candidate lncRNA was verified and its functional role in renal inflammation was investigated using cultured murine tubular epithelial cells.

Results: Loss of TLR4 in tubular cells resulted in less renal inflammation as compared to WT mice after 7 days of UUO. Expression of pro-inflammatory cytokines including CCL-2, CXCL-2 and TNF-α was reduced in the obstructed KO kidneys and accompanied by decreased NFκB signaling. Data from deep RNA sequencing showed that lncRNA maternally expressed gene 3 (Meg3) was upregulated in WT mice upon UUO, but its expression was down-regulated in KO mice. *In vitro*, LPS induced Meg3 expression in tubular epithelial cells. Knock down of Meg3 in tubular epithelial cells diminished inflammatory responses, as evidenced by reduced LPS-induced CCL-2 and CXCL-2 expression.

Conclusions: Our findings suggest that tubular TLR4 is important for mediating inflammatory responses in UUO model and lncRNA Meg3 may be a novel regulator in TLR4-driven renal inflammation. **Funding:** Research Grants Council of Hong Kong (Collaborative Research Fund, grant number C7018-16G).

SA-PO833

TSC1 Mediated Metabolic Switch to Glycolysis in Tubular Epithelial Cell Accelerates Renal Interstitial Fibrosis

Hongdi Cao, Lei Jiang, Junwei Yang. *Second Affliliated Hospital, Nanjing Medical University, Nanjing, China.*

Background: Renal interstitial fibrosis is a key factor in the progression of chronic kidney disease (CKD). Energy reprogram to glycolysis is closely related to the development of CKD. As an important negative regulatory factor of mTORC1 signal,tuberous sclerosis complex 1 (Tsc1) is also the key regulatory point of glycolysis. In this study, we investigated whether Tsc1 could mediate the progress of renal interstitial fibrosis by regulating glycolysis in proximal tubular epithelial cells.

Methods: In vitro and in vivo models of renal interstitial fibrosis were established. The changes of Tsc1 in the progress of renal interstitial fibrosis and the relationship of glycolysis and Tsc1 were analyzed. The glycolysis level and degree of fibrosis in kidneys between proximal tubular epithelial cells-Tsc1 specific knockout mice($Tsc1^{ptKO}$ mice) and control mice were compared to explore the role Tsc1 in renal interstitial fibrosis.

Results: In TGF-β1 induced tubular epithelial cell phenotype transformation and UUO models, Tsc1 in tubular epithelial cells was reduced markedly. In $Tsc1^{ptKO}$ mice, mTORC1 signal was activated and showed the significant feature of renal interstitial fibrosis. Mitochondrial damage and enhanced glycolysis were observed in tubular epithelial cell phenotype transformation, UUO mice and $Tsc1^{ptKO}$ mice. Inhibiting glycolysis of proximal tubular cells induced by Tsc1 downregulation with 2-DG, the fibrotic phenotypic changes induced by Tsc1 decline were improved. The renal fibrotic degree was also alleviated by inhibiting the glycolysis of $Tsc1^{ptKO}$ mice with 2-DG.

Conclusions: Tsc1 could mediate the progress of renal interstitial fibrosis by regulating glycolysis in proximal tubular epithelial cells. It might be helpful to provide theoretical basis for design of new therapeutic strategies of CKD.

Knockdown of Cxcl10 Alleviates Renal Fibrosis in UUO Mice

Jie Gao, Lingling Wu, Xiangmei Chen. *Nephrology, State Key Laboratory of Kidney Diseas, Chinease PLA Institute of Nephrology & Key Lab, Chinese PLA Hospital, Beijing, China.*

Background: Renal fibrosis is a common pathological manifestation of almost all renal diseases, including chronic kidney disease (CKD) and acute kidney injury (AKI), which can eventually lead to end-stage renal disease (ESRD). IFN-γ-inducible protein 10 (IP-10, CXCL10) has been widely demonstrated to be involved in chemotaxis, regulation of cell growth and angiogenesis inhibition. It has been reported that CXCL10 is involved in the pathogenesis of fibrosis in a variety of human tissues. However, the underlying mechanism of CXCL10 in renal fibrosis reminds unclear.

Methods: Wildtype ($CXCL10^{+/+}$) mice and CXCL10-deficient ($CXCL10^{-/-}$) mice were used to generate the unilateral ureteral obstruction (UUO) model and sacrificed at 3, 5, 7 and 14 days after surgery. The histological changes and collagen deposition levels in kidney tissue was examined by PAS, Masson and Sirius red staining. The expression of fibrosis related proteins were examined by Western blot. The macrophage infiltration was examined by immunofluorescence of F4/80. Furthermore, the effects of CXCL10 on transforming growth factor β1 (TGF-β1)-stimulated rat renal fibroblasts was investigated in vitro.

Results: A marked increase expression of Cxcl10 mRNA and protein were observed in whole kidney tissue in UUO model. The levels of serum creatinine and urea nitrogen were significantly lower in $Cxcl10^{-/-}$ mice than in $Cxcl10^{+/+}$ mice. Pathological staining results showed that the injury degree of renal tissue and the collagen deposition levels were lighter in $Cxcl10^{-/-}$ mice. Western blot results showed that the expression of α-SMA, FN and Col1 in $Cxcl10^{-/-}$ mice was significantly reduced compared with $Cxcl10^{+/+}$ mice. However, Interstitial F4/80-positive macrophages were unaffected by knockdown of Cxcl10. Furthermore, recombinant CXCL10 protein stimulation could obviously promote the expression of α-SMA, FN and collagen I in TGF-β1-treated NRK-49F cells.

Conclusions: Cxcl10 knockout could reduce renal injury, mitigate the deposition of collagen and inhibit renal fibrosis through promoting renal fibroblast activation in murine UUO model. These results may provide a novel insight into the mechanism and a potential therapy target of renal fibrosis.

NF-κB Inhibition During Short-Term LNAME and Salt Overload Strongly Attenuates the Late Development of CKD

Karin C. Oliveira, Fernanda F. Zambom, Amanda H. Albino, Victor F. Avila, Simone C. Arias, Denise M. Malheiros, Niels O. Camara, Clarice K. Fujihara, Roberto Zatz. *University of Sao Paulo, Sao Paulo, Brazil.*

Background: Brief NO inhibition by LNAME + high-salt diet (HS) results in marked hypertension (HT) and renal injury that abate upon treatment interruption but evolve to CKD along ensuing months. Activation of the NLRP3 and NF-κB pathways may participate in this process. Here we investigated whether NF-κB inhibition during LNAME+HS would prevent the acute and/or chronic effects of this treatment.

Methods: Male Munich-Wistar rats (N=11) received oral LNAME+HS. A second group (N=12) received in addition the NF-κB inhibitor pyrrolidine dithiocarbamate (PDTC), 60 mg/kg/day vo. Control rats (C) received HS only (N=10). All treatments were ceased at 4 wks. Assessed at 4, 8 and 24 wks were: tail-cuff pressure (TCP, mmHg), albuminuria (ALB, mg/d), glomerulosclerosis (GS, %), interstitial collagen-1 (COLL, %), infiltration (cells/mm²) by macrophages (MΦ), lymphocytes (Ly), angiotensin 2+ (Ang2+) and NLRP3+ cells, and the renal abundance (x HS) of IL1β (pg/mg), nuclear p65 (NFκB), Casp1, TLR4, and IL-6.

Results: At 4 wks, HS+LNAME caused severe hypertension, ALB, GS, COLL, MΦ/Ly/Ang2+-cell infiltration and activation of the TLR4/NFκB/IL6 and NLRP3/Casp1/IL1β pathways, all of which were prevented or strongly attenuated by PDTC. Partial regression at 8wks was followed by progression to CKD at 28 wks, also largely prevented by early PDTC.

Conclusions: Early NF-κB activation is essential for subsequent autonomous activation of innate immunity and progression to CKD in this model, and may be the basis for future therapeutic strategies. FAPESP/CNPq

UCP2-Regulated HIF-1α Stabilization Promotes Reprogramming of Mitochondrial Metabolism and Induces Tubulointerstitial Fibrosis After Ischemic AKI

Yang Zhou,[1] Nan Qin,[2] Junwei Yang.[1] *[1]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China; [2]Nanjing Medical University, Nanjing, China.*

Background: Acute kidney injury (AKI) is a global public health concern associated with hospitalizations and is especially common in critically ill patients. The transition of AKI to consequence chronic kidney disease (CKD) has major clinical significance. Tubular reabsorption is an energy consumption process relies mainly on mitochondrial metabolism, which is regulated by uncoupling protein 2 (UCP2). Whether UCP2 contributes to the progression of AKI-to-CKD is unknown.

Methods: We generated proximal tubular cells specific UCP2 knockout mice. AKI-to-CKD model was induced using ischemia-reperfusion injury (I/R). Mice kidney tissues were harvested six weeks after I/R. Alternations of mitochondrial morphology, metabolic products and critical enzymes that govern fatty acid oxidation and glycolysis were examined. Pimonidazole was used to evaluate hypoxia in kidney tissue.

Results: In I/R-induced AKI-to-CKD model, expression of UCP2 was markedly increased in fibrosis kidneys. Impairment of renal function and remarkable accumulation of extracellular matrix in the tubulointerstitial spaces were quite evident six weeks after I/R injury. Mitochondria reduction and swellings, as well as lipid droplets deposition suggested metabolic abnormalities of fatty acid. However, increased glycolytic enzyme expression and inhibitory phosphorylation of pyruvate dehydrogenase were exhibited indicating a switch to glycolysis. *Ucp2*-deficient mice suffered I/R injury experienced less tubulointerstitial fibrosis and metabolic disorders. Furthermore, tissue hypoxia was observed in I/R-induced fibrotic kidney and renal expression of hypoxia-inducible factor 1α (HIF-1α) was increased suggested hypoxia-induced stabilization of HIF-1α in fibrosis kidney. Nevertheless, knockout of UCP2 relieves the tissue hypoxia and reduces the stabilization of HIF-1α in the kidney.

Conclusions: UCP2 regulates tissue hypoxia-induced stabilization of HIF-1a, which promotes the reprogramming of mitochondrial metabolism from fatty acid oxidation to glycolysis and contribute to pathogenesis of AKI-to-CKD. UCP2 may provide a novel therapeutic target for prevention of chronic fibrosis caused by AKI.

Mitochondrial Dysfunction in FOXD1 Lineage Cells Is Associated with Renal Fibrogenesis and Anemia

Hanako Kobayashi, Ken Ishii, Volker H. Haase. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Mitochondria play an important role in the pathophysiology of chronic kidney diseases (CKD), as mitochondrial uncoupling and dysfunction changes cellular metabolism impacting CKD pathogenesis and its progression. It is well established that renal function impairment correlates with the degree of tubulointerstitial fibrosis. Furthermore, fate-mapping studies have previously shown that the majority of collagen-producing renal myofibroblasts are derived from perivascular interstitial cells and pericytes. Despite the importance of these findings for renal fibrogenesis, the role of mitochondria and oxidative phosphorylation in renal interstitial cell function and myofibroblast transdifferentiation is only poorly understood.

Methods: To investigate mitochondrial function and the role of oxidative phosphorylation in renal interstitial cells, we have generated and analyzed mice with interstitial cell-specific inactivation of mitochondrial transcription factor A (TFAM) using *FoxD1-cre* transgenics. TFAM is required for mitochondrial gene transcription and DNA replication and thus essential for the maintenance of mitochondrial function and mass.

Results: We demonstrate that suppression of mitochondrial function in interstitial cells has a pivotal role in the pathogenesis of CKD, as inactivation of stromal TFAM resulted in progressive renal failure (BUN at 6-weeks of age: 76.0 ± 1.5 mg/dl vs. 27.8 ± 0.9 mg/dl in control; p<0.0001, n=4 each), which was associated with an increased number of α-SMA-expressing cells, the development of tubulointerstitial fibrosis and proteinuria at older age. Furthermore, interstitial cell-specific TFAM knockout mice developed anemia (Hct: 42.8 ± 1.5 % in control vs. 36.2 ± 1.0 % in mutants; p= 0.006, n=5 each) and were characterized by a reduction in their capacity to produce erythropoietin in response to hypoxic stimuli, a major pathologic feature of CKD.

Conclusions: Our data demonstrate that mitochondria play an important role in the maintenance of normal renal interstitial cell homeostasis and hypoxia responses. A detailed metabolic characterization of interstitial cell-specific TFAM knockout mice will be presented at the meeting.

Dyslipidemia in Nephrotic Rats Associates with Increased Hepatic PCSK9 – Heparan Sulfate Interaction

Pragyi Shrestha,[1,2] Bart Van de sluis,[4] Jacob van den Born.[3] *[1]University of Groningen, Groningen, Netherlands; [2]Department of Nephrology, University Medical Center Groningen, Groningen, Netherlands; [3]Univ. Med. Center Groningen, Groningen, Netherlands; [4]UMC Groningen, Groningen, Netherlands.*

Background: Dyslipidemia characterized by higher levels of plasma lipids (triglyceride and cholesterol) increases the risk for cardiovascular disease in patients with Chronic Kidney Diseases (CKD). Here, our aim is to investigate the role of the LDL receptor (LDLR), heparan sulfate (HS) side chains of syndecan-1 and Proprotein convertase subtilisin/kexin type 9 (PCSK9) in CKD-related dyslipidemia using a dyslipidemic proteinuric rat model.

Methods: Eight male Wistar rats received 1.8 mg adriamycin/kg BW i.v. to induce proteinuria (ADR). Six control rats were injected with saline. Kidney function, proteinuria, and serum lipids were monitored weekly. Animals were sacrificed after 12 weeks. Tissues and plasma were collected. Expression of LDLR, syndecan-1, HS and PCSK9 were evaluated in the liver by immunofluorescence staining (IF), western blotting (WB) and qRT-PCR. Plasma PCSK9 was measured by ELISA. Mann Whitney test and Spearman Rank correlation were used for statistics.

Results: ADR showed increased proteinuria and serum lipids (all $p<0.001$) compared to controls without differences in protein and mRNA expression of LDLR. Interestingly, the localization of PCSK9 to the liver sinusoids was however significantly increased in ADR compared to controls ($p<0.001$, IF), without changes in gene expression. Serum triglyceride and cholesterol correlated with serum PCSK9 ($r=0.59$, $p=0.0035$; $r=0.71$, $p=0.006$) and with liver PCSK9 ($r=0.83$, $p=0.0004$; $r=0.80$, $p=0.001$ respectively). Moreover, PCSK9 protein was found to interact strongly with HS, and interaction was highly dependent on HS sulfation and chain length. Disaccharide profiling of HS revealed a remarkable increase in 6-O-sulfation of liver HS, which could be due to lower hepatic Sulf2 mRNA expression ($p=0.06$). Inverse association was found between serum triglyceride and cholesterol with Sulf2 mRNA levels ($r=-0.67$, $p=0.01$; $r=-0.64$, $p=0.02$).

Conclusions: Dyslipidemia in nephrotic rats is related to increased interaction of PCSK9 with hepatic syndecan-1/HS, which might hamper TRL clearance capacity.

The Role of CPT1α on Fatty Acid Metabolism and Development of Renal Fibrosis

Qi Yuan,[2] Yang Zhou,[1] Hao Ding,[1] Yi Fang,[1] Junwei Yang.[1] *[1]Second Affiliated Hospital, Nanjing Medical University, Nanjing, China; [2]Nanjing Medical University, Jiangsu Nanjing, China.*

Background: Renal fibrosis is the common pathologic feature of chronic kidney disease (CKD). Proximal tubular epithelial cells (PTCs) prefer fatty acid as their energy source. Defective fatty acid oxidation plays a key role in kidney fibrosis development. CPT1α is the rate limiting enzyme that transport fatty acid into mitochondria. Moreover, CPT1α has a lysine succinyltransferase activity. In this study, we investigated the role of CPT1α in modulation of cellular fatty acid homeostasis in tubular epithelial cells during renal fibrosis.

Methods: Renal fibrosis was induced by folic acid (FA) injection. Relationship between renal fibrosis and expression of CPT1α was examined using renal biopsy samples from 30 patients and kidneys from FA mice. Mice with PTCs' specific ablation of CPT1α (KO) were generated and pharmacologic and genetic upregulation of CPT1α were used to investigate the role of CPT1α on renal fibrosis.

Results: Expression of CPT1α in proximal tubular epithelial cells was negatively correlated with the area of renal fibrosis in both human samples and FA model. Tubular $CPT1\alpha^{KO}$ mice experienced severe renal fibrosis and increased expressions of fibrotic markers, such as collagen I, fibronectin and vimentin than wild-type mice. While upregulation of CPT1α by administration of fenofibrate or transfection of CPT1α plasmid attenuated the accumulation of extracellular matrix and renal fibrosis in mice kidney. Moreover, upregulation of CPT1α increased the key enzymes of fatty acid metabolism, including ACAD, FASN, GPAT and GPD1. The decreased succinylation of the enzymes and regulators of fatty acid metabolism in fibrosis kidney were relieved by fenofibrate treatment.

Conclusions: These results demonstrate that CPT1α plays a major role in fatty acid metabolism disturbance in the tubular epithelial cells and contributes to renal fibrosis. Restoring the lysine succinyltransferase activity of CPT1α may provide novel therapeutic approach for kidney fibrosis.

Sodium Butyrate Alleviates Renal Failure (RF) in Animals by Mitigating Inflammation and Fibrosis

Austin J. Gonzalez,[1] Siddhartha S. Ghosh,[2] Richard Krieg,[3] Todd W. Gehr.[1] *[1]Virginia Commonwealth University, Fredericksburg, VA; [2]VCU Medical Ctr, Richmond, VA; [3]VCU, Richmond, VA.*

Background: Renal failure (RF) is largely associated with inflammation and damage of kidney tissue. NFkB is a well-known marker for inflammation and for the regulation of fibrosis. Phosphorylated NFkB (pNFkB) is translocated into the nucleus and promotes transcription of various genes which play a role in inflammation and fibrosis. Treatment with sodium butyrate, a short-chain fatty acid (SCFA) and histone deacetylase (HDAC) inhibitor, has been shown to have anti-inflammatory effects in RF. We demonstrate that sodium-butyrate treatment can ameliorate RF at both the biochemical and histopathological level.

Methods: Five-sixth nephrectomized Sprague-Dawley rats were used as a model for RF. Animals were divided into three groups: Sham-operated control (SH), untreated nephrectomy (Nx), and nephrectomy with butyrate treatment (Nx+BU) 100 mg/kg/day sodium butyrate in drinking water. Kidney tissue cytosolic NFkB and nuclear pNFkB were measured by Western Blot analysis. Histological analysis was performed on the kidney tissues with both Periodic Acid-Schiff stain and Picro-Sirius Red stain to measure the extent of collagen networks in fibrosis. Renal biomarkers were measured by chemical assay.

Results: There was 3.5 fold increased translocation of pNFkB in the nucleus of Nx rats, which was significantly lowered in the Nx+BU group. There was no difference in cytosolic NFkB. Kidney tissue of the Nx animals had 35±4.4% segmental sclerosis, whereas Nx+BU animals had reduced to 24±5.6% ($p=0.003$). In Nx, 26% of the area was positively stained with sirius red compared to 1.7% in SH ($p<0.0001$), but was reduced by 50% in Nx+BU ($p<0.01$). The serum urea, urinary protein/creatinine ratio, and serum creatinine of Nx rats were significantly higher (3.6, 3, and 3.2-fold respectively) than SH. Nx+BU had significantly improved proteinuria and serum urea levels. Serum creatinine levels were reduced by 22% in Nx+BU ($p=0.05$).

Conclusions: Treatment with sodium butyrate has been shown to have beneficial effects on the translocation of NFkB, subsequent histological data on kidney fibrosis, and renal function in RF. Sodium butyrate, among other systemic and gut-related benefits, acts as an HDAC inhibitor and provides a possible mechanism for anti-inflammatory action in RF.

SA-PO841

Self-Assembled Polypeptide Gold Nanoparticles Selectively Target the Kidney for High-Efficiency Anti-Fibrosis Treatment

Lishan Tan,[1] Xuandi Lai,[2] Jianqiang Hu,[2] Aiqing Li.[1] *[1]Nanfang Hospital, Southern Medical University, Guangzhou, China; [2]Department of Chemistry, School of Chemistry and Chemical Engineering, South China University of Technology, Guangzhou, Guangzhou, China.*

Background: Many preclinical agents (e.g., cobalt chloride) have attracted great attentions because they can ameliorate chronic kidney fibrosis. However, many of these drugs are lack of kidney targeting ability or/and exhibit biological toxicity, which limits their clinical applications. Here we produced glutathione- and lipoic acid-modified Au nanoassemblies (GLAuNPs-Co) with good biocompatibility, high renal targeting capability and excellent anti-fibrosis efficacy through a Co^{2+}-induced coordination self-assembled strategy.

Methods: The LAuNPs and GLAuNPs were investigated using transmission electron microscopy (TEM), dynamic light scattering (DLS), fourier transform infrared (FTIR) spectra and thermogravimetric analysis (TGA). In vitro, Cell Counting Kit-8 (CCK-8) and Elisa Kits were used to evaluate the biocompatibility of GLAuNPs. Celluar uptake mechanism was explored by fluorescence microscopy and inductively coupled plasma-mass spectrometry (ICP-MS). Organs' distribution was examined using in- and ex-vivo fluorescence imaging software. The loading and release efficiency was evaluated by ICP-MS. The anti-fibrosis efficacy and mechanism were tested by pathological staining, western blot and real-time PCR in vivo using unilateral ureteral obstruction (UUO) mice.

Results: In aqueous solution, GLAuNPs-Co could self-assemble at neutral pH, and disassemble and release Co^{2+} when pH stwich to acid. Cytotoxicity and immunotoxicity assays and in vivo fluorescence imaging revealed that GLAuNPs had excellent biocompatibility, non-immunotoxicity and kidney-targeting ability. Pathological staining, western blot and real-time PCR analyses showed that GLAuNPs-Co had more excellent anti-fibrosis, anti-inflammatory, anti-oxidative stress, and anti-apoptosis efficacy than that of free $CoCl_2$ in UUO nephropathy mice.

Conclusions: With attractive characteristics of specific renal-targeting, controllable drug-release, non-toxicity and outstanding fibrosis therapeutic efficacy, the GLAuNPs-Co is hopeful to become a promising drug against renal fibrosis in clinic in the near future, which represents an innovative avenue of designing and developing therapy system for kidney diseases.

Association Between Urine Output, Furosemide Stress Test, and Fibrosis in Kidney Biopsies

Jesus Arturo R. Martinez,[2] Lakhmir S. Chawla,[1] Ravindra L. Mehta,[1] Sucheta M. Vaingankar,[1] Francisco Rodríguez,[2] Virgilia Soto,[2] María F. Camacho briseño,[4] Ricardo Duarte,[3] Alejandro Cabrera-Jara,[4] Carlos A. Garza-Garcia,[5] Magdalena Madero.[2] *[1]University of California, San Diego, San Diego, CA; [2]Instituto Nacional de Cardiologia Ignacio Chavez, Tlalpan, Mexico; [3]Public, MEXICO CITY, Mexico; [4]UNAM, Ciudad de México, Mexico; [5]Private Practice, Monterrey, Mexico.*

Background: Interstitial fibrosis (IF) is one of the most potent risk factors for kidney disease progression. The Furosemide Stress Test (FST) is a validated tool that predicts the severity of acute kidney injury in critically ill patients. To our knowledge there is no data on the association between the functional tubular capacity by urine output (UO) and FST with IF on kidney biopsies. The aim of this study was to determine the correlation between UO, FST and the severity of IF in kidney biopsies

Methods: 84 patients that underwent kidney biopsy were included. Furosemde was administred at 1 mg/kg and UO was measured every h for 6 after confirmation of empty

bladder by US. Serum biochemical markers were measured and urine concentrations of furosemide at different times (2, 4 and 6 hours). IF was evaluated by subjective visualization by an experienced nephropathologist in addition to morphometry. We used the FEM equation to determine the Mass of Excretion of Furosemide (FEM: Furosemide Urine x Volume urinary)/furosemide administered dose). Values were expressed as mean, SD or % and Pearson Correlation

Results: Nephrotic syndrome and acute kidney graft dysfunction were the most frequent indications for biopsy. eGFR was inversely proportional to the degree of fibrosis. Subjects with grade 3 IF showed a significant decrease in urine volume at hour 1 when compared with grades I and II (155 mL ± 181 vs 316 mL ± 261 vs 328 mL ± 352 p=0.015 respectively). Likewise, the total urine volume and the excreted mass of Furosemide was progressively lower with higher degrees of IF, at 2 and 4 hours. An inversely proportional linear correlation between uresis and the degree of IF ($R^2$0.072) was observed

Conclusions: Our findings support that IF correlates with total UO and FEM. Both urine output and FST acould be a non invasive tool to predict IF.

Long-Noncoding RNA Atrolnc-1 Promotes Muscle Wasting in Mice with CKD

Lijing Sun,[1,2] Zhaoyong Hu,[2] William E. Mitch.[2] *[1]Xinhua Hospital Affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China; [2]Baylor College of Medicine, Houston, TX.*

Background: Chronic kidney disease (CKD) is commonly associated with cachexia, a condition that causes skeletal muscle wasting and an unfavorable prognosis. Although mechanisms leading to cachexia have been intensively studied, the advance of biological knowledges and technologies encourages us to make progress in understanding the pathogenesis of this disorder. Long non-coding RNAs (lncRNAs) are defined as >200 nucleotides RNAs but lack the protein-coding potential. LncRNAs are involved in the pathogenesis of many diseases, but whether they functionally involve in muscle protein loss has not been investigated.

Methods: We performed lncRNA array and identified an lncRNA, which we named Atrolnc-1, remarkably elevated in atrophying muscles from mice with cachexia. We examined how overexpression or knockdown of Atrolnc-1 could influence muscle protein synthesis and degradation. We also examined whether inhibition of Atrolnc-1 ameliorates muscle wasting in mice with CKD.

Results: We documented that Atrolnc-1 expression is continuously increased in muscles of mice with fasting, cancer or CKD. We found that depressed insulin signaling stimulates the transcription factor, C/EBP-α binding to the promoter of Atrolnc-1 and promotes the expression of Atrolnc-1. In cultured C2C12 myotubes, overexpression of Atrolnc-1 increases protein degradation; Atrolnc-1 knockdown significantly reduces the rate of protein degradation stimulated by serum depletion. Using mass spectrometry and a lncRNA pull-down assay, we identified that Atrolnc-1 interacts with A20 binding inhibitor of NF-κB-1(ABIN-1). The interaction impairs function, resulting in enhanced NF-κB activity plus MuRF-1 transcription. This response is counteracted by CRISPR/dCas9 mediated overexpression. In muscles from normal mice, overexpression of Atrolnc-1 stimulates MuRF-1 expression leading to myofibers atrophy. In contrast, Atrolnc-1 knockdown attenuates muscle wasting in mice with CKD via suppression of NF-κB activity and MuRF-1 expression.

Conclusions: Our findings provide evidence that lncRNAs initiates the pathophysiological process of muscle wasting. The interaction between Atrolnc-1 and NF-κB signaling modulates muscle mass and proteolysis in CKD and perhaps other catabolic conditions.

SA-PO844

Omega-3 Fatty Acid Modulates Molecules Associated with Sarcopenia in Muscle of 5/6 Nephrectomy Rats

Young ki Son,[1] Su mi Lee,[1] Seong Eun Kim,[2] Won Suk An.[1] *[1]Dong-A University, Busan, Republic of Korea; [2]Dong-A University Hospital, Busan, Republic of Korea.*

Background: Sarcopenia is common in dialysis patients and result in frail status. Myostatin, a member of TGF-β superfamily, inhibits myocyte differentiation and is increased in patients with chronic kidney disease. Myogenin is also important mediator for myogensis. Recent report showed that omega-3 fatty acid (FA) supplementation improved muscle volume in elderly. The present study aimed to investigate whether omega-3 FA effect on myostatin and myogenin related with sarcopenia in 5/6 subtotal nephrectomy (Nx) rats.

Methods: Male Sprague Dawley rats were divided into three groups and treated for 6 weeks: sham control (0.9% saline), 5/6 Nx control (0.9% saline) and 5/6 Nx treated with omega-3 FA (300 mg/kg/day by gastric gavage). The expression of muscular myostatin, myogenin, MyoD, Akt, phosphorylated(p) Akt, PI3K, p-PI3k, AMPK, p-AMPK, smad2/3/4, NF-κB, IL-6, mTOR, FoxO, MuRF1, MAFbx and USP14 were examined by western blot analysis. H & E staining of gastrocnemius muscle was performed.

Results: BUN and serum creatinine levels were significantly increased in 5/6 Nx groups compared to sham control and were not significantly different between 5/6 Nx group treated with omega-3 FA and 5/6 Nx control group. Compared with sham control, 5/6 Nx control significantly up-regulated myostatin and down-regulated myogenin and MyoD in skeletal muscle. Increased expression of myostatin and decreased expression of myogenin were significantly recovered by omega-3 FA supplementation. However, MyoD expression was not changed by omega-3 FA supplementation. The expression of p-Akt and mTOR was down-regulated in skeletal muscle of 5/6 Nx control compared to sham control and was recovered by omega-3 FA supplementation. The expression of smad2/3/4, NF-κB, IL-6, FoxO, MuRF1, MAFbx and USP14 was significantly up-regulated in skeletal muscle of 5/6 Nx control compared to sham control but were not changed by omega-3 FA supplementation. The thickness of myofiber was decreased in 5/6 Nx control compared to sham control and was recovered by omega-3 FA supplementation.

Conclusions: Omega-3 FA may prevent sarcopenia mainly by decreasing myostatin, increasing myogenin expression and partly affecting Akt-mTOR axis in skeletal muscle of 5/6 Nx rats.

SA-PO845

AMPK Deficiency Worsens Albuminuria Post Uninephrectomy (UNX)

Daniel Rivera,[1] Roshan Rajani,[1] Valeria Mancino,[2] Parisa Rezapoor,[1] Hamidreza Zohoorkari,[1] Biagio Saitta,[1] Pei-Yin Ho,[1] Hui Li,[1] Kenneth R. Hallows,[1] Nuria M. Pastor-Soler.[1] *[1]Keck School of Medicine of USC, Los Angeles, CA; [2]University of Southern California, Los Angeles, CA.*

Background: Living donor (LD) kidney transplant offers the best prognosis for end-stage kidney disease patients. LDs have excellent outcomes, yet recent studies show that in the first year post-UNX there is an increased risk of hypertension that also drives microalbuminuria, a marker of kidney injury. Although hypertrophy contributes to a new steady-state in kidney function, it is unclear whether compensatory changes are beneficial long term for the LD. In several chronic kidney disease (CKD) models activity of the metabolic sensor AMP-activated kinase (AMPK) decreases compared to healthy kidneys. We hypothesize that low AMPK activity pre-UNX could worsen CKD post-UNX when combined with a high-Na+ diet. Our work aims to inform mechanisms that could lead to protective interventions for LDs with approved AMPK activators.

Methods: We used adult female mice with double-floxed AMPK alpha subunits (AMPKfl) and ± tamoxifen-driven(Tam) expression of CAG-Cre recombinase (Cre+ vs. Cre-AMPKfl). All mice underwent UNX 5 wks post-Tam and were placed on a high-Na+ (HNa) diet at that time (intervention). We measured GFR, urine albumin and plasma electrolytes at different time points. Explanted Kidneys (EK) were examined by immunoblot and qPCR.

Results: EK from Cre+AMPKfl have significant (>75%) AMPK knockdown (KD) compared to Cre-AMPKfl mice after Tam. No changes in kidney injury marker-1 gene expression were found in EK between the two groups. However, AMPK-KD (Cre+ mice) had a significant increase in albuminuria (overnight: 22.1±4 vs. 9.2±2 mg, Cre+ vs. Cre-, P<0.03) and anemia. UNX+HNa significantly increased albuminuria in Cre-AMPK (9.2 pre vs. 27.7 post, P<0.02), while in the AMPK-KD group this difference was more pronounced (22.1 pre vs 65.5 post, P<0.01). At two weeks after UNX+HNa there was a statistically significant increase in GFR and metabolic acidosis in both groups compared to pre-intervention. However, at that time there was no difference in GFR between Cre+ and Cre-AMPK mice.

Conclusions: Although female rodents have less severe kidney injury post-UNX than males, our studies show that AMPK KD in female mice worsens kidney injury (albuminuria) in a model of kidney donation and HNa diet. These findings implicate AMPK as an important target for potential pharmacologic interventions to prevent CKD in LDs.

Transcriptomic Profiling of Mitochondrial Dysfunction in Uremic Cardiomyopathy

Kenneth Lim,[2] Frank Xu,[1] Arvin Halim,[1] Li-lun Ho,[6] Sahir Kalim,[3] Elizabeth D. Ankers,[2] Thomas F. Hiemstra,[5] Ravi I. Thadhani,[4] Tzongshi Lu.[1] *[1]Renal, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Massachusetts General Hospital/ Harvard Medical School, Cambridge, MA; [4]Cedars-Sinai, Los Angeles, CA; [5]University of Cambridge, Cambridge, United Kingdom; [6]Massachusetts Institute of Technology, Cambridge, MA.*

Background: Uremic cardiomyopathy is a life-limiting condition that occurs in chronic kidney disease (CKD). Emerging evidence suggests that mitochondrial dysfunction may be a cardinal event that occurs in the failing myocardium under uremic conditions. We previously reported mitochondrial structural deformity and reduction in its respiratory chain enzyme activity in septic rat hearts. These changes were mitigated by upregulation of the inducible molecular chaperone, Heat Shock Protein (HSP) 70. Whether HSP70 may induce cytoprotective effects in uremic cardiomyopathy is currently unknown. The goal of this study was to investigate mitochondrial changes and their association with the HSP70 system in uremic cardiomyopathy.

Methods: Human left ventricular tissues collected from CKD (n=23), CAD (n=11) and healthy donors (n=20) were subjected to RNA sequencing, *ex vivo*. We developed a digital cell sorting study model using deconvolution to enhance interpretation of heterogenous transcriptomic profiles inherent of mixed-cell type tissue. Primary human cardiomyocytes and cardiac-myofibroblasts were treated with calcification medium (CM) in time-course experiments (0-48 hours), *in vitro*.

Results: Cytoprotective mtHSP (HSPA9) and the HSP70 co-chaperone, Bcl2 associated Athanogene 1 (BAG1) were highly expressed in healthy control hearts compared to CKD and CAD. However, mitochondrial fusion regulation genes MFN1 and OPA1 were down-regulated in CKD hearts, together with down-regulation of downstream anti-apoptotic gene Bcl2 and up-regulation of pro-apoptotic genes cytochrome c, caspase 3, BAX and P53. The same pattern of changes were observed in cardiomyocytes and cardio-myofibroblasts treated with CM, *in vitro*. BAG1 was significantly increased at 6 hours prior to upregulation of Bcl2 at 12 hours after treatment. Furthermore, stress respondent genes, HSPA5 and DNAJB6 (HSP40) was significantly increased at 12 hours and 24 hours respectively in CM-treated primary cells.

Conclusions: The present study is the first to describe complex differential genomic changes involved in uremic cardiomyopathy. Mitochondrial dysfunction was associated with upregulation of apoptotic genes and reduced expression of cytoprotective HSP70 components. We postulate that induction of the HSP70 system may be a therapeutic target in uremic cardiomyopathy.

Tolvaptan Activates Nrf2/HO-1 Pathway Through PERK Phosphorylation

Tamami Fujiki, Fumiaki Ando, Kiyoshi Isobe, Takayasu Mori, Koichiro Susa, Naohiro Nomura, Eisei Sohara, Tatemitsu Rai, Shinichi Uchida. *Tokyo Medical and Dental University, Bunkyo-Ku, Japan*.

Background: Tolvaptan slows the increase in total kidney volume (TKV) and the decline in kidney function in Autosomal Dominant Polycystic Kidney Disease (ADPKD). In addition, vasopressin type2 receptor (V2R) antagonists improve renal function in various rodent models of chronic kidney disease (CKD). However, the mechanism of tolvaptan improving renal function remains totally unclear. It has been reported that oxidative stress is associated with CKD progression, and the antioxidant transcription factor, nuclear factor erythroid 2-related factor 2 (Nrf2), is attracting the attention as therapeutic target. In fact, Nrf2 activator, bardoxolone methyl, improves renal function in patients with CKD. In this study, we examined the effects of tolvaptan on Nrf2.

Methods: The effect of tolvaptan was examined by mouse cortical collecting duct (mpkCCD) cells, H9C2 cells, and mice kidneys that endogenously express V2R.

Results: Tolvaptan led to Nrf2 nuclear translocation and induced mRNA and protein expression of heme oxygenase 1 (HO-1) in mpkCCD cells and H9C2 cells. Phosphorylation of unfolded protein kinase RNA-like endoplasmic reticulum(ER) kinase (PERK) by tolvaptan played an important role in activation of Nrf2/HO-1 pathway. Moreover, tolvaptan successfully activated Nrf2/HO-1 pathway in the outer medulla of mice kidneys.

Conclusions: This is the first report describing that tolvaptan activates Nrf2/HO-1 pathway through PERK phosphorylation. Tolvaptan may be a potential therapeutic target of CKD.

Tadalafil Treatment Attenuates Renal Dysfunction in Hypertensive Model Independent of Blood Pressure Lowering

Natsumi Tomita,[1] Yuji Hotta,[1] Aya Naiki-Ito,[2] Tomoya Kataoka,[3] Yasuhiro Maeda,[1] Satoru Takahashi,[2] Kazunori Kimura.[1,3] *[1]Department of Hospital Pharmacy, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; [2]Department of Experimental Pathology and Tumor Biology, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan; [3]Department of Clinical Pharmaceutics, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan.*

Background: Recently, phosphodiesterase 5 inhibitor (PDE5i) reportedly has renoprotective effects, which may be due to blood pressure (BP) lowering by PDE5i. Here, we assessed if the renopretective effect of tadalafil, a PDE5i, depends on its BP lowering using salt-sensitive hypertension rats.

Methods: Dahl salt-sensitive rats were divided into 4 groups (n=5-7): normal salt (NS), high salt (8 % NaCl included in diet; HS), low-dose (1 mg/kg/day, p.o; TL), and high-dose tadalafil treatment (10 mg/kg/day, p.o; TH). SCre, proteinuria, and BP were evaluated at 0 and 8 weeks. PAS staining and αSMA immunohistochemistry were performed. mRNA level of PAI1, which is reported to increase αSMA expression, was evaluated.

Results: In the HS, BP significantly increased at 8 weeks. The TH showed attenuated BP elevation. However, the TL showed BP elevation similar to the HS (Fig.1A). Proteinuria and SCre levels, which markedly increased in the HS at 8 weeks, were suppressed in the TH and TL (Fig.1B,C). PAS staining showed severe glomerulosclerosis in the HS and was prevented in the TH and TL (Fig. 2A). αSMA-positive area significantly increased in the HS and decreased in the TH and TL (Fig. 2B). PAI1 mRNA level was significantly upregurated in the HS. Tadalafil treatment dose-dependantly decreased PAI1 mRNA level.

Conclusions: Tadalafil treatment could prevent decline of the renal function independently of BP lowering. This effect might be associated with suppression of PAI1.

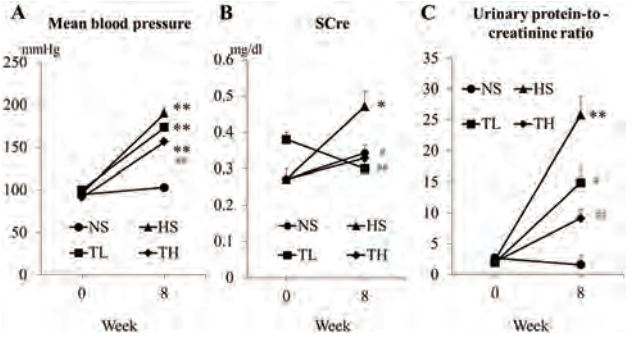

Fig.1 Variations of mean blood pressure (A), SCre (B), and Urinary protein (C) in each groups (n=5-7). *Turkey's* test. *P<0.05,**P<0.01 vs. NS, # P<0.05, ##P<0.01vs. HS.

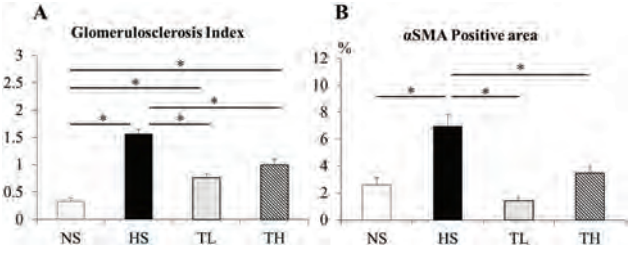

Fig.2 Histopathological assessment; glomerulosclerosis index (A) and αSMA positive area (B). (n=4-6). *Turkey's* test. *P<0.01

SA-PO849

TNF-α Blockade Attenuates Hypertension and Renal Expression of the Epithelial Sodium Channel A-Subunit in the Remnant Kidney CKD Model Using ATRAP Deficient Mice

Ryu Kobayashi,[1] Hiromichi Wakui,[2] Kengo Azushima,[2] Kazushi Uneda,[2] Kohji Ohki,[3] Sho Kinguchi,[2] Takahiro Yamaji,[4] Shingo Urate,[1] Yoshiyuki Toya,[2] Kouichi Tamura.[1] *[1]Yokohama City University Graduate School of Medicine, Kanazawa-Ku, Japan; [2]Yokohama City University, Yokohama, Japan; [3]Yokohama City University School of Medicine, Yokohama, Japan; [4]Yokohama city unversity, Yokohama, Japan.*

Background: We previously identified an angiotensin type 1 receptor (AT1R)-associated protein (ATRAP/Agtrap), which promotes AT1R internalization along with suppression of hyperactivation of tissue AT1R signaling. We hypothesized that dysregulation of renal ATRAP expression and subsequent AT1R hyperactivation plays a critical role in development of hypertension in remnant kidney chronic kidney disease (CKD) model.

Methods: First, we compared changes in endogenous ATRAP expression and blood pressure between 129/Sv and C57BL/6 mice using the remnant kidney model after 5/6

nephrectomy. Second, we examined the effect of ATRAP deficiency in C57BL/6 mice (with a hypertension-resistant strain background) on blood pressure regulation after 5/6 nephrectomy. Third, ATRAP-knockout (KO) mice were treated with the soluble TNF-α receptor, etanercept, or with vehicle after 5/6 nephrectomy.

Results: While 129/Sv mice that underwent 5/6 nephrectomy showed decreased renal ATRAP expression and developed hypertension, C57BL/6 mice exhibited increased renal ATRAP expression and resistance to progressive hypertension. Next, we performed 5/6 nephrectomy in ATRAP-KO mice on the hypertension-resistant C57BL/6 background. ATRAP-KO mice that underwent 5/6 nephrectomy showed hypertension with increased plasma volume. Moreover, in ATRAP-KO mice compared with wild-type C57BL/6 mice after 5/6 nephrectomy, renal expression of the epithelial sodium channel α-subunit (αENaC) and tumor necrosis factor-α (TNF-α) was significantly enhanced, concomitant with increased plasma membrane AT1R in the kidneys. TNF-α inhibition with etanercept significantly suppressed 5/6 nephrectomy-induced blood pressure elevation in ATRAP-KO mice. Furthermore, renal expression of αENaC protein was significantly decreased in ATRAP-KO mice treated with etanercept, compared with vehicle, at 4 weeks after 5/6 nephrectomy.

Conclusions: These results indicate that promotion of primary sodium reabsorption in the renal tubules of the remnant kidney via activation of the AT1R-TNF-α-αENaC axis is a plausible mechanism for the increased circulating plasma volume observed in ATRAP-KO mice after 5/6 nephrectomy.

Functional Characterization of A1CF, a Novel eGFR Locus

Jennie Lin,[1] Philipp Tauber,[4] Yuka Takemon,[4] Jihwan Park,[3] Leslie S. Gewin,[2] Katalin Susztak,[3] Ron Korstanje.[5] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Vanderbilt University, Nashville, TN; [3]University of Pennsylvania, Philadelphia, PA; [4]The Jackson Laboratory, Bar Harbor, ME; [5]The Jackson Laboratory, Bar Harbor, ME.*

Background: A recent human genome-wide association study identified a common 5' UTR variant at the *A1CF* locus associated with eGFR. *A1CF* encodes an RNA binding protein (RBP) previously known to facilitate APOBEC1's editing of *APOB* mRNA in non-renal tissues to produce a shorter isoform. However, A1CF's role in modulating renal function remains unclear.

Methods: Leveraging human and rodent systems, we studied A1CF in a renal context with an integrated approach. We localized *A1CF* expression in human kidney organoids and mouse kidneys and assessed expression in human nephrectomy tissue and mouse models of renal fibrosis. Next we used RIP-seq to identify A1CF's RNA binding targets and their enriched pathways. To determine A1CF's renal effects *in vivo*, we measured markers of renal function and injury at baseline and after induction of stress conditions in *A1cf* knockout mice.

Results: Immunostaining of human kidney organoids and fluorescent RNA labeling of mouse kidneys demonstrate that *A1CF* expression is specific to the proximal tubule. Profiling of human nephrectomy tissue revealed that *A1CF* mRNA expression is decreased in CKD samples compared to healthy control (N=58, P=7.4 x 10^{-4}), correlates positively with eGFR (P= 9.5 x 10^{-5}), and correlates negatively with percent interstitial fibrosis (P=2.0 x 10^{-6}). This decreased expression was recapitulated in mice with folic acid (FA) nephropathy and unilateral ureteral obstruction (UUO) on the mRNA (P=2.7 x 10^{-7}; P=3.4 x 10^{-13}) and protein levels (P=6.4x10^{-4}; P=1.9x10^{-7}). To investigate how A1CF as an RBP might interact with injury pathways, we performed RIP-seq and identified 276 binding targets which were enriched in pathways for endoplasmic reticulum protein trafficking (P=6.6 x 10^{-5}) and peroxisomal function (P=3.6 x 10^{-4}), relevant to intracellular stress when perturbed. Although no baseline abnormalities were detected in *A1cf* ko mice, when subjected to stress of water deprivation or FA treatment we observed an increase in urinary albumin to creatinine ratio (N=16, P=0.03; N=16, P=8.0 x 10^{-3}). Furthermore, after FA treatment, *A1cf* ko mice exhibited higher *Bax/Bcl-2* ratios and higher *Acta2* expression in the kidney (N=7, P=0.01, P=4x10^{-3}).

Conclusions: Taken together, these findings suggest that A1CF plays a previously undiscovered role in modulating the intracellular stress response relevant to CKD.

Identification of β-Mannosidase (Manba) as a Key Gene for CKD

Hongliu Yang,[1,3] Chengxiang Qiu,[2] Jihwan Park,[2] Shizheng Huang,[2] Katalin Susztak.[2] Katalin Susztak Lab *[1]West China Hospital of Sichuan University, Chengdu, China; [2]University of Pennsylvania, Philadelphia, PA; [3]University of Pennsylvania, Philadelphia, PA.*

Background: Chronic kidney disease (CKD) is a complex gene-environmental disease affecting close to 10% of the population worldwide. We integrated the CKD Genome-wide association studies (GWASs) and kidney expression quantitative trait loci (eQTL) analysis results and identified the lysosomal beta-mannosidase (Manba) as a candidate gene for CKD. We found that when compared to reference allele, expression of Manba was much lower in healthy human kidney tissue samples obtained from subjects with risk alleles. We used Manba knockout mouse model to explore the functional significance of lower Manba expression and precise pathomechanism of Manba in CKD.

Methods: Genotype and gene expression data by RNA sequencing for 121 healthy human kidney tissue samples of European descent were obtained and eQTL analysis was conducted. Single cell RNA-sequencing on healthy mouse kidneys was performed to define the expression of Manba. Manba$^{-/-}$ mice and age-matched WT mice were generated for experiment. CKD was studied in aging mice or following folic acid administration. Renal tubule epithelial cells (TECs) from WT and Manba$^{-/-}$ mice were primary cultured and treated with fed (F), starve (S) and starve+cholorquine (S+CQ) for in vitro study.

Results: Single cell RNA-sequencing analysis of healthy mouse kidneys indicated Manba is mainly expressed in proximal tubule (PT) and principal cell (PC) of collecting duct (CD). QPCR and Western blot showed the deletion of Manba and immunohistochemical staining in human kidney and mouse kidney confirmed the location of Manba. In aging mice, Manba$^{-/-}$ mice showed increased number of lysosome and increased number of vacuoles in tubule cells. In kidney fibrosis model, Manba$^{-/-}$ mice demonstrated worsened renal damage after folic acid (FA) injection. In vitro study, Treatment with CQ heightened the amounts of LC3B-II in nutrientdeprived WT TECs, whereas it did not change the already elevated levels of LC3B-II in nutrient-deprived Manba$^{-/-}$ cells.

Conclusions: This is the first study demonstrated the expression of Manba in mouse kidney and found that Manba deficiency induces kidney fibrosis development. Manba deficiency impair autophagy in CKD predominantly from a slower autophagosome clearance.

SA-PO852

LncRNA GAS5 Regulates TGF-β-Induced Renal Fibrosis via Smad3-Dependent Pathway

Yingying Zhang,[1] Chen Yu.[2] *[1]shanghai tongji hospital, Shanghai, China; [2]Shanghai Tongji Hospital, Shanghai, China.*

Background: Increasing evidence shows that long noncoding RNAs (lncRNAs) play an important role in kidney disease. It is well known that some lncRNAs have been reported in renal fibrosis and renal inflammation, such as PVT1 is the first identified lncRNA-associated kidney disease. In our previous study, we found lncRNA- growth arrest-specific 5 (GAS5) was highly decreased in the fibrotic kidney of mouse unilateral ureteral obstructive nephropathy (UUO), however, the underlying mechanism of GAS5 in the pathogenesis of kidney disease remain largely unclear.

Methods: Firstly, we detected GAS5 expression in UUO kidney by using realtime-PCR and in situ hybridization(ISH). Then, we tested whether TGF-β1 had any effect on GAS5 expression in mouse tubule epithelial cell (mTEC), since TGF-β signaling is one of the major mediators of renal fibrosis. Finally, we aimed to investigate the biological role of GAS5 after over-expression or silencing its expression in mTEC.

Results: ISH staining showed that GAS5 was expressed by mTECs, interstitial fibroblasts in normal renal tissue, both in the nucleus and cytoplasm pattern. In vitro, GAS5 was down-regulated by TGF-b1 as dose-dependent. Over-expression of GAS5 blocked TGF-b1-induced collagen I, fibronectin and alpha-smooth muscle actin (a-SMA) expressions, however, silencing GAS5 promoted the expressions of these markers. Mechanistic studies revealed that Smad3, not Smad2, drove the expression of GAS5. TGF-b1 reduced GAS5 expression in both of the Smad3 and Smad2 wild-type MEFs, which was bΔlunted in Smad3 knock-out MEFs but still decreased in Smad2 knock-out MEFs. The addition of SIS3 recovered TGF-b1-induced expression of GAS5 in mTECs. Finally, we also found knockdown of GAS5 promoted TGF-β1-induced G2/M arrest, which might contribute to renal fibrosis via Smad3 pathway.

Conclusions: Taken together, our results have uncovered a GAS5-based mechanism that modulated TGF-β/Smad3 signaling by targeting extracellular matrix formation and cell cycle disruption.

SA-PO853

Newly Designed Recombinant Bone Morphogenetic Protein 7 Is a Potential Therapeutic in Renal Tubulointerstitial Fibrosis

Jimin Park, Sukyung Kang, Boyoung Nam, Arum Choi, Seung Hyeok Han, Tae-Hyun Yoo. *Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Renal tubulointerstitial fibrosis, final common mechanism for all kidney diseases, is characterized by extracellular matrix (ECM) accumulation. In addition, transforming growth factor-β1 (TGF-β1) is known to plays a principal mediator in the accumulation of ECM. Bone morphogenetic protein-7 (BMP-7) is counteract of the profibrogenic role of TGF-β1. Recently, our group designed recombinant BMP-7 linked by protein transduction domain (PTD), which has capability to effectively deliver a large molecule protein in eukaryotic cells. In this study, we investigated the effect of PTD-mediated BMP-7 (tissue-regeneration polypeptide 2, TRP2) on renal tubulointerstitial fibrosis.

Methods: In vitro, inner medullary collecting duct cells (IMCDs) were cultured in DMEM/F12 media (Control) or TGF-β1 (5 ng/ml) with or without TRP2 (10 ng/ml) for 48 hours. *In vivo*, tubule-interstitial fibrosis were established by unilateral ureteral obstruction (UUO) in C57BL/6 mice, and TRP2 (1 μg) were directly injected intraureterally after UUO operation, and were sacrificed after 7 days. The protein expression of fibronectin, type I collagen (ColI), and α-smooth muscle actin (αSMA) were determined in cultured IMCDs and the kidneys by western blot analysis. Masson's trichrome staining and immunohistochemistry were also evaluated in the mouse kidneys.

Results: Xpress, reporter protein of TRP2, was expressed in TRP2-treated IMCDs after 2 hours in dose-dependent manner. Compared to control, the expression of fibronectin, ColI, and αSMA were significantly increased in TGF-β1-stimulated IMCDs. These changes in cultured IMCDs exposed to TGF-β1 were significantly abrogated by TRP2 treatment. A significant increase in ECM proteins expression was also observed in the kidney of UUO mice compared to the control group kidney. These changes were significantly ameliorated in TRP2-treated group.

Conclusions: These results suggest that TRP2 is directly suppressing the process of TGF-β1-induced ECM accumulation *in vitro* and *in vivo*. The effect of TRP2 can be

promising potential therapeutic for prevention of renal tubulointerstitial fibrosis in various kidney diseases.

SA-PO854

The Farnesoid X Receptor (FXR) Agonist EDP-305 Reduces Interstitial Renal Fibrosis in a Mouse Model of Unilateral Ureteral Obstruction

Shen Li,[1] Sarani Ghoshal,[1] Gunisha Arora,[1] Ricard Masia,[1] Mozhdeh Sojoodi,[1] Derek Erstad,[1] Diego Dos santos ferreira,[1] Yang Li,[2] Peter Caravan,[1] Yat sun Or,[2] Li-Juan Jiang,[2] Bryan C. Fuchs.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Enanta Pharmaceuticals, Inc, Watertown, MA.*

Background: Farnesoid X receptor (FXR) is a nuclear receptor that has emerged as a key regulator in the maintenance of bile acid homeostasis. FXR agonists are currently under clinical investigation for the management of various clinical diseases such as primary biliary cholangitis and nonalcoholic steatohepatitis where they have been shown to reduce hepatic steatosis, inflammation, and fibrosis. However, the role of FXR in renal fibrosis remains to be established. Here, we investigate the effects of the FXR agonist EDP-305 in a mouse model of tubulointerstitial fibrosis via unilateral ureteral obstruction (UUO).

Methods: Male C57Bl/6 mice received a UUO on their left kidney. On postoperative day 4, mice received daily treatment by oral gavage with either vehicle control (0.5% methylcellulose) or 10 or 30 mg/kg EDP-305. All animals were sacrificed on postoperative day 12.

Results: EDP-305 dose-dependently decreased macrophage infiltration as measured by the F4/80 staining area with significant differences seen at the higher dose (4.5±0.46 vs. 1.4±0.49, $p<0.01$) which were associated with reduced pro-inflammatory cytokine gene expression (*Il-6* 208.3±59.46 vs. 32.53±3.28, $p<0.01$; *Tnf-α* 34.2±10.35 vs. 13.41±2.81, $p<0.05$). EDP-305 also dose-dependently reduced interstitial fibrosis as assessed by morphometric quantification of the collagen proportional area (CPA) and kidney hydroxyproline (HYP) levels with statistically significant differences observed at the higher dose (CPA 6.73±0.94 vs 2.58±0.39, $p<0.01$; and HYP 1504±140 vs. 1089±54, $p<0.05$). Finally, Yap activation, a major driver of fibrosis, increased after UUO injury and was diminished by EDP-305 treatment. Consistently, EDP-305 decreased TGF-β1-induced YAP nuclear localization in HK2 cells by increasing inhibitory YAP phosphorylation.

Conclusions: Our results suggest that Yap inhibition may be a novel anti-fibrotic mechanism of FXR agonism and that FXR agonists could be used to treat renal fibrosis in patients with chronic kidney disease.

SA-PO855

Targeted Disruption of CD40 in Human Proximal Tubular Epithelial Cells Significantly Reduces Pro-Inflammatory and Pro-Fibrotic Signaling

Shungang Zhang,[1] Terry Hinds,[2] Fatimah K. Khalaf,[1] Apurva Lad,[2] Andrew Kleinhenz,[2] Deepak K. Malhotra,[4] David J. Kennedy,[3] Steven T. Haller.[2] *[1]University of Toledo, Toledo, OH; [2]University of Toledo College of Medicine and Life Sciences, Toledo, OH; [3]The University of Toledo Health Science Campus, Toledo, OH; [4]The University of Toledo, Toledo, OH.*

Background: We have demonstrated that levels of the TNF-α superfamily member CD40 predict progression of renal dysfunction in patients with ischemic and chronic kidney disease, and that CD40's soluble ligand (sCD40L) is significantly elevated in these settings. In the two-kidney one clip (2K1C) model of renal ischemia, CD40 expression is significantly elevated in the ischemic renal proximal tubule epithelium, and CD40 knockout (KO) rats show significantly reduced tubular interstitial fibrosis in the ischemic kidney and improved renal function verses controls. To test the hypothesis that activation of CD40 in the proximal tubule epithelium induces a significant pro-inflammatory and pro-fibrotic response contributing to ischemic renal injury we performed the following study.

Methods: Renal ischemia was induced via 2K1C in both Dahl-S wild type and Dahl-S CD40 KO male rats and kidneys were assessed for evidence of inflammation and fibrosis after 4 weeks. CRISPR/Cas9 was used for the creation of a CD40 KO human proximal tubular cell line (HK2/CD40KO) and confirmed by immunoblotting and gene expression. Parent HK2 cells and HK2/CD40KO cells were treated with sCD40L (100 ng/ml) or TNF-α (10 ng/ml) for 24h.

Results: Renal expression of the pro-fibrotic marker plasminogen activator inhibitor-1 (PAI-1) was elevated in Dahl-S rats after 2K1C renal ischemia and this was significantly attenuated in kidneys from Dahl-S CD40KO animals ($p<0.05$). In HK2 proximal tubular cells, sCD40L induced a significant increase in cytokine gene expression [CXCL2, CXCL5, IL23A, colony stimulating factor-1, and lymphotoxin beta (all > 5 fold increase)] as assessed by quantitative PCR. Importantly, sCD40L treatment also induced a significant increase in monocyte chemoattractant protein-1 (>20 fold increase) and PAI-1 (>2 fold increase) gene compared to TNF-α treatment. The responses to both sCD40L and TNF-α were substantially attenuated in the HK2/CD40KO cells ($p<0.05$).

Conclusions: Activation of CD40 in the proximal tubule epithelium induces a significant pro-inflammatory and pro-fibrotic response, and represents an attractive therapeutic target for treatment of ischemic renal disease.

SA-PO856

CD11c-Specific Ablation of SHP-1 Results in Renal Fibrosis with Age

Mitsuharu Watanabe,[1] Yoriaki Kaneko,[1] Masato Kinoshita,[1] Yuko Ohishi,[1] Toru Sakairi,[1] Hidekazu Ikeuchi,[1] Yoshihisa Nojima,[2] Keiju Hiromura.[1] *[1]Gunma University Graduate School of Medicine, Maebashi, Japan; [2]Japan Red Cross Maebashi Hospital, Maebashi, Japan.*

Background: Renal mononuclear phagocytes (rMoPh) which express traditional macrophage and dendritic cell marker, F4/80 and CD11c respectively, have attracted attention because of their immunoregulatory roles in healthy and diseased kidneys (JASN 23:194, 2012). We have previously generated CD11c-specific SHP-1 conditional knockout mice (SHP-1 CKO) which lack a protein tyrosine phosphatase, SHP-1, and reported that they spontaneously develop tubulointerstitial nephritis characterized by the marked accumulation of $CD11c^+F4/80^+$ double-positive rMoPh, (J Immunol 2012, ASN 2016). In the present study, we further analyzed the kidney of SHP-1 CKO to clarify the precise contribution of rMoPh to the development of the nephritis.

Methods: The kidneys obtained from SHP-1 CKO and its control mice (Ctrl) at the age of 40 weeks and were analyzed; in particular, the expressions of vimentin, a marker of mesenchymal cells, and α-smooth muscle actin (α-SMA), a marker of myofibroblasts, were evaluated by immunohistochemistry. Collagen-digested renal mononuclear cells from SHP-1 CKO and Ctrl were analyzed by flow cytometry (FCM).

Results: Masson's trichrome and Sirius Red staining showed that the area of renal fibrosis was significantly increased in SHP-1 CKO compared to Ctrl. The immunohistochemical analysis revealed marked expression of vimentin and moderate expression of α-SMA in tubulointerstitial area of SHP-1 CKO. Intracellular FCM staining revealed majority of vimentin as well as α-SMA positive-cells were $CD11c^+F4/80^+$ double-positive rMoPh in SHP-1 CKO. A small number of $CD45^-$, non-hematopoietic cells, were positive for vimentin or α-SMA, but not significantly different compared to Ctrl. To confirm the efficacy of depletion of SHP-1, we examined the SHP-1 expression in rMoPh by intracellular FCM staining. About 70% of $CD11c^+F4/80^+$ rMoPh did not express SHP-1. These results suggested that SHP-1 depletion in $CD11c^+F4/80^+$ rMoPh led to the upregulation of vimentin and α-SMA, and directly caused renal fibrosis.

Conclusions: Depletion of SHP-1 in $CD11c^+F4/80^+$ rMoPh induces renal tubulointerstitial nephritis and fibrosis with age. In addition, transformation of $CD11c^+F4/80^+$ rMoPh into myofibroblasts could be involved in underlying mechanisms of renal fibrosis.

SA-PO857

Endothelial Tie2 Deficiency Increases Capillary Rarefaction and Tubulointerstitial Fibrosis

Marie Jeansson. *Uppsala University, Uppsala, Sweden.*

Background: Renal tubulointerstitial fibrosis is predictive of progressive decline in kidney function, independent of underlying disease. It is characterized by an increase in aSMA+ fibroblasts, myofibroblasts, that produce collagen. We previously showed that loss of Angiopoietin-1 (Angpt1) in adult mice predisposes to fibrosis in wound healing, diabetic nephropathy, and the unilateral ureter obstruction (UUO) model. The tyrosine kinase receptor, Tie2, is expressed on endothelial cells and Angpt1 binding results in Tie2 signaling that is pro-survival and anti-inflammatory. Here, we test the hypothesis that loss of Tie2 signaling in endothelial cells results in capillary defects leading to an increased fibrotic response in kidney fibrosis.

Methods: Tie2 floxed mice were crossed with tamoxifen inducible endothelial specific Cadh5-Cre and a reporter line expressing TdTomato upon Cre-activation. This line enables both an endothelial specific KO of Tie2 and an endothelial lineage tracer. To study the role of Tie2 signaling in renal fibrosis we utilized the unilateral ureter obstruction (UUO) model of kidney fibrosis. An additional line (Pdgfra-H2b-GFP) was crossed into the above line, resulting in a reporter of myofibroblasts.

Results: Endothelial specific KO of Tie2 resulted in an increase in fibrosis as seen by increased expression of aSMA and vimentin compared to WT mice 3 days after UUO. At the same time, there was significant increase in Kim1 and tubular ferroptosis, suggesting a more severe injury in ecTie2KO. Electron micrographs of peritubular capillaries 3 days after UUO showed significantly more loss of fenestrations in ecTie2KO mice. Investigation of blood vessels before fibrotic onset 1 day after UUO, revealed less perfused capillary area and increased hypoxia in Tie2 KO mice. Ongoing work is designed to investigate blood vessel function in the early fibrotic process and to estimate the endothelial-mesenchymal contribution after UUO in controls and Tie2 knockout mice, utilizing the lineage tag of endothelial cells and myofibroblast reporter.

Conclusions: Our results suggest that loss of Tie2 signaling destabilizes the endothelial cell and increases tubulointerstitial fibrosis. The mechanisms we are investigating are an early loss of endothelial cells due to endothelial-mesenchymal transition and/or apoptosis, resulting in less functional peritubular capillaries and more fibrosis.

Dose-Effect Response of Remote Ischemic Preconditioning for the Prevention of Hemodialysis-Induced Myocardial Stunning: Preliminary Results of a Randomized Controlled Trial

Fabio R. Salerno,[1] Lisa Crowley,[3] Jarrin D. Penny,[2] Christopher W. McIntyre.[1,2]
[1]Medical Biophysics, University of Western Ontario, London, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada; [3]Royal Stoke University Hospital, Stoke-on-Trent, United Kingdom.

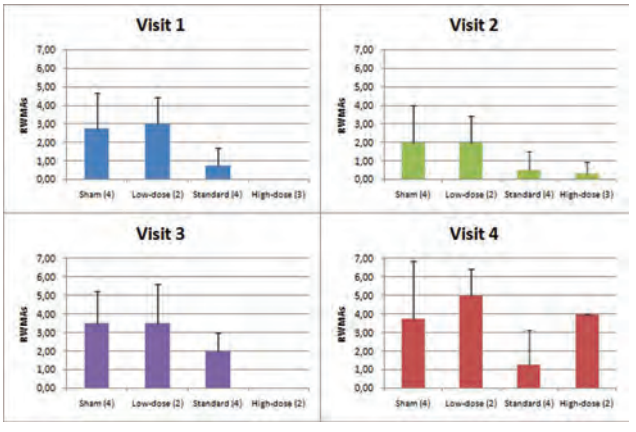
Background: Myocardial stunning is a common complication of standard hemodialysis and is implicated in the high cardiovascular mortality of end-stage kidney disease patients. This is an interim analysis of a randomized controlled trial aimed at testing the effects of different doses of remote ischemic preconditioning (RIPC) for the prevention of hemodialysis-induced myocardial stunning.

Methods: Study patients underwent speckle-tracking echocardiography predialysis and at peak stress (15 minutes before the end) at each visit. Images were analyzed for longitudinal systolic strain and the number of new regional wall motion abnormalities (RWMAs) (> 30% reduction in longitudinal systolic strain at peak stress) was recorded. Patients were screened for myocardial stunning (>/= 2 RWMAs) before enrolment: so far, 13 chronic hemodialysis patients showing evidence of hemodialysis-induced myocardial stunning were enrolled. Patients were followed-up for 4 weeks, once a week. They were randomized in a 1:1 ratio to receive either: predialysis Sham RIPC, Low-dose RIPC (2 RIPC cycles on visit 1), Standard RIPC (4 cycles on visit 1) or High-dose RIPC (4 cycles at each visit). Primary outcome was the reduction in RWMAs.

Results: See attached image.

Conclusions: These preliminary results show a trend towards a dose-effect response to RIPC: sham and low-dose RIPC failed at reducing hemodialysis-induced RWMAs, while standard and high-dose RIPC seem effective in preventing hemodialysis-induced myocardial stunning. These effects seem to last for at least 2 weeks after the delivery of the RIPC stimulus. We expect to confirm our hypotheses with further enrollments.

Funding: Government Support - Non-U.S.



Mean (+ Standard Deviation) RWMAs per group per visit. The RIPC stimulus was administered on visit 1 for the Sham, Low-dose and Standard groups and on visits 1 through 4 for the High-dose. Differences were not statistically significant.

Prescribing Patterns of Anticoagulants in Dialysis Patients with Incident Atrial Fibrillation in the United States Between 2012 and 2014

Katherine Garlo,[1] Thomas Mavrakanas,[1,3] Bridget A. Neville,[3] David M. Charytan.[2] *[1]Renal Division Department of Internal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Brigham and Women's Hospital/Harvard Medical School, Brookline, MA; [3]Brigham and Women's Hospital, Boston, MA.*

Background: Four direct acting oral anticoagulants are approved for stroke prevention in atrial fibrillation (AF) and offer advantages over warfarin. However, individuals with advanced kidney disease and dialysis were excluded from phase 3 trials and all agents are excreted by the kidney. Understanding longitudinal prescribing patterns of anticoagulation in dialysis patients is especially important as these agents become integrated into clinical care.

Methods: We used United States Data Renal System (USRDS) data to identify prevalent and incident dialysis patients with new onset atrial fibrillation occurring between Jan 1, 2012-December 31, 2014. Trends in use of apixaban, rivaroxaban, warfarin, or no anticoagulation were identified from Part D Medicare records. Subgroup analyses for demographics and comorbidities were also examined.

Results: Among 743,639 patients receiving maintenance dialysis (399,024 prevalent prior to Jan 1, 2012 and 344,615 incident patients from Jan 1, 2012 - Dec 31, 2014),85,032 had a new diagnosis of AF or flutter after Jan 1, 2012. Upon exclusion for non-continuous part A, B, and D Medicare coverage, death within 30 days of AF diagnosis, and or valvular disease, 27,202 individuals were included in the final analysis (25,372 on hemodialysis and 1,830 on peritoneal dialysis). Of these 6,717 (24.7%) were prescribed warfarin, 309 (1.1%) apixaban, 91 (0.3%) rivaroxaban, and 20,085 (73.8%) did not receive anticoagulation.

Conclusions: Results from this large observational study of 27,202 individuals on dialysis in the United States with AFshow that the majority did not receive anticoagulation (73.8%) between 2012-2014. Warfarin remains the most frequently prescribed anti-coagulant (24.7%). Use of direct acting oral anti-coagulants remains infrequent with the majority receiving apixaban.

Association Between Body Mass Index and the Incidence of Cardiovascular Disease in Patients Undergoing Hemodialysis: Ten-Years Outcome of the Q-Cohort Study

Yasuhiro Kawai,[1] Hiroto Hiyamuta,[1] Shigeru Tanaka,[2] Masatomo Taniguchi,[3] Kazuhiko Tsuruya,[4] Toshiaki Nakano,[1] Takanari Kitazono.[1] *[1]Kyushu University, Graduate School of Medical Sciences, Fukuoka City, Japan; [2]Fukuoka Dental College, Fukuoka, Japan; [3]Fukuoka Renal Clinic, Fukuoka, Japan; [4]Nara Medical University, Kashihara, Japan.*

Background: In hemodialysis (HD) patients, high body mass index (BMI) is paradoxically associated with better outcomes including a lower risk of cardiovascular and all-cause mortality (obesity paradox). However, the impact of BMI on the incidence of cardiovascular disease (CVD) [stroke, ischemic heart disease (IHD), or peripheral artery disease (PAD)] in patients undergoing hemodialysis remains unclear.

Methods: A total of 3,506 participants undergoing maintenance HD were followed up for 10 years. The primary outcome was the incidence of stroke, IHD, or PAD. The subjects were divided into 4 groups based on the quartile of the baseline BMI values (Q1, ≤19.1; Q2, 19.2–20.9; Q3, 21.0–22.6; Q4, ≥22.7 kg/m^2). The association between BMI and the incidence of each CVD was examined using Cox proportional hazards model.

Results: During the follow-up period, 526 (15%), 456 (13%), and 257 (7.3%) patients experienced stroke, IHD, and PAD, respectively. The 10-year incidence rate of stroke was significantly higher with lower BMI, whereas incidence rates of IHD and PAD were significantly lower with lower BMI. Compared with the highest quartile of BMI (Q4), the multivariable-adjusted hazard ratios (95% confidence interval) for stroke were 1.45 (1.13–1.85) in patients with Q1. Whereas, compared with the lowest quartile of BMI (Q1), the multivariable-adjusted hazard ratios (95% confidence intervals) for IHD and PAD were 2.04 (1.54–2.72) and 1.76 (1.21–2.55) in patients with Q4, respectively.

Conclusions: Low BMI was associated with high risk of stroke, whereas high BMI was associated with high risk of IHD and PAD in patients undergoing HD. Our results suggest that the influence of BMI on the incidence of CVD may be different depending on the type of cardiovascular events.

Long-Term Trends in Oral Anticoagulant (OAC) Use in US Patients with ESRD on Hemodialysis (HD) and Atrial Fibrillation (AF)

Austin Hu,[1] Jingbo Niu,[1] Tara I. Chang,[2] Wolfgang C. Winkelmayer.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Stanford University School of Medicine, Palo Alto, CA.*

Background: OACs are recommended for most patients with AF to prevent thromboembolic complications. Low OAC use has been reported in patients with ESRD on HD and AF. We tested whether OAC practices in this population have changed during the decade, 2006-2015.

Methods: From the USRDS, 2006-2015, we selected subsequent 6-month interval cohorts of Medicare-insured HD patients diagnosed with AF in the current or preceding intervals. From Medicare Part D claims we identified any warfarin or direct-target OAC use in each interval. Study outcomes were the prevalence of any OAC use, or use of specific agents. We used repeated measures logistic regression and interrupted time series analysis to 1) determine whether OAC use increased during 2006-2015, and 2) whether this longer-term trend changed after the approval of a labeled dose for apixaban in ESRD in Jan 2014.

Results: While the number of period-prevalent HD patients with AF increased from 33,052 (Jan-Jun 2006) to 63,675 (Jul-Dec 2015), the proportion receiving any OAC remained remarkably stable during the decade, at ~25% (Figure). There was a slight increase starting in 2014, which was mostly attributable to increasing apixaban use, with >27% of patients receiving OAC in Jul-Dec 2015, and apixaban representing 13% of all OAC use. Compared with Jul-Dec 2006, adjusted odds ratios were near unity throughout time, with an aOR of 1.07 (CI, 1.04-1.09) for any OAC and 0.96 (CI, 0.93-0.98) for warfarin use for Jul-Dec 2015. Adjusted interrupted time series analyses failed to reject the null hypothesis of a zero slope over the decade and did not identify a significant difference in level or slope for 2014-15 vs. 2006-2013, either.

Conclusions: The proportion of HD patients with AF receiving any OAC remained remarkably stable over the decade, at ~25%, with increasing substitution of warfarin by apixaban after 2014.

SA-PO862

Peripheral Vascular Calcification Score Is Better Than Abdominal Aortic Calcification Score of Plain Radiographs in Predicting Cardiovascular Mortality in Hemodialysis Patients

Min Mo, Jianyi Pan, Wei Zhang, Qingkun Zheng, Jinzhong Chen, Xianrui Dou. *Shunde Hospital Southern Medical University, Foshan, China.*

Background: Cardiovascular disease (CVD) is the major cause of death for dialysis patients. Vascular calcification (VC) serves as a key pathological factor resulting in the CVD. KDIGO advocates abdominal aortic calcification score (AACS) to evaluate VC. Meanwhile, some studies showed that the peripheral vascular calcification score (PVCS) could predict cardiovascular mortality. However, no studies compare two VC score systems in clinic. Thus, this study compared two VC score systems in predicting mortality of HD patients.

Methods: In this retrospective study with 243 HD patients, AACS and PVCS were measured from plain radiograph of lateral abdominal radiograph and pelvis and both hands radiographs, respectively.

Results: The prevalence of VC was 68.5% (167 patients), most patients showed AAC (63.7%). During the follow-up period of 24 (13,44) months, 65(26.6%) patients died. Among these died patients, 35 (53.8%) patients died of cardiovascular disease. The patients died showed higher AACS (5.0 (1.25,14.0) vs. 2.0 (0,6.75), *P*=0.001), PVCS (2.0(0,5) vs. 0(0,2.0),*P*=0.000), and overall VC score (5 (0,16) vs. 1 (0,6), *P*=0.001) compared to alive patients. When ROC curve was used to predict all-cause mortality, for PVCS, the area under ROC curve (AUROC) was 0.695 with 57.4% of specificity and 71.8% of sensitivity (*P*=0.000). As for AACS, the AUROC was 0.666 with 62.9% of specificity and 61.7% of sensitivity (*P*=0.001). The AUROC for PVCS was 0.668 with 68.0% of specificity and 62.5% of sensitivity (P=0.007), while the AUROC for AACS was 0.574 with 38.1% of specificity and 75.0% of sensitivity (P=0.239) when used to predict cardiovascular mortality. By the COX multivariate regression analysis (adjusted for age, gender, diabetes, period of dialysis, albumin, hypertension, cholesterol, phosphorus, calcium, intact-parathyroid and Kt/V), the PVCS was independently associated with all-cause mortality and cardiovascular mortality (HR, 1.287;95%CI, 1.140-1.453, and HR, 1.272;95%CI,1.079-1.499), respectively. However, AACS was only associated with all-cause mortality (HR, 1.069; 95%CI, 1.008-1.133) but not cardiovascular mortality.

Conclusions: VC score is independently associated with mortality. The PVCS is a better parameter in predicting cardiovascular mortality as compared with AACS.

SA-PO863

Predictors of Change in Left Ventricular Mass in a Randomized Trial of Extended Hours Dialysis

Brendan Smyth,[1,2] Christopher T. Chan,[3] Rajesh Puranik,[4] Nicholas A. Gray,[5,6] Janak R. de Zoysa,[7,8] Anish Scaria,[1] Martin P. Gallagher,[1,9] Vlado Perkovic,[1] Meg J. Jardine.[1,9] *[1]The George Institute for Global Health, UNSW, Newtown, NSW, Australia; [2]Sydney School of Public Health, University of Sydney, Sydney, NSW, Australia; [3]Toronto General Hospital, Toronto, ON, Canada; [4]Department of Cardiology, Royal Prince Alfred Hospital, Sydney, NSW, Australia; [5]Sunshine Coast University Hospital, Birtinya, QLD, Australia; [6]Sunshine Coast Clinical School, University of Queensland, Birtinya, QLD, Australia; [7]Waitemata District Health Board, AUCKLAND, New Zealand; [8]Department of Medicine, University of Auckland, Auckland, New Zealand; [9]Renal Unit, Concord Repatriation General Hospital, Sydney, NSW, Australia.*

Background: Extended hours dialysis was not associated with a significant reduction in LVMI in the ACTIVE Dialysis trial. Other factors, such as changes in fluid status and biochemical parameters, may predict regression of LV hypertrophy. We aimed to determine predictors of change in left ventricular mass index (LVMI) in the ACTIVE Dialysis study.

Methods: In the ACTIVE Dialysis study patients randomised to extended and standard dialysis, received median 24 and 12 haemodialysis hours per week respectively, predominantly delivered as three sessions per week. Ninety-five participants underwent cardiac magnetic resonance imaging (MRI) at baseline and 12 months. Predictors of change in LVMI were examined by multivariable linear regression in an observational analysis.

Results: In the overall MRI cohort, the change from baseline to 12 months in LVMI was -6.7g (95% confidence interval (CI) -11.2, -2.2; P=0.004) with non-significant reductions in mean normalised sessional ultrafiltration rate -1.0mL/kg/hr (95%CI -2.2, 0.24; P=0.114) and weekly total ultrafiltration -0.8L (95%CI -0.3, 2.0; P=0.165) and a significant reduction in systolic blood pressure (BP) -5.4mmHg (95%CI -8.8, -2.0; P=0.002). Baseline LVMI (P=0.003) was associated with improved LVMI in univariable analysis and this remained significant in the multivariable analysis (P=0.046). A non-significant improvement in LVMI was observed with longer dialysis vintage (P=0.137). There were no significant associations between changes in ultrafiltration rates and volumes, systolic and diastolic blood pressure, phosphate, and parathyroid hormone and change in LVMI.

Conclusions: Higher baseline LVMI, but not improvements in volume control, blood pressure or biochemical parameters, predicts regression of left ventricular hypertrophy over 12 months. Further study is warranted to identify predictors of change in this important treatment target.

SA-PO864

Association Between Bone-Derived Biomarkers and Aortic Arch Calcification in Maintenance Hemodialysis Patients

Kosaku Nitta. *Tokyo Women's Medical University, Shinjuku-ku, Japan.*

Background: Aortic arch calcification (AoAC) is frequently detected in maintenance hemodialysis (MHD) patients and is associated with cardiovascular and all-cause mortality. We investigated the factors associated with AoAC and analyzed the relationship between bone-derived biomarkers and AoAC.

Methods: We enrolled 389 stable MHD patients. AoAC was assessed using chest-X ray examination. Demographic data was collected in addition to serum levels of biochemical and bone-derived biomarkers, including sclerostin and fibroblast growth factor 23 (FGF23).

Results: Two hundred sixteen patients (55.0%) had AoAC. Patients with AoAC score ≧ 4 were older, with a higher percentage being male, and exhibited lower serum levels of albumin and triglyceride. Serum FGF23 levels were inversely associated with AoAC severity, and FGF23was directly related to vascular calcification. Age, gender, and dialysis vintage were independent predictors of AoAC.

Conclusions: MHD patients have a high prevalence of AoAC. Levels of circulating FGF23 but not sclerostin were related to AoAC severity. Serum FGF23 levels were independently associated with AoAC.

SA-PO865

Lower Serum Magnesium (sMg) Is a Strong Predictor of Left Ventricular Hypertrophy (LVH) and Patterns of LV Remodeling in Patients with CKD Stage 5D

Periklis P. Kyriazis,[1] Charalampos Kalogeropoulos,[2] Ourania Tsotsorou,[2] Eleftheria-Kleio Dermitzaki,[3] Ioannis E. Giannikouris,[4] Dimitra Lygerou,[3] Apostolo Kokkalis,[5] Dimitra Bacharaki,[2] Dimitrios V. Vlahakos.[2] *[1]Internal Medicine, Baystate Medical Center/University of Massachusetts, Springfield, MA; [2]Nephrology, Attikon University Hospital, Athens, Greece; [3]Nephrology, University Hospital of Heraklion, Heraklion, Greece; [4]Medifil SA Hemodialysis Center, Athens, Greece; [5]Clinitest E.E Hemodialysis Center, Athens, Greece.*

Background: To evaluate the prognostic role of sMg on LVH and cardiac geometry in patients with stage 5D CKD

Methods: The study included 127 patients with stage 5D CKD (69 on hemodialysis and 58 on peritoneal dialysis) and a mean age of 62±15 years. Echocardiographic LVH was defined by LV mass index (LVMI) > 95 g/m^2 in women and > 115 g/m^2 in men. Based on LVMI and relative wall thickness (RWT), four LV geometric patterns were defined: normal (normal LVMI and RWT), concentric remodeling (normal LVMI and increased RWT>0.42), eccentric LVH (increased LVMI and normal RWT) and concentric LVH (increased LVMI and RWT). sMg and serum Ca (sCa) values were defined as the mean of all predialysis measurements available during the preceding 3 months.

Results: Patients (n=81) with LVH as compared to patients with no LVH (n=46) were older in age (p <0.001), had lower sMg (p<0.001) and higher sCa (p<0.05), malnutrition-inflammation score (p<0.05), body mass index (p<0.001), pulse pressure (p<0.01), prevalence of diabetes (p<0.05), coronary artery disease (p<0.05) and peripheral vascular disease) (p<0.01). In a multivariate logistic regression analysis adjusted for all factors mentioned above, each increase of sMg by 1 mg/dl was associated with 91% (OR= 0.09, 95% CI: 0.024-0.36; p <0.001) lower odds of having LVH. In a forward stepwise multivariate model (R^2= 0.271; p<0.001), sMg emerged a strong independent predictor of LVMI (p<0.01) explaining about 5.7% of its variance. The area under the ROC curve for predicting the development of LVH was 0.696 (p<0.001) and at an optimal sMg cutoff of 2.26 mg/dl the sensitivity and specificity of sMg in predicting the occurrence of LVH were 67.4 % and 66.7 %, respectively. Considering LV geometry, there was a progressive decrease in sMg from the normal group (2.38±0.38 mg/dl) to concentric remodeling group (2.37±0.40 mg/dl), eccentric (2.19±0.30 mg/dl) and then to concentric (2.08±0.36 mg/dl) group (p<0.01 for the trend).

Conclusions: A lower sMg is a major determinant of echocardiographic LVH. Prospective studies may determine whether therapeutic adjustments of sMg can prevent or reduce the risk of LVH in patients with stage 5D CKD

SA-PO866

Pre-Dialysis Serum Phosphorus and Intradialytic Hypotension

Patrick Reeves,[1,2] Sushrut S. Waikar,[1,2] Finnian R. McCausland.[1,2] *[1]Division of Renal Medicine, Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Intradialytic hypotension (IDH) is a common complication of maintenance hemodialysis (HD) and is associated with excess morbidity and mortality. Higher serum phosphorus is associated with vascular calcification and adverse cardiovascular outcomes, however its association with the development of IDH is unclear. We hypothesized that higher pre-dialysis serum phosphorus is associated with a higher risk of IDH.

Methods: We performed a post-hoc analysis in 1825 participants (n=10,551 HD sessions) from the Hemodialysis (HEMO) Study, a multicenter randomized control trial examining standard or high dose dialysis and low-flux or high-flux membranes. Unadjusted and adjusted generalized linear models were fit to determine the association of pre-dialysis serum phosphorus with IDH (defined as any hypotensive event requiring an intervention). Serum phosphorus was examined as a continuous and categorical variable to assess for non-linear associations.

Results: Mean age of participants was 57.8 years (43.8% men, 37.4% white). Mean pre-dialysis serum phosphorus was 5.8 mg/dL; IDH occurred in 17.5% of HD sessions. In adjusted models (accounting for age, sex, race, comorbidities, flux group, Kt/V group, dialysis vintage, session length, ultrafiltration volume, access, pre-dialysis blood pressure, and pre-dialysis laboratory tests), higher pre-dialysis serum phosphorus (per 1 mg/dL) was associated with a higher risk of IDH (odds ratio (OR) 1.07; 95% confidence interval (CI) 1.03-1.12). Participants in the highest (≥ 6.9 mg/dL) vs. lowest (≤ 4.5 mg/dL) quartile of pre-dialysis serum phosphorus had a 30% greater risk (OR 1.30; 95% CI 1.05-1.60) of IDH (Figure 1).

Conclusions: Higher pre-dialysis serum phosphorus is independently associated with higher risk of IDH, even after adjustment for variables associated with 'compliance'. As HD may cause an acute decline in serum phosphorus, future studies to investigate the temporal association of changes in phosphorus and IDH should be performed.

U-EVE, a Method for Estimating the Extra-Cellular Fluid Volume with Serum Uric Acid Concentrations, Would Help to Find Latent Overhydration of Hemodialysis Patients

Takahito Ito,[1] Takahiro Shinzato,[2] Kazuhiko Shibata,[3] Shigeru Nakai,[4] Takeshi Aoki.[5] *[1]Kataguilli Medical Center, Shibata, Japan; [2]Daiko Medical Engineering Research Institute, Nagoya-shi, Japan; [3]Yokohama Minami Clinic, Yokohama, Japan; [4]Fujita Health University School of Health Scieneces, Toyoake, Aichi, Japan; [5]Nagoya Municipal Industrial Research Institute, Iwakura-shi, Aichi-ken, Japan.*

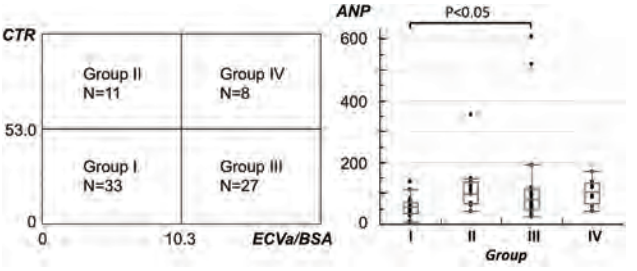
Background: We have developed a new method to estimate the extra-cellular fluid volume after HD (ECVa) with serum uric acid (UA) concentrations at pre- and post-hemodialysis (HD) sessions, which was named UA-assisted ECV Estimation (U-EVE). We studied the clinical value of U-EVE.

Methods: Among 108 Japanese outpatients undergoing HD in Kataguilli medical center, 79 patients maintaining stable blood flow and ultrafiltration rates on the day of blood sampling were studied. They had no cardiac events at least during the last twelve months. Plasma ANP concentrations and cardio-thorax ratios (CTR) of X-ray were measured after HD. ECVa was estimated by the U-EVE method as reported separately and was standardized by the body surface area (ECVa/BSA).

Results: ECVa/BSA values were significantly high in the patients with persistent atrial fibrillation. They, however, were unaffected by sex, diabetes, dialysis modality, and past events of myocardial infarction, pacemaker implantation, aortic valve replacement, percutaneous coronary intervention, and/or coronary artery bypass grafting. In univariate analysis, serum creatinine (Cr), ANP and Kt/V correlated with ECVa/BSA [R=-0.29133 (P=0.0092), R=0.2624 (P=0.0195), and R=-0.254 (P=0.0236), respectively]. Age, HD vintage, CTR, hemoglobin, and BNP at the pre-HD session were not significant. When the subjects were categorized into four groups, ANP concentrations of Group III were significantly higher than those of Group I (Figure). The increase of ECVa/BSA during the last twelve months correlated with age (R=0.280, P=0.0162), Cr (R=-0.386, P=0.0007), and Alb (R=-0.265, P=0.023), which suggested that the increase of ECVa/BSA might reflect the progression of sarcopenia.

Conclusions: U-EVE/BSA would help to find potentially overhydrated HD patients.

Funding: Clinical Revenue Support



The study subjects were categorized into 4 groups according to CTR and ECVa/BSA. Statistical comparison was done by Tukey-Kramer analysis. The cut-off values of CTR and ECVa/BSA were 53.0% and 10.3 L/m^2, respectively.

A New Method to Estimate the Extra-Cellular Fluid Volume with Serum Uric Acid Concentrations at Pre- and Post-Hemodialysis

Takahito Ito,[1] Takahiro Shinzato,[2] Kazuhiko Shibata,[3] Shigeru Nakai,[4] Takeshi Aoki.[5] *[1]Kataguilli Medical Center, Shibata, Japan; [2]Daiko Medical Engineering Research Institute, Nagoya-shi, Japan; [3]Yokohama Minami Clinic, Yokohama, Japan; [4]Fujita Health University School of Health Scieneces, Toyoake, Aichi, Japan; [5]Nagoya Municipal Industrial Research Institute, Iwakura-shi, Aichi-ken, Japan.*

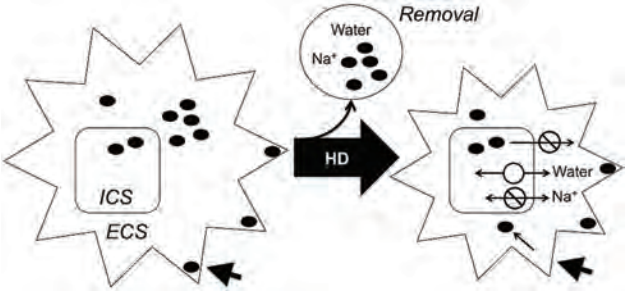
Background: Uric acid (UA) with a molecular weight of 168 Da is synthesized mainly in the liver and intestines as the end-product of purine metabolism, and is located throughout the body. We have found that we could approximate the extra-cellular fluid volume (ECV) with the amount of UA that was removed by hemodialysis (HD).

Methods: Our calculation is based on assumptions shown in the figure. The dialyzer mass transfer-area coefficient (KoA) and the physiologically-appropriate patient clearance time (tp) for UA were obtained in advance. In order to estimate ECV after HD (ECVa), clinical parameters required other than C_{UA} at pre- and post-HD were height, treatment time of HD, blood flow rate of HD, dialysate flow rate of HD, surface area of dialysis membranes, hematocrit at pre-HD, body weight values at pre- and post-HD, C_{UN} at pre- and post-HD, and C_{Na} at pre- and post-HD. The ECAa values estimated by our method were compared with those which were measured by multi-frequency bioimpedance analysis (BIA).

Results: We named our new method UA-assisted ECV Estimation (U-EVE) and assembled it as a Microsoft EXCEL® file for practice. ECVa values by U-EVE correlated with those by BIA: R=0.456 (P=0.0100, N=31, age 62.3±11.4, BIA was done by MLT555N), R=0.578 (P=0.0190, N=16, age 65.5±9.3, by InBody S10), and R=0.616 (P<0.0001, N=49, age 59.6±11.3, by MLT50) in three independent measurements. The formulas used in our program will be explained step by step.

Conclusions: U-EVE is innovative yet easy to estimate ECVa of HD patients without special devices. Clinical significances of U-EVE need to be further verified.

Funding: Clinical Revenue Support



Major assumptions about our method. (1) Removed UA molecules come only from ECS, (2) UA and Na^+ do not cross cell membrane during HD, (3) Water crosses cell membrane to maintain the ratio of C_{Na}^+ of ECS to that of ICS, (4) C_{UA} of ECS rebounds after HD simply due to redistribution of UA from hypo-perfused space of ECS (arrowhead). *ECS* and *ICS* stand for extra-cellular and intra-cellular spaces, respectively. Black dots represent UA molecules.

Correlation of Intracellular Volume Calculated by Uric Acid Kinetic Modeling with Intracellular Volume Estimated by Bioimpedance Analysis

Shigeru Nakai,[1] Takahito Ito,[2] Kazuhiko Shibata,[3] Takeshi Aoki,[4] Midori Hasegawa,[5] Daijo Inaguma,[5] Yukio Yuzawa,[5] Takahiro Shinzato.[6] *[1]Fujita Health University School of Health Scieneces, Toyoake, Aichi, Japan; [2]Kataguilli Medical Center, Shibata, Japan; [3]Yokohama Minami Clinic, Yokohama, Japan; [4]Nagoya Municipal Industrial Research Institute, Iwakura-shi, Aichi-ken, Japan; [5]Fujita Health University School of Medicine, Aichi, Japan; [6]Daiko Medical Engineering Research Institute, Nagoya-shi, Japan*.

Background: Previous studies indicate that uric acid is not transported through the cell membranes of erythrocytes during hemodialysis (HD). If uric acid is not transported through the cell membranes of not only erythrocytes, but also general body cells, the uric acid distribution volume is theoretically consistent with extracellular volume, and the difference between urea distribution volume and uric acid distribution volume is consistent with intracellular volume (ICV). We tentatively designated the difference between urea distribution volume and uric acid distribution volumeas kinetic modeling ICV (KM-ICV).

Methods: We calculated whole-body KM-ICV based on regular blood test results obtained at 49 occasions in 7 patients. Subsequently, we compared whole-body KM-ICVandbioimpedance analysis (BIA)-ICV, which were measured after HD on the day the regular blood tests were performed and examined their correlation. Moreover, we examined the correlation between KM-ICVnormalized to body surface area (normalized KM-ICV) andserum albumin level, and between normalizedKM-ICVandserum creatinine level.

Results: A significant difference was found between whole-bodyKM-ICV andBIA-ICV(17.30 ±4.30 ml/m^{2}and 15.88 ±2.43 ml/m^2[mean ±s.d.], respectively; p = 0.002). Moreover, a significant correlation was observed between whole-bodyKM-ICV(x) and BIA-ICV (y) (y = 0.402x + 8.931, r = 0.711, p = 0.0001). A significant correlation was found between normalizedKM-ICV(x) and serum albumin level(y) (y = 0.0324x + 3.072, r = 0.463, p = 0.0008). However, no correlation was found betweennormalizedKM-ICV and serum creatinine level.

Conclusions: NormalizedKM-ICV can be used as an alternative nutritional index.

Inflammation Is an Amplifier of Lung Congestion by High LV Filling Pressure in Hemodialysis Patients: A Longitudinal Study

Claudia Torino. on behalf of the LUST study working group* *Institute of Clinical Physiology, National Research Council, Reggio Calabria, Italy*.

Background: Lung congestion is exceedingly common in symptomatic and asymptomatic hemodialysis (HD) patients. Since inflammation alters vascular permeability, including vascular permeability in the lung, we hypothesized that it can be an amplifier of lung congestion in HD patients.

Methods: We investigated the effect modification by systemic inflammation as measured by serum C Reactive Protein (CRP) on the longitudinal relationship between a surrogate of the filling pressure of the LV [left atrial volume (LAV)] and lung water in a series of 273 patients participating into the LUng congeSTion in hemodialysis patients trial (LUST). Lung water was quantified by the number of ultrasound B lines (US-B) registered over the thorax. Paired lung-US and LAV (Echo-CG) recordings were performed at baseline, 6, 2 and 24 months. Overall, 407 simultaneous US-Echo-C estimates were obtained during follow up. Data analysis was made by the mixed Linear Model.

Results: Ninety-two patients had mild to moderate lung congestion (5-30 B lines) and 33 severe congestion (>30 B lines). The median LAV was 73 ml (Inter Quartile Range 53-105). The longitudinal series of US-B lines associated with simultaneous estimates of LAV in analyses adjusting for age, gender, dialysis vintage, SBP, diabetes, smoking, cholesterol, calcium (P=0.001). Effect modification analysis by CRP showed that this biomarker of inflammation was a strong modifier of the LAV- US B lines relationship both in unadjusted and adjusted analyses (P<0.001) so that at an identical increase in LAV the number of US-B lines was higher in more severely inflamed than in patients with less severe inflammation.

Conclusions: These data extend to the lung the detrimental effects of inflammation in HD patients and suggest that, at comparable LV filling pressure levels, patients with more severe degrees of inflammation are exposed to higher risk for pulmonary edema than those with no or mild systemic inflammation. ***Mallamaci F, Gargani L, Sicari R, Letachowicz K, Ekart R, Fliser D, Covic A, Siamopoulos K, Stavroulopoulos A, Massy ZA, Fiaccadori E, Caiazza A, Bachelet T, Slotki I, Martinez-Castelao A, Coudert-Krier MJ, Rossignol P, Gueler F, Hannedouche T, Wiecek A, Sarafidis P, Klinger M, Hojs R, Seiler-Mussler S, Lizzi F, Siriopol D, Balafa O, Shavit L, Loutradis C, Tripepi R, Tripepi G, Picano E, London GM, Zoccali C.**

Long-Term Course of Peri-Dialytic Blood Pressures in Hemodialysis and Online Post-Dilution Hemodiafiltration Patients

Paul A. Rootjes,[1] Camiel L. de Roij van Zuijdewijn,[2] Peter J. Blankestijn,[3] Bernard J. Canaud,[4] Andrew Davenport,[5] Frans J. van Ittersum,[6] Muriel P. Grooteman,[1] Francisco Maduell,[7] Menso Nube.[8] on behalf of the HDF Pooling Project Investigators *[1]VU University Medical Center, Amsterdam, Netherlands; [2]VU University Medical Center, Amsterdam, Netherlands; [3]University Medical Center----, Utrecht, Netherlands; [4]FMC Deutschland GmbH, Bad Homburg, Germany; [5]Royal Free Hospital, London, United Kingdom; [6]VU University Medical Center Amsterdam, Amsterdam, Netherlands; [7]Hospital Clinic Barcelona, Barcelona, Spain; [8]VU Medical Center, Bergen, Netherlands*.

Background: Data on the course of blood pressure (BP) changes over time in dialysis patients is scarce. We investigated the long-term course of the pre-dialytical and post-dialytical (peri-dialytical) systolic BP (SBP), diastolic BP (DBP), mean arterial pressure (MAP) and pulse pressure (PP), as well as the difference between these values (delta) in patients from 3 randomized controlled trials comparing conventional hemodialysis (HD) with online post-dilution hemodiafiltration (HDF).

Methods: Individual participant data (IPD) were pooled from the Estudio de Supervivencia de Hemodiafiltración (ESHOL, n=906), the Dutch Convective Transport Study (CONTRAST, n=714) and the French HDF study (Frenchie, n=391). Due to censoring only 1613 (80%) of the included 2011 patients had complete follow-up. After additional data were obtained, 2006 (99,8%) were available for the present IPD meta-analysis (Peters SAE et al. Nephrol Dial Transplant 2016 31 978). BP measurements were available every three months. Two-years changes were assessed with linear mixed models.

Results: Mean pre-dialytic SBP decreased by 0.09 mmHg/month (P<0.001) and post-dialytic SBP by 0.07 mmHg/month (P=0.005). Mean pre-dialytic DBP decreased by 0.12 mmHg/month (P<0.001) and post-dialytic DBP by 0.13 mmHg/month (P<0.001). Mean pre-dialytic MAP decreased by 0.11mmHg/month (P<0.001) and post-dialytic MAP by 0.11 mmHg (P<0.001). Mean pre-dialytic PP increased by 0.02 mmHg/month (P=0.064) and post-dialytic PP increased by 0.06 mmHg/month (P=0.004). The mean delta SBP, DBP, MAP and PP did not change significantly over time. None of the above mentioned parameters differed significantly between HD and HDF patients.

Conclusions: This is the first report comparing the longitudinal course of the peri-dialytical SBP, DBP, MAP and PP between HD and HDF patients. While both pre- and post-dialysis mean SBP, DBP and MAP decreased significantly over time and PP increased, differences between HD and HDF patients were not observed.

SA-PO872

The Course of Peri-Dialytic Blood Pressure over Time in Online Post-Dilution Hemodiafiltration Is Not Influenced by the Magnitude of the Convection Volume

Paul A. Rootjes,[1] Camiel L. de Roij van Zuijdewijn,[1] Peter J. Blankestijn,[2] Bernard J. Canaud,[3] Andrew Davenport,[4] Frans J. van Ittersum,[7] Muriel P. Grooteman,[1] Francisco Maduell,[5] Menso Nube.[6] on behalf of the HDF Pooling Project Investigators. *[1]VU University Medical Center, Amsterdam, Netherlands; [2]University Medical Center----, Utrecht, Netherlands; [3]FMC Deutschland GmbH, Bad Homburg, Germany; [4]Royal Free Hospital, London, United Kingdom; [5]Hospital Clinic Barcelona, Barcelona, Spain; [6]VU Medical Center, Bergen, Netherlands; [7]VU University Medical Center Amsterdam, Amsterdam, Netherlands*.

Background: Online post-dilution hemodiafiltration (HDF) is associated with a lower mortality rate than conventional hemodialysis (HD). The mechanism(s) behind this effect is (are) unknown. In a previous analysis on chronic HD and HDF patients we showed first, that pre- and post-dialytical (peri-dialytic) systolic blood pressure (SBP), diastolic BP (DBP) and mean arterial pressure (MAP) declined over time, while pulse pressure (PP) increased. Second, differences between HD and HDF patients were not observed. Since the beneficial effect of HDF is highly dependent on the magnitude of the convection volume (CV), in the present analysis we investigated whether different CVs have a dissimilar influence on the course of peri-dialytic BP over time.

Methods: We used the pooled individual participant data (IPD) from the Spanish Estudio de Supervivencia de Hemodiafiltración (ESHOL, n=906), the Dutch Convective Transport Study (CONTRAST, n=714) and the French HDF study (Frenchie, n=391) (Peters SAE et al. Nephrol Dial Transplant 2016 31 978). The CV was divided in quartiles (<20L, 20-23L, 23-26L and >26L). Hereafter, we investigated whether the change in BP over time was different for these quartiles by using an interaction term (convection volume * time) in linear mixed models.

Results: The longitudinal courses of the pre- and post-dialysis SBP, DBP, MAP and PP were similar in the CV quartiles (P >0.05 for all interaction terms). The difference between pre- and post-dialysis values (delta) was also similar in all 4 categories.

Conclusions: The course of the peri-dialytical and delta SBP, DBP, MAP and PP over time in HDF patients is not related to the magnitude of the CV. Therefore, the lower mortality rate in HDF patients may not depend on a superior peri-dialytic BP regulation.

Personalized Ultrafiltration Profile Design Using Crit-Line

Rammah M. Abohtyra,[2] Joseph Horowitz,[2] Christopher V. Hollot,[2] Michael J. Germain,[1] Yossi Chait.[2] [1]*Renal and Transplant Assoc of New England, Hampden, MA;* [2]*University of Massachusetts, Amherst, MA.*

Background: Intradialytic hypotension (IDH) occurs in as many as 25%-50% of patients during fluid removal by ultrafiltration. We recently presented a novel approach for the design of personalized ultrafiltration rate (UFR) profiles. Our aim was to integrate this design with a parameter estimation algorithm for a patient's fluid volume dynamics during hemodialysis (HD) from Crit-Line hematocrit (HCT) measurements.

Methods: We used a validated fluid volume model during HD comprising intravascular and interstitial pools, microvascular refilling/filtration, and lymphatic flow. We used several 20-min segments of UFR and HCT (Fig. 2) data from an actual HD treatment (3.5L removed in 227 min) and advanced algorithms to estimate key model parameters: plasma volume, interstitial volume, red blood cell volume, and filtration coefficient. Based on the estimated parameter ranges (Fig. 1), a personalized UFR profile was designed to minimize max UFR level, maintain HCT below a critical HCT profile, and achieve same UF goal.

Results: The estimated model parameters in five segments of an HD treatment are consistent with expected physiological changes during HD (Fig. 1 left/bottom). These parameter ranges were used to design personalized UFR profile (right/top). Simulations of the fluid volume model with the designed UFR profile over the estimated range of model parameters confirmed expected outcomes: similar UF goal achieved with 17% lower max UFR and lower HCT increases (right/bottom).

Conclusions: The successful estimation of fluid volume model parameters during HD supports the design of personalized UFR profiles that could lead to reduction in the incidence of IDH events.

Time-Integrated Fluid Load (TIFL) Predicts Left Ventricular Mass (LVM) reduction: Results from the Frequent Hemodialysis Network (FHN) Daily Trial

Jochen G. Raimann,[1] Christopher T. Chan,[2] John T. Daugirdas,[3] Thomas A. Depner,[4] Brett Larive,[5] Gerald J. Beck,[10] Tom Greene,[6] George A. Kaysen,[4] Alan S. Kliger,[7] Peter Kotanko,[1] Robert M. Lindsay,[11] Michael V. Rocco,[8] Nathan W. Levin,[1] The FHN Trial Group.[9] [1]*Renal Research Institute, New York, NY;* [2]*Toronto General Hospital, Toronto, ON, Canada;* [3]*University of Illinois College of Medicine, Chicago, IL;* [4]*University of California Davis, Sacramento, CA;* [5]*Cleveland Clinic, Cleveland, OH;* [6]*University of Utah, Salt Lake City, UT;* [7]*Yale New Haven Health System, New Haven, CT;* [8]*Wake Forest School of Medicine, Winston-Salem, NC;* [9]*NIDDK, NIH, Bethesda, MD;* [10]*Cleveland Clinic Foundation, Cleveland, OH;* [11]*London Health Sciences Centre, London, ON, Canada.*

Background: Serum sodium concentrations (SNa) less than 138 mEq/L act as effect modifiers to LVM reduction with increased hemodialysis (HD) frequency. Greater time-integrated fluid overload TIFL (incorporating interdialytic period length and increased fluid intake after Na-positive gradient HD) associates with LVM reduction (FHN Trial Group). We tested the interaction between the treatment effect of increased HD frequency on TIFL and change in LVM in the Daily Trial and evaluated, in the light of the "sick-cell" syndrome as a possible cause of low SNa, predictors of low SNa.

Methods: Treatment effects on LVM were analyzed in subgroups of subjects with a TIFL of ≤3 and >3 L*day. In a second step the interaction of the treatment effect with TIFL was tested using a mixed model. We measured CRP, Pentraxin, ICAM, IL-6 and -10, MCP-1, pre-albumin, TNF-Alpha, MPO at baseline of the FHN Daily Trial and compared between SNa greater or less than 138 mEq/L. Data presented as means and 95% CI.

Results: More frequent daily HD associated with a significant treatment effect on LVM when baseline TIFL was >3 L*day. The treatment effect on LVM showed a borderline significant interaction with TIFL [-5.8 (-15.0 to 3.5) g]. Significantly higher baseline CRP, IL-6, MPO, pre-albumin and pentraxin were found in the low SNa group, the intervention had no effect on inflammatory biomarkers.

Conclusions: Low SNa leads to increases in thirst and fluid intake, increasing TIFL and LVM. Decrease of TIFL by higher HD frequency, results in greater LVM reduction. A positive association between low SNa and inflammatory markers suggests inflammation to cause low SNa level and inflamed patients may benefit most from increased HD frequency.

Funding: NIDDK Support

LVM reduction [in g] as per TIFL

	Daily Trial (N=170)
TIFL ≤ 3 L*days	-5.6 (-21.5 to 10.44)
TIFL > 3 L*days	-26.0 (-39.4 to -12.6)

SA-PO875

Assessment of Plasma Refilling Rate in Dialysis Patients Using Plasma Body Weight Index Can Predict Intradialytic Hypotension

Tadashi Otsuka,[1,2] Yoshikatsu Kaneko,[2] Ryohei Kaseda,[2] Suguru Yamamoto,[2] Valentina Kon,[1] Ichiei Narita.[2] [1]*Vanderbilt University, Nashville, TN;* [2]*Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: Intradialytic hypotension (IDH) is a major risk factor for mortality in hemodialysis (HD). IDH often occurs when plasma fluid removal outpaces plasma refilling rate (PRR) from the interstitial space. Increasing dry weight (DW) can easily increase PRR, but it can precipitate congestive heart failure (CHF). Plasma body weight index (PWI), calculated from plasma total protein (TP) concentration and body weight before and after HD, has been proposed as a convenient surrogate marker, which inversely correlates to PRR. Our aim was to determine if PWI can predict IDH, and if a combination with hANP can be used as a clinical index to determine relevant DW.

Methods: This study retrospectively examined records of 156 dialysis patients from December 30, 2015, to January 5, 2016 in Tachikawa Medical Hospital. IDH was defined by current KDOQI guidelines [a decrease in either systolic BP (SBP) ≥20 mmHg or mean arterial pressure≥10 mmHg as well as associated symptoms]. CHF was defined as patients with dyspnea and low SpO2 level (<96%). PWI was calcurated by using this formula: *PWI = [(post TP - pre TP)*100/post TP]/[(pre body weight - post body weight)*100/pre body weight].*

Results: IDH and CHF occurred in 28.2% and 7.7% of all patients, respectively. Patients with IDH had higher PWI levels than those without IDH (1.71±1.40 vs. 2.65±1.70, P = 0.007). PWI > 2.0 was predictive of high incidence of IDH (OR = 2.40, 95%CI, 1.12-5.12, P = 0.020), but was not associated with incidence of CHF (OR 1.00, 95%CI, 0.30-3.30, P = 1.000). On the other hand, hANP >100 pg/ml was predictive of high incidence of CHF (OR 3.52, 95%CI, 1.06- 11.71, P = 0.004), but not associated with incidence of IDH (OR 0.79, 95%CI, 0.37-1.71, P = 0.5504). Subdividing the patients into 4 groups by the two cut-off points of PWI and hANP revealed that in the cohort of PWI < 2.0/hANP < 100 pg/ml, there was no incidence of CHF and incidence of IDH was low (13.7%).

Conclusions: PWI is a useful marker to predict IDH. Evaluating hydration status by combining PWI and hANP ia a useful parameter to estimate DW.

Associations between PWI and IDH and CHF

	PWI ≥ 2.0 (n [%])	PWI < 2.0 (n [%])	OR (95% CI)	P Value
Intradialytic hypotension	32 (35.2)	12 (18.5)	2.40 (1.12-5.12)	0.0201
Congestive heart failure	7 (7.7)	5 (7.7)	1.00 (0.30-3.30)	1.0000

OR, odds ratio; 95% CI, 95% confidence interval.

SA-PO876

Agreement Between Spectra Hemoglobin and Crit-Line® Monitor Estimated Hemoglobin

Mirell Tapia, Hanjie Zhang, Xia Tao, Stephan Thijssen, Peter Kotanko. *Renal Research Institute, New York City, NY.*

Background: Monitoring hemoglobin (Hgb) in hemodialysis is key in anemia management. Due to hemodilution, Hgb by Crit-Line® monitor ($Hgb_{CritLine}$) underestimates the pre-dialysis values measured by Spectra ($Hgb_{Spectra}$). An equation that considers blood volume, ultrafiltration rate, and saline dissipations can correct Hgb measured by Crit-Line ($Hgb^{CritLine}_{corrected}$). The aim of this study was to explore the concordance between the $Hgb_{Spectra}$ and $Hgb^{CritLine}_{corrected}$.

Methods: Pre-dialysis Hgb was measured by Spectra East, Inc. (Rockleigh, NJ, USA). ΔHgb ($Hgb_{Spectra}$ - $Hgb_{CritLine}$) and $Hgb^{CritLine}_{corrected}$ were estimated mathematically. The difference between $Hgb^{CritLine}_{corrected}$ and $Hgb_{Spectra}$ was denominated Hgb_{offset}. $Hgb_{CritLine}$ was determined by averaging the measurements between 0-2 minutes after the beginning of Crit-Line recording. Pre-dialysis blood volume was derived using anthropometric equations, then back-calculating the start of dialysis absolute blood volume based on the change in relative blood volume over the course of the treatment as measured by the Crit-Line® monitor and subtracting the saline infused (V_{saline} = 250ml). Saline's half-life was considered of 20min.

Results: 5731 hemodialysis treatments from 952 patients with $Hgb_{Spectra}$ and estimated $Hgb^{CritLine}_{corrected}$ measurements were analyzed. Hgb_{offset} average was –0.068g/dL, the standard deviation 0.59g/dL, and the bias -0.07g/dL. To asses the comparability between $Hgb^{CritLine}_{corrected}$ and $Hgb_{Spectra}$ measurements, the Hgb_{offset} was plotted against the mean of the two measurements in a Bland-Altman plot.

Conclusions: With Crit-Line Hgb correction for hemodilution, the $Hbg_{CritLine}$ values are on average identical to the $Hgb_{Spectra}$ and they share similar accuracy. This could be an opportunity in the future to replace Hgb laboratory measurements in the management of anemia.

Intradialytic Exercise Preconditioning: The Effect on Myocardial Stunning

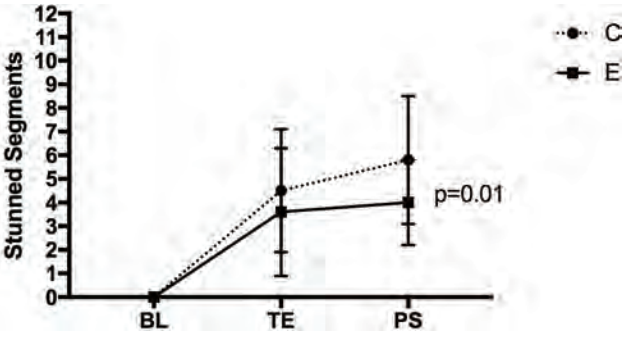
Jarrin D. Penny,[2,1] Fabio R. Salerno,[2,1] Ranveer S. Brar,[4] Eric Garcia,[3] Krista F. Rossum,[3] Christopher W. McIntyre,[2,1] Clara Bohm.[3] *[1]Nephrology, London Health Sciences Centre, London, ON, Canada; [2]The Lilibeth Caberto Kidney Clinical Research unit, University of Western Ontario, London, ON, Canada; [3]University of Manitoba, Winnipeg, MB, Canada; [4]Seven Oaks General Hospital, Winnipeg, MB, Canada.*

Background: Exercise preconditioning provides immediate protection against cardiac ischemia in clinical and pre-clinical studies. Intradialytic exercise (IDE) has been utilized to improve functional status in individuals receiving HD. The effect of intradialytic exercise on myocardial stunning is unknown.

Methods: 19 adult patients participating in a clinical IDE program were evaluated over 2 HD sessions (control visit - no exercise, exposure visit - exercise). Echocardiography was performed, pre-HD, post exercise and at peak HD stress in each visit. Longitudinal strain (LS) for 12 left ventricular segments were generated using speckle-tracking software [EchoPac, GE], to assess the presence of HD-induced regional wall motion abnormalities (RWMA), indicative of myocardial stunning (>20% reduction in LS in two or more segments).

Results: Mean age was 59.2 and participants were 40% female with median dialysis vintage of 3.8 years. The number of stunned segments at usual exercise time was 4.5 (SD2.6) and 3.9 (SD2.8) in the control and exercise groups, respectively; p=0.168. The number of stunned segments at peak HD stress was 5.8 (SD2.7) and 4.0 (SD 1.8) in the control and exposed groups, respectively; p=0.012. Mean change in number of stunned segments post exercise between control and exposure sessions was -0.95 (SD 2.88). Mean change in number of stunned segments at peak HD was -1.8 (SD 2.8).

Conclusions: IDE significantly reduced HD-induced myocardial stunning at peak HD stress and was not associated with a reduction in intradialytic hypotension.



Number of RWMA at each echo timepoint(BL = baseline, TE = time of exercise, PS = peak stress)

The Effects of Intradialytic Exercise on the Improvement of Daily Physical Activity in Online Hemodiafiltration Patients

Nawaporn Assawasaksakul,[1] Khajohn Tiranathanagul,[5] Worawan Sirichana,[4] Onanong Kulaputana,[3] Somchai Eiam-Ong,[2] Kearkiat Praditpornsilpa.[2] *[1]Chulalongkorn university, Bangkok, Thailand; [2]Chulalongkorn University, Bangkok, Thailand; [3]chulalongkorn university, Bangkok, Thailand; [4]chulalongkorn, Bangkok, Thailand; [5]Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand.*

Background: The mortality of hemodialysis (HD) patients treated with the novel online hemodiafiltration (OL-HDF) is better than conventional HD but is still higher than the healthy population. A low level of daily physical activity, associated with sarcopenia, uremic toxins, and functional impairment correlates with increased cardiovascular mortality. The effect of adding the intradialytic exercise program to improve daily physical activity and overall health status in patients particularly with online hemodiafiltration technique has yet to be explored.

Methods: Twelve OL-HDF treated patients (age 53.1±14.5 years, BMI 23.23 ± 5.5 kg/m^2) were randomly assigned to control or adding intradialytic exercise (IDX) group. The subjects in IDX group were trained with the customized exercise program to exercise, initiated by a multidisciplinary team, on a cycle ergometer (Figure 1) within the first hour of OL-HDF. Physical activity was measured in terms of the number of daily steps counted by a wrist-worn wearable triaxial accelerometer (Fitbit flex2®). The muscle mass and biochemical parameters were measured and compared at baseline and 6 months.

Results: The baseline physical activities measured by daily step count were 5,945±3715 and 6525±5389 steps (NS) in IDX and control groups, respectively. At 6 months, improvement of physical activity level in IDX group was greater than that in the control group (+1956.2 ± 2164.18 vs. -1302.92 ± 1956.03 steps, P = 0.021). The muscle mass changes were slightly higher, though non-significant, in IDX group [0.59 (IQR -0.58, 1.46) vs. -1.49 (-2.14, 0.28) kg., P=0.200]. Hemoglobin (+1.0 (-0.1,2.7) vs. -1.4 (-3.4,0.2) g/dL, P= 0.025) and albumin (+0.30(0.08, 0.50) vs. -0.15(-0.28, 0.05) g/dL, P=0.012) increased in IDX compared with the control group. The phosphate reduction was more favorable in IDX group (-1.95 (-2.80, -0.63) vs. -0.50 (-0.88,0.55), P=0.037).

Conclusions: Intradialytic exercise training as the add-on program for OL-HDF patients could improve daily physical activity as well as muscle mass and other metabolic controls. The regular intradialytic exercise program may contribute to reverse inactive behaviors and further improvement in the quality of life and cardiovascular mortality of dialysis patients.

Pedometers and Exercise in Dialysis

Anoop Sheshadri,[1] Piyawan Kittiskulnam,[3] Kirsten L. Johansen.[2] *[1]Nephrology, University of California, San Francisco, San Francisco, CA; [2]University of California, San Franicsco, San Francisco, CA; [3]Chulalongkorn university, Bangkok, Thailand.*

Background: Dialysis patients report very low levels of physical activity. We conducted a study using a pedometer based intervention to investigate whether it would result in increased physical activity and whether increasing activity could improve physical and endothelial function, heart rate variability (HRV), and symptom severity.

Methods: We conducted a randomized controlled trial of 60 patients receiving HD or PD. Patients were given a pedometer and instructed to record steps for one week. Patients were then randomized to either standard of care or a 12-week intervention program during which they were asked to record steps and given weekly activity goals. At baseline, 12 weeks, and 24 weeks (3 months after the intervention), we assessed physical function (SF-36 Physical Function scores, Short Physical Performance Battery), endothelial function (reactive hyperemia index with peripheral arterial tonometry), HRV, and symptoms (Dialysis Symptoms Index [DSI], KDQOL Vitality score).

Results: At 3 months, patients in the intervention increased average daily step count by 2,060 (95% CI 80; 4,060) compared to controls, though physical function, endothelial function, HRV, and symptoms did not change significantly. However, patients reverted to baseline levels of activity 3 months after the intervention. In post-hoc analyses increases in step count were associated with decreases in symptom burden (-0.38 symptoms on DSI per 1,000 steps), symptom severity (-1.34 points on DSI score per 1,000 steps), fatigue (2.33 points on KDQOL Vitality score per 1,000 steps), and increased HRV (2.29 ms SDNN per 1,000 steps).

Conclusions: Dialysis patients can effectively use pedometers to increase physical activity but may need continued counselling in order to maintain increases. We found preliminary evidence that increasing step counts may also lead to improvements in symptoms and heart rate variability.

The Acute Effects of Intra-Dialytic Exercise on Arterial and Central Venous Oxygen Saturation and Oxygen Extraction Ratio

Diana Aguirre,[1] Daniel E. Ayala,[1] Armando Vazquez Avila,[1] Jesus Arellano,[1] Luis A. Mariscal,[2,1] Victor H. Gomez,[1] Israel Campos.[2,1] *[1]Hospital General "Dr. Miguel Silva", Morelia, Mexico; [2]NausLife Hemodialysis Clinics, Morelia, Michoacán, Mexico.*

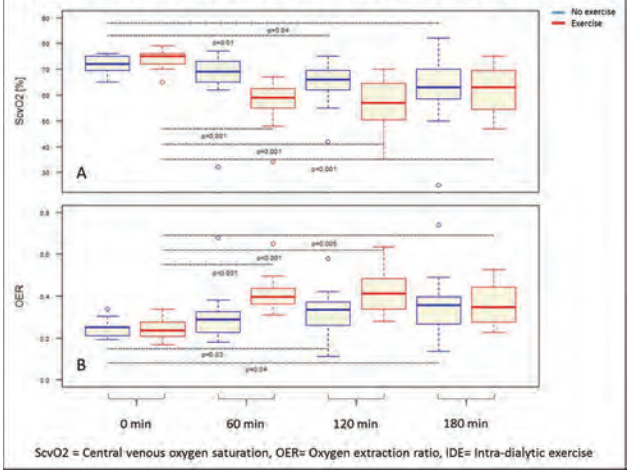
Background: Intra-dialytic exercise (IDE) improves cardiovascular function, physical function and quality of life. Arterial (SaO2) and central venous oxygen saturation (ScvO2) can be measured during hemodialysis (HD). The oxygen extraction ratio (OER) is the result from: SaO2-ScvO2/SaO2; its increment during HD has been associated with a higher mortality. The aim of this study was to explore the acute effects of IDE on SaO2, ScvO2 and OER.

Methods: Crossover study in maintenance adult HD patients. The ScvO2 by gas analyzer and SaO2 by pulse-oximetry were measured at 0, 60, 120 and 180 minutes during one HD treatment without IDE, same measurements were repeated in one HD treatment with IDE. The SaO2, ScvO2 and OER were compared at each time point and between treatments.

Results: 11 patients (22 HD treatments) were analyzed. The ScvO2 and OER trend during HD with and without IDE are reported (Figure 1). The ScvO2 median (P25, P75) with vs without IDE at 60 and 120 min were 59(55, 62.5) vs 69(65, 73) p=0.005; and 57(50.5, 64.5) vs 66(62, 69.5) p=0.04, respectively. OER median (P25, P75) with vs without IDE at 60 and 120 min were 0.39(0.36, 0.43) vs 0.28(0.22, 0.32) p=0.005, and 0.41(0.43, 0.48) vs 0.33(0.25, 0.37) p=0.05, respectively, no differences were found in SaO2.

Conclusions: The ScvO2 decreases during HD, this decline is deeper during IDE compare to non-exercise treatments. OER increases during HD and is higher during IDE compare to non-exercise treatments. Further studies are required to elucidate the oxygen dynamics during intra-dialytic exercise.

Figure 1. ScvO2 and OER trend across HD treatment with and without IDE



ScvO2 = Central venous oxygen saturation, OER= Oxygen extraction ratio, IDE= Intra-dialytic exercise

SA-PO881

Exercise During Dialysis Ameliorates the Decline in Plasma Volume by Ultrafiltration

Jose Manuel R. Chagolla,[1] Monica Sanchez cardenas,[3] Hector A. Perez-grovas.[2] Instituto nacional de cardiología "Ignacio Chávez" *[1]Nephrology, Instituto nacional de cardiología, México City, Mexico; [2]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico; [3]UNAM, CIUDAD DE MEXICO, Mexico.*

Background: Patients in hemodialysis (HD) remove the excess of water and Na+ by ultrafiltration (UF) that leads to an increase of hypotensive (Ht) episodes by a decline in circulating blood volumen (CBV). Exercise (EXE) leads an increase of CBV by mechanisms like redistribution of CBV and sympathetic activation. We evaluate the effects of acute moderate aerobic EXE in CBV during UF in comparison with sessions without EXE.

Methods: 19 CKD patients in regular HD (11 women, Age 40±6) were randomized for one HD session with EXE by bicycle pedaling without resistance in sitting position (P) during all the session or sedentary HD session (one in sitting P, in recumbent P or recumbent P with elastic socks). All patients received the four different sessions with BVM in line during all the session with exactly the same UF rate. Besides blood pressure and heart rate were registered.

Results: We observed a lesser decline in CBV in the EXE HD session in comparison with sedentary HD. The difference were stadistically significant ($p<0.001$). In EXE HD we observed lesser Ht episodes (0 vs 13), and the fall in systolic and dyastolic pressure at the end of the session were lesser in EXE HD (-3 vs. 3.6 and -0.4 vs. 1.9 mmHg). Incidentally, it was observed that the effect of EXE during dialysis on the decline in CBV was clearer among males.

Conclusions: EXE during dialysis ameliorate the decline in plama volume by UF, especially in men.

Low BMI Is Associated with Higher Risk of Frequent Intradialytic Hypertension

Maurilo Leite,[1] Thays C. Pereira,[1] Renata M. Rodrigues,[1] Mahesh Krishnan.[2]
[1]DaVita-Brazil, Rio De Janeiro, Brazil; [2]DaVita, Inc, Denver, CO.

Background: Intradialytic hypertension (IDH) has been associated with high mortality and morbidity among hemodialysis (HD) patients. Factors such as fluid overload, dialysate sodium, clearance of anti-hypertensive drugs, and an endothelin effect have all been suggested to affect IDH. However, IDH has not been uniformly characterized: studies have defined IDH as a post-HD increase in systolic arterial pressure (SAP) occurring with differing monthly frequency. In this study we examined the associations between BMI and IDH ocurring with various monthly frequencies.

Methods: We followed 217 patients who were stable on HD for at least 90 days and evaluated the number of dialysis treatments affected by IDH (defined as pre- to post-HD increase in SAP of ≥ 10 mmHg, reaching values ≥ 140/90 mmHg) over 90 days. We assessed associations of IDH frequency (% of treatments affected) with patient gender, age, race, time on HD, as well as with hospitalizations and mortality over 6 months. Patients were stratified into 5 groups based on BMI (< 18.5, 18.5 to 24.9, 25 to 29.9, 30 to 35, and > 35 kg/m^2); numbers of patients experiencing IDH in at least 5% or at least 50% of treatments were assessed for each BMI group. Statistical tests applied were Chi-square and Pearson correlation.

Results: We found no significant correlation between IDH frequency and patient gender, age, or race. However, we found a positive correlation between IDH frequency and time on dialysis (r=0.17, *P*<0.01). No association of IDH frequency with hospitalization or mortality was observed. 78% of patients with BMI < 35 kg/m^{2}experienced IDH during at least 5% of treatments, compared with 100% of patients with BMI > 35 kg/m^2. In contrast, the proportion of patients who had 50% or more of treatments affected by IDH was strongly associated with BMI < 18.5 kg/m^2; RR: 3.2 (2.7-4.6).

Conclusions: Monthly frequency of IDH, observed over a period of 90 days in HD patients, was found to be slightly correlated with time on dialysis. Patients with BMI > 35 kg/m^2 experienced at least 1 episode of IDH during follow-up; patients with BMI < 18.5 kg/m^2 presented higher risk for IDH affecting ≥ 50% of HD sessions. Frequent IDH may contribute to high cardiovascular mortality and morbidity in HD patients with longer time on dialysis and lower BMI.

Continuous Intra-Access Pressure (IAP) Monitoring Helps Predict Intradialytic Hypotension (IDH)

Gerard Zasuwa,[1] Jeffrey J. Sands,[3] Jerry Yee,[2] Stanley Frinak.[2] *[1]Henry Ford Health System, Detoit, MI; [2]Henry Ford Hospital, Detroit, MI; [3]Vasc-Alert LLC, Orlando, FL.*

Background: IDH is a frequent hemodialysis (HD) complication associated with increased patient morbidity and mortality. Reliable IDH prediction that facilitates early intervention may reduce HD morbidity. We conducted a preliminary study exploring the hypothesis that that continuous IAP measurement using the Vasc-Alert™algorithm (Am J Kidney Dis. 2002;40(4):760-768)can predict IDH during hemodialysis (HD).

Methods: Fresenius™T2 dialysis machines (DM) were equipped with onboard computers and customized software to calculate IAP at 20-second intervals via Vasc-Alert. 24 DMs were monitored during routine use during 3 daily shifts 6 days weekly. Treatment and relative blood volume data, collected by the CLiC™ device, was digitally acquired and stored. IDH episodes and measures to resolve them including repositioning, saline administration, and ultrafiltration rate adjustmentwere charted, abstracted, and mergedwith the electronic medical records. IAP waveform was correlated with IDH. Duration and rate of decline of IAPs from a moving average of 10 readings were analyzed.

Results: 1,272,290 DM data points were collected from 2,290 HD treatments. A total of 139 IDH events (6%) were recorded and analyzed, yielding an equation demonstrating a linear correlation between IDH and IAP slope:*y*= –1986*x*+ 1136.5;RSqr= 0.69). An IAP drop ≥20 mm Hg over 15 seconds correlated with impending BP decrements. A representative example is shown (figure) where IDH at 11:02 correlated with a BP reduction from 145/84 mm Hg to 113/69 mm Hg. Subsequent IDH episodes at 12:02 and 13:02 were associated with abrupt, significant IAP slope declines.

Conclusions: The IAP slope and prolonged IAP declines of 20 mm Hg or more correlate with IDH during HD. Future analysis of relative blood volume may facilitate development of a more powerfully predictive model of IDH.

SA-PO884

Intra-Dialytic Hypotension and Risk of Intra-Dialytic Cardiac Arrhythmia

Finnian R. McCausland,[1,2] Prabir Roy-Chaudhury,[3] James A. Tumlin,[5] David M. Charytan.[4] *[1]Renal, Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]University of Arizona, Tucson, AZ; [4]Brigham and Women's Hospital/Harvard Medical School, Brookline, MA; [5]NephroNet Clinical Trials Consortium, Atlanta, GA.*

Background: Patients with end-stage renal disease receiving hemodialysis (HD) are at high risk of adverse cardiac events, including arrhythmia and sudden cardiac death. Intra-dialytic hypotension (IDH) is a common complication of HD and is associated with development of reduced myocardial perfusion, but its association with cardiac arrhythmia is unclear.

Methods: The Monitoring in Dialysis (MiD) study used implantable loop recorders to detect and continuously record all electrocardiographic data from maintenance HD patients (n=66 from the United States and India) over a six-month period. Negative binomial mixed effects regression models were fit to determine the association of IDH (decline in SBP >20 mmHg from pre-dialysis SBP) with the subsequent development of clinically significant arrhythmia (CSA) during the corresponding HD sessions.

Results: Average age was 56 years; 70% were male; and 65% were from the US. IDH occurred in 48% of 4,761 HD sessions, while 1.3% of total sessions were complicated by development of at least one intra-dialytic CSA. Participants who experienced IDH (vs. those with SBP decline ≤0mmHg) had a 9-fold greater rate of developing an intra-dialytic CSA (IRR 9.4; 95%CI 3.0-29.4).

Conclusions: IDH is common in maintenance HD patients and is associated with a greater risk of developing intra-dialytic CSA. Future studies investigating the effect of interventions to minimize IDH may wish to incorporate arrhythmia as a clinically relevant end-point.

Midodrine Is Effective in the Management of Intradialytic Hypotension Among Critically-Ill Patients with AKI (A Randomized Clinical Trial

Mahmoud H. Imam,[1] Mohammed Shawki,[1] Tareq Essawy.[2] *[1]Internal Medicine Department, Faculty of medicine,Benha University, Benha, Egypt; [2]Chest medicine Department, Faculty of medicine,Benha University, Benha, Egypt.*

Background: Intradialytic hypotension commonly occurs among critically ill patients. Different tools were exploited to mitigate IDH. Midodrine showed promising results in small interventional studies. There was no randomized clinical trial to assess the efficacy

of midodrine. This study aims to evaluate the effectiveness of midodrine in a randomized placebo-controlled study among critically ill patients.

Methods: Eighty intensive care unit patients were eligible for this study. After IDH episode, they were randomized to either midodrine tablets or placebo. The count of IDH episodes, systolic blood pressure (SBP) and diastolic blood pressure (DBP) and lowest blood pressure were recorded. Mortality and adverse effects were recorded for both groups. The duration of the study was 30 days.

Results: eventy-five patients completed the study. Midodrine significantly decreased the count of IDH episodes. Both SBP and DBP were significantly higher among midodrine group. There was a reduction in mortality with midodrine therapy; the reduction was statistically insignificant (p = 0.43). The drug was tolerable with no adverse effects.

Conclusions: Oral midodrine therapy yielded beneficial results and was an adequate tool for management of IDH among critically-ill patients with the AKI.

SA-PO886

Midodrine in the Context of Intradialytic Hypotension: Association with Outcomes

Steven M. Brunelli,[1,2] Dena E. Cohen,[1,2] Gilbert Marlowe,[1,2] David B. Van Wyck.[2] *[1]DaVita Clinical Research, Minneapolis, MN; [2]DaVita Institute for Patient Safety, Denver, CO.*

Background: Intradialytic hypotension (IDH) is a frequent complication of hemodialysis, and is associated with significant morbidity and mortality. Off-label use of the alpha-1 andrenergic receptor agonist midodrine to reduce the frequency and severity of IDH is common. Small-scale clinical trial data support this practice; however, limited data exist with regard to real-world efficacy.

Methods: In this retrospective, observational study, clinical and hemodynamic outcomes were compared among patients who began midodrine (N=1046) and controls (N=2037) to whom they were matched on the basis of baseline pre-dialysis blood pressure, nadir intra-dialytic blood pressure and the frequency of intradialytic hypotension, all of whom were adults receiving in-center hemodialysis in the United States (July 2015-September 2016). All study data were derived from deidentified patient electronic health records. Outcomes were considered from the month following initiation of midodrine (or corresponding month for controls) until censoring for loss to follow-up or study end (30 September 2016). Outcomes were compared using adjusted Poisson or linear mixed models following intention-to-treat principles.

Results: Compared to non-use, midodrine use was associated with higher rates of death (adjusted incidence rate ratio 1.37, 95% confidence interval 1.15- 1.62), all-cause hospitalization (1.31, 1.19-1.43) and cardiovascular hospitalization (1.41, 1.17-1.71). With respect to hemodynamic outcomes, midodrine use tended to be associated with lower pre-dialysis systolic blood pressure (SBP), lower nadir SBP, greater fall in SBP during dialysis, and a greater proportion of treatments affected by IDH.

Conclusions: Although residual confounding may have influenced results, the observed associations are not consistent with a potent protective effect of midodrine with respect to either clinical or hemodynamic outcomes.

SA-PO887

Time-Specific Effects of Patient Factors on Intradialytic Systolic Blood Pressure Changes in Patients Receiving Maintenance Hemodialysis

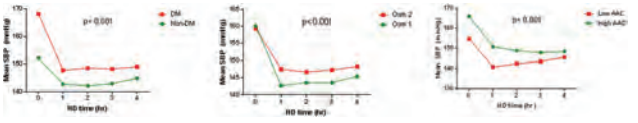
Sinae Lee,[1] Seoung Woo Lee.[2] *[1]Division of Nephrology and Hypertension, Incheon Medical Center, Incheon, Republic of Korea; [2]Division of Nephrology and Hypertension, Inha University Hospital, Inchon City, Republic of Korea.*

Background: Intradialytic systolic blood pressure (SBP) changes are affected by patient factors. However, the specific time point at which these factors predominantly affect blood pressure during a hemodialysis (HD) session is unknown.

Methods: Laboratory and HD data from previous 1 year were collected for 97 patients who were receiving maintenance HD. The subjects were classified into 2 groups according to diabetes mellitus (DM) status, abdominal aortic calcification (AAC) score, and the median values of serum hemoglobin (Hb), sodium (Na), albumin (Alb), and osmolality (Osm): DM vs. non-DM, high AAC (≥8) vs. low AAC (<8), Hb1 (≥10.17 g/dL) vs. Hb2(<10.17 g/dL), Na1(≥136.5 mEq/L) vs. Na2(<136.5 mEq/L), Alb1(≥3.93 g/dL) vs. Alb2(<3.93 g/dL), Osm1(≥312 mOsm/kg) vs. Osm2(<312 mOsm/kg). SBP measurements were standardized as SBP at 0 (SBP0), 1 (SBP1), 2 (SBP2), 3 (SBP3), and 4 (SBP4) hours. Intradialytic SBP changes were assessed on the basis of hourly SBP changes (ΔSBP_1: SBP0-SBP1, ΔSBP_2: SBP1-SBP2, ΔSBP_3: SBP2-SBP3, ΔSBP_4: SBP3-SBP4). Linear mixed regression analysis was used to identify patient factors associated with ΔSBP_1, ΔSBP_2, ΔSBP_3, and ΔSBP_4, respectively.

Results: The subject characteristics were as follows: number of females, 45; number of subjects with DM, 49; mean age, 59±15 years; HD duration, 69±64 months; AAC score, 8.0±7.7 (median, 6.0); and number of subjects with high AAC (≥8), 42. ΔSBP_1 was negatively associated with non-DM status (vs. DM) (β= -7.71, p=0.04), and positively associated with mean Hb level (β= 4.93, p=0.009). ΔSBP_2 was positively associated with high AAC (β= 5.22, p=0.001). ΔSBP_3 was positively associated with high AAC (β= 2.34, p=0.021), and negatively associated with mean albumin level (β= -4.19, p=0.044). ΔSBP_4 was positively associated with high AAC (β= 2.66, p=0.054), and negatively associated with mean Hb level (β= -2.90, p=0.008).

Conclusions: The effects of patient factors on intradialytic SBP changes during an HD session predominated at different time points and differed at an individual level.



SA-PO888

Intradialytic Hypotension in Hospitalized Patients: Does the Definition Matter?

Etienne Macedo, Bethany E. Karl, Euyhyun Lee, Lea D. Jacinto, Ravindra L. Mehta. *University of California San Diego Medical Center, La Jolla, CA.*

Background: Intradialytic hypotension (IDH) is a frequent, occurring from 15 to 50% of ambulatory sessions, and more frequent among hospitalized patients. Several complications can be associated with IDH: vascular access thrombosis, inadequate dialysis dose, fluid administration, early hemodialysis (HD) termination and mortality. Recently a large epidemiologic study, have shown that an absolute nadir systolic blood pressure (SBP)<90 mmHg was associated with mortality. However, several different definitions continue to be used in the literature and the clinical practice, preventing the appreciation of the effects of IDH and patient outcomes.

Methods: Patients from a prospective interventional study that included patients with albumin < 3 g/dl with AKI or ESRD who required fluid removal with HD were analyzed. Vital signs and ultrafiltration removal rate were recorded every 15 to 30 minutes during HD. The dialysis nurse recorded all symptoms associated with hypotension as well as interventions during the dialysis. We utilized 7 different classifications to determine hypotensive episodes.

Results: 65 patients completed 249 sessions; mean age was 58 (+/-12), 46 (70%) were male with a mean weight of 76 (+/-18) kg. Mean SBP and diastolic (DBP) at dialysis initiation were 126 (+/- 25) and 67.38 (+/-17), respectively. Presence of hypotension episode during a session varied from 12 (4.9%) to 111 (44%) according to the definition applied (Table). The HEMO definition, considering hypotension when an intervention results from an unspecific fall in BP, was more liberal, and occurred 50% more frequently than the KDOQI definition. Of the sessions with an absolute intradialytic nadir SBP<90 mmHg, only 30(56%) were followed by an intervention.

Conclusions: Intradialytic hypotension definitions that considered symptoms and interventions often miss episodes of hypotension that have been shown to be associated with increased mortality. Nadir based definitions of hypotension should trigger planned interventions and active questioning about symptoms, especially in hospitalized patients.

Funding: Commercial Support - Grifols

Intradialytic hypotension definition and frequency

Term	Definition	Sessions N(%)	Interventions N(%)
Nadir90	Min IHD SBP< 90 mmHg	53(21)	30(56)
KDOQI	Pre-HD SBP-min IHD ≥ 20 and symptoms of cramping, headache, lightheadedness, vomiting, or chest pain during HD	28(11)	18(64)
HEMO	Fall in SBP resulting in intervention of UF reduction, blood flow reduction, or saline administration	42(17)	42(100)

SA-PO889

Intradialytic Hemodynamics and Autonomic Activity in Patients Without and with Blood Pressure Instability

Dvora Rubinger, Michal Dranitzki Elhalel, Dan Sapoznikov. *Hadassah Hebrew University Medical Center, Jerusalem, Israel.*

Background: The present study was undertaken to assess the intradialytic hemodynamics and autonomic activity in patients (pts.) without (*stable*) and with frequent hypotensive episodes (*unstable*).

Methods: Beat-to-beat systolic blood pressure (SBP) and interbeat intervals (IBI) were monitored using Finometer during a single constant blood flow hemodialysis (HD) session in 14 *unstable* and 18 age-matched *stable* chronic non-diabetic HD pts. Stroke volume (SV), cardiac output (CO) and total peripheral resistance (TPR) were calculated using Modelflow simulation. LF/HF (the ratio of average IBI powers in the low (LF) and high (HF) frequency ranges) was considered to represent sympatho-vagal balance, whereas LF α (the ratio of IBI and SBP powers in the LF range) was considered to represent sympathetic activity. Positive correlation between IBI and SBP was considered representative of baroreflex

(*Baro)* activity. Repeated measures ANOVA was performed to assess time variations in both groups. Mixed design ANOVA was performed to assess differences in time variations between groups.

Results: During HD, SBP remained constant in both groups and there were no episodes of symptomatic hypotension. Comparable decreases in SV, CO and an increase in TPR were noted in all pts. LFα increased during HD in both *stable* and *unstable* groups. LF/HF increased in *unstable* and decreased in *stable* pts. *Baro* activity was predominant in the *stable* pts, in whom it consistently increased during HD, while in *unstable* pts. an increase in *Baro* activity was noted only at the beginning of dialysis (Figure 1).

Conclusions: Our data show that similar hemodynamic changes in *stable* and *unstable* pts are mediated by slightly different mechanisms. During HD, the sympatho-vagal balance is attenuated in *stable* and enhanced in *unstable* pts.SBP in *stable* seems to be predominantly controlled by *Baro*, while in *unstable* pts. SBP is controlled by both *Baro* and non-*Baro* mechanisms.

Blood Pressure Control and Days-in-Hospital Before and After Initiating Nocturnal In-Center Hemodialysis

Janice P. Lea,[3,2] Courtney E. Hoge,[1] Harold A. Franch,[3,2] Laura Plantinga,[2,1] Adam S. Wilk.[1] *[1]Rollins School of Public Health, Emory University, Atlanta, GA; [2]Emory University School of Medicine, Atlanta, GA; [3]Emory Dialysis Centers, Atlanta, GA.*

Background: Nocturnal dialysis (ND) can support longer sessions with lower ultrafiltration (UF) rates, compared to traditional in-center hemodialysis (HD). We compared UF rates, key blood pressure (BP) measures, and days hospitalized for ND patients before and after they initiated ND treatment.

Methods: We identified ND patients at a medium-sized dialysis organization to be those HD patients for whom ≥80% of dialysis sessions were ND sessions—starting at 6:30pm or later and lasted ≥5 hours—over the 3 months after their first ND session (≥20 sessions total) during 2010-16. Outpatient dialysis session and hospitalization dates were extracted for these patients within 12 months of ND transition (pre and post). BP measures included pre- and post-session sitting SBP and DBP, and minimum intradialytic SBP and DBP. Descriptive patient-month-level analyses of all outcomes were performed for all months with ≥7 sessions (i.e., still in care). We tested effects of ND care post-transition using generalized linear models with a Gaussian distribution and random intercepts and slopes; standard errors were clustered at the patient level.

Results: We identified 64 ND patients (4.7% of 1,357 eligible patients in care), with 354 pre-transition patient-months (3,974 sessions) and 496 post-transition patient-months (5,841 sessions). Post- vs pre-transition, we observed significant declines in UF rates (5.16 vs 9.34 mL/kg/hr, p<0.01), pre-SBP (154.1 vs 157.1 mmHg, p=0.05) and DBP (85.8 vs 88.0 mmHg, p=0.02), post-SBP (138.1 vs 142.6 mmHg, p<0.01) and DBP (77.0 vs 80.2 mmHg, p<0.01), and minimum intradialytic SBP (113.6 mmHg vs. 120.6 mmHg, p<0.01) and DBP (60.4 mmHg vs. 65.0 mmHg, p<0.01). We observed no change in hospitalized days per month (0.78 vs 0.82 days, p=0.80). Regression results accounting for patient-level clustering were similar, including a decline in UF rates (-3.57 mL/kg/hr, p<0.01) and no change in hospitalized days (-0.095 days, p=0.60) post-transition.

Conclusions: While patients experienced significant improvements in BP control both inter- and intradialytically after initiating ND treatment, we observed no change in their days hospitalized.

SA-PO891

Association Between Coronary Artery Calcification Density and Serum Magnesium Levels in Maintenance Hemodialysis (MHD) Patients

Yoshiko Nishizawa,[1] Sonoo Mizuiri,[1] Kyoka Ono,[1] Kazuomi Yamashita,[1] Kenichiro Shigemoto,[1] Takao Masaki.[2] *[1]Ichiyokai Harada Hospital, Hiroshima-shi, Japan; [2]Hiroshima University, Division of Nephrology, Hiroshima, Japan.*

Background: Coronary artery calcification score (CACS) is determined by the plaque area and density. In general population, calcified plaques with lower density are associated with higher risk of incident cardiovascular events, but report on calcification density in hemodialysis patients was scanty. This study aimed to analyze the association between coronary artery calcification density (CACD) and clinical parameters in MHD patients.

Methods: Methods: The subjects were 289 Japanese MHD patients. Total calcified area (area), CACD, CACS, laboratory parameters, and medication use were studied at baseline. The subjects were stratified into CACD level tertiles (T1–T3) and assessed by Kruskal-Wallis test. Regression analyses for CACD and CACS were examined, respectively. Independent variables were age, sex, diabetes, CVD, serum magnesium, phosphate, uric acid, C-reactive protein (CRP), low-density lipoprotein cholesterol (LDL-C) levels and use of proton pump inhibitors (PPI) or sevelamer hydrochloride. Spearman's correlations of the area and CACS or CACD were also analyzed, respectively.

Results: Among all patients, the mean age was 65±13 years, 37.2% were diabetics, and the median dialysis vintage was 72±99 months. The values of CACD of T1 (n=96), T2 (n=96), and T3 (n=97), were 3.61<, 3.62-3.89, and >3.90, respectively. The patients in T3 exhibited significantly higher serum magnesium, serum CRP and LDL-C levels (P<0.05). Multivariate regression analysis for CACD showed that age, diabetes, CVD [β 0.13, 95% confidence interval (CI) 0.00-0.12], and serum magnesium level [β 0.12, 95% CI (0.00-0.13)] were significantly related factors (P<0.05). While, multivariate regression analysis for CACS showed that age, diabetes, CVD [β 0.13, 95% CI 0.00-0.13], serum phosphate level [β 0.13, 95% CI (0.01-0.22)] were significantly related factors (P<0.05). CACS was correlated with total area (r = 013, P < 0.05), but the correlation between CACD and total area was not significant (r = 013, *P=0.07*).

Conclusions: CACD was significantly associated with serum magnesium levels, while CACS was significantly associated with serum phosphate levels in MHD patients. This may have a distinct clinical implication especially for coronary events.

SA-PO892

Pulmonary Artery Catheterization and Coronary Care Unit Location Predict Higher Incidence of Thrombocytopenia in Patients Receiving Continuous Veno-Venous Hemodialysis

Blaithin A. McMahon, Jan Griffin, Steven Menez, Anam Tariq, Yousuf Kyeso, Alice Chedid, Amr Habbach, Michael J. Choi. *Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Thrombocytopenia can occur in as much as 70% of patients receiving continuous renal replacement therapy (CRRT). The extent and temporal relation of thrombocytopenia is poorly understood. We recognized a high incidence of CRRT-related thrombocytopenia in the coronary care unit (CCU) at our institution. The purpose of our study was to compare the incidence of thrombocytopenia in patients receiving CRRT in the CCU and medical intensive care unit (MICU) and identify differences in risk factors for CRRT-related thrombocytopenia.

Methods: We performed a retrospective observational study of all patients admitted to the CCU and MICU of the Johns Hopkins Hospital who received CRRT for any reason between June 2010 to June 2017. Thrombocytopenia was defined as a decrease in platelet count of ≥ 50% within 72 hours of initiation of CRRT. The exclusion criteria included platelet count < 100 x 10^9 / liter prior to initiation of CRRT, decrease in platelet count of > 30% in the 48 hours prior to initiation of CRRT, duration of CRRT < 48 hours and death within 48 hours of CRRT initiation.

Results: We identified 795 patients who received CRRT in the CCU and MICU over a 7 year time period, 298 in the CCU and 497 in the MICU. 65 patients in the CCU and 67 patients in the MICU met inclusion criteria. The patients were well matched based on age, sex, race, comorbid illness and APACHE II score. There was a significant difference between the rates of those patients with a history of coronary artery disease (CAD) (55.8% vs 21.4%, P<0.001) and congestive heart failure (CHF) (84.9% vs 29.1%, P<0.001) in the CCU and MICU, respectively. Development of CRRT-related thrombocytopenia was seen in 22.5% of CCU patients compared to 13.9% of MICU patients. On adjusted MLoR, the odds ratio for development of thrombocytopenia-related CRRT based on CCU location was 2.5 (95% CI 1.4-4.5, P< 0.005). Patients with pulmonary artery catheterization were more likely to develop thrombocytopenia (OR 2.9; CI 1.1-7.9, P< 0.05).

Conclusions: The incidence of CRRT-related thrombocytopenia appears to be higher in the CCU as compared to the MICU. PA catheterization was significantly-associated with CRRT-related thrombocytopenia and requires further investigation.

Soluble Urokinase Plasminogen Activator Receptor Is Associated with Coronary Artery Calcification and Cardiovascular Disease in Patients Undergoing Hemodialysis

Ruyi Liao,[1] Wenjuan Wu,[1] Juan Hu,[1] Jianchao Ma,[1] Lixia Xu,[1] Zhiwen Liang,[1] Xueqin Chen,[1] Guibao Ke,[1] Xinling Liang,[2] Wei Shi,[1] Shuangxin Liu.[1] *[1]Guangdong General Hospital, Guangzhou, China; [2]Guangdong general hospital, Guangzhou, China.*

Background: Cardiovascular disease (CVD) is an important cause of morbidity and mortality in hemodialysis patients. Vascular calcification is thought to play an important role in causing CVD. Soluble urokinase plasminogen activator receptor (suPAR) is a biomarker strongly predictive of cardiovascular outcomes in the pathogenesis of diabetic patients with renal disease treated with hemodialysis. We investigated the relationship between suPAR and coronary artery calcification (CAC) in patients undergoing maintenance hemodialysis.

Methods: A total of 99 adult hemodialysis patients were enrolled in this study. Plasma samples were analyzed for suPAR with an enzyme-linked immunosorbent assay and the CAC score was determined with multidetector computed tomography. The occurrence of cardiovascular events and all-cause mortality during follow-up were recorded from January 1, 2010 to June 1, 2016.

Results: In 99 patients treated with maintenance hemodialysis, 91 (91.9%) had varying degrees of CAC, and suPAR correlated positively with the CAC score in a Spearman analysis. In a mean follow-up period of 33 months, 36 patients (36.4%) experienced at least one cardiovascular event. When the quartiles of suPAR concentrations were used as the cutoff points for a subgroup analysis, the incidence of CVD and all-cause mortality was much higher in the higher quartiles of suPAR. In a univariate Cox regression analysis, high suPAR was a risk factor for CVD and all-cause mortality.

Conclusions: suPAR is associated with the CAC score and is a risk factor for new-onset CVD in patients undergoing hemodialysis.

The Relationship Between Uric Acid and New-Onset Cardio-Cerebrovascular Disease in Maintenance Hemodialysis Patients

Wei Wang,[1] Yuehong Li,[2] Xianglan Wu.[3] *[1]Department of Nephrology, Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Beijing, China; [2]Department of Nephrology, Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Beijing, China; [3]Department of Nephrology, Beijing Tsinghua Changgung Hospital, School of Clinical Medicine, Tsinghua University, Beijing, China.*

Background: Serum uric acid (SUA) has been found to be a new marker of cardiovascular risk in patients with chronic kidney disease. In hemodialysis patients, the relevant studies are rare, and the conclusions were controversial. The aim of this study was to investigate the relationship between SUA and new-onset cardio-cerebrovascular disease in maintenance hemodialysis patients.

Methods: 96 maintenance hemodialysis patients who received hemodialysis more than 3 months were analyzed retrospectively between Aug. 2016 and Nov. 2017 in Beijing Tsinghua Changgung Hospital, including 66 males and 30 females. 44 (45.8%) patients had diabetes. The average age were 60.4±13.6 years (27 to 86 years old), and the average duration of dialysis was 3.0±3.5 years (6 months to 17 years). The basic characters of patients and new-onset cardio-cerebrovascular diseases during the period were recorded. Pre-dialysis laboratory tests were observed monthly. Patients were divided into two groups according to serum uric acid level as non-HUA group (155μmol/L<female≤357μmol/l or 208μmol/l<male≤428μmol/l), HUA group (>357μmol/l for female or >428μmol/L for male) respectively. SPSS 20.0 software was used to analyze the relationship between serum uric acid levels and new-onset cardio-cerebrovascular disease.

Results: 1. The mean pre-dialysis uric acid was 444.68±67.43umol/L, the prevalence of hyperuricemia was 68.75% (n=66). The prevalence of female (30, 100%) were significantly higher than male (36, 54.5%), $P<0.01$. 2. Multivariate logistic regression analysis showed that simultaneous hyperuricemia and diabetes were risk factors for new-onset cardio-cerebrovascular disease (OR=4.251, 95% CI 1.241-14.567, $P=0.021$). In diabetic patients, serum uric acid levels (OR=1.004, 95%CI 1.000-1.008, $P=0.040$) and ferritin (OR=1.022, 95% CI 1.004-1.041, $P=0.017$) were risk factor for new-onset cardio-cerebrovascular disease.

Conclusions: Higher serum uric acid was a risk factor for new-onset cardio-cerebrovascular disease in maintenance hemodialysis patients with diabetes.

SA-PO895

Mitral Annular Calcification (MAC) in Stage 5 CKD on Dialysis Therapy (CKD-5D)

Sidra Saleem,[2,1] Shahbaz Sarwar,[1] Haris Naveed,[1] Afshan Ittifaq,[1] Asad Mahmood,[1] Abeera Mansur.[1] *[1]DHMC, Lahore, Pakistan; [2]AIMC/JHL, Lahore, Pakistan.*

Background: MAC is a degenerative process involving the mitral valve and is a marker of advanced cardiovascular disease. Prevalence in the general population is upto 10% and increases in advanced age, females, systemic hypertension, hypercholesterolemia, diabetes mellitus (DM), atrial fibrillation, chronic kidney disease, end stage renal disease (upto 40%) and mitral valve prolapse. MAC has also been found in Egyptian mummies as a marker of atherosclerosis in the Horus study. The aims of this study were to assess the prevalence of MAC in CKD-5D patients and correlate with patients' characteristics.

Methods: Echocardiograms were obtained in 84 hemodialysis patients. Association of MAC with patient age, DM, Ischemic Heart Disease (IHD), duration of dialysis, smoking, dyslipidemia, serum calcium and phosphorus (PO4), Intact Parathyroid Hormone (iPTH) was studied. The individual highest values of serum PO4 and iPTH in the course of this study were used. Data was analysed using IBM SPSS v. 22.

Results: The mean age of the patients was 63.38 ± 12.3 years and 48(57%) were males. 36(43%) patients were females. 68 patients(81%) had DM and 79(94%) had hypertension. MAC was present in 37 out of 84(44%) patients. 64(72%) were diagnosed with IHD. The presence of MAC correlated significantly with IHD(Odds Ratio 6.42, p = 0.006). Mean follow up of the patients was 30.30 ±29.22 months and 37(44%) of the patients suffered mortality during this period. Patients who had been on dialysis for longer than 36 months were also found to be at elevated risk of developing MAC (OR=3.32, p=0.019). Among these findings we also saw that patients with the following risk factors: serum PO4 greater than 5.5 (OR=2.03), DM (OR=1.95), HTN (OR=3.35), Age >60 (OR=1.83), AFIB (OR=1.28); had an observable increase in incidence of MAC with time but they weren't statistically significant. There was no correlation between MAC and serum Calcium and iPTH.

Conclusions: MAC is common in hemodialysis patients and correlates significantly with IHD. Etiology of MAC in ESRD is multifactorial and needs to be analyzed further. Our findings support the recommendation by Kidney Disease Improving Global Outcomes (KDIGO) 2017 guidelines on Mineral and Bone Disease on the use of echocardiography for the detection of valvular calcification.

SA-PO896

Involvements of AGEs on Vascular Calcification in Hemodialysis Patients

Hajime Nagasawa,[1] Seiji Ueda,[1] Takashi Kobayashi,[1] Yasuhiko Kanaguchi,[1] Sho-ichi Yamagishi,[2] Yusuke Suzuki.[1] *[1]Nephrology, Juntendo University Faculty of Medicine, TOKYO, Japan; [2]Nephrology, Kurume University Faculty of Medicine, Kurume, Japan.*

Background: Vascular calcification is one of the strong risk factors for cardiovascular events and mortality in chronic kidney disease (CKD) patients. Advanced glycation end products (AGEs) are known to be accumulated in diabetes and/ or CKD patients and contributing to the development of vascular complications such as the arteriosclerosis and vascular calcification. However, the mechanisms why and how AGEs are increased in patients with hemodialysis and its precise roles on the development of vascular calcification are remained to be elucidated.

Methods: To address this issue, we investigate the relationship among the serum levels of AGEs and metabolic factors in 37 chronic hemodialysis patients in our hospital. We also evaluated the relationship between AGEs levels and vascular calcification assessed by agaston score and abdominal aorta calcification score (ACI) in the abdominal CT.

Results: Serum AGEs levels are significantly associated with not only age, presence of diabetes and peripheral artery disease (PAD), geriatric nutritional risk index (GNRI), and inflammatory markers such as IL-6, TNF-alpha but also agaston score and ACI. Moreover, retrospective analysis reveals that annual increasing rates of vascular calcification score are tended to be associated with AGEs in addition to age, presence of diabetes, and TNF-alpha levels.

Conclusions: These observations strongly suggest that chronic inflammatory responses may be involved in AGEs formation in chronic hemodialysis patients and accumulated AGEs may contribute to the development of vascular calcification and cardiovascular disease such as PAD.

SA-PO897

Performance of Stroke Risk Scores in Dialysis Patients

Gurbey Ocak,[1] Maarten B. Rookmaaker,[1] Peter J. Blankestijn,[1] Marianne C. Verhaar,[1] Friedo W. Dekker,[2] Merel Van diepen.[2] *[1]Department of Nephrology and Hypertension, University Medical Center Utrecht, Utrecht, Netherlands; [2]Department of Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands.*

Background: Dialysis patients have an increased ischemic stroke risk. Stroke risk scores, including the CHADS2, ATRIA and CHA2DS2VASC, have been developed to identify patients with an increased stroke risk in patients with atrial fibrillation allowing for personalization of vitamin K antagonist prescription. In the original articles, CHADS2 (C-statistic 0.82), ATRIA (C-statistic 0.73) and CHA2DS2VASC (C-statistic 0.67) had reasonable predictive abilities. However, the predictive performances of these stroke risk scores have not been validated in dialysis patients. Therefore, the aim of this study was to validate existing stroke risk scores in dialysis patients.

Methods: A total of 755 incident dialysis patients from the NECOSAD study were prospectively followed for validated ischemic stroke within five years of dialysis. Hazard ratios with 95% confidence intervals (CIs) were calculated using Cox proportional hazards analyses for high and intermediate risk scores as compared with low risk scores for the CHADS2 (low risk= 0, intermediate risk=1-2 and high risk= ≥3), ATRIA (low risk= 0-5, intermediate risk=6 and high risk=≥7) and the CHA2DS2VASC (low risk= 0, intermediate risk=1 and high risk= ≥2). Furthermore, we evaluated the discriminative performance of these bleeding risk groups by calculating Harrell's C-statistics.

Results: During a median follow-up of 2.0 years (interquartile range 0.9-3.7), 58 (7.7% of all patients) first ischemic stroke events occurred. Of the 755 patients, 14% were classified as high risk by the CHADS2, 28% by the ATRIA and 72% by the CHA2DS2VASC. A high risk score as compared with a low risk score was associated with a 8.2-fold (95% CI 1.1-63.1) increased ischemic stroke risk for the CHADS2 and a 2.2-fold (95% CI 1.3-3.9)

increased ischemic stroke risk for the ATRIA. A high CHA2DS2VASC risk score as compared with an intermediate risk score was associated with a 8.7-fold (2.1-35.7) increased ischemic stroke (no stroke events in low risk group). The C-statistics were **0.59** for the CHADS2, **0.61** for the ATRIA and **0.62** for the CHA2DS2VASC.

Conclusions: In this prospective cohort with validated data on ischemic stroke, we showed that the CHADS2, ATRIA and CHA2DS2VASC had poor predictive abilities. Therefore, these stroke risk scores may not be useful for guiding individual decision-making in dialysis patients.

SA-PO898

DNA Methylation of Klotho Promotor Gene Is Associated with Cardiovascular Disease and Malnutrition in Patients Under Hemodialysis

Hirokazu Honda,[1] Yasuna Kobayashi,[2] Seiki Aruga,[3] Daijiro Uetake,[4] Takanori Shibata.[5] *[1]Showa University Koto Toyosu Hospital, Tokyo, Japan; [2]Niigata University of Pharmaceutical Sciences, Niigata, Japan; [3]Monnaka Jin Clinic, Tokyo, Japan; [4]Toyosu Jin Clinic, Tokyo, Japan; [5]Showa University School of Medicine, Tokyo, Japan.*

Background: Cardiovascular disease (CVD) and protein-energy wasting are common in patients under hemodialysis (HD). While multiple factors are associated with those comorbidities, we hypothesized that gene silencing, including alteration of epigenome might influence the comorbidities in HD patients. Thus, the aim of this ongoing study is to assess the prevalence of epigenetic modifications of Klotho, aging-related genes, and its association of comorbidities.

Methods: Whole blood samples were drawn in 131 prevalent HD patients and genomic DNA were purified from white blood cells. Epigenetic modifications of Klotho promotor gene were defined by methylation of CpG sites. Extracted DNA were modified by bisulfate treatment and then the methylated sequences were selectively amplified by methylation-specific PCR. The products were visualized by agarose gels and were quantified. Patient characteristics, complication and baseline laboratory data were recorded.

Results: Epigenetic analysis had performed in one hundred and twenty-five patients of 131. Of 125, 48 patients showed the DNA methylation of Klotho promotor gene. Patients with Klotho gene methylation had high prevalence rate of CVD such as acute coronary syndrome and myocardial infarction, and low levels of serum albumin and creatinine and geriatric nutritional risk index compared with those without Klotho gene methylation.

Conclusions: Epigenetic modifications of Klotho promotor gene may be associated with CVD complication and malnutrition in patients under HD.

SA-PO899

Blood Myostatin Levels Are Related with Abdominal Aortic Calcification in Dialysis Patients

Su mi Lee,[1] Yun Jung Oh,[2] Young ki Son,[1] Seong Eun Kim,[3] Won Suk An.[1] *[1]Dong-A University, Busan, Republic of Korea; [2]Cheju Halla General Hospital, Jeju, Republic of Korea; [3]Dong-A University Hospital, Busan, Republic of Korea.*

Background: Myostatin which is a member of the transforming growth factor-β superfamily, regulates synthesis and degradation of skeletal muscle protein and it is up-regulated in the skeletal muscle of chronic kidney disease (CKD) patients. There are few studies on relationship between myostatin levels and vascular calcification, important risk factors for cardiovascular disease in CKD. The aim of this study was to assess the association between serum myostatin levels and abdominal aortic calcification (AAC) in patients with dialysis.

Methods: In this cross-sectional study, 71 outpatients undergoing dialysis were included. We assessed AAC semiquantitatively from the lateral lumbar spine obtained using plain radiograph. Serum myostatin level was determined by commercially available enzyme-linked immunosorbent assay and divided by median for analysis.

Results: Our study included 37 hemodialysis patients and 34 peritoneal dialysis (PD) patients with a median age of 59.0 years and a median myostatin level of 4991.4 pg/mL. Patients with low myostatin level were older and had a higher proportion of men, PD, and AAC scores ≥ 5 than those with high myostatin level. The median myostatin level for patients with AAC scores ≥ 5 was 4073.5 pg/mL, whereas that for AAC scores <5 was 5838.6 pg/mL. Age and AAC scores showed a significantly negative correlation with myostatin levels. After adjustment for potential confounding factors, including age, gender, diabetes mellitus, dialysis vintage, dialysis modality, osteoprotegerin, and AAC score ≥ 5, the presence of AAC was significantly and negatively associated with serum myostatin levels.

Conclusions: Low serum myostatin levels were associated with elevated AAC scores in dialysis patients. Further studies are necessary to determine the significance of measuring serum myostatin level in patient with dialysis.

SA-PO900

A Global Study Assessing Albumin Levels on Expanded Hemodialysis

Colin A. Hutchison,[5] Marc Dorval,[6] Maria Eugenia F. Canziani,[1] Mohamed Belmouaz,[4] Jyoti B. Baharani,[3] Claudio Ronco.[2] *[1]Federal University of Sao Paulo, Sao Paulo, Brazil; [2]Ospedale "S. Bortolo" AZ. ULSS 6, Vicenza, Italy; [3]Heart of England Foundation Trust, Birmingham, United Kingdom; [4]Service Nephrologie, Poitiers, France; [5]Nephrology, Hawke's Bay DHB, Hastings, New Zealand; [6]Nephrology, Dr. Georges-L.-Dumont University Hospital Centre, Moncton, NB, Canada.*

Background: Expanded hemodialysis (expHD) utilises a new form of hemodialysis membranes which enable more effective removal of middle and large molecular weight uremic toxins. These medium cut-off (MCO) membranes have pores which are significantly larger and more uniform than conventional high flux dialysis membranes but have the potential to allow some albumin leak. The purpose of this study was to assess expHD's effect on patients' pre-dialysis serum albumin levels over 6 months.

Methods: Patients receiving expHD were identified from dialysis centres in North and South America, Europe and Australasia. Details of basic demographics, dialysis prescription, laboratory parameters and recombinant erythropoietin dose were captured retrospectively.

Results: Data was available for 56 patients from 5 centres in Brazil, Canada, France, Italy, New Zealand and the United Kingdom. Median age was 67 years (range 23-91), 69% were male, 41% were diabetic, average time on hemodialysis was 55 months (10-215); median dry weight was 76 kg (44-124). 55% received dialysis on the larger MCO membrane dialyzer (Theranova 500 ©). Average dialysis prescription was: 4 hours (range 4-5.5) with Qb 300 ml/min (250-400) delivering an average Kt/V of 1.4 (1-2.5). Pre-dialysis serum albumin levels over the study period are presented in the table. No significant changes in albumin levels at 3 or 6 months from baseline are observed, p=0.42 and 0.66 respectively. CRP and haemoglobin levels were 4 mg/L (1.5-16) and 11 g/dL (8.2-14.2) pre-MCO use and 6 (1.5-25) and 11.3 (8.1-13) at 6 months respectively. Recombinant erythropoeitin dose increased in 15%, remained the same in 35% and decreased in 50% of participants over the observation period.

Conclusions: ExpHD did not result in any significant change in pre-dialysis serum albumin concentrations over 6 months treatment. Over this observation period, inflammatory markers and haemoglobin levels were stable but of potential interest 50% of the population had a reduction in erythropoietin dose.

Serum albumin levels

	Serum albumin (g/dL)			
	Pre-MCO	1 month	3 months	6 months
Median	3.7	3.5	3.6	3.7
Min	2.8	2.8	2.9	2.8
Max	4.5	4.6	4.5	5.1

Outcome of Open Heart Surgery in ESRD Patients: A Single Center Experience for 16 Years

Ji-Young Choi, Kye hwa Jeong, Jeong-Hoon Lim, Kyung hee Lee, Min jung Kim, Hee-Yeon Jung, Jang-Hee Cho, Chan-Duck Kim, Yong-Lim Kim, Sun-Hee Park. *School of Medicine, Kyungpook National University, Daegu, Republic of Korea.*

Background: Mortality risk for cardiovascular disease is extremely high in ESRD patients. Nevertheless, dialysis patients are often undertreated due to the higher risk of operation or intervention compared to the general population. However, there are few studies comparing postoperative mortality and morbidity between dialysis and non-dialysis patients in Korea.

Methods: A retrospective analysis of 2,432 patients who underwent open heart surgery from 2002 to 2017 was performed to determine the mortality and morbidity after cardiac surgery in dialysis patients. Of total patients, we obtained comorbidities, NYHA classification, laboratory data, surgical method and postoperative outcomes from the two groups; dialysis group consisting of 38 patients with ESRD undergoing maintenance dialysis and control group consisting of 78 age-, sex-, and status of diabetes- matched control with normal kidney function.

Results: Dialysis group showed significantly higher postoperative mortality rate compared to the control group (18.4% versus 2.6%, P= 0.005). Dialysis group presented with more comorbidities, worse functional class of heart failure than control group. Urgent operation was more frequent (68.4% vs 32.1%, P = 0.000) in dialysis group, but there were no differences in the type of procedure between both groups. The postoperative hospitalization and time in ventilator were significantly increased in dialysis group (OR 4.631, P = 0.034; OR 7.617, P= 0.002). However, there were no significant difference in complication rate including rate of pneumonia, sepsis, stroke, wound infection, arrhythmia, bleeding, heart failure, except pulmonary edema and postoperative CRRT.

Conclusions: Dialysis patients showed higher in-hospital mortality rate compared to the control patients. The duration of postoperative hospitalization and time in ventilator were significantly increased in dialysis group. In dialysis patients, various comorbidities as well as dialysis itself may have contributed to the increase in hospital mortality. However, postoperative complications related to surgery were not significantly different between the two groups.

SA-PO902

The Hemodialysis Outcome Assessment: Troponin I Measurement Study

David T. Collister,[3,1] Andrea E. Mazzetti,[4] Anuja Bhalerao,[3] Peter Kavsak,[2] K. S. Brimble,[3,1] Michael Walsh.[3,1] *[1]Medicine, McMaster University, Hamilton, ON, Canada; [2]Juravinski Hospital and Cancer Centre, Hamilton, ON, Canada; [3]Nephrology, St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada; [4]St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada.*

Background: The impact of hemodialysis (HD) on cardiac biomarkers is unclear. The objectives of this study were to 1) To evaluate the intradialytic variability of high sensitivity troponin I (hs-TnI), galectin 3 (gal3) and human fatty acid binding protein (hfabp) and 2) To determine the factors associated with these changes.

Methods: In this prospective cohort study, hs-TnI, gal3 and hfabp were measured pre and post-HD for one week every month for 6 months in 178 prevalent adult HD patients with at least 2 HD treatments per week from a tertiary HD unit in Hamilton, Canada. Multilevel linear regression with HD treatments clustered within patients was performed to determine independent predictors of post-dialysis hs-TnI, gal3 and hfabp.

Results: The median (interquartile range) difference in pre and post-HD hs-TnI was -1ng/L (-2ng/L to +1ng/L) and the mean (standard deviation) differences in gal3 and hfabp were -38.06ng/mL (16.97ng/mL) and -20.85ng/mL (11.40ng/mL) respectively. Increases in hs-TnI, gal3 and hfabp were associated with ultrafiltration with B coefficients of +0.991ng/L, +1.053ng/mL and +1.877ng/mL per liter of fluid removal respectively. A change in hs-TnI was not associated with the total blood processed per HD session while decreases in gal3 and hfabp were associated with the total blood processed with B coefficients of -0.139ng/mL and -0.072ng/mL per liter of blood processed respectively. Dialysis length was associated with a decrease in all three cardiac biomarkers with B coefficients of -0.025ng/L for hs-TnI, -0.020ng/mLfor gal3 and -0.011mg/mL for hfabp per minute of HD.

Conclusions: Gal3 and hfabp decrease during dialysis while hs-TnI does not change. Increases in hs-TnI, gal3 and hfabp during HD are associated with ultrafiltration. Decreases in gal3 and hfabp during HD are associated with the total blood processed per HD session while hs-TnI is not.

Funding: Commercial Support - Abbott Diagnostics, Roche Modular, Private Foundation Support

Plasma Levels of Endocan in Patients with ESRD on Hemodialysis as Biomarker for Prediction of Cardiovascular Disease

Ji yung Lee,[1] Tae won Lee,[1] Chun-Gyoo Ihm,[1] Kyung-hwan Jeong,[2] Jin sug Kim,[3] Hyung-seok Ihm,[1] Hyeon Seok Hwang.[4] *[1]Kyung Hee University School of Medicine, Seoul, Republic of Korea; [2]Kyung Hee University, School of Medicine, Seoul, Republic of Korea; [3]Kyung Hee University Medical Center, Seoul, Republic of Korea; [4]Division of Nephrology, Department of Internal Medicine, College of Medicine, Kyung Hee University, Seoul, Republic of Korea.*

Background: Endocan, a proteoglycan which is a potential biomarker of endothelial dysfunction, has been shown to be associated with increased cardiovascular risk. We investigated plasma levels of endocan in patients with end-stage renal disease (ESRD) on hemodialysis to predict the risk of cardiovascular diseases.

Methods: A total of 400 adult patients with ESRD undergoing hemodialysis were prospectively enrolled in 4 tertiary hospitals of South Korea from June 2016 to May 2018. They were observed for development of the cardiovascular composite outcomes. We compared clinical characteristics and the plasma levels of endocan between 47 patients with cardiovascular composite outcomes and 353 control patients without cardiovascular composite outcomes, and developed the predictive markers of cardiovascular diseases using Cox proportional-hazard analysis.

Results: Previous histories of diabetes, acute coronary syndrome, arrhythmia and congestive heart failure were higher in ESRD patients with the cardiovascular composite outcomes than control patients. Patients with cardiovascular composite outcomes showed lower levels of hemoglobin, albumin, and high-density lipoproteins compared with control patients. Higher level of plasma endocan and white blood cells were associated with patients with cardiovascular composite outcomes. Cox proportional-hazard analysis showed that previous histories of diabetes and plasma level endocan were significantly associated with cardiovascular composite outcomes: hazard ratios were 2.1 (95% confidential interval (CI), 1.1 to 4.3) ($p = 0.03$) for diabetes and 15.4 (95% CI, 3.2 to 75.2) ($p < 0.001$) for endocan (log pg/mL). The patients with level of endocan > 2.96 log pg/mL showed significantly higher cumulative incidence of the cardiovascular composite outcomes in Kaplan-Meier curve ($p = 0.03$).

Conclusions: Plasma Endocan level can a useful biomarker for prediction of cardiovascular diseases in patients with ESRD on hemodialysis.

SA-PO904

Investigation of Concentration of Blood Solubilized CD40 Ligand (sCD40L) in Maintenance Dialysis Patients

Miho Karube, Shinya Kaname. *Kyorin University School of Medicine, Tokyo, Japan.*

Background: The soluble CD40 ligand (sCD40L), one of the factors released from activated platelets, has been recently suggested to relate to the pathogenesis of atherothrombotic events for a possible biomarker predicting cardiovascular outcomes. Thus, we examined the sCD40L levels in patients on maintenance dialysis.

Methods: The 15 patients undergoing maintenance dialysis in our hospital were enrolled after informed consents. The sCD40L levels before hemodialysis, 1 hour and 4 hours after initiation of hemodialysis were measured by enzyme-linked immunosorbent assays.

Results: The mean concentration of sCD40L before dialysis was 221.3 pg/ml, higher than that 34.3 pg/ml in healthy controls (n=3). The sCD40L levels were positively correlated with platelet counts and appeared to be higher in patients with a long duration of hemodialysis. The kinetics of sCD40L during hemodialysis showed that the concentrations increased to 271.0 pg/ml after 1 hour and decreased to 160.2 pg/ml after 4 hours, suggesting 30% of removal by hemodialysis. The rate of an increase during the first one hour were greater in diabetic patients (n=7) than that in non-diabetic patients (n=8). The average removal rate was 27.6%, with no differences among various types of dialyzers.

Conclusions: The sCD40L levels in hemodialysis patients are higher, although partially removed by dialysis, as compared to healthy people, and might be associated with an increased risk of atherosclerosis possibly through the platelet activation.

SA-PO905

Diagnostic Performance of Lung Ultrasound and a Clinical Score for the Evaluation of Hydration Status in Hemodialysis Patients

Mickaël Bobot,[2,1] Noemie Jourde-Chiche,[2,1] Marion Sallée,[2,1] Bertrand Dussol,[2,1] Yvon Berland,[1,2] Thomas Robert.[1,2] *[1]Service de Nephrologie CHU Conception Marseille, Marseille, France; [2]Aix-Marseille University, Marseille, France.*

Background: Estimating the hydration status of the hemodialysis patients is a key point in their management. So far, there is no gold standard feasible in daily routine. We performed a prospective study in chronic hemodialysis patients to evaluate the diagnostic performance of lung ultrasound and clinical examination for the evaluation of fluid overload using transthoracic echocardiography (TTE) as gold standard.

Methods: 31 patients performing chronic hemodialysis for more than 3 months in a dialysis center were included. Patients with pulmonary fibrosis were not included. The hydration status was assessed weekly by: a clinical score (Major criteria: dyspnea NYHA> III, orthopnea, minor criteria: jugular turgor (JT), hepatic jugular reflux (HJR), pulmonary crackles, peripheral edema and pre-dialysis hypertension); a TTE score (inferior vena cava diameter, E / E' ratio and systolic pulmonary arterial pressures); and Echo-comet score by lung ultrasound (sum of anterior and lateral B-lines in 28 chest areas).

Results: 5 patients had a TTE fluid overload. Compared with TTE, the diagnostic performance of the clinical score was: a sensitivity (Se) of 100%, a specificity (Sp) of 81%, a positive predictive value (PPV) of 50% and a negative predictive value (NPV) of 100%. Only orthopnea ($p = 0.008$), JT ($p = 0.005$) and HJR ($p = 0.008$) were significantly associated with TTE fluid overload diagnosis. The diagnostic performance of Echo-comet score by lung ultrasound has a Se of 80%, a Sp of 59%, a PPV of 26% and a NPV of 94%. 10 patients (32.3%) had an increase of extravascular lung water without evidence fluid overload with TTE or clinical score.

Conclusions: This is the first study that defines a clinical score to assess fluid overload in hemodialysis patients. This clinical score has a satisfying diagnostic performance compared to TTE and would be easily used in daily clinical routine to adjust dry weight. Fluid overload evaluation using the echo-comet score by lung ultrasound seems poorly correlated with the fluid overload evaluated by TTE score. Noteworthy, asymptomatic pulmonary congestion was detected with lung ultrasound without fluid overload according the clinical and TTE score. This particular patient group need further investigation to determine a diagnostic and prognostic significance.

Online Hemodiafiltration Inhibits Endothelial Dysfunction and Vascular Calcification of Uremic Patients Modulating miR-223 Expression in Plasma Extracellular Vesicles

Marita Marengo,[4] Massimiliano Migliori,[1] Vincenzo Panichi,[2] Sergio Dellepiane,[3] Vincenzo Cantaluppi.[5] *[1]Asl Toscana Nordovest, Camaiore, Italy; [2]ASl Toscana Nordovest, Camaiore, Italy; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Nephrology and Dialysis Unit, ASLCN1, Cuneo, Italy; [5]University of Piemonte Orientale (UPO), Novara, Italy*.

Background: Decreased inflammation and cardiovascular mortality is evident in patients with end stage chronic kidney disease (CKD) treated by on-line hemodiafiltration (OL-HDF). Extracellular vesicles (EV) are key mediators of cell-to-cell communication. This study investigated whether OL-HDF may modulate the concentration and the RNA content of plasma EV.

Methods: 30 bicarbonate hemodialysis (BHD) patients were randomized 1:1 to continue BHD or switch to OL-HDF. Concentration, size, and microRNA content of plasma EV were evaluated for 9 months; we also studied EV effects on inflammation, angiogenesis and apoptosis of human endothelial cells (EC), and on osteoblast mineralization of vascular smooth muscle cells (VSMC).

Results: OL-HDF reduced different inflammatory markers such as CRP, IL6 and NGAL. All hemodialysis patients showed higher plasma levels of endothelial derived EV than healthy subjects, with no differences between BHD and OL-HDF. However, BHD-derived EV had an increased expression of the pro-atherogenic miR-223 in respect to healthy subjects or OL-HDF. Compared to EV from healthy subjects, those from hemodialysis patients reduced angiogenesis, increased EC apoptosis and VSMC calcification; however, all these detrimental effects were reduced with OL-HDF in respect to BHD. Cell transfection with miR-223 mimic or antagomiR proved the role of this miRNA in EV-induced EC and VSMC dysfunction.

Conclusions: Switch from BHD to OL-HDF significantly reduced systemic inflammation and miR-223 expression in plasma-EV, thus improving EC angiogenesis and reducing VSMC calcification.

The Relation Between Peri-Dialytic Blood Pressure Changes over Time and Mortality Is Similar in Hemodialysis and Online Post-Dilution Hemodiafiltration

Camiel L. de Roij van Zuijdewijn,[1] Paul A. Rootjes,[1] Peter J. Blankestijn,[2] Bernard J. Canaud,[3] Andrew Davenport,[4] Frans J. van Ittersum,[5] Muriel P. Grooteman,[5] Francisco Maduell,[6] Menso Nube.[7] on behalf of the HDF Pooling Project Investigators *[1]VU University Medical Center, Amsterdam, Netherlands; [2]University Medical Center----, Utrecht, Netherlands; [3]FMC Deutschland GmbH, Bad Homburg, Germany; [4]Royal Free Hospital, London, United Kingdom; [5]VU University Medical Center Amsterdam, Amsterdam, Netherlands; [6]Hospital Clinic Barcelona, Barcelona, Spain; [7]VU Medical Center, Bergen, Netherlands*.

Background: Online post-dilution hemodiafiltration (HDF) is associated with a lower mortality rate than hemodialysis (HD). The mechanism(s) behind this effect, however, is (are) unknown. In the present study we evaluated whether long-term changes in pre-, post-dialytical and delta (peri-dialytic) systolic blood pressure (SBP), diastolic BP (DBP), mean arterial pressure (MAP) or pulse pressure (PP) may contribute to the beneficial effect of HDF on survival.

Methods: Individual Participant Data (IPD) from the Spanish Estudio de Supervivencia de Hemodiafiltración (ESHOL, n=906), the Dutch Convective Transport Study (CONTRAST, n=714) and the French HDF study (Frenchie, n=391) were pooled. The difference in peri-dialytic SBP, DBP, MAP and PP was calculated between baseline and 6 months and divided into tertiles: stable, decreasing and increasing peri-dialytic values. The stable tertile (which included a change of 0mmHg in 6 months) was used as reference group. All values were related to mortality for the entire study follow-up using Cox regression models using an intention-to-treat approach. Hereafter, models were adjusted for relevant confounders (age, sex, BMI, dialysis vintage, diabetes and history of cardiovascular disease).

Results: In 6 months, SBP, DBP, MAP and PP changed with a median of 0 (interquartile range [IQR] -18 to 18.25), 0 (IQR -10 to 10), 0.33 (IQR -11 to 11) and 0 (IQR -16 to 16) mmHg, respectively. While patients with a decreasing peri-dialytical SBP had a HR of 0.82 (95% CI 0.65-1.03), patients with an increasing peri-dialytical SBP had a HR of 1.01 (95% CI 0.81-1.26). For DBP, these HRs were 0.88 (95% CI 0.71-1.10) and 0.87 (95% CI 0.70-1.10), for MAP 0.79 (95% CI 0.62-0.99) and 1.09 (95% CI 0.88-1.35) and for PP 0.76 (95% CI 0.61-0.96) and 0.93 (95% CI 0.75-1.15). After correction for confounders, no significant relation was found.

Conclusions: Since the relation between the long-term peri-dialytical BP course (SBP, DBP, MAP or PP) and mortality was similar in HD and HDF patients and mortality is lower in HDF (Peters SAE et al. NDT 2016), other mechanisms, such as intradialytical BP stability, may more fundamentally affect survival. This hypothesis is currently under investigation.

SA-PO908

Individualizing Dialysate Sodium Concentrations to Improve Fluid Management in Chronic Dialysis Patients: A Prospective, Nonrandomized, Open-Label Trial

Kavitha Ramaswamy,[1] Jin Xia,[2] Yiqing Song,[2] JingJing Zhang.[1] *[1]Sidney Kimmel Medical College at Thomas Jefferson University, Philadelphia, PA; [2]Indiana University, Indianapolis, IN*.

Background: Excessive fluid is associated with increased morbidity and mortality in patients on chronic dialysis. Excessive fluid measured as excessive interdialytic weight gain (EIDWG)% and above target weight (ATW)% in our dialysis unit reached nearly 50% of our patients despite interventions such as dietary counseling. We thus conducted a nonrandomized, open-label trial of 73 patients undergoing hemodialysis to explore the benefit of an individualized Na prescription.

Methods: Patients in the individualized Na group (n=33) received lower dialysate Na (135-137mmol/L) if their serum Na level<138 mmol/L, predialysis systolic blood pressure (SBP) >120 mmHg, and EIDWG% and ATW% being higher than the goal levels. Forty patients who used the standard dialysate Na at 138 mmol/L were considered the control group. All the variables were collected before and 2 months after intervention. We used student *t* tests to compare continuous variables between two groups. Multivariate-adjusted linear regression models were performed to assess the differences in each continuous outcome between two groups with adjustment for age and sex. Multivariable logistic regression models were conducted by modeling IDWG decrease and ATW decrease as dependent variables, adjusting for age, sex, and EDW change. All p values will be two-tailed. All statistical analyses were performed using SAS software, version 9.4 (SAS Institute, Cary, NC).

Results: Overall, such a moderate reduction of dialysate Na concentration was well tolerated. The SBP in patient group with individualized dialysate Na did not change from before intervention. Elevation in serum Na in the individualized dialysate Na group was significantly higher than that in the control group by 3.54 mmol/L (95% CI, 2.02 to 5.05) (P<0.0001), which may indicate the improvement of volume status. Patients with individualized dialysate Na were 3.50 times more likely to have IDWG decrease. The significant association remained after adjustment for age, sex, and EDW changes (OR:3.63; 95% CI, 1.03-12.9).

Conclusions: Our preliminary results showed that individualized dialysate Na prescription in patients on chronic dialysis is safe and well-tolerated and may be effective in the fluid management in hemodialysis patients. Future randomized controlled trials are warranted.

SA-PO909

Pre- and Post-Kidney Transplantation Body Weights: Assessing Dry Weight Levels

Yossi Chait,[1] David Wojciechowski,[2] Kerry Crisalli,[2] Michael J. Germain,[3] Ravi I. Thadhani.[4] *[1]University of Massachusetts, Amherst, MA; [2]Massachusetts General Hospital, Boston, MA; [3]Renal and Transplant Assoc of New England, Hampden, MA; [4]Cedars-Sinai, Los Angeles, CA*.

Background: The single most important variable in fluid management during hemodialysis (HD) is dry weight (DW). Incorrect DW values result in hypo- or hypervolemic patients at the end of HD treatments, conditions with serious morbidity and mortality consequences. There is lack of consensus about the definition and assessment of DW; however, consensus opinion is that the optimal DW (ODW) target should be near a patient's weight at euvolemic state. We investigated this hypothesis by comparing patient weights pre- and post-transplantation (Tx) in hemodialysis patients early post transplant with functional grafts. We assumed that patients with functioning allografts achieve euvolemia by week 2 post transplant.

Methods: DW before Tx, weights, demographics, and biomarkers, were retrospectively collected for 42 patients that underwent kidney transplantation at Massachusetts General Hospital during 2016-2017. A creatinine level Cr<1.5 mg/dL was assumed to indicate a functioning graft and a euvolemic state. The ODW target was defined as the weight at week 2 post transplant for patients with a functioning graft. Patients with DW within +1% and -3% of ODW were considered to have DW values "sufficiently close" to ODW (+0.5 to -1.5 kg in a 50kg patient). In patients with a functioning graft, we used Wilcoxon signed rank test to analyze the agreement between paired changes in weight and hemoglobin (Hb) between weeks 1 and 2 post-Tx.

Results: 73% (N=31) of the 42 patients were males; 40% (N=17) received transplants from living donors; 10 patients had a functioning graft at week 1 (all living donor type) and 10 additional patients achieved that at week 2 (8 cadaver donor type). In the group with a functioning graft by week 2 (N=20) 21% had too low DW values (i.e., 3% or more below ODW), and 47% had too high DW values. Weight changes in the group with a functioning graft were significantly correlated with Hb changes between weeks 1 and 2 post-Tx r=-0.7 (p<0.001).

Conclusions: A high number (68%) of HD patients may have incorrect DW values with 21% rendered hypovolemic and 47% hypervolemic. Weight reduction in group with a functioning graft at week 2 issignificantly correlated with fluid volume reduction. It is imperative that new dry-weight assessment methods be developed that could improve cardiovascular outcomes in hemodialysis.

Metabolic and Volemic Evaluation in the Long Interdialytic Interval of Patients in Hemodialysis with and Without Residual Renal Function

Lenina L. Almeida,[1,3] Luis H. Sette,[2] Francisco H. Oliveira,[1] Fernando L. Fonseca,[3] Ronaldo R. Bergamo,[3] Leila S. Bezerra.[4] *[1]Federal University of Cariri, Juazeiro do Norte, Brazil; [2]Universidade Federal de Pernambuco, Recife, Brazil; [3]Faculdade de Medicina do ABC, SAnto - André, Brazil; [4]Fmabc, Juazeiro do Norte, Brazil.*

Background: It is unclear whether residual renal function (RRF) in dialysis patients can attenuate the metabolic impact of the long 68-hour interdialytic interval, in which volume, acid and electrolyte accumulation occurs. The aim of this study was to evaluate serum electrolyte levels, water balance and acid-base status in dialytic patients with and without RRF over the the long interdialytic interval (LII).

Methods: It was a unicentric, transversal and analytical study, which compared patients with and without RRF, defined by diuresis above 200 mL in 24 hours. Patients were weighed and subjected to the collection of serum samples for biochemical and gasometric analysis after the last hemodialysis (HD) of the week and before the first session of the subsequent week.

Results: We evaluated 24 and 27 patients with and without RRF, respectively. The mean urea and creatinine *clearance* was 3.6 ± 2.12 mL/min/1.73 m2 in the RRF group. Patients without RRF had a higher increase of serum potassium during the LII (2.67 x 1.14 mEq/L, p<0.001) reaching higher values at the end of the study (6.8 x 5.72 mEq/L,p< 0.001), as well as lower post-HD pH value (7.40 x 7.43, p=0.018) and tendency to lower pre-HD pH value (7.30 x 7.27, p=0.07) (table). In addition, at the end of the LII, they presented a higher proportion of patients with serum bicarbonate<18mEq/L (50 x 14.8%, p = 0.007), mixed acid-base disorder (57.7 x 29.2%,p=0.042), higher interdialytic weight gain (14.67 x 8.87 mL/kg/h,p<0.001) and lower natremia (137 x 139 mEq/L,p=0.02). Serum calcium and phosphorus levels, as well as blood pressure, were not different between groups.

Conclusions: Patients with RRF had better control of serum potassium, sodium, acid-base status, and volemia throughout the LII.

Clinical Impact of CMS' Ultrafiltration Limit on Hemodialysis Patients

Jeffrey I. Silberzweig,[1,2] Daniel Levine,[1] Thomas Parker,[1] Diane Morris.[1] The Governing Body of The Rogosin Institute *[1]The Rogosin Institute, New York, NY; [2]Medicine/Nephrology, Weill Cornell Medicine, New York, NY.*

Background: In January 2018, CMS instituted a reporting requirement: dialysis facilities must report the percentage of treatments during which patients removed less than 13 cc/kg/hr of fluid based on data demonstrating a relationship between higher ultrafiltration (UF) rates and adverse cardiac effects including myocardial stunning. Many dialysis patients demonstrate adverse effects from volume overload both acutely and chronically including hospitalizations for related complications and poorly controlled hypertension. We sought to evaluate the effect of the new CMS requirement on the clinical status of our maintenance hemodialysis (HD) patients.

Methods: As part of the QAPI program at The Rogosin Institute, we began monitoring the percentage of patients meeting CMS' UF requirement in January 2018. After three months living with this limit, we asked facilities to report on the proportion of patients demonstrating evidence of fluid overload and methods for managing patients not thriving in the face of the UF limit. We analyzed the data using descriptive statistics to look for relationships between the measured variables.

Results: More than 90% of the 1,197 patients dialyzed in our seven facilities met CMS' UF requirement each month. Problems living with the fluid restriction and problems reaching target weight with the UF requirement were reported by 283 (24%) and 143 (12%) of our patients, respectively. Despite 27 patients (2%) receiving more than three treatments weekly, 50 (4%) patients were hospitalized during a three month period for symptoms related to volume overload. In our population, 299 patients (25%) had inadequate blood pressure control and 262 (22%) required more than three medications to control blood pressure.

Conclusions: Despite the documented benefits of limiting UF rates for patients treated by maintenance HD, the restriction has adverse effects: more than 4% of our population was hospitalized during the first three months of the restriction and more than 25% of our population has inadeaquate blood pressure control despite standard interventions. We are developing best practices for managing fluid overload and attempting to improve the clinical outcomes for patients struggling to live with the new CMS UF limit.

SA-PO912

Global Trends of Stroke in Haemodialysis (2000-2012): A Retrospective Cohort Study of the Monitoring Dialysis Outcomes Initiative

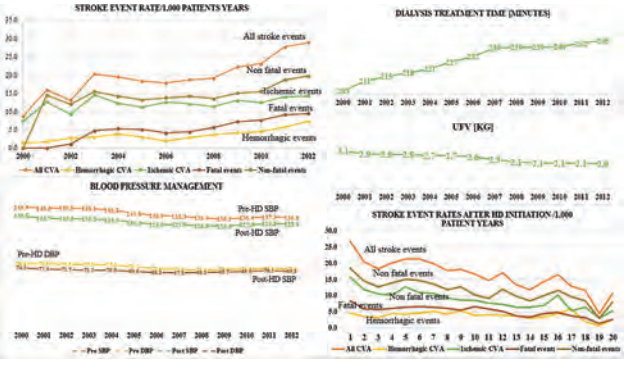
Albert J. Power,[2] Xiaoling Ye,[1] Len A. Usvyat,[3] Stefano Stuard,[4] Jochen G. Raimann,[1] Adrian M. Guinsburg,[4] Bernard J. Canaud,[5] Xiaoqi Xu,[6] Michael Etter,[6] Jeroen Kooman,[7] Frank van der Sande,[7] Neill D. Duncan,[8] Charles D. Pusey,[9] Peter Kotanko.[1] The MONDO Initiative *[1]Renal Research Institute, New York, NY; [2]Richard Bright Renal Unit, Bristol, United Kingdom; [3]Fresenius Medical Care North America, Melrose, MA; [4]Fresenius Medical Care, Bad Homburg, Germany; [5]FMC Deutschland GmbH, Bad Homburg, Germany; [6]Fresenius Medical Care Asia Pacific, Hong Kong, China; [7]Maastricht University Medical Centre, Maastricht, Netherlands; [8]Imperial College Renal and Transplant Centre, London, United Kingdom; [9]Imperial College London, London, United Kingdom.*

Background: Stroke remains a key cause of death&morbidity in HD patients(pts) that exhibit stroke rates 10-12x higher than the general population(GP). Primary&secondary prevention strategies have progressively reduced the burden of stroke in the GP but it is unclear if this trend has transposed to HD pts globally.

Methods: We studied 4,388 strokes in 150k pts. The MONDO Initiative consists of HD pts from 41 countries [von Gersdorff GD et al.]. All adult pts from the MONDO database [2000-2012] were studied with fatal&non-fatal hospitalized stroke defined by ICD-9&10 codes and excluded transient ischemic attack.

Results: The overall incidence of stroke rose from 8.7-28.7/1k pt yrs. This compares to static rates worldwide in the GP[2.5-2.6/1k pt yrs,1990-2010] with falling rates in high-income countries. A sharper rise in hemorrhagic stroke rate was seen compared to ischemic stroke in HD pts[Fig], reflecting trends seen in younger age groups worldwide. Despite falling stroke mortality worldwide[1.4-1.1/1k pt yrs,1990-2012], there was a progressive rise in HD populations [1.5-10.5/1k pt yrs, 2000-2012]. These stroke trends occurred despite increasing treatment time[203-245 mins], better BP control[mean pre-HD BP 150/80-137/72mmHg] and falling ultrafiltration rates. Stroke rates remained high 3 months after HD started and continued to fall for 2 yrs, driven by ischemic stroke incidence and with stable hemorrhagic stroke rates.

Conclusions: There is a progressive rise in stroke incidence and mortality over time in HD pts globally which starkly contrasts with global trends. This appears to be driven predominantly with rising rates of hemorrhagic stroke which carries a higher case-fatality rate. Stroke rates are at their highest within the first year of HD and there is a pressing need to reduce stroke risk in a particularly vulnerable pts at an early stage.



SA-PO913

Racial Disparities in Percutaneous Coronary Intervention in the ESKD Population

Robert Nee,[1,2] Keith C. Norris,[3] Christina M. Yuan,[1,2] Lawrence Agodoa,[4] Kevin C. Abbott.[4] *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Department of Medicine, Uniformed Services University, Bethesda, MD; [3]UCLA, Marina Del Rey, CA; [4]The National Institutes of Health, NIDDK, Bethesda, MD.*

Background: Racial disparities in invasive cardiac procedures such as percutaneous coronary intervention (PCI) in the general population are well documented. However, contemporary national-level data on such disparities in the end-stage kidney disease

(ESKD) population are lacking. Herein we assessed racial differences in the receipt of PCI between Blacks and Whites with ESKD, after the start of maintenance dialysis.

Methods: Using the US Renal Data System database, we abstracted Medicare inpatient procedure claims for PCI in a cohort of 269,984 Medicare primary patients who initiated on maintenance dialysis from 1 January 2009 through 1 June 2013, and followed until 31 December 2013. We conducted Cox regression analyses, adjusted for demographic characteristics, cause of ESKD, comorbidities, and socioeconomic factors (Medicare-Medicaid dual eligibility as a proxy measure of individual-level poverty, employment status, and ZIP code-level median household income obtained from the 2010 US Census). We also modeled death as a competing event in competing risk regression using the Fine and Gray method.

Results: The crude incidence rates of PCI among Whites were 32.9 per 1000 patient-years (PY) vs. Blacks 20.4 per 1000 PY, respectively [Figure 1]. Cox regression analyses demonstrated that Blacks were significantly less likely to undergo PCI compared to Whites (adjusted hazard ratio [aHR] 0.64, 95% CI 0.55-0.74, p<0.001). The aHR was similar in non-Hispanic Blacks vs. non-Hispanic Whites (aHR 0.62, 95% CI 0.53-0.73, p<0.001). In the competing risk model, the racial gap for PCI among Blacks and Whites narrowed but remained significant (subdistribution HR 0.73, 95% CI 0.62-0.88, p<0.001).

Conclusions: There exists a racial gap among incident dialysis patients undergoing PCI despite having comprehensive coverage with Medicare. These findings persisted despite accounting for demographic, clinical, socioeconomic factors and death as a competing risk.

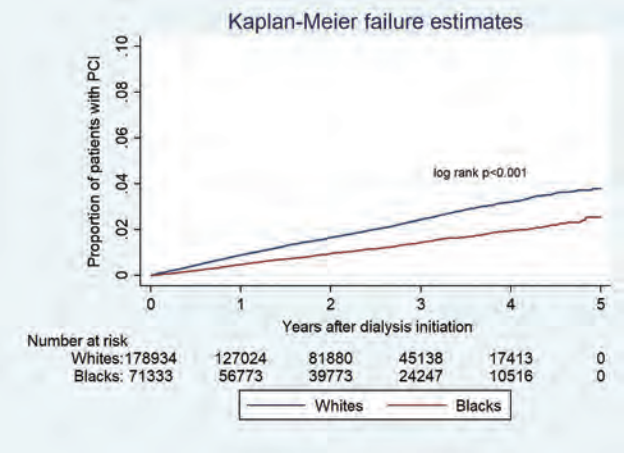


Figure 1

SA-PO914

Survey of Patient Awareness of and Attitudes Towards Home Dialysis in New York City

Frank Liu,[1,3] David L. Epstein,[1,3] Daniel Levine,[1] Samuel Baskharoun,[2] Jonathan T. Lin,[1,3] Victoria Gutgarts,[3] Molly R. Phillips,[1] Omar Farrukh,[3] Perola Lamba,[3] Weeraporn Srisung,[3] Thomas Parker,[1] Xunxi S. Guo,[3] Alan Perlman.[1,3] *[1]Rogosin Institute, New York, NY; [2]Frank H. Netter MD School of Medicine, New Haven, CT; [3]NYP-Weill Cornell, New York, NY.*

Background: Since 2008, CMS regulations have obligated dialysis practitioners to inform in-unit hemodialysis(HD) patients about alternatives to in-unit HD, including home dialysis modalities. Despite this mandate, home dialysis remains underutilized nationwide with just 8.6% of prevalent patients performing any home modality. Home modalities are even more disproportionately underutilized in New York City (NYC), with only 3.6% of patients using a home modality. Because of the unique challenges faced by patients living an intensely urban setting such as NYC, we attempted to understand the factors that might be responsible for that underutilization.

Methods: The PRIMARY CARES (Primary Care Attitudes and Renal Replacement Selection) survey was performed in 7 HD units in the NYC area representing a diverse population of ethnicities, languages, and socioeconomic categories with the objective of assessing factors influencing the utilization of home dialysis.

Results: 832 in-unit HD patients were approached and 511 completed the survey. Of these, 469 (92%) indicated they received education regarding any renal replacement modality. Of those, only 180 (35%) reported having been educated about home hemodialysis (HHD) and only 142 (28%) reported having been educated about peritoneal dialysis (PD). Of the 180 patients educated about HHD, 39 (21.7%) seriously considered the modality after receiving education. Only 5 (12.8%) of the 39 patients who seriously considered HHD came to the conclusion they "would never do HHD". Of the 142 patients educated about PD, 61 (43%) seriously considered the modality after receiving education. Only 11 (18%) of patients who seriously considered PD came to the conclusion they "would never do PD".

Conclusions: Patient awareness of home modalities remains poor despite mandated modalities education. A significant proportion of patients educated about home modalities seriously considered dialyzing at home, whereas only a small minority indicated they would never consider dialyzing at home after receiving that education. Our data suggests that there may be a large reservoir of home dialysis patients within the NYC in-unit HD population, and that current in-unit modalities education programs could be improved.

SA-PO915

The Impact of Frailty on Technique Failure and Mortality in Patients on Home Dialysis

Ranveer S. Brar,[2,3] Reid Whitlock,[2,3] Blake Lerner,[3] Clara Bohm,[2,3] Paul Komenda,[2,3] Claudio Rigatto,[2,3] Bhanu Prasad,[4] Bjoerg Thorsteinsdottir,[1] Navdeep Tangri.[2,3] *[1]Mayo Clinic, Rochester, MN; [2]Chronic Disease Innovation Center, Seven Oaks General Hospital, Winnipeg, MB, Canada; [3]University of Manitoba, Winnipeg, MB, Canada; [4]Nephrology, Regina Qu'Appelle Health Region, Regina, SK, Canada.*

Background: Patients on home based dialysis therapies will experience technique failure, which is associated with morbidity and mortality. Reasons for technique failure are complex, and often related to functional decline in the patient or caregiver. Frailty is associated with an increased risk of adverse health outcomes. The aim of the study was to investigate the impact of frailty on technique failure and mortality in a prospective cohort of patients on home dialysis therapies.

Methods: We studied 109 prevalent patients from the Peritoneal Dialysis (PD) and Home Hemodialysis (HHD) programs at our institution between 2012 and 2016. We collected objective [Fried criteria and Short Physical Performance Battery (SPPB)], and subjective measures (physician and nurse impression) of frailty. Our primary outcome was a composite of technique failure, defined as a permanent transition (> 30 days in duration) to facility based hemodialysis or all cause death. The association between different frailty assessment tools and the primary composite outcome was evaluated using Cox proportional hazards models.

Results: Frail status, as determined by the Fried criteria and physician impression was associated with a greater than two-fold increase in risk of our composite outcome (HR: 2.10 [95% CI 1.09-3.99], 2.15 [95% CI: 1.15-4.00, respectively] in models adjusted for age, sex and comorbidity. Weakness and weight loss subdomains of the Fried criteria were both associated with an increased risk of technique failure or death in adjusted analyses (HR: 2.16 [95% CI: 1.23-3.78], 2.69 [95% CI 1.39-5.40], respectively).

Conclusions: Objective and subjective measures of frailty are associated with a more than two-fold higher risk of technique failure or death in patients undergoing home dialysis. Assessing frailty as part of the clinical evaluation for home dialysis therapies may be useful for prognostication and clinical management.

SA-PO916

The Effect of Interim Assessment on Home Hemodialysis Patient Readiness

Nalinee Saiprasertkit,[1] Christopher T. Chan.[2] *[1]University Health Network, Toronto, ON, Canada; [2]Toronto General Hospital, Toronto, ON, Canada.*

Background: Studies have demonstrated the favorable clinical outcomes and better quality of life of home hemodialysis (HHD) compared with conventional hemodialysis. Teaching strategies to ensure the patients' ability to administer their own therapies safely without supervision at home is fundamental to the success of home hemodialysis. Several studies showed mid-training assessments followed by final assessment at completion of training improved learning outcomes. The purpose of this study is to determine the impact of interim assessments on the readiness of HHD before transitioning home.

Methods: This is a prospective feasibility study examining consecutive end stage renal disease (ESRD) patient and caregiver who were undergoing HHD training between September 1, 2017 to May 31, 2018. Every potential home hemodialysis candidate was observed for their hemodialysis performance skills and asked basic knowledge questions regarding hemodialysis by an independent HHD nurse after 16 sessions of HHD training and at the end of training. HHD candidates and training nurse were provided feedback for observed errors. The confidence in performing dialysis at home was assessed by global rating scale (GRS) in every HHD patient and their primary nurse before and after every interim assessment.

Results: Of 11 candidates; 9 candidates were ESRD patients, 2 candidates were ESRD patients' caregivers. Mean age was 47.3 ± 14.3 years, 63.6 % was male, 54% was Asian, 81.8% graduated from college or higher education, 54% used central venous catheter for vascular access. The confidence level scores in performing HHD in both candidates and primary nurses before the 2nd interim exam was significantly higher than the 1st interim exam (57.6 vs 64.4 (p 0.014); 53.1 vs 60.3 (p 0.026). The confidence level scores in performing HHD in both candidates and primary nurses before the 2nd interim exam was significantly higher than the 1st interim exam (57.6 vs 64.4 (p 0.014); 53.1 vs 60.3 (p 0.026).

Conclusions: Interim observed evaluation is a feasible strategy to enhance patients and nurses' ability to train a complex medical procedure. Prospective evaluation of the clinical impact of interim training evaluation on adverse outcomes warrant further evaluation.

SA-PO917

Home Hemodialysis Assisted by Personal Support Workers Among Eight Pilot Programs in Ontario

Philip McFarlane,[1] Janet L. Graham,[4] Marc Hebert,[2] Monisha Patel,[2] Leena Taji,[2] Angie Yeung,[5] Andreas Pierratos.[3] *[1]St. Michael's Hospital, Toronto, ON, Canada; [2]Ontario Renal Network, Toronto, ON, Canada; [3]University of Toronto, Toronto, ON, Canada; [4]The Ottawa Hospital, Ottawa, ON, Canada; [5]Cancer Care Ontario, Toronto, ON, Canada.*

Background: Increasing the uptake of home dialysis is a strategic priority of the Ontario Renal Network (ORN). Home hemodialysis (HHD) is associated with a higher

quality of life and improved symptom control. Barriers to the adoption of HHD can include patient inability to manage HHD independently, psychological barriers such as fear of catastrophic events, concerns about burdening family, or lack of appropriate support. This pilot project utilized Personal Support Workers (PSWs) to support patients who required additional assistance to dialyze at home.

Methods: The ORN funded 8 Regional Renal Programs (RRPs) to initiate PSW-assisted HHD. PSWs were trained in a manner consistent to that of independent HHD patients. Patient information was collected via the Ontario Renal Reporting System. Patients, PSWs, nurses and administrators were surveyed to gather feedback on patient experience and outcomes, model feasibility, training success, safety, and monitoring and support processes(e.g. including ongoing focus groups to obtain information about project progress).

Results: Between October 2015 and March 2018, approximately 65 patients participated in the PSW-assisted HHD project. As of March 2018, 35 prevalent patients were actively receiving PSW-assisted HHD. Rates of HHD increased by 0.1% to 2.2% across the 8 RRPs due to PSW-assisted HHD since the implementation of the project. The main challenge of the pilot was the PSW turnover rate (41%). Key survey measures include: 94.5% (n=35) of patients indicated that they switched to HHD due to the PSW support received. 91% (n=33) of patients indicated that are happier dialyzing at home than in an in-centre dialysis unit.

Conclusions: Successful implementation of a PSW-assisted HHD was achieved across 8 RRPs in Ontario. PSW-assisted HHD appears to be a promising model of care to increase uptake of HHD and was associated with high patient satisfaction scores. Further evaluations of the program are underway to inform the operational and financial sustainability of this model of care.

SA-PO918

Nurse Assisted Home Hemodialysis (NAHHD) by Using NxStage Cycler for Home Bound, And Multi-Comorbid Hemodialysis Patients: One Year Experience

Bassam O. Bernieh, Fredric Calaud. *HHD for Home Health Care, Al Ain-Abu Dhabi, United Arab Emirates.*

Background: Home hemodialysis (HHD) is used to treat active, HD patients. The steady increase in the number of HD patients, with multi comorbidities, and bed bound, is creating a significant burden on the active hospital beds. We are presenting our one year experience of treating those highly comorbid HD patients, with (NAHHD), at home or in long term care facilities.

Methods: HD patients who were fulfilling criteria for HHD were accepted in the NAHHD program. NxStage System One is used to deliver HD therapy at home or at long term care, by an experienced HD nurse. Dialysate volume, length, and weekly number of the HD sessions, were calculated by a calculator given by NxStage Company, targeting weekly standardized KT/V≥ 2. Only patients who were at least for three months and those who completed one year in the (NAHHD) program were included in the study.

Results: Forty seven dialysis patients on NAHHD were included in this study. Eighteen males (38%), and 29 females (62%). Mean age 69.2±17.7 year. Mean duration on NAHHD was 12 months. Etiology of end stage renal disease was DM 35(74%), HTN 10 (21%), and others 2(5%). Average number of comorbidities 9.3±3(6–16). Indications of NAHHD were: bed bound 27 (57%), morbid obesity 9(19%), psychiatric disorders, mental retardation 7(15%), and others 4(9%). Vascular access: AVF 23 (49%), AVG 2(5%), and tunneled catheter 22 (46%). Average dialysate volume was 25 L. Number of weekly session was 4, and average duration of session 3.3 hours. All patients tolerated well their dialysis sessions. The average weekly standardized KT/V was 2. There were 7 line sepsis, with an incidence of 0.6 episode/ 1000 catheter days. There was 56 hospital admissions (1.2 admission/ patient/year), with average hospital stay of 7.4 days. The annual mortality rate of the total cohort was 17.7%. There was a positive impact of the NAHHD on the patients' quality of life, as measured by time of recovery of 21 minutes, average sleeping of 6.5 hours, good appetite in 81%, along with patients and families satisfaction of 80%.

Conclusions: The results of one year experience of NAHHD by using NxStage machine in bed, home bound, and multi comorbid, HD patients, confirmed its efficacy, good quality of care, and its safety. It has significant positive impact on the quality of life and satisfaction of both patients, and their families.

SA-PO919

An Audit of Compliance with Prescribed Dialysis Hours in a Home Hemodialysis Population

Carolyn L. Van Eps, Carmel M. Hawley, Yeoung Jee Cho, David W. Johnson. Patients and Staff of Home Haemodialysis Unit Princess Alexandra Hospital, Brisbane *Princess Alexandra Hospital, Woolloongabba, QLD, Australia.*

Background: Increased weekly hemodialysis(HD) hours(hrs) completed is associated with improved quality and quantity of life. There are no studies examining compliance with prescribed dialysis hours(PDH) in home hemodialysis(HHD) populations who are not remotely monitored.

Methods: The number of hours each HD machine has run, as displayed on machines, was recorded on 2 occasions during routine home visits to all prevalent HHD patients of Princess Alexandra Hospital. With ethics approval, patients and staff were unaware this information was being collected. The number of HDhrs completed between the 2 readings was calculated, accounting for periods of HD away from home, set up and maintenance. This was compared with PDH documented in the medical record. Nurses and Nephrologists blindly rated compliance based upon clinical acumen. Descriptive statistics were performed to analyze trends and examined for predictors of %PDH completed.

Results: 54 HHD patients were included:Age:52±14years; 26% female; diabetic nephropathy:28%, duration HHD 4(2-8)years. Duration between the 2 readings was 11(7-17)weeks. %PDR dialysed:≥90%hrs: 52%, 70-89% hrs:30%, 50-69%hrs:11% and <50%hrs:7%. Average number of hrs/week performed was 16±7. 41% of patients dialysed <15hrs/week. 46% were prescribed but only 35% performed ≥18hrs/week. Compliance was accurately estimated by nurses in 48% and by nephrologists in 43% of cases. Nephrologists rated patient compliance as significantly worse than nurses. Out of 27 demographic, psychosocial, medical and laboratory parameters, only age(coefficient 0.64, 95% confidence interval (CI) 0.26-1.02, p=0.002) and diabetes mellitus (-14.8, 95% CI -26- -3.6, p=0.01) were significantly associated with compliance with PDH in multivariable regression analysis.

Conclusions: Recording the hours HD machines have run provides a useful estimate of the HDhrs completed at home. It is minimally intrusive on patient privacy, requires no special equipment and little staff time. It does not provide information on HD session frequency or duration being performed. Accuracy of clinicians' impressions of compliance is poor and common parameters used to monitor HHD patients are poorly predictive of compliance with PDH. Rates of poor compliance with PDH in HHD patients are significant and may contribute to the lack of consistent improvement in outcomes seen in clinical trials.

SA-PO920

Single Centre Experience of Vascular Access Related Infection Rates in Frequent HD

Natalie L. Borman, Venkat Gangaram, Nicholas Sangala. *Nephrology, Wessex Kidney Centre, Portsmouth, United Kingdom.*

Background: There are many benefits to Frequent Home HD (FHHD) but it only accounts for 0.4% of the dialysis population worldwide. One of the perceived barriers to FHHD relates to vascular acces srelated infections (VARI), as Infection is still the leading cause of morbidity and mortality in the dialysis population. Fear exists that frequent cannulation or use of vascular catheters (CVC) at home will increase this. Wessex Kidney Centre (WKC), Portsmouth, UK has a large HHD programme using NxStage. This retrospective study will review VARI and the strategies put in place to minimise them.

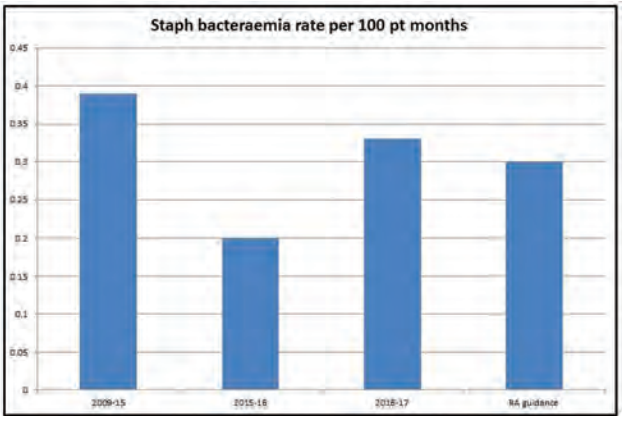
Methods: Data was collected on HHD patients between 2009- 2017. Demographic data, type of vascular access, proven bacteraemia via blood cultures and exit/cannulation site infections was collected. Rates of staph aureus bacteraemia were compared to UK Renal Association (UKRA) standards for HD. Monitoring methods in place were reviewed.

Results: Table 1 shows demographic data and number of VARI during this period. All patients received dialysis 5 or 6 times per week (20 patients received alternate night therapy). Figure 1 shows staph aureus related bacteraemia per 100 patient months compared to UKRA standard. The rate of all VARI were highest in the first 5 years and have since reduced despite increasing numbers on HHD. They are comparable to the UKRA standard. Monitoring strategies and educational material have been put in place, including a real time monitoring app alerting the HHD team to any concerns, aiming to treat any infections early.

Conclusions: In this large FFHD cohort an increase in VARI rates were not observed despite frequent cannulation or use of CVC at home. Careful monitoring and ongoing education is essential to reduce infection rates and ensure prompt treatment.

Table 1

Year	No of patients	Age	Sex	AVF / PTFE / CVC usage	Bactereamia	Exit/cannulation site infections
2009-15	89	50 (18-80)	60% Male	69 / 7 / 13	11	7
2015-16	94	53 (19-82)	65% Male	66 / 15 / 26	3	1
2016-17	107	53 (19-83)	66% Male	70 / 8 / 29	5	5



SA-PO921

European Experience of Nocturnal Home HD Using NxStage System One

Natalie L. Borman,[1] Venkat Gangaram,[6] Eric Goffin,[3] Kristine Kubisiak,[4] Mari K. Vilpakka,[5] Eric D. Weinhandl.[2] *[1]Nephrology, Wessex Kidney centre, Portsmouth, United Kingdom; [2]NxStage Medical, Inc., Victoria, MN; [3]Cliniques universitaires St Luc, Brussels, Belgium; [4]NxStage, Medical, Minneapolis, MN; [5]Paijat-Hame Central Hospital, LAHTI, Finland; [6]Wessex Kidney Centre, Waterlooville, United Kingdom.*

Background: More frequent HD is associated with increased survival, improved physical health, and reduced LVH. Studies have shown benefits with long, slow dialysis, with reduction in blood pressure, improved solute removal, anaemia, and quality of life. This study documents for the first time the outcome of a cohort treated with nocturnal home HD (NHHD) with low-volume dialysate in Europe.

Methods: A retrospective analysis of 20 patients at 4 European centres who received ≥12 months NHHD with the NxStage System One, a device that uses ≤60 L/session of lactate-buffered dialysate. Single-bolus low-molecular weight heparin was administered at the start of therapy. Fistulas were cannulated with double needle and button hole technique; needle strapping and moisture sensors were used. Data analysis included demographics, prescriptions, biochemical data, training and safety measures. Descriptive analysis was used to assess patient characteristics and prescriptions. Mean, standard deviation, and range of biochemical data at baseline, 6 and 12 months were calculated.

Results: Mean age was 44.4 years (range, 26-66). Most patients received 3.5 sessions per week, with 60 L/session of dialysate and ≥24.5 cumulative treatment hours. The table summarises biochemical outcomes, which met European standards. Reduced pill burden was also noted.

Conclusions: Data from this cohort supports the use of NHHD with low-volume dialysate, providing biochemical outcomes that meet European standards and reduced pill burden. Therapy was safe and effective, and extends a viable option for more patients to receive NHHD and its associated benefits.

Biochemical data

Biochemical parameter	Baseline Mean (SD)	6 Months Mean(SD)	12 Months Mean(SD)
Standardised Kt/V	2.1 (0.6)	2.4 (0.3)	2.5 (0.4)
Pre Phosphate mmol/L	1.7 (0.5)	1.6 (0.4)	1.6 (0.6)
Pre Calcium mmol/L	2.4 (0.1)	2.4 (0.2)	2.4 (0.2)
Pre Potassium mmol/L	5.0 (0.7)	4.6 (0.7)	5.0 (0.7)
Pre Bicarbonate mmol/L	24.6 (2.8)	25.9 (3.4)	25.7 (3.0)
Pre Hemoglobin g/dL	11.5 (1.6)	12.0 (2.1)	12.1 (1.5)
Pre Albumin g/L	35.6 (6.5)	37.7 (6.3)	37.5 (7.3)
No. phosphate binders	4.3 (5.0)	1.9 (2.8)	1.5 (2.3)
No. of BP meds	1.2 (1.3)	1.0 (1.1)	1.1 (1.2)

SA-PO922

Frequent Home Haemodialysis as "Palliative Dialysis": Time for a Paradigm Shift

Natalie L. Borman,[1] Sunita Nair.[2] *[1]Wessex Renal and Transplantation unit, Hayling Island, United Kingdom; [2]Royal Shrewsbury Hospital, Shrewsbury, United Kingdom.*

Introduction: Increasingly the profile of dialysis patients has changed from young and fit to older and multi-comorbid. Dialysing these patients is fraught with difficulties due to their comorbidities. Managing such complex patients requires a collaborative approach by Renal and Palliative physicians. A Palliative approach to dialysis embraces the transition from a conventional disease-oriented focus on dialysis as a rehabilitative treatment to an approach prioritizing comfort and alignment with patient goals. Palliative care affirms life, provides symptom relief by integrating medical, psychological and spiritual needs of a patient and considers dying as a normal process. Palliative dialysis as part of palliative medicine is not a well-recognized concept.

Case Description: We describe our experience with six individual patients on Home Haemodialysis (HHD) using NxStage system One, who have benefitted from a palliative approach to dialysis as part of their holistic treatment. Table 1 outlines the patients included. As outlined in the table, we had patients with variable age and comorbidities who underwent dialysis for symptom control on a palliative basis, either at home or at the hospice. All patients had significant symptom burden and co-existing illness, but wished to continue dialysis at home spending quality time with family. Dialysis was continued in the context of palliation, focusing on symptom control. This also offered flexibility and thereby improved the quality of the final month of life.

Discussion: Palliative care programs result in beneficial effects on symptoms, reduced hospital costs, increase likelihood of death at home, and improve patient and family satisfaction, compared to conventional care. Patients undergoing maintenance dialysis with associated significant comorbidities, a high mortality rate, and possibly co-existing terminal illness could be candidates for a palliative approach to dialysis. It is time to incorporate this as a part of the continuum of renal treatment, providing a patient centered holistic approach.

Table 1

Age at Death	Sex	Total time on dialysis (months)	Terminal Diagnosis	Time on HHD (Months)	Dialysis in hospice setting?	Place of Death
32	F	360	Frailty	30	Yes	Hospice
83	M	97	lymphoma	37	No	Home
76	M	31	Lung Cancer	7	No	Home
54	F	34	Ovarian cancer	24	No	Home
46	F	72	Myeloma	48	Yes	Hospice
68	M	106	Bladder Cancer	10	No	Home

SA-PO923

Human Factors Testing of the Quanta SC+ Hemodialysis System: An Innovative System for Home and Clinic Use

James Grainger,[2] Oksana Harasemiw,[1] David Bond,[2] Paul Komenda,[1] Thomas W. Ferguson.[1] *[1]Chronic Disease Innovation Centre, Winnipeg, MB, Canada; [2]Quanta Dialysis Technologies, Alcester, United Kingdom.*

Background: Compared to traditional in-centre hemodialysis, home hemodialysis (HHD) is a more cost-effective option, offering patients more autonomy, better quality of life, and improved health outcomes. However, uptake rates of HHD are the lowest among all other modality types. Therefore, there is a need to develop efficient HHD systems that are user-friendly and appealing to patients. The SC+ Hemodialysis System developed by Quanta Dialysis Technologies for home and clinic use, provides patients with a compact, safe, and easy-to-use HHD system that minimizes the burden of traditional dialysis treatments, whilst providing equivalent dialysis adequacy.

Methods: As part of the design validation of the SC+, Human Factors Testing (HFT) was performed with 15 Home Users (patients and caregivers) and 17 Healthcare Professionals (nephrology nurses and healthcare assistants), to assess safety, performance, and ease of usability. The HFT involved a training session with each participant at Smethwick Dialysis Centre in Birmingham, United Kingdom, which was subsequently followed by a test session where participants independently performed 38 subtasks on the SC+. A detailed study protocol was used to critically evaluate each participant in a standardized manner.

Results: In aggregate, 1,171 from the 1,216 subtasks attempted between the two user groups were completed successfully. Overall, the Healthcare Professionals performed with a higher degree of use safety, with a task-specific success rate of 97.4%, compared to 95.1% in the Home Users (patient and caregiver) group. Healthcare Professionals encountered use errors in 0.9% of sub-tasks attempted. In contrast, 0.2% of subtasks attempted by home users resulted in a close call (they initially encountered a use error, but were able to self-correct), and 3.9% resulted in use errors. Due to circumstances unrelated to the study itself, 1.7% of subtasks attempted by healthcare professionals, and 0.9% by home users, were unperformed. No errors resulted in adverse events.

Conclusions: The SC+ Hemodialysis System was found to have minimal issues related to ease of usability by patients, caregivers, and healthcare professionals. The data from this usability study indicates that in the real world, a high degree of use safety will likely be achieved, resulting in an optimal user experience.

SA-PO924

Effect of Dialysate Lactate Concentration During Daily Hemodialysis (DHD) on Serum Bicarbonate (BIC) Concentration After Transfer from In-Center Hemodialysis (ICHD)

J. Ken Leypoldt,[1] Michael A. Kraus,[4] Bertrand L. Jaber,[2] Eric D. Weinhandl,[3] Allan J. Collins.[3] *[1]Unaffiliated, San Clemente, CA; [2]St. Elizabeth's Medical Center, Boston, MA; [3]NxStage Medical, Inc., Victoria, MN; [4]NxStage Medical, Inc, FISHERS, IN.*

Background: Lactate is used as an alternative dialysate buffer to BIC during DHD, but the outcome of dialysate lactate concentration on acid-base balance is unclear. We examined the effect of the dialysate lactate concentration during DHD on serum BIC concentration after transfer from ICHD.

Methods: This post hoc analysis evaluated data from patients who transferred from ICHD to DHD during the FREEDOM Study (N=284). DHD was performed at low dialysate flow rates; treatment frequency per week and dialysate volume per session were 5.9±0.2 and 22.1±4.0 L, respectively. Dialysate lactate concentration during DHD was either 40 or 45 mM. Serum BIC was the average concentration from the last 3 months of ICHD or the first 3 months of DHD.

Results: Mean±SD serum BIC values are tabulated. Overall, a larger increase in serum BIC after transfer from ICHD to DHD was associated with higher dialysate lactate concentration during DHD ($P<0.001$) and lower serum BIC during ICHD ($P<0.001$), the latter is illustrated for dialysate lactate concentration of 45 mM in the figure.

Conclusions: Transfer from ICHD to DHD using lactate as the dialysate buffer may be accompanied by changes in serum BIC. This study provides guidance for choosing dialysate lactate concentrations for DHD at low dialysate flow rates.

Funding: Commercial Support - NxStage Medical

Associations of Treatment Frequency and Dialysate Volume with Conversion from Home Hemodialysis to Another Dialytic Modality

Kristine Kubisiak,[1] Debabrata Ray,[1] Allan J. Collins,[1,2] Eric D. Weinhandl.[1,2] *[1]NxStage Medical, Inc., Victoria, MN; [2]University of Minnesota, Minneapolis, MN.*

Background: Home hemodialysis (HHD) readily permits increased treatment frequency, which reduces left ventricular mass, blood pressure, and serum phosphorus and improves physical health-related quality of life. However, conversion from HHD to another dialytic modality (*e.g.*, in-center hemodialysis) is common, particularly during the first year of HHD. There is little literature about clinical predictors of conversion. We assessed associations of treatment frequency and dialysate volume with conversion in a contemporary cohort of HHD patients.

Methods: We identified patients who initiated HHD training with the NxStage System One between January 1, 2013, and December 31, 2017, in a large dialysis organization. We retained patients who completed HHD training and were initially prescribed 4-6 sessions/week and ≥90 L/week of dialysate. We followed patients from the first treatment at home until the earliest of conversion to another dialytic modality, death, kidney transplant, or January 31, 2018. We used Cox regression to estimate the hazard of conversion to another dialytic modality, as a dynamic function of treatment frequency and cumulative dialysate volume per week, with adjustment for age, race, sex, body mass index, and vascular access type.

Results: We identified 5545 patients who completed HHD training. Mean age was 54.6 years, 69% of patients were white, 65% were male, and 71% used a fistula. Patients accumulated 6645 patient-years of follow-up. Prescriptions of 4, 5, and 6 sessions/week constituted 28%, 59%, and 14% of follow-up time, respectively, and prescriptions of 90-119, 120-149, 150-179, 180-209, and ≥210 L/week of dialysate constituted 8%, 23%, 34%, 21%, and 14% of follow-up time, respectively. There were 1727 conversions from HHD to another dialytic modality, 685 deaths, and 467 kidney transplants. The adjusted hazard ratio of conversion from HHD to another dialytic modality was 1.06 (95% confidence interval, 0.95-1.18; $p = 0.31$) for 4 vs. 5 sessions/week and 0.99 (0.85-1.44; $p = 0.86$) for 6 vs. 5 sessions/week. The corresponding hazard ratio for each 30-L/week increment in dialysate was 1.00 (0.96-1.04; $p = 0.96$).

Conclusions: Among patients on frequent HHD with low-volume dialysate, neither HD frequency nor dialysate volume per week were associated with conversion to another dialytic modality.

Home Dialysis Utilization by African-Americans Is Influenced by Psychosocial Factors

Janice P. Lea,[1] Joshua B. Ang,[2] Jason Cobb,[3] Tahsin Masud,[1] James L. Bailey,[3] Laura Plantinga.[1] *[1]Emory University, Atlanta, GA; [2]Philadelphia College of Osteopathic Medicine-GA, Duluth, GA; [3]Emory University School of Medicine, Atlanta, GA.*

Background: Racial disparities have been reported in utilization of home dialysis modalities. While psychosocial factors are assumed to play a role, there is a paucity of definitive data. The aim of this study was to examine the relationship between psychosocial factors and the utilization of home dialysis among prevalent African-American dialysis patients.

Methods: Data were extracted from the initial comprehensive assessment performed by social workers for patients starting dialysis treatment between 2010- 2016. Our exposures were social worker-assessed psychosocial factors; depression/anxiety, substance abuse, marital status, employment status, and level of independence (daily social support, no ambulatory assistance, and community-dwelling). Our outcome was dialysis modality assignment: in-center hemodialysis (ICH), peritoneal dialysis (PD), or home hemodialysis (HHD). Statistical analysis was performed using ANOVA, *t* test, and Pearson's chi-square.

Results: Of 1338 patients, 85 were on PD, and 18 on HHD. Our population is predominantly AA with 91% of ICH, 69% of PD, and 77% of HHD patients being AA. Compared to ICH patients, PD and HHD patients were younger, less likely to have history of substance abuse, and more likely to be employed and independent (Table 1). There was no difference in depression/anxiety across modalities. When just the AA sample (n=1094) was analyzed, history of substance abuse, employment status, and independence similarly varied between modalities.

Conclusions: Our results suggest that African-American ESRD patients who utilize home dialysis are more likely to be employed, live independently, and less likely to have substance abuse history. Comparisons of outcomes of home vs. in-center modalities should take these psychosocial factors into account. Further investigation of other factors which could inform targeted interventions to improve utilization of home dialysis is warranted.

Table 1. Baseline demographic and psychosocial data for all dialysis patients by modality (ICH: N = 1338, PD: N = 85, HHD: N = 18)

Characteristics	ICH (% or mean ± SD)	PD (% or mean ± SD)	HHD (% or mean ± SD)	P-Value
Mean age/SD	56.59 ± 14.99	53.01 ± 14.98	46.67 ± 12.79	0.0051
Patients with depression/anxiety	15.35	15.38	16.67	0.988
Patients with a history of substance abuse	13.36	4.94	0.00	0.023
Married, Partner	31.27	45.78	41.18	0.075
Employed	8.76	24.10	12.50	<0.001
Lives alone	20.00	18.07	0.00	0.098
Has daily social support	72.80	56.25	50.00	0.001
No ambulatory assistance	58.02	77.38	88.89	<0.001
Lives in a community dwelling	88.61	98.73	94.44	0.015

The Mechanism of Intestinal Mucosal Dysfunction Induced by Long-Term Peritoneal Dialysis - Activating the P38MPAK Signaling Pathway

Chen Jiang. *Nephrology, First teaching hospital of Tianjin university of TCM, Tianjin, China, TIANJIN, China.*

Background: During long-term PD treatment, the abdominal cavity is always in a high pressure, high glucose environment, resulting in peritoneal and intestinal injury. The peritoneal and intestinal injury lead to a series of complications including endogenous peritonitis, abdominal infection, malnutrition, gastrointestinal disorders inadequate dialysis. Unfortunately, the underlying mechanisms of long-term PD induced intestinal mucosal dysfunction remain unclear The present study was designed to investigate the potential molecular mechanisms of intestinal mucosal dysfunction induced by long-term peritoneal dialysis (PD) treatment.

Methods: Modified peritoneal dialysis rat model and lipopolysaccharide induced IEC-6 cell were used to observe. We examined the intestinal mucosal architecture injury induced by long-term PD by HE staining. Intestinal mucosal permeability was determined by measuring the intestinal clearance of fluorescein-isothiocyanate dextran (FD4), the transepithelial electrical resistance (TER) and the serum levels of D-lactate, Diamine oxidase (DAO) and endotoxin. the potential molecular mechanisms were explored by detecting the mRNA expression of ICAM-1, IL-1β, iNOS and TNF-α via real-time qPCR and the protein expression levels of P-p38MAPK, occludin, ZO-1 and DUSP1 via western blot.

Results: Long-term PD could increase the intestinal mucosal permeability by decreasing the level of TER and increasing the intestinal clearance of FD4, resulting in the serum levels of D-lactate, DAO and endotoxin significantly increased. Co-treatment with Fushen granule could decrease the intestinal mucosal permeability. In vivo and vitro studies, long-term PD markedly decreased the mRNA expression of ICAM-1, IL-1β, iNOS and TNF-α, and further activated the p38MPAK signaling pathway via up-regulating the protein expression of P-p38MPAK and down-regulating the protein expression of occludin, ZO-1 and DUSP1. Co-treatment with Fushen granule could markedly increase the mRNA expression of ICAM-1, IL-1β, iNOS and TNF-α and inhibit the activation of p38MPAK signaling pathway.

Conclusions: The present study is the first to demonstrate that long-term PD induces intestinal mucosal dysfunction by activating the p38MAPK signaling pathway.

High Salt Intake Increases Baseline Peritoneal Transport Rate Through Local TonEBP Activation in Subtotal Nephrectomized Mice

Ting Sun,[1] Masashi Mizuno,[1] Yasuhiro Suzuki,[1] Takako Tomita,[1] Fumiko Sakata,[1] Shoichi Maruyama,[1] Takayuki Katsuno,[2] Hiroshi Kinashi,[2] Yasuhiko Ito.[2,1] *[1]Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Aichi Medical University, Nagakute, Aichi, Japan.*

Background: Baseline peritoneal solute transport rate (PSTR) measured by peritoneal equilibration test (PET) within 6 months after PD commencement varies between patients independently of PD therapy. Previously, we have reported a positive association between baseline D/P Cr and the number of peritoneal blood vessels, macrophages and IL-6-positive cells (2011,NDT). Besides, our recent work has shown that high salt intake promotes tissue inflammation in uremic mice (2017, Lab Invest). The present study aims to probe whether high salt intake causes pre-dialysis intraperitoneal inflammation and leads to high PSTR in subtotal nephrectomized mice.

Methods: Sham-operated (Sham) and subtotal nephrectomized (Nx) mice were randomly given tap water or 1% salt (NaCl)-containing water. After 8 weeks, 4.25% glucose-based PET was performed to evaluate peritoneal function. In another experiment,

overexpressed intraperitoneal IL-6 was functionally blocked by MR16-1 to examine the role of IL-6 in this process. Human mesothelial cell line Met5A was used for in vitro studies.

Results: A significant elevation of D/P Cr and a decrease of D/D0 glucose were observed in Nx+salt group. There was also enhanced angiogenesis and macrophage infiltration in the peritoneum of Nx+salt mice, along with elevated VEGF-A and MCP-1 concentration in the dialysate. Compared to Nx+water group, the increased concentration of effluent but not serum IL-6 suggested a strong local production in Nx+salt group. Blockade of IL-6 signaling by MR16-1 alleviated angiogenesis and macrophage infiltration in Nx+salt mice and rescued peritoneal transport function. In cultured human mesothelial cells, 40mM additional NaCl in the medium could significantly upregulate the expression of IL-6, as well as VEGF-A and -C, companied by an increased expression and nuclear translocation of TonEBP, an osmolality-sensing transcription factor. Knockdown of TonEBP by siRNA could lower such overexpression caused by high tonicity. Notably, peritoneal expression of TonEBP in Nx+salt group also showed an upregulation, indicating a key role of it in higher peritoneal transport status.

Conclusions: These findings suggest that high salt intake under uremic status could increase peritoneal transport rate via local TonEBP activation.

Attenuation of Glucose-Induced Inflammatory Reaction by Blocking of TonEBP in Primary Cultured Human Peritoneal Mesothelial Cells

Un Sil Jeon,[1,2] Yon Su Kim,[4] Seung Hee Yang.[3] *[1]Sheikh Khalifa Specialty Hospital, Ras Al Khaimah, United Arab Emirates; [2]Internal Medicine, Seoul National University Hospital, Seoul, Republic of Korea; [3]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [4]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Long-term exposure to high-glucose concentration in peritoneal dialysate can cause peritoneal damage by inflammatory reaction and fibrosis in the peritoneum, which finally leads to withdrawal from peritoneal dialysis. Recently, it is known that tonicity induced transcriptional activator, TonE binding protein (TonEBP), is involved in the pathogenesis of diabetic complications such as retinopathy and nephropathy (*Cardiovasc Diabetol. 2016 Jan 29;15:18, J Am Soc Nephrol. 2018 Feb;29(2):492-504*).

Methods: Here, we examined the role of TonEBP in glucose induced inflammation using primary cultured human peritoneal mesothelial cells (HPMCs). HPMCs were isolated from peritoneal effluents of patients on peritoneal dialysis. Isolation and characterization of HPMCs were verified by cobblestone like characteristic morphology and the expression of the standard mesothelial markers.

Results: First, we observed that both high concentration of NaCl and 2% glucose induced increase in TonEBP mRNA expression and activation of TonEBP by nuclear translocation in cultured HPMCs. Aldose reductase (AR) mRNA expression, a target gene of TonEBP, was increased by high NaCl and glucose as expected. The treatment of NaCl and glucose increased in abundance of p65, NF-κB protein, but did not induce nuclear translocation of it. The gene expression of inflammatory markers such as IL-6, IL-8, MCP-1 and IκB was increased in culture HPMCs by high glucose treatment. High glucose also increased cytokine levels of IL-6, IL-8 and MCP-1 in supernatant of HPMCs. Next, we examined the role of TonEBP in those inflammatory reactions by blocking of TonEBP using TonEBP disrupted MEF cells and TonEBP siRNA in HPMCs. IL-6 and IL-8 mRNA expression was decreased in both TonEBP disrupted MEF cells and TonEBP si-RNA treated HPMCs. However, there was discrepancy in the effect of high glucose on MCP-1 and IκB expression by TonEBP blocking between TonEBP disrupted MEF cells and TonEBP si-RNA in HPMCs.

Conclusions: Our findings suggest that TonEBP is involved in high-glucose induced inflammatory changes in the peritoneum of peritoneal dialysis patients, which could be prevented by blocking TonEBP action.

SA-PO930

Transcriptomic Analysis of PCK Rat Peritoneum After Long -Term Infusion of Dialysate with Mono or Dual Therapy of a JAK1/2 Inhibitor and/or Losartan

Sonny T. Nguyen,[1] Sharon G. Adler,[1] Kana N. Miyata,[1] Pei Zhang,[2] Janine A. La page,[1] Tiane Dai.[1] *[1]Los Angeles Biomedical Research institute at Harbor-UCLA Medical Center, Torrance, CA; [2]The First Affiliated Hospital of Anhui Medical University, Anhui, China.*

Background: Peritoneal dialysis (PD) is limited by reduced efficacy over time. Peritoneal membrane (PM) injury is characterized by inflammation, hypervascularity, and fibrosis. JAK/STAT signaling mediates inflammatory pathways, including angiotensin signaling. Our previous work showed in rats with polycystic kidneys (PCK) chronically infused with 4.25% Dianeal x 16 wks, treatments with JAK1/2 inhibitor (JAK1/2i), losartan, or both preserved PM structure; JAK1/2i conferred better structural preservation vs losartan. Monotherapy with either JAK1/2i or losartan failed to consistently preserve PM function; dual infusion consistently preserved PM function. In order to elucidate mechanism at the transcriptomic level, we performed RNAseq analysis on PCK rat peritoneum.

Methods: PCK rats received dialysate infusions BID via an implanted subcutaneous port in the neck tunneled to the intraperitoneal cavity for 16 wks in the following groups: **(1)** 4.25% Dianeal; **(2)** 4.25% Dianeal + JAK1/2i (5mg/kg BID); **(3)** 4.25% Dianeal + Losartan (5mg/kg BID); and **(4)** 4.25% Dianeal + Losartan +JAK1/2i (5mg/kg BID each). PM with muscle was sampled for RNAseq. Total RNA was used, cDNA libraries were single-end sequenced (50bp) on an Illumina HiSeq 3000. Differentially expressed genes are defined as at least 2-fold change and $p<0.05$.

Results: Compared to PCK rats receiving Dianeal only, concomitant infusion of Dianeal and JAK1/2i or losartan up- or downregulated expression of 88 genes in 132 canonical pathways and 36 genes in 55 pathways respectively. Combination treatment with JAK1/2i and losartan caused differential expression of 29 genes in 65 pathways. When comparing PCK rats that received JAK1/2i to losartan, 38 genes in 98 pathways were differentially expressed. 12 genes were regulated by either JAK1/2i or losartan with a similar pattern, of which, only three were similarly regulated when both JAK1/2i and losartan were infused.

Conclusions: The differentially expressed gene pattern may explain superior morphologic protection in the JAK1/2i group and the functional preservation in the dual therapy group that we previously showed in our study. The transcriptomic analysis in this study provides gene differential expression profiles of JAK1/2i and losartan that helps explain different treatment effects.

Trehalose Ameliorates Peritoneal Fibrosis Through the Suppression of Fibroblast Proliferation and Extracellular Matrix Production in Fibroblasts

Taito Miyake, Norihiko Sakai, Koichi Sato, Akihiro Sagara, Shinji Kitajima, Tadashi Toyama, Akinori Hara, Yasunori Iwata, Miho Shimizu, Kengo Furuichi, Takashi Wada. *Kanazawa University, Kanazawa, Japan.*

Background: Peritoneal fibrosis is a severe complication of peritoneal dialysis, but there are few effective therapies to treat and/or prevent for it. Trehalose is a non-reducing disaccharide and can be an osmolyte of peritoneal dialysis solution. We have previously revealed that trehalose ameliorated peritoneal fibrosis through the induction of autophagy and the downregulation of Snail protein in peritoneal mesothelial cells. In this study, we examined if trehalose also has anti-fibrotic effects on fibroblasts in the peritoneum.

Methods: Peritoneal fibrosis was induced by intraperitoneal injection of chlorhexidine gluconate (CG). 5% trehalose or vehicle (normal saline) was administered by intraperitoneal injection to mice every other day.

Results: Trehalose attenuated CG-induced increases in peritoneal thickness, type I pro-collagen mRNA expression and hydroxyproline content (n=4-9). In addition, CG challenges induced a marked peritoneal accumulation of α smooth muscle actin $(\alpha SMA)^+$ fibroblasts that was significantly reduced by trehalose. We next examined fibroblast proliferation induced by CG challenges in $ColI\alpha_2$-enhanced green fluorescent protein (GFP) transgenic mice. In order to specifically identify proliferating fibroblasts, we double-stained peritoneal sections with anti-PCNA antibody and anti-GFP antibody. The number of PCNA and GFP dual positive proliferating fibroblasts in the peritoneal tissue after CG challenges was significantly increased in the vehicle group as compared to the trehalose group, as was the percentage of proliferating fibroblasts among total fibroblasts. We also performed an in vitro study to confirm the effects of trehalose on the proliferation of fibroblasts. TGF-β_1 induced fibroblast proliferation; however, trehalose suppressed the fibroblast proliferation in a dose-dependent manner. In addition, trehalose attenuated αSMA, $ColI\alpha_1$, $Col3\alpha_1$ and fibronectin mRNA expression induced by TGF-β_1.

Conclusions: Our results suggest that trehalose might be a novel therapeutic reagent for peritoneal fibrosis through the suppression of fibroblasts proliferation and extracellular matrix production in fibroblasts.

SA-PO932

Novel Role of Nuclear Factor of Activated T-Cells 5 (NFAT5) as a Mediator of EMT of Peritoneal Mesothelial Cells (MCs) via Modulation of Nod-Like Receptor-3 (NLRP3) Inflammasome

Duk-Hee Kang,[2] Eun sun Ryu,[1] Dal-ah Kim,[3] Hyun-Jung Kang,[4] You Jin Kim,[5] Sun-Hee Park,[6] Yong-Lim Kim,[6] Hyug M. Kwon.[7] *[1]Ewha Womans University School of Medicine, Seoul, Republic of Korea; [2]Ewha University College of Medicine, Seoul, Republic of Korea; [3]Ewha Womans University Medical Center, Seoul, Seoul, Republic of Korea; [4]Ewha Womans University, Seoul, Republic of Korea; [5]Kyungpook National University, Daegu, Republic of Korea; [6]Kyungpook National University Hospital, Daegu, Republic of Korea; [7]UNIST, Ulsan, Republic of Korea.*

Background: Epithelial-to-mesenchymal Transition (EMT) of MCs is known as an early mechanism of peritoneal fibrosis in PD. NLRP3 inflammasome is comprised of the NLRP3, ASC and procaspase-1, which leads to the maturation of IL-1β and IL-18. NFAT5 is an essential transcription factor regulating cellular homeostasis to hypertonicity-induced osmotic stress, and recently reported as a pro-inflammatory mediator. We investigated whether NFAT5 plays a role in peritoneal EMT via a modulation of NLRP3 inflammasome in MCs.

Methods: The expressions of NFAT5, components of NLRP3 inflammasome, nuclear translocation of NFAT5, β-catenin and snail were evaluated by western blotting. EMT was evaluated by the changes in morphology and markers of epithelial and mesenchymal cells. E-cadherin promoter activity was confirmed by luciferase assay. Effect of gene silencing of NFAT5, NLRP3 and ASC on EMT was examined using siRNA. Animal model of peritoneal fibrosis was established by intraperitoneal injection of adenoviral vector of TGFβ in BL6 mouse.

Results: TGFβ increased NFAT5 expression and its nuclear translocation in MC. TGFβ-induced EMT was associated with an up-regulation of NLRP3, ASC, procaspase-1 and an increased production of IL-1β/IL-18. In adenoviral TGFβ-injected mice, EMT of MC with submesothelial fibrosis was observed with an increased expression of NFAT5 and NLRP3. siNFAT5 ameliorated TGFβ-induced EMT with an increase in E-cadherin

promotor activity as well as a decrease in snail expression and nuclear translocation of β-catenin. siNLRP3, siASC and neutralizing antibodies of IL-1β and IL-18 alleviated TGFβ1-induced EMT. siNFAT5 also alleviated TGFβ1-induced activation of NLRP3 inflammasome. Neither MAPK inhibitors (PD98059, SB203580) nor antioxidants (NAC, Apocynin, Mitotempo) altered TGFβ1-induced up-regulation of NFAT5 of MC.

Conclusions: This data suggest NFAT5 plays a key role in peritoneal EMT via tonicity-independent mechanism by either an inhibition of E-cadherin transcription and activation of NLRP3 inflammasome. Modulation of NFAT5 and NLRP3 inflammasome in MCs could be a novel approach to protect the peritoneum from the development of EMT and peritoneal fibrosis in PD patients.

SA-PO933

Intra-Nuclear Binding of NFAT5/TonEBP to ß-Catenin Is a Key Process of Hypertonicity-Induced Phenotype Transition of Peritoneal Mesothelial Cells (MCs)

Duk-Hee Kang,[2] Hyun-Jung Kang,[4] Eun sun Ryu,[3] Dal-ah Kim.[1] *[1]Ewha Womans University Medical Center, Seoul, seoul, Republic of Korea; [2]Ewha University College of Medicine, Seoul, Republic of Korea; [3]Ewha Womans University School of Medicine, Seoul, Republic of Korea; [4]Ewha Womans University, Seoul, Republic of Korea.*

Background: Epithelial-to-mesenchymal transition (EMT) of MCs is an early mechanism of peritoneal fibrosis in peritoneal dialysis. Nuclear Factor of Activated T Cells-5 (NFAT5), also known as TonEBP, is a transcriptional factor that enables cellular adaptation to hypertonic osmotic stress. Recent data demonstrated the role of NFAT5/TonEBP in phenotype transition of cancer cells. The aim of this study is to investigate whether NFAT5/TonEBP is involved in hypertonicity-induced EMT of MCs and to identify the potential mechanisms of NFAT5/TonEBP-mediated peritoneal EMT.

Methods: The expressions of NFAT5/TonEBP, other osmotic stress-related genes including sodium-myoinositol cotransporter (SMIT), betaine/γ-aminobutyric acid transporter (BGT1) and aldose reductase (AR) and nuclear translocation of β-catenin were evaluated by real-time PCR and western blotting. EMT was evaluated by morphological changes of MCs and the expressions of E-cadherin and α-SMA after stimulation of high glucose (HG, 30-120 mM) and mannitol (30-120 mM). E-cadherin promoter activity was confirmed by luciferase assay. The interaction between TonEBP and β-catenin was analyzed by immunoprecipitation.

Results: Both HG or Mannitol enhanced the expression of NFAT5/TonEBP as well as SMIT, BGT1 and AR at transcriptional and translational levels from the concentration of 30 mM. HG induced EMT of MCs, however mannitol did not show the evidence of EMT even at the concentration of 120 mM. HG (>30 mM) induced nuclear translocation of NFAT5/TonEBP which was associated with an enhanced binding to β-catenin. Mannitol also promoted nuclear translocation of NFAT5/TonEBP only at the highest concentration we tested (120 mM), however it was not associated with intra-nuclear binding of NFAT5/TonEBP to β-catenin. In contrast to persistent increase in intra-nuclear β-catenin in HG-exposed MCs, there was only a transient increase in β-catenin with 120 mM of mannitol at 1 hour. HG decreased E-cadherin promoter activity whereas mannitol did not alter the transcription of E-cadherin.

Conclusions: The role of NFAT5/TonEBP as a mediator of peritoneal EMT is demonstrated in this study for the first time. Not the increased expression of NFAT5/TonEBP per se but intra-nuclear translocation with binding to β-catenin is a key mechanism by which NFAT5/TonEBP induced EMT of MCs.

SA-PO934

The Expression of Glucose Transporters (GLUTs) and Sodium-Glucose Co-Transporters (SGLTs) in Peritoneal Mesothelial Cell (MC) and Its Role in Phenotype Transition of MC

Duk-Hee Kang,[2] Eun sun Ryu,[1] Dal-ah Kim,[3] Hyun-Jung Kang.[4] *[1]Ewha Womans University School of Medicine, Seoul, Republic of Korea; [2]Ewha University College of Medicine, Seoul, Republic of Korea; [3]Ewha Womans University Medical Center, Seoul, SEOUL, Republic of Korea; [4]Ewha Womans University, Seoul, Republic of Korea.*

Background: Phenotype transition of MCs such as epithelial-to-mesenchymal transition (EMT) by glucose or proinflammatory cytokines is known as an early mechanism of peritoneal dysfunction in peritoneal dialysis (PD). Given the consideration of high glucose concentration in peritoneal dialysate, the expressions of GLUTs and SGLTs in MC may play a role in peritoneal EMT. However, there are few data on the expression and regulation of GLUTs and SGLTs in MCs. We investigated the expression of each isoform of GLUTs and SGLTs, and their role in EMT of peritoneal MCs.

Methods: MCs were also isolated from overnight dwell dialysate effluents from clinically stable PD patients (MCs-DE) as well as omentum (MCs-OT) to assess the expression of GLUTs and SGLTs. The expressions of GLUT-1, -2, -3, SGLT-1, and -2 were investigated by real-time PCR and Western botting. EMT was evaluated by the changes in cell morphology and expression of epithelial and mesenchymal cell markers. To investigate the role of SGLTs in peritoneal EMT, the effects of Dapagliflozin (SGLT2 inhibitor, 500nM) and Empagliflozin (SGLT 1/2 inhibitor, 500nM) were evaluated.

Results: GLUT-1, -2, -3, SGLT-1 and -2 were constitutively expressed in MC, and up-regulated by the stimulation with high glucose (HG, 60 mM) both at mRNA and protein levels. GLUT-1 and -3 were quantitatively major transporters in MCs, however HG-induced upregulation was more prominent in SGLT-1 and -2. The expression of GLUT-1, -2, SGLT-1 and -2 were higher in MCs-DE compared to MCs-OT which have never been exposed to dialysate. TGFβ also increased the expression of GLUT-1, -2, -3, SGLT-1 and -2. High glucose- and TGFβ-induced EMT in MCs-OT were ameliorated by pre-treatment with Dapagliflozin or Empagliflozin.

Conclusions: Modulation of the activity and expression of glucose transporters in MCs by specific inhibitors or glucose-sparing prescription of peritoneal dialysis could be a novel therapeutic approach to protect the peritoneum from the development of EMT and peritoneal fibrosis in PD patients.

SA-PO935

Astragalus Inhibits Epithelial-to-Mesenchymal Transition of Peritoneal Mesothelial Cells by Down-regulating β-Catenin

Manshu Yu,[1] Jun Shi,[1] Meixiao Sheng.[2] *[1]Nanjing University of Chinese Medicine, Nanjing, China; [2]Jiangsu Province Hosiptal of Chinese Medicine, Nanjing, China.*

Background: The epithelial-to-mesenchymal transition (EMT) of peritoneal mesothelial cells (PMCs) is a crucial event in the induction of peritoneal fibrosis (PF), in which canonical Wnt/β-catenin signaling participates. Smads signaling is reported to interact with β-catenin and synergistically regulates EMT. Astragalus is the traditional Chinese herbal which has an effect to restrain the ROS, anti-inflammatory, anti-fibrosis, etc. This study was aimed to reveal the effect of Astragalus on β-catenin in EMT of PMCs.

Methods: The HMrSV5 cell line and gene transfection rats were treated with Astragalus. EMT markers or signaling pathway-related indicators were detected by western blotting, immunofluorescence, immunohistochemistry, immunoprecipitation and real-time PCR.

Results: HMrSV5 EMT model was established by TGF-β1, and the peritoneal fibrosis rat model was established by 4.25% glucose peritoneal dialysis solution. Astragalus inhibited EMT of PMCs including increased E-cadherin and decreased α-SMA and Vimentin, as well as attenuated peritoneal thickening and fibrosis in rats. During the process of PMCs EMT, Astragalus could inhibit β-catenin expression. Astragalus down-regulated β-catenin by stabilizing the GSK-3β/β-catenin complex and further inhibited the nuclear translocation of β-catenin. Meanwhile, Akt is the upstream protein of GSK-3β/β-catenin, which could regulate the degradation of β-catenin. On the other hand, Astragalus down-regulated β-catenin by enhancing Smad7 expression. Silencing Smad7 in HMrSV5 and rats antagonized the EMT-inhibitory effect of Astragalus.

Conclusions: Astragalus inhibits EMT of PMCs by down-regulating β-catenin. The modulation of β-catenin in peritoneum can be a novel tool to prevent PF.

SA-PO936

Connective Tissue Growth Factor Is Correlated with Peritoneal Lymphangiogenesis

Hiroshi Kinashi,[1,2] Naohiro Toda,[3] Tri Q. Nguyen,[2] Yasuhiro Suzuki,[4] Takayuki Katsuno,[1] Hideki Yokoi,[5] Jan Aten,[6] Masashi Mizuno,[4] Shoichi Maruyama,[4] Motoko Yanagita,[5] Roel Goldschmeding,[2] Yasuhiko Ito.[1] *[1]Aichi Medical University, Nagakute, Japan; [2]University Medical Center Utrecht, Utrecht, Netherlands; [3]Kansai Electric Power Hospital, Osaka, Japan; [4]Nagoya University Graduate School of Medicine, Nagoya, Japan; [5]Kyoto University Graduate School of Medicine, Kyoto City, Japan; [6]Academic Medical Center, Amsterdam, Netherlands.*

Background: Lymphatic absorption in peritoneal cavity may contribute to ultrafiltration failure in peritoneal dialysis (PD). Lymphatic vessels develop during PD-related peritoneal fibrosis. Connective tissue growth factor (CTGF, also known as CCN2) is an important determinant of fibrotic tissue remodeling, but little is known about its possible involvement in lymphangiogenesis. We studied the relationship between CTGF and lymphangiogenesis in association with PD.

Methods: Protein levels of CTGF and vascular endothelial growth factor-C (VEGF-C), a major lymphangiogenic factor, were measured in 77 human PD effluents. Messenger RNA (mRNA) expression of CTGF, lymphatic markers (lymphatic endothelial hyaluronan receptor-1 [LYVE-1] and podoplanin), and VEGF-C was analyzed in 56 human peritoneal biopsies. CTGF and VEGF-C mRNA were assessed in cultured human peritoneal mesothelial cells (HPMC) (N=21) treated with transforming growth factor-β1 (TGF-β1). CTGF involvement in diaphragamatic lymphangiogenesis was explored in a rat peritoneal fibrosis model induced by chlorhexidine gluconate (CG). Finally, the role of CTGF inhibition in peritoneal lymphangiogenesis was evaluated in the CG model using CTGF knockout mice.

Results: A positive correlation was observed between CTGF and VEGF-C concentration in human PD effluents ($R=0.428$, $p<0.001$). CTGF mRNA positively correlated with VEGF-C ($R=0.67$, $p<0.001$), LYVE-1 ($R=0.638$, $p<0.001$), and podoplanin ($R=0.592$, $p<0.001$) mRNA in human peritoneal biopsies. There was a positive relationship between CTGF and VEGF-C mRNA fold-increase in HPMC at 12 hours after TGF-β1 treatment ($R=0.722$, $p<0.001$). Immunohistochemstry and in situ hybridization showed that CTGF, VEGF-C, and LYVE-1-positive lymphatic vessels were increased in the rat diaphragm of CG model compared with controls. CTGF expression positively correlated with VEGF-C expression ($p<0.001$) and lymphatics ($p<0.05$) in the rat diaphragm of CG model. Finally, CTGF gene deletion significantly reduced VEGF-C expression and suppressed lymphangiogenesis in the mouse peritoneum of CG model.

Conclusions: Our results suggest a close relationship between CTGF and PD-associated lymphangiogenesis.

SA-PO937

The Role of Suppression of Tumorigenicity-2 (ST2) in the Peritoneal Fibrosis and Peritoneal Dialysis (PD) Outcomes

Yong Chul Kim,[1] Mi-yeon Yu,[1] Hajeong Lee,[2] Yun Jung Oh,[6] Jae Wook Lee,[5] Un Sil Jeon,[4] Jung Pyo Lee,[3] Kook-Hwan Oh,[7] Ran-hui Cha,[9] Seung Hee Yang,[8] Yon Su Kim.[2] *[1]SNUH, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [4]Sheikh Khalifa Specialty Hospital, Ras Al Khaimah, United Arab Emirates; [5]National Cancer Center, Seoul, Republic of Korea; [6]Cheju Halla General Hospital, Jeju, Republic of Korea; [7]Seoul National University Hospital, Seoul, Republic of Korea; [8]Kidney Research Institute, Seoul National University, Seoul, Republic of Korea; [9]National Medical Center, Seoul, Republic of Korea*.

Background: Peritoneal fibrosis (PF) is an intractable complication which leads to peritoneal membrane failure in PD. The aim of this study is to investigate the role of ST2 involved in PF.

Methods: Samples of dialysate and clinical data were prospectively collected from 54 patients at Seoul National University Hospital between 2010 and 2016. Dialysate soluble ST2 (sST2) levels were measured after 1 month of PD initiation (baseline) using the ELISA technique. Fibrosis induced by TGFβ and high concentration of glucose in primary cultured human peritoneal mesothelial cells (HPMCs) were evaluated with ST2, fibronectin, β-galactosidase, snail and E-cadherin protein expressions. Anti-ST2 monoclonal antibody (mAb) was treated to evaluate the neutralizing effect of ST2 on PF. Immunohistochemistry (IHC) stain of ST2 was performed in peritoneum tissue samples of chlorhexidine gluconate (CG)-induced PF mice and control.

Results: Baseline dialysate sST2 (sST2-b) levels were 2063.4 ± 2457.8 pg/mL and mean duration of follow-up periods was 53.4 ± 18.8 months. We observed that patients who changed dialysis modality to hemodialysis due to PD failure had high sST2-b levels in peritoneal effluent compared with others (1576.2 ± 199.9 vs 4143.1 ± 1107.3, P = 0.03). High sST2-b was associated with a hazard ratio (HR) for PD failure of 7.72 (95% CI 1.10-54.3, P = 0.04) in a fully adjusted model. sST2-b showed a good performance of predicting PD failure; the area under the ROC curve was 0.784 (P = 0.001). We found that in primary cultured HPMCs, TGFβ treatment increased protein expressions of ST2, fibronectin, β-galactosidase, snail and decreased expression of E-cadherin in a dose-dependent manner. Protein expression of ST2 and fibronectin were decreased after anti-ST2 Ab administration. High concentration of glucose (100mmol/L) also induced fibrosis in HPMCs and fibrosis was ameliorated after treating anti-ST2 Ab. ST2 was found in fibroblasts and mesothelial cells within the underlying submesothelial zones of CG-induced PF mice.

Conclusions: Elevated dialysate levels of sST2 is associated with PD failure. Thus, an elevated dialysate levels of ST2 appears to play a role in fibrosis and inflammation during peritoneal injury. And ST2 blockade is a potential therapeutic target for renal preservation.

Longitudinal Changes of NF-kB Downstream Mediators and Peritoneal Transport Characteristics in New Peritoneal Dialysis Patients

Winston W. Fung,[2] Cheuk-Chun Szeto.[1] *[1]The Chinese University of Hong Kong, Shatin, China; [2]Prince of Wales Hospital, Hong Kong, China*.

Background: The success of peritoneal dialysis (PD) depends on the semi-permeable peritoneal membrane. The regulation of peritoneal transport remained to be fully elucidated, but intra-peritoneal cytokines, notably interleukin-6 (IL-6), cyclo-oxygenase-2 (COX-2), and hepatocyte growth factor (HGF), probably play important roles. We investigate the relation between longitudinal changes in PD effluent cytokine levels and the corresponding alterations in peritoneal transport parameters over 1 year.

Methods: We studied 46 new PD patients who had peritoneal equilibration test performed at baseline and then one year later. Dialysate-to-plasma creatinine level at 4 hours (D/P4), mass transfer area coefficient of creatinine (MTAC), and ultrafiltration (UF) volume were taken as peritoneal transport parameters. Concomitant PD effluent levels of IL-6, COX-2 and HGF were measured and compared.

Results: There were significant correlations between baseline as well as one-year PD effluent IL-6 and COX-2 levels with the corresponding D/P4 and MTAC. The change in PD effluent IL-6 and COX-2 levels from baseline to one year also correlated with the change in D/P4 and MTAC during the same time. In contrast, PD effluent HGF did not showed any significant correlation with the corresponding D/P4 and MTAC, both at baseline and one year later. After one year, patients who had peritonitis had higher PD effluent IL-6 (26.6 ± 17.4 vs 15.1 ± 12.3 pg/ml, p = 0.037) and COX-2 levels (4.97 ± 6.25 vs 1.60 ± 1.53 ng/ml, p = 0.007) than those without peritonitis, and the number of peritonitis episode during follow up period significantly correlated with the PD effluent IL-6 and COX-2 levels after one year. No significant difference in PD effluent HGF level after 1 year of dialysis are noted between patient with and without peritonitis. There was no significant difference in any cytokine level between patients who received conventional and low glucose degradation product PD solutions.

Conclusions: PD effluent IL-6 and COX-2 levels significantly correlate with the peritoneal transport characteristics. Patients who had peritonitis during the follow up period had higher PD effluent IL-6 and COX-2 levels after one year than patients without peritonitis. Our result suggests that intra-peritoneal IL-6 and COX-2 play important roles in the short-term regulation of peritoneal transport.

SA-PO939

Inhibition of mPGES-1 Blocks High Glucose-Induced Mesothelial-to-Mesenchymal Transition of Peritoneal Mesothelial Cells

Qimei Luo. *Shunde Hospital of Southern Medical University, Foshan, China*.

Background: Peritoneal mesangial cells (PMC) undergoing mesothelial-to-mesenchymal transition (MMT) induced by chronic sterile inflammation promotes peritoneal fibrosis. Microsomal prostaglandin E2 synthase-1 (mPGES-1)-derived PGE2 plays an important role in inflammatory disease. Previous studies have shown that the secretion of PGE2 increased significantly in PMC under the circumstance of high glucose. This study aimed to investigate the role of mPGES-1 in phenotype transition of PMC.

Methods: The expression of mPGES-1 in human peritoneum tissue was evaluated by immunohistochemical. Human mesothelial cells were incubated with 138mmol/L glucose for various periods of time. After transfection of shRNA plasmid targeting mPGES-1, human mesothelial cells were incubated with 138mmol/L glucose and harvested for further analysis.

Results: Immunohistochemical analysis displayed mPGES-1 was expressed in the outermost layer of the peritoneal membrane and upregulated in peritoneal tissue of patients with peritoneal ultrafiltration failure. In cultured human mesothelial cells, high glucose time-dependently increased the expression of mPGES-1. Western blots confirmed that mPGES-1 was increased more than threefold by high glucose. Besides, application of mPGES-1 shRNA plasmid significantly reduced protein and mRNA expressions of mPGES-1 in human mesothelial cells. Moreover, inhibition of mPGES-1 in human mesothelial cells dramatically reversed levels of E-cadherin and decreased the synthesis of MMT-related proteins, such as fibronectin and vimentin.

Conclusions: The findings suggest that mPGES-1 could be activated by high glucose and could contribute to MMT of PMC.

SA-PO940

Hyaluronan Generated During Peritoneal Dialysis Does Not Drive Fibrosis, but Regulates Inflammatory Cell Recruitment Through Differential Hyaluronan Synthase (HAS) Expression

Aled P. Williams,[3,1] Adam C. Midgley,[2,3] Aled O. Phillips,[3,1] Robert Steadman,[3,1] Timothy Bowen,[3,1] Donald Fraser,[3,1] Soma Meran.[3,1] *[1]Cardiff University, Llanelli, United Kingdom; [2]Nankai University, Tianjin, China; [3]Wales Kidney Research Unit, Cardiff, United Kingdom*.

Background: Peritoneal membrane dysfunction is a key determinant of Peritoneal Dialysis (PD) failure, and is associated with repeated episodes of peritonitis and exposure to bio-incompatible dialysis solutions. TGF-β1-driven transdifferentiation of mesothelial cells to myofibroblasts through mesothelial to mesenchymal transition (MMT) underlies peritoneal membrane dysfunction and ultimately peritoneal fibrosis. In solid organ fibrosis (kidneys & lungs), pro-fibrotic cell differentiation is driven by changes in synthesis and macromolecular organisation of the matrix polysaccharide hyaluronan (HA). In this work, we determine whether factors that regulate HA synthesis in the peritoneum have a the role in driving peritoneal inflammation and in the prevention/reversal of fibrosis

Methods: *In-vitro* studies were performed on human peritoneal mesothelial cells and *ex-vivo* PD effluent from patients with peritonitis. Genetic and histological analysis of peritoneal membranes from a murine model of peritoneal inflammation (live attenuated *staphylococcus epidermidis* induced peritonitis) were utilised *in-vivo*

Results: Patients with PD peritonitis had significantly increased HA concentrations day-1 after developing acute bacterial peritonitis compared to non-infected patients. TGF-β1-driven MMT in primary human mesothelial cells significantly increased extracellular HA generation, predominantly driven by Hyaluronan Synthase-1 (HAS1) isoenzyme expression. In contrast to kidney and lung fibrosis this increased HA was not causally involved in driving MMT. Instead, HAS1 in peritoneal tissues and mesothelial cells was associated with enhanced leukocyte recruitment and activation in the peritoneum. Blockade of HAS1 driven HA synthesis in mice led to delayed neutrophil clearance and monocyte recruitment indicating a delayed inflammatory response

Conclusions: In contrast to solid-organ fibrosis where HA seems to have an important role in driving fibrosis through a HAS2 dependent phenotype, TGF-β1 driven MMT in mesothelial cells generates HA that is not involved in peritoneal fibrosis. HAS1 generated by mesothelial cells appears to be involved in regulating the acute inflammatory response and may be involved in reparative processes that limit fibrosis in the peritoneum

SA-PO941

Protein Kinase C-Beta Deficiency and Inhibition Exacerbate High Glucose-Induced Peritoneal Damage via M1/M2 Macrophage Polarization

Michael S. Balzer, Alexandra Helmke, Song Rong, Sibylle Von Vietinghoff, Hermann G. Haller, Nelli Shushakova. *Dpt. of Nephrology and Hypertension, Hannover Medical School, Hannover, Germany*.

Background: Macrophage (MØ)-driven inflammation is a key hallmark of glucose-mediated damage to the peritoneal membrane (PM) during peritoneal dialysis. We have recently shown that in mesothelium PKCα is a major mediator of PM damage, whereas PKCβ deficiency results in increased glucose-mediated PM damage. PKCβ is expressed most abundantly in MØ. We hypothesized that within a high glucose milieu PKCβ plays an important role in controlling MØ activation and function.

Methods: Combining qPCR, ELISA, Western blot, and flow cytometry we investigated primary murine peritoneal MØ of *PKCβ*$^{-/-}$ and wild type (WT) mice, murine bone marrow-derived MØ of WT mice, and primary human peripheral blood monocyte-derived MØ

during normal (10mM) and high glucose (120mM) conditions. Some experiments involved LPS stimulation and pharmacological PKCβ inhibition using ruboxistaurin. *In vivo* PM damage was evaluated in a chronic peritoneal dialysis mouse model in *PKCβ*$^{-/-}$ and WT mice using flow cytometry and immunofluorescence.

Results: *In vitro* murine MØ, in comparison to PKCα, abundantly (>50-fold) expressed PKCβ mRNA at normal glucose conditions. A high glucose milieu induced PKCβ and suppressed PKCα mRNA and protein expression. High glucose conditions facilitated murine and human MØ polarization towards M2. Both genetic deficiency and pharmacological inhibition of PKCβ increased high glucose+LPS-mediated IL-6, TNFα, and MCP-1 production and decreased IL-10 release compared to a state of genetic or functional presence of PKCβ. *In vivo* catheter-delivered treatment with high glucose peritoneal dialysis fluid for 5 weeks induced PKCβ up-regulation in omentum rich of MØ in WT mice and resulted in an inflammatory response and PM damage characterized by fibrosis and neo-angiogenesis. In comparison to WT mice, destructive changes were strongly aggravated in *PKCβ*$^{-/-}$ animals. Finally, flow cytometry and immunofluorescence demonstrated a substantial M1 polarization of peritoneal MØ in *PKCβ*$^{-/-}$ mice, while WT mice predominantly mounted an M2 response.

Conclusions: PKCβ is the dominant PKC isoform in peritoneal macrophages. It is up-regulated and exerts peritoneal anti-inflammatory effects in a high glucose milieu both *in vitro* and in an *in vivo* mouse model of chronic peritoneal dialysis via M1/M2 macrophage polarization.

The Global DNA Methylation Profile of Human Peritoneal Fibrosis

Pengpeng Yan,[1,2] Jia Shen,[1,2] Rending Wang,[1,2] Jianghua Chen.[1,2] [1]*Kidney Disease Center, the First Affiliated Hospital, College of Medicine, Hangzhou, China;* [2]*Zhejiang University School of Medicine, Hangzhou, China.*

Background: Long-term exposure to biocompatible peritoneal dialysate induced peritoneum fibrosis, exacerbating peritoneal dialysis (PD) efficiency.

Methods: Peritoneal tissues of PD patients were obtained during kidney transplantation (PD group, n=10), along with Control group from normal individuals (n=6). Histological staining and qRT-PCR were applied to evaluate the peritoneal fibrosis level, while Infinium® HumanMethylation EPIC was used to analyze differentially methylated probes (DMPs), which formed the gene clusters (corrected p<0.05, |Δβ|>0.2). Functional network analysis was applied to extract the key regions within the interaction.

Results: Structural remodeling was found in Peritoneum from PD patients, including SMC significant thickening, vascular wall of peritoneal postcapillary venules thickening (p<0.001). The number of α-SMA positive cells in PD peritoneum increased, with up-regulation of Fibronectin and Vimentin mRNA (p<0.05). The global DNA methylation level decreased in PD peritoneum, with 9,948 up-regulated DMPs and 39,109 down-regulated DMPs, which covered all euchromosome and were enriched in function or pathway terms such as cell morphology, cell migration, and ECM buildup; functional analysis of the CpG-rich regions revealed THBS1 and PRKACA are two key functional blocks related to cell proliferation/migration, which involved Wnt/β-catenin signaling pathway and PKA signaling pathway, respectively.

Conclusions: Fibrotic structural remodeling was presented in the peritoneum of PD patients, with a hypomethylated reprogramming of the global DNA methylation profile.

Direct Interaction of Mesothelial Cells with Macrophages via Stalked Fractalkine Promotes Dialysate Induced Peritoneal Fibrosis

Alexandra Helmke,[1] Johannes Nordlohne,[1] Michael S. Balzer,[1] Marcus Hiss,[1] Nelli Shushakova,[2] Hermann G. Haller,[1] Sibylle Von Vietinghoff.[1] [1]*Hannover Medical School, Hannover, Germany;* [2]*Nephrology and Hypertensiology, Hannover, Germany.*

Background: Fibrosis limits the use of peritoneal dialysis (PD) as renal replacement therapy. PD solution induces mesothelial cell activation and macrophage accumulation in the peritoneal wall. Macrophages highly express chemokine receptor CX3CR1. Its ligand fractalkine (CX3CL1) exists in a stalked surface-bound and a soluble form. This study addressed their role in peritoneal fibrosis.

Methods: Wildtype and CX3CR1 deficient mice received dialysis solution for human use via a peritoneal catheter for six weeks and tissues were analyzed by histology. Murine and human primary cells were investigated using a combination of qPCR, ELISA, flow cytometry and confocal microscopy.

Results: Human and murine peritoneal mesothelial cells expressed surface-bound and secreted fractalkine/CX3CL1. During experimental PD treatment in mice, CX3CL1 increased on the peritoneal membrane. Cytokines TNFα, IL-1β and TGFβ markedly induced CX3CL1 expression by mesothelial cells in vitro. In addition, direct co-culture with CX3CR1-competent macrophages induced CX3CL1 and also TGFβ, a main promoter of fibrosis. The increase of CX3CL1 and TGFβ in direct macrophage-mesothelial coculture was no longer observed in transwell co-cultures and also disappeared in direct coculture with CX3CR1 deficient macrophages, indicating a role for cellular CX3CR1-CX3CL1 interaction. TGFβ increased macrophage CX3CR1 expression and Increased CX3CR1 was observed during PD treatment. Wildtype mice developed significantly more peritoneal fibrosis than CX3CR1 deficient animals. Peritoneal dialysis solution directly induced macrophage IL-1β, one of the mesothelial CX3CL1-promoting cytokines, thus providing a mechanism of initiation for this pro-fibrotic interaction loop. Peritoneal dialysis patients' peritoneum expressed more CX3CL1 than untreated tissue and CX3CR1 was higher in serum of patients that recently started PD than in controls, providing evidence of relevance in the human situation.

Conclusions: PD solution initiates a pro-fibrotic loop of mesothelial CX3CL1 binding to macrophage CX3CR1 that promote peritoneal fibrosis in vivo. Similar observations in human cells suggest that CX3CR1-CX3CL1 interaction should be investigated further as a new therapeutic angle in peritoneal fibrosis.

Early Peritoneal Dialysis Ameliorates Acute Lung Injury Induced by Blast Injury in Rats

Kehong Chen,[1] Yani He.[2] [1]*Daping hospital, Chongqing, Chongqing, China;* [2]*Daping Hospital, Chongqing, China.*

Background: Blast injury frequently occurs in wars and disasters. Blast lung injury is the most common type of blast injury with a remarkable lack of effective treatment. Blast lung injury manifested as pulmonary hemorrhage, edema and secondary systemic inflammation. This study aimed to investigate the therapeutic efficacy and mechanism of peritoneal dialysis in rats with blast lung injury.

Methods: 75 SD rats were randomly divided into five groups: control group, sham group, glucocorticoid (GC) group, peritoneal dialysis (PD) group, PD+GC (PDGC) group. All rats were injured by bio-shock tube (BST-I) apparatus. PD group was treated with continuous peritoneal dialysis for 6 hours. GC group were injected with a small dose of

methylprednisolone. Lung function, pathological changes and pneumonedema in rats were detected after 24h treatment. Inflammatory cytokine levels in serum were determined by the technology of Milliplex.

Results: 37 rats (49.3%) survived at 24 hours after blast injury. There was no significant difference in the mortality rate between the groups. Lung water content of rats in PD and PDGC groups were significantly lower than that of the control group. Pathological staining showed that the degree of pulmonary interstitial edema in PD and PDGC rats was significantly lower than that in the control group. Pulmonary function (FVC, functional residual capacity, oxygen saturation, arterial oxygen pressure, oxygenation index, and maximal mid expiratory flow) in PD and PDGC groups was significantly higher than that of the control group. The serum levels of IL-1β, IL-6, MCP-1 and TNFα in the PD and PDGC rats were significantly lower than those in the control group. The levels of IL-1β and TNFα in the serum of GC rats were significantly lower than those of the control group.

Conclusions: Early peritoneal dialysis improves acute lung injury and systemic inflammation induced by blast injury.

Is Abdominal Muscle the Right Parietal Peritoneal Tissue for Gene Expression Analysis?

Pei Zhang,[1] Kana N. Miyata,[2] Sharon G. Adler,[2] Cynthia C. Nast,[3] Hashim Mapara,[2] Janine A. La page,[2] Tiane Dai.[2] *[1]The First Affiliated Hospital of Anhui Medical University, Anhui, China; [2]Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA; [3]Cedars Sinai Medical Center, Los Angeles, CA.*

Background: Recently there has been increased interest in studying peritoneal membrane pathophysiology at a transcriptomic level in animal models. Standard tissue sampling includes abdominal wall muscle. Some consider muscle as part of the peritoneal barrier. However the massive muscle mass overwhelms signals from the mesothelium and sub mesothelial compact zone where much of the peritoneal ultrafiltration occurs. To address this, we performed RNAseq in microdissected parietal peritoneum without muscle compared to the samples with muscle in rats with polycystic kidneys (PCK) chronically infused with 4.25% Dianeal, with or without JAK1/2 inhibitor (JAK1/2i) or losartan for 16 wks.

Methods: PCK rats received dialysate infusions BID for 16 wks in the following groups: Control-no infusion; 4.25% Dianeal; 4.25% Dianeal + JAK1/2i (5mg/kg BID); 4.25% Dianeal + Losartan (5mg/kg BID). Parietal peritoneum was sampled either with microdissection under anesthesia without muscle or standardly with muscle. Total RNA was used, cDNA libraries were single-end sequenced (50bp) on an Illumina HiSeq 3000. Differentially expressed (DE) genes are defined as at least 2-fold change and $p<0.05$. Comprehensive pathway analysis was performed using Ingenuity's Pathway Analysis (IPA).

Results: As shown (Table), there are significant differences in DE genes or pathways when using different samples with the same intervention. The peritoneum without muscle shows significantly more DE genes with more pathways involved. When comparing samples ± muscle, only a few shared gene transcript changes were observed.

Conclusions: Microdisseted parietal peritoneum samples showed more DE genes and pathways than samples with muscle. Our study suggests more precise tissue sampling should be considered to better reflect peritoneal signals in transcriptomic analysis studies.

Vascular Access Practices in Japan

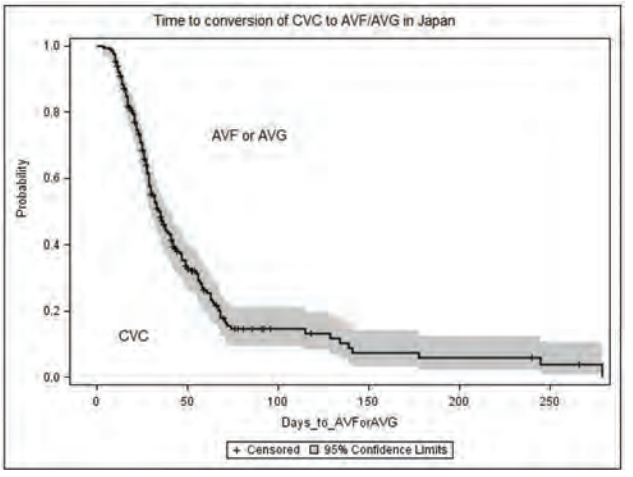
Genta Uehara,[1] Tomoki Tsukahara,[2] Mary S. Hammes,[3] Rita L. McGill.[3] *[1]Okinawa Chubu Hospital, Uruma, Japan; [2]Tsukuba Central Hospital, Ushiku, Japan; [3]University of Chicago Medicine, Chicago, IL.*

Background: Increasing fistulas (AVF) and grafts (AVG) and decreasing catheters (CVC) is a priority for all hemodialysis (HD) patients. DOPPS data indicate that Japanese patients have superior vascular access outcomes, so we examined vascular access practices for new HD patients in Japan.

Methods: Chart review identified patients presenting to two Japanese hospitals (an academic medical center in Okinawa and a private referral hospital in Ibaraki prefecture) for new kidney failure with no vascular access, from 2013-2017. Demographic and clinical data were collected, as well as the timing of vascular access surgery, hospital discharge/transfer, and cannulation of any new AVF or AVG. Time data are shown as median (interquartile range). Patients were censored upon transfer from facility or death.

Results: Among 222 patients (103 from Okinawa and 119 from Ibaraki), 36.9% were female, age was 70 (60, 79) years, and weight 54.6 (46.7, 61.3) kg. AVF/G were successful during 164/222 (73.9%) of hospitalizations. 58 patients left hospital with CVC, of whom 4 had unsuccessful surgery. Time from admit to surgery was 14 (7,26) days. There were 9 AVG, 9 upper arm AVF, and the remainder were Cimino or snuffbox AVF. AVF/G were cannulated with 17 gauge needles at a median of 13 (8,16) days after surgery. Hospital length of stay was 30 (20, 49) days, so cannulation usually occurred prior to hospital discharge. A Kaplan-Meier curve shows time to conversion from CVC to AVF or AVG in days. Treatments were 240 (240,240) min; blood pump rates were 150 (120,180) mL/min at first use and increased to 200 mL/min over time.

Conclusions: Initial hospitalization of a new Japanese HD patient frequently includes creation and first use of AVF/AVG; hospital length of stay is longer than in many other countries. Early construction and early use of native fistulas in the forearm and wrist is associated with very low usage of CVC in Japan, which may be facilitated by low blood pump speeds and longer treatments.



SA-PO947

Octogenarians in Pre-Dialysis Phase Do Not Have Worse Results of Radio Cephalic Arteriovenous Fistula Compared to Younger Patients

Raffaella Mauro, Mohammad Abualhin, Rodolfo Pini, Anna Laura Croci Chiocchini, Gabriele Donati, Alessia Pini, Gianluca Faggioli, Gaetano La Manna, Andrea Stella, Mauro Gargiulo. *Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy.*

Background: KDOQI guidelines recommend radiocephalic arteriovenous fistula (RCAVF) as a first choice access for hemodialytic treatment, but there is no clear indication in octogenarians. The study aim was to compare the results of RCAVF in octogenarians and younger patients.

Methods: All patients treated by RCAVF from Jan-2013 to Dec-2017 were included in a retrospective study. The population was divided according to age: <80 years (Group-A: mean age 61 years ±15; 80.9% males) and ≥80 years (Group-B: mean age 83 years ±3; 91.8% males). Patient demographics, comorbidities, and dialytic treatment were collected prospectively. The endpoints were technical success, defined as AVF presenting vascular murmur and thrill at the end of operation, primary patency defined as patency of vascular access with no significant arterial/venous stenosis, and assisted patency defined as patency of vascular access following a salvage procedure (PTA or surgical).

Results: Within the study period, 366 RCAVF were performed. 72(19.6%) patients were lost to follow-up. A total of 294 RCAVF were analyzed: 249(83.3%) RCAVF were performed in Group-A and 49(16.7%) in Group-B. Technical success was obtained in 95.9% of cases with no differences between the two groups (P=0.70). The mean follow up was 25 months. Primary and assisted patency rates were significantly higher in Group A (P=0.002 and P=0.023, respectively). Primary patency rates at 12,24 and 36 months were respectively 77.5%,73.9% and 73.9% in Group-A and 66.0%,49.8% and 46.0% in Group-B. Assisted patency rates at 12,24 and 36 months were respectively 79.6%,76.5% and 75.8% in Group-A and 70.2%,62.4% and 54.8% in Group-B. At univariate analysis pre-dialytic phase was an independent positive predictor for patency in Group-B (P=0,013) but not in global population (P=0.66). Considering all patients in pre-dialytic phase, there was no significant difference in primary patency rates between Group-A and B (P=0.59). Considering the octogenarians, 81.6% RCAVF became functional within the first 3 months.

Conclusions: According to the study results, RCAVF is associated with good results in octogenarians in pre-dialytic phase with suitable anatomical features and could be indicated as a first choice treatment.

SA-PO948

Influence of Arteriovenous Fistula on Daily Living Behaviors Involving the Upper Limbs in Hemodialysis Patients: A Questionnaire Study

Daiki Aomura,[1] Yuji Kamijo,[1] Shigekazu Kurihara,[2] Takayuki Nimura.[3] *[1]Shinshu University School of Medicine, Matsumoto, Japan; [2]Department of Nephrology, Shinshu University School of Medicine, Matsumoto, Japan; [3]Shinshu university, Matsumoto, Japan.*

Background: Arteriovenous fistulae can restrict daily living behaviors involving the upper limbs in hemodialysis patients, but no studies have investigated the detailed effects

of an arteriovenous fistula on routine life activities. Accordingly, many medical caregivers are unable to explain the effects of an arteriovenous fistula on daily life, particularly during non-dialysis periods, because they cannot observe them directly.

Methods: Thirty outpatients undergoing hemodialysis at 2 facilities scored the difficulty due to an arteriovenous fistula in performing 48 living behaviors during non-dialysis and 10 behaviors during dialysis into 5 grades in a comprehensive questionnaire survey. These behaviors were selected based on an open-answer pre-questionnaire administered to the 30 patients beforehand. The scores were also compared between dominant arm and non-dominant arm arteriovenous fistula groups.

Results: During non-dialysis, the difficulty scores of behaviors restricted out of concern for arteriovenous fistula obstruction (wear a wristwatch, hang a bag on the arm, carry a baby or a dog in the arms, wear a short-sleeved shirt, etc.) increased. The difficulties of "wear a wristwatch" and "hang a bag on the arm" were significantly higher in the nondominant arm arteriovenous fistula group (both P<0.05). In contrast, scores related to motor function (write, eat or drink, scratch an itch, etc.) increased remarkably during dialysis because of connection of the arteriovenous fistula to the dialysis machine. The difficulties of "write" and "eat or drink" were significantly higher in the dominant arm arteriovenous fistula group (both P<0.05)

Conclusions: Several key daily living behaviors restricted by an arteriovenous fistula were identified in this questionnaire survey. These results will be useful for preoperative explanation of arteriovenous fistula surgery and arm selection in end-stage renal disease patients.

SA-PO949

Gender Disparities in Vascular Access Surgical Outcomes Among Elderly Hemodialysis Patients

Timmy C. Lee,[1,5] Joyce Z. Qian,[4] Mae Thamer,[3] Michael Allon.[2] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL; [3]MTPPI, Bethesda, MD; [4]Johns Hopkins University, Baltimore, MD; [5]Veterans Affairs Medical Center, Birmingham, AL.*

Background: Despite national vascular access guidelines promoting use of arteriovenous fistulas (AVF) over arteriovenous grafts (AVG) for dialysis, AVF use is substantially lower in females. The objective of this study was to assess clinically relevant AVF and AVG surgical outcomes in elderly male and female patients initiating hemodialysis with a central venous catheter (CVC).

Methods: Using the United States Renal Data System standard analytic files linked with Medicare claims, we assessed incident hemodialysis patients in the United States, 9,458 elderly patients (≥67 years) (4,927 males and 4,531 females) initiating hemodialysis from July 2010 to June 2011 with a catheter, and received an AVF or AVG placed within 6 months. We evaluated vascular access placement, maturation (successful use for diaysis), assisted maturation (requiring an intervention before maturation), abandonment after maturation, and rate of interventions after maturation.

Results: Females were less likely than males to receive an AVF (adjusted likelihood 0.57, 95% confidence interval [CI] 0.52-0.63). Among patients receiving an AVF (Fig. 1), females had higher adjusted likelihoods of AVF non-maturation (HR 1.46, 95% CI 1.36-1.56), assisted AVF maturation (OR 1.34, 95% CI 1.17-1.54), and AVF abandonment (HR 1.28, 95% CI 1.10-1.50), but similar relative rate of AVF interventions after maturation (RR 1.01, 95% CI 0.94-1.08). Among patients receiving an AVG, females had a lower likelihood of AVG non-maturation (HR 0.83, 95% CI 0.73-0.94), similar rates of assisted AVG maturation (OR 1.05, 95% CI 0.78-1.40) and AVG abandonment, and greater relative rate of interventions after AVG maturation (RR 1.16, 95% CI, 1.01-1.33).

Conclusions: In elderly patients initiating hemodialysis with a catheter, clinical AVF surgical outcomes are uniformly worse in females. AVGs may be a viable alternative, notwithstanding current national recommendations.

SA-PO950

A Novel Prospective in Maturation of Native Arteriovenous Fistula (AVF): Preliminary Data from a Single Center

Ioannis E. Giannikouris,[1,2] Ioannis Koutis,[2] Periklis P. Kyriazis,[3] Sotiris Mikros,[4] Giovanni Giordano,[5] Giuseppe Bacchini.[6] *[1]Medifil SA, Athens, Greece; [2]Thriasio General Hospital of Elefsina, Elefsina, Greece; [3]Internal Medicine, Baystate Medical Center/University of Massachusetts, Springfield, MA; [4]General Hospital of Piraeus, Athens, Greece; [5]Vanvitelli L. Hospital, Tramonti, Italy; [6]Alessandro Manzoni Hospital Lecco, Lecco, Italy.*

Background: Our objective was to quantitatively evaluate time alterations of parameters, predictive of hemodynamic maturation of the newly created AVF, in the immediate and late postoperative period (60 days).

Methods: Observational prospective cohort study of 80 incident hemodialysis (HD) and non-dialysis dependent end-stage renal disease (ESRD) patients, who were referred to for AVF creation. Measured parameters predictive of AVF hemodynamic maturation were; lumen diameter of feeding artery (brachial artery, dBA), efferent vein lumen diameter (dEV) and wall thickness (tEV), access volume flow rate (VF) and brachial artery resistive index (RI). Measurements were conducted daily from postoperative day 1 to 7, days 14, 21, 28 and day 60 from AVF creation (day 0). Daily average alteration value of each parameter was assessed and comparison of average observed values followed.

Results: A total of 80 patients, 63 males and 17 females aged 62±15 years, 48 on HD and 32 with non-dialysis dependent ESRD, were enrolled. Fistulae of 4 patients failed during the study period (5% primary failure rate). In total, 43 distal and 33 proximal AVF were successfully created and studied upon completion of follow-up. A daily increase of 0.71% in dBA and 0.70% in dEV from day 1 to 7 was observed. Daily increment rate of dBA a nd dEV, from day 8 to 28, was calculated at 0.07% and 0.06%, respectively, whereas from day 29 to 60 dBA was daily increased by 0.01% and dEV by 0.01%. Regarding tEV, a daily increase by 2.75% from day 1 to 7, 0.08% (days 8 to 28) and 0.01% daily from day 29 to 60 was observed. Resistive Index RI was decreased by 1.33% (days 1 to 7), 0.10% from day 8 to 28, while from day 29 to 60 it was increased by 0.03%. Lastly, VF was increased daily by 1.79% (day 1 to 7), while increase rate was calculated at 0.01% (day 8 to 28) and 0.004% from day 29 to 60.

Conclusions: Hemodynamic maturation of a newly created AVF is thought to be concluded in the first postoperative week. These findings may offer a new perspective to determine the optimal time to assess the hemodynamic and clinical maturation of AVF but most importantly contribute on decisions making about time of interventions to assist maturation. However, future research is considered mandatory for establishment of firm conclusions.

SA-PO951

Surgeon Variation in Dialysis Vascular Access Outcomes in the United States

Vahakn Shahinian,[1] Xiaosong Zhang,[1] Anca Tilea,[1] Kevin He,[1] Douglas E. Schaubel,[1] Ronald L. Pisoni,[2] Bruce M. Robinson,[2] Rajiv Saran,[1] Kenneth J. Woodside.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: An arteriovenous fistula (AVF) is the access of choice for most patients on chronic hemodialysis. Operating surgeon characteristics have been proposed as contributors to successful AVF creation and AVF survival, but previous studies have been limited by small sample size. We examined surgeon-related vascular access outcomes at the national level.

Methods: From the United States Renal Data System, we used Medicare claims and web-based data submitted by dialysis facilities to examine the primary outcome: % of AVFs with successful use within 6 months of placement, i.e. 'maturation', over the period 2013-2014. A multilevel logistic regression model was used to examine the association of surgeon characteristics (year of graduation, type of surgical specialty, volume, ie number of AVF placements per year) with the outcome, adjusted for patient characteristics (age, sex, race, comorbidities, dialysis vintage, prior access placement) and dialysis facility effects.

Results: Over the study period, 2,770 surgeons were identified as placing at least 5 AVFs, with a total of 49,826 AVF placements. The median AVF maturation rate was 59% (interquartile range 44% to 71%). In the model, more recent year of medical school graduation, but not surgical specialty (general surgery, transplant surgery, vascular surgery) was associated with higher odds of AVF maturation. In addition, increasing historical volume of AVF placement was associated with higher odds of successful AVF maturation: odds ratio 1.46 (95%CI 1.37-1.57) for highest (>84 AVF placements in 2 years) vs lowest (<14) volume quintile. Expressed as AVF maturation probability, outcomes varied from 56.8% to 66.6% from lowest to highest volume decile (Figure).

Conclusions: We observed wide surgeon level variation and a strong surgeon volume-outcome relationship for the outcome of AVF maturation.

SA-PO952

Risk Factors Associated with Distal Hypoperfusion Ischemic Syndrome in Patients with an Arteriovenous Access

Muhammad Sohaib Karim,[1] Ali I. Gardezi,[1] Kyla M. Bennett,[3] Brad C. Astor,[1,2] Micah R. Chan.[1] *[1]Division of Nephrology, University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]Department of Population Health Sciences, University of Wisconsin School of Medicine and Public Health, Madison, WI; [3]University of Wisconsin, Madison, WI.*

Background: Steal syndrome, or distal hypoperfusion ischemic syndrome (DHIS), is a complication in up to 20% of patients using an arteriovenous access such as a fistula or synthetic graft for chronic hemodialysis. The purpose of this study was to determine the risk factors associated with the development of DHIS.

Methods: Thirty-nine (39) patients with a diagnosis of DHIS were identified and compared to thirty-nine (39) randomly selected patients with arteriovenous access without DHIS (control group) from December 2008 to September 2017. Univariate and multivariate analysis were done to assess the relationship between development of DHIS and risk factors such as age, gender, race, distal versus proximal location of vascular access, peripheral vascular disease, diabetes and congestive heart failure.

Results: Risk of DHIS did not differ significantly by age, race, diabetes mellitus, coronary artery disease or peripheral vascular disease (Table 1). Proximal versus distal placement of access (odds ratio= 5.98, 95 % CI: 1.35, 26.42) as well as female gender (odds ratio= 4.15, 95 % CI: 1.35, 12.76) were associated with a higher incidence of DHIS.

Conclusions: Age, race, congestive heart failure, diabetes and peripheral vascular disease did not appear to be risk factors associated with the development of distal hypoperfusion ischemic syndrome. Female gender and proximal location of vascular access were associated with significantly higher risk of DHIS. Further studies are required to investigate these findings.

Results

Distal hypoperfusion ischemic syndrome	Odds ratio	95 % CI	Standard Error	P Value
Age per Decade	1.07	0.69 to 1.66	0.240	0.752
Female	4.15	1.35 to 12.76	2.37	0.013
African American	2.71	0.67 to 10.95	1.93	0.161
Diabetes Mellitus	0.91	0.29 to 2.85	0.53	0.877
CHF	1.43	0.45 to 4.45	0.82	0.536
PVD	2.68	0.66 to 10.83	1.91	0.166
Proximal versus distal location of access	5.98	1.35 to 26.42	4.53	0.018

Using Machine Learning to Predict Optimal Renal Replacement Therapy Starts in Patients with Advanced Renal Function Loss

Ollie Fielding,[1] Chris Kipers,[1] Jung Hoon Son,[1] Edward Lee,[1] Daniel Levine,[2] Thomas Parker,[2] Barry H. Smith,[2] Jeffrey I. Silberzweig.[2] *[1]pulseData, New York, NY; [2]The Rogosin Institute, New York, NY.*

Background: Building on our previous work using machine learning techniques to identify patients at risk of progression to End Stage Renal Disease (ESRD), we focused this model more precisely on identifying patients with advanced kidney function loss who should plan for optimal renal replacement therapy. The most recent USRDS data indicates that more than 80% of patients begin hemodialysis with a catheter and only 2.5% receive preemptive renal transplants.

Methods: Using longitudinal patient data of 109,028 patients from The Rogosin Institute, we identified a cohort of patients with advanced kidney function loss, defined as an eGFR <20, and built a machine learning model to predict which patients would need to begin renal replacement therapy in the next six months, based on progression to an eGFR <10. Information in the model included patient demographics, vital signs, comorbidities, laboratory values, and medications. We used an algorithm to remove measurements taken during an AKI episode. We evaluated whether the model could identify the need for renal replacement therapy prior to clinical need.

Results: Between 2014 and 2016, only 17 of 214 patients who progressed within a six month period received an AV fistula prior to their decline to an eGFR <10. The model identified 181 patients as the top quintile of risk who would benefit from preparation for renal replacement therapy. Our model has an AUC of 0.93, a sensitivity of 0.81 and a specificity of 0.89 at the top quintile.

Conclusions: We demonstrate improved ability to identify patients who will need renal replacement therapy using an advanced machine learning model incorporating longitudinal data commonly available in EHRs. We plan to augment clinical decision making with machine learning tools.

Funding: Commercial Support - pulseData

Numbers for 2014-2016

Total patient cohort	109,028
Patients in dataset who progress to an eGFR <20	2,416
Patients who continue on to an eGFR <10	241
Patients who received an AV fistula in the six months prior to their decline to an eGFR <10	17
Patients identified by the model (at the top risk quintile) in the six months prior to a decline to an eGFR <10	181

A Randomized, Open-Label Study to Evaluate the Efficacy and Safety of Plastic Cannula Compared with Metal Needle in Incident Hemodialysis Patients

Sung gyun Kim, Narae Joo, Jwa-kyung Kim. *Hallym University, Anyang, Republic of Korea.*

Background: Successful cannulation of arteriovenous fistula (AVF) is an important issue especially in patients who start hemodialysis. Metal needles have been used for decades, but more recently, the usefulness of plastic cannula has been introduced. In this study, a

Methods: This was a single-center, prospective, randomized, open-label study with incident hemodialysis patients. Eligible patients were randomized into 2 groups in a 1:1 ratio (n=20 in each group). Maturation of AVF was confirmed using Doppler US, and well-trained two nursing staffs implemented AVF cannulation. Primary endpoint was the rate of early successful cannulation, defined as the successful completion of three consecutive dialysis sessions with adequate blood flow rates. Secondary outcomes were incidence of vessel injuries (bruising, swelling, erythema, and hematoma), degree of pain, difficulties during cannulation, and urea clearance. Devices examined were metal needle (JMS, 16G, Singapore), and plastic cannula (Supercath Clampcath®, 17G, Togo Medikit, Japan).

Results: Among the 40 patients, radiocephalic AVFs were 47.5 % (n=19) and mean duration from AVF creation to first cannulation was 51.7 ± 26.5 days. No significant difference was found between groups with respect to patient age, sex, prevalence of diabetes, or types of AVF. Failure of early successful cannulation was observed in 9 patients, and the failure risks tended to be higher in metal group (2 cases in plastic group, but 7 cases in metal group, p=0.060). In addition, the risk of vessel injury was significantly higher in metal group than in plastic group (44.4% vs 11.1%, p=0.030). However, the degrees of pain that patients feel was slightly higher in plastic group than in metal group (4.5 vs. 2.9, p=0.066). The difficulties during cannulation felt by nursing staffs or urea clearance were similar in both groups.

Conclusions: Use of plastic cannulas provided less vascular injury and may increase the rate of successful cannulation especially in early period of dialysis. It could be a new and innovative tool for improve dialysis quality.

SA-PO955

Lower Access Flow After Banding Reduces Frequency of Interventions and Increases Access Patency

Florian Toegel,[1] Patrick McGlynn,[2] Adina S. Voiculescu,[3] Dirk M. Hentschel.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Brigham and Womens Hospital, Boston, MA.*

Background: Patency of brachial-cephalic autogenous accesses is mainly limited by cephalic arch stenosis (CAS). Shear stress is one factor believed to contribute to recurrence and high flow may be associated with less favorable shear stress. Angioplasty (PTA) is effective in the short term but complicated by high recurrence rates and stent grafts have been used to prolong patency. We report the long-term outcome after CAS PTA and stent graft placement in relation to access flow reduction.

Methods: The Brigham Health Interventional Nephrology dataset was reviewed for all patients with angioplasty and stent graft placement in patients with brachial-cephalic fistula 2008-2018, including only those patients with CAS interventions prior to the banding procedure. We used this dataset to compare the frequency of patients requiring cephalic arch angioplasty or stenting in a subset without banding procedure (control), and those with a banding procedure (exposure) to reduce the inflow segment to 3-5 mm diameter. We compared the frequency of interventions using Wilcoxon matched pair signed rank test given the non-parametric distribution of frequency of interventions.

Results: 22 patients meeting inclusion criteria were included in the study. We observed a flow reduction from 1807 ± 477 pre- to 1300 ± 454 post- banding; p<0.001. Along with the flow reduction we observed an increased intervention free period from 229 (IQR: 129-320) pre- to 432 (IQR: 232-717) post-banding; p=0.02. We did not appreciate an association between the absolute flow value and number of days per procedure.

Conclusions: High blood flow is common in brachial-cephalic autogenous accesses and banding significantly decreases access flows. This access flow reduction increases the days between procedures for CAS suggesting a protective role for the development of restenosis.

SA-PO956

Arteriovenous Shunt for Hemodialysis – A Viable and Cost-Effective Vascular Access Option in Hemodialysis Patients

Anil Bhalla, Ashwani Gupta, Anurag Gupta, Vinant Bhargava, Devinder S. Rana.
Nephrology, Sir Ganga Ram Hospital, New Delhi, India.

Background: In India, the most common vascular access for HD(95%) is Arteriovenous fistula (AVF). Primary AVF is the most preferred permanent vascular access - which can be created by radiocephalic or brachiocephalic anastomosis. Ageing population and diabetic patients presenting with sub-optimal veins, along with the issue of late referral makes timely AVF creation an unmet goal. Managing associated complications is an indispensable part of patient care but is also responsible for drain of fiscal resources.

Methods: We started hemodialysis programme in the Dept. of Nephrology, Sir Ganga Ram Hospital in 1981. Due to late referral and immediate need of dialysis, AV shunts were created. In patient with AKI, this shunt could be removed after recovery. In ESRD patients, the same shunt could be converted into AV fistula. Thus, a fistula created after maturation of veins following shunt placement could be used as early as 1-2 weeks. Since its inception, at our centre, vascular access creation has been in the domain of nephrologists.

Results: We have created 2640 AV Shunts till 2014 with infection rates <5% and 3-month shunt blockage <10%. In view of logistic reasons, due to non-availability of shunt material, the programme suffered a setback. We continued to re-use shunts after sterilization, but, they are no longer available now. We have created 7920 AV Fistulas since 1981 till December 2017–achieving a primary patency rate of 95% and incidence of infection of <5%. From 1981-2010, the standard practice was to convert AV Shunt into AV Fistula after 4-6weeks or primary AVF was created asvascular access. Due to non-availability of AV Shunts, now we use Internal-jugular (IJ) catheter for acute dialysis. We have placed over 300 IJ catheters/year since 2014. However, the incidence of IJ catheter related blood stream infection is very high (around 90%) requiring catheter removal usually within 1 month of placement. We have put permcath in 10 patients last year, with average life of 1 year; with permcath thrombosis rates of 20% within 6 months.

Conclusions: To conclude, AV Shunt is still a viable, cost effective and preferred mode of vascular access in patients requiring hemodialysis and should be reintroduced in our practice.

SA-PO957

Likelihood of Failed Thrombectomy (LOFT)

Phillip Ribeiro,[1] Moarij A. Qazi,[2] Jennifer Morse,[3] Thomas G. Stewart,[3] Rizwan A. Qazi.[4] *[1]Nephrology, Vanderbilt University, NASHVILLE, TN; [2]Internal Medicine, UNLV, LAS VEGAS, NV; [3]Vanderbilt University Medical Center, Nashville, TN; [4]KSOSN, Las Vegas, NV.*

Background: Currently percutaneous thrombectomy (PCT) is widely used for clot removal, however if unsuccessful, the patient is referred for open surgical thrombectomy. The current literature suggests that the success rates for thrombolysis of thrombosed fistulas ranges from 76-96%. To date it is unknown what risk factors and or access characteristics result in PCT failure.

Methods: Retrospective single center study including 212 hemodialysis patients, with 179 successful and 33 failed dialysis access thrombectomies. The following characteristics were evaluated for each patient: age, sex, diabetes, clot burden, central venous stenosis, presence of ≥ 2 aneurysms, previous stent placement, on outpatient anticoagulation, SBP<100mmHg, type and location of access, venous outflow stenosis, juxta-anastomotic stenosis, feeding artery diameter, arterial anastomotic stenosis, mid access stenosis, use of TPA or teratola, time of procedure, and presence of venous outflow stenosis. To assess the impacts of several risk factors, we constructed various models of success as a function of age group, sex, diabetes, and one of the other risk factors. The Holm-bonferroni step down method was used to adjust the p-values to deal with familywise error rates for multiple hypothesis tests.

Results: Risk factors for failed thrombectomies included the presence of ≥ 2 aneurysms and or patients with a forearm access. Patients with AV grafts and or venous outflow stenosis had significantly longer procedure times, and the use of teratola or TPA in patients with AV grafts did not affect PCT outcomes.

Conclusions: Our data illustrates that two indepednent risk factors for PCT failure include patients with a forearm access and or the presence of ≥ 2 aneurysms. A patient with both of these independent risk factors is perhaps better off being sent directly for open surgical thrombectomy. Moving forward, larger trials and a larger sample size are needed in order to prove the aforementioned results.

SA-PO958

Predictors of Complications During Outpatient Dialysis Access Procedures

Gregg Miller,[1] Elsie Koh,[1] Yue Jiao,[2] Sophia Rosen,[2] Marta Reviriego-Mendoza,[2] John W. Larkin,[2] Len A. Usvyat,[2] Nancy Mclaughlin,[1] Catherina Madormo,[1] Murat Sor,[1] Franklin W. Maddux.[2] *[1]Azura Vascular Care, Malvern, PA; [2]Fresenius Medical Care North America, Waltham, MA.*

Background: It is unknown if patient specific factors contribute to complications during dialysis vascular access (VA) interventions. We detailed the characteristics of dialysis patients who underwent a VA procedure and investigated risk factors for perioperative complications.

Methods: We analyzed data from patients treated at a large dialysis provider who had ≥1 VA procedure at an affiliated freestanding outpatient access center during 2016 and 2017. The distribution of perioperative complications (e.g. adverse drug reactions, falls, post-operative infections, required interoperative airway management, medication/fluids, and/or additional surgery/procedure) was assessed across strata for age (≤30, 31-40, 41-50, 51-60, 61-70, 71-80, 81-90, >90 years), body mass index (BMI) (≤25, 26-30, 31-35, 36-40, 41-45, 46-50, >50 kg/m^2), and hemoglobin (HgB) levels (<9, 9-<10, 10-<11, 11-<12, 12-<13, ≥13 g/dL). Chi-square tests were used to compare the percent (%) of complications within strata.

Results: We analyzed data from 29,322 unique dialysis patients who underwent a total of 100,070 VA procedures. The % of perioperative complications were evenly distributed for age (p=0.54) and BMI (p=0.09) strata (Figure 1 A & B). However, the % of perioperative complications was observed to be elevated for those with a HgB level <10 g/dL versus ≥10 g/dL (Figure 1 C; p<0.0001).

Conclusions: This research indicates that patients with low HgB levels may be at a higher risk for perioperative complications as compared to those with higher HgB levels; however, patients with low HgB levels are also at a higher risk of all-cause hospital admissions and mortality.

A Hybrid Technique in Recanalization of Multiple Central Venous Occlusions in Hemodialysis Patients: A Cohort Study

Yuliang Zhao, Ping Fu. *Division of Nephrology, West China Hospital, Sichuan University, Chengdu, China.*

Background: The management to multiple central venous occlusions (CVO) in hemodialysis patients remains difficult. This present study aims to assess the feasibility and safety of a hybrid technique in recanalizing multiple CVO in hemodialysis population.

Methods: From January 2014 to November 2017, hemodialysis patients with multiple CVO were enrolled. Under DSA guidance, patients received a hybrid technique combining direct puncture, sharp transversal, and balloon dilation of the SVC, followed by tunneled cuffed catheter implantation (figure). The demographic information and clinical outcomes were recorded.

Results: A total of 16 patients were involved in this study. The procedure was successfully performed in 15 cases and failed in 1 patient due to full-length obstruction of the SVC. 1 patient presented with transient cardiac arrest. 2 patients suffered mild pericardial tamponade, both stabilized afterwards. All 14 patients with successful catheter implantation had satisfactory patency after the procedure.

Conclusions: This hybrid technique could be performed effectively in selected hemodialysis patients with multiple CVO. It could be a viable alternative for hemodialysis catheterization in the setting of an exhausted central venous system with multiple CVO.

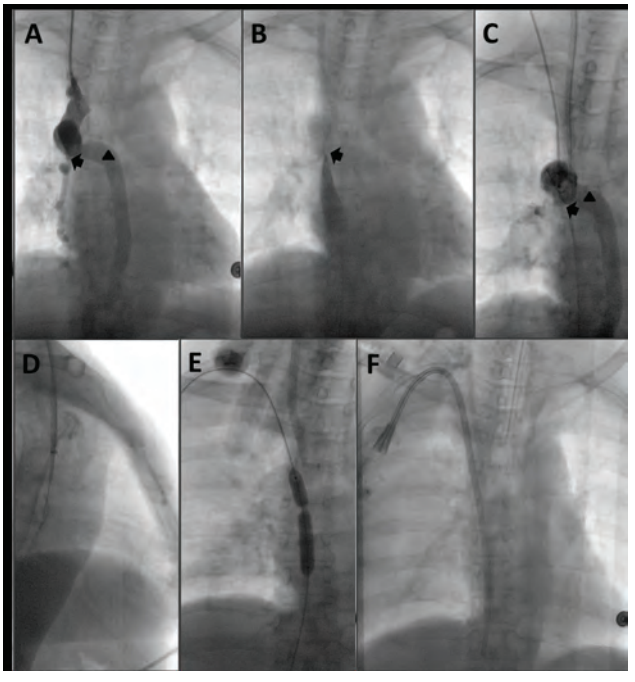

Figure: the procedure of the hybrid technique(Under DSA guidance, patients with SVC occlusion (arrow head) with dilated azygos vein (triangle) were identified (figure A, B). The distal part of SVC was directly punctured (figure C), as verified by contrast. Under guidance in anterior-posterior view and lateral view of DSA, we penetrated the occlusive SVC segment and then advance guide wire through the SVC into the IVC (figure D). The occlusive lesion was dilated with balloon (figure E), which enabled successful tunneled cuffed catheter implantation (figure F).)

SA-PO960

Reasons for Dialysis Catheter Insertion at a National Level – Real Time Data from the REDUCCTION Project

Sradha S. Kotwal,[1,2] Girish S. Talaulikar,[4] Nicholas A. Gray,[5] Kevan Polkinghorne,[6] Stephen P. McDonald,[7] Alan Cass,[8] Martin P. Gallagher.[1,3] REDUCCTION Project Investigators *[1]The George Institute for Global Health, Sydney, NSW, Australia; [2]Nephrology, Prince of Wales Hospital, Sydney, NSW, Australia; [3]Concord Clinical School, Sydney, NSW, Australia; [4]The Canberra Hospital, Garran, ACT, Australia; [5]Sunshine Coast University Hospital, Birtinya, QLD, Australia; [6]Monash Medical Centre and Monash University, Melbourne, VIC, Australia; [7]Royal Adelaide Hospital, Adelaide, SA, Australia; [8]Menzies School of Health Research, Darwin, NT, Australia.*

Background: Dialysis catheters are inserted for reasons which are not well measured or understood. Understanding reasons for catheter insertion on a real-time basis allows units to measure practice and catheter use in a national context. We aimed to understand the reasons for dialysis catheter insertion in patients of Australian renal units participating in a prospective national project (Reducing the burden of dialysis catheter complications - REDUCCTION).

Methods: Data was collected using a web-based data collection tool on all patients who had a dialysis catheter inserted between 20/12/2016 and 23/03/2018 (censored) at any of the 37 units participating in the REDUCCTION project. The reasons for insertions were grouped into Acute Kidney Injury (AKI), commencement of maintenance dialysis, arteriovenous fistula/graft (AVF/AVG) dysfunction, transition from Peritoneal Dialysis (PD) without permanent vascular access and other as reported by study site. Study data collection continues.

Results: Data on 3572 (2522 patients) dialysis catheters were captured so far, representing 316,039 catheter days. Of these, 1176 (32.5%; 60% Tunnelled) catheters were inserted for AKI, 1047 (29.4%; 85.8% tunnelled) for commencement of maintenance dialysis, 464 (13%) for AVF/AVG dysfunction, 401 (11.3%) for transition from PD and 481 catheters (13.5%) for other reasons. Twenty-nine catheters were inserted in 27 patients for failing renal transplants. A total of 1075 catheters remained in situ at the censor date while 2497 catheters were removed after a median of 18 days (IQR 6-71 days). The median duration for tunnelled catheters was 75 days (IQR 26-170) and non-tunnelled catheters was 6 (IQR 3-9) days.

Conclusions: This prospective national data highlights the reasons for dialysis catheter exposure, most notably the high burden arising from AKI. Understanding the outcomes, such as catheter-related bacteraemia (the primary outcome of REDUCCTION), for these different patient groups may aid in reducing complications.

SA-PO961

Surveillance of Catheter Conversion (CC) and Future Vascular Access (VA)

Jeffrey J. Sands,[1,3] Lalathaksha Murthy Kumbar,[2] Kim Hirschman,[1] Stanley Frinak,[2] Gerard Zasuwa,[2] John B. Kennedy.[1] *[1]Vasc-Alert LLC, Evanston, IL; [2]Henry Ford Health System, Troy, MI; [3]Renal Systems Consulting LLC, Orlando, FL.*

Background: We evaluated the impact of AV access (AVF or AVG) conversion (CC) to a central venous catheter (CVC) on patients future VA. Recent efforts focus primarily on AVF placement and maturation. VA outcomes including the extent of CVC use post access complications are less appreciated.

Methods: We identified CC from downloaded treatment (Tx) records utilized for Vasc-Alert™ VA surveillance from 1/1/14—6/30/17 in patients (pts) using a single AV access from 10/2013-12/2013. CC was defined as a recorded change to a CVC for ≥4 Tx within 30 days. Missed treatments were identified from Tx records gaps.

Results: Data included 1,598,680 Tx from 4923 pts (76.1% AVF; 23.9% AVG); mean age 61.1±14.5 yrs (60.6±14.6 AVF; 62.8±14.3 AVG), mean vintage 4.1±3.8 yrs (3.8±3.5 AVF; 5.0±4.6 AVG) in 137 facilities (10 dialysis providers). CC occurred in 16.7% (820/4923) of pts (13.1% AVF, 28.1% AVG; P<0.001); CC rate: 8.2/100 pt-yrs (6.2 AVF; 15.5 AVG). At 1 yr, mean CVC exposure was 168.1 days/pt-yr (162.8 AVF; 176.6 AVG). Vasc-Alert™ provided an alert prior to CC in 57.2% (52.9% AVF; 63.6% AVG). Missed Tx (%) were greater in AVG (P<0.001) and similar in non-CC (4.8% Tx; 4.6% AVF; 5.5% AVG) and pre-CC pts (4.7%; 4.5% AVF, 5.1% AVG)(P=NS). Missed Tx then increased post-CC (6.4%; 5.7% AVF; 7.3% AVG)(P<0.001). Post CC, 52.9% were CVC dependent at 3 months, 33.9% at 6 months and 21.3% at 1 year. Only 23.9%, 27.7% and 30.1% returned to their original VA at 3, 6 and 12 months respectively and 44.3% had a new AV access at 1 yr.

Conclusions: CC results in prolonged CVC use in a high percentage of HD patients. Only ~30% of patients returned to their original access and >44% had a new AV access at 1 year. CC was more frequent in AVG, led to significantly more missed Tx and catheter exposure of >168 days/pt-yr. These data emphasize the importance of access surveillance and preventing terminal access failure to decrease CVC prevalence.

Utilizing a Multidisciplinary Approach to Lower the Central Venous Catheter Rate Among Chronic Hemodialysis Patients: A Quality Improvement Project

Irma Husain,[1,2] Aisha Shaikh.[3] *[1]Internal Medicine, James J Peters VA Medical Center, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]James J. Peters Medical Center VA, New York, NY.*

Background: United States Renal Data System (USRDS) evidence shows that the number of Central Venous Catheter (CVC) dependent patients is 20% and 12% after 1 and 2 years of hemodialysis (HD) initiation respectively. At our hospital, the CVC dependence among chronic hemodialysis patients remains very high. Therefore, we sought to determine if a multi-disciplinary approach, involving the Nephrologists, Interventional Radiologists, and the Vascular Surgeons could reduce CVC use in long-term HD patients.

Methods: From August 2016 to July 2017, we identified 26 CVC-dependent long-term HD patients, 73% of who had a history of at least one failed Arterio-Venous (AV)

access. The Interventional Nephrologist reviewed their records including comorbidities, access failure and complications history and venograms or fistulograms. This data was then presented at monthly multi-disciplinary meetings, also attended by Interventional Radiologists and Vascular Surgeons, during which, potential AV access options including arteriovenous fistulas (AVF) and arteriovenous grafts (AVG) were discussed in detail. A viable AV access option was then identified and placed after discussion with the patient.

Results: 27% (7/26) patients developed a functional AV access. Of these 57% (4/7) were AVGs, 29% (2/7) were AVFs and 14% (1/7) were HeRO (Hemodialysis Reliable Outflow) grafts. 46% (12/26) patients were not able to receive an AV access due to severe peripheral vascular disease or poor overall prognosis while 27% (7/26) patients died through the course of the year.

Conclusions: Monthly multi-disciplinary vascular access meetings with an individualized approach led to an increase in the prevalence of AV accesses among chronic HD patients. We impress that AVG and HeRO graft creation should be considered in patients who are poor candidates for an AVF, as any functional AV access leads to a reduction in CVC dependence and its related complications.

Minimizing Complications During Renal Replacement Therapy with Tunneled Dialysis Catheters in Patients with AKI

Lumen A. Mendez Castaner,[2] Marco A. LadinoAvellaneda,[1] Antonio A. Armstrong,[2] Emilian A. Cristea,[2] Lorena Cuebas-Rosado,[3] Daniel J. Soberon,[3] Vasuki N. Venkat.[3] *[1]Miami VA Medical Center/University of Miami/ Jackson Memorial Hospital, Plantation, FL; [2]Jackson Memorial Hospital, Miami, FL; [3]Miami VA Hospital, Miami, FL.*

Background: Patients with acute kidney injury that need renal replacement therapy have an increased morbidity and mortality. Bacteremia and poor renal replacement therapy delivery are complications that are present with the use of non-tunneled dialysis catheter. There is not enough data to support which option is the best vascular access to start renal replacement therapy in patients with acute kidney injury. We report our protocol using tunneled dialysis catheters for renal replacement therapy based on our 5-year experience.

Methods: This is a retrospective study of 62 patients with AKI that had indications to start renal replacement therapy. The vascular access for renal replacement therapy was a tunneled dialysis catheter. Patients did not have bacteremia or sepsis prior to catheter placement.

Results: All 62 patients had a tunneled dialysis catheter placed. 14 patients were started on continuous replacement therapy (CRT), 48 patients were started on intermittent hemodialysis (IHD). No infections (bacteremia, exit site infection, tunnelitis) in the first 14 days after tunneled catheter placement were reported. A good clearance was obtained in the patients on CRT with a median duration of the dialyzer (No need for exchange) of 3 days. Appropriate clearance was also obtained in the patients on IHD. Blood flows were appropriate in both modalities.

Conclusions: TDCs should be the vascular access of choice for patients (Figure 1) with AKI in need for dialysis if no contraindications are present (bacteremia, sepsis, hemodynamic instability). Patients didn't have catheter related infections. Dialysis delivery was always appropriate without complications. The use of TDCs decreases length of stay in the hospital, costs and complications from non-tunneled catheters.

SA-PO964

Clinical Outcome in the Use of Biopatch in Preventing CRBSI Among Hemodialysis Patients via Hemodialysis Catheters in a Private Tertiary Hospital

Melani T. Gallero,[1] Jeanne B. Bayaca.[2] *[1]Nephrology, St. Luke's Medical Center, Quezon City, Philippines; [2]Goodfellow Pharma Corporation, Pasig, Philippines.*

Background: According to CDC, CLABSI result in thousands of deaths each year. Biopatch is a novel catheter dressing impregnated with chlorhexidine gluconate, used in conjunction with the standard catheter dressing to prevent CRBSI.

Methods: This is a retrospective cohort study design with target population of in hospitalized and outpatients who had HD via HD catheters exclusively in St. Luke's Medical Center–QC, a private tertiary hospital from January 2013 to December 2017.

Results: A total of 427 HD patients via HD catheters (IJ,Femoral,Permanent Catheter) met the inclusion criteria. Of which, 255 HD patients on biopatch and 172 without biopatch.117 in the biopatch group developed CRBSI and 72 patients in those without biopatch. The incidence rate of CRBSI with biopatch was 6.47/1000 catheter days (6 cases of CRBSI/1000 Catheter days) and was higher than those without biopatch, 3.4/1000 catheter days (3 cases of CRBSI/1000 Catheter days) and was statistically significant (P=0.002;HR, 1.614 times among those with biopatch as compared to those without biopatch). Those with significant association with CRBSI among those with biopatch were aged 18 to 60 y/o (P=0.001;HR, 2.841), male patients (P=0.034;HR, 1.57), female patients (P=0.025;HR, 1.717), those with ESRD secondary to DKD (HR, 1.67), other causes of ESRD from solitary kidney, CTIN (P=0.013;HR, 6.564), those with other causes of AKI (P=0.000) and PVD (P=0.000) as compared to those without biopatch. Of the organisms isolated, Klebsiella pneumonia was common among those with biopatch and Pseudomonas aeruginosa among those without biopatch. The risk of CRBSI using permanent catheter with biopatch was 2.853 (P=0.000).

Conclusions: The use of Biopatch had a higher incidence rate of CRBSI among HD patients with biopatch compared to those without biopatch. There was significant association with CRBSI and those with biopatch </=60 y/o, male and female, those with ESRD due to DKD, other causes of ESRD, other causes of AKI and PVD. Majority of organisms isolated were gram positive bacteria, Staphylococcus epidermidis, both in HD patients with and without biopatch. Among CRBSI patients who had Klebsiella pneumonia, the use of biopatch may not be preventive in the development of CRBSI. However, among CRBSI patients with Pseudomonas aeruginosa, biopatch may decrease the risk of CRBSI.

SA-PO965

A New Initiative to Measure the Provincial Rate of Catheter-Related Bacteremia in Ontario

Gihad E. Nesrallah,[1] Angie Yeung,[2] Janet L. Graham,[3] Jane Ip,[2] Monisha Patel,[5] Philip McFarlane.[4] *[1]Medicine, University of Toronto, Toronto, ON, Canada; [2]Cancer Care Ontario, Toronto, ON, Canada; [3]The Ottawa Hospital, Ottawa, ON, Canada; [4]St. Michael's Hospital, Toronto, ON, Canada; [5]Ontario Renal Network, Toronto, ON, Canada.*

Background: The use of a Central Venous Catheter (CVC) is associated with high morbidity and mortality, in part due to increased risk of catheter-related bacteremia (CRB). Patients using a CVC have a greater risk of infection and sepsis compared to patients dialyzing using an arteriovenous access. In 2016, the Ontario Renal Network (which funds dialysis in Ontario) launched a provincial quality improvement (QI) initiative with the aim to shift from local monitoring of CRB rates to a province-wide standardized tracking system. The initiative was launched with the objectives of: 1) Defining a provincial average rate of CRB, and an individualized rate for each of the Regional Renal Programs (RRP); and 2) sharing provincial data and developing program-level QI plans to help minimize CRB risk.

Methods: All 26 RRPs in Ontario collected and reported data from May 2016 – December 2017 using a tracking tool incorporating indicator methodology developed by an expert panel. Reported CRB events formed the numerator for the rate calculation, while the denominator was derived from the Ontario Renal Reporting System database (ORRS) to calculate person-time with a hemodialysis catheter. The CRB rate is expressed as infections

per 1000 patient days, combining patient-time from all in-centre chronic dialysis patients at each RRP.

Results: Over a period of 20 months (May 2016 to December 2017), 696 unique CRB cases were reported over a total of 3,096,046 patient days (approximately 8482 annualized patients). Program-level CRB rates ranged from 0.09 – 0.56 and the provincial average was 0.22 episodes/1000 catheter-days. Quarterly reports were shared with the programs for data validation, comparison and monitoring purposes. The initiative enabled consistent measurement and reporting of CRB, allowed programs to benchmark themselves against their peers, and design local plans for improvement.

Conclusions: The risk of CRB is deemed to be relatively low in Ontario. This initiative has produced a sustainable system of data collection for monitoring the risk of CRB. This initiative is part of a larger strategy to ensure that all patients receiving dialysis therapy experience as few complications regardless of the type of access they have.

SA-PO966

Differential Impact of Central Venous Catheters versus Arteriovenous Fistulas on Quality of Life Among Irish Haemodialysis Patients

Leonard Browne,[2] Gasim Ahmed,[2,3] Aidan G. O'Sullivan,[1] Eoin J. White,[1] Elshaeima Mohammed,[2,3] Fiona Leahy,[5] Elaine C. Conway,[4] Maria Ryan,[4] Leonard W. Osullivan,[1,4] Austin G. Stack.[2,3] *[1]Science & Engineering, University of Limerick, Limerick, Ireland; [2]Graduate Entry Medical School, University of Limerick, Limerick, Ireland; [3]Nephrology, University Hospital Limerick, Limerick, Ireland; [4]Health Research Institute, University of Limerick, Limerick, Ireland; [5]University Hospital Limerick, Limerick, Ireland.*

Background: The arteriovenous fistula (AVF) is associated with superior clinical outcomes than central venous catheters (CVC) in haemodialysis (HD). Recent studies have questioned the relative benefits in survival and quality of life using an AVF strategy over a CVC strategy. We compared the attitudes and opinions of HD patients using an AVF versus a CVC in an Irish cohort.

Methods: A cross-sectional study was conducted in maintenance HD patients (n=119) at a centre-based HD programme in 2018. A validated Vascular Access Questionnaire wasused to measure and compare quality of life across key domains. Patient satisfaction between AVF and CVC was compared in physical functioning, social functioning and dialysis complications using Likert scale with a p-value of <0.05 indicating statistical significance. Comparisons between groups were conducted using student t test and multivariable logistic regression expressed as odds ratio and (95% Confidence intervals).

Results: Average age was 66.1 years, 52.1% were using AVF with 47.9% a CVC. Patients with an AVF experienced higher overall satisfaction scores than a CVC (6.2 vs 4.9, P<0.01), however AVF patients reported more problems with bleeding, swelling and bruising than CVC patients [2.9 (2.2) vs 1.6(1.4), 2.9 (2.1) vs 1.7 (1.5), and 3.6 (2.2 vs 1.8) respectively, all p<0.005]. In contrast CVC patients reported greater difficulties in bathing and showering than AVF (4.5 (2.3) vs 2.1 (1.8), p <0.001). In multivariable analysis, adjusting for demographic and clinical factors, dialysing with a CVC (vs AVF) was associated with less difficulties in physical functioning OR, 0.35 (0.13-0.96), P=0.04, and higher odds of dialysis complications OR, 2.14 (0.78-5.89), P=0.1.

Conclusions: Compared to AVF, CVC use is associated with less physical complaints from bleeding and bruising but greater negative impact on social activities including bathing and showering. Minimising the impact of these on QOL should be considered in any long term vascular access strategy.

Funding: Government Support - Non-U.S.

Table 1. Association between Access type (Catheter vs Fistula) and Upper Quartile QOL score for each domain

Variable	AOR (95 %CI)	P-value
Physical Functioning		
Unadjusted	0.36 (0.15-0.85)	0.02
Model1	0.38 (0.16-0.93)	0.03
Model2	0.35 (0.13-0.96)	0.04
Social Functioning		
Unadjusted	1.28 (0.56-2.94)	0.56

Interim Analysis of Randomized Trial Comparing VectorFlow and Palindrome Tunneled Dialysis Catheters

Gregory Nadolski,[1] Benjamin J. Shin,[2] Raphael M. Cohen.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]Hospital of University of Pennsylvania, Philadephia, PA.*

Background: Tunneled dialysis catheters (TDC) remain an important bridge to permanent hemodialysis (HD) access, a critical transition to new access creation when surgical access fails, and the only source of HD access when venous anatomy is exhausted for surgical access. Selection of an HD catheter capable of providing efficient HD with high primary patency is of utmost importance to improving outcomes in ESRD patients. The purpose of this trial is to compare a widely used symmetrical tip TDC, Palindrome (P), to a recently FDA-approved symmetrical design with helical flow at the tip to reduce blood cell shear stress, VectorFlow (VF).

Methods: The target recruitment of the study was 100 subjects enrolled at two centers with 1:1 randomization. Exclusion criteria included uncorrectable coagulopathy or thrombocytopenia; neutropenia, bacteremia, or infected surgical HD access within 7 days prior to enrollment; central venous stenosis or occlusion preventing jugular catheter insertion. The primary endpoint was primary patency at 90 days. Secondary endpoints include dialysis adequacy with Kt/V and URR monthly for 3 months, catheter flow (Qb) and lumen pressures at initial HD and monthly for 3 months.

Results: At present, the trial has enrolled 78 subjects and is anticipated to complete enrollment by the fall of 2018. Interim analysis showed 90-day primary patency of 74% in the VF group compared to 71% in the Palindrome group (P=0.81). Mean Kt/V at 30, 60 and 90 days was higher with the VF than P (30 d ay, 1.48 vs. 1.40; 60 days, 1.48 vs. 1.37; 90 days, 1.51 vs. 1.35); mean Kt/V averaged across all time points was significantly higher among subjects receiving the VF catheter compared to P (1.48 vs. 1.38, P=0.020). No significant differences were seen with URR (69 vs. 69) or Qb. Additional study data are pending final subject enrollment.

Conclusions: The ongoing trial comparing VectorFlow tunneled dialysis catheter to Palindrome tunneled dialysis catheter is the first US randomized trial comparing different HD catheter tip designs in nearly two decades, and the first to address dialysis adequacy. The results of this trial may elucidate which catheter design provides optimal HD adequacy and catheter patency.

Relationship Between Central Venous Catheter Protein Adsorption and Water Infused Surface Protection Mechanisms

David W. Sutherland,[1,2] Joseph L. Charest.[2] *[1]Boston University, Cambridge, MA; [2]Draper Laboratory, Cambridge, MA.*

Background: Many dialysis patients are implanted with central venous catheters (CVCs) despite increased patient risk due to thrombosis and biofilm formation. These complications are caused by fibrin sheath formation, which is initiated by blood protein adsorption upon exposure. Current solutions to prevent thrombotic occlusion and biofilm formation remain ineffective at preventing these failure modes and remediation treatment options are limited and often harmful. We propose an active method to reduce protein adsorption and effectively disrupt adherent protein sheaths, water infused surface protection (WISP).

Methods: Experiments were performed *in vitro* using a modeled CVC that simulated the WISP mechanism. A hollow fiber membrane (HFM), representing the CVC lumen, was mounted in a concentric chamber. The WISP was achieved by pressurizing the concentric chamber with saline while blood flowed through the HFM, causing a continuous saline infusion across the HFM wall. The resulting water boundary layer at the lumen surface limited the blood contact with the HFM wall resulting in decreased protein adsorption.

Results: Analytic lubrication models matched our experimental pressure measurements suggesting the WISP created a blood-free boundary layer on the HFM surface. Figure 1 shows the WISP boundary layer reduced the average density of adsorbed protein on the model CVC with increasing WISP flowrates, up to 96.4% over the 0% WISP condition (* denotes P≤0.016, 2-way ANOVA). Additionally, the WISP CVC displayed the ability to reduce previously-adsorbed protein films, and deliver chemical agents, such as heparin, within the WISP flow.

Conclusions: The proposed WISP technology has functionality that could reduce failure incidence to improve clinical outcomes. WISP shows the ability to significantly reduce protein adsorption, as well as presents a new methodology to treat major CVC complications; removing pre-adsorbed material or treating a resulting infection by more effectively delivering drugs to the point of adhesion.

SA-PO969

Gaining Central Venous Access Safely and Quickly in Patients with Occlusion of the Upper Central Veins with a Novel Device Using an Inside-Out Approach

Roman Reindl-Schwaighofer, Gurkan Sengoelge. *Nephrology, Medical University of Vienna, Vienna, Austria.*

Background: Left-sided and subclavian central accesses cause the highest rate of central venous thromboses and occlusions. Exhaustion of vascular access options caused by thoracic central venous occlusion (TCVO) adds to dialysis-related morbidity and mortality. We report the first case series of a novel device, the Surfacer, for repeated right-sided central venous access in patients with TCVO.

Methods: The Surfacer consists of a metal pole with a sharp wire inside attached to a handle. The procedure is performed on an outpatient basis using local anesthesia under fluoroscopy as follows: A 10F sheath is introduced up to the TCVO over a standard guidewire from the right femoral vein. After removal of this wire, the 7F metal pole of the Surfacer is introduced through the sheath to the TCVO and pushed through until its tip has passed the clavicle. The sharp wire is then released using a plunger at the handle from the tip of the Surfacer piercing the skin inside out in the right supraclavicular region. This now serves as a guidewire for a central venous access. We analyzed success rate, duration of procedure and complications of all Surfacer cases performed at the Department of Nephrology, Medical University of Vienna between July 2016 and April 2018.

Results: The Surfacer procedure was considered in 37 cases. Following CT angiography, four patients did not qualify because of complete occlusion of either right external iliac vein or inferior or superior vena cava. The majority of patients had a TCVO type 3 with occlusion of both brachiocephalic veins but a patent azygous vein. The procedure had a 97% success rate (32 out of 33; one patient had a massive scoliosis which blocked the passage of the device). The mean intervention time was 14 min. There were no Surfacer related complications defined as early infections, bleeding, hematoma or pericardial effusions. In five patients the procedure was repeated due to infection or dysfunction > 3 months after initial placement.

Conclusions: This is the first case series of a novel device for inside-out placement of central venous access in patients with TCVO requiring dialysis. The procedure is highly successful, safe and repeatable allowing for an "always right, never subclavian" approach.

SA-PO970

Catheter-Related Right Atrial Thrombus on Hemodialysis Patients: Results of a Cohort Study

Ismael A. Gómez Ruiz, Lucas Porto-Silva, Zuilma Vazquez ortiz, Jaime Galindo uribe, Ricardo Correa-Rotter, Juan Carlos Ramirez-Sandoval. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, México city, Mexico.*

Background: Catheter-induced right atrial thrombus (CRAT) is a serious complication in hemodialysis (HD) patients and optimal treatment is not well defined. We reviewed clinical characteristics, treatments options, and outcomes of CRAT in HD patients

Methods: Single-center retrospective cohort study of CRAT confirmed by echocardiogram (2008-2018).

Results: We identified 23 CRAT cases in HD. Thrombus was visualized initially by transthoracic echocardiogram in 74% (17/23); all but one had transesophageal echocardiogram. The largest thrombus dimension was 52x23 mm. Factors related to CRAT were long catheter vintage (7 [IQR 4-13] months) and catheter misplacement in 65% (15/23). All cases received anticoagulation as initial treatment. The most relevant clinical data for subsequent treatment decision was suspicion of catheter-related bloodstream infection (CRBSI). Patients were divided in those that had early catheter removal due CRBSI (39%, 9/23) and those who had non-urgent indication of catheter removal (61%,14/23) [Table]. Early removal group had worse outcomes:100% had catheter removal before therapeutic anticoagulation was achieved, 44% had embolic complications after catheter removal, 78% required surgical definitive treatment, and 44% (4/9) died. Non-urgent catheter removal group received total anticoagulation for 22 [IQR 13-28] weeks, dissolution of thrombus occurred in 64% (9/14), thrombus shrinking in 14% and 42% required delayed catheter removal without major adverse events.

Conclusions: To our knowledge, this is the first large cohort of CRAT on HD. Total anticoagulation is essential after CRAT diagnosis and may be sufficient to dissolve or shrink thrombus <52 mm in asymptomatic or stable febrile HD patients without an urgent indication for catheter removal. Infection related to CRAT had a high risk of adverse outcomes, including mortality.

Characteristics of the HD cohort and clinical outcomes.

	All CRAT(n=23)	Urgent catheter removal (n=9)	Non-urgent catheter removal (n=14)	p value

SA-PO971

Anxiety and Pain with Tunneled Dialysis Catheter Insertion in Patients with ESRD

Stewart Nadurak,[1] Claudio Rigatto,[1] Paul Komenda,[1] Navdeep Tangri,[1] Reid Whitlock,[1] Sara E. Dunsmore,[1] Alissa Lloyd,[2] Sean Armstrong.[1] *[1]Seven Oaks Hospital, Chronic Disease Innovation Centre, Winnipeg, MB, Canada; [2]St. Boniface Hospital, Winnipeg, MB, Canada.*

Background: About 50% of hemodialysis patients require tunneled catheters for hemoaccess because a fistula is not feasible. Tunneled catheters are typically inserted with local anesthetic (LA) alone. However, conscious sedation (CS) is sometimes used and may be associated with slightly increased cardiorespiratory risk, or require several hours of post-procedure observation in hospital. Given limited access to recovery beds, patients receiving CS are usually bridged with a non-tunneled catheter until conversion to a tunneled catheter can be booked. As there is no consensus on the benefit of CS in this setting, clinical practice varies widely and patient preferences regarding this choice are unknown. Our objectives are to assess: 1) pain and anxiety experienced by patients during tunneled catheter procedures; 2) patient preferences with respect to the time vs. discomfort trade-off inherent in the choice of using or not using CS.

Methods: We mailed a 10-item questionnaire to all patients >18y who had tunneled catheter procedures in Manitoba, Canada between Apr-16 and Oct -17; as well as to incident patients from Nov-17 until present. Participants rated their experience of pain and anxiety from their most recent procedure on a Likert scale from '0' to '10'. Patients were also asked which procedure they would prefer in the future.

Results: A total of 148 of 651 questionnaires were returned (22.7%); where 80 patients had LA only and 37 had CS. Pain (median = 2) and anxiety (median = 4) during the procedure were low in both groups. Patients undergoing CS experienced a higher level of pain post-procedure (median of 2.5 vs. 1; p = 0.02) and anxiety during procedure (median of 5.5 vs 3; p=0.01). The majority of respondents preferred one procedure with LA only to two procedures (non-tunneled insertion, then CS for tunneled catheter) (68% vs. 32%), or to waiting for a CS procedure at a later date (76% vs. 24%). Limitations: retrospective survey. Response rate was low.

Conclusions: Low levels of pain and anxiety were experienced regardless of procedure type. When faced with a trade-off, patients preferred a procedure that took less time even if more discomfort was involved. We conclude that LA alone can be used without significant additional distress in most patients.

SA-PO972

Nitric Oxide (NO) Releasing Tunneled Dialysis Catheters (TDC) Reduce Catheter Related Blood Stream Infection (CRBSI) and Dysfunction

Diego Celdran-Bonafonte,[1] Li H. Wang,[2] Orsolya Lautner-Csorba,[6] Elizabeth Brisbois,[3] Aous Jarrouj,[5] Maria Kim,[6] Jaroslav Janda,[4] Lindsay N. Kohler,[4] Taylor G. Lewis,[4] Frank C. Brosius,[4] Mark Meyerhoff,[6] Prabir Roy-Chaudhury.[4] *[1]Department of Medicine, University of Arizona, Tucson, AZ; [2]The Second Hospital of Tianjin Medical University, Tianjin, China; [3]University of Central Florida, Orlando, FL; [4]University of Arizona, Tucson, AZ; [5]Banner-University of Arizona, Tucson, AZ; [6]University of Michigan, Ann Arbor, MI.*

Background: Tunneled dialysis catheter complications, due to infection, thrombosis and central vein stenosis are responsible for a very significant morbidity, mortality and economic cost. Nitric oxide (NO) is an important biological mediator, which has potent anti-microbial, anti-platelet and anti-smooth muscle cell activities. We have previously developed a novel and innovative technology that results in a prolonged polymer based (silicone rubber, polyurethanes, etc.) release of NO. The goal of this study, therefore, was to assess the impact of NO releasing TDCs on infection, thrombosis and central vein stenosis, using a validated pig model of TDC complications

Methods: 9 Yorkshire cross pigs were used in this study. 4 non-treated commercial catheters and 5 NO-releasing catheters were placed using a percutanous jugular approach. Catheters were accessed twice a week in a sterile fashion, in order to mimic the dialysis procedure and to score TDC dysfunction using a semi-quantitative scale. Study animals were monitored daily for signs and symptoms of infection. Catheter and tissue samples were collected in a standardized fashion at the time of sacrifice or at 28 days, and analyzed using standard histological and scanning electron microscopy(SEM) techniques

Results: NO-releasing catheters had a significantly delayed time to onset of infection (19.4±8.6d vs 8±3.36d; p = 0.03) and also a delayed (but not significant), onset of catheter dysfunction (12.4±9.9d vs 6.7±3.4d). Despite this significant clinical benefit, a compact fibrin sheath was detected in both the control and treated arms, together with a significant degree of central stenosis. SEM imaging revealed the presence of biofilm formation in both groups.

Conclusions: Our data demonstrate for the first time, an important clinical benefit of NO releasing TDCs on infection and dysfunction. Interestingly, this clinical benefit seemed to occur independently of the presence of a fibrin sheath, venous wall thickening and biofilm formation. We believe that a prolonged release of NO using our innovative polymer technology could result in a very significant reduction of the morbidity, mortality and economic cost currently associated with TDC complications.

Echocardiographic Measurements Before Different AVF Types Created Before and After Hemodialysis Initiation and the Contribution to Pulmonary Hypertension

Juan C. Duque Ballesteros,[1] Laisel Martinez,[1] Roberto I. Vazquez-Padron,[1] Hannah Labove,[2] Luis A. Escobar,[1] Marwan Tabbara.[3] *[1]University of Miami, Miami, FL; [2]University of Miami/Jackson Memorial Hospital, Miami, FL; [3]University of Miami, Miller School of Medicine, Miami, FL.*

Background: Pulmonary hypertension (PH; PAP of 25 mmHg at rest or higher than 30 mmHg with exercise) is common in end-stage renal disease patients, which has been associated with uremic toxins, volume status, and hemodynamic changes that occur with vascular access creation. Little is known about the effects that different vascular access techniques, performed before or after initiation of dialysis, have on echocardiographic measurements.

Methods: A retrospective study was performed at the University of Miami Hospital/ Jackson Memorial Health System from 2009 to 2014, evaluating patients who underwent an arteriovenous fistula (AVF) creation for hemodialysis. Patients who had a 2-D echocardiogram done before and after surgical AVF creation were analyzed. A total of 125 patients were included. From these, 22 patients had the AVF created before the need for dialysis, while 103 patients had already initiated hemodialysis (HD) using a dialysis catheter. The 2-D echo measurements analyzed were ejection fraction EF (%), right ventricular systolic pressure (RVSP; mmHg), and right ventricular end diastole (RVDd; cm).

Results: The mean age at the time of AVF creation was 50 ± 12 years in patients with AVFs created before HD initiation, and 51 ± 13 in the after HD subgroup. 55 and 62% of patients were men, and essential hypertension was present in 100% of participants in both cohorts. The prevalence of diabetes mellitus was 68% and 59% in patients with AVF created before and after HD initiation, respectively. The AVF inflow was brachial-based in 50% and radial-based in 50% of the accesses in the pre-dialysis group, compared to 58% brachial vs. 42% radial in AVFs created after HD initiation. No statistical differences were found in RVSP or RVDd comparing brachial-based vs. radial-based inflow AVFs in patients with access created before or after HD initiation. However, EF (%) was higher in patients with radial-based vs. brachial-based AVFs when the access was created after HD initiation (53.8 ± 11 vs. 57.8 ± 6, p=0.04).

Conclusions: With these results, we can conclude that timing of AVF creation or type of arterial inflow has no correlation with PH in end-stage renal disease patients. The differences in EF in the after HD subgroup need to be further investigated.

The First-in-Man Trial of the av-Guardian Vascular Access System

Chieh-suai Tan,[1] Lina Choong,[1] Titus W. Lau,[2] Shervanthi Homer-Vanniasinkam.[3,4] Singapore av-Guardian consortium *[1]Renal Medicine, Singapore General Hospital, Singapore, Singapore; [2]National University Health System, Singapore, Singapore; [3]The General Infirmary at Leeds, Leeds, United Kingdom; [4]University College London, London, United Kingdom.*

Background: The ability to successfully cannulate the AVF reliably is a critical step in the delivery of hemodialysis therapy. The av-Guardian vascular access system (avGD; Advent Access, Singapore) is designed to overcome the technical barrier to establishing reliable blunt needle access in patients with mature AVF. avGD is a single component titanium device (15mm x 5mm x 3 mm) with a palpable entry point that is subcutaneously implanted between the skin and the AVF to allow repeated cannulation through a single puncture site.

Methods: This was a first-in-man, prospective, non-randomized trial performed to assess the safety and feasibility of avGD in facilitating blunt needle access in patients with matured AVF. The primary end points of the study included rate of successful hemodialysis sessions via avGD cannulation over 3 months and changes in AVF flow rates after implantation

Results: Six patients were enrolled in the study, of which 5 had AVFs that were difficult to cannulate. A pair of avGD was implanted each at the arterial and venous cannulation sites under local anaesthesia as shown in figure 1. Cannulation via the avGD commenced 14 days post-implantation. Overall, the rate of successful cannulation through the avGD over 3 months in 216 hemodialysis session was 98.1%(424/432) at the arterial site and 94.4% (408/432) at the venous site. Significantly, 85.5% and 90% of the cannulations at the A and V site respectively were successful at first attempt. Blood flow rates within the AVF were unaffected by the devices. The patients were transited to blunt needle cannulation after a median of 15.5 and 18.5 sessions at the A and V site respectively.

Conclusions: The results of this first in man trial demonstrated the safety and feasibility of a subcutaneously implanted, extravascular device to facilitate blunt needle access in matured AVF. The device did not adversely affect flows within the AVF after implantation and successful cannulation through the devices can be achieved > 94% of the time

Extracellular Matrix Stiffness Mediates Human Aortic Smooth Muscle Cell Phenotype via Rho-Kinase

I-Chia Liu,[1] Shiyu Li,[1] Brandon To,[1] Rajesh Mohandas.[1,2] *[1]University of Florida, Gainesville, FL; [2]North Florida/South Georgia Veterans Health System, Gainesville, FL.*

Background: Chronic Kidney Disease (CKD) is associated with increased vascular stiffness and accelerated atherosclerosis. However, the mechanisms by which stiffness accelerates the development of atherosclerosis is not known. Rho-kinase (ROCK), a key mechanosensor, influences the phenotype of vascular smooth muscle cells. A synthetic phenotype characterized by increased migration and proliferation of vascular smooth muscle cells is associated with atherosclerosis. We hypothesized that matrix stiffness upregulates ROCK activity to affect vascular smooth muscle cell phenotype.

Methods: Human aortic smooth cells (HASMC) were plated on regular tissue culture plates or polyacrylamide gels engineered to varying stiffness (2kPa – 50kPa). Proliferation of cells was measured by a formazan-based assay. ROCK activity was measured using an ELISA based detection of substrate phosphorylation, and ROCK transcription was assayed by PCR.

Results: Proliferation of HASMC increased with increasing stiffness of the matrix (Fig 1A). Stiffness increased ROCK activity in these cells (Fig 1B). In addition, PCR showed that stiffness increases ROCK1 mRNA but not ROCK2. Inhibition of ROCK with Fasudil abolished the stiffness induced increase in proliferation.

Conclusions: Our results suggest that stiffness increases proliferation of HASMC via Rho-kinase. Thus, ROCK pathways might be a target to prevent vascular complications of kidney disease.

Funding: Other NIH Support - NHLBI, K-08HL130945

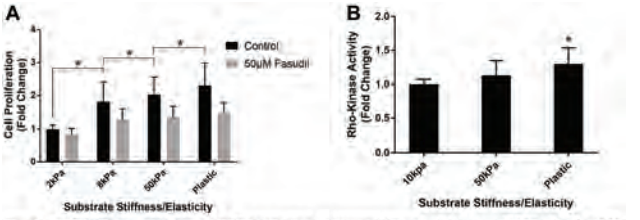

Figure 1. (A) ECM stiffness causes increased HASMC proliferations. (B) Increased stiffness leads to increased ROCK activity. * p < 0.05.

Iron Stimulation Induced Calcification in Human Aortic Vascular Smooth Muscle Cells Through Interleukin-24 (IL-24)

Yasuyuki Nagasawa,[1] Sayuri Kawada,[1] Mutsuki Kawabe,[2] Aritoshi Kida,[1] Kosuke Mizusaki,[1] Masayoshi Nanami,[1] Yukiko Hasuike,[1] Keiji Nakasho,[2] Takahiro Kuragano,[1] Takeshi Nakanishi.[1] *[1]Department of Internal medicine, Devision of Kidney and Dialysis, Hyogo college of medicine, Nishinomiya, Japan; [2]Department of pathology, Hyogo College of Medicine, Nishinomiya, Japan.*

Background: In CKD patients, atherosclerosis is one of important life-limitting factors. The feature of the atherosclerosis in CKD patients was called as Moenckeberg's arteriosclerosis which was seen in vascular media, but the relationship between iron and calcification in vascular smooth muscle cell remained unclear. To reveal the relationship between calcification in vascular media and iron stimulation using cultured vascular smooth muscle cells.

Methods: The aorta smooth muscle cells were cultured for three weeks. At day 0, we changed the usual culture medium to calcification medium, and TNF-alpha and iron were added to the calcification medium. Calcification in each condition was confirmed by Alizarin staining. And to reveal early mechanism to enhance the calcification by iron and TNF-alpha stimulation, we compared the gene expression profile between each condition in day 1 and day 3 using microarray analyses. We confirmed gene expression of IL-24 which had increased in microarray analysis by mRNA level (real-time PCR) and by protein level (ELISA) in time course. Calcification induced by recombinant IL-2 instead of iron was also evaluated.

Results: Both iron and TNF-alpha stimulation enhanced calcification by Alizarin Staining. Moreover, both iron and TNF-alpha stimulation at the same time enhanced

calcification more strongly than single stimulation. We picked up IL-24 which had increased with both iron and TNF-alpha stimulation. We confirmed IL-24 expression by real-time PCR. Gene expression was increased at day1 by stimulation of iron(5.8±3.0 fold change vs control), TNF-alpha (7.8±1.9 fold change vs control), and both stimulation(53.1±27.1fold change vs control), synergistically(shown below). At day 3, gene expression showed as same increase as at day 1. The time course of IL-24 was confirmed in mRNA level by real time PCR and in protein level by ELISA. Calcification was induced in human vascular smooth muscle cells by IL-24 instead of iron, and quantification of calcification also confirmed the result.

Conclusions: Iron stimulation enhanced calcification in vascular smooth muscle cells along with TNF-alpha stimulation. Iron stimulation along with inflammatory might induce calcification in human vascular smooth muscle cells through IL-24.

Indoxyl Sulfate Aggravates Vascular Calcification via Suppress the Matrix Gla Protein by the the ROS/NF-κB Signaling Pathway

Xin He,[2] Hongli Jiang.[1] [1]*First Affiliated Hospital of Medicine School, Xi?an Jiaotong University, Xi?an, China;* [2]*Dialysis Department of Nephrology Hospital of the First Affiliated Hospital of Medicine School, Xi'an Jiaotong University, Xi'an, China.*

Background: Vascular calcification (VC) is the major complication and contributes to the cardiovascular mortality in chronic kidney diseases (CKD). Indoxyl sulfate (IS) has been recognized as the major uremic toxin involved in the vascular calcification in CKD due to its high oxidative stress, but the underlying mechanisms remain largely unknown. Matrix Gla protein (MGP) plays roles in vascular calcification as an important inhibitor of calcification. Here, we investigated whether MGP is involved in IS-induced vascular calcification.

Methods: In vitro, radial arteries from CKD patients were used for histological examination. In vitro, HASMCs were cultured with IS to induce vascular calcification, which was detected by Alizarin red S staining. Gene expression and protein levels of MGP and osteogenic differentiation markers were determined by qRT-PCR and western blotting, respectively. ROS were detected using probes with a fluorescence detector. The phosphorylation of Ikkβ, NF-κB and IκB degradation were detected by western blotting, and the role of ROS/NF-κB was further confirmed by using the inhibitor of DPI and PDTC.

Results: We observed the average level of MGP expression was decreased in the calcified vessels in CKD patients. Simultaneously, IS also decreased MGP expression accompanied by the calcification of HASMCs. osteogenic differentiation was confirmed by the increased expression of BMP2 and Cbfa1 and decreased expression of the α-SMA, which was accompanied by the increased level of ROS. The phosphorylation of Ikkβ, NF-κB and IκB degradation increased by IS but reversed by an ROS inhibitor of DPI. In contrast, suppression of MGP and calcification of HASMCs calcification were attenuated by pretreatment with PDTC, an NF-κB inhibitor.

Conclusions: These observations provide evidence that inhibition of MGP expression may contribute to the pathogenesis of IS-induced vascular calcification in CKD.

SA-PO978

CDK9-Cyclin T1 Complex Mediates Medial Calcification Through the Induction of CHOP

Yuji Shiozaki,[1] Shohei Kohno,[1] Audrey L. Keenan,[3] Shinobu Miyazaki-anzai,[2] Makoto Miyazaki.[2] [1]*University of Colorado Denver, Aurora, CO;* [2]*University of Colorado-Denver, Aurora, CO;* [3]*University of Colorado AMC, Aurora, CO.*

Background: Our recent studies indicate that activation of the Activating transcription factor 4 (ATF4) pathway through the ER stress response induced by saturated fatty acids (SFAs) plays a causative role in vascular calcification in chronic kidney disease (CKD). we 1) studied a pro-apoptotic CHOP transcription factor that contributes to CKD-dependent medial calcification and 2) identified a novel regulator of ER stress-mediated CHOP expression

Methods: 1) To study the smooth muscle cells (SMC)-specific role of CHOP in regulating medial calcification, we generated SMC-specific CHOP conditional transgenic mice and analyzed aortic region of control and SMC-specific CHOP TG mice under CKD (5/6 nephrectomy). 2) To explore a signaling pathway that blocks SFA-induced CHOP expression, we screened a kinase inhibitor library containing >140 compounds by treating human vascular smooth muscle cells with a saturated fatty acid.

Results: SMC-specific CHOP transgenic mice developed severe vascular apoptosis and medial calcification under CKD. Protein kinase inhibitor library screening identified 16 compounds, including 7 cyclin-dependent kinase (CDK) inhibitors, that significantly suppressed the induction of CHOP through ER stress. In addition, selective inhibitors against CDK9 and CDK9-specific inhibition through a gene-editing technique blocked SFA-mediated induction of CHOP, while other CDK isoform inhibitors did not affect CHOP expression. Knockout of cyclin T1 inhibited SFA-mediated induction of CHOP and mineralization, whereas deletion of cyclin T2 and cyclin K promoted CHOP expression levels and mineralization. The CDK9-cyclin T1 complex directly phosphorylated and activated ATF4.

Conclusions: These results demonstrate that 1) the CDK9-cyclin T1 and CDK9-cyclin T2/K complexes have opposing roles in CHOP expression and vascular calcification and 2) the CDK9-cyclin T1 complex mediates vascular calcification due to CHOP induction through phosphorylation-mediated ATF4 activation.

Mechanisms Linking CKD and Atherosclerosis: CD34+ Cell in the Atherosclerosis Plaque

Miguel Hueso,[1] Estanislao Navarro,[3] Nuria Bolanos,[3] Cristian Varela,[3] Angela I. Casas Parra,[2] Jordi Guiteras,[3] Joan Torras.[2] [1]*Hospital of Bellvitge, L'Hospitalet de Llobregat (Barcelona), Spain;* [2]*Laboratory Experimental Nephrology, IDIBELL. Hospital Universitari de Bellvitge, Barcelona, Spain;* [3]*IDIBELL, Hospitalet de Llobregat, Spain.*

Background: Chronic kidney disease (CKD) is associated with a higher incidence of atherosclerotic vascular disease (ASVD) but its pathogenic mechanism is not well known. CKD is associated with lower circulating $CD34^+$ Endothelial Progenitor Cells (EPCs) and atherosclerotic lesions have a focal distribution suggesting an impaired vascular repair mechanism. The aim of this study was to localize stems and $CD34^+$ EPCs in the vascular wall from humans and in a mouse model of atherosclerosis.

Methods: We assessed CD34 + hematopoietic stem cells in the atherosclerotic plaque by IHQ in the abdominal aorta obtained from 10 human necropsies (5 patients with CKD). CD34 levels were quantified by qPCR. Furthermore, we analyzed CD34+ by IHQ in 10 $APOE^{-/-}$ mice with a CD40 blockade using a specific siRNA (siCD40) and in 10 $APOE^{-/-}$ controls (5 mice treated with scrambled siRNA (SC) and 5 mice treated with vehicle (veh)) at 24 weeks.

Results: We included 18 samples (9 atherosclerotic plaques and 9 samples from normal abdominal aorta without injury) from 9 patients (5 patients with CKD). Atherosclerotic plaque was associated with increased inflammation in the intima (14 ± 15% in the sample without injury, n=9 vs 54 ± 25% in the plaque, n=8, p=0.004). $CD34^+$ cells were increased in the atherosclerotic plaque (-4.7 ± 0.76 cycles, n=6 in normal aorta vs -3.2±1 cycles, n=4 in plaque, p=0.028). Furthermore, we have identified niches of $CD34^+$ cells in the neointima and in the adventitia of human arteries. Then, we analyzed mRNA levels of CD34+ patients in normal vascular walls with CKD and we observed a trend to display lower number of CD34 cells (-4.5±0.7 cycles in non-CKD patients, n=4, -5.3±0.75 cycles in CKD patients, n=2; p=0.3). Finally CD34+ cells were identified especially in the perivascular adipose tissue (PVAT) of mice treated with siCD40 (9±1% in 5 mice treated with veh, 3±2% in 5 mice treated with SC, vs 13±6% in 10 mice treated with siCD40, p<0.0001).

Conclusions: Atherosclerotic plaque is associated with increased inflammation and an increase number of cells hematopoietic stem cells (HSCs)/endothelial progenitor cells (EPCs) $CD34^+$cells. HSCs/EPCs could participate in vascular remodeling (regeneration), but also in the neovascularization that may contribute to plaque growth and its destabilization.

SA-PO980

Exosomes from Activated Kidney Fibroblast Stimulate Transcription of PlGF on Endothelial Cells

Noritoshi Kato,[1] Fumitoshi Nishio,[2] Yoshio Funahashi,[2] Takuji Ishimoto,[3] Tomoki Kosugi,[3] Naotake Tsuboi,[3] Shoichi Maruyama.[3] [1]*Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan;* [2]*Nagoya University, Nagoya, Japan;* [3]*Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Exosomes are small membrane vesicles that contain host cell's proteins, mRNAs, and microRNAs. The body of evidence revealed that these contents were biologically active and had roles in intracellular communication. On the other hand, it is well known that CKD patients are at risk of cardiovascular diseases, but the mechanism of this distant organ crosstalk is not fully understood. Recently, placental growth factor (PlGF) received attention in pathogenesis of cardio-renal syndrome (CRS). Under the hypothesis that exosomes are involved in pathophysiology of CRS, the aim of this study is to explore the role of exosomes from kidney fibroblasts, which actively proliferate in diseased kidney, on vascular endothelial cells.

Methods: Clinical samples; HUVECs were stimulated by serum exosomes from stage G5 CKD patients and healthy donor. Exosomes tracking; Activated kidney fibroblasts were isolated from unilateral ureteral obstruction (UUO) mice kidney. These exosomes were labeled by microRNA of C. elegance (Cel-miR-39), then labeled Exosomes were injected to the mice through tail vein. Effects of exosomes on endothelial cells; We purified exosomes from culture media of TGF-b stimulated kidney fibroblasts cell line (NRK-49f), and then primary culture of vascular endothelial cells (RAOEC) was stimulated using these exosomes. By qPCR, we evaluated the expression of PlGF genes.

Results: (1) Not only the serum but also exosomes from CKD stage G5 patients stimulated PlGF expression on HUVECs. (2) Injected labeled exosomes from activated kidney fibroblast distributed mainly in lung, liver, and aorta. (3) RAOEC stimulated with exosomes form TGF-b activated rat kidney fibroblast (RAOEC-T) showed higher expression of PlGF than control (RAOEC-C).

Conclusions: So far, CRS is considered to be caused by uremic factor, RAS system, chronic inflammation, and so on. From this study, both serum and exosomes from CKD patients stimulated PlGF transcription on endothelial cells. Exosomes from activated kidney fibloblast had same tendency. We speculated that exosomes from diseased kidney have some roles in atherosclerotic change by modulating the expression of PlGF on endothelial cells. Farther studies are needed to elucidate the degree of contribution to CRS.

SA-PO981

Senescent MVs from IS-Treated Endothelial Cells Induce Vascular Calcification

Matilde Alique,[1] Julia Carracedo,[2] Guillermo Bodega,[3] Elena Corchete,[4] Estefanya Garcia menendez,[5] Patricia De Sequera,[6] Maria Marques Vidas,[7] Rafael Perez-Garcia,[8] J.M. Portolés,[9] Rafael Ramirez.[1] *[1]Departamento de Biología de Sistemas, Universidad de Alcalá, Alcalá de Henares, Spain; [2]Complutense University, MADRID., Spain; [3]Universidad de Alcalá, Alcalá de Henares, Spain; [4]Hospital Universitario Fundación Alcorcon, Alcorcon (Madrid), Spain; [5]Hospital Puerta de Hierro Majadahonda, Majadahonda, Spain; [6]University Hospital Infanta Leonor, MADRID, Spain; [7]Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda, Spain; [8]Hospital Infanta Leonor, Madrid, Spain; [9]Hospital Puerta De Hierro, Majadahonda (Madrid), Spain.*

Background: Vascular calcification (VC) is a premature event of cardiovascular inflammatory diseases (CVD) in patients with chronic kidney disease (CKD). But identifying patients at risk of developing VC is complex, and it is necessary to expand the knowledge of the initial events that allow the progression of this pathology. Recently, we reported that senescent endothelial cells produce microvesicles (MV) which can act triggering the development of VC. As induction of premature endothelial senescence is a physiopathological mechanism in CVD associated with CKD, the objective of this study is to investigate whether MVs from endothelial cells that undergo premature senescence induced by the uremic toxin indoxyl sulfate (IS) can also modify vascular smooth muscle cells by making them susceptible to bone transformation. Besides, we study the mechanism(s) involved in VC promotion.

Methods: Endothelial cells (HUVEC) were treated with IS (250 μM; 4 days) and senescence was quantified with the β-galactosidase kit. The MV produced by these senescent HUVECs were isolated and subsequently characterized by flow cytometry and used for the treatment of vascular smooth muscle cells (HASMC). In HASMC, the calcium deposits were evaluated by alizarin red. At 30 days, the calcium content was quantified by the phenolsulfonephthalein kit. Expression of pro-calcifying genes was determined in HASMC by quantitative PCR. Western blot established the expression of a specific HASMC marker.

Results: IS-treated induced early senescence in HUVEC (control: 7.07±2.87% vs. IS: 72.90±13.09%, p <0.0001) and an increase in the production of MV was observed (control: 1.68±1.00 vs. IS: 9.92±4.29 MV/cell, p <0.005). Senescent MVs from IS-treated endothelial cells induced calcification in HASMC associated with deregulation in the expression of procalcifying genes (Runx2, BMP2). Also, the MV generated in HUVEC treated with IS produce a dedifferentiation process of the HASMC (SM22α expression).

Conclusions: MV produced by endothelial cells which develop early senescence as a consequence of the stress generated by the uremic toxins promote the development of VC. These results may be useful to develop biomarkers and therapeutic tools to prevent or treated patients with CVD and/or CKD at risk of developing VC.

SA-PO982

The Circadian Clock Provides Beneficial Effects Against the Endothelial Dysfunction to Promote Atherogenesis by Regulating PDGF Generation and iNOS Expression

Hideyuki Negoro. *Harvard Medical School, The Graduate School of Project Design, Tokyo, Japan.*

Background: The circadian clock is a molecular mechanism that confers 24 hour variations in gene expression and function to regulate number of physiological functions in humans. Disruption of the clock is associated with pathological remodeling in the arterial structure and vascular stiffness. Chronic circadian clock disruption is also associated with dysfunction in endothelial signaling and responses. In this study, we observed if the deletion of Bmal1, a critical component of the circadian clock, can influence growth factors, such as platelet-derived growth factor (PDGF) or inducible nitric oxide synthase (iNOS) which play an important part in the progression of vascular diseases.

Methods: Congenic 12- to 16-week-old male, wild-type and Bmal1-KO littermate mice were generated from heterozygote breedings to be used for these studies. We also knocked down Bmal1 to evaluate the protein levels of PDGF and iNOS expression in the knocked down cells.

Results: Endothelial function was reduced in aorta from Bmal1-KO mice. In aorta from Bmal1 KO mice, there was an increase in PDGF and iNOS expression in mice with a dysfunctional circadian rhythm. Moreover, Bmal1 KO mice display pre-mature aging to have a dramatic prothrombotic phenotype. This phenotype is linked to changes in the regulation of key risk factors for cardiovascular disease. These include PDGF and iNOS, which are significantly elevated in Bmal1 KO mice. We also confirmed that PDGF levels follow a circadian pattern and this pattern was absent in Bmal1 KO mice.

Conclusions: These findings indicate that circadian clock provides beneficial effects against the endothelial dysfunction to promote atherogenesis by regulating PDGF generation and iNOS expression. This study establishes a mechanistic connection between Bmal1 and cardiovascular phenotype.

Endothelial-Specific Krüppel-Like Factor 2 Inactivation Promotes Endothelial Dysfunction in the Setting of Uremia

Keith L. Saum,[2] Begoña Campos,[2] Aous Jarrouj,[3] Diego Celdran-Bonafonte,[1] Prabir Roy-Chaudhury,[4] Albert P. Owens.[2] *[1]University of Arizona / BIO 5 Institute, Tucson, AZ; [2]University of Cincinnati, Cincinnati, OH; [3]Banner-University of Arizona, Tucson, AZ; [4]University of Arizona, Tucson, AZ.*

Background: Uremic solutes that accumulate in end-stage renal disease(ESRD) may contribute to endothelial dysfunction and subsequent cardiovascular disease and vascular access dysfunction in ESRD patients. However, the mechanisms which mediate uremia-induced endothelial dysfunction in ESRD are not understood. Kruppel-like factors(KLFs) are key regulators of endothelial homeostasis which may be affected by the uremic milieu. In this study we examined the role of endothelial KLF2 in mediating endothelial dysfunction in the setting of uremia

Methods: We used serum from a porcine model of chronic renal failure to assess the impact of uremia on endothelial KLF2 expression in vitro. Human umbilical vein endothelial cells (HUVECs) were treated with increasing concentrations of uremic or non-uremic porcine serum and analyzed for KLF2 expression. Similarly, cells were treated with individual protein-bound toxins at average uremic concentrations. Reactive oxygen species (ROS) production and monocyte adhesion were then assessed in treated cells with and without KLF2 overexpression. To assess if the loss of KLF2 impairs endothelial function in vivo, we quantified flow-mediated dilation (FMD) of the femoral artery in endothelial-specific KLF2 conditional knockout (cKO) mice after 5 minutes of hindlimb ischemia

Results: KLF2 expression was dose-dependently decreased in HUVECs with uremic serum versus normal serum. Carboxymethyl-lysine(CML) modified albumin, a uremic advanced glycation end-product(AGE), also inhibited KLF2 expression. KLF2 suppression also promoted endothelial dysfunction in vitro, as adenoviral overexpression of KLF2 inhibited reactive oxygen species production and leukocyte adhesion in HUVECs treated with uremic serum or CML-AGE. Assessment of FMD in KLF2cKO mice demonstrated a 50%reduction in vasodilation compared to controls. The lack of femoral artery vasodilation in KLF2cKO mice was also accompanied by an attenuated return of wall shear stress to baseline independent of blood velocity

Conclusions: Collectively, these observations implicate loss of endothelial KLF2 as a mediator of endothelial dysfunction in the setting of uremia, and suggest that elevating KLF2 expression may be a novel strategy for prevention and treatment of vascular access dysfunction and cardiovascular disease in ESRD

SA-PO984

The Role of Autophagy in Neutrophil Extracellular Trap (NET) Formation in CKD

Jwa-kyung Kim,[1] Narae Joo,[2] Sung gyun Kim.[3] *[1]Internal medicine, Hallym University, Seoul, Republic of Korea; [2]Halyym University Sacred Heart Hospital, AnYang, Republic of Korea; [3]Hallym University, Antang, Republic of Korea.*

Background: Increased neutrophil extracellular trap (NET) formation could be an endogenous stimulus of chronic vascular inflammation despite its bacterial killing effect. However, researches about the degree of NET formation in chronic uremic conditions and its relationship with vascular complications have been limited. We assessed the relationship between NETs and vascular endothelial dysfunction in maintenance hemodialysis (MHD) patients, and evaluated the role of autophagy in NET formation in uremia

Methods: To quantify extracellular DNA level, serum cell-free nucleosome was measured between MHD patients (n=60) and healthy volunteer (HV, n=20). Then, neutrophils were isolated and stimulated with phorbol 12-myristate 13-acetate (PMA). The NET formation was visualized with confocal microscopy and the activity of neutrophil elastase (NE) were directly measured to confirm the amount of NETs in both groups. Endothelial dysfunction was measured by flow-mediated dilatation (FMD) of brachial artery using an automated device. The autophagic status were evaluated, and the effect of autophagy inhibition on NET formation was further investigated.

Results: The median basal levels of serum cell-free nucleosome were prominently increased in MHD patients than HV (p<0.001). Also, neutrophils isolated from MHD patients showed an increased NE activity as well as higher NET formation than controls both at basal and activated state, suggesting neutrophil priming in MHD group. The increased extracellular DNA level as well as NE activities were strongly associated with FMD (%) even after adjustments for traditional cardiovascular risk factors and uremic toxin levels (nucleosome: β=-0.429 p=0.001, NE β=-0.429 p=0.001). Moreover, neutrophils isolated from MHD patients showed an increase in autophagy function, especially autophagy induction. Interestingly, after treatment of 3-MA or ammonium chloride, inhibitors of autophagy pathways at early and late stages respectively, the levels of NET formation were markedly augmented, suggesting the protective role of autophagy in uremia.

Conclusions: Increased NETs formation may be one of important contributing factors of vascular endothelial dysfunction in hemodialysis patients. Increased autophagy induction in uremia could be an adaptive response as a protective manner to remove uremic toxins, and the inhibition of autophagy may induce excessive NET formation.

SA-PO985

Macrophage and T-Cell Infiltration in a Rat Model of Limb Ischemia: Effect of Impaired Kidney Function on the Pattern of Post-Ischemic Cell Infiltration

Andrea Hartner,[2] Kerstin U. Amann,[3] Roland Veelken,[1] Karl F. Hilgers.[1] *[1]University of Erlangen, Erlangen, Germany; [2]University Hospital of Erlangen, Erlangen, Germany; [3]University Hospital Erlangen, Erlangen, Germany.*

Background: The outcome of limb ischemia is worse in rats with chronic kidney disease (CKD) as was previously shown by others and us. We hypothesized that a different pattern of T-lymphocyte and macrophage infiltration into the ischemic muscle in rats with CKD may underlie the deficient repair and angiogenesis processes.

Methods: CKD rats (N=10) underwent 5/6 nephrectomy; controls (N=8) sham operation. After 8 weeks, ischemia of the right limb was induced by ligation and resection of the femoral artery. Rats were sacrificed 3 days later. Cross sections of musculus soleus of the ischemic and non-ischemic limbs were stained for macrophage markers ED-1 and CD163 as well as lymphocyte markers CD3, CD4 and CD8a. Positive cells were counted in 20 high-power fields. The expression of a panel of cytokines (including CCL2, CCL5, CCL7, osteopontin, IL-6 and TNFα) in muscle tissue was measured by RT-PCR.

Results: All investigated cell types were increased in ischemic versus non-ischemic limbs. There was a trend towards a higher increase of ED-1 macrophages in ischemic limbs of CKD (15±3-fold versus 10±3-fold in controls, p=0.492) but there was no significant difference. Absolute numbers of ED-1 and CD163 positive cells as well as the ratio between ED-1 and CD163 (M2 macrophages) did not differ between CKD and control. The number of CD3 T-cells in ischemic limbs was not different between CKD (5.4±0.7 cells/view) and controls (4.9±0.5, p=0.897). However, the number of CD8a cells in ischemic limbs was higher in CKD (1.8±0.2) than in controls (1.0±0.1, p=0.006). The ratio of CD8a to CD4 cells was significantly elevated in CKD rat ischemic limbs, as was the ratio of CD8a to CD3 cells. All investigated cytokines increased in ischemic limbs but there was no consistent difference between CKD and controls. In ischemic limbs, CD8a cells correlated tightly with the expression of CCL5 (r=0.722, p=0.001) but not with other cytokines.

Conclusions: Our results point to a higher infiltration of CD8a cytotoxic T-cells into ischemic limbs in CKD rats which may contribute to a worse outcome. In contrast, we did not find an altered pattern of M1/M2 macrophages.

Soluble Klotho Acts as a Co-Receptor for FGF23 That Interferes with FGF23's Action on the Heart

Christopher Yanucil,[1,2] Beatrice Richter,[3] Brian A. Czaya,[4] Isaac D. Campos,[4] Dominik R. Kentrup,[4] Christian Faul.[5] *[1]Cell Biology, University of Alabama Birmingham, Birmingham, AL; [2]Nephrology, University of Alabama Birmingham, Birmingham, AL; [3]The University of Alabama at Birmingham (UAB), Birmingham, AL; [4]University of Alabama at Birmingham, Birmingham, AL; [5]The University of Alabama at Birmingham, Birmingham, AL.*

Background: Fibroblast growth factor (FGF) 23 is a bone-derived hormone that increases phosphate excretion by targeting the kidney via klotho and FGF receptor (FGFR) 1. Klotho also exists in a soluble form that is released from the kidney. In patients with chronic kidney disease (CKD), changes in FGF23 and circulating sKL levels are associated with the development of cardiovascular disease and mortality. We have reported that FGF23 can contribute to cardiac hypertrophy by directly targeting cardiac myocytes via FGFR4 and inducing phospholipase Cg (PLCg) signaling. Experimental studies have shown that sKL has pleiotropic functions, including cardio-protective actions. Since a recent structural study has shown sKL acts as a scaffold to mediate FGF23-FGFR1 binding, we tested whether sKL interferes with FGF23-FGFR4 complex formation and effects in cardiac myocytes.

Methods: We purified recombinant sKL from stably transfected HEK293 cells, and determined its ability to bind recombinant FGF23 coated to a 96-well plate in the presence or absence of different FGFR isoforms. Furthermore, we co-treated neonatal rat ventricular myocytes (NRVM) with FGF23 and sKL and analyzed the activation of downstream signaling events by immunoblotting and hypertrophy via ^{3}H-phenylalanine incorporation.

Results: sKL binds FGF23 in the absence of FGFRs and exponentially increases the affinity of FGF23 for multiple FGFR isoforms. In NRVM, co-treatment with sKL blocks FGF23-mediated PLCγ activation and stimulates Ras/MAPK signaling. Furthermore, sKL inhibits FGF23-induced hypertrophic growth of NRVM, but has no effect on FGF2-mediated hypertrophy.

Conclusions: The binding of sKL to FGF23 does not require FGFRs and might therefore act as the initial event in the formation of FGF23/sKL/FGFR signaling complexes. Similar to membrane-associated klotho, sKL increases the affinity of FGF23 for FGFR binding, and thereby causes FGF23 responsiveness of cells that express FGFRs but lack klotho. The sKL-mediated interaction between FGF23 and FGFRs appears to be more promiscuous than previously reported by not only involving FGFR1, which might explain the pleiotropic actions of sKL on various cells types. By inducing a switch in downstream signaling, sKL blocks FGF23-induced hypertrophy in cardiac myocytes and might serve as a cardio-protective therapy in CKD.

Cardiac-Specific FGF23 Knockout Leads to Increased Cardiovascular Risk

Maren Leifheit-Nestler,[1] Saskia Schmaltz,[1] Malgorzata Szaroszyk,[1] Beatrice Richter,[2] Joerg Heineke,[3,1] Dieter Haffner.[1] *[1]Hannover Medical School, Hannover, Germany; [2]The University of Alabama at Birmingham, Birmingham, AL; [3]Medical Faculty Mannheim of Heidelberg University, Mannheim, Germany.*

Background: Patients with CKD have an higher risk for cardiovascular disease (CVD) and mortality associated with increased levels of FGF23. Recent studies indicate that FGF23 is expressed by cardiac myocytes and activates the calcineurin/NFAT pathway via activation of FGFR4 in the heart and may contribute to the development of LVH. We hypothesized that cardiac FGF23 is a modifier of CVD risk in mice.

Methods: To this aim we generated a mouse model with a cardiac myocyte-specific FGF23 knockout (FGF23-KO) in the C57BL/6 background using the Cre/loxP system. we evaluated the impact of cardiac FGF23 on the heart. Cardiovascular outcome in FGF23-KO receiving a standard diet was compared to wild-type littermates (WT) during an observational period of up-to 6-months. In addition, we compared pressure overload-induced cardiac hypertrophy induced by transverse aortic constriction (TAC) in 8-weeks old FGF23-KO and WT mice.

Results: Body weight, heart weight, tibia length and parameter of mineral metabolism including FGF23 synthesis in bone and plasma intact FGF23 levels did not differ between FGF23-KO mice and WT group. FGF23-KO mice showed significantly increased mortality compared to WT associated with enhanced end-diastolic LV volume and stroke volume examined by cardiac magnetic resonance imaging (cMRI). On molecular level, pro-hypertrophic and pro-fibrotic markers ANP, BNP, collagen 1, TGF-β and CTGF were enhanced in heart tissue of FGF23-KO mice and local cardiac renin-angiotensin-aldosterone system was activated compared to WT mice. As expected, heart function was impaired in WT mice 2 weeks after TAC compared with Sham along with increased relative heart weight, cardiac myocyte size and the induction of pro-hypertrophic genes and bone and cardiac FGF23 synthesis. Interestingly, FGF23-KO mice after TAC showed the same heart phenotype like WT TAC with exception of cardiac FGF23 synthesis. Moreover, cMRI revealted increased end-systolic LV volume and systolic LV diameter in FGF23-KO TAC compared to WT TAC mice.

Conclusions: In conclusion, cardiac myocyte-specific FGF23 knockout leads to impaired heart function and increased mortality in mice and results in increased CVD in the high pressure-induced hypertrophic mouse model. Thus our data suggest a physiological role of cardiac FGF23 in heart function and adaption to pressure overload.

SA-PO988

Cardiac-Specific Overexpression of FGF23 Fails to Induce Cardiac Hypertrophy in Mice Without CKD

Maren Leifheit-Nestler,[1] Miriam Wagner,[1] Beatrice Richter,[2] Dieter Haffner.[1] *[1]Hannover Medical School, Hannover, Germany; [2]The University of Alabama at Birmingham, Birmingham, AL.*

Background: High circulating and cardiac FGF23 levels are associated with increased risk of cardiovascular events and all cause mortality in CKD patients. We showed on molecular level that FGF23 stimulates hypertrophic growth of isolated cardiac myocytes in the absence of klotho via activation of FGFR4/calcineurin/NFAT pathway leading to left ventricular hypertrophy (LVH). It is still a matter of debate if elevated FGF23 results in LVH under healthy conditions, e.g. in the absence of CKD.

Methods: By generating a mouse model with cardiac specific overexpression of FGF23 using cardiovascular gene transfer with an adeno-associated virus expressing FGF23 (AAV-FGF23) under the control of the cardiac troponin T promotor, we investigated the pro-hypertrophic properties of cardiac FGF23 in C57BL/6N wild-type mice.

Results: The detection of AAV expression within various organs verified the specific accumulation of AAV-FGF23 in the heart. Cardiac *Fgf23* mRNA expression was 2,000-fold increased in AAV-FGF23-treated mice compared to controls and immunoblot analysis point out that the cardiac FGF23 protein was full-length biologically active. This was further confirmed by enhanced cardiac and plasma intact FGF23 levels in AAV-FGF23 mice. Parameters of mineral metabolism and renal expression of klotho did not differ between AAV-FGF23 and controls, whereas *NaPi2a* and *NaPi2c* mRNA levels were significantly reduced. Although, AAV-FGF23-treated mice showed a moderate induction of cardiac *Fgfr4* mRNA expression, relative heart weight and cardiac myocyte size did not differ between both groups and pro-hypertrophic NFAT target genes *Rcan1*, *Trpc6*, *b-MHC*, and *ANP* remained unchanged. Moreover, *BNP* levels were even significantly reduced in AAV-FGF23 mice compared to controls. Cardiac MRI analysis demonstrated no impairment of heart function in AAV-FGF23 mice but echocardiography studies showed significant increased stroke volume and cardiac output, which might be due to increased cardiac preload and/or enhanced contractility.

Conclusions: In conclusion, AAV-FGF23 induces the expression of full-length biological active FGF23 in the heart but fails to induce LVH under healthy conditions, suggesting that additional factors associated with CKD, e.g. klotho deficiency or high phosphate load, are necessary for FGF23 to tackle the heart.

SA-PO989

FGF23 Contributes to Cardiac Fibrosis in CKD

Beatrice Richter, Christopher Yanucil, Brian A. Czaya, Isaac D. Campos, Dominik R. Kentrup, Christian Faul. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: The risk for cardiovascular diseases is enormously increased in patients with chronic kidney disease (CKD). Over 90% of patients with end-stage renal disease develop pathologic cardiac remodeling, including hypertrophy and fibrosis that can lead to heart failure. Fibroblast growth factor (FGF) 23 is a bone-derived hormone that increases phosphate excretion by targeting the kidney via FGF receptor (FGFR) 1 and klotho. In early stages of CKD, serum FGF23 levels increase to compensate the rise in serum phosphate concentrations. High FGF23 concentrations are associated with the development of cardiovascular disease and a strong predictor for mortality in CKD. Our previous studies in rodents have shown that FGF23 can directly target the heart and contribute to cardiac hypertrophy. FGF23 binds to FGFR4 on cardiac myocytes in a klotho-independent manner, leading to the activation of a pro-hypertrophic signaling cascade, including phospholipase Cγ (PLCγ) and calcineurin. Since in animal models with elevated serum FGF23 levels cardiac hypertrophy is accompanied by fibrosis, we wanted to test if FGF23 can also directly target cardiac fibroblasts, using isolated primary cell culture models.

Methods: We have established primary cardiac fibroblast cultures from newborn rats, as well as adult mice and rats, and we analyze expression levels of different FGFR isoforms and klotho by qPCR. We treat cells with increasing FGF23 concentrations and investigate the activation of FGFRs, downstream signal mediators and pro-fibrotic gene programs by qPCR, immunoblotting and enzymatic assays. Furthermore, we study cell proliferation, migration and survival. We determine if co-treatment with inhibitors against FGFRs, PLCγ or calcineurin blocks FGF23-mediated effects on fibroblasts.

Results: Cardiac fibroblasts isolated from mice and rats express high levels of FGFR1 and to a lower extent also FGFR4. FGF23 promotes proliferation, migration and activation of fibroblasts when compared to vehicle-treated control cells.

Conclusions: We postulate that FGF23 contributes to pathologic cardiac remodeling by directly targeting different cell types in the myocardium, i.e. cardiac myocytes via FGFR4 and cardiac fibroblasts via FGFR1. Pharmacological blockade of FGFRs might serve as novel cardio-protective therapy in CKD.

Cytoskeletal Dysregulation in Uremic Cardiomyopathy

Kenneth Lim,[1] Arvin Halim,[5] Li-lun Ho,[6] Sahir Kalim,[2] Elizabeth D. Ankers,[1] Andrew M. Siedlecki,[5] Thomas F. Hiemstra,[3] Ravi I. Thadhani,[4] Tzongshi Lu.[5] *[1]Massachusetts General Hospital, Boston, MA; [2]Massachusetts General Hospital/ Harvard Medical School, Cambridge, MA; [3]University of Cambridge, Cambridge, United Kingdom; [4]Cedars-Sinai, Los Angeles, CA; [5]Renal, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [6]Massachusetts Institute of Technology, Cambridge, MA.*

Background: Ventricular remodeling involving left ventricular (LV) hypertrophy, dilatation and fibrosis in uremic cardiomyopathy contribute to the high rate of premature cardiovascular death in chronic kidney disease (CKD). Alterations in the cytoskeleton are well described in hypertrophied and failing myocardium and appear to be an important regulator of pro-fibrotic pathways in CKD. The mechanisms of cytoskeletal dysregulation in uremic cardiomyopathy remain largely unknown. Herein, we performed a comprehensive investigation of cytoskeletal adaptations in uremic cardiomyopathy.

Methods: We conducted a cross-sectional analysis of explanted human LV tissues from advanced CKD donors (n=23; hemodialysis (HD; n=20); peritoneal dialysis (PD; n=3)) compared to CAD (coronary artery disease; n=11) and healthy (n=20) controls. Primary human cardiomyocytes and cardiac-myofibroblasts were treated with calcification medium (CM) in time-course experiments (0-48 hours), *in vitro*. We developed a novel digital cell sorting study model using deconvolution to accurately assess hetereogenous transcriptomic profiles inherent of mixed-cell type tissues from RNA sequencing. qPCR and western blotting was used to confirm expression of target genes.

Results: Cross-sectional analysis revealed that the major cytoskeletal proteins β-tubulin and type III intermediate filament Vimentin, were significantly down-regulated in both CAD and CKD hearts compared to controls ($p<0.01$). However, major anchor protein Vinculin was upregulated in both CAD and CKD hearts compared to controls ($p<0.05$). Interestingly, β-actin, a critical component of the microfilament system was down-regulated in CAD hearts, but further down-regulated in CKD hearts compared to CAD and controls ($p<0.01$). Furthermore, on subanalysis HD patients had significantly lower β-actin expression compared to PD patients ($p<0.01$). Analysis of primary human cardiomyocytes and cardiac-myofibroblasts treated with CM revealed the same pattern of changes, *in vitro.*

Conclusions: We show for the first time severely reduced β-actin expression in human CKD hearts compared to CAD and controls. These findings may contribute to accelerated cardiac remodeling in uremic conditions and may be affected by dialysis modality. Upregulation of Vinculin may be involved in reduced contractile function of cardiomyocytes in uremia.

Cardiac structure in Patients with Mild to Moderate CKD – an MRI Study

Markus P. Schneider,[4] Johannes B. Scheppach,[1] Thorsten Klink,[2] Christoph Wanner,[2] Georg Schlieper,[3] Turgay Saritas,[3] Jürgen Floege,[3] Roland E. Schmieder,[4] Kai-Uwe Eckardt.[5] *[1]Johns Hopkins University, Baltimore, MD; [2]University Hospital Würzburg, Würzburg, Germany; [3]RWTH University of Aachen, Aachen, Germany; [4]University Hospital Erlangen, Erlangen, Germany; [5]University Medicine-Charite, Berlin, Germany.*

Background: Abnormal cardiac structure, in particular left ventricular hypertrophy (LVH), is common in patients with advanced chronic kidney disease (CKD), and predisposes to heart failure and sudden cardiac death. The prevalence, patterns and determinants of abnormal cardiac structure in patients with mild to moderate CKD has not been studied with magnetic resonance imaging (MRI).

Methods: We examined cardiac structure by MRI in 290 patients with mild to moderate CKD (median eGFR 50 ml/min), and explored associations with clinical and hemodynamic parameters (Mobil-O-Graph®, IEM, Germany), hydration status (bioimpedance spectroscopy), endothelial function (flow-mediated vasodilation), inflammation (high sensitive C-reactive protein, interleukin-6, tumor necrosis factor(TNF)-α, soluble TNF-receptors I and II) and CKD-mineral bone disease (MBD) markers (calcium, phosphate, 1,25-OH Vitamin D, intact parathyroid hormone, α-klotho, intact fibroblast growth factor (FGF)-23, C-terminal FGF-23). Linear regression analyses were used to identify variables independently associated with cardiac structure.

Results: Normal geometry was found in 56%, dilation in 4%, concentric remodeling in 10%, and LVH in 29% of patients. Abnormal cardiac structure was more prevalent in women than in men with CKD (P=0.06). Greater left ventricular mass (LVM) was independently associated with the variables male gender, greater BMI and higher 24h-systolic blood pressure (24h-SBP). Concentric remodeling was independently associated with male gender, higher 24h-SBP and greater hemoglobin levels. Neither endothelial function, nor hydration status or any of the inflammatory or CKD-MBD parameters contributed to the models.

Conclusions: Using state-of-the art MRI, abnormal cardiac structure was found in almost half of all patients with mild to moderate CKD. Targeting the modifiable factors 24h-SBP, BMI (for LVM) and avoiding high hemoglobin concentrations (for concentric remodeling) may prevent the development of adverse cardiac structure in patients with mild to moderate CKD.

SA-PO992

Renal Functional Reserve Mirrors the Sympathetic Overdrive Influence on the Heart

Aikaterini A. Damianaki,[1] Kyriakos Dimitriadis,[2] Zoe Alexakou,[1] Aglaia Chalkia,[1] Konstantinos Tsioufis,[2] Dimitrios I. Petras.[1] *[1]Nephrology Department, Hippokration Hospital of Arhens, Athens, Greece; [2]First Cardiology Clinic, University of Athens, Hippokration Hospital, Athens, Greece.*

Background: Renal functional reserve (RFR) refers to the capacity of the kidney to increase the Glomerular Filtration Rate (GFR) under the influence of certain stimuli. It is a promising diagnostic tool for assessing the risk of Acute Kidney Injury and of Chronic Kidney disease development in specific populations. The aim of our study was to assess the relation of RFR with diverse clinical parameters in normotensive patients with eGFR>60ml/min/1.73m^{2}and without any evidence of kidney damage (proteinuria, anatomic lesion etc).

Methods: 15 normotensive subjects (mean age=52 years, BMI= 26 kg/m^2, office systolic/diastolic BP =138/88 mmHg, ABPM 120/76mmHg) were included. All subjects underwent the exercise treadmill stress test, 24hour ABPM, office BP measurements, kidney ultrasound and ACR test. All subjects were fasted for 8 hours and then baseline hydration status was recorded using bioimpedance analysis. Basal GFR was measured after hydration and stress GFR was achieved after ingestion of oral protein 1g/kg as cooked meal. Basal and Stress GFR were determined by Creatinine Clearance = Urine Creatinine/Serum Creatinine x Urine Volume/time× 1.73/BSA). RFR was calculated as Stress GFR – Basal GFR. Patients having adequate renal reserves considered as having values of RFR greater than 30ml/min/1.73m^2

Results: There was no correlation of RFR values with respect to family history of hypertension, smoking, age, BMI or office BP. In contrast, patients with higher RFR values, achieved lower maximum systolic BP during the treadmill test ($p<0.05$) (175.7 ± 9.75 mmHg vs 176.2±22.48mmHg). Additionally, a statistically significant positive correlation was found between RFR values and maximum heart rate (HR) during treadmill test ($r=0.517$, $p=0.048$).

Conclusions: RFR is related to treadmill exercise maximum systolic BP in normotensive patients and appears to correlate with maximum HR. These findings underlie the pleiotropic effects of sympathetic nervous system in kidneys and their long term influences in kidney function. Treadmill test could be used to identify normotensive patients with normal eGFR who may have susceptibility to renal injury.

SA-PO993

Chronic, Isolated Renal Venous Pressure Increase Induces Extensive Renal Venous Collateral Formation and Exacerbates Renal and Cardiovascular Dysfunction in Rats

Shereen M. Hamza,[1,2] Xiaohua Huang,[1] Wenqing Zhuang,[1] Tayyaba Zehra,[1] Morgan Lapierre,[1] William A. Cupples,[3] Branko Braam.[1,2] *[1]Medicine, University of Alberta, Edmonton, AB, Canada; [2]Physiology, University of Alberta, Edmonton, AB, Canada; [3]Biomedical Physiology & Kinesiology, Simon Fraser University, Burnaby, BC, Canada.*

Background: Coexisting cardiac/renal dysfunction may be perpetuated by increased renal venous pressure (RVP). We previously showed that acute RVP elevation depresses renal blood flow (RBF), GFR and induces renal vasoconstriction in the absence of changes in blood pressure. Since physiological consequence of long-term, isolated RVP elevation are unknown, we tested whether chronic RVP elevation would impair baseline renal perfusion, exacerbating renal dysfunction and cardiovascular instability in response to superimposed acute RVP increase. **Objectives:** (1) Develop and characterize chronic, isolated RVP model (2) Evaluate baseline cardiovascular and renal response to chronic RVP elevation and superimposed acute increases in RVP.

Methods: Male rats were subjected to partial, graded occlusion of the left renal vein to induce chronic RVP elevation (20-25mmHg) and allowed to recover for either 1 (n=5) or 3 weeks (n=6). Rats were subsequently anesthetized and blood pressure, RVP, RBF and GFR were measured at baseline and during further RVP increase for 120 min.

Results: Chronic RVP elevation induced extensive renal venous collateral formation, evident within 1 week. This adaptation reduced RVP from 20-25 mmHg to 3.6±0.2 (1 wk) and 1.3±0.5 mmHg (3wk). Baseline blood pressure was unchanged by chronic RVP elevation (1 wk: 102±25; 3wk: 91±5 mmHg); however RBF and GFR were severely reduced at 1wk (RBF: 3.6±0.5 mL/min; GFR: 0.7±0.2 ml/min) and 3 wks (RBF: 3.1±1.2 mL/min). GFR was too low at 3 weeks to be reliably measured. Upon further RVP increase, blood pressure dropped in both 1 wk (-37±10 mmHg, $p<0.05$) and 3 wk groups (-19±1 mmHg, $p<0.05$). RBF also fell (1 wk: -2.3±0.7; 3wk: -1.3±0.6 mL/min, $p<0.05$), with reductions in renal vascular conductance (1 wk: -0.020±0.006; 3 wk: -0.010±0.007 mL/min.mmHg^{-1}) and GFR (1wk: -0.56±0.14 mL/min).

Conclusions: Chronic RVP elevation elicits extensive renal venous collateral formation which alleviates venous congestion; however baseline renal function is suppressed. RVP-induced renal and cardiovascular dysfunction is exacerbated compared to our previous report of acute increase in RVP alone, thus long-term RVP elevation impairs critical mechanisms required to stabilize hemodynamics.

SA-PO994

Lysyl Oxidase Insufficiency Exacerbates the Cardiovascular Phenotype Seen in a Mouse Model of Cutis Laxa

Carmen M. Halabi. *Washington University School of Medicine, Saint Louis, MO.*

Background: Mutations in the elastogenic extracellular matrix protein Fibulin-4 (*FBLN4*) have been identified in humans with cutis laxa (ARCL 1B). Mice carrying the E57K mutation in *Fbln4* recapitulate the cardiovascular phenotype observed in humans, including ascending aortic aneurysms and arterial tortuosity. Mutations in lysyl oxidase (LOX), the enzyme that crosslinks elastin, have recently been identified in patients with familial thoracic aortic aneurysms and dissection. The phenotypic similarities between mutant and knock-out mouse models of *Fbln4* and *Lox*, in addition to *in vitro* data showing that FBLN4 promotes binding of pro-LOX to tropoelastin have led to the currently accepted hypothesis that FBLN4 facilitates elastin's crosslinking by LOX. Whether this occurs *in vivo* is unclear however.

Methods: To determine whether FBLN4 interacts with LOX in the process of elastic fiber formation and arterial development, we bred recently characterized $Fbln4^{E57K}$ mice to *Lox* hemizygous mice ($Lox^{+/-}$) and assessed the structural and functional effects of LOX insufficiency on the cardiovascular system of $Fbln4^{E57K}$ mice.

Results: By 3-4 months of age $Fbln4^{E57K}$;$Lox^{+/-}$ mice were similar in size to $Fbln4^{E57K}$ mice and littermates. Ascending aortic aneurysms, which were incompletely penetrant and confined to the ascending aorta in $Fbln4^{E57K}$ mice were significantly worsened by LOX insufficiency as they were fully penetrant and extended from the aortic root through the aortic arch in $Fbln4^{E57K}$;$Lox^{+/-}$ mice. Additionally, arterial tortuosity and elastic fiber fragmentation of large conduit arteries were exacerbated by LOX insufficiency. Interestingly, muscular arteries remained intact. $Fbln4^{E57K}$;$Lox^{+/-}$ mice had significant cardiac hypertrophy and widening of the pulse pressure that was due to lower diastolic blood compared to $Fbln4^{E57K}$ mice.

Conclusions: In summary, LOX insufficiency exacerbated the vascular phenotype seen in mice with mutant FBLN4 suggesting that there is a functional interaction between the two molecules. Interestingly, elastic fiber formation was unaffected in muscular arteries raising the possibility that the process of elastic fiber assembly, previously thought to be the same in all elastic tissues, may differ between vascular beds. Further studies are underway to determine whether a direct interaction between FBLN4 and LOX occurs in the process of elastic fiber formation.

Effect of Omega-3 Fatty Acid on AKT-mTOR and FoxO in Heart of 5/6 Nephrectomy Rat Model

Su mi Lee,[1] Yun Jung Oh,[2] Young ki Son,[1] Seong Eun Kim,[3] Won Suk An.[1] *[1]Dong-A University, Busan, Republic of Korea; [2]Cheju Halla General Hospital, Jeju, Republic of Korea; [3]Dong-A University Hospital, Busan, Republic of Korea.*

Background: Cardiac hypertrophy is common and results in mortality in patients with chronic kidney disease (CKD). Akt-mammalian target of rapamycin (mTOR) axis is related with cardiac hypertrophy. Forkhead box class O (FoxO) family is related with autophagy and apoptosis, but there is no report in the heart of CKD. The present study aimed to investigate whether omega-3 fatty acid (ω-3 FA) effect on Akt-mTOR axis and FoxO in heart of 5/6 subtotal nephrectomy (Nx) rat model.

Methods: Male Sprague Dawley rats were divided into three groups and treated for 6 weeks: sham control (0.9% saline), 5/6 Nx control (0.9% saline) and 5/6 Nx treated with ω-3 FA (300 mg/kg/day by gastric gavage). The expression of cardiac Akt, phosphorylated(p) Akt, mTOR, FoxO, PI3K, p-PI3k, AMPK, p-AMPK, smad2/3, NF-κB, cleaved caspase 3/7, LC3, muscle-specific ring finger protein-1 (MuRF1), and muscle atrophy F-box protein (MAFbx) were examined by western blot analysis. Hematoxylin and eosin staining of heart was performed.

Results: Serum creatinine level was significantly increased in 5/6 Nx group compared to control group and were not significantly different between 5/6 Nx group treated with ω-3 FA and 5/6 Nx group. Compared with control group, cardiac hypertrophy of 5/6 Nx group was found in gross and microscopic findings. No definite cardiac hypertrophy was found in 5/6 Nx group treated with ω-3 FA. P-Akt and mTOR were significantly up-regulated in heart of 5/6 Nx group compared to control group and were recovered by ω-3 FA. Compared with control group, 5/6 Nx group significantly up-regulated FoxO1 and FoxO3a expression of heart, which were significantly recovered by ω-3 FA. However, the expression of MuRF1 and MAFbx was not different among three groups. The expression of smad2/3, NF-κB, cleaved caspase 3/7, LC3 was up-regulated in the heart of 5/6 Nx group compared to control group and was recovered by ω-3 FA. The expression of p-AMPK was down-regulated in the heart of 5/6 Nx group compared to control group and was recovered by ω-3 FA.

Conclusions: ω-3 FA may prevent cardiac hypertrophy not only by decreasing p-Akt, mTOR and FoxO expression but also by reducing molecules of inflammation, autophagy and apoptosis.

Subsequent Impaction on Renal Tissue After Myocardial Infarction in Animal Models

Chi-Ting Su,[1,2] Yen-wen Liu,[3] Jenq-wen Huang.[4] *[1]Renal Division, National Taiwan University Hospital, Yun-Lin Branch, Taipei, Taiwan; [2]Human Genetics, University of Pittsburgh, Pittsburgh, PA; [3]Department of Internal Medicine, National Cheng Kung University Hospital, Taiwan, Tainan, Taiwan; [4]Renal Division, National Taiwan University Hospital, Taipei, Taiwan.*

Background: The interaction between kidney and heart has been an important entity for decades. Investigation of pathogenesis may optimize therapeutic strategies and modalities, which potentially leads patients with cardiac and renal impairments to better outcomes. The major goal for this research is to investigate the biological functions of the latent transforming growth factor-beta-binding proteins (LTBPs) and identify pathophysiological role in renal impairment after myocardial infarction.

Methods: We created myocardial infarction with ligation over left anterior descending artery in mice. Echocardiogarphy and picrosirius red/fast green-stained histology studies were used to demonstrate the cardiac dysfunction after myocardial infarction. Gene and protein expression have been studied one week, two weeks, and four weeks after the surgery.

Results: Echocardiography successfully demonstrated cardiac wall motion abnormalities after myocardial infarction and cardiac fibrosis had been shown in histology studies. Ltbp4, pSMAD2 and pERK had been up-regulated in cardiac tissue obviously two weeks after myocardial infarction. On the other hand, one week after myocardial infarction, interleukin 6 (IL- 6) and monocyte chemoattractant protein -1(MCP-1) in renal tissues had been up-regulated significantly ($p<0.001$). It is interesting that increasing expression of kidney injury molecule-1 (KIM-1), ltbp4 and transforming growth factor beta (TGF-β) in renal tissue had been detected until two weeks after the surgery. Moreover, renal platelet-derived growth factor receptor beta (Pdgfrb) was detected increasing steadily. In addition, increased ltbp4 expression in renal after kidney injury had been found as an essential regulatory factor in TGF-β pathways.

Conclusions: Cardiac fibrosis can enhance renal inflammation early and induce KIM-1 and Pdgfrb expression in renal tissue. Inflammation served as a prelude before the expression of fibrotic factors. Ltbp4 is an essential regulatory in TGF-β signaling and is one of the significant factors to manipulate the progress of renal injury and the crosstalk between kidney and heart, the cardiorenal syndrome.

The Role of the Adipocyte Na/K-ATPase Oxidant Amplification Loop in Uremic Cardiomyopathy

Komal Sodhi,[4] Muhammad A. Chaudhry,[2] Rebecca L. Klug,[1] Rebecca Pratt,[2] Cameron Brickman,[6] Hari Vishal Lakhani,[3] Jiang Liu,[5] Zi-jian Xie,[3] Joseph I. Shapiro.[2] *[1]Marshall University, Joan C. Edwards School of Medicine, Huntington, WV; [2]Marshall University School of Medicine, Huntington, WV; [3]Marshall University, Huntington, WV; [4]Marshall University Joan C. Edwards School of Medicine, Huntington, WV; [5]Marshall University JCE School of Medicine, Huntington, WV; [6]Marshall University JCESOM, Huntington, WV.*

Background: Chronic kidney disease upregulates oxidative stress, increasing morbidity and mortality of cardiovascular disease. We demonstrated that administration of pNaKtide, a peptide mimicking control of Src activation via plasmalemmal Na/K-ATPase, halts development and reverses experimental uremic cardiomyopathy. Adipocyte contribution to systemic disease is an important topic; we investigated the expression of adipocyte production of NaKtide, a component of pNaKtide lacking the cell-permeant sequence derived from TAT, to observe the affects on the development of uremic cardiomyopathy. We examined high fat diet (HFD) on the development of cardiomyopathy in the model involving partial nephrectomy (PNx).

Methods: C57Bl6 mice, 10 weeks old male, subjected to 2-part sham or PNx surgical procedure and injected with lentivirus+adiponectin+NaKtide. Then randomly divided into 4 groups: (1) Sham, (2) Sham+NaKtide, (3) PNx (4) PNx+NaKtide. Metabolic function was assessed via oxygen consumption cages, blood pressure readings, glucose tolerance tests, and echocardiography. Following four weeks of treatment, the animals were sacrificed, tissues and fluid samples were collected.

Results: Plasma creatinine levels significantly increased with PNx compared to Naktide treatment ($p \leq 0.05$). Histological analysis of cardiac tissue shows increased fibrosis with PNx and decreased with NaKtide treatment ($p \leq 0.05$). Mice developed cardiomyopathy with diastolic dysfunction and left ventricular hypertrophy 4 weeks after PNx. Concomitant administration of HFD worsened changes and caused decreased ejection fraction and fractional shortening (both $p<0.01$). Transfection with adiponectin promoting lentivirus for NaKtide expression normalized cardiac abnormalities in PNx and PNx + HFD. Normal hematocrit values, IL6 and TNFa were seen with NaKtide transfection as opposed PNx and PNx + HFD (both $p<0.01$). Transfection with empty vector or NaKtide with myoD promoter did not affect any measurements.

Conclusions: Our study demonstrates that adipocytes contribute to oxidant stress associated with uremic cardiomyopathy. These data suggest that the adipocyte Na/K-ATPase oxidant amplification loop may be a viable clinical target for the prevention or treatment of uremic cardiomyopathy.

Plasma Lipidomic Analysis Reveals Differential Mitochondrial Fatty Acid Metabolism in Diabetic and Non-Diabetic CKD-Associated Heart Failure

Farsad Afshinnia,[1] Thekkelnaycke Rajendiran,[2] Subramaniam Pennathur.[1] Michigan Kidney Translational Core CPROBE Investigator Group *[1]University of Michigan, Ann Arbor, MI; [2]Univeraity of MIchigan, Ann Arbor, MI.*

Background: Cardiac myocytes utilize fatty acids predominantly for mitochondrial energy metabolism. Diabetic cardiomyopathy is characterized by increased β-oxidation due to elevated free fatty acids (FFA). Alterations in energy metabolism in diabetic and non-diabetic heart failure (HF) with chronic kidney disease (CKD) is less clear. This study investigated lipid metabolism by comparing the FFAs, acylcarnitines (ACs, a metric of β-oxidation), and complex lipids in diabetic and non-diabetic CKD patients with and without HF.

Methods: From the Clinical Phenotyping Resource and Biobank Core (CPROBE) 214 patients at various stages of CKD were selected for plasma lipidomic analysis. Of the 89 patients with diabetes, 10 had HF; in 125 subjects without diabetes 21 had HF. Plasma lipids and ACs were measured using mass spectrometry based untargeted and targeted lipidomic platforms, respectively.

Results: The mean age was 60 years (standard deviation=16). One hundred ten patients were males (51.4%), 64 were African-Americans (29.9%), and 150 were Caucasians (70.1%). In patients without diabetes median (interquartile range) of ACs in patients with HF were significantly higher than the patients without HF (Table, $P<0.05$ for all). In patients with diabetes the ACs were not different in patients with and without HF. Mixed linear model showed decreased abundance of saturated FFAs with lower carbon numbers in non-diabetic patients with HF, but an increased abundance of these metabolites in diabetic patients with HF as compared to no HF ($p=0.002$). In non-diabetic patients with HF, linear regression showed an inverse association between abundance of saturated FFAs with intermediate-chain ACs ($p=0.025$) and a direct association with long-chain ACs ($p=0.044$), a relationship which disappeared in diabetic patients with HF.

Conclusions: In non-diabetic HF, increased ACs at the cost of depletion of saturated FFAs is noted, while in diabetic HF saturated FFA increases without change in AC. Differential energy metabolism in HF with and without diabetes in CKD highlights the need for differential targeted therapies by etiology to optimize heart function and outcome in CKD.

Hyperreactivity of Aldosterone to Renin Contributes to Pathogenesis of Malignant Hypertension and Renovascular Hypertension

Shun Watanabe,[1] Keiichi Sumida,[2] Masayuki Yamanouchi,[1] Tatsuya Suwabe,[1] Junichi Hoshino,[3] Yoshifumi Ubara.[1] *[1]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [2]Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Japan; [3]Toranomon Hospital, Tokyo, Japan.*

Background: Malignant hypertension (MH) and renovascular hypertension (RVH) are known as diseases exhibiting high renin hypertension. By comparing the two groups, we examine how renin-angiotensin aldosterone system (RAAS) participates not only in the onset of hypertension but also in the onset of nephropathy.

Methods: A total of 33 patients who were diagnosed as MH(n=19) and RVH (n=14) at Toranomon Hospital from 1986 to 2017 were evaluated retrospectively.

Results: There was no significant difference in plasma renin concentration (PRC) between MH group and RVH group. While, age was younger in MH group than in RVH group with median [interquartile range]; 40 years [32-48 years] vs. 65 years [62-76 years], $P=0.0001$). Blood pressure (median; 230/130 vs 164/98 mmHg), UN (median;53.0 vs 28.8 mg/dl), Cre (median; 6.0 vs 2.0 mg/dl), plasma aldosterone concentration (PAC) (mrdian;49.7 vs 32.0 ng/dl)and aldosterone -renin-ratio (ARR)(1.10 VS 0.64)were significantly higher in MH group than in RVH group. Serum K (median; 3.7 vs 4.3 mEq/L) was significantly lower in MH group than in RVH group. The majority of MH group showed intimal edematous thickening (onion skin lesion) of small arteries including arteriole by renal biopsy. While four patients out of patients with RVH showed focal glomerular sclerosis on non-narrowed kidney by renal biopsy, but did not show onion skin lesion of small arteries.

Conclusions: Hyperreninemia was similar on both groups, but aldosterone value and APR were significantly higher in MH group. This indicates that hyperreactivity of aldosterone to renin might contribute not only to the formation of MH with onion-skin lesion via higher blood pressure, and result in also to hypokalemia, though renal function was higher on MH group. Whenever hyperreactivity of aldosterone to renin exists on MH group remains unknown. These results suggest that the mechanism by which renin stimulation leads to overproduction of aldosterone may be thought to be involved in MH and the progression of nephropathy.

Critical Role of Histone Deacetylase 3 in the Pathogenesis of Hypertensive Kidney Disease

Changlong An,[1,2] Jia Wen,[1] Sandhya S. Thomas,[1,2] Zhaoyong Hu,[1] William E. Mitch,[1] Yanlin Wang.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Michael E. DeBakey VA Medical Center, Houston, TX.*

Background: Hypertension is a major cause of chronic kidney disease, which is characterized byinflammation and fibrosis. However, the underlying molecular mechanisms are not fully understood. In this study, we examined the function role of histone deacetylase 3 (HDAC3) in renal inflammation and fibrosis in a mouse model of angiotensin II-induced hypertension.

Methods: Myeloid HDAC3 knockout mice were generated by crossing $HDAC3^{f/f}$mice with Lyz-Cre mice. Both Lyz-$Cre^{-/-}HDAC3^{f/f}$mice and Lyz-$Cre^{+/+}HDAC3^{f/f}$mice were infused with angiotensin II at 1.5ug/kg/min or vehicle for 28 days. Blood pressure was monitored by tail-cuff method. Renal function was assessed by measuring blood urea nitrogen (BUN). Kidney sections were prepared and stained for histological and immunological analysis. Western blot analysis was performed to detect the levels of fibronectin and a-SMA. Quantitative RT-PCR was performed to examine mRNA levels of proinflammatory cytokines. Cultured macrophages were used to study the role of HDAC3 in proinflammatory molecule expression in vitro.

Results: There is no significant difference in blood pressure at baseline. Blood pressure increased after angiotensin II treatment in both Lyz-$Cre^{-/-}HDAC3^{f/f}$ and Lyz-$Cre^{+/+}HDAC3^{f/f}$ mice that are similar between the two treatment groups. Compared with Lyz-$Cre^{-/-}HDAC3^{f/f}$ mice, mice with myeloid HDAC3 deficiency were protected from angiotensin II-induced renal injury with lower BUN. Furthermore, mice with HDAC3 deficiency in myeloid cells accumulated significantly fewer macrophages, T cells, and myeloid fibroblasts. HDAC3 deficiency in myeloid cells significantly reduced the mRNA expression of pro-inflammatory molecules the kidney after angiotensin II treatment. HDAC3 deficiency in myeloid cells significantly attenuated the protein levels of fibronectin and a-SMA and markedly inhibited collagen deposition in the kidney following angiotensin II treatment. In cultured macrophages, knockdown of HDAC3 with shRNA suppressed pro-inflammatory molecule expression. Furthermore, knockdown of HDAC3 inhibited NF-kB p65 binding to IL-6 promoter.

Conclusions: Our study identifies a critical role of HDAC3 in the regulation of hypertension-induced renal inflammation and fibrosis. Therefore, targeting HDAC3 may represent a novel therapeutic strategy for hypertensive kidney disease.

Prevalence of Angiotensin II Type 1 Receptor Antibodies (AT1RAbs) in Persons with Hypertension and Relation to Blood Pressure and Kidney Outcomes

Mary Carmelle Philogene,[1] Dingfen Han,[1] Alan B. Zonderman,[2] Michele K. Evans,[3] Deidra C. Crews.[1] *[1]Johns Hopkins School of Medicine, Baltimore, MD; [2]Intramural Research Program, NIA, NIH, Baltimore, MD; [3]National Institutes of Health/National Institute on Aging, Baltimore, MD.*

Background: AT1RAbs are associated with vascular hypertension and allograft dysfunction after kidney transplantation. We aimed to determine the prevalence of AT1RAb in a non-transplanted hypertensive population and the relationship to blood pressure (BP) control and kidney outcomes.

Methods: We used data on 1006 Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study participants with hypertension, and treated with angiotensin receptor blockers (ARB), angiotensin converting enzyme inhibitors (ACEi) or other anti-hypertensive medications. AT1RAb detection was performed by ELISA (One Lambda) and levels ≥ 17 units/ml were considered positive. BP, uncontrolled BP (systolic BP ≥140 or diastolic ≥90 mmHg), albuminuria [urine albumin-to-creatinine ratio (ACR) ≥30mg/g] and rapid kidney function decline (loss of eGFR >3ml/min per 1.73m^2 per year over a median of 5 years) were compared for AT1RAb positive (+) versus negative (-) participants using descriptive statistics and multivariable regression models.

Results: Overall, 132 (13%) participants were AT1RAb+. Compared to AT1RAb-, AT1RAb+ persons were more likely to be Caucasian (47% versus 37%) and non-smokers (44% versus 30%). In models adjusting for age, sex and race, AT1RAb+ persons had 2.6 mmHg higher diastolic BP than AT1RAb- persons (p=0.01). The adjusted odds ratio (aOR) for uncontrolled BP was 1.33 (95% CI 0.9, 2.0) comparing AT1RAb+ to AT1RAb- persons. In adjusted models, AT1RAb+ persons treated with either ARB or ACEi had 12.3 mmHg higher systolic and 5.4 mmHg higher diastolic BP compared to AT1RAb+ persons using other BP medications (p=0.003 and 0.03); aOR for uncontrolled BP was 1.48 (95% CI 0.68-3.21). BP did not differ for AT1RAb- participants regardless of medication. The prevalence of albuminuria was similar between AT1RAb+ (19.1%) and AT1RAb- (19.5%) groups. Rapid kidney function decline occured in 18.1% of AT1RAb+ and 15.5% of AT1RAb- persons (p=0.5). There was no statistically significant association between AT1RAb status and rapid kidney function decline (aOR 1.23; 95% CI 0.74-2.05).

Conclusions: AT1RAbs were associated with higher diastolic BP in this hypertensive population, and use of ARB or ACEi was associated with higher BP among AT1RAb+ persons compared to use of other medications.

Proximal Tubule Angiotensin II Type 1 Receptor-Associated Protein Does Not Influence Angiotensin-Dependent Hypertension

Hiromichi Wakui,[1] Sho Kinguchi,[1] Takahiro Yamaji,[4] Kazushi Uneda,[1] Shingo Urate,[3] Kotaro Haruhara,[2] Kohji Ohki,[5] Ryu Kobayashi,[3] Kengo Azushima,[1] Yoshiyuki Toya,[1] Kouichi Tamura.[3] *[1]Yokohama City University, Kanagawa, Yokohama city, Japan; [2]The Jikei University School of Medcine, Tokyo, Japan; [3]Yokohama City University Graduate School of Medicine, Kanazawa-Ku, Japan; [4]Yokohama city unversity, Yokohama City, Japan; [5]Yokohama City University School of Medicine, Yokohama City, Japan.*

Background: The activation of renal angiotensin II (Ang II) type 1 receptor (AT1R) can evoke excessive sodium retention, resulting in hypertension when inappropriately stimulated. The AT1R-associated protein (ATRAP) has been identified as the specific binding protein of the C-terminal domain of AT1R, and functions as an endogenous inhibitor that suppresses AT1R hyper-activation at local tissue sites. We previously reported that systemic ATRAP-knockout mice (ATRAP-KO) exhibited an exacerbation of Ang II-induced hypertension, concomitant with an increase in sodium retention, compared wild-type mice (WT). We here report a functional role of proximal tubule ATRAP in angiotensin-dependent hypertension using proximal tubule-specific ATRAP-knockout (PT-KO) mice.

Methods: In the present study, we generated PT-KO mice for the first time by the Cre/loxP system using *Pepck*-Cre. We next compared blood pressure in response to Ang II (1000ng/kg/min) treatment in wild-type littermate control (LC) and PT-KO mice. Since cardiac hypertrophy is closely associated with the blood pressure elevation, we further examined heart weight/body weight ratio in PT-KO and LC mice.

Results: The ATRAP mRNA expression in the proximal tubules of the PT-KO mice was decreased by approximately 80% compared with LC mice, estimated by laser capture microdissection method. Ang II infusion for 2 weeks significantly and similarly increased systolic blood pressure in both PT-KO and LC mice. Ang II infusion for 2 weeks significantly increased heart weight/body weight ratio in both PT-KO and LC mice to the same extent.

Conclusions: These results indicate that ATRAP deficiency in proximal nephron does not influence angiotensin-dependent hypertension *in vivo*.
